Introduction to the SAS System

SAS is an integrated system of software solutions that enables you to perform the following tasks:

☐ data entry, retrieval, and management
☐ report writing and graphics design
☐ statistical and mathematical analysis
☐ business forecasting and decision support
☐ operations research and project management
☐ applications development

How you use SAS depends on what you want to accomplish. Some people use many of the capabilities of the SAS System, and others use only a few.
At the core of the SAS System is Base SAS software which is the software product that you will learn to use in this documentation. This section presents an overview of Base SAS. It introduces the capabilities of Base SAS, addresses methods of running SAS, and outlines various types of output.

Components of Base SAS Software

Overview of Base SAS Software

Base SAS software contains the following:
- a data management facility
- a programming language
- data analysis and reporting utilities

Learning to use Base SAS enables you to work with these features of SAS. It also prepares you to learn other SAS products, because all SAS products follow the same basic rules.

Data Management Facility

SAS organizes data into a rectangular form or table that is called a SAS data set. The following figure shows a SAS data set. The data describes participants in a 16-week weight program at a health and fitness club. The data for each participant includes an identification number, name, team name, and weight (in U.S. pounds) at the beginning and end of the program.

Figure 1.1  Rectangular Form of a SAS Data Set

</tbody>
</table>

In a SAS data set, each row represents information about an individual entity and is called an observation. Each column represents the same type of information and is called a variable. Each separate piece of information is a data value. In a SAS data set,
an observation contains all the data values for an entity; a variable contains the same
type of data value for all entities.

To build a SAS data set with Base SAS, you write a program that uses statements in
the SAS programming language. A SAS program that begins with a DATA statement
and typically creates a SAS data set or a report is called a DATA step.

The following SAS program creates a SAS data set named WEIGHT_CLUB from the
health club data:

```sas
data weight_club;  
  input IdNumber 1-4 Name $ 6-24 Team $ StartWeight EndWeight;  
  Loss=StartWeight-EndWeight;  
  datalines;  
  1023 David Shaw red 189 165  
  1049 Amelia Serrano yellow 145 124  
  1219 Alan Nance red 210 192  
  1246 Ravi Sinha yellow 194 177  
  1078 Ashley McKnight red 127 118  
;  
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The DATA statement tells SAS to begin building a SAS data set named
   WEIGHT_CLUB.

2. The INPUT statement identifies the fields to be read from the input data and
   names the SAS variables to be created from them (IdNumber, Name, Team,
   StartWeight, and EndWeight).

3. The third statement is an assignment statement. It calculates the weight each
   person lost and assigns the result to a new variable, Loss.

4. The DATALINES statement indicates that data lines follow.

5. The data lines follow the DATALINES statement. This approach to processing
   raw data is useful when you have only a few lines of data. (Later sections show
   ways to access larger amounts of data that are stored in files.)

6. The semicolon signals the end of the raw data, and is a step boundary. It tells
   SAS that the preceding statements are ready for execution.

Note: By default, the data set WEIGHT_CLUB is temporary; that is, it exists only
for the current job or session. For information about how to create a permanent SAS
data set, see Chapter 2, “Introduction to DATA Step Processing,” on page 19.

---

**Programming Language**

**Elements of the SAS Language**

The statements that created the data set WEIGHT_CLUB are part of the SAS
programming language. The SAS language contains statements, expressions, functions
and CALL routines, options, formats, and informats – elements that many
programming languages share. However, the way you use the elements of the SAS
language depends on certain programming rules. The most important rules are listed in
the next two sections.
Rules for SAS Statements

The conventions that are shown in the programs in this documentation, such as indenting of subordinate statements, extra spacing, and blank lines, are for the purpose of clarity and ease of use. They are not required by SAS. There are only a few rules for writing SAS statements:

- SAS statements end with a semicolon.
- You can enter SAS statements in lowercase, uppercase, or a mixture of the two.
- You can begin SAS statements in any column of a line and write several statements on the same line.
- You can begin a statement on one line and continue it on another line, but you cannot split a word between two lines.
- Words in SAS statements are separated by blanks or by special characters (such as the equal sign and the minus sign in the calculation of the Loss variable in the WEIGHT_CLUB example).

Rules for Most SAS Names

SAS names are used for SAS data set names, variable names, and other items. The following rules apply:

- A SAS name can contain from one to 32 characters.
- The first character must be a letter or an underscore (_).
- Subsequent characters must be letters, numbers, or underscores.
- Blanks cannot appear in SAS names.

Special Rules for Variable Names

For variable names only, SAS remembers the combination of uppercase and lowercase letters that you use when you create the variable name. Internally, the case of letters does not matter. “CAT,” “cat,” and “Cat” all represent the same variable. But for presentation purposes, SAS remembers the initial case of each letter and uses it to represent the variable name when printing it.

Data Analysis and Reporting Utilities

The SAS programming language is both powerful and flexible. You can program any number of analyses and reports with it. SAS can also simplify programming for you with its library of built-in programs known as SAS procedures. SAS procedures use data values from SAS data sets to produce preprogrammed reports, requiring minimal effort from you.

For example, the following SAS program produces a report that displays the values of the variables in the SAS data set WEIGHT_CLUB. Weight values are presented in U.S. pounds.

```sas
options linesize=80 pagesize=60 pageno=1 nodate;
proc print data=weight_club;
   title 'Health Club Data';
run;
```

This procedure, known as the PRINT procedure, displays the variables in a simple, organized form. The following output shows the results:
Output 1.1 Displaying the Values in a SAS Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Id Number</th>
<th>Name</th>
<th>Team</th>
<th>Start Weight</th>
<th>End Weight</th>
<th>Loss</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1023</td>
<td>David Shaw</td>
<td>red</td>
<td>189</td>
<td>165</td>
<td>24</td>
</tr>
<tr>
<td>2</td>
<td>1049</td>
<td>Amelia Serrano</td>
<td>yellow</td>
<td>145</td>
<td>124</td>
<td>21</td>
</tr>
<tr>
<td>3</td>
<td>1219</td>
<td>Alan Nance</td>
<td>red</td>
<td>210</td>
<td>192</td>
<td>18</td>
</tr>
<tr>
<td>4</td>
<td>1246</td>
<td>Ravi Sinha</td>
<td>yellow</td>
<td>194</td>
<td>177</td>
<td>17</td>
</tr>
<tr>
<td>5</td>
<td>1078</td>
<td>Ashley McKnight</td>
<td>red</td>
<td>127</td>
<td>118</td>
<td>9</td>
</tr>
</tbody>
</table>

To produce a table showing mean starting weight, ending weight, and weight loss for each team, use the TABULATE procedure.

```sas
options linesize=80 pagesize=60 pageno=1 nodate;
proc tabulate data=weight_club;
   class team;
   var StartWeight EndWeight Loss;
   table team, mean*(StartWeight EndWeight Loss);
   title 'Mean Starting Weight, Ending Weight,';
   title2 'and Weight Loss';
run;
```

The following output shows the results:

Output 1.2 Table of Mean Values for Each Team

<table>
<thead>
<tr>
<th>Mean Starting Weight, Ending Weight,</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>and Weight Loss</td>
<td></td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>---</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>---</td>
</tr>
<tr>
<td>Team</td>
<td></td>
</tr>
<tr>
<td>red</td>
<td></td>
</tr>
<tr>
<td>175.33</td>
<td>158.33</td>
</tr>
<tr>
<td>yellow</td>
<td></td>
</tr>
<tr>
<td>169.50</td>
<td>150.50</td>
</tr>
</tbody>
</table>

A portion of a SAS program that begins with a PROC (procedure) statement and ends with a RUN statement (or is ended by another PROC or DATA statement) is called a PROC step. Both of the PROC steps that create the previous two outputs comprise the following elements:

- a PROC statement, which includes the word PROC, the name of the procedure you want to use, and the name of the SAS data set that contains the values. (If you omit the DATA= option and data set name, the procedure uses the SAS data set that was most recently created in the program.)
- additional statements that give SAS more information about what you want to do, for example, the CLASS, VAR, TABLE, and TITLE statements.
Traditionally, a RUN statement, which indicates that the preceding group of statements is ready to be executed.

Output Produced by the SAS System

Traditional Output

A SAS program can produce some or all of the following kinds of output:

- a SAS data set
  contains data values that are stored as a table of observations and variables. It also stores descriptive information about the data set, such as the names and arrangement of variables, the number of observations, and the creation date of the data set. A SAS data set can be temporary or permanent. The examples in this section create the temporary data set WEIGHT_CLUB.

- the SAS log
  is a record of the SAS statements that you entered and of messages from SAS about the execution of your program. It can appear as a file on disk, a display on your monitor, or a hardcopy listing. The exact appearance of the SAS log varies according to your operating environment and your site. The output in Output 1.3 shows a typical SAS log for the program in this section.

- a report or simple listing
  ranges from a simple listing of data values to a subset of a large data set or a complex summary report that groups and summarizes data and displays statistics. The appearance of procedure output varies according to your site and the options that you specify in the program, but the output in Output 1.1 and Output 1.2 illustrate typical procedure output. You can also use a DATA step to produce a completely customized report (see “Creating Customized Reports” on page 391).

- other SAS files such as catalogs
  contain information that cannot be represented as tables of data values. Examples of items that can be stored in SAS catalogs include function key settings, letters that are produced by SAS/FSP software, and displays that are produced by SAS/GRAPH software.

- external files or entries in other databases
  can be created and updated by SAS programs. SAS/ACCESS software enables you to create and update files that are stored in databases such as Oracle.
Output 1.3  Traditional Output: A SAS Log

```sas
NOTE: PROCEDURE PRINTTO used:
  real time 0.02 seconds
  cpu time 0.01 seconds

options pagesize=60 linesize=80 pageno=1 nodate;

data weight_club;
  input IdNumber 1-4 Name $ 6-24 Team $ StartWeight EndWeight;
  Loss=StartWeight-EndWeight;
datalines;
NOTE: The data set WORK.WEIGHT_CLUB has 5 observations and 6 variables.
NOTE: DATA statement used:
  real time 0.14 seconds
  cpu time 0.07 seconds

; proc tabulate data=weight_club;
  class team;
  var StartWeight EndWeight Loss;
  table team, mean*(StartWeight EndWeight Loss);
  title 'Mean Starting Weight, Ending Weight,';
  title2 'and Weight Loss';
run;
NOTE: There were 5 observations read from the data set WORK.WEIGHT_CLUB.
NOTE: PROCEDURE TABULATE used:
  real time 0.18 seconds
  cpu time 0.09 seconds

proc printto; run;
```

---

### Output from the Output Delivery System (ODS)

The Output Delivery System (ODS) enables you to produce output in a variety of formats, such as
- an HTML file
- a traditional SAS Listing (monospace)
- a PostScript file
- an RTF file (for use with Microsoft Word)
- an output data set

The following figure illustrates the concept of output for SAS Version 8.
The following definitions describe the terms in the preceding figure:

**data**
Each procedure that supports ODS and each DATA step produces data, which contains the results (numbers and characters) of the step in a form similar to a SAS data set.

**table definition**
The table definition is a set of instructions that describes how to format the data. This description includes but is not limited to
- the order of the columns
- text and order of column headings
- formats for data
- font sizes and font faces

**output object**
ODS combines formatting instructions with the data to produce an output object. The output object, therefore, contains both the results of the procedure or DATA step and information about how to format the results. An output object has a name, a label, and a path.

*Note:* Although many output objects include formatting instructions, not all do. In some cases the output object consists of only the data.

**ODS destinations**
An ODS destination specifies a specific type of output. ODS supports a number of destinations, which include the following:
RTF
produces output that is formatted for use with Microsoft Word.

Output
produces a SAS data set.

Listing
produces traditional SAS output (monospace format).

HTML
produces output that is formatted in Hyper Text Markup Language (HTML).
You can access the output on the web with your web browser.

Printer
produces output that is formatted for a high-resolution printer. An example of this type of output is a PostScript file.

**ODS output**
ODS output consists of formatted output from any of the ODS destinations.

For complete information about ODS, see *SAS Output Delivery System: User’s Guide*.

---

## Ways to Run SAS Programs

### Selecting an Approach

There are several ways to run SAS programs. They differ in the speed with which they run, the amount of computer resources that are required, and the amount of interaction that you have with the program (that is, the kinds of changes you can make while the program is running).

The examples in this documentation produce the same results, regardless of the way you run the programs. However, in a few cases, the way that you run a program determines the appearance of output. The following sections briefly introduce different ways to run SAS programs.

### SAS Windowing Environment

The SAS windowing environment enables you to interact with SAS directly through a series of windows. You can use these windows to perform common tasks, such as locating and organizing files, entering and editing programs, reviewing log information, viewing procedure output, setting options, and more. If needed, you can issue operating system commands from within this environment. Or, you can suspend the current SAS windowing environment session, enter operating system commands, and then resume the SAS windowing environment session at a later time.

Using the SAS windowing environment is a quick and convenient way to program in SAS. It is especially useful for learning SAS and developing programs on small test files. Although it uses more computer resources than other techniques, using the SAS windowing environment can save a lot of program development time.

For more information about the SAS windowing environment, see Chapter 39, “Using the SAS Windowing Environment,” on page 655.
SAS/ASSIST Software

One important feature of SAS is the availability of SAS/ASSIST software. SAS/ASSIST provides a point-and-click interface that enables you to select the tasks that you want to perform. SAS then submits the SAS statements to accomplish those tasks. You do not need to know how to program in the SAS language in order to use SAS/ASSIST.

SAS/ASSIST works by submitting SAS statements just like the ones shown earlier in this section. In that way, it provides a number of features, but it does not represent the total functionality of SAS software. If you want to perform tasks other than those that are available in SAS/ASSIST, you need to learn to program in SAS as described in this documentation.

Noninteractive Mode

In noninteractive mode, you prepare a file that contains SAS statements and any system statements that are required by your operating environment, and submit the program. The program runs immediately and occupies your current workstation session. You cannot continue to work in that session while the program is running,* and you usually cannot interact with the program.** The log and procedure output go to prespecified destinations, and you usually do not see them until the program ends. To modify the program or correct errors, you must edit and resubmit the program.

Noninteractive execution may be faster than batch execution because the computer system runs the program immediately rather than waiting to schedule your program among other programs.

Batch Mode

To run a program in batch mode, you prepare a file that contains SAS statements and any system statements that are required by your operating environment, and then you submit the program.

You can then work on another task at your workstation. While you are working, the operating environment schedules your job for execution (along with jobs submitted by other people) and runs it. When execution is complete, you can look at the log and the procedure output.

The central feature of batch execution is that it is completely separate from other activities at your workstation. You do not see the program while it is running, and you cannot correct errors at the time they occur. The log and procedure output go to prespecified destinations; you can look at them only after the program has finished running. To modify the SAS program, you edit the program with the editor that is supported by your operating environment and submit a new batch job.

When sites charge for computer resources, batch processing is a relatively inexpensive way to execute programs. It is particularly useful for large programs or when you need to use your workstation for other tasks while the program is executing. However, for learning SAS or developing and testing new programs, using batch mode might not be efficient.

* In a workstation environment, you can switch to another window and continue working.
** Limited ways of interaction are available. You can, for example, use the asterisk (*) option in a %INCLUDE statement in your program.
Interactive Line Mode

In an interactive line-mode session, you enter one line of a SAS program at a time, and SAS executes each DATA or PROC step automatically as soon as it recognizes the end of the step. You usually see procedure output immediately on your display monitor. Depending on your site’s computer system and on your workstation, you may be able to scroll backward and forward to see different parts of your log and procedure output, or you may lose them when they scroll off the top of your screen. There are limited facilities for modifying programs and correcting errors.

Interactive line-mode sessions use fewer computer resources than a windowing environment. If you use line mode, you should familiarize yourself with the %INCLUDE, %LIST, and RUN statements in SAS Language Reference: Dictionary.

Running Programs in the SAS Windowing Environment

You can run most programs in this documentation by using any of the methods that are described in the previous sections. This documentation uses the SAS windowing environment (as it appears on Windows and UNIX operating environments) when it is necessary to show programming within a SAS session. The SAS windowing environment appears differently depending on the operating environment that you use. For more information about the SAS windowing environment, see Chapter 39, “Using the SAS Windowing Environment,” on page 655.

The following example gives a brief overview of a SAS session that uses the SAS windowing environment. When you invoke SAS, the following windows appear.

Display 1.1 SAS Windowing Environment

The specific window placement, display colors, messages, and some other details vary according to your site, your monitor, and your operating environment. The window on the left side of the display is the SAS Explorer window, which you can use to assign and locate SAS libraries, files, and other items. The window at the top right is the Log
window; it contains the SAS log for the session. The window at the bottom right is the Program Editor window. This window provides an editor in which you edit your SAS programs.

To create the program for the health and fitness club, type the statements in the Program Editor window. You can turn line numbers on or off to facilitate program creation. The following display shows the beginning of the program.

Display 1.2  Editing a Program in the Program Editor Window

When you fill the Program Editor window, scroll down to continue typing the program. When you finish editing the program, submit it to SAS and view the output. (If SAS does not create output, check the SAS log for error messages.)

The following displays show the first and second pages of the Output window.

Display 1.3  The First Page of Output in the Output Window
Display 1.4  The Second Page of Output in the Output Window

After you finish viewing the output, you can return to the Program Editor window to begin creating a new program.

By default, the output from all submissions remains in the Output window, and all statements that you submit remain in memory until the end of your session. You can view the output at any time, and you can recall previously submitted statements for editing and resubmitting. You can also clear a window of its contents.

All the commands that you use to move through the SAS windowing environment can be executed as words or as function keys. You can also customize the SAS windowing environment by determining which windows appear, as well as by assigning commands to function keys. For more information about customizing the SAS windowing environment, see Chapter 40, “Customizing the SAS Environment,” on page 695.

Review of SAS Tools

Statements

DATA SAS-data-set;
   begins a DATA step and tells SAS to begin creating a SAS data set. SAS-data-set names the data set that is being created.

%INCLUDE source(s) <<SOURCE2> <S2=length> <host-options>>;
   brings SAS programming statements, data lines, or both into a current SAS program.

RUN;
   tells SAS to begin executing the preceding group of SAS statements.

For more information, see Statements in SAS Language Reference: Dictionary.

Procedures

PROC procedure <DATA=SAS-data-set>;
   begins a PROC step and tells SAS to invoke a particular SAS procedure to process the SAS data set that is specified in the DATA= option. If you omit the DATA= option, then the procedure processes the most recently created SAS data set in the program.
For more information about using procedures, see the *Base SAS Procedures Guide.*

Introduction to DATA Step Processing

Purpose

The DATA step is one of the basic building blocks of SAS programming. It creates the data sets that are used in a SAS program's analysis and reporting procedures. Understanding the basic structure, functioning, and components of the DATA step is fundamental to learning how to create your own SAS data sets. In this section, you will learn the following:
- what a SAS data set is and why it is needed
- how the DATA step works
- what information you have to supply to SAS so that it can construct a SAS data set for you

Prerequisites

You should understand the concepts introduced in Chapter 1, “What Is the SAS System?,” on page 3 before continuing.

The SAS Data Set: Your Key to the SAS System

Understanding the Function of the SAS Data Set

SAS enables you to solve problems by providing methods to analyze or to process your data in some way. You need to first get the data into a form that SAS can recognize and process. After the data is in that form, you can analyze it and generate reports. The following figure shows this process in the simplest case.
You begin with *raw data*, that is, a collection of data that has not yet been processed by SAS. You use a set of statements known as a *DATA step* to get your data into a SAS data set. Then you can further process your data with additional DATA step programming or with SAS procedures.

In its simplest form, the DATA step can be represented by the three components that are shown in the following figure.

SAS processes input in the form of raw data and creates a SAS data set. When you have a SAS data set, you can use it as input to other DATA steps. The following figure shows the SAS statements that you can use to create a new SAS data set.
Understanding the Structure of the SAS Data Set

Think of a SAS data set as a rectangular structure that identifies and stores data. When your data is in a SAS data set, you can use additional DATA steps for further processing, or perform many types of analyses with SAS procedures.

The rectangular structure of a SAS data set consists of rows and columns in which data values are stored. The rows in a SAS data set are called observations, and the columns are called variables. In a raw data file, the rows are called records and the columns are called fields. Variables contain the data values for all of the items in an observation.

For example, the following figure shows a collection of raw data about participants in a health and fitness club. Each record contains information about one participant.

Figure 2.4 Raw Data from the Health and Fitness Club

The following figure shows how easily the health club records can be translated into parts of a SAS data set. Each record becomes an observation. In this case, each observation represents a participant in the program. Each field in the record becomes a variable. The variables represent each participant’s identification number, name, team name, and weight at the beginning and end of a 16-week program.
In a SAS data set, every variable exists for every observation. What if you do not have all the data for each observation? If the raw data is incomplete because a value for the numeric variable EndWeight was not recorded for one observation, then this missing value is represented by a period that serves as a placeholder, as shown in observation 6 in the previous figure. (Missing values for character variables are represented by blanks. Character and numeric variables are discussed later in this section.) By coding a value as missing, you can add an observation to the data set for which the data is incomplete and still retain the rectangular shape necessary for a SAS data set.

Along with data values, each SAS data set contains a descriptor portion, as illustrated in the following figure:

The descriptor portion consists of details that SAS records about a data set, such as the names and attributes of all the variables, the number of observations in the data set, and the date and time that the data set was created and updated.

Operating Environment Information: Depending on your operating environment and the engine used to write the SAS data set, SAS may store additional information about a SAS data set in its descriptor portion. For more information, refer to the SAS documentation for your operating environment.
Creating and Using Temporary SAS Data Sets

When you use a DATA step to create a SAS data set with a one-level name, you normally create a temporary SAS data set, one that exists only for the duration of your current session. SAS places this data set in a SAS data library referred to as WORK. In most operating environments, all files that SAS stores in the WORK library are deleted at the end of a session.

The following is an example of a DATA step that creates the temporary data set WEIGHT_CLUB.

```sas
data weight_club;
  input IdNumber Name $ 6--20 Team $ 22--27 StartWeight EndWeight;
datalines;
1023 David Shaw red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance red 210 192
1246 Ravi Sinha yellow 194 177
1078 Ashley McKnight red 127 118
1221 Jim Brown yellow 220 .
;
run;
```

The preceding program code refers to the temporary data set as WEIGHT_CLUB. However, it assigns the first-level name WORK to all temporary data sets, and refers to the WEIGHT_CLUB data set with its two-level name, WORK.WEIGHT_CLUB. The following output from the SAS log shows the name of the temporary data set.

```
NOTE: The data set WORK.WEIGHT_CLUB has 6 observations and 5 variables.
```

Because SAS assigns the first-level name WORK to all SAS data sets that have only a one-level name, you do not need to use WORK. You can refer to these temporary data sets with a one-level name, such as WEIGHT_CLUB.

To reference this SAS data set in a later DATA step or in a PROC step, you can use a one-level name:

```sas
proc print data = weight_club;
run;
```

Creating and Using Permanent SAS Data Sets

To create a permanent SAS data set, you must indicate a SAS data library other than WORK. (WORK is a reserved libref that SAS automatically assigns to a temporary SAS data library.) Use a LIBNAME statement to assign a libref to a SAS data library on
Introduction to DATA Step Processing

Temporary versus Permanent SAS Data Sets

Your operating environment’s file system. The libref functions as a shorthand way of referring to a SAS data library. Here is the form of the LIBNAME statement:

```
LIBNAME libref 'your-data-library';
```

where

libref

is a shortcut name to where your SAS files are stored. libref must be a valid SAS name. It must begin with a letter or an underscore, and it can contain uppercase and lowercase letters, numbers, or underscores. A libref has a maximum length of 8 characters.

'your-data-library'

must be the physical name for your SAS data library. The physical name is the name that is recognized by the operating environment.

Operating Environment Information: Additional restrictions can apply to librefs and physical file names under some operating environments. For more information, refer to the SAS documentation for your operating environment.

The following is an example of the LIBNAME statement that is used with a DATA step:

```
liname saveit 'your-data-library'; 1
data saveit.weight_club; 2
   ...more SAS statements...
;
proc print data = saveit.weight_club; 3
run;
```

The following list corresponds to the numbered items:

1 The LIBNAME statement associates the libref SAVEIT with your-data-library, where your-data-library is your operating environment’s name for a SAS data library.

2 To create a new permanent SAS data set and store it in this SAS data library, you must use the two-level name SAVEIT.WEIGHT_CLUB in the DATA statement.

3 To reference this SAS data set in a later DATA step or in a PROC step, you must use the two-level name SAVEIT.WEIGHT_CLUB in the PROC step.

For more information, see Chapter 33, “Understanding SAS Data Libraries,” on page 595.

Conventions That Are Used in This Documentation

Data sets that are used in examples are usually shown as temporary data sets specified with a one-level name:

```
data fitness;
```

In rare cases in this documentation, data sets are created as permanent SAS data sets. These data sets are specified with a two-level name, and a LIBNAME statement precedes each DATA step in which a permanent SAS data set is created:

```
liname saveit 'your-data-library';
data saveit.weight_club;
```
Overview of the DATA Step

The DATA step consists of a group of SAS statements that begins with a DATA statement. The DATA statement begins the process of building a SAS data set and names the data set. The statements that make up the DATA step are compiled, and the syntax is checked. If the syntax is correct, then the statements are executed. In its simplest form, the DATA step is a loop with an automatic output and return action. The following figure illustrates the flow of action in a typical DATA step.
**Introduction to DATA Step Processing**

**Overview of the DATA Step**

**Figure 2.7  Flow of Action in a Typical DATA Step**

- **Compiles**
  - Compiles SAS statements (includes syntax checking)

- **Creates**
  - An input buffer
  - A program data vector
  - Descriptor information

- **Begins**
  - Begins with a DATA statement (counts iterations)

- **Sets**
  - Variable values to missing in the program data vector

- **Data-reading statement:**
  - Is there a record to read?

  **YES**

- **Reads**
  - Reads an input record

- **Executes**
  - Executes additional executable statements

- **Writes**
  - Writes an observation to the SAS data set

- **Returns**
  - Returns to the beginning of the DATA step

- **Closes**
  - Closes data set; goes on to the next DATA or PROC step

**Compile Phase**

**Execution Phase**
During the Compile Phase

When you submit a DATA step for execution, SAS checks the syntax of the SAS statements and compiles them, that is, automatically translates the statements into machine code. SAS further processes the code, and creates the following three items:

**input buffer** is a logical area in memory into which SAS reads each record of data from a raw data file when the program executes. (When SAS reads from a SAS data set, however, the data is written directly to the program data vector.)

**program data vector** is a logical area of memory where SAS builds a data set, one observation at a time. When a program executes, SAS reads data values from the input buffer or creates them by executing SAS language statements. SAS assigns the values to the appropriate variables in the program data vector. From here, SAS writes the values to a SAS data set as a single observation.

The program data vector also contains two automatic variables, _N_ and _ERROR_. The _N_ variable counts the number of times the DATA step begins to iterate. The _ERROR_ variable signals the occurrence of an error caused by the data during execution. These automatic variables are not written to the output data set.

**descriptor information** is information about each SAS data set, including data set attributes and variable attributes. SAS creates and maintains the descriptor information.

During the Execution Phase

All executable statements in the DATA step are executed once for each iteration. If your input file contains raw data, then SAS reads a record into the input buffer. SAS then reads the values in the input buffer and assigns the values to the appropriate variables in the program data vector. SAS also calculates values for variables created by program statements, and writes these values to the program data vector. When the program reaches the end of the DATA step, three actions occur by default that make using the SAS language different from using most other programming languages:

1. SAS writes the current observation from the program data vector to the data set.
2. The program loops back to the top of the DATA step.
3. Variables in the program data vector are reset to missing values.

   *Note:* The following exceptions apply:

   □ Variables that you specify in a RETAIN statement are not reset to missing values.

   □ The automatic variables _N_ and _ERROR_ are not reset to missing.

For information about the RETAIN statement, see “Using a Value in a Later Observation” on page 198. △

If there is another record to read, then the program executes again. SAS builds the second observation, and continues until there are no more records to read. The data set is then closed, and SAS goes on to the next DATA or PROC step.
Example of a DATA Step

The DATA Step

The following simple DATA step produces a SAS data set from the data collected for a health and fitness club. As discussed earlier, the input data contains each participant’s identification number, name, team name, and weight at the beginning and end of a 16-week weight program:

data weight_club;
  input IdNumber 1-4 Name $ 6-24 Team $ StartWeight EndWeight;
  Loss = StartWeight - EndWeight;
datalines;
1023 David Shaw red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance red 210 192
1246 Ravi Sinha yellow 194 177

1259 Raoul Sanchez green 189 172
1017 Jennifer Brooks blue 138 127
1099 Asha Garg yellow 148 132
1329 Larry Goss yellow 188 174;

The Statements

The following list corresponds to the numbered items in the preceding program:

1 The DATA statement begins the DATA step and names the data set that is being created.
The INPUT statement creates five variables, indicates how SAS reads the values from the input buffer, and assigns the values to variables in the program data vector.

The assignment statement creates an additional variable called Loss, calculates the value of Loss during each iteration of the DATA step, and writes the value to the program data vector.

The DATALINES statement marks the beginning of the input data. The single semicolon marks the end of the input data and the DATA step.

Note: A DATA step that does not contain a DATALINES statement must end with a RUN statement.

The Process

When you submit a DATA step for execution, SAS automatically compiles the DATA step and then executes it. At compile time, SAS creates the input buffer, program data vector, and descriptor information for the data set WEIGHT_CLUB. As the following figure shows, the program data vector contains the variables that are named in the INPUT statement, as well as the variable Loss. The values of the _N_ and the _ERROR_ variables are automatically generated for every DATA step. The _N_ automatic variable represents the number of times that the DATA step has iterated. The _ERROR_ automatic variable acts like a binary switch whose value is 0 if no errors exist in the DATA step, or 1 if one or more errors exist. These automatic variables are not written to the output data set.

All variable values, except _N_ and _ERROR_, are initially set to missing. Note that missing numeric values are represented by a period, and missing character values are represented by a blank.

Figure 2.8 Variable Values Initially Set to Missing

<table>
<thead>
<tr>
<th>IdNumber</th>
<th>Name</th>
<th>Team</th>

<th>EndWeight</th>
<th>Loss</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td></td>
<td></td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

The syntax is correct, so the DATA step executes. As the following figure illustrates, the INPUT statement causes SAS to read the first record of raw data into the input buffer. Then, according to the instructions in the INPUT statement, SAS reads the data values in the input buffer and assigns them to variables in the program data vector.
Introduction to DATA Step Processing

Example of a DATA Step

Figure 2.9  Values Assigned to Variables by the INPUT Statement

Input Buffer

1023  David Shaw   red   189 165

Program Data Vector

<table>
<thead>
<tr>
<th>IdNumber</th>
<th>Name</th>
<th>Team</th>
<th>StartWeight</th>
<th>EndWeight</th>
<th>Loss</th>
</tr>
</thead>
<tbody>
<tr>
<td>1023</td>
<td>David Shaw</td>
<td>red</td>
<td>189</td>
<td>165</td>
<td>.</td>
</tr>
</tbody>
</table>

When SAS assigns values to all variables that are listed in the INPUT statement, SAS executes the next statement in the program:

\[
\text{Loss} = \text{StartWeight} - \text{EndWeight};
\]

This assignment statement calculates the value for the variable Loss and writes that value to the program data vector, as the following figure shows.

Figure 2.10  Value Computed and Assigned to the Variable Loss

Input Buffer

1023  David Shaw   red   189 165

Program Data Vector

<table>
<thead>
<tr>
<th>IdNumber</th>
<th>Name</th>
<th>Team</th>
<th>StartWeight</th>
<th>EndWeight</th>
<th>Loss</th>
</tr>
</thead>
<tbody>
<tr>
<td>1023</td>
<td>David Shaw</td>
<td>red</td>
<td>189</td>
<td>165</td>
<td>24</td>
</tr>
</tbody>
</table>

SAS has now reached the end of the DATA step, and the program automatically does the following:

- writes the first observation to the data set
- loops back to the top of the DATA step to begin the next iteration
- increments the _N_ automatic variable by 1
- resets the _ERROR_ automatic variable to 0
- except for _N_ and _ERROR_, sets variable values in the program data vector to missing values, as the following figure shows
Execution continues. The INPUT statement looks for another record to read. If there are no more records, then SAS closes the data set and the system goes on to the next DATA or PROC step. In this example, however, more records exist and the INPUT statement reads the second record into the input buffer, as the following figure shows.

The following figure shows that SAS assigned values to the variables in the program data vector and calculated the value for the variable Loss, building the second observation just as it did the first one.

This entire process continues until SAS detects the end of the file. The DATA step iterates as many times as there are records to read. Then SAS closes the data set WEIGHT_CLUB, and SAS looks for the beginning of the next DATA or PROC step.
Now that SAS has transformed the collected data from raw data into a SAS data set, it can be processed by a SAS procedure. The following output, produced with the PRINT procedure, shows the data set that has just been created.

```sas
proc print data=weight_club;
title 'Fitness Center Weight Club';
run;
```

Output 2.2  PROC PRINT Output of the WEIGHT_CLUB Data Set

Supplying Information to Create a SAS Data Set

Overview of Creating a SAS Data Set

You supply SAS with specific information for reading raw data so that you can create a SAS data set from the raw data. You can use the data set for further processing, data analysis, or report writing. To process raw data in a DATA step, you must:

- use an INPUT statement to tell SAS how to read the data
- define the variables and indicate whether they are character or numeric
- specify the location of the raw data
Telling SAS How to Read the Data: Styles of Input

SAS provides many tools for reading raw data into a SAS data set. These tools include three basic input styles as well as various format modifiers and pointer controls.

**List input** is used when each field in the raw data is separated by at least one space and does not contain embedded spaces. The INPUT statement simply contains a list of the variable names. List input, however, places numerous restrictions on your data. These restrictions are discussed in detail in Chapter 3, “Starting with Raw Data: The Basics,” on page 43. The following example shows list input. Note that there is at least one blank space between each data value.

```sas
data scores;
   input Name $ Test_1 Test_2 Test_3;
   datalines;
   Bill 187 97 103
   Carlos 156 76 74
   Monique 99 102 129
;
```

**Column input** enables you to read the same data if it is located in fixed columns:

```sas
data scores;
   input Name $ 1-7 Test_1 9-11 Test_2 13-15 Test_3 17-19;
   datalines;
   Bill 187 97 103
   Carlos 156 76 74
   Monique 99 102 129
;
```

**Formatted input** enables you to supply special instructions in the INPUT statement for reading data. For example, to read numeric data that contains special symbols, you need to supply SAS with special instructions so that it can read the data correctly. These instructions, called **informat**, are discussed in more detail in Chapter 3, “Starting with Raw Data: The Basics,” on page 43. In the INPUT statement, you can specify an informat to be used to read a data value, as in the example that follows:

```sas
data total_sales;
   input Date mmddyy10. +2 Amount comma5.;
   datalines;
   09/05/2000 1,382
   10/19/2000 1,235
   11/30/2000 2,391
;
```

In this example, the MMDDYY10. informat for the variable Date tells SAS to interpret the raw data as a month, day, and year, ignoring the slashes. The COMMA5. informat for the variable Amount tells SAS to interpret the raw data as a number, ignoring the comma. The +2 is a **pointer control** that tells SAS where to look for the next item. For more information about pointer controls, see Chapter 3, “Starting with Raw Data: The Basics,” on page 43.

SAS also enables you to mix these styles of input as required by the way values are arranged in the data records. Chapter 3, “Starting with Raw Data: The Basics,” on page 43 discusses in detail input styles (including their rules and restrictions), as well as additional data-reading tools.
Reading Dates with Two-Digit and Four-Digit Year Values

In the previous example, the year values in the dates in the raw data had four digits:

09/05/2000
10/19/2000
11/30/2000

However, SAS is also capable of reading two-digit year values (for example, 09/05/99). In this example, use the MMDDYY8. informat for the variable Date.

How does SAS know to which century a two-digit year belongs? SAS uses the value of the YEARCUTOFF= SAS system option. In Version 7 and later of SAS, the default value of the YEARCUTOFF= option is 1920. This means that two-digit years from 00 to 19 are assumed to be in the twenty-first century, that is, 2000 to 2019. Two-digit years from 20 to 99 are assumed to be in the twentieth century, that is, 1920 to 1999.

Note: The YEARCUTOFF= option and the default setting may be different at your site.

To avoid confusion, you should use four-digit year values in your raw data wherever possible. For more information, see the Dates, Times, and Intervals section of SAS Language Reference: Concepts.

Defining Variables in SAS

So far you have seen that the INPUT statement instructs SAS on how to read raw data lines. At the same time that the INPUT statement provides instructions for reading data, it defines the variables for the data set that come from the raw data. By assuming default values for variable attributes, the INPUT statement does much of the work for you. Later in this documentation, you will learn other statements that enable you to define variables and assign attributes to variables, but this section and Chapter 3, “Starting with Raw Data: The Basics,” on page 43 concentrate on the use of the INPUT statement.

SAS variables can have these attributes:

- name
- type
- length
- informat
- format
- label
- position in observation
- index type

See the SAS Variables section of SAS Language Reference: Concepts for more information about variable attributes.

In an INPUT statement, you must supply each variable name. Unless you also supply an informat, the type is assumed to be numeric, and its length is assumed to be eight bytes. The following INPUT statement creates four numeric variables, each with a length of eight bytes, without requiring you to specify either type or length. The table summarizes this information.

```
input IdNumber Test_1 Test_2 Test_3;
```
The values of numeric variables can contain only numbers. To store values that contain alphabetic or special characters, you must create a character variable. By following a variable name in an INPUT statement with a dollar sign ($), you create a character variable. The default length of a character variable is also eight bytes. The following statement creates a data set that contains one character variable and four numeric variables, all with a default length of eight bytes. The table summarizes this information.

```
input IdNumber Name $ Test_1 Test_2 Test_3;
```

In addition to specifying the types of variables in the INPUT statement, you can also specify the lengths of character variables. Character variables can be up to 32,767 bytes in length. To specify the length of a character variable in an INPUT statement, you need to supply an informat or use column numbers. For example, following a variable name in the INPUT statement with the informat $20., or with column specifications such as 1-20, creates a character variable that is 20 bytes long.

Note that the length of numeric variables is not affected by informats or column specifications in an INPUT statement. See *SAS Language Reference: Concepts* for more information about numeric variables and lengths.

Two other variable attributes, format and label, affect how variable values and names are represented when they are printed or displayed. These attributes are assigned with different statements that you will learn about later.

### Indicating the Location of Your Data

#### Data Locations

To create a SAS data set, you can read data from one of four locations:

- raw data in the data (job) stream, that is, following a DATALINES statement
- raw data in a file that you specify with an INFILE statement
- data from an existing SAS data set
- data in a database management system (DBMS) file

**Raw Data in the Job Stream**

You can place data directly in the job stream with the programming statements that make up the DATA step. The DATALINES statement tells SAS that raw data follows. The single semicolon that follows the last line of data marks the end of the data. The DATALINES statement and data lines must occur last in the DATA step statements:

```sas
data weight_club;
  input IdNumber 1-4 Name $ 6-24 Team $ StartWeight EndWeight;
  Loss = StartWeight - EndWeight;
  datalines;
1023 David Shaw  red  189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance  red  210 192
1246 Ravi Sinha  yellow 194 177
1078 Ashley McKnight red  127 118
;
```

**Data in an External File**

If your raw data is already stored in a file, then you do not have to bring that file into the data stream. Use an INFILE statement to specify the file containing the raw data. (See “Using External Files in Your SAS Job” on page 38 for details about INFILE, FILE, and FILENAME statements.) The statements in the code that follows demonstrate the same example, this time showing that the raw data is stored in an external file:

```sas
data weight_club;
  infile 'your-input-file';
  input IdNumber $ 1-4 Name $ 6-23 StartWeight 24-26 EndWeight 28-30;
  Loss=StartWeight-EndWeight;
run;
```

**Data in a SAS Data Set**

You can also use data that is already stored in a SAS data set as input to a new data set. To read data from an existing SAS data set, you must specify the existing data set’s name in one of these statements:

- SET statement
- MERGE statement
- MODIFY statement
- UPDATE statement

For example, the statements that follow create a new SAS data set named RED that adds the variable LossPercent:

```sas
data red;
  set weight_club;
  LossPercent = Loss / StartWeight * 100;
run;
```
The SET statement indicates that the input data is already in the structure of a SAS data set and gives the name of the SAS data set to be read. In this example, the SET statement tells SAS to read the WEIGHT_CLUB data set in the WORK library.

Data in a DBMS File

If you have data that is stored in another vendor's database management system (DBMS) files, then you can use SAS/ACCESS software to bring this data into a SAS data set. SAS/ACCESS software enables you to assign a libref to a library containing the DBMS file. In this example, a libref is declared, and points to a library containing Oracle data. SAS reads data from an Oracle file into a SAS data set:

```sas
libname dblib oracle user=scott password=tiger path='hrdept_002';
data employees;
    set dblib.employees;
run;
```

See SAS/ACCESS for Relational Databases: Reference for more information about using SAS/ACCESS software to access DBMS files.

Using External Files in Your SAS Job

Your SAS programs often need to read raw data from a file, or write data or reports to a file that is not a SAS data set. To use a file that is not a SAS data set in a SAS program, you need to tell SAS where to find it. You can do the following:

- Identify the file directly in the INFILE, FILE, or other SAS statement that uses the file.
- Set up a fileref for the file by using the FILENAME statement, and then use the fileref in the INFILE, FILE, or other SAS statement.
- Use operating environment commands to set up a fileref, and then use the fileref in the INFILE, FILE, or other SAS statement.

The first two methods are described here. The third method depends on the operating environment that you use.

Operating Environment Information: For more information, refer to the SAS documentation for your operating environment.

Identifying an External File Directly

The simplest method for referring to an external file is to use the name of the file in the INFILE, FILE, or other SAS statement that needs to refer to the file. For example, if your raw data is stored in a file in your operating environment, and you want to read the data using a SAS DATA step, you can tell SAS where to find the raw data by putting the name of the file in the INFILE statement:

```sas
data temp;
    infile 'your-input-file';
    input IdNumber $ 1-4 Name $ 6-23 StartWeight 24-26 EndWeight 28-30;
run;
```

The INFILE statement for this example may appear as follows for various operating environments:
Referencing an External File with a Fileref

An alternate method for referencing an external file is to use the FILENAME statement to set up a fileref for a file. The fileref functions as a shorthand way of referring to an external file. You then use the fileref in later SAS statements that reference the file, such as the FILE or INFILE statement. The advantage of this method is that if the program contains many references to the same external file and the external filename changes, then the program needs to be modified in only one place, rather than in every place where the file is referenced.

Here is the form of the FILENAME statement:

FILENAME fileref 'your-input-or-output-file';

The fileref must be a valid SAS name, that is, it must

- begin with a letter or an underscore
- contain only letters, numbers, or underscores
- have no more than 8 characters.

Operating Environment Information: Additional restrictions may apply under some operating environments. For more information, refer to the SAS documentation for your operating environment.

For example, you can reference the raw data that is stored in a file in your operating environment by first using the FILENAME statement to specify the name of the file and its fileref, and then using the INFILE statement with the same fileref to reference the file.

filename fitclub 'your-input-file';

data temp;
  infile fitclub;
  input IdNumber $ 1-4 Name $ 6-23 StartWeight 24-26 EndWeight 28-30;
run;

In this example, the INFILE statement stays the same for all operating environments. The FILENAME statement, however, can appear differently in different operating environments, as the following table shows:

### Table 2.1 Example INFILE Statements for Various Operating Environments

<table>
<thead>
<tr>
<th>Operating environment</th>
<th>INFILE statement example</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS</td>
<td>infile 'fitness.weight.rawdata(club1)';</td>
</tr>
<tr>
<td>CMS</td>
<td>infile 'club1 weight a';</td>
</tr>
<tr>
<td>OpenVMS</td>
<td>infile '{fitness.weight.rawdata}club1.dat';</td>
</tr>
<tr>
<td>UNIX</td>
<td>infile '/usr/local/fitness/club1.dat';</td>
</tr>
<tr>
<td>Windows</td>
<td>infile 'c:\fitness\club1.dat';</td>
</tr>
</tbody>
</table>
Referencing an External File with a Fileref

Chapter 2

Table 2.2 Example FILENAME Statements for Various Operating Environments

<table>
<thead>
<tr>
<th>Operating environment</th>
<th>FILENAME statement example</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS</td>
<td>filename fitclub ‘fitness.weight.rawdata(club1)’;</td>
</tr>
<tr>
<td>CMS</td>
<td>filename fitclub ‘club1 weight a’;</td>
</tr>
<tr>
<td>OpenVMS</td>
<td>filename fitclub ‘[fitness.weight.rawdata]club1.dat’;</td>
</tr>
<tr>
<td>UNIX</td>
<td>filename fitclub ‘/usr/local/fitness/club1.dat’;</td>
</tr>
<tr>
<td>Windows</td>
<td>filename fitclub ‘c:\fitness\club1.dat’;</td>
</tr>
</tbody>
</table>

If you need to use several files or members from the same directory, partitioned data set (PDS), or MACLIB, then you can use the FILENAME statement to create a fileref that identifies the name of the directory, PDS, or MACLIB. Then you can use the fileref in the INFILE statement and enclose the name of the file, PDS member, or MACLIB member in parentheses immediately after the fileref, as in this example:

```
filename fitclub 'directory-or-PDS-or-MACLIB';
```

data temp;
  infile fitclub(club1);
  input IdNumber $ 1-4 Name $ 6-23 StartWeight 24-26 EndWeight 28-30;
run;

data temp2;
  infile fitclub(club2);
  input IdNumber $ 1-4 Name $ 6-23 StartWeight 24-26 EndWeight 28-30;
run;

In this case, the INFILE statements stay the same for all operating environments. The FILENAME statement, however, can appear differently for different operating environments, as the following table shows:

Table 2.3 Referencing Directories, PDSs, and MACLIBs in Various Operating Environments

<table>
<thead>
<tr>
<th>Operating environment</th>
<th>FILENAME statement example</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS</td>
<td>filename fitclub ‘fitness.weight.rawdata’;</td>
</tr>
<tr>
<td>CMS</td>
<td>filename fitclub ‘use1 maclib’;¹</td>
</tr>
<tr>
<td>OpenVMS</td>
<td>filename fitclub ‘[fitness.weight.rawdata]’;</td>
</tr>
<tr>
<td>UNIX</td>
<td>filename fitclub ‘/usr/local/fitness’;</td>
</tr>
<tr>
<td>Windows</td>
<td>filename fitclub ‘c:\fitness’;</td>
</tr>
</tbody>
</table>

¹ Under CMS, the external file must be a CMS MACLIB, a CMS TXTLIB, or a z/OS PDS.
Review of SAS Tools

Statements

DATA <libref.:>SAS-data-set;
tells SAS to begin creating a SAS data set. If you omit the libref, then SAS creates a temporary SAS data set. (SAS attaches the libref WORK for its internal processing.) If you give a previously defined libref as the first level of the name, then SAS stores the data set permanently in the library referenced by the libref. A SAS program or a portion of a program that begins with a DATA statement and ends with a RUN statement, another DATA statement, or a PROC statement is called a DATA step.

FILENAME fileref ‘your-input-or-output-file’;
associates a fileref with an external file. Enclose the name of the external file in quotation marks.

INFILE fileref ’your-input-file’;
identifies an external file to be read by an INPUT statement. Specify a fileref that has been assigned with a FILENAME statement or with an appropriate operating environment command, or specify the actual name of the external file.

INPUT variable <$>;
reads raw data using list input. At least one blank must occur between any two data values. The $ denotes a character variable.

INPUT variable <$>column-range;
reads raw data that is aligned in columns. The $ denotes a character variable.

INPUT variable informat;
reads raw data using formatted input. An informat supplies special instructions for reading the data.

LIBNAME libref ’your-SAS-data-library’;
associates a libref with a SAS data library. Enclose the name of the library in quotation marks. SAS locates a permanent SAS data set by matching the libref in a two-level SAS data set name with the library associated with that libref in a LIBNAME statement. The rules for creating a SAS data library depend on your operating environment.

Learning More

ATTRIBUTE statement
For information about how the ATTRIBUTE statement enables you to assign attributes to variables, see SAS Language Reference: Dictionary.

DBMS access
This documentation explains how to use SAS for reading files of raw data and SAS data sets and writing to SAS data sets. However, SAS documentation for SAS/ACCESS provides complete information about using SAS to read and write information stored in several types of database management system (DBMS) files.

Informats
For a discussion about informats that you use with dates, see Chapter 14, “Working with Dates in the SAS System,” on page 213.

Length of variables
For more information about how a variable’s length affects the values you can store in the variable, see Chapter 7, “Working with Numeric Variables,” on page 107 and Chapter 8, “Working with Character Variables,” on page 119.

LINESIZE= option
For information about how to use the LINESIZE= option in an INPUT statement to limit how much of each data line the INPUT statement reads, see SAS Language Reference: Dictionary.

MERGE, MODIFY, or UPDATE statements
In addition to the SET statement, you can read a SAS data set with the MERGE, MODIFY, or UPDATE statements. For more information, see Chapter 18, “Merging SAS Data Sets,” on page 271 and Chapter 19, “Updating SAS Data Sets,” on page 295.

SET statement
For information about the SET statement, see Chapter 5, “Starting with SAS Data Sets,” on page 81.

USER= SAS system option
You can specify the USER= SAS system option to use one-level names to point to permanent SAS files. (If you specify USER=WORK, then SAS assumes that files referenced with one-level names refer to temporary work files.) See the SAS System Options section in SAS Language Reference: Dictionary for details.

Introduction to Raw Data

Purpose

To create a SAS data set from raw data, you must examine the data records first to determine how the data values that you want to read are arranged. Then you can look at the styles of reading input that are available in the INPUT statement. SAS provides three basic input styles:

- list
- column
- formatted

You can use these styles individually, in combination with each other, or in conjunction with various line-hold specifiers, line-pointer controls, and column-pointer controls.

This section demonstrates various ways of using the INPUT statement to turn your raw data into SAS data sets.

You can enter the data directly in a DATA step or use an existing file of raw data. If your data is machine readable, then you need to learn how to use those tools that enable SAS to read them. If your data is not yet entered, then you can choose the input style that enables you to enter the data most easily.

Prerequisites

You should understand the concepts presented in Chapter 1, “What Is the SAS System?,” on page 3 and Chapter 2, “Introduction to DATA Step Processing,” on page 19 before continuing.

Examine the Structure of the Raw Data: Factors to Consider

Before you can select the appropriate style of input, examine the structure of the raw data that you want to read. Consider some of the following factors:

- how the data is arranged in the input records (For example, are data fields aligned in columns or unaligned? Are they separated by blanks or by other characters?)
- whether character values contain embedded blanks
- whether numeric values contain non-numeric characters such as commas
- whether the data contains time or date values
- whether each input record contains data for more than one observation
- whether data for a single observation is spread over multiple input records

Reading Unaligned Data

Understanding List Input

The simplest form of the INPUT statement uses list input. List input is used to read data values that are separated by a delimiter character (by default, a blank space). With list input, SAS reads a data value until it encounters a blank space. SAS assumes the
value has ended and assigns the data to the appropriate variable in the program data vector. SAS continues to scan the record until it reaches a nonblank character again. SAS reads a data value until it encounters a blank space or the end of the input record.

**Program: Basic List Input**

This program uses the health and fitness club data from Chapter 2, “Introduction to DATA Step Processing,” on page 19 to illustrate a DATA step that uses list input in an INPUT statement.

```
data club1;
  input IdNumber Name $ Team $ StartWeight EndWeight;
  datalines;
1023 David red 189 165
1049 Amelia yellow 145 124
1219 Alan red 210 192
1246 Ravi yellow 194 177
1078 Ashley red 127 118
1221 Jim yellow 220 .
;  
proc print data=club1;
  title 'Weight of Club Members';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The DATALINES statement marks the beginning of the data lines. The semicolon that follows the data lines marks the end of the data lines and the end of the DATA step.

2. Each data value in the raw data record is separated from the next by at least one blank space. The last record contains a missing value, represented by a period, for the value of EndWeight.

3. The variable names in the INPUT statement are specified in exactly the same order as the fields in the raw data records.

The output that follows shows the resulting data set. The PROC PRINT statement that follows the DATA step produces this listing.

**Output 3.1 Data Set Created with List Input**

<table>
<thead>
<tr>
<th>Obs</th>
<th>Id Number</th>
<th>Name</th>
<th>Team</th>
<th>Start Weight</th>
<th>End Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1023</td>
<td>David</td>
<td>red</td>
<td>189</td>
<td>165</td>
</tr>
<tr>
<td>2</td>
<td>1049</td>
<td>Amelia</td>
<td>yellow</td>
<td>145</td>
<td>124</td>
</tr>
<tr>
<td>3</td>
<td>1219</td>
<td>Alan</td>
<td>red</td>
<td>210</td>
<td>192</td>
</tr>
<tr>
<td>4</td>
<td>1246</td>
<td>Ravi</td>
<td>yellow</td>
<td>194</td>
<td>177</td>
</tr>
<tr>
<td>5</td>
<td>1078</td>
<td>Ashley</td>
<td>red</td>
<td>127</td>
<td>118</td>
</tr>
<tr>
<td>6</td>
<td>1221</td>
<td>Jim</td>
<td>yellow</td>
<td>220</td>
<td>.</td>
</tr>
</tbody>
</table>
Program: When the Data Is Delimited by Characters, Not Blanks

This program also uses the health and fitness club data but notice that here the data is delimited by a comma instead of a blank space, the default delimiter.

```
options pagesize=60 linesize=80 pageno=1 nodate;
data club1;
  infile datalines dlm=',';
  input IdNumber Name $ Team $ StartWeight EndWeight;
  datalines;
1023,David,red,189,165
1049,Amelia,yellow,145,124
1219,Alan,red,210,192
1246,Ravi,yellow,194,177
1078,Ashley,red,127,118
1221,Jim,yellow,220,.
;
proc print data=club1;
  title 'Weight of Club Members';
run;
```

The following list corresponds to the numbered items in the preceding output:

1. These data values are separated by commas instead of blanks.
2. List input, by default, scans the input records, looking for blank spaces to delimit each data value. The DLM= option enables list input to recognize a character, here a comma, as the delimiter.
3. This example required the DLM= option, which is available only in the INFILE statement. Usually this statement is used only when the input data resides in an external file. The DATALINES specification, however, enables you to take advantage of INFILE statement options, when you are reading data records from the job stream.

Output 3.2  Reading Data Delimited by Commas

<table>
<thead>
<tr>
<th>Obs</th>
<th>Id Number</th>
<th>Name</th>
<th>Team</th>
<th>Start Weight</th>
<th>End Weight</th>
</tr>

List Input: Points to Remember

The points to remember when you use list input are:

- Use list input when each field is separated by at least one blank space or delimiter.
- Specify each field in the order that they appear in the records of raw data.
Represent missing values by a placeholder such as a period. (Under the default behavior, a blank field causes the variable names and values to become mismatched.)

Character values cannot contain embedded blanks.

The default length of character variables is eight bytes. SAS truncates a longer value when it writes the value to the program data vector. (To read a character variable that contains more than eight characters with list input, use a LENGTH statement. See “Defining Enough Storage Space for Variables” on page 103.)

Data must be in standard character or numeric format (that is, it can be read without an informat).

Note: List input requires the fewest specifications in the INPUT statement. However, the restrictions that are placed on the data may require that you learn to use other styles of input to read your data. For example, column input, which is discussed in the next section, is less restrictive. This section has introduced only simple list input. See “Understanding How to Make List Input More Flexible” on page 53 to learn about modified list input.

Reading Data That Is Aligned in Columns

Understanding Column Input

With column input, data values occupy the same fields within each data record. When you use column input in the INPUT statement, list the variable names and specify column positions that identify the location of the corresponding data fields. You can use column input when your raw data is in fixed columns and does not require the use of informats to be read.

Program: Reading Data Aligned in Columns

The following program also uses the health and fitness club data, but now two more data values are missing. The data is aligned in columns and SAS reads the data with column input:

data club1;
  input IdNumber 1-4 Name $ 6-11 Team $ 13-18 StartWeight 20-22 EndWeight 24-26;
  datalines;
  1023 David red 189 165
  1049 Amelia yellow 145
  1219 Alan red 210 192
  1246 Ravi yellow 177
  1078 Ashley red 127 118
  1221 Jim yellow 220
;

proc print data=club1;
  title 'Weight Club Members';
run;
The specification that follows each variable name indicates the beginning and ending columns in which the variable value will be found. Note that with column input you are not required to indicate missing values with a placeholder such as a period.

The following output shows the resulting data set. Missing numeric values occur three times in the data set, and are indicated by periods.

</tr>
</tbody>
</table>

Understanding Some Advantages of Column Input over Simple List Input

Here are several advantages of using column input:

- With column input, character variables can contain embedded blanks.
- Column input also enables the creation of variables that are longer than eight bytes. In the preceding example, the variable Name in the data set CLUB1 contains only the members' first names. By using column input, you can read the first and last names as a single value. These differences between input styles are possible for two reasons:
  - Column input uses the columns that you specify to determine the length of character variables.
  - Column input, unlike list input, reads data until it reaches the last specified column, not until it reaches a blank space.
- Column input enables you to skip some data fields when reading records of raw data. It also enables you to read the data fields in any order and reread some fields or parts of fields.

Reading Embedded Blanks and Creating Longer Variables

This DATA step uses column input to create a new data set named CLUB2. The program still uses the health and fitness club weight data. However, the data has been modified to include members' first and last names. Now the second data field in each record or raw data contains an embedded blank and is 18 bytes long.

data club2;
  input IdNumber 1-4 Name $ 6-23 Team $ 25-30 StartWeight 32-34 EndWeight 36-38;
datalines;
1023 David Shaw red 189 165
Starting with Raw Data: The Basics

Program: Skipping Fields When Reading Data Records

Column input also enables you to skip over fields or to read the fields in any order. This example uses column input to read the same health and fitness club data, but it reads the value for the variable Team first and omits the variable IdNumber altogether.

You can read or reread part of a value when using column input. For example, because the team names begin with different letters, this program saves storage space by reading only the first character in the field that contains the team name. Note the INPUT statement:

```plaintext
data club2;
  input Team $ 25 Name $ 6-23 StartWeight 32-34 EndWeight 36-38;
datalines;
1023 David Shaw    red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance    red 210 192
1246 Ravi Sinha    yellow 194 177
1078 Ashley McKnight red 127 118
1221 Jim Brown     yellow 220
;
proc print data=club2;
  title 'Weight Club Members';
run;
```

The following output shows the resulting data set. The variable that contains the identification number is no longer in the data set. Instead, Team is the first variable in the new data set, and it contains only one character to represent the team value.

### Program: Skipping Fields When Reading Data Records

Column input also enables you to skip over fields or to read the fields in any order. This example uses column input to read the same health and fitness club data, but it reads the value for the variable Team first and omits the variable IdNumber altogether.

You can read or reread part of a value when using column input. For example, because the team names begin with different letters, this program saves storage space by reading only the first character in the field that contains the team name. Note the INPUT statement:

```plaintext
data club2;
  input Team $ 25 Name $ 6-23 StartWeight 32-34 EndWeight 36-38;
datalines;
1023 David Shaw    red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance    red 210 192
1246 Ravi Sinha    yellow 194 177
1078 Ashley McKnight red 127 118
1221 Jim Brown     yellow 220
;
proc print data=club2;
  title 'Weight Club Members';
run;
```

The following output shows the resulting data set. The variable that contains the identification number is no longer in the data set. Instead, Team is the first variable in the new data set, and it contains only one character to represent the team value.

**Column Input: Points to Remember**

Remember the following rules when you use column input:

- Character variables can be up to 32,767 bytes (32KB) in length and are not limited to the default length of eight bytes.
- Character variables can contain embedded blanks.
- You can read fields in any order.
- A placeholder is not required to indicate a missing data value. A blank field is read as missing and does not cause other values to be read incorrectly.
- You can skip over part of the data in the data record.
- You can reread fields or parts of fields.
- You can read standard character and numeric data only. Informats are ignored.

**Reading Data That Requires Special Instructions**

**Understanding Formatted Input**

Sometimes the INPUT statement requires special instructions to read the data correctly. For example, SAS can read numeric data that is in special formats such as binary, packed decimal, or date/time. SAS can also read numeric values that contain special characters such as commas and currency symbols. In these situations, use formatted input. Formatted input combines the features of column input with the ability to read nonstandard numeric or character values. The following data shows formatted input:

- 1,262
- $55.64
- 02JAN2003

**Program: Reading Data That Requires Special Instructions**

The data in this program includes numeric values that contain a comma, which is an invalid character for a numeric variable:

```sas
data january_sales;
   input Item $ 1-16 Amount comma5.;
```
Starting with Raw Data: The Basics △ Program: Reading Data That Requires Special Instructions

### datalines;
trucks 1,382
vans 1,235
sedans 2,391;

proc print data=january_sales;
  title 'January Sales in Thousands';
run;

The INPUT statement cannot read the values for the variable Amount as valid numeric values without the additional instructions provided by an informat. The informat COMMA5. enables the INPUT statement to read and store this data as a valid numeric value.

The following figure shows that the informat COMMA5. instructs the program to read five characters of data (the comma counts as part of the length of the data), to remove the comma from the data, and to write the resulting numeric value to the program data vector. Note that the name of an informat always ends in a period (.)

**Figure 3.1** Reading a Value with an Informat

<table>
<thead>
<tr>
<th>raw data value</th>
<th>read with INPUT statement containing COMMA5. informat</th>
<th>stored data value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,382</td>
<td>COMMA5. informat</td>
<td>1382</td>
</tr>
<tr>
<td>1,235</td>
<td></td>
<td>1235</td>
</tr>
<tr>
<td>2,391</td>
<td></td>
<td>2391</td>
</tr>
</tbody>
</table>

The following figure shows that the data values are read into the input buffer exactly as they occur in the raw data records, but they are written to the program data vector (and then to the data set as an observation) as valid numeric values without any special characters.

**Figure 3.2** Input Value Compared to Variable Value

Input Buffer

```
---------1---------2---------3
trucks  1,382
```

Program Data Vector

<table>
<thead>
<tr>
<th>Item</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>trucks</td>
<td>1382</td>
</tr>
</tbody>
</table>

The following output shows the resulting data set. The values for Amount contain only numbers. Note that the commas are removed.
In a report, you might want to include the comma in numeric values to improve readability. Just as the informat gives instructions on how to read a value and to remove the comma, a format gives instructions to add characters to variable values in the output. See “Writing Output without Creating a Data Set” on page 522 for an example.

In the next example, SAS reads data lines by using formatted input with a column-pointer control:

```sas
data january_sales;
  input Item $10. *17 Amount comma5.;
datalines;
  trucks 1,382
  vans 1,235
  sedans 2,391
;
```

After SAS reads the first value for the variable Item, the pointer is left in the next position, column 11. The absolute column-pointer control, @17, then directs the pointer to move to column 17 in the input buffer. Now, it is in the correct position to read a value for the variable Amount.

In the following program, the relative column-pointer control, +6, instructs the pointer to move six columns to the right before SAS reads the next data value.

```sas
data january_sales;
  input Item $10. +6 Amount comma5.;
datalines;
  trucks 1,382
```

In the next example, SAS reads data lines by using formatted input with a column-pointer control:

```sas
data january_sales;
  input Item $10. *17 Amount comma5.;
datalines;
  trucks 1,382
  vans 1,235
  sedans 2,391
;
```

After SAS reads the first value for the variable Item, the pointer is left in the next position, column 11. The absolute column-pointer control, @17, then directs the pointer to move to column 17 in the input buffer. Now, it is in the correct position to read a value for the variable Amount.

In the following program, the relative column-pointer control, +6, instructs the pointer to move six columns to the right before SAS reads the next data value.

```sas
data january_sales;
  input Item $10. +6 Amount comma5.;
datalines;
  trucks 1,382
```
The data in these two programs is aligned in columns. As with column input, you instruct the pointer to move from field to field. With column input you use column specifications; with formatted input you use the length that is specified in the informat together with pointer controls.

**Formatted Input: Points to Remember**

Remember the following rules when you use formatted input:

- SAS reads formatted input data until it has read the number of columns that the informat indicates. This method of reading the data is different from list input, which reads until a blank space (or other defined delimiter character) is reached.
- You can position the pointer to read the next value by using pointer controls.
- You can read data stored in nonstandard form such as packed decimal, or data that contains commas.
- You have the flexibility of using informats with all the features of column input, as described in “Column Input: Points to Remember” on page 50.

**Reading Unaligned Data with More Flexibility**

**Understanding How to Make List Input More Flexible**

While list input is the simplest to code, remember that it places restrictions on your data. By using format modifiers, you can take advantage of the simplicity of list input without the inconvenience of the usual restrictions. For example, you can use modified list input to do the following:

- Create character variables that are longer than the default length of eight bytes.
- Read numeric data with special characters like commas, dashes, and currency symbols.
- Read character data that contains embedded blanks.
- Read data values that can be stored as SAS date variables.

**Creating Longer Variables and Reading Numeric Data That Contains Special Characters**

By simply modifying list input with the *colon format modifier* (:) you can read

- character data that contains more than eight characters
- numeric data that contains special characters.

To use the colon format modifier with list input, place the colon between the variable name and the informat. As in simple list input, at least one blank (or other defined delimiter character) must separate each value from the next, and character values cannot contain embedded blanks (or other defined delimiter characters). Consider this DATA step:

```sas
data january_sales;
    input Item : $12. Amount : comma5.;
```

```sas
vans 1,235
sedans 2,391
```

The data is read until the number of columns that the informat indicates.
Chapter 3

Reading Character Data That Contains Embedded Blanks

Because list input uses a blank space to determine where one value ends and the
next one begins, values normally cannot contain blanks. However, with the \texttt{ampersand}
format modifier (\texttt{&}) you can use list input to read data that contains single embedded
blanks. The only restriction is that at least two blanks must divide each value from the
next data value in the record.

To use the ampersand format modifier with list input, place the ampersand between
the variable name and the informat. The following DATA step uses the ampersand
format modifier with list input to create the data set \texttt{CLUB2}. Note that the data is not
in fixed columns; therefore, column input is not appropriate.

```r
data club2;
  input IdNumber Name &18. Team $ StartWeight EndWeight;
  datalines;
1023 David Shaw red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance red 210 192
1246 Ravi Sinha yellow 194 177
1078 Ashley McKnight red 127 118
1221 Jim Brown yellow 220 .
;
proc print data=club2;
  title 'Weight Club Members';
run;
```
The character variable Name, with a length of 18, contains members’ first and last names separated by one blank space. The data lines must have two blank spaces between the values for the variable Name and the variable Team for the INPUT statement to correctly read the data.

The following output shows the resulting data set.

Output 3.8  Data Set Created with Modified List Input (& $18.)

Mixing Styles of Input

An Example of Mixed Input

When you begin an INPUT statement in a particular style (list, column, or formatted), you are not restricted to using that style alone. You can mix input styles in a single INPUT statement as long as you mix them in a way that appropriately describes the raw data records. For example, this DATA step uses all three input styles:

data club1;
  input IdNumber 1
    Name $18. 2
    Team $ 25-30 3
    StartWeight EndWeight;
  datalines;
  1023 David Shaw red 189 165
  1049 Amelia Serrano yellow 145 124
  1219 Alan Nance red 210 192
  1246 Ravi Sinha yellow 194 177
  1078 Ashley McKnight red 127 118
  1221 Jim Brown yellow 220 .
;
proc print data=club1;
  title 'Weight Club Members';
run;

The following list corresponds to the numbered items in the preceding program:

1  The variables IdNumber, StartWeight, and EndWeight are read with list input.
2  The variable Name is read with formatted input.
3  The variable Team is read with column input.

The following output demonstrates that the data is read correctly.
Understanding the Effect of Input Style on Pointer Location

Why You Can Get into Trouble by Mixing Input Styles

**CAUTION:**

When you mix styles of input in a single INPUT statement, you can get unexpected results if you do not understand where the input pointer is positioned after SAS reads a value in the input buffer. As the INPUT statement reads data values from the record in the input buffer, it uses a *pointer* to keep track of its position. Read the following sections so that you understand how the pointer movement differs between input styles before mixing multiple input styles in a single INPUT statement.

**Pointer Location with Column and Formatted Input**

With column and formatted input, you supply the instructions that determine the exact pointer location. With column input, SAS reads the columns that you specify in the INPUT statement. With formatted input, SAS reads the exact length that you specify with the informat. In both cases, the pointer moves as far as you instruct it and stops. The pointer is left in the column that immediately follows the last column that is read.

Here are two examples of input followed by an explanation of the pointer location. The first DATA step shows column input:

```sas
data scores;
  input Team $ 1-6 Score 12-13;
datalines;
red  59
blue 95
yellow 63
green 76
;
```

---

**Output 3.9**  Data Set Created with Mixed Styles of Input

<table>
<thead>
<tr>
<th>Obs</th>
<th>Id</th>
<th>Number</th>
<th>Name</th>
<th>Team</th>
<th>Start</th>
<th>End</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1023</td>
<td>David Shaw</td>
<td>red</td>
<td>189</td>
<td>165</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1049</td>
<td>Amelia Serrano</td>
<td>yellow</td>
<td>145</td>
<td>124</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>1219</td>
<td>Alan Nance</td>
<td>red</td>
<td>210</td>
<td>192</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>1246</td>
<td>Ravi Sinha</td>
<td>yellow</td>
<td>194</td>
<td>177</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>1078</td>
<td>Ashley McKnight</td>
<td>red</td>
<td>127</td>
<td>118</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>1221</td>
<td>Jim Brown</td>
<td>yellow</td>
<td>220</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>
The second DATA step uses the same data to show formatted input:

```plaintext
data scores;
  input Team $6. +5 Score 2.;
datalines;
red   59
blue  95
yellow 63
green 76
;
```

The following figure shows that the pointer is located in column 7 after the first value is read with either of the two previous INPUT statements.

**Figure 3.3** Pointer Position: Column and Formatted Input

```
-----+----1----+----2
red        59
```

Unlike list input, column and formatted input rely totally on your instructions to move the pointer and read the value for the second variable, Score. Column input uses column specifications to move the pointer to each data field. Formatted input uses informats and pointer controls to control the position of the pointer.

This INPUT statement uses column input with the column specifications 12-13 to move the pointer to column 12 and read the value for the variable Score:

```plaintext
input Team $ 1-6 Score 12-13;
```

This INPUT statement uses formatted input with the +5 column-pointer control to move the pointer to column 12. Then the value for the variable Score is read with the 2. numeric informat.

```plaintext
input Team $6. +5 Score 2.;
```

Without the use of a pointer control, which moves the pointer to the column where the value begins, this INPUT statement would attempt to read the value for Score in columns 7 and 8, which are blank.
**Pointer Location with List Input**

List input, on the other hand, uses a scanning method to determine the pointer location. With list input, the pointer reads until a blank is reached and then stops in the next column. To read the next variable value, the pointer moves automatically to the first nonblank column, discarding any leading blanks it encounters. Here is the same data that is read with list input:

```sas
data scores;
  input Team $ Score;
datalines;
  red  59
  blue 95
  yellow 63
  green 76
;
```

The following figure shows that the pointer is located in column 5 after the value **red** is read. Because **Score**, the next variable, is read with list input, the pointer scans for the next nonblank space before it begins to read a value for **Score**. Unlike column and formatted input, you do not have to explicitly move the pointer to the beginning of the next field in list input.

![Figure 3.4](image)

**Review of SAS Tools**

**Statements**

**DATALINES;**

indicates that data lines immediately follow the DATALINES statement. A semicolon in the line that immediately follows the last data line indicates the end of the data and causes the DATA step to compile and execute.

**INFILE DATALINES DLM='character';**

identifies the source of the input records as data lines in the job stream rather than as an external file. When your program contains the input data, the data lines directly follow the DATALINES statement. Because you can specify DATALINES in the INFILE statement, you can take advantage of many data-reading options that are available only through the INFILE statement.

The DLM= option specifies the character that is used to separate data values in the input records. By default, a blank space denotes the end of a data value. This option is useful when you want to use list input to read data records in which a character other than a blank separates data values.
INPUT variable <&> <$>;  
reads the input data record using list input. The & (ampersand format modifier) enables character values to contain embedded blanks. When you use the ampersand format modifier, two blanks are required to signal the end of a data value. The $ indicates a character variable.

INPUT variable start-column <- end-column>;  
reads the input data record using column input. You can omit end-column if the data is only 1 byte long. This style of input enables you to skip columns of data that you want to omit.

INPUT variable : informat;  
INPUT variable & informat;  
read the input data record using modified list input. The : (colon format modifier) instructs SAS to use the informat that follows to read the data value. The & (ampersand format modifier) instructs SAS to use the informat that follows to read the data value. When you use the ampersand format modifier, two blanks are required to signal the end of a data value.

INPUT <pointer-control> variable informat;  
reads raw data using formatted input. The informat supplies special instructions to read the data. You can also use a pointer-control to direct SAS to start reading at a particular column.

The syntax given above for the three styles of input shows only one variable. Subsequent variables in the INPUT statement may or may not be described in the same input style as the first one. You may use any of the three styles of input (list, column, and formatted) in a single INPUT statement.

---

**Column-Pointer Controls**

@n  
moves the pointer to the nth column in the input buffer.

+n  
moves the pointer forward n columns in the input buffer.

/  
moves the pointer to the next line in the input buffer.

#n  
moves the pointer to the nth line in the input buffer.

---

**Learning More**

Advanced features  
For some more advanced data-reading features, see Chapter 4, “Starting with Raw Data: Beyond the Basics,” on page 61.

Character-delimited data  
For more information about reading data that is delimited by a character other than a blank space, see the DELIMITER= option in the INFILE statement in *SAS Language Reference: Dictionary*.
Pointer controls
For a complete discussion and listing of column-pointer controls, line-pointer controls, and line-hold specifiers, see *SAS Language Reference: Dictionary*.

Types of input
For more information about the INPUT statement, see *SAS Language Reference: Dictionary*. 
Introduction to Beyond the Basics with Raw Data

**Purpose**

To create a SAS data set from raw data, you often need more than the most basic features. In this section, you will learn advanced features for reading raw data that include the following:

- how to understand and then control what happens when a value is unexpectedly missing in an input record
- how to read a record more than once so that you may test a condition before taking action on the current record
- how to create multiple observations from a single input record
- how to read multiple observations to create a single record
Prerequisites

You should understand the concepts presented in Chapter 1, “What Is the SAS System?,” on page 3 and Chapter 2, “Introduction to DATA Step Processing,” on page 19 before continuing.

Testing a Condition before Creating an Observation

Sometimes you need to read a record, and hold that record in the input buffer while you test for a specified condition before a decision can be made about further processing. As an example, the ability to hold a record so that you can read from it again, if necessary, is useful when you need to test for a condition before SAS creates an observation from a data record. To do this, you can use the trailing at-sign (@).

For example, to create a SAS data set that is a subset of a larger group of records, you might need to test for a condition to decide if a particular record will be used to create an observation. The trailing at-sign placed before the semicolon at the end of an INPUT statement instructs SAS to hold the current data line in the input buffer. This makes the data line available for a subsequent INPUT statement. Otherwise, the next INPUT statement causes SAS to read a new record into the input buffer.

You can set up the process to read each record twice by following these steps:

1. Use an INPUT statement to read a portion of the record.
2. Use a trailing @ at the end of the INPUT statement to hold the record in the input buffer for the execution of the next INPUT statement.
3. Use an IF statement on the portion that is read in to test for a condition.
4. If the condition is met, use another INPUT statement to read the remainder of the record to create an observation.
5. If the condition is not met, the record is released and control passes back to the top of the DATA step.

To read from a record twice, you must prevent SAS from automatically placing a new record into the input buffer when the next INPUT statement executes. Use of a trailing @ in the first INPUT statement serves this purpose. The trailing @ is one of two line-hold specifiers that enable you to hold a record in the input buffer for further processing.

For example, the health and fitness club data contains information about all members. This DATA step creates a SAS data set that contains only members of the red team:

```sas
   data red_team;
      input Team $ 13-18 @;  ①  
      if Team='red';  ②  
      input IdNumber 1-4 StartWeight 20-22 EndWeight 24-26;  ③  
      datalines;
   1023 David red 189 165
   1049 Amelia yellow 145 124
   1219 Alan red 210 192
   1246 Ravi yellow 194 177
   1078 Ashley red 127 118
   1221 Jim yellow 220 .  ④  
;  
   proc print data=red_team;
```

① Use an INPUT statement to read a portion of the record.
② Use a trailing @ at the end of the INPUT statement to hold the record in the input buffer for the execution of the next INPUT statement.
③ Use an IF statement on the portion that is read in to test for a condition.
④ If the condition is met, use another INPUT statement to read the remainder of the record to create an observation.
⑤ If the condition is not met, the record is released and control passes back to the top of the DATA step.
In this DATA step, these actions occur:

1. The INPUT statement reads a record into the input buffer, reads a data value from columns 13 through 18, and assigns that value to the variable Team in the program data vector. The single trailing @ holds the record in the input buffer.

2. The IF statement enables the current iteration of the DATA step to continue only when the value for Team is red. When the value is not red, the current iteration stops and SAS returns to the top of the DATA step, resets values in the program data vector to missing, and releases the held record from the input buffer.

3. The INPUT statement executes only when the value of Team is red. It reads the remaining data values from the record held in the input buffer and assigns values to the variables IdNumber, StartWeight, and EndWeight.

4. The record is released from the input buffer when the program returns to the top of the DATA step.

The following output shows the resulting data set:

**Output 4.1  Subset Data Set Created with Trailing @**

**Creating Multiple Observations from a Single Record**

**Using the Double Trailing @ Line-Hold Specifier**

Sometimes you may need to create multiple observations from a single record of raw data. One way to tell SAS how to read such a record is to use the other line-hold specifier, the double trailing at-sign (@@ or “double trailing @”). The double trailing @ not only prevents SAS from reading a new record into the input buffer when a new INPUT statement is encountered, but it also prevents the record from being released when the program returns to the top of the DATA step. (Remember that the trailing @ does not hold a record in the input buffer across iterations of the DATA step.)

For example, this DATA step uses the double trailing @ in the INPUT statement:

```sas
data body_fat;
   input Gender $ PercentFat @@;
datalines;
m 13.3 f 22
m 22   f 23.2
m 16   m 12
;
proc print data=body_fat;
```
Understanding How the Double Trailing @ Affects DATA Step Execution

To understand how the data records in the previous example were read, look at the data lines that were used in the previous DATA step:

- m 13.3 f 22
- m 22 f 23.2
- m 16 m 12

Each record contains the raw data for two observations instead of one. Consider this example in terms of the flow of the DATA step, as explained in Chapter 2, “Introduction to DATA Step Processing,” on page 19.

When SAS reaches the end of the DATA step, it returns to the top of the program and begins the next iteration, executing until there are no more records to read. Each time it returns to the top of the DATA step and executes the INPUT statement, it automatically reads a new record into the input buffer. The second set of data values in each record, therefore, would never be read:

- m 13.3 f 22
- m 22 f 23.2
- m 16 m 12

To allow the second set of data values in each record to be read, the double trailing @ tells SAS to hold the record in the input buffer. Each record is held in the input buffer until the end of the record is reached. The program does not automatically place the next record into the input buffer each time the INPUT statement is executed, and the current record is not automatically released when it returns to the top of the DATA step. As a result, the pointer location is maintained on the current record which enables the program to read each value in that record. Each time the DATA step completes an iteration, an observation is written to the data set.

The next five figures demonstrate what happens in the input buffer when a double trailing @ appears in the INPUT statement, as in this example:

```
input Gender $ PercentFat @@;
```

The first figure shows that all values in the program data vector are set to missing. The INPUT statement reads the first record into the input buffer. The program begins
to read values from the current pointer location, which is the beginning of the input buffer.

**Figure 4.1** First Iteration: First Record Is Read

Input Buffer

```
--------1--------2
m 13.3 f 22
```

Program Data Vector

<table>
<thead>
<tr>
<th>Gender</th>
<th>PercentFat</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>.</td>
</tr>
</tbody>
</table>

The following figure shows that the value m is written to the program data vector. When the pointer reaches the blank space that follows 13.3, the complete value for the variable PercentFat has been read. The pointer stops in the next column, and the value 13.3 is written to the program data vector.

**Figure 4.2** First Observation Is Created

Input Buffer

```
--------1--------2
m 13.3 f 22
```

Program Data Vector

<table>
<thead>
<tr>
<th>Gender</th>
<th>PercentFat</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>13.3</td>
</tr>
</tbody>
</table>

There are no other variables in the INPUT statement and no more statements in the DATA step, so three actions take place:

1. The first observation is written to the data set.
2. The DATA step begins its next iteration.
3. The values in the program data vector are set to missing.

The following figure shows the current position of the pointer. SAS is ready to read the next piece of data in the same record.
Figure 4.3  Second Iteration: First Record Remains in the Input Buffer

Input Buffer
+---------------------+
| m 13.3 f 22         |
+---------------------+

Program Data Vector

<table>
<thead>
<tr>
<th>Gender</th>
<th>PercentFat</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>.</td>
</tr>
</tbody>
</table>

The following figure shows that the INPUT statement reads the next two values from the input buffer and writes them to the program data vector.

Figure 4.4  Second Observation Is Created

Input Buffer
+---------------------+
| m 13.3 f 22         |
+---------------------+

Program Data Vector

<table>
<thead>
<tr>
<th>Gender</th>
<th>PercentFat</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
<td>22</td>
</tr>
</tbody>
</table>

When the DATA step completes the second iteration, the values in the program data vector are written to the data set as the second observation. Then the DATA step begins its third iteration. Values in the program data vector are set to missing, and the INPUT statement executes. The pointer, which is now at column 13 (two columns to the right of the last data value that was read), continues reading. Because this is list input, the pointer scans for the next nonblank character to begin reading the next value. When the pointer reaches the end of the input buffer and fails to find a nonblank character, SAS reads a new record into the input buffer.

The final figure shows that values for the third observation are read from the beginning of the second record.
The process continues until SAS reads all the records. The resulting SAS data set contains six observations instead of three.

Note: Although this program successfully reads all of the data in the input records, SAS writes a message to the log noting that the program had to go to a new line.

---

### Reading Multiple Records to Create a Single Observation

#### How the Data Records Are Structured

An earlier example (see “Reading Character Data That Contains Embedded Blanks” on page 54) shows data for several observations that are contained in a single record of raw data:

```
1023 David Shaw red 189 165
```

This INPUT statement reads all the data values arranged across a single record:

```
input IdNumber 1-4 Name $ 6-23 Team $ StartWeight EndWeight;
```

Now, consider the opposite situation: when information for a single observation is not contained in a single record of raw data but is scattered across several records. For example, the health and fitness club data could be constructed in such a way that the information about a single member is spread across several records instead of in a single record:

```
1023 David Shaw
red
189 165
```

---

### Method 1: Using Multiple Input Statements

Multiple INPUT statements, one for each record, can read each record into a single observation, as in this example:

```
input IdNumber 1-4 Name $ 6-23;
input Team $ 1-6;
input StartWeight 1-3 EndWeight 5-7;
```

To understand how to use multiple INPUT statements, consider what happens as a DATA step executes. Remember that one record is read into the INPUT buffer.
automatically as each INPUT statement is encountered during each iteration. SAS reads the data values from the input buffer and writes them to the program data vector as variable values. At the end of the DATA step, all the variable values in the program data vector are written automatically as a single observation.

This example uses multiple INPUT statements in a DATA step to read only selected data fields and create a data set containing only the variables IdNumber, StartWeight, and EndWeight.

``` SAS
data club2;
  input IdNumber 1-4;  \1
  input;  \2
  input StartWeight 1-3 EndWeight 5-7;  \3
  datalines;
1023 David Shaw
red
189 165
1049 Amelia Serrano
yellow
145 124
1219 Alan Nance
red
210 192
1246 Ravi Sinha
yellow
194 177
1078 Ashley McKnight
red
127 118
1221 Jim Brown
yellow
220 .
;
proc print data=club2;
  title 'Weight Club Members';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The first INPUT statement reads only one data field in the first record and assigns a value to the variable IdNumber.
2. The second INPUT statement, without arguments, is a null INPUT statement that reads the second record into the input buffer. However, it does not assign a value to a variable.
3. The third INPUT statement reads the third record into the input buffer and assigns values to the variables StartWeight and EndWeight.

The following output shows the resulting data set:
Output 4.3  Data Set Created with Multiple INPUT Statements

<table>
<thead>
<tr>
<th>Weight Club Members</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>Id Number</td>
</tr>
<tr>
<td>1</td>
<td>1023</td>
</tr>
<tr>
<td>2</td>
<td>1049</td>
</tr>
<tr>
<td>3</td>
<td>1219</td>
</tr>
<tr>
<td>4</td>
<td>1246</td>
</tr>
<tr>
<td>5</td>
<td>1078</td>
</tr>
<tr>
<td>6</td>
<td>1221</td>
</tr>
</tbody>
</table>

Method 2: Using the / Line-Pointer Control

Writing a separate INPUT statement for each record is not the only way to create a single observation. You can write a single INPUT statement and use the slash (/) line-pointer control. The *slash line-pointer control* forces a new record into the input buffer and positions the pointer at the beginning of that record.

This example uses only one INPUT statement to read multiple records:

```sas
data club2;
  input IdNumber 1-4 / / StartWeight 1-3 EndWeight 5-7;
datalines;
1023 David Shaw red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance red 210 192
1246 Ravi Sinha yellow 194 177
1078 Ashley McKnight red 127 118
1221 Jim Brown yellow 220 .
;
proc print data=club2;
  title 'Weight Club Members';
run;
```

The / line-pointer control appears exactly where a new INPUT statement begins in the previous example (see “Method 1: Using Multiple Input Statements” on page 67). The sequence of events in the input buffer and the program data vector as this DATA step executes is identical to the previous example in method 1. The / is the signal to read a new record into the input buffer, which happens automatically when the DATA step encounters a new INPUT statement. The preceding example shows two slashes
(/ /), indicating that SAS skips a record. SAS reads the first record, skips the second record, and reads the third record.

The following output shows the resulting data set:

Output 4.4  Data Set Created with the / Line-Pointer Control

<table>
<thead>
<tr>
<th>Obs</th>
<th>Id Number</th>
<th>Start Weight</th>
<th>End Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1023</td>
<td>189</td>
<td>165</td>
</tr>
<tr>
<td>2</td>
<td>1049</td>
<td>145</td>
<td>124</td>
</tr>
<tr>
<td>3</td>
<td>1219</td>
<td>210</td>
<td>192</td>
</tr>
<tr>
<td>4</td>
<td>1246</td>
<td>194</td>
<td>177</td>
</tr>
<tr>
<td>5</td>
<td>1078</td>
<td>127</td>
<td>118</td>
</tr>
<tr>
<td>6</td>
<td>1221</td>
<td>220</td>
<td></td>
</tr>
</tbody>
</table>

Reading Variables from Multiple Records in Any Order

You can also read multiple records to create a single observation by pointing to a specific record in a set of input records with the \#n line-pointer control. As you saw in the last section, the advantage of using the / line-pointer control over multiple INPUT statements is that it requires fewer statements. However, using the \#n line-pointer control enables you to read the variables in any order, no matter which record contains the data values. It is also useful if you want to skip data lines.

This example uses one INPUT statement to read multiple data lines in a different order:

```sas
data club2;
    input #2 Team $ 1-6 #1 Name $ 6-23 IdNumber 1-4
         #3 StartWeight 1-3 EndWeight 5-7;
    datalines;
1023 David Shaw red 189 165
1049 Amelia Serrano yellow 145 124
1219 Alan Nance red 210 192
1246 Ravi Sinha yellow 194 177
1078 Ashley McKnight red 127 118
1221 Jim Brown yellow 220 .
;
proc print data=club2;
```
title 'Weight Club Members';
run;

The following output shows the resulting data set:

Output 4.5  Data Set Created with the \#n Line-Pointer Control

<table>
<thead>
<tr>
<th>Obs</th>
<th>Team</th>
<th>Name</th>
<th>Id</th>
<th>Start</th>
<th>End</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>red</td>
<td>David Shaw</td>
<td>1023</td>
<td>189</td>
<td>165</td>
</tr>
<tr>
<td>2</td>
<td>yellow</td>
<td>Amelia Serrano</td>
<td>1049</td>
<td>145</td>
<td>124</td>
</tr>
<tr>
<td>3</td>
<td>red</td>
<td>Alan Nance</td>
<td>1219</td>
<td>210</td>
<td>192</td>
</tr>
<tr>
<td>4</td>
<td>yellow</td>
<td>Ravi Sinha</td>
<td>1246</td>
<td>194</td>
<td>177</td>
</tr>
<tr>
<td>5</td>
<td>red</td>
<td>Ashley McKnight</td>
<td>1078</td>
<td>127</td>
<td>118</td>
</tr>
<tr>
<td>6</td>
<td>yellow</td>
<td>Jim Brown</td>
<td>1221</td>
<td>220</td>
<td></td>
</tr>
</tbody>
</table>

The order of the observations is the same as in the raw records (shown in the section “Reading Variables from Multiple Records in Any Order” on page 70). However, the order of the variables in the data set differs from the order of the variables in the raw input data records. This occurs because the order of the variables in the INPUT statements corresponds with their order in the resulting data sets.

Understanding How the \#n Line-Pointer Control Affects DATA Step Execution

To understand the importance of the \#n line-pointer control, remember the sequence of events in the DATA steps that demonstrate the / line-pointer control and multiple INPUT statements. Each record is read into the input buffer sequentially. The data is read, and then a / or a new INPUT statement causes the program to read the next record into the input buffer. It is impossible for the program to read a value from the first record after a value from the second record is read because the data in the first record is no longer available in the input buffer.

To solve this problem, use the \#n line-pointer control. The \#n line-pointer control signals the program to create a multiple-line input buffer so that all the data for a single observation is available while the observation is being built in the program data vector. The \#n line-pointer control also identifies the record in which data for each variable appears. To use the \#n line-pointer control, the raw data must have the same number of records for each observation; for example, it cannot have three records for one observation and two for the next.

When the program compiles and builds the input buffer, it looks at the INPUT statement and creates an input buffer with as many lines as are necessary to contain the number of records it needs to read for a single observation. In this example, the highest number of records specified is three, so the input buffer is built to contain three records at one time. The following figures demonstrate the flow of the DATA step in this example.

This figure shows that the values are set to missing in the program data vector and that the INPUT statement reads the first three records into the input buffer.
Figure 4.6  Three Records Are Read into the Input Buffer as a Single Observation

Input Buffer

\[
\begin{array}{cccccc}
1023 & \text{David Shaw} \\
\text{red} \\
189 & 165
\end{array}
\]

Program Data Vector

<table>
<thead>
<tr>
<th>Team</th>
<th>Name</th>
<th>IdNumber</th>
<th>StartWeight</th>
<th>EndWeight</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

The INPUT statement for this example is as follows:

```
input #2 Team $ 1-6  
  #1 Name $ 6-23 IdNumber 1-4  
  #3 StartWeight 1-3 EndWeight 5-7;
```

The first variable is preceded by #2 to indicate that the value in the second record is assigned to the variable Team. The following figure shows that the pointer advances to the second line in the input buffer, reads the value, and writes it to the program data vector.

Figure 4.7  Reading from the Second Record First

Input Buffer

\[
\begin{array}{cccccc}
1023 & \text{David Shaw} \\
\text{red} \\
189 & 165
\end{array}
\]

Program Data Vector

<table>
<thead>
<tr>
<th>Team</th>
<th>Name</th>
<th>IdNumber</th>
<th>StartWeight</th>
<th>EndWeight</th>
</tr>
</thead>
<tbody>
<tr>
<td>red</td>
<td></td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

The following figure shows that the pointer then moves to the sixth column in the first record, reads a value, and assigns it to the variable Name in the program data vector. It then moves to the first column to read the ID number, and assigns it to the variable IdNumber.
Starting with Raw Data: Beyond the Basics △ Understanding How the #n Line-Pointer Control Affects DATA Step Execution 73

**Figure 4.8** Reading from the First Record

Input Buffer

<thead>
<tr>
<th>Team</th>
<th>Name</th>
<th>IdNumber</th>
<th>StartWeight</th>
<th>EndWeight</th>
</tr>
</thead>
<tbody>
<tr>
<td>red</td>
<td>David Shaw</td>
<td>1023</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

The following figure shows that the process continues with the pointer moving to the third record in the first observation. Values are read and assigned to StartWeight and EndWeight, the last variable that is listed.

**Figure 4.9** Reading from the Third Record

Input Buffer

```
1023 David Shaw
```

```
1023 David Shaw
```

```
red
```

```
189 165
```

Program Data Vector

<table>
<thead>
<tr>
<th>Team</th>
<th>Name</th>
<th>IdNumber</th>
<th>StartWeight</th>
<th>EndWeight</th>
</tr>
</thead>
<tbody>
<tr>
<td>red</td>
<td>David Shaw</td>
<td>1023</td>
<td>189</td>
<td>165</td>
</tr>
</tbody>
</table>

When the bottom of the DATA step is reached, variable values in the program data vector are written as an observation to the data set. The DATA step returns to the top, and values in the program data vector are set to missing. The INPUT statement executes again. The final figure shows that the next three records are read into the input buffer, ready to create the second observation.

Problem Solving: When an Input Record Unexpectedly Does Not Have Enough Values

Understanding the Default Behavior

When a DATA step reads raw data from an external file, problems can occur when SAS encounters the end of an input line before reading in data for all variables specified in the input statement. This problem can occur when reading variable-length records and/or records containing missing values.

The following is an example of an external file that contains variable-length records:

```
22
333
4444
55555
```

This DATA step uses the numeric informat 5. to read a single field in each record of raw data and to assign values to the variable TestNumber:

```sas
data numbers;
  infile 'your-external-file';
  input TestNumber 5.;
run;
```

```sas
proc print data=numbers;
  title 'Test DATA Step';
run;
```

The DATA step reads the first value (22). Because the value is shorter than the 5 characters expected by the informat, the DATA step attempts to finish filling the value with the next record (333). This value is entered into the PDV and becomes the value of
the TestNumber variable for the first observation. The DATA step then goes to the next record, but encounters the same problem because the value (4444) is shorter than the value that is expected by the informat. Again, the DATA step goes to the next record, reads the value (55555), and assigns that value to the TestNumber variable for the second observation.

The following output shows the results. After this program runs, the SAS log contains a note to indicate the places where SAS went to the next record to search for data values.

Methods of Control: Your Options

Four Options: FLOWOVER, STOPOVER, MISSOVER, and TRUNCOVER

To control how SAS behaves after it attempts to read past the end of a data line, you can use the following options in the INFILE statement:

infile 'your-external-file' flowover;

is the default behavior. The DATA step simply reads the next record into the input buffer, attempting to find values to assign to the rest of the variable names in the INPUT statement.

infile 'your-external-file' stopover;

causes the DATA step to stop processing if an INPUT statement reaches the end of the current record without finding values for all variables in the statement. Use this option if you expect all of the data in the external file to conform to a given standard and if you want the DATA step to stop when it encounters a data record that does not conform to the standard.

infile 'your-external-file' missover;

prevents the DATA step from going to the next line if it does not find values in the current record for all of the variables in the INPUT statement. Instead, the DATA step assigns a missing value for all variables that do not have values.

infile 'your-external-file' truncover;

causes the DATA step to assign the raw data value to the variable even if the value is shorter than expected by the INPUT statement. If, when the DATA step encounters the end of an input record, there are variables without values, the variables are assigned missing values for that observation.

You can also use these options even when your data lines are in the program itself, that is, when they follow the DATALINES statement. Simply use datalines instead of a reference to an external file to indicate that the data records are in the DATA step itself:

-(infile datalines flowover;
-(infile datalines stopover;
Methods of Control: Your Options

Chapter 4

infile datalines missover;
infile datalines truncover;

Note: The examples in this section show the use of the MISSOVER and TRUNCOVER options with formatted input. You can also use these options with list input and column input.

Understanding the MISSOVER Option

The MISSOVER option prevents the DATA step from going to the next line if it does not find values in the current record for all of the variables in the INPUT statement. Instead, the DATA step assigns a missing value for all variables that do not have complete values according to any specified informats. The input file contains the following raw data:

```
----+-----1-----+-----2
  22
  333
  4444
  55555
```

The following example uses the MISSOVER option:

```sas
data numbers;
  infile 'your-external-file' missover;
  input TestNumber 5.;
run;
```

```sas
proc print data=numbers;
  title 'Test DATA Step';
run;
```

Output 4.7  Output from the MISSOVER Option

<table>
<thead>
<tr>
<th>Test DATA Step</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>Number</td>
</tr>
<tr>
<td>1</td>
<td>.</td>
</tr>
<tr>
<td>2</td>
<td>.</td>
</tr>
<tr>
<td>3</td>
<td>.</td>
</tr>
<tr>
<td>4</td>
<td>55555</td>
</tr>
</tbody>
</table>

Because the fourth record is the only one whose value matches the informat, it is the only record whose value is assigned to the TestNumber variable. The other observations receive missing values. This result is probably not the desired outcome for this example, but the MISSOVER option can sometimes be valuable. For an example, see “Updating a Data Set” on page 297.

Note: If there is a blank line at the end of the last record, the DATA step attempts to load another record into the input buffer. Because there are no more records, the MISSOVER option instructs the DATA step to assign missing values to all variables, and an extra observation is added to the data set. To prevent this situation from
occurring, make sure that your input data does not have a blank line at the end of the last record.

Understanding the TRUNCOVER Option

The TRUNCOVER option causes the DATA step to assign the raw data value to the variable even if the value is shorter than the length that is expected by the INPUT statement. If, when the DATA step encounters the end of an input record, there are variables without values, the variables are assigned missing values for that observation. The following example demonstrates the use of the TRUNCOVER statement:

```sas
data numbers;
    infile 'your-external-file' truncover;
    input TestNumber 5.;
run;
```

```sas
proc print data=numbers;
    title 'Test DATA Step';
run;
```

Output 4.8  Output from the TRUNCOVER Option

<table>
<thead>
<tr>
<th>Obs</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>22</td>
</tr>
<tr>
<td>2</td>
<td>333</td>
</tr>
<tr>
<td>3</td>
<td>4444</td>
</tr>
<tr>
<td>4</td>
<td>55555</td>
</tr>
</tbody>
</table>

This result shows that all of the values were assigned to the TestNumber variable, despite the fact that three of them did not match the informat. For another example using the TRUNCOVER option, see “Input SAS Data Set for Examples” on page 140.

Review of SAS Tools

Column-Pointer Controls

@ \text{n}

moves the pointer to the \text{n} column in the input buffer.

+n

moves the pointer forward \text{n} columns in the input buffer.

/

moves the pointer to the next line in the input buffer.

#\text{n}

moves the pointer to the \text{n}th line in the input buffer.
Line-Hold Specifiers

@ (trailing @) prevents SAS from automatically reading a new data record into the input buffer when a new INPUT statement is executed within the same iteration of the DATA step. When used, the trailing @ must be the last item in the INPUT statement.

@@ (double trailing @) prevents SAS from automatically reading a new data record into the input buffer when the next INPUT statement is executed, even if the DATA step returns to the top for another iteration. When used, the double trailing @ must be the last item in the INPUT statement.

Statements

DATALINES;
indicates that data lines immediately follow. A semicolon in the line that immediately follows the last data line indicates the end of the data and causes the DATA step to compile and execute.

INFILE fileref< FLOWOVER | STOPOVER | MISSOVER | TRUNCOVER>;
INFILE 'external-file' <FLOWOVER | STOPOVER | MISSOVER | TRUNCOVER>;
identifies an external file to be read by an INPUT statement. Specify a fileref that has been assigned with a FILENAME statement or with an appropriate operating environment command. Or you can specify the actual name of the external file.
These options give you control over how SAS behaves if the end of a data record is encountered before all of the variables are assigned values. You can use these options with list, modified list, formatted, and column input.

FLOWOVER is the default behavior. It causes the DATA step to look in the next record if the end of the current record is encountered before all of the variables are assigned values

MISSOVER causes the DATA step to assign missing values to any variables that do not have values when the end of a data record is encountered. The DATA step continues processing.

STOPOVER causes the DATA step to stop execution immediately and write a note to the SAS log.

TRUNCOVER causes the DATA step to assign values to variables, even if the values are shorter than expected by the INPUT statement, and to assign missing values to any variables that do not have values when the end of a record is encountered.

INPUT variable <&> <$>;
reads the input data record using list input. The & (ampersand format modifier) allows character values to contain embedded blanks. When you use the ampersand format modifier, two blanks are required to signal the end of a data value. The $ indicates a character variable.
INPUT variable start-column<end-column>;
   reads the input data record using column input. You can omit end-column if the
data is only 1 byte long. This style of input enables you to skip columns of data
that you want to omit.

INPUT variable : informat;
INPUT variable & informat;
   reads the input data record using modified list input. The : (colon format modifier)
instructs SAS to use the informat that follows to read the data value. The &
(ampersand format modifier) instructs SAS to use the informat that follows to read
the data value. When you use the ampersand format modifier, two blanks are
required to signal the end of a data value.

INPUT <pointer-control> variable informat;
   reads raw data using formatted input. The informat supplies special instructions
to read the data. You can also use a pointer-control to direct SAS to start reading
at a particular column.

   The syntax given above for the three styles of input shows only one variable.
Subsequent variables in the INPUT statement may or may not be described in the
same input style as the first one. You may use any of the three styles of input (list,
column, and formatted) in a single INPUT statement.

Learning More

Handling missing data values

specifiers, see SAS Language Reference: Dictionary.
CHAPTER 5

Starting with SAS Data Sets

Introduction to Starting with SAS Data Sets

Purpose

In this section, you will learn how to do the following:

- display information about a SAS data set
- create a new SAS data set from an existing SAS data set rather than creating it from raw data records

Reading a SAS data set in a DATA step is simpler than reading raw data because the work of describing the data to SAS has already been done.

Prerequisites

You should understand the concepts presented in Chapter 1, “What Is the SAS System?,” on page 3 and Chapter 2, “Introduction to DATA Step Processing,” on page 19 before continuing with this section.
Understanding the Basics

When you use a SAS data set as input into a DATA step, the description of the data set is available to SAS. In your DATA step, use a SET, MERGE, MODIFY, or UPDATE statement to read the SAS data set. Use SAS programming statements to process the data and create an output SAS data set.

In a DATA step, you can create a new data set that is a subset of the original data set. For example, if you have a large data set of personnel data, you might want to look at a subset of observations that meet certain conditions, such as observations for employees hired after a certain date. Alternatively, you might want to see all observations but only a few variables, such as the number of years of education or years of service to the company.

When you use existing SAS data sets, as well as with subsets created from SAS data sets, you can make more efficient use of computer resources than if you use raw data or if you are working with large data sets. Reading fewer variables means that SAS creates a smaller program data vector, and reading fewer observations means that fewer iterations of the DATA step occur. Reading data directly from a SAS data set is more efficient than reading the raw data again, because the work of describing and converting the data has already been done.

One way of looking at a SAS data set is to produce a listing of the data in a SAS data set by using the PRINT procedure. Another way to look at a SAS data set is to display information that describes its structure rather than its data values. To display information about the structure of a data set, use the DATASETS procedure with the CONTENTS statement. If you need to work with a SAS data set that is unfamiliar to you, the CONTENTS statement in the DATASETS procedure displays valuable information such as the name, type, and length of all the variables in the data set. An example that shows the CONTENTS statement in the DATASETS procedure is shown in “Input SAS Data Set for Examples” on page 82.

Input SAS Data Set for Examples

The examples in this section use a SAS data set named CITY, which contains information about expenditures for a small city. It reports total city expenditures for the years 1980 through 2000 and divides the expenses into two major categories: services and administration. (To see the program that creates the CITY data set, see “DATA Step to Create the Data Set CITY” on page 714.)

The following example uses the DATASETS procedure with the NOLIST option to display the CITY data set. The NOLIST option prevents the DATASETS procedure from listing other data sets that are also located in the WORK library:

```sas
proc datasets library=work nolist;
   contents data=city;
run;
```
Output 5.1  The Structure of CITY as Shown by PROC DATASETS

The following list corresponds to the numbered items in the previous SAS output:

1 The Observations and the Variables fields identify the number of observations and the number of variables.
2 The Engine/Host Dependent Information section lists detailed information about the data set. This information is generated by the engine, which is the mechanism for reading from and writing to files.

Operating Environment Information:  The output in this section may differ, depending on your operating environment. For more information, refer to the SAS documentation for your operating environment.

3 The Alphabetic List of Variables and Attributes lists the name, type, length, and position of each variable.
4 The Label lists the format, informat, and label for each variable, if they exist.
Reading Selected Observations

If you are interested in only part of a large data set, you can use data set options to create a subset of your data. Data set options specify which observations you want the new data set to include. In Chapter 10, “Creating Subsets of Observations,” on page 159 you learn how to use the subsetting IF statement to create a subset of a large SAS data set. In this section, you learn how to use the FIRSTOBS= and OBS= data set options to create subsets of a larger data set.

For example, you might not want to read the observations at the beginning of the data set. You can use the FIRSTOBS= data set option to define which observation should be the first one that is processed. For the data set CITY, this example creates a data set that excludes observations that contain data prior to 1991 by specifying FIRSTOBS=12. As a result, SAS does not read the first 11 observations, which contain data prior to 1991. (To see the program that creates the CITY data set, see “DATA Step to Create the Data Set CITY” on page 714.)

The following program creates the data set CITY2, which contains the same number of variables but fewer observations than CITY.

data city2;
   set city(firstobs=12);
run;

proc print;
   title 'City Expenditures';
   title2 '1991 - 2000';
run;

The following output shows the results:
You can also specify the last observation you want to include in a new data set with the OBS= data set option. For example, the next program creates a SAS data set containing only the observations for 1989 (the 10th observation) through 1994 (the 15th observation).

```sas
data city3;
    set city (firstobs=10 obs=15);
run;
```

### Reading Selected Variables

#### Overview of Reading Selected Variables

You can create a subset of a larger data set not only by excluding observations but also by specifying which variables you want the new data set to contain. In a DATA step you can use the SET statement and the KEEP= or DROP= data set options (or the DROP and KEEP statements) to create a subset from a larger data set by specifying which variables you want the new data set to include.
Keeping Selected Variables

This example uses the KEEP= data set option in the SET statement to read only the variables that represent the services-related expenditures of the data set CITY.

```sas
data services;
  set city (keep=Year ServicesTotal ServicesPolice ServicesFire ServicesWater_Sewer);
run;
```

```sas
proc print data=services;
title 'City Services-Related Expenditures';
run;
```

The following output shows the resulting data set. Note that the data set SERVICES contains only those variables that are specified in the KEEP= option.

### Output 5.3 Selecting Variables with the KEEP= Option

</tbody>
</table>

The following example uses the KEEP statement instead of the KEEP= data set option to read all of the variables from the CITY data set. The KEEP statement creates a new data set (SERVICES) that contains only the variables listed in the KEEP statement. The following program gives results that are identical to those in the previous example:

```sas
data services;
  set city;
  keep Year ServicesTotal ServicesPolice ServicesFire ServicesWater_Sewer;
run;
```
The following example has the same effect as using the KEEP= data set option in the DATA statement. All of the variables are read into the program data vector, but only the specified variables are written to the SERVICES data set:

```sas
data services (keep=Year ServicesTotal ServicesPolice ServicesFire ServicesWater_Sewer);
set city;
run;
```

## Dropping Selected Variables

Use the DROP= option to create a subset of a larger data set when you want to specify which variables are being excluded rather than which ones are being included. The following DATA step reads all of the variables from the data set CITY except for those that are specified with the DROP= option, and then creates a data set named SERVICES2:

```sas
data services2;
set city (drop=Total AdminTotal AdminLabor AdminSupplies AdminUtilities);
run;
```

```sas
proc print data=services2;
title 'City Services-Related Expenditures';
run;
```

The following output shows the resulting data set:

**Output 5.4  Excluding Variables with the DROP= Option**

```
Obs Year Services Police Services Services Services
    Year   | Police | Fire | Services | Water_Sewer | Total
--------+--------+------|----------+------------|-----------
  1 1980 | 2819   | 1120 | 422      | 4361        |
  2 1981 | 2477   | 1160 | 500      | 4137        |
  3 1982 | 2028   | 1061 | 510      | 3599        |
  4 1983 | 2754   | 893  | 540      | 4187        |
  5 1984 | 2195   | 963  | 541      | 3699        |
  6 1985 | 1877   | 926  | 535      | 3338        |
  7 1986 | 1727   | 1111 | 535      | 3373        |
  8 1987 | 1532   | 1220 | 519      | 3271        |
  9 1988 | 1448   | 1156 | 577      | 3181        |
 10 1989 | 1500   | 1076 | 606      | 3182        |
 11 1990 | 1934   | 969  | 646      | 3549        |
 12 1991 | 2195   | 1002 | 643      | 3840        |
 13 1992 | 2204   | 964  | 692      | 3860        |
 14 1993 | 2175   | 1144 | 735      | 4054        |
 15 1994 | 2556   | 1341 | 813      | 4710        |
 16 1995 | 2026   | 1380 | 868      | 4274        |
 17 1996 | 2526   | 1454 | 946      | 4926        |
 18 1997 | 2027   | 1486 | 1043     | 4556        |
 19 1998 | 2037   | 1667 | 1152     | 4856        |
 20 1999 | 2852   | 1834 | 1318     | 6004        |
 21 2000 | 2787   | 1701 | 1317     | 5805        |
```
The following example uses the DROP statement instead of the DROP= data set option to read all of the variables from the CITY data set and to exclude the variables that are listed in the DROP statement from being written to the new data set. The results are identical to those in the previous example:

```sas
data services2;
  set city;
  drop Total AdminTotal AdminLabor AdminSupplies AdminUtilities;
run;
proc print data=services2;
run;
```

### Choosing between Data Set Options and Statements

When you create only one data set in the DATA step, the data set options to drop and keep variables have the same effect on the output data set as the statements to drop and keep variables. When you want to control which variables are read into the program data vector, using the data set options in the statement (such as a SET statement) that reads the SAS data set is generally more efficient than using the statements. Later topics in this section show you how to use the data set options in some cases where the statements will not work.

### Choosing between the DROP= and KEEP= Data Set Option

In a simple case, you might decide to use the DROP= or KEEP= option, depending on which method enables you to specify fewer variables. If you work with large jobs that read data sets, and you expect that variables might be added between the times your batch jobs run, you may want to use the KEEP= option to specify which variables are included in the subset data set.

The following figure shows two data sets named SMALL. They have different contents because the new variable F was added to data set BIG before the DATA step ran on Tuesday. The DATA step uses the DROP= option to keep variables D and E from being written to the output data set. The result is that the data sets contain different contents: the second SMALL data set has an extra variable, F. If the DATA step used the KEEP= option to specify A, B, and C, then both of the SMALL data sets would have the same variables (A, B, and C). The addition of variable F to the original data set BIG would have no effect on the creation of the SMALL data set.
Creating More Than One Data Set in a Single DATA Step

You can use a single DATA step to create more than one data set at a time. You can create data sets with different contents by using the KEEP= or DROP= data set options. For example, the following DATA step creates two SAS data sets: SERVICES contains variables that show services-related expenditures, and ADMIN contains variables that represent the administration-related expenditures. Use the KEEP= option after each data set name in the DATA statement to determine which variables are written to each SAS data set being created.

```sas
data services(keep=ServicesTotal ServicesPolice ServicesFire ServicesWater_Sewer)
   admin(keep=AdminTotal AdminLabor AdminSupplies AdminUtilities);
set city;
run;

proc print data=services;
  title 'City Expenditures: Services';
run;
```

**Figure 5.1 Using the DROP= Option**

<table>
<thead>
<tr>
<th>contents of data set</th>
<th>add variable =</th>
<th>contents of data set</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG on Monday</td>
<td>+ F</td>
<td>BIG on Tuesday</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

Using the DROP= and KEEP= Data Set Options for Efficiency

The DROP= and KEEP= data set options are valid in both the DATA statement and the SET statement. However, you can write a more efficient DATA step if you understand the consequences of using these options in the DATA statement rather than the SET statement.

In the DATA statement, these options affect which variables SAS writes from the program data vector to the resulting SAS data set. In the SET statement, these options determine which variables SAS reads from the input SAS data set. Therefore, they determine how the program data vector is built.

When you specify the DROP= or KEEP= option in the SET statement, SAS does not read the excluded variables into the program data vector. If you work with a large data set (perhaps one containing thousands or millions of observations), you can construct a more efficient DATA step by not reading unneeded variables from the input data set.

Note also that if you use a variable from the input data set to perform a calculation, the variable must be read into the program data vector. If you do not want that variable to appear in the new data set, however, use the DROP= option in the DATA statement to exclude it.

The following DATA step creates the same two data sets as the DATA step in the previous example, but it does not read the variable Total into the program data vector. Compare the SET statement here to the one in “Creating More Than One Data Set in a Single DATA Step” on page 89.

```sas
data services (keep=ServicesTotal ServicesPolice ServicesFire ServicesWater_Sewer)
```
In contrast with previous examples, the data set options in this example appear in both the DATA and SET statements. In the SET statement, the DROP= option determines which variables are omitted from the program data vector. In the DATA statement, the KEEP= option controls which variables are written from the program data vector to each data set being created.

**Note:** Using a DROP or KEEP statement is comparable to using a DROP= or KEEP= option in the DATA statement. All variables are included in the program data vector; they are excluded when the observation is written from the program data vector to the new data set. When you create more than one data set in a single DATA step, using the data set options enables you to drop or keep different variables in each of the new data sets. A DROP or KEEP statement, on the other hand, affects all of the data sets that are created.

---

**Data Set Options**

**DROP=variable(s)**
- specifies the variables to be excluded.
  - Used in the SET statement, DROP= specifies the variables that are not to be read from the existing SAS data set into the program data vector. Used in the DATA statement, DROP= specifies the variables to be excluded from the data set that is being created.

**FIRSTOBS=n**
- specifies the first observation to be read from the SAS data set that you specify in the SET statement.

**KEEP=variable(s)**
- specifies the variables to be included.
  - Used in the SET statement, KEEP= specifies the variables to be read from the existing SAS data set into the program data vector. Used in the DATA statement, KEEP= specifies which variables in the program data vector are to be written to the data set being created.

**OBS=n**
- specifies the last observation to be read from the SAS data set that you specify in the SET statement.
Procedures

PROC DATASETS <LIBRARY=SAS-data-library>;
CONTENTS <DATA=SAS-data set>;

describes the structure of a SAS data set, including the name, type, and length of all variables in the data set.

Statements

DATA SAS-data-set<(data-set-options)>;

begins a DATA step and names the SAS data set or data sets that are being created. You can specify the DROP= or KEEP= data set options in parentheses after each data set name to control which variables are written to the output data set from the program data vector.

DROP variable(s);

specifies the variables to be excluded from the data set that is being created. See also the DROP= data set option.

KEEP variable(s)

specifies the variables to be written to the data set that is being created. See also the KEEP= data set option.

SET SAS-data-set(data-set-options);

reads observations from a SAS data set rather than records of raw data. You can specify the DROP= or KEEP= data set options in parentheses after a data set name to control which variables are read into the program data vector from the input data set.

Understanding DATA Step Processing

Introduction to DATA Step Processing

Purpose
To add, modify, and delete information in a SAS data set, you use a DATA step. In this section, you will learn how the DATA step works, the general form of the statements, and some programming techniques.

Prerequisites
You should understand the concepts presented in Chapter 2, “Introduction to DATA Step Processing,” on page 19 and Chapter 3, “Starting with Raw Data: The Basics,” on page 43 before proceeding with this section.

Input SAS Data Set for Examples

Tradewinds Travel Inc. has an external file that they use to manipulate and store data about their tours. The external file contains the following information:

France 8 793 575 Major
Spain 10 805 510 Hispania
India 10 . 489 Royal
Peru 7 722 590 Mundial

The numbered fields represent

1. the name of the country toured
2. the number of nights on the tour
3. the airfare in US dollars
4. the cost of the land package in US dollars
5. the name of the company that offers the tour

Notice that the cost of the airfare for the tour to India has a missing value, which is indicated by a period.

The following DATA step creates a permanent SAS data set named MYLIB.INTERNATIONALTOURS:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';

data mylib.internationaltours;
  infile 'input-file';
  input Country $ Nights AirCost LandCost Vendor $;

proc print data = mylib.internationaltours;
  title 'Data Set MYLIB.INTERNATIONALTOURS';
run;
```

The PROC PRINT statement that follows the DATA step produces this display of the MYLIB.INTERNATIONALTOURS data set:

**Output 6.1 Creating a Permanent SAS Data Set**

**Adding Information to a SAS Data Set**

**Understanding the Assignment Statement**

One of the most common reasons for using program statements in the DATA step is to produce new information from the original information or to change the information read by the INPUT or SET/MERGE/MODIFY/UPDATE statement. How do you add information to observations with a DATA step?
The basic method of adding information to a SAS data set is to create a new variable in a DATA step with an assignment statement. An assignment statement has the form:

\[ \text{variable}=\text{expression}; \]

The variable receives the new information; the expression creates the new information. You specify the calculation necessary to produce the information and write the calculation as the expression. When the expression contains character data, you must enclose the data in quotation marks. SAS evaluates the expression and stores the new information in the variable that you name. It is important to remember that if you need to add the information to only one or two observations out of many, SAS creates that variable for all observations. The SAS data set that is being created must have information in every observation and every variable.

### Making Uniform Changes to Data by Creating a Variable

Sometimes you want to make a particular change to every observation. For example, at Tradewinds Travel the airfare must be increased for every tour by $10 because of a new tax. One way to do this is to write an assignment statement that creates a new variable that calculates the new airfare:

\[ \text{NewAirCost} = \text{AirCost} + 10; \]

This statement directs SAS to read the value of AirCost, add 10 to it, and assign the result to the new variable, NewAirCost.

When this assignment statement is included in a DATA step, the DATA step looks like this:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data newair;
  set mylib.internationaltours;
  NewAirCost = AirCost + 10;
proc print data=newair;
  var Country AirCost NewAirCost;
  title 'Increasing the Air Fare by $10 for All Tours';
run;
```

**Note:** In this example, the VAR statement in the PROC PRINT step determines which variables are displayed in the output.

The following output shows the resulting SAS data set, NEWAIR:

### Output 6.2 Adding Information to All Observations by Using a New Variable

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Air Cost</th>
<th>New Air Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>793</td>
<td>803</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>805</td>
<td>815</td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>4</td>
<td>Peru</td>
<td>722</td>
<td>732</td>
</tr>
</tbody>
</table>
Notice in this data set that

1. because SAS carries out each statement in the DATA step for every observation, NewAirCost is calculated during each iteration of the DATA step.
2. the observation for India contains a missing value for AirCost; SAS therefore assigns a missing value to NewAirCost for that observation.

The SAS data set has information in every observation and every variable.

### Adding Information to Some Observations but Not Others

Often you need to add information to some observations but not to others. For example, some tour operators award bonus points to travel agencies for scheduling particular tours. Two companies, Hispania and Mundial, are offering bonus points this year.

IF-THEN/ELSE statements can cause assignment statements to be carried out only when a condition is met. In the following DATA step, the IF statements check the value of the variable Vendor. If the value is either Hispania or Mundial, information about the bonus points is added to those observations.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data bonus;
  set mylib.internationaltours;
  if Vendor = 'Hispania' then BonusPoints = 'For 10+ people';
  else if Vendor = 'Mundial' then BonusPoints = 'Yes';
run;

proc print data=bonus;
  var Country Vendor BonusPoints;
  title1 'Adding Information to Observations for';
  title2 'Vendors Who Award Bonus Points';
run;
```

The following output displays the results:

### Output 6.3  Specifying Values for Specific Observations by Using a New Variable

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Vendor</th>
<th>BonusPoints</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>Major</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>Hispania</td>
<td>For 10+ people</td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>Royal</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Peru</td>
<td>Mundial</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The new variable BonusPoints has the following information:

1. In the two observations that are not assigned a value for BonusPoints, SAS assigns a missing value, represented by a blank in this case, to indicate the absence of a character value.
2. The first value that SAS encounters for BonusPoints contains 14 characters; therefore, SAS sets aside 14 bytes of storage in each observation for BonusPoints, regardless of the length of the value for that observation.
Making Uniform Changes to Data Without Creating Variables

Sometimes you want to change the value of existing variables without adding new variables. For example, in one DATA step a new variable, NewAirCost, was created to contain the value of the airfare plus the new $10 tax:

```sas
NewAirCost = AirCost + 10;
```

You can also decide to change the value of an existing variable rather than create a new variable. Following the example, AirCost is changed as follows:

```sas
AirCost = AirCost + 10;
```

SAS processes this statement just as it does other assignment statements. It evaluates the expression on the right side of the equal sign and assigns the result to the variable on the left side of the equal sign. The fact that the same variable appears on the right and left sides of the equal sign does not matter. SAS evaluates the expression on the right side of the equal sign before looking at the variable on the left side.

The following program contains the new assignment statement:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data newair2;
  set mylib.internationaltours;
  AirCost = AirCost + 10;
proc print data=newair2;
  var Country AirCost;
  title 'Adding Tax to the Air Cost Without Adding a New Variable';
run;
```

The following output displays the results:

```
Output 6.4 Changing the Information in a Variable

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Air</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>803</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>815</td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>.</td>
</tr>
<tr>
<td>4</td>
<td>Peru</td>
<td>732</td>
</tr>
</tbody>
</table>
```

When you change the kind of information that a variable contains, you change the meaning of that variable. In this case, you are changing the meaning of AirCost from *airfare without tax* to *airfare with tax*. If you remember the current meaning and if you know that you do not need the original information, then changing a variable’s values is useful. However, for many programmers, having separate variables is easier than recalling one variable whose definition changes.

Using Variables Efficiently

Variables that contain information that applies to only one or two observations use more storage space than necessary. When possible, create fewer variables that apply to
more observations in the data set, and allow the different values in different observations to supply the information.

For example, the Major company offers discounts, not bonus points, for groups of 30 or more people. An inefficient program would create separate variables for bonus points and discounts, as follows:

```sas
/* inefficient use of variables */
options pagesize=60 linesize=80 pageno=1 nodate;
data tourinfo;
  set mylib.internationaltours;
  if Vendor = 'Hispania' then BonusPoints = 'For 10+ people';
  else if Vendor = 'Mundial' then BonusPoints = 'Yes';
  else if Vendor = 'Major' then Discount = 'For 30+ people';
run;

proc print data=tourinfo;
  var Country Vendor BonusPoints Discount;
  title 'Information About Vendors';
run;
```

The following output displays the results:

**Output 6.5  Inefficient: Using Variables That Scatter Information Across Multiple Variables**

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Vendor</th>
<th>BonusPoints</th>
<th>Discount</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>Major</td>
<td></td>
<td>For 30+ people</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>Hispania</td>
<td>For 10+ people</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>Royal</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Peru</td>
<td>Mundial</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>

As you can see, storage space is used inefficiently. Both BonusPoints and Discount have a significant number of missing values.

With a little planning, you can make the SAS data set much more efficient. In the following DATA step, the variable Remarks contains information about bonus points, discounts, and any other special features of any tour.

```sas
/* efficient use of variables */
options pagesize=60 linesize=80 pageno=1 nodate;
data newinfo;
  set mylib.internationaltours;
  if Vendor = 'Hispania' then Remarks = 'Bonus for 10+ people';
  else if Vendor = 'Mundial' then Remarks = 'Bonus points';
  else if Vendor = 'Major' then Remarks = 'Discount: 30+ people';
run;

proc print data=newinfo;
  var Country Vendor Remarks;
  title 'Information About Vendors';
run;
```
The following output displays a more efficient use of variables:

Output 6.6 Efficient: Using Variables to Contain Maximum Information

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Vendor</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>Major</td>
<td>Discount: 30+ people</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>Hispania</td>
<td>Bonus for 10+ people</td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>Royal</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Peru</td>
<td>Mundial</td>
<td>Bonus points</td>
</tr>
</tbody>
</table>

Remarks has fewer missing values and contains all the information that is used by BonusPoints and Discount in the inefficient example. Using variables efficiently can save storage space and optimize your SAS data set.

Defining Enough Storage Space for Variables

The first time that a value is assigned to a variable, SAS enables as many bytes of storage space for the variable as there are characters in the first value assigned to it. At times, you may need to specify the amount of storage space that a variable requires. For example, as shown in the preceding example, the variable Remarks contains miscellaneous information about tours:

    if Vendor = 'Hispania' then Remarks = 'Bonus for 10+ people';

In this assignment statement, SAS enables 20 bytes of storage space for Remarks as there are 20 characters in the first value assigned to it. The longest value may not be the first one assigned, so you specify a more appropriate length for the variable before the first value is assigned to it:

    length Remarks $ 30;

This statement, called a LENGTH statement, applies to the entire data set. It defines the number of bytes of storage that is used for the variable Remarks in every observation. SAS uses the LENGTH statement during compilation, not when it is processing statements on individual observations. The following DATA step shows the use of the LENGTH statement:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data newlength;
    set mylib.internationaltours;
    length Remarks $ 30;
    if Vendor = 'Hispania' then Remarks = 'Bonus for 10+ people';
    else if Vendor = 'Mundial' then Remarks = 'Bonus points';
    else if Vendor = 'Major' then Remarks = 'Discount for 30+ people';
    run;

proc print data=newlength;
    var Country Vendor Remarks;
    title 'Information About Vendors';
    run;
```
The following output displays the NEWLENGTH data set:

### Output 6.7 Using a LENGTH Statement

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Vendor</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>Major</td>
<td>Discount for 30+ people</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>Hispania</td>
<td>Bonus for 10+ people</td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>Royal</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Peru</td>
<td>Mundial</td>
<td>Bonus points</td>
</tr>
</tbody>
</table>

Because the LENGTH statement affects variable storage, not the spacing of columns in printed output, the Remarks variable appears the same in Output 6.6 and Output 6.7. To show the effect of the LENGTH statement on variable storage using the DATASETS procedures, see Chapter 35, “Getting Information about Your SAS Data Sets,” on page 607.

### Conditionally Deleting an Observation

If you do not want the program data vector to write to a data set based on a condition, use the DELETE statement in the DATA step. For example, if the tour to Peru has been discontinued, it is no longer necessary to include the observation for Peru in the data set that is being created. The following example uses the DELETE statement to prevent SAS from writing that observation to the output data set:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data subset;
set mylib.internationaltours;
if Country = 'Peru' then delete;
run;

proc print data=subset;
  title 'Omitting a Discontinued Tour';
run;
```

The following output displays the results:

### Output 6.8 Deleting an Observation

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Nights</th>
<th>Air Cost</th>
<th>Land Cost</th>
<th>Vendor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>8</td>
<td>793</td>
<td>575</td>
<td>Major</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>10</td>
<td>805</td>
<td>510</td>
<td>Hispania</td>
</tr>
<tr>
<td>3</td>
<td>India</td>
<td>10</td>
<td>.</td>
<td>489</td>
<td>Royal</td>
</tr>
</tbody>
</table>

The observation for Peru has been deleted from the data set.
Review of SAS Tools

Statements

DELETE;
prevents SAS from writing a particular observation to the output data set. It usually appears as part of an IF-THEN/ELSE statement.

If condition THEN action ELSE action;
tests whether the condition is true. When the condition is true, the THEN statement specifies the action to take. When the condition is false, the ELSE statement provides an alternative action. The action can be one or more statements, including assignment statements.

LENGTH variable <$> length;
assigns the number of bytes of storage (length) for a variable. Include a dollar sign ($) if the variable is character. The LENGTH statement must appear before the first use of the variable.

variable=expression;
is an assignment statement. It causes SAS to evaluate the expression on the right side of the equal sign and assign the result to the variable on the left. You must select the name of the variable and create the proper expression for calculating its value. The same variable name can appear on the left and right sides of the equal sign because SAS evaluates the right side before assigning the result to the variable on the left side.

Learning More

Character variables
For information about expressions involving alphabetic and special characters as well as numbers, see Chapter 8, “Working with Character Variables,” on page 119.

DATA step
For general DATA step information, see Chapter 2, “Introduction to DATA Step Processing,” on page 19. Complete information about the DATA step can be found in the “DATA Step Concepts” section of SAS Language Reference: Concepts.

IF-THEN/ELSE statements
The IF-THEN/ELSE statements are discussed in Chapter 9, “Acting on Selected Observations,” on page 139.

LENGTH statement
Additional information about the LENGTH statement can be found in Chapter 7, “Working with Numeric Variables,” on page 107 and Chapter 8, “Working with Character Variables,” on page 119. To show the effect of the LENGTH statement on variable storage using the DATASETS procedures, see Chapter 35, “Getting Information about Your SAS Data Sets,” on page 607.

Missing values
For more information about missing values, see the in Chapter 7, “Working with Numeric Variables,” on page 107 and Chapter 8, “Working with Character Variables,” on page 119.
Numeric variables

Information about working with numeric variables and expressions can be found in Chapter 7, “Working with Numeric Variables,” on page 107.

SAS statements

For complete reference information about the IF-THEN/ELSE, LENGTH, DELETE, assignment, and comment statements, see SAS Language Reference: Dictionary.
Introduction to Working with Numeric Variables

Purpose

In this section, you will learn the following:

- how to perform arithmetic calculations in SAS using arithmetic operators and the SAS functions ROUND and SUM
- how to compare numeric variables using logical operators
- how to store numeric variables efficiently when disk space is limited

Prerequisites

Before proceeding with this section, you should understand the concepts presented in the following topics:
About Numeric Variables in SAS

A numeric variable is a variable whose values are numbers.

Note: SAS uses double-precision floating point representation for calculations and, by default, for storing numeric variables in SAS data sets.

SAS accepts numbers in many forms, such as scientific notation, and hexadecimal. For more information, see the discussion on the types of numbers that SAS can read from data lines in SAS Language Reference: Concepts. For simplicity, this documentation concentrates on numbers in standard representation, as shown here:

1254
336.05
-243

You can use SAS to perform all kinds of mathematical operations. To perform a calculation in a DATA step, you can write an assignment statement in which the expression contains arithmetic operators, SAS functions, or a combination of the two. To compare numeric variables, you can write an IF-THEN/ELSE statement using logical operators. For more information on numeric functions, see the discussion in the “Functions and CALL Routines” section in SAS Language Reference: Dictionary.

Input SAS Data Set for Examples

Tradewinds Travel Inc. has an external file that contains information about their most popular tours:

</tbody>
</table>

The numbered fields represent

1 the name of the country toured
2 the number of nights on the tour
3 the airfare in US dollars
4 the cost of the land package in US dollars
5 the name of the company that offers the tour

The following program creates a permanent SAS data set named MYLIB.POPULARTOURS:
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';

data mylib.populartours;
  infile 'input-file';
  input Country $ 1-11 Nights AirCost LandCost Vendor $;
run;

proc print data=mylib.populartours;
  title 'Data Set MYLIB.POPULARTOURS';
run;

The following output shows the data set:

Output 7.1  Data Set MYLIB.POPULARTOURS

<table>
<thead>

In MYLIB.POPULARTOURS, the variables Nights, AirCost, and LandCost contain numbers and are stored as numeric variables. For comparison, variables Country and Vendor contain alphabetic and special characters as well as numbers; they are stored as character variables.

Calculating with Numeric Variables

Using Arithmetic Operators in Assignment Statements

One way to perform calculations on numeric variables is to write an assignment statement using arithmetic operators. Arithmetic operators indicate addition, subtraction, multiplication, division, and exponentiation (raising to a power). For more information on arithmetic expressions, see the discussion in SAS Language Reference: Concepts. The following table shows operators that you can use in arithmetic expressions.
Table 7.1  Operators in Arithmetic Expressions

<table>
<thead>
<tr>
<th>Operation</th>
<th>Symbol</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>addition</td>
<td>+</td>
<td>( x = y + z; )</td>
</tr>
<tr>
<td>subtraction</td>
<td>–</td>
<td>( x = y - z; )</td>
</tr>
<tr>
<td>multiplication</td>
<td>*</td>
<td>( x = y \times z )</td>
</tr>
<tr>
<td>division</td>
<td>/</td>
<td>( x = y / z )</td>
</tr>
<tr>
<td>exponentiation</td>
<td>**</td>
<td>( x = y^{\text{** ( z )}} )</td>
</tr>
</tbody>
</table>

The following examples show some typical calculations using the Tradewinds Travel sample data.

Table 7.2  Examples of Using Arithmetic Operators

<table>
<thead>
<tr>
<th>Action</th>
<th>SAS Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add the airfare and land cost to produce the total cost.</td>
<td>TotalCost = AirCost + LandCost;</td>
</tr>
<tr>
<td>Calculate the peak season airfares by increasing the basic fare by 10% and adding an $8 departure tax.</td>
<td>PeakAir = (AirCost * 1.10) + 8;</td>
</tr>
<tr>
<td>Show the cost per night of each land package.</td>
<td>NightCost = LandCost / Nights;</td>
</tr>
</tbody>
</table>

In each case, the variable on the left side of the equal sign receives the calculated value from the numeric expression on the right side of the equal sign. Including these statements in the following DATA step produces data set NEWTOUR:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data newtour;
  set mylib.populartours;
  TotalCost = AirCost + LandCost;
  PeakAir = (AirCost * 1.10) + 8;
  NightCost = LandCost / Nights;
run;
```

```sas
proc print data=newtour;
  var Country Nights AirCost LandCost TotalCost PeakAir NightCost;
  title 'Costs for Tours';
  run;
```

The VAR statement in the PROC PRINT step causes only the variables listed in the statement to be displayed in the output.

Understanding Numeric Expressions and Assignment Statements

Numeric expressions in SAS share some features with mathematical expressions:

- When an expression contains more than one operator, the operations have the same order of precedence as in a mathematical expression: exponentiation is done first, then multiplication and division, and finally addition and subtraction.
- When operators of equal precedence appear, the operations are performed from left to right (except exponentiation, which is performed right to left).
- Parentheses are used to group parts of an expression; as in mathematical expressions, operations in parentheses are performed first.

Note: The equal sign in an assignment statement does not perform the same function as the equal sign in a mathematical equation. The sequence variable= in an assignment statement defines the statement, and the variable must appear on the left side of the equal sign. You cannot switch the positions of the result variable and the expression as you can in a mathematical equation.

Understanding How SAS Handles Missing Values

Why SAS Assigns Missing Values

What if an observation lacks a value for a particular numeric variable? For example, in the data set MYLIB.POPULARTOURS, as shown in Output 7.2, the observation for Greece has no value for the variable AirCost. To maintain the rectangular structure of a SAS data set, SAS assigns a missing value to the variable in that observation. A missing value indicates that no information is present for the variable in that observation.

Rules for Missing Values

The following rules describe missing values in several situations:

- In data lines, a missing numeric value is represented by a period, for example, Greece 8 12 . 748 Express
By default, SAS interprets a single period in a numeric field as a missing value. (If the INPUT statement reads the value from particular columns, as in column input, a field that contains only blanks also produces a missing value.)

□ In an expression, a missing numeric value is represented by a period, for example,

\[
\text{if AirCost= . then Status = 'Need air cost'};
\]

□ In a comparison and in sorting, a missing numeric value is a lower value than any other numeric value.

□ In procedure output, SAS by default represents a missing numeric value with a period.

□ Some procedures eliminate missing values from their analyses; others do not. Documentation for individual procedures describes how each procedure handles missing values.

Propagating Missing Values

When you use a missing value in an arithmetic expression, SAS sets the result of the expression to missing. If you use that result in another expression, the next result is also missing. In SAS, this method of treating missing values is called propagation of missing values. For example, Output 7.2 shows that in the data set NEWTOUR, the values for TOTALCOST and PEAKAIR are also missing in the observation for Greece.

Note: SAS enables you to distinguish between various kinds of numeric missing values. See “Missing Values” section of SAS Language Reference: Concepts. The SAS language contains 27 special missing values based on the letters A–Z and the underscore (_).

Calculating Numbers Using SAS Functions

Rounding Values

In the example data that lists costs of the different tours (Output 7.1), some of the tours have odd prices: $748 instead of $750, $1299 instead of $1300, and so on. Rounded numbers, created by rounding the tour prices to the nearest $10, would be easier to work with.

Programming a rounding calculation with only the arithmetic operators is a lengthy process. However, SAS contains around 280 built-in numeric expressions called functions. You can use them in expressions just as you do the arithmetic operators. For example, the following assignment statement rounds the value of AirCost to the nearest $50:

\[
\text{RoundAir = round(AirCost,50)};
\]

The following statement calculates the total cost of each tour, rounded to the nearest $100:

\[
\text{TotalCostR = round(AirCost + LandCost,100)};
\]

Calculating a Cost When There Are Missing Values

As another example, the travel agent can calculate a total cost for the tours based on all nonmissing costs. Therefore, when the airfare is missing (as it is for Greece) the total cost represents the land cost, not a missing value. (Of course, you must decide whether skipping missing values in a particular calculation is a good idea.) The SUM
function calculates the sum of its arguments, ignoring missing values. This example illustrates the SUM function:

\[ \text{SumCost} = \text{sum(AirCost,LandCost)}; \]

### Combining Functions

It is possible for you to combine functions. The ROUND function rounds the quantity given in the first argument to the nearest unit given in the second argument. The SUM function adds any number of arguments, ignoring missing values. The calculation in the following assignment statement rounds the sum of all nonmissing airfares and land costs to the nearest $100 and assigns the value to RoundSum:

\[ \text{RoundSum} = \text{round(sum(AirCost,LandCost),100)}; \]

Using the ROUND and SUM functions in the following DATA step creates the data set MORETOUR:

``` SAS
options pagesize=60 linesize=80 pageno=1 nodate;
data moretour;
  set mylib.populartours;
  RoundAir = round(AirCost,50);
  TotalCostR = round(AirCost + LandCost,100);
  CostSum = sum(AirCost,LandCost);
  RoundSum = round(sum(AirCost,LandCost),100);
run;
```

``` SAS
proc print data=moretour;
  var Country AirCost LandCost RoundAir TotalCostR CostSum RoundSum;
  title 'Rounding and Summing Values';
run;
```

The following output displays the results:

```
Output 7.3  Creating New Variables with ROUND and SUM Functions

</tr>
<tr>
<td>10</td>
<td>Brazil</td>
<td>682</td>
<td>610</td>
<td>700</td>
<td>1300</td>
<td>1292</td>
<td>1300</td>
</tr>
</tbody>
</table>
```

### Comparing Numeric Variables

Often in a program you need to know if variables are equal to each other, or if they are greater than or less than each other. To compare two numeric variables, you can
write an IF-THEN/ELSE statement using logical operators. The following table lists some of the logical operators you can use for variable comparisons.

Table 7.3 Logical Operators

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Mnemonic Equivalent</th>
<th>Logical Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>eq</td>
<td>equal</td>
</tr>
<tr>
<td>^=, ^=, ^=</td>
<td>ne</td>
<td>not equal to ( the ^=, ^=, or ^= symbol, depending on your keyboard)</td>
</tr>
<tr>
<td>&gt;</td>
<td>gt</td>
<td>greater than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>ge</td>
<td>greater than or equal to</td>
</tr>
<tr>
<td>&lt;</td>
<td>lt</td>
<td>less than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>le</td>
<td>less than or equal to</td>
</tr>
</tbody>
</table>

In this example, the total cost of each tour in the POPULARTOURS data set is compared to 2000 using the greater-than logical operator (gt). If the total cost of the tour is greater than 2000, the tour is excluded from the data set. The resulting data set TOURSUNDER2K contains tours that are $2000 or less.

```plaintext
options pagesize=60 linesize=80 pageno=1 nodate;
data toursunder2K;
  set mylib.populartours;
  TotalCost = AirCost + LandCost;
  if TotalCost gt 2000 then delete;
run;
proc print data=toursunder2K;
  var Country Nights AirCost Landcost TotalCost Vendor;
  title 'Tours $2000 or Less';
run;
```

The following output shows the tours that are less than $2000 in total cost:

Output 7.4 Comparing Numeric Variables

<table>
<thead>
<tr>
<th>Tours $2000 or Less</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
</tbody>
</table>

The TotalCost value for Greece is a missing value because any calculation that includes a missing value results in a missing value. In a comparison, missing numeric values are lower than any other numeric value.

If you need to compare a variable to more than one value, you can include multiple comparisons in a condition. To eliminate tours with missing values, a second comparison is added:
options pagesize=60 linesize=80 pageno=1 nodate;
data toursunder2K2;
set mylib.populartours;
TotalCost = AirCost + LandCost;
if TotalCost gt 2000 or Totalcost = . then delete;
run;

proc print data=toursunder2K2;
var Country Nights TotalCost Vendor;
title 'Tours $2000 or Less';
run;

The following output displays the results:

Output 7.5  Multiple Comparisons in a Condition

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Nights</th>
<th>Total Cost</th>
<th>Vendor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ireland</td>
<td>7</td>
<td>1415</td>
<td>Express</td>
</tr>
<tr>
<td>2</td>
<td>Venezuela</td>
<td>9</td>
<td>931</td>
<td>Mundial</td>
</tr>
<tr>
<td>3</td>
<td>Italy</td>
<td>8</td>
<td>1450</td>
<td>Express</td>
</tr>
<tr>
<td>4</td>
<td>Switzerland</td>
<td>9</td>
<td>1650</td>
<td>Tour2000</td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>8</td>
<td>1292</td>
<td>Almeida</td>
</tr>
</tbody>
</table>

Notice that Greece is no longer included in the tours for under $2000.

Storing Numeric Variables Efficiently

The data sets shown in this section are very small, but data sets are often very large. If you have a large data set, you may need to think about the storage space that your data set occupies. There are ways to save space when you store numeric variables in SAS data sets.

Note: The SAS documentation for your operating environment provides information about storing numeric variables whose values are limited to 1 or 0 in the minimum number of bytes used by SAS (either 2 or 3 bytes, depending on your operating environment).

By default, SAS uses 8 bytes of storage in a data set for each numeric variable. Therefore, storing the variables for each observation in the earlier data set MORETOUR requires 75 bytes:

- 56 bytes for numeric variables
  - (8 bytes per variable * 7 numeric variables)
- 11 bytes for Country
- 8 bytes for Vendor

75 bytes for all variables

When numeric variables contain only integers (whole numbers), you can often shorten them in the data set being created. For example, a length of 4 bytes accurately stores all integers up to at least 2,000,000.
Note: Under some operating environments, the maximum number of bytes is much greater. For more information, refer to the documentation provided by the vendor for your operating environment.

To change the number of bytes used for each variable, use a LENGTH statement.

A LENGTH statement contains the names of the variables followed by the number of bytes to be used for their storage. For numeric variables, the LENGTH statement affects only the data set being created; it does not affect the program data vector. The following program changes the storage space for all numeric variables that are in the data set SHORTER:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data shorter;
  set mylib.populartours;
  length Nights AirCost LandCost RoundAir TotalCostR Costsum RoundSum 4;
  RoundAir = round(AirCost,50);
  TotalCostR = round(AirCost + LandCost,100);
  CostSum = sum(AirCost,LandCost);
  RoundSum = round(sum(AirCost,LandCost),100);
run;
```

By calculating the storage space that is needed for the variables in each observation of SHORTER, you can see how the LENGTH statement changes the amount of storage space used:

28 bytes for numeric variables
   (4 bytes per variable in the LENGTH statement X 7 numeric variables)
11 bytes for Country
8 bytes for Vendor

47 bytes for all variables

Because of the 7 variables in SHORTER are shortened by the LENGTH statement, the storage space for the variables in each observation is reduced by almost half.

**CAUTION:**

Be careful in shortening the length of numeric variables if your variable values are not integers. Fractional numbers lose precision permanently if they are truncated. In general, use the LENGTH statement to truncate values only when disk space is limited. Use the default length of 8 bytes to store variables containing fractions.

---

**Functions**

ROUND (expression, round-off-unit)

rounds the quantity in expression to the figure given in round-off-unit. The expression can be a numeric variable name, a numeric constant, or an arithmetic expression. Separate round-off-unit from expression with a comma.

SUM (expression-1, . . . expression-n)

produces the sum of all expressions that you specify in the parentheses. The SUM function ignores missing values as it calculates the sum of the expressions. Each expression can be a numeric variable, a numeric constant, another arithmetic expression, or another numeric function.
Statements

LENGTH variable-list number-of-bytes;
indicates that the variables in the variable-list are to be stored in the data set according to the number-of-bytes that you specify. Numeric variables are not affected while they are in the program data vector. The default length for a numeric variable is 8 bytes. In general, the minimum you should use is 4 bytes for variables that contain integers and 8 bytes for variables that contain fractions. You can assign lengths to both numeric and character variables (discussed in the next section) in a single LENGTH statement.

variable=expression;
is an assignment statement. It causes SAS to calculate the value of the expression on the right side of the equal sign and assign the result to the variable on the left. When variable is numeric, the expression can be an arithmetic calculation, a numeric constant, or a numeric function.

Learning More

Abbreviating lists of variables
Ways to abbreviate lists of variables in function arguments are documented in SAS Language Reference: Concepts. Many functions, including the SUM function, accept abbreviated lists of variables as arguments.

DEFAULT= option
Information about using the DEFAULT= option in the LENGTH statement to assign a default storage length to all newly created numeric variables can be found in SAS Language Reference: Dictionary.

Logical expressions
Additional information about the use of logical expressions can be found in SAS Language Reference: Concepts.

Numeric precision
For a discussion about numeric precision, see SAS Language Reference: Concepts. Because the computer’s hardware determines the way that a computer stores numbers, the precision with which SAS can store numbers depends on the hardware of the computer system on which it is installed. Specific limits for hardware are discussed in the SAS documentation for each operating environment.

Saving space
For information about how you can save space by treating some numeric values as character values see Chapter 8, “Working with Character Variables,” on page 119.

Introduction to Working with Character Variables

Purpose

In this section, you will learn how to do the following:

- identify character variables
- set the length of character variables
- align character values within character variables
- handle missing values of character variables
work with character variables, character constants, and character expressions in SAS program statements
- instruct SAS to read fields that contain numbers as character variables in order to save space

**Prerequisites**

Before proceeding with this section, you should understand the concepts presented in the following topics:
- Part 1, “Introduction to SAS”
- Part 2, “Getting Your Data into Shape”
- Chapter 6, “Understanding DATA Step Processing,” on page 97

**Character Variables in SAS**

A character variable is a variable whose value contains letters, numbers, and special characters, and whose length can be from 1 to 32,767 characters long. Character variables can be used in declarative statements, comparison statements, or assignment statements where they can be manipulated to create new character variables.

**Input SAS Data Set for Examples**

Tradewinds Travel has an external file with data on flight schedules for tours. The following DATA step reads the information and stores it in a data set named AIR.DEPARTURES:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';
data mylib.departures;
  input Country $ 1-9 CitiesInTour 11-12 USGate $ 14-26 ArrivalDepartureGates $ 28-48;
datalines;
Japan 5 San Francisco Tokyo, Osaka
Italy 8 New York Rome, Naples
Australia 12 Honolulu Sydney, Brisbane
Venezuela 4 Miami Caracas, Maracaibo
Brazil 4 Rio de Janeiro, Belem;
proc print data=mylib.departures;
title 'Data Set AIR.DEPARTURES';
run;
```

The numbered fields represent:
- 1 the name of the country toured
- 2 the number of cities in the tour
- 3 the city from which the tour leaves the United States (the gateway city)
- 4 the cities of arrival and departure in the destination country

The PROC PRINT statement that follows the DATA step produces this display of the AIR.DEPARTURES data set:
Identifying Character Variables and Expressing Character Values

To store character values in a SAS data set, you need to create a character value. One way to create a character variable is to define it in an input statement. Simply place a dollar sign after the variable name in the INPUT statement, as shown in the DATA step that created AIR.DEPARTURES:

```
input Country $ 1-9 CitiesInTour 11-12 USGate $ 14-26
            ArrivalDepartureGates $ 28-48;
```

You can also create a character variable and assign a value to it in an assignment statement. Simply enclose the value in quotation marks:

```
Schedule = '3-4 tours per season';
```

Either single quotation marks (apostrophes) or double quotation marks are acceptable. If the value itself contains a single quote, then surround the value with double quotation marks, as in

```
Remarks = "See last year’s schedule";
```

**Note:** Matching quotation marks properly is important. Missing or extraneous quotation marks cause SAS to misread both the erroneous statement and the statements following it.

When you specify a character value in an expression, you must also enclose the value in quotation marks. For example, the following statement compares the value of USGate to San Francisco and, when a match occurs, assigns the airport code SFO to the variable Airport:

```
if USGate = 'San Francisco' then Airport = 'SFO';
```

In character values, SAS distinguishes uppercase letters from lowercase letters. For example, in the data set AIR.DEPARTURES, the value of USGate in the observation for Australia is *Honolulu*. The following IF condition is true; therefore, SAS assigns to Airport the value `HNL`:

```
else if USGate = 'Honolulu' then Airport = 'HNL';
```
However, the following condition is false:

```
if USGate = 'HONOLULU' then Airport = 'HNL';
```

SAS does not select that observation because the characters in Honolulu and HONOLULU are not equivalent.

The following program places these shaded statements in a DATA step:

```
options pagesize=60 linesize=80 pageno=1 nodate;

data charvars;
  set mylib.departures;
  Schedule = '3-4 tours per season';
  Remarks = "See last year’s schedule";
  if USGate = 'San Francisco' then Airport = 'SFO';
  else if USGate = 'Honolulu' then Airport = 'HNL';
run;
```

```
proc print data=charvars noobs;
  var Country Schedule Remarks USGate Airport;
  title 'Tours By City of Departure';
run;
```

The NOOBS option in the PROC PRINT statement suppresses the display of observation numbers in the output.

The following output displays the character variables in the data set CHARVARS:

```
Output 8.2  Examples of Character Variables

<table>
<thead>
<tr>
<th>Country</th>

```

### Setting the Length of Character Variables

This example illustrates why you may want to specify a length for a character variable, rather than let the first assigned value determine the length. Because New York City has two airports, both the abbreviations for John F. Kennedy International Airport and La Guardia Airport can be assigned to the Airport variable as in the DATA step.

**Note:** When you create character variables, SAS determines the length of the variable from its first occurrence in the DATA step. Therefore, you must allow for the longest possible value in the first statement that mentions the variable. If you do not assign the longest value the first time the variable is assigned, then data can be truncated. △
/* first attempt */
options pagesize=60 linesize=80 pageno=1 nodate;
data aircode;
  set mylib.departures;
  if USGate = 'San Francisco' then Airport = 'SFO';
  else if USGate = 'Honolulu' then Airport = 'HNL';
  else if USGate = 'New York' then Airport = 'JFK or LGA';
run;

proc print data=aircode;
  var Country USGate Airport;
  title 'Country by US Point of Departure';
run;

The following output displays the results:

Output 8.3  Truncation of Character Values

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>USGate</th>
<th>Airport</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>San Francisco</td>
<td>SFO</td>
</tr>
<tr>

</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>Miami</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Only the characters JFK appear in the observation for New York. SAS first encounters Airport in the statement that assigns the value SFO. Therefore, SAS creates Airport with a length of three bytes and uses only the first three characters in the New York observation.

To allow space to write JFK or LGA, use a LENGTH statement as the first reference to Airport. The LENGTH statement is a declarative statement and has the form

```
LENGTH variable-list $ number-of-bytes;
```

where variable-list is the variable or variables to which you are assigning the length number-of-bytes. The dollar sign ($) indicates that the variable is a character variable. The LENGTH statement determines the length of a character variable in both the program data vector and the data set that are being created. (In contrast, a LENGTH statement determines the length of a numeric variable only in the data set that is being created.) The maximum length of any character value in SAS is 32,767 bytes.

This LENGTH statement assigns a length of 10 to the character variable Airport:

```
length Airport $ 10;
```

Note: If you use a LENGTH statement to assign a length to a character variable, then it must be the first reference to the character variables in the DATA step. Therefore, the best position in the DATA step for a LENGTH statement is immediately after the DATA statement.

The following DATA step includes the LENGTH statement for Airport. Remember that you can use the DATASETS procedure to display the length of variables in a SAS data set.
/* correct method */
options pagesize=60 linesize=80 pageno=1 nodate;
data aircode2;
  length Airport $ 10;
  set mylib.departures;
  if USGate = 'San Francisco' then Airport = 'SFO';
  else if USGate = 'Honolulu' then Airport = 'HNL';
    else if USGate = 'New York' then Airport = 'JFK or LGA';
    else if USGate = 'Miami' then Airport = 'MIA';
run;

proc print data=aircode2;
  var Country USGate Airport;
  title 'Country by US Point of Departure';
run;

The following output displays the results:

### Output 8.4 Using a LENGTH Statement to Capture Complete Variable Information

<td></td>
<td></td>
</tr>
</tbody>
</table>

### Handling Missing Values

#### Reading Missing Values

SAS uses a blank to represent a missing value of a character variable. For example, the data line for Brazil lacks the departure city from the United States:

| Japan      | 5 | San Francisco | Tokyo, Osaka |
| Italy      | 8 | New York      | Rome, Naples |
| Australia  | 12| Honolulu      | Sydney, Brisbane |
| Venezuela  | 4 | Miami         | Caracas, Maracaibo |
| Brazil     | 4 |               | Rio de Janeiro, Belem |

As Output 8.1 shows, when the INPUT statement reads the data line for Brazil and determines that the value for USGate in columns 14-26 is missing, SAS assigns a missing value to USGate for that observation. The missing value is represented by a blank when printing.

One special case occurs when you read character data values with list input. In that case, you must use a period to represent a missing value in data lines. (Blanks in list input separate values; therefore, SAS interprets blanks as a signal to keep searching for the value, not as a missing value.) In the following DATA step, the TourGuide information for Venezuela is missing and is represented with a period:
options pagesize=60 linesize=80 pageno=1 nodate;

data missingval;
  length Country $ 10 TourGuide $ 10;
  input Country TourGuide;
  datalines;
  Japan  Yamada
  Italy  Militello
  Australia Edney
  Venezuela .
  Brazil Cardoso;

  proc print data=missingval;
    title 'Missing Values for Character List Input Data';
  run;

  The following output displays the results:

  Output 8.5 Using a Period in List Input for Missing Character Data

<table>
<thead>
<tr>
<th>Missing Values for Character List Data</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>Country</td>
</tr>
<tr>
<td>1</td>
<td>Japan</td>
</tr>
<tr>
<td>2</td>
<td>Italy</td>
</tr>
<tr>
<td>3</td>
<td>Australia</td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
</tr>
</tbody>
</table>

  SAS recognized the period as a missing value in the fourth data line; therefore, it recorded a missing value for the character variable TourGuide in the resulting data set.

Checking for Missing Character Values

When you want to check for missing character values, compare the character variable to a blank surrounded by quotation marks:

  if USGate = '' then GateInformation = 'Missing';

  The following DATA step includes this statement to check USGate for missing information. The results are recorded in GateInformation:

  options pagesize=60 linesize=80 pageno=1 nodate;

data checkgate;
  length GateInformation $ 15;
  set mylib.departures;
  if USGate = '' then GateInformation = 'Missing';
  else GateInformation = 'Available';
  run;
  proc print data=checkgate;
var Country CitiesInTour USGate ArrivalDepartureGates GateInformation;
title 'Checking For Missing Gate Information';
run;

The following output displays the results:

**Output 8.6 Checking for Missing Character Values**

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Cities InTour</th>
<th>USGate</th>
<th>ArrivalDepartureGates</th>
<th>Gate Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>5</td>
<td>San Francisco</td>
<td>Tokyo, Osaka, Osaka</td>
<td>Available</td>
</tr>
<tr>
<td>2</td>
<td>Italy</td>
<td>8</td>
<td>New York</td>
<td>Rome, Naples, Naples</td>
<td>Available</td>
</tr>
<tr>
<td>3</td>
<td>Australia</td>
<td>12</td>
<td>Honolulu</td>
<td>Sydney, Brisbane, Brisbane</td>
<td>Available</td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>4</td>
<td>Miami</td>
<td>Caracas, Maracaibo, Maracaibo</td>
<td>Available</td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>4</td>
<td></td>
<td>Rio de Janeiro, Belem, Belem</td>
<td>Missing</td>
</tr>
</tbody>
</table>

**Setting a Character Variable Value to Missing**

You can assign missing character values in assignment statements by setting the character variable to a blank surrounded by quotation marks. For example, the following statement sets the day of departure based on the number of days in the tour. If the number of cities in the tour is a week or less, then the day of departure is a Sunday. Otherwise, the day of departure is not known and is set to a missing value.

```
if CitiesInTour <= 7 then DayOfDeparture = 'Sunday';
else DayOfDeparture = ' ';
```

The following DATA step includes these statements:

```
options pagesize=60 linesize=80 pageno=1 nodate;
data departuredays;
  set mylib.departures;
  length DayOfDeparture $ 8;
  if CitiesInTour <= 7 then DayOfDeparture = 'Sunday';
  else DayOfDeparture = ' ';
run;
```

```
proc print data=departuredays;
  var Country CitiesInTour DayOfDeparture;
  title 'Departure Day is Sunday or Missing';
run;
```

The following output displays the results:
Output 8.7 Assigning Missing Character Values

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Cities</th>
<th>InTour</th>
<th>DayOfDeparture</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>5</td>
<td>Sunday</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Italy</td>
<td>8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Australia</td>
<td>12</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>4</td>
<td>Sunday</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>4</td>
<td>Sunday</td>
<td></td>
</tr>
</tbody>
</table>

Creating New Character Values

Extracting a Portion of a Character Value

Understanding the SCAN Function

Some character values may contain multiple pieces of information that need to be isolated and assigned to separate character variables. For example, the value of ArrivalDepartureGates contains two cities: the city of arrival and the city of departure. How can the individual values be isolated so that separate variables can be created for the two cities?

The SCAN function returns a character string when it is given the source string, the position of the desired character string, and a character delimiter:

```
SCAN(source, n<,list-of-delimiters>)
```

The `source` is the value that you want to examine. It can be any kind of character expression, including character variables, character constants, and so on. The `n` is the position of the term to be selected from the source. The `list-of-delimiters` can list one, multiple, or no delimiters. If you specify more than one delimiter, then SAS uses any of them; if you omit the delimiter, then SAS divides words according to a default list of delimiters (including the blank and some special characters).

For example, to select the first term in the value of ArrivalDepartureGates and assign it to a new variable named ArrivalGate, write

```
ArrivalGate = scan(ArrivalDepartureGates,1,',');
```

The SCAN function examines the value of ArrivalDepartureGates and selects the first string as identified by a comma.

Although default values can be used for the delimiter, it is a good idea to specify the delimiter to be used. If the default delimiter is used in the SCAN function when the observation for Brazil is processed, then SAS recognizes a blank space as the delimiter and selects `Rio` rather than `Rio de Janeiro` as the first term. Specifying the delimiter enables you to control where the division of the term occurs.

To select the second term from ArrivalDepartureGates and assign it to a new variable term named DEPARTUREGATE, specify the following:

```
DepartureGate = scan(ArrivalDepartureGates,2,’,’);
```

Note: The default length of a target variable where the expression contains the SCAN function is 200 bytes.
Aligning New Values

Remember that SAS maintains the existing alignment of a character value used in an expression; it does not perform any automatic realignment. This example creates the values for a new variable DepartureGate from the values of ArrivalDepartureGates.

The value of ArrivalDepartureGates contains a comma and a blank between the two city names as shown in the following output:

Output 8.8  Dividing Values into Separate Words Using the SCAN Function

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>InTour</th>
<th>USGate</th>
<th>ArrivalDepartureGates</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>5</td>
<td>San Francisco</td>
<td>Tokyo, Osaka</td>
</tr>
<tr>
<td>2</td>
<td>Italy</td>
<td>8</td>
<td>New York</td>
<td>Rome, Naples</td>
</tr>
<tr>
<td>3</td>
<td>Australia</td>
<td>12</td>
<td>Honolulu</td>
<td>Sydney, Brisbane</td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>4</td>
<td>Miami</td>
<td>Caracas, Maracaibo</td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>4</td>
<td></td>
<td>Rio de Janeiro, Belem</td>
</tr>
</tbody>
</table>

When the SCAN function divides the names at the comma, the second term begins with a blank; therefore, all the values that are assigned to DepartureGate begin with a blank. To left-align the values, use the LEFT function:

**LEFT**(source)

The LEFT function produces a value that has all leading blanks in the source moved to the right side of the value; therefore, the result is left aligned. The source can be any kind of character expression, including a character variable, a character constant enclosed in quotation marks, or another character function.

This example uses the LEFT function in the second assignment statement:

```
DepartureGate = left(scan(ArrivalDepartureGates,2,','));
```

You can also nest the two functions:

```
DepartureGate = left(scan(ArrivalDepartureGates,2,','));
```

When you nest functions, SAS performs the action in the innermost function first. It uses the result of that function as the argument of the next function, and so on.

The following DATA step creates separate variables for the arrival gates and the departure gates:

```
options pagesize=60 linesize=80 pageno=1 nodate;
data gates;
  set mylib.departures;
  ArrivalGate = scan(ArrivalDepartureGates,1,’,’);
  DepartureGate = left(scan(ArrivalDepartureGates,2,’,’));
run;
```

```
proc print data=gates;
  var Country ArrivalDepartureGates ArrivalGate DepartureGate;
title ‘Arrival and Departure Gates’;
run;
```
The following output displays the results:

Output 8.9  Dividing Values into Separate Words with the SCAN Function

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>ArrivalDepartureGates</th>
<th>ArrivalGate</th>
<th>DepartureGates</th>
<th>DepartureGate</th>
</tr>

<td>Rome</td>
<td>Naples</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Australia</td>
<td>Sydney, Brisbane</td>
<td>Sydney</td>
<td>Brisbane</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>Caracas, Maracaibo</td>
<td>Caracas</td>
<td>Maracaibo</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>Rio de Janeiro, Belem</td>
<td>Rio de Janeiro</td>
<td>Belem</td>
<td></td>
</tr>
</tbody>
</table>

**Saving Storage Space When Using the SCAN Function**

The SCAN function causes SAS to assign a length of 200 bytes to the target variable in an assignment statement. Most of the other character functions cause the target to have the same length as the original value. In the data set GATELENGTH, the variable ArrivalGate has a length of 200 because the SCAN function creates it. The variable DepartureGate also has a length of 200 because the argument of the LEFT function contains the SCAN function.

Setting the lengths of ArrivalGate and DepartureGate to the needed values rather than to the default length saves a lot of storage space. Because SAS sets the length of a character variable the first time SAS encounters it, the LENGTH statement must appear before the assignment statements that create values for the variables:

```sas
data gatelength;
    length ArrivalGate $ 14 DepartureGate $ 9;
    set mylib.departures;
    ArrivalGate = scan(ArrivalDepartureGate,1,’,’);
    DepartureGate = left(scan(ArrivalDepartureGate,2,’,’));
run;
```

**Combining Character Values: Using Concatenation**

**Understanding Concatenation of Variable Values**

SAS enables you to combine character values into longer ones using an operation known as **concatenation**. Concatenation combines character values by placing them one after the other and assigning them to a variable. In SAS programming, the concatenation operator is a pair of vertical bars (||). If your keyboard does not have a solid vertical bar, use two broken vertical bars (¦¦) or two exclamation points (!!!). The length of the new variable is the sum of the lengths of the pieces or number of characters that is specified in a LENGTH statement for the new variable. Concatenation is illustrated in the following figure:
Combining Character Values: Using Concatenation

Chapter 8

Display 8.1  Concatenation of Two Values

<table>
<thead>
<tr>
<th>Value 1</th>
<th>Value 2</th>
</tr>
</thead>
</table>

Performing a Simple Concatenation

The following statement combines all the cities named as gateways into a single variable named AllGates:

```
AllGates = USGate || ArrivalDepartureGates;
```

SAS attaches the beginning of each value of ArrivalDepartureGates to the end of each value of USGate and assigns the results to AllGates. The following DATA step includes this statement:

```
/* first try */
options pagesize=60 linesize=80 pageno=1 nodate;
data all;
  set mylib.departures;
  AllGates = USGate || ArrivalDepartureGates;
run;

proc print data=all;
  var Country USGate ArrivalDepartureGates AllGates;
  title 'All Tour Gates';
run;
```

The following output displays the results:

Output 8.10  Simple Concatenation: Interior Blanks Not Removed

<table>
<thead>
<tr>
<th>All Tour Gates</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>

</tr>
<tr>
<td>4</td>
<td>Miami Caracas, Maracaibo</td>
</tr>
<tr>
<td>5</td>
<td>Rio de Janeiro, Belem</td>
</tr>
</tbody>
</table>

Removing Interior Blanks

Why, in the previous output, does \( \text{1} \) the middle of AllGates contain blanks?
the beginning of AllGates in the Brazil observation contain blanks?

When a character value is shorter than the length of the variable to which it belongs, SAS pads the value with trailing blanks. The length of USGate is 13 bytes, but only San Francisco uses all of them. Therefore, the other values contain blanks at the end, and the value for Brazil is entirely blank. SAS concatenates USGate and ArrivalDepartureGates without change; therefore, the middle of AllGates contains blanks for most observations. Most of the values of ArrivalDepartureGates also contain trailing blanks. If you concatenate another variable such as Country to ArrivalDepartureGates, you will see the trailing blanks in ArrivalDepartureGates. To eliminate trailing blanks, use the TRIM function:

**TRIM (source)**

The TRIM function produces a value without the trailing blanks in the `source`.

*Note:* Other rules about trailing blanks in SAS still apply. If the trimmed result is shorter than the length of the variable to which the result is assigned, SAS pads the result with new blanks as it makes the assignment.

To eliminate the trailing blanks in USGate from AllGates, add the TRIM function to the expression:

```plaintext
AllGate2 = trim(USGate) || ArrivalDepartureGates;
```

The following program adds this statement to the DATA step:

```plaintext
/* removing interior blanks */
options pagesize=60 linesize=80 pageno=1 nodate;
data all2;
  set mylib.departures;
  AllGate2 = trim(USGate) || ArrivalDepartureGates;
run;

proc print data=all2;
  var Country USGate ArrivalDepartureGates AllGate2;
  title 'All Tour Gates';
run;
```

The following output displays the results:

**Output 8.11** Removing Blanks with the TRIM Function

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>USGate</th>
<th>ArrivalDepartureGates</th>
<th>AllGate2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>San Francisco</td>
<td>Tokyo, Osaka</td>
<td>San FranciscoTokyo, Osaka</td>
</tr>
<tr>
<td>2</td>
<td>Italy</td>
<td>New York</td>
<td>Rome, Naples</td>
<td>New YorkRome, Naples</td>
</tr>
<tr>
<td>3</td>
<td>Australia</td>
<td>Honolulu</td>
<td>Sydney, Brisbane</td>
<td>HonoluluSydney, Brisbane</td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>Miami</td>
<td>Caracas, Maracaibo</td>
<td>MiamiCaracas, Maracaibo</td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>Miami</td>
<td>Rio de Janeiro, Belem</td>
<td>Rio de Janeiro, Belem</td>
</tr>
</tbody>
</table>

Notice at 1 that the AllGate2 value for Brazil has a blank space before Rio de Janeiro, Belem. When the TRIM function encounters a missing value in the argument, one blank space is returned. In this observation, USGate has a missing value; therefore, one blank space is concatenated with Rio de Janeiro, Belem.
Adding Additional Characters

Data set ALL2 shows that removing the trailing blanks from USGate causes all the values of ArrivalDepartureGates to appear immediately after the corresponding values of USGate. To make the result easier to read, you can concatenate a comma and blank between the trimmed value of USGate and the value of ArrivalDepartureGates. Also, to align the AllGate3 value for Brazil with all other values of AllGate3, use an IF-THEN statement to equate the value of AllGate3 with the value of ArrivalDepartureGates in that observation.

\[
\text{AllGate3} = \text{trim(USGate)}||', '|\text{ArrivalDepartureGates};
\]

if Country = 'Brazil' then AllGate3 = ArrivalDepartureGates;

This DATA step includes these statements:

```plaintext
/* final version */
options pagesize=60 linesize=80 pageno=1 nodate;
data all3;
   set mylib.departures;
   AllGate3 = trim(USGate)||', '|ArrivalDepartureGates;
   if Country = 'Brazil' then AllGate3 = ArrivalDepartureGates;
run;

proc print data=all3;
   var Country USGate ArrivalDepartureGates AllGate3;
   title 'All Tour Gates';
run;
```

The following output displays the results:

**Output 8.12  Concatenating Additional Characters for Readability**

<table>
<thead>
<tr>

<td>Honolulu</td>
<td>Sydney, Brisbane</td>
<td>Honolulu, Sydney, Brisbane</td>
</tr>
<tr>
<td>4</td>
<td>Venezuela</td>
<td>Miami</td>
<td>Caracas, Maracaibo</td>
<td>Miami, Caracas, Maracaibo</td>
</tr>
<tr>
<td>5</td>
<td>Brazil</td>
<td>Miami</td>
<td>Rio de Janeiro, Belem</td>
<td>Belem</td>
</tr>
</tbody>
</table>

Troubleshooting: When New Variables Appear Truncated

When you concatenate variables, you might see the apparent loss of part of a concatenated value. Earlier in this section, ArrivalDepartureGates was divided into two new variables, ArrivalGate and DepartureGate, each with a default length of 200 bytes. (Remember that when a variable is created by an expression that uses the SCAN function, the variable length is 200 bytes.) For reference, this example re-creates the DATA step:

```plaintext
options pagesize=60 linesize=80 pageno=1 nodate;
data gates;
   set mylib.departures;
   ArrivalGate = scan(ArrivalDepartureGates,1,',');
   DepartureGate = left(scan(ArrivalDepartureGates,2,','));
run;
```
If the variables ArrivalGate and DepartureGate are concatenated, as they are in the next DATA step, then the length of the resulting concatenation is 402 bytes: 200 bytes for each variable and 1 byte each for the comma and the blank space. This example uses the VLENGTH function to show the length of ADGates.

```sas
/* accidentally omitting the TRIM function */
options pagesize=60 linesize=80 pageno=1 nodate;
data gates2;
set gates;
ADGates = ArrivalGate || ', ' || DepartureGate;;
ADLength = vlength(ADGates);
run;
```

```
proc print data=gates2;
var Country ArrivalDepartureGates ADGates ADLength;
title 'All Tour Gates';
run;
```

The following output displays the results:

</tr>
</tbody>
</table>

The concatenated value from DepartureGate appears to be truncated in the output. It has been concatenated after the trailing blanks of ArrivalGate, and it does not appear because the output does not display 402 bytes.

There is a two-step solution to the problem:

1. The TRIM function can trim the trailing blanks from ArrivalGate, as shown in the preceding section. The significant characters from all three pieces that are assigned to ADGates can then fit in the output.

2. The length of ADGates remains 402 bytes. The LENGTH statement can assign to the variable a length that is shorter but large enough to contain the significant pieces.
The following DATA step uses the TRIM function and the LENGTH statement to remove interior blanks from the concatenation:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data gates3;
  length ADGates $ 30;
  set gates;
  ADGates = trim(ArrivalGate)||', '|DepartureGate;
run;

proc print data=gates3;
  var country ArrivalDepartureGates ADGates;
  title 'All Tour Gates';
run;
```

The following output displays the results:

**Output 8.14**  Showing All of a Newly Concatenated Value

### Saving Storage Space by Treating Numbers as Characters

Remember that SAS uses eight bytes of storage for every numeric value in the DATA step; by default, SAS also uses eight bytes of storage for each numeric value in an output data set. However, a character value can contain a minimum of one character; in that case, SAS uses one byte for the character variable, both in the program data vector and in the output data set. In addition, SAS treats the digits 0 through 9 in a character value like any other character. When you are not going to perform calculations on a variable, you can save storage space by treating a value that contains digits as a character value.

For example, some tours offer various prices, depending on the quality of the hotel room. The brochures rank the rooms as two stars, three stars, and so on. In this case the values 2, 3, and 4 are really the names of categories, and arithmetic operations are not expected to be performed on them. Therefore, the values can be read into a character variable. The following DATA step reads HotelRank as a character variable and assigns it a length of one byte:

```sas
data hotels;
  input Country $ 1-9 HotelRank $ 11 LandCost;
datalines;
Italy  2 498
Italy  4 698
Australia 2 915
Australia 3 1169
```
In the previous example, the INPUT statement assigns HotelRank a length of one byte because the INPUT statement reads one column to find the value (shown by the use of column input). If you are using list input, place a LENGTH statement before the INPUT statement to set the length to one byte.

If you read a number as a character value and then discover that you need to use it in a numeric expression, then you can do so without making changes in your program. SAS automatically produces a numeric value from the character value for use in the expression; it also issues a note in the log that the conversion occurred. (Of course, the conversion causes the DATA step to use slightly more computer resources.) The original variable remains unchanged.

The following output displays the results:

Output 8.15  Saving Storage Space by Creating a Character Variable

<table>
<thead>
<tr>
<th>Hotel Rankings 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

Note:  Note that the width of the column is not the default width of eight.

---

Review of SAS Tools

**Functions**

**LEFT** *(source)*

left-aligns the *source* by moving any leading blanks to the end of the value. The *source* can be any kind of character expression, including a character variable, a character constant enclosed in quotation marks, or another character function. Because any blanks removed from the left are added to the right, the length of the result matches the length of the source.

**SCAN** *(source,n,<list-of-delimiters>)*

selects the *n*th term from the *source*. The source can be any kind of character expression, including a character variable, a character constant enclosed in quotation marks, or another character function. To choose the character that divides the terms, use a delimiter; if you omit the delimiter, then SAS divides the terms using a default list of delimiters (the blank and some special characters).
TRIM (source)
trims trailing blanks from the source. The source can be any kind of character expression, including a character variable, a character constant enclosed in quotation marks, or another character function. The TRIM function does not affect the way a variable is stored. If you use the TRIM function to remove trailing blanks and assign the trimmed value to a variable that is longer than that value, then SAS pads the value with new trailing blanks to make the value match the length of the new variable.

Statements

LENGTH variable-list $ number-of-bytes;
assigns a length that you specify in number-of-bytes to the character variable or variables in variable-list. You can assign any number of lengths in a single LENGTH statement, and you can assign lengths to both character and numeric variables in the same statement. Place a dollar sign ($) before the length of any character variable.

Learning More

Character values
This section illustrates the flexibility that SAS provides for manipulating character values. In addition to the functions that are described in this section, the following character functions are also frequently used:

COMPBL
removes multiple blanks from a character string.

COMPRESS
removes specified character(s) from the source.

INDEX
searches the source data for a pattern of characters.

LOWCASE
converts all letters in an argument to lowercase.

RIGHT
right-aligns the source.

SUBSTR
extracts a group of characters.

TRANSLATE
replaces specific characters in a character expression.

UPCASE
returns the source data in uppercase.

Character variables
Detailed information about character variables is found in *SAS Language Reference: Concepts*.

Comparing uppercase and lowercase characters
How to compare uppercase and lowercase characters is shown in Chapter 9, “Acting on Selected Observations,” on page 139.

Concatenation operator
Information about the concatenation operator can be found in *SAS Language Reference: Concepts*.

DATASETS procedure
Using the DATASETS procedure to display the length of variables in a SAS data set is explained in Chapter 35, “Getting Information about Your SAS Data Sets,” on page 607.

IF-THEN statements
A detailed explanation of the IF-THEN statements can be found in Chapter 9, “Acting on Selected Observations,” on page 139.

Informats and formats
Complete information about the SAS System’s numerous informats and formats for reading and writing character variables is found in *SAS Language Reference: Dictionary*.

Missing values
Detailed information about missing values is found in *SAS Language Reference: Concepts*.

VLENGTH function
The VLENGTH function is explained in detail in *SAS Language Reference: Dictionary*. 
Introduction to Acting on Selected Observations

Purpose

One of the most useful features of SAS is its ability to perform an action on only the observations that you have selected. In this section, you will learn the following:

- how the selection process works
- how to write statements that select observations based on a condition
Prerequisites

You should understand the concepts presented in all previous sections before proceeding with this section.

Input SAS Data Set for Examples

Tradewinds Travel offers tours to art museums and galleries in various cities. The company has decided that in order to make its process more efficient, additional information is needed. For example, if the tour covers too many museums and galleries within a time period, then the number of museums visited must be decreased or the number of days for the tour needs to change. If the guide who is assigned to the tour is not available, then another guide must be assigned. Most of the process involves selecting observations that meet or that do not meet various criteria and then taking the required action.

The Tradewinds Travel tour data is stored in an external file that contains the following information:

- **u**: the name of the city
- **v**: the number of nights in the city
- **w**: the cost of the land package (not airfare) in US dollars
- **x**: the number of events the trip offers (such as visits to museums and galleries)
- **y**: a brief description of the events (where M indicates a museum; G, a gallery; and other, another kind of event)
- **U**: the name of the tour guide
- **V**: the name of the backup tour guide

The numbered fields represent

1. the name of the city
2. the number of nights in the city
3. the cost of the land package (not airfare) in US dollars
4. the number of events the trip offers (such as visits to museums and galleries)
5. a brief description of the events (where M indicates a museum; G, a gallery; and other, another kind of event)

The following DATA step creates MYLIB.ARTTOURS:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';

data mylib.arttours;
   infile 'input-file' truncover;
   input City $ 1-9 Nights 11 LandCost 13-16 NumberOfEvents 18
   EventDescription $ 20-36 TourGuide $ 38-45
   BackUpGuide $ 47-54;
run;

proc print data=mylib.arttours;
   title 'Data Set MYLIB.ARTTOURS';
run;
```
Note: When the TRUNCOVER option is specified in the INFILE statement, and when the record is shorter than what the INPUT statement expects, SAS will read a variable length record.

The PROC PRINT statement that follows the DATA step produces this display of the MYLIB.ARTTOURS data set:

Output 9.1  Data Set MYLIB.ARTTOURS

The following list corresponds to the numbered items in the preceding output:

1. the variable NumberOfEvents contains the number of attractions visited during the tour
2. EventDescription lists the number of museums (M), art galleries (G), and other attractions (other) visited
3. TourGuide lists the name of the tour guide assigned to the tour
4. BackUpGuide lists the alternate tour guide in case the original tour guide is unavailable

Selecting Observations

Understanding the Selection Process

The most common way that SAS selects observations for action in a DATA step is through the IF-THEN statement:

IF condition THEN action;

The condition is one or more comparisons, for example,

- City = ‘Rome’
- NumberOfEvents > Nights
- TourGuide = ‘Lucas’ and Nights > 7

(The symbol > stands for greater than. You will see how to use symbols as comparison operators in “Understanding Construct Conditions” on page 145.)

For a given observation, a comparison is either true or false. In the first example, the value of City is either Rome or it is not. In the second example, the value of NumberOfEvents in the current observation is either greater than the value of Nights in the same observation or it is not. If the condition contains more than one
comparison, as in the third example, then SAS evaluates all of them according to its rules (discussed later) and declares the entire condition to be true or false.

When the condition is true, SAS takes the action in the THEN clause. The action must be expressed as a SAS statement that can be executed in an individual iteration of the DATA step. Such statements are called executable statements. The most common executable statements are assignment statements, such as

- \[ \text{LandCost} = \text{LandCost} + 30; \]
- \[ \text{Calendar} = \text{’Check schedule’}; \]
- \[ \text{TourGuide} = \text{’Torres’}; \]

This section concentrates on assignment statements in the THEN clause, but examples in other sections show other types of statements that are used with the THEN clause.

Statements that provide information about a data set are not executable. Such statements are called declarative statements. For example, the LENGTH statement affects a variable as a whole, not how the variable is treated in a particular observation. Therefore, you cannot use a LENGTH statement in a THEN clause.

When the condition is false, SAS ignores the THEN clause and proceeds to the next statement in the DATA step.

### Selecting Observations Based on a Simple Condition

The following DATA step uses the previous example conditions and actions in IF-THEN statements:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data revise;
  set mylib.arttours;
  if City = ‘Rome’ then LandCost = LandCost + 30;
  if NumberOfEvents > Nights then Calendar = ‘Check schedule’;
  if TourGuide = ‘Lucas’ and Nights > 7 then TourGuide = ‘Torres’;
run;

proc print data=revise;
  var City Nights LandCost NumberOfEvents TourGuide Calendar;
  title ‘Tour Information’;
run;
```

The following output displays the results:

**Output 9.2** Selecting Observations with IF-THEN Statements

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>LandCost</th>
<th>NumberOfEvents</th>
<th>TourGuide</th>
<th>Calendar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>3</td>
<td>780</td>
<td>7</td>
<td>D’Amico</td>
<td>Check schedule</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>6</td>
<td>Torres</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>5</td>
<td>Wilson</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>6</td>
<td></td>
<td>8</td>
<td>Lucas</td>
<td>Check schedule</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>5</td>
<td>Torres</td>
<td>Check schedule</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>6</td>
<td></td>
<td>Check schedule</td>
</tr>
</tbody>
</table>
You can see in the output that
1. the land cost was increased by $30 in the observation for Rome
2. four observations have a greater number of events than they do number of days in the tour
3. the tour guide for Paris is replaced by Torres because the original tour guide is Lucas and the number of nights in the tour is greater than 7

Providing an Alternative Action

Remember that SAS creates a variable in all observations, even if you do not assign the variable a value in all observations. In the previous output, the value of Calendar is blank in two observations. A second IF-THEN statement can assign a different value, as in these examples:

```sas
if NumberOfEvents > Nights then Calendar = 'Check schedule';
if NumberOfEvents <= Nights then Calendar = 'No problems';
```

(The symbol <= means less than or equal to.) In this case, SAS compares the values of Events and Nights twice, once in each IF condition. A more efficient way to provide an alternative action is to use an ELSE statement:

```sas
ELSE action;
```

An ELSE statement names an alternative action to be taken when the IF condition is false. It must immediately follow the corresponding IF-THEN statement, as shown here:

```sas
if NumberOfEvents > Nights then Calendar = 'Check schedule';
else Calendar = 'No problems';
```

The REVISE2 DATA step adds the preceding ELSE statement to the previous DATA step:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data revise2;
set mylib.arttours;
if City = 'Rome' then LandCost = LandCost + 30;
if NumberOfEvents > Nights then Calendar = 'Check schedule';
else Calendar = 'No problems';
if TourGuide = 'Lucas' and Nights > 7 then TourGuide = 'Torres';
run;
```

```sas
proc print data=revise2;
var City Nights LandCost NumberOfEvents TourGuide Calendar;
title 'Tour Information';
run;
```

The following output displays the results:
Output 9.3  Providing an Alternative Action with the ELSE Statement

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Number OfEvents</th>
<th>Tour Guide</th>
<th>Calendar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>3</td>
<td>780</td>
<td>7</td>
<td>D’Amico</td>
<td>Check schedule</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>6</td>
<td>Torres</td>
<td>No problems</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>5</td>
<td>Wilson</td>
<td>No problems</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>6</td>
<td>.</td>
<td>8</td>
<td>Lucas</td>
<td>Check schedule</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>5</td>
<td>Torres</td>
<td>Check schedule</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>6</td>
<td></td>
<td>Check schedule</td>
</tr>
</tbody>
</table>

Creating a Series of Mutually Exclusive Conditions

Using an ELSE statement after an IF-THEN statement provides one alternative action when the IF condition is false. However, many cases involve a series of mutually exclusive conditions, each of which requires a separate action. In this example, tour prices can be classified as high, medium, or low. A series of IF-THEN and ELSE statements classifies the tour prices appropriately:

```sas
if LandCost >= 1500 then Price = 'High';
else if LandCost >= 700 then Price = 'Medium';
   else Price = 'Low';
```

(The symbol >= is greater than or equal to.) To see how SAS executes this series of statements, consider two observations: Amsterdam, whose value of LandCost is 580, and Paris, whose value is 1680.

When the value of LandCost is 580:

1. SAS tests whether 580 is equal to or greater than 1500, determines that the comparison is false, ignores the THEN clause, and proceeds to the ELSE statement.
2. The action in the ELSE statement is to evaluate another condition. SAS tests whether 580 is equal to or greater than 700, determines that the comparison is false, ignores the THEN clause, and proceeds to the accompanying ELSE statement.
3. SAS executes the action in the ELSE statement and assigns Price the value Low.

When the value of LandCost is 1680:

1. SAS tests whether 1680 is greater than or equal to 1500, determines that the comparison is true, and executes the action in the THEN clause. The value of Price becomes High.
2. SAS ignores the ELSE statement. Because the entire remaining series is part of the first ELSE statement, SAS skips all remaining actions in the series.

A simple way to think of these actions is to remember that when an observation satisfies one condition in a series of mutually exclusive IF-THEN/ELSE statements, SAS processes that THEN action and skips the rest of the statements. (Therefore, you can increase the efficiency of a program by ordering the IF-THEN/ELSE statements so that the most common conditions appear first.)

The following DATA step includes the preceding series of statements:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data prices;
```
set mylib.arttours;
if LandCost >= 1500 then Price = 'High';
else if LandCost >= 700 then Price = 'Medium';
   else Price = 'Low';
run;

proc print data=prices;
   var City LandCost Price;
   title 'Tour Prices';
run;

The following output displays the results:

Output 9.4 Assigning Mutually Exclusive Values with IF-THEN/ELSE Statements

<table>
<thead>
<tr>
<th>Tour Prices 1</th>
<th>Land</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>
</tr>
<tr>
<td>1</td>
<td>Rome</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
</tr>
</tbody>
</table>

Note the value of Price in the fourth observation. The Price value is Low because the LandCost value for the New York trip is a missing value. Remember that a missing value is the lowest possible numeric value.

Constructing Conditions

Understanding Construct Conditions

When you use an IF-THEN statement, you ask SAS to make a comparison. SAS must determine whether a value is equal to another value, greater than another value, and so on. SAS has six main comparison operators:

Table 9.1 Comparison Operators

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Mnemonic Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>EQ</td>
<td>equal to</td>
</tr>
<tr>
<td>^=, ^=, -=</td>
<td>NE</td>
<td>not equal to (the ~, ^, or ~ symbol, depending on your keyboard)</td>
</tr>
<tr>
<td>&gt;</td>
<td>GT</td>
<td>greater than</td>
</tr>
<tr>
<td>&lt;</td>
<td>LT</td>
<td>less than</td>
</tr>
</tbody>
</table>
### Chapter 9

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Mnemonic Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;=</td>
<td>GE</td>
<td>greater than or equal to</td>
</tr>
<tr>
<td>&lt;=</td>
<td>LE</td>
<td>less than or equal to</td>
</tr>
</tbody>
</table>

The symbols in the table are based on mathematical symbols; the letter abbreviations, known as **mnemonic operators**, have the same effect. Use the form that you prefer, but remember that you can use the mnemonic operators only in comparisons. For example, the equal sign in an assignment statement must be represented by the symbol =, not the mnemonic operator. Both of the following statements compare the number of nights in the tour to six:

- if Nights $\geq 6$ then Stay = 'Week+';
- if Nights $\geq 6$ then Stay = 'Week+';

The terms on each side of the comparison operator can be variables, expressions, or constants. The side a particular term appears on does not matter, as long as you use the correct operator. All of the following comparisons are constructed correctly for use in SAS statements:

- Guide = ''
- LandCost ne .
- LandCost lt 600
- 600 ge LandCost
- NumberOfEvents / Nights $> 2$
- $2 \leq$ NumberOfEvents / Nights

## Selecting an Observation Based on Simple Conditions

The following DATA step illustrates some of these conditions:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data changes;
  set mylib.arttours;
  if Nights $\geq 6$ then Stay = 'Week+';
  else Stay = 'Days';
  if LandCost ne . then Remarks = 'OK ';
  else Remarks = 'Redo';
  if LandCost lt 600 then Budget = 'Low ';
  else Budget = 'Medium';
  if NumberOfEvents / Nights $> 2$ then Pace = 'Too fast';
  else Pace = 'OK';
run;

proc print data=changes;
  var City Nights LandCost NumberOfEvents Stay Remarks Budget Pace;
  title 'Tour Information';
run;
```

The following output displays the results:
Using More Than One Comparison in a Condition

Specifying Multiple Comparisons

You can specify more than one comparison in a condition with these operators:

- `&` or **AND**
- `|` or **OR**

A condition can contain any number of ANDs, ORs, or both.

Making Comparisons When All of the Conditions Must Be True

When comparisons are connected by **AND**, all of the comparisons must be true for the condition to be true. Consider this example:

```basic
if City = 'Paris' and TourGuide = 'Lucas' then Remarks = 'Bilingual';
```

The comparison is true for observations in which the value of City is **Paris** and the value of TourGuide is **Lucas**.

A common comparison is to determine whether a value is between two quantities, greater than one quantity and less than another quantity. For example, to select observations in which the value of LandCost is greater than or equal to 1000, and less than or equal to 1500, you can write a comparison with **AND**:

```basic
if LandCost >= 1000 and LandCost <= 1500 then Price = '1000-1500';
```

A simpler way to write this comparison is

```basic
if 1000 <= LandCost <= 1500 then Price = '1000-1500';
```

This comparison has the same meaning as the previous one. You can use any of the operators `<`, `<=`, `>`, `>=`, or their mnemonic equivalents in this way.

The following DATA step includes these multiple comparison statements:

```basic
options pagesize=60 linesize=80 pageno=1 nodate;
data showand;
  set mylib.arttours;
  if City = 'Paris' and TourGuide = 'Lucas' then Remarks = 'Bilingual';
  if 1000 <= LandCost <= 1500 then Price = '1000-1500';
run;
```

```basic
proc print data=showand;
  var City LandCost TourGuide Remarks Price;
```
Using More Than One Comparison in a Condition

Chapter 9

The following output displays the results:

Output 9.6 Using AND When Making Multiple Comparisons

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Land Cost</th>
<th>Tour Guide</th>
<th>Remarks</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>750</td>
<td>D’Amico</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>1680</td>
<td>Lucas</td>
<td>Bilingual</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>1230</td>
<td>Wilson</td>
<td></td>
<td>1000-1500</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td></td>
<td>Lucas</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>370</td>
<td>Torres</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>580</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When Only One Condition Must Be True

When comparisons are connected by OR, only one of the comparisons needs to be true for the condition to be true. Consider the following example:

```
if LandCost gt 1500 or LandCost / Nights gt 200 then Level = 'Deluxe';
```

Any observation in which the land cost is over $1500, the cost per night is over $200, or both, satisfies the condition. The following DATA step shows this condition:

```
options pagesize=60 linesize=80 pageno=1 nodate;
data showor;
set mylib.arttours;
if LandCost gt 1500 or LandCost / Nights gt 200 then Level = 'Deluxe';
run;
proc print data=showor;
var City LandCost Nights Level;
title 'Tour Information';
run;
```

The following output displays the results:

Output 9.7 Using OR When Making Multiple Comparisons

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Land Cost</th>
<th>Nights</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>750</td>
<td>3</td>
<td>Deluxe</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>1680</td>
<td>8</td>
<td>Deluxe</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>1230</td>
<td>6</td>
<td>Deluxe</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>.</td>
<td>6</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>370</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>580</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>
Using Negative Operators with AND or OR

Be careful when you combine negative operators with OR. Often, the operator that you really need is AND. For example, the variable TourGuide contains some problems with the data. In the observation for Paris, the tour guide and the backup tour guide are both Lucas; in the observation for Amsterdam, the name of the tour guide is missing. You want to label the observations that have no problems with TourGuide as OK. Should you write the IF condition with OR or with AND?

The following DATA step shows both conditions:

```plaintext
options pagesize=60 linesize=80 pageno=1 nodate;
data test;
  set mylib.arttours;
  if TourGuide ne BackUpGuide or TourGuide ne ' ' then GuideCheckUsingOR = 'OK';
  else GuideCheckUsingOR = 'No';
  if TourGuide ne BackUpGuide and TourGuide ne ' ' then GuideCheckUsingAND = 'OK';
  else GuideCheckUsingAND = 'No';
run;
```

```plaintext
proc print data = test;
  title 'Negative Operators with OR and AND';
run;
```

The following output displays the results:

Output 9.8 Using Negative Operators When Making Comparisons

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>D’Amico</td>
<td>Torres</td>
<td>OK</td>
<td>OK</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>Lucas</td>
<td>Lucas</td>
<td>OK</td>
<td>No</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>Wilson</td>
<td>Lucas</td>
<td>OK</td>
<td>OK</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>Lucas</td>
<td>D’Amico</td>
<td>OK</td>
<td>OK</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>Torres</td>
<td>D’Amico</td>
<td>OK</td>
<td>OK</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>Vandever</td>
<td>OK</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

In the IF-THEN/ELSE statements that create GuideCheckUsingOR, only one comparison needs to be true to make the condition true. Note that for the Paris and Amsterdam observations in the data set MYLIB.ARTTOURS,

1 in the observation for Paris, TourGuide does not have a missing value and the comparison `TourGuide NE ' '` is true.

2 for Amsterdam, the comparison `TourGuide NE BackUpGuide` is true.

Because one OR comparison is true in each observation, GuideCheckUsingOR is labeled OK for all observations. The IF-THEN/ELSE statements that create GuideCheckUsingAND achieve better results. That is, the AND operator selects the observations in which the value of TourGuide is not the same as BackUpGuide and is not missing.
Using Complex Comparisons That Require AND and OR

A condition can contain both ANDs and ORs. When it does, SAS evaluates the ANDs before the ORs. The following example specifies a list of cities and a list of guides:

/* first attempt */
if City = 'Paris' or City = 'Rome' and TourGuide = 'Lucas' or
   TourGuide = "D'Amico" then Topic = 'Art history';

SAS first joins the items that are connected by AND:

City = 'Rome' and TourGuide = 'Lucas'

Then SAS makes the following OR comparisons:

City = 'Paris'
   or
City = 'Rome' and TourGuide = 'Lucas'
   or
TourGuide = "D'Amico"

To group the City comparisons and the TourGuide comparisons, use parentheses:

/* correct method */
if (City = 'Paris' or City = 'Rome') and
   (TourGuide = 'Lucas' or TourGuide = "D'Amico") then
   Topic = 'Art history';

SAS evaluates the comparisons within parentheses first and uses the results as the terms of the larger comparison. You can use parentheses in any condition to control the grouping of comparisons or to make the condition easier to read.

The following DATA step illustrates these conditions:

options pagesize=60 linesize=80 pageno=1 nodate;
data combine;
   set mylib.arttours;
   if (City = 'Paris' or City = 'Rome') and
      (TourGuide = 'Lucas' or TourGuide = "D'Amico") then
      Topic = 'Art history';
run;

proc print data=combine;
   var City TourGuide Topic;
   title 'Tour Information';
run;

The following output displays the results:

Output 9.9  Using Parentheses to Combine Comparisons with AND and OR

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Tour Guide</th>
<th>Topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>D'Amico</td>
<td>Art history</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>Lucas</td>
<td>Art history</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>Wilson</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>Lucas</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>Torres</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Abbreviating Numeric Comparisons

Two points about numeric comparisons are especially helpful to know:

- An abbreviated form of comparison is possible.
- Abbreviated comparisons with OR require you to use caution.

In computing terms, a value of TRUE is 1 and a value of FALSE is 0. In SAS, the following is true:

- Any numeric value other than 0 or missing is true.
- A value of 0 or missing is false.

Therefore, a numeric variable or expression can stand alone in a condition. If its value is a number other than 0 or if the value is missing, then the condition is true; if its value is 0 or missing, then the condition is false.

The following example assigns a value to the variable Remarks only if the value of LandCost is present for a given observation:

```sas
if LandCost then Remarks = 'Ready to budget';
```

This statement is equivalent to:

```sas
if LandCost ne . and LandCost ne 0 then Remarks = 'Ready to budget';
```

Be careful when you abbreviate comparisons with OR; it is easy to produce unexpected results. For example, this IF-THEN statement selects tours that last six or eight nights:

```sas
/* first try */
if Nights = 6 or 8 then Stay = 'Medium';
```

SAS treats the condition as the following comparisons:

```
Nights=6
or
8
```

The second comparison does not use the values of Nights; it is simply the number 8 standing alone. Because the number 8 is neither 0 nor a missing value, it always has the value TRUE. Because only one comparison in a series of OR comparisons needs to be true to make the condition true, this condition is true for all observations.

The following comparisons correctly select observations that have six or eight nights:

```sas
/* correct way */
if Nights = 6 or Nights = 8 then Stay = 'Medium';
```

The following DATA step includes these IF-THEN statements:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data morecomp;
  set mylib.arttours;
  if LandCost then Remarks = 'Ready to budget';
  else Remarks = 'Need land cost';
  if Nights = 6 or Nights = 8 then Stay = 'Medium';
  else Stay = 'Short';
run;

proc print data=morecomp;
  var City Nights LandCost Remarks Stay;
  title 'Tour Information';
run;
```

The following output displays the results:
Comparing Characters

Types of Character Comparisons

Some special situations occur when you make character comparisons. You might need to do the following:

- Compare uppercase and lowercase characters.
- Select all values beginning with a particular group of characters.
- Select all values beginning with a particular range of characters.
- Find a particular value anywhere within another character value.

Comparing Uppercase and Lowercase Characters

SAS distinguishes between uppercase and lowercase letters in comparisons. For example, the values Madrid and MADRID are not equivalent. To compare values that may occur in different cases, use the UPCASE function to produce an uppercase value; then make the comparison between two uppercase values, as shown here:

```
options pagesize=60 linesize=80 pageno=1 nodate;
data newguide;
  set mylib.arttours;
  if upcase(City) = 'MADRID' then TourGuide = 'Balarezo';
run;
```

```
proc print data=newguide;
  var City TourGuide;
  title 'Tour Guides';
run;
```

Within the comparison, SAS produces an uppercase version of the value of City and compares it to the uppercase constant MADRID. The value of City in the observation remains in its original case. The following output displays the results:

---

Output 9.10 Abbreviating Numeric Comparisons

<table>
<thead>
<tr>
<th>City</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Remarks</th>
<th>Stay</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rome</td>
<td>3</td>
<td>750</td>
<td>Ready to budget</td>
<td>Short</td>
</tr>
<tr>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>Ready to budget</td>
<td>Medium</td>
</tr>
<tr>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>Ready to budget</td>
<td>Medium</td>
</tr>
<tr>
<td>New York</td>
<td>6</td>
<td>.</td>
<td>Need land cost</td>
<td>Medium</td>
</tr>
<tr>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>Ready to budget</td>
<td>Short</td>
</tr>
<tr>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>Ready to budget</td>
<td>Short</td>
</tr>
</tbody>
</table>
Now Balarezo is assigned as the tour guide for Madrid because the \textsc{upcase} function compares the uppercase value of Madrid with the value MADRID. The \textsc{upcase} function enables SAS to read the two values as equal.

**Selecting All Values That Begin with the Same Group of Characters**

Sometimes you need to select a group of character values, such as all tour guides whose names begin with the letter D.

By default, SAS compares values of different lengths by adding blanks to the end of the shorter value and testing the result against the longer value. In this example,

```sas
/* first attempt */
if Tourguide = 'D' then Chosen = 'Yes';
else Chosen = 'No';
```

SAS interprets the comparison as

\[
\text{TourGuide} = \text{D } \text{ } \text{ } \text{ } \text{ } \text{ } \text{ } \text{ } \text{ }
\]

where D is followed by seven blanks (because TourGuide, a character variable created by column input, has a length of eight bytes). Because the value of TourGuide never consists of the single letter D, the comparison is never true.

To compare a long value to a shorter standard, put a colon (:) after the operator, as in this example:

```sas
/* correct method */
if TourGuide =: 'D' then Chosen = 'Yes';
else Chosen = 'No';
```

The colon causes SAS to compare the same number of characters in the shorter value and the longer value. In this case, the shorter string contains one character; therefore, SAS tests only the first character from the longer value. All names beginning with a D make the comparison true. (If you are not sure that all the values of TourGuide begin with a capital letter, then use the \textsc{upcase} function.) The following DATA step selects names beginning with D:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data dguide;
  set mylib.arttours;
  if TourGuide =: 'D' then Chosen = 'Yes';
  else Chosen = 'No';
run;
proc print data=dguide;
```
var City TourGuide Chosen;
title 'Guides Whose Names Begin with D';
run;

The following output displays the results:

**Output 9.12** Selecting All Values That Begin with a Particular String

<table>
<thead>
<tr>
<th>Guides Whose Names Begin with D</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>
</tr>
<tr>
<td>1</td>
<td>Rome</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
</tr>
</tbody>
</table>

**Selecting a Range of Character Values**

You may want to select values beginning with a range of characters, such as all names beginning with A through L or M through Z. To select a range of character values, you need to understand the following points:

- In computer processing, letters have magnitude. A is the smallest letter in the alphabet and Z is the largest. Therefore, the comparison A<B is true; so is the comparison D>C.*
- A blank is smaller than any letter.

The following statements divide the names of the guides into two groups beginning with A-L and M-Z by combining the comparison operator with the colon:

```sas
if TourGuide <=: 'L' then TourGuideGroup = 'A-L';
else TourGuideGroup = 'M-Z';
```

The following DATA step creates the groups:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data guidegrp;
  set mylib.arttours;
  if TourGuide <=: 'L' then TourGuideGroup = 'A-L';
  else TourGuideGroup = 'M-Z';
run;

proc print data=guidegrp;
  var City TourGuide TourGuideGroup;
  title 'Tour Guide Groups';
run;
```

The following output displays the results:

---

* The magnitude of letters in the alphabet is true for all operating environments under which SAS runs. Other points, such as whether uppercase or lowercase letters are larger and how to treat numbers in character values, depend on your operating system. For more information about how character values are sorted under various operating environments, see Chapter 11, “Working with Grouped or Sorted Observations,” on page 173.
Output 9.13  Selecting All Values Beginning with a Range of Characters

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Tour Guide</th>
<th>Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>D’Amico</td>
<td>A-L</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>Lucas</td>
<td>A-L</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>Wilson</td>
<td>M-Z</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>Lucas</td>
<td>A-L</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>Torres</td>
<td>M-Z</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td></td>
<td>A-L</td>
</tr>
</tbody>
</table>

All names beginning with A through L, as well as the missing value, go into group A-L. The missing value goes into that group because a blank is smaller than any letter.

Finding a Value Anywhere within Another Character Value

A data set is needed that lists tours that visit other attractions in addition to museums and galleries. In the data set MYLIB.ARTTOURS, the variable EventDescription refers to those events as other. However, the position of the word other varies in different observations. How can it be determined that other exists anywhere in the value of EventDescription for a given observation?

The INDEX function determines whether a specified character string (the excerpt) is present within a particular character value (the source):

\[
\text{INDEX} \left( \text{source}, \text{excerpt} \right)
\]

Both source and excerpt can be any kind of character expression, including character strings enclosed in quotation marks, character variables, and other character functions. If excerpt does occur within source, then the function returns the position of the first character of excerpt, which is a positive number. If it does not, then the function returns a 0. By testing for a value greater than 0, you can determine whether a particular character string is present in another character value.

The following statements select observations containing the string other:

``` Sas
if index(EventDescription,'other') > 0 then OtherEvents = 'Yes';
else OtherEvents = 'No';
```

You can also write the condition as

``` Sas
if index(EventDescription,'other') then OtherEvents = 'Yes';
else OtherEvents = 'No';
```

The second example uses the fact that any value other than 0 or missing makes the condition true. This statement is included in the following DATA step:

``` Sas
options pagesize=60 linesize=80 pageno=1 nodate;
data otherevent;
  set mylib.arttours;
  if index(EventDescription,'other') then OtherEvents = 'Yes';
  else OtherEvents = 'No';
run;
```

``` Sas
proc print data=otherevent;
  var City EventDescription OtherEvents;
```
title 'Tour Events';
run;

The following output displays the results:

Output 9.14 Finding a Character String within Another Value

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>EventDescription</th>
<th>Other Events</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>4 M, 3 G</td>
<td>No</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>5 M, 1 other</td>
<td>Yes</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>3 M, 2 G</td>
<td>No</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>5 M, 1 G, 2 other</td>
<td>Yes</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>3 M, 2 other</td>
<td>Yes</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>3 M, 3 G</td>
<td>No</td>
</tr>
</tbody>
</table>

In the observations for Paris and Madrid, the INDEX function returns the value 8 because the string other is found in the eighth field of the variable (5 M, 1 other for Paris and 3 M, 2 other for Madrid). For New York, it returns the value 13 because the string other is found in the thirteenth field of the variable (5 M, 1 G, 2 other). In the remaining observations, the function does not find the string other and returns a 0.

Review of SAS Tools

Statements

IF condition THEN action;
<ELSE action;>

tests whether the condition is true; if so, the action in the THEN clause is carried out. If the condition is false and an ELSE statement is present, then the ELSE action is carried out. If the condition is false and no ELSE statement is present, then the next statement in the DATA step is processed. The condition is one or more numeric or character comparisons. The action must be an executable statement; that is, one that can be processed in an individual iteration of the DATA step. (Statements that affect the entire DATA step, such as LENGTH, are not executable.)

In SAS processing, any numeric value other than 0 or missing is true; 0 and missing are false. Therefore, a numeric value can stand alone in a comparison. If its value is 0 or missing, then the comparison is false; otherwise, the comparison is true.

Functions

INDEX(source,excerpt)

searches the source for the string given in excerpt. Both the source and excerpt can be any kind of character expression, such as character variables, character strings enclosed in quotation marks, other character functions, and so on. When excerpt is present in source, the function returns the position of the first character of excerpt (a positive number). When excerpt is not present, the function returns a 0.
UPCASE(argument) produces an uppercase value of argument, which can be any kind of character expression, such as character variables, character strings enclosed in quotation marks, other character functions, and so on.

Learning More

Base SAS functions
Base SAS functions are documented in SAS Language Reference: Dictionary.

Comparison and logical operators
Complete information about comparison and logical operators is provided in SAS Language Reference: Concepts.

Executable statements
You can issue only executable statements in IF-THEN/ELSE statements. For a complete list of executable and nonexecutable statements, see SAS Language Reference: Dictionary.

IF-THEN and ELSE statement and clauses
The IF-THEN and ELSE statement and clauses are documented in SAS Language Reference: Dictionary.

IN operator
Information about the IN operator can be found in SAS Language Reference: Concepts. You can use the IN operator to shorten a comparison when you are comparing a value to a series of numeric or character constants (not variables or expressions).

SELECT statement
The SELECT statement, which selects observations based on a condition, is documented in SAS Language Reference: Dictionary. Its action is equivalent to a series of IF-THEN/ELSE statements. If you have a long series of conditions and actions, then the DATA step may be easier to read if you write them in a SELECT group.

TRUNCOVER option
The TRUNCOVER option in the INFILE statement is described in Chapter 3, “Starting with Raw Data: The Basics,” on page 43.
Introduction to Creating Subsets of Observations

Purpose

In this section, you will learn to select specific observations from existing SAS data sets in order to create the following:

- a new SAS data set that includes only some of the observations from the input data source
- several new SAS data sets by writing observations from an input data source, using a single DATA step

Prerequisites

Before proceeding with this section, you should understand the concepts presented in the following topics:

- Part 1, “Introduction to the SAS System”
- Part 2, “Getting Your Data into Shape”
- Chapter 6, “Understanding DATA Step Processing,” on page 97
Tradewinds Travel has a schedule for tours to various art museums and galleries. It would be convenient to keep different SAS data sets that contain different information about the tours. The tour data is stored in an external file that contains the following information:

<table>
<thead>
<tr>
<th>City</th>
<th>Nights</th>
<th>LandCost</th>
<th>Budget</th>
<th>TourGuide</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rome</td>
<td>3</td>
<td>750</td>
<td>Medium</td>
<td>D’Amico</td>
</tr>
<tr>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>High</td>
<td>Lucas</td>
</tr>
<tr>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>High</td>
<td>Wilson</td>
</tr>
<tr>
<td>New York</td>
<td>6</td>
<td>.</td>
<td>Lucas</td>
<td></td>
</tr>
<tr>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>Low</td>
<td>Torres</td>
</tr>
<tr>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>Low</td>
<td></td>
</tr>
</tbody>
</table>

The numbered fields represent:
1. the name of the destination city
2. the number of nights on the tour
3. the cost of the land package in US dollars
4. a rating of the budget
5. the name of the tour guide

The following program creates a permanent SAS data set named MYLIB.ARTS:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';
data mylib.arts;
  infile 'input-file' truncover;
  input City $ 1-9 Nights 11 LandCost 13-16 Budget $ 18-23
    TourGuide $ 25-32;
;
proc print data=mylib.arts;
  title 'Data Set MYLIB.ARTS';
run;
```

The PROC PRINT statement that follows the DATA step produces this display of the MYLIB.ARTS data set:

**Output 10.1** Data Set MYLIB.ARTS

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>LandCost</th>
<th>Budget</th>
<th>TourGuide</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>3</td>
<td>750</td>
<td>Medium</td>
<td>D’Amico</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>High</td>
<td>Lucas</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>High</td>
<td>Wilson</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>Low</td>
<td>Torres</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>Low</td>
<td></td>
</tr>
</tbody>
</table>
Selecting Observations for a New SAS Data Set

Deleting Observations Based on a Condition

There are two ways to select specific observations in a SAS data set when creating a new SAS data set:

1. Delete the observations that do not meet a condition, keeping only the ones that you want.
2. Accept only the observations that meet a condition.

To delete an observation, first identify it with an IF condition; then use a DELETE statement in the THEN clause:

```
IF condition THEN DELETE
```

Processing the DELETE statement for an observation causes SAS to return immediately to the beginning of the DATA step for a new observation without writing the current observation to the output DATA set. The DELETE statement does not include the observation in the output data set, but it does not delete the observation from the input data set. For example, the following statement deletes observations that contain a missing value for LandCost:

```
if LandCost = . then delete;
```

The following DATA step includes this statement:

```
options pagesize=60 linesize=80 pageno=1 nodate;
data remove;
set mylib.arts;
if LandCost = . then delete;
;
proc print data=remove;
title 'Tours With Complete Land Costs';
run;
```

The following output displays the results:

Output 10.2 Deleting Observations That Have a Particular Value

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Budget</th>
<th>Tour Guide</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>3</td>
<td>750</td>
<td>Medium</td>
<td>D’Amico</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>High</td>
<td>Lucas</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>High</td>
<td>Wilson</td>
</tr>
<tr>
<td>4</td>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>Low</td>
<td>Torres</td>
</tr>
<tr>
<td>5</td>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>Low</td>
<td></td>
</tr>
</tbody>
</table>

New York, the observation that is missing a value for LandCost, is not included in the resulting data set, REMOVE.

You can also delete observations as you enter data from an external file. The following DATA step produces the same SAS data set as the REMOVE data set:
Accepting Observations Based on a Condition

One data set that is needed by the travel agency contains observations for tours that last only six nights. One way to make the selection is to delete observations in which the value of Nights is not equal to 6:

```sql
if Nights ne 6 then delete;
```

A more straightforward way is to select only observations meeting the criterion. The subsetting IF statement selects the observations that you specify. It contains only a condition:

```sql
IF condition;
```

The implicit action in a subsetting IF statement is always the same: if the condition is true, then continue processing the observation; if it is false, then stop processing the observation and return to the top of the DATA step for a new observation. The statement is called subsetting because the result is a subset of the original observations. For example, if you want to select only observations in which the value of Nights is equal to 6, then you specify the following statement:

```sql
if Nights = 6;
```

The following DATA step includes the subsetting IF:

```sql
options pagesize=60 linesize=80 pageno=1 nodate;
data subset6;
   set mylib.arts;
   if nights=6;
;
proc print data=subset6;
   title 'Tours With Complete Land Costs';
run;
```

The following output displays the results:

Output 10.3  Deleting Observations While Reading from an External File

<table>
<thead>
<tr>
<th>Tours With Complete Land Costs</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>
</tr>
<tr>

<td>-------</td>
</tr>
<tr>
<td>1</td>
<td>Rome</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
</tr>
<tr>
<td>4</td>
<td>Madrid</td>
</tr>
<tr>
<td>5</td>
<td>Amsterdam</td>
</tr>
</tbody>
</table>

Accepting Observations Based on a Condition

One data set that is needed by the travel agency contains observations for tours that last only six nights. One way to make the selection is to delete observations in which the value of Nights is not equal to 6:

```sql
if Nights ne 6 then delete;
```

A more straightforward way is to select only observations meeting the criterion. The subsetting IF statement selects the observations that you specify. It contains only a condition:

```sql
IF condition;
```

The implicit action in a subsetting IF statement is always the same: if the condition is true, then continue processing the observation; if it is false, then stop processing the observation and return to the top of the DATA step for a new observation. The statement is called subsetting because the result is a subset of the original observations. For example, if you want to select only observations in which the value of Nights is equal to 6, then you specify the following statement:

```sql
if Nights = 6;
```

The following DATA step includes the subsetting IF:

```sql
options pagesize=60 linesize=80 pageno=1 nodate;
data subset6;
   set mylib.arts;
   if nights=6;
;
proc print data=subset6;
   title 'Tours With Complete Land Costs';
run;
```

The following output displays the results:

Output 10.3  Deleting Observations While Reading from an External File

<table>
<thead>
<tr>
<th>Tours With Complete Land Costs</th>
<th>1</th>

</table>
Creating Subsets of Observations

Comparing the DELETE and Subsetting IF Statements

proc print data=subset6;
    title 'Six-Night Tours';
run;

The following output displays the results:

Output 10.4  Selecting Observations with a Subsetting IF Statement

<table>
<thead>
<tr>
<th>Six-Night Tours</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>
</tr>
<tr>
<td>------</td>
<td>---------</td>
</tr>
<tr>
<td>1</td>
<td>London</td>
</tr>
<tr>
<td>2</td>
<td>New York</td>
</tr>
</tbody>
</table>

Two observations met the criteria for a six-night tour.

Comparing the DELETE and Subsetting IF Statements

The main reasons for choosing between a DELETE statement and a subsetting IF statement are that

- it is usually easier to choose the statement that requires the fewest comparisons to identify the condition.
- it is usually easier to think in positive terms than negative ones (this favors the subsetting IF).

One additional situation favors the subsetting IF: it is the safer method if your data has missing or misspelled values. Consider the following situation.

Tradewinds Travel needs a SAS data set of low- to medium-priced tours. Knowing that the values of Budget are Low, Medium, and High, a first thought would be to delete observations with a value of High. The following program creates a SAS data set by deleting observations that have a Budget value of HIGH:

/* first attempt */
options pagesize=60 linesize=80 pageno=1 nodate;
data lowmed;
    set mylib.arts;
    if upcase(Budget) = 'HIGH' then delete;
;
proc print data=lowmed;
    title 'Medium and Low Priced Tours';
run;

The following output displays the results:
Output 10.5  Producing a Subset by Deletion

The data set LOWMED contains both the tours that you want and the tour to New York. The inclusion of the tour to New York is erroneous because the value of Budget for the New York observation is missing. Using a subsetting IF statement ensures that the data set contains exactly the observations you want. This DATA step creates the subset with a subsetting IF statement:

```sas
/* a safer method */
options pagesize=60 linesize=80 pageno=1 nodate;
data lowmed2;
set mylib.arts;
  if upcase(Budget) = 'MEDIUM' or upcase(Budget) = 'LOW';
;
proc print data=lowmed2;
  title 'Medium and Low Priced Tours';
run;
```

The following output displays the results:

Output 10.6  Producing an Exact Subset with Subsetting IF

The result is a SAS data set with no missing values for Budget.

Conditionally Writing Observations to One or More SAS Data Sets

Understanding the OUTPUT Statement

SAS enables you to create multiple SAS data sets in a single DATA step using an OUTPUT statement:

```sas
OUTPUT <SAS-data-set(s)>;
```
When you use an OUTPUT statement without specifying a data set name, SAS writes the current observation to all data sets named in the DATA statement. If you want to write observations to a selected data set, then you specify that data set name directly in the OUTPUT statement. Any data set name appearing in the OUTPUT statement must also appear in the DATA statement.

Example for Conditionally Writing Observations to Multiple Data Sets

One of the SAS data sets contains tours that are guided by the tour guide Lucas and the other contains tours led by other guides. Writing to multiple data sets is accomplished by doing one of the following:

1. naming both data sets in the DATA statement.
2. selecting the observations using an IF condition
3. using an OUTPUT statement in the THEN and ELSE clauses to output the observations to the appropriate data sets

The following DATA step shows these steps:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data lucastour othertours;
  set mylib.arts;
  if TourGuide = 'Lucas' then output lucastour;
  else output othertours;
;
proc print data=lucastour;
  title "Data Set with TourGuide = 'Lucas'";
;
proc print data=othertours;
  title "Data Set with Other Guides";
run;
```

The following output displays the results:

**Output 10.7  Creating Two Data Sets with One DATA Step**

<table>
<thead>
<tr>
<th>Data Set with TourGuide = 'Lucas'</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>
</tr>
<tr>
<td>-----</td>
<td>------</td>
</tr>
<tr>
<td>1</td>
<td>Paris</td>
</tr>
<tr>
<td>2</td>
<td>New York</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Set with Other Guides</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>
</tr>
<tr>
<td>-----</td>
<td>------</td>
</tr>
<tr>
<td>1</td>
<td>Rome</td>
</tr>
<tr>
<td>2</td>
<td>London</td>
</tr>
<tr>
<td>3</td>
<td>Madrid</td>
</tr>
<tr>
<td>4</td>
<td>Amsterdam</td>
</tr>
</tbody>
</table>
A Common Mistake When Writing to Multiple Data Sets

If you use an OUTPUT statement, then you suppress the automatic output of observations at the end of the DATA step. Therefore, if you plan to use any OUTPUT statements in a DATA step, then you must program all output for that step with OUTPUT statements. For example, in the previous DATA step you sent output to both LUCASTOUR and OTHERTOURS. For comparison, the following program shows what would happen if you omit the ELSE statement in the DATA step:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data lucastour2 othertour2;
  set mylib.arts;
  if TourGuide = 'Lucas' then output lucastour2;
run;

proc print data=lucastour2;
  title "Data Set with Guide = 'Lucas'";
run;

proc print data=othertour2;
  title "Data Set with Other Guides";
run;
```

The following output displays the results:

**Output 10.8** Failing to Direct Output to a Second Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Budget</th>
<th>Guide</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>High</td>
<td>Lucas</td>
</tr>
<tr>
<td>2</td>
<td>New York</td>
<td>6</td>
<td>.</td>
<td></td>
<td>Lucas</td>
</tr>
</tbody>
</table>

No observations are written to OTHERTOUR2 because output was not directed to it.

Understanding Why the Placement of the OUTPUT Statement Is Important

By default SAS writes an observation to the output data set at the end of each iteration. When you use an OUTPUT statement, you override the automatic output feature. Where you place the OUTPUT statement, therefore, is very important. For example, if a variable value is calculated after the OUTPUT statement executes, then that value is not available when the observation is written to the output data set.

For example, in the following DATA step, an assignment statement is placed after the IF-THEN/ELSE group:

```sas
/* first attempt to combine assignment and OUTPUT statements */
options pagesize=60 linesize=80 pageno=1 nodate;
data lucasdays otherdays;
  set mylib.arts;
  if TourGuide = 'Lucas' then output lucasdays;
  else output otherdays;
```
Days = Nights+1;
run;

proc print data=lucasdays;
    title "Number of Days in Lucas’s Tours";
run;

proc print data=otherdays;
    title "Number of Days in Other Guides’ Tours";
run;

Output 10.9  Unintended Results: Outputting Observations before Assigning Values

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Budget</th>
<th>Guide</th>
<th>Days</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Paris</td>
<td>8</td>
<td>1680</td>
<td>High</td>
<td>Lucas</td>
<td>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Budget</th>
<th>Guide</th>
<th>Days</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>3</td>
<td>750</td>
<td>Medium</td>
<td>D’Amico</td>
<td>.</td>
</tr>
<tr>
<td>2</td>
<td>London</td>
<td>6</td>
<td>1230</td>
<td>High</td>
<td>Wilson</td>
<td>.</td>
</tr>
<tr>
<td>3</td>
<td>Madrid</td>
<td>3</td>
<td>370</td>
<td>Low</td>
<td>Torres</td>
<td>.</td>
</tr>
<tr>
<td>4</td>
<td>Amsterdam</td>
<td>4</td>
<td>580</td>
<td>Low</td>
<td></td>
<td>.</td>
</tr>
</tbody>
</table>

The value of DAYS is missing in all observations because the OUTPUT statement writes the observation to the SAS data sets before the assignment statement is processed. If you want the value of DAY to appear in the data sets, then use the assignment statement before you use the OUTPUT statement. The following program shows the correct position:

```sas
/* correct position of assignment statement */
options pagesize=60 linesize=80 pageno=1 nodate;
data lucasdays2 otherdays2;
    set mylib.arts;
    Days = Nights + 1;
    if TourGuide = 'Lucas' then output lucasdays2;
    else output otherdays2;
run;

proc print data=lucasdays2;
    title "Number of Days in Lucas’s Tours";
run;
proc print data=otherdays2;
```
Writing an Observation Multiple Times to One or More Data Sets

After SAS processes an OUTPUT statement, the observation remains in the program data vector and you can continue programming with it. You can even output it again to the same SAS data set or to a different one. The following example creates two pairs of data sets, one pair based on the name of the tour guide and one pair based on the number of nights.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data lucastour othertour weektour daytour;
  set mylib.arts;
  if TourGuide = 'Lucas' then output lucastour;
  else output othertour;
  if nights >= 6 then output weektour;
  else output daytour;
run;

proc print data=lucastour;
  title "Number of Days in Lucas’ Tours";
run;

proc print data=othertour;
  title "Number of Days in Other Guides’ Tours";
run;

proc print data=weektour;
  title "Number of Days in Other Guides’ Tours";
run;
```

Output 10.10  Intended Results: Assigning Values after Outputting Observations

<table>
<thead>
<tr>
<th>Number of Days in Lucas’s Tours</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>City</td>

<td></td>
</tr>
</tbody>
</table>

The first IF-THEN/ELSE group outputs all observations to either data set LUCASTOUR or OTHERTOUR. The second IF-THEN/ELSE group outputs the same observations to a different pair of data sets, WEEKTOUR and DAYTOUR. This repetition is possible because each observation remains in the program data vector after the first OUTPUT statement is processed and can be output again.
**Review of SAS Tools**

**Statements**

names the SAS data set(s) to be created in the DATA step.

DELETE;

deeiates the current observation. The DELETE statement is usually used as part of an IF-THEN/ELSE group.

IF condition;

tests whether the condition is true. If it is true, then SAS continues processing the current observation; if it is not true, then SAS stops processing the observation, does not add it to the SAS data set, and returns to the top of the DATA step. The conditions used are the same as in the IF-THEN/ELSE statements. This type of IF statement is called a subsetting IF statement because it produces a subset of the original observations.

OUTPUT <SAS data set>;

immediately writes the current observation to the SAS data set. The observation remains in the program data vector, and you can continue programming with it, including outputting it again if you desire. When an OUTPUT statement appears in a DATA step, SAS does not automatically output observations to the SAS data set; you must specify the destination for all output in the DATA step with OUTPUT statements. Any SAS data set that you specify in an OUTPUT statement must also appear in the DATA statement.

**Learning More**

Comparison and logical operators

DROP= and KEEP= data set options

Using the DROP= and KEEP= data set options to output a subset of variables to a SAS data set are discussed in Chapter 5, “Starting with SAS Data Sets,” on page 81.

FIRSTOBS= and OBS= data set options

Using these data set options to select observations from the beginning, middle, or end of a SAS data set are discussed in Chapter 5, “Starting with SAS Data Sets,” on page 81. They are documented completely in SAS Language Reference: Dictionary.

IF-THEN/ELSE, DELETE, and OUTPUT statements

The IF-THEN/ELSE, DELETE, and OUTPUT statements are completely documented in SAS Language Reference: Dictionary.

WHERE statement

See Chapter 25, “Producing Detail Reports with the PRINT Procedure,” on page 371. The WHERE statement selects observations based on a condition. Its action is similar to that of a subsetting IF statement. The WHERE statement is
extremely useful in PROC steps, and it can also be useful in some DATA steps. The WHERE statement selects observations before they enter the program data vector (in contrast to the subsetting IF statement, which selects observations already in the program data vector).

Note: In some cases, the same condition in a WHERE statement in the DATA step and in a subsetting IF statement produces different subsets. The difference is described in the discussion of the WHERE statement in *SAS Language Reference: Dictionary*. Be sure you understand the difference before you use the WHERE statement in the DATA step. With that caution in mind, a WHERE statement can increase the efficiency of the DATA step considerably.

Introduction to Working with Grouped or Sorted Observations

Purpose

Sometimes you need to create reports where observations are grouped according to the values of a particular variable, or where observations are sorted alphabetically. In this section you will learn the following:

- how to group observations by variables and how to work with grouped observations
- how to sort the observations and how to work with sorted observations

Prerequisites

Before proceeding with this section, you should understand the concepts presented in the following parts:

- Part 1, “Introduction to the SAS System”
Tradewinds Travel has an external file that contains data about tours that emphasize either architecture or scenery. After the data is created in a SAS data set and the observations for those tours are grouped together, SAS can produce reports on each group separately. In addition, if the observations need to be alphabetized by country, SAS can sort them. The external file looks like this:

```
Spain architecture 10 510 World
Japan architecture 8 720 Express
Switzerland scenery 9 734 World
France architecture 8 575 World
Ireland scenery 7 558 Express
New Zealand scenery 16 1489 Southsea
Italy architecture 8 468 Express
Greece scenery 12 698 Express
```

The numbered fields represent:

1. the name of the destination country
2. the tour's area of emphasis
3. the number of nights on the tour
4. the cost of the land package in US dollars
5. the name of the tour vendor

The following DATA step creates the permanent SAS data set MYLIB.ARCH_OR_SCEN:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

libname mylib 'permanent-data-library';
data mylib.arch_or_scen;
  infile 'input-file' truncover;
  input Country $ 1-11 TourType $ 13-24 Nights LandCost Vendor $;
run;

proc print data=mylib.arch_or_scen;
  title 'Data Set MYLIB.ARCH_OR_SCEN';
run;
```

The PROC PRINT statement that follows the DATA step produces this display of the MYLIB.ARCH_OR_SCEN data set:
Working with Grouped or Sorted Observations

Grouping Observations with the SORT Procedure

Output 11.1  Data Set MYLIB.ARCH_OR_SCEN

</tbody>
</table>

Working with Grouped Data

Understanding the Basics of Grouping Data

The basic method for grouping data is to use a BY statement:

```
BY list-of-variables;
```

The BY statement can be used in a DATA step with a SET, MERGE, MODIFY, or UPDATE statement, or it can be used in SAS procedures.

To work with grouped data using the SET, MERGE, MODIFY, or UPDATE statements, the data must meet these conditions:

- The observations must be in a SAS data set, not an external file.
- The variables that define the groups must appear in the BY statement.
- All observations in the input data set must be in ascending or descending numeric or character order, or grouped in some way, such as by calendar month or a formatted value, according to the variables that will be specified in the BY statement.

**Note:** If you use the MODIFY statement, the input data does not need to be in any order. However, ordering the data can improve performance. △

If the third condition is not met, the data are in a SAS data set but are not arranged in the groups you want, you can order the data using the SORT procedure (discussed in the next section).

Once the SAS data set is arranged in some order, you can use the BY statement to group values of one or more common variables.

Grouping Observations with the SORT Procedure

All observations in the input data set must be in a particular order. To meet this condition, the observations in MYLIB.ARCH_OR_SCEN can be ordered by the values of TourType, **architecture** and **scenery**:

```
proc sort data=mylib.arch_or_scen out=tourorder;
    by TourType;
run;
```
The SORT procedure sorts the data set MYLIB.ARCH_OR_SCEN alphabetically according to the values of TourType. The sorted observations go into a new data set specified by the OUT= option. In this example, TOURORDER is the sorted data set. If the OUT= option is omitted, the sorted version of the data set replaces the data set MYLIB.ARCH_OR_SCEN.

The SORT procedure does not produce output other than the sorted data set. A message in the SAS log says that the SORT procedure was executed:

Output 11.2 Message That the SORT Procedure Has Executed Successfully

```sas
2 proc sort data=mylib.arch_or_scen out=tourorder;
3 by TourType;
4 run;
```

To see the sorted data set, add a PROC PRINT step to the program:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=tourorder;
  by TourType;
run;

proc print data=tourorder;
  var TourType Country Nights LandCost Vendor;
  title 'Tours Sorted by Architecture or Scenic Tours';
run;
```

The following output displays the results:

Output 11.3 Displaying the Sorted Output

<table>
<thead>
<tr>
<th>Obs</th>
<th>TourType</th>
<th>Country</th>
<th>Nights</th>
<th>Land Cost</th>
<th>Vendor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>architecture</td>
<td>Spain</td>
<td>10</td>
<td>510</td>
<td>World</td>
</tr>
<tr>
<td>2</td>
<td>architecture</td>
<td>Japan</td>
<td>8</td>
<td>720</td>
<td>Express</td>
</tr>
<tr>
<td>3</td>
<td>architecture</td>
<td>France</td>
<td>8</td>
<td>575</td>
<td>World</td>
</tr>
<tr>
<td>4</td>
<td>architecture</td>
<td>Italy</td>
<td>8</td>
<td>468</td>
<td>Express</td>
</tr>
<tr>
<td>5</td>
<td>scenery</td>
<td>Switzerland</td>
<td>9</td>
<td>734</td>
<td>World</td>
</tr>
<tr>
<td>6</td>
<td>scenery</td>
<td>Ireland</td>
<td>7</td>
<td>558</td>
<td>Express</td>
</tr>
<tr>
<td>7</td>
<td>scenery</td>
<td>New Zealand</td>
<td>16</td>
<td>1489</td>
<td>Southsea</td>
</tr>
<tr>
<td>8</td>
<td>scenery</td>
<td>Greece</td>
<td>12</td>
<td>698</td>
<td>Express</td>
</tr>
</tbody>
</table>

By default, SAS arranges groups in ascending order of the BY values, smallest to largest. Sorting a data set does not change the order of the variables within it. However, most examples in this section use a VAR statement in the PRINT procedure to display the BY variable in the first column. (The PRINT procedure and other procedures used in this documentation can also produce a separate report for each BY group.)
Grouping by More Than One Variable

You can group observations by as many variables as you want. This example groups observations by TourType, Vendor, and LandCost:

```latex
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=tourorder2;
  by TourType Vendor Landcost;
run;

proc print data=tourorder2;
  var TourType Vendor Landcost Country Nights;
  title 'Tours Grouped by Type of Tour, Vendor, and Price';
run;
```

The following output displays the results:

```
Output 11.4  Grouping by Several Variables

<table>
<thead>
<tr>
<th>Obs</th>
<th>TourType</th>
<th>Vendor</th>
<th>Cost</th>
<th>Country</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>architecture</td>
<td>Express</td>
<td>468</td>
<td>Italy</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>architecture</td>
<td>Express</td>
<td>720</td>
<td>Japan</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>architecture</td>
<td>World</td>
<td>510</td>
<td>Spain</td>
<td>10</td>
</tr>
<tr>
<td>4</td>
<td>architecture</td>
<td>World</td>
<td>575</td>
<td>France</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>scenery</td>
<td>Express</td>
<td>558</td>
<td>Ireland</td>
<td>7</td>
</tr>
<tr>
<td>6</td>
<td>scenery</td>
<td>Express</td>
<td>698</td>
<td>Greece</td>
<td>12</td>
</tr>
<tr>
<td>7</td>
<td>scenery</td>
<td>Southsea</td>
<td>1489</td>
<td>New Zealand</td>
<td>16</td>
</tr>
<tr>
<td>8</td>
<td>scenery</td>
<td>World</td>
<td>734</td>
<td>Switzerland</td>
<td>9</td>
</tr>
</tbody>
</table>
```

As this example shows, SAS groups the observations by the first variable that is named within those groups, by the second variable named; and so on. The groups defined by all variables contain only one observation each. In this example, no two variables have the same values for all observations. In other words, this example does not have any duplicate entries.

Arranging Groups in Descending Order

In the data sets that are grouped by TourType, the group for `architecture` comes before the group for `scenery` because `architecture` begins with an “a”; “a” is smaller than “s” in computer processing. (The order of characters, known as their collating sequence, is discussed later in this section.) To produce a descending order for a particular variable, place the DESCENDING option before the name of the variable in the BY statement of the SORT procedure. In the next example, the observations are grouped in descending order by TourType, but in ascending order by Vendor and LandCost:

```latex
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=tourorder3;
  by descending TourType Vendor LandCost;
run;
```
proc print data=tourorder3;
  var TourType Vendor LandCost Country Nights;
  title 'Descending Order of TourType';
run;

The following output displays the results:

Output 11.5  Combining Descending and Ascending Sorted Observations

<table>
<thead>
<tr>
<th>Obs</th>
<th>TourType</th>
<th>Vendor</th>
<th>LandCost</th>
<th>Country</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>scenery</td>
<td>Express</td>
<td>558</td>
<td>Ireland</td>
<td>7</td>
</tr>
<tr>
<td>2</td>
<td>scenery</td>

<td>468</td>
<td>Italy</td>
<td>8</td>
</tr>
<tr>
<td>6</td>
<td>architecture</td>
<td>Express</td>
<td>720</td>
<td>Japan</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>architecture</td>
<td>World</td>
<td>510</td>
<td>Spain</td>
<td>10</td>
</tr>
<tr>
<td>8</td>
<td>architecture</td>
<td>World</td>
<td>575</td>
<td>France</td>
<td>8</td>
</tr>
</tbody>
</table>

Finding the First or Last Observation in a Group

If you do not want to display the entire data set, how can you create a data set containing only the least expensive tour that features architecture, and the least expensive tour that features scenery?

First, sort the data set by TourType and LandCost:

options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=tourorder4;
  by TourType LandCost;
run;

proc print data=tourorder4;
  var TourType LandCost Country Nights Vendor;
  title 'Tours Arranged by TourType and LandCost';
run;

The following output displays the results:
Working with Grouped or Sorted Observations

Finding the First or Last Observation in a Group

Output 11.6  Sorting to Find the Least Expensive Tours

<table>
<thead>
<tr>
<th>Obs</th>
<th>TourType</th>
<th>Land Cost</th>
<th>Country</th>
<th>Nights</th>
<th>Vendor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>architecture</td>
<td>468</td>
<td>Italy</td>
<td>8</td>
<td>Express</td>
</tr>
<tr>
<td>2</td>
<td>architecture</td>
<td>510</td>
<td>Spain</td>
<td>10</td>
<td>World</td>
</tr>
<tr>
<td>3</td>
<td>architecture</td>
<td>575</td>
<td>France</td>
<td>8</td>
<td>World</td>
</tr>
<tr>
<td>4</td>
<td>architecture</td>
<td>720</td>
<td>Japan</td>
<td>8</td>
<td>Express</td>
</tr>
<tr>
<td>5</td>
<td>scenery</td>
<td>558</td>
<td>Ireland</td>
<td>7</td>
<td>Express</td>
</tr>
<tr>
<td>6</td>
<td>scenery</td>
<td>698</td>
<td>Greece</td>
<td>12</td>
<td>Express</td>
</tr>
<tr>
<td>7</td>
<td>scenery</td>
<td>734</td>
<td>Switzerland</td>
<td>9</td>
<td>World</td>
</tr>
<tr>
<td>8</td>
<td>scenery</td>
<td>1489</td>
<td>New Zealand</td>
<td>16</td>
<td>Southsea</td>
</tr>
</tbody>
</table>

You sorted LandCost in ascending order, so the first observation in each value of TourType has the lowest value of LandCost. If you can locate the first observation in each BY group in a DATA step, you can use a subsetting IF statement to select that observation. But how can you locate the first observation with each value of TourType?

When you use a BY statement in a DATA step, SAS automatically creates two additional variables for each variable in the BY statement. One is named \texttt{FIRST.variable}, where \texttt{variable} is the name of the BY variable, and the other is named \texttt{LAST.variable}. Their values are either 1 or 0. They exist in the program data vector and are available for DATA step programming, but SAS does not add them to the SAS data set being created. For example, the DATA step begins with these statements:

```sas
data lowcost;
  set touorder4;
  by TourType;
  ...more SAS statements...
run;
```

The BY statement causes SAS to create one variable called \texttt{FIRST.TOURTYPE} and another variable called \texttt{LAST.TOURTYPE}. When SAS processes the first observation with the value \texttt{architecture}, the value of \texttt{FIRST.TOURTYPE} is 1; in other observations with the value \texttt{architecture}, it is 0. Similarly, when SAS processes the last observation with the value \texttt{architecture}, the value of \texttt{LAST.TOURTYPE} is 1; in other \texttt{architecture} observations, it is 0. The same result occurs in the \texttt{scenery} group with the observations.

SAS does not write \texttt{FIRST.} and \texttt{LAST.} variables to the output data set, so you cannot display their values with the PRINT procedure. Therefore, the simplest method of displaying the values of \texttt{FIRST.} and \texttt{LAST.} variables is to assign their values to other variables. This example assigns the value of \texttt{FIRST.TOURTYPE} to a variable named \texttt{FirstTour} and the value of \texttt{LAST.TOURTYPE} to a variable named \texttt{LastTour}:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data temp;
  set touorder4;
  by TourType;
  FirstTour = first.TourType;
  LastTour = last.TourType;
run;
proc print data=temp;
```
var Country Tourtype FirstTour LastTour;
title 'Specifying FIRST.TOURTYPE and LAST.TOURTYPE';
run;

The following output displays the results:

**Output 11.7**  Demonstrating FIRST. and LAST. Values

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>TourType</th>
<th>First Tour</th>
<th>Last Tour</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Italy</td>
<td>architecture</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>architecture</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>France</td>
<td>architecture</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>Japan</td>
<td>architecture</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>Ireland</td>
<td>scenery</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>Greece</td>
<td>scenery</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>Switzerland</td>
<td>scenery</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>New Zealand</td>
<td>scenery</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

In this data set, Italy is the first observation with the value *architecture*; for that observation, the value of FIRST.TOURTYPE is 1. Italy is not the last observation with the value *architecture*, so its value of LAST.TOURTYPE is 0. The observations for Spain and France are neither the first nor the last with the value *architecture*; both FIRST.TOURTYPE and LAST.TOURTYPE are 0 for them. Japan is the last with the value *architecture*; the value of LAST.TOURTYPE is 1. The same rules apply to observations in the *scenery* group.

Now you’re ready to use FIRST.TOURTYPE in a subsetting IF statement. When the data are sorted by TourType and LandCost, selecting the first observation in each type of tour gives you the lowest price of any tour in that category:

``` Sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=tourorder4;
  by TourType LandCost;
run;

data lowcost;
  set tourorder4;
  by TourType;
  if first.TourType;
run;

proc print data=lowcost;
  title 'Least Expensive Tour for Each Type of Tour';
run;
```
The following output displays the results:

**Output 11.8  Selecting One Observation from Each BY Group**

<table>
<thead>
<tr>
<th>Least Expensive Tour for Each Type of Tour</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>Country</td>
</tr>
<tr>
<td>-----</td>
<td>---------</td>
</tr>
<tr>
<td>1</td>
<td>Italy</td>
</tr>
<tr>
<td>2</td>
<td>Ireland</td>
</tr>
</tbody>
</table>

**Working with Sorted Data**

**Understanding Sorted Data**

By default, groups appear in ascending order of the BY values. In some cases you want to emphasize the order in which the observations are sorted, not the fact that they can be grouped. For example, you may want to alphabetize the tours by country.

To sort your data in a particular order, use the SORT procedure just as you do for grouped data. When the sorted order is more important than the grouping, you usually want only one observation with a given BY value in the resulting data set. Therefore, you may need to remove duplicate observations.

**Operating Environment Information:** The SORT procedure accesses either a sorting utility that is supplied as part of SAS, or a sorting utility supplied by the host operating system. All examples in this documentation use the SAS sorting utility. Some operating system utilities do not accept particular options, including the NODUPRECS option described later in this section. The default sorting utility is set by your site. For more information about the utilities available to you, see the documentation for your operating system.

**Sorting Data**

The following example sorts data set MYLIB.ARCH_OR_SCEN by COUNTRY:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=bycountry;
   by Country;
run;

proc print data=bycountry;
   title 'Tours in Alphabetical Order by Country';
run;
```
The following output displays the results:

**Output 11.9  Sorting Data**

<table>
<thead>
<tr>
<th>Tours in Alphabetical Order by Country</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>

**Deleting Duplicate Observations**

You can eliminate duplicate observations in a SAS data set by using the NODUPRECS option with the SORT procedure. The following programs show you how to create a SAS data set and then remove duplicate observations.

The external file shown below contains a duplicate observation for Switzerland:

```
Spain architecture 10 510 World
Japan architecture 8 720 Express
Switzerland scenery 9 734 World
France architecture 8 575 World
Switzerland scenery 9 734 World
Ireland scenery 7 558 Express
New Zealand scenery 16 1489 Southsea
Italy architecture 8 468 Express
Greece scenery 12 698 Express
```

The following DATA step creates a permanent SAS data set named MYLIB.ARCH_OR_SCEN2.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'SAS-data-library';
data mylib.arch_or_scen2;	infile 'input-file';	input Country $ 1--11 TourType $ 13--24 Nights LandCost Vendor $;
run;
proc print data=mylib.arch_or_scen2;	title 'Data Set MYLIB.ARCH_OR_SCEN2';
run;
```
The following output shows that this data set contains a duplicate observation for Switzerland:

**Output 11.10**  Data Set MYLIB.ARCH_OR_SCEN2

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>TourType</th>
<th>Nights</th>
<th>Cost</th>
<th>Vendor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Spain</td>
<td>architecture</td>
<td>10</td>
<td>510</td>
<td>World</td>
</tr>
<tr>
<td>2</td>
<td>Japan</td>
<td>architecture</td>
<td>8</td>
<td>720</td>
<td>Express</td>
</tr>
<tr>
<td>3</td>
<td>Switzerland</td>
<td>scenery</td>
<td>9</td>
<td>734</td>
<td>World</td>
</tr>
<tr>
<td>4</td>
<td>France</td>
<td>architecture</td>
<td>8</td>
<td>575</td>
<td>World</td>
</tr>
<tr>
<td>5</td>
<td>Switzerland</td>
<td>scenery</td>
<td>9</td>
<td>734</td>
<td>World</td>
</tr>
<tr>
<td>6</td>
<td>Ireland</td>
<td>scenery</td>
<td>7</td>
<td>558</td>
<td>Express</td>
</tr>
<tr>
<td>7</td>
<td>New Zealand</td>
<td>scenery</td>
<td>16</td>
<td>1489</td>
<td>Southsea</td>
</tr>
<tr>
<td>8</td>
<td>Italy</td>
<td>architecture</td>
<td>8</td>
<td>468</td>
<td>Express</td>
</tr>
<tr>
<td>9</td>
<td>Greece</td>
<td>scenery</td>
<td>12</td>
<td>698</td>
<td>Express</td>
</tr>
</tbody>
</table>

The following program uses the NODUPRECS option in the SORT procedure to delete duplicate observations. The program creates a new data set called FIXED.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.arch_or_scen out=fixed noduprecs;
   by Country;
run;

proc print data=fixed;
   title 'Data Set FIXED: MYLIB.ARCH_OR_SCEN2 With Duplicates Removed';
run;
```

The following output displays messages that appear in the SAS log:

**Output 11.11**  Partial SAS Log Indicating Duplicate Observations Deleted

```sas
NOTE: 1 duplicate observations were deleted.
NOTE: There were 9 observations read from the data set MYLIB.ARCH_OR_SCEN.
NOTE: The data set WORK.FIXED has 8 observations and 5 variables.
proc print data=fixed;
   title 'Data Set FIXED: MYLIB.ARCH_OR_SCEN2 With Duplicates Removed';
run;
```

NOTE: There were 8 observations read from the data set WORK.FIXED.
The following output shows the results of the NODUPRECS option:

Output 11.12  Data Set FIXED with No Duplicate Observations

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>TourType</th>
<th>Nights</th>
<th>Cost</th>
<th>Vendor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>architecture</td>

<td>9</td>
<td>734</td>
<td>World</td>
</tr>
</tbody>
</table>

Understanding Collating Sequences

Both numeric and character variables can be sorted into ascending or descending order. For numeric variables, ascending or descending order is easy to understand, but what about the order of characters? Character values include uppercase and lowercase letters, special characters, and the digits 0 through 9 when they are treated as characters rather than as numbers. How does SAS sort these characters?

The order in which characters sort is called a collating sequence. By default, SAS sorts characters in one of two sequences: EBCDIC or ASCII, depending on the operating environment under which SAS is running. For reference, both sequences are displayed here.

As long as you work under a single operating system, you seldom need to think about the details of collating sequences. However, when you transfer files from an operating system using EBCDIC to an operating system using ASCII or vice versa, character values that are sorted on one operating system are not necessarily in the correct order for the other operating system. The simplest solution to the problem is to re-sort character data (not numeric data) on the destination operating system. For detailed information about collating sequences, see the documentation for your operating environment.
ASCII Collating Sequence

The following operating systems use the ASCII collating sequence:

- Macintosh
- MS-DOS
- OpenVMS
- OS/2
- PC DOS
- UNIX and its derivatives
- Windows

From the smallest to the largest displayable character, the English-language ASCII sequence is

blank!"#$%&'()*+,-./0123456789:;<=>?@
ABCDEFGHIJKLMNOPQRSTUVWXYZ\ _
abcdefghijklmnopqrstuvwxyz{}~

The main features of the ASCII sequence are that digits are smaller than uppercase letters and uppercase letters are smaller than lowercase ones. The blank is the smallest displayable character, followed by the other types of characters:

blank < digits < uppercase letters < lowercase letters

EBCDIC Collating Sequence

The following operating systems use the EBCDIC collating sequence:

- CMS
- z/OS

From the smallest to largest displayable character, the English-language EBCDIC sequence is

blank.<(+|&!$*);,-/,%>?:#@'="
abcdefghijklmnopqrstuvwxyz
{ABCDEFGHIJKLMNOPQRSTUVWXYZ\STUVWXYZ
0123456789

The main features of the EBCDIC sequence are that lowercase letters are smaller than uppercase letters and uppercase letters are smaller than digits. The blank is the smallest displayable character, followed by the other types of characters:

blank < lowercase letters < uppercase letters < digits

Review of SAS Tools

Procedures

PROC SORT <DATA= SAS-data-set> <OUT= SAS-data-set> <NODUPRECS>;
    sorts a SAS data set by the values of variables listed in the BY statement. If you specify the OUT= option, the sorted data are stored in a different SAS data set
than the input data. The NODUPRECS option tells PROC SORT to eliminate identical observations.

Statements

BY <DESCENDING> variable-1 < . . . <DESCENDING> variable-n>;

in a DATA step causes SAS to create FIRST. and LAST. variables for each variable named in the statement. The value of FIRST. variable-1 is 1 for the first observation with a given BY value and 0 for other observations. Similarly, the value of LAST. variable-1 is 1 for the last observation for a given BY value and 0 for other observations. The BY statement can follow a SET, MERGE, MODIFY, or UPDATE statement in the DATA step; it cannot be used with an INPUT statement. By default, SAS assumes that data being read with a BY statement are in ascending order of the BY values. The DESCENDING option indicates that values of the variable that follow are in the opposite order, that is, largest to smallest.

Learning More

Alternative to sorting observations
Information about an alternative to sorting observations: creating an index that identifies the observations with particular values of a variable, can be found in the “SAS Data Files” section of SAS Language Reference: Concepts.

BY statement and BY-group processing

Interleaving, merging, and updating SAS data sets

NOTSORTED option
The NOTSORTED option can be used in both DATA and PROC steps, except for the SORT procedure. Information about the NOTSORTED option can be found in Chapter 30, “Writing Lines to the SAS Log or to an Output File,” on page 521. The NOTSORTED option is useful when data are grouped according to the values of a variable, but the groups are not in ascending or descending order. Using the NOTSORTED option in the BY statement enables SAS to process them.

SORT procedure
The SORT procedure and the role of the BY statement in it is documented in Base SAS Procedures Guide. It also describes how to specify different sorting utilities.

□ When you work with large data sets, plan your work so that you sort the data set as few times as possible. For example, if you need to sort a data set by STATE at the beginning of a program and by CITY within STATE later, sort the data set by STATE and CITY at the beginning of the program.
To eliminate observations whose BY values duplicate BY values in other observations (but not necessarily values of other variables), use the NODUPKEY option in the SORT procedure.

SAS can sort data in sequences other than English-language EBCDIC or ASCII. Examples include the Danish-Norwegian and Finnish/Swedish sequences.

The SAS documentation for your operating system presents operating system-specific information about the SORT procedure. In general, many points about sorting data depend on the operating system and other local conditions at your site (such as whether various operating system utilities are available).
CHAPTER
12
Using More Than One Observation in a Calculation

Introduction to Using More Than One Observation in a Calculation

Purpose
In this section you will learn about calculations that require more than one observation. Examples of those calculations include:
- accumulating a total across a data set or a BY group
- saving a value from one observation in order to compare it to a value in a later observation

Prerequisites
Before proceeding with this section, you should understand the concepts presented in the following parts:
- Chapter 6, “Understanding DATA Step Processing,” on page 97.
Tradewinds Travel needs to know how much business the company did with various tour vendors during the peak season. The data that the company wants to look at is the total number of people that are scheduled on tours with various vendors, and the total value of the tours that are scheduled.

The following external file contains data about Tradewinds Travel tours:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>575</td>
<td>Express</td>
</tr>
<tr>
<td>Spain</td>
<td>510</td>
<td>World</td>
</tr>
<tr>
<td>Brazil</td>
<td>540</td>
<td>World</td>
</tr>
<tr>
<td>India</td>
<td>489</td>
<td>Express</td>
</tr>
<tr>
<td>Japan</td>
<td>720</td>
<td>Express</td>
</tr>
<tr>
<td>Greece</td>
<td>698</td>
<td>Express</td>
</tr>
<tr>
<td>New Zealand</td>
<td>1489</td>
<td>Southsea</td>

</tr>
<tr>
<td>Australia</td>
<td>1079</td>
<td>Southsea</td>
</tr>
<tr>
<td>Ireland</td>
<td>558</td>
<td>Express</td>
</tr>
</tbody>
</table>

The numbered fields represent:

1. the destination country for the tour
2. the cost of the land package in US dollars
3. the name of the vendor
4. the number of people that were scheduled on that tour

The first step is to create a permanent SAS data set. The following program creates the data set MYLIB.TOURREVENUE:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';
data mylib.tourrevenue;
infile 'input-file' truncover;
input Country $ 1-11 LandCost Vendor $ NumberOfBookings;
run;

proc print data=mylib.tourrevenue;
title 'SAS Data Set MYLIB.TOURREVENUE';
run;
```

The PROC PRINT statement that follows the DATA step produces this display of the MYLIB.TOURREVENUE data set:
Using More Than One Observation in a Calculation

Creating a Running Total

Each observation in the data set MYLIB.TOURREVENUE contains the cost of a tour and the number of people who scheduled that tour. The tasks of Tradewinds Travel are as follows:

- to determine how much money was spent with each vendor and with all vendors together
- to store the totals in a SAS data set that is separate from the individual vendors’ records
- to find the tour that produced the most revenue, which is determined by the land cost times the number of people who scheduled the tour

Accumulating a Total for an Entire Data Set

Creating a Running Total

The first task in performing calculations on the data set MYLIB.TOURREVENUE is to find out the total number of people who scheduled tours with Tradewinds Travel. Therefore, a variable is needed whose value starts at 0 and increases by the number of schedulings in each observation. The sum statement gives you that capability:

\[ \text{variable} + \text{expression} \]

In a sum statement, the value of the \text{variable} on the left side of the plus sign is 0 before the statement is processed for the first time. Processing the statement adds the value of the \text{expression} on the right side of the plus sign to the initial value; the sum variable retains the new value until the next processing of the statement. The sum statement ignores a missing value for the expression; the previous total remains unchanged.

The following statement creates the total number of schedulings:

\[ \text{TotalBookings} + \text{NumberOfBookings} ; \]

The following DATA step includes the sum statement above:

\[
\text{options pagesize=60 linesize=80 pageno=1 nodate;}
\text{data total;}
\]
set mylib.tourrevenue;
  TotalBookings + NumberOfBookings;
run;

proc print data=total;
  var Country NumberOfBookings TotalBookings;
  title 'Total Tours Booked';
run;

The following output displays the results:

Output 12.2  Accumulating a Total for a Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>NumberOfBookings</th>
<th>TotalBookings</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>Spain</td>
<td>12</td>
<td>22</td>
</tr>
<tr>
<td>3</td>
<td>Brazil</td>
<td>6</td>
<td>28</td>
</tr>
<tr>
<td>4</td>
<td>India</td>
<td>.</td>
<td>28</td>
</tr>
<tr>
<td>5</td>
<td>Japan</td>
<td>10</td>
<td>38</td>
</tr>
<tr>
<td>6</td>
<td>Greece</td>
<td>20</td>
<td>58</td>
</tr>
<tr>
<td>7</td>
<td>New Zealand</td>
<td>6</td>
<td>64</td>
</tr>
<tr>
<td>8</td>
<td>Venezuela</td>
<td>8</td>
<td>72</td>
</tr>
<tr>
<td>9</td>
<td>Italy</td>
<td>9</td>
<td>81</td>
</tr>
<tr>
<td>10</td>
<td>USSR</td>
<td>6</td>
<td>87</td>
</tr>
<tr>
<td>11</td>
<td>Switzerland</td>
<td>20</td>
<td>107</td>
</tr>
<tr>
<td>12</td>
<td>Australia</td>
<td>10</td>
<td>117</td>
</tr>
<tr>
<td>13</td>
<td>Ireland</td>
<td>9</td>
<td>126</td>
</tr>
</tbody>
</table>

The TotalBookings variable in the last observation of the TOTAL data set contains the total number of schedulings for the year.

Printing Only the Total

If the total is the only information that is needed from the data set, a data set that contains only one observation and one variable (the TotalBookings variable) can be created by writing a DATA step that does all of the following:

- specifies the END= option in the SET statement to determine if the current observation is the last observation
- uses a subsetting IF to write only the last observation to the SAS data set
- specifies the KEEP= option in the DATA step to keep only the variable that totals the schedulings.

When the END= option in the SET statement is specified, the variable that is named in the END= option is set to 1 when the DATA step is processing the last observation; the variable that is named in the END= option is set to 0 for other observations:

```
SET SAS-data-set <END=variable>;
```

SAS does not add the END= variable to the data set that is being created. By testing the value of the END= variable, you can determine which observation is the last observation.
The following program selects the last observation with a subsetting IF statement and uses a KEEP= data set option to keep only the variable TotalBookings in the data set:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data total2(keep=TotalBookings);
set mylib.tourrevenue end=Lastobs;
   TotalBookings + NumberOfBookings;
   if Lastobs;
run;
```

```sas
proc print data=total2;
   title 'Total Number of Tours Booked';
run;
```

The following output displays the results:

```
Output 12.3  Selecting the Last Observation in a Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Total Bookings</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>126</td>
</tr>
</tbody>
</table>
```

The condition in the subsetting IF statement is true when Lastobs has a value of 1. When SAS is processing the last observation from MYLIB.TOURREVENUE, it assigns to Lastobs the value 1. Therefore, the subsetting IF statement accepts only the last observation from MYLIB.TOURREVENUE, and SAS writes the last observation to the data set TOTAL2.

---

**Obtaining a Total for Each BY Group**

An additional requirement of Tradewinds Travel is to determine the number of tours that are scheduled with each vendor. In order to accomplish this task, a program must group the data by a variable; that is, the program must organize the data set into groups of observations, with one group for each vendor. In this case, the program must group the data by the Vendor variable. Each group is known generically as a **BY group**; the variable that is used to determine the groupings is called a **BY variable**.

In order to group the data by the Vendor variable, the program must
- include a PROC SORT step to group the observations by the Vendor variable
- use a BY statement in the DATA step
- use a sum statement to total the schedulings
- reset the sum variable to 0 at the beginning of each group of observations.

The following program sorts the data set by Vendor and sums the total schedulings for each vendor.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.tourrevenue out=mylib.sorttour;
   by Vendor;
run;
```
data totalby;
  set mylib.sorttour;
  by Vendor;
  if First.Vendor then VendorBookings = 0;
  VendorBookings + NumberOfBookings;
run;

proc print data=totalby;
  title 'Summary of Bookings by Vendor';
run;

In the preceding program, the FIRST.Vendor variable is used in an IF-THEN statement to set the sum variable (VendorBookings) to 0 in the first observation of each BY group. (For more information on the FIRST. variable and LAST. variable temporary variables, see “Finding the First or Last Observation in a Group” on page 178.)

The following output displays the results.

Output 12.4  Creating Totals for BY Groups

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>LandCost</th>
<th>Vendor</th>
<th>Number Of Bookings</th>
<th>Vendor Bookings</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>France</td>
<td>575</td>
<td>Express</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>India</td>
<td>489</td>
<td>Express</td>
<td>.</td>
<td>10</td>
</tr>
<tr>
<td>3</td>
<td>Japan</td>
<td>720</td>
<td>Express</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>4</td>
<td>Greece</td>
<td>698</td>
<td>Express</td>
<td>20</td>
<td>40</td>
</tr>
<tr>
<td>5</td>
<td>Italy</td>
<td>468</td>
<td>Express</td>
<td>9</td>
<td>49</td>
</tr>
<tr>
<td>6</td>
<td>Ireland</td>
<td>558</td>

<td>World</td>
<td>6</td>
<td>32</td>
</tr>
<tr>
<td>13</td>
<td>Switzerland</td>
<td>734</td>
<td>World</td>
<td>20</td>
<td>52</td>
</tr>
</tbody>
</table>

Notice that while this output does in fact include the total number of schedulings for each vendor, it also includes a great deal of extraneous information. Reporting the total schedulings for each vendor requires only the variables Vendor and VendorBookings from the last observation for each vendor. Therefore, the program can

- use the DROP= or KEEP= data set options to eliminate the variables Country, LandCost, and NumberOfBookings from the output data set
- use the LAST.Vendor variable in a subsetting IF statement to write only the last observation in each group to the data set TOTALBY.

The following program creates data set TOTALBY:

```plaintext
options pagesize=60 linesize=80 nodate;
proc sort data=mylib.tourrevenue out=mylib.sorttour;
  by Vendor;
run;

data totalby(drop=country landcost);
```
set mylib.sorttour;
by Vendor;
if First.Vendor then VendorBookings = 0;
VendorBookings + NumberofBookings;
if Last.Vendor;
run;

proc print data=totalby;
  title 'Total Bookings by Vendor';
run;

The following output displays the results:

Output 12.5 Putting Totals for Each BY Group in a New Data Set

</table>

Writing to Separate Data Sets

Writing Observations to Separate Data Sets

Tradewinds Travel wants overall information about the tours that were conducted this year. One SAS data set is needed to contain detailed information about each tour, including the total money that was spent on that tour. Another SAS data set is needed to contain the total number of schedulings with each vendor and the total money spent with that vendor. Both of these data sets can be created using the techniques that you have learned so far.

Begin the program by creating two SAS data sets from the SAS data set MYLIB.SORTTOUR using the following DATA and SET statements:

data tourdetails vendordetails;
  set mylib.sorttour;

The data set TOURDETAILS will contain the individual records, and VENDORDETAILS will contain the information about vendors. The observations do not need to be grouped for TOURDETAILS, but they need to be grouped by Vendor for VENDORDETAILS.

If the data are not already grouped by Vendor, first use the SORT procedure. Add a BY statement to the DATA step for use with VENDORDETAILS.

proc sort data=mylib.tourrevenue out=mylib.sorttour;
  by Vendor;
run;

data tourdetails vendordetails;
set mylib.sorttour;
by Vendor;
run;

The only calculation that is needed for the individual tours is the amount of money that was spent on each tour. Therefore, calculate the amount in an assignment statement and write the record to TOURDETAILS.

Money = LandCost * NumberOfBookings;
output tourdetails;

The portion of the DATA step that builds TOURDETAILS is now complete.

---

Writing Totals to Separate Data Sets

Because observations remain in the program data vector after an OUTPUT statement executes, you can continue using them in programming statements. The rest of the DATA step creates information for the VENDORDETAILS data set.

Use the FIRST.Vendor variable to determine when SAS is processing the first observation in each group.

Then set the sum variables VendorBookings and VendorMoney to 0 in that observation. VendorBookings totals the schedulings for each vendor, and VendorMoney totals the costs. Add the following statements to the DATA step:

if First.Vendor then
    do;
        VendorBookings = 0;
        VendorMoney = 0;
    end;
    VendorBookings + NumberOfBookings;
    VendorMoney + Money;

Note: The program uses a DO group. Using DO groups enables the program to evaluate a condition once and take more than one action as a result. For more information on DO groups, see “Performing More Than One Action in an IF-THEN Statement” on page 205.

The last observation in each BY group contains the totals for that vendor; therefore, use the following statement to output the last observation to the data set VENDORDETAILS:

if Last.Vendor then output vendordetails;

As a final step, use KEEP= and DROP= data set options to remove extraneous variables from the two data sets so that each data set has just the variables that are wanted.

data tourdetails(drop=VendorBookings VendorMoney)
    vendordetails(keep=Vendor VendorBookings VendorMoney);

---

The Program

The following is the complete program that creates the VENDORDETAILS and TOURDETAILS data sets:

options pagesize=60 linesize=80 pageno=1 nodate;
Using More Than One Observation in a Calculation

The Program

```sas
proc sort data=mylib.tourrevenue out=mylib.sorttour;
   by Vendor;
run;

data tourdetails(drop=VendorBookings VendorMoney)
   vendordetails(keep=Vendor VendorBookings VendorMoney);
   set mylib.sorttour;
   by Vendor;
   Money = LandCost * NumberOfBookings;
   output tourdetails;
   if First.Vendor then
      do;
         VendorBookings = 0;
         VendorMoney = 0;
      end;
      VendorBookings + NumberOfBookings;
      VendorMoney + Money;
   if Last.Vendor then output vendordetails;
run;

proc print data=tourdetails;
   title 'Detail Records: Dollars Spent on Individual Tours';
run;

proc print data=vendordetails;
   title 'Vendor Totals: Dollars Spent and Bookings by Vendor';
run;

The following output displays the results:

Output 12.6  Detail Tour Records in One SAS Data Set and Vendor Totals in Another

Using a Value in a Later Observation

A further requirement of Tradewinds Travel is a separate SAS data set that contains the tour that generated the most revenue. (The revenue total equals the price of the tour multiplied by the number of schedulings.) One method of creating the new data set might be to follow these three steps:

1. Calculate the revenue in a DATA step.
2. Sort the data set in descending order by the revenue.
3. Use another DATA step with the OBS= data set option to write that observation.

A more efficient method compares the revenue from all observations in a single DATA step. SAS can retain a value from the current observation to use in future observations. When the processing of the DATA step reaches the next observation, the held value represents information from the previous observation.

The RETAIN statement causes a variable that is created in the DATA step to retain its value from the current observation into the next observation rather than being set to missing at the beginning of each iteration of the DATA step. It is a declarative statement, not an executable statement. This statement has the following form:

```
RETAIN variable-1 <... variable-n>;
```

To compare the Revenue value in one observation to the Revenue value in the next observation, create a retained variable named HoldRevenue and assign the value of the current Revenue variable to it. In the next observation, the HoldRevenue variable contains the Revenue value from the previous observation, and its value can be compared to that of Revenue in the current observation.

To see how the RETAIN statement works, look at the next example. The following DATA step outputs observations to data set TEMP before SAS assigns the current revenue to HoldRevenue:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data temp;
  set mylib.tourrevenue;
  retain HoldRevenue;
  Revenue = LandCost * NumberOfBookings;
  output;
  HoldRevenue = Revenue;
run;
proc print data=temp;
  var Country LandCost NumberOfBookings Revenue HoldRevenue;
  title 'Tour Revenue';
run;
```
The following output displays the results:

**Output 12.7  Retaining a Value By Using the Retain Statement**

</tr>
</tbody>
</table>

The value of HoldRevenue is missing at the beginning of the first observation; it is still missing when the OUTPUT statement writes the first observation to TEMP. After the OUTPUT statement, an assignment statement assigns the value of Revenue to HoldRevenue. Because HoldRevenue is retained, that value is present at the beginning of the next iteration of the DATA step. When the OUTPUT statement executes again, the value of HoldRevenue still contains that value.

To find the largest value of Revenue, assign the value of Revenue to HoldRevenue only when Revenue is larger than HoldRevenue, as shown in the following program:

```plaintext
options pagesize=60 linesize=80pageno=1 nodate;
do mostrevenue;
    set mylib.tourrevenue;
    retain HoldRevenue;
    Revenue = LandCost * NumberOfBookings;
    if Revenue > HoldRevenue then HoldRevenue = Revenue;
run;

proc print data=mostrevenue;
    var Country LandCost NumberOfBookings Revenue HoldRevenue;
    title 'Tour Revenue';
run;
```
The following output displays the results:

**Output 12.8  Holding the Largest Value in a Retained Variable**

</tbody>
</table>

The value of HoldRevenue in the last observation represents the largest revenue that is generated by any tour. To determine which observation the value came from, create a variable named HoldCountry to hold the name of the country from the observations with the largest revenue. Include HoldCountry in the RETAIN statement to retain its value until explicitly changed. Then use the END= data set option to select the last observation, and use the KEEP= data set option to keep only HoldRevenue and HoldCountry in MOSTREVENUE.

```plaintext
options pagesize=60 linesize=80 pageno=1 nodate;
data mostrevenue (keep=HoldCountry HoldRevenue);
  set mylib.tourrevenue   end=LastOne;
  retain HoldRevenue HoldCountry;
  Revenue = LandCost * NumberOfBookings;
  if Revenue > HoldRevenue then do;
    HoldRevenue = Revenue;
    HoldCountry = Country;
  end;
  if LastOne;
run;
proc print data=mostrevenue;
  title 'Country with the Largest Value of Revenue';
run;
```

*Note:* The program uses a DO group. Using DO groups enables the program to evaluate a condition once and take more than one action as a result. For more information on DO groups, see “Performing More Than One Action in an IF-THEN Statement” on page 205. △
The following output displays the results:

```

</tr>
</tbody>
</table>
```

### Review of SAS Tools

#### Statements

**RETAIN variable-1 <... variable-n>**;
rets the value of the `variable` for use in a subsequent observation. The RETAIN statement prevents the value of the variable from being reinitialized to missing when control returns to the top of the DATA step.

The RETAIN statement affects variables that are created in the current DATA step (for example, variables that are created with an INPUT or assignment statement). Variables that are read with a SET, MERGE, or UPDATE statement are retained automatically; naming them in a RETAIN statement has no effect.

The RETAIN statement can assign an initial value to a variable. If you need a variable to have the same value in all observations of a DATA step, it is more efficient to put the value in a RETAIN statement rather than in an assignment statement. SAS assigns the value in the RETAIN statement when it is compiling the DATA step, but it carries out the assignment statement during each execution of the DATA step.

The plus sign is required in the sum statement; to subtract successive values from a starting value, add negative values to the sum variable.

**SET SAS-data-set <END=variable>**;
reads from the `SAS-data-set` specified. The `variable` specified in the END= option has the value 0 until SAS is processing the last observation in the data set. Then the variable has the value 1. SAS does not include the END= variable in the data set that is being created.

`variable + expression`;
is called a sum statement; it adds the result of the expression on the right side of the plus sign to the `variable` on the left side of the plus sign and holds the new value of `variable` for use in subsequent observations. The expression can be a numeric variable or expression. The value of `variable` is retained. If the expression is a missing value, the variable maintains its previous value. Before the sum statement is executed for the first time, the default value of the variable is 0.

The plus sign is required in the sum statement; to subtract successive values from a starting value, add negative values to the sum variable.
Automatic variable _N_
The automatic variable _N_, which provides a way to count the number of times SAS executes a DATA step, is discussed in Chapter 30, “Writing Lines to the SAS Log or to an Output File,” on page 521. Using _N_ is more efficient than using a sum statement. SAS creates _N_ in each DATA step. The first time SAS begins to execute the DATA step, the value of _N_ is 1; the second time, 2; and so on. SAS does not add _N_ to the output data set.

DO groups
information about DO groups can be found in Chapter 13, “Finding Shortcuts in Programming,” on page 203.

END= option
Another example of using the END= option in the SET statement is presented in Chapter 21, “Conditionally Processing Observations from Multiple SAS Data Sets,” on page 325.

KEEP= and DROP= data set options
see Chapter 5, “Starting with SAS Data Sets,” on page 81.

LAG family of functions
See SAS Language Reference: Dictionary. LAG functions provide another way to retain a value from one observation for use in a subsequent observation. LAG functions can retain a value for up to 100 observations.

RETAIN, SUM, and SET statements

SUM and SUMBY statements
The SUM and SUMBY statements in the PRINT procedure are discussed in Chapter 25, “Producing Detail Reports with the PRINT Procedure,” on page 371. The SUM and SUMBY statements can be used in the PRINT procedure if the only purpose in getting a total is to display it in a report.

SUMMARY and MEANS procedures
The SUMMARY and MEANS procedures, which can also be used to compute totals are documented in the Base SAS Procedures Guide.
Introduction to Shortcuts

Purpose

In this section you will learn two DATA step programming techniques that make the code easier to write and read. They are the following:

- using a DO group to perform more than one action after evaluating an IF condition
- using arrays to perform the same action on more than one variable with a single group of statements

Prerequisites

You should understand the topics presented in Chapter 6, “Understanding DATA Step Processing,” on page 97 and Chapter 9, “Acting on Selected Observations,” on page 139 before proceeding with this section.
Input File and SAS Data Set

In the following example, Tradewinds Travel is making adjustments to their data about tours to art museums and galleries. The data for the tours is as follows:

1. Rome 4 3 . D'Amico 2
2. Paris 5 . 1 Lucas 5
3. London 3 2 . Wilson 3
4. New York 5 1 2 Lucas 5
5. Madrid . . 5 Torres 4
6. Amsterdam 3 3 .

The numbered fields represent:

1. the name of the city
2. the number of museums to be visited
3. the number of art galleries in the tour
4. the number of other attractions to be toured
5. the last name of the tour guide
6. the number of years of experience the guide has

The following program creates the permanent SAS data set MYLIB.ATTRACTIIONS:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';

data mylib.attractions;
    infile 'input-file';
    input City $ 1-9 Museums 11 Galleries 13 Other 15 TourGuide $ 17-24 YearsExperience 26;
run;

proc print data=mylib.attractions;
    title 'Data Set MYLIB.ATTRACTIIONS';
run;
```

The PROC PRINT statement that follows the DATA step produces this report of the MYLIB.ATTRACTIIONS data set:

```plaintext
<table>
<thead>
<tr>
<th>Obs</th>
<th>City</th>
<th>Museums</th>
<th>Galleries</th>
<th>Other</th>
<th>Tour</th>
<th>Years Experience</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rome</td>
<td>4</td>
<td>3</td>
<td>.</td>
<td>D'Amico</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>Paris</td>
<td>5</td>
<td>.</td>
<td>1</td>
<td>Lucas</td>
<td>5</td>
</tr>
<tr>
<td>3</td>
<td>London</td>
<td>3</td>
<td>2</td>
<td>.</td>
<td>Wilson</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>New York</td>
<td>5</td>
<td>1</td>
<td>2</td>
<td>Lucas</td>
<td>5</td>
</tr>
<tr>
<td>5</td>
<td>Madrid</td>
<td>.</td>
<td>.</td>
<td>5</td>
<td>Torres</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>Amsterdam</td>
<td>3</td>
<td>3</td>
<td>.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Performing More Than One Action in an IF-THEN Statement

Several changes are needed in the observations for Madrid and Amsterdam. One way to select those observations is to evaluate an IF condition in a series of IF-THEN statements, as follows:

```sas
/* multiple actions based on the same condition */
data updatedattractions;
   set mylib.attractions;
   if City = 'Madrid' then Museums = 3;
   if City = 'Madrid' then Other = 2;
   if City = 'Amsterdam' then TourGuide = 'Vandever';
   if City = 'Amsterdam' then YearsExperience = 4;
run;
```

To avoid writing the IF condition twice for each city, use a DO group in the THEN clause, for example:

```sas
IF condition THEN
   DO;
      ...
   END;
```

The DO statement causes all statements following it to be treated as a unit until a matching END statement appears. A group of SAS statements that begin with DO and end with END is called a **DO group**.

The following DATA step replaces the multiple IF-THEN statements with DO groups:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
/* a more efficient method */
data updatedattractions2;
   set mylib.attractions;
   if City = 'Madrid' then
      do;
      Museums = 3;
      Other = 2;
      end;
   else if City = 'Amsterdam' then
      do;
      TourGuide = 'Vandever';
      YearsExperience = 4;
      end;
run;
```

```sas
proc print data=updatedattractions2;
   title 'Data Set MYLIB.UPDATEDATTRCTIONS';
run;
```
Performing the Same Action for a Series of Variables

Using a Series of IF-THEN statements

In the data set MYLIB.ATTR ACTIONS, the variables Museums, Galleries, and Other contain missing values when the tour does not feature that kind of attraction. To change the missing values to 0, you can write a series of IF-THEN statements with assignment statements, as the following program illustrates:

```sas
/* same action for different variables */
data changes;
  set mylib.attractions;
  if Museums = . then Museums = 0;
  if Galleries = . then Galleries = 0;
  if Other = . then Other = 0;
run;
```

The pattern of action is the same in the three IF-THEN statements; only the variable name is different. To make the program easier to read, you can write SAS statements that perform the same action several times, changing only the variable that is affected. This technique is called array processing, and consists of the following three steps:

1. grouping variables into arrays
2. repeating the action
3. selecting the current variable to be acted upon
Grouping Variables into Arrays

In DATA step programming you can put variables into a temporary group called an array. To define an array, use an ARRAY statement. A simple ARRAY statement has the following form:

```
ARRAY array-name{number-of-variables} variable-1 < . . . variable-n;
```

The array-name is a SAS name that you choose to identify the group of variables. The number-of-variables, enclosed in braces, tells SAS how many variables you are grouping, and variable-1 < . . . variable-n lists their names.

Note: If you have worked with arrays in other programming languages, note that arrays in SAS are different from those in many other languages. In SAS, an array is simply a convenient way of temporarily identifying a group of variables by assigning an alias to them. It is not a permanent data structure; it exists only for the duration of the DATA step. The array-name identifies the array and distinguishes it from any other arrays in the same DATA step; it is not a variable.

The following ARRAY statement lists the three variables Museums, Galleries, and Other:

```
array changelist{3} Museums Galleries Other;
```

This statement tells SAS to do the following:

- make a group named CHANGLIST for the duration of this DATA step
- put three variable names in CHANGLIST: Museums, Galleries, and Other

In addition, by listing a variable in an ARRAY statement, you assign the variable an extra name with the form `array-name {position}`, where position is the position of the variable in the list (1, 2, or 3 in this case). The position can be a number, or the name of a variable whose value is the number. This additional name is called an array reference, and the position is called the subscript. The previous ARRAY statement assigns to Museums the array reference CHANGLIST{1}; Galleries, CHANGLIST{2}; and Other, CHANGLIST{3}. From that point in the DATA step, you can refer to the variable by either its original name or by its array reference. For example, the names Museums and CHANGLIST{1} are equivalent.

Repeating the Action

To tell SAS to perform the same action several times, use an iterative DO loop of the following form:

```
DO index-variable=1 TO number-of-variables-in-array;
    ...SAS statements...
END;
```

An iterative DO loop begins with an iterative DO statement, contains other SAS statements, and ends with an END statement. The loop is processed repeatedly (iterated) according to the directions in the iterative DO statement. The iterative DO statement contains an index-variable whose name you choose and whose value changes in each iteration of the loop. In array processing, you usually want the loop to execute as many times as there are variables in the array; therefore, you specify that the values of index-variable are 1 TO number-of-variables-in-array. By default, SAS increases the
value of index-variable by 1 before each new iteration of the loop. When the value becomes greater than number-of-variables-in-array, SAS stops processing the loop. By default, SAS adds the index variable to the data set that is being created.

An iterative DO loop that processes three times and has an index variable named Count looks like this:

```sas
do Count = 1 to 3;
   SAS statements
end;
```

The first time the loop is processed, the value of Count is 1; the second time, the value is 2; and the third time, the value is 3. At the beginning of the fourth execution, the value of Count is 4, exceeding the specified range of 1 TO 3. SAS stops processing the loop.

---

**Selecting the Current Variable**

Now that you have grouped the variables and you know how many times the loop will be processed, you must tell SAS which variable in the array to use in each iteration of the loop. Recall that variables in an array can be identified by their array references, and that the subscript of the reference can be a variable name as well as a number. Therefore, you can write programming statements in which the index variable of the DO loop is the subscript of the array reference:

```
array-name {index-variable}
```

When the value of the index variable changes, the subscript of the array reference (and, therefore, the variable that is referenced) also changes.

The following statement uses the index variable Count as the subscript of array references:

```sas
if changelist{Count} = . then changelist{Count} = 0;
```

You can place this statement inside an iterative DO loop. When the value of Count is 1, SAS reads the array reference as CHANGELIST[1] and processes the IF-THEN statement on CHANGELIST[1], that is, Museums. When Count has the value 2 or 3, SAS processes the statement on CHANGELIST[2], Galleries, or CHANGELIST[3], Other. The complete iterative DO loop with array references looks like this:

```sas
do Count = 1 to 3;
   if changelist{Count} = . then changelist{Count} = 0;
end;
```

These statements tell SAS to do the following:

- perform the actions in the loop three times
- replace the array subscript Count with the current value of Count for each iteration of the IF-THEN statement
- locate the variable with that array reference and process the IF-THEN statement on that variable

The following DATA step uses the ARRAY statement and iterative DO loop:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data changes;
   set mylib.attractions;
   array changelist{3} Museums Galleries Other;
   do Count = 1 to 3;
      if changelist{Count} = . then changelist{Count} = 0;
   end;
```

---

---
Finding Shortcuts in Programming

Selecting the Current Variable

The following output displays the results:

Output 13.3 Using an Array and an Iterative DO Loop to Produce a Data Set

The data set CHANGES shows that the missing values for the variables Museums, Galleries, and Other are now zero. In addition, the data set contains the variable Count with the value 4 (the value that caused processing of the loop to cease in each observation). To exclude Count from the data set, use a DROP= data set option:

```plaintext
options pagesize=60 linesize=80 nodate;
proc print data=changes;
  title 'Tour Attractions';
run;
```

The following output displays the results:

Output 13.4 Dropping the Index Variable from a Data Set

The data set CHANGES shows that the missing values for the variables Museums, Galleries, and Other are now zero. In addition, the data set contains the variable Count with the value 4 (the value that caused processing of the loop to cease in each observation). To exclude Count from the data set, use a DROP= data set option:

```plaintext
options pagesize=60 linesize=80 nodate;
proc print data=changes2;
  title 'Tour Attractions';
run;
```
Review of SAS Tools

Statements

ARRAY array-name(number-of-variables) variable-1 < . . . variable-n>;
creates a named, ordered list of variables that exists for processing of the current
DATA step. The array-name must be a valid SAS name. Each variable is the
name of a variable to be included in the array. Number-of-variables is the number
of variables listed.

When you place a variable in an array, the variable can also be accessed by
array-name (position), where position is the position of the variable in the list (from
1 to number-of-variables). This way of accessing the variable is called an array
reference, and the position is known as the subscript of the array reference. After
you list a variable in an ARRAY statement, programming statements in the same
DATA step can use either the original name of the variable or the array reference.
This documentation uses curly braces around the subscript. Parentheses ( ) are
also acceptable, and square brackets [ ] are acceptable on operating environments
that support those characters. Refer to the documentation provided by the vendor
for your operating environment to determine the supported characters.

DO;
...SAS statements...
END;
treats the enclosed SAS statements as a unit. A group of statements beginning
with DO and ending with END is called a DO group. DO groups usually appear in
THEN clauses or ELSE statements.

DO index-variable=1 TO number-of-variables-in-array;
... SAS statements...
END;
is known as an iterative DO loop. In each execution of the DATA step, an iterative
DO loop is processed repeatedly (is iterated) based on the value of index-variable.
To create an index variable, simply use a SAS variable name in an iterative DO
statement.

When you use iterative DO loops for array processing, the value of
index-variable usually starts at 1 and increases by 1 before each iteration of the
loop. When the value becomes greater than the number-of-variables-in-array
(usually the number of variables in the array being processed), SAS stops
processing the loop and proceeds to the next statement in the DATA step.

In array processing, the SAS statements in an iterative DO loop usually contain
array references whose subscript is the name of the index variable (as in
array-name (index-variable)). In each iteration of the loop, SAS replaces the
subscript in the reference with the index variable’s current value. Therefore,
successive iterations of the loop cause SAS to process the statements on the first
variable in the array, then on the second variable, and so on.
Learning More

Arrays
Detailed information about using arrays can be found in *SAS Language Reference: Concepts*. Arrays can be single or multidimensional.

DO groups
information about DO groups and iterative DO loops can be found in *SAS Language Reference: Dictionary*.
Iterative DO statements are flexible and powerful; they are useful in many situations other than array processing. The range of the index variable can start and stop with any number, and the increment can be any positive or negative number. The range of the index variable can be given as starting and stopping values; the values of the DIM, LBOUND, and HBOUND functions; a list of values separated by commas; or a combination of these. A range can also contain a WHILE or UNTIL clause. The index variable can also be a character variable (in that case, the range must be given as a list of character values). The DIM, LBOUND, and HBOUND functions are documented in *SAS Language Reference: Dictionary*.

DO WHILE and DO UNTIL statements
A DO WHILE statement processes a loop as long as a condition is true; a DO UNTIL statement processes a loop until a condition is true. (A DO UNTIL loop always processes at least once; a DO WHILE loop is not processed at all if the condition is initially false.) For more information, see *SAS Language Reference: Dictionary*. 
Introduction to Working with Dates

Purpose

SAS stores dates as single, unique numbers so that they can be used in programs like any other numeric variable. In this section you will learn how to do the following:

- make SAS read dates in raw data files and store them as SAS date values
You should understand the following topics before proceeding with this section:

- Chapter 6, “Understanding DATA Step Processing,” on page 97
- Chapter 10, “Creating Subsets of Observations,” on page 159
- Chapter 11, “Working with Grouped or Sorted Observations,” on page 173

Understanding How SAS Handles Dates

How SAS Stores Date Values

Dates are written in many different ways. Some dates contain only numbers, while others contain various combinations of numbers, letters, and characters. For example, all the following forms represent the date July 26, 2000:

<table>
<thead>
<tr>
<th>Form 1</th>
<th>Form 2</th>
<th>Form 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>072600</td>
<td>26JUL00</td>
<td>002607</td>
</tr>
<tr>
<td>7/26/00</td>
<td>26JUL2000</td>
<td>July 26, 2000</td>
</tr>
</tbody>
</table>

With so many different forms of dates, there must be some common ground, a way to store dates and use them in calculations, regardless of how dates are entered or displayed.

The common ground that SAS uses to represent dates is called a SAS date value. No matter which form you use to write a date, SAS can convert and store that date as the number of days between January 1, 1960, and the date that you enter. The following figure shows some dates written in calendar form and as SAS date values:

![Figure 14.1](image_url)

In SAS, every date is a unique number on a number line. Dates before January 1, 1960, are negative numbers; those after January 1, 1960, are positive. Because SAS date values are numeric variables, you can sort them easily, determine time intervals, and use dates as constants, as arguments in SAS functions, or in calculations.
Note: SAS date values are valid for dates based on the Gregorian calendar from A.D. 1582 through A.D. 19,900. Use caution when working with historical dates. Although the Gregorian calendar was used throughout most of Europe from 1582, Great Britain and the American colonies did not adopt the calendar until 1752.

Determining the Century for Dates with Two-Digit Years

If dates in your external data sources or SAS program statements contain two-digit years, then you can determine which century prefix should be assigned to them by using the YEARCUTOFF= system option. The YEARCUTOFF= system option specifies the first year of the 100-year span that is used to determine the century of a two-digit year.

Before you use the YEARCUTOFF= system option, examine the dates in your data:

- If the dates in your data fall within a 100-year span, then you can use the YEARCUTOFF= system option.
- If the dates in your data do not fall within a 100-year span, then you must either convert the two-digit years to four-digit years or use a DATA step with conditional logic to assign the proper century prefix.

After you have determined that the YEARCUTOFF= system option is appropriate for your range of data, you can determine the setting to use. The best setting for YEARCUTOFF= is the year before the lowest year in your data. For example, if you have data in a range from 1921 to 2001, then set YEARCUTOFF= to 1920, if that is not already your system default. The result of setting YEARCUTOFF= to 1920 is that SAS interprets all two-digit dates in the range of 20 through 99 as 1920 through 1999.

With YEARCUTOFF= set to 1920, a two-digit year of 10 would be interpreted as 2010 and a two-digit year of 22 would be interpreted as 1922.

Input File and SAS Data Set for Examples

In the travel industry, some of the most important data about a tour includes dates, when the tour leaves and returns, when payments are due, when refunds are allowed, and so on. Tradewinds Travel has data that contains dates of past and upcoming popular tours as well as the number of nights spent on the tour. The raw data is stored in an external file that looks like this:

<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Japan</td>
<td>13may2000</td>
<td>8</td>
</tr>
<tr>
<td>Greece</td>
<td>17oct99</td>
<td>12</td>
</tr>
<tr>
<td>New Zealand</td>
<td>03feb2001</td>
<td>16</td>
</tr>
<tr>
<td>Brazil</td>
<td>28feb2001</td>
<td>8</td>
</tr>
<tr>
<td>Venezuela</td>
<td>10nov00</td>
<td>9</td>
</tr>
<tr>
<td>Italy</td>
<td>25apr2001</td>
<td>8</td>
</tr>
<tr>
<td>USSR</td>
<td>03jun1997</td>
<td>14</td>
</tr>
<tr>
<td>Switzerland</td>
<td>14jan2001</td>
<td>9</td>
</tr>
<tr>
<td>Australia</td>
<td>24oct98</td>
<td>12</td>
</tr>
<tr>
<td>Ireland</td>
<td>27aug2000</td>
<td>7</td>
</tr>
</tbody>
</table>

The numbered fields represent:

1. the name of the country toured
the departure date

the number of nights on the tour

Understanding Informats for Date Values

In order for SAS to read a value as a SAS date value, you must give it a set of directions called an informat. By default, SAS reads numeric variables with a standard numeric informat that does not include letters or special characters. When a field that contains data does not match the standard patterns, you specify the appropriate informat in the INPUT statement.

SAS provides many informats. Four informats that are commonly used to read date values are:

- **MMDDYY8.** reads dates written as \textit{mm/dd/yy}.
- **MMDDYY10.** reads dates written as \textit{mm/dd/yyyy}.
- **DATE7.** reads dates in the form \textit{ddMMMyy}.
- **DATE9.** reads dates in the form \textit{ddMMMyyyy}.

Note that each informat name ends with a period and contains a width specification that tells SAS how many columns to read.

Reading a Date Value

To create a SAS data set for the Tradewinds Travel data, the DATE9. informat is used in the INPUT statement to read the variable DepartureDate.

```
input Country $ 1-11 @13 DepartureDate date9. Nights;
```

Using an informat in the INPUT statement is called formatted input. The formatted input in this example contains the following items:

- a pointer to indicate the column in which the value begins (@13)
- the name of the variable to be read (DepartureDate)
- the name of the informat to use (DATE9.)

The following DATA step creates MYLIB.TOURDATES using the DATE9. informat to create SAS date values:

```
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;
libname mylib 'permanent-data-library';

data mylib.tourdates;
  infile 'input-file';
  input Country $ 1-11 @13 DepartureDate date9. Nights;
run;

proc print data=mylib.tourdates;
  title 'Tour Departure Dates as SAS Date Values';
run;
```

The following output displays the results:
Using Good Programming Practices to Read Dates

When reading dates, it is good programming practice to always use the DATE9. or MMDDYY10. informats to be sure that the data is read correctly. If you use the DATE7. or MMDDYY8. informat, then SAS reads only the first two digits of the year. If the data contains four-digit years, then SAS reads the century and not the year.

Consider the Tradewinds Travel external file with both two-digit years and four-digit years:

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>DepartureDate</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>14743</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>Greece</td>
<td>14534</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>New Zealand</td>
<td>15009</td>
<td>16</td>
</tr>
<tr>
<td>4</td>
<td>Brazil</td>
<td>15034</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>Venezuela</td>
<td>14924</td>
<td>9</td>
</tr>
<tr>
<td>6</td>
<td>Italy</td>
<td>15090</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>Russia</td>
<td>13668</td>
<td>14</td>
</tr>
<tr>
<td>8</td>
<td>Switzerland</td>
<td>14989</td>
<td>9</td>
</tr>
<tr>
<td>9</td>
<td>Australia</td>
<td>14176</td>
<td>12</td>
</tr>
<tr>
<td>10</td>
<td>Ireland</td>
<td>14849</td>
<td>7</td>
</tr>
</tbody>
</table>

The following DATA step creates a SAS data set MYLIB.TOURDATES7 by using the DATE7. informat:

```sas
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;

data mylib.tourdates7;
  infile 'input-file';
  input Country $ 1-11 @13 DepartureDate date7. Nights;
run;

proc print data=mylib.tourdates7;
  title 'Tour Departure Dates Using the DATE7. Informat';
```
title2 'Displayed as Two-Digit Calendar Dates';
format DepartureDate date7.;
run;

proc print data=mylib.tourdates7;
title 'Tour Departure Dates Using the DATE7. Informat';
title2 'Displayed as Four-Digit Calendar Dates';
format DepartureDate date9.;
run;

The PRINT procedures format DepartureDate using two-digit year (DATE7.) and four-digit year (DATE9.) calendar dates. The following output displays the results:

Output 14.2 Using the Wrong Informat Can Produce Invalid SAS Data Sets

Tour Departure Dates Using the DATE7. Informat Displayed as Two-Digit Calendar Dates

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Departure</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>

<td>14JAN20</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>Australia</td>
<td>24OCT98</td>
<td>12</td>
</tr>
<tr>
<td>10</td>
<td>Ireland</td>
<td>27AUG20</td>
<td>0</td>
</tr>
</tbody>
</table>

Tour Departure Dates Using the DATE7. Informat Displayed as Four-Digit Calendar Dates

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Departure</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>13MAY1920</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>Greece</td>
<td>17OCT1999</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>New Zealand</td>
<td>03FEB1920</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>Brazil</td>
<td>28FEB1920</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>Venezuela</td>
<td>10NOV2000</td>
<td>9</td>
</tr>
<tr>
<td>6</td>
<td>Italy</td>
<td>25APR1920</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>Russia</td>
<td>03JUN1920</td>
<td>97</td>
</tr>
<tr>
<td>8</td>
<td>Switzerland</td>
<td>14JAN1920</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>Australia</td>
<td>24OCT1998</td>
<td>12</td>
</tr>
<tr>
<td>10</td>
<td>Ireland</td>
<td>27AUG1920</td>
<td>0</td>
</tr>
</tbody>
</table>

Notice that the four-digit years in the input file do not match the years in MYLIB.TOURDATES7 for observations 1, 3, 4, 6, 7, 8, and 10:

1. SAS stopped reading the date after seven characters; it read the first two digits, the century, and not the complete four-digit year.
2. To read the data for the next variable, SAS moved the pointer one column and read the next two numeric characters (the years 00, 01, and 97) as the value for the variable Nights. The data for Nights in the input file was ignored.
3. When the dates were formatted for four-digit calendar dates, SAS used the YEARCUTOFF= 1920 system option to determine the century for the two-digit
year. What was originally 1997 in observation 7 became 2019, and what was originally 2000 and 2001 in observations 1, 3, 4, 6, 8, and 10 became 1920.

Using Dates as Constants

If the tour of Switzerland leaves on January 21, 2001 instead of January 14, then you can use the following assignment statement to make the update:

```sas
if Country = 'Switzerland' then DepartureDate = '21jan2001'd;
```

The value '21jan2001'D is a SAS date constant. To write a SAS date constant, enclose a date in quotation marks in the standard SAS form ddMMMyyyy and immediately follow the final quotation mark with the letter D. The D suffix tells SAS to convert the calendar date to a SAS date value. The following DATA step includes the use of the SAS date constant:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data correctdates;
set mylib.tourdates;
if Country = 'Switzerland' then DepartureDate = '21jan2001'd;
run;
```

```sas
proc print data=correctdates;
title 'Corrected Departure Date for Switzerland';
format DepartureDate date9.;
run;
```

The following output displays the results:

Output 14.3 Changing a Date by Using a SAS Date Constant

</tbody>
</table>

Displaying Dates

Understanding How SAS Displays Values

To understand how to display the departure dates, you need to understand how SAS displays values in general. SAS displays all data values with a set of directions called a format. By default, SAS uses a standard numeric format with no commas, letters, or
other special notation to display the values of numeric variables. Output 14.1 shows that printing SAS date values with the standard numeric format produces numbers that are difficult to recognize. To display these numbers as calendar dates, you need to specify a SAS date format for the variable.

SAS date formats are available for the most common ways of writing calendar dates. The DATE9. format represents dates in the form ddMMyyyy. If you want the month, day, and year to be spelled out, then use the WORDDATE18. format. The WEEKDATE29. format includes the day of the week. There are also formats available for number representations such as the format MMDDYY8., which displays the calendar date in the form mm/dd/yy, or the format MMDDYY10., which displays the calendar date in the form mm/dd/yyyy. Like informat names, each format name ends with a period and contains a width specification that tells SAS how many columns to use when displaying the date value.

### Formatting a Date Value

You tell SAS which format to use by specifying the variable and the format name in a FORMAT statement. The following FORMAT statement assigns the MMDDYY10. format to the variable DepartureDate:

```sas
format DepartureDate mmddyy10.;
```

In this example, the FORMAT statement contains the following items:

- the name of the variable (DepartureDate)
- the name of the format to be used (MMDDYY10.)

The following PRINT procedures format the variable DepartureDate in both the two-digit year calendar format and the four-digit year calendar format:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc print data=mylib.tourdates;
  title 'Departure Dates in Two-Digit Calendar Format';
  format DepartureDate mmddyy8.;
run;

proc print data=mylib.tourdates;
  title 'Departure Dates in Four-Digit Calendar Format';
  format DepartureDate mmddyy10.;
run;
```

The following output displays the results:

**Output 14.4  Displaying a Formatted Date Value**

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Departure Date</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>05/13/00</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>Greece</td>
<td>10/17/99</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>New Zealand</td>
<td>02/03/01</td>
<td>16</td>
</tr>
<tr>
<td>4</td>
<td>Brazil</td>
<td>02/28/01</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>Venezuela</td>
<td>11/10/00</td>
<td>9</td>
</tr>
<tr>
<td>6</td>
<td>Italy</td>
<td>04/25/01</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>Russia</td>
<td>06/03/97</td>
<td>14</td>
</tr>
<tr>
<td>8</td>
<td>Switzerland</td>
<td>01/14/01</td>
<td>9</td>
</tr>
<tr>
<td>9</td>
<td>Australia</td>
<td>10/24/98</td>
<td>12</td>
</tr>
<tr>
<td>10</td>
<td>Ireland</td>
<td>08/27/00</td>
<td>7</td>
</tr>
</tbody>
</table>
Assigning Permanent Date Formats to Variables

The next example creates a new permanent SAS data set and assigns the DATE9. format in the DATA step. Now all subsequent procedures and DATA steps that use the variable DepartureDate will use the DATE9. format by default. The PROC CONTENTS step displays the characteristics of the data set MYLIB.TOURDATE.

```sas
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;

data mylib.fmttourdate;
  set mylib.tourdates;
  format DepartureDate date9.;
  run;

proc contents data=mylib.fmttourdate nodetails;
  run;
```

The following output shows that the DATE9. format is permanently associated with DepartureDate:

```
Departure Dates in Four-Digit Calendar Format

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Departure Date</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>05/13/2000</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>Greece</td>
<td>10/17/1999</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>New Zealand</td>
<td>02/03/2001</td>
<td>16</td>
</tr>
<tr>
<td>4</td>
<td>Brazil</td>
<td>02/28/2001</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>Venezuela</td>
<td>11/10/2000</td>
<td>9</td>
</tr>
<tr>
<td>6</td>
<td>Italy</td>
<td>04/25/2001</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>Russia</td>
<td>06/03/1997</td>
<td>14</td>
</tr>
<tr>
<td>8</td>
<td>Switzerland</td>
<td>01/14/2001</td>
<td>9</td>
</tr>
<tr>
<td>9</td>
<td>Australia</td>
<td>10/24/1998</td>
<td>12</td>
</tr>
<tr>
<td>10</td>
<td>Ireland</td>
<td>08/27/2000</td>
<td>7</td>
</tr>
</tbody>
</table>
```
Changing Formats Temporarily

If you are preparing a report that requires the date in a different format, then you can override the permanent format by using a FORMAT statement in a PROC step. For example, to display the value for DepartureDate in the data set MYLIB.TOURDATES in the form of *month-name dd, yyyy*, you can issue a FORMAT statement in a PROC PRINT step. The following program specifies the WORDDATE18. format for the variable DepartureDate:

```
options pagesize=60 linesize=80 nodate;
proc print data=mylib.tourdates;
  title 'Tour Departure Dates';
    format DepartureDate worddate18.;
run;
```

The following output displays the results:
Output 14.6 Overriding a Previously Specified Format

<table>
<thead>
<tr>
<th>Obs</th>
<th>Country</th>
<th>Departure Date</th>
<th>Nights</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Japan</td>
<td>May 13, 2000</td>
<td>8</td>

</tbody>
</table>

The format DATE9. is still permanently assigned to DepartureDate. Calendar dates in the remaining examples are in the form ddMMMyyyy unless a FORMAT statement is included in the PROC PRINT step.

Using Dates in Calculations

Sorting Dates

Because SAS date values are numeric variables, you can sort them and use them in calculations. The following example uses the data set MYLIB.TOURDATES to extract other information about the Tradewinds Travel data.

To help determine how frequently tours are scheduled, you can print a report with the tours listed in chronological order. The first step is to specify the following BY statement in a PROC SORT step to tell SAS to arrange the observations in ascending order of the date variable DepartureDate:

```
by DepartureDate;
```

By using a VAR statement in the following PROC PRINT step, you can list the departure date as the first column in the report:

```
options pagesize=60 linesize=80 pageno=1 nodate;
proc sort data=mylib.fmttourdate out=sortdate;
   by DepartureDate;
run;
proc print data=sortdate;
   var DepartureDate Country Nights;
   title 'Departure Dates Listed in Chronological Order';
run;
```

The following output displays the results:
Creating New Date Variables

Because you know the departure date and the number of nights spent on each tour, you can calculate the return date for each tour. To start, create a new variable by adding the number of nights to the departure date, as follows:

\[
\text{Return} = \text{DepartureDate} + \text{Nights};
\]

The result is a SAS date value for the return date that you can display by assigning it the DATE9. format, as follows:

```sas
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;
data home;
  set mylib.tourdates;
  Return = DepartureDate + Nights;
  format Return date9.;
run;
```

```sas
proc print data=home;
  title 'Dates of Departure and Return';
run;
```
Finding the Day of the Week

SAS has various functions that produce calendar dates from SAS date values. SAS date functions enable you to do such things as derive partial date information or use the current date in calculations.

If the final payment for a tour is due 30 days before the tour leaves, then the final payment date can be calculated using subtraction; however, Tradewinds Travel is closed on Sundays. If the payment is due on a Sunday, then an additional day must be subtracted to make the payment due on Saturday. The WEEKDAY function, which returns the day of the week as a number from 1 through 7 (Sunday through Saturday) can be used to determine if the return day is a Sunday.

The following statements determine the final payment date by

- subtracting 30 from the departure date
- checking the value returned by the WEEKDAY function
- subtracting an additional day if necessary

\[
\text{DueDate} = \text{DepartureDate} - 30; \\
\text{if Weekday(DueDate) = 1 then DueDate = DueDate - 1;}
\]

Constructing a data set with these statements produces a list of payment due dates. The following program includes these statements and assigns the format WEEKDATE29. to the new variable DueDate:

```sas
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;
data pay;
  set mylib.tourdates;
  DueDate = DepartureDate - 30;
  if Weekday(DueDate) = 1 then DueDate = DueDate - 1;
```

Note that because the variable DepartureDate in the data set MYLIB.TOURDATES has no permanent format, you see a numeric value instead of a readable calendar date for that variable.
Calculating a Date from Today

Tradewinds Travel occasionally gets the opportunity to do special advertising promotions. In general, tours that depart more than 90 days from today’s date, but less than 180 days from today’s date, are advertised. The following figure illustrates the time frame for advertising:

Figure 14.2 Optimum Interval for Advertising Tours Based on Today’s Date

A program is needed that determines which tours leave between 90 and 180 days from the date the program is run, regardless of when you run the program. The TODAY function produces a SAS date value that corresponds to the date when the program is run. The following statements determine which tours depart at least 90 days from today’s date but not more than 180 days from now:

```
Now = today();
if Now + 90 <= DepartureDate <= Now + 180;
```
To print the value that is returned by the TODAY function, this example creates a variable that is equal to the value returned by the TODAY function. This step is not necessary but is used here to clarify the program. You can also use the function as part of the program statement.

```
if today() + 90 <= DepartureDate <= today() + 180;
```

The following program uses the TODAY function to determine which tours to advertise:

```
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;
data ads;
   set mylib.tourdates;
   Now = today();
   if Now + 90 <= DepartureDate <= Now + 180;
run;

proc print data=ads;
   title 'Tours Departing between 90 and 180 Days from Today';
   format DepartureDate Now date9.;
run;
```

The following output displays the results:

```
Output 14.10 Using the Current Date as a SAS Date Value

<table>
<thead>
<tr>
<th>Tours Departing between 90 and 180 Days from Today</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>Country</td>
</tr>
<tr>
<td>-----</td>
<td>---------</td>
</tr>
<tr>
<td>1</td>
<td>Japan</td>
</tr>
</tbody>
</table>
```

Note that the PROC PRINT step contains a FORMAT statement that temporarily assigns the format DATE9. to the variables DepartureDate and Now.

### Comparing Durations and SAS Date Values

You can use SAS date values to find the units of time between dates. Tradewinds Travel was founded on February 8, 1982. On November 23, 1999, you decide to find out how old Tradewinds Travel is, and you write the following program:

```
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;
/* Calculating a duration in days */
data ttage;
   Start = '08feb82'd;
   RightNow = today();
   Age = RightNow - Start;
   format Start RightNow date9.;
run;

proc print data=ttage;
   title 'Age of Tradewinds Travel';
run;
```
The value of Age is 6497, a number that looks like an unformatted SAS date value. However, Age is actually the difference between February 8, 1982, and November 23, 1999, and represents a duration in days, not a SAS date value. To make the value of Age more understandable, divide the number of days by 365 (more precisely, 365.25) to produce a duration in years. The following DATA step calculates the age of Tradewinds Travel in years:

```sas
options yearcutoff=1920 pagesize=60 linesize=80 pageno=1 nodate;
/* Calculating a duration in years */
data ttage2;
  Start = '08feb82'd;
  RightNow = today();
  AgeInDays = RightNow - Start;
  AgeInYears = AgeInDays / 365.25;
  format AgeInYears 4.1 Start RightNow date9.;
run;
```

The following output displays the results:

```
   Obs  Start      RightNow  AgeInDays  AgeInYears
      1  08FEB1982  23NOV1999    6497        17.8
```

To show a portion of a year, the value for AgeInYears is assigned a numeric format of 4.1 in the FORMAT statement of the DATA step. The 4 tells SAS that the number contains up to four characters. The 1 tells SAS that the number includes one digit after the decimal point.
Review of SAS Tools

Statements

date-variable='ddMMMyy'D;
   is an assignment statement that tells SAS to convert the date in quotation marks
to a SAS date value and assign it to date-variable. The SAS date constant
'ddMMMyy'D specifies a particular date, for example, '23NOV00'D, and can be
used in many SAS statements and expressions, not only assignment statements.

FORMAT date-variable date-format;
   tells SAS to format the values of the date-variable using the date-format. A
   FORMAT statement within a DATA step permanently associates a format with a
date-variable.

INPUT date-variable date-informat;
   tells SAS how to read the values for the date-variable from an external file. The
date-informat is an instruction that tells SAS the form of the date in the external
file.

Formats and Informats for Dates

DATE9.
   the form of the date-variable is ddMMMyyyy, for example 23NOV2000.

DATE7.
   the form of the date-variable is ddMMMyy, for example 23NOV00.

MMDDYY10.
   the form of the date-variable is mm/dd/yyyy, for example, 11/23/2000.

MMDDYY8.
   the form of the date-variable is mm/dd/yy, for example, 11/23/00.

WORDDATE18.
   the form of the date-variable is month-name dd, yyyy, for example, November 23,
   2000.

WEEKDATE29.
   the form of the date-variable is day-of-the-week, month-name dd, yyyy, for example,

Functions

WEEKDAY (SAS-date-value)
   is a function that returns the day of the week on which the SAS-date-value falls as
   a number 1 through 7, with Sunday assigned the value 1.

TODAY()
   is a function that returns a SAS date value corresponding to the date on which the
   SAS program is initiated.
System Options

YEARCUTOFF=
specifies the first year of a 100-year span that is used by informats and functions to read two-digit years, and used by formats to display two-digit years. The value that is specified in YEARCUTOFF= can result in a range of years that span two centuries. If YEARCUTOFF=1950, then any two-digit value between 50 and 99 inclusive refers to the first half of the 100-year span, which is in the 1900s. Any two-digit value between 00 and 49 inclusive refers to the second half of the 100-year span, which is in the 2000s. YEARCUTOFF= has no effect on existing SAS dates or dates that are read from input data that include a four-digit year.

Learning More

ATTRIB statement
Information about using the ATTRIB statement to assign or change a permanent format can be found in SAS Language Reference: Dictionary.

DATASETS procedure
To assign or change a variable to a permanent format see the DATASETS procedure in Chapter 34, “Managing SAS Data Libraries,” on page 603.

PUT and INPUT functions
The PUT and INPUT functions can be used for correcting two common errors in working with SAS dates: treating date values that contain letters or symbols as character variables or storing dates written as numbers as ordinary numeric variables. Neither method enables you to use dates in calculations. Information about these functions can be found in SAS Language Reference: Dictionary.

SAS date values
Documentation on informats, formats, and functions for working with SAS date values, SAS time, and SAS datetime values can be found in SAS Language Reference: Concepts. This documentation includes the following date and time information:

- SAS stores a time as the number of seconds since midnight of the current day. For example, 9:30 am. is 34200. A number of this type is known as a SAS time value. A SAS time value is independent of the date; the count begins at 0 each midnight.

- When a date and a time are both present, SAS stores the value as the number of seconds since midnight, January 1, 1960. For example, 9:30 am, November 23, 2000, is 1290591000. This type of number is known as a SAS datetime value.

- SAS date and time informats read fields of different widths. SAS date and time formats can display date variables in different ways according to the widths that you specify in the format name. The number at the end of the format or informat name indicates the number of columns that SAS can use. For example, the DATE9. informat reads up to nine columns (as in 23NOV2000). The WEEKDATE8. format displays eight columns, as in Thursday, and WEEKDATE27. displays 27 columns, as in Thursday, November 23, 2000.
SAS provides date, time, and datetime intervals for counting different periods of elapsed time, such as MONTH, which represents an interval from the beginning of one month to the next, not a period of 30 or 31 days.

International date, time, and datetime formats.

SYSDATE9
To include the current date in a title, you can use the macro variable SYSDATE9, which is explained in Chapter 25, “Producing Detail Reports with the PRINT Procedure,” on page 371.

CHAPTER 15

Methods of Combining SAS Data Sets

Introduction to Combining SAS Data Sets

Purpose

SAS provides several different methods for combining SAS data sets. In this section, you will be introduced to five methods of combining data sets:

- concatenating
- interleaving
- merging
- updating
- modifying

Subsequent sections teach you how to use these methods.

Prerequisites

Before continuing with this section, you should understand the concepts presented in the following sections:

- Chapter 2, “Introduction to DATA Step Processing,” on page 19
- Chapter 5, “Starting with SAS Data Sets,” on page 81
- Chapter 6, “Understanding DATA Step Processing,” on page 97
Definition of Concatenating

*Concatenating* combines two or more SAS data sets, one after the other, into a single SAS data set. You concatenate data sets using either the SET statement in a DATA step or the APPEND procedure. The following figure shows the results of concatenating two SAS data sets, and the DATA step that produces the results.

**Figure 15.1** Concatenating Two SAS Data Sets

<table>

<tr>
<td>1999</td>
<td>1999</td>
<td>1999</td>
</tr>
</tbody>
</table>

```
data combined;
  set data1 data2;
run;
```

Definition of Interleaving

*Interleaving* combines individual, sorted SAS data sets into one sorted SAS data set. For each observation, the following figure shows the value of the variable by which the data sets are sorted. (In this example, the data sets are sorted by the variable Year.) You interleave data sets using a SET statement along with a BY statement.
Definition of Merging

Merging combines observations from two or more SAS data sets into a single observation in a new data set.

A one-to-one merge, shown in the following figure, combines observations based on their position in the data sets. You use the MERGE statement for one-to-one merging.

A match-merge, shown in the following figure, combines observations based on the values of one or more common variables. If you are performing a match-merge, then use the MERGE statement along with a BY statement. (In this example, two data sets are match-merged by the value of the variable Year.)
Definition of Updating

*Updating* a SAS data set replaces the values of variables in one data set (the master data set) with values from another data set (the transaction data set). If the `UPDATEMODE=` option in the `UPDATE` statement is set to `MISSINGCHECK`, then missing values in a transaction data set do not replace existing values in a master data set. If the `UPDATEMODE=` option is set to `NOMISSINGCHECK`, then missing values in a transaction data set replace existing values in a master data set. The default setting is `MISSINGCHECK`.

You update a data set by using the `UPDATE` statement along with a `BY` statement. Both of the input data sets must be sorted by the variable that you use in the `BY` statement. The following figure shows the results of updating a SAS data set.
**Definition of Modifying**

*Modifying* a SAS data set replaces, deletes, or appends observations in an existing data set. Modifying a SAS data set is similar to updating a SAS data set, but the following differences exist:

- Modifying cannot create a new data set, while updating can.
- Unlike updating, modifying does not require that the master data set or the transaction data set be sorted.

You change an existing file by using the MODIFY statement along with a BY statement. The following figure shows the results.
Comparing Modifying, Merging, and Updating Data Sets

The table that follows summarizes several differences among the MERGE, UPDATE, and MODIFY statements.

### Learning More

**Concatenating data sets**
For more information about concatenating data sets, see Chapter 16, “Concatenating SAS Data Sets,” on page 243.

**Interleaving data sets**
For more information about interleaving data sets, see Chapter 17, “Interleaving SAS Data Sets,” on page 265.

**Manipulating data sets**
You can manipulate data sets as you combine them. For example, you can select certain observations from each data set and determine which data set an observation came from. For more information, see Chapter 21, “Conditionally Processing Observations from Multiple SAS Data Sets,” on page 325.

**MERGE, MODIFY, and UPDATE statements**
For more information about these statements, see the Statements section of SAS Language Reference: Dictionary, and the Reading, Combining, and Modifying SAS Data Sets section of SAS Language Reference: Concepts.

**Merging data sets**
For more information about merging data sets, see Chapter 18, “Merging SAS Data Sets,” on page 271.

**Modifying data sets**
For more information about modifying data sets, see Chapter 20, “Modifying SAS Data Sets,” on page 313, and Chapter 21, “Conditionally Processing Observations from Multiple SAS Data Sets,” on page 325.

**Updating data sets**
For more information about updating data sets, see Chapter 19, “Updating SAS Data Sets,” on page 295.
Introduction to Concatenating SAS Data Sets

Purpose

Concatenating combines two or more SAS data sets, one after the other, into a single data set. The number of observations in the new data set is the sum of the number of observations in the original data sets.

You can concatenate SAS data sets by using

- the SET statement in a DATA step
- the APPEND procedure

If the data sets that you concatenate contain the same variables, and each variable has the same attributes in all data sets, then the results of the SET statement and PROC
APPEND are the same. In other cases, the results differ. In this section you will learn both of these methods and their differences so that you can decide which one to use.

**Prerequisites**

Before continuing with this section, you should be familiar with the concepts presented in Chapter 5, “Starting with SAS Data Sets,” on page 81 through Chapter 8, “Working with Character Variables,” on page 119.

**Concatenating Data Sets with the SET Statement**

**Understanding the SET Statement**

The SET statement reads observations from one or more SAS data sets and uses them to build a new data set. The SET statement for concatenating data sets has the following form:

```sas
SET SAS-data-set(s);
```

where

**SAS-data-set**

is two or more SAS data sets to concatenate. The observations from the first data set that you name in the SET statement appear first in the new data set. The observations from the second data set follow those from the first data set, and so on. The list can contain any number of data sets.

**Using the SET Statement: The Simplest Case**

In the simplest situation, the data sets that you concatenate contain the same variables (variables with the same name). In addition, the type, length, informat, format, and label of each variable match across all data sets. In this case, SAS copies all observations from the first data set into the new data set, then copies all observations from the second data set into the new data set, and so on. Each observation is an exact copy of the original.

In the following example, a company that uses SAS to maintain personnel records for six separate departments decided to combine all personnel records. Two departments, Sales and Customer Support, store their data in the same form. Each observation in both data sets contains values for these variables:

- **EmployeeID** is a character variable that contains the employee’s identification number.
- **Name** is a character variable that contains the employee’s name in the form last name, comma, first name.
- **HireDate** is a numeric variable that contains the date the employee was hired. This variable has a format of DATE9.
- **Salary** is a numeric variable that contains the employee’s annual salary in US dollars.
- **HomePhone** is a character variable that contains the employee’s home telephone number.
The following program creates the SAS data sets SALES and CUSTOMER_SUPPORT:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data sales;
  input EmployeeID $ 1-9 Name $ 11-29 @30 HireDate date9. Salary HomePhone $;
  format HireDate date9.;
  datalines;
  429685482 Martin, Virginia 09aug1990 34800 493-0824
  244967839 Singleton, MaryAnn 24apr1995 27900 929-2623
  996740216 Leighton, Maurice 16dec1993 32600 933-6908
  675443925 Freuler, Carl 15feb1998 29900 493-3993
  845729308 Cage, Merce 19oct1992 39800 286-0519;
  proc print data=sales;
    title 'Sales Department Employees';
  run;

data customer_support;
  input EmployeeID $ 1-9 Name $ 11-29 @30 HireDate date9. Salary HomePhone $;
  format HireDate date9.;
  datalines;
  324987451 Sayre, Jay 15nov1994 44800 933-2998
  596771321 Tolson, Andrew 18mar1998 41200 929-4800
  477562122 Jensen, Helga 01feb1991 47400 286-2816
  894724859 Kulenic, Marie 24jun1993 41400 493-1472
  988427431 Zweerink, Anna 07jul1995 43700 929-3885;
  proc print data=customer_support;
    title 'Customer Support Department Employees';
  run;

The following output shows the results of both DATA steps:

**Output 16.1** The SALES and the CUSTOMER_SUPPORT Data Sets

<table>
<thead>
<tr>
<th>Obs</th>
<th>Employee ID</th>
<th>Name</th>
<th>HireDate</th>
<th>Salary</th>
<th>Home Phone</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
To concatenate the two data sets, list them in the SET statement. Use the PRINT procedure to display the resulting DEPT1_2 data set.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data dept1_2;
    set sales customer_support;
run;

proc print data=dept1_2;
    title 'Employees in Sales and Customer Support Departments';
run;
```

The following output shows the new DEPT1_2 data set. The data set contains all observations from SALES followed by all observations from CUSTOMER_SUPPORT:

```
Output 16.2 The Concatenated DEPT1_2 Data Set

Using the SET Statement When Data Sets Contain Different Variables

The two data sets in the previous example contain the same variables, and each variable is defined the same way in both data sets. However, you might want to concatenate data sets when not all variables are common to the data sets that are named in the SET statement. In this case, each observation in the new data set includes all variables from the SAS data sets that are named in the SET statement.

The examples in this section show the SECURITY data set, and the concatenation of this data set to the SALES and the CUSTOMER_SUPPORT data sets. Not all variables are common to the three data sets. The personnel records for the Security department...
do not include the variable HomePhone, and do include the new variable Gender, which does not appear in the SALES or the CUSTOMER_SUPPORT data sets.

The following program creates the SECURITY data set:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data security;
  input EmployeeID $ 1-9 Name $ 11-29 Gender $ 30 @32 HireDate date9. Salary;
  format HireDate date9.;
  datalines;
  744289612 Saparilas, Theresa F 09may1998 33400
  824904032 Brosnihan, Dylan M 04jan1992 38200
  242779184 Chao, Daeyong M 28sep1995 37500
  544382887 Slifkin, Leah F 24jul1994 45000
  933476520 Perry, Marguerite F 19apr1992 39900
;

proc print data=security;
  title 'Security Department Employees';
run;
```

The following output shows the results:

**Output 16.3 The SECURITY Data Set**

<table>
<thead>
<tr>
<th>Obs</th>
<th>Employee ID</th>
<th>Name</th>
<th>Gender</th>
<th>HireDate</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>

The following program concatenates the SALES, CUSTOMER_SUPPORT, and SECURITY data sets, and creates the new data set, DEPT1_3:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data dept1_3;
  set sales customer_support security;
run;
```

```sas
proc print data=dept1_3;
  title 'Employees in Sales, Customer Support,';
  title2 ' and Security Departments';
run;
```

The following output shows the results:
Output 16.4  The Concatenated DEPT1_3 Data Set

</tbody>
</table>

All observations in the data set DEPT1_3 have values for both the variable Gender and the variable HomePhone. Observations from data sets SALES and CUSTOMER_SUPPORT, the data sets that do not contain the variable Gender, have missing values for Gender (indicated by blanks under the variable name). Observations from SECURITY, the data set that does not contain the variable HomePhone, have missing values for HomePhone (indicated by blanks under the variable name).

Using the SET Statement When Variables Have Different Attributes

Understanding Attributes

Each variable in a SAS data set can have as many as six attributes that are associated with it. These attributes are:

- **name**: identifies a variable. That is, when SAS looks at two or more data sets, it considers variables with the same name to be the same variable.
- **type**: identifies a variable as character or numeric.
- **length**: refers to the number of bytes that SAS uses to store each of the variable’s values in a SAS data set. Length is an especially important consideration when you use character variables, because the default length of character variables is eight bytes. If your data values are greater than eight bytes, then you can use a LENGTH statement to specify the number of bytes of storage that you need so that your data is not truncated.
- **informat**: refers to the instructions that SAS uses when reading data values. These instructions specify the form of an input value.
- **format**: refers to the instructions that SAS uses when writing data values. These instructions specify the form of an output value.
- **label**: refers to descriptive text that is associated with a specific variable.
If the data sets that you name in the SET statement contain variables with the same names and types, then you can concatenate the data sets without modification. However, if variable types differ, then you must modify one or more data sets before concatenating them. When lengths, formats, informats, or labels differ, you might want to modify one or more data sets before proceeding.

**Using the SET Statement When Variables Have Different Types**

If a variable is defined as a character variable in one data set that is named in the SET statement, and as a numeric variable in another, then SAS issues an error message and does not concatenate the data sets.

In the following example, the Accounting department in the company treats the employee identification number (EmployeeID) as a numeric variable, whereas all other departments treat it as a character variable.

The following program creates the ACCOUNTING data set:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data accounting;
  input EmployeeID 1-9 Name $ 11-29 Gender $ 30 @32 HireDate date9. Salary;
  format HireDate date9.;
datalines;
  634875680 Gardinski, Barbara F 29may1998 49800
  824576630 Robertson, Hannah F 14mar1995 52700
  744826703 Gresham, Jean F 28apr1992 54000
  824447605 Kruize, Ronald M 23may1994 49200
  988674342 Linzer, Fritz M 23jul1992 50400
;

proc print data=accounting;
  title 'Accounting Department Employees';
run;
```

The following output shows the results:

**Output 16.5  The ACCOUNTING Data Set**

<table>
<thead>
<tr>
<th>Obs</th>
<th>Employee ID</th>
<th>Name</th>
<th>Gender</th>
<th>HireDate</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>634875680</td>
<td>Gardinski, Barbara</td>
<td>F</td>
<td>29MAY1998</td>
<td>49800</td>
</tr>
<tr>
<td>2</td>
<td>824576630</td>
<td>Robertson, Hannah</td>
<td>F</td>
<td>14MAR1995</td>
<td>52700</td>
</tr>
<tr>
<td>3</td>
<td>744826703</td>
<td>Gresham, Jean</td>
<td>F</td>
<td>28APR1992</td>
<td>54000</td>
</tr>
<tr>
<td>4</td>
<td>824447605</td>
<td>Kruize, Ronald</td>
<td>M</td>
<td>23MAY1994</td>
<td>49200</td>
</tr>
<tr>
<td>5</td>
<td>988674342</td>
<td>Linzer, Fritz</td>
<td>M</td>
<td>23JUL1992</td>
<td>50400</td>
</tr>
</tbody>
</table>

The following program attempts to concatenate the data sets for all four departments:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data dept1_4;
  set sales customer_support security accounting;
run;
```
The program fails because of the difference in variable type among the four departments, and SAS writes the following error message to the log:

ERROR: Variable EmployeeID has been defined as both character and numeric.

### Changing the Type of a Variable

One way to correct the error in the previous example is to change the type of the variable EmployeeID in ACCOUNTING from numeric to character. Because performing calculations on employee identification numbers is unlikely, EmployeeID can be a character variable.

To change the type of the variable EmployeeID, you can

- re-create the data set, changing the INPUT statement so that it identifies EmployeeID as a character variable
- use the PUT function to create a new variable, and data set options to rename and drop variables.

The following program uses the PUT function and data set options to change the variable type of EmployeeID from numeric to character:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data new_accounting (rename=(TempVar=EmployeeID) drop=EmployeeID);
  set accounting;
  TempVar=put(EmployeeID, 9.);
run;

proc datasets library=work;
  contents data=new_accounting;
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The RENAME= data set option renames the variable TempVar to EmployeeID when SAS writes an observation to the output data set. The DROP= data set option is applied before the RENAME= option. The result is a change in the variable type for EmployeeID from numeric to character.

   *Note:* Although this example creates a new data set called NEW_ACCOUNTING, you can create a data set that has the same name as the data set that is listed on the SET statement. If you do this, then the type attribute for EmployeeID will be permanently altered in the ACCOUNTING data set.

2. The SET statement reads observations from the ACCOUNTING data set.

3. The PUT function converts a numeric value to a character value, and applies a format to the variable EmployeeID. The assignment statement assigns the result of the PUT function to the variable TempVar.

4. The DATASETS procedure enables you to verify the new attribute type for EmployeeID.

The following output shows a partial listing from PROC DATASETS:
Output 16.6  PROC DATASETS Output for the NEW_ACCOUNTING Data Set

<table>
<thead>
<tr>
<th>#</th>
<th>Variable</th>
<th>Type</th>
<th>Len</th>
<th>Pos</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>EmployeeID</td>
<td>Char</td>
<td>9</td>
<td>36</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>Char</td>
<td>1</td>
<td>35</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>HireDate</td>
<td>Num</td>
<td>8</td>
<td>0</td>
<td>DATE9.</td>
</tr>
<tr>
<td>1</td>
<td>Name</td>
<td>Char</td>
<td>19</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Salary</td>
<td>Num</td>
<td>8</td>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

Now that the types of all variables match, you can easily concatenate all four data sets using the following program:

```
options pagesize=60 linesize=80 pageno=1 nodate;

data dept1_4;
  set sales customer_support security new_accounting;
run;

proc print data=dept1_4;
  title 'Employees in Sales, Customer Support, Security,';
  title2 'and Accounting Departments';
run;
```

The following output shows the results:

Output 16.7  The Concatenated DEPT1_4 Data Set

</tbody>
</table>
Using the SET Statement When Variables Have Different Formats, Informats, or Labels

When you concatenate data sets with the SET statement, the following rules determine which formats, informats, and labels are associated with variables in the new data set.

- An explicitly defined format, informat, or label overrides a default, regardless of the position of the data sets in the SET statement.
- If two or more data sets explicitly define different formats, informats, or labels for the same variable, then the variable in the new data set assumes the attribute from the first data set in the SET statement that explicitly defines that attribute.

Returning to the examples, you may have noticed that the DATA steps that created the SALES, CUSTOMER_SUPPORT, SECURITY, and ACCOUNTING data sets use a FORMAT statement to explicitly assign a format of DATE9. to the variable HireDate. Therefore, although HireDate is a numeric variable, it appears in all displays as DDMMYYYY (for example, 13DEC2000). The SHIPPING data set that is created in the following example, however, uses a format of DATE7. for HireDate. The DATE7. format displays as DDMMYY (for example, 13DEC00).

In addition, the SALES, CUSTOMER_SUPPORT, SECURITY, and ACCOUNTING data sets contain a default format for Salary, whereas the SHIPPING data set contains an explicitly defined format, COMMA6., for the same variable. The COMMA6. format inserts a comma in the appropriate place when SAS displays the numeric variable Salary.

The following program creates the data set for the Shipping department:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data shipping;
  input employeeID $ 1-9 Name $ 11-29 Gender $ 30
       @32 HireDate date9. @42 Salary;
  format HireDate date7. Salary comma6.;
  datalines;
  688774609 Carlton, Susan F 28jan1995 29200
  922448328 Hoffmann, Gerald M 12oct1997 27600
  544909752 DePuis, David M 23aug1994 32900
  745609821 Hahn, Kenneth M 23aug1994 33300
  634774295 Landau, Jennifer F 30apr1996 32900
;

proc print data=shipping;
  title 'Shipping Department Employees';
run;
```

The following output shows the results:
Output 16.8  The SHIPPING Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>ID</th>
<th>Name</th>
<th>Gender</th>
<th>Date</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>5</td>
<td>634774295</td>
<td>Landau, Jennifer</td>
<td>F</td>
<td>30APR96</td>
<td>32,900</td>
</tr>
</tbody>
</table>

Now consider what happens when you concatenate SHIPPING with the previous four data sets.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data dept1_5;
   set sales customer_support security new_accounting shipping;
run;

proc print data=dept1_5;
   title 'Employees in Sales, Customer Support, Security,';
   title2 'Accounting, and Shipping Departments';
run;
```

The following output shows the results:
Chapter 16

Output 16.9  The DEPT1_5 Data Set: Concatenation of Five Data Sets

In this concatenation, the input data sets contain the variable HireDate, which was explicitly defined using two different formats. The data sets also contain the variable Salary, which has both a default and an explicit format. You can see from the output that SAS creates the new data set according to the rules mentioned earlier:

- In the case of HireDate, SAS uses the format that is defined in the first data set that is named in the SET statement (DATE9. in SALES).
- In the case of Salary, SAS uses the explicit format (COMMA6.) that is defined in the SHIPPING data set. In this case, SAS does not use the default format.

Notice the difference if you perform a similar concatenation but reverse the order of the data sets in the SET statement.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data dept5_1;
  set shipping new_accounting security customer_support sales;
run;

proc print data=dept5_1;
  title 'Employees in Shipping, Accounting, Security, Customer Support, and Sales Departments';
run;
```

The following output shows the results:
Output 16.10 The DEPT5_1 Data Set: Changing the Order of Concatenation

</table>

Compared with the output in Output 16.9, this example shows that not only does the order of the observations change, but in the case of HireDate, the DATE7. format specified in SHIPPING now prevails because that data set now appears first in the SET statement. The COMMA6. format prevails for the variable Salary because SHIPPING is the only data set that explicitly specifies a format for the variable.

Using the SET Statement When Variables Have Different Lengths

If you use the SET statement to concatenate data sets in which the same variable has different lengths, then the outcome of the concatenation depends on whether the variable is character or numeric. The SET statement determines the length of variables as follows:

- For a character or numeric variable, an explicitly defined length overrides a default, regardless of the position of the data sets in the SET statement.
- If two or more data sets explicitly define different lengths for the same numeric variable, then the variable in the new data set has the same length as the variable in the data set that appears first in the SET statement.
- If the length of a character variable differs among data sets, whether or not the differences are explicit, then the variable in the new data set has the same length as the variable in the data set that appears first in the SET statement.

The following program creates the RESEARCH data set for the sixth department, Research. Notice that the INPUT statement for this data set creates the variable Name with a length of 27; in all other data sets, Name has a length of 19.

```
options pagesize=60 linesize=80 pageno=1 nodate;
```

If you concatenate all six data sets, naming RESEARCH in any position except the first in the SET statement, then SAS defines Name with a length of 19.

If you want your program to use the Name variable that has a length of 27, then you have two options. You can

- change the order of data sets in the SET statement
- change the length of Name in the new data set.

In the first case, list the data set (RESEARCH) that uses the longer length first:

data dept6_1;
  set research shipping new_accounting
    security customer_support sales;
run;

In the second case, include a LENGTH statement in the DATA step that creates the new data set. If you change the length of a numeric variable, then the LENGTH statement can appear anywhere in the DATA step. However, if you change the length of a character variable, then the LENGTH statement must precede the SET statement.

The following program creates the data set DEPT1_6A. The LENGTH statement gives the character variable Name a length of 27, even though the first data set in the SET statement (SALES) assigns it a length of 19.

options pagesize=60 linesize=80 pageno=1 nodate;
data dept1_6a;
  length Name $ 27;
  set sales customer_support security
      new_accounting shipping research;
run;

proc print data=dept1_6a;
  title 'Employees in All Departments';
run;

The following output shows that all values of Name are complete. Note that the order of the variables in the new data set changes because Name is the first variable encountered in the DATA step.

Concatenating Data Sets Using the APPEND Procedure

Understanding the APPEND Procedure

The APPEND procedure adds the observations from one SAS data set to the end of another SAS data set. PROC APPEND does not process the observations in the first
data set. It adds the observations in the second data set directly to the end of the original data set.

The APPEND procedure has the following form:

```
```

where

**base-SAS-data-set**

names the SAS data set to which you want to append the observations. If this data set does not exist, then SAS creates it. At the completion of PROC APPEND, the value of **base-SAS-data-set** becomes the current (most recently created) SAS data set.

**SAS-data-set-to-append**

names the SAS data set that contains the observations to add to the end of the base data set. If you omit this option, then PROC APPEND adds the observations in the current SAS data set to the end of the base data set.

**FORCE**

forces PROC APPEND to concatenate the files in some situations in which the procedure would normally fail.

---

**Using the APPEND Procedure: The Simplest Case**

The following program appends the data set CUSTOMER_SUPPORT to the data set SALES. Both data sets contain the same variables and each variable has the same attributes in both data sets.

```
options pagesize=60 linesize=80 pageno=1 nodate;
proc append base=sales data=customer_support;
run;
```

```
proc print data=sales;
  title 'Employees in Sales and Customer Support Departments';
run;
```

The following output shows the results:

**Output 16.13**  Output from PROC APPEND

```
Employees in Sales and Customer Support Departments  1

    Obs Employee Home
     | ID Name       HireDate Salary Phone
    1  429685482  Martin, Virginia  09AUG1990  34800  493-0824
    2  244967839  Singleton, MaryAnn  24APR1995  27900  929-2623
    3  996740216  Leighton, Maurice  16DEC1993  32600  933-6908
    4  675443925   Freuler, Carl   15FEB1998  29900  493-3993
    5  845729308     Cage, Merce  19OCT1992  39800  286-0519
    6  324987451    Sayre, Jay    15NOV1994  44800  933-2998
    7  596771321    Tolson, Andrew  18MAR1998  41200  929-4800
    8  477562122   Jensen, Helga    01FEB1991  47400  286-2816
    9  894724859      Kulenic, Marie  24JUN1993  41400  493-1472
   10  988427431   Zweerink, Anna  07JUL1995  43700  929-3885
```
The resulting data set is identical to the data set that was created by naming SALES and CUSTOMER_SUPPORT in the SET statement (see Output 16.2). It is important to realize that PROC APPEND permanently alters the SALES data set, which is the data set for the BASE= option. SALES now contains observations from both the Sales and the Customer Support departments.

### Using the APPEND Procedure When Data Sets Contain Different Variables

Recall that the SECURITY data set contains the variable Gender, which is not in the SALES data set, and lacks the variable HomePhone, which is present in the SALES data set. What happens if you try to use PROC APPEND to concatenate data sets that contain different variables?

If you try to append SECURITY to SALES using the following program, then the concatenation fails:

```sas
proc append base=sales data=security;
run;
```

SAS writes the following messages to the log:

**Output 16.14  SAS Log: PROC APPEND Error**

```
2 proc append base=sales data=security;
3 run;
NOTE: Appending WORK.SECURITY to WORK.SALES.
WARNING: Variable Gender was not found on BASE file.
WARNING: Variable HomePhone was not found on DATA file.
ERROR: No appending done because of anomalies listed above.
    Use FORCE option to append these files.
NOTE: 0 observations added.
NOTE: The data set WORK.SALES has 5 observations and 5 variables.
NOTE: Statements not processed because of errors noted above.
NOTE: The SAS System stopped processing this step because of errors.
```

You must use the FORCE option with PROC APPEND when the DATA= data set contains a variable that is not in the BASE= data set. If you modify the program to include the FORCE option, then it successfully concatenates the files.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

proc append base=sales data=security force;
run;

proc print data=sales;
   title 'Employees in the Sales and the Security Departments';
run;
```

The following output shows the results:
Using the APPEND Procedure When Variables Have Different Attributes

When you use PROC APPEND with variables that have different attributes, the following applies:

- If a variable has different attributes in the BASE= data set than it does in the DATA= data set, then the attributes in the BASE= data set prevail. In the cases of differing formats, informatms, and labels, the concatenation succeeds.

- If the length of a variable is longer in the BASE= data set than in the DATA= data set, then the concatenation succeeds.

- If the length of a variable is longer in the DATA= data set than in the BASE= data set, or if the same variable is a character variable in one data set and a numeric variable in the other, then PROC APPEND fails to concatenate the files unless you specify the FORCE option.

Using the FORCE option has these consequences:

- The length that is specified in the BASE= data set prevails. Therefore, SAS truncates values from the DATA= data set to fit them into the length that is specified in the BASE= data set.
The type that is specified in the BASE= data set prevails. The procedure replaces values of the wrong type (all values for the variable in the DATA= data set) with missing values.

Choosing between the SET Statement and the APPEND Procedure

If two data sets contain the same variables and the variables possess the same attributes, then the file that results from concatenating them with the SET statement is the same as the file that results from concatenating them with the APPEND procedure. The APPEND procedure concatenates much faster than the SET statement, particularly when the BASE= data set is large, because the APPEND procedure does not process the observations from the BASE= data set. However, the two methods of concatenating are sufficiently different when the variables or their attributes differ between data sets. In this case, you must consider the differences in behavior before you decide which method to use.

The following table summarizes the major differences between using the SET statement and using the APPEND procedure to concatenate files.

<table>
<thead>
<tr>
<th>Criterion</th>
<th>SET statement</th>
<th>APPEND procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of data sets that you can concatenate</td>
<td>Uses any number of data sets.</td>
<td>Uses two data sets.</td>
</tr>
<tr>
<td>Handling of data sets that contain different variables</td>
<td>Uses all variables and assigns missing values where appropriate.</td>
<td>Uses all variables in the BASE= data set and assigns missing values to observations from the DATA= data set where appropriate. Requires the FORCE option to concatenate data sets if the DATA= data set contains variables that are not in the BASE= data set. Cannot include variables found only in the DATA= data set when concatenating the data sets.</td>
</tr>
<tr>
<td>Handling of different formats, informats, or labels</td>
<td>Uses explicitly defined formats, informats, and labels rather than defaults. If two or more data sets explicitly define the format, informat, or label, then SAS uses the definition from the data set you name first in the SET statement.</td>
<td>Uses formats, informats, and labels from the BASE= data set.</td>
</tr>
</tbody>
</table>
Criterion | SET statement | APPEND procedure
---|---|---
Handling of different variable lengths | If the same variable has a different length in two or more data sets, then SAS uses the length from the data set you name first in the SET statement. | Requires the FORCE option if the length of a variable is longer in the DATA= data set. Truncates the values of the variable to match the length in the BASE= data set.
Handling of different variable types | Does not concatenate the data sets. | Requires the FORCE option to concatenate data sets. Uses the type attribute from the BASE= data set and assigns missing values to the variable in observations from the DATA= data set.

Review of SAS Tools

**Statements**

LENGTH variable(s) <$\rangle$ length;

specifies the number of bytes that are used for storing variables.

SET SAS-data-set(s);

reads one or more SAS data sets and creates a single SAS data set that you specify in the DATA statement.

**Procedures**

appends the DATA= data set to the BASE= data set. base-SAS-data-set names the SAS data set to which you want to append the observations. If this data set does not exist, then SAS creates it. At the completion of PROC APPEND the base data set becomes the current (most recently created) SAS data set. SAS-data-set-to-append names the SAS data set that contains the observations to add to the end of the base data set. If you omit this option, then PROC APPEND adds the observations in the current SAS data set to the end of the base data set. The FORCE option forces PROC APPEND to concatenate the files in situations in which the procedure would otherwise fail.

**Learning More**

CONTENTS statement

The CONTENTS statement in the DATASETS procedure displays information about a data set, including the names and attributes of all variables. This
information reveals any problems that you might have when you try to concatenate data sets, and helps you decide whether to use the SET statement or PROC APPEND. For more information about using the CONTENTS statement in the DATASETS procedure, see Chapter 33, “Understanding SAS Data Libraries,” on page 595.

END= statement option
 enables you to determine when SAS is processing the last observation in the DATA step. For more information about using the END= option in the SET statement, see Chapter 21, “Conditionally Processing Observations from Multiple SAS Data Sets,” on page 325.

IN= data set option
 enables you to process observations from each data set differently. For more information about using the IN= option in the SET statement, see Chapter 21, “Conditionally Processing Observations from Multiple SAS Data Sets,” on page 325.

Variable attributes
 For more information about variable attributes, see SAS Language Reference: Dictionary.
CHAPTER 17

Interleaving SAS Data Sets

Introduction to Interleaving SAS Data Sets

Purpose

Interleaving combines individual sorted SAS data sets into one sorted data set. You interleave data sets using a SET statement and a BY statement in a DATA step. The number of observations in the new data set is the sum of the number of observations in the original data sets.

In this section, you will learn how to use the BY statement, how to sort data sets to prepare for interleaving, and how to use the SET and BY statements together to interleave observations.

Prerequisites

Before continuing with this section, you should be familiar with the concepts presented in Chapter 3, “Starting with Raw Data: The Basics,” on page 43 and Chapter 5, “Starting with SAS Data Sets,” on page 81.

Understanding BY-Group Processing Concepts

The BY statement specifies the variable or variables by which you want to interleave the data sets. In order to understand interleaving, you must understand BY variables, BY values, and BY groups.

*BY variable*
is a variable that is named in a BY statement and by which the data is sorted or needs to be sorted.

*BY value*  
is the value of a BY variable.

*BY group*  
is the set of all observations with the same value for a BY variable (when only one BY variable is specified). If you use more than one variable in a BY statement, then a BY group is a group of observations with a unique combination of values for those variables. In discussions of interleaving, BY groups commonly span more than one data set.

### Interleaving Data Sets

#### Preparing to Interleave Data Sets

Before you can interleave data sets, the data must be sorted by the same variable or variables you will use with the BY statement that accompanies your SET statement.

For example, the Research and Development division and the Publications division of a company both maintain data sets containing information about each project currently under way. Each data set includes these variables:

- **Project** is a unique code that identifies the project.
- **Department** is the name of a department involved in the project.
- **Manager** is the last name of the manager from Department.
- **StaffCount** is the number of people working for Manager on this project.

Senior management for the company wants to combine the data sets by Project so that the new data set shows the resources that both divisions are devoting to each project. Both data sets must be sorted by Project before they can be interleaved.

The program that follows creates and displays the data set RESEARCH_DEVELOPMENT. See Output 17.1. Note that the input data is already sorted by Project.

```sas
data research_development;
  length Department Manager $ 10;
  input Project $ Department $ Manager $ StaffCount;
  datalines;
  MP971 Designing Daugherty 10
  MP971 Coding Newton 8
  MP971 Testing Miller 7
  SL827 Designing Ramirez 8
  SL827 Coding Cho 10
  SL827 Testing Baker 7
  WP057 Designing Hascal 11
  WP057 Coding Constant 13
  WP057 Testing Slivko 10
; run;
```
Interleaving SAS Data Sets  Preparing to Interleave Data Sets 267

```sas
proc print data=research_development;
title 'Research and Development Project Staffing';
run;
```

**Output 17.1** The RESEARCH_DEVELOPMENT Data Set

Understanding the Interleaving Process

When interleaving, SAS creates a new data set as follows:

1. Before executing the SET statement, SAS reads the descriptor portion of each data set that you name in the SET statement. Then SAS creates a program data vector that, by default, contains all the variables from all data sets as well as any variables created by the DATA step. SAS sets the value of each variable to missing.

2. SAS looks at the first BY group in each data set in the SET statement in order to determine which BY group should appear first in the new data set.

3. SAS copies to the new data set all observations in that BY group from each data set that contains observations in the BY group. SAS copies from the data sets in the same order as they appear in the SET statement.

4. SAS looks at the next BY group in each data set to determine which BY group should appear next in the new data set.

5. SAS sets the value of each variable in the program data vector to missing.

6. SAS repeats steps 3 through 5 until it has copied all observations to the new data set.

Using the Interleaving Process

The following program uses the SET and BY statements to interleave the data sets RESEARCH_DEVELOPMENT and PUBLICATIONS. “Interleaving Data Sets” on page 266 shows the new data set.

```sas
data rnd_pubs;
  set research_development publications;
    by Project;
run;

proc print data=rnd_pubs;
  title 'Project Participation by Research and Development';
  title2 'and Publications Departments';
  title3 'Sorted by Project'
run;
```

The new data set RND_PUBS includes all observations from both data sets. Each BY group in the new data set contains observations from RESEARCH_DEVELOPMENT followed by observations from PUBLICATIONS.

Review of SAS Tools

Statements

SET SAS-data-set-list;
BY variable-list;
read multiple sorted SAS data sets and create one sorted SAS data set.
SAS-data-set-list is a list of the SAS data sets to interleave; variable-list contains the names of one or more variables (BY variables) by which to interleave the data sets. All of the data sets must be sorted by the same variable(s) before you can interleave them.

Learning More

Indexes
You do not need to sort unordered data sets before interleaving them if the data sets have an index on the variable or variables by which you want to interleave.
For more information about indexes, see *SAS Language Reference: Concepts* and the *Base SAS Procedures Guide*.

**Interleaving data sets**
For information about interleaving data sets when they contain different variables or when the same variables have different attributes, see Chapter 16, “Concatenating SAS Data Sets,” on page 243. The same rules apply to interleaving data sets as to concatenating them.

Chapter 18: Introduction to Merging SAS Data Sets

Purpose

Merging combines observations from two or more SAS data sets into a single observation in a new SAS data set. The new data set contains all variables from all the original data sets unless you specify otherwise.

In this section, you will learn about two types of merging: one-to-one merging and match merging. In one-to-one merging, you do not use a BY statement. Observations are combined based on their positions in the input data sets. In match merging, you use a BY statement to combine observations from the input data sets based on common values of the variable by which you merge the data sets.

Prerequisites

Before continuing with this section, you should be familiar with the concepts presented in Chapter 3, “Starting with Raw Data: The Basics,” on page 43 and Chapter 5, “Starting with SAS Data Sets,” on page 81.

Understanding the MERGE Statement

You merge data sets using the MERGE statement in a DATA step. The form of the MERGE statement that is used in this section is the following:

```
MERGE SAS-data-set-list;
   BY variable-list;
```

- `SAS-data-set-list` is the names of two or more SAS data sets to merge. The list may contain any number of data sets.
- `variable-list` is one or more variables by which to merge the data sets. If you use a BY statement, then the data sets must be sorted by the same BY variables before you can merge them.

One-to-One Merging

Definition of One-to-One Merging

When you use the MERGE statement without a BY statement, SAS combines the first observation in all data sets you name in the MERGE statement into the first observation in the new data set, the second observation in all data sets into the second observation in the new data set, and so on. In a one-to-one merge, the number of observations in the new data set is equal to the number of observations in the largest data set you name in the MERGE statement.
Performing a Simple One-to-One Merge

Input SAS Data Set for Examples

For example, the instructor of a college acting class wants to schedule a conference with each student. One data set, CLASS, contains these variables:

Name is the student's name.
Year is the student's year: first, second, third, or fourth.
Major is the student's area of specialization. This value is always missing for first-year and second-year students, who have not selected a major subject yet.

The following program creates and displays the data set CLASS:

```sas
data class;
  input Name $ 1-25 Year $ 26-34 Major $ 36-50;
  datalines;
  Abbott, Jennifer first
  Carter, Tom third Theater
  Kirby, Elissa fourth Mathematics
  Tucker, Rachel first
  Uhl, Roland second
  Wacenske, Maurice third Theater
;
proc print data=class;
  title 'Acting Class Roster';
run;
```

The following output displays the data set CLASS:

Output 18.1 The CLASS Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Year</th>
<th>Major</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Abbott, Jennifer</td>
<td>first</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Carter, Tom</td>
<td>third</td>
<td>Theater</td>
</tr>
<tr>
<td>3</td>
<td>Kirby, Elissa</td>
<td>fourth</td>
<td>Mathematics</td>
</tr>
<tr>
<td>4</td>
<td>Tucker, Rachel</td>
<td>first</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Uhl, Roland</td>
<td>second</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Wacenske, Maurice</td>
<td>third</td>
<td>Theater</td>
</tr>
</tbody>
</table>

A second data set contains a list of the dates and times the instructor has scheduled conferences and the rooms in which the conferences are to take place. The following program creates and displays the data set TIME_SLOT. Note the use of the date format and informat.

```sas
data time_slot;
  input Date date9. @12 Time $ @19 Room $;
  format date date9.;
  datalines;
```
Performing a Simple One-to-One Merge

Chapter 18

The following output displays the data set TIME SLOT:

Output 18.2 The TIME SLOT Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Date</th>
<th>Time</th>
<th>Room</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>14SEP2000</td>
<td>10:00</td>
<td>103</td>
</tr>
<tr>
<td>2</td>
<td>14SEP2000</td>
<td>10:30</td>
<td>103</td>
</tr>
<tr>
<td>3</td>
<td>14SEP2000</td>
<td>11:00</td>
<td>207</td>
</tr>
<tr>
<td>4</td>
<td>15SEP2000</td>
<td>10:00</td>
<td>105</td>
</tr>
<tr>
<td>5</td>
<td>15SEP2000</td>
<td>10:30</td>
<td>105</td>
</tr>
<tr>
<td>6</td>
<td>17SEP2000</td>
<td>11:00</td>
<td>207</td>
</tr>
</tbody>
</table>

The Program

The following program performs a one-to-one merge of these data sets, assigning a time slot for a conference to each student in the class.

```sas
data schedule;
  merge class time_slot;
run;
```

proc print data=schedule;
  title 'Student Conference Assignments';
run;

The following output displays the conference schedule data set:

Output 18.3 One-to-One Merge

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Year</th>
<th>Major</th>
<th>Date</th>
<th>Time</th>
<th>Room</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Abbott, Jennifer</td>
<td>first</td>
<td></td>
<td>14SEP2000</td>
<td>10:00</td>
<td>103</td>
</tr>
<tr>
<td>2</td>
<td>Carter, Tom</td>
<td>third</td>
<td>Theater</td>
<td>14SEP2000</td>
<td>10:30</td>
<td>103</td>
</tr>
<tr>
<td>3</td>
<td>Kirby, Elissa</td>
<td>fourth</td>
<td>Mathematics</td>
<td>14SEP2000</td>
<td>11:00</td>
<td>207</td>
</tr>
<tr>
<td>4</td>
<td>Tucker, Rachel</td>
<td>first</td>
<td></td>
<td>15SEP2000</td>
<td>10:00</td>
<td>105</td>
</tr>
<tr>
<td>5</td>
<td>Uhl, Roland</td>
<td>second</td>
<td></td>
<td>15SEP2000</td>
<td>10:30</td>
<td>105</td>
</tr>
<tr>
<td>6</td>
<td>Wacenske, Maurice</td>
<td>third</td>
<td>Theater</td>
<td>17SEP2000</td>
<td>11:00</td>
<td>207</td>
</tr>
</tbody>
</table>
Explanation

Output 18.3 shows that the new data set combines the first observation from CLASS with the first observation from TIME SLOT, the second observation from CLASS with the second observation from TIME SLOT, and so on.

Performing a One-to-One Merge on Data Sets with the Same Variables

Input SAS Data Set for Examples

The previous example illustrates the simplest case of a one-to-one merge: the data sets contain the same number of observations, all variables have unique names, and you want to keep all variables from both data sets in the new data set. This example merges data sets that contain variables with the same names. Also, the second data set in this example contains one more observation than the first data set. Each data set contains data on a separate acting class.

In addition to the data set CLASS, the instructor also uses the data set CLASS2, which contains the same variables as CLASS but one more observation. The following program creates and displays the data set CLASS2:

data class2;
  input Name $ 1-25 Year $ 26-34 Major $ 36-50;
datalines;
  Hitchcock-Tyler, Erin  second
  Keil, Deborah third  Theater
  Nacewicz, Chester third  Theater
  Norgaard, Rolf  second
  Prism, Lindsay fourth  Anthropology
  Singh, Rajiv second
  Wittich, Stefan third  Physics
;

proc print data=class2;
title 'Acting Class Roster';
title2 '(second section)';
run;

The following output displays the data set CLASS2:

Output 18.4 The CLASS2 Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Year</th>
<th>Major</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Hitchcock-Tyler, Erin</td>
<td>second</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Keil, Deborah</td>
<td>third</td>
<td>Theater</td>
</tr>
<tr>
<td>3</td>
<td>Nacewicz, Chester</td>
<td>third</td>
<td>Theater</td>
</tr>
<tr>
<td>4</td>
<td>Norgaard, Rolf</td>
<td>second</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Prism, Lindsay</td>
<td>fourth</td>
<td>Anthropology</td>
</tr>
<tr>
<td>6</td>
<td>Singh, Rajiv</td>
<td>second</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>Wittich, Stefan</td>
<td>third</td>
<td>Physics</td>
</tr>
</tbody>
</table>
The Program

Instead of scheduling conferences for one class, the instructor wants to schedule acting exercises for pairs of students, one student from each class. The instructor wants to create a data set in which each observation contains the name of one student from each class and the date, time, and location of the exercise. The variables Year and Major should not be in the new data set.

This new data set can be created by merging the data sets CLASS, CLASS2, and TIME_SLOT. Because Year and Major are not wanted in the new data set, the DROP= data set option can be used to drop them. Notice that the data sets CLASS and CLASS2 both contain the variable Name, but the values for Name are different in each data set. To preserve both sets of values, the RENAME= data set option must be used to rename the variable in one of the data sets.

The following program uses these data set options to merge the three data sets:

```sas
data exercise;
merge class (drop=Year Major)
class2 (drop=Year Major rename=(Name=Name2))
time_slot;
run;
```

```sas
proc print data=exercise;
title 'Acting Class Exercise Schedule';
run;
```

The following output displays the new data set:

Output 18.5 Merging Three Data Sets

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Name2</th>
<th>Date</th>
<th>Time</th>
<th>Room</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>11:00</td>
<td>207</td>
</tr>
<tr>
<td>7</td>
<td>Wacenske, Maurice</td>
<td>Wittich, Stefan</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Explanation

The following steps describe how SAS merges the data sets:

1 Before executing the DATA step, SAS reads the descriptor portion of each data set that you name in the MERGE statement. Then SAS creates a program data vector for the new data set that, by default, contains all the variables from all data sets, as well as variables created by the DATA step. In this case, however, the DROP= data set option excludes the variables Year and Major from the program data vector. The RENAME= data set option adds the variable Name2 to the program data vector. Therefore, the program data vector contains the variables Name, Name2, Date, Time, and Room.

2 SAS sets the value of each variable in the program data vector to missing, as the next figure illustrates.
3 Next, SAS reads and copies the first observation from each data set into the program data vector (reading the data sets in the same order they appear in the MERGE statement), as the next figure illustrates.

Figure 18.2 Program Data Vector after Reading from Each Data Set

<table>
<thead>
<tr>
<th>Name</th>
<th>Name2</th>
<th>Date</th>
<th>Time</th>
<th>Room</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abbott, Jennifer</td>
<td></td>
<td>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Hitchcock-Tyler, Erin</td>
<td>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Abbott, Jennifer</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Hitchcock-Tyler, Erin</td>
<td>14SEP2000</td>
<td>10:00</td>
<td>103</td>
</tr>
</tbody>
</table>

4 After processing the first observation from the last data set and executing any other statements in the DATA step, SAS writes the contents of the program data vector to the new data set. If the DATA step attempts to read past the end of a data set, then the values of all variables from that data set in the program data vector are set to missing.

This behavior has two important consequences:

- If a variable exists in more than one data set, then the value from the last data set SAS reads is the value that goes into the new data set, even if that value is missing. If you want to keep all the values for like-named variables from different data sets, then you must rename one or more of the variables with the RENAME= data set option so that each variable has a unique name.
- After SAS processes all observations in a data set, the program data vector and all subsequent observations in the new data set have missing values for the variables unique to that data set. So, as the next figure shows, the program data vector for the last observation in the new data set contains missing values for all variables except Name2.

Figure 18.3 Program Data Vector for the Last Observation

<table>
<thead>
<tr>
<th>Name</th>
<th>Name2</th>
<th>Date</th>
<th>Time</th>
<th>Room</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wittich, Stefan</td>
<td></td>
<td>.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
SAS continues to merge observations until it has copied all observations from all data sets.

## Match-Merging

### Merging with a BY Statement

Merging with a BY statement enables you to match observations according to the values of the BY variables that you specify. Before you can perform a match-merge, all data sets must be sorted by the variables that you want to use for the merge.

In order to understand match-merging, you must understand three key concepts:

- **BY variable** is a variable named in a BY statement.
- **BY value** is the value of a BY variable.
- **BY group** is the set of all observations with the same value for the BY variable (if there is only one BY variable). If you use more than one variable in a BY statement, then a BY group is the set of observations with a unique combination of values for those variables. In discussions of match-merging, BY groups commonly span more than one data set.

### Input SAS Data Set for Examples

For example, the director of a small repertory theater company, the Little Theater, maintains company records in two SAS data sets, COMPANY and FINANCE.

<table>
<thead>
<tr>
<th>Data Set</th>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPANY</td>
<td>Name</td>
<td>player's name</td>
</tr>
<tr>
<td></td>
<td>Age</td>
<td>player's age</td>
</tr>
<tr>
<td></td>
<td>Gender</td>
<td>player's gender</td>
</tr>
<tr>
<td>FINANCE</td>
<td>Name</td>
<td>player's name</td>
</tr>
<tr>
<td></td>
<td>IdNumber</td>
<td>player's employee ID number</td>
</tr>
<tr>
<td></td>
<td>Salary</td>
<td>player's annual salary</td>
</tr>
</tbody>
</table>

The following program creates, sorts, and displays COMPANY and FINANCE:

```sas
data company;
  input Name $ 1-25 Age 27-28 Gender $ 30;
datalines;
Vincent, Martina 34 F
Phillipon, Marie-Odile 28 F
Gunter, Thomas 27 M
Harbinger, Nicholas 36 M
Benito, Gisela 32 F
Rudelich, Herbert 39 M
```
The following output displays the data sets. Notice that the FINANCE data set does not contain an observation for Michael Morrison.

**Output 18.6** The COMPANY and FINANCE Data Sets

<table>
<thead>
<tr>
<th>Little Theater Company Roster</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
<td>Name</td>
</tr>
<tr>
<td>-----</td>
<td>-----------------------</td>
</tr>
<tr>
<td>1</td>
<td>Benito, Gisela</td>
</tr>
<tr>
<td>2</td>
<td>Gunter, Thomas</td>
</tr>
<tr>
<td>3</td>
<td>Harbinger, Nicholas</td>
</tr>
<tr>
<td>4</td>
<td>Morrison, Michael</td>
</tr>
<tr>
<td>5</td>
<td>Phillipon, Marie-Odile</td>
</tr>
<tr>
<td>6</td>
<td>Rudelich, Herbert</td>
</tr>
<tr>
<td>7</td>
<td>Sirignano, Emily</td>
</tr>
<tr>
<td>8</td>
<td>Vincent, Martina</td>
</tr>
</tbody>
</table>
The Program

To avoid having to maintain two separate data sets, the director wants to merge the records for each player from both data sets into a new data set that contains all the variables. The variable that is common to both data sets is Name. Therefore, Name is the appropriate BY variable.

The data sets are already sorted by NAME, so no further sorting is required. The following program merges them by NAME:

```sas
data employee_info;
  merge company finance;
  by name;
run;
```

The following output displays the merged data set:

**Output 18.7 Match-Merging**

<table>

</tbody>
</table>

**Explanation**

The new data set contains one observation for each player in the company. Each observation contains all the variables from both data sets. Notice in particular the fourth observation. The data set FINANCE does not have an observation for Michael.
Morrison. In this case, the values of the variables that are unique to FINANCE (IdNumber and Salary) are missing.

**Match-Merging Data Sets with Multiple Observations in a BY Group**

**Input SAS Data Set for Examples**

The Little Theater has a third data set, REPERTORY, that tracks the casting assignments in each of the season’s plays. REPERTORY contains these variables:

- **Play** is the name of one of the plays in the repertory.
- **Role** is the name of a character in Play.
- **IdNumber** is the employee ID number of the player playing Role.

The following program creates and displays REPERTORY:

```sas
data repertory;
  input Play $ 1-23 Role $ 25-48 IdNumber $ 50-60;
  datalines;
  No Exit Estelle 074-53-9892
  No Exit Inez 776-84-5391
  No Exit Valet 929-75-0218
  No Exit Garcin 446-93-2122
  Happy Days Winnie 074-53-9892
  Happy Days Willie 446-93-2122
  The Glass Menagerie Amanda Wingfield 228-88-9649
  The Glass Menagerie Laura Wingfield 776-84-5391
  The Glass Menagerie Tom Wingfield 929-75-0218
  The Glass Menagerie Jim O’Connor 029-46-9261
  The Dear Departed Mrs. Slater 228-88-9649
  The Dear Departed Mrs. Jordan 074-53-9892
  The Dear Departed Henry Slater 029-46-9261
  The Dear Departed Ben Jordan 446-93-2122
  The Dear Departed Victoria Slater 442-21-8075
  The Dear Departed Abel Merryweather 929-75-0218
;
```

```sas
proc print data=repertory;
  title 'Little Theater Season Casting Assignments';
run;
```

The following output displays the REPERTORY data set:
To maintain confidentiality during preliminary casting, this data set identifies players by employee ID number. However, casting decisions are now final, and the manager wants to replace each employee ID number with the player’s name. Of course, it is possible to re-create the data set, entering each player’s name instead of the employee ID number in the raw data. However, it is more efficient to make use of the data set FINANCE, which already contains the name and employee ID number of all players (see Output 18.6). When the data sets are merged, SAS takes care of adding the players’ names to the data set.

Of course, before you can merge the data sets, you must sort them by IdNumber.

```sas
proc sort data=finance;
    by IdNumber;
run;

proc sort data=repertory;
    by IdNumber;
run;
```

The following output displays the FINANCE and REPERTORY data sets, sorted by IdNumber:

</tbody>
</table>

These two data sets contain seven BY groups; that is, among the 23 observations are seven different values for the BY variable, IdNumber. The first BY group has a value of 029-46-9261 for IdNumber. FINANCE has one observation in this BY group; REPERTORY has two. The last BY group has a value of 929-75-0218 for IdNumber. FINANCE has one observation in this BY group; REPERTORY has three.

The Program

The following program merges the data sets FINANCE and REPERTORY and illustrates what happens when a BY group in one data set has more observations in it than the same BY group in the other data set.

The resulting data set contains all variables from both data sets.

```sas
options linesize=120;

data repertory_name;
  merge finance repertory;
  by IdNumber;
run;

proc print data=repertory_name;
```
title 'Little Theater Season Casting Assignments';
    title2 'with employee financial information';
run;

Note: The OPTIONS statement extends the line size to 120 so that PROC PRINT can display all variables on one line. Most output in this section is created with line size set to 76 in the OPTIONS statement. An OPTIONS statement appears only in examples using a different line size. When you set the LINESIZE= option, it remains in effect until you reset it or end the SAS session.

The following output displays the merged data set:

Explanation

Carefully examine the first few observations in the new data set and consider how SAS creates them.

1  Before executing the DATA step, SAS reads the descriptor portion of the two data sets and creates a program data vector that contains all variables from both data sets:

- IdNumber, Name, and Salary from FINANCE
- Play and Role from REPERTORY.

IdNumber is already in the program data vector because it is in FINANCE. SAS sets the values of all variables to missing, as the following figure illustrates.

Figure 18.4  Program Data Vector before Reading from Data Sets

<table>
<thead>
<tr>
<th>IdNumber</th>
<th>Name</th>
<th>Salary</th>
<th>Play</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Merging SAS Data Sets

2 SAS looks at the first BY group in each data set to determine which BY group should appear first. In this case, the first BY group, observations with the value 029-46-9261 for IdNumber, is the same in both data sets.

3 SAS reads and copies the first observation from FINANCE into the program data vector, as the next figure illustrates.

4 SAS reads and copies the first observation from REPERTORY into the program data vector, as the next figure illustrates. If a data set does not have any observations in a BY group, then the program data vector contains missing values for the variables that are unique to that data set.

5 SAS writes the observation to the new data set and retains the values in the program data vector. (If the program data vector contained variables created by the DATA step, then SAS would set them to missing after writing to the new data set.)

6 SAS looks for a second observation in the BY group in each data set. REPERTORY has one; FINANCE does not. The MERGE statement reads the second observation in the BY group from REPERTORY. Because FINANCE has only one observation in the BY group, the statement uses the values of Name (Rudelich, Herbert) and Salary (35000) retained in the program data vector for the second observation in the new data set. The next figure illustrates this behavior.

7 SAS writes the observation to the new data set. Neither data set contains any more observations in this BY group. Therefore, as the final figure illustrates, SAS sets all values in the program data vector to missing and begins processing the next BY group. It continues processing observations until it exhausts all observations in both data sets.
Chapter 18

Match-Merging Data Sets with Dropped Variables

Now that casting decisions are final, the director wants to post the casting list, but does not want to include salary or employee ID information. As the next program illustrates, Salary and IdNumber can be eliminated by using the DROP= data set option when creating the new data set.

data newrep (drop=IdNumber);
merge finance (drop=Salary) repertory;
by IdNumber;
run;

proc print data=newrep;
title 'Final Little Theater Season Casting Assignments';
run;

Note: The difference in placement of the two DROP= data set options is crucial. Dropping IdNumber in the DATA statement means that the variable is available to the MERGE and BY statements (to which it is essential) but that it does not go into the new data set. Dropping Salary in the MERGE statement means that the MERGE statement does not even read this variable, so Salary is unavailable to the program statements. Because the variable Salary is not needed for processing, it is more efficient to prevent it from being read into the PDV in the first place.

The following output displays the merged data set without the IdNumber and Salary variables:

Output 18.11 Match-Merging Data Sets with Dropped Variables

</table>

Match-Merging Data Sets with the Same Variables

You can match-merge data sets that contain the same variables (variables with the same name) by using the RENAME= data set option, just as you would when
performing a one-to-one merge (see “Performing a One-to-One Merge on Data Sets with the Same Variables” on page 275).

If you do not use the RENAME= option and a variable exists in more than one data set, then the value of that variable in the last data set read is the value that goes into the new data set.

**Match-Merging Data Sets That Lack a Common Variable**

You can name any number of data sets in the MERGE statement. However, if you are match-merging the data sets, then you must be sure they all have a common variable and are sorted by that variable. If the data sets do not have a common variable, then you might be able to use another data set that has variables common to the original data sets to merge them.

For instance, consider the data sets that are used in the match-merge examples. The table that follows shows the names of the data sets and the names of the variables in each data set.

<table>
<thead>
<tr>
<th>Data Set</th>
<th>Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPANY</td>
<td>Name, Age, Gender</td>
</tr>
<tr>
<td>FINANCE</td>
<td>Name, IdNumber, Salary</td>
</tr>
<tr>
<td>REPERTORY</td>
<td>Play, Role, IdNumber</td>
</tr>
</tbody>
</table>

These data sets do not share a common variable. However, COMPANY and FINANCE share the variable Name. Similarly, FINANCE and REPERTORY share the variable IdNumber. Therefore, as the next program shows, you can merge the data sets into one with two separate DATA steps. As usual, you must sort the data sets by the appropriate BY variable. (REPERTORY is already sorted by IdNumber.)

```sas
options linesize=120;
   /* Sort FINANCE and COMPANY by Name */
    proc sort data=finance;
       by Name;
    run;

    proc sort data=company;
       by Name;
    run;

    /* Merge COMPANY and FINANCE into a */
    /* temporary data set. */
    data temp;
       merge company finance;
       by Name;
    run;

    proc sort data=temp;
       by IdNumber;
    run;

    /* Merge the temporary data set with REPERTORY */
    data all;
```
Choosing between One-to-One Merging and Match-Merging

### Chapter 18

Choosing between One-to-One Merging and Match-Merging

merge temp repertory;
by IdNumber;
run;

proc print data=all;
title 'Little Theater Complete Casting Information';
run;

In order to merge the three data sets, this program
- sorts FINANCE and COMPANY by Name
- merges COMPANY and FINANCE into a temporary data set, TEMP
- sorts TEMP by IdNumber
- merges TEMP and REPERTORY by IdNumber.

The following output displays the resulting data set, ALL:

#### Output 18.12  Match-Merging Data Sets That Lack a Common Variable

</tbody>
</table>

Choosing between One-to-One Merging and Match-Merging

#### Comparing Match-Merge Methods

Use one-to-one merging when you want to combine one observation from each data set, but it is not important to match observations. For example, when merging an observation that contains a student’s name, year, and major with an observation that contains a date, time, and location for a conference, it does not matter which student gets which time slot; therefore, a one-to-one merge is appropriate.

In cases where you must merge certain observations, use a match-merge. For example, when merging employee information from two different data sets, it is crucial that you merge observations that relate to the same employee. Therefore, you must use a match-merge.

Sometimes you might want to merge by a particular variable, but your data is arranged in such a way that you can see that a one-to-one merge will work. The next
example illustrates a case when you could use a one-to-one merge for matching observations because you are certain that your data is ordered correctly. However, as a subsequent example shows, it is risky to use a one-to-one merge in such situations.

**Input SAS Data Set for Examples**

Consider the data set COMPANY2. Each observation in this data set corresponds to an observation with the same value of Name in FINANCE. The program that follows creates and displays COMPANY2; it also displays FINANCE for comparison.

```sas
data company2;
  input name $ 1-25 age 27-28 gender $ 30;
datalines;
Benito, Gisela 32 F
Gunter, Thomas 27 M
Harbinger, Nicholas 36 M
Phillipon, Marie-Odile 28 F
Rudelich, Herbert 39 M
Sirignano, Emily 12 F
Vincent, Martina 34 F;

proc print data=company2;
  title 'Little Theater Company Roster';
run;

proc print data=finance;
  title 'Little Theater Employee Information';
run;
```

The following output displays the two data sets:

**Output 18.13 The COMPANY2 and FINANCE Data Sets**

<table>
<thead>
<tr>

<td>Sirignano, Emily</td>
</tr>
<tr>
<td>7</td>
<td>Vincent, Martina</td>
</tr>
</tbody>
</table>
When to Use a One-to-One Merge

The following program shows that because both data sets are sorted by NAME and because each observation in one data set has a corresponding observation in the other data set, a one-to-one merge has the same result as merging by Name.

```sas
/* One-to-one merge */
data one_to_one;
  merge company2 finance;
run;

proc print data=one_to_one;
title 'Using a One-to-One Merge to Combine';
title2 'COMPANY2 and FINANCE';
run;

/* Match-merge */
data match;
  merge company2 finance;
  by name;
run;

proc print data=match;
title 'Using a Match-Merge to Combine';
title2 'COMPANY2 and FINANCE';
run;
```

The following output displays the results of the two merges. You can see that they are identical.

Output 18.14  Comparing a One-to-One Merge with a Match-Merge When Observations Correspond

<table>

When to Use a Match-Merge

In the previous example, you can easily determine that the data sets contain the same values for Name and that the values appear in the same order. However, if the data sets contained hundreds of observations, then it would be difficult to ascertain that all the values match. If the observations do not match, then serious problems can occur. The next example illustrates why you should not use a one-to-one merge for matching observations.

Consider the original data set, COMPANY, which contains an observation for Michael Morrison (see Output 18.6). FINANCE has no corresponding observation. If a programmer did not realize this fact and tried to use the following program to perform a one-to-one merge with FINANCE, then several problems could appear.

```sas
data badmerge;
  merge company finance;
run;
```

```sas
proc print data=badmerge;
  title 'Using a One-to-One Merge Instead of a Match-Merge';
run;
```

The following output shows the potential problems:

Output 18.15  One-to-One Merge with Unequal Numbers of Observations in Each Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Age</th>
<th>Gender</th>
<th>IdNumber</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>

<td>35000</td>
</tr>
</tbody>
</table>

Even though the resulting data sets are identical, it is not wise to use a one-to-one merge when it is essential to merge a particular observation from one data set with a particular observation from another data set.
The first three observations merge correctly. However, FINANCE does not have an observation for Michael Morrison. A one-to-one merge makes no attempt to match parts of the observations from the different data sets. It simply combines observations based on their positions in the data sets that you name in the MERGE statement. Therefore, the fourth observation in BADMERGE combines the fourth observation in COMPANY (Michael’s name, age, and gender) with the fourth observation in FINANCE (Marie-Odile’s name, employee ID number, and salary). As SAS combines the observations, Marie-Odile’s name overwrites Michael’s. After writing this observation to the new data set, SAS processes the next observation in each data set. These observations are similarly mismatched.

This type of mismatch continues until the seventh observation when the MERGE statement exhausts the observations in the smaller data set, FINANCE. After writing the seventh observation to the new data set, SAS begins the next iteration of the DATA step. Because SAS has read all observations in FINANCE, it sets the values for variables from that data set to missing in the program data vector. Then it reads the values for Name, Age, and Gender from COMPANY and writes the contents of the program data vector to the new data set. Therefore, the last observation has the same value for NAME as the previous observation and contains missing values for IdNumber and Salary.

These missing values and the duplication of the value for Name might make you suspect that the observations did not merge as you intended them to. However, if instead of being an additional observation, the observation for Michael Morrison replaced another observation in COMPANY2, then no observations would have missing values, and the problem would not be as easy to spot. Therefore, you are safer using a match-merge in situations that call for it even if you think the data is arranged so that a one-to-one merge will have the same results.

**Review of SAS Tools**

**Statements**

MERGE SAS-data-set-list;
BY variable-list;
read observations in multiple SAS data sets and combine them into one observation in one new SAS data set. SAS-data-set-list is a list of the SAS data sets to merge. The list may contain any number of data sets; variable-list is the name of one or more variables by which to merge the data sets. If you use a BY statement, then the data sets must be sorted by the same BY variables before you can merge them. If you do not use a BY statement, then SAS merges observations based on their positions in the original data sets.

**Learning More**

Indexes

If a data set has an index on the variable or variables named in the BY statement that accompanies the MERGE statement, then you do not need to sort that data
set. For more information about indexes, see *SAS Language Reference: Concepts* and the *Base SAS Procedures Guide*.

SAS date and time formats and informats
The examples in this section read Time as a character variable, and they read Date with a SAS date informat. You could read Time using special SAS time informats. For more information about SAS date and time formats and informats, see *SAS Language Reference: Dictionary*. 
Introduction to Updating SAS Data Sets

Purpose

Updating replaces the values of variables in one data set with nonmissing values from another data set. In this section, you will learn about the following:

- master data sets and transaction data sets
- using the UPDATE statement
- how to choose between updating and merging

Prerequisites

Before using this section, you should be familiar with the concepts presented in

- Chapter 3, “Starting with Raw Data: The Basics,” on page 43
- Chapter 5, “Starting with SAS Data Sets,” on page 81
- Chapter 18, “Merging SAS Data Sets,” on page 271
Understanding the UPDATE Statement

When you update, you work with two SAS data sets. The data set that contains the original information is the master data set. The data set that contains the new information is the transaction data set. Many applications, such as maintaining mailing lists and inventories, call for periodic updates of information.

In a DATA step, the UPDATE statement reads observations from the transaction data set and updates corresponding observations (observations with the same value of all BY variables) from the master data set. All nonmissing values for variables in the transaction data set replace the corresponding values that are read from the master data set. SAS writes the modified observations to the data set that you name in the DATA statement without modifying either the master or the transaction data set.

The general form of the UPDATE statement is

```
UPDATE master-SAS-data-set transaction-SAS-data-set;
BY identifier-list;
```

where

- `master-SAS-data-set` is the SAS data set containing information you want to update.
- `transaction-SAS-data-set` is the SAS data set containing information with which you want to update the master data set.
- `identifier-list` is the list of BY variables by which you identify corresponding observations.

If the master data set contains an observation that does not correspond to an observation in the transaction data set, the DATA step writes that observation to the new data set without modification. An observation from the transaction data set that does not correspond to any observation in the master data set becomes the basis for a new observation. The new observation may be modified by other observations from the transaction data set before it is written to the new data set.

Understanding How to Select BY Variables

The master data set and the transaction data set must be sorted by the same variable or variables that you specify in the BY statement. Select a variable that meets these criteria:

- The value of the variable is unique for each observation in the master data set. If you use more than one BY variable, no two observations in the master data set should have the same values for all BY variables.
- The variable or variables never need to be updated.

Some examples of variables that you can use in the BY statement include employee or student identification numbers, stock numbers, and the names of objects in an inventory.

If you are updating a data set, you probably do not want duplicate values of BY variables in the master data set. For example, if you update by NAME, each observation in the master data set should have a unique value of NAME. If you update by NAME and AGE, two or more observations can have the same value for either NAME or AGE but should not have the same values for both. SAS warns you if it finds
duplicates but proceeds with the update. It applies all transactions only to the first observation in the BY group in the master data set.

---

**Updating a Data Set**

In this example, the circulation department of a magazine maintains a mailing list that contains tens of thousands of names. Each issue of the magazine contains a form for readers to fill out when they change their names or addresses. To simplify the maintenance job, the form requests that readers send only new information. New subscribers can start a subscription by completing the entire form. When a form is received, a data entry operator enters the information on the form into a raw data file. The mailing list is updated once per month from the raw data file.

The mailing list includes these variables for each subscriber:

- **SubscriberId** is a unique number assigned to the subscriber at the time the subscription begins. A subscriber’s SubscriberId never changes.
- **Name** is the subscriber’s name. The last name appears first, followed by a comma and the first name.
- **StreetAddress** is the subscriber’s street address.
- **City** is the subscriber’s city.
- **StateProv** is the subscriber’s state or province. This variable is missing for addresses outside the United States and Canada.
- **PostalCode** is the subscriber’s postal code (zip code for addresses in the United States).
- **Country** is the subscriber’s country.

The following program creates and displays the first part of this data set. The raw data are already sorted by SubscriberId.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data mail_list;
   input SubscriberId 1-8 Name $ 9-27 StreetAddress $ 28-47 City $ 48-62
                  StateProv $ 63-64 PostalCode $ 67-73 Country $ ;
   datalines;
   1001 Ericson, Jane 111 Clancey Court Chapel Hill NC 27514 USA
   1002 Dix, Martin 4 Shepherd St. Vancouver BC V6C 3E8 Canada
   1003 Gabrielli, Theresa Via Pisanelli, 25 Roma 00196 Italy
   1004 Clayton, Aria 14 Bridge St. San Francisco CA 94124 USA
   1005 Archuleta, Ruby Box 108 Milagro NM 87429 USA
   1006 Misiewicz, Jeremy 43-C Lakeview Apts. Madison WI 53704 USA
   1007 Ahmadi, Hafez 52 Rue Marston Paris 75019 France
   1008 Jacobson, Becky 1 Lincoln St. Tallahassee FL 32312 USA

</table>

This month the information that follows is received for updating the mailing list:

- Martin Dix changed his name to Martin Dix-Rosen.
- Jane Ericson’s postal code changed.
- Jeremy Misiewicz moved to a new street address. His city, state, and postal code remain the same.
- Ing An moved from Toronto, Ontario, to Calgary, Alberta.
- Martin Dix-Rosen, shortly after changing his name, moved from Vancouver, British Columbia, to Seattle, Washington.
- Two new subscribers joined the list. They are given SubscriberID numbers 1011 and 1012.

Each change is entered into the raw data file as soon as it is received. In each case, only the customer’s SubscriberID and the new information are entered. The raw data file looks like this:

<table>
<thead>
<tr>
<th>SubscriberID</th>
<th>Name</th>
<th>Address</th>
<th>City</th>
<th>State</th>
<th>Postal Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>1002</td>
<td>Dix-Rosen, Martin</td>
<td>932 Webster St.</td>
<td>2540 Pleasant St.</td>
<td>Calgary</td>
<td>AB</td>
</tr>
<tr>
<td>1006</td>

<td>212 Northampton Rd.</td>
<td>South Hadley</td>
<td>MA</td>
</tr>
</tbody>
</table>

The data is in fixed columns, matching the INPUT statement that created MAIL_LIST.
First, you must transform the raw data into a SAS data set and sort that data set by SubscriberId so that you can use it to update the master list.

```sas
data mail_trans;
  infile 'your-input-file' missover;
  input SubscriberId 1-8 Name $ 9-27 StreetAddress $ 28-47 City $ 48-62
    StateProv $ 63-64 PostalCode $ 67-73 Country $ 75-80;
run;
```

```sas
proc sort data=mail_trans;
  by SubscriberId;
run;
```

```sas
proc print data=mail_trans;
  title 'Magazine Mailing List Changes';
  title2 '(for current month)';
run;
```

Note the MISSOVER option in the INFILE statement. The MISSOVER option prevents the INPUT statement from going to a new line to search for values for variables which have not received values; instead, any variables that have not received values are set to missing. For example, when the first record is read, the end of the record is encountered before any value has been assigned to the Country variable; instead of going to the next record to search for a value for Country, the Country variable is assigned a missing value. For more information about the MISSOVER option, see Chapter 4, “Starting with Raw Data: Beyond the Basics,” on page 61.

The following output shows the sorted data set MAIL_TRANS:

**Output 19.2 The MAIL_TRANS Data Set**

<table>
<thead>

The data for subscriber 1002, who has two update transactions, is used below to show what happens when you update an observation in the master data set with corresponding observations from the transaction data set.

1 Before executing the DATA step, SAS reads the descriptor portion of each data set named in the UPDATE statement and, by default, creates a program data vector that contains all the variables from all data sets. As the following figure illustrates, SAS sets the value of each variable to missing. (Use the DROP= or KEEP= data set option to exclude one or more variables.)
Next, SAS reads the first observation from the master data set and copies it into the program data vector, as the following figure illustrates.

Figure 19.2 Program Data Vector after Reading the First Observation from the Master Data Set

<table>
<thead>
<tr>
<th>SubscriberId</th>
<th>Name</th>
<th>Street Address</th>
<th>City</th>
<th>StateProv</th>
<th>PostalCode</th>
<th>Country</th>
</tr>
</thead>
<tbody>
<tr>
<td>1002</td>
<td>Dix-Rosen, Martin</td>
<td>4 Shepherd St.</td>
<td>Vancouver</td>
<td>BC</td>
<td>V6C 3E8</td>
<td>Canada</td>
</tr>
</tbody>
</table>

SAS applies the first transaction by copying all nonmissing values (the value of Name) from the first observation in this BY group (ID=1002) into the program data vector, as the following figure illustrates.

Figure 19.3 Program Data Vector after Applying the First Transaction

<table>
<thead>
<tr>
<th>SubscriberId</th>
<th>Name</th>
<th>Street Address</th>
<th>City</th>
<th>StateProv</th>
<th>PostalCode</th>
<th>Country</th>
</tr>
</thead>
<tbody>
<tr>
<td>1002</td>
<td>Dix-Rosen, Martin</td>
<td>4 Shepherd St.</td>
<td>Vancouver</td>
<td>BC</td>
<td>V6C 3E8</td>
<td>Canada</td>
</tr>
</tbody>
</table>

After completing this transaction, SAS looks for another observation in the same BY group in the transaction data set. If it finds a second observation with the same value for ID, then it applies the second transaction too (new values for StreetAddress, City, StateProv, PostalCode, and Country). Now the observation contains the new values from both transactions, as the following figure illustrates.

Figure 19.4 Program Data Vector after Applying the Second Transaction

<table>
<thead>
<tr>
<th>SubscriberId</th>
<th>Name</th>
<th>Street Address</th>
<th>City</th>
<th>StateProv</th>
<th>Postal Code</th>
<th>Country</th>
</tr>
</thead>
<tbody>
<tr>
<td>1002</td>
<td>Dix-Rosen, Martin</td>
<td>P.O. Box 1850</td>
<td>Seattle</td>
<td>WA</td>
<td>98101</td>
<td>USA</td>
</tr>
</tbody>
</table>

After completing the second transaction, SAS looks for a third observation in the same BY group. Because no such observation exists, it writes the observation in its current form to the new data set and sets the values in the program data vector to missing.

As the DATA step iterates, the UPDATE statement continues processing observations in this way until it reaches the end of the master and transaction data sets. The two observations in the transaction data set that describe new subscribers (and therefore have no corresponding observation in the master data set) become observations in the new data set.

Remember that if there are duplicate observations in the master data set, all matching observations in the transaction data set are applied only to the first of the duplicate observations in the master data set.
Chapter 19

Updating with Incremental Values

Some applications do not update a data set by overwriting values in the master data set with new values from a transaction data set. Instead, they update a variable by mathematically manipulating its value based on the value of a variable in the transaction data set.

In this example, a bookstore uses SAS to keep track of weekly sales and year-to-date sales. The program that follows creates, sorts by Title, and displays the data set, YEAR_SALES, which contains the year-to-date information.

```sas
data year_sales;
  input Title $ 1-25 Author $ 27-50 Sales;
datalines;
The Milagro Beanfield War Nichols, John 303
The Stranger Camus, Albert 150
Always Coming Home LeGuin, Ursula 79
Falling through Space Gilchrist, Ellen 128
Don Quixote Cervantes, Miguel de 87
The Handmaid’s Tale Atwood, Margaret 64;

proc sort data=year_sales;
  by title;
run;

proc print data=year_sales (obs=6);
  title 'Bookstore Sales, Year-to-Date';
  title2 'By Title';
run;
```

The following output displays the YEAR_SALES data set:

**Output 19.4** The YEAR_SALES Data Set, Sorted by Title

<table>
<thead>
<tr>
<th>Obs</th>
<th>Title</th>
<th>Author</th>
<th>Sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Always Coming Home</td>
<td>LeGuin, Ursula</td>
<td>79</td>
</tr>
<tr>
<td>2</td>
<td>Don Quixote</td>
<td>Cervantes, Miguel de</td>
<td>87</td>
</tr>
<tr>
<td>3</td>
<td>Falling through Space</td>
<td>Gilchrist, Ellen</td>
<td>128</td>
</tr>
<tr>
<td>4</td>
<td>The Handmaid’s Tale</td>
<td>Atwood, Margaret</td>
<td>64</td>
</tr>
<tr>
<td>5</td>
<td>The Milagro Beanfield War</td>
<td>Nichols, John</td>
<td>303</td>
</tr>
<tr>
<td>6</td>
<td>The Stranger</td>
<td>Camus, Albert</td>
<td>150</td>
</tr>
</tbody>
</table>

Every Saturday a SAS data set is created containing information about all the books that were sold during the past week. The program following creates, sorts by Title, and displays the data set WEEK_SALES, which contains the current week’s information.

```sas
data week_sales;
  input Title $ 1-25 Author $ 27-50 Sales;
datalines;
The Milagro Beanfield War Nichols, John 32
```
The Stranger Camus, Albert 17
Always Coming Home LeGuin, Ursula 10
Falling through Space Gilchrist, Ellen 12
The Accidental Tourist Tyler, Anne 15
The Handmaid’s Tale Atwood, Margaret 8

; proc sort data=week_sales;
   by title;
run;

proc print data=week_sales;
   title ‘Bookstore Sales for Current Week’;
   title2 ‘By Title’;
run;

The following output shows the data set, which contains the same variables as the year-to-date data set, but the variable Sales represents sales for only one week:

Output 19.5 The WEEK_SALES Data Set, Sorted by Title

<table>
<thead>
<tr>
<th>Obs</th>

</tbody>
</table>

Note: If the transaction data set is updating only titles that are already in YEAR_SALES, it does not need to contain the variable Author. However, because this variable is there, the transaction data set can be used to add complete observations to the master data set.

The program that follows uses the weekly information to update the year-to-date data set and displays the new data set.

data total_sales;
   drop NewSales; ①
   update year_sales week_sales (rename=(Sales=NewSales)); ①
      by Title;
      sales=sum(Sales,NewSales); ②
run;

proc print data=total_sales;
   title ‘Updated Year-to-Date Sales’;
run;

The following list corresponds to the numbered items in the preceding program:

① The RENAME= data set option in the UPDATE statement changes the name of the variable Sales in the transaction data set (WEEK_SALES) to NewSales. As a
Understanding the Differences between Updating and Merging

Chapter 19

result, these values do not replace the value of Sales that are read from the master data set (YEAR_SALES).

2 The Sales value that is in the updated data set (TOTAL_SALES) is the sum of the year-to-date sales and the weekly sales.

3 The program drops the variable NewSales because it is not needed in the new data set.

The following output shows that in addition to updating sales information for the titles already in the master data set, the UPDATE statement has added a new title, The Accidental Tourist.

Output 19.6  Updating Year-to-Date Sales with Weekly Sales

General Comparisons between Updating and Merging

The MERGE statement and the UPDATE statement both match observations from two SAS data sets; however, the two statements differ significantly. It is important to distinguish between the two processes and to choose the one that is appropriate for your application.

The most straightforward differences are as follows:

- The UPDATE statement uses only two data sets. The number of data sets that the MERGE statement can use is limited only by machine-dependent factors such as memory and disk space.
- A BY statement must accompany an UPDATE statement. The MERGE statement performs a one-to-one merge if no BY statement follows it.
- The two statements also process observations differently when a data set contains missing values or multiple observations in a BY group.

To illustrate the differences, compare updating the SAS data set MAIL_LIST with the data set MAIL_TRANS to merging the two data sets. You have already seen the results of updating in the example that created Output 19.3. That output appears again in the following output for easy comparison.
In contrast, the following program merges the two data sets.

```sas
data mail_merged;
merge mail_list mail_trans;
by SubscriberId;
run;

proc print data=mail_merged;
   title 'Magazine Mailing List';
run;
```

The following output shows the results of the merge:

Output 19.7 Updating a Data Set

</table>
The MERGE statement produces a data set containing 13 observations, whereas UPDATE produces a data set containing 12 observations. In addition, merging the data sets results in several missing values, whereas updating does not. Obviously, using the wrong statement may result in incorrect data. The differences between the merged and updated data sets result from the ways the two statements handle missing values and multiple observations in a BY group.

How the UPDATE and MERGE Statements Process Missing Values Differently

During an update, if a value for a variable is missing in the transaction data set, SAS uses the value from the master data set when it writes the observation to the new data set. When merging the same observations, SAS overwrites the value in the program data vector with the missing value. For example, the following observation exists in data set MAILING.MASTER.

1001 Ericson, Jane 111 Clancey Court Chapel Hill NC 27514

The following corresponding observation exists in MAILING.TRANS.

1001 27516

Updating combines the two observations and creates the following observation:

1001 Ericson, Jane 111 Clancey Court Chapel Hill NC 27516

Merging combines the two observations and creates this observation:

1001 27516
How the UPDATE and MERGE Statements Process Multiple Observations in a BY Group Differently

SAS does not write an updated observation to the new data set until it has applied all the transactions in a BY group. When merging data sets, SAS writes one new observation for each observation in the data set with the largest number of observations in the BY group. For example, consider this observation from MAILING.MASTER:

1002  DIX, MARTIN  4 SHEPHERD ST.  NORWICH  VT  05055

and the corresponding observations from MAILING.TRANS:

1002  DIX-ROSEN, MARTIN
1002  R.R. 2, BOX 1850  HANOVER  NH  03755

The UPDATE statement applies both transactions and combines these observations into a single one:

1002  DIX-ROSEN, MARTIN  R.R. 2, BOX 1850  HANOVER  NH  03755

The MERGE statement, on the other hand, first merges the observation from MAILING.MASTER with the first observation in the corresponding BY group in MAILING.TRANS. All values of variables from the observation in MAILING.TRANS are used, even if they are missing. Then SAS writes the observation to the new data set:

1002  DIX-ROSEN, MARTIN

Next, SAS looks for other observations in the same BY group in each data set. Because more observations are in the BY group in MAILING.TRANS, all the values in the program data vector are retained. SAS merges them with the second observation in the BY group from MAILING.TRANS and writes the result to the new data set:

1002  R.R. 2, BOX 1850  HANOVER  NH  03755

Therefore, merging creates two observations for the new data set, whereas updating creates only one.

Handling Missing Values

If you update a master data set with a transaction data set, and the transaction data set contains missing values, you can use the UPDatemode option on the UPDATE statement to tell SAS how you want to handle the missing values. The UPDatemode option specifies whether missing values in a transaction data set will replace existing values in a master data set.

The syntax for using the UPDatemode option with the UPDATE statement is as follows:

```
UPDATE master-SAS-data-set transaction-SAS-data-set
   <UPDatemode=MISSINGCHECK | NOMISSINGCHECK>;
```

```
BY by-variable;
```

The MISSINGCHECK value in the UPDatemode option prevents missing values in a transaction data set from replacing values in a master data set. This is the default. The NOMISSINGCHECK value in the UPDatemode option enables missing values in a transaction data set to replace values in a master data set by preventing the check for missing data from being performed.
The following examples show how SAS handles missing values when you use the UPDATEMODE option on the UPDATE statement.

The following example creates and sorts a master data set:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data inventory;
  input PartNumber $ Description $ Stock @17
       ReceivedDate date9. @27 Price;
  format ReceivedDate date9.;
datalines;
K89R seal 34 27jul2004 245.00
M4J7 sander 98 20jun2004 45.88
LK43 filter 121 19may2005 10.99
MN21 brace 43 10aug2005 27.87
BC85 clamp 80 16aug2005 9.55
NCF3 valve 198 20mar2005 24.50;

proc sort data=inventory;
  by PartNumber;
run;

proc print data=inventory;
  title 'Master Data Set';
  title2 'Tool Warehouse Inventory';
run;
```

The following output shows the results:

```
Output 19.9 The Master Data Set

<td>28.87</td>
</tr>
<tr>
<td>6</td>
<td>NCF3</td>
<td>valve</td>
<td>121</td>
<td></td>
</tr>
</tbody>
</table>

In the following example, SAS uses the NOMISSINGCHECK value of the UPDATEMODE option on the UPDATE statement:

options pagesize=60 linesize=80 pageno=1 nodate;

data new_inventory;
 update inventory add_inventory updatemode=nomissingcheck;
 by PartNumber;
 ReceivedDate=today();
run;

proc print data=new_inventory;
  title 'Updated Master Data Set';
  title2 'Tool Warehouse Inventory';
run;

The following output shows the results of using the NOMISSINGCHECK value. Observations 2 and 5 contain missing values for STOCK because the transaction data set contains missing values for STOCK for these items. Because checking for missing values in the transaction data set is not done, the original value in STOCK is replaced by missing values. In the sixth observation, the original value of PRICE is replaced by a missing value.
Output 19.11 Updated Master Data Set: UPDATEMODE=NOMISSINGCHECK

Updated Master Data Set 1
Tool Warehouse Inventory

For more information about using the UPDATE statement, see SAS Language Reference: Dictionary.

Review of SAS Tools

Statements

UPDATE master-SAS-data-set transaction-SAS-data-set;
BY identifier-list;
replace the values of variables in one SAS data set with nonmissing values from another SAS data set. Master-SAS-data-set is the SAS data set containing information that you want to update; transaction-SAS-data-set is the SAS data set containing information with which you want to update the master data set; identifier-list is the list of BY variables by which you identify corresponding observations.
Learning More

DATASETS procedure
When you update a data set, you create a new data set containing the updated information. Typically, you want to use PROC DATASETS to delete the old master data set and rename the new one so that you can use the same program the next time you update the information. For more information about the DATASETS procedure, see Chapter 34, “Managing SAS Data Libraries,” on page 603.

Indexes
If a data set has an index on the variable or variables named in the BY statement that accompanies the UPDATE statement, you do not need to sort that data set. For more information about indexes, see the SAS Language Reference: Dictionary and the SAS Language Reference: Concepts.

Merge statement
Introduction

In this section, you will learn how to use the MODIFY statement in a DATA step to do the following:

- replace values in a data set
- replace values in a master data set with values from a transaction data set
- append observations to an existing SAS data set
- delete observations from an existing SAS data set.

The MODIFY statement modifies observations directly in the original master file. It does not create a copy of the file.

Prerequisites

Before continuing with this section, you should be familiar with the concepts presented in the following parts:

- Chapter 3, “Starting with Raw Data: The Basics,” on page 43
Input SAS Data Set for Examples

In this section you will look at examples from an inventory tracking system that is used by a tool vendor. The examples use the SAS data set INVENTORY as input. The data set contains these variables:

PartNumber is a character variable that contains a unique value that identifies each item.

Description is a character variable that contains the text description of each item.

InStock is a numeric variable that contains a value that describes how many units of each tool the warehouse has in stock.

ReceivedDate is a numeric variable that contains the SAS date value that is the day for which InStock values are current.

Price is a numeric variable that contains the price of each item.

The following program creates and displays the INVENTORY data set:

options pagesize=60 linesize=80 pageno=1 nodate;

data inventory;
   input PartNumber $ Description $ InStock @17
   ReceivedDate date9. @27 Price;
   format ReceivedDate date9.;
   datalines;
   K89R seal 34 27jul1998 245.00
   M4J7 sander 98 20jun1998 45.88
   LK43 filter 121 19may1999 10.99
   MN21 brace 43 10aug1999 27.87
   BC85 clamp 80 16aug1999 9.55
   NCF3 valve 198 20mar1999 24.50
   KJ66 cutter 6 18jun1999 19.77
   UYN7 rod 211 09sep1999 11.55
   JD03 switch 383 09jan2000 13.99
   BV1E timer 26 03aug2000 34.50
;

proc print data=inventory;
   title 'Tool Warehouse Inventory';
run;

The following output shows the results:
Modifying a SAS Data Set: The Simplest Case

You can use the MODIFY statement to replace all values for a specific variable or variables in a data set. The syntax for using the MODIFY statement for this purpose is

```
MODIFY SAS-data-set;
```

In the following program, the price of each part in the inventory is increased by 15%. The new values for PRICE replace the old values on all records in the original INVENTORY data set. The FORMAT statement in the print procedure writes the price of each item with two-digit decimal precision.

```
data inventory;
   modify inventory;
      price=price+(price*.15);
   run;

proc print data=inventory;
   title 'Tool Warehouse Inventory';
   title2 '(Price reflects 15% increase)';
   format price 8.2;
   run;
```

The following output shows the results:
Output 20.2  The INVENTORY Data Set with Updated Prices

Modifying a Master Data Set with Observations from a Transaction Data Set

Understanding the MODIFY Statement

The MODIFY statement replaces data in a master data set with data from a transaction data set, and makes the changes in the original master data set. You can use a BY statement to match observations from the transaction data set with observations in the master data set. The syntax for using the MODIFY statement and the BY statement is

```
MODIFY master-SAS-data-set transaction-SAS-data-set;
BY by-variable;
```

The `master-SAS-data-set` specifies the SAS data set that you want to modify. The `transaction-SAS-data-set` specifies the SAS data set that provides the values for updating the master data set. The `by-variable` specifies one or more variables by which you identify corresponding observations.

When you use a BY statement with the MODIFY statement, the DATA step uses dynamic WHERE processing to find observations in the master data set. Neither the master data set nor the transaction data set needs to be sorted. For large data sets, however, sorting the data before you modify it can enhance performance significantly.

Adding New Observations to the Master Data Set

You can use the MODIFY statement to add observations to an existing master data set. If the transaction data set contains an observation that does not match an observation in the master data set, then SAS enables you to write a new observation to the master data set if you use an explicit OUTPUT statement in your program. When you specify an explicit OUTPUT statement, you must also specify a REPLACE statement if you want to replace observations in place. All new observations append to the end of the master data set.
Checking for Program Errors

You can use the _IORC_ automatic variable for error checking in your DATA step program. The _IORC_ automatic variable contains the return code for each I/O operation that the MODIFY statement attempts to perform.

The best way to test the values of _IORC_ is with the mnemonic codes that are provided by the SYSRC autocall macro. Each mnemonic code describes one condition. The mnemonics provide an easy method for testing problems in a DATA step program. The following is a partial list of codes:

- **_DSENMR**
  - specifies that the transaction data set observation does not exist in the master data set (used only with MODIFY and BY statements). If consecutive observations with different BY values do not find a match in the master data set, then both of them return _DSENMR.

- **_DSEMTR**
  - specifies that multiple transaction data set observations with a given BY value do not exist in the master data set (used only with MODIFY and BY statements). If consecutive observations with the same BY values do not find a match in the master data set, then the first observation returns _DSENMR and the subsequent observations return _DSEMTR.

- **_SOK**
  - specifies that the observation was located in the master data set.

For a complete list of mnemonic codes, see the MODIFY statement in SAS Language Reference: Dictionary.

The Program

The program in this section updates values in a master data set with values from a transaction data set. If a transaction does not exist in the master data set, then the program adds the transaction to the master data set.

In this example, a warehouse received a shipment of new items, and the INVENTORY master data set must be modified to reflect the changes. The master data set contains a complete list of the inventory items. The transaction data set contains items that are on the master inventory as well as new inventory items.

The following program creates the ADD_INVENTORY transaction data set, which contains items for updating the master data set. The PartNumber variable contains the part number for the item and corresponds to PartNumber in the INVENTORY data set. The Description variable names the item. The NewStock variable contains the number of each item in the current shipment. The NewPrice variable contains the new price of the item.

The program attempts to update the master data set INVENTORY (see Output 20.1) according to the values in the transaction data set ADD_INVENTORY. The program uses the _IORC_ automatic variable to detect errors.

```sas
data add_inventory;
  input PartNumber $ Description $ NewStock @16 NewPrice;
datalines;
K89R seal 6 247.50
AA11 hammer 55 32.26
BB22 wrench 21 17.35
```

         ReceivedDate=today();
         Price=NewPrice;
         output; ⑤
         _error_=0;
      end;
   otherwise do; ⑥
      put 'An unexpected I/O error has occurred.'; ⑦
      'Check your data and your program.'; ⑧
      _error_=0;
      stop;
   end;
end;

proc print data=inventory;
   title 'Tool Warehouse Inventory';
run;

The following list corresponds to the numbered items in the preceding program:
① The DATA statement creates the transaction data set ADD_INVENTORY.
② The MODIFY statement loads the data from the INVENTORY and ADD_INVENTORY data sets.
③ The _IORC_ automatic variable is used for error checking. The value of _IORC_ is a numeric return code that indicates the status of the most recent I/O operation.
④ The SYSRC autocall macro checks to see if the value of _IORC_ is _SOK. If the value is _SOK, then an observation in the transaction data set matches an observation in the master data set.
⑤ The REPLACE statement updates the master data set INVENTORY by replacing the observation in the master data set with the observation from the transaction data set.
⑥ The SYSRC autocall macro checks to see if the value of _IORC_ is _DSENMR. If the value is _DSENMR, then an observation in the transaction data set does not exist in the master data set.
The OUTPUT statement writes the current observation to the end of the master data set.

If neither condition is met, the PUT statement writes a message to the log.

The following output shows the results:

Output 20.3  The Updated INVENTORY Data Set

SAS writes the following message to the log:

NOTE: The data set WORK.INVENTORY has been updated. There were 3 observations rewritten, 3 observations added and 0 observations deleted.

CAUTION:
If you execute your program without the OUTPUT and REPLACE statements, then your master file might not update correctly. Using OUTPUT or REPLACE in a DATA step overrides the default replacement of observations. If you use these statements in a DATA step, then you must explicitly program each action that you want to take.

For more information about the MODIFY, OUTPUT, and REPLACE statements, see the Statements section in SAS Language Reference: Dictionary.

Understanding How Duplicate BY Variables Affect File Update

How the DATA Step Processes Duplicate BY Variables

When you use a BY statement with MODIFY, both the master and the transaction data sets can have observations with duplicate values of BY variables. Neither the master nor the transaction data set needs to be sorted, because BY-group processing uses dynamic WHERE processing to find an observation in the master data set.

The DATA step processes duplicate observations in the following ways:

- If duplicate BY values exist in the master data set, then MODIFY applies the current transaction to the first occurrence in the master data set.
If duplicate BY values exist in the transaction data set, then the observations are applied one on top of another so that the values overwrite each other. The value in the last transaction is the final value in the master data set.

If both the master and the transaction data sets contain duplicate BY values, then MODIFY applies each transaction to the first occurrence in the group in the master data set.

The Program

The program in this section updates the master data set INVENTORY_2 with observations from the transaction data set ADD_INVENTORY_2. Both data sets contain consecutive and nonconsecutive duplicate values of the BY variable PartNumber.

The following program creates the master data set INVENTORY_2. Note that the data set contains three observations for PartNumber M4J7.

```sas
proc print data=inventory_2;
    input PartNumber $ Description $ InStock @17
        ReceivedDate date9. @27 Price;
    format ReceivedDate date9.;
    datalines;
    K89R seal 34 27jul1998 245.00
    M4J7 sander 98 20jun1998 45.88
    M4J7 sander 98 20jun1998 45.88
    LK43 filter 121 19may1999 10.99
    MN21 brace 43 10aug1999 27.87
    M4J7 sander 98 20jun1998 45.88
    BC85 clamp 80 16aug1999 9.55
    NCF3 valve 198 20mar1999 24.50
    KJ66 cutter 6 18jun1999 19.77
    ;
```

The following program creates the transaction data set ADD_INVENTORY_2, and then modifies the master data set INVENTORY_2. Note that the data set ADD_INVENTORY_2 contains three observations for PartNumber M4J7.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
proc print data=add_inventory_2;
    input PartNumber $ Description $ NewStock;
    datalines;
    K89R abc 17
    M4J7 def 72
    M4J7 ghi 66
    LK43 jkl 311
    M4J7 mno 43
    BC85 pqr 75
    ;
```

```sas
data inventory_2;
    modify inventory_2 add_inventory_2;
    by PartNumber;
    ReceivedDate=today();
    InStock=InStock+NewStock;
run;
```
Handling Missing Values

By default, if the transaction data set contains missing values for a variable that is common to both the master and the transaction data sets, then the MODIFY statement does not replace values in the master data set with missing values.

If you want to replace values in the master data set with missing values, then you use the UPDATEMODE= option on the MODIFY statement. UPDATEMODE specifies whether missing values in a transaction data set will replace existing values in a master data set.

The syntax for using the UPDATEMODE= option with the MODIFY statement is

```
MODIFY master-SAS-data-set transaction-SAS-data-set
<UPDATEMODE=MISSINGCHECK | NOMISSINGCHECK>;
```

```
BY by-variable;
```

MISSINGCHECK prevents missing values in a transaction data set from replacing values in a master data set. This is the default. NOMISSINGCHECK enables missing values in a transaction data set to replace values in a master data set by preventing the check for missing data from being performed.

The following example creates the master data set Event_List, which contains the schedule and codes for athletic events. The example then updates Event_List with the transaction data set Event_Change, which contains new information about the schedule. Because the MODIFY statement uses the NOMISSINGCHECK value of the UPDATEMODE= option, values in the master data set are replaced by missing values from the transaction data set.

The following program creates the EVENT_LIST master data set:

```
data Event_List;
  input Event $ 1-10 Weekday $ 12-20 TimeofDay $ 22-30 Fee Code;
datalines;
Basketball Monday evening 10 58
Soccer Tuesday morning 5 33
Yoga Wednesday afternoon 15 92
```

```
proc print data=inventory_2;
title "Tool Warehouse Inventory";
run;
```

The following output shows the results:

```
Output 20.4 The Updated INVENTORY_2 Data Set: Duplicate BY Variables

Review of SAS Tools

**Statements**

**BY by-variable;**

specifies one or more variables to use with the BY statement. You use the BY variable to identify corresponding observations in a master data set and a transaction data set.

**MODIFY master-SAS-data-set transaction-SAS-data-set**

<UPDATEMODE=MISSINGCHECK | NOMISSINGCHECK>;

replaces the values of variables in one SAS data set with values from another SAS data set. The master-SAS-data-set contains data that you want to update. The
transaction-SAS-data-set contains observations with which to update the master data set.

The UPDATEMODE argument determines whether missing values in the transaction data set overwrite values in the master data set. The MISSINGCHECK option prevents missing values in a transaction data set from replacing values in a master data set. This is the default. The NOMISSINGCHECK option enables missing values in a transaction data set to replace values in a master data set by preventing the check for missing data from being performed.

MODIFY SAS-data-set;
replaces the values of variables in a data set with values that you specify in your program.

OUTPUT;
if a MODIFY statement is present, writes the current observation to the end of the master data set.

REPLACE;
if a MODIFY statement is present, writes the current observation to the same physical location from which it was read in a data set that is named in the DATA statement.

MERGE statement

MODIFY statement
For complete information about the various applications of the MODIFY statement, see SAS Language Reference: Dictionary.

UPDATE statement
Introduction to Conditional Processing from Multiple SAS Data Sets

Purpose

When combining SAS data sets, you can process observations conditionally, based on which data set contributed that observation. You can do the following:

- Determine which data set contributed each observation in the combined data set.
- Create a new data set that includes only selected observations from the data sets that you combine.
- Determine when SAS is processing the last observation in the DATA step so that you can execute conditional operations, such as creating totals.

You have seen some of these concepts in earlier topics, but in this section you will apply them to the processing of multiple data sets. The examples use the SET statement, but you can also use all of the features that are discussed here with the MERGE, MODIFY, and UPDATE statements.

Prerequisites

Before using this section, you should understand the concepts presented in the following sections:

- Chapter 3, “Starting with Raw Data: The Basics,” on page 43
Input SAS Data Sets for Examples

The following program creates two SAS data sets, SOUTHAMERICAN and EUROPEAN. Each data set contains the following variables:

- **Year**: is the year that South American and European countries competed in the World Cup Finals from 1954 to 1998.
- **Country**: is the name of the competing country.
- **Score**: is the final score of the game.
- **Result**: is the result of the game. The value for winners is **won**; the value for losers is **lost**.

```sas
data southamerican;
  title "South American World Cup Finalists from 1954 to 1998";
  input Year $ Country $ 9-23 Score $ 25-28 Result $ 32-36;
  datalines;
  1998 Brazil 0-3 lost
  1994 Brazil 3-2 won
  1990 Argentina 0-1 lost
  1986 Argentina 3-2 won
  1978 Argentina 3-1 won
  1970 Brazil 4-1 won
  1962 Brazil 3-1 won
  1958 Brazil 5-2 won
;

data european;
  title "European World Cup Finalists From 1954 to 1998";
  input Year $ Country $ 9-23 Score $ 25-28 Result $ 32-36;
  datalines;
  1998 France 3-0 won
  1994 Italy 2-3 lost
  1990 West Germany 1-0 won
  1986 West Germany 2-3 lost
  1982 Italy 3-1 won
  1982 West Germany 1-3 lost
  1978 Holland 1-2 lost
  1974 West Germany 2-1 won
  1974 Holland 1-2 lost
  1970 Italy 1-4 lost
  1966 England 4-2 won
  1966 West Germany 2-4 lost
  1962 Czechoslovakia 1-3 lost
  1958 Sweden 2-5 lost
  1954 West Germany 3-2 won
  1954 Hungary 2-3 lost
;
```
options pagesize=60 linesize=80 pageno=1 nodate;

proc sort data=southamerican;
    by year;
run;

proc print data=southamerican;
    title 'World Cup Finalists: South American Countries from 1954 to 1998';
run;

proc sort data=european;
    by year;
run;

proc print data=european;
    title 'World Cup Finalists: European Countries from 1954 to 1998';
run;

The PROC SORT statement sorts the data set in ascending order according to the BY variable. To create the interleaved data set in the next example, the data must be in ascending order.

Output 21.1  World Cup Finalists by Continent

### Determining Which Data Set Contributed the Observation

#### Understanding the IN= Data Set Option

When you create a new data set by combining observations from two or more data sets, knowing which data set an observation came from can be useful. For example, you might want to perform a calculation based on which data set contributed an observation. Otherwise, you might lose important contextual information that you need for later processing. You can determine which data set contributed a particular observation by using the IN= data set option.

The IN= data set option enables you to determine which data sets have contributed to the observation that is currently in the program data vector. The syntax for this option on the SET statement is

```
SET SAS-data-set-1 (IN=variable) SAS-data-set-2;
```

BY a-common-variable;

When you use the IN= option with a data set in a SET, MERGE, MODIFY, or UPDATE statement, SAS creates a temporary variable associated with that data set. The value of variable is 1 if the data set has contributed to the observation currently in the program data vector. The value is 0 if it has not contributed. You can use the IN= option with any or all the data sets you name in a SET, MERGE, MODIFY, or UPDATE statement, but use a different variable name in each case.

**Note:** The IN= variable exists during the execution of the DATA step only; it is not written to the output data set that is created.

#### The Program

The original data sets, SOUTHAMERICAN and EUROPEAN, do not need a variable that identifies the countries’ continent because all observations in SOUTHAMERICAN pertain to the South American continent, and all observations in EUROPEAN pertain...
to the European continent. However, when you combine the data sets, you lose the context, which in this case is the relevant continent for each observation. The following example uses the SET statement with a BY statement to combine the two data sets into one data set that contains all the observations in chronological order:

```
options pagesize=60 linesize=80 pageno=1 nodate;

data finalists;
  set southamerican european;
  by year;
run;
```

```
proc print data=finalists;
  title 'World Cup Finalists';
  title2 'from 1958 to 1998';
run;
```

### Output 21.2 World Cup Finalists Grouped by Year

<td>won</td>
</tr>
</tbody>
</table>

Notice that this output would be more useful if it showed from which data set each observation originated. To solve this problem, the following program uses the IN= data set option in conjunction with IF-THEN/ELSE statements. By determining which data set contributed an observation, the conditional statement executes and assigns the appropriate value to the variable Continent in each observation in the new data set FINALISTS.

```
options pagesize=60 linesize=80 pageno=1 nodate;

data finalists;
```
set southamerican (in=S) european;
by Year;
if S then Continent='South America';
else Continent='Europe';
run;

proc print data=finalists;
title 'World Cup Finalists';
title2 'from 1954 to 1998';
run;

The following list corresponds to the numbered items in the preceding program:

1 The IN= option in the SET statement tells SAS to create a variable named S.

2 When the current observation comes from the data set SOUTHAMERICAN, the value of S is 1. Otherwise, the value is 0. The IF-THEN/ELSE statements execute one of two assignment statements, depending on the value of S. If the observation comes from the data set SOUTHAMERICAN, then the value that is assigned to Continent is South America. If the observation comes from the data set EUROPEAN, then the value that is assigned to Continent is Europe.

The following output shows the results:

Combining Selected Observations from Multiple Data Sets

To create a data set that contains only the observations that are selected according to a particular criterion, you can use the subsetting IF statement and a SET statement.
that specifies multiple data sets. The following DATA step reads two input data sets to create a combined data set that lists only the winning teams:

```sas
data champions(drop=result);
  set southamerican (in=S) european;
  by Year;
  if result='won';
    if S then Continent='South America';
    else Continent='Europe';
run;
```

```sas
proc print data=champions;
  title 'World Cup Champions from 1954 to 1998';
  title2 'including Countries' Continent';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The DROP= data set option drops the variable Result from the new data set CHAMPIONS because all values for this variable will be the same.

2. The SET statement reads observations from two data sets: SOUTHAMERICAN and EUROPEAN. The S= data option creates the variable S which is set to 1 each time an observation is contributed by the SOUTHAMERICAN data set.

3. A subsetting IF statement writes the observation to the output data set CHAMPIONS only if the value of the Result variable is won.

4. When the current observation comes from the data set SOUTHAMERICAN, the value of S is 1. Otherwise, the value is 0. The IF-THEN/ELSE statements execute one of two assignment statements, depending on the value of S. If the observation comes from the data set SOUTHAMERICAN, then the value assigned to Continent is South America. If the observation comes from the data set EUROPEAN, then the value assigned to Continent is Europe.

The following output shows the resulting data set CHAMPIONS:

**Output 21.4 Combining Selected Observations**

</table>
Performing a Calculation Based on the Last Observation

Understanding When the Last Observation Is Processed

Many applications require that you determine when the DATA step processes the last observation in the input data set. For example, you might want to perform calculations only on the last observation in a data set, or you might want to write an observation only after the last observation has been processed. For this purpose, you can use the END= option for the SET, MERGE, MODIFY, or UPDATE statement. The syntax for this option is:

```
SET SAS-data-set-list END=variable;
```

The END= option defines a temporary variable whose value is 1 when the DATA step is processing the last observation. At all other times, the value of variable is 0. Although the DATA step can use the END= variable, SAS does not add it to the resulting data set.

Note: Chapter 12, “Using More Than One Observation in a Calculation,” on page 189 explains how to use the END= option in the SET statement with a single data set. The END= option works the same way with multiple data sets, but it is important to note that END= is set to 1 only when the last observation from all input data sets is being processed.

The Program

This example uses the data in SOUTHAMERICAN and EUROPEAN to calculate how many years a team from each continent won the World Cup from 1954 to 1998. To perform this calculation, this program must perform the following tasks:

1. Identify on which continent a country is located.
2. Keep a running total of how many times a team from each continent won the World Cup.
3. After processing all observations, multiply the final total for each continent by 4 (the length of time between World Cups) to determine the length of time each continent has been a World Cup champion.
4. Write only the final observation to the output data set. The variables that contain the totals do not contain the final total until the last observation is processed.

The following DATA step calculates the running totals and produces the output data set that contains only those totals.

```
data timespan (keep=YearsSouthAmerican keep=YearsEuropean);
data timespan (keep=YearsSouthAmerican keep=YearsEuropean);
    set southamerican (in=S) european end=LastYear;
    by Year;
    if result='won' then do;
        if S then SouthAmericanWins+1;
        else EuropeanWins+1;
    end;
    if lastyear then do;
        YearsSouthAmerican=SouthAmericanWins*4;
    end;
```

```
data timespan (keep=YearsSouthAmerican keep=YearsEuropean);
data timespan (keep=YearsSouthAmerican keep=YearsEuropean);
    set southamerican (in=S) european end=LastYear;
    by Year;
    if result='won' then do;
        if S then SouthAmericanWins+1;
        else EuropeanWins+1;
    end;
    if lastyear then do;
        YearsSouthAmerican=SouthAmericanWins*4;
    end;
```

The following list corresponds to the numbered items in the preceding program:

1. The END= option creates the temporary variable LastYear. The value of LastYear is 0 until the DATA step begins processing the last observation. At that point, the value of LastYear is set to 1.

2. Two new variables, SouthAmericanWins and EuropeanWins, keep a running total of the number of victories each continent achieves. For each observation in which the value of the variable Result is won, a different sum statement executes, based on the data set that the observation came from:

   SouthAmericanWins+1;

   or

   EuropeanWins+1;

3. When the DATA step begins processing the last observation, the value of LASTYEAR changes from 0 to 1. When this change occurs, the conditional statement IF LastYear becomes true, and the statements that follow it are executed. The assignment statement multiplies the total number of victories for each continent by 4 and assigns the result to the appropriate variable, YearsSouthAmerican or YearsEuropean.

4. The OUTPUT statement writes the observation to the newly created data set. Remember that the DATA step automatically writes an observation at the end of each iteration. However, the OUTPUT statement turns off this automatic feature. The DATA step writes only the last observation to TIMESSPAN. When the DATA step writes the observation from the program data vector to the output data set, it writes only two variables, YearsSouthAmerican and YearsEuropean, as directed by the KEEP= data set option in the DATA statement.

Output 21.5 Using the END= Option to Perform a Calculation Based on the Last Observation in the Data Sets

```
YearsEuropean=EuropeanWins*4;
output;
end;

proc print data=timespan;
   title 'Total Years as Reigning World Cup Champions';
   title2 'from 1954 to 1998';
run;
```

Review of SAS Tools

Statements

IF condition;
  tests whether the condition is true. If it is true, then SAS continues processing the current observation; if it is false, then SAS stops processing the observation and returns to the beginning of the DATA step. This type of IF statement is called a subsetting IF statement because it produces a subset of the original observations.

IF condition THEN action;
<ELSE action;>
  tests whether the condition is true; if so, then the action in the THEN clause is executed. If the condition is false and an ELSE statement is present, then the ELSE action is executed. If the condition is false and no ELSE statement is present, then execution proceeds to the next statement in the DATA step.

SET SAS-data-set (IN=variable) SAS-data-set-list;
  creates a variable that is associated with a SAS data set. The value of variable is 1 if the data set has contributed to the observation currently in the program data vector; 0 if it has not. The IN= variable exists only while the DATA step executes; it is not written to the output data set.

  You can use the option with any data set that you name in the SET, MERGE, MODIFY, or UPDATE statement, but use a different variable name for each one.

SET SAS-data-set-list END=variable;
  creates a variable whose value is 0 until the DATA step starts to process its last observation. When processing of the last observation begins, the value of variable changes to 1. The END= variable exists only while the DATA step executes; it is not written to the output data set.

  You can also use the END= option with the MERGE, MODIFY, and UPDATE statements.

Introduction to Analyzing Your SAS Session with the SAS Log

Purpose

The SAS log is a useful tool for analyzing your SAS session and programs. In this section, you will learn about the following:

- the log in relation to output
- the log structure
- the log’s default destination, which depends on the method that you use to run SAS

You will also learn how to do the following:

- write to the log
Prerequisites

You should understand the basic SAS programming concepts that are presented in the following sections:

- Chapter 1, “What Is the SAS System?,” on page 3
- Chapter 2, “Introduction to DATA Step Processing,” on page 19
- Chapter 3, “Starting with Raw Data: The Basics,” on page 43

Understanding the SAS Log

The SAS log results from executing a SAS program, and in that sense it is output. The SAS log provides a record of everything that you do in your SAS session or with your SAS program, from the names of the data sets that you have created to the number of observations and variables in those data sets. This record can tell you what statements were executed, how much time the DATA and PROC steps required, and whether your program contains errors.

As with SAS output, the destination of the SAS log varies depending on your method of running SAS and on your operating environment. The content of the SAS log varies according to the DATA and PROC steps that are executed and the options that are used. The sample log in the following output was generated by a SAS program that contains two PROC steps.* Another typical log is described in detail later in the section.

Output 22.1 A Sample SAS Log

```sas
NOTE: Libref OUT was successfully assigned as follows:
Engine: V8
Physical Name: YOUR-DATA-LIBRARY
57 options linesize=120;
58 proc sort data=out.sat_scores;
59 by test;
60 run;
61 proc plot data=out.sat_scores;
62 by test;
63 label SATscore='SAT score';
66 title1 'SAT Scores by Year, 1972-1999';
67 title3 'Separate statistics by Test Type';
68 run;
NOTE: There were 108 observations read from the data set OUT.SAT_SCORES.
```

* The DATA step that created this data set is shown in the Appendix. The data set is stored in a SAS data library referenced by the libref OUT throughout the rest of this section. For examples in which raw data is read, the raw data is shown in the Appendix.
Resolving Errors with the Log

The SAS program that generated the log in the previous example ran without errors. If the program had contained errors, then those errors would have been reflected, as part of the session, in the log. SAS generates messages for data errors, syntax errors, and programming errors. You can browse those messages, make necessary changes to your program, and then rerun it successfully.

Locating the SAS Log

The destination of your log depends on the method you are using to start, run, and exit SAS. It also depends on your operating environment and on the setting of SAS system options. The following table shows the default destination for each method of operation:

<table>
<thead>
<tr>
<th>Method of Operation</th>
<th>Destination of SAS Log</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAS windowing environment (interactive full-screen)</td>
<td>Log window</td>
</tr>
<tr>
<td>interactive line mode</td>
<td>on the terminal display, as statements are entered</td>
</tr>
<tr>
<td>noninteractive SAS programs</td>
<td>depends on the operating environment</td>
</tr>
<tr>
<td>batch jobs</td>
<td>line printer or disk file</td>
</tr>
</tbody>
</table>

Understanding the Log Structure

Detecting a Syntax Error

The following SAS program contains one DATA step and two PROC steps. However, the DATA statement has a syntax error— that is, it does not have a semicolon.

```sas
/* omitted semicolon */
data out.sat_scores4;
  infile 'your-input-file';
  input test $ 1-8 gender $ 18 year 20-23 score 25-27;
run;

proc sort data = out.sat_scores4;
  by test;
run;

proc print data = out.sat_scores4;
  by test;
run;
```
The following output shows the results. Although some variation occurs across operating environments and among methods of running SAS, the SAS log is a representative sample.

Output 22.2  Analyzing a SAS Log with Error Messages

```sas
3   /* omitted semicolon */
4     data out.sat_scores4;
5     infile 'your-input-file';
6     input test $ 1-8 gender $ 18 year 20-23
7     scores 25-27;
8     run;
9
10   proc sort data=out.sat_scores4;
11     by test;
12   run;
13
14   proc print data=out.sat_scores4;
15  run;
```

Examining the Components of a Log

The SAS log provides valuable information, especially if you have questions and need to contact your site’s SAS Support Consultant or SAS Technical Support, because the contents of the log will help them diagnose your problem.

The following list corresponds to the numbered items in the preceding log:

1. SAS statements for the DATA and PROC steps
2. error messages
3. notes, which might include warning messages.
4. notes that contain the number of observations and variables for each data set that is created.
Writing to the SAS Log

Default Output to the SAS Log

The previous sample logs show the information that appears on the log by default. You can also write to the log by using the PUT statement or the LIST statement within a DATA step. These statements can be used to debug your SAS programs.

Using the PUT Statement

The PUT statement enables you to write information that you specify, including text strings and variable values, to the log. Values can be written in column, list, formatted, or named output style.* Used as a screening device, the PUT statement can also be a useful debugging tool. For example, the following statement writes the values of all variables, including the automatic variables _ERROR_ and _N_, that are defined in the current DATA step:

```
put _all_;
```

The following program reads the data set OUT.SAT_SCORES and uses the PUT statement to write to the SAS log the records for which the score is 500 points or more. The following partial output shows that the records are written to the log immediately after the SAS statements:

```
libname out 'your-data-library';

data _null_;  
  set out.sat_scores;  
  if SATscore >= 500 then put test gender year; 
run;
```

Output 22.3  Writing to the SAS Log with the PUT Statement

```
NOTE: Libref OUT was successfully assigned as follows:
  Engine:   V8
  Physical Name: YOUR-DATA-LIBRARY

123 124 data _null_;  
125   set out.sat_scores;  
126 if SATscore >= 500 then put test gender year; 
127 run;
Math m 1972
Math m 1973
Math m 1974
.
.
```

* Named output enables you to write a variable’s name as well as its value to the SAS log. For more information, see “PUT, Named” in the Statements section of SAS Language Reference: Dictionary.
Use the LIST statement in the DATA step to list on the log the current input record. The following program shows that the LIST statement, like the PUT statement, can be very effective when combined with conditional processing to write selected information to the log:

```sas
data out.sat_scores3;
  infile 'your-input-file';
  input test $ gender $ year SATscore @@;
  if SATscore < 500 then delete;
  else list;
run;
```

When the LIST statement is executed, SAS causes the current input buffer to be printed following the DATA step. The following partial output shows the results. Note the presence of the columns ruler before the first line. The ruler indicates that input data has been written to the log. It can be used to reference column positions in the input buffer. Also notice that, because two observations are created from each input record, the entire input record is printed whenever either value of the SATscore variable from that input line is at least 500. Finally, note that the LIST statement causes the record length to be printed at the end of each line (in this case, each record has a length of 36). This feature of the LIST statement works only in operating environments that support variable-length (as opposed to fixed-length) input records.
Analyzing Your SAS Session with the SAS Log  △  Suppressing SAS Statements  343

Output 22.4  Writing to the SAS Log with the LIST Statement

NOTE: Libref OUT was successfully assigned as follows:
    Engine:  VB
    Physical Name:  YOUR-DATA-LIBRARY
248    data out.sat_scores3;
249    infile ‘YOUR-DATA-FILE’;
250    input test $ gender $ year SATscore @@;
251    if SATscore < 500 then delete;
252    else list;
253    run;
NOTE: The infile ‘YOUR-DATA-FILE’ is:
    File
        Name=YOUR-DATA-FILE,
        Owner Name=userid,Group Name=dev,
        Access Permission=rw-r--r--,
        File Size (bytes)=1998
RULE:      --------+--------+--------+--------+--------+--------+--------+--------+
1  Verbal m 1972 531  Verbal f 1972 529 36
2  Verbal m 1973 523  Verbal f 1973 521 36
3  Verbal m 1974 524  Verbal f 1974 520 36
   .
   .
53  Math m 1997 530  Math f 1997 494 36
54  Math m 1998 531  Math f 1998 496 36
NOTE: 54 records were read from the infile ‘YOUR-DATA-FILE’.
    The minimum record length was 36.
    The maximum record length was 36.
NOTE: SAS went to a new line when INPUT statement reached past the end of a line.
NOTE: The data set OUT.SAT_SCORES3 has 69 observations and 4 variables.

Suppressing Information to the SAS Log

Using SAS System Options to Suppress Log Output

There might be times when you want to prevent some information from being written to the SAS log. You can suppress SAS statements, system messages, and error messages with the NOSOURCE, NONOTES, and ERRORS= SAS system options. You can specify these options when you invoke SAS, in the OPTIONS window, or in an OPTIONS statement. In this section, the options are specified in OPTIONS statements. Note that all SAS system options remain in effect for the duration of your session or until you change them.

Suppressing SAS Statements

If you regularly execute large SAS programs without making changes, then you can use the NOSOURCE system option as follows to suppress the listing of the SAS statements to the log:

options nosource;

The NOSOURCE option causes only source lines that contain errors to be printed. You can return to the default by specifying the SOURCE system option as follows:
The SOURCE option causes all subsequent source lines to be printed. You can also control whether secondary source statements (from files that are included with a `%INCLUDE` statement) are printed on the SAS log. Specify the following statement to suppress secondary statements:

```sas
options nosource2;
```

The following OPTIONS statement causes secondary source statements to print to the log:

```sas
options source2;
```

### Suppressing System Notes

Much of the information that is supplied by the log appears as notes, including:

- copyright information
- licensing and site information
- number of observations and variables in the data set.

SAS also issues a note to tell you that it has stopped processing a step because of errors. If you do not want the notes to appear on the log, then use the NONOTES system option to suppress their printing:

```sas
options nonotes;
```

All messages starting with `NOTE:` are suppressed. You can return to the default by specifying the NOTES system option:

```sas
options notes;
```

### Limiting the Number of Error Messages

SAS prints messages for data input errors that appear in your SAS program; the default number is usually 20 but might vary from site to site. Use the `ERRORS=` system option to specify the maximum number of observations for which error messages are printed.

Note that this option limits only the error messages that are produced for incorrect data. This kind of error is caused primarily by trying to read character values for a variable that the `INPUT` statement defines as numeric.

If data errors are detected in more observations than the number you specify, then processing continues, but error messages do not print for the additional errors. For example, the following OPTIONS statement specifies printing for a maximum of five observations:

```sas
options errors=5;
```

However, as discussed in “Suppressing SAS Statements, Notes, and Error Messages” on page 345, it might be dangerous to suppress error messages.

*Note:* No option is available to eliminate warning messages.
Suppressing SAS Statements, Notes, and Error Messages

The following SAS program reads the test score data as in the other examples in this section, but in this example the character symbol for the variable GENDER is omitted. Also, the data is not sorted before using a BY statement with PROC PRINT. At the same time, for efficiency, SAS statements, notes, and error messages are suppressed.

```
libname out 'your-data-library';
options nosource nonotes errors=0;

data out.sats5;
  infile 'your-input-file';
  input test $ gender year SATscore 25-27;
run;

proc print;
  by test;
run;
```

This program does not generate output. The SAS log that appears is shown in the following output. Because the SAS system option ERRORS=0 is specified, the error limit is reached immediately, and the errors that result from trying to read GENDER as a numeric value are not printed. Also, specifying the NOSOURCE and NONOTES system options causes the log to contain no SAS statements that can be verified and no notes to explain what happened. The log does contain an error message that explains that OUT.SATS5 is not sorted in ascending sequence. This error is not caused by invalid input data, so the ERRORS=0 option has no effect on this error.

Output 22.5  Suppressing Information to the SAS Log

```
NOTE: Libref OUT was successfully assigned as follows:
  Engine:   VR
  Physical Name: YOUR-DATA-LIBRARY
370   options nosource nonotes errors=0;
ERROR: Limit set by ERRORS= option reached. Further errors of this type will not be printed.
ERROR: Data set OUT.SAT_SCORES5 is not sorted in ascending sequence. The current by-group has test = Verbal and the next by-group has test = Math.
```

Note: The NOSOURCE, NONOTES, and ERRORS= system options are used to save space. They are most useful with an already-tested program, perhaps one that is run regularly. However, as demonstrated in this section, they are not always appropriate. During development of a new program, the error messages in the log might be essential for debugging, and should not be limited. Similarly, notes should not be suppressed because they can help you pinpoint problems with a program. They are especially important if you seek help in debugging your program from someone not already familiar with it. In short, you should not suppress any information in the log until you have already executed the program without errors.

The following partial output shows the results if the previous sample SAS code is reexecuted with the SOURCE, NOTES, and ERRORS= options.
Again, this program does not generate output, but this time the log is a more effective problem-solving tool. The log includes all the SAS statements from the program as well as many informative notes. Specifically, it includes enough messages about the invalid data for the variable GENDER that the problem can be spotted. With this information, the program can be modified and rerun successfully.

### Changing the Log’s Appearance

Chapter 31, “Understanding and Customizing SAS Output: The Basics,” on page 537 shows you how to customize your output. Except in an interactive session, you can also
customize the log by using the PAGE and SKIP statements. Use the PAGE statement to move to a new page on the log; use the SKIP statement to skip lines on the log. With the SKIP statement, specify the number of lines that you want to skip; if you do not specify a number, then one line is skipped. If the number that you specify exceeds the number of lines remaining on the page, then SAS treats the SKIP statement like a PAGE statement and skips to the top of the next page. The PAGE and SKIP statements do not appear on the log.

The following output shows the result if a PAGE statement is inserted before the PROC PRINT step in the previous example:

**Output 22.7** Using the PAGE Statement

```sas
options source notes errors=20;
data out.sat_scores5;
infile '/dept/pub/doc/901/authoring/basess/miscsrc/rawdata/sat_scores.raw';
input test $ gender year score @@;
run;
NOTE: The infile 'YOUR-DATA-FILE' is:
File Name=YOUR-DATA-FILE,
Owner Name=userid,Group Name=dev,
Access Permission=rw-r--r--,
File Size (bytes)=1998
NOTE: Invalid data for gender in line 1 8-8.
RULE: ----+----1----+----2----+----3----+----4----+----5----+----6----+----7
1 Verbal m 1972 531 Verbal f 1972 529 36

NOTE: Invalid data for gender in line 2 27-27.
NOTE: Invalid data for gender in line 1 8-8.
10 Verbal m 1981 508 Verbal f 1981 496 36
test=Verbal gender=. year=1981 score=508 _ERROR_=1 _N_=19
NOTE: Invalid data for gender in line 10 27-27.
ERROR: Limit set by ERRORS= option reached. Further errors of this type will not be printed.
test=Verbal gender=. year=1981 score=496 _ERROR_=1 _N_=20
NOTE: 54 records were read from the infile
'/dept/pub/doc/901/authoring/basess/miscsrc/rawdata/sat_scores.raw'.
The minimum record length was 36.
The maximum record length was 36.
NOTE: SAS went to a new line when INPUT statement reached past the end of a line.
NOTE: The data set OUT.SAT_SCORES5 has 108 observations and 4 variables.

proc print;
by test;
run;
ERROR: Data set OUT.SAT_SCORES5 is not sorted in ascending sequence. The current by-group has test = Verbal and the next by-group has test = Math.
NOTE: The SAS System stopped processing this step because of errors.
NOTE: There were 55 observations read from the data set OUT.SAT_SCORES5.
```
Statements

The following statements are used to write to the log and to change the log’s appearance:

LIST;
lists on the SAS log the contents of the input buffer for the observation being processed.

PAGE;
skips to a new page on the log.

PUT <variable-list> | <_ALL_>;
writes lines to the SAS log, the output file, or any file that is specified in a FILE statement. If no FILE statement has been executed in this iteration of the DATA step, then the PUT statement writes to the SAS log. Variable-list names the variables whose values are to be written, and _ALL_ signifies that the values of all variables, including _ERROR_ and _N_, are to be written to the log.

SKIP <n>;
on the SAS log, skips the number of lines that you specify with the value n. If the number is greater than the number of lines remaining on the page, then SAS treats the SKIP statement like a PAGE statement and skips to the top of the next page.

System Options

The following system options are used to suppress information to the log. In this section, they are specified in OPTIONS statements.

ERRORS=n
specifies the maximum number of observations for which error messages about data input errors are printed.

NOTES|NONOTES
controls whether notes are printed to the log.

SOURCE|NOSOURCE
controls whether SAS statements are printed to the log.

SOURCE2|NOSOURCE2
controls whether secondary SAS statements from files included by %INCLUDE statements are printed to the log.

Introduction to Directing SAS Output and the SAS Log

Purpose

The SAS provides several methods to direct SAS output and the SAS log to different destinations. In this section, you will learn how to use the following SAS language elements:

- PRINTTO procedure from within a program or session to route DATA step output, the SAS log, or procedure output from their default destinations to another destination
- FILE command, in the SAS windowing environment, to store the contents of the Log and Output windows in files
- PRINT= and LOG= system options when you invoke SAS to redefine the destination of the log and output for an entire SAS session
Prerequisites

Before proceeding with this section, you should be familiar with the following features and concepts:

- creating DATA step or PROC step output
- locating the log and procedure output
- referencing external files

Input File and SAS Data Set for Examples

The examples in this section are based on data from a university entrance exam called the Scholastic Aptitude Test, or SAT. The data is provided in one input file that contains the average SAT scores of entering university classes from 1972 to 1998.* The input file has the following structure:

Verbal m 1972 531
Verbal f 1972 529
Verbal m 1973 523
Verbal f 1973 521
Verbal m 1974 524
Verbal f 1974 520
Verbal m 1975 515
Verbal f 1975 509
Verbal m 1976 511
Verbal f 1976 508

The input file contains the following values from left to right:

- type of SAT exam
- gender of student
- year of the exam
- average exam score of the first-year class

The following program creates the data set that this section uses:

```sas
data sat_scores;
  input Test $ Gender $ Year SATscore @@;
datalines;
Verbal m 1972 531 Verbal f 1972 529
Verbal m 1973 523 Verbal f 1973 521
Verbal m 1974 524 Verbal f 1974 520
Verbal m 1975 515 Verbal f 1975 509
Verbal m 1976 511 Verbal f 1976 508
...
Math m 1996 527 Math f 1996 492
Math m 1997 530 Math f 1997 494
Math m 1998 531 Math f 1998 496
;
```

* See Chapter 31, “Understanding and Customizing SAS Output: The Basics,” on page 537 for a complete listing of the input data.
Routing the Output and the SAS Log with PROC PRINTTO

Routing Output to an Alternate Location

You can use the PRINTTO procedure to redirect SAS procedure output from the listing destination to an alternate location. These locations are:

- a permanent file
- a SAS catalog entry
- a dummy file, which serves to suppress the output

After PROC PRINTTO executes, all procedure output is sent to the alternate location until you execute another PROC PRINTTO statement or until your program or session ends.

The default destination for the procedure output depends on how you configure SAS to handle output. For more information, see the discussion of SAS output in Chapter 31, “Understanding and Customizing SAS Output: The Basics,” on page 537.

Note: If you used the Output Delivery System (ODS) to close the listing destination, then PROC PRINTTO does not receive any output to redirect. However, the procedure results still go to the destination that you specified with ODS.

You use the PRINT= option in the PROC PRINTTO statement to specify the name of the file or SAS catalog that will contain the procedure output. If you specify a file, then either use the complete name of the file in quotation marks or use a fileref for the file. (See “Using External Files in Your SAS Job” on page 38 for more information about filerefs and filenames.) You can also specify the NEW option in the PROC PRINTTO statement so that SAS replaces the previous contents of the output file. Otherwise, SAS appends the output to any output that is currently in the file.

To route output to an alternate file, insert a PROC PRINTTO step in the program before the PROC step that generates the procedure output. The following program routes the output from PROC PRINT to an external file:

```
proc printto print='alternate-output-file' new;
run;
```

```
proc print data=sat_scores;
   title 'Mean SAT Scores for Entering University Classes';
run;
```

```
proc printto;
run;
```

After the PROC PRINT step executes, alternate-output-file contains the procedure output. The second PROC PRINTTO step redirects output back to its default destination.

The PRINTTO procedure does not produce the output. Instead it tells SAS to route the results of all subsequent procedures until another PROC PRINTTO statement executes. Therefore, the PROC PRINTTO statement must precede the procedure whose output you want to route.

Figure 23.1 on page 354 shows how SAS uses PROC PRINTTO to route procedure output. You can also use PROC PRINTTO multiple times in a program so that output from different steps of a SAS job is stored in different files.
Routing the SAS Log to an Alternate Location

You can use the PRINTTO procedure to redirect the SAS log to an alternate location. The location can be one of the following:

- a permanent file
- a SAS catalog entry
- a dummy file to suppress the log

After PROC PRINTTO executes, the log is sent either to a permanent external file or to a SAS catalog entry until you execute another PROC PRINTTO statement, or until your program or session ends.

You use the LOG= option in the PROC PRINTTO statement to specify the name of the file or SAS catalog that will contain the log. If you specify a file, then either use the complete name of the file in quotation marks or use a fileref for the file. You can also specify the NEW option in the PROC PRINTTO statement so that SAS replaces the previous contents of the file. Otherwise, SAS appends the log to any log that is currently in the file.

The following program routes the SAS log to an alternate file:

```sas
proc printto log='alternate-log-file';
run;
```

After the PROC PRINT step executes, `alternate-log-file` contains the SAS log. The contents of this file are shown in the following output:
Output 23.1 Using the PRINTTO Procedure to Route the SAS Log to an Alternate File

```sas
8     data sat_scores;
9     input Test $ Gender $ Year SATscore @@;
10    datalines;
NOTE: SAS went to a new line when INPUT statement reached past the end of a line.
NOTE: The data set WORK.SAT_SCORES has 108 observations and 4 variables.
65    ;
66    proc print data=sat_scores;
67    title 'Mean SAT Scores for Entering University Classes';
68    run;
NOTE: There were 108 observations read from the dataset WORK.SAT_SCORES.
69    proc printto; run;
```

Restoring the Default Destination

Specify the PROC PRINTTO statement with no argument when you want to route the log and the output back to their default destinations:

```sas
proc printto;
run;
```

You might want to return only the log or only the procedure output to its default destination. The following PROC PRINTTO statement routes only the log back to the default destination:

```sas
proc printto log=log;
run;
```

The following PROC PRINTTO statement routes only the procedure output to the default destination:

```sas
proc printto print=print;
run;
```

Storing the Output and the SAS Log in the SAS Windowing Environment

Understanding the Default Destination

Within the SAS windowing environment, the default destination for most procedure output is a monospace listing that appears in the Output window. However, you can use the Output Delivery System (ODS) to change which destinations are opened and closed.

Each time you execute a procedure within a single session, SAS appends the output to the existing output. To view the results, you can

- scroll the Output window, which contains the output in the order in which you generated it
- use the Results window to select a pointer that is a link to the procedure output.

The SAS windowing environment interacts with certain aspects of the ODS to format, control, and manage your output.

In the SAS windowing environment, the default destination for the SAS log messages is the Log window. When you execute a procedure, SAS appends the log messages to the existing log messages in the Log window. You can scroll the Log window to see the results. To print your log messages, execute the PRINT command. To clear the contents
of the Log window, execute the CLEAR command. When your session ends, SAS automatically clears the window.

Within the SAS windowing environment, you can use the PRINTTO procedure to route log messages or procedure output to a location other than the default location, just as you can in other methods of operation. For details, see “Routing the Output and the SAS Log with PROC PRINTTO” on page 353. You can also use ODS to change the destination of the procedure output.

For additional information about using ODS, viewing procedure output, and changing the destination of the procedure output, see Chapter 31, “Understanding and Customizing SAS Output: The Basics,” on page 537.

### Storing the Contents of the Output and Log Windows

If you want to store a copy of the contents of the Output or Log window in a file, then use the FILE command. On the command line, specify the FILE command followed by the name of the file:

```
file 'file-to-store-contents-of-window'
```

SAS has a built-in safeguard that prevents you from accidentally overwriting a file. If you inadvertently specify an existing file, then a dialog box appears. The dialog box asks you to choose a course of action, provides you with information, and might prevent you from overwriting the file by mistake. You are asked whether to:

- replace the contents of the file
- append the contents of the file
- cancel the FILE command

---

### Redefining the Default Destination in a Batch or Noninteractive Environment

#### Determining the Default Destination

Usually, in a batch or noninteractive environment, SAS routes procedure output to the listing file and routes the SAS log to a log file. These files are usually defined by your installation and are created automatically when you invoke SAS. Contact your SAS Support Consultant if you have questions pertaining to your site.

#### Changing the Default Destination

If you want to redefine the default destination for procedure output, then use the PRINT= system option. If you want to redefine the default destination for the SAS log, then use the LOG= system option. You specify these options only at initialization.

**Operating Environment Information:** The way that you specify output destinations when you use SAS system options depends on your operating environment. For details, see the SAS documentation for your operating environment.

Options that you must specify at initialization are called configuration options. The configuration options affect the following:

- the initialization of the SAS System
- the hardware interface
In contrast to other SAS system options, which affect the appearance of output, file handling, use of system variables, or processing of observations, you cannot change configuration options in the middle of a program. You specify configuration options when SAS is invoked, either in the configuration file or in the SAS command.

**Understanding the Configuration File**

The configuration file is a special file that contains configuration options as well as other SAS system options and their settings. Each time you invoke SAS, the settings of the configuration file are examined. You can specify the options in the configuration file in the same format as they are used in the SAS command for your operating environment. For example, under UNIX this file's contents might include the following:

```
WORK=WORK
SASUSER=SASUSER
EXPLORER
```

SAS automatically sets the options as they appear in the configuration file. If you specify options both in the configuration file and in the SAS command, then the options are concatenated. If you specify the same option in the SAS command and in the configuration file, then the setting in the SAS command overrides the setting in the file. For example, specifying the NOEXPLORER option in the SAS command overrides the EXPLORER option in the configuration file and tells SAS to start your session without displaying the Explorer window.

**Review of SAS Tools**

**PROC PRINTTO Statement Options**

```
PROC PRINTTO <PRINT='alternate-output-file'> <LOG='alternate-log-file'> <NEW>;
```

- **LOG='alternate-log-file'** identifies the location and routes the SAS log to this alternate location.
- **NEW** specifies that the current log or procedure output writes over the previous contents of the file.
- **PRINT='alternate-output-file'** identifies the location and routes the procedure output to this alternate location.
SAS Windowing Environment Commands

CLEAR
   clears the contents of a window, as specified.

FILE <file-to-store-contents-of-window>
   routes a copy of the contents of a window to the file that you specify; the original contents remain in place.

PRINT
   prints the contents of the window.

SAS System Options

LOG=system-filename
   redefines the default destination for the SAS log to the file named system-filename.

PRINT=system-filename
   redefines the default destination for procedure output to the file named system-filename.

Introduction to Diagnosing and Avoiding Errors

**Purpose**

In this section, you will learn how to diagnose errors in your programs by learning the following:

- how the SAS Supervisor checks a program for errors
- how to distinguish among the types of errors
- how to interpret the notes, warning messages, and error messages in the log
- what to check for as you develop a program

**Prerequisites**

You should understand the concepts that are presented in the following sections:

- Chapter 2, “Introduction to DATA Step Processing,” on page 19
- Chapter 3, “Starting with Raw Data: The Basics,” on page 43
- Chapter 6, “Understanding DATA Step Processing,” on page 97
- Chapter 22, “Analyzing Your SAS Session with the SAS Log,” on page 337

Understanding How the SAS Supervisor Checks a Job

To better understand the errors that you make so that you can avoid others, it is important to understand how the SAS Supervisor checks a job. The SAS Supervisor is
the part of SAS that is responsible for executing SAS programs. To check the syntax of
a SAS program, the SAS Supervisor does the following:
- reads the SAS statements and data
- translates the program statements into executable machine code or intermediate
code
- creates data sets
- calls SAS procedures, as requested
- prints error messages
- ends the job

The SAS Supervisor knows
- the forms and types of statements that can be present in a DATA step
- the types of statements and the options that can be present in a PROC step

To process a program, the SAS Supervisor scans all the SAS statements and breaks
each statement into words. Each word is processed separately; when all the words in a
step are processed, the step is executed. If the SAS Supervisor detects an error, then it
flags the error at its location and prints an explanation. The SAS Supervisor assumes
that anything it does not recognize is an error.

Understanding How SAS Processes Errors

When SAS detects an error, it usually underlines the error or underlines the point at
which it detects the error, identifying the error with a number. Each number is
uniquely associated with an error message. Then SAS enters syntax check mode. SAS
reads the remaining program statements, checks their syntax, and underlines
additional errors if necessary.

In a batch or noninteractive program, an error in a DATA step statement causes SAS
to remain in syntax check mode for the rest of the program. It does not execute any
more DATA or PROC steps that create external files or SAS data sets. Procedures that
read from SAS data sets execute with 0 observations, and procedures that do not read
SAS data sets execute normally. A syntax error in a PROC step usually affects only
that step. At the end of the step, SAS writes a message in the SAS log for each error
that is detected.

Distinguishing Types of Errors

SAS recognizes four kinds of errors:
- syntax errors
- execution-time errors
- data errors
- semantic errors

Syntax errors are errors made in the SAS statements of a program. They include
misspelled keywords, missing or invalid punctuation, and invalid statement or data set
options. SAS detects syntax errors as it compiles each DATA or PROC step.
Execution-time errors cause a program to fail when it is submitted for execution.
Most execution-time errors that are not serious produce notes in the SAS log, but the
program is allowed to run to completion. For more serious errors, however, SAS issues
error messages and stops all processing.
Data errors are actually a type of execution-time error. They occur when the raw data that you are analyzing with a SAS program contains invalid values. For example, a data error occurs if you specify numeric variables in the INPUT statement for character data. Data errors do not cause a program to stop but instead generate notes in the SAS log.

Semantic errors, another type of execution-time error, occur when the form of a SAS statement is correct, but some elements are not valid in that usage. Examples include the following:
- specifying the wrong number of arguments for a function
- using a numeric variable name where only character variables are valid
- using a libref that has not yet been assigned

Diagnosing Errors

Examples in This Section

This section uses nationwide test results from the Scholastic Aptitude Test (SAT) for university-bound students from 1972 through 1998* to show what happens when errors occur.

Diagnosing Syntax Errors

The SAS Supervisor detects syntax errors as it compiles each step, and then SAS does the following:
- prints the word ERROR
- identifies the error’s location
- prints an explanation of the error.

In the following program, the CHART procedure is used to analyze the data. Note that a semicolon in the DATA statement is omitted, and the keyword INFILE is misspelled.

```sas
/* omitted semicolon and misspelled keyword */
libname out 'your-data-library';

data out.error1
  infill 'your-input-file';
  input test $ gender $ year SATscore @@;
run;

proc chart data = out.error1;
  hbar test / sumvar=SATscore type=mean group=gender discrete;
run;
```

* See the Appendix for a complete listing of the input data that is used to create the data sets in this section.
The following output shows the result of the two syntax errors:

**Output 24.1  Diagnosing Syntax Errors**

```plaintext
NOTE: Libref OUT was successfully assigned as follows:
  Engine: V8
  Physical Name: ‘YOUR-DATA-LIBRARY’
data out.error1
infill ‘YOUR-INPUT-FILE’;
input test $ gender $ year SATscore @@;
run;
ERROR: No CARDS or INFILE statement.
ERROR: Memtype field is invalid.
NOTE: The SAS System stopped processing this step because of errors.
WARNING: The data set OUT.ERROR1 may be incomplete. When this step was stopped there were 0 observations and 4 variables.
WARNING: Data set WORK.INFILL may be incomplete. When this step was stopped there were 0 observations and 4 variables.
WARNING: Data set WORK.INFILL may not be replaced because this step was stopped.
proc chart data=out.error1;
hbar test / sumvar=SATscore type=mean group=gender discrete;
run;
NOTE: No observations in data set OUT.ERROR1.
```

As the log indicates, SAS recognizes the keyword DATA and attempts to process the DATA step. Because the DATA statement must end with a semicolon, SAS assumes that INFILL is a data set name and that two data sets are being created: OUT.ERROR1 and WORK.INFILL. Because it considers INFILL the name of a data set, it does not recognize it as part of another statement and, therefore, does not detect the spelling error. Because the quoted string is invalid in a DATA statement, SAS stops processing here and creates no observations for either data set.

SAS attempts to execute the program logically based on the statements that it contains, according to the steps outlined earlier in this section. The second syntax error, the misspelled keyword, is never recognized because SAS considers the DATA statement to be in effect until a semicolon ends the statement. The point to remember is that when multiple errors are made in the same program, not all of them might be detected the first time the program is executed, or they might be flagged differently in a group than if they were made alone. You might find that one correction uncovers another error or at least changes its explanation in the log.

To illustrate this point, the previous program is reexecuted with the semicolon added to the DATA statement. An attempt to correct the misspelled keyword simply introduces a different spelling error, as follows.

```plaintext
/* misspelled keyword */
libname out 'your-data-library';
data out.error2;
  unfile 'your-input-file';
  input test $ gender $ year SATscore @@;
run;
proc chart data = out.error1;
hbar test / sumvar=SATscore type=mean group=gender discrete;
run;
```
Diagnosing and Avoiding Errors

Diagnosing Execution-Time Errors

Several types of errors are detected at execution time. Execution-time errors include the following:

- illegal mathematical operations
- observations out of order for BY-group processing
- an incorrect reference in an INFILE statement (for example, misspelling or otherwise incorrectly stating the external file)

When the SAS Supervisor encounters an execution-time error, it does the following:

- prints a note, warning, or error message, depending on the seriousness of the error
- in some cases, lists the values that are stored in the program data vector
- continues or stops processing, depending on the seriousness of the error

If the previous program is rerun with the correct spelling for INFILE but with a misspelling of the filename in the INFILE statement, then the error is detected at execution time and the data is not read.

/* misspelled file in the INFILE statement */
libname out 'your-data-library';

data out.error3;
  infile 'an-incorrect-filename';
  input test $ gender $ year SATscore @@;
run;

proc chart data = out.error3;
hbar test / sumvar=SATscore type=mean group=gender discrete;
run;

As the SAS log in the following output indicates, SAS cannot find the file. SAS stops processing because of errors and creates no observations in the data set.

**Output 24.3 Diagnosing an Error in the INFILE Statement**

```
NOTE: Libref OUT was successfully assigned as follows:
  Engine: V8
  Physical Name: YOUR-DATA-LIBRARY
10 data out.error3;
11 infile 'AN-INCORRECT-FILENAME';
12 input test $ gender $ year SATscore @@;
13 run;
ERROR: Physical file does not exist, AN-INCORRECT-FILENAME
NOTE: The SAS System stopped processing this step because of errors.
WARNING: The data set OUT.ERROR3 may be incomplete. When this step was stopped there were 0 observations and 4 variables.
14 15 proc chart data=out.error3;
16  hbar test / sumvar=SATscore type=mean group=gender discrete;
17  run;
NOTE: No observations in data set OUT.ERROR3.
```

### Diagnosing Data Errors

When SAS detects data errors during execution, it continues processing and then does the following:

- prints a note that describes the error
- lists the values that are stored in the input buffer
- lists the values that are stored in the program data vector

Note that the values listed in the program data vector include two variables created automatically by SAS:

- `_N_` counts the number of times the DATA step iterates.
- `_ERROR_` indicates the occurrence of an error during an execution of the DATA step. The value that is assigned to the variable `_ERROR_` is 0 when no error is encountered and 1 when an error is encountered.

These automatic variables are assigned temporarily to each observation and are not stored with the data set. The raw data that is shown here is read by a program that uses formats to determine how variable values are printed:

```
verbal       m 1967 463
verbal       f 1967 468
verbal       m 1970 459
verbal       f 1970 461
math         m 1967 514
math         f 1967 467
math         m 1970 509
math         f 1970 509
```
However, the data is not aligned correctly in the columns that are described by the INPUT statement. The sixth data line is shifted two spaces to the right, and the rest of the data lines, except for the first, are shifted one space to the right, as shown by a comparison of the raw data with the following program:

```sas
/* data in wrong columns */
libname out 'your-data-library';
proc format;
  value xscore . ='accurate scores unavailable';
run;

data out.error4;
  infile 'your--input-file';
  input test $ 1-8 gender $ 18 year 20-23 score 25-27;
  format score xscore.;
run;

proc print data = out.error4;
  title 'Viewing Incorrect Output';
run;
```

The following output shows the results of the SAS program:

<table>
<thead>
<tr>
<th>Obs</th>
<th>test</th>
<th>gender</th>
<th>year</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

</tr>
</tbody>
</table>

This program generates output, but it is not the expected output. The first observation appears to be correct, but subsequent observations have the following problems:

- The values for the variable GENDER are missing.
- Only the first three digits of the value for the variable YEAR are shown except in the sixth observation where a missing value is indicated.
- The third digit of the value for the variable SCORE is missing, again except in the sixth observation, which does show the assigned value for the missing value.
The SAS log in the following output contains an explanation:

**Output 24.5  Diagnosing Data Errors**

```
NOTE: Libref OUT was successfully assigned as follows:
  Engine: V8
  Physical Name: YOUR–DATA–LIBRARY
10 proc format;
NOTE: Format xscore has been output.
11 value xscore . = 'accurate scores unavailable';
12 run;
13
14 data out.error4;
15 infile 'YOUR–INPUT–FILE';
16 input test $ 1-8 gender $ 18 year 20-23
17 score 25-27;
18 format score xscore.;
19 run;
NOTE: The infile 'YOUR–INPUT–FILE' is:
  File Name=YOUR–INPUT–FILE,
  Owner Name=userid,Group Name=dev,
  Access Permission=rw–r–r–
  File Size (bytes)=233

NOTE: Invalid data for year in line 6 20–23.
NOTE: Invalid data for score in line 6 25–27.
RULE: ----+----1----+----2----+----3----+----4----+----5----+----6----+----7
  6 math f 1967 467 29
test=math gender= year=. score=accurate scores unavailable _ERROR_=1 _N_=6
NOTE: 9 records were read from the infile
  'YOUR–INPUT–FILE'.
The minimum record length was 0.
The maximum record length was 29.
NOTE: SAS went to a new line when INPUT statement reached past the end of a
  line.
NOTE: The data set OUT.ERROR4 has 8 observations and 4 variables.
20 21 proc print data=out.error4;
22 title 'Viewing Incorrect Output';
23 run;
NOTE: There were 8 observations read from the data set OUT.ERROR4.
```

The errors are flagged, starting with the first message that line 6 contains invalid data for the variable YEAR. The rule indicates that input data has been written to the log. SAS lists on the log the values that are stored in the program data vector. The following lines from the log indicate that SAS has encountered an error:

```
NOTE: Invalid data for year in line 6 20–23.
NOTE: Invalid data for score in line 6 25–27.
RULE: ----+----1----+----2----+----3----+----4----+----5----+----6----+----7
  6 math f 1967 467 29
test=math gender= year=. score=accurate scores unavailable _ERROR_=1 _N_=6
```

Missing values are shown for the variables GENDER and YEAR. The NOTEs in the log indicate that the sixth line of input contained the error.

To debug the program, either the raw data can be repositioned or the INPUT statement can be rewritten, remembering that all the data lines were shifted at least one space to the right. The variable TEST was unaffected, but the variable GENDER was completely removed from its designated field; therefore, SAS reads the variable GENDER as a missing value. In the sixth observation, for which the data was shifted right an additional space, the character value for GENDER occupied part of the field for the numeric variable YEAR. When SAS encounters invalid data, it treats the value as a...
missing value but also notes on the log that the data is invalid. The important point to remember is that SAS can use only the information that you provide to it, not what you intend to provide to it.

---

**Using a Quality Control Checklist**

If you follow some basic guidelines as you develop a program, then you can avoid common errors. Use the following checklist to flag and correct common mistakes before you submit your program.

- **Check the syntax of your program.** In particular, check the following:
  - All SAS statements end with a semicolon; be sure you have not omitted any semicolons or accidentally typed the wrong character.
  - Any starting and ending quotation marks must match; you can use either single or double quotation marks.
  - Most SAS statements begin with a SAS keyword. (Exceptions are assignment statements and sum statements.) Be sure you have not misspelled or omitted any of the keywords.
  - Every DO and SELECT statement must be followed by an END statement.

- **Check the order of your program.** SAS usually executes the statements in a DATA step one by one, in the order they appear. After executing the DATA step, SAS moves to the next step and continues in the same fashion. Be sure that all the SAS statements appear in order so that SAS can execute them properly. For example, an INFILE statement, if used, must precede an INPUT statement.

  Also, be sure to end steps with the RUN statement. This is especially important at the end of your program because the RUN statement causes the previous step to be executed.

- **Check your INPUT statement and your data.** SAS classifies all variables as either character or numeric. The assignment in the INPUT statement as either character or numeric must correspond to the actual values of variables in your data. Also, SAS allows for list, column, formatted, or named input. The method of input that you specify in the INPUT statement must correspond with the actual arrangement of raw data.

---

**Learning More**

INFILE statement options

*SAS Language Reference: Dictionary* contains information about using the MISSOVER and STOPOVER options in the INFILE statement as debugging tools. The MISSOVER option prevents a SAS program from going past the end of a line to read values with list input if it does not find values in the current line for all INPUT statement variables. Then SAS assigns missing values to variables for which no values appear on the current input line. The STOPOVER option stops processing the DATA step when an INPUT statement using list input reaches the end of the current record without finding values for all variables in the statement. Then SAS sets _ERROR_ to 1, stops building the data set, and prints an incomplete data line.

Introduction to Producing Detail Reports with the PRINT Procedure

**Purpose**

*Detail reports*, or simple data listings, contain one row for every observation that is selected for inclusion in the report. A detail report provides information about every record that is processed. For example, a detail report for a sales company includes all the information about every sale made during a particular quarter of the year. The PRINT procedure is one of several report writing tools that you can use to create a variety of detail reports.

In this section, you will learn how to do the following:

- produce simple reports by using a few basic PROC PRINT options and statements
- produce enhanced reports by adding additional statements that format values, sum columns, group observations, and compute totals
- customize the appearance of reports by adding titles, footnotes, and column labels
- substitute text by using macro variables

**Prerequisites**

Before proceeding with this section, you should be familiar with the following features and concepts:

- the assignment statement
- the OUTPUT statement
- the SORT procedure
- the BY statement
- the location of the procedure output

**Input File and SAS Data Sets for Examples**

The examples in this section use one input file* and five SAS data sets. The input file contains sales records for a company, TruBlend Coffee Makers, that distributes the coffee machines. The file has the following structure:

```plaintext
01 1 Hollingsworth Deluxe 260 49.50
01 1 Garcia Standard 41 30.97
01 1 Hollingsworth Deluxe 330 49.50
01 1 Jensen Standard 1110 30.97
01 1 Garcia Standard 715 30.97
01 1 Jensen Deluxe 675 49.50
```

* See the “Data Set YEAR_SALES” on page 717 for a complete listing of the input data.
Producing Detail Reports with the PRINT Procedure

Showing All the Variables

The input file contains the following values from left to right:
- the month that a sale was made
- the quarter of the year that a sale was made
- the name of the sales representative
- the type of coffee maker sold (standard or deluxe)
- the number of units sold
- the price of each unit in US dollars

The first of the five SAS data sets is named YEAR-SALES. This data set contains all the sales data from the input file, and a new variable named AmountSold, which is created by multiplying Units by Price.

The following program creates the five SAS data sets that this section uses:

```sas
data year_sales;
  infile 'your-input-file';
  input Month $ Quarter $ SalesRep $14. Type $ Units Price;
  AmountSold = Units * Price;
run;
```

Creating Simple Reports

Showing All the Variables

By default, the PRINT procedure generates a simple report that shows the values of all the variables and the observations in the data set. For example, the following PROC PRINT step creates a report for the first sales quarter:

```sas
options linesize=80 pageno=1 nodate;
proc print data=qtr01;
  title 'TruBlend Coffee Makers Quarterly Sales Report';
run;
```

The following output shows the values of all the variables for all the observations in QTR01:

```
02  1    Jensen    Standard    45       30.97
02  1    Garcia   Deluxe      10       49.50
...
12  4    Hollingsworth Deluxe 125      49.50
12  4    Jensen    Standard    1254     30.97
12  4    Hollingsworth Deluxe 175      49.50
```
Labeling the Observation Column

A quick way to modify the report is to label the observation number (Obs column). The following SAS program includes the OBS= option in the PROC PRINT statement to change the column label for the Obs column:

```sas
options linesize=80 pageno=1 nodate;
proc print data=qtr01 obs='Observation Number';
   title 'TruBlend Coffee Makers Quarterly Sales Report';
run;
```

The following output shows the report:

```

</tr>
</tbody>
</table>
```

The following list corresponds to the numbered items in the preceding output:

1. The Obs column identifies each observation by a number. By default, SAS automatically displays the observation number at the beginning of each row.
2. The top of the report has a title and a page number.

The TITLE statement in the PROC PRINT step produces the title. “Creating Customized Reports” on page 391 discusses the TITLE statement in more detail. For now, be aware that all the examples include at least one TITLE statement that produces a descriptive title similar to the one in this example.

The content of the report is very similar to the contents of the original data set QTR01; however, the report is easy to produce and to enhance.

</table>

Suppressing the Observation Column

A quick way to simplify the report is to suppress the observation number (Obs column). Usually it is unnecessary to identify each observation by number. (In some cases, you might want to show the observation numbers.) The following SAS program includes the NOOBS option in the PROC PRINT statement to suppress the Obs column:

```sas
options linesize=80 pageno=1 nodate;
proc print data=qtr01 noobs;
  title 'TruBlend Coffee Makers Quarterly Sales Report';
run;
```

The following output shows the report:
Emphasizing a Key Variable

Understanding the ID Statement

To emphasize a key variable in a data set, you can use the ID statement in the PROC PRINT step. When you identify a variable in the ID statement, PROC PRINT displays the values of this variable in the first column of each row of the report. Highlighting a key variable in this way can help answer questions about your data. For example, the report can answer this question: “For each sales representative, what are the sales figures for the first quarter of the year?” The following two examples demonstrate how to answer this question quickly using data that is unsorted and sorted.

Using an Unsorted Key Variable

To produce a report that emphasizes the sales representative, the PROC PRINT step includes an ID statement that specifies the variable SalesRep. The revised program follows:

```plaintext
options linesize=80 pageno=1 nodate;
proc print data=qtr01;
    id SalesRep;
    title 'TruBlend Coffee Makers Quarterly Sales Report';
run;
```

Because the ID statement automatically suppresses the observation numbers, the NOOBS option is not needed in the PROC PRINT statement.

The following output shows the new report:

<table>

Notice that the names of the sales representatives are not in any particular order. The report will be easier to read when the observations are grouped together in alphabetical order by sales representative.

### Using a Sorted Key Variable

If your data is not already ordered by the key variable, then use PROC SORT to sort the observations by this variable. If you do not specify an output data set, then PROC SORT permanently changes the order of the observations in the input data set.

The following program shows how to alphabetically order the observations by sales representative:

```plaintext
options linesize=80 pageno=1 nodate;

proc sort data=qtr01;
  by SalesRep;
run;

proc print data=qtr01;
  id SalesRep;
  title 'TruBlend Coffee Makers Quarterly Sales Report';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. A PROC SORT step precedes the PROC PRINT step. PROC SORT orders the observations in the data set alphabetically by the values of the BY variable and overwrites the input data set.
2. A BY statement sorts the observations alphabetically by SalesRep.
3. An ID statement identifies the observations with the value of SalesRep rather than with the observation number. PROC PRINT uses the sorted order of SalesRep to create the report.
The following output shows the report:

Output 25.5 Using the ID Statement with a Sorted Key Variable

<table>

</tbody>
</table>

Now, the report clearly shows what each sales representative sold during the first three months of the year.

Reporting the Values of Selected Variables

By default, the PRINT procedure reports the values of all the variables in the data set. However, to control which variables are shown and in what order, add a VAR statement to the PROC PRINT step.

For example, the information for the variables Quarter, Type, and Price is unnecessary. Therefore, the report needs to show only the values of the variables that are specified in the following order:

SalesRep Month Units AmountSold

The following program adds the VAR statement to create a report that lists the values of the four variables in a specific order:

```
options linesize=80 pageno=1 nodate;
proc print data=qtr01 noobs;
  var SalesRep Month Units AmountSold;
  title 'TruBlend Coffee Makers Quarterly Sales Report';
run;
```

This program does not include the ID statement. It is unnecessary to identify the observations because the variable SalesRep is the first variable that is specified in the VAR statement. The NOOBS option in the PROC PRINT statement suppresses the observation numbers so that the sales representative appears in the first column of the report.

The following output shows the report:
Output 25.6  Showing Selected Variables

<table>
<thead>
<tr>
<th>SalesRep</th>

</tr>
</tbody>
</table>

The report is concise because it contains only those variables that are specified in the VAR statement. The next example revises the report to show only those observations that satisfy a particular condition.

Selecting Observations

Understanding the WHERE Statement

To select observations that meet a particular condition from a data set, use a WHERE statement. The WHERE statement subsets the input data by specifying certain conditions that each observation must meet before it is available for processing.

The condition that you define in a WHERE statement is an arithmetic or logical expression that generally consists of a sequence of operands and operators.* To compare character values, you must enclose them in single or double quotation marks and the values must match exactly, including capitalization. You can also specify multiple comparisons that are joined by logical operators in the WHERE statement.

Using the WHERE statement might improve the efficiency of your SAS programs because SAS is not required to read all the observations in the input data set.

Making a Single Comparison

You can select observations based on a single comparison by using the WHERE statement. The following program uses a single comparison in a WHERE statement to produce a report that shows the sales activity for a sales representative named Garcia:

```sas
options linesize=80 pageno=1 nodate;
```

* The construction of the WHERE statement is similar to the construction of IF and IF-THEN statements.
In the WHERE statement, the value *Garcia* is enclosed in quotation marks because `SalesRep` is a character variable. In addition, the letter G in the value *Garcia* is uppercase so that it matches exactly the value in the data set QTR01.

The following output shows the report:

**Output 25.7  Making a Single Comparison**

```
<table>
<thead>
<tr>
<th>Sales Rep</th>
<th>Month</th>
<th>Units</th>
<th>Amount Sold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>01</td>
<td>41</td>
<td>1269.77</td>
</tr>
<tr>
<td>Garcia</td>
<td>01</td>
<td>715</td>
<td>35392.50</td>
</tr>
<tr>
<td>Garcia</td>
<td>02</td>
<td>2045</td>
<td>63333.65</td>
</tr>
<tr>
<td>Garcia</td>
<td>02</td>
<td>10</td>
<td>495.00</td>
</tr>
<tr>
<td>Garcia</td>
<td>02</td>
<td>40</td>
<td>1238.80</td>
</tr>
<tr>
<td>Garcia</td>
<td>02</td>
<td>98</td>
<td>3035.06</td>
</tr>
<tr>
<td>Garcia</td>
<td>03</td>
<td>118</td>
<td>3654.46</td>
</tr>
<tr>
<td>Garcia</td>
<td>03</td>
<td>310</td>
<td>9600.70</td>
</tr>
</tbody>
</table>
```

**Making Multiple Comparisons**

You can also select observations based on two or more comparisons by using the WHERE statement. However, when you use multiple WHERE statements in a PROC step, then only the last statement is used. You can create a compound comparison by using AND operator. For example, the following WHERE statement selects observations where Garcia sold only the deluxe coffee maker:

```
where SalesRep = 'Garcia' and Type='Deluxe'
```

The following program uses two comparisons in a WHERE statement to produce a report that shows sales activities for a sales representative (Garcia) during the first month of the year:

```
options linesize=80 pageno=1 nodate;

proc print data=year_sales noobs;
  var SalesRep Month Units AmountSold;
  where SalesRep='Garcia' and Month='01';
  title 'TruBlend Coffee Makers Monthly Sales for Garcia';
run;
```

The WHERE statement uses the logical AND operator. Therefore, both comparisons must be true for PROC PRINT to include an observation in the report.

The following output shows the report:
Output 25.8  Making Two Comparisons

You might also want to select observations that meet at least one of several conditions. The following program uses two comparisons in the WHERE statement to create a report that shows every sale during the first quarter of the year that was greater than 500 units or more than $20,000:

```plaintext
options linesize=80 pageno=1 nodate;
proc print data=qtr01 noobs;
var SalesRep Month Units AmountSold;
where Units>500 or AmountSold>20000;
title 'Quarterly Report for Sales above 500 Units or $20,000';
run;
```

Notice this WHERE statement uses the logical OR operator. Therefore, only one of the comparisons must be true for PROC PRINT to include an observation in the report.

The following output shows the report:

Output 25.9  Making Comparisons for One Condition or Another

Creating Enhanced Reports

Ways to Enhance a Report

With just a few PROC PRINT statements and options, you can produce a variety of detail reports. By using additional statements and options that enhance the reports, you can do the following:

- format the columns
- sum the numeric variables
- group the observations based on variable values
Specifying Formats for the Variables

Specifying the formats of variables is a simple yet effective way to enhance the readability of your reports. By adding the FORMAT statement to your program, you can specify formats for variables. The format of a variable is a pattern that SAS uses to write the values of the variables. For example, SAS contains formats that add commas to numeric values, that add dollar signs to figures, or that report values as Roman numerals.

Using a format can make the values of the variables Units and AmountSold easier to read than in the previous reports. Specifically, Units can use a COMMA format with a total field width of 7, which includes commas to separate every three digits and omits decimal values. AmountSold can use a DOLLAR format with a total field width of 14, which includes commas to separate every three digits, a decimal point, two decimal places, and a dollar sign.

The following program illustrates how to apply these formats in a FORMAT statement:

```sas
options linesize=80 pageno=1 nodate;

proc print data=qtr02 noobs;
  var SalesRep Month Units AmountSold;
  where Units>500 or AmountSold>20000;
  format Units comma7. AmountSold dollar14.2;
  title 'Quarterly Report for Sales above 500 Units or $20,000';
run;
```

PROC PRINT applies the COMMA7. format to the values of the variable Units and the DOLLAR14.2 format to the values of the variable AmountSold.

The following output shows the report:

```
Quarterly Report for Sales above 500 Units or $20,000

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Month</th>
<th>Units</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hollingsworth</td>
<td>04</td>
<td>530</td>
<td>$16,414.10</td>
</tr>
<tr>
<td>Jensen</td>
<td>04</td>
<td>1,110</td>
<td>$34,376.70</td>
</tr>
<tr>
<td>Garcia</td>
<td>04</td>
<td>1,715</td>
<td>$53,113.55</td>
</tr>
<tr>
<td>Jensen</td>
<td>04</td>
<td>675</td>
<td>$20,904.75</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>05</td>
<td>1,120</td>
<td>$34,686.40</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>05</td>
<td>1,030</td>
<td>$31,899.10</td>
</tr>
<tr>
<td>Garcia</td>
<td>06</td>
<td>512</td>
<td>$15,856.64</td>
</tr>
<tr>
<td>Garcia</td>
<td>06</td>
<td>1,000</td>
<td>$30,970.00</td>
</tr>
</tbody>
</table>
```

The following list corresponds to the numbered items in the preceding output:

1. AmountSold uses the DOLLAR14.2 format. The maximum column width is 14 spaces. Two spaces are reserved for the decimal part of a value. The remaining 12 spaces include the decimal point, whole numbers, the dollar sign, commas, and a minus sign if a value is negative.
Units uses the COMMA7. format. The maximum column width is seven spaces. The column width includes the numeric value, commas, and a minus sign if a value is negative.

The formats do not affect the internal data values that are stored in the SAS data set. The formats change only how the current PROC step displays the values in the report.

\textit{Note:} Be sure to specify enough columns in the format to contain the largest value. If the format that you specify is not wide enough to contain the largest value, including special characters such as commas and dollar signs, then SAS applies the most appropriate format.

---

**Summing Numeric Variables**

In addition to reporting the values in a data set, you can add the SUM statement to compute subtotals and totals for the numeric variables. The SUM statement enables you to request totals for one or more variables.

The following program produces a report that shows totals for the two numeric variables Units and AmountSold:

```sas
options linesize=80 pageno=1 nodate;
proc print data=qtr02 noobs;
var SalesRep Month Units AmountSold;
where Units>500 or AmountSold>20000;
format Units comma7. AmountSold dollar14.2;
sum Units AmountSold;
title 'Quarterly Sales Total for Sales above 500 Units or $20,000';
run;
```

The following output shows the report:

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Month</th>
<th>Units</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hollingsworth</td>
<td>04</td>
<td>530</td>
<td>$16,414.10</td>
</tr>
<tr>
<td>Jensen</td>
<td>04</td>
<td>1,110</td>
<td>$34,376.70</td>
</tr>
<tr>
<td>Garcia</td>
<td>04</td>
<td>1,715</td>
<td>$53,113.55</td>
</tr>
<tr>
<td>Jensen</td>
<td>04</td>
<td>675</td>
<td>$20,904.75</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>05</td>
<td>1,120</td>
<td>$34,686.40</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>05</td>
<td>1,030</td>
<td>$31,899.10</td>
</tr>
<tr>
<td>Garcia</td>
<td>06</td>
<td>512</td>
<td>$15,856.64</td>
</tr>
<tr>
<td>Garcia</td>
<td>06</td>
<td>1,000</td>
<td>$30,970.00</td>
</tr>
<tr>
<td>-------------</td>
<td>-------</td>
<td>-------</td>
<td>------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>7,692</td>
<td>$238,221.24</td>
</tr>
</tbody>
</table>

The totals for Units and AmountSold are computed by summing the values for each sale made by all the sales representatives. As the next example shows, the PRINT procedure can also separately compute subtotals for each sales representative.

---

**Grouping Observations by Variable Values**

The BY statement enables you to obtain separate analyses on groups of observations. The previous example used the SUM statement to compute totals for the variables
Units and AmountSold. However, the totals were for all three sales representatives as one group. The next two examples show how to use the BY and ID statements as a part of the PROC PRINT step to separate the sales representatives into three groups with three separate subtotals and one grand total.

**Computing Group Subtotals**

To obtain separate subtotals for specific numeric variables, add a BY statement to the PROC PRINT step. When you use a BY statement, the PRINT procedure expects that you already sorted the data set by using the BY variables. Therefore, if your data is not sorted in the proper order, then you must add a PROC SORT step before the PROC PRINT step.

The BY statement produces a separate section of the report for each BY group. Do not specify in the VAR statement the variable that you use in the BY statement. Otherwise, the values of the BY variable appear twice in the report, as a header across the page and in columns down the page.

The following program uses the BY statement in the PROC PRINT step to obtain separate subtotals of the variables Units and AmountSold for each sales representative:

```plaintext
options linesize=80 pageno=1 nodate;
proc sort data=qtr02;
   by SalesRep;
run;

proc print data=qtr02 noobs;
   var Month Units AmountSold;
   where Units>500 or AmountSold>20000;
   format Units comma7. AmountSold dollar14.2;
   sum Units AmountSold;
   by SalesRep;
   title1 'Sales Rep Quarterly Totals for Sales Above 500 Units or $20,000';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The BY statement in the PROC SORT step sorts the data.
2. The variable SalesRep becomes part of the BY statement instead of the VAR statement.

The following output shows the report:
### Output 25.12  Grouping Observations with the BY Statement

<table>
<thead>
<tr>
<th>Sales Rep Quarterly Totals for Sales above 500 Units or $20,000</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Month</td>
<td>Units</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>04</td>
<td>1,715</td>
</tr>
<tr>
<td>06</td>
<td>512</td>
</tr>
<tr>
<td>06</td>
<td>1,000</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>SalesRep</td>
<td>3,227</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>Month</td>
<td>Units</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>04</td>
<td>530</td>
</tr>
<tr>
<td>05</td>
<td>1,120</td>
</tr>
<tr>
<td>05</td>
<td>1,030</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>SalesRep</td>
<td>2,680</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>Month</td>
<td>Units</td>
</tr>
<tr>

<td>-------</td>
</tr>
<tr>
<td>04</td>
<td>1,110</td>
</tr>
<tr>
<td>04</td>
<td>675</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>SalesRep</td>
<td>1,785</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td></td>
<td>7,692</td>
</tr>
</tbody>
</table>

The following list corresponds to the numbered items in the preceding report:

1. The values of the BY variables appear in dashed lines, called BY lines, above the output for the BY group.
2. The subtotal for the numeric variables is computed for each BY group (the three sales representatives).
3. A grand total is computed for the numeric variables.

### Identifying Group Subtotals

You can use both the BY and ID statements in the PROC PRINT step to modify the appearance of your report. When you specify the same variables in both the BY and ID statements, the PRINT procedure uses the ID variable to identify the start of the BY group.

The following example uses the data set that was sorted in the last example and adds the ID statement to the PROC PRINT step:

```plaintext
options linesize=80 pageno=1 nodate;

proc print data=qtr02;
  var Month Units AmountSold;
  where Units>500 or AmountSold>20000;
  format Units comma7. AmountSold dollar14.2;
  sum Units AmountSold;
  by SalesRep;
```

id SalesRep;
title1 'Sales Rep Quarterly Totals for Sales above 500 Units or $20,000';
run;

The following output shows the report:

**Output 25.13  Grouping Observations with the BY and ID Statements**

<table>
<thead>
<tr>
<th>Sales Rep Quarterly Totals for Sales above 500 Units or $20,000</th>
<th></th>

</tbody>
</table>

The report has two distinct features. PROC PRINT separates the report into groups and suppresses the repetitive values of the BY and ID variables. The dashed lines above the BY groups do not appear because the BY and ID statements are used together in the PROC PRINT step.

Remember these general rules about the SUM, BY, and ID statements:

- You can specify a variable in the SUM statement while omitting it in the VAR statement. PROC PRINT simply adds the variable to the list of variables in the VAR statement.
- You do not specify variables in the SUM statement that you used in the ID or BY statement.
- When you use a BY statement and you specify only one BY variable, PROC PRINT subtotals the SUM variable for each BY group that contains more than one observation.
- When you use a BY statement and you specify multiple BY variables, PROC PRINT shows a subtotal for a BY variable only when the value changes and when there are multiple observations with that value.

**Computing Multiple Group Subtotals**

You can also use two or more variables in a BY statement to define groups and subgroups. The following program produces a report that groups observations first by sales representative and then by month:

```plaintext
options linesize=80 pageno=1 nodate;
```
proc sort data=qtr02;
   by SalesRep Month;
run;

proc print data=qtr02 noobs n='Sales Transactions:' v='Total Sales Transactions:';
   var Units AmountSold;
   where Units>500 or AmountSold>20000;
   format Units comma7. AmountSold dollar14.2;
   sum Units AmountSold;
   by SalesRep Month;
   title1 'Monthly Sales Rep Totals for Sales above 500 Units or $20,000';
run;

The following list corresponds to the numbered items in the preceding program:

1. The BY statement in the PROC SORT step sorts the data by SalesRep and Month.
2. The N= option in the PROC PRINT statement reports the number of observations in a BY group and (because of the SUM statement) the overall total number of observations at the end of the report. The first piece of explanatory text that N= provides precedes the number for each BY group. The second piece of explanatory text that N= provides precedes the number for the overall total.
3. The variables SalesRep and Month are omitted in the VAR statement because the variables are specified in the BY statement. This prevents PROC PRINT from reporting the values for these variables twice.

The following output shows the report:
### Output 25.14

</tr>
</tbody>
</table>

The following list corresponds to the numbered items in the preceding report:

1 The number of observations in the BY group is computed. This corresponds to the number of sales transactions for a sales representative in the month.
When the BY group contains two or more observations, then a subtotal is computed for each numeric variable.

When the value of the first variable in the BY group changes, then an overall subtotal is computed for each numeric variable. The values of Units and AmountSold are summed for every month that Garcia had sales transactions because the sales representative changes in the next BY group.

The grand total is computed for the numeric variables.

The number of observations in the whole report is computed. This corresponds to the total number of sales transactions for every sales representative during the second quarter.

---

### Computing Group Totals

When you use multiple BY variables as in the previous example, you can suppress the subtotals every time a change occurs for the value of the BY variables. Use the SUMBY statement to control which BY variable causes subtotals to appear.

You can specify only one SUMBY variable, and this variable must also be specified in the BY statement. PROC PRINT computes sums when a change occurs to the following values:

- the value of the SUMBY variable
- the value of any variable in the BY statement that is specified before the SUMBY variable

For example, consider the following statements:

```sas
by Quarter SalesRep Month;
sumby SalesRep;
```

SalesRep is the SUMBY variable. In the BY statement, Quarter comes before SalesRep while Month comes after SalesRep. Therefore, these statements cause PROC PRINT to compute totals when either Quarter or SalesRep changes value, but not when Month changes value.

The following program omits the monthly subtotals for each sales representative by designating SALESREP as the variable to sum by:

```sas
options linesize=80 pageno=1 nodate;
proc print data=qtr02;
  var Units AmountSold;
  where Units>500 or AmountSold>20000;
  format Units comma7. AmountSold dollar14.2;
  sum Units AmountSold;
  by SalesRep Month;
  id SalesRep Month;
  sumby SalesRep;
  title1 'Sales Rep Quarterly Totals for Sales above 500 Units or $20,000';
run;
```

This program assumes that QTR02 data has been previously sorted by the variables SalesRep and Month.

The following output shows the report:
Output 25.15  Combining Subtotals for Groups of Observations

</tr>
</tbody>
</table>

Grouping Observations on Separate Pages

You can also create a report with multiple sections that appear on separate pages by using the PAGEBY statement with the BY statement. The PAGEBY statement identifies a variable in the BY statement that causes the PRINT procedure to begin the report on a new page when a change occurs to the following values:

- the value of the BY variable
- the value of any BY variable that precedes it in the BY statement

The following program uses a PAGEBY statement with the BY statement to create a report with multiple sections:

```plaintext
options linesize=80 pageno=1 nodate;

proc print data=qtr02 noobs;
  var Units AmountSold;
  where Units>500 or AmountSold>20000;
  format Units comma7. AmountSold dollar14.2;
  sum Units AmountSold;
  by SalesRep Month;
  id SalesRep Month;
  sumby SalesRep;
  pageby SalesRep;
  title1 'Sales Rep Quarterly Totals for Sales above 500 Units or $20,000';
run;
```

This program assumes that QTR02 data has been previously sorted by the variables SalesRep and Month.

The following output shows the report:
Producing Detail Reports with the PRINT Procedure

Ways to Customize a Report

As you have seen from the previous examples, the PRINT procedure produces simple detail reports quickly and easily. With additional statements and options, you can enhance the readability of your reports. For example, you can do the following:

- Add descriptive titles and footnotes.
- Define and split labels across multiple lines.
- Add double spacing.
- Ensure that the column widths are uniform across the pages of the report.
Adding Titles and Footnotes

Adding descriptive titles and footnotes is one of the easiest and most effective ways to improve the appearance of a report. You can use the TITLE statement to include from 1 to 10 lines of text at the top of the report. You can use the FOOTNOTE statement to include from 1 to 10 lines of text at the bottom of the report.

In the TITLE statement, you can specify n immediately following the keyword TITLE, to indicate the level of the TITLE statement. n is a number from 1 to 10 that specifies the line number of the TITLE. You must enclose the text of each title in single or double quotation marks.

Skipping over some values of n indicates that those lines are blank. For example, if you specify TITLE1 and TITLE3 statements but skip TITLE2, then a blank line occurs between the first and third lines.

When you specify a title, SAS uses that title for all subsequent output until you cancel it or define another title for that line. A TITLE statement for a given line cancels the previous TITLE statement for that line and for all lines below it, that is, for those with larger n values.

To cancel all existing titles, specify a TITLE statement without the n value:

```
title;
```

To suppress the nthe title and all titles below it, use the following statement:

```
title n;
```

Footnotes work the same way as titles. In the FOOTNOTE statement, you can specify n immediately following the keyword FOOTNOTE, to indicate the level of the FOOTNOTE statement. n is a number from 1 to 10 that specifies the line number of the FOOTNOTE. You must enclose the text of each footnote in single or double quotation marks. As with the TITLE statement, skipping over some values of n indicates that those lines are blank.

Remember that the footnotes are pushed up from the bottom of the report. In other words, the FOOTNOTE statement with the largest number appears on the bottom line.

When you specify a footnote, SAS uses that footnote for all subsequent output until you cancel it or define another footnote for that line. You cancel and suppress footnotes in the same way that you cancel and suppress titles.

**Note:** The maximum title length and footnote length that is allowed depends on your operating environment and the value of the LINESIZE= system option. Refer to the SAS documentation for your operating environment for more information.

---

Adding Titles and Footnotes

The following program includes titles and footnotes in a report of second quarter sales during the month of April:

```sas
options linesize=80 pageno=1 nodate;

proc sort data=qtr02;
  by SalesRep;
run;

proc print data=qtr02 noobs;
  var SalesRep Month Units AmountSold;
  where Month='04';
  format Units comma7. AmountSold dollar14.2;
```
sum Units AmountSold;
title1 'TruBlend Coffee Makers, Inc.';
title3 'Quarterly Sales Report';
footnote1 'April Sales Totals';
footnote2 'COMPANY CONFIDENTIAL INFORMATION';
run;

The report includes three title lines and two footnote lines. The program omits the TITLE2 statement so that the second title line is blank.

The following output shows the report:

Output 25.17  Adding Titles and Footnotes

</tbody>
</table>

April Sales Totals
COMPANY CONFIDENTIAL INFORMATION

The following list corresponds to the numbered items in the preceding report:

1. a descriptive title line that is generated by a TITLE statement
2. a blank title line that is generated by omitting a TITLE statement for the second line
3. a descriptive footnote line that is generated by a FOOTNOTE statement.

Defining Labels

By default, SAS uses variable names for column headings. However, to improve the appearance of a report, you can specify your own column headings.

To override the default headings, you need to do the following:

- Add the LABEL option to the PROC PRINT statement.
- Define the labels in the LABEL statement.

The LABEL option causes the report to display labels, instead of variable names, for the column headings. You use the LABEL statement to assign the labels for the specific variables. A label can be up to 256 characters long, including blanks, and must be enclosed in single or double quotation marks. If you assign labels when you created the SAS data set, then you can omit the LABEL statement from the PROC PRINT step.
The following program modifies the previous program and defines labels for the variables SalesRep, Units, and AmountSold:

```sas
options linesize=80 pageno=1 nodate;

proc sort data=qtr02;
   by SalesRep;
run;

proc print data=qtr02 noobs label;
   var SalesRep Month Units AmountSold;
   where Month='04';
   format Units comma7. AmountSold dollar14.2;
   sum Units AmountSold;
   label SalesRep = 'Sales Rep.'
       Units = 'Units Sold'
       AmountSold = 'Amount Sold';
   title 'TruBlend Coffee Maker Sales Report for April';
   footnote;
run;
```

The TITLE statement redefines the first title and cancels any additional titles that might have been previously defined. The FOOTNOTE statement cancels any footnotes that might have been previously defined.

The following output shows the report:

Output 25.18  Defining Labels

<table>
<thead>
<tr>
<th>Sales Rep.</th>
<th>Month</th>
<th>Units Sold</th>
<th>Amount Sold</th>
</tr>
</thead>
<tbody>
<tr>

<td>04</td>
<td>1,715</td>
<td>$53,113.55</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>04</td>
<td>260</td>
<td>$8,052.20</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>04</td>
<td>530</td>
<td>$16,414.10</td>
</tr>
<tr>
<td>Jensen</td>
<td>04</td>
<td>1,110</td>
<td>$34,376.70</td>
</tr>
<tr>
<td>Jensen</td>
<td>04</td>
<td>675</td>
<td>$20,904.75</td>
</tr>
</tbody>
</table>

4,440 $137,506.80

The label Units Sold is split between two lines. The PRINT procedure splits the label to conserve space.

**Splitting Labels across Two or More Lines**

Sometimes labels are too long to fit on one line, or you might want to split a label across two or more lines. By default, SAS automatically splits labels on the basis of column width. You can use the SPLIT= option to control where the labels are separated into multiple lines.

The SPLIT= option replaces the LABEL option in the PROC PRINT statement. (You do not need to use both SPLIT= and LABEL because SPLIT= implies that PROC PRINT use labels.) In the SPLIT= option, you specify an alphanumeric character that indicates where to split labels. To use the SPLIT= option, you need to do the following:
Define the split character as a part of the PROC PRINT statement.

Define the labels with a split character in the LABEL statement.

The following PROC PRINT step defines the slash (/) as the split character and includes slashes in the LABEL statements to split the labels Sales Representative, Units Sold, and Amount Sold into two lines each:

```plaintext
options linesize=80 pageno=1 nodate;
proc sort data=qtr02;
  by SalesRep;
run;

proc print data=qtr02 noobs split='/';
  var SalesRep Month Units AmountSold;
  where Month='04';
  format Units comma7. AmountSold dollar14.2;
  sum Units AmountSold;
  title 'TruBlend Coffee Maker Sales Report for April';
  label SalesRep = 'Sales/Representative'
       Units = 'Units/Sold'
       AmountSold = 'Amount/Sold';
run;
```

The following output shows the report:

![Output 25.19 Reporting: Splitting Labels into Two Lines](image)

---

Adding Double Spacing

You might want to improve the appearance of a report by adding double spaces between the rows of the report. The following program uses the DOUBLE option in the PROC PRINT statement to double-space the report:

```plaintext
options linesize=80 pageno=1 nodate;
proc sort data=qtr02;
  by SalesRep;
run;

proc print data=qtr02 noobs split='/' double;
  var SalesRep Month Units AmountSold;
```
where Month='04';
format Units comma7. AmountSold dollar14.2;
sum Units AmountSold;
title 'TruBlend Coffee Maker Sales Report for April';
label SalesRep = 'Sales/Representative'
   Units = 'Units/Sold'
   AmountSold = 'Amount/Sold';
run;

The following output shows the report:

Output 25.20  Adding Double Spacing

<table>
<thead>
<tr>
<th>Sales Representative</th>
<th>Month</th>

4,440 $137,506.80

Requesting Uniform Column Widths

By default, PROC PRINT uses the width of the formatted variable as the column width. If you do not assign a format to the variable that explicitly specifies a field width, then the column width is the widest value of the variable on that page. This can cause the column widths to vary on different pages of a report.

The WIDTH=UNIFORM option ensures that the columns of data line up from one page to the next. PROC PRINT will use a variable's formatted width or, if no format is assigned, the widest data value as the variable's column width on all pages. Unless you specify this option, PROC PRINT individually constructs each page of output. Each page contains as many variables and observations as possible. As a result, the report might have different numbers of variables or different column widths from one page to the next.

If the sales records for TruBlend Coffee Makers* are sorted by the sales representatives and a report is created without using the WIDTH=UNIFORM option in the PROC PRINT statement, then the columns of values on the first page will not line up with those on the next page. The column shift occurs because of differences in the name length of the sales representatives. PROC PRINT lines up the columns on the first

* See “Input File and SAS Data Sets for Examples” on page 372 to examine the sales records.
page of the report, allowing enough space for the longest name, Hollingsworth. On the second page the longest name is Jensen, so the columns shift relative to the first page. The following example uses the WIDTH= option in the PROC PRINT statement to prevent the shifting of columns:

```
options pagesize=66 linesize=80 pageno=1 nodate;
proc sort data=qtr03;
  by SalesRep;
run;

proc print data=qtr03 split='/' width=uniform;
  var SalesRep Month Units AmountSold;
  format Units comma7. AmountSold dollar14.2;
  sum Units AmountSold;
  title 'TruBlend Coffee Makers 3rd Quarter Sales Report';
  label SalesRep   = 'Sales/Rep.'
                 Units      = 'Units/Sold'
                 AmountSold = 'Amount/Sold';
run;
```

The following output shows the report:
### Output 25.21 Reporting: Using Uniform Column Widths

Making Your Reports Easy to Change

Understanding the SAS Macro Facility

Base SAS includes the macro facility as a tool to customize SAS and to reduce the amount of text you must enter to do common tasks. The macro facility enables you to assign a name to character strings or groups of SAS programming statements.

From that point on, you can work with the names rather than with the text itself. When you use a macro facility name in a SAS program, the macro facility generates SAS statements and commands as needed. The rest of SAS receives those statements and uses them in the same way it uses the ones you enter in the standard manner.

The macro facility enables you to create macro variables to substitute text in SAS programs. One of the major advantages of using macro variables is that it enables you to change the value of a variable in one place in your program and then have the change appear in multiple references throughout your program. You can substitute text by using automatic macro variables or by using your own macro variables, which you define and assign values to.

Using Automatic Macro Variables

The SAS macro facility includes many automatic macro variables. Some of the values associated with the automatic macro variables depend on your operating environment. You can use automatic macro variables to provide the time, the day of the week, and the date based on your computer’s internal clock as well as other processing information.

To include a second title on a report that displays the text string “Produced on” followed by today’s date, add the following TITLE statement to your program:

```
title2 "Produced on &SYSDATE9";
```

Notice the syntax for this statement. First, the ampersand that precedes SYSDATE9 tells the SAS macro facility to replace the reference with its assigned value. In this case, the assigned value is the date the SAS session started and is expressed as ddmmmyyyy, where

- **dd** is a two-digit date
- **mmm** is the first three letters of the month name
- **yyyy** is a four-digit year

Second, the text of the TITLE statement is enclosed in double quotation marks because the SAS macro facility resolves macro variable references in the TITLE statement and the FOOTNOTE statement only if they are in double quotation marks.

The following program, which includes a PROC SORT step and the TITLE statement, demonstrates how to use the SYSDATE9. automatic macro variable:
options linesize=80 pageno=1 nodate;

proc sort data=qtr04;
   by SalesRep;
run;

proc print data=qtr04 noobs split='/' width=uniform;
   var SalesRep Month Units AmountSold;
   format Units comma7. AmountSold dollar14.2;
   sum Units AmountSold;
   title1 'TruBlend Coffee Maker Quarterly Sales Report';
   title2 "Produced on &SYSDATE9";
   label SalesRep = 'Sales/Rep.'
         Units = 'Units/Sold'
         AmountSold = 'Amount/Sold';
run;

The following output shows the report:

</tbody>
</table>

Using Your Own Macro Variables

In addition to using automatic macro variables, you can use the %LET statement to define your own macro variables and refer to them with the ampersand prefix. Defining macro variables at the beginning of your program enables you to change other parts of the program easily. The following example shows how to define two macro variables, Quarter and Year, and how to refer to them in a TITLE statement.
Defining Macro Variables

To use two macro variables that produce flexible report titles, first define the macro variables. The following %LET statements define the two macro variables:

```sas
%let Quarter=Fourth;
%let Year=2000;
```

The name of the first macro variable is Quarter and it is assigned the value Fourth. The name of the second macro variable is Year and it is assigned the value 2000.

Macro variable names such as these conform to the following rules for SAS names:
- Macro variable names are one to 32 characters long
- Macro variable names begin with a letter or an underscore
- Letters, numbers, and underscores follow the first character.

In these simple situations, do not assign values to macro variables that contain unmatched quotation marks or semicolons. If the values contain leading or trailing blanks, then SAS removes the blanks.

Referring to Macro Variables

To refer to the value of a macro variable, place an ampersand prefix in front of the name of the variable. The following TITLE statement contains references to the values of the macro variables Quarter and Year, which were previously defined in %LET statements:

```sas
title3 "&Quarter Quarter &Year Sales Totals";
```

The complete program, which includes the two %LET statements and the TITLE3 statement, follows:

```sas
options linesize=80 pageno=1 nodate;
%let Quarter=Fourth;
%let Year=2000;
proc sort data=qtr04;
  by SalesRep;
run;
proc print data=qtr04 noobs split='/' width=uniform;
  var SalesRep Month Units AmountSold;
  format Units comma7. AmountSold dollar14.2;
  sum Units AmountSold;
  title1 'TruBlend Coffee Maker Quarterly Sales Report';
  title2 "Produced on &SYSDATE9";
  title3 "&Quarter Quarter &Year Sales Totals";
  label SalesRep = 'Sales/Rep.'
            Units = 'Units/Sold'
            AmountSold = 'Amount/Sold';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The %LET statement creates a macro variable with the sales quarter. When an ampersand precedes Quarter, the SAS macro facility knows to replace any reference to &Quarter with the assigned value of Fourth.
2. The %LET statement creates a macro variable with the year. When ampersand precedes Year, the SAS macro facility knows to replace any reference to &Year with the assigned value of 2000.
The text of the TITLE2 and TITLE3 statements are enclosed in double quotation marks so that the SAS macro facility can resolve them.

The following output shows the report:

**Output 25.23 Using Your Own Macro Variables**

</tr>
<tr>
<td>Jensen</td>
<td>12</td>
<td>1,254</td>
<td>$38,836.38</td>
</tr>
</tbody>
</table>

Using macro variables can make your programs easy to modify. For example, if the previous program contained many references to Quarter and Year, then changes in only three places will produce an entirely different report:

- the two values in the `%LET` statements
- the data set name in the PROC PRINT statement

---

**Review of SAS Tools**

**PROC PRINT Statements**

\[
\text{PROC PRINT <DATA=SAS-data-set> <option(s)>;} \\
\hspace{1cm} \text{BY variable(s);} \\
\hspace{1cm} \text{FOOTNOTE<n> '<footnote>'}; \\
\hspace{1cm} \text{FORMAT variable(s) format-name;} \\
\hspace{1cm} \text{ID variable(s);} \\
\hspace{1cm} \text{LABEL variable='label';} \\
\hspace{1cm} \text{PAGEBY variable;} \\
\hspace{1cm} \text{SUM variable(s);} \\
\hspace{1cm} \text{SUMBY variable;} \\
\]
TITLE<\n> <'title'>;
VAR variable(s);
WHERE where-expression;

PROC PRINT <DATA=SAS-data-set> <options>;
starts the procedure and, when used alone, shows all variables for all observations
in the SAS-data-set in the report. Other statements, that are listed below, enable
you to control what to report.
You can specify the following options in the PROC PRINT statement:
DATA=SAS-data-set
names the SAS data set that PROC PRINT uses. If you omit DATA=, then
PROC PRINT uses the most recently created data set.
DOUBLE|D
writes a blank line between observations.
LABEL
uses variable labels instead of variable names as column headings for any
variables that have labels defined. Variable labels appear only if you use the
LABEL option or the SPLIT= option. You can specify labels in LABEL
statements in the DATA step that creates the data set or in the PROC PRINT
step. If you do not specify the LABEL option or if there is no label for a
variable, then PROC PRINT uses the variable name.
N<"string-1"<"string-2">>
shows the number of observations in the data set, in BY groups, or both and
optionally specifies explanatory text to include with the number.
NOOBS
suppresses the observation numbers in the output. This option is useful when
you omit an ID statement and do not want to show the observation numbers.
SPLIT='split-character'
specifies the split character, which controls line breaks in column headers.
PROC PRINT breaks a column heading when it reaches the split character
and continues the header on the next line. The split character is not part of
the column heading.
PROC PRINT uses variable labels only when you use the LABEL option or
the SPLIT= option. It is not necessary to use both the LABEL and SPLIT=
options because SPLIT= implies to use labels.
WIDTH=UNIFORM
uses each variable's formatted width as its column width on all pages. If the
variable does not have a format that explicitly specifies a field width, then
PROC PRINT uses the widest data value as the column width. Without this
option, PROC PRINT fits as many variables and observations on a page as
possible. Therefore, the report might contain a different number of columns
on each page.
BY variable(s);
produces a separate section of the report for each BY group. The BY group is
made up of the variables that you specify. When you use a BY statement, the
procedure expects that the input data set is sorted by the variables.
FOOTNOTE<\n> </footnote'>;
specifies a footnote. The argument n is a number from 1 to 10 that immediately
follows the word FOOTNOTE, with no intervening blank, and specifies the line
number of the FOOTNOTE. The text of each footnote must be enclosed in single or double quotation marks. The maximum footnote length that is allowed depends on your operating environment and the value of the LINESIZE= system option. Refer to the SAS documentation for your operating environment for more information.

FORMAT variable(s) format-name;
   enables you to report the value of a variable using a special pattern that you specify as format-name.

ID variable(s);
   specifies one or more variables that PROC PRINT uses instead of observation numbers to identify observations in the report.

LABEL variable='label';
   specifies to use labels for column headings. Variable names the variable to label, and label specifies a string of up to 256 characters, which includes blanks. The label must be enclosed in single or double quotation marks.

OBS='column-header'
   specifies a column header for the column that identifies each observation by number.

PAGEBY variable;
   causes PROC PRINT to begin a new page when the variable that you specify changes value or when any variable that you list before it in the BY statement changes value. You must use a BY statement with the PAGEBY statement.

SUM variable(s);
   identifies the numeric variables to total in the report. You can specify a variable in the SUM statement and omit it in the VAR statement because PROC PRINT will add the variable to the VAR list. PROC PRINT ignores requests to total the BY and ID variables. In general, when you also use the BY statement, the SUM statement produces subtotals each time the value of a BY variable changes.

SUMBY variable;
   limits the number of sums that appear in the report. PROC PRINT reports totals only when variable changes value or when any variable that is listed before it in the BY statement changes value. You must use a BY statement with the SUMBY statement.

TITLE<
   specifies a title. The argument n is a number from 1 to 10 that immediately follows the word TITLE, with no intervening blank, and specifies the level of the TITLE. The text of each title must be enclosed in single or double quotation marks. The maximum title length that is allowed depends on your operating environment and the value of the LINESIZE= system option. Refer to the SAS documentation for your operating environment for more information.

VAR variable(s);
   identifies one or more variables that appear in the report. The variables appear in the order that you list them in the VAR statement. If you omit the VAR statement, then all the variables appear in the report.

WHERE where-expression;
   subsets the input data set by identifying certain conditions that each observation must meet before an observation is available for processing. Where-expression defines the condition. The condition is a valid arithmetic or logical expression that generally consists of a sequence of operands and operators.
PROC SORT Statements

PROC SORT <DATA=SAS-data-set>;
   BY variable(s);

PROC SORT DATA=SAS-data-set;
   sorts a SAS data set by the values of variables that you list in the BY statement.
   BY variable(s);
   specifies one or more variables by which PROC SORT sorts the observations. By default, PROC SORT arranges the data set by the values in ascending order (smallest value to largest).

SAS Macro Language

%LET macro-variable=value;
   is a macro statement that defines a macro-variable and assigns it a value. The value that you define in the %LET statement is substituted for the macro-variable in output. To use the macro-variable in a program, include an ampersand (&) prefix before it.

SYSDATE9
   is an automatic macro variable that contains the date that a SAS job or session began to execute. SYSDATE9 contains a SAS date value in the DATE9 format (ddmmyyyy). The date displays a two-digit date, the first three letters of the month name, and a four-digit year. To use it in a program, you include an ampersand (&) prefix before SYSDATE9.

Data Set Indexes
   For information about indexing data sets, see SAS Language Reference: Dictionary. You do not need to sort data sets before using a BY statement in the PRINT procedure if the data sets have an index for the variable or variables that are specified in the BY statement.

PROC PRINT
   For complete documentation, see Base SAS Procedures Guide.

PROC SORT
   For a discussion, see Chapter 11, “Working with Grouped or Sorted Observations,” on page 173. For complete reference documentation about the SORT procedure, see Base SAS Procedures Guide.

SAS formats
   For complete documentation, see SAS Language Reference: Dictionary. Formats that are available with SAS software include fractions, hexadecimal values, roman
numerals, social security numbers, date and time values, and numbers written as words.

SAS macro facility
For complete reference documentation, see *SAS Macro Language: Reference*.

WHERE statement
For complete reference documentation, see *SAS Language Reference: Dictionary*. For a complete discussion of WHERE processing, see *SAS Language Reference: Concepts*.

Purpose

Summary tables display the relationships that exist among the variables in a data set. The variables in the data set form the columns, rows, and pages of summary tables. The data at each intersection of a column and row (that is, each cell) shows a relationship between the variables. The TABULATE procedure enables you to create a variety of summary tables.

In this section, you learn how to do the following:
- Produce simple summary tables by using a few basic PROC TABULATE options and statements.
- Produce enhanced summary tables by summarizing more complex relationships between and across variables, applying formats to variables, and calculating statistics for variables.
- Add the finishing touches to tables by using labels, by specifying fonts and colors with the Output Delivery System, and by ordering class variables.

Prerequisites

To understand the examples in this section, you should be familiar with the following features and concepts:
- summary table design (see the next section)
- locating procedure output (see Chapter 31, “Understanding and Customizing SAS Output: The Basics,” on page 537)
- the TITLE statement (see Chapter 25, “Producing Detail Reports with the PRINT Procedure,” on page 371)

Understanding Summary Table Design

If you design your summary table in advance, then you can save time and write simpler SAS code to produce the summary table. The basic steps of summary table design and construction are listed next. For a detailed step-by-step example of the design process, see PROC TABULATE by Example.

Prior to designing a summary table, it is important to understand that the summary table produces summary data wherever values for two or more variables intersect. The point of intersection is a cell. When values for two or more variables intersect, the variables are said to be crossed. The process of crossing variables to form intersections is called cross-tabulation. Variables in columns, rows, and pages can be crossed to produce summary data. The following summary table displays how two variables are crossed by highlighting a single value for each variable:
Here are the basic steps for designing and constructing a summary table:

1. Start with a question that you want to answer with a summary table.

2. Identify the variables necessary to answer your question.
   - See if any of the data sets that you are using already use the variables that you identified. If they do not, then you might be able to use the FORMAT procedure to reclassify the variable values in these data sets so that they produce the data that you need.
     
     For example, you can apply a new format to values for a variable MONTH so that they become values for a variable QUARTER. To do this, assign the values representing the first three months to a value for quarter one, values representing the second set of three months to a value for quarter two, and so on.
   - If possible, use discrete variables rather than continuous variables for categories or headings. If you must use continuous variables, then it might be helpful to create categories. For example, you can group ages into categories such as ages 15-19, 20-35, 36-55, and 56-higher. This creates four categories rather than a possible 56+ categories. You can use PROC FORMAT to categorize the data.
   - Choose formats for the variables and the data that you want to display in your summary table. See if the data in your data sets is in a format that you can use. You might need to create new formats with PROC FORMAT, or copy the formats of variables from another data set so that the data will be formatted in the same way.

3. Review the data for anything that might cause discrepancies in your report.
   - Remove data that does not relate to your needs.
   - Identify missing data.
   - Make sure that the data overall seems to make logical sense.

4. Choose statistics that will help answer your question. For a complete list of statistics, see “Statistics Available in PROC TABULATE” in the Base SAS Procedures Guide.
5. Decide on the basic structure of the table. Use the variables that you have identified to determine the headings for the columns, rows, and pages. The values of the variables are the subheadings. Statistics are usually represented as subheadings, but are sometimes represented as headings. Display 26.1 on page 409 is an example of a template for a very basic table.

---

Understanding the Basics of the TABULATE Procedure

**Required Statements for the TABULATE Procedure**

The TABULATE procedure requires three statements, usually in the following order:

1. **PROC TABULATE statement**
2. **CLASS statements or VAR statements or both**
3. **TABLE statements**

Note that there can be multiple CLASS statements, VAR statements and TABLE statements.

**Begin with the PROC TABULATE Statement**

The TABULATE procedure begins with a PROC TABULATE statement. Many options are available with the PROC TABULATE statement; however, most of the examples in this section use only two options, the DATA= option and the FORMAT= option. The PROC TABULATE statement that follows is used for all of the examples in this section:

```
proc tabulate data=year_sales format=comma10.;
```

You can direct PROC TABULATE to use a specific SAS data set with the DATA= option. If you omit the DATA= option in the current job or session, then the TABULATE procedure uses the SAS data set that was created most recently.

You can specify a default format for PROC TABULATE to apply to the value in each cell in the table with the FORMAT= option. You can specify any valid SAS numeric format or user-defined format.

**Specify Class Variables with the CLASS Statement**

Use the CLASS statement to specify which variables are class variables. **Class variables** (that is, classification variables) contain values that are used to form categories. In summary tables, the categories are used as the column, row, and page headings. The categories are crossed to obtain descriptive statistics. See Display 26.1 on page 409 for an example of crossing categories (variable values).

Class variables can be either character or numeric. The default statistic for class variables is N, which is the frequency or number of observations in the data set for which there are nonmissing variable values.

The following CLASS statement specifies the variables SalesRep and Type as class variables:

```
class SalesRep Type;
```

For important information about how PROC TABULATE behaves when class variables that have missing values are listed in a CLASS statement but are not used in a TABLE statement, see “Identifying Missing Values for Class Variables” on page 411.
Specify Analysis Variables with the VAR Statement

Use the VAR statement to specify which variables are analysis variables. Analysis variables contain numeric values for which you want to compute statistics. The default statistic for analysis variables is SUM.

The following VAR statement specifies the variable AmountSold as an analysis variable:

```
var AmountSold;
```

Define the Table Structure with the TABLE Statement

Syntax of a TABLE Statement

Use the TABLE statement to define the structure of the table that you want PROC TABULATE to produce. A TABLE statement consists of one to three dimension expressions, separated by commas. Dimension expressions define the columns, rows, and pages of a summary table. Options can follow dimension expressions. You must specify at least one TABLE statement, because there is no default table in a PROC TABULATE step. Here are three variations of the syntax for a basic TABLE statement:

```
TABLE column-expression;
TABLE row-expression, column-expression;
TABLE page-expression, row-expression, column-expression;
```

In this syntax
- a column expression is required
- a row expression is optional
- a page expression is optional
- the order of the expressions must be page expression, row expression, and then column expression

Here is an example of a basic TABLE statement with three dimension expressions:

```
table SalesRep, Type, AmountSold;
```

This TABLE statement defines a three-dimensional summary table that places the values of the variable AmountSold in the column dimension, the values of the variable Type in the row dimension, and the values of the variable SalesRep in the page dimension.

Restrictions on a TABLE Statement

Here are restrictions on the TABLE statement:
- A TABLE statement must have a column dimension.
- Every variable that is used in a dimension expression in a TABLE statement must appear in either a CLASS statement or a VAR statement, but not both.
- All analysis variables must be in the same dimension and cannot be crossed. Therefore, only one dimension of any TABLE statement can contain analysis variables.

Identifying Missing Values for Class Variables

You can identify missing values for class variables with the MISSING option. By default, if an observation contains a missing value for any class variable, that
observation will be excluded from all tables even if the variable does not appear in the TABLE statement for one or more tables. Therefore, it is helpful to run your program at least once with the MISSING option to identify missing values.

The MISSING option creates a separate category in the summary table for missing values. It can be used with the PROC TABULATE statement or the CLASS statement. If you specify the MISSING option in the PROC TABULATE statement, the procedure considers missing values as valid levels for all class variables:

```sas
proc tabulate data=year_sales format=comma10. missing;
  class SalesRep;
  class Month Quarter;
  var AmountSold;
```

Because the MISSING option is in the PROC TABULATE statement in this example, observations with missing values for SalesRep, Month, or Quarter will display in the summary table.

If you specify the MISSING option in a CLASS statement, PROC TABULATE considers missing values as valid levels for the class variable(s) that are specified in that CLASS statement:

```sas
proc tabulate data=year_sales format=comma10. ;
  class SalesRep;
  class Month Quarter / missing;
  var AmountSold;
```

Because the MISSING option is in the second CLASS statement, observations with missing values for Month or Quarter will display in the summary table, but observations with a missing value for SalesRep will not display.

If you have class variables with missing values in your data set, then you must decide whether or not the observations with the missing values should be omitted from every table. If the observations should not be omitted, then you can fill in the missing values where appropriate or continue to run the PROC TABULATE step with the MISSING option. For other options for handling missing values, see “Handling Missing Data” in PROC TABULATE by Example. For general information about missing values, see “Missing Values” in SAS Language Reference: Concepts.

---

### Input File and SAS Data Set for Examples

The examples in this section use one input file* and one SAS data set. The input file contains sales records for a company, TruBlend Coffee Makers, that distributes the coffee machines. The file has the following structure:

<table>
<thead>
<tr>
<th>01</th>
<th>1</th>
<th>Hollingsworth Deluxe</th>
<th>260</th>
<th>49.50</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>1</td>
<td>Garcia Standard</td>
<td>41</td>
<td>30.97</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>Hollingsworth Deluxe</td>
<td>330</td>
<td>49.50</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>Jensen Standard</td>
<td>1110</td>
<td>30.97</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>Garcia Standard</td>
<td>715</td>
<td>30.97</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>Jensen Deluxe</td>
<td>675</td>
<td>49.50</td>
</tr>
<tr>
<td>02</td>
<td>1</td>
<td>Jensen Standard</td>
<td>45</td>
<td>30.97</td>
</tr>
<tr>
<td>02</td>
<td>1</td>
<td>Garcia Deluxe</td>
<td>10</td>
<td>49.50</td>
</tr>
</tbody>
</table>

...more data lines...

---

* See the “Data Set YEAR_SALES” on page 717 for a complete listing of the input data.
Creating Simple Summary Tables

Creating a Basic One-Dimensional Summary Table

The simplest summary table contains multiple columns but only a single row. It is called a one-dimensional summary table because it has only a column dimension. The PROC TABULATE step that follows creates a one-dimensional summary table that answers the question, “How many times did each sales representative make a sale?”

The input file contains the following data from left to right:

- the month that a sale was made
- the quarter of the year that a sale was made
- the name of the sales representative
- the type of coffee maker sold (standard or deluxe)
- the number of units sold
- the price of each unit in US dollars

The SAS data set is named YEAR_SALES. This data set contains all the sales data from the input file and data from a new variable named AmountSold, which is created by multiplying Units by Price.

The following program creates the SAS data set that is used in this section:

```sas
data year_sales;
  infile 'your-input-file';
  input Month $ Quarter $ SalesRep $14. Type $ Units Price;
  AmountSold = Units * Price;
run;
```

The numbered items in the previous program correspond to the following:

1. The variable SalesRep is specified as a class variable in the CLASS statement. A category will be created for each value of SalesRep wherever SalesRep is used in a TABLE statement.

2. The variable SalesRep is specified in the column dimension of the TABLE statement. A column will be created for each category of SalesRep. Each column will show the number of times (N) that values belonging to the category appear in the data set.
The following summary table displays the results of this program:

**Output 26.1  Basic One-Dimensional Summary Table**

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Hollingsworth</th>
<th>Garcia</th>
<th>Jensen</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>N</td>
<td>40</td>
<td>32</td>
</tr>
<tr>
<td>N</td>
<td>N</td>
<td>38</td>
<td></td>
</tr>
</tbody>
</table>

The values 40, 32, and 38 are the frequency with which each sales representative’s name (Garcia, Hollingsworth, and Jensen) occurs in the data set. For this data set, each occurrence of the sales representative’s name in the data set represents a sale.

---

**Creating a Basic Two-Dimensional Summary Table**

The most commonly used form of a summary table has at least one column and multiple rows, and is called a two-dimensional summary table. The PROC TABULATE step that follows creates a two-dimensional summary table that answers the question, “What was the amount that was sold by each sales representative?”

```plaintext
options linesize=84 pageno=1 nodate;
proc tabulate data=year_sales format=comma10.;
  title1 'TruBlend Coffee Makers, Inc.';
  title2 'Amount Sold by Each Sales Representative';
  class SalesRep;  // The variable SalesRep is specified as a class variable in the CLASS statement. A category will be created for each value of SalesRep wherever SalesRep is used in a TABLE statement.
  var AmountSold;   // The variable AmountSold is specified as an analysis variable in the VAR statement. The values of AmountSold will be used to compute statistics wherever AmountSold is used in a TABLE statement.
  table SalesRep,  // The variable SalesRep is in the row dimension of the TABLE statement. A row will be created for each value or category of SalesRep.
                  AmountSold;  // The variable AmountSold is in the column dimension of the TABLE statement. The default statistic for analysis variables, SUM, will be used to summarize the values of AmountSold.
run;
```

The numbered items in the previous program correspond to the following:

1. The variable SalesRep is specified as a class variable in the CLASS statement. A category will be created for each value of SalesRep wherever SalesRep is used in a TABLE statement.
2. The variable AmountSold is specified as an analysis variable in the VAR statement. The values of AmountSold will be used to compute statistics wherever AmountSold is used in a TABLE statement.
3. The variable SalesRep is in the row dimension of the TABLE statement. A row will be created for each value or category of SalesRep.
4. The variable AmountSold is in the column dimension of the TABLE statement. The default statistic for analysis variables, SUM, will be used to summarize the values of AmountSold.

The following summary table displays the results of this program:
Creating Summary Tables with the TABULATE Procedure

Creating a Basic Three-Dimensional Summary Table

Three-dimensional summary tables produce the output on separate pages with rows and columns on each page. The PROC TABULATE step that follows creates a three-dimensional summary table that answers the question, “What was the amount that was sold during each quarter of the year by each sales representative?”

```
options linesize=84 pageno=1 nodate;
proc tabulate data=year_sales format=comma10.;
title1 'TruBlend Coffee Makers, Inc.';
title2 'Quarterly Sales by Each Sales Representative';
class SalesRep Quarter;
var AmountSold;
table SalesRep, Quarter, AmountSold;
run;
```

The numbered items in the previous program correspond to the following:

1. The variables SalesRep and Quarter are specified as class variables in the CLASS statement. A category will be created for each value of SalesRep wherever SalesRep is used in the TABLE statement. Similarly, a category will be created for each value of Quarter wherever Quarter is used in a TABLE statement.
2. The variable AmountSold is specified as an analysis variable in the VAR statement. The values of AmountSold will be used to compute statistics wherever AmountSold is used in a TABLE statement.
3. The variable SalesRep is used in the page dimension of the TABLE statement. A page will be created for each value or category of SalesRep.

The numbered items in the previous SAS output correspond to the following:

1. The variable AmountSold has been crossed with the variable SalesRep to produce each data cell of the summary table.
2. The column heading AmountSold includes the subheading SUM. The values that are displayed in the column dimension are sums of the amount sold by each sales representative.

---

Output 26.2  Basic Two-Dimensional Summary Table

```
<table>
<thead>
<tr>
<th>SalesRep</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>512,071</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>347,246</td>
</tr>
<tr>
<td>Jensen</td>
<td>461,163</td>
</tr>
</tbody>
</table>
```

TruBlend Coffee Makers, Inc.
Amount Sold by Each Sales Representative

The variable AmountSold has been crossed with the variable SalesRep to produce each data cell of the summary table. The column heading AmountSold includes the subheading SUM. The values that are displayed in the column dimension are sums of the amount sold by each sales representative.
The variable Quarter is used in the row dimension of the TABLE statement. A row will be created for each value or category of Quarter.

The variable AmountSold is used in the column dimension of the TABLE statement. The default statistic for analysis variables, SUM, will be used to summarize the values of AmountSold.

The following summary table displays the results of this program:

**Output 26.3  Basic Three-Dimensional Summary Table**

<table>
<thead>
<tr>
<th>Quarter</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>118,020</td>
</tr>
<tr>
<td>2</td>
<td>108,860</td>
</tr>
<tr>
<td>3</td>
<td>225,326</td>
</tr>
<tr>
<td>4</td>
<td>59,865</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Quarter</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>59,635</td>
</tr>
<tr>
<td>2</td>
<td>96,161</td>
</tr>
<tr>
<td>3</td>
<td>109,704</td>
</tr>
<tr>
<td>4</td>
<td>81,747</td>
</tr>
</tbody>
</table>
Creating Summary Tables with the TABULATE Procedure

Producing Multiple Tables in a Single PROC TABULATE Step

You can produce multiple tables in a single PROC TABULATE step. However, you cannot change the way a variable is used or defined in the middle of the step. In other words, the variables in the CLASS or VAR statements are defined only once for all TABLE statements in the PROC TABULATE step. If you need to change the way a variable is used or defined for different TABLE statements, then you must place the TABLE statements, and define the variables, in multiple PROC TABULATE steps. The program that follows produces three summary tables during one execution of the TABULATE procedure:

```sas
options linesize=84 pageno=1 nodate;
proc tabulate data=year_sales format=comma10.;
  title1 'TruBlend Coffee Makers, Inc.';
  title2 'Sales of Deluxe Model Versus Standard Model';
  class SalesRep Type;
  var AmountSold Units;
  table Type;  
  table Type, Units;  
  table SalesRep, Type, AmountSold; 
run;
```

The numbered items in the previous program correspond to the following:

1. The first TABLE statement produces a one-dimensional summary table with the values for the variable Type in the column dimension.
2. The second TABLE statement produces a two-dimensional summary table with the values for the variable Type in the row dimension and the variable Units in the column dimension.
The third TABLE statement produces a three-dimensional summary table with the values for the variable SalesRep in the page dimension, the values for the variable Type in the row dimension, and the variable AmountSold in the column dimension.

The following summary table displays the results of this program:

**Output 26.4  Multiple Tables Produced by a Single PROC TABULATE Step**

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers, Inc.</th>
<th>Sales of Deluxe Model Versus Standard Model</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Deluxe</td>
<td>Standard</td>
</tr>
<tr>
<td>N</td>
<td>N</td>
</tr>
<tr>
<td>16</td>
<td>94</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers, Inc.</th>
<th>Sales of Deluxe Model Versus Standard Model</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Deluxe</td>
<td>2,525</td>
</tr>
<tr>
<td>Standard</td>
<td>38,464</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers, Inc.</th>
<th>Sales of Deluxe Model Versus Standard Model</th>
</tr>
</thead>
<tbody>
<tr>
<td>SalesRep Garcia</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Deluxe</td>
<td>46,778</td>
</tr>
<tr>
<td>Standard</td>
<td>465,293</td>
</tr>
</tbody>
</table>
Creating More Sophisticated Summary Tables

Creating Hierarchical Tables to Report on Subgroups

You can create a hierarchical table to report on subgroups of your data by crossing elements within a dimension. Crossing elements is the operation that combines two or more elements, such as class variables, analysis variables, format modifiers, statistics, or styles. Dimensions are automatically crossed. When you cross variables in a single dimension expression, values for one variable are placed within the values for the other variable in the same dimension. This forms a hierarchy of variables and, therefore, a hierarchical table. The order in which variables are listed when they are crossed determines the order of the headings in the table. In the column dimension, variables are stacked top to bottom; in the row dimension, left to right; and in the page dimension, front to back. You cross elements in a dimension expression by putting an asterisk between them. Note that two analysis variables cannot be crossed. Also, because dimensions are automatically crossed, all analysis variables must occur in one dimension.

The PROC TABULATE step that follows creates a two-dimensional summary table that crosses two variables and that answers the question, “What was the amount sold of each type of coffee maker by each sales representative?”

```
options linesize=84 pageno=1 nodate;
proc tabulate data=year_sales format=comma10;
```
title1 'TruBlend Coffee Makers, Inc.';
title2 'Amount Sold Per Item by Each Sales Representative';
class SalesRep Type;
var AmountSold;
table SalesRep*Type,
    AmountSold;
run;

The expression SalesRep*Type in the row dimension uses the asterisk operator to cross the values of the variable SalesRep with the values of the variable Type. Because SalesRep is listed before Type when crossed, and because the elements are crossed in the row dimension, values for Type will be listed to the right of values of SalesRep. Values for Type will be repeated for each value of SalesRep.

The following summary table displays the results:

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Type</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>Deluxe</td>
<td>46,778</td>
</tr>
<tr>
<td></td>
<td></td>
<td>465,293</td>
</tr>
<tr>
<td>Hollings-</td>
<td>Deluxe</td>
<td>37,620</td>
</tr>
<tr>
<td>worth</td>
<td></td>
<td>309,626</td>
</tr>
<tr>
<td>Jensen</td>
<td>Deluxe</td>
<td>40,590</td>
</tr>
<tr>
<td></td>
<td></td>
<td>420,573</td>
</tr>
</tbody>
</table>

Notice the hierarchy of values that are created when the values for Type are repeated to the right of each value of SalesRep.

**Formatting Output**

You can override formats in summary table output by crossing variables with format modifiers. You cross a variable with a format modifier by putting an asterisk between them.

The PROC TABULATE step that follows creates a two-dimensional summary table that crosses a variable with a format modifier and that answers the question, “What was the amount sold of each type of coffee maker by each sales representative?”

```
options linesize=84 pageno=1 nodate;

proc tabulate data=year_sales format=comma10.;
title1 'TruBlend Coffee Makers, Inc.';
title2 'Amount Sold Per Item by Each Sales Representative';
class SalesRep Type;
```
Creating Summary Tables with the TABULATE Procedure

Calculating Descriptive Statistics

```
Var AmountSold;
Table SalesRep*Type,
   AmountSold*f=dollar16.2;
Run;
```

The expression `AmountSold*f=dollar16.2` in the column dimension uses the
asterisk operator to cross the values of the variable `AmountSold` with the SAS format
modifier `f=dollar16.2`. The values for AmountSold will now display using the
DOLLAR16.2 format. The DOLLAR16.2 format is better suited for dollar figures than
the COMMA10. format, which is specified as the default in the PROC TABULATE
statement.

The following summary table displays the results:

```
Output 26.6 Crossign Variables with Format Modifiers

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers, Inc.</th>
<th>Amount Sold Per Item by Each Sales Representative</th>
</tr>
</thead>
<tbody>
<tr>
<td>SalesRep</td>
<td>Type</td>
</tr>
<tr>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>Garcia</td>
<td>Deluxe</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>Deluxe</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
</tr>
<tr>
<td>Jensen</td>
<td>Deluxe</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
</tr>
</tbody>
</table>
```

Calculating Descriptive Statistics

You can request descriptive statistics for a variable by crossing that variable with the
appropriate statistic keyword. Crossing either a class variable or an analysis variable
with a statistic tells PROC TABULATE what type of calculations to perform. Note that
two statistics cannot be crossed. Also, because dimensions are automatically crossed, all
statistics must occur in one dimension.

The default statistic crossed with a class variable is the N statistic or frequency.
Class variables can only be crossed with frequency and percent frequency statistics.
The default statistic crossed with an analysis variable is the SUM statistic. Analysis
variables can be crossed with any of the many descriptive statistics that are available
with PROC TABULATE including commonly used statistics like MIN, MAX, MEAN,
STD, and MEDIAN. For a complete list of statistics available for use with analysis
variables, see “Statistics Available in PROC TABULATE” in the Base SAS Procedures
Guide.

The PROC TABULATE step that follows creates a two-dimensional summary table
that crosses elements with a statistic and that answers the question, “What was the
average amount per sale of each type of coffee maker by each sales representative?”
In this program, the column dimension crosses the variable \textit{AmountSold} with the statistic \textit{mean} and with the format modifier \textit{f=dollar16.2}. The \textit{MEAN} statistic provides the arithmetic mean for \textit{AmountSold}.

The following summary table displays the results:

\textbf{Output 26.7} Crossing a Variable with a Statistic

\begin{table}[h]
\centering
\begin{tabular}{l|l|c}
\hline
\textbf{TruBlend Coffee Makers, Inc.} & 1 & \\
\hline
\multicolumn{2}{c|}{Average Amount Sold Per Item by Each Sales Representative} & \\
\hline
\hline
\textbf{SalesRep} & \textbf{Type} & \textbf{AmountSold} \\
\hline
Garcia & Deluxe & $11,694.38 \\
& Standard & $12,924.81 \\
Hollingsworth & Deluxe & $4,702.50 \\
& Standard & $12,901.09 \\
Jensen & Deluxe & $10,147.50 \\
& Standard & $12,369.78 \\
\hline
\end{tabular}
\end{table}

\section*{Reporting on Multiple Statistics}

You can create summary tables that report on two or more statistics by concatenating variables. \textit{Concatenating} is the operation that joins the information of two or more elements, such as class variables, analysis variables, or statistics, by placing the output of the second and subsequent elements immediately after the output of the first element. You concatenate elements in a dimension expression by putting a blank space between them.

The \textsc{PROC TABULATE} step that follows creates a two-dimensional summary table that uses concatenation and that answers the question, “How many sales were made, and what was the total sales figure for each type of coffee maker sold by each sales representative?”

\begin{verbatim}
options linesize=84 pageno=1 nodate;
proc tabulate data=year_sales format=comma10.;
\end{verbatim}
title1 'TruBlend Coffee Makers, Inc.';
title2 'Sales Summary by Representative and Product';
class SalesRep Type;
var AmountSold;
table SalesRep*Type,
    AmountSold*n AmountSold*f=dollar16.2;
run;

In this program, because the expressions AmountSold*n and AmountSold*f=dollar16.2 in the column dimension are separated by a blank space, their output will be concatenated.

The following summary table displays the results:

Output 26.8 Concatenating Variables

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Type</th>
<th>N</th>
<th>Sum</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Deluxe</td>
<td>4</td>
<td>$46,777.50</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>36</td>
<td>$465,293.28</td>
</tr>
<tr>
<td></td>
<td>Deluxe</td>
<td>8</td>
<td>$37,620.00</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>24</td>
<td>$309,626.10</td>
</tr>
<tr>
<td></td>
<td>Deluxe</td>
<td>4</td>
<td>$40,590.00</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>34</td>
<td>$420,572.60</td>
</tr>
</tbody>
</table>

In this summary table the frequency (N) of AmountSold 1 is shown in the same table as the SUM of AmountSold 2.

Reducing Code and Applying a Single Label to Multiple Elements

You can use parentheses to group concatenated elements (variables, formats, statistics, and so on) that are concatenated or crossed with a common element. This can reduce the amount of code used and can change how labels are displayed. The PROC TABULATE step that follows uses parentheses to group elements that are crossed with AmountSold and answers the question, “How many sales were made, and what was the total sales figure for each type of coffee maker sold by each sales representative?”

options linesize=84 pageno=1 nodate;
proc tabulate data=year_sales format=comma10.;
title1 'TruBlend Coffee Makers, Inc.';
title2 'Sales Summary by Representative and Product';
class SalesRep Type;
In this program, $\text{AmountSold}*(n \text{ sum} f=dollar16.2)$ takes the place of $\text{AmountSold}*n \text{ AmountSold}^*f=dollar16.2$. Notice the default statistic SUM from $\text{AmountSold}^*f=dollar16.2$ must now be included in the expression. This is because the format modifier must be crossed with a variable or a statistic. It cannot be in the expression by itself.

The following summary table displays the results:

**Output 26.9 Using Parentheses to Group Elements**

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Type</th>
<th>N</th>
<th>AmountSold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>Deluxe</td>
<td>4</td>
<td>$46,777.50</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>36</td>
<td>$465,293.28</td>
</tr>
<tr>
<td>Hollingsw</td>
<td>Deluxe</td>
<td>8</td>
<td>$37,620.00</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>24</td>
<td>$309,626.10</td>
</tr>
<tr>
<td>Jensen</td>
<td>Deluxe</td>
<td>4</td>
<td>$40,590.00</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>34</td>
<td>$420,572.60</td>
</tr>
</tbody>
</table>

Note that the label, AmountSold, spans multiple columns rather than appearing twice in the summary table, as it does in Output 26.8.

**Getting Summaries for All Variables**

You can summarize all of the class variables in a dimension with the universal class variable ALL. ALL can be concatenated with each of the three dimensions of the TABLE statement and within groups of elements delimited by parentheses. The PROC TABULATE step that follows creates a two-dimensional summary table with the universal class variable ALL, and answers the question, “For each sales representative and for all of the sales representatives as a group, how many sales were made, what was the average amount per sale, and what was the amount sold?”

```plaintext
renaming
options linesize=84 pageno=1 nodate;

proc tabulate data=year_sales format=comma10.;
  title1 'TruBlend Coffee Makers, Inc.';
  title2 'Sales Report';
  class SalesRep Type;
  var AmountSold;
  table SalesRep*Type all,
```
Creating Summary Tables with the TABULATE Procedure

Defining Labels

In this program, the TABLE statement now includes the universal class variable ALL in the row dimension. SalesRep and Type will be summarized.

The following summary table displays the results:

Output 26.10  Crossing with the Universal Class Variable ALL

```
<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Type</th>
<th>N</th>
<th>Mean</th>
<th>Sum</th>
</tr>
</thead>
<tbody>
<tr>

<td>4</td>
<td>$10,147.50</td>
<td>$40,590.00</td>
</tr>
<tr>
<td></td>
<td>Standard</td>
<td>34</td>
<td>$12,369.78</td>
<td>$420,572.60</td>
</tr>
<tr>
<td>All</td>
<td></td>
<td>110</td>
<td>$12,004.36</td>
<td>$1,320,479.48</td>
</tr>
</tbody>
</table>
```

This summary table reports the frequency (N), the MEAN, and the SUM of AmountSold for each category of SalesRep and Type. This data has been summarized for all categories of SalesRep and Type in the row labeled All.

Defining Labels

You can add your own labels to a summary table or remove headings from a summary table by assigning labels to variables in the TABLE statement. Simply follow the variable with an equal sign (=) followed by either the desired label or by a blank space in quotation marks. A blank space in quotation marks removes the heading from the summary table. The PROC TABULATE step that follows creates a two-dimensional summary table that uses labels in the TABLE statement and that answers the question, “What is the percent of total sales and average amount sold by each sales representative of each type of coffee maker and all coffee makers?”

```
options linesize=84 pageno=1 nodate;

proc tabulate data=year_sales format=comma10.;
title1 'TruBlend Coffee Makers, Inc. Sales Report';
title2 'Sales Performance';
class SalesRep Type;
var AmountSold;
table SalesRep='Sales Representative';
```
(Type='Type of Coffee Maker' all) all,
AmountSold='Amount'
(N='Sales' SUM='Amount' colpctsum='% Sales'
mean='Average Sale');

run;

The numbered items in the previous program correspond to the following:
1. The variables SalesRep and Type are assigned labels.
2. The frequency statistic N, the statistic SUM, and the statistic MEAN are assigned labels.
3. The statistic COLPCTSUM is used to calculate the percentage of the value in a single table cell in relation to the total of the values in the column and is assigned the label '% Sales'.
4. The variable AmountSold is assigned a blank label. As a result, the heading for AmountSold does not appear in the summary table.

The following summary table displays the results:

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers, Inc.</th>
<th>Sales Performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sales Representative</td>
<td>Type of Coffee Maker</td>
</tr>
<tr>

</tr>
</tbody>
</table>
Creating Summary Tables with the TABULATE Procedure

Using Styles and the Output Delivery System

If you use the Output Delivery System to create output from PROC TABULATE, for any destination other than Listing or Output destinations, you can do the following:

- Set certain style elements (such as font style, font weight, and color) that the procedure uses for various parts of the table.
- Specify style elements for the labels for variables by adding the option to the CLASS statement.
- Specify style elements for cells in the summary table by crossing the STYLE= option with an element of a dimension expression.

When it is used in a dimension expression, the STYLE= option must be enclosed within square brackets ([ and ]) or braces ({ and }). The PROC TABULATE step that follows creates a two-dimensional summary table that uses the STYLE= option in a CLASS statement and in the TABLE statement and that answers the question, “What is the percent of total sales and average amount sold by each sales representative of each type of coffee maker and all coffee makers?”

```
options linesize=84 pageno=1 nodate;
ods html file='summary-table.htm';
ods printer file='summary-table.ps';

proc tabulate data=year_sales format=comma10.;
title1 'TruBlend Coffee Makers, Inc.';
title2 'Sales Performance';
class SalesRep;
class Type / style=[font_style=italic];
var AmountSold;
table SalesRep='Sales Representative'*(Type='Type of Coffee Maker'
   all*[style=[background=yellow font_weight=bold]]
   all*[style=[font_weight=bold]],
   AmountSold=' '*(colpctsum='% Sales' mean='Average Sale'*
   f=dollar16.2));
run;
```

ods html close;
ods printer close;

The numbered items in the previous program correspond to the following:

- The ODS HTML statement opens the HTML destination and creates HTML output. FILE= identifies the file that contains the HTML output. Some browsers require an extension of HTM or HTML on the filename.
- The ODS PRINTER statement opens the Printer destination and creates Printer output. FILE= identifies the file that contains the Printer output.
3 The `STYLE=` option is specified in the second `CLASS` statement, which sets the font style of the label for `Type` to italic. The label for `SalesRep` is not affected by the `STYLE=` option because it is in a separate `CLASS` statement.

4 The universal class variable `ALL` is crossed with the `STYLE=` option, which sets the background for the table cells to yellow and the font weight for these cells to bold.

5 The universal class variable `ALL` is crossed with the `STYLE=` option, which sets the font weight for the table cells to bold.

6 The last ODS HTML statement closes the HTML destination and all of the files that are associated with it. You must close the HTML destination before you can view the HTML output with a browser.

7 The last ODS PRINTER statement closes the Printer destination. You must close the Printer destination before you can print the output on a physical printer.

The following summary table displays the results:

Display 26.2  Using Style Modifiers and the ODS HTML Statement

<table>
<thead>
<tr>
<th>Sales Representative</th>
<th>Type of Coffee Maker</th>
<th>% Sales</th>
<th>Average Sale</th>
</tr>

</tbody>
</table>

This summary table shows the effects of the three uses of the `STYLE=` option with the ODS HTML statement in the previous SAS program:

- The repeated label, Type of Coffee Maker, is in italics.
- The subtotals for each value of sales representative are highlighted in a lighter color (yellow) and are bold.
- The totals for all sales representatives are bold.

The following summary table displays the results:
Display 26.3  Using Style Modifiers and the ODS PRINTER Statement

**TruBlend Coffee Makers, Inc.**
**Sales Performance**

<table>
<thead>
<tr>
<th>Sales Representative</th>
<th>Type of Coffee Maker</th>
<th>% Sales</th>
<th>Average Sale</th>
</tr>
</thead>
<tbody>

<td>$12,135.86</td>
</tr>
<tr>
<td>All</td>
<td></td>
<td>100</td>
<td>$12,004.36</td>
</tr>
</tbody>
</table>

This summary table shows the effects of the three uses of the STYLE= option with the ODS PRINTER statement in the previous SAS program:

- The repeated label, Type of Coffee Maker, is in italics.
The subtotals for each value of sales representative are highlighted and are bold. The totals for all sales representatives are bold.

**Ordering Class Variables**

You can control the order in which class variable values and their headings display in a summary table with the ORDER= option. You can use the ORDER= option with the PROC TABULATE statement and with individual CLASS statements. The syntax is `ORDER=sort-order`. The four possible sort orders (DATA, FORMATTED, FREQ, and UNFORMATTED) are defined in “Review of SAS Tools” on page 431. The PROC TABULATE step that follows creates a two-dimensional summary table that uses the ORDER= option with the PROC TABULATE statement to order all class variables by frequency, and that answers the question, “Which quarter produced the greatest number of sales, and which sales representative made the most sales overall?”

```
options linesize=84 pageno=1 nodate;

proc tabulate data=year_sales format=comma10. order=freq;
   title1 'TruBlend Coffee Makers, Inc.';
   title2 'Quarterly Sales and Representative Sales by Frequency';
   class SalesRep Quarter;
   table SalesRep all,
       Quarter all;
run;
```

The following summary table displays the results of this program:

**Output 26.12  Ordering Class Variables**

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>3</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>21</td>
<td>8</td>
<td>6</td>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>Jensen</td>
<td>21</td>
<td>5</td>
<td>6</td>
<td>6</td>
<td>38</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>15</td>
<td>5</td>
<td>6</td>
<td>32</td>
<td></td>
</tr>
<tr>
<td>All</td>
<td>57</td>
<td>18</td>
<td>18</td>
<td>17</td>
<td>110</td>
</tr>
</tbody>
</table>

The numbered items in the previous SAS output correspond to the following:

1. The order of the values of the class variable Quarter shows that most sales occurred in quarter 3 followed by quarters 1, 2, and then 4.
2. The order of the values of the class variable SalesRep shows that Garcia made the most sales overall, followed by Jensen and then Hollingsworth.
The universal class variable ALL is included in both dimensions of this example to show the frequency data that SAS used to order the data when creating the summary table.

Review of SAS Tools

Global Statement

TITLE<cn> <title>;
specifies a title. The argument n is a number from 1 to 10 that immediately follows the word TITLE, with no intervening blank, and specifies the level of the TITLE. The text of each title can be up to 132 characters long (256 characters long in some operating environments) and must be enclosed in single or double quotation marks.

TABULATE Procedure Statements

PROC TABULATE <option(s)>;
CLASS variable(s)<option(s)>;
VAR analysis-variable(s);
TABLE <<page-expression,> row-expression,> column-expression;

PROC TABULATE <option(s)>;
starts the procedure.

You can specify the following options in the PROC TABULATE statement:

DATA=SAS-data-set
specifies the SAS-data-set to be used by PROC TABULATE. If you omit the DATA= option, then the TABULATE procedure uses the SAS data set that was created most recently in the current job or session.

FORMAT=format-name
specifies a default format for formatting the value in each cell in the table. You can specify any valid SAS numeric format or user-defined format.

MISSING
considers missing values as valid values to create the combinations of class variables. A heading for each missing value appears in the table.

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
specifies the sort order that is used to create the unique combinations of the values of the class variables, which form the headings of the table. A brief description of each sort order follows:

DATA
orders values according to their order in the input data set.

FORMATTED
orders values by their ascending formatted values. This order depends on your operating environment.

FREQ
orders values by descending frequency count.
UNFORMATTED
orders values by their unformatted values, which yields the same order as PROC SORT. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

ORDER= used on a CLASS statement overrides ORDER= used on the PROC TABULATE statement.

CLASS variable(s)/option(s);
identifies class variables for the table. Class variables determine the categories that PROC TABULATE uses to calculate statistics.

MISSING
considers missing values as valid values to create the combinations of class variables. A heading for each missing value appears in the table. If MISSING should apply only to a subset of the class variables, then specify MISSING in a separate CLASS statement with the subset of the class variables.

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
specifies the sort order used to create the unique combinations of the values of the class variables, which form the headings of the table. If ORDER= should apply only to a subset of the class variables, then specify ORDER= in a separate CLASS statement with the subset of the class variables. In this way, a separate sort order can be specified for each class variable. A brief description of each sort order follows:

DATA
orders values according to their order in the input data set.

FORMATTED
orders values by their ascending formatted values. This order depends on your operating environment.

FREQ
orders values by descending frequency count.

UNFORMATTED
orders values by their unformatted values, which yields the same order as PROC SORT. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

ORDER= used on a CLASS statement overrides ORDER= used on the PROC TABULATE statement.

VAR analysis-variable(s);
identifies analysis variables for the table. Analysis variables contain values for which you want to compute statistics.

TABLE <<page-expression, >row-expression, >column-expression;
defines the table that you want PROC TABULATE to produce. You must specify at least one TABLE statement. In the TABLE statement you specify page-expressions, row-expressions, and column-expressions, all of which are constructed in the same way and are referred to collectively as dimension expressions. Use commas to separate dimension expressions from one another. You define relationships among variables, statistics, and other elements within a dimension by combining them with one or more operators. Operators are symbols that tell PROC TABULATE what actions to perform on the variables, statistics, and other elements. The table that follows lists the common operators and the actions that they symbolize:
<table>
<thead>
<tr>
<th>Operator</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>, comma</td>
<td>separates dimensions of the table</td>
</tr>
<tr>
<td>* asterisk</td>
<td>crosses elements within a dimension</td>
</tr>
<tr>
<td>blank space</td>
<td>concatenates elements within a dimension</td>
</tr>
<tr>
<td>= equal</td>
<td>overrides default cell format or assigns label to an element</td>
</tr>
<tr>
<td>() parentheses</td>
<td>groups elements and associates an operator with each concatenated element in the group</td>
</tr>
<tr>
<td>[ ] square brackets</td>
<td>groups the STYLE= option for crossing, and groups style attribute specifications within the STYLE= option</td>
</tr>
<tr>
<td>{ } braces</td>
<td>groups the STYLE= option for crossing, and groups style attribute specifications within the STYLE= option</td>
</tr>
</tbody>
</table>

Introduction to Creating Detail and Summary Reports with the REPORT Procedure

Purpose

SAS provides a variety of report writing tools that produce detail and summary reports. The reports enable you to communicate information about your data in an organized, concise manner. The REPORT procedure enables you to create detail and summary reports in a single report writing tool. In this section, you will learn how to use PROC REPORT to do the following:

- produce simple detail reports
- produce simple summary reports
- produce enhanced reports by adding additional statements that order and group observations, sum columns, and compute overall totals
- customize the appearance of reports by adding column spacing, column labels, line separators, and formats

Prerequisites

To understand the examples in this section, you should be familiar with the following features and concepts:

- data set options
- the TITLE statement
- the LABEL statement
- WHERE processing
- creating and assigning SAS formats

Understanding How to Construct a Report

Using the Report Writing Tools

The REPORT procedure combines the features of PROC MEANS, PROC PRINT, and PROC TABULATE along with features of the DATA step report writing into a powerful report writing tool. PROC REPORT enables you to do the following:

- Create customized, presentation-quality reports.
- Develop and store report definitions that control the structure and layout.
- View previously defined reports.
- Generate multiple reports from one report definition.

There are three different ways that you can use PROC REPORT to construct reports:

- in a windowing environment with a prompting facility
- in a windowing environment without a prompting facility
- in a nonwindowing environment where you use PROC REPORT to submit a series of statements
The windowing environment requires minimal SAS programming skills and allows immediate, visual feedback as you develop the report. This section explains how you use the nonwindowing environment to create summary and detail reports.

### Types of Reports

The REPORT procedure enables you to construct two types of reports:

**detail report**
- contains one row for every observation that is selected for the report (see Output 27.1). Each of these rows is a detail row.

**summary report**
- consolidates data so that each row represents multiple observations (see Output 27.5). Each of these rows is also called a detail row.

Both detail and summary reports can contain summary lines as well as detail rows. A summary line summarizes numerical data for a set of detail rows or for all detail rows. You can use PROC REPORT to provide both default summaries and customized summaries.

### Laying Out a Report

#### Establishing the Layout

If you first decide on the layout of the report, then creating the report is easier. You need to determine the following:

- which columns to display in the report
- the order of the columns and rows
- how to label the rows and columns
- which statistics to display
- whether to display a column for each value of a particular variable
- whether to display a row for every observation, or to consolidate multiple observations in a single row

Once you establish the layout of the report, use the COLUMN statement and DEFINE statement in the PROC REPORT step to construct the layout.

#### Constructing the Layout

The COLUMN statement lists the report items to include as columns of the report, describes the arrangement of the columns, and defines headers that span multiple columns. A report item is a data set variable, a calculated statistic, or a variable that you compute based on other items in the report.

The DEFINE statement defines the characteristics of an item in the report. These characteristics include how PROC REPORT uses an item in the report, the text of the column header, and the format to display the values.

You control much of a report’s layout by the usages that you specify for variables in the DEFINE statements. The types of variable usages are:

**ACROSS**
- creates a column for each value of an ACROSS variable.
ANALYSIS computes a statistic from a numeric variable for all the observations represented by a cell of the report. The value of the variable depends on where it appears in the report. By default, PROC REPORT treats all numeric variables as ANALYSIS variables and computes the sum.

COMPUTED computes a report item from variables that you define for the report. They are not in the input data set, and PROC REPORT does not add them to the input data set.

DISPLAY displays a row for every observation in the input data set. By default, PROC REPORT treats all character variables as DISPLAY variables.

GROUP consolidates into one row all of the observations from the data set that have a unique combination of the formatted values for all GROUP variables.

ORDER specifies to order the rows for every observation in the input data set according to the ascending, formatted values of the ORDER variable.

The position and usage of each variable in the report determine the report’s structure and content. For example, PROC REPORT orders the detail rows of the report according to the values of ORDER and GROUP variables (from left to right). Similarly, PROC REPORT orders columns for an ACROSS variable from top to bottom, according to the values of the variable. For a complete discussion of how PROC REPORT determines the layout of a report, see the Base SAS Procedures Guide.

---

Input File and SAS Data Set for Examples

The examples in this section use one input file* and one SAS data set. The input file contains sales records for a company, TruBlend Coffee Makers, that distributes the coffee machines. The file has the following structure:

```
01 1 Hollingsworth Deluxe 260 49.50
01 1 Garcia Standard 41 30.97
01 1 Hollingsworth Deluxe 330 49.50
01 1 Jensen Standard 1110 30.97
01 1 Garcia Standard 715 30.97
01 1 Jensen Deluxe 675 49.50
02 1 Garcia Deluxe 10 49.50
...more data lines...
12 4 Hollingsworth Deluxe 125 49.50
12 4 Jensen Standard 1254 30.97
12 4 Hollingsworth Deluxe 175 49.50
```

The input file contains the following values from left to right:

- the month that a sale was made
- the quarter of the year that a sale was made

* See the “Data Set YEAR_SALES” on page 717 for a complete listing of the input data.
the name of the sales representative
the type of coffee maker sold (standard or deluxe)
the number of units sold
the price of each unit in US dollars

The SAS data set is named YEAR_SALES. This data set contains all the sales data from the input file and a new variable named AmountSold, which is created by multiplying Units by Price.

The following program creates the SAS data set that this section uses:

```sas
data year_sales;
  infile 'your-input-file';
  input Month $ Quarter $ SalesRep $14. Type $ Units Price;
  AmountSold = Units * Price;
run;
```

Creating Simple Reports

Displaying All the Variables

By default, PROC REPORT uses all of the variables in the data set. The layout of the report depends on the type of variables in the data set. If the data set contains any character variables, then PROC REPORT generates a simple detail report that lists the values of all the variables and the observations in the data set. If the data set contains only numeric variables, then PROC REPORT sums the value of each variable over all observations in the data set and produces a one-line summary of the sums. To produce a detail report for a data set with only numeric values, you have to define the columns in the report.

By default, PROC REPORT opens the REPORT window so that you can modify a report repeatedly and see the modifications immediately. To run PROC REPORT without the REPORT window and send your results to the SAS procedure output, you must use the NOWINDOWS option in the PROC REPORT statement.

The following PROC REPORT step creates the default detail report for the first quarter sales:

```sas
options linesize=80 pageno=1 nodate;
proc report data=year_sales nowindows;
  where quarter='1';
  title1 'TruBlend Coffee Makers, Inc.';
  title2 'First Quarter Sales Report';
run;
```

The WHERE statement specifies a condition that SAS uses to select observations from the YEAR_SALES data set. Before PROC REPORT builds the report, SAS selectively processes observations so that the report contains only data for the observations from the first quarter. For additional information about WHERE processing, see “Selecting Observations” on page 379.
The following detail report shows all the variable values for those observations in YEAR_SALES that contains first quarter sales data:

<td>1</td>
<td>Garcia</td>
<td>Standard</td>
<td>310</td>
<td>30.97</td>
<td>9600.7</td>
</tr>
</tbody>
</table>

The following list corresponds to the numbered items in the preceding report:

1. The order of the columns corresponds to the position of the variables in the data set.
2. The default column width for numeric variables is nine. Therefore, the column label for AmountSold wraps across two lines.
3. A blank line does not automatically appear between the column labels and the data values.
4. The top of the report has a title, produced by the TITLE statement.

The following PROC REPORT step produces the default summary report when the YEAR_SALES data set contains only numeric values:

```sas
options linesize=80 pageno=1 nodate;
proc report data=year_sales (keep=Units AmountSold) colwidth=10 nowindows;
   title1 'TruBlend Coffee Makers, Inc.';
   title2 'Total Yearly Sales';
run;
```

The KEEP= data set option specifies to process only the numeric variables Units and AmountSold. PROC REPORT uses these variables to create the report. The COLWIDTH= option increases the column width so that the column label for AmountSold displays on a single line.
The following report displays a one-line summary for the two numeric variables:

Output 27.2  The Default Report When the Data Set Contains Only Numeric Values

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers, Inc.</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Yearly Sales</td>
<td></td>
</tr>
<tr>
<td>Units</td>
<td>40989</td>
</tr>
<tr>
<td>AmountSold</td>
<td>1320479.48</td>
</tr>
</tbody>
</table>

PROC REPORT computed the one-line summary for Units and AmountSold by summing the value of each variable for all the observations in the data set.

Specifying and Ordering the Columns

The first step in constructing a report is to select the columns that you want to appear in the report. By default, the report contains a column for each variable and the order of the columns corresponds to the order of the variables in the data set.

You use the COLUMN statement to specify the variables to use in the report and the arrangement of the columns. In the COLUMN statement you can list data set variables, statistics that are calculated by PROC REPORT, or variables that are computed from other items in the report.

The following program creates a four column sales report for the first quarter:

```plaintext
options linesize=80 pageno=1 nodate;

proc report data=year_sales nowindows;
   where Quarter='1';
   column SalesRep Month Type Units;
   title1 'TruBlend Coffee Makers, Inc.';
   title2 'First Quarter Sales Report';
run;
```

The COLUMN statement specifies the order of the items in the report. The first column lists the values in SalesRep, the second column lists the values in Month, and so forth.
The following output shows the report:

**Output 27.3  Displaying Selected Columns**

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Month</th>
<th>Type</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

---

**Ordering the Rows**

You control much of the layout of a report by deciding how you use the variables. You tell PROC REPORT how to use a variable by specifying a usage option in the DEFINE statement for the variable.

To specify the order of the rows in the report, you can use the ORDER option in one or more DEFINE statements. PROC REPORT orders the rows of the report according to the values of the ORDER variables. If the report contains multiple ORDER variables, then PROC REPORT first orders rows according to the values of the first ORDER variable in the COLUMN statement.* Within each value of the first ORDER variable, the procedure orders rows according to the values of the second ORDER variable in the COLUMN statement, and so forth.

The following program creates a detail report of sales for the first quarter that is ordered by the sales representatives and month:

``` SAS
options linesize=80 pageno=1 nodate;

proc report data=year_sales nowindows;
  where Quarter='1';
  column SalesRep Month Type Units;
  define SalesRep / order;
  define Month / order;
  title1 'TruBlend Coffee Makers, Inc.';
  title2 'First Quarter Sales Report';
run;
```

* If you omit the COLUMN statement, then PROC REPORT processes the ORDER variables according to their position in the input data set.
The DEFINE statements specify that SalesRep and Month are the ORDER variables. The COLUMN statement specifies the order of the columns. By default, the rows are ordered by the ascending formatted values of SalesRep. The rows for each sales representative are ordered by the values of Month.

The following output shows the report:

**Output 27.4 Ordering the Rows**

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Month</th>
<th>Type</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>01</td>
<td>Standard</td>
<td>41</td>

<td>02</td>
<td>Standard</td>
<td>153</td>
</tr>
<tr>
<td></td>
<td>03</td>
<td>Standard</td>
<td>154</td>
</tr>
</tbody>
</table>

PROC REPORT does not repeat the values of the ORDER variables from one row to the next when the values are the same.

**Consolidating Several Observations into a Single Row**

You can create summary reports with PROC REPORT by defining one or more GROUP variables. A group is a set of observations that has a unique combination of values for all GROUP variables. PROC REPORT tries to consolidate, or summarize, each group into one row of the report.

To consolidate all columns across a row, you must define all variables in the report as either GROUP, ANALYSIS, COMPUTED, or ACROSS. The GROUP option in one or more DEFINE statements identifies the variables that PROC REPORT uses to form groups. You can define more than one variable as a GROUP variable, but GROUP variables must precede variables of the other types of usage. PROC REPORT determines the nesting by the order of the variables in the COLUMN statement. For more information about defining the usage of a variable, see “Constructing the Layout” on page 437.

The value of an ANALYSIS variable for a group is the value of the statistic that PROC REPORT computes for all observations in a group. For each ANALYSIS variable, you can specify the statistic in the DEFINE statement. By default, PROC REPORT uses all numeric variables as the ANALYSIS variables and computes the SUM statistic.
The statistics that you can request in the DEFINE statement are as follows:

Table 27.1 Descriptive Statistics

<table>
<thead>

<td>PRT</td>
<td>T</td>
</tr>
</tbody>
</table>

For definitions and discussion of these elementary statistics, see the Appendix in the Base SAS Procedures Guide.

The following program creates a summary report that shows the total yearly sales for each sales representative:

```sas
options linesize=80 pageno=1 nodate;

proc report data=year_sales nowindows colwidth=10;
column SalesRep Units AmountSold;
define SalesRep / group;  
define Units / analysis sum;  
define AmountSold / analysis sum;  
title1 'TruBlend Coffee Makers Sales Report';
title2 'Total Yearly Sales';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The DEFINE statement specifies that SalesRep is the GROUP variable.
2. The DEFINE statement specifies that Units is an ANALYSIS variable and specifies that PROC REPORT computes the SUM statistic.
3. The DEFINE statement specifies that AmountSold is an ANALYSIS variable and specifies that PROC REPORT computes the SUM statistic.
The following output shows the report:

**Output 27.5  Grouping Multiple Observations in a Summary Report**

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers Sales Report</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Yearly Sales</td>
<td></td>
</tr>
<tr>
<td>SalesRep</td>
<td>Units</td>
</tr>
<tr>
<td>Garcia</td>
<td>15969</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>10620</td>
</tr>
<tr>
<td>Jensen</td>
<td>14400</td>
</tr>
</tbody>
</table>

Each row of the report represents one group and summarizes all observations that have a unique value for SalesRep. PROC REPORT orders these rows in ascending order of the GROUP variable, which in this example is the sales representative ordered alphabetically. The values of the ANALYSIS variables are the sum of Units and AmountSold for all observations in a group, which in this case is the total units and amount sold by each sales representative.

---

**Changing the Default Order of the Rows**

You can modify the default ordering sequence for the rows of a report by using the ORDER= or DESCENDING option in the DEFINE statement. The ORDER= option specifies the sort order for a variable. You can order the rows by:

- **DATA** the order of the data in the input data set.
- **FORMATTED** ascending formatted values.
- **FREQ** ascending frequency count.
- **INTERNAL** ascending unformatted or internally stored values.

By default, PROC REPORT uses the formatted values of a variable to order the rows. The DESCENDING option reverses the sort sequence so that PROC REPORT uses descending values to order the rows.

The following program creates a detail report of the first quarter sales that is ordered by number of sales:

```plaintext
options linesize=80 pageno=1 nodate;
proc report data=year_sales nowindows;
  where Quarter='1';
  column SalesRep Type Units Month;
  define SalesRep / order=u order=freq;
  define Units / order=freq descending;
  define Type / order=descending;
  title1 'TruBlend Coffee Makers, Inc.';
  title2 'First Quarter Sales Report';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The DEFINE statements specify that SalesRep, Units, and Type are ORDER variables that correspond to the number of sales each sales representative made.
2. The ORDER=FREQ option orders the rows of the report by the frequency of SalesRep.
The DESCENDING option orders the rows for UNITS from the largest to the smallest value.

The following output shows the report:

**Output 27.6** Changing the Order Sequence of the Rows

<table>
<thead>
<tr>
<th>SalesRep</th>
<th>Type</th>
<th>Units</th>
<th>Month</th>
</tr>
</thead>
<tbody>

<td>41</td>
<td>01</td>
</tr>
<tr>
<td></td>
<td></td>
<td>40</td>
<td>02</td>
</tr>
</tbody>
</table>

The following list corresponds to the numbered items in the preceding report:

1. The order of the columns corresponds to the order in which the variables are specified in the COLUMN statement. The order of the DEFINE statements does not affect the order of the columns.

2. The order of the rows is by ascending frequency of SalesRep so that the sales representative with the least number of sales (observations) appears first while the sales representative with the greatest number of sales appears last.

3. The order of the rows within SalesRep is by ascending formatted values of Type so that sales information about the deluxe coffee maker occurs before the standard coffee maker.

4. The order of the rows within Type is by descending formatted values of Units so that the observation with the highest number of units sold appears first.

---

**Creating More Sophisticated Reports**

---

**Adjusting the Column Layout**

**Understanding Column Width and Spacing**

You can modify the column spacing and the column width by specifying options in either the PROC REPORT statement or the DEFINE statement. To control the spacing between columns, you can use the SPACING= option in the following statements:
PROC REPORT statement to specify the default number of blank characters between all columns
- DEFINE statement to override the default value and to specify the number of blank characters to the left of a particular column

By default, PROC REPORT inserts two blank spaces between the columns. To remove space between columns, specify SPACING=0. The maximum space that PROC REPORT allows between columns depends on the number of columns in the report. The sum of all column widths plus the blank characters to left of each column cannot exceed the line size.

To specify the column widths, you can use the following options:
- COLWIDTH= option in the PROC REPORT statement to specify the default number of characters for columns that contain computed variables or numeric data set variables
- WIDTH= option in the DEFINE statement to specify the width of the column that PROC REPORT uses to display a report item

By default, the column width is nine characters for numeric values. You can specify the column width as small as one character and as large as the line size. PROC REPORT sets the width of a column by first looking at the WIDTH= option in the DEFINE statement. If you omit WIDTH=, then PROC REPORT uses a column width large enough to accommodate the format for a report item. If you do not assign a format, then the column width is either the length of the character variable or the value of the COLWIDTH= option.

You can adjust the column layout by specifying how to align the formatted values of a report item and the column header with the column width. The following options in the DEFINE statement align the columns:
- CENTER centers the column values and column header.
- LEFT left-aligns the column values and column header.
- RIGHT right-aligns the column values and column header.

### Modifying the Column Width and Spacing

The following program modifies column spacing in a summary report that shows the total yearly sales for each sales representative:

```plaintext
options linesize=80 pageno=1 nodate;

proc report data=year_sales nowindows spacing=3;
  column SalesRep Units AmountSold;
  define SalesRep /group right;
  define Units / analysis sum width=5;
  define AmountSold / analysis sum width=10;
  title1 'TruBlend Coffee Makers Sales Report';
  title2 'Total Yearly Sales';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The SPACING= option in the PROC REPORT statement inserts three blank characters between all the columns.
2. The RIGHT option in the DEFINE statement right-aligns the name of the sales representative and the column header in the column.
3. The WIDTH= options in the DEFINE statements specify enough space to accommodate column headers on one line.
The following output shows the report:

### Output 27.7  Adjusting Column Width and Spacing

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers Sales Report</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Yearly Sales</td>
<td></td>
</tr>
<tr>
<td>SalesRep Units AmountSold</td>
<td></td>
</tr>
<tr>
<td>Garcia 15969 512070.78</td>
<td></td>
</tr>
<tr>
<td>Hollingsworth 10620 347246.1</td>
<td></td>
</tr>
<tr>
<td>Jensen 14400 461162.6</td>
<td></td>
</tr>
</tbody>
</table>

The column width for SalesRep is 14 characters wide, which is the length of the variable.

### Customizing Column Headers

#### Understanding the Structure of Column Headers

By default, PROC REPORT does not insert a vertical space beneath column headers to visually separate the detail rows from the headers. To further improve the appearance of a report, you can underline the column headers, insert a blank line beneath column headers, and specify your own column headers. The HEADLINE and HEADSKIP options in the PROC REPORT statement enable you to underline the column headers and insert a blank line after the column headers, respectively.

By default, SAS uses the variable name or the variable label, if the data set variable was previously assigned a label, for the column header. To specify a different column header, place text between single or double quotation marks in the DEFINE statement for the report item.

By default, PROC REPORT produces line breaks in the column header based on the width of the column. When you use multiple sets of quotation marks in the label, each set defines a separate line of the header. If you include split characters in the label, then PROC REPORT breaks the header when it reaches the split character and continues the header on the next line. By default, the split character is the slash (/). Use the SPLIT= option in the PROC REPORT statement to specify an alternative split character.

#### Modifying the Column Headers

The following program creates a summary report with multiple-line column headers for the variables SalesRep, Units, and AmountSold:

```sas
options linesize=80 pageno=1 nodate;
proc report data=year_sales nowindows spacing=3 headskip;
  column SalesRep Units AmountSold;
  define SalesRep / group 'Sales/Representative';
  define Units / analysis sum 'Units Sold' width=5;
  define AmountSold / analysis sum 'Amount Sold';
  title1 'TruBlend Coffee Makers Sales Report';
  title2 'Total Yearly Sales';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The HEADSKIP option inserts a blank line after the column headers.
The text in quotation marks specifies the column headers.

The \texttt{SPLIT=} option in the \texttt{PROC REPORT} statement is omitted because the label for \texttt{SalesRep} uses the default split character and the label for \texttt{AmountSold} identifies where to split the label by using multiple sets of quotation marks.

The following output shows the report:

\begin{verbatim}
Output 27.8  Modifying the Column Headers

\begin{tabular}{lrr}
\hline
TruBlend Coffee Makers Sales Report & 1 \\
Total Yearly Sales & & \\
\hline
Sales Representative & Units Sold & Amount Sold \\
\hline
Garcia & 15969 & 512070.78 \\
Hollingsworth & 10620 & 347246.1 \\
Jensen & 14400 & 461162.6 \\
\hline
\end{tabular}
\end{verbatim}

The label Units Sold is split between two lines because the column width for this report item is 5 characters wide.

### Specifying Formats

#### Using SAS Formats

A simple and effective way to enhance the readability of your reports is to specify a format for the report items. To assign a format to a column, you can use the \texttt{FORMAT} statement or the \texttt{FORMAT=} option in the \texttt{DEFINE} statement. The \texttt{FORMAT} statement only works for data set variables. The \texttt{FORMAT=} option assigns a SAS format or a user-defined format to any report item.

\texttt{PROC REPORT} determines how to format a report item by searching for the format to use in these places and in this order:

1. the \texttt{FORMAT=} option in the \texttt{DEFINE} statement
2. the \texttt{FORMAT} statement
3. the data set

\texttt{PROC REPORT} uses the first format that it finds. If you have not assigned a format, then \texttt{PROC REPORT} uses the \texttt{BEST9.} format for numeric variables and the \texttt{$w.} format for character variables.

#### Applying Formats to Report Items

The following program illustrates how to apply formats to the columns of a summary report of total yearly sales for each sales representative:

\begin{verbatim}
options linesize=80 pageno=1 nodate;
proc report data=year_sales nowindows spacing=3 headskip;
  column SalesRep Units AmountSold;
  define SalesRep / group ‘Sales/Representative’;
  define Units / analysis sum ‘Units Sold’ format=comma7.;
  define AmountSold / analysis sum ‘Amount Sold’ format=dollar14.2;
  title1 ‘TruBlend Coffee Makers Sales Report’;
\end{verbatim}
title2 'Total Yearly Sales';
run;

PROC REPORT applies the COMMA7. format to the values of the variable Units and the DOLLAR14.2 format to the values of the variable AmountSold.

The following output shows the report:

Output 27.9  Formatting the Numeric Columns

<table>
<thead>
<tr>
<th>TruBlend Coffee Makers Sales Report 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Yearly Sales</td>
</tr>
<tr>
<td>Sales Representative</td>
</tr>
<tr>
<td>----------------------</td>
</tr>
<tr>
<td>García</td>
</tr>
<tr>
<td>Hollingsworth</td>
</tr>
<tr>
<td>Jensen</td>
</tr>
</tbody>
</table>

The following list corresponds to the numbered items in the preceding report:

1. The variable AmountSold uses the DOLLAR14.2 format for a maximum column width of 14 spaces. Two spaces are reserved for the decimal part of a value. The remaining 12 spaces include the decimal point, whole numbers, the dollar sign, commas, and a minus sign if a value is negative.

2. The variable Units uses the COMMA7. format for a maximum column width of seven spaces. The column width includes the numeric value, commas, and a minus sign if a value is negative.

These formats do not affect the actual data values that are stored in the SAS data set. That is, the formats only affect the way values appear in a report.

Using Variable Values as Column Headers

Creating the Column Headers

To create column headers from the values of the data set variables and produce cross-tabulations, you can use the ACROSS option in a DEFINE statement. When you define an ACROSS variable, PROC REPORT creates a column for each value of the ACROSS variable.

Columns created by an ACROSS variable contain statistics or computed values. If nothing is above or below an ACROSS variable, then PROC REPORT displays the number of observations in the input data set that belong to a cell of the report (N statistic). A cell is a single unit of a report, formed by the intersection of a row and a column.

The examples in this section show you how to display frequency counts (the N statistic) and statistics that are computed for ANALYSIS variables. For information about placing computed variables in the cells of the report, see the REPORT procedure in Base SAS Procedures Guide.

Creating Frequency Counts

The following program creates a report that tabulates the number of sales for each sales representative:
options linesize=84 pageno=1 nodate;

c proc report data=year_sales nowindows colwidth=5 headline; ①
column SalesRep Type N; ②
define SalesRep / group ‘Sales Representative’;
define Type / across ‘Coffee Maker’; ③
define N / ‘Total’;
title1 ‘TruBlend Coffee Makers Yearly Sales Report’;
title2 ‘Number of Sales’;
run;

The following list corresponds to the numbered items in the preceding program:
① The HEADLINE option in the PROC REPORT statement underlines all column headers and the spaces between them.
② The COLUMN statement specifies that the report contain two data set variables and a calculated statistic, N. The N statistic causes PROC REPORT to add a third column that displays the number of observations for each sales representative.
③ The DEFINE statement specifies that Type is an ACROSS variable.

The following output shows the report:

Output 27.10  Showing Frequency Counts

<table>
<thead>
<tr>
<th>Sales Representative</th>
<th>Deluxe</th>
<th>Standard</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>4</td>
<td>36</td>
<td>40</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>8</td>
<td>24</td>
<td>32</td>
</tr>
<tr>
<td>Jensen</td>
<td>4</td>
<td>34</td>
<td>38</td>
</tr>
</tbody>
</table>

The following list corresponds to the numbered items in the preceding report:
① Type is an ACROSS variable with nothing above or below it. Therefore, the report shows how many observations the input data set contains for each sales representative and coffee maker type.
② The column for N statistic is labeled Total and contains the total number of observations for each sales representative.

By default, PROC REPORT ordered the columns of the ACROSS variable according to its formatted values. You can use the ORDER= option in the DEFINE statement to alter the sort order for an ACROSS variable. See “Changing the Default Order of the Rows” on page 445 for more information.

Sharing a Column with Multiple Analysis Variables

You can create sophisticated cross-tabulation by having the value of ANALYSIS variables appear in columns that the ACROSS variable creates. When an ACROSS variable shares columns with one or more ANALYSIS variables, PROC REPORT will stack the columns. For example, you can share the columns of the ACROSS variable Type with the ANALYSIS variable Units so that each column contains the number of units sold for a type of coffee maker.

To stack the value of an ANALYSIS variable in the columns created by the ACROSS variable, place that variable next to the ACROSS variable in the COLUMN statement:

column SalesRep Type, Unit;
The comma separates the ACROSS variable from the ANALYSIS variable. To specify multiple ANALYSIS variables, list their names in parentheses next to the ACROSS variable in the COLUMN statement:

```
column SalesRep Type,(Unit AmountSold);
```

If you place the ACROSS variable before the ANALYSIS variable, then the name and values of the ACROSS variable are above the name of the ANALYSIS variable in the report. If you place the ACROSS variable after the ANALYSIS variable, then the name and the values of the ACROSS variable are below the name of the ANALYSIS variable.

By default, `PROC REPORT` calculates the SUM statistic for the ANALYSIS variables. To display another statistic for the column, use the DEFINE statement to specify the statistic that you want computed for the ANALYSIS variable. See the list Table 27.1 on page 444 for a list of the available statistics.

The following program creates a report that tabulates the number of coffee makers sold and the average sale in dollars for each sales representative:

```
options linesize=84 pageno=1 nodate;
proc report data=year_sales nowindows headline;
  column SalesRep Type,(Units AmountSold);
  define SalesRep / group 'Sales Representative';
  define Type / across '';
  define units / analysis sum 'Units Sold' format=comma7.;
  define AmountSold /analysis mean 'Average/Sale' format=dollar12.2;
  title1 'TruBlend Coffee Makers Yearly Sales Report';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. The COLUMN statement creates columns for `SalesRep` and `Type`. The ACROSS variable `Type` shares its columns with the ANALYSIS variables `Units` and `Amountsold`.

2. The DEFINE statement uses a blank as the label of `Type` in the column header.

3. The DEFINE statement uses the ANALYSIS variable `Units` to compute a SUM statistic.

4. The DEFINE statement uses the ANALYSIS variable `AmountSold` to compute a MEAN statistic.

The following output shows the report:

Output 27.11  Sharing a Column with Multiple Analysis Variables

```
<table>
<thead>
<tr>
<th>Sales Representative</th>
<th>Deluxe Units Sold</th>
<th>Deluxe Average Sale</th>
<th>Standard Units Sold</th>
<th>Standard Average Sale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Garcia</td>
<td>945</td>
<td>$11,694.38</td>
<td>15,024</td>
<td>$12,924.81</td>
</tr>
<tr>
<td>Hollingsworth</td>
<td>760</td>
<td>$4,702.50</td>
<td>9,860</td>
<td>$12,901.09</td>
</tr>
<tr>
<td>Jensen</td>
<td>820</td>
<td>$10,147.50</td>
<td>13,580</td>
<td>$12,369.78</td>
</tr>
</tbody>
</table>
```

The values in the columns for a particular type of coffee maker are the total units sold and the average dollar sale for each sales representative.
Summarizing Groups of Observations

Using Group Summaries

For some reports, you may want to summarize information about a group of observations and visually separate each group. To do so, you can create a break in the report before or after each group.

To visually separate each group, you insert lines of text, called break lines, at a break. Break lines can occur at the beginning or end of a report, at the top or bottom of each page, and whenever the value of a group or order variable changes. The break line can contain the following items:

- text (including blanks)
- summaries of statistics
- report variables
- computed variables

To create group summaries, use the BREAK statement. A BREAK statement must include (in this order) the following:

- the keyword BREAK
- the location of the break (BEFORE or AFTER)
- the name of a GROUP variable that is called the break variable

PROC REPORT creates a break each time the value of the break variable changes. If you want summaries to appear before the first row of each group, then use the BEFORE argument. If you want the summaries to appear after the last row of each group, then use the AFTER argument.

To create summary information for the whole report, use the RBREAK statement. An RBREAK statement must include (in this order) the following:

- the keyword RBREAK
- the location of the break (BEFORE or AFTER)

When you use the RBREAK statement, PROC REPORT inserts text, summary statistics for the entire report, or computed variables at the beginning or end of the detail rows of a report. If you want the summary to appear before the first row of the report, then use the BEFORE argument. If you want the summaries to appear after the last row of each group, then use the AFTER argument.

Both the BREAK and RBREAK statements support options that control the appearance of the group and the report summaries. You can use any combination of options in the statement in any order. For a list of the available options, see the REPORT procedure in Base SAS Procedures Guide.

Creating Group Summaries

The following program creates a summary report that uses break lines to display subtotals with yearly sales for each sales representative, and a yearly grand total for all sales representatives:

```sas
options linesize=80 pageno=1 nodate linesize=84;
proc report data=year_sales nowindows headskip;
  column Salesrep Quarter Units AmountSold;
  define SalesRep / group ‘Sales Representative’;
  define Quarter / group center;
```
define Units / analysis sum ‘Units Sold’ format=comma7.;
define AmountSold / analysis sum ‘Amount/Sold’ format=dollar14.2;
break after SalesRep / summarize skip ol suppress;
rbreak after / summarize skip dol;
title1 ‘TruBlend Coffee Makers Sales Report’;
title2 ‘Total Yearly Sales’;
run;

The following list corresponds to the numbered items in the preceding program:

1. The CENTER option in the DEFINE statement centers the values of the variable Quarter and the label of the column header.

2. The BREAK statement adds break lines after a change in the value of the GROUP variable SalesRep. The SUMMARIZE option writes a summary line to summarize the statistics for each group of break lines. The SKIP option inserts a blank line after each group of break lines. The OL option writes a line of hyphens (-) above each value in the summary line. The SUPPRESS option suppresses printing the value of the break variable and the overlines in the break variable column.

3. The RBREAK statement adds a break line at the end of the report. The SUMMARIZE option writes a summary line that summarizes the SUM statistics for the ANALYSIS variables Units and AmountSold. The SKIP option inserts a blank line before the break line. The DOL option writes a line of equal signs (=) above each value in the summary line.

The following output shows the report:

Output 27.12  Creating Group Summaries

<table>

| Hollingsworth        | 1       | 1,770      | $59,634.70  |
|                      | 2       | 3,090      | $96,160.55  |
|                      | 3       | 3,285      | $109,704.35 |
|                      | 4       | 2,475      | $81,746.50  |
|                      | --------|------------|-------------|
|                     | 10,620  | 347,246.10 |

| Jensen               | 1       | 1,617      | $50,078.49  |
|                      | 2       | 2,413      | $74,730.61  |
|                      | 3       | 6,687      | $222,290.99 |
|                      | 4       | 3,683      | $114,062.51 |
|                      | --------|------------|-------------|
|                     | 14,400  | 461,162.60 |
|                     | --------|------------|-------------|
|                     | 40,989  | 1,320,479.48 |
The following list corresponds to the numbered items in the preceding report:

1. The values of the ANALYSIS variables Units and AmountSold in the group summary lines are sums for all rows in the group (subtotals).
2. The values of the ANALYSIS variables Units and AmountSold in the report summary line are sums for all rows in the report (grand totals).

In this report, Units and AmountSold are ANALYSIS variables that are used to calculate the SUM statistic. If these variables were defined to calculate a different statistic, then the values in the summary lines would be the value of that statistic for all rows in the group and all rows in the report.

---

**Review of SAS Tools**

**PROC REPORT Statements**

```sas
PROC REPORT <DATA=SAS-data-set><option(s)>
BREAK location break-variable <option(s)>;
COLUMN column-specification(s);
DEFINE report-item /<usage> <option(s)>;
RBREAK location<option(s)>;
TITLE<n> '<title'>;
WHERE where-expression;
```

**PROC REPORT** <DATA=SAS-data-set> <option(s)>;
starts the procedure. If no other statements are used, then SAS shows all variables in the SAS-data-set in a detail report in the REPORT window. If the data set contains only numeric data, then PROC REPORT shows all variables in a summary report. Other statements, listed below, enable you to control the structure of the report.

You can specify the following options in the PROC REPORT statement:

- **COLWIDTH=column-width**
  specifies the default number of characters for columns that contain computed variables or numeric data set variables.

- **DATA=SAS-data-set**
  names the SAS data set that PROC REPORT uses. If you omit DATA=, then PROC REPORT uses the most recently created data set.

- **HEADLINE**
  inserts a line of hyphens (-) under the column headers at the top of each page of the report.

- **HEADSKIP**
  inserts a blank line beneath all column headers (or beneath the line that the HEADLINE option inserts) at the top of each page of the report.

- **SPACING=space-between-columns**
  specifies the number of blank characters between columns. For each column, the sum of its width and the blank characters between it and the column to its left cannot exceed the line size.
SPLIT='character'
specifies the split character. PROC REPORT breaks a column header when it reaches that character and continues the header on the next line. The split character itself is not part of the column header, although each occurrence of the split character is counted toward the 256-character maximum for a label.

WINDOWS|NOWINDOWS
selects a windowing or nonwindowing environment.
When you use WINDOWS, SAS opens the REPORT window, which enables you to modify a report repeatedly and to see the modifications immediately. When you use NOWINDOWS, PROC REPORT runs without the REPORT window and sends its results to the SAS procedure output.

BREAK location break-variable <option(s)>;
produces a default summary at a break (a change in the value of a GROUP or ORDER variable). The information in a summary applies to a set of observations. The observations share a unique combination of values for the break variable and all other GROUP or ORDER variables to the left of the break variable in the report.
You must specify the following arguments in the BREAK statement:

  location
  controls the placement of the break lines, where location is
  
  AFTER
  places the break lines immediately after the last row of each set of rows that have the same value for the break variable.
  
  BEFORE
  places the break lines immediately before the first row of each set of rows that have the same value for the break variable.

  break-variable
  is a GROUP or ORDER variable. PROC REPORT writes break lines each time the value of this variable changes.
You can specify the following options in the BREAK statement:

  OL
  inserts a line of hyphens (-) above each value that appears in the summary line.
  
  SKIP
  writes a blank line for the last break line.
  
  SUMMARIZE
  writes a summary line in each group of break lines.
  
  SUPPRESS
  suppresses the printing of the value of the break variable in the summary line, and of any underlining or overlining in the break lines.

COLUMN <column-specification(s)>;
identifies items that form columns in the report and describes the arrangement of all columns. You can specify the following column-specification(s) in the COLUMN statement:

  □ report-item(s)
  □ report-item-1, report-item-2 < ... , report-item-n>

where report-item identifies items that form columns in the report. A report-item is either the name of a data set variable, a computed variable, or a statistic.
report-item-1, report-item-2 ..., report-item-n
identifies report items that collectively determine the contents of the column or columns. These items are said to be stacked in the report because each item generates a header, and the headers are stacked one above the other. The header for the leftmost item is on top. If one of the items is an ANALYSIS variable, then a computed variable, or a statistic, its values fill the cells in that part of the report. Otherwise, PROC REPORT fills the cells with frequency counts.

DEFINE report-item / <usage> <option(s)>;
 describes how to use and display a report item. A report item is either the name or alias (established in the COLUMN statement) of a data set variable, a computed variable, or a statistic. The usage of the report item is
- ACROSS
- ANALYSIS
- COMPUTED
- DISPLAY
- GROUP
- ORDER

You can specify the following options in the DEFINE statement:

CENTER
  centers the formatted values of the report item within the column width, and centers the column header over the values.

column-header
  defines the column header for the report item. Enclose each header in single or double quotation marks. When you specify multiple column headers, PROC REPORT uses a separate line for each one. The split character also splits a column header over multiple lines.

DESCENDING
  reverses the order in which PROC REPORT displays rows or values of a GROUP, ORDER, or ACROSS variable.

FORMAT= format
  assigns a SAS format or a user-defined format to the report item. This format applies to report-item as PROC REPORT displays it; the format does not alter the format associated with a variable in the data set.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
  orders the values of a GROUP, ORDER, or ACROSS variable according to the specified order, where
  - DATA
    orders values according to their order in the input data set.
  - FORMATTED
    orders values by their formatted (external) values. By default, the order is ascending.
  - FREQ
    orders values by ascending frequency count.
  - INTERNAL
    orders values by their unformatted values, which yields the same order that PROC SORT would yield. This order is operating environment...
dependent. This sort sequence is particularly useful for displaying dates chronologically.

RIGHT
right-justifies the formatted values of the specified report item within the column width and right-justifies the column headers over the values. If the format width is the same as the width of the column, then RIGHT has no affect on the placement of values.

SPACING=horizontal-positions
defines the number of blank characters to leave between the column that is being defined and the column immediately to its left. For each column, the sum of its width and the blank characters between it and the column to its left cannot exceed the line size.

statistic
associates a statistic with an ANALYSIS variable. PROC REPORT uses this statistic to calculate values for the ANALYSIS variable for the observations represented by each cell of the report. If you do not associate a statistic with the variable, then PROC REPORT calculates the SUM statistic. You cannot use statistic in the definition of any other kind of variable.

WIDTH=column-width
defines the width of the column in which PROC REPORT displays report-item.

RBREAK location </option(s)>;
produces a default summary at the beginning or end of a report.
You must specify the following argument in the RBREAK statement:

location
controls the placement of the break lines and is either
AFTER
places the break lines at the end of the report.
BEFORE
places the break lines at the beginning of the report.
You can specify the following options in the RBREAK statement:

DOL
specifies to double overline each value that appears in the summary line.

SKIP
writes a blank line after the last break line of a break located at the beginning of the report.

SUMMARIZE
includes a summary line as one of the break lines. A summary line at the beginning or end of a report contains values for statistics, ANALYSIS variables, or computed variables.

TITLE<n> <'title'>;
specifies a title. The argument n is a number from 1 to 10 that immediately follows the word TITLE, with no intervening blank, and it specifies the level of the TITLE. The text of each title must be enclosed in single or double quotation marks. The maximum title length depends on your operating environment and the value of the LINESIZE= system option. Refer to the SAS documentation for your operating environment for more information.

WHERE where-expression;
subsets the input data set by identifying certain conditions that each observation must meet before an observation is available for processing. Where-expression
defines the condition. The condition is a valid arithmetic or logical expression that generally consists of a sequence of operands and operators.

**Learning More**

**KEEP= data set option**
For an additional example, see “Reading Selected Variables” on page 85. For a complete documentation about the KEEP= data set option, see the SAS Language Reference: Dictionary.

**PROC PRINT**
For a discussion of how to create several types of detail reports, see Chapter 25, “Producing Detail Reports with the PRINT Procedure,” on page 371.

**PROC REPORT**
For complete documentation, see Base SAS Procedures Guide.

**PROC TABULATE**
For a discussion of how to create several types of summary reports, see Chapter 26, “Creating Summary Tables with the TABULATE Procedure,” on page 407.

**Report writing examples**
For step-by-step instructions for creating a variety of reports, see SAS Guide to Report Writing: Examples.

**SAS formats**
For complete documentation, see SAS Language Reference: Dictionary. Many formats are available with the SAS software, such as fractions, hexadecimal values, roman numerals, social security numbers, date and time values, and numbers written as words.

**WHERE statement**
For a discussion, see “Understanding the WHERE Statement” on page 379. For complete reference documentation about the WHERE statement, see SAS Language Reference: Dictionary. For a complete discussion of WHERE processing, see SAS Language Reference: Concepts.
PART 7

Producing Plots and Charts

Chapter 28. . . . . . . Plotting the Relationship between Variables 463
Chapter 29. . . . . . Producing Charts to Summarize Variables 483
Introduction to Plotting the Relationship between Variables

An effective way to examine the relationship between variables is to plot their values. You can use the PLOT procedure to display relationships and patterns in the data.

In this section, you will learn how to do the following:
- plot one set of variables
- enhance the appearance of a plot
- create multiple plots on separate pages
- create multiple plots on the same page
- plot multiple sets of variables on the same pair of axes

Prerequisites

To understand the examples in this section, you should be familiar with the following features and concepts:
- the LOG function
- the FORMAT statement
- the LABEL statement
- the TITLE statement
- SAS system options
Input File and SAS Data Set for Examples

The examples in this section use one input file* and one SAS data set. The input file contains information about the high and low values of the Dow Jones Industrial Average from 1954 to 1998. The input file has the following structure:

```
1954 31DEC1954 404.39 11JAN1954 279.87
1955 30DEC1955 488.40 17JAN1955 388.20
1956 06APR1956 521.05 23JAN1956 462.35
1957 12JUL1957 520.77 22OCT1957 419.79
1958 31DEC1958 583.65 25FEB1958 436.89
...more data lines...
1995 13DEC1995 5216.47 30JAN1995 3832.08
1996 27DEC1996 6560.91 10JAN1996 5032.94
1997 06AUG1997 8259.31 11APR1997 6391.69
1998 23NOV1998 9374.27 31AUG1998 7539.07
```

The input file contains the following values from left to right:
- the year that the observation describes
- the date of the yearly high for the Dow Jones Industrial Average
- the yearly high value for the Dow Jones Industrial Average
- the date of the yearly low for the Dow Jones Industrial Average
- the yearly low value for the Dow Jones Industrial Average

The following program creates the SAS data set HIGHLOW:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
data highlow;
  infile 'your-input-file';
  input Year @7 DateOfHigh date9. DowJonesHigh @28 DateOfLow date9. DowJonesLow;
  format LogDowHigh LogDowLow 5.2 DateOfHigh DateOfLow date9.;
  LogDowHigh=log(DowJonesHigh);
  LogDowLow=log(DowJonesLow);
run;
```

The computed variables LogDowHigh and LogDowLow contain the log transformation of the yearly high and low values for the Dow Jones Industrial Average.

```
proc print data=highlow;
  title 'Dow Jones Industrial Average Yearly High and Low Values';
run;
```

* Refer to Appendix 1, “Additional Data Sets,” on page 713 for a complete listing of the input data.
Plotting the Relationship between Variables

Output 28.1

Note: All graphics output in this section uses an OPTIONS statement that specifies
PAGESIZE=40 and LINESIZE=76. When the PAGESIZE= and LINESIZE= options are
set, they remain in effect until you reset the options with another OPTIONS statement,
or you end the SAS session. 4


Plotting One Set of Variables

Understanding the PLOT Statement

The PLOT procedure produces two-dimensional graphs that plot one variable against another within a set of coordinate axes. The coordinates of each point on the plot correspond to the values of two variables. Graphs are automatically scaled to the values of your data, although you can control the scale by specifying the coordinate axes.

You can create a simple two-dimensional plot for one set of measures by using the following PLOT statement:

```
PROC PLOT <DATA=SAS-data-set>;
   PLOT vertical*horizontal;
```

where `vertical` is the name of the variable to plot on the vertical axis and `horizontal` is the name of the variable to plot on the horizontal axis.

By default, PROC PLOT selects plotting symbols. The data determines the labels for the axes, the values of the axes, and the values of the tick marks. The plot displays the following:

- the name of the vertical variable that is next to the vertical axis and the name of the horizontal variable that is beneath the horizontal axis
- the axes and the tick marks that are based on evenly spaced intervals
- the letter A as the plotting symbol to indicate one observation; the letter B as the plotting symbol if two observations coincide; the letter C if three coincide, and so on
- a legend with the name of the variables in the plot and meaning of the plotting symbols

The following display shows the axes, values, and tick marks on a plot.

![Diagram of Axes, Values, and Tick Marks](image)

**Display 28.1** Diagram of Axes, Values, and Tick Marks

*Note:* PROC PLOT is an interactive procedure. After you issue the PROC PLOT statement, you can continue to submit any statements that are valid with the procedure without resubmitting the PROC statement. Therefore, you can easily and quickly experiment with changing labels, values for tick marks, and so on.
Example

The following program uses the PLOT statement to create a simple plot that shows the trend in high Dow Jones values from 1954 to 1998:

```sas
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow;
    plot DowJonesHigh*Year;
    title 'Dow Jones Industrial Average Yearly High';
run;
```

The following output shows the plot:

Output 28.2 Using a Simple Plot to Show Data Trends

The plot graphically depicts the exponential trend in the high value of the Dow Jones Industrial Average over the last 50 years. The greatest growth has occurred in the last 10 years, increasing by almost 6,000 points.
Enhancing the Plot

Specifying the Axes Labels

Sometimes you might want to supply additional information about the axes. You can enhance the plot by specifying the labels for the vertical and horizontal axes.

The following program plots the log transformation of DowJonesHigh for each year and uses the LABEL statement to change the axes labels:

```sas
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow;
   plot LogDowHigh*Year;
   label LogDowHigh='Log of Highest Value'
               Year='Year Occurred';
   title 'Dow Jones Industrial Average Yearly High';
run;
```

The following output shows the plot:

Output 28.3  Specifying the Labels for the Axes
Plotting the log transformation of DowJonesHigh changes the exponential trend to a linear trend. The label for each variable is centered parallel to its axis.

### Specifying the Tick Marks Values

In the previous plots, the range on the horizontal axis is from 1950 to 2000. Tick marks and labels representing the years are spaced at intervals of 10. You can control the selection of the range and the interval on the horizontal axis with the HAXIS= option in the PLOT statement. A corresponding PLOT statement option, VAXIS=, controls the values of the tick mark on the vertical axis.

The forms of the HAXIS= and VAXIS= options follow. You must precede the first option in a PLOT statement with a slash.

\[
\text{PLOT } \text{vertical}^*\text{horizontal} / \text{HAXIS}=\text{tick-value-list}; \\
\text{PLOT } \text{vertical}^*\text{horizontal} / \text{VAXIS}=\text{tick-value-list};
\]

where tick-value-list is a list of all values to assign to tick marks.

For example, to specify tick marks every five years from 1950 to 2000, use the following option:

\[\text{haxis}=1950 \text{ to } 2000 \text{ by } 5\]

Or, you can abbreviate this list of tick marks:

\[\text{haxis}=1950 \text{ to } 2000 \text{ by } 5\]

The following program uses the HAXIS= option to specify the tick mark values for the horizontal axis:

```latex
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow;
  plot LogDowHigh*Year / haxis=1954 to 1998 by 4;
  label LogDowHigh='Log of Highest Value'
              Year='Year Occurred';
  title 'Dow Jones Industrial Average Yearly High';
run;
```

The following output shows the plot:
Specifying Plotting Symbols

The range of the horizontal axis is from 1954 to 1998, and the tick marks are now arranged at four-year intervals.

**Specifying Plotting Symbols**

By default, PROC PLOT uses the letter A as the plotting symbol to indicate one observation, the letter B as the plotting symbol if two observations coincide, the letter C if three coincide, and so on. The letter Z represents 26 or more coinciding observations.

In many instances, particularly if you are plotting two sets of data on the same pair of axes, then you use the following form of the PLOT statement to specify your own plotting symbols:

```
PLOT vertical*horizontal='character';
```

where `character` is a plotting symbol to mark each point on the plot. PROC PLOT uses this character to represent values from one or more observations.

The following program uses the plus sign (+) as the plotting symbol for the plot:

```plaintext
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow;
    plot LogDowHigh*Year='+' / haxis=1954 to 1998 by 4;
```
label LogDowHigh='Log of Highest Value'
    Year='Year Occurred';
title 'Dow Jones Industrial Average Yearly High';
run;

The plotting symbol must be enclosed in either single or double quotation marks.
The following output shows the plot:

**Output 28.5  Specifying a Plotting Symbol**

```
Dow Jones Industrial Average Yearly High

Plot of LogDowHigh*Year. Symbol used is ‘+’.
```

<table>
<thead>
<tr>
<th>Year Occurred</th>
</tr>
</thead>
</table>

*Note:* When a plotting symbol is specified, PROC PLOT uses that symbol for all points on the plot regardless of how many observations might coincide. If observations coincide, then a message appears at the bottom of the plot telling how many observations are hidden. △

**Removing the Legend**

Often, a few simple changes to a plot will improve its appearance. You can draw a frame around the entire plot, rather than just on the left side and bottom. This makes it easier to determine the values that the plotting symbols represent on the left side of the
plot. Also, you can suppress the legend when the labels clearly identify the variables in the plot or when the association between the plotting symbols and the variables is clear.

The following program uses the NOLEGEND option in the PROC PLOT statement to suppress the legend and the BOX option in the PLOT statement to box the entire plot:

```plaintext
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow nolegend;
   plot LogDowHigh*Year='+' / haxis=1954 to 1998 by 4
       box;
   label LogDowHigh='Log of Highest Value'
         Year='Year Occurred';
   title 'Dow Jones Industrial Average Yearly High';
run;
```

The following output shows the plot:

**Output 28.6  Removing the Legend**

![Dow Jones Industrial Average Yearly High Plot](image)
Creating Multiple Plots on Separate Pages

You can compare trends for different sets of measures by creating multiple plots. To request more than one plot from the same SAS data set, simply specify additional sets of variables in the PLOT statement. The form of the statement is

```
PLOT vertical-1*horizontal-1 vertical-2*horizontal-2;
```

All the options that you list in a PLOT statement apply to all of the plots that the statement produces.

The following program uses the PLOT statement to produce separate plots of the highest and lowest values of the Dow Jones Industrial Average from 1954 to 1998:

```sas
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow;
  plot LogDowHigh*Year='+' LogDowLow*Year='o'
       / haxis=1954 to 1998 by 4 box;
  label LogDowHigh='Log of Highest Value'
       LogDowLow='Log of Lowest Value'
       Year='Year Occurred';
  title 'Dow Jones Industrial Average Yearly High';
run;
```

The following output shows the plots:
Creating Multiple Plots on Separate Pages

Output 28.7 Creating Multiple Plots on Separate Pages

Dow Jones Industrial Average Yearly High
Plot of LogDowHigh*Year. Symbol used is ‘+’.

Year Occurred

Creating Multiple Plots on the Same Page

You can more easily compare the trends in different sets of measures when the plots appear on the same page. PROC PLOT provides two options that display multiple plots on the same page:

- the VPERCENT= option
- the HPERCENT= option

You can specify these options in the PROC PLOT statement by using one of the following forms:

```
PROC PLOT <DATA=SAS-data-set> VPERCENT=number;
```

```
PROC PLOT <DATA=SAS-data-set> HPERCENT=number;
```

where number is the percent of the vertical or the horizontal space given to each plot. You can substitute the aliases VPCT= and HPCT= for these options.

To fit two plots on a page, one beneath the other, as in Figure 28.1 on page 476, use VPERCENT=50; to fit three plots, use VPERCENT=33; and so on. To fit two plots on a page, side by side, use HPERCENT=50; to fit three plots, as in Figure 28.2 on page 476, use HPERCENT=33; and so on. Figure 28.3 on page 477 combines both of these options.
in the same PLOT statement to create a matrix of plots. Because the VPERCENT= option and the HPERCENT= option appear in the PROC PLOT statement, they affect all plots that are created in the PROC PLOT step.

**Figure 28.1**  Plots Produced with VPERCENT=50

![Plot 1 and Plot 2](image)

**Figure 28.2**  Plots Produced with HPERCENT=33

![Plot 1, Plot 2, Plot 3](image)
The following program uses the VPERCENT= option to display two plots on the same page so that you can compare the trends for the high and the low Dow Jones values:

options pagesize=40 linesize=76 pageno=1 nodate;

proc plot data=highlow vpercent=50;
  plot LogDowHigh*Year='+' LogDowLow*Year='o'
     / haxis=1954 to 1998 by 4 box;
  label LogDowHigh='Log of High'
     LogDowLow='Log of Low'
     Year='Year Occurred';
  title 'Dow Jones Industrial Average Yearly High';
run;

PROC PLOT will use 50% of the vertical space on the page to display each plot. The following output shows the plots:
Output 28.8  Creating Multiple Plots on the Same Page

The two plots appear on the same page, one beneath the other.

Plotting Multiple Sets of Variables on the Same Axes

The easiest way to compare trends in multiple sets of measures is to superimpose the plots on one set of axes by using the OVERLAY option in the PLOT statement. The variable names, or variable labels if they exist, from the first plot become the axes labels. Unless you use the HAXIS= option or the VAXIS= option, PROC PLOT automatically scales the axes to best fit all the variables.

The following program uses the OVERLAY option to plot the high and the low Dow Jones Industrial Average values on the same pair of axes:

```sas
options pagesize=40 linesize=76 pageno=1 nodate;
proc plot data=highlow;
  plot LogDowHigh*Year='+' LogDowLow*Year='o'
      / haxis=1954 to 1998 by 4
      overlay box;
  label LogDowHigh='Log of High or Low'
```

Year='Year Occurred';
title 'Dow Jones Industrial Average';
run;

A new label for the variable LogDowHigh is specified because PROC PLOT uses only this variable to label the vertical axis.
The following output shows the plot:

Output 28.9  Overlying Two Plots

The linear trends in the high and low Dow Jones values over the years from 1954 to 1998 are easily noticed.

*Note*: When the SAS system option OVP is in effect and overprinting is allowed, the plots are superimposed; otherwise, when NOOVP is in effect, PROC PLOT uses the plotting symbol from the first plot to represent points that appear in more than one plot. In such a case, the output includes a message telling you how many observations are hidden. △
PROC PLOT Statements

PROC PLOT <DATA=SAS-data-set> <options>;
  LABEL variable='label';
  PLOT request-list </option(s)>;
  TITLE<n> '<title'>;
PROC PLOT <DATA=SAS-data-set> <option(s)> ;
starts the PLOT procedure. You can specify the following option(s) in the PROC
PLOT statement:

DATA=SAS-data-set
  names the SAS data set that PROC PLOT uses. If you omit DATA=, then
PROC PLOT uses the most recently created data set.

HPERCENT=percent(s)
  specifies one or more percentages of the available horizontal space to use for
  each plot. HPERCENT= enables you to put multiple plots on one page.
  PROC PLOT tries to fit as many plots as possible on a page. After using each
  of the percent(s), PROC PLOT cycles back to the beginning of the list. A zero
  in the list forces PROC PLOT to go to a new page even though it could fit the
  next plot on the same page.

NOLEGEND
  suppresses the default legend. The legend lists the names of the variables
  being plotted and the plotting symbols that are used in the plot.

VPERCENT=percent(s)
  specifies one or more percentages of the available vertical space to use for
  each plot. If you use a percentage greater than 100, then PROC PLOT prints
  sections of the plot on successive pages.

LABEL variable='label';
  specifies to use labels for the axes. Variable names the variable to label and label
  specifies a string of up to 256 characters, which includes blanks. The label must
  be enclosed in single or double quotation marks.

PLOT request-list </option(s)>;
  enables you to request individual plots in the request-list in the PLOT statement.
  Each element in the list has the following form:

    vertical*horizontal<=symbol>

  where vertical and horizontal are the names of the variables that appear on the
  axes and symbol is the character to use for all points on the plot.
  You can request any number of plot statements in one PROC PLOT step. A list
  of options pertains to a single plot statement.

  BOX
    draws a box around the entire plot, rather than only on the left side and
    bottom.

  HAXIS=<tick-value-list>
    specifies the tick mark values for the horizontal axis. The tick-value-list
    consists of a list of values to use for tick marks.
OVERLAY
superimposes all of the plots that are requested in the PLOT statement on one set of axes. The variable names, or variable labels if they exist, from the first plot are used to label the axes. Unless you use the HAXIS= or the VAXIS= option, PROC PLOT automatically scales the axes in the way that best fits all the variables.

VAXIS=<tick-value-list>
specifies tick mark values for the vertical axis. The tick-value-list consists of a list of values to use for tick marks.

TITLE<n> <'title'>;
specifies a title. The argument n is a number from 1 to 10 that immediately follows the word TITLE, with no intervening blank, and specifies the level of the TITLE. The text of each title must be enclosed in single or double quotation marks. The maximum title length that is allowed depends on your operating environment and the value of the LINESIZE= system option. Refer to the SAS documentation for your operating environment for more information.

Learning More

PROC CHART and PROC UNIVARIATE
When you are preparing graphics presentations, some data lends itself to charts, while other data is better suited for plots. For a discussion about how to make a variety of charts, see Chapter 29, “Producing Charts to Summarize Variables,” on page 483.

PROC PLOT
In addition to the features that are described in this section, you can use PROC PLOT to create contour plots, to draw a reference line at a particular value on a plot, and to change the characters that are used to draw the borders of the plot. For complete documentation, see Base SAS Procedures Guide.

SAS functions
SAS provides a wide array of numeric functions that include arithmetic and algebraic expressions, trigonometric and hyperbolic expressions, probability distributions, simple statistics, and random number generation. For complete documentation, see SAS Language Reference: Dictionary.

Introduction to Producing Charts to Summarize Variables

Purpose

Charts, like plots, provide a technique to summarize data graphically. You can use a chart to show the values of a single variable or several variables. A bar chart also enables you to graphically examine the distribution of the values of a variable.

In this section, you will learn how to create the following:

- vertical bar charts
- horizontal bar charts
- pie charts
- block charts
- high-resolution histograms and comparative histograms

The examples range in complexity from simple frequency bar charts to more complex charts that group variables and include summary statistics.

Prerequisites

To understand the examples in this section, you should be familiar with the following features and concepts:

- the LABEL statement
- the TITLE statement
- SAS system options
- creating and assigning SAS formats

Understanding the Charting Tools

Base SAS software provides two procedures that produce charts:

- PROC CHART
- PROC UNIVARIATE

PROC CHART produces a variety of charts for character or numeric variables. The charts include vertical and horizontal bar charts, block charts, pie charts, and star charts. These types of charts graphically display the values of a variable or a statistic.
that are associated with those values. PROC UNIVARIATE produces histograms for continuous numeric variables that enable you to visualize the distribution of your data.

PROC CHART is a useful tool to visualize data quickly. However, you can use PROC GCHART* to produce high-resolution, publication-quality bar charts that include color and various fonts when your site licenses SAS/GRAPH software. You can use PROC UNIVARIATE to customize the histograms by adding tables with summary statistics directly on the graphical display. PROC UNIVARIATE also enables you to overlay the histogram with fitted density curves or kernel density estimates so that you can examine the underlying distribution of your data.

**Input File and SAS Data Set for Examples**

The examples in this section use one input file** and one SAS data set. The input file contains the enrollment and exam grades for an introductory chemistry course. The 50 students enrolled in the course attend several lectures, and a discussion section one day a week. The input file has the following structure:

<table>
<thead>
<tr>
<th>Name</th>
<th>Gender</th>
<th>Section</th>
<th>Exam Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abdallah</td>
<td>F Mon</td>
<td>46 Anderson</td>
<td>M Wed 75</td>
</tr>
<tr>
<td>Aziz</td>
<td>F Wed</td>
<td>67 Bayer</td>
<td>M Wed 77</td>
</tr>
<tr>
<td>Bhatt</td>
<td>M Fri</td>
<td>79 Blair</td>
<td>F Fri 70</td>
</tr>
<tr>
<td>Bledsoe</td>
<td>F Mon</td>
<td>63 Boone</td>
<td>M Wed 58</td>
</tr>
<tr>
<td>Burke</td>
<td>F Mon</td>
<td>63 Chung</td>
<td>M Wed 85</td>
</tr>
<tr>
<td>Cohen</td>
<td>F Fri</td>
<td>89 Drew</td>
<td>F Mon 49</td>
</tr>
<tr>
<td>Dubos</td>
<td>M Mon</td>
<td>41 Elliott</td>
<td>F Wed 85</td>
</tr>
</tbody>
</table>

...more data lines...

| Simonson | M Wed 62 Smith N | M Wed 71 |
| Smith R  | M Mon 79 Sullivan | M Fri 77 |
| Swift    | M Wed 63 Wolfson | F Fri 79 |
| Wong     | F Fri 89 Zabriski | M Fri 89 |

The input file contains the following values from left to right:
- the student’s last name (and first initial if necessary)
- the student’s gender (F or M)
- the day of the week for the student’s discussion section (Mon, Wed, or Fri)
- the student’s first exam grade

The following program creates the GRADES data set that this section uses:

```sas
options pagesize=60 linesize=80 pageno=1 nodate;

data grades;
  infile 'your-input-file';
  input Name & $14. Gender : $2. Section : $3. ExamGrade1 @@;
run;

proc print data=grades;
  title 'Introductory Chemistry Exam Scores';
run;
```

* PROC GCHART and PROC CHART produce identical charts.
** See the “Data Set YEAR_SALES” on page 717 for a complete listing of the input data.
Note: Most output in this section uses an OPTIONS statement that specifies PAGESIZE=40 and LINESIZE=80. Other examples use an OPTIONS statement with a different line size or page size to make a chart more readable. When the PAGESIZE= and LINESIZE= options are set, they remain in effect until you reset the options with another OPTIONS statement, or you end the SAS session.

Output 29.1  A Listing of the GRADES Data Set

</table>
You can create bar charts with this data set to do the following:
- Examine the distribution of grades.
- Determine a letter grade for each student.
- Compare the number of students in each section.
- Compare the number of males and females in each section.
- Compare the performance of the students in different sections.

### Charting Frequencies with the CHART Procedure

#### Types of Frequency Charts

By default, PROC CHART creates a frequency chart in which each bar, section, or block in the chart represents a range of values. By default, PROC CHART selects ranges based on the values of the chart variable. At the center of each range is a midpoint. A midpoint does not always correspond to an actual value of the chart variable. The size of each bar, block, or section represents the number of observations that fall in that range.

PROC CHART makes several different types of charts:

- **vertical and horizontal bar charts**
  - display the magnitude of data with the length or height of bars.
- **block charts**
  - display the relative magnitude of data with blocks of varying size.
- **pie charts**
  - display data as wedge-shaped sections of a circle that represent the relative contribution of each section to the whole circle.
- **star charts**
  - display data as bars that radiate from a center point, like spokes in a wheel.

The shape of each type of chart emphasizes a certain aspect of the data. The chart that you choose depends on the nature of your data and the aspect that you want to emphasize.

#### Creating Vertical Bar Charts

##### Understanding Vertical Bar Charts

A vertical bar chart emphasizes individual ranges. The horizontal, or midpoint, axis shows the values of the variable divided into ranges. By default, the vertical axis shows the frequency of values for a given range. The differences in bar heights enable you to quickly determine which ranges contain many observations and which contain few observations.

The VBAR statement in a PROC CHART step produces vertical bar charts. If you use the VBAR statement without any options, then PROC CHART automatically does the following:

- scales the vertical axis
- determines the bar width
selects the spacing between bars
labels the axes

For continuous numeric data, PROC CHART determines the number of bars and the midpoint for each bar from the minimum and maximum value of the chart variable. For character variables or discrete numeric variables, PROC CHART creates a bar for each value of the chart variable. However, you can change how PROC CHART determines the axes by using options.

Note: If the number of characters per line (LINESIZE=) is not sufficient to display vertical bars, then PROC CHART automatically produces a horizontal bar chart.

The Program

The following program uses the VBAR statement to create a vertical bar chart of frequencies for the numeric variable ExamGrade1:

```plaintext
options pagesize=40 linesize=80 pageno=1 nodate;

proc chart data=grades;
    vbar ExamGrade1;
    title 'Grades for First Chemistry Exam';
run;
```

The following output shows the bar chart:

**Output 29.2 Using a Vertical Bar Chart to Show Frequencies**

```
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Grades for First Chemistry Exam</td>
</tr>
<tr>
<td>Frequency</td>
</tr>
<tr>
<td>-------------------------------</td>
</tr>
<tr>
<td>14 +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>13 +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>12 +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>11 +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>10 +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>9  +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>8  +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>7  +</td>
</tr>
<tr>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td></td>
</tr>
<tr>
<td>-----------------------------</td>
</tr>
</tbody>
</table>

ExamGrade1 Midpoint
```

---

488 Creating Vertical Bar Charts  Chapter 29
The midpoint axis for the above chart ranges from 40 to 100 and is incremented in intervals of 10. The following table shows the values and frequency of each bar:

<table>
<thead>
<tr>
<th>Range</th>
<th>Midpoint</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>35 to 44</td>
<td>40</td>
<td>3</td>
</tr>
<tr>
<td>45 to 54</td>
<td>50</td>
<td>6</td>
</tr>
<tr>
<td>55 to 64</td>
<td>60</td>
<td>14</td>
</tr>
<tr>
<td>65 to 74</td>
<td>70</td>
<td>5</td>
</tr>
<tr>
<td>75 to 84</td>
<td>80</td>
<td>11</td>
</tr>
<tr>
<td>85 to 94</td>
<td>90</td>
<td>10</td>
</tr>
<tr>
<td>95 to 104</td>
<td>10</td>
<td>1</td>
</tr>
</tbody>
</table>

*Note:* Because PROC CHART selects the size of the ranges and the location of their midpoints based on all values of the numeric variable, the highest and lowest ranges can extend beyond the values in the data. In this example the lowest grade is 39 while the lowest range extends from 35 to 44. Similarly, the highest grade is 98 while the highest range extends from 95 to 104.

---

### Creating a Horizontal Bar Chart

#### Understanding Horizontal Bar Charts

A horizontal bar chart has essentially the same characteristics as a vertical bar chart. Both charts emphasize individual ranges. However, a horizontal bar chart rotates the bars so that the horizontal axis shows frequency and the vertical axis shows the values of the chart variable. To the right of the horizontal bars, PROC CHART displays a table of statistics that summarizes the data.

The HBAR statement in a PROC CHART step produces horizontal bar charts. By default, the table of statistics includes frequency, cumulative frequency, percentage, and cumulative percentage. You can request specific statistics so that the table contains only these statistics and the frequency.

#### Understanding HBAR Statistics

The default horizontal bar chart uses less space than charts of other shapes. PROC CHART takes advantage of the small size of horizontal bar charts and displays statistics to the right of the chart. The statistics include

- **Frequency**
  - is the number of observations in a given range.

- **Cumulative Frequency**
  - is the number of observations in all ranges up to and including a given range. The cumulative frequency for the last range is equal to the number of observations in the data set.

- **Percent**
  - is the percentage of observations in a given range.
Cumulative Percent

is the percentage of observations in all ranges up to and including a given range.
The cumulative percentage for the last range is always 100.

Various options enable you to control the statistics that appear in the table. You can select the statistics by using the following options: FREQ, CFREQ, PERCENT, and CPERCENT. To suppress the table of statistics, use the NOSTAT option.

**The Programs**

The following program uses the HBAR statement to create a horizontal bar chart of the frequency for the variable ExamGrade1:

```plaintext
options pagesize=40 linesize=80 pageno=1 nodate;
proc chart data=grades;
  hbar Examgrade1;
  title 'Grades for First Chemistry Exam';
run;
```

The following output shows the bar chart:

**Output 29.3 Using a Horizontal Bar Chart to Show Frequencies**

<table>
<thead>
<tr>
<th>ExamGrade1 Midpoint</th>
<th>Freq</th>
<th>Cum. Freq</th>
<th>Percent</th>
<th>Cum. Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>*****</td>
<td>3</td>
<td>6.00</td>
<td>6.00</td>
</tr>
<tr>
<td>50</td>
<td>********</td>
<td>6</td>
<td>12.00</td>
<td>18.00</td>
</tr>
<tr>
<td>60</td>
<td>**************</td>
<td>14</td>
<td>28.00</td>
<td>46.00</td>
</tr>
<tr>
<td>70</td>
<td>********</td>
<td>5</td>
<td>10.00</td>
<td>56.00</td>
</tr>
<tr>
<td>80</td>
<td>**************</td>
<td>11</td>
<td>22.00</td>
<td>78.00</td>
</tr>
<tr>
<td>90</td>
<td>**************</td>
<td>10</td>
<td>20.00</td>
<td>98.00</td>
</tr>
<tr>
<td>100</td>
<td>**</td>
<td>1</td>
<td>2.00</td>
<td>100.00</td>
</tr>
</tbody>
</table>

The cumulative percent shows that the median grade for the exam (the grade that 50% of observations lie above and 50% below) lies within the midpoint of 70.

The next example produces the same horizontal bar chart as above, but the program uses the NOSTAT option to eliminate the table of statistics.

```plaintext
options pagesize=40 linesize=80 pageno=1 nodate;
proc chart data=grades;
  hbar Examgrade1 / nostat;
  title 'Grades for First Chemistry Exam';
run;
```
Producing Charts to Summarize Variables

Creating Block Charts

The following output shows the bar chart:

Output 29.4  Removing Statistics from a Horizontal Bar Chart

<table>
<thead>
<tr>
<th>Midpoint</th>
<th>Grades for First Chemistry Exam</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>********************************</td>
</tr>
<tr>
<td>50</td>
<td>********************************</td>
</tr>
<tr>
<td>60</td>
<td>***************************************************</td>
</tr>
<tr>
<td>70</td>
<td>*********************************</td>
</tr>
<tr>
<td>80</td>
<td>******************************************</td>
</tr>
<tr>
<td>90</td>
<td>****************************************</td>
</tr>
<tr>
<td>100</td>
<td>****</td>
</tr>
</tbody>
</table>

Creating Block Charts

Understanding Block Charts

A block chart displays the relative magnitude of data by using blocks of varying height. Each block in a square represents a category of data. A block chart is similar to a vertical bar chart. It uses a more sophisticated presentation of the data to emphasize the individual ranges. However, a block chart is less precise than a bar chart because the maximum height of a block is 10 lines.

The BLOCK statement in a PROC CHART step produces a block chart. You can also use the BLOCK statement to create three-dimensional frequency charts. For an example, see “Creating a Three-Dimensional Chart” on page 501. If you create block charts with a large number of charted values, then you might have to adjust the SAS system options LINESIZE= and PAGESIZE= so that the block chart fits on one page.

Note: If the line size or page size is not sufficient to display all the bars, then PROC CHART automatically produces a horizontal bar chart.

The Program

The following program uses the BLOCK statement to create a block frequency chart for the numeric variable ExamGrade1:

```sas
options linesize=120 pagesize=40 pageno=1 nodate;

proc chart data=grades;
  block ExamGrade1;
  title 'Grades for First Chemistry Exam';
run;
```
The OPTIONS statement increases the line size to 120.

The following output shows the block chart:

Output 29.5  Using a Block Chart to Show Frequencies

```
Grades for First Chemistry Exam

Frequency of ExamGrade

<table>
<thead>
<tr>
<th>ExamGrade</th>
<th>Midpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>3</td>
</tr>
<tr>
<td>50</td>
<td>6</td>
</tr>
<tr>
<td>60</td>
<td>14</td>
</tr>
<tr>
<td>70</td>
<td>5</td>
</tr>
<tr>
<td>80</td>
<td>11</td>
</tr>
<tr>
<td>90</td>
<td>10</td>
</tr>
<tr>
<td>100</td>
<td>1</td>
</tr>
</tbody>
</table>

ExamGrade Midpoint
```

The chart shows the effects of using the BLOCK statement.

1. PROC CHART uses the same midpoints for both the bar chart and block chart. The midpoints appear beneath the chart.
2. The number of observations represented by each block appear beneath the block.
3. The height of a block is proportional to the number of observations in a block.

Creating Pie Charts

Understanding Pie Charts

A pie chart emphasizes the relative contribution of parts (a range of values) to the whole. Graphing the distribution of grades as a pie chart shows you the size of each range relative to the others just as the vertical bar chart does. However, the pie chart also enables you to visually compare the number of grades in a range to the total number of grades.

The PIE statement in a PROC CHART step produces a pie chart. PROC CHART determines the number of sections for the pie chart the same way it determines the number of bars for a vertical chart, with one exception: if any slices of the pie account for fewer than three print positions, then PROC CHART groups them into a category called “Other.”

PROC CHART displays the values of the midpoints around the perimeter of the pie chart. Inside each section of the chart, PROC CHART displays the number of observations in the range and the percentage of observations that the number represents.

The SAS system options LINESIZE= and PAGESIZE= determine the size of the pie. If your printer does not print 6 lines per inch and 10 columns per inch, then the pie looks elliptical. To make a circular pie chart, you must use the LPI= option in the
PROC CHART statement. For more information, see the CHART procedure in the Base SAS Procedures Guide.

The Program

The following program uses the PIE statement to create a pie chart of frequencies for the numeric variable ExamGrade1:

```sas
options pagesize=40 linesize=80 pageno=1 nodate;

proc chart data=grades;
  pie ExamGrade1;
  title 'Grades for First Chemistry Exam';
run;
```

The following output shows the pie chart:

Output 29.6 Using a Pie Chart to Show Frequencies

In this pie chart the Other section represents the one grade in the range with a midpoint of 100. The size of a section corresponds to the number of observations that fall in its range.
Customizing Frequency Charts

Changing the Number of Ranges

You can change the appearance of the charts in the following ways:

<table>
<thead>
<tr>
<th>Action</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>specify midpoints that define the range of values that each bar, block,</td>
<td>MIDPOINTS= option</td>
</tr>
<tr>
<td>or section represents.</td>
<td></td>
</tr>
<tr>
<td>specify the number of bars on the chart and let PROC CHART</td>
<td>LEVELS= option</td>
</tr>
<tr>
<td>compute the midpoints.</td>
<td></td>
</tr>
<tr>
<td>specify a variable that contains discrete numeric values. PROC</td>
<td>DISCRETE option</td>
</tr>
<tr>
<td>CHART will produce a bar chart with a bar for each distinct value.</td>
<td></td>
</tr>
</tbody>
</table>

*Note:* Most examples in this section use vertical bar charts. However, unless documented otherwise, you can use any of the options in the PIE, BLOCK, or HBAR statements.

Specifying Midpoints for a Numeric Variable

You can specify midpoints for a continuous numeric variable by using the MIDPOINTS= option in the VBAR statement. The form of this option is

```vbardollar var=variable / MIDPOINTS=midpoints-list;```

where `midpoints-list` is a list of the numbers to use as midpoints.

For example, to specify the traditional grading ranges with midpoints from 55 to 95, use the following option:

```midpoints=55 65 75 85 95```

Or, you can abbreviate the list of midpoints:

```midpoints=55 to 95 by 10```

The corresponding ranges are as follows:

- 50 to 59
- 60 to 69
- 70 to 79
- 80 to 89
- 90 to 99

The following program uses the MIDPOINTS= option to create a bar chart for ExamGrade1:

```options pagesize=40 linesize=80 pageno=1 nodate;

proc chart data=grades;
   vbar Examgrade1 / midpoints=55 to 95 by 10;
   title 'Assigning Grades for First Chemistry Exam';
run;```
The MIDPOINTS= option forces PROC CHART to center the five bars around the traditional midpoints for exam grades.

The following output shows the bar chart:

**Output 29.7  Specifying the Midpoints for a Vertical Bar Chart**

<table>
<thead>
<tr>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>16 + *****</td>
</tr>
<tr>
<td>15 + ***** *****</td>
</tr>
<tr>
<td>14 + ***** *****</td>
</tr>
<tr>
<td>13 + ***** *****</td>
</tr>
<tr>
<td>12 + ***** *****</td>
</tr>
<tr>
<td>11 + ***** *****</td>
</tr>
<tr>
<td>10 + ***** ***** *****</td>
</tr>
<tr>
<td>9 + ***** ***** *****</td>
</tr>
<tr>
<td>8 + ***** ***** ***** *****</td>
</tr>
<tr>
<td>7 + ***** ***** ***** ***** *****</td>
</tr>
<tr>
<td>6 + ***** ***** ***** ***** *****</td>
</tr>
<tr>
<td>5 + ***** ***** ***** ***** *****</td>
</tr>
<tr>
<td>4 + ***** ***** ***** ***** *****</td>
</tr>
<tr>
<td>3 + ***** ***** ***** ***** *****</td>
</tr>
<tr>
<td>2 + ***** ***** ****</td>
</tr>
<tr>
<td>1 + ***** ***** ***** *****</td>
</tr>
</tbody>
</table>

---

55 65 75 85 95

ExamGrade1 Midpoint

A traditional method to assign grades assumes the data is normally distributed. However, the bars do not appear as a normal (bell-shaped) curve. If grades are assigned based on these midpoints and the traditional pass/fail boundary of 60, then a substantial portion of the class will fail the exam because more observations fall in the bar around the midpoint of 55 than in any other bar.

**Specifying the Number of Midpoints in a Chart**

You can specify the number of midpoints in the chart rather than the values of the midpoints by using the LEVELS= option. The procedure selects the midpoints. The form of the option is

**VBAR variable / LEVELS=number-of-midpoints;**
where `number-of-midpoints` specifies the number of midpoints.

The following program uses the `LEVELS=` option to create a bar chart with five bars:

```sas
options pagesize=40 linesize=80 pageno=1 nodate;
proc chart data=grades;
  vbar Examgrade1 / levels=5;
  title 'Assigning Grades for First Chemistry Exam';
run;
```

The `LEVELS=` option forces PROC CHART to compute only five midpoints.

The following output shows the bar chart:

Output 29.8 Specifying Five Midpoints for a Vertical Bar Chart

Assigning grades for these midpoints results in three students with exam grades in the lowest range.

## Charting Every Value

By default, PROC CHART assumes that all numeric variables are continuous and automatically chooses intervals for them unless you use `MIDPOINTS=` or `LEVELS=`. You can specify that a numeric variable is discrete rather than continuous by using the `DISCRETE` option. PROC CHART will create a frequency chart with bars for each distinct value of the discrete numeric variable.

The following program uses the `DISCRETE` option to create a bar chart with a bar for each value of `ExamGrade1`:

---

*You can use SAS to normalize the data before the chart is created.*
options pagesize=40 linesize=80 pageno=1 nodate;

proc chart data=grades;
  vbar Examgrade1 / discrete;
  title 'Grades for First Chemistry Exam';
run;

The following output shows the bar chart:

**Output 29.9** Specifying a Bar for Each Exam Grade

The chart shows that in most cases only one or two students earned a given grade. However, clusters of three or more students earned grades of 58, 63, 77, 79, 85, and 89. The mode for this exam (most frequently earned exam grade) is 79.

*Note:* PROC CHART does not proportionally space the values of a discrete numeric variable on the horizontal axis.
Charting the Frequency of a Character Variable

You can create charts of a character variable as well as a numeric variable. For instance, to compare enrollment among sections, PROC CHART creates a chart that shows the number of students in each section.

Creating a frequency chart of a character variable is the same as creating a frequency chart of a numeric variable. However, the main difference between charting a numeric variable and charting a character variable is how PROC CHART selects the midpoints. By default, PROC CHART uses each value of a character variable as a midpoint, as if the DISCRETE option were in effect. You can limit the selection of midpoints to a subset of the variable's values, but if you do not define a format for the chart variable, then a single bar, block, or section represents a single value of the variable.

Specifying Midpoints for a Character Variable

By default, the midpoints that PROC CHART uses for character variables are in alphabetical order. However, you can easily rearrange the order of the midpoints with the MIDPOINTS= option. When you use the MIDPOINTS= option for character variables, you must enclose the value of each midpoint in single or double quotation marks, and the values must correspond to values in the data set. For example,

```
midpoints='Mon' 'Wed' 'Fri'
```

uses the three days the class sections meet as midpoints.

The following program uses the MIDPOINTS= option to create a bar chart that shows the number of students enrolled in each section:

```
options pagesize=40 linesize=80 pageno=1 nodate;

proc chart data=grades;
  vbar Section / midpoints='Mon' 'Wed' 'Fri';
  title 'Enrollment for an Introductory Chemistry Course';
run;
```

The MIDPOINTS= option alters the chart so that the days of the week appear in chronological rather than alphabetical order.

The following output shows the bar chart:
Output 29.10  Ordering Character Midpoints Chronologically

The chart shows that the Monday and Wednesday sections have the same number of students; the Friday section has one fewer student.

Creating Subgroups within a Range

You can show how a subgroup contributes to each bar or block by using the
SUBGROUP= option in the BLOCK statement, HBAR statement, or VBAR statement. For example, you can use the SUBGROUP= option to explore patterns within a population (gender differences).

The SUBGROUP= option defines a variable called the subgroup variable. PROC CHART uses the first character of each value to fill in the portion of the bar or block that corresponds to that value, unless more than one value begins with the same first character. In that case, PROC CHART uses the letters A, B, C, and so on to fill in the bars or blocks.

If you assign a format to the variable, then PROC CHART uses the first character of the formatted value. The characters that PROC CHART uses in the chart and the values that they represent are shown in a legend at the bottom of the chart.

PROC CHART orders the subgroup symbols as A through Z, and as 0 through 9, with the characters in ascending order. PROC CHART calculates the height of a bar or block for each subgroup individually and rounds the percentage of the total bar up or down. So the total height of the bar might be greater or less than the height of the same bar without the SUBGROUP= option.

The following program uses GENDER as the subgroup variable to show how many members in each section are male and female:

```plaintext
options pagesize=40 linesize=80 pageno=1 nodate;

proc chart data=grades;
  vbar Section / midpoints='Mon' 'Wed' 'Fri'
     subgroup=Gender;
  title 'Enrollment for an Introductory Chemistry Course';
```
The following output shows the bar chart:

### Output 29.11 Using Gender to Form Subgroups

<table>
<thead>
<tr>
<th>Enrollment for an Introductory Chemistry Course</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Frequency</td>
<td></td>
</tr>
</tbody>
</table>

|            | | | |
|------------| | | |
| 15         | | | |
| 10         | | | |
| 5          | | | |
|------------| | | |

---

PROC CHART fills each bar in the chart with the characters that represent the value of the variable GENDER. The portion of the bar that is filled with Fs represents the number of observations that correspond to females; the portion that is filled with Ms represents the number of observations that correspond to males. Because the value of Gender contains a single character (F or M), the symbol that PROC CHART uses as the fill character is identical to the value of the variable.

### Charting Mean Values

PROC CHART enables you to specify what the bars or sections in the chart represent. By default, each bar, block, or section represents the frequency of the chart variable. You can also identify a variable whose values determine the sizes of the bars, blocks, or sections in the chart.

You define a variable called the *sumvar variable* by using the SUMVAR= option. With the SUMVAR= option, you can also use the TYPE= option to specify whether the sum of the Sumvar variable or the mean of the Sumvar variable determines the size of the bars or sections. The available types are
SUM
sums the values of the Sumvar variable in each range. Then PROC CHART uses the sums to determine the size of each bar, block, or section. SUM is the default type.

MEAN
determines the mean value of the Sumvar variable in each range. Then PROC CHART uses the means to determine the size of each bar, block, or section.

The following program creates a bar chart grouped by gender to compare the mean value of all grades in each section:

```sas
options pagesize=40 linesize=80 pageno=1 nodate;
proc chart data=grades;
  vbar Section / midpoints='Mon' 'Wed' 'Fri' group=Gender
     sumvar=Examgrade1 type=mean;
  title 'Mean Exam Grade for Introductory Chemistry Sections';
run;
```

The SUMVAR= option specifies that the values of ExamGrade1 determine the size of the bars. The TYPE=MEAN option specifies to compare the mean grade for each group.

The following output shows the bar chart:

Output 29.12 Using the SUMVAR= Option to Compare Mean Values

The chart shows that the females in the Friday section achieved the highest mean grade, followed by the males in the same section.

Creating a Three-Dimensional Chart

Complicated relationships such as the ones charted with the GROUP= option might be easier to understand if you present them as three-dimensional block charts. The
following program uses the BLOCK statement to create a block chart for the numeric variable ExamGrade1:

```plaintext
options linesize=120 pagesize=40 pageno=1 nodate;
proc chart data=grades;
    block Section / midpoints='Mon' 'Wed' 'Fri'
        sumvar=ExamGrade1 type=mean
        group=Gender;
    format ExamGrade1 4.1;
    title 'Mean Exam Grade for Introductory Chemistry Sections';
run;
```

The FORMAT statement specifies the number of decimals that PROC CHART uses to report the mean value of ExamGrade1 beneath each block.

*Note:* If the line size or page size is not sufficient to display all the bars, then PROC CHART produces a horizontal bar chart.

The following output shows the block chart:

### Output 29.13 Using a Block Chart to Compare Group Means

<table>
<thead>
<tr>
<th>Gender</th>
<th>Mon</th>
<th>Wed</th>
<th>Fri</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>60.3</td>
<td>69.8</td>
<td>83.6</td>
</tr>
<tr>
<td></td>
<td>60.7</td>
<td>61.4</td>
<td></td>
</tr>
</tbody>
</table>

The value that is shown beneath each block is the mean of ExamGrade1 for that combination of Section and Gender. You can easily see that both females and males in the Friday section earned higher grades than their counterparts in the other sections.
Creating High-Resolution Histograms

Understanding How to Use the HISTOGRAM Statement

A histogram is similar to a vertical bar chart. This type of bar chart emphasizes the individual ranges of continuous numeric variables and enables you to examine the distribution of your data.

The HISTOGRAM statement in a PROC UNIVARIATE step produces histograms and comparative histograms. PROC UNIVARIATE creates a histogram by dividing the data into intervals of equal length, counting the number of observations in each interval, and plotting the counts as vertical bars that are centered around the midpoint of each interval.

If you use the HISTOGRAM statement without any options, then PROC UNIVARIATE automatically does the following:
- scales the vertical axis to show the percentage of observations in an interval
- determines the bar width based on the method of Terrell and Scott (1985)
- labels the axes

The HISTOGRAM statement provides various options that enable you to control the layout of the histogram and enhance the graph. You can also fit families of density curves and superimpose kernel density estimates on the histograms, which can be useful in examining the data distribution. For additional information about the density curves that SAS computes, see the UNIVARIATE procedure in the Base SAS Procedures Guide.

Understanding How to Use SAS/GRAPH to Create Histograms

If your site licenses SAS/GRAPH software, then you can use the HISTOGRAM statement to create high-resolution graphs. When you create charts with a graphics device, you can also use the AXIS, LEGEND, PATTERN, and SYMBOL statements to enhance your plots.

To control the appearance of a high-resolution graph, you can specify a GOPTIONS statement before the PROC step that creates the graph. The GOPTIONS statement changes the values of the graphics options that SAS uses when graphics output is created. Graphics options affect the characteristics of a graph, such as size, colors, type fonts, fill patterns, and line thickness. In addition, they affect the settings of device parameters such as the appearance of the display, the type of output that is produced, and the destination of the output.

Most of the examples in this section use the following GOPTIONS statement:

```bash
goptions reset=global
  gunit=pct
  hsize= 5.625 in
  vsize= 3.5 in
  htitle=4
  htext=3
  vorigin=0 in
  horigin= 0 in
  cback=white border
  ctext=black
  colors=(black blue green red yellow)
  ftext=swoff
  lfactor=3;
```
For additional information about how to modify the appearance of your graphics output, see *SAS/GRAPH Software: Reference, Volumes 1 and 2*.

**Creating a Simple Histogram**

The following program uses the HISTOGRAM statement to create a histogram for the numeric variable ExamGrade1:

```sas
proc univariate data=grades noprint;
   histogram ExamGrade1;
   title 'Grades for First Chemistry Exam';
run;
```

The NOPRINT option suppresses the tables of statistics that the PROC UNIVARIATE statement creates.

The following figure shows the histogram:

![Histogram](image)

The midpoint axis for the above histogram goes from 40 to 100 and is incremented in intervals of 10. The following table shows the values:

<table>
<thead>
<tr>
<th>Interval</th>
<th>Midpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>35 to 44</td>
<td>40</td>
</tr>
<tr>
<td>45 to 54</td>
<td>50</td>
</tr>
<tr>
<td>55 to 64</td>
<td>60</td>
</tr>
<tr>
<td>65 to 74</td>
<td>70</td>
</tr>
<tr>
<td>75 to 84</td>
<td>80</td>
</tr>
</tbody>
</table>
Note: Because PROC UNIVARIATE selects the size of the intervals and the location of their midpoints based on all values of the numeric variable, the highest and lowest intervals can extend beyond the values in the data. In this example the lowest grade is 39 while the lowest interval extends from 35 to 44. Similarly, the highest grade is 98 while the highest interval extends from 95 to 104.

### Changing the Axes of a Histogram

#### Enhancing the Vertical Axis

The exact value of a histogram bar is sometimes difficult to determine. By default, PROC UNIVARIATE does not provide minor tick marks between the vertical axis values (major tick marks). You can specify the number of minor tick marks between major tick marks with the VMINOR= option.

To make it easier to see the location of major tick marks, you can use the GRID option to add grid lines on the histogram. Grid lines are horizontal lines that are positioned at major tick marks on the vertical axis. PROC UNIVARIATE provides two options to change the appearance of the grid line:

<table>
<thead>
<tr>
<th>Action</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>set the color of the grid lines</td>
<td>CGRID=</td>
</tr>
<tr>
<td>set the line type of the grid lines</td>
<td>LGRID=</td>
</tr>
</tbody>
</table>

By default, PROC UNIVARIATE draws a solid line using the first color in the device color list. For a list of the available line types, see *SAS/GRAPH Software: Reference, Volumes 1 and 2*.

The following program creates a histogram that displays minor tick marks and grid lines for the numeric variable ExamGrade1:

```sas
proc univariate data=grades noprint;
    histogram Examgrade1 / vminor=4 grid lgrid=34;
    title 'Grades for First Chemistry Exam';
run;
```

Four minor tick marks are inserted between each major tick mark. Narrowly spaced dots are used to draw the grid lines.

The following figure shows the histogram:

<table>
<thead>
<tr>
<th>Interval</th>
<th>Midpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>85 to 94</td>
<td>90</td>
</tr>
<tr>
<td>95 to 104</td>
<td>10</td>
</tr>
</tbody>
</table>
Now, the height of each histogram bar is easily determined from the chart. The following table shows the percentage each interval represents:

<table>
<thead>
<tr>
<th>Interval</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>35 to 44</td>
<td>6</td>
</tr>
<tr>
<td>45 to 54</td>
<td>12</td>
</tr>
<tr>
<td>55 to 64</td>
<td>28</td>
</tr>
<tr>
<td>65 to 74</td>
<td>10</td>
</tr>
<tr>
<td>75 to 84</td>
<td>22</td>
</tr>
<tr>
<td>85 to 94</td>
<td>20</td>
</tr>
<tr>
<td>95 to 104</td>
<td>2</td>
</tr>
</tbody>
</table>

**Specifying the Vertical Axis Values**

PROC UNIVARIATE enables you to specify what the bars in the histogram represent, and the values of the vertical axis. By default, each bar represents the percentage of observations that fall into the given interval.

The VSCALE= option enables you to specify the following scales for the vertical axis:

- COUNT
- PERCENT
- PROPORTION

The VAXIS= option enables you to specify evenly spaced tick mark values for the vertical axis. The form of this option is

```
HISTOGRAM variable / VAXIS=value-list;
```
where `value-list` is a list of numbers to use as major tick mark values. The first value is always equal to zero and the last value is always greater than or equal to the height of the largest bar.

The following program creates a histogram that displays counts on the vertical axis for the numeric variable ExamGrade1:

```sas
proc univariate data=grades noprint;
    histogram ExamGrade1 / vscale=count vaxis=0 to 16 by 2 vminor=1;
    title 'Grades for First Chemistry Exam';
run;
```

The values of the vertical axis range from 0 to 16 in increments of two. One minor tick mark is inserted between each major tick mark.

The following figure shows the histogram:

![Figure 29.3 Using a Histogram to Show Counts](image)

**Specifying the Midpoints of a Histogram**

You can control the width of the histogram bars by using the MIDPOINTS= option. PROC UNIVARIATE uses the value of the midpoints to determine the width of the histogram bars. The difference between consecutive midpoints is the bar width.

To specify midpoints, use the MIDPOINTS= option in the HISTOGRAM statement. The form of the MIDPOINTS= option is

```
HISTOGRAM variable / MIDPOINTS=midpoint-list;
```

where `midpoint-list` is a list of numbers to use as midpoints. You must use evenly spaced midpoints that are listed in increasing order.

For example, to specify the traditional grading ranges with midpoints from 55 to 95, use the following option:

```
midpoints=55 65 75 85 95
```

Or, you can abbreviate this list of midpoints:
The midpoint axis for the above histogram goes from 55 to 95 and is incremented in intervals of 10. The histogram excludes any exam scores that are below 50.

**Displaying Summary Statistics in a Histogram**

**Understanding How to Use the INSET Statement**

PROC UNIVARIATE enables you to add a box or table of summary statistics, called an *inset*, directly in the histogram. Typically, an inset displays statistics that PROC
UNIVARIATE has calculated, but an inset can also display values that you provide in a SAS data set.

To add a table of summary statistics, use the INSET statement. You can use multiple INSET statements in the UNIVARIATE procedure to add more than one table to a histogram. The INSET statements must follow the HISTOGRAM statement that creates the plot that you want augmented. The inset appears in all the graphs that the preceding HISTOGRAM statement produces.

The form of the INSET statement is as follows:

\[ \text{INSET} \langle \text{keyword(s)} \rangle < / \langle \text{option(s)} \rangle > \]

You specify the keywords for inset statistics (such as N, MIN, MAX, MEAN, and STD) immediately after the word INSET. You can also specify the keyword DATA= followed by the name of a SAS data set to display customized statistics that are stored in a SAS data set. The statistics will appear in the order in which you specify the keywords.

By default, PROC UNIVARIATE uses appropriate labels and appropriate formats to display the statistics in the inset. To customize a label, specify the keyword followed by an equal sign (=) and the desired label in quotation marks. To customize the format, specify a numeric format in parentheses after the keyword. You can assign labels that are up to 24 characters. If you specify both a label and a format for a keyword, then the label must appear before the format. For example,

\[ \text{inset n='Sample Size' std='Std Dev' (5.2);} \]

requests customized labels for two statistics (sample size and standard deviation). The standard deviation is also assigned a format that has a field width of five and includes two decimal places.

Various options enable you to customize the appearance of the inset. For example, you can do the following:

- Specify the position of the inset.
- Specify a heading for the inset table.
- Specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows.

For a complete list of the keywords and the options that you can use in the INSET statement, see the Base SAS Procedures Guide.

The Program

The following program uses the INSET statement to add summary statistics for the numeric variable ExamGrade1 to the histogram:

```
proc univariate data=grades noprint;
   histogram Examgrade1 /vscale=count vaxis=0 to 16 by 2 vminor=1 hoffset=10
                   midpoints=55 65 75 85 95 vaxislabel='Frequency';
   inset n='No. Students' mean='Mean Grade' min='Lowest Grade'
         max='Highest Grade' / header='Summary Statistics'
         vposition=ne wformat=3.1;
   title 'Grade Distribution for the First Chemistry Exam';
run;
```

The following list corresponds to the numbered items in the preceding program:

1 The statistical keywords N, MEAN, MIN, and MAX specify that the number of observations, the mean exam grade, the minimum exam grade, and the maximum exam grade appear in the inset. Each keyword is assigned a customized label to identify the statistic in the inset.

2 The HEADER= option specifies the heading text that appears at the top of the inset.
The POSITION= option uses a compass point to position the inset. The table will appear at the northeast corner of the histogram.

The FORMAT= option requests a format with a field width of three for all the statistics in the inset.

The following figure shows the histogram:

Figure 29.5  Adding an Inset to a Histogram

The histogram shows the data distribution. The table of summary statistics in the upper-right corner of the histogram provides information about the sample size, the mean grade, the lowest value, and the highest value.

Creating a Comparative Histogram

Understanding Comparative Histograms

A comparative histogram is a series of component histograms that are arranged as an array or a matrix. PROC UNIVARIATE uses uniform horizontal and vertical axes to display the component histograms. This enables you to use the comparative histogram to visually compare the distribution of a numeric variable across the levels of up to two classification variables.

You use the CLASS statement with a HISTOGRAM statement to create either a one-way or a two-way comparative histogram. The form of the CLASS statement is as follows:

```
CLASS variable-1<(<variable-option(s)>)> <variable-2<(<variable-option(s)>)>></options>;
```

Class variables can be numeric or character. Class variables can have continuous values, but they typically have a few discrete values that define levels of the variable.
You can reduce the number of classification levels by using a FORMAT statement to combine the values of a class variable.

When you specify one class variable, PROC UNIVARIATE displays an array of component histograms (stacked or side-by-side). To create the one-way comparative histogram, PROC UNIVARIATE categorizes the values of the analysis variable by the formatted values (levels) of the class variable. Each classification level generates a separate histogram.

When you specify two class variables, PROC UNIVARIATE displays a matrix of component plots. To create the two-way comparative histogram, PROC UNIVARIATE categorizes the values of the analysis variable by the cross-classified values (levels) of the class variables. Each combination of the cross-classified levels generates a separate histogram. The levels of class variable-1 are the labels for the rows of the matrix, and the levels of class variable-2 are the labels for the columns of the matrix.

You can specify options in the HISTOGRAM statement to customize the appearance of the comparative histogram. For example, you can do the following:

- Specify the number of rows for the comparative histogram.
- Specify the number of columns for the comparative histogram.
- Specify graphical enhancements, such as background colors and text colors for the labels.

For a complete list of the keywords and the options that you can use in the HISTOGRAM statement, see the Base SAS Procedures Guide.

**The Program**

The following program uses the CLASS statement to create a comparative histogram by gender and section for the numeric variable ExamGrade1:

```sas
proc format;
   value $gendfmt 'M'='Male'
   'F'='Female';
run;

proc univariate data=grades noprint;
   class Gender Section(order=data);
   histogram Examgrade1 / midpoints=45 to 95 by 10 vscale=count vaxis=0 to 6 by 2
   vaxislabel='Frequency' turnvlabels
   nrows=2 ncols=3
   cframe=ligr cframeside=gwh cframetop=gwh cfill=gwh;
   inset mean(4.1) n / noframe position=(2,65);
   format Gender $gendfmt.;
   title 'Grade Distribution for the First Chemistry Exam';
run;
```

The following list corresponds to the numbered items in the preceding program:

1. PROC FORMAT creates a user-written format that will label Gender with a character string. The FORMAT statement assigns the format to Gender.
2. The CLASS statement creates a two-way comparative histogram that uses Gender and Section as the classification variables. PROC UNIVARIATE produces a component histogram for each level (a distinct combination of values) of these variables.
3. The ORDER= option positions the values of Section according to their order in the input data set. The comparative histogram displays the levels of Section according to the days of the week (Mon, Wed, and Fri). The default order of the levels is determined by sorting the internal values of Section (Fri, Mon, and Wed).
The TURNLABELS option turns the characters in the vertical axis labels so that they display vertically instead of horizontally.

The NROWS= option and the NCOLS= option specify a $2 \times 3$ arrangement for the component histograms.

The CFRA M E= option specifies the color that fills the area of each component histogram that is enclosed by the axes and the frame. The CFRAMESIDE= option and the CFRAMETOP= option specify the color to fill the frame area for the column labels and the row labels that appear down the side and across the top of the comparative histogram. By default, these areas are not filled.

The CFILL= option specifies the color to fill the bars of each component histogram. By default, the bars are not filled.

The NOFRAME option suppresses the frame around the inset table.

The POSITION= option uses axis percentage coordinates to position the inset. The position of the bottom-left corner of the inset is 2% of the way across the horizontal axis and 65% of the way up the vertical axis.

The following figure shows the comparative histogram:

![Figure 29.6 Using a Comparative Histogram to Examine Exam Grades by Gender and Section](image)

The comparative histogram is a $2 \times 3$ matrix of component histograms for each combination of Section and Gender. Each component histogram displays a table of statistics that reports the mean of ExamGrade1 and the number of students. You can easily see that both females and males in the Friday section earned higher grades than their counterparts in the other sections.
Review of SAS Tools

PROC CHART Statements

PROC CHART <DATA=SAS-data-set> <options>;
    chart-type variable(s) </options>;

PROC CHART <DATA=SAS-data-set> <options>;
starts the CHART procedure. You can specify the following options in the PROC
CHART statement:

DATA=SAS-data-set
    names the SAS data set that PROC CHART uses. If you omit DATA=, then
    PROC CHART uses the most recently created data set.

LPI=value
    specifies the proportions of PIE and STAR charts.

chart-type variable(s) </options>;
    is a chart statement where

chart-type
    specifies the kind of chart and can be any of the following:
    □ BLOCK
    □ HBAR
    □ PIE
    □ VBAR

You can use any number of chart statements in one PROC CHART step. A
list of options pertains to a single chart statement.

variable(s)
    identifies the variables to chart (called the chart variables).

options
    specifies a list of options. Not all types of chart support all options.
    You can use the following options in the VBAR, HBAR, and BLOCK
    statements:

GROUP=variable
    produces a set of bars or blocks for each value of variable.

SUBGROUP=variable
    proportionally fills each block or bar with characters that represent
different values of variable.

You can use the following options in the VBAR, HBAR, BLOCK, and PIE
statements:

DISCRETE
    creates a bar, block, or section for every value of the chart variable.

LEVELS=number-of-midpoints
    specifies the number-of-midpoints. The procedure selects the midpoints.

MIDPOINTS=midpoints-list
    specifies the values of the midpoints.
SUMVAR=variable
  specifies the variable to use to determine the size of the bars, blocks, or sections.

TYPE=SUM | MEAN
  specifies the type of chart to create, where

  SUM
    sums the values of the Sumvar variable in each range. Then PROC CHART uses the sums to determine the size of each bar, block, or section.

  MEAN
    determines the mean value of the Sumvar variable in each range. Then PROC CHART uses the means to determine the size of each bar, block, or section.

You can use the following options in the HBAR statement:

  NOSTAT
    suppresses the printing of the statistics that accompany the chart by default.

  FREQ
    requests frequency statistics.

  CFREQ
    requests cumulative frequency statistics.

  PERCENT
    requests percentage statistics.

  CPERCENT
    requests cumulative percentage statistics.

---

**PROC UNIVARIATE Statements**

**PROC UNIVARIATE** <option(s)>;

**CLASS** variable-1<(<variable-option(s)>)
  <variable-2<(<variable-option(s)>)> <option(s)>;

**HISTOGRAM** <variable(s)> <option(s)>;

**INSET** <keyword(s) > <option(s)>;

**PROC UNIVARIATE** option(s);

starts the UNIVARIATE procedure. You can specify the following options in the PROC UNIVARIATE statement:

  **DATA=SAS-data-set**
    names the SAS data set that PROC UNIVARIATE uses. If you omit DATA=, then PROC UNIVARIATE uses the most recently created data set.

  **NOPRINT**
    suppresses the descriptive statistics that the PROC UNIVARIATE statement creates.

**CLASS** variable-1<(<variable-option(s)>) <variable-2<(<variable-option(s)>)> <option(s)>;

specifies up to two variables whose values determine the classification levels for the component histograms. Variables in a CLASS statement are referred to as class variables.
You can specify the following option(s) in the CLASS statement:

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the display order for the class variable values, where

DATA
orders values according to their order in the input data set.

FORMATTED
orders values by their ascending formatted values. This order depends on your operating environment.

FREQ
orders values by descending frequency count so that levels with the most observations are listed first.

INTERNAL
orders values by their unformatted values, which yields the same order as PROC SORT. This order depends on your operating environment.

HISTOGRAM <variable(s)> <option(s)>;
creates histograms and comparative histograms using high-resolution graphics for the analysis variables that are specified. If you omit variable(s) in the HISTOGRAM statement, then the procedure creates a histogram for each variable that you list in the VAR statement, or for each numeric variable in the DATA= data set if you omit a VAR statement.

You can specify the following options in the PROC UNIVARIATE statement:

CGRID=color
specifies the color for grid lines when a grid displays on the histogram.

GRID
specifies to display a grid on the histogram. Grid lines are horizontal lines that are positioned at major tick marks on the vertical axis.

HOFFSET=value
specifies the offset in percentage screen units at both ends of the horizontal axis.

LGRID=linetype
specifies the line type for the grid when a grid displays on the histogram. The default is a solid line.

MIDPOINTS=value(s)
determines the width of the histogram bars as the difference between consecutive midpoints. PROC UNIVARIATE uses the same value(s) for all variables. You must use evenly spaced midpoints that are listed in increasing order.

VAXIS=value(s)
specifies tick mark values for the vertical axis. Use evenly spaced values that are listed in increasing order. The first value must be zero and the last value must be greater than or equal to the height of the largest bar. You must scale the values in the same units as the bars.

VMINOR=n
specifies the number of minor tick marks between each major tick mark on the vertical axis. PROC UNIVARIATE does not label minor tick marks.
VSCEL=scale
    specifies the scale of the vertical axis, where scale is

    COUNT
    scales the data in units of the number of observations per data unit.

    PERCENT
    scales the data in units of percentage of observations per data unit.

    PROPORTION
    scales the data in units of proportion of observations per data unit.

INSET <keyword(s)> <option(s)>;
    places a box or table of summary statistics, called an inset, directly in the
    histogram.

    You can specify the following options in the PROC UNIVARIATE statement:

    keyword(s)
    specifies one or more keywords that identify the information to display in the
    inset. PROC UNIVARIATE displays the information in the order that you
    request the keywords. For a complete list of keywords, see the INSET
    statement in SAS/GRAPH Software: Reference, Volumes 1 and 2.

    FORMAT=format
    specifies a format for all the values in the inset. If you specify a format for a
    particular statistic, then this format overrides FORMAT=format.

    HEADER=string
    specifies the heading text where string cannot exceed 40 characters.

    NOFRAME
    suppresses the frame drawn around the text.

    POSITION=position
    determines the position of the inset. The position is a compass point keyword, a
    margin keyword, or a pair of coordinates (x, y). The default position is NW, which
    positions the inset in the upper-left (northwest) corner of the display.

GOPTIONS Statement

GOPTIONS options-list;
    specifies values for graphics options. Graphics options control characteristics of
    the graph, such as size, colors, type fonts, fill patterns, and symbols. In addition,
    they affect the settings of device parameters, which are defined in the device entry.
    Device parameters control such characteristics as the appearance of the display,
    the type of output that is produced, and the destination of the output.

FORMAT Statement

FORMAT variable format-name;
    enables you to display the value of a variable by using a special pattern that you
    specify as format-name.
**Learning More**

PROC CHART
For complete documentation, see the *Base SAS Procedures Guide*. In addition to the features that are described in this section, you can use PROC CHART to create star charts, to draw a reference line at a particular value on a bar chart, and to change the symbol that is used to draw charts. You can also create charts based, not only on frequency, sum, and mean, but also on cumulative frequency, percent, and cumulative percent.

PROC UNIVARIATE
For complete documentation, see the *Base SAS Procedures Guide*.

PROC PLOT
For a discussion about how to plot the relationship between variables, see Chapter 28, “Plotting the Relationship between Variables,” on page 463. When you are preparing graphics presentations, some data lends itself to charts, while other data is better suited for plots.

SAS formats
For complete documentation, see *SAS Language Reference: Dictionary*. Many formats are available with SAS, including fractions, hexadecimal values, roman numerals, social security numbers, date and time values, and numbers written as words.

PROC FORMAT
For complete documentation about how to create your own formats, see the *Base SAS Procedures Guide*.

SAS/GRAPH software
For complete documentation, see *SAS/GRAPH Software: Reference, Volumes 1 and 2*. If your site has SAS/GRAPH software, then you can use the GCHART procedure to take advantage of the high-resolution graphics capabilities of output devices and produce charts that include color, different fonts, and text.

TITLE and FOOTNOTE statements
For a discussion about using titles and footnotes in a report, see “Understanding Titles and Footnotes” on page 392.
PART 8

Designing Your Own Output

Chapter 30........... Writing Lines to the SAS Log or to an Output File 521
Chapter 31........... Understanding and Customizing SAS Output: The Basics 537
Chapter 32........... Understanding and Customizing SAS Output: The Output Delivery System (ODS) 565
CHAPTER 30
Writing Lines to the SAS Log or to an Output File

Introduction to Writing Lines to the SAS Log or to an Output File

Purpose
In previous sections you learned how to store data values in a SAS data set and to use SAS procedures to produce a report that is based on these data values. In this section, you will learn how to do the following:

- design output by positioning data values and character strings in an output file
- prevent SAS from creating a data set by using the DATA _NULL_ statement
- produce reports by using the DATA step instead of using a procedure
- direct data to an output file by using a FILE statement

Prerequisites
Before proceeding with this section, you should be familiar with the concepts presented in the following sections:
Understanding the PUT Statement

When you create output using the DATA step, you can customize that output by using the PUT statement to write text to the SAS log or to another output file. The PUT statement has the following form:

`PUT variable<format>'character-string';`

where

- `variable` names the variable that you want to write.
- `format` specifies a format to use when you write variable values.
- `'character-string'` specifies a string of text to write. Be sure to enclose the string in quotation marks.

Writing Output without Creating a Data Set

In many cases, when you use a DATA step to write a report, you do not need to create an additional data set. When you use the DATA _NULL_ statement, SAS processes the DATA step without writing observations to a data set. Using the DATA _NULL_ statement can increase program efficiency considerably.

The following is an example of a DATA _NULL_ statement:

```plaintext
data _null_;```

The following program uses a PUT statement to write newspaper circulation values to the SAS log. Because the program uses a DATA _NULL_ statement, SAS does not create a data set.

```plaintext
data _null_; length state $ 15; input state $ morning_copies evening_copies year; put state morning_copies evening_copies year; datalines;
Massachusetts 798.4 984.7 1999
Massachusetts 834.2 793.6 1998
Massachusetts 750.3 . 1997
Alabama . 698.4 1999
Alabama 463.8 522.0 1998
Alabama 583.2 234.9 1997
Alabama . 339.6 1996
;```

The following output shows the results:
Writing Lines to the SAS Log or to an Output File

Writing a Character String

In its simplest form, the PUT statement writes the character string that you specify to the SAS log, to a procedure output file, or to an external file. If you omit the destination (as in this example), then SAS writes the string to the log. In the following example, SAS executes the PUT statement once during each iteration of the DATA step. When SAS encounters missing values for MORNING_VALUES or EVENING_COPIES, the PUT statement writes a message to the log.

data _null_
  length state $ 15;
  infile 'your-input-file';
  input state $ morning_copies evening_copies year;
  if morning_copies=. then put '** Morning Circulation Figures Missing';
  else
    if evening_copies=. then put '** Evening Circulation Figures Missing';
  run;

The following output shows the results:

SAS indicates missing numeric values with a period. Note that the log contains three missing values.

Writing Simple Text
Writing Variable Values

Output 30.2 shows that the value for MORNING_COPIES is missing for two observations in the data set, and the value for EVENING_COPIES is missing for one observation. To identify which observations have the missing values, write the value of one or more variables along with the character string. The following program writes the value of YEAR and STATE, as well as the character string:

```sas
data _null_;  
  length state $ 15;  
  infile 'your-input-file';  
  input state $ morning_copies evening_copies year;  
  if morning_copies = . then put '** Morning Circulation Figures Missing: ' year state;  
  else  
  if evening_copies = . then put '** Evening Circulation Figures Missing: ' year state;  
run;
```

Notice that the last character in each of the strings is blank. This is an example of list output. In list output, SAS automatically moves one column to the right after writing a variable value, but not after writing a character string. The simplest way to include the required space is to include it in the character string.

SAS keeps track of its position in the output line with a pointer. Another way to describe the action in this PUT statement is to say that in list output, the pointer moves one column to the right after writing a variable value, but not after writing a character string. In later parts of this section, you will learn ways to move the pointer to control where the next piece of text is written.

The following output shows the results:
Writing Lines to the SAS Log or to an Output File

Output 30.3 Writing a Character String and Variable Values

```sas
164 disc_null;
165   length state $ 15;
166   infile 'your-input-file';
167   input state $ morning_copies evening_copies year;
168   if morning_copies =. then put
169       '** Morning Circulation Figures Missing: ' year state;
170   else
171     if evening_copies =. then put
172       '** Evening Circulation Figures Missing: ' year state;
173     run;
```

NOTE: The infile 'your-file-name' is:
File Name=file-name,
Owner Name=xxxxxx,Group Name=xxxx,
Access Permission=rw-r--r--,
File Size (bytes)=223

** Evening Circulation Figures Missing: 1997 Massachusetts
** Morning Circulation Figures Missing: 1999 Alabama
** Morning Circulation Figures Missing: 1996 Alabama
NOTE: 7 records were read from the infile 'your-input-file'.
The minimum record length was 30.
The maximum record length was 31.

Writing on the Same Line More than Once

By default, each PUT statement begins on a new line. However, you can write on the same line if you use more than one PUT statement and at least one trailing @ (“at” sign).

The trailing @ is a type of pointer control called a line-hold specifier. Pointer controls are one way to specify where SAS writes text. In the following example, using the trailing @ causes SAS to write the item in the second PUT statement on the same line rather than on a new line. The execution of either PUT statement holds the output line for further writing because each PUT statement has a trailing @. SAS continues to write on that line when a later PUT statement in the same iteration of the DATA step is executed and also when a PUT statement in a later iteration is executed.

```sas
options linesize=80 pagesize=60;

data _null_
  length state $ 15;
  infile 'your-input-file';
  input state $ morning_copies evening_copies year;
  if morning_copies =. then put
    '** Morning Tot Missing: ' year state @;
  if evening_copies =. then put
    '** Evening Tot Missing: ' year state @;
  run;
```

The following output shows the results:
If the output line were long enough, then SAS would write all three messages about missing data on a single line. Because the line is not long enough, SAS continues writing on the next line. When it determines that an individual data value or character string does not fit on a line, SAS brings the entire item down to the next line. SAS does not split a data value or character string.

### Releasing a Held Line

In the following example, the input file has five missing values. One record has missing values for both the MORNING_COPIES and EVENING_COPIES variables. Three other records have missing values for either the MORNING_COPIES or the EVENING_COPIES variable.

To improve the appearance of your report, you can write all the missing variables for each observation on a separate line. When values for the two variables MORNING_COPIES and EVENING_COPIES are missing, two PUT statements write to the same line. When either MORNING_COPIES or EVENING_COPIES is missing, only one PUT statement writes to that line.

SAS determines where to write the output by the presence of the trailing @ sign in the PUT statement and the presence of a null PUT statement that releases the hold on the line. Executing a PUT statement with a trailing @ causes SAS to hold the current output line for further writing, either in the current iteration of the DATA step or in a future iteration. Executing a PUT statement without a trailing @ releases the held line.

To release a line without writing a message, use a null PUT statement:

```
put;
```

A null PUT statement has the same characteristics of other PUT statements: by default, it writes output to a new line, writes what you specify in the statement (nothing in this case), and releases the line when it finishes executing. If a trailing @ is in effect, then the null PUT statement begins on the current line, writes nothing, and releases the line.

The following program shows how to write one or more items to the same line:
If a value for MORNING_COPIES is missing, then the first PUT statement holds the line in case EVENING_COPIES is missing a value for that observation.

If a value for EVENING_COPIES is missing, then the next PUT statement writes a message and releases the line.

If EVENING_COPIES does not have a missing value, but if a message has been written for MORNING_COPIES (MORNING_COPIES=.), then the null PUT statement releases the line.

If neither EVENING_COPIES nor MORNING_COPIES has missing values, then the line is not released and no PUT statement is executed.

```sas
options linesize=80 pagesize=60;

data _null_;
  length state $ 15;
  infile 'your-input-file';
  input state $ morning_copies evening_copies year;
  if morning_copies=. then put
    '** Morning Tot Missing: ' year state @;
  if evening_copies=. then put
    '** Evening Tot Missing: ' year state;
  else if morning_copies=. then put;
run;
```

The following output shows the results:

**Output 30.5** Writing One or More Times to a Line and Releasing the Line

```
** Evening Tot Missing: 1997 Massachusetts
** Morning Tot Missing: 1999 Alabama
** Morning Tot Missing: 1996 Alabama
NOTE: 7 records were read from the infile 'your-input-file'.
The minimum record length was 30.
The maximum record length was 31.
```
Writing a Report

Writing to an Output File

The PUT statement writes lines of text to the SAS log. However, the SAS log is not usually a good destination for a formal report because it also contains the source statements for the program and messages from SAS.

The simplest destination for a printed report is the SAS output file, which is the same place SAS writes output from procedures. SAS automatically defines various characteristics such as page numbers for the procedure output file, and you can take advantage of them instead of defining all the characteristics yourself.

To route lines to the procedure output file, use the FILE statement. The FILE statement has the following form:

```
FILE PRINT <options>;
```

PRINT is a reserved fileref that directs output that is produced by PUT statements to the same print file as the output that is produced by SAS procedures.

**Note:** Be sure that the FILE statement precedes the PUT statement in the program code.

FILE statement options specify options that you can use to customize output. The report that is produced in this section uses the following options:

- **NOTITLES**
  - eliminates the default title line and makes that line available for writing. By default, the procedure output file contains the title “The SAS System.” Because the report creates another title that is descriptive, you can remove the default title by specifying the NOTITLES option.

- **FOOTNOTES**
  - controls whether currently defined footnotes are written to the report.

  **Note:** When you use the FILE statement to include footnotes in a report, you must use the FOOTNOTES option in the FILE statement and include a FOOTNOTE statement in your program. The FOOTNOTE statement contains the text of the footnote.

**Note:** You can also remove the default title with a null TITLE statement: `title;`. In this case, SAS writes a line that contains only the date and page number in place of the default title, and the line is not available for writing other text.

Designing the Report

After choosing a destination for your report, the next step in producing a report is to decide how you want it to look. You create the design and determine which lines and columns the text will occupy. Planning how you want your final report to look helps you write the necessary PUT statements to produce the report. The rest of the examples in this section show how to modify a program to produce a final report that resembles the one shown here.
Writing Data Values

After you design your report, you can begin to write the program that will create it. The following program shows how to display the data values for the YEAR, MORNING_COPIES, and EVENING_COPIES variables in specific positions.

In a PUT statement, the @ followed by a number is a pointer control, but it is different from the trailing @ described earlier. The @n argument is a column-pointer control. It tells SAS to move to column n. In this example the pointer moves to the specified locations, and the PUT statement writes values at those points using list output. Combining list output with pointer controls is a simple but useful way of writing data values in columns.

options pagesize=30 linesize=80 pageno=1 nodate;

data _null_;   
  infile 'your-input-file';   
  input state $ morning_copies evening_copies year;   
  file print notitles;   
  put @26 year @53 morning_copies @66 evening_copies;   
run;
The following output shows the results:

**Output 30.6**  Data Values in Specific Locations in the Output

<table>
<thead>
<tr>
<th>Year</th>
<th>Morning Copies</th>
<th>Evening Copies</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999</td>
<td>798.4</td>
<td>984.7</td>
</tr>
<tr>
<td>1998</td>
<td>834.2</td>
<td>793.6</td>
</tr>
<tr>
<td>1997</td>
<td>750.3</td>
<td>.</td>
</tr>
<tr>
<td>1999</td>
<td>.</td>
<td>698.4</td>
</tr>
<tr>
<td>1998</td>
<td>463.8</td>
<td>522.0</td>
</tr>
<tr>
<td>1997</td>
<td>583.2</td>
<td>234.9</td>
</tr>
<tr>
<td>1996</td>
<td>.</td>
<td>339.6</td>
</tr>
</tbody>
</table>

**Improving the Appearance of Numeric Data Values**

In the design for your report, all numeric values are aligned on the decimal point (see Output 30.6). To achieve this result, you have to alter the appearance of the numeric data values by using SAS formats. In the input data all values for MORNING_COPIES and EVENING_COPIES contain one decimal place, except in one case where the decimal value is 0. In list output SAS writes values in the simplest way, that is, by omitting the 0s in the decimal portion of a value. In formatted output, you can show one decimal place for every value by associating a format with a variable in the PUT statement. Using a format can also align your output values.

The format that is used in the program is called the *w.d* format. The *w.d* format specifies the number of columns to be used for writing the entire value, including the decimal point. It also specifies the number of columns to be used for writing the decimal portion of each value. In this example the format 5.1 causes SAS to use five columns, including one decimal place, for writing each value. Therefore, SAS prints the 0s in the decimal portion as necessary. The format also aligns the periods that SAS uses to indicate missing values with the decimal points.

```sas
optionspagesize=30 linesize=80 pageno=1 nodate;

data _null_;
infile 'your-input-file';
input state $ morning_copies evening_copies year;
file print notitles;
put @26 year @53 morning_copies 5.1 @66 evening_copies 5.1;
run;
```

The following output shows the results:

**Output 30.7**  Formatted Numeric Output

<table>
<thead>
<tr>
<th>Year</th>
<th>Morning Copies</th>
<th>Evening Copies</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999</td>
<td>798.4</td>
<td>984.7</td>
</tr>
<tr>
<td>1998</td>
<td>834.2</td>
<td>793.6</td>
</tr>
<tr>
<td>1997</td>
<td>750.3</td>
<td>.</td>
</tr>
<tr>
<td>1999</td>
<td>.</td>
<td>698.4</td>
</tr>
<tr>
<td>1998</td>
<td>463.8</td>
<td>522.0</td>
</tr>
<tr>
<td>1997</td>
<td>583.2</td>
<td>234.9</td>
</tr>
<tr>
<td>1996</td>
<td>.</td>
<td>339.6</td>
</tr>
</tbody>
</table>
Writing Lines to the SAS Log or to an Output File

Writing a Value at the Beginning of Each BY Group

The next step in creating your report is to add the name of the state to your output. If you include the name of the state in the PUT statement with other data values, then the state will appear on every line. However, remembering what you want your final report to look like, you need to write the name of the state only for the first observation of a particular state. Performing a task once for a group of observations requires the use of the BY statement for BY-group processing. The BY statement has the following form:

```
BY by-variable(s)<NOTSORTED>;
```

The by-variable names the variable by which the data set is sorted. The optional NOTSORTED option specifies that observations with the same BY value are grouped together but are not necessarily sorted in alphabetical or numerical order.

For BY-group processing,
- ensure that observations come from a SAS data set, not an external file.
- when the data is grouped in BY groups but the groups are not necessarily in alphabetical order, use the NOTSORTED option in the BY statement. For example, use
  ```
  by state notsorted;
  ```

The following program creates a permanent SAS data set named NEWS.CIRCULATION, and writes the name of the state on the first line of the report for each BY group.

```sas
options pagesize=30 linesize=80 pageno=1 nodate;
libname news 'SAS-data-library';
data news.circulation;
  length state $ 15;
  input state $ morning_copies evening_copies year;
datalines;
Massachusetts 798.4 984.7 1999
Massachusetts 834.2 793.6 1998
Massachusetts 750.3 . 1997
Alabama . 698.4 1999
Alabama 463.8 522.0 1998
Alabama 583.2 234.9 1997
Alabama . 339.6 1996
;
```

```sas
data _null_;
  set news.circulation;
  by state notsorted;
  file print notitles;
  if first.state then put / @7 state @;
  put @26 year @53 morning_copies 5.1 @66 evening_copies 5.1;
run;
```

During the first observation for a given state, a PUT statement writes the name of the state and holds the line for further writing (the year and circulation figures). The next PUT statement writes the year and circulation figures and releases the held line. In observations after the first, only the second PUT statement is processed. It writes the year and circulation figures and releases the line as usual.
The first PUT statement contains a slash (/), a pointer control that moves the pointer to the beginning of the next line. In this example, the PUT statement prepares to write on a new line (the default action). Then the slash moves the pointer to the beginning of the next line. As a result, SAS skips a line before writing the value of STATE. In the output, a blank line separates the data for Massachusetts from the data for Alabama. The output for Massachusetts also begins one line farther down the page than it would have otherwise. (That blank line is used later in the development of the report.)

The following output shows the results:

Output 30.8  Effect of BY-Group Processing

| Massachusetts  | 1999  | 798.4 | 984.7 |
|               | 1998  | 834.2 | 793.6 |
|               | 1997  | 750.3 | .     |
| Alabama       | 1999  | .     | 698.4 |
|               | 1998  | 463.8 | 522.0 |
|               | 1997  | 583.2 | 234.9 |
|               | 1996  | .     | 339.6 |

Calculating Totals

The next step is to calculate the total morning circulation figures, total evening circulation figures, and total overall circulation figures for each state. Sum statements accumulate the totals, and assignment statements start the accumulation at 0 for each state. When the last observation for a given state is being processed, an assignment statement calculates the overall total, and a PUT statement writes the totals and additional descriptive text.

```sas
options pagesize=30 linesize=80 pageno=1 nodate;
libname news 'SAS-data-library';
data _null_;  set news.circulation;  by state notsorted;
  file print notitles;
  /* Set values of accumulator variables to 0 */
  /* at beginning of each BY group. */
  if first.state then
    do;
      morning_total=0;
      evening_total=0;
      put / @7 state @;
    end;
  put @26 year @53 morning_copies 5.1 @66 evening_copies 5.1;
  /* Accumulate separate totals for morning and */
  /* evening circulations. */
  morning_total+morning_copies;
  evening_total+evening_copies;
  /* Calculate total circulation at the end of */
/* each BY group. */

if last.state then
  do;
    all_totals=morning_total+evening_total;
    put @52 '------' @65 '------' /
           @26 'Total for each category'
           @52 morning_total 6.1 @65 evening_total 6.1 /
           @35 'Combined total' @59 all_totals 6.1;
  end;
run;

The following output shows the results:

Output 30.9  Calculating and Writing Totals for Each BY Group

<table>
<thead>
<tr>
<th>State</th>
<th>1999</th>
<th>1998</th>
<th>1997</th>
<th>Total for each category</th>
<th>Combined total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Massachusetts</td>
<td>798.4</td>
<td>834.2</td>
<td>750.3</td>
<td>2382.9</td>
<td>4161.2</td>
</tr>
<tr>
<td>Alabama</td>
<td>.</td>
<td>463.8</td>
<td>583.2</td>
<td>1047.0</td>
<td>2841.9</td>
</tr>
</tbody>
</table>

Notice that Sum statements ignore missing values when they accumulate totals. Also, by default, Sum statements assign the accumulator variables (in this case, MORNING_TOTAL and EVENING_TOTAL) an initial value of 0. Therefore, although the assignment statements in the DO group are executed for the first observation for both states, you need them only for the second state.

Writing Headings and Footnotes for a One-Page Report

The report is complete except for the title lines, column headings, and footnote. Because this is a simple, one-page report, you can write the heading with a PUT statement that is executed only during the first iteration of the DATA step. The automatic variable _N_ counts the number of times the DATA step has iterated or looped, and the PUT statement is executed when the value of _N_ is 1.

The FOOTNOTES option on the FILE statement and the FOOTNOTE statement create the footnote. The following program is complete:

```sas
options pagesize=30 linesize=80 pageno=1 nodate;
libname news 'SAS-data-library';

data _null_;
  set news.circulation;
  by state notsorted;
  file print notitles footnotes;
  if _n_=1 then put @16 'Morning and Evening Newspaper Circulation' //
                @7 'State' @26 'Year' @51 'Thousands of Copies' /
```
$51 \ 'Morning \quad Evening';$

if first.state then
do;
    morning_total=0;
    evening_total=0;
    put / $7 state $;
end;

put $26 year $53 morning_copies 5.1 $66 evening_copies 5.1;
    morning_total+morning_copies;
    evening_total+evening_copies;
if last.state then
do;
    all_totals=morning_total+evening_total;
    put $52 '--------' $65 '--------' /
        $26 'Total for each category'
        $52 morning_total 6.1 $65 evening_total 6.1 /
        $35 'Combined total' $59 all_totals 6.1;
end;

footnote 'Preliminary Report';
run;

The following output shows the results:

Output 30.10  The Final Report

<table>
<thead>
<tr>
<th></th>
<th>Massachusetts</th>
<th>Alabama</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>State</td>
<td>Year</td>
</tr>
<tr>
<td>Massachusetts</td>
<td>1999</td>
<td>798.4</td>
</tr>
<tr>
<td></td>
<td>1998</td>
<td>834.2</td>
</tr>
<tr>
<td></td>
<td>1997</td>
<td>750.3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>------</td>
</tr>
<tr>
<td></td>
<td>Total for each category</td>
<td>2382.9</td>
</tr>
<tr>
<td></td>
<td>Combined total</td>

</tr>
<tr>
<td>Alabama</td>
<td>1999</td>
<td>.</td>
</tr>
<tr>
<td></td>
<td>1998</td>
<td>463.8</td>
</tr>
<tr>
<td></td>
<td>1997</td>
<td>582.3</td>
</tr>
<tr>
<td></td>
<td>1996</td>
<td>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>------</td>
</tr>
<tr>
<td></td>
<td>Total for each category</td>
<td>1047.0</td>
</tr>
<tr>
<td></td>
<td>Combined total</td>
<td></td>
</tr>
</tbody>
</table>

Preliminary Report

Notice that a blank line appears between the last line of the heading and the first data for Massachusetts although the PUT statement for the heading does not write a blank line. The line comes from the slash (/) in the PUT statement that writes the value of STATE in the first observation of each BY group.
Executing a PUT statement during the first iteration of the DATA step is a simple way to produce headings, especially when a report is only one page long.

**Review of SAS Tools**

**Statements**

BY variable-1 < . . . variable-n > <NOTSORTED>;
indicates that all observations with common values of the BY variables are grouped together. The NOTSORTED option indicates that the variables are grouped but that the groups are not necessarily in alphabetical or numerical order.

DATA _NULL_;  
specifies that SAS will not create an output data set.

FILE PRINT <NOTITLES> <FOOTNOTES>;
directs output to the SAS procedure output file. Place the FILE statement before the PUT statements that write to that file. The NOTITLES option suppresses titles that are currently in effect, and makes the lines unavailable for writing other text. The FOOTNOTES option, along with the FOOTNOTE statement, writes a footnote to the file.

PUT;  
by default, begins a new line and releases a previously held line. A PUT statement that does not write any text is known as a null PUT statement.

PUT <variable <format>> <character string>;
writes lines to the destination that is specified in the FILE statement; if no FILE statement is present, then the PUT statement writes to the SAS log. By default, each PUT statement begins on a new line, writes what is specified, and releases the line. A DATA step can contain any number of PUT statements.

By default, SAS writes a variable or character-string at the current position in the line. SAS automatically moves the pointer one column to the right after writing a variable value but not after writing a character string; that is, SAS places a blank after a variable value but not after a character string. This form of output is called list output. If you place a format after a variable name, then SAS writes the value of the variable beginning at its current position in the line and using the format that you specify. The position of the pointer after a formatted value is the following column; that is, SAS does not automatically skip a column. Using a format in a PUT statement is called formatted output. You can combine list and formatted output in a single PUT statement.

PUT<@<n><variable <format>> <character-string> </>@>;
writes lines to the destination that is specified in the FILE statement; if no FILE statement is present, then the PUT statement writes to the SAS log. The @n pointer control moves the pointer to column n in the current line. The / moves the pointer to the beginning of a new line. (You can use slashes anywhere in the PUT statement to skip lines.) Multiple slashes skip multiple lines. The trailing @, if present, must be the last item in the PUT statement. Executing a PUT statement with a trailing @ holds the current line for use by a later PUT statement either in the same iteration of the DATA step or a later iteration. Executing a PUT statement without a trailing @ releases a held line.

TITLE;  
specifies title lines for SAS output.

Introduction to the Basics of Understanding and Customizing SAS Output

Purpose

In this section you will learn to understand your output so that you can enhance its appearance and make it more informative. It discusses DATA step and PROC step output.

This section describes how to enhance the appearance of your output by doing the following:

- adding titles, column headings, footnotes, and labels
- customizing headings
- changing a portion of a heading
- numbering pages and controlling page divisions
- printing date and time values
- representing missing numeric values with a character

Prerequisites

Before proceeding with this section, you should understand the concepts that are presented in the following sections:

- Chapter 2, “Introduction to DATA Step Processing,” on page 19
- Chapter 30, “Writing Lines to the SAS Log or to an Output File,” on page 521

Understanding Output

Output from Procedures

When you invoke a SAS procedure, SAS analyzes or processes your data. You can read a SAS data set, compute statistics, print results, or create a new data set. One of the results of executing a SAS procedure is creating procedure output. The destination of procedure output varies with the method of running SAS, the operating environment, and the options that you use. The form and content of the output varies with each procedure. Some procedures, such as the SORT procedure, do not produce printed output.

SAS has numerous procedures that you can use to process your data. For example, you can use the PRINT procedure to print a report that lists the values of each variable in your SAS data set. You can use the MEANS procedure to compute descriptive statistics for variables across all observations and within groups of observations. You can use the UNIVARIATE procedure to produce information on the distribution of numeric variables. For a graphic representation of your data, you can use the CHART procedure. Many other procedures are available through SAS.

Output from DATA Step Applications

Although output is usually generated by a procedure, you can also generate output by using a DATA step application. Using the DATA step, you can do the following:
To generate output, you can use the FILE and PUT statements together within the DATA step. Use the FILE statement to identify your current output file. Then use the PUT statement to write lines that contain variable values or text strings to the output file. You can write the values in column, list, or formatted style.

You can use the FILE and PUT statements to target a subset of data. If you have a large data set that includes unnecessary information, this kind of DATA step processing can save time and computer resources. Write your code so that the FILE statement executes before a PUT statement in the current execution of a DATA step. Otherwise, your data will be written to the SAS log.

If you have a SAS data set, you can use the FILE and PUT statements to create an external file that another computer language can process. For example, you can create a SAS data set that lists the test scores for high school students. You can then use this file as input to a FORTRAN program that analyzes test scores. The following table lists the variables and the column positions that an existing FORTRAN program expects to find in the input SAS data set:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Column location</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>10-13</td>
</tr>
<tr>
<td>TEST</td>
<td>15-25</td>
</tr>
<tr>
<td>GENDER</td>
<td>30</td>
</tr>
<tr>
<td>SCORE</td>
<td>35-37</td>
</tr>
</tbody>
</table>

You can use the FILE and PUT statements in the DATA step to create the data set that the FORTRAN program reads:

```sas
data _null_;
  set out.sats1;
  file 'your-output-file';
  put @10 year @15 test
     @30 gender @35 score;
run;
```

Output from the Output Delivery System (ODS)

Beginning with Version 7, procedure output is much more flexible because of the Output Delivery System (ODS). ODS is a method of delivering output in a variety of formats and of making the formatted output easy to access. Important features of ODS include the following:

- ODS combines raw data with one or more table definitions to produce one or more output objects. When you send these objects to any or all ODS destinations, your output is formatted according to the instructions in the table definition. ODS destinations can produce an output data set, traditional monospace output, output that is formatted for a high-resolution printer, output that is formatted in HyperText Markup Language (HTML), and so on.
- ODS provides table definitions that define the structure of the output from procedures and from the DATA step. You can customize the output by modifying these definitions or by creating your own definitions.
ODS provides a way for you to choose individual output objects to send to ODS destinations. For example, PROC UNIVARIATE produces five output objects. You can easily create HTML output, an output data set, traditional Listing output, or Printer output from any or all of these output objects. You can send different output objects to different destinations.

ODS stores a link to each output object in the Results folder in the Results window. In addition, ODS removes responsibility for formatting output from individual procedures and from the DATA step. The procedure or DATA step supplies raw data and the name of the table definition that contains the formatting instructions; then ODS formats the output. Because formatting is now centralized in ODS, the addition of a new ODS destination does not affect any procedures or the DATA step. As future destinations are added to ODS, they will automatically become available to the DATA step and to all procedures that support ODS.

For more information and examples, see Chapter 32, “Understanding and Customizing SAS Output: The Output Delivery System (ODS),” on page 565.

Input SAS Data Set for Examples

The following program creates a SAS data set that contains Scholastic Aptitude Test (SAT) information for university-bound high school seniors from 1972 through 1998. (To view the entire DATA step, see “DATA Step to Create the Data Set SAT_SCORES” on page 716.) The data set in this example is stored in a SAS data library that is referenced by the libref ADMIN. For selected years between 1972 and 1998, the data set shows estimated scores that are based on the total number of students nationwide taking the test. Scores are estimated for male (m) and female (f) students, for both the verbal and math portions of the test.

```
options pagesize=60 linesize=80 pageno=1 nodate;
libname admin 'your-data-library';

data admin.sat_scores;
  input Test $ Gender $ Year SATscore @@;
datalines;
  Verbal m 1972 531 Verbal f 1972 529
  Verbal m 1973 523 Verbal f 1973 521
  Verbal m 1974 524 Verbal f 1974 520
  ...more SAS data lines...
  Math  m 1996 527 Math  f 1996 492
  Math  m 1997 530 Math  f 1997 494
  Math  m 1998 531 Math  f 1998 496
;

proc print data=admin.sat_scores;
run;
```

The following output shows a partial list of the results:
Output 31.1 The ADMIN.SAT_SCORES Data Set: Partial List of Output

Locating Procedure Output

The destination of your procedure output depends on the method that you use to start, run, and exit SAS. It also depends on your operating environment and on the settings of SAS system options. The following table shows the default destination for each method of operation.

<table>
<thead>
<tr>
<th>Method of operation</th>
<th>Destination of procedure output</th>
</tr>
</thead>
<tbody>
<tr>
<td>windowing environment</td>
<td>OUTPUT and RESULTS windows</td>
</tr>
<tr>
<td>interactive line mode</td>
<td>on the terminal display, as each step executes</td>
</tr>
<tr>
<td>noninteractive SAS programs</td>
<td>depends on the operating environment</td>
</tr>
<tr>
<td>batch jobs</td>
<td>line printer or disk file</td>
</tr>
</tbody>
</table>
Adding Titles

At the top of each page of output, SAS automatically writes the following title:

The SAS System

You can make output more informative by using the TITLE statement to specify your own title. A TITLE statement writes the title you specify at the top of every page. The form of the TITLE statement is:

`TITLE<n><text>;

where \( n \) specifies the relative line that contains the title, and \( text \) specifies the text of the title. The value of \( n \) can be 1 to 10. If you omit \( n \), SAS assumes a value of 1. Therefore, you can specify TITLE or TITLE1 for the first title line. By default, SAS centers a title.

To add the title 'SAT Scores by Year, 1972-1998' to your output, use the following TITLE statement:

`title 'SAT Scores by Year, 1972-1998';`

The TITLE statement is a global statement. This means that within a SAS session, SAS continues to use the most recently created title until you change or eliminate it, even if you generate different output later. You can use the TITLE statement anywhere in your program.

You can specify up to ten titles per page by numbering them in ascending order. If you want to add a subtitle to your previous title, for example, the subtitle 'Separate Statistics by Test Type,' then number your titles by the order in which you want them to appear. To add a blank line between titles, skip a number as you number your TITLE statements. Your TITLE statements now become

`title1 'SAT Scores by Year, 1972-1998';
title3 'Separate Statistics by Test Type';`

To modify a title line, you change the text in the title and resubmit your program, including all of the TITLE statements. Be aware that a TITLE statement for a given line cancels the previous TITLE statement for that line and for all lines with higher-numbered titles.

To eliminate all titles including the default title, specify

`title;`

or

`title1;`

The following example shows how to use multiple TITLE statements.

```sas
options linesize=80 pagesize=60 pageno=1 nodate;
libname admin 'SAS-data-library';

data report;
  set admin.sat_scores;
  if year ge 1995 then output;
```
title1 'SAT Scores by Year, 1995-1998';
    title3 'Separate Statistics by Test Type';
    run;

    proc print data=report;
    run;

    The following output shows the results:

Output 31.2  Report Showing Multiple TITLE Statements

</tbody>
</table>

Although the TITLE statement can appear anywhere in your program, you can associate the TITLE statement with a particular procedure step by positioning it in one of the following locations:

- □ before the step that produces the output
- □ after the procedure statement but before the next DATA or RUN statement, or the next procedure

Remember that the TITLE statement applies globally until you change or eliminate it.

Adding Footnotes

The FOOTNOTE statement follows the same guidelines as the TITLE statement. The FOOTNOTE statement is a global statement. This means that within a SAS session, SAS continues to use the most recently created footnote until you change or eliminate it, even if you generate different output later. You can use the FOOTNOTE statement anywhere in your program.

A footnote writes up to ten lines of text at the bottom of the procedure output or DATA step output. The form of the FOOTNOTE statement is:

\[
\text{FOOTNOTE}<n> \langle \text{text} \rangle; 
\]

where \( n \) specifies the relative line to be occupied by the footnote, and \( \text{text} \) specifies the text of the footnote. The value of \( n \) can be 1 to 10. If you omit \( n \), SAS assumes a value of 1.
To add the footnote '1967 and 1970 SAT scores estimated based on total number of people taking the SAT,' specify the following statements anywhere in your program:

```plaintext
footnote1 '1967 and 1970 SAT scores estimated based on total number';
footnote2 'of people taking the SAT';
```

You can specify up to ten lines of footnotes per page by numbering them in ascending order. When you alter the text of one footnote in a series and execute your program again, SAS changes the text of that footnote. However, if you execute your program with numbered FOOTNOTE statements, SAS eliminates all higher-numbered footnotes.

```plaintext
footnote;
```

or

```plaintext
footnote1;
```

The following example shows how to use multiple FOOTNOTE statements.

```plaintext
options linesize=80 pagesize=30 pageno=1 nodate;
libname admin ‘SAS-data-library’;

data report;
    set admin.sat_scores;
    if year ge 1996 then output;
    title1 ‘SAT Scores by Year, 1996-1998’;
    title3 ‘Separate Statistics by Test Type’;
    footnote1 ‘1996 through 1998 SAT scores estimated based on total number’;
    footnote2 ‘of people taking the SAT’;
run;

proc print data=report;
run;
```

The following output shows the results:
Labeling Variables

In procedure output, SAS automatically writes the variables with the names that you specify. However, you can designate a label for some or all of your variables by specifying a LABEL statement either in the DATA step or, with some procedures, in the PROC step of your program. Your label can be up to 256 characters long, including blanks.

For example, to describe the variable SATscore with the phrase ‘SAT Score,’ specify

`label SATscore = 'SAT Score';`

If you specify the LABEL statement in the DATA step, the label is permanently stored in the data set. If you specify the LABEL statement in the PROC step, the label is associated with the variable only for the duration of the PROC step. In either case, when a label is assigned, it is written with almost all SAS procedures. The exception is the PRINT procedure. Whether you put the LABEL statement in the DATA step or in the PROC step, with the PRINT procedure you must specify the LABEL option as follows:
The following example shows how to use a label statement.

```sas
options linesize=80 pagesize=30 pageno=1 nodate;
libname admin 'SAS-data-library';

data report;
    set admin.sat_scores;
    if year ge 1996 then output;
    label Test='Test Type'
         SATscore='SAT Score';
    title1 'SAT Scores by Year, 1996-1998';
    title3 'Separate Statistics by Test Type';
run;

proc print data=report label;
run;
```

The following output shows the results:

Developing Descriptive Output

The following example incorporates the TITLE, LABEL, and FOOTNOTE statements, and produces output.

```sas
options linesize=80 pagesize=40 pageno=1 nodate;
libname admin 'SAS-data-library';

proc sort data=admin.satscores;
    by gender;
run;
```
proc means data=admin.satscores maxdec=2 fw=8;
by gender;
label SATscore='SAT score';
title1 'SAT Scores by Year, 1967-1976';
title3 'Separate Statistics by Test Type';
footnote1 '1972 and 1976 SAT scores estimated based on the';
footnote2 'total number of people taking the SAT';
run;

The following output shows the results:

Output 31.5  Titles, Labels, and Footnotes in SAS Output

<td>531.00</td>
</tr>
</tbody>
</table>

1972 and 1976 SAT scores estimated based on the total number of people taking the SAT
Specifying SAS System Options

You can enhance the appearance of your output by specifying SAS system options on the OPTIONS statement. The changes that result from specifying system options remain in effect for the rest of the job, session, or SAS process, or until you issue another OPTIONS statement to change the options.

You can specify SAS system options through the OPTIONS statement, through the OPTIONS window, at SAS invocation, at the initiation of a SAS process, and in a configuration file. Default option settings can vary among sites. To determine the settings at your site, execute the OPTIONS procedure or browse the OPTIONS window.

The OPTIONS statement has the following form:

```
OPTIONS option(s);
```

where `option` specifies one or more SAS options that you want to change.

Note: An OPTIONS statement can appear at any place in a SAS program, except within data lines.

Numbering Pages

By default, SAS numbers pages of output starting with page 1. However, you can suppress page numbers with the NONUMBER system option. To suppress page numbers, specify the following OPTIONS statement:

```
options nonumber;
```

This option, like all SAS system options, remains in effect for the duration of your session or until you change it. Change the option by specifying

```
options number;
```

You can use the PAGENO= system option to specify a beginning page number for the next page of output that SAS writes. The PAGENO= option enables you to reset page numbering in the middle of a SAS session. For example, the following OPTIONS statement resets the next output page number to 5:

```
options pageno=5;
```

Centering Output

By default, SAS centers both the output and output titles. However, you can left-align your output by specifying the following OPTIONS statement:

```
options nocenter;
```

The NOCENTER option remains in effect for the duration of your SAS session or until you change it. Change the option by specifying

```
options center;
```

Specifying Page and Line Size

Procedure output is scaled automatically to fit the size of the page and line. The number of lines per page and the number of characters per line of printed output are
determined by the settings of the PAGESIZE= and LINESIZE= system options. The default settings vary from site to site and are further affected by the machine, operating environment, and method of running SAS. For example, when SAS runs in interactive mode, the PAGESIZE= option by default assumes the size of the device that you specify. You can adjust both your page size and line size by resetting the PAGESIZE= and LINESIZE= options.

For example, you can specify the following OPTIONS statement:

```sas
options pagesize=40 linesize=64;
```

The PAGESIZE= and LINESIZE= options remain in effect for the duration of your SAS session or until you change them.

---

**Writing Date and Time Values**

By default, SAS writes at the top of your output the beginning date and time of the SAS session during which your job executed. This automatic record is especially useful when you execute a program many times. However, you can use the NODATE system option to specify that these values not appear. To do this, specify the following OPTIONS statement:

```sas
options nodate;
```

The NODATE option remains in effect for the duration of your SAS session or until you change it.

---

**Choosing Options Selectively**

Choose the system options that you need to meet your specifications. The following program, which uses the conditional IF-THEN/ELSE statement to subset the data set, includes a number of SAS options. The OPTIONS statement specifies a line size of 64, left-aligns the output, numbers the output pages and supplies the date that the SAS session was started.

```sas
options linesize=64 nocenter number date;
libname admin ’/u/lirezn/saslearnV8’;
data high_scores;
  set admin.sat_scores;
  if SATscore < 525 then delete;
run;

data high_scores;
  title ’SAT Scores: 525 and Above’;
run;
```

The following output shows the results:
Output 31.6  Effect of System Options on SAS Output

Controlling the Appearance of Pages

Input Data Set for Examples of Multiple-page Reports

In the sections that follow, you learn how to customize multiple-page reports. The following program creates and prints a SAS data set that contains newspaper circulation figures for morning and evening editions. Each record lists the state, morning circulation figures (in thousands), evening circulation figures (in thousands), and year that the data represents.

```sas
data circulation_figures;
  length state $ 15;
  input state $ morning_copies evening_copies year;
  datalines;
Colorado 738.6 210.2 1984
Colorado 742.2 212.3 1985
Colorado 731.7 209.7 1986
Colorado 789.2 155.9 1987
Vermont 623.4 566.1 1984
Vermont 533.1 455.9 1985
Vermont 544.2 566.7 1986
Vermont 322.3 423.8 1987
Alaska 51.0 80.7 1984
Alaska 58.7 78.3 1985
Alaska 59.8 70.9 1986
Alaska 64.3 64.6 1987
Alabama 256.3 480.5 1984
Alabama 291.5 454.3 1985
Alabama 303.6 454.7 1986
Alabama . 454.5 1987
Maine . 68.0 1984
Maine . 68.0 1985
Maine 222.7 68.6 1986
Maine 224.1 66.7 1987
Hawaii 433.5 122.3 1984
Hawaii 455.6 245.1 1985
Hawaii 499.3 355.2 1986
```
Hawaii 503.2 488.6 1987;

proc print data=circulation_figures;
run;

The following output shows the results:

Output 31.7 SAS Data Set CIRCULATION_FIGURES

Writing Centered Title and Column Headings

Producing centered titles with TITLE statements is easy, because centering is the default for the TITLE statement. Producing column headings is not so easy. You must insert the correct number of blanks in the TITLE statements so that the entire title, when centered, causes the text to fall in the correct columns. The following example shows how to write centered lines and column headings. The titles and column headings appear at the top of every page of output.
options linesize=80 pagesize=20 nodate;

data report1;
  infile 'your-data-file';
  input state $ morning_copies evening_copies year;
run;

title 'Morning and Evening Newspaper Circulation';
title2;
title3 'State Year Thousands of Copies';
title4    'Morning Evening';

data _null_;  
  set report1;  
  by state notsorted;  
  file print;  
  if first.state then  
    do;  
      morning_total=0;  
      evening_total=0;  
      put / @7 state @;  
    end;
  put @26 year @53 morning_copies 5.1 @66 evening_copies 5.1;  
  morning_total+morning_copies;  
  evening_total+evening_copies;  
  if last.state then  
    do;  
      all_totals=morning_total+evening_total;  
      put @52 '------' @65 '------' /  
        @26 'Total for each category'  
        @52 morning_total 6.1 @65 evening_total 6.1 /  
        @35 'Combined total' @59 all_totals 6.1;
    end;
run;

The following output shows the results:
Output 31.8  Centered Lines and Column Headings in SAS Output

</table>
When you create titles and column headings with TITLE statements, consider the following:

- SAS writes page numbers on title lines by default. Therefore, page numbers appear in this report. If you do not want page numbers, specify the NONUMBER system option.
- The PUT statement pointer begins on the first line after the last TITLE statement. SAS does not skip a line before beginning the text as it does with procedure output. In this example, the blank line between the TITLE statement and the first line of data for each state is produced by the slash (/) in the PUT statement in the FIRST.STATE group.

**Writing Titles and Column Headings in Specific Columns**

The easiest way to program headings in specific columns is to use a PUT statement. Instead of calculating the exact number of blanks that are required to make text fall in particular columns, you move the pointer to the appropriate column with pointer controls and write the text. To write headings with a PUT statement, you must execute the PUT statement at the beginning of each page, regardless of the observation that is being processed or the iteration of the DATA step. The FILE statement with the HEADER= option specifies the headings you want to write.

Use the following form of the FILE statement to specify column headings.

```
FILE PRINT HEADER=label;
```

PRINT is a reserved fileref that directs output that is produced by any PUT statements to the same print file as the output that is produced by SAS procedures. The label variable defines a statement label that identifies a group of SAS statements that execute each time SAS begins a new output page.

The following program uses the HEADER= option of the FILE statement to add a header routine to the DATA step. The routine uses pointer controls in the PUT statement to write the title, skip two lines, and then write column headings in specific locations.

```
options linesize=80 pagesize=24;
```
data _null_;  
set circulation_figures;  
by state notsorted;  
file print notitles header=pagetop;  
if first.state then  
do;  
morning_total=0;  
evening_total=0;  
put / @7 state @;  
end;  
put @26 year @53 morning_copies 5.1 @66 evening_copies 5.1;  
morning_total+morning_copies;  
evening_total+evening_copies;  
if last.state then  
do;  
all_totals=morning_total+evening_total;  
put @52 ‘------’ @65 ‘------’ /  
@26 ‘Total for each category’  
@52 morning_total 6.1 @65 evening_total 6.1 /  
@35 ‘Combined total’ @59 all_totals 6.1;  
end;  
return;  
pagetop:  
put @16 ‘Morning and Evening Newspaper Circulation’ //  
@7 ‘State’ @26 ‘Year’ @51 ‘Thousands of Copies’/  
@51 ‘Morning’ @51 ‘Evening’;  
return;  
run;

The following list corresponds to the numbered items in the preceding program:

1. The PRINT fileref in the FILE statement creates Listing output. The NOTITLES option eliminates title lines so that the lines can be used by the PUT statement. The HEADER= option defines a statement label that points to a group of SAS statements that executes each time SAS begins a new output page. (You can use the HEADER= option only for creating print files.)

2. The RETURN statement that is located before the header routine marks the end of the main part of the DATA step. It causes execution to return to the beginning of the step for another iteration. Without this return statement, the statements in the header routine would be executed during each iteration of the DATA step, as well as at the beginning of each page.

3. The pagetop: label identifies the header routine. Each time SAS begins a new page, execution moves from its current position to the label pagetop: and continues until SAS encounters the RETURN statement. When execution reaches the RETURN statement at the end of the header routine, execution returns to the statement that was being executed when SAS began a new page.

4. The RETURN statement ends the header routine. Execution returns to the statement that was being executed when SAS began a new page.

The following output shows the results:
### Changing a Portion of a Heading

You can use variable values to create headings that change on every page. For example, if you eliminate the default page numbers in the procedure output file, you can create your own page numbers as part of the heading. You can also write the numbers differently from the default method. For example, you can write “Page 1” rather than “1.” Page numbers are an example of a heading that changes with each new page.

The following program creates page numbers using a Sum statement and writes the numbers as part of the header routine.

Controlling Page Divisions

The report in Output 31.10 automatically split the data for Alaska over two pages. To make attractive page divisions, you need to know that there is sufficient space on a page to print all the data for a particular state before you print any data for it.

First, you must know how many lines are needed to print a group of data. Then you use the LINESLEFT= option in the FILE statement to create a variable whose value is the number of lines remaining on the current page. Before you begin writing a group of data, compare the number of lines that you need to the value of that variable. If more
lines are required than are available, use the _PAGE_ pointer control to advance the pointer to the first line of a new page.

In your report, the maximum number of lines that you need for any state is eight (four years of circulation data for each state plus four lines for the underline, the totals, and the blank line between states). The following program creates a variable named CKLINES and compares its value to eight at the beginning of each BY group. If the value is less than eight, SAS begins a new page before writing that state.

```
options pagesize=24;

data _null_;
  set circulation_figures;
  by state notsorted;
  file print notitles header=pagetop linesleft=cklines;
  if first.state then do;
    morning_total=0;
    evening_total=0;
    if cklines<8 then put _page_;
    put / @7 state @;
  end;
  put @26 year @53 morning_copies 5.1 @66 evening_copies 5.1;
  morning_total+morning_copies;
  evening_total+evening_copies;
  if last.state then do;
    all_totals=morning_total+evening_total;
    put @52 '------' @65 '------' / @26 'Total for each category' @52 morning_total 6.1 @65 evening_total 6.1 / @35 'Combined total' @59 all_totals 6.1;
  end;
return;

pagetop:
pagenum+1;
  put @16 'Morning and Evening Newspaper Circulation' @67 'Page ' pagenum // @7 'State' @26 'Year' @51 'Thousands of Copies' / @51 'Morning Evening';
return;
run;
```

The following output shows the results:

Representing Missing Values

Recognizing Default Values

In the following example, numeric data for male verbal and math scores is missing for 1972. Character data for gender is missing for math scores in 1975. By default, SAS replaces a missing numeric value with a period, and a missing character value with a blank when it creates the data set.

```sas
options pagesize=60 linesize=80 pageno=1 nodate;
libname admin 'SAS-data-library';
data admin.sat_scores2;	input Test $ 1-8 Gender $ 10 Year 12-15 SATscore 17-19;
datalines;
verbal m 1972 .
verbal f 1972 529
verbal m 1975 515
verbal f 1975 509
math m 1972 .
math f 1972 489
math 1975 518
math 1975 479
;
run;
proc print data=admin.sat_scores2;
title 'SAT Scores for Years 1972 and 1975';
run;
```

The following output shows the results:

Output 31.12  Default Display of Missing Values

<table>
<thead>
<tr>
<th>SAT Scores for Years 1972 and 1975</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>

Customizing Output of Missing Values by Using a System Option

If your data set contains missing numeric values, you can use the MISSING= system option to display the missing values as a single character rather than as the default
period. You specify the character you want to use as the value of the MISSING= option. You can specify any single character.

In the following program, the MISSING= option in the OPTIONS statement causes the PRINT procedure to display the letter M, rather than a period, for each numeric missing value.

```sas
options missing='M' pageno=1;
libname admin 'SAS-data-library';
data admin.sat_scores2;
  input Test $ 1-8 Gender $ 10 Year 12-15 SATscore 17-19;
datalines;
verbal m 1972
verbal f 1972 529
verbal m 1975 515
verbal f 1975 509
math m 1972
math f 1972 489
math 1975 518
math 1975 479;
proc print data=admin.sat_scores2;
  title 'SAT Scores for Years 1972 and 1975';
run;
```

The following output shows the results:

**Customizing Output of Missing Values by Using a Procedure**

Using the FORMAT procedure is another way to represent missing numeric values. It enables you to customize missing values by formatting them. You first use the FORMAT procedure to define a format, and then use a FORMAT statement in a PROC or DATA step to associate the format with a variable.

The following program uses the FORMAT procedure to define a format, and then uses a FORMAT statement in the PROC step to associate the format with the variable SCORE. Note that you do not follow the format name with a period in the VALUE statement but a period always accompanies the format when you use it in a FORMAT statement.
options pageno=1;
libname admin 'SAS-data-library';

proc format;
    value xscore .'score unavailable';
runc;

proc print data=admin.sat_scores2;
    format SATscore xscore.;
    title 'SAT Scores for Years 1972 and 1975';
runc;

The following output shows the results:

Review of SAS Tools

Statements

FILE file-specification;
    identifies an external file that the DATA step uses to write output from a PUT statement.

FILE PRINT <HEADER=label> <LINESLEFT=number-of-lines>;
    directs the output that is produced by any PUT statements to the same print file as the output that is produced by SAS procedures. The HEADER option defines a statement label that identifies a group of SAS statements that you want to execute each time SAS begins a new output page. The LINESLEFT= option defines a variable whose value is the number of lines left on the current page.

FOOTNOTE <n> <text>;
    specifies up to ten footnote lines to be printed at the bottom of a page of output. The variable n specifies the relative line to be occupied by the footnote, and text specifies the text of the footnote.

LABEL variable='label';
    associates the variable that you specify with the descriptive text that you specify as the label. Your label can be up to 256 characters long, including blanks. You can use the LABEL statement in either the DATA step or the PROC step.
OPTIONS option(s);
changes the value of one or more SAS system options.

TITLE <n> <text>;
specifies up to ten title lines to be printed on each page of the procedure output file and other SAS output. The variable n specifies the relative line that contains the title line, and text specifies the text of the title.

SAS System Options

NUMBER|NONUMBER
controls whether the page number prints on the first title line of each page of output.

PAGENO=n
resets the page number for the next page of output.

CENTER|NOCENTER
controls whether SAS procedure output is centered.

PAGESIZE=n
specifies the number of lines that can be printed per page of output.

LINESIZE=n
specifies the printer line width for the SAS log and the standard procedure output file used by the DATA step and procedures.

DATE|NODATE
controls whether the date and time are printed at the top of each page of the SAS log, the standard print file, or any file with the PRINT attribute.

MISSING='character'
specifies the character to be printed for missing numeric variable values.

Learning More

SAS output
- Chapter 30, “Writing Lines to the SAS Log or to an Output File,” on page 521
- Chapter 32, “Understanding and Customizing SAS Output: The Output Delivery System (ODS),” on page 565
Introduction to Customizing SAS Output by Using the Output Delivery System

Purpose

The Output Delivery System (ODS) enables you to produce output in a variety of formats, such as:
- an HTML file
- a traditional SAS Listing
- a PostScript file
- an RTF file (for use with Microsoft Word)
Prerequisites

Before using this chapter, you should be familiar with the concepts presented in:

- Chapter 1, “What Is the SAS System?,” on page 3
- Chapter 23, “Directing SAS Output and the SAS Log,” on page 351

You should also be familiar with DATA step processing, and creating procedure output.

Input Data Set for Examples

The examples in this chapter are based on data from a college entrance exam called the Scholastic Aptitude Test, or SAT. The data is provided in one input file that contains the average SAT scores of students that are entering the university from 1972 to 1998. The input file has the following structure:

```
Verbal m 1972 531
Verbal f 1972 529
Verbal m 1973 523
Verbal f 1973 521
Math m 1972 527
Math f 1972 489
Math m 1973 525
Math f 1973 489
```

The input file contains the following kinds of values:

- type of SAT test
- gender of the student
- year the test was given
- average test score of the entering first-year college class

The following program creates the data set that this chapter uses. (For a complete listing of the input data, see “Data Set SAT_SCORES” on page 716.)

```
data sat_scores;
    input Test $ Gender $ Year SATscore @@;
datalines;
Verbal m 1972 531  Verbal f 1972 529
Verbal m 1973 523  Verbal f 1973 521
Verbal m 1974 524  Verbal f 1974 520
...more data lines...
Math m 1996 527  Math f 1996 492
Math m 1997 530  Math f 1997 494
Math m 1998 531  Math f 1998 496
;
```

Note: The examples use file names that may not be valid in all operating environments. For information about how your operating environment uses file specifications, see the documentation for your operating environment.
Understanding ODS Output Formats and Destinations

The Output Delivery System (ODS) enables you to produce output in a variety of formats that you can easily access. ODS removes responsibility for formatting output from individual procedures and from the DATA step. The procedure or DATA step supplies the data and the table definition, which contains formatting instructions for the output.

The following figure illustrates the concept of output for SAS Version 8. The data and the table definition form an output object, which creates the type of ODS output that you specified in the table definition.

Figure 32.1 Model of the Production of ODS Output

The following definitions describe the terms in the preceding figure:

data
Each procedure that supports ODS and each DATA step produces data, which contains the results (numbers and characters) of the step in a form similar to a SAS data set.

table definition
The table definition is a set of instructions that describes how to format the data. This description includes but is not limited to the following items:

- the order of the columns
- text and order of column headings
- formats for data
- font sizes and font faces
output object
ODS combines formatting instructions with the data to produce an output object. The output object, therefore, contains both the results of the procedure or DATA step and information about how to format the results. An output object has a name, a label, and a path.

Note: Although many output objects include formatting instructions, not all of them do. In some cases the output object consists of only the data.

ODS destinations
An ODS destination specifies a specific type of output. ODS supports a number of destinations, including the following:

- **RTF**
  produces output that is formatted for use with Microsoft-Word.

- **Output**
  produces a SAS data set.

- **Listing**
  produces traditional SAS output (monospace format).

- **HTML**
  produces output that is formatted in Hyper Text Markup Language (HTML). You can access the output on the web with your web browser.

- **Printer**
  produces output that is formatted for a high-resolution printer. An example of this type of output is a PostScript file.

ODS output
ODS output consists of formatted output from any of the ODS destinations.

For detailed information about ODS, see *SAS Output Delivery System: User’s Guide*.

---

**Selecting an Output Format**

You select the format for your output by opening and closing ODS destinations in your program. When one or more destinations are open, ODS can send output objects to them and produce formatted output. When a destination is closed, ODS does not send an output object to it and no output is produced.

By default, all programs automatically produce Listing output along with output for other destinations that you specifically open. Therefore, by default, the Listing destination is open, and all other destinations are closed.

To create formatted output, open one or more destinations by using the following ODS statements:

- **ODS HTML** file-specification(s);
- **ODS OUTPUT** data-set-definition;
- **ODS PRINTER** file-specification;
- **ODS RTF** file-specification;

The argument file-specification opens the destination and specifies one or more files to write to. The argument data-set-definition opens the Output destination and enables SAS to create a data set from an output object.

To view or print the ODS output that you have selected, you need to close all the destinations that you opened, except for the Listing destination. You can use separate
statements to close individual destinations, or use one statement to close all destinations (including the Listing destination). To close ODS destinations, use the following statements:

- `ODS HTML CLOSE;`
- `ODS OUTPUT CLOSE;`
- `ODS PRINTER CLOSE;`
- `ODS RTF CLOSE;`
- `ODS_ALL_CLOSE;`

*Note:* The `ODS_ALL_CLOSE` statement, which closes all open destinations, is available with SAS Release 8.2 and higher.

In some cases you might not want to create Listing output. Use the `ODS LISTING CLOSE;` statement at the beginning of your program to close the Listing destination and prevent SAS from producing Listing output. Closing unnecessary destinations conserves system resources.

*Note:* Because ODS statements are global statements, it is good practice to open the Listing destination at the end of your program. If you execute other programs in your current SAS session, Listing output is then available. To open the Listing destination, use the `ODS LISTING;` statement at the end of your program.

---

### Creating Formatted Output

#### Creating HTML Output for a Web Browser

##### Understanding the Four Types of HTML Output Files

When you use the ODS HTML statement, you can create output that is formatted in HTML. You can browse the output files with Internet Explorer, Netscape, or any other browser that fully supports the HTML 3.2 tag set.

The ODS HTML statement can create four types of HTML files:

- a body file that contains the results of the DATA step or procedure
- a table of contents that links to items in the body file
- a table of pages that links to items in the body file
- a frame file that displays the results of the procedure or DATA step, the table of contents, and the table of pages

The body file is required with all ODS HTML output. If you do not want to link to your output, then creating a table of contents, a table of pages, and a frame file is not necessary.

##### Creating HTML Output: The Simplest Case

To produce the simplest kind of HTML output, the only file you need to create is a body file.

The following example executes the MEANS procedure and creates an HTML body file and the default Listing file. These files contain summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the CLASS variables Test and Gender.
The following list corresponds to the numbered items in the preceding program:

1. The ODS HTML statement opens the HTML destination and creates the body file SUMMARY-RESULTS.HTM.
2. The MEANS procedure produces summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the CLASS variables Test and Gender.
3. The ODS HTML CLOSE statement closes the HTML destination to make output available for viewing.

The following output shows the results in HTML format:

Display 32.1   ODS Output: HTML Format

```

Creating HTML Output: Linking Results with a Table of Contents

The ODS HTML destination enables you to link to your results from a table of contents and a table of pages. To do this, you need to create the following HTML files: a body file, a frame file, a table of contents, and a table of pages (see “Understanding the Four Types of HTML Output Files” on page 569). When you view the frame file and select a link in the table of contents or the table of pages, the HTML table that contains the selected part of the procedure results appears at the top of your browser.

The following example creates multiple pages of output from the UNIVARIATE procedure. You can access specific output results (tables) from links in the table of contents or the table of pages. The results contain statistics for the average SAT scores of entering first-year college classes. The output is grouped by the value of Gender in the CLASS statement and by the value of Test in the BY statement.

```sas
proc sort data=sat_scores out=sorted_scores;
   by Test;
run;

options pageno=1 nodate;
ods listing close;
ods html file='odshtml-body.htm'
   contents='odshtml-contents.htm'
   page='odshtml-page.htm'
   frame='odshtml-frame.htm';
```
proc univariate data=sorted_scores;
  var SATscore;
  class Gender;
  by Test;
  title1 'Average SAT Scores Entering College Classes, 1972-1998*';
  footnote1 '* Recentered Scale for 1987-1995';
run;

ods html close;
ods listing;

The following list corresponds to the numbered items in the preceding program:

1. By default, the Listing destination is open. To conserve resources, the ODS LISTING CLOSE statement closes this destination.
2. The ODS HTML statement opens the HTML destination and creates four types of files:
   - the body file (created with the FILE= option), which contains the formatted data
   - the contents file, which is a table of contents with links to items in the body file
   - the page file, which is a table of pages with links to items in the body file
   - the frame file, which displays the table of contents, the table of pages, and the body file
3. The UNIVARIATE procedure produces statistics for the average SAT scores of entering first-year college students. The output is grouped by the value of Gender in the CLASS statement and the value of Test in the BY statement.
4. The ODS HTML CLOSE statement closes the HTML destination to make output available for viewing.
5. The ODS LISTING statement reopens the Listing destination so that the next program that you run can produce Listing output.

The following SAS log shows that four HTML files are created with the ODS HTML statement:

Output 32.2 Partial SAS Log: HTML File Creation

```
489 ods listing close;
490 ods html file='odshtml-body.htm'
491 contents='odshtml-contents.htm'
492 page='odshtml-page.htm'
493 frame='odshtml-frame.htm';
NOTE: Writing HTML Body file: odshtml-body.htm
NOTE: Writing HTML Contents file: odshtml-contents.htm
NOTE: Writing HTML Pages file: odshtml-page.htm
NOTE: Writing HTML Frames file: odshtml-frame.htm
494 proc univariate data=sorted_scores;
495 var SATscore;
496 class Gender;
497 by Test;
498 title1 'Average SAT Scores Entering College Classes, 1972-1998*';
499 footnote1 '* Recentered Scale for 1987-1995';
500 run;
```
The following output shows the frame file, which displays the table of contents (upper left side), the table of pages (lower left side), and the body file (right side).

Display 32.2  View of the HTML Frame File

Both the Table of Contents and the Table of Pages contain links to the results in the body file. If you click on a link in the Table of Contents or the Table of Pages, SAS displays the corresponding results at the top of the browser.

Creating PostScript Output for a High-Resolution Printer

You can create output that is formatted for a high-resolution printer if you open the Printer destination. Before you can access the file, however, you must close the Printer destination.

The following example executes the MEANS procedure and creates a PostScript file which contains summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the value of Gender in the CLASS statement and the value of Test in the BY statement.

```sas
proc sort data=sat_scores out=sorted_scores;
   by Test;
run;

options pageno=1 nodate;
ods listing close; ①
do printer ps file=odsprinter_output.ps'; ②
```

① Close the listing destination.
② Create a PostScript file named `odsprinter_output.ps'.

The code snippet above sorts the data by `Test` and saves it as `sorted_scores`. It then closes the listing destination and opens the printer destination to create a PostScript file named `odsprinter_output.ps'.
proc means data=sorted_scores fw=8;
    var SATscore;
    class Gender;
    by Test;
    title1 'Average SAT Scores Entering College Classes, 1972-1998*';
    footnote1 '** Recentered Scale for 1987-1995';
run;
ods printer close; ①
ods listing; ②

The following list corresponds to the numbered items in the preceding program:
① By default, the Listing destination is open. To conserve resources, the program uses the ODS LISTING CLOSE statement to close this destination.
② The ODS PRINTER statement opens the Printer destination and specifies the file to write to. The PS (PostScript) option ensures that you create a generic PostScript file. If this option is missing, ODS produces output for your current printer, if possible.
③ The MEANS procedure produces summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the value of Gender in the CLASS statement and the value of Test in the BY statement.
④ The ODS PRINTER CLOSE statement closes the Printer destination to make output available for printing.
⑤ The ODS LISTING statement reopen the Listing destination so that the next program that you run can produce Listing output.

The following output shows the results:

Display 32.3  ODS Output: PostScript Format

Creating RTF Output for Microsoft Word

You can create output that is formatted for use with Microsoft Word if you open the RTF destination. Before you can access the file, you must close the RTF destination.

The following example executes the UNIVARIATE procedure and creates an RTF file that contains summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the CLASS variable Gender.

ods listing close; ①
ods rtf file='odsrtf_output.rtf'; ②

proc univariate data=sat_scores; ③
    var SATscore;
    class Gender;
    title1 'Average SAT Scores Entering College Classes, 1972-1998*';
    footnote1 '** Recentered Scale for 1987-1995';
run;
ods rtf close; ④
ods listing; ⑤
The following list corresponds to the numbered items in the preceding program:

1. By default, the Listing destination is open. To conserve resources, the ODS LISTING CLOSE statement closes this destination.

2. The ODS RTF statement opens the RTF destination and specifies the file to write to.

3. The UNIVARIATE procedure produces summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the CLASS variable Gender.

4. The ODS RTF CLOSE statement closes the RTF destination to make output available.

5. The ODS LISTING statement reopens the Listing destination so that the next program that you run can produce Listing output.

The following output shows the first page of the RTF output:
Display 32.4  ODS Output: RTF Format

Selecting the Output That You Want to Format

Identifying Output

Program output, in the form of output objects, contain both the results of a procedure or DATA step and information about how to format the results. To select an output object for formatting, you need to know which output objects your program creates. To identify the output objects, use the ODS TRACE statement. The simplest form of the ODS TRACE statement is as follows:

```
ODS TRACE ON|OFF;
```

ODS TRACE determines whether to write to the SAS log a record of each output object that a program creates. The ON option writes the trace record to the log, and the OFF option suppresses the writing of the trace record.

The trace record has the following components:

- **Name** is the name of the output object.
- **Label** is the label that briefly describes the contents of the output object.
- **Template** is the name of the table definition that ODS used to format the output object.
- **Path** shows the location of the output object.

In the ODS SELECT statement in your program, you can refer to an output object by name, label, or path.

The following program executes the UNIVARIATE procedure and writes a trace record to the SAS log.

```
ods trace on;
proc univariate data=sat_scores;
  var SATscore;
  class Gender;
  title1 'Average SAT Scores Entering College Classes, 1972-1998*';
  footnote1 '* Recentered Scale for 1987-1995';
run;
ods trace off;
```

The following output shows the results of ODS TRACE. Two sets of output objects are listed because the program uses the class variable Gender to separate male and female results. The path component of the output objects identifies the female (f) and male (m) objects.
Identifying Output

Template: base.univariate.Measures
Path:     Univariate.SATscore.m.BasicMeasures
Selecting and Excluding Program Output

For each destination, ODS maintains a selection list or an exclusion list. The selection list is a list of output objects that produce formatted output. The exclusion list is a list of output objects for which no output is produced.

You can select and exclude output objects by specifying the destination in an ODS SELECT or ODS EXCLUDE statement. If you do not specify a destination, ODS sends output to all open destinations.

Selection and exclusion lists can be modified and reset at different points in a SAS session, such as at procedure boundaries. If you end each procedure with an explicit QUIT statement, rather than waiting for the next PROC or DATA step to end it for you, the QUIT statement resets the selection list.

To choose one or more output objects and send them to open ODS destinations, use the ODS SELECT statement. The simplest form of the ODS SELECT statement is as follows:

**ODS SELECT <ODS-destination> output-object(s);**

The argument ODS-destination identifies the output format, and output-object specifies one or more output objects to add to a selection list.

To exclude one or more output objects from being sent to open destinations, use the ODS EXCLUDE statement. The simplest form of the ODS EXCLUDE statement is as follows:

**ODS EXCLUDE <ODS-destination> output-object(s);**

The argument ODS-destination identifies the output format, and output-object specifies one or more output objects to add to an exclusion list.

The following example executes the UNIVARIATE procedure and creates 10 output objects. The ODS SELECT statement uses the name component in the trace records to select only the BasicMeasures and the TestsForLocation output objects. Because the HTML and Printer destinations are open, ODS creates HTML and Printer output from the output objects.
options nodate pageno=1;
ods listing close;
ods html file='odssselect-body.htm'
    contents='odssselect-contents.htm'
    page='odssselect-page.htm'
    frame='odssselect-frame.htm';
ods printer file='odssprinter-select.ps';
ods select BasicMeasures TestsForLocation;
proc univariate data=sat_scores;
    var SATscore;
    class Gender;
    title1 'Average SAT Scores Entering College Classes, 1972-1998*';
    footnote1 '** Recentered Scale for 1987-1995';
run;
ods html close;
ods printer close;
ods listing;

The following two displays show the results in Printer format. They show the Basic Statistical Measures and Tests for Location tables based on gender.

Creating a SAS Data Set

ODS enables you to create a SAS data set from an output object. To create a single output data set, use the following form of the ODS OUTPUT statement:

```
ODS OUTPUT output-object(s)=SAS-data-set;
```

The argument `output-object` specifies one or more output objects to turn into a SAS data set, and `SAS-data-set` specifies the data set that you want to create.

In the following program, ODS opens the Output destination and creates the SAS data set MYFILE.MEASURES from the output object BasicMeasures. ODS then closes the Output destination.

```
libname myfile 'SAS-data-library';
ods listing close;
ods output BasicMeasures=myfile.measures;
proc univariate data=sat_scores;
  var SATscore;
  class Gender;
run;
ods output close;
ods listing;
```

The following list corresponds to the numbered items in the preceding program:

1. By default, the Listing destination is open. To conserve resources, the ODS LISTING CLOSE statement closes this destination.
2. The ODS OUTPUT statement opens the Output destination and specifies the permanent data set to create from the output object BasicMeasures.
3. The UNIVARIATE procedure produces summary statistics for the average SAT scores of entering first-year college students. The output is grouped by the CLASS variable Gender.
4. The ODS OUTPUT CLOSE statement closes the Output destination.
5. The ODS LISTING statement reopens the default Listing destination so that the next program that you run can produce Listing output.

The following SAS log shows that the MYFILE.MEASURES data set was created with the ODS OUTPUT statement:

```
404 libname myfile 'SAS-data-library';
405 ods listing close;
406 ods output BasicMeasures=myfile.measures;
407 proc univariate data=sat_scores;
408  var SATscore;
409  class Gender;
410 run;
NOTE: The data set MYFILE.MEASURES has 8 observations and 6 variables.
```
Customizing ODS Output

Customizing ODS Output at the Level of a SAS Job

ODS provides a way for you to customize output at the level of the SAS job. To do this, you use a style definition, which describes how to show such items as color, font face, font size, and so on. The style definition determines the appearance of the output. The fancyprinter style definition is one of several that is available with SAS.

The following example uses the fancyprinter style definition to customize program output. The output consists of two output objects, Moments and BasicMeasures, that the UNIVARIATE procedure creates. The STYLE= option on the ODS PRINTER statement specifies that the program use the fancyprinter style.

```
options nodate pageno=1;
ods listing close;
ods printer ps file='style_job.ps' style=fancyprinter;
ods select Moments BasicMeasures;
proc univariate data=sat_scores;
  var SATscore;
  title 'Average SAT Scores for Entering College Classes, 1972-1982*';
  footnote1 '* Recentered Scale for 1987-1995';
run;
ods printer close;
ods listing;
```

The following output shows the results:

Display 32.9 Printer Output: Titles, Footnote, and Variables Printed in Italics

For detailed information about style and table definitions, as well as the TEMPLATE procedure, see SAS Output Delivery System: User’s Guide.

Customizing ODS Output by Using a Template

Another way to customize ODS output is by using a template. In ODS, templates are called table definitions. A table definition describes how to format the output. It can determine the order of table headings and footnotes, the order of columns, and the appearance of the output. A table definition can contain one or more columns, headings, or footnotes.

Many procedures that fully support ODS provide table definitions that you can customize. You can also create your own table definition by using the TEMPLATE procedure. The following is a simplified form of the TEMPLATE procedure:

```
PROC TEMPLATE;
  DEFINE table-definition;
  HEADER header(s);
```

The DEFINE statement creates the table definition that serves as the template for writing the output. The HEADER statement specifies the order of the headings, and the COLUMN statement specifies the order of the columns. The arguments in each of these statements point to routines in the program that format the output. The END statement ends the table definition.

The following example shows how to use PROC TEMPLATE to create customized HTML and printer output. In the example, the SAS program creates a customized table definition for the Basic Measures output table from PROC UNIVARIATE. The following customized version shows that

- the “Measures of Variability” section precedes the “Measures of Location” section
- column headings are modified
- statistics are displayed in a bold, italic font with a 7.3 format.

```sas
options nodate nonumber linesize=80 pagesize=60;

proc template;
    define table base.univariate.Measures;
        header h1 h2 h3;
        column VarMeasure VarValue LocMeasure LocValue;

        define h1;
            text "Basic Statistical Measures";
            spill_margin=on;
            space=1;
        end;
        define h2;
            text "Measures of Variability";
            start=VarMeasure;
            end=VarValue;
        end;
        define h3;
            text "Measures of Location";
            start=LocMeasure;
            end=LocValue;
        end;

        define LocMeasure;
            print_headers=off;
            glue=2;
            space=3;
            style=rowheader;
        end;
        define LocValue;
            print_headers=off;
            space=5;
            format=7.3;
            style=data{font_style=italic font_weight=bold};
        end;
        define VarMeasure;
            print_headers=off;
            glue=2;
    end;
end;
```
space=3;
style=rowheader;
end;
define VarValue;
print_headers=off;
format=7.3;
style=data{font_style=italic font_weight=bold};
end;
end;
run;
ods listing close;
ods html file='scores-body.htm'
contents='scores-contents.htm'
page='scores-page.htm'
frame='scores-frame.htm';
ods printer file='scores.ps';
ods select BasicMeasures;
title;
proc univariate data=sorted_scores mu0=3.5;
var SATscore;
run;
ods html close;
ods printer close;
ods listing;
The following list corresponds to the numbered items in the preceding program:

1. All four options affect the Listing output. The NODATE and NONUMBER options affect the Printer output. None of the options affects the HTML output.
2. PROC TEMPLATE begins the procedure for creating a table.
3. The DEFINE statement creates the table definition base.univariate.Measures in SASUSER.
4. The HEADER statement determines the order in which the table definition uses the headings, which are defined later in the program.
5. The COLUMN statement determines the order in which the variables appear. PROC UNIVARIATE names the variables.
6. These DEFINE blocks define the three headings and specify the text to use for each heading. By default, a heading spans all columns. This is the case for H1. H2 spans the variables VarMeasure and VarValue. H3 spans LocMeasure and LocValue.
7. These DEFINE blocks specify characteristics for each of the four variables. They use FORMAT= to specify a format of 7.3 for LocValue and VarValue. They also use STYLE= to specify a bold, italic font for these two variables. The STYLE= option does not affect the Listing output.
8. The END statement ends the table definition.
9. The RUN statement executes the procedure.
10. The ODS HTML statement begins the program that uses the customized table definition. It opens the HTML destination and identifies the files to write to.
11. The ODS PRINTER statement opens the Printer destination and identifies the file to write to.
The ODS SELECT statement selects the output object that contains the basic measures.

PROC UNIVARIATE produces one object for each variable. It uses the customized table definition to format the data.

The ODS statements close the HTML and the PRINTER destinations.

The ODS LISTING statement opens the listing destination for output.

The following display shows the printer output:

Display 32.10 Customized Printer Output from the TEMPLATE Procedure

Storing Links to ODS Output

When you run a procedure that supports ODS, SAS automatically stores a link to each piece of ODS output in the Results folder in the Results window. It marks the link with an icon that identifies the output destination that created the output.

In the following example, SAS executes the UNIVARIATE procedure and generates Listing, HTML, Printer, and Rich Text Format (RTF) output as well as a SAS data set (Output). The output contains statistics for the average SAT scores of entering first-year college students. The output is grouped by the CLASS variable Gender.

```
ods listing close;
ods html file='store-links.htm';
ods printer file='store-links.ps';
ods rtf file='store-links.rtf';
ods output basicmeasures=measures;

proc univariate data=sat_scores;
  var SATscore;
  class Gender;
  title;
run;

ods _all_ close;
ods listing;

PROC UNIVARIATE generates a folder called Univariate in the Results folder. Within this folder is another folder (SAT score) for the variable in the VAR statement. This folder contains two folders (Gender=f and Gender=m), one for each variable in the CLASS statement. The Gender=f and Gender=m folders each contain a folder for each output object. Within the folder for each output object is a link to each piece of output. The icon next to the link indicates which ODS destination created the output. In this example, the Moments output was sent to the Listing, HTML, Printer, and RTF destinations. The Basic Measures of Location and Variability output was sent to the Listing, HTML, Printer, RTF, and Output destinations.

The Results folder in the display that follows shows the folders and output objects that the UNIVARIATE procedure creates.
Review of SAS Tools

ODS Statements

ODS EXCLUDE <ODS-destination> output-object(s);
specifies one or more output objects to add to an exclusion list.
ODS HTML <HTML-file-specification(s)> <STYLE='style-definition'>;
opens the HTML destination and specifies the HTML file or files to write to. After the destination is open, you can create output that is written in Hyper Text Markup Language (HTML).

You can specify up to four HTML files to write to. The specifications for these files have the following form:

- **BODY='body-file-name'**
  - identifies the file that contains the HTML output.
  - **Alias:** FILE=

- **CONTENTS='contents-file-name'**
  - identifies the file that contains a table of contents for the HTML output. The contents file has links to the body file.

- **FRAME='frame-file-name'**
  - identifies the file that integrates the table of contents, the page contents, and the body file. If you open the frame file, you see a table of contents, a table of pages, or both, as well as the body file. If you specify FRAME=, you must also specify CONTENTS= or PAGE= or both.

- **PAGE='page-file-name'**
  - identifies the file that contains a description of each page of the body file and links to the body file. ODS produces a new page of output whenever a procedure explicitly asks for a new page. The SAS system option PAGESIZE= has no effect on pages in HTML output.
  
  The **STYLE=** option enables you to choose HTML presentation styles.

ODS LISTING;
- opens the Listing destination.

  **Note:** The Listing destination is open by default.

ODS LISTING CLOSE;
- closes the Listing destination so that no Listing output is created.

ODS OUTPUT output-object(s)=SAS-data-set;
- opens the Output destination and converts one or more output objects to a SAS data set.

ODS PRINTER PS file-specification;
- opens the Printer destination and specifies the file to write to. The PS (PostScript) option ensures that you create a generic PostScript file. If this option is missing, ODS produces output for your current printer.

ODS RTF file-specification;
- opens the RTF destination and specifies the file to write to. After the destination is open, you can create RTF output.

ODS HTML CLOSE;
ODS OUTPUT CLOSE;
ODS PRINTER CLOSE;
ODS RTF CLOSE;
- closes the specific destination and enables you to view the output.

ODS _ALL_ CLOSE;
- closes all open destinations.

ODS SELECT <ODS-destination> output-object(s);
- specifies one or more output objects to add to a selection list.

ODS TRACE ON | OFF;
turns the writing of the trace record on or off. Turning trace on is useful because the results list the output objects that your program creates.

Procedures

PROC MEANS DATA=SAS-data-set <FW=>;
CLASS variable(s);
VAR variable(s);
provides data summarization tools to compute descriptive statistics for variables across all observations and within groups of observations. The DATA= option specifies the input SAS data set, and FW= specifies the field width for statistics.
The CLASS statement specifies the variables whose values define the subgroup combinations for the analysis.
The VAR statement identifies the analysis variables and determines their order in the output.

PROC TEMPLATE;
DEFINE table-definition;
COLUMN header(s);
HEADER column(s);
END;
creates an ODS table definition. The DEFINE statement uses the COLUMN and HEADER statements to create column and table headings.

PROC UNIVARIATE DATA=SAS-data-set;
VAR variable(s);
CLASS variable(s);
BY variable(s);
provides data summarization tools and information about the distribution of numeric variables. The DATA= option specifies the input SAS data set.
The VAR statement identifies the analysis variables and determines their order in the output.
The CLASS statement specifies up to two variables whose values define the classification levels for the analysis.
The BY statement calculates separate statistics for each BY group.

Introduction to Understanding SAS Data Libraries

**Purpose**

The way in which SAS handles data libraries is different from one operating environment to another. In this section, you will learn basic concepts about the SAS data library and how to use libraries in SAS programs. For more detailed information, see the SAS documentation for your operating environment.

**Prerequisites**

Before proceeding with this section, you should understand the concepts presented in the following sections:

- Chapter 1, “What Is the SAS System?,” on page 3
- Chapter 2, “Introduction to DATA Step Processing,” on page 19
What Is a SAS Data Library?

A SAS data library is a collection of one or more SAS files that are recognized by SAS and can be referenced and stored as a unit. Each file is a member of the library. SAS data libraries help to organize your work. For example, if a SAS program uses more than one SAS file, then you can keep all the files in the same library. Organizing files in libraries makes it easier to locate the files and reference them in a program.

Under most operating environments, a SAS data library roughly corresponds to the level of organization that the operating environment uses to organize files. For example, in directory-based operating environments, a SAS data library is a group of SAS files in the same directory. The directory might contain other files, but only the SAS files are part of the SAS data library.

Operating Environment Information: Under the CMS operating environment, a SAS data library is a group of SAS files with the same filetype. Under the z/OS operating environment, a SAS data library is a specially formatted z/OS data set. This kind of data set can contain only SAS files.

Accessing a SAS Data Library

Telling SAS Where the SAS Data Library Is Located

No matter which operating environment you are using, to access a SAS data library, you must tell SAS where it is. To do so, you can do one of the following:

- directly specify the operating environment’s physical name for the location of the SAS data library. The physical name must conform to the naming conventions of your operating environment, and it must be in single quotation marks. For example, in the SAS windowing environment, the following DATA statement creates a data set named MYFILE:

  ```
  data 'c:\my documents\sasfiles\myfile';
  ```

- assign a SAS libref (library reference), which is a SAS name that is temporarily associated with the physical location name of the SAS data library.

Assigning a Libref

After you assign a libref to the location of a SAS data library, then in your SAS program you can reference files in the library by using the libref instead of using the long physical name that the operating environment uses. The libref is a SAS name that is temporarily associated with the physical location of the SAS data library. There are several ways to assign a libref:

- use the LIBNAME statement
- use the LIBNAME function
- use the New Library window from the SAS Explorer window
- for some operating environments, use operating environment commands

A common method for assigning a libref is to use the LIBNAME statement to associate a name with a SAS data library. Here is the simplest form of the LIBNAME statement:
LIBNAME libref 'SAS-data-library';

where

libref is a shortcut name to associate with the SAS data library. This name must conform to the rules for SAS names. A libref cannot exceed eight characters.

Operating Environment Information: Under the z/OS operating environment, the libref must also conform to the rules for operating environment names.

Think of the libref as an abbreviation for the operating environment's name for the library. Because the libref endures only for the duration of the SAS session, you do not have to use the same libref for a particular SAS data library each time you use SAS.

Operating Environment Information: Under the CMS operating environment, the libref typically specifies the filetype of all files in the library. In this case, you must always use the same libref for a SAS data library because the filetype does not change.

SAS-data-library is the physical name for the SAS data library. The physical name is the name that is recognized by your operating environment. Enclose the physical name in single or double quotation marks.

Operating Environment Information: Here are examples of the LIBNAME statement for different operating environments. For more examples, see the SAS documentation for your operating environment.

Windows libname mydata 'c:\my documents\sasfiles';

UNIX libname mydata '/u/myid/sasfiles';

z/OS libname mydata 'edc.company.sasfiles';

When you assign a libref with the LIBNAME statement, SAS writes a note to the SAS log confirming the assignment. This note also includes the operating environment's physical name for the SAS data library.

Using Librefs for Temporary and Permanent Libraries

When a libref is assigned to a SAS data library, you can use the libref throughout the SAS session to access the SAS files that are stored in that library or to create new files.

When you start a SAS session, SAS automatically assigns the libref WORK to a special SAS data library. Normally, the files in the WORK library are temporary files; that is, usually SAS initializes the WORK library when you begin a SAS session, and deletes all files in the WORK library when you end the session. Therefore, the WORK library is a useful place to store SAS files that you do not need to save for a subsequent SAS session. The automatic deletion of the WORK library files at the end of the session prevents you from wasting disk space.

Files that are stored in any SAS data library other than the WORK library are usually permanent files; that is, they endure from one SAS session to the next. Store SAS files in a permanent library if you plan to use them in multiple SAS sessions.
What Is a SAS File?

You store all SAS files in a SAS data library. A SAS file is a specially structured file that is created, organized, and maintained by SAS. The files reside in SAS data libraries as members with specific types. Examples of SAS files are as follows:

- SAS data sets (which can be SAS data files or SAS data views)
- SAS catalogs
- SAS/ACCESS descriptor files
- stored compiled DATA step programs

Note: A file that contains SAS statements, even one that is created during a SAS session, is usually not considered a SAS file. For example, in directory-based operating environments, a .sas file is a text file that typically contains a program and is not considered a SAS file.

Understanding SAS Data Sets

A SAS data set is a SAS file that is stored in a SAS data library that consists of descriptor information. Descriptor information identifies the attributes of a SAS data set and its contents, and data values that are organized as a table of observations (rows) and variables (columns). A SAS data set can be either a SAS data file or a SAS data view.

If the descriptor information and the observations are in the same physical location, then the data set is a SAS data file, which has a member type DATA. A SAS data file can have an index associated with it. One purpose of an index is to optimize the performance of WHERE processing. Basically, an index contains values in ascending order for a specific variable or variables. The index also includes information about the location of those values within observations in the SAS data file.

If the descriptor and the observations are stored separately, then they form a SAS data view, which has a member type VIEW. The observations in a SAS data view might be stored in a SAS data file, an external database, or an external file. The descriptor contains information about where the data is located and which observations and variables to process. You use a view like a SAS data file. You might use a view when you need only a subset of a large amount of data. In addition to saving storage space, views simplify maintenance because they automatically reflect any changes to the data.

There are three types of SAS data views:

- DATA step views
- SAS/ACCESS views
- PROC SQL views

Note: SAS data views usually behave like SAS data files. Other topics in this documentation do not distinguish between the two types of SAS data sets.

Understanding Other SAS Files

In addition to SAS data sets, a SAS data library can contain the following types of SAS files:
SAS catalog is a SAS file that stores many kinds of information, in separate units called catalog entries. Each entry is distinguished by an entry name and an entry type. Some catalog entries contain system information such as key definitions. Other catalog entries contain application information about window definitions, help windows, formats, informats, macros, or graphics output. A SAS catalog has a member type CATALOG.

SAS/ACCESS descriptor is a SAS file that contains information about the layout of an external database. SAS uses this information in order to build a SAS data view in which the observations are stored in an external database. An access descriptor has a member type ACCESS.

stored compiled DATA step program is a SAS file that contains a DATA step, which has been compiled and stored in a SAS data library. A stored compiled DATA step program has a member type PROGRAM.

Complete discussion of all SAS files, except SAS data sets, is beyond the scope of this section. For more information about SAS files, see SAS Language Reference: Concepts.

Referencing SAS Data Sets in a SAS Data Library

Understanding Data Set Names

Every SAS data set has a two-level name of the form libref:filename. You can always reference a file with its two-level name. However, you can also use a one-level name (just filename) to reference a file. By default, a one-level name references a file that uses the libref WORK for the temporary SAS data library.

Note: This section separates the issues of permanent versus temporary files and one-level versus two-level names. Other topics in this documentation and most SAS documentation assume typical use of the WORK libref and refer to files that are referenced with a one-level name as temporary and to files that are referenced with a two-level name as permanent. 

Operating Environment Information: The documentation that is provided by the vendor for your operating environment provides information about how to create temporary and permanent files. From the point of view of SAS, files in the WORK library are temporary unless you specify the NOWORKINIT and NOWORKTERM options and the files in all other SAS data libraries are permanent. However, your operating environment’s point of view might be different. For example, the operating environment might enable you to create a temporary directory or a z/OS data set, that is, one that is deleted when you log off. Because all files in a SAS data library are deleted if the underlying operating environment structure is deleted, the way the operating environment views the SAS data library determines whether the library endures from one session to the next.

Using a One-Level Name

Typically, when you reference a SAS data set with a one-level name, SAS by default uses the libref WORK for the temporary library. For example, the following program creates a temporary SAS data set named WORK.GRADES:
However, if you want to use a one-level name to reference a permanent SAS data set, you can assign the reserved libref USER. When USER is assigned and you reference a SAS data set with a one-level name, SAS by default uses the libref USER for a permanent SAS data library. For example, the following program creates a permanent SAS data set named USER.GRADES. Note that you assign the libref USER as you do any other libref.

```sas
libname user 'SAS-data-library';

data grades;
  infile 'file-specification';
  input Name $ 1-14 Gender $ 15-20 Section $ 22-24 Grade;
run;
```

Therefore, when you reference a SAS data set with a one-level name, SAS

1 looks for the libref USER. If it is assigned to a SAS data library, then USER becomes the default libref for one-level names.

2 uses WORK as the default libref for one-level names if the libref USER has not been assigned.

If USER is assigned, then you must use a two-level name (for example, WORK.TEST) to access a temporary data set in the WORK library. For example, if USER is assigned, then to print the data set WORK.GRADES requires a two-level name in the PROC PRINT statement:

```sas
proc print data=work.grades;
run;
```

If USER is assigned, then you need to make only one change in order to use the same program with files of the same name in different SAS data libraries. Instead of specifying two-level names, simply assign USER differently in each case. For example, the following program concatenates five SAS data sets in SAS-data-library-1 and puts them in a new SAS data set, WEEK, in the same library:

```sas
libname user 'SAS-data-library-1';

data week;
  set mon tues wed thurs fri;
run;
```

By changing just the name of the library in the LIBNAME statement, you can combine files with the same names in another library, SAS-data-library-2:

```sas
libname user 'SAS-data-library-2';

data week;
  set mon tues wed thurs fri;
run;
```

**Note:** At your site, the libref USER might be assigned for you when you start a SAS session. Your SAS Support Consultant will know whether the libref is assigned. △
Using a Two-Level Name

You can always reference a SAS data set with a two-level name, whether the libref you use is WORK, USER, or some other libref that you have assigned. Usually, any two-level name with a libref other than WORK references a permanent SAS data set.

In the following program, the LIBNAME statement establishes a connection between the SAS name INTRCHEM and SAS-data-library, which is the physical name for the location of an existing z/OS data set or a directory, for example. The DATA step creates the SAS data set GRADES in the SAS data library INTRCHEM. SAS uses the INPUT statement to construct the data set from the raw data in file-specification.

```
libname intrchem 'SAS-data-library';

data intrchem.grades;
  infile 'file-specification';
  input Name $ 1-14 Gender $ 15-20 Section $ 22-24 Grade;
run;
```

When the SAS data set INTRCHEM.GRADES is created, you can read from it by using its two-level name. The following program reads the file INTRCHEM.GRADES and creates a new SAS data set named INTRCHEM.FRIDAY, which is a subset of the original data set:

```
data intrchem.friday;
  set intrchem.grades;
  if Section='Fri';
run;
```

The following program displays the SAS data set INTRCHEM.FRIDAY:

```
proc print data=intrchem.friday;
run;
```

| LIBNAME statement |
For more information about the LIBNAME statement, including options for the statement and information about specifying an engine other than the default engine, see “Statements” in *SAS Language Reference: Dictionary.*

Operating environment
For operating environment specifics, see the SAS documentation for your operating environment.

SAS files
For detailed information about PROC SQL views, see the *Base SAS Procedures Guide.*

SAS tools
To learn about the tools that are available for managing SAS data libraries, including the DATASETS procedure, see Chapter 34, “Managing SAS Data Libraries,” on page 603.

USER libref
For information about the USER= system option, which you can use instead of the LIBNAME statement to assign the USER libref, see “SAS System Options” in *SAS Language Reference: Dictionary.* Note that if you assign the libref both ways or if you assign it more than once with either method, then the last definition holds.

WORK library
For more information about the WORKINIT and NOWORKINIT and the WORKTERM and NOWORKTERM system options, which control when SAS initializes the WORK library, see “SAS System Options” in *SAS Language Reference: Dictionary.*

*Operating Environment Information:* These options are implemented slightly differently on the VMS operating environment. For details, see the SAS *Companion for the OpenVMS Operating Environment.*
CHAPTER 34

Managing SAS Data Libraries

Introduction

Purpose

In this section, you will learn about the tools that are available for managing SAS data libraries, including the DATASETS procedure. Subsequent sections describe how to use the DATASETS procedure.

Prerequisites

Before using this section, you should understand the concepts presented in Chapter 33, “Understanding SAS Data Libraries,” on page 595.

Choosing Your Tools

As you accumulate more SAS files, you will need to manage the SAS data libraries. Managing libraries generally involves using SAS procedures or operating environment commands to perform routine tasks such as

- getting information about the contents of libraries and individual SAS files
- renaming, deleting, and moving files
- renaming variables
- copying libraries and files.

You can use operating environment commands to manage SAS files, but for the most part, their use is restricted to the library level. To delete or copy individual SAS files, such as a SAS data set, it is necessary to use SAS utility procedures.
Operating Environment Information: For SAS files that are stored on directory-based computers or in the CMS operating environment and that do not have auxiliary files (such as a SAS data set without an index or audit trail file), you can use operating environment utilities at both the library and file level. If a SAS data set has either an index file or an audit trail file, then you must use SAS utility procedures to delete the file.

One advantage of SAS utility procedures is that you can use them in any operating environment at any level. If you learn SAS procedures, then you can handle any file management task for your SAS data libraries without knowing the corresponding operating environment commands.

There are several SAS tools that are available for basic file management. You can use these features alone or in combination.

- **SAS Explorer** includes windows that enable you to perform most file management tasks without submitting SAS program statements. For example, you can create new libraries and SAS files, open existing SAS files, and perform most file management tasks such as moving, copying, and deleting files. To use SAS Explorer windows, type `libname`, `catalog`, or `dir` in the command bar, or select the Explorer icon from the Toolbar menu.

- **CATALOG procedure** provides catalog management utilities with the `COPY` and `CONTENTS` statements.

- **COPY procedure** copies all members of a library or individual files within the library.

- **CONTENTS procedure** lists the contents of libraries and provides general information about characteristics of library members.

- **DATASETS procedure** combines all library management functions into one procedure. If you do not use SAS Explorer or if SAS executes in a batch or interactive line mode, then using this procedure can save you time and resources.

Understanding the DATASETS Procedure

The DATASETS procedure is an interactive procedure; that is, the procedure remains active after a RUN statement is executed. After you start the procedure, you can continue to manipulate files within a SAS data library until you have finished all the tasks that you have planned. This capability can save time and resources when you have a number of tasks for one session.

Here are some important features to know about the DATASETS procedure:

- You can specify the input library in the PROC DATASETS statement.
  
  When you start the DATASETS procedure, you can also specify the input library, which is referred to as the procedure input library. If you do not specify a library as the source of files, then SAS uses the default library, which could be the temporary library WORK or the USER library. To specify a different input library, you must start the procedure again.

- Statements execute in the order in which they are written.
  
  For example, to see the contents of a SAS data set, to copy a data set from another library, and then to see the contents of the second data set so that you can visually compare with the first data set, the SAS statements that perform those tasks must be specified in that order so that they execute correctly.

- Groups of statements can execute without a RUN statement.
For the DATASETS procedure *only*, SAS recognizes these statements as implied RUN statements and therefore executes them immediately when you submit them:

- APPEND statement
- CONTENTS statement
- MODIFY statement
- COPY statement
- PROC DATASETS statement.

SAS reads the statements that are associated with one task until it reaches one of the above statements. SAS executes all of the preceding statements immediately and then continues reading until it reaches another of the above statements. To cause the last task to execute, you must submit a RUN or QUIT statement.

*Note:* If you are running in interactive line mode, then this feature enables you to receive messages that statements have already executed before you submit a RUN statement.

- The RUN statement does not stop a PROC DATASETS step. You must submit a QUIT statement, a new PROC statement, or a DATA step. Submitting a QUIT statement executes any statements that have not executed and ends the procedure.

**Looking at a PROC DATASETS Session**

The following example illustrates how PROC DATASETS behaves in a typical session. In the example, a file from one SAS data library is used to create a test file in another SAS data library. A data set is copied and its contents are described so that the output can be visually checked in order to be sure that the variables are compatible with an existing file in the test library.

The following program is arranged in groups to show which statements are executed as one task. The tasks and the action by SAS are numbered in the order in which they occur in the program.

```sas
proc datasets library=test89; ①
    copy in=realdata out=test89; ②
    select income88;

    contents data=income88; ③
    run;

    modify income88; ④
    rename Sales=Sales88;

quit; ⑤
```

The following list corresponds to the numbered items in the preceding program:

- **①** Starts the DATASETS procedure and specifies the procedure input library TEST89.
- **②** Copies the data set INCOME88 from the SAS data library REALDATA. SAS recognizes these statements as one task. When SAS reads the CONTENTS statement, it immediately copies INCOME88 into the library TEST89. The CONTENTS statement acts as an implied RUN statement, which causes the
COPY statement to execute. This action is more noticeable if you are running SAS in the windowing environment.

Describes the contents of the data set. Visually checking the output can verify that the variables are compatible with an existing SAS data set. When SAS receives the RUN statement, it describes the contents of INCOME88. Because the previous task has executed, it finds the data set in the procedure input library TEST89.

After visually checking the contents, you determine that it is necessary to rename the variable Sales. Because the DATASETS procedure is still active, you can submit more statements.

Renames the variable Sales to Sales88.

Stops the DATASETS procedure. SAS executes the last two statements and ends the DATASETS procedure.

---

**Review of SAS Tools**

**Procedures**

PROC DATASETS <LIBRARY=libref>;
starts the procedure and specifies the library that the procedure processes, that is, the procedure input library. If you do not specify the LIBRARY= option, then the default is the WORK or USER library. PROC DATASETS automatically sends a directory listing to the SAS log when it is submitted.

**Statements**

QUIT;
executes any preceding statements that have not run and stops the procedure.

RUN;
executes the preceding group of statements that have not run without ending the procedure.

---

**Learning More**

DATASETS procedure
To learn about using the DATASETS procedure to manage SAS data libraries whose members are primarily data sets, see

- Chapter 35, “Getting Information about Your SAS Data Sets,” on page 607
- Chapter 36, “Modifying SAS Data Set Names and Variable Attributes,” on page 617
- Chapter 37, “Copying, Moving, and Deleting SAS Data Sets,” on page 629.

SAS windowing environment
For information about managing SAS files through the SAS windowing environment, see Chapter 39, “Using the SAS Windowing Environment,” on page 655.

Operating environment commands
For information about managing SAS files using operating environment commands, see the SAS documentation for your operating environment.
Introduction to Getting Information about Your SAS Data Sets

Purpose

As you create libraries of SAS data sets, SAS generates and maintains information about where the library is stored in your operating environment, how and when the data sets were created, and how their contents are defined. Using the DATASETS procedure, you can view this information without displaying the contents of the data set or referring to additional documentation.

In this section, you will learn how to get the following information about SAS data libraries and SAS data sets:

- names and types of SAS files that are included in a SAS data library
- names and attributes for variables in SAS data sets
- summary information about storage parameters for the operating environment
- summary information about the history and structure of SAS data sets
Prerequisites

Before using this section, you should understand the concepts presented in the following sections:

- Chapter 33, “Understanding SAS Data Libraries,” on page 595
- Chapter 34, “Managing SAS Data Libraries,” on page 603

Input Data Library for Examples

The examples in this section use a SAS data library that contains information about the climate of the United States. The DATA steps that create the data sets are shown in “Data Sets for the Storing and Managing Data in SAS Files Section” on page 720.

Requesting a Directory Listing for a SAS Data Library

Understanding a Directory Listing

A directory listing is a list of files in a SAS data library. Each file is called a member, and each member has a member type that is assigned to it by SAS. The member type indicates the type of SAS file, such as DATA or CATALOG. When SAS processes statements, SAS not only looks for the specified file, it verifies that the file has a member type that can be processed by the statement.

The directory listing contains two parts:

- heading
- list of library member names and their member types

Listing All Files in a Library

To obtain a directory listing of all members in a library, you need only the PROC DATASETS statement and the LIBRARY= option. For example, the following statements send a directory listing to the SAS log for a library that contains climate information. The LIBNAME statement assigns the libref USCLIM to this library.

```sas
options pagesize=60 linesize=80 nonumber nodate;
libname usclim 'SAS-data-library';
proc datasets library=usclim;
```
The following output shows the resulting SAS log, which contains the directory listing:

**Output 35.1 Directory Listing for the Library USCLIM**

```
22 options pagesize=60 linesize=80 nonumber nodate;
23 libname usclim 'SAS-data-library';
NOTE: Libref USCLIM was successfully assigned as follows:
   Engine: V8
   Physical Name: external-file
24 proc datasets library=usclim;
-----Directory-----
    Libref: USCLIM
    Engine: V8
    Physical Name: external-file
    File Name: external-file
    Inode Number: 1864992
    Access Permission: rwxr-xr-x
    Owner Name: userid
    File Size (bytes): 4096

<table>
<thead>
<tr>
<th>#</th>
<th>Name</th>
<th>Memtype</th>
<th>Size</th>
<th>Last Modified</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>BASETEMP</td>
<td>CATALOG</td>
<td>20480</td>
<td>15NOV2000:14:38:35</td>
</tr>
<tr>
<td>2</td>
<td>HIGHTEMP</td>
<td>DATA</td>
<td>16384</td>
<td>15NOV2000:14:26:48</td>

<tr>
<td>6</td>
<td>TEMPCHNG</td>
<td>DATA</td>
<td>16384</td>
<td>15NOV2000:14:30:41</td>
</tr>
</tbody>
</table>
```

The following list corresponds to the numbered items in the preceding output:

1. **Heading**
   - gives the physical name as well as the libref for the library. Note that some operating environments provide additional and different information. For example, not all operating environments have an inode number.

2. **Name**
   - contains the second-level SAS member name that is assigned to the file. If the files are different member types, then you can have two files of the same name in one library.

3. **Memtype**
   - indicates the SAS file member type. The most common member types are DATA and CATALOG. For example, the library USCLIM contains two catalogs of type CATALOG and four data sets of type DATA.

---

## Listing Files That Have the Same Member Type

To show only certain types of SAS files in the directory listing, use the MEMTYPE= option in the PROC DATASETS statement. The following statement produces a listing for USCLIM that contains only the information about data sets:

```
proc datasets library=usclim memtype=data;
```
The following output shows the SAS log, which lists only the data sets that are stored in USCLIM:

**Output 35.2 Directory Listing of Data Sets Only for the Library USCLIM**

<table>
<thead>
<tr>
<th>#</th>
<th>Name</th>
<th>Memtype</th>
<th>Size</th>
<th>Last Modified</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>HIGHTEMP</td>
<td>DATA</td>
<td>16384</td>
<td>15NOV2000:14:26:48</td>
</tr>
<tr>
<td>2</td>
<td>HURRICANE</td>
<td>DATA</td>
<td>16384</td>
<td>15NOV2000:14:29:11</td>
</tr>
<tr>
<td>3</td>
<td>LOWTEMP</td>
<td>DATA</td>
<td>16384</td>
<td>15NOV2000:14:30:08</td>
</tr>
<tr>
<td>4</td>
<td>TEMPCHNG</td>
<td>DATA</td>
<td>16384</td>
<td>15NOV2000:14:30:41</td>
</tr>
</tbody>
</table>

**Note:** Examples in this documentation focus on using PROC DATASETS to manage only SAS data sets; you can also list other member types by specifying MEMTYPE=. For example, MEMTYPE=CATALOG lists only SAS catalogs.

---

**Requesting Contents Information about SAS Data Sets**

**Using the DATASETS Procedure for SAS Data Sets**

To look at the contents of a SAS data set without displaying the observations, use the CONTENTS statement in the DATASETS procedure. The CONTENTS statement and its options provide descriptive information about data sets and a list of variables and their attributes.

**Listing the Contents of One Data Set**

The SAS data library USCLIM contains four data sets, with the data set TEMPCHNG containing data for extreme changes in temperature. The following program displays the variables in the data set TEMPCHNG:

```sas
proc datasets library=usclim memtype=data;
    contents data=tempchng;
run;
```
The CONTENTS statement produces a contents listing, and the DATA= option specifies the name of the data set. The following output shows the results from the CONTENTS statement, which are sent to SAS output rather than to the SAS log. Note that output from the CONTENTS statement varies for different operating environments.

**Output 35.3  Contents Listing for the Data Set TEMPCHNG**

```
The SAS System

The DATASETS Procedure

```

The following list describes information that you might find in contents listing and corresponds to the numbered items in the preceding output:

1. **Heading** contains field names. Fields are empty if they do not apply to the data set. Field names are listed below:
   - **Data Set Name** is the two-level name that is assigned to the data set.
   - **Member Type** is the type of library member.
   - **Engine** is the access method that SAS uses to read from or write to the data set.
   - **Created** is the date that the data set was created.
Listing the Contents of One Data Set

Chapter 35

Last Modified is the last date that the data set was modified.

Protection indicates whether the data set is password protected for READ, WRITE, or ALTER operations.

Data Set Type applies only to files with the member type DATA. Information in this field indicates that the data set contains special observations and variables for use with SAS statistical procedures.

Label is the descriptive information that you supply in a LABEL= data set option to identify the data set.

Observations is the total number of observations currently in the data set.

Variables is the number of variables in the data set.

Indexes is the number of indexes for the data set.

Observation Length is the length of each observation in bytes.

Deleted Observations is the number of observations marked for deletion, if applicable.

Compressed indicates whether the data is in fixed-length or variable-length records. If the data set is compressed, then additional fields indicate whether new observations are added to the end of the data set or written to unused space within the data set and whether the data set can be randomly accessed by observation number rather than sequential access only.

Sorted indicates whether the data set has been sorted.

Engine/Host Dependent Information lists information about the engine, which is the mechanism for reading from and writing to files, and about how the data set is stored by the operating environment. Depending on the engine, the output in this section might differ. For more information, see the SAS documentation for your operating environment.

Alphabetical List of Variables and Attributes lists all the variable names in the data set in alphabetical order and describes the attributes that are assigned to the variable when it is defined. The attributes are described below:

# is the logical position of the variable in the observation. This is the number that is assigned to the variable when it is defined.

Variable is the name of the variable.

Type indicates whether the variable is character or numeric.

Len is the length of the variable in bytes.

Pos is the physical position in the observation buffer of the first byte of the variable’s associated value.

Format is the format of the variable.
Informat is the informat of the variable.

In addition, if applicable, the output also displays a table that describes the following information:

- indexes for indexed variable(s)
- any defined integrity constraints
- sort information

### Listing the Contents of All Data Sets in a Library

You can list the contents of all the data sets in a library by specifying the keyword _ALL_ with the DATA= option. The following statements produce a directory listing in SAS output for the library and a contents listing for each data set in the directory:

```sas
contents data=_all_; run;
```

To send only a directory listing to SAS output, add the NODS option. The following statements produce a directory listing but suppress a contents listing for individual data sets. Use this form if you want the directory listing for the procedure input library:

```sas
contents data=_all_ nods; run;
```

Include the libref if you want the directory listing for another library. This example specifies the library STORM:

```sas
contents data=storm._all_ nods; run;
```

### Requesting Contents Information in Different Formats

For a variation of the contents listing, use the VARNUM option or the SHORT option in the CONTENTS statement. For example, the following statements produce a list of variable names in the order in which they were defined, which is their logical position in the data set:

```sas
contents data=tempchng varnum; run;
```

The CONTENTS statement specifies the data set TEMPCHNG and includes the VARNUM option to list variables in order of their logical position. (By default, the CONTENTS statement lists variables alphabetically.)
The following output shows the contents in variable number order:

**Output 35.4** Listing Contents of the Data Set TEMPCHNG in Variable Number Order

```
The SAS System

The DATASETS Procedure

Data Set Name: USCLIM.TEMPCHNG Observations: 5

</table>
```

If you do not need all of the information in the contents listing, then you can request an abbreviated version by using the SHORT option in the CONTENTS statement. The following statements request an abbreviated version and then end the DATASETS procedure by issuing the QUIT statement:

```
contents data=tempchng short;
run;
quit;
```
The following output lists the variable names for the TEMPCHNG data set:

Output 35.5  Listing Variable Names Only for the Data Set TEMPCHNG

Review of SAS Tools

Procedures

PROC DATASETS <LIBRARY=libref <MEMTYPE=mtype(s)>>;

The MEMTYPE= option restricts processing to a certain type or types of SAS files and restricts the library directory listing to SAS files of the specified member types.

DATASETS Procedure Statements

CONTENTS <DATA=libref>SAS-data-set> <NODS> <SHORT> <VARNUM> ;

describes the contents of a specific SAS data set in the library. The default data set is the most recently created data set for the job or session. For the CONTENTS statement in PROC DATASETS, when you specify DATA=, the default libref is the procedure input library. However, for the CONTENTS procedure, the default libref is either WORK or USER.

Use the NODS option with the keyword _ALL_ in the DATA= option to produce only the directory listing of the library in SAS output. That is, the NODS option suppresses the contents of individual files. You cannot use the NODS option when you specify only one SAS data set in the DATA= option.

The SHORT option produces only an alphabetical list of variable names, index information, integrity constraint information, and sort information for the SAS data set.

The VARNUM option produces a list of variable names in the order in which they were defined, which is their logical position in the data set. By default, the CONTENTS statement lists variables alphabetically.
Learning More

CATALOG procedure
You can use the CATALOG procedure to obtain contents information about catalogs. For more information, see the *Base SAS Procedures Guide*.

DATASETS procedure
For more information about the DATASETS procedure and the CONTENTS statement as well as the CONTENTS procedure, see the *Base SAS Procedures Guide*.

Windowing environment
For information about using the windowing environment in order to obtain information about SAS data sets, see Chapter 39, “Using the SAS Windowing Environment,” on page 655.
Introduction to Modifying SAS Data Set Names and Variable Attributes

Purpose

SAS enables you to modify data set names and variable attributes without creating new data sets. In this section, you will learn how to use statements in the DATASETS procedure to do the following:

- rename data sets
- rename variables
- modify variable formats
- modify variable labels

This section focuses on using the DATASETS procedure to modify data sets. However, you can also use some of the illustrated statements and options to modify other types of SAS files.

Note: You cannot use the DATASETS procedure to change the values of observations, to create or delete variables, or to change the type or length of variables. These modifications are done with DATA step statements and functions.

Prerequisites

Before using this section, you should understand the concepts presented in the following sections:
Input Data Library for Examples

The examples in this section use a SAS data library that contains information about the climate of the United States. The DATA steps that create the data sets in the SAS data library are shown in “Data Sets for the Storing and Managing Data in SAS Files Section” on page 720.

Renaming SAS Data Sets

Renaming data sets is often required for effective library management. For example, you might rename a data set when you archive it or when you add new data values. Use the CHANGE statement in the DATASETS procedure to rename one or more data sets in the same library. Here is the syntax for the CHANGE statement:

```
CHANGE old-name=new-name;
```

where

- `old-name` is the current name of the SAS data set.
- `new-name` is the name that you want to give the data set.

This example renames two data sets in the SAS data library USCLIM, which contains information about the climate of the United States. The following program starts the DATASETS procedure, then changes the name of the data set HIGHTEMP to USHIGH and the name of the data set LOWTEMP to USLOW:

```
options pagesize=60 linesize=80 nonumber nodate;
libname usclim 'SAS-data-library';

proc datasets library=usclim;
   change hightemp=ushigh lowtemp=uslow;
run;
```

As it processes these statements, SAS sends messages to the SAS log, as shown in the following output. The messages verify that the data sets are renamed.
Modifying Variable Attributes

Understanding How to Modify Variable Attributes

Each variable in a SAS data set has attributes such as name, type, length, format, informat, label, and so on. These attributes enable you to identify a variable as well as define to SAS how the variable can be used.

By using the DATASETS procedure, you can assign, change, or remove certain attributes with the MODIFY statement and subordinate statements. For example, using MODIFY and subordinate statements enables you to

- rename variables
- assign, change, or remove a format, which changes the way the values are printed or displayed
- assign, change, or remove labels.

Note: You cannot use the MODIFY statement to modify fixed attributes such as the type or length of a variable.
Renaming Variables

You might need to rename variables, for example, before combining data sets that have one or more matching variable names. The DATASETS procedure enables you to rename one or more variables by using the MODIFY statement and its subordinate RENAME statement. Here is the syntax for the statements:

```
MODIFY SAS-data-set;
RENAME old-name=new-name;
```

where

- `SAS-data-set` is the name of the SAS data set that contains the variable that you want to rename.
- `old-name` is the current name of the variable.
- `new-name` is the name that you want to give the variable.

This example renames two variables in the data set HURRICANE, which is in the SAS data library USCLIM. The following statements change the variable name State to Place and the variable name Deaths to USDeaths. The DATASETS procedure is already active, so the PROC DATASETS statement is not necessary.

```
modify hurricane;
rename State=Place Deaths=USDeaths;
run;
```

The SAS log messages verify that the variables are renamed to Place and USDeaths as shown in the following output. All other attributes that are assigned to these variables remain unchanged.

Output 36.2  Renaming Variables in the Data Set HURRICANE

```
38  modify hurricane;
39   rename State=Place Deaths=USDeaths;
    NOTE: Renaming variable State to Place.
    NOTE: Renaming variable Deaths to USDeaths.
40   run;
```

Assigning, Changing, or Removing Formats

SAS enables you to assign and store formats, which are used by many SAS procedures for output. Assigning, changing, or removing a format changes the way the values are printed or displayed. By using the DATASETS procedure, you can change a variable's format with the MODIFY statement and its subordinate FORMAT statement. You can change a variable's format either to a SAS format or to a format that you have defined and stored, or you can remove a format. Here is the syntax for these statements:

```
MODIFY SAS-data-set;
FORMAT variable(s) <format>;
```

where

- `SAS-data-set` is the name of the SAS data set that contains the variable whose format you want to modify.
variable(s) is the name of one or more variables whose format you want to assign, change, or remove.

format is the format that you want to give the variable(s). If you do not specify a format, then SAS removes any format that is associated with the specified variable(s).

When you assign or change a format, follow these rules:

- List the variable name before the format.
- List multiple variable names or use an abbreviated variable list if you want to assign the format to more than one variable.
- Do not use punctuation to separate items in the list.

The following FORMAT statement illustrates ways to include many variables and formats in the same FORMAT statement:

```
format Date1-Date5 date9. Cost1 Cost2 dollar4.2 Place $char25.;
```

The variables Date1 through Date5 are written in abbreviated list form, and the format DATE9. is assigned to all five variables. The variables Cost1 and Cost2 are listed individually before their format. The format $CHAR25. is assigned to the variable Place.

There are two rules when you are removing formats from variables:

- List the variable names only.
- Place the variable names last in the list if you are using the same FORMAT statement to assign or change formats.

For example, by using the SAS data set HURRICANE, the following statements change the format for the variable Date from a full spelling of the month, date, and year to an abbreviation of the month and year, remove the format for the variable Millions, and display the contents of the data set HURRICANE before and after the changes. Note that because the FORMAT statement does not send messages to the SAS log, you must use the CONTENTS statement if you want to make sure that the changes were made.

```
contents data=hurricane;
modify hurricane;
   format Date monyy7. Millions;
contents data=hurricane;
run;
```

The following output from the two CONTENTS statements displays the contents of the data set before and after the changes. The format for the variable Date is changed from WORDDATE18. to MONYY7., and the format for the variable Millions is removed.
Output 36.3  Modifying Variable Formats in the Data Set HURRICANE

Assigning, Changing, or Removing Labels

A label is the descriptive information that identifies variables in tables, plots, and graphs. You usually assign labels when you create a variable. If you do not assign a label, then SAS uses the variable name as the label. However, in CONTENTS output, if a label is not assigned, then the field is blank. By using the MODIFY statement and its subordinate LABEL statement, you can assign, change, or remove a label. Here is the syntax for these statements:

**MODIFY SAS-data-set;**

**LABEL** variable='label';

where

*SAS-data-set* is the name of the SAS data set that contains the variable whose label you want to modify.

*variable* is the name of the variable whose label you want to assign, change, or remove.

*label* is the label, which can be from 1 to 256 characters, that you want to give the variable. If you do not specify a label and one exists, then SAS removes the current label.
When you use the LABEL statement, follow these rules:

- Enclose the text of the label in single or double quotation marks. If a single quotation mark appears in the label (for example, an apostrophe), then enclose the text with double quotation marks.
- Limit the label to no more than 256 characters, including blanks.
- To remove a label, use a blank as the text of the label, that is, `variable=' '`.

For example, by using the SAS data set HURRICANE, the following statements change the label for the variable Millions and assign a label for the variable Place. Because the LABEL statement does not send messages to the SAS log, the CONTENTS statement is specified to verify that the changes were made. The QUIT statement stops the DATASETS procedure.

```sas
contents data=hurricane;
modify hurricane;
   label Millions='Damage in Millions' Place='State Hardest Hit';
contents data=hurricane;
run;
quit;
```

The following output from the two CONTENTS statements displays the contents of the data set before and after the changes:
Output 36.4  Modifying Variable Labels in the Data Set HURRICANE

**Review of SAS Tools**

**DATASETS Procedure Statements**

CHANGE old-name=new-name;
renames the SAS data set that you specify with old-name to the name that you specify with new-name. You can rename more than one data set in the same library by using one CHANGE statement. All new names must be valid SAS names.

MODIFY SAS-data-set;
identifies the SAS data set that you want to modify. These are some of the subordinate statements that you can use with the MODIFY statement:

FORMAT variable(s) <format>;
assigns, changes, or removes the format for the variable(s) that you specify with variable(s) by using the format that you specify with format. You can
give more than one variable the same format by listing more than one variable before the format. Do not specify `format` if you want to remove a format.

```sas
LABEL variable='label';
```

assigns, changes, or removes the label for the variable that you specify with `variable`. To remove a label, place a blank space inside the quotation marks.

```sas
RENAME old-name=new-name;
```

changes the name of the variable(s) that you specify with `old-name` to the name that you specify with `new-name`. You can rename more than one variable in the same data set by using one RENAME statement. All names must be valid SAS names.

---

**Learning More**

**Informats and formats**

For more information about informats and formats available for reading and displaying data, see *SAS Language Reference: Dictionary*.

**LABEL statement**

For information about the LABEL statement that is used in the DATA step, see *SAS Language Reference: Dictionary*.

**MODIFY statement**

The MODIFY statement in the DATASETS procedure has additional statements that change informats and that create and delete indexes for variables. See the *Base SAS Procedures Guide*.

**Renaming variables**

You can use the RENAME= data set option and the RENAME statement in the DATA step to rename variables. See *SAS Language Reference: Dictionary*.

**Variables**

To learn how to create and delete variables in the DATA step, see Chapter 5, “Starting with SAS Data Sets,” on page 81.
Introduction to Copying, Moving, and Deleting SAS Data Sets

Purpose

Copying, moving, and deleting SAS data sets are the library management tasks that you will perform most frequently. For example, you perform these tasks to create test files, make backups, archive files, and remove unused files. The DATASETS procedure enables you to work with all the files in a SAS data library or with specific files in the library.

In this section, you will learn how to use the DATASETS procedure to do the following:

- copy an entire library
- copy specific SAS data sets
- move specific SAS data sets
- delete specific SAS data sets
- delete all files in a library
This section focuses on using the DATASETS procedure to copy, move, and delete data sets. You can also use the illustrated statements and options to copy, move, and delete other types of SAS files.

**Prerequisites**

Before using this section, you should understand the concepts presented in the following sections:

- Chapter 33, “Understanding SAS Data Libraries,” on page 595
- Chapter 34, “Managing SAS Data Libraries,” on page 603
- Chapter 36, “Modifying SAS Data Set Names and Variable Attributes,” on page 617

**Input Data Libraries for Examples**

The examples in this section use five SAS data libraries that contain sample data sets that are used to collect and store weather statistics for the United States and other countries. The libraries have the librefs PRECIP, USCLIM, CLIMATE, WEATHER, and STORM. The following LIBNAME statements assign the librefs:

```
libname precip 'SAS-data-library-1';
libname usclim 'SAS-data-library-2';
libname climate 'SAS-data-library-3';
libname weather 'SAS-data-library-4';
libname storm 'SAS-data-library-5';
```

*Note:* For each LIBNAME statement, `SAS-data-library` is a different physical name for the location of the SAS data library. In order to copy all or some SAS data sets from one library to another, the input and output libraries must be in different physical locations.

The DATA steps that create the data sets in the SAS data libraries CLIMATE, PRECIP, and STORM are shown in the Appendix. The DATA steps that create the data sets in the SAS data library USCLIM are shown in Appendix.

**Copying SAS Data Sets**

**Copying from the Procedure Input Library**

You can use the COPY statement in the DATASETS procedure to copy all or some SAS data sets from one library to another. When copying data sets, SAS duplicates the contents of each file, including the descriptor information, and updates information in the directory for each library.

*CAUTION:* During processing, SAS automatically writes the data from the input library into an output data set of the same name. If there are duplicate data set names, then you do not receive a warning message before copying starts. Before you make changes to libraries, it is important to obtain directory listings of the input and output libraries in order to visually check for duplicate data set names.
To copy files from the procedure input library (specified in the PROC DATASETS statement), use the COPY statement. Here is the syntax of the COPY statement:

\[ \text{COPY OUT=libref <options>;} \]

where

\text{libref} \quad \text{is the libref for the SAS data library to which you want to copy the files. You must specify an output library.}

For example, the library PRECIP contains data sets for snowfall and rainfall amounts, and the library CLIMATE contains data sets for temperature. The following program lists the contents so that they can be visually compared before any action is taken:

\begin{verbatim}
options pagesize=60 linesize=80 nonumber nodate;

proc datasets library=precip;
   contents data=_all_ nods;
   contents data=climate._all_ nods;
run;
\end{verbatim}

The PROC DATASETS statement starts the procedure and specifies the procedure input library PRECIP. The first CONTENTS statement produces a directory listing of the library PRECIP. Then, the second CONTENTS statement produces a directory listing of the library CLIMATE.

The following SAS output shows the two directory listings:

\begin{verbatim}
Output 37.1  Checking Directories of PRECIP and CLIMATE before Copying

The SAS System
The DATASETS Procedure
-----Directory-----
Libref: PRECIP
Engine: V8
Physical Name: external-file
File Name: external-file
Inode Number: 1864994
Access Permission: rwxr-xr-x
Owner Name: userid
File Size (bytes): 4096

     # Name Memtype Size Last Modified
-------------------------------
     1 RAIN DATA 16384 15NOV2000:14:32:09
     2 SNOW DATA 16384 15NOV2000:14:32:35
\end{verbatim}
There are no duplicate names in the directories, so the COPY statement can be issued to achieve the desired results.

```sas
COPY OUT=climate;
run;
```

The following SAS log shows the messages as the data sets in the library PRECIP are copied to the library CLIMATE. There are now two copies of the data sets RAIN and SNOW: one in the PRECIP library and one in the CLIMATE library.

Output 37.2  Messages Sent to the SAS Log during Copying

```
35 copy out=climate;
36 run;
NOTE: Copying PRECIP.RAIN to CLIMATE.RAIN (memtype=DATA).
NOTE: There were 5 observations read from the data set PRECIP.RAIN.
NOTE: The data set CLIMATE.RAIN has 5 observations and 4 variables.
NOTE: Copying PRECIP.SNOW to CLIMATE.SNOW (memtype=DATA).
NOTE: There were 3 observations read from the data set PRECIP.SNOW.
NOTE: The data set CLIMATE.SNOW has 3 observations and 4 variables.
```

### Copying from Other Libraries

You can copy from a library other than the procedure input library without using another PROC DATASETS statement. To do so, use the IN= option in the COPY statement to override the procedure input library. Here is the syntax for the option:

```
COPY OUT=libref-1 IN=libref-2;
```

where

- `libref-1` is the libref for the SAS data library to which you want to copy files.
- `libref-2` is the libref for the SAS data library from which you want to copy files.
The IN= option is a useful tool when you want to copy more than one library into the output library. You can use one COPY statement for each input library without repeating the PROC DATASETS statement.

For example, the following statements copy the libraries PRECIP, STORM, CLIMATE, and USCLIM to the library WEATHER. The procedure input library is PRECIP, which was specified in the previous PROC DATASETS statement.

```sas
   copy out=weather;
   copy in=storm out=weather;
   copy in=climate out=weather;
   copy in=usclim out=weather;
run;
```

The following SAS log shows that the data sets from these libraries have been consolidated in the library WEATHER:

Output 37.3  Copying Four Libraries into the Library WEATHER

```
54   copy out=weather;
    NOTE: Copying PRECIP.RAIN to WEATHER.RAIN (memtype=DATA).
    NOTE: There were 5 observations read from the data set PRECIP.RAIN.
    NOTE: The data set WEATHER.RAIN has 5 observations and 4 variables.
    NOTE: Copying PRECIP.SNOW to WEATHER.SNOW (memtype=DATA).
    NOTE: There were 3 observations read from the data set PRECIP.SNOW.
    NOTE: The data set WEATHER.SNOW has 3 observations and 4 variables.
55   copy in=storm out=weather;
    NOTE: Copying STORM.TORNADO to WEATHER.TORNADO (memtype=DATA).
    NOTE: There were 5 observations read from the data set STORM.TORNADO.
    NOTE: The data set WEATHER.TORNADO has 5 observations and 4 variables.
    NOTE: Copying CLIMATE.HIGHTEMP to WEATHER.HIGHTEMP (memtype=DATA).
    NOTE: There were 5 observations read from the data set CLIMATE.HIGHTEMP.
    NOTE: The data set WEATHER.HIGHTEMP has 5 observations and 4 variables.
    NOTE: Copying CLIMATE.LOWTEMP to WEATHER.LOWTEMP (memtype=DATA).
    NOTE: There were 5 observations read from the data set CLIMATE.LOWTEMP.
    NOTE: The data set WEATHER.LOWTEMP has 5 observations and 4 variables.
    NOTE: Copying CLIMATE.RAIN to WEATHER.RAIN (memtype=DATA).
    NOTE: There were 5 observations read from the data set CLIMATE.RAIN.
    NOTE: The data set WEATHER.RAIN has 5 observations and 4 variables.
    NOTE: Copying CLIMATE.SNOW to WEATHER.SNOW (memtype=DATA).
    NOTE: There were 3 observations read from the data set CLIMATE.SNOW.
    NOTE: The data set WEATHER.SNOW has 3 observations and 4 variables.
57   copy in=usclim out=weather;
58   run;
    NOTE: Copying USCLIM.BASETEMP to WEATHER.BASETEMP (memtype=CATALOG).
    NOTE: Copying USCLIM.HURRICANE to WEATHER.HURRICANE (memtype=DATA).
    NOTE: There were 5 observations read from the data set USCLIM.HURRICANE.
    NOTE: The data set WEATHER.HURRICANE has 5 observations and 5 variables.
    NOTE: Copying USCLIM.REPORT to WEATHER.REPORT (memtype=CATALOG).
    NOTE: Copying USCLIM.TEMPCHNG to WEATHER.TEMPCHNG (memtype=DATA).
    NOTE: There were 5 observations read from the data set USCLIM.TEMPCHNG.
    NOTE: The data set WEATHER.TEMPCHNG has 5 observations and 6 variables.
    NOTE: Copying USCLIM.USHIGH to WEATHER.USHIGH (memtype=DATA).
    NOTE: There were 6 observations read from the data set USCLIM.USHIGH.
    NOTE: The data set WEATHER.USHIGH has 6 observations and 5 variables.
    NOTE: Copying USCLIM.USLOW to WEATHER.USLOW (memtype=DATA).
    NOTE: There were 7 observations read from the data set USCLIM.USLOW.
    NOTE: The data set WEATHER.USLOW has 7 observations and 5 variables.
```
Copying Specific SAS Data Sets

Selecting Data Sets to Copy

To copy only a few data sets from a large SAS data library, use the SELECT statement with the COPY statement. After the keyword SELECT, list the data set name(s) with a blank space between the names, or use an abbreviated member list (such as YRDATA1-YRDATA5) if applicable.

For example, the following statements copy the data set HURRICANE from the library USCLIM to the library STORM. The input procedure library is PRECIP, so the COPY statement includes the IN= option in order to specify the USCLIM input library.

```sas
    copy in=usclim out=storm;
    select hurricane;
    run;
```

The following SAS log shows that only the data set HURRICANE was copied to the library STORM:

```
Output 37.4  Copying the Data Set HURRICANE to the Library STORM

    76        copy in=usclim out=storm;
    77             select hurricane;
    78        run;
    NOTE: Copying USCLIM.HURRICANE to STORM.HURRICANE (memtype=DATA).
    NOTE: There were 5 observations read from the data set USCLIM.HURRICANE.
    NOTE: The data set STORM.HURRICANE has 5 observations and 5 variables.
```

Excluding Data Sets from Copying

To copy an entire library except for a few data sets, use the EXCLUDE statement with the COPY statement. After the keyword EXCLUDE, simply list the data set name(s) that you want to exclude with a blank space between the names, or use an abbreviated member list (such as YRDATA1-YRDATA5) if applicable.

The following statements copy the files in the library PRECIP to USCLIM except for the data set SNOW. The procedure input library is PRECIP, so the IN= option is not needed.

```sas
    copy out=usclim;
    exclude snow;
    run;
```

The following SAS log shows that the data set RAIN was copied to USCLIM and that the data set SNOW remains only in the library PRECIP:
Moving SAS Data Libraries and SAS Data Sets

Moving Libraries

The COPY statement provides the MOVE option to move SAS data sets from the input library (either the procedure input library or the input library named with the IN= option) to the output library (named with the OUT= option). Note that with the MOVE option, SAS first copies the files to the output library, then deletes them from the input library.

The following statements move all the data sets in the library PRECIP to the library CLIMATE:

```sas
   copy out=climate move;
   run;
```

The following SAS log shows that the data sets in PRECIP were moved to CLIMATE:

Output 37.6 Moving Data Sets in the Library PRECIP to the Library CLIMATE

```sas
116   copy out=climate move;
117   run;
NOTE: Moving PRECIP.RAIN to CLIMATE.RAIN (memtype=DATA).
NOTE: There were 5 observations read from the data set PRECIP.RAIN.
NOTE: The data set CLIMATE.RAIN has 5 observations and 4 variables.
NOTE: Moving PRECIP.SNOW to CLIMATE.SNOW (memtype=DATA).
NOTE: There were 3 observations read from the data set PRECIP.SNOW.
NOTE: The data set CLIMATE.SNOW has 3 observations and 4 variables.
```

After moving files with the MOVE option, a directory listing of PRECIP from the CONTENTS statement confirms that there are no members in the library. As the output from the following statements illustrates, the library PRECIP no longer contains any data sets; therefore, the library CLIMATE contains the only copy of the data sets RAIN and SNOW.

```sas
   contents data=_all_ nods;
   run;
```

The following outputs show the SAS log, then the directory listing for the library PRECIP:
Moving Specific Data Sets

Output 37.7  SAS Log from the CONTENTS Statement

```sas
135 contents data=_all_ nods;
136 run;
WARNING: No matching members in directory.
```

Output 37.8  Directory Listing of the Library PRECIP Showing No Data Sets

```
The SAS System
The DATASETS Procedure
-----Directory-----
 Libref:  PRECIP
 Engine:  V8
 Physical Name:  external-file
 File Name:  external-file
 Inode Number:  1864994
 Access Permission:  rwxr-xr-x
 Owner Name:  userid
 File Size (bytes):  4096
```

Note:  The data sets are deleted from the SAS data library PRECIP, but the libref is still assigned. The name that is assigned to the library in your operating environment is not removed when you move all files from one library to another. ▲

Moving Specific Data Sets

You can use the SELECT and EXCLUDE statements to move one or more SAS data sets. For example, the following statements move the data set HURRICANE from the library USCLIM to the library STORM:

```
copy in=usclim out=storm move;
  select hurricane;
run;
```

Output 37.9  Moving the Data Set HURRICANE from the Library USCLIM to the Library STORM

```
173 copy in=usclim out=storm move;
174   select hurricane;
175 run;
NOTE: Moving USCLIM.HURRICANE to STORM.HURRICANE (memtype=DATA).
NOTE: There were 5 observations read from the data set USCLIM.HURRICANE.
NOTE: The data set STORM.HURRICANE has 5 observations and 5 variables.
```

Similarly, the following code uses the EXCLUDE statement to move all files except the data set SNOW from the library CLIMATE to the library USCLIM:

```
copy in=climate out=usclim move;
  exclude snow;
run;
```
### Deleting SAS Data Sets

#### Specifying Data Sets to Delete

Use the DELETE statement to delete one or more data sets from a SAS data library. If you want to delete more than one data set, then simply list the names after the DELETE keyword with a blank space between the names, or use an abbreviated member list if applicable (such as YRDATA1-YRDATA5).

**CAUTION:**

SAS immediately deletes the files in a SAS data library when the program statements are submitted. You are not asked to verify the delete operation before it begins, so be sure that you intend to delete the files before submitting the program.

For example, the following program specifies USCLIM as the procedure input library, then deletes the data set RAIN from the library:

```sas
proc datasets library=usclim;
   delete rain;
run;
```

The following output shows that SAS sends messages to the SAS log when it processes the DELETE statement:

Output 37.10  Moving All Data Sets Except SNOW from the Library CLIMATE to the Library USCLIM

```sas
193    copy in=climate out=usclim move;
194        exclude snow;
195    run;
NOTE: Moving CLIMATE.HIGHTEMP to USCLIM.HIGHTEMP (memtype=DATA).
NOTE: There were 5 observations read from the data set CLIMATE.HIGHTEMP.
NOTE: The data set USCLIM.HIGHTEMP has 5 observations and 4 variables.
NOTE: Moving CLIMATE.LOWTEMP to USCLIM.LOWTEMP (memtype=DATA).
NOTE: There were 5 observations read from the data set CLIMATE.LOWTEMP.
NOTE: The data set USCLIM.LOWTEMP has 5 observations and 4 variables.
NOTE: Moving CLIMATE.RAIN to USCLIM.RAIN (memtype=DATA).
NOTE: There were 5 observations read from the data set CLIMATE.RAIN.
```
Specifying Data Sets to Save

To delete all data sets but a few, you can use the SAVE statement to list the names of the data sets that you want to keep. List the data set names with a blank space between the names, or use an abbreviated member list (such as YRDATA1-YRDATA5) if applicable.

The following statements delete all the data sets except TEMPCHNG from the library USCLIM:

```
save tempchng;
run;
```

The following output shows the SAS log from the delete operation. SAS sends messages to the SAS log, verifying that it has kept the data sets that you specified in the SAVE statement and deleted all other members of the library.

Output 37.12  Deleting All Members of the Library USCLIM Except the Data Set TEMPCHNG

```
232  save tempchng;
233  run;
NOTE: Saving USCLIM.TEMPCHNG (memtype=DATA).
NOTE: Deleting USCLIM.BASETEMP (memtype=CATALOG).
NOTE: Deleting USCLIM.HIGHTEMP (memtype=DATA).
NOTE: Deleting USCLIM.LOWTEMP (memtype=DATA).
NOTE: Deleting USCLIM.REPORT (memtype=CATALOG).
NOTE: Deleting USCLIM.USHIGH (memtype=DATA).
NOTE: Deleting USCLIM.USLOW (memtype=DATA).
```
Deleting All Files in a SAS Data Library

To delete all files in a SAS data library at one time, use the KILL option in the PROC DATASETS statement.

**CAUTION:**

The KILL option deletes all members of the library immediately after the statement is submitted. You are not asked to verify the delete operation, so be sure that you intend to delete the files before submitting the program.

For example, the following program deletes all data sets in the library WEATHER and stops the DATASETS procedure:

```sas
proc datasets library=weather kill;
run;
quit;
```

The following output shows the SAS log:

```
Output 37.13 Deleting All Members of the Library WEATHER

250 proc datasets library=weather kill;
    -----Directory-----
    Libref: WEATHER
    Engine: V8
    Physical Name: external-file
    File Name: external-file
    Inode Number: 1864996
    Access Permission: rwxr-xr-x
    Owner Name: userid
    File Size (bytes): 4096

    #   Name     Memtype   Size    Last Modified
    ----------------------------------------------
   1  BASETEMP  CATALOG  20480  16NOV2000:11:15:14

    NOTE: Deleting WEATHER.HIGHTEMP (memtype=DATA).
    NOTE: Deleting WEATHER.HURRICANE (memtype=DATA).
    NOTE: Deleting WEATHER.LOWTEMP (memtype=DATA).
    NOTE: Deleting WEATHER.RAIN (memtype=DATA).
    NOTE: Deleting WEATHER.REPORT (memtype=CATALOG).
    NOTE: Deleting WEATHER.SNOW (memtype=DATA).
    NOTE: Deleting WEATHER.TEMPCHNG (memtype=DATA).
    NOTE: Deleting WEATHER.TORNADO (memtype=DATA).
    NOTE: Deleting WEATHER.USHIGH (memtype=DATA).
    NOTE: Deleting WEATHER.USLOW (memtype=DATA).
251 run;
252 quit;
```
Review of SAS Tools

Procedures

PROC DATASETS LIBRARY=libref <KILL>;
starts the procedure and specifies the procedure input library for subsequent statements. The KILL option deletes all members and member types from the library.

DATASETS Procedure Statements

COPY OUT=libref <IN=libref> <MOVE>;
copies files from the procedure input library that is specified in the PROC DATASETS statement to the output library that is specified in the OUT= option. The IN= option specifies a different input library. The MOVE option deletes files from the input library after copying them to the output library.
You can use the following statements with the COPY statement:

EXCLUDE SAS-data-set;
specifies a SAS data set that you want to exclude from the copy process. Files that you do not list in this statement are copied to the output library.

SELECT SAS-data-set;
specifies a SAS data set that you want to copy to the output library.

DELETE SAS-data-set;
deletes only the SAS data set that you specify in this statement.

SAVE SAS-data-set;
deletes all members of the library except those that you specify in this statement.

Learning More

CATALOG procedure
You can use the CATALOG procedure to copy, move, and delete entries in SAS catalogs. See the Base SAS Procedures Guide.

DATASETS procedure
For more information about the DATASETS procedure, which you use to copy, move, and delete other member types, see the Base SAS Procedures Guide.

Note: All data sets and catalogs are deleted from the SAS data library, but the libref is still assigned for the session. The name that is assigned to the library in your operating environment is not removed when you delete the files that are included in the library.

Introduction to the SAS Environment

Purpose

In this section you will learn about the various ways that you can run SAS programs. More importantly, it explains the different modes that SAS can run in, and which modes are best, depending on the types of jobs you are doing.

This section introduces the SAS windowing environment, which is the default processing mode.

Even though SAS has a different appearance for each operating environment, most of the actions that are available from the menus are the same.

One of the biggest differences between operating environments is the way that you select menu items. If your workstation is not equipped with a mouse, then here are the keyboard equivalents to mouse actions:

<table>
<thead>
<tr>
<th>Mouse Action</th>
<th>Keyboard Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-click</td>
<td>type an s or an x in the space next to the item, then press the ENTER or RETURN key.</td>
</tr>
<tr>
<td>right-click</td>
<td>instead of right-clicking an item, type ? in the space next to the item, then press the ENTER or RETURN key.</td>
</tr>
</tbody>
</table>

Examples in this documentation show SAS windows as they appear in the Microsoft Windows environment. For the most part, corresponding windows in other operating environments show similar results. If you do not see the drop-down menus in your operating environment, then enter the global command PMENU at a command prompt.

Prerequisites

To understand the discussions in this section, you should be familiar with the basics of DATA step programming that are presented in Chapter 6, “Understanding DATA Step Processing,” on page 97.

Operating Environment Differences

Even though SAS has a different appearance for each operating environment, most of the actions that are available from the menus are the same.
One of the biggest differences between operating environments is the way that you select menu items. If your workstation is not equipped with a mouse, then here are the keyboard equivalents to mouse actions:

<table>
<thead>
<tr>
<th>Mouse Action</th>
<th>Keyboard Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-click the item</td>
<td>type an s or an x in the space next to the item, then press the ENTER or RETURN key</td>
</tr>
<tr>
<td>right-click the item</td>
<td>type ? in the space next to the item, then press the ENTER or RETURN key</td>
</tr>
</tbody>
</table>

Examples in this documentation show SAS windows as they appear in the Microsoft Windows environment. For the most part, corresponding windows in other operating environments show similar results. If you do not see the drop-down menus in your operating environment, then enter the global command PMENU at a command prompt.

**Starting a SAS Session**

To start a SAS session, you must invoke SAS. At the operating environment prompt, execute the SAS command. In most cases, the SAS command is

```
sas
```

*Note:* The SAS command may vary from site to site. Consult your SAS Software Representative if you need more information.

You can customize your SAS session when it starts by specifying SAS system options, which then remain in effect throughout a session. For example, you can use the LINESIZE= system option to specify a line size for the SAS log and print file. Some system options can be specified only at initialization, and other system options can be specified during a SAS session. For details, see “Customizing SAS Sessions and Programs at Startup” on page 697.

**Selecting a SAS Processing Mode**

**Processing Modes and Categories**

All four modes that you can use to run SAS belong to one of two categories:

- foreground processing
- background processing

The following figure shows the four different modes and the processing types they belong to. As your processing requirements change, you might find it helpful to change from one processing mode to another.
Understanding Foreground Processing

Foreground processing includes all the ways that you can run SAS in except batch mode. Foreground processing begins immediately, but as your program runs, your current workstation session is occupied, so you can not use it to do anything else.* With foreground processing, you can route your output to the workstation display, to a file, to a printer, or to tape.

If you can answer yes to one or more of the following questions, then you might want to consider foreground processing:

- Are you learning SAS programming?
- Are you testing a program to see if it works?
- Do you need fast turnaround?
- Are you processing a fairly small data file?
- Are you using an interactive application?

Understanding Background Processing

Batch processing is the only way to run SAS in the background. Your operating environment coordinates all the work, so you can use your workstation session to do other work at the same time that your program runs. However, because the operating environment also schedules your program for execution and assigns it a priority, the program may have to wait in the input queue (the operating environment’s list of jobs to be run) before it is executed. When your program runs to completion, you can browse, delete, or print your output.

Background processing may be required at your site. In addition, consider the following questions:

- Are you an experienced SAS user, likely to make fewer errors than a novice?
- Are you running a program that has already been tested and refined?
- Is fast turnaround less important than minimizing the use of computer resources?
- Are you processing a large data file?
- Will your program run for a long time?
- Are you using a tape?

If you answer yes to one or more of these questions, then you might want to choose background processing.

* In a workstation environment, you can switch to another window and continue working.
Introducing the SAS Environment

Processing in the SAS Windowing Environment

Overview of Processing in the SAS Windowing Environment

The SAS windowing environment is a graphical user interface (GUI) that consists of a series of windows with which you can organize files and folders, edit and execute programs, view program output, and view messages about your programs and your SAS session.

Because it is an interactive and graphical facility, you can use a single session to prepare and submit a program and, if necessary, to modify and resubmit the program after browsing the output and messages. You can move from window to window and even interrupt and return to a session at the same point you left it.

General Characteristics

The SAS windowing environment is the default environment for a SAS session (unless your environment is customized at your site).

Note: Because it is the default environment, many topics in this documentation describe tasks as you would perform them in the SAS windowing environment.

The five most commonly used windows in the SAS windowing environment are Explorer, Results, Editor, Log, and Output.

**Explorer**

is a hierarchical system of folders, subfolders, and individual items. It provides a primary graphical interface to SAS from which you can do the following:

- access and work with data, such as catalogs, tables, libraries, and operating environment files
- open SAS programming windows
- access the Output Delivery System (ODS)
- create and define customized folders

You can use Explorer to view or set libraries and file shortcuts, view or set library members and catalog entries, or open and edit SAS files.

Note that when you start the SAS windowing environment, the Explorer might appear as a single-paned window that lists libraries that are currently available. You can add a navigational tree to the Explorer window by selecting **View ▶ Show Tree** or by issuing the TREE command.

**Editor or Program Editor**

provides an area to enter, edit, and submit SAS statements and to save SAS source files.

**Log**

enables you to browse and scroll the SAS log. The SAS log provides messages about what is happening in your SAS session.

**Output**

enables you to browse and scroll procedure output.

**Results**

enables you to browse and manipulate an index of your procedure output.
Display 38.1  SAS Windowing Environment: SAS Explorer, Log and Editor Windows, (Windows Operating System)

**Note:** Together, the Program Editor, Log, and Output windows are sometimes referred to as the *programming windows*.

Additional windows are also available in the SAS windowing environment that enable you to do the following:

- access online help
- view and change some SAS system options
- view and change function key settings
- create and store text information

For more information about these windows and about performing tasks in the windowing environment, see Chapter 39, “Using the SAS Windowing Environment,” on page 655.

**Invoking the SAS Windowing Environment**

To invoke the SAS windowing environment, execute the SAS command followed by any system options that you want to put into effect. The SAS windowing environment is set as the default method of operation for SAS, but it may not be the default setting at your work site.

If the SAS windowing environment is not the default method of operation, you can specify the DMSEXP option in the SAS command. Or, you can include the DMSEXP option in the configuration file, which contains settings for system options. For more information about the configuration file, see “Customizing SAS Sessions and Programs at Startup” on page 697.

You specify options in the SAS command as you do any other command options on your system. The following table shows how you would start the SAS windowing environment and specify the DMSEXP option under various operating environments:
<table>
<thead>
<tr>
<th>Operating Environment</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS</td>
<td>sas options (dmsexp)</td>
</tr>
<tr>
<td>Windows</td>
<td>sas -dmsexp</td>
</tr>
<tr>
<td>UNIX</td>
<td>sas -dmsexp</td>
</tr>
<tr>
<td>OpenVMS</td>
<td>sas /dmsexp</td>
</tr>
<tr>
<td>CMS</td>
<td>sas (dmsexp)</td>
</tr>
</tbody>
</table>

For details about how to specify command options on other systems, see the SAS documentation for your operating environment.

**Ending a SAS Windowing Environment Session**

You can end your SAS windowing environment session with the BYE or ENDSAS command. Specify BYE or ENDSAS on the SAS command line, and then execute the command by pressing ENTER or RETURN (depending on which operating environment you use).

You can also end your session with the ENDSAS statement in the Program Editor window. Type the following statement on a data line and submit it for execution:

```plaintext
endsas;
```

**Interrupting a SAS Windowing Environment Session**

You might occasionally find it necessary to return to your operating environment from a SAS session. If you do not want to end your SAS session, then you can escape to the operating environment by issuing the X command. Simply execute the following command on the command line:

```plaintext
x
```

From your operating environment, you can then return to the same SAS session as you left it, by executing the appropriate operating environment command. For example, under the z/OS operating environment, the operating environment command is RETURN or END; under the OpenVMS operating environment, the command is LOGOFF.

Use this form of the X command to execute a single operating environment command:

```plaintext
X operating-environment-command
```

or, if the command contains embedded blanks,

```plaintext
X 'operating-environment-command'
```

For example, on many systems you can display the current time by specifying

```plaintext
x time
```

After the command executes, you can take the appropriate action to return to your SAS session.

For information about interrupting a SAS session in other operating environments, see the SAS documentation for your operating environment.
Processing Interactively in Line Mode

General Characteristics

With line mode processing, you enter programming statements one line at a time; DATA and PROC steps are executed after you enter a RUN statement, or after another step boundary. Program messages and output appear on the monitor.

You can modify program statements only when you first enter them, before you press ENTER or RETURN, which means that you must type your entries carefully.

Invoking SAS in Line Mode

To invoke SAS in line mode, execute the SAS command followed by any system options that you want to put into effect. The NODMS system option activates an interactive line mode session. If NODMS is not the default system option at your site, you can either specify the option with the SAS command or include the NODMS specification in the configuration file, the file that contains settings for system options that are put into effect at invocation. The following table shows you how to specify the NODMS system option with the SAS command under various operating environments.

<table>
<thead>
<tr>
<th>Operating environment</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS</td>
<td>sas options ('nodms')</td>
</tr>
<tr>
<td>UNIX</td>
<td>sas -nodms</td>
</tr>
<tr>
<td>OpenVMS</td>
<td>sas /nodms</td>
</tr>
<tr>
<td>CMS</td>
<td>sas (nodms)</td>
</tr>
</tbody>
</table>

Using the Run Statement to Execute a Program in Line Mode

In line mode, DATA steps are executed only when a new step boundary is encountered. This occurs after you enter a RUN DATA or PROC statement. In other words, if you submit DATA X; X=1; in the windowing environment, then you will not see execution until the next RUN DATA or PROC statement is submitted.

At the beginning of each line, SAS prompts you with a number and a question mark to enter more statements. If you use a DATALINES statement, then a greater-than symbol (>) replaces the question mark, indicating that data lines are expected.

When you are using line mode, the log will be easier to read if you follow this programming tip: cause each DATA or PROC step to execute before you begin entering programming statements for the next step. Either an END statement or a semicolon that marks the end of datalines causes a step to execute immediately.

Ending a Line Mode SAS Session

To end your session, type endsas; at the SAS prompt, then press ENTER or RETURN. Your session ends, and you are returned to your operating environment.
Interrupting a Line Mode SAS Session

In line mode, you can escape to the operating environment by executing the following statement:

```
x;
```

You can return to your SAS session by executing the appropriate operating environment command. Use this form of the X statement to execute a single operating environment command:

```
X operating-environment-command;
```

or, if the command contains embedded blanks,

```
X 'operating-environment-command';
```

For example, on many systems you can display the current time by specifying

```
x time;
```

When you use this form of the X command, the command executes, and you are returned to your SAS session.

Processing in Batch Mode

The first step in executing a program in batch mode is to prepare files that include:

- any control language statements that are required by the operating environment that you are using to manage the program
- the SAS statements necessary to execute the program

Then you submit your file to the operating environment, and your workstation session is free for other work while the operating environment executes the program. This is called background processing because you cannot view or change the program in any way until after it executes. The log and output are routed to the destination that you specify in the operating environment control language; without a specification, they are routed to the default. For examples of batch processing, see the SAS documentation for your operating environment.

Processing Noninteractively

General Characteristics

Noninteractive processing has some characteristics of interactive processing and some of batch processing. When you process noninteractively, you execute SAS program statements that are stored in an external file. You use a SAS command to submit the program statements to your operating environment.

Note: The SAS command is implemented differently under each operating environment. For example, under z/OS the command is typically a CLIST, and under CMS it is an EXEC.

As in interactive processing, processing begins immediately, and your current workstation session is occupied. However, as with batch processing, you cannot interact with your program.

Note: For some exceptions to this, see the SAS documentation for your operating environment.
You can see the log or procedure output immediately after the program has run. Log and listing output are routed to the workstation, unlike the SAS windowing environment, where you must explicitly save output to a file. If you decide that you must correct or modify your program, then you must use an editor to make necessary changes and then resubmit your program.

**Executing a Program in Noninteractive Mode**

When you run a program in noninteractive mode, you do not enter a SAS session as you do in interactive mode; instead of starting a SAS session, you are executing a SAS program. The first step is to enter the SAS statements in a file, just as you would for a batch job. Then, at the system prompt, you specify the SAS command followed by the complete name of the file and any system options that you want to specify.

The following example executes the SAS statements in the member TEMP in the partitioned data set `your-userid.UGWRITE.TEXT` in the z/OS operating environment:

```bash
sas input(ugwrite.text(temp))
```

Note that the INPUT operand points to the file that contains the SAS statements for a noninteractive session.

The next example executes the SAS statements that are stored in the subdirectory `[USERID.UGWRITE.TEXT]` on the OpenVMS operating environment in the file TEMP:SAS:

```bash
$sas [userid.ugwrite.text] temp
```

SAS looks for the file on the current disk.

The following example executes the SAS statements in the CMS file TEMP SAS A:

```bash
sas temp
```

*Note:* Note that in CMS, SAS looks for filetype SAS on any accessed disk. CMS executes the first file called temp that it finds on any accessible mini disk. If TEMP SAS lives on disk 'G', then it will still be executed.

For details about how to use noninteractive mode on other operating environments, see the SAS documentation for your operating environment. Consult your SAS Site Representative for information specific to your site.

**Browsing the Log and Output**

Log and output information either appears in your workstation display or it is sent to a file. The default action is dependent on your operating environment. In either case, you can browse the information within your display or by opening the appropriate file. See your operating environment documentation for more information.

---

**Review of SAS Tools**

**Command**

OPTIONS

view the option settings when you use the windowing environment.
Options

PROC OPTIONS options;
    lists the current values of all SAS system options.

System Options

DMS | NODMS
    at invocation, specifies whether the SAS Programming windows are to be active in
    a SAS session.

LINESIZE=n
    specifies the line width for SAS output.

VERBOSE
    at invocation, displays a listing of all options in the configuration file and on the
    command line.

Statements

DATALINES;
    signals to SAS that the data follows immediately.

ENDSAS
    causes a SAS job or session to terminate at the end of the current DATA or PROC
    step.

OPTIONS option;
    changes one or more system options from the default value set at a site.

RUN
    causes the previously entered SAS step to be executed.

X 'operating-environment-command';
    is used to issue an operating environment command from within a SAS session.
    Operating-environment-command specifies the command. Omitting the command
    puts you into the operating environment’s submode.

Commands

BYE
    ends a SAS session.

ENDSAS
    ends a SAS session.

EXPLORER
    invokes the Explorer window.

PMENU
    turns on drop-down menus in windows.

X '<operating-environment-command'>
    executes the operating environment command and then prompts you to take the
    appropriate action to return to SAS. Omitting the command puts you into the
    operating environment’s submode.
Operating environment information

For information about specific customization options and preferences, see the documentation for your operating environment.

Windowing environment commands

For a list of all the commands that you can use in the SAS windowing environment, see SAS online Help.

Help ▶ SAS System HelpSelect

Base SAS software

The help topic is called Command Reference.

Documentation

For more examples of using the SAS windowing environment, see Getting Started with the SAS System.

Introduction to Using the SAS Windowing Environment

Purpose

In this section you will learn about the SAS windowing environment, including how to get organized, how to access help, and how to find and use appropriate commands. In addition, you will learn how to use the SAS windowing environment to work with files, SAS programs, and SAS output.

Prerequisites

Before proceeding with this section, you should understand the concepts presented in Chapter 38, “Introducing the SAS Environment,” on page 643.

Operating Environment Differences

Even though SAS has a different appearance for each operating environment, most of the actions that are available from the menus are the same.

One of the biggest differences between operating environments is the way that you select menu items. If your workstation is not equipped with a mouse, then here are the keyboard equivalents to mouse actions:

<table>
<thead>
<tr>
<th>Mouse action</th>
<th>Keyboard equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-click the item</td>
<td>type an ( s ) or an ( x ) in the space next to the item, then press the ENTER or RETURN key</td>
</tr>
<tr>
<td>right-click the item</td>
<td>type ? in the space next to the item, then press the ENTER or RETURN key</td>
</tr>
</tbody>
</table>

Examples in this documentation show SAS windows as they appear in the Microsoft Windows environment. For the most part, corresponding windows in other operating environments will yield similar results. If you do not see the drop-down menus in your operating environment, then enter the global command PMENU at a command prompt.

Getting Organized

Overview of Data Organization

The SAS windowing environment helps you to organize your data, and to locate and access your files easily. In this section, you learn how to use windows to do the following:

- explore libraries and library members
- assign a library reference
Exploring Libraries and Library Members

The SAS windowing environment opens to the Explorer window by default on many hosts. You can issue the EXPLORER command to invoke this window if it does not appear by default. You can use Explorer to view the libraries that are currently available, as well as to explore their contents.

- To list available libraries, select the Libraries folder, and then select **Open** from the pop-up menu.
- To explore the contents of a library, select a specific library, and then select **Explore from Here** from the pop-up menu.
- To explore the contents of a library member, select a specific library member, and then select **Open** from the pop-up menu.

*Note:* If the Explorer Tree view is on, then you can explore libraries and library members by expanding and collapsing tree nodes. You can expand or collapse Tree nodes by selecting their expansion icons, which look like + and - symbols. You can toggle the Explorer Tree view by selecting **View ➤ Show Tree** from the Explorer window.

Display 39.1  SAS Explorer Window with Tree View On

Assigning a Library Reference

Assign a library reference before continuing your work in a SAS session, so that you can have a permanent storage location for your working SAS files:

1. From the Explorer window, select the **Libraries** folder.
2. Select **File ➤ New**
   - The New Library window appears.
3. Enter a name for the library.
4. Select an engine type.
5. Enter an operating environment directory pathname or browse to select the directory.
6 Fill in any other fields as necessary for the engine, and enter any options that you want to specify.

If you are not sure which engine to choose, then use the Default engine (which is selected automatically).

The Default engine enables SAS to choose which engine to use for any data sets that exist at the given path of your new library. If no data sets exist, then the Base SAS engine is assigned.

7 Select OK. The new library will appear under the Libraries folder in the Explorer window.

Note: If you want SAS to assign the new library automatically at startup, then select the Enable at Startup check box in the New Library window. △

You can use the following ways to assign a library, depending on your operating environment:

Menu File ➤ New
   (from the Explorer window only)
Command DMLIBASSIGN (from any window)
Pop-up New (from the Explorer window only)
Toolbar New Library (from any window)

Managing Library Assignment Problems

If any permanent library assignment that is stored in the SAS Registry fails at startup, then the following note appears in the SAS Log:

NOTE: One or more library startup assignments were not restored.

The following errors are common causes of library assignment problems:

- library dependencies are missing
- required field values for library assignment in the SAS Registry are missing
- required field values for library assignment in the SAS Registry are invalid

For example, library names are limited to eight characters, and engine values must match actual engine names.

- encrypted password data for a library reference has changed in the SAS Registry

CAUTION:

You can correct many library assignment errors in the SAS Registry Editor. If you are unfamiliar with library references or the SAS Registry Editor, ask for assistance. Errors can be made easily in the SAS Registry Editor, and can prevent your libraries from being assigned at startup. △

To correct a library assignment error in the SAS Registry Editor:

1 Select Solutions ➤ Accessories ➤ Registry Editor or issue the REGEDIT command.

2 Select one of the following paths, depending on your operating system, and then make modifications to keys and key values as needed:

   CORE\OPTIONS\LIBNAMES

   or

   CORE\OPTIONS\LIBNAMES\CONCATENATED
For example, if you determine that a key for a permanent concatenated library has been renamed to something other than a positive whole number, then you can rename that key again so that it is in compliance. Select the key, and then select Rename from the pop-up menu to begin the process.

---

**Finding Online Help**

**Accessing SAS Online Help System**

To access the SAS online Help, select Help ➤ SAS System Help.

**Accessing Window Help**

You can access help on an individual window in any of the following ways:

- Issue the HELP command from the command line of the window.
- Select the window’s help button, if one exists.
- Select the Help icon on the toolbar.
- From the window for which you want help, select Help ➤ Using This Window

**Accessing SAS OnlineDoc and SAS OnlineTutor**

SAS OnlineDoc is a CD that provides reference information about SAS. The SAS OnlineDoc has a table of contents, index, and a search engine that enables you to find information quickly. For some operating systems, you can access it by selecting Help ➤ Books and Training ➤ OnlineDoc.

SAS OnlineTutor is an interactive online training application that enables you to learn about the SAS environment, SAS programming, and specific SAS products. SAS OnlineTutor is available on CD and must be licensed. If your site has licensed and installed SAS OnlineTutor, then you can access this product by selecting Help ➤ Books and Training ➤ OnlineTutor.

For more information about configuring the SAS OnlineDoc CD or installing SAS OnlineTutor at your site, contact your SAS Installation Representative.

---

**Using SAS Windowing Environment Command Types**

**Overview of SAS Windowing Environment Command Types**

There are specific types of SAS windowing environment commands. The type of commands that you use might depend on the task that you need to complete, or on your personal preferences. These commands can be in the form of:

- command line commands
- pull-down menu commands
- line commands (in text editing windows)
- keyboard function keys

For information about specific commands that can be issued in the SAS windowing environment, see “Working with SAS Windows” on page 663. For information about specific commands that can be used in the SAS text editor, see “Working with Text” on page 668.

### Using Command Line Commands

Command line commands can be entered in two places:

- on the command line (if it is turned on)
- in the Command window (if it is available)

If the command line is turned on, then you can place your cursor on the command line and type commands. You can toggle the command line on or off for a specific window by selecting **Tools** ▶️ **Options** ▶️ **Turn Command Line On** or **Tools** ▶️ **Options** ▶️ **Turn Command Line Off**.

The Command window (if it is available in your operating environment) includes a text area. You can place your cursor in this area and then issue commands.

To execute a command, type the command on the command line and then press the ENTER or RETURN key, depending on which operating environment you are using. You can specify a simple one-word command, multiple commands separated by semicolons, or a command followed by an option.

For example, if you want to move from the Editor window and open both the Log and the Output windows, on the command line of the Editor window, specify

```
log; output
```

### Display 39.2  Entering Commands on the Command Line

![Display 39.2](image)

Next, press ENTER or RETURN to execute both commands. The Log and Output windows appear. The Output window is the active window because the command to open this window was executed last.

### Using Pull-Down Menus

SAS windowing environment windows can display pull-down menus instead of a command line. You can then make menu selections to do things that you would usually accomplish by typing commands.
If your operating environment does not default to using drop-down menus, then issue the PMENU command at a command line to turn on menus for all windows that support them.

You can point and click menus and menu items with a mouse to make your selections. In some operating environments, you can also make menu selections by moving your cursor over the menu items and then pressing ENTER or RETURN. Depending on the item that you select, one of three things happens:

- a command executes
- a pull-down menu appears
- a dialog box appears

In many cases, double-clicking on items and right-clicking on items will cause different menus to appear. Sometimes you might want to try one or the other when selecting an item does not give you the expected result.

In other operating environments with workstations that are not equipped with a mouse, here are the keyboard equivalents to mouse actions:

<table>
<thead>
<tr>
<th>Mouse action</th>
<th>Keyboard equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-click</td>
<td>type an s or an x in the space next to the item, then press the ENTER or RETURN key.</td>
</tr>
<tr>
<td>right-click</td>
<td>instead of right-clicking an item, type ? in the space next to the item, then press the ENTER or RETURN key.</td>
</tr>
</tbody>
</table>

### Using Line Commands

Line commands are one or more letters that copy, move, delete, and otherwise edit text. You can execute line commands by typing them in the numbered part of a text editing window (such as the Editor or the SAS NOTEPAD).

Although line commands are usually executed in the numbered part of the display or with function keys, they can also be executed from the command line if preceded by a colon.

**Note:** Issue the NUMBERS command to toggle line numbers on or off in text editing windows.

For more information about line commands, see “Working with Text” on page 668.

### Using Function Keys

Your keyboard includes function keys to which default values have already been assigned. You can browse or alter those values in the Keys window. To open the Keys window, select Tools ▶️ Options ▶️ Keys or issue the KEYS command.

To change the setting of a key in the Keys window, type the new value over the old value. The new setting takes effect immediately and is saved permanently when you execute the END command to close the Keys window.

Function keys enable you to tailor your key settings to meet your needs in a particular SAS session. For example, If you might need to submit a number of programs and need to move between the Editor window and the Output window. Then each time you finish viewing your output, you must type the PGM and ZOOM...
commands on the command line and press ENTER or RETURN. As a shortcut, define one of your function keys to perform this action by typing the following commands over an unwanted value or where no value existed before:

```
pgm; zoom
```

Then, each time you press that function key, the commands are executed, saving you time. You can also use function keys to execute line commands. Simply precede the line command with a colon as you would if you were issuing the line command from the command line.

---

**Working with SAS Windows**

---

**Opening Windows**

The SAS windowing environment has numerous windows that you can use to complete tasks. You can enter commands to open windows. For more information about how to execute commands, see “Using SAS Windowing Environment Command Types” on page 660.

You can use the following commands to open a window and make it active.

<table>
<thead>
<tr>
<th>Window command</th>
<th>Window name</th>
</tr>
</thead>
<tbody>
<tr>
<td>AF C=library.catalog.entry.type</td>
<td>Build</td>
</tr>
<tr>
<td>DMFILEASSIGN</td>
<td>File Shortcut Assignment</td>
</tr>
<tr>
<td>DMLIBASSIGN</td>
<td>New Library</td>
</tr>
<tr>
<td>EDOP</td>
<td>Editor Options</td>
</tr>
<tr>
<td>EXPFIND</td>
<td>Find</td>
</tr>
<tr>
<td>EXPLORER</td>
<td>Explorer</td>
</tr>
<tr>
<td>FOOTNOTES</td>
<td>Footnotes</td>
</tr>
<tr>
<td>FSBROWSE</td>
<td>FSBrowse</td>
</tr>
<tr>
<td>FSEDIT</td>
<td>FSEdit</td>
</tr>
<tr>
<td>FSFORM formname</td>
<td>FSForm</td>
</tr>
<tr>
<td>FSVIEW</td>
<td>FSView</td>
</tr>
<tr>
<td>HELP</td>
<td>Help</td>
</tr>
<tr>
<td>KEYS</td>
<td>Keys</td>
</tr>
<tr>
<td>LOG</td>
<td>Log</td>
</tr>
<tr>
<td>NOTEPAD, NOTE</td>
<td>Notepad</td>
</tr>
<tr>
<td>ODSRESULTS</td>
<td>Results</td>
</tr>
<tr>
<td>ODESTEMPATES</td>
<td>Templates</td>
</tr>
<tr>
<td>OPTIONS</td>
<td>Options</td>
</tr>
<tr>
<td>OUTPUT, LISTING, LIST, LST</td>
<td>Output</td>
</tr>
<tr>
<td>PROGRAM, PGM, PROG</td>
<td>Program Editor</td>
</tr>
<tr>
<td>REGEDIT</td>
<td>Registry Editor</td>
</tr>
</tbody>
</table>
You can use window commands at any command prompt. You might find it helpful to use multiple window commands together.

For example, from the Log window, the following string of commands changes the active window, maximizes it, and changes the word *paint* to *print*:

```
pgm; zoom; change paint print
```

The following display shows that the cursor immediately moves to the Editor, which has been maximized to fill the entire display (due to the ZOOM command). The word *paint* has been changed to *print*, and the cursor rests after the last character of that text string.

**Display 39.3 Executing a Window-Call Command in a Series**

Managing Windows

Window management commands enable you to access and use windows more efficiently. The following list includes the commands that you might use most often when managing windows:

- **BYE** ends a SAS session.
- **CLEAR** removes all text from an active window.
END closes a window. In the Editor, this command acts like the SUBMIT command.

NEXT moves the cursor to the next open window and makes it active.

PREVWIND moves the cursor to the previous open window and makes it active.

RECALL returns statements that are submitted from a text editor window (such as the Editor or SAS NOTEPAD) to the text editor.

ZOOM enlarges a window to occupy the entire display. Execute it again to return a window to its previous size. This command is not available in all operating environments.

---

**Scrolling Windows**

Scrolling commands enable you to maneuver within text, and the command names indicate what they do. They include the following:

- **BACKWARD** moves the contents of a window backward.
- **FORWARD** moves the contents of a window forward.
- **LEFT** moves the contents of a window to the left.
- **RIGHT** moves the contents of a window to the right.
- **TOP** moves the cursor to the first character of the first line in a window.
- **BOTTOM** displays the last line of text.
- **HSCROLL, VSCROLL**
  - **HSCROLL** determines the amount that you move to the left or right when using the LEFT or RIGHT commands. **VSCROLL** determines the amount that you move forward or backward when using the FORWARD or BACKWARD commands.
  - Use the following options with the HSCROLL and VSCROLL commands as needed. **HALF** is the default scroll amount.
    - **PAGE** is the entire amount that shows in the window.
    - **HALF** is half the amount that shows in the window.
    - **MAX** is the maximum portion to the left or right or to the top or bottom that shows in the window.
    - **n** is **n** lines or columns, where **n** is the number that you specify.
    - **CURSOR** When used with HSCROLL, the cursor moves to the left or right of the display, when the LEFT or RIGHT command is executed.

    *Note:* This option is valid only in windows that allow editing. ▲

    When used with VSCROLL, the cursor moves up and down when the FORWARD and BACKWARD command is executed.

---

**Example: Scrolling Windows**

To set the automatic horizontal scrolling value to five character spaces, then specify
Now, when you execute the LEFT or RIGHT command, you move five character spaces in the appropriate direction. If you want to set the automatic vertical scrolling value to half a page, then specify

```
vscroll half
```

Then, when you execute the FORWARD command, half of the previous page remains on the display and half of a new page is scrolled into view.

If you need to scroll a specific number of lines forward or backward, then use the scroll amount on the FORWARD command to temporarily override the default scrolling value. You can specify scrolling values with the BACKWARD and FORWARD commands and the LEFT and RIGHT commands.

### Changing Colors and Highlighting in Windows

SAS gives you a simple way to customize your environment if your display supports color. You can change SAS windowing environment colors with the COLOR command. You can also change SAS code color schemes by using the SYNCONFIG command. To change windowing environment colors, simply specify the COLOR command followed by the field or window element that you want changed, and the desired color. You might also be able to change highlighting attributes, such as blinking and reverse video.

For example, to change the border of a window to red, specify

```
color border red
```

This changes the border to red.

Other available colors are blue, green, cyan, pink, yellow, white, black, magenta, gray, brown, and orange. If the color that you specify is not available, then SAS attempts to match the color to its closest counterpart.

Some color selections are valid only for certain windows.

For more information, see the online help for the SASColor window. You can access the SASColor window with the SASCOLOR command.

You can also change the color scheme of text in the windows in which you enter code, such as the Editor window and NOTEpad. This is useful, because you can make different elements of the SAS language appear in different colors, which makes it easier to parse code. To change the color scheme for code, use the SYNCONFIG command. The SYNCOLOR command toggles color coding off and on in these windows.

For more information about changing the color schemes for windows in which you create and edit code, see the online help that is available when you issue the SYNCOLOR command.

### Finding and Changing Text

Often, you might want to search for a character string and change it. You can locate the character string by specifying the FIND command and then the character string. Then the cursor moves to the first occurrence of the string that you want to locate. Remember to enclose a string in quotation marks if CAPS ON is in effect.

You can change a string by specifying the CHANGE command, then a space and the current character string, and then a space and the new character string. Remember to enclose in quotation marks any string that contains an embedded blank or special characters. For both the FIND and CHANGE commands, the character string can be any length.

With both the FIND and CHANGE commands, you can specify the following options to locate or change a particular occurrence of a string:
ALL
FIRST
ICASE
LAST
NEXT
PREFIX
PREV
For details about which options you can use together, see the SAS Language Reference: Dictionary. Note that the option ALL finds or changes all occurrences of the specified string. In the following example, all occurrences of host are changed to operating environment:

```
change host 'operating environment' all
```

To resume the search for a string that was previously specified with the FIND command, specify the RFIND command. To continue changing a string that was previously specified with the CHANGE command, specify the RCHANGE command. To find the previous occurrence of a string, specify the BFIND or FIND PREV command; you can use the PREFIX, SUFFIX, and WORD options with the BFIND command.

Cutting, Pasting, and Storing Text

With the cut and paste facility, you can do the following:

- Identify the text that you want to manipulate.
- Store a copy of the text in a temporary storage place called a paste buffer.
- Insert text.
- List the names of all current paste buffers or delete them.

You can manipulate and store text by using the following commands:

- **MARK** identifies the text that you want to cut or paste.
- **CUT** removes the marked text from the display and stores it in the paste buffer.
- **STORE** copies the marked text and stores it in the paste buffer.
- **PASTE** inserts the text that you have stored in the paste buffer at the cursor location.

Working with Text

The SAS Text Editor

The SAS text editor is an editing facility that is available in the Editor and SAS NOTEPAD windows of Base SAS, SAS/FSP, and SAS/AF software. You can edit text from the command line and from any line on which code appears in an edit window.

This section provides information about commands that you can use to perform common text editing tasks by using the SAS text editor. For more information about all SAS windowing environment commands, see “Using SAS Windowing Environment Command Types” on page 660.

Moving and Rearranging Text

Some of the basics of moving, deleting, inserting, and copying single lines of text have already been reviewed. The rules are similar for working with a block of text; simply use double letters on the beginning and ending lines that you want to edit.
For example, alphabetizing the following list requires that you move a block of text. Note the MM (move) block command on lines 5 and 6 and the B line command on line 1 of the example.

```
b 001 c signifies the line command copy
00002 d signifies the line command delete
00003 i signifies the line command insert
00004 m signifies the line command move
mm 05 a signifies the line command after
mm 06 b signifies the line command before
00007 r signifies the line command repeat
```

Press the ENTER or RETURN key to execute the changes. Here are the results:

```
00001 a signifies the line command after
00002 b signifies the line command before
00003 c signifies the line command copy
00004 d signifies the line command delete
00005 i signifies the line command insert
00006 m signifies the line command move
00007 r signifies the line command repeat
```

Mastering a few more commands greatly increases the complexity of what you can do within the text editor. Several commands enable you to justify text. Specify the JL (justify left) command to left justify, the JR (justify right) command to right justify, and the JC (justify center) command to center text. To justify blocks of text, use the JJJ, JJR, and JJC commands. For example, if you want to center the following text,

```
00001 Study of Advertising Responses
00002 Topnotch Hotel Website
00003 Conducted by Global Information, Inc.
```

then simply add the JJC block command on the first and last lines and press ENTER or RETURN.

You can also shift text right or left the number of spaces that you choose by executing the following set of line commands:

```
>\[n]\] shifts text to the right the number of spaces that you specify; the default is one space.
<\[n]\] shifts text to the left the number of spaces that you specify; the default is one space.
```

To shift a block of text left, specify the following command on the beginning and ending line numbers of the block:

```
<<\[n]\]
```

Specify the following command to shift a block of text to the right:

```
>>\[n]\]
```

---

**Displaying Columns and Line Numbers**

To display column numbers in the text editor, specify the COLS line command. This command is especially useful if you are writing an INPUT statement in column mode, as shown in the following figure:
To remove the COLS line command or any other pending line command, execute the RESET command on the command line. You can also execute the D (delete) line command on the line where you have specified the COLS command to achieve the same results.

The NUMBERS command numbers the data lines in the Editor and SAS NOTEPAD windows. Specify the following command to add numbers to the data lines:

```
numbers on
```

To remove the numbers, specify

```
numbers off
```

You can also use the NUMBERS command without an argument, executing the command once to turn numbers on, and again to turn them off.

## Making Text Uppercase and Lowercase

### Overview

Making text uppercase and lowercase involves two sets of commands to accomplish two kinds of tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAPS</td>
<td>changes the default</td>
</tr>
<tr>
<td>CU, CL line commands</td>
<td>change the case of existing text</td>
</tr>
</tbody>
</table>

### Changing the Default

To change the default case of text as you enter it, use the CAPS command. After you execute the CAPS command, the text that you enter is converted to uppercase as soon as you press ENTER or RETURN. Under some operating environments, with CAPS ON, characters that are entered or modified are translated into uppercase when you move the cursor from the line. Character strings that you specify with a FIND, RFIND,
or BFIND command are interpreted as having been entered in uppercase unless you enclose the character strings in quotation marks.

For example, if you want to find the word value in the Log window, then on the command line, specify

    find value

If the CAPS command has already been specified, then SAS searches for the word VALUE instead of value. You receive a message indicating that no occurrences of VALUE have been found, as shown in the following display:

Display 39.5  The Results of the FIND Command with CAPS ON

```
WARNING: No occurrences of "VALUE" found.
8  ;
9  run;
10  proc print;
11  run;

NOTE: There were 4 observations read from the data set
NOTE: PROCEDURE PRINT used:
    real time       0.26 seconds
    cpu time        0.08 seconds
```

However, specify the following command and SAS searches for the word value, and finds it:

    find 'value'

Setting CAPS ON remains in effect until the end of your session or until you turn it off. You can execute the CAPS command by specifying

    caps on

To discontinue the automatic uppercasing of text, specify

    caps off

You can also use the CAPS command like a toggle switch, executing it once to turn the command on, and again to turn it off.

### Changing the Case of Existing Text

To uppercase or lowercase text that has already been entered, use the line commands CU and CL. Execute the CU (case upper) command to uppercase a line of text and the CL (case lower) command to lowercase a line of text.

In the following example, the CU and CL line commands each mark a line of text that will be converted to uppercase and lowercase, respectively.

```
00001  Study of Gifted Seventh Graders
cu002  Burns County Schools, North Carolina
cl003  Conducted by Educomp, Inc.
```
Press ENTER or RETURN to execute the commands. The lines of text are converted as follows:

```
00001 Study of Gifted Seventh Graders
00002 BURNS COUNTY SCHOOLS, NORTH CAROLINA
00003 conducted by educomp, inc.
```

For a block of text, you have two choices. First, you can execute the CCU block command to uppercase a block of text and the CCL block command to lowercase a block of text. Position the block command on both the first and last lines of text that you want to convert. Second, you can designate a number of lines that you want to uppercase or lowercase by specifying a numeric argument, as shown below:

```
cu3 1 Study of Gifted Seventh Graders
00002 Burns County Schools, North Carolina
00003 Conducted by Educomp, Inc.
```

Press ENTER or RETURN to execute the command. The three lines of text are converted to uppercase, as shown below:

```
00001 STUDY OF GIFTED SEVENTH GRADERS
00002 BURNS COUNTY SCHOOLS, NORTH CAROLINA
00003 CONDUCTED BY EDUCOMP, INC.
```

---

### Combining and Separating Text

You can combine and separate pieces of text with a number of line commands. With the TC (text connect) command, you can connect two lines of text. For example, if you want to join the following lines, then type the TC line command as shown below. Note that the second line is deliberately started in column 2 to create a space between the last word of the first line and the first word of the second line.

```
tc001 This study was conducted by
00002 Educomp, Inc., of Annapolis, Md.
```

Press ENTER or RETURN to execute the command. The lines appear as shown below:

```
00001 This study was conducted by Educomp, Inc., of Annapolis, Md.
```

Conversely, the TS (text split) command shifts text after the cursor's current position to the beginning of a new line.

Remember that you can also use a function key to execute the TC line command, the TS line command, or any other line command as long as you precede it with a colon.

---

### Working with Files

#### Ways to Find a File

There are a number of ways in which you can find a file or library member in the SAS windowing environment, including the following:

- using the Explorer window
- using the Find window
Using the SAS Windowing Environment

Ways to Find a File 673

Using Explorer to Find a File

When the SAS windowing environment opens, the Explorer window also opens by default in many operating environments. You can issue the EXPLORER command to open the Explorer window if it does not open by default.

- To find a file in the Contents Only view of the Explorer window, select the Libraries folder or the File Shortcuts folder, and then select Open from the pop-up menu. You can continue this process with subfolders until you locate the appropriate file.

- To find a file in the Tree view of the Explorer window, use the expansion icons (+ and – icons) located in the tree until the appropriate file appears in the window.

Note: You might find it useful to use specific navigational tools to move through the different levels of the Explorer window:

Menu

- View ➤ Up One Level

Command

- UPLEVEL

For more information about selecting an Explorer window view, see “Customizing the Explorer Window” on page 704.

Using the Find Window to Find a File

The Find window enables you to search for an expression (such as a text string or a library member) that exists in a SAS library. The default search looks at everything in the library, except catalogs, but you can click the check box for the search to include the catalogs in the library as well.

Display 39.6 The Find Window

To search for a file:

1. Select Tools ➤ Find from the Explorer window to open the Find window.

   Alternatively, issue the EXPFIND or EXPFIND <library-name> command. If you issue the EXPFIND command, then SASUSER is the default library. If you issue the EXPFIND WORK command, then WORK is the default library.

2. In the Search For field, enter the expression that you want to find. Wildcard characters are acceptable.

3. From the Search In drop-down list, select the library in which you want to search.
4 Click **Search Catalogs** to expand the search to include the catalogs of the library that you have selected.

   Searching catalogs can lengthen search time considerably depending on the size and number of catalogs in the library.

5 Click **Find**.

**Example: Finding Files with the Find Window**

You can find TABLE files that begin with a specific letter and exist in a specific library. For a file that starts with the letter S and which exists in the SASHELP library

1 Select **Tools** ▶ **Find** to open the Find window.
2 Type `s*.table` in the Search For field.
3 Select **SASHELP** from the **Search In** drop-down list.
4 Click **Find**.

---

**Issuing File-Specific Commands**

There are a number of commands that you can issue against a file after you find the file in the SAS windowing environment. The commands that are available are determined by the type of file with which you are working.

1 Find the file with which you want to work. For more information, see “Ways to Find a File” on page 672.
2 Select the file, and then right-click the file. A list of file-specific commands appears from which you can make a selection.

**Operating Environment Information:** If you are using the z/OS or CMS operating environment, then you can open a pop-up menu by typing `?` in the selection field next to an item. Alternatively, you can type an `s` or `x` in the selection field next to an item.

---

**Opening Files**

There are a number of ways in which you can open files in the SAS windowing environment.

To open a SAS file from Explorer:

1 Open a library and appropriate library members until you see the file that you want to open.
2 Select the file, then select **Open** from the pop-up menu.

   Depending on the file type, you might also be able to select **Open in Editor**.

   **Note:** In some cases, the pop-up menu also enables you to select **Browse in SAS Notepad**, which enables you to open a file in the SAS NOTEPAD window.

To open a file that has a file shortcut:

1 Open the **File Shortcuts** folder.
2 Select a file shortcut, and then select **Open** from the pop-up menu.

---

**Assigning a File Shortcut**

File shortcut references provide aliases to external files (such as a `.sas` program file or a `.dat` text file). A file shortcut is the same as a file reference or fileref. In operating
environments that support drag and drop functionality, you can drag file shortcuts from the Explorer window to the Editor window to display their contents.

To assign a file shortcut

1. From the Explorer window, select the **File Shortcuts** folder.

2. Select **File ▶ New**.

3. In the Name field of the File Shortcut Assignment window, enter a name for the file shortcut.

4. Select the method or device that you want to use for the file shortcut.

   The methods or devices that are available from the **Method** drop-down list depend on your operating environment. The DISK method is the default method (if it is available for your operating environment).

5. Select the **Enable at Startup** check box if you want SAS to automatically assign the file shortcut each time SAS starts. This option is not available for all the file shortcut methods.

   If you want to stop a file shortcut from being enabled at startup, then select the file shortcut in the SAS Explorer window, and then select **Delete** from the pop-up menu.

6. Fill in the fields of the Method Information area, including the name and location of the file for which you want to create a file shortcut. You can select **Browse** to locate the actual file. The fields that are available in this area depend on the type of method or device that you select.

   *Note:* Selecting a new method type erases any entries that you might have made in the Method Information fields.

7. Select **OK** to create the new file shortcut. The file shortcut appears in the File Shortcut folder of the SAS Explorer window.

You can use the following ways to create a file shortcut, depending on your operating environment:

**Menus**

   File ▶ New while your mouse is positioned on **File Shortcuts** in the Explorer window.

**Command**

   DMFILEASSIGN<file-shortcut-name><METHOD=><AUTO=>

   file-shortcut-name specifies an existing file shortcut reference.

   METHOD= method-name specifies which method to use when the File Shortcut Assignment window opens.

   AUTO= Yes|No sets the state of the File Shortcut Assignment window’s **Enable at Startup** check box when the window opens.

**Pop-up**

   New File Shortcut if you have opened the **File Shortcuts** folder in the Explorer window.

**Toolbar**

   New (while your mouse is positioned on **File Shortcuts** in the Explorer window.)

---

**Modifying an Existing File Shortcut**

You can modify existing file shortcut references, if needed.
From the command line:
1. Issue the following command:

   DMFILEASSIGN file-shortcut-name

   The File Shortcut Assignment window appears. Its fields include information
   that is specific to the chosen file shortcut.
2. Edit the fields of the File Shortcut Assignment window as needed.

From the SAS Explorer:
1. Right-click the File Shortcuts folder and select Open. Alternatively, you can
double-click the folder to open it.
2. Right-click the file shortcut reference that you want to change, and then select
Modify.
3. Edit the fields of the File Shortcut Assignment window as needed.

Operating Environment Information: If you are using the z/OS or CMS operating
environment, then you can open a pop-up menu by typing ? in the selection field next
to an item. Alternatively, you can type an s or x in the selection field next to an item.

Printing Files

There are a number of ways in which you can print files. Often, printing capabilities
depend on the type of file with which you are working, as well as your operating
environment.

Nonetheless, the following lists common ways in which you might be able to print a
file.

- Printing from Explorer: Find the appropriate file in the SAS Explorer window. Right-click
  over the file, and then select Print.
- Printing from a Text Editor: Open your file into a text editor such as the Editor or the SAS
  NOTEPAD. Use the text editor’s printing commands.

Refer to your operating environment documentation for information about printing
files.

Working with SAS Programs

Editor Window

When you work with SAS programs, you typically use the SAS programming
windows (the Editor, Log, and Output windows). Of these programming windows, the
Editor is the window that you might use most often. It enables you to do the following:

- Enter and submit the program statements that define a SAS program.
- Edit text.
- Store your program in a file.
- Copy contents from an already-created file.
- Copy contents into another file.
Using the SAS Windowing Environment

Editor Window

Display 39.7 The Editor Window with Line Numbers Turned On

Note: The Editor window shown here includes line numbers. You might find line numbers helpful when creating or editing programs. To toggle line numbers on or off, issue the NUMBERS command.

Command Line Commands and the Editor

There are a number of commands that you might find useful while working on programs in the Editor. You can execute these commands from the command line:

- **TOP**: scrolls to the beginning of the Editor.
- **BOTTOM**: scrolls to the last line of text.
- **BACKWARD**: scrolls back toward the beginning of the text.
- **FORWARD**: scrolls forward toward the end of the text.
- **LEFT**: scrolls to the left of the window.
- **RIGHT**: scrolls to the right of the window.
- **ZOOM**: increases the size of the window. You can issue this command again to return the window to its previous size.
- **UNDO**: cancels the effect of the most recently submitted text editing command. Continuing to execute the UNDO command undoes previous commands, starting with the most recent and moving backward.
- **SUBMIT**: submits the block of statements in your current SAS windowing environment session.
- **RECALL**: returns to the Editor window the most recently submitted block of statements in your current SAS windowing environment session. Continuing to execute the RECALL command recalls previous statements, starting with the most recent and moving backward.
- **CLEAR**: clears a window as specified. You can clear the Editor, Log, or Output windows from another window by executing the CLEAR command with the appropriate option as shown in the following examples:
clear pgm  
clear log  
clear output

CAPS
converts everything that you type to uppercase.

FIND
searches for a specified string of characters. Enclose the string in quotation marks if it contains embedded blanks or special characters.

CHANGE
changes a specified string of characters to another. Follow the command keyword with the first string, a space, and then the second string. The rules for embedded blanks and special characters apply. For example, you might specify

change 'operating system' platform

This CHANGE command replaces the first occurrence of operating system with the word platform. Note that the first string must be enclosed in quotation marks because it contains an embedded blank.

Note: Some of the more useful command line commands have been listed here. Almost all SAS commands are valid in the Editor window. For more information about other command line commands, see “Working with SAS Windows” on page 663.

Line Commands and the Editor

The left-most portion of the Editor window includes a numbered field. This field is where you enter line commands. These commands are denoted by one or more letters, and can move, copy, delete, justify, or insert lines.

Some common line commands include

- M — moves a line of text
- C — copies a line of text
- D — deletes a line of text
- I — inserts a line of text

When you use some line commands, you also need to specify a location. For example, if you type an M in the numbered field for a line in the Editor, then you must specify where you want the line of text to be moved. You can use the A (after) and B (before) line commands to specify a location.

If you type an A in the numbered field for a line, then the line of text that you want to move will be placed after the line marked with an A after you press the ENTER or RETURN key. If you type a B in the numbered field for a line, then the line of text that you want to move will be placed before the line marked with a B after you press the ENTER or RETURN key.

The following examples show how to use line commands to move a line of text in the Editor window to a new location. To make the following lines alphabetical, place the first line after the last line. To do this, use the M and A line commands:

```
m 001 Lincoln f Wake Ligon 135
00002 Andrews f Wake Martin 140
00003 Black m Wake Martin 149
a 004 Jones m Wake Ligon 142
```

After pressing the ENTER or RETURN key, your Editor window lines appear as follows:

```
00001 Andrews f Wake Martin 140
00002 Black m Wake Martin 149
00003 Jones m Wake Ligon 142
```
Output Window

You can browse and scroll procedure output from your current SAS session with the Output window. The results of submitting a program, if it contains a PROC step that produces output, are usually displayed in the Output window.

Display 39.8  The Output Window Showing the Results of a Submitted Procedure

Most of the command line commands described earlier for the Editor window can be used in the Output window. The CLEAR command is particularly useful in the Output window because all output is appended to the previous output within a SAS session. If you want to avoid accumulating output, then execute the CLEAR command before you submit your next program. From any other window, you can clear the Output window by specifying

clear output

Log Window

The Log window enables you to:

- recognize when you have made programming errors
- understand what is necessary to correct those errors
- receive feedback on the steps that you take to correct errors
The Log window shows the SAS statements that you have submitted as well as messages from SAS concerning your program. Under most operating environments, the Log window tells you:
- when the program was executed
- the release of SAS under which the program was run
- details about the computer installation and its site number
- the number of observations and variables for a given output data set
- the computer resources that each step used

You can use command line commands in the Log window, just as you can in the Editor and Output windows. For more information, see “Editor Window” on page 676.

Using Other Editors

NOTEPAD Window

Although the Editor was designed for writing SAS programs, you can also use the NOTEPAD window to create and edit SAS programs. The NOTEPAD is a text editor that you can use to create, edit, save, and submit SAS programs. You might find NOTEPAD useful as a separate place to work on code. To open NOTEPAD, issue the NOTEPAD or NOTES command.
Note: The SAS NOTEPAD window shown here includes line numbers. You might find line numbers helpful when you create or edit programs. To toggle line numbers on or off in NOTEPAD, issue the NUMBERS command.

If you open multiple NOTEPADS, then you can cut, copy, and paste text between NOTEPAD windows and the Editor window, multiple SAS sessions, and other applications.

Note: To submit a program from NOTEPAD, you must either select Run ➤ Submit or issue the NOTESUBMIT command.

Note: The program information that is presented in this documentation uses the Editor windows as the default editor.

Creating and Submitting a Program

To create and submit a SAS program:

1. Type the text of your program in the Editor.
2. Type submit on the command line, and then press ENTER or RETURN.
   You can also use the function key, menu command, or toolbar item that is assigned to submit programs in your environment.

Note: If you are submitting a program from the SAS NOTEPAD window, then you must use the NOTESUBMIT command instead of the SUBMIT command.

Storing a Program

To store a program:

1. In the Editor window, create or edit a program.
2. On the command line, issue the FILE command followed by a fileref or an actual filename. If you use an actual filename, then enclose it in quotation marks.

The FILE command does not clear the contents of the Editor window. You can store one copy of a program and then continue working in the Editor window.

If you try to store a program with a fileref or filename that already exists, then SAS displays a dialog box. The dialog box enables you to choose to

- overwrite the contents of the existing file with the new file
- append the new file to the existing file
- cancel the FILE command

Often you will want to replace a file with an updated version. To suppress the dialog box, add the REPLACE option to the FILE command after the fileref or complete filename. To add the text in the Editor window to the end of an existing file, specify the APPEND option with the FILE command after the fileref or complete filename.

Note: You can also store a program as a SAS object or as a file that is specific to your operating environment. After you have created or edited a program, select File ➤ Save As Object or File ➤ Save As, respectively.

Debugging a Program

You or someone in your organization might be able to help debug a program with the information that appears in the Log window after a program is submitted. If you are
having problems with your program, save the contents of the Log window to an external file, if you need to study it after your SAS session has ended.

To save the contents of the Log window to an external file:

1. Open the Log window if it is not already open.
2. From the command line, execute the FILE command followed by a fileref or an actual filename. If you use a filename, then enclose the name in quotation marks.

The FILE command stores a copy of the information in the Log window without removing what is currently displayed. If you specify the name of an existing fileref or file, then a dialog box appears and offers you three choices: overwriting the contents of the existing file with the new file, appending the new file to the existing file, or canceling the command.

---

**Opening a Program**

There is more than one way to open a SAS program. Two of the most popular methods are listed in this section.

To open a SAS program from the Editor window:

1. Select: **File ➤ Open**.
2. Use the Open window to locate the appropriate SAS program file.

To open a SAS program with commands:

1. Open the Editor window if it is not already open.
2. On the command line, specify the INCLUDE command followed by an assigned fileref or an actual filename. Remember to enclose an actual filename in single or double quotation marks.

   By default, a program is appended to the end of any existing program statements.

   **Note:** If program statements already exist in the Editor, then you can determine where your program is appended by using the B (before) or A (after) line commands. For more information about line commands, see Line Commands “Using Line Commands” on page 662.

   If you want to replace the text that is already in the Editor window with the program that you open, then specify the REPLACE option with the INCLUDE command after the fileref or filename.

---

**Editing a Program**

To edit a program:

1. Open an existing program in the Editor window.
2. Edit existing program statements or append new statements to the program.
3. Use command line commands and line commands as needed.

---

**Assigning a Program to a File Shortcut**

You can assign a program to a file shortcut to make it easier to find and work with the file in the future. For more information about file shortcuts, see “Assigning a File Shortcut” on page 674.
Working with Output

Overview of Working with Output

You can manage your SAS procedure output with the SAS Output Delivery System (ODS). Procedures that fully support ODS can do the following:

- combine the raw data that they produce with one or more table definitions to produce one or more output objects that contain formatted results
- store a link to each output object in the Results folder in the Results window
- can generate various types of file output, such as HTML, Listing, and in some cases, SAS/Graph output
- can generate output data sets from procedure output
- provide a way for you to customize the procedure output by creating table definitions that you can use whenever you run the procedure

The SAS windowing environment enables you to use many features of ODS through the Results, Templates, Preferences, and SAS Registry Editor windows. The Results window provides pointers to the procedure output that is produced by SAS. The Templates window provides a way to manage all the table, column header, and style definitions (sometimes called templates) that can be associated with procedure output.

Finally, the Preferences window and the SAS Registry Editor can be used to set the type(s) of procedure output that you want SAS to produce.

This section details only those portions of ODS that are related to the SAS windowing environment. For more information about ODS, see Chapter 23, “Directing SAS Output and the SAS Log,” on page 351 and SAS Output Delivery System: User’s Guide.

Setting Output Format

Depending on your operating environment, SAS output can be produced in one or more formats (or types). Listing output is the default type. Other output types include HTML, Output Data Sets, and PostScript. Pointers to procedure output appear in the Results window.

To set your output type, use either the Preferences window (if available in your operating environment), the SAS Registry Editor, or both.

Setting Output Type with the Preferences Window

If your operating environment supports the Preferences window, you can set output type as follows:

1. Select Tools ▶ Options ▶ Preferences or issue the DLGPREF command to open the Preferences window.
2. Select the Results tab.
3. Select or deselect the check boxes that match the output types that you want to produce.
   - If you choose to produce HTML output, then you can further define the output by selecting:
     - an HTML style

       Click the Style box and highlight a style. Styles among other things, define output colors and fonts.
the folder to which the output is saved

Select Use WORK folder to save HTML output only for the duration of the current session. Your output is deleted when your current SAS session ends.

Enter a path in the Folder text box to save HTML output to a folder that is not deleted when your SAS session ends.

the View Results as they are Generated check box

If selected, then each time HTML output is produced, your browser automatically opens and loads the output.

Setting Output Type with the SAS Registry Editor

To set output type with the SAS Registry Editor:

1 Select Solutions ► Accessories ► Registry Editor or issue the REGEDIT command to open the SAS Registry Editor.
2 From the tree on the left side, expand the ODS folder.
3 Expand the Preferences folder.
4 Select the appropriate output type.
5 On the right side, select the Value key, and then select Modify from the pop-up menu.
6 In the dialog box that appears, edit the Value Data field as needed.
   If this field is set to 1, then the output type is produced. If this field is set to 0, then the output type is not produced.

Assigning a Default Viewer to a SAS Output Type

When you produce output in SAS, output pointers appear in the Results window. You can assign a default viewer for each of the types of output that you produce. After a default viewer is assigned, you can double-click an output pointer in the Results window to open output in its default viewer. For example, double-clicking on a PostScript output pointer could open Ghostview with your PostScript output loaded.

Operating Environment Information: In the Windows operating environment, default viewers are established automatically with information from your Windows Registry.

To assign a default viewer to a SAS Output Type:

1 From the Explorer window, select Tools ► Options ► Explorer.
2 Select Host Files from the drop-down menu at the top of the Explorer Options window.
3 Scroll through the registered file types until you find the file type with which you want to work.
4 Select the appropriate file type, and then select Edit.
5 Select Add, and then enter an action name and action command for the file type in the Edit Action window.
   For example, add the following action name and action command to set Ghostview as the default viewer for PostScript file types:

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Action Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;Edit</td>
<td>x ghostview '%s' &amp;</td>
</tr>
</tbody>
</table>
6 Select **OK** from the Edit Action window.
7 Select the action that you just specified, and then select **Set Default**.

*Operating Environment Information:* In the Windows operating environment, default viewers are established automatically with information from your Windows Registry.

---

**Working with Output in the Results Window**

The Results window provides pointers to the procedure or DATA step output that SAS produces. This window might open by default when you start a SAS session. You can also open the Results window by selecting View ▶ Results or by issuing the ODSRESULTS command.

**Display 39.11**  The Results Window in Tree View

You can use the Results window to do the following:
- Navigate pointers to output.
- Delete results pointers.
- Rename results pointers.
- Save listing output to other formats.
- Quickly view the first output pointer item.
- View results properties.

**Customizing the Results Window View**

You can have the Results window display in one of three views:
- Tree
- Contents Only
- Explorer

In Tree view (the default), only a navigational tree is present. In Contents Only view, the tree is turned off, and contents appear as folders. In Explorer view, the Results window appears with two panes: one for the tree and one for the contents.
To toggle the Tree view pane, issue the TREE command from the Results window. To toggle the Contents pane, issue the CHILD command from the Results window. You can also select commands from the View menu of the Results window to perform the same actions, such as Show Tree, Show Contents, and others.

Note: By default, output pointers are listed by label rather than by name in the Tree pane. Labels are typically more descriptive than output names. You can use the following SAS system option to change this setting: LABEL.

Using Results Pointers to Navigate Output

When SAS runs a procedure or a DATA step, pointers to the output are placed in the Results window. To use the pointers in the Results window, see “Navigating the Results Window in Tree View” on page 686, “Navigating the Results Window in Contents Only View” on page 686, or “Navigating the Results Window in Explorer View” on page 687.

Navigating the Results Window in Tree View

In Tree view, output pointers appear in a procedural hierarchy. To work with your SAS output:

1. Locate the folder that matches the procedure output that you want to view.
2. Use the expansion icons (+ or – icons) next to the folder to open or hide its contents.
   
   You can also:
   - Double-click a folder to make it expand or collapse.
   - Select a folder, and then select Open from the pop-up menu.
3. When you locate the appropriate pointer, double-click the pointer or select the pointer and then select Open from the pop-up menu.

   The appropriate output appears.

Operating Environment Information: If you are using the z/OS or CMS operating environment, then you can open a pop-up menu by typing (?) in the selection field next to an item. Alternatively, you can type an s or x in the selection field next to an item.

You can also use the following ways to navigate in the Tree view:

<table>
<thead>
<tr>
<th>Menu</th>
<th>View ▶ Up One Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command</td>
<td>UPLEVEL</td>
</tr>
<tr>
<td>Toolbar</td>
<td>Up One Level icon</td>
</tr>
<tr>
<td>Key</td>
<td>Depending on your operating environment, you might also use arrow and backspace keys to navigate.</td>
</tr>
</tbody>
</table>

Navigating the Results Window in Contents Only View

In Contents Only view, output pointers appear in a procedural hierarchy, beginning with the top level of the hierarchy. You can drill down or roll up within the hierarchy to find the appropriate output.

When you open a folder, the current window contents are replaced with the contents of the selected folder. To work with your SAS output:

1. Locate the folder that matches the procedure output that you want to view.
2. Select the folder, and then select Open from the pop-up menu.

   You can also double-click a folder to open it.
3 When you locate the appropriate pointer, double-click the pointer or select the pointer, and then select **Open** from the pop-up menu.

The appropriate output appears.

*Operating Environment Information:* If you are using the z/OS or CMS operating environment, then you can open a pop-up menu by typing `?` in the selection field next to an item. Alternatively, you can type an `s` or `x` in the selection field next to an item.

### Navigating the Results Window in Explorer View

In Explorer view, two window panes exist. The left pane includes a hierarchical view (the Tree view) of the procedure output that you can view. The right pane shows the contents (the Contents view) of the item that is currently in focus.

### Deleting Results Pointers

You can delete results pointers by deleting the procedure folder in which the pointers exist. When you delete a procedure folder in the Results window, any output pointer that exists in that folder is removed.

*Note:* When you delete a procedure folder that contains a listing output pointer, the actual listing output is removed from the Output window. If other output pointers exist in the folder (such as HTML), then only the pointer is removed; the actual output remains available.

To delete procedure output:

1. In the Results window, select the procedure folder that matches the procedure that you want to delete.
2. Select **Delete** from the pop-up menu.
3. Select **Yes** to confirm the deletion.

*Tip*

You can also delete output pointers by selecting the procedure folder that you want to delete, and then selecting **Edit ▶ Delete**.

### Renaming Results Pointers

To rename results pointers:

1. Select the pointer that you want to rename.
2. Select **Rename** from the pop-up menu.
3. Type in a new name and/or a description, and then select **OK**.

*Tip*

You can also rename results pointers by selecting the pointer that you want to rename, and then selecting **Edit ▶ Rename**.

### Saving Listing Output to Other Formats

To save listing output to a file from the Results window:

1. Expand the Results window tree until you find the appropriate listing output pointer.
2. Select the listing output pointer, and then select **Save As** from the pop-up menu.

To save listing output to a file from the Output window:
1 Access the Output window.
2 On the command line, specify the FILE command followed by a fileref or an actual filename. If you use a filename, then surround the filename with quotation marks.

*Note:* The FILE command stores a copy of the information in the Output window without removing what is currently displayed.

To save listing output as a catalog object:
1 Expand the Results window tree until you find the appropriate listing output item.
2 Select the listing output item, and then select **Save As Object** from the pop-up menu.

**Viewing the First Output Pointer Item**

To view the first output pointer item:
1 Select the appropriate results pointer.
2 Select **View** from the pop-up menu.

The first output pointer item listed for the results pointer that you selected appears. For example, if you produced listing and HTML output for a procedure and the listing output was created first, then the listing output would appear.

**Viewing Results Properties**

You can view the properties of a Results window folder, an output pointer, or an output pointer item (such as listing or HTML output).
1 In the Results window, select the appropriate folder, output pointer, or output pointer item.
2 Select **Properties** from the pop-up menu.

---

**Working with Output Templates**

**Overview of Working with Output Templates**

Templates contain descriptive information that enables the Output Delivery System (ODS) to determine the desired layout of a procedure's results.

The Templates window provides a way to manage all the templates that are currently available to SAS. Specifically, you can use the Templates window to do the following:

- Browse PROC TEMPLATE source code.
- Edit PROC TEMPLATE source code.
- View template properties.
Using the SAS Windowing Environment △ Working with Output Templates 689

Display 39.12  The Templates Window in Explorer View

You can open the Templates window by selecting **View ➤ Templates** from the Results window, or by issuing the ODSTEMPLET command.

You can create or modify templates with PROC TEMPLATE.

**Note:** Templates that are supplied by SAS are stored in SASHELP. Templates that are created with PROC TEMPLATE are stored in SASUSER or whatever library that you specify in the ODS PATH statement. △

**Customizing the Templates Window View**

The Templates window appears in one of three views:

- Explorer
- Tree
- Contents Only

In Explorer view (the default), the Templates window appears with two panes: one for the tree and one for the contents. In Tree view, only a navigational tree is present. In Contents Only view, the tree is turned off.

To toggle the Contents pane, issue the CHILD command from the Templates window.

To toggle the Tree pane, issue the TREE command from the Templates window.

For more information, see “Navigating the Templates Window in Explorer View” on page 689, “Navigating the Templates Window in Tree View” on page 689, or “Navigating the Templates Window in Contents Only View” on page 690.

**Navigating the Templates Window in Explorer View**

In Explorer view, two window panes exist. The left pane includes a hierarchical view (the Tree view) of the templates that you can view. The right pane shows the contents (the Contents view) of the template currently in focus.

You can open additional template windows from the Explorer view by selecting a template, and then selecting **Explore from Here** from the pop-up menu.

**Navigating the Templates Window in Tree View**

In Tree view, templates appear in a hierarchy. To work with a template:

1  Locate the folder that includes the template that you want to view.
2 Use the expansion icons (+ or – icons) next to the folder to open or hide its contents. You can also do the following:
   - Double-click a folder to make it expand or collapse.
   - Select a folder, and then select **Open** from the pop-up menu.

3 Double-click the template that you want to see, or select the template, and then select **Open** from the pop-up menu.

   The template code appears in a browser window.

*Operating Environment Information:* If you are using the z/OS or CMS operating environments, then you can open a pop-up menu by typing ? in the selection field next to an item. Alternatively, you can double-click by typing an s or x in the selection field next to an item. △

**Navigating the Templates Window in Contents Only View**

In Contents Only view, templates appear as folders. When you open a folder, the current window contents are replaced with the contents of the selected folder. To work with your templates in this view:

1 Locate the folder that includes the template that you want to view.
2 Select the folder, and then select **Open** from the pop-up menu.
   - You can also double-click on a folder to open it.
3 Double-click on the template that you want to see, or select the template, and then select **Open** from the pop-up menu.
   - The template code appears in a browser window.

*Operating Environment Information:* If you are using the z/OS or CMS operating environments, then you can open a pop-up menu by typing ? in the selection field next to an item. Alternatively, you can double-click by typing an s or x in the selection field next to an item. △

**Browsing PROC TEMPLATE Source Code**

To browse the PROC TEMPLATE source code:

1 Locate the appropriate template in the Templates window.
2 Select the template, and then select **Open** from the pop-up menu.
   - Template code appears in a browser window.

**Editing PROC TEMPLATE Source Code**

To edit the PROC TEMPLATE source code:

1 Locate the appropriate template in the Templates window.
2 Select the template, and then select **Edit** from the pop-up menu. Template code appears in an editor window.
3 Modify the template code as needed.
4 Select **Run ➤ Submit** to submit your modified template code.

*Note:* If syntax errors occur when the code for an edited template is submitted, then the errors appear in the Log window. △

*Note:* Additional information for PROC TEMPLATE is available in the *Base SAS Procedures Guide*. △
Viewing Template Properties

To view template properties:

1. Locate the appropriate template in the Templates window.
2. Select the template, and then select **Properties** from the pop-up menu.

The Properties dialog box lists the type, path, size, description, and modification date for the template. You can also view this information by selecting **View ▶ Details** when the Templates window is active.

Printing Output

The method that you use to print output depends on the type of output that you produce, as well as your operating environment. SAS windowing environment windows have menus with print options that enable you to print the contents of that particular window. This feature varies from operating system to operating system, but is available in all operating environments.

If you produce HTML output, then you can open the output in a Web browser, and then print the output from the Web browser with the Web browser’s printing command.

For more information about printing, refer to your SAS operating environment companion documentation and your operating environment documentation.

Review of SAS Tools

Statements

ODS PATH *location(s)*

specifies which locations to search for definitions that were created by PROC TEMPLATE, as well as the order in which to search for them.

`<libname.>item-store <(READ | UPDATE | WRITE)>`

item-store

identifies an item store that contains style definitions, table definitions, or both.

Windows

File Shortcut Assignment

enables you to create or edit file shortcut references. To open this window, issue the DMFILEASSIGN command.

Find

enables you to search for an expression that exists in a SAS library. To open this window, select **Tools ▶ Find** from Explorer or issue the EXPFIND command.

Log

enables you to review information about the programs that you have run. To open this window, select **View ▶ Log** or issue the LOG command.

Output

enables you to see listing output. To open this window, select **View ▶ Output** or issue the OUTPUT command.
Editor
   enables you to enter, edit, submit, and save SAS program statements. To open this
   window, select View ▶ Editor or issue the PGM command.

Results
   provides pointers to the procedure output that you produce with SAS. To open this
   window, select View ▶ Results or issue the ODSRESULTS command.

SAS NOTEPAD
   enables you to enter, edit, submit, and save SAS program statements. To open this
   window, issue the NOTEPAD or NOTES command.

SAS Registry Editor
   enables you to edit the SAS Registry and to customize aspects of the SAS
   windowing environment. To access this window, issue the REGEDIT command.

Templates
   provides a way to manage the output templates that are currently available. To
   access this window, select View ▶ Templates from within the Results window.

---

**Commands**

**AUTOEXPAND**
   automatically expands the tree hierarchy when you select a tree node or when procedure output is produced.

**AUTOSYNC**
   enables you to automatically navigate to the first available output in the Output window by means of a single click.

**CHILD**
   toggles the Contents pane on and off.

**CLEAR**
   removes all the SAS output pointers.

**DELETESELS**
   removes the item currently in focus.

   *Note:* If the output pointer is associated with listing output, then
   the listing output is also removed. △

**DESELECT_ALL**
   deselects any items that are selected while the Contents pane is viewable.

**DETAILS**
   toggles the item details on and off while the Contents pane is viewable.

**DMOPTLOAD**
   recalls system option settings saved by DMOPTSsave.

**DMOPTSAVE**
   saves all system option settings for recall in later SAS sessions.

**FIND**
   searches for a match to the string that you provide.

**LARGEVIEW**
   displays large icons (on some operating environments) while the Contents pane is viewable.

**PMENU**
   turns on menus in windows.

**PRINT**
   prints the desired SAS listing output.

**REFRESH**
   refreshes the window’s contents.

**RENAMESELS**
   enables you to rename the output pointer that currently has focus.

**SELECT_ALL**
   selects all items while the Contents pane is viewable.

**SMALLVIEW**
   displays small icons (on some operating environments) in a horizontal fashion while the Contents pane is viewable.
TREE toggles the Tree view (hierarchical view) on and off.

UPLEVEL moves focus up one level in the hierarchy.

#### Procedures

Use PROC TEMPLATE to set template information.

#### Learning More

To learn more about SAS language elements, see *SAS Language Reference: Dictionary*.

To learn more about printing and the SAS Output Delivery System, see *SAS Output Delivery System: User's Guide*.

To find examples that will help you get started, see *Getting Started with the SAS System*.

Introduction to Customizing the SAS Environment

Purpose

In this section, you will learn how to make the following types of customizations in SAS:

- those that remain in effect for the current session only
- those that remain in effect from session to session
- those that you can apply to the SAS windowing environment, which is the default SAS environment

Prerequisites

To use this section, you should be familiar with the SAS windowing environment. For more information about the SAS windowing environment, see Chapter 39, "Using the SAS Windowing Environment," on page 655.

Operating Environment Differences

Even though SAS has a different appearance for each operating environment, most of the actions that are available from the menus are the same.

One of the biggest differences between operating environments is the way that you select menu items. If your workstation is not equipped with a mouse, then here are the keyboard equivalents to mouse actions:

<table>
<thead>
<tr>
<th>Mouse action</th>
<th>Keyboard equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-click the item</td>
<td>type an s or an x in the space next to the item, then press the ENTER or RETURN key</td>
</tr>
<tr>
<td>right-click the item</td>
<td>type ? in the space next to the item, then press the ENTER or RETURN key</td>
</tr>
</tbody>
</table>

Examples in this documentation show SAS windows as they appear in the Microsoft Windows environment. For the most part, corresponding windows in other operating environments will yield similar results. If you do not see the drop-down menus in your operating environment, then enter the global command PMENU at a command prompt.
Customizing the SAS Environment  △  Customizing SAS Sessions and Programs at Startup  697

Customizing Your Current Session

Ways to Customize

As you become familiar with SAS, you will probably develop preferences for how you want SAS configured. Many options are available to you to make SAS conform to your preferred working style. Some of the things that you can change are the following:

- window color and font attributes
- library and file shortcuts
- output appearance
- file-handling capabilities
- the use of system variables

You can customize your current SAS session in the following ways:

- at the startup of a SAS session or program
- through SAS system options
- with drop-down menu options

Customizing SAS Sessions and Programs at Startup

Setting Invocation-Only Options Automatically

You can specify some system options only when you invoke SAS. These system options affect the following:

- the way SAS interacts with your operating system
- the hardware that you are using
- the way in which your session or program is configured

Note: There are other system options that you can specify at any time. For more information, see “Customizing with SAS System Options” on page 698. △

Usually, any invocation-only options are set by default when SAS is installed at your site. However, you can specify invocation-only options on the command line each time you invoke SAS.

To avoid having to specify options that you use every time you run SAS, set the options in a configuration file. Each time you invoke SAS, SAS looks for that file and uses the customized settings it contains. Be sure to examine the default configuration file before creating your own.

Note: If you specify options both in the configuration file and in the SAS command, then the options are concatenated. If you specify an option in the SAS command that also appears in the configuration file, then the setting from the SAS command overrides the setting in the configuration file. △

To display the current settings for all options that are listed in the configuration file and on your command line as you invoke the system, use the VERBOSE system option in the SAS command.
Executing SAS Statements Automatically

Just as you can set SAS system options automatically when you invoke SAS, you can also execute statements automatically when you invoke SAS by creating a special autoexec file. Each time you invoke SAS, it looks for this special file and executes any of the statements it contains.

You can save time by using this file to execute statements that you use routinely. For example, you might add the following statements:

- OPTIONS statements that include system options that you use regularly
- FILENAME and LIBNAMEx statements to define the file shortcuts and libraries that you use regularly

Operating Environment Information: In order to execute SAS statements automatically in the CMS operating environment, you must have a file shortcut defined as SASEXEC.

Customizing with SAS System Options

Using the OPTIONS Statement and the Options Window

SAS system options determine global SAS settings. For example, the global options can affect the following:

- how your SAS output appears
- how files are handled by SAS
- how observations from SAS data sets are processed
- how system variables are used

The previous section discusses some invocation-only options that must be set at startup. However, there are many system options that can be set at any time. These system options can be set in an OPTIONS statement as well as in the SAS Options window.

It is important to note that system option settings remain in effect until you change them again, or until your current session ends.

There are several ways to view your system option settings. The two most common methods are the following:

- the SAS Options window (type OPTIONS at a command line)
- the OPTIONS procedure

To obtain a complete list of system option settings using the OPTIONS procedure, submit the following statements:

```
proc options;
run;
```

The SAS Options window groups options by function. The left side of the window includes a tree that lists the available option groups. You can expand option groups to see subgroups.

Operating Environment Information: Mainframe users can expand groups and subgroups by using the mouse or by typing an $ or an x before the group or subgroup name. When you select a subgroup, the individual options of that subgroup appear on the right side of the window.
To open the SAS Options window, do one of the following tasks:

- Issue the OPTIONS command.
- Select Tools ▶ Options ▶ System.

The options in each group or subgroup are listed alphabetically, followed by options that are specific to your operating environment (which are also listed alphabetically).

**Finding Options in the SAS Options Window**

You can find options in a number of ways.

- Expand the option groups and subgroups on the left side of the window until the appropriate option appears on the right side of the window.
- Select an option group or subgroup, then select **Find Option** from the pop-up menu. In the Find Option window, enter the name of the option that you want to locate, and then select **OK**.

**Setting Options in the SAS Options Window**

1. In the SAS Options window, find the option that you want to set.
2. Select the option from the right side of the SAS Options window.
3. Select **Modify Value** or **Set to Default** from the pop-up menu. Mainframe users can type an S or an X before the option name to access the pop-up menu.
   - If you choose **Modify Value**, then a dialog box appears that enables you to edit the option value.
   - If you choose **Set to Default**, then the option value is reset to the default SAS System value.
4. Select **OK** to save your changes. Select **Reset** to return all edited options to their previous values.

**Note:** If all the items on the pop-up menu are grayed out (that is, unavailable), then the options are invocation-only options and can be set only when a SAS session is started. △
Customizing Session-to-Session Settings

Overview of Customizing Session-to-Session Settings

The previous section discusses making customizations that stay in effect for the duration of the current SAS session only. This section provides information about making customizations that remain from SAS session to SAS session.

You can make customizations that remain from session to session by using one of the following windows:

- SAS Registry Editor
- Preferences window
- Options window

Customizing SAS Sessions and Applications with the SAS Registry Editor

Understanding the SAS Registry

The SAS Registry stores information about specific SAS sessions and applications. Unlike system options, customizations to the SAS Registry remain in effect for more than one SAS session. You can make SAS Registry customizations by using either PROC REGISTRY or the SAS Registry Editor.

This section shows you how to use the SAS Registry Editor, which is a graphical alternative to PROC REGISTRY. For more information about PROC REGISTRY, see the Base SAS Procedures Guide.

CAUTION:
Changes to SAS Registry should be well planned. In many cases, it is appropriate to have a designated person in charge of SAS Registry edits. Inappropriate SAS Registry edits can adversely affect your SAS session performance.

SAS Registry Editor values, which store data, exist in keys and subkeys. Keys and subkeys, which look like folders, appear in a tree on the left side of the SAS Registry Editor. If a key has subkeys, then you can expand or collapse it with the + and – icons that are found in the tree. If a key or subkey has values, then the values appear on the right side of the window.

Operating Environment Information: In the z/OS and CMS operating environments, you can select a + or – icon by positioning your cursor on it and then pressing the ENTER key.
Customizing SAS sessions and applications with the SAS Registry Editor

Display 40.2  The SAS Registry Editor

To customize SAS sessions and applications, use the SAS Registry Editor to add, modify, rename, and delete keys and key values.

You can also use the SAS Registry Editor to do the following:

- import registry files (starting at any key)
- export the contents of the registry (starting at any key)
- unregister a registry file

Opening the SAS Registry Editor

To open the SAS Registry Editor, select Solutions ➤ Accessories ➤ Registry Editor, or issue the REGEDIT command.

Finding Information in the SAS Registry Editor

You can search for specific information in the SAS Registry Editor, including specific keys, key value names, and key value data:

1. Select the key from which you want to start a search.
2. Open the drop-down menu and select Find.
3. In the Registry Editor Find window, type your search string in the Find What field.
4. Check one or more of the Keys, Value Name, or Value Data check boxes, depending on where you want to perform your search.
5. Select Find to begin the search.

Setting Keys in the SAS Registry Editor

You can add, modify, rename, or delete keys in the SAS Registry Editor. For example, you might want SAS to be able to work with a new paper type when printing output. Therefore, you might need to create a new key that represents the paper type. Additionally, you would have to create and set key values for this new paper type. For more information, see “Setting New Key Values in the SAS Registry Editor” on page 702.

Note:  When you add a key, the new key becomes a subkey of the most recently selected key.
To set a key in the SAS Registry Editor:
1 Expand or collapse the keys on the left side of the SAS Registry Editor (using the + and – icons) until you find the appropriate key.
2 With a key selected, select an action from the drop-down menu (such as New Key, Rename, or Delete). A dialog box appears that enables you to enter additional information or confirm an action.

CAUTION:
Delete removes all subkeys and values (if any) under the key that you are deleting.

Setting New Key Values in the SAS Registry Editor

If you create a new key, then you might want to add values to that key. Adding values includes assigning a value name as well as the value data.

Note: If your new key is similar to an existing key, then you might want to review that key’s subkeys and key values. The review process might help you determine which subkeys and key values you should have for the new key.

To add a new key value, do the following:
1 Select the new key on the left side of the SAS Registry Editor.
2 Select an action from the pop-up menu (such as New String Value, New Binary Value, or New Double Value).
3 In the dialog box, enter a name and a value for the new key value.
4 Select OK to complete the process.

Editing Existing Key Values in the SAS Registry Editor

1 Select a key on the left side of the SAS Registry Editor.
2 If the key contains subkeys, then continue to expand the key by selecting the + icon.
3 Select the key value that you want to edit on the right side of the SAS Registry Editor.
4 Select the appropriate action from the pop-up menu (such as Modify, Rename, or Delete). A dialog box appears that enables you to enter additional information or confirm an action.

Importing Registry Files

You can import a registry file to populate and modify the SAS Registry quickly. Registry files are text files that you create with a text editor. For information about registry file syntax, see PROC REGISTRY in the Base SAS Procedures Guide.

1 Select File ➤ Import Registry File.
2 Select the file that you want to import, and then select OK.

If errors occur during the import, then a message appears in the status bar and the errors are reported in the Log window. All registry changes can be sent to the log if you use the SAS Registry Editor option Output full status to Log. For more information, see “Setting Registry Editor Options” on page 703.

Exporting Registry Files

You can export (or copy) all or a portion of the SAS Registry to a file:
1 Select the key in the existing registry from where you want to begin exporting the file. Selecting a root key exports the entire tree, beginning at the root key that you select.

2 Select File ➤ Export Registry File.

3 Enter the full path to the file or browse to select the file to which you want to save the existing registry, and then select OK.

If errors occur during the export, then a message appears in the status bar and the errors are reported in the Log window. All registry changes can be sent to the log if you use the Output full status to Log SAS Registry Editor option.

### Uninstalling an Imported Registry File

The uninstall function reads an imported registry file and removes the keys found in the file from the registry. If any errors occur during this process, then a message appears in the status bar and errors are reported in the Log window.

*Note:* SAS ships with a set of ROOT keys. ROOT keys are not removed during an uninstall process. △

1 Select File ➤ Uninstall Registry File.

2 Select the external registry file that you want to uninstall from the SAS Registry, and then select OK. A message appears in the message line when the uninstall is complete.

### Setting Registry Editor Options

1 Open the SAS Registry Editor if it is not already open.

2 From the Registry Editor window, select Tools ➤ Options ➤ Registry Editor.

3 In the Select Registry View group box, choose a view for the Registry Editor.

   □ View Overlay mode enables you to modify data anywhere in the registry. The HKEY_USER_ROOT overlays the HKEY_SYSTEM_ROOT. The parent root for overlay view mode is shown as SAS REGISTRY.

   □ In View All mode, the Registry Editor shows all the entries that are contained in the two main entry points into the registry: HKEY_SYSTEM_ROOT and HKEY_USER_ROOT. Typically, the HKEY_SYSTEM_ROOT tree is stored in the SASHELP library and the HKEY_USER_ROOT is stored in the SASUSER library.

4 Select or deselect appropriate check boxes:

   - **Open HKEY_SYSTEM_ROOT for write access** enables you to open the registry for write access if you have write access to SASHELP.

   - **Output full status to Log** writes to the log all changes that were made when the registry file was imported or uninstalled. Usually, only errors appear in the Log window.

   - **View unsigned integers in hexadecimal format** enables you to view unsigned integers in the value list in HEX or DECIMAL format.

You can select Reset all options to return all Registry Editor Options window settings to the default values.
Customizing SAS Sessions with the Preferences Window

The Preferences window includes a series of tabs that you can access to set SAS preferences. Preferences enable you to customize and control your SAS environment. For example, you might use the General tab to select a startup logo, or the Results tab to control your output preferences, or even the Editing tab to set editor preferences, if, for example, your cursor inserts or overtypes text in an editor.

Preference window settings remain in effect from one SAS session to the next.

To access the Preferences window, select Tools > Options > Preferences or issue the DLGPREF command.

Operating Environment Information: The Preferences window is unavailable in some operating environments. Additionally, some preference settings are specific to your operating environment. Refer to the SAS documentation for your operating environment for more information about setting preferences.

Saving System Option Settings with the DMOPTSAVE and DMOPTLOAD Commands

Perhaps the easiest way to save your system option settings from one SAS session to another is to use the global commands DMOPTSAVE and DMOPTLOAD. After you set up your system options in a way that best suits your working style, type DMOPTSAVE at the command line and press ENTER. This saves the current system option settings for later use. Later, when you have started another SAS session and would like to retrieve your saved settings, type DMOPTLOAD at the command line and press ENTER. This changes your system option settings back to the system option settings in effect when you issued the DMOPTSAVE command.

The DMOPTSAVE and DMOPTLOAD commands have other useful features:
- You can issue parameters to name different sets of system option settings and control where they are saved.
- You can view the saved system option settings by using SAS Explorer, because they are saved by default as a data set.
- You can also issue parameters to save the system option settings to a registry key.

When you issue a DMOPTSAVE command without parameters, SAS saves a data set (myopts) that contains the system option settings to the default library. The default library is usually the library where the current user profile is. In most cases, this is the SASUSER library.

See SAS online Help for more details about using these commands.

Customizing the SAS Windowing Environment

Customizing the Explorer Window

Ways to Customize the Explorer Window

You can customize the Explorer window in these ways:
Customizing the SAS Environment

Customizing the Explorer Window

Select Contents Only view or Explorer view.

Change how items appear in the contents view.

Add and remove folders (including one that adds access to files in your operating environment).

Enable member, entry, and operating environment file types to appear.

Add a pop-up menu action.

Hide member, entry, and operating environment file types.

Selecting Contents Only View or Explorer View

The Explorer window can appear in either Explorer view or Contents Only view. In Explorer view, the Explorer window includes two sides: a tree view on the left that lists folders, and a contents view on the right that shows the contents of the folder that is selected in the tree view.

Display 40.3 The Explorer Window with Explorer View Enabled

In Contents Only view, the Explorer window is a single-paned window that shows the contents of your SAS environment. As you open folders, the folder contents replace the previous contents in the same window. In Contents Only view, you navigate the Explorer window using pull-down and pop-up menu actions, and toolbar items (if a toolbar is available).
Display 40.4  The Explorer Window with Contents Only View Enabled

Operating Environment Information:  In most operating environments, the Explorer appears in Contents Only view by default.

Depending on your operating environment, you can toggle between the two views in these ways:

Menu:   View ▶ Show Tree
Command: TREE
Toolbar  Toggle the Tree tool button

Changing How Items Appear in the Contents View

You can make selections from the View menu to determine how files appear in the Contents view of the Explorer window. All possible selections follow, although not all the selections may be available in your operating environment:

Large Icons displays a large icon for each file.
Small Icons displays a small icon for each file (only available on PC hosts).
List displays a left-justified list of files.
Details lists files along with columns of descriptive information (such as file size, type, and so on).

You might also be able to use the following commands in your operating environment instead of making selections from the View menu:

DETAILS lists files along with columns of descriptive information (such as file size, type, and so on).
LARGEVIEW displays a large icon for each file.
SMALLVIEW depending on your operating environment, this command displays either a list of files or a small icon for each file.

Adding and Removing Folders

The Explorer window shows the Libraries and File Shortcuts folders by default in many operating environments. You can turn off these folders, or turn on other folders, including Extensions, My Favorite Folders, and Results.
From the Explorer window, select **Tools > Options > Explorer**.

From the drop-down list at the top of the window, select **Initialization**.

Select the folder that you want to add or remove, and then select **Add** or **Remove**. The Description field changes to On or Off to reflect your change.

**Operating Environment Information:** The My Favorite Folders window enables you to access operating environment-specific files from the Explorer. This feature is not available in CMS and z/OS operating environments.

**Enabling Member, Entry, and Operating Environment File Types to Appear**

Commonly used members, catalog entries, and operating environment files are registered and appear in the Explorer window. Registered types must have at least an icon defined and might also have pop-up menu actions defined. Undefined types do not appear in the Explorer window and have no actions associated with them.

To add (register) an undefined type:

1. From the Explorer window, select **Tools > Options > Explorer**.
2. From the drop-down list at the top of the window, select a category (such as Members, Catalog Entries, or Host Files). The registered types are displayed in the window.
3. Select the **View Undefined Types** check box to see the undefined types for the category.
4. Select a type and then select **Edit**.
5. Select **Select Icon**.
6. In the Select Icon dialog box, choose a category from the drop-down list at the top, select an icon, and then select **OK** to close the dialog box.
7. Add actions for the type (if desired) and then select **OK**. For more information about adding actions to a type, see “Adding a Pop-Up Menu Action to a Member, Entry, or Operating Environment File Type” on page 707. The type is added to the Registered Types list.

**Adding a Pop-Up Menu Action to a Member, Entry, or Operating Environment File Type**

You can add a pop-up menu action to any catalog entry, member, or operating environment file type.

1. From the Explorer window, select **Tools > Options > Explorer**.
2. From the drop-down list at the top of the window, select a category (such as Members, Catalog Entries, or Host Files). The registered types are displayed in the window.
3. Select the registered type that you want to edit.
4. Select **Edit**.
5. In the Options dialog box for that entry, select **Add**.
6. Enter a name for the action (this is the action that will appear on the pop-up menu for the item), and an action command. To see examples of action commands, look at the commands for registered types.
7. Select **OK**.

**Note:** The letter immediately after the ampersand (&) in the Action section denotes the shortcut key that can be used to perform that action.
Hiding Member, Entry, and Host File Types

You can hide members, catalog entries, and host files so that they do not appear in the Explorer window:

1. From the Explorer window, select **Tools ▶ Options ▶ Explorer**.
2. From the drop-down list at the top of the window, select a category (such as Members, Catalog Entries, or Host Files). The registered types are displayed in the window.
3. Select the registered type that you want to remove from view.
4. Select **Remove**. Confirm the removal by selecting **OK** when prompted.

When you remove a registered type, it is moved to the View Undefined Types view. To add the registered type back, you must redefine its icon.

Customizing an Editor

You can customize general and text editing options for your editor. For example, if you use line commands when you edit programs, then you might always want the Program Editor to appear with line numbers.

To customize your editor, do the following:

1. Select a SAS programming window (such as the Program Editor, Log, Output, or SAS Notepad window).
2. Select **Tools ▶ Options ▶ Editor**.
3. From the drop-down list, select the category of options that you want to edit.
4. In the Options group box, select an option, and then select **Modify** from the pop-up menu.
5. In the dialog box that appears, edit the option name, value, or both.

Customizing Fonts

You can set default font information for the SAS windowing environment with the Font window. To access the Font window, issue the DLGFONT command, or select **Tools ▶ Options ▶ Fonts**.

The Font window is host-specific. Refer to your host documentation for more information.

Customizing Colors

*Note:* Changes made with the SASColor window are visible only after affected SAS windows are closed and then reopened.

You can also change the default colors in edit windows, such as the Notepad and the Program Editor by using the SYNCONFIG command. This command controls the color of SAS language and programming elements, which makes it easier to parse through a SAS program and understand how it works. SYNCONFIG opens the Edit Scheme window, which gives you several different color schemes to select. You can also modify the provided color schemes.

Setting SAS Windowing Environment Preferences

You can use the Preferences window to customize portions of the SAS windowing environment to your liking. For more information, see “Customizing SAS Sessions with the Preferences Window” on page 704.
Review of SAS Tools

**Commands**

DLGFONT
   opens the Font window, which is used to control the fonts in the SAS windowing environment.

DLGPREF
   opens the Preferences window, in some operating environments.

OPTIONS
   opens the SAS System Options window.

PMENU
   turns on the menu bar in the windowing environment.

REGEDIT
   opens the Registry Editor window.

SASCOLOR
   opens the SASCOLOR window, which is used to change the color of window elements, such as backgrounds and borders.

SYNCONFIG
   opens the Edit Scheme window, which is used to edit color schemes in the Editor, NOTEPAD, or Program Editor windows.

**Procedures**

PROC OPTIONS <SHORT|LONG>;
   lists the current values of all SAS system options. The SHORT and LONG options determine the format in which you want SAS system options listed.

   *Note:* You can also use the SAS Options window to see the current values of all SAS system options. △

PROC REGISTRY <options>;
   maintains the SAS Registry.

   *Note:* You can also use the SAS Registry Editor to maintain the SAS Registry. △

**Statements**

OPTIONS option-1<... option-n>;
   changes the value of one or more SAS system options.
System Options

VERBOSE|NOVERBOSE
controls whether SAS writes the settings of all the system options that are specified in the configuration file to either the workstation or batch log.

Windows

Editor Options window
enables you to set options for specific SAS windowing environment windows, such as the Program Editor. To open the Editor Options window, go to the window that you want to change, and then select Tools ► Options ► Editor or issue the EDOPT command.

Explorer Options window
enables you to set Explorer window options. To open this window, select Tools ► Options ► Explorer Options or issue the EXPOPTS command.

Fonts window
enables you to select the default font that you want to use in the SAS windowing environment. To access this window, issue the DLGFONT command.

Note: This window is specific to your operating environment.

Preferences window
enables you to set SAS system preferences. To access this window, issue the DLGPREF command.

Note: This window is specific to your operating environment.

SASColor window
enables you to change the default colors for the different window elements in your SAS windows. To access this window, issue the SASCOLOR command.

SAS Registry Editor
enables you to edit the SAS Registry and to customize aspects of the SAS windowing environment. To access this window, issue the REGEDIT command.

SAS System Options window
enables you to view or change current SAS system options. To access this window, issue the OPTIONS command.

Learning More

- For information about operating environment-specific customization options and preferences, refer to the SAS documentation for your operating environment.
- For more information about SAS procedures, see the Base SAS Procedures Guide.
- For more information about the statements and options that are discussed in this section, see SAS Language Reference: Dictionary.
- For more tips and examples on using the SAS windowing environment, see Getting Started with the SAS System.
Appendix

Appendix 1. Additional Data Sets 713
Additional Data Sets

Introduction

This documentation shows how to create the data sets that are used in each section. However, when the input data are lengthy or the actual contents of the data set are not crucial to the section, the DATA steps or raw data to create data sets are listed in this appendix instead of within the section.

Only the raw data, or DATA steps that are not provided in detail in the section, are included here.
DATA Step to Create the Data Set CITY

data city;
    input Year 4. @7 ServicesPolice comma6.

Note on Catalogs USCLIM.BASETEMP and USCLIM.REPORT

The catalogs USCLIM.BASETEMP and USCLIM.REPORT are used to show how the DATASETS procedure processes both SAS data sets and catalogs. The contents of these catalogs are not important in the context of this book. In most cases, you would use SAS/AF, SAS/FSP, or other SAS products to create catalog entries. You can test the examples in this section without having these catalogs.

DATA Step to Create the Data Set CLIMATE.HIGHTEMP

```
libname climate 'SAS-data-library';

data climate.hightemp;
   input Place $ 1-13 Date $ Degree_f Degree_c;
   datalines;
   Libya   13sep22 136 58
   California 10jul13 134 57

**Glossary**

**across variable**

in the REPORT procedure, a variable used so that each formatted value of the variable forms a column in the report. If the variable does not have a format, each value forms a column.

**active data set**

the SAS data set specified in the current analysis.

**active window**

a window that is open, displayed, and to which keyboard input is directed. Only one window can be active at a time.

**alphanumeric characters**

a string of characters that can include alphabetic letters, numerals, and special characters or blanks. Most computer systems store strictly numeric data differently from alphanumeric or textual data.

**analysis variable**

1 (1) a numeric variable used to calculate statistics. Usually an analysis variable contains quantitative or continuous values, but this is not required.
2 in the REPORT procedure, you must associate a statistic with an analysis variable. By default, the REPORT procedure treats a numeric variable as an analysis variable that is used to calculate the SUM statistic.

**argument**

1 in a SAS function or CALL routine, the values or expressions a user supplies within parentheses on which the function or CALL routine performs the indicated operation.
2 in syntax descriptions, any word that follows the keyword in a SAS statement.

**arithmetic expression**

see SAS expression.

**arithmetic operators**

the symbols (+, -, /, *, and **) used to perform addition, subtraction, division, multiplication, and exponentiation in SAS expressions.

**array**

a group of variables of the same type available for processing under a single name.
array name
   a name selected to identify a group of variables or temporary data objects. It must be
   a valid SAS name that is not the name of a variable in the same DATA step. See also
   array.

array reference
   a reference to the object to be processed in an array. See also array.

ASCII
   an acronym for the American Standard Code for Information Interchange. ASCII is a
   7-bit character coding scheme (8 bits when a parity check bit is included) including
   graphic (printable) and control (nonprintable) codes.

ASCII collating sequence
   an ordering of characters that follows the order of the characters in the American
   Standard Code for Information Interchange (ASCII) character coding scheme. SAS
   uses the same collating sequence as its host operating environment. See also
   EBCDIC collating sequence.

assignment statement
   a DATA step statement that evaluates an expression and stores the result in a
   variable. An assignment statement has the following form: variable=expression;

attributes
   See variable attributes.

autocall facility
   a feature of SAS that enables you to store the source statements that define a macro
   and invoke the macro as needed, without having to include the definition in your
   program.

autoexec file
   a file containing SAS statements that are executed automatically when SAS is
   invoked. The autoexec file can be used to specify some SAS system options, as well
   as librefs and filerefs that are commonly used.

automatic macro variable
   a macro variable defined by SAS rather than by the user.

automatic variable
   a variable that is created automatically by the DATA step, some DATA step
   statements, some SAS procedures, and the SAS macro facility.

background processing
   processing in which you cannot interact with the computer. Background sessions
   may run somewhat slower than foreground sessions because this type of session
   executes as processor time becomes available. See also foreground processing.

Base SAS
   software that includes a programming language that manages your data, procedures
   for data analysis and reporting, procedures for managing SAS files, a macro facility,
   help menus, and a windowing environment for text editing and file management.

batch job
   a job submitted to the operating environment for batch processing.

batch mode
   a method of executing SAS programs in which you prepare a file containing SAS
   statements and any necessary operating environment commands and submit the
   program to the computer's batch queue. While the program executes, control returns
   to your terminal or workstation environment where you can perform other tasks.
Batch mode is sometimes referred to as running in the background. The job output can be written to files or printed on an output device.

**Boolean operator**
See logical operator.

**break**
in the REPORT procedure, a section of the report that does one or more of the following: visually separates parts of the report; summarizes statistics and computed variables; displays text, values calculated for a set of rows of the report, or both; executes DATA step statements. You can create breaks when the value of a selected variable changes or at the beginning or end of a report. See also break variable.

**break line**
in the REPORT procedure, a line of a report that contains one of the following: characters that visually separate parts of the report; summaries of statistics and computed variables (called a summary line); text, values calculated for a set of rows of the report, or both.

**break variable**
in the REPORT procedure, a group or order variable you select to determine the location of break lines. The REPORT procedure performs the actions you specify for the break each time the value of this variable changes.

**BY group**
all observations with the same values for all BY variables.

**BY value**
the value of a BY variable.

**BY variable**
a variable named in a BY statement whose values define groups of observations to process.

**BY-group processing**
the process of using the BY statement to process observations that are ordered, grouped, or indexed according to the values of one or more variables. Many SAS procedures and the DATA step support BY-group processing. For example, you can use BY-group processing with the PRINT procedure to print separate reports for different groups of observations in a single SAS data set.

**CALL routine**
a program that can be called in a DATA step by issuing a CALL statement. A CALL routine may change the value of some of the arguments passed to it, but it does not return a value as a function does.

**calling a macro**
See macro invocation.

**carriage-control character**
a specific symbol that tells the printer how many lines to advance the paper, when to begin a new page, when to skip a line, and when to hold the current line for overprint.

**catalog**
See SAS catalog.

**catalog directory**
in SAS, a part of a SAS catalog that stores and maintains information about the name, type, description, and update status of each member of the catalog.

**catalog entry**
See entry type and SAS catalog entry.
category
in the TABULATE procedure, the combination of unique values of class variables. The TABULATE procedure creates a separate category for each unique combination of values that exists in the observations of the data set. Each category created by PROC TABULATE is represented by one or more cells in the table where the pages, rows, and columns that describe the category intersect.

cell
a single unit of a table produced by a SAS procedure, such as the TABULATE or FREQ procedure. The value contained in the cell is a summary statistic for the input data set. The contents of the cell are described by the page, row, and column that contain the cell.

character constant
one or more characters enclosed in quotes in a SAS statement (sometimes called a character literal). The maximum number of characters allowed is 200. See also character string.

character format
instructions to SAS to write character data values using a specific pattern.

character function
a function that enables you to perform character string manipulations, comparisons, evaluations, or analyses.

character informat
instructions to SAS to read character data values into character variables using a specific pattern.

character literal
See character constant.

character string
one or more alphanumeric or other keyboard characters or both. See also character constant.

character value
a value that can contain alphabetic characters, numeric characters 0 through 9, and other special characters. See also character variable.

character variable
a variable whose values can consist of alphabetic and special characters as well as numeric characters.

chart
a graph in which graphics objects (bars, pie slices, and so on) show the magnitude of a statistic. The graphics objects can represent one data value or a range of data values.

chart statistic
the statistical value calculated for the chart variable: frequency, cumulative frequency, percentage, cumulative percentage, sum, or mean.

chart variable
a variable in the input data set whose values are categories of data represented by bars, blocks, slices, or spines.

check box
an item in a window that you can select without affecting any other items. You can deactivate a check box by selecting it again.
class variable
in some SAS procedures, a variable used to group, or classify, data. Class variables
can be character or numeric. Class variables can have continuous values, but they
typically have a few discrete values that define the classifications of the variable.

collating sequence
See ASCII collating sequence and EBCDIC collating sequence.

column concatenation
in TABULATE procedure output, two or more tables produced by one TABLE
statement and placed side by side.

column input
in the DATA step, a style of input that gives column specifications in the INPUT
statement for reading data in fixed columns.

command
a keyword that gives directions to the host operating environment or to the SAS
windowing environment.

command bar
a row of push buttons at the bottom of a window. The push buttons represent actions
or classes of actions that can be executed in that window.

comment
text that provides additional information in a SAS program. SAS ignores comments
during processing but writes them to the SAS log. Comments have two forms. A
comment can appear as a statement that begins with an asterisk and ends with a
semicolon:* message; A comment can also appear as text that begins with a forward
slash and an asterisk and ends with an asterisk and a forward slash:/* message */

comment statement
See comment.

comparison operator
a symbolic or mnemonic instruction that tests for a particular relationship between
two values. If the comparison is true, the result of executing the instruction is the
value 1; if the comparison is false, the result is the value 0.

compilation
the process of checking syntax and translating a portion of a program into a form
that the computer can execute.

composite index
an index that locates observations in a SAS data set by the values of two or more key
variables. See also index and simple index.

compound expression
an expression containing more than one operator.

computed variable
in the REPORT procedure, a variable whose value is calculated by statements
entered in the COMPUTE window.

concatenating
1 for character values, a process in which SAS combines two or more character
values, one after the other, into a single character value.
2 for SAS data sets, a process in which SAS combines two or more SAS data sets,
one after the other, into a single data set.
3 for external files, the process that enables SAS to access two or more files as if
they were one by specifying the filenames one after another in the same SAS
statement.
in the TABULATE procedure, the operation that instructs the procedure to join information for two or more table objects by placing the output for the second object immediately after the output for the first object. Concatenated objects produce tables consisting of two or more subtables. See also column concatenation.

**condition**
in a SAS program, one or more numeric or character expressions that result in a value upon which some decision depends.

**configuration file**
an external file containing SAS system options that are put into effect when SAS is invoked.

**configuration option**
a SAS option that can be specified in the SAS command or in a configuration file. Configuration options affect how SAS interfaces with the computer hardware and operating environment.

**constant**
a number or a character string that indicates a fixed value. Character constants must be enclosed in quotation marks.

**constant text**
in the SAS macro facility, the strings stored as part of a macro or as a macro variable's value in open code, from which the macro processor generates text to be used as SAS statements, display manager commands, or other macro program statements. Constant text is also called model text.

**crossing**
in the TABULATE procedure, the process that combines the effects of two or more objects.

**data error**
a type of execution error that occurs when a SAS program analyzes data containing invalid values. For example, a data error occurs if you specify numeric variables in the INPUT statement for character data. By default, data errors do not cause a program to stop but, instead, to generate notes in the SAS log. See also programming error and syntax error.

**data file**
See SAS data file.

**data lines**
lines of unprocessed (raw) data. In a SAS program, data lines follow a CARDS or DATALINES statement.

**data set label**
in a SAS data set, a user-defined attribute of up to 40 characters used for documenting the SAS data set.

**data set option**
See SAS data set option.

**data set reference**
a SAS argument that specifies a SAS data set similar to DATA= *libref*.member or OUT= *libref*.member.

**DATA step**
a group of statements in a SAS program that begins with a DATA statement and ends with either a RUN statement, another DATA statement, a PROC statement, the end
of the job, or the semicolon that immediately follows instream data lines. The DATA step enables you to read raw data or other SAS data sets and use programming logic to create a SAS data set, write a report, or write to an external file.

data value
1 in SAS, a unit of character or numeric information in a SAS data set. A data value represents one variable in an observation.
2 in the rectangular structure of a SAS data set, intersection of a row and a column.

date and time format
the instructions that tell SAS how to write numeric values as dates, times, and datetimes.

date and time informat
the instructions that tell SAS how to read numeric values represented as dates, times, and datetimes.

date value
See SAS date value.

declarative statement
a statement that supplies information to SAS and that takes effect when SAS compiles program statements, rather than when it executes them. See also executable statement.

default directory
the directory you are working in at any given time. When you log in, your default directory is usually your home directory.

delimiter
a character that serves as a boundary separating the objects of a character string, programming statement, data line, or list of arguments.

descriptor information
the information SAS creates and maintains identifying the attributes of a SAS data set and its contents.

destination
a specific type of output from the Output Delivery System. Types of output include HTML, Listing, PostScript, RTF, and SAS data sets.

detail row
in the REPORT procedure, a row of a report that either contains information from a single observation in the data set or consolidates the information for a group of observations that have a unique combination of values for all group variables.

dialog box
a type of window that opens to prompt you for additional information, provide additional information, or ask you to confirm a request.

dialog window
a window that prompts a user for additional information in order to perform a specified action.

dimension
in the TABULATE procedure, the page, row, or column portion of a table. PROC TABULATE can produce tables that have one, two, or three dimensions.

dimension expression
in the TABULATE procedure, the portion of the TABLE statement that defines what variables and statistics make up a single dimension of the table. The format of a
dimension expression is the same for any of the three dimensions page, row, and column.

**DO group**
a sequence of statements headed by a simple DO statement and ended by a corresponding END statement. See also DO loop.

**DO loop**
a sequence of statements headed by an iterative DO, DO WHILE, or DO UNTIL statement; ended by a corresponding END statement; and executed (usually repeatedly) according to directions in the DO statement. See also DO group.

double trailing at sign (@@)
a special symbol used to hold a line in the input buffer across iterations of the DATA step. See also trailing at sign (@).

**EBCDIC**
an acronym for Extended Binary Coded Decimal Interchange Code. EBCDIC is an 8-bit character coding scheme including graphic (printable) and control (nonprintable) codes.

**EBCDIC collating sequence**
an ordering of characters that follows the order in the Extended Binary Coded Decimal Interchange Code (EBCDIC) character coding scheme. SAS uses the same collating sequence as its host operating environment. See also ASCII collating sequence.

**entry**
a unit of information stored in a SAS catalog. Catalog entries differ widely in content and purpose. See also entry type.

**entry type**
a characteristic of a SAS catalog entry that identifies its structure and attributes to SAS. When you create an entry, SAS automatically assigns the entry type as part of the name.

**error message**
a message in the SAS log or Message window that indicates that SAS was not able to continue processing the program.

**executable statement**
in the DATA step, a SAS statement that causes some action to occur while the DATA step executes rather than when SAS compiles the DATA step. See also declarative statement.

**execution**

1 in the DATA step, the process in which SAS carries out statements for each observation or record in the file. See also compilation.

2 in contexts other than the DATA step, such as SAS macros, procedures, and global statements, the process in which SAS performs the actions indicated.

**explicit array**
an array that consists of a valid SAS name, reference to the number of variables or temporary data elements, and an optional list of the array elements. In an explicit array, you must explicitly specify the subscript in the reference when referring to an element. See also explicit array reference.

**explicit array reference**
a description of the element to be processed in an explicit array. See also explicit array.
**exponent**

in a mathematical expression, the number or expression that indicates the power to which you raise a base number or expression.

**expression**

See SAS expression.

**external file**

1. a file maintained by the host operating environment that SAS can read data from and route output to. External files can contain raw data, SAS programming statements, procedure output, or output created by the PUT statement. An external file is not a SAS data set. See also fileref.
2. in a DATA step, a file that SAS can use the INFILE and INPUT statements to read or a file that SAS can use the FILE and PUT statements to write.

**field**

1. in a hierarchical database, the smallest unit of data storage.
2. in an external file, the smallest logical unit of data. See also file and record.
3. in windowing environments, a window area that is defined to contain a value that users usually can view, enter, or modify.

**file**

1. a collection of related records treated as a unit. SAS files are processed and controlled through the SAS System and are stored in a SAS data library.
2. A Prime INFORMATION file is made up of two parts, a data part and a dictionary part.
3. An ADABAS file can contain from 0 to 16,777,215 records. The records are physically stored in compressed form in Data Storage. File control information, field definitions, and inverted list entries are contained in the Associator.
4. In CA-DATACOM/DB, each database contains one or more FILE entity-occurrences that comprise specific records, fields, and elements. Each FILE entity-occurrence requires a unique name and specific attributes in the CA-DATADICTIONARY database.
5. In SYSTEM 2000 software, each database contains six database files, which together hold the definition, the indexes, the values, and the hierarchical structure of the database. Database files 7 and 8 are optional files for the Update Log and Rollback Log.

**file pathname**

a pathname that identifies a specific file. A file pathname includes a filename, filename extension, and whatever partition and directory specification is necessary.

**file reference**

See fileref.

**file specification**

1. the name of an external file. This name is the name by which the host operating environment recognizes the file. On directory-based systems, the file specification can be either the complete pathname or the relative pathname from the current working directory.
2. the pathname or fileref required to identify a file in a SAS command or statement. See also file pathname and fileref.

**fileref**

a name temporarily assigned to an external file or to an aggregate storage location that identifies it to SAS. You assign a fileref with a FILENAME statement or with an
operating environment command. Do not confuse filerefs with librefs. Filerefs are used for external files; librefs are used for SAS data libraries. See also libref.

**first-level name**

See libref.

**FIRST:**variable

a temporary variable that SAS creates to identify the first observation of each BY group. The variable is not added to the SAS data set. See also LAST:**variable**.

**foreground processing**

a type of processing in which you interact with the computer while the process is executing. See also background processing.

**format**

an instruction SAS uses to display or write each value of a variable. Some formats are supplied by SAS software. Other formats can be written by the user with the FORMAT procedure in Base SAS. See also user-written format.

**format modifier**

1. a special symbol used in the INPUT and PUT statements that enables you to control the way SAS reads input data and writes output data.
2. in the TABULATE procedure, an element of the form \( F=\text{format} \) that can be crossed in a dimension expression to indicate how the values in cells should be formatted.

**format, variable**

See format.

**formatted input**

a style of input that uses special instructions called informats in the INPUT statement to determine how values entered in data fields should be interpreted. See also informat.

**formatted output**

a style of output that uses special instructions called formats in the PUT statement to determine how to write variable values. See also format.

**function**

in Base SAS, a routine that can accept arguments, perform an operation, and return a value. For example, the ABS function returns the absolute value of a numeric argument. Functions can return either numeric or character results. Some functions are included with SAS.

**global command**

a command valid in all windows for a given SAS software product.

**global macro variable**

a macro variable that, once created, can be referenced in any referencing environment in a SAS program, except where blocked by a local macro variable of the same name. A global macro variable exists until the end of the session or program. See also macro variable.

**global option**

See system option.

**group**

in Program Manager, a collection of applications, such as Main or Accessories. You can run SAS by adding it to a group.
group variable

1. in the REPORT procedure, a variable that orders the detail rows in a report according to their formatted values and consolidates multiple observations that have a unique combination of values for all group variables into one row.
2. a variable in the input data set that is used to categorize chart variable values into groups.

header

in the REPORT procedure, a string of characters that spans the top of one or more columns in the report. A header can occupy multiple lines. See also heading and split character.

header routine

a group of DATA step statements that produces page headers in print files. You identify with the HEADER= option in the FILE statement. A header routine begins with a statement label and ends with a RETURN statement.

heading

1. in reporting procedures, a label that describes the contents of some portion of the table. This includes page, row, and column headings in the TABULATE procedure and column headings in many other procedures. See also header.
2. in SAS output, the text located near the beginning of each page of output. This includes text produced by a HEADER= option in a FILE statement, titles written with a TITLE statement, and default information such as date and page numbers.

host

the operating environment that provides facilities, computer services, and the environment for software applications.

identification variable

in Proc GMAP, a variable common to both the map data set and the response data set that the procedure uses to associate each pair of map coordinates and each response value with a unique map area.

index

1. a component of a SAS data set that enables SAS to access observations in the SAS data set quickly and efficiently. The purpose of SAS indexes is to optimize WHERE-clause processing and facilitate BY-group processing.
2. a component of a SAS data set that contains the data values of a key variable or variables paired with a location identifier for the observation containing the value. The value/identifier pairs are ordered in a structure that enables SAS to search by a value of a variable. See also composite index and simple index.

informat

an instruction that SAS uses to read raw data values to create variable values. Some informats are supplied by SAS software. Other informats can be written by the user with the FORMAT procedure in Base SAS. See also user-written informat.

informat, variable

See informat.

input buffer

the temporary area of memory into which each record of data is read when the INPUT statement executes. Note that the input buffer is a logical concept independent of physical implementation.
interactive line mode
a method of running SAS programs in which you enter one line of a SAS program at a time at the SAS session prompt. SAS processes each line immediately after you press the ENTER or RETURN key. Procedure output and informative messages are returned directly to the display monitor.

interleaving
a process in which SAS combines two or more sorted SAS data sets into one sorted SAS data set based on the values of the BY variables. See also merging and concatenating.

item
in the REPORT procedure, a data set variable, a statistic, or a computed variable. An item can occupy one or more columns in a report. Under some circumstances, multiple items can share a column.

label
in Base SAS, data set label, statement label, label, and variable.

label assignment
in the TABULATE procedure, a method of changing the default heading for a page, row, or column by assigning the new heading in the TABLE statement. A label assignment can change the name of a class or analysis variable or the name of a statistic, but it cannot change the values of a class variable. You use the LABEL statement to assign labels.

label, variable
a descriptive label of up to 40 characters that can be printed in the output by certain procedures instead of, or in addition to, the variable name.

LAST. variable
a temporary variable that SAS creates to identify the last observation of each BY group. This variable is not added to the SAS data set. See also FIRST. variable.

length, variable
the number of bytes used to store each of a variable's values in a SAS data set.

library reference
See libref.

libref
the name temporarily associated with a SAS data library. For example, in the name SASUSERS.ACCOUNTS, the name SASUSER is the libref. You assign a libref with a LIBNAME statement or with operating environment control language. See also first-level name.

line mode
See interactive line mode.

line-hold specifier
a special symbol used in INPUT and PUT statements that enables you to hold a record in the input or output buffer for further processing. Line-hold specifiers include the trailing at sign (@) and the double trailing at sign (@@).

list input
a style that supplies variable names, not column locations, in the INPUT statement to scan input records for data values separated by at least one blank or other delimiter.

list input, modified
a style that uses special instructions called informats and format modifiers in the INPUT statement to scan input records for data values that are separated by at least one blank or other delimiter, and in some cases, by two blanks.
list input, simple
a style that gives only variable names and dollar signs ($) in the INPUT statement to scan input records for data values that are separated by at least one blank or other delimiter.

list output
a style in which a character string or variable is specified in a PUT statement without explicit directions that specify where SAS should place the string or value.

literal
any character or numeric value in a SAS program that is not the value of a variable, but the literal value of numbers or characters representing it. Character literals are usually enclosed in quotes. See also numeric constant.

logical operator
an operator used in expressions to link sequences of comparisons. The logical operators are AND, OR, and NOT.

macro facility
a portion of Base SAS that you can use for extending and customizing your SAS programs and for reducing the amount of text that must be entered to do common tasks. It consists of the macro processor and the macro language.

macro invocation
an instruction to the macro processor to execute a macro; it is also known as a macro call. A macro invocation can be either name-style (%name) or statement-style (name;) depending on how the macro was defined.

macro language
the programming language used to communicate with the macro processor.

macro variable
a variable belonging to the macro language whose value is a string that remains constant until you change it. A macro variable is also called a symbolic variable.

macro variable reference
the name of a macro variable preceded by an ampersand (&) that the macro processor replaces with the value of the macro variable named.

master data set
in an update operation, the data set containing the information you want to update. See also transaction data set.

match-merging
a process in which SAS joins observations from two or more SAS data sets according to the values of the BY variables. See also one-to-one merging.

member
a SAS file in a SAS library.

member type
a name assigned by SAS that identifies the type of information stored in a SAS file. Member types include ACCESS, DATA, CATALOG, PROGRAM, and VIEW.

merging
the process of combining observations from two or more SAS data sets into a single observation in a new SAS data set. See also match-merging and one-to-one merging.

methods of running the SAS System
standard methods of operation used to run SAS System programs. These methods are the SAS windowing environment, SAS/ASSIST software, interactive line mode, noninteractive mode, and batch mode.
missing value
a value that indicates that no data are stored for the variable in the current observation. By default, SAS prints a missing numeric value as a single period (.) and a missing character value as a blank space.

mnemonic operator
an arithmetic or logical (Boolean) operator composed of letters rather than symbols (for example, EQ rather than =).

multi-panel report
output that uses sets of columns on a page to display the values of variables. For example, telephone books are usually arranged in multi-panels of names, addresses, and phone numbers on a single page.

name, variable
the identifying attribute of a variable. A variable name must conform to SAS naming rules.

named input
a style in which equal signs appear in the INPUT statement to read data values in the form variable=data-value.

named output
a style in which equal signs appear in the PUT statement to write variable values in the form variable=data-value.

noninteractive mode
a method of running SAS programs in which you prepare a file of SAS statements and submit the program to the operating environment. The program runs immediately and occupies your current session.

nonstandard data
data that SAS can read or write only with the aid of informats or formats. Examples of nonstandard data are hexadecimal or binary values.

null statement
a statement consisting of a single semicolon or four semicolons, most commonly used to designate the end of instream data in a DATA step.

null value
1 a special value that means absence of information. It is analogous to a SAS missing value.
2 in the SAS macro language, a value consisting of zero characters.

numeric constant
a number that appears in a SAS expression. See also literal.

numeric format
an instruction to SAS to write numeric variable values using a specific pattern.

numeric informat
an instruction to SAS to read numeric data values using a specific pattern.

numeric value
a value that usually contains only numbers, including numbers in E-notation and hexadecimal notation. A numeric value can sometimes contain a decimal point, plus sign, or minus sign. Numeric values are stored in numeric variables.

numeric variable
a variable that can contain only numeric values. By default, SAS stores all numeric variables in floating-point representation.
**observation**

1. a row in a SAS data set. An observation is a collection of data values associated with a single entity, such as a customer or state. Each observation contains one data value for each variable.
2. the horizontal component of a SAS data file. An observation is a collection of data values associated with a single entity, such as a customer or state. Each observation contains one data value for each variable in the data file.

**observation number**

a number indicating the relative position of an observation in a SAS data set when you read the entire data set sequentially. This number is not stored internally. See also record ID.

**ODS**

See Output Delivery System.

**one-to-one matching**

the process of combining observations from two or more data sets into one observation using two or more SET statements to read observations independently from each data set. See also match-merging.

**one-to-one merging**

the process of using the MERGE statement (without a BY statement) to combine observations from two or more data sets based on the observations’ positions in the data sets. See also match-merging.

**output buffer**

in the DATA step, the area of memory to which a PUT statement writes before writing to a designated file or output device.

**Output Delivery System (ODS)**

a system that can produce output in a variety of formats such as HTML, PDF, Listing, PostScript, and a SAS data set.

**output object**

a combination of procedure or DATA step output and a table definition. An output object tells the Output Delivery System how to format the output.

**padding a value with blanks**

in SAS, a process in which the software adds blanks to the end of a character value that is shorter than the length of the variable.

**period**

the default character that SAS uses to print or display a missing value for a numeric variable.

**permanent SAS data library**

a library that is not deleted when the SAS session terminates; it is available for subsequent SAS sessions. Unless the USER libref is defined, you use a two-level name to access a file in a permanent library. The first-level name is the libref, and the second-level name is the member name.

**permanent SAS data set**

a data set that remains after the current program or interactive SAS session terminates. Permanent SAS data sets are available for future SAS sessions.

**permanent SAS file**

a file in a SAS data library that is not deleted when the SAS session or job terminates.
**physical filename**
the name that the operating environment uses to identify a file.

**pointer**
in the DATA step, a programming tool that SAS uses to keep track of its position in the input or output buffer.

**pointer control**
the process of instructing SAS to move the pointer before reading or writing data.

**print file**
an external file containing carriage-control (printer-control) information. See also carriage-control character and external file.

**PROC step**
a group of SAS statements that call and execute a procedure, usually with a SAS data set as input.

**procedure**
See SAS procedure.

**PROFILE catalog**
a SAS catalog in a special SAS data library that contains information used by the SAS System to control various aspects of your display manager session. See also SASUSER library.

**program data vector**
the temporary area of memory, or storage area, where SAS builds a SAS data set, one observation at a time. Note that the program data vector is a logical concept that is independent of physical implementation.

**programming error**
a flaw in the logic of a SAS program that can cause it to fail or to perform differently than the programmer intended. See also syntax error.

**propagation of missing values**
a consequence of using missing values in which a missing value in an arithmetic expression causes SAS to set the result of the expression to missing. Using that result in another expression causes the next result to be missing, and so on.

**raw data**
data that has not been read into a SAS data set. See also data lines and raw data file.

**raw data file**
an external file whose records contain data values in fields. A DATA step can read a raw data file by using the INFILE and INPUT statements.

**record**
a logical unit of information consisting of fields of related data. A collection of records makes up a file. A record is analogous to a SAS observation or a row in a SAS data set.

**SAS catalog**
a SAS file that stores many different kinds of information in smaller units called catalog entries. A single SAS catalog can contain several different types of catalog entries.

**SAS catalog entry**
a separate storage unit within a SAS catalog. Each entry has an entry type that identifies its purpose to SAS. Some catalog entries contain system information such as key definitions. Other catalog entries contain application information such as
window definitions, help windows, formats, informats, macros, or graphics output. See also entry type.

**SAS command**
a command that invokes SAS software. This command may vary depending on operating environment and site. See also SAS invocation.

**SAS compilation**
the process of converting statements in the SAS language from the form in which you enter them into a form ready for SAS software to use.

**SAS data file**
a SAS data set that contains both data values and descriptor information associated with the data, such as the variable attributes. SAS files have the type DATA. See also SAS data set and SAS data view.

**SAS data library**
a collection of one or more SAS files that are recognized by SAS software and that are referenced and stored as a unit. Each file is a member of the library.

**SAS data set**
descriptor information and its related data values organized as a table of observations and variables that can be processed by SAS. A SAS data set can be either a SAS data file or a SAS data view.

**SAS data set option**
an option that appears in parentheses after a SAS data set name. Data set options specify actions that apply only to the processing of that SAS data set. See also SAS system option.

**SAS data view**
a SAS data set in which the descriptor information and the observations are obtained from other files. A SAS data view contains only the descriptor and other information required to retrieve the data values from other SAS files. Both PROC SQL views and SAS/ACCESS views are considered SAS data views. SAS data views are of member type VIEW. See also SAS data set and SAS data file.

**SAS date constant**
a string in the form `'ddMMMyy'd or 'ddMMMyyyy'd representing a date in a SAS statement. The string should be enclosed in quotes and followed by the character d (for example '06JUL2001'd).

**SAS date value**
an integer representing a date in SAS software. The integer represents the number of days between January 1, 1960, and another specified date. (For example, the SAS date value 366 represents the calendar date January 1, 2001.)

**SAS datetime constant**
a string in the form `'ddMMMyy:hh:mm:ss'dt or 'ddMMMyyyy:hh:mm:ss'dt representing a date and time in SAS. The string should be enclosed in quotes and followed by the characters dt (for example, '06JUL2001:09:53:22'dt).

**SAS datetime value**
an integer representing a date and time in SAS. The integer represents the number of seconds between midnight, January 1, 1960, and another specified date and time. (For example, the SAS datetime value for 9:30 a.m., June 5, 2000, is 928661400.)

**SAS Display Manager System**
an interactive, windowing interface to SAS System software. Display manager commands can be issued by typing them on the command line, pressing function keys, or selecting items from the PMENU facility. Within one session, many different
tasks can be accomplished, including preparing and submitting programs, viewing and printing results, and debugging and resubmitting programs.

**SAS Editor**
a text-editing facility available in some windows of the SAS windowing environment, as well as in windows of SAS/AF, SAS/FSP, and SAS/GRAPH software.

**SAS expression**
a sequence of operands and operators forming a set of instructions that SAS performs to produce a result value. A single variable name, constant, or function is also a SAS expression.

**SAS file**
a specially structured file that is created, organized, and, optionally, maintained by SAS. A SAS file can be a SAS data set, a catalog, a stored program, or an access descriptor.

**SAS initialization**
the setting of global characteristics that must be in place at start-up for a SAS programming environment. SAS performs initialization by setting certain SAS system options called initialization options. Invoking SAS software initiates SAS initialization. See also SAS invocation.

**SAS invocation**
the process of calling or starting up SAS software by an individual user through execution of the SAS command. Invoking SAS initiates SAS initialization. See also SAS initialization.

**SAS keyword**
a literal that is a primary part of the SAS language. Keywords are statement names, function names, command names, macro statement names, and macro function names.

**SAS language**
1 a programming language used to manage data.
2 as a grouping in SAS documentation, all parts of Base SAS except procedures and the windowing environment.

**SAS log**
a file that contains the SAS statements you have submitted, messages about the execution of your program, and in some cases, output from the DATA step and from certain procedures.

**SAS name**
a name whose construction follows certain rules and that can appear in a SAS statement (for example, names of variables and SAS data sets).

**SAS print file**
an obsolete term that refers to an external file to which a DATA step or a SAS procedure writes output that contains, by default, carriage-control characters, titles, footnotes, and page numbers. Do not use this term. It blurs the distinction between SAS files and external files. Instead, use the term "procedure output file."

**SAS procedure**
a program accessed with a PROC statement that produces reports, manages files, or analyzes data. Many procedures are included in SAS software.

**SAS procedure output file**
an obsolete term that makes an external file sound like a SAS file. Use the term "procedure output file" when you need to refer to the destination instead of to the procedure output itself.
SAS program
a group of SAS statements that guide SAS through a process or series of processes.

SAS session
an environment created by invoking SAS in which you can give commands, submit SAS statements, receive responses to the commands, and receive results of the SAS statements until you exit the environment or until the environment is terminated.

SAS Software Consultant
an individual at your computing installation who is designated as a support person for SAS software users at the installation. The consultant can help you with questions about using SAS software.

SAS Software Representative
an individual at your computing installation who is designated as SAS Institute’s contact for information on new and existing software. The representative receives any distribution package of software from SAS.

SAS statement
a string of SAS keywords, SAS names, and special characters and operators ending in a semicolon that instructs SAS to perform an operation or that gives information to SAS.

SAS system option
an option that affects processing the entire SAS program or interactive SAS session from the time the option is specified until it is changed. Examples of items controlled by SAS system options include appearance of SAS output, handling of some files used by SAS, use of system variables, processing observations in SAS data sets, features of SAS System initialization, and the way SAS interacts with your computer hardware and with the host operating environment.

SAS time constant
a string in the form ‘hh: mm : ss’t representing a time in a SAS statement. The string should be enclosed in quotes and followed by the character t (for example, ‘09:53:22’t).

SAS time value
an integer representing a time in SAS software. The integer represents the number of seconds between midnight of the current day and another specified time value. (For example, the SAS time value for 9:30 a.m. is 34200.)

SAS windowing environment
See SAS Display Manager System.

SASUSER library
a default permanent SAS data library that is created at the beginning of your first SAS session. It contains a PROFILE catalog that stores the tailoring features you specify for SAS. You can also store other SAS files in this library. See also PROFILE catalog and SAS data library.

selection field
the portion of a window (shown on the display as an underscore) where you can enter a short command to perform an action, such as B for browse.

selection-field command
a command that enables you to perform actions from a selection field in a SAS windowing environment. For example, entering D in the selection field beside the name of a SAS data set in the DIRECTORY window enables you to delete that SAS data set.

simple expression
a SAS expression that uses only one operator.
simple index
an index that locates observations by the values of one variable. See also composite index and index.

site number
the number used by SAS to identify the site to which SAS software is licensed. The site number appears near the top of the log in every SAS session.

split character
in some SAS procedures, a character that splits headers across multiple lines. If you use the split character in a column header, the procedure breaks the header when it reaches that character and continues the header on the next line. The split character itself is not part of the column header.

standard data
data that are stored with one digit or character per byte.

statement label
a SAS name followed by a colon that prefixes a statement in a DATA step so that other statements can direct execution to that statement as necessary, bypassing other statements in the step.

statement option
a word you specify in a given SAS statement that affects only the processing that statement performs.

step boundary
a point in a SAS program when SAS recognizes that a DATA step or PROC step is complete.

sum statement
a DATA step statement that adds the result of the expression on the right side of the plus sign to the accumulator variable on the left side of the plus sign. A sum statement has the following form: \texttt{variable + expression};

summary table
output that provides a concise overview of the information in a data set.

syntax checking
the process by which SAS checks each SAS statement for proper usage, correct spelling, proper SAS naming conventions, and so on.

syntax error
an error in the spelling or grammar of a SAS statement. SAS finds syntax errors as it compiles each SAS step before execution.

system option
See SAS system option.

table definition
a set of instructions that describes how to format output in the Output Delivery System.

temporary SAS data library
a library that exists only for the current SAS session or job. The most common temporary library is the WORK library. See also WORK library.

temporary SAS data set
a data set that exists only for the duration of the current program or interactive SAS session. Temporary SAS data sets are not available for future SAS sessions.
temporary SAS file
   a SAS file in a SAS data library (usually the WORK library) that is deleted at the end of the SAS session or job.

text-editing command
   a command specific to the text editor.

title
   in SAS, a heading printed at the top of each page of SAS output or of the SAS log.

toggle
   an option, parameter, or other mechanism that enables you to turn on or turn off a processing feature.

trailing at sign (@)
   a special symbol used to hold a line so that you can read from it or write to it with another INPUT or PUT statement.

transaction data set
   in an update operation, the data set containing the information needed to update the master data set. See also master data set.

type, variable
   See variable type.

updating
   a process in which SAS replaces the values of variables in the master data set with values from observations in the transaction data set.

user-written format
   a format you define with the FORMAT procedure. See also format.

user-written informat
   an informat you define with the FORMAT procedure. See also informat.

variable
   a column in a SAS data set. A variable is a set of data values that describe a given characteristic across all observations. See also macro variable.

variable attributes
   the name, label, format, informat, type, and length associated with a particular variable.

variable list
   a list of variables. You can use abbreviated variable lists in many SAS statements instead of listing all the variable names.

variable type
   the classification of a variable as either numeric or character. Type is an attribute of SAS variables.

WHERE expression
   a type of SAS expression used to specify a condition for selecting observations for processing by a DATA or PROC step. WHERE expressions can contain special operators not available in other SAS expressions. WHERE expressions can appear in a WHERE statement, a WHERE= data set option, a WHERE clause, or a WHERE command. See also SAS expression and WHERE processing.

WHERE processing
   a method of conditionally selecting observations for processing in a DATA or PROC step. WHERE processing involves using a WHERE expression in a WHERE statement, a WHERE= data set option, a WHERE clause, or a WHERE command. See also WHERE expression.
**WORK library**
the SAS data library automatically defined by SAS at the beginning of each SAS session or SAS job. It contains SAS files that are temporary by default. When the libref USER is not defined, SAS uses WORK as the default library for SAS files created with one-level names.

**WORK library**
See WORK library.

SAS® Publishing delivers!

Whether you are new to the workforce or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS® Publishing provides you with a wide range of resources to help you set yourself apart.

**SAS® Press Series**

Need to learn the basics? Struggling with a programming problem? You’ll find the expert answers that you need in example-rich books from the SAS Press Series. Written by experienced SAS professionals from around the world, these books deliver real-world insights on a broad range of topics for all skill levels. [support.sas.com/saspress](http://support.sas.com/saspress)

**SAS® Documentation**

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information—SAS documentation. We currently produce the following types of reference documentation: online help that is built into the software, tutorials that are integrated into the product, reference documentation delivered in HTML and PDF—free on the Web, and hard-copy books. [support.sas.com/publishing](http://support.sas.com/publishing)

**SAS® Learning Edition 4.1**

Get a workplace advantage, perform analytics in less time, and prepare for the SAS Base Programming exam and SAS Advanced Programming exam with SAS® Learning Edition 4.1. This inexpensive, intuitive personal learning version of SAS includes Base SAS® 9.1.3, SAS/STAT®, SAS/GRAPH®, SAS/QC®, SAS/ETS®, and SAS® Enterprise Guide® 4.1. Whether you are a professor, student, or business professional, this is a great way to learn SAS. [support.sas.com/LE](http://support.sas.com/LE)
