What's New in the SAS 9.3 XML LIBNAME Engine

Overview

In SAS 9.3, the engine nickname to access the enhanced XML LIBNAME engine functionality is **XMLV2**. The previous nickname—**XML92**—is supported as an alias.

In SAS 9.3, XMLV2 functionality is production, except in the z/OS environment, where it is preproduction.

The XMLMap syntax for version 2.1 now supports XML namespaces.

Enhanced LIBNAME Statement

The LIBNAME statement for XMLV2 no longer supports the WSDL markup type for the XMLTYPE= option.

Updated XMLMap Functionality

XMLMap syntax is updated to version 2.1 with the following enhancements:

- XMLV2 supports XML namespaces in an XMLMap. XML namespaces distinguish element and attribute names by qualifying them with Uniform Resource Identifier (URI) references. See [“Elements for Namespaces” on page 114](#).
- If an XML namespace is defined in the XMLMap, all elements that specify a location path support the XML namespace definition. Specify the type of syntax as XPathENR, include the identification number for the XML namespace in the location path preceding the appropriate element, and enclose the identification number in braces. See [PATH syntax="type" on page 125](#).
- For the COLUMN element, the ordinal= attribute, which determines whether the variable is a counter variable, is no longer supported. The functionality is provided with the class="ORDINAL" attribute. For details, see the [COLUMN element on page 120](#).

What Does the XML LIBNAME Engine Do?

The XML LIBNAME engine processes an *XML document*. The engine can:

- export (write to an output location) an XML document from a SAS data set of type DATA by translating the SAS proprietary file format to XML markup. The output XML document can then be:
 - used by a product that processes XML documents.
 - moved to another host for the XML engine to process by translating the XML markup back to a SAS data set.
- import (read from an input location) an external XML document. The input XML document is translated to a SAS data set.

Understanding How the XML LIBNAME Engine Works

Assigning a Libref

The XML LIBNAME engine works much like other SAS engines. That is, you execute a LIBNAME statement in order to assign a libref and specify an engine. You use that libref throughout the SAS session where a libref is valid.

A libref for the XML LIBNAME engine can be associated with either a specific XML document or, for the XMLV2 engine nickname, the physical location of a SAS library in a directory-based environment. When you use the libref, SAS either translates the data in a SAS data set into XML markup, or translates the XML markup into SAS format.

Importing an XML Document

To import an XML document as a SAS data set, the following LIBNAME statement assigns a libref to a specific XML document and specifies the XML engine:

```
libname myxml xml 'C:\My Files\XML\Students.xml';
```

Executing the DATASETS procedure shows that SAS interprets the XML document as a SAS data set:

```
proc datasets library=myxml;
```

Display 1.1 DATASETS Procedure Output for MYXML Library

The screenshot shows the output of the DATASETS procedure for the MYXML library. It consists of two tables. The first table, titled 'Directory', lists the following properties: Libref (MYXML), Engine (XML), Physical Name (C:\My Files\XML\Students.xml), XMLType (GENERIC), and XMLMap (NO XMLMAP IN EFFECT). The second table lists the members of the library, with one member named 'STUDENTS' of type 'DATA'.

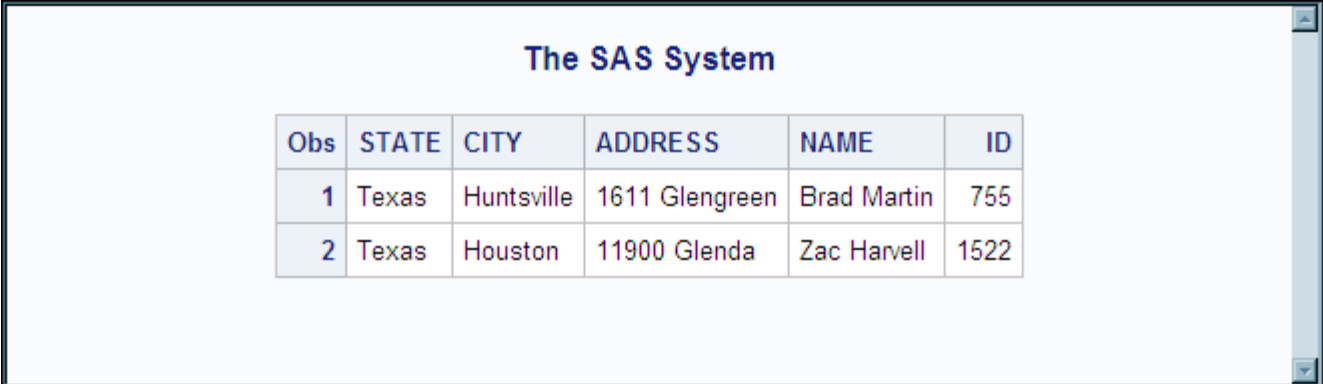

Directory	
Libref	MYXML
Engine	XML
Physical Name	C:\My Files\XML\Students.xml
XMLType	GENERIC
XMLMap	NO XMLMAP IN EFFECT

#	Name	Member Type
1	STUDENTS	DATA

The PRINT procedure results in the following output:

```
proc print data=myxml.students;
run;
```

Display 1.2 PRINT Procedure Output for MYXML.STUDENTS

Obs	STATE	CITY	ADDRESS	NAME	ID
1	Texas	Huntsville	1611 Glengreen	Brad Martin	755
2	Texas	Houston	11900 Glenda	Zac Harvell	1522

Exporting an XML Document

To export an XML document from a SAS data set, the LIBNAME statement for the XML engine assigns a libref to the XML document to be created.

In the following code, the first LIBNAME statement assigns the libref MYFILES to the SAS library that contains the SAS data set Singers. The second LIBNAME statement assigns the libref MYXML to the physical location of the XML document that is to be exported from Myfiles.Singers:

```
libname myfiles 'C:\My Files\';

libname myxml xml 'C:\My Files\XML\Singers.xml';
```

Executing these statements creates the XML document named Singers.XML:

```
data myxml.Singers;
  set myfiles.Singers;
run;
```

Output 1.1 XML Document Singers.XML

```
<?xml version="1.0" encoding="windows-1252" ?>
<TABLE>
  <SINGERS>
    <FirstName> Tom </FirstName>
    <Age> 62 </Age>
  </SINGERS>
  <SINGERS>
    <FirstName> Willie </FirstName>
    <Age> 70 </Age>
  </SINGERS>
  <SINGERS>
    <FirstName> Randy </FirstName>
    <Age> 43 </Age>
  </SINGERS>
</TABLE>
```

SAS Processing Supported by the XML Engine

The XML engine supports the following processing:

- The XML engine supports input (read) and output (create) processing. The XML engine does not support update processing.
- The XML engine is a sequential access engine in that it processes data one record after the other. The engine starts at the beginning of the file and continues in sequence to the end of the file. The XML engine does not provide random (direct) access, which is required for some SAS applications and features. For example, with the XML engine, you cannot use the SORT procedure or ORDER BY in the SQL procedure. If you request processing that requires random access, a message in the SAS log notifies you that the processing is not valid for sequential access. If this message occurs, put the XML data into a temporary SAS data set before you continue.

Transferring an XML Document across Environments

When you transfer an XML document across environments (for example using FTP), you must be aware of the document's content in order to determine the appropriate transfer mode. If the document contains either an encoding attribute in the XML declaration or if a byte order mark precedes the XML declaration, transfer the file in binary mode. If the document contains neither criteria and you are transferring the document across similar hosts, transfer the file in text mode.

When you export an XML document using the XML engine, by default, the XML document contains an encoding attribute in the XML declaration from the SAS data set's encoding (for example, `<?xml version="1.0" encoding="windows-1252" ? >`). You can override the SAS data set's encoding when you export the XML document by specifying the `XMLENCODING= LIBNAME` statement option.

Frequently Asked Questions

Is the XML Engine a DOM or SAX Application?

The XML engine uses a Simple API for XML (SAX) model, not a Document Object Model (DOM). SAX does not provide a random-access lookup to the document's contents. It scans the document sequentially and presents each item to the application one item at a time.

Does the XML Engine Validate an XML Document?

The XML engine does not validate an input XML document. The engine assumes that the data passed to it is in valid, well-formed XML markup. Because the engine does not

use a DTD (Document Type Definition) or SCHEMA, there is nothing to validate against.

What Is the Difference between Using the XML Engine and the ODS MARKUP Destination?

The XML engine creates and reads XML documents. ODS MARKUP creates, but does not read XML documents. Typically, you use the XML engine to transport data, and you use the ODS MARKUP destination to create XML from SAS output.

Why Do I Get Errors When Importing XML Documents Not Created with SAS?

The XML engine reads only files that conform to the markup types supported in the XMLTYPE= LIBNAME statement option. Attempting to import free-form XML documents that do not conform to the specifications required by the supported markup types will generate errors. To successfully import files that do not conform to the XMLTYPE= markup types, you can create a separate XML document, called an XMLMap. The XMLMap syntax tells the XML engine how to interpret the XML markup into a SAS data set or data sets, variables (columns), and observations (rows). See [“Importing XML Documents Using an XMLMap” on page 45](#).

What Are the XML Engine Nicknames?

SAS provides two versions of XML LIBNAME engine functionality by supporting the engine nicknames **XML** and **XMLV2** in the LIBNAME statement. See [“Understanding the XML LIBNAME Engine Versions: XML and XMLV2” on page 91](#).

Accessibility Features of the XML LIBNAME Engine

The XML LIBNAME engine is a command-based product. For this release, no features were added to address accessibility, but the product might be compliant to accessibility standards because it does not have a graphical user interface, and all of its features are available to anyone who can type or otherwise produce a command. If you have specific questions about the accessibility of SAS products, send them to accessibility@sas.com or call SAS Technical Support.

Chapter 2

Exporting XML Documents

Understanding How to Export an XML Document	9
Exporting an XML Document for Use by Oracle	9
Exporting an XML Document Containing SAS Dates, Times, and Datetimes	11
Exporting Numeric Values	13
Exporting an XML Document with Separate Metadata	17
Exporting an XML Document in CDISC ODM Markup	21

Understanding How to Export an XML Document

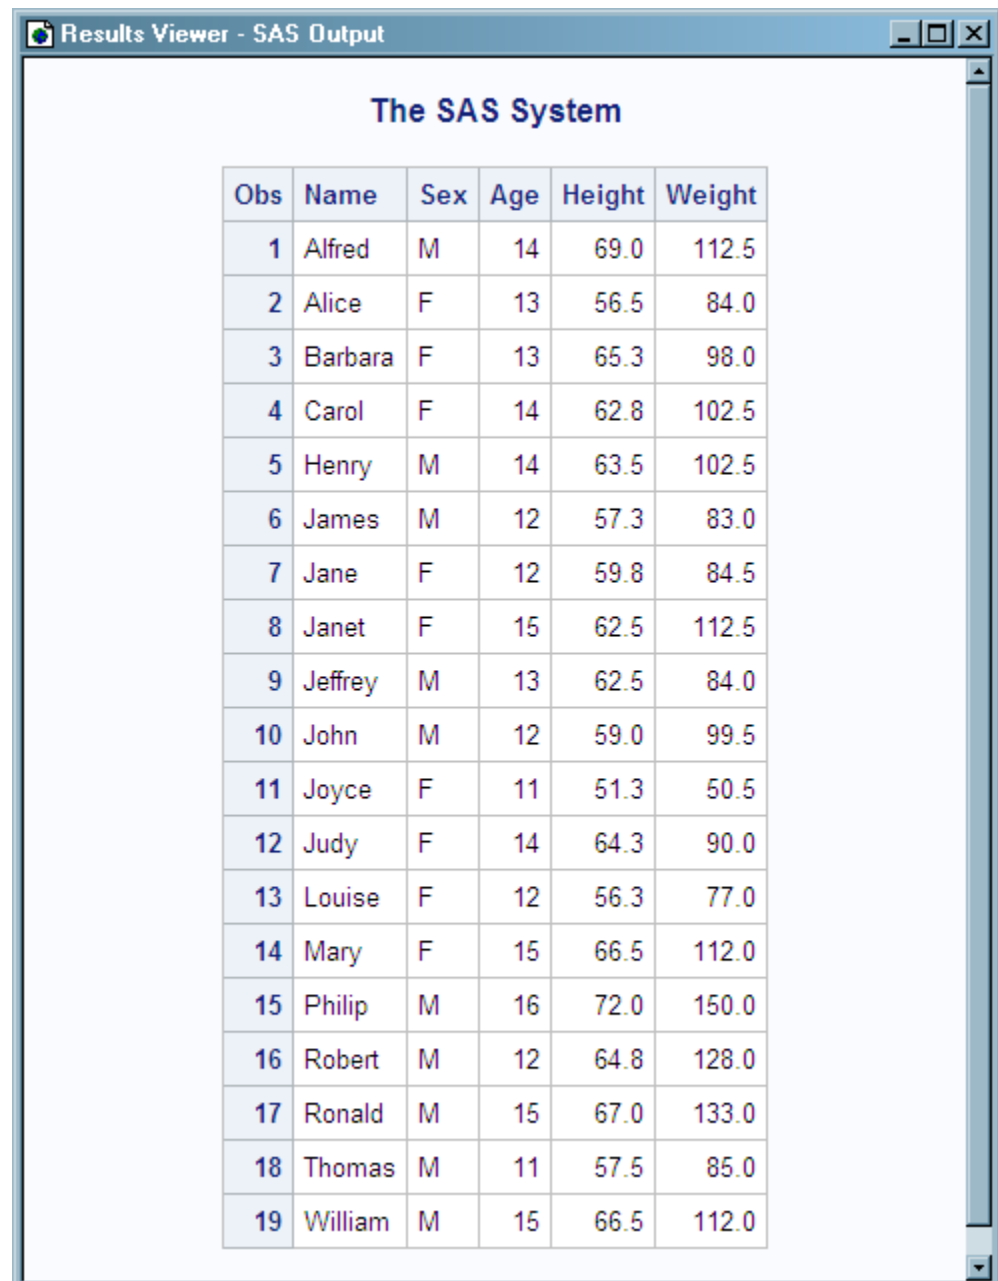

Exporting an XML document is the process of writing a SAS data set of type DATA to an output XML document. The XML engine exports an XML document by translating SAS proprietary format to XML markup.

To export an XML document, you execute the LIBNAME statement for the XML engine in order to assign a libref to the physical location of an XML document to be created. Then, you execute SAS code that produces output such as a DATA step or the COPY procedure.

Exporting an XML Document for Use by Oracle

This example exports an XML document from a SAS data set for use by Oracle. By specifying the ORACLE markup type, the XML engine generates tags that are specific to Oracle standards.

The following output shows the SAS data set MYFILES.CLASS to be exported to Oracle.

Display 2.1 SAS Data Set MYFILES.CLASS

The screenshot shows a window titled "Results Viewer - SAS Output". Inside the window, there is a table titled "The SAS System". The table has six columns: Obs, Name, Sex, Age, Height, and Weight. It contains 19 rows of data, numbered 1 through 19. The data is as follows:

Obs	Name	Sex	Age	Height	Weight
1	Alfred	M	14	69.0	112.5
2	Alice	F	13	56.5	84.0
3	Barbara	F	13	65.3	98.0
4	Carol	F	14	62.8	102.5
5	Henry	M	14	63.5	102.5
6	James	M	12	57.3	83.0
7	Jane	F	12	59.8	84.5
8	Janet	F	15	62.5	112.5
9	Jeffrey	M	13	62.5	84.0
10	John	M	12	59.0	99.5
11	Joyce	F	11	51.3	50.5
12	Judy	F	14	64.3	90.0
13	Louise	F	12	56.3	77.0
14	Mary	F	15	66.5	112.0
15	Philip	M	16	72.0	150.0
16	Robert	M	12	64.8	128.0
17	Ronald	M	15	67.0	133.0
18	Thomas	M	11	57.5	85.0
19	William	M	15	66.5	112.0

The following SAS program exports an XML document from the SAS data set MYFILES.CLASS:

```
libname myfiles 'SAS-library'; 1

libname trans xml 'XML-document' xmltype=oracle; 2

data trans.class; 3
  set myfiles.class;
run;
```

- 1 The first LIBNAME statement assigns the libref MYFILES to the physical location of the SAS library that stores the SAS data set CLASS. The V9 engine is the default.

- 2 The second LIBNAME statement assigns the libref TRANS to the physical location of the file (complete pathname, filename, and file extension) that will store the exported XML document and specifies the XML engine. The engine option XMLTYPE=ORACLE produces tags that are equivalent to the Oracle 8i XML implementation.
- 3 The DATA step reads the SAS data set MYFILES.CLASS and writes its content in ORACLE XML markup to the specified XML document.

Here is the resulting XML document.

Output 2.1 XML Document Exported from MYFILES.CLASS to Be Used by Oracle

```

<?xml version="1.0" encoding="windows-1252" ?>
<ROWSET>
  <ROW>
    <Name> Alfred </Name>
    <Gender> M </Gender>
    <Age> 14 </Age>
    <Height> 69 </Height>
    <Weight> 112.5 </Weight>
  </ROW>
  <ROW>
    <Name> Alice </Name>
    <Gender> F </Gender>
    <Age> 13 </Age>
    <Height> 56.5 </Height>
    <Weight> 84 </Weight>
  </ROW>
  .
  .
  .
  <ROW>
    <Name> William </Name>
    <Gender> M </Gender>
    <Age> 15 </Age>
    <Height> 66.5 </Height>
    <Weight> 112 </Weight>
  </ROW>
</ROWSET>

```

Exporting an XML Document Containing SAS Dates, Times, and Datetimes

This example exports an XML document from a SAS data set that contains datetime, date, and time values. The XML document is generated for the GENERIC markup type.

First, the following SAS program creates a simple SAS data set and prints the contents of the data set. The variable DateTime contains a datetime value, Date contains a date value, and Time contains a time value.

```

data test;
  DateTime=14686;
  format DateTime datetime.;
  Date=14686;
  format Date date9.;

```

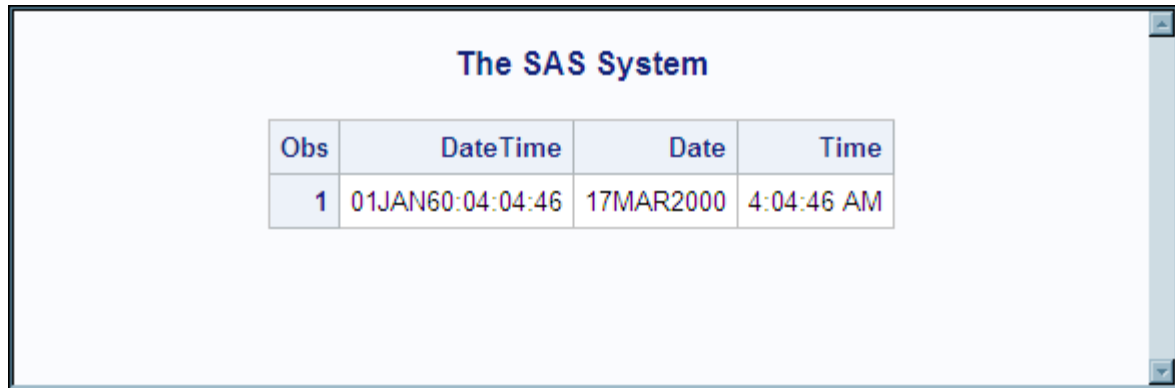

```

Time=14686;
format Time timeampm.;

proc print data=test;
run;

```

Display 2.2 PRINT Procedure Output for WORK.TEST Containing SAS Dates, Times, and Datetimes

Obs	DateTime	Date	Time
1	01JAN60:04:04:46	17MAR2000	4:04:46 AM

The following code exports an XML document for the GENERIC markup type that includes the SAS date, time, and datetime information:

```

libname trans xml 'XML-document' xmltype=generic; 1

data trans.test; 2
  set work.test;
run;

```

- 1 The LIBNAME statement assigns the libref TRANS to the physical location of the file (complete pathname, filename, and file extension) that will store the exported XML document and specifies the XML engine. XMLTYPE= specifies the GENERIC markup type, which is the default.
- 2 The DATA step reads the SAS data set WORK.TEST and writes its content in XML markup to the specified XML document.

Here is the resulting XML document.

Output 2.2 XML Document Using GENERIC Markup

```

<?xml version="1.0" encoding="windows-1252" ?>
<TABLE>
  <TEST>
    <DateTime> 1960-01-01T04:04:46.000000 </DateTime>
    <Date> 2000-03-17 </Date>
    <Time> 04:04:46 </Time>
  </TEST>
</TABLE>

```

Exporting Numeric Values

This example uses a small SAS data set, with a numeric variable that contains values with a high precision. The following SAS program creates the data set with an assigned user-defined format, and then exports two XML documents to show the difference in output:

```
libname format xml 'C:\My Documents\format.xml'; 1

libname prec xml 'C:\My Documents\precision.xml' xmldouble=internal; 2

data npi; 3
  do n=1 to 10;
    n_pi = n*3.141592653589793;
    output;
  end;
format n_pi f14.2;
run;

data format.dbltest; 4
  set npi;
run;

data prec.rawtest; 5
  set npi;
run;

title 'Drops the Precision'; 6
proc print data=format.dbltest;
  format n_pi f14.10;
run;

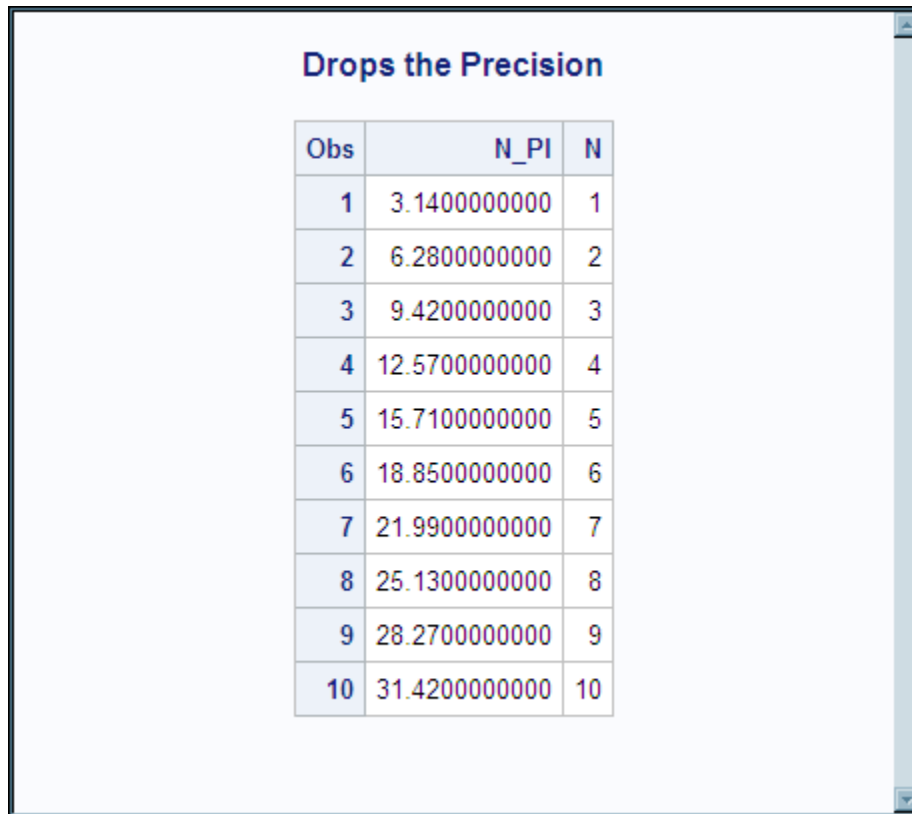

title 'Keeps the Precision'; 7
proc print data=prec.rawtest;
  format n_pi f14.10;
run;
```

- 1 The first LIBNAME statement assigns the libref FORMAT to the file that will store the generated XML document FORMAT.XML. The default behavior for the engine is that an assigned SAS format controls numeric values.
- 2 The second LIBNAME statement assigns the libref PREC to the file that will store the generated XML document PRECISION.XML. The XMLDOUBLE= option specifies INTERNAL, which causes the engine to retrieve the stored raw values.
- 3 The DATA step creates the temporary data set NPI. The data set has a numeric variable that contains values with a high precision. The variable has an assigned user-defined format that specifies two decimal points.
- 4 The DATA step creates the data set FORMAT.DBLTEST from WORK.NPI.
- 5 The DATA step creates the data set PREC.RAWTEST from WORK.NPI.
- 6 From the data set FORMAT.DBLTEST, the PRINT procedure generates the XML document FORMAT.XML, which contains numeric values controlled by the SAS format. See [Output 2.3 on page 14](#).

- 7 For the PRINT procedure output, a format was specified in order to show the precision loss. In the output, the decimals after the second digit are zeros. See [Display 2.3 on page 15](#).
- 8 From the data set PREC.RAWTEST, the PRINT procedure generates the XML document PRECISION.XML, which contains the stored numeric values. See [Output 2.4 on page 16](#).
- 9 For the PRINT procedure output, a format was specified in order to show the retained precision. See [Display 2.4 on page 17](#).

Output 2.3 XML Document FORMAT.XML

```
<?xml version="1.0" encoding="iso-8859-1" ?>

Exporting an XML Document with Separate Metadata

This example exports an XML document from a SAS data set and specifies a separate file to contain metadata-related information. The example illustrates using the XMLMETA= option and XMLSCHEMA= option and uses a SAS data set that was created from a Microsoft Access database.

First, here is the CONTENTS procedure output for the SAS data set INPUT.SUPPLIERS:

Display 2.5 CONTENTS Procedure Output for INPUT.SUPPLIERS

Alphabetic List of Variables and Attributes						
#	Variable	Type	Len	Format	Informat	Label
8	ADDRESS	Char	45	\$45.	\$45.	ADDRESS
7	CITY	Char	13	\$13.	\$13.	CITY
11	COMPANYNAME	Char	38	\$38.	\$38.	COMPANYNAME
10	CONTACTNAME	Char	26	\$26.	\$26.	CONTACTNAME
9	CONTACTTITLE	Char	28	\$28.	\$28.	CONTACTTITLE
4	COUNTRY	Char	11	\$11.	\$11.	COUNTRY
2	FAX	Char	15	\$15.	\$15.	FAX
1	HOMEPAGE	Char	94	\$94.	\$94.	HOMEPAGE
3	PHONE	Char	15	\$15.	\$15.	PHONE
5	POSTALCODE	Char	8	\$8.	\$8.	POSTALCODE
6	REGION	Char	8	\$8.	\$8.	REGION
12	SUPPLIERID	Num	8	F8.	F8.	SUPPLIERID

The following SAS program exports an XML document from the SAS data set INPUT.SUPPLIERS:

```
libname input 'c:\My Documents\myfiles'; 1

filename xsd 'c:\My Documents\XML\suppliers.xsd'; 2

libname output xml 'c:\My Documents\XML\suppliers.xml' xmltype=msaccess
xmlmeta=schemadata xmlschema=xsd; 3

data output.suppliers; 4
  set input.suppliers;
run;
```

- 1 The first LIBNAME statement assigns the libref INPUT to the physical location of the SAS library that stores the SAS data set SUPPLIERS.
- 2 The FILENAME statement assigns the fileref XSD to the physical location of the separate external file that will contain the metadata-related information.
- 3 The second LIBNAME statement assigns the libref OUTPUT to the physical location of the file (complete pathname, filename, and file extension) that will store the exported XML document and specifies the XML engine. The engine options
 - XMLTYPE=MSACCESS supports the markup standards for a Microsoft Access database.
 - XMLMETA=SCHEMADATA specifies to include both data content and metadata-related information in the exported markup.

- XMLSCHEMA= specifies the fileref that is assigned, in the previous FILENAME statement, to the separate external file that will contain the metadata-related information.
- 4 The DATA step reads the SAS data set INPUT.SUPPLIERS and writes its data content in Microsoft Access database XML markup to the XML document Suppliers.XML, and then writes the metadata information to the separate external file Suppliers.XSD.

Part of the resulting XML document is shown in [Output 2.5 on page 19](#). The separate metadata information is shown in [Output 2.6 on page 20](#).

Output 2.5 XML Document Suppliers.XML

Exporting an XML Document in CDISC ODM Markup

This example exports the SAS data set that was imported in [“Importing a CDISC ODM Document” on page 37](#) back to an XML document that is in CDISC ODM markup. Because the CDISCODM markup type is specified, the XML engine generates tags that are specific to the CDISC Operational Data Model.

The following SAS program exports an XML document from the SAS data set ODM.AE:

```
filename output 'C:\myoutput.xml'; 1  
  
libname output xml xmltype=CDISCODM formatactive=yes; 2  
  
data output.AE2;  
    set odm.AE;  
run;
```

- 1 The FILENAME statement assigns the fileref OUTPUT to the physical location of the external file (complete pathname, filename, and file extension) to which the exported information will be written.
- 2 The LIBNAME statement uses the fileref OUTPUT as the output location and specifies the XML engine. It includes the following engine options:
 - XMLTYPE=CDISCODM supports the markup standards for CDISC ODM 1.2.
 - FORMATACTIVE=YES specifies to convert SAS formats to the corresponding CDISC ODM CodeList elements.

The output is the same as the XML document that is shown in [“Example CDISC ODM Document”](#) on page 137.

Chapter 3

Importing XML Documents

Understanding How to Import an XML Document	23
Importing an XML Document Using the GENERIC Markup Type	23
Importing an XML Document with Numeric Values	25
Importing an XML Document with Non-Escaped Character Data	27
Importing an XML Document Created by Microsoft Access	29
Importing Concatenated XML Documents	35
Importing a CDISC ODM Document	37

Understanding How to Import an XML Document

Importing an XML document is the process of reading an external XML document as a SAS data set. The XML engine translates the input XML document to the SAS proprietary file format.

To import an XML document, you execute the LIBNAME statement for the XML engine in order to assign a libref to the physical location of an existing XML document. Then, you execute SAS code to access the XML document as a SAS data set.

Importing an XML Document Using the GENERIC Markup Type

This example imports the following XML document, which conforms to the physical structure for the GENERIC markup type. For information about the required physical structure, see [“Understanding the Required Physical Structure for an XML Document to Be Imported Using the GENERIC Markup Type”](#) on page 46.

```
<?xml version="1.0" encoding="windows-1252" ?>
<TABLE>
  <CLASS>
    <Name> Alfred </Name>
    <Gender> M </Gender>
    <Age> 14 </Age>
```

```

        <Height> 69 </Height>
        <Weight> 112.5 </Weight>
    </CLASS>
    <CLASS>
        <Name> Alice </Name>
        <Gender> F </Gender>
        <Age> 13 </Age>
        <Height> 56.5 </Height>
        <Weight> 84 </Weight>
    </CLASS>
.
.
.
    <CLASS>
        <Name> William </Name>
        <Gender> M </Gender>
        <Age> 15 </Age>
        <Height> 66.5 </Height>
        <Weight> 112 </Weight>
    </CLASS>
</TABLE>

```

The following SAS program translates the XML markup to SAS proprietary format:

```

libname trans xml 'XML-document'; 1

libname myfiles 'SAS-library'; 2

data myfiles.class; 3
    set trans.class;
run;

```

- 1 The first LIBNAME statement assigns the libref TRANS to the physical location of the XML document (complete pathname, filename, and file extension) and specifies the XML engine. By default, the XML engine expects GENERIC markup.
- 2 The second LIBNAME statement assigns the libref MYFILES to the physical location of the SAS library that will store the resulting SAS data set. The V9 engine is the default.
- 3 The DATA step reads the XML document and writes its content in SAS proprietary format.

Issuing the following PRINT procedure produces the output for the data set that was translated from the XML document:

```

proc print data=myfiles.class;
run;

```

Display 3.1 PRINT Procedure Output for MYFILES.CLASS

The SAS System

Obs	WEIGHT	HEIGHT	AGE	SEX	NAME
1	112.5	69	14	M	Alfred
2	84	56.5	13	F	Alice
3	98	65.3	13	F	Barbara
4	102.5	62.8	14	F	Carol
5	102.5	63.5	14	M	Henry
6	83	57.3	12	M	James
7	84.5	59.8	12	F	Jane
8	112.5	62.5	15	F	Janet
9	84	62.5	13	M	Jeffrey

13	77	56.3	12	F	Louise
14	112	66.5	15	F	Mary
15	150	72	16	M	Philip
16	128	64.8	12	M	Robert
17	133	67	15	M	Ronald
18	85	57.5	11	M	Thomas
19	112	66.5	15	M	William

Importing an XML Document with Numeric Values

This example imports the XML document PRECISION.XML, which was exported in “Exporting Numeric Values” on page 13. This example illustrates how you can change the behavior for importing numeric values.

The first SAS program imports the XML document using the default behavior, which retrieves parsed character data (PCDATA) from the element:

```
libname default xml 'C:\My Documents\precision.xml';
```

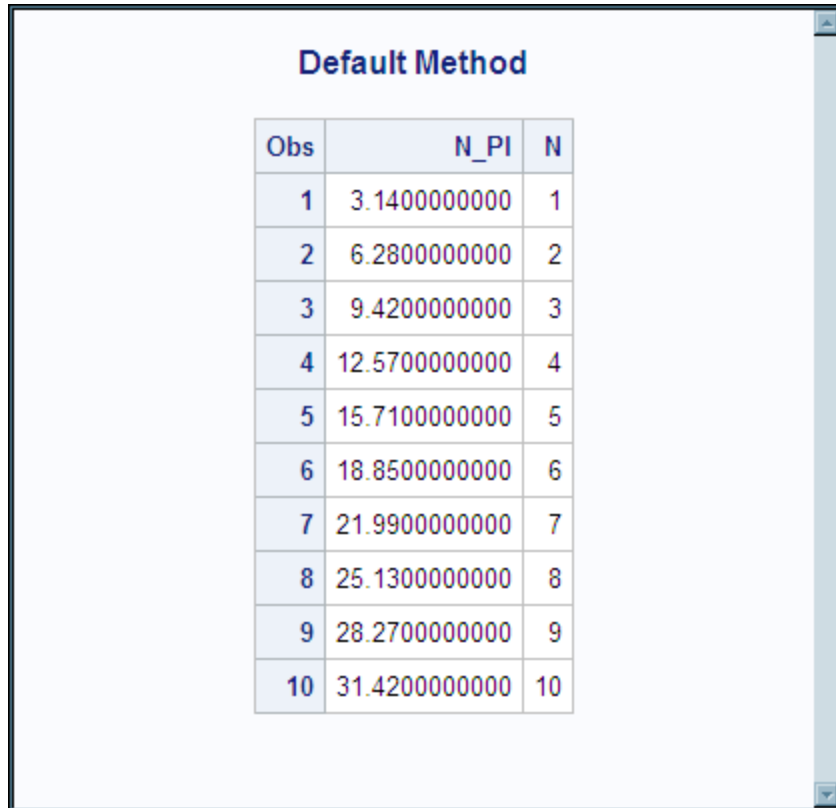

```

title 'Default Method';
proc print data=default.rawtest;
    format n_pi f14.10;
run;

```

The result of the import is the SAS data set DEFAULT.RAWTEST.

Display 3.2 PRINT Procedure Output for DEFAULT.RAWTEST

Obs	N_PI	N
1	3.1400000000	1
2	6.2800000000	2
3	9.4200000000	3
4	12.5700000000	4
5	15.7100000000	5
6	18.8500000000	6
7	21.9900000000	7
8	25.1300000000	8
9	28.2700000000	9
10	31.4200000000	10

The second SAS program imports the XML document using the XMLDOUBLE= option in order to change the behavior, which retrieves the value from the rawdata= attribute in the element:

```

libname new xml 'C:\My Documents\precision.xml' xmldouble=internal;

title 'Precision Method';
proc print data=new.rawtest;
    format n_pi f14.10;
run;

```

The result of the import is SAS data set NEW.RAWTEST.

Display 3.3 PRINT Procedure Output for NEW.RAWTEST

Obs	N_PI	N
1	3.1415926536	1

10	31.4159265359	10

Importing an XML Document with Non-Escaped Character Data

W3C specifications (section 4.6 Predefined Entities) state that for character data, certain characters such as the left angle bracket (<), the ampersand (&), and the apostrophe (') must be escaped using character references or strings like `<`, `&`, and `'`. For example, to allow attribute values to contain both single and double quotation marks, the apostrophe or single-quotation character (') can be represented as `'` and the double-quotation character (") as `"`.

To import an XML document that contains non-escaped characters, you can specify the LIBNAME statement option `XMLPROCESS=PERMIT` in order for the XML engine to accept character data that does not conform to W3C specifications. That is, non-escaped characters like the apostrophe, double quotation marks, and the ampersand are accepted in character data.

Note: Use `XMLPROCESS=PERMIT` cautiously. If an XML document consists of non-escaped characters, the content is not standard XML construction. The option is provided for convenience, not to encourage invalid XML markup.

This example imports the following XML document named `Permit.XML`, which contains non-escaped character data:

```
<?xml version="1.0" ?>
```

```

<PERMIT>
  <CHARS>
    <accept>OK</accept>
    <status>proper escape sequence</status>
    <ampersand>&amp;</ampersand>
    <quote>&apos;</quote>
    <dquote>&quot;</dquote>
    <less>&lt;</less>
    <greater>&gt;</greater>
  </CHARS>
  <CHARS>
    <accept>OK</accept>
    <status>unescaped character in CDATA</status>
    <ampersand><![CDATA[Abbott & Costello]]></ampersand>
    <quote><![CDATA[Logan's Run]]></quote>
    <dquote><![CDATA[This is "realworld" stuff]]></dquote>
    <less><![CDATA[ e < pi ]]></less>
    <greater><![CDATA[ pen > sword ]]></greater>
  </CHARS>
  <CHARS>
    <accept>NO</accept>
    <status>single unescaped character</status>
    <ampersand>&</ampersand>
    <quote>'</quote>
    <dquote>"</dquote>
    <less></less>
    <greater></greater>
  </CHARS>
  <CHARS>
    <accept>NO</accept>
    <status>unescaped character in string</status>
    <ampersand>Dunn & Bradstreet</ampersand>
    <quote>Isn't this silly?</quote>
    <dquote>Quoth the raven, "Nevermore!"</dquote>
    <less></less>
    <greater></greater>
  </CHARS>
</PERMIT>

```

First, using the default XML engine behavior, which expects XML markup to conform to W3C specifications, the following SAS program imports only the first two observations, which contain valid XML markup, and produces errors for the last two records, which contain non-escaped characters:

```

libname permit xmlv2 'c:\My Documents\XML\permit.xml';

proc print data=permit.chars;
run;

```

Log 3.1 SAS Log Output

```

ERROR: There is an illegal character in the entity name.
       encountered during XMLInput parsing
       occurred at or near line 24, column 22
NOTE: There were 2 observations read from the data set PERMIT.CHARS.

```

Specifying the LIBNAME statement option XMLPROCESS=PERMIT enables the XML engine to import the XML document:

```
libname permit xmlv2 'c:\My Documents\XML\permit.xml' xmlprocess=permit;

proc print data=permit.chars;
run;
```

Display 3.4 PRINT Procedure Output for PERMIT.CHARS

The SAS System							
Obs	accept	status	ampersand	squote	dquote	less	greater
1	OK	proper escape sequence	&	'	"	<	>
2	OK	unescaped character in CDATA	Abbott & Costello	Logan's Run	This is "realworld" stuff	e < pi	pen > sword
3	NO	single unescaped character	&	'	"		
4	NO	unescaped character in string	Dunn & Bradstreet	Isn't this silly?	Quoth the raven, "Nevermore!"		

Importing an XML Document Created by Microsoft Access

This example imports the following XML document, which was created from a Microsoft Access database. Because the XML document contains an embedded XML schema, you must specify the MSACCESS markup type rather than the default GENERIC type. MSACCESS obtains a variable's attributes from the embedded schema.

```
<?xml version="1.0" encoding="windows-1252" ?>
<root xmlns:xs="http://www.w3.org/2001/XMLSchema"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:od="urn:schemas-microsoft-com:officedata">
  <xs:schema>
    <xs:element name="dataroot">
      <xs:complexType>
        <xs:sequence>
          <xs:element ref="SUPPLIERS" minOccurs="0"
maxOccurs="unbounded" />
        </xs:sequence>
      </xs:complexType>
    </xs:element>
```

```

<xs:element name="SUPPLIERS">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="HOMEPAGE" minOccurs="0"
        od:jetType="text" od:sqlSType="nvarchar">
        <xs:simpleType>
          <xs:restriction base="xs:string">

```

The following SAS program interprets the XML document as a SAS data set:

```

libname access xml '/u/myid/XML/suppliers.xml' xmltype=msaccess 1
  xmlmeta=schemadata; 1

proc print data=access.suppliers (obs=2); 2
  var contactname companyname;
run;

```

- 1 The LIBNAME statement assigns the libref ACCESS to the physical location of the XML document (complete pathname, filename, and file extension) and specifies the XML engine. By default, the XML engine expects GENERIC markup, so you must include the XMLTYPE= option in order to read the XML document in MSACCESS markup and to obtain a variable's attributes from the embedded schema. The option XMLMETA=SCHEMADATA specifies to import both data and metadata-related information from the input XML document.
- 2 The PRINT procedure produces the output. The procedure uses the OBS= data set option to print only the first two observations, and the VAR statement to print only specific variables (columns).

Display 3.5 PRINT Procedure Output for ACCESS.SUPPLIERS

Obs	CONTACTNAME	COMPANYNAME
1	Charlotte Smith	Exotic Flowers
2	Shelley Martin	New Orleans Cajun Foods

Using the CONTENTS procedure, the output displays the file's attributes, as well as the attributes of each interpreted column (variable), such as the variable's type and length, which are obtained from the embedded XML schema. Without the embedded XML schema, the results for the attributes would be default values.

```
proc contents data=access.suppliers;  
run;
```

Importing Concatenated XML Documents

For a file that is a concatenation of multiple XML documents, you can use the XML engine to import the file. To import concatenated XML documents, simply specify the LIBNAME statement option XMLCONCATENATE=YES.

Note: Use XMLCONCATENATE=YES cautiously. If an XML document consists of concatenated XML documents, the content is not standard XML construction. The option is provided for convenience, not to encourage invalid XML markup.

This example imports the following file named ConcatStudents.XML, which consists of two XML documents:

```
<?xml version="1.0" ?>
<LIBRARY>
  <STUDENTS>
    <ID>1345</ID>
    <NAME>Linda Kay</NAME>
    <SCHOOL>Bellaire</SCHOOL>
    <CITY>Houston</CITY>
  </STUDENTS>
  <STUDENTS>
    <ID>2456</ID>
    <NAME>Chas Wofford</NAME>
    <SCHOOL>Sam Houston</SCHOOL>
    <CITY>Houston</CITY>
  </STUDENTS>
  <STUDENTS>
    <ID>3567</ID>
    <NAME>Jerry Kolar</NAME>
    <SCHOOL>Sharpstown</SCHOOL>
    <CITY>Houston</CITY>
  </STUDENTS>
</LIBRARY>

<?xml version="1.0" ?>
<LIBRARY>
  <STUDENTS>
    <ID>1234</ID>
    <NAME>Brad Martin</NAME>
    <SCHOOL>Reagan</SCHOOL>
    <CITY>Austin</CITY>
  </STUDENTS>
  <STUDENTS>
    <ID>2345</ID>
    <NAME>Zac Harvell</NAME>
    <SCHOOL>Westwood</SCHOOL>
    <CITY>Austin</CITY>
  </STUDENTS>
  <STUDENTS>
    <ID>3456</ID>
    <NAME>Walter Smith</NAME>
    <SCHOOL>Bowie</SCHOOL>
  </STUDENTS>
</LIBRARY>
```

```

        <CITY>Austin</CITY>
    </STUDENTS>
</LIBRARY>

```

First, using the default XML engine behavior, which does not support concatenated XML documents (XMLCONCATENATE=NO), the following SAS program imports the first XML document, which consists of three observations, and produces an error for the second XML document:

```

libname concat xml '/u/My Documents/XML/ConcatStudents.xml';

proc datasets library=concat;

```

Log 3.2 SAS Log Output

```

NOTE: Libref CONCAT was successfully assigned as follows:
      Engine:          XML
      Physical Name:  /u/My Documents/XML/ConcatStudents.xml
20  proc datasets library=concat;
ERROR: "xml" is illegal as a processing-instruction target name.
      encountered during XMLMap parsing
      occurred at or near line 23, column 7

```

Directory

```

Libref          CONCAT
Engine          XML
Physical Name   /u/My Documents/XML/ConcatStudents.xml
XMLType        GENERIC
XMLMap         NO XMLMAP IN EFFECT

```

#	Name	Member Type
1	STUDENTS	DATA

Specifying the LIBNAME statement option XMLCONCATENATE=YES enables the XML engine to import the concatenated XML documents as one SAS data set:

```

libname concat xml '/u/My Documents/XML/ConcatStudents.xml' xmlconcatenate=yes;

proc print data=concat.students;
run;

```

Display 3.7 PRINT Procedure Output for CONCAT.STUDENTS

2	Houston	Sam Houston	Chas Wofford	2456
3	Houston	Sharpstown	Jerry Kolar	3567
4	Austin	Reagan	Brad Martin	1234
5	Austin	Westwood	Zac Harvell	2345
6	Austin	Bowie	Walter Smith	3456

Importing a CDISC ODM Document

This example imports the XML document that is shown in “[Example CDISC ODM Document](#)” on page 137. The document conforms to Version 1.2 of the CDISC Operational Data Model (ODM). To import a CDISC ODM document, you specify CDISCODM as the XML markup type, and you can specify values for the `FORMATACTIVE=` option, `FORMATLIBRARY=` option, and `FORMATNOREPLACE=` option.

The following SAS program imports the XML document as a SAS data set:

```
filename odm 'C:\Documents and Settings\myid\My Documents\CDISC\AE.XML'; 1

libname odm xml xmltype=CDISCODM 2 FormatActive=YES 3
      FormatNoReplace=NO 4 FormatLibrary="Work"; 5

proc contents data=odm.AE varnum; 6
run;

proc print data=odm.AE; 7
run;
```

- 1 The `FILENAME` statement assigns the fileref `ODM` to the physical location of the XML document (complete pathname, filename, and file extension).
- 2 The `LIBNAME` statement uses the fileref `ODM` to reference the XML document and specifies the XML engine. If the fileref matches the libref, you do not need to specify the physical location of the XML document in the `LIBNAME` statement. By default, the XML engine expects `GENERIC` markup, so you must include the `XMLTYPE=` option in order to read the XML document in `CDISCODM` markup.
- 3 `FORMATACTIVE=YES` specifies to convert CDISC ODM CodeList elements in the document to SAS formats.

- 4 `FORMATNOREPLACE=NO` specifies to replace any existing SAS formats in the format catalog that have the same name as the converted formats.
- 5 `FORMATACTIVE="Work"` specifies to create the format catalog in the temporary Work library. The Work library is also the default if you omit the `FORMATACTIVE=` option.
- 6 The output from the `CONTENTS` procedure displays the file's attributes as well as the attributes of each interpreted column (variable), such as the variable's type and length. The attributes are obtained from the embedded ODM metadata content. The `VARNUM` option causes the variables to be printed first in alphabetical order and then in the order of their creation.
- 7 The `PRINT` procedure produces the output.

Chapter 4

Exporting XML Documents Using an XMLMap

Why Use an XMLMap when Exporting?	41
Using an XMLMap to Export an XML Document with a Hierarchical Structure	41

Why Use an XMLMap when Exporting?

To export an XML document that was imported using an XMLMap, you can use the XMLMap. The XMLMap syntax tells the XML engine how to map the SAS data set back into the specific XML document structure.

To export an XML document using an XMLMap, specify the XML engine nickname XMLV2 in the LIBNAME statement, and use the XMLMAP= option to specify the file.

Using an XMLMap to Export an XML Document with a Hierarchical Structure

This example explains how to use an existing XMLMap to tell the XML engine how to map a SAS data set back into the specific XML document structure. The XMLMap was used to import the SAS data set NHL.TEAMS in the section [“Using an XMLMap to Import an XML Document as One SAS Data Set”](#) on page 49.

First, here is the SAS data set named NHL.TEAMS to be exported:

Display 4.1 PRINT Procedure Output of Data Set NHL.TEAMS

The screenshot shows a window titled "Results Viewer - SAS Output". Inside the window, there is a table titled "The SAS System". The table has five columns: "Obs", "NAME", "ABBREV", "CONFERENCE", and "DIVISION". It contains 10 rows of data representing NHL teams.

Obs	NAME	ABBREV	CONFERENCE	DIVISION
1	Thrashers	ATL	Eastern	Southeast
2	Hurricanes	CAR	Eastern	Southeast
3	Panthers	FLA	Eastern	Southeast
4	Lightning	TB	Eastern	Southeast
5	Capitals	WSH	Eastern	Southeast
6	Stars	DAL	Western	Pacific
7	Kings	LA	Western	Pacific
8	Ducks	ANA	Western	Pacific
9	Coyotes	PHX	Western	Pacific
10	Sharks	SJ	Western	Pacific

If the data were exported without an XMLMap, the structure of the resulting XML document would be rectangular and consist of a TEAMS element for each observation in the SAS data set. For example:

```
<?xml version="1.0" encoding="windows-1252" ?>
<TABLE>
  <TEAMS>
    <NAME>Thrashers</NAME>
    <ABBREV>ATL</ABBREV>
    <CONFERENCE>Eastern</CONFERENCE>
    <DIVISION>Southeast</DIVISION>
  </TEAMS>
  <TEAMS>
    <NAME>Hurricanes</NAME>
    <ABBREV>CAR</ABBREV>
    <CONFERENCE>Eastern</CONFERENCE>
    <DIVISION>Southeast</DIVISION>
  </TEAMS>
  .
  .
  .
</TABLE>
```

To export the SAS data set as an XML document that structures data hierarchically by division within each conference, an XMLMap is required. The only change to the existing XMLMap is to include the OUTPUT element. Notations in the XMLMap syntax are explained.

```

<?xml version="1.0" ?>
<SXLEMAP version="2.1"> 1
  <OUTPUT> 2
    <HEADING> 2
      <ATTRIBUTE name="description" 3
        value="Teams of the National Hockey League" />
    </HEADING>
    <TABLEREF name="TEAMS" /> 4
  </OUTPUT>

  <TABLE name="TEAMS">

    <TABLE-PATH syntax="XPath">/NHL/CONFERENCE/DIVISION/TEAM</TABLE-PATH>

    <COLUMN name="NAME">
      <PATH syntax="XPath">/NHL/CONFERENCE/DIVISION/TEAM/@name</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>30</LENGTH>
    </COLUMN>

    <COLUMN name="ABBREV">
      <PATH syntax="XPath">/NHL/CONFERENCE/DIVISION/TEAM/@abbrev</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>3</LENGTH>
    </COLUMN>

    <COLUMN name="CONFERENCE" retain="YES">
      <PATH syntax="XPath">/NHL/CONFERENCE</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>10</LENGTH>
    </COLUMN>

    <COLUMN name="DIVISION" retain="YES">
      <PATH syntax="XPath">/NHL/CONFERENCE/DIVISION</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>10</LENGTH>
    </COLUMN>
  </TABLE>
</SXLEMAP>

```

- 1 To use an XMLMap to export the SAS data set as an XML document, you must specify 1.9 or 2.1 as the XMLMap version number.
- 2 To use an XMLMap to export the SAS data set as an XML document, you must include the OUTPUT element in the XMLMap. The OUTPUT element contains one or more HEADING elements and one TABLEREF element.
- 3 The ATTRIBUTE element, which defines additional file attribute information, specifies a name and description for the exported XML document.
- 4 The TABLEREF element, which references the name of the table to be exported, specifies the table TEAMS.

The following SAS statements export the SAS data set named NHL.TEAMS to an XML document named NHLOUT.XML, using an XMLMap named NHLEXPORT.MAP:

```
libname nhl 'C:\My Documents\myfiles';

filename out 'C:\My Documents\XML\NHLOUT.xml';

libname out xmlv2 xmltype=xmlmap xmlmap='C:\My Documents\XML\NHLEXPORT.map';

data out.TEAMS;
  set nhl.teams;
run;
```

Here is the resulting XML document:

```
<?xml version="1.0" encoding="windows-1252" ?>
<!-- SAS XML Libname Engine (SAS92XML)
      SAS XMLMap Generated Output
      Version 9.03.01B0D11142010
      Created 2010-11-15T09:46:32
-->

<NHL description="Teams of the National Hockey League">
  <CONFERENCE>Eastern
    <DIVISION>Southeast
      <TEAM name="Thrashers" abbrev="ATL" />
      <TEAM name="Hurricanes" abbrev="CAR" />
      <TEAM name="Panthers" abbrev="FLA" />
      <TEAM name="Lightning" abbrev="TB" />
      <TEAM name="Capitals" abbrev="WSH" />
    </DIVISION>
  </CONFERENCE>
  <CONFERENCE>Western
    <DIVISION>Pacific
      <TEAM name="Stars" abbrev="DAL" />
      <TEAM name="Kings" abbrev="LA" />
      <TEAM name="Ducks" abbrev="ANA" />
      <TEAM name="Coyotes" abbrev="PHX" />
      <TEAM name="Sharks" abbrev="SJ" />
    </DIVISION>
  </CONFERENCE>
</NHL>
```

Chapter 5

Importing XML Documents Using an XMLMap

Why Use an XMLMap When Importing?	45
Understanding the Required Physical Structure for an XML Document to Be Imported Using the GENERIC Markup Type	46
What Is the Required Physical Structure?	46
Why Is a Specific Physical Structure Required?	47
Handling XML Documents That Are Not in the Required Physical Structure	49

Referencing a Fileref Using the URL Access Method	74
Specifying a Location Path on the PATH Element	74
Including Namespace Elements in an XMLMap	77

Why Use an XMLMap When Importing?

The XML engine imports only XML documents that conform to the markup types supported in the XMLTYPE= option. Attempting to import free-form XML documents that do not conform to the specifications required by the supported markup types will generate errors. To successfully import files that do not conform to the XMLTYPE= markup types, you can create a separate XML document, called an *XMLMap*.

If your XML document does not import successfully, rather than transform the document, you can tell the XML engine how to interpret the XML markup in order to successfully import the XML document. You create an XMLMap that contains specific XMLMap syntax, which is XML markup. The XMLMap syntax tells the XML engine how to interpret the XML markup into a SAS data set or data sets, variables (columns), and observations (rows).

As an alternative to you creating an XMLMap by coding XMLMap syntax, the SAS XML Mapper can generate XMLMap syntax. SAS XML Mapper removes the tedium of creating and modifying an XMLMap by providing a GUI that generates the appropriate XML elements for you. SAS XML Mapper analyzes the structure of an XML document or an XML schema, and generates basic syntax for the XMLMap. See [“Using SAS XML Mapper to Generate and Update an XMLMap” on page 131](#).

After the XMLMap is created, use the XMLMAP= option in the LIBNAME statement to specify the file.

Understanding the Required Physical Structure for an XML Document to Be Imported Using the GENERIC Markup Type

What Is the Required Physical Structure?

For an XML document to be successfully imported, the requirements for well-formed XML must translate as follows:

- The root-enclosing element (top-level node) of an XML document is the document container. For SAS, it is like the SAS library.
- The nested elements (repeating element instances) that occur within the container begin with the second-level instance tag.
- The repeating element instances must represent a rectangular organization. For a SAS data set, they determine the observation boundary that becomes a collection of *rows* with a constant set of *columns*.

Here is an example of an XML document that illustrates the physical structure that is required:

```
<?xml version="1.0" encoding="windows-1252" ?>
<LIBRARY> 1
  <STUDENTS> 2
    <ID> 0755 </ID>
    <NAME> Brad Martin </NAME>
    <ADDRESS> 1611 Glengreen </ADDRESS>
    <CITY> Huntsville </CITY>
    <STATE> Texas </STATE>
  </STUDENTS>

  <STUDENTS> 3
    <ID> 1522 </ID>
    <NAME> Zac Harvell </NAME>
    <ADDRESS> 11900 Glenda </ADDRESS>
    <CITY> Houston </CITY>
    <STATE> Texas </STATE>
  </STUDENTS>

  .
  . more instances of <STUDENTS>
  .
</LIBRARY>
```

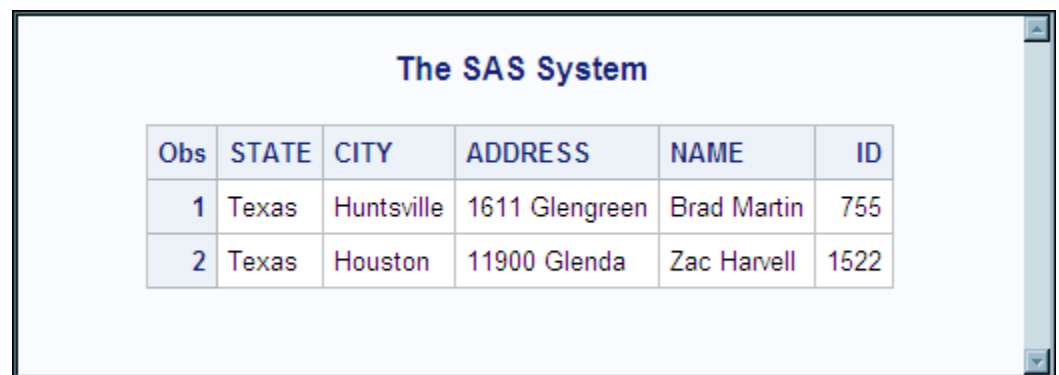

When the previous XML document is imported, the following happens:

- 1 The XML engine recognizes <LIBRARY> as the root-enclosing element.
- 2 The engine goes to the second-level instance tag, which is <STUDENTS>, translates it as the data set name, and begins scanning the elements that are nested (contained) between the <STUDENTS> start tag and the </STUDENTS> end tag, looking for variables.
- 3 Because the instance tags <ID>, <NAME>, <ADDRESS>, <CITY>, and <STATE> are contained within the <STUDENTS> start tag and </STUDENTS> end tag, the XML engine interprets them as variables. The individual instance tag names become the data set variable names. The repeating element instances are translated into a collection of rows with a constant set of columns.

These statements result in the following SAS output:

```
libname test xml 'C:\My Documents\students.xml';  
  
proc print data=test.students;  
run;
```

Display 5.1 PRINT Procedure Output for TEST.STUDENTS

Obs	STATE	CITY	ADDRESS	NAME	ID
1	Texas	Huntsville	1611 Glengreen	Brad Martin	755
2	Texas	Houston	11900 Glenda	Zac Harvell	1522

Why Is a Specific Physical Structure Required?

Well-formed XML is determined by structure, not content. Therefore, while the XML engine can assume that the XML document is valid, well-formed XML, the engine cannot assume that the root element encloses only instances of a single node element, that is, only a single data set. Therefore, the XML engine has to account for the possibility of multiple nodes, that is, multiple SAS data sets.

For example, when the following correctly structured XML document is imported, it is recognized as containing two SAS data sets: HIGHTEMP and LOWTEMP.

```
<?xml version="1.0" encoding="windows-1252" ?>  
<CLIMATE> 1  
  <HIGHTEMP> 2  
    <PLACE> Libya </PLACE>  
    <DATE> 1922-09-13 </DATE>  
    <DEGREE-F> 136 </DEGREE-F>  
    <DEGREE-C> 58 </DEGREE-C>  
  </HIGHTEMP>  
.  
. more instances of <HIGHTEMP>
```

```

.
  <LOWTEMP> 3
    <PLACE> Antarctica </PLACE>
    <DATE> 1983-07-21 </DATE>
    <DEGREE-F> -129 </DEGREE-F>
    <DEGREE-C> -89 </DEGREE-C>
  </LOWTEMP>
.
. more instances of <LOWTEMP>
.
</CLIMATE>

```

When the previous XML document is imported, the following happens:

- 1 The XML engine recognizes the first instance tag <CLIMATE> as the root-enclosing element, which is the container for the document.
- 2 Starting with the second-level instance tag, which is <HIGHTEMP>, the XML engine uses the repeating element instances as a collection of rows with a constant set of columns.
- 3 When the second-level instance tag changes, the XML engine interprets that change as a different SAS data set.

The result is two SAS data sets: HIGHTEMP and LOWTEMP. Both happen to have the same variables, but of course, different data.

To ensure that an import result is what you expect, use the DATASETS procedure. For example, these SAS statements result in the following:

```

libname climate xml 'C:\My Documents\climate.xml';

proc datasets library=climate;
quit;

```

Display 5.2 DATASETS Procedure Output for CLIMATE Library

Handling XML Documents That Are Not in the Required Physical Structure

If your XML document is not in the required physical structure, you can tell the XML engine how to interpret the XML markup in order to successfully import the document. See “Why Use an XMLMap When Importing?” on page 45.

Using an XMLMap to Import an XML Document as One SAS Data Set

This example explains how to create and use an XMLMap in order to tell the XML engine how to map XML markup to a SAS data set, variables, and observations.

First, here is the XML document NHL.XML to be imported. Although simply constructed and relatively easy for you to read, it does not import successfully because its XML markup is not in the required physical structure:

```
<?xml version="1.0" encoding="iso-8859-1" ?>
<NHL>
  <CONFERENCE> Eastern
    <DIVISION> Southeast
      <TEAM name="Thrashers" abbrev="ATL" />
      <TEAM name="Hurricanes" abbrev="CAR" />
      <TEAM name="Panthers" abbrev="FLA" />
      <TEAM name="Lightning" abbrev="TB" />
    </DIVISION>
  </CONFERENCE>
</NHL>
```

```

        <TEAM name="Capitals" abbrev="WSH" />
    </DIVISION>
</CONFERENCE>

<CONFERENCE> Western
  <DIVISION> Pacific
    <TEAM name="Stars" abbrev="DAL" />
    <TEAM name="Kings" abbrev="LA" />
    <TEAM name="Ducks" abbrev="ANA" />
    <TEAM name="Coyotes" abbrev="PHX" />
    <TEAM name="Sharks" abbrev="SJ" />
  </DIVISION>
</CONFERENCE>
</NHL>

```

To successfully import the XML document, an XMLMap is needed. After familiarizing yourself with the data to be imported, you can code the XMLMap syntax so that the data is successfully imported. Here is the XMLMap used to import the XML document, with notations for the data investigation:

```

<?xml version="1.0" ?>
<SXLEMAP version="2.1">
  <TABLE name="TEAMS"> 1
    <TABLE-PATH syntax="XPath"> 2
      /NHL/CONFERENCE/DIVISION/TEAM
    </TABLE-PATH>

    <COLUMN name="NAME"> 3
      <PATH> 5
        /NHL/CONFERENCE/DIVISION/TEAM@name
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>30</LENGTH>
    </COLUMN>

    <COLUMN name="ABBREV"> 3
      <PATH> 5
        /NHL/CONFERENCE/DIVISION/TEAM/@abbrev
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>3</LENGTH>
    </COLUMN>

    <COLUMN name="CONFERENCE" retain="YES"> 4
      <PATH>/NHL/CONFERENCE</PATH> 5
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>10</LENGTH>
    </COLUMN>

    <COLUMN name="DIVISION" retain="YES"> 4
      <PATH> 5
        /NHL/CONFERENCE/DIVISION
      </PATH>

```

```

        <TYPE>character</TYPE>
        <DATATYPE>STRING</DATATYPE>
        <LENGTH>10</LENGTH>
    </COLUMN>
</TABLE>
</SXLEMAP>

```

The previous XMLMap syntax defines how to translate the XML markup as explained below, using the following data investigation steps:

1 Locate and identify distinct tables of information.

You want a SAS data set (table) that contains some of the teams of the National Hockey League. Because that is the only information contained in the XML document, you can define a single data set named TEAMS in the XMLMap. (Note that other XML documents might contain more than one table of related information. Importing multiple tables is supported by the XMLMap syntax as shown in “Using an XMLMap to Import an XML Document as Multiple SAS Data Sets” on page 52.)

2 Identify the SAS data set observation boundary, which translates into a collection of rows with a constant set of columns.

In the XML document, information about individual teams occurs in a <TEAM> tag located with <CONFERENCE> and <DIVISION> enclosures. You want a new observation generated each time a TEAM element is read.

3 Collect column definitions for each table.

For this XML document, the data content form is mixed. Some data occurs as XML PCDATA (for example, CONFERENCE), and other data is contained in attribute-value pairs (for example, NAME). Data types are all string values. The constructed observation will also include the team NAME and ABBREV. A length of 30 characters is sufficient for the NAME, and three characters is enough for the ABBREV field contents.

4 Add foreign keys or required external context.

You want to include information about the league orientation for the teams. Also, you want to extract CONFERENCE and DIVISION data.

Note: The retain= attribute in the column definition forces retention of processed data values after an observation is written to the output data set. Because the foreign key fields occur outside the observation boundary (that is, they are more sparsely populated in the hierarchical XML data than in the SAS observation), their values for additional rows need to be retained as they are encountered.

5 Define a location path for each variable definition.

The PATH element identifies a position in the XML document from which to extract data for each column. Element-parsed character data is treated differently than attribute values. There is no conditional selection criteria involved.

The following SAS statements import the XML document NHL.XML:

```

filename NHL 'C:\My Documents\XML\NHL.xml'; 1
filename MAP 'C:\My Documents\XML\NHL.map'; 2

libname NHL xmlv2 xmlmap=MAP; 3

proc print data=NHL.TEAMS; 4
run;

```

- 1 The first FILENAME statement assigns the file reference NHL to the physical location (complete pathname, filename, and file extension) of the XML document named NHL.XML.
- 2 The second FILENAME statement assigns the file reference MAP to the physical location of the XMLMap named NHL.MAP.
- 3 The LIBNAME statement uses the file reference NHL to reference the XML document. It specifies the XMLV2 engine, and uses the file reference MAP to reference the XMLMap.
- 4 The PRINT procedure produces output, verifying that the import was successful.

Display 5.3 PRINT Procedure Output for NHL.TEAMS

The SAS System				
Obs	NAME	ABBREV	CONFERENCE	DIVISION
1	Thrashers	ATL	Eastern	Southeast
2	Hurricanes	CAR	Eastern	Southeast
3	Panthers	FLA	Eastern	Southeast
4	Lightning	TB	Eastern	Southeast

Using an XMLMap to Import an XML Document as Multiple SAS Data Sets

This example explains how to create and use an XMLMap in order to define how to map XML markup into two SAS data sets. The example uses the XML document RSS.XML, which does not import successfully because its XML markup is incorrectly structured for the XML engine to translate successfully.

Note: The XML document RSS.XML uses the XML format RSS (Rich Site Summary), which was designed by Netscape originally for exchange of content within the My Netscape Network (MNN) community. The RSS format has been widely adopted for sharing headlines and other Web content and is a good example of XML as a transmission format.

First, here is the XML document RSS.XML to be imported:

```

<?xml version="1.0" encoding="ISO-8859-1" ?>
- <rss version="0.91">
- <channel>

</channel>
</rss>

```

The XML document can be successfully imported by creating an XMLMap that defines how to map the XML markup. The following is the XMLMap named RSS.MAP, which contains the syntax that is needed to successfully import RSS.XML. The syntax tells the XML engine how to interpret the XML markup as explained in the subsequent descriptions. The contents of RSS.XML results in two SAS data sets: CHANNEL to contain content information and ITEMS to contain the individual news stories.

```

<?xml version="1.0" encoding="UTF-8"?>

<SXLEMAP name="SXLEMap" version="2.1"> 1

    <TABLE name="CHANNEL"> 2
        <TABLE-PATH syntax="XPath">/rss/channel</TABLE-PATH> 3
        <TABLE-END-PATH beginend="BEGIN" syntax="XPath">
            /rss/channel/item</TABLE-END-PATH> 4

        <COLUMN name="title"> 5
            <PATH syntax="XPath">/rss/channel/title</PATH>
            <TYPE>character</TYPE>
            <DATATYPE>string</DATATYPE>
            <LENGTH>200</LENGTH>
        </COLUMN>

        <COLUMN name="link"> 6
            <PATH syntax="XPath">/rss/channel/link</PATH>
            <DESCRIPTION>Story link</DESCRIPTION>
            <TYPE>character</TYPE>
            <DATATYPE>string</DATATYPE>
            <LENGTH>200</LENGTH>
        </COLUMN>

        <COLUMN name="description">
            <PATH syntax="XPath">/rss/channel/description</PATH>
            <TYPE>character</TYPE>
            <DATATYPE>string</DATATYPE>
            <LENGTH>1024</LENGTH>
        </COLUMN>

        <COLUMN name="language">
            <PATH syntax="XPath">/rss/channel/language</PATH>
            <TYPE>character</TYPE>
            <DATATYPE>string</DATATYPE>
            <LENGTH>8</LENGTH>
        </COLUMN>

```

```

    <COLUMN name="version"> 7
      <PATH syntax="XPath">/rss@version</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>8</LENGTH>
    </COLUMN>
  </TABLE>

  <TABLE description="Individual news stories" name="ITEMS"> 8
    <TABLE-PATH syntax="XPath">/rss/channel/item</TABLE-PATH>

    <COLUMN name="title"> 9
      <PATH syntax="XPath">/rss/channel/item/title</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>200</LENGTH>
    </COLUMN>

    <COLUMN name="URL"> 10
      <PATH syntax="XPath">/rss/channel/item/link</PATH>
      <DESCRIPTION>Story link</DESCRIPTION>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>200</LENGTH>
    </COLUMN>

    <COLUMN name="description"> 10
      <PATH syntax="XPath">/rss/channel/item/description</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>1024</LENGTH>
    </COLUMN>
  </TABLE>

</SXLEMAP>

```

The previous XMLMap defines how to translate the XML markup as explained below:

- 1 Root-enclosing element for SAS data set definitions.
- 2 Element for the CHANNEL data set definition.
- 3 Element specifying the location path that defines where in the XML document to collect variables for the CHANNEL data set.
- 4 Element specifying the location path that specifies when to stop processing data for the CHANNEL data set.
- 5 Element containing the attributes for the TITLE variable in the CHANNEL data set. The XPath construction specifies where to find the current tag and to access data from the named element.
- 6 Subsequent COLUMN elements define the variables LINK, DESCRIPTION, and LANGUAGE for the CHANNEL data set.

- 7 Element containing the attributes for the last variable in the CHANNEL data set, which is VERSION. This XPath construction specifies where to find the current tag and uses the attribute form to access data from the named attribute.
- 8 Element for the ITEMS data set definition.
- 9 Element containing the attributes for the TITLE variable in the ITEMS data set.
- 10 Subsequent COLUMN elements define other variables for the ITEMS data set, which are URL and DESCRIPTION.

The following SAS statements import the XML document RSS.XML and specify the XMLMap named RSS.MAP. The DATASETS procedure then verifies the import results:

```
filename rss 'C:\My Documents\rss.xml';
filename map 'C:\My Documents\rss.map';

libname rss xmlv2 xmlmap=map access=readonly;

proc datasets library=rss;
run;
quit;
```

Importing Hierarchical Data as Related Data Sets

XML documents often contain hierarchical data in that the data is structured into different levels like a company organization chart. Hierarchical structures are one-to-

many relationships, with top items having one or more items below it (for example, customer to orders).

This example explains how to define an XMLMap in order to import an XML document as two data sets that have related information.

First, here is the XML document Pharmacy.XML. The file contains hierarchical data with related entities in the form of individual customers and their prescriptions. Each customer can have one or multiple prescriptions. Notice that PRESCRIPTION elements are nested within each <PERSON> start tag and </PERSON> end tag:

```
<?xml version="1.0" ?>
<PHARMACY>
  <PERSON>
    <NAME>Brad Martin</NAME>
    <STREET>11900 Glenda Court</STREET>
    <CITY>Austin</CITY>
    <PRESCRIPTION>
      <NUMBER>1234</NUMBER>
      <DRUG>Tetracycline</DRUG>
    </PRESCRIPTION>
    <PRESCRIPTION>
      <NUMBER>1245</NUMBER>
      <DRUG>Lomotil</DRUG>
    </PRESCRIPTION>
  </PERSON>
  <PERSON>
    <NAME>Jim Spano</NAME>
    <STREET>1611 Glengreen</STREET>
    <CITY>Austin</CITY>
    <PRESCRIPTION>
      <NUMBER>1268</NUMBER>
      <DRUG>Nexium</DRUG>
    </PRESCRIPTION>
  </PERSON>
</PHARMACY>
```

To import separate data sets, one describing the customers and the other containing prescription information, a relation between each customer and associated prescriptions must be designated in order to know which prescriptions belong to each customer.

An XMLMap defines how to translate the XML markup into two SAS data sets. The customer table imports the name and address of each customer, and the prescription table imports the customer's name, prescription number, and drug. Notations in the XMLMap syntax are explained below.

Note: The XMLMap was generated by using SAS XML Mapper.

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- ##### -->
<!-- 2011-01-10T14:39:38 -->
<!-- SAS XML Libname Engine Map -->
<!-- Generated by XML Mapper, 903000.1.0.20101208190000_v930 -->
<!-- ##### -->
<!-- ### Validation report ### -->
<!-- ##### -->
<!-- XMLMap validation completed successfully. -->
<!-- ##### -->
```

```

<SXLEMAP name="AUTO_GEN" version="2.1"> 1
  <NAMESPACES count="0"/>
  <!-- ##### -->
  <TABLE description="PERSON" name="PERSON"> 2
    <TABLE-PATH syntax="XPath">/PHARMACY/PERSON</TABLE-PATH>
    <COLUMN name="NAME"> 3
      <PATH syntax="XPath">/PHARMACY/PERSON/NAME</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>11</LENGTH>
    </COLUMN>
    <COLUMN name="STREET"> 3
      <PATH syntax="XPath">/PHARMACY/PERSON/STREET</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>18</LENGTH>
    </COLUMN>
    <COLUMN name="CITY"> 3
      <PATH syntax="XPath">/PHARMACY/PERSON/CITY</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>6</LENGTH>
    </COLUMN>
  </TABLE>
  <!-- ##### -->
  <TABLE description="PRESCRIPTION" name="PRESCRIPTION"> 4
    <TABLE-PATH syntax="XPath">/PHARMACY/PERSON/PRESCRIPTION</TABLE-PATH>
    <COLUMN name="NUMBER" retain="YES"> 6
      <PATH syntax="XPath">/PHARMACY/PERSON/PRESCRIPTION/NUMBER</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>integer</DATATYPE>
    </COLUMN>
    <COLUMN name="DRUG"> 6
      <PATH syntax="XPath">/PHARMACY/PERSON/PRESCRIPTION/DRUG</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>12</LENGTH>
    </COLUMN>
  </TABLE>
</SXLEMAP>

```

- 1 SXLEMAP is the root-enclosing element for the two SAS data set definitions.
- 2 First TABLE element defines the Person data set.

- 3 COLUMN elements contain the attributes for the Name, Street, and City variables in the Person data set.
- 4 Second TABLE element defines the Prescription data set.
- 5 COLUMN element contains the attributes for the Name variable in the Prescription data set. Specifying the `retain="YES"` attribute causes the name to be held for each observation until it is replaced by a different value. (The `retain=` attribute is like the SAS DATA step RETAIN statement, which causes a variable to retain its value from one iteration of the DATA step to the next.)
- 6 COLUMN elements contain the attributes for the Number and Drug variables in the Prescription data set.

The following SAS statements import the XML document and specify the XMLMap:

```
filename pharm 'c:\My Documents\Pharmacy.xml';
filename map 'c:\My Documents\Pharmacy.map';

libname pharm xmlv2 xmlmap=map;
quit;
```

The DATASETS procedure verifies that SAS interprets the XML document Pharmacy.XML as two SAS data sets: PHARM.PERSON and PHARM.PRESCRIPTION.

```
proc datasets library=pharm;
quit;
```

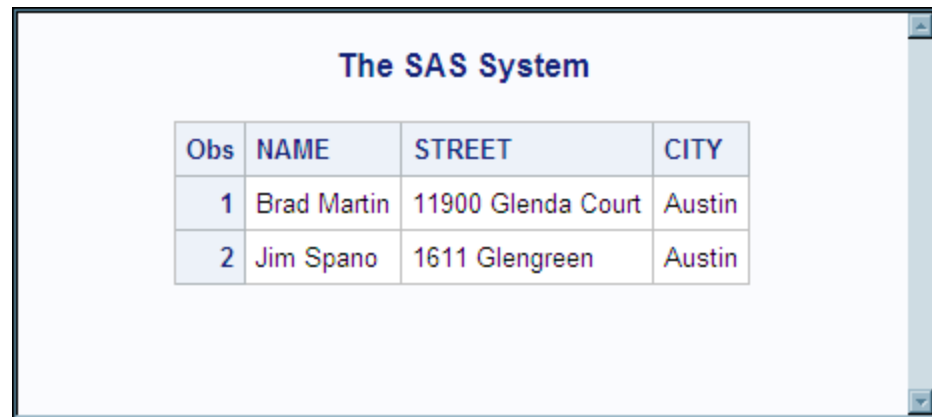

Display 5.5 DATASETS Procedure Output for PHARM Library

Including a Key Field with Generated Numeric Keys

This example imports the XML document Pharmacy.XML, which contains hierarchical data and is used in the example “[Importing Hierarchical Data as Related Data Sets](#)” on [page 56](#). This example continues with the XMLMap by adding a key field with generated numeric key values in order to provide a relationship between the two data sets. (A key field holds unique data in order to identify that record from the other records. For example, account number, product code, and customer name are typical key fields.)

To generate key field values, use the class="ORDINAL" attribute in the COLUMN element in order to create a counter variable. A counter variable keeps track of the number of times the location path, which is specified by the INCREMENT-PATH element, is encountered. The counter variable increments its count by 1 each time the location path is matched. (The counter variable is similar to the `_N_` automatic variable in DATA step processing in that it counts the number of observations being read into a SAS data set.)

Note: When using a counter variable to create a key field for related data sets, you must specify the same location paths for both TABLE elements. Otherwise, the results

will not match. Each table must have the same generated key for like-named data elements.

The following XMLMap imports Pharmacy.XML document as two SAS data sets that have related information and also creates a key field that holds generated numeric key values:

```
<?xml version="1.0" encoding="UTF-8"?>

    <TYPE>character</TYPE>
    <DATATYPE>string</DATATYPE>
    <LENGTH>12</LENGTH>
  </COLUMN>
</TABLE>

</SXLEMAP>

```

The following explains the XMLMap syntax that generates the key fields:

- 1 In the TABLE element that defines the Person data set, the TABLE-PATH element identifies the observation boundary for the data set. The location path generates a new observation each time a PERSON element is read.
- 2 For the Person data set, the COLUMN element for the Key variable contains the class="ORDINAL" attribute as well as the INCREMENT-PATH element. The XML engine follows this process in order to generate the key field values for the Person data set:
 1. When the XML engine encounters the <PERSON> start tag, it reads the value into the input buffer, and then increments the value for the Key variable by 1.
 2. The XML engine continues reading values into the input buffer until it encounters the </PERSON> end tag, at which time it writes the completed input buffer to the SAS data set as one observation.
 3. The process is repeated for each <PERSON> start tag (from INCREMENT-PATH) and </PERSON> end tag (from TABLE-PATH) sequence.
 4. The result is four variables and two observations.
- 3 In the TABLE element that defines the Prescription data set, the TABLE-PATH element identifies the observation boundary for the data set. The location path generates a new observation each time a PRESCRIPTION element is read.
- 4 For the Prescription data set, the COLUMN element for the Key variable contains the class="ORDINAL" attribute as well as the INCREMENT-PATH element.

The XML engine follows this process in order to generate the key field values for the Prescription data set:

1. When the XML engine encounters the <PERSON> start tag, it reads the value into the input buffer, and then increments the value for the Key variable by 1.
2. The XML engine continues reading values into the input buffer until it encounters the </PRESCRIPTION> end tag, at which time it writes the completed input buffer to the SAS data set as one observation. Because the location paths for the counter variables must be the same for both TABLE elements, the behavior of the XML engine for the Prescription table Key variable is the same as the Person table Key variable. While the XML engine tracks the occurrence of a PERSON tag as a key for both counter variables, the observations are derived from different TABLE-PATH locations.
3. The process is repeated for each <PERSON> start tag (from INCREMENT-PATH) and </PRESCRIPTION> end tag (from TABLE-PATH) sequence.
4. The result is three variables and three observations.

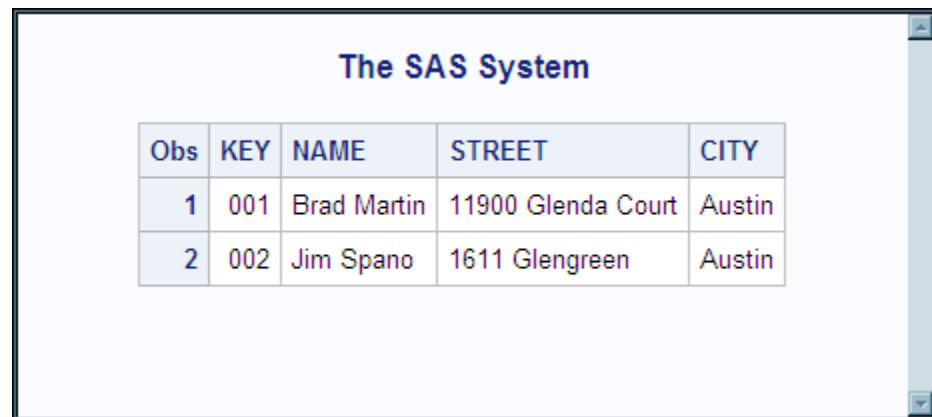

The following SAS statements import the XML document:

```
filename pharm 'c:\My Documents\XML\Pharmacy.xml';
filename map 'c:\My Documents\XML\PharmacyOrdinal.map';

libname pharm xmlv2 xmlmap=map;
```

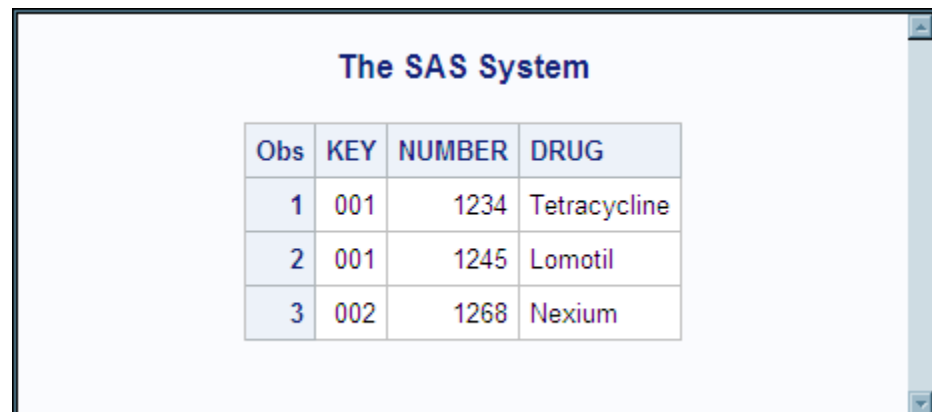

Here is the PRINT procedure output for both of the imported SAS data sets with a numeric key:

Display 5.8 PRINT Procedure Output for PHARM.PERSON

Obs	KEY	NAME	STREET	CITY

2	001	1245	Lomotil
3	002	1268	Nexium

Determining the Observation Boundary to Avoid Concatenated Data

This example imports an XML document that illustrates how to determine the observation boundary so that the result is separate observations and not concatenated data.

The observation boundary translates into a collection of rows with a constant set of columns. Using an XMLMap, you determine the observation boundary with the TABLE-PATH element by specifying a location path. The end tag for the location path determines when data is written to the SAS data set as an observation.

Identifying the observation boundary can be tricky due to sequences of start tag and end-tag pairing. If you do not identify the appropriate observation boundary, the result could be a concatenated data string instead of separate observations. This example illustrates pairing situations that can cause unwanted results.

For the following XML document, an XMLMap is necessary in order to import the file successfully. Without an XMLMap, the XML engine would import a data set named FORD with columns ROW0, MODEL0, YEAR0, ROW1, MODEL1, YEAR1, and so on.

```
<?xml version="1.0" ?>
<VEHICLES>
  <FORD>
    <ROW>
      <Model>Mustang</Model>
      <Year>1965</Year>
    </ROW>
    <ROW>
      <Model>Explorer</Model>
      <Year>1982</Year>
    </ROW>
    <ROW>
      <Model>Taurus</Model>
      <Year>1998</Year>
    </ROW>
    <ROW>
      <Model>F150</Model>
      <Year>2000</Year>
    </ROW>
  </FORD>
</VEHICLES>
```

Looking at the above XML document, there are three sequences of element start tags and end tags: VEHICLES, FORD, and ROW. If you specify the following table location path and column locations paths, the XML engine processes the XML document as follows:

```
<TABLE-PATH syntax="XPath"> /VEHICLES/FORD </TABLE-PATH>
<PATH syntax="XPath"> /VEHICLES/FORD/ROW/Model </PATH>
<PATH syntax="XPath"> /VEHICLES/FORD/ROW/Year </PATH>
```

1. The XML engine reads the XML markup until it encounters the <FORD> start tag, because FORD is the last element specified in the table location path.

2. The XML engine clears the input buffer and scans subsequent elements for variables based on the column location paths. As a value for each variable is encountered, it is read into the input buffer. For example, after reading the first ROW element, the input buffer contains the values **Mustang** and **1965**.
3. The XML engine continues reading values into the input buffer until it encounters the `</FORD>` end tag, at which time it writes the completed input buffer to the SAS data set as an observation.
4. The end result is one observation, which is not what you want.

Here is the PRINT procedure listing output showing the concatenated observation. (The data in the observation is truncated due to the LENGTH element.)

Output 5.1 PRINT Procedure Output Showing Unacceptable FORD Data Set

The SAS System		1
Model	Year	
Mustang Explorer Tau	1965	

To get separate observations, you must change the table location path so that the XML engine writes separate observations to the SAS data set. Here are the correct location paths and the process that the engine would follow:

```
<TABLE-PATH syntax="XPath"> /VEHICLES/FORD/ROW </TABLE-PATH>
<PATH syntax="XPath"> /VEHICLES/FORD/ROW/Model </PATH>
<PATH syntax="XPath"> /VEHICLES/FORD/ROW/Year </PATH>
```

1. The XML engine reads the XML markup until it encounters the `<ROW>` start tag, because ROW is the last element specified in the table location path.
2. The XML engine clears the input buffer and scans subsequent elements for variables based on the column location paths. As a value for each variable is encountered, it is read into the input buffer.
3. The XML engine continues reading values into the input buffer until it encounters the `</ROW>` end tag, at which time it writes the completed input buffer to the SAS data set as an observation. That is, one observation is written to the SAS data set that contains the values **Mustang** and **1965**.
4. The process is repeated for each `<ROW>` start-tag and `</ROW>` end-tag sequence.
5. The result is four observations.

Here is the complete XMLMap syntax:

```
<?xml version="1.0" ?>
<SXLEMAP version="2.1" name="path" description="XMLMap for path">
  <TABLE name="FORD">
    <TABLE-PATH syntax="XPath"> /VEHICLES/FORD/ROW </TABLE-PATH>
    <COLUMN name="Model">
      <DATATYPE> string </DATATYPE>
      <LENGTH> 20 </LENGTH>
      <TYPE> character </TYPE>
      <PATH syntax="XPath"> /VEHICLES/FORD/ROW/Model </PATH>
    </COLUMN>
    <COLUMN name="Year">
```

```

        <DATATYPE> string </DATATYPE>
        <LENGTH> 4 </LENGTH>
        <TYPE> character </TYPE>
        <PATH syntax="XPath"> /VEHICLES/FORD/ROW/Year </PATH>
    </COLUMN>
</TABLE>
</SXLEMAP>

```

The following SAS statements import the XML document and specify the XMLMap. The PRINT procedure verifies the results.

```

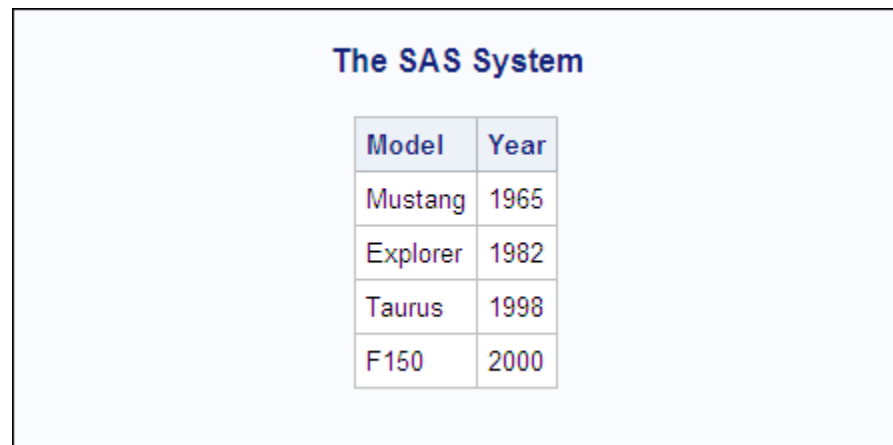

filename PATH 'c:\My Documents\XML\path.xml';
filename MAP 'c:\My Documents\XML\path.map';

libname PATH xmlv2 xmlmap=MAP;

proc print data=PATH.FORD noobs;
run;

```

Determining the Observation Boundary to Select the Best Columns

This example imports an XML document that illustrates how to determine the observation boundary so that the result is the best collection of columns.

The observation boundary translates into a collection of rows with a constant set of columns. Using an XMLMap, you determine the observation boundary with the TABLE-PATH element by specifying a location path.

In the following XML document, PUBLICATION appears to be a possible element to use as the observation boundary, which would result in these columns: TITLE, ACQUIRED, TOPIC. However, the TOPIC element occurs arbitrarily within a single PUBLICATION container, so the result would be a set of columns with TOPIC occurring more than once. Therefore, the TOPIC element is the better choice to use as the observation boundary in order to result in these columns: TITLE, ACQUIRED, TOPIC, MAJOR.

```

<?xml version="1.0" encoding="iso-8859-1" ?>
<Library>
  <Publication>
    <Title>Developer's Almanac</Title>
    <Acquired>12-11-2000</Acquired>
    <Topic Major="Y">JAVA</Topic>
  </Publication>
  <Publication>
    <Title>Inside Visual C++</Title>
    <Acquired>06-19-1998</Acquired>
    <Topic>Major="Y">C</Topic>
    <Topic>Reference</Topic>
  </Publication>
  <Publication>
    <Title>Core Servlets</Title>
    <Acquired>05-30-2001</Acquired>
    <Topic Major="Y">JAVA</Topic>
    <Topic>Servlets</Topic>
    <Topic>Reference</Topic>
  </Publication>
</Library>

```

Here is the XMLMap syntax to use in order to import the previous XML document:

```

<?xml version="1.0" ?>
<SXLEMAP version="1.2">
  <TABLE name="Publication">
    <TABLE-PATH syntax="XPath">
      /Library/Publication/Topic 1
    </TABLE-PATH>

    <COLUMN name="Title" retain="YES">
      <PATH>
        /Library/Publication/Title
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>19</LENGTH>
    </COLUMN>

    <COLUMN name="Acquired" retain="YES">
      <PATH>
        /Library/Publication/Acquired
      </PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>FLOAT</DATATYPE>
      <LENGTH>10</LENGTH>
      <FORMAT width="10" >mmddy</FORMAT> 2
      <INFORMAT width="10" >mmddy</INFORMAT>
    </COLUMN>

    <COLUMN name="Topic">
      <PATH>
        /Library/Publication/Topic</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>9</LENGTH>
    </COLUMN>
  </TABLE>
</SXLEMAP>

```

```

</COLUMN>

<COLUMN name="Major">
  <PATH>
    /Library/Publication/Topic/@Major
  </PATH>
  <TYPE>character</TYPE>
  <DATATYPE>STRING</DATATYPE>
  <LENGTH>1</LENGTH>
  <ENUM> 3
    <VALUE>Y</VALUE>
    <VALUE>N</VALUE>
  </ENUM>
  <DEFAULT>N</DEFAULT> 4
</COLUMN>
</TABLE>
</SXLEMAP>

```

The previous XMLMap tells the XML engine how to interpret the XML markup as explained below:

- 1 The TOPIC element determines the location path that defines where in the XML document to collect variables for the SAS data set. An observation is written each time a </TOPIC> end tag is encountered in the XML document.
- 2 For the ACQUIRED column, the date is constructed using the XMLMap syntax FORMAT element. Elements like FORMAT and INFORMAT are useful for situations where data must be converted for use by SAS. The XML engine also supports user-written formats and informats, which can be used independently of each other.
- 3 Enumerations are also supported by XMLMap syntax. The ENUM element specifies that the values for the column MAJOR must be either Y or N. Incoming values not contained within the ENUM list are set to MISSING.
- 4 By default, a missing value is set to MISSING. The DEFAULT element specifies a default value for a missing value, which for this example is specified as N. Note that when the ENUM element is used, a value specified by DEFAULT must be one of the ENUM values in order to be valid.

The following SAS statements import the XML document and specify the XMLMap. The PRINT procedure verifies the results.

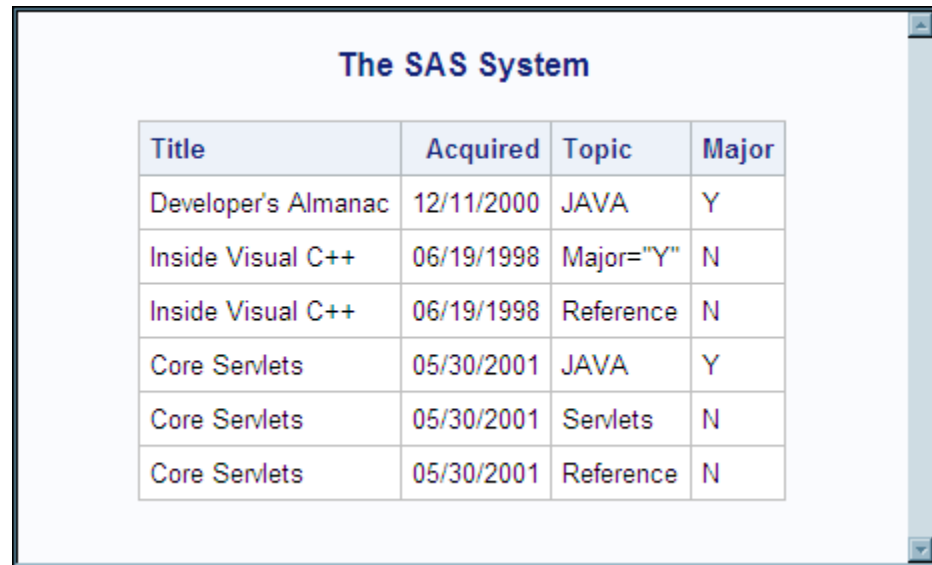

```

filename REP 'C:\My Documents\XML\Rep.xml';
filename MAP 'C:\My Documents\XML\Rep.map';

libname REP xml xmlmap=MAP;

proc print data=REP.Publication noobs;
run;

```

Display 5.11 PRINT Procedure Output for PUBLICATION Data Set

Using ISO 8601 SAS Informats and Formats to Import Dates

This simple example illustrates importing an XML document that contains date values in both the basic format and the extended format. The XMLMap uses the FORMAT and INFORMAT elements to specify the appropriate SAS format and SAS informat in order to represent the dates according to ISO 8601 standards.

First, here is the XML document:

```
<?xml version="1.0" ?>
<Root>
  <ISODATE>
    <BASIC>20010911</BASIC>
    <EXTENDED>2001-09-11</EXTENDED>
  </ISODATE>
</Root>
```

The following XMLMap imports the XML document using the SAS informats and formats to read and write the date values:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- ##### -->
<!-- 2011-01-11T13:20:17 -->
<!-- SAS XML Libname Engine Map -->
<!-- Generated by XML Mapper, 903000.1.0.20101208190000_v930 -->
<!-- ##### -->
<!-- ### Validation report ### -->
<!-- ##### -->
<!-- XMLMap validation completed successfully. -->
<!-- ##### -->
```

```

<SXLEMAP description="Reading a Basic and Extended format ISO date field"
  name="ISODate" version="2.1">

  <NAMESPACES count="0"/>

  <!-- ##### -->
  <TABLE name="ISODATE">
    <TABLE-PATH syntax="XPath">/Root/ISODATE</TABLE-PATH>

    <COLUMN name="BASIC">
      <PATH syntax="XPath">/Root/ISODATE/BASIC</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>date</DATATYPE>
      <FORMAT width="10">E8601DA</FORMAT> 1
      <INFORMAT width="8">B8601DA</INFORMAT> 2
    </COLUMN>

    <COLUMN name="EXTENDED">
      <PATH syntax="XPath">/Root/ISODATE/EXTENDED</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>date</DATATYPE>
      <FORMAT>E8601DA</FORMAT> 3
      <INFORMAT width="10">E8601DA</INFORMAT> 4
    </COLUMN>

  </TABLE>

</SXLEMAP>

```

The following explains the XMLMap syntax that imports the date values:

- 1 For the Basic variable, the FORMAT element specifies the E8601DA SAS format, which writes data values in the extended format *yyyy-mm-dd*.
- 2 For the Basic variable, the INFORMAT element specifies the B8601DA SAS informat, which reads date values into a variable in the basic format *yyyymmdd*.

Note: As recommended, when you read values into a variable with a basic format SAS informat, this example writes the values with the corresponding extended format SAS format.

- 3 For the Extended variable, the FORMAT element specifies the E8601DA SAS format, which writes data values in the extended format *yyyy-mm-dd*.
- 4 For the Extended variable, the INFORMAT element specifies the E8601DA SAS informat, which reads date values into a variable in the basic format *yyyy-mm-dd*.

The following SAS statements import the XML document and display PRINT procedure output:

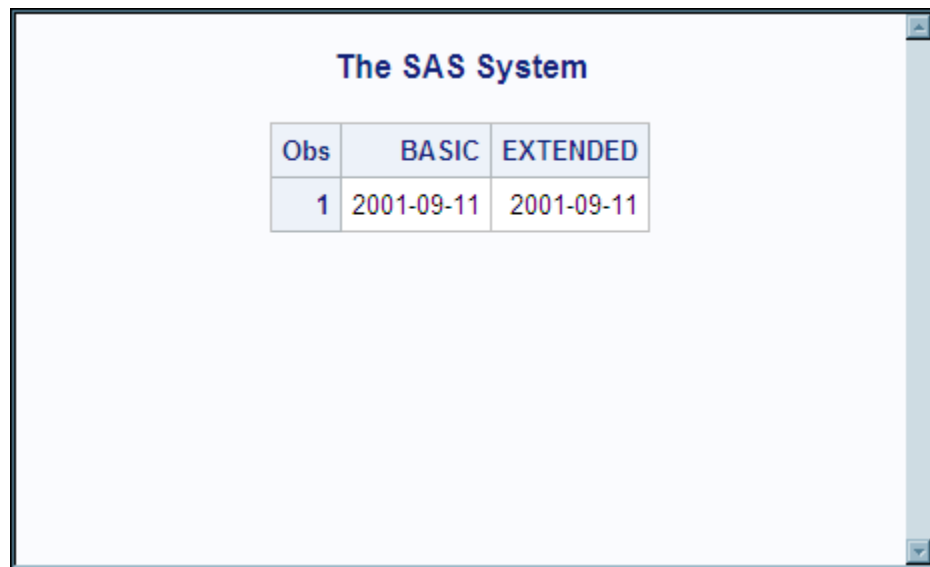

```

filename dates 'c:\My Documents\XML\ISODate.xml';
filename map 'c:\My Documents\XML\ISODate.map';

libname dates xmlv2 xmlmap=map;

proc print data=dates.isodate;
run;

```

Display 5.12 PRINT Procedure Output for Imported Data Set DATES.ISODATE

Obs	BASIC	EXTENDED
1	2001-09-11	2001-09-11

Using ISO 8601 SAS Informat and Formats to Import Time Values with a Time Zone

This example illustrates importing an XML document that contains time values in various forms. The XMLMap uses the FORMAT and INFORMAT elements to specify the appropriate SAS formats and SAS informats in order to represent the times appropriately.

First, here is an XML document that contains a variety of time values:

```
<?xml version="1.0" ?>
<Root>
  <TIME>
    <LOCAL>09:00:00</LOCAL>
    <UTC>09:00:00Z</UTC>
    <OFFSET>14:00:00+05:00</OFFSET>
  </TIME>
</Root>
```

The following XMLMap imports the XML document using the SAS informats and formats to read and write the time values:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- ##### -->
<!-- 2011-01-11T13:31:41 -->
<!-- SAS XML Libname Engine Map -->
<!-- Generated by XML Mapper, 903000.1.0.20101208190000_v930 -->
<!-- ##### -->
<!-- ### Validation report ### -->
<!-- ##### -->
<!-- XMLMap validation completed successfully. -->
```

```

<!-- ##### -->
<SXLEMAP name="ISOtime" version="2.1">

  <NAMESPACES count="0"/>

  <!-- ##### -->
  <TABLE name="TIME">
    <TABLE-PATH syntax="XPath">/Root/TIME</TABLE-PATH>

    <COLUMN name="LOCAL">
      <PATH syntax="XPath">/Root/TIME/LOCAL</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>time</DATATYPE>
      <FORMAT width="8">E8601TM</FORMAT> 1
      <INFORMAT width="8">E8601TM</INFORMAT>
    </COLUMN>

    <COLUMN name="LOCALZONE">
      <PATH syntax="XPath">/Root/TIME/LOCAL</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>time</DATATYPE>
      <FORMAT width="14">E8601LZ</FORMAT> 2
      <INFORMAT width="8">E8601TM</INFORMAT>
    </COLUMN>

    <COLUMN name="UTC">
      <PATH syntax="XPath">/Root/TIME/UTC</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>time</DATATYPE>
      <FORMAT width="9">E8601TZ</FORMAT> 3
      <INFORMAT width="9">E8601TZ</INFORMAT>
    </COLUMN>

    <COLUMN name="OFFSET">
      <PATH syntax="XPath">/Root/TIME/OFFSET</PATH>
      <TYPE>numeric</TYPE>
      <DATATYPE>time</DATATYPE>
      <FORMAT width="14">E8601TZ</FORMAT> 4
      <INFORMAT width="14">E8601TZ</INFORMAT>
    </COLUMN>

  </TABLE>

</SXLEMAP>

```

The following explains the XMLMap syntax that imports the time values:

- 1 For the Local variable, the INFORMAT and FORMAT elements specify the E8601TM SAS informat and format, which reads and writes time values in the extended format *hh:mm:ss.fffff*. Because there is no time zone indicator, the context of the value is local time.
- 2 For the Localzone variable, which reads the same value as the Local variable, the INFORMAT element specifies the E8601TM SAS informat, which reads time values in the extended format *hh:mm:ss.fffff*. Because there is no time zone indicator, the context of the value is local time.

The FORMAT element, however, specifies the E8601LZ SAS format, which writes time values in the extended format *hh:mm:ss+|-hh:mm*. The E8601LZ format appends the UTC offset to the value as determined by the local, current SAS session. Using the E8601LZ format enables you to provide a time notation in order to eliminate the ambiguity of local time.

Note: Even with the time notation, it is recommended that you do not mix time-based values.

- 3 For the UTC variable, the INFORMAT and FORMAT elements specify the E8601TZ SAS informat and format, which reads and writes time values in the extended format *hh:mm:ss+|-hh:mm*. Because there is a time zone indicator, the value is assumed to be expressed in UTC. No adjustment or conversion is made to the value.
- 4 For the Offset variable, the INFORMAT and FORMAT elements specify the E8601TZ SAS informat and format, which reads and writes time values in the extended format *hh:mm:ss+|-hh:mm*. Because there is a time zone offset present, when the time value is read into the variable using the time zone sensitive SAS informat, the value is adjusted to UTC as requested via the time zone indicator, but the time zone context is not stored with the value. When the time value is written using the time zone sensitive SAS format, the value is expressed as UTC with a zero offset value and is not adjusted to or from local time.

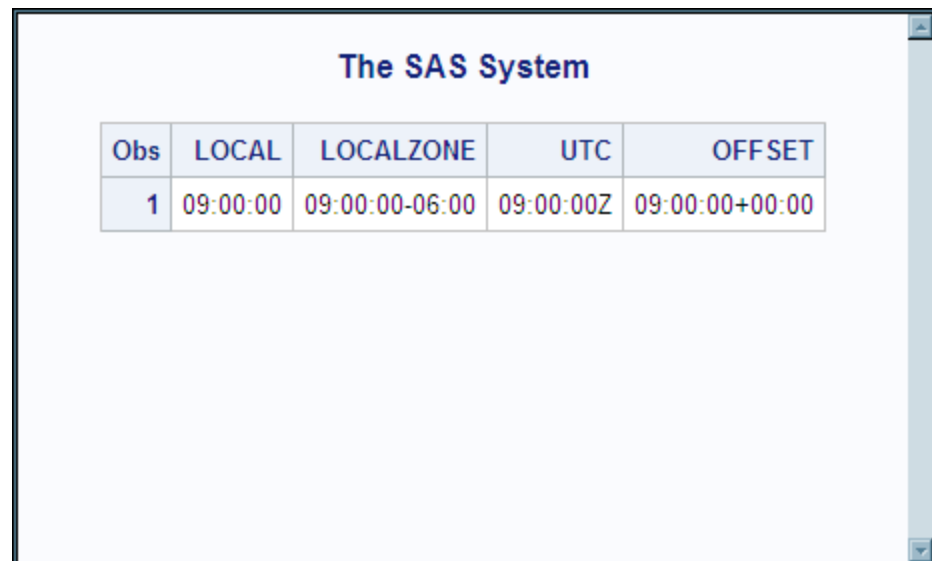

The following SAS statements import the XML document and display the PRINT procedure output:

```
filename timzn 'c:\My Documents\XML\Time.xml';
filename map 'c:\My Documents\XML\Time.map';

libname timzn xmlv2 xmlmap=map;

proc print data=timzn.time;
run;
```

Display 5.13 PRINT Procedure Output for Imported Data Set TIMZN.TIME

Obs	LOCAL	LOCALZONE	UTC	OFFSET
1	09:00:00	09:00:00-06:00	09:00:00Z	09:00:00+00:00

Referencing a Fileref Using the URL Access Method

Using several methods, the XML engine can access an XML document that is referenced by a fileref. When using the URL access method to reference a fileref, you should also specify an XMLMap. Specifying an XMLMap causes the XML engine to process the XML document with a single pass of the file, rather than a double pass, which is what happens when you do not specify an XMLMap.

This example illustrates how to access an XML document by referencing a fileref and using the URL access method:

```
filename NHL url 'http://www.a.com/NHL.xml'; 1
filename MAP 'C:\My Documents\XML\NHL.map'; 2

libname NHL xml xmlmap=MAP; 3

proc copy indd=NHL outdd=work; 4
  select NHL;
run;
```

- 1 The first FILENAME statement assigns the fileref NHL to the XML document by using the URL access method.
- 2 The second FILENAME statement assigns the fileref MAP to the physical location of the XMLMap NHL.map.
- 3 The LIBNAME statement uses the fileref NHL to reference the XML document, specifies the XML engine, and uses the fileref MAP to reference the XMLMap.
- 4 The COPY procedure reads the XML document, and writes its content as a temporary SAS data set. When using the URL access method, you should include the step to create the SAS data set with either a COPY procedure or a DATA step.

Specifying a Location Path on the PATH Element

The XMLMap PATH element supports several XPath forms to specify a location path. The location path tells the XML engine where in the XML document to locate and access a specific tag for the current variable. In addition, the location path tells the XML engine to perform a function, which is determined by the XPath form, to retrieve the value for the variable.

This example imports an XML document and illustrates each of the supported XPath forms, which include three element forms and two attribute forms.

First, here is the XML document NHL.XML to be imported:

```
<?xml version="1.0" encoding="iso-8859-1" ?>
<NHL>
  <CONFERENCE> Eastern
  <DIVISION> Southeast
    <TEAM founded="1999" abbrev="ATL"> Thrashers </TEAM>
    <TEAM founded="1997" abbrev="CAR"> Hurricanes </TEAM>
```

```

    <TEAM founded="1993" abbrev="FLA"> Panthers </TEAM>
    <TEAM founded="1992" abbrev="TB" > Lightning </TEAM>
    <TEAM founded="1974" abbrev="WSH"> Capitals </TEAM>
  </DIVISION>
</CONFERENCE>
</NHL>

```

Here is the XMLMap used to import the XML document, with notations for each XPath form on the PATH element:

```

<?xml version="1.0" ?>
<SXLEMAP version="1.2">
  <TABLE name="TEAMS">
    <TABLE-PATH syntax="XPath">
      /NHL/CONFERENCE/DIVISION/TEAM
    </TABLE-PATH>

    <COLUMN name="ABBREV">
      <PATH syntax="XPath">
        /NHL/CONFERENCE/DIVISION/TEAM/@abbrev 1
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>3</LENGTH>
    </COLUMN>

    <COLUMN name="FOUNDED">
      <PATH syntax="XPath">
        /NHL/CONFERENCE/DIVISION/TEAM/@founded [@abbrev="ATL"] 2
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>10</LENGTH>
    </COLUMN>

    <COLUMN name="CONFERENCE" retain="YES">
      <PATH syntax="XPath">
        /NHL/CONFERENCE 3
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>10</LENGTH>
    </COLUMN>

    <COLUMN name="TEAM">
      <PATH syntax="XPath">
        /NHL/CONFERENCE/DIVISION/TEAM [@founded="1993"] 4
      </PATH>
      <TYPE>character</TYPE>
      <DATATYPE>STRING</DATATYPE>
      <LENGTH>10</LENGTH>
    </COLUMN>

    <COLUMN name="TEAMS5">
      <PATH syntax="XPath">
        /NHL/CONFERENCE/DIVISION/TEAM [position()=5] 5
      </PATH>

```

```

        <TYPE>character</TYPE>
        <DATATYPE>STRING</DATATYPE>
        <LENGTH>10</LENGTH>
    </COLUMN>

```

```

    </TABLE>
</SXLEMAP>

```

- 1 The Abbrev variable uses the attribute form that selects values from a specific attribute. The engine scans the XML markup until it finds the TEAM element. The engine retrieves the value from the abbrev= attribute, which results in each team abbreviation.
- 2 The Founded variable uses the attribute form that conditionally selects from a specific attribute based on the value of another attribute. The engine scans the XML markup until it finds the TEAM element. The engine retrieves the value from the founded= attribute where the value of the abbrev= attribute is ATL, which results in the value 1999. The two attributes must be for the same element.
- 3 The Conference variable uses the element form that selects PCDATA from a named element. The engine scans the XML markup until it finds the CONFERENCE element. The engine retrieves the value between the <CONFERENCE> start tag and the </CONFERENCE> end tag, which results in the value Eastern.
- 4 The Team variable uses the element form that conditionally selects PCDATA from a named element. The engine scans the XML markup until it finds the TEAM element where the value of the founded= attribute is 1993. The engine retrieves the value between the <TEAM> start tag and the </TEAM> end tag, which results in the value Panthers.
- 5 The Team5 variable uses the element form that conditionally selects PCDATA from a named element based on a specific occurrence of the element. The position function tells the engine to scan the XML markup until it finds the fifth occurrence of the TEAM element. The engine retrieves the value between the <TEAM> start tag and the </TEAM> end tag, which results in the value Capitals.

The following SAS statements import the XML document NHLShort.XML and specify the XMLMap named NHL1.MAP. The PRINT procedure shows the resulting variables with selected values:

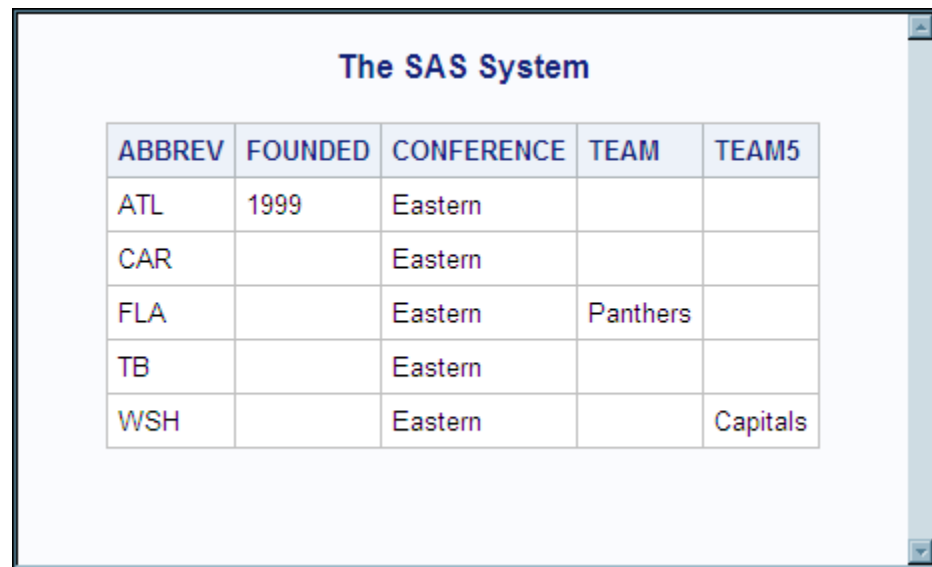

```

filename NHL 'C:\My Documents\XML\NHLShort.xml';
filename MAP 'C:\My Documents\XML\NHL1.map';

libname NHL xml xmlmap=MAP;

proc print data=NHL.TEAMS noobs;
run;

```

Display 5.14 PRINT Procedure Output Showing Resulting Variables with Selected Values

The screenshot shows a window titled "The SAS System" containing a table with the following data:

ABBREV	FOUNDED	CONFERENCE	TEAM	TEAM5
ATL	1999	Eastern		
CAR		Eastern		
FLA		Eastern	Panthers

WSH		Eastern		Capitals

Including Namespace Elements in an XMLMap

This example illustrates the XMLMap namespace elements. The XMLMap namespace elements enable you to import an XML document with like-named elements that are qualified with XML namespaces. The XMLMap namespace elements maintain XML namespaces from the imported XML document in order to export an XML document with namespaces from the SAS data set.

Here is an XML document named NSSample.xml to be imported. The XML document contains three XML namespaces. The namespaces distinguish ADDRESS elements by qualifying them with references to unique URIs. The ADDRESS elements are highlighted below in the first PERSON repeating element:

```
<?xml version="1.0" encoding="UTF-8"?>
<PEOPLE xmlns:HOME="http://sample.url.org/home"
  xmlns:IP="http://sample.url.org/ip"
  xmlns:WORK="http://sample.url.org/work">
  <PERSON>
    <NAME>Joe Smith</NAME>
    <HOME:ADDRESS>1234 Elm Street</HOME:ADDRESS>
    <HOME:PHONE>999-555-0011</HOME:PHONE>
    <WORK:ADDRESS>2001 Office Drive, Box 101</WORK:ADDRESS>
    <WORK:PHONE>999-555-0101</WORK:PHONE>
    <IP:ADDRESS>192.168.1.1</IP:ADDRESS>
  </PERSON>
  <PERSON>
    <NAME>Jane Jones</NAME>
    <HOME:ADDRESS>9876 Main Street</HOME:ADDRESS>
    <HOME:PHONE>999-555-0022</HOME:PHONE>
    <WORK:ADDRESS>2001 Office Drive, Box 102</WORK:ADDRESS>
    <WORK:PHONE>999-555-0102</WORK:PHONE>
    <IP:ADDRESS>172.16.1.2</IP:ADDRESS>
  </PERSON>
</PEOPLE>
```

```

<PERSON>
  <NAME>Pat Perkinson</NAME>
  <HOME:ADDRESS>1395 Half Way</HOME:ADDRESS>
  <HOME:PHONE>999-555-0033</HOME:PHONE>
  <WORK:ADDRESS>2001 Office Drive, Box 103</WORK:ADDRESS>
  <WORK:PHONE>999-555-0103</WORK:PHONE>
  <IP:ADDRESS>10.0.1.3</IP:ADDRESS>
</PERSON>
</PEOPLE>

```

Here is the XMLMap that was used to import the XML document. Notations describe the namespace elements.

```

<SXLEMAP name="Namespace" version="2.1">

  <NAMESPACES count="3"> 1
    <NS id="1" prefix="HOME">http://sample.url.org/home</NS> 2
    <NS id="2" prefix="IP">http://sample.url.org/ip</NS>
    <NS id="3" prefix="WORK">http://sample.url.org/work</NS>
  </NAMESPACES>

  <TABLE description="PERSON" name="PERSON"> 3
    <TABLE-PATH syntax="XPath">/PEOPLE/PERSON</TABLE-PATH>

    <COLUMN name="NAME"> 4
      <PATH syntax="XPath">/PEOPLE/PERSON/NAME</PATH>
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>13</LENGTH>
    </COLUMN>

    <COLUMN name="ADDRESS"> 4
      <PATH syntax="XPathENR">/PEOPLE/PERSON/{1}ADDRESS</PATH> 5
      <TYPE>character</TYPE>
      <DATATYPE>string</DATATYPE>
      <LENGTH>16</LENGTH>

  <TYPE>character</TYPE>
  <DATATYPE>string</DATATYPE>
  <LENGTH>11</LENGTH>
</COLUMN>

</TABLE>

</SXLEMAP>

```

1. A NAMESPACES element contains NS elements for defining XML namespaces. The count= attribute specifies that there are three defined XML namespaces.
2. Three NS elements define the XML namespaces by referencing unique URIs. The id= attribute specifies the identification numbers 1, 2, and 3 for the three XML namespaces. The prefix= attribute assigns the names HOME, WORK, and IP to the referenced URIs.
3. The XMLMap TABLE element contains the data set definition for the PERSON repeating element.
4. XMLMap COLUMN elements contain variable definitions for each nested element within PERSON, which includes NAME, ADDRESS, PHONE, ADDRESS1, PHONE1, and ADDRESS2.
5. In the PATH element for each COLUMN element, the type of syntax is specified as XPathENR (XPath with Embedded Namespace Reference). This type indicates that the syntax is not compliant with the XPath specification. In addition, the identification number is included in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, this is the PATH element for the ADDRESS element: **<PATH syntax="XPathENR">/PEOPLE/PERSON/{1}ADDRESS</PATH>**.

The following SAS statements import the XML document, and specify an XMLMap named NSSample.map. The PRINT procedure shows the resulting SAS data set:

```

filename NS 'C:\My Documents\XML\NSSample.xml';
filename NSMAP 'C:\My Documents\XML\NSSample.map';

libname NS xmlv2 xmlmap=NSMAP;

proc print data=NS.PERSON noobs;
run;

```

Chapter 6

Understanding and Using Tagsets for the XML Engine

What Is a Tagset?	81
Creating Customized Tagsets	81
Exporting an XML Document Using a Customized Tagset	82
Example Overview	82
Define Customized Tagset Using TEMPLATE Procedure	82
Export XML Document Using Customized Tagset	87

What Is a Tagset?

A tagset specifies instructions for generating a markup language from your SAS data set. The resulting output contains embedded instructions defining layout and some content. SAS provides tagsets for a variety of markup languages, including the XML markup language.

Creating Customized Tagsets

In addition to using the tagsets provided by SAS, you can modify the SAS tagsets, and you can create your own tagsets. To create a tagset, use the TEMPLATE procedure to define the tagset definition. For information about defining customized tagsets, see the TEMPLATE procedure in *SAS Output Delivery System: User's Guide*.

CAUTION:

Use customized tagsets with caution. If you are unfamiliar with XML output, do not specify different tagsets. If you alter the tagset when exporting an XML document, and then attempt to import the XML document generated by that altered tagset, the XML engine might not be able to translate the XML markup back to SAS proprietary format.

Exporting an XML Document Using a Customized Tagset

Example Overview

This example defines a customized tagset, and then uses the tagset with the XML engine to export an XML document with customized tags.

Define Customized Tagset Using *TEMPLATE* Procedure

The following *TEMPLATE* procedure defines a customized tagset named `Tagsets.Custom`.

You can use the following code as a template to define your own customized tagsets. For example, to create your own customized tagset, only the `EmitMeta`, `EmitRow`, and `EmitCol` events would require minor modifications.

```
proc template;

/* +-----+
|                                     |
+-----+ */

define tagset tagsets.custom ;
  notes "SAS XML Engine output event model(interface)";

  indent = 3;
  map = '<>''';
  mapsub = '/&lt;/&gt;/&amp;/&quot;/&apos;/';

/* +-----+
|                                     |
+-----+ */

define event XMLversion;
  put '<?xml version="1.0"';
  putq ' encoding=' ENCODING;
  put ' ?>' CR;
  break;
end;

define event XMLcomment;
  put '<!-- ' CR;
  put ' ' TEXT CR;
  put ' -->' CR;
  break;
end;

define event initialize;
```

```

set   $LIBRARYNAME      'LIBRARY' ;
set   $TABLENAME        'DATASET' ;
set   $COLTAG           'column' ;
set   $META             'FULL' ;

eval  $is_engine        1;
eval  $is_procprint     0;
eval  $is_OUTBOARD     1;
end;

/* +-----+
   |                                           |
   +-----+ */

define event doc;
start:
    trigger initialize;
    trigger XMLversion;
    break;
finish:
    break;
end;

define event doc_head;

finish:
    break;
end;

define event table_body;
start:
    trigger EmitMeta ;
    break;
finish:
    trigger EmitMeta ;
    break;
end;

/* +-----+
   |                                             |
   +-----+ */

define event row;
start:
    break / if !cmp(SECTION, "body");
    break / if cmp(XMLMETADATA, "ONLY");
    eval $index 1;
    unset $col_values;
    break;
finish:
    break / if !cmp(SECTION, "body");
    break / if cmp(XMLMETADATA, "ONLY");
    trigger EmitRow ;
    break;

```

```

end;

define event data;
start:
  break / if !cmp(SECTION, "body");
  do / if $is_engine ;
    break / if !cmp(XMLCONTROL, "Data");
  else ;
    break / if !cmp(HTMLCLASS, "Data");
  done ;
  break / if cmp(XMLMETADATA, "ONLY");
  set $name $col_names[$index];
  do / if exists(MISSING);
    eval $is_MISSING 1;
    eval $value_MISSING MISSING;
    set $col_values[$name] " ";
  else ;
    eval $is_MISSING 0;
    set $col_values[$name] VALUE;
  done;
  break;
finish:
  break / if !cmp(SECTION, "body");
  do / if $is_engine ;
    break / if !cmp(XMLCONTROL, "Data");
  else ;
    break / if !cmp(HTMLCLASS, "Data");
  done ;
  break / if cmp(XMLMETADATA, "ONLY");
  set $name $col_names[$index];
  eval $index $index+1;
  break;
end;

/* +-----+
|
| at this point, we just take over XML output. |
| EmitRow() is triggered each time the data is |
|         loaded into the $col_values array. |
|
| we can output anything we desire from here... |
|
+-----+ */

define event EmitMeta; 1
start:
  put '<' $LIBRARYNAME '>' CR ;
  put '  <!-- ' CR ;
  put '        List of available columns' CR ;

  eval $index 1;
  iterate $col_names ;
  do /while _value_;
    put '          ' $index ' ' _value_ CR ;

```

```

        next $col_names;
        eval $index $index+1;
        done;
    put '  -->' CR ;
    break;
finish:
    put '</' $LIBRARYNAME '>' ;
    break;
end;

define event EmitRow; 2
    ndent;
    put "<STUDENT>" CR ;
    ndent;

    set $name "Name"; trigger EmitCol ;
    set $name "Height"; trigger EmitCol ;
    set $name "Weight"; trigger EmitCol ;

    xdent;
    put "</STUDENT>" CR ;
    xdent;
    break;
end;

define event EmitCol; 3
    unset $value;
    set $value $col_values[$name];
    put '<' $name '>' ;
    put $value ;
    put '</' $name '>' CR ;
    break;
end;

end; /* custom */
run;

```

- 1 The EmitMeta event generates an XML comment that contains a list of the variables from the SAS data set. The event contains an example of iteration for a list variable, which processes all of the variables in the SAS data set. For more information about iteration, see the ITERATE statement in the TEMPLATE procedure DEFINE EVENT statement in *SAS Output Delivery System: User's Guide*.
- 2 The EmitRow event creates XML output from the three SAS data set observations. The EmitRow event names specific variables to process, which are Name, Height, and Weight.
- 3 The EmitCol event creates generic-looking XML for each processed variable.

Export XML Document Using Customized Tagset

The following SAS program exports a SAS data set as an XML document using the customized tagset:

```

data work.class; 1
  set sashelp.class (obs=3);
run;

filename XMLout "C:\My Documents\XML\engine92.xml"; 2

libname XMLout xml xmltype=GENERIC tagset=tagsets.custom; 3

data XMLout.class; 4
  set work.class;
run;

```

- 1 The DATA step creates a data set named WORK.CLASS that consists of only three observations.
- 2 The FILENAME statement assigns the fileref XMLOUT to the physical location of the file that will store the exported XML document (complete pathname, filename, and file extension).
- 3 The LIBNAME statement uses the fileref to reference the XML document and specifies the XML engine. The TAGSET= option specifies the customized tagset named Tagsets.Custom.
- 4 The DATA step reads the data set WORK.CLASS and writes its content to the specified XML document in the format that is defined by the customized tagset.

Here is the resulting XML document:

Output 6.1 Exported XML Document Using Customized Tagset

```

<?xml version="1.0" encoding="windows-1252" ?>
<LIBRARY>
  <!--
    List of available columns
    1 Name
    2 Sex
    3 Age
    4 Height
    5 Weight
  -->
  <STUDENT>
    <Name>Alfred</Name>
    <Height>69</Height>
    <Weight>112.5</Weight>
  </STUDENT>
  <STUDENT>
    <Name>Alice</Name>
    <Height>56.5</Height>
    <Weight>84</Weight>
  </STUDENT>
  <STUDENT>
    <Name>Barbara</Name>
    <Height>65.3</Height>
    <Weight>98</Weight>
  </STUDENT>
</LIBRARY>

```

LIBNAME Statement: Overview

Using the LIBNAME Statement	91
Understanding the XML LIBNAME Engine Versions: XML and XMLV2	91
About the XML Engine Versions	91
Comparing the XML Engine Versions: XMLV2 and XML	92
LIBNAME Statement Options	93

Using the LIBNAME Statement

For the XML engine, the LIBNAME statement associates a SAS libref with either a SAS library that stores XML documents or a specific XML document in order to import or export an XML document.

For basic examples, see [“Importing XML Documents” on page 23](#) and [“Exporting XML Documents” on page 9](#).

Understanding the XML LIBNAME Engine Versions: XML and XMLV2

About the XML Engine Versions

SAS provides two versions of XML LIBNAME engine functionality by implementing engine nicknames in the LIBNAME statement.

- By specifying the engine nickname **XML**, you access the SAS 9.1.3 XML engine functionality.
- By specifying the engine nickname **XMLV2**, you access XML engine functionality with enhancements and changes after SAS 9.1.3. For example, the XMLV2 version provides enhanced LIBNAME statement functionality, new XMLMap functionality, and diagnostics of obsolete syntax.

The major differences between the versions include the following:

- The XMLV2 version is XML compliant.
- LIBNAME statement functionality for XMLV2 includes the XMLMAP markup type, additional options, and the ability to assign a libref to a SAS library.

- XMLMap functionality for XMLV2 includes the ability to use an XMLMap for exporting, and support for XML namespaces.

Comparing the XML Engine Versions: XMLV2 and XML

XML Compliance

The XMLV2 version is XML compliant, which means that XMLV2 requires XML markup to be well-formed and in valid construction that is in compliance with the W3C specifications. Because the XMLV2 version is XML compliant, using XMLV2 could affect the following situations:

- XML documents that are imported with the XML version might not pass the more strict parsing rules in the XMLV2 version. For example, like XML markup, the XMLV2 version is case sensitive. Opening and closing tags must be written in the same case, such as `<BODY> ...</BODY>` and `<Message>...</Message>`. For the XMLV2 version, the tag `<Letter>` is different from the tag `<letter>`. Attribute names are also case sensitive, and the attribute value must be enclosed in quotation marks, such as `<Note date="09/24/1975">`.
- XMLMap files that are accepted by the XML version might not work with the XMLV2 version. The XMLV2 version requires that XMLMap files be XML compliant, which means that the markup is case sensitive. In addition, the XMLMap markup must follow the specific XMLMap rules. Tag names must be uppercase. Element attributes must be lowercase. An example is `<SXLEMAP version="2.1">`. In addition, the supported XPath syntax is case sensitive.

XMLMap Files

The XML version supports all XMLMap files starting with XMLMap version 1.0. The XMLV2 version supports XMLMap files starting with XMLMap version 1.2. The documented XMLMap syntax version is 2.1. See [“XMLMap Syntax: Overview” on page 109](#).

LIBNAME Statement Functionality Enhancements for XMLV2

The XMLV2 version provides the following LIBNAME statement functionality:

- The ability to assign a libref to a SAS library, rather than assigning the libref to a specific XML document.
- The XMLMAP markup type.
- Additional options. For a list of the LIBNAME statement options that are available for the XML and XMLV2 nicknames, see [“LIBNAME Statement Options” on page 93](#).
- Using the XMLV2 nickname and the GENERIC markup type, you can export an XML document from multiple SAS data sets. For example, if you have two SAS data sets named Grades.Fred and Grades.Wilma, the following code exports an XML document named Grades.xml that includes the grades from both SAS data sets:

```
libname stones xmlv2 'c:\Grades.xml';

data stones.fred;
    set grades.fred;
run;

data stones.wilma;
```

```

set grades.wilma;
run;

```

LIBNAME Statement Options

The following table lists the available LIBNAME statement options. The ■ symbol indicates whether the option is available for an engine nickname.

Chapter 8

LIBNAME Statement Syntax

Dictionary	95
LIBNAME Statement Syntax	95

Dictionary

LIBNAME Statement Syntax

Processes an XML document.

Valid in: Anywhere

Category: Data Access

Syntax

```
LIBNAME libref engine <'SAS-library | XML-document-path'> <options>;
```

Required Arguments

libref

is a valid SAS name that serves as a shortcut name to associate with the physical location of the XML document. The name must conform to the rules for SAS names. A libref cannot exceed eight characters.

engine

is the engine nickname for the SAS XML LIBNAME engine that imports and exports an XML document.

XML

specifies the XML engine nickname that accesses the SAS 9.1.3 XML engine functionality. The syntax for functionality that is available only for the XML engine nickname is labeled with **XML Only**.

XMLV2

specifies the XML engine nickname that accesses the SAS 9.2 and 9.3 XML engine functionality. The syntax for functionality that is available only for the XMLV2 engine nickname is labeled with **XMLV2 Only**.

Alias: XML92

Note: If syntax is not labeled with either **XML Only** or **XMLV2 Only**, the functionality is available for both engine nicknames.

Tip: At your site, the engine nicknames could be different if your system administrator assigned an alias to the XML LIBNAME engine. See your system administrator to determine whether an alias is assigned.

'SAS-library | XML-document-path'

is the physical location of the XML document for export or import. Enclose the physical location in single or double quotation marks.

SAS-library XMLV2 Only

is the pathname for a collection of one or more files that are recognized by SAS, and that are referenced and stored as a unit. For example, '**C:\My Documents \XML**'.

XML-document-path

includes the pathname, filename, and file extension. For example, '**C:\My Documents \XML\myfile.xml**'.

Operating Environment Information

For details about specifying the physical location of files, see the SAS documentation for your operating environment.

Interactions:

You can use the FILENAME statement in order to assign a fileref to be associated with the physical location of the XML document to be exported or imported. If the fileref matches the libref, you do not need to specify the physical location of the XML document in the LIBNAME statement. For example, the following code writes to the XML document Fred.XML:

```
filename bedrock 'C:\XMLdata\fred.xml';

libname bedrock xml;

proc print data=bedrock.fred;
run;
```

To specify a fileref for the XML document that does not match the libref, you can use the [XMLFILEREf= option on page 101](#). For example, the following code writes to the XML document Wilma.XML:

```
filename cartoon 'C:\XMLdata\wilma.xml';

libname bedrock xml xmlfileref=cartoon;

proc print data=bedrock.wilma;
run;
```

Optional Arguments

FORMATACTIVE=NO | YES

determines whether SAS formats are used.

For the CDISCODM markup type, FORMATACTIVE= specifies whether CDISC ODM CodeList elements, which contain instructions for transcoding display data in a CDISC ODM document, are to be converted to SAS formats, and vice versa.

NO XML Only

causes formatting controls to be suppressed for both importing and exporting.

YES XML Only

when importing, converts the CDISC ODM CodeList elements to the corresponding SAS formats, registers the SAS formats on the referenced variables, and stores the created SAS formats in the format catalog.

When exporting, converts the SAS formats to the corresponding CDISC ODM CodeList elements.

Tips:

By default, the format catalog is created in the Work library. If you want to store the catalog in a permanent library, use the [FORMATLIBRARY= option on page 97](#).

When the format catalog is updated, the default behavior is that any new SAS formats that are created by converting CDISC ODM CodeList elements will overwrite any existing SAS formats that have the same name. To prevent existing SAS formats from being overwritten, specify `FORMATNOREPLACE=YES`.

Example: “Exporting an XML Document in CDISC ODM Markup” on page 21

For the GENERIC markup type, specifies whether output values are affected by SAS formats.

NO

writes the actual data value to the XML markup.

YES

causes the XML markup to contain the formatted data value.

Restriction: For the GENERIC markup type, if you export a SAS data set with formatted data values, and then you try to import the XML document back into the existing SAS data set, the import might fail. Exporting a SAS data set with formatted data values can result in different variables or different variable attributes.

Default: NO

Restriction: Use this option for the CDISCODM and GENERIC markup types only.

FORMATLIBRARY=libref XML Only

specifies the libref of an existing SAS library in which to create the format catalog.

Restrictions:

Use this option when importing an XML document only.

Use this option only for the CDISCODM markup type with `FORMATACTIVE=YES`.

FORMATNOREPLACE=NO | YES XML Only

specifies whether to replace existing format entries in the format catalog search path in cases where an existing format entry has the same name as a format that is being created by the XML engine when it converts a CDISC ODM CodeList element.

NO

does not replace formats that have the same name.

YES

replaces formats that have the same name.

Default: NO

Restrictions:

Use this option when importing an XML document only.

Use this option for the CDISCODM markup type only.

INDENT=*integer*

specifies the number of columns to indent each nested element in the exported XML document. The value can be from 0 (which specifies no indentation) through 32. This specification is cosmetic and is ignored by an XML-enabled browser.

Default: 3

Restriction: Use this option when exporting an XML document only.

ODSCHARSET=*character-set*

specifies the character set to use for the output file. A character set includes letters, logograms, digits, punctuation, symbols, and control characters that are used for display and printing. An example of a character set is ISO-8859-1.

Restriction: Use this option when exporting an XML document only.

Requirement: Use this option with caution. If you are unfamiliar with character sets, encoding methods, or translation tables, do not use this option without proper technical advice.

Tip: The combination of the character set and translation table (encoding method) results in the file's encoding.

See: ODSCHARSET= Option in *SAS National Language Support (NLS): Reference Guide*.

ODSRECSEP= DEFAULT | NONE | YES

controls the generation of a record separator that marks the end of a line in the output XML document.

DEFAULT

enables the XML engine to determine whether to generate a record separator based on the operating environment where you run the SAS job.

The use of a record separator varies by operating environment.

Tip: If you do not transfer XML documents across environments, use the default behavior.

NONE

specifies to not generate a record separator.

The XML engine uses the logical record length of the file that you are writing to and writes one line of XML markup at a time to the output file.

Requirement: The logical record length of the file that you are writing to must be at least as long as the longest line that is produced. If the logical record length of the file is not long enough, then the markup might wrap to another line at an inappropriate place.

Interaction: Transferring an XML document that does not contain a record separator can be a problem. For example, FTP needs a record separator in order to transfer data properly in ASCII (text) mode.

YES

specifies to generate a record separator.

Default: The XML engine determines whether to generate a record separator based on the operating environment where you run the SAS job.

Restriction: Use this option when exporting an XML document only.

Interaction: Most transfer utilities interpret the record separator as a carriage return sequence. For example, using FTP in ASCII (text) mode to transfer an XML document that contains a record separator results in properly constructed line breaks for the target environment.

ODSTRANTAB=table-name

specifies the translation table to use for the output file. The translation table (encoding method) is a set of rules that are used to map characters in a character set to numeric values. An example of a translation table is one that converts characters from EBCDIC to ASCII-ISO. The *table-name* can be any translation table that SAS provides or any user-defined translation table. The value must be the name of a SAS catalog entry in either the SASUSER.PROFILE catalog or the SASHELP.HOST catalog.

Restriction: Use this option when exporting an XML document only.

Requirement: Use this option with caution. If you are unfamiliar with character sets, encoding methods, or translation tables, do not use this option without proper technical advice.

Tip: The combination of the character set and translation table results in the file's encoding.

See: ODSTRANTAB= Option in *SAS National Language Support (NLS): Reference Guide*.

TAGSET=tagset-name

specifies the name of a tagset in order to override the default tagset that is used by the markup type that is specified with XMLTYPE=.

To change the tags that are produced, you can create a customized tagset and specify it with the TAGSET= option. For information about creating customized tagsets, see the TEMPLATE procedure in the *SAS Output Delivery System: User's Guide*.

Restriction: Use this option when exporting an XML document only.

Requirement: Use this option with caution. If you are unfamiliar with XML markup, do not use this option.

See: “Understanding and Using Tagsets for the XML Engine” on page 81

Example: “Exporting an XML Document Using a Customized Tagset ” on page 82

CAUTION: If you alter the tagset when exporting an XML document and then attempt to import the XML document generated by that altered tagset, the XML engine might not be able to translate the XML markup back to SAS proprietary format.

XMLCONCATENATE=NO | YES

specifies whether the file to be imported contains multiple, concatenated XML documents. Importing multiple, concatenated XML documents can be useful (for example, if an application is producing a complete document per query or response, as in a Web form).

Alias: XMLCONCAT=

Default: NO

Restriction: Use this option when importing an XML document only.

Requirement: Use XMLCONCATENATE=YES cautiously. If an XML document consists of concatenated XML documents, the content is not standard XML construction. The option is provided for convenience, not to encourage invalid XML markup.

Example: “Importing Concatenated XML Documents” on page 35

XMLDATAFORM=ELEMENT | ATTRIBUTE

specifies whether the tag for the element to contain SAS variable information (name and data) is in open element or enclosed attribute format. For example, if the variable name is PRICE and the value of one observation is 1.98, the generated output for ELEMENT is `<PRICE> 1.98 </PRICE>` and for ATTRIBUTE is `<COLUMN name="PRICE" value="1.98" />`.

Default: ELEMENT

Restrictions:

Use this option when exporting an XML document only.

Use this option for the GENERIC markup type only.

XMLDOUBLE=DISPLAY | INTERNAL

controls the results of importing or exporting numeric values.

DISPLAY

when exporting, the SAS XML LIBNAME engine retrieves the stored value for the numeric variable, determines an appropriate display for the value in a readable form, and writes the display value to the XML document. The display value is affected by the specified engine nickname and whether a format is assigned:

- The XML engine nickname uses an assigned format. The maximum value is 16 digits. For example, if a numeric variable has an assigned format width that is 20 digits, such as BEST20., the engine truncates the exported value. If there is not an assigned format, the engine displays the value using BEST10.
- The XMLV2 engine nickname ignores any assigned format, and displays the value using BEST16.

When importing, the SAS XML LIBNAME engine retrieves PCDATA (parsed character data) from the named element in the XML document, and converts the data into numeric variable content.

Alias: FORMAT

INTERNAL

when exporting, the SAS XML LIBNAME engine retrieves the stored value for the numeric variable, and writes the raw value to a generated attribute value pair (of the form `rawvalue="value"`). SAS uses the base64 encoding of a portable machine representation. (The base64 encoding method converts binary data into ASCII text, and vice versa, and is similar to the MIME format.)

When importing, the SAS XML LIBNAME engine retrieves the stored value from the `rawvalue=` attribute from the named element in the XML document. It converts that value into numeric variable content. The PCDATA content of the element is ignored. When importing, XMLDOUBLE=INTERNAL is not supported for the XMLV2 engine nickname.

Alias: PRECISION

Tip: Typically, you use XMLDOUBLE=INTERNAL to import or export an XML document when content is more important than readability.

Default: DISPLAY

Restriction: You can specify the XMLDOUBLE= option for the GENERIC markup type only.

Examples:

“Exporting Numeric Values” on page 13

“Importing an XML Document with Numeric Values” on page 25

XMLENCODING='encoding-value'

overrides the SAS data set's encoding for the output file. If an encoding value contains a hyphen, enclose the value in quotation marks.

Restriction: Use this option when exporting an XML document only.

Requirement: Use this option with caution. If you are unfamiliar with character sets, encoding methods, or translation tables, do not use this option without proper technical advice.

Tips:

When transferring an XML document across environments (for example, using FTP), you must be aware of the document's content to determine the appropriate transfer mode. If the document contains an encoding attribute in the XML declaration, or if a byte-order mark (BOM) precedes the XML declaration, transfer the XML document in binary mode. If the document contains neither of these, and you are transferring the document across similar environments, transfer the XML document in text mode.

The combination of the character set and translation table (encoding method) results in the file's encoding.

See: XMLENCODING= option in *SAS National Language Support (NLS) Reference Guide*.

XMLFILEREf=*fileref*

is the SAS name that is associated with the physical location of the XML document to be exported or imported. To assign the fileref, use the FILENAME statement. The XML engine can access any data referenced by a fileref. For example, the following code writes to the XML document Wilma.XML:

```
filename cartoon 'C:\XMLdata\wilma.xml';

libname bedrock xml xmlfileref=cartoon;

proc print data=bedrock.wilma;
run;
```

Tip: When using the URL access method to reference a fileref that is assigned to an XML document, you should also specify an XMLMap. Specifying an XMLMap causes the XML engine to process the XML document with a single pass.

Whether you need to specify an XMLMap depends on your Web server. For an example, see [“Referencing a Fileref Using the URL Access Method”](#) on page 74.

XMLMAP=*fileref* | '*XMLMap*'

specifies an XML document that you create that contains specific XMLMap syntax. The syntax tells the XML engine how to interpret the XML markup for importing or exporting. The XMLMap syntax is itself XML markup.

fileref

is the SAS name that is associated with the physical location of the XMLMap. To assign a fileref, use the FILENAME statement.

Tip: To assign a fileref to an XMLMap using the URL access method, your Web server might require that the file extension be **.xml** instead of **.map**.

'XMLMap'

is the physical location of the XMLMap. Include the complete pathname and the filename. It is suggested that you use the filename extension **.map**. Enclose the physical name in single or double quotation marks.

For example, the following statements import an XML document named MY.XML and specify the XMLMap named MY.MAP, which contains specific XMLMap syntax. The XML engine interprets the XML document as a SAS data set named TEST.MY. In this example, XMLMAP= is used as an option in the LIBNAME statement:

```
libname test xml 'C:\XMLdata\my.xml' xmlmap='C:\XMLdata\my.map';

proc print data=test.my;
run;
```

Restrictions:

The XMLV2 engine nickname supports XMLMap syntax versions 1.2, 1.9, and 2.1. The XMLV2 engine nickname does not support XMLMap versions 1.0 or 1.1.

The XML engine nickname supports XMLMap syntax versions 1.0, 1.1, and 1.2. The XML engine nickname does not support XMLMap syntax versions 1.9 or 2.1.

Requirement: If you specify an XMLMap, specify XMLTYPE=XMLMAP or do not specify a markup type. If you explicitly specify a markup type other than XMLMAP (such as XMLTYPE=GENERIC), an error occurs.

See: [“XMLMap Syntax: Overview” on page 109](#)

Example: [“Importing XML Documents Using an XMLMap” on page 45](#)

XMLMETA=DATA | SCHEMADATA | SCHEMA

specifies whether to include metadata-related information in the exported markup, or specifies whether to import metadata-related information that is included in the input XML document.

Metadata-related information is metadata that describes the characteristics (types, lengths, levels, and so on) of columns within the table markup. Including the metadata-related information can be useful when exporting an XML document from a SAS data set to process on an external product.

DATA

ignores metadata-related information. DATA includes only data content in the exported markup and imports only data content in the input XML document.

SCHEMADATA

includes both data content and metadata-related information in the exported markup and imports both data content and metadata-related information in the input XML document.

SCHEMA

ignores data content. SCHEMA includes only metadata-related information in the exported markup and imports only metadata-related information in the input XML document.

Default: DATA

Restriction: Use this option for the GENERIC and MSACCESS markup types only.

Interaction: If XMLMETA=SCHEMADATA and XMLSCHEMA= is specified, the data is written to the physical location of the XML document specified in the LIBNAME statement. Separate metadata-related information is written to the physical location specified with XMLSCHEMA=. If XMLSCHEMA= is not specified, the metadata-related information is embedded with the data content in the XML document.

Tip: Before SAS 9, the functionality for the XMLMETA= option used the keyword XMLSCHEMA=. SAS 9 changed the option keyword XMLSCHEMA= to XMLMETA=. SAS 9.1 added new functionality using the XMLSCHEMA= option.

Examples:

[“Exporting an XML Document with Separate Metadata” on page 17](#)

[“Importing an XML Document Created by Microsoft Access” on page 29](#)

XMLPROCESS=CONFORM | PERMIT

determines how the XML engine processes character data that does not conform to W3C specifications.

CONFORM

requires that the XML conform to W3C specifications. W3C specifications state that for character data, certain characters such as the left angle bracket (<), the ampersand (&), and the apostrophe (') must be escaped using character references or strings like `&`. For example, to allow attribute values to contain both single and double quotation marks, the apostrophe or single-quotation mark character (') can be represented as `'`; and the double-quotation mark character (") can be represented as `"`.

PERMIT

permits character data that does not conform to W3C specifications to be accepted. That is, in character data, non-escaped characters such as the apostrophe, double quotation marks, and the ampersand are accepted.

Restrictions:

Non-escaped angle brackets in character data are not accepted.

Use XMLPROCESS=PERMIT cautiously. If an XML document consists of non-escaped characters, the content is not standard XML construction. The option is provided for convenience, not to encourage invalid XML markup.

Default: CONFORM

Example: [“Importing an XML Document with Non-Escaped Character Data” on page 27](#)

XMLSCHEMA=fileref | 'external-file'

specifies an external file to contain metadata-related information.

fileref

is the SAS name that is associated with the physical location of the output file. To assign a fileref, use the FILENAME statement.

'external-file'

is the physical location of the file to contain the metadata-related information. Include the complete pathname and the filename. Enclose the physical name in single or double quotation marks.

Restrictions:

Use this option when exporting an XML document only.

Use this option only for the GENERIC and MSACCESS markup types with XMLMETA=SCHEMADATA.

Interaction: If XMLMETA=SCHEMADATA and XMLSCHEMA= is specified, the data is written to the physical location of the XML document specified in the LIBNAME statement. Separate metadata-related information is written to the physical location specified with XMLSCHEMA=. If XMLSCHEMA= is not specified, the metadata-related information is embedded with the data content in the XML document.

Example: [“Exporting an XML Document with Separate Metadata” on page 17](#)

XMLTYPE=GENERIC | CDISCODM | EXPORT | MSACCESS | ORACLE | XMLMAP

specifies the XML markup type.

GENERIC

is a simple, well-formed XML markup type. The XML document consists of a root (enclosing) element and repeating element instances. GENERIC determines a variable's attributes from the data content.

Requirement: When importing, the GENERIC markup type requires a specific physical structure.

See: “Understanding the Required Physical Structure for an XML Document to Be Imported Using the GENERIC Markup Type” on page 46

Examples:

“Exporting an XML Document Containing SAS Dates, Times, and Datetimes” on page 11

“Exporting Numeric Values” on page 13

“Importing an XML Document Using the GENERIC Markup Type” on page 23

CDISCODM XML Only

is the XML markup type for the markup standards that are defined in the Operational Data Model (ODM) that was created by the Clinical Data Interchange Standards Consortium (CDISC). The XML engine supports the ODM 1.2 schema specification. ODM supports the electronic acquisition, exchange, and archiving of clinical trials data and metadata for medical and biopharmaceutical product development.

Tip: Use the `FORMATACTIVE=`, `FORMATNOREPLACE=`, and `FORMATLIBRARY=` options to specify how display data are read and stored in the target environment.

Examples:

“Importing a CDISC ODM Document” on page 37

“Exporting an XML Document in CDISC ODM Markup” on page 21

EXPORT XML Only

is an alias to specify the XML format that is most commonly used in the industry. For the XML engine, specifying `XMLTYPE=EXPORT` is the same as specifying `XMLTYPE=OIMDBM`, which was deprecated in SAS 9. Future releases will upgrade this format specification, as needed.

MSACCESS XML Only

is the XML markup type for the markup standards supported for a Microsoft Access database (.mdb). If the Microsoft Access file contains metadata-related information, then you must specify `MSACCESS` rather than the default `GENERIC` markup type. If there is an embedded XML schema, specifying `MSACCESS` and the `XMLMETA=SCHEMADATA` option causes a variable's attributes to be obtained from the embedded schema. If there is not an embedded schema, `MSACCESS` uses default values for attributes.

Example: “Importing an XML Document Created by Microsoft Access” on page 29

ORACLE XML Only

is the XML markup type for the markup standards equivalent to the Oracle 8i XML implementation. The number of columns to indent each nested element is one, and the enclosing element tag for the contents of the SAS data set is `ROWSET`.

Example: “Exporting an XML Document for Use by Oracle” on page 9

XMLMAP XMLV2 Only

specifies that XML markup is determined by an XMLMap, which is an XML document that you create that contains specific XMLMap syntax. The XMLMap syntax tells the XML engine how to map the SAS data back into the specific XML document structure. To specify the XMLMap in the `LIBNAME` statement, use the `XMLMAP=` option on page 101.

Restriction: Exporting an XML document that is controlled by an XMLMap is limited to a single SAS data set.

Example: “Using an XMLMap to Export an XML Document with a Hierarchical Structure” on page 41

Default: GENERIC

Tip: You can control the markup by specifying options such as INDENT=, XMLDATAFORM=, XMLMETA= (when applicable), and TAGSET=.

Using SAS XML Mapper to Generate and Update an XMLMap	<i>131</i>

Chapter 9

XMLMap Syntax: Overview

Using XMLMap Syntax	109
Comparing the XMLMap Syntax	109

Using XMLMap Syntax

The XML elements for the XMLMap syntax for version 2.1 are explained in this chapter. The elements are listed in the order in which you would typically include them in an XMLMap. That is:

- The first element in the XMLMap is the SXLEMAP element, which is the primary (root) enclosing element that contains the definition for the generated output file. See “SXLEMAP Element” on page 113.
- The namespace elements define XML namespaces, which distinguish element and attribute names by qualifying them with Uniform Resource Identifier (URIs). See “Elements for Namespaces” on page 114.
- If you use an XMLMap for exporting, you must include the exporting elements. See “Elements for Exporting” on page 115.
- The table elements define the SAS data set. See “Elements for Tables” on page 116.
- The column elements define the variables for the SAS data set. See “Elements for Columns” on page 120.

CAUTION:

The XMLMap markup, as XML itself, is case sensitive. The tag names must be uppercase, and the element attributes must be lowercase. For example, `<SXLEMAP version="2.1">`. In addition, the supported XPath syntax is case sensitive as well.

Comparing the XMLMap Syntax

The following table lists the available XMLMap syntax. The ■ symbol indicates whether the syntax is available for importing or exporting, and whether the syntax is available for an engine nickname.

Table 9.1 XMLMap Syntax

Syntax	Description	Import	Export	XML	XMLV2
SXLEMAP on page 113	Primary (root) enclosing element	■	■	■	■
NAMESPACES on page 114	Contains one or more NS elements for defining XML namespaces	■	■		■
NS on page 115	Defines an XML namespace by referencing a unique URI	■	■		■
OUTPUT on page 116	Contains one or more HEADING elements and one TABLEREF element for exporting a SAS data set		■		■
HEADING on page 116	Contains one or more ATTRIBUTE elements		■		■
ATTRIBUTE on page 116	Contains file attribute information		■		■
TABLEREF on page 116	Specifies the name of the table		■		■
TABLE on page 117	Contains a data set definition	■	■	■	■
TABLE-PATH on page 117	Specifies a location path for variables	■	■	■	■
TABLE-END-PATH on page 118	Specifies a location path to stop processing	■	■	■	■
TABLE-DESCRIPTION on page 120	Specifies a SAS data set description	■	■	■	■
COLUMN name= on page 120	Specifies the variable name	■	■	■	■
COLUMN retain= on page 121	Determines the contents of the input buffer	■	■	■	■
COLUMN replace= on page 121	Controls the concatenation of data	■	■	■	■
COLUMN class= on page 121	Determines the type of variable	■	■		■

Syntax	Description	Import	Export	XML	XMLV2
TYPE on page 122	Specifies the SAS data type for the variable	■	■	■	■
DATATYPE on page 122	Specifies the type of data being read	■	■	■	■
DEFAULT on page 123	Specifies a default value for a missing value	■	■	■	■
ENUM on page 123	Contains a list of valid values for the variable	■	■	■	■
FORMAT on page 124	Specifies a SAS format for the variable	■	■	■	■
INFORMAT on page 124	Specifies a SAS informat for the variable	■	■	■	■
DESCRIPTION on page 125	Specifies a description for the variable	■	■	■	■
LENGTH on page 125	Determines the maximum field storage length for a character variable	■	■	■	■
PATH on page 125	Specifies a location path for the current variable	■	■	■	■
INCREMENT-PATH on page 127	Specifies a location path for incrementing the accumulated value for a counter variable	■	■	■	■
RESET-PATH on page 127	Specifies a location path for resetting the accumulated value for a counter variable to zero	■	■	■	■
DECREMENT-PATH on page 128	Specifies a location path to decrement the accumulated value for the counter variable by 1	■	■	■	■

Chapter 10

XMLMap Syntax Version 2.1

Dictionary	113
SXLEMAP Element	113
Elements for Namespaces	114
Elements for Exporting	115
Elements for Tables	116
Elements for Columns	120

Dictionary

SXLEMAP Element

Is the primary (root) enclosing element that contains the definition for the generated output file. The element provides the XML well-formed constraint for the definition.

Restriction: When importing an XML document, the definition can define more than one output SAS data set. When exporting an XML document from a SAS data set, the definition can define only one output XML document.

Requirement: The SXLEMAP element is required.

Syntax

```
SXLEMAP version="number" name="XMLMap" description="description"
```

Attributes

version="*number*"

specifies the version of the XMLMap syntax. The documented XMLMap syntax version is 2.1 and must be specified to obtain full functionality.

Default: The default version is the first version of XMLMap syntax. It is retained for compatibility with prior releases of the XMLMap syntax. It is recommended that you update existing XMLMaps to version 2.1.

Restrictions:

The XMLV2 engine nickname supports XMLMap syntax versions 1.2, 1.9, and 2.1. The XMLV2 engine nickname does not support XMLMap versions 1.0 or 1.1.

The XML engine nickname supports XMLMap syntax versions 1.0, 1.1, and 1.2. The XML engine nickname does not support XMLMap syntax versions 1.9 or 2.1.

Tip: To update an XMLMap to version 2.1, load the existing XMLMap into SAS 9.3 XML Mapper, and then save the XMLMap. For information about SAS XML Mapper, see [“Using SAS XML Mapper to Generate and Update an XMLMap”](#) on page 131.

name="XMLMap"

is an optional attribute that specifies the filename of the XMLMap.

description="description"

is an optional attribute that specifies a description of the XMLMap.

Details

In the example below, the SXLEMAP element specifies all three attributes and contains two TABLE elements.

```
<?xml version="1.0" ?>
<SXLEMAP version="2.1" name="Myxmlmap" description="sample XMLMap">
  <TABLE name="test1">
    .
    .
    .
  </TABLE>
  <TABLE name="test2">
    .
    .
    .
  </TABLE>
</SXLEMAP>
```

Elements for Namespaces

Define XML namespaces.

Syntax

NAMESPACES count="*number*"

NS id="*number*" <prefix="*name*">

Elements

NAMESPACES count="*number*" XMLV2 Only

is an optional element that contains one or more NS elements for defining XML namespaces. For example, **<NAMESPACES count="2">**.

XMLMap namespace elements enable you to import an XML document with like-named elements that are qualified with XML namespaces. In addition, XMLMap namespace elements maintain XML namespaces from the imported XML document in order to export an XML document from the SAS data set.

An XML namespace is a W3C specification that distinguishes element and attribute names by qualifying them with Uniform Resource Identifiers (URIs). For example, if an XML document contains a CUSTOMER element and a PRODUCT element, and both elements contain a nested ID element, XML namespaces make each nested ID element unique.

count="number"

specifies the number of defined XML namespaces.

Requirement: The count= attribute is required. The specified value must match the total number of NS elements.

Example: [“Including Namespace Elements in an XMLMap” on page 77](#)

NS id="number" <prefix="name"> XMLV2 Only

is an optional element that defines an XML namespace by referencing a unique URI. The URI is a string of characters that identifies a resource on the Internet. The URI is treated by an XML parser as simply a string. Specifying the URI does not require that it be used to retrieve information. The most common URI is the Uniform Resource Locator (URL), which identifies an Internet domain address. The use of URIs as namespace names must follow the same rules as the W3C specification for XML namespaces. For example, <NS id="1" prefix="freq"> http://www.hurricanefrequency.com </NS>.

Note: It is recommended that you do not use non-escaped characters in a URI.

id="number"

specifies an identification number for the XML namespace.

Requirements:

The id= attribute is required.

In the variable definition, the identification number must be included in the location path preceding the element that is being defined. See [PATH syntax="type" on page 125](#).

prefix="name"

specifies a qualified name that is associated with the referenced URI. The prefix is used with each element or attribute to indicate to which XML namespace it belongs. Prefix names must follow the same rules as the W3C specification for element names.

Requirements:

The referenced URI must be unique.

The total number of NS elements must match the specified value in the NAMESPACES count= attribute.

Tip: It is recommended that you do not use non-escaped characters in a URI.

Example: [“Including Namespace Elements in an XMLMap” on page 77](#)

Elements for Exporting

Export an XML document from a SAS data set by using the XMLMap that was created to import the XML document.

Restriction: The engine supports exporting from one SAS data set only.

Syntax

OUTPUT

HEADING**ATTRIBUTE** name="*name*" value="*value*"**TABLEREF** name="*name*"**Elements****OUTPUT** XMLV2 Only

is an optional element that contains one or more **HEADING** elements and one **TABLEREF** element for exporting a SAS data set as an XML document.

Requirement: If you specify version 1.9 or 2.1 in an XMLMap to export a SAS data set as an XML document, you must include the **OUTPUT** element in the XMLMap.

Example: [“Using an XMLMap to Export an XML Document with a Hierarchical Structure” on page 41](#)

HEADING XMLV2 Only

is an optional element that contains one or more **ATTRIBUTE** elements.

ATTRIBUTE name="*name*" value="*value*" XMLV2 Only

is an optional element that contains additional file attribute information for the exported XML document, such as a schema reference or other general attributes. The specified name-value pairs are added as attributes to the first generated element in the exported XML document, such as, `<NHL description="Teams of the National Hockey League">`.

name="*name*"

specifies a name for a file attribute, such as `name="description"`.

value="*value*"

specifies a value for the attribute, such as `value="Teams of the National Hockey League"`.

TABLEREF name="*name*" XMLV2 Only

is an optional element that specifies the name of the table in the XMLMap to be exported.

name="*name*"

specifies the name of the table in the XMLMap to be exported. The name must be unique in the XMLMap definition, and the name must be a valid SAS name, which can be up to 32 characters.

Restriction: You can specify one **TABLEREF** element only.

Requirement: The specified name must match a **TABLE** element name= attribute.

Elements for Tables

Define the SAS data set.

Syntax**TABLE** name="*data-set-name*"**TABLE-PATH** syntax="*type*"**TABLE-END-PATH** syntax="*type*" beginend="BEGIN | END"**TABLE-DESCRIPTION**

Elements

TABLE name="data-set-name"

is an element that contains a data set definition. For example, `<TABLE name="channel">`.

name="data-set-name"

specifies the name for the SAS data set. The name must be unique in the XMLMap, and the name must be a valid SAS name, which can be up to 32 characters.

Requirement: The name= attribute is required.

Requirement: The TABLE element is required.

Interaction: The TABLE element can contain one or more of the following elements: TABLE-PATH, TABLE-END-PATH, TABLE-DESCRIPTION, and COLUMN.

TABLE-PATH syntax="type"

specifies a location path that tells the XML engine where in the XML document to locate and access specific elements in order to collect variables for the SAS data set. The location path defines the repeating element instances in the XML document, which is the SAS data set observation boundary. The observation boundary is translated into a collection of rows with a constant set of columns.

For example, using the XML document RSS.XML, which is used in the example [“Using an XMLMap to Import an XML Document as Multiple SAS Data Sets”](#) on page 52, this TABLE-PATH element causes the following to occur:

```
<TABLE-PATH syntax="XPath"> /rss/channel/item </TABLE-PATH>
```

1. The XML engine reads the XML markup until it encounters the `<ITEM>` start tag.
2. The XML engine clears the input buffer, sets the contents to MISSING (by default), and scans elements for variable names based on the COLUMN element definitions. As values are encountered, they are read into the input buffer. (Note that whether the XML engine resets to MISSING is determined by the DEFAULT element as well as the COLUMN element retain= attribute.)
3. When the `</ITEM>` end tag is encountered, the XML engine writes the completed input buffer to the SAS data set as a SAS observation.
4. The process is repeated for each `<ITEM>` start-tag and `</ITEM>` end-tag sequence until the end-of-file is encountered in the input stream or until the TABLE-END-PATH (if specified) is achieved, which results in six observations.

syntax="type"

is an optional attribute that specifies the type of syntax in the location path. The syntax is valid XPath construction in compliance with the W3C specifications. For example, `syntax="XPath"`.

Default: XPath

Requirements:

The value must be XPath or XPathENR.

If an XML namespace is defined with the NAMESPACES element, you must specify the type of syntax as XPathENR (XPath with Embedded Namespace Reference). This is because the syntax is different from the XPath specification. For example, `syntax="XPathENR"`.

CAUTION:

Specifying the table location path, which is the observation boundary, can be tricky due to start-tag and end-tag pairing. The table location path determines which end tag causes the XML engine to write the completed input buffer to the SAS data set. If you do not identify the appropriate end tag, the result could be concatenated data instead of separate observations, or an unexpected set of columns. For examples, see [“Determining the Observation Boundary to Avoid Concatenated Data” on page 64](#) and [“Determining the Observation Boundary to Select the Best Columns” on page 66](#).

Requirements:

The TABLE-PATH element is required.

If an XML namespace is defined with the NAMESPACES element, you must include the identification number in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, `<TABLE-PATH syntax="XPathENR">/Table/{1}Hurricane</TABLE-PATH>`.

The XPath construction is a formal specification that puts a path description similar to UNIX on each element of the XML structure. Note that XPath syntax is case sensitive. For example, if an element tag name is uppercase, it must be uppercase in the location path. If it is lowercase, it must be lowercase. All location paths must begin with the root-enclosing element (denoted by a slash '/') or with the "any parent" variant (denoted by double slashes '//'). Other W3C documented forms are not currently supported.

TABLE-END-PATH syntax="type" beginend="BEGIN | END"

is an optional, optimization element that saves resources by stopping the processing of the XML document before the end of file. The location path tells the XML engine where in the XML document to locate and access a specific element in order to stop processing the XML document.

For example, using the XML document RSS.XML, which is used in the example [“Using an XMLMap to Import an XML Document as Multiple SAS Data Sets” on page 52](#), there is only one `<CHANNEL>` start-tag and one `</CHANNEL>` end-tag. With the TABLE-PATH location path `<TABLE-PATH syntax="XPath"> /rss/channel </TABLE-PATH>`, the XML engine would process the entire XML document, even though it does not store new data in the input buffer after it encounters the first `<ITEM>` start tag, because the remaining elements no longer qualify. The TABLE-END-PATH location path `<TABLE-END-PATH syntax="XPath" beginend="BEGIN"> /rss/channel/item </TABLE-END-PATH>` tells the XML engine to stop processing when the `<ITEM>` start tag is encountered.

Therefore, with the two location path specifications, the XML engine processes only the highlighted data in the RSS.XML document for the CHANNEL data set, rather than the entire XML document:

```
<?xml version="1.0" encoding="ISO-8859-1" ?>
<rss version="0.91">
  <channel>
    <title>WriteTheWeb</title>
    <link>http://writetheweb.com</link>

```

syntax="type"

is an optional attribute that specifies the type of syntax in the location path. The syntax is valid XPath construction in compliance with the W3C specifications. The XPath form supported by the XML engine allows elements and attributes to be individually selected for exclusion in the generated SAS data set. For example, **syntax="XPath"**.

Default: XPath

Requirements:

The value must be XPath or XPathENR.

If an XML namespace is defined with the NAMESPACES element, you must specify the type of syntax as XPathENR (XPath with Embedded Namespace Reference). This is because the syntax is different from the XPath specification. For example, **syntax="XPathENR"**.

beginend="BEGIN | END"

is an optional attribute that specifies to stop processing when either the element start tag is encountered or the element end tag is encountered.

Default: BEGIN

Default: Processing continues until the last end tag in the XML document.

Requirements:

If an XML namespace is defined with the NAMESPACES element, you must include the identification number in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, **<TABLE-END-PATH syntax="XPathENR">/Table/{1}Hurricane</TABLE-END-PATH>**.

The XPath construction is a formal specification that puts a path description similar to UNIX on each element of the XML structure. Note that XPath syntax

is case sensitive. For example, if an element tag name is uppercase, it must be uppercase in the location path. If it is lowercase, it must be lowercase. All location paths must begin with the root-enclosing element (denoted by a slash '/') or with the "any parent" variant (denoted by double slashes '//'). Other W3C documented forms are not currently supported.

Interaction: The TABLE-END-PATH element does not affect the observation boundary; that is determined with the TABLE-PATH element.

Tip: Specifying a location to stop processing is useful for an XML document that is hierarchical, but generally not appropriate for repeating instance data.

Example: [“Using an XMLMap to Import an XML Document as Multiple SAS Data Sets” on page 52](#)

TABLE-DESCRIPTION

is an optional element that specifies a description for the SAS data set, which can be up to 256 characters. For example, `<TABLE-DESCRIPTION> Data Set contains TV channel information </TABLE-DESCRIPTION>`.

Elements for Columns

Define the variables for the SAS data set.

Syntax

COLUMN name="*name*" retain="NO | YES" replace="NO | YES"
class="ORDINAL | FILENAME | FILEPATH"

TYPE

DATATYPE

DEFAULT

ENUM

FORMAT width="*w*" ndec="*d*"

INFORMAT width="*w*" ndec="*d*"

DESCRIPTION

LENGTH

PATH syntax="*type*"

INCREMENT-PATH syntax="*type*" beginend="BEGIN | END"

RESET-PATH syntax="*type*" beginend="BEGIN | END"

DECREMENT-PATH syntax="*type*" beginend="BEGIN | END"

Elements

COLUMN name="*name*" retain="NO | YES" replace="NO | YES"
class="ORDINAL | FILENAME | FILEPATH"

is an element that contains a variable definition. For example, `<COLUMN name="Title">`.

name="*name*"

specifies the name for the variable. The name must be a valid SAS name, which can be up to 32 characters.

Requirement: The name= attribute is required.

retain="NO | YES"

is an optional attribute that determines the contents of the input buffer at the beginning of each observation.

NO

sets the value for the beginning of each observation either to MISSING or to the value of the DEFAULT element if specified.

YES

keeps the current value until it is replaced by a new, nonmissing value. Specifying YES is much like the RETAIN statement in DATA step processing. It forces the retention of processed values after an observation is written to the output SAS data set.

Default: NO

Example: [“Importing Hierarchical Data as Related Data Sets” on page 56](#)

replace="NO | YES"

is an optional attribute that controls the concatenation of data.

NO

concatenates data until the end of the observation boundary.

YES

replaces existing content with new content. Specifying replace="YES" operates like the REPLACE statement in DATA step processing.

Default: NO

Tip: Concatenated data might be the result of an improperly identified end of the observation boundary, which is determined with the TABLE-PATH element.

class="ORDINAL | FILENAME | FILEPATH" XMLV2 Only

is an optional attribute that determines the type of variable.

ORDINAL

specifies that the variable is a numeric counter variable that keeps track of the number of times the location path, which is specified by the INCREMENT-PATH element or the DECREMENT-PATH element, is encountered. (This is similar to the `_N_` automatic variable in DATA step processing.) The counter variable increments or decrements its count by 1 each time the location path is encountered. Counter variables can be useful for identifying individual occurrences of like-named data elements, or for counting observations.

Restriction: When exporting an XML document, variables with class="ORDINAL" are not included in the output XML document.

Requirements:

You must use the INCREMENT-PATH element or the DECREMENT-PATH element. The PATH element is not allowed.

The TYPE element must specify the SAS data type as numeric, and the DATATYPE element must specify the type of data as integer.

Example: [“Including a Key Field with Generated Numeric Keys” on page 60](#)

FILENAME

generates a character variable that contains the filename and extension of the input document. This functionality can be useful when you assign a libref for the XML engine that is associated with a physical location of a SAS library to determine which file contains a particular value.

Requirement: The TYPE element must specify the SAS data type as character, and the DATATYPE element must specify the type of data as string.

FILEPATH

generates a character variable that contains the pathname, filename, and extension of the input document. This functionality can be useful when you assign a libref for the XML engine that is associated with a physical location of a SAS library to determine which file contains a particular observation.

Requirement: The TYPE element must specify the SAS data type as character, and the DATATYPE element must specify the type of data as string.

Requirement: At least one COLUMN element is required.

Interaction: COLUMN can contain one or more of the following elements that describe the variable attributes: DATATYPE, DEFAULT, ENUM, FORMAT, INFORMAT, DESCRIPTION, LENGTH, TYPE, PATH, INCREMENT-PATH, DECREMENT-PATH, and RESET-PATH.

TYPE

specifies the SAS data type (character or numeric) for the variable, which is how SAS stores the data. For example, `<TYPE> numeric </TYPE>` specifies that the SAS data type for the variable is numeric.

Requirement: The TYPE element is required.

Tips:

To assign a floating-point type, use

```
<DATATYPE> float </DATATYPE>
<TYPE> numeric </TYPE>
```

To apply output formatting in SAS, use the FORMAT element.

To control data type conversion on input, use the INFORMAT element. For example, `<INFORMAT> datetime </INFORMAT>`.

DATATYPE

specifies the type of data being read from the XML document for the variable. For example, `<DATATYPE> string </DATATYPE>` specifies that the data contains alphanumeric characters.

The type of data specification can be

string

specifies that the data contains alphanumeric characters and does not contain numbers used for calculations.

integer

specifies that the data contains whole numbers used for calculations.

double

specifies that the data contains floating-point numbers.

datetime

specifies that the input represents a valid datetime value, which is either

- in the form of the XML specification ISO 8601 format. The default form is: `yyyy-mm-ddThh:mm:ss.ffffff`.
- in a form for which a SAS informat (either supplied by SAS or user-written) properly translates the input into a valid SAS datetime value. See also the [INFORMAT element on page 124](#).

date

specifies that the input represents a valid date value, which is either

- in the form of the XML specification ISO 8601 format. The default form is: *yyyy-mm-dd*.
- in a form for which a SAS informat (either supplied by SAS or user-written) properly translates the input into a valid SAS date value. See also the [INFORMAT element on page 124](#).

time

specifies that the input represents a valid time value, which is either

- in the form of the XML specification ISO 8601 format. The default form is: *hh:mm:ss.ffffff*.
- in a form for which a SAS informat (either supplied by SAS or user-written) properly translates the input into a valid SAS date value. See also the [INFORMAT element on page 124](#).

Restriction: The values for previous versions of XMLMap syntax are not accepted by versions 1.9 and 2.1.

Requirement: The DATATYPE element is required.

DEFAULT

is an optional element that specifies a default value for a missing value for the variable. Use the DEFAULT element to assign a nonmissing value to missing data. For example, `<DEFAULT> single </DEFAULT>` assigns the value `single` when a missing value occurs.

Default: By default, the XML engine sets a missing value to MISSING.

Example: [“Determining the Observation Boundary to Select the Best Columns” on page 66](#)

ENUM

is an optional element that contains a list of valid values for the variable. The ENUM element can contain one or more VALUE elements in order to list the values. By using ENUM, values in the XML document are verified against the list of values. If a value is not valid, it is either set to MISSING (by default) or set to the value specified by the DEFAULT element. Note that a value specified for DEFAULT must be one of the ENUM values in order to be valid.

```
<COLUMN name="filing_status">
  .
  .
  .
  <DEFAULT> single </DEFAULT>
  .
  .
  .
  <ENUM>
    <VALUE> single </VALUE>
    <VALUE> married filing joint return </VALUE>
    <VALUE> married filing separate return </VALUE>
    <VALUE> head of household </VALUE>
    <VALUE> qualifying widow(er) </VALUE>
  </ENUM>
</COLUMN>
```

Example: “Determining the Observation Boundary to Select the Best Columns” on page 66

FORMAT width="w" ndec="d"

is an optional element that specifies a SAS format for the variable. A format name can be up to 31 characters for a character format and 32 characters for a numeric format. A SAS format is an instruction that SAS uses to write values. You use formats to control the written appearance of values. Do not include a period (.) as part of the format name. Specify a width and length as attributes, not as part of the format name.

For a list of the SAS formats, including the ISO 8601 SAS formats, see *SAS Formats and Informats: Reference*.

width="w"

is an optional attribute that specifies a format width, which for most formats is the number of columns in the output data.

ndec="d"

is an optional attribute that specifies a decimal scaling factor for numeric formats.

Here is an example:

```
<FORMAT> E8601DA </FORMAT>
<FORMAT width="8"> best </FORMAT>
<FORMAT width="8" ndec="2"> dollar </FORMAT>
```

Example: “Determining the Observation Boundary to Select the Best Columns” on page 66

INFORMAT width="w" ndec="d"

is an optional element that specifies a SAS informat for the variable. An informat name can be up to 30 characters for a character informat and 31 characters for a numeric informat. A SAS informat is an instruction that SAS uses to read values into a variable, that is, to store the values. Do not include a period (.) as part of the informat name. Specify a width and length as attributes, not as part of the informat name.

For a list of the SAS informats, including the ISO 8601 SAS informats, see *SAS Formats and Informats: Reference*.

Here is an example:

```
<INFORMAT> E8601DA </INFORMAT>
<INFORMAT width="8"> best </INFORMAT>
<INFORMAT width="8" ndec="2"> dollar </INFORMAT>
```

width="w"

is an optional attribute that specifies an informat width, which for most informats is the number of columns in the input data.

ndec="d"

is an optional attribute that specifies a decimal scaling factor for numeric informats. SAS divides the input data by 10 to the power of this value.

Example: “Determining the Observation Boundary to Select the Best Columns” on page 66

DESCRIPTION

is an optional element that specifies a description for the variable, which can be up to 256 characters. The following example shows that the description is assigned as the variable label.

```
<DESCRIPTION> Story link </DESCRIPTION>
```

LENGTH

is the maximum field storage length from the XML data for a character variable. The value refers to the number of bytes used to store each of the variable's values in the SAS data set. The value can be 1 to 32,767. During the input process, a maximum length of characters is read from the XML document and transferred to the observation buffer. For example, `<LENGTH> 200 </LENGTH>`.

Restriction: LENGTH is not valid for numeric data.

Requirement: For data that is defined as a STRING data type, the LENGTH element is required.

Tip: You can use LENGTH to truncate a long field.

PATH syntax="type"

specifies a location path that tells the XML engine where in the XML document to locate and access a specific tag for the current variable. In addition, the location path tells the XML engine to perform a function, which is determined by the location path form, to retrieve the value for the variable. The XPath forms that are supported allow elements and attributes to be individually included in the generated SAS data set.

syntax="type"

is an attribute that specifies the type of syntax used in the location path. The syntax is valid XPath construction in compliance with the W3C specifications. The XPath form supported by the XML engine allows elements and attributes to be individually included in the generated SAS data set.

Default: XPath

Requirements:

The value must be XPath or XPathENR.

If an XML namespace is defined with the NAMESPACES element, you must specify the type of syntax as XPathENR (XPath with Embedded Namespace Reference). This is because the syntax is different from the XPath specification. For example, `syntax="XPathENR"`.

To specify the PATH location path, use one of the following forms:

CAUTION:

These forms are the only XPath forms that the XML engine supports. If you use any other valid W3C form, the results will be unpredictable.

element-form

selects PCDATA (parsed character data) from a named element. The following element forms enable you to select from a named element, conditionally select from a named element based on a specific attribute value, or conditionally select from a named element based on a specific occurrence of the element using the position function:

```
<PATH> /LEVEL/ITEM </PATH>
<PATH> /LEVEL/ITEM[@attr="value"] </PATH>
<PATH> /LEVEL/ITEM[position()=n] | [n] </PATH>
```

The following examples illustrate the element forms. For more information about the examples, see [“Specifying a Location Path on the PATH Element”](#) on page 74.

- The following location path tells the XML engine to scan the XML markup until it finds the CONFERENCE element. The XML engine retrieves the value between the <CONFERENCE> start tag and the </CONFERENCE> end tag.

```
<PATH> /NHL/CONFERENCE </PATH>
```

- The following location path tells the XML engine to scan the XML markup until it finds the TEAM element where the value of the founded= attribute is 1993. The XML engine retrieves the value between the <TEAM> start tag and the </TEAM> end tag.

```
<PATH> /NHL/CONFERENCE/DIVISION/TEAM[@founded="1993"] </PATH>
```

- The following location path uses the position function to tell the XML engine to scan the XML markup until it finds the fifth occurrence of the TEAM element. The XML engine retrieves the value between the <TEAM> start tag and the </TEAM> end tag.

```
<PATH> /NHL/CONFERENCE/DIVISION/TEAM[position()=5] </PATH>
```

You can use the following shorter version for the position function:

```
<PATH> /NHL/CONFERENCE/DIVISION/TEAM[5] </PATH>
```

attribute-form

selects values from an attribute. The following attribute forms enable you to select from a specific attribute, or conditionally select from a specific attribute based on the value of another attribute:

```
<PATH> /LEVEL/ITEM/@attr </PATH>
```

```
<PATH> /LEVEL/ITEM/@attr[attr2="value"] </PATH>
```

The following examples illustrate the attribute forms. For more information about the examples, see [“Specifying a Location Path on the PATH Element” on page 74](#).

- The following location path tells the XML engine to scan the XML markup until it finds the TEAM element. The XML engine retrieves the value from the abbrev= attribute.

```
<PATH syntax="XPath"> /NHL/CONFERENCE/DIVISION/TEAM/@abbrev </PATH>
```

- The following location path tells the XML engine to scan the XML markup until it finds the TEAM element. The XML engine retrieves the value from the founded= attribute where the value of the abbrev= attribute is ATL. The two attributes must be for the same element.

```
<PATH> /NHL/CONFERENCE/DIVISION/TEAM/@founded[@abbrev="ATL"] </PATH>
```

Requirements:

Whether the PATH element is required or allowed is determined by the class="ORDINAL" attribute for the COLUMN element. If the class="ORDINAL" attribute is not specified, which is the default, PATH is required and INCREMENT-PATH, DECREMENT-PATH, and RESET-PATH are not allowed. If the class="ORDINAL" attribute is specified, PATH is not allowed, INCREMENT-PATH or DECREMENT-PATH is required, and RESET-PATH is optional.

If an XML namespace is defined with the NAMESPACES element, you must include the identification number in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, `<PATH syntax="XPathENR">/Table/Hurricane/{1}Month</PATH>`. See [“Including Namespace Elements in an XMLMap” on page 77](#).

The XPath construction is a formal specification that puts a path description similar to UNIX on each element of the XML structure. XPath syntax is case sensitive. For example, if an element tag name is uppercase, it must be uppercase in the location path. If it is lowercase, it must be lowercase in the location path. All location paths must begin with the root-enclosing element (denoted by a slash '/'), or with the "any parent" variant (denoted by double slashes '//'). Other W3C-documented forms are not currently supported.

Example: “Specifying a Location Path on the PATH Element” on page 74

INCREMENT-PATH syntax="type" beginend="BEGIN | END"

specifies a location path for a counter variable, which is established by specifying the COLUMN element attribute class="ORDINAL". The location path tells the XML engine where in the input data to increment the accumulated value for the counter variable by 1.

syntax="type"

is an optional attribute that specifies the type of syntax in the location path. The syntax is valid XPath construction in compliance with the W3C specifications. The XPath form supported by the XML engine allows elements and attributes to be individually included in the generated SAS data set. For example, **syntax="XPath"**.

Default: XPath

Requirements:

The value must be XPath or XPathENR.

If an XML namespace is defined with the NAMESPACES element, you must specify the type of syntax as XPathENR (XPath with Embedded Namespace Reference). This is because the syntax is different from the XPath specification. For example, **syntax="XPathENR"**.

beginend="BEGIN | END"

is an optional attribute that specifies to stop processing when either the element start tag is encountered or the element end tag is encountered.

Default: BEGIN

Requirements:

If an XML namespace is defined with the NAMESPACES element, you must include the identification number in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, **<INCREMENT-PATH syntax="XPathENR">/Table/Hurricane/{1}Month</INCREMENT-PATH>**.

The XPath construction is a formal specification that puts a path description similar to UNIX on each element of the XML structure. Note that XPath syntax is case sensitive. For example, if an element tag name is uppercase, it must be uppercase in the location path. If it is lowercase, it must be lowercase. All location paths must begin with the root-enclosing element (denoted by a slash '/') or with the "any parent" variant (denoted by double slashes '//'). Other W3C documented forms are not currently supported.

If the variable is not a counter variable, PATH is required and INCREMENT-PATH and RESET-PATH are not allowed. If the variable is a counter variable, PATH is not allowed and either INCREMENT-PATH or DECREMENT-PATH is required.

Example: “Including a Key Field with Generated Numeric Keys” on page 60

RESET-PATH syntax="type" beginend="BEGIN | END"

specifies a location path for a counter variable, which is established by specifying the COLUMN element attribute class="ORDINAL". The location path tells the XML

engine where in the XML document to reset the accumulated value for the counter variable to zero.

`syntax="type"`

is an optional attribute that specifies the type of syntax in the location path. The syntax is valid XPath construction in compliance with the W3C specifications. The XPath form supported by the XML engine allows elements and attributes to be individually included in the generated SAS data set. For example,

syntax="XPATH".

Default: XPath

Requirements:

The value must be XPath or XPathENR.

If an XML namespace is defined with the NAMESPACES element, you must specify the type of syntax as XPathENR (XPath with Embedded Namespace Reference). This is because the syntax is different from the XPath specification. For example, **syntax="XPathENR".**

`beginend="BEGIN | END"`

is an optional attribute that specifies to stop processing when either the element start tag is encountered or the element end tag is encountered.

Default: BEGIN

Requirements:

If the variable is not a counter variable, RESET-PATH is not allowed. If the variable is a counter variable, RESET-PATH is optional.

If an XML namespace is defined with the NAMESPACES element, you must include the identification number in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, **<RESET-PATH syntax="XPathENR">/Table/Hurricane/{1}Month</RESET-PATH>**.

The XPath construction is a formal specification that puts a path description similar to UNIX on each element of the XML structure. Note that XPath syntax is case sensitive. For example, if an element tag name is uppercase, it must be uppercase in the location path. If it is lowercase, it must be lowercase. All location paths must begin with the root-enclosing element (denoted by a slash '/') or with the "any parent" variant (denoted by double slashes '//'). Other W3C documented forms are not currently supported.

DECREMENT-PATH syntax="type" beginend="BEGIN | END"

specifies a location path for a counter variable, which is established by specifying the COLUMN element attribute `class="ORDINAL"`. The location path tells the XML engine where in the input data to decrement the accumulated value for the counter variable by 1.

`syntax="type"`

is an optional attribute that specifies the type of syntax in the location path. The syntax is valid XPath construction in compliance with the W3C specifications. The XPath form supported by the XML engine allows elements and attributes to be individually included in the generated SAS data set. For example,

syntax="XPath".

Default: XPath

Requirements:

The value must be XPath or XPathENR.

If an XML namespace is defined with the NAMESPACES element, you must specify the type of syntax as XPathENR (XPath with Embedded Namespace

Reference). This is because the syntax is different from the XPath specification. For example, **syntax="XPathENR"**.

beginend="BEGIN | END"

is an optional attribute that specifies to stop processing when either the element start tag is encountered, or the element end tag is encountered.

Default: BEGIN

Requirements:

If the variable is not a counter variable, DECREMENT-PATH is not allowed. If the variable is a counter variable, either DECREMENT-PATH or INCREMENT-PATH is required.

If an XML namespace is defined with the NAMESPACES element, you must include the identification number in the location path preceding the element that is being defined. The identification number is enclosed in braces. For example, **<DECREMENT-PATH syntax="XPathENR">/Table/Hurricane/{1}Month</DECREMENT-PATH>**.

The XPath construction is a formal specification that puts a path description similar to UNIX on each element of the XML structure. XPath syntax is case sensitive. For example, if an element tag name is uppercase, it must be uppercase in the location path. If it is lowercase, it must be lowercase in the location path. All location paths must begin with the root-enclosing element (denoted by a slash '/'), or with the "any parent" variant (denoted by double slashes '//'). Other W3C-documented forms are not currently supported.

Chapter 11

Using SAS XML Mapper to Generate and Update an XMLMap

What is SAS XML Mapper?	131
Using the Windows	132
Using the Menu Bar	133
Using the Toolbar	133
How Do I Get SAS XML Mapper?	133

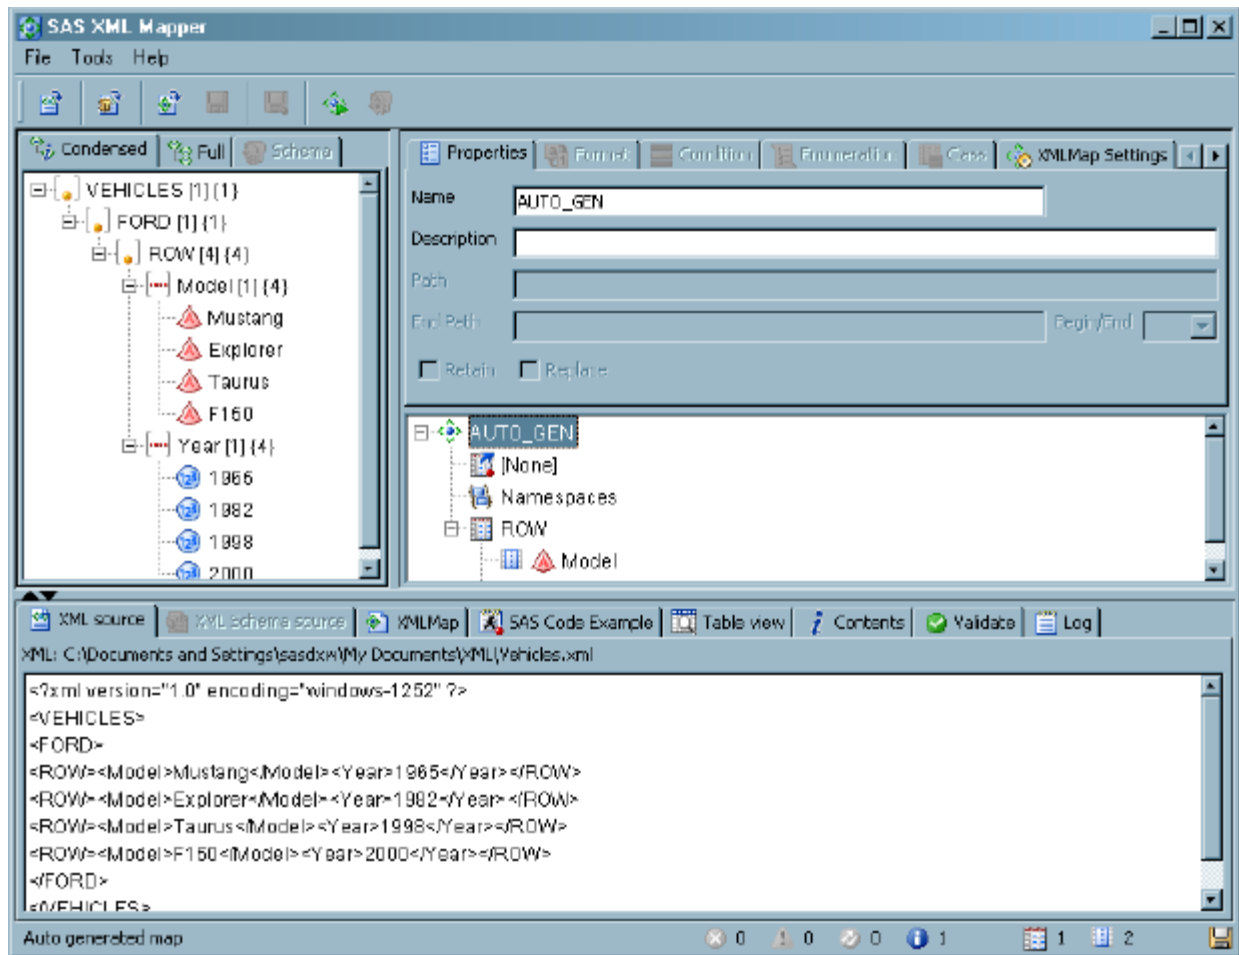

What is SAS XML Mapper?

SAS XML Mapper is an XMLMap support tool for the XML engine. SAS XML Mapper is a Java-based, stand-alone application that removes the tedium of creating and modifying an XMLMap.

SAS XML Mapper provides a graphical interface that you can use to generate the appropriate XML elements. SAS XML Mapper analyzes the structure of an XML document or an XML schema and generates basic XML syntax for the XMLMap.

The interface consists of windows, a menu bar, and a toolbar. Using SAS XML Mapper, you can display an XML document or an XML schema, create and modify an XMLMap, and generate example SAS programs.

Display 11.1 SAS XML Mapper Graphical User Interface

Using the Windows

The XML window and the XMLMap window are the two primary windows. The XML window, which is on the left, displays an XML document in a tree structure. The XMLMap window, which is on the right, displays an XMLMap in a tree structure. The map tree displays three layers: the top level is the map itself, the second tier includes tables, and the leaf nodes are columns. The detail area at the top displays information about the currently selected item, such as attributes for the table or column. The information is subdivided into tabs.

There are several source windows on the bottom of the interface, such as the XML source window, the XMLMap source window, the SAS code Example window, and so on.

Using the Menu Bar

The menu bar provides menus in order to request functionality. For example, select the **File** menu, and then **Open XML** in order to display a browser so that you can select an XML document to open.

Using the Toolbar

The toolbar contains icons for shortcuts to several items on the menu bar. For example, the first icon from the left is the **Open an XML file** icon. Select it to display a browser so that you can select an XML document to open.

How Do I Get SAS XML Mapper?

SAS XML Mapper can be installed from the installation media for Windows and UNIX platforms, or it can be downloaded from the SAS Web site http://www.sas.com/apps/demosdownloads/92_SDL_sysdep.jsp?packageID=000713.

The latest version of SAS XML Mapper, which is SAS 9.3, can be downloaded and used with SAS 9.3 or with versions of SAS before SAS 9.3. There are some features that can be used only with SAS 9.3 XML Mapper, such as the 2.1 XMLMap version.

SAS XML Mapper has online Help attached, which includes usage examples. From the menu bar, select **Help**, and then **Help Topics**.

Glossary

DTD

Document Type Definition. A file that specifies how the markup tags in a group of SGML or XML documents should be interpreted by an application that displays, prints, or otherwise processes the documents.

encoding

the result of mapping a coded character set to code values.

Extensible Markup Language

See XML.

file reference

See fileref.

File Transfer Protocol

a telecommunications protocol that is used for transferring files from one computer to another over a network. Short form: FTP.

fileref

a name that is temporarily assigned to an external file or to an aggregate storage location such as a directory or a folder. The fileref identifies the file or the storage location to SAS.

format

See SAS format.

FTP

See File Transfer Protocol.

informat

See SAS informat.

key field

See sequence field.

library reference

See libref.

libref

a SAS name that is associated with the location of a SAS library. For example, in the name MYLIB.MYFILE, MYLIB is the libref, and MYFILE is a file in the SAS library.

markup language

a set of codes that are embedded in text in order to define layout and certain content.

metadata

descriptive data about data that is stored and managed in a database, in order to facilitate access to captured and archived data for further use.

observation

a row in a SAS data set. All of the data values in an observation are associated with a single entity such as a customer or a state. Each observation contains either one data value or a missing-value indicator for each variable.

ODS template

a description of how output should appear when it is formatted. ODS templates are stored as compiled entries in a template store (item store). Common template types include STATGRAPH, STYLE, CROSSTABS, TAGSET, and TABLE.

SAS data file

a type of SAS data set that contains data values as well as descriptor information that is associated with the data. The descriptor information includes information such as the data types and lengths of the variables, as well as the name of the engine that was used to create the data.

SAS data set

a file whose contents are in one of the native SAS file formats. There are two types of SAS data sets: SAS data files and SAS data views. SAS data files contain data values in addition to descriptor information that is associated with the data. SAS data views contain only the descriptor information plus other information that is required for retrieving data values from other SAS data sets or from files whose contents are in other software vendors' file formats.

SAS data view

a type of SAS data set that retrieves data values from other files. A SAS data view contains only descriptor information such as the data types and lengths of the variables (columns) plus other information that is required for retrieving data values from other SAS data sets or from files that are stored in other software vendors' file formats. Short form: data view.

SAS format

a type of SAS language element that applies a pattern to or executes instructions for a data value to be displayed or written as output. Types of formats correspond to the data's type: numeric, character, date, time, or timestamp. The ability to create user-defined formats is also supported. Examples of SAS formats are BINARY and DATE. Short form: format.

SAS informat

a type of SAS language element that applies a pattern to or executes instructions for a data value to be read as input. Types of informats correspond to the data's type: numeric, character, date, time, or timestamp. The ability to create user-defined informats is also supported. Examples of SAS informats are BINARY and DATE. Short form: informat.

SAS library

one or more files that are defined, recognized, and accessible by SAS and that are referenced and stored as a unit. Each file is a member of the library.

SAS variable

a column in a SAS data set or in a SAS data view. The data values for each variable describe a single characteristic for all observations (rows).

SAS XML Mapper

a graphical interface that you can use to create and modify XMLMaps for use by the SAS XML LIBNAME engine. The SAS XML Mapper analyzes the structure of an XML document and generates basic XML markup for the XMLMap.

sequence field

a field that identifies and provides access to segments in a database. It contains the record's key, which is located in the same position in each record of a key-sequenced data set.

tagset

a template that defines how to create a type of markup language output from a SAS format. Tagsets produce markup output such as Hypertext Markup Language (HTML), Extensible Markup Language (XML), and LaTeX.

Uniform Resource Identifier

See URI.

Uniform Resource Locator

See URL.

URI

a string that identifies resources such as files, images, and services on the World Wide Web. A URL is a type of URI. Short form: URI.

URL

a character string that is used by a Web browser or other software application to access or identify a resource on the Internet or on an intranet. The resource could be a Web page, an electronic image file, an audio file, a JavaServer page, or any other type of electronic object. The full form of a URL specifies which communications protocol to use for accessing the resource, as well as the directory path and filename of the resource. Short form: URL.

variable

See SAS variable.

XML

a markup language that structures information by tagging it for content, meaning, or use. Structured information contains both content (for example, words or numbers) and an indication of what role the content plays. For example, content in a section heading has a different meaning from content in a database table. Short form: XML.

XML engine

See XML LIBNAME engine.

XML LIBNAME engine

the SAS engine that processes XML documents. The engine exports an XML document from a SAS data set by translating the proprietary SAS file format to XML.

markup. The engine also imports an external XML document by translating XML markup to a SAS data set.

XMLMap file

a file that contains XML tags that tell the SAS XML LIBNAME engine how to interpret an XML document.

 OUTPUT element 116
 output files
 translation tables for 99
 output processing 6
 overriding tagsets 99

P

PATH element 125
 specifying location path on 74
 physical structure
 importing XML documents with GENERIC markup 46
 prefix= attribute
 NS element 115

R

read processing 6
 record separators
 XML documents 98
 replace= attribute
 COLUMN element 121
 RESET-PATH element 127
 retain= attribute
 COLUMN element 121

S

SAS processing
 supported by XML engine 6
 SAS XML Mapper 131
 generating and updating XMLMap 131
 installing 133

- menu bar 133
- toolbar 133
- windows 132
- SAX application
 - XML engine as 6
- sequential access engine 6
