For FIT tasks, the DATA= option specifies which input data set to use in estimating parameters. Variables in the model program are looked up in the DATA= data set and, if found, their attributes (type, length, label, and format) are set to be the same as those in the DATA= data set (if not defined otherwise within PROC MODEL).

ESTDATA= Input Data Set

The ESTDATA= option specifies an input data set that contains an observation that gives values for some or all of the model parameters. The data set can also contain observations that give the rows of a covariance matrix for the parameters.

Parameter values read from the ESTDATA= data set provide initial starting values for parameters estimated. Observations that provide covariance values, if any are present in the ESTDATA= data set, are ignored.

The ESTDATA= data set is usually created by the OUTEST= option in a previous FIT statement. You can also create an ESTDATA= data set with a SAS DATA step program. The data set must contain a numeric variable for each parameter to be given a value or covariance column. The name of the variable in the ESTDATA= data set must match the name of the parameter in the model. Parameters with names longer than 32 characters cannot be set from an ESTDATA= data set. The data set must also contain a character variable `_NAME_` of length 32. `_NAME_` has a blank value for the observation that gives values to the parameters. `_NAME_` contains the name of a parameter for observations that define rows of the covariance matrix.

More than one set of parameter estimates and covariances can be stored in the ESTDATA= data set if the observations for the different estimates are identified by the variable `_TYPE_`. `_TYPE_` must be a character variable of length 8. The TYPE= option is used to select for input the part of the ESTDATA= data set for which the `_TYPE_` value matches the value of the TYPE= option.

In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used.

The following SAS statements generate the ESTDATA= data set shown in [Figure 18.64](#). The second FIT statement uses the TYPE= option to select the estimates from the GMM estimation as starting values for the FIML estimation.

```

/* Generate test data */
data gmm2;
  do t=1 to 50;
    x1 = sqrt(t) ;
    x2 = rannor(10) * 10;
    y1 = -.002 * x2 * x2 - .05 / x2 - 0.001 * x1 * x1;
    y2 = 0.002* y1 + 2 * x2 * x2 + 50 / x2 + 5 * rannor(1);
    y1 = y1 + 5 * rannor(1);
    z1 = 1; z2 = x1 * x1; z3 = x2 * x2; z4 = 1.0/x2;
    output;
  end;
run;

proc model data=gmm2 ;
  exogenous x1 x2;
  parms a1 a2 b1 2.5 b2 c2 55 d1;
  inst b1 b2 c2 x1 x2;

```

```

y1 = a1 * y2 + b1 * x1 * x1 + d1;
y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

fit y1 y2 / 3sls gmm kernel=(qs,1,0.2) outest=gmmest;

fit y1 y2 / fiml type=gmm estdata=gmmest;
run;

proc print data=gmmest;
run;

```

MISSING=PAIRWISE | DELETE

When missing values are encountered for any one of the equations in a system of equations, the default action is to drop that observation for all of the equations. The new `MISSING=PAIRWISE` option in the `FIT` statement provides a different method of handling missing values that avoids losing data for nonmissing equations for the observation. This is especially useful for SUR estimation on equations with unequal numbers of observations.

The option `MISSING=PAIRWISE` specifies that missing values are tracked on an equation-by-equation basis. The `MISSING=DELETE` option specifies that the entire observation is omitted from the analysis when any equation has a missing predicted or actual value for the equation. The default is `MISSING=DELETE`.

When you specify the `MISSING=PAIRWISE` option, the **S** matrix is computed as

$$\mathbf{S} = \mathbf{D}(\mathbf{R}'\mathbf{R})\mathbf{D}$$

where **D** is a diagonal matrix that depends on the `VARDEF=` option, the matrix **R** is $(\mathbf{r}_1, \dots, \mathbf{r}_g)$, and \mathbf{r}_i is the vector of residuals for the i th equation with r_{ij} replaced with zero when r_{ij} is missing.

For `MISSING=PAIRWISE`, the calculation of the diagonal element $d_{i,i}$ of **D** is based on n_i , the number of nonmissing observations for the i th equation, instead of on n . Similarly, for `VARDEF=WGT` or `WDF`, the calculation is based on the sum of the weights for the nonmissing observations for the i th equation instead of on the sum of the weights for all observations. See the description of the `VARDEF=` option for the definition of **D**.

The degrees-of-freedom correction for a shared parameter is computed by using the average number of observations used in its estimation.

The MISSING=PAIRWISE option is not valid for the GMM and FIML estimation methods.

For the instrumental variables estimation methods (2SLS, 3SLS), when an instrument is missing for an observation, that observation is dropped for all equations, regardless of the MISSING= option.

PARMSDATA= Input Data Set

The option PARMSDATA= reads values for all parameters whose names match the names of variables in the PARMSDATA= data set. Values for any or all of the parameters in the model can be reset by using the PARMSDATA= option. The PARMSDATA= option goes in the PROC MODEL statement, and the data set is read before any FIT or SOLVE statements are executed.

In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used.

Together, the OUTPARMS= and PARMSDATA= options enable you to change part of a model and recompile the new model program without the need to reestimate equations that were not changed.

Suppose you have a large model with parameters estimated and you now want to replace one equation, Y, with a new specification. Although the model program must be recompiled with the new equation, you don't need to reestimate all the equations, just the one that changed.

Using the OUTPARMS= and PARMSDATA= options, you could do the following:

```
proc model model=oldmod outparms=temp; run;
proc model outmodel=newmod parmsdata=temp data=in;
    ... include new model definition with changed y eq. here ...
    fit y;
run;
```

The model file NEWMOD then contains the new model and its estimated parameters plus the old models with their original parameter values.

SDATA= Input Data Set

The SDATA= option allows a cross-equation covariance matrix to be input from a data set. The **S** matrix read from the SDATA= data set, specified in the FIT statement, is used to define the objective function for the OLS, N2SLS, SUR, and N3SLS estimation methods and is used as the initial **S** for the methods that iterate the **S** matrix.

Most often, the SDATA= data set has been created by the OUTS= or OUTSUSED= option in a previous FIT statement. The OUTS= and OUTSUSED= data sets from a FIT statement can be read back in by a FIT statement in the same PROC MODEL step.

You can create an input `SDATA=` data set by using the `DATA` step. `PROC MODEL` expects to find a character variable `_NAME_` in the `SDATA=` data set as well as variables for the equations in the estimation or solution. For each observation with a `_NAME_` value that matches the name of an equation, `PROC MODEL` fills the corresponding row of the **S** matrix with the values of the names of equations found in the data set. If a row or column is omitted from the data set, a 1 is placed on the diagonal for the row or column. Missing values are ignored, and since the **S** matrix is symmetric, you can include only a triangular part of the **S** matrix in the `SDATA=` data set with the omitted part indicated by missing values. If the `SDATA=` data set contains multiple observations with the same `_NAME_`, the last values supplied for the `_NAME_` are used. The structure of the expected data set is further described in the section “[OUTS= Data Set](#)” on page 1112.

Use the `TYPE=` option in the `PROC MODEL` or `FIT` statement to specify the type of estimation method used to produce the **S** matrix you want to input.

The following SAS statements are used to generate an **S** matrix from a GMM and a 3SLS estimation and to store that estimate in the data set `GMMS`:

```
proc model data=gmm2 ;
  exogenous x1 x2;
  parms a1 a2 b1 2.5 b2 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / 3s1s gmm kernel=(qs,1,0.2)
             outest=gmmest outs=gmm;
run;

proc print data=gmm;
run;
```

The data set `GMMS` is shown in [Figure 18.65](#).

Figure 18.65 `SDATA=` Data Set

Obs	<code>_NAME_</code>	<code>_TYPE_</code>	<code>_NUSED_</code>	y1	y2
1	y1	3SLS	50	27.1032	38.1599
2	y2	3SLS	50	38.1599	74.6253
3	y1	GMM	50	27.6248	32.2811
4	y2	GMM	50	32.2811	58.8387

VDATA= Input data set

The `VDATA=` option enables a variance matrix for GMM estimation to be input from a data set. When the `VDATA=` option is used in the `PROC MODEL` or `FIT` statement, the matrix that is input is used to define the objective function and is used as the initial **V** for the methods that iterate the **V** matrix.

Normally the `VDATA=` matrix is created from the `OUTV=` option in a previous `FIT` statement. Alternately an input `VDATA=` data set can be created by using the `DATA` step. Each row and

column of the \mathbf{V} matrix is associated with an equation and an instrument. The position of each element in the \mathbf{V} matrix can then be indicated by an equation name and an instrument name for the row of the element and an equation name and an instrument name for the column. Each observation in the `VDATA=` data set is an element in the \mathbf{V} matrix. The row and column of the element are indicated by four variables (`EQ_ROW`, `INST_ROW`, `EQ_COL`, and `INST_COL`) that contain the equation name or instrument name. The variable name for an element is `VALUE`. Missing values are set to 0. Because the variance matrix is symmetric, only a triangular part of the matrix needs to be input.

The following SAS statements are used to generate a \mathbf{V} matrix estimation from GMM and to store that estimate in the data set `GMMV`:

```
proc model data=gmm2;
  exogenous x1 x2;
  parms a1 a2 b2 b1 2.5 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / gmm outv=gmmv;
run;

proc print data=gmmv(obs=15);
run;
```

The data set `GMM2` was generated by the example in the preceding `ESTDATA=` section. The \mathbf{V} matrix stored in `GMMV` is selected for use in an additional GMM estimation by the following `FIT` statement:

```
fit y1 y2 / gmm vdata=gmmv;
run;
```

A partial listing of the `GMMV` data set is shown in [Figure 18.66](#). There are a total of 78 observations in this data set. The \mathbf{V} matrix is 12 by 12 for this example.

Figure 18.66 The First 15 Observations in the VDATA= Data Set

Output Data Sets

OUT= Data Set

For normalized form equations, the OUT= data set specified in the FIT statement contains residuals, actuals, and predicted values of the dependent variables computed from the parameter estimates. For general form equations, actual values of the endogenous variables are copied for the residual and predicted values.

The variables in the data set are as follows:

- BY variables
- RANGE variable
- ID variables
- _ESTYPE_, a character variable of length 8 that identifies the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- _TYPE_, a character variable of length 8 that identifies the type of observation: RESIDUAL, PREDICT, or ACTUAL
- _WEIGHT_, the weight of the observation in the estimation. The _WEIGHT_ value is 0 if the observation was not used. It is equal to the product of the _WEIGHT_ model program variable and the variable named in the WEIGHT statement, if any, or 1 if weights were not used.
- the WEIGHT statement variable if used

- the model variables. The dependent variables for the normalized form equations in the estimation contain residuals, actuals, or predicted values, depending on the `_TYPE_` variable, whereas the model variables that are not associated with estimated equations always contain actual values from the input data set.
- any other variables named in the `OUTVARS` statement. These can be program variables computed by the model program, `CONTROL` variables, parameters, or special variables in the model program.

The following SAS statements are used to generate and print an `OUT=` data set:

```
proc model data=gmm2;
  exogenous x1 x2;
  parms a1 a2 b2 b1 2.5 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / 3sls gmm out=resid outall ;
run;

proc print data=resid(obs=20);
run;
```

The data set `GMM2` was generated by the example in the preceding `ESTDATA=` section above. A partial listing of the `RESID` data set is shown in [Figure 18.67](#).

OUTEST= Data Set

The OUTEST= data set contains parameter estimates and, if requested, estimates of the covariance of the parameter estimates.

The variables in the data set are as follows:

- BY variables
- `_NAME_`, a character variable of length 32, blank for observations that contain parameter estimates or a parameter name for observations that contain covariances
- `_TYPE_`, a character variable of length 8 that identifies the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- `_STATUS_`, variable that gives the convergence status of estimation. `_STATUS_ = 0` when convergence criteria are met, `= 1` when estimation converges with a note, `= 2` when estimation converges with a warning, and `= 3` when estimation fails to converge
- `_NUSED_`, the number of observations used in estimation
- the parameters estimated

If the COVOUT option is specified, an additional observation is written for each row of the estimate of the covariance matrix of parameter estimates, with the `_NAME_` values that contain the parameter names for the rows. Parameter names longer than 32 characters are truncated.

OUTPARMS= Data Set

The option OUTPARMS= writes all the parameter estimates to an output data set. This output data set contains one observation and is similar to the OUTEST= data set, but it contains all the parameters, is not associated with any FIT task, and contains no covariances. The OUTPARMS= option is used in the PROC MODEL statement, and the data set is written at the end, after any FIT or SOLVE steps have been performed.

OUTS= Data Set

The OUTS= SAS data set contains the estimate of the covariance matrix of the residuals across equations. This matrix is formed from the residuals that are computed by using the parameter estimates.

The variables in the OUTS= data set are as follows:

- BY variables
- `_NAME_`, a character variable that contains the name of the equation
- `_TYPE_`, a character variable of length 8 that identifies the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML

- variables with the names of the equations in the estimation

Each observation contains a row of the covariance matrix. The data set is suitable for use with the `SDATA=` option in a subsequent `FIT` or `SOLVE` statement. (See the section “[Tests on Parameters](#)” on page 1078 in this chapter for an example of the `SDATA=` option.)

OUTSUSED= Data Set

The `OUTSUSED=` SAS data set contains the covariance matrix of the residuals across equations that is used to define the objective function. The form of the `OUTSUSED=` data set is the same as that for the `OUTS=` data set.

Note that `OUTSUSED=` is the same as `OUTS=` for the estimation methods that iterate the **S** matrix (`ITOLS`, `IT2SLS`, `ITSUR`, and `IT3SLS`). If the `SDATA=` option is specified in the `FIT` statement, `OUTSUSED=` is the same as the `SDATA=` matrix read in for the methods that do not iterate the **S** matrix (`OLS`, `SUR`, `N2SLS`, and `N3SLS`).

OUTV= Data Set

The `OUTV=` data set contains the estimate of the variance matrix, **V**. This matrix is formed from the instruments and the residuals that are computed by using the final parameter estimates obtained from the estimation method chosen.

An estimate of **V** obtained from 2SLS is used in GMM estimation. Hence if you input the dataset obtained from the `OUTV` statement in 2SLS into the `VDATA` statement while fitting GMM, you get the same result by fitting GMM directly without specifying the `VDATA` option.

ODS Table Names

`PROC MODEL` assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 18.4 ODS Tables Produced in `PROC MODEL`

ODS Table Name	Description	Option
ODS Tables Created by the <code>FIT</code> Statement		
<code>AugGMMCovariance</code>	Crossproducts matrix	<code>GMM ITALL</code>
<code>ChowTest</code>	Structural change test	<code>CHOW=</code>
<code>CollinDiagnostics</code>	Collinearity diagnostics	
<code>ConfInterval</code>	Profile likelihood confidence intervals	<code>PRL=</code>
<code>ConvCrit</code>	Convergence criteria for estimation	default

Table 18.4 (continued)

ODS Table Name	Description	Option

TransitiveClosure	Transitive closure graph	GRAPH

The AugGMMCovariance table is the \mathbf{V} matrix augmented with the moment vector at iteration zero, produced when the ITALL option is used with the GMM option. If the \mathbf{V} matrix to be used in GMM is read in by the VDATA option, then AugGMMCovariance would be the same matrix augmented with the moment vectors. The GMMCovariance ODS output is produced only when you read in a covariance matrix to be used in the GMM method. This table is produced by using DETAILS option with the GMM option.

ODS Graphics

This section describes the use of ODS for creating graphics with the MODEL procedure.

ODS Graph Names

PROC MODEL assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in [Table 18.5](#).

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 18.5 ODS Graphics Produced by PROC MODEL

ODS Graph Name	Plot Description
ACFPlot	Autocorrelation of residuals
ActualByPredicted	Predicted versus actual plot
CooksD	Cook's D plot
IACFPlot	Inverse autocorrelation of residuals
QQPlot	Q-Q plot of residuals
PACFPlot	Partial autocorrelation of residuals
ResidualHistogram	Histogram of the residuals
StudentResidualPlot	Studentized residual plot

Details: Simulation by the MODEL Procedure

The *solution*, given the vector \mathbf{k} , of the following nonlinear system of equations is the vector \mathbf{u} that satisfies this equation:

$$\mathbf{q}(\mathbf{u}, \mathbf{k}, \boldsymbol{\theta}) = 0$$

A *simulation* is a set of solutions \mathbf{u}_t for a specific sequence of vectors \mathbf{k}_t .

Model simulation can be performed to do the following:

- check how well the model predicts the actual values over the historical period
- investigate the sensitivity of the solution to changes in the input values or parameters
- examine the dynamic characteristics of the model
- check the stability of the simultaneous solution
- estimate the statistical distribution of the predicted values of the nonlinear model using Monte Carlo methods

By combining the various solution modes with different input data sets, model simulation can answer many different questions about the model. This section presents details of model simulation and solution.

Solution Modes

The following solution modes are commonly used:

- The *dynamic simultaneous forecast* mode is used for forecasting with the model. Collect the historical data on the model variables, the future assumptions of the exogenous variables, and any prior information on the future endogenous values, and combine them in a SAS data set. Use the FORECAST option in the SOLVE statement.
- The *dynamic simultaneous simulation* mode is often called *ex post simulation*, *historical simulation*, or *ex post forecasting*. Use the DYNAMIC option. This mode is the default.
- The *static simultaneous simulation* mode can be used to examine the within-period performance of the model without the complications of previous period errors. Use the STATIC option.
- The *NAHEAD=n dynamic simultaneous simulation* mode can be used to see how well *n*-period-ahead forecasting would have performed over the historical period. Use the NAHEAD=*n* option.

The different solution modes are explained in detail in the following sections.

Dynamic and Static Simulations

In model simulation, either solved values or actual values from the data set can be used to supply lagged values of an endogenous variable. A *dynamic* solution refers to a solution obtained by using only solved values for the lagged values. Dynamic mode is used both for forecasting and for simulating the dynamic properties of the model.

A *static* solution refers to a solution obtained by using the actual values when available for the lagged endogenous values. Static mode is used to simulate the behavior of the model without the complication of previous period errors. Dynamic simulation is the default.

If you want to use static values for lags only for the first *n* observations, and dynamic values thereafter, specify the START=*n* option. For example, if you want a dynamic simulation to start after observation twenty-four, specify START=24 on the SOLVE statement. If the model being simulated had a value lagged for four time periods, then this value would start using dynamic values when the simulation reached observation number 28.

n-Period-Ahead Forecasting

Suppose you want to regularly forecast 12 months ahead and produce a new forecast each month as more data becomes available. *n*-period-ahead forecasting allows you to test how well you would have done over time if you had been using your model to forecast one year ahead.

To see how well a model predicts n time periods in the future, perform an n -period-ahead forecast on real data and compare the forecast values with the actual values.

n -period-ahead forecasting refers to using dynamic values for the lagged endogenous variables only for lags 1 through $n-1$. For example, one-period-ahead forecasting, specified by the NAHEAD=1 option in the SOLVE statement, is the same as if a static solution had been requested. Specifying NAHEAD=2 produces a solution that uses dynamic values for lag one and static, actual, values for longer lags.

The following example is a two-year-ahead dynamic simulation. The output is shown in Figure 18.68.

```

data yearly;
  input year x1 x2 x3 y1 y2 y3;
  datalines;
84 4 9 0 7 4 5
85 5 6 1 1 27 4
86 3 8 2 5 8 2
87 2 10 3 0 10 10
88 4 7 6 20 60 40
89 5 4 8 40 40 40
90 3 2 10 50 60 60
91 2 5 11 40 50 60
;
run;

proc model data=yearly outmodel=yearlyModel;
  endogenous y1 y2 y3;
  exogenous x1 x2 x3;

  y1 = 2 + 3*x1 - 2*x2 + 4*x3;
  y2 = 4 + lag2( y3 ) + 2*y1 + x1;
  y3 = lag3( y1 ) + y2 - x2;

  solve y1 y2 y3 / nahead=2 out=c;
run;

proc print data=c;
run;

```

The C data set is shown in [Figure 18.69](#):

Figure 18.69 C Data Set

Obs	_TYPE_	_MODE_	_LAG_	_ERRORS_	y1	y2	y3	x1	x2	x3
1	PREDICT	SIMULATE	0	0	0	10	7	2	10	3
2	PREDICT	SIMULATE	1	0	24	58	52	4	7	6
3	PREDICT	SIMULATE	1	0	41	101	102	5	4	8
4	PREDICT	SIMULATE	1	0	47	141	139	3	2	10
5	PREDICT	SIMULATE	1	0	42	130	145	2	5	11

The preceding two-year-ahead simulation can be emulated without using the NAHEAD= option by the following PROC MODEL statements:

```
proc model data=yearly model=yearlyModel;
  range year = 87 to 88;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 88 to 89;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 89 to 90;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 90 to 91;
  solve y1 y2 y3 / dynamic solveprint;
```

The totals shown under “Observations Processed” in Figure 18.68 are equal to the sum of the four individual runs.

Simulation and Forecasting

You can perform a simulation of your model or use the model to produce forecasts. *Simulation* refers to the determination of the endogenous or dependent variables as a function of the input values of the other variables, even when actual data for some of the solution variables are available in the input data set. The simulation mode is useful for verifying the fit of the model parameters. Simulation is selected by the SIMULATE option in the SOLVE statement. Simulation mode is the default.

In forecast mode, PROC MODEL solves only for those endogenous variables that are missing in the data set. The actual value of an endogenous variable is used as the solution value whenever nonmissing data for it is available in the input data set. Forecasting is selected by the FORECAST option in the SOLVE statement.

For example, an econometric forecasting model can contain an equation to predict future tax rates, but tax rates are usually set in advance by law. Thus, for the first year or so of the forecast, the predicted tax rate should really be exogenous. Or, you might want to use a prior forecast of a certain variable from a short-run forecasting model to provide the predicted values for the earlier periods of a longer-range forecast of a long-run model. A common situation in forecasting is when historical data needed to fill the initial lags of a dynamic model are available for some of the variables but have not yet been obtained for others. In this case, the forecast must start in the past to supply the missing initial lags. Clearly, you should use the actual data that are available for the lags. In all the preceding cases, the forecast should be produced by running the model in the FORECAST mode; simulating the model over the future periods would not be appropriate.

Monte Carlo Simulation

The accuracy of the forecasts produced by PROC MODEL depends on four sources of error (Pindyck and Rubinfeld 1981, 405–406):

- The system of equations contains an implicit random error term ϵ

$$\mathbf{g}(\mathbf{y}, \mathbf{x}, \hat{\boldsymbol{\theta}}) = \boldsymbol{\epsilon}$$

where \mathbf{y} , \mathbf{x} , \mathbf{g} , $\hat{\boldsymbol{\theta}}$, and $\boldsymbol{\epsilon}$ are vector valued.

- The estimated values of the parameters, $\hat{\boldsymbol{\theta}}$, are themselves random variables.
- The exogenous variables might have been forecast themselves and therefore might contain errors.
- The system of equations might be incorrectly specified; the model only approximates the process modeled.

The `RANDOM=` option is used to request Monte Carlo (or stochastic) simulations to generate confidence intervals for errors that arise from the first two sources. The Monte Carlo simulations can be performed with ϵ , θ , or both vectors represented as random variables. The `SEED=` option is used to control the random number generator for the simulations. `SEED=0` forces the random number generator to use the system clock as its seed value.

In Monte Carlo simulations, repeated simulations are performed on the model for random perturbations of the parameters and the additive error term. The random perturbations follow a multivariate normal distribution with expected value of 0 and covariance described by a covariance matrix of the parameter estimates in the case of θ , or a covariance matrix of the equation residuals for the case of ϵ . `PROC MODEL` can generate both covariance matrices or you can provide them.

The `ESTDATA=` option specifies a data set that contains an estimate of the covariance matrix of the parameter estimates to use for computing perturbations of the parameters. The `ESTDATA=` data set is usually created by the `FIT` statement with the `OUTEST=` and `OUTCOV` options. When the `ESTDATA=` option is specified, the matrix read from the `ESTDATA=` data set is used to compute vectors of random shocks or perturbations for the parameters. These random perturbations are computed at the start of each repetition of the solution and added to the parameter values. The perturbed parameters are fixed throughout the solution range. If the covariance matrix of the parameter estimates is not provided, the parameters are not perturbed.

The `SDATA=` option specifies a data set that contains the covariance matrix of the residuals to use for computing perturbations of the equations. The `SDATA=` data set is usually created by the `FIT` statement with the `OUTS=` option. When `SDATA=` is specified, the matrix read from the `SDATA=` data set is used to compute vectors of random shocks or perturbations for the equations. These random perturbations are computed at each observation. The simultaneous solution satisfies the model equations plus the random shocks. That is, the solution is not a perturbation of a simultaneous solution of the structural equations; rather, it is a simultaneous solution of the stochastic equations by using the simulated errors. If the `SDATA=` option is not specified, the random shocks are not used.

The different random solutions are identified by the `_REP_` variable in the `OUT=` data set. An unperturbed solution with `_REP_=0` is also computed when the `RANDOM=` option is used. `RANDOM=n` produces $n + 1$ solution observations for each input observation in the solution range. If the `RANDOM=` option is not specified, the `SDATA=` and `ESTDATA=` options are ignored, and no Monte Carlo simulation is performed.

`PROC MODEL` does not have an automatic way of modeling the exogenous variables as random variables for Monte Carlo simulation. If the exogenous variables have been forecast, the error bounds for these variables should be included in the error bounds generated for the endogenous variables. If the models for the exogenous variables are included in `PROC MODEL`, then the error bounds created from a Monte Carlo simulation contain the uncertainty due to the exogenous variables.

Alternatively, if the distribution of the exogenous variables is known, the built-in random number generator functions can be used to perturb these variables appropriately for the Monte Carlo simulation. For example, if you know the forecast of an exogenous variable, X , has a standard error of 5.2 and the error is normally distributed, then the following statements can be used to generate random values for X :

```
x_new = x + 5.2 * rannor(456);
```

During a Monte Carlo simulation, the random number generator functions produce one value at each observation. It is important to use a different seed value for all the random number generator functions in the model program; otherwise, the perturbations will be correlated. For the unperturbed solution, `_REP_=0`, the random number generator functions return 0.

PROC UNIVARIATE can be used to create confidence intervals for the simulation (see the Monte Carlo simulation example in the section “[Getting Started: MODEL Procedure](#)” on page 949).

Multivariate t Distribution Simulation

To perform a Monte Carlo analysis of models that have residuals distributed as a multivariate t , use the ERRORMODEL statement with either the $\sim t(\text{variance}, df)$ option or with the CDF= $t(\text{variance}, df)$ option. The CDF= option specifies the distribution that is used for simulation so that the estimation can be done for one set of distributional assumptions and the simulation for another.

The following is an example of estimating and simulating a system of equations with t distributed errors by using the ERRORMODEL statement.

```
/* generate simulation data set */
data five;
  set xfrate end=last;
  if last then do;
    todate = date +5;
    do date = date to todate;
      output;
    end;
  end;
run;
```

The preceding DATA step generates the data set to request a five-days-ahead forecast. The following statements estimate and forecast the three forward-rate models of the following form.

$$\begin{aligned} rate_t &= rate_{t-1} + \mu * rate_{t-1} + v \\ v &= \sigma * rate_{t-1} * \epsilon \\ \epsilon &\sim N(0, 1) \end{aligned}$$

```
title "Daily Multivariate Geometric Brownian Motion Model "
      "of D-Mark/USDollar Forward Rates";

proc model data=xfrate;

  parms df 15;          /* Give initial value to df */

  demusdlm = lag(demusdlm) + mulm * lag(demusdlm);
```

```

var_demusd1m = sigma1m ** 2 * lag(demusd1m **2);
demusd3m = lag(demusd3m) + mu3m * lag(demusd3m);
var_demusd3m = sigma3m ** 2 * lag(demusd3m ** 2);
demusd6m = lag(demusd6m) + mu6m * lag(demusd6m);
var_demusd6m = sigma6m ** 2 * lag(demusd6m ** 2);

/* Specify the error distribution */
errormodel demusd1m demusd3m demusd6m
  ~ t( var_demusd1m var_demusd3m var_demusd6m, df );

/* output normalized S matrix */
fit demusd1m demusd3m demusd6m / outsn=s;
run;

/* forecast five days in advance */
solve demusd1m demusd3m demusd6m /
  data=five sdata=s random=1500 out=monte;
id date;
run;

/* select out the last date ---*/
data monte; set monte;
  if date = '10dec95'd then output;
run;

title "Distribution of demusd1m Five Days Ahead";
proc univariate data=monte noprint;
  var demusd1m;
  histogram demusd1m /
    normal(noprint color=red)
    kernel(noprint color=blue) cfill=ligr;
run;

```

The Monte Carlo simulation specified in the preceding example draws from a multivariate t distribution with constant degrees of freedom and forecasted variance, and it computes future states of DEMUSD1M, DEMUSD3M, and DEMUSD6M. The OUTSN= option in the FIT statement is used to specify the data set for the normalized Σ matrix. That is, the Σ matrix is created by crossing the normally distributed residuals. The normally distributed residuals are created from the t distributed residuals by using the normal inverse CDF and the t CDF. This matrix is a correlation matrix.

The distribution of DEMUSD1M on the fifth day is shown in the [Figure 18.70](#). The two curves overlaid on the graph are a kernel density estimation and a normal distribution fit to the results.

Figure 18.70 Distribution of DEMUSD1M

Alternate Distribution Simulation

As an alternate to the normal distribution, the `ERRORMODEL` statement can be used in a simulation to specify other distributions. The distributions available for simulation are Cauchy, chi-squared, F , Poisson, t , and uniform. An empirical distribution can also be used if the residuals are specified by using the `RESIDDATA=` option in the `SOLVE` statement.

Except for the t distribution, all of these alternate distributions are univariate but can be used together in a multivariate simulation. The `ERRORMODEL` statement applies to solved for equations only. That is, the normal form or general form equation referred to by the `ERRORMODEL` statement must be one of the equations you have selected in the `SOLVE` statement.

In the following example, two Poisson distributed variables are used to simulate the calls that arrive at and leave a call center.

```
data s;    /* Covariance between arriving and leaving */
  arriving = 1; leaving = 0.7; _name_ = "arriving";
  output;
  arriving = 0.7; leaving = 1.0; _name_ = "leaving";
```

```

    output;
run;

data calls;
    date = '20mar2001'd;
    output;
run;

```

The first DATA step generates a data set that contains a covariance matrix for the ARRIVING and LEAVING variables. The covariance is

$$\begin{vmatrix} 1 & .7 \\ .7 & 1 \end{vmatrix}$$

The following statements create the number of waiting clients data:

```

proc model data=calls;
    arriving = 0;
    errormodel arriving ~ poisson( 10 );
    leaving = 4;
    errormodel leaving ~ poisson( 11 );

    waiting = arriving - leaving;
    if waiting < 0 then waiting=0;
    outvars waiting;

    solve arriving leaving / random=500 sdata=s out=sim;
run;

title "Distribution of Clients Waiting";
proc univariate data=sim noprint;
    var waiting ;
    histogram waiting / cfill=ligr;
run;

```

The distribution of number of waiting clients is shown in [Figure 18.71](#).

Figure 18.71 Distribution of Number of Clients Waiting

Mixtures of Distributions—Copulas

The theory of copulas is what enables the MODEL procedure to combine and simulate multivariate distributions with different marginals. This section provides a brief overview of copulas.

Modeling a system of variables accurately is a difficult task. The underlying, ideal, distributional assumptions for each variable are usually different from each other. An individual variable might be best modeled as a t distribution or as a Poisson process. The correlation of the various variables are very important to estimate as well. A joint estimation of a set of variables would make it possible to estimate a correlation structure but would restrict the modeling to single, simple multivariate distribution (for example, the normal). Even with a simple multivariate distribution, the joint estimation would be computationally difficult and would have to deal with issues of missing data.

By using the MODEL procedure `ERRORMODEL` statement, you can combine and simulate from models of different distributions. The covariance matrix for the combined model is constructed by using the copula induced by the multivariate normal distribution. A copula is a function that couples joint distributions to their marginal distributions.

By default, the copula used in the MODEL procedure is based on the multivariate normal. This

particular multivariate normal has zero mean and covariance matrix \mathbf{R} . The user provides \mathbf{R} , which can be created by using the following steps:

1. Each model is estimated separately and their residuals are saved.
2. The residuals for each model are converted to a normal distribution by using their CDFs, $F_i(\cdot)$, using the relationship $\Phi^{-1}(F(\epsilon_{it}))$.
3. These normal residuals are crossed to create a covariance matrix \mathbf{R} .

If the model of interest can be estimated jointly, such as multivariate T, then the OUTSN= option can be used to generate the correct covariance matrix.

A draw from this mixture of distributions is created by using the following steps that are performed automatically by the MODEL procedure.

1. Independent $N(0, 1)$ variables are generated.
2. These variables are transformed to a correlated set by using the covariance matrix \mathbf{R} .
3. These correlated normals are transformed to a uniform by using $\Phi()$.
4. $F^{-1}()$ is used to compute the final sample value.

Alternate Copulas

The Gaussian, t , and the normal mixture copula are available in the MODEL procedure. These copulas support asymmetric parameters and can use alternate estimation methods for creating the base covariance matrix.

The normal (Gaussian) copula is the default. A draw from a Gaussian copula is obtained from

$$\mathbf{x} = \mathbf{A}\mathbf{z}$$

where $\mathbf{z} \in R^d$ is a vector of independent random normal(0, 1) draws, $\mathbf{A} \in R^{d \times d}$ is the square root of the covariance matrix, \mathbf{R} . For the normal mixture and t copula, a draw is created as

$$\mathbf{x} = w\boldsymbol{\gamma} + \sqrt{w}\mathbf{A}\mathbf{z}$$

where w is a scalar random variable and $\boldsymbol{\gamma} \in R^d$ is a vector of asymmetry parameters. $\boldsymbol{\gamma}$ is specified in the SDATA= data set. If $W \sim \text{inverse gamma}(df/2, df/2)$, then \mathbf{x} is multivariate t or skewed t if $\boldsymbol{\gamma}$ is provided. When NORMALMIX is specified, w is distributed as a step function with each of the n positive variances, $v_1 \dots v_n$, having probability $p_1 \dots p_n$.

The covariance matrix $\mathbf{R} = \mathbf{A}'\mathbf{A}$ is specified with the SDATA= option. The vector of asymmetry parameters, $\boldsymbol{\gamma}$, defaults to zero or is specified in the SDATA= data set with _TYPE_=ASYM. The ASYM option specifies that the nonzero asymmetry vector, $\boldsymbol{\gamma}$, is to be used.

The actual draw for an individual variable, y_i , depends on the marginal distribution of the variable, \tilde{F} , and the chosen copula F as

$$y_i = \tilde{F}_i^{-1}(F(x_i))$$

Asymmetrical Copula Example

In this example, an asymmetrical t copula is used to correlate two uniform distributions. The asymmetrical parameter is varied over a range of values to demonstrate its effect. The resulting graphs is produced by using ODS graphics.

```

data histdata;
  do asym = -1.3 to 1.1 by .3;
    date='01aug2007'd;
    y = .5;
    z = .5;
    output;
  end;
run ;

/* Add the asymmetric parameter to cov mat */
data asym;
  do asym = -1.3 to 1.1 by .3;
    y = asym;
    z = 0;
    _name_ = " ";
    _type_ = "asym";
    output;
    y = 1;
    z = .65;
    _name_ = "y";
    _type_ = "cov";
    output;
    y = .65;
    z = 1;
    _name_ = "z";
    _type_ = "cov";
    output;
  end;
run;

proc model out=sim(where=( _REP_ > 0)) data=histdata sdata=asym;
  y = 0;
  errormodel y ~ Uniform(0,1);

  z = 0;
  errormodel z ~ Uniform(0,1);

  solve y z / random=500 seed=12345 copula=(t(5) asym );
  by asym;
run;

```

To produce a panel plot of this joint distribution, use the following SAS/GRAPH statements.

```

ods graphics on / height=800 width=800;
proc template;
  define statgraph myplot.panel;

```

```

BeginGraph;
  entrytitle halign=left halign=center
    textattrs=GRAPHTITLETEXT "t Copula with a Range of Asymmetry";

  layout datapanel classvars=(asym) / rows=3 columns=3
    order=rowmajor height=1024 width=1420
    rowaxisopts=(griddisplay=on label=' ')
    columnaxisopts=(griddisplay=on label=' ');
  layout prototype;
    scatterplot x=z y=y ;
  endlayout;
endlayout;
EndGraph;
end;
run;

proc sgrender data=sim template='myplot.panel';
run;

```

Figure 18.72 *t* Copula with Asymmetry

Quasi-Random Number Generators

Traditionally high-discrepancy pseudo-random number generators are used to generate innovations in Monte Carlo simulations. Loosely translated, a high-discrepancy pseudo-random number generator is one in which there is very little correlation between the current number generated and the past numbers generated. This property is ideal if indeed independence of the innovations is required. If, on the other hand, the efficient spanning of a multidimensional space is desired, a low discrepancy, quasi-random number generator can be used. A quasi-random number generator produces numbers that have no random component.

A simple one-dimensional quasi-random sequence is the van der Corput sequence. Given a prime number r ($r \geq 2$), any integer has a unique representation in terms of base r . A number in the interval $[0,1)$ can be created by inverting the representation base power by base power. For example, consider $r=3$ and $n=1$, 1 in base 3 is

$$1_{10} = 1 \cdot 3^0 = 1_3$$

When the powers of 3 are inverted,

$$\phi(1) = \frac{1}{3}$$

Also, 11 in base 3 is

$$11_{10} = 1 \cdot 3^2 + 2 \cdot 3^0 = 102_3$$

When the powers of 3 are inverted,

$$\phi(11) = \frac{1}{9} + 2 \cdot \frac{1}{3} = \frac{7}{9}$$

The first 10 numbers in this sequence $\phi(1) \dots \phi(10)$ are provided below

$$0, \frac{1}{3}, \frac{2}{3}, \frac{1}{9}, \frac{4}{9}, \frac{7}{9}, \frac{2}{9}, \frac{5}{9}, \frac{8}{9}, \frac{1}{27}$$

As the sequence proceeds, it fills in the gaps in a uniform fashion.

Several authors have expanded this idea to many dimensions. Two versions supported by the MODEL procedure are the Sobol sequence (QUASI=SOBOL) and the Faure sequence (QUASI=FAURE). The Sobol sequence is based on binary numbers and is generally computationally faster than the Faure sequence. The Faure sequence uses the dimensionality of the problem to determine the number base to use to generate the sequence. The Faure sequence has better distributional properties than the Sobol sequence for dimensions greater than 8.

As an example of the difference between a pseudo-random number and a quasi-random number, consider simulating a bivariate normal with 100 draws.

Figure 18.73 Kernel Density of a Bivariate Normal produced by 100 Faure-Random Draws

Figure 18.74 Kernel Density of a Bivariate Normal produced by 100 Pseudo-Random Draws

Solution Mode Output

The following SAS statements dynamically forecast the solution to a nonlinear equation:

```
proc model data=sashelp.citimon;
  parameters a 0.010708 b -0.478849 c 0.929304;
  lhur = 1/(a * ip) + b + c * lag(lhur);
  solve lhur / out=sim forecast dynamic;
run;
```

The first page of output produced by the SOLVE step is shown in [Figure 18.75](#). This is the summary description of the model. The error message states that the simulation was aborted at observation 144 because of missing input values.

Figure 18.75 Solve Step Summary Output

```

                                The MODEL Procedure

Variables Solved For	LHUR

This solution summary table includes the names of the input data set and the output data set followed by a description of the model. The table also indicates that the solution method defaulted to Newton's method. The remaining output is defined as follows.

Maximum CC	is the maximum convergence value accepted by the Newton procedure. This number is always less than the value for the CONVERGE= option.
Maximum Iterations	is the maximum number of Newton iterations performed at each observation and each replication of Monte Carlo simulations.
Total Iterations	is the sum of the number of iterations required for each observation and each Monte Carlo simulation.
Average Iterations	is the average number of Newton iterations required to solve the system at each step.
Solved	is the number of observations used times the number of random replications selected plus one, for Monte Carlo simulations. The one additional simulation is the original unperturbed solution. For simulations that do not involve Monte Carlo, this number is the number of observations used.

Summary Statistics

The STATS and THEIL options are used to select goodness-of-fit statistics. Actual values must be provided in the input data set for these statistics to be printed. When the RANDOM= option is specified, the statistics do not include the unperturbed ($_REP_=0$) solution.

STATS Option Output

The following statements show the addition of the STATS and THEIL options to the model in the previous section:

```
proc model data=sashelp.citimon;
  parameters a 0.010708 b -0.478849 c 0.929304;
  lhur= 1/(a * ip) + b + c * lag(lhur) ;
  solve lhur / out=sim dynamic stats theil;
  range date to '01nov91'd;
run;
```

The STATS output in [Figure 18.78](#) and the THEIL output in [Figure 18.79](#) are generated.

Figure 18.78 STATS Output

The MODEL Procedure

Statistics of fit							
Variable	R-Square	Label					
LHUR	0.7049	UNEMPLOYMENT RATE: ALL WORKERS, 16 YEARS					

The number of observations (Nobs), the number of observations with both predicted and actual values nonmissing (N), and the mean and standard deviation of the actual and predicted values of the determined variables are printed first. The next set of columns in the output are defined as

follows:

Mean Error	$\frac{1}{N} \sum_{j=1}^N (\hat{y}_j - y_j)$
Mean % Error	$\frac{100}{N} \sum_{j=1}^N (\hat{y}_j - y_j)/y_j$
Mean Abs Error	$\frac{1}{N} \sum_{j=1}^N \hat{y}_j - y_j $
Mean Abs % Error	$\frac{100}{N} \sum_{j=1}^N (\hat{y}_j - y_j)/y_j $
RMS Error	$\sqrt{\frac{1}{N} \sum_{j=1}^N (\hat{y}_j - y_j)^2}$
RMS % Error	$100 \sqrt{\frac{1}{N} \sum_{j=1}^N ((\hat{y}_j - y_j)/y_j)^2}$
R-square	$1 - SSE/CSSA$
SSE	$\sum_{j=1}^N (\hat{y}_j - y_j)^2$
SSA	$\sum_{j=1}^N (y_j)^2$
CSSA	$SSA - \left(\sum_{j=1}^N y_j\right)^2$
\hat{y}	predicted value
y	actual value

When the RANDOM= option is specified, the statistics do not include the unperturbed (_REP_=0) solution.

THEIL Option Output

The THEIL option specifies that Theil forecast error statistics be computed for the actual and predicted values and for the relative changes from lagged values. Mathematically, the quantities are

$$\hat{y}c = (\hat{y} - \text{lag}(y))/\text{lag}(y)$$

$$yc = (y - \text{lag}(y))/\text{lag}(y)$$

where $\hat{y}c$ is the relative change for the predicted value and yc is the relative change for the actual value.

Figure 18.79 THEIL Output

Theil Forecast Error Statistics

LHUR	0.1086	0.0539	UNEMPLOYMENT RATE: ALL WORKERS, 16 YEARS

Theil Relative Change Forecast Error Statistics								
Variable	N	Relative Change MSE	Corr (R)	MSE Decomposition Proportions				
				Bias (UM)	Reg (UR)	Dist (UD)	Var (US)	Covar (UC)
LHUR	142	0.0126	-0.08	0.09	0.85	0.06	0.43	0.47

Theil Relative Change Forecast Error Statistics			
Variable	Inequality Coef		Label
	U1	U	
LHUR	4.1226	0.8348	UNEMPLOYMENT RATE: ALL WORKERS, 16 YEARS

The columns have the following meaning:

Corr (R) is the correlation coefficient, ρ , between the actual and predicted values.

$$\rho = \frac{\text{cov}(y, \hat{y})}{\sigma_a \sigma_p}$$

where σ_p and σ_a are the standard deviations of the predicted and actual values.

Bias (UM) is an indication of systematic error and measures the extent to which the average values of the actual and predicted deviate from each other.

$$\frac{(E(y) - E(\hat{y}))^2}{\frac{1}{N} \sum_{t=1}^N (y_t - \hat{y}_t)^2}$$

Reg (UR) is defined as $(\sigma_p - \rho * \sigma_a)^2 / \text{MSE}$. Consider the regression

$$y = \alpha + \beta \hat{y}$$

If $\hat{\beta} = 1$, UR will equal zero.

Dist (UD) is defined as $(1 - \rho^2)\sigma_a\sigma_a/MSE$ and represents the variance of the residuals obtained by regressing yc on $\hat{y}c$.

Var (US) is the variance proportion. US indicates the ability of the model to replicate the degree of variability in the endogenous variable.

$$US = \frac{(\sigma_p - \sigma_a)^2}{MSE}$$

Covar (UC) represents the remaining error after deviations from average values and average variabilities have been accounted for.

$$UC = \frac{2(1 - \rho)\sigma_p\sigma_a}{MSE}$$

U1 is a statistic that measures the accuracy of a forecast defined as follows:

$$U1 = \frac{\sqrt{MSE}}{\sqrt{\frac{1}{N} \sum_{t=1}^N (y_t)^2}}$$

U is the Theil's inequality coefficient defined as follows:

$$U = \frac{\sqrt{MSE}}{\sqrt{\frac{1}{N} \sum_{t=1}^N (y_t)^2} + \sqrt{\frac{1}{N} \sum_{t=1}^N (\hat{y}_t)^2}}$$

MSE is the mean square error. In the case of the relative change Theil statistics, the MSE is computed as follows:

$$MSE = \frac{1}{N} \sum_{t=1}^N (\hat{y}c_t - yc_t)^2$$

More information about these statistics can be found in the references Maddala (1977, 344–347) and Pindyck and Rubinfeld (1981, 364–365).

Goal Seeking: Solving for Right-Hand-Side Variables

The process of computing input values that are needed to produce target results is often called *goal seeking*. To compute a goal-seeking solution, use a SOLVE statement that lists the variables you want to solve for and provide a data set that contains values for the remaining variables.

Consider the following demand model for packaged rice

$$\text{quantity demanded} = \alpha_1 + \alpha_2 \text{price}^{2/3} + \alpha_3 \text{income}$$

where *price* is the price of the package and *income* is disposable personal income. The only variable the company has control over is the price it charges for rice. This model is estimated by using the following simulated data and PROC MODEL statements:

```

data demand;
  do t=1 to 40;
    price = (rannor(10) +5) * 10;
    income = 8000 * t ** (1/8);
    demand = 7200 - 1054 * price ** (2/3) +
              7 * income + 100 * rannor(1);
    output;
  end;
run;

data goal;
  demand = 85000;
  income = 12686;
run;

```

The goal is to find the price the company would have to charge to meet a sales target of 85,000 units. To do this, a data set is created with a DEMAND variable set to 85000 and with an INCOME variable set to 12686, the last income value.

The desired price is then determined by using the following PROC MODEL statements:

```

proc model data=demand
  outmodel=demandModel;
  demand = a1 - a2 * price ** (2/3) + a3 * income;
  fit demand / outest=demest;
  solve price / estdata=demest data=goal solveprint;
run;

```

The SOLVEPRINT option prints the solution values, number of iterations, and final residuals at each observation. The SOLVEPRINT output from this solve is shown in [Figure 18.80](#).

Figure 18.80 Goal Seeking, SOLVEPRINT Output

The MODEL Procedure						
Single-Equation Simulation						
Observation	1	Iterations	6	CC	0.000000	ERROR.demand 0.000000
Solution Values						
price						
33.59016						

The output indicates that it took six Newton iterations to determine the PRICE of 33.5902, which makes the DEMAND value within $16E-11$ of the goal of 85,000 units.

Consider a more ambitious goal of 100,000 units. The output shown in [Figure 18.81](#) indicates that the sales target of 100,000 units is not attainable according to this model.

```

data goal;

```

```

    demand = 100000;
    income = 12686;
run;

proc model model=demandModel;
    solve price / estdata=demest data=goal solveprint;
run;

```

```

                                The MODEL Procedure
                                Single-Equation Simulation

ERROR: Could not reduce norm of residuals in 10 subiterations.
ERROR: The solution failed because 1 equations are missing or have extreme
       values for observation 1 at NEWTON iteration 1.

      Observation      1      Iteration      1      CC      -1.000000
                        Missing      1

--- Listing of Program Data Vector ---
_N_:                12  ACTUAL.demand:    100000  ERROR.demand:      .
PRED.demand:        .   a1:                7126.437997  a2:                1040.841492
a3:                 6.992694  demand:          100000  income:            12686
price:              -0.000172
@PRED.demand/@pri:  .

```

The program data vector with the error note indicates that even after 10 subiterations, the norm of the residuals could not be reduced. The sales target of 100,000 units are unattainable with the given model. You might need to reformulate your model or collect more data to more accurately reflect the market response.

Numerical Solution Methods

If the SINGLE option is not used, PROC MODEL computes values that simultaneously satisfy the model equations for the variables named in the SOLVE statement. PROC MODEL provides three iterative methods, Newton, Jacobi, and Seidel, for computing a simultaneous solution of the system of nonlinear equations.

Single-Equation Solution

For normalized form equation systems, the solution either can simultaneously satisfy all the equations or can be computed for each equation separately, by using the actual values of the solution variables in the current period to compute each predicted value. By default, PROC MODEL com-

puts a simultaneous solution. The SINGLE option in the SOLVE statement selects single-equation solutions.

Single-equation simulations are often made to produce residuals (which estimate the random terms of the stochastic equations) rather than the predicted values themselves. If the input data and range are the same as that used for parameter estimation, a static single-equation simulation reproduces the residuals of the estimation.

Newton's Method

The NEWTON option in the SOLVE statement requests Newton's method to simultaneously solve the equations for each observation. Newton's method is the default solution method. Newton's method is an iterative scheme that uses the derivatives of the equations with respect to the solution variables, \mathbf{J} , to compute a change vector as

$$\Delta \mathbf{y}^i = \mathbf{J}^{-1} \mathbf{q}(\mathbf{y}^i, \mathbf{x}, \boldsymbol{\theta})$$

PROC MODEL builds and solves \mathbf{J} by using efficient sparse matrix techniques. The solution variables \mathbf{y}^i at the i th iteration are then updated as

$$\mathbf{y}^{i+1} = \mathbf{y}^i + d \times \Delta \mathbf{y}^i$$

where d is a damping factor between 0 and 1 chosen iteratively so that

$$\|\mathbf{q}(\mathbf{y}^{i+1}, \mathbf{x}, \boldsymbol{\theta})\| < \|\mathbf{q}(\mathbf{y}^i, \mathbf{x}, \boldsymbol{\theta})\|$$

The number of subiterations allowed for finding a suitable d is controlled by the MAXSUBITER= option. The number of iterations of Newton's method allowed for each observation is controlled by MAXITER= option. See Ortega and Rheinbolt (1970) for more details.

Jacobi Method

The JACOBI option in the SOLVE statement selects a matrix-free alternative to Newton's method. This method is the traditional nonlinear Jacobi method found in the literature. The Jacobi method as implemented in PROC MODEL substitutes predicted values for the endogenous variables and iterates until a fixed point is reached. Then necessary derivatives are computed only for the diagonal elements of the jacobian, \mathbf{J} .

If the normalized form equation is

$$\mathbf{y} = \mathbf{f}(\mathbf{y}, \mathbf{x}, \boldsymbol{\theta})$$

the Jacobi iteration has the form

$$\mathbf{y}^{i+1} = \mathbf{f}(\mathbf{y}^i, \mathbf{x}, \boldsymbol{\theta})$$

Seidel Method

The Seidel method is an order-dependent alternative to the Jacobi method. The Seidel method is selected by the SEIDEL option in the SOLVE statement. The Seidel method is like the Jacobi method except that in the Seidel method the model is further edited to substitute the predicted values into the solution variables immediately after they are computed. Seidel thus differs from the other methods in that the values of the solution variables are not fixed within an iteration. With the other methods, the order of the equations in the model program makes no difference, but the Seidel method might work much differently when the equations are specified in a different sequence. Note that this fixed point method is the traditional nonlinear Seidel method found in the literature.

The iteration has the form

$$\mathbf{y}_j^{i+1} = \mathbf{f}(\hat{\mathbf{y}}^i, \mathbf{x}, \boldsymbol{\theta})$$

where \mathbf{y}_j^{i+1} is the j th equation variable at the i th iteration and

$$\hat{\mathbf{y}}^i = (y_1^{i+1}, y_2^{i+1}, y_3^{i+1}, \dots, y_{j-1}^{i+1}, y_j^i, y_{j+1}^i, \dots, y_g^i)'$$

If the model is recursive, and if the equations are in recursive order, the Seidel method converges at once. If the model is block-recursive, the Seidel method might converge faster if the equations are grouped by block and the blocks are placed in block-recursive order. The BLOCK option can be used to determine the block-recursive form.

Jacobi and Seidel Methods with General Form Equations

Jacobi and Seidel solution methods support general form equations.

There are two cases where derivatives are (automatically) computed. The first case is for equations with the solution variable on the right-hand side and on the left-hand side of the equation

$$y^i = f(\mathbf{x}, y^i)$$

In this case the derivative of `ERROR.y` with respect to y is computed, and the new y approximation is computed as

$$y^{i+1} = y^i - \frac{f(\mathbf{x}, y^i) - y^i}{\partial(f(\mathbf{x}, y^i) - y^i)/\partial y}$$

The second case is a system of equations that contains one or more `EQ.var` equations. In this case, a heuristic algorithm is used to make the assignment of a unique solution variable to each general form equation. Use the DETAILS option in the SOLVE statement to print a listing of the assigned variables.

Once the assignment is made, the new y approximation is computed as

$$y^{i+1} = y^i - \frac{f(\mathbf{x}, \mathbf{y}^i) - y^i}{\partial(f(\mathbf{x}, \mathbf{y}^i) - y^i)/\partial y}$$

If k is the number of general form equations, then k derivatives are required.

The convergence properties of the Jacobi and Seidel solution methods remain significantly poorer than the default Newton's method.

Comparison of Methods

Newton's method is the default and should work better than the others for most small- to medium-sized models. The Seidel method is always faster than the Jacobi for recursive models with equations in recursive order. For very large models and some highly nonlinear smaller models, the Jacobi or Seidel methods can sometimes be faster. Newton's method uses more memory than the Jacobi or Seidel methods.

Both the Newton's method and the Jacobi method are order-invariant in the sense that the order in which equations are specified in the model program has no effect on the operation of the iterative solution process. In order-invariant methods, the values of the solution variables are fixed for the entire execution of the model program. Assignments to model variables are automatically changed to assignments to corresponding equation variables. Only after the model program has completed execution are the results used to compute the new solution values for the next iteration.

Troubleshooting Problems

In solving a simultaneous nonlinear dynamic model you might encounter some of the following problems.

Missing Values

For SOLVE tasks, there can be no missing parameter values. Missing right-hand-side variables result in missing left-hand-side variables for that observation.

Unstable Solutions

A solution might exist but be unstable. An unstable system can cause the Jacobi and Seidel methods to diverge.

Explosive Dynamic Systems

A model might have well-behaved solutions at each observation but be dynamically unstable. The solution might oscillate wildly or grow rapidly with time.

Propagation of Errors

During the solution process, solution variables can take on values that cause computational errors. For example, a solution variable that appears in a LOG function might be positive at the solution but might be given a negative value during one of the iterations. When computational errors occur, missing values are generated and propagated, and the solution process might collapse.

Convergence Problems

The following items can cause convergence problems:

- There are illegal function values (for example $\sqrt{-1}$).
- There are local minima in the model equation.
- No solution exists.
- Multiple solutions exist.
- Initial values are too far from the solution.
- The CONVERGE= value is too small.

When PROC MODEL fails to find a solution to the system, the current iteration information and the program data vector are printed. The simulation halts if actual values are not available for the simulation to proceed. Consider the following program, which produces the output shown in Figure 18.82:

```
data test1;
  do t=1 to 50;
    x1 = sqrt(t) ;
    y = .;
    output;
  end;

proc model data=test1;
  exogenous x1 ;
  control a1 -1 b1 -29 c1 -4 ;
  y = a1 * sqrt(y) + b1 * x1 * x1 + c1 * lag(x1);
  solve y / out=sim forecast dynamic ;
run;
```

Figure 18.82 SOLVE Convergence Problems

```

y:           -0.00109
@PRED.y/@y:    .   @ERROR.y/@y:    .

NOTE: Check for missing input data or uninitialized lags.
      (Note that the LAG and DIF functions return missing values for the
initial lag starting observations. This is a change from the 1982 and earlier
versions of SAS/ETS which returned zero for uninitialized lags.)
NOTE: Simulation aborted.

```

At the first observation, a solution to the following equation is attempted:

$$y = -\sqrt{y} - 62$$

There is no solution to this problem. The iterative solution process got as close as it could to making Y negative while still being able to evaluate the model. This problem can be avoided in this case by altering the equation.

In other models, the problem of missing values can be avoided by either altering the data set to provide better starting values for the solution variables or by altering the equations.

You should be aware that, in general, a nonlinear system can have any number of solutions and the solution found might not be the one that you want. When multiple solutions exist, the solution that is found is usually determined by the starting values for the iterations. If the value from the input data set for a solution variable is missing, the starting value for it is taken from the solution of the last period (if nonmissing) or else the solution estimate is started at 0.

Iteration Output

The iteration output, produced by the ITPRINT option, is useful in determining the cause of a convergence problem. The ITPRINT option forces the printing of the solution approximation and equation errors at each iteration for each observation. A portion of the ITPRINT output from the following statements is shown in [Figure 18.83](#).

```

proc model data=test1;
  exogenous x1 ;
  control a1 -1 b1 -29 c1 -4 ;
  y = a1 * sqrt(abs(y)) + b1 * x1 * x1 + c1 * lag(x1);
  solve y / out=sim forecast dynamic itprint;
run;

```

For each iteration, the equation with the largest error is listed in parentheses after the Newton convergence criteria measure. From this output you can determine which equation or equations in the system are not converging well.

Numerical Integration

The differential equation system is numerically integrated to obtain a solution for the derivative variables at each data point. The integration is performed by evaluating the provided model at

multiple points between each data point. The integration method used is a variable order, variable step-size backward difference scheme; for more detailed information, see Aiken (1985) and Byrne and Hindmarsh (1975). The step size or time step is chosen to satisfy a *local truncation error* requirement. The term *truncation error* comes from the fact that the integration scheme uses a truncated series expansion of the integrated function to do the integration. Because the series is truncated, the integration scheme is within the truncation error of the true value.

To further improve the accuracy of the integration, the total integration time is broken up into small intervals (time steps or step sizes), and the integration scheme is applied to those intervals. The integration at each time step uses the values computed at the previous time step so that the truncation error tends to accumulate. It is usually not possible to estimate the global error with much precision. The best that can be done is to monitor and to control the local truncation error, which is the truncation error committed at each time step relative to

$$d = \max_{0 \leq t \leq T} (\|y(t)\|_{\infty}, 1)$$

where $y(t)$ is the integrated variable. Furthermore, the $y(t)$ s are dynamically scaled to within two orders of magnitude one to keep the error monitoring well behaved.

The local truncation error requirement defaults to $1.0E-9$. You can specify the `LTEBOUND=` option to modify that requirement. The `LTEBOUND=` option is a relative measure of accuracy, so a value smaller than $1.0E-10$ is usually not practical. A larger bound increases the speed of the simulation and estimation but decreases the accuracy of the results. If the `LTEBOUND=` option is set too small, the integrator is not able to take time steps small enough to satisfy the local truncation error requirement and still have enough machine precision to compute the results. Since the integrations are scaled to within $1.0E-2$ of one, the simulated values should be correct to at least seven decimal places.

There is a default minimum time step of $1.0E-14$. This minimum time step is controlled by the `MINTIMESTEP=` option and the machine epsilon. If the minimum time step is smaller than the machine epsilon times the final time value, the minimum time step is increased automatically.

For the points between each observation in the data set, the values for nonintegrated variables in the data set are obtained from a linear interpolation from the two closest points. Lagged variables can be used with integrations, but their values are discrete and are not interpolated between points. Lagging, therefore, can then be used to input step functions into the integration.

The derivatives necessary for estimation (the gradient with respect to the parameters) and goal seeking (the Jacobian) are computed by numerically integrating analytical derivatives. The accuracy of the derivatives is controlled by the same integration techniques mentioned previously.

Limitations

There are limitations to the types of differential equations that can be solved or estimated. One type is an explosive differential equation (finite escape velocity) for which the following differential equation is an example:

$$y' = a \times y, a > 0$$

If this differential equation is integrated too far in time, y exceeds the maximum value allowed on the computer, and the integration terminates.

Likewise, differential systems that are singular cannot be solved or estimated in general. For example, consider the following differential system:

$$\begin{aligned}x' &= -y' + 2x + 4y + \exp(t) \\y' &= -x' + y + \exp(4t)\end{aligned}$$

This system has an analytical solution, but an accurate numerical solution is very difficult to obtain. The reason is that y' and x' cannot be isolated on the left-hand side of the equation. If the equation is modified slightly to

$$\begin{aligned}x' &= -y' + 2x + 4y + \exp(t) \\y' &= x' + y + \exp(4t)\end{aligned}$$

the system is nonsingular, but the integration process could still fail or be extremely slow. If the MODEL procedure encounters either system, a warning message is issued.

This system can be rewritten as the following recursive system, which can be estimated and simulated successfully with the MODEL procedure:

$$\begin{aligned}x' &= 0.5y + 0.5\exp(4t) + x + 1.5y - 0.5\exp(t) \\y' &= x' + y + \exp(4t)\end{aligned}$$

Petzold (1982) mentions a class of differential algebraic equations that, when integrated numerically, could produce incorrect or misleading results. An example of such a system is

$$\begin{aligned}y_2'(t) &= y_1(t) + g_1(t) \\0 &= y_2(t) + g_2(t)\end{aligned}$$

The analytical solution to this system depends on g and its derivatives at the current time only and not on its initial value or past history. You should avoid systems of this and other similar forms mentioned in Petzold (1982).

SOLVE Data Sets

SDATA= Input Data Set

The SDATA= option reads a cross-equation covariance matrix from a data set. The covariance matrix read from the SDATA= data set specified in the SOLVE statement is used to generate random equation errors when the RANDOM= option specifies Monte Carlo simulation.

Typically, the `SDATA=` data set is created by the `OUTS=` option in a previous `FIT` statement. (The `OUTS=` data set from a `FIT` statement can be read back in by a `SOLVE` statement in the same `PROC MODEL` step.)

You can create an input `SDATA=` data set by using the `DATA` step. `PROC MODEL` expects to find a character variable `_NAME_` in the `SDATA=` data set as well as variables for the equations in the estimation or solution. For each observation with a `_NAME_` value that matches the name of an equation, `PROC MODEL` fills the corresponding row of the **S** matrix with the values of the names of equations found in the data set. If a row or column is omitted from the data set, an identity matrix row or column is assumed. Missing values are ignored. Since the **S** matrix is symmetric, you can include only a triangular part of the **S** matrix in the `SDATA=` data set with the omitted part indicated by missing values. If the `SDATA=` data set contains multiple observations with the same `_NAME_`, the last values supplied for the `_NAME_` variable are used. The section “[OUTS= Data Set](#)” on page 1112 contains more details on the format of this data set.

Use the `TYPE=` option to specify the type of estimation method used to produce the **S** matrix you want to input.

ESTDATA= Input Data Set

The `ESTDATA=` option specifies an input data set that contains an observation with values for some or all of the model parameters. It can also contain observations with the rows of a covariance matrix for the parameters.

When the `ESTDATA=` option is used, parameter values are set from the first observation. If the `RANDOM=` option is used and the `ESTDATA=` data set contains a covariance matrix, the covariance matrix of the parameter estimates is read and used to generate pseudo-random shocks to the model parameters for Monte Carlo simulation. These random perturbations have a multivariate normal distribution with the covariance matrix read from the `ESTDATA=` data set.

The `ESTDATA=` data set is usually created by the `OUTEST=` option in a `FIT` statement. The `OUTEST=` data set contains the parameter estimates produced by the `FIT` statement and also contains the estimated covariance of the parameter estimates if the `OUTCOV` option is used. This `OUTEST=` data set can be read in by the `ESTDATA=` option in a `SOLVE` statement.

You can also create an `ESTDATA=` data set with a `SAS DATA` step program. The data set must contain a numeric variable for each parameter to be given a value or covariance column. The name of the variable in the `ESTDATA=` data set must match the name of the parameter in the model. Parameters with names longer than 32 characters cannot be set from an `ESTDATA=` data set. The data set must also contain a character variable `_NAME_` of length 32. `_NAME_` has a blank value for the observation that gives values to the parameters. `_NAME_` contains the name of a parameter for observations that define rows of the covariance matrix.

More than one set of parameter estimates and covariances can be stored in the `ESTDATA=` data set if the observations for the different estimates are identified by the variable `_TYPE_`. `_TYPE_` must be a character variable of length eight. The `TYPE=` option is used to select for input the part of the `ESTDATA=` data set for which the value of the `_TYPE_` variable matches the value of the `TYPE=` option.

OUT= Data Set

The OUT= data set contains solution values, residual values, and actual values of the solution variables.

The OUT= data set contains the following variables:

- BY variables
- RANGE variable
- ID variables
- `_TYPE_`, a character variable of length eight that identifies the type of observation. The `_TYPE_` variable can be PREDICT, RESIDUAL, ACTUAL, or ERROR.
- `_MODE_`, a character variable of length eight that identifies the solution mode. `_MODE_` takes the value FORECAST or SIMULATE.
- if lags are used, a numeric variable, `_LAG_`, that contains the number of dynamic lags that contribute to the solution. The value of `_LAG_` is always zero for STATIC mode solutions. `_LAG_` is set to a missing value for lag-starting observations.
- if the RANDOM= option is used, `_REP_`, a numeric variable that contains the replication number. For example, if RANDOM=10, each input observation results in eleven output observations with `_REP_` values 0 through 10. The observations with `_REP_=0` are from the unperturbed solution. (The random-number generator functions are suppressed, and the parameter and endogenous perturbations are zero when `_REP_=0`.)
- `_ERRORS_`, a numeric variable that contains the number of errors that occurred during the execution of the program for the last iteration for the observation. If the solution failed to converge, this is counted as one error, and the `_ERRORS_` variable is made negative.
- solution and other variables. The solution variables contain solution or predicted values for `_TYPE_=PREDICT` observations, residuals for `_TYPE_=RESIDUAL` observations, or actual values for `_TYPE_=ACTUAL` observations. The other model variables, and any other variables read from the input data set, are always actual values from the input data set.
- any other variables named in the OUTVARS statement. These can be program variables computed by the model program, CONTROL variables, parameters, or special variables in the model program. Compound variable names longer than 32 characters are truncated in the OUT= data set.

By default, only the predicted values are written to the OUT= data set. The OUTRESID, OUTACTUAL, and OUTERERROR options are used to add the residual, actual, and ERROR. values, respectively, to the data set.

For examples of the OUT= data set, see [Example 18.6](#).

DATA= Input Data Set

The input data set should contain all of the exogenous variables and should supply nonmissing values for them for each period to be solved.

Solution variables can be supplied in the input data set and are used as follows:

- to supply initial lags. For example, if the lag length of the model is three, three observations are read in to feed the lags before any solutions are computed.
- to evaluate the goodness of fit. Goodness-of-fit measures are computed based on the difference between the solved values and the actual values supplied from the data set.
- to supply starting values for the iterative solution. If the value from the input data set for a solution variable is missing, the starting value for it is taken from the solution of the last period (if nonmissing) or else the solution estimate is started at zero.
- for STATIC mode solutions, actual values from the data set are used by the lagging functions for the solution variables.
- for FORECAST mode solutions, actual values from the data set are used as the solution values when nonmissing.

Programming Language Overview: MODEL Procedure

Variables in the Model Program

Variable names are alphanumeric but must start with a letter. The length is limited to 32 characters.

PROC MODEL uses several classes of variables, and different variable classes are treated differently. The variable class is controlled by *declaration statements*: the VAR, ENDOGENOUS, and EXOGENOUS statements for model variables, the PARAMETERS statement for parameters, and the CONTROL statement for control class variables. These declaration statements have several valid abbreviations. Various *internal variables* are also made available to the model program to allow communication between the model program and the procedure. RANGE, ID, and BY variables are also available to the model program. Those variables not declared as any of the preceding classes are *program variables*.

Some classes of variables can be lagged; that is, their value at each observation is remembered, and previous values can be referred to by the lagging functions. Other classes have only a single value and are not affected by lagging functions. For example, parameters have only one value and are not affected by lagging functions; therefore, if P is a parameter, $DIF_n(P)$ is always 0, and $LAG_n(P)$ is always the same as P for all values of n .

The different variable classes and their roles in the model are described in the following.

Model Variables

Model variables are declared by VAR, ENDOGENOUS, or EXOGENOUS statements, or by FIT and SOLVE statements. The model variables are the variables that the model is intended to explain or predict.

PROC MODEL enables you to use expressions on the left-hand side of the equal sign to define model equations. For example, a log-linear model for Y can be written as

$$\log(y) = a + b * x;$$

Previously, only a variable name was allowed on the left-hand side of the equal sign.

The text on the left-hand side of the equation serves as the equation name used to identify the equation in printed output, in the OUT= data sets, and in FIT or SOLVE statements. To refer to equations specified by using left-hand side expressions (in the FIT statement, for example), place the left-hand side expression in quotes. For example, the following statements fit a log-linear model to the dependent variable Y:

```
proc model data=in;
  log( y ) = a + b * x;
  fit "log(y)";
run;
```

The estimation and simulation is performed by transforming the models into general form equations. No actual or predicted value is available for general form equations, so no R^2 or adjusted R^2 is computed.

Equation Variables

An equation variable is one of several special variables used by PROC MODEL to control the evaluation of model equations. An equation variable name consists of one of the prefixes EQ, RESID, ERROR, PRED, or ACTUAL, followed by a period and the name of a model equation.

Equation variable names can appear in parts of the PROC MODEL printed output, and they can be used in the model program. For example, RESID-prefixed variables can be used in LAG functions to define equations with moving-average error terms. See the section “[Autoregressive Moving-Average Error Processes](#)” on page 1088 for details.

The meaning of these prefixes is detailed in the section “[Equation Translations](#)” on page 1155.

Parameters

Parameters are variables that have the same value for each observation. Parameters can be given values or can be estimated by fitting the model to data. During the SOLVE stage, parameters are treated as constants. If no estimation is performed, the SOLVE stage uses the initial value provided

in the ESTDATA= data set, the MODEL= file, or in the PARAMETER statement, as the value of the parameter.

The PARAMETERS statement declares the parameters of the model. Parameters are not lagged, and they cannot be changed by the model program.

Control Variables

Control variables supply constant values to the model program that can be used to control the model in various ways. The CONTROL statement declares control variables and specifies their values. A control variable is like a parameter except that it has a fixed value and is not estimated from the data.

Control variables are not reinitialized before each pass through the data and can thus be used to retain values between passes. You can use control variables to vary the program logic. Control variables are not affected by lagging functions.

For example, if you have two versions of an equation for a variable Y, you could put both versions in the model and, by using a CONTROL statement to select one of them, produce two different solutions to explore the effect the choice of equation has on the model, as shown in the following statements:

```
select (case);
  when (1) y = ...first version of equation... ;
  when (2) y = ...second version of equation... ;
end;

control case 1;
solve / out=case1;
run;

control case 2;
solve / out=case2;
run;
```

RANGE, ID, and BY Variables

The RANGE statement controls the range of observations in the input data set that is processed by PROC MODEL. The ID statement lists variables in the input data set that are used to identify observations in the printout and in the output data set. The BY statement can be used to make PROC MODEL perform a separate analysis for each BY group. The variable in the RANGE statement, the ID variables, and the BY variables are available for the model program to examine, but their values should not be changed by the program. The BY variables are not affected by lagging functions.

Internal Variables

You can use several internal variables in the model program to communicate with the procedure. For example, if you want PROC MODEL to list the values of all the variables when more than 10

iterations are performed and the procedure is past the 20th observation, you can write

```
if _obs_ > 20 then if _iter_ > 10 then _list_ = 1;
```

Internal variables are not affected by lagging functions, and they cannot be changed by the model program except as noted. The following internal variables are available. The variables are all numeric except where noted.

<code>_ERRORS_</code>	is a flag that is set to 0 at the start of program execution and is set to a nonzero value whenever an error occurs. The program can also set the <code>_ERRORS_</code> variable.
<code>_ITER_</code>	is the iteration number. For FIT tasks, the value of <code>_ITER_</code> is negative for preliminary grid-search passes. The iterative phase of the estimation starts with iteration 0. After the estimates have converged, a final pass is made to collect statistics with <code>_ITER_</code> set to a missing value. Note that at least one pass, and perhaps several subiteration passes as well, is made for each iteration. For SOLVE tasks, <code>_ITER_</code> counts the iterations used to compute the simultaneous solution of the system.
<code>_LAG_</code>	is the number of dynamic lags that contribute to the solution at the current observation. <code>_LAG_</code> is always 0 for FIT tasks and for STATIC solutions. <code>_LAG_</code> is set to a missing value during the lag starting phase.
<code>_LIST_</code>	is a list flag that is set to 0 at the start of program execution. The program can set <code>_LIST_</code> to a nonzero value to request a listing of the values of all the variables in the program after the program has finished executing.
<code>_METHOD_</code>	is the solution method in use for SOLVE tasks. <code>_METHOD_</code> is set to a blank value for FIT tasks. <code>_METHOD_</code> is a character-valued variable. Values are NEWTON, JACOBI, SIEDEL, or ONEPASS.
<code>_MODE_</code>	takes the value ESTIMATE for FIT tasks and the value SIMULATE or FORECAST for SOLVE tasks. <code>_MODE_</code> is a character-valued variable.
<code>_NMISS_</code>	is the number of missing or otherwise unusable observations during the model estimation. For FIT tasks, <code>_NMISS_</code> is initially set to 0; at the start of each iteration, <code>_NMISS_</code> is set to the number of unusable observations for the previous iteration. For SOLVE tasks, <code>_NMISS_</code> is set to a missing value.
<code>_NUSED_</code>	is the number of nonmissing observations used in the estimation. For FIT tasks, PROC MODEL initially sets <code>_NUSED_</code> to the number of parameters; at the start of each iteration, <code>_NUSED_</code> is reset to the number of observations used in the previous iteration. For SOLVE tasks, <code>_NUSED_</code> is set to a missing value.
<code>_OBS_</code>	counts the observations being processed. <code>_OBS_</code> is negative or 0 for observations in the lag starting phase.
<code>_REP_</code>	is the replication number for Monte Carlo simulation when the RANDOM= option is specified in the SOLVE statement. <code>_REP_</code> is 0 when the RANDOM= option is not used and for FIT tasks. When <code>_REP_=0</code> , the random-number generator functions always return 0.

`_WEIGHT_` is the weight of the observation. For FIT tasks, `_WEIGHT_` provides a weight for the observation in the estimation. `_WEIGHT_` is initialized to 1.0 at the start of execution for FIT tasks. For SOLVE tasks, `_WEIGHT_` is ignored.

Program Variables

Variables not in any of the other classes are called program variables. Program variables are used to hold intermediate results of calculations. Program variables are reinitialized to missing values before each observation is processed. Program variables can be lagged. The RETAIN statement can be used to give program variables initial values and enable them to keep their values between observations.

Character Variables

PROC MODEL supports both numeric and character variables. Character variables are not involved in the model specification but can be used to label observations, to write debugging messages, or for documentation purposes. All variables are numeric unless they are the following.

- character variables in a DATA= SAS data set
- program variables assigned a character value
- declared to be character by a LENGTH or ATTRIB statement

Equation Translations

Equations written in normalized form are always automatically converted to general form equations. For example, when a normalized form equation such as

$$y = a + b*x;$$

is encountered, it is translated into the equations

$$\begin{aligned} \text{PRED.y} &= a + b*x; \\ \text{RESID.y} &= \text{PRED.y} - \text{ACTUAL.y}; \\ \text{ERROR.y} &= \text{PRED.y} - y; \end{aligned}$$

If the same system is expressed as the following general form equation, then this equation is used unchanged.

$$\text{EQ.y} = y - a + b*x;$$

This makes it easy to solve for arbitrary variables and to modify the error terms for autoregressive or moving average models.

Use the LIST option to see how this transformation is performed. For example, the following statements produce the listing shown in Figure 18.84.

```
proc model data=line list;
  y = a1 + b1*x1 + c1*x2;
  fit y;
run;
```

Figure 18.84 LIST Output

The MODEL Procedure		
Listing of Compiled Program Code		
Stmnt	Line:Col	Statement as Parsed
1	3676:4	PRED.y = a1 + b1 * x1 + c1 * x2;
1	3676:4	RESID.y = PRED.y - ACTUAL.y;
1	3676:4	ERROR.y = PRED.y - y;

PRED.Y is the predicted value of Y, and ACTUAL.Y is the value of Y in the data set. The predicted value minus the actual value, RESID.Y, is then the error term, ϵ , for the original Y equation. Note that the residuals obtained from the OUTRESID option in the OUT=dataset for both the FIT and SOLVE statements are defined as *actual* – *predicted*, the negative of RESID.Y. See the section “Syntax: MODEL Procedure” on page 962 for details. ACTUAL.Y and Y have the same value for parameter estimation. For solve tasks, ACTUAL.Y is still the value of Y in the data set but Y becomes the solved value; the value that satisfies PRED.Y – Y = 0.

The following are the equation variable definitions.

- EQ.** The value of an EQ.-prefixed equation variable (normally used to define a general form equation) represents the failure of the equation to hold. When the EQ.name variable is 0, the name equation is satisfied.
- RESID.** The RESID.name variables represent the stochastic parts of the equations and are used to define the objective function for the estimation process. A RESID.-prefixed equation variable is like an EQ.-prefixed variable but makes it possible to use or transform the stochastic part of the equation. The RESID. equation is used in place of the ERROR. equation for model solutions if it has been reasigned or used in the equation.
- ERROR.** An ERROR.name variable is like an EQ.-prefixed variable, except that it is used only for model solution and does not affect parameter estimation.
- PRED.** For a normalized form equation (specified by assignment to a model variable), the PRED.name equation variable holds the predicted value, where name is the name of both the model variable and the corresponding equation. (PRED.-prefixed variables are not created for general form equations.)

- ACTUAL. For a normalized form equation (specified by assignment to a model variable), the ACTUAL.*name* equation variable holds the value of the *name* model variable read from the input data set.
- DERT. The DERT.*name* variable defines a differential equation. Once defined, it might be used on the right-hand side of another equation.
- H. The H.*name* variable specifies the functional form for the variance of the named equation.
- GMM_H. This is created for H.*vars* and is the moment equation for the variance for GMM. This variable is used only for GMM.

```
GMM_H.name = RESID.name**2 - H.name;
```

- MSE. The MSE.*y* variable contains the value of the mean squared error for *y* at each iteration. An MSE. variable is created for each dependent/endogenous variable in the model. These variables can be used to specify the missing lagged values in the estimation and simulation of GARCH type models.

```
demret = intercept ;
h.demret = arch0 +
           arch1 * xlag( resid.demret ** 2, mse.demret) +
           garch1 * xlag(h.demret, mse.demret) ;
```

- NRESID. This is created for H.*vars* and is the normalized residual of the variable <*name*>. The formula is

```
NRESID.name = RESID.name / sqrt(H.name) ;
```

The three equation variable prefixes, RESID., ERROR., and EQ. allow for control over the objective function for the FIT, the SOLVE, or both the FIT and the SOLVE stages. For FIT tasks, PROC MODEL looks first for a RESID.*name* variable for each equation. If defined, the RESID.-prefixed equation variable is used to define the objective function for the parameter estimation process. Otherwise, PROC MODEL looks for an EQ.-prefixed variable for the equation and uses it instead.

For SOLVE tasks, PROC MODEL looks first for an ERROR.*name* variable for each equation. If defined, the ERROR.-prefixed equation variable is used for the solution process. Otherwise, PROC MODEL looks for an EQ.-prefixed variable for the equation and uses it instead. To solve the simultaneous equation system, PROC MODEL computes values of the solution variables (the model variables being solved for) that make all of the ERROR.*name* and EQ.*name* variables close to 0.

Derivatives

Nonlinear modeling techniques require the calculation of derivatives of certain variables with respect to other variables. The MODEL procedure includes an analytic differentiator that determines the model derivatives and generates program code to compute these derivatives. When parameters are estimated, the MODEL procedure takes the derivatives of the equation with respect to the parameters. When the model is solved, Newton's method requires the derivatives of the equations with respect to the variables solved for.

PROC MODEL uses exact mathematical formulas for derivatives of non-user-defined functions. For other functions, numerical derivatives are computed and used.

The differentiator differentiates the entire model program, including the conditional logic and flow of control statements. Delayed definitions, as when the LAG of a program variable is referred to before the variable is assigned a value, are also differentiated correctly.

The differentiator includes optimization features that produce efficient code for the calculation of derivatives. However, when flow of control statements such as GOTO statements are used, the optimization process is impeded, and less efficient code for derivatives might be produced. Optimization is also reduced by conditional statements, iterative DO loops, and multiple assignments to the same variable.

The table of derivatives is printed with the LISTDER option. The code generated for the computation of the derivatives is printed with the LISTCODE option.

Derivative Variables

When the differentiator needs to generate code to evaluate the expression for the derivative of a variable, the result is stored in a special derivative variable. Derivative variables are not created when the derivative expression reduces to a previously computed result, a variable, or a constant. The names of derivative variables, which might sometimes appear in the printed output, have the form *@obj/@wrt*, where *obj* is the variable whose derivative is being taken and *wrt* is the variable that the differentiation is with respect to. For example, the derivative variable for the derivative of *Y* with respect to *X* is named *@Y/@X*.

The derivative variables can be accessed or used as part of the model program using the GETDER() function.

GETDER(*x*, *a*) the derivative of *x* with respect to *a*.

GETDER(*x*, *a*, *b*) the second derivative of *x* with respect to *a* and *b*.

The main purpose of the GETDER() function is for surfacing the derivatives so they can be stored in a data set for further processing. Only derivatives that are implied by the problem are available to the GETDER() function. When derivatives are requested that aren't already created, a missing value will be returned. The derivative of the GETDER() function is always zero so the results of the GETDER() function shouldn't be used in any of the equations in the FIT or the SOLVE statement.

The following example adds the gradient of the PRED.y value with respect to the parameters to the OUT= data set.

```
proc model data=line ;
  y = a1 + b1**2 *x1 + c1*x2;
  Dy_a1 = getder(PRED.y, a1);
  Dy_b1 = getder(PRED.y, b1);
  Dy_c1 = getder(PRED.y, c1);
  outvars Dy_a1 Dy_b1 Dy_c1;
  fit y / out=grad;
run;
```

Mathematical Functions

The following is a brief summary of SAS functions that are useful for defining models. Additional functions and details are in *SAS Language: Reference*. Information about creating new functions can be found in *SAS/BASE Software: Procedure Reference*, Chapter 18, “The FCMP Procedure.”

ABS(x)	the absolute value of x
ARCOS(x)	the arccosine in radians of x ; x should be between -1 and 1 .
ARSIN(x)	the arcsine in radians of x ; x should be between -1 and 1 .
ATAN(x)	the arctangent in radians of x
COS(x)	the cosine of x ; x is in radians.
COSH(x)	the hyperbolic cosine of x
EXP(x)	e^x
LOG(x)	the natural logarithm of x
LOG10(x)	the log base ten of x
LOG2(x)	the log base two of x
SIN(x)	the sine of x ; x is in radians.
SINH(x)	the hyperbolic sine of x
SQRT(x)	the square root of x
TAN(x)	the tangent of x ; x is in radians and is not an odd multiple of $\pi/2$.
TANH(x)	the hyperbolic tangent of x

Random-Number Functions

The MODEL procedure provides several functions for generating random numbers for Monte Carlo simulation. These functions use the same generators as the corresponding SAS DATA step functions.

The following random number functions are supported: RANBIN, RANCAU, RAND, RANEXP, RANGAM, RANNOR, RANPOI, RANTBL, RANTRI, and RANUNI. For more information, refer to *SAS Language: Reference*.

Each reference to a random number function sets up a separate pseudo-random sequence. Note that this means that two calls to the same random function with the same seed produce identical results. This is different from the behavior of the random number functions used in the SAS DATA step. For example, the following statements produce identical values for X and Y, but Z is from an independent pseudo-random sequence:

```
x=rannor(123);
y=rannor(123);
z=rannor(567);
q=rand('BETA', 1, 12);
```

For FIT tasks, all random number functions always return 0. For SOLVE tasks, when Monte Carlo simulation is requested, a random number function computes a new random number on the first iteration for an observation (if it is executed on that iteration) and returns that same value for all later iterations of that observation. When Monte Carlo simulation is not requested, random number functions always return 0.

Functions across Time

PROC MODEL provides four types of special built-in functions that refer to the values of variables and expressions in previous time periods. These functions have the following forms where n represents the number of periods, x is any expression, and the argument i is a variable or expression that gives the lag length ($0 \leq i \leq n$). If the index value i is omitted, the maximum lag length n is used.

$LAGn (< i, > x)$ returns the i th lag of x , where n is the maximum lag;

$DIFn (x)$ is the difference of x at lag n

$ZLAGn (< i, > x)$ returns the i th lag of x , where n is the maximum lag, with missing lags replaced with zero

$XLAGn (x, y)$ returns the n th lag of x if x is nonmissing, or y if x is missing

$ZDIFn (x)$ is the difference with lag length truncated and missing values converted to zero; x is the variable or expression to compute the moving average of

$MOVAVGn (x)$ is the moving average if X_t denotes the observation at time point t , to ensure compatibility with the number n of observations used to calculate the moving average $MOVAVGn$, the following definition is used:

$$MOVAVGn(X_t) = \frac{X_t + X_{t-1} + X_{t-2} + \dots + X_{t-n+1}}{n}$$

The moving average calculation for SAS 9.1 and earlier releases is as follows:

$$MOVAVGn(X_t) = \frac{X_t + X_{t-1} + X_{t-2} + \dots + X_{t-n}}{n + 1}$$

Missing values of x are omitted in computing the average.

If you do not specify n , the number of periods is assumed to be one. For example, $LAG(X)$ is the same as $LAG1(X)$. No more than four digits can be used with a lagging function; that is, $LAG9999$ is the greatest LAG function, $ZDIF9999$ is the greatest ZDIF function, and so on.

The LAG functions get values from previous observations and make them available to the program. For example, $LAG(X)$ returns the value of the variable X as it was computed in the execution of the program for the preceding observation. The expression $LAG2(X+2*Y)$ returns the value of the expression $X+2*Y$, computed by using the values of the variables X and Y that were computed by the execution of the program for the observation two periods ago.

The DIF functions return the difference between the current value of a variable or expression and the value of its LAG. For example, DIF2(X) is a short way of writing $X - \text{LAG2}(X)$, and DIF15(SQRT(2*Z)) is a short way of writing $\text{SQRT}(2*Z) - \text{LAG15}(\text{SQRT}(2*Z))$.

The ZLAG and ZDIF functions are like the LAG and DIF functions, but they are not counted in the determination of the program lag length, and they replace missing values with 0s. The ZLAG function returns the lagged value if the lagged value is nonmissing, or 0 if the lagged value is missing. The ZDIF function returns the differenced value if the differenced value is nonmissing, or 0 if the value of the differenced value is missing. The ZLAG function is especially useful for models with ARMA error processes. See the next section for details.

Lag Logic

The LAG and DIF lagging functions in the MODEL procedure are different from the queuing functions with the same names in the DATA step. Lags are determined by the final values that are set for the program variables by the execution of the model program for the observation. This can have upsetting consequences for programs that take lags of program variables that are given different values at various places in the program, as shown in the following statements:

```
temp = x + w;
t    = lag( temp );
temp = q - r;
s    = lag( temp );
```

The expression LAG(TEMP) always refers to LAG(Q-R), never to LAG(X+W), since Q-R is the final value assigned to the variable TEMP by the model program. If LAG(X+W) is wanted for T, it should be computed as $T = \text{LAG}(X+W)$ and not $T = \text{LAG}(\text{TEMP})$, as in the preceding example.

Care should also be exercised in using the DIF functions with program variables that might be reassigned later in the program. For example, the program

```
temp = x ;
s    = dif( temp );
temp = 3 * y;
```

computes values for S equivalent to

```
s = x - lag( 3 * y );
```

Note that in the preceding examples, TEMP is a program variable, *not* a model variable. If it were a model variable, the assignments to it would be changed to assignments to a corresponding equation variable.

Note that whereas LAG1(LAG1(X)) is the same as LAG2(X), DIF1(DIF1(X)) is *not* the same as DIF2(X). The DIF2 function is the difference between the current period value at the point in the program where the function is executed and the final value at the end of execution two periods ago; DIF2 is not the second difference. In contrast, DIF1(DIF1(X)) is equal to $\text{DIF1}(X) - \text{LAG1}(\text{DIF1}(X))$, which equals $X - 2 * \text{LAG1}(X) + \text{LAG2}(X)$, which is the second difference of X.

More information about the differences between PROC MODEL and the DATA step LAG and DIF functions is found in Chapter 3, “[Working with Time Series Data.](#)”

Lag Lengths

The lag length of the model program is the number of lags needed for any relevant equation. The program lag length controls the number of observations used to initialize the lags.

PROC MODEL keeps track of the use of lags in the model program and automatically determines the lag length of each equation and of the model as a whole. PROC MODEL sets the program lag length to the maximum number of lags needed to compute any equation to be estimated, solved, or needed to compute any instrument variable used.

In determining the lag length, the ZLAG and ZDIF functions are treated as always having a lag length of 0. For example, if Y is computed as

```
y = lag2( x + zdif3( temp ) );
```

then Y has a lag length of 2 (regardless of how TEMP is defined). If Y is computed as

```
y = zlag2( x + dif3( temp ) );
```

then Y has a lag length of 0.

This is so that ARMA errors can be specified without causing the loss of additional observations to the lag starting phase and so that recursive lag specifications, such as moving-average error terms, can be used. Recursive lags are not permitted unless the ZLAG or ZDIF functions are used to truncate the lag length. For example, the following statement produces an error message:

```
t = a + b * lag( t );
```

The program variable T depends recursively on its own lag, and the lag length of T is therefore undefined.

In the following equation RESID.Y depends on the predicted value for the Y equation but the predicted value for the Y equation depends on the LAG of RESID.Y, and thus, the predicted value for the Y equation depends recursively on its own lag.

```
y = yhat + ma * lag( resid.y );
```

The lag length is infinite, and PROC MODEL prints an error message and stops. Since this kind of specification is allowed, the recursion must be truncated at some point. The ZLAG and ZDIF functions do this.

The following equation is valid and results in a lag length for the Y equation equal to the lag length of YHAT:

```
y = yhat + ma * zlag( resid.y );
```

Initially, the lags of RESID.Y are missing, and the ZLAG function replaces the missing residuals with 0s, their unconditional expected values.

The ZLAG0 function can be used to zero out the lag length of an expression. ZLAG0(x) returns the current period value of the expression x , if nonmissing, or else returns 0, and prevents the lag length of x from contributing to the lag length of the current statement.

Initializing Lags

At the start of each pass through the data set or BY group, the lag variables are set to missing values and an initialization is performed to fill the lags. During this phase, observations are read from the data set, and the model variables are given values from the data. If necessary, the model is executed to assign values to program variables that are used in lagging functions. The results for variables used in lag functions are saved. These observations are not included in the estimation or solution.

If, during the execution of the program for the lag starting phase, a lag function refers to lags that are missing, the lag function returns missing. Execution errors that occur while starting the lags are not reported unless requested. The modeling system automatically determines whether the program needs to be executed during the lag starting phase.

If L is the maximum lag length of any equation being fit or solved, then the first L observations are used to prime the lags. If a BY statement is used, the first L observations in the BY group are used to prime the lags. If a RANGE statement is used, the first L observations prior to the first observation requested in the RANGE statement are used to prime the lags. Therefore, there should be at least L observations in the data set.

Initial values for the lags of model variables can also be supplied in VAR, ENDOGENOUS, and EXOGENOUS statements. This feature provides initial lags of solution variables for dynamic solution when initial values for the solution variable are not available in the input data set. For example, the statement

```
var x 2 3 y 4 5 z 1;
```

feeds the initial lags exactly like these values in an input data set:

Lag	X	Y	Z
2	3	5	.
1	2	4	1

If initial values for lags are available in the input data set and initial lag values are also given in a declaration statement, the values in the VAR, ENDOGENOUS, or EXOGENOUS statements take priority.

The RANGE statement is used to control the range of observations in the input data set that are processed by PROC MODEL. In the following statement, '01jan1924' specifies the starting period of the range, and '01dec1943' specifies the ending period:

```
range date = '01jan1924'd to '01dec1943'd;
```

The observations in the data set immediately prior to the start of the range are used to initialize the lags.

Language Differences

For the most part, PROC MODEL programming statements work the same as they do in the DATA step as documented in *SAS Language: Reference*. However, there are several differences that should be noted.

DO Statement Differences

The DO statement in PROC MODEL does not allow a character index variable. Thus, the following DO statement is not valid in PROC MODEL, although it is supported in the DATA step:

```
do i = 'A', 'B', 'C'; /* invalid PROC MODEL code */
```

IF Statement Differences

The IF statement in PROC MODEL does not allow a character-valued condition. For example, the following IF statement is not supported by PROC MODEL:

```
if 'this' then statement;
```

Comparisons of character values are supported in IF statements, so the following IF statement is acceptable:

```
if 'this' < 'that' then statement;
```

PROC MODEL allows for embedded conditionals in expressions. For example the following two statements are equivalent:

```
flag = if time = 1 or time = 2 then conc+30/5 + dose*time
      else if time > 5 then (0=1) else (patient * flag);

if time = 1 or time = 2 then flag= conc+30/5 + dose*time;
else if time > 5 then flag=(0=1); else flag=patient*flag;
```

Note that the ELSE operator involves only the first object or token after it so that the following assignments are not equivalent:

```
total = if sum > 0 then sum else sum + reserve;
total = if sum > 0 then sum else (sum + reserve);
```

The first assignment makes TOTAL always equal to SUM plus RESERVE.

PUT Statement Differences

The PUT statement, mostly used in PROC MODEL for program debugging, supports only some of the features of the DATA step PUT statement. It also has some new features that the DATA step PUT statement does not support.

The PROC MODEL PUT statement does not support line pointers, factored lists, iteration factors, overprinting, the `_INFILE_` option, or the colon (`:`) format modifier.

The PROC MODEL PUT statement does support expressions, but an expression must be enclosed in parentheses. For example, the following statement prints the square root of `x`:

```
put (sqrt(x));
```

Subscripted array names must be enclosed in parentheses. For example, the following statement prints the *i*th element of the array `A`:

```
put (a i);
```

However, the following statement is an error:

```
put a i;
```

The PROC MODEL PUT statement supports the print item `_PDV_` to print a formatted listing of all the variables in the program. For example, the following statement prints a much more readable listing of the variables than does the `_ALL_` print item:

```
put _pdv_;
```

To print all the elements of the array `A`, use the following statement:

```
put a;
```

To print all the elements of `A` with each value labeled by the name of the element variable, use the following statement:

```
put a=;
```

ABORT Statement Difference

In the MODEL procedure, the ABORT statement does not allow any arguments.

SELECT/WHEN/OTHERWISE Statement Differences

The WHEN and OTHERWISE statements allow more than one target statement. That is, DO groups are not necessary for multiple statement WHENs. For example in PROC MODEL, the following syntax is valid:

```
select;
  when (exp1)
    stmt1;
    stmt2;
  when (exp2)
    stmt3;
    stmt4;
end;
```

The ARRAY Statement

ARRAY *arrayname* < {*dimensions*} > < \$ [*length*] > < *variables and constants* > ; ;

The ARRAY statement is used to associate a name with a list of variables and constants. The array name can then be used with subscripts in the model program to refer to the items in the list.

In PROC MODEL, the ARRAY statement does not support all the features of the DATA step ARRAY statement. Implicit indexing cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

On the other hand, the ARRAY statement supported by PROC MODEL does allow both variables and constants to be used as array elements. You cannot make assignments to constant array elements. Both dimension specification and the list of elements are optional, but at least one must be supplied. When the list of elements is not given or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

The following are valid PROC MODEL array statements:

```
array x[120];           /* array X of length 120          */
array q[2,2];          /* Two dimensional array Q        */
array b[4] va vb vc vd; /* B[2] = VB, B[4] = VD          */
array x x1-x30;        /* array X of length 30, X[7] = X7 */
array a[5] (1 2 3 4 5); /* array A initialized to 1,2,3,4,5 */
```

RETAIN Statement

RETAIN *variables initial-values* ;

The RETAIN statement causes a program variable to hold its value from a previous observation until the variable is reassigned. The RETAIN statement can be used to initialize program variables.

The RETAIN statement does not work for model variables, parameters, or control variables because the values of these variables are under the control of PROC MODEL and not programming statements. Use the PARMs and CONTROL statements to initialize parameters and control variables. Use the VAR, ENDOGENOUS, or EXOGENOUS statement to initialize model variables.

Storing Programs in Model Files

Models can be saved in and recalled from SAS catalog files as well as XML-based data sets. SAS catalogs are special files that can store many kinds of data structures as separate units in one SAS file. Each separate unit is called an entry, and each entry has an entry type that identifies its structure to the SAS system. Starting with SAS 9.2, model files are being stored as SAS data sets instead of being stored as members of a SAS catalog as in earlier releases. This makes MODEL files more readily extendable in the future and enables Java-based applications to read the MODEL files directly. You can choose between the two formats by specifying a global CMPMODEL option in an OPTIONS statement. Details are given below.

In general, to save a model, use the OUTMODEL=*name* option in the PROC MODEL statement, where *name* is specified as *libref.catalog.entry*, *libref.entry*, or *entry* for catalog entry and, starting with SAS 9.2, *libref.datasetname* or *datasetname* for XML-based SAS datasets. The *libref*, *catalog*, *datasetnames* and *entry* names must be valid SAS names no more than 32 characters long. The *catalog* name is restricted to seven characters on the CMS operating system. If not given, the *catalog* name defaults to MODELS, and the *libref* defaults to WORK. The entry type is always MODEL. Thus, OUTMODEL=X writes the model to the file WORK.MODELS.X.MODEL in the SAS catalog or creates a WORK.X XML-based dataset in the WORK library depending on the format chosen by using the CMPMODEL= option. By default, both these formats are chosen.

The CMPMODEL= option can be used in an OPTIONS statement to modify the behavior when reading and writing MODEL files. The values allowed are CMPMODEL= BOTH | XML | CATALOG. For example, the following statements restore the previous behavior:

```
options cmpmodel=catalog;
```

The CMPMODEL= option defaults to BOTH in SAS 9.2 and is intended for transitional use. If CMPMODEL=BOTH, the MODEL procedure writes both formats; when loading model files PROC MODEL attempts to load the XML version first and the CATALOG version second (if the XML version is not found). If CMPMODEL=XML, the MODEL procedure reads and writes only the XML format. If CMPMODEL=CATALOG, only the catalog format is used.

The MODEL= option is used to read in a model. A list of model files can be specified in the MODEL= option, and a range of names with numeric suffixes can be given, as in

MODEL=(MODEL1–MODEL10). When more than one model file is given, the list must be placed in parentheses, as in MODEL=(A B C), except in case of a single name. If more than one model file is specified, the files are combined in the order listed in the MODEL= option.

The MODEL procedure continues to read and write catalog MODEL files, and model files created by previous releases of SAS/ETS continue to work, so you should experience no direct impact from this change.

When the MODEL= option is specified in the PROC MODEL statement and model definition statements are also given later in the PROC MODEL step, the model files are read in first, in the order listed, and the model program specified in the PROC MODEL step is appended after the model program read from the MODEL= files. The class assigned to a variable, when multiple model files are used, is the last declaration of that variable. For example, if Y1 was declared endogenous in the model file M1 and exogenous in the model file M2, the following statement causes Y1 to be declared exogenous.

```
proc model model=(m1 m2);
```

The INCLUDE statement can be used to append model code to the current model code. In contrast, when the MODEL= option is used in the RESET statement, the current model is deleted before the new model is read.

By default, no model file is output if the PROC MODEL step performs any FIT or SOLVE tasks, or if the MODEL= option or the NOSTORE option is used. However, to ensure compatibility with previous versions of SAS/ETS software, when the PROC MODEL step does nothing but compile the model program, no input model file is read, and the NOSTORE option is not used, a model file is written. This model file is the default input file for a later PROC SYSLIN or PROC SIMLIN step. The default output model filename in this case is WORK.MODELS._MODEL_.MODEL.

If FIT statements are used to estimate model parameters, the parameter estimates written to the output model file are the estimates from the last estimation performed for each parameter.

Diagnostics and Debugging

PROC MODEL provides several features to aid in finding errors in the model program. These debugging features are not usually needed; most models can be developed without them.

The example model program that follows is used in the following sections to illustrate the diagnostic and debugging capabilities. This example is the estimation of a segmented model.

```

Program Listing

The LIST option produces a listing of the model program. The statements are printed one per line with the original line number and column position of the statement.

The program listing from the example program is shown in [Figure 18.85](#).

Figure 18.85 LIST Output for Segmented Model

```

                                QUADRATIC MODEL WITH PLATEAU

                                The MODEL Procedure

                                Listing of Compiled Program Code
      Stmt      Line:Col      Statement as Parsed
      1      3712:4      x0 = (-0.5 * b) / c;
      2      3713:4      if x < x0 then
      3      3714:7      PRED.y = a + b * x + c * x * x;
      3      3714:7      RESID.y = PRED.y - ACTUAL.y;
      3      3714:7      ERROR.y = PRED.y - y;
      4      3715:4      else
      5      3716:7      PRED.y = a + b * x0 + c * x0 * x0;
      5      3716:7      RESID.y = PRED.y - ACTUAL.y;
      5      3716:7      ERROR.y = PRED.y - y;

```

The LIST option also shows the model translations that PROC MODEL performs. LIST output is useful for understanding the code generated by the %AR and the %MA macros.

Cross-Reference

The XREF option produces a cross-reference listing of the variables in the model program. The XREF listing is usually used in conjunction with the LIST option. The XREF listing does not include derivative (@-prefixed) variables. The XREF listing does not include generated assignments to equation variables, PRED., RESID., and ERROR.-prefixed variables, unless the DETAILS option is used.

The cross-reference from the example program is shown in [Figure 18.86](#).

Figure 18.86 XREF Output for Segmented Model

```

Compiler Listing

The LISTCODE option lists the model code and derivatives tables produced by the compiler. This listing is useful only for debugging and should not normally be needed.

LISTCODE prints the operator and operands of each operation generated by the compiler for each model program statement. Many of the operands are temporary variables generated by the compiler and given names such as #temp1. When derivatives are taken, the code listing includes the operations generated for the derivatives calculations. The derivatives tables are also listed.

A LISTCODE option prints the transformed equations from the example shown in [Figure 18.87](#) and [Figure 18.88](#).

Analyzing the Structure of Large Models

PROC MODEL provides several features to aid in analyzing the structure of the model program. These features summarize properties of the model in various forms.

The following Klein's model program is used to introduce the LISTDEP, BLOCK, and GRAPH options.

```
proc model out=m data=klein listdep graph block;
  endogenous c p w i x wsum k y;
  exogenous wp g t year;
  parms c0-c3 i0-i3 w0-w3;
  a: c = c0 + c1 * p + c2 * lag(p) + c3 * wsum;
  b: i = i0 + i1 * p + i2 * lag(p) + i3 * lag(k);
  c: w = w0 + w1 * x + w2 * lag(x) + w3 * year;
  x = c + i + g;
  y = c + i + g-t;
  p = x-w-t;
  k = lag(k) + i;
  wsum = w + wp;
  id year;
run;
```

Dependency List

The LISTDEP option produces a dependency list for each variable in the model program. For each variable, a list of variables that depend on it and a list of variables it depends on is given. The dependency list produced by the example program is shown in [Figure 18.89](#).

BLOCK Listing

The BLOCK option prints an analysis of the program variables based on the assignments in the model program. The output produced by the example is shown in [Figure 18.90](#).

Figure 18.90 The BLOCK Output for Klein's Model

```

                                The MODEL Procedure
                                Model Structure Analysis
                                (Based on Assignments to Endogenous Model Variables)

                                Exogenous Variables      wp g t year
                                Endogenous Variables     c p w i x wsum k y

                                Block Structure of the System

                                Block 1      c p w i x wsum

                                Dependency Structure of the System

                                Block 1      Depends On All_Exogenous
                                k           Depends On Block 1 All_Exogenous
                                y           Depends On Block 1 All_Exogenous

```

One use for the block output is to put a model in recursive form. Simulations of the model can be done with the SEIDEL method, which is efficient if the model is recursive and if the equations are in recursive order. By examining the block output, you can determine how to reorder the model equations for the most efficient simulation.

Adjacency Graph

The GRAPH option displays the same information as the BLOCK option with the addition of an adjacency graph. An X in a column in an adjacency graph indicates that the variable associated with the row depends on the variable associated with the column. The output produced by the example is shown in [Figure 18.91](#).

The first and last graphs are straightforward. The middle graph represents the dependencies of the nonexogenous variables after transitive closure has been performed (that is, A depends on B, and B depends on C, so A depends on C). The preceding transitive closure matrix indicates that K and Y do not directly or indirectly depend on each other.

Examples: MODEL Procedure

Example 18.1: OLS Single Nonlinear Equation

This example illustrates the use of the MODEL procedure for nonlinear ordinary least squares (OLS) regression. The model is a logistic growth curve for the population of the United States. The data is the population in millions recorded at ten-year intervals starting in 1790 and ending in 2000. For an explanation of the starting values given by the START= option, see the section “[Troubleshooting Convergence Problems](#)” on page 1030. Portions of the output from the following statements are shown in [Output 18.1.1](#) through [Output 18.1.3](#).

```

title 'Logistic Growth Curve Model of U.S. Population';

Output 18.1.3 Logistic Growth Curve Estimates

Logistic Growth Curve Model of U.S. Population						
The MODEL Procedure						
Nonlinear OLS Summary of Residual Errors						
Equation	DF Model	DF Error	SSE	MSE	R-Square	Adj R-Sq
pop	3	18	345.6	19.2020	0.9972	0.9969
Nonlinear OLS Parameter Estimates						
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label	
a	387.9307	30.0404	12.91	<.0001	Maximum Population	
b	3.990385	0.0695	57.44	<.0001	Location Parameter	
c	0.022703	0.00107	21.22	<.0001	Initial Growth Rate	

The adjusted R^2 value indicates the model fits the data well. There are only 21 observations and the model is nonlinear, so significance tests on the parameters are only approximate. The significance tests and associated approximate probabilities indicate that all the parameters are significantly different from 0.

The FIT statement included the options OUT=RESID and OUTRESID so that the residuals from the estimation are saved to the data set RESID. The residuals are plotted to check for heteroscedasticity by using PROC SGLOT as follows.

```

title2 "Residuals Plot";
proc sgplot data=resid;
  refile 0;
  scatter x=year y=pop / markerattrs=(symbol=circlefilled);
  xaxis values=(1780 to 2000 by 20);

```

run;

The plot is shown in [Output 18.1.4](#).

Output 18.1.4 Residual for Population Model (Actual–Predicted)

The residuals do not appear to be independent, and the model could be modified to explain the remaining nonrandom errors.

Example 18.2: A Consumer Demand Model

This example shows the estimation of a system of nonlinear consumer demand equations based on the translog functional form by using seemingly unrelated regression (SUR). Expenditure shares and corresponding normalized prices are given for three goods.

Since the shares add up to one, the system is singular; therefore, one equation is omitted from the estimation process. The choice of which equation to omit is arbitrary. The nonlinear system is first

estimated in unrestricted form by the following statements:

```

title1 'Consumer Demand--Translog Functional Form';
title2 'Asymmetric Model';

proc model data=tlog1;
  endogenous share1 share2;
  parms a1 a2 b11 b12 b13 b21 b22 b23 b31 b32 b33;

  bm1 = b11 + b21 + b31;
  bm2 = b12 + b22 + b32;
  bm3 = b13 + b23 + b33;
  lp1 = log(p1);
  lp2 = log(p2);
  lp3 = log(p3);
  share1 = ( a1 + b11 * lp1 + b12 * lp2 + b13 * lp3 ) /
            ( -1 + bm1 * lp1 + bm2 * lp2 + bm3 * lp3 );
  share2 = ( a2 + b21 * lp1 + b22 * lp2 + b23 * lp3 ) /
            ( -1 + bm1 * lp1 + bm2 * lp2 + bm3 * lp3 );

  fit share1 share2
  start=( a1 -.14 a2 -.45 b11 .03 b12 .47 b22 .98 b31 .20
          b32 1.11 b33 .71 ) / outsused=smatrix sur;
run;

```

```

Hypothesis testing requires that the **S** matrix from the unrestricted model be imposed on the restricted model, as explained in the section “[Tests on Parameters](#)” on page 1078. The **S** matrix saved in the data set SMATRIX is requested by the SDATA= option.

A chi-square test is used to see if the hypothesis of symmetry is accepted or rejected. (*Oc*–*Ou*) has a chi-square distribution asymptotically, where *Oc* is the constrained OBJECTIVE*N and *Ou* is the unconstrained OBJECTIVE*N. The degrees of freedom is equal to the difference in the number of

free parameters in the two models.

In this example, O_u is 76.9697 and O_c is 78.4097, resulting in a difference of 1.44 with 3 degrees of freedom. You can obtain the probability value by using the following statements:

```
data _null_;
  /* probchi( reduced-full, n-restrictions )*/
  p = 1-probchi( 1.44, 3 );
  put p=;
run;
```

The output from this DATA step run is $p = 0.6961858724$. With this p -value you cannot reject the hypothesis of symmetry. This test is asymptotically valid.

Example 18.3: Vector AR(1) Estimation

This example shows the estimation of a two-variable vector AR(1) error process for the Grunfeld model (Grunfeld and Griliches 1960) by using the %AR macro. First, the full model is estimated. Second, the model is estimated with the restriction that the errors are univariate AR(1) instead of a vector process. The following statements produce [Output 18.3.1](#) through [Output 18.3.5](#).

```
data grunfeld;
  input year gei gef gec whi whf whc;
  label gei = 'Gross Investment GE'
        gec = 'Capital Stock Lagged GE'
        gef = 'Value of Outstanding Shares GE Lagged'
        whi = 'Gross Investment WH'
        whc = 'Capital Stock Lagged WH'
        whf = 'Value of Outstanding Shares Lagged WH';
datalines;
1935    33.1      1170.6    97.8      12.93     191.5     1.8
1936    45.0      2015.8   104.4     25.90     516.0     .8
... more lines ...

title1 'Example of Vector AR(1) Error Process Using Grunfeld''s Model';
/* Note: GE stands for General Electric
        WH stands for Westinghouse      */

proc model outmodel=grunmod;
  var gei whi gef gec whf whc;
  parms ge_int ge_f ge_c wh_int wh_f wh_c;
  label ge_int = 'GE Intercept'
        ge_f   = 'GE Lagged Share Value Coef'
        ge_c   = 'GE Lagged Capital Stock Coef'
        wh_int = 'WH Intercept'
        wh_f   = 'WH Lagged Share Value Coef'
        wh_c   = 'WH Lagged Capital Stock Coef';
```

```

    gei = ge_int + ge_f * gef + ge_c * gec;
    whi = wh_int + wh_f * whf + wh_c * whc;
run;

```

The preceding PROC MODEL step defines the structural model and stores it in the model file named GRUNMOD.

The following PROC MODEL step reads in the model, adds the vector autoregressive terms using %AR, and requests SUR estimation by using the FIT statement.

```

    title2 'With Unrestricted Vector AR(1) Error Process';

    proc model data=grunfeld model=grunmod;
        %ar( ar, 1, gei whi )
        fit gei whi / sur;
    run;

```

The final PROC MODEL step estimates the restricted model, as shown in the following statements:

```

    title2 'With restricted AR(1) Error Process';

    proc model data=grunfeld model=grunmod;
        %ar( gei, 1 )
        %ar( whi, 1 )
        fit gei whi / sur;
    run;

```

Number of Residuals				20				

The model stored in [Example 18.3](#) is read in by using the MODEL= option and the moving-average terms are added using the %MA macro.

The MA(1) model using maximum likelihood is estimated by using the following statements:

```
title2 'MA(1) Error Process Using Maximum Likelihood ';

proc model data=grunfeld model=grunmod;
  %ma(gei,1, m=ml);
  %ma(whi,1, m=ml);
  fit whi gei;
run;
```

For comparison, the model is estimated by using PROC ARIMA as follows:

```
title2 'PROC ARIMA Using Maximum Likelihood ';

proc arima data=grunfeld;
  identify var=whi cross=(whf whc) noprint;
  estimate q=1 input=(whf whc) method=ml;
run;
```

PROC ARIMA does not estimate systems, so only one equation is evaluated.

The estimation results are shown in [Output 18.4.3](#) and [Output 18.4.4](#). The small differences in the parameter values between PROC MODEL and PROC ARIMA can be eliminated by tightening the convergence criteria for both procedures.

Example 18.5: Polynomial Distributed Lags by Using %PDL

This example shows the use of the %PDL macro for polynomial distributed lag models. Simulated data is generated so that Y is a linear function of six lags of X , with the lag coefficients following a quadratic polynomial. The model is estimated by using a fourth-degree polynomial, both with and without endpoint constraints. The example uses simulated data generated from the following model:

$$y_t = 10 + \sum_{z=0}^6 f(z)x_{t-z} + \epsilon$$

$$f(z) = -5z^2 + 1.5z$$

The LIST option prints the model statements added by the %PDL macro. The following statements generate simulated data as shown:

```

/*-----*/
/* Generate Simulated Data for a Linear Model with a PDL on X */
/*      y = 10 + x(6,2) + e */
/*      pdl(x) = -5.*(lg)**2 + 1.5*(lg) + 0. */
/*-----*/
data pdl;
  pdl2=-5.; pdl1=1.5; pdl0=0;
  array zz(i) z0-z6;
  do i=1 to 7;

```

```

z=i-1;
zz=pd12*z**2 + pd11*z + pd10;
end;
do n=-11 to 30;
x =10*ranuni(1234567)-5;
pdl=z0*x + z1*x11 + z2*x12 + z3*x13 + z4*x14 + z5*x15 + z6*x16;
e =10*rannor(123);
y =10+pdl+e;
if n>=1 then output;
x16=x15; x15=x14; x14=x13; x13=x12; x12=x11; x11=x;
end;
run;

title1 'Polynomial Distributed Lag Example';
title3 'Estimation of PDL(6,4) Model-- No Endpoint Restrictions';

proc model data=pd1;
  parms int; /* declare the intercept parameter */
  %pdl( xpd1, 6, 4 ) /* declare the lag distribution */
  y = int + %pdl( xpd1, x ); /* define the model equation */
  fit y / list; /* estimate the parameters */
run;

```

The LIST output for the model without endpoint restrictions is shown in [Output 18.5.1](#). The first seven statements in the generated program are the polynomial expressions for lag parameters XPDL_L0 through XPDL_L6. The estimated parameters are INT, XPDL_0, XPDL_1, XPDL_2, XPDL_3, and XPDL_4.

The FIT results for the model without endpoint restrictions are shown in [Output 18.5.2](#).

Output 18.5.3 PROC MODEL Results Specifying Both Endpoint Restrictions

Polynomial Distributed Lag Example							
Estimation of PDL(6,4) Model-- Both Endpoint Restrictions							
The MODEL Procedure							
Nonlinear OLS Summary of Residual Errors							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj R-Sq
y	4	20	449868	22493.4	150.0	0.9596	0.9535
Nonlinear OLS Parameter Estimates							
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label		
int	17.08581	32.4032	0.53	0.6038			
XPDL_2	13.88433	5.4361	2.55	0.0189	PDL(XPDL, 6, 4) parameter for (L)**2		
XPDL_3	-9.3535	1.7602	-5.31	<.0001	PDL(XPDL, 6, 4) parameter for (L)**3		
XPDL_4	1.032421	0.1471	7.02	<.0001	PDL(XPDL, 6, 4) parameter for (L)**4		

Note that XPDL_0 and XPDL_1 are not shown in the estimate summary. They were used to satisfy the endpoint restrictions analytically by the generated %PDL macro code. Their values can be determined by back substitution.

To estimate the PDL model with one or more of the polynomial terms dropped, specify the largest degree of the polynomial desired with the %PDL macro and use the DROP= option in the FIT statement to remove the unwanted terms. The dropped parameters should be set to 0. The following PROC MODEL statements demonstrate estimation with a PDL of degree 2 without the 0th order term.

```

title3 'Estimation of PDL(6,2) Model-- With XPDL_0 Dropped';

proc model data=pd1 list;
  parms int; /* declare the intercept parameter */
  %pdl( xpdl, 6, 2 ) /* declare the lag distribution */
  y = int + %pdl( xpdl, x ); /* define the model equation */
  xpdl_0 =0;
  fit y drop=xpdl_0; /* estimate the parameters */
run;

```

The results from this estimation are shown in [Output 18.5.4](#).

Output 18.5.4 PROC MODEL Results That Specify %PDL(XPDL, 6, 2)

Example 18.6: General Form Equations

Data for this example are generated. General form equations are estimated and forecast by using PROC MODEL. The system is a basic supply and demand model.

The following statements specify the form of the model:

```

title1 "General Form Equations for Supply-Demand Model";

proc model outmodel=model;
  var price quantity income unitcost;
  parms d0-d2 s0-s2;
  eq.demand=d0+d1*price+d2*income-quantity;
  eq.supply=s0+s1*price+s2*unitcost-quantity;
run;

```

Three data sets are used in this example. The first data set, HISTORY, is used to estimate the parameters of the model. The ASSUME data set is used to produce a forecast of PRICE and QUANTITY. Notice that the ASSUME data set does not need to contain the variables PRICE and QUANTITY. The HISTORY data set is shown as follows:

```

data history;
  input year income unitcost price quantity;
datalines;

```

1976	2221.87	3.31220	0.17903	266.714
1977	2254.77	3.61647	0.06757	276.049
... more lines ...				

The ASSUME data set is shown as follows:

```
data assume;
  input year income unitcost;
datalines;
1986    2571.87    2.31220
1987    2609.12    2.45633
1988    2639.77    2.51647
1989    2667.77    1.65617
1990    2705.16    1.01601
;
```

The third data set, GOAL, used in a forecast of PRICE and UNITCOST as a function of INCOME and QUANTITY is as follows:

```
data goal;
  input year income quantity;
datalines;
1986    2571.87    371.4
1987    2721.08    416.5
1988    3327.05    597.3
1989    3885.85    764.1
1990    3650.98    694.3
;
```

The following statements fit the model to the HISTORY data set and solve the fitted model for the ASSUME data set.

```
proc model model=model outmodel=model;

/* estimate the model parameters */
  fit supply demand / data=history outest=est n2sls;
  instruments income unitcost year;
run;

/* produce forecasts for income and unitcost assumptions */
  solve price quantity / data=assume out=pq;
run;

title2 "Parameter Estimates for the System";
proc print data=est;
run;

title2 "Price Quantity Solution";
proc print data=pq;
run;
```

The model summary of the supply and demand model is shown as follows:

Output 18.6.1 Model Summary

Example 18.7: Spring and Damper Continuous System

This model simulates the mechanical behavior of a spring and damper system shown in [Figure 18.92](#).

Figure 18.92 Spring and Damper System Model

A mass is hung from a spring with spring constant K . The motion is slowed by a damper with damper constant C . The damping force is proportional to the velocity, while the spring force is

proportional to the displacement.

This is actually a continuous system; however, the behavior can be approximated by a discrete time model. We approximate the differential equation

$$\frac{\partial \text{disp}}{\partial \text{time}} = \text{velocity}$$

with the difference equation

$$\frac{\Delta \text{disp}}{\Delta \text{time}} = \text{velocity}$$

This is rewritten as

$$\frac{\text{disp} - \text{LAG}(\text{disp})}{dt} = \text{velocity}$$

where dt is the time step used. In PROC MODEL, this is expressed with the program statement

```
disp = lag(disp) + vel * dt;
```

or

```
dert.disp = vel;
```

The first statement is simply a computing formula for Euler's approximation for the integral

$$\text{disp} = \int \text{velocity} dt$$

If the time step is small enough with respect to the changes in the system, the approximation is good. Although PROC MODEL does not have the variable step-size and error-monitoring features of simulators designed for continuous systems, the procedure is a good tool to use for less challenging continuous models.

The second form instructs the MODEL procedure to do the integration for you.

This model is unusual because there are no exogenous variables, and endogenous data are not needed. Although you still need a SAS data set to count the simulation periods, no actual data are brought in.

Since the variables DISP and VEL are lagged, initial values specified in the VAR statement determine the starting state of the system. The mass, time step, spring constant, and damper constant are declared and initialized by a CONTROL statement as shown in the following statements:

```
title1 'Simulation of Spring-Mass-Damper System';

/*- Data to drive the simulation time periods ----*/
data one;
  do n=1 to 100;
```

```

        output;
    end;
run;

proc model data=one outmodel=spring;
    var      force -200  disp  10  vel  0  accel -20  time 0;
    control  mass   9.2  c    1.5  dt   .1  k     20;
    force = -k * disp -c * vel;
    disp  = lag(disp) + vel * dt;
    vel   = lag(vel) + accel * dt;
    accel = force / mass;
    time  = lag(time) + dt;
run;

```

The displacement scale is zeroed at the point where the force of gravity is offset, so the acceleration of the gravity constant is omitted from the force equation. The control variable C and K represent the damper and the spring constants respectively.

The model is simulated three times, and the simulation results are written to output data sets. The first run uses the original initial conditions specified in the VAR statement. In the second run, the initial displacement is doubled; the results show that the period of the motion is unaffected by the amplitude. In the third run, the DERT. syntax is used to do the integration. Notice that the path of the displacement is close to the old path, indicating that the original time step is short enough to yield an accurate solution. These simulations are performed by the following statements:

```

proc model data=one model=spring;
    title2 "Simulation of the model for the base case";
    control run '1';
    solve / out=a;
run;

    title2 "Simulation of the model with twice the initial displacement";
    control run '2';
    var disp 20;
    solve / out=b;
run;

data two;
    do time = 0 to 10 by .2; output;end;
run;

title2 "Simulation of the model using the dert. syntax";
proc model data=two;
    var      force -200  disp  10  vel  0  accel -20  time 0;
    control  mass   9.2  c    1.5  dt   .1  k     20;
    control  run '3' ;
    force = -k * disp -c * vel;
    dert.disp = vel ;
    dert.vel   = accel;
    accel = force / mass;
    solve / out=c;
    id time ;
run;

```

The output SAS data sets that contain the solution results are merged and the displacement time paths for the three simulations are plotted. The three runs are identified on the plot as 1, 2, and 3. The following statements produce [Output 18.7.1](#) through [Output 18.7.5](#).

```
data p;
  set a b c;
run;

title2 'Overlay Plot of All Three Simulations';
proc sgplot data=p;
  series x=time y=disp / group=run lineattrs=(pattern=1);
  xaxis values=(0 to 10 by 1);
  yaxis values=(-20 to 20 by 10);
run;

Output 18.7.5 Overlay Plot of Three Simulations**Example 18.8: Nonlinear FIML Estimation**

The data and model for this example were obtained from Bard (1974, p.133–138). The example is a two-equation econometric model used by Bodkin and Klein to fit U.S production data for the years 1909–1949. The model is the following:

$$g_1 = c_1 10^{c_2 z_4} (c_5 z_1^{-c_4} + (1 - c_5) z_2^{-c_4})^{-c_3/c_4} - z_3 = 0$$

$$g_2 = [c_5 / (1 - c_5)] (z_1 / z_2)^{(-1 - c_4)} - z_5 = 0$$

where z_1 is capital input, z_2 is labor input, z_3 is real output, z_4 is time in years with 1929 as year zero, and z_5 is the ratio of price of capital services to wage scale. The c_i 's are the unknown parameters. z_1 and z_2 are considered endogenous variables. A FIML estimation is performed by using the following statements:

```
data bodkin;
```

```

      input z1 z2 z3 z4 z5;
datalines;
1.33135 0.64629 0.4026 -20 0.24447
1.39235 0.66302 0.4084 -19 0.23454

... more lines ...

title1 "Nonlinear FIML Estimation";

proc model data=bodkin;
  parms c1-c5;
  endogenous z1 z2;
  exogenous z3 z4 z5;

  eq.g1 = c1 * 10 ** (c2 * z4) * (c5*z1**(-c4)+
      (1-c5)*z2**(-c4))**(-c3/c4) - z3;
  eq.g2 = (c5/(1-c5))*(z1/z2)**(-1-c4) -z5;

  fit g1 g2 / fiml ;
run;

```

When FIML estimation is selected, the log likelihood of the system is output as the objective value. The results of the estimation are shown in [Output 18.8.1](#).

Example 18.9: Circuit Estimation

Consider the nonlinear circuit shown in [Figure 18.93](#).

Figure 18.93 Nonlinear Resistor Capacitor Circuit

The theory of electric circuits is governed by Kirchhoff's laws: the sum of the currents flowing to a node is zero, and the net voltage drop around a closed loop is zero. In addition to Kirchhoff's laws, there are relationships between the current I through each element and the voltage drop V across the elements. For the circuit in [Figure 18.93](#), the relationships are

$$C \frac{dV}{dt} = I$$

for the capacitor and

$$V = (R_1 + R_2(1 - \exp(-V)))I$$

for the nonlinear resistor. The following differential equation describes the current at node 2 as a function of time and voltage for this circuit:

$$C \frac{dV_2}{dt} - \frac{V_1 - V_2}{R_1 + R_2(1 - \exp(-V))} = 0$$

This equation can be written in the form

$$\frac{dV_2}{dt} = \frac{V_1 - V_2}{(R_1 + R_2(1 - \exp(-V)))C}$$

Consider the following data.

```
data circ;
  input v2 v1 time@@;
datalines;
```

```

```

You can estimate the parameters in the preceding equation by using the following SAS statements:

```

title1 'Circuit Model Estimation Example';

proc model data=circ mintimestep=1.0e-23;
  parm R2 2000 R1 4000 C 5.0e-13;
  dert.v2 = (v1-v2)/((r1 + r2*(1-exp( -(v1-v2)))) * C);
  fit v2;
run;

```

The results of the estimation are shown in [Output 18.9.1](#).

Output 18.9.1 Circuit Estimation

Circuit Model Estimation Example				
The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
R2	3002.465	1517.1	<-----	Biased
R1	4984.848	1466.8	<-----	Biased
C	5E-13	0	<-----	Biased

NOTE: The model was singular. Some estimates are marked 'Biased'.

In this case, the model equation is such that there is linear dependency that causes biased results and inflated variances. The Jacobian matrix is singular or nearly singular, but eliminating one of the parameters is not a solution in this case.

Example 18.10: Systems of Differential Equations

The following is a simplified reaction scheme for the competitive inhibitors with recombinant human renin (Morelock et al. 1995).

Figure 18.94 Competitive Inhibition of Recombinant Human Renin

In Figure 18.94, E =enzyme, D =probe, and I =inhibitor.

The differential equations that describe this reaction scheme are as follows:

$$\frac{dD}{dt} = k_{1r} * ED - k_{1f} * E * D$$

$$\frac{dED}{dt} = k_{1f} * E * D - k_{1r} * ED$$

$$\frac{dE}{dt} = k_{1r} * ED - k_{1f} * E * D + k_{2r} * EI - k_{2f} * E * I$$

$$\frac{dEI}{dt} = k_{2f} * E * I - k_{2r} * EI$$

$$\frac{dI}{dt} = k_{2r} * EI - k_{2f} * E * I$$

For this system, the initial values for the concentrations are derived from equilibrium considerations (as a function of parameters) or are provided as known values.

The experiment used to collect the data was carried out in two ways; preincubation (type='disassoc') and no preincubation (type='assoc'). The data also contain repeated measurements. The data contain values for fluorescence F, which is a function of concentration. Since there are no direct data for the concentrations, all the differential equations are simulated dynamically.

The SAS statements used to fit this model are as follows:

```

Example 18.11: Monte Carlo Simulation

This example illustrates how the form of the error in a ODE model affects the results from a static and dynamic estimation. The differential equation studied is

$$\frac{dy}{dt} = a - ay$$

The analytical solution to this differential equation is

$$y = 1 - \exp(-at)$$

The first data set contains errors that are strictly additive and independent. The data for this estimation are generated by the following DATA step:

```
data drive1;
  a = 0.5;
  do iter=1 to 100;
    do time = 0 to 50;
      y = 1 - exp(-a*time) + 0.1 *rannor(123);
      output;
    end;
  end;
run;
```

The second data set contains errors that are cumulative in form.

```
data drive2;
  a = 0.5;
  yp = 1.0 + 0.01 *rannor(123);
  do iter=1 to 100;
    do time = 0 to 50;
      y = 1 - exp(-a)*(1 - yp);
      yp = y + 0.01 *rannor(123);
      output;
    end;
  end;
```

```
end;
run;
```

The following statements perform the 100 static estimations for each data set:

```
title1 'Monte Carlo Simulation of ODE';

proc model data=drive1 noprint;
  parm a 0.5;
  dert.y = a - a * y;
  fit y / outest=est;
  by iter;
run;
```

Similar statements are used to produce 100 dynamic estimations with a fixed and an unknown initial value. The first value in the data set is used to simulate an error in the initial value. The following PROC UNIVARIATE statements process the estimations:

```
proc univariate data=est noprint;
  var a;
  output out=monte mean=mean p5=p5 p95=p95;
run;

proc print data=monte;
run;
```

The results of these estimations are summarized in [Table 18.6](#).

Table 18.6 Monte Carlo Summary, A=0.5

Estimation Type	Additive Error			Cumulative Error		
	mean	p95	p5	mean	p95	p5
static	0.77885	1.03524	0.54733	0.57863	1.16112	0.31334
dynamic fixed	0.48785	0.63273	0.37644	3.8546E24	8.88E10	-51.9249
dynamic unknown	0.48518	0.62452	0.36754	641704.51	1940.42	-25.6054

For this example model, it is evident that the static estimation is the least sensitive to misspecification.

Example 18.12: Cauchy Distribution Estimation

In this example a nonlinear model is estimated by using the Cauchy distribution. Then a simulation is done for one observation in the data.

The following DATA step creates the data for the model.

```
/* Generate a Cauchy distributed Y */
data c;
```

```

format date monyy.;
call streaminit(156789);
do t=0 to 20 by 0.1;
    date=intnx('month', '01jun90'd, (t*10)-1);
    x=rand('normal');
    e=rand('cauchy') + 10;
    y=exp(4*x)+e;
    output;
end;
run;

```

The model to be estimated is

$$y = e^{-ax} + \epsilon$$

$$\epsilon \sim \text{Cauchy}(nc)$$

That is, the residuals of the model are distributed as a Cauchy distribution with noncentrality parameter nc .

The log likelihood for the Cauchy distribution is

$$like = -\log(1 + (x - nc)^2 * \pi)$$

The following SAS statements specify the model and the log-likelihood function.

```

title1 'Cauchy Distribution';

proc model data=c;
    dependent y;
    parm a -2 nc 4;
    y=exp(-a*x);

    /* Likelihood function for the residuals */
    obj = log(1+(-resid.y-nc)**2 * 3.1415926);

    errormodel y ~ general(obj) cdf=cauchy(nc);

    fit y / outsn=s1 method=marquardt;
    solve y / sdata=s1 data=c(obs=1) random=1000
            seed=256789 out=out1;
run;

title 'Distribution of Y';
proc sgplot data=out1;
    histogram y;
run;

```

The FIT statement uses the OUTSN= option to output the Σ matrix for residuals from the normal distribution. The Σ matrix is 1×1 and has value 1.0 because it is a correlation matrix. The OUTS= matrix is the scalar 2989.0. Because the distribution is univariate (no covariances), the OUTS= option would produce the same simulation results. The simulation is performed by using the SOLVE statement.

The distribution of y is shown in the following output.

Output 18.12.1 Distribution of Y

Example 18.13: Switching Regression Example

Take the usual linear regression problem

$$y = \mathbf{X}\beta + u$$

where Y denotes the n column vector of the dependent variable, \mathbf{X} denotes the $(n \times k)$ matrix of independent variables, β denotes the k column vector of coefficients to be estimated, n denotes the number of observations ($i=1, 2, \dots, n$), and k denotes the number of independent variables.

You can take this basic equation and split it into two regimes, where the i th observation on y is

generated by one regime or the other:

$$y_i = \sum_{j=1}^k \beta_{1j} X_{ji} + u_{1i} = x_i' \beta_1 + u_{1i}$$

$$y_i = \sum_{j=1}^k \beta_{2j} X_{ji} + u_{2i} = x_i' \beta_2 + u_{2i}$$

where x_{hi} and x_{hj} are the i th and j th observations, respectively, on x_h . The errors, u_{1i} and u_{2i} , are assumed to be distributed normally and independently with mean zero and constant variance. The variance for the first regime is σ_1^2 , and the variance for the second regime is σ_2^2 . If $\sigma_1^2 \neq \sigma_2^2$ and $\beta_1 \neq \beta_2$, the regression system given previously is thought to be switching between the two regimes.

The problem is to estimate β_1 , β_2 , σ_1 , and σ_2 without knowing *a priori* which of the n values of the dependent variable, y , was generated by which regime. If it is known *a priori* which observations belong to which regime, a simple Chow test can be used to test $\sigma_1^2 = \sigma_2^2$ and $\beta_1 = \beta_2$.

Using Goldfeld and Quandt's D-method for switching regression, you can solve this problem. Assume that observations exist on some exogenous variables $z_{1i}, z_{2i}, \dots, z_{pi}$, where z determines whether the i th observation is generated from one equation or the other. The equations are given as follows:

$$y_i = x_i' \beta_1 + u_{1i} \quad \text{if } \sum_{j=1}^p \pi_j z_{ji} \leq 0$$

$$y_i = x_i' \beta_2 + u_{2i} \quad \text{if } \sum_{j=1}^p \pi_j z_{ji} > 0$$

where π_j are unknown coefficients to be estimated. Define $d(z_i)$ as a continuous approximation to a step function. Replacing the unit step function with a continuous approximation by using the cumulative normal integral enables a more practical method that produces consistent estimates.

$$d(z_i) = \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{\sum \pi_j z_{ji}} \exp\left[-\frac{1}{2} \frac{\xi^2}{\sigma^2}\right] d\xi$$

\mathbf{D} is the n dimensional diagonal matrix consisting of $d(z_i)$:

$$\mathbf{D} = \begin{bmatrix} d(z_1) & 0 & 0 & 0 \\ 0 & d(z_2) & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & d(z_n) \end{bmatrix}$$

The parameters to estimate are now the k β_1 's, the k β_2 's, σ_1^2 , σ_2^2 , p π 's, and the σ introduced in the $d(z_i)$ equation. The σ can be considered as given *a priori*, or it can be estimated, in which case, the estimated magnitude provides an estimate of the success in discriminating between the two regimes (Goldfeld and Quandt 1976). Given the preceding equations, the model can be written as:

$$Y = (\mathbf{I} - \mathbf{D}) \mathbf{X} \beta_1 + \mathbf{D} \mathbf{X} \beta_2 + W$$

where $W = (\mathbf{I} - \mathbf{D})U_1 + \mathbf{D}U_2$, and W is a vector of unobservable and heteroscedastic error terms. The covariance matrix of W is denoted by $\mathbf{\Omega}$, where $\mathbf{\Omega} = (\mathbf{I} - \mathbf{D})^2\sigma_1^2 + \mathbf{D}^2\sigma_2^2$. The maximum likelihood parameter estimates maximize the following log-likelihood function.

$$\log L = -\frac{n}{2} \log 2\pi - \frac{1}{2} \log |\mathbf{\Omega}| - \frac{1}{2} * [[Y - (\mathbf{I} - \mathbf{D})\mathbf{X}\beta_1 - \mathbf{D}\mathbf{X}\beta_2]' \mathbf{\Omega}^{-1} [Y - (\mathbf{I} - \mathbf{D})\mathbf{X}\beta_1 - \mathbf{D}\mathbf{X}\beta_2]]$$

As an example, you now can use this switching regression likelihood to develop a model of housing starts as a function of changes in mortgage interest rates. The data for this example are from the U.S. Census Bureau and cover the period from January 1973 to March 1999. The hypothesis is that there are different coefficients on your model based on whether the interest rates are going up or down.

So the model for z_i is

$$z_i = p * (\text{rate}_i - \text{rate}_{i-1})$$

where rate_i is the mortgage interest rate at time i and p is a scale parameter to be estimated.

The regression model is

$$\begin{aligned} \text{starts}_i &= \text{intercept}_1 + \text{ar1} * \text{starts}_{i-1} + \text{djf1} * \text{decjanfeb} & z_i < 0 \\ \text{starts}_i &= \text{intercept}_2 + \text{ar2} * \text{starts}_{i-1} + \text{djf2} * \text{decjanfeb} & z_i \geq 0 \end{aligned}$$

where starts_i is the number of housing starts at month i and decjanfeb is a dummy variable that indicates that the current month is one of December, January, or February.

This model is written by using the following SAS statements:

```

title1 'Switching Regression Example';

proc model data=switch;
  parms sig1=10 sig2=10 int1 b11 b13 int2 b21 b23 p;
  bounds 0.0001 < sig1 sig2;

  decjanfeb = ( month(date) = 12 | month(date) <= 2 );

  a = p*dif(rate);          /* Upper bound of integral */
  d = probnorm(a);         /* Normal CDF as an approx of switch */

                                /* Regime 1 */
  y1 = int1 + zlag(starts)*b11 + decjanfeb *b13 ;
                                /* Regime 2 */
  y2 = int2 + zlag(starts)*b21 + decjanfeb *b23 ;
                                /* Composite regression equation */
  starts = (1 - d)*y1 + d*y2;

                                /* Resulting log-likelihood function */
  logL = (1/2)* ( log(2*3.1415) ) +

```

```

      log( (sig1**2)*((1-d)**2)+(sig2**2)*(d**2) )
+ (resid.starts*( 1/( (sig1**2)*((1-d)**2)+
  (sig2**2)*(d**2) ) )*resid.starts) ) ;

errormodel starts ~ general(logL);

fit starts / method=marquardt converge=1.0e-5;

/* Test for significant differences in the parms */
test int1 = int2 ,/ lm;
test b11 = b21 ,/ lm;
test b13 = b23 ,/ lm;
test sig1 = sig2 ,/ lm;

run;

```

Four TEST statements are added to test the hypothesis that the parameters are the same in both regimes. The parameter estimates and ANOVA table from this run are shown in [Output 18.13.1](#).

Example 18.14: Simulating from a Mixture of Distributions

This example illustrates how to perform a multivariate simulation by using models that have different error distributions. Three models are used. The first model has t distributed errors. The second model is a GARCH(1,1) model with normally distributed errors. The third model has a noncentral Cauchy distribution.

The following SAS statements generate the data for this example. The t and the CAUCHY data sets use a common seed so that those two series are correlated.

```

/* set distribution parameters */
%let df = 7.5;
%let sig1 = .5;
%let var2 = 2.5;

data t;
  format date monyy.;
  do date='1jun2001'd to '1nov2002'd;
    /* t-distribution with df,sig1 */
    t = .05 * date + 5000 + &sig1*tinv(ranuni(1234),&df);
    output;
  end;
run;

data normal;
  format date monyy.;
  le = &var2;
  lv = &var2;
  do date='1jun2001'd to '1nov2002'd;
    /* Normal with GARCH error structure */
    v = 0.0001 + 0.2 * le**2 + .75 * lv;
    e = sqrt(v) * rannor(12345);
    normal = 25 + e;
    le = e;
    lv = v;
    output;
  end;
run;

```

```

data cauchy;
  format date monyy.;
  PI = 3.1415926;
  do date='1jun2001'd to '1nov2002'd;
    cauchy = -4 + tan((ranuni(1234) - 0.5) * PI);
    output;
  end;
run;

```

Since the multivariate joint likelihood is unknown, the models must be estimated separately. The residuals for each model are saved by using the OUT= option. Also, each model is saved by using the OUTMODEL= option. The ID statement is used to provide a variable in the residual data set to merge by. The XLAG function is used to model the GARCH(1,1) process. The XLAG function returns the lag of the first argument if it is nonmissing, otherwise it returns the second argument.

```

title 't-distributed Errors Example';

proc model data=t outmod=tModel;
  parms df 10 vt 4;
  t = a * date + c;
  errormodel t ~ t( vt, df );
  fit t / out=tresid;
  id date;
run;

title 'GARCH-distributed Errors Example';

proc model data=normal outmodel=normalModel;
  normal = b0 ;
  h.normal = arch0 + arch1 * xlag(resid.normal **2 , mse.normal)
    + GARCH1 * xlag(h.normal, mse.normal);

  fit normal /fiml out=nresid;
  id date;
run;

title 'Cauchy-distributed Errors Example';

proc model data=cauchy outmod=cauchyModel;
  parms nc = 1;
  /* nc is noncentrality parm to Cauchy dist */
  cauchy = nc;
  obj = log(1+resid.cauchy**2 * 3.1415926);
  errormodel cauchy ~ general(obj) cdf=cauchy(nc);

  fit cauchy / out=cresid;
  id date;
run;

```

The simulation requires a covariance matrix created from normal residuals. The following DATA step statements use the inverse CDFs of the t and Cauchy distributions to convert the residuals to the normal distribution. The CORR procedure is used to create a correlation matrix that uses the

converted residuals.

```

/* Merge and normalize the 3 residual data sets */
data c; merge tresid nresid cresid; by date;
    t = probit(cdf("T", t/sqrt(0.2789), 16.58 ));
    cauchy = probit(cdf("CAUCHY", cauchy, -4.0623));
run;

proc corr data=c out=s;
    var t normal cauchy;
run;

```

Now the models can be simulated together by using the MODEL procedure SOLVE statement. The data set created by the CORR procedure is used as the correlation matrix.

```

title1 'Simulating Equations with Different Error Distributions';

/* Create one observation driver data set */
data sim; merge t normal cauchy; by date;
data sim; set sim(firstobs = 519 );

proc model data=sim model=( tModel normalModel cauchyModel );
    errormodel t ~ t( vt, df );
    errormodel cauchy ~ cauchy(nc);
    solve t cauchy normal / random=2000 seed=1962 out=monte
        sdata=s(where=( _type_="CORR" ));
run;

```

An estimation of the joint density of the t and Cauchy distribution is created by using the KDE procedure. Bounds are placed on the Cauchy dimension because of its fat tail behavior. The joint PDF is shown in [Output 18.14.1](#).

```

Example 18.16: Simulated Method of Moments—AR(1) Process

This example illustrates how to use SMM to estimate an AR(1) regression model for the following process:

$$\begin{aligned}y_t &= a + bx_t + u_t \\u_t &= \alpha u_{t-1} + \epsilon_t \\ \epsilon_t &\sim iid N(0, s^2)\end{aligned}$$

In the following SAS statements, *ysim* is simulated by using this model, and the endogenous variable *y* is set to be equal to *ysim*. The MOMENT statement creates two more moments for the estimation. One is the second moment and the other is the first-order autocovariance. The NPRESOBS=20 option instructs PROC MODEL to run the simulation 20 times before *ysim* is compared to the first observation of *y*. Because the initial *zlag(u)* is zero, the first *ysim* is $a + b * x + s * rannor(8003)$. Without the NPRESOBS option, this *ysim* is matched with the first observation of *y*. With NPRESOBS, this *ysim*, along with the next 19 *ysim*, is thrown away, and the moment match starts with the twenty-first *ysim* with the first observation of *y*. This way, the initial values do not exert a large inference on the simulated endogenous variables.

```

Example 18.17: Simulated Method of Moments—Stochastic Volatility Model

This example illustrates how to use SMM to estimate a stochastic volatility model as in Andersen and Sorensen (1996):

$$\begin{aligned}
 y_t &= \sigma_t z_t \\
 \log(\sigma_t^2) &= a + b \log(\sigma_{t-1}^2) + s u_t \\
 (z_t, u_t) &\sim iid N(0, I_2)
 \end{aligned}$$

This model is widely used in modeling the return process of stock prices and foreign exchange rates. This is called the stochastic volatility model because the volatility is stochastic as the random variable u_t appears in the volatility equation. The following SAS statements use three moments: absolute value, the second-order moment, and absolute value of the first-order autoregressive moment.

Note the ADJSMMV option in the FIT statement to request the SMM covariance adjustment for the parameter estimates. Although these moments have closed form solution as shown by Andersen and Sorensen (1996), the simulation approach significantly simplifies the moment conditions.

```
%let nobs=1000;

Example 18.18: Duration Data Model with Unobserved Heterogeneity

All of the previous three models actually have closed-form moment conditions, so the simulation approach is not necessarily required for the estimation. This example illustrates how to use SMM to estimate a model for which there is no closed-form solution for the moments and thus the traditional GMM method does not apply. The model is the duration data model with unobserved heterogeneity in *Gourieroux and Monfort (1993)*:

$$y_i = -\exp(-bx_i - \sigma u_i) \log(v_i)$$

$$u_i \sim N(0, 1) \quad v_i \sim U_{[0,1]}$$

The SAS statements are:

```

Example 18.19: EMM Estimation of a Stochastic Volatility Model

The efficient method of moments (EMM), introduced by Bansal et al. (1993 and 1995) and Gallant and Tauchen (2001), can be considered a variant of SMM. The idea is to match the efficiency of the maximum likelihood (ML) estimation with the flexibility of the SMM procedure. ML itself can be interpreted as a method of moments procedure, where the *score vector*, the vector of derivatives of the log-likelihood function with respect to the parameters, provides the exactly identifying moment conditions. EMM employs an auxiliary (or pseudo) model that closely matches the true model. The score vector of the auxiliary model provides the moment conditions in the SMM step.

This example uses the SMM feature of PROC MODEL to estimate the simple stochastic volatility (SV) model of Example 18.17 with the EMM method.

Suppose that your data are the time series $\{y_1, y_2, \dots, y_n\}$, and the model that you want to estimate, or the structural model, is characterized by the vector of parameters θ . For the SV model, θ is given by (a, b, s) .

The first step of the EMM method is to fit the data with an auxiliary model (or score generator) that has transition density $f(y_t|Y_{t-1}, \eta)$, parametrized by the pseudo parameter η , where $Y_{t-1} = \{y_{t-1}, \dots, y_1\}$. The auxiliary model must approximate the true data-generating process as closely as possible and be such that ML estimation is feasible.

The only identification requirement is that the dimension of the pseudo parameter η be greater than or equal to that of the structural parameter θ .

Andersen, Chung, and Sorensen (1999) showed that the GARCH(1,1) is an appropriate auxiliary model that leads to a good performance of the EMM estimator for the SV model.

The analytical expression for the GARCH(1,1) model with mean zero is

$$\begin{aligned} y_t &= \sigma_t z_t \\ \sigma_t^2 &= \omega + \alpha y_{t-1} + \beta \sigma_{t-1}^2 \end{aligned}$$

The pseudo parameter vector η is given by (ω, α, β) .

One advantage of such a class of models is that the conditional density of y_t is Gaussian—that is,

$$f(y_t|Y_{t-1}, \eta) \propto \frac{1}{\sigma_t} \exp\left(-\frac{y_t^2}{2\sigma_t^2}\right)$$

Therefore the score vector can easily be computed analytically.

The AUTOREG procedure provides the ML estimates, $\hat{\eta}_n$. The output is stored in the garchout data set, while the estimates are stored in the garchest data set.

```

title1 'Efficient Method of Moments for Stochastic Volatility Model';

/* estimate GARCH(1,1) model */
proc autoreg data=svdata(keep=y)

```

```

        outest=garchest
        noprint covout;
    model y = / noint garch=(q=1,p=1);
        output out=garchout cev=gsigmasq r=resid;
run;

```

If the pseudo model is close enough to the structural model, in a suitable sense, Gallant and Long (1997) showed that a consistent estimator of the asymptotic covariance matrix of the sample pseudo-score vector can be obtained from the formula

$$\hat{V}_n = \frac{1}{n} \sum_{t=1}^n s_f(Y_t, \hat{\eta}_n) s_f(Y_t, \hat{\eta}_n)'$$

where $s_f(Y_t, \hat{\eta}_n) = (\partial/\partial\eta_n) \log f(y_t|Y_{t-1}, \hat{\eta}_n)$ denotes the score function of the auxiliary model computed at the ML estimates.

The ML estimates of the GARCH(1,1) model are used in the following SAS statements to compute the variance-covariance matrix \hat{V}_n .

```

/* compute the V matrix */
data vvalues;
    set garchout(keep=y gsigmasq resid);

    /* compute scores of GARCH model */
    score_1 = (-1 + y**2/gsigmasq)/ gsigmasq;
    score_2 = (-1 + y**2/gsigmasq)*lag(gsigmasq) / gsigmasq;
    score_3 = (-1 + y**2/gsigmasq)*lag(y**2) / gsigmasq;

    array score{*} score_1-score_3;
    array v_t{*} v_t_1-v_t_6;
    array v{*} v_1-v_6;

    /* compute external product of score vector */
    do i=1 to 3;
        do j=i to 3;
            v_t{j*(j-1)/2 + i} = score{i}*score{j};
        end;
    end;

    /* average them over t */
    do s=1 to 6;
        v{s}+ v_t{s}/&nobs;
    end;
run;

```

The \hat{V} matrix must be formatted to be used with the VDATA= option of the MODEL procedure. See the section “[VDATA= Input data set](#)” on page 1108 for more information about the VDATA= data set.

```

/* Create a VDATA dataset acceptable to PROC MODEL */

/* Transpose the last obs in the dataset */
proc transpose data=vvalues(firstobs=&nobs keep=v_1-v_6)

```

```

                                out=tempv;
run;

/* Add eq and inst labels */
data vhat;
  set tempv(drop=_name_);
  value = coll;
  drop coll;
  input _type_ $ eq_row $ eq_col $ inst_row $ inst_col $; *$;
  datalines;
    gmm m1 m1 1 1 /* intcpt is the only inst we use */
    gmm m1 m2 1 1
    gmm m2 m2 1 1
    gmm m1 m3 1 1
    gmm m2 m3 1 1
    gmm m3 m3 1 1
  ;

```

The last step of the EMM procedure is to estimate θ by using SMM, where the moment conditions are given by the scores of the auxiliary model.

Given a fixed value of the parameter vector θ and an arbitrarily large T , one can simulate a series $\{\hat{y}_1(\theta), \hat{y}_2(\theta), \dots, \hat{y}_T(\theta)\}$ from the structural model. The EMM estimator is the value $\hat{\theta}_n$ that minimizes the quantity

$$m_T(\theta, \hat{\eta}_n)' \hat{V}_n^{-1} m_T(\theta, \hat{\eta}_n)$$

where

$$m_T(\theta, \hat{\eta}_n) = \frac{1}{T} \sum_{k=1}^T s_f(\hat{Y}_k(\theta), \hat{\eta}_n)$$

is the sample moment condition evaluated at the fixed estimated pseudo parameter $\hat{\eta}_n$. Note that the target function depends on the parameter θ only through the simulated series \hat{y}_k .

The following statements generate a data set that contains $T = 20,000$ replicates of the estimated pseudo parameter $\hat{\eta}_n$ and that is then input to the MODEL procedure. The EMM estimates are found by using the SMM option of the FIT statement. The \hat{V}_n matrix computed above serves as weighting matrix by using the VDATA= option, and the scores of the GARCH(1,1) auxiliary model evaluated at the ML estimates are the moment conditions in the GMM step.

Since the number of structural parameters to estimate (3) is equal to the number of moment equations (3) times the number of instruments (1), the model is exactly identified and the objective function has value zero at the minimum.

For simplicity, the starting values are set to the true values of the parameters.

```

/* USE SMM TO FIND EMM ESTIMATES */

/* Generate dataset of length T */
data emm;
  set garchest(obs=1 keep = _ah_0 _ah_1 _gh_1 _mse_);

Example 18.20: Illustration of ODS Graphics

This example illustrates graphical output from PROC MODEL. This is a continuation of the section “[Nonlinear Regression Analysis](#)” on page 949. These graphical displays are requested by specifying the ODS GRAPHICS ON statement. For information about the graphics available in the MODEL procedure, see the section “[ODS Graphics](#)” on page 1115.

The following statements show how to generate ODS graphics plots with the MODEL procedure. The plots are displayed in [Output 18.20.1](#) and [Output 18.20.2](#). Note that the variable date in the ID statement is used to define the horizontal tick mark values when appropriate.

```

title1 'Example of Graphical Output from PROC MODEL';

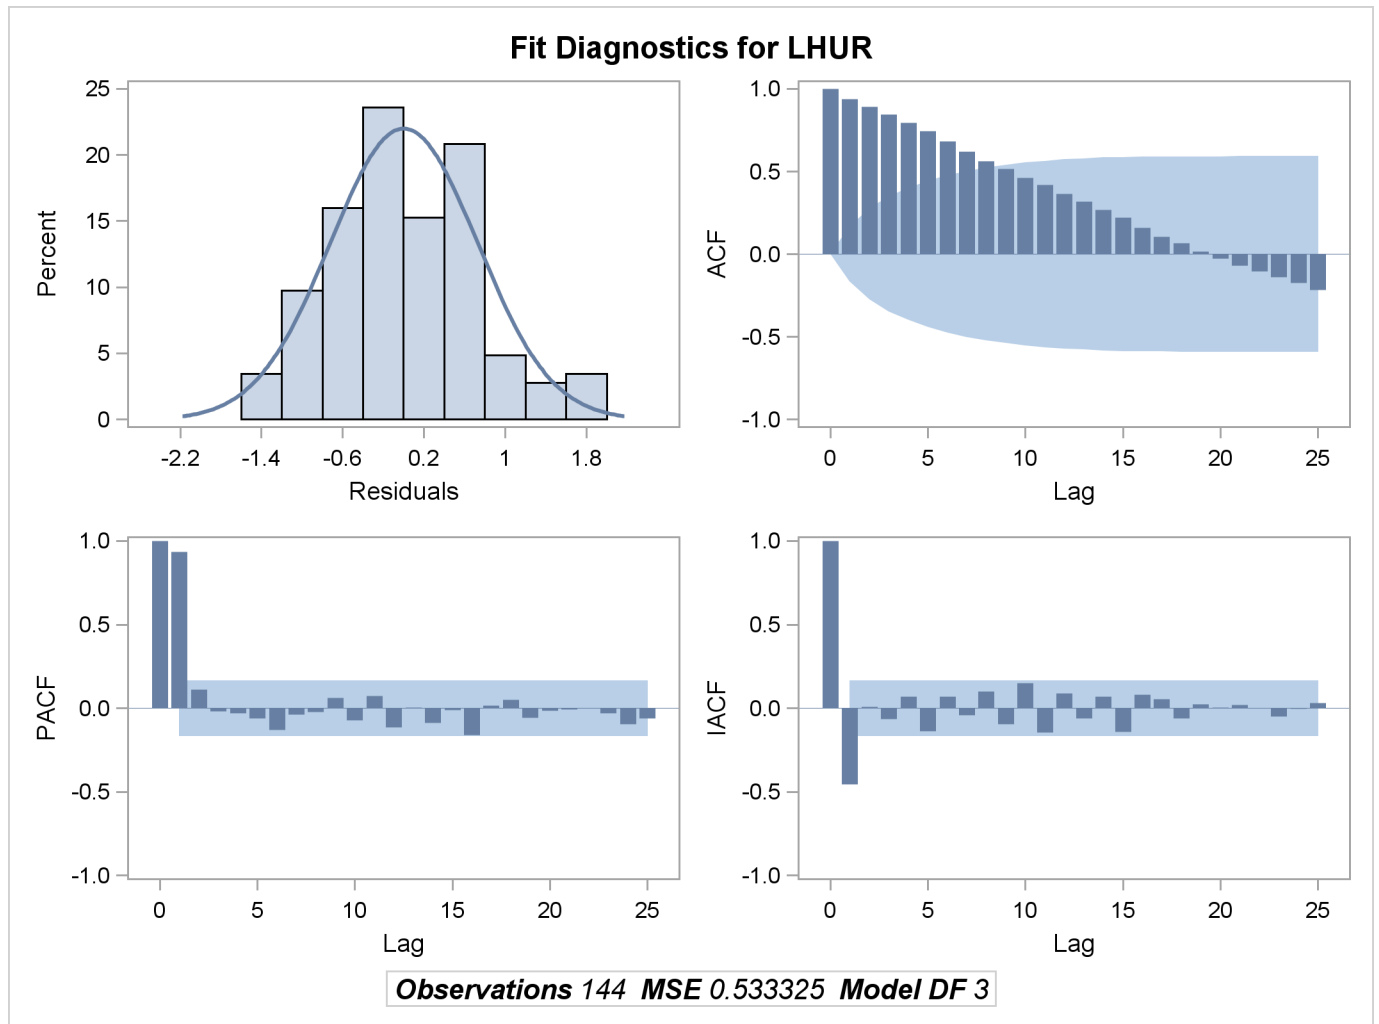

proc model data=sashelp.citimon;
  lhur = 1/(a * ip + b) + c;
  fit lhur;
  id date;
run;

```

Output 18.20.1 Diagnostics Plots

Output 18.20.2 Diagnostics Plots

You can also obtain the plots in the diagnostics panel as separate graphs by specifying the PLOTS(UNPACK) option. These plots are displayed in [Output 18.20.3](#) through [Output 18.20.10](#).

```

title1 'Unpacked Graphical Output from PROC MODEL';

proc model data=sashelp.citimon plots(unpack);
  lhur = 1/(a * ip + b) + c;
  fit lhur;
  id date;
run;

```

Output 18.20.3 Studentized Residuals Plot

Output 18.20.4 Cook's D Plot

Output 18.20.5 Predicted versus Actual Plot

Output 18.20.6 Autocorrelation of Residuals Plot

Output 18.20.7 Partial Autocorrelation of Residuals Plot

Output 18.20.8 Inverse Autocorrelation of Residuals Plot

Output 18.20.9 Q-Q Plot of Residuals

Output 18.20.10 Histogram of Residuals

Overview: PANEL Procedure

The PANEL procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. This type of pooled data on time series cross-sectional bases is often referred to as panel data. Typical examples of panel data include observations in time on households, countries, firms, trade, and so on. For example, in the case of survey data on household income, the panel is created by repeatedly surveying the same households in different time periods (years).

The panel data models can be grouped into several categories depending on the structure of the error term. The error structures and the corresponding methods that the PANEL procedure uses to analyze data are as follows:

- one-way and two-way models
- fixed-effects and random-effects models

- autoregressive models
- moving-average models

If the specification is dependent only on the cross section to which the observation belongs, such a model is referred to as a one-way model. A specification that depends on both the cross section and the time period to which the observation belongs is called a two-way model.

Apart from the possible one-way or two-way nature of the effect, the other dimension of difference between the possible specifications is the nature of the cross-sectional or time-series effect. The models are referred to as fixed-effects models if the effects are nonrandom and as random-effects models otherwise.

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is the best linear unbiased estimator. Random-effects models use a two-stage approach. In the first stage, variance components are calculated by using methods described by Fuller and Battese, Wansbeek and Kapteyn, Wallace and Hussain, or Nerlove. In the second stage, variance components are used to standardize the data, and ordinary least squares(OLS) regression is performed.

There are two types of models in the PANEL procedure that accommodate an autoregressive structure. The Parks method is used to estimate a first-order autoregressive model with contemporaneous correlation. The dynamic panel estimator is used to estimate an autoregressive model with lagged dependent variable.

The Da Silva method is used to estimate mixed variance-component moving-average error process. The regression parameters are estimated by using a two-step generalized least squares(GLS)-type estimator.

The new PANEL procedure enhances the features that were implemented in the TSCSREG procedure. The following list shows the most important additions.

- New estimation methods include between estimators, pooled estimators, and dynamic panel estimators that use the generalized method of moments (GMM). The variance components for random-effects models can be calculated for both balanced and unbalanced panels by using the methods described by Fuller and Battese, Wansbeek and Kapteyn, Wallace and Hussain, or Nerlove.
- The CLASS statement creates classification variables that are used in the analysis.
- The TEST statement includes new options for Wald, Lagrange multiplier, and the likelihood ratio tests.
- The new RESTRICT statement specifies linear restrictions on the parameters.
- The FLATDATA statement enables the data to be in a compressed form.
- Several methods that produce heteroscedasticity-consistent covariance matrices (HCCME) are added because the presence of heteroscedasticity can result in inefficient and biased estimates of the variance covariance matrix in the OLS framework.

- The LAG statement can generate a large number of missing values, depending on lag order. Typically, it is difficult to create lagged variables in the panel setting. If lagged variables are created in a DATA step, several programming steps that include loops are often needed. By including the LAG statement, the PANEL procedure makes the creation of lagged values easy. The missing values can be replaced with zeros, overall mean, time mean, or cross section mean by using the LAG, ZLAG, XLAG, SLAG, and CLAG statements.
- ODS Graphics plots can now be produced by the PANEL procedure. The new plots include residual, predicted, and actual value plots, Q-Q plots, histograms, and profile plots. The OUTPUT statement enables you to output data and estimates that can be used in other analyses.

Getting Started: PANEL Procedure

This section demonstrates the use of the PANEL procedure.

Specifying the Input Data

The PANEL procedure is similar to other regression procedures in SAS. Suppose you want to regress the variable *Y* on regressors *X1* and *X2*. Cross sections are identified by the variable *STATE*, and time periods are identified by the variable *DATE*. The input data set used by PROC PANEL must be sorted by cross section and by time within each cross section. Therefore, the first step in PROC PANEL is to make sure that the input data set is sorted. The following statements sort the data set *A* appropriately:

```
proc sort data=a;
  by state date;
run;
```

The next step is to invoke the PANEL procedure and specify the cross section and time series variables in an ID statement. The following statements shows the correct syntax:

```
proc panel data=a;
  id state date;
  model y = x1 x2;
run;
```

Alternatively, PROC PANEL has the capability to read “flat” data. Say that you are using the data set *A*, which has observations on states. Specifically, the data are composed of observations on *Y*, *X1*, and *X2*. Unlike the previous case, the data is not recorded with a PROC PANEL structure. Instead, you have all of a state’s information on a single row. You have variables to denote the name of the state (say *state*). The time observations for the *Y* variable are recorded horizontally.

So the variable Y_{1_1} is the first period's time observation, $Y_{1_{10}}$ is the tenth period's observation for some state. The same holds for the other variables. You have variables $X1_{1_1}$ to $X1_{1_{10}}$, $X2_{1_1}$ to $X2_{1_{10}}$, and $X3_{1_1}$ to $X3_{1_{10}}$ for others. With such data, PROC PANEL could be called by using the following syntax:

```
proc panel data=a;
  flatdata indid = state base = (Y X1 X2) tsname = t;
  id state t;
  model Y = X1 X2;
run;
```

See “[FLATDATA Statement](#)” on page 1272 and [Example 19.2](#) for more information about the use of the FLATDATA statement.

Specifying the Regression Model

The MODEL statement in PROC PANEL is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables, as shown in the following statements:

```
proc panel data=a;
  id state date;
  model y = x1 x2;
run;
```

The major advantage of using PROC PANEL is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the PANEL procedure are FIXONE, FIXONETIME, FIXTWO, RANONE, RANTWO, PARKS, DASILVA, GMM and ITGMM(iterated GMM). See the section “[Details: PANEL Procedure](#)” on page 1282 for more information about these methods and the error structures they assume. The following statements fit a Fuller-Battese one-way random-effects model.

```
proc panel data=a;
  id state date;
  model y = x1 x2 / rantwo vcomp=fb;
run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each specified method. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options. See [Example 19.1](#) for more information.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an F statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman m statistic that provides information about the appropriateness of the random-effects specification. The m statistic is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure. This number is interpreted as a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.

Unbalanced Data

In the case of fixed-effects models, random-effects models, between estimators, and dynamic panel estimators, the PANEL procedure can process data with different numbers of time series observations across different cross sections. The Parks and Da Silva methods cannot be used with unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Introductory Example

The following statements use the cost function data from Greene (1990) to estimate the variance components model. The variable PRODUCTION is the log of output in millions of kilowatt-hours, and COST is the log of cost in millions of dollars. Refer to Greene (1990) for details.

```
data greene;
  input firm year production cost @@;
datalines;
  1 1955 5.36598 1.14867 1 1960 6.03787 1.45185
  1 1965 6.37673 1.52257 1 1970 6.93245 1.76627
  2 1955 6.54535 1.35041 2 1960 6.69827 1.71109
  2 1965 7.40245 2.09519 2 1970 7.82644 2.39480
... more lines ...
```

You decide to fit the following model to the data:

$$C_{it} = \text{Intercept} + \beta P_{it} + v_i + e_t + \epsilon_{it} \quad i = 1, \dots, N; t = 1, \dots, T$$

where C_{it} and P_{it} represent the cost and production, and v_i , e_t and ϵ_{it} are the cross-sectional, time series, and error variance components.

If you assume that the time and cross-sectional effects are random, you are left with four possible estimators for the variance components. You choose Fuller-Battese.

The following statements fit this model.

```
proc sort data=greene;
  by firm year;
run;

proc panel data=greene;
  model cost = production / rantwo vcomp = fb;
  id firm year;
run;
```

The PANEL procedure output is shown in [Figure 19.1](#). A model description is printed first, which reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and t tests.

Figure 19.1 The Variance Components Estimates

The PANEL Procedure			
Fuller and Battese Variance Components (RanTwo)			
Dependent Variable: cost			
Model Description			
Estimation Method		RanTwo	
Number of Cross Sections		6	
Time Series Length		4	
Fit Statistics

Syntax: PANEL Procedure

The following statements are used with the PANEL procedure.

```

PROC PANEL options ;
  BY variables ;
  CLASS options ;
  FLATDATA options ;
  ID cross-section-id time-series-id ;
  INSTRUMENTS options ;
  LAG options ;
  MODEL dependent = regressors < / options > ;
  RESTRICT equation1 < ,equation2... > ;
  TEST equation1 < ,equation2... > ;

```

Functional Summary

The statements and options used with the PANEL procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
includes correlations in the OUTEST= data set	PANEL	CORROUT
includes covariances in the OUTEST= data set	PANEL	COVOUT
specifies the input data set	PANEL	DATA=
specifies variables to keep but not transform	FLATDATA	KEEP=
specifies the output data set for CLASS STATEMENT	CLASS	OUT =
specifies the output data set	FLATDATA	OUT =
specifies the name of an output SAS data set	OUTPUT	OUT=
writes parameter estimates to an output data set	PANEL	OUTEST=

Description	Statement	Option
writes the transformed series to an output data set	PANEL	OUTTRANS=
requests that the procedure produce graphics via the Output Delivery System	PANEL	PLOTS=
Declaring the Role of Variables		
specifies BY group processing	BY	
specifies the cross section and time ID variables	ID	
declares instrumental variables	INSTRUMENTS	
Lag Generation		
specifies output data set for lags	CLAG	OUT=
specifies output data set for lags	LAG	OUT=
specifies output data set for lags	SLAG	OUT=
specifies output data set for lags	XLAG	OUT=
specifies output data set for lags	ZLAG	OUT=
Printing Control Options		
prints correlations of the estimates	MODEL	CORRB
prints covariances of the estimates	MODEL	COVB
suppresses printed output	MODEL	NOPRINT
performs tests of linear hypotheses	TEST	
Model Estimation Options		
requests the Breusch-Pagan Test for one-way random effects	MODEL	BP
requests the Breusch-Pagan Test for two-way random effects	MODEL	BP2
specifies the between groups model	MODEL	BTWNG
specifies the between time periods model	MODEL	BTWNT
specifies Da Silva method	MODEL	DASILVA
specifies the one-way fixed-effects model	MODEL	FIXONE
specifies the one-way fixed-effects model with respect to time	MODEL	FIXONETIME
specifies the two-way fixed-effects model	MODEL	FIXTWO
specifies the Moore-Penrose generalized inverse	MODEL	GINV = G4
specifies the dynamic panel estimator model	MODEL	GMM
requests the HCCME estimator for the variance covariance matrix	MODEL	HCCME=
specifies order of the moving-average error process for Da Silva method	MODEL	M=
suppresses the intercept term	MODEL	NOINT

Description	Statement	Option
specifies the Parks method	MODEL	PARKS
prints Φ matrix for Parks method	MODEL	PHI
specifies the pooled model	MODEL	POOLED
specifies the one-way random-effects model	MODEL	RANONE
specifies the two-way random-effects model	MODEL	RANTWO
prints autocorrelation coefficients for Parks method	MODEL	RHO
control check for singularity	MODEL	SINGULAR=
specifies the method for the variance components estimator	MODEL	VCOMP=
specifies linear equality restrictions on the parameters	RESTRICT	

PROC PANEL Statement

PROC PANEL *options* ;

The following options can be specified on the PROC PANEL statement.

DATA=SAS-data-set

names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

OUTEST=SAS-data-set

names an output data set to contain the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created. See the section “[The OUTEST= Data Set](#)” on page 1321 for details about the structure of the OUTEST= data set.

OUTTRANS=SAS-data-set

names an output data set to contain the transformed series for further analysis and computation of models with time observations greater than two. See the section “[The OUTTRANS= Data Set](#)” on page 1322 for details about the structure of the OUTTRANS= data set.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set. See the section “[The OUTEST= Data Set](#)” on page 1321 for details.

OUTCORR

CORROUT

writes the correlation matrix of the parameter estimates to the OUTEST= data set. See the section “[The OUTEST= Data Set](#)” on page 1321 for details.

PLOTS<(global-plot-options)> < = (specific-plot-options)>

requests that the PANEL procedure produce statistical graphics via the Output Delivery System, provided that the ODS GRAPHICS statement has been specified. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*). The global plot options apply to all relevant plots generated by the PANEL procedure. The global plot options supported by the PANEL procedure follow.

Global Plot Options

ONLY	suppresses the default plots. Only the plots specifically requested are produced.
UNPACKPANEL	breaks a graphic that is otherwise paneled into individual component plots.

Specific Plot Options

ACTSURFACE	produces surface plot of actual values.
ALL	produces all appropriate plots.
FITPLOT	plots the predicted and actual values.
NONE	suppresses all plots.
PREDSURFACE	produces surface plot of predicted values.
QQ	produces QQ plot of residuals.
RESIDSTACK RESSTACK	produces a stacked plot of residuals.
RESIDSURFACE	produces surface plot of residual values.
RESIDUAL RES	plots the residuals.
RESIDUALHISTOGRAM RESIDHISTOGRAM	plots the histogram of residuals.

For more details, see the section “[ODS Graphics](#)” on page 1320. In addition, any of the following MODEL statement options can be specified in the PROC PANEL statement: CORRB, COVB, FIXONE, FIXONETIME, FIXTWO, BTWNG, BTWNT, POOLED, RANONE, RANTWO, FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, VCOMP=, and SINGULAR=. When specified in the PROC PANEL statement, these options are equivalent to specifying the options for every MODEL statement. See the section “[MODEL Statement](#)” on page 1276 for a complete description of each of these options.

BY Statement

BY variables ;

A BY statement can be used with PROC PANEL to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

The following statements show an example:

```
proc sort data=a;
  by byvar1 byvar2 csid tsid;
run;

proc panel data=a;
  by byvar1 byvar2;
  id csid tsid;
  ...
run;
```

CLASS Statement

CLASS *variables* < / out= SAS-data-set > ;

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

In PROC PANEL, the CLASS statement enables you to output class variables to a data set that contains a copy of the original data.

FLATDATA Statement

FLATDATA *options* / out= SAS-data-set ;

The following options must be specified in the FLATDATA statement:

BASE=(*variable, variable, ..., variable*)

specifies the variables that are to be transformed into a proper PROC PANEL format. All variables to be transformed must be named according to the convention: *basename_timeperiod*. You supply just the *basename*, and the procedure extracts the appropriate variables to transform. If some year's data are missing for a variable, then PROC PANEL detects this and fills in with missing values.

INDID=*variable*

names the variable in the input data set that uniquely identifies each individual. The INDID variable can be a character or numeric variable.

KEEP=(*variable, variable, ..., variable*)

specifies the variables that are to be copied without any transformation. These variables

remain constant with respect to time when the data are converted to PROC PANEL format. This is an optional item.

TSNAME=*name*

specifies a name for the generated time identifier. The name must satisfy the requirements for the name of a SAS variable. The name can be quoted, but it must not be the name of a variable in the input data set.

The following options can be specified on the FLATDATA statement after the slash (/):

OUT =*SAS-data-set*

saves the converted flat data set to a PROC PANEL formatted data set.

ID Statement

ID *cross-section-id time-series-id* ;

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the PANEL procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The PANEL procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT to sort the input data set with a BY statement with the variables listed exactly as they are listed in the ID statement, as shown in the following statements:

```
proc sort data=a;
  by csid tsid;
run;
```

```
proc panel data=a;
  id csid tsid;
  ... etc. ...
run;
```

INSTRUMENT Statement

INSTRUMENTS *options* ;

The INSTRUMENTS statement denotes which variables are used in the moment condition equations of the dynamic panel estimator. The following options can be used with the INSTRUMENTS statement.

CONSTANT

includes an intercept (column of ones) as an uncorrelated exogenous instrument.

DEPVAR

specifies that a dependent variable be used at an appropriate lag as an instrument.

CORRELATED=(variable, variable, ..., variable)

specifies a list of variables correlated with the error term. These variables are not used in forming moment conditions from level equations.

EXOGENOUS=(variable, variable, ..., variable)

specifies a list of variables that are not correlated with the error term.

PREDETERMINED=(variable, variable, ..., variable)

specifies a list of variables whose future realizations can be correlated with the error term but whose present and past realizations are not.

If a variable listed in the EXOGENOUS list is not included in the CORRELATED list, then it is considered to be uncorrelated to the error term. For example, in the following statements, the exogenous instruments are Z1, Z2 and X1. Z1 is an instrument that is correlated to the individual fixed effects.

```
proc panel data=a;
  inst exogenous=(Z1 Z2 X1)
    correlated = (Z1) constant depvar;
  model Y = X1 X2 X3 / gmm;
run;
```

For a detailed discussion of the model set up and the use of the INSTRUMENTS statement, see “[Dynamic Panel Estimator](#)” on page 1304.

Note that for each MODEL statement, one INSTRUMENT statement is required. In other words, if there are two models to be estimated by using GMM within one PANEL procedure, then there should be two INSTRUMENT statements. For example,

```
proc panel data=test;
  inst depvar pred=(x1 x2) exog=(x3 x4 x5) correlated=(x3 x4 x5);
  model y = y_1 x1 x2 / gmm maxband=6 nolevels ginv=g4 artest=5;
  inst pred=(x2 x4) exog=(x3 x5) correlated=(x3 x4);
  model y = y_1 x2 / gmm maxband=6 nolevels ginv=g4 artest=5;
  id cs ts;
run;
```

LAG, ZLAG, XLAG, SLAG or CLAG Statement

LAG $var_1(lag_1 lag_2 \dots lag_T), \dots, var_N(lag_1 lag_2 \dots lag_T) < /OUT= SAS-data-set > ;$

Generally, creating lags of variables in a panel setting is a tedious process in which you must generate many DATA STEP statements. The PANEL procedure now enables you to generate lags of any series without jumping across any individual’s boundary. The lag statement is a data set

generation tool. Using the data created by a LAG statement requires a subsequent PROC PANEL call. There can be more than one LAG statement in each call to PROC PANEL.

The LAG statement tends to generate many missing values in the data. This can be problematic, because the number of usable observations diminishes with the lag length. Therefore, PROC PANEL offers alternatives to the LAG statement. The OUT= option must be specified on the LAG statement. The output data set includes all variables in the input set, plus the lags that are denoted with the convention originalvar_lag. The following statements can be used instead of LAG with otherwise identical syntax:

CLAG

replaces missing values with the cross section mean for that variable in that cross section. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

SLAG

replaces missing values with the time mean for that variable in that time period. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

XLAG

replaces missing values with the overall mean for that variable. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

ZLAG

replaces missing values with zero for that variable. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

Assume that data set A has been sorted by cross section and time period within cross section (or FLATDATA has been specified), and the variables are Y, X1, X2 and X3. You desire the lags 1 and 3 of the X1 variable; lag 3, 6, and 9 of X2; and lag 2 of variable X3. The following PROC PANEL statements generate a series with those characteristics.

```
proc panel data=A;
  id i t;
  lag X1(1 3) X2(3 6 9) X3(2) / out=A_lag;
run;
```

If you want a zeroing instead of missing values, then you specify the following:

```
proc panel data=A;
  id i t;
  zlag X1(1 3) X2(3 6 9) X3(2) / out=A_zlag;
run;
```

Similarly, you can specify XLAG to replace with overall means, SLAG to replace with time means, and CLAG to replace with cross section means.

MODEL Statement

MODEL *response* = *regressors* < / *options* > ;

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FULLER, PARKS, DASILVA, FIXONE, FIXONETIME, FIXTWO, RANONE, RANTWO, GMM, and ITGMM options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label : MODEL ... ;

The following options can be specified in the MODEL statement after a slash (/).

ARTEST=*integer*

specifies the maximum order of the test for the presence of AR effects in the residual. The acceptable range of values for this option is 1 to $t - 3$. See the section “[Instrument Choice](#)” on page 1311 for details.

ATOL=*number*

specifies the convergence criterion for iterated GMM when convergence of the method is determined by convergence in the weighting matrix. The convergence criterion must be positive. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

BANDOPT=TRAILING | CENTERED | LEADING

specifies which observations are included in the instrument list when the MAXBAND option is employed. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

BP

requests the Breusch-Pagan one-way test for random effects.

BP2

requests the Breusch-Pagan two-way test for random effects.

BTOL=*number*

specifies the convergence criterion for iterated GMM when convergence of the method is determined by convergence in the parameter matrix. The convergence criterion must be positive. The default is BTOL=1e-8. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

BTWNG

specifies that a between-groups model be estimated.

BTWNT

specifies that a between-time-periods model be estimated.

CORRB**CORR**

prints the matrix of estimated correlations between the parameter estimates.

COVB**VAR**

prints the matrix of estimated covariances between the parameter estimates.

DASILVA

specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure. See the section “[Da Silva Method \(Variance-Component Moving-Average Model\)](#)” on page 1302 for details.

FIXONE

specifies that a one-way fixed-effects model be estimated with the one-way model corresponding to cross-sectional effects only.

FIXONETIME

specifies that a one-way fixed-effects model be estimated with the one-way model corresponding to time effects only.

FIXTWO

specifies that a two-way fixed-effects model be estimated.

FULLER

specifies that the model be estimated by using the Fuller-Battese method, which assumes a variance components model for the error structure. See the section “[Fuller and Battese’s Method](#)” on page 1292 later in this chapter for details.

GINV= G2 | G4

specifies what type of generalized inverse to use. The default is a G2 inverse. The G4 inverse is generally more desirable except that it is a more numerically intensive methodology.

GMM

specifies that the model be estimated by using the dynamic panel estimator method, which allows for autoregressive processes. This is the single-step model. Note that with this option one INSTRUMENT statement is required for each MODEL statement. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

HCCME=number

specifies the type of HCCME variance-covariance matrix requested. The expected range of values is no or 0 to 4. The default is zero, no correction. See the section “[Heteroscedasticity-Corrected Covariance Matrices](#)” on page 1313 for details.

ITGMM

specifies that the model be estimated by using the dynamic panel estimator method, but that PROC PANEL keep updating the weighting matrix until either the parameter vector converges

or the weighting matrix converges. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

ITPRINT

prints out the iteration history of the parameter and transformed sum of error squared.

M=number

specifies the order of the moving-average process in the Da Silva method. The value of the M=option must be less than $T - 1$. The default is M=1.

MAXBAND=integer

specifies the maximum number of time periods (per instrumental variable) that are allowed into the moment condition. The acceptable range of values for this option is 1 to $t - 1$. The default value is MAXBAND=1 or MAXBAND=2, depending on the BANDOPT option. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

MAXITER= integer

specifies the maximum number of iterations allowed for the iterated GMM option. The default value is MAXITER=200. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

NODIFFS

specifies that the dynamic panel model be estimated without moment conditions from the difference equations. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

NOESTIM

limits the estimation of a FIXONE, FIXONETIME, RANONE model to the generation of the transformed series. This option is intended for use with an OUTTRANS= data set.

NOINT

suppresses the intercept parameter from the model.

NOLEVELS

specifies that the dynamic panel model be estimated without moment conditions from the level equations. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

NOPRINT

suppresses the normal printed output.

PARKS

specifies that the model be estimated by using the Parks method, which assumes a first-order autoregressive model for the error structure. See the section “[Parks Method \(Autoregressive Model\)](#)” on page 1300 for details.

PHI

prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used. See the section “[Parks Method \(Autoregressive Model\)](#)” on page 1300 for details.

POOLED

specifies that a pooled (OLS) model be estimated.

RANONE

specifies that a one-way random-effects model be estimated.

RANTWO

specifies that a two-way random-effects model be estimated.

RHO

prints the estimated autocorrelation coefficients for the Parks method.

ROBUST

specifies that robust weighting matrix be used in the calculation of the variance-covariance matrix of the single step estimator. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

SINGULAR=*number*

specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TIME

specifies that the model be estimated by using the dynamic panel estimator method, but that PROC PANEL includes time dummy variables to model any time effects present in the data. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

TWOSTEP

specifies that the model be estimated by using the dynamic panel estimator method, but that two steps be used in the estimation. An initial first step is used to form an estimator for the weighting matrix used in the second step. See the section “[Dynamic Panel Estimator](#)” on page 1304 for details.

VCOMP=*FB* | *NL* | *WH* | *WK*

specifies the type of variance component estimate to use. The default is VCOMP=FB for balanced data and VCOMP=WK for unbalanced data. See the section “[The One-Way Random-Effects Model](#)” on page 1292 for details.

OUTPUT Statement

```
OUTPUT OUT=SAS-data-set < = options ... > ;
```

The OUTPUT statement creates an output SAS data set as specified by the following options:

OUT=*SAS-data-set*

names the output SAS data set to contain the predicted and transformed values. If the OUT= option is not specified, the new data set is named according to the DATA*n* convention.

PREDICTED=*name***P=*name***

writes the predicted values to the output data set.

RESIDUAL=*name***R=***name*

writes the residuals from the predicted values based on both the structural and time series parts of the model to the output data set.

RESTRICT Statement

RESTRICT *"string" equation <,equation2... >* ;

The RESTRICT statement specifies linear equality restrictions on the parameters in the previous model statement. There can be as many unique restrictions as the number of parameters in the preceding model statement. Multiple RESTRICT statements are understood as joint restrictions on a model's parameters. Restrictions on the intercept are obtained by the use of the keyword INTERCEPT.

Currently, only linear equality restrictions are permitted in PROC PANEL. Tests and restriction expressions can only be composed of algebraic operations that involve the addition symbol (+), subtraction symbol (−), and multiplication symbol (*).

The RESTRICT statement accepts labels that are produced in the printed output. RESTRICT statement can be labeled in two ways. A RESTRICT statement can be preceded by a label followed by a colon. This is illustrated in **rest1** in the example below. Alternatively, the keyword RESTRICT can be followed by a quoted string.

The following statements illustrate the use of the RESTRICT statement:

```
proc panel;
  model y = x1 x2 x3;
  restrict x1 = 0, x2 * .5 + 2 * x3 = 0;
  rest1: restrict x2 = 0, x3 = 0;
  restrict "rest2" intercept=1;
run;
```

Note that a restrict statement cannot include a division sign in its formulation.

TEST Statement

TEST *"string" equation <,equation2... >< / options >* ;

The TEST statement performs Wald, Lagrange multiplier and likelihood ratio tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following options can be specified on the TEST statement after the slash (/):

ALL

specifies Wald, Lagrange multiplier and likelihood ratio tests.

WALD

specifies the WALD test.

LM

specifies the Lagrange multiplier test.

LR

specifies the likelihood ratio test.

The following statements illustrate the use of the TEST statement:

```
proc panel;
  id csid tsid;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0;
  test_int: test intercept = 0, x3 = 0;
run;
```

The first test investigates the joint hypothesis that

$$\beta_1 = 0$$

and

$$.5\beta_2 + 2\beta_3 = 0$$

Currently, only linear equality restrictions and tests are permitted in PROC PANEL. Tests and restriction expressions can be composed only of algebraic operations that involve the addition symbol (+), subtraction symbol (-), and multiplication symbol (*).

The TEST statement accepts labels that are produced in the printed output. The TEST statement can be labeled in two ways. A TEST statement can be preceded by a label followed by a colon. Alternatively, the keyword TEST can be followed by a quoted string. If both are presented, PROC PANEL uses the quoted string. In the event no label is present, PROC PANEL automatically labels the tests. If both a TEST and a RESTRICT statement are specified, the test is run with restrictions applied.

Note that for the DaSilva method, only the WALD test is available.

Details: PANEL Procedure

Missing Values

Any observation in the input data set with a missing value for one or more of the regressors is ignored by PROC PANEL and is not used in the model fit.

If there are observations in the input data set with missing dependent variable values but with non-missing regressors, PROC PANEL can compute predicted values and store them in an output data set by using the OUTPUT statement. Note that the presence of such observations with missing dependent variable values does not affect the model fit because these observations are excluded from the calculation.

If either some regressors or the dependent variable values are missing, the model is estimated as unbalanced where the number of time series observations across different cross sections does not have to be equal. The Parks and Da Silva methods cannot be used with unbalanced data.

Computational Resources

The more parameters there are to be estimated, the more memory and time are required to estimate the model. Also affecting these resources are the estimation method chosen and the method to calculate variance components. If the model has p parameters including the intercept, there are at least $p + [p * (p + 1)]/2$ numbers being held in the memory.

If the Arellano and Bond GMM approach is used, the amount of memory grows proportionately to the number of instruments in the INSTRUMENT statement. If the ITGMM (iterated GMM) option is selected, the computation time also depends on the convergence criteria selected and the maximum number of iterations allowed.

Restricted Estimates

A consequence of estimating a linear model with a restriction is that the error degrees of freedom increase by the number of restrictions. PROC PANEL produces the Lagrange multiplier associated with each restriction.

Say that you are interested in linear regression in which there are r restrictions. A linear restriction

implies the following set of equations that relate the regression coefficients:

$$\begin{aligned} R_{1,1}\beta_1 + R_{1,2}\beta_2 + \cdots + R_{1,p}\beta_p &= q_1 \\ R_{2,1}\beta_1 + R_{2,2}\beta_2 + \cdots + R_{2,p}\beta_p &= q_2 \\ &\dots\dots\dots \\ R_{r,1}\beta_1 + R_{r,2}\beta_2 + \cdots + R_{r,p}\beta_p &= q_r \end{aligned}$$

To economize on notation, you can represent the restriction structure in the following matrix notation $\mathbf{R}\boldsymbol{\beta} = \mathbf{q}$. The restricted $\boldsymbol{\beta}$ estimator is given by:

$$\boldsymbol{\beta}^* = \boldsymbol{\beta} - (\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1} (\mathbf{R}\boldsymbol{\beta} - \mathbf{q})$$

The Lagrange multipliers are given as:

$$\boldsymbol{\lambda}_* = \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1} (\mathbf{R}\boldsymbol{\beta} - \mathbf{q})$$

The standard errors of the Lagrange Multipliers are calculated from the following relationship:

$$\text{Var}(\boldsymbol{\lambda}_*) = \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1} \mathbf{R}\text{Var}(\boldsymbol{\beta})\mathbf{R}' \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1}$$

A significant Lagrange multiplier implies that you can reject the null hypothesis that the restrictions are not binding.

Note that in the special case of the fixed-effects models, the NOINT option and RESTRICT INTERCEPT=0 option give different estimates. This is not an error; it reflects two perspectives on the same issue. In the FIXONE case, the intercept is the last cross section's fixed effect (or the last time affecting the case of FIXONETIME). Specifying the NOINT option removes the intercept, but allows the last effect in. The NOINT command simply reclassifies the effects. The dummy variables become true cross section effects. If you specify the NOINT option with the FIXTWO option, the restriction is imposed that the last time effect is zero. A RESTRICT INTERCEPT=0 statement suppresses the estimation of the last effect in the FIXONE and FIXONETIME case. A RESTRICT INTERCEPT=0 has similar effects on the FIXTWO estimator. In general, restricting the intercept to zero is not recommended because OLS loses its unbiased nature.

Notation

The following notation represents the usual panel structure, with the specification of u_{it} dependent on the particular model:

$$y_{it} = \sum_{k=1}^K x_{itk}\beta_k + u_{it} \quad i = 1, \dots, N; t = 1, \dots, T_i$$

The total number of observations $M = \sum_{i=1}^N T_i$. For the balanced data case, $T_i = T$ for all i . The $M \times M$ covariance matrix of u_{it} is denoted by \mathbf{V} . Let \mathbf{X} and \mathbf{y} be the independent and dependent variables arranged by cross section and by time within each cross section. Let \mathbf{X}_s be the X matrix without the intercept. All other notation is specific to each section.

The One-Way Fixed-Effects Model

The specification for the one-way fixed-effects model is

$$u_{it} = \gamma_i + \epsilon_{it}$$

where the γ_i s are nonrandom parameters to be estimated.

Let $\mathbf{Q}_0 = \text{diag}(\mathbf{E}_{T_i})$, with $\bar{\mathbf{J}}_{T_i} = \mathbf{J}_{T_i}/T_i$ and $\mathbf{E}_{T_i} = \mathbf{I}_{T_i} - \bar{\mathbf{J}}_{T_i}$, where \mathbf{J}_{T_i} is a matrix of T_i ones.

The matrix \mathbf{Q}_0 represents the within transformation. In the one-way model, the within transformation is the conversion of the raw data to deviations from a cross section's mean. The vector $\tilde{\mathbf{x}}_{it}$ is a row of the general matrix \mathbf{X}_s , where the subscripted s implies the constant (column of ones) is missing.

Let $\tilde{\mathbf{X}}_s = \mathbf{Q}_0\mathbf{X}_s$ and $\tilde{\mathbf{y}} = \mathbf{Q}_0\mathbf{y}$. The estimator of the slope coefficients is given by

$$\tilde{\beta}_s = (\tilde{\mathbf{X}}_s'\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}}$$

Once the slope estimates are in hand, the estimation of an intercept or the cross-sectional fixed effects is handled as follows. First, you obtain the cross-sectional effects:

$$\gamma_i = \bar{y}_i - \tilde{\beta}_s\bar{x}_i \quad \text{for } i = 1 \dots N$$

If the NOINT option is specified, then the dummy variables' coefficients are set equal to the fixed effects. If an intercept is desired, then the i th dummy variable is obtained from the following expression:

$$D_i = \gamma_i - \gamma_N \quad \text{for } i = 1 \dots N - 1$$

The intercept is the N th fixed effect γ_N .

The within model sum of squared errors is:

$$\text{SSE} = \sum_{i=1}^N \sum_{t=1}^{T_i} (y_{it} - \gamma_i - \mathbf{X}_s\tilde{\beta}_s)^2$$

The estimated error variance can be written:

$$\hat{\sigma}_\epsilon^2 = \text{SSE}/(M - N - (K - 1))$$

Alternatively, an equivalent way to express the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}'\mathbf{Q}_0\tilde{\mathbf{u}}/(M - N - (K - 1))$$

where the residuals $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M\mathbf{j}'_M/M)(\mathbf{y} - \mathbf{X}_s\tilde{\beta}_s)$ if there is an intercept and by $\tilde{\mathbf{u}} = (\mathbf{y} - \mathbf{X}_s\tilde{\beta}_s)$ if there is not. The drawback is that the formula changes (but the results do not) with the inclusion of a constant.

The variance covariance matrix of $\tilde{\beta}_s$ is given by:

$$\text{Var}[\tilde{\beta}_s] = \hat{\sigma}_\epsilon^2(\tilde{\mathbf{X}}_s'\tilde{\mathbf{X}}_s)^{-1}$$

The covariance of the dummy variables and the dummy variables with the $\tilde{\beta}_s$ is dependent on whether the intercept is included in the model.

- *no intercept:*

$$\text{Var}[\gamma_i] = \text{Var}[D_i] = \frac{\hat{\sigma}_\epsilon^2}{T_i} + \bar{\mathbf{x}}_i' \text{Var}[\tilde{\beta}_s] \bar{\mathbf{x}}_i$$

$$\text{Cov}[\gamma_i, \gamma_j] = \text{Cov}[D_i D_j] = \bar{\mathbf{x}}_i' \text{Var}[\tilde{\beta}_s] \bar{\mathbf{x}}_j$$

$$\text{Cov}[\gamma_i, \tilde{\beta}_s] = \text{Cov}[D_i \tilde{\beta}_s] = -\bar{\mathbf{x}}_i' \text{Var}[\tilde{\beta}_s]$$

- *intercept:*

$$\text{Var}[D_i] = \frac{\hat{\sigma}_\epsilon^2}{T_i} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})$$

$$\text{Cov}[D_i, D_j] = \frac{\hat{\sigma}_\epsilon^2}{T_i} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_j - \bar{\mathbf{x}}_{N\cdot})$$

$$\text{Var}[\text{Intercept}] = \text{Var}[\gamma_N] = \frac{\hat{\sigma}_\epsilon^2}{T_N} + \bar{\mathbf{x}}_N' \text{Var}[\tilde{\beta}_s] \bar{\mathbf{x}}_N$$

$$\text{Cov}[D_i, \tilde{\beta}_s] = -(\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}[\tilde{\beta}_s]$$

$$\text{Cov}[\text{Intercept}, D_i] = -\frac{\hat{\sigma}_\epsilon^2}{T_i} + \bar{\mathbf{x}}_N' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})$$

$$\text{Cov}[\text{Intercept}, \tilde{\beta}_s] = -\bar{\mathbf{x}}_N' \text{Var}[\tilde{\beta}_s]$$

Alternatively, the model option `FIXONETIME` estimates a one-way model where the heterogeneity comes from time effects. This option is analogous to re-sorting the data by time and then by cross section and running a `FIXONE` model. The advantage of using the `FIXONETIME` option is that sorting is avoided and the model remains labeled correctly.

The Two-Way Fixed-Effects Model

The specification for the two-way fixed-effects model is

$$u_{it} = \gamma_i + \alpha_t + \epsilon_{it}$$

where the γ_i s and α_t s are nonrandom parameters to be estimated.

If you do not specify the `NOINT` option, which suppresses the intercept, the estimates for the fixed effects are reported under the restriction that $\gamma_N = 0$ and $\alpha_T = 0$. If you specify the `NOINT` option to suppress the intercept, only the restriction $\alpha_T = 0$ is imposed.

Balanced Panels

Assume that the data are balanced (for example, all cross sections have T observations). Then you can write the following:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i - \bar{y}_t + \bar{\bar{y}}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i - \bar{\mathbf{x}}_t + \bar{\bar{\mathbf{x}}}$$

where the symbols:

y_{it} and \mathbf{x}_{it} are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables not including a constant), respectively

\bar{y}_i and $\bar{\mathbf{x}}_i$ are cross section means

\bar{y}_t and $\bar{\mathbf{x}}_t$ are time means

$\bar{\bar{y}}$ and $\bar{\bar{\mathbf{x}}}$ are the overall means

The two-way fixed-effects model is simply a regression of \tilde{y}_{it} on $\tilde{\mathbf{x}}_{it}$. Therefore, the two-way β is given by:

$$\tilde{\beta}_s = (\tilde{\mathbf{X}}' \tilde{\mathbf{X}})^{-1} \tilde{\mathbf{X}}' \tilde{\mathbf{y}}$$

The calculations of cross section dummy variables, time dummy variables, and intercepts follow in a fashion similar to that used in the one-way model.

First, you obtain the net cross-sectional and time effects. Denote the cross-sectional effects by γ and the time effects by α . These effects are calculated from the following relations:

$$\hat{\gamma}_i = (\bar{y}_i - \bar{\bar{y}}) - \tilde{\beta}_s (\bar{x}_i - \bar{\bar{x}})$$

$$\hat{\alpha}_t = (\bar{y}_t - \bar{\bar{y}}) - \tilde{\beta}_s (\bar{x}_t - \bar{\bar{x}})$$

Denote the cross-sectional dummy variables and time dummy variables with the superscript C and T. Under the NOINT option the following equations give the dummy variables:

$$D_i^C = \hat{\gamma}_i + \hat{\alpha}_T$$

$$D_t^T = \hat{\alpha}_t - \hat{\alpha}_T$$

When an intercept is specified, the equations for dummy variables and intercept are:

$$D_i^C = \hat{\gamma}_i - \hat{\gamma}_N$$

$$D_t^T = \hat{\alpha}_t - \hat{\alpha}_T$$

$$\text{Intercept} = \hat{\gamma}_N + \hat{\alpha}_T$$

The sum of squared errors is:

$$\text{SSE} = \sum_{i=1}^N \sum_{t=1}^{T_i} (y_{it} - \gamma_i - \alpha_t - \mathbf{X}_s \tilde{\beta}_s)^2$$

The estimated error variance is:

$$\hat{\sigma}_\epsilon^2 = \text{SSE}/(M - N - T - (K - 1))$$

With or without a constant, the variance covariance matrix of $\tilde{\beta}_s$ is given by:

$$\text{Var}[\tilde{\beta}_s] = \hat{\sigma}_\epsilon^2 (\tilde{\mathbf{X}}_s' \tilde{\mathbf{X}}_s)^{-1}$$

Variance Covariance of Dummy variables with No Intercept

The variances and covariances of the dummy variables are given with the NOINT specification as follows:

$$\begin{aligned} \text{Var}(D_i^C) &= \hat{\sigma}_\epsilon^2 \left(\frac{1}{T} + \frac{1}{N} - \frac{1}{NT} \right) \\ &+ (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}}) \end{aligned}$$

$$\text{Var}(D_i^T) = \frac{2\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)$$

$$\begin{aligned} \text{Cov}(D_i^C, D_j^C) &= \hat{\sigma}_\epsilon^2 \left(\frac{1}{N} - \frac{1}{NT} \right) \\ &+ (\bar{\mathbf{x}}_{mi} i \cdot + \bar{\mathbf{x}}_{mi} \cdot t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_{mj} j \cdot + \bar{\mathbf{x}}_{mj} \cdot t - \bar{\bar{\mathbf{x}}}) \end{aligned}$$

$$\text{Cov}(D_i^T, D_u^T) = \frac{\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_u - \bar{\mathbf{x}}_T)$$

$$\text{Cov}(D_i^C, D_i^T) = -\frac{\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)$$

$$\text{Cov}(D_i^C, \beta) = -(\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s]$$

$$\text{Cov}(D_i^T, \beta) = -(\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)' \text{Var}[\tilde{\beta}_s]$$

Variance Covariance of Dummy variables with Intercept

The variances and covariances of the dummy variables are given when the intercept is included as follows:

$$\begin{aligned}\text{Var}\left(D_i^C\right) &= \frac{\hat{\sigma}_\epsilon^2}{T} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot}) \\ \text{Var}\left(D_t^T\right) &= \frac{2\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T}) \\ \text{Var}(\text{Intercept}) &= \hat{\sigma}_\epsilon^2 \left(\frac{1}{T} + \frac{1}{N} - \frac{1}{NT}\right) + (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}}) \\ \text{Cov}\left(D_i^C, D_j^C\right) &= \frac{\hat{\sigma}_\epsilon^2}{T} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_j - \bar{\mathbf{x}}_{N\cdot}) \\ \text{Cov}\left(D_t^T, D_u^T\right) &= (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_u - \bar{\mathbf{x}}_{\cdot T}) \\ \text{Cov}\left(D_i^C, \text{Intercept}\right) &= -\left(\frac{\hat{\sigma}_\epsilon^2}{T}\right) + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}}) \\ \text{Cov}\left(D_t^T, \text{Intercept}\right) &= -\left(\frac{\hat{\sigma}_\epsilon^2}{N}\right) + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var}\left[\tilde{\beta}_s\right] (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}}) \\ \text{Cov}\left(D_i^C, \tilde{\beta}\right) &= -(\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var}\left[\tilde{\beta}_s\right] \\ \text{Cov}\left(D_t^T, \tilde{\beta}\right) &= -(\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var}\left[\tilde{\beta}_s\right] \\ \text{Cov}\left(\text{Intercept}, \tilde{\beta}\right) &= -(\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}})' \text{Var}\left[\tilde{\beta}_s\right]\end{aligned}$$

Unbalanced Panels

Let \mathbf{X}_* and \mathbf{y}_* be the independent and dependent variables arranged by time and by cross section within each time period. (Note that the input data set used by the PANEL procedure must be sorted by cross section and then by time within each cross section.) Let M_t be the number of cross sections observed in year t and let $\sum_t M_t = M$. Let \mathbf{D}_t be the $M_t \times N$ matrix obtained from the $N \times N$ identity matrix from which rows that correspond to cross sections not observed at time t have been omitted. Consider

$$\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2)$$

where $\mathbf{Z}_1 = (\mathbf{D}'_1, \mathbf{D}'_2, \dots, \mathbf{D}'_T)'$ and $\mathbf{Z}_2 = \text{diag}(\mathbf{D}_1 \mathbf{j}_N, \mathbf{D}_2 \mathbf{j}_N, \dots, \mathbf{D}_T \mathbf{j}_N)$. The matrix \mathbf{Z} gives the dummy variable structure for the two-way model.

Let

$$\begin{aligned}\Delta_N &= \mathbf{Z}'_1 \mathbf{Z}_1 \\ \Delta_T &= \mathbf{Z}'_2 \mathbf{Z}_2 \\ \mathbf{A} &= \mathbf{Z}'_2 \mathbf{Z}_1 \\ \bar{\mathbf{Z}} &= \mathbf{Z}_2 - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{A}' \\ \mathbf{Q} &= \Delta_T - \mathbf{A} \Delta_N^{-1} \mathbf{A}' \\ \mathbf{P} &= (\mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1) - \bar{\mathbf{Z}} \mathbf{Q}^{-1} \bar{\mathbf{Z}}'\end{aligned}$$

The estimate of the regression slope coefficients is given by

$$\tilde{\beta}_s = (\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{P} \mathbf{y}_*$$

where \mathbf{X}_{*s} is the \mathbf{X}_* matrix without the vector of 1s.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / (M - T - N + 1 - (K - 1))$$

where the residuals are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M / M)(\mathbf{y}_* - \mathbf{X}_{*s} \tilde{\beta}_s)$ if there is an intercept in the model and by $\tilde{\mathbf{u}} = \mathbf{y}_* - \mathbf{X}_{*s} \tilde{\beta}_s$ if there is no intercept.

The actual implementation is quite different from the theory. The PANEL procedure transforms all series using the \mathbf{P} matrix.

$$\tilde{\mathbf{v}} = \mathbf{P} \mathbf{v}$$

The variable being transformed is v , which could be \mathbf{y} or any column of \mathbf{X} . After the data are properly transformed, OLS is run on the resulting series.

Given $\tilde{\beta}_s$, the next step is estimating the cross-sectional and time effects. Given that $\boldsymbol{\gamma}$ is the column vector of cross-sectional effects and $\boldsymbol{\alpha}$ is the column vector of time effects,

$$\begin{aligned}\tilde{\boldsymbol{\alpha}} &= \mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{y} - \mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{X}_s \tilde{\beta}_s \\ \tilde{\boldsymbol{\gamma}} &= (\Theta_1 + \Theta_2 - \Theta_3) \mathbf{y} - (\Theta_1 + \Theta_2 - \Theta_3) \mathbf{X}_s \tilde{\beta}_s \\ \Theta_1 &= \Delta_N^{-1} \mathbf{Z}'_1 \\ \Theta_2 &= \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{Z}'_2 \\ \Theta_3 &= \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1} \mathbf{Z}'_1\end{aligned}$$

Given the cross-sectional and time effects, the next step is to derive the associated dummy variables. Using the NOINT option, the following equations give the dummy variables:

$$\begin{aligned}D_i^C &= \hat{\gamma}_i + \hat{\alpha}_T \\ D_t^T &= \hat{\alpha}_t - \hat{\alpha}_T\end{aligned}$$

When an intercept is desired, the equations for dummy variables and intercept are:

$$D_i^C = \hat{\gamma}_i - \hat{\gamma}_N$$

$$D_t^T = \hat{\alpha}_t - \hat{\alpha}_T$$

$$\text{Intercept} = \hat{\gamma}_N + \hat{\alpha}_T$$

The calculation of the variance-covariance matrix is as follows:

$$\begin{aligned} \text{Var}[\hat{\boldsymbol{\gamma}}] &= \hat{\sigma}_\epsilon^2 (\Delta_N^{-1} - \Sigma_1 + \Sigma_2) \\ &\quad + (\Theta_1 + \Theta_2 - \Theta_3) \text{Var}[\tilde{\boldsymbol{\beta}}_s] (\Theta_1 + \Theta_2 - \Theta_3)' \end{aligned}$$

where

$$\Sigma_1 = \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1}$$

$$\Sigma_2 = \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \Delta_T \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1}$$

$$\text{Var}[\hat{\boldsymbol{\alpha}}] = \hat{\sigma}_\epsilon^2 (\mathbf{Q}^{-1} \bar{\mathbf{Z}}' \bar{\mathbf{Z}} \mathbf{Q}^{-1}) + (\mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{X}_s) \text{Var}[\tilde{\boldsymbol{\beta}}_s] (\mathbf{X}_s' \bar{\mathbf{Z}} \mathbf{Q}^{-1})$$

$$\begin{aligned} \text{Cov}[\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\gamma}}'] &= \hat{\sigma}_\epsilon^2 \Delta_N^{-1} [\mathbf{A}' \mathbf{Q}^{-1} \Delta_T - \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1} \mathbf{A}'] \mathbf{Q}^{-1} \\ &\quad + (\Theta_1 + \Theta_2 - \Theta_3) \text{Var}[\tilde{\boldsymbol{\beta}}_s] (\mathbf{X}_s' \bar{\mathbf{Z}} \mathbf{Q}^{-1}) \end{aligned}$$

$$\text{Cov}[\hat{\boldsymbol{\gamma}}, \tilde{\boldsymbol{\beta}}] = (\Theta_1 + \Theta_2 - \Theta_3) \text{Var}[\tilde{\boldsymbol{\beta}}_s]$$

$$\text{Cov}[\hat{\boldsymbol{\alpha}}, \tilde{\boldsymbol{\beta}}] = (\mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{X}_s) \text{Var}[\tilde{\boldsymbol{\beta}}_s]$$

Now you work out the variance covariance estimates for the dummy variables.

Variance Covariance of Dummy variables with No Intercept

The variances and covariances of the dummy variables are given under the NOINT selection as follows:

$$\text{Cov}(D_i^C, D_j^C) = \text{Cov}(\hat{\gamma}_i, \hat{\gamma}_j) + \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_T) + \text{Cov}(\hat{\gamma}_j, \hat{\alpha}_T) + \text{Var}(\hat{\alpha}_T)$$

$$\text{Cov}(D_t^T, D_u^T) = \text{Cov}(\hat{\alpha}_t, \hat{\alpha}_u) - \text{Cov}(\hat{\alpha}_t, \hat{\alpha}_T) - \text{Cov}(\hat{\alpha}_u, \hat{\alpha}_T) + \text{Var}(\hat{\alpha}_T)$$

$$\text{Cov}(D_i^C, D_t^T) = \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_t) + \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_T) - \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_T) - \text{Var}(\hat{\alpha}_T)$$

$$\text{Cov}(D_i^C, \tilde{\boldsymbol{\beta}}) = -\text{Cov}(\hat{\gamma}_i, \tilde{\boldsymbol{\beta}}) - \text{Cov}(\hat{\alpha}_T, \tilde{\boldsymbol{\beta}})$$

$$\text{Cov}(D_t^T, \tilde{\boldsymbol{\beta}}) = -\text{Cov}(\hat{\alpha}_t, \tilde{\boldsymbol{\beta}}) + \text{Cov}(\hat{\alpha}_T, \tilde{\boldsymbol{\beta}})$$

Variance Covariance of Dummy variables with Intercept

The variances and covariances of the dummy variables are given as follows when the intercept is included:

$$\begin{aligned}\text{Cov}\left(D_i^C, D_j^C\right) &= \text{Cov}\left(\hat{\gamma}_i, \hat{\gamma}_j\right) - \text{Cov}\left(\hat{\gamma}_i, \hat{\gamma}_N\right) - \text{Cov}\left(\hat{\gamma}_j, \hat{\gamma}_N\right) + \text{Var}\left(\hat{\gamma}_N\right) \\ \text{Cov}\left(D_i^T, D_u^T\right) &= \text{Cov}\left(\hat{\alpha}_t, \hat{\alpha}_u\right) - \text{Cov}\left(\hat{\alpha}_t, \hat{\alpha}_T\right) - \text{Cov}\left(\hat{\alpha}_u, \hat{\alpha}_T\right) + \text{Var}\left(\hat{\alpha}_T\right) \\ \text{Cov}\left(D_i^C, D_i^T\right) &= \text{Cov}\left(\hat{\gamma}_i, \hat{\alpha}_t\right) - \text{Cov}\left(\hat{\gamma}_i, \hat{\alpha}_T\right) - \text{Cov}\left(\hat{\gamma}_N, \hat{\alpha}_t\right) + \text{Cov}\left(\hat{\gamma}_N, \hat{\alpha}_T\right) \\ \text{Cov}\left(D_i^C, \text{Intercept}\right) &= \text{Cov}\left(\hat{\gamma}_i, \hat{\gamma}_N\right) + \text{Cov}\left(\hat{\gamma}_i, \hat{\alpha}_T\right) - \text{Cov}\left(\hat{\gamma}_j, \hat{\alpha}_T\right) - \text{Var}\left(\hat{\gamma}_N\right) \\ \text{Cov}\left(D_i^T, \text{Intercept}\right) &= \text{Cov}\left(\hat{\alpha}_t, \hat{\alpha}_T\right) + \text{Cov}\left(\hat{\alpha}_t, \hat{\gamma}_N\right) - \text{Cov}\left(\hat{\alpha}_T, \hat{\alpha}_N\right) - \text{Var}\left(\hat{\alpha}_T\right) \\ \text{Cov}\left(D_i^C, \tilde{\beta}\right) &= -\text{Cov}\left(\hat{\gamma}_i, \tilde{\beta}\right) - \text{Cov}\left(\hat{\gamma}_N, \tilde{\beta}\right) \\ \text{Cov}\left(D_i^T, \tilde{\beta}\right) &= -\text{Cov}\left(\hat{\alpha}_t, \tilde{\beta}\right) + \text{Cov}\left(\hat{\alpha}_T, \tilde{\beta}\right) \\ \text{Cov}\left(\text{Intercept}, \tilde{\beta}_f\right) &= -\text{Cov}\left(\hat{\alpha}_T, \tilde{\beta}\right) - \text{Cov}\left(\hat{\gamma}_N, \tilde{\beta}\right)\end{aligned}$$

Between Estimators

The between groups estimator is the regression of the cross section means of \mathbf{y} on the cross section means of $\tilde{\mathbf{X}}_S$. In other words, you fit the following regression:

$$\bar{y}_i = \bar{\mathbf{x}}_i \beta^{BG} + \eta_i$$

The between time periods estimator is the regression of the time means of \mathbf{y} on the time means of $\tilde{\mathbf{X}}_S$. In other words, you fit the following regression:

$$\bar{y}_t = \bar{\mathbf{x}}_t \beta^{BT} + \zeta_t$$

In either case, the error is assumed to be normally distributed with mean zero and a constant variance.

Pooled Estimator

PROC PANEL allows you to pool time series cross-sectional data and run regressions on the data. Pooling is admissible if there are no fixed effects or random effects present in the data. This feature is included to aid in analysis and comparison across model types and to give you access to HCCME standard errors and other panel diagnostics. In general, this model type should not be used with time series cross-sectional data.

The One-Way Random-Effects Model

The specification for the one-way random-effects model is

$$u_{it} = v_i + \epsilon_{it}$$

Let $\mathbf{Z}_0 = \text{diag}(\mathbf{j}_{T_i})$, $\mathbf{P}_0 = \text{diag}(\bar{\mathbf{J}}_{T_i})$, and $\mathbf{Q}_0 = \text{diag}(\mathbf{E}_{T_i})$, with $\bar{\mathbf{J}}_{T_i} = \mathbf{J}_{T_i}/T_i$ and $\mathbf{E}_{T_i} = \mathbf{I}_{T_i} - \bar{\mathbf{J}}_{T_i}$. Define $\tilde{\mathbf{X}}_s = \mathbf{Q}_0\mathbf{X}_s$ and $\tilde{\mathbf{y}} = \mathbf{Q}_0\mathbf{y}$.

In the one-way model, estimation proceeds in a two-step fashion. First, you obtain estimates of the variance of the σ_ϵ^2 and σ_v^2 . There are multiple ways to derive these estimates; PROC PANEL provides four options. All four options are valid for balanced or unbalanced panels. Once these estimates are in hand, they are used to form a weighting factor θ , and estimation proceeds via OLS on partial deviations from group means.

PROC PANEL gives the following options for variance component estimators.

Fuller and Battese's Method

The Fuller and Battese method for estimating variance components can be obtained with the option VCOMP = FB and the option RANONE. The variance components are given by the following equations (see Baltagi and Chang (1994) and Fuller and Battese (1974) for the approach in the two-way model). Let

$$R(v) = \mathbf{y}'\mathbf{Z}_0(\mathbf{Z}_0'\mathbf{Z}_0)^{-1}\mathbf{Z}_0'\mathbf{y}$$

$$R(\beta|v) = ((\tilde{\mathbf{X}}_s'\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}})'(\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}})$$

$$R(\beta) = (\mathbf{X}_s'\mathbf{y})'(\mathbf{X}_s'\mathbf{X}_s)^{-1}\mathbf{X}_s'\mathbf{y}$$

$$R(v|\beta) = R(\beta|v) + R(v) - R(\beta)$$

The estimator of the error variance is given by

$$\hat{\sigma}_\epsilon^2 = (\mathbf{y}'\mathbf{y} - R(\beta|v) - R(v))/(M - N - (K - 1))$$

If the NOINT option is specified, the estimator is

$$\hat{\sigma}_\epsilon^2 = (\mathbf{y}'\mathbf{y} - R(\beta|v) - R(v))/(M - N - K)$$

The estimator of the cross-sectional variance component is given by

$$\hat{\sigma}_v^2 = (R(v|\beta) - (N - 1)\hat{\sigma}_\epsilon^2)/(M - \text{tr}(\mathbf{Z}_0'\mathbf{X}_s(\mathbf{X}_s'\mathbf{X}_s)^{-1}\mathbf{X}_s'\mathbf{Z}_0))$$

Note that the error variance is the variance of the residual of the within estimator.

According to Baltagi and Chang (1994), the Fuller and Battese method is appropriate to apply to both balanced and unbalanced data. The Fuller and Battese method is the default for estimation of one-way random-effects models with balanced panels. However, the Fuller and Battese method does not always obtain nonnegative estimates for the cross section (or group) variance. In the case of a negative estimate, a warning is printed and the estimate is set to zero.

Wansbeek and Kapteyn's Method

The Wansbeek and Kapteyn method for estimating variance components can be obtained by setting VCOMP = WK (together with the option RANONE). The estimation of the one-way unbalanced data model is performed by using a specialization (Baltagi and Chang 1994) of the approach used by Wansbeek and Kapteyn (1989) for unbalanced two-way models. The Wansbeek and Kapteyn method is the default for unbalanced data. If just RANONE is specified, without the VCOMP= option, PROC PANEL estimates the variance component under Wansbeek and Kapteyn's method.

The estimation of the variance components is performed by using a quadratic unbiased estimation (QUE) method. This involves focusing on quadratic forms of the centered residuals, equating their expected values to the realized quadratic forms, and solving for the variance components.

Let

$$q_1 = \tilde{\mathbf{u}}' \mathbf{Q}_0 \tilde{\mathbf{u}}$$

$$q_2 = \tilde{\mathbf{u}}' \mathbf{P}_0 \tilde{\mathbf{u}}$$

where the residuals $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M / M)(\mathbf{y} - \mathbf{X}_s (\tilde{\mathbf{X}}'_s \tilde{\mathbf{X}}_s)^{-1} \tilde{\mathbf{X}}'_s \tilde{\mathbf{y}})$ if there is an intercept and by $\tilde{\mathbf{u}} = \mathbf{y} - \mathbf{X}_s (\tilde{\mathbf{X}}'_s \tilde{\mathbf{X}}_s)^{-1} \tilde{\mathbf{X}}'_s \tilde{\mathbf{y}}$ if there is not.

Consider the expected values

$$E(q_1) = (M - N - (K - 1))\sigma_\epsilon^2$$

$$E(q_2) = (N - 1 + \text{tr}[(\mathbf{X}'_s \mathbf{Q}_0 \mathbf{X}_s)^{-1} \mathbf{X}'_s \mathbf{P}_0 \mathbf{X}_s] - \text{tr}[(\mathbf{X}'_s \mathbf{Q}_0 \mathbf{X}_s)^{-1} \mathbf{X}'_s \bar{\mathbf{J}}_M \mathbf{X}_s])\sigma_\epsilon^2 \\ [M - (\sum_i T_i^2 / M)]\sigma_v^2$$

where $\hat{\sigma}_\epsilon^2$ and $\hat{\sigma}_v^2$ are obtained by equating the quadratic forms to their expected values.

The estimator of the error variance is the residual variance of the within estimate. The Wansbeek and Kapteyn method can also generate negative variance components estimates.

Wallace and Hussain's Method

The Wallace and Hussain method for estimating variance components can be obtained by setting VCOMP = WH (together with the option RANONE). Wallace-Hussain estimates start from OLS residuals on a data that are assumed to exhibit groupwise heteroscedasticity. As in the Wansbeek and Kapteyn method, you start with

$$q_1 = \tilde{\mathbf{u}}'_{OLS} \mathbf{Q}_0 \tilde{\mathbf{u}}_{OLS}$$

$$q_2 = \tilde{\mathbf{u}}'_{OLS} \mathbf{P}_0 \tilde{\mathbf{u}}_{OLS}$$

However, instead of using the 'true' errors, you substitute the OLS residuals. You solve the system

$$E(\hat{q}_1) = E(\hat{\mathbf{u}}'_{OLS} \mathbf{Q}_0 \hat{\mathbf{u}}_{OLS}) = \delta_{11} \hat{\sigma}_v^2 + \delta_{12} \hat{\sigma}_\epsilon^2$$

$$E(\hat{q}_2) = E(\hat{\mathbf{u}}'_{OLS} \mathbf{P}_0 \hat{\mathbf{u}}_{OLS}) = \delta_{21} \hat{\sigma}_v^2 + \delta_{22} \hat{\sigma}_\epsilon^2$$

The constants δ_{11} , δ_{12} , δ_{21} , δ_{22} are given by

$$\delta_{11} = \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{Z}_0\mathbf{Z}_0'\mathbf{X} \right) - \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{Z}_0\mathbf{Z}_0'\mathbf{X} \right)$$

$$\delta_{12} = M - N - K + \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \right)$$

$$\delta_{21} = M - 2tr \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{Z}_0\mathbf{Z}_0'\mathbf{X} \right) + \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \right)$$

$$\delta_{22} = N - \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \right)$$

where $\text{tr}()$ is the trace operator on a square matrix.

Solving this system produces the variance components. This method is applicable to balanced and unbalanced panels. However, there is no guarantee of positive variance components. Any negative values are fixed equal to zero.

Nerlove's Method

The Nerlove method for estimating variance components can be obtained by setting $\text{VCOMP} = \text{NL}$. The Nerlove method (see Baltagi 1995, page 17) is assured to give estimates of the variance components that are always positive. Furthermore, it is simple in contrast to the previous estimators.

If γ_i is the i th fixed effect, Nerlove's method uses the variance of the fixed effects as the estimate of $\hat{\sigma}_v^2$. You have $\hat{\sigma}_v^2 = \sum_{i=1}^N \frac{(y_i - \bar{y})^2}{N-1}$, where \bar{y} is the mean fixed effect. The estimate of σ_ϵ^2 is simply the residual sum of squares of the one-way fixed-effects regression divided by the number of observations.

With the variance components in hand, from any method, the next task is to estimate the regression model of interest. For each individual, you form a weight (θ_i) as follows:

$$\theta_i = 1 - \sigma_\epsilon / w_i$$

$$w_i^2 = T_i \sigma_v^2 + \sigma_\epsilon^2$$

where T_i is the i th cross section's time observations.

Taking the θ_i , you form the partial deviations,

$$\tilde{y}_{it} = y_{it} - \theta_i \bar{y}_i.$$

$$\tilde{x}_{it} = x_{it} - \theta_i \bar{x}_i.$$

where \bar{y}_i and \bar{x}_i are cross section means of the dependent variable and independent variables (including the constant if any), respectively.

The random-effects β is then the result of simple OLS on the transformed data.

The Two-Way Random-Effects Model

The specification for the two-way random-effects model is

$$u_{it} = v_i + e_t + \epsilon_{it}$$

As in the one-way random-effects model, the PANEL procedure provides four options for variance component estimators. Unlike the one-way random-effects model, unbalanced panels present some special concerns.

Let \mathbf{X}_* and \mathbf{y}_* be the independent and dependent variables arranged by time and by cross section within each time period. (Note that the input data set used by the PANEL procedure must be sorted by cross section and then by time within each cross section.) Let M_t be the number of cross sections observed in time t and $\sum_t M_t = M$. Let \mathbf{D}_t be the $M_t \times N$ matrix obtained from the $N \times N$ identity matrix from which rows that correspond to cross sections not observed at time t have been omitted. Consider

$$\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2)$$

where $\mathbf{Z}_1 = (\mathbf{D}'_1, \mathbf{D}'_2, \dots, \mathbf{D}'_T)'$ and $\mathbf{Z}_2 = \text{diag}(\mathbf{D}_1 \mathbf{j}_N, \mathbf{D}_2 \mathbf{j}_N, \dots, \mathbf{D}_T \mathbf{j}_N)$.

The matrix \mathbf{Z} gives the dummy variable structure for the two-way model.

For notational ease, let

$$\Delta_N = \mathbf{Z}'_1 \mathbf{Z}_1, \Delta_T = \mathbf{Z}'_2 \mathbf{Z}_2, \mathbf{A} = \mathbf{Z}'_2 \mathbf{Z}_1$$

$$\bar{\mathbf{Z}} = \mathbf{Z}_2 - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{A}'$$

$$\bar{\Delta}_1 = \mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1$$

$$\bar{\Delta}_2 = \mathbf{I}_M - \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2$$

$$\mathbf{Q} = \Delta_T - \mathbf{A} \Delta_N^{-1} \mathbf{A}'$$

$$\mathbf{P} = (\mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1) - \bar{\mathbf{Z}} \mathbf{Q}^{-1} \bar{\mathbf{Z}}'$$

Fuller and Battese's Method

The Fuller and Battese method for estimating variance components can be obtained by setting VCOMP = FB (with the option RANTWO). FB is the default method for a RANTWO model with balanced panel. If RANTWO is requested without specifying the VCOMP= option, PROC PANEL proceeds under the Fuller and Battese method.

Following the discussion in Baltagi, et. al. (2002), the Fuller and Battese method forms the estimates as follows.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / (M - T - N + 1 - (K - 1))$$

where \mathbf{P} is the Wansbeek and Kapteyn within estimator for unbalanced (or balanced) panel in a two-way setting.

The estimator of the error variance is the same as that in the Wansbeek and Kapteyn method.

Consider the expected values

$$\begin{aligned} E(q_N) &= \sigma_\epsilon^2 [M - T - K + 1] \\ &+ \sigma_v^2 \left[M - T - \text{tr} \left(\mathbf{X}'_s \bar{\Delta}_2 \mathbf{Z}_1 \mathbf{Z}'_1 \bar{\Delta}_2 \mathbf{X}_s \left(\mathbf{X}'_s \bar{\Delta}_2 \mathbf{X}_s \right)^{-1} \right) \right] \\ E(q_T) &= \sigma_\epsilon^2 [M - N - K + 1] \\ &+ \sigma_e^2 \left[M - N - \text{tr} \left(\mathbf{X}'_s \bar{\Delta}_1 \mathbf{Z}_2 \mathbf{Z}'_2 \bar{\Delta}_1 \mathbf{X}_s \left(\mathbf{X}'_s \bar{\Delta}_1 \mathbf{X}_s \right)^{-1} \right) \right] \end{aligned}$$

Just as in the one-way case, there is always the possibility that the (estimated) variance components will be negative. In such a case, the negative components are fixed to equal zero. After substituting the group sum of the within residuals for (q_N) , the time sums of the within residuals for (q_T) , and $\hat{\sigma}_\epsilon^2$, the two equations are solved for $\hat{\sigma}_v^2$ and $\hat{\sigma}_e^2$.

Wansbeek and Kapteyn's Method

The Wansbeek and Kapteyn method for estimating variance components can be obtained with by setting VCOMP = WK. The following methodology, outlined in Wansbeek and Kapteyn (1989) is used to handle both balanced and unbalanced data. The Wansbeek and Kapteyn method is the default for a RANTWO model with unbalanced panel. If RANTWO is requested without specifying the VCOMP= option, PROC PANEL proceeds under the Wansbeek and Kapteyn method if the panel is unbalanced.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / (M - T - N + 1 - (K - 1))$$

where the $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M / M)(\mathbf{y}_* - \mathbf{X}_{*S}(\mathbf{X}'_{*S} \mathbf{P} \mathbf{X}_{*S})^{-1} \mathbf{X}'_{*S} \mathbf{P} \mathbf{y}_*)$ if there is an intercept and by $\tilde{\mathbf{u}} = (\mathbf{y}_* - \mathbf{X}_{*S}(\mathbf{X}'_{*S} \mathbf{P} \mathbf{X}_{*S})^{-1} \mathbf{X}'_{*S} \mathbf{P} \mathbf{y}_*)$ if there is not.

The estimation of the variance components is performed by using a quadratic unbiased estimation (QUE) method that involves computing on quadratic forms of the residuals $\tilde{\mathbf{u}}$, equating their expected values to the realized quadratic forms, and solving for the variance components.

Let

$$q_N = \tilde{\mathbf{u}}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \tilde{\mathbf{u}}$$

$$q_T = \tilde{\mathbf{u}}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \tilde{\mathbf{u}}$$

The expected values are

$$E(q_N) = (T + k_N - (1 + k_0))\sigma^2 + (T - \frac{\lambda_1}{M})\sigma_v^2 + (M - \frac{\lambda_2}{M})\sigma_e^2$$

$$E(q_T) = (N + k_T - (1 + k_0))\sigma^2 + \left(M - \frac{\lambda_1}{M}\right)\sigma_v^2 + \left(N - \frac{\lambda_2}{M}\right)\sigma_e^2$$

where

$$\begin{aligned} k_0 &= \mathbf{j}'_M \mathbf{X}_{*s} (\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{j}_M / M \\ k_N &= \text{tr}((\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \mathbf{X}_{*s}) \\ k_T &= \text{tr}((\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \mathbf{X}_{*s}) \\ \lambda_1 &= \mathbf{j}'_M \mathbf{Z}_1 \mathbf{Z}'_1 \mathbf{j}_M \\ \lambda_2 &= \mathbf{j}'_M \mathbf{Z}_2 \mathbf{Z}'_2 \mathbf{j}_M \end{aligned}$$

The quadratic unbiased estimators for σ_v^2 and σ_e^2 are obtained by equating the expected values to the quadratic forms and solving for the two unknowns.

When the NOINT option is specified, the variance component equations change slightly. In particular, the following is true (Wansbeek and Kapteyn 1989):

$$\begin{aligned} E(q_N) &= (T + k_N)\sigma^2 + T\sigma_v^2 + M\sigma_e^2 \\ E(q_T) &= (N + k_T)\sigma^2 + M\sigma_v^2 + N\sigma_e^2 \end{aligned}$$

Wallace and Hussain's Method

The Wallace and Hussain method for estimating variance components can be obtained by setting VCOMP = WH. Wallace and Hussain's method is by far the most computationally intensive. It uses the OLS residuals to estimate the variance components. In other words, the Wallace and Hussain method assumes that the following holds:

$$\begin{aligned} q_\epsilon &= \tilde{\mathbf{u}}'_{OLS} \mathbf{P} \tilde{\mathbf{u}}_{OLS} \\ q_N &= \tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \tilde{\mathbf{u}}_{OLS} \\ q_T &= \tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \tilde{\mathbf{u}}_{OLS} \end{aligned}$$

Taking expectations yields

$$\begin{aligned} E(q_\epsilon) &= E\left(\tilde{\mathbf{u}}'_{OLS} \mathbf{P} \tilde{\mathbf{u}}_{OLS}\right) = \delta_{11}\sigma_\epsilon^2 + \delta_{12}\sigma_v^2 + \delta_{13}\sigma_e^2 \\ E(q_N) &= E\left(\tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \tilde{\mathbf{u}}_{OLS}\right) = \delta_{21}\sigma_\epsilon^2 + \delta_{22}\sigma_v^2 + \delta_{23}\sigma_e^2 \\ E(q_T) &= E\left(\tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \tilde{\mathbf{u}}_{OLS}\right) = \delta_{31}\sigma_\epsilon^2 + \delta_{32}\sigma_v^2 + \delta_{33}\sigma_e^2 \end{aligned}$$

where the δ_{js} constants are defined by

$$\delta_{11} = M - N - T + 1 - \text{tr}\left(\mathbf{X}' \mathbf{P} \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1}\right)$$

$$\delta_{12} = \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \left(\mathbf{X}' \mathbf{P} \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \right)$$

$$\delta_{13} = \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \left(\mathbf{X}' \mathbf{P} \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \right)$$

$$\delta_{21} = T - \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right)$$

$$\begin{aligned} \delta_{22} &= T - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

$$\begin{aligned} \delta_{23} &= T - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

$$\delta_{31} = N - \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right)$$

$$\begin{aligned} \delta_{32} &= M - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

$$\begin{aligned} \delta_{33} &= N - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

The PANEL procedure solves this system for the estimates $\hat{\sigma}_\epsilon$, $\hat{\sigma}_\nu$, and $\hat{\sigma}_e$. Some of the estimated variance components can be negative. Negative components are set to zero and estimation proceeds.

Nerlove's Method

The Nerlove method for estimating variance components can be obtained with by setting VCOMP = NL.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / M$$

The variance components for cross section and time effects are:

$$\hat{\sigma}_v^2 = \sum_{i=1}^N \frac{(\gamma_i - \bar{\gamma})^2}{N-1} \text{ where } \gamma_i \text{ is the } i\text{th cross section effect}$$

and

$$\hat{\sigma}_e^2 = \sum_{t=1}^T \frac{(\alpha_t - \bar{\alpha})^2}{T-1} \text{ where } \alpha_t \text{ is the } t\text{th time effect}$$

With the estimates of the variance components in hand, you can proceed to the final estimation. If the panel is balanced, partial mean deviations are used:

$$\tilde{y}_{it} = y_{it} - \theta_1 \bar{y}_i - \theta_2 \bar{y}_{\cdot t} + \theta_3 \bar{y}_{\cdot\cdot}$$

$$\tilde{x}_{it} = x_{it} - \theta_1 \bar{x}_i - \theta_2 \bar{x}_{\cdot t} + \theta_3 \bar{x}_{\cdot\cdot}$$

The θ estimates are obtained from

$$\begin{aligned} \theta_1 &= 1 - \frac{\sigma_\epsilon}{\sqrt{T\sigma_v^2 + \sigma_\epsilon^2}} \\ \theta_2 &= 1 - \frac{\sigma_\epsilon}{\sqrt{N\sigma_e^2 + \sigma_\epsilon^2}} \\ \theta_3 &= \theta_1 + \theta_2 + \frac{\sigma_\epsilon}{\sqrt{T\sigma_v^2 + N\sigma_e^2 + \sigma_\epsilon^2}} - 1; \end{aligned}$$

With these partial deviations, PROC PANEL uses OLS on the transformed series (including an intercept if so desired).

The case of an unbalanced panel is somewhat trickier. You could naively substitute the variance components in the equation below:

$$\Omega = \sigma_\epsilon^2 \mathbf{I}_M + \sigma_v^2 \mathbf{Z}_1 \mathbf{Z}_1' + \sigma_e^2 \mathbf{Z}_2 \mathbf{Z}_2'$$

After inverting the expression for Ω , it is possible to do GLS on the data (even if the panel is unbalanced). However, the inversion of Ω is no small matter because the dimension is at least $\frac{M(M+1)}{2}$.

Wansbeek and Kapteyn show that the inverse of Ω can be written as

$$\sigma_\epsilon^2 \Omega^{-1} = \mathbf{V} - \mathbf{V} \mathbf{Z}_2 \tilde{\mathbf{P}}^{-1} \mathbf{Z}_2' \mathbf{V}$$

with the following:

$$\begin{aligned} \mathbf{V} &= \mathbf{I}_M - \mathbf{Z}_1 \tilde{\Delta}_N^{-1} \mathbf{Z}_1' \\ \tilde{\mathbf{P}} &= \tilde{\Delta}_T - \mathbf{A} \tilde{\Delta}_N^{-1} \mathbf{A}' \\ \tilde{\Delta}_N &= \Delta_N + \begin{pmatrix} \sigma_\epsilon^2 \\ \sigma_v^2 \end{pmatrix} \mathbf{I}_N \\ \tilde{\Delta}_T &= \Delta_T + \begin{pmatrix} \sigma_\epsilon^2 \\ \sigma_e^2 \end{pmatrix} \mathbf{I}_T \end{aligned}$$

Computationally, this is a much less intensive approach.

By using the inverse of the variance-covariance matrix of the error, it becomes possible to complete GLS on the unbalanced panel.

Parks Method (Autoregressive Model)

Parks (1967) considered the first-order autoregressive model in which the random errors u_{it} , $i = 1, 2, \dots, N$, and $t = 1, 2, \dots, T$ have the structure

$$\begin{aligned} E(u_{it}^2) &= \sigma_{ii}(\text{heteroscedasticity}) \\ E(u_{it}u_{jt}) &= \sigma_{ij}(\text{contemporaneously correlated}) \\ u_{it} &= \rho_i u_{i,t-1} + \epsilon_{it}(\text{autoregression}) \end{aligned}$$

where

$$\begin{aligned} E(\epsilon_{it}) &= 0 \\ E(u_{i,t-1}\epsilon_{jt}) &= 0 \\ E(\epsilon_{it}\epsilon_{jt}) &= \phi_{ij} \\ E(\epsilon_{it}\epsilon_{js}) &= 0(s \neq t) \\ E(u_{i0}) &= 0 \\ E(u_{i0}u_{j0}) &= \sigma_{ij} = \phi_{ij}/(1 - \rho_i\rho_j) \end{aligned}$$

The model assumed is first-order autoregressive with contemporaneous correlation between cross sections. In this model, the covariance matrix for the vector of random errors \mathbf{u} can be expressed as

$$E(\mathbf{uu}') = \mathbf{V} = \begin{bmatrix} \sigma_{11}P_{11} & \sigma_{12}P_{12} & \dots & \sigma_{1N}P_{1N} \\ \sigma_{21}P_{21} & \sigma_{22}P_{22} & \dots & \sigma_{2N}P_{2N} \\ \vdots & \vdots & \vdots & \vdots \\ \sigma_{N1}P_{N1} & \sigma_{N2}P_{N2} & \dots & \sigma_{NN}P_{NN} \end{bmatrix}$$

where

$$P_{ij} = \begin{bmatrix} 1 & \rho_j & \rho_j^2 & \dots & \rho_j^{T-1} \\ \rho_i & 1 & \rho_j & \dots & \rho_j^{T-2} \\ \rho_i^2 & \rho_i & 1 & \dots & \rho_j^{T-3} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \rho_i^{T-1} & \rho_i^{T-2} & \rho_i^{T-3} & \dots & 1 \end{bmatrix}$$

The matrix \mathbf{V} is estimated by a two-stage procedure, and $\boldsymbol{\beta}$ is then estimated by generalized least squares. The first step in estimating \mathbf{V} involves the use of ordinary least squares to estimate $\boldsymbol{\beta}$ and obtain the fitted residuals, as follows:

$$\hat{\mathbf{u}} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{OLS}$$

A consistent estimator of the first-order autoregressive parameter is then obtained in the usual manner, as follows:

$$\hat{\rho}_i = \left(\sum_{t=2}^T \hat{u}_{it}\hat{u}_{i,t-1} \right) / \left(\sum_{t=2}^T \hat{u}_{i,t-1}^2 \right) \quad i = 1, 2, \dots, N$$

Finally, the autoregressive characteristic of the data is removed (asymptotically) by the usual transformation of taking weighted differences. That is, for $i = 1, 2, \dots, N$,

$$y_{i1} \sqrt{1 - \hat{\rho}_i^2} = \sum_{k=1}^p X_{i1k} \beta_k \sqrt{1 - \hat{\rho}_i^2} + u_{i1} \sqrt{1 - \hat{\rho}_i^2}$$

$$y_{it} - \hat{\rho}_i y_{i,t-1} = \sum_{k=1}^p (X_{itk} - \hat{\rho}_i X_{i,t-1,k}) \beta_k + u_{it} - \hat{\rho}_i u_{i,t-1} \quad t = 2, \dots, T$$

which is written

$$y_{it}^* = \sum_{k=1}^p X_{itk}^* \beta_k + u_{it}^* \quad i = 1, 2, \dots, N; \quad t = 1, 2, \dots, T$$

Notice that the transformed model has not lost any observations (Seely and Zyskind 1971).

The second step in estimating the covariance matrix \mathbf{V} is applying ordinary least squares to the preceding transformed model, obtaining

$$\hat{\mathbf{u}}^* = \mathbf{y}^* - \mathbf{X}^* \boldsymbol{\beta}_{OLS}^*$$

from which the consistent estimator of σ_{ij} is calculated as follows:

$$s_{ij} = \frac{\hat{\phi}_{ij}}{(1 - \hat{\rho}_i \hat{\rho}_j)}$$

where

$$\hat{\phi}_{ij} = \frac{1}{(T - p)} \sum_{t=1}^T \hat{u}_{it}^* \hat{u}_{jt}^*$$

Estimated generalized least squares (EGLS) then proceeds in the usual manner,

$$\hat{\boldsymbol{\beta}}_P = (\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} \mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{y}$$

where $\hat{\mathbf{V}}$ is the derived consistent estimator of \mathbf{V} . For computational purposes, $\hat{\boldsymbol{\beta}}_P$ is obtained directly from the transformed model,

$$\hat{\boldsymbol{\beta}}_P = (\mathbf{X}^{*'} (\hat{\Phi}^{-1} \otimes I_T) \mathbf{X}^*)^{-1} \mathbf{X}^{*'} (\hat{\Phi}^{-1} \otimes I_T) \mathbf{y}^*$$

where $\hat{\Phi} = [\hat{\phi}_{ij}]_{i,j=1,\dots,N}$.

The preceding procedure is equivalent to Zellner's two-stage methodology applied to the transformed model (Zellner 1962).

Parks demonstrates that this estimator is consistent and asymptotically, normally distributed with

$$\text{Var}(\hat{\boldsymbol{\beta}}_P) = (\mathbf{X}' \mathbf{V}^{-1} \mathbf{X})^{-1}$$

Standard Corrections

For the PARKS option, the first-order autocorrelation coefficient must be estimated for each cross section. Let ρ be the $N \times 1$ vector of true parameters and $R = (r_1, \dots, r_N)'$ be the corresponding vector of estimates. Then, to ensure that only range-preserving estimates are used in PROC PANEL, the following modification for R is made:

$$r_i = \begin{cases} r_i & \text{if } |r_i| < 1 \\ \max(.95, r_{\max}) & \text{if } r_i \geq 1 \\ \min(-.95, r_{\min}) & \text{if } r_i \leq -1 \end{cases}$$

where

$$r_{\max} = \begin{cases} 0 & \text{if } r_i < 0 \text{ or } r_i \geq 1 \quad \forall i \\ \max_j[r_j : 0 \leq r_j < 1] & \text{otherwise} \end{cases}$$

and

$$r_{\min} = \begin{cases} 0 & \text{if } r_i > 0 \text{ or } r_i \leq -1 \quad \forall i \\ \max_j[r_j : -1 < r_j \leq 0] & \text{otherwise} \end{cases}$$

Whenever this correction is made, a warning message is printed.

Da Silva Method (Variance-Component Moving-Average Model)

The Da Silva method assumes that the observed value of the dependent variable at the t th time point on the i th cross-sectional unit can be expressed as

$$y_{it} = \mathbf{x}'_{it}\beta + a_i + b_t + e_{it} \quad i = 1, \dots, N; t = 1, \dots, T$$

where

$\mathbf{x}'_{it} = (x_{it1}, \dots, x_{itp})$ is a vector of explanatory variables for the t th time point and i th cross-sectional unit

$\beta = (\beta_1, \dots, \beta_p)'$ is the vector of parameters

a_i is a time-invariant, cross-sectional unit effect

b_t is a cross-sectionally invariant time effect

e_{it} is a residual effect unaccounted for by the explanatory variables and the specific time and cross-sectional unit effects

Since the observations are arranged first by cross sections, then by time periods within cross sections, these equations can be written in matrix notation as

$$\mathbf{y} = \mathbf{X}\beta + \mathbf{u}$$

where

$$\begin{aligned} \mathbf{u} &= (\mathbf{a} \otimes \mathbf{1}_T) + (\mathbf{1}_N \otimes \mathbf{b}) + \mathbf{e} \\ \mathbf{y} &= (y_{11}, \dots, y_{1T}, y_{21}, \dots, y_{NT})' \\ \mathbf{X} &= (\mathbf{x}_{11}, \dots, \mathbf{x}_{1T}, \mathbf{x}_{21}, \dots, \mathbf{x}_{NT})' \\ \mathbf{a} &= (a_1 \dots a_N)' \\ \mathbf{b} &= (b_1 \dots b_T)' \\ \mathbf{e} &= (e_{11}, \dots, e_{1T}, e_{21}, \dots, e_{NT})' \end{aligned}$$

Here $\mathbf{1}_N$ is an $N \times 1$ vector with all elements equal to 1, and \otimes denotes the Kronecker product.

The following conditions are assumed:

1. \mathbf{x}_{it} is a sequence of nonstochastic, known $p \times 1$ vectors in \Re^p whose elements are uniformly bounded in \Re^p . The matrix \mathbf{X} has a full column rank p .
2. $\boldsymbol{\beta}$ is a $p \times 1$ constant vector of unknown parameters.
3. \mathbf{a} is a vector of uncorrelated random variables such that $E(a_i) = 0$ and $\text{var}(a_i) = \sigma_a^2$, $\sigma_a^2 > 0, i = 1, \dots, N$.
4. \mathbf{b} is a vector of uncorrelated random variables such that $E(b_t) = 0$ and $\text{var}(b_t) = \sigma_b^2$ where $\sigma_b^2 > 0$ and $t = 1, \dots, T$.
5. $\mathbf{e}_i = (e_{i1}, \dots, e_{iT})'$ is a sample of a realization of a finite moving-average time series of order $m < T - 1$ for each i ; hence,

$$e_{it} = \alpha_0 \epsilon_t + \alpha_1 \epsilon_{t-1} + \dots + \alpha_m \epsilon_{t-m} \quad t = 1, \dots, T; i = 1, \dots, N$$

where $\alpha_0, \alpha_1, \dots, \alpha_m$ are unknown constants such that $\alpha_0 \neq 0$ and $\alpha_m \neq 0$, and $\{\epsilon_j\}_{j=-\infty}^{j=\infty}$ is a white noise process—that is, a sequence of uncorrelated random variables with $E(\epsilon_t) = 0, E(\epsilon_t^2) = \sigma_\epsilon^2$, and $\sigma_\epsilon^2 > 0$.

6. The sets of random variables $\{a_i\}_{i=1}^N, \{b_t\}_{t=1}^T$, and $\{e_{it}\}_{t=1}^T$ for $i = 1, \dots, N$ are mutually uncorrelated.
7. The random terms have normal distributions $a_i \sim N(0, \sigma_a^2), b_t \sim N(0, \sigma_b^2)$, and $\epsilon_{t-k} \sim N(0, \sigma_\epsilon^2)$, for $i = 1, \dots, N; t = 1, \dots, T$; and $k = 1, \dots, m$.

If assumptions 1–6 are satisfied, then

$$E(\mathbf{y}) = \mathbf{X}\boldsymbol{\beta}$$

and

$$\text{var}(\mathbf{y}) = \sigma_a^2 (\mathbf{I}_N \otimes \mathbf{J}_T) + \sigma_b^2 (\mathbf{J}_N \otimes \mathbf{I}_T) + (\mathbf{I}_N \otimes \boldsymbol{\Psi}_T)$$

where Ψ_T is a $T \times T$ matrix with elements ψ_{ts} as follows:

$$\text{Cov}(e_{it}e_{is}) = \begin{cases} \psi(|t-s|) & \text{if } |t-s| \leq m \\ 0 & \text{if } |t-s| > m \end{cases}$$

where $\psi(k) = \sigma_\epsilon^2 \sum_{j=0}^{m-k} \alpha_j \alpha_{j+k}$ for $k = |t-s|$. For the definition of I_N , I_T , J_N , and J_T , see the section “[Fuller and Battese’s Method](#)” on page 1292.

The covariance matrix, denoted by \mathbf{V} , can be written in the form

$$\mathbf{V} = \sigma_a^2(I_N \otimes J_T) + \sigma_b^2(J_N \otimes I_T) + \sum_{k=0}^m \psi(k)(I_N \otimes \Psi_T^{(k)})$$

where $\Psi_T^{(0)} = I_T$, and, for $k=1, \dots, m$, $\Psi_T^{(k)}$ is a band matrix whose k th off-diagonal elements are 1’s and all other elements are 0’s.

Thus, the covariance matrix of the vector of observations \mathbf{y} has the form

$$\text{Var}(\mathbf{y}) = \sum_{k=1}^{m+3} v_k V_k$$

where

$$\begin{aligned} v_1 &= \sigma_a^2 \\ v_2 &= \sigma_b^2 \\ v_k &= \psi(k-3) \quad k = 3, \dots, m+3 \\ V_1 &= I_N \otimes J_T \\ V_2 &= J_N \otimes I_T \\ V_k &= I_N \otimes \Psi_T^{(k-3)} \quad k = 3, \dots, m+3 \end{aligned}$$

The estimator of $\boldsymbol{\beta}$ is a two-step GLS-type estimator—that is, GLS with the unknown covariance matrix replaced by a suitable estimator of \mathbf{V} . It is obtained by substituting Seely estimates for the scalar multiples v_k , $k = 1, 2, \dots, m+3$.

Seely (1969) presents a general theory of unbiased estimation when the choice of estimators is restricted to finite dimensional vector spaces, with a special emphasis on quadratic estimation of functions of the form $\sum_{i=1}^n \delta_i v_i$.

The parameters v_i ($i=1, \dots, n$) are associated with a linear model $E(\mathbf{y}) = \mathbf{X}\boldsymbol{\beta}$ with covariance matrix $\sum_{i=1}^n v_i V_i$ where V_i ($i=1, \dots, n$) are real symmetric matrices. The method is also discussed by Seely (1970a, 1970b) and Seely and Zyskind (1971). Seely and Soong (1971) consider the MINQUE principle, using an approach along the lines of Seely (1969).

Dynamic Panel Estimator

For an example on dynamic panel estimation using GMM option, see “[Example 19.6: The Cigarette Sales Data: Dynamic Panel Estimation with GMM](#)” on page 1343.

Consider the case of the following general model:

$$y_{it} = \sum_{l=1}^{\text{maxlag}} \phi_l y_{i(t-l)} + \sum_{k=1}^K \beta_k x_{itk} + \gamma_i + \alpha_t + \epsilon_{it}$$

The x variables can include ones that are correlated or uncorrelated to the individual effects, predetermined, or strictly exogenous. The γ and α are cross-sectional and time series fixed effects, respectively. Arellano and Bond (1991) show that it is possible to define conditions that should result in a consistent estimator.

Consider the simple case of an autoregression in a panel setting (with only individual effects):

$$y_{it} = \phi y_{i(t-1)} + \gamma_i + \epsilon_{it}$$

Differencing the preceding relationship results in:

$$\Delta y_{it} = \phi \Delta y_{i(t-1)} + v_{it}$$

where $v_{it} = \epsilon_{it} - \epsilon_{i(t-1)}$.

Obviously, y is not exogenous. However, Arellano and Bond (1991) show that it is still useful as an instrument, if properly lagged.

For $t = 2$ (assuming the first observation corresponds to time period 1) you have,

$$\Delta y_{i2} = \phi \Delta y_{i1} + v_{i2}$$

Using y_{i1} as an instrument is not a good idea since $\text{Cov}(\epsilon_{i1}, v_{i2}) \neq 0$. Therefore, since it is not possible to form a moment restriction, you discard this observation.

For $t = 3$ you have,

$$\Delta y_{i3} = \phi \Delta y_{i2} + v_{i3}$$

Clearly, you have every reason to suspect that $\text{Cov}(\epsilon_{i1}, v_{i3}) = 0$. This condition forms one restriction.

For $t = 4$, both $\text{Cov}(\epsilon_{i1}, v_{i4}) = 0$ and $\text{Cov}(\epsilon_{i2}, v_{i4}) = 0$ must hold.

Proceeding in that fashion, you have the following matrix of instruments,

$$\mathbf{Z}_i = \begin{pmatrix} y_{i1} & 0 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & y_{i1} & y_{i2} & 0 & \cdots & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & y_{i1} & y_{i2} & y_{i3} & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & & & & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & y_{i1} & \cdots & y_{i(T-2)} \end{pmatrix}$$

Using the instrument matrix, you form the weighting matrix \mathbf{A}_N as

$$\mathbf{A}_N = \left(\frac{1}{N} \sum_i \mathbf{Z}_i' \mathbf{H}_i \mathbf{Z}_i \right)^{-1}$$

The initial weighting matrix is

$$\mathbf{H}_i = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 & \cdots & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & & & & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 2 \end{pmatrix}$$

Note that the maximum size of the \mathbf{H}_i matrix is $T-2$. The origins of the initial weighting matrix are the expected error covariances. Notice that on the diagonals,

$$E(v_{it}v_{it}) = E(\epsilon_{it}^2 - 2\epsilon_{it}\epsilon_{i(t-1)} + \epsilon_{i(t-1)}^2) = 2\sigma_\epsilon^2$$

and off diagonals,

$$E(v_{it}v_{i(t-1)}) = E(\epsilon_{it}\epsilon_{i(t-1)} - \epsilon_{it}\epsilon_{i(t-2)} - \epsilon_{i(t-1)}\epsilon_{i(t-1)} + \epsilon_{i(t-1)}\epsilon_{i(t-2)}) = -\sigma_\epsilon^2$$

If you let the vector of lagged differences (in the series y_{it}) be denoted as Δy_{i-} and the dependent variable as Δy_i , then the optimal GMM estimator is

$$\phi = \left[\left(\sum_i \Delta y_{i-}' \mathbf{Z}_i \right) A_N \left(\sum_i \mathbf{Z}_i' \Delta y_{i-} \right) \right]^{-1} \left(\sum_i \Delta y_{i-}' \mathbf{Z}_i \right) A_N \left(\sum_i \mathbf{Z}_i' \Delta y_i \right)$$

Using the estimate, $\hat{\phi}$, you can obtain estimates of the errors, $\hat{\epsilon}$, or the differences, \hat{v} . From the errors, the variance is calculated as,

$$\sigma^2 = \frac{\hat{\epsilon}'\hat{\epsilon}}{M-1}$$

where $M = \sum_{i=1}^N T_i$ is the total number of observations.

Furthermore, you can calculate the variance of the parameter as,

$$\sigma^2 \left[\left(\sum_i \Delta y_{i-}' \mathbf{Z}_i \right) A_N \left(\sum_i \mathbf{Z}_i' \Delta y_{i-} \right) \right]^{-1}$$

Alternatively, you can view the initial estimate of the ϕ as a first step. That is, by using $\hat{\phi}$, you can improve the estimate of the weight matrix, A_N .

Instead of imposing the structure of the weighting, you form the \mathbf{H}_i matrix through the following:

$$\mathbf{H}_i = \hat{v}_i \hat{v}_i'$$

You then complete the calculation as previously shown. The PROC PANEL option TWOSTEP specifies this estimation.

The case of multiple right-hand-side variables illustrates more clearly the power of Arellano and Bond (1991) and Arellano and Bover (1995).

Considering the general case you have:

$$y_{it} = \sum_{l=1}^{maxlag} \phi_l y_{i(t-l)} + \mathbf{X}_i + \gamma_i + \alpha_t + \epsilon_{it}$$

It is clear that lags of the dependent variable are both not exogenous and correlated to the fixed effects. However, the independent variables can fall into one of several categories. An independent variable can be correlated and exogenous, uncorrelated and exogenous, correlated and predetermined, and uncorrelated and predetermined. The category in which an independent variable is found influences when or whether it becomes a suitable instrument. Note, however, that neither PROC PANEL nor Arellano and Bond require that a regressor be an instrument or that an instrument be a regressor.

First, consider the question of exogenous or endogenous. An exogenous variable is not correlated with the error term in the model at all. Therefore, all observations (on the exogenous variable) become valid instruments at all time periods. If the model has only one instrument and it happens to be exogenous, then the optimal instrument matrix looks like,

$$\mathbf{Z}_i = \begin{pmatrix} x_{i1} \cdots x_{iT} & 0 & 0 & 0 & 0 \\ 0 & x_{i1} \cdots x_{iT} & 0 & 0 & 0 \\ 0 & 0 & x_{i1} \cdots x_{iTS} & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & x_{i1} \cdots x_{iTS} \end{pmatrix}$$

The situation for the predetermined variables becomes a little more difficult. A predetermined variable is one whose future realizations can be correlated to current shocks in the dependent variable. With such an understanding, it is admissible to allow all current and lagged realizations as instruments. In other words you have,

$$\mathbf{Z}_i = \begin{pmatrix} x_{i1} & 0 & 0 & 0 & 0 \\ 0 & x_{i1}x_{i2} & 0 & 0 & 0 \\ 0 & 0 & x_{i1} \cdots x_{i3} & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & x_{i1} \cdots x_{i(TS-2)} \end{pmatrix}$$

When the data contain a mix of endogenous, exogenous, and predetermined variables, the instrument matrix is formed by combining the three. The third observation would have one observation on the dependent variable as an instrument, three observations on the predetermined variables as instruments, and all observations on the exogenous variables.

There is yet another set of moment restrictions that can be employed. An uncorrelated variable means that the variable's level is not affected by the individual specific effect. You write the general model presented above as:

$$y_{it} = \sum_{l=1}^{maxlag} \phi_l y_{i(t-l)} + \sum_{k=1}^K \beta_k x_{itk} + \alpha_t + \mu_{it}$$

where $\mu_{it} = \gamma_i + \epsilon_{it}$.

Since the variables are uncorrelated with γ and uncorrelated with the error, you can perform a system estimation with the difference and level equations. That is, the uncorrelated variables imply moment restrictions on the level equation. If you denote the new instrument matrix with the full complement of instruments available by a $*$ and both x^p and x^e are uncorrelated, then you have:

$$\mathbf{Z}_i^* = \begin{pmatrix} \mathbf{Z}_i & 0 & 0 & 0 & 0 \\ 0 & x_{i1}^p & x_{i1}^e & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & x_{iTS}^p & x_{iTS}^e \end{pmatrix}$$

The formation of the initial weighting matrix becomes somewhat problematic. If you denote the new weighting matrix with a $*$, then you can write the following:

$$A_N^* = \left(\frac{1}{N} \sum_i \mathbf{Z}_i^{*'} \mathbf{H}_i^* \mathbf{Z}_i^* \right)^{-1}$$

where

$$\mathbf{H}_i^* = \begin{pmatrix} \mathbf{H}_i & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \end{pmatrix}$$

To finish, you write out the two equations (or two stages) that are estimated.

$$\Delta y_{it} = \boldsymbol{\beta}^* \Delta \mathbf{S}_i + \alpha_t - \alpha_{t-1} + v_{it} \qquad y_{it} = \boldsymbol{\beta}^* \mathbf{S}_i + \gamma_i + \alpha_t + \epsilon_{it}$$

where \mathbf{S}_i is the matrix of all explanatory variables, lagged endogenous, exogenous, and predetermined.

Let \mathbf{y}_{it}^* be given by

$$\mathbf{y}_{it}^* = \begin{pmatrix} \Delta y_{it} \\ y_{it} \end{pmatrix} \quad \boldsymbol{\beta}^* = (\boldsymbol{\phi} \quad \boldsymbol{\beta}) \quad \mathbf{S}_i^* = \begin{pmatrix} \Delta \mathbf{S}_i \\ \mathbf{S}_i \end{pmatrix}$$

Using the information above,

$$\boldsymbol{\beta}^* = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i \right) \right]^{-1} \left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{y}_i^* \right)$$

If the TWOSTEP or ITGMM option is not requested, estimation terminates here. If it terminates, you can obtain the following information.

Variance of the error term comes from the second stage equation—that is,

$$\sigma^2 = \frac{\hat{\boldsymbol{\epsilon}}' \hat{\boldsymbol{\epsilon}}}{M - p}$$

where p is the number of regressors.

The variance covariance matrix can be obtained from

$$\left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1} \sigma^2$$

Alternatively, a robust estimate of the variance covariance matrix can be obtained by specifying the ROBUST option. Without further reestimation of the model, the \mathbf{H}_i^* matrix is recalculated as follows:

$$\mathbf{H}_{i,2}^* = \begin{pmatrix} \mathbf{v}\mathbf{v}' & 0 \\ 0 & \boldsymbol{\epsilon}\boldsymbol{\epsilon}' \end{pmatrix}$$

And the weighting matrix becomes

$$A_{N,2}^* = \left(\frac{1}{N} \sum_i \mathbf{Z}_i^{*'} \mathbf{H}_{i,2}^* \mathbf{Z}_i^* \right)^{-1}$$

Using the information above, you construct the robust variance covariance matrix from the following:

Let \mathbf{G} denote a temporary matrix.

$$\mathbf{G} = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_{*i} \right) \right]^{-1} \left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^*$$

The robust variance covariance estimate of $\boldsymbol{\beta}^*$ is:

$$\mathbf{V}^{robust}(\boldsymbol{\beta}^*) = \mathbf{G} A_{N,2}^{*-1} \mathbf{G}'$$

Alternatively, the new weighting matrix can be used to form an updated estimate of the regression parameters. This results when the TWOSTEP option is requested. In short,

$$\boldsymbol{\beta}^* = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1} \left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right)$$

The variance covariance estimate of the two step $\boldsymbol{\beta}^*$ becomes

$$\mathbf{V}(\boldsymbol{\beta}^*) = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1}$$

As a final note, it is possible to iterate more than twice by specifying the ITGMM option. Such a multiple iteration should result in a more stable estimate of the variance covariance estimate. PROC

PANEL allows two convergence criteria. Convergence can occur in the parameter estimates or in the weighting matrices. Iterate until

$$\max_{i,j \leq \dim(A_{N,k})} \frac{|A_{N,k+1}^*(i,j) - A_{N,k}^*(i,j)|}{|A_{N,k}^*(i,j)|} \leq \text{ATOL}$$

or

$$\max_{i \leq \dim(\beta_k^*)} \frac{|\beta_{k+1}^*(i) - \beta_k^*(i)|}{|\beta_k^*(i)|} \leq \text{BTOL}$$

where ATOL is the tolerance for convergence in the weighting matrix and BTOL is the tolerance for convergence in the parameter estimate matrix. The default convergence criteria is BTOL = 1E-8 for PROC PANEL.

Specification Testing For Dynamic Panel

Specification tests under the GMM in PROC PANEL follow Arellano and Bond (1991) very generally. The first test available is a Sargan/Hansen test of over-identification. The test for a one-step estimation is constructed as

$$\left(\sum_i \eta_i' \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \eta_i \right) \sigma^2$$

where η_i is the stacked error term (of the differenced equation and level equation).

When the robust weighting matrix is used, the test statistic is computed as

$$\left(\sum_i \eta_i' \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \eta_i \right)$$

This definition of the Sargan test is used for all iterated estimations. The Sargan test is distributed as a χ^2 with degrees of freedom equal to the number of moment conditions minus the number of parameters.

In addition to the Sargan test, PROC PANEL tests for autocorrelation in the residuals. These tests are distributed as standard normal. PROC PANEL tests the hypothesis that the autocorrelation of the l th lag is significant.

Define ω_l as the lag of the differenced error, with zero padding for the missing values generated. Symbolically,

$$\omega_l = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ v_1 \\ \vdots \\ v_{TS-2-l} \end{pmatrix}$$

You define the constant k_0 as

$$k_0(l) = \sum_i \omega'_{l,i} v_i$$

You next define the constant k_1 as

$$k_1(l) = \sum_i \omega'_{l,i} \mathbf{H}_i \omega_{l,i}$$

Note that the choice of \mathbf{H}_i is dependent on the stage of estimation. If the estimation is first stage, then you would use the matrix with twos along the main diagonal, and minus ones along the primary subdiagonals. In a robust estimation or multi-step estimation, this matrix would be formed from the outer product of the residuals (from the previous step).

Define the constant k_2 as

$$k_2(l) = -2 \left(\sum_i \omega'_{l,i} \Delta S_i \right) \mathbf{G} \left(\sum_i \Delta S_i' \mathbf{Z}_i \right) A_{N,k} \left(\sum_i \mathbf{Z}_i' \mathbf{H}_i \omega_{l,i} \right)$$

The matrix \mathbf{G} is defined as

$$\mathbf{G} = \left[\left(\sum_i \Delta S_i^{*'} \mathbf{Z}_i^* \right) A_{N,k}^* \left(\sum_i \mathbf{Z}_i^{*'} \Delta S_i^* \right) \right]^{-1}$$

The constant k_3 is defined as

$$k_3(l) = \left(\sum_i \omega'_{l,i} \Delta S_i \right) V(\beta^*) \left(\sum_i \Delta S_i' \omega_{l,i} \right)$$

Using the four quantities, the test for autoregressive structure in the differenced residual is

$$m(l) = \frac{k_0(l)}{\sqrt{k_1(l) + k_2(l) + k_3(l)}}$$

The m statistic is distributed as a normal random variable with mean zero and standard deviation of one.

Instrument Choice

Arellano and Bond's technique is a very useful method for dealing with any autoregressive characteristics in the data. However, there is one caveat to consider. Too many instruments bias the estimator to the within estimate. Furthermore, many instruments make this technique not scalable. The weighting matrix becomes very large, so every operation that involves it becomes more computationally intensive. The PANEL procedure enables you to specify a bandwidth for instrument selection. For example, specifying MAXBAND=10 means that at most there will be ten time observations for each variable entering as an instrument. The default is to follow the Arellano-Bond methodology.

In specifying a maximum bandwidth, you can also specify the selection of the time observations. There are three possibilities: leading, trailing (default), and centered. The exact consequence of choosing any of those possibilities depends on the variable type (correlated, exogenous, or predetermined) and the time period of the current observation.

If the MAXBAND option is specified, then the following is true under any selection criterion (let t be the time subscript for the current observation). The first observation for the endogenous variable (as instrument) is $\max(t - \text{MAXBAND}, 2)$ and the last instrument is $t - 2$. The first observation for a predetermined variable is $\max(t - \text{MAXBAND}, 2)$ and $t - 1$. The first and last observation for an exogenous variable is given in the list below.

- *Trailing*: If $t < \text{MAXBAND}$, then the first instrument is for the first time period and the last observation is MAXBAND. Otherwise, if $t \geq \text{MAXBAND}$, then the first observation is $t - \text{MAXBAND}$, while the last instrument to enter is t .
- *Centered*: If $t \leq \frac{\text{MAXBAND}}{2}$, then the first observation is the first time period and the last observation is MAXBAND. If $t > T - \frac{\text{MAXBAND}}{2}$, then the first instrument included is the $T - \text{MAXBAND} + 1$ and the last observation is T . If $\frac{\text{MAXBAND}}{2} < t \leq T - \frac{\text{MAXBAND}}{2}$, then the first included instrument is $t - \frac{\text{MAXBAND}}{2} + 1$ and the last observation is $t + \frac{\text{MAXBAND}}{2}$. If the MAXBAND value is an odd number, the procedure decrements by one.
- *Leading* : If $t > T - \text{MAXBAND}$, then the first instrument corresponds to time period $T - \text{MAXBAND}$, while the last observation is TS . Otherwise, if $t \leq T - \text{MAXBAND}$, then the first observation is t and the last observation is $t +$.

The PANEL procedure enables you to include dummy variables to deal with the presence of time effects not captured by including the lagged dependent variable. The dummy variables directly affect the level equations. However, this implies that the difference of the dummy variables for dummy variable of time period t and $t - 1$ enters the difference equation. The first usable observation occurs at $t = 3$. If the level equation is not used in the estimation, then there is no way to identify the dummy variables. Selecting the TIME option gives the same result as that which would be obtained by creating dummy variables in the data set and using those in the regression.

The PANEL procedure gives you several options when it comes to missing values and unbalanced panel. By default, any time period for which there are missing values is skipped. The corresponding rows and columns of \mathbf{H} matrices are zeroed, and the calculation is continued. Alternatively, you can elect to replace missing values and missing observations with zeros (ZERO), the overall mean of the series (OAM), the cross-sectional mean (CSM), or the time series mean (TSM).

Linear Hypothesis Testing

For a linear hypothesis of the form $\mathbf{R}\beta = \mathbf{r}$ where \mathbf{R} is $J \times K$ and \mathbf{r} is $J \times 1$, the F -statistic with $J, M - K$ degrees of freedom is computed as

$$(\mathbf{R}\hat{\beta} - \mathbf{r})' [\mathbf{R}\hat{\mathbf{V}}\mathbf{R}]^{-1} (\mathbf{R}\hat{\beta} - \mathbf{r})$$

However, it is also possible to write the F statistic as

$$F = \frac{(\hat{\mathbf{u}}_*' \hat{\mathbf{u}}_* - \hat{\mathbf{u}}' \hat{\mathbf{u}}) / J}{\hat{\mathbf{u}}' \hat{\mathbf{u}} / (M - K)}$$

where

$\hat{\mathbf{u}}_*$ is the residual vector from the restricted regression

$\hat{\mathbf{u}}$ is the residual vector from the unrestricted regression

J is the number of restrictions

$(M - K)$ are the degrees of freedom

The Wald, likelihood ratio (LR) and Lagrange multiplier (LM) tests are all related to the F test. You use this relationship of the F test to the likelihood ratio and Lagrange multiplier tests. The Wald test is calculated from its definition.

The Wald test statistic is:

$$W = (\mathbf{R}\hat{\boldsymbol{\beta}} - \mathbf{r})' [\hat{\mathbf{R}}\hat{\mathbf{V}}\hat{\mathbf{R}}']^{-1} (\mathbf{R}\hat{\boldsymbol{\beta}} - \mathbf{r})$$

The advantage of calculating Wald in this manner is that it enables you to substitute a heteroscedasticity-corrected covariance matrix for the matrix \mathbf{V} . PROC PANEL makes such a substitution if you request the HCCME option in the MODEL statement.

The likelihood ratio is:

$$LR = M \ln \left[1 + \frac{1}{M - K} JF \right]$$

The Lagrange multiplier test statistic is:

$$LM = M \left[\frac{JF}{M - K + JF} \right]$$

Note that only the Wald is changed when the HCCME option is selected. The LR and LM tests are unchanged.

The distribution of these test statistics is the χ^2 with degrees of freedom equal to the number of restrictions imposed (J). The three tests are asymptotically equivalent, but they have differing small sample properties. Greene (2000, p. 392) and Davidson and MacKinnon (1993, pg. 456-458) discuss the small sample properties of these statistics.

Heteroscedasticity-Corrected Covariance Matrices

The MODEL statement HCCME= option is used to select the type of heteroscedasticity-consistent covariance matrix. In the presence of heteroscedasticity, the covariance matrix has a complicated structure which can result in inefficiencies in the OLS estimates and biased estimates of the variance

covariance matrix. Consider the simple linear model (this discussion parallels the discussion in Davidson and MacKinnon, 1993, pg. 548-562):

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

The assumptions that make the linear regression best linear unbiased estimator (BLUE) are $E(\boldsymbol{\epsilon}) = 0$ and $E(\boldsymbol{\epsilon}\boldsymbol{\epsilon}') = \boldsymbol{\Omega}$, where $\boldsymbol{\Omega}$ has the simple structure $\sigma^2\mathbf{I}$. Heteroscedasticity results in a general covariance structure, so that it is not possible to simplify $\boldsymbol{\Omega}$. The result is the following:

$$\tilde{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'(\mathbf{X}_c + \boldsymbol{\gamma}) = \boldsymbol{\beta} + (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\gamma}$$

As long as the following is true, then you are assured that the OLS estimate is consistent and unbiased:

$$plim_{n \rightarrow \infty} \left(\frac{1}{n}\mathbf{X}'\boldsymbol{\epsilon} \right) = 0$$

If the regressors are nonrandom, then it is possible to write the variance of the estimated $\boldsymbol{\beta}$ as the following:

$$\text{Var}(\boldsymbol{\beta} - \tilde{\boldsymbol{\beta}}) = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}$$

The effect of structure in the variance covariance matrix can be ameliorated by using generalized least squares (GLS), provided that $\boldsymbol{\Omega}^{-1}$ can be calculated. Using $\boldsymbol{\Omega}^{-1}$, you premultiply both sides of the regression equation,

$$\boldsymbol{\Omega}^{-1}\mathbf{y} = \boldsymbol{\Omega}^{-1}\mathbf{X}_c + \boldsymbol{\Omega}^{-1}\boldsymbol{\epsilon}$$

The resulting GLS $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{y}$$

Using the GLS $\boldsymbol{\beta}$, you can write

$$\begin{aligned} \hat{\boldsymbol{\beta}} &= (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{y} \\ &= (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}\mathbf{X}'(\boldsymbol{\Omega}^{-1}\mathbf{X}_c + \boldsymbol{\Omega}^{-1}\boldsymbol{\epsilon}) \\ &= \boldsymbol{\beta} + (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}^{-1}\boldsymbol{\epsilon} \end{aligned}$$

The resulting variance expression for the GLS estimator is

$$\begin{aligned} \text{Var}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}}) &= (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}^{-1}\boldsymbol{\epsilon}\boldsymbol{\epsilon}'\boldsymbol{\Omega}^{-1}\mathbf{X}(\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1} \\ &= (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}^{-1}\boldsymbol{\Omega}\boldsymbol{\Omega}^{-1}\mathbf{X}(\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1} \\ &= (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1} \end{aligned}$$

The difference in variance between the OLS estimator and the GLS estimator can be written as

$$(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\Omega}\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1} - (\mathbf{X}'\boldsymbol{\Omega}^{-1}\mathbf{X})^{-1}$$

By the Gauss Markov Theory, the difference matrix must be positive definite under most circumstances (zero if OLS and GLS are the same, when the usual classical regression assumptions are

met). Thus, OLS is not efficient under a general error structure. It is crucial to realize is that OLS does not produce biased results. It would suffice if you had a method for estimating a consistent covariance matrix and you used the OLS β . Estimation of the Ω matrix is by no means simple. The matrix is square and has M^2 elements, so unless some sort of structure is assumed, it becomes an impossible problem to solve. However, the heteroscedasticity can have quite a general structure. White (1980) shows that it is not necessary to have a consistent estimate of Ω . On the contrary, it suffices to get an estimate of the middle expression. That is, you need an estimate of:

$$\Lambda = \mathbf{X}' \Omega \mathbf{X}$$

This matrix, Λ , is easier to estimate because its dimension is K . PROC PANEL provides the following classical HCCME estimators:

The matrix Λ is approximated by:

- *HCCME=N0*: This is the simple OLS estimator so $(\mathbf{X}'\mathbf{X})$. If you do not request the *HCCME=* option, then PROC PANEL defaults to this estimator.
- *HCCME=0*:

$$\frac{1}{M} \sum_{i=0}^M \hat{\epsilon}_i^2 \mathbf{x}_i \mathbf{x}_i'$$

The \mathbf{x}_i constitutes the *i*th row of the matrix \mathbf{X}_s .

- *HCCME=1*:

$$\frac{1}{M} \sum_{i=0}^M \left(\frac{M}{M-K} \hat{\epsilon}_i^2 \mathbf{x}_i \mathbf{x}_i' \right)$$

- *HCCME=2*:

$$\frac{1}{M} \sum_{i=0}^M \frac{\hat{\epsilon}_i^2}{1 - \hat{h}_i} \mathbf{x}_i \mathbf{x}_i'$$

The \hat{h}_i term is *i*th diagonal element of the so called hat matrix. The expression for \hat{h}_i is $\mathbf{X}_i (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}_i'$. The hat matrix attempts to adjust the estimates for the presence of influence or leverage points.

- *HCCME=3*:

$$\frac{1}{n} \sum_{i=0}^M \frac{\hat{\epsilon}_i^2}{(1 - \hat{h}_i)^2} \mathbf{x}_i \mathbf{x}_i'$$

- *HCCME=4*: This is the Arellano (1987) version of the White (1980) HCCME for panel. PROC PANEL includes an option for the calculation of the Arellano (1987) version of the White HCCME in the panel setting. Arellano's insight is that in a panel there are N covariance matrices, each corresponding to a cross section. Forming the White (1980) HCCME for each panel, you need to take only the average of those N estimators that yield Arellano. The details

of the estimation follow. First, you arrange the data such that the first cross section occupies the first T_i observations. You treat the panels as separate regressions with the form:

$$\mathbf{y}_i = \alpha_i \mathbf{i} + \mathbf{X}_{i,s} \tilde{\boldsymbol{\beta}} + \boldsymbol{\epsilon}_i$$

The parameter estimates $\tilde{\boldsymbol{\beta}}$ and α_i are the result of LSDV or within estimator. \mathbf{i} is a vector ones of length T_i . The estimate of the i th cross section's $\mathbf{X}'\Omega\mathbf{X}$ matrix (where the s subscript indicates that no constant column has been suppressed to avoid confusion) is $\mathbf{X}'_i\Omega\mathbf{X}_i$. The estimate for the whole sample is:

$$\mathbf{X}'_s\Omega\mathbf{X}_s = \sum_{i=1}^N \mathbf{X}'_i\Omega\mathbf{X}_i$$

The Arellano standard error is in fact a White-Newey-West estimator with constant and equal weight on each component. It should be noted that, in the between estimators, selecting HCCME = 4 returns the HCCME = 0 result since there is no 'other' variable to group by.

In their discussion, Davidson and MacKinnon (1993, pg. 554) argue that HCCME=1 should always be preferred to HCCME=0. While generally HCCME=3 is preferred to 2 and 2 is preferred to 1, the calculation of HCCME=1 is as simple as the calculation of HCCME=0. Therefore, it is clear that HCCME=1 is preferred when the calculation of the hat matrix is too tedious.

All HCCME estimators have well defined asymptotic properties. The small sample properties are not well known, and care must be exercised when sample sizes are small.

The HCCME estimator of $\text{Var}(\boldsymbol{\beta})$ is used to drive the covariance matrices for the fixed effects and the Lagrange multiplier standard errors. Robust estimates of the variance covariance matrix for $\boldsymbol{\beta}$ imply robust variance covariance matrices for all other parameters.

R-Square

The conventional R-square measure is inappropriate for all models that the PANEL procedure estimates by using GLS since a number outside the [0,1] range might be produced. Hence, a generalization of the R-square measure is reported. The following goodness-of-fit measure (Buse 1973) is reported:

$$R^2 = 1 - \frac{\hat{\mathbf{u}}' \hat{\mathbf{V}}^{-1} \hat{\mathbf{u}}}{\mathbf{y}' \mathbf{D}' \hat{\mathbf{V}}^{-1} \mathbf{D} \mathbf{y}}$$

where $\hat{\mathbf{u}}$ are the residuals of the transformed model, $\hat{\mathbf{u}} = \mathbf{y} - \mathbf{X}(\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} \mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{y}$,

and $\mathbf{D} = \mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M \left(\frac{\hat{\mathbf{V}}^{-1}}{\mathbf{j}'_M \hat{\mathbf{V}}^{-1} \mathbf{j}_M} \right)$.

This is a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables.

If there is no intercept in the model, the corresponding measure (Theil 1961) is

$$R^2 = 1 - \frac{\hat{\mathbf{u}}' \hat{\mathbf{V}}^{-1} \hat{\mathbf{u}}}{\mathbf{y}' \hat{\mathbf{V}}^{-1} \mathbf{y}}$$

However, the fixed-effects models are somewhat different. In the case of a fixed-effects model, the choice of including or excluding an intercept becomes merely a choice of classification. Suppressing the intercept in the FIXONE or FIXONETIME case merely changes the name of the intercept to a fixed effect. It makes no sense to redefine the R-square measure since nothing material changes in the model. Similarly, for the FIXTWO model there is no reason to change R-square. In the case of the FIXONE, FIXONETIME, and FIXTWO models, the R-square is defined as the Theil (1961) R-square (detailed above). This makes intuitive sense since you are regressing a transformed (demeaned) series on transformed regressors, excluding a constant. In other words, you are looking at one minus the sum of squared errors divided by the sum of squares of the (transformed) dependent variable.

In the case of OLS estimation, both of the R-square formulas given here reduce to the usual R-square formula.

Specification Tests

The PANEL procedure outputs the results of one specification test for fixed effects and two specification tests for random effects.

For fixed effects, let β_f be the n dimensional vector of fixed-effects parameters. The specification test reported is the conventional F statistic for the hypothesis $\beta_f = \mathbf{0}$. The F statistic with $n, M - K$ degrees of freedom is computed as

$$\hat{\beta}_f' \hat{\mathbf{S}}_f^{-1} \hat{\beta}_f / n$$

where $\hat{\mathbf{S}}_f$ is the estimated covariance matrix of the fixed-effects parameters.

Hausman's (1978) specification test or m statistic can be used to test hypotheses in terms of bias or inconsistency of an estimator. This test was also proposed by Wu (1973) and further extended in Hausman and Taylor (1982). Hausman's m statistic is as follows.

Consider two estimators, $\hat{\beta}_a$ and $\hat{\beta}_b$, which under the null hypothesis are both consistent, but only $\hat{\beta}_a$ is asymptotically efficient. Under the alternative hypothesis, only $\hat{\beta}_b$ is consistent. The m statistic is

$$m = (\hat{\beta}_b - \hat{\beta}_a)' (\hat{\mathbf{S}}_b - \hat{\mathbf{S}}_a)^{-1} (\hat{\beta}_b - \hat{\beta}_a)$$

where $\hat{\mathbf{S}}_b$ and $\hat{\mathbf{S}}_a$ are consistent estimates of the asymptotic covariance matrices of $\hat{\beta}_b$ and $\hat{\beta}_a$. Then m is distributed χ^2 with k degrees of freedom, where k is the dimension of $\hat{\beta}_a$ and $\hat{\beta}_b$.

In the random-effects specification, the null hypothesis of no correlation between effects and regressors implies that the OLS estimates of the slope parameters are consistent and inefficient but the GLS estimates of the slope parameters are consistent and efficient. This facilitates a Hausman

specification test. The reported χ^2 statistic has degrees of freedom equal to the number of slope parameters.

Breusch and Pagan (1980) lay out a Lagrange multiplier test for random effects based on the simple OLS (pooled) estimator. If \hat{u}_{it} is the it th residual from the OLS regression, then the Breusch-Pagan (BP) test for one-way random effects is

$$BP = \frac{NT}{2(T-1)} \left[\frac{\sum_{i=1}^N \left[\sum_{t=1}^T \hat{u}_{it} \right]^2}{\sum_{i=1}^N \sum_{t=1}^T \hat{u}_{it}^2} - 1 \right]^2$$

The BP test generalizes to the case of a two-way random-effects model (Greene 2000, page 589). Specifically,

$$BP2 = \frac{NT}{2(T-1)} \left[\frac{\sum_{i=1}^n \left[\sum_{t=1}^T \hat{u}_{it} \right]^2}{\sum_{i=1}^n \sum_{t=1}^T \hat{u}_{it}^2} - 1 \right]^2 + \frac{NT}{2(N-1)} \left[\frac{\sum_{t=1}^T \left[\sum_{i=1}^N \hat{u}_{it} \right]^2}{\sum_{i=1}^N \sum_{t=1}^T \hat{u}_{it}^2} - 1 \right]^2$$

is distributed as a χ^2 statistic with two degrees of freedom. Since the BP2 test generalizes (nests the BP test) the test for random effects, the absence of random effects (nonrejection of the null of no random effects) in the BP2 is a fairly clear indication that there will probably not be any one-way effects either. In both cases (BP and BP2), the residuals are obtained from a pooled regression. There is very little extra cost in selecting both the BP and BP2 test. Notice that in the case of just groupwise heteroscedasticity, the BP2 test approaches BP. In the case of time based heteroscedasticity, the BP2 test reduces to a BP test of time effects. In the case of unbalanced panels, neither the BP nor BP2 statistics are valid.

Finally, you should be aware that the BP option generates different results depending on whether the estimation is FIXONE or FIXONET. Specifically, under the FIXONE estimation technique, the BP tests for cross-sectional random effects. Under the FIXONET estimation, the BP tests for time random effects.

While the Hausman statistic is automatically generated, you request Breusch-Pagan via the BP or BP2 option (see Baltagi 1995 for details).

Troubleshooting

Some guidelines need to be followed when you use PROC PANEL for analysis. For each cross section, PROC PANEL requires at least two time series observations with nonmissing values for all model variables. There should be at least two cross sections for each time point in the data. If these two conditions are not met, then an error message is printed in the log stating that there is only one cross section or time series observation and further computations will be terminated. You have to

give adequate data for an estimation method to produce results, and you should check the log for any data related errors.

If the number of cross sections is greater than the number of time series observations per cross section, PROC PANEL while using PARKS method produces an error message stating that the phi matrix is singular. This is analogous to seemingly unrelated regression with fewer observations than equations in the model. To avoid the problem, reduce the number of cross sections.

Your data set could have multiple observations for each time ID within a particular cross section. However, PROC PANEL is applicable only in cases where you have only a single observation for each time ID within each cross section. In such a case, after you have sorted the data, an error warning specifying that the data has not been sorted in ascending sequence with respect to time series ID appears in the log.

The cause of the error is due to multiple observations for each time ID for a given cross section. PROC PANEL allows only one observation for each time ID within each cross section.

The following data set shown in [Figure 19.2](#) illustrates the preceding instance with the correct representation.

Figure 19.2 Single Observation for Each Time Series

Obs	firm	year	production	cost
1	1	1955	5.36598	1.14867
2	1	1960	6.03787	1.45185
3	1	1965	6.37673	1.52257
4	1	1970	6.93245	1.76627
5	2	1955	6.54535	1.35041
6	2	1960	6.69827	1.71109
7	2	1965	7.40245	2.09519
8	2	1970	7.82644	2.39480

In this case, you can observe that there are no multiple observations with respect to a given time series ID within a cross section. This is the correct representation of a data set where PROC PANEL is applicable.

If for state ID 1 you have two observations for the year=1955, then PROC PANEL produces the following error message:

“The data set is not sorted in ascending sequence with respect to time series ID. The current time period has year=1955 and the previous time period has year=1955 in cross section firm=1.”

A data set similar to the previous example with multiple observations for the YEAR=1955 is shown in [Figure 19.3](#); this data set results in an error message due to multiple observations while using PROC PANEL.

Figure 19.3 Multiple Observations for Each Time Series

Obs	firm	year	production	cost
1	1	1955	5.36598	1.14867
2	1	1955	6.37673	1.52257
3	1	1960	6.03787	1.45185
4	1	1970	6.93245	1.76627
5	2	1955	6.54535	1.35041
6	2	1960	6.69827	1.71109
7	2	1965	7.40245	2.09519
8	2	1970	7.82644	2.39480

In order to use PROC PANEL, you need to aggregate the data so that you have unique time ID values within each cross section. One possible way to do this is to run a PROC MEANS on the input data set and compute the mean of all the variables by FIRM and YEAR, and then use the output data set.

ODS Graphics

This section describes the use of ODS for creating graphics with the PANEL procedure. Both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. The table below lists the graph names, the plot descriptions, and the options used.

Table 19.2 ODS Graphics Produced by PROC PANEL

ODS Graph Name	Plot Description	Plots=Option
ResidualPlot	Plot of the residuals	Residual, Resid
FitPlot	Predicted versus actual plot	Fitplot
QQPlot	Plot of the quantiles of the residuals	QQ
ResidSurfacePlot	Surface plot of the residuals	Residsurface
PredSurfacePlot	Surface plot of the predicted values	Predsurface
ActSurfacePlot	Surface plot of the actual values	Actsurface
ResidStackPlot	Stack plot of the residuals	Residstack, Resstack
ResidHistogram	Plot of the histogram of residuals	Residualhistogram, Residhistogram

The OUTPUT OUT= Data Set

PROC PANEL writes the initial data of the estimated model, predicted values, and residuals to an output data set when the OUTPUT OUT= statement is specified. The OUT= data set contains the following variables:

<code>_MODELL_</code>	is a character variable that contains the label for the MODEL statement if a label is specified.
<code>_METHOD_</code>	is a character variable that identifies the estimation method.
<code>_MODLNO_</code>	is the number of the model estimated.
<code>_ACTUAL_</code>	contains the value of the dependent variable.
<code>_WEIGHT_</code>	contains the weighing variable.
<code>_CSID_</code>	is the value of the cross section ID.
<code>_TSID_</code>	is the value of the time period in the dynamic model.
regressors	are the values of regressor variables specified in the MODEL statement.
<i>name</i>	if <code>PRED= name1</code> and/or <code>RESIDUAL= name2</code> options are specified, then <i>name1</i> and <i>name2</i> are the columns of predicted values of dependent variable and residuals of the regression, respectively.

The OUTEST= Data Set

PROC PANEL writes the parameter estimates to an output data set when the OUTEST= option is specified. The OUTEST= data set contains the following variables:

<code>_MODEL_</code>	is a character variable that contains the label for the MODEL statement if a label is specified.
<code>_METHOD_</code>	is a character variable that identifies the estimation method. Current methods are FULLER, PARKS, and DASILVA.
<code>_TYPE_</code>	is a character variable that identifies the type of observation. Values of the <code>_TYPE_</code> variable are CORRB, COVB, CSPARMS, and PARMS; the CORRB observation contains correlations of the parameter estimates; the COVB observation contains covariances of the parameter estimates; the CSPARMS observation contains cross-sectional parameter estimates; and the PARMS observation contains parameter estimates.
<code>_NAME_</code>	is a character variable that contains the name of a regressor variable for COVB and CORRB observations and is left blank for other observations. The <code>_NAME_</code> variable is used in conjunction with the <code>_TYPE_</code> values COVB and CORRB to identify rows of the correlation or covariance matrix.
<code>_DEPVAR_</code>	is a character variable that contains the name of the response variable.
<code>_MSE_</code>	is the mean square error of the transformed model.
<code>_CSID_</code>	is the value of the cross section ID for CSPARMS observations. The <code>_CSID_</code> variable is used with the <code>_TYPE_</code> value CSPARMS to identify the cross section for the first-order autoregressive parameter estimate contained in the observation. The <code>_CSID_</code> variable is missing for observations with other <code>_TYPE_</code> values. (Currently, only the <code>_A_1</code> variable contains values for CSPARMS observations.)

<code>_VARCS_</code>	is the variance component estimate due to cross sections. The <code>_VARCS_</code> variable is included in the <code>OUTEST=</code> data set when either the <code>FULLER</code> or <code>DASILVA</code> option is specified.
<code>_VARTS_</code>	is the variance component estimate due to time series. The <code>_VARTS_</code> variable is included in the <code>OUTEST=</code> data set when either the <code>FULLER</code> or <code>DASILVA</code> option is specified.
<code>_VARERR_</code>	is the variance component estimate due to error. The <code>_VARERR_</code> variable is included in the <code>OUTEST=</code> data set when the <code>FULLER</code> option is specified.
<code>_A_1</code>	is the first-order autoregressive parameter estimate. The <code>_A_1</code> variable is included in the <code>OUTEST=</code> data set when the <code>PARKS</code> option is specified. The values of <code>_A_1</code> are cross-sectional parameters, meaning that they are estimated for each cross section separately. The <code>_A_1</code> variable has a value only for <code>_TYPE_=CSPARMS</code> observations. The cross section to which the estimate belongs is indicated by the <code>_CSID_</code> variable.
<code>INTERCEP</code>	is the intercept parameter estimate. (<code>INTERCEP</code> is missing for models when the <code>NOINT</code> option is specified.)
regressors	are the regressor variables specified in the <code>MODEL</code> statement. The regressor variables in the <code>OUTEST=</code> data set contain the corresponding parameter estimates for the model identified by <code>_MODEL_</code> for <code>_TYPE_=PARMS</code> observations, and the corresponding covariance or correlation matrix elements for <code>_TYPE_=COVB</code> and <code>_TYPE_=CORRB</code> observations. The response variable contains the value -1 for the <code>_TYPE_=PARMS</code> observation for its model.

The OUTTRANS= Data Set

PROC PANEL writes the transformed series to an output data set. That is, if the user selects `FIXONE`, `FIXONETIME`, or `RANONE` and supplies the `OUTTRANS =` option, the transformed dependent variable and independent variables are written out to a SAS data set; other variables in the input data set are copied unchanged.

Say that your data set contains variables `y`, `x1`, `x2`, `x3`, and `z2`. The following statements result in a SAS data set with several characteristics:

```
proc panel data=datain outtrans=dataout;
  id cs ts;
  model y = x1 x2 x3 / fixone;
run;
```

First, `z2` is copied over. Then `y`, `x1`, `x2`, and `x3`, are replaced with their mean deviates (from cross sectional). Furthermore, two new variables are created.

<code>_MODELL_</code>	is the model's label (if it exists).
<code>_TRTYPE_</code>	is the model's transformation type. In the <code>FIXONE</code> case, this is <code>_FIXONE_</code> or <code>_FIXONET_</code> . If the model <code>RANONE</code> model is selected, the <code>_TRTYPE_</code> variable

is either `_Ran1FB_`, `_Ran1WK_`, `_Ran1WH_` or `_Ran1NL_` depending on the variance component estimators chosen.

Printed Output

For each MODEL statement, the printed output from PROC PANEL includes the following:

- a model description, which gives the estimation method used, the model statement label if specified, the number of cross sections and the number of observations in each cross section, and the order of moving average error process for the DASILVA option. For fixed-effects model analysis, an F test for the absence of fixed effects is produced, and for random-effects model analysis, a Hausman test is used for the appropriateness of the random-effects specification.
- the estimates of the underlying error structure parameters
- the regression parameter estimates and analysis. For each regressor, this includes the name of the regressor, the degrees of freedom, the parameter estimate, the standard error of the estimate, a t statistic for testing whether the estimate is significantly different from 0, and the significance probability of the t statistic.

Optionally, PROC PANEL prints the following:

- the covariance and correlation of the resulting regression parameter estimates for each model and assumed error structure
- the $\hat{\Phi}$ matrix that is the estimated contemporaneous covariance matrix for the PARKS option

ODS Table Names

PROC PANEL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 19.3](#).

Table 19.3 ODS Tables Produced in PROC PANEL

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ModelDescription	Model description	Default
FitStatistics	Fit statistics	Default
FixedEffectsTest	F test for no fixed effects	FIXONE, FIXTWO, FIXONET
ParameterEstimates	Parameter estimates	Default

Table 19.3 (continued)

ODS Table Name	Description	Option
CovB	Covariance of parameter estimates	COVB
CorrB	Correlations of parameter estimates	CORRB
VarianceComponents	Variance component estimates	RANONE, RANTWO, DASILVA
RandomEffectsTest	Hausman test for random effects	RANONE, RANTWO
AR1Estimates	First-order autoregressive parameter estimates	RHO(PARKS)
TestResults	Tests of linear restrictions	
BreuschPaganTest	Breusch-Pagan one-way test	BP

Example: PANEL Procedure

Example 19.1: Analyzing Demand for Liquid Assets

In this example, the demand equations for liquid assets are estimated. The demand function for the demand deposits is estimated under three error structures while demand equations for time deposits and savings and loan (S&L) association shares are calculated using the Parks method. The data for seven states (CA, DC, FL, IL, NY, TX, and WA) are selected out of 49 states. See Feige (1964) for data description. All variables were transformed via natural logarithm. The data set A is shown below.

```
data a;
  length state $ 2;
  input state $ year d t s y rd rt rs;
  label d = 'Per Capita Demand Deposits'
```

```

t = 'Per Capita Time Deposits'
s = 'Per Capita S & L Association Shares'
y = 'Permanent Per Capita Personal Income'
rd = 'Service Charge on Demand Deposits'
rt = 'Interest on Time Deposits'
rs = 'Interest on S & L Association Shares';
datalines;

... more lines ...

```

As shown in the following statements, the SORT procedure is used to sort the data into the required time series cross-sectional format; then PROC PANEL analyzes the data.

```

proc sort data=a;
  by state year;
run;

proc panel data=a;
  model d = y rd rt rs / fuller parks dasilva m=7;
  model t = y rd rt rs / parks;
  model s = y rd rt rs / parks;
  id state year;
run;

```

The income elasticities for liquid assets are greater than 1 except for the demand deposit income elasticity (0.692757) estimated by the Da Silva method. In [Output 19.1.1](#), [Output 19.1.2](#), and [Output 19.1.3](#), the coefficient estimates (-0.29094 , -0.43591 , and -0.27736) of demand deposits (RD) imply that demand deposits increase significantly as the service charge is reduced. The price elasticities (0.227152 and 0.408066) for time deposits (RT) and S&L association shares (RS) have the expected sign. Thus an increase in the interest rate on time deposits or S&L shares will increase the demand for the corresponding liquid asset. Demand deposits and S&L shares appear to be substitutes (see [Output 19.1.2](#), [Output 19.1.3](#), and [Output 19.1.5](#)). Time deposits are also substitutes for S&L shares in the time deposit demand equation (see [Output 19.1.4](#)), while these liquid assets are independent of each other in [Output 19.1.5](#) (insignificant coefficient estimate of RT, -0.02705). Demand deposits and time deposits appear to be weak complements in [Output 19.1.3](#) and [Output 19.1.4](#), while the cross elasticities between demand deposits and time deposits are not significant in [Output 19.1.2](#) and [Output 19.1.5](#).

Example 19.2: The Airline Cost Data: Fixtwo Model

The Christenson Associates airline data are a frequently cited data set (see Greene 2000). The data measure costs, prices of inputs, and utilization rates for six airlines over the time span 1970–1984. This example analyzes the log transformations of the cost, price and quantity, and the raw (not logged) capacity utilization measure. You speculate the following model:

$$\ln(TC_{it}) = \alpha_N + \gamma_T + (\alpha_i - \alpha_N) + (\gamma_t - \gamma_T) + \beta_1 \ln(Q_{it}) + \beta_2 \ln(PF_{it}) + \beta_3 LF_{it} + \epsilon_{it}$$

where the α are the pure cross-sectional effects and γ are the time effects. The actual model speculated is highly nonlinear in the original variables. It would look like the following:

$$TC_{it} = \exp(\alpha_i + \gamma_t + \beta_3 LF_{it} + \epsilon_{it}) Q_{it}^{\beta_1} PF_{it}^{\beta_2}$$

The data and preliminary SAS statements are:

```

data airline;
  input  Obs I T C Q PF LF;
  label obs = "Observation number";
  label I  = "Firm Number (CSID)";
  label T  = "Time period (TSID)";
  label Q  = "Output in revenue passenger miles (index)";
  label C  = "Total cost, in thousands";
  label PF = "Fuel price";
  label LF = "Load Factor (utilization index)";
datalines;

... more lines ...

data airline;
  set airline;
  lC = log(C);
  lQ = log(Q);
  lPF = log(PF);
  label lC = "Log transformation of costs";
  label lQ = "Log transformation of quantity";
  label lPF= "Log transformation of price of fuel";
run;

```

The following statements fit the model.

```

proc panel data=airline;
  id i t;
  model lC = lQ lPF LF / fixtwo;
run;

```

First, you see the model's description in [Output 19.2.1](#). The model is a two-way fixed-effects model. There are six cross sections and fifteen time observations.

Output 19.2.1 The Airline Cost Data—Model Description

The PANEL Procedure	
Fixed Two Way Estimates	
Dependent Variable: lC Log transformation of costs	
Model Description	
Estimation Method	FixTwo
Number of Cross Sections	6
Time Series Length	15

The R-square and degrees of freedom can be seen in [Table 19.2.2](#). On the whole, you see a large R-square, so there is a reasonable fit. The degrees of freedom of the estimate are 90 minus 14 time dummy variables minus 5 cross section dummy variables and 4 regressors.

Output 19.2.2 The Airline Cost Data—Fit Statistics

Fit Statistics			
SSE	0.1768	DFE	67
MSE	0.0026	Root MSE	0.0514
R-Square	0.9984		

The F test for fixed effects is shown in [Table 19.2.3](#). Testing the hypothesis that there are no fixed effects, you easily reject the null of poolability. There are group effects, or time effects, or both. The test is highly significant. OLS would not give reasonable results.

Output 19.2.3 The Airline Cost Data—Test for Fixed Effects

F Test for No Fixed Effects			
Num DF	Den DF	F Value	Pr > F
19	67	23.10	<.0001

Looking at the parameters, you see a more complicated pattern. Most of the cross-sectional effects are highly significant (with the exception of CS2). This means that the cross sections are significantly different from the sixth cross section. Many of the time effects show significance, but this is not uniform. It looks like the significance might be driven by a large 16th period effect, since the first six time effects are negative and of similar magnitude. The time dummy variables taper off in size and lose significance from time period 12 onward. There are many causes to which you could attribute this decay of time effects. The time period of the data spans the OPEC oil embargoes and the dissolution of the Civil Aeronautics Board (CAB). These two forces are two possible reasons to observe the decay and parameter instability. As for the regression parameters, you see that quantity affects cost positively, and the price of fuel has a positive effect, but load factors negatively affect the costs of the airlines in this sample. The somewhat disturbing result is that the fuel cost is not significant. If the time effects are proxies for the effect of the oil embargoes, then an insignificant fuel cost parameter would make some sense. If the dummy variables proxy for the dissolution of the CAB, then the effect of load factors is also not being precisely estimated.

ODS Graphics Plots

ODS graphics plots can be obtained to graphically analyze the results. The following statements show how to generate the plots. If the PLOTS=ALL option is specified, all available plots are produced in two panels. For a complete list of options, see the section “ODS Graphics” on page 1320.

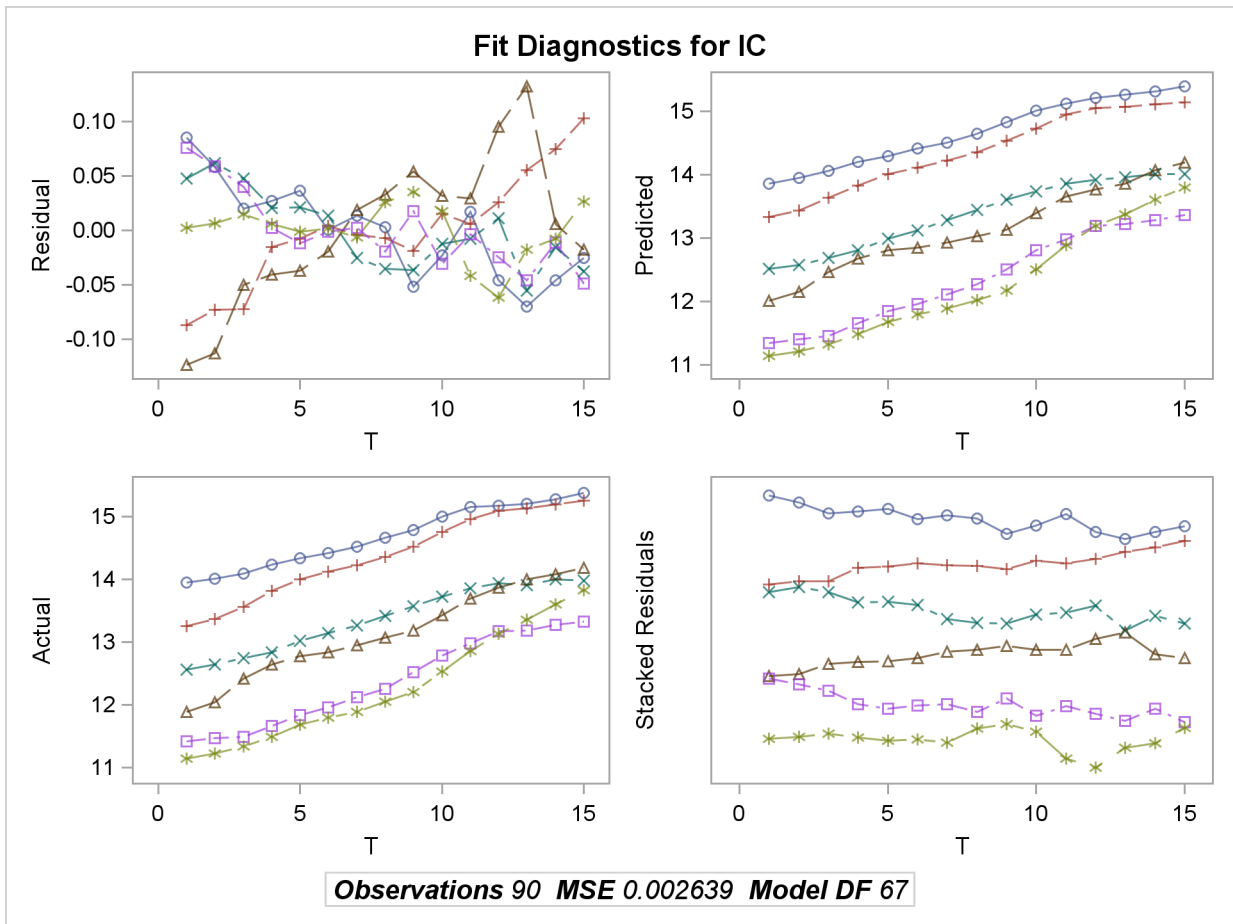

```
proc panel data=airline;
  id i t;
  model IC = IQ LPF LF / fixtwo plots = all;
run;
```

The preceding statements result in plots shown in [Output 19.2.5](#) and [Output 19.2.6](#).

Output 19.2.5 Diagnostic Panel 1

Output 19.2.6 Diagnostic Panel 2

The UNPACK and ONLY options produce individual detail images of paneled plots. The graph shown in [Output 19.2.7](#) shows a detail plot of residuals by cross section. The packed version always puts all cross sections on one plot while the unpacked one shows the cross sections in groups of ten to avoid loss of detail.

```
proc panel data=airline;
  id i t;
  model lC = lQ lPF lF / fixtwo plots(unpack only) = residsurface;
run;
```

Output 19.2.7 Surface Plot of the Residual

Example 19.3: The Airline Cost Data: Further Analysis

Using the same data as in [Example 19.2](#), you further investigate the ‘true’ effect of fuel prices. Specifically, you run the `FixOne` model, ignoring time effects. You specify the following statements in `PROC PANEL` to run this model:

```
proc panel data=airline;
  id i t;
  model lC = lQ lPF lF / fixone;
run;
```

The preceding statements result in [Output 19.3.1](#). The fit seems to have deteriorated somewhat. The SSE rises from 0.1768 to 0.2926.

Output 19.3.1 The Airline Cost Data—Fit Statistics

The PANEL Procedure			
Fixed One Way Estimates			
Dependent Variable: 1C Log transformation of costs			
Fit Statistics			
SSE	0.2926	DFE	81
MSE	0.0036	Root MSE	0.0601
R-Square	0.9974		

You still reject poolability based on the F test in [Output 19.3.2](#) at all accepted levels of significance.

Output 19.3.2 The Airline Cost Data—Test for Fixed Effects

F Test for No Fixed Effects			
Num DF	Den DF	F Value	Pr > F
5	81	57.74	<.0001

The parameters change somewhat dramatically as shown in [Output 19.3.3](#). The effect of fuel costs comes in very strong and significant. The load factor's coefficient increases, although not as dramatically. This suggests that the fixed time effects might be proxies for both the oil shocks and deregulation.

Output 19.3.3 The Airline Cost Data—Parameter Estimates

Parameter Estimates

Example 19.4: The Airline Cost Data: Random-Effects Models

This example continues to use the Christenson Associates airline data, which measures costs, prices of inputs, and utilization rates for six airlines over the time span 1970–1984. There are six cross sections and fifteen time observations. Here, you examine the different estimates generated from the one-way random-effects and two-way random-effects models, by using four different methods to estimate the variance components: Fuller and Battese, Wansbeek and Kapteyn, Wallace and Hussain, and Nerlove.

The data for this example is created by the PROC PANEL statements shown in [Example 19.2](#). The PROC PANEL statements necessary to generate the estimates are as follows:

```
proc panel data=airline outest=estimates;
  id I T;
  RANONE:  model 1C = 1Q 1PF 1F / ranone vcomp=fb;
  RANONEwk: model 1C = 1Q 1PF 1F / ranone vcomp=wk;
  RANONEwh: model 1C = 1Q 1PF 1F / ranone vcomp=wh;
  RANONEnl: model 1C = 1Q 1PF 1F / ranone vcomp=nl;
  RANTWO:  model 1C = 1Q 1PF 1F / rantwo vcomp=fb;
  RANTWOwk: model 1C = 1Q 1PF 1F / rantwo vcomp=wk;
  RANTWOwh: model 1C = 1Q 1PF 1F / rantwo vcomp=wh;
  RANTWOnl: model 1C = 1Q 1PF 1F / rantwo vcomp=nl;
  POOLED:  model 1C = 1Q 1PF 1F / pooled;
  BTWNG:   model 1C = 1Q 1PF 1F / btwng;
  BTWNT:   model 1C = 1Q 1PF 1F / btwnt;
run;

data table;
  set estimates;
  VarCS = round(_VARCS_, .00001);
  VarTS = round(_VARTS_, .00001);
  VarErr = round(_VARERR_, .00001);
  Int = round(Intercept, .0001);
  1Q2 = round(1Q, .0001);
  1PF2 = round(1PF, .0001);
  1F2 = round(1F, .0001);
  if _n_ >= 9 then do;
    VarCS = . ;
    VarTS = . ;
  keep _MODEL_ _METHOD_ VarCS VarTS VarErr Int 1Q2 1PF2 1F2;
run;
```

The parameter estimates and variance components for both models are reported in [Output 19.4.1](#) and [Output 19.4.2](#).

```
title "Parameter Estimates";
proc print data=table label noobs;
  label _MODEL_ = "Model"
        _METHOD_ = "Method"
        Int = "Intercept"
        1Q2 = "1Q"
```

```

    1PF2 = "1PF"
    1F2  = "1F";
var _METHOD_ _MODEL_ Int 1Q2 1PF2 1F2;
run;

```

Output 19.4.1 Parameter Estimates

In the random-effects model, individual constant terms are viewed as randomly distributed across cross-sectional units and not as parametric shifts of the regression function, as in the fixed-effects model. This is appropriate when the sampled cross-sectional units are drawn from a large population. Clearly, in this example, the six airlines are a sample of all the airlines in the industry and not an exhaustive, or nearly exhaustive, list.

There are four ways of computing the variance components in the one-way random-effects model. The method by Fuller and Battese (1974) (FB), uses a “fitting of constants” methods to estimate them. The Wansbeek and Kapteyn (1989) (WK) method uses the true disturbances, while the Wallace and Hussain (WH) method uses ordinary least squares residuals.

Looking at the estimates of the variance components for cross section and error in [Output 19.4.2](#), you see that equal variance components for error are computed for both FB and WK, while WH and NL are nearly equal.

All four techniques produce different variance components for cross sections. These estimates are then used to estimate the values of the parameters in [Output 19.4.1](#). All the parameters appear to have similar and equally plausible estimates. Both the index for output in revenue passenger miles (IQ) and fuel price (IPF) have small, positive effects on total costs, which you would expect. The load factor (LF) has a somewhat larger and negative effect on total costs, suggesting that as utilization increases, costs decrease.

As in the one-way random-effects model, the variance components for error produced by the FB and WK methods are equal. However, in this case, the WH and NL methods produce variance estimates that are dissimilar. The estimates of the variance component for cross sections are all different, but in a close range. The same cannot be said for the variance component for time series. As varied as each of the variance estimates may be, they produce parameter estimates that are similar and plausible. As with the one-way effects model, the index for output (IQ) and fuel price (IPF) are small and positive. The load factor (LF) estimates are all negative and, with the exception of the estimate produced by the WH method, somewhat smaller than the estimates produced in the one-way model. During the time the data were collected, the Civil Aeronautics Board dissolved, so it is possible that the dummy variables are proxies for this dissolution. This would lead to the decay of time effects and an imprecise estimation of the effects of the load factors, even though the estimates are statistically significant.

The pooled estimates give you something to compare the random-effects estimates against. You see that signs and magnitudes of output and fuel price are similar but that the magnitude of the load factor coefficient is somewhat larger under pooling. Since the model appears to have both cross-sectional and time series effects, the pooled model should not be used.

Finally, you examine the between groups estimators. For the between groups estimate, you are looking at each airline’s data averaged across time. You see in [Output 19.4.1](#) that the between groups parameter estimates are radically different from all other parameter estimates. This could indicate that the time component is not being appropriately handled with this technique. For the between times estimate, you are looking at the average across all airlines in each time period. In this case, the parameter estimates are of the same sign and closer in magnitude to the previously computed estimates. Both the output and load factor effects appear to have more bearing on total costs.

Example 19.5: Using the FLATDATA Statement

Sometimes the data can be found in compressed form, where each line consists of all observations for the dependent and independent variables for the cross section. To illustrate, suppose you have a data set with 20 cross sections where each cross section consists of observations for six time periods. Each time period has values for dependent and independent variables $Y_1 \dots Y_6$ and $X_1 \dots X_6$. The *cs* and *num* variables represent other character and numeric variables that are constant across each cross section.

The observations for first five cross sections along with other variables are shown in [Output 19.5.1](#). In this example, *i* represents the cross section. The time period is identified by the subscript on the *Y* and *X* variables; it ranges from 1 to 6.

Output 19.5.1 Compressed Data Set

Since the PANEL procedure cannot work directly with the data in compressed form, the FLATDATA statement can be used to transform the data. The OUT= option can be used to output transformed data to a data set.

```
proc panel data=flattest;
  flatdata indid=i tsname="t" transform=(X Y)
           keep=( cs num seed ) / out=flat_out;
  id i t;
  model y = x / fixone noint;
run;
```

First, six observations for the uncompressed data set and results for the one-way fixed-effects model fitted are shown in [Output 19.5.2](#) and [Output 19.5.3](#).

Output 19.5.2 Uncompressed Data Set

Example 19.6: The Cigarette Sales Data: Dynamic Panel Estimation with GMM

In this example, a dynamic panel demand model for cigarette sales is estimated. It illustrates the application of the method described in the section “[Dynamic Panel Estimator](#)” on page 1304. The data are a panel from 46 American states over the period 1963–92. See Baltagi and Levin (1992) and Baltagi (1995) for data description. All variables were transformed by taking the natural logarithm. The data set CIGAR is shown in the following statements.

```
data cigar;
  input state year price pop pop_16 cpi ndi sales pimin;
  label
  state = 'State abbreviation'
  year  = 'YEAR'
  price = 'Price per pack of cigarettes'
  pop   = 'Population'
  pop_16 = 'Population above the age of 16'
  cpi   = 'Consumer price index with (1983=100)'
  ndi   = 'Per capita disposable income'
  sales = 'Cigarette sales in packs per capita'
  pimin = 'Minimum price in adjoining states per pack of cigarettes';
  datalines;
1 63 28.6 3383 2236.5 30.6 1558.3045298 93.9 26.1
1 64 29.8 3431 2276.7 31.0 1684.0732025 95.4 27.5
1 65 29.8 3486 2327.5 31.5 1809.8418752 98.5 28.9
1 66 31.5 3524 2369.7 32.4 1915.1603572 96.4 29.5
1 67 31.6 3533 2393.7 33.4 2023.5463678 95.5 29.6
1 68 35.6 3522 2405.2 34.8 2202.4855362 88.4 32
1 69 36.6 3531 2411.9 36.7 2377.3346665 90.1 32.8
1 70 39.6 3444 2394.6 38.8 2591.0391591 89.8 34.3
1 71 42.7 3481 2443.5 40.5 2785.3159706 95.4 35.8

... more lines ...
```

The following statements sort the data by STATE and YEAR variables.

```
proc sort data=cigar;
  by state year;
run;
```

Next, logarithms of the variables required for regression estimation are calculated, as shown in the following statements:

```
data cigar;
  set cigar;
  lsales = log(sales);
  lprice = log(price);
  lndi   = log(ndi);
  lpimin = log(pimin);
```

```

label lprice = 'Log price per pack of cigarettes';
label lndi = 'Log per capita disposable income';
label lsales = 'Log cigarette sales in packs per capita';
label lpimin = 'Log minimum price in adjoining states
                per pack of cigarettes';
run;

```

The following statements create the CIGAR_LAG data set with lagged variable for each cross section.

```

proc panel data=cigar;
  id state year;
  clag lsales(1) / out=cigar_lag;
run;

data cigar_lag;
  set cigar_lag;
  label lsales_1 = 'Lagged log cigarette sales in packs per capita';
run;

```

Finally, the model is estimated by a two step GMM method. Five lags (MAXBAND=5) of the dependent variable are used as instruments. NOLEVELS options is specified to avoid use of level equations, as shown in the following statements:

```

proc panel data=cigar_lag;
  inst depvar;
  model lsales = lsales_1 lprice lndi lpimin
    / gmm nolevels twostep maxband=5;
  id state year;
run;

```

Overview: PDLREG Procedure

The PDLREG procedure estimates regression models for time series data in which the effects of some of the regressor variables are distributed across time. The distributed lag model assumes that the effect of an input variable X on an output Y is distributed over time. If you change the value of X at time t , Y will experience some immediate effect at time t , and it will also experience a delayed effect at times $t + 1$, $t + 2$, and so on up to time $t + p$ for some limit p .

The regression model supported by PROC PDLREG can include any number of regressors with distribution lags and any number of covariates. (Simple regressors without lag distributions are called

covariates.) For example, the two-regressor model with a distributed lag effect for one regressor is written

$$y_t = \alpha + \sum_{i=0}^p \beta_i x_{t-i} + \gamma z_t + u_t$$

Here, x_t is the regressor with a distributed lag effect, z_t is a simple covariate, and u_t is an error term.

The distribution of the lagged effects is modeled by Almon lag polynomials. The coefficients b_i of the lagged values of the regressor are assumed to lie on a polynomial curve. That is,

$$b_i = \alpha_0^* + \sum_{j=1}^d \alpha_j^* i^j$$

where $d(\leq p)$ is the degree of the polynomial. For the numerically efficient estimation, the PDLREG procedure uses *orthogonal polynomials*. The preceding equation can be transformed into orthogonal polynomials:

$$b_i = \alpha_0 + \sum_{j=1}^d \alpha_j f_j(i)$$

where $f_j(i)$ is a polynomial of degree j in the lag length i , and α_j is a coefficient estimated from the data.

The PDLREG procedure supports endpoint restrictions for the polynomial. That is, you can constrain the estimated polynomial lag distribution curve so that $b_{-1} = 0$ or $b_{p+1} = 0$, or both. You can also impose linear restrictions on the parameter estimates for the covariates.

You can specify a minimum degree and a maximum degree for the lag distribution polynomial, and the procedure fits polynomials for all degrees in the specified range. (However, if distributed lags are specified for more than one regressor, you can specify a range of degrees for only one of them.)

The PDLREG procedure can also test for autocorrelated residuals and perform autocorrelated error correction by using the autoregressive error model. You can specify any order autoregressive error model and can specify several different estimation methods for the autoregressive model, including exact maximum likelihood.

The PDLREG procedure computes generalized Durbin-Watson statistics to test for autocorrelated residuals. For models with lagged dependent variables, the procedure can produce Durbin h and Durbin t statistics. You can request significance level p -values for the Durbin-Watson, Durbin h , and Durbin t statistics. See Chapter 8, “[The AUTOREG Procedure](#),” for details about these statistics.

The PDLREG procedure assumes that the input observations form a time series. Thus, the PDLREG procedure should be used only for ordered and equally spaced time series data.

Getting Started: PDLREG Procedure

Use the MODEL statement to specify the regression model. The PDLREG procedure's MODEL statement is written like MODEL statements in other SAS regression procedures, except that a regressor can be followed by a lag distribution specification enclosed in parentheses.

For example, the following MODEL statement regresses Y on X and Z and specifies a distributed lag for X:

```
model y = x(4,2) z;
```

The notation X(4,2) specifies that the model includes X and 4 lags of X, with the coefficients of X and its lags constrained to follow a second-degree (quadratic) polynomial. Thus, the regression model specified by this MODEL statement is

$$y_t = a + b_0x_t + b_1x_{t-1} + b_2x_{t-2} + b_3x_{t-3} + b_4x_{t-4} + cz_t + u_t$$

$$b_i = \alpha_0 + \alpha_1 f_1(i) + \alpha_2 f_2(i)$$

where $f_1(i)$ is a polynomial of degree 1 in i and $f_2(i)$ is a polynomial of degree 2 in i .

Lag distribution specifications are enclosed in parentheses and follow the name of the regressor variable. The general form of the lag distribution specification is

regressor-name (length, degree, minimum-degree, end-constraint)

where

<i>length</i>	is the length of the lag distribution—that is, the number of lags of the regressor to use.
<i>degree</i>	is the degree of the distribution polynomial.
<i>minimum-degree</i>	is an optional minimum degree for the distribution polynomial.
<i>end-constraint</i>	is an optional endpoint restriction specification, which can have the value FIRST, LAST, or BOTH.

If the *minimum-degree* option is specified, the PDLREG procedure estimates models for all degrees between *minimum-degree* and *degree*.

Introductory Example

The following statements generate simulated data for variables Y and X. Y depends on the first three lags of X, with coefficients .25, .5, and .25. Thus, the effect of changes of X on Y takes effect 25% after one period, 75% after two periods, and 100% after three periods.

```

data test;
  x11 = 0; x12 = 0; x13 = 0;
  do t = -3 to 100;
    x = ranuni(1234);
    y = 10 + .25 * x11 + .5 * x12 + .25 * x13
        + .1 * rannor(1234);
    if t > 0 then output;
    x13 = x12; x12 = x11; x11 = x;
  end;
run;

```

The following statements use the PDLREG procedure to regress Y on a distributed lag of X. The length of the lag distribution is 4, and the degree of the distribution polynomial is specified as 3.

```

proc pdlreg data=test;
  model y = x( 4, 3 );
run;

```

The PDLREG procedure first prints a table of statistics for the residuals of the model, as shown in Figure 20.1. See Chapter 8, “The AUTOREG Procedure,” for an explanation of these statistics.

Figure 20.1 Residual Statistics

The PDLREG Procedure			
Dependent Variable		y	
The PDLREG Procedure			
Ordinary Least Squares Estimates			
SSE	0.86604442	DFE	91
MSE	0.00952	Root MSE	0.09755
SBC	-156.72612	AIC	-169.54786
MAE	0.07761107	AICC	-168.88119
MAPE	0.73971576	Regress R-Square	0.7711
Durbin-Watson	1.9920	Total R-Square	0.7711

The PDLREG procedure next prints a table of parameter estimates, standard errors, and *t* tests, as shown in Figure 20.2.

Figure 20.2 Parameter Estimates

Variable	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	10.0030	0.0431	231.87	<.0001
x**0	1	0.4406	0.0378	11.66	<.0001
x**1	1	0.0113	0.0336	0.34	0.7377
x**2	1	-0.4108	0.0322	-12.75	<.0001
x**3	1	0.0331	0.0392	0.84	0.4007

The table in Figure 20.2 shows the model intercept and the estimated parameters of the lag distribution polynomial. The parameter labeled X**0 is the constant term, α_0 , of the distribution polynomial. X**1 is the linear coefficient, α_1 ; X**2 is the quadratic coefficient, α_2 ; and X**3 is the cubic coefficient, α_3 .

The parameter estimates for the distribution polynomial are not of interest in themselves. Since the PDLREG procedure does not print the orthogonal polynomial basis that it constructs to represent the distribution polynomial, these coefficient values cannot be interpreted.

However, because these estimates are for an orthogonal basis, you can use these results to test the degree of the polynomial. For example, this table shows that the X**3 estimate is not significant; the p -value for its t ratio is 0.4007, while the X**2 estimate is highly significant ($p < .0001$). This indicates that a second-degree polynomial might be more appropriate for this data set.

The PDLREG procedure next prints the lag distribution coefficients and a graphical display of these coefficients, as shown in Figure 20.3.

Figure 20.3 Coefficients and Graph of Estimated Lag Distribution

Estimate of Lag Distribution				
Variable	Estimate	Standard Error	t Value	Approx Pr > t
x(0)	-0.040150	0.0360	-1.12	0.2677
x(1)	0.324241	0.0307	10.55	<.0001
x(2)	0.416661	0.0239	17.45	<.0001
x(3)	0.289482	0.0315	9.20	<.0001
x(4)	-0.004926	0.0365	-0.13	0.8929

Estimate of Lag Distribution				
Variable	-0.04			0.4167
x(0)	***			
x(1)		*****		
x(2)		*****		
x(3)		*****		
x(4)				

The lag distribution coefficients are the coefficients of the lagged values of X in the regression model. These coefficients lie on the polynomial curve defined by the parameters shown in Figure 20.2. Note that the estimated values for X(1), X(2), and X(3) are highly significant, while X(0) and X(4) are not significantly different from 0. These estimates are reasonably close to the true values used to generate the simulated data.

The graphical display of the lag distribution coefficients plots the estimated lag distribution polynomial reported in Figure 20.2. The roughly quadratic shape of this plot is another indication that a third-degree distribution curve is not needed for this data set.

Syntax: PDLREG Procedure

The following statements can be used with the PDLREG procedure:

```

PROC PDLREG option ;
  BY variables ;
  MODEL dependents = effects / options ;
  OUTPUT OUT= SAS-data-set keyword = variables ;
  RESTRICT restrictions ;

```

Functional Summary

The statements and options used with the PDLREG procedure are summarized in the following table.

Table 20.1 PDLREG Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	PDLREG	DATA=
write predicted values to an output data set	OUTPUT	OUT=
BY-Group Processing		
specify BY-group processing	BY	
Printing Control Options		
request all print options	MODEL	ALL
print correlations of the estimates	MODEL	CORRB
print covariances of the estimates	MODEL	COVB
print DW statistics up to order j	MODEL	DW= j
print the marginal probability of DW statistics	MODEL	DWPROB
print inverse of the crossproducts matrix	MODEL	I
print details at each iteration step	MODEL	ITPRINT
print Durbin t statistic	MODEL	LAGDEP
print Durbin h statistic	MODEL	LAGDEP=
suppress printed output	MODEL	NOPRINT
print partial autocorrelations	MODEL	PARTIAL
print standardized parameter estimates	MODEL	STB
print crossproducts matrix	MODEL	XPX
Model Estimation Options		
specify order of autoregressive process	MODEL	NLAG=
suppress intercept parameter	MODEL	NOINT
specify convergence criterion	MODEL	CONVERGE=
specify maximum number of iterations	MODEL	MAXITER=
specify estimation method	MODEL	METHOD=

output upper confidence limit for the structural predicted values	OUTPUT	UCLM=

PROC PDLREG Statement

PROC PDLREG *option* ;

The PROC PDLREG statement has the following option:

DATA= *SAS-data-set*

specifies the name of the SAS data set containing the input data. If you do not specify the DATA= option, the most recently created SAS data set is used.

In addition, you can place any of the following MODEL statement options in the PROC PDLREG statement, which is equivalent to specifying the option for every MODEL statement: ALL, CONVERGE=, CORRB, COVB, DW=, DWPROB, ITPRINT, MAXITER=, METHOD=, NOINT, NOPRINT, and PARTIAL.

BY Statement

BY *variables* ;

A BY statement can be used with PROC PDLREG to obtain separate analyses on observations in groups defined by the BY variables.

MODEL Statement

MODEL *dependent = effects / options ;*

The MODEL statement specifies the regression model. The keyword MODEL is followed by the dependent variable name, an equal sign, and a list of independent effects. Only one MODEL statement is allowed.

Every variable in the model must be a numeric variable in the input data set. Specify an independent effect with a variable name optionally followed by a polynomial lag distribution specification.

Specifying Independent Effects

The general form of an effect is

variable (length, degree, minimum-degree, constraint)

The term in parentheses following the variable name specifies a polynomial distributed lag (PDL) for the variable. The PDL specification is as follows:

<i>length</i>	specifies the number of lags of the variable to include in the lag distribution.
<i>degree</i>	specifies the maximum degree of the distribution polynomial. If not specified, the degree defaults to the lag length.
<i>minimum-degree</i>	specifies the minimum degree of the polynomial. By default <i>minimum-degree</i> is the same as <i>degree</i> .
<i>constraint</i>	specifies endpoint restrictions on the polynomial. The value of <i>constraint</i> can be FIRST, LAST, or BOTH. If a value is not specified, there are no endpoint restrictions.

If you do not specify the *degree* or *minimum-degree* parameter, but you do specify endpoint restrictions, you must use commas to show which parameter, *degree* or *minimum-degree*, is left out.

MODEL Statement Options

The following options can appear in the MODEL statement after a slash (/).

ALL

prints all the matrices computed during the analysis of the model.

CORRB

prints the matrix of estimated correlations between the parameter estimates.

COVB

prints the matrix of estimated covariances between the parameter estimates.

DW= *j*

prints the generalized Durbin-Watson statistics up to the order of *j*. The default is DW=1. When you specify the LAGDEP or LAGDEP=*name* option, the Durbin-Watson statistic is not printed unless you specify the DW= option.

DWPROB

prints the marginal probability of the Durbin-Watson statistic.

CONVERGE= *value*

sets the convergence criterion. If the maximum absolute value of the change in the autoregressive parameter estimates between iterations is less than this amount, then convergence is assumed. The default is CONVERGE=.001.

I

prints $(\mathbf{X}'\mathbf{X})^{-1}$, the inverse of the crossproducts matrix for the model; or, if restrictions are specified, it prints $(\mathbf{X}'\mathbf{X})^{-1}$ adjusted for the restrictions.

ITPRINT

prints information on each iteration.

LAGDEP**LAGDV**

prints the *t* statistic for testing residual autocorrelation when regressors contain lagged dependent variables.

LAGDEP= *name***LAGDV= *name***

prints the Durbin *h* statistic for testing the presence of first-order autocorrelation when regressors contain the lagged dependent variable whose name is specified as LAGDEP=*name*. When the *h* statistic cannot be computed, the asymptotically equivalent *t* statistic is given.

MAXITER= *number*

sets the maximum number of iterations allowed. The default is MAXITER=50.

METHOD= *value*

specifies the type of estimates for the autoregressive component. The values of the METHOD= option are as follows:

METHOD=ML	specifies the maximum likelihood method.
METHOD=ULS	specifies unconditional least squares.
METHOD=YW	specifies the Yule-Walker method.
METHOD=ITYW	specifies iterative Yule-Walker estimates.

The default is METHOD=ML if you specified the LAGDEP or LAGDEP= option; otherwise, METHOD=YW is the default.

NLAG= *m*

NLAG= (*number-list*)

specifies the order of the autoregressive process or the subset of autoregressive lags to be fit. If you do not specify the NLAG= option, PROC PDLREG does not fit an autoregressive model.

NOINT

suppresses the intercept parameter from the model.

NOPRINT

suppresses the printed output.

PARTIAL

prints partial autocorrelations if the NLAG= option is specified.

STB

prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a *standardized parameter estimate* is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the regressed variable.

XPX

prints the crossproducts matrix, $\mathbf{X}'\mathbf{X}$, used for the model. \mathbf{X} refers to the transformed matrix of regressors for the regression.

OUTPUT Statement

OUTPUT *OUT= SAS-data-set keyword= option ... ;*

The OUTPUT statement creates an output SAS data set with variables as specified by the following keyword options. See the section “Predicted Values” in Chapter 8, “[The AUTOREG Procedure](#),” for a description of the associated computations for these options.

ALPHACLI= *number*

sets the confidence limit size for the estimates of future values of the current realization of the response time series to *number*, where *number* is less than one and greater than zero. The resulting confidence interval has $1-\textit{number}$ confidence. The default value for *number* is 0.05, corresponding to a 95% confidence interval.

ALPHACL= *number*

sets the confidence limit size for the estimates of the structural or regression part of the model to *number*, where *number* is less than one and greater than zero. The resulting confidence interval has $1-\textit{number}$ confidence. The default value for *number* is 0.05, corresponding to a 95% confidence interval.

OUT= *SAS-data-set*

names the output data.

The following specifications are of the form *KEYWORD=names*, where *KEYWORD=* specifies the statistic to include in the output data set and *names* gives names to the variables that contain the statistics.

CONSTANT= *variable*

writes the transformed intercept to the output data set.

LCL= *name*

requests that the lower confidence limit for the predicted value (specified in the **PREDICTED=** option) be added to the output data set under the name given.

LCLM= *name*

requests that the lower confidence limit for the structural predicted value (specified in the **PREDICTEDM=** option) be added to the output data set under the name given.

PREDICTED= *name*

P= *name*

stores the predicted values in the output data set under the name given.

PREDICTEDM= *name*

PM= *name*

stores the structural predicted values in the output data set under the name given. These values are formed from only the structural part of the model.

RESIDUAL= *name*

R= *name*

stores the residuals from the predicted values based on both the structural and time series parts of the model in the output data set under the name given.

RESIDUALM= *name*

RM= *name*

requests that the residuals from the structural prediction be given.

TRANSFORM= *variables*

requests that the specified variables from the input data set be transformed by the autoregressive model and put in the output data set. If you need to reproduce the data suitable for reestimation, you must also transform an intercept variable. To do this, transform a variable that only takes the value 1 or use the **CONSTANT=** option.

UCL= *name*

stores the upper confidence limit for the predicted value (specified in the **PREDICTED=** option) in the output data set under the name given.

UCLM= *name*

stores the upper confidence limit for the structural predicted value (specified in the **PREDICTEDM=** option) in the output data set under the name given.

For example, the SAS statements

```
proc pdlreg data=a;
  model y=x1 x2;
  output out=b p=yhat r=resid;
run;
```

create an output data set named B. In addition to the input data set variables, the data set B contains the variable YHAT, whose values are predicted values of the dependent variable Y, and RESID, whose values are the residual values of Y.

RESTRICT Statement

RESTRICT *equation* , . . . , *equation* ;

The RESTRICT statement places restrictions on the parameter estimates for covariates in the preceding MODEL statement. A parameter produced by a distributed lag cannot be restricted with the RESTRICT statement.

Each restriction is written as a linear equation. If you specify more than one restriction in a RESTRICT statement, the restrictions are separated by commas.

You can refer to parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. You can use labels to distinguish results for different restrictions in the printed output. Labels are specified as follows:

label : **RESTRICT** . . .

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1:

```
proc pdlreg data=a;
  model y = x1 x2;
  restrict x1 + x2 = 1;
run;
```

Parameter names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Rayner 1971). The estimates of these Lagrangian parameters are printed in

the parameter estimates table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter, λ , measures the sensitivity of the SSE to the restriction. If the restriction is changed by a small amount ϵ , the SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted ones.

You can specify any number of restrictions in a RESTRICT statement, and you can use any number of RESTRICT statements. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

Details: PDLREG Procedure

Missing Values

The PDLREG procedure skips any observations at the beginning of the data set that have missing values. The procedure uses all observations with nonmissing values for all the independent and dependent variables such that the lag distribution has sufficient nonmissing lagged independent variables.

Polynomial Distributed Lag Estimation

The simple finite distributed lag model is expressed in the form

$$y_t = \alpha + \sum_{i=0}^p \beta_i x_{t-i} + \epsilon_t$$

When the lag length (p) is long, severe multicollinearity can occur. Use the Almon or *polynomial distributed lag* model to avoid this problem, since the relatively low-degree d ($\leq p$) polynomials can capture the true lag distribution. The lag coefficient can be written in the Almon polynomial lag

$$\beta_i = \alpha_0^* + \sum_{j=1}^d \alpha_j^* i^j$$

Emerson (1968) proposed an efficient method of constructing orthogonal polynomials from the preceding polynomial equation as

$$\beta_i = \alpha_0 + \sum_{j=1}^d \alpha_j f_j(i)$$

where $f_j(i)$ is a polynomial of degree j in the lag length i . The polynomials $f_j(i)$ are chosen so that they are orthogonal:

$$\sum_{i=1}^n w_i f_j(i) f_k(i) = \begin{cases} 1 & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases}$$

where w_i is the weighting factor, and $n = p + 1$. PROC PDLREG uses the equal weights ($w_i = 1$) for all i . To construct the orthogonal polynomials, the following recursive relation is used:

$$f_j(i) = (A_j i + B_j) f_{j-1}(i) - C_j f_{j-2}(i) \quad j = 1, \dots, d$$

The constants A_j , B_j , and C_j are determined as follows:

$$\begin{aligned} A_j &= \left\{ \sum_{i=1}^n w_i i^2 f_{j-1}^2(i) - \left(\sum_{i=1}^n w_i i f_{j-1}^2(i) \right)^2 \right. \\ &\quad \left. - \left(\sum_{i=1}^n w_i i f_{j-1}(i) f_{j-2}(i) \right)^2 \right\}^{-1/2} \\ B_j &= -A_j \sum_{i=1}^n w_i i f_{j-1}^2(i) \\ C_j &= A_j \sum_{i=1}^n w_i i f_{j-1}(i) f_{j-2}(i) \end{aligned}$$

where $f_{-1}(i) = 0$ and $f_0(i) = 1/\sqrt{\sum_{i=1}^n w_i}$.

PROC PDLREG estimates the orthogonal polynomial coefficients, $\alpha_0, \dots, \alpha_d$, to compute the coefficient estimate of each independent variable (X) with distributed lags. For example, if an independent variable is specified as X(9,3), a third-degree polynomial is used to specify the distributed lag coefficients. The third-degree polynomial is fit as a constant term, a linear term, a quadratic term, and a cubic term. The four terms are constructed to be orthogonal. In the output produced by the PDLREG procedure for this case, parameter estimates with names X**0, X**1, X**2, and X**3 correspond to $\hat{\alpha}_0, \hat{\alpha}_1, \hat{\alpha}_2$, and $\hat{\alpha}_3$, respectively. A test using the t statistic and the approximate p -value (“Approx Pr > | t ””) associated with X**3 can determine whether a second-degree polynomial rather than a third-degree polynomial is appropriate. The estimates of the 10 lag coefficients associated with the specification X(9,3) are labeled X(0), X(1), X(2), X(3), X(4), X(5), X(6), X(7), X(8), and X(9).

Autoregressive Error Model Estimation

The PDLREG procedure uses the same autoregressive error model estimation methods as the AUTOREG procedure. These two procedures share the same computational resources for computing estimates. See Chapter 8, “[The AUTOREG Procedure](#),” for details about estimation methods for autoregressive error models.

OUT= Data Set

The OUT= data set produced by the PDLREG procedure's OUTPUT statement is similar in form to the OUT= data set produced by the AUTOREG procedure. See Chapter 8, “[The AUTOREG Procedure](#),” for details on the OUT= data set.

Printed Output

The PDLREG procedure prints the following items:

1. the name of the dependent variable
2. the ordinary least squares (OLS) estimates
3. the estimates of autocorrelations and of the autocovariance, and if line size permits, a graph of the autocorrelation at each lag. The autocorrelation for lag 0 is 1. These items are printed if you specify the NLAG= option.
4. the partial autocorrelations if the PARTIAL and NLAG= options are specified. The first partial autocorrelation is the autocorrelation for lag 1.
5. the preliminary mean square error, which results from solving the Yule-Walker equations if you specify the NLAG= option
6. the estimates of the autoregressive parameters, their standard errors, and the ratios of estimates to standard errors (t) if you specify the NLAG= option
7. the statistics of fit for the final model if you specify the NLAG= option. These include the error sum of squares (SSE), the degrees of freedom for error (DFE), the mean square error (MSE), the root mean square error (Root MSE), the mean absolute error (MAE), the mean absolute percentage error (MAPE), the Schwarz information criterion (SBC), the Akaike's information criterion (AIC), Akaike's information criterion corrected (AICC), the regression R^2 (Regress R-Square), the total R^2 (Total R-Square), and the Durbin-Watson statistic (Durbin-Watson). See Chapter 8, “[The AUTOREG Procedure](#),” for details of the regression R^2 and the total R^2 .
8. the parameter estimates for the structural model (B), a standard error estimate, the ratio of estimate to standard error (t), and an approximation to the significance probability for the parameter being 0 (“Approx Pr > $|t|$ ”)
9. a plot of the lag distribution (estimate of lag distribution)
10. the covariance matrix of the parameter estimates if the COVB option is specified

ODS Table Names

PROC PDLREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 20.2 ODS Tables Produced in PROC PDLREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ARParameterEstimates	Estimates of autoregressive parameters	NLAG=

Examples: PDLREG Procedure

Example 20.1: Industrial Conference Board Data

In this example, a second-degree Almon polynomial lag model is fit to a model with a five-period lag, and dummy variables are used for quarter effects. The PDL model is estimated using capital appropriations data series for the period 1952 to 1967. The estimation model is written

$$CE_t = a_0 + b_1 Q1_t + b_2 Q2_t + b_3 Q3_t + c_0 CA_t + c_1 CA_{t-1} + \dots + c_5 CA_{t-5}$$

where CE represents capital expenditures and CA represents capital appropriations.

```

The following statements use the REG procedure to fit the same polynomial distributed lag model. A DATA step computes lagged values of the regressor X, and RESTRICT statements are used to impose the polynomial lag distribution. Refer to Judge et al. (1985, pp. 357–359) for the restricted least squares estimation of the Almon distributed lag model.

```

data b;
  set a;
  ca_1 = lag( ca );
  ca_2 = lag2( ca );
  ca_3 = lag3( ca );
  ca_4 = lag4( ca );
  ca_5 = lag5( ca );
run;

proc reg data=b;
  model ce = q1 q2 q3 ca ca_1 ca_2 ca_3 ca_4 ca_5;
  restrict - ca + 5*ca_1 - 10*ca_2 + 10*ca_3 - 5*ca_4 + ca_5;
  restrict ca - 3*ca_1 + 2*ca_2 + 2*ca_3 - 3*ca_4 + ca_5;
  restrict -5*ca + 7*ca_1 + 4*ca_2 - 4*ca_3 - 7*ca_4 + 5*ca_5;
run;

```

Example 20.2: Money Demand Model

This example estimates the demand for money by using the following dynamic specification:

$$m_t = a_0 + b_0 m_{t-1} + \sum_{i=0}^5 c_i y_{t-i} + \sum_{i=0}^2 d_i r_{t-i} + \sum_{i=0}^3 f_i p_{t-i} + u_t$$

where

m_t = log of real money stock (M1)

y_t = log of real GNP

r_t = interest rate (commercial paper rate)

p_t = inflation rate

$c_i, d_i,$ and f_i ($i > 0$) are coefficients for the lagged variables

The following DATA step reads the data and transforms the real money and real GNP variables using the natural logarithm. Refer to Balke and Gordon (1986) for a description of the data.

```
data a;
  input m1 gnp gdf r @@;
  m   = log( 100 * m1 / gdf );
  lagm = lag( m );
  y   = log( gnp );
  p   = log( gdf / lag( gdf ) );
  date = intnx( 'qtr', '1jan1968'd, _n_-1 );
```

```
format date yyqq6.;
label m      = 'Real Money Stock (M1)'
      lagm   = 'Lagged Real Money Stock'
      y      = 'Real GNP'
      r      = 'Commercial Paper Rate'
      p      = 'Inflation Rate';
datalines;

... more lines ...
```

Overview: QLIM Procedure

The QLIM (qualitative and limited dependent variable model) procedure analyzes univariate and multivariate limited dependent variable models where dependent variables take discrete values or dependent variables are observed only in a limited range of values. This procedure includes logit, probit, tobit, selection, and multivariate models. The multivariate model can contain discrete choice and limited endogenous variables as well as continuous endogenous variables.

The QLIM procedure supports the following models:

- linear regression model with heteroscedasticity
- Box-Cox regression with heteroscedasticity
- probit with heteroscedasticity
- logit with heteroscedasticity
- tobit (censored and truncated) with heteroscedasticity
- bivariate probit
- bivariate tobit
- sample selection and switching regression models
- multivariate limited dependent variables
- stochastic frontier production and cost models

In the linear regression models with heteroscedasticity, the assumption that error variance is constant across observations is relaxed. The QLIM procedure allows for a number of different linear and nonlinear variance specifications. Another way to make the linear model more appropriate to fit the data and reduce skewness is to apply Box-Cox transformation. If the nature of data is such that the dependent variable is discrete and it takes only two possible values, OLS estimates are inconsistent. The QLIM procedure offers probit and logit models to overcome these estimation problems. Assumptions about the error variance can also be relaxed in order to estimate probit or logit with heteroscedasticity.

The QLIM procedure also offers a class of models where the dependent variable is censored or truncated from below and/or above. When a continuous dependent variable is observed only

within a certain range and values outside this range are not available, the QLIM procedure offers a class of models adjusting for truncation. In some cases, the dependent variable is continuous only in a certain range and all values outside this range are reported as being on its boundary. For example, if it is not possible to observe negative values, the value of the dependent variable is reported as equal to zero. Because the data are censored, OLS results are inconsistent, and it cannot be guaranteed that the predicted values from the model fall in the appropriate region.

Most of the models in the QLIM procedure can be extended to accommodate bivariate and multivariate scenarios. The assumption that one variable is observed only if another variable takes on certain values lead to the introduction of sample selection models. If the dependent variables are mutually exclusive and observed only for certain ranges of the selection variable, the sample selection can be extended to include cases of switching regression. Stochastic frontier production and cost models allow for random shocks of the production or cost. They include a systematic positive component in the error term adjusting for technological or cost inefficiency.

The QLIM procedure uses maximum likelihood methods. Initial starting values for the non-linear optimizations are typically calculated by OLS.

Getting Started: QLIM Procedure

The QLIM procedure is similar in use to the other regression or simultaneous equations model procedures in the SAS System. For example, the following statements are used to estimate a binary choice model by using the probit probability function:

```
proc qlim data=a;
  model y = x1;
  endogenous y ~ discrete;
run;
```

The response variable, y , is numeric and has discrete values. PROC QLIM enables the user to specify the type of endogenous variables in the ENDOGENOUS statement. The binary probit model can be also specified as follows:

```
model y = x1 / discrete;
```

When multiple endogenous variables are specified in the QLIM procedure, these equations are estimated as a system. Multiple endogenous variables can be specified with one MODEL statement in the QLIM procedure when these models have the same exogenous variables:

```
model y1 y2 = x1 x2 / discrete;
```

The preceding specification is equivalent to the following statements:

```
proc qlim data=a;
  model y1 = x1 x2;
  model y2 = x1 x2;
  endogenous y1 y2 ~ discrete;
run;
```

The standard tobit model is estimated by specifying the endogenous variable to be truncated or censored. The limits of the dependent variable can be specified with the CENSORED or TRUNCATED option in the ENDOGENOUS or MODEL statement when the data are limited by specific values or variables. For example, the two-limit censored model requires two variables that contain the lower (bottom) and upper (top) bound:

```
proc qlim data=a;
  model y = x1 x2 x3;
  endogenous y ~ censored(lb=bottom ub=top);
run;
```

The bounds can be numbers if they are fixed for all observations in the data set. For example, the standard tobit model can be specified as follows:

```
proc qlim data=a;
  model y = x1 x2 x3;
  endogenous y ~ censored(lb=0);
run;
```

Introductory Example: Binary Probit and Logit Models

The following example illustrates the use of PROC QLIM. The data were originally published by Mroz (1987) and downloaded from Wooldridge (2002). This data set is based on a sample of 753 married white women. The dependent variable is a discrete variable of labor force participation (`inlf`). Explanatory variables are the number of children ages 5 or younger (`kidslt6`), the number of children ages 6 to 18 (`kidsge6`), the woman's age (`age`), the woman's years of schooling (`educ`), wife's labor experience (`exper`), square of experience (`expersq`), and the family income excluding the wife's wage (`nwifeinc`). The program (with data values omitted) is as follows:

```
/*-- Binary Probit --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
              age kidslt6 kidsge6 / discrete;
run;
```

Results of this analysis are shown in the following four figures. In the first table, shown in [Figure 21.1](#), PROC QLIM provides frequency information about each choice. In this example, 428 women participate in the labor force (`inlf = 1`).

Figure 21.1 Choice Frequency Summary

Binary Data			
The QLIM Procedure			
Discrete Response Profile of inlf			
Index	Value	Frequency	Percent
1	0	325	43.16
2	1	428	56.84

The second table is the estimation summary table shown in [Figure 21.2](#). Included are the number of dependent variables, names of dependent variables, the number of observations, the log-likelihood function value, the maximum absolute gradient, the number of iterations, AIC, and Schwarz criterion.

Figure 21.2 Fit Summary Table of Binary Probit

Model Fit Summary	
Number of Endogenous Variables	1
Endogenous Variable	inlf
Number of Observations	753
Log Likelihood	-401.30219
Maximum Absolute Gradient	0.0000669
Number of Iterations	15
Optimization Method	Quasi-Newton
AIC	818.60439
Schwarz Criterion	855.59691

Goodness-of-fit measures are displayed in [Figure 21.3](#). All measures except McKelvey-Zavoina's definition are based on the log-likelihood function value. The likelihood ratio test statistic has chi-square distribution conditional on the null hypothesis that all slope coefficients are zero. In this example, the likelihood ratio statistic is used to test the hypothesis that $\text{kidslt6} = \text{kidge6} = \text{age} = \text{educ} = \text{exper} = \text{expersq} = \text{nwifeinc} = 0$.

Figure 21.3 Goodness of Fit

Goodness-of-Fit Measures		
Measure	Value	Formula
Likelihood Ratio (R)	227.14	$2 * (\text{LogL} - \text{LogL0})$
Upper Bound of R (U)	1029.7	$- 2 * \text{LogL0}$
Aldrich-Nelson	0.2317	$R / (R+N)$
Cragg-Uhler 1	0.2604	$1 - \exp(-R/N)$
Cragg-Uhler 2	0.3494	$(1 - \exp(-R/N)) / (1 - \exp(-U/N))$
Estrella	0.2888	$1 - (1 - R/U)^{(U/N)}$
Adjusted Estrella	0.2693	$1 - ((\text{LogL} - K) / \text{LogL0})^{(-2/N * \text{LogL0})}$
McFadden's LRI	0.2206	R / U
Veall-Zimmermann	0.4012	$(R * (U+N)) / (U * (R+N))$
McKelvey-Zavoina	0.4025	

N = # of observations, K = # of regressors

Finally, the parameter estimates and standard errors are shown in [Figure 21.4](#).

Figure 21.4 Parameter Estimates of Binary Probit

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.270077	0.508590	0.53	0.5954
nwifeinc	1	-0.012024	0.004840	-2.48	0.0130
educ	1	0.130905	0.025255	5.18	<.0001
exper	1	0.123348	0.018720	6.59	<.0001
expersq	1	-0.001887	0.000600	-3.14	0.0017
age	1	-0.052853	0.008477	-6.24	<.0001
kidslt6	1	-0.868329	0.118519	-7.33	<.0001
kidsge6	1	0.036005	0.043477	0.83	0.4076

When the error term has a logistic distribution, the binary logit model is estimated. To specify a logistic distribution, add D=LOGIT option as follows:

```

/*-- Binary Logit --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
              age kidslt6 kidsge6 / discrete(d=logit);
run;

```

The estimated parameters are shown in [Figure 21.5](#).

Figure 21.5 Parameter Estimates of Binary Logit

Binary Data					
The QLIM Procedure					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.425452	0.860365	0.49	0.6210
nwifeinc	1	-0.021345	0.008421	-2.53	0.0113
educ	1	0.221170	0.043441	5.09	<.0001
exper	1	0.205870	0.032070	6.42	<.0001
expersq	1	-0.003154	0.001017	-3.10	0.0019
age	1	-0.088024	0.014572	-6.04	<.0001
kidslt6	1	-1.443354	0.203575	-7.09	<.0001
kidsge6	1	0.060112	0.074791	0.80	0.4215

The heteroscedastic logit model can be estimated using the HETERO statement. If the variance of the logit model is a function of the family income level excluding wife's income (nwifeinc), the variance can be specified as

$$\text{Var}(\epsilon_i) = \sigma^2 \exp(\gamma * \text{nwifeinc}_i)$$

where σ^2 is normalized to 1 because the dependent variable is discrete. The following SAS statements estimate the heteroscedastic logit model:

```

/*-- Binary Logit with Heteroscedasticity --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
              age kidslt6 kidsge6 / discrete(d=logit);
  hetero inlf ~ nwifeinc / noconst;
run;

```

The parameter estimate, γ , of the heteroscedasticity variable is listed as `_H.nwifeinc`; see [Figure 21.6](#).

Syntax: QLIM Procedure

The QLIM procedure is controlled by the following statements:

```

PROC QLIM options ;
BOUNDS bound1 < , bound2 ... > ;
BY variables ;
CLASS variables ;
ENDOGENOUS variables ~ options ;
HETERO dependent variables ~ exogenous variables / options ;
INIT initvalue1 < , initvalue2 ... > ;
MODEL dependent variables = regressors / options ;
NLOPTIONS options ;
OUTPUT options ;
RESTRICT restriction1 < , restriction2 ... > ;
TEST options ;
WEIGHT variable ;

```

At least one MODEL statement is required. If more than one MODEL statement is used, the QLIM procedure estimates a system of models. Main effects and higher-order terms can be specified in the MODEL statement, as in the GLM procedure and PROBIT procedure in SAS/STAT. If a CLASS statement is used, it must precede the MODEL statement.

Functional Summary

The statements and options used with the QLIM procedure are summarized in the following table.

Table 21.1 QLIM Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	QLIM	DATA=
write parameter estimates to an output data set	QLIM	OUTEST=
write predictions to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify classification variables	CLASS	
specify a weight variable	WEIGHT	
Printing Control Options		
request all printing options	QLIM	PRINTALL
print correlation matrix of the estimates	QLIM	CORRB
print covariance matrix of the estimates	QLIM	COVB
print a summary iteration listing	QLIM	ITPRINT
suppress the normal printed output	QLIM	NOPRINT
Options to Control the Optimization Process		
specify the optimization method	QLIM	METHOD=
specify the optimization options	NLOPTIONS	see Chapter 6, “ Nonlinear Optimization Methods ,”
set initial values for parameters	INIT	
set linear restrictions on parameters	BOUNDS	RE- STRICT
Model Estimation Options		
specify options specific to Box-Cox transformation	MODEL	BOXCOX()
suppress the intercept parameter	MODEL	NOINT
specify a seed for pseudo-random number generation	QLIM	SEED=
specify number of draws for Monte Carlo integration	QLIM	NDRAW=
specify method to calculate parameter covariance	QLIM	COVEST=
Endogenous Variable Options		
specify discrete variable	ENDOGENOUS	DISCRETE()
specify censored variable	ENDOGENOUS	CENSORED()
specify truncated variable	ENDOGENOUS	TRUNCATED()
specify variable selection condition	ENDOGENOUS	SELECT()

Table 21.1 *continued*

Description	Statement	Option
specify stochastic frontier variable	ENDOGENOUS	FRONTIER()
Heteroscedasticity Model Options		
specify the function for heteroscedasticity models	HETERO	LINK=
square the function for heteroscedasticity models	HETERO	SQUARE
specify no constant for heteroscedasticity models	HETERO	NOCONST
Output Control Options		
output predicted values	OUTPUT	PREDICTED
output structured part	OUTPUT	XBETA
output residuals	OUTPUT	RESIDUAL
output error standard deviation	OUTPUT	ERRSTD
output marginal effects	OUTPUT	MARGINAL
output probability for the current response	OUTPUT	PROB
output probability for all responses	OUTPUT	PROBALL
output expected value	OUTPUT	EXPECTED
output conditional expected value	OUTPUT	CONDITIONAL
output inverse Mills ratio	OUTPUT	MILLS
include covariances in the OUTEST= data set	QLIM	COVOUT
include correlations in the OUTEST= data set	QLIM	CORROUT
Test Request Options		
Requests Wald, Lagrange multiplier, and likelihood ratio tests	TEST	ALL
Requests the WALD test	TEST	WALD
Requests the Lagrange multiplier test	TEST	LM
Requests the likelihood ratio test	TEST	LR

PROC QLIM Statement

PROC QLIM *options* ;

The following options can be used in the PROC QLIM statement.

Data Set Options

DATA=*SAS-data-set*

specifies the input SAS data set. If the DATA= option is not specified, PROC QLIM uses the most recently created SAS data set.

Output Data Set Options

OUTEST=SAS-data-set

writes the parameter estimates to an output data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

CORROUT

writes the correlation matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

Printing Options

NOPRINT

suppresses the normal printed output but does not suppress error listings. If NOPRINT option is set, then any other print option is turned off.

PRINTALL

turns on all the printing-control options. The options set by PRINTALL are COVB and CORRB.

CORRB

prints the correlation matrix of the parameter estimates.

COVB

prints the covariance matrix of the parameter estimates.

ITPRINT

prints the initial parameter estimates, convergence criteria, and all constraints of the optimization. At each iteration, objective function value, step size, maximum gradient, and slope of search direction are printed as well.

Model Estimation Options

COVEST=covariance-option

specifies the method to calculate the covariance matrix of parameter estimates. The supported covariance types are as follows:

OP	specifies the covariance from the outer product matrix.
HESSIAN	specifies the covariance from the inverse Hessian matrix.
QML	specifies the covariance from the outer product and Hessian matrices (the quasi-maximum likelihood estimates).

The default is COVEST=HESSIAN.

NDRAW=value

specifies the number of draws for Monte Carlo integration.

SEED=value

specifies a seed for pseudo-random number generation in Monte Carlo integration.

Options to Control the Optimization Process

PROC QLIM uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. All the NLO options are available from the NLOPTIONS statement. For details, see Chapter 6, “[Nonlinear Optimization Methods](#).”

METHOD=value

specifies the optimization method. If this option is specified, it overwrites the TECH= option in NLOPTIONS statement. Valid values are as follows:

CONGRA	performs a conjugate-gradient optimization
DBLDOG	performs a version of double dogleg optimization
NMSIMP	performs a Nelder-Mead simplex optimization
NEWRAP	performs a Newton-Raphson optimization combining a line-search algorithm with ridging
NRRIDG	performs a Newton-Raphson optimization with ridging
QUANEW	performs a quasi-Newton optimization
TRUREG	performs a trust region optimization

The default method is METHOD=QUANEW.

BOUNDS Statement

BOUNDS *bound1* < , *bound2* ... > ;

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the QLIM procedure. Any number of BOUNDS statements can be specified.

Each *bound* is composed of parameters and constants and inequality operators. Parameters associated with regressor variables are referred to by the names of the corresponding regressor variables:

item operator item < operator item < operator item ... > >

Each *item* is a constant, the name of a parameter, or a list of parameter names. See the section “[Naming of Parameters](#)” on page 1414 for more details on how parameters are named in the QLIM procedure. Each *operator* is '<', '>', '<=', or '>='.

Both the BOUNDS statement and the RESTRICT statement can be used to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the “[RESTRICT Statement](#)” on page 1393 for more information.

The following BOUNDS statement constrains the estimates of the parameters associated with the variable `ttime` and the variables `x1` through `x10` to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < ttime x1-x10 < 1;
```

The following BOUNDS statement constrains the estimates of the correlation (`_RHO`) and sigma (`_SIGMA`) in the bivariate model:

```
bounds _rho >= 0, _sigma.y1 > 1, _sigma.y2 < 5;
```

BY Statement

BY *variables* ;

A BY statement can be used with PROC QLIM to obtain separate analyses on observations in groups defined by the BY variables.

CLASS Statement

CLASS *variables* ;

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in *SAS Language Reference: Dictionary* for details.

If the CLASS statement is used, it must appear before any of the MODEL statements.

ENDOGENOUS Statement

ENDOGENOUS *variables ~ options* ;

The ENDOGENOUS statement specifies the type of dependent variables that appear on the left-hand side of the equation. Endogenous variables listed refer to the dependent variables that appear on the left-hand side of the equation. Currently, no right-hand side endogeneity is handled in PROC QLIM. All variables appearing on the right-hand side of the equation are treated as exogenous.

Discrete Variable Options

DISCRETE < (*discrete-options*) >

specifies that the endogenous variables in this statement are discrete. Valid *discrete-options* are as follows:

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of the discrete variables specified in the ENDOGENOUS statement. This ordering determines which parameters in the model correspond to each level in the data. The following table shows how PROC QLIM interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	formatted value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For the values FORMATTED and INTERNAL, the sort order is machine dependent. For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide*.

DISTRIBUTION=*distribution-type*

DIST=*distribution-type*

D=*distribution-type*

specifies the cumulative distribution function used to model the response probabilities. Valid values for *distribution-type* are as follows:

NORMAL the normal distribution for the probit model
 LOGISTIC the logistic distribution for the logit model

By default, DISTRIBUTION=NORMAL.

If a multivariate model is specified, logistic distribution is not allowed. Only normal distribution is supported.

Censored Variable Options

CENSORED < (*censored-options*) >

specifies that the endogenous variables in this statement be censored. Valid *censored-options* are as follows:

LB=*value or variable*

LOWERBOUND=*value or variable*

specifies the lower bound of the censored variables. If *value* is missing or the value in *variable* is missing, no lower bound is set. By default, no lower bound is set.

UB=*value or variable*

UPPERBOUND=*value or variable*

specifies the upper bound of the censored variables. If *value* is missing or the value in *variable* is missing, no upper bound is set. By default, no upper bound is set.

Truncated Variable Options

TRUNCATED <(truncated-options)>

specifies that the endogenous variables in this statement be truncated. Valid *truncated-options* are as follows:

LB=*value or variable*

LOWERBOUND=*value or variable*

specifies the lower bound of the truncated variables. If *value* is missing or the value in *variable* is missing, no lower bound is set. By default, no lower bound is set.

UB=*value or variable*

UPPERBOUND=*value or variable*

specifies the upper bound of the truncated variables. If *value* is missing or the value in *variable* is missing, no upper bound is set. By default, no upper bound is set.

Stochastic Frontier Variable Options

FRONTIER <(frontier-options)>

specifies that the endogenous variable in this statement follow a production or cost frontier. Valid *frontier-options* are as follows:

TYPE=

HALF specifies half-normal model.

EXPONENTIAL specifies exponential model.

TRUNCATED specifies truncated normal model.

PRODUCTION

specifies that the model estimated be a production function.

COST

specifies that the model estimated be a cost function.

If neither PRODUCTION nor COST option is specified, production function is estimated by default.

Selection Options

SELECT (*select-option*)

specifies selection criteria for sample selection model. *Select-option* specifies the condition for the endogenous variable to be selected. It is written as a variable name, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a number:

variable operator number

The *variable* is the endogenous variable that the selection is based on. The *operator* can be =, <, >, <=, or >=. Multiple *select-options* can be combined with the logic operators: AND, OR. The following example illustrates the use of the SELECT option:

```
endogenous y1 ~ select (z=0);
endogenous y2 ~ select (z=1 or z=2);
```

The SELECT option can be used together with the DISCRETE, CENSORED, or TRUNCATED option. For example:

```
endogenous y1 ~ select (z=0) discrete;
endogenous y2 ~ select (z=1) censored (lb=0);
endogenous y3 ~ select (z=1 or z=2) truncated (ub=10);
```

For more details about selection models with censoring or truncation, see the section “[Selection Models](#)” on page 1408.

HETERO Statement

HETERO ;

dependent variables ~ exogenous variables </ options >

The HETERO statement specifies variables that are related to the heteroscedasticity of the residuals and the way these variables are used to model the error variance. The heteroscedastic regression model supported by PROC QLIM is

$$y_i = \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i$$

$$\epsilon_i \sim N(0, \sigma_i^2)$$

See the section “[Heteroscedasticity](#)” on page 1405 for more details on the specification of functional forms.

LINK=*value*

The functional form can be specified using the LINK= option. The following option values are allowed:

EXP specifies the exponential link function

$$\sigma_i^2 = \sigma^2 (1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma}))$$

LINEAR specifies the linear link function

$$\sigma_i^2 = \sigma^2(1 + \mathbf{z}'_i \boldsymbol{\gamma})$$

When the LINK= option is not specified, the exponential link function is specified by default.

NOCONST

specifies that there be no constant in the linear or exponential heteroscedasticity model.

$$\sigma_i^2 = \sigma^2(\mathbf{z}'_i \boldsymbol{\gamma})$$

$$\sigma_i^2 = \sigma^2 \exp(\mathbf{z}'_i \boldsymbol{\gamma})$$

SQUARE

estimates the model by using the square of linear heteroscedasticity function. For example, you can specify the following heteroscedasticity function:

$$\sigma_i^2 = \sigma^2(1 + (\mathbf{z}'_i \boldsymbol{\gamma})^2)$$

```
model y = x1 x2 / discrete;
hetero y ~ z1 / link=linear square;
```

The option SQUARE does not apply to exponential heteroscedasticity function because the square of an exponential function of $\mathbf{z}'_i \boldsymbol{\gamma}$ is the same as the exponential of $2\mathbf{z}'_i \boldsymbol{\gamma}$. Hence the only difference is that all $\boldsymbol{\gamma}$ estimates are divided by two.

INIT Statement

```
INIT initvalue1 < , initvalue2 ... > ;
```

The INIT statement is used to set initial values for parameters in the optimization. Any number of INIT statements can be specified.

Each *initvalue* is written as a parameter or parameter list, followed by an optional equality operator (=), followed by a number:

```
parameter <=> number
```

MODEL Statement

```
MODEL dependent = regressors < / options > ;
```

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model.

The following options can be used in the MODEL statement after a slash (/).

LIMIT1=value

specifies the restriction of the threshold value of the first category when the ordinal probit or logit model is estimated. LIMIT1=ZERO is the default option. When LIMIT1=VARYING is specified, the threshold value is estimated.

NOINT

suppresses the intercept parameter.

Endogenous Variable Options

The endogenous variable options are the same as the options specified in the ENDOGENOUS statement. If an endogenous variable has an endogenous option specified in both the MODEL statement and the ENDOGENOUS statement, the option in the ENDOGENOUS statement is used.

BOXCOX Estimation Options

BOXCOX (option-list)

specifies options that are used for Box-Cox regression or regressor transformation. For example, the Box-Cox regression is specified as

```
model y = x1 x2 / boxcox(y=lambda, x1 x2)
```

PROC QLIM estimates the following Box-Cox regression model:

$$y_i^{(\lambda)} = \beta_0 + \beta_1 x_{1i}^{(\lambda_1)} + \beta_2 x_{2i}^{(\lambda_2)} + \epsilon_i$$

The *option-list* takes the form *variable-list* <= varname > separated by ','. The *variable-list* specifies that the list of variables have the same Box-Cox transformation; *varname* specifies the name of this Box-Cox coefficient. If *varname* is not specified, the coefficient is called *_Lambdai*, where *i* increments sequentially.

NLOPTIONS Statement

```
NLOPTIONS < options > ;
```

PROC QLIM uses the be nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 6, “[Nonlinear Optimization Methods](#).”

OUTPUT Statement

```
OUTPUT < OUT=SAS-data-set > < output-options > ;
```

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the estimates of \mathbf{x}'_{ι} , predicted value, residual, marginal effects, probability, standard deviation of the error, expected value, conditional expected value, and inverse Mills ratio. When the response values are missing for the observation, all output estimates except residual are still computed as long as none of the explanatory variables is missing. This enables you to compute these statistics for prediction. You can specify only one OUTPUT statement.

Details on the specifications in the OUTPUT statement are as follows:

CONDITIONAL

output estimates of conditional expected values of continuous endogenous variables.

ERRSTD

output estimates of σ_j , the standard deviation of the error term.

EXPECTED

output estimates of expected values of continuous endogenous variables.

MARGINAL

output marginal effects.

MILLS

output estimates of inverse Mills ratios of censored or truncated continuous, binary discrete, and selection endogenous variables.

OUT=SAS-data-set

names the output data set.

PREDICTED

output estimates of predicted endogenous variables.

PROB

output estimates of probability of discrete endogenous variables taking the current observed responses.

PROBALL

output estimates of probability of discrete endogenous variables for all possible responses.

RESIDUAL

output estimates of residuals of continuous endogenous variables.

XBETA

output estimates of \mathbf{x}'_{ι} .

RESTRICT Statement

RESTRICT *restriction1* < , *restriction2* ... > ;

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. Any number of RESTRICT statements can be specified, but the number of restrictions imposed is limited by the number of regressors.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <=, or >=. The operator and second expression are optional.

Restriction expressions can be composed of parameter names, multiplication (*), addition (+) and substitution (−) operators, and constants. Parameters named in restriction expressions must be among the parameters estimated by the model. Parameters associated with a regressor variable are referred to by the name of the corresponding regressor variable. The restriction expressions must be a linear function of the parameters.

The following is an example of the use of the RESTRICT statement:

```
proc qlim data=one;
  model y = x1-x10 / discrete;
  restrict x1*2 <= x2 + x3;
run;
```

The RESTRICT statement can also be used to impose cross-equation restrictions in multivariate models. The following RESTRICT statement imposes an equality restriction on coefficients of x_1 in equation y_1 and x_1 in equation y_2 :

```
proc qlim data=one;
  model y1 = x1-x10;
  model y2 = x1-x4;
  endogenous y1 y2 ~ discrete;
  restrict y1.x1=y2.x1;
run;
```

TEST Statement

<label'> **TEST** <string'> equation [,equation...]/options ;

The TEST statement performs Wald, Lagrange multiplier, and likelihood ratio tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following options can be specified in the TEST statement after the slash (/):

ALL

requests Wald, Lagrange multiplier, and likelihood ratio tests.

WALD

requests the Wald test.

LM

requests the Lagrange multiplier test.

LR

requests the likelihood ratio test.

The following illustrates the use of the TEST statement:

```
proc qlim;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0;
  test _int: test intercept = 0, x3 = 0;
run;
```

The first test investigates the joint hypothesis that

$$\beta_1 = 0$$

and

$$0.5\beta_2 + 2\beta_3 = 0$$

Only linear equality restrictions and tests are permitted in PROC QLIM. Tests expressions can be composed only of algebraic operations involving the addition symbol (+), subtraction symbol (-), and multiplication symbol (*).

The TEST statement accepts labels that are reproduced in the printed output. TEST statement can be labeled in two ways. A TEST statement can be preceded by a label followed by a colon. Alternatively, the keyword TEST can be followed by a quoted string. If both are present, PROC QLIM uses the label preceding the colon. In the event no label is present, PROC QLIM automatically labels the tests.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters. The log likelihood for each observation is multiplied by the corresponding weight variable value.

If the weight of an observation is nonpositive, that observation is not used in the estimation.

Details: QLIM Procedure

Ordinal Discrete Choice Modeling

Binary Probit and Logit Model

The binary choice model is

$$y_i^* = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

where value of the latent dependent variable, y_i^* , is observed only as follows:

$$\begin{aligned} y_i &= 1 && \text{if } y_i^* > 0 \\ &= 0 && \text{otherwise} \end{aligned}$$

The disturbance, ϵ_i , of the probit model has standard normal distribution with the distribution function (CDF)

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp(-t^2/2) dt$$

The disturbance of the logit model has standard logistic distribution with the CDF

$$\Lambda(x) = \frac{\exp(x)}{1 + \exp(x)} = \frac{1}{1 + \exp(-x)}$$

The binary discrete choice model has the following probability that the event $\{y_i = 1\}$ occurs:

$$P(y_i = 1) = F(\mathbf{x}_i' \boldsymbol{\beta}) = \begin{cases} \Phi(\mathbf{x}_i' \boldsymbol{\beta}) & \text{(probit)} \\ \Lambda(\mathbf{x}_i' \boldsymbol{\beta}) & \text{(logit)} \end{cases}$$

The log-likelihood function is

$$\ell = \sum_{i=1}^N \{y_i \log[F(\mathbf{x}_i' \boldsymbol{\beta})] + (1 - y_i) \log[1 - F(\mathbf{x}_i' \boldsymbol{\beta})]\}$$

where the CDF $F(x)$ is defined as $\Phi(x)$ for the probit model while $F(x) = \Lambda(x)$ for logit. The first order derivative of the logit model are

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N (y_i - \Lambda(\mathbf{x}_i' \boldsymbol{\beta})) \mathbf{x}_i$$

The probit model has more complicated derivatives

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N \left[\frac{(2y_i - 1)\phi(\mathbf{x}_i' \boldsymbol{\beta})}{\Phi(\mathbf{x}_i' \boldsymbol{\beta})} \right] \mathbf{x}_i = \sum_{i=1}^N r_i \mathbf{x}_i$$

where

$$r_i = \frac{(2y_i - 1)\phi(\mathbf{x}'_i\boldsymbol{\beta})}{\Phi(\mathbf{x}'_i\boldsymbol{\beta})}$$

Note that the logit maximum likelihood estimates are $\frac{\pi}{\sqrt{3}}$ times greater than probit maximum likelihood estimates, since the probit parameter estimates, $\boldsymbol{\beta}$, are standardized, and the error term with logistic distribution has a variance of $\frac{\pi^2}{3}$.

Ordinal Probit/Logit

When the dependent variable is observed in sequence with M categories, binary discrete choice modeling is not appropriate for data analysis. McKelvey and Zavoina (1975) proposed the ordinal (or ordered) probit model.

Consider the following regression equation:

$$y_i^* = \mathbf{x}'_i\boldsymbol{\beta} + \epsilon_i$$

where error disturbances, ϵ_i , have the distribution function F . The unobserved continuous random variable, y_i^* , is identified as M categories. Suppose there are $M + 1$ real numbers, μ_0, \dots, μ_M , where $\mu_0 = -\infty, \mu_1 = 0, \mu_M = \infty$, and $\mu_0 \leq \mu_1 \leq \dots \leq \mu_M$. Define

$$R_{i,j} = \mu_j - \mathbf{x}'_i\boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the j th category can be written as

$$P[\mu_{j-1} < y_i^* \leq \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The log-likelihood function is

$$\ell = \sum_{i=1}^N \sum_{j=1}^M d_{ij} \log [F(R_{i,j}) - F(R_{i,j-1})]$$

where

$$d_{ij} = \begin{cases} 1 & \text{if } \mu_{j-1} < y_i \leq \mu_j \\ 0 & \text{otherwise} \end{cases}$$

The first derivatives are written as

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N \sum_{j=1}^M d_{ij} \left[\frac{f(R_{i,j-1}) - f(R_{i,j})}{F(R_{i,j}) - F(R_{i,j-1})} \mathbf{x}_i \right]$$

$$\frac{\partial \ell}{\partial \mu_k} = \sum_{i=1}^N \sum_{j=1}^M d_{ij} \left[\frac{\delta_{j,k} f(R_{i,j}) - \delta_{j-1,k} f(R_{i,j-1})}{F(R_{i,j}) - F(R_{i,j-1})} \right]$$

where $f(x) = \frac{dF(x)}{dx}$ and $\delta_{j,k} = 1$ if $j = k$. When the ordinal probit is estimated, it is assumed that $F(R_{i,j}) = \Phi(R_{i,j})$. The ordinal logit model is estimated if $F(R_{i,j}) = \Lambda(R_{i,j})$. The first

threshold parameter, μ_1 , is estimated when the LIMIT1=VARYING option is specified. By default (LIMIT1=ZERO), so that $M - 2$ threshold parameters (μ_2, \dots, μ_{M-1}) are estimated.

The ordered probit models are analyzed by Aitchison and Silvey (1957), and Cox (1970) discussed ordered response data by using the logit model. They defined the probability that y_i^* belongs to j th category as

$$P[\mu_{j-1} < y_i \leq \mu_j] = F(\mu_j + \mathbf{x}_i' \boldsymbol{\theta}) - F(\mu_{j-1} + \mathbf{x}_i' \boldsymbol{\theta})$$

where $\mu_0 = -\infty$ and $\mu_M = \infty$. Therefore, the ordered response model analyzed by Aitchison and Silvey can be estimated if the LIMIT1=VARYING option is specified. Note that $\boldsymbol{\theta} = -\boldsymbol{\beta}$.

Goodness-of-Fit Measures

The goodness-of-fit measures discussed in this section apply only to discrete dependent variable models.

McFadden (1974) suggested a likelihood ratio index that is analogous to the R^2 in the linear regression model:

$$R_M^2 = 1 - \frac{\ln L}{\ln L_0}$$

where L is the value of the maximum likelihood function and L_0 is a likelihood function when regression coefficients except an intercept term are zero. It can be shown that L_0 can be written as

$$L_0 = \sum_{j=1}^M N_j \ln\left(\frac{N_j}{N}\right)$$

where N_j is the number of responses in category j .

Estrella (1998) proposes the following requirements for a goodness-of-fit measure to be desirable in discrete choice modeling:

- The measure must take values in $[0, 1]$, where 0 represents no fit and 1 corresponds to perfect fit.
- The measure should be directly related to the valid test statistic for significance of all slope coefficients.
- The derivative of the measure with respect to the test statistic should comply with corresponding derivatives in a linear regression.

Estrella's (1998) measure is written

$$R_{E1}^2 = 1 - \left(\frac{\ln L}{\ln L_0}\right)^{-\frac{2}{N} \ln L_0}$$

An alternative measure suggested by Estrella (1998) is

$$R_{E2}^2 = 1 - [(\ln L - K) / \ln L_0]^{-\frac{2}{N} \ln L_0}$$

where $\ln L_0$ is computed with null slope parameter values, N is the number observations used, and K represents the number of estimated parameters.

Other goodness-of-fit measures are summarized as follows:

$$R_{CU1}^2 = 1 - \left(\frac{L_0}{L}\right)^{\frac{2}{N}} \quad (\text{Cragg - Uhler1})$$

$$R_{CU2}^2 = \frac{1 - (L_0/L)^{\frac{2}{N}}}{1 - L_0^{\frac{2}{N}}} \quad (\text{Cragg - Uhler2})$$

$$R_A^2 = \frac{2(\ln L - \ln L_0)}{2(\ln L - \ln L_0) + N} \quad (\text{Aldrich - Nelson})$$

$$R_{VZ}^2 = R_A^2 \frac{2 \ln L_0 - N}{2 \ln L_0} \quad (\text{Veall - Zimmermann})$$

$$R_{MZ}^2 = \frac{\sum_{i=1}^N (\hat{y}_i - \bar{\hat{y}})^2}{N + \sum_{i=1}^N (\hat{y}_i - \bar{\hat{y}})^2} \quad (\text{McKelvey - Zavoina})$$

where $\hat{y}_i = \mathbf{x}'_i \hat{\boldsymbol{\beta}}$ and $\bar{\hat{y}} = \sum_{i=1}^N \hat{y}_i / N$.

Limited Dependent Variable Models

Censored Regression Models

When the dependent variable is censored, values in a certain range are all transformed to a single value. For example, the standard tobit model can be defined as

$$y_i^* = \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \leq 0 \end{cases}$$

where $\epsilon_i \sim iidN(0, \sigma^2)$. The log-likelihood function of the standard censored regression model is

$$\ell = \sum_{i \in \{y_i=0\}} \ln[1 - \Phi(\mathbf{x}'_i \boldsymbol{\beta} / \sigma)] + \sum_{i \in \{y_i>0\}} \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right]$$

where $\Phi(\cdot)$ is the cumulative density function of the standard normal distribution and $\phi(\cdot)$ is the probability density function of the standard normal distribution.

The tobit model can be generalized to handle observation-by-observation censoring. The censored model on both of the lower and upper limits can be defined as

$$y_i = \begin{cases} R_i & \text{if } y_i^* \geq R_i \\ y_i^* & \text{if } L_i < y_i^* < R_i \\ L_i & \text{if } y_i^* \leq L_i \end{cases}$$

The log-likelihood function can be written as

$$\begin{aligned} \ell = & \sum_{i \in \{L_i < y_i < R_i\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) / \sigma \right] + \sum_{i \in \{y_i = R_i\}} \ln \left[\Phi \left(-\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] + \\ & \sum_{i \in \{y_i = L_i\}} \ln \left[\Phi \left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] \end{aligned}$$

Log-likelihood functions of the lower- or upper-limit censored model are easily derived from the two-limit censored model. The log-likelihood function of the lower-limit censored model is

$$\ell = \sum_{i \in \{y_i > L_i\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) / \sigma \right] + \sum_{i \in \{y_i = L_i\}} \ln \left[\Phi \left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right]$$

The log-likelihood function of the upper-limit censored model is

$$\ell = \sum_{i \in \{y_i < R_i\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) / \sigma \right] + \sum_{i \in \{y_i = R_i\}} \ln \left[1 - \Phi \left(\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right]$$

Types of Tobit Models

Amemiya (1984) classified Tobit models into five types based on characteristics of the likelihood function. For notational convenience, let P denote a distribution or density function, y_{ji}^* is assumed to be normally distributed with mean $\mathbf{x}'_{ji} \boldsymbol{\beta}_j$ and variance σ_j^2 .

Type 1 Tobit

The Type 1 Tobit model was already discussed in the preceding section.

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\ y_{1i} &= y_{1i}^* \quad \text{if } y_{1i}^* > 0 \\ &= 0 \quad \text{if } y_{1i}^* \leq 0 \end{aligned}$$

The likelihood function is characterized as $P(y_1 < 0)P(y_1)$.

Type 2 Tobit

The Type 2 Tobit model is defined as

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\ y_{1i} &= 1 \quad \text{if } y_{1i}^* > 0 \\ &= 0 \quad \text{if } y_{1i}^* \leq 0 \\ y_{2i} &= y_{2i}^* \quad \text{if } y_{1i}^* > 0 \\ &= 0 \quad \text{if } y_{1i}^* \leq 0 \end{aligned}$$

where $(u_{1i}, u_{2i}) \sim N(0, \Sigma)$. The likelihood function is described as $P(y_1 < 0)P(y_1 > 0, y_2)$.

Type 3 Tobit

The Type 3 Tobit model is different from the Type 2 Tobit in that y_{1i}^* of the Type 3 Tobit is observed when $y_{1i}^* > 0$.

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\ y_{1i} &= y_{1i}^* \text{ if } y_{1i}^* > 0 \\ &= 0 \text{ if } y_{1i}^* \leq 0 \\ y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\ &= 0 \text{ if } y_{1i}^* \leq 0 \end{aligned}$$

where $(u_{1i}, u_{2i})' \sim iidN(0, \Sigma)$.

The likelihood function is characterized as $P(y_1 < 0)P(y_1, y_2)$.

Type 4 Tobit

The Type 4 Tobit model consists of three equations:

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\ y_{3i}^* &= \mathbf{x}'_{3i} \boldsymbol{\beta}_3 + u_{3i} \\ y_{1i} &= y_{1i}^* \text{ if } y_{1i}^* > 0 \\ &= 0 \text{ if } y_{1i}^* \leq 0 \\ y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\ &= 0 \text{ if } y_{1i}^* \leq 0 \\ y_{3i} &= y_{3i}^* \text{ if } y_{1i}^* \leq 0 \\ &= 0 \text{ if } y_{1i}^* > 0 \end{aligned}$$

where $(u_{1i}, u_{2i}, u_{3i})' \sim iidN(0, \Sigma)$. The likelihood function of the Type 4 Tobit model is characterized as $P(y_1 < 0, y_3)P(y_1, y_2)$.

Type 5 Tobit

The Type 5 Tobit model is defined as follows:

$$\begin{aligned}
 y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\
 y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\
 y_{3i}^* &= \mathbf{x}'_{3i} \boldsymbol{\beta}_3 + u_{3i} \\
 y_{1i} &= 1 \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{3i} &= y_{3i}^* \text{ if } y_{1i}^* \leq 0 \\
 &= 0 \text{ if } y_{1i}^* > 0
 \end{aligned}$$

where $(u_{1i}, u_{2i}, u_{3i})'$ are from *iid* trivariate normal distribution. The likelihood function of the Type 5 Tobit model is characterized as $P(y_1 < 0, y_3)P(y_1 > 0, y_2)$.

Code examples for these models can be found in “[Example 21.6: Types of Tobit Models](#)” on page 1426.

Truncated Regression Models

In a truncated model, the observed sample is a subset of the population where the dependent variable falls in a certain range. For example, when neither a dependent variable nor exogenous variables are observed for $y_i^* \leq 0$, the truncated regression model can be specified.

$$\ell = \sum_{i \in \{y_i > 0\}} \left\{ -\ln \Phi(\mathbf{x}'_i \boldsymbol{\beta} / \sigma) + \ln \left[\frac{\phi((y_i - \mathbf{x}'_i \boldsymbol{\beta}) / \sigma)}{\sigma} \right] \right\}$$

Two-limit truncation model is defined as

$$y_i = y_i^* \text{ if } L_i < y_i^* < R_i$$

The log-likelihood function of the two-limit truncated regression model is

$$\ell = \sum_{i=1}^N \left\{ \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right] - \ln \left[\Phi\left(\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) - \Phi\left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) \right] \right\}$$

The log-likelihood functions of the lower- and upper-limit truncation model are

$$\begin{aligned}
 \ell &= \sum_{i=1}^N \left\{ \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right] - \ln \left[1 - \Phi\left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) \right] \right\} \quad (\text{lower}) \\
 \ell &= \sum_{i=1}^N \left\{ \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right] - \ln \left[\Phi\left(\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) \right] \right\} \quad (\text{upper})
 \end{aligned}$$

Stochastic Frontier Production and Cost Models

Stochastic frontier production models were first developed by Aigner, Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Specification of these models allow for random shocks of the production or cost but also include a term for technological or cost inefficiency. Assuming that the production function takes a log-linear Cobb-Douglas form, the stochastic frontier production model can be written as

$$\ln(y_i) = \beta_0 + \sum_n \beta_n \ln(x_{ni}) + \epsilon_i$$

where $\epsilon_i = v_i - u_i$. The v_i term represents the stochastic error component and u_i is the nonnegative, technology inefficiency error component. The v_i error component is assumed to be distributed iid normal and independently from u_i . If $u_i > 0$, the error term, ϵ_i , is negatively skewed and represents technology inefficiency. If $u_i < 0$, the error term ϵ_i is positively skewed and represents cost inefficiency. PROC QLIM models the u_i error component as a half normal, exponential, or truncated normal distribution.

The Normal-Half Normal Model

In case of the normal-half normal model, v_i is iid $N(0, \sigma_v^2)$, u_i is iid $N^+(0, \sigma_u^2)$ with v_i and u_i independent of each other. Given the independence of error terms, the joint density of v and u can be written as

$$f(u, v) = \frac{2}{2\pi\sigma_u\sigma_v} \exp\left\{-\frac{u^2}{2\sigma_u^2} - \frac{v^2}{2\sigma_v^2}\right\}$$

Substituting $v = \epsilon + u$ into the preceding equation gives

$$f(u, \epsilon) = \frac{2}{2\pi\sigma_u\sigma_v} \exp\left\{-\frac{u^2}{2\sigma_u^2} - \frac{(\epsilon + u)^2}{2\sigma_v^2}\right\}$$

Integrating u out to obtain the marginal density function of ϵ results in the following form:

$$\begin{aligned} f(\epsilon) &= \int_0^{\infty} f(u, \epsilon) du \\ &= \frac{2}{\sqrt{2\pi}\sigma} \left[1 - \Phi\left(\frac{\epsilon\lambda}{\sigma}\right)\right] \exp\left\{-\frac{\epsilon^2}{2\sigma^2}\right\} \\ &= \frac{2}{\sigma} \phi\left(\frac{\epsilon}{\sigma}\right) \Phi\left(-\frac{\epsilon\lambda}{\sigma}\right) \end{aligned}$$

where $\lambda = \sigma_u/\sigma_v$ and $\sigma = \sqrt{\sigma_u^2 + \sigma_v^2}$.

In the case of a stochastic frontier cost model, $v = \epsilon - u$ and

$$f(\epsilon) = \frac{2}{\sigma} \phi\left(\frac{\epsilon}{\sigma}\right) \Phi\left(\frac{\epsilon\lambda}{\sigma}\right)$$

The log-likelihood function for the production model with N producers is written as

$$\ln L = \text{constant} - N \ln \sigma + \sum_i \ln \Phi \left(-\frac{\epsilon_i \lambda}{\sigma} \right) - \frac{1}{2\sigma^2} \sum_i \epsilon_i^2$$

The Normal-Exponential Model

Under the normal-exponential model, v_i is iid $N(0, \sigma_v^2)$ and u_i is iid exponential. Given the independence of error term components u_i and v_i , the joint density of v and u can be written as

$$f(u, v) = \frac{1}{\sqrt{2\pi}\sigma_u\sigma_v} \exp \left\{ -\frac{u}{\sigma_u} - \frac{v^2}{2\sigma_v^2} \right\}$$

The marginal density function of ϵ for the production function is

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \left(\frac{1}{\sigma_u} \right) \Phi \left(-\frac{\epsilon}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right) \exp \left\{ \frac{\epsilon}{\sigma_u} + \frac{\sigma_v^2}{2\sigma_u^2} \right\} \end{aligned}$$

and the marginal density function for the cost function is equal to

$$f(\epsilon) = \left(\frac{1}{\sigma_u} \right) \Phi \left(\frac{\epsilon}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right) \exp \left\{ -\frac{\epsilon}{\sigma_u} + \frac{\sigma_v^2}{2\sigma_u^2} \right\}$$

The log-likelihood function for the normal-exponential production model with N producers is

$$\ln L = \text{constant} - N \ln \sigma_u + N \left(\frac{\sigma_v^2}{2\sigma_u^2} \right) + \sum_i \frac{\epsilon_i}{\sigma_u} + \sum_i \ln \Phi \left(\frac{\epsilon_i}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right)$$

The Normal-Truncated Normal Model

The normal-truncated normal model is a generalization of the normal-half normal model by allowing the mean of u_i to differ from zero. Under the normal-truncated normal model, the error term component v_i is iid $N^+(0, \sigma_v^2)$ and u_i is iid $N(\mu, \sigma_u^2)$. The joint density of v_i and u_i can be written as

$$f(u, v) = \frac{1}{\sqrt{2\pi}\sigma_u\sigma_v\Phi(\mu/\sigma_u)} \exp \left\{ -\frac{(u-\mu)^2}{2\sigma_u^2} - \frac{v^2}{2\sigma_v^2} \right\}$$

The marginal density function of ϵ for the production function is

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \frac{1}{\sqrt{2\pi}\sigma\Phi(\mu/\sigma_u)} \Phi \left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon\lambda}{\sigma} \right) \exp \left\{ -\frac{(\epsilon+\mu)^2}{2\sigma^2} \right\} \\ &= \frac{1}{\sigma} \phi \left(\frac{\epsilon+\mu}{\sigma} \right) \Phi \left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon\lambda}{\sigma} \right) \left[\Phi \left(\frac{\mu}{\sigma_u} \right) \right]^{-1} \end{aligned}$$

and the marginal density function for the cost function is

$$f(\epsilon) = \frac{1}{\sigma} \phi\left(\frac{\epsilon - \mu}{\sigma}\right) \Phi\left(\frac{\mu}{\sigma\lambda} + \frac{\epsilon\lambda}{\sigma}\right) \left[\Phi\left(\frac{\mu}{\sigma_u}\right)\right]^{-1}$$

The log-likelihood function for the normal-truncated normal production model with N producers is

$$\begin{aligned} \ln L = & \text{constant} - N \ln \sigma - N \ln \Phi\left(\frac{\mu}{\sigma_u}\right) + \sum_i \ln \Phi\left(\frac{\mu}{\sigma\lambda} + \frac{\epsilon_i \lambda}{\sigma}\right) \\ & - \frac{1}{2} \sum_i \left(\frac{\epsilon_i + \mu}{\sigma}\right)^2 \end{aligned}$$

For more detail on normal-half normal, normal-exponential, and normal-truncated models, see Kumbhakar and Knox Lovell (2000) and Coelli, Prasada Rao, and Battese (1998).

Heteroscedasticity and Box-Cox Transformation

Heteroscedasticity

If the variance of regression disturbance, (ϵ_i) , is heteroscedastic, the variance can be specified as a function of variables

$$E(\epsilon_i^2) = \sigma_i^2 = f(\mathbf{z}'_i \boldsymbol{\gamma})$$

The following table shows various functional forms of heteroscedasticity and the corresponding options to request each model.

No.	Model	Options
1	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma}))$	link=EXP (default)
2	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2 \exp(\mathbf{z}'_i \boldsymbol{\gamma})$	link=EXP noconst
3	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(1 + \sum_{l=1}^L \gamma_l z_{li})$	link=LINEAR
4	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(1 + (\sum_{l=1}^L \gamma_l z_{li})^2)$	link=LINEAR square
5	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(\sum_{l=1}^L \gamma_l z_{li})$	link=LINEAR noconst
6	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2((\sum_{l=1}^L \gamma_l z_{li})^2)$	link=LINEAR square noconst

For discrete choice models, σ^2 is normalized ($\sigma^2 = 1$) since this parameter is not identified. Note that in models 3 and 5, it may be possible that variances of some observations are negative. Although the QLIM procedure assigns a large penalty to move the optimization away from such region, it is possible that the optimization cannot improve the objective function value and gets locked in the region. Signs of such outcome include extremely small likelihood values or missing standard errors in the estimates. In models 2 and 6, variances are guaranteed to be greater or equal to zero, but

it may be possible that variances of some observations are very close to zero. In these scenarios, standard errors may be missing. Models 1 and 4 do not have such problems. Variances in these models are always positive and never close to zero.

The heteroscedastic regression model is estimated using the following log-likelihood function:

$$\ell = -\frac{N}{2} \ln(2\pi) - \sum_{i=1}^N \frac{1}{2} \ln(\sigma_i^2) - \frac{1}{2} \sum_{i=1}^N \left(\frac{e_i}{\sigma_i}\right)^2$$

where $e_i = y_i - \mathbf{x}'_i \boldsymbol{\beta}$.

Box-Cox Modeling

The Box-Cox transformation on x is defined as

$$x^{(\lambda)} = \begin{cases} \frac{x^\lambda - 1}{\lambda} & \text{if } \lambda \neq 0 \\ \ln(x) & \text{if } \lambda = 0 \end{cases}$$

The Box-Cox regression model with heteroscedasticity is written as

$$\begin{aligned} y_i^{(\lambda_0)} &= \beta_0 + \sum_{k=1}^K \beta_k x_{ki}^{(\lambda_k)} + \epsilon_i \\ &= \mu_i + \epsilon_i \end{aligned}$$

where $\epsilon_i \sim N(0, \sigma_i^2)$ and transformed variables must be positive. In practice, too many transformation parameters cause numerical problems in model fitting. It is common to have the same Box-Cox transformation performed on all the variables — that is, $\lambda_0 = \lambda_1 = \dots = \lambda_K$. It is required for the magnitude of transformed variables to be in the tolerable range if the corresponding transformation parameters are $|\lambda| > 1$.

The log-likelihood function of the Box-Cox regression model is written as

$$\ell = -\frac{N}{2} \ln(2\pi) - \sum_{i=1}^N \ln(\sigma_i) - \frac{1}{2\sigma_i^2} \sum_{i=1}^N e_i^2 + (\lambda_0 - 1) \sum_{i=1}^N \ln(y_i)$$

where $e_i = y_i^{(\lambda_0)} - \mu_i$.

When the dependent variable is discrete, censored, or truncated, the Box-Cox transformation can be applied only to explanatory variables.

Bivariate Limited Dependent Variable Modeling

The generic form of a bivariate limited dependent variable model is

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + \epsilon_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + \epsilon_{2i} \end{aligned}$$

where the disturbances, ϵ_{1i} and ϵ_{2i} , have joint normal distribution with zero mean, standard deviations σ_1 and σ_2 , and correlation of ρ . y_1^* and y_2^* are latent variables. The dependent variables y_1 and y_2 are observed if the latent variables y_1^* and y_2^* fall in certain ranges:

$$\begin{aligned} y_1 &= y_{1i} \text{ if } y_{1i}^* \in D_1(y_{1i}) \\ y_2 &= y_{2i} \text{ if } y_{2i}^* \in D_2(y_{2i}) \end{aligned}$$

D is a transformation from (y_{1i}^*, y_{2i}^*) to (y_{1i}, y_{2i}) . For example, if y_1 and y_2 are censored variables with lower bound 0, then

$$\begin{aligned} y_1 &= y_{1i} \text{ if } y_{1i}^* > 0, & y_1 &= 0 \text{ if } y_{1i}^* \leq 0 \\ y_2 &= y_{2i} \text{ if } y_{2i}^* > 0, & y_2 &= 0 \text{ if } y_{2i}^* \leq 0 \end{aligned}$$

There are three cases for the log likelihood of (y_{1i}, y_{2i}) . The first case is that $y_{1i} = y_{1i}^*$ and $y_{2i} = y_{2i}^*$. That is, this observation is mapped to one point in the space of latent variables. The log likelihood is computed from a bivariate normal density,

$$\ell_i = \ln \left[\phi_2 \left(\frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}, \frac{y_2 - \mathbf{x}_2' \boldsymbol{\beta}_2}{\sigma_2}, \rho \right) \right] - \ln \sigma_1 - \ln \sigma_2$$

where $\phi_2(u, v, \rho)$ is the density function for standardized bivariate normal distribution with correlation ρ ,

$$\phi_2(u, v, \rho) = \frac{e^{-(1/2)(u^2 + v^2 - 2\rho uv)/(1-\rho^2)}}{2\pi(1-\rho^2)^{1/2}}$$

The second case is that one observed dependent variable is mapped to a point of its latent variable and the other dependent variable is mapped to a segment in the space of its latent variable. For example, in the bivariate censored model specified, if observed $y_1 > 0$ and $y_2 = 0$, then $y_1^* = y_1$ and $y_2^* \in (-\infty, 0]$. In general, the log likelihood for one observation can be written as follows (the subscript i is dropped for simplicity): If one set is a single point and the other set is a range, without loss of generality, let $D_1(y_1) = \{y_1\}$ and $D_2(y_2) = [L_2, R_2]$,

$$\begin{aligned} \ell_i &= \ln \left[\phi \left(\frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1} \right) \right] - \ln \sigma_1 \\ &+ \ln \left[\Phi \left(\frac{R_2 - \mathbf{x}_2' \boldsymbol{\beta}_2 - \rho \frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}}{\sigma_2} \right) - \Phi \left(\frac{L_2 - \mathbf{x}_2' \boldsymbol{\beta}_2 - \rho \frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}}{\sigma_2} \right) \right] \end{aligned}$$

where ϕ and Φ are the density function and the cumulative probability function for standardized univariate normal distribution.

The third case is that both dependent variables are mapped to segments in the space of latent variables. For example, in the bivariate censored model specified, if observed $y_1 = 0$ and $y_2 = 0$, then $y_1^* \in (-\infty, 0]$ and $y_2^* \in (-\infty, 0]$. In general, if $D_1(y_1) = [L_1, R_1]$ and $D_2(y_2) = [L_2, R_2]$, the log likelihood is

$$\ell_i = \ln \int_{\frac{L_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}}^{\frac{R_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}} \int_{\frac{L_2 - \mathbf{x}_2' \boldsymbol{\beta}_2}{\sigma_2}}^{\frac{R_2 - \mathbf{x}_2' \boldsymbol{\beta}_2}{\sigma_2}} \phi_2(u, v, \rho) du dv$$

Selection Models

In sample selection models, one or several dependent variables are observed when another variable takes certain values. For example, the standard Heckman selection model can be defined as

$$\begin{aligned} z_i^* &= \mathbf{w}'_i \boldsymbol{\gamma} + u_i \\ z_i &= \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \leq 0 \end{cases} \\ y_i &= \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i \quad \text{if } z_i = 1 \end{aligned}$$

where u_i and ϵ_i are jointly normal with zero mean, standard deviations of 1 and σ , and correlation of ρ . z is the variable that the selection is based on, and y is observed when z has a value of 1. Least squares regression using the observed data of y produces inconsistent estimates of $\boldsymbol{\beta}$. Maximum likelihood method is used to estimate selection models. It is also possible to estimate these models by using Heckman's method, which is more computationally efficient. But it can be shown that the resulting estimates, although consistent, are not asymptotically efficient under normality assumption. Moreover, this method often violates the constraint on correlation coefficient $|\rho| \leq 1$.

The log-likelihood function of the Heckman selection model is written as

$$\begin{aligned} \ell &= \sum_{i \in \{z_i=0\}} \ln[1 - \Phi(\mathbf{w}'_i \boldsymbol{\gamma})] \\ &+ \sum_{i \in \{z_i=1\}} \left\{ \ln \phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) - \ln \sigma + \ln \Phi\left(\frac{\mathbf{w}'_i \boldsymbol{\gamma} + \rho \frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}}{\sqrt{1 - \rho^2}}\right) \right\} \end{aligned}$$

Only one variable is allowed for the selection to be based on, but the selection may lead to several variables. For example, in the following switching regression model,

$$\begin{aligned} z_i^* &= \mathbf{w}'_i \boldsymbol{\gamma} + u_i \\ z_i &= \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \leq 0 \end{cases} \\ y_{1i} &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + \epsilon_{1i} \quad \text{if } z_i = 0 \\ y_{2i} &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + \epsilon_{2i} \quad \text{if } z_i = 1 \end{aligned}$$

z is the variable that the selection is based on. If $z = 0$, then y_1 is observed. If $z = 1$, then y_2 is observed. Because it is never the case that y_1 and y_2 are observed at the same time, the correlation between y_1 and y_2 cannot be estimated. Only the correlation between z and y_1 and the correlation between z and y_2 can be estimated. This estimation uses the maximum likelihood method.

A brief example of the code for this model can be found in “[Example 21.4: Sample Selection Model](#)” on page 1422.

The Heckman selection model can include censoring or truncation. For a brief example of the code for these models see “[Example 21.5: Sample Selection Model with Truncation and Censoring](#)” on page 1423. The following example shows a variable y_i that is censored from below at zero.

$$z_i^* = \mathbf{w}'_i \boldsymbol{\gamma} + u_i$$

$$z_i = \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \leq 0 \end{cases}$$

$$y_i^* = \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i \quad \text{if } z_i = 1$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \leq 0 \end{cases}$$

In this case, the log-likelihood function of the Heckman selection model needs to be modified to include the censored region.

$$\begin{aligned} \ell &= \sum_{\{i|z_i=0\}} \ln[1 - \Phi(\mathbf{w}'_i \boldsymbol{\gamma})] \\ &+ \sum_{\{i|z_i=1, y_i=y_i^*\}} \left\{ \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] - \ln \sigma + \ln \left[\Phi \left(\frac{\mathbf{w}'_i \boldsymbol{\gamma} + \rho \frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}}{\sqrt{1 - \rho^2}} \right) \right] \right\} \\ &+ \sum_{\{i|z_i=1, y_i=0\}} \ln \int_{-\infty}^{-\frac{\mathbf{x}'_i \boldsymbol{\beta}}{\sigma}} \int_{-\mathbf{w}'_i \boldsymbol{\gamma}}^{\infty} \phi_2(u, v, \rho) du dv \end{aligned}$$

In case y_i is truncated from below at zero instead of censored, the likelihood function can be written as

$$\begin{aligned} \ell &= \sum_{\{i|z_i=0\}} \ln[1 - \Phi(\mathbf{w}'_i \boldsymbol{\gamma})] \\ &+ \sum_{\{i|z_i=1\}} \left\{ \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] - \ln \sigma + \ln \left[\Phi \left(\frac{\mathbf{w}'_i \boldsymbol{\gamma} + \rho \frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}}{\sqrt{1 - \rho^2}} \right) \right] - \ln [\Phi(\mathbf{x}'_i \boldsymbol{\beta} / \sigma)] \right\} \end{aligned}$$

Multivariate Limited Dependent Models

The multivariate model is similar to bivariate models. The generic form of the multivariate limited dependent variable model is

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + \epsilon_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + \epsilon_{2i} \\ &\dots \\ y_{mi}^* &= \mathbf{x}'_{mi} \boldsymbol{\beta}_m + \epsilon_{mi} \end{aligned}$$

where m is the number of models to be estimated. The vector ϵ has multivariate normal distribution with mean 0 and variance-covariance matrix Σ . Similar to bivariate models, the likelihood may involve computing multivariate normal integrations. This is done using Monte Carlo integration. (See Genz (1992) and Hajivassiliou and McFadden (1998).)

When the number of equations, N , increases in a system, the number of parameters increases at the rate of N^2 because of the correlation matrix. When the number of parameters is large, sometimes the optimization converges but some of the standard deviations are missing. This usually means that the model is over-parameterized. The default method for computing the covariance is to use the inverse Hessian matrix. The Hessian is computed by finite differences, and in over-parameterized cases, the inverse cannot be computed. It is recommended that you reduce the number of parameters in such cases. Sometimes using the outer product covariance matrix (COVEST=OP option) may also help.

Tests on Parameters

Tests on Parameters

In general, the hypothesis tested can be written as

$$H_0 : \mathbf{h}(\theta) = 0$$

where $\mathbf{h}(\theta)$ is an r by 1 vector valued function of the parameters θ given by the r expressions specified in the TEST statement.

Let \hat{V} be the estimate of the covariance matrix of $\hat{\theta}$. Let $\hat{\theta}$ be the unconstrained estimate of θ and $\tilde{\theta}$ be the constrained estimate of θ such that $h(\tilde{\theta}) = 0$. Let

$$A(\theta) = \partial h(\theta) / \partial \theta |_{\hat{\theta}}$$

Using this notation, the test statistics for the three kinds of tests are computed as follows.

The Wald test statistic is defined as

$$W = h'(\hat{\theta}) \left(A(\hat{\theta}) \hat{V} A'(\hat{\theta}) \right)^{-1} h(\hat{\theta})$$

The Wald test is not invariant to reparameterization of the model (Gregory 1985; Gallant 1987, p. 219). For more information about the theoretical properties of the Wald test, see Phillips and Park (1988).

The Lagrange multiplier test statistic is

$$LM = \lambda' A(\tilde{\theta}) \tilde{V} A'(\tilde{\theta}) \lambda$$

where λ is the vector of Lagrange multipliers from the computation of the restricted estimate $\tilde{\theta}$.

The likelihood ratio test statistic is

$$LR = 2 \left(L(\hat{\theta}) - L(\tilde{\theta}) \right)$$

where $\tilde{\theta}$ represents the constrained estimate of θ and L is the concentrated log-likelihood value.

For each kind of test, under the null hypothesis the test statistic is asymptotically distributed as a χ^2 random variable with r degrees of freedom, where r is the number of expressions in the TEST statement. The p -values reported for the tests are computed from the $\chi^2(r)$ distribution and are only asymptotically valid.

Monte Carlo simulations suggest that the asymptotic distribution of the Wald test is a poorer approximation to its small sample distribution than that of the other two tests. However, the Wald test has the lowest computational cost, since it does not require computation of the constrained estimate $\tilde{\theta}$.

The following is an example of using the TEST statement to perform a likelihood ratio test:

```
proc qlim;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0 /lr;
run;
```

Output to SAS Data Set

XBeta, Predicted, Residual

Xbeta is the structural part on the right-hand side of the model. Predicted value is the predicted dependent variable value. For censored variables, if the predicted value is outside the boundaries, it is reported as the closest boundary. For discrete variables, it is the level whose boundaries Xbeta falls between. Residual is defined only for continuous variables and is defined as

$$\text{Residual} = \text{Observed} - \text{Predicted}$$

Error Standard Deviation

Error standard deviation is σ_i in the model. It varies only when the HETERO statement is used.

Marginal Effects

Marginal effect is defined as a contribution of one control variable to the response variable. For the binary choice model with two response categories, $\mu_0 = -\infty$, $\mu_1 = 0$, $\mu_2 = \infty$; and ordinal response model with M response categories, μ_0, \dots, μ_M , define

$$R_{i,j} = \mu_j - \mathbf{x}'_i \boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the j th category can be written as

$$P[\mu_{j-1} < y_i^* \leq \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The marginal effect of changes in the regressors on the probability of $y_i = j$ is then

$$\frac{\partial \text{Prob}[y_i = j]}{\partial \mathbf{x}} = [f(\mu_{j-1} - \mathbf{x}'_i \boldsymbol{\beta}) - f(\mu_j - \mathbf{x}'_i \boldsymbol{\beta})] \boldsymbol{\beta}$$

where $f(x) = \frac{dF(x)}{dx}$. In particular,

$$f(x) = \frac{dF(x)}{dx} = \begin{cases} \frac{1}{\sqrt{2\pi}} e^{-x^2/2} & \text{(probit)} \\ \frac{e^{-x}}{[1+e^{(-x)}]^2} & \text{(logit)} \end{cases}$$

The marginal effects in the Box-Cox regression model are

$$\frac{\partial E[y_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \frac{x^{\lambda_k - 1}}{y^{\lambda_0 - 1}}$$

The marginal effects in the truncated regression model are

$$\frac{\partial E[y_i | L_i < y_i^* < R_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \left[1 - \frac{(\phi(a_i) - \phi(b_i))^2}{(\Phi(b_i) - \Phi(a_i))^2} + \frac{a_i \phi(a_i) - b_i \phi(b_i)}{\Phi(b_i) - \Phi(a_i)} \right]$$

where $a_i = \frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$.

The marginal effects in the censored regression model are

$$\frac{\partial E[y | \mathbf{x}_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \times \text{Prob}[L_i < y_i^* < R_i]$$

Inverse Mills Ratio, Expected and Conditionally Expected Values

Expected and conditionally expected values are computed only for continuous variables. The inverse Mills ratio is computed for censored or truncated continuous, binary discrete, and selection endogenous variables.

Let L_i and R_i be the lower boundary and upper boundary, respectively, for the y_i . Define $a_i = \frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$. Then the inverse Mills ratio is defined as

$$\lambda = \frac{(\phi(a_i) - \phi(b_i))}{(\Phi(b_i) - \Phi(a_i))}$$

for a continuous variable and defined as

$$\lambda = \frac{\phi(\mathbf{x}'_i \boldsymbol{\beta})}{\Phi(\mathbf{x}'_i \boldsymbol{\beta})}$$

for a binary discrete variable.

The expected value is the unconditional expectation of the dependent variable. For a censored variable, it is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}'_i \boldsymbol{\beta} + \lambda \sigma_i)(\Phi(b_i) - \Phi(a_i)) + (1 - \Phi(b_i))R_i$$

For a left-censored variable ($R_i = \infty$), this formula is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}'_i\boldsymbol{\beta} + \lambda\sigma_i)(1 - \Phi(a_i))$$

where $\lambda = \frac{\phi(a_i)}{1 - \Phi(a_i)}$.

For a right-censored variable ($L_i = -\infty$), this formula is

$$E[y_i] = (\mathbf{x}'_i\boldsymbol{\beta} + \lambda\sigma_i)\Phi(b_i) + (1 - \Phi(b_i))R_i$$

where $\lambda = -\frac{\phi(b_i)}{\Phi(b_i)}$.

For a noncensored variable, this formula is

$$E[y_i] = \mathbf{x}'_i\boldsymbol{\beta}$$

The conditional expected value is the expectation given that the variable is inside the boundaries:

$$E[y_i | L_i < y_i < R_i] = \mathbf{x}'_i\boldsymbol{\beta} + \lambda\sigma_i$$

Probability

Probability applies only to discrete responses. It is the marginal probability that the discrete response is taking the value of the observation. If the PROBALL option is specified, then the probability for all of the possible responses of the discrete variables is computed.

OUTEST= Data Set

The OUTEST= data set contains all the parameters estimated in a MODEL statement. The OUTEST= option can be used when the PROC QLIM call contains one MODEL statement:

```
proc qlim data=a outest=e;
  model y = x1 x2 x3;
  endogenous y ~ censored(lb=0);
run;
```

Each parameter contains the estimate for the corresponding parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

<code>_NAME_</code>	the name of the independent variable
<code>_TYPE_</code>	type of observation. PARM indicates the row of coefficients; STD indicates the row of standard deviations of the corresponding coefficients.
<code>_STATUS_</code>	convergence status for optimization

The rest of the columns correspond to the explanatory variables.

The OUTEST= data set contains one observation for the MODEL statement, giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement, giving the rows of the covariance matrix of parameter estimates. For covariance observations, the value of the `_TYPE_` variable is COV, and the `_NAME_` variable identifies the parameter associated with that row of the covariance matrix. If the CORROUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement, giving the rows of the correlation matrix of parameter estimates. For correlation observations, the value of the `_TYPE_` variable is CORR, and the `_NAME_` variable identifies the parameter associated with that row of the correlation matrix.

Naming

Naming of Parameters

When there is only one equation in the estimation, parameters are named in the same way as in other SAS procedures such as REG, PROBIT, etc. The constant in the regression equation is called Intercept. The coefficients on independent variables are named by the independent variables. The standard deviation of the errors is called `_Sigma`. If there are Box-Cox transformations, the coefficients are named `_Lambdai`, where i increments from 1, or as specified by the user. The limits for the discrete dependent variable are named `_Limiti`. If the LIMIT=varying option is specified, then `_Limiti` starts from 1. If the LIMIT=varying option is not specified, then `_Limit1` is set to 0 and the limit parameters start from $i = 2$. If the HETERO statement is included, the coefficients of the independent variables in the hetero equation are called `_H.x`, where x is the name of the independent variable. If the parameter name includes interaction terms, it needs to be enclosed in quotation marks followed by N . The following example restricts the parameter that includes the interaction term to be greater than zero:

```
proc qlim data=a;
  model y = x1|x2;
  endogenous y ~ discrete;
  restrict "x1*x2" > 0;
run;
```

When there are multiple equations in the estimation, the parameters in the main equation are named in the format of `y.x`, where y is the name of the dependent variable and x is the name of the independent variable. The standard deviation of the errors is called `_Sigma.y`. The correlation of the errors is called `_Rho` for bivariate model. For the model with three variables it is `_Rho.y1.y2`, `_Rho.y1.y3`, `_Rho.y2.y3`. The construction of correlation names for multivariate models is analogous. Box-Cox parameters are called `_Lambdai.y` and limit variables are called `_Limiti.y`. Parameters in the HETERO statement are named as `_H.y.x`. In the OUTEST= data set, all variables are changed from `'_'` to `'_'`.

Naming of Output Variables

The following table shows the option in the OUTPUT statement, with the corresponding variable names and their explanation.

Option	Name	Explanation
PREDICTED	P_y	Predicted value of y
RESIDUAL	RESID_y	Residual of y , (y -PredictedY)
XBETA	XBETA_y	Structure part ($\mathbf{x}'\boldsymbol{\beta}$) of y equation
ERRSTD	ERRSTD_y	Standard deviation of error term
PROB	PROB_y	Probability that y is taking the observed value in this observation (discrete y only)
PROBALL	PROB i _y	Probability that y is taking the i th value (discrete y only)
MILLS	MILLS_y	Inverse Mills ratio for y
EXPECTED	EXPCT_y	Unconditional expected value of y
CONDITIONAL	CEXPCT_y	Conditional expected value of y , condition on the truncation.
MARGINAL	MEFF_x	Marginal effect of x on y ($\frac{\partial y}{\partial x}$) with single equation
	MEFF_y_x	Marginal effect of x on y ($\frac{\partial y}{\partial x}$) with multiple equations
	MEFF_Pi_x	Marginal effect of x on y ($\frac{\partial Prob(y=i)}{\partial x}$) with single equation and discrete y
	MEFF_Pi_y_x	Marginal effect of x on y ($\frac{\partial Prob(y=i)}{\partial x}$) with multiple equations and discrete y

If you prefer to name the output variables differently, you can use the RENAME option in the data set. For example, the following statements rename the residual of y as *Resid*:

```
proc qlim data=one;
  model y = x1-x10 / censored;
  output out=outds(rename=(resid_y=resid)) residual;
run;
```

ODS Table Names

PROC QLIM assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the [Table 21.2](#).

Table 21.2 ODS Tables Produced in PROC QLIM by the Model Statement

Examples: QLIM Procedure

Example 21.1: Ordered Data Modeling

Cameron and Trivedi (1986) studied Australian Health Survey data. Variable definitions are given in Cameron and Trivedi (1998, p. 68).

The dependent variable, `dvisits`, has nine ordered values. The following SAS statements estimate the ordinal probit model:

```

/*-- Ordered Discrete Responses ---*/
proc qlim data=docvisit;
    model dvisits = sex age agesq income levyplus
                freepoor freerepa illness actdays hscore
                chcond1 chcond2 / discrete;
run;

```

The output of the QLIM procedure for ordered data modeling is shown in [Output 21.1.1](#).

Output 21.1.1 Ordered Data Modeling

_Limit7	1	2.789796	0.156189	17.86	<.0001

By default, ordinal probit/logit models are estimated assuming that the first threshold or limit parameter (μ_1) is 0. However, this parameter can also be estimated when the LIMIT1=VARYING option is specified. The probability that y_i^* belongs to the j th category is defined as

$$P[\mu_{j-1} < y_i^* < \mu_j] = F(\mu_j - \mathbf{x}_i' \boldsymbol{\beta}) - F(\mu_{j-1} - \mathbf{x}_i' \boldsymbol{\beta})$$

where $F(\cdot)$ is the logistic or standard normal CDF, $\mu_0 = -\infty$ and $\mu_9 = \infty$. Output 21.1.2 lists ordinal probit estimates computed in the following program. Note that the intercept term is suppressed for model identification when μ_1 is estimated.

```

/*-- Ordered Probit --*/
proc qlim data=docvisit;
  model dvisits = sex age agesq income levyplus
              freepoor freerepa illness actdays hscore
              chcond1 chcond2 / discrete(d=normal) limit1=varying;
run;

```

Example 21.2: Tobit Analysis

The following statements show a subset of the Mroz (1987) data set. In these data, Hours is the number of hours the wife worked outside the household in a given year, Yrs_Ed is the years of education, and Yrs_Exp is the years of work experience. A Tobit model will be fit to the hours worked with years of education and experience as covariates.

By the nature of the data it is clear that there are a number of women who committed some positive number of hours to outside work ($y_i > 0$ is observed). There are also a number of women who did not work at all ($y_i = 0$ is observed). This gives us the following model:

$$y_i^* = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \leq 0 \end{cases}$$

where $\epsilon_i \sim iidN(0, \sigma^2)$. The set of explanatory variables is denoted by \mathbf{x}_i .

_Sigma	1	1582.859635	390.076480	4.06	<.0001

In the “Parameter Estimates” table there are four rows. The first three of these rows correspond to the vector estimate of the regression coefficients β . The last one is called `_Sigma`, which corresponds to the estimate of the error variance σ .

Example 21.3: Bivariate Probit Analysis

This example shows how to estimate a bivariate probit model. Note the INIT statement in the following program, which sets the initial values for some parameters in the optimization:

```

data a;
  keep y1 y2 x1 x2;
  do i = 1 to 500;
    x1 = rannor( 19283 );
    x2 = rannor( 98721 );
    u1 = rannor( 76527 );
    u2 = rannor( 65721 );
    y11 = 1 + 2 * x1 + 3 * x2 + u1;
    y21 = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
    if ( y11 > 0 ) then y1 = 1;
    else y1 = 0;
    if ( y21 > 0 ) then y2 = 1;
    else y2 = 0;
    output;
  end;
run;

/*-- Bivariate Probit --*/
proc qlim data=a method=qn;
  init y1.x1 2.8, y1.x2 2.1, _rho .1;
  model y1 = x1 x2;
  model y2 = x1 x2;
  endogenous y1 y2 ~ discrete;
run;

```

The output of the QLIM procedure is shown in [Output 21.3.1](#).

Output 21.3.1 Bivariate Probit Analysis Results

Example 21.4: Sample Selection Model

This example illustrates the use of PROC QLIM for sample selection models. The data set is the same one from Mroz (1987). The goal is to estimate a wage offer function for married women, accounting for potential selection bias. Of the 753 women, the wage is observed for 428 working women. The labor force participation equation estimated in the introductory example is used for selection. The wage equation uses log wage (`lwage`) as the dependent variable. The explanatory variables in the wage equation are the woman's years of schooling (`educ`), wife's labor experience (`exper`), and square of experience (`expersq`). The program is as follows:

```

/*-- Sample Selection --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
             age kidslt6 kidsge6 /discrete;
  model lwage = educ exper expersq / select(inlf=1);
run;

```

The output of the QLIM procedure is shown in [Output 21.4.1](#).

Output 21.4.1 Sample Selection

Binary Data					
The QLIM Procedure					
Model Fit Summary					
Number of Endogenous Variables					2
Endogenous Variable				inlf	lwage
Number of Observations					753
Log Likelihood					-832.88509
Maximum Absolute Gradient					0.00502
Number of Iterations					78
Optimization Method					Quasi-Newton
AIC					1694
Schwarz Criterion					1759
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
lwage.Intercept	1	-0.552716	0.260371	-2.12	0.0338
lwage.educ	1	0.108351	0.014861	7.29	<.0001
lwage.exper	1	0.042837	0.014878	2.88	0.0040
lwage.expersq	1	-0.000837	0.000417	-2.01	0.0449
_Sigma.lwage	1	0.663397	0.022706	29.22	<.0001
inlf.Intercept	1	0.266459	0.508954	0.52	0.6006
inlf.nwifeinc	1	-0.012132	0.004877	-2.49	0.0129
inlf.educ	1	0.131341	0.025383	5.17	<.0001
inlf.exper	1	0.123282	0.018728	6.58	<.0001
inlf.expersq	1	-0.001886	0.000601	-3.14	0.0017
inlf.age	1	-0.052829	0.008479	-6.23	<.0001
inlf.kidslt6	1	-0.867398	0.118647	-7.31	<.0001
inlf.kidsge6	1	0.035872	0.043476	0.83	0.4093
_Rho	1	0.026617	0.147073	0.18	0.8564

Note the correlation estimate is insignificant. This indicates that selection bias is not a big problem in the estimation of wage equation.

Example 21.5: Sample Selection Model with Truncation and Censoring

In this example the data are generated such that the selection variable is discrete and the variable Y is truncated from below by zero. The program follows, with the results shown in [Output 21.5.1](#):

```
data trunc;
  keep z y x1 x2;
  do i = 1 to 500;
    x1 = rannor( 19283 );
    x2 = rannor( 98721 );
```

```

u1 = rannor( 76527 );
u2 = rannor( 65721 );
z1 = 1 + 2 * x1 + 3 * x2 + u1;
y = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
if ( z1 > 0 ) then z = 1;
else z = 0;
if y>=0 then output;
end;
run;

/*-- Sample Selection with Truncation --*/
proc qlim data=trunc method=qn;
  model z = x1 x2 / discrete;
  model y = x1 x2 / select(z=1) truncated(lb=0);
run;

```

Output 21.5.1 Sample Selection with Truncation

Example 21.7: Stochastic Frontier Models

This example illustrates the estimation of stochastic frontier production and cost models.

First, a production function model is estimated. The data for this example were collected by Christensen Associates; they represent a sample of 125 observations on inputs and output for 10 airlines between 1970 and 1984. The explanatory variables (inputs) are fuel (LF), materials (LM), equipment (LE), labor (LL), and property (LP), and (LQ) is an index that represents passengers, charter, mail, and freight transported.

The following statements create the dataset:

```

title1 'Stochastic Frontier Production Model';
data airlines;
  input TS FIRM NI LQ LF LM LE LL LP;
datalines;
1 1 15 -0.0484 0.2473 0.2335 0.2294 0.2246 0.2124
1 1 15 -0.0133 0.2603 0.2492 0.241 0.2216 0.1069
2 1 15 0.088 0.2666 0.3273 0.3365 0.2039 0.0865

... more lines ...

```

The following statements estimate a stochastic frontier exponential production model that uses Christensen Associates data:

```

/*-- Stochastic Frontier Production Model --*/
proc qlim data=airlines method=congra;
  model LQ=LF LM LE LL LP;

```

```
endogenous LQ ~ frontier (type=exponential production);
run;
```

Output 21.7.1 shows the results from this production model.

Output 21.7.1 Stochastic Frontier Production Model

_Sigma_u	1	0.060611	0.017603	3.44	0.0006

Similarly, the stochastic frontier production function can be estimated with (type=half) or (type=truncated) options that represent half-normal and truncated normal production or cost models.

In the next step, stochastic frontier cost function is estimated. The data for the cost model are provided by Christensen and Greene (1976). The data describe costs and production inputs of 145 U.S. electricity producers in 1955. The model being estimated follows the nonhomogenous version of the Cobb-Douglas cost function:

$$\log\left(\frac{\text{Cost}}{\text{FPrice}}\right) = \beta_0 + \beta_1 \log\left(\frac{\text{KPrice}}{\text{FPrice}}\right) + \beta_2 \log\left(\frac{\text{LPrice}}{\text{FPrice}}\right) + \beta_3 \log(\text{Output}) + \beta_4 \frac{1}{2} \log(\text{Output})^2 + \epsilon$$

All dollar values are normalized by fuel price. The quadratic log of the output is added to capture nonlinearities due to scale effects in cost functions. New variables, log_C_PF, log_PK_PF, log_PL_PF, log_y, and log_y_sq, are created to reflect transformations. The following statements create the data set and transformed variables:

```

data electricity;
  input Firm Year Cost Output LPrice LShare KPrice KShare FPrice FShare;

Overview: SIMILARITY Procedure

The SIMILARITY procedure computes similarity measures associated with time-stamped data, time series, and/or other sequentially ordered numeric data. The procedure computes similarity measures for time-stamped transactional data (transactions) with respect to time by accumulating the data into a time series format (time series). The procedure computes similarity measures for sequentially ordered numeric data (sequences) by respecting the ordering of the data.

Given two ordered numeric sequences (input and target), a similarity measure is a metric that measures the distance between the input and target sequences while taking into account the ordering of the data. The SIMILARITY procedure computes similarity measures between an input sequence and a target sequence, as well as similarity measures that “slide” the target sequence with respect to the input sequence. The “slides” can be by observation index (sliding-sequence similarity measures) or by seasonal index (seasonal-sliding-sequence similarity measures).

In order to compare the raw input and target time-stamped data, the raw data must be accumulated to a time series format. After the input and target time series is formed, the two accumulated time series can be compared as two ordered numeric sequences.

For raw time-stamped data, after the transactional data are accumulated to form time series and any missing values are interpreted, each accumulated time series can be functionally transformed, if desired. Transformations are useful when you want to stabilize the time series before computing the similarity measures. Transformations performed by the SIMILARITY procedure include the following:

- log (LOG)
- square-root (SQRT)
- logistic (LOGISTIC)
- Box-Cox (BOXCOX)
- user-defined transformations

Each time series can be transformed further by using simple and/or seasonal differencing. Additional time series transformations can be performed by using various time series transformation and analysis techniques provided by this procedure or other procedures in SAS/ETS.

After optionally transforming each time series, the accumulated and transformed time series can be stored in an output data set (OUT= data set).

After optional accumulation and transformation, each of these time series are the “working series,” which can now be analyzed as sequences of numeric data. Each of these sequences can be a target sequence, an input sequence, or both a target and an input sequence. Throughout the remainder of this chapter, the term “original sequence” applies to both the original input and target sequence. The term “working sequence” applies to a version both the original input and target sequence under investigation.

Each original sequence can be normalized prior to similarity analysis. Normalizations are useful when you want to compare the “shape” or “profile” of the time series. Normalizations performed by the SIMILARITY procedure include the following:

- standard (STANDARD)
- absolute (ABSOLUTE)
- user-defined normalizations

After each original sequence is optionally normalized as described above, each working input sequence can be scaled to the target sequence prior to similarity analysis. Scaling is useful when you want to compare the input sequence to the target sequence while discounting the variation of the target sequence. Input sequence scaling performed by the SIMILARITY procedure include the following:

- standard (STANDARD)
- absolute (ABSOLUTE)
- user-defined scaling

Once the working input sequence is optionally scaled to the target sequence as described above, similarity measures can be computed. Similarity measures computed by the SIMILARITY procedure include:

- squared deviation (SQRDEV)
- absolute deviation (ABSDEV)
- mean square deviation (MSQRDEV)
- mean absolute deviation (MABSDEV)
- user-defined similarity measures

In computing the similarity measure between two time series, tasks are needed for transforming time series, normalizing sequences, scaling sequences, and computing metrics or measures. The SIMILARITY procedure provides built-in routines to perform these tasks. The SIMILARITY procedure also provides a facility that allows you to extend the procedure with user-defined routines.

All results of the similarity analysis can be stored in output data sets, printed, or graphed using the Output Delivery System (ODS).

The SIMILARITY procedure can process large amounts of time-stamped transactional data, time series, or sequential data. Therefore, the analysis results are useful for large-scale time series analysis, analogous time series forecasting, new product forecasting, or time series (temporal) data mining.

In SAS/ETS, the EXPAND procedure can be used for frequency conversion and transformations of time series. The TIMESERIES procedure can be used for large-scale time series analysis. In SAS/STAT, the DISTANCE procedure can be used to compute various measures of distance, dissimilarity, or similarity between observations (rows) of a SAS data set.

Getting Started: SIMILARITY Procedure

This section outlines the use of the SIMILARITY procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data, time series, or sequentially-ordered numeric data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the SIMILARITY procedure can form equally spaced input and target time series as follows:

```
PROC SIMILARITY DATA=<input-data-set>
                OUT=<output-data-set>
                OUTSUM=<summary-data-set>;
  ID <time-ID-variable> INTERVAL=<frequency>
                ACCUMULATE=<statistic>;
  INPUT <input-time-stamp-variables>;
  TARGET <target-time-stamp-variables>;
RUN;
```

The SIMILARITY procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats using the Output Delivery System (ODS). The examples in this section are more fully illustrated in the section “[Examples: SIMILARITY Procedure](#)” on page 1485.

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains three variables related to the customer transactions (CUSTOMER, DATE, and WITHDRAWAL) and one variable that contains an example fraudulent behavior (FRAUD).

The following statements illustrate how to use the SIMILARITY procedure to accumulate time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and FRAUD).

```
proc similarity data=transactions out=timedata;
  by customer;
  id date interval=day accumulate=total;
  input withdrawals;
  target fraud;
run;
```

The OUT=TIMEDATA option specifies that the resulting time series data for each customer is to be stored in the data set WORK.TIMEDATA. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions are to be accumulated. After the transactional data are accumulated into a time series format, the time series data can be normalized so that the “shape” or “profile” is analyzed.

For example, the following statements build on the previous statements and demonstrate normalization of the accumulated time series.

```
proc similarity data=transactions out=timedata;
  by customer;
  id date interval=day accumulate=total;
  input withdrawals / NORMALIZE=STANDARD;
  target fraud      / NORMALIZE=STANDARD;
run;
```

The NORMALIZE=STANDARD option specifies that each accumulated time series observation is normalized by subtracting the mean and then dividing by the standard deviation of the accumulated time series. The WORK.TIMEDATA data set now contains the accumulated and normalized time series data for each customer.

After the transactional data are accumulated into a time series format and normalized to mean of zero and standard deviation of one, similarity analysis can be performed on the accumulated and normalized time series.

For example, the following statements build on the previous statements and demonstrate similarity analysis of the accumulated and normalized time series.

```
proc similarity data=transactions
  out=timedata OUTSUM=SUMMARY;
  by customer;
  id date interval=day accumulate=total;
  input withdrawals / normalize=standard;
  target fraud      / normalize=standard SIMILARITY=MABSDEV;
run;
```

The SIMILARITY=MABSDEV option specifies the accumulated and normalized time series data associated with the variables WITHDRAWALS and FRAUD are to be compared by using mean absolute deviation. The OUTSUM=SUMMARY option specifies that the similarity analysis summary for each customer is to be stored in the data set WORK.SUMMARY.

Syntax: SIMILARITY Procedure

The following statements are used with the SIMILARITY procedure.

```

PROC SIMILARITY options ;
  BY variables ;
  ID variable INTERVAL= interval options ;
  FCMPOPT options ;
  INPUT variable-list / options ;
  TARGET variable-list / options ;

```

Functional Summary

The statements and options that control the SIMILARITY procedure are summarized in the following table.

Table 22.1 SIMILARITY Functional Summary

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify the time ID variable	ID	
specify the FCMP options	FCMPOPT	
specify input variables to analyze	INPUT	
specify target variables to analyze	TARGET	
Data Set Options		
specify the input data set	PROC SIMILARITY	DATA=
specify the time series output data set	PROC SIMILARITY	OUT=
specify measure summary output data set	PROC SIMILARITY	OUTMEASURE=
specify path output data set	PROC SIMILARITY	OUTPATH=
specify sequence output data set	PROC SIMILARITY	OUTSEQUENCE=
specify summary output data set	PROC SIMILARITY	OUTSUM=
User-Defined Functions and Subroutine Options		
specify FCMP quiet mode	FCMPOPT	QUIET=
specify FCMP trace mode	FCMPOPT	TRACE=
Accumulation and Seasonality Options		
specify accumulation frequency	ID	INTERVAL=
specify length of seasonal cycle	PROC SIMILARITY	SEASONALITY=
specify interval alignment	ID	ALIGN=
specify time ID variable values are not sorted	ID	NOTSORTED

Description	Statement	Option
specify starting time ID value	ID	START=
specify ending time ID value	ID	END=
specify accumulation statistic	ID, INPUT, TARGET	ACCUMULATE=
specify missing value interpretation	ID, INPUT, TARGET	SETMISS=
specify zero value interpretation	ID, INPUT, TARGET	ZEROMISS=
specify missing value trimming	INPUT, TARGET	TRIMMISS=
Time Series Transformation Options		
specify simple differencing	INPUT, TARGET	DIF=
specify seasonal differencing	INPUT, TARGET	SDIF=
specify transformation	INPUT, TARGET	TRANSFORM=
Input Sequence Options		
specify normalization	INPUT	NORMALIZE=
specify scaling	INPUT	SCALE=
Target Sequence Options		
specify normalization	TARGET	NORMALIZE=
Similarity Measure Options		
specify compression limits	TARGET	COMPRESS=
specify expansion limits	TARGET	EXPAND=
specify similarity measure	TARGET	MEASURE=
specify similarity measure and path	TARGET	PATH=
specify sequence slide	TARGET	SLIDE=
Printing and Graphical Control Options		
specify time ID format	ID	FORMAT=
specify printed output	PROC SIMILARITY	PRINT=
specify detailed printed output	PROC SIMILARITY	PRINTDETAILS
specify graphical output	PROC SIMILARITY	PLOTS=
Miscellaneous Options		
specify that analysis variables are processed in ascending order	PROC SIMILARITY	SORTNAMES
specify the ordering of the processing of the input and target variables	PROC SIMILARITY	ORDER=

PROC SIMILARITY Statement

PROC SIMILARITY *options* ;

The following options can be used in the PROC SIMILARITY statement.

DATA=SAS-data-set

names the SAS data set that contains the time series, transactional, or sequence input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used.

ORDER=

specifies the order that the variables listed in the INPUT and TARGET statements are processed. This ordering affects the OUTSEQUENCE=, OUTPATH=, OUTMEASURE=, and OUTSUM= data sets, as well as the printed and graphical output. The SORTNAMES option also affects the ordering of the analysis.

OUT=SAS-data-set

names the output data set to contain the time series variables specified in the subsequent INPUT and TARGET statements. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= option or the ACCUMULATE= options or both. The values are transformed based on the INPUT or TARGET statement TRANSFORM=, DIF=, and/ or SDIF= options in this order. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTMEASURE=SAS-data-set

names the output data set to contain the detailed similarity measures by time ID value. The form of the OUTMEASURE= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTPATH=SAS-data-set

names the output data set to contain the path used to compute the similarity measures for each slide and warp. The form of the OUTPATH= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTSEQUENCE=SAS-data-set

names the output data set to contain the sequences used to compute the similarity measures for each slide and warp. The form of the OUTSEQUENCE= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTSUM=SAS-data-set

names the output data set to contain the similarity measure summary. The OUTSUM= data set is particularly useful when analyzing large numbers of series and only the summary of the results are needed. The form of the OUTSUM= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

INPUT specifies that each INPUT variable is processed and then the TARGET variables are processed. The results are stored and printed based only on the INPUT variables.

INPUTTARGET specifies that each INPUT variable is processed and then the TARGET variables are processed. The results are stored and printed based on both the INPUT and TARGET variables. This is the default.

TARGET specifies that each TARGET variable is processed and then the INPUT variables are processed. The results are stored and printed based only on the TARGET variables.

TARGETINPUT specifies that each TARGET variable is processed and then the INPUT variables are processed. The results are stored and printed based on both the TARGET and INPUT variables.

PLOTS=option

PLOTS=(options ...)

specifies the graphical output desired. The *options* are separated by spaces. By default, the SIMILARITY procedure produces no graphical output. The following graphical options are available:

ALL same as PLOTS=(INPUTS TARGETS SEQUENCES NORMALIZED SCALED DISTANCES PATHS MAPS WARPS COST MEASURES).

COSTS plots time warp costs graphics.

DISTANCES plots similarity absolute and relative distances graphics. (OUTPATH= data set)

INPUTS plots input variable time series graphics. (OUT= data set)

MAPS plots time warp maps graphics. (OUTPATH= data set)

MEASURES plots similarity measure graphics. (OUTMEASURE= data set)

NORMALIZED plots both the input and target variable normalized sequence graphics. These plots are displayed only when the INPUT or TARGET statement NORMALIZE= option is specified.

PATHS plots time warp paths graphics. (OUTPATH= data set)

SCALED plots both the input variable scaled sequence graphics. These plots are displayed only when the INPUT statement SCALE= option is specified.

SEQUENCES plots both the input and target variable sequence graphics. (OUTSEQUENCE= data set)

TARGETS plots target variable time series graphics. (OUT= data set)

WARPS plots time warps graphics. (OUTPATH= data set)

PRINT=option

PRINT=(options ...)

specifies the printed output desired. The *options* are separated by spaces. By default, the SIMILARITY procedure produces no printed output. The following printing options are available:

DESCSTATS prints the descriptive statistics for the working time series.

PATHS prints the path statistics table.

COSTS prints the cost statistics table.

WARPS prints the warp summary table.

SLIDES	prints the slides summary table.
SUMMARY	prints the similarity measure summary table.
ALL	same as PRINT=(DESCSTATS PATHS COSTS WARPS SLIDES SUMMARY).

PRINTDETAILS

specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY=*integer*

specifies the length of the seasonal cycle where *integer* ranges from one to 10,000. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is twelve.

SORTNAMES

specifies that the variables specified in the INPUT and TARGET statements are processed in order sorted by the variable names. By default, the SIMILARITY procedure processes the variables in the order they are listed. The ORDER= option also affects the ordering of the analysis.

BY Statement

A BY statement can be used with PROC SIMILARITY to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the SIMILARITY procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FCMPOPT Statement

FCMPOPT *options* ;

The FCMPOPT statement specifies the options related to user-defined functions and subroutines.

The following options can be used with the FCMPOPT statement:

QUIET=ON | OFF

specifies whether the nonfatal errors and warnings generated by the user-defined SAS language functions and subroutines are printed to the log. Nonfatal errors are usually associated with operations with missing values. The default is QUIET=ON.

TRACE=ON | OFF

specifies whether the user-defined SAS language functions and subroutines tracings are printed to the log. Tracings are the results of every operation executed. This option is generally used for debugging. The default is TRACE=OFF.

ID Statement

ID *variable* **INTERVAL=** *interval options* ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The options specified affect all variables listed in subsequent INPUT and TARGET statements. If an ID statement is specified, the INTERVAL= option must also be specified. The other ID statement options are optional. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following options can be used with the ID statement.

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is particularly useful when there are zero or more than one input observations coinciding with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following options determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE AVG	Observations are accumulated based on the average of their values.
MINIMUM MIN	Observations are accumulated based on the minimum of their values.
MEDIAN MED	Observations are accumulated based on the median of their values.
MAXIMUM MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. The DETAILS section describes accumulation in greater detail.

ALIGN=option

controls the alignment of SAS dates that are used to identify output observations. The ALIGN= option accepts the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. ALIGN=BEGINNING is the default.

END=option

specifies a SAS date, datetime, or time value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. The START= and END= options can be used to ensure that data associated within each BY group contains the same number of observations.

FORMAT=*format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied by the INTERVAL= option. For example, FORMAT=DATE9. specifies that the DATE9. SAS format is to be used. Notice that the terminating “.” is required when specifying a SAS format.

INTERVAL= *interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations.

NOTSORTED

specifies that the time ID values are not in sorted order. The SIMILARITY procedure sorts the data with respect to the time ID prior to analysis if the NOTSORTED option is specified.

SETMISSING=*option* | *number*

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series. If a *number* is specified, missing values are set to that number. If a missing value indicates an unknown value, the SETMISSING= option should not be used. If a missing value indicates no value, then SETMISSING=0 should be used. You typically use SETMISSING=0 for transactional data, because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE AVG	Missing values are set to the accumulated average value.
MINIMUM MIN	Missing values are set to the accumulated minimum value.
MEDIAN MED	Missing values are set to the accumulated median value.
MAXIMUM MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS PREV	Missing values are set to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START= *option*

specifies a SAS date, datetime, or time value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prepended with missing values. If the first time ID variable value is less than the START= value, the series is truncated. The START= and END= options can be used to ensure that data associated with each BY group contains the same number of observations.

ZEROMISS=option

specifies how beginning and/or ending zero values (either actual or accumulated) are interpreted in the accumulated time series. The following options can also be used to determine how beginning and/or ending zero values are assigned:

NONE	Beginning and/or ending zeros are unchanged. This is the default.
LEFT	Beginning zeros are set to missing.
RIGHT	Ending zeros are set to missing.
BOTH	Both beginning and ending zeros are set to missing.

If the accumulated series is all missing and/or zero, the series is not changed.

INPUT Statement

INPUT *variable-list* < / *options* > ;

The INPUT statement lists the input numeric variables in the DATA= data set whose values are to be accumulated to form the time series or represent ordered numeric sequences (when no ID statement is specified).

An input data set variable can be specified in only one INPUT or TARGET statement. Any number of INPUT statements can be used. The following options can be used with an INPUT statement.

ACCUMULATE=option

specifies how the data set observations are accumulated within each time period for the variables listed in the INPUT statement. If the ACCUMULATE= option is not specified in the INPUT statement, accumulation is determined by the ACCUMULATE= option of the ID statement. If the ACCUMULATE= option is not specified on the ID statement or the INPUT statement, no accumulation is performed. See the ID statement ACCUMULATE= option for more details.

DIF=(numlist)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first, then third order, differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option. Simple differencing is useful when you want to detrend the time series before computing the similarity measures.

NORMALIZE=Argumentoption

specifies the sequence normalization to be applied to the working input sequence. The following normalization options are provided:

NONE	No normalization is applied. This option is the default.
ABSOLUTE	Absolute normalization is applied.
STANDARD	Standard normalization is applied.

User-Defined Normalization is computed by a user-defined subroutine created using the FCMP procedure, where *User-Defined* is the subroutine name.

Normalization is applied to the working input sequence, which can be a subset of the working input time series if the SLIDE=INDEX or SLIDE=SEASON options are specified.

SCALE=*option*

specifies the scaling of the working input sequence with respect to the working target sequence. Scaling is performed after normalization. The following scaling options are provided:

NONE	No scaling is applied. This option is the default.
ABSOLUTE	Absolute scaling is applied.
STANDARD	Standard scaling is applied.
<i>User-Defined</i>	Scaling is computed by a user-defined subroutine created using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

Scaling is applied to the working input sequence, which can be a subset of the working input time series if the SLIDE=INDEX or SLIDE=SEASON options are specified.

SDIF=*(numlist)*

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first, then third, order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option. Seasonal differencing is useful when you want to deseasonalize the time series before computing the similarity measures.

SETMISSING=*option | number*

SETMISS=*option | number*

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the INPUT statement. If the SETMISSING= option is not specified in the INPUT statement, missing values are set based on the SETMISSING= option of the ID statement. If the SETMISSING= option is not specified on the ID statement or the INPUT statement, no missing value interpretation is performed. See the ID statement SETMISSING= option for more details.

TRANSFORM= *option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation is applied.
SQRT	Square-root transformation is applied.
LOGISTIC	Logistic transformation is applied.

BOXCOX(*number*) Box-Cox transformation with parameter is applied, where the real *number* is between -5 and 5.

User-Defined Transformation is computed by a user-defined subroutine created using the FCMP procedure where *User-Defined* is the subroutine name.

When the TRANSFORM= option is specified, the time series must be strictly positive unless a user-defined function is used.

TRIMMISSING= *option*

TRIMMISSING= *option*

specifies how missing values (either actual or accumulated) are trimmed from the accumulated time series or ordered sequence for variables listed in the INPUT statement. The following trimming options are provided:

NONE	No missing value trimming is applied.
LEFT	Beginning missing values are trimmed.
RIGHT	Ending missing values are trimmed.
BOTH	Both beginning and ending missing value are trimmed. This is the default.

ZEROMISS= *option*

specifies how beginning and/or ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the INPUT statement. If the ZEROMISS= option is not specified in the INPUT statement, beginning and/or ending zero values are set based on the ZEROMISS= option of the ID statement. If the ZERO= option is not specified on the ID statement or the INPUT statement, no zero value interpretation is performed. ZEROMISS= option of the ID statement. See the ID statement ZEROMISS= option for more details.

TARGET Statement

TARGET *variable-list* < / *options* > ;

The TARGET statement lists the numeric target variables in the DATA= data set whose values are to be accumulated to form the time series or represent ordered numeric sequences (when no ID statement is specified).

An input data set variable can be specified in only one INPUT or TARGET statement. Any number of TARGET statements can be used. The following options can be used with a TARGET statement.

ACCUMULATE= *option*

specifies how the data set observations are accumulated within each time period for the variables listed in the TARGET statement. If the ACCUMULATE= option is not specified in the TARGET statement, accumulation is determined by the ACCUMULATE= option of the ID statement. If the ACCUMULATE= option is not specified on the ID statement or the

TARGET statement, no accumulation is performed. See the ID statement ACCUMULATE= option for more details.

COMPRESS=option | (options)

specifies the sliding sequence (global) and warping (local) compression range of the target sequence with respect to the input sequence. Compression of the target sequence is the same as expansion of the input sequence and vice versa. The compression limits are defined based on the length of the target sequence and are imposed on the target sequence. The following compression options are provided:

GLOBALABS=integer specifies the absolute global compression, where *integer* ranges from zero to 10,000. GLOBALABS=0 implies no global compression, which is the default unless the GLOBALPCT= option is specified.

GLOBALPCT=number specifies global compression as a percentage of the length of the target sequence, where *number* ranges from zero to 100. GLOBALPCT=0 implies no global compression, which is the default. GLOBALPCT=100 implies maximum allowable compression.

LOCALABS=integer specifies the absolute local compression, where *integer* ranges from zero to 10,000. The default is maximum allowable absolute local compression unless the LOCALPCT= option is specified.

LOCALPCT=number specifies local compression as a percentage of the length of the input sequence, where *number* ranges from zero to 100. The percentage specified by the LOCALPCT= option must be less than the GLOBALPCT= option. LOCALPCT=0 implies no local compression. LOCALPCT=100 implies maximum allowable local compression. The default is LOCALPCT=100.

If the SLIDE=NONE or the SLIDE=SEASON option is specified in the TARGET statement, the global compression options are ignored. To disallow local compression, use the option COMPRESS=(LOCALPCT=0 LOCALABS=0).

If the SLIDE=INDEX option is specified, the global compression options are not ignored. To completely disallow both global and local compression, use the option COMPRESS=(GLOBALPCT=0 LOCALPCT=0) or COMPRESS=(GLOBALABS=0 LOCALABS=0). To allow only local compression, use the option COMPRESS=(GLOBALPCT=0 GLOBALABS=0). These are the default compression options.

The above options can be used in combination to specify the desired amount of global and local compression as the following examples illustrate.

Let L_c denote the global compression limit and l_c denote the local compression limit.

COMPRESS=(GLOBALPCT=20) specifies the global and local compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$.

COMPRESS=(GLOBALPCT=20 GLOBALABS=10) allows for the global and local compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$.

COMPRESS=(LOCALPCT=10) allows for the local compression to range from zero to $l_c = \min(\lfloor 0.1N_y \rfloor, (N_y - 1))$.

COMPRESS=(LOCALPCT=20 LOCALABS=5) allows for the local compression to range from zero to $l_c = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 5))$.

COMPRESS=(GLOBALPCT=20 LOCALPCT=20) allows for the global compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$ and allows for the local compression to range from zero to $l_c = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$.

COMPRESS=(GLOBALPCT=20 GLOBALABS=10 LOCALPCT=10 LOCALABS=5) allows for the global compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$ and allows for the local compression to range from zero to $l_c = \min(\lfloor 0.1N_y \rfloor, \min((N_y - 1), 5))$.

Suppose T_z is the length of the input time series and N_y is the length of the target sequence. The *valid* global compression limit, L_c , is always limited by the length of the target sequence: $0 \leq L_c < N_y$.

Suppose N_x is the length of the input sequence, and N_y is the length of the target sequence. The *valid* local compression limit, l_c , is always limited by the lengths of the input and target sequence: $\max(0, (N_y - N_x)) \leq l_c < N_y$.

DIF=(numlist)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first, then third, order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option. Simple differencing is useful when you want to detrend the time series before computing the similarity measures.

EXPAND=option | (options)

specifies the sliding sequence (global) and warping (local) expansion range of the target sequence with respect to the input sequence. Expansion of the target sequence is the same as compression of the input sequence and vice versa. The expansion limits are defined based on the length of the input sequence, but are imposed on the target sequence. The following expansion options are provided:

GLOBALABS=*integer* specifies the absolute global expansion, where *integer* ranges from zero to 10,000. GLOBALABS=0 implies no global expansion, which is the default unless the GLOBALPCT= option is specified.

GLOBALPCT=*number* specifies global expansion as a percentage of the length of the target sequence, where *number* ranges from zero to 100. GLOBALPCT=0 implies no global expansion, which is the default unless the GLOBALABS= option is specified. GLOBALPCT=100 implies maximum allowable global expansion.

LOCALABS=*integer* specifies the absolute local expansion, where *integer* ranges from zero to 10,000. The default is maximal allowable absolute local expansion unless the LOCALPCT= option is specified.

LOCALPCT=*number* specifies local expansion as a percentage of the length of the target sequence, where *number* ranges from zero to 100. LOCALPCT=0 implies no local expansion. LOCALPCT=100 implies maximum allowable local expansion. The default is LOCALPCT=100.

If the SLIDE=NONE or the SLIDE=SEASON option is specified in the TARGET statement, the global expansion options are ignored. To disallow local expansion, use the option EXPAND=(LOCALPCT=0 LOCALABS=0).

If the SLIDE=INDEX option is specified, the global expansion options are not ignored. To completely disallow both global and local expansion, use the option EXPAND=(GLOBALPCT=0 LOCALPCT=0) or EXPAND=(GLOBALABS=0 LOCALABS=0). To allow only local expansion, use the option EXPAND=(GLOBALPCT=0 GLOBALABS=0). These are the default expansion options.

The above options can be used in combination to specify the desired amount of global and local expansion as the following examples illustrate.

Let L_e denote the global expansion limit and l_e denote the local expansion limit.

EXPAND=(GLOBALPCT=20) allows for the global and local expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$.

EXPAND=(GLOBALPCT=20 GLOBALABS=10) allows for the global and local expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$.

EXPAND=(LOCALPCT=10) allows for the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, (N_y - 1))$.

EXPAND=(LOCALPCT=10 LOCALABS=5) allows for the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, \min((N_y - 1), 5))$.

EXPAND=(GLOBALPCT=20 LOCALPCT=10) allows for the global expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$ and allows for the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, (N_y - 1))$.

EXPAND=(GLOBALPCT=20 GLOBALABS=10 LOCALPCT=10 LOCALABS=5) allows for the global expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$ and allows for the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, \min((N_y - 1), 5))$.

Suppose T_z is the length of the input time series and N_y is the length of the target sequence. The *valid* global expansion limit, L_e , is always limited by the length of the input time series: $0 \leq L_e < T_z$.

Suppose N_x is the length of the input sequence and N_y is the length of the target sequence. The *valid* local expansion limit, l_e , is always limited by the lengths of the input and target sequence: $\max(0, (N_x - N_y)) \leq l_e < N_x$.

MEASURE=option

specifies the similarity measure to be computed by using the working input and target sequences. The following similarity measures are provided:

SQRDEV	squared deviation. This option is the default.
ABSDEV	absolute deviation
MSQRDEV	mean squared deviation
MSQRDEVINP	mean squared deviation relative to the length of the input sequence

MSQRDEVTAR	mean squared deviation relative to the length of the target sequence
MSQRDEVMIN	mean squared deviation relative to the minimum valid path length
MSQRDEVMAX	mean squared deviation relative to the maximum valid path length
MABSDEV	mean absolute deviation
MABSDEVINP	mean absolute deviation relative to the length of the input sequence
MABSDEVTAR	mean absolute deviation relative to the length of the target sequence
MABSDEVMIN	mean absolute deviation relative to the minimum valid path length
MABSDEVMAX	mean absolute deviation relative to the maximum valid path length
<i>User-Defined</i>	Measure computed by a user-defined function created by using the FCMP procedure, where <i>User-Defined</i> is the function name

NORMALIZE=option

specifies the sequence normalization to be applied to the working target sequence. The following normalization options are provided:

NONE	No normalization is applied. This option is the default.
ABSOLUTE	Absolute normalization is applied.
STANDARD	Standard normalization is applied.
<i>User-Defined</i>	Normalization computed by a user-defined subroutine, created by using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

PATH=option

specifies the similarity measure and warping path information to be computed using the working input and target sequences. The following similarity measures and warping path are provided:

<i>User-Defined</i>	measure and path computed by a user-defined subroutine created by using the FCMP procedure, where <i>User-Defined</i> is the subroutine name
---------------------	--

For computational efficiency, the PATH= option should be only used when it is desired to compute both the similarity measure and the warping path information. If only the similarity measure is needed, use the MEASURE= option. If both the MEASURE= and PATH= option are specified in the TARGET statement, the PATH= option takes precedence.

SDIF=(numlist)

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first, then third, order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option. Seasonal differencing is useful when you want to deseasonalize the time series before computing the similarity measures.

SETMISSING=option | number

SETMISS= *option* | *number*

option specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series for variables listed in the TARGET statement. If the SETMISSING= option is not specified in the TARGET statement, missing values are set, based on the SETMISSING= option of the ID statement. If the SETMISSING= option is not specified on the ID statement or the TARGET statement, no missing value interpretation is performed. See the ID statement SETMISSING= option for more details.

SLIDE= *option*

specifies the sliding of the target sequence with respect to the input sequence. The following slides are provided:

NONE	No sequence sliding. The input time series is compared with the target sequence directly with no sliding. This option is the default.
INDEX	Slide by time index. The input time series is compared with the target sequence by observation index.
SEASON	Slide by seasonal index. The input time series is compared with the target sequence by seasonal index.

NOTE: The SLIDE= option takes precedence over the COMPRESS= and EXPAND= option.

TRANSFORM= *option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation is applied.
SQRT	Square-root transformation is applied.
LOGISTIC	Logistic transformation is applied.
BOXCOX(<i>number</i>)	Box-Cox transformation with parameter <i>number</i> is applied, where the real <i>number</i> is between -5 and 5
<i>User-Defined</i>	transformation is computed by a user-defined subroutine created by using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

When the TRANSFORM= option is specified, the time series must be strictly positive unless a user-defined function is used.

TRIMMISSING= *option***TRIMMISS=** *option*

specifies how missing values (either actual or accumulated) are trimmed from the accumulated time series or ordered sequence for variables listed in the TARGET statement. The following trimming options are provided:

NONE	No missing value trimming is applied.
LEFT	Beginning missing values are trimmed.

RIGHT	Ending missing values are trimmed.
BOTH	Both beginning and ending missing values are trimmed. This is the default.

ZEROMISS=option

specifies how beginning and/or ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the TARGET statement. If the ZEROMISS= option is not specified in the TARGET statement, beginning and/or ending values are set based on the ZEROMISS= option of the ID statement. See the ID statement ZEROMISS= option for more details.

Details: SIMILARITY Procedure

The SIMILARITY procedure can be used to form time series data from transactional data.

1. accumulation ACCUMULATE= option
2. missing value interpretation SETMISSING= option
3. zero value interpretation ZEROMISS= option

The accumulated time series can then be transformed to form the working time series. Transformations are useful when you want to stabilize the time series before computing the similarity measures. Simple and seasonal differencing are useful when you want to detrend or deseasonalize the time series before computing the similarity measures. Often, but not always, the TRANSFORM=, DIF=, and SDIF= options should be specified in the same way for both the target and input variables.

1. time series transformation TRANSFORM= option
2. time series differencing DIF= and SDIF= option
3. time series missing value trimming TRIMMISSING= option
4. time series descriptive statistics PRINT=DESCSTATS option

After the working series is formed, it can be treated as an ordered sequence that can be normalized or scaled. Normalizations are useful when you want to compare the “shape” or “profile” of the time series. Scaling is useful when you want to compare the input sequence to the target sequence while discounting the variation of the target sequence.

1. normalization NORMALIZE= option
2. scaling SCALE= option

After the working sequences are formed, similarity measures can be computed between input and target sequences.

- | | |
|-----------------------|------------------------------|
| 1. sliding | SLIDE= option |
| 2. warping | COMPRESS= and EXPAND= option |
| 3. similarity measure | MEASURE= and PATH= option |

The SLIDE= option is used to specify observation-index sliding, seasonal-index sliding, or no sliding. The COMPRESS= and EXPAND= options are used to specify the warping limits. The MEASURE= and PATH= options are used to specify how the similarity measures are computed.

Accumulation

If the ACCUMULATE= option is specified in the ID, INPUT, or TARGET statement, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option in the ID statement. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is particularly useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```

19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20

```

If the INTERVAL=MONTH is specified, all of the preceding observations fall within three time periods of March 1999, April 1999, and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the data are accumulated as follows:

```

01MAR1999    40
01APR1999    .
01MAY1999    90

```

If the ACCUMULATE=AVERAGE option is specified, the data are accumulated as follows:

```

O1MAR1999    20
O1APR1999    .
O1MAY1999    30

```

If the ACCUMULATE=MINIMUM option is specified, the data are accumulated as follows:

```

O1MAR1999    10
O1APR1999    .
O1MAY1999    20

```

If the ACCUMULATE=MEDIAN option is specified, the data are accumulated as follows:

```

O1MAR1999    20
O1APR1999    .
O1MAY1999    20

```

If the ACCUMULATE=MAXIMUM option is specified, the data are accumulated as follows:

```

O1MAR1999    30
O1APR1999    .
O1MAY1999    50

```

If the ACCUMULATE=FIRST option is specified, the data are accumulated as follows:

```

O1MAR1999    10
O1APR1999    .
O1MAY1999    50

```

If the ACCUMULATE=LAST option is specified, the data are accumulated as follows:

```

O1MAR1999    30
O1APR1999    .
O1MAY1999    20

```

If the ACCUMULATE=STDDEV option is specified, the data are accumulated as follows:

```

O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32

```

As can be seen from the preceding examples, even though the data set observations contained no missing values, the accumulated time series can have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no (zero) value. In the former case, the SETMISSING= option in the ID, INPUT, or TARGET statement can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Zero Value Interpretation

When querying certain databases for time stamp data based on a particular time range, time periods that contain no data are sometimes assigned zero values. For certain analyses, it is more desirable to assign these values to missing. Often, these beginning or ending zero values need to be interpreted as missing values. The ZEROMISS= option in the ID, INPUT, or TARGET statement specifies that the beginning, ending, or both the beginning and ending values are to be interpreted as zero values.

Time Series Transformation

Transformations are useful when you want to stabilize the time series before computing the similarity measures. There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation,

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation,

$$w_t = \ln(cy_t/(1 - cy_t))$$

where the scaling factor c is

$$c = (1 - e^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square root is the square root transformation,

$$w_t = \sqrt{y_t}$$

Box-Cox is the Box-Cox transformation,

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

User-Defined is the transformation computed by a user-defined subroutine created by using the FCMP procedure, where *User-Defined* is the subroutine name.

Other time series transformations can be performed prior to invoking the SIMILARITY procedure by using the EXPAND procedure of SAS/ETS or the DATA step.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced using the INPUT or TARGET statement DIF= and SDIF= option. Simple and seasonal differencing are useful when you want to detrend or deseasonalize the time series before computing the similarity measures.

For example, suppose y_t is a monthly time series, the following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

DIF=(1,3) specifies first, then third, order differencing. SDIF=(1,3) specifies first, then third, order seasonal differencing.

Additionally, assuming that y_t is strictly positive, the INPUT or TARGET statement TRANSFORM= option and the DIF= and SDIF= options can be combined.

Time Series Missing Value Trimming

Sometimes time series missing values are interpreted as unknown values or are generated due to functional transformation or differencing. Either way the time series can contain missing values. The missing values can be trimmed from the beginning, the end, or both the beginning and the end of the time series with the TRIMMISS= option on the INPUT and TARGET statement.

Time Series Descriptive Statistics

After a series has been optionally accumulated and transformed with missing values interpreted, descriptive statistics can be computed for the resulting working series by specifying the PRINT=DESCSTATS option. This option produces an ODS table that contains the sum, mean, minimum, maximum, and standard deviation of the working series.

Input and Target Sequences

After the input and target working series are formed, they can be treated as two ordered sequences. Given an input time sequence, x_i , for $i = 1$ to N_x , where i is the input sequence index, and a target time sequence, y_j , for $j = 1$ to N_y , where j is the target sequence index, these sequences analyzed for similarity.

Sliding Sequences

Similarity measures can be computed between the target sequence and any contiguous subsequences of the input time series.

There are three types of sequence sliding:

- No Sliding
- Slide by Time Index
- Slide by Season Index

For more information see Leonard et al (2008).

Time Warping

Time warping allows for the comparison between target and input sequences of differing lengths by compressing or expanding the input sequence with respect the target sequence while respecting the order of the sequence elements.

For more information see Leonard et al (2008).

Sequence Normalization

The working (input or target) sequence can be normalized to prior to further analysis. Let q_i be the original sequence with mean, μ_q , and standard deviation, σ_q ; and let r_i be the normalized sequence. The normalizations are defined as follows:

- Standard is the standard normalization

$$r_i = (q_i - \mu_q) / \sigma_q$$

- Absolute is the absolute normalization

$$r_i = (q_i - \min(q_i)) / (\max(q_i) - \min(q_i))$$

- User-Defined User-defined normalization

Sequence Scaling

The working input sequence can be scaled to the working target sequence. Sequence scaling is applied after normalization. Let y_j be the working target sequence with mean, μ_y , and standard deviation, σ_y . Let x_i be the working input sequence and let q_i be the scaled sequence. The scaling is defined as follows:

- Standard is the standard normalization

$$q_i = (x_i - \mu_y) / \sigma_y$$

- Absolute is the absolute scaling

$$q_i = (x_i - \min(y_j)) / (\max(y_j) - \min(y_j))$$

- User-Defined is a user-defined scaling

Similarity Measures

The working input sequence can be compared to the working target sequence.

For more information see Leonard et al (2008).

User-Defined Functions and Subroutines

A user-defined routine can be written in the SAS language by using the FCMP procedure or the C language by using both the FCMP procedure and the PROTO procedure, respectively. The SIMILARITY procedure cannot use C language routines directly. The procedure can only use SAS language routines that might or might not call C language routines. Creating user-defined routines is more completely described in the FCMP procedure and the PROTO procedure documentation. The FCMP and PROTO procedures are part of Base SAS software.

The SAS language provides integrated memory management and exception handling such as operations on missing values. The C language provides flexibility and allows the integration of existing C language libraries. However, proper memory management and exception handling are solely the

responsibility of the user. Additionally, the support for standard C libraries is restricted. If given a choice, it is highly recommended that user-defined functions and subroutines be written in the SAS language using the FCMP procedure.

For each of the tasks described above, the following sections describe the required subroutine/function signature and provide examples of using a user-defined routine with the SIMILARITY procedure.

Time Series Transformations

A user-defined transformation subroutine has the following subroutine signature:

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*] );
```

where the array-name is the time series to be transformed.

For example, to duplicate the functionality of the built-in TRANSFORM=LOG option in the INPUT and TARGET statement, the following SAS statements create a user-defined version of this transformation called MYTRANSFORM and store this subroutine in the catalog SASUSER.MYSIMILAR.

```
proc fcmp outlib=sasuser.mysimilar.package;

  subroutine mytransform( series[*] );

    outargs series;

    length = DIM(series);

    do i = 1 to length;
      value = series[i];
      if value > 0 then do;
        series[i] = log( value );
      end;
      else do;
        series[i] = .;
      end;
    end;

  endsub;

run;
```

This user-defined subroutine can be specified in the TRANSFORM= option of the INPUT or TARGET statement as follows:

```
options cmlib = sasuser.mysimilar;

proc similarity ...;
...
```

```

input  myinput  / transform=mytransform;
target mytarget / transform=mytransform;
...
run;

```

Sequence Normalizations

A user-defined normalization subroutine has the following signature:

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*] );
```

where the array-name is the sequence to be normalized.

For example, to duplicate the functionality of the built-in NORMALIZE=ABSOLUTE option in the INPUT and TARGET statement, the following SAS statements create a user-defined version of this normalization called MYNORMALIZE and store this subroutine in the catalog SASUSER.MYSIMILAR.

```

proc fcmp outlib=sasuser.mysimilar.package;

  subroutine mynormalize( sequence[*] );

    outargs sequence;

    length = DIM(sequence);
    minimum = .; maximum = .;

    do i = 1 to length;
      value = sequence[i];
      if nmiss(minimum) | nmiss(maximum) then do;
        minimum = value;
        maximum = value;
      end;
      if nmiss(value) = 0 then do;
        if value < minimum then minimum = value;
        if value > maximum then maximum = value;
      end;
    end;

    do i = 1 to length;
      value = sequence[i];
      if nmiss( value ) | minimum > maximum then do;
        sequence[i] = .;
      end;
      else do;
        sequence[i] = (value - minimum) / (maximum - minimum);
      end;
    end;

  endsub;

run;

```

This user-defined subroutine can be specified in the NORMALIZE= option of INPUT or TARGET statement as follows:

```
options cmplib = sasuser.mysimilar;

proc similarity ...;
  ...
  input myinput / normalize=mynormalize;
  target mytarget / normalize=mynormalize;
  ...
run;
```

Sequence Scaling

A user-defined scaling subroutine has the following signature:

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*] );
```

where the first array-name is the target sequence and the second array-name is the input sequence to be scaled.

For example, to duplicate the functionality of the built-in SCALE=ABSOLUTE option in the INPUT statement, the following SAS statements create a user-defined version of this scaling called MYSCALE and store this subroutine in the catalog SASUSER.MYSIMILAR.

```
proc fcmp outlib=sasuser.mysimilar.package;

  subroutine myscale( target[*], input[*] );

    outargs input;

    length = DIM(target);
    minimum = .; maximum = .;

    do i = 1 to length;
      value = target[i];
      if nmiss(minimum) | nmiss(maximum) then do;
        minimum = value;
        maximum = value;
      end;
      if nmiss(value) = 0 then do;
        if value < minimum then minimum = value;
        if value > maximum then maximum = value;
      end;
    end;

    do i = 1 to length;
      value = input[i];
      if nmiss( value ) | minimum > maximum then do;
        input[i] = .;
      end;
    end;
  endsubroutine;
endproc;
```

```

        end;
      else do;
        input[i] = (value - minimum) / (maximum - minimum);
      end;
    end;

  endsub;

run;

```

This user-defined subroutine can be specified in the SCALE= option of INPUT statement as follows:

```

options cmlib=sasuser.mysimilar;

proc similarity ...;
  ...
  input myinput / scale=myscale;
  ...
run;

```

Similarity Measures

A user-defined similarity measure function has the following signature:

```

FUNCTION <FUNCTION-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*] );

```

where the first array-name is the target sequence and the second array-name is the input sequence. The return value of the function is the similarity measure associated with the target sequence and the input sequence.

For example, to duplicate the functionality of the built-in MEASURE=ABSDEV option in the TARGET statement with no warping, the following SAS statements create a user-defined version of this measure called MYMEASURE and store this subroutine in the catalog SASUSER.MYSIMILAR.

```

proc fcmp outlib=sasuser.mysimilar.package;

  function mymeasure( target[*], input[*] );

    length = min(DIM(target), DIM(input));
    sum = 0; num = 0;

    do i = 1 to length;
      x = input[i];
      w = target[i];
      if nmiss(x) = 0 & nmiss(w) = 0 then do;
        d = x - w;
        sum = sum + abs(d);
      end;
    end;

  end;

```

```

    if num <= 0 then return(.);

    return(sum);

endsub;

run;

```

This user-defined function can be specified in the MEASURE= option of TARGET statement as follows:

```

options cmlib=sasuser.mysimilar;

proc similarity ...;
    ...
    target mytarget / measure=mymmeasure;
    ...
run;

```

For another example, to duplicate the functionality of the built-in MEASURE=SQRDEV and MEASURE=ABSDEV options by using the C language, the following SAS statements create a user-defined C language version of these measures called DTW_SQRDEV_C and DTW_ABSDEV_C; and store these functions in the catalog SASUSER.CSIMIL.CFUNCS. DTW refers to dynamic time warping. These C language functions can be then called by SAS language functions and subroutines.

```

proc proto package=sasuser.csimil.cfuncs;

mapmiss double = 999999999;

double dtw_sqrdev_c( double * target / iotype=input,
                    int      targetLength,
                    double * input / iotype=input,
                    int      inputLength );

externc dtw_sqrdev_c;
double dtw_sqrdev_c( double * target,
                    int      targetLength,
                    double * input,
                    int      inputLength )
{
    int      i,j;
    double   x,w,d;
    double * prev = (double *)malloc( sizeof(double)*targetLength);
    double * curr = (double *)malloc( sizeof(double)*inputLength);
    if ( prev == 0 || curr == 0 ) return 999999999;

    x = input[0];
    for ( j=0; j<targetLength; j++ ) {
        w = target[j];
        d = x - w;
    }
}

```

```

        d = d*d;
        if ( j == 0 ) prev[j] = d;
        else          prev[j] = d + prev[j-1];
    }

    for (i=1; i<inputLength; i++ ) {
        x = input[i];

        j = 0;
        w = target[j];
        d = x - w;
        d = d*d;
        curr[j] = d + prev[j];

        for (j=1; j<targetLength; j++ ) {
            w = target[j];
            d = x - w;
            d = d*d;
            curr[j] = d + fmin( prev[j],
                               fmin( prev[j-1], curr[j]));
        }

        if ( i < targetLength ) {
            for( j=0; j<inputLength; j++ )
                prev[j] = curr[j];
        }
    }

    d = curr[inputLength-1];

        d = fabs(d);
        curr[j] = d + fmin( prev[j],
                           fmin( prev[j-1], curr[j] ));
    }

    if ( i < inputLength) {
        for ( j=0; j<targetLength; j++ )
            prev[j] = curr[j];
    }

}

d = curr[inputLength-1];
free( (char*) prev);
free( (char*) curr);
return( d );
}
externcend;

run;

```

The preceding SAS statements create two C language functions which can then be used in SAS language functions and/or subroutines. However, these functions cannot be directly used by the SIMILARITY procedure. In order to use these C language functions in the SIMILARITY procedure, two SAS language functions must be created that call these two C language functions. The following SAS statements create two user-defined SAS language versions of these measures called DTW_SQRDEV and DTW_ABSDEV and stores these functions in the catalog SASUSER.MYSIMILAR.FUNCS. These SAS language functions use the previously created C language function; the SAS language functions can then be used by the SIMILARITY procedure.

```

proc fcmp outlib=sasuser.mysimilar.funcs
    inlib=sasuser.cfuncs;

    function dtw_sqrdev( target[*], input[*] );

```

```

        dev = dtw_sqrdev_c(target,DIM(target),input,DIM(input));
        return( dev );
    endsub;

function dtw_absdev( target[*], input[*] );
    dev = dtw_absdev_c(target,DIM(target),input,DIM(input));
    return( dev );
endsub;

run;

```

This user-defined function can be specified in the MEASURE= option of TARGET statement as follows:

```

options cmlib=sasuser.mysimilar;

proc similarity ...;
    ...
    target mytarget / measure=dtw_sqrdev;
    target yourtarget / measure=dtw_absdev;
    ...
run;

```

Similarity Measures and Warping Path

A user-defined similarity measure and warping path information function has the following signature:

```

FUNCTION <FUNCTION-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*],
                           <ARRAY-NAME>[*], <ARRAY-NAME>[*],
                           <ARRAY-NAME>[*] );

```

where the first array-name is the target sequence, the second array-name is the input sequence, the third array-name is the returned target sequence indices, the fourth array-name is the returned input sequence indices, the fifth array-name is the returned path distances. The returned value of the function is the similarity measure. The last three returned arrays are used to compute the path and cost statistics.

The returned sequence indices must represent a valid warping path, that is, integers greater than zero and less than or equal to the sequence length and recorded in ascending order. The returned path distances must be nonnegative numbers.

Output Data Sets

The SIMILARITY procedure can create the OUT=, OUTSUM=, OUTMEASURE=, OUTSEQUENCE=, and OUTPATH= data sets. In general, these data sets contain the variables listed in

the BY statement. The ID statement time ID variable is also included in the data sets when the time dimension is important. If an analysis step related to an output data step fails, then the values of this step are not recorded or are set to missing in the related output data set, and appropriate error and/or warning messages are recorded in the SAS log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, INPUT, and TARGET statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN=, INTERVAL=, START=, and END= options. The values of the variables specified in the INPUT and TARGET statements are accumulated based on the ACCUMULATE= option, missing values are interpreted based on the SETMISSING= option, and zero values are interpreted using the ZEROMISS= option. The accumulated time series is transformed based on the TRANSFORM=, DIF=, and/ or SDIF= options.

OUTMEASURE= Data Set

The OUTMEASURE= data set records the similarity measures between each INPUT and TARGET statement variable with respect to each time ID value. The form of the OUTMEASURE= data set depends on the SORTNAMES and ORDER= option. The OUTMEASURE= data set contains the variables specified in the BY statement as well as the variables listed below.

For ORDER=INPUTTARGET and ORDER=TARGETINPUT, the OUTMEASURE= data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_INPSEQ_</code>	input sequence values
<code>_TARSEQ_</code>	target sequence values
<code>_SIM_</code>	similarity measures

The OUTMEASURE= data set is ordered by the variables `_INPUT_`, then `_TARGET_`, then `_TIMEID_` when ORDER=INPUTTARGET. The OUTMEASURE= data set is ordered by the variables `_TARGET_`, then `_INPUT_`, then `_TIMEID_` when ORDER=TARGETINPUT.

For ORDER=INPUT, the OUTMEASURE= data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_TIMEID_</code>	time ID values
<code>_INPSEQ_</code>	input sequence values

target-names similarity measures associated with each TARGET statement variable name

The OUTMEASURE= data set is ordered by the variables `_INPUT_`, then `_TIMEID_`.

For ORDER=TARGET, the OUTMEASURE= data set has the following form:

<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_TARSEQ_</code>	target sequence values
<i>input-names</i>	similarity measures associated with each INPUT statement variable name

The OUTMEASURE= data set is ordered by the variables `_TARGET_`, then `_TIMEID_`.

OUTSUM= Data Set

The OUTSUM= data set summarizes the similarity measures between each INPUT and TARGET statement variable. The form of the OUTSUM= data set depends on the SORTNAMES and ORDER= option. If the SORTNAMES option is specified, each variable (INPUT or TARGET) is analyzed in ascending order. The OUTSUM= data set contains the variables specified in the BY statement as well as the variables listed below.

For ORDER=INPUTTARGET and ORDER=TARGETINPUT, the OUTSUM= data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>_TIMEID_</code>	time ID values
<code>_SIM_</code>	similarity measure summary

The OUTSUM= data set is ordered by the variables `_INPUT_`, then `_TARGET_` when ORDER=INPUTTARGET. The OUTSUM= data set is ordered by the variables `_TARGET_`, then `_INPUT_` when ORDER=TARGETINPUT.

For ORDER=INPUT, the OUTSUM= data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<i>target-names</i>	similarity measure summary associated with each TARGET statement variable name

The OUTSUM= data set is ordered by the variable `_INPUT_`.

For ORDER=TARGET, the OUTSUM= data set has the following form:

<code>_TARGET_</code>	target variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>input-names</code>	similarity measure summary associated with each INPUT statement variable name

The OUTSUM= data set is ordered by the variable `_TARGET_`.

OUTSEQUENCE= Data Set

The OUTSEQUENCE= data set records the input and target sequences associated with each INPUT and TARGET statement variable. This data set records the input and target sequence values for each slide index and for each warp index associated with the slide index. The sequence values recorded are normalized and scaled based on the NORMALIZE= and SCALE= options. This data set also contains the similarity measure associated with the two sequences.

The OUTSEQUENCE= data set contains the variables specified in the BY statement as well as the variables listed below.

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_SLIDE_</code>	slide index
<code>_WARP_</code>	warp Index
<code>_INPSEQ_</code>	input sequence values
<code>_TARSEQ_</code>	target sequence values
<code>_SIM_</code>	similarity measure
<code>_STATUS_</code>	sequence Status

The sorting of the OUTSEQUENCE= data set depends on the SORTNAMES and the ORDER= option.

The OUTSEQUENCE= data set is ordered by the variables `_INPUT_`, then `_TARGET_`, then `_TIMEID_` when ORDER=INPUTTARGET or ORDER=INPUT. The OUTSEQUENCE= data set is ordered by the variables `_TARGET_`, then `_INPUT_`, then `_TIMEID_` when ORDER=TARGETINPUT or ORDER=TARGET.

If there are a large number of slides and/or warps, this data set may be large.

OUTPATH= Data Set

The OUTPATH= data set records the path analysis between each INPUT and TARGET statement variable. This data set records the path sequences for each slide index and for each warp index associated with the slide index. The sequence values recorded are normalized and scaled based on the NORMALIZE= and SCALE= options.

The OUTPATH= data set contains the variables specified in the BY statement as well as the variables listed below.

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_SLIDE_</code>	slide index
<code>_WARP_</code>	warp index
<code>_INPSEQ_</code>	input sequence values
<code>_TARSEQ_</code>	target sequence values
<code>_INPPATH_</code>	input path index
<code>_TARPATH_</code>	target path index
<code>_METRIC_</code>	distance metric values

The sorting of the OUTPATH= data set depends on the SORTNAMES and the ORDER= option.

The OUTPATH= data set is ordered by the variables `_INPUT_`, then `_TARGET_`, then `_TIMEID_` when `ORDER=INPUTTARGET` or `ORDER=INPUT`. The OUTPATH= data set is ordered by the variables `_TARGET_`, then `_INPUT_`, then `_TIMEID_` when `ORDER=TARGETINPUT` or `ORDER=TARGET`.

If there are a large number of slides and/or warps, this data set may be large.

`_STATUS_` Variable Values

The `_STATUS_` variable contains a code that specifies whether the similarity analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	Success
3000	Accumulation failure
4000	Missing value interpretation failure
6000	Series is all missing
7000	Transformation failure

8000	Differencing failure
9000	Unable to compute descriptive statistics
10000	Normalization failure
11000	Input contains imbedded missing values
12000	Target contains imbedded missing values
13000	Scaling failure
14000	Measure failure
15000	Path failure
16000	Slide summarization failure

Printed Output

The SIMILARITY procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= and PRINTDETAILS options in the PROC SIMILARITY statement.

The sort, order, and form of the printed output depends on both the SORTNAMES option and the ORDER= option. If the SORTNAMES option is specified, each variable (INPUT or TARGET) is analyzed in ascending order. For ORDER=INPUTTARGET, the printed output is ordered by the INPUT statement variables (row) and then by the TARGET statement variables (row). For ORDER=TARGETINPUT, the printed output is ordered by the TARGET statement variables (row) and then by the INPUT statement variables (row). For ORDER=INPUT, the printed output is ordered by the INPUT statement variables (row) and then the TARGET statement variables (column). For ORDER=TARGET, the printed output is ordered by the TARGET statement variables (row) and then the INPUT statement variables (column).

In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error and/or warning messages are recorded in the SAS log. The printed output is similar to the output data set, these similarities are described below.

PRINT=COSTS

prints the costs statistics.

PRINT=DESCSTATS

prints the descriptive statistics.

PRINT=PATHS

prints the path statistics.

PRINT=SLIDES

prints the sliding sequence summary.

PRINT=SUMMARY

prints the summary of similarity measures similar to the OUTSUM= data set.

PRINT=WARPS

prints the warp summary.

PRINTDETAILS

prints each table with greater detail.

ODS Tables Names

The table below relates the PRINT= options to ODS tables:

Table 22.2 ODS Tables Produced in PROC SIMILARITY

ODS Table Name	Description	Option
CostStatistics	Cost statistics	PRINT=COSTS
DescStats	Descriptive statistics	PRINT=DESCSTATS
PathLimits	Path limits	PRINT=PATHS
PathStatistics	Path statistics	PRINT=PATHS
SlideMeasuresSummary	Summary of measure per slide	PRINT=SLIDES
MeasuresSummary	Measures summary	PRINT=SUMMARY
InputMeasuresSummary	Measures summary	PRINT=SUMMARY
TargetMeasuresSummary	Measures summary	PRINT=SUMMARY
WarpMeasuresSummary	Summary of measure per warp	PRINT=WARPS

The tables are related to a single series within a BY group.

ODS Graphics

This section describes the use of ODS for creating graphics with the SIMILARITY procedure.

To request these graphs, you must specify the ODS GRAPHICS statement. In addition, you can specify the **PLOTS=** option in the PROC SIMILARITY statement as described in [Table 22.3](#).

ODS Graph Names

PROC SIMILARITY assigns a name to each graph it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in [Table 22.3](#).

Table 22.3 ODS Graphics Produced by PROC SIMILARITY

ODS Graph Name	Plot Description	Statement	PLOTS= Option
CostsPlot	Costs plot	SIMILARITY	PLOTS=COSTS
PathDistancePlot	Path distances plot	SIMILARITY	PLOTS=DISTANCES
PathDistanceHistogram	Path distances histogram	SIMILARITY	PLOTS=DISTANCES
PathRelativeDistancePlot	Path relative distances plot	SIMILARITY	PLOTS=DISTANCES
PathRelativeDistanceHistogram	Path relative distances histogram	SIMILARITY	PLOTS=DISTANCES
SeriesPlot	Input time series plot	SIMILARITY	PLOTS=INPUTS
TargetSequencePlot	Target sequence plot	SIMILARITY	PLOTS=TARGETS
SequencePlot	Sequence plot	SIMILARITY	PLOTS=SEQUENCES
SimilarityPlot	Similarity measures plot	SIMILARITY	PLOTS=MEASURES
PathPlot	Path plot	SIMILARITY	PLOTS=PATHS
PathSequencesPlot	Path sequences plot	SIMILARITY	PLOTS=MAPS
PathSequencesScaledPlot	Scaled path sequences map plot	SIMILARITY	PLOTS=MAPS
WarpPlot	Warping plot	SIMILARITY	PLOTS=WARPS
ScaledWarpPlot	Scaled warping plot	SIMILARITY	PLOTS=WARPS

Time Series Plots

The time series plots (SeriesPlot) illustrate the input time series to be compared. The horizontal axis represents the input series time ID values, and the vertical axis represents the input series values.

Sequence Plots

The sequence plots (SequencePlot) illustrate the target and input sequences to be compared. The horizontal axis represents the (target or input) sequence index, and the vertical axis represents the (target or input) sequence values.

Path Plots

The path plot (PathPlot) and path limits plot (PathPlot) illustrate the path through the distance matrix. The horizontal axis represents the input sequence index, and the vertical axis represents the target sequence index. The dots represent the path coordinates. The upper parallel line represents the compression limit and the lower parallel line represents the expansion limit. These plots visualize the path through the distance matrix. Vertical movements indicate compression, and horizontal movements represent expansion of the target sequence with respect to the input sequence. These plots are useful for visualizing the amount of expansion and compression along the path.

Time Warp Plots

The time warp plot (WarpPlot) and scaled time warp plot (ScaledWarpPlot) illustrate the time warping. The horizontal axis represents the (input and target) sequence index. The upper line plot represents the target sequence. The lower line plot represents the input sequence. The lines that connect the input and target sequence values represent the mapping between the input and target sequence indices along the optimal path. These plots visualize the warping of the time index with respect to the input and target sequence values. Expansion of a single target sequence value occurs when it is mapped to more than one input sequence value. Expansion of a single input sequence value occurs when it is mapped to more than one target sequence value. The plots are useful for visualizing the mapping between the input and target sequence values along the path. The plots are useful for comparing the path sequences or input and target sequence after time warping.

Path Sequence Plots

The path sequence plot (PathSequencesPlot) and scaled path sequence plot (PathSequencesScaled-Plot) illustrate the sequence mapping along the optimal path. The horizontal axis represents the path index. The dashed line represents the time warped input sequence. The solid line represents the time warped target sequence. These plots visualize the mapping between the input and target sequence values with respect to the path index. The scaled plot with the input and target sequence values are scaled and evenly separated for visual convenience.

Path Distance Plots

The path distance plots (PathDistancePlot) and path relative distance plots (PathRelativeDistance-Plot) illustrate the path (relative) distances. The horizontal axis represents the path index. The vertical needles represent the (relative) distances. The horizontal reference lines indicate one and two standard deviations.

The path distance histogram (PathDistanceHistogram) and path relative distance histogram (PathDistanceRelativeHistogram) illustrate the distribution of the path (relative) distances. The bars represent the histogram, and the solid line represents a normal distribution with the same mean and variance.

Cost Plots

The cost plot (CostPlot) and cost limits plot (CostPlot) illustrate the cost of traversing the distance matrix. The horizontal axis represents the input sequence index, and the vertical axis represents the target sequence index. The colors/shading within the plot illustrate the incremental cost of traversing the distance matrix. The upper parallel line represents the compression limit, and the lower parallel line represents the expansion limit.

Examples: SIMILARITY Procedure

Example 22.1: Accumulating Transactional Data into Time Series Data

This example uses the SIMILARITY procedure to illustrate the accumulation of time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, similarity analysis, seasonal adjustment/decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP.

The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. The accumulated time series values for time periods with no transactions are set to zero instead of missing (SETMISS=0). Only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31DEC2000'D) are considered and if needed are extended to include this range.

```
proc similarity data=work.retail out=mseries;
  by store;
  id timestamp interval=month
      accumulate=median
      setmiss=0
      start='01jan1998'd
      end  ='31dec2000'd;
  var _NUMERIC_;
run;
```

The monthly time series data are stored in the data WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the

years 1998, 1999, and 2000. Each observation contains the variable STORE, TIMESTAMP, and each of the analysis variables in the input DATA= data set.

After each set of transactions has been accumulated to form corresponding time series, accumulated time series can be analyzed by using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM.

```
proc expand data=mseries
            out=smoothed
            from=month;
  by store;
  id timestamp;
  convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series is stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contained SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options in the SIMILARITY procedure must be changed accordingly, and the following statements could be used to accumulate the datetime transactions to a monthly interval:

```
proc similarity data=work.retail
              out=tseries;
  by store;
  id timestamp interval=dtmonth
              accumulate=median
              setmiss=0
              start='01jan1998:00:00:00' dt
              end  ='31dec2000:00:00:00' dt;
  var _NUMERIC_;
run;
```

The monthly time series data are stored in the data WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 22.2: Similarity Analysis

This simple example illustrates how to compare two time sequences using similarity analysis. The following statements create an example data set that contains two time sequences of differing lengths.

```
data test;
input i y x;
datalines;
1 2 3
2 4 5
3 6 3
4 7 3
```

```

5  3  3
6  8  6
7  9  3
8  3  8
9 10  .
10 11 .
;
run;

```

The following statements perform similarity analysis on the example data set:

```

ods graphics on;
proc similarity data=test out=_null_
  print=all plot=all;
  input x;
  target y / measure=absdev;
run;

```

The DATA=TEST option specifies that the input data set WORK.TEST is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The PRINT=ALL and PLOTS=ALL options specify that all ODS tables and graphs are to be produced. The INPUT statement specifies that the input variable is X. The TARGET statement specifies that the target variable is Y and that the similarity measure is computed using absolute deviation (MEASURE=ABSDEV).

Output 22.2.16 Time Warp Plot

Output 22.2.17 Time Warp Scaled Plot

The following statements repeat the above similarity analysis on the example data set with warping limits:

```
ods graphics on;
proc similarity data=test out=_null_
  print=all plot=all;
  input x;
  target y / measure=absdev
  compress=(localabs=2)
  expand=(localabs=2);
run;
```

The COMPRESS=(LOCALABS=2) option limits local absolute compression to 2. The EXPAND=(LOCALABS=2) option limits local absolute expansion to 2.

Output 22.2.18 Path Plot with Warping Limits

Output 22.2.19 Warped Path Limits

Path Limits					
Limit	Specified Absolute	Specified Percentage	Minimum Allowed	Maximum Allowed	Applied
Compression	2	None	2	9	2
Expansion	2	None	0	7	2

Output 22.2.20 Cost Plot with Warping Limits

The following statements repeat the above similarity analysis on the example data set but store the results in output data sets:

```
proc similarity data=test out=series
  outsequence=sequences outpath=path outsum=summary;
  input x;
  target y / measure=absdev
  compress=(localabs=2)
  expand=(localabs=2);
run;
```

The `OUT=SERIES`, `OUTSEQUENCE=SEQUENCES`, `OUTPATH=PATH`, and `OUTSUM=SUMMARY` options specify that the output time series, time sequences, path analysis, and summary data sets be created, respectively.

Example 22.3: Sliding Similarity Analysis

This example illustrates how to compare two time sequences using sliding similarity analysis. The SASHELP.WORKERS data set contains two similar time series variables (ELECTRIC and MASONRY), which represent employment over time. The following statements create an example data set that contains two time series of differing lengths, where the variable MASONRY has the first 12 and last 7 observations set to missing to simulate the lack of data associated with the target series.

```
data workers; set sashelp.workers;
  if '01JAN1978'D <= date < '01JAN1982'D then masonry = masonry;
  else masonry = .;
run;
```

The goal of sliding similarity measures analysis is find the slide index that corresponds to the most similar subsequence of the input series when compared to the target sequence. The following statements perform sliding similarity analysis on the example data set:

```
proc similarity data=workers out=_NULL_ print=(slides summary);
  id date interval=month;
  input electric;
  target masonry / slide=index measure=msqrdev
                  expand=(localabs=3 globalabs=3)
                  compress=(localabs=3 globalabs=3);
run;
```

The DATA=WORKERS option specifies that the input data set WORK.WORKERS is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The PRINT=(SLIDES SUMMARY) option specifies that the ODS tables related to the sliding similarity measures and their summary are produced. The INPUT statement specifies that the input variable is ELECTRIC. The TARGET statement specifies that the target variable is MASONRY and that the similarity measure is computed using mean squared deviation (MEASURE=MSQRDEV). The SLIDE=INDEX option specifies observation index sliding. The COMPRESS=(LOCALABS=3 GLOBALABS=3) option limits local and global absolute compression to 3. The EXPAND=(LOCALABS=3 GLOBALABS=3) option limits local and global absolute expansion to 3.

Output 22.3.1 Summary of the Slide Measures

The SIMILARITY Procedure					
Slide Measures Summary for Input=ELECTRIC and Target=MASONRY					
Slide Index	DATE	Slide Target Sequence Length	Slide Input Sequence Length	Slide Warping Amount	Slide Minimum Measure

Output 22.3.2 Minimum Measure

Minimum Measure Summary	
Input Variable	MASONRY
ELECTRIC	322.5460

This analysis results in 23 slides based on the observation index with the minimum measure (322.5460) occurring at slide index 14 which corresponds to the time value FEB1978. Note that the original data set SASHELP.WORKERS was modified beginning at the time value JAN1978. This similarity analysis justifies the belief the ELECTRIC lags MASONRY by one month based on the time series cross-correlation analysis despite the lack of target data (MASONRY).

The goal of seasonal sliding similarity measures is to find the seasonal slide index which corresponds to the most similar seasonal subsequence of the input series when compared to the target

sequence. The following statements repeat the above similarity analysis on the example data set with seasonal sliding:

```
proc similarity data=workers out=NULL_ print=(slides summary);
  id date interval=month;
  input electric;
  target masonry / slide=season measure=msqrdev;
run;
```

Output 22.3.3 Summary of the Seasonal Slide Measures

The SIMILARITY Procedure					
Slide Measures Summary for Input=ELECTRIC and Target=MASONRY					
Slide Index	DATE	Slide Target Sequence Length	Slide Input Sequence Length	Slide Warping Amount	Slide Minimum Measure
0	JAN1977	48	48	0	1040.086
12	JAN1978	48	48	0	641.927

Output 22.3.4 Seasonal Minimum Measure

Minimum Measure Summary	
Input Variable	MASONRY
ELECTRIC	641.9273

The analysis differs from the previous analysis in that the slides are performed based on the seasonal index (SLIDE=SEASON) with no warping. With a seasonality of 12, two seasonal slides are considered at slide indices 0 and 12 with the minimum measure (641.9273) occurring at slide index 12 which corresponds to the time value JAN1978. Note that the original data set SASHELP.WORKERS was modified beginning at the time value JAN1978. This similarity analysis justifies the belief that ELECTRIC and MASONRY have similar seasonal properties based on seasonal decomposition analysis despite the lack of target data (MASONRY).

Example 22.4: Searching for Historical Analogies

This example illustrates how to search for historical analogies by using seasonal sliding similarity analysis of transactional time stamp data. The SASHELP.TIMEDATA data set contains the variable (VOLUME), which represents activity over time. The following statements create an example data

set that contains two time series of differing lengths, where the variable HISTORY represents the historical activity and RECENT represents the more recent activity.

```
data timedata; set sashelp.timedata;
  drop volume;
  recent = .;
  history = volume;
  if datetime >= '20AUG2000:00:00:00'DT then do;
    recent = volume;
    history = .;
  end;
run;
```

The goal of seasonal sliding similarity measures is to find the seasonal slide index that corresponds to the most similar seasonal subsequence of the input series when compared to the target sequence. The following statements perform similarity analysis on the example data set with seasonal sliding:

```
proc similarity data=timedata out=_NULL_ outsequence=sequences
              outsum=summary;
  id datetime interval=dtday accumulate=total
    start='27JUL1997:00:00:00'dt end='21OCT2000:11:59:59'DT;
  input history / normalize=absolute;
  target recent / slide=season normalize=absolute measure=mabsdev;
run;
```

The DATA=TIMEDATA option specifies that the input data set WORK.TIMEDATA is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The OUTSEQUENCE=SEQUENCES and OUTSUM=SUMMARY options specify the output sequences and summary data sets, respectively. The ID statement specifies that the time ID variable is DATETIME, which is to be accumulated on a daily basis (INTERVAL=DTDAY) by summing the transactions (ACCUMULATE=TOTAL). The ID statement also specifies that the data is accumulated on the weekly boundaries starting on the week of 27JUL1997 and ending on the week of 15OCT2000 (START='27JUL1997:00:00:00'DT END='21OCT2000:11:59:59'DT). The INPUT statement specifies that the input variable is HISTORY, which is to be normalized using absolute normalization (NORMALIZE=ABSOLUTE). The TARGET statement specifies that the target variable is RECENT, which is to be normalized by using absolute normalization (NORMALIZE=ABSOLUTE) and that the similarity measure is computed by using mean absolute deviation (MEASURE=MABSDEV). The SLIDE=SEASON options specifies season index sliding.

To illustrate the results of the similarity analysis, the output sequence data set must be subset by using the output summary data set.

```
data _NULL_; set summary;
  call symput('MEASURE', left(trim(putn(recent,'BEST20.'))));
run;

data result; set sequences;
  by _SLIDE_;
  retain flag 0;
  if first._SLIDE_ then do;
    if (&measure - 0.00001 < _SIM_ < &measure + 0.00001)
      then flag = 1;
```

```

end;
if flag then output;
if last._SLIDE_ then flag = 0;
run;

```

The following statements generate a cross series plot of the results:

```

proc timeseries data=result out=NULL_ crossplot=series;
  id datetime interval=dtday;
  var _TARSEQ_;
  crossvar _INPSEQ_;
run;

```

The cross series plot illustrates that the historical time series analogy most similar to the most recent time series data that started on 20AUG2000 occurred on 02AUG1998.

Output 22.4.1 Cross Series Plot of the Historical Time Series

Overview: SIMLIN Procedure

The SIMLIN procedure reads the coefficients for a set of linear structural equations, which are usually produced by the SYSLIN procedure. PROC SIMLIN then computes the reduced form

and, if input data are given, uses the reduced form equations to generate predicted values. PROC SIMLIN is especially useful when dealing with sets of structural difference equations. The SIMLIN procedure can perform simulation or forecasting of the endogenous variables.

The SIMLIN procedure can be applied only to models that are:

- linear with respect to the parameters
- linear with respect to the variables
- square (as many equations as endogenous variables)
- nonsingular (the coefficients of the endogenous variables form an invertible matrix)

Getting Started: SIMLIN Procedure

The SIMLIN procedure processes the coefficients in a data set created by the SYSLIN procedure using the OUTEST= option or by another regression procedure such as PROC REG. To use PROC SIMLIN you must first produce the coefficient data set and then specify this data set on the EST= option of the PROC SIMLIN statement. You must also tell PROC SIMLIN which variables are endogenous and which variables are exogenous. List the endogenous variables in an ENDOGENOUS statement, and list the exogenous variables in an EXOGENOUS statement.

The following example illustrates the creation of an OUTEST= data set with PROC SYSLIN and the computation and printing of the reduced form coefficients for the model with PROC SIMLIN.

```
proc syslin data=in outest=e;
  model y1 = y2 x1;
  model y2 = y1 x2;
run;

proc simlin est=e;
  endogenous y1 y2;
  exogenous x1 x2;
run;
```

If the model contains lagged endogenous variables you must also use a LAGGED statement to tell PROC SIMLIN which variables contain lagged values, which endogenous variables they are lags of, and the number of periods of lagging. For dynamic models, the TOTAL and INTERIM= options can be used on the PROC SIMLIN statement to compute and print total and impact multipliers. (See "Dynamic Multipliers" later in this section for an explanation of multipliers.)

In the following example the variables Y1LAG1, Y2LAG1, and Y2LAG2 contain lagged values of the endogenous variables Y1 and Y2. Y1LAG1 and Y2LAG1 contain values of Y1 and Y2 for the previous observation, while Y2LAG2 contains 2 period lags of Y2. The LAGGED statement specifies the lagged relationships, and the TOTAL and INTERIM= options request multiplier analysis. The INTERIM=2 option prints matrices showing the impact that changes to the exogenous variables have on the endogenous variables after 1 and 2 periods.

```

data in; set in;
  y1lag1 = lag(y1);
  y2lag1 = lag(y2);
  y2lag2 = lag2(y2);
run;

proc syslin data=in outest=e;
  model y1 = y2 y1lag1 y2lag2 x1;
  model y2 = y1 y2lag1 x2;
run;

proc simlin est=e total interim=2;
  endogenous y1 y2;
  exogenous x1 x2;
  lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
run;

```

After the reduced form of the model is computed, the model can be simulated by specifying an input data set on the PROC SIMLIN statement and using an OUTPUT statement to write the simulation results to an output data set. The following example modifies the PROC SIMLIN step from the preceding example to simulate the model and stores the results in an output data set.

```

proc simlin est=e total interim=2 data=in;
  endogenous y1 y2;
  exogenous x1 x2;
  lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
  output out=sim predicted=y1hat y2hat
         residual=y1resid y2resid;
run;

```

Prediction and Simulation

If an input data set is specified with the DATA= option in the PROC SIMLIN statement, the procedure reads the data and uses the reduced form equations to compute predicted and residual values for each of the endogenous variables. (If no data set is specified with the DATA= option, no simulation of the system is performed, and only the reduced form and multipliers are computed.)

The character of the prediction is based on the START= value. Until PROC SIMLIN encounters the START= observation, actual endogenous values are found and fed into the lagged endogenous terms. Once the START= observation is reached, dynamic simulation begins, where predicted values are fed into lagged endogenous terms until the end of the data set is reached.

The predicted and residual values generated here are different from those produced by the SYSLIN procedure since PROC SYSLIN uses the structural form with actual endogenous values. The predicted values computed by the SIMLIN procedure solve the simultaneous equation system. These reduced-form predicted values are functions only of the exogenous and lagged endogenous variables and do not depend on actual values of current period endogenous variables.

Syntax: SIMLIN Procedure

The following statements can be used with PROC SIMLIN:

```

PROC SIMLIN options ;
  BY variables ;
  ENDOGENOUS variables ;
  EXOGENOUS variables ;
  ID variables ;
  LAGGED lag-var endogenous-var number ellipsis ;
  OUTPUT OUT=SAS-data-set options ;

```

Functional Summary

The statements and options controlling the SIMLIN procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set containing structural coefficients	PROC SIMLIN	EST=
specify type of estimates read from EST= data set	PROC SIMLIN	TYPE=
write reduced form coefficients and multipliers to an output data set	PROC SIMLIN	OUTEST=
specify the input data set for simulation	PROC SIMLIN	DATA=
write predicted and residual values to an output data set	OUTPUT	
Printing Control Options		
print the structural coefficients	PROC SIMLIN	ESTPRINT
suppress printing of reduced form coefficients	PROC SIMLIN	NORED
suppress all printed output	PROC SIMLIN	NO PRINT
Dynamic Multipliers		
compute interim multipliers	PROC SIMLIN	INTERIM=
compute total multipliers	PROC SIMLIN	TOTAL
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the endogenous variables	ENDOGENOUS	
specify the exogenous variables	EXOGENOUS	
specify identifying variables	ID	

Description	Statement	Option
specify lagged endogenous variables	LAGGED	
Controlling the Simulation		
specify the starting observation for dynamic simulation	PROC SIMLIN	START=

PROC SIMLIN Statement

PROC SIMLIN *options* ;

The following options can be used in the PROC SIMLIN statement:

DATA= *SAS-data-set*

specifies the SAS data set containing input data for the simulation. If the DATA= option is used, the data set specified must supply values for all exogenous variables throughout the simulation. If the DATA= option is not specified, no simulation of the system is performed, and only the reduced form and multipliers are computed.

EST= *SAS-data-set*

specifies the input data set containing the structural coefficients of the system. If EST= is omitted the most recently created SAS data set is used. The EST= data set is normally a "TYPE=EST" data set produced by the OUTEST= option of PROC SYSLIN. However, you can also build the EST= data set with a SAS DATA step. See "The EST= Data Set" later in this chapter for details.

ESTPRINT

prints the structural coefficients read from the EST= data set.

INTERIM= *n*

requests that interim multipliers be computed for interims 1 through *n*. If not specified, no interim multipliers are computed. This feature is available only if there are no lags greater than 1.

NOPRINT

suppresses all printed output.

NORED

suppresses the printing of the reduced form coefficients.

OUTEST= *SAS-data-set*

specifies an output SAS data set to contain the reduced form coefficients and multipliers, in addition to the structural coefficients read from the EST= data set. The OUTEST= data set has the same form as the EST= data set. If the OUTEST= option is not specified, the reduced form coefficients and multipliers are not written to a data set.

START= *n*

specifies the observation number in the DATA= data set where the dynamic simulation is to be started. By default, the dynamic simulation starts with the first observation in the DATA= data set for which all variables (including lags) are not missing.

TOTAL

requests that the total multipliers be computed. This feature is available only if there are no lags greater than 1.

TYPE= *value*

specifies the type of estimates to be read from the EST= data set. The TYPE= value must match the value of the `_TYPE_` variable for the observations that you want to select from the EST= data set (TYPE=2SLS, for example).

BY Statement

BY *variables* ;

A BY statement can be used with PROC SIMLIN to obtain separate analyses for groups of observations defined by the BY variables.

The BY statement can be applied to one or both of the EST= and the DATA= input data set. When a BY statement is used and both an EST= and a DATA= input data set are specified, PROC SIMLIN checks to see if one or both of the data sets contain the BY variables.

Thus, there are three ways of using the BY statement with PROC SIMLIN:

1. If the BY variables are found in the EST= data set only, PROC SIMLIN simulates over the entire DATA= data set once for each set of coefficients read from the BY groups in the EST= data set.
2. If the BY variables are found in the DATA= data set only, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set, using the single set of coefficients in the EST= data set.
3. If the BY variables are found in both the EST= and the DATA= data sets, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set using the coefficients from the corresponding BY group in the EST= data set.

ENDOGENOUS Statement

ENDOGENOUS *variables* ;

List the names of the endogenous (jointly dependent) variables in the ENDOGENOUS statement. The ENDOGENOUS statement can be abbreviated as ENDOG or ENDO.

EXOGENOUS Statement

EXOGENOUS *variables* ;

List the names of the exogenous (independent) variables in the EXOGENOUS statement. The EXOGENOUS statement can be abbreviated as EXOG or EXO.

ID Statement

ID *variables* ;

The ID statement can be used to restrict the variables copied from the DATA= data set to the OUT= data set. Use the ID statement to list the variables you want copied to the OUT= data set besides the exogenous, endogenous, lagged endogenous, and BY variables. If the ID statement is omitted, all the variables in the DATA= data set are copied to the OUT= data set.

LAGGED Statement

LAGGED *lag-var endogenous-var number ellipsis* ;

For each lagged endogenous variable, specify the name of the lagged variable, the name of the endogenous variable that was lagged, and the degree of the lag. Only one LAGGED statement is allowed.

The following is an example of the use of the LAGGED statement:

```
proc simlin est=e;
  endog y1 y2;
  lagged y1lag1 y1 1 y2lag1 y2 1 y2lag3 y2 3;
run;
```

This statement specifies that the variable Y1LAG1 contains the values of the endogenous variable Y1 lagged one period; the variable Y2LAG1 refers to the values of Y2 lagged one period; and the variable Y2LAG3 refers to the values of Y2 lagged three periods.

OUTPUT Statement

OUTPUT *OUT= SAS-data-set options* ;

The OUTPUT statement specifies that predicted and residual values be put in an output data set. A DATA= input data set must be supplied if the OUTPUT statement is used, and only one OUTPUT statement is allowed. The following options can be used in the OUTPUT statement:

OUT= *SAS-data-set*

names the output SAS data set to contain the predicted values and residuals. If OUT= is not specified, the output data set is named using the DATA*n* convention.

PREDICTED= *names*

P= *names*

names the variables in the output data set that contain the predicted values of the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. If you specify names on the PREDICTED= option for only some of the endogenous variables, predicted values for the remaining variables are not output. The names must not match any variable name in the input data set.

RESIDUAL= *names*

R= *names*

names the variables in the output data set that contain the residual values from the simulation. The residuals are the differences between the actual values of the endogenous variables from the DATA= data set and the predicted values from the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. The names must not match any variable name in the input data set.

The following is an example of the use of the OUTPUT statement. This example outputs predicted values for Y1 and Y2 and outputs residuals for Y1.

```
proc simlin est=e;
  endog y1 y2;
  output out=b predicted=y1hat y2hat
          residual=y1resid;
run;
```

Details: SIMLIN Procedure

The following sections explain the structural and reduced forms, dynamic multipliers, input data sets, and the model simulation process in more detail.

Defining the Structural Form

An EST= input data set supplies the coefficients of the equation system. The data set containing the coefficients is normally a "TYPE=EST" data set created by the OUTEST= option of PROC SYSLIN or another regression procedure. The data set contains the special variables _TYPE_, _DEPVAR_, and INTERCEPT. You can also supply the structural coefficients of the system to PROC SIMLIN in a data set produced by a SAS DATA step as long as the data set is of the form TYPE=EST. Refer to SAS/STAT software documentation for a discussion of the special TYPE=EST type of SAS data set.

Suppose that there is a $g \times 1$ vector of endogenous variables \mathbf{y}_t , an $l \times 1$ vector of lagged endogenous variables \mathbf{y}_t^L , and a $k \times 1$ vector of exogenous variables \mathbf{x}_t , including the intercept. Then, there are g structural equations in the simultaneous system that can be written

$$\mathbf{G}\mathbf{y}_t = \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where \mathbf{G} is the matrix of coefficients of current period endogenous variables, \mathbf{C} is the matrix of coefficients of lagged endogenous variables, and \mathbf{B} is the matrix of coefficients of exogenous variables. \mathbf{G} is assumed to be nonsingular.

Computing the Reduced Form

First, the SIMLIN procedure computes reduced form coefficients by premultiplying by \mathbf{G}^{-1} :

$$\mathbf{y}_t = \mathbf{G}^{-1}\mathbf{C}\mathbf{y}_t^L + \mathbf{G}^{-1}\mathbf{B}\mathbf{x}_t$$

This can be written as

$$\mathbf{y}_t = \Pi_1\mathbf{y}_t^L + \Pi_2\mathbf{x}_t$$

where $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$ and $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$ are the reduced form coefficient matrices.

The reduced form matrices $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$ and $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$ are printed unless the NORED option is specified in the PROC SIMLIN statement. The structural coefficient matrices \mathbf{G} , \mathbf{C} , and \mathbf{B} are printed when the ESTPRINT option is specified.

Dynamic Multipliers

For models that have only first-order lags, the equation of the reduced form of the system can be rewritten

$$\mathbf{y}_t = \mathbf{D}\mathbf{y}_{t-1} + \Pi_2\mathbf{x}_t$$

\mathbf{D} is a matrix formed from the columns of Π_1 plus some columns of zeros, arranged in the order in which the variables meet the lags. The elements of Π_2 are called *impact multipliers* because they show the immediate effect of changes in each exogenous variable on the values of the endogenous variables. This equation can be rewritten as

$$\mathbf{y}_t = \mathbf{D}^2 \mathbf{y}_{t-2} + \mathbf{D} \Pi_2 \mathbf{x}_{t-1} + \Pi_2 \mathbf{x}_t$$

The matrix formed by the product $\mathbf{D} \Pi_2$ shows the effect of the exogenous variables one lag back; the elements in this matrix are called *interim multipliers* and are computed and printed when the INTERIM= option is specified in the PROC SIMLIN statement. The i th period interim multipliers are formed by $\mathbf{D}^i \Pi_2$.

The series can be expanded as

$$\mathbf{y}_t = \mathbf{D}^\infty \mathbf{y}_{t-\infty} + \sum_{i=0}^{\infty} \mathbf{D}^i \Pi_2 \mathbf{x}_{t-i}$$

A permanent and constant setting of a value for x has the following cumulative effect:

$$\left(\sum_{i=0}^{\infty} \mathbf{D}^i \right) \Pi_2 \mathbf{x} = (\mathbf{I} - \mathbf{D})^{-1} \Pi_2 \mathbf{x}$$

The elements of $(\mathbf{I} - \mathbf{D})^{-1} \Pi_2$ are called the *total multipliers*. Assuming that the sum converges and that $(\mathbf{I} - \mathbf{D})$ is invertible, PROC SIMLIN computes the total multipliers when the TOTAL option is specified in the PROC SIMLIN statement.

Multipliers for Higher Order Lags

The dynamic multiplier options require the system to have no lags of order greater than one. This limitation can be circumvented, since any system with lags greater than one can be rewritten as a system where no lag is greater than one by forming new endogenous variables that are single-period lags.

For example, suppose you have the third-order single equation

$$y_t = ay_{t-3} + b\mathbf{x}_t$$

This can be converted to a first-order three-equation system by introducing two additional endogenous variables, $y_{1,t}$ and $y_{2,t}$, and computing corresponding first-order lagged variables for each endogenous variable: y_{t-1} , $y_{1,t-1}$, and $y_{2,t-1}$. The higher order lag relations are then produced by adding identities to link the endogenous and identical lagged endogenous variables:

$$y_{1,t} = y_{t-1}$$

$$y_{2,t} = y_{1,t-1}$$

$$y_t = ay_{2,t-1} + b\mathbf{x}_t$$

This conversion using the SYSLIN and SIMLIN procedures requires three steps:

1. Add the extra endogenous and lagged endogenous variables to the input data set using a DATA step. Note that two copies of each lagged endogenous variable are needed for each lag reduced, one to serve as an endogenous variable and one to serve as a lagged endogenous variable in the reduced system.
2. Add IDENTITY statements to the PROC SYSLIN step to equate each added endogenous variable to its lagged endogenous variable copy.
3. In the PROC SIMLIN step, declare the added endogenous variables in the ENDOGENOUS statement and define the lag relations in the LAGGED statement.

See [Example 23.2](#) for an illustration of how to convert an equation system with higher-order lags into a larger system with only first-order lags.

EST= Data Set

Normally, PROC SIMLIN uses an EST= data set produced by PROC SYSLIN with the OUTEST= option. This data set is in the form expected by PROC SIMLIN. If there is more than one set of estimates produced by PROC SYSLIN, you must use the TYPE= option in the PROC SIMLIN statement to select the set to be simulated. Then PROC SIMLIN reads from the EST= data set only those observations with a _TYPE_ value corresponding to the TYPE= option (for example, TYPE=2SLS) or with a _TYPE_ value of IDENTITY.

The SIMLIN procedure can only solve square, nonsingular systems. If you have fewer equations than endogenous variables, you must specify IDENTITY statements in the PROC SYSLIN step to bring the system up to full rank. If there are g endogenous variables and $m < g$ stochastic equations with unknown parameters, then you use m MODEL statements to specify the equations with parameters to be estimated and you must use $g-m$ IDENTITY statements to complete the system.

You can build your own EST= data set with a DATA step rather than use PROC SYSLIN. The EST= data set must contain the endogenous variables, the lagged endogenous variables (if any), and the exogenous variables in the system (if any). If any of the equations have intercept terms, the variable INTERCEPT must supply these coefficients. The EST= data set should also contain the special character variable comp _DEPVAR_ to label the equations.

The EST= data set must contain one observation for each equation in the system. The values of the lagged endogenous variables must contain the **C** coefficients. The values of the exogenous variables and the INTERCEPT variable must contain the **B** coefficients. The values of the endogenous variables, however, must contain the negatives of the **G** coefficients. This is because the SYSLIN procedure writes the coefficients to the OUTEST= data set in the form

$$0 = \mathbf{H}\mathbf{y}_t + \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where $\mathbf{H} = -\mathbf{G}$.

See "Multipliers for Higher Order Lags" and [Example 23.2](#) later in this chapter for more information on building the EST= data set.

DATA= Data Set

The DATA= data set must contain all of the exogenous variables. Values for all of the exogenous variables are required for each observation for which predicted endogenous values are desired. To forecast past the end of the historical data, the DATA= data set should contain nonmissing values for all of the exogenous variables and missing values for the endogenous variables for the forecast periods, in addition to the historical data. (See [Example 23.1](#) for an illustration.)

In order for PROC SIMLIN to output residuals and compute statistics of fit, the DATA= data set must also contain the endogenous variables with nonmissing actual values for each observation for which residuals and statistics are to be computed.

If the system contains lags, initial values must be supplied for the lagged variables. This can be done by including either the lagged variables or the endogenous variables, or both, in the DATA= data set. If the lagged variables are not in the DATA= data set or if they have missing values in the early observations, PROC SIMLIN prints a warning and uses the endogenous variable values from the early observations to initialize the lags.

OUTEST= Data Set

The OUTEST= data set contains all the variables read from the EST= data set. The variables in the OUTEST= data set are as follows.

- the BY statement variables, if any
- `_TYPE_`, a character variable that identifies the type of observation
- `_DEPVAR_`, a character variable containing the name of the dependent variable for the observation
- the endogenous variables
- the lagged endogenous variables
- the exogenous variables
- INTERCEPT, a numeric variable containing the intercept values
- `_MODEL_`, a character variable containing the name of the equation
- `_SIGMA_`, a numeric variable containing the estimated error variance of the equation (output only if present in the EST= data set)

The observations read from the EST= data set that supply the structural coefficients are copied to the OUTEST= data set, except that the signs of endogenous coefficients are reversed. For these observations, the `_TYPE_` variable values are the same as in the EST= data set.

In addition, the OUTEST= data set contains observations with the following `_TYPE_` values:

REDUCED	the reduced form coefficients. The endogenous variables for this group of observations contain the inverse of the endogenous coefficient matrix \mathbf{G} . The lagged endogenous variables contain the matrix $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$. The exogenous variables contain the matrix $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$.
IMULT <i>i</i>	the interim multipliers, if the INTERIM= option is specified. There are gn observations for the interim multipliers, where g is the number of endogenous variables and n is the value of the INTERIM= n option. For these observations the <code>_TYPE_</code> variable has the value IMULT <i>i</i> , where the interim number i ranges from 1 to n . The exogenous variables in groups of g observations that have a <code>_TYPE_</code> value of IMULT <i>i</i> contain the matrix $\mathbf{D}^i \Pi_2$ of multipliers at interim i . The endogenous and lagged endogenous variables for this group of observations are set to missing.
TOTAL	the total multipliers, if the TOTAL option is specified. The exogenous variables in this group of observations contain the matrix $(\mathbf{I} - \mathbf{D})^{-1} \Pi_2$. The endogenous and lagged endogenous variables for this group of observations are set to missing.

OUT= Data Set

The OUT= data set normally contains all of the variables in the input DATA= data set, plus the variables named in the PREDICTED= and RESIDUAL= options in the OUTPUT statement.

You can use an ID statement to restrict the variables that are copied from the input data set. If an ID statement is used, the OUT= data set contains only the BY variables (if any), the ID variables, the endogenous and lagged endogenous variables (if any), the exogenous variables, plus the PREDICTED= and RESIDUAL= variables.

The OUT= data set contains an observation for each observation in the DATA= data set. When the actual value of an endogenous variable is missing in the DATA= data set, or when the DATA= data set does not contain the endogenous variable, the corresponding residual is missing.

Printed Output

Structural Form

The following items are printed as they are read from the EST= input data set. Structural zeros are printed as dots in the listing of these matrices.

1. Structural Coefficients for Endogenous Variables. This is the \mathbf{G} matrix, with g rows and g columns.

2. Structural Coefficients for Lagged Endogenous Variables. These coefficients make up the **C** matrix, with g rows and l columns.
3. Structural Coefficients for Exogenous Variables. These coefficients make up the **B** matrix, with g rows and k columns.

Reduced Form

1. The reduced form coefficients are obtained by inverting **G** so that the endogenous variables can be directly expressed as functions of only lagged endogenous and exogenous variables.
2. Inverse Coefficient Matrix for Endogenous Variables. This is the inverse of the **G** matrix.
3. Reduced Form for Lagged Endogenous Variables. This is $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$, with g rows and l columns. Each value is a dynamic multiplier that shows how past values of lagged endogenous variables affect values of each of the endogenous variables.
4. Reduced Form for Exogenous Variables. This is $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$, with g rows and k columns. Its values are called *impact multipliers* because they show the immediate effect of each exogenous variable on the value of the endogenous variables.

Multipliers

Interim and total multipliers show the effect of a change in an exogenous variable over time.

1. Interim Multipliers. These are the interim multiplier matrices. They are formed by multiplying Π_2 by powers of **D**. The d th interim multiplier is $\mathbf{D}^d \Pi_2$. The interim multiplier of order d shows the effects of a change in the exogenous variables after d periods. Interim multipliers are only available if the maximum lag of the endogenous variables is 1.
2. Total Multipliers. This is the matrix of total multipliers, $\mathbf{T} = (\mathbf{I} - \mathbf{D})^{-1} \Pi_2$. This matrix shows the cumulative effect of changes in the exogenous variables. Total multipliers are only available if the maximum lag is one.

Statistics of Fit

If the DATA= option is used and the DATA= data set contains endogenous variables, PROC SIMLIN prints a statistics-of-fit report for the simulation. The statistics printed include the following. (Summations are over the observations for which both y_t and \hat{y}_t are nonmissing.)

1. the number of nonmissing errors. (Number of observations for which both y_t and \hat{y}_t are nonmissing.)
2. the mean error: $\frac{1}{n} \sum (y_t - \hat{y}_t)$
3. the mean percent error: $\frac{100}{n} \sum \frac{(y_t - \hat{y}_t)}{y_t}$
4. the mean absolute error: $\frac{1}{n} \sum |y_t - \hat{y}_t|$

5. the mean absolute percent error $\frac{100}{n} \sum \frac{|y_t - \hat{y}_t|}{y_t}$
6. the root mean square error: $\sqrt{\frac{1}{n} \sum (y_t - \hat{y}_t)^2}$
7. the root mean square percent error: $\sqrt{\frac{100}{n} \sum \left(\frac{y_t - \hat{y}_t}{y_t}\right)^2}$

ODS Table Names

PROC SIMLIN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 23.2 ODS Tables Produced in PROC SIMLIN

ODS Table Name	Description	Option
Endogenous	Structural Coefficients for Endogenous Variables	default
LaggedEndogenous	Structural Coefficients for Lagged Endogenous Variables	default
Exogenous	Structural Coefficients for Exogenous Variables	default
InverseCoeff	Inverse Coefficient Matrix for Endogenous Variables	default
RedFormLagEndo	Reduced Form for Lagged Endogenous Variables	default
RedFormExog	Reduced Form for Exogenous Variables	default
InterimMult	Interim Multipliers	INTERIM= option
TotalMult	Total Multipliers	TOTAL= option
FitStatistics	Fit statistics	default

Examples: SIMLIN Procedure

Example 23.1: Simulating Klein's Model I

In this example, the SIMLIN procedure simulates a model of the U.S. economy called Klein's Model I. The SAS data set KLEIN is used as input to the SYSLIN and SIMLIN procedures.

```

data klein;
  input year c p w i x wp g t k wsum;
  date=mdy(1,1,year);
  format date year.;
  y = c + i + g - t;
  yr = year - 1931;
  klag = lag( k );
  plag = lag( p );
  xlag = lag( x );
  if year >= 1921;
  label c = 'consumption'
        p = 'profits'
        w = 'private wage bill'
        i = 'investment'
        k = 'capital stock'
        y = 'national income'
        x = 'private production'
        wsum='total wage bill'
        wp = 'govt wage bill'
        g = 'govt demand'
        t = 'taxes'
        klag='capital stock lagged'
        plag='profits lagged'
        xlag='private product lagged'
        yr = 'year-1931';
datalines;
1920      .  12.7      .      .  44.9      .      .      .  182.8      .
... more lines ...

```

First, the model is specified and estimated using the SYSLIN procedure, and the parameter estimates are written to an OUTEST= data set. The printed output produced by the SYSLIN procedure is not shown here; see [Example 26.1](#) in [Chapter 26](#) for the printed output of the PROC SYSLIN step.

```

title1 'Simulation of Klein''s Model I using SIMLIN';
proc syslin 3sls data=klein outest=a;

  instruments klag plag xlag wp g t yr;
  endogenous c p w i x wsum k y;

  consume: model    c = p plag wsum;
  invest:  model    i = p plag klag;
  labor:   model    w = x xlag yr;

  product: identity x = c + i + g;
  income:  identity y = c + i + g - t;
  profit:  identity p = x - w - t;
  stock:   identity k = klag + i;
  wage:    identity wsum = w + wp;
run;

```

The OUTEST= data set A created by the SYSLIN procedure contains parameter estimates to be used by the SIMLIN procedure. The OUTEST= data set is shown in [Output 23.1.1](#).

Output 23.1.1 The OUTEST= Data Set Created by PROC SYSLIN

Using the OUTEST= data set A produced by the SYSLIN procedure, the SIMLIN procedure can now compute the reduced form and simulate the model. The following statements perform the simulation.

```

title1 'Simulation of Klein''s Model I using SIMLIN';
proc simlin data=klein
    est=a type=3sls
    estprint
    total interim=2
    outest=b;
endogenous c p w i x wsum k y;
exogenous wp g t yr;
lagged klag k 1 plag p 1 xlag x 1;
id year;
output out=c p=chat phat what ihat xhat wsumhat khat yhat
        r=cres pres wres ires xres wsumres kres yres;
run;

```

The reduced form coefficients and multipliers are added to the information read from EST= data set A and written to the OUTEST= data set B. The predicted and residual values from the simulation are written to the OUT= data set C specified in the OUTPUT statement.

The SIMLIN procedure first prints the structural coefficient matrices read from the EST= data set, as shown in [Output 23.1.2](#) through [Output 23.1.4](#).

Output 23.1.2 SIMLIN Procedure Output – Endogenous Structural Coefficients

Simulation of Klein's Model I using SIMLIN				
The SIMLIN Procedure				
Structural Coefficients for Endogenous Variables				
Variable	c	p	w	i
c	1.0000	-0.1249	.	.
i	.	0.0131	.	1.0000
w	.	.	1.0000	.
x	-1.0000	.	.	-1.0000
y	-1.0000	.	.	-1.0000
p	.	1.0000	1.0000	.
k	.	.	.	-1.0000
wsum	.	.	-1.0000	.

Structural Coefficients for Endogenous Variables

Example 23.2: Multipliers for a Third-Order System

This example shows how to fit and simulate a single equation dynamic model with third-order lags. It then shows how to convert the third-order equation into a three equation system with only first-order lags, so that the SIMLIN procedure can compute multipliers. (See the section "Multipliers for Higher Order Lags" earlier in this chapter for more information.)

The input data set TEST is created from simulated data. A partial listing of the data set TEST produced by PROC PRINT is shown in [Output 23.2.1](#).

Overview: SPECTRA Procedure

The SPECTRA procedure performs spectral and cross-spectral analysis of time series. You can use spectral analysis techniques to look for periodicities or cyclical patterns in data.

The SPECTRA procedure produces estimates of the spectral and cross-spectral densities of a multivariate time series. Estimates of the spectral and cross-spectral densities of a multivariate time series are produced using a finite Fourier transform to obtain periodograms and cross-periodograms. The

periodogram ordinates are smoothed by a moving average to produce estimated spectral and cross-spectral densities. PROC SPECTRA can also test whether or not the data are white noise.

PROC SPECTRA uses the finite Fourier transform to decompose data series into a sum of sine and cosine waves of different amplitudes and wavelengths. The Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^m [a_k \cos(\omega_k t) + b_k \sin(\omega_k t)]$$

where

t	is the time subscript, $t = 1, 2, \dots, n$
x_t	are the equally spaced time series data
n	is the number of observations in the time series
m	is the number of frequencies in the Fourier decomposition: $m = \frac{n}{2}$ if n is even; $m = \frac{n-1}{2}$ if n is odd
a_0	is the mean term: $a_0 = 2\bar{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{n}$

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wave length to form *periodograms*. The amplitude periodogram J_k is defined as follows:

$$J_k = \frac{n}{2}(a_k^2 + b_k^2)$$

Several definitions of the term periodogram are used in the spectral analysis literature. The following discussion refers to the J_k sequence as the periodogram.

The periodogram can be interpreted as the contribution of the k th harmonic ω_k to the total sum of squares (in an analysis of variance sense) in the decomposition of the process into two-degree-of-freedom components for each of the m frequencies. When n is even, $\sin(\omega_{\frac{n}{2}})$ is zero, and thus the last periodogram value is a one-degree-of-freedom component.

The periodogram is a volatile and inconsistent estimator of the spectrum. The spectral density estimate is produced by smoothing the periodogram. Smoothing reduces the variance of the estimator but introduces a bias. The weight function used for the smoothing process, $W()$, often called the kernel or spectral window, is specified with the WEIGHTS statement. It is related to another weight function, $w()$, the lag window, that is used in other methods to taper the correlogram rather than to smooth the periodogram. Many specific weighting functions have been suggested in the literature (Fuller 1976, Jenkins and Watts 1968, Priestly 1981). Table 24.3 later in this chapter gives the relevant formulas when the WEIGHTS statement is used.

Letting i represent the imaginary unit $\sqrt{-1}$, the cross-periodogram is defined as follows:

$$J_k^{xy} = \frac{n}{2}(a_k^x a_k^y + b_k^x b_k^y) + i \frac{n}{2}(a_k^x b_k^y - b_k^x a_k^y)$$

The cross-spectral density estimate is produced by smoothing the cross-periodogram in the same way as the periodograms are smoothed using the spectral window specified by the WEIGHTS statement.

The SPECTRA procedure creates an output SAS data set whose variables contain values of the periodograms, cross-periodograms, estimates of spectral densities, and estimates of cross-spectral densities. The form of the output data set is described in the section “[OUT= Data Set](#)” on page 1552.

Getting Started: SPECTRA Procedure

To use the SPECTRA procedure, specify the input and output data sets and options for the analysis you want in the PROC SPECTRA statement, and list the variables to analyze in the VAR statement. The procedure produces no printed output unless the WHITETEST option is specified in the PROC SPECTRA statement. The periodogram, spectral density, and other results are written to the OUT= data set, depending on the options used.

For example, to compute the Fourier transform of a variable X in a data set A, use the following statements:

```
proc spectra data=a out=b coef;
  var x;
run;
```

This PROC SPECTRA step writes the Fourier coefficients a_k and b_k to the variables COS_01 and SIN_01 in the output data set B.

When a WEIGHTS statement is specified, the periodogram is smoothed by a weighted moving average to produce an estimate of the spectral density of the series. The following statements write a spectral density estimate for X to the variable S_01 in the output data set B.

```
proc spectra data=a out=b s;
  var x;
  weights 1 2 3 4 3 2 1;
run;
```

When the VAR statement specifies more than one variable, you can perform cross-spectral analysis by specifying the CROSS option in the PROC SPECTRA statement. The CROSS option by itself produces the cross-periodograms for all two-way combinations of the variables listed in the VAR statement. For example, the following statements write the real and imaginary parts of the cross-periodogram of X and Y to the variables RP_01_02 and IP_01_02 in the output data set B.

```
proc spectra data=a out=b cross;
  var x y;
run;
```

To produce cross-spectral density estimates, specify both the CROSS option and the S option. The cross-periodogram is smoothed using the weights specified by the WEIGHTS statement in the same way as the spectral density. The squared coherency and phase estimates of the cross-spectrum are computed when the K and PH options are used.

The following example computes cross-spectral density estimates for the variables X and Y.

```
proc spectra data=a out=b cross s;
  var x y;
  weights 1 2 3 4 3 2 1;
run;
```

The real part and imaginary part of the cross-spectral density estimates are written to the variables CS_01_02 and QS_01_02, respectively.

Syntax: SPECTRA Procedure

The following statements are used with the SPECTRA procedure:

```
PROC SPECTRA options ;
BY variables ;
VAR variables ;
WEIGHTS < weights > < kernel > ;
```

Functional Summary

Table 24.1 summarizes the statements and options that control the SPECTRA procedure.

Table 24.1 SPECTRA Functional Summary

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify the variables to be analyzed	VAR	
specify weights for spectral density estimates	WEIGHTS	
Data Set Options		
specify the input data set	PROC SPECTRA	DATA=
specify the output data set	PROC SPECTRA	OUT=

specify the quadratic spectral kernel	WEIGHTS	QS
specify the Tukey-Hanning kernel	WEIGHTS	TUKEY
specify the truncated kernel	WEIGHTS	TRUNCAT
Other Options		
subtract the series mean	PROC SPECTRA	ADJMEAN
specify an alternate quadrature spectrum estimate	PROC SPECTRA	ALTW
request tests for white noise	PROC SPECTRA	WHITESTEST

PROC SPECTRA Statement

PROC SPECTRA *options* ;

The following options can be used in the PROC SPECTRA statement:

A

outputs the amplitude variables ($A_{nn \text{ } mm}$) of the cross-spectrum.

ADJMEAN

CENTER

subtracts the series mean before performing the Fourier decomposition. This sets the first periodogram ordinate to 0 rather than $2n$ times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot.

ALTW

specifies that the quadrature spectrum estimate is computed at the boundaries in the same way as the spectral density estimate and the cospectrum estimate are computed.

COEF

outputs the Fourier cosine and sine coefficients of each series.

CROSS

is used with the P and S options to output cross-periodograms and cross-spectral densities when more than one variable is listed in the VAR statement.

DATA=SAS-data-set

names the SAS data set that contains the input data. If the DATA= option is omitted, the most recently created SAS data set is used.

K

outputs the squared coherency variables (K_{nn_mm}) of the cross-spectrum. The K_{nn_mm} variables are identically 1 unless weights are given in the WEIGHTS statement and the S option is specified.

OUT=SAS-data-set

names the output data set created by PROC SPECTRA to store the results. If the OUT= option is omitted, the output data set is named by using the DATA n convention.

P

outputs the periodogram variables. The variables are named P $_{nn}$, where nn is an index of the original variable with which the periodogram variable is associated. When both the P and CROSS options are specified, the cross-periodogram variables RP $_{nn_mm}$ and IP $_{nn_mm}$ are also output.

PH

outputs the phase variables (PH $_{nn_mm}$) of the cross-spectrum.

S

outputs the spectral density estimates. The variables are named S $_{nn}$, where nn is an index of the original variable with which the estimate variable is associated. When both the S and CROSS options are specified, the cross-spectral variables CS $_{nn_mm}$ and QS $_{nn_mm}$ are also output.

WHITETEST

prints two tests of the hypothesis that the data are white noise. See the section “[White Noise Test](#)” on page 1551 for details.

Note that the CROSS, A, K, and PH options are meaningful only if more than one variable is listed in the VAR statement.

BY Statement

BY variables ;

A BY statement can be used with PROC SPECTRA to obtain separate analyses for groups of observations defined by the BY variables.

VAR Statement

VAR *variables* ;

The VAR statement specifies one or more numeric variables that contain the time series to analyze. The order of the variables in the VAR statement list determines the index, *nn*, used to name the output variables. The VAR statement is required.

WEIGHTS Statement

WEIGHTS *weight-constants | kernel-specification* ;

The WEIGHTS statement specifies the relative weights used in the moving average applied to the periodogram ordinates to form the spectral density estimates. A WEIGHTS statement must be used to produce smoothed spectral density estimates. You can specify the relative weights in two ways: you can specify them explicitly as explained in the section “[Using Weight Constants Specification](#)” on page 1547, or you can specify them implicitly by using the kernel specification as explained in the section “[Using Kernel Specifications](#)” on page 1547. If the WEIGHTS statement is not used, only the periodogram is produced.

Using Weight Constants Specification

Any number of weighting constants can be specified. The constants should be positive and symmetric about the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants are specified) is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS statement scaled so that they sum to $\frac{1}{4\pi}$.

The moving average reflects at each end of the periodogram. The first periodogram ordinate is not used; the second periodogram ordinate is used in its place.

For example, a simple triangular weighting can be specified using the following WEIGHTS statement:

```
weights 1 2 3 2 1;
```

Using Kernel Specifications

You can specify five different kernels in the WEIGHTS statement. The syntax for the statement is

```
WEIGHTS [PARZEN][BART][TUKEY][TRUNCAT][QS] [c e] ;
```

where $c \geq 0$ and $e \geq 0$ are used to compute the bandwidth parameter as

$$l(q) = cq^e$$

and q is the number of periodogram ordinates +1:

$$q = \text{floor}(n/2) + 1$$

To specify the bandwidth explicitly, set $c =$ to the desired bandwidth and $e = 0$.

For example, a Parzen kernel can be specified using the following WEIGHTS statement:

```
weights parzen 0.5 0;
```

For details, see the section “[Kernels](#)” on page 1549.

Details: SPECTRA Procedure

Input Data

Observations in the data set analyzed by the SPECTRA procedure should form ordered, equally spaced time series. No more than 99 variables can be included in the analysis.

Data are often detrended before analysis by the SPECTRA procedure. This can be done by using the residuals output by a SAS regression procedure. Optionally, the data can be centered using the ADJMEAN option in the PROC SPECTRA statement, since the zero periodogram ordinate corresponding to the mean is of little interest from the point of view of spectral analysis.

Missing Values

Missing values are excluded from the analysis by the SPECTRA procedure. If the SPECTRA procedure encounters missing values for any variable listed in the VAR statement, the procedure determines the longest contiguous span of data that has no missing values for the variables listed in the VAR statement and uses that span for the analysis.

Computational Method

If the number of observations n factors into prime integers that are less than or equal to 23, and the product of the square-free factors of n is less than 210, then PROC SPECTRA uses the fast

Fourier transform developed by Cooley and Tukey and implemented by Singleton (1969). If n cannot be factored in this way, then PROC SPECTRA uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1976). To reduce memory requirements, when n is small, the Fourier coefficients are computed directly using the defining formulas.

Kernels

Kernels are used to smooth the periodogram by using a weighted moving average of nearby points. A smoothed periodogram is defined by the following equation.

$$\hat{J}_i(l(q)) = \sum_{\tau=-l(q)}^{l(q)} w\left(\frac{\tau}{l(q)}\right) \tilde{J}_{i+\tau}$$

where $w(x)$ is the kernel or weight function. At the endpoints, the moving average is computed cyclically; that is,

$$\tilde{J}_{i+\tau} = \begin{cases} J_{i+\tau} & 0 \leq i + \tau \leq q \\ J_{-(i+\tau)} & i + \tau < 0 \\ J_{q-(i+\tau)} & i + \tau > q \end{cases}$$

The SPECTRA procedure supports the following kernels. They are listed with their default bandwidth functions.

Bartlett: KERNEL BART

$$w(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = \frac{1}{2}q^{1/3}$$

Parzen: KERNEL PARZEN

$$w(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = q^{1/5}$$

Quadratic spectral: KERNEL QS

$$w(x) = \frac{25}{12\pi^2 x^2} \left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5) \right)$$

$$l(q) = \frac{1}{2}q^{1/5}$$

Tukey-Hanning: KERNEL TUKEY

$$w(x) = \begin{cases} (1 + \cos(\pi x))/2 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = \frac{2}{3}q^{1/5}$$

Truncated: KERNEL TRUNCAT

$$w(x) = \begin{cases} 1 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = \frac{1}{4}q^{1/5}$$

A summary of the default values of the bandwidth parameters, c and e , associated with the kernel smoothers in PROC SPECTRA are listed below in [Table 24.2](#):

Table 24.2 Bandwidth Parameters

Kernel	c	e
Bartlett	1/2	1/3
Parzen	1	1/5
quadratic	1/2	1/5
Tukey-Hanning	2/3	1/5
truncated	1/4	1/5

Figure 24.1 Kernels for Smoothing

See Andrews (1991) for details about the properties of these kernels.

White Noise Test

PROC SPECTRA prints two test statistics for white noise when the WHITETEST option is specified: Fisher's Kappa (Davis 1941, Fuller 1976) and Bartlett's Kolmogorov-Smirnov statistic (Bartlett 1966, Fuller 1976, Durbin 1967).

If the time series is a sequence of independent random variables with mean 0 and variance σ^2 , then the periodogram, J_k , will have the same expected value for all k . For a time series with nonzero autocorrelation, each ordinate of the periodogram, J_k , will have different expected values. The Fisher's Kappa statistic tests whether the largest J_k can be considered different from the mean of the J_k . Critical values for the Fisher's Kappa test can be found in Fuller 1976.

The Kolmogorov-Smirnov statistic reported by PROC SPECTRA has the same asymptotic distribution as Bartlett's test (Durbin 1967). The Kolmogorov-Smirnov statistic compares the normalized cumulative periodogram with the cumulative distribution function of a uniform(0,1) random variable. The normalized cumulative periodogram, F_j , of the series is

$$F_j = \frac{\sum_{k=1}^j J_k}{\sum_{k=1}^m J_k}, j = 1, 2, \dots, m-1$$

where $m = \frac{n}{2}$ if n is even or $m = \frac{n-1}{2}$ if n is odd. The test statistic is the maximum absolute difference of the normalized cumulative periodogram and the uniform cumulative distribution function. Approximate p -values for Bartlett's Kolmogorov-Smirnov test statistics are provided with the test statistics. Small p -values cause you to reject the null-hypothesis that the series is white noise.

Transforming Frequencies

The variable `FREQ` in the data set created by the `SPECTRA` procedure ranges from 0 to π . Sometimes it is preferable to express frequencies in cycles per observation period, which is equal to $\frac{2}{\pi}\text{FREQ}$.

To express frequencies in cycles per unit time (for example, in cycles per year), multiply `FREQ` by $\frac{d}{2\pi}$, where d is the number of observations per unit of time. For example, for monthly data, if the desired time unit is years then d is 12. The period of the cycle is $\frac{2\pi}{d \times \text{FREQ}}$, which ranges from $\frac{2}{d}$ to infinity.

OUT= Data Set

The `OUT=` data set contains $\frac{n}{2} + 1$ observations, if n is even, or $\frac{n+1}{2}$ observations, if n is odd, where n is the number of observations in the time series or the span of data being analyzed if missing values are present in the data. See the section “[Missing Values](#)” on page 1548 for details.

The variables in the new data set are named according to the following conventions. Each variable to be analyzed is associated with an index. The first variable listed in the `VAR` statement is indexed as 01, the second variable as 02, and so on. Output variables are named by combining indexes with prefixes. The prefix always identifies the nature of the new variable, and the indices identify the original variables from which the statistics were obtained.

Variables that contain spectral analysis results have names that consist of a prefix, an underscore, and the index of the variable analyzed. For example, the variable `S_01` contains spectral density estimates for the first variable in the `VAR` statement. Variables that contain cross-spectral analysis results have names that consist of a prefix, an underscore, the index of the first variable, another underscore, and the index of the second variable. For example, the variable `A_01_02` contains the amplitude of the cross-spectral density estimate for the first and second variables in the `VAR` statement.

[Table 24.3](#) shows the formulas and naming conventions used for the variables in the `OUT=` data set. Let X be variable number nm in the `VAR` statement list and let Y be variable number mm in the `VAR` statement list. [Table 24.3](#) shows the output variables that contain the results of the spectral and cross-spectral analysis of X and Y .

In [Table 24.3](#) the following notation is used. Let W_j be the vector of $2p + 1$ smoothing weights given by the `WEIGHTS` statement, normalized to sum to $\frac{1}{4\pi}$. Note that the weights are either explicitly provided using the constant specification or are implicitly determined by the kernel specification in the `WEIGHTS` statement.

The subscript of W_j runs from W_{-p} to W_p , so that W_0 is the middle weight in the list. Let $\omega_k = \frac{2\pi k}{n}$, where $k = 0, 1, \dots, \text{floor}(\frac{n}{2})$.

Table 24.3 Variables Created by PROC SPECTRA

Variable	Description
FREQ	frequency in radians from 0 to π (Note: Cycles per observation is $\frac{\text{FREQ}}{2\pi}$.)
PERIOD	period or wavelength: $\frac{2\pi}{\text{FREQ}}$ (Note: PERIOD is missing for FREQ=0.)
COS_nn	cosine transform of X: $a_k^x = \frac{2}{n} \sum_{t=1}^n X_t \cos(\omega_k(t-1))$
SIN_nn	sine transform of X: $b_k^x = \frac{2}{n} \sum_{t=1}^n X_t \sin(\omega_k(t-1))$
P_nn	periodogram of X: $J_k^x = \frac{n}{2} [(a_k^x)^2 + (b_k^x)^2]$
S_nn	spectral density estimate of X: $F_k^x = \sum_{j=-p}^p W_j J_{k+j}^x$ (except across endpoints)
RP_nn_mm	real part of cross-periodogram X and Y: $\text{real}(J_k^{xy}) = \frac{n}{2} (a_k^x a_k^y + b_k^x b_k^y)$
IP_nn_mm	imaginary part of cross-periodogram of X and Y: $\text{imag}(J_k^{xy}) = \frac{n}{2} (a_k^x b_k^y - b_k^x a_k^y)$
CS_nn_mm	cospectrum estimate (real part of cross-spectrum) of X and Y: $C_k^{xy} = \sum_{j=-p}^p W_j \text{real}(J_{k+j}^{xy})$ (except across endpoints)
QS_nn_mm	quadrature spectrum estimate (imaginary part of cross-spectrum) of X and Y: $Q_k^{xy} = \sum_{j=-p}^p W_j \text{imag}(J_{k+j}^{xy})$ (except across endpoints)
A_nn_mm	amplitude (modulus) of cross-spectrum of X and Y: $A_k^{xy} = \sqrt{(C_k^{xy})^2 + (Q_k^{xy})^2}$
K_nn_mm	coherency squared of X and Y: $K_k^{xy} = (A_k^{xy})^2 / (F_k^x F_k^y)$
PH_nn_mm	phase spectrum in radians of X and Y: $\Phi_k^{xy} = \arctan(Q_k^{xy} / C_k^{xy})$

Printed Output

By default PROC SPECTRA produces no printed output.

When the WHITETEST option is specified, the SPECTRA procedure prints the following statistics for each variable in the VAR statement:

1. the name of the variable
2. $M-1$, the number of two-degree-of-freedom periodogram ordinates used in the test
3. $\text{MAX}(P(*))$, the maximum periodogram ordinate
4. $\text{SUM}(P(*))$, the sum of the periodogram ordinates
5. Fisher's Kappa statistic
6. Bartlett's Kolmogorov-Smirnov test statistic
7. Approximate p -value for Bartlett's Kolmogorov-Smirnov test statistic

See the section “[White Noise Test](#)” on page 1551 for details.

ODS Table Names: SPECTRA procedure

PROC SPECTRA assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 24.4 ODS Tables Produced in PROC SPECTRA

ODS Table Name	Description	Option
WhiteNoiseTest	white noise test	WHITETEST
Kappa	Fishers Kappa statistic	WHITETEST
Bartlett	Bartletts Kolmogorov-Smirnov statistic	WHITETEST

Examples: SPECTRA Procedure

Example 24.1: Spectral Analysis of Sunspot Activity

This example analyzes Wolfer's sunspot data (Anderson 1971). The following statements read and plot the data.

```
title "Wolfer's Sunspot Data";
data sunspot;
  input year wolfer @@;
datalines;

... more lines ...

proc sgplot data=sunspot;
  series x=year y=wolfer / markers markerattrs=(symbol=circlefilled);
  xaxis values=(1740 to 1930 by 10);
  yaxis values=(0 to 1600 by 200);
run;
```

The plot of the sunspot series is shown in [Output 24.1.1](#).

Output 24.1.1 Plot of Original Sunspot Data

The spectral analysis of the sunspot series is performed by the following statements:

```
proc spectra data=sunspot out=b p s adjmean whitetest;
  var wolfer;
  weights 1 2 3 4 3 2 1;
run;
proc print data=b(obs=12);
run;
```

The PROC SPECTRA statement specifies the P and S options to write the periodogram and spectral density estimates to the OUT= data set B. The WEIGHTS statement specifies a triangular spectral window for smoothing the periodogram to produce the spectral density estimate. The ADJMEAN option zeros the frequency 0 value and avoids the need to exclude that observation from the plots. The WHITETEST option prints tests for white noise.

The Fisher's Kappa test statistic of 16.070 is larger than the 5% critical value of 7.2, so the null hypothesis that the sunspot series is white noise is rejected (see the table of critical values in Fuller (1976)).

The Bartlett's Kolmogorov-Smirnov statistic is 0.6501, and its approximate p -value is < 0.0001 . The small p -value associated with this test leads to the rejection of the null hypothesis that the spectrum represents white noise.

The printed output produced by PROC SPECTRA is shown in [Output 24.1.2](#). The output data set B created by PROC SPECTRA is shown in part in [Output 24.1.3](#).

Output 24.1.2 White Noise Test Results

```

                Wolfer's Sunspot Data

                The SPECTRA Procedure

                Test for White Noise for Variable wolfer

                M-1                87
                Max(P(*))         4062267
                Sum(P(*))         21156512

                Fisher's Kappa: (M-1)*Max(P(*)/Sum(P(*))

                Kappa    16.70489

                Bartlett's Kolmogorov-Smirnov Statistic:

                partial sums of the periodogram and the CDF of a
                uniform(0,1) random variable.

                Test Statistic                0.650055
                Approximate P-Value          <.0001
    
```

Output 24.1.3 First 12 Observations of the OUT= Data Set

Wolfer's Sunspot Data				
Obs	FREQ	PERIOD	P_01	S_01
1	0.00000	.	0.00	59327.52
2	0.03570	176.000	3178.15	61757.98
3	0.07140	88.000	2435433.22	69528.68
4	0.10710	58.667	1077495.76	66087.57
5	0.14280	44.000	491850.36	53352.02
6	0.17850	35.200	2581.12	36678.14
7	0.21420	29.333	181163.15	20604.52
8	0.24990	25.143	283057.60	15132.81
9	0.28560	22.000	188672.97	13265.89
10	0.32130	19.556	122673.94	14953.32
11	0.35700	17.600	58532.93	16402.84
12	0.39270	16.000	213405.16	18562.13

The following statements plot the periodogram and spectral density estimate by the frequency and period.

```

proc sgplot data=b;
    series x=freq y=p_01 / markers markerattrs=(symbol=circlefilled);
run;
    
```

```

proc sgplot data=b;
  series x=period y=p_01 / markers markerattrs=(symbol=circlefilled);
run;

proc sgplot data=b;
  series x=freq y=s_01 / markers markerattrs=(symbol=circlefilled);
run;

proc sgplot data=b;
  series x=period y=s_01 / markers markerattrs=(symbol=circlefilled);
run;

```

The periodogram is plotted against the frequency in [Output 24.1.4](#) and plotted against the period in [Output 24.1.5](#). The spectral density estimate is plotted against the frequency in [Output 24.1.6](#) and plotted against the period in [Output 24.1.7](#).

Output 24.1.4 Plot of Periodogram by Frequency

Output 24.1.5 Plot of Periodogram by Period

Output 24.1.6 Plot of Spectral Density Estimate by Frequency

Output 24.1.7 Plot of Spectral Density Estimate by Period

Since PERIOD is the reciprocal of frequency, the plot axis for PERIOD is stretched for low frequencies and compressed at high frequencies. One way to correct for this is to use a WHERE statement to restrict the plots and exclude the low frequency components. The following statements plot the spectral density for periods less than 50.

```
proc sgplot data=b;
  where period < 50;
  series x=period y=s_01 / markers markerattrs=(symbol=circlefilled);
  refline 11 / axis=x;
run;
```

The spectral analysis of the sunspot series confirms a strong 11-year cycle of sunspot activity. The plot makes this clear by drawing a reference line at the 11 year period, which highlights the position of the main peak in the spectral density.

Output 24.1.8 shows the plot. Contrast Output 24.1.8 with Output 24.1.7.

Output 24.1.8 Plot of Spectral Density Estimate by Period to 50 Years

Example 24.2: Cross-Spectral Analysis

This example uses simulated data to show cross-spectral analysis for two variables X and Y. X is generated by an AR(1) process; Y is generated as white noise plus an input from X lagged 2 periods. All output options are specified in the PROC SPECTRA statement. PROC CONTENTS shows the contents of the OUT= data set.

```

data a;
  x1 = 0; x11 = 0;
  do i = - 10 to 100;
    x = .4 * x1 + rannor(123);
    y = .5 * x11 + rannor(123);
    if i > 0 then output;
    x11 = x1; x1 = x;
  end;
run;

proc spectra data=a out=b cross coef a k p ph s;
  var x y;

```

```

weights 1 1.5 2 4 8 9 8 4 2 1.5 1;
run;

proc contents data=b position;
run;

```

The PROC CONTENTS report for the output data set B is shown in [Output 24.2.1](#).

Output 24.2.1 Contents of PROC SPECTRA OUT= Data Set

Overview: STATESPACE Procedure

The STATESPACE procedure uses the state space model to analyze and forecast multivariate time series. The STATESPACE procedure is appropriate for jointly forecasting several related time series that have dynamic interactions. By taking into account the autocorrelations among all the variables in a set, the STATESPACE procedure can give better forecasts than methods that model each series separately.

By default, the STATESPACE procedure automatically selects a state space model appropriate for the time series, making the procedure a good tool for automatic forecasting of multivariate time series. Alternatively, you can specify the state space model by giving the form of the state vector and the state transition and innovation matrices.

The methods used by the STATESPACE procedure assume that the time series are jointly stationary. Nonstationary series must be made stationary by some preliminary transformation, usually by differencing. The STATESPACE procedure enables you to specify differencing of the input data. When differencing is specified, the STATESPACE procedure automatically integrates forecasts of the differenced series to produce forecasts of the original series.

The State Space Model

The *state space model* represents a multivariate time series through auxiliary variables, some of which might not be directly observable. These auxiliary variables are called the *state vector*. The state vector summarizes all the information from the present and past values of the time series that is relevant to the prediction of future values of the series. The observed time series are expressed as linear combinations of the state variables. The state space model is also called a Markovian representation, or a canonical representation, of a multivariate time series process. The state space approach to modeling a multivariate stationary time series is summarized in Akaike (1976).

The state space form encompasses a very rich class of models. Any Gaussian multivariate stationary time series can be written in a state space form, provided that the dimension of the predictor space is finite. In particular, any autoregressive moving average (ARMA) process has a state space representation and, conversely, any state space process can be expressed in an ARMA form (Akaike 1974). More details on the relation of the state space and ARMA forms are given in the section “[Relation of ARMA and State Space Forms](#)” on page 1599.

Let \mathbf{x}_t be the $r \times 1$ vector of observed variables, after differencing (if differencing is specified) and subtracting the sample mean. Let \mathbf{z}_t be the state vector of dimension s , $s \geq r$, where the first r components of \mathbf{z}_t consist of \mathbf{x}_t . Let the notation $\mathbf{x}_{t+k|t}$ represent the conditional expectation (or prediction) of \mathbf{x}_{t+k} based on the information available at time t . Then the last $s - r$ elements of \mathbf{z}_t consist of elements of $\mathbf{x}_{t+k|t}$, where $k > 0$ is specified or determined automatically by the procedure.

There are various forms of the state space model in use. The form of the state space model used by the STATESPACE procedure is based on Akaike (1976). The model is defined by the following

state transition equation :

$$\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$$

In the state transition equation, the $s \times s$ coefficient matrix \mathbf{F} is called the *transition matrix*; it determines the dynamic properties of the model.

The $s \times r$ coefficient matrix \mathbf{G} is called the *input matrix*; it determines the variance structure of the transition equation. For model identification, the first r rows and columns of \mathbf{G} are set to an $r \times r$ identity matrix.

The input vector \mathbf{e}_t is a sequence of independent normally distributed random vectors of dimension r with mean $\mathbf{0}$ and covariance matrix Σ_{ee} . The random error \mathbf{e}_t is sometimes called the innovation vector or shock vector.

In addition to the state transition equation, state space models usually include a *measurement equation* or *observation equation* that gives the observed values \mathbf{x}_t as a function of the state vector \mathbf{z}_t . However, since PROC STATESPACE always includes the observed values \mathbf{x}_t in the state vector \mathbf{z}_t , the measurement equation in this case merely represents the extraction of the first r components of the state vector.

The measurement equation used by the STATESPACE procedure is

$$\mathbf{x}_t = [\mathbf{I}_r \mathbf{0}] \mathbf{z}_t$$

where \mathbf{I}_r is an $r \times r$ identity matrix. In practice, PROC STATESPACE performs the extraction of \mathbf{x}_t from \mathbf{z}_t without reference to an explicit measurement equation.

In summary:

\mathbf{x}_t	is an observation vector of dimension r .
\mathbf{z}_t	is a state vector of dimension s , whose first r elements are \mathbf{x}_t and whose last $s - r$ elements are conditional prediction of future \mathbf{x}_t .
\mathbf{F}	is an $s \times s$ transition matrix.
\mathbf{G}	is an $s \times r$ input matrix, with the identity matrix \mathbf{I}_r forming the first r rows and columns.
\mathbf{e}_t	is a sequence of independent normally distributed random vectors of dimension r with mean $\mathbf{0}$ and covariance matrix Σ_{ee} .

How PROC STATESPACE Works

The design of the STATESPACE procedure closely follows the modeling strategy proposed by Akaike (1976). This strategy employs canonical correlation analysis for the automatic identification of the state space model.

Following Akaike (1976), the procedure first fits a sequence of unrestricted vector autoregressive (VAR) models and computes Akaike's information criterion (AIC) for each model. The vector

autoregressive models are estimated using the sample autocovariance matrices and the Yule-Walker equations. The order of the VAR model that produces the smallest Akaike information criterion is chosen as the order (number of lags into the past) to use in the canonical correlation analysis.

The elements of the state vector are then determined via a sequence of canonical correlation analyses of the sample autocovariance matrices through the selected order. This analysis computes the sample canonical correlations of the past with an increasing number of steps into the future. Variables that yield significant correlations are added to the state vector; those that yield insignificant correlations are excluded from further consideration. The importance of the correlation is judged on the basis of another information criterion proposed by Akaike. See the section “[Canonical Correlation Analysis Options](#)” on page 1583 for details. If you specify the state vector explicitly, these model identification steps are omitted.

After the state vector is determined, the state space model is fit to the data. The free parameters in the \mathbf{F} , \mathbf{G} , and Σ_{ee} matrices are estimated by approximate maximum likelihood. By default, the \mathbf{F} and \mathbf{G} matrices are unrestricted, except for identifiability requirements. Optionally, conditional least squares estimates can be computed. You can impose restrictions on elements of the \mathbf{F} and \mathbf{G} matrices.

After the parameters are estimated, the Kalman filtering technique is used to produce forecasts from the fitted state space model. If differencing was specified, the forecasts are integrated to produce forecasts of the original input variables.

Getting Started: STATESPACE Procedure

The following introductory example uses simulated data for two variables X and Y. The following statements generate the X and Y series.

```
data in;
  x=10;  y=40;
  x1=0;  y1=0;
  a1=0;  b1=0;
  iseed=123;
  do t=-100 to 200;
    a=rannor(iseed);
    b=rannor(iseed);
    dx = 0.5*x1 + 0.3*y1 + a - 0.2*a1 - 0.1*b1;
    dy = 0.3*x1 + 0.5*y1 + b;
    x = x + dx + .25;
    y = y + dy + .25;
    if t >= 0 then output;
    x1 = dx; y1 = dy;
    a1 = a; b1 = b;
  end;
  keep t x y;
run;
```

The simulated series X and Y are shown in [Figure 25.1](#).

Figure 25.1 Example Series

Automatic State Space Model Selection

The STATESPACE procedure is designed to automatically select the best state space model for forecasting the series. You can specify your own model if you want, and you can use the output from PROC STATESPACE to help you identify a state space model. However, the easiest way to use PROC STATESPACE is to let it choose the model.

Stationarity and Differencing

Although PROC STATESPACE selects the state space model automatically, it does assume that the input series are stationary. If the series are nonstationary, then the process might fail. Therefore the first step is to examine your data and test to see if differencing is required. (See the section “Stationarity and Differencing” on page 1588 for further discussion of this issue.)

The series shown in [Figure 25.1](#) are nonstationary. In order to forecast X and Y with a state space model, you must difference them (or use some other detrending method). If you fail to difference

when needed and try to use PROC STATESPACE with nonstationary data, an inappropriate state space model might be selected, and the model estimation might fail to converge.

The following statements identify and fit a state space model for the first differences of X and Y, and forecast X and Y 10 periods ahead:

```
proc statespace data=in out=out lead=10;
  var x(1) y(1);
  id t;
run;
```

The DATA= option specifies the input data set and the OUT= option specifies the output data set for the forecasts. The LEAD= option specifies forecasting 10 observations past the end of the input data. The VAR statement specifies the variables to forecast and specifies differencing. The notation X(1) Y(1) specifies that the state space model analyzes the first differences of X and Y.

Descriptive Statistics and Preliminary Autoregressions

The first page of the printed output produced by the preceding statements is shown in [Figure 25.2](#).

Figure 25.2 Descriptive Statistics and VAR Order Selection

The STATESPACE Procedure								
Number of Observations								200
Variable	Mean	Standard Error						
x	0.144316	1.233457	Has been differenced. With period(s) = 1.					
y	0.164871	1.304358	Has been differenced. With period(s) = 1.					
The STATESPACE Procedure								
Information Criterion for Autoregressive Models								
Lag=0	Lag=1	Lag=2	Lag=3	Lag=4	Lag=5	Lag=6	Lag=7	Lag=8
149.697	8.387786	5.517099	12.05986	15.36952	21.79538	24.00638	29.88874	33.55708
Information Criterion for Autoregressive Models								
			Lag=9	Lag=10				
			41.17606	47.70222				

Figure 25.2 continued

Schematic Representation of Correlations											
Name/Lag	0	1	2	3	4	5	6	7	8	9	10
x	++	++	++	++	++	++	+.	..	+.	+.	..
y	++	++	++	++	++	+.	+.	+.	+.

+ is > 2*std error, - is < -2*std error, . is between

Descriptive statistics are printed first, giving the number of nonmissing observations after differencing and the sample means and standard deviations of the differenced series. The sample means are subtracted before the series are modeled (unless the NOCENTER option is specified), and the sample means are added back when the forecasts are produced.

Let X_t and Y_t be the observed values of X and Y, and let x_t and y_t be the values of X and Y after differencing and subtracting the mean difference. The series \mathbf{x}_t modeled by the STATESPACE procedure is

$$\mathbf{x}_t = \begin{bmatrix} x_t \\ y_t \end{bmatrix} = \begin{bmatrix} (1 - B)X_t - 0.144316 \\ (1 - B)Y_t - 0.164871 \end{bmatrix}$$

where B represents the backshift operator.

After the descriptive statistics, PROC STATESPACE prints the Akaike information criterion (AIC) values for the autoregressive models fit to the series. The smallest AIC value, in this case 5.517 at lag 2, determines the number of autocovariance matrices analyzed in the canonical correlation phase.

A schematic representation of the autocorrelations is printed next. This indicates which elements of the autocorrelation matrices at different lags are significantly greater than or less than 0.

The second page of the STATESPACE printed output is shown in Figure 25.3.

Figure 25.3 Partial Autocorrelations and VAR Model

Schematic Representation of Partial Autocorrelations											
Name/Lag	1	2	3	4	5	6	7	8	9	10	
x	++	+.	
y	++	

+ is > 2*std error, - is < -2*std error, . is between

Yule-Walker Estimates for Minimum AIC

	-----Lag=1-----		-----Lag=2-----	
	x	y	x	y
x	0.257438	0.202237	0.170812	0.133554
y	0.292177	0.469297	-0.00537	-0.00048

Figure 25.3 shows a schematic representation of the partial autocorrelations, similar to the autocorrelations shown in Figure 25.2. The selection of a second order autoregressive model by the AIC statistic looks reasonable in this case because the partial autocorrelations for lags greater than 2 are not significant.

Next, the Yule-Walker estimates for the selected autoregressive model are printed. This output shows the coefficient matrices of the vector autoregressive model at each lag.

Selected State Space Model Form and Preliminary Estimates

After the autoregressive order selection process has determined the number of lags to consider, the canonical correlation analysis phase selects the state vector. By default, output for this process is not printed. You can use the CANCORR option to print details of the canonical correlation analysis. See the section “[Canonical Correlation Analysis Options](#)” on page 1583 for an explanation of this process.

After the state vector is selected, the state space model is estimated by approximate maximum likelihood. Information from the canonical correlation analysis and from the preliminary autoregression is used to form preliminary estimates of the state space model parameters. These preliminary estimates are used as starting values for the iterative estimation process.

The form of the state vector and the preliminary estimates are printed next, as shown in Figure 25.4.

Figure 25.4 Preliminary Estimates of State Space Model

The STATESPACE Procedure		
Selected Statespace Form and Preliminary Estimates		
State Vector		
$x(T;T)$	$y(T;T)$	$x(T+1;T)$
Estimate of Transition Matrix		
0	0	1
0.291536	0.468762	-0.00411
0.24869	0.24484	0.204257
Input Matrix for Innovation		
1	0	
0	1	
0.257438	0.202237	
Variance Matrix for Innovation		
0.945196	0.100786	
0.100786	1.014703	

Figure 25.4 first prints the state vector as $X[T;T]$ $Y[T;T]$ $X[T+1;T]$. This notation indicates that

the state vector is

$$\mathbf{z}_t = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \end{bmatrix}$$

The notation $x_{t+1|t}$ indicates the conditional expectation or prediction of x_{t+1} based on the information available at time t , and $x_{t|t}$ and $y_{t|t}$ are x_t and y_t , respectively.

The remainder of Figure 25.4 shows the preliminary estimates of the transition matrix \mathbf{F} , the input matrix \mathbf{G} , and the covariance matrix Σ_{ee} .

Estimated State Space Model

The next page of the STATESPACE output prints the final estimates of the fitted model, as shown in Figure 25.5. This output has the same form as in Figure 25.4, but it shows the maximum likelihood estimates instead of the preliminary estimates.

Figure 25.5 Fitted State Space Model

The STATESPACE Procedure		
Selected Statespace Form and Fitted Model		
State Vector		
$\mathbf{x}(T; T)$	$\mathbf{y}(T; T)$	$\mathbf{x}(T+1; T)$
Estimate of Transition Matrix		
0	0	1
0.297273	0.47376	-0.01998
0.2301	0.228425	0.256031
Input Matrix for Innovation		
1	0	
0	1	
0.257284	0.202273	
Variance Matrix for Innovation		
0.945188	0.100752	
0.100752	1.014712	

The estimated state space model shown in Figure 25.5 is

$$\begin{bmatrix} x_{t+1|t+1} \\ y_{t+1|t+1} \\ x_{t+2|t+1} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 \\ 0.297 & 0.474 & -0.020 \\ 0.230 & 0.228 & 0.256 \end{bmatrix} \begin{bmatrix} x_t \\ y_t \\ x_{t+1|t} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0.257 & 0.202 \end{bmatrix} \begin{bmatrix} e_{t+1} \\ n_{t+1} \end{bmatrix}$$

$$\text{var} \begin{bmatrix} e_{t+1} \\ n_{t+1} \end{bmatrix} = \begin{bmatrix} 0.945 & 0.101 \\ 0.101 & 1.015 \end{bmatrix}$$

The next page of the STATESPACE output lists the estimates of the free parameters in the **F** and **G** matrices with standard errors and *t* statistics, as shown in Figure 25.6.

Figure 25.6 Final Parameter Estimates

Parameter Estimates				
Parameter	Estimate	Standard Error	t Value	
F(2,1)	0.297273	0.129995	2.29	
F(2,2)	0.473760	0.115688	4.10	
F(2,3)	-0.01998	0.313025	-0.06	
F(3,1)	0.230100	0.126226	1.82	
F(3,2)	0.228425	0.112978	2.02	
F(3,3)	0.256031	0.305256	0.84	
G(3,1)	0.257284	0.071060	3.62	
G(3,2)	0.202273	0.068593	2.95	

Convergence Failures

The maximum likelihood estimates are computed by an iterative nonlinear maximization algorithm, which might not converge. If the estimates fail to converge, warning messages are printed in the output.

If you encounter convergence problems, you should recheck the stationarity of the data and ensure that the specified differencing orders are correct. Attempting to fit state space models to nonstationary data is a common cause of convergence failure. You can also use the MAXIT= option to increase the number of iterations allowed, or experiment with the convergence tolerance options DETTOL= and PARMTOL=.

Forecast Data Set

The following statements print the output data set. The WHERE statement excludes the first 190 observations from the output, so that only the forecasts and the last 10 actual observations are printed.

```
proc print data=out;
  id t;
  where t > 190;
```

```
run;
```

The PROC PRINT output is shown in Figure 25.7.

Figure 25.7 OUT= Data Set Produced by PROC STATESPACE

The OUT= data set produced by PROC STATESPACE contains the VAR and ID statement variables. In addition, for each VAR statement variable, the OUT= data set contains the variables FOR i , RES i , and STD i . These variables contain the predicted values, residuals, and forecast standard errors for the i th variable in the VAR statement list. In this case, X is listed first in the VAR statement, so FOR1 contains the forecasts of X, while FOR2 contains the forecasts of Y.

The following statements plot the forecasts and actuals for the series.

```
proc sgplot data=out noautolegend;
  where t > 150;
  series x=t y=for1 / markers
    markerattrs=(symbol=circle color=blue)
    lineattrs=(pattern=solid color=blue);
  series x=t y=for2 / markers
    markerattrs=(symbol=circle color=blue)
    lineattrs=(pattern=solid color=blue);
  series x=t y=x / markers
    markerattrs=(symbol=circle color=red)
    lineattrs=(pattern=solid color=red);
  series x=t y=y / markers
    markerattrs=(symbol=circle color=red)
    lineattrs=(pattern=solid color=red);
  refline 200.5 / axis=x;
run;
```

The forecast plot is shown in Figure 25.8. The last 50 observations are also plotted to provide context, and a reference line is drawn between the historical and forecast periods.

Figure 25.8 Plot of Forecasts

Controlling Printed Output

By default, the STATESPACE procedure produces a large amount of printed output. The NOPRINT option suppresses all printed output. You can suppress the printed output for the autoregressive model selection process with the PRINTOUT=NONE option. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. You can produce more detailed output with the PRINTOUT=LONG option and by specifying the printing control options CANCORR, COVB, and PRINT.

Specifying the State Space Model

Instead of allowing the STATESPACE procedure to select the model automatically, you can use FORM and RESTRICT statements to specify a state space model.

Specifying the State Vector

Use the FORM statement to control the form of the state vector. You can use this feature to force PROC STATESPACE to estimate and forecast a model different from the model it would select automatically. You can also use this feature to reestimate the automatically selected model (possibly with restrictions) without repeating the canonical correlation analysis.

The FORM statement specifies the number of lags of each variable to include in the state vector. For example, the statement FORM X 3; forces the state vector to include $x_{t|t}$, $x_{t+1|t}$, and $x_{t+2|t}$. The following statement specifies the state vector $(x_{t|t}, y_{t|t}, x_{t+1|t})$, which is the same state vector selected in the preceding example:

```
form x 2 y 1;
```

You can specify the form for only some of the variables and allow PROC STATESPACE to select the form for the other variables. If only some of the variables are specified in the FORM statement, canonical correlation analysis is used to determine the number of lags included in the state vector for the remaining variables not specified by the FORM statement. If the FORM statement includes specifications for all the variables listed in the VAR statement, the state vector is completely defined and the canonical correlation analysis is not performed.

Restricting the F and G matrices

After you know the form of the state vector, you can use the RESTRICT statement to fix some parameters in the **F** and **G** matrices to specified values. One use of this feature is to remove insignificant parameters by restricting them to 0.

In the introductory example shown in the preceding section, the F[2,3] parameter is not significant. (The parameters estimation output shown in [Figure 25.6](#) gives the t statistic for F[2,3] as -0.06 . F[3,3] and F[3,1] also have low significance with $t < 2$.)

The following statements reestimate this model with F[2,3] restricted to 0. The FORM statement is used to specify the state vector and thus bypass the canonical correlation analysis.

```
proc statespace data=in out=out lead=10;
  var x(1) y(1);
  id t;
  form x 2 y 1;
  restrict f(2,3)=0;
run;
```

The final estimates produced by these statements are shown in [Figure 25.10](#).

Syntax: STATESPACE Procedure

The STATESPACE procedure uses the following statements:

PROC STATESPACE *options* ;
BY *variable* ... ;
FORM *variable value* ... ;
ID *variable* ;
INITIAL *F (row,column)=value ... G (row,column)=value ...* ;
RESTRICT *F (row,column)=value ... G (row,column)=value ...* ;
VAR *variable (difference, difference, ...) ...* ;

Functional Summary

Table 25.1 summarizes the statements and options used by PROC STATESPACE.

PROC STATESPACE Statement

PROC STATESPACE *options* ;

The following options can be specified in the PROC STATESPACE statement.

Printing Options

NOPRINT

suppresses all printed output.

Input Data Options

DATA=SAS-data-set

specifies the name of the SAS data set to be used by the procedure. If the DATA= option is omitted, the most recently created SAS data set is used.

LAGMAX=k

specifies the number of lags for which the sample autocovariance matrix is computed. The

LAGMAX= option controls the number of lags printed in the schematic representation of the autocorrelations.

The sample autocovariance matrix of lag i , denoted as C_i , is computed as

$$C_i = \frac{1}{N-1} \sum_{t=1+i}^N \mathbf{x}_t \mathbf{x}'_{t-i}$$

where \mathbf{x}_t is the differenced and centered data and N is the number of observations. (If the NOCENTER option is specified, 1 is not subtracted from N .) LAGMAX= k specifies that C_0 through C_k are computed. The default is LAGMAX=10.

NOCENTER

prevents subtraction of the sample mean from the input series (after any specified differencing) before the analysis.

Options for Preliminary Autoregressive Models

ARMAX= n

specifies the maximum order of the preliminary autoregressive models. The ARMAX= option controls the autoregressive orders for which information criteria are printed, and controls the number of lags printed in the schematic representation of partial autocorrelations. The default is ARMAX=10. See the section “[Preliminary Autoregressive Models](#)” on page 1590 for details.

MINIC

writes to the OUTAR= data set only the preliminary Yule-Walker estimates for the VAR model that produces the minimum AIC. See the section “[OUTAR= Data Set](#)” on page 1601 for details.

OUTAR=*SAS-data-set*

writes the Yule-Walker estimates of the preliminary autoregressive models to a SAS data set. See the section “[OUTAR= Data Set](#)” on page 1601 for details.

PRINTOUT=SHORT | LONG | NONE

determines the amount of detail printed. PRINTOUT=LONG prints the lagged covariance matrices, the partial autoregressive matrices, and estimates of the residual covariance matrices from the sequence of autoregressive models. PRINTOUT=NONE suppresses the output for the preliminary autoregressive models. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. PRINTOUT=SHORT is the default.

Canonical Correlation Analysis Options

CANCORR

prints the canonical correlations and information criterion for each candidate state vector considered. See the section “[Canonical Correlation Analysis Options](#)” on page 1583 for details.

DIMMAX=*n*

specifies the upper limit to the dimension of the state vector. The DIMMAX= option can be used to limit the size of the model selected. The default is DIMMAX=10.

PASTMIN=*n*

specifies the minimum number of lags to include in the canonical correlation analysis. The default is PASTMIN=0. See the section “[Canonical Correlation Analysis Options](#)” on page 1583 for details.

SIGCORR=*value*

specifies the multiplier of the degrees of freedom for the penalty term in the information criterion used to select the state space form. The default is SIGCORR=2. The larger the value of the SIGCORR= option, the smaller the state vector tends to be. Hence, a large value causes a simpler model to be fit. See the section “[Canonical Correlation Analysis Options](#)” on page 1583 for details.

State Space Model Estimation Options

COVB

prints the inverse of the observed information matrix for the parameter estimates. This matrix is an estimate of the covariance matrix for the parameter estimates.

DETTOL=*value*

specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is DETTOL=1E-5.

ITPRINT

prints the iterations during the estimation process.

KLAG=*n*

sets an upper limit for the number of lags of the sample autocovariance matrix used in computing the approximate likelihood function. If the data have a strong moving average character, a larger KLAG= value might be necessary to obtain good estimates. The default is KLAG=15. See the section “[Parameter Estimation](#)” on page 1596 for details.

MAXIT=*n*

sets an upper limit to the number of iterations in the maximum likelihood or conditional least squares estimation. The default is MAXIT=50.

NOEST

suppresses the final maximum likelihood estimation of the selected model.

OUTMODEL=*SAS-data-set*

writes the parameter estimates and their standard errors to a SAS data set. See the section “[OUTMODEL= Data Set](#)” on page 1602 for details.

PARMTOL=*value*

specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is PARMTOL=0.001.

RESIDEST

computes the final estimates by using conditional least squares on the raw data. This type of estimation might be more stable than the default maximum likelihood method but is usually more computationally expensive. See the section “[Parameter Estimation](#)” on page 1596 for details about the conditional least squares method.

SINGULAR=*value*

specifies the criterion for testing for singularity of a matrix. A matrix is declared singular if a scaled pivot is less than the SINGULAR= value when sweeping the matrix. The default is SINGULAR=1E-7.

Forecasting Options

BACK=*n*

starts forecasting *n* periods before the end of the input data. The BACK= option value must not be greater than the number of observations. The default is BACK=0.

INTERVAL=*interval*

specifies the time interval between observations. The INTERVAL= value is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for details about the INTERVAL= values allowed.

INTPER=*n*

specifies that each input observation corresponds to *n* time periods. For example, the options INTERVAL=MONTH and INTPER=2 specify bimonthly data and are equivalent to specifying INTERVAL=MONTH2. If the INTERVAL= option is not specified, the INTPER= option controls the increment used to generate ID values for the forecast observations. The default is INTPER=1.

LEAD=*n*

specifies how many forecast observations are produced. The forecasts start at the point set by the BACK= option. The default is LEAD=0, which produces no forecasts.

OUT=*SAS-data-set*

writes the residuals, actual values, forecasts, and forecast standard errors to a SAS data set. See the section “[OUT= Data Set](#)” on page 1601 for details.

PRINT

prints the forecasts.

BY Statement

BY *variable* ... ;

A BY statement can be used with the STATESPACE procedure to obtain separate analyses on observations in groups defined by the BY variables.

FORM Statement

FORM *variable value* ... ;

The FORM statement specifies the number of times a variable is included in the state vector. Values can be specified for any variable listed in the VAR statement. If a value is specified for each variable in the VAR statement, the state vector for the state space model is entirely specified, and automatic selection of the state space model is not performed.

The FORM statement forces the state vector, \mathbf{z}_t , to contain a specific variable a given number of times. For example, if Y is one of the variables in \mathbf{x}_t , then the statement

form y 3;

forces the state vector to contain Y_t , $Y_{t+1|t}$, and $Y_{t+2|t}$, possibly along with other variables.

The following statements illustrate the use of the FORM statement:

```
proc statespace data=in;
  var x y;
  form x 3 y 2;
run;
```

These statements fit a state space model with the following state vector:

$$\mathbf{z}_t = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \\ y_{t+1|t} \\ x_{t+2|t} \end{bmatrix}$$

ID Statement

ID *variable* ;

The ID statement specifies a variable that identifies observations in the input data set. The variable specified in the ID statement is included in the OUT= data set. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= and INTPER= options.

INITIAL Statement

INITIAL $F(\text{row}, \text{column}) = \text{value} \dots G(\text{row}, \text{column}) = \text{value} \dots ;$

The INITIAL statement gives initial values to the specified elements of the **F** and **G** matrices. These initial values are used as starting values for the iterative estimation.

Parts of the **F** and **G** matrices represent fixed structural identities. If an element specified is a fixed structural element instead of a free parameter, the corresponding initialization is ignored.

The following is an example of an INITIAL statement:

```
initial f(3,2)=0 g(4,1)=0 g(5,1)=0;
```

RESTRICT Statement

RESTRICT $F(\text{row}, \text{column}) = \text{value} \dots G(\text{row}, \text{column}) = \text{value} \dots ;$

The RESTRICT statement restricts the specified elements of the **F** and **G** matrices to the specified values.

To use the restrict statement, you need to know the form of the model. Either specify the form of the model with the FORM statement, or do a preliminary run (perhaps with the NOEST option) to find the form of the model that PROC STATESPACE selects for the data.

The following is an example of a RESTRICT statement:

```
restrict f(3,2)=0 g(4,1)=0 g(5,1)=0 ;
```

Parts of the **F** and **G** matrices represent fixed structural identities. If a restriction is specified for an element that is a fixed structural element instead of a free parameter, the restriction is ignored.

VAR Statement

VAR *variable (difference, difference, ...) ... ;*

The VAR statement specifies the variables in the input data set to model and forecast. The VAR statement also specifies differencing of the input variables. The VAR statement is required.

Differencing is specified by following the variable name with a list of difference periods separated by commas. See the section “[Stationarity and Differencing](#)” on page 1588 for more information about differencing of input variables.

The order in which variables are listed in the VAR statement controls the order in which variables are included in the state vector. Usually, potential inputs should be listed before potential outputs.

For example, assuming the input data are monthly, the following VAR statement specifies modeling and forecasting of the one period and seasonal second difference of X and Y:

```
var x(1,12) y(1,12);
```

In this example, the vector time series analyzed is

$$\mathbf{x}_t = \begin{bmatrix} (1-B)(1-B^{12})X_t - \bar{x} \\ (1-B)(1-B^{12})Y_t - \bar{y} \end{bmatrix}$$

where B represents the back shift operator and \bar{x} and \bar{y} represent the means of the differenced series. If the NOCENTER option is specified, the mean differences are not subtracted.

Details: STATESPACE Procedure

Missing Values

The STATESPACE procedure does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the VAR statement variables. Observations at the beginning of the data set with missing values for any VAR statement variable are not used or included in the output data set.

Stationarity and Differencing

The state space model used by the STATESPACE procedure assumes that the time series are stationary. Hence, the data should be checked for stationarity. One way to check for stationarity is to plot the series. A graph of series over time can show a time trend or variability changes.

You can also check stationarity by using the sample autocorrelation functions displayed by the ARIMA procedure. The autocorrelation functions of nonstationary series tend to decay slowly. See Chapter 7, “[The ARIMA Procedure](#),” for more information.

Another alternative is to use the STATIONARITY= option in the IDENTIFY statement in PROC ARIMA to apply Dickey-Fuller tests for unit roots in the time series. See Chapter 7, “[The ARIMA Procedure](#),” for more information about Dickey-Fuller unit root tests.

The most popular way to transform a nonstationary series to stationarity is by differencing. Differencing of the time series is specified in the VAR statement. For example, to take a simple first difference of the series X, use this statement:

```
var x(1);
```

In this example, the change in X from one period to the next is analyzed. When the series has a seasonal pattern, differencing at a period equal to the length of the seasonal cycle can be desirable. For example, suppose the variable X is measured quarterly and shows a seasonal cycle over the year. You can use the following statement to analyze the series of changes from the same quarter in the previous year:

```
var x(4);
```

To difference twice, add another differencing period to the list. For example, the following statement analyzes the series of second differences $(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}$:

```
var x(1,1);
```

The following statement analyzes the seasonal second difference series:

```
var x(1,4);
```

The series that is being modeled is the 1-period difference of the 4-period difference:

$$(X_t - X_{t-4}) - (X_{t-1} - X_{t-5}) = X_t - X_{t-1} - X_{t-4} + X_{t-5}.$$

Another way to obtain stationary series is to use a regression on time to detrend the data. If the time series has a deterministic linear trend, regressing the series on time produces residuals that should be stationary. The following statements write residuals of X and Y to the variable RX and RY in the output data set `DETTREND`.

```
data a;
  set a;
  t=_n_;
run;

proc reg data=a;
  model x y = t;
  output out=detrend r=rx ry;
run;
```

You then use `PROC STATESPACE` to forecast the detrended series RX and RY . A disadvantage of this method is that you need to add the trend back to the forecast series in an additional step. A more serious disadvantage of the detrending method is that it assumes a deterministic trend. In practice, most time series appear to have a stochastic rather than a deterministic trend. Differencing is a more flexible and often more appropriate method.

There are several other methods to handle nonstationary time series. For more information and examples, see Brockwell and Davis (1991).

Preliminary Autoregressive Models

After computing the sample autocovariance matrices, PROC STATESPACE fits a sequence of vector autoregressive models. These preliminary autoregressive models are used to estimate the autoregressive order of the process and limit the order of the autocovariances considered in the state vector selection process.

Yule-Walker Equations for Forward and Backward Models

Unlike a univariate autoregressive model, a multivariate autoregressive model has different forms, depending on whether the present observation is being predicted from the past observations or from the future observations.

Let \mathbf{x}_t be the r -component stationary time series given by the VAR statement after differencing and subtracting the vector of sample means. (If the NOCENTER option is specified, the mean is not subtracted.) Let n be the number of observations of \mathbf{x}_t from the input data set.

Let \mathbf{e}_t be a vector white noise sequence with mean vector $\mathbf{0}$ and variance matrix Σ_p , and let \mathbf{n}_t be a vector white noise sequence with mean vector $\mathbf{0}$ and variance matrix Ω_p . Let p be the order of the vector autoregressive model for \mathbf{x}_t .

The forward autoregressive form based on the past observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^p \Phi_i^p \mathbf{x}_{t-i} + \mathbf{e}_t$$

The backward autoregressive form based on the future observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^p \Psi_i^p \mathbf{x}_{t+i} + \mathbf{n}_t$$

Letting E denote the expected value operator, the autocovariance sequence for the \mathbf{x}_t series, Γ_i , is

$$\Gamma_i = E \mathbf{x}_t \mathbf{x}'_{t-i}$$

The Yule-Walker equations for the autoregressive model that matches the first p elements of the autocovariance sequence are

$$\begin{bmatrix} \Gamma_0 & \Gamma_1 & \cdots & \Gamma_{p-1} \\ \Gamma_1' & \Gamma_0 & \cdots & \Gamma_{p-2} \\ \vdots & \vdots & \ddots & \vdots \\ \Gamma_{p-1}' & \Gamma_{p-2}' & \cdots & \Gamma_0 \end{bmatrix} \begin{bmatrix} \Phi_1^p \\ \Phi_2^p \\ \vdots \\ \Phi_p^p \end{bmatrix} = \begin{bmatrix} \Gamma_1 \\ \Gamma_2 \\ \vdots \\ \Gamma_p \end{bmatrix}$$

and

$$\begin{bmatrix} \Gamma_0 & \Gamma'_1 & \cdots & \Gamma'_{p-1} \\ \Gamma_1 & \Gamma_0 & \cdots & \Gamma'_{p-2} \\ \vdots & \vdots & & \vdots \\ \Gamma_{p-1} & \Gamma_{p-2} & \cdots & \Gamma_0 \end{bmatrix} \begin{bmatrix} \Psi_1^p \\ \Psi_2^p \\ \vdots \\ \Psi_p^p \end{bmatrix} = \begin{bmatrix} \Gamma'_1 \\ \Gamma'_2 \\ \vdots \\ \Gamma'_p \end{bmatrix}$$

Here Φ_i^p are the coefficient matrices for the past observation form of the vector autoregressive model, and Ψ_i^p are the coefficient matrices for the future observation form. More information about the Yule-Walker equations in the multivariate setting can be found in Whittle (1963) and Ansley and Newbold (1979).

The innovation variance matrices for the two forms can be written as follows:

$$\Sigma_p = \Gamma_0 - \sum_{i=1}^p \Phi_i^p \Gamma'_i$$

$$\Omega_p = \Gamma_0 - \sum_{i=1}^p \Psi_i^p \Gamma_i$$

The autoregressive models are fit to the data by using the preceding Yule-Walker equations with Γ_i replaced by the sample covariance sequence C_i . The covariance matrices are calculated as

$$C_i = \frac{1}{N-i} \sum_{t=i+1}^N \mathbf{x}_t \mathbf{x}'_{t-i}$$

Let $\hat{\Phi}_p$, $\hat{\Psi}_p$, $\hat{\Sigma}_p$, and $\hat{\Omega}_p$ represent the Yule-Walker estimates of Φ_p , Ψ_p , Σ_p , and Ω_p , respectively. These matrices are written to an output data set when the OUTAR= option is specified.

When the PRINTOUT=LONG option is specified, the sequence of matrices $\hat{\Sigma}_p$ and the corresponding correlation matrices are printed. The sequence of matrices $\hat{\Sigma}_p$ is used to compute Akaike information criteria for selection of the autoregressive order of the process.

Akaike Information Criterion

The Akaike information criterion (AIC) is defined as $-2(\text{maximum of log likelihood}) + 2(\text{number of parameters})$. Since the vector autoregressive models are estimates from the Yule-Walker equations, not by maximum likelihood, the exact likelihood values are not available for computing the AIC. However, for the vector autoregressive model the maximum of the log likelihood can be approximated as

$$\ln(L) \approx -\frac{n}{2} \ln(|\hat{\Sigma}_p|)$$

Thus, the AIC for the order p model is computed as

$$AIC_p = n \ln(|\hat{\Sigma}_p|) + 2pr^2$$

You can use the printed AIC array to compute a likelihood ratio test of the autoregressive order. The log-likelihood ratio test statistic for testing the order p model against the order $p - 1$ model is

$$-n\ln(|\widehat{\Sigma}_p|) + n\ln(|\widehat{\Sigma}_{p-1}|)$$

This quantity is asymptotically distributed as a χ^2 with r^2 degrees of freedom if the series is autoregressive of order $p - 1$. It can be computed from the AIC array as

$$AIC_{p-1} - AIC_p + 2r^2$$

You can evaluate the significance of these test statistics with the PROBCHI function in a SAS DATA step or with a χ^2 table.

Determining the Autoregressive Order

Although the autoregressive models can be used for prediction, their primary value is to aid in the selection of a suitable portion of the sample covariance matrix for use in computing canonical correlations. If the multivariate time series \mathbf{x}_t is of autoregressive order p , then the vector of past values to lag p is considered to contain essentially all the information relevant for prediction of future values of the time series.

By default, PROC STATESPACE selects the order p that produces the autoregressive model with the smallest AIC_p . If the value p for the minimum AIC_p is less than the value of the PASTMIN= option, then p is set to the PASTMIN= value. Alternatively, you can use the ARMAX= and PASTMIN= options to force PROC STATESPACE to use an order you select.

Significance Limits for Partial Autocorrelations

The STATESPACE procedure prints a schematic representation of the partial autocorrelation matrices that indicates which partial autocorrelations are significantly greater than or significantly less than 0. Figure 25.11 shows an example of this table.

Figure 25.11 Significant Partial Autocorrelations

Schematic Representation of Partial Autocorrelations										
Name/Lag	1	2	3	4	5	6	7	8	9	10
x	++	+
y	++
+ is > 2*std error, - is < -2*std error, . is between										

The partial autocorrelations are from the sample partial autoregressive matrices $\widehat{\Phi}_p^p$. The standard errors used for the significance limits of the partial autocorrelations are computed from the sequence of matrices Σ_p and Ω_p .

Under the assumption that the observed series arises from an autoregressive process of order $p - 1$, the p th sample partial autoregressive matrix $\widehat{\Phi}_p^p$ has an asymptotic variance matrix $\frac{1}{n}\Omega_p^{-1} \otimes \Sigma_p$.

The significance limits for $\widehat{\Phi}_p^p$ used in the schematic plot of the sample partial autoregressive sequence are derived by replacing Ω_p and Σ_p with their sample estimators to produce the variance estimate, as follows:

$$\widehat{Var}(\widehat{\Phi}_p^p) = \left(\frac{1}{n - rp} \right) \widehat{\Omega}_p^{-1} \otimes \widehat{\Sigma}_p$$

Canonical Correlation Analysis

Given the order p , let \mathbf{p}_t be the vector of current and past values relevant to prediction of \mathbf{x}_{t+1} :

$$\mathbf{p}_t = (\mathbf{x}'_t, \mathbf{x}'_{t-1}, \dots, \mathbf{x}'_{t-p})'$$

Let \mathbf{f}_t be the vector of current and future values:

$$\mathbf{f}_t = (\mathbf{x}'_t, \mathbf{x}'_{t+1}, \dots, \mathbf{x}'_{t+p})'$$

In the canonical correlation analysis, consider submatrices of the sample covariance matrix of \mathbf{p}_t and \mathbf{f}_t . This covariance matrix, \mathbf{V} , has a block Hankel form:

$$\mathbf{V} = \begin{bmatrix} \mathbf{C}_0 & \mathbf{C}'_1 & \mathbf{C}'_2 & \cdots & \mathbf{C}'_p \\ \mathbf{C}'_1 & \mathbf{C}'_2 & \mathbf{C}'_3 & \cdots & \mathbf{C}'_{p+1} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ \mathbf{C}'_p & \mathbf{C}'_{p+1} & \mathbf{C}'_{p+2} & \cdots & \mathbf{C}'_{2p} \end{bmatrix}$$

State Vector Selection Process

The canonical correlation analysis forms a sequence of potential state vectors \mathbf{z}_t^j . Examine a sequence \mathbf{f}_t^j of subvectors of \mathbf{f}_t , form the submatrix \mathbf{V}^j that consists of the rows and columns of \mathbf{V} that correspond to the components of \mathbf{f}_t^j , and compute its canonical correlations.

The smallest canonical correlation of \mathbf{V}^j is then used in the selection of the components of the state vector. The selection process is described in the following discussion. For more details about this process, see Akaike (1976).

In the following discussion, the notation $\mathbf{x}_{t+k|t}$ denotes the wide sense conditional expectation (best linear predictor) of \mathbf{x}_{t+k} , given all \mathbf{x}_s with s less than or equal to t . In the notation $x_{i,t+1}$, the first subscript denotes the i th component of \mathbf{x}_{t+1} .

The initial state vector \mathbf{z}_t^1 is set to \mathbf{x}_t . The sequence \mathbf{f}_t^j is initialized by setting

$$\mathbf{f}_t^1 = (\mathbf{z}_t^1, x_{1,t+1|t})' = (\mathbf{x}'_t, x_{1,t+1|t})'$$

That is, start by considering whether to add $x_{1,t+1|t}$ to the initial state vector \mathbf{z}_t^1 .

The procedure forms the submatrix \mathbf{V}^1 that corresponds to \mathbf{f}_t^1 and computes its canonical correlations. Denote the smallest canonical correlation of \mathbf{V}^1 as ρ_{min} . If ρ_{min} is significantly greater than 0, $x_{1,t+1|t}$ is added to the state vector.

If the smallest canonical correlation of \mathbf{V}^1 is not significantly greater than 0, then a linear combination of \mathbf{f}_t^1 is uncorrelated with the past, \mathbf{p}_t . Assuming that the determinant of \mathbf{C}_0 is not 0, (that is, no input series is a constant), you can take the coefficient of $x_{1,t+1|t}$ in this linear combination to be 1. Denote the coefficients of \mathbf{z}_t^1 in this linear combination as ℓ . This gives the relationship:

$$x_{1,t+1|t} = \ell' \mathbf{x}_t$$

Therefore, the current state vector already contains all the past information useful for predicting $x_{1,t+1}$ and any greater leads of $x_{1,t}$. The variable $x_{1,t+1|t}$ is not added to the state vector, nor are any terms $x_{1,t+k|t}$ considered as possible components of the state vector. The variable x_1 is no longer active for state vector selection.

The process described for $x_{1,t+1|t}$ is repeated for the remaining elements of \mathbf{f}_t . The next candidate for inclusion in the state vector is the next component of \mathbf{f}_t that corresponds to an active variable. Components of \mathbf{f}_t that correspond to inactive variables that produced a zero ρ_{min} in a previous step are skipped.

Denote the next candidate as $x_{l,t+k|t}$. The vector \mathbf{f}_t^j is formed from the current state vector and $x_{l,t+k|t}$ as follows:

$$\mathbf{f}_t^j = (\mathbf{z}_t^{j'}, x_{l,t+k|t})'$$

The matrix \mathbf{V}^j is formed from \mathbf{f}_t^j and its canonical correlations are computed. The smallest canonical correlation of \mathbf{V}^j is judged to be either greater than or equal to 0. If it is judged to be greater than 0, $x_{l,t+k|t}$ is added to the state vector. If it is judged to be 0, then a linear combination of \mathbf{f}_t^j is uncorrelated with the \mathbf{p}_t , and the variable x_l is now inactive.

The state vector selection process continues until no active variables remain.

Testing Significance of Canonical Correlations

For each step in the canonical correlation sequence, the significance of the smallest canonical correlation ρ_{min} is judged by an information criterion from Akaike (1976). This information criterion is

$$-n \ln(1 - \rho_{min}^2) - \lambda(r(p+1) - q + 1)$$

where q is the dimension of \mathbf{f}_t^j at the current step, r is the order of the state vector, p is the order of the vector autoregressive process, and λ is the value of the SIGCORR= option. The default is SIGCORR=2. If this information criterion is less than or equal to 0, ρ_{min} is taken to be 0; otherwise, it is taken to be significantly greater than 0. (Do not confuse this information criterion with the AIC.)

Variables in $\mathbf{x}_{t+p|t}$ are not added in the model, even with positive information criterion, because of the singularity of \mathbf{V} . You can force the consideration of more candidate state variables by increasing the size of the \mathbf{V} matrix by specifying a PASTMIN= option value larger than p .

Printing the Canonical Correlations

To print the details of the canonical correlation analysis process, specify the CANCELL option in the PROC STATESPACE statement. The CANCELL option prints the candidate state vectors, the canonical correlations, and the information criteria for testing the significance of the smallest canonical correlation.

Bartlett's χ^2 and its degrees of freedom are also printed when the CANCELL option is specified. The formula used for Bartlett's χ^2 is

$$\chi^2 = -(n - .5(r(p + 1) - q + 1))\ln(1 - \rho_{min}^2)$$

with $r(p + 1) - q + 1$ degrees of freedom.

Figure 25.12 shows the output of the CANCELL option for the introductory example shown in the “Getting Started: STATESPACE Procedure” on page 1570.

```
proc statespace data=in out=out lead=10 cancell;
  var x(1) y(1);
  id t;
run;
```

Figure 25.12 Canonical Correlations Analysis

The STATESPACE Procedure					
Canonical Correlations Analysis					
x(T;T)	y(T;T)	x(T+1;T)	Information Criterion	Chi Square	DF
1	1	0.237045	3.566167	11.4505	4

New variables are added to the state vector if the information criteria are positive. In this example, $\mathbf{y}_{t+1|t}$ and $\mathbf{x}_{t+2|t}$ are not added to the state space vector because the information criteria for these models are negative.

If the information criterion is nearly 0, then you might want to investigate models that arise if the opposite decision is made regarding ρ_{min} . This investigation can be accomplished by using a FORM statement to specify part or all of the state vector.

Preliminary Estimates of F

When a candidate variable $x_{l,t+k|t}$ yields a zero ρ_{min} and is not added to the state vector, a linear combination of \mathbf{f}_t^j is uncorrelated with the \mathbf{p}_t . Because of the method used to construct the \mathbf{f}_t^j

sequence, the coefficient of $x_{l,t+k|t}$ in \mathbf{I} can be taken as 1. Denote the coefficients of \mathbf{z}_t^j in this linear combination as \mathbf{l} .

This gives the relationship:

$$x_{l,t+k|t} = \mathbf{l}'\mathbf{z}_t^j$$

The vector \mathbf{l} is used as a preliminary estimate of the first r columns of the row of the transition matrix \mathbf{F} corresponding to $x_{l,t+k-1|t}$.

Parameter Estimation

The model is $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$, where \mathbf{e}_t is a sequence of independent multivariate normal innovations with mean vector $\mathbf{0}$ and variance $\Sigma_{\mathbf{e}\mathbf{e}}$. The observed sequence \mathbf{x}_t composes the first r components of \mathbf{z}_t , and thus $\mathbf{x}_t = \mathbf{H}\mathbf{z}_t$, where \mathbf{H} is the $r \times s$ matrix $[\mathbf{I}_r \ \mathbf{0}]$.

Let \mathbf{E} be the $r \times n$ matrix of innovations:

$$\mathbf{E} = [\mathbf{e}_1 \ \cdots \ \mathbf{e}_n]$$

If the number of observations n is reasonably large, the log likelihood L can be approximated up to an additive constant as follows:

$$L = -\frac{n}{2}\ln(|\Sigma_{\mathbf{e}\mathbf{e}}|) - \frac{1}{2}\text{trace}(\Sigma_{\mathbf{e}\mathbf{e}}^{-1}\mathbf{E}\mathbf{E}')$$

The elements of $\Sigma_{\mathbf{e}\mathbf{e}}$ are taken as free parameters and are estimated as follows:

$$\mathbf{S}_0 = \frac{1}{n}\mathbf{E}\mathbf{E}'$$

Replacing $\Sigma_{\mathbf{e}\mathbf{e}}$ by \mathbf{S}_0 in the likelihood equation, the log likelihood, up to an additive constant, is

$$L = -\frac{n}{2}\ln(|\mathbf{S}_0|)$$

Letting B be the backshift operator, the formal relation between \mathbf{x}_t and \mathbf{e}_t is

$$\begin{aligned}\mathbf{x}_t &= \mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1}\mathbf{G}\mathbf{e}_t \\ \mathbf{e}_t &= (\mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1}\mathbf{G})^{-1}\mathbf{x}_t = \sum_{i=0}^{\infty} \mathbf{E}_i\mathbf{x}_{t-i}\end{aligned}$$

Letting \mathbf{C}_i be the i th lagged sample covariance of \mathbf{x}_t and neglecting end effects, the matrix \mathbf{S}_0 is

$$\mathbf{S}_0 = \sum_{i,j=0}^{\infty} \mathbf{E}_i\mathbf{C}_{-i+j}\mathbf{E}_j'$$

For the computation of \mathbf{S}_0 , the infinite sum is truncated at the value of the KLAG= option. The value of the KLAG= option should be large enough that the sequence Ξ_i is approximately 0 beyond that point.

Let θ be the vector of free parameters in the \mathbf{F} and \mathbf{G} matrices. The derivative of the log likelihood with respect to the parameter θ is

$$\frac{\partial L}{\partial \theta} = -\frac{n}{2} \text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \theta} \right)$$

The second derivative is

$$\frac{\partial^2 L}{\partial \theta \partial \theta'} = \frac{n}{2} \left(\text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \theta'} \mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \theta} \right) - \text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial^2 \mathbf{S}_0}{\partial \theta \partial \theta'} \right) \right)$$

Near the maximum, the first term is unimportant and the second term can be approximated to give the following second derivative approximation:

$$\frac{\partial^2 L}{\partial \theta \partial \theta'} \cong -n \text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{E}}{\partial \theta} \frac{\partial \mathbf{E}'}{\partial \theta'} \right)$$

The first derivative matrix and this second derivative matrix approximation are computed from the sample covariance matrix \mathbf{C}_0 and the truncated sequence Ξ_i . The approximate likelihood function is maximized by a modified Newton-Raphson algorithm that employs these derivative matrices.

The matrix \mathbf{S}_0 is used as the estimate of the innovation covariance matrix, Σ_{ee} . The negative of the inverse of the second derivative matrix at the maximum is used as an approximate covariance matrix for the parameter estimates. The standard errors of the parameter estimates printed in the parameter estimates tables are taken from the diagonal of this covariance matrix. The parameter covariance matrix is printed when the COVB option is specified.

If the data are nearly nonstationary, a better estimate of Σ_{ee} and the other parameters can sometimes be obtained by specifying the RESIDEST option. The RESIDEST option estimates the parameters by using conditional least squares instead of maximum likelihood.

The residuals are computed using the state space equation and the sample mean values of the variables in the model as start-up values. The estimate of \mathbf{S}_0 is then computed using the residuals from the i th observation on, where i is the maximum number of times any variable occurs in the state vector. A multivariate Gauss-Marquardt algorithm is used to minimize $|\mathbf{S}_0|$. See Harvey (1981a) for a further description of this method.

Forecasting

Given estimates of \mathbf{F} , \mathbf{G} , and Σ_{ee} , forecasts of \mathbf{x}_t are computed from the conditional expectation of \mathbf{z}_t .

In forecasting, the parameters \mathbf{F} , \mathbf{G} , and Σ_{ee} are replaced with the estimates or by values specified in the RESTRICT statement. One-step-ahead forecasting is performed for the observation \mathbf{x}_t , where $t \leq n - b$. Here n is the number of observations and b is the value of the BACK= option. For the observation \mathbf{x}_t , where $t > n - b$, m -step-ahead forecasting is performed for $m = t - n + b$. The forecasts are generated recursively with the initial condition $\mathbf{z}_0 = \mathbf{0}$.

The m -step-ahead forecast of \mathbf{z}_{t+m} is $\mathbf{z}_{t+m|t}$, where $\mathbf{z}_{t+m|t}$ denotes the conditional expectation of \mathbf{z}_{t+m} given the information available at time t . The m -step-ahead forecast of \mathbf{x}_{t+m} is $\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$, where the matrix $\mathbf{H} = [\mathbf{I}_r \mathbf{0}]$.

Let $\Psi_i = \mathbf{F}^i \mathbf{G}$. Note that the last $s - r$ elements of \mathbf{z}_t consist of the elements of $\mathbf{x}_u|t$ for $u > t$.

The state vector \mathbf{z}_{t+m} can be represented as

$$\mathbf{z}_{t+m} = \mathbf{F}^m \mathbf{z}_t + \sum_{i=0}^{m-1} \Psi_i \mathbf{e}_{t+m-i}$$

Since $\mathbf{e}_{t+i|t} = \mathbf{0}$ for $i > 0$, the m -step-ahead forecast $\mathbf{z}_{t+m|t}$ is

$$\mathbf{z}_{t+m|t} = \mathbf{F}^m \mathbf{z}_t = \mathbf{F} \mathbf{z}_{t+m-1|t}$$

Therefore, the m -step-ahead forecast of \mathbf{x}_{t+m} is

$$\mathbf{x}_{t+m|t} = \mathbf{H} \mathbf{z}_{t+m|t}$$

The m -step-ahead forecast error is

$$\mathbf{z}_{t+m} - \mathbf{z}_{t+m|t} = \sum_{i=0}^{m-1} \Psi_i \mathbf{e}_{t+m-i}$$

The variance of the m -step-ahead forecast error is

$$\mathbf{V}_{z,m} = \sum_{i=0}^{m-1} \Psi_i \Sigma_{ee} \Psi_i'$$

Letting $\mathbf{V}_{z,0} = \mathbf{0}$, the variance of the m -step-ahead forecast error of \mathbf{z}_{t+m} , $\mathbf{V}_{z,m}$, can be computed recursively as follows:

$$\mathbf{V}_{z,m} = \mathbf{V}_{z,m-1} + \Psi_{m-1} \Sigma_{ee} \Psi_{m-1}'$$

The variance of the m -step-ahead forecast error of \mathbf{x}_{t+m} is the $r \times r$ left upper submatrix of $\mathbf{V}_{z,m}$; that is,

$$\mathbf{V}_{x,m} = \mathbf{H} \mathbf{V}_{z,m} \mathbf{H}'$$

Unless the NOCENTER option is specified, the sample mean vector is added to the forecast. When differencing is specified, the forecasts $\mathbf{x}_{t+m|t}$ plus the sample mean vector are integrated back to produce forecasts for the original series.

Let \mathbf{y}_t be the original series specified by the VAR statement, with some 0 values appended that correspond to the unobserved past observations. Let B be the backshift operator, and let $\Delta(B)$ be the $s \times s$ matrix polynomial in the backshift operator that corresponds to the differencing specified by the VAR statement. The off-diagonal elements of Δ_i are 0. Note that $\Delta_0 = \mathbf{I}_s$, where \mathbf{I}_s is the $s \times s$ identity matrix. Then $\mathbf{z}_t = \Delta(B)\mathbf{y}_t$.

This gives the relationship

$$\mathbf{y}_t = \Delta^{-1}(B)\mathbf{z}_t = \sum_{i=0}^{\infty} \Lambda_i \mathbf{z}_{t-i}$$

where $\Delta^{-1}(B) = \sum_{i=0}^{\infty} \Lambda_i B^i$ and $\Lambda_0 = \mathbf{I}_s$.

The m -step-ahead forecast of \mathbf{y}_{t+m} is

$$\mathbf{y}_{t+m|t} = \sum_{i=0}^{m-1} \Lambda_i \mathbf{z}_{t+m-i|t} + \sum_{i=m}^{\infty} \Lambda_i \mathbf{z}_{t+m-i}$$

The m -step-ahead forecast error of \mathbf{y}_{t+m} is

$$\sum_{i=0}^{m-1} \Lambda_i (\mathbf{z}_{t+m-i} - \mathbf{z}_{t+m-i|t}) = \sum_{i=0}^{m-1} \left(\sum_{u=0}^i \Lambda_u \Psi_{i-u} \right) \mathbf{e}_{t+m-i}$$

Letting $\mathbf{V}_{y,0} = \mathbf{0}$, the variance of the m -step-ahead forecast error of \mathbf{y}_{t+m} , $\mathbf{V}_{y,m}$, is

$$\begin{aligned} \mathbf{V}_{y,m} &= \sum_{i=0}^{m-1} \left(\sum_{u=0}^i \Lambda_u \Psi_{i-u} \right) \Sigma_{ee} \left(\sum_{u=0}^i \Lambda_u \Psi_{i-u} \right)' \\ &= \mathbf{V}_{y,m-1} + \left(\sum_{u=0}^{m-1} \Lambda_u \Psi_{m-1-u} \right) \Sigma_{ee} \left(\sum_{u=0}^{m-1} \Lambda_u \Psi_{m-1-u} \right)' \end{aligned}$$

Relation of ARMA and State Space Forms

Every state space model has an ARMA representation, and conversely every ARMA model has a state space representation. This section discusses this equivalence. The following material is adapted from Akaike (1974), where there is a more complete discussion. Pham-Dinh-Tuan (1978) also contains a discussion of this material.

Suppose you are given the following ARMA model:

$$\Phi(B)\mathbf{x}_t = \Theta(B)\mathbf{e}_t$$

or, in more detail,

$$\mathbf{x}_t - \Phi_1 \mathbf{x}_{t-1} - \cdots - \Phi_p \mathbf{x}_{t-p} = \mathbf{e}_t + \Theta_1 \mathbf{e}_{t-1} + \cdots + \Theta_q \mathbf{e}_{t-q} \quad (1)$$

where \mathbf{e}_t is a sequence of independent multivariate normal random vectors with mean $\mathbf{0}$ and variance

matrix Σ_{ee} , B is the backshift operator ($B\mathbf{x}_t = \mathbf{x}_{t-1}$), $\Phi(B)$ and $\Theta(B)$ are matrix polynomials in B , and \mathbf{x}_t is the observed process.

If the roots of the determinantal equation $|\Phi(B)| = 0$ are outside the unit circle in the complex plane, the model can also be written as

$$\mathbf{x}_t = \Phi^{-1}(B)\Theta(B)\mathbf{e}_t = \sum_{i=0}^{\infty} \Psi_i \mathbf{e}_{t-i}$$

The Ψ_i matrices are known as the impulse response matrices and can be computed as $\Phi^{-1}(B)\Theta(B)$.

You can assume $p > q$ since, if this is not initially true, you can add more terms Φ_i that are identically 0 without changing the model.

To write this set of equations in a state space form, proceed as follows. Let $\mathbf{x}_{t+i|t}$ be the conditional expectation of \mathbf{x}_{t+i} given \mathbf{x}_w for $w \leq t$. The following relations hold:

$$\begin{aligned} \mathbf{x}_{t+i|t} &= \sum_{j=i}^{\infty} \Psi_j \mathbf{e}_{t+i-j} \\ \mathbf{x}_{t+i|t+1} &= \mathbf{x}_{t+i|t} + \Psi_{i-1} \mathbf{e}_{t+1} \end{aligned}$$

However, from equation (1) you can derive the following relationship:

$$\mathbf{x}_{t+p|t} = \Phi_1 \mathbf{x}_{t+p-1|t} + \cdots + \Phi_p \mathbf{x}_t \quad (2)$$

Hence, when $i = p$, you can substitute for $\mathbf{x}_{t+p|t}$ in the right-hand side of equation (2) and close the system of equations.

This substitution results in the following model in the state space form $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$:

$$\begin{bmatrix} \mathbf{x}_{t+1} \\ \mathbf{x}_{t+2|t+1} \\ \vdots \\ \mathbf{x}_{t+p|t+1} \end{bmatrix} = \begin{bmatrix} 0 & \mathbf{I} & 0 & \cdots & 0 \\ 0 & 0 & \mathbf{I} & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_p & \Phi_{p-1} & \cdots & \Phi_1 & \end{bmatrix} \begin{bmatrix} \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+p-1|t} \end{bmatrix} + \begin{bmatrix} \mathbf{I} \\ \Psi_1 \\ \vdots \\ \Psi_{p-1} \end{bmatrix} \mathbf{e}_{t+1}$$

Note that the state vector \mathbf{z}_t is composed of conditional expectations of \mathbf{x}_t and the first r components of \mathbf{z}_t are equal to \mathbf{x}_t .

The state space form can be cast into an ARMA form by solving the system of difference equations for the first r components.

When converting from an ARMA form to a state space form, you can generate a state vector larger than needed; that is, the state space model might not be a minimal representation. When going from a state space form to an ARMA form, you can have nontrivial common factors in the autoregressive and moving average operators that yield an ARMA model larger than necessary.

If the state space form used is not a minimal representation, some but not all components of $\mathbf{x}_{t+i|t}$ might be linearly dependent. This situation corresponds to $[\Phi_p \Theta_{p-1}]$ being of less than full rank when $\Phi(B)$ and $\Theta(B)$ have no common nontrivial left factors. In this case, \mathbf{z}_t consists of a subset

of the possible components of $[\mathbf{x}_{t+i|t}] \quad i = 1, 2, \dots, p - 1$. However, once a component of $\mathbf{x}_{t+i|t}$ (for example, the j th one) is linearly dependent on the previous conditional expectations, then all subsequent j th components of $\mathbf{x}_{t+k|t}$ for $k > i$ must also be linearly dependent. Note that in this case, equivalent but seemingly different structures can arise if the order of the components within \mathbf{x}_t is changed.

OUT= Data Set

The forecasts are contained in the output data set specified by the OUT= option in the PROC STATESPACE statement. The OUT= data set contains the following variables:

- the BY variables
- the ID variable
- the VAR statement variables. These variables contain the actual values from the input data set.
- FOR i , numeric variables that contain the forecasts. The variable FOR i contains the forecasts for the i th variable in the VAR statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option.
- RES i , numeric variables that contain the residual for the forecast of the i th variable in the VAR statement list. For forecast observations, the actual values are missing and the RES i variables contain missing values.
- STD i , numeric variables that contain the standard deviation for the forecast of the i th variable in the VAR statement list. The values of the STD i variables can be used to construct univariate confidence limits for the corresponding forecasts. However, such confidence limits do not take into account the covariance of the forecasts.

OUTAR= Data Set

The OUTAR= data set contains the estimates of the preliminary autoregressive models. The OUTAR= data set contains the following variables:

- ORDER, a numeric variable that contains the order p of the autoregressive model that the observation represents
- AIC, a numeric variable that contains the value of the information criterion AIC_p
- SIGF l , numeric variables that contain the estimate of the innovation covariance matrices for the forward autoregressive models. The variable SIGF l contains the l th column of $\widehat{\Sigma}_p$ in the observations with ORDER= p .

- SIGB*l*, numeric variables that contain the estimate of the innovation covariance matrices for the backward autoregressive models. The variable SIGB*l* contains the *l*th column of $\widehat{\Omega}_p$ in the observations with ORDER=*p*.
- FOR*k* _*l*, numeric variables that contain the estimates of the autoregressive parameter matrices for the forward models. The variable FOR*k* _*l* contains the *l*th column of the lag *k* autoregressive parameter matrix $\widehat{\Phi}_k^p$ in the observations with ORDER=*p*.
- BACK _*l*, numeric variables that contain the estimates of the autoregressive parameter matrices for the backward models. The variable BACK _*l* contains the *l*th column of the lag *k* autoregressive parameter matrix $\widehat{\Psi}_k^p$ in the observations with ORDER=*p*.

The estimates for the order *p* autoregressive model can be selected as those observations with ORDER=*p*. Within these observations, the *k,l*th element of Φ_i^p is given by the value of the FOR*i* _*l* variable in the *k*th observation. The *k,l*th element of Ψ_i^p is given by the value of BAC*i* _*l* variable in the *k*th observation. The *k,l*th element of Σ_p is given by SIGF*l* in the *k*th observation. The *k,l*th element of Ω_p is given by SIGB*l* in the *k*th observation.

Table 25.2 shows an example of the OUTAR= data set, with ARMAX=3 and \mathbf{x}_t of dimension 2. In Table 25.2, (*i, j*) indicate the *i,j*th element of the matrix.

The estimated autoregressive parameters can be used in the IML procedure to obtain autoregressive estimates of the spectral density function or forecasts based on the autoregressive models.

OUTMODEL= Data Set

The OUTMODEL= data set contains the estimates of the **F** and **G** matrices and their standard errors, the names of the components of the state vector, and the estimates of the innovation covariance matrix. The variables contained in the OUTMODEL= data set are as follows:

- the BY variables
- STATEVEC, a character variable that contains the name of the component of the state vector corresponding to the observation. The STATEVEC variable has the value STD for standard deviations observations, which contain the standard errors for the estimates given in the preceding observation.
- F_j, numeric variables that contain the columns of the **F** matrix. The variable F_j contains the *j*th column of **F**. The number of F_j variables is equal to the value of the DIMMAX= option. If the model is of smaller dimension, the extraneous variables are set to missing.
- G_j, numeric variables that contain the columns of the **G** matrix. The variable G_j contains the *j*th column of **G**. The number of G_j variables is equal to *r*, the dimension of **x**_{*t*} given by the number of variables in the VAR statement.
- SIG_j, numeric variables that contain the columns of the innovation covariance matrix. The variable SIG_j contains the *j*th column of Σ_{ee} . There are *r* variables SIG_j.

Table 25.3 shows an example of the OUTMODEL= data set, with $\mathbf{x}_t = (x_t, y_t)'$, $\mathbf{z}_t = (x_t, y_t, x_{t+1|t})'$, and DIMMAX=4. In Table 25.3, $F_{i,j}$ and $G_{i,j}$ are the *i,j*th elements of **F** and **G** respectively. Note that all elements for F₄ are missing because **F** is a 3 × 3 matrix.

Printed Output

The printed output produced by the STATESPACE procedure includes the following:

1. descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (Std), and the differencing operations used
2. the Akaike information criteria for the sequence of preliminary autoregressive models
3. if the PRINTOUT=LONG option is specified, the sample autocovariance matrices of the input series at various lags
4. if the PRINTOUT=LONG option is specified, the sample autocorrelation matrices of the input series

5. a schematic representation of the autocorrelation matrices, showing the significant autocorrelations
6. if the PRINTOUT=LONG option is specified, the partial autoregressive matrices. (These are Φ_p^p as described in the section “Preliminary Autoregressive Models” on page 1590.)
7. a schematic representation of the partial autocorrelation matrices, showing the significant partial autocorrelations
8. the Yule-Walker estimates of the autoregressive parameters for the autoregressive model with the minimum AIC
9. if the PRINTOUT=LONG option is specified, the autocovariance matrices of the residuals of the minimum AIC model. This is the sequence of estimated innovation variance matrices for the solutions of the Yule-Walker equations.
10. if the PRINTOUT=LONG option is specified, the autocorrelation matrices of the residuals of the minimum AIC model
11. If the CANCORR option is specified, the canonical correlations analysis for each potential state vector considered in the state vector selection process. This includes the potential state vector, the canonical correlations, the information criterion for the smallest canonical correlation, Bartlett’s χ^2 statistic (“Chi Square”) for the smallest canonical correlation, and the degrees of freedom of Bartlett’s χ^2 .
12. the components of the chosen state vector
13. the preliminary estimate of the transition matrix, **F**, the input matrix, **G**, and the variance matrix for the innovations, Σ_{ee}
14. if the ITPRINT option is specified, the iteration history of the likelihood maximization. For each iteration, this shows the iteration number, the number of step halvings, the determinant of the innovation variance matrix, the damping factor Lambda, and the values of the parameters.
15. the state vector, printed again to aid interpretation of the following listing of **F** and **G**
16. the final estimate of the transition matrix **F**
17. the final estimate of the input matrix **G**
18. the final estimate of the variance matrix for the innovations Σ_{ee}
19. a table that lists the estimates of the free parameters in **F** and **G** and their standard errors and *t* statistics
20. if the COVB option is specified, the covariance matrix of the parameter estimates
21. if the COVB option is specified, the correlation matrix of the parameter estimates
22. if the PRINT option is specified, the forecasts and their standard errors

ODS Table Names

PROC STATESPACE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 25.4 ODS Tables Produced in PROC STATESPACE

ODS Table Name	Description	Option
NObs	number of observations	default
Summary	simple summary statistics table	default
InfoCriterion	information criterion table	default
CovLags	covariance matrices of input series	PRINTOUT=LONG
CorrLags	correlation matrices of input series	PRINTOUT=LONG
PartialAR	partial autoregressive matrices	PRINTOUT=LONG
YWEstimates	Yule-Walker estimates for minimum AIC	default
CovResiduals	covariance of residuals	PRINTOUT=LONG
CorrResiduals	residual correlations from AR models	PRINTOUT=LONG
StateVector	state vector table	default
CorrGraph	schematic representation of correlations	default
TransitionMatrix	transition matrix	default
InputMatrix	input matrix	default
VarInnov	variance matrix for the innovation	default
CovB	covariance of parameter estimates	COVB
CorrB	correlation of parameter estimates	COVB
CanCorr	canonical correlation analysis	CANCORR
IterHistory	iterative fitting table	ITPRINT
ParameterEstimates	parameter estimates table	default
Forecasts	forecasts table	PRINT
ConvergenceStatus	convergence status table	default

Examples: STATESPACE Procedure

Example 25.1: Series J from Box and Jenkins

This example analyzes the gas furnace data (series J) from Box and Jenkins. (The data are not shown; see Box and Jenkins (1976) for the data.)

First, a model is selected and fit automatically using the following statements.

```

title1 'Gas Furnace Data';
title2 'Box & Jenkins Series J';
title3 'Automatically Selected Model';

proc statespace data=seriesj cancorr;
    var x y;
run;

```

The results for the automatically selected model are shown in [Output 25.1.1](#).

The two series are believed to have a transfer function relation with the gas rate (variable X) as the input and the CO₂ concentration (variable Y) as the output. Since the parameter estimates shown in Output 25.1.1 support this kind of model, the model is reestimated with the feedback parameters restricted to 0. The following statements fit the transfer function (no feedback) model.

```
title3 'Transfer Function Model';
proc statespace data=seriesj printout=none;
```

```

var x y;
restrict f(3,2)=0 f(3,4)=0
          g(3,2)=0 g(4,1)=0 g(5,1)=0;
run;

```

Overview: SYSLIN Procedure

The SYSLIN procedure estimates parameters in an interdependent system of linear regression equations.

Ordinary least squares (OLS) estimates are biased and inconsistent when current period endogenous variables appear as regressors in other equations in the system. The errors of a set of related regression equations are often correlated, and the efficiency of the estimates can be improved by taking these correlations into account. The SYSLIN procedure provides several techniques that produce consistent and asymptotically efficient estimates for systems of regression equations.

The SYSLIN procedure provides the following estimation methods:

- ordinary least squares (OLS)
- two-stage least squares (2SLS)
- limited information maximum likelihood (LIML)
- K-class
- seemingly unrelated regressions (SUR)
- iterated seemingly unrelated regressions (ITSUR)
- three-stage least squares (3SLS)
- iterated three-stage least squares (IT3SLS)
- full information maximum likelihood (FIML)
- minimum expected loss (MELO)

Other features of the SYSLIN procedure enable you to:

- impose linear restrictions on the parameter estimates
- test linear hypotheses about the parameters
- write predicted and residual values to an output SAS data set
- write parameter estimates to an output SAS data set
- write the crossproducts matrix (SSCP) to an output SAS data set
- use raw data, correlations, covariances, or cross products as input

Getting Started: SYSLIN Procedure

This section introduces the use of the SYSLIN procedure. The problem of dependent regressors is introduced using a supply and demand example. This section explains the terminology used for variables in a system of regression equations and introduces the SYSLIN procedure statements for declaring the roles the variables play. The syntax used for the different estimation methods and the output produced is shown.

An Example Model

In simultaneous systems of equations, endogenous variables are determined jointly rather than sequentially. Consider the following supply and demand functions for some product:

$$Q_D = a_1 + b_1P + c_1Y + d_1S + \epsilon_1(\text{demand})$$

$$Q_S = a_2 + b_2P + c_2U + \epsilon_2(\text{supply})$$

$$Q = Q_D = Q_S(\text{market equilibrium})$$

The variables in this system are as follows:

Q_D	quantity demanded
Q_S	quantity supplied
Q	the observed quantity sold, which equates quantity supplied and quantity demanded in equilibrium
P	price per unit
Y	income
S	price of substitutes

U	unit cost
ϵ_1	the random error term for the demand equation
ϵ_2	the random error term for the supply equation

In this system, quantity demanded depends on price, income, and the price of substitutes. Consumers normally purchase more of a product when prices are lower and when income and the price of substitute goods are higher. Quantity supplied depends on price and the unit cost of production. Producers supply more when price is high and when unit cost is low. The actual price and quantity sold are determined jointly by the values that equate demand and supply.

Since price and quantity are jointly endogenous variables, both structural equations are necessary to adequately describe the observed values. A critical assumption of OLS is that the regressors are uncorrelated with the residual. When current endogenous variables appear as regressors in other equations (endogenous variables depend on each other), this assumption is violated and the OLS parameter estimates are biased and inconsistent. The bias caused by the violated assumptions is called *simultaneous equation bias*. Neither the demand nor supply equation can be estimated consistently by OLS.

Variables in a System of Equations

Before explaining how to use the SYSLIN procedure, it is useful to define some terms. The variables in a system of equations can be classified as follows:

- *Endogenous variables*, which are also called *jointly dependent* or *response variables*, are the variables determined by the system. Endogenous variables can also appear on the right-hand side of equations.
- *Exogenous variables* are independent variables that do not depend on any of the endogenous variables in the system.
- *Predetermined variables* include both the exogenous variables and *lagged endogenous variables*, which are past values of endogenous variables determined at previous time periods. PROC SYSLIN does not compute lagged values; any lagged endogenous variables must be computed in a preceding DATA step.
- *Instrumental variables* are predetermined variables used in obtaining predicted values for the current period endogenous variables by a first-stage regression. The use of instrumental variables characterizes estimation methods such as two-stage least squares and three-stage least squares. Instrumental variables estimation methods substitute these first-stage predicted values for endogenous variables when they appear as regressors in model equations.

Using PROC SYSLIN

First specify the input data set and estimation method in the PROC SYSLIN statement. If any model uses dependent regressors, and you are using an instrumental variables regression method, declare the dependent regressors with an ENDOGENOUS statement and declare the instruments with an INSTRUMENTS statement. Next, use MODEL statements to specify the structural equations of the system.

The use of different estimation methods is shown by the following examples. These examples use the simulated dataset WORK.IN given below.

```
data in;
  label q = "Quantity"
        p = "Price"
        s = "Price of Substitutes"
        y = "Income"
        u = "Unit Cost";
  drop i e1 e2;
  p = 0; q = 0;
  do i = 1 to 60;
    y = 1 + .05*i + .15*rannor(123);
    u = 2 + .05*rannor(123) + .05*rannor(123);
    s = 4 - .001*(i-10)*(i-110) + .5*rannor(123);
    e1 = .15 * rannor(123);
    e2 = .15 * rannor(123);
    demandx = 1 + .3 * y + .35 * s + e1;
    supplyx = -1 - 1 * u + e2 - .4*e1;
    q = 1.4/2.15 * demandx + .75/2.15 * supplyx;
    p = ( - q + supplyx ) / -1.4;
  output;
end;
run;
```

OLS Estimation

PROC SYSLIN performs OLS regression if you do not specify a method of estimation in the PROC SYSLIN statement. OLS does not use instruments, so the ENDOGENOUS and INSTRUMENTS statements can be omitted.

The following statements estimate the supply and demand model shown previously:

```
proc syslin data=in;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The PROC SYSLIN output for the demand equation is shown in [Figure 26.1](#), and the output for the

supply equation is shown in Figure 26.2.

Error	57	1.003337	0.017602			
Corrected Total	59	10.03724				

Figure 26.2 continued

	Root MSE	0.13267	R-Square	0.90004		
	Dependent Mean	1.30095	Adj R-Sq	0.89653		
	Coeff Var	10.19821				
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.30389	0.471397	-0.64	0.5217	Intercept
p	1	1.218743	0.053914	22.61	<.0001	Price
u	1	-1.07757	0.234150	-4.60	<.0001	Unit Cost

For each MODEL statement, the output first shows the model label and dependent variable name and label. This is followed by an analysis-of-variance table for the model, which shows the model, error, and total mean squares, and an F test for the no-regression hypothesis. Next, the procedure prints the root mean squared error, dependent variable mean and coefficient of variation, and the R^2 and adjusted R^2 statistics.

Finally, the table of parameter estimates shows the estimated regression coefficients, standard errors, and t tests. You would expect the price coefficient in a demand equation to be negative. However, note that the OLS estimate of the price coefficient P in the demand equation (0.1233) has a positive sign. This could be caused by simultaneous equation bias.

Two-Stage Least Squares Estimation

In the supply and demand model, P is an endogenous variable, and consequently the OLS estimates are biased. The following example estimates this model using two-stage least squares.

```
proc syslin data=in 2sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The 2SLS option in the PROC SYSLIN statement specifies the two-stage least squares method. The ENDOGENOUS statement specifies that P is an endogenous regressor for which first-stage predicted values are substituted. You need to declare an endogenous variable in the ENDOGENOUS statement only if it is used as a regressor; thus although Q is endogenous in this model, it is not necessary to list it in the ENDOGENOUS statement.

Usually, all predetermined variables that appear in the system are used as instruments. The INSTRUMENTS statement specifies that the exogenous variables Y, U, and S are used as instruments for the first-stage regression to predict P.

The 2SLS results are shown in Figure 26.3 and Figure 26.4. The first-stage regressions are not shown. To see the first-stage regression results, use the FIRST option in the PROC SYSLIN statement.

Label			Quantity			
Analysis of Variance						
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F	
Model	2	9.646109	4.823054	253.96	<.0001	
Error	57	1.082503	0.018991			
Corrected Total	59	10.03724				

Figure 26.4 continued

Root MSE	0.13781	R-Square	0.89910			
Dependent Mean	1.30095	Adj R-Sq	0.89556			
Coeff Var	10.59291					
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

The 2SLS output is similar in form to the OLS output. However, the 2SLS results are based on predicted values for the endogenous regressors from the first stage instrumental regressions. This makes the analysis-of-variance table and the R^2 statistics difficult to interpret. See the sections “ANOVA Table for Instrumental Variables Methods” on page 1650 and “The R-Square Statistics” on page 1651 for details.

Note that, unlike the OLS results, the 2SLS estimate for the P coefficient in the demand equation (-1.115) is negative.

LIML, K-Class, and MELO Estimation

To obtain limited information maximum likelihood, general K-class, or minimum expected loss estimates, use the ENDOGENOUS, INSTRUMENTS, and MODEL statements as in the 2SLS case but specify the LIML, K=, or MELO option instead of 2SLS in the PROC SYSLIN statement. The following statements show this for K-class estimation.

```
proc syslin data=in k=.5;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

For more information about these estimation methods, see the section “Estimation Methods” on page 1647 and consult econometrics textbooks.

SUR, 3SLS, and FIML Estimation

In a multivariate regression model, the errors in different equations might be correlated. In this case, the efficiency of the estimation might be improved by taking these cross-equation correlations into

account.

Seemingly Unrelated Regression

Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems. Like OLS, the SUR method assumes that all the regressors are independent variables, but SUR uses the correlations among the errors in different equations to improve the regression estimates. The SUR method requires an initial OLS regression to compute residuals. The OLS residuals are used to estimate the cross-equation covariance matrix.

The SUR option in the PROC SYSLIN statement specifies seemingly unrelated regression, as shown in the following statements:

```
proc syslin data=in sur;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

INSTRUMENTS and ENDOGENOUS statements are not needed for SUR, because the SUR method assumes there are no endogenous regressors. For SUR to be effective, the models must use different regressors. SUR produces the same results as OLS unless the model contains at least one regressor not used in the other equations.

Three-Stage Least Squares

The three-stage least squares method generalizes the two-stage least squares method to take into account the correlations between equations in the same way that SUR generalizes OLS. Three-stage least squares requires three steps: first-stage regressions to get predicted values for the endogenous regressors; a two-stage least squares step to get residuals to estimate the cross-equation correlation matrix; and the final 3SLS estimation step.

The 3SLS option in the PROC SYSLIN statement specifies the three-stage least squares method, as shown in the following statements.

```
proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The 3SLS output begins with a two-stage least squares regression to estimate the cross-model correlation matrix. This output is the same as the 2SLS results shown in [Figure 26.3](#) and [Figure 26.4](#), and is not repeated here. The next part of the 3SLS output prints the cross-model correlation matrix computed from the 2SLS residuals. This output is shown in [Figure 26.5](#) and includes the cross-model covariances, correlations, the inverse of the correlation matrix, and the inverse covariance matrix.

Figure 26.5 Estimated Cross-Model Covariances Used for 3SLS Estimates

Figure 26.6 continued

Model		SUPPLY				
Dependent Variable		q				
Label		Quantity				
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

This output first prints the system weighted mean squared error and system weighted R^2 statistics. The system weighted MSE and system weighted R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances. See the section “[The R-Square Statistics](#)” on page 1651 for details.

Next, the table of 3SLS parameter estimates for each model is printed. This output has the same form as for the other estimation methods.

Note that, in some cases, the 3SLS and 2SLS results can be the same. Such a case could arise because of the same principle that causes OLS and SUR results to be identical, unless an equation includes a regressor not used in the other equations of the system. However, the application of this principle is more complex when instrumental variables are used. When all the exogenous variables are used as instruments, linear combinations of all the exogenous variables appear in the third-stage regressions through substitution of first-stage predicted values.

In this example, 3SLS produces different (and, it is hoped, more efficient) estimates for the demand equation. However, the 3SLS and 2SLS results for the supply equation are the same. This is because the supply equation has one endogenous regressor and one exogenous regressor not used in other equations. In contrast, the demand equation has fewer endogenous regressors than exogenous regressors not used in other equations in the system.

Full Information Maximum Likelihood

The FIML option in the PROC SYSLIN statement specifies the full information maximum likelihood method, as shown in the following statements.

```
proc syslin data=in fiml;
  endogenous p q;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The FIML results are shown in [Figure 26.7](#).

Computing Reduced Form Estimates

A system of structural equations with endogenous regressors can be represented as functions of only the predetermined variables. For this to be possible, there must be as many equations as endogenous variables. If there are more endogenous variables than regression models, you can use IDENTITY statements to complete the system. See the section “[Reduced Form Estimates](#)” on page 1653 for details.

The REDUCED option in the PROC SYSLIN statement prints reduced form estimates. The following statements show this by using the 3SLS estimates of the structural parameters.

```
proc syslin data=in 3sls reduced;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
```

```
run;
```

The first four pages of this output were as shown previously and are not repeated here. (See Figure 26.3, Figure 26.4, Figure 26.5, and Figure 26.6.) The final page of the output from this example contains the reduced form coefficients from the 3SLS structural estimates, as shown in Figure 26.8.

Figure 26.8 Reduced Form 3SLS Results

Q	0.808682	0.214662	0.190804	-0.53737

Restricting Parameter Estimates

You can impose restrictions on the parameter estimates with `RESTRICT` and `SRESTRICT` statements. The `RESTRICT` statement imposes linear restrictions on parameters in the equation specified by the preceding `MODEL` statement. The `SRESTRICT` statement imposes linear restrictions that relate parameters in different models.

To impose restrictions involving parameters in different equations, use the `SRESTRICT` statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the `MODEL` statement does not have a label, you can use the dependent variable name as the label for the model,

provided the dependent variable uniquely labels the model.)

Tests for the significance of the restrictions are printed when RESTRICT or SRESTRICT statements are used. You can label RESTRICT and SRESTRICT statements to identify the restrictions in the output.

The RESTRICT statement in the following example restricts the price coefficient in the demand equation to equal 0.015. The SRESTRICT statement restricts the estimate of the income coefficient in the demand equation to be 0.01 times the estimate of the unit cost coefficient in the supply equation.

```
proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  peq015: restrict p = .015;
  supply: model q = p u;
  yeq01u: srestric demand.y = .01 * supply.u;
run;
```

The restricted estimation results are shown in [Figure 26.9](#).

Figure 26.9 Restricted Estimates

Figure 26.9 continued

Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
RESTRICT	-1	342.3605	38.12094	8.98	<.0001	YEQ01U

The standard error for P in the demand equation is 0, since the value of the P coefficient was specified by the RESTRICT statement and not estimated from the data. The “Parameter Estimates” table for the demand equation contains an additional row for the restriction specified by the RESTRICT statement. The parameter estimate for the restriction is the value of the Lagrange multiplier used to impose the restriction. The restriction is highly significant ($t = 6.777$), which means that the data are not consistent with the restriction, and the model does not fit as well with the restriction imposed. See the section “[RESTRICT Statement](#)” on page 1641 for details.

Following the “Parameter Estimates” table for the supply equation, the results for the cross model restrictions are printed. This shows that the restriction specified by the SRESTRICT statement is not consistent with the data ($t = 8.98$). See the section “[SRESTRICT Statement](#)” on page 1642 for details.

Testing Parameters

You can test linear hypotheses about the model parameters with TEST and STEST statements. The TEST statement tests hypotheses about parameters in the equation specified by the preceding MODEL statement. The STEST statement tests hypotheses that relate parameters in different models.

For example, the following statements test the hypothesis that the price coefficient in the demand equation is equal to 0.015.

```
/*--- 3SLS Estimation with Tests ---*/

proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  test_1: test p = .015;
  supply: model q = p u;
run;
```

The TEST statement results are shown in [Figure 26.10](#). This reports an F test for the hypothesis specified by the TEST statement. In this case, the F statistic is 6.79 (3.879/.571) with 1 and 113 degrees of freedom. The p value for this F statistic is 0.0104, which indicates that the hypothesis tested is almost but not quite rejected at the 0.01 level. See the section “[TEST Statement](#)” on page 1644 for details.

Figure 26.10 TEST Statement Results

The SYSLIN Procedure						
Three-Stage Least Squares Estimation

Dependent Variable		q				
Label		Quantity				
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	1.980269	1.169176	1.69	0.0959	Intercept
p	1	-1.17654	0.605015	-1.94	0.0568	Price
y	1	0.404117	0.117179	3.45	0.0011	Income
s	1	0.359204	0.085077	4.22	<.0001	Price of Substitutes
Test Results						
Num DF	Den DF	F Value	Pr > F	Label		
1	113	6.79	0.0104	TEST_1		

To test hypotheses that involve parameters in different equations, use the `STEST` statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the `MODEL` statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

For example, the following statements test the hypothesis that the income coefficient in the demand equation is 0.01 times the unit cost coefficient in the supply equation:

```
proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
  stest1: stest demand.y = .01 * supply.u;
run;
```

The `STEST` statement results are shown in [Figure 26.11](#). The form and interpretation of the `STEST` statement results are like the `TEST` statement results. In this case, the *F* test produces a *p* value less than 0.0001, and strongly rejects the hypothesis tested. See the section “[STEST Statement](#)” on page 1643 for details.

Figure 26.11 STEST Statement Results

The SYSLIN Procedure						
Three-Stage Least Squares Estimation

Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost
Test Results						
Num DF	Den DF	F Value	Pr > F	Label		
1	113	22.46	0.0001	STEST1		

You can combine TEST and STEST statements with RESTRICT and SRESTRICT statements to perform hypothesis tests for restricted models. Of course, the validity of the TEST and STEST statement results depends on the correctness of any restrictions you impose on the estimates.

Saving Residuals and Predicted Values

You can store predicted values and residuals from the estimated models in a SAS data set. Specify the OUT= option in the PROC SYSLIN statement and use the OUTPUT statement to specify names

for new variables to contain the predicted and residual values.

For example, the following statements store the predicted quantity from the supply and demand equations in a data set PRED:

```

/*--- Saving Output Data from 3SLS Estimation ---*/

proc syslin data=in out=pred 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  output predicted=q_demand;
  supply: model q = p u;
  output predicted=q_supply;
run;

```

Plotting Residuals

You can plot the residuals against the regressors by using the PROC SGPLOT. For example, the following statements plot the 2SLS residuals for the demand model against price, income, and price of substitutes.

```

proc syslin data=in 2sls out=out;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  output residual=residual_q;
run;

proc sgplot data=out;
  scatter x=p y=residual_q;
  refline 0 / axis=y;
run;

proc sgplot data=out;
  scatter x=y y=residual_q;
  refline 0 / axis=y;
run;

proc sgplot data=out;
  scatter x=s y=residual_q;
  refline 0 / axis=y;
run;

```

The plot for income is shown in [Figure 26.12](#). The other plots are not shown.

Figure 26.12 Plot of Residuals against Income

Syntax: SYSLIN Procedure

The SYSLIN procedure uses the following statements:

```

PROC SYSLIN options ;
  BY variables ;
  ENDOGENOUS variables ;
  IDENTITY identities ;
  INSTRUMENTS variables ;
  MODEL response = regressors / options ;
  OUTPUT PREDICTED= variable RESIDUAL= variable ;
  RESTRICT restrictions ;
  SRESTRICT restrictions ;
  STEST equations ;
  TEST equations ;
  VAR variables ;
  WEIGHT variable ;

```

Functional Summary

The SYSLIN procedure statements and options are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set	PROC SYSLIN	DATA=
specify the output data set	PROC SYSLIN	OUT=
write parameter estimates to an output data set	PROC SYSLIN	OUTEST=
write covariances to the OUTEST= data set	PROC SYSLIN	OUTCOV OUTCOV3
write the SSCP matrix to an output data set	PROC SYSLIN	OUTSSCP=
Estimation Method Options		
specify full information maximum likelihood estimation	PROC SYSLIN	FIML
specify iterative SUR estimation	PROC SYSLIN	ITSUR
specify iterative 3SLS estimation	PROC SYSLIN	IT3SLS
specify K-class estimation	PROC SYSLIN	K=
specify limited information maximum likelihood estimation	PROC SYSLIN	LIML
specify minimum expected loss estimation	PROC SYSLIN	MELO
specify ordinary least squares estimation	PROC SYSLIN	OLS
specify seemingly unrelated estimation	PROC SYSLIN	SUR
specify two-stage least squares estimation	PROC SYSLIN	2SLS
specify three-stage least squares estimation	PROC SYSLIN	3SLS
specify Fuller's modification to LIML	PROC SYSLIN	ALPHA=
specify convergence criterion	PROC SYSLIN	CONVERGE=
specify maximum number of iterations	PROC SYSLIN	MAXIT=
use diagonal of \mathbf{S} instead of \mathbf{S}	PROC SYSLIN	SDIAG
exclude RESTRICT statements in final stage	PROC SYSLIN	NOINCLUDE
specify criterion for testing for singularity	PROC SYSLIN	SINGULAR=
specify denominator for variance estimates	PROC SYSLIN	VARDEF=
Printing Control Options		
print all results	PROC SYSLIN	ALL
print first-stage regression statistics	PROC SYSLIN	FIRST
print estimates and SSE at each iteration	PROC SYSLIN	ITPRINT
print the reduced form estimates	PROC SYSLIN	REDUCED
print descriptive statistics	PROC SYSLIN	SIMPLE
print uncorrected SSCP matrix	PROC SYSLIN	USSCP
print correlations of the parameter estimates	MODEL	CORRB

Description	Statement	Option
print covariances of the parameter estimates	MODEL	COVB
print Durbin-Watson statistics	MODEL	DW
print Basman's test	MODEL	OVERID
plot residual values against regressors	MODEL	PLOT
print standardized parameter estimates	MODEL	STB
print unrestricted parameter estimates	MODEL	UNREST
print the model crossproducts matrix	MODEL	XPX
print the inverse of the crossproducts matrix	MODEL	I
suppress printed output	MODEL	NOPRINT
suppress all printed output	PROC SYSLIN	NOPRINT
Model Specification		
specify structural equations	MODEL	
suppress the intercept parameter	MODEL	NOINT
specify linear relationship among variables	IDENTITY	
perform weighted regression	WEIGHT	
Tests and Restrictions on Parameters		
place restrictions on parameter estimates	RESTRICT	
place restrictions on parameter estimates	SRESTRICT	
test linear hypothesis	STEST	
test linear hypothesis	TEST	
Other Statements		
specify BY-group processing	BY	
specify the endogenous variables	ENDOGENOUS	
specify instrumental variables	INSTRUMENTS	
write predicted and residual values to a data set	OUTPUT	
name variable for predicted values	OUTPUT	PREDICTED=
name variable for residual values	OUTPUT	RESIDUAL=
include additional variables in $X'X$ matrix	VAR	

PROC SYSLIN Statement

PROC SYSLIN *options* ;

The following options can be used with the PROC SYSLIN statement.

Data Set Options

DATA=SAS-data-set

specifies the input data set. If the DATA= option is omitted, the most recently created SAS data set is used. In addition to ordinary SAS data sets, PROC SYSLIN can analyze data sets of TYPE=CORR, TYPE=COV, TYPE=UCORR, TYPE=UCOV, and TYPE=SSCP. See the section “[Special TYPE= Input Data Sets](#)” on page 1647 for details.

OUT=SAS-data-set

specifies an output SAS data set for residuals and predicted values. The OUT= option is used in conjunction with the OUTPUT statement. See the section “[OUT= Data Set](#)” on page 1655 for details.

OUTEST=SAS-data-set

writes the parameter estimates to an output data set. See the section “[OUTEST= Data Set](#)” on page 1655 for details.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set in addition to the parameter estimates.

OUTCOV3

COV3OUT

writes covariance matrices for each model in a system to the OUTEST= data set when the 3SLS, SUR, or FIML option is used.

OUTSSCP=SAS-data-set

writes the sum-of-squares-and-crossproducts matrix to an output data set. See the section “[OUTSSCP= Data Set](#)” on page 1656 for details.

Estimation Method Options

2SLS

specifies the two-stage least squares estimation method.

3SLS

specifies the three-stage least squares estimation method.

ALPHA=value

specifies Fuller’s modification to the LIML estimation method. See the section “[Fuller’s Modification to LIML](#)” on page 1654 for details.

CONVERGE=value

specifies the convergence criterion for the iterative estimation methods IT3SLS, ITSUR, and FIML. The default is CONVERGE=0.0001.

FIML

specifies the full information maximum likelihood estimation method.

ITSUR

specifies the iterative seemingly unrelated estimation method.

IT3SLS

specifies the iterative three-stage least squares estimation method.

K=value

specifies the K-class estimation method.

LIML

specifies the limited information maximum likelihood estimation method.

MAXITER=n

specifies the maximum number of iterations allowed for the IT3SLS, ITSUR, and FIML estimation methods. The MAXITER= option can be abbreviated as MAXIT=. The default is MAXITER=30.

MELO

specifies the minimum expected loss estimation method.

NOINCLUDE

excludes the RESTRICT statements from the final stage for the 3SLS, IT3SLS, SUR, and ITSUR estimation methods.

OLS

specifies the ordinary least squares estimation method. This is the default.

SDIAG

uses the diagonal of **S** instead of **S** to do the estimation, where **S** is the covariance matrix of equation errors. See the section “[Uncorrelated Errors across Equations](#)” on page 1654 for details.

SINGULAR=value

specifies a criterion for testing singularity of the crossproducts matrix. This is a tuning parameter used to make PROC SYSLIN more or less sensitive to singularities. The value must be between 0 and 1. The default is SINGULAR=1E-8.

SUR

specifies the seemingly unrelated estimation method.

Printing Control Options

ALL

specifies the CORRB, COVB, DW, I, OVERID, PLOT, STB, and XPX options for every MODEL statement.

FIRST

prints first-stage regression statistics for the endogenous variables regressed on the instruments. This output includes sums of squares, estimates, variances, and standard deviations.

ITPRINT

prints parameter estimates, system-weighted residual sum of squares, and R^2 at each iteration for the IT3SLS and ITSUR estimation methods. For the FIML method, the ITPRINT option prints parameter estimates, negative of log-likelihood function, and norm of gradient vector at each iteration.

NOPRINT

suppresses all printed output. Specifying NOPRINT in the PROC SYSLIN statement is equivalent to specifying NOPRINT in every MODEL statement.

REDUCED

prints the reduced form estimates. If the REDUCED option is specified, you should specify any IDENTITY statements needed to make the system square. See the section “[Reduced Form Estimates](#)” on page 1653 for details.

SIMPLE

prints descriptive statistics for the dependent variables. The statistics printed include the sum, mean, uncorrected sum of squares, variance, and standard deviation.

USSCP

prints the uncorrected sum-of-squares-and-crossproducts matrix.

USSCP2

prints the uncorrected sum-of-squares-and-crossproducts matrix for all variables used in the analysis, including predicted values of variables generated by the procedure.

VARDEF=DF | N | WEIGHT | WGT

specifies the denominator to use in calculating cross-equation error covariances and parameter standard errors and covariances. The default is VARDEF=DF, which corrects for model degrees of freedom. VARDEF=N specifies no degrees-of-freedom correction. VARDEF=WEIGHT specifies the sum of the observation weights. VARDEF=WGT specifies the sum of the observation weights minus the model degrees of freedom. See the section “[Computation of Standard Errors](#)” on page 1653 for details.

BY Statement

BY *variables* ;

A BY statement can be used with PROC SYSLIN to obtain separate analyses on observations in groups defined by the BY variables.

ENDOGENOUS Statement

ENDOGENOUS *variables* ;

The ENDOGENOUS statement declares the jointly dependent variables that are projected in the first-stage regression through the instrument variables. The ENDOGENOUS statement is not needed for the SUR, ITSUR, or OLS estimation methods. The default ENDOGENOUS list consists of all the dependent variables in the MODEL and IDENTITY statements that do not appear in the INSTRUMENTS statement.

IDENTITY Statement

IDENTITY *equation* ;

The IDENTITY statement specifies linear relationships among variables to write to the OUTEST= data set. It provides extra information in the OUTEST= data set but does not create or compute variables. The OUTEST= data set can be processed by the SIMLIN procedure in a later step.

The IDENTITY statement is also used to compute reduced form coefficients when the REDUCED option in the PROC SYSLIN statement is specified. See the section “[Reduced Form Estimates](#)” on page 1653 for details.

The *equation* given by the IDENTITY statement has the same form as equations in the MODEL statement. A label can be specified for an IDENTITY statement as follows:

label : **IDENTITY** ... ;

INSTRUMENTS Statement

INSTRUMENTS *variables* ;

The INSTRUMENTS statement declares the variables used in obtaining first-stage predicted values. All the instruments specified are used in each first-stage regression. The INSTRUMENTS statement is required for the 2SLS, 3SLS, IT3SLS, LIML, MELO, and K-class estimation methods. The INSTRUMENTS statement is not needed for the SUR, ITSUR, OLS, or FIML estimation methods.

MODEL Statement

MODEL *response = regressors / options* ;

The MODEL statement regresses the response variable on the left side of the equal sign against the regressors listed on the right side.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. Model labels are also used in SRESTRICT and STEST statements to refer to parameters in different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label : **MODEL** ...;

The following options can be used in the MODEL statement after a slash (/).

ALL

specifies the CORR, COVB, DW, I, OVERID, PLOT, STB, and XPX options.

ALPHA=*value*

specifies the α parameter for Fuller's modification to the LIML estimation method. See the section "[Fuller's Modification to LIML](#)" on page 1654 for details.

CORR

prints the matrix of estimated correlations between the parameter estimates.

COVB

prints the matrix of estimated covariances between the parameter estimates.

DW

prints Durbin-Watson statistics and autocorrelation coefficients for the residuals. If there are missing values, d' is calculated according to Savin and White (1978). Use the DW option only if the data set to be analyzed is an ordinary SAS data set with time series observations sorted in time order. The Durbin-Watson test is not valid for models with lagged dependent regressors.

I

prints the inverse of the crossproducts matrix for the model, $(\mathbf{X}'\mathbf{X})^{-1}$. If restrictions are specified, the crossproducts matrix printed is adjusted for the restrictions. See the section "[Computational Details](#)" on page 1651 for details.

K=*value*

specifies K-class estimation.

NOINT

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

OVERID

prints Basman's (1960) test for over identifying restrictions. See the section "[Overidentification Restrictions](#)" on page 1654 for details.

PLOT

plots residual values against regressors. A plot of the residuals for each regressor is printed.

STB

prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a standardized parameter estimate is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the response variable.

UNREST

prints parameter estimates computed before restrictions are applied. The UNREST option is valid only if a RESTRICT statement is specified.

XPX

prints the model crossproducts matrix, $X'X$. See the section “[Computational Details](#)” on page 1651 for details.

OUTPUT Statement

OUTPUT < *PREDICTED=variable* > < *RESIDUAL=variable* > ;

The OUTPUT statement writes predicted values and residuals from the preceding model to the data set specified by the OUT= option in the PROC SYSLIN statement. An OUTPUT statement must come after the MODEL statement to which it applies. The OUT= option must be specified in the PROC SYSLIN statement.

The following options can be specified in the OUTPUT statement:

PREDICTED=variable

names a new variable to contain the predicted values for the response variable. The PREDICTED= option can be abbreviated as PREDICT=, PRED=, or P=.

RESIDUAL=variable

names a new variable to contain the residual values for the response variable. The RESIDUAL= option can be abbreviated as RESID= or R=.

For example, the following statements create an output data set named B. In addition to the variables in the input data set, the data set B contains the variable YHAT, with values that are predicted values of the response variable Y, and YRESID, with values that are the residual values of Y.

```
proc syslin data=a out=b;
  model y = x1 x2;
  output p=yhat r=yresid;
run;
```

For example, the following statements create an output data set named PRED. In addition to the variables in the input data set, the data set PRED contains the variables Q_DEMAND and Q_SUPPLY, with values that are predicted values of the response variable Q for the demand and supply equations respectively, and R_DEMAND and R_SUPPLY, with values that are the residual values of the demand and supply equations respectively.

```
proc syslin data=in out=pred;
  demand: model q = p y s;
  output p=q_demand r=r_demand;
  supply: model q = p u;
  output p=q_supply r=r_supply;
run;
```

See the section “[OUT= Data Set](#)” on page 1655 for details.

RESTRICT Statement

RESTRICT *equation* , ... , *equation* ;

The RESTRICT statement places restrictions on the parameter estimates for the preceding MODEL statement. Any number of RESTRICT statements can follow a MODEL statement. Each restriction is written as a linear equation. If more than one restriction is specified in a single RESTRICT statement, the restrictions are separated by commas.

Parameters are referred to by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. The keyword INTERCEPT is used to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label : **RESTRICT** ... ;

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1.

```
proc syslin data=a;
  model y = x1 x2;
  restrict x1 + x2 = 1;
run;
```

Variable names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Rayner 1971). The estimates of these Lagrangian parameters are printed in the “Parameter Estimates” table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter λ measures the sensitivity of the sum of squared errors (SSE) to the restriction. If the restriction is changed by a small amount ϵ , the SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted.

Any number of restrictions can be specified on a RESTRICT statement, and any number of RESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

NOTE: The RESTRICT statement is not supported for the FIML estimation method.

SRESTRICT Statement

SRESTRICT *equation* , . . . , *equation* ;

The SRESTRICT statement imposes linear restrictions that involve parameters in two or more MODEL statements. The SRESTRICT statement is like the RESTRICT statement but is used to impose restrictions across equations, whereas the RESTRICT statement applies only to parameters in the immediately preceding MODEL statement.

Each restriction is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

SRESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label : **SRESTRICT** . . . ;

The following is an example of the use of the SRESTRICT statement, in which the coefficient for the regressor X2 is constrained to be the same in both models.

```
proc syslin data=a 3sls;
  endogenous y1 y2;
  instruments x1 x2;
  model y1 = y2 x1 x2;
  model y2 = y1 x2;
  srestrict y1.x2 = y2.x2;
run;
```

When no equal sign is used, the linear combination is set equal to 0. Thus, the restriction in the preceding example can also be specified as

```
srestrict y1.x2 - y2.x2;
```

Any number of restrictions can be specified on an SRESTRICT statement, and any number of SRESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

When a system restriction is requested for a single equation estimation method (such as OLS or 2SLS), PROC SYSLIN produces the restricted estimates by actually using a corresponding system method. For example, when SRESTRICT is specified along with OLS, PROC SYSLIN produces the restricted OLS estimates via a two-step process equivalent to using SUR estimation with the SDIAG option. First, the unrestricted OLS results are produced. Then, the GLS (SUR) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals. When SRESTRICT is specified along with 2SLS, PROC SYSLIN produces the restricted 2SLS estimates via a multistep process equivalent to using 3SLS estimation with the SDIAG option. First, the unrestricted 2SLS results are produced. Then, the GLS (3SLS) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals.

The results of the SRESTRICT statements are printed after the parameter estimates for all the models in the system. The format of the SRESTRICT statement output is the same as the “Parameter Estimates” table. In this output the parameter estimate is the Lagrangian parameter λ used to impose the restriction.

The Lagrangian parameter λ measures the sensitivity of the system sum of square errors to the restriction. The system SSE is the system MSE shown in the printed output multiplied by the degrees of freedom. If the restriction is changed by a small amount ϵ , the system SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restriction. If λ is zero, the restricted estimates are the same as the unrestricted estimates.

The model degrees of freedom are not adjusted for the cross-model restrictions imposed by SRESTRICT statements.

NOTE: The SRESTRICT statement is not supported for the LIML and the FIML estimation methods.

STEST Statement

STEST *equation* , . . . , *equation* / *options* ;

The STEST statement performs an F test for the joint hypotheses specified in the statement.

The hypothesis is represented in matrix notation as

$$\mathbf{L}\beta = \mathbf{c}$$

and the F test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β , m is the number of restrictions, and $\hat{\sigma}^2$ is the system weighted mean squared error. See the section “Computational Details” on page 1651 for information about the matrix $\mathbf{X}'\mathbf{X}$.

Each hypothesis to be tested is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which

the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

STEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of STEST statements can be specified. Labels are specified as follows:

label : STEST ...;

The following is an example of the STEST statement:

```
proc syslin data=a 3sls;
  endogenous y1 y2;
  instruments x1 x2;
  model y1 = y2 x1 x2;
  model y2 = y1 x2;
  stest y1.x2 = y2.x2;
run;
```

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the F test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the STEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The following are examples of STEST statements:

```
stest a.x1 + b.x2 = 1;
stest 2 * b.x2 = c.x3 + c.x4 ,
      a.intercept + b.x2 = 0;
stest a.x1 = c.x2 = b.x3 = 1;
stest 2 * a.x1 - b.x2 = 0;
```

The PRINT option can be specified in the STEST statement after a slash (/):

PRINT

prints intermediate calculations for the hypothesis tests.

NOTE: The STEST statement is not supported for the FIML estimation method.

TEST Statement

TEST *equation* , ... , *equation* / *options* ;

The TEST statement performs F tests of linear hypotheses about the parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Variable names must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT is used to refer to the model intercept.

TEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of TEST statements can be specified. Labels are specified as follows:

label : TEST ...;

The following is an example of the use of TEST statement, which tests the hypothesis that the coefficients of X1 and X2 are the same:

```
proc syslin data=a;
  model y = x1 x2;
  test x1 = x2;
run;
```

The following statements perform F tests for the hypothesis that the coefficients of X1 and X2 are equal, for the hypothesis that the sum of the X1 and X2 coefficients is twice the intercept, and for the joint hypothesis.

```
proc syslin data=a;
  model y = x1 x2;
  x1eqx2: test x1 = x2;
  sumeq2i: test x1 + x2 = 2 * intercept;
  joint: test x1 = x2, x1 + x2 = 2 * intercept;
run;
```

The following are additional examples of TEST statements:

```
test x1 + x2 = 1;
test x1 = x2 = x3 = 1;
test 2 * x1 = x2 + x3, intercept + x4 = 0;
test 2 * x1 - x2;
```

The TEST statement performs an F test for the joint hypotheses specified. The hypothesis is represented in matrix notation as follows:

$$\mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

The F test is computed as

$$\frac{(\mathbf{L}\mathbf{b} - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}\mathbf{b} - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β , m is the number of restrictions, and $\hat{\sigma}^2$ is the model mean squared error. See the section “[Computational Details](#)” on page 1651 for information about the matrix $\mathbf{X}'\mathbf{X}$.

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the F test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the TEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The PRINT option can be specified in the TEST statement after a slash (/):

PRINT

prints intermediate calculations for the hypothesis tests.

NOTE: The TEST statement is not supported for the FIML estimation method.

VAR Statement

VAR *variables* ;

The VAR statement is used to include variables in the crossproducts matrix that are not specified in any MODEL statement. This statement is rarely used with PROC SYSLIN and is used only with the OUTSSCP= option in the PROC SYSLIN statement.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement is used to perform weighted regression. The WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE).

Details: SYSLIN Procedure

Input Data Set

PROC SYSLIN does not compute new values for regressors. For example, if you need a lagged variable, you must create it with a DATA step. No values are computed by IDENTITY statements; all values must be in the input data set.

Special TYPE= Input Data Sets

The input data set for most applications of the SYSLIN procedure contains standard rectangular data. However, PROC SYSLIN can also process input data in the form of a crossproducts, covariance, or correlation matrix. Data sets that contain such matrices are identified by values of the TYPE= data set option.

These special kinds of input data sets can be used to save computer time. It takes nk^2 operations, where n is the number of observations and k is the number of variables, to calculate cross products; the regressions are of the order k^3 . When n is in the thousands and k is much smaller, you can save most of the computer time in later runs of PROC SYSLIN by reusing the SSCP matrix rather than recomputing it.

The SYSLIN procedure can process TYPE=CORR, COV, UCORR, UCOV, or SSCP data sets. TYPE=CORR and TYPE=COV data sets, usually created by the CORR procedure, contain means and standard deviations, and correlations or covariances. TYPE=SSCP data sets, usually created in previous runs of PROC SYSLIN, contain sums of squares and cross products. See the *SAS/STAT User's Guide* for more information about special SAS data sets.

When special SAS data sets are read, you must specify the TYPE= data set option. PROC CORR and PROC SYSLIN automatically set the type for output data sets; however, if you create the data set by some other means, you must specify its type with the TYPE= data set option.

When the special data sets are used, the DW (Durbin-Watson test) and PLOT options in the MODEL statement cannot be performed, and the OUTPUT statements are not valid.

Estimation Methods

A brief description of the methods used by the SYSLIN procedure follows. For more information about these methods, see the references at the end of this chapter.

There are two fundamental methods of estimation for simultaneous equations: least squares and maximum likelihood. There are two approaches within each of these categories: single equation methods (also referred to as limited information methods) and system methods (also referred to as

full information methods). System methods take into account cross-equation correlations of the disturbances in estimating parameters, while single equation methods do not.

OLS, 2SLS, MELO, K-class, SUR, ITSUR, 3SLS, and IT3SLS use the least squares method; LIML and FIML use the maximum likelihood method.

OLS, 2SLS, MELO, K-class, and LIML are single equation methods. The system methods are SUR, ITSUR, 3SLS, IT3SLS, and FIML.

Single Equation Estimation Methods

Single equation methods do not take into account correlations of errors across equations. As a result, these estimators are not asymptotically efficient compared to full information methods; however, there are instances in which they may be preferred. (See the section “[Choosing a Method for Simultaneous Equations](#)” on page 1650 for details.)

Let y_i be the dependent endogenous variable in equation i , and X_i and Y_i be the matrices of exogenous and endogenous variables appearing as regressors in the same equation.

The 2SLS method owes its name to the fact that, in a first stage, the instrumental variables are used as regressors to obtain a projected value \hat{Y}_i that is uncorrelated with the residual in equation i . In a second stage, \hat{Y}_i replaces Y_i on the right-hand side to obtain consistent least squares estimators.

Normally, the predetermined variables of the system are used as the instruments. It is possible to use variables other than predetermined variables from your system as instruments; however, the estimation might not be as efficient. For consistent estimates, the instruments must be uncorrelated with the residual and correlated with the endogenous variables.

The LIML method results in consistent estimates that are equal to the 2SLS estimates when an equation is exactly identified. LIML can be viewed as a least-variance ratio estimation or as a maximum likelihood estimation. LIML involves minimizing the ratio $\lambda = (rvar_eq)/(rvar_sys)$, where $rvar_eq$ is the residual variance associated with regressing the weighted endogenous variables on all predetermined variables that appear in that equation, and $rvar_sys$ is the residual variance associated with regressing weighted endogenous variables on all predetermined variables in the system.

The MELO method computes the minimum expected loss estimator. MELO estimators “minimize the posterior expectation of generalized quadratic loss functions for structural coefficients of linear structural models” (Judge et al. 1985, p. 635).

K-class estimators are a class of estimators that depends on a user-specified parameter k . A k value less than 1 is recommended but not required. The parameter k can be deterministic or stochastic, but its probability limit must equal 1 for consistent parameter estimates. When all the predetermined variables are listed as instruments, they include all the other single equation estimators supported by PROC SYSLIN. The instance when some of the predetermined variables are not listed among the instruments is not supported by PROC SYSLIN for the general K-class estimation. However, it is supported for the other methods.

For $k = 1$, the K-class estimator is the 2SLS estimator, while for $k = 0$, the K-class estimator is the OLS estimator. The K-class interpretation of LIML is that $k = \lambda$. Note that k is stochastic in the LIML method, unlike for OLS and 2SLS.

MELO is a Bayesian K-class estimator. It yields estimates that can be expressed as a matrix-weighted average of the OLS and 2SLS estimates. MELO estimators have finite second moments and hence finite risk. Other frequently used K-class estimators might not have finite moments under some commonly encountered circumstances, and hence there can be infinite risk relative to quadratic and other loss functions.

One way of comparing K-class estimators is to note that when $k = 1$, the correlation between regressor and the residual is completely corrected for. In all other cases, it is only partially corrected for.

See “[Computational Details](#)” on page 1651 for more details about K-class estimators.

SUR and 3SLS Estimation Methods

SUR might improve the efficiency of parameter estimates when there is contemporaneous correlation of errors across equations. In practice, the contemporaneous correlation matrix is estimated using OLS residuals. Under two sets of circumstances, SUR parameter estimates are the same as those produced by OLS: when there is no contemporaneous correlation of errors across equations (the estimate of the contemporaneous correlation matrix is diagonal) and when the independent variables are the same across equations.

Theoretically, SUR parameter estimates are always at least as efficient as OLS in large samples, provided that your equations are correctly specified. However, in small samples the need to estimate the covariance matrix from the OLS residuals increases the sampling variability of the SUR estimates. This effect can cause SUR to be less efficient than OLS. If the sample size is small and the cross-equation correlations are small, then OLS is preferred to SUR. The consequences of specification error are also more serious with SUR than with OLS.

The 3SLS method combines the ideas of the 2SLS and SUR methods. Like 2SLS, the 3SLS method uses \hat{Y} instead of Y for endogenous regressors, which results in consistent estimates. Like SUR, the 3SLS method takes the cross-equation error correlations into account to improve large sample efficiency. For 3SLS, the 2SLS residuals are used to estimate the cross-equation error covariance matrix.

The SUR and 3SLS methods can be iterated by recomputing the estimate of the cross-equation covariance matrix from the SUR or 3SLS residuals and then computing new SUR or 3SLS estimates based on this updated covariance matrix estimate. Continuing this iteration until convergence produces ITSUR or IT3SLS estimates.

FIML Estimation Method

The FIML estimator is a system generalization of the LIML estimator. The FIML method involves minimizing the determinant of the covariance matrix associated with residuals of the reduced form of the equation system. From a maximum likelihood standpoint, the LIML method involves assuming that the errors are normally distributed and then maximizing the likelihood function subject to restrictions on a particular equation. FIML is similar, except that the likelihood function is maximized subject to restrictions on all of the parameters in the model, not just those in the equation being estimated.

NOTE: The RESTRICT, SRESTRICT, TEST, and STEST statements are not supported when the FIML method is used.

Choosing a Method for Simultaneous Equations

A number of factors should be taken into account in choosing an estimation method. Although system methods are asymptotically most efficient in the absence of specification error, system methods are more sensitive to specification error than single equation methods.

In practice, models are never perfectly specified. It is a matter of judgment whether the misspecification is serious enough to warrant avoidance of system methods.

Another factor to consider is sample size. With small samples, 2SLS might be preferred to 3SLS. In general, it is difficult to say much about the small sample properties of K-class estimators because the results depend on the regressors used.

LIML and FIML are invariant to the normalization rule imposed but are computationally more expensive than 2SLS or 3SLS.

If the reason for contemporaneous correlation among errors across equations is a common, omitted variable, it is not necessarily best to apply SUR. SUR parameter estimates are more sensitive to specification error than OLS. OLS might produce better parameter estimates under these circumstances. SUR estimates are also affected by the sampling variation of the error covariance matrix. There is some evidence from Monte Carlo studies that SUR is less efficient than OLS in small samples.

ANOVA Table for Instrumental Variables Methods

In the instrumental variables methods (2SLS, LIML, K-class, MELO), first-stage predicted values are substituted for the endogenous regressors. As a result, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares for the dependent variable (TSS). The analysis-of-variance table included in the second-stage results gives these sums of squares and the mean squares that are used for the F test, but this table is not a variance decomposition in the usual sense.

The F test shown in the instrumental variables case is a valid test of the no-regression hypothesis that the true coefficients of all regressors are 0. However, because of the first-stage projection of the regression mean square, this is a Wald-type test statistic, which is asymptotically F but not exactly F -distributed in finite samples. Thus, for small samples the F test is only approximate when instrumental variables are used.

The R-Square Statistics

As explained in the section “ANOVA Table for Instrumental Variables Methods” on page 1650, when instrumental variables are used, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares. In this case, there are several ways that the R^2 statistic can be defined.

The definition of R^2 used by the SYSLIN procedure is

$$R^2 = \frac{RSS}{RSS + ESS}$$

This definition is consistent with the F test of the null hypothesis that the true coefficients of all regressors are zero. However, this R^2 might not be a good measure of the goodness of fit of the model.

System Weighted R-Square and System Weighted Mean Squared Error

The system weighted R^2 , printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows.

$$R^2 = \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y}/\mathbf{Y}'\mathbf{W}\mathbf{Y}$$

In this equation, the matrix $\mathbf{X}'\mathbf{X}$ is $\mathbf{R}'\mathbf{W}\mathbf{R}$ and \mathbf{W} is the projection matrix of the instruments:

$$\mathbf{W} = \mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$$

The matrix \mathbf{Z} is the instrument set, \mathbf{R} is the regressor set, and \mathbf{S} is the estimated cross-model covariance matrix.

The system weighted MSE, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows:

$$MSE = \frac{1}{tdf}(\mathbf{Y}'\mathbf{W}\mathbf{Y} - \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y})$$

In this equation, tdf is the sum of the error degrees of freedom for the equations in the system.

Computational Details

This section discusses various computational details.

Computation of Least Squares-Based Estimators

Let the system be composed of G equations and let the i th equation be expressed in this form:

$$y_i = Y_i \beta_i + X_i \gamma_i + \mathbf{u}$$

where

- y_i is the vector of observations on the dependent variable
- Y_i is the matrix of observations on the endogenous variables included in the equation
- β_i is the vector of parameters associated with Y_i
- X_i is the matrix of observations on the predetermined variables included in the equation
- γ_i is the vector of parameters associated with X_i
- \mathbf{u} is a vector of errors

Let $\hat{V}_i = Y_i - \hat{Y}_i$, where \hat{Y}_i is the projection of Y_i onto the space spanned by the instruments matrix \mathbf{Z} .

Let

$$\delta_i = \begin{bmatrix} \beta_i \\ \gamma_i \end{bmatrix}$$

be the vector of parameters associated with both the endogenous and exogenous variables.

The K-class of estimators (Theil 1971) is defined by

$$\hat{\delta}_{i,k} = \begin{bmatrix} Y_i' Y_i - k \hat{V}_i' \hat{V}_i & Y_i' X_i \\ X_i' Y_i & X_i' X_i \end{bmatrix}^{-1} \begin{bmatrix} (Y_i - k \hat{V}_i)' y_i \\ X_i' y_i \end{bmatrix}$$

where k is a user-defined value.

Let

$$\mathbf{R} = [Y_i X_i]$$

and

$$\hat{\mathbf{R}} = [\hat{Y}_i X_i]$$

The 2SLS estimator is defined as

$$\hat{\delta}_{i,2SLS} = [\hat{\mathbf{R}}' \hat{\mathbf{R}}]^{-1} \hat{\mathbf{R}}' y_i$$

Let \mathbf{y} and $\boldsymbol{\delta}$ be the vectors obtained by stacking the vectors of dependent variables and parameters for all G equations, and let \mathbf{R} and $\hat{\mathbf{R}}$ be the block diagonal matrices formed by R_i and \hat{R}_i , respectively.

The SUR and ITSUR estimators are defined as

$$\hat{\delta}_{(IT)SUR} = \left[\mathbf{R}' \left(\hat{\boldsymbol{\Sigma}}^{-1} \otimes \mathbf{I} \right) \mathbf{R} \right]^{-1} \mathbf{R}' \left(\hat{\boldsymbol{\Sigma}}^{-1} \otimes \mathbf{I} \right) \mathbf{y}$$

while the 3SLS and IT3SLS estimators are defined as

$$\hat{\delta}_{(IT)3SLS} = \left[\hat{\mathbf{R}}' (\hat{\Sigma}^{-1} \otimes \mathbf{I}) \hat{\mathbf{R}} \right]^{-1} \hat{\mathbf{R}}' (\hat{\Sigma}^{-1} \otimes \mathbf{I}) \mathbf{y}$$

where \mathbf{I} is the identity matrix, and $\hat{\Sigma}$ is an estimator of the cross-equation correlation matrix. For 3SLS, $\hat{\Sigma}$ is obtained from the 2SLS estimation, while for SUR it is derived from the OLS estimation. For IT3SLS and ITSUR, it is obtained iteratively from the previous estimation step, until convergence.

Computation of Standard Errors

The VARDEF= option in the PROC SYSLIN statement controls the denominator used in calculating the cross-equation covariance estimates and the parameter standard errors and covariances. The values of the VARDEF= option and the resulting denominator are as follows:

N	uses the number of nonmissing observations.
DF	uses the number of nonmissing observations less the degrees of freedom in the model.
WEIGHT	uses the sum of the observation weights given by the WEIGHTS statement.
WDF	uses the sum of the observation weights given by the WEIGHTS statement less the degrees of freedom in the model.

The VARDEF= option does not affect the model mean squared error, root mean squared error, or R^2 statistics. These statistics are always based on the error degrees of freedom, regardless of the VARDEF= option. The VARDEF= option also does not affect the dependent variable coefficient of variation (CV).

Reduced Form Estimates

The REDUCED option in the PROC SYSLIN statement computes estimates of the reduced form coefficients. The REDUCED option requires that the equation system be square. If there are fewer models than endogenous variables, IDENTITY statements can be used to complete the equation system.

The reduced form coefficients are computed as follows. Represent the equation system, with all endogenous variables moved to the left-hand side of the equations and identities, as

$$\mathbf{B}\mathbf{Y} = \mathbf{\Gamma}\mathbf{X}$$

Here \mathbf{B} is the estimated coefficient matrix for the endogenous variables \mathbf{Y} , and $\mathbf{\Gamma}$ is the estimated coefficient matrix for the exogenous (or predetermined) variables \mathbf{X} .

The system can be solved for \mathbf{Y} as follows, provided \mathbf{B} is square and nonsingular:

$$\mathbf{Y} = \mathbf{B}^{-1}\mathbf{\Gamma}\mathbf{X}$$

The reduced form coefficients are the matrix $\mathbf{B}^{-1}\mathbf{\Gamma}$.

Uncorrelated Errors across Equations

The SDIAG option in the PROC SYSLIN statement computes estimates by assuming uncorrelated errors across equations. As a result, when the SDIAG option is used, the 3SLS estimates are identical to 2SLS estimates, and the SUR estimates are the same as the OLS estimates.

Overidentification Restrictions

The OVERID option in the MODEL statement can be used to test for overidentifying restrictions on parameters of each equation. The null hypothesis is that the predetermined variables that do not appear in any equation have zero coefficients. The alternative hypothesis is that at least one of the assumed zero coefficients is nonzero. The test is approximate and rejects the null hypothesis too frequently for small sample sizes.

The formula for the test is given as follows. Let $y_i = \beta_i \mathbf{Y}_i + \gamma_i \mathbf{Z}_i + e_i$ be the i th equation. \mathbf{Y}_i are the endogenous variables that appear as regressors in the i th equation, and \mathbf{Z}_i are the instrumental variables that appear as regressors in the i th equation. Let N_i be the number of variables in \mathbf{Y}_i and \mathbf{Z}_i .

Let $v_i = y_i - \mathbf{Y}_i \hat{\beta}_i$. Let \mathbf{Z} represent all instrumental variables, T be the total number of observations, and K be the total number of instrumental variables. Define \hat{l} as follows:

$$\hat{l} = \frac{v'_i (\mathbf{I} - \mathbf{Z}_i (\mathbf{Z}'_i \mathbf{Z}_i)^{-1} \mathbf{Z}'_i) v_i}{v'_i (\mathbf{I} - \mathbf{Z} (\mathbf{Z}' \mathbf{Z})^{-1} \mathbf{Z}') v_i}$$

Then the test statistic

$$\frac{T - K}{K - N_i} (\hat{l} - 1)$$

is distributed approximately as an F with $K - N_i$ and $T - K$ degrees of freedom. See Basmann (1960) for more information.

Fuller's Modification to LIML

The ALPHA= option in the PROC SYSLIN and MODEL statements parameterizes Fuller's modification to LIML. This modification is $k = \gamma - (\alpha/(n - g))$, where α is the value of the ALPHA= option, γ is the LIML k value, n is the number of observations, and g is the number of predetermined variables. Fuller's modification is not used unless the ALPHA= option is specified. See Fuller (1977) for more information.

Missing Values

Observations that have a missing value for any variable in the analysis are excluded from the computations.

OUT= Data Set

The output SAS data set produced by the OUT= option in the PROC SYSLIN statement contains all the variables in the input data set and the variables that contain predicted values and residuals specified by OUTPUT statements.

The residuals are computed as actual values minus predicted values. Predicted values never use lags of other predicted values, as would be desirable for dynamic simulation. For these applications, PROC SIMLIN is available to predict or simulate values from the estimated equations.

OUTEST= Data Set

The OUTEST= option produces a TYPE=EST output SAS data set that contains estimates from the regressions. The variables in the OUTEST= data set are as follows:

BY variables	identifies the BY statement variables that are included in the OUTEST= data set.
TYPE	identifies the estimation type for the observations. The _TYPE_ value INST indicates first-stage regression estimates. Other values indicate the estimation method used: 2SLS indicates two-stage least squares results, 3SLS indicates three-stage least squares results, LIML indicates limited information maximum likelihood results, and so forth. Observations added by IDENTITY statements have the _TYPE_ value IDENTITY.
STATUS	identifies the convergence status of the estimation. _STATUS_ equals 0 when convergence criteria are met. Otherwise, _STATUS_ equals 1 when the estimation converges with a note, 2 when it converges with a warning, or 3 when it fails to converge.
MODEL	identifies the model label. The model label is the label specified in the MODEL statement or the dependent variable name if no label is specified. For first-stage regression estimates, _MODEL_ has the value FIRST.
DEPVAR	identifies the name of the dependent variable for the model.
NAME	identifies the names of the regressors for the rows of the covariance matrix, if the COVOUT option is specified. _NAME_ has a blank value for the parameter estimates observations. The _NAME_ variable is not included in the OUTEST= data set unless the COVOUT option is used to output the covariance of parameter estimates matrix.
SIGMA	contains the root mean squared error for the model, which is an estimate of the standard deviation of the error term. The _SIGMA_ variable contains the same values reported as Root MSE in the printed output.
INTERCEPT	identifies the intercept parameter estimates.
regressors	identifies the regressor variables from all the MODEL statements that are included in the OUTEST= data set. Variables used in IDENTIFY statements are also included in the OUTEST= data set.

The parameter estimates are stored under the names of the regressor variables. The intercept parameters are stored in the variable INTERCEPT. The dependent variable of the model is given a coefficient of -1 . Variables that are not in a model have missing values for the OUTEST= observations for that model.

Some estimation methods require computation of preliminary estimates. All estimates computed are output to the OUTEST= data set. For each BY group and each estimation, the OUTEST= data set contains one observation for each MODEL or IDENTITY statement. Results for different estimations are identified by the `_TYPE_` variable.

For example, consider the following statements:

```
proc syslin data=a outest=est 3sls;
  by b;
  endogenous y1 y2;
  instruments x1-x4;
  model y1 = y2 x1 x2;
  model y2 = y1 x3 x4;
  identity x1 = x3 + x4;
run;
```

The 3SLS method requires both a preliminary 2SLS stage and preliminary first-stage regressions for the endogenous variable. The OUTEST= data set thus contains three different kinds of estimates. The observations for the first-stage regression estimates have the `_TYPE_` value INST. The observations for the 2SLS estimates have the `_TYPE_` value 2SLS. The observations for the final 3SLS estimates have the `_TYPE_` value 3SLS.

Since there are two endogenous variables in this example, there are two first-stage regressions and two `_TYPE_=INST` observations in the OUTEST= data set. Since there are two model statements, there are two OUTEST= observations with `_TYPE_=2SLS` and two observations with `_TYPE_=3SLS`. In addition, the OUTEST= data set contains an observation with the `_TYPE_` value IDENTITY that contains the coefficients specified by the IDENTITY statement. All these observations are repeated for each BY group in the input data set defined by the values of the BY variable B.

When the COVOUT option is specified, the estimated covariance matrix for the parameter estimates is included in the OUTEST= data set. Each observation for parameter estimates is followed by observations that contain the rows of the parameter covariance matrix for that model. The row of the covariance matrix is identified by the variable `_NAME_`. For observations that contain parameter estimates, `_NAME_` is blank. For covariance observations, `_NAME_` contains the regressor name for the row of the covariance matrix and the regressor variables contain the covariances.

See [Example 26.1](#) for an example of the OUTEST= data set.

OUTSSCP= Data Set

The OUTSSCP= option produces a TYPE=SSCP output SAS data set that contains sums of squares and cross products. The data set contains all variables used in the MODEL, IDENTITY, and VAR

statements. Observations are identified by the variable `_NAME_`.

The `OUTSSCP=` data set can be useful when a large number of observations are to be explored in many different SYSLIN runs. The sum-of-squares-and-crossproducts matrix can be saved with the `OUTSSCP=` option and used as the `DATA=` data set on subsequent SYSLIN runs. This is much less expensive computationally because PROC SYSLIN never reads the original data again. In the step that creates the `OUTSSCP=` data set, include in the VAR statement all the variables you expect to use.

Printed Output

The printed output produced by the SYSLIN procedure is as follows:

1. If the `SIMPLE` option is used, a table of descriptive statistics is printed that shows the sum, mean, sum of squares, variance, and standard deviation for all the variables used in the models.
2. If the `FIRST` option is specified and an instrumental variables method is used, first-stage regression results are printed. The results show the regression of each endogenous variable on the variables in the `INSTRUMENTS` list.
3. The results of the second-stage regression are printed for each model. (See the following section “[Printed Output for Each Model](#)” on page 1657 for details.)
4. If a systems method like 3SLS, SUR, or FIML is used, the cross-equation error covariance matrix is printed. This matrix is shown four ways: the covariance matrix itself, the correlation matrix form, the inverse of the correlation matrix, and the inverse of the covariance matrix.
5. If a systems method like 3SLS, SUR, or FIML is used, the system weighted mean squared error and system weighted R^2 statistics are printed. The system weighted MSE and R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances.
6. If a systems method like 3SLS, SUR, or FIML is used, the final results are printed for each model.
7. If the `REDUCED` option is used, the reduced form coefficients are printed. These consist of the structural coefficient matrix for the endogenous variables, the structural coefficient matrix for the exogenous variables, the inverse of the endogenous coefficient matrix, and the reduced form coefficient matrix. The reduced form coefficient matrix is the product of the inverse of the endogenous coefficient matrix and the exogenous structural coefficient matrix.

Printed Output for Each Model

The results printed for each model include the analysis-of-variance table, the “Parameter Estimates” table, and optional items requested by TEST statements or by options in the MODEL statement.

The printed output produced for each model is described in the following.

The analysis-of-variance table includes the following:

- the model degrees of freedom, sum of squares, and mean square
- the error degrees of freedom, sum of squares, and mean square. The error mean square is computed by dividing the error sum of squares by the error degrees of freedom and is not affected by the VARDEF= option.
- the corrected total degrees of freedom and total sum of squares. Note that for instrumental variables methods, the model and error sums of squares do not add to the total sum of squares.
- the F ratio, labeled “F Value,” and its significance, labeled “PROB>F,” for the test of the hypothesis that all the nonintercept parameters are 0
- the root mean squared error. This is the square root of the error mean square.
- the dependent variable mean
- the coefficient of variation (CV) of the dependent variable
- the R^2 statistic. This R^2 is computed consistently with the calculation of the F statistic. It is valid for hypothesis tests but might not be a good measure of fit for models estimated by instrumental variables methods.
- the R^2 statistic adjusted for model degrees of freedom, labeled “Adj R-SQ”

The “Parameter Estimates” table includes the following:

- estimates of parameters for regressors in the model and the Lagrangian parameter for each restriction specified
- a degrees of freedom column labeled DF. Estimated model parameters have 1 degree of freedom. Restrictions have a DF of -1 . Regressors or restrictions dropped from the model due to collinearity have a DF of 0.
- the standard errors of the parameter estimates
- the t statistics, which are the parameter estimates divided by the standard errors
- the significance of the t tests for the hypothesis that the true parameter is 0, labeled “Pr > |t|.” As previously noted, the significance tests are strictly valid in finite samples only for OLS estimates but are asymptotically valid for the other methods.
- the standardized regression coefficients, if the STB option is specified. This is the parameter estimate multiplied by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable.
- the labels of the regressor variables or restriction labels

In addition to the analysis-of-variance table and the “Parameter Estimates” table, the results printed for each model can include the following:

- If TEST statements are specified, the test results are printed.
- If the DW option is specified, the Durbin-Watson statistic and first-order autocorrelation coefficient are printed.
- If the OVERID option is specified, the results of Basmann’s test for overidentifying restrictions are printed.
- If the PLOT option is used, plots of residual against each regressor are printed.
- If the COVB or CORRB options are specified, the results for each model also include the covariance or correlation matrix of the parameter estimates. For systems methods like 3SLS and FIML, the COVB and CORB output is printed for the whole system after the output for the last model, instead of separately for each model.

The third-stage output for 3SLS, SUR, IT3SLS, ITSUR, and FIML does not include the analysis-of-variance table. When a systems method is used, the second-stage output does not include the optional output, except for the COVB and CORRB matrices.

ODS Table Names

PROC SYSLIN assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. If the estimation method used is 3SLS, IT3SLS, ITSUR or SUR, you can obtain tables by specifying ODS OUTPUT CorrResiduals, InvCorrResiduals, InvCovResiduals.

Table 26.2 ODS Tables Produced in PROC SYSLIN

ODS Table Name	Description	Option
ANOVA	Summary of the SSE, MSE for the equations	default
AugXPXMat	Model crossproducts	XPX or USSCP
AutoCorrStat	Autocorrelation statistics	DW
ConvergenceStatus	Convergence status	default
CorrB	Correlations of parameters	CORRB
CorrResiduals	Correlations of residuals	
CovB	Covariance of parameters	COVB
CovResiduals	Covariance of residuals	
EndoMat	Endogenous variables	REDUCED
ExogMat	Exogenous variables	REDUCED
FitStatistics	Statistics of fit	default
InvCorrResiduals	Inverse correlations of residuals	
InvCovResiduals	Inverse covariance of residuals	

Table 26.2 (continued)

ODS Table Name	Description	Option
InvEndoMat	Inverse endogenous variables	REDUCED
InvXPX	$X'X$ inverse for system	I
IterHistory	Iteration printing	ITPRINT
MissingValues	Missing values generated by the program	default
ModelVars	Name and label for the model	default
ParameterEstimates	Parameter estimates	default
RedMat	Reduced form	REDUCED
SimpleStatistics	Descriptive statistics	SIMPLE
SSCP	Model crossproducts	XPX or USSCP
TestResults	Test for overidentifying restrictions	
Weight	Weighted model statistics	

ODS Graphics

This section describes the use of ODS for creating graphics with the SYSLIN procedure.

ODS Graph Names

PROC SYSLIN assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in [Table 26.3](#).

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 26.3 ODS Graphics Produced by PROC SYSLIN

ODS Graph Name	Plot Description
ActualByPredicted	Predicted versus actual plot
QQPlot	Q-Q plot of residuals
ResidualHistogram	Histogram of the residuals
ResidualPlot	Residual plot

Examples: SYSLIN Procedure

Example 26.1: Klein's Model I Estimated with LIML and 3SLS

This example uses PROC SYSLIN to estimate the classic Klein Model I. For a discussion of this model, see Theil (1971). The following statements read the data.

```

*-----Klein's Model I-----*
| By L.R. Klein, Economic Fluctuations in the United States, 1921-1941 |
| (1950), NY: John Wiley. A macro-economic model of the U.S. with |
| three behavioral equations, and several identities. See Theil, p.456. |

```

The following statements estimate the Klein model using the limited information maximum likelihood method. In addition, the parameter estimates are written to a SAS data set with the OUTEST= option.

```
proc syslin data=klein outest=b liml;
  endogenous c p w i x wsum k y;
  instruments klag plag xlag wp g t yr;
  consume: model c = p plag wsum;
  invest:  model i = p plag klag;
  labor:   model w = x xlag yr;
run;

proc print data=b;
run;
```

The PROC SYSLIN estimates are shown in [Output 26.1.1](#) through [Output 26.1.3](#).

The following statements estimate the model using the 3SLS method. The reduced form estimates are produced by the REDUCED option; IDENTITY statements are used to make the model complete.

```
proc syslin data=klein 3sls reduced;
  endogenous c p w i x wsum k y;
  instruments klag plag xlag wp g t yr;
  consume: model    c = p plag wsum;
  invest:  model    i = p plag klag;
  labor:   model    w = x xlag yr;
  product: identity x = c + i + g;
  income:  identity y = c + i + g - t;
  profit:  identity p = y - w;
  stock:   identity k = klag + i;
  wage:    identity wsum = w + wp;
run;
```

The preliminary 2SLS results and estimated cross-model covariance matrix are not shown. The 3SLS estimates are shown in [Output 26.1.5](#) through [Output 26.1.7](#). The reduced form estimates are shown in [Output 26.1.8](#) through [Output 26.1.11](#).

Example 26.2: Grunfeld's Model Estimated with SUR

The following example was used by Zellner in his classic 1962 paper on seemingly unrelated regressions. Different stock prices often move in the same direction at a given point in time. The SUR technique might provide more efficient estimates than OLS in this situation.

The following statements read the data. (The prefix GE stands for General Electric and WH stands for Westinghouse.)

```

Example 26.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics. This is a continuation of the section “[Example 26.1: Klein’s Model I Estimated with LIML and 3SLS](#)” on page 1661. These graphical displays are requested by specifying the ODS GRAPHICS statement before running PROC SYSLIN. For information about the graphics available in the SYSLIN procedure, see the section “[ODS Graphics](#)” on page 1660.

The following statements show how to generate ODS graphics plots with the SYSLIN procedure. The plots of residuals for each one of the equations in the model are displayed in [Figure 26.3.1](#) through [Figure 26.3.3](#).

Overview: *TIMESERIES* Procedure

The *TIMESERIES* procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format. The procedure can perform trend and seasonal analysis on the transactions. After the transactional data are accumulated, time domain and frequency domain analysis can be performed on the accumulated time series.

For seasonal analysis of the transaction data, various statistics can be computed for each season. For trend analysis of the transaction data, various statistics can be computed for each time period. The analysis is similar to applying the *MEANS* procedure of Base SAS software to each season or time period of concern.

After the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple and/or seasonal differencing. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

Time series analyses performed by the *TIMESERIES* procedure include:

- descriptive (global) statistics
- seasonal decomposition/adjustment analysis
- correlation analysis
- cross-correlation analysis

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

The *TIMESERIES* procedure can process large amounts of time-stamped transactional data. Therefore, the analysis results are useful for large-scale time series analysis or (temporal) data mining. All of the results can be stored in output data sets in either a time series format (default) or in a coordinate format (transposed). The time series format is useful for preparing the data for subsequent analysis with other SAS/ETS procedures. For example, the working time series can be further analyzed, modeled, and forecast with other SAS/ETS procedures. The coordinate format is useful

when using this procedure with SAS/STAT procedures or SAS Enterprise Miner. For example, clustering time-stamped transactional data can be achieved by using the results of this procedure with the clustering procedures of SAS/STAT and the nodes of SAS Enterprise Miner.

The EXPAND procedure can be used for the frequency conversion and transformations of time series output from this procedure.

Getting Started: TIMESERIES Procedure

This section outlines the use of the TIMESERIES procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMESERIES procedure can form time series as follows:

```
PROC TIMESERIES DATA=<input-data-set>
                OUT=<output-data-set>;
  ID <time-ID-variable> INTERVAL=<frequency>
    ACCUMULATE=<statistic>;
  VAR <time-series-variables>;
RUN;
```

The TIMESERIES procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS).

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains four variables that are related to these transactions: CUSTOMER, DATE, WITHDRAWAL, and DEPOSITS. The following examples illustrate possible ways to analyze these transactions by using the TIMESERIES procedure.

To accumulate the time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and DEPOSITS), the following TIMESERIES procedure statements can be used:

```
proc timeseries data=transactions
                out=timeseries;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The `OUT=TIMESERIES` option specifies that the resulting time series data for each customer is to be stored in the data set `WORK.TIMESERIES`. The `INTERVAL=DAY` option specifies that the transactions are to be accumulated on a daily basis. The `ACCUMULATE=TOTAL` option specifies that the sum of the transactions is to be calculated. After the transactional data is accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the resulting time series data.

For example, the ARIMA procedure can be used to model and forecast each customer's withdrawal data by using an $ARIMA(0,1,1)(0,1,1)_s$ model (where the number of seasons is $s=7$ days in a week) using the following statements:

```
proc arima data=timeseries;
    identify var=withdrawals(1,7) noprint;
    estimate q=(1)(7) outest=estimates noprint;
    forecast id=date interval=day out=forecasts;
quit;
```

The `OUTEST=ESTIMATES` data set contains the parameter estimates of the model specified. The `OUT=FORECASTS` data set contains forecasts based on the model specified. See the SAS/ETS ARIMA procedure for more detail.

A single set of transactions can be very large and must be summarized in order to analyze them effectively. Analysts often want to examine transactional data for trends and seasonal variation. To analyze transactional data for trends and seasonality, statistics must be computed for each time period and season of concern. For each observation, the time period and season must be determined and the data must be analyzed based on this determination.

The following statements illustrate how to use the `TIMESERIES` procedure to perform trend and seasonal analysis of time-stamped transactional data.

```
proc timeseries data=transactions out=out
    outseason=season outtrend=trend;
    by customer;
    id date interval=day accumulate=total;
    var withdrawals deposits;
run;
```

Since the `INTERVAL=DAY` option is specified, the length of the seasonal cycle is seven (7) where the first season is Sunday and the last season is Saturday. The output data set specified by the `OUTSEASON=SEASON` option contains the seasonal statistics for each day of the week by each customer. The output data set specified by the `OUTTREND=TREND` option contains the trend statistics for each day of the calendar by each customer.

Often it is desired to seasonally decompose into seasonal, trend, cycle, and irregular components or to seasonally adjust a time series. The following techniques describe how the changing seasons influence the time series.

The following statements illustrate how to use the `TIMESERIES` procedure to perform seasonal adjustment/decomposition analysis of time-stamped transactional data.

```
proc timeseries data=transactions
                out=out
                outdecomp=decompose;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The output data set specified by the OUTDECOMP=DECOMPOSE data set contains the decomposed/adjusted time series for each customer.

A single time series can be very large. Often, a time series must be summarized with respect to time lags in order to be efficiently analyzed using time domain techniques. These techniques help describe how a current observation is related to the past observations with respect to the time (season) lag.

The following statements illustrate how to use the TIMESERIES procedure to perform time domain analysis of time-stamped transactional data.

```
proc timeseries data=transactions
                out=out
                outcorr=timedomain;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The output data set specified by the OUTCORR=TIMEDOMAIN data set contains the time domain statistics, such as sample autocorrelations and partial autocorrelations, by each customer.

By default, the TIMESERIES procedure produces no printed output.

Syntax: TIMESERIES Procedure

The following statements are used with the TIMESERIES procedure:

```
PROC TIMESERIES options ;
  BY variables ;
  CORR statistics-list / options ;
  CROSSCORR statistics-list / options ;
  CROSSVAR variable-list / options ;
  DECOMP component-list / options ;
  ID variable INTERVAL= interval-option ;
  SEASON statistics-list / options ;
  TREND statistics-list / options ;
  VAR variable-list / options ;
```

Functional Summary

Table 27.1 summarizes the statements and options that control the TIMESERIES procedure.

Table 27.1 TIMESERIES Functional Summary

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify variables to analyze	VAR	
specify cross variables to analyze	CROSSVAR	
specify the time ID variable	ID	
specify correlation options	CORR	
specify cross-correlation options	CROSSCORR	
specify decomposition options	DECOMP	
specify seasonal statistics options	SEASON	
specify trend statistics options	TREND	
Data Set Options

Miscellaneous Options		
specify that analysis variables be processed in sorted order	PROC TIMESERIES	SORTNAMES
limit error and warning messages	PROC TIMESERIES	MAXERROR=
ODS Graphics Options		
specify the cross-variable graphical output	PROC TIMESERIES	CROSSPLOT=
specify the variable graphical output	PROC TIMESERIES	PLOT=

PROC TIMESERIES Statement

PROC TIMESERIES *options* ;

The following options can be used in the PROC TIMESERIES statement:

DATA= *SAS-data-set*

names the SAS data set that contains the input data for the procedure to create the time series. If the DATA= option is not specified, the most recently created SAS data set is used.

CROSSPLOTS= *option* | (*options*)

specifies the cross-variable graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES	plots the time series (OUT= data set).
CCF	plots the cross-correlation functions (OUTCROSSCORR= data set).
ALL	same as PLOTS=(SERIES CCF).

For example, CROSSPLOTS=SERIES plots the two time series. The CROSSPLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The CROSSPLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

MAXERROR= *number*

limits the number of warning and error messages that are produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

OUT= *SAS-data-set*

names the output data set to contain the time series variables specified in the subsequent VAR and CROSSVAR statements. If BY variables are specified, they are also included in the OUT= data set. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= or the ACCUMULATE= option or both. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTCORR= *SAS-data-set*

names the output data set to contain the univariate time domain statistics.

OUTCROSSCORR= *SAS-data-set*

names the output data set to contain the cross-correlation statistics.

OUTDECOMP= *SAS-data-set*

names the output data set to contain the decomposed and/or seasonally adjusted time series.

OUTSEASON= *SAS-data-set*

names the output data set to contain the seasonal statistics. The statistics are computed for each season as specified by the ID statement INTERVAL= option or the PROC TIMESERIES

statement SEASONALITY= option. The OUTSEASON= data set is particularly useful when analyzing transactional data for seasonal variations.

OUTSUM= *SAS-data-set*

names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the ACCUMULATE= and/or SETMISSING= options are specified in the ID or VAR statements. The OUTSUM= data set is particularly useful when analyzing large numbers of series and a summary of the results are needed.

OUTTREND= *SAS-data-set*

names the output data set to contain the trend statistics. The statistics are computed for each time period as specified by the ID statement INTERVAL= option. The OUTTREND= data set is particularly useful when analyzing transactional data for trends.

PLOTS= *option | (options)*

specifies the univariate graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES	plots the time series (OUT= data set).
RESIDUAL	plots the residual time series (OUT= data set).
CYCLES	plots the seasonal cycles (OUT= data set).
CORR	plots the correlation panel (OUTCORR= data set).
ACF	plots the autocorrelation function (OUTCORR= data set).
PACF	plots the partial autocorrelation function (OUTCORR= data set).
IACF	plots the inverse autocorrelation function (OUTCORR= data set).
WN	plots the white noise probabilities (OUTCORR= data set).
DECOMP	plots the seasonal adjustment panel (OUTDECOMP= data set).
TCS	plots the trend-cycle-seasonal component (OUTDECOMP= data set).
TCC	plots the trend-cycle component (OUTDECOMP= data set).
SIC	plots the seasonal-irregular component (OUTDECOMP= data set).
SC	plots the seasonal component (OUTDECOMP= data set).
SA	plots the seasonal adjusted component (OUTDECOMP= data set).
PCSA	plots the percent change in the seasonal adjusted component (OUTDECOMP= data set).
IC	plots the irregular component (OUTDECOMP= data set).
TC	plots the trend component (OUTDECOMP= data set).
CC	plots the cycle component (OUTDECOMP= data set).
ALL	same as PLOTS=(SERIES ACF PACF IACF WN).

For example, PLOTS=SERIES plots the time series. The PLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The PLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINT= *option* | (*options*)

specifies the printed output desired. By default, the TIMESERIES procedure produces no printed output. The following printing options are available:

DECOMP	prints the seasonal decomposition/adjustment table (OUTDECOMP= data set).
SEASONS	prints the seasonal statistics table (OUTSEASON= data set).
DESCSTATS	prints the descriptive statistics for the accumulated time series (OUTSUM= data set).
SUMMARY	prints the descriptive statistics table for all time series (OUTSUM= data set).
TRENDS	prints the trend statistics table (OUTTREND= data set).

For example, PRINT=SEASONS prints the seasonal statistics. The PRINT= option produces printed output for these results by using the Output Delivery System (ODS). The PRINT= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINTDETAILS

specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY= *number*

specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES

specifies that the variables specified in the VAR and CROSSVAR statements be processed in sorted order by the variable names. This option allows the output data sets to be presorted by the variable names.

BY Statement

A BY statement can be used with PROC TIMESERIES to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIME-SERIES procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CORR Statement

CORR *statistics* < / *options* > ;

A CORR statement can be used with the TIMESERIES procedure to specify options related to time domain analysis of the accumulated time series. Only one CORR statement is allowed.

The following time domain statistics are available:

LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	two standard errors beyond autocorrelations
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	two standard errors beyond partial autocorrelations
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	inverse autocorrelation standard errors
IACF2STD	two standard errors beyond inverse autocorrelations
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities

IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

If none of the correlation statistics are specified, the default is as follows:

```
corr lag n acov acf acfstd pacf pacfstd iacf iacfstd wn wnprob;
```

The following options can be specified in the CORR statement following the slash (/):

NLAG= *number*

specifies the number of lags to be stored in the OUTCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

LAGS= (*numlist*)

specifies the list of lags to be stored in OUTCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

NPARMS= *number*

specifies the number of parameters used in the model that created the residual time series. The number of parameters determines the degrees of freedom associated with the Ljung-Box statistics. The default is NPARMS=0. This option is useful when analyzing the residuals of a time series model with the number of parameters specified by NPARMS=*number* option.

TRANSPOSE= NO|YES

TRANSPOSE=YES specifies that the OUTCORR= data set is recorded with the lags as the column names instead of with the correlation statistics as the column names. The TRANSPOSE=NO option is useful for graphing the correlation results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the correlation results from other SAS procedures such as the CLUSTER procedure of SAS/STAT or SAS Enterprise Miner. The default is TRANSPOSE=NO.

CROSSCORR Statement

```
CROSSCORR statistics < / options > ;
```

A CROSSCORR statement can be used with the TIMESERIES procedure to specify options that are related to cross-correlation analysis of the accumulated time series. Only one CROSSCORR statement is allowed.

The following time domain statistics are available:

LAG	time lag
N	number of variance products
CCOV	cross covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	two standard errors beyond cross-correlation
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

If none of the cross-correlation statistics are specified, the default is as follows:

```
crosscorr lag n ccov ccf ccfstd;
```

The following options can be specified in the CROSSCORR statement following the slash (/):

NLAG= *number*

specifies the number of lags to be stored in the OUTCROSSCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

LAGS= (*numlist*)

specifies a list of lags to be stored in OUTCROSSCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

TRANSPPOSE= NO|YES

TRANSPPOSE=YES specifies that the OUTCROSSCORR= data set be recorded with the lags as the column names instead of with the cross-correlation statistics as the column names. The TRANSPPOSE=NO option is useful for graphing the cross-correlation results with SAS/GRAPH procedures. The TRANSPPOSE=YES option is useful for analyzing the cross-correlation results from using other procedures such as the CLUSTER procedure of SAS/STAT or SAS Enterprise Miner. The default is TRANSPPOSE=NO.

DECOMP Statement

```
DECOMP components < / options > ;
```

A DECOMP statement can be used with the TIMESERIES procedure to specify options related to classical seasonal decomposition of the time series data. Only one DECOMP statement is allowed. The options specified affect all variables listed in the VAR statements. Decomposition can be performed only when the length of the seasonal cycle specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option is greater than one.

The following seasonal decomposition components are available:

ORIG originAL	original series
TCC TRENDCYCLE	trend-cycle component
SIC SEASONIRREGULAR	seasonal-irregular component
SC seasonal	seasonal component
SCSTD	seasonal component standard errors
TCS TRENDCYCLESEASON	trend-cycle-seasonal component
IC IRREGULAR	irregular component
SA ADJUSTED	seasonally adjusted series
PCSA	percent change seasonally adjusted series
TC	trend component
CC CYCLE	cycle component

If none of the components are specified, the default is as follows:

```
decomp orig tcc sc ic sa;
```

The following options can be specified in the DECOMP statement following the slash (/):

MODE= *option*

specifies the type of decomposition to be used to decompose the time series. The following values can be specified for the MODE= option:

ADD ADDITIVE	additive decomposition
MULT MULTIPLICATIVE	multiplicative decomposition
LOGADD LOGADDITIVE	log-additive decomposition
PSEUDOADD PSEUDOADDITIVE	pseudo-additive decomposition
MULTORADD	multiplicative or additive decomposition, depending on data

Multiplicative and log additive decomposition require strictly positive time series. If the accumulated time series contains nonpositive values and the MODE=MULT or MODE=LOGADD option is specified, an error results. Pseudo-additive decomposition requires a nonnegative-valued time series. If the accumulated time series contains negative values and the MODE=PSEUDOADD option is specified, an error results. The MODE=MULTORADD option specifies that multiplicative decomposition be used when the accumulated time series contains only positive values, that pseudo-additive decomposition be used when the accumulated time series contains only nonnegative values, and that additive decomposition be used otherwise. The default is MODE=MULTORADD.

LAMBDA= *number*

specifies the Hodrick-Prescott filter parameter for trend-cycle decomposition. The default is LAMBDA=1600. Filtering applies when the trend component or the cycle component is requested. If filtering is not specified, this option is ignored.

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTDECOMP= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE=NO option is specified, the NPERIODS= option is ignored. If the NPERIODS= option is positive, the first or beginning time periods are recorded. If the NPERIODS= option is negative, the last or ending time periods are recorded. The NPERIODS= option specifies the number of OUTDECOMP= data set variables to contain the seasonal decomposition and is therefore limited to the maximum allowable number of SAS variables. If the number of time periods exceeds this limit, a warning is printed in the log and the number periods stored is reduced to the limit.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If either of the START= or END= options are not specified, the default magnitude is the seasonality specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option. If only the START= option is specified, the default sign is positive. If only the END= option is specified, the default sign is negative.

TRANSPOSE= NO | YES

TRANSPOSE=YES specifies that the OUTDECOMP= data set be recorded with the time periods as the column names instead of with the statistics as the column names. The first and last time periods stored in the OUTDECOMP= data set correspond to the period of the ID statement START= option and END= option, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for analyzing or displaying the decomposition results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the decomposition results from using other SAS procedures or SAS Enterprise Miner. The default is TRANSPOSE=NO.

ID Statement

ID *variable* INTERVAL=*interval* < *options* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The information specified affects all variables listed in subsequent VAR statements. If the ID statement is specified, the INTERVAL= option must also be used. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following options can be used with the ID statement:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following options determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE AVG	Observations are accumulated based on the average of their values.
MINIMUM MIN	Observations are accumulated based on the minimum of their values.
MEDIAN MED	Observations are accumulated based on the median of their values.
MAXIMUM MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are to be treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. The section “[Details: TIMESERIES Procedure](#)” on page 1699 describes accumulation in greater detail.

ALIGN= *option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option accepts the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

END= *option*

specifies a SAS date, datetime, or time value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. The START= and END= options can be used to ensure that data associated within each BY group contains the same number of observations.

FORMAT= *format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied from the INTERVAL= option.

INTERVAL= *interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the PROC TIMESERIES statement SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations. The INTERVAL= option is required and must be the first option specified in the ID statement.

NOTSORTED

specifies that the time ID values not be in sorted order. The TIMESERIES procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING= *option | number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series. If a number is specified, missing values are set to the number. If a missing value indicates an unknown value, this option should not be used. If a missing value indicates no value, SETMISSING=0 should be used. You would typically use SETMISSING=0 for transactional data because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE AVG	Missing values are set to the accumulated average value.
MINIMUM MIN	Missing values are set to the accumulated minimum value.
MEDIAN MED	Missing values are set to the accumulated median value.
MAXIMUM MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS PREV	Missing values are set to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START= *option*

specifies a SAS date, datetime, or time value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prepended with missing values. If the first time ID variable value is less than the START= value, the series is truncated. The START= and END= options can be used to ensure that data associated with each by group contains the same number of observations.

SEASON Statement

SEASON *statistics* < / *options* > ;

A SEASON statement can be used with the TIMESERIES procedure to specify options that are related to seasonal analysis of the time-stamped transactional data. Only one SEASON statement is allowed. The options specified affect all variables specified in the VAR statements. Seasonal analysis can be performed only when the length of the seasonal cycle specified by the PROC TIME-SERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option is greater than one.

The following seasonal statistics are available:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If none of the season statistics are specified, the default is as follows:

```
season n min max mean std;
```

The following option can be specified in the SEASON statement following the slash (/):

TRANSPPOSE= NO | YES

TRANSPPOSE=YES specifies that the OUTSEASON= data set be recorded with the seasonal

indices as the column names instead of with the statistics as the column names. The TRANSPOSE=NO option is useful for graphing the seasonal analysis results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the seasonal analysis results using other SAS procedures or SAS Enterprise Miner. The default is TRANSPOSE=NO.

TREND Statement

TREND *statistics* < / *options* > ;

A TREND statement can be used with the TIMESERIES procedure to specify options related to trend analysis of the time-stamped transactional data. Only one TREND statement is allowed. The options specified affect all variables specified in the VAR statements.

The following trend statistics are available:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
sum	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If none of the trend statistics are specified, the default is as follows:

```
trend n min max mean std;
```

The following options can be specified in the TREND statement following the slash (/):

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTTREND= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTTREND= data set variables to contain the trend statistics and is therefore limited to the maximum allowable number of SAS variables.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options is stored. If either of the START= or END= options are not

specified, the default is the seasonality specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option. If the seasonality is zero, the default is NPERIODS=5.

TRANSPPOSE= NO | YES

TRANSPPOSE=YES specifies that the OUTTREND= data set be recorded with the time periods as the column names instead of with the statistics as the column names. The first and last time periods stored in the OUTTREND= data set correspond to the period of the ID statement START= and END= options, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPPOSE=NO option is useful for analyzing or displaying the trend analysis results with SAS/GRAPH procedures. The TRANSPPOSE=YES option is useful for analyzing the trend analysis results from using other SAS procedures or SAS Enterprise Miner. The default is TRANSPPOSE=YES.

VAR and CROSSVAR Statements

VAR *variable-list* < / options > ;

CROSSVAR *variable-list* < / options > ;

The VAR and CROSSVAR statements list the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR or CROSSVAR statement. Any number of VAR and CROSSVAR statements can be used. The following options can be used with the VAR and CROSSVAR statements:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period for the variables listed in the VAR or CROSSVAR statement. If the ACCUMULATE= option is not specified in the VAR or CROSSVAR statement, accumulation is determined by the ACCUMULATE= option of the ID statement. See the ID statement ACCUMULATE= option for more details.

DIF=(*numlist*)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first then third order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option.

SDIF=(*numlist*)

specifies the seasonal differencing to be applied to the accumulated time series. The list

of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first then third order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option.

SETMISS= *option* | *number*

SETMISSING= *option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series for variables listed in the VAR or CROSSVAR statement. If the SETMISSING= option is not specified in the VAR or CROSSVAR statement, missing values are set based on the SETMISSING= option of the ID statement. See the ID statement SETMISSING= option for more details.

TRANSFORM= *option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	logarithmic transformation
SQRT	square-root transformation
LOGISTIC	logistic transformation
BOXCOX(<i>n</i>)	Box-Cox transformation with parameter number where the number is between -5 and 5

When the TRANSFORM= option is specified, the time series must be strictly positive.

Details: TIMESERIES Procedure

The TIMESERIES procedure can be used to perform trend and seasonal analysis on transactional data. For trend analysis, various sample statistics are computed for each time period defined by the time ID variable and INTERVAL= option. For seasonal analysis, various sample statistics are computed for each season defined by the INTERVAL= or the SEASONALITY= option. For example, if the transactional data ranges from June 1990 to January 2000 and the data are to be accumulated on a monthly basis, then the trend statistics are computed for every month: June 1990, July 1990, ..., January 2000. The seasonal statistics are computed for each season: January, February, ..., December.

The TIMESERIES procedure can be used to form time series data from transactional data. The accumulated time series can then be analyzed using time series techniques. The data is analyzed in the order described.

1. accumulation ACCUMULATE= option
2. missing value interpretation SETMISSING= option

- | | |
|-------------------------------|---|
| 3. time series transformation | TRANSFORM= option |
| 4. time series differencing | DIF= and SDIF= option |
| 5. descriptive statistics | OUTSUM= option, PRINT=DESCSTATS |
| 6. seasonal decomposition | DECOMP statement, OUTDECOMP= option |
| 7. correlation analysis | CORR statement, OUTCORR= option |
| 8. cross-correlation analysis | CROSSCORR statement, OUTCROSSCORR= option |

Accumulation

If the ACCUMULATE= option in the ID, VAR, or CROSSVAR statement is specified, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the ID statement INTERVAL= option. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```

19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20

```

If the INTERVAL=MONTH is specified, all of the above observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is:

```

01MAR1999    40
01APR1999    .
01MAY1999    90

```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is:

```

01MAR1999    20
01APR1999    .
01MAY1999    30

```

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is:

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the resulting time series is:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the resulting time series is:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the resulting time series is:

```
O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32
```

As can be seen from the above examples, even though the data set observations contain no missing values, the accumulated time series can have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should

be interpreted as no value—that is, zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

There are four transformations available for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation.

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation.

$$w_t = \ln(cy_t/(1 - cy_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square root is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed by using the EXPAND procedure of SAS/ETS.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced by using the VAR and CROSSVAR statement DIF= and SDIF= options. For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally, assuming y_t is strictly positive, the VAR and CROSSVAR statement TRANSFORM=, DIF=, and SDIF= options can be combined.

Descriptive Statistics

Descriptive statistics can be computed from the working series by specifying the `OUTSUM=` option or `PRINT=DESCSTATS`.

Seasonal Decomposition

Seasonal decomposition/analysis can be performed on the working series by specifying the `OUTDECOMP=` option, the `PRINT=DECOMP` option, or one of the `PLOTS=` options associated with decomposition in the `PROC TIMESERIES` statement. The `DECOMP` statement enables you to specify options related to decomposition. The `TIMESERIES` procedure uses classical decomposition. More complex seasonal decomposition/adjustment analysis can be performed by using the `X11` or the `X12` procedure of `SAS/ETS`.

The `DECOMP` statement `MODE=` option determines the mode of the seasonal adjustment decomposition to be performed. There are four modes: multiplicative (`MODE=MULT`), additive (`MODE=ADD`), pseudo-additive (`MODE=PSEUDOADD`), and log-additive (`MODE=LOGADD`) decomposition. The default is `MODE=MULTORADD` which specifies `MODE=MULT` for series that are strictly positive, `MODE=PSEUDOADD` for series that are nonnegative, and `MODE=ADD` for series that are not nonnegative.

When `MODE=LOGADD` is specified, the components are exponentiated to the original metric.

The `DECOMP` statement `LAMBDA=` option specifies the Hodrick-Prescott filter parameter (Hodrick and Prescott 1980). The default is `LAMBDA=1600`. The Hodrick-Prescott filter is used to decompose the trend-cycle component into the trend component and cycle component in an additive fashion. A smaller parameter assigns less significance to the cycle; that is, `LAMBDA=0` implies no cycle component.

The notation and keywords associated with seasonal decomposition/adjustment analysis are defined in [Table 27.2](#).

Table 27.2 Seasonal Adjustment Formulas

Component	Keyword	MODE= Option	Formula
original series	ORIGINAL	MULT	$O_t = TC_t S_t I_t$
		ADD	$O_t = TC_t + S_t + I_t$
		LOGADD	$\log(O_t) = TC_t + S_t + I_t$
		PSEUDOADD	$O_t = TC_t(S_t + I_t - 1)$
trend-cycle component	TCC	MULT	centered moving average of O_t
		ADD	centered moving average of O_t
		LOGADD	centered moving average of $\log(O_t)$
		PSEUDOADD	centered moving average of O_t
seasonal-irregular component	SIC	MULT	$SI_t = S_t I_t = O_t / TC_t$
		ADD	$SI_t = S_t + I_t = O_t - TC_t$
		LOGADD	$SI_t = S_t + I_t = \log(O_t) - TC_t$
		PSEUDOADD	$SI_t = S_t + I_t - 1 = O_t / TC_t$
seasonal component	SC	MULT	seasonal Averages of SI_t
		ADD	seasonal Averages of SI_t
		LOGADD	seasonal Averages of SI_t
		PSEUDOADD	seasonal Averages of SI_t
irregular component	IC	MULT	$I_t = SI_t / S_t$
		ADD	$I_t = SI_t - S_t$
		LOGADD	$I_t = SI_t - S_t$
		PSEUDOADD	$I_t = SI_t - S_t + 1$
trend-cycle-seasonal component	TCS	MULT	$TCS_t = TC_t S_t = O_t / I_t$
		ADD	$TCS_t = TC_t + S_t = O_t - I_t$
		LOGADD	$TCS_t = TC_t + S_t = O_t - I_t$
		PSEUDOADD	$TCS_t = TC_t S_t$
trend component	TC	MULT	$T_t = TC_t - C_t$
		ADD	$T_t = TC_t - C_t$
		LOGADD	$T_t = TC_t - C_t$
		PSEUDOADD	$T_t = TC_t - C_t$
cycle component	CC	MULT	$C_t = TC_t - T_t$
		ADD	$C_t = TC_t - T_t$
		LOGADD	$C_t = TC_t - T_t$
		PSEUDOADD	$C_t = TC_t - T_t$
seasonally adjusted series	SA	MULT	$SA_t = O_t / S_t = TC_t I_t$
		ADD	$SA_t = O_t - S_t = TC_t + I_t$
		LOGADD	$SA_t = O_t / \exp(S_t) = \exp(TC_t + I_t)$
		PSEUDOADD	$SA_t = TC_t I_t$

The trend-cycle component is computed from the s -period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} y_{t+k} / s$$

The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{T/s}$$

where $0 \leq j \leq T/s$ and $1 \leq k \leq s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

Correlation Analysis

Correlation analysis can be performed on the working series by specifying the OUTCORR= option or one of the PLOTS= options that are associated with correlation. The CORR statement enables you to specify options that are related to correlation analysis.

Autocovariance Statistics

LAGS	$h \in \{0, \dots, H\}$
N	N_h is the number of observed products at lag h , ignoring missing values
ACOV	$\hat{\gamma}(h) = \frac{1}{T} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$
ACOV	$\hat{\gamma}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$ when embedded missing values are present

Autocorrelation Statistics

ACF	$\hat{\rho}(h) = \hat{\gamma}(h)/\hat{\gamma}(0)$
ACFSTD	$Std(\hat{\rho}(h)) = \sqrt{\frac{1}{T} \left(1 + 2 \sum_{j=1}^{h-1} \hat{\rho}(j)^2\right)}$
ACFNORM	$Norm(\hat{\rho}(h)) = \hat{\rho}(h)/Std(\hat{\rho}(h))$
ACFPROB	$Prob(\hat{\rho}(h)) = 2(1 - \Phi(Norm(\hat{\rho}(h))))$
ACFLPROB	$LogProb(\hat{\rho}(h)) = -\log_{10}(Prob(\hat{\rho}(h)))$
ACF2STD	$Flag(\hat{\rho}(h)) = \begin{cases} 1 & \hat{\rho}(h) > 2Std(\hat{\rho}(h)) \\ 0 & -2Std(\hat{\rho}(h)) < \hat{\rho}(h) < 2Std(\hat{\rho}(h)) \\ -1 & \hat{\rho}(h) < -2Std(\hat{\rho}(h)) \end{cases}$

Partial Autocorrelation Statistics

PACF	$\hat{\phi}(h) = \Gamma_{(0,h-1)}\{\gamma_j\}_{j=1}^h$
PACFSTD	$Std(\hat{\phi}(h)) = 1/\sqrt{N_0}$
PCFNORM	$Norm(\hat{\phi}(h)) = \hat{\phi}(h)/Std(\hat{\phi}(h))$
PACFPROB	$Prob(\hat{\phi}(h)) = 2(1 - \Phi(Norm(\hat{\phi}(h))))$

PACFLPROB	$LogProb(\hat{\varphi}(h)) = -\log_{10}(Prob(\hat{\varphi}(h)))$
PACF2STD	$Flag(\hat{\varphi}(h)) = \begin{cases} 1 & \hat{\varphi}(h) > 2Std(\hat{\varphi}(h)) \\ 0 & -2Std(\hat{\varphi}(h)) < \hat{\varphi}(h) < 2Std(\hat{\varphi}(h)) \\ -1 & \hat{\varphi}(h) < -2Std(\hat{\varphi}(h)) \end{cases}$

Inverse Autocorrelation Statistics

IACF	$\hat{\theta}(h)$
IACFSTD	$Std(\hat{\theta}(h)) = 1/\sqrt{N_0}$
IACFNORM	$Norm(\hat{\theta}(h)) = \hat{\theta}(h)/Std(\hat{\theta}(h))$
IACFPROB	$Prob(\hat{\theta}(h)) = 2 \left(1 - \Phi \left(Norm(\hat{\theta}(h)) \right) \right)$
IACFLPROB	$LogProb(\hat{\theta}(h)) = -\log_{10}(Prob(\hat{\theta}(h)))$
IACF2STD	$Flag(\hat{\theta}(h)) = \begin{cases} 1 & \hat{\theta}(h) > 2Std(\hat{\theta}(h)) \\ 0 & -2Std(\hat{\theta}(h)) < \hat{\theta}(h) < 2Std(\hat{\theta}(h)) \\ -1 & \hat{\theta}(h) < -2Std(\hat{\theta}(h)) \end{cases}$

White Noise Statistics

WN	$Q(h) = T(T+2) \sum_{j=1}^h \rho(j)^2 / (T-j)$
WN	$Q(h) = \sum_{j=1}^h N_j \rho(j)^2$ when embedded missing values are present
WNPROB	$Prob(Q(h)) = \chi_{\max(1, h-p)}(Q(h))$
WNLPROB	$LogProb(Q(h)) = -\log_{10}(Prob(Q(h)))$

Cross-Correlation Analysis

Cross-correlation analysis can be performed on the working series by specifying the OUTCROSS-CORR= option or one of the CROSSPLOTS= options that are associated with cross-correlation. The CROSSCORR statement enables you to specify options that are related to cross-correlation analysis.

Cross-Correlation Statistics

LAGS	$h \in \{0, \dots, H\}$
N	N_h is the number of observed products at lag h , ignoring missing values
CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{T} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y})$
CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y})$ when embedded missing values are present
CCF	$\hat{\rho}_{x,y}(h) = \hat{\gamma}_{x,y}(h) / \sqrt{\hat{\gamma}_x(0)\hat{\gamma}_y(0)}$

CCFSTD	$Std(\hat{\rho}_{x,y}(h)) = 1/\sqrt{N_0}$
CCFNORM	$Norm(\hat{\rho}_{x,y}(h)) = \hat{\rho}_{x,y}(h)/Std(\hat{\rho}_{x,y}(h))$
CCFPROB	$Prob(\hat{\rho}_{x,y}(h)) = 2(1 - \Phi(Norm(\hat{\rho}_{x,y}(h))))$
CCFLPROB	$LogProb(\hat{\rho}_{x,y}(h)) = -\log_{10}(Prob(\hat{\rho}_{x,y}(h)))$
CCF2STD	$Flag(\hat{\rho}_{x,y}(h)) = \begin{cases} 1 & \hat{\rho}_{x,y}(h) > 2Std(\hat{\rho}_{x,y}(h)) \\ 0 & -2Std(\hat{\rho}_{x,y}(h)) < \hat{\rho}_{x,y}(h) < 2Std(\hat{\rho}_{x,y}(h)) \\ -1 & \hat{\rho}_{x,y}(h) < -2Std(\hat{\rho}_{x,y}(h)) \end{cases}$

Data Set Output

The TIMESERIES procedure can create the OUT=, OUTCORR=, OUTCROSSCORR=, OUTDECOMP=, OUTSEASON=, OUTSUM=, and OUTTREND= data sets. In general, these data sets contain the variables listed in the BY statement. If an analysis step that is related to an output data step fails, the values of this step are not recorded or are set to missing in the related output data set, and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, VAR, and CROSSVAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR and CROSSVAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option.

OUTCORR= Data Set

The OUTCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCORR= data set records the correlations for each variable specified in a VAR statement (not the CROSSVAR statement).

When the CORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to correlation statistics specified in the CORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

<u>_NAME_</u>	variable name
LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations

ACFSTD	autocorrelation standard errors
ACF2STD	two standard errors beyond autocorrelation
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	two standard errors beyond partial autocorrelation
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	inverse autocorrelation standard errors
IACF2STD	two standard errors beyond inverse autocorrelation
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test Statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

The preceding correlation statistics are computed for each specified time lag.

When the CORR statement TRANSPOSE=YES option is specified, the variable *values* are related to correlation statistics specified in the CORR statement and the variable *names* are related to the NLAG= or LAGS= options.

<u>_NAME_</u>	variable name
<u>_STAT_</u>	correlation statistic name
<u>_LABEL_</u>	correlation statistic label
LAG h	correlation statistics for lag h

OUTCROSSCORR= Data Set

The OUTCROSSCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCROSSCORR= data set records the cross-correlations for each variable specified in a VAR and the CROSSVAR statements.

When the CROSSCORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to cross-correlation statistics specified in the CROSSCORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

<u>_NAME_</u>	variable name
<u>_CROSS_</u>	cross variable name
LAG	time lag
N	number of variance products
CCOV	cross-covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	two standard errors beyond cross-correlation
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

The preceding cross-correlation statistics are computed for each specified time lag.

When the CROSSCORR statement TRANSPOSE=YES option is specified, the variable *values* are related to cross-correlation statistics specified in the CROSSCORR statement and the variable *names* are related to the NLAG= or LAGS= options.

<u>_NAME_</u>	variable name
<u>_CROSS_</u>	cross variable name
<u>_STAT_</u>	cross-correlation statistic name
<u>_LABEL_</u>	cross-correlation statistic label
LAG h	cross-correlation statistics for lag h

OUTDECOMP= Data Set

The OUTDECOMP= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTDECOMP= data set records the seasonal decomposition/adjustments for each variable specified in a VAR statement (not the CROSSVAR statement).

When the DECOMP statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to decomposition/adjustments specified in the DECOMP statement and the variable *values* are related to the ID statement INTERVAL= option and the PROC TIMESERIES statement SEASONALITY= option.

<u>_NAME_</u>	variable name
<u>_MODE_</u>	mode of decomposition

<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	seasonal index
<code>ORIGINAL</code>	original series values
<code>TCC</code>	trend-cycle component
<code>SIC</code>	seasonal-irregular component
<code>SC</code>	seasonal component
<code>SCSTD</code>	seasonal component standard errors
<code>TCS</code>	trend-cycle-seasonal component
<code>IC</code>	irregular component
<code>SA</code>	seasonally adjusted series
<code>PCSA</code>	percent change seasonally adjusted series
<code>TC</code>	trend component
<code>CC</code>	cycle component

The preceding decomposition components are computed for each time period.

When the DECOMP statement `TRANSPPOSE=YES` option is specified, the variable *values* are related to decomposition/adjustments specified in the DECOMP statement and the variable *names* are related to the ID statement `INTERVAL=` option, the PROC TIMESERIES statement `SEASONALITY=` option, and the DECOMP statement `NPERIODS=` option.

<code>_NAME_</code>	variable name
<code>_MODE_</code>	mode of decomposition name
<code>_COMP_</code>	decomposition component name
<code>_LABEL_</code>	decomposition component label
<code>PERIODt</code>	decomposition component value for time period t

OUTSEASON= Data Set

The OUTSEASON= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSEASON= data set records the seasonal statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SEASON statement `TRANSPPOSE=NO` option is omitted or specified explicitly, the variable *names* are related to seasonal statistics specified in the SEASON statement and the variable *values* are related to the ID statement `INTERVAL=` option or the PROC TIMESERIES statement `SEASONALITY=` option.

<code>_NAME_</code>	variable name
<code>_TIMEID_</code>	time ID values

<code>_SEASON_</code>	seasonal index
<code>NOBS</code>	number of observations
<code>N</code>	number of nonmissing observations
<code>NMISS</code>	number of missing observations
<code>MINIMUM</code>	minimum value
<code>MAXIMUM</code>	maximum value
<code>RANGE</code>	maximum value
<code>SUM</code>	summation value
<code>MEAN</code>	mean value
<code>STDDEV</code>	standard deviation
<code>CSS</code>	corrected sum of squares
<code>USS</code>	uncorrected sum of squares
<code>MEDIAN</code>	median value

The preceding statistics are computed for each season.

When the SEASON statement `TRANSPPOSE=YES` option is specified, the variable *values* are related to seasonal statistics specified in the SEASON statement and the variable *names* are related to the ID statement `INTERVAL=` option or the PROC TIMESERIES statement `SEASONALITY=` option.

<code>_NAME_</code>	variable name
<code>_STAT_</code>	season statistic name
<code>_LABEL_</code>	season statistic name
<code>SEASONS</code>	season statistic value for season <i>s</i>

OUTSUM= Data Set

The OUTSUM= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSUM= data set records the descriptive statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

Variables related to descriptive statistics are based on the `ACCUMULATE=` and `SETMISSING=` options in the ID and VAR statements:

<code>_NAME_</code>	variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>NOBS</code>	number of observations
<code>N</code>	number of nonmissing observations

NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
AVG	average value
STDDEV	standard deviation

The OUTSUM= data set contains the descriptive statistics of the (accumulated) time series.

OUTTREND= Data Set

The OUTTREND= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTTREND= data set records the trend statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the TREND statement TRANSPOSE=NO option is omitted or explicitly specified, the variable *names* are related to trend statistics specified in the TREND statement and the variable *values* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

NAME	variable name
TIMEID	time ID values
SEASON	seasonal index
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	maximum value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

The preceding statistics are computed for each time period.

When the TREND statement TRANSPOSE=YES option is specified, the variable *values* related to trend statistics specified in the TREND statement and the variable *name* are related to the ID statement INTERVAL=, the PROC TIMESERIES statement SEASONALITY= option, and the TREND statement NPERIODS= option.

<code>_NAME_</code>	variable name
<code>_STAT_</code>	trend statistic name
<code>_LABEL_</code>	trend statistic name
<code>PERIODt</code>	trend statistic value for time period t

`_STATUS_` Variable Values

The `_STATUS_` variable contains a code that specifies whether the analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	success
1000	transactional trend statistics failure
2000	transactional seasonal statistics failure
3000	accumulation failure
4000	missing value interpretation failure
6000	series is all missing
7000	transformation failure
8000	differencing failure
9000	unable to compute descriptive statistics
10000	seasonal decomposition failure
11000	correlation analysis failure

Printed Output

The `TIMESERIES` procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the `PRINT=` and `PRINTDETAILS` options associated with the `PROC TIMESERIES` statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error and/or warning messages are recorded in the log. The printed output is similar to the output data set, and these similarities are described below. The printed output produced by different printing option values is described as follows:

`PRINT=DECOMP` prints the seasonal decomposition similar to the `OUTDECOMP=` data set.

`PRINT=DESCSTATS` prints a table of descriptive statistics for each variable.

`PRINT=SEASONS` prints the seasonal statistics similar to the `OUTSEASON=` data set.

`PRINT=SUMMARY` prints the summary statistics similar to the `OUTSUM=` data set.

`PRINT=TRENDS` prints the trend statistics similar to the `OUTTREND=` data set.

PRINTDETAILS prints each table with greater detail.

If PRINT=SEASONS and the PRINTDETAILS options are both specified, all seasonal statistics are printed.

ODS Table Names

Table 27.3 relates the PRINT= options to ODS tables:

Table 27.3 ODS Tables Produced in PROC TIMESERIES

ODS Table Name	Description	Statement	Option
SeasonalDecomposition	seasonal decomposition	PRINT	DECOMP
DescStats	descriptive statistics	PRINT	DESCSTATS
GlobalStatistics	global statistics	PRINT	SEASONS
SeasonStatistics	season statistics	PRINT	SEASONS
StatisticsSummary	statistics summary	PRINT	SUMMARY
TrendStatistics	trend statistics	PRINT	TRENDS
GlobalStatistics	global statistics	PRINT	TRENDS

The tables are related to a single series within a BY group.

ODS Graphics Names

This section describes the graphical output produced by the TIMESERIES procedure. To request these graphs, you must specify the **ODS GRAPHICS ON;** statement in your SAS program before the PROC TIMESERIES step, and you must specify the **PLOTS=** or **CROSSPLOTS=** option in the PROC TIMESERIES statement.

PROC TIMESERIES assigns a name to each graph it creates. These names are listed in Table 27.4.

Table 27.4 ODS Graphics Produced by PROC TIMESERIES

ODS Graph Name	Plot Description	Statement	Option
ACFPlot	autocorrelation function	PLOTS	ACF
ACFNORMPlot	normalized autocorrelation function	PLOTS	ACF
CCFNORMPlot	normalized cross-correlation function	CROSSPLOTS	CCF
CCFPlot	cross-correlation function	CROSSPLOTS	CCF
CorrelationPlots	correlation graphics panel	PLOTS	CORR
CrossSeriesPlot	cross series plot	CROSSPLOTS	SERIES
CycleComponentPlot	cycle component	PLOTS	CC
DecompositionPlots	decomposition graphics panel	PLOTS	DECOMP

Table 27.4 (continued)

ODS Graph Name	Plot Description	Statement	Option
IACFPlot	inverse autocorrelation function	PLOTS	IACF
IACFNORMPlot	normalized inverse autocorrelation function	PLOTS	IACF
IrregularComponentPlot	irregular component	PLOTS	IC
PACFPlot	partial autocorrelation function	PLOTS	PACF
PACFNORMPlot	standardized partial autocorrelation function	PLOTS	PACF
PercentChangeAdjustedplot	percent-change seasonally adjusted	PLOTS	PCSA
ResidualPlot	residual time series plot	PLOTS	RESIDUAL

Examples: TIMESERIES Procedure

Example 27.1: Accumulating Transactional Data into Time Series Data

This example illustrates using the TIMESERIES procedure to accumulate time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment/decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP. The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of to missing (SETMISS=0) and only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31JAN2000'D) are considered and,

if needed, extended to include this range.

```
proc timeseries data=retail out=mseries;
  by store;
  id timestamp interval=month
      accumulate=median
      setmiss=0
      start='01jan1998'd
      end  ='31dec2000'd;
  var _numeric_;
run;
```

The monthly time series data are stored in the data WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the variable STORE, TIMESTAMP, and each of the analysis variables in the input data set.

After each set of transactions has been accumulated to form corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM.

```
proc expand data=mseries out=smoothed from=month;
  by store;
  id date;
  convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series are stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options must be changed accordingly and the following statements could be used:

```
proc timeseries data=retail out=tseries;
  by store;
  id timestamp interval=dtmonth
      accumulate=median
      setmiss=0
      start='01jan1998:00:00:00' dt
      end  ='31dec2000:00:00:00' dt;
  var _numeric_;
run;
```

The monthly time series data are stored in the data WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 27.2: Trend and Seasonal Analysis

This example illustrates using the TIMESERIES procedure for trend and seasonal analysis of time-stamped transactional data.

Suppose that the data set SASHELP.AIR contains two variables: DATE and AIR. The variable DATE contains sorted SAS date values recorded at no particular frequency. The variable AIR contains the transaction values to be analyzed.

The following statements accumulate the transactional data on an average basis to form a quarterly time series and perform trend and seasonal analysis on the transactions.

```
proc timeseries data=sashelp.air
    out=series
    outtrend=trend
    outseason=season print=seasons;
    id date interval=qtr accumulate=avg;
    var air;
run;
```

The time series is stored in the data set WORK.SERIES, the trend statistics are stored in the data set WORK.TREND, and the seasonal statistics are stored in the data set WORK.SEASON. Additionally, the seasonal statistics are printed (PRINT=SEASONS) and the results of the seasonal analysis are shown in [Output 27.2.1](#).

Output 27.2.1 Seasonal Statistics Table

The TIMESERIES Procedure						
Season Statistics for Variable AIR						
Season Index	N	Minimum	Maximum	Sum	Mean	Standard Deviation
1	36	112.0000	419.0000	8963.00	248.9722	95.65189
2	36	121.0000	535.0000	10207.00	283.5278	117.61839
3	36	136.0000	622.0000	12058.00	334.9444	143.97935
4	36	104.0000	461.0000	9135.00	253.7500	101.34732

Using the trend statistics stored in the WORK.TREND data set, the following statements plot various trend statistics associated with each time period over time.

```
title1 "Trend Statistics";
proc sgplot data=trend;
    series x=date y=max / lineattrs=(pattern=solid);
    series x=date y=mean / lineattrs=(pattern=solid);
    series x=date y=min / lineattrs=(pattern=solid);
    yaxis display=(nolabel);
    format date year4.;
run;
```

The results of this trend analysis are shown in [Output 27.2.2](#).

Output 27.2.2 Trend Statistics Plot

Using the trend statistics stored in the WORK.TREND data set, the following statements chart the sum of the transactions associated with each time period for the second season over time.

```

title1 "Trend Statistics for 2nd Season";
proc sgplot data=trend;
  where _season_ = 2;
  vbar date / freq=sum;
  format date year4.;
  yaxis label='Sum';
run;

```

The results of this trend analysis are shown in [Output 27.2.3](#).

Output 27.2.3 Trend Statistics Bar Chart

Using the trend statistics stored in the WORK.TREND data set, the following statements plot the mean of the transactions associated with each time period by each year over time.

```

data trend;
  set trend;
  year = year(date);
run;

title "Trend Statistics by Year";
proc sgplot data=trend;
  series x=_season_ y=mean / group=year lineattrs=(pattern=solid);
  xaxis values=(1 to 4 by 1);
run;

```

The results of this trend analysis are shown in [Output 27.2.4](#).

Output 27.2.4 Trend Statistics

Using the season statistics stored in the WORK.SEASON data set, the following statements plot various season statistics for each season.

```

title "Seasonal Statistics";
proc sgplot data=season;
  series x=_season_ y=max / lineattrs=(pattern=solid);
  series x=_season_ y=mean / lineattrs=(pattern=solid);
  series x=_season_ y=min / lineattrs=(pattern=solid);
  yaxis display=(nolabel);
  xaxis values=(1 to 4 by 1);
run;

```

The results of this seasonal analysis are shown in [Output 27.2.5](#).

Output 27.2.5 Seasonal Statistics Plot**Example 27.3: Illustration of ODS Graphics**

This example illustrates the use of ODS graphics.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the series of masonry workers. The series plot, the correlation panel, the seasonal adjustment panel, and all cross-series plots are requested. [Output 27.3.1](#) through [Output 27.3.4](#) show a selection of the plots created.

The graphical displays are requested by specifying the ODS GRAPHICS statement and the PLOTS= or CROSSPLOTS= options in the PROC TIMESERIES statement. For information about the graphics available in the TIMESERIES procedure, see the section “[ODS Graphics Names](#)” on page 1714.

```

title "Illustration of ODS Graphics";
proc timeseries data=sashelp.workers out=_null_
               plots=(series corr decomp)
               crossplots=all;
  id date interval=month;
  var electric;

```

```
crossvar masonry;
run;
```

Output 27.3.1 Series Plot

Output 27.3.2 Correlation Panel

Output 27.3.3 Seasonal Decomposition Panel

Output 27.3.4 Cross-Correlation Plot

Overview: The TSCSREG Procedure

The TSCSREG (time series cross section regression) procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. The TSCSREG procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

The TSCSREG procedure is very similar to the PANEL procedure; for full description, syntax details, models, and estimation methods, see Chapter 19, “[The PANEL Procedure](#).” The TSCSREG procedure is no longer being updated, and it shares the code base with the PANEL procedure.

Getting Started: The TSCSREG Procedure

Specifying the Input Data

The input data set used by the TSCSREG procedure must be sorted by cross section and by time within each cross section. Therefore, the first step in using PROC TSCSREG is to make sure that the input data set is sorted. Normally, the input data set contains a variable that identifies the cross section for each observation and a variable that identifies the time period for each observation.

To illustrate, suppose that you have a data set A that contains data over time for each of several states. You want to regress the variable Y on regressors X1 and X2. Cross sections are identified by the variable STATE, and time periods are identified by the variable DATE. The following statements sort the data set A appropriately:

```
proc sort data=a;
  by state date;
run;
```

The next step is to invoke the TSCSREG procedure and specify the cross section and time series variables in an ID statement. List the variables in the ID statement exactly as they are listed in the BY statement.

```
proc tscsreg data=a;
  id state date;
```

Alternatively, you can omit the ID statement and use the CS= and TS= options on the PROC TSCSREG statement to specify the number of cross sections in the data set and the number of time series observations in each cross section.

Unbalanced Data

In the case of fixed-effects and random-effects models, the TSCSREG procedure is capable of processing data with different numbers of time series observations across different cross sections. You must specify the ID statement to estimate models that use unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Specifying the Regression Model

Next, specify the linear regression model with a MODEL statement, as shown in the following statements.

```
proc tscsreg data=a;
  id state date;
  model y = x1 x2;
run;
```

The MODEL statement in PROC TSCSREG is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables.

The reason for using PROC TSCSREG instead of other SAS regression procedures is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the TSCSREG procedure are FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA. See “[Details: The TSCSREG Procedure](#)” on page 1738 for more information about these methods and the error structures they assume.

By default, the two-way random-effects error model structure is used while Fuller-Battese and Wansbeek-Kapteyn methods are used for the estimation of variance components in balanced data and unbalanced data, respectively. Thus, the preceding example is the same as specifying the RANTWO option, as shown in the following statements:

```
proc tscsreg data=a;
  id state date;
  model y = x1 x2 / rantwo;
run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each method specified. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an F statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman m -statistic that provides information about the appropriateness of the random-effects specification. It is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure, which is the most appropriate goodness-of-fit measure for models estimated by using GLS. This number is interpreted as a measure of the

proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.

Estimation Techniques

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is equivalent to best linear unbiased estimation.

The output from TSCSREG is identical to what one would obtain from creating dummy variables to represent the cross-sectional and time (fixed) effects. The output is presented in this manner to facilitate comparisons to the least squares dummy variables estimator (LSDV). As such, the inclusion of an intercept term implies that one dummy variable must be dropped. The actual estimation of the fixed-effects models is not LSDV. LSDV is much too cumbersome to implement. Instead, TSCSREG operates in a two step fashion. In the first step, the following occurs:

- *One-way fixed-effects model:* In the one-way fixed-effects model, the data is transformed by removing the cross-sectional means from the dependent and independent variables. The following is true:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i$$

- *Two-way fixed-effects model:* In the two-way fixed-effects model, the data is transformed by removing the cross-sectional and time means and adding back the overall means:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i - \bar{y}_t + \bar{\bar{y}}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i - \bar{\mathbf{x}}_t + \bar{\bar{\mathbf{x}}}$$

where the symbols:

y_{it} and \mathbf{x}_{it} are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables not including a constant), respectively

\bar{y}_i and $\bar{\mathbf{x}}_i$ are cross section means

\bar{y}_t and $\bar{\mathbf{x}}_t$ are time means

$\bar{\bar{y}}$ and $\bar{\bar{\mathbf{x}}}$ are the overall means

The second step consists of running OLS on the properly demeaned series, provided that the data are balanced. The unbalanced case is slightly more difficult, because the structure of the missing data must be retained. For this case, PROC TSCSREG uses a slight specialization on Wansbeek and Kapteyn.

The other alternative is to assume that the effects are random. In the one-way case, $E(v_i) = 0$, $E(v_i^2) = \sigma_v^2$, and $E(v_i v_j) = 0$ for $i \neq j$, and v_i is uncorrelated with ϵ_{it} for all i and t . In the two-way case, in addition to all of the preceding, $E(e_t) = 0$, $E(e_t^2) = \sigma_e^2$, and $E(e_t e_s) = 0$ for $t \neq s$, and the e_t are uncorrelated with the v_i and the ϵ_{it} for all i and t . Thus, the model is a variance components model, with the variance components σ_v^2 , σ_e^2 , and σ_ϵ^2 , to be estimated. A crucial implication of such a specification is that the effects are independent of the regressors. For random-effects models, the estimation method is an estimated generalized least squares (EGLS) procedure that involves estimating the variance components in the first stage and using the estimated variance covariance matrix thus obtained to apply generalized least squares (GLS) to the data.

Introductory Example

The following example uses the cost function data from Greene (1990) to estimate the variance components model. The variable OUTPUT is the log of output in millions of kilowatt-hours, and COST is the log of cost in millions of dollars. Refer to Greene (1990) for details.

```

title1;
data greene;
  input firm year output cost @@;
  df1 = firm = 1;
  df2 = firm = 2;
  df3 = firm = 3;
  df4 = firm = 4;
  df5 = firm = 5;
  d60 = year = 1960;
  d65 = year = 1965;
  d70 = year = 1970;
datalines;
... more lines ...

```

Usually you cannot explicitly specify all the explanatory variables that affect the dependent variable. The omitted or unobservable variables are summarized in the error disturbances. The TSCSREG procedure used with the RANTWO option specifies the two-way random-effects error model where the variance components are estimated by the Fuller-Battese method, because the data are balanced and the parameters are efficiently estimated by using the GLS method. The variance components model used by the Fuller-Battese method is

$$y_{it} = \sum_{k=1}^K X_{itk} \beta_k + v_i + e_t + \epsilon_{it} \quad i = 1, \dots, N; t = 1, \dots, T$$

The following statements fit this model.

```

proc sort data=greene;
  by firm year;
run;

```

```

proc tscsreg data=greene;
  model cost = output / rantwo;
  id firm year;
run;

```

The TSCSREG procedure output is shown in Figure 28.1. A model description is printed first; it reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and t tests.

Syntax: The TSCSREG Procedure

The following statements are used with the TSCSREG procedure.

```

PROC TSCSREG options ;
  BY variables ;
  ID cross-section-id-variable time-series-id-variable ;
  MODEL dependent = regressor-variables / options ;
  TEST equation1 <,equation2... > ;

```

Functional Summary

The statements and options used with the TSCSREG procedure are summarized in the following table.

Table 28.1 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	TSCSREG	DATA=
write parameter estimates to an output data set	TSCSREG	OUTEST=
include correlations in the OUTEST= data set	TSCSREG	CORROUT
include covariances in the OUTEST= data set	TSCSREG	COVOUT
specify number of time series observations	TSCSREG	TS=
specify number of cross sections	TSCSREG	CS=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the cross section and time ID variables	ID	
Printing Control Options		
print correlations of the estimates	MODEL	CORRB
print covariances of the estimates	MODEL	COVB
suppress printed output	MODEL	NOPRINT
perform tests of linear hypotheses	TEST	
Model Estimation Options		
specify the one-way fixed-effects model	MODEL	FIXONE
specify the two-way fixed-effects model	MODEL	FIXTWO
specify the one-way random-effects model	MODEL	RANONE
specify the two-way random-effects model	MODEL	RANTWO
specify Fuller-Battese method	MODEL	FULLER
specify PARKS	MODEL	PARKS

Description	Statement	Option
specify Da Silva method	MODEL	DASILVA
specify order of the moving-average error process for Da Silva method	MODEL	M=
print Φ matrix for Parks method	MODEL	PHI
print autocorrelation coefficients for Parks method	MODEL	RHO
suppress the intercept term	MODEL	NOINT
control check for singularity	MODEL	SINGULAR=

PROC TSCSREG Statement

PROC TSCSREG *options* ;

The following options can be specified in the PROC TSCSREG statement.

DATA=SAS-data-set

names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

TS=number

specifies the number of observations in the time series for each cross section. The TS= option value must be greater than 1. The TS= option is required unless an ID statement is used. Note that the number of observations for each time series must be the same for each cross section and must cover the same time period.

CS=number

specifies the number of cross sections. The CS= option value must be greater than 1. The CS= option is required unless an ID statement is used.

OUTEST=SAS-data-set

the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set.

OUTCORR

CORROUT

writes the correlation matrix of the parameter estimates to the OUTEST= data set.

In addition, any of the following MODEL statement options can be specified in the PROC TSCSREG statement: CORRB, COVB, FIXONE, FIXTWO, RANONE, RANTWO,

FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, and SINGULAR=. When specified in the PROC TSCSREG statement, these options are equivalent to specifying the options for every MODEL statement.

BY Statement

BY variables ;

A BY statement can be used with PROC TSCSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

When both an ID statement and a BY statement are specified, the input data set must be sorted first with respect to BY variables and then with respect to the cross section and time series ID variables. For example,

```
proc sort data=a;
    by byvar1 byvar2 csid tsid;
run;

proc tscsreg data=a;
    by byvar1 byvar2;
    id csid tsid;
    ...
run;
```

When both a BY statement and an ID statement are used, the data set might have a different number of cross sections or a different number of time periods in each BY group. If no ID statement is used, the CS= N and TS= T options must be specified and each BY group must contain $N \times T$ observations.

ID Statement

ID cross-section-id-variable time-series-id-variable ;

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the TSCSREG procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The TSCSREG procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT with a BY statement with the variables listed exactly as they are listed in the ID statement to sort the input data set. For example,

```
proc sort data=a;
```

```

        by csid tsid;
run;

proc tscsreg data=a;
    id csid tsid;
    ... etc. ...
run;

```

If the ID statement is not used, the TS= and CS= options must be specified on the PROC TSCSREG statement. Note that the input data must be sorted by time within cross section, regardless of whether the cross section structure is given by an ID statement or by the options TS= and CS=.

If an ID statement is specified, the time series length T is set to the minimum number of observations for any cross section, and only the first T observations in each cross section are used. If both the ID statement and the TS= and CS= options are specified, the TS= and CS= options are ignored.

MODEL Statement

MODEL *response = regressors / options ;*

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels up to 32 characters in length. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label: **MODEL** *response = regressors / options ;*

The following options can be specified on the MODEL statement after a slash (/).

CORRB

CORR

prints the matrix of estimated correlations between the parameter estimates.

COVB

VAR

prints the matrix of estimated covariances between the parameter estimates.

FIXONE

specifies that a one-way fixed-effects model be estimated with the one-way model that corresponds to group effects only.

FIXTWO

specifies that a two-way fixed-effects model be estimated.

RANONE

specifies that a one-way random-effects model be estimated.

RANTWO

specifies that a two-way random-effects model be estimated.

FULLER

specifies that the model be estimated by using the Fuller-Battese method, which assumes a variance components model for the error structure.

PARKS

specifies that the model be estimated by using the Parks method, which assumes a first-order autoregressive model for the error structure.

DASILVA

specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure.

M=number

specifies the order of the moving-average process in the Da Silva method. The M= value must be less than $T - 1$. The default is M=1.

PHI

prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used.

RHO

prints the estimated autocorrelation coefficients for the Parks method.

NOINT**NOMEAN**

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

SINGULAR=number

specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TEST Statement

TEST *equation* < , *equation* ... > < / *options* > ;

The TEST statement performs F tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following statements illustrate the use of the TEST statement:

```
proc tscsreg;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3= 0;
  test_int: test intercept=0, x3 = 0;
```

Note that a test of the following form is not permitted:

```
test_bad: test x2 / 2 + 2 * x3= 0;
```

Do not use the division sign in test/restrict statements.

Details: The TSCSREG Procedure

Models, estimators, and methods are covered in detail in Chapter 19, “[The PANEL Procedure](#).”

ODS Table Names

PROC TSCSREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 28.2 ODS Tables Produced in PROC TSCSREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ModelDescription	Model description	default
FitStatistics	Fit statistics	default
FixedEffectsTest	F test for no fixed effects	FIXONE, FIXTWO, RANONE, RANTWO
ParameterEstimates	Parameter estimates	default
CovB	Covariance of parameter estimates	COVB

Table 28.2 continued

ODS Table Name	Description	Option
CorrB	Correlations of parameter estimates	CORRB
VarianceComponents	Variance component estimates	FULLER, DASILVA, M=, RANONE, RANTWO
RandomEffectsTest	Hausman test for random effects	FULLER, DASILVA, M=, RANONE, RANTWO
AR1Estimates	First order autoregressive parameter estimates	PARKS, RHO
EstimatedPhiMatrix	Estimated phi matrix	PARKS
EstimatedAutocovariances	Estimates of autocovariances	DASILVA, M=
ODS Tables Created by the TEST Statement		
TestResults	Test results	

Examples: The TSCSREG Procedure

For examples of analysis of panel data, see Chapter 19, “[The PANEL Procedure](#).”

Acknowledgments: TSCSREG Procedure

The original TSCSREG procedure was developed by Douglas J. Drummond and A. Ronald Gallant, and contributed to the Version 5 SUGI Supplemental Library in 1979. The original code was changed substantially over the years. Additional new methods as well as other new features are currently included in the PANEL PROCEDURE. SAS Institute would like to thank Dr. Drummond and Dr. Gallant for their contribution of the original version of the TSCSREG procedure.

Overview: UCM Procedure

The UCM procedure analyzes and forecasts equally spaced univariate time series data by using an unobserved components model (UCM). The UCMs are also called *structural models* in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in explaining and predicting its behavior. Harvey (1989) is a good reference for time series modeling that uses the UCMs. Harvey calls the components in a UCM the “stylized facts” about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the exponential smoothing models have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of UCM and ARIMA modeling, is given in Harvey (1989). The UCMs are also very similar to another set of models, called the *dynamic models*, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS/ETS you can use PROC ARIMA for ARIMA modeling (see Chapter 7, “[The ARIMA Procedure](#)”), PROC ESM for exponential smoothing modeling (see Chapter 13, “[The ESM Procedure](#)”), and use the Time Series Forecasting System for a point-and-click interface to ARIMA and exponential smoothing modeling.

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of time series

analysis using the UCMs. Once a suitable UCM is found for the series under consideration, it can be used for a variety of purposes. For example, it can be used for the following:

- forecasting the values of the response series and the component series in the model
- obtaining a model-based seasonal decomposition of the series
- obtaining a “denoised” version and interpolating the missing values of the response series in the historical period
- obtaining the full sample or “smoothed” estimates of the component series in the model

Getting Started: UCM Procedure

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for estimating and forecasting the commonly observed features in time series. These models are discussed in detail later in the section “[An Introduction to Unobserved Component Models](#)” on page 1781. First the procedure is illustrated using an example.

A Seasonal Series with Linear Trend

The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a steady rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. The following DATA step prepares the log-transformed passenger series analyzed in this example:

```
data seriesG;
  set sashelp.air;
  logair = log( air );
run;
```

The following statements produce a time series plot of the series by using the TIMESERIES procedure (see Chapter 27, “[The TIMESERIES Procedure](#)”). The trend and seasonal features of the series are apparent in the plot in [Figure 29.1](#).

```
proc timeseries data=seriesG plot=series;
  id date interval=month;
  var logair;
run;
```

Figure 29.1 Series Plot of Log-Transformed Airline Passenger Series

In this example this series is modeled using an unobserved component model called the basic structural model (BSM). The BSM models a time series as a sum of three stochastic components: a trend component μ_t , a seasonal component γ_t , and random error ϵ_t . Formally, a BSM for a response series y_t can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error ϵ_t , also called the *irregular component*, is modeled simply as a sequence of independent, identically distributed (i.i.d.) zero-mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a *locally linear time trend*. This trend model can be written as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

These equations specify a trend where the level μ_t as well as the slope β_t is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms η_t and ξ_t in their respective equations. Some interesting special cases of this model arise when you

manipulate these disturbance variances. For example, if the variance of ξ_t is zero, the slope will be constant (equal to β_0); if the variance of η_t is also zero, μ_t will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model used in this example is called a trigonometric seasonal. The stochastic equations governing a trigonometric seasonal are explained later (see the section “[Modeling Seasons](#)” on page 1783). However, it is interesting to note here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is equal to zero. The following statements specify a BSM with these three components:

```
proc ucm data=seriesG;
  id date interval=month;
  model logair;
  irregular;
  level;
  slope;
  season length=12 type=trig print=smooth;
  estimate;
  forecast lead=24 print=decomp;
run;
```

The PROC UCM statement signifies the start of the UCM procedure, and the input data set, `seriesG`, containing the dependent series is specified there. The optional `ID` statement is used to specify a date, datetime, or time identification variable, `date` in this example, to label the observations. The `INTERVAL=MONTH` option in the `ID` statement indicates that the measurements were collected on a monthly basis. The model specification begins with the `MODEL` statement, where the response series is specified (`logair` in this case). After this the components in the model are specified using separate statements that enable you to control their individual properties. The irregular component ϵ_t is specified using the `IRREGULAR` statement and the trend component μ_t is specified using the `LEVEL` and `SLOPE` statements. The seasonal component γ_t is specified using the `SEASON` statement. The specifics of the seasonal characteristics such as the season length, its stochastic evolution properties, etc., are specified using the options in the `SEASON` statement. The seasonal component used in this example has a season length of 12, corresponding to the monthly seasonality, and is of the *trigonometric* type. Different types of seasonals are explained later (see the section “[Modeling Seasons](#)” on page 1783).

The parameters of this model are the variances of the disturbance terms in the evolution equations of μ_t , β_t , and γ_t and the variance of the irregular component ϵ_t . These parameters are estimated by maximizing the likelihood of the data. The `ESTIMATE` statement options can be used to specify the span of data used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts—for example, `PRINT=SMOOTH` option in the `SEASON` statement requests the displaying of smoothed forecasts of the seasonal component γ_t . The series forecasts and forecasts of the sum of components can be requested using the `FORECAST` statement. The option `PRINT=DECOMP` in the `FORECAST` statement requests the printing of the smoothed trend μ_t and the trend plus seasonal component ($\mu_t + \gamma_t$).

The parameter estimates for this model are displayed in [Figure 29.2](#).

Figure 29.2 BSM for the Logair Series

The UCM Procedure					
Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00023436	0.0001079	2.17	0.0298
Level	Error Variance	0.00029828	0.0001057	2.82	0.0048
Slope	Error Variance	8.47911E-13	6.2271E-10	0.00	0.9989
Season	Error Variance	0.00000356	1.32347E-6	2.69	0.0072

The estimates suggest that except for the slope component, the disturbance variances of all the components are significant—that is, all these components are *stochastic*. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It might then be useful to check if the slope component can be dropped from the model—that is, if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in [Figure 29.3](#).

Figure 29.3 Component Significance Analysis for the Logair Series

Significance Analysis of Components (Based on the Final State)			
Component	DF	Chi-Square	Pr > ChiSq
Irregular	1	0.08	0.7747
Level	1	117867	<.0001
Slope	1	43.78	<.0001
Season	11	507.75	<.0001

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic, then this analysis pertains only to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component's contribution appears insignificant toward the end of the estimation span; however, since it is a stochastic component, it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at zero. This is done by modifying the SLOPE statement as follows:

```
slope variance=0 noest;
```

After a tentative model is fit, its adequacy can be checked by examining different goodness-of-fit measures and other diagnostic tests and plots that are based on the model residuals. Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components

in the model. The plots of component forecasts can be useful in understanding their contributions to the series. In order to obtain the plots, you need to turn ODS Graphics on by using the **ODS GRAPHICS ON;** statement. The following statements illustrate some of these features:

```
ods graphics on;
proc ucm data=seriesG;
  id date interval = month;
  model logair;
  irregular;
  level plot=smooth;
  slope variance=0 noest;
  season length=12 type=trig
    plot=smooth;
  estimate;
  forecast lead=24 plot=decomp;
run;
```

The table given in [Figure 29.4](#) shows the goodness-of-fit statistics that are computed by using the one-step-ahead prediction errors (see the section “[Statistics of Fit](#)” on page 1819). These measures indicate a good agreement between the model and the data. Additional diagnostic measures are also printed by default but are not shown here.

Figure 29.4 Fit Statistics for the Logair Series

The UCM Procedure	
Fit Statistics Based on Residuals	
Mean Squared Error	0.00147
Root Mean Squared Error	0.03830
Mean Absolute Percentage Error	0.54132
Maximum Percent Error	2.19097
R-Square	0.99061
Adjusted R-Square	0.99046
Random Walk R-Square	0.87288
Amemiya's Adjusted R-Square	0.99017
Number of non-missing residuals used for computing the fit statistics = 131	

The first plot, shown in [Figure 29.5](#), is produced by the **PLOT=SMOOTH** option in the **LEVEL** statement, it shows the smoothed level of the series.

Figure 29.5 Smoothed Trend in the Logair Series

The second plot (Figure 29.6), produced by the PLOT=SMOOTH option in the SEASON statement, shows the smoothed seasonal component by itself.

Figure 29.6 Smoothed Seasonal in the Logair Series

The plot of the sum of the trend and seasonal component, produced by the PLOT=DECOMP option in the FORECAST statement, is shown in [Figure 29.7](#). You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future based on the LEAD=24 option specified in the FORECAST statement.

Figure 29.7 Smoothed Trend plus Seasonal in the Logair Series

Syntax: UCM Procedure

The UCM procedure uses the following statements:

```

PROC UCM < options > ;
  AUTOREG < options > ;
  BLOCKSEASON options ;
  BY variables ;
  CYCLE < options > ;
  DEPLAG options ;
  ESTIMATE < options > ;
  FORECAST < options > ;
  ID variable options ;
  IRREGULAR < options > ;
  LEVEL < options > ;
  MODEL dependent variable < = regressors > ;
  NLOPTIONS options ;
  OUTLIER options ;
  RANDOMREG regressors < / options > ;
  SEASON options ;
  SLOPE < options > ;
  SPLINEREG regressor < options > ;
  SPLINESEASON options ;

```

The **PROC UCM** and **MODEL** statements are required. In addition, the model must contain at least one component with nonzero disturbance variance.

Functional Summary

The statements and options controlling the UCM procedure are summarized in the following table. Most commonly needed scenarios are listed; see the individual statements for additional details. You can use the **PRINT=** and **PLOT=** options in the individual component statements for printing and plotting the corresponding component forecasts.

Table 29.1 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	PROC UCM	DATA=
write parameter estimates to an output data set	ESTIMATE	OUTEST=
write series and component forecasts to an output data set	FORECAST	OUTFOR=
Model Specification		
specify the dependent variable and simple predictors	MODEL	
specify predictors with time-varying coefficients	RANDOMREG	
specify a nonlinear predictor	SPLINEREG	

Table 29.1 *continued*

Description	Statement	Option
specify the irregular component	IRREGULAR	
specify the random walk trend	LEVEL	
specify the locally linear trend	LEVEL and SLOPE	
specify a cycle component	CYCLE	
specify a dummy seasonal component	SEASON	TYPE=DUMMY
specify a trigonometric seasonal component	SEASON	TYPE=TRIG

turn on a variety of plotting options for the procedure	PROC UCM	PLOTS=
ID		
specify a variable that provides the time index for the series values	ID	

PROC UCM Statement

PROC UCM < options > ;

The PROC UCM statement is required. The following options can be used in the PROC UCM statement:

DATA=SAS-data-set

specifies the name of the SAS data set containing the time series. If the DATA= option is not specified in the PROC UCM statement, the most recently created SAS data set is used.

NOPRINT

turns off all the printing for the procedure. The subsequent print options in the procedure are ignored.

PLOTS<(global-plot-options)> <= plot-request <(options)>>

PLOTS<(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>> controls the plots produced with ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Here are some examples:

```
plots=none
plots=all
plots=residuals(acf loess)
plots(noclm)=(smooth(decomp) residual(panel loess))
```

You must enable ODS Graphics before requesting plots, as shown in the following example. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*).

```
ods graphics on;

proc ucm;
  model y = x;
  irregular;
  level;
run;

proc ucm plots=all;
  model y = x;
  irregular;
  level;
run;
```

The first PROC UCM step does not specify the PLOTS= option, so the default plot that displays the series forecasts in the forecast region is produced. The PLOTS=ALL option in the second PROC UCM step produces all the plots that are appropriate for the specified model.

In addition to the PLOTS= option in the PROC UCM statement, you can request plots by using the PLOT= option in other statements of the UCM procedure. This way of requesting plots provides finer control over the plot production. If you have enabled ODS Graphics but do not specify any specific plot request, then PROC UCM produces the plot of series forecasts in the forecast horizon by default.

Global Plot Options:

The *global-plot-options* apply to all relevant plots generated by the UCM procedure. The following *global-plot-option* is supported:

NOCLM

suppresses the confidence limits in all the component and forecast plots.

Specific Plot Options:

The following list describes the specific plots and their options:

ALL

produces all plots appropriate for the particular analysis.

NONE

suppresses all plots.

FILTER (< filter-plot-options >)

produces time series plots of the filtered component estimates. The following *filter-plot-options* are available:

ALL

produces all the filtered component estimate plots appropriate for the particular analysis.

LEVEL

produces a time series plot of the filtered level component estimate, provided the model contains the level component.

SLOPE

produces a time series plot of the filtered slope component estimate, provided the model contains the slope component.

CYCLE

produces time series plots of the filtered cycle component estimates for all cycle components in the model, if there are any.

SEASON

produces time series plots of the filtered season component estimates for all seasonal components in the model, if there are any.

DECOMP

produces time series plots of the filtered estimates of the series decomposition.

RESIDUAL (< residual-plot-options >)

produces the residuals plots. The following *residual-plot-options* are available:

ALL

produces all the residual diagnostics plots appropriate for the particular analysis.

ACF

produces the autocorrelation plot of residuals.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF

produces the partial-autocorrelation plot of residuals.

PANEL

produces a summary panel of the residual diagnostics consisting of the following:

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces the plot of Ljung-Box white-noise test p -values at different lags (in log scale).

SMOOTH (< *smooth-plot-options* >)

produces time series plots of the smoothed component estimates. The following *smooth-plot-options* are available:

ALL

produces all the smoothed component estimate plots appropriate for the particular analysis.

LEVEL

produces time series plot of the smoothed level component estimate, provided the model contains the level component.

SLOPE

produces time series plot of the smoothed slope component estimate, provided the model contains the slope component.

CYCLE

produces time series plots of the smoothed cycle component estimates for all cycle components in the model, if there are any.

SEASON

produces time series plots of the smoothed season component estimates for all season components in the model, if there are any.

DECOMP

produces time series plots of the smoothed estimates of the series decomposition.

PRINTALL

turns on all the printing options for the procedure. The subsequent NOPRINT options in the procedure are ignored.

AUTOREG Statement

AUTOREG < options > ;

The AUTOREG statement specifies an autoregressive component in the model. An autoregressive component is a special case of cycle that corresponds to the frequency of zero or π . It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component r_t can be written as follows:

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim i.i.d. N(0, \sigma_v^2)$$

The damping factor ρ can take any value in the interval $(-1, 1)$, including -1 but excluding 1 . If $\rho = 1$, the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$, the autoregressive component corresponds to a seasonal component with a season length of 2, or a nonstationary cycle with period 2. If $|\rho| < 1$, then the autoregressive component is stationary. The following example illustrates the AUTOREG statement. This statement includes an autoregressive component in the model. The damping factor ρ and the disturbance variance σ_v^2 are estimated from the data.

```
autoreg;
```

NOEST=RHO

NOEST=VARIANCE

NOEST=(RHO VARIANCE)

fixes the values of ρ and σ_v^2 to those specified in the **RHO=** and **VARIANCE=** options.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of the filtered or smoothed estimate of the autoreg component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of the filtered or smoothed estimate of the autoreg component.

RHO=valuespecifies an initial value for the damping factor ρ during the parameter estimation process. The value of ρ must be in the interval $(-1, 1)$, including -1 but excluding 1 .**VARIANCE=value**specifies an initial value for the disturbance variance σ_v^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BLOCKSEASON Statement

BLOCKSEASON *NBLOCKS* = integer *BLOCKSIZE* = integer < options > ;

The **BLOCKSEASON** or **BLOCKSEASONAL** statement is used to specify a seasonal component γ_t that has a special block structure. The seasonal γ_t is called a *block seasonal* of block size m and number of blocks k if its season length, s , can be factored as $s = m * k$ and its seasonal effects have a block form—that is, the first m seasonal effects are all equal to some number τ_1 , the next m effects are all equal to some number τ_2 , and so on.

This type of seasonal structure can be appropriate in some cases; for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the hour-of-the-day effect and the day-of-the-week effect are additive. In this situation the hour-of-the-week seasonality, having a season length of 168, can be modeled as a sum of two components. The hour-of-the-day effect is modeled using a simple seasonal of season length 24, while the day-of-the-week is modeled as a block seasonal component that has the days of the week as blocks. This day-of-the-week block seasonal component has seven blocks, each of size 24.

A block seasonal specification requires, at the minimum, the block size m and the number of blocks in the seasonal k . These are specified using the **BLOCKSIZE=** and **NBLOCKS=** option, respectively. In addition, you might need to specify the position of the first observation of the series by using the **OFFSET=** option if it is not at the beginning of one of the blocks. In the example just considered, this corresponds to a situation where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as **OFFSET=7**.

The other options in this statement are very similar to the options in the **SEASON** statement; for example, a block seasonal can also be of one of the two types, **DUMMY** and **TRIG**. There can be

more than one block seasonal component in the model, each specified using a separate BLOCKSEASON statement. No two block seasonals in the model can have the same NBLOCKS= and BLOCKSIZE= specifications. The following example illustrates the use of the BLOCKSEASON statement to specify the additive, hour-of-the-week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```

BLOCKSIZE=integer

specifies the block size, m . This is a required option in this statement. The block size can be any integer larger than or equal to two. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, etc.

NBLOCKS=integer

specifies the number of blocks, k . This is a required option in this statement. The number of blocks can be any integer greater than or equal to two.

NOEST

specifies the value of the disturbance variance parameter to the value specified in the [VARIANCE=](#) option.

OFFSET=integer

specifies the position of the first measurement within the block, if the first measurement is not at the start of a block. The OFFSET= value must be between one and the block size. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ ANNUAL

PLOT=S_ ANNUAL

PLOT=(< plot request > ... < plot request >)

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component γ_t . You can use the F_ ANNUAL and S_ ANNUAL options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years. The first period in each block is plotted over the years.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**requests the printing of the filtered or smoothed estimate of the block seasonal component γ_t .**TYPE=DUMMY | TRIG**

specifies the type of the block seasonal component. The default type is DUMMY.

VARIANCE=valuespecifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BY Statement

BY variables ;

A BY statement can be used in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model specified using the MODEL and other component statements is applied to all the groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

CYCLE Statement

CYCLE < options > ;

The CYCLE statement is used to specify a cycle component, ψ_t , in the model. The stochastic equation governing a cycle component of period p and damping factor ρ is as follows:

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2 and $\lambda = 2 * \pi / p$ is the angular frequency of the cycle. Any p strictly greater than two is an admissible value for the period, and the damping factor ρ can be any value in the interval (0, 1), including one but excluding zero. The cycles with frequency zero and π , which correspond to the periods equal to infinity and two, respectively, can be specified using the AUTOREG statement. The values of ρ less than one give rise to a stationary cycle, while $\rho = 1$ gives rise to a nonstationary cycle. As a default, values of ρ , p , and σ_ν^2 are estimated from the data. However, if necessary, you can fix the values of some or all of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. The examples that follow illustrate the use of the CYCLE statement.

The following statements request including two cycles in the model. The parameters of each of these cycles are estimated from the data.

```
cycle;
cycle;
```

The following statement requests inclusion of a nonstationary cycle in the model. The cycle period p and the disturbance variance σ_v^2 are estimated from the data.

```
cycle rho=1 noest=rho;
```

In the following statement a nonstationary cycle with a fixed period of 12 is specified. Moreover, a starting value is supplied for σ_v^2 .

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```

NOEST=PERIOD

NOEST=RHO

NOEST=VARIANCE

NOEST=(< RHO > < PERIOD > < VARIANCE >)

fixes the values of the component parameters to those specified in the **RHO=**, **PERIOD=**, and **VARIANCE=** options. This option enables you to fix any combination of parameter values.

PERIOD=value

specifies an initial value for the cycle period during the parameter estimation process. Period value must be strictly greater than 2.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the cycle component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests the printing of a filtered or smoothed estimate of the cycle component ψ_t .

RHO=value

specifies an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including one but excluding zero, is an acceptable initial value for the damping factor.

VARIANCE=value

specifies an initial value for the disturbance variance parameter, σ_v^2 , to be used during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

DEPLAG Statement

DEPLAG *LAGS* = *order* < *PHI* = *value* ... > < *NOEST* > ;

The DEPLAG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of DEPLAG statement.

If the dependent series is denoted by y_t , the following statement specifies the inclusion of $\phi_1 y_{t-1} + \phi_2 y_{t-2}$ in the model. The parameters ϕ_1 and ϕ_2 are estimated from the data.

```
deplag lags=2;
```

The following statement requests including $\phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1 \phi_2 y_{t-5}$ in the model. The values of ϕ_1 and ϕ_2 are fixed at 0.8 and -1.2.

```
deplag lags=(1) (4) phi=0.8 -1.2 noest;
```

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an irregular component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLAG statement, if an initial value is supplied for any one of the parameters, the initial values must also be supplied for all other parameters.

LAGS=*order*

LAGS=(*lag*, ..., *lag*) ... (*lag*, ..., *lag*)

is a required option in this statement. $\text{LAGS}=(l_1, l_2, \dots, l_k)$ defines a model with specified lags of the dependent variable included as predictors. $\text{LAGS}=\textit{order}$ is equivalent to $\text{LAGS}=(1, 2, \dots, \textit{order})$.

A concatenation of parenthesized lists specifies a factored model. For example, $\text{LAGS}=(1)(12)$ specifies that the lag values, 1, 12, and 13, corresponding to the following polynomial in the backward shift operator, be included in the model

$$(1 - \phi_{1,1}B)(1 - \phi_{2,1}B^{12})$$

Note that, in this case, the coefficient of the thirteenth lag is constrained to be the product of the coefficients of the first and twelfth lags.

NOEST

fixes the values of the parameters to those specified in **PHI**= option.

PHI=*value* ...

lists starting values for the coefficients of the lagged dependent variable. The order of the values listed corresponds with the order of the lags specified in the **LAGS**= option.

ESTIMATE Statement

ESTIMATE < options > ;

The ESTIMATE statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model by using the SKIPFIRST= and BACK= options. This can be useful in model diagnostics. You can request a variety of goodness-of-fit statistics and other model diagnostic information including different residual diagnostic plots. Note that the ESTIMATE statement is not used to control the nonlinear optimization process itself. That is done using the [NLOPTIONS](#) statement, where you can control the number of iterations, choose between the different optimization techniques, and so on. You can save the estimated parameters and other related information in a data set by using the OUTEST= option. You can request the optimization of the profile likelihood, the likelihood obtained by concentrating out a disturbance variance, for parameter estimation by using the [PROFILE](#) option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the model-fitting process. The actual observation span used to fit the model is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the measurements between observation numbers $n_0 + 12$ and $n_1 - 24$ form the estimation span. Of course, the model fitting might not take place if there are insufficient data in the resulting span. The model fitting does not take place if there are regressors in the model that have missing values in the estimation span.

BACK=integer

SKIPLAST=integer

indicates that some ending part of the data needs to be ignored during the parameter estimation. This can be useful when you want to study the forecasting performance of a model on the observed data. BACK=10 results in skipping the last 10 measurements of the response series during the parameter estimation. The default is BACK=0.

EXTRADIFFUSE=k

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead residuals are produced only after the diffuse state is initialized. Delaying the initialization leads to a reduction in the number of one-step-ahead residuals available for computing the residual diagnostic measures. This option is useful when you want to ignore the first few one-step-ahead residuals that often have large variance.

NOPROFILE

requests that the usual likelihood be optimized for parameter estimation. For more information, see the section [“Parameter Estimation by Profile Likelihood Optimization”](#) on page 1798.

OUTEST=SAS-data-set

specifies an output data set for the estimated parameters.

In the ESTIMATE statement, the PLOT= option is used to obtain different residual diagnostic plots. The different possibilities are as follows:

PLOT=ACF**PLOT=MODEL****PLOT=LOESS****PLOT=HISTOGRAM****PLOT=PACF****PLOT=PANEL****PLOT=QQ****PLOT=RESIDUAL****PLOT=WN****PLOT=(< plot request > ... < plot request >)**

requests different residual diagnostic plots. The different options are as follows:

ACF

produces the residual-autocorrelation plot.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

MODEL

produces the plot of one-step-ahead forecasts in the estimation span.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF

produces the residual-partial-autocorrelation plot.

PANEL

produces a summary panel of the residual diagnostics consisting of

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces a plot of p -values, in log-scale, at different lags for the Ljung-Box portman-teau white noise test statistics.

PRINT=NONE

suppresses all the printed output related to the model fitting, such as the parameter estimates, the goodness-of-fit statistics, and so on.

PROFILE

requests that the profile likelihood, obtained by concentrating out one of the disturbance variances from the likelihood, be optimized for parameter estimation. By default, the profile likelihood is not optimized if any of the disturbance variance parameters is held fixed to a nonzero value. For more information see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 1798.

SKIPFIRST=*integer*

indicates that some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the parameter estimation. The default is SKIPFIRST=0.

FORECAST Statement

FORECAST < *options* > ;

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to use to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, is specified using the LEAD= and ALPHA= options. You can request one-step-ahead series and component forecasts by using the PRINT= option. You can save the series forecasts, and the model-based decomposition of the series, in a data set by using the OUTFOR= option. The following example illustrates the use of this statement:

```
forecast skipfirst=12 back=24 lead=30;
```

This statement requests that the initial 12 and the last 24 response values be excluded during the forecast computations. The forecast horizon, specified using the LEAD= option, is 30 periods; that is, multistep forecasting begins at the end of the historical period and continues for 30 periods. The actual observation span used to compute the multistep forecasting is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the historical period, or the

forecast span, begins at $n_0 + 12$ and ends at $n_1 - 24$. Multistep forecasts are produced for the next 30 periods—that is, for the observation numbers $n_1 - 23$ to $n_1 + 6$. Of course, the forecast computations can fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon—that is, between the observations $n_1 - 23$ and $n_1 + 6$ —the forecast horizon is reduced accordingly.

ALPHA=value

specifies the significance level of the forecast confidence intervals; for example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

BACK=integer**SKIPLAST=integer**

specifies the holdout sample for the evaluation of the forecasting performance of the model. For example, BACK=10 results in treating the last 10 observed values of the response series as unobserved. A post-sample-prediction-analysis table is produced for comparing the predicted values with the actual values in the holdout period. The default is BACK=0.

EXTRADIFFUSE=k

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead forecasts are produced only after the diffuse state is initialized. Delaying the initialization leads to reduction in the number of one-step-ahead forecasts. This option is useful when you want to ignore the first few one-step-ahead forecasts that often have large variance.

LEAD=integer

specifies the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and BACK= options; for example, LEAD=10 results in the forecasting of 10 future values of the response series. The default is LEAD=12.

OUTFOR=SAS-data-set

specifies an output data set for the forecasts. The output data set contains the ID variable (if specified), the response and predictor series, the one-step-ahead and out-of-sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series, and the smoothed forecasts produced as a result of the model-based decomposition of the series.

PLOT=DECOMP**PLOT=DECOMPVAR****PLOT=FDECOMP****PLOT=FDECOMPVAR****PLOT=FORECASTS****PLOT=TREND****PLOT=(< plot request > ... < plot request >)**

requests forecast and model decomposition plots. The FORECASTS option provides the plot of the series forecasts, the TREND and DECOMP options provide the plots of the smoothed trend and other decompositions, the DECOMPVAR option can be used to plot the variance of

these components, and the FDECOMP and FDECOMPVAR options provide the same plots for the filtered decomposition estimates and their variances.

PRINT=DECOMP

PRINT=FDECOMP

PRINT=FORECASTS

PRINT=NONE

PRINT=(< print request > ... < print request >)

controls the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon specified by the LEAD= option; that is, the one-step-ahead predicted values are not printed. You can request forecasts for the entire forecast span by specifying the PRINT=FORECASTS option. Using PRINT=DECOMP, you can get smoothed estimates of the following effects: trend, trend plus regression, trend plus regression plus cycle, and sum of all components except the irregular. If some of these effects are absent in the model, then they are ignored. Similarly you can get filtered estimates of these effects by using PRINT=FDECOMP. You can use PRINT=NONE to suppress the printing of all the forecast output.

SKIPFIRST=integer

indicates that some early part of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model being used for forecasting is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the forecast calculations. The default is SKIPFIRST=0.

ID Statement

ID variable *INTERVAL=value* < *ALIGN=value* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the frequency associated with the time series. The ID statement options also specify how the observations are aligned to form the time series. If the ID statement is specified, the INTERVAL= option must also be specified. If the ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

ALIGN=value

controls the alignment of SAS dates used to identify output observations. The ALIGN= option has the following possible values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable with the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL=value

specifies the time interval between observations. This option is required in the ID statement.

INTERVAL=*value* is used in conjunction with the ID variable to check that the input data are in order and have no gaps. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. For a complete discussion of the intervals supported, please see Chapter 4, “Date Intervals, Formats, and Functions.”

IRREGULAR Statement

IRREGULAR < options > ;

The IRREGULAR statement is used to include an irregular component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error, ϵ_t , in the model. By default the irregular component is modeled as white noise—that is, as a sequence of independent, identically distributed, zero-mean, Gaussian random variables. However, as an experimental feature in this release of the UCM procedure, you can also model it as an autoregressive moving-average (ARMA) process. The options for specifying an ARMA model for the irregular component are given in a separate subsection: “ARMA Specification (Experimental)” on page 1769.

The options in this statement enable you to specify the value of σ_ϵ^2 and to output the forecasts of ϵ_t . As a default, σ_ϵ^2 is estimated using the data. Two examples of the IRREGULAR statement are given next. In the first example the statement is in its simplest form, resulting in the inclusion of an irregular component that is white noise with unknown variance:

```
irregular;
```

The following statement provides a starting value for σ_ϵ^2 , to be used in the nonlinear parameter estimation process. It also requests the printing of smoothed predictions of ϵ_t . The smoothed irregulars are useful in model diagnostics.

```
irregular variance=4 print=smooth;
```

NOEST

fixes the value of σ_ϵ^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the irregular component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the irregular component.

VARIANCE=*value*

specifies an initial value for σ_ϵ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

ARMA Specification (Experimental)

This section details the options for specifying an ARMA model for the irregular component. The specification of ARMA models requires some notation, which is explained first.

Let B denote the backshift operator—that is, for any sequence ϵ_t , $B\epsilon_t = \epsilon_{t-1}$. The higher powers of B represent larger shifts (for example, $B^3\epsilon_t = \epsilon_{t-3}$). A random sequence ϵ_t follows a zero-mean $\text{ARMA}(p,q)\times(P,Q)_s$ model with nonseasonal autoregressive order p , seasonal autoregressive order P , nonseasonal moving-average order q , and seasonal moving-average order Q , if it satisfies the following difference equation specified in terms of the polynomials in the backshift operator:

$$\phi(B)\Phi(B^s)\epsilon_t = \theta(B)\Theta(B^s)a_t$$

where a_t is a white noise sequence and s is the season length. The polynomials ϕ , Φ , θ , and Θ are of orders p , P , q , and Q , respectively, which can be any nonnegative integers. The season length s must be a positive integer. For example, ϵ_t satisfies an $\text{ARMA}(1,1)$ model—that is, $p = 1$, $q = 1$, $P = 0$, and $Q = 0$ —if

$$\epsilon_t = \phi_1\epsilon_{t-1} + a_t - \theta_1a_{t-1}$$

for some coefficients ϕ_1 and θ_1 and a white noise sequence a_t . Similarly ϵ_t satisfies an $\text{ARMA}(1,1)\times(1,1)_{12}$ model if

$$\epsilon_t = \phi_1\epsilon_{t-1} + \Phi_1\epsilon_{t-12} - \phi_1\Phi_1\epsilon_{t-13} + a_t - \theta_1a_{t-1} - \Theta_1a_{t-12} + \theta_1\Theta_1a_{t-13}$$

for some coefficients ϕ_1 , Φ_1 , θ_1 , and Θ_1 and a white noise sequence a_t . The ARMA process is stationary and invertible if the defining polynomials ϕ , Φ , θ , and Θ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the ARMA model specified for the irregular component is stationary and invertible—that is, the coefficients of the polynomials ϕ , Φ , θ , and Θ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated using the data.

The notation for a closely related class of models, autoregressive integrated moving-average (ARIMA) models, is also given here. A random sequence y_t is said to follow an $\text{ARIMA}(p,d,q)\times(P,D,Q)_s$ model if, for some nonnegative integers d and D , the differenced series $\epsilon_t = (1 - B)^d(1 - B^s)^D y_t$ follows an $\text{ARMA}(p,q)\times(P,Q)_s$ model. The integers d and D are called nonseasonal and seasonal differencing orders, respectively. You can specify ARIMA models by using the [DEPLAG](#) statement for specifying the differencing orders and by using the [IRREGULAR](#) statement for the ARMA specification. See [Example 29.8](#) for an example of $\text{ARIMA}(0,1,1)\times(0,1,1)_{12}$ model specification. Brockwell and Davis (1991) can be consulted for additional information about ARIMA models.

You can use options of the [IRREGULAR](#) statement to specify the desired ARMA model and to request printed and graphical output. Several examples of the [IRREGULAR](#) statement are given next.

The following statement specifies an irregular component that is modeled as an $\text{ARMA}(1,1)$ process. It also requests plotting its smoothed estimate.

```
irregular p=1 q=1 plot=smooth;
```

The following statement specifies an ARMA(1,1)×(1,1)₁₂ model. It also fixes the coefficient of the first-order seasonal moving-average polynomial to 0.1. The other coefficients and the white noise variance are estimated using the data.

```
irregular p=1 sp=1 q=1 sq=1 s=12 sma=0.1 noest=(sma);
```

AR= $\phi_1 \phi_2 \dots \phi_p$

lists the starting values of the coefficients of the nonseasonal autoregressive polynomial:

$$\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$$

where the order p is specified in the **P=** option. The coefficients ϕ_i must define a stationary autoregressive polynomial.

MA= $\theta_1 \theta_2 \dots \theta_q$

lists the starting values of the coefficients of the nonseasonal moving-average polynomial:

$$\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$$

where the order q is specified in the **Q=** option. The coefficients θ_i must define an invertible moving-average polynomial.

NOEST=(<**VARIANCE**> <**AR**> <**SAR**> <**MA**> <**SMA**>)

fixes the values of the ARMA parameters and the value of the white noise variance to those specified in the **AR=**, **SAR=**, **MA=**, **SMA=**, or **VARIANCE=** options.

P=integer

specifies the order of the nonseasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

Q=integer

specifies the order of the nonseasonal moving-average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

S=integer

specifies the season length used during the specification of the seasonal autoregressive or seasonal moving-average polynomial. The season length can be any positive integer; for example, $S=4$ might be an appropriate value for a quarterly series. The default value is $S=1$.

SAR= $\Phi_1 \Phi_2 \dots \Phi_P$

lists the starting values of the coefficients of the seasonal autoregressive polynomial:

$$\Phi(B^s) = 1 - \Phi_1 B^s - \dots - \Phi_P B^{sP}$$

where the order P is specified in the **SP=** option and the season length s is specified in the **S=** option. The coefficients Φ_i must define a stationary autoregressive polynomial.

SMA= $\Theta_1 \Theta_2 \dots \Theta_Q$

lists the starting values of the coefficients of the seasonal moving-average polynomial:

$$\Theta(B^s) = 1 - \Theta_1 B^s - \dots - \Theta_Q B^{sQ}$$

where the order Q is specified in the **SQ**= option and the season length s is specified in the **S**= option. The coefficients Θ_i must define an invertible moving-average polynomial.

SP=integer

specifies the order of the seasonal autoregressive polynomial. The order can be any non-negative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

SQ=integer

specifies the order of the seasonal moving-average polynomial. The order can be any non-negative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

LEVEL Statement

LEVEL <options> ;

The LEVEL statement is used to include a level component in the model. The level component, either by itself or together with a slope component (see the **SLOPE** statement), forms the trend component, μ_t , of the model. If the slope component is absent, the resulting trend is a random walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma_\eta^2)$$

If the slope component is present, signified by the presence of a **SLOPE** statement, a locally linear trend (LLT) is obtained. The equations of LLT are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

In either case, the options in the LEVEL statement are used to specify the value of σ_η^2 and to request forecasts of μ_t . The SLOPE statement is used for similar purposes in the case of slope β_t . The following examples illustrate the use of the LEVEL statement. Assuming that a SLOPE statement is not added subsequently, a simple random walk trend is specified by the following statement:

level;

The following statements specify a locally linear trend with value of σ_η^2 fixed at 4. It also requests printing of filtered values of μ_t . The value of σ_ξ^2 , the disturbance variance in the slope equation, is estimated from the data.

```
level variance=4 noest print=filter;
slope;
```

CHECKBREAK

turns on the checking of breaks in the level component.

NOEST

fixes the value of σ_{η}^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of the filtered or smoothed estimate of the level component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of the filtered or smoothed estimate of the level component.

VARIANCE=value

specifies an initial value for σ_{η}^2 , the disturbance variance in the μ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

MODEL Statement

```
MODEL dependent < = regressors > ;
```

The MODEL statement specifies the response variable and, optionally, the predictor or regressor variables for the UCM model. This is a required statement in the UCM procedure. The predictors specified in the MODEL statement are assumed to have a linear and time-invariant relationship with the response. The predictors that have time-varying regression coefficients are specified separately in the **RANDOMREG** statement. Similarly, the predictors that have a nonlinear effect on the response variable are specified separately in the **SPLINEREG** statement. Only one MODEL statement can be specified.

NLOPTIONS Statement

```
NLOPTIONS < options > ;
```

PROC UCM uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems the

default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. This can be done by using the TECH= and MAXITER= options in the NLOPTIONS statement as follows:

```
nloptions tech=dbldog maxiter=200;
```

This sets the maximum number of iterations to 200 and changes the optimization technique to DBLDOG rather than the default technique, TRUREG, used in PROC UCM. A discussion of the full range of options that can be used with the NLOPTIONS statement is given in Chapter 6, “[Nonlinear Optimization Methods](#).” In PROC UCM all these options are available except the options related to the printing of the optimization history. In this version of PROC UCM all the printed output from the NLO subsystem is suppressed.

OUTLIER Statement

OUTLIER < options > ;

The OUTLIER statement enables you to control the reporting of the additive outliers (AO) and level shifts (LS) in the response series. The AOs are searched by default. You can turn on the search for LSs by using the [CHECKBREAK](#) option in the LEVEL statement.

ALPHA=*significance-level*

specifies the significance level for reporting the outliers. The default is 0.05.

MAXNUM=*number*

limits the number of outliers to search. The default is MAXNUM=5.

MAXPCT=*number*

is similar to the MAXNUM= option. In the MAXPCT= option you can limit the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=1. When both of these options are specified, the minimum of the two search numbers is used.

PRINT=SHORT | DETAIL

enables you to control the printed output of the outlier search. The PRINT=SHORT option, which is the default, produces an outlier summary table containing the most significant outliers, either AO or LS, discovered in the outlier search. The PRINT=DETAIL option produces, in addition to the outlier summary table, separate tables containing the AO and LS structural break chi-square statistics computed at each time point in the estimation span.

RANDOMREG Statement

RANDOMREG *regressors* < / options > ;

The RANDOMREG statement is used to specify regressors with time-varying regression coefficients. Each regression coefficient—say, β_t —is assumed to evolve as a random walk:

$$\beta_t = \beta_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma^2)$$

Of course, if the random walk disturbance variance σ^2 is zero, then the regression coefficient is not time varying, and it reduces to the standard regression setting. There can be multiple RANDOMREG statements, and each statement can contain one or more regressors. The regressors in a given RANDOMREG statement form a group that is assumed to share the same disturbance variance parameter. The random walks associated with different regressors are assumed to be independent. For an example of using this statement see [Example 29.4](#). See the section “[Reporting Parameter Estimates for Random Regressors](#)” on page 1794 for additional information about the way parameter estimates are reported for this type of regressors.

NOEST

fixes the value of σ^2 to the value specified in the `VARIANCE=` option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=value

specifies an initial value for σ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SEASON Statement

SEASON LENGTH = integer < options > ;

The SEASON or SEASONAL statement is used to specify a seasonal component, γ_t , in the model. A seasonal component can be one of the two types, DUMMY or TRIG. A DUMMY seasonal with season length s satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim i.i.d. N(0, \sigma_\omega^2)$$

The equations for a TRIG (short for trigonometric) seasonal component are as follows:

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s - 1)/2$ if it is odd. The sinusoids, also called *harmonics*, $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

In the TRIG seasonal case, the option **KEEPH=** or **DROPH=** can be used to obtain *subset trigonometric* seasonals that contain only a subset of the full set of harmonics $\gamma_{j,t}$, $j = 1, 2, \dots, [s/2]$. This is particularly useful when the season length s is large and the seasonal pattern is relatively smooth.

Note that whether the seasonal type is DUMMY or TRIG, there is only one parameter, the disturbance variance σ_ω^2 , in the seasonal model.

There can be more than one seasonal component in the model, necessarily with different season lengths if the seasons are full. You can have multiple *subset* season components with the same season length, if you need to use separate disturbance variances for different sets of harmonics. Each seasonal component is specified using a separate SEASON statement. A model with multiple seasonal components can easily become quite complex and might need a large amount of data and computing resources for its estimation and forecasting. The examples that follow illustrate the use of SEASON statement.

The following statement specifies a DUMMY type (default) seasonal component with a season length of four, corresponding to the quarterly seasonality. The disturbance variance σ_ω^2 is estimated from the data.

```
season length=4;
```

The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for σ_ω^2 .

```
season length=12 type=trig variance=4;
```

DROPHARMONICS|DROPH=number-list | n TO m BY p

enables you to drop some harmonics $\gamma_{j,t}$ from the full set of harmonics used to obtain a trigonometric seasonal. The drop list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length 12 that consists of only the first four harmonics $\gamma_{j,t}$, $j = 1, 2, 3, 4$:

```
season length=12 type=trig DROPH=5 6;
```

The last two *high* frequency harmonics are dropped. The **DROPH=** option cannot be used with the **KEEPH=** option.

KEEPHARMONICS|KEEPH=number-list | n TO m BY p

enables you to keep only the harmonics $\gamma_{j,t}$ listed in the option to obtain a trigonometric seasonal. The keep list can include any integer between 1 and $\lfloor s/2 \rfloor$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length of 12 that consists of all the six harmonics $\gamma_{j,t}$, $j = 1, \dots, 6$:

```
season length=12 type=trig KEEPH=1 to 3;
season length=12 type=trig KEEPH=4 to 6;
```

However, these six harmonics are grouped into two groups, each having its own disturbance variance parameter. The **DROPH=** option cannot be used with the **KEEPH=** option.

LENGTH=integer

specifies the season length, s . This is a required option in this statement. The season length can be any integer greater than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=F_ ANNUAL****PLOT=S_ ANNUAL****PLOT=(<plot request> ... <plot request>)**

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component γ_t . You can use the **F_ ANNUAL** and **S_ ANNUAL** options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

PRINT=HARMONICS

requests printing of the summary of harmonics present in the seasonal component. This option is valid only for the trigonometric seasonal component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(<print request> ... <print request>)**

requests printing of the filtered or smoothed estimate of the seasonal component γ_t .

TYPE=DUMMY | TRIG

specifies the type of the seasonal component. The default type is **DUMMY**.

VARIANCE=value

specifies an initial value for the disturbance variance, σ_{ω}^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SLOPE Statement

SLOPE < options > ;

The SLOPE statement is used to include a slope component in the model. The slope component cannot be used without the level component (see the **LEVEL** statement). The level and slope specifications jointly define the trend component of the model. A SLOPE statement without the accompanying **LEVEL** statement is ignored. The equations of the trend, defined jointly by the level μ_t and slope β_t , are as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_{\eta}^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_{\xi}^2)\end{aligned}$$

The SLOPE statement is used to specify the value of the disturbance variance, σ_{ξ}^2 , in the slope equation, and to request forecasts of β_t . The following examples illustrate this statement:

```
level;
slope;
```

The preceding statements fit a model with a locally linear trend. The disturbance variances σ_{η}^2 and σ_{ξ}^2 are estimated from the data. You can request a locally linear trend with fixed slope by using the following statements:

```
level;
slope variance=0 noest;
```

NOEST

fixes the value of the disturbance variance, σ_{ξ}^2 , to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH**

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the slope component.

PRINT=FILTER**PRINT=SMOOTH**

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the slope component β_t .

VARIANCE=value

specifies an initial value for the disturbance variance, σ_{ξ}^2 , in the β_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINEREG Statement

SPLINEREG *regressor* < options > ;

The SPLINEREG statement is used to specify a regressor that has a nonlinear relationship with the dependent series that can be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it is known that it can be written as a linear combination of $(n + d + 1)$ regressors that are derived from the original regressor. The span of these $(n + d + 1)$ derived regressors includes constant; therefore, to avoid multicollinearity with the level component, one of these regressors is dropped. Specifying the SPLINEREG statement is equivalent to specifying a RANDOMREG statement with these derived regressors. There can be multiple SPLINEREG statements. You must specify at least one interior knot, either using the NKNOTS= option or the KNOTS= option. For additional information about splines, see Chapter 90, “The TRANSREG Procedure” (*SAS/STAT User’s Guide*). For an example of using this statement, see [Example 29.6](#). See the section “[Reporting Parameter Estimates for Random Regressors](#)” on page 1794 for additional information about the way parameter estimates are reported for this type of regressors.

DEGREE=integer

specifies the degree of the spline. It can be any integer larger than or equal to zero. The default value is 3. The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

KNOTS=number-list | n TO m BY p

specifies the interior knots or break points. The values in the knot list must be nondecreasing and must lie between the minimum and the maximum of the spline regressor values in the input data set. The first time you specify a value in the knot list, it indicates a discontinuity in the n th (from DEGREE= n) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n - 1)$ th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the **KNOTS=** option with the **NKNOTS=** option. You should keep the number of knots small.

NKNOTS=m

creates m knots, the first at the $100/(m + 1)$ percentile, the second at the $200/(m + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. The value specified for the NKNOTS= option must be ≥ 1 . You cannot use the **NKNOTS=** option with the **KNOTS=** option.

NOTE: Specifying knots by using the `NKNOTS=` option can result in different sets of knots in the estimation and forecast stages if the distributions of regressor values in the estimation and forecast spans differ. The estimation span is based on the `BACK=` and `SKIPFIRST=` options in the `ESTIMATE` statement, and the forecast span is based on the `BACK=` and `SKIPFIRST=` options in the `FORECAST` statement.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the `VARIANCE=` option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINESEASON Statement

SPLINESEASON *LENGTH* = *integer* **KNOTS** = *integer*₁ *integer*₂ ... < options > ;

The `SPLINESEASON` statement is used to specify a seasonal pattern that is to be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it can be written as a linear combination of $(n + d)$ regressors that are derived from the seasonal dummy regressors. The `SPLINESEASON` specification is equivalent to specifying a `RANDOM-REG` specification with these derived regressors. Such approximation is useful only if the season length is relatively large, at least larger than $(n + d)$. For additional information about splines, see Chapter 90, “[The TRANSREG Procedure](#)” (*SAS/STAT User's Guide*). For an example of using this statement, see [Example 29.3](#).

DEGREE=*integer*

specifies the degree of the spline. It can be any integer greater than or equal to zero. The default value is 3.

KNOTS=*integer*₁ *integer*₂ ...

lists the *internal* knots. This list of values must be a nondecreasing sequence of integers within the range of 2 to $(s - 1)$, where s is the season length specified in the `LENGTH=` option. This is a required option in this statement.

LENGTH=integer

specifies the season length, s . This is a required option in this statement. The length can be any integer greater than or equal to three.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the **VARIANCE=** option.

OFFSET=integer

specifies the position of the first measurement within the season, if the first measurement is not at the start of the season. The **OFFSET=** value must be between one and the season length. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the season length.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests the printing of the filtered or smoothed estimate of the spline season component.

RKNOTS=(knot, ..., knot) ... (knot, ..., knot)

specifies a grouping of knots such that the knots within the same group have identical seasonal values. The knots specified in this option must already be present in the list specified by the **KNOTS=** option. The knot groups must be non-overlapping and without any repeated knots.

Experimental

VARIANCE=value

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

Details: UCM Procedure

An Introduction to Unobserved Component Models

A UCM decomposes the response series into components such as trend, seasons, cycles, and the regression effects due to predictor series. The following model shows a possible scenario:

$$y_t = \mu_t + \gamma_t + \psi_t + \sum_{j=1}^m \beta_j x_{jt} + \epsilon_t$$

$$\epsilon_t \sim i.i.d. N(0, \sigma_\epsilon^2)$$

The terms μ_t , γ_t , and ψ_t represent the trend, seasonal, and cyclical components, respectively. In fact the model can contain multiple seasons and cycles, and the seasons can be of different types. For simplicity of discussion the preceding model contains only one of each of these components. The regression term, $\sum_{j=1}^m \beta_j x_{jt}$, includes contribution of regression variables with *fixed* regression coefficients. A model can also contain regression variables that have *time varying* regression coefficients or that have a nonlinear relationship with the dependent series (see “[Incorporating Predictors of Different Kinds](#)” on page 1793). The disturbance term ϵ_t , also called the *irregular* component, is usually assumed to be Gaussian white noise. In some cases it is useful to model the irregular component as a stationary ARMA process. See the section “[Modeling the Irregular Component](#)” on page 1785 for additional information.

By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as *log* and *difference*.

The components μ_t , γ_t , and ψ_t model structurally different aspects of the time series. For example, the trend μ_t models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables, while the seasonal component γ_t models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

Modeling the Trend

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component μ_t . The first model, called the random walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The

RW model can be described as

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma_\eta^2)$$

Note that if $\sigma_\eta^2 = 0$, then the model becomes $\mu_t = \text{constant}$. In the LLT model the trend is locally linear, consisting of both the *level* and *slope*. The LLT model is

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

The disturbances η_t and ξ_t are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances σ_η^2 and σ_ξ^2 equal to zero. If σ_ξ^2 is set equal to zero, then you get a linear trend model with fixed slope. If σ_η^2 is set to zero, then the resulting model usually has a smoother trend. If both the variances are set to zero, then the resulting model is the deterministic linear time trend: $\mu_t = \mu_0 + \beta_0 t$.

You can incorporate these trend patterns in your model by using the **LEVEL** and **SLOPE** statements.

Modeling a Cycle

A deterministic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, can be written as

$$\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)$$

If the argument t is measured on a continuous scale, then ψ_t is a periodic function with period $2\pi/\lambda$, amplitude $\gamma = (\alpha^2 + \beta^2)^{1/2}$, and phase $\phi = \tan^{-1}(\beta/\alpha)$. Equivalently, the cycle can be written in terms of the amplitude and phase as

$$\psi_t = \gamma \cos(\lambda t - \phi)$$

Note that when ψ_t is measured only at the integer values, it is not exactly periodic, unless $\lambda = (2\pi j)/k$ for some integers j and k . The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed period but time-varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing ψ_t :

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix}$$

starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that ψ_t and ψ_t^* satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle ψ_t can be obtained by adding random noise to this recursion and by introducing a damping factor, ρ , for additional modeling flexibility. This model can be described as follows:

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} v_t \\ v_t^* \end{bmatrix}$$

where $0 \leq \rho \leq 1$, and the disturbances v_t and v_t^* are independent $N(0, \sigma_v^2)$ variables. The resulting stochastic cycle has a fixed period but time-varying amplitude and phase. The stationarity properties of the random sequence ψ_t depend on the damping factor ρ . If $\rho < 1$, ψ_t has a stationary distribution with mean zero and variance $\sigma_v^2/(1 - \rho^2)$. If $\rho = 1$, ψ_t is nonstationary.

You can incorporate a cycle in a UCM by specifying a **CYCLE** statement. You can include multiple cycles in the model by using separate **CYCLE** statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonal components is considered next.

Modeling Seasons

The seasonal fluctuations are a common source of variation in time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to zero when summed over the full season cycle. Therefore the seasonal component γ_t is modeled as a stochastic periodic pattern of an integer period s such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always zero in the mean. The period s is called the season length. Two different models for the seasonal component are considered here. The first model is called the *dummy* variable form of the seasonal component. It is described by the equation

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim i.i.d. N(0, \sigma_\omega^2)$$

The other model is called the *trigonometric* form of the seasonal component. In this case γ_t is modeled as a sum of cycles of different frequencies. This model is given as follows:

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s - 1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called *harmonics*. If the seasonal component is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high-frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals, the situation might not be so transparent; however, similar considerations still apply. Note that if the disturbance variance $\sigma_\omega^2 = 0$, then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

In the UCM procedure you can specify a seasonal component in a variety of ways, the **SEASON** statement being the simplest of these. The dummy and the trigonometric seasonal components discussed so far can be considered as *saturated* seasonal components that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal might be more appropriate. This is particularly useful for seasonal components with large season lengths. In the UCM procedure you can obtain parsimonious representations of the seasonal components by one of the following ways:

- Use a *subset* trigonometric seasonal component obtained by deleting a few of the $[s/2]$ harmonics used in its sum. For example, a slightly smoother seasonal component of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest-frequency harmonic of period 2. That is, such a seasonal component will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. You can specify such subset seasonal components by using the **KEEPH=** or **DROPH=** option in the **SEASON** statement.
- Approximate the seasonal pattern by a suitable spline approximation. You can do this by using the **SPLINESEASON** statement.
- A *block-seasonal* pattern is a seasonal pattern where the pattern is divided into a few blocks of equal length such that the season values within a block are the same—for example, a monthly seasonal pattern that has only four different values, one for each quarter. In some situations a long seasonal pattern can be approximated by the sum of block season and a simple season, the length of the simple season being equal to the block length of the block season. You can obtain such approximation by using a combination of **BLOCKSEASON** and **SEASON** statements.
- Consider a seasonal component of a large season length as a sum of two or more seasonal components that are each of much smaller season lengths. This can be done by specifying more than one **SEASON** statements.

Note that the preceding techniques of obtaining parsimonious seasonal components can also enable you to specify seasonal components that are more *general* than the simple saturated seasonal components. For example, you can specify a saturated trigonometric seasonal component that has some of its harmonics evolving according to one disturbance variance parameter while the others evolve with another disturbance variance parameter.

Modeling an Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency λ is either 0 or π . Modeling this special case separately helps interpretation and parameter estimation. The autoregression component r_t is modeled as follows:

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim i.i.d. N(0, \sigma_v^2)$$

where $-1 \leq \rho < 1$. An autoregression can also provide an alternative to the **IRREGULAR** component when the model errors show some autocorrelation. You can incorporate an autoregression in your model by using the **AUTOREG** statement.

Modeling Regression Effects

A predictor variable can affect the response variable in a variety of ways. The UCM procedure enables you to model several different types of predictor-response relationships:

- The predictor-response relationship is *linear*, and the regression coefficient does not change with time. This is the simplest kind of relationship and such predictors are specified in the **MODEL** statement.
- The predictor-response relationship is *linear*, but the regression coefficient does change with time. Such predictors are specified in the **RANDOMREG** statement. Here the regression coefficient is assumed to evolve as a random walk.
- The predictor-response relationship is *nonlinear* and the relationship can change with time. This type of relationship can be approximated by an appropriate time-varying spline. Such predictors are specified in the **SPLINEREG** statement.

A response variable can depend on its own past values—that is, lagged dependent values. Such a relationship can be specified in the **DEPLAG** statement.

Modeling the Irregular Component

The components—such as trend, seasonal and regression effects, and nonstationary cycles—are used to capture the structural dynamics of a response series. In contrast, the stationary cycles and the autoregression are used to capture the transient aspects of the response series that are important for its short-range prediction but have little impact on its long-term forecasts. The irregular component represents the residual variation remaining in the response series that is modeled using an appropriate selection of structural and transient effects. In most cases, the irregular component can be assumed to be simply Gaussian white noise. In some other cases, however, the residual variation can be more complicated. In such situations, it might be necessary to model the irregular component as a stationary ARMA process. Moreover, you can use the ARMA irregular component together with the dependent lag specification (see the **DEPLAG** statement) to specify an $ARIMA(p,d,q) \times (P,D,Q)_s$ model for the response series. See the **IRREGULAR** statement for the explanation of the ARIMA notation. See [Example 29.8](#) for an example of modeling a series by using an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model.

The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user-specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

consisting of the irregular, level, slope, and seasonal components. This model is called the basic structural model (BSM) by Harvey (1989). The syntax for a BSM with monthly seasonality of trigonometric type is as follows:

```
model y;
irregular;
level;
slope;
season length=12 type=trig;
```

Similarly the following syntax specifies a BSM with a response variable y , a regressor x , and dummy-type monthly seasonality:

```
model y = x;
irregular;
level;
slope variance=0 noest;
season length=12 type=dummy;
```

Moreover, the disturbance variance of the slope component is restricted to zero, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for a model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
irregular;
level;
cycle;
cycle;
```

The UCMs as State Space Models

The UCMs considered in PROC UCM can be thought of as special cases of more general models, called (linear) Gaussian state space models (GSSM). A GSSM can be described as follows:

$$\begin{aligned}y_t &= Z_t \alpha_t \\ \alpha_{t+1} &= T_t \alpha_t + \zeta_{t+1}, \quad \zeta_t \sim N(0, Q_t) \\ \alpha_1 &\sim N(0, P)\end{aligned}$$

The first equation, called the *observation equation*, relates the response series y_t to a state vector α_t that is usually unobserved. The second equation, called the *state equation*, describes the evolution of the state vector in time. The system matrices Z_t and T_t are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series ζ_t consists of independent, zero-mean, Gaussian vectors with covariance matrices Q_t . For most of the UCMs considered here, the system matrices Z_t and T_t , and the noise covariances Q_t , are time invariant—that is, they do not depend on time. In a few cases, however, some or all of them can depend on time. The initial state vector α_1 is assumed to be independent of the noise series, and its covariance matrix P can be partially diffuse. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite—that is, you have no prior information about this part of the vector. The covariance of the initial state α_1 is assumed to have the following form:

$$P = P_* + \kappa P_\infty$$

where P_* and P_∞ are nonnegative definite, symmetric matrices and κ is a constant that is assumed to be close to ∞ . In the case of UCMs considered here, P_∞ is always a diagonal matrix that consists of zeros and ones, and, if a particular diagonal element of P_∞ is one, then the corresponding row and column in P_* are zero.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states $\{\alpha_t\}$ by using the observed series $\{y_t\}$. These algorithms also yield the in-sample and out-of-sample forecasts and the likelihood of $\{y_t\}$. The state space representation of a UCM does not need to be unique. In the representation used here, the unobserved components in the UCM often appear as elements of the state vector. This makes the elements of the state interpretable and, more important, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information about the computational aspects of the state space modeling, see Durbin and Koopman (2001). Next, some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let $\{y_t, t = 1, \dots, n\}$ be the observed sample from a series that satisfies a state space model. Next, for $1 \leq t \leq n$, let the one-step-ahead forecasts of the series, the states, and their variances be defined as follows, using the usual notation to denote the conditional expectation and conditional

variance:

$$\begin{aligned}\hat{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \Gamma_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \hat{y}_t &= E(y_t | y_1, y_2, \dots, y_{t-1}) \\ F_t &= \text{Var}(y_t | y_1, y_2, \dots, y_{t-1})\end{aligned}$$

These are also called the *filtered* estimates of the series and the states. Similarly, for $t \geq 1$, let the following denote the full-sample estimates of the series and the state values at time t :

$$\begin{aligned}\tilde{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_n) \\ \Delta_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_n) \\ \tilde{y}_t &= E(y_t | y_1, y_2, \dots, y_n) \\ G_t &= \text{Var}(y_t | y_1, y_2, \dots, y_n)\end{aligned}$$

If the time t is in the historical period— that is, if $1 \leq t \leq n$ — then the full-sample estimates are called the *smoothed* estimates, and if t lies in the future then they are called out-of-sample forecasts. Note that if $1 \leq t \leq n$, then $\tilde{y}_t = y_t$ and $G_t = 0$, unless y_t is missing.

All the filtered and smoothed estimates ($\hat{\alpha}_t, \tilde{\alpha}_t, \dots, G_t$, and so on) are computed by using the Kalman filtering and smoothing (KFS) algorithm, which is an iterative process. If the initial state is diffuse, as is often the case for the UCMs, its treatment requires modification of the traditional KFS, which is called the diffuse KFS (DKFS). The details of DKFS implemented in the UCM procedure can be found in de Jong and Chu-Chun-Lin (2003). Additional information on the state space models can be found in Durbin and Koopman (2001). The likelihood formulas described in this section are taken from the latter reference.

In the case of diffuse initial condition, the effect of the improper prior distribution of α_1 manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse; that is, during these iterations the one-step-ahead series and state forecast variances F_t and Γ_t have the following form:

$$\begin{aligned}F_t &= F_{*t} + \kappa F_{\infty t} \\ \Gamma_t &= \Gamma_{*t} + \kappa \Gamma_{\infty t}\end{aligned}$$

The actual number of iterations—say, I — affected by this improper prior depends on the nature of the vectors Z_t , the number of nonzero diagonal elements of P_∞ , and the pattern of missing values in the dependent series. After I iterations, $\Gamma_{\infty t}$ and $F_{\infty t}$ become zero and the one-step-ahead series and state forecasts have proper distributions. These first I iterations constitute the *initialization* phase of the DKFS algorithm. The post-initialization phase of the DKFS and the traditional KFS is the same. In the state space modeling literature the pre-initialization and post-initialization phases are some times called *pre-collapse* and *post-collapse* phases of the diffuse Kalman filtering. In certain missing value patterns it is possible for I to exceed the sample size; that is, the sample information can be insufficient to create a proper prior for the filtering process. In these cases, parameter estimation and forecasting is done on the basis of this improper prior, and some or all

of the series and component forecasts can have infinite variances (or zero precision). The forecasts that have infinite variance are set to missing. The same situation can occur if the specified model contains components that are essentially multicollinear. In these situations no residual analysis is possible; in particular, no residuals-based goodness-of-fit statistics are produced.

The log likelihood of the sample (L_∞), which takes account of this diffuse initialization step, is computed by using the one-step-ahead series forecasts as follows:

$$L_\infty(y_1, \dots, y_n) = -\frac{(n-d)}{2} \log 2\pi - \frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \left(\log F_t + \frac{v_t^2}{F_t} \right)$$

where d is the number of diffuse elements in the initial state α_1 , $v_t = y_t - Z_t \hat{\alpha}_t$ are the one-step-ahead residuals, and

$$\begin{aligned} w_t &= \log F_{\infty t} && \text{if } F_{\infty t} > 0 \\ &= \log F_{*t} + \frac{v_t^2}{F_{*t}} && \text{if } F_{\infty t} = 0 \end{aligned}$$

If y_t is missing at some time t , then the corresponding summand in the log likelihood expression is deleted, and the constant term is adjusted suitably. Moreover, if the initialization step does not complete—that is, if I exceeds the sample size—then the value of d is reduced to the number of diffuse states that are successfully initialized.

The portion of the log likelihood that corresponds to the post-initialization period is called the nondiffuse log likelihood (L_0). The nondiffuse log likelihood is given by

$$L_0(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=I+1}^n \left(\log F_t + \frac{v_t^2}{F_t} \right)$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^I w_t$, does not depend on the model parameters, and in these cases the maximization of nondiffuse and diffuse likelihoods is equivalent. However, in some cases, such as when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and nondiffuse likelihood can produce different parameter estimates.

In some situations it is convenient to reparameterize the nondiffuse initial state covariance P_* as $\sigma^2 P_*$ and the state noise covariance Q_t as $\sigma^2 Q_t$ for some common scalar parameter σ^2 . In this case the preceding log-likelihood expression, up to a constant, can be written as

$$L_\infty(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \log F_t - \frac{1}{2\sigma^2} \sum_{t=I+1}^n \frac{v_t^2}{F_t} - \frac{(n-d)}{2} \log \sigma^2$$

Solving analytically for the optimum, the maximum likelihood estimate of σ^2 can be shown to be

$$\hat{\sigma}^2 = \frac{1}{(n-d)} \sum_{t=I+1}^n \frac{v_t^2}{F_t}$$

When this expression of σ^2 is substituted back into the likelihood formula, an expression called the *profile likelihood* ($L_{profile}$) of the data is obtained:

$$-2L_{profile}(y_1, \dots, y_n) = \sum_{t=1}^I w_t + \sum_{t=I+1}^n \log F_t + (n-d) \log \left(\sum_{t=I+1}^n \frac{v_t^2}{F_t} \right)$$

In some situations the parameter estimation is done by optimizing the profile likelihood (see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 1798 and the **PROFILE** option in the ESTIMATE statement).

In the remainder of this section the state space formulation of UCMs is further explained by using some particular UCMs as examples. The examples show that the state space formulation of the UCMs depends on the components in the model in a simple fashion; for example, the system matrix T is usually a block diagonal matrix with blocks that correspond to the components in the model. The only exception to this pattern is the UCMs that consist of the lags of dependent variable. This case is considered at the end of the section.

In what follows, $Diag [a, b, \dots]$ denotes a diagonal matrix with diagonal entries $[a, b, \dots]$, and the transpose of a matrix T is denoted as T' .

Local Level Model

Recall that the dynamics of a local level model are

$$\begin{aligned} y_t &= \mu_t + \epsilon_t \\ \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t \\ \beta_t &= \beta_{t-1} + \xi_t \end{aligned}$$

Here y_t is the response series and ϵ_t , η_t , and ξ_t are independent, zero-mean Gaussian disturbance sequences with variances σ_ϵ^2 , σ_η^2 , and σ_ξ^2 , respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [\epsilon_t \ \mu_t \ \beta_t]'$ and the state noise $\zeta_t = [\epsilon_t \ \eta_t \ \xi_t]'$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices T and Z and the noise covariance Q corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$Z = [1 \ 1 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad Q = Diag [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2]$$

The distribution of the initial state vector α_1 is diffuse, with $P_* = Diag [\sigma_\epsilon^2, 0, 0]$ and $P_\infty = Diag [0, 1, 1]$. The parameter vector θ consists of all the disturbance variances—that is, $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2)$.

Basic Structural Model

The basic structural model (BSM) is obtained by adding a seasonal component, γ_t , to the local level model. In order to economize on the space, the state space formulation of a BSM with a relatively

short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t 0 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

and $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$.

In the case of the trigonometric type of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

and $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Seasons with Blocked Seasonal Values

Block seasonals are special seasonal components that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure—that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal component is a block seasonal with block size m equal to 3 and the number of blocks k equal to 4. The state space structure for such a model with dummy-type seasonality is as follows: The state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t 0 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag m and $\gamma_{3,t}$

to lag $2m$. All the system matrices are time invariant, except the matrix T . They can be seen to be $Z = [1\ 1\ 0\ 1\ 0\ 0]$, $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. Note that when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$.

Similarly in the case of the trigonometric form of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . $Z = [1\ 1\ 0\ 1\ 0\ 1]$, $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. As before, when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Cycles and Autoregression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There you can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, and damping coefficient ρ can be modeled as

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} v_t \\ v_t^* \end{bmatrix}$$

where v_t and v_t^* are independent, zero-mean, Gaussian disturbances with variance σ_v^2 . In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = [\epsilon_t \psi_t \psi_t^*]'$, and the state noise vector $\zeta_t = [\epsilon_t v_t v_t^*]'$. The system matrices are

$$Z = [1 \ 1 \ 0] \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \rho \cos \lambda & \rho \sin \lambda \\ 0 & -\rho \sin \lambda & \rho \cos \lambda \end{bmatrix} \quad Q = \text{Diag} [\sigma_\epsilon^2, \sigma_v^2, \sigma_v^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag} [\sigma_\epsilon^2, \sigma_\psi^2, \sigma_\psi^2]$, where $\sigma_\psi^2 = \sigma_v^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \lambda, \sigma_v^2)$.

An autoregression r_t can be considered as a special case of cycle with frequency λ equal to 0 or π . In this case the equation for ψ_t^* is not needed. Therefore, for a UCM consisting of an autoregressive component and an irregular component, the state space model simplifies to the following form.

The state vector $\alpha_t = [\epsilon_t r_t]'$, and the state noise vector $\zeta_t = [\epsilon_t v_t]'$. The system matrices are

$$Z = [1 \ 1], \quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \quad \text{and} \quad Q = \text{Diag} [\sigma_\epsilon^2, \sigma_v^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag} [\sigma_\epsilon^2, \sigma_r^2]$, where $\sigma_r^2 = \sigma_v^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \sigma_v^2)$.

Incorporating Predictors of Different Kinds

In the UCM procedure, predictors can be incorporated in a UCM in a variety of ways: simple time-invariant linear predictors are specified in the **MODEL** statement, predictors with time-varying coefficients can be specified in the **RANDOMREG** statement, and predictors that have a nonlinear relationship with the response variable can be specified in the **SPLINEREG** statement. As with earlier examples, how to obtain a state space form of a UCM consisting of such variety of predictors is illustrated using a simple special case. Consider a random walk trend model with predictors

x , u_1 , u_2 , and v . Let us assume that x is a simple regressor specified in the MODEL statement, u_1 and u_2 are random regressors with time-varying regression coefficients that are specified in the same RANDOMREG statement, and v is a nonlinear regressor specified on a SPLINEREG statement. Let us further assume that the spline associated with v has degree one and is based on two internal knots. As explained in the section “[SPLINEREG Statement](#)” on page 1778, using v is equivalent to using $(nknots + degree) = (2 + 1) = 3$ derived (random) regressors: say, s_1, s_2, s_3 . In all there are $(1 + 2 + 3) = 6$ regressors, the first one being a simple regressor and the others being time-varying coefficient regressors. The time-varying regressors are in two groups, the first consisting of u_1 and u_2 and the other consisting of s_1, s_2 , and s_3 . The dynamics of this model are as follows:

$$\begin{aligned}
 y_t &= \mu_t + \beta x_t + \kappa_{1t} u_{1t} + \kappa_{2t} u_{2t} + \sum_{i=1}^3 \gamma_{it} s_{it} + \epsilon_t \\
 \mu_t &= \mu_{t-1} + \eta_t \\
 \kappa_{1t} &= \kappa_{1(t-1)} + \xi_{1t} \\
 \kappa_{2t} &= \kappa_{2(t-1)} + \xi_{2t} \\
 \gamma_{1t} &= \gamma_{1(t-1)} + \zeta_{1t} \\
 \gamma_{2t} &= \gamma_{2(t-1)} + \zeta_{2t} \\
 \gamma_{3t} &= \gamma_{3(t-1)} + \zeta_{3t}
 \end{aligned}$$

All the disturbances $\epsilon_t, \eta_t, \xi_{1t}, \xi_{2t}, \zeta_{1t}, \zeta_{2t}$, and ζ_{3t} are independent, zero-mean, Gaussian variables, where ξ_{1t}, ξ_{2t} share a common variance parameter σ_ξ^2 and $\zeta_{1t}, \zeta_{2t}, \zeta_{3t}$ share a common variance σ_ζ^2 . These dynamics can be captured in the state space form by taking state $\alpha_t = [\epsilon_t \mu_t \beta \kappa_{1t} \kappa_{2t} \gamma_{1t} \gamma_{2t} \gamma_{3t}]'$, state disturbance $\zeta_t = [\epsilon_t \eta_t 0 \xi_{1t} \xi_{2t} \zeta_{1t} \zeta_{2t} \zeta_{3t}]'$, and the system matrices

$$\begin{aligned}
 Z_t &= [1 \ 1 \ x_t \ u_{1t} \ u_{2t} \ s_{1t} \ s_{2t} \ s_{3t}] \\
 T &= \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1] \\
 Q &= \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, 0, \sigma_\xi^2, \sigma_\xi^2, \sigma_\zeta^2, \sigma_\zeta^2, \sigma_\zeta^2]
 \end{aligned}$$

Note that the regression coefficients are elements of the state vector and that the system vector Z_t is not time invariant. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1]$. The parameters of this model are the disturbance variances, $\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2$, and σ_ζ^2 , which get estimated by maximizing the likelihood. The regression coefficients, time-invariant β and time-varying $\kappa_{1t}, \kappa_{2t}, \gamma_{1t}, \gamma_{2t}$ and γ_{3t} , get implicitly estimated during the state estimation (smoothing).

Reporting Parameter Estimates for Random Regressors

If the random walk disturbance variance associated with a random regressor is held fixed at zero, then its coefficient is no longer time-varying. In the UCM procedure the random regressor parameter estimates are reported differently if the random walk disturbance variance associated with a random regressor is held fixed at zero. The following points explain how the parameter estimates are reported in the parameter estimates table and in the OUTEST= data set.

- If the random walk disturbance variance associated with a random regressor is not held fixed, then its estimate is reported in the parameter estimates table and in the OUTEST= data set.
- If more than one random regressor is specified in a **RANDOMREG** statement, then the first regressor in the list is used as a representative of the list while reporting the corresponding common variance parameter estimate.
- If the random walk disturbance variance is held fixed at zero, then the parameter estimates table and the OUTEST= data set contain the corresponding regression parameter estimate rather than the variance parameter estimate.
- Similar considerations apply in the case of the derived random regressors associated with a spline-regressor.

ARMA Irregular Component (Experimental)

The state space form for the irregular component that follows an $ARMA(p,q) \times (P,Q)_s$ model is described in this section. The notation for ARMA models is explained in the **IRREGULAR** statement. A number of alternate state space forms are possible in this case; the one given here is based on Jones (1980). With slight abuse of notation, let $p = p + sP$ denote the effective autoregressive order and $q = q + sQ$ denote the effective moving-average order of the model. Similarly, let ϕ be the effective autoregressive polynomial and θ be the effective moving-average polynomial in the backshift operator with coefficients ϕ_1, \dots, ϕ_p and $\theta_1, \dots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence ϵ_t that follows an $ARMA(p,q) \times (P,Q)_s$ model with a white noise sequence a_t has a state space form with state vector of size $m = \max(p, q + 1)$. The system matrices, which are time invariant, are as follows: $Z = [1 \ 0 \ \dots \ 0]$. The state transition matrix T , in a blocked form, is given by

$$T = \begin{bmatrix} 0 & I_{m-1} \\ \phi_m & \dots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and I_{m-1} is an $(m - 1)$ dimensional identity matrix. The covariance of the state disturbance matrix $Q = \sigma^2 \psi \psi'$ where σ^2 is the variance of the white noise sequence a_t and the vector $\psi = [\psi_0 \ \dots \ \psi_{m-1}]'$ contains the first m values of the impulse response function—that is, the first m coefficients in the expansion of the ratio θ/ϕ . Since ϵ_t is a stationary sequence, the initial state is nondiffuse and $P_\infty = 0$. The description of P_* , the covariance matrix of the initial state, is a little involved; the details are given in Jones (1980).

Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Consider a model that has random walk trend, two simple time-invariant regressors, and that also includes a few—say, k —lags of the dependent variable. That is,

$$y_t = \sum_{i=1}^k \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t$$

$$\mu_t = \mu_{t-1} + \eta_t$$

The state space form of this augmented model can be described in terms of the state space form of a model that has random walk trend with two simple time-invariant regressors. A superscript dagger (\dagger) has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha_t^\dagger = [\alpha_t' y_t y_{t-1} \dots y_{t-k+1}]'$ and the new state noise vector $\zeta_t^\dagger = [\zeta_t' u_t 0 \dots 0]'$, where u_t is the matrix product $Z_t \zeta_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in block form, are

$$Z_t^\dagger = [0 \ 0 \ 0 \ 0 \ 1 \ \dots \ 0], \quad T_t^\dagger = \begin{bmatrix} T_t & 0 & \dots & 0 \\ Z_{t+1} T_t & \phi_1 & \dots & \phi_k \\ 0 & I_{k-1, k-1} & & 0 \end{bmatrix}$$

where $I_{k-1, k-1}$ is the $k - 1$ dimensional identity matrix and

$$Q_t^\dagger = \begin{bmatrix} Q_t & Q_t Z_t' & 0 \\ Z_t Q_t & Z_t Q_t Z_t' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Note that the T and Q matrices of the random walk with predictors model are time invariant, and in the expressions above their time indices are kept because they illustrate the pattern for more general models. The initial state vector is diffuse, with

$$P_*^\dagger = \begin{bmatrix} P_* & 0 \\ 0 & 0 \end{bmatrix}, \quad P_\infty^\dagger = \begin{bmatrix} P_\infty & 0 \\ 0 & I_{k, k} \end{bmatrix}$$

The parameters of this model are the disturbance variances σ_ϵ^2 and σ_η^2 , the lag coefficients $\phi_1, \phi_2, \dots, \phi_k$, and the regression coefficients β_1 and β_2 . As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

Outlier Detection

In time series analysis it is often useful to detect changes over time in the characteristics of the response series. In the UCM procedure you can search for two types of changes, additive outliers (AO) and level shifts (LS). An additive outlier is an unusual value in the series, the cause of which might be a data recording error or a temporary shock to the series generation process. A level shift represents a permanent shift, either up or down, in the level of the series. You can control different aspects of the outlier search, such as the significance level of the reported outliers, by choosing different options in the **OUTLIER** statement. The search for AOs is done by default, whereas the **CHECKBREAK** option in the **LEVEL** statement must be used to turn on the search for LSs.

The outlier detection process implemented in the UCM procedure is based on de Jong and Penzer (1998). In this approach the fitted model is taken to be the *null* model, and the series values and level shifts that are not adequately accounted for by the null model are flagged as outliers. The unusualness of a response series value at a particular time point t_0 , with respect to the fitted model, can be judged by estimating its value based on the rest of the data (that is, the series obtained

by *deleting* the series value at t_0) and comparing the estimated value to the observed value. If the difference between the estimated and observed values is statistically significant, then such value can be regarded as an AO. Note that this difference between the estimated and observed values is also the regression coefficient of a *dummy* regressor that takes the value 1.0 at t_0 and is 0.0 elsewhere, assuming such a regressor is added to the null model. In this way the series value at t_0 is regarded as AO if the regression coefficient of this dummy regressor is significant. Similarly, you can say that a level shift has occurred at a time point t_0 if the regression coefficient of a regressor, which is 0.0 before t_0 and 1.0 at t_0 and thereafter, is statistically significant. De Jong and Penzer (1998) provide an efficient way to compute such AO and LS regression coefficients and their standard errors at all time points in the series. The outlier summary table, which is produced by default, simply lists the most statistically significant candidates among these.

Missing Values

Embedded missing values in the dependent variable usually cause no problems in UCM modeling. However, no embedded missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can lead to failure of the initialization step of the diffuse Kalman filtering for some models. For example, if in a monthly series all values are missing for a certain month—say, May—then a BSM with monthly seasonality leads to such a situation. However, in this case the initialization step can complete successfully for a nonseasonal model such as local linear model.

Parameter Estimation

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the nondiffuse likelihood. The decision to use the full diffuse likelihood or the nondiffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the nondiffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients, the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either full or nondiffuse, is carried out using one of several nonlinear optimization algorithms. The user can control many aspects of the optimization process by using the `NLOPTIONS` statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In

most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

Parameter Estimation by Profile Likelihood Optimization

If a disturbance variance, such as the disturbance variance of the irregular component, is a part of the UCM and is a free parameter, then it can be profiled out of the likelihood. This means solving analytically for its optimum and plugging this expression back into the likelihood formula, giving rise to the so-called *profile* likelihood. The expression of the profile likelihood and the MLE of the profiled variance are given earlier in the section “[The UCMs as State Space Models](#)” on page 1787, where the computation of the likelihood of the state space model is also discussed.

In some situations the optimization of the profile likelihood can be more efficient because the number of parameters to optimize is reduced by one; however, for a variety of reasons such gains might not always be observed. Moreover, in theory the estimates obtained by optimizing the profile likelihood and the usual likelihood should be the same, but in practice this might not hold because of numerical rounding and other conditions.

In the UCM procedure, by default the usual likelihood is optimized if any of the disturbance variance parameters is held fixed to a nonzero value by using the NOEST option in the corresponding component statement. In other cases the decision whether to optimize the profile likelihood or the usual likelihood is based on several factors that are difficult to document. You can choose which likelihood to optimize during parameter estimation by specifying the **PROFILE** option for the profile likelihood optimization or the **NOPROFILE** option for the usual likelihood optimization. In the presence of the **PROFILE** option, the disturbance variance to profile is checked in a specific order, so that if the irregular component disturbance variance is free then it is always chosen. The situation in other cases is more complicated.

Profiling in the Presence of Fixed Variance Parameters

Note that when the parameter estimation is done by optimizing the profile likelihood, the interpretation of the variance parameters that are held fixed to nonzero values changes. In the presence of the **PROFILE** option, the disturbance variances that are held at a fixed value by using the NOEST option in their respective component statements are interpreted as being restricted to be that fixed multiple of the profiled variance rather than being fixed at that nominal value. That is, implicitly, the parameter estimation is done under the restriction of holding the disturbance variance *ratio* fixed at a given value rather than the disturbance variance itself. See [Example 29.5](#) for an example of this type of restriction to obtain a UC model that is equivalent to the famous Hodrick-Prescott filter.

***t* values**

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully; therefore the probability values that correspond to a *t* distribution should be interpreted carefully, as they can be misleading. This is particularly true if the

parameters in question are close to the boundary of the parameter space. The two sources by Harvey (1989, 2001) are good references for information about this topic. For some parameters, such as, the cycle period, the reported t values are uninformative because comparison of the estimated parameter with zero is never needed. In such cases the t values and the corresponding probability values should be ignored.

Computational Issues

Convergence Problems

As explained in the section “[Parameter Estimation](#)” on page 1797, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, the following points might be helpful:

- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.
- Examine your model for redundancies in the included components and regressors. If some of the included components or regressors are nearly collinear to each other, then the optimization process can become unstable.
- Experimenting with different options offered by the `NLOPTIONS` statement can help.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement for the smoothing stage of the Kalman filter is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed then the memory requirement is of the order of $6 \times 8 \times (m^2 + n)$ bytes. Besides m and n , the computing time for the parameter estimation depends on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Displayed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set, including the data set name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, including the names of the variables in the model, their categorization as dependent or predictor, the index of the beginning and ending observations in the spans, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation
- information about the model parameters at the start of the model-fitting stage, including the fixed parameters in the model and the initial estimates of the free parameters in the model
- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting-stage, including the parameter estimates, their approximate standard errors, t statistics, and the approximate p -value
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
- the fit statistics that are based on the raw residuals (observed minus predicted), including the mean squared error (MSE), the root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R square, the adjusted R square, the random walk R square, and Amemiya's R square
- the significance analysis of the components included in the model that is based on the estimation span
- brief information about the components included in the model
- additive outliers in the series, if any are detected
- the multistep series forecasts
- post-sample-prediction analysis table that compares the multistep forecasts with the observed series values, if the BACK= option is used in the FORECAST statement

Statistical Graphics

This section provides information about the basic ODS statistical graphics produced by the UCM procedure. To request graphics with PROC UCM, you must first enable ODS Graphics by specifying the **ODS GRAPHICS ON;** statement. See Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User's Guide*), for more information.

You can obtain most plots relevant to the specified model by using the global `PLOTS=` option in the `PROC UCM` statement. The plot of series forecasts in the forecast horizon is produced by default. You can further control the production of individual plots by using the `PLOT=` options in the different statements.

The main types of plots available are as follows:

- Time series plots of the component estimates, either filtered or smoothed, can be requested by using the `PLOT=` option in the respective component statements. For example, the use of `PLOT=SMOOTH` option in a `CYCLE` statement produces a plot of smoothed estimate of that cycle.
- Residual plots for model diagnostics can be obtained by using the `PLOT=` option in the `ESTIMATE` statement.
- Plots of series forecasts and model decompositions can be obtained by using the `PLOT=` option in the `FORECAST` statement.

The following example is a simple illustration of the available plot options.

Analysis of Sunspot Data: Illustration of ODS Graphics

In this example a well-known series, Wolfer's sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with a period of about eleven years. The following `DATA` step creates the input data set:

```
data sunspot;
  input year wolfer @@;
  year = mdy(1,1, year);
  format year year4.;
datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755  96
1756  102 1757  324 1758  476 1759  540 1760  629 1761  859 1762  612

... more lines ...
```

The following statements specify a UCM that includes a cycle component and a random walk trend component:

```
ods graphics on;
proc ucm data=sunspot;
  id year interval=year;
  model wolfer;
  irregular;
  level ;
  cycle plot=(filter smooth);
  estimate back=24 plot=(loess panel cusum wn);
```

```
forecast back=24 lead=24 plot=(forecasts decomp);
run;
```

The following subsections explain the graphics produced by the above statements.

Component Plots

The plots in [Figure 29.8](#) and [Figure 29.9](#), produced by specifying PLOT=(FILTER SMOOTH) in the CYCLE statement, show the filtered and smoothed estimates, respectively, of the cycle component in the model. Note that the smoothed estimate appears smoother than the filtered estimate. This is always true because the filtered estimate of a component at time t is based on the observations prior to time t —that is, it uses measurements from the first observation up to the $(t - 1)$ th observation. On the other hand, the corresponding smoothed estimate uses all the available observations—that is, all the measurements from the first observation to the last. This makes the smoothed estimate of the component more precise than the filtered estimate for the time points within historical period. In the forecast horizon, both filtered and smoothed estimates are identical, being based on the same set of observations.

Figure 29.8 Sunspots Series: Filtered Cycle

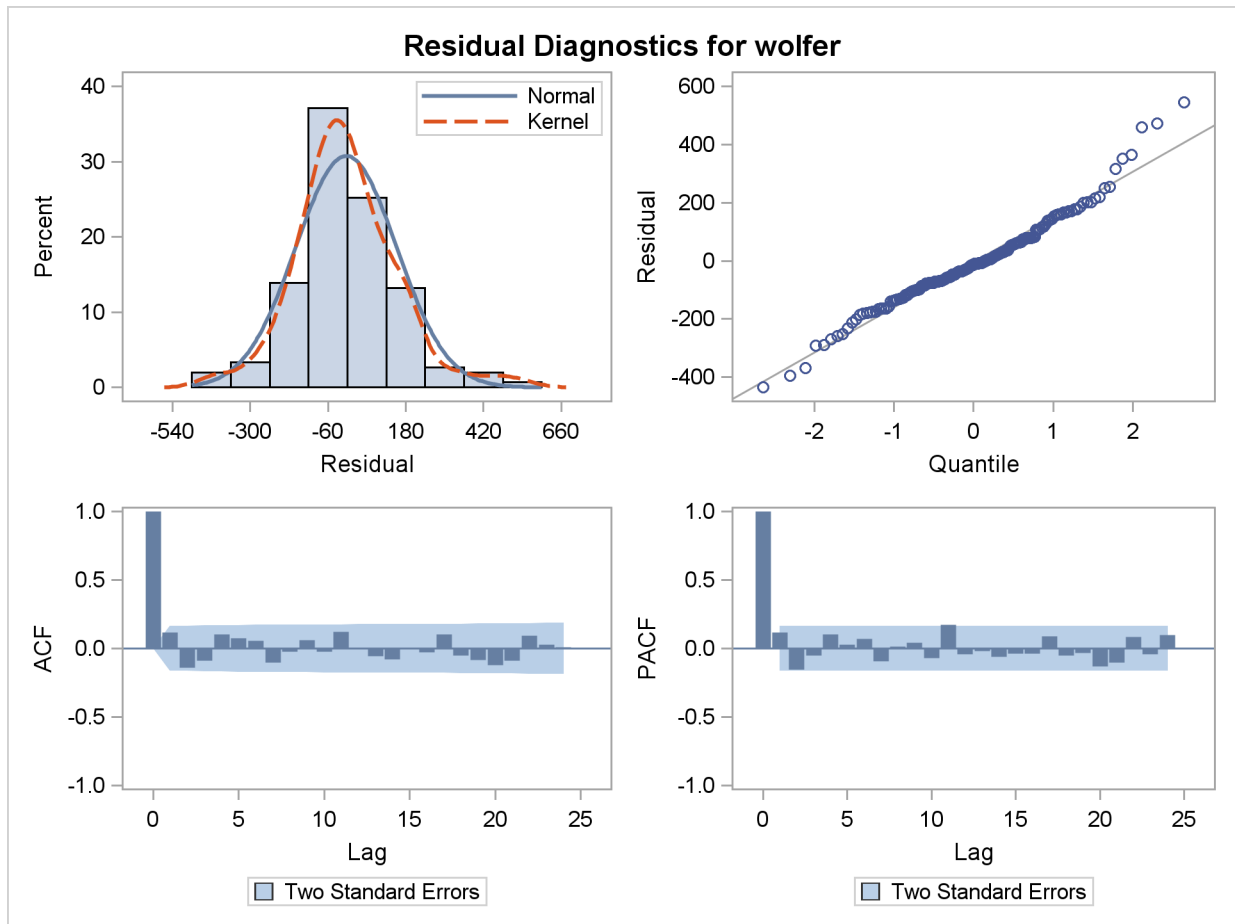

Figure 29.9 Sunspots Series: Smoothed Cycle

Residual Diagnostics

If the fitted model is appropriate for the given data, then the corresponding one-step-ahead residuals should be approximately *white*—that is, uncorrelated—and approximately normal. Moreover, the residuals should not display any discernible pattern. You can detect departures from these conditions graphically. Different residual diagnostic plots can be requested by using the PLOT= option in the ESTIMATE statement.

The normality can be checked by examining the histogram and the normal quantile plot of residuals. The whiteness can be checked by examining the ACF and PACF plots that show the sample autocorrelation and sample partial-autocorrelation at different lags. The diagnostic panel shown in [Figure 29.10](#), produced by specifying PLOT=PANEL, contains these four plots.

Figure 29.10 Sunspots Series: Residual Diagnostics

The residual histogram and Q-Q plot show no serious violation of normality. The histogram appears reasonably symmetric and follows the overlaid normal density curve reasonably closely. Similarly in the Q-Q plot the residuals follow the reference line fairly closely. The ACF and PACF plots also do not exhibit any violation of the whiteness assumption; the correlations at all nonzero lags seem to be insignificant.

The residual whiteness can also be formally tested by using the Ljung-Box portmanteau test. The plot in Figure 29.11, produced by specifying PLOT=WN, shows the p -values of the Ljung-Box test statistics at different lags. In these plots the p -values for the first few lags, equal to the number of estimated parameters in the model, are not shown because they are always missing. This portion of the plot is shaded blue to indicate this fact. In the case of this model, five parameters are estimated so the p -values for the first five lags are not shown. The p -values are displayed on a log scale in such a way that higher bars imply more extreme test statistics. In this plot some early p -values appear extreme. However, these p -values are based on large sample theory, which suggests that these statistics should be examined for lags larger than the square root of sample size. In this example it means that the p -values for the first $\sqrt{154} \approx 12$ lags can be ignored. With this consideration, the plot shows no violation of whiteness since the p -values after the 12th lag do not appear extreme.

Figure 29.11 Sunspots Series: Ljung-Box Portmanteau Test

The plot in [Figure 29.12](#), produced by specifying PLOT=LOESS, shows the residuals plotted against time with an overlaid LOESS curve. This plot is useful for checking whether any discernible pattern remains in the residuals. Here again, no significant pattern appears to be present.

Figure 29.12 Sunspots Series: Residual Loess Plot

The plot in [Figure 29.13](#), produced by specifying `PLOT=CUSUM`, shows the cumulative residuals plotted against time. This plot is useful for checking structural breaks. Here, there appears to be no evidence of structural break since the cumulative residuals remain within the confidence band throughout the sample period. Similarly you can request a plot of the squared cumulative residuals by specifying `PLOT=CUSUMSQ`.

Figure 29.13 Sunspots Series: CUSUM Plot

Brockwell and Davis (1991) can be consulted for additional information on diagnosing residuals. For more information on CUSUM and CUSUMSQ plots, you can consult Harvey (1989).

Forecast and Series Decomposition Plots

You can use the PLOT= option in the FORECAST statement to obtain the series forecast plot and the series decomposition plots. The series decomposition plots show the result of successively adding different components in the model starting with the trend component. The IRREGULAR component is left out of this process. The following two plots, produced by specifying PLOT=DECOMP, show the results of successive component addition for this example. The first plot, shown in Figure 29.14, shows the smoothed trend component and the second plot, shown in Figure 29.15, shows the sum of smoothed trend and cycle.

Figure 29.14 Sunspots Series: Smoothed Trend

Figure 29.15 Sunspots Series: Smoothed Trend plus Cycle

Finally, Figure 29.16 shows the forecast plot.

Figure 29.16 Sunspots Series: Series Forecasts

ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 29.2](#).

Table 29.2 ODS Tables Produced by PROC UCM

ODS Table Name	Description	Statement	Option
Tables Summarizing the Estimation and Forecast Spans			
EstimationSpan	Estimation span summary information		default
ForecastSpan	Forecast span summary information		default
Tables Related to Model Parameters			
ConvergenceStatus	Convergence status of the estimation process		default

Table 29.2 *continued*

ODS Table Name	Description	Statement	Option
FixedParameters	Fixed parameters in the model		default
InitialParameters	Initial estimates of the free parameters		default
ParameterEstimates	Final estimates of the free parameters		default
Tables Related to Model Information and Diagnostics			
BlockSeasonDescription	Information about the block seasonals in the model		default
ComponentSignificance	Significance analysis of the components in the model		default
CycleDescription	Information about the cycles in the model		default
FitStatistics	Fit statistics based on the one-step-ahead predictions		default
FitSummary	Likelihood-based fit statistics		default
OutlierSummary	Summary table of the detected outliers		default
SeasonDescription	Information about the seasonals in the model		default
SeasonHarmonics	Summary of harmonics in a trigonometric seasonal component	SEASON	PRINT=HARMONICS
SplineSeasonDescription	Information about the spline-seasonals in the model		default
TrendInformation	Summary information of the level and slope components		default
Tables Related to Filtered Component Estimates			
FilteredAutoReg	Filtered estimate of an autoreg component	AUTOREG	PRINT=FILTER
FilteredBlockSeason	Filtered estimate of a block seasonal component	BLOCKSEASON	PRINT=FILTER
FilteredCycle	Filtered estimate of a cycle component	CYCLE	PRINT=FILTER
FilteredIrregular	Filtered estimate of the irregular component	IRREGULAR	PRINT=FILTER
FilteredLevel	Filtered estimate of the level component	LEVEL	PRINT=FILTER
FilteredRandomReg	Filtered estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=FILTER

Table 29.2 continued

ODS Table Name	Description	Statement	Option
FilteredSeason	Filtered estimate of a seasonal component	SEASON	PRINT=FILTER
FilteredSlope	Filtered estimate of the slope component	SLOPE	PRINT=FILTER
FilteredSplineReg	Filtered estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=FILTER
FilteredSplineSeason	Filtered estimate of a spline-seasonal component	SPLINESEASON	PRINT=FILTER
Tables Related to Smoothed Component Estimates			
SmoothedAutoReg	Smoothed estimate of an autoreg component	AUTOREG	PRINT=SMOOTH
SmoothedBlockSeason	Smoothed estimate of a block seasonal component	BLOCKSEASON	PRINT=SMOOTH
SmoothedCycle	Smoothed estimate of the cycle component	CYCLE	PRINT=SMOOTH
SmoothedIrregular	Smoothed estimate of the irregular component	IRREGULAR	PRINT=SMOOTH
SmoothedLevel	Smoothed estimate of the level component	LEVEL	PRINT=SMOOTH
SmoothedRandomReg	Smoothed estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=SMOOTH
SmoothedSeason	Smoothed estimate of a seasonal component	SEASON	PRINT=SMOOTH
SmoothedSlope	Smoothed estimate of the slope component	SLOPE	PRINT=SMOOTH
SmoothedSplineReg	Smoothed estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=SMOOTH
SmoothedSplineSeason	Smoothed estimate of a spline-seasonal component	SPLINESEASON	PRINT=SMOOTH
Tables Related to Series Decomposition and Forecasting			
FilteredAllExceptIrreg	Filtered estimate of sum of all components except the irregular component	FORECAST	PRINT=FDECOMP
FilteredTrend	Filtered estimate of trend	FORECAST	PRINT= FDECOMP
FilteredTrendReg	Filtered estimate of trend plus regression	FORECAST	PRINT=FDECOMP
FilteredTrendRegCyc	Filtered estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=FDECOMP

Table 29.2 *continued*

ODS Table Name	Description	Statement	Option
Forecasts	Dependent series forecasts		default
PostSamplePrediction	Forecasting performance in the holdout period	FORECAST	BACK=
SmoothedAllExceptIrreg	Smoothed estimate of sum of all components except the irregular component	FORECAST	PRINT=DECOMP
SmoothedTrend	Smoothed estimate of trend	FORECAST	PRINT= DECOMP
SmoothedTrendReg	Smoothed estimate of trend plus regression	FORECAST	PRINT=DECOMP
SmoothedTrendRegCyc	Smoothed estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=DECOMP

NOTE: The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonal components, or block seasonal components, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal component and the PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal component.

ODS Graph Names

To request graphics with PROC UCM, you must first enable ODS Graphics by specifying the **ODS GRAPHICS ON;** statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for more information. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC UCM generates are listed in Table 29.3, along with the required statements and options.

Table 29.3 ODS Graphics Produced by PROC UCM

ODS Graph Name	Description	Statement	Option
Plots Related to Residual Analysis			
ErrorACFPlot	Prediction error auto-correlation plot	ESTIMATE	PLOT=ACF
ErrorPACFPlot	Prediction error partial-autocorrelation plot	ESTIMATE	PLOT=PACF

Table 29.3 continued

ODS Graph Name	Description	Statement	Option
ErrorHistogram	Prediction error histogram	ESTIMATE	PLOT=NORMAL
ErrorQQPlot	Prediction error normal quantile plot	ESTIMATE	PLOT=QQ
ErrorPlot	Plot of prediction errors	ESTIMATE	PLOT=RESIDUAL
ErrorWhiteNoiseLogProbPlot	Plot of p -values at different lags for the Ljung-Box portman-teau white noise test statistics	ESTIMATE	PLOT=WN
CUSUMPlot	Plot of cumulative residuals	ESTIMATE	PLOT=CUSUM
CUSUMSQPlot	Plot of cumulative squared residuals	ESTIMATE	PLOT=CUSUMSQ
ModelPlot	Plot of one-step-ahead forecasts in the estimation span	ESTIMATE	PLOT=MODEL
PanelResidualPlot	Panel of residual diagnostic plots	ESTIMATE	PLOT=PANEL
ResidualLoessPlot	Time series plot of residuals with superimposed LOESS smoother	ESTIMATE	PLOT=LOESS
Plots Related to Filtered Component Estimates

OUTFOR= Data Set

You can use the `OUTFOR=` option in the `FORECAST` statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified, then a numerical variable, `_ID_`, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- `FORECAST`, a numerical variable containing the one-step-ahead predicted values and the multistep forecasts
- `RESIDUAL`, a numerical variable containing the difference between the actual and forecast values
- `STD`, a numerical variable containing the standard error of prediction
- `LCL` and `UCL`, numerical variables containing the lower and upper forecast confidence limits
- `S_SERIES` and `VS_SERIES`, numerical variables containing the smoothed values of the dependent series and their variances
- `S_IRREG` and `VS_IRREG`, numerical variables containing the smoothed values of the irregular component and their variances. These variables are present only if the model has an irregular component.
- `F_LEVEL`, `VF_LEVEL`, `S_LEVEL`, and `VS_LEVEL`, numerical variables containing the filtered and smoothed values of the level component and the respective variances. These variables are present only if the model has a level component.
- `F_SLOPE`, `VF_SLOPE`, `S_SLOPE`, and `VS_SLOPE`, numerical variables containing the filtered and smoothed values of the slope component and the respective variances. These variables are present only if the model has a slope component.

- F_AUTOREG, VF_AUTOREG, S_AUTOREG, and VS_AUTOREG, numerical variables containing the filtered and smoothed values of the autoreg component and the respective variances. These variables are present only if the model has an autoreg component.
- F_CYCLE, VF_CYCLE, S_CYCLE, and VS_CYCLE, numerical variables containing the filtered and smoothed values of the cycle component and the respective variances. If there are multiple cycles in the model, these variables are sequentially numbered as F_CYCLE1, F_CYCLE2, etc. These variables are present only if the model has at least one cycle component.
- F_SEASON, VF_SEASON, S_SEASON, and VS_SEASON, numerical variables containing the filtered and smoothed values of the season component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as F_SEASON1, F_SEASON2, etc. These variables are present only if the model has at least one season component.
- F_BLKSEAS, VF_BLKSEAS, S_BLKSEAS, and VS_BLKSEAS, numerical variables containing the filtered and smoothed values of the blockseason component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as F_BLKSEAS1, F_BLKSEAS2, etc.
- F_SPLSEAS, VF_SPLSEAS, S_SPLSEAS, and VS_SPLSEAS, numerical variables containing the filtered and smoothed values of the splinesseason component and the respective variances. If there are multiple spline seasons in the model, these variables are sequentially numbered as F_SPLSEAS1, F_SPLSEAS2, etc. These variables are present only if the model has at least one splinesseason component.
- Filtered and smoothed estimates, and their variances, of the time-varying regression coefficients of the variables specified in the RANDOMREG and SPLINEREG statements. A variable is not included if its coefficient is time-invariant, that is, if the associated disturbance variance is zero.
- S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.
- S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.
- S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one seasonal or block seasonal component.

OUTEST= Data Set

You can use the OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was fixed by the user or estimated
- _STATUS_, a character variable indicating whether the parameter estimation process converged or failed or there was an error of some other kind
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This has a missing value if the parameter value is fixed.
- TVALUE, a numerical variable containing the t -statistic. This has a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the p -value. This has a missing value if the parameter value is fixed.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, $y_t - \hat{y}_t$, are considered. In these formulas, n is the number of nonmissing prediction errors and k is the number of fitted parameters in the model. Moreover, the sum of squared errors, $SSE = \sum (y_t - \hat{y}_t)^2$, and the total sum of squares for the series corrected for the mean, $SST = \sum (y_t - \bar{y})^2$, where \bar{y} is the series mean, and the sums are over all the nonmissing prediction errors.

Mean Squared Error

The mean squared prediction error, $MSE = \frac{1}{n}SSE$

Root Mean Squared Error

The root mean square error, $RMSE = \sqrt{MSE}$

Mean Absolute Percent Error

The mean absolute percent prediction error, $MAPE = \frac{100}{n} \sum_{t=1}^n |(y_t - \hat{y}_t)/y_t|$.

The summation ignores observations where $y_t = 0$.

R-square

The R-square statistic, $R^2 = 1 - SSE/SST$.

If the model fits the series badly, the model error sum of squares, SSE , might be larger than SST and the R-square statistic will be negative.

Adjusted R-square

The adjusted R-square statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$

Amemiya's Adjusted R-square

Amemiya's adjusted R-square, $1 - \left(\frac{n+k}{n-k}\right)(1 - R^2)$

Random Walk R-square

The random walk R-square statistic (Harvey's R-square statistic that uses the random walk model for comparison), $1 - \left(\frac{n-1}{n}\right)SSE/RWSSE$, where $RWSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$

Maximum Percent Error

The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. In this computation the observations where $y_t = 0$ are ignored.

The likelihood-based fit statistics are reported separately (see the section “The UCMs as State Space Models” on page 1787). They include the full log likelihood (L_∞), the diffuse part of the log likelihood, the normalized residual sum of squares, and several information criteria: AIC, AICC, HQIC, BIC, and CAIC. Let q denote the number of estimated parameters, n be the number of nonmissing measurements in the estimation span, and d be the number of diffuse elements in the initial state vector that are successfully initialized during the Kalman filtering process. Moreover, let $n^* = (n - d)$. The reported information criteria, all in smaller-is-better form, are described in Table 29.4:

Table 29.4 Information Criteria

Criterion	Formula	Reference
AIC	$-2L_\infty + 2q$	Akaike (1974)
AICC	$-2L_\infty + 2qn^*/(n^* - q - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
HQIC	$-2L_\infty + 2q \log \log(n^*)$	Hannan and Quinn (1979)
BIC	$-2L_\infty + q \log(n^*)$	Schwarz (1978)
CAIC	$-2L_\infty + q(\log(n^*) + 1)$	Bozdogan (1987)

Examples: UCM Procedure

Example 29.1: The Airline Series Revisited

The series in this example, the monthly airline passenger series, has already been discussed earlier; see the section “A Seasonal Series with Linear Trend” on page 1743. Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here additional output features of the UCM procedure are illustrated, such as how to use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following statements fit a BSM to the logarithm of the airline passenger numbers. The disturbance variance for the slope component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data,

some of the observed data are withheld during parameter estimation and forecast computations. The observations in the last two years, years 1959 and 1960, are not used in parameter estimation, while the observations in the last year, year 1960, are not used in the forecasting computations. This is done using the `BACK=` option in the `ESTIMATE` and `FORECAST` statements. In addition, a panel of residual diagnostic plots is obtained using the `PLOT=``PANEL` option in the `ESTIMATE` statement.

```
data seriesG;
  set sashelp.air;
  logair = log(air);
run;

proc ucm data = seriesG;
  id date interval = month;
  model logair;
  irregular;
  level;
  slope var = 0 noest;
  season length = 12 type=trig;
  estimate back=24 plot=panel;
  forecast back=12 lead=24 print=forecasts;
run;
```

The following tables display the summary of data used in estimation and forecasting ([Output 29.1.1](#) and [Output 29.1.2](#)). These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the beginning and ending dates of the span, the number of nonmissing values, etc.

Output 29.1.1 Observation Span Used in Parameter Estimation (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1958	120	5.43035

Output 29.1.2 Observation Span Used in Forecasting (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1959	132	5.48654

The following tables display the fixed parameters in the model, the preliminary estimates of the free parameters, and the final estimates of the free parameters ([Output 29.1.3](#), [Output 29.1.4](#), and [Output 29.1.5](#)).

Output 29.1.3 Fixed Parameters in the Model

The UCM Procedure		
Fixed Parameters in the Model		
Component	Parameter	Value
Slope	Error Variance	0

Output 29.1.4 Starting Values for the Parameters to Be Estimated

Preliminary Estimates of the Free Parameters		
Component	Parameter	Estimate
Irregular	Error Variance	6.64120
Level	Error Variance	2.49045
Season	Error Variance	1.26676

Output 29.1.5 Maximum Likelihood Estimates of the Free Parameters

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00018686	0.0001212	1.54	0.1233
Level	Error Variance	0.00040314	0.0001566	2.57	0.0100
Season	Error Variance	0.00000350	1.66319E-6	2.10	0.0354

Two types of goodness-of-fit statistics are reported after a model is fit to the series (see [Output 29.1.6](#) and [Output 29.1.7](#)). The first type is the likelihood-based goodness-of-fit statistics, which include the full likelihood of the data, the diffuse portion of the likelihood (see the section “[Details: UCM Procedure](#)” on page 1781), and the information criteria. The second type of statistics is based on the raw residuals, $\text{residual} = \text{observed} - \text{predicted}$. If the model is nonstationary, then one-step-ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

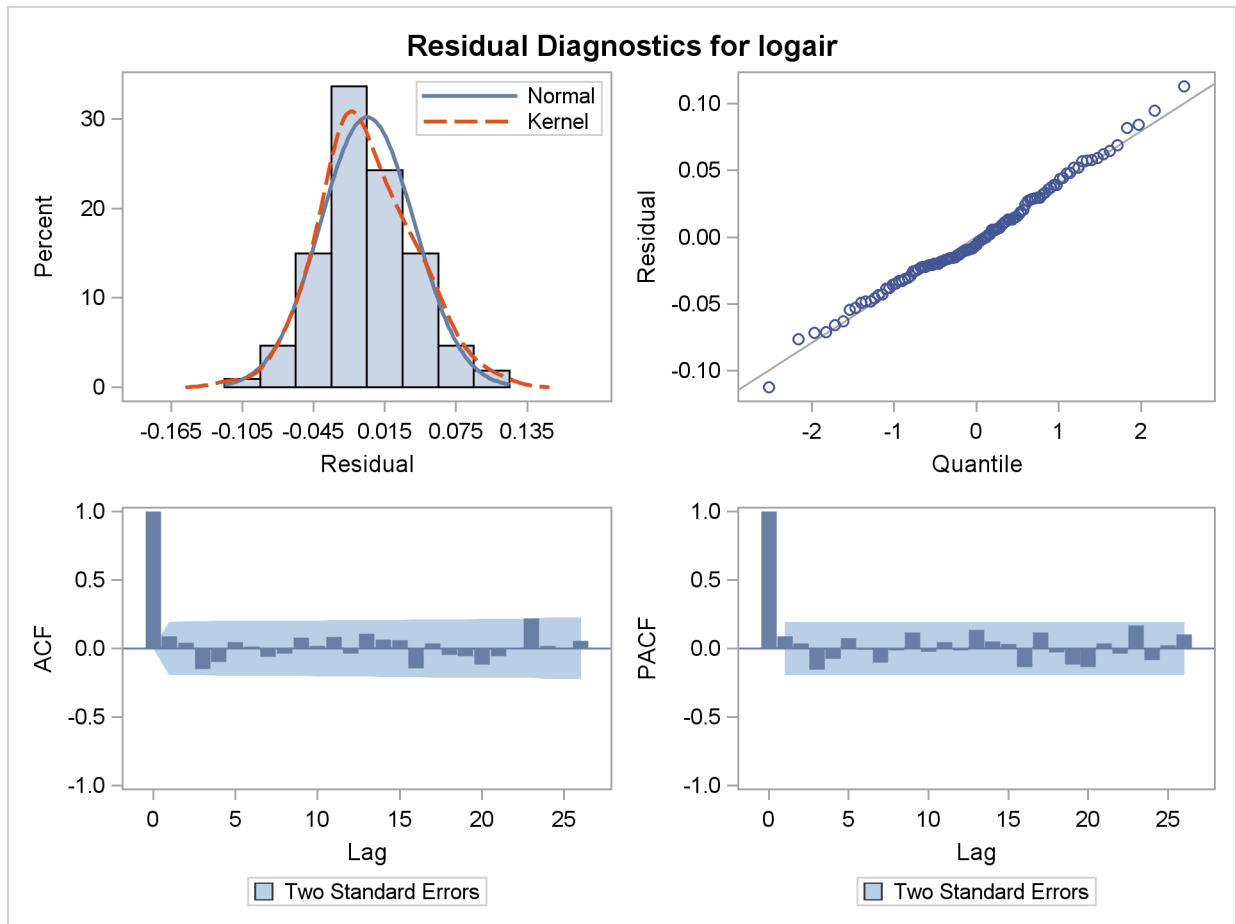

Output 29.1.6 Likelihood-Based Fit Statistics for the Airline Data

Likelihood Based Fit Statistics	
Statistic	Value
Full Log Likelihood	180.63
Diffuse Part of Log Likelihood	-13.93
Non-Missing Observations Used	120
Estimated Parameters	3
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	107
AIC (smaller is better)	-355.3
BIC (smaller is better)	-347.2
AICC (smaller is better)	-355
HQIC (smaller is better)	-352
CAIC (smaller is better)	-344.2

Output 29.1.7 Residuals-Based Fit Statistics for the Airline Data

Fit Statistics Based on Residuals	
Mean Squared Error	0.00156
Root Mean Squared Error	0.03944
Mean Absolute Percentage Error	0.57677
Maximum Percent Error	2.19396
R-Square	0.98705
Adjusted R-Square	0.98680
Random Walk R-Square	0.86370
Amemiya's Adjusted R-Square	0.98630
Number of non-missing residuals used for computing the fit statistics = 107	

The diagnostic plots based on the one-step-ahead residuals are shown in [Output 29.1.8](#). The residual histogram and the Q-Q plot show no reasons to question the approximate normality of the residual distribution. The remaining plots check for the *whiteness* of the residuals. The sample correlation plots, the autocorrelation function (ACF) and the partial autocorrelation function (PACF), also do not show any significant violations of the whiteness of the residuals. Therefore, on the whole, the model seems to fit the data well.

Output 29.1.8 Residual Diagnostics for the Airline Series Using a BSM

The forecasts are given in [Output 29.1.9](#). In order to save the space,

the upper and lower confidence limit columns are dropped from the output, and only the rows corresponding to the year 1960 are shown. Recall that the actual measurements in the years 1959 and 1960 were withheld during the parameter estimation, and the ones in 1960 were not used in the forecast computations.

Output 29.1.9 Forecasts for the Airline Data

Obs	date	Forecast	StdErr	logair	Residual
133	JAN60	6.050	0.038	6.033	-0.017
134	FEB60	5.996	0.044	5.969	-0.027
135	MAR60	6.156	0.049	6.038	-0.118
136	APR60	6.124	0.053	6.133	0.010
137	MAY60	6.168	0.058	6.157	-0.011
138	JUN60	6.303	0.061	6.282	-0.021
139	JUL60	6.435	0.065	6.433	-0.002
140	AUG60	6.450	0.068	6.407	-0.043
141	SEP60	6.265	0.071	6.230	-0.035
142	OCT60	6.138	0.073	6.133	-0.005
143	NOV60	6.015	0.075	5.966	-0.049
144	DEC60	6.121	0.077	6.068	-0.053

The figure [Output 29.1.10](#) shows the forecast plot. The forecasts in the year 1960 show that the model predictions were quite good.

Output 29.1.10 Forecast Plot of the Airline Series Using a BSM

Example 29.2: Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (<http://www.york.ac.uk/depts/math/data/ts/welcome.htm> (series number 26)). The following DATA step statements read the data in a SAS data set.

```
data star;
  input magnitude @@;
  day = _n_;
datalines;
  25 28 31 32 33 33 32 31 28 25 22 18
  14 10 7 4 2 0 0 0 2 4 8 11
  15 19 23 26 29 32 33 34 33 32 30 27
  24 20 17 13 10 7 5 3 3 3 4 5
  7 10 13 16 19 22 24 26 27 28 29 28
  27 25 24 21 19 17 15 13 12 11 11 10

... more lines ...
```

The following statements use the TIMESERIES procedure to get a timeseries plot of the series (see [Output 29.2.1](#)).

```
proc timeseries data=star plot=series;
  var magnitude;
run;
```

Output 29.2.1 Plot of Star Brightness on Successive Days

The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also mentions the difficulty involved in estimating the periods from the data (see Bloomfield 2000, Chapter 3). In his case the cycle periods are estimated by least squares, and the sum of squares surface has multiple local optima and ridges. The following statements show how to use the UCM procedure to fit this two-cycle model to the series. The constant term in the model is specified by holding the variance parameter of the level component to zero.

```
proc ucm data=star;
  model magnitude;
  irregular;
  level var=0 noest;
  cycle;
  cycle;
  estimate;
run;
```

The final parameter estimates and the goodness-of-fit statistics are shown in [Output 29.2.2](#) and [Output 29.2.3](#), respectively. The model fit appears to be good.

Output 29.2.2 Two-Cycle Model: Parameter Estimates

The UCM Procedure					
Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.09257	0.0053845	17.19	<.0001
Cycle_1	Damping Factor	1.00000	1.81175E-7	5519514	<.0001
Cycle_1	Period	29.00036	0.0022709	12770.4	<.0001
Cycle_1	Error Variance	0.0000882	5.27213E-6	1.67	0.0944
Cycle_2	Damping Factor	1.00000	2.11939E-7	4718334	<.0001
Cycle_2	Period	24.00011	0.0019128	12547.2	<.0001
Cycle_2	Error Variance	0.00000535	3.56374E-6	1.50	0.1330

Output 29.2.3 Two-Cycle Model: Goodness of Fit

Fit Statistics Based on Residuals	
Mean Squared Error	0.12072
Root Mean Squared Error	0.34745
Mean Absolute Percentage Error	2.65141
Maximum Percent Error	36.38991

Adjusted R-Square	0.99849
Random Walk R-Square	0.97281
Amemiya's Adjusted R-Square	0.99847
Number of non-missing residuals used for computing the fit statistics = 599	

A summary of the cycles in the model is given in [Output 29.2.4](#).

Output 29.2.4 Two-Cycle Model: Summary

Name	Type	period	Rho	ErrorVar
Cycle_1	Stationary	29.00036	1.00000	0.00000882
Cycle_2	Stationary	24.00011	1.00000	0.00000535

Note that the estimated periods are the same as in Bloomfield's model, the damping factors are nearly equal to 1.0, and the disturbance variances are very close to zero, implying persistent deterministic cycles. In fact, this model is identical to Bloomfield's model.

Example 29.3: Modeling Long Seasonal Patterns

This example illustrates some of the techniques you can use to model long seasonal patterns in a series. If the seasonal pattern is of moderate length and the underlying dynamics are simple, then it is easily modeled by using the basic settings of the SEASON statement and these additional techniques are not needed. However, if the seasonal pattern has a long season length and/or has a complex stochastic dynamics, then the techniques discussed here can be useful. You can obtain parsimonious models for a long seasonal pattern by using an appropriate subset of trigonometric harmonics, or by using a suitable spline function, or by using a block-season pattern in combination with a seasonal component of much smaller length. You can also vary the disturbance variances of the subcomponents that combine to form the seasonal component.

The time series used in this example consists of number of calls received per shift at a call center. Each shift is six hours long, and the first shift of the day begins at midnight, resulting in four shifts per day. The observations are available from December 15, 1999, to April 30, 2000. This series is seasonal with season length 28, which is moderate, and in fact there is no particular need to use pattern approximation techniques in this case. However, it is adequate for demonstration purposes. The plan of this example is as follows. First an initial model with a full seasonal component is created. This model is used as a baseline for comparing alternate models created by the techniques that are being illustrated. In practice any candidate model is first checked for adequacy by using various diagnostic procedures. In this illustration the main focus is on the different ways a long seasonal pattern can be modeled and no model diagnostics are done for the models being entertained. The alternate models are compared by using the sum of absolute prediction errors in the holdout region.

The following DATA step statements create the input data set used in this example.

```
data callCenter;
  input calls @@;
  label calls= "Number of Calls Received in a 6 Hour Shift";
  start = '15dec99:00:00'dt;
  datetime = INTNX( 'dthour6', start, _n_-1 );
  format datetime datetime10.;
datalines;
  18    122    244    128    19    113    230    119    17    112
  219    93    14    73    139    53    11    32    74    56
  15    137    289    153    20    125    227    106    16    101
... more lines ...
```

Initial exploration of the series clearly indicates that the series does not show any significant trend, and time of day and day of the week have a significant influence on the number of calls received. These considerations suggest a simple random walk trend model along with a seasonal component of season length 28, the total number of shifts in a week. The following statements specify this model. Note the PRINT=HARMONICS option in the SEASON statement, which produces a table that lists the full set of harmonics contributing to the seasonal along with the significance of their contribution. This table will be useful later in choosing a subset trigonometric model. The BACK=28 and the LEAD=28 specifications in the FORECAST statement create a holdout region of 28 observations. The sum of absolute prediction errors (SAE) in this holdout region are used to

compare the different models.

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig
    print=(harmonics);
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The forecasting performance of this model in the holdout region is shown in [Output 29.3.1](#). The sum of absolute prediction errors $SAE = 516.22$, which appears in the last row of the holdout analysis table.

Output 29.3.1 Predictions in the Holdout Region: Baseline Model

552	30APR00:18	61	40.071	20.929	516.216

Now that a baseline model is created, the exploration for alternate models can begin. The review of the harmonic table in [Output 29.3.2](#) shows that all but the last three harmonics are significant, and deleting any of them to form a subset trigonometric seasonal component will lead to a poorer model.

The last three harmonics, 12th, 13th and 14th, with periods of 2.333, 2.15 and 2.0, respectively, do appear to be possible choices for deletion. Note that the disturbance variance of the seasonal component is not very insignificant (see [Output 29.3.3](#)); therefore the seasonal component is stochastic and the preceding logic, which is based on the final state estimate, provides only a rough guideline.

Output 29.3.2 Harmonic Analysis of the Season: Initial Model

The UCM Procedure						
Harmonic Analysis of Trigonometric Seasons (Based on the Final State)						
Name	Season Length	Harmonic	Period	Chi-Square	DF	Pr > ChiSq

Season	Error Variance	0.01250	0.0065153	1.92	0.0551

The following statements fit a subset trigonometric model formed by dropping the last three harmonics by specifying the DROPH= option in the SEASON statement:

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig droph=12 13 14;
  estimate back=28;
  forecast back=28 lead=28;
```

```
run;
```

The last row of the holdout region prediction analysis table for the preceding model is shown in [Output 29.3.4](#). It shows that the subset trigonometric model has better prediction performance in the holdout region than the full trigonometric model, its SAE = 471.53 compared to the SAE = 516.22 for the full model.

Output 29.3.4 SAE for the Subset Trigonometric Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	40.836	20.164	471.534

The following statements illustrate a spline approximation to this seasonal component. In the spline specification the knot placement is quite important, and usually some experimentation is needed. In the following model the knots are placed at the beginning and the middle of each day. Note that the knots at the beginning and end of the season, 1 and 28 in this case, should not be listed in the knot list because knots are always placed there anyway.

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  splineseason length=28
    knots=3 5 7 9 11 13 15 17 19 21 23 25 27
    degree=3;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The spline season model takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 29.3.5](#), which shows that the spline season model performs even better than the previous two models in the holdout region, its SAE = 313.79 compared to SAE = 471.53 for the previous model.

Output 29.3.5 SAE for the Spline Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	23.350	37.650	313.792

The following statements illustrate yet another way to approximate a long seasonal component. Here a combination of BLOCKSEASON and SEASON statements results in a seasonal component that is a sum of two seasonal patterns: one seasonal pattern is simply a regular season with season length 4 that captures the *within-day* seasonal pattern, and the other seasonal pattern is a block seasonal pattern that remains constant during the day but varies from day to day within a week.

Note the use of NLOPTIONS statement to change the optimization technique during the parameter estimation to DBLDOG, which in this case performs better than the default technique, TRUREG.

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=4 type=trig;
  blockseason nblocks=7 blocksize=4
    type=trig;
  estimate back=28;
  forecast back=28 lead=28;
  nloptions tech=dbldog;
run;
```

This model also takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 29.3.6](#), which shows that the block season model does slightly better than the baseline model but not as good as the other two models, its SAE = 508.52 compared to the SAE = 516.22 of the baseline model.

Output 29.3.6 SAE for the Block Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	39.339	21.661	508.522

This example showed a few different ways to model a long seasonal pattern. It showed that parsimonious models for long seasonal patterns can be useful, and in some cases even more effective than the full model. Moreover, for very long seasonal patterns the high memory requirements and long computing times might make full models impractical.

Example 29.4: Modeling Time-Varying Regression Effects Using the RANDOMREG Statement

In April 1979 the Albuquerque Police Department began a special enforcement program aimed at reducing the number of DWI (driving while intoxicated) accidents. The program was administered by a squad of police officers, who used breath alcohol testing (BAT) devices and a van that houses a BAT device (Batmobile). These data were collected by the Division of Governmental Research of the University of New Mexico, under a contract with the National Highway Traffic Safety Administration of the U.S. Department of Transportation, to evaluate the Batmobile program. The first 29 observations are for a control period, and the next 23 observations are for the experimental (Batmobile) period. The data, freely available at <http://lib.stat.cmu.edu/DASL/Datafiles/batdat.html>, consist of two variables: ACC, which represents injuries and fatalities from Wednesday to Saturday nighttime accidents, and FUEL, which represents fuel consumption (millions of gallons) in Albu-

querque. The variables are measured quarterly starting from the first quarter of 1972 up to the last quarter of 1984, covering the span of 13 years. The following DATA step statements create the input data set.

```

data bat;
  input ACC FUEL @@;
  batProgram = 0;
  if _n_ > 29 then batProgram = 1;
  date = INTNX( 'qtr', '1jan1972'd, _n_- 1 );
  format date qtr8.;
datalines;
192    32.592    238    37.250    232    40.032
246    35.852    185    38.226    274    38.711
266    43.139    196    40.434    170    35.898
234    37.111    272    38.944    234    37.717
210    37.861    280    42.524    246    43.965
248    41.976    269    42.918    326    49.789
342    48.454    257    45.056    280    49.385
290    42.524    356    51.224    295    48.562
279    48.167    330    51.362    354    54.646
331    53.398    291    50.584    377    51.320
327    50.810    301    46.272    269    48.664
314    48.122    318    47.483    288    44.732
242    46.143    268    44.129    327    46.258
253    48.230    215    46.459    263    50.686
319    49.681    263    51.029    206    47.236
286    51.717    323    51.824    306    49.380
230    47.961    304    46.039    311    55.683
292    52.263
;

```

There are a number of ways to study these data and the question of the effectiveness of the BAT program. One possibility is to study the *before-after* difference in the injuries and fatalities per million gallons of fuel consumed, by regressing ACC on the FUEL and the dummy variable BATPROGRAM, which is zero before the program began and one while the program is in place. However, it is possible that the effect of the Batmobiles might well be cumulative, because as awareness of the program becomes dispersed, its effectiveness as a deterrent to driving while intoxicated increases. This suggests that the regression coefficient of the BATPROGRAM variable might be *time varying*. The following program fits a model that incorporates these considerations. A seasonal component is included in the model since it is easy to see that the data show strong quarterly seasonality.

```

proc ucm data=bat;
  model acc = fuel;
  id date interval=qtr;
  irregular;
  level var=0 noest;
  randomreg batProgram / plot=smooth;
  season length=4 var=0 noest plot=smooth;
  estimate plot=(panel residual);
  forecast plot=forecasts lead=0;
run;

```

The model seems to fit the data adequately. No data are withheld for model validation because the series is relatively short. The plot of the time-varying coefficient of BATPROGRAM is shown in [Output 29.4.1](#). As expected, it shows that the effectiveness of the program increases as awareness of the program becomes dispersed. The effectiveness eventually seems to level off. The residual diagnostic plots are shown in [Output 29.4.2](#) and [Output 29.4.3](#), the forecast plot is in [Output 29.4.4](#), the goodness-of-fit statistics are in [Output 29.4.5](#), and the parameter estimates are in [Output 29.4.6](#).

Example 29.5: Trend Removal Using the Hodrick-Prescott Filter

Hodrick-Prescott filter (see Hodrick and Prescott (1997)) is a popular tool in macroeconomics for fitting smooth trend to time series. It is well known that the trend computation according to this filter is equivalent to fitting the local linear trend plus irregular model with the level disturbance variance restricted to zero and the slope disturbance variance restricted to be a suitable multiple of the irregular component variance. The multiple used depends on the frequency of the series; for example, for quarterly series the commonly recommended multiple is $1/1600 = 0.000625$. For other intervals there is no consensus, but a frequently suggested value for monthly series is $1/14400$ and the value for an annual series can range from $1/400 = 0.0025$ to $1/7 = 0.15$. The data set considered in this example consists of quarterly GNP values for the United States from 1960 to 1991. In the UCM procedure statements that follow, the presence of the PROFILE option in the ESTIMATE statement implies that the restriction that the disturbance variance of the slope component be fixed at 0.000625 is interpreted differently: it implies that the disturbance variance of the slope component be restricted to be 0.000625 *times* the estimated irregular component variance, as needed for the Hodrick-Prescott filter. The plot of the fitted trend is shown in [Output 29.5.1](#), and the plot of the smoothed irregular component, which corresponds to the detrended series, is given in [Output 29.5.2](#). The detrended series can be further analyzed for business cycles.

```
proc ucm data=sashelp.gnp;
  id date interval=qtr;
  model gnp;
  irregular plot=smooth;
  level var=0 noest plot=smooth;
  slope var=0.000625 noest;
  estimate PROFILE;
  forecast plot=(decomp);
run;
```

Output 29.5.1 Smoothed Trend for the GNP Series as per the Hodrick-Prescott Filter

Output 29.5.2 Detrended GNP Series**Example 29.6: Using Splines to Incorporate Nonlinear Effects**

The data in this example are created to mirror the electricity demand and temperature data recorded at a utility company in the midwest region of the United States. The data set (not shown), `utility`, has three variables: `load`, `temp`, and `date`. The `load` column contains the daily electricity demand, the `temp` column has the average daily temperature readings, and the `date` column records the observation date.

The following statements produce a plot, shown in [Output 29.6.1](#), of electricity load versus temperature. Clearly the relationship is smooth but nonlinear: the load generally increases when the temperatures are away from the comfortable sixties.

```
proc sgplot data=utility;
    loess x=temp y=load / smooth=0.4;
run;
```

Output 29.6.1 Load versus Temperature Plot

The time series plot of the load (not shown) also shows that, apart from a day-of-the-week seasonal effect, there are no additional easily identifiable patterns in the series. The series has no apparent upward or downward trend. The following statements fit a UCM to the series that takes into account these observations. The particular choice of the model is a result of a little modeling exercise that compared a small number of competing models. The chosen model is adequate but by no means the best possible. The temperature effect is modeled by a deterministic three-degree spline with knots at 30, 40, 50, 60, and 75. The knot locations and the degree were chosen by visual inspection of the plot (Output 29.6.1). An autoreg component is used in place of the simple irregular component, which improved the residual analysis. The last 60 days of data are withheld for out-of-sample forecast evaluation (note the `BACK=` option in both the `ESTIMATE` and `FORECAST` statements). The `OUTLIER` statement is used to increase the number of outliers reported to 10. Since no `CHECKBREAK` option is used in the `LEVEL` statement, only the additive outliers are searched. In this example the use of the `EXTRADIFFUSE=` option in the `ESTIMATE` and `FORECAST` statements is useful for discarding some early one-step-ahead forecasts and residuals with large variance.

```
proc ucm data=utility;
  id date interval=day;
  model load;
```

```

autoreg;
level plot=smooth;
splinereg temp knots=30 40 50 65 75 degree=3
  variance=0 noest;
season length=7 var=0 noest;
estimate plot=panel back=60
  extradiffuse=50;
outlier maxnum=10;
forecast back=60 lead=60
  extradiffuse=50;
run;

```

The parameter estimates are given in [Output 29.6.2](#), and the residual goodness-of-fit statistics are shown in [Output 29.6.3](#). The residual diagnostic plots are shown in [Output 29.6.4](#). The ACF and PACF plots appear satisfactory, but the normality plots, particularly the Q-Q plot, show possible violations. It appears that, at least in part, this nonNormal behavior of the residuals might be attributable to the outliers in the series. The outlier summary table, [Output 29.6.5](#), shows the most likely outlying observations. Notice that most of these outliers are holidays, like July 4th, when the electricity load is lower than usual for that day of the week.

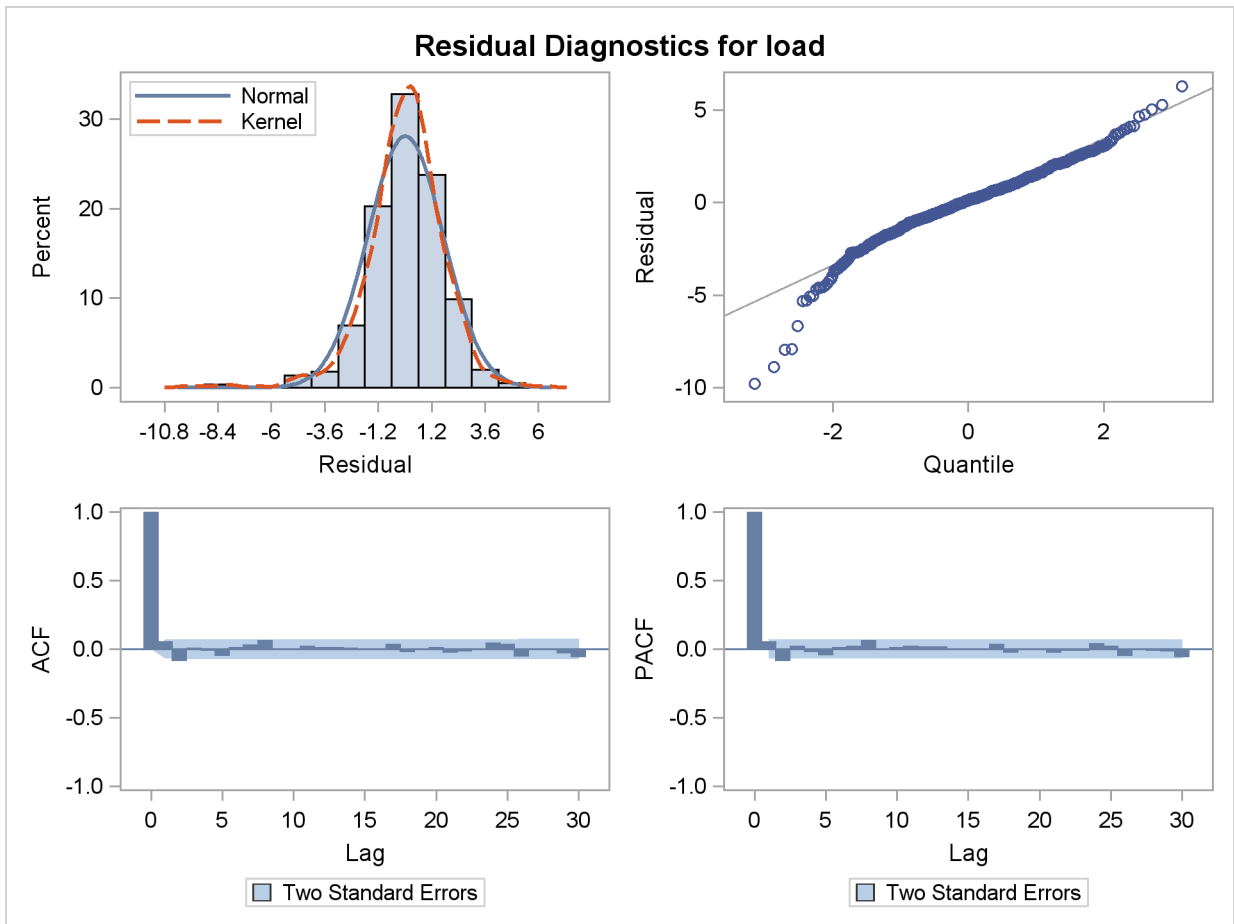

Output 29.6.2 Electricity Load: Parameter Estimates

The UCM Procedure					
Final Estimates of the Free Parameters

The plot of the load forecasts for the withheld data is shown in [Output 29.6.6](#).

Output 29.6.6 Electricity Load: Forecast Evaluation of the Withheld Data

Example 29.7: Detection of Level Shift

The series in this example consists of the yearly water level readings of the Nile River recorded at Aswan, Egypt (see Cobb (1978) and de Jong and Penzer (1998)). The readings are from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the water level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in [Output 29.7.1](#). The following DATA step statements create the input data set.

```

data nile;
  input waterlevel @@;
  year = intnx( 'year', '1jan1871'd, _n_-1 );
  format year year4.;
datalines;
  1120 1160 963 1210 1160 1160 813 1230 1370 1140
  995 935 1110 994 1020 960 1180 799 958 1140
  1100 1210 1150 1250 1260 1220 1030 1100 774 840
  874 694 940 833 701 916 692 1020 1050 969
  831 726 456 824 702 1120 1100 832 764 821
  768 845 864 862 698 845 744 796 1040 759
  781 865 845 944 984 897 822 1010 771 676
  649 846 812 742 801 1040 860 874 848 890
  744 749 838 1050 918 986 797 923 975 815
  1020 906 901 1170 912 746 919 718 714 740
;

proc timeseries data=nile plot=series;
  id year interval=year;
  var waterlevel;
run;

```

Output 29.7.1 Nile Water Level

In this situation it is known that a shift in the water level occurred within the span of the series, and its effect can be easily taken into account by including an appropriate indicator variable as a regressor. However, in many situation such prior information is not available, and it is useful to detect such a shift in a data analytic fashion. You can check for breaks in the level by using the [CHECKBREAK](#) option in the LEVEL statement. The following statements fit a simple locally constant level plus error model to the series:

```
proc ucm data=nile;
  id year interval=year;
  model waterlevel;
  irregular;
  level plot=smooth checkbreak;
  estimate;
  forecast plot=decomp;
run;
```

The plot in [Output 29.7.2](#) shows a noticeable drop in the smoothed water level around 1899.

Output 29.7.2 Smoothed Trend without the Shift of 1899

The “Outlier Summary” table in [Output 29.7.3](#) shows the most likely types of breaks and their locations within the series span. The shift of 1899 is easily detected.

Output 29.7.3 Detection of Structural Breaks in the Nile River Level

Outlier Summary						
Obs	year	Break Type	Standard			
			Estimate	Error	Chi-Square	DF Pr > ChiSq
29	1899	Level	-315.73791	97.639753	10.46	1 0.0012

The following statements specify a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (SHIFT1899):

```
data nile;
  set nile;
  shift1899 = ( year >= '1jan1899'd );
run;
```

```

proc ucm data=nile;
  id year interval=year;
  model waterlevel = shift1899;
  irregular;
  level;
  estimate;
  forecast plot=decomp;
run;

```

The plot in [Output 29.7.4](#) shows the smoothed trend, including the correction due to the shift in the year 1899. Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

Output 29.7.4 Smoothed Trend plus Shift of 1899

Example 29.8: ARIMA Modeling (Experimental)

This example shows how you can use the UCM procedure for ARIMA modeling. The parameter estimates and predictions for ARIMA models obtained by using PROC UCM will be close to those obtained by using PROC ARIMA (in the presence of the ML option in its ESTIMATE statement) if the model is stationary or if the model is nonstationary and there are no missing values in the

data. See Chapter 7, “[The ARIMA Procedure](#),” for additional details about the ARIMA procedure. However, if there are missing values in the data and the model is nonstationary, then the UCM and ARIMA procedures can produce significantly different parameter estimates and predictions. An article by Kohn and Ansley (1986) suggests a statistically sound method of estimation, prediction, and interpolation for nonstationary ARIMA models with missing data. This method is based on an algorithm that is equivalent to the Kalman filtering and smoothing algorithm used in the UCM procedure. The results of an illustrative example in their article are reproduced here using the UCM procedure. In this example an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model is applied to the logarithm of the air series in the `sashelp.air` data set. Four different missing value patterns are considered to highlight different aspects of the problem:

- *Data1*. The full data set of 144 observations.
- *Data2*. The set of 78 observations that omit January through November in each of the last 6 years.
- *Data3*. The data set with the 5 observations July 1949, June, July, and August 1957, and July 1960 missing.
- *Data4*. The data set with all July observations missing and June and August 1957 also missing.

The following DATA steps create these data sets:

```
data Data1;
    set sashelp.air;
    logair = log(air);
run;

data Data2;
    set data1;
    if year(date) >= 1955 and month(date) < 12 then logair = .;
run;

data Data3;
    set data1;
    if (year(date) = 1949 and month(date) = 7) then logair = .;
    if ( year(date) = 1957 and
        (month(date) = 6 or month(date) = 7 or month(date) = 8) )
        then logair = .;
    if (year(date) = 1960 and month(date) = 7) then logair = .;
run;

data Data4;
    set data1;
    if month(date) = 7 then logair = .;
    if year(date) = 1957 and (month(date) = 6 or month(date) = 8)
        then logair = .;
run;
```

The following statements specify the $ARIMA(0, 1, 1) \times (0, 1, 1)_{12}$ model for the `logair` series in the first data set (`Data1`):

```
proc ucm data=Data1;
  id date interval=month;
  model logair;
  irregular q=1 sq=1 s=12;
  deplag lags=(1) (12) phi=1 1 noest;
  estimate outest=est1;
  forecast outfor=for1;
run;
```

Note that the moving-average part of the model is specified by using the Q=, SQ=, and S= options in the IRREGULAR statement and the differencing operator, $(1 - B)(1 - B^{12})$, is specified by using the DEPLAG statement. The model does not contain an intercept term; therefore no LEVEL statement is needed. The parameter estimates are saved in a data set EST1 by using the OUTEST= option in the ESTIMATE statement and the forecasts and the component estimates are saved in a data set FOR1 by using the OUTFOR= option in the FORECAST statement. The same analysis is performed on the other three data sets, but is not shown here.

Output 29.8.1 resembles Table 1 in Kohn and Ansley (1986). This table is generated by merging the parameter estimates from the four analyses. Only the moving-average parameter estimates and their standard errors are reported. The columns EST1 and STD1 correspond to the estimates for Data1. The parameter estimates and their standard errors for other three data sets are similarly named. Note that the parameter estimates closely match the parameter estimates in the article. However, their standard errors differ slightly. This difference could be the result of different ways of computing the Hessian at the optimum. The white noise error variance estimates are not reported here, but they agree quite closely with those in the article.

Output 29.8.1 Data Sets 1–4: Parameter Estimates and Standard Errors

P A R A M E T E R	e		s		e		s	
	s	t	s	t	s	t	s	t
R	1	1	2	2	3	3	4	4
MA_1	0.402	0.090	0.457	0.121	0.408	0.092	0.431	0.091
SMA_1	0.557	0.073	0.758	0.236	0.566	0.075	0.573	0.074

Output 29.8.2 resembles Table 2 in Kohn and Ansley (1986). It contains forecasts and their standard errors for the four data sets. The numbers are very close to those in the article.

Output 29.8.2 Data Sets 1–4: Forecasts and Standard Errors

DATE	for1	std1	for2	std2	for3	std3	for4	std4

NOV61	6.063	0.079	6.043	0.089	6.064	0.079	6.064	0.077
DEC61	6.168	0.082	6.174	0.086	6.168	0.082	6.169	0.080

Output 29.8.3 is based on Data2. It resembles Table 3 in Kohn and Ansley (1986). The columns S_SERIES and VS_SERIES in the **OUTFOR=** data set contain the interpolated values of logair and their variances. The estimate column in **Output 29.8.3** reports interpolated values (which are the same as S_SERIES), and the std column reports their standard errors (which are computed as square root of VS_SERIES) for January–November 1957. The actual logair values for these months, which are missing in Data2, are also provided for comparison. The numbers are very close to those in the article.

Output 29.8.3 Data Set 2: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JAN57	5.753	5.733	0.045
FEB57	5.707	5.738	0.049
MAR57	5.875	5.893	0.052
APR57	5.852	5.850	0.054
MAY57	5.872	5.843	0.055
JUN57	6.045	5.951	0.055
JUL57	6.142	6.051	0.055
AUG57	6.146	6.055	0.054
SEP57	6.001	5.938	0.052
OCT57	5.849	5.812	0.049
NOV57	5.720	5.680	0.045

Output 29.8.4 resembles Table 4 in Kohn and Ansley (1986). These numbers are based on Data3, and they also are very close to those in the article.

Output 29.8.4 Data Set 3: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUL49	4.997	5.013	0.031
JUN57	6.045	6.024	0.030
JUL57	6.142	6.147	0.031
AUG57	6.146	6.148	0.030
JUL60	6.433	6.409	0.031

Output 29.8.5 resembles Table 5 in Kohn and Ansley (1986). As before, the numbers are very close to those in the article.

Output 29.8.5 Data Set 4: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUN57	6.045	6.023	0.030
AUG57	6.146	6.147	0.030

The similarity between the outputs in this example and the results shown in Kohn and Ansley (1986) demonstrate that PROC UCM can be effectively used for nonstationary ARIMA models with missing data.

Overview: VARMAX Procedure

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts associated with vector autoregressive moving-average processes with exogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated to each other, they are also correlated to each other's past values. The VARMAX procedure can be used to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables). The VARMAX procedure enables you to model the dynamic relationship both between the dependent variables and also between the dependent and independent variables.

VARMAX models are defined in terms of the orders of the autoregressive or moving-average process (or both). When you use the VARMAX procedure, these orders can be specified by options or they can be automatically determined. Criteria for automatically determining these orders include the following:

- Akaike information criterion (AIC)
- corrected AIC (AICC)
- Hannan-Quinn (HQ) criterion
- final prediction error (FPE)

- Schwarz Bayesian criterion (SBC), also known as Bayesian information criterion (BIC)

If you do not want to use the automatic order selection, the VARMAX procedure provides autoregressive order identification aids:

- partial cross-correlations
- Yule-Walker estimates
- partial autoregressive coefficients
- partial canonical correlations

For situations where the stationarity of the time series is in question, the VARMAX procedure provides tests to aid in determining the presence of unit roots and cointegration. These tests include the following:

- Dickey-Fuller tests
- Johansen cointegration test for nonstationary vector processes of integrated order one
- Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
- Johansen cointegration test for nonstationary vector processes of integrated order two

For stationary vector times series (or nonstationary series made stationary by appropriate differencing), the VARMAX procedure provides for vector autoregressive and moving-average (VARMA) and Bayesian vector autoregressive (BVAR) models. To cope with the problem of high dimensionality in the parameters of the VAR model, the VARMAX procedure provides both vector error correction model (VECM) and Bayesian vector error correction model (BVECM). Bayesian models are used when prior information about the model parameters is available. The VARMAX procedure also allows independent (exogenous) variables with their distributed lags to influence dependent (endogenous) variables in various models such as VARMAX, BVARX, VECMX, and BVECMX models.

Forecasting is one of the main objectives of multivariate time series analysis. After successfully fitting the VARMAX, BVARX, VECMX, and BVECMX models, the VARMAX procedure computes predicted values based on the parameter estimates and the past values of the vector time series.

The model parameter estimation methods are the following:

- least squares (LS)
- maximum likelihood (ML)

The VARMAX procedure provides various hypothesis tests of long-run effects and adjustment coefficients by using the likelihood ratio test based on Johansen cointegration analysis. The VARMAX procedure offers the likelihood ratio test of the weak exogeneity for each variable.

After fitting the model parameters, the VARMAX procedure provides for model checks and residual analysis by using the following tests:

- Durbin-Watson (DW) statistics
- F test for autoregressive conditional heteroscedastic (ARCH) disturbance
- F test for AR disturbance
- Jarque-Bera normality test
- Portmanteau test

The VARMAX procedure supports several modeling features, including the following:

- seasonal deterministic terms
- subset models
- multiple regression with distributed lags
- dead-start model that does not have present values of the exogenous variables
- GARCH-type multivariate conditional heteroscedasticity models

The VARMAX procedure provides a Granger causality test to determine the Granger-causal relationships between two distinct groups of variables. It also provides the following:

- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle
- contemporaneous relationships among the components of the vector time series

Getting Started: VARMAX Procedure

This section outlines the use of the VARMAX procedure and gives five different examples of the kinds of models supported.

Vector Autoregressive Process

Let $\mathbf{y}_t = (y_{1t}, \dots, y_{kt})'$, $t = 1, 2, \dots$, denote a k -dimensional time series vector of random variables of interest. The p th-order VAR process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \dots + \Phi_p \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where the ϵ_t is a vector white noise process with $\epsilon_t = (\epsilon_{1t}, \dots, \epsilon_{kt})'$ such that $E(\epsilon_t) = 0$, $E(\epsilon_t \epsilon_t') = \Sigma$, and $E(\epsilon_t \epsilon_s') = 0$ for $t \neq s$; $\delta = (\delta_1, \dots, \delta_k)'$ is a constant vector and Φ_i is a $k \times k$ matrix.

Analyzing and modeling the series jointly enables you to understand the dynamic relationships over time among the series and to improve the accuracy of forecasts for individual series by using the additional information available from the related series and their forecasts.

Example of Vector Autoregressive Model

Consider the first-order stationary bivariate vector autoregressive model

$$y_t = \begin{pmatrix} 1.2 & -0.5 \\ 0.6 & 0.3 \end{pmatrix} y_{t-1} + \epsilon_t, \quad \text{with } \Sigma = \begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 1.25 \end{pmatrix}$$

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  /* simulate the vector time series */
  call varmasim(y,phi) sigma = sig n = 100 seed = 34657;
  cn = {'y1' 'y2'};
  create simull from y[colname=cn];
  append from y;
quit;
```

The following statements plot the simulated vector time series y_t shown in [Figure 30.1](#):

```
data simull;
  set simull;
  date = intnx('year', '01jan1900'd, _n_-1);
  format date year4.;
run;

proc timeseries data=simull vectorplot=series;
  id date interval=year;
  var y1 y2;
run;
```

Figure 30.1 Plot of Generated Data Process

The following statements fit a VAR(1) model to the simulated data. First, you specify the input data set in the PROC VARMAX statement. Then, you use the MODEL statement to designate the dependent variables, y_1 and y_2 . To estimate a VAR model with mean zero, you specify the order of the autoregressive model with the P= option and the NOINT option. The MODEL statement fits the model to the data and prints parameter estimates and their significance. The PRINT=ESTIMATES option prints the matrix form of parameter estimates, and the PRINT=DIAGNOSE option prints various diagnostic tests. The LAGMAX=3 option is used to print the output for the residual diagnostic checks.

To output the forecasts to a data set, you specify the OUTPUT statement with the OUT= option. If you want to forecast five steps ahead, you use the LEAD=5 option. The ID statement specifies the yearly interval between observations and provides the Time column in the forecast output.

The VARMAX procedure output is shown in [Figure 30.2](#) through [Figure 30.10](#).

```

/*--- Vector Autoregressive Model ---*/

proc varmax data=simul1;
  id date interval=year;
  model y1 y2 / p=1 noint lagmax=3
              print=(estimates diagnose);

```

```
output out=for lead=5;
run;
```

Figure 30.2 Descriptive Statistics

The VARMAX Procedure						
Number of Observations						100
Number of Pairwise Missing						0
Simple Summary Statistics						
Variable	Type	N	Mean	Standard Deviation	Min	Max
y1	Dependent	100	-0.21653	2.78210	-4.75826	8.37032
y2	Dependent	100	0.16905	2.58184	-6.04718	9.58487

The VARMAX procedure first displays descriptive statistics. The Type column specifies that the variables are dependent variables. The column N stands for the number of nonmissing observations.

Figure 30.3 shows the type and the estimation method of the fitted model for the simulated data. It also shows the AR coefficient matrix in terms of lag 1, the parameter estimates, and their significance, which can indicate how well the model fits the data.

The second table schematically represents the parameter estimates and allows for easy verification of their significance in matrix form.

In the last table, the first column gives the left-hand-side variable of the equation; the second column is the parameter name ARl_i_j , which indicates the (i, j) th element of the lag l autoregressive coefficient; the last column is the regressor that corresponds to the displayed parameter.

Figure 30.3 Model Type and Parameter Estimates

The VARMAX Procedure

Model Parameter Estimates						
Equation	Parameter	Estimate	Standard Error	t Value	Pr > t	Variable
y1	AR1_1_1	1.15977	0.05508	21.06	0.0001	y1(t-1)
	AR1_1_2	-0.51058	0.05898	-8.66	0.0001	y2(t-1)
y2	AR1_2_1	0.54634	0.05779	9.45	0.0001	y1(t-1)
	AR1_2_2	0.38499	0.06188	6.22	0.0001	y2(t-1)

The fitted VAR(1) model with estimated standard errors in parentheses is given as

$$y_t = \begin{pmatrix} 1.160 & -0.511 \\ (0.055) & (0.059) \\ 0.546 & 0.385 \\ (0.058) & (0.062) \end{pmatrix} y_{t-1} + \epsilon_t$$

Clearly, all parameter estimates in the coefficient matrix Φ_1 are significant.

The model can also be written as two univariate regression equations.

$$y_{1t} = 1.160 y_{1,t-1} - 0.511 y_{2,t-1} + \epsilon_{1t}$$

$$y_{2t} = 0.546 y_{1,t-1} + 0.385 y_{2,t-1} + \epsilon_{2t}$$

The table in [Figure 30.4](#) shows the innovation covariance matrix estimates and the various information criteria results. The smaller value of information criteria fits the data better when it is compared to other models. The variable names in the covariance matrix are printed for convenience; y_1 means the innovation for y_1 , and y_2 means the innovation for y_2 .

The VARMAX procedure provides diagnostic checks for the univariate form of the equations. The table in [Figure 30.8](#) describes how well each univariate equation fits the data. From two univariate regression equations in [Figure 30.3](#), the values of R^2 in the second column are 0.84 and 0.80 for each equation. The standard deviations in the third column are the square roots of the diagonal elements of the covariance matrix from [Figure 30.4](#). The F statistics are in the fourth column for hypotheses to test $\phi_{11} = \phi_{12} = 0$ and $\phi_{21} = \phi_{22} = 0$, respectively, where ϕ_{ij} is the (i, j) th element of the matrix Φ_1 . The last column shows the p -values of the F statistics. The results show that each univariate model is significant.

Figure 30.8 Univariate Diagnostic Checks

Univariate Model ANOVA Diagnostics				
Variable	R-Square	Standard Deviation	F Value	Pr > F
y1	0.8369	1.13523	497.67	<.0001
y2	0.7978	1.19096	382.76	<.0001

The check for white noise residuals in terms of the univariate equation is shown in [Figure 30.9](#). This output contains information that indicates whether the residuals are correlated and heteroscedastic. In the first table, the second column contains the Durbin-Watson test statistics to test the null hypothesis that the residuals are uncorrelated. The third and fourth columns show the Jarque-Bera normality test statistics and their p -values to test the null hypothesis that the residuals have normality. The last two columns show F statistics and their p -values for ARCH(1) disturbances to test the null hypothesis that the residuals have equal covariances. The second table includes F statistics and their p -values for AR(1), AR(1,2), AR(1,2,3) and AR(1,2,3,4) models of residuals to test the null hypothesis that the residuals are uncorrelated.

Bayesian Vector Autoregressive Process

The Bayesian vector autoregressive (BVAR) model is used to avoid problems of collinearity and over-parameterization that often occur with the use of VAR models. BVAR models do this by imposing priors on the AR parameters.

The following statements fit a BVAR(1) model to the simulated data. You specify the PRIOR= option with the hyperparameters. The LAMBDA=0.9 and THETA=0.1 options are hyperparameters controlling the prior covariance. Part of the VARMAX procedure output is shown in [Figure 30.11](#).

```

/*--- Bayesian Vector Autoregressive Process ---*/

proc varmax data=simul1;
  model y1 y2 / p=1 noint
          prior=(lambda=0.9 theta=0.1);
run;

```

The output in [Figure 30.11](#) shows that parameter estimates are slightly different from those in [Figure 30.3](#). By choosing the appropriate priors, you might be able to get more accurate forecasts by using a BVAR model rather than by using an unconstrained VAR model. See the section “[Bayesian VAR and VARX Modeling](#)” on page 1947 for details.

Vector Error Correction Model

A vector error correction model (VECM) can lead to a better understanding of the nature of any nonstationarity among the different component series and can also improve longer term forecasting over an unconstrained model.

The VECM(p) form with the cointegration rank $r(\leq k)$ is written as

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where Δ is the differencing operator, such that $\Delta \mathbf{y}_t = \mathbf{y}_t - \mathbf{y}_{t-1}$; $\Pi = \alpha\beta'$, where α and β are $k \times r$ matrices; Φ_i^* is a $k \times k$ matrix.

It has an equivalent VAR(p) representation as described in the preceding section.

$$\mathbf{y}_t = \boldsymbol{\delta} + (I_k + \Pi + \Phi_1^*) \mathbf{y}_{t-1} + \sum_{i=2}^{p-1} (\Phi_i^* - \Phi_{i-1}^*) \mathbf{y}_{t-i} - \Phi_{p-1}^* \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where I_k is a $k \times k$ identity matrix.

Example of Vector Error Correction Model

An example of the second-order nonstationary vector autoregressive model is

$$\mathbf{y}_t = \begin{pmatrix} -0.2 & 0.1 \\ 0.5 & 0.2 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

with

$$\Sigma = \begin{pmatrix} 100 & 0 \\ 0 & 100 \end{pmatrix} \text{ and } \mathbf{y}_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

This process can be given the following VECM(2) representation with the cointegration rank one:

$$\Delta \mathbf{y}_t = \begin{pmatrix} -0.4 \\ 0.1 \end{pmatrix} (1, -2) \mathbf{y}_{t-1} - \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The following PROC IML statements generate simulated data for the VECM(2) form specified above and plot the data as shown in [Figure 30.12](#):

```
proc iml;
  sig = 100*i(2);
  phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
  call varmasim(y,phi) sigma=sig n=100 initial=0
              seed=45876;

  cn = {'y1' 'y2'};
  create simul2 from y[colname=cn];
  append from y;
quit;

data simul2;
  set simul2;
  date = intnx('year', '01jan1900'd, _n_-1 );
  format date year4. ;
run;

proc timeseries data=simul2 vectorplot=series;
  id date interval=year;
  var y1 y2;
run;
```

Figure 30.12 Plot of Generated Data Process

Cointegration Testing

The following statements use the Johansen cointegration rank test. The `COINTTEST=(JOHANSEN)` option does the Johansen trace test and is equivalent to specifying `COINTTEST` with no additional options or the `COINTTEST=(JOHANSEN=(TYPE=TRACE))` option.

```
/*--- Cointegration Test ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint dftest cointtest=(johansen);
run;
```

Figure 30.13 shows the output for Dickey-Fuller tests for the nonstationarity of each series and Johansen cointegration rank test between series.

Figure 30.13 Dickey-Fuller Tests and Cointegration Rank Test

The VARMAX Procedure						
Unit Root Test						
Variable	Type	Rho	Pr < Rho	Tau	Pr < Tau	
y1	Zero Mean	1.47	0.9628	1.65	0.9755	
	Single Mean	-0.80	0.9016	-0.47	0.8916	
	Trend	-10.88	0.3573	-2.20	0.4815	
y2	Zero Mean	-0.05	0.6692	-0.03	0.6707	
	Single Mean	-6.03	0.3358	-1.72	0.4204	
	Trend	-50.49	0.0003	-4.92	0.0006	
Cointegration Rank Test Using Trace						
H0:	H1:			5%		
Rank=r	Rank>r	Eigenvalue	Trace	Critical Value	Drift in ECM	Drift in Process
0	0	0.5086	70.7279	12.21	NOINT	Constant
1	1	0.0111	1.0921	4.14		

In Dickey-Fuller tests, the second column specifies three types of models, which are zero mean, single mean, or trend. The third column (Rho) and the fifth column (Tau) are the test statistics for unit root testing. Other columns are their p -values. You can see that both series have unit roots. For a description of Dickey-Fuller tests, see the section “[PROBDF Function for Dickey-Fuller Tests](#)” on page 158 in Chapter 5, “[SAS Macros and Functions](#).”

In the cointegration rank test, the last two columns explain the drift in the model or process. Since the NOINT option is specified, the model is

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \Phi_1^* \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The column Drift In ECM means there is no separate drift in the error correction model, and the column Drift In Process means the process has a constant drift before differencing.

H0 is the null hypothesis, and H1 is the alternative hypothesis. The first row tests $r = 0$ against $r > 0$; the second row tests $r = 1$ against $r > 1$. The Trace test statistics in the fourth column are computed by $-T \sum_{i=r+1}^k \log(1 - \lambda_i)$ where T is the available number of observations and λ_i is the eigenvalue in the third column. By default, the critical values at 5% significance level are used for testing. You can compare the test statistics and critical values in each row. There is one cointegrated process in this example since the Trace statistic for testing $r = 0$ against $r > 0$ is greater than the critical value, but the Trace statistic for testing $r = 1$ against $r > 1$ is not greater than the critical value.

The following statements fit a VECM(2) form to the simulated data. From the result in [Figure 30.13](#), the time series are cointegrated with rank=1. You specify the ECM= option with the RANK=1 option. For normalizing the value of the cointegrated vector, you specify the normalized variable

with the NORMALIZE= option. The PRINT=(IARR) option provides the VAR(2) representation. The VARMAX procedure output is shown in Figure 30.14 through Figure 30.16.

```

/*--- Vector Error-Correction Model ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint lagmax=3
           ecm=(rank=1 normalize=y1)
           print=(iarr estimates);
run;

```

The ECM= option produces the estimates of the long-run parameter, β , and the adjustment coefficient, α . In Figure 30.14, “1” indicates the first column of the α and β matrices. Since the cointegration rank is 1 in the bivariate system, α and β are two-dimensional vectors. The estimated cointegrating vector is $\hat{\beta} = (1, -1.96)'$. Therefore, the long-run relationship between y_{1t} and y_{2t} is $y_{1t} = 1.96y_{2t}$. The first element of $\hat{\beta}$ is 1 since y_1 is specified as the normalized variable.

Figure 30.14 Parameter Estimates for the VECM(2) Form

The VARMAX Procedure		
Type of Model	VECM(2)	
Estimation Method	Maximum Likelihood Estimation

y1	1.00000	
y2	-1.95575	
Alpha		
Variable	1	
y1	-0.46680	
y2	0.10667	

Figure 30.15 shows the parameter estimates in terms of lag one coefficients, y_{t-1} , and lag one first differenced coefficients, Δy_{t-1} , and their significance. “Alpha * Beta” indicates the coefficients of y_{t-1} and is obtained by multiplying the “Alpha” and “Beta” estimates in Figure 30.14. The parameter AR1_ i _ j corresponds to the elements in the “Alpha * Beta” matrix. The t values and p -values corresponding to the parameters AR1_ i _ j are missing since the parameters AR1_ i _ j have non-Gaussian distributions. The parameter AR2_ i _ j corresponds to the elements in the differenced lagged AR coefficient matrix. The “D_” prefixed to a variable name in Figure 30.15 implies differencing.

Figure 30.15 Parameter Estimates for the VECM(2) Form

	AR2_2_1	0.40493	0.04867	8.32	0.0001	D_y1 (t-1)
	AR2_2_2	-0.57157	0.05128	-11.15	0.0001	D_y2 (t-1)

The fitted model is given as

$$\Delta \mathbf{y}_t = \begin{pmatrix} -0.467 & 0.913 \\ (0.048) & (0.094) \\ 0.107 & -0.209 \\ (0.051) & (0.100) \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} -0.743 & -0.746 \\ (0.045) & (0.048) \\ 0.405 & -0.572 \\ (0.049) & (0.051) \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

Figure 30.16 Change the VECM(2) Form to the VAR(2) Model

Infinite Order AR Representation				
Lag	Variable	y1	y2	
1	y1	-0.21013	0.16674	
	y2	0.51160	0.21980	
2	y1	0.74332	0.74621	
	y2	-0.40493	0.57157	
3	y1	0.00000	0.00000	
	y2	0.00000	0.00000	

The PRINT=(IARR) option in the previous SAS statements prints the reparameterized coefficient estimates. For the LAGMAX=3 in the SAS statements, the coefficient matrix of lag 3 is zero.

The VECM(2) form in [Figure 30.16](#) can be rewritten as the following second-order vector autoregressive model:

$$\mathbf{y}_t = \begin{pmatrix} -0.210 & 0.167 \\ 0.512 & 0.220 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.743 & 0.746 \\ -0.405 & 0.572 \end{pmatrix} \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

Bayesian Vector Error Correction Model

Bayesian inference on a cointegrated system begins by using the priors of $\boldsymbol{\beta}$ obtained from the VECM(p) form. Bayesian vector error correction models can improve forecast accuracy for cointegrated processes.

The following statements fit a BVECM(2) form to the simulated data. You specify both the PRIOR= and ECM= options for the Bayesian vector error correction model. The VARMAX procedure output is shown in [Figure 30.17](#).

```
/*--- Bayesian Vector Error-Correction Model ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint
          prior=( lambda=0.5 theta=0.2 )
          ecm=( rank=1 normalize=y1 )
          print=(estimates);
run;
```

[Figure 30.17](#) shows the model type fitted to the data, the estimates of the adjustment coefficient ($\boldsymbol{\alpha}$), the parameter estimates in terms of lag one coefficients (\mathbf{y}_{t-1}), and lag one first differenced coefficients ($\Delta\mathbf{y}_{t-1}$).

Vector Autoregressive Process with Exogenous Variables

A VAR process can be affected by other observable variables that are determined outside the system of interest. Such variables are called exogenous (independent) variables. Exogenous variables can be stochastic or nonstochastic. The process can also be affected by the lags of exogenous variables. A model used to describe this process is called a VARX(p,s) model.

The VARX(p,s) model is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\mathbf{x}_t = (x_{1t}, \dots, x_{rt})'$ is an r -dimensional time series vector and Θ_i^* is a $k \times r$ matrix.

For example, a VARX(1,0) model is

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \Theta_0^* \mathbf{x}_t + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_t = (y_{1t}, y_{2t}, y_{3t})'$ and $\mathbf{x}_t = (x_{1t}, x_{2t})'$.

The following statements fit the VARX(1,0) model to the given data:

```

data grunfeld;
  input year y1 y2 y3 x1 x2 x3;
  label y1='Gross Investment GE'
        y2='Capital Stock Lagged GE'
        y3='Value of Outstanding Shares GE Lagged'

Figure 30.19 shows the parameter estimates for the constant, the lag zero coefficients of exogenous variables, and the lag one AR coefficients. From the schematic representation of parameter estimates, the significance of the parameter estimates can be easily verified. The symbol “C” means the constant and “XL0” means the lag zero coefficients of exogenous variables.

	AR1_3_3	0.93801	0.01821	51.50	0.0001	y3(t-1)

The fitted model is given as

$$\begin{pmatrix} y_{1t} \\ y_{2t} \\ y_{3t} \end{pmatrix} = \begin{pmatrix} -12.013 \\ (27.471) \\ 702.086 \\ (256.480) \\ -22.421 \\ (10.312) \end{pmatrix} + \begin{pmatrix} 1.693 & -0.009 \\ (0.544) & (0.054) \\ -6.099 & 2.580 \\ (5.078) & (0.501) \\ -0.023 & -0.013 \\ (0.204) & (0.020) \end{pmatrix} \begin{pmatrix} x_{1t} \\ x_{2t} \end{pmatrix} \\
 + \begin{pmatrix} 0.237 & 0.008 & 0.029 \\ (0.207) & (0.016) & (0.049) \\ -2.467 & 0.164 & -0.841 \\ (1.930) & (0.152) & (0.453) \\ 0.951 & 0.002 & 0.938 \\ (0.078) & (0.006) & (0.018) \end{pmatrix} \begin{pmatrix} y_{1,t-1} \\ y_{2,t-1} \\ y_{3,t-1} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \\ \epsilon_{3t} \end{pmatrix}$$

Parameter Estimation and Testing on Restrictions

In the previous example, the VARX(1,0) model is written as

$$y_t = \delta + \Theta_0^* x_t + \Phi_1 y_{t-1} + \epsilon_t$$

with

$$\Theta_0^* = \begin{pmatrix} \theta_{11}^* & \theta_{12}^* \\ \theta_{21}^* & \theta_{22}^* \\ \theta_{31}^* & \theta_{32}^* \end{pmatrix} \quad \Phi_1 = \begin{pmatrix} \phi_{11} & \phi_{12} & \phi_{13} \\ \phi_{21} & \phi_{22} & \phi_{23} \\ \phi_{31} & \phi_{32} & \phi_{33} \end{pmatrix}$$

In [Figure 30.20](#) of the preceding section, you can see several insignificant parameters. For example, the coefficients XL0_1_2, AR1_1_2, and AR1_3_2 are insignificant.

The following statements restrict the coefficients of $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model.

```

/*--- Models with Restrictions and Tests ---*/

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 print=(estimates);
  restrict XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;

```

The output in [Figure 30.21](#) shows that three parameters θ_{12}^* , ϕ_{12} , and ϕ_{32} are replaced by the restricted values, zeros. In the schematic representation of parameter estimates, the three restricted parameters θ_{12}^* , ϕ_{12} , and ϕ_{32} are replaced by *.

Figure 30.21 Parameter Estimation with Restrictions

The VARMAX Procedure				
XLag				
Lag	Variable	x1	x2	
0	y1	1.67592	0.00000	
	y2	-6.30880	2.65308	
	y3	-0.03576	-0.00919	
AR				
Lag	Variable	y1	y2	y3
1	y1	0.27671	0.00000	0.01747
	y2	-2.16968	0.10945	-0.93053
	y3	0.96398	0.00000	0.93412
Schematic Representation				
Variable/ Lag	C	XL0	AR1	
y1	.	**	.*.	
y2	+	..+	..-	
y3	-	..	+++	
+ is > 2*std error, - is < -2*std error, . is between, * is N/A				

The output in [Figure 30.22](#) shows the estimates of the Lagrangian parameters and their significance. Based on the p -values associated with the Lagrangian parameters, you cannot reject the null hypotheses $\theta_{12}^* = 0$, $\phi_{12} = 0$, and $\phi_{32} = 0$ with the 0.05 significance level.

Figure 30.22 RESTRICT Statement Results

Testing of the Restricted Parameters				
Parameter	Estimate	Standard Error	t Value	Pr > t
XL0_1_2	1.74969	21.44026	0.08	0.9389
AR1_1_2	30.36254	70.74347	0.43	0.6899
AR1_3_2	55.42191	164.03075	0.34	0.7524

The TEST statement in the following example tests $\phi_{31} = 0$ and $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model:

```

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1;
  test AR(1,3,1)=0;
  test XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;

```

The output in [Figure 30.23](#) shows that the first column in the output is the index corresponding to each TEST statement. You can reject the hypothesis test $\phi_{31} = 0$ at the 0.05 significance level, but you cannot reject the joint hypothesis test $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ at the 0.05 significance level.

Figure 30.23 TEST Statement Results

The VARMAX Procedure			
Testing of the Parameters			
Test	DF	Chi-Square	Pr > ChiSq
1	1	150.31	<.0001
2	3	0.34	0.9522

Causality Testing

The following statements use the CAUSAL statement to compute the Granger causality test for a VAR(1) model. For the Granger causality tests, the autoregressive order should be defined by the P= option in the MODEL statement. The variable groups are defined in the MODEL statement as well. Regardless of whether the variables specified in the GROUP1= and GROUP2= options are designated as dependent or exogenous (independent) variables in the MODEL statement, the CAUSAL statement fits the VAR(p) model by considering the variables in the two groups as dependent variables.

```

/*--- Causality Testing ---*/

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 noprint;
  causal group1=(x1) group2=(y1-y3);
  causal group1=(y3) group2=(y1 y2);
run;

```

The output in [Figure 30.24](#) is associated with the CAUSAL statement. The first CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_2 , y_3 , and x_1 . The second CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_3 , and y_2 .

Figure 30.24 CAUSAL Statement Results

The VARMAX Procedure			
Granger-Causality Wald Test			
Test	DF	Chi-Square	Pr > ChiSq
1	3	2.40	0.4946
2	2	262.88	<.0001
Test 1: Group 1 Variables: x1			
Group 2 Variables: y1 y2 y3			
Test 2: Group 1 Variables: y3			
Group 2 Variables: y1 y2			

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2.

The first column in the output is the index corresponding to each CAUSAL statement. The output shows that you cannot reject that *x1* is influenced by itself and not by (*y1*, *y2*, *y3*) at the 0.05 significance level for Test 1. You can reject that *y3* is influenced by itself and not by (*y1*, *y2*) for Test 2. See the section “[VAR and VARX Modeling](#)” on page 1941 for details.

Functional Summary

The statements and options used with the VARMAX procedure are summarized in the following table:

Table 30.1 VARMAX Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	VARMAX	DATA=
write parameter estimates to an output data set	VARMAX	OUTEST=
include covariances in the OUTEST= data set	VARMAX	OUTCOV
write the diagnostic checking tests for a model and the cointegration test results to an output data set	VARMAX	OUTSTAT=
write actuals, predictions, residuals, and confidence limits to an output data set	OUTPUT	OUT=
write the conditional covariance matrix to an output data set	GARCH	OUTHT=
BY Groups		
specify BY-group processing	BY	
ID Variable		
specify identifying variable	ID	
specify the time interval between observations	ID	INTERVAL=
control the alignment of SAS Date values	ID	ALIGN=
Options to Control the Optimization Process		
specify the optimization options	NLOPTIONS	
Printing Control Options		
specify how many lags to print results	MODEL	LAGMAX=
suppress the printed output	MODEL	NOPRINT
request all printing options	MODEL	PRINTALL
request the printing format	MODEL	PRINTFORM=
controls plots produced through ODS GRAPHICS	VARMAX	PLOTS=
PRINT= Option		
print the correlation matrix of parameter estimates	MODEL	CORRB
print the cross-correlation matrices of independent variables	MODEL	CORRX
print the cross-correlation matrices of dependent variables	MODEL	CORRY
print the covariance matrices of prediction errors	MODEL	COVPE
print the cross-covariance matrices of the independent variables	MODEL	COVX

Table 30.1 *continued*

Description	Statement	Option
print the cross-covariance matrices of the dependent variables	MODEL	COVY
print the covariance matrix of parameter estimates	MODEL	COVB
print the decomposition of the prediction error covariance matrix	MODEL	DECOMPOSE
print the residual diagnostics	MODEL	DIAGNOSE
print the contemporaneous relationships among the components of the vector time series	MODEL	DYNAMIC
print the parameter estimates	MODEL	ESTIMATES
print the infinite order AR representation	MODEL	IARR
print the impulse response function	MODEL	IMPULSE=
print the impulse response function in the transfer function	MODEL	IMPULSX=
print the partial autoregressive coefficient matrices	MODEL	PARCOEF
print the partial canonical correlation matrices	MODEL	PCANCORR
print the partial correlation matrices	MODEL	PCORR
print the eigenvalues of the companion matrix	MODEL	ROOTS
print the Yule-Walker estimates	MODEL	YW
Model Estimation and Order Selection Options		
center the dependent variables	MODEL	CENTER
specify the degrees of differencing for the specified model variables	MODEL	DIF=
specify the degrees of differencing for all independent variables	MODEL	DIFX=
specify the degrees of differencing for all dependent variables	MODEL	DIFY=
specify the vector error correction model	MODEL	ECM=
specify the estimation method	MODEL	METHOD=
select the tentative order	MODEL	MINIC=
suppress the current values of independent variables	MODEL	NOCURRENTX
suppress the intercept parameters	MODEL	NOINT
specify the number of seasonal periods	MODEL	NSEASON=
specify the order of autoregressive polynomial	MODEL	P=
specify the Bayesian prior model	MODEL	PRIOR=
specify the order of moving-average polynomial	MODEL	Q=
center the seasonal dummies	MODEL	SCENTER
specify the degree of time trend polynomial	MODEL	TREND=
specify the denominator for error covariance matrix estimates	MODEL	VARDEF=
specify the lag order of independent variables	MODEL	XLAG=

Table 30.1 *continued*

Description	Statement	Option
GARCH Related Options		
specify the GARCH-type model	GARCH	FORM=
specify the order of the GARCH polynomial	GARCH	P=
specify the order of the ARCH polynomial	GARCH	Q=
Cointegration Related Options		
print the results from the weak exogeneity test of the long-run parameters	COINTEG	EXOGENEITY
specify the restriction on the cointegrated coefficient matrix	COINTEG	H=
specify the restriction on the adjustment coefficient matrix	COINTEG	J=
specify the variable name whose cointegrating vectors are normalized	COINTEG	NORMALIZE=
specify a cointegration rank	COINTEG	RANK=
print the Johansen cointegration rank test	MODEL	COINTTEST= (JOHANSEN=)
print the Stock-Watson common trends test	MODEL	COINTTEST=(SW=)
print the Dickey-Fuller unit root test	MODEL	DFTEST=
Tests and Restrictions on Parameters		
test the Granger causality	CAUSAL	GROUP1= GROUP2=
place and test restrictions on parameter estimates	RESTRICT	
test hypotheses on parameter estimates	TEST	
Forecasting Control Options		
specify the size of confidence limits for forecasting	OUTPUT	ALPHA=
start forecasting before end of the input data	OUTPUT	BACK=
specify how many periods to forecast	OUTPUT	LEAD=
suppress the printed forecasts	OUTPUT	NOPRINT

PROC VARMAX Statement

PROC VARMAX *options* ;

The following options can be used in the PROC VARMAX statement:

DATA=SAS-data-set

specifies the input SAS data set. If the DATA= option is not specified, the PROC VARMAX statement uses the most recently created SAS data set.

OUTEST=SAS-data-set

writes the parameter estimates to the output data set.

COVOUT**OUTCOV**

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

OUTSTAT=SAS-data-set

writes residual diagnostic results to an output data set. If the COINTTEST=(JOHANSEN) option is specified, the results of this option are also written to the output data set.

The following statements are the examples of these options in the PROC VARMAX statement:

```
proc varmax data=one outest=est outcov outstat=stat;
  model y1-y3 / p=1;
run;

proc varmax data=one outest=est outstat=stat;
  model y1-y3 / p=1 cointtest=(johansen);
run;
```

PLOTS<(global-plot-option)> = plot-request-option <(options)>

PLOTS<(global-plot-option)> = (plot-request-option <(options)> ... plot-request-option <(options)>)

controls the plots produced through ODS Graphics. When you specify only one plot, you can omit the parentheses around the plot request. Some examples follow:

```
plots=none
plots=all
plots(unpack)=residual(residual normal)
plots=(forecasts model)
```

You must enable ODS Graphics before requesting plots as shown in the following example. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*).

```
ods graphics on;

proc varmax data=one plots=impulse(simple);
  model y1-y3 / p=1;
run;

proc varmax data=one plots=(model residual);
  model y1-y3 / p=1;
run;
```

```
proc varmax data=one plots=forecasts;
  model y1-y3 / p=1;
  output lead=12;
run;
```

The first VARMAX program produces the simple response impulse plots. The second VARMAX program produces the plots associated with the model and prediction errors. The plots associated with prediction errors are the ACF, PACF, IACF, distribution, white-noise, and Normal quantile plots and the prediction error plot. The third VARMAX program produces the FORECASTS and FORECASTSONLY plots.

The *global-plot-option* applies to the impulse and prediction error analysis plots generated by the VARMAX procedure. The following *global-plot-option* is available:

UNPACK breaks a graphic that is otherwise paneled into individual component plots.

The following *plot-request-options* are available:

- ALL produces all plots appropriate for the particular analysis.
- FORECASTS <(forecasts-plot-options)> produces plots of the forecasts. The forecasts-only plot that shows the multistep forecasts in the forecast region is produced by default. The following *forecasts-plot-options* are available:
- ALL produces the FORECASTSONLY and the FORECASTS plots. This is the default.
 - FORECASTS produces a plot that shows the one-step-ahead as well as the multistep forecasts.
 - FORECASTSONLY produces a plot that shows only the multistep forecasts.
- IMPULSE <(impulse-plot-options)> produces the plots of impulse response function and the impulse response of the transfer function.
- ALL produces all impulse plots. This is the default.
 - ACCUM produces the accumulated impulse plot.
 - ORTH produces the orthogonalized impulse plot.
 - SIMPLE produces the simple impulse plot.
- MODEL produces plots of dependent variables listed in the MODEL statement and plots of the one-step-ahead predicted values for each dependent variables.
- NONE suppresses all plots.
- RESIDUAL <(residual-plot-options)> produces plots associated with the prediction errors obtained after modeling the data. The following *residual-plot-options* are available:
- ALL produces all plots associated with the analysis of the prediction errors. This is the default.
 - RESIDUAL produces prediction error plot.

- DIAGNOSTICS** produces a panel of plots useful in assessing the autocorrelations and white-noise of the prediction errors. The panel consists of the following:
- the autocorrelation plot of the prediction errors
 - the partial autocorrelation plot of the prediction errors
 - the inverse autocorrelation plot of the prediction errors
 - the log scaled white noise plot of the prediction errors
- NORMAL** produces a panel of plots useful in assessing normality of the prediction errors. The panel consists of the following:
- distribution of the prediction errors with overlaid the normal curve
 - normal quantile plot of the prediction errors

Other Options

In addition, any of the following MODEL statement options can be specified in the PROC VARMAX statement, which is equivalent to specifying the option for every MODEL statement: CENTER, DFTEST=, DIF=, DIFX=, DIFY=, LAGMAX=, METHOD=, MINIC=, NOCURRENTX, NOINT, NOPRINT, NSEASON=, P=, PRINT=, PRINTALL, PRINTFORM=, Q=, SCENTER, TREND=, VARDEF=, and XLAG= options.

The following is an example of the options in the PROC VARMAX statement:

```
proc varmax data=one lagmax=3 method=ml;
  model y1-y3 / p=1;
run;
```

BY Statement

BY *variables* ;

A BY statement can be used with PROC VARMAX to obtain separate analyses on observations in groups defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.

- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARMAX procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information about the BY statement, see in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

The following is an example of the BY statement:

```
proc varmax data=one;
  by region;
  model y1-y3 / p=1;
run;
```

CAUSAL Statement

CAUSAL *GROUP1*=(variables) *GROUP2*=(variables) ;

A CAUSAL statement prints the Granger causality test by fitting the VAR(p) model by using all variables defined in GROUP1 and GROUP2. Any number of CAUSAL statements can be specified. The CAUSAL statement proceeds with the MODEL statement and uses the variables and the autoregressive order, p , specified in the MODEL statement. Variables in the GROUP1= and GROUP2= options should be defined in the MODEL statement. If the P=0 option is specified in the MODEL statement, the CAUSAL statement is not applicable.

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2. If the hypothesis test fails to reject the null, then the variables listed in GROUP1 might be considered as independent variables.

See the section “[VAR and VARX Modeling](#)” on page 1941 for details.

The following is an example of the CAUSAL statement. You specify the CAUSAL statement with the GROUP1= and GROUP2= options.

```
proc varmax data=one;
  model y1-y3 = x1 / p=1;
  causal group1=(x1) group2=(y1-y3);
  causal group1=(y2) group2=(y1 y3);
run;
```

The first CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_2 , y_3 , and x_1 and tests the null hypothesis that x_1 causes the other variables, y_1 , y_2 , and y_3 , but the other variables do not cause x_1 . The second CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_3 , and y_2 and tests the null hypothesis that y_2 causes the other variables, y_1 and y_3 , but the other variables do not cause y_2 .

COINTEG Statement

```
COINTEG RANK=number < H=(matrix) > < J=(matrix) >
          < EXOGENEITY > < NORMALIZE=variable > ;
```

The COINTEG statement fits the vector error correction model to the data, tests the restrictions of the long-run parameters and the adjustment parameters, and tests for the weak exogeneity in the long-run parameters. The cointegrated system uses the maximum likelihood analysis proposed by Johansen and Juselius (1990) and Johansen (1995a, 1995b). Only one COINTEG statement is allowed.

You specify the ECM= option in the MODEL statement or the COINTEG statement to fit the VECM(p). The P= option in the MODEL statement is used to specify the autoregressive order of the VECM.

The following statements are equivalent for fitting a VECM(2).

```
proc varmax data=one;
  model y1-y3 / p=2 ecm=(rank=1);
run;
```

```
proc varmax data=one;
  model y1-y3 / p=2;
  cointeg rank=1;
run;
```

To test restrictions of either α or β or both, you specify either J= or H= or both, respectively. You specify the EXOGENEITY option in the COINTEG statement for tests of the weak exogeneity in the long-run parameters.

The following is an example of the COINTEG statement.

```
proc varmax data=one;
  model y1-y3 / p=2;
  cointeg rank=1 h=(1 0, -1 0, 0 1)
              j=(1 0, 0 0, 0 1) exogeneity;
run;
```

The following options can be used in the COINTEG statement:

EXOGENEITY

formulates the likelihood ratio tests for testing weak exogeneity in the long-run parameters. The null hypothesis is that one variable is weakly exogenous for the others.

H=(matrix)

specifies the restrictions H on the $k \times r$ or $(k + 1) \times r$ cointegrated coefficient matrix β such that $\beta = H\phi$, where H is known and ϕ is unknown. If the VECM(p) is specified with the COINTEG statement or with the ECM= option in the MODEL statement and the ECTREND

option is not included with the ECM= specification, then the H matrix has dimension $k \times m$. If the VECM(p) is specified with the COINTEG statement or with the ECM= option in the MODEL statement and the ECTREND option is also used, then the H matrix has dimension $(k + 1) \times m$. Here k is the number of dependent variables, and m is $r \leq m < k$ where r is defined with the RANK= r option.

For example, consider a system that contains four variables and the RANK=1 option with $\beta = (\beta_1, \beta_2, \beta_3, \beta_4)'$. The restriction matrix for the test of $\beta_1 + \beta_2 = 0$ can be specified as

```
cointeg rank=1 h=(1 0 0, -1 0 0, 0 1 0, 0 0 1);
```

Here the matrix H is 4×3 where $k = 4$ and $m = 3$, and each row of the matrix H is separated by commas.

When the series has no separate deterministic trend, the constant term should be restricted by $\alpha'_\perp \delta = 0$. In the preceding example, the β can be either $\beta = (\beta_1, \beta_2, \beta_3, \beta_4, 1)'$ or $\beta = (\beta_1, \beta_2, \beta_3, \beta_4, t)'$. You can specify the restriction matrix for the previous test of $\beta_1 + \beta_2 = 0$ as follows:

```
cointeg rank=1
h=(1 0 0 0, -1 0 0 0, 0 1 0 0, 0 0 1 0, 0 0 0 1);
```

When the cointegrated system contains three dependent variables and the RANK=2 option, you can specify the restriction matrix for the test of $\beta_{1j} = -\beta_{2j}$ for $j = 1, 2$ as follows:

```
cointeg rank=2 h=(1 0, -1 0, 0 1);
```

J=(matrix)

specifies the restrictions J on the $k \times r$ adjustment matrix α such that $\alpha = J\psi$, where J is known and ψ is unknown. The $k \times m$ matrix J is specified by using this option, where k is the number of dependent variables, m is $r \leq m < k$, and r is defined with the RANK= r option.

For example, when the system contains four variables and the RANK=1 option is used, you can specify the restriction matrix for the test of $\alpha_j = 0$ for $j = 2, 3, 4$ as follows:

```
cointeg rank=1 j=(1, 0, 0, 0);
```

When the system contains three variables and the RANK=2 option, you can specify the restriction matrix for the test of $\alpha_{2j} = 0$ for $j = 1, 2$ as follows:

```
cointeg rank=2 j=(1 0, 0 0, 0 1);
```

NORMALIZE=variable

specifies a single dependent (endogenous) variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTEST=(JOHANSEN=) or ECM= option in the MODEL statement, the variable name specified in the COINTEG statement is used. If the normalized variable is not specified, cointegrating vectors are not normalized.

RANK=number

specifies the cointegration rank of the cointegrated system. This option is required in the COINTEG statement. The rank of cointegration should be greater than zero and less than the number of dependent (endogenous) variables. If the value of the RANK= option in the COINTEG statement is different from that specified in the ECM= option, the rank specified in the COINTEG statement is used.

ID Statement

ID *variable* INTERVAL=value < ALIGN=value > ;

The ID statement specifies a variable that identifies observations in the input data set. The datetime variable specified in the ID statement is included in the OUT= data set if the OUTPUT statement is specified. Note that the ID *variable* is usually a SAS datetime variable. The values of the ID variable are extrapolated for the forecast observations based on the value of the INTERVAL= option.

ALIGN=value

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL=value

specifies the time interval between observations. This option is required in the ID statement. The INTERVAL= option is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data when the OUTPUT statement is specified.

The following is an example of the ID statement:

```
proc varmax data=one;
  id date interval=qtr align=mid;
  model y1-y3 / p=1;
run;
```

MODEL Statement

MODEL *dependents* < = *regressors* >
 < , *dependents* < = *regressors* > ... >
 < / *options* > ;

The MODEL statement specifies dependent (endogenous) variables and independent (exogenous) variables for the VARMAX model. The multivariate model can have the same or different independent variables corresponding to the dependent variables. As a special case, the VARMAX procedure allows you to analyze one dependent variable. Only one MODEL statement is allowed.

For example, the following statements are equivalent ways of specifying the multivariate model for the vector (y_1, y_2, y_3) :

```
model y1 y2 y3 </options>;
model y1-y3 </options>;
```

The following statements are equivalent ways of specifying the multivariate model with independent variables, where $y_1, y_2, y_3,$ and y_4 are the dependent variables and $x_1, x_2, x_3, x_4,$ and x_5 are the independent variables:

```
model y1 y2 y3 y4 = x1 x2 x3 x4 x5 </options>;
model y1 y2 y3 y4 = x1-x5 </options>;
model y1 = x1-x5, y2 = x1-x5, y3 y4 = x1-x5 </options>;
model y1-y4 = x1-x5 </options>;
```

When the multivariate model has different independent variables that correspond to each of the dependent variables, equations are separated by commas (,) and the model can be specified as illustrated by the following MODEL statement:

```
model y1 = x1-x3, y2 = x3-x5, y3 y4 = x1-x5 </options>;
```

The following options can be used in the MODEL statement after a forward slash (/):

CENTER

centers the dependent (endogenous) variables by subtracting their means. Note that centering is done after differencing when the DIF= or DIFY= option is specified. If there are exogenous (independent) variables, this option is not applicable.

```
model y1 y2 / p=1 center;
```

DIF(variable (number-list) <... variable (number-list)>)

DIF=(variable (number-list) <... variable (number-list)>)

specifies the degrees of differencing to be applied to the specified dependent or independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. The differencing can be the same for all variables, or it can vary among variables. For example, the DIF=($y_1(1,4)$ $y_3(1)$ $x_2(2)$) option specifies that the series y_1 is differenced at lag 1 and at lag 4, which is

$$(1 - B^4)(1 - B)y_{1t} = (y_{1t} - y_{1,t-1}) - (y_{1,t-4} - y_{1,t-5})$$

the series y_3 is differenced at lag 1, which is $(y_{3t} - y_{3,t-1})$; and the series x_2 is differenced at lag 2, which is $(x_{2t} - x_{2,t-2})$.

The following uses the data $dy_1, y_2, x_1,$ and dx_2 , where $dy_1 = (1 - B)y_{1t}$ and $dx_2 = (1 - B)^2x_{2t}$.

```
model y1 y2 = x1 x2 / p=1 dif=(y1(1) x2(2));
```

DIFX(number-list)**DIFX=(number-list)**

specifies the degrees of differencing to be applied to all independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For example, the DIFX=(1) option specifies that all of the independent series are differenced once at lag 1. The DIFX=(1,4) option specifies that all of the independent series are differenced at lag 1 and at lag 4. If independent variables are specified in the DIF= option, then the DIFX= option is ignored.

The following statement uses the data y_1 , y_2 , dx_1 , and dx_2 , where $dx_1 = (1 - B)x_{1t}$ and $dx_2 = (1 - B)x_{2t}$.

```
model y1 y2 = x1 x2 / p=1 difx(1);
```

DIFY(number-list)**DIFY=(number-list)**

specifies the degrees of differencing to be applied to all dependent (endogenous) variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For details, see the DIFX= option. If dependent variables are specified in the DIF= option, then the DIFY= option is ignored.

```
model y1 y2 / p=1 dify(1);
```

METHOD=value

requests the type of estimates to be computed. The possible values of the METHOD= option are as follows:

- | | |
|----|---|
| LS | specifies least squares estimates. |
| ML | specifies maximum likelihood estimates. |

When the ECM=, PRIOR=, and Q= options and the GARCH statement are specified, the default ML method is used regardless of the method given by the METHOD= option.

```
model y1 y2 / p=1 method=ml;
```

NOCURRENTX

suppresses the current values x_t of the independent variables. In general, the VARX(p, s) model is

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where p is the number of lags of the dependent variables included in the model, and s is the number of lags of the independent variables included in the model, including the contemporaneous values of x_t .

A VARX(1,2) model can be specified as:

```
model y1 y2 = x1 x2 / p=1 xlag=2;
```

If the NOCURRENTX option is specified, it suppresses the current values \mathbf{x}_t and starts with \mathbf{x}_{t-1} . The VARX(p, s) model is redefined as:

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \sum_{i=1}^s \Theta_i^* x_{t-i} + \epsilon_t$$

This model with $p = 1$ and $s = 2$ can be specified as:

```
model y1 y2 = x1 x2 / p=1 xlag=2 nocurrentx;
```

NOINT

suppresses the intercept parameter δ .

```
model y1 y2 / p=1 noint;
```

NSEASON=*number*

specifies the number of seasonal periods. When the NSEASON=*number* option is specified, (*number* - 1) seasonal dummies are added to the regressors. If the NOINT option is specified, the NSEASON= option is not applicable.

```
model y1 y2 / p=1 nseason=4;
```

SCENTER

centers seasonal dummies specified by the NSEASON= option. The centered seasonal dummies are generated by $c - (1/s)$, where c is a seasonal dummy generated by the NSEASON= s option.

```
model y1 y2 / p=1 nseason=4 scenter;
```

TREND=*value*

specifies the degree of deterministic time trend included in the model. Valid values are as follows:

LINEAR includes a linear time trend as a regressor.

QUAD includes linear and quadratic time trends as regressors.

The TREND=QUAD option is not applicable for a cointegration analysis.

```
model y1 y2 / p=1 trend=linear;
```

VARDEF=*value*

corrects for the degrees of freedom of the denominator for computing an error covariance matrix for the METHOD=LS option. If the METHOD=ML option is specified, the VARDEF=N option is always used. Valid values are as follows:

DF specifies that the number of nonmissing observation minus the number of regressors be used.

N specifies that the number of nonmissing observation be used.

```
model y1 y2 / p=1 vardef=n;
```

Printing Control Options

LAGMAX=*number*

specifies the maximum number of lags for which results are computed and displayed by the PRINT=(CORRX CORRY COVX COVY IARR IMPULSE= IMPULSX= PARCOEF PCANCORR PCORR) options. This option is also used to limit the printed results for the cross covariances and cross-correlations of residuals. The default is LAGMAX=min(12, $T-2$), where T is the number of nonmissing observations.

```
model y1 y2 / p=1 lagmax=6;
```

NOPRINT

suppresses all printed output.

```
model y1 y2 / p=1 noprint;
```

PRINTALL

requests all printing control options. The options set by the option PRINTALL are DFTEST=, MINIC=, PRINTFORM=BOTH, and PRINT=(CORRB CORRX CORRY COVB COVPE COVX COVY DECOMPOSE DYNAMIC IARR IMPULSE=(ALL) IMPULSX=(ALL) PARCOEF PCANCORR PCORR ROOTS YW).

You can also specify this option as the option ALL.

```
model y1 y2 / p=1 printall;
```

PRINTFORM=*value*

requests the printing format of the output generated by the PRINT= option and cross covariances and cross-correlations of residuals. Valid values are as follows:

BOTH	prints output in both MATRIX and UNIVARIATE forms.
MATRIX	prints output in matrix form. This is the default.
UNIVARIATE	prints output by variables.

```
model y1 y2 / p=1 print=(impulse) printform=univariate;
```

Printing Options

PRINT=(*options*)

The following options can be used in the PRINT=() option. The options are listed within parentheses. If a number in parentheses follows an option listed below, then the option prints the number of lags specified by *number* in parentheses. The default is the number of lags specified by the LAGMAX=*number* option.

CORRB

prints the estimated correlations of the parameter estimates.

CORRX**CORRX(*number*)**

prints the cross-correlation matrices of exogenous (independent) variables. The *number* should be greater than zero.

CORRY**CORRY(*number*)**

prints the cross-correlation matrices of dependent (endogenous) variables. The *number* should be greater than zero.

COVB

prints the estimated covariances of the parameter estimates.

COVPE**COVPE(*number*)**

prints the covariance matrices of *number*-ahead prediction errors for the VARMAX(*p,q,s*) model. The *number* should be greater than zero. If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the section “[Forecasting](#)” on page 1930 for details.

COVX**COVX(*number*)**

prints the cross-covariance matrices of exogenous (independent) variables. The *number* should be greater than zero.

COVY**COVY(*number*)**

prints the cross-covariance matrices of dependent (endogenous) variables. The *number* should be greater than zero.

DECOMPOSE**DECOMPOSE(*number*)**

prints the decomposition of the prediction error covariances using up to the number of lags specified by *number* in parentheses for the VARMA(*p,q*) model. The *number* should be greater than zero. It can be interpreted as the contribution of innovations in one variable to the mean squared error of the multistep forecast of another variable. The DECOMPOSE option also prints proportions of the forecast error variance.

If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the section “[Forecasting](#)” on page 1930 for details.

DIAGNOSE

prints the residual diagnostics and model diagnostics.

DYNAMIC

prints the contemporaneous relationships among the components of the vector time series.

ESTIMATES

prints the coefficient estimates and a schematic representation of the significance and sign of the parameter estimates.

IARR**IARR(*number*)**

prints the infinite order AR representation of a VARMA process. The *number* should be greater than zero. If the ECM= option and the COINTEG statement are specified, then the reparameterized AR coefficient matrices are printed.

IMPULSE**IMPULSE(*number*)****IMPULSE=(SIMPLE ACCUM ORTH STDERR ALL)****IMPULSE(*number*)=(SIMPLE ACCUM ORTH STDERR ALL)**

prints the impulse response function. The *number* should be greater than zero. It investigates the response of one variable to an impulse in another variable in a system that involves a number of other variables as well. It is an infinite order MA representation of a VARMA process. See the section “[Impulse Response Function](#)” on page 1919 for details.

The following options can be used in the IMPULSE=() option. The options are specified within parentheses.

ACCUM	prints the accumulated impulse response function.
ALL	is equivalent to specifying all of SIMPLE, ACCUM, ORTH, and STDERR.
ORTH	prints the orthogonalized impulse response function.
SIMPLE	prints the impulse response function. This is the default.
STDERR	prints the standard errors of the impulse response function, the accumulated impulse response function, or the orthogonalized impulse response function.

If the exogenous variables are used to fit the model, then the STDERR option is ignored.

IMPULSX**IMPULSX(*number*)****IMPULSX=(SIMPLE ACCUM ALL)****IMPULSX(*number*)=(SIMPLE ACCUM ALL)**

prints the impulse response function related to exogenous (independent) variables. The *number* should be greater than zero. See the section “[Impulse Response Function](#)” on page 1919 for details.

The following options can be used in the IMPULSX=() option. The options are specified within parentheses.

ACCUM	prints the accumulated impulse response matrices for the transfer function.
ALL	is equivalent to specifying both SIMPLE and ACCUM.

SIMPLE prints the impulse response matrices for the transfer function. This is the default.

PARCOEF

PARCOEF(*number*)

prints the partial autoregression coefficient matrices, Φ_{mm} up to the lag *number*. The *number* should be greater than zero. With a VAR process, this option is useful for the identification of the order since the Φ_{mm} have the property that they equal zero for $m > p$ under the hypothetical assumption of a VAR(*p*) model. See the section “[Tentative Order Selection](#)” on page 1935 for details.

PCANCORR

PCANCORR(*number*)

prints the partial canonical correlations of the process at lag *m* and the test for testing $\Phi_m=0$ for $m > p$ up to the lag *number*. The *number* should be greater than zero. The lag *m* partial canonical correlations are the canonical correlations between \mathbf{y}_t and \mathbf{y}_{t-m} , after adjustment for the dependence of these variables on the intervening values $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$. See the section “[Tentative Order Selection](#)” on page 1935 for details.

PCORR

PCORR(*number*)

prints the partial correlation matrices. The *number* should be greater than zero. With a VAR process, this option is useful for a tentative order selection by the same property as the partial autoregression coefficient matrices, as described in the PRINT=(PARCOEF) option. See the section “[Tentative Order Selection](#)” on page 1935 for details.

ROOTS

prints the eigenvalues of the $kp \times kp$ companion matrix associated with the AR characteristic function $\Phi(B)$, where *k* is the number of dependent (endogenous) variables, and $\Phi(B)$ is the finite order matrix polynomial in the backshift operator *B*, such that $B^i \mathbf{y}_t = \mathbf{y}_{t-i}$. These eigenvalues indicate the stationary condition of the process since the stationary condition on the roots of $|\Phi(B)| = 0$ in the VAR(*p*) model is equivalent to the condition in the corresponding VAR(1) representation that all eigenvalues of the companion matrix be less than one in absolute value. Similarly, you can use this option to check the invertibility of the MA process. In addition, when the GARCH statement is specified, this option prints the roots of the GARCH characteristic polynomials to check covariance stationarity for the GARCH process.

YW

prints Yule-Walker estimates of the preliminary autoregressive model for the dependent (endogenous) variables. The coefficient matrices are printed using the maximum order of the autoregressive process.

Some examples of the PRINT= option are as follows:

```
model y1 y2 / p=1 print=(covy(10) corry(10));
model y1 y2 / p=1 print=(parcoef pcancorr pcorr);
model y1 y2 / p=1 print=(impulse(8) decompose(6) covpe(6));
model y1 y2 / p=1 print=(dynamic roots yw);
```

Lag Specification Options

P=number

P=(number-list)

specifies the order of the vector autoregressive process. Subset models of vector autoregressive orders can be specified by listing the desired set of lags. For example, you can specify the P=(1,3,4) option. The P=3 option is equivalent to the P=(1,2,3) option. The default is P=0.

If P=0 and there are no exogenous (independent) variables, then the AR polynomial order is automatically determined by minimizing an information criterion. If P=0 and the PRIOR= or ECM= option or both are specified, then the AR polynomial order is determined automatically.

If the ECM= option is specified, then subset models of vector autoregressive orders are not allowed and the AR maximum order specified is used.

Examples illustrating the P= option follow:

```
model y1 y2 / p=3;
model y1 y2 / p=(1,3);
model y1 y2 / p=(1,3) prior;
```

Q=number

Q=(number-list)

specifies the order of the moving-average error process. Subset models of moving-average orders can be specified by listing the desired set of lags. For example, you can specify the Q=(1,5) option. The default is Q=0.

```
model y1 y2 / p=1 q=1;
model y1 y2 / q=(2);
```

XLAG=number

XLAG=(number-list)

specifies the lags of exogenous (independent) variables. Subset models of distributed lags can be specified by listing the desired set of lags. For example, XLAG=(2) selects only a lag 2 of the exogenous variables. The default is XLAG=0. To exclude the present values of exogenous variables from the model, the NOCURRENTX option must be used.

```
model y1 y2 = x1-x3 / xlag=2 nocurrentx;
model y1 y2 = x1-x3 / p=1 xlag=(2);
```

Tentative Order Selection Options

MINIC

MINIC=(TYPE=value P=number Q=number PERROR=number)

prints the information criterion for the appropriate AR and MA tentative order selection and for the diagnostic checks of the fitted model.

If the MINIC= option is not specified, all types of information criteria are printed for diagnostic checks of the fitted model.

The following options can be used in the MINIC=() option. The options are specified within parentheses.

P=number

P=($p_{min}:p_{max}$)

specifies the range of AR orders to be considered in the tentative order selection. The default is P=(0:5). The P=3 option is equivalent to the P=(0:3) option.

PERROR=number

PERROR=($p_{\epsilon,min}:p_{\epsilon,max}$)

specifies the range of AR orders for obtaining the error series. The default is PERROR=($p_{max} : p_{max} + q_{max}$).

Q=number

Q=($q_{min}:q_{max}$)

specifies the range of MA orders to be considered in the tentative order selection. The default is Q=(0:5).

TYPE=value

specifies the criterion for the model order selection. Valid criteria are as follows:

AIC	specifies the Akaike information criterion.
AICC	specifies the corrected Akaike information criterion. This is the default criterion.
FPE	specifies the final prediction error criterion.
HQC	specifies the Hanna-Quinn criterion.
SBC	specifies the Schwarz Bayesian criterion. You can also specify this value as TYPE=BIC.

```
model y1 y2 / minic;
model y1 y2 / minic=(type=aic p=5);
```

Cointegration Related Options

Two options are related to integrated time series; one is the DFTEST option to test for a unit root and the other is the COINTTEST option to test for cointegration.

DFTEST

DFTEST=(DLAG=number)

DFTEST=(DLAG=(number) ... (number))

prints the Dickey-Fuller unit root tests. The DLAG=(number) ... (number) option specifies the regular or seasonal unit root test. Supported values of number are in 1, 2, 4, 12. If the number is greater than one, a seasonal Dickey-Fuller test is performed. If the TREND= option is specified, the seasonal unit root test is not available. The default is DLAG=1.

For example, the DFTEST=(DLAG=(1)(12)) option produces two tables: the Dickey-Fuller regular unit root test and the seasonal unit root test.

Some examples of the DFTEST= option follow:

```

model y1 y2 / p=2 dfctest;
model y1 y2 / p=2 dfctest=(dlag=4);
model y1 y2 / p=2 dfctest=(dlag=(1) (12));
model y1 y2 / p=2 dfctest cointttest;

```

COINTTEST

COINTTEST=(JOHANSEN < (=options) > SW < (=options) > SIGLEVEL=number)

The following options can be used with the COINTTEST=() option. The options are specified within parentheses.

JOHANSEN

JOHANSEN=(TYPE=value IORDER=number NORMALIZE=variable)

prints the cointegration rank test for multivariate time series based on Johansen's method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 11. See the section “[Vector Error Correction Modeling](#)” on page 1962 for details.

The VARX(p,s) model can be written as the error correction model

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where Π , Φ_i^* , A , and Θ_i^* are coefficient parameters; D_t is a deterministic term such as a constant, a linear trend, or seasonal dummies.

The $I(1)$ model is defined by one reduced-rank condition. If the cointegration rank is $r < k$, then there exist $k \times r$ matrices $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ of rank r such that $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$.

The $I(1)$ model is rewritten as the $I(2)$ model

$$\Delta^2 \mathbf{y}_t = \Pi \mathbf{y}_{t-1} - \Psi \Delta \mathbf{y}_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 \mathbf{y}_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\Psi = I_k - \sum_{i=1}^{p-1} \Phi_i^*$ and $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j^*$.

The $I(2)$ model is defined by two reduced-rank conditions. One is that $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$, where $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are $k \times r$ matrices of full-rank r . The other is that $\boldsymbol{\alpha}'_{\perp} \Psi \boldsymbol{\beta}_{\perp} = \boldsymbol{\xi}\boldsymbol{\eta}'$ where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ are $(k-r) \times s$ matrices with $s \leq k-r$; $\boldsymbol{\alpha}_{\perp}$ and $\boldsymbol{\beta}_{\perp}$ are $k \times (k-r)$ matrices of full-rank $k-r$ such that $\boldsymbol{\alpha}'_{\perp} \boldsymbol{\alpha}_{\perp} = 0$ and $\boldsymbol{\beta}'_{\perp} \boldsymbol{\beta}_{\perp} = 0$.

The following options can be used in the JOHANSEN=() option. The options are specified within parentheses.

IORDER=number specifies the integrated order.

- IORDER=1** prints the cointegration rank test for an integrated order 1 and prints the long-run parameter, β , and the adjustment coefficient, α . This is the default. If the IORDER=1 option is specified, then the AR order should be greater than or equal to 1. When the P=0 option, the value of P is set to 1 for the Johansen test.
- IORDER=2** prints the cointegration rank test for integrated orders 1 and 2. If the IORDER=2 option is specified, then the AR order should be greater than or equal to 2. If the P=1 option with the IORDER=2 option, then the value of IORDER is set to 1; if the P=0 option with the IORDER=2 option, then the value of P is set to 2.

NORMALIZE=variable specifies the dependent (endogenous) variable name whose cointegration vectors are to be normalized. If the normalized variable is different from that specified in the ECM= option or the COINTEG statement, then the value specified in the COINTEG statement is used.

TYPE=value specifies the type of cointegration rank test to be printed. Valid values are as follows:

MAX prints the cointegration maximum eigenvalue test.

TRACE prints the cointegration trace test. This is the default.

If the NOINT option is not specified, the procedure prints two different cointegration rank tests in the presence of the unrestricted and restricted deterministic terms (constant or linear trend) models. If the IORDER=2 option is specified, the procedure automatically determines that the TYPE=TRACE option.

Some examples illustrating the COINTTEST= option follow:

```
model y1 y2 / p=2 cointtest=(johansen=(type=max normalize=y1));
model y1 y2 / p=2 cointtest=(johansen=(iorder=2 normalize=y1));
```

SIGLEVEL=value

sets the size of cointegration rank tests and common trends tests.

The SIGLEVEL=value can be set to 0.1, 0.05, or 0.01. The default is SIGLEVEL=0.05.

```
model y1 y2 / p=2 cointtest=(johansen siglevel=0.1);
model y1 y2 / p=2 cointtest=(sw siglevel=0.1);
```

SW

SW=(TYPE=value LAG=number)

prints common trends tests for a multivariate time series based on the Stock-Watson method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 6. See the section “[Common Trends](#)” on page 1960 for details.

The following options can be used in the SW=() option. The options are listed within parentheses.

LAG=number	specifies the number of lags. The default is $\text{LAG}=\max(1,p)$ for the TYPE=FILTDIF or TYPE=FILTRES option, where p is the AR maximum order specified by the P= option; $\text{LAG}=T^{1/4}$ for the TYPE=KERNEL option, where T is the number of nonmissing observations. If the specified LAG=number exceeds the default, then it is replaced by the default.
TYPE=value	specifies the type of common trends test to be printed. Valid values are as follows:
FILTDIF	prints the common trends test based on the filtering method applied to the differenced series. This is the default.
FILTRES	prints the common trends test based on the filtering method applied to the residual series.
KERNEL	prints the common trends test based on the kernel method.

```

model y1 y2 / p=2 cointtest=(sw);
model y1 y2 / p=2 cointtest=(sw=(type=kernel));
model y1 y2 / p=2 cointtest=(sw=(type=kernel lag=3));

```

Bayesian VARX Estimation Options

PRIOR

PRIOR=(prior-options)

specifies the prior value of parameters for the $\text{BVARX}(p, s)$ model. The BVARX model allows for a subset model specification. If the **ECM=** option is specified with the **PRIOR** option, the $\text{BVECMX}(p, s)$ form is fitted. To compute the standard errors of the forecasts, a bootstrap procedure is used. See the section “[Bayesian VAR and VARX Modeling](#)” on page 1947 for details.

The following options can be used with the **PRIOR=(prior-options)** option. The *prior-options* are listed within parentheses.

IVAR

IVAR=(variables)

specifies an integrated $\text{BVAR}(p)$ model. The *variables* should be specified in the **MODEL** statement as dependent variables. If you use the **IVAR** option without *variables*, then it sets the overall prior mean of the first lag of each variable equal to one in its own equation and sets all other coefficients to zero. If *variables* are specified, it sets the prior mean of the first lag of the specified variables equal to one in its own equation and sets all other coefficients to zero. When the series $\mathbf{y}_t = (y_1, y_2)'$ follows a bivariate $\text{BVAR}(2)$ process, the **IVAR** or **IVAR=(y1 y2)** option is equivalent to specifying **MEAN=(1 0 0 0 0 1 0 0)**.

If the **PRIOR=(MEAN=)** or **ECM=** option is specified, the **IVAR=** option is ignored.

LAMBDA=value

specifies the prior standard deviation of the AR coefficient parameter matrices. It should be a positive number. The default is **LAMBDA=1**. As the value of the **LAMBDA=** option is increased, the $\text{BVAR}(p)$ model becomes closer to a $\text{VAR}(p)$ model.

MEAN=(vector)

specifies the mean vector in the prior distribution for the AR coefficients. If the vector is not specified, the prior value is assumed to be a zero vector. See the section “[Bayesian VAR and VARX Modeling](#)” on page 1947 for details.

You can specify the mean vector by order of the equation. Let $(\delta, \Phi_1, \dots, \Phi_p)$ be the parameter sets to be estimated and $\Phi = (\Phi_1, \dots, \Phi_p)$ be the AR parameter sets. The mean vector is specified by row-wise from Φ ; that is, the MEAN=(vec(Φ')) option.

For the PRIOR=(mean) option in the BVAR(2),

$$\Phi = \begin{pmatrix} \phi_{1,11} & \phi_{1,12} & \phi_{2,11} & \phi_{2,12} \\ \phi_{1,21} & \phi_{1,22} & \phi_{2,21} & \phi_{2,22} \end{pmatrix} = \begin{pmatrix} 2 & 0.1 & 1 & 0 \\ 0.5 & 3 & 0 & -1 \end{pmatrix}$$

where $\phi_{l,i,j}$ is an element of Φ , l is a lag, i is associated with the first dependent variable, and j is associated with the second dependent variable.

```
model y1 y2 / p=2 prior=(mean=(2 0.1 1 0 0.5 3 0 -1));
```

The deterministic terms and exogenous variables are considered to shrink toward zero; you must omit prior means of exogenous variables and deterministic terms such as a constant, seasonal dummies, or trends.

For a Bayesian error correction model estimated when both the ECM= and PRIOR= options are used, a mean vector for only lagged AR coefficients, Φ_i^* , in terms of regressors $\Delta \mathbf{y}_{t-i}$, for $i = 1, \dots, (p - 1)$ is used in the VECM(p) representation. The diffused prior variance of α is used, since β is replaced by $\hat{\beta}$ estimated in a nonconstrained VECM(p) form.

$$\Delta \mathbf{y}_t = \alpha \mathbf{z}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

where $\mathbf{z}_t = \beta' \mathbf{y}_t$.

For example, in the case of a bivariate ($k = 2$) BVECM(2) form, the option

$$\text{MEAN} = (\phi_{1,11}^* \phi_{1,12}^* \phi_{1,21}^* \phi_{1,22}^*)$$

where $\phi_{1,i,j}^*$ is the (i, j) th element of the matrix Φ_1^* .

NREP=number

specifies the number of periods to compute the measure of forecast accuracy. The default is NREP=0.5T, where T is the number of observations.

THETA=value

specifies the prior standard deviation of the AR coefficient parameter matrices. The value is in the interval (0,1). The default is THETA=0.1. As the value of the THETA= option approaches 1, the specified BVAR(p) model approaches a VAR(p) model.

Some examples of the PRIOR= option follow:

```

model y1 y2 / p=2 prior;
model y1 y2 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2
    prior=(theta=0.2 lambda=5 mean=(2 0.1 1 0 0.5 3 0 -1));

```

See the section “[Bayesian VAR and VARX Modeling](#)” on page 1947 for details.

Vector Error Correction Model Options

ECM=(RANK=*number* NORMALIZE=*emphvariable* ECTREND)

specifies a vector error correction model.

The following options can be used in the ECM=() option. The options are specified within parentheses.

NORMALIZE=*variable*

specifies a single dependent variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTEG statement, then the value specified in the COINTEG statement is used.

RANK=*number*

specifies the cointegration rank. This option is required in the ECM= option. The value of the RANK= option should be greater than zero and less than or equal to the number of dependent (endogenous) variables, k . If the rank is different from that specified in the COINTEG statement, then the value specified in the COINTEG statement is used.

ECTREND

specifies the restriction on the drift in the VECM(p) form.

- There is no separate drift in the VECM(p) form, but a constant enters only through the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_0)(\mathbf{y}'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

An example of the ECTREND option follows:

```
model y1 y2 / p=2 ecm=(rank=1 ectrend);
```

- There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only through the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_1)(\mathbf{y}'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

An example of the ECTREND option with the TREND= option follows:

```
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

If the NSEASON option is specified, then the NSEASON option is ignored; if the NOINT option is specified, then the ECTREND option is ignored.

Some examples of the ECM= option follow:

```
model y1 y2 / p=2 ecm=(rank=1 normalized=y1);
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

See the section “[Vector Error Correction Modeling](#)” on page 1962 for details.

GARCH Statement

GARCH options ;

The GARCH statement specifies a GARCH-type multivariate conditional heteroscedasticity model.

The following options can be used in the GARCH statement.

FORM=value

specifies the representation for a GARCH model. Valid values are as follows:

BEKK specifies a *BEKK* representation. This is the default.

CCC specifies a constant conditional correlation representation.

OUTHT=SAS-data-set

writes the conditional covariance matrix to an output data set.

P=number

P=(number-list)

specifies the order of the process or the subset of GARCH terms to be fitted. For example, you can specify the P=(1,3) option. The P=3 option is equivalent to the P=(1,2,3) option. The default is P=0.

Q=number

Q=(number-list)

specifies the order of the process or the subset of ARCH terms to be fitted. This option is required in the GARCH statement. For example, you can specify the Q=(2) option. The Q=2 option is equivalent to the Q=(1,2) option.

For the VAR(1)–ARCH(1) model,

```
model y1 y2 / p=1;
garch q=1 form=bekk;
```

For the multivariate GARCH(1,1) model,

```
model y1 y2;
garch q=1 p=1 form=ccc;
```

Other multivariate GARCH-type models are

```
model y1 y2 = x1 / xlag=1;
garch q=1;

model y1 y2 / q=1;
garch q=1 p=1;
```

See the section “[Multivariate GARCH Modeling](#)” on page 1981 for details.

NLOPTIONS Statement

NLOPTIONS *options* ;

The VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 6, “[Nonlinear Optimization Methods](#).”

An example of the NLOPTIONS statement follows:

```
proc varmax data=one;
  nloptions tech=qn;
  model y1 y2 / p=2;
run;
```

The VARMAX procedure uses the dual quasi-Newton optimization method by default when no NLOPTIONS statement is specified. However, it uses Newton-Raphson ridge optimization when the NLOPTIONS statement is specified.

The following example uses the TECH=QUANEW by default.

```
proc varmax data=one;
  model y1 y2 / p=2 method=ml;
run;
```

The next example uses the TECH=NRRIDG by default.

```
proc varmax data=one;
  nloptions maxiter=500 maxfunc=5000;
  model y1 y2 / p=2 method=ml;
run;
```

OUTPUT Statement

OUTPUT < *options* > ;

The OUTPUT statement generates and prints forecasts based on the model estimated in the previous MODEL statement and, optionally, creates an output SAS data set that contains these forecasts.

When the GARCH model is estimated, the upper and lower confidence limits of forecasts are calculated by assuming that the error covariance has homoscedastic conditional covariance.

ALPHA=*number*

sets the forecast confidence limit size, where *number* is between 0 and 1. When you specify the ALPHA=*number* option, the upper and lower confidence limits define the $100(1 - \alpha)\%$ confidence interval. The default is ALPHA=0.05, which produces 95% confidence intervals.

BACK=*number*

specifies the number of observations before the end of the data at which the multistep forecasts begin. The BACK= option value must be less than or equal to the number of observations minus the number of lagged regressors in the model. The default is BACK=0, which means that the forecasts start at the end of the available data.

LEAD=*number*

specifies the number of multistep forecast values to compute. The default is LEAD=12.

NOPRINT

suppresses the printed forecast values of each dependent (endogenous) variable.

OUT=*SAS-data-set*

writes the forecast values to an output data set.

Some examples of the OUTPUT statements follow:

```
proc varmax data=one;
  model y1 y2 / p=2;
  output lead=6 back=2;
run;

proc varmax data=one;
  model y1 y2 / p=2;
  output out=for noprint;
run;
```

RESTRICT Statement

RESTRICT *restriction, . . . , restriction* ;

The RESTRICT statement restricts the specified parameters to the specified values. Only one RESTRICT statement is allowed, but multiple restrictions can be specified in one RESTRICT statement.

The *restriction*'s form is *parameter=value* and each restriction is separated by commas. Parameters are referred by the following keywords:

- CONST(*i*) is the intercept parameter of the *i*th time series y_{it}

- $AR(l, i, j)$ is the autoregressive parameter of the lag l value of the j th dependent (endogenous) variable, $y_{j,t-l}$, to the i th dependent variable at time t , y_{it}
- $MA(l, i, j)$ is the moving-average parameter of the lag l value of the j th error process, $\epsilon_{j,t-l}$, to the i th dependent variable at time t , y_{it}
- $XL(l, i, j)$ is the exogenous parameter of the lag l value of the j th exogenous (independent) variable, $x_{j,t-l}$, to the i th dependent variable at time t , y_{it}
- $SDUMMY(i, j)$ is the j th seasonal dummy of the i th time series at time t , y_{it} , where $j = 1, \dots, (nseason - 1)$, where $nseason$ is based on the `NSEASON=` option in the `MODEL` statement
- $LTREND(i)$ is the linear trend parameter of the current value i th time series y_{it}
- $QTREND(i)$ is the quadratic trend parameter of the current value i th time series y_{it}

The following keywords are for the fitted GARCH model. The indexes i and j refer to the position of the element in the coefficient matrix.

- $GCHC(i, j)$ is the constant parameter of the covariance matrix, H_t , and (i, j) is $1 \leq i = j \leq k$ for *CCC* representation and $1 \leq i \leq j \leq k$ for *BEKK* representations, where k is the number of dependent variables
- $ACH(l, i, j)$ is the ARCH parameter of the lag l value of $\epsilon_t \epsilon_t'$, where $i, j = 1, \dots, k$ for *BEKK* representation and $i = j = 1, \dots, k$ for *CCC* representation
- $GCH(l, i, j)$ is the GARCH parameter of the lag l value of covariance matrix, H_t , where $i, j = 1, \dots, k$ for *BEKK* representation and $i = j = 1, \dots, k$ for *CCC* representation
- $CCC(i, j)$ is the constant conditional correlation parameter for only the *CCC* representation; (i, j) is $1 \leq i < j \leq k$

To use the `RESTRICT` statement, you need to know the form of the model. If the `P=`, `Q=`, and `XLAG=` options are not specified, then the `RESTRICT` statement is not applicable.

Restricted parameter estimates are computed by introducing a Lagrangian parameter for each restriction (Pringle and Rayner 1971). The Lagrangian parameter measures the sensitivity of the sum of square errors to the restriction. The estimates of these Lagrangian parameters and their significance are printed in the restriction results table.

The following are examples of the `RESTRICT` statement. The first example shows a bivariate ($k=2$) VAR(2) model,

```
proc varmax data=one;
  model y1 y2 / p=2;
  restrict AR(1,1,2)=0, AR(2,1,2)=0.3;
run;
```

The AR(1,1,2) and AR(2,1,2) parameters are fixed as AR(1,1,2)=0 and AR(2,1,2)=0.3, respectively, and other parameters are to be estimated.

The following shows a bivariate ($k=2$) VARX(1,1) model with three exogenous variables,

```
proc varmax data=two;
  model y1 = x1 x2, y2 = x2 x3 / p=1 xlag=1;
  restrict XL(0,1,1)=-1.2, XL(1,2,3)=0;
run;
```

The XL(0,1,1) and XL(1,2,3) parameters are fixed as XL(0,1,1)=-1.2 and XL(1,2,3)=0, respectively, and other parameters are to be estimated.

TEST Statement

TEST *restriction, ..., restriction* ;

The TEST statement performs the Wald test for the joint hypothesis specified in the statement. The *restriction*'s form is *parameter=value*, and each restriction is separated by commas. The *restrictions* are specified in the same manner as in the RESTRICT statement. See the RESTRICT statement for description of model parameter naming conventions used by the RESTRICT and TEST statements. Any number of TEST statements can be specified.

To use the TEST statement, you need to know the form of the model. If the P=, Q=, and XLAG= options are not specified, then the TEST statement is not applicable.

See the section “[Granger Causality Test](#)” on page 1944 for the Wald test.

The following is an example of the TEST statement. In the case of a bivariate ($k=2$) VAR(2) model,

```
proc varmax data=one;
  model y1 y2 / p=2;
  test AR(1,1,2)=0, AR(2,1,2)=0;
run;
```

After estimating the parameters, the TEST statement tests the null hypothesis that AR(1,1,2)=0 and AR(2,1,2)=0.

Details: VARMAX Procedure

Missing Values

The VARMAX procedure currently does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the MODEL statement variables. Observations at the beginning of the data set with missing values for any MODEL statement variables are not used or included in the output data set. At the end of the data set, observations can have dependent (endogenous) variables with missing values and independent (exogenous) variables with nonmissing values.

VARMAX Model

The vector autoregressive moving-average model with exogenous variables is called the VARMAX(p, q, s) model. The form of the model can be written as

$$\mathbf{y}_t = \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

where the output variables of interest, $\mathbf{y}_t = (y_{1t}, \dots, y_{kt})'$, can be influenced by other input variables, $\mathbf{x}_t = (x_{1t}, \dots, x_{rt})'$, which are determined outside of the system of interest. The variables \mathbf{y}_t are referred to as dependent, response, or endogenous variables, and the variables \mathbf{x}_t are referred to as independent, input, predictor, regressor, or exogenous variables. The unobserved noise variables, $\boldsymbol{\epsilon}_t = (\epsilon_{1t}, \dots, \epsilon_{kt})'$, are a vector white noise process.

The VARMAX(p, q, s) model can be written

$$\Phi(B)\mathbf{y}_t = \Theta^*(B)\mathbf{x}_t + \Theta(B)\boldsymbol{\epsilon}_t$$

where

$$\begin{aligned} \Phi(B) &= I_k - \Phi_1 B - \dots - \Phi_p B^p \\ \Theta^*(B) &= \Theta_0^* + \Theta_1^* B + \dots + \Theta_s^* B^s \\ \Theta(B) &= I_k - \Theta_1 B - \dots - \Theta_q B^q \end{aligned}$$

are matrix polynomials in B in the backshift operator, such that $B^i \mathbf{y}_t = \mathbf{y}_{t-i}$, the Φ_i and Θ_i are $k \times k$ matrices, and the Θ_i^* are $k \times r$ matrices.

The following assumptions are made:

- $E(\boldsymbol{\epsilon}_t) = 0$, $E(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t') = \Sigma$, which is positive-definite, and $E(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_s') = 0$ for $t \neq s$.

- For stationarity and invertibility of the VARMAX process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.
- The exogenous (independent) variables \mathbf{x}_t are not correlated with residuals ϵ_t , $E(\mathbf{x}_t \epsilon_t') = 0$. The exogenous variables can be stochastic or nonstochastic. When the exogenous variables are stochastic and their future values are unknown, forecasts of these future values are needed to forecast the future values of the endogenous (dependent) variables. On occasion, future values of the exogenous variables can be assumed to be known because they are deterministic variables. The VARMAX procedure assumes that the exogenous variables are nonstochastic if future values are available in the input data set. Otherwise, the exogenous variables are assumed to be stochastic and their future values are forecasted by assuming that they follow the VARMA(p, q) model, prior to forecasting the endogenous variables, where p and q are the same as in the VARMAX(p, q, s) model.

State-Space Representation

Another representation of the VARMAX(p, q, s) model is in the form of a state-variable or a state-space model, which consists of a state equation

$$\mathbf{z}_t = F\mathbf{z}_{t-1} + K\mathbf{x}_t + G\epsilon_t$$

and an observation equation

$$\mathbf{y}_t = H\mathbf{z}_t$$

where

$$\mathbf{z}_t = \begin{bmatrix} \mathbf{y}_t \\ \vdots \\ \mathbf{y}_{t-p+1} \\ \mathbf{x}_t \\ \vdots \\ \mathbf{x}_{t-s+1} \\ \epsilon_t \\ \vdots \\ \epsilon_{t-q+1} \end{bmatrix}, \quad K = \begin{bmatrix} \Theta_0^* \\ 0_{k \times r} \\ \vdots \\ 0_{k \times r} \\ I_r \\ 0_{r \times r} \\ \vdots \\ 0_{r \times r} \\ 0_{k \times r} \\ \vdots \\ 0_{k \times r} \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ 0_{k \times k} \\ \vdots \\ 0_{k \times k} \\ 0_{r \times k} \\ \vdots \\ 0_{r \times k} \\ I_{k \times k} \\ 0_{k \times k} \\ \vdots \\ 0_{k \times k} \end{bmatrix}$$

$$F = \begin{bmatrix} \Phi_1 & \cdots & \Phi_{p-1} & \Phi_p & \Theta_1^* & \cdots & \Theta_{s-1}^* & \Theta_s^* & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & I_r & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & I_r & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \dots, 0_{k \times k}, 0_{k \times r}, \dots, 0_{k \times r}, 0_{k \times k}, \dots, 0_{k \times k}]$$

On the other hand, it is assumed that \mathbf{x}_t follows a VARMA(p, q) model

$$\mathbf{x}_t = \sum_{i=1}^p A_i \mathbf{x}_{t-i} + \mathbf{a}_t - \sum_{i=1}^q C_i \mathbf{a}_{t-i}$$

The model can also be expressed as

$$A(B)\mathbf{x}_t = C(B)\mathbf{a}_t$$

where $A(B) = I_r - A_1 B - \dots - A_p B^p$ and $C(B) = I_r - C_1 B - \dots - C_q B^q$ are matrix polynomials in B , and the A_i and C_i are $r \times r$ matrices. Without loss of generality, the AR and MA orders can be taken to be the same as the VARMAX(p, q, s) model, and \mathbf{a}_t and $\boldsymbol{\epsilon}_t$ are independent white noise processes.

Under suitable conditions such as stationarity, \mathbf{x}_t is represented by an infinite order moving-average process

$$\mathbf{x}_t = A(B)^{-1} C(B) \mathbf{a}_t = \Psi^x(B) \mathbf{a}_t = \sum_{j=0}^{\infty} \Psi_j^x \mathbf{a}_{t-j}$$

where $\Psi^x(B) = A(B)^{-1} C(B) = \sum_{j=0}^{\infty} \Psi_j^x B^j$.

The optimal minimum mean squared error (minimum MSE) i -step-ahead forecast of \mathbf{x}_{t+i} is

$$\begin{aligned} \mathbf{x}_{t+i|t} &= \sum_{j=i}^{\infty} \Psi_j^x \mathbf{a}_{t+i-j} \\ \mathbf{x}_{t+i|t+1} &= \mathbf{x}_{t+i|t} + \Psi_{i-1}^x \mathbf{a}_{t+1} \end{aligned}$$

For $i > q$,

$$\mathbf{x}_{t+i|t} = \sum_{j=1}^p A_j \mathbf{x}_{t+i-j|t}$$

The VARMAX(p, q, s) model has an absolutely convergent representation as

$$\begin{aligned} \mathbf{y}_t &= \Phi(B)^{-1} \Theta^*(B) \mathbf{x}_t + \Phi(B)^{-1} \Theta(B) \boldsymbol{\epsilon}_t \\ &= \Psi^*(B) \Psi^x(B) \mathbf{a}_t + \Phi(B)^{-1} \Theta(B) \boldsymbol{\epsilon}_t \\ &= V(B) \mathbf{a}_t + \Psi(B) \boldsymbol{\epsilon}_t \end{aligned}$$

or

$$\mathbf{y}_t = \sum_{j=0}^{\infty} V_j \mathbf{a}_{t-j} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$, $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B)$, and $V(B) = \Psi^*(B)\Psi^x(B) = \sum_{j=0}^{\infty} V_j B^j$.

The optimal (minimum MSE) i -step-ahead forecast of \mathbf{y}_{t+i} is

$$\begin{aligned} \mathbf{y}_{t+i|t} &= \sum_{j=i}^{\infty} V_j \mathbf{a}_{t+i-j} + \sum_{j=i}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+i-j} \\ \mathbf{y}_{t+i|t+1} &= \mathbf{y}_{t+i|t} + V_{i-1} \mathbf{a}_{t+1} + \Psi_{i-1} \boldsymbol{\epsilon}_{t+1} \end{aligned}$$

for $i = 1, \dots, v$ with $v = \max(p, q + 1)$. For $i > q$,

$$\begin{aligned} \mathbf{y}_{t+i|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \mathbf{x}_{t+i|t} + \sum_{j=1}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \sum_{j=1}^p A_j \mathbf{x}_{t+i-j|t} + \sum_{j=1}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=1}^u (\Theta_0^* A_j + \Theta_j^*) \mathbf{x}_{t+i-j|t} \end{aligned}$$

where $u = \max(p, s)$.

Define $\Pi_j = \Theta_0^* A_j + \Theta_j^*$. For $i = v > q$ with $v = \max(p, q + 1)$, you obtain

$$\begin{aligned} \mathbf{y}_{t+v|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^u \Pi_j \mathbf{x}_{t+v-j|t} \text{ for } u \leq v \\ \mathbf{y}_{t+v|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^r \Pi_j \mathbf{x}_{t+v-j|t} \text{ for } u > v \end{aligned}$$

From the preceding relations, a state equation is

$$\mathbf{z}_{t+1} = F \mathbf{z}_t + K \mathbf{x}_t^* + G \boldsymbol{\epsilon}_{t+1}$$

and an observation equation is

$$\mathbf{y}_t = H \mathbf{z}_t$$

where

$$\mathbf{z}_t = \begin{bmatrix} \mathbf{y}_t \\ \mathbf{y}_{t+1|t} \\ \vdots \\ \mathbf{y}_{t+v-1|t} \\ \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+v-1|t} \end{bmatrix}, \quad \mathbf{x}_t^* = \begin{bmatrix} \mathbf{x}_{t+v-u} \\ \mathbf{x}_{t+v-u+1} \\ \vdots \\ \mathbf{x}_{t-1} \end{bmatrix}, \quad \mathbf{e}_{t+1} = \begin{bmatrix} \mathbf{a}_{t+1} \\ \boldsymbol{\epsilon}_{t+1} \end{bmatrix}$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 & \Pi_v & \Pi_{v-1} & \Pi_{v-2} & \cdots & \Pi_1 \\ 0 & 0 & 0 & \cdots & 0 & 0 & I_r & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & I_r & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & A_v & A_{v-1} & A_{v-2} & \cdots & A_1 \end{bmatrix}$$

$$K = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \Pi_u & \Pi_{u-1} & \cdots & \Pi_{v+1} \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}, \quad G = \begin{bmatrix} V_0 & I_k \\ V_1 & \Psi_1 \\ \vdots & \vdots \\ V_{v-1} & \Psi_{v-1} \\ I_r & 0_{r \times k} \\ \Psi_1^x & 0_{r \times k} \\ \vdots & \vdots \\ \Psi_{v-1}^x & 0_{r \times k} \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \dots, 0_{k \times k}, 0_{k \times r}, \dots, 0_{k \times r}]$$

Note that the matrix K and the input vector \mathbf{x}_t^* are defined only when $u > v$.

Dynamic Simultaneous Equations Modeling

In the econometrics literature, the VARMAX(p, q, s) model is sometimes written in a form that is slightly different than the one shown in the previous section. This alternative form is referred to as a *dynamic simultaneous equations* model or a *dynamic structural equations* model.

Since $E(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t') = \Sigma$ is assumed to be positive-definite, there exists a lower triangular matrix A_0 with ones on the diagonals such that $A_0 \Sigma A_0' = \Sigma^d$, where Σ^d is a diagonal matrix with positive diagonal elements.

$$A_0 \mathbf{y}_t = \sum_{i=1}^p A_i \mathbf{y}_{t-i} + \sum_{i=0}^s C_i^* \mathbf{x}_{t-i} + C_0 \boldsymbol{\epsilon}_t - \sum_{i=1}^q C_i \boldsymbol{\epsilon}_{t-i}$$

where $A_i = A_0\Phi_i$, $C_i^* = A_0\Theta_i^*$, $C_0 = A_0$, and $C_i = A_0\Theta_i$.

As an alternative form,

$$A_0\mathbf{y}_t = \sum_{i=1}^p A_i\mathbf{y}_{t-i} + \sum_{i=0}^s C_i^*\mathbf{x}_{t-i} + \mathbf{a}_t - \sum_{i=1}^q C_i\mathbf{a}_{t-i}$$

where $A_i = A_0\Phi_i$, $C_i^* = A_0\Theta_i^*$, $C_i = A_0\Theta_i A_0^{-1}$, and $\mathbf{a}_t = C_0\boldsymbol{\epsilon}_t$ has a diagonal covariance matrix Σ^d . The PRINT=(DYNAMIC) option returns the parameter estimates that result from estimating the model in this form.

A dynamic simultaneous equations model involves a leading (lower triangular) coefficient matrix for \mathbf{y}_t at lag 0 or a leading coefficient matrix for $\boldsymbol{\epsilon}_t$ at lag 0. Such a representation of the VARMAX(p,q,s) model can be more useful in certain circumstances than the standard representation. From the linear combination of the dependent variables obtained by $A_0\mathbf{y}_t$, you can easily see the relationship between the dependent variables in the current time.

The following statements provide the dynamic simultaneous equations of the VAR(1) model.

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  /* simulate the vector time series */
  call varmasim(y,phi) sigma = sig n = 100 seed = 34657;
  cn = {'y1' 'y2'};
  create simull from y[colname=cn];
  append from y;
quit;

data simull;
  set simull;
  date = intnx('year', '01jan1900'd, _n_-1 );
  format date year4.;
run;

proc varmax data=simull;
  model y1 y2 / p=1 noint print=(dynamic);
run;
```

This is the same data set and model used in the section “[Getting Started: VARMAX Procedure](#)” on page 1858. You can compare the results of the VARMA model form and the dynamic simultaneous equations model form.

Figure 30.25 Dynamic Simultaneous Equations (DYNAMIC Option)

y1	AR1_1_1	1.15977	0.05508	21.06	0.0001	y1(t-1)
	AR1_1_2	-0.51058	0.07140	-7.15	0.0001	y2(t-1)
y2	AR0_2_1	0.30845				y1(t)
	AR1_2_1	0.18861	0.05779	3.26	0.0015	y1(t-1)
	AR1_2_2	0.54247	0.07491	7.24	0.0001	y2(t-1)

In Figure 30.4 in the section “Getting Started: VARMAX Procedure” on page 1858, the covariance of ϵ_t estimated from the VARMAX model form is

$$\Sigma_{\epsilon} = \begin{pmatrix} 1.28875 & 0.39751 \\ 0.39751 & 1.41839 \end{pmatrix}$$

Figure 30.25 shows the results from estimating the model as a dynamic simultaneous equations model. By the decomposition of Σ_{ϵ} , you get a diagonal matrix (Σ_a) and a lower triangular matrix (A_0) such as $\Sigma_a = A_0 \Sigma_{\epsilon} A_0'$ where

$$\Sigma_a = \begin{pmatrix} 1.28875 & 0 \\ 0 & 1.29578 \end{pmatrix} \text{ and } A_0 = \begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix}$$

The lower triangular matrix (A_0) is shown in the left side of the simultaneous equations model. The parameter estimates in equations system are shown in the right side of the two-equations system.

The simultaneous equations model is written as

$$\begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix} \mathbf{y}_t = \begin{pmatrix} 1.15977 & -0.51058 \\ 0.18861 & 0.54247 \end{pmatrix} \mathbf{y}_{t-1} + \mathbf{a}_t$$

The resulting two-equation system can be written as

$$\begin{aligned}y_{1t} &= 1.15977y_{1,t-1} - 0.51058y_{2,t-1} + a_{1t} \\y_{2t} &= 0.30845y_{1t} + 0.18861y_{1,t-1} + 0.54247y_{2,t-1} + a_{2t}\end{aligned}$$

Impulse Response Function

Simple Impulse Response Function (IMPULSE=SIMPLE Option)

The VARMAX(p,q,s) model has a convergent representation

$$\mathbf{y}_t = \Psi^*(B)\mathbf{x}_t + \Psi(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B) = \sum_{j=0}^{\infty} \Psi_j^* B^j$ and $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$.

The elements of the matrices Ψ_j from the operator $\Psi(B)$, called the impulse response, can be interpreted as the impact that a shock in one variable has on another variable. Let $\psi_{j,in}$ be the i th element of Ψ_j at lag j , where i is the index for the impulse variable, and n is the index for the response variable (impulse \rightarrow response). For instance, $\psi_{j,11}$ is an impulse response to $y_{1t} \rightarrow y_{1t}$, and $\psi_{j,12}$ is an impulse response to $y_{1t} \rightarrow y_{2t}$.

Accumulated Impulse Response Function (IMPULSE=ACCUM Option)

The accumulated impulse response function is the cumulative sum of the impulse response function, $\Psi_l^a = \sum_{j=0}^l \Psi_j$.

Orthogonalized Impulse Response Function (IMPULSE=ORTH Option)

The MA representation of a VARMA(p,q) model with a standardized white noise innovation process offers another way to interpret a VARMA(p,q) model. Since Σ is positive-definite, there is a lower triangular matrix P such that $\Sigma = PP'$. The alternate MA representation of a VARMA(p,q) model is written as

$$\mathbf{y}_t = \Psi^o(B)\mathbf{u}_t$$

where $\Psi^o(B) = \sum_{j=0}^{\infty} \Psi_j^o B^j$, $\Psi_j^o = \Psi_j P$, and $\mathbf{u}_t = P^{-1}\boldsymbol{\epsilon}_t$.

The elements of the matrices Ψ_j^o , called the *orthogonal impulse response*, can be interpreted as the effects of the components of the standardized shock process \mathbf{u}_t on the process \mathbf{y}_t at lag j .

Impulse Response of Transfer Function (IMPULSX=SIMPLE Option)

The coefficient matrix Ψ_j^* from the transfer function operator $\Psi^*(B)$ can be interpreted as the effects that changes in the exogenous variables \mathbf{x}_t have on the output variable \mathbf{y}_t at lag j ; it is called an impulse response matrix in the transfer function.

Impulse Response of Transfer Function (IMPULSX=ACCUM Option)

The accumulated impulse response in the transfer function is the cumulative sum of the impulse response in the transfer function, $\Psi_l^{*a} = \sum_{j=0}^l \Psi_j^*$.

The asymptotic distributions of the impulse functions can be seen in the section “[VAR and VARX Modeling](#)” on page 1941.

The following statements provide the impulse response and the accumulated impulse response in the transfer function for a VARX(1,0) model.

```
proc varmax data=grunfeld plot=impulse;
  model y1-y3 = x1 x2 / p=1 lagmax=5
          printform=univariate
          print=(impulsx=(all) estimates);
run;
```

In [Figure 30.26](#), the variables x_1 and x_2 are impulses and the variables y_1 , y_2 , and y_3 are responses. You can read the table matching the pairs of *impulse* \rightarrow *response* such as $x_1 \rightarrow y_1$, $x_1 \rightarrow y_2$, $x_1 \rightarrow y_3$, $x_2 \rightarrow y_1$, $x_2 \rightarrow y_2$, and $x_2 \rightarrow y_3$. In the pair of $x_1 \rightarrow y_1$, you can see the long-run responses of y_1 to an impulse in x_1 (the values are 1.69281, 0.35399, 0.09090, and so on for lag 0, lag 1, lag 2, and so on, respectively).

Figure 30.29 shows the accumulated responses of y_1 , y_2 , and y_3 to a forecast error impulse in x_1 .

Figure 30.29 Plot of Accumulated Impulse Response in Transfer Function

The following statements provide the impulse response function, the accumulated impulse response function, and the orthogonalized impulse response function with their standard errors for a VAR(1) model. Parts of the VARMAX procedure output are shown in [Figure 30.30](#), [Figure 30.32](#), and [Figure 30.34](#).

```
proc varmax data=simul1 plot=impulse;
  model y1 y2 / p=1 noint lagmax=5
          print=(impulse=(all))
          printform=univariate;
run;
```

[Figure 30.30](#) is the output in a univariate format associated with the `PRINT=(IMPULSE=)` option for the impulse response function. The keyword `STD` stands for the standard errors of the elements. The matrix in terms of the lag 0 does not print since it is the identity. In [Figure 30.30](#), the variables `y1` and `y2` of the first row are impulses, and the variables `y1` and `y2` of the first column are responses. You can read the table matching the *impulse* → *response* pairs, such as `y1` → `y1`, `y1` → `y2`, `y2` → `y1`, and `y2` → `y2`. For example, in the pair of `y1` → `y1` at lag 3, the response is 0.8055. This represents the impact on `y1` of one-unit change in `y1` after 3 periods. As the lag gets higher, you can see the long-run responses of `y1` to an impulse in itself.

In Figure 30.4, there is a positive correlation between ε_{1t} and ε_{2t} . Therefore, shock in y_1 can be accompanied by a shock in y_2 in the same period. For example, in the pair of $y_1_innovation \rightarrow y_2$, you can see the long-run responses of y_2 to an impulse in $y_1_innovation$.

Figure 30.35 shows the orthogonalized responses of y_1 and y_2 to a forecast error impulse in y_1 with two standard errors.

Figure 30.35 Plot of Orthogonalized Impulse Response

Forecasting

The optimal (minimum MSE) l -step-ahead forecast of \mathbf{y}_{t+l} is

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^p \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+l-j|t} - \sum_{j=l}^q \Theta_j \boldsymbol{\epsilon}_{t+l-j}, \quad l \leq q$$

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^p \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+l-j|t}, \quad l > q$$

with $\mathbf{y}_{t+l-j|t} = \mathbf{y}_{t+l-j}$ and $\mathbf{x}_{t+l-j|t} = \mathbf{x}_{t+l-j}$ for $l \leq j$. For the forecasts $\mathbf{x}_{t+l-j|t}$, see the section “[State-Space Representation](#)” on page 1913.

Covariance Matrices of Prediction Errors without Exogenous (Independent) Variables

Under the stationarity assumption, the optimal (minimum MSE) l -step-ahead forecast of \mathbf{y}_{t+l} has an infinite moving-average form, $\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$. The prediction error of the optimal l -step-ahead forecast is $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$, with zero mean and covariance matrix,

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi_j' = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$$

where $\Psi_j^o = \Psi_j P$ with a lower triangular matrix P such that $\Sigma = PP'$. Under the assumption of normality of the $\boldsymbol{\epsilon}_t$, the l -step-ahead prediction error $\mathbf{e}_{t+l|t}$ is also normally distributed as multivariate $N(0, \Sigma(l))$. Hence, it follows that the diagonal elements $\sigma_{ii}^2(l)$ of $\Sigma(l)$ can be used, together with the point forecasts $y_{i,t+l|t}$, to construct l -step-ahead prediction intervals of the future values of the component series, $y_{i,t+l}$.

The following statements use the COVPE option to compute the covariance matrices of the prediction errors for a VAR(1) model. The parts of the VARMAX procedure output are shown in Figure 30.36 and Figure 30.37.

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=5
          printform=both
          print=(decompose(5) impulse=(all) covpe(5));
run;
```

Figure 30.36 is the output in a matrix format associated with the COVPE option for the prediction error covariance matrices.

Figure 30.36 Covariances of Prediction Errors (COVPE Option)

The VARMAX Procedure

Covariance Matrices of Prediction Errors in the Presence of Exogenous (Independent) Variables

Exogenous variables can be both stochastic and nonstochastic (deterministic) variables. Considering the forecasts in the VARMAX(p, q, s) model, there are two cases.

When exogenous (independent) variables are stochastic (future values not specified):

As defined in the section “[State-Space Representation](#)” on page 1913, $\mathbf{y}_{t+l|t}$ has the representation

$$\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} V_j \mathbf{a}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and hence

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} V_j \mathbf{a}_{t+l-j} + \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Therefore, the covariance matrix of the l -step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} V_j \Sigma_a V_j' + \sum_{j=0}^{l-1} \Psi_j \Sigma_{\epsilon} \Psi_j'$$

where Σ_a is the covariance of the white noise series \mathbf{a}_t , and \mathbf{a}_t is the white noise series for the VARMA(p, q) model of exogenous (independent) variables, which is assumed not to be correlated with $\boldsymbol{\epsilon}_t$ or its lags.

When future exogenous (independent) variables are specified:

The optimal forecast $\mathbf{y}_{t+l|t}$ of \mathbf{y}_t conditioned on the past information and also on known future values $\mathbf{x}_{t+1}, \dots, \mathbf{x}_{t+l}$ can be represented as

$$\mathbf{y}_{t+l|t} = \sum_{j=0}^{\infty} \Psi_j^* \mathbf{x}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and the forecast error is

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Thus, the covariance matrix of the l -step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma_{\epsilon} \Psi_j'$$

Decomposition of Prediction Error Covariances

In the relation $\Sigma(l) = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$, the diagonal elements can be interpreted as providing a decomposition of the l -step-ahead prediction error covariance $\sigma_{ii}^2(l)$ for each component series y_{it} into contributions from the components of the standardized innovations $\boldsymbol{\epsilon}_t$.

If you denote the (i, n) th element of Ψ_j^o by $\psi_{j,in}$, the MSE of $y_{i,t+h|t}$ is

$$\text{MSE}(y_{i,t+h|t}) = \text{E}(y_{i,t+h} - y_{i,t+h|t})^2 = \sum_{j=0}^{l-1} \sum_{n=1}^k \psi_{j,in}^2$$

Note that $\sum_{j=0}^{l-1} \psi_{j,in}^2$ is interpreted as the contribution of innovations in variable n to the prediction error covariance of the l -step-ahead forecast of variable i .

The proportion, $\omega_{l,in}$, of the l -step-ahead forecast error covariance of variable i accounting for the innovations in variable n is

$$\omega_{l,in} = \sum_{j=0}^{l-1} \psi_{j,in}^2 / \text{MSE}(y_{i,t+h|t})$$

The following statements use the DECOMPOSE option to compute the decomposition of prediction error covariances and their proportions for a VAR(1) model:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint print=(decompose(15))
          printform=univariate;
run;
```

The proportions of decomposition of prediction error covariances of two variables are given in Figure 30.38. The output explains that about 91.356% of the one-step-ahead prediction error covariances of the variable y_{2t} is accounted for by its own innovations and about 8.644% is accounted for by y_{1t} innovations.

Figure 30.38 Decomposition of Prediction Error Covariances (DECOMPOSE Option)

Proportions of Prediction Error Covariances by Variable			
Variable	Lead	y1	y2
y1	1	1.00000	0.00000

	5	0.53549	0.46451

Forecasting of the Centered Series

If the CENTER option is specified, the sample mean vector is added to the forecast.

Forecasting of the Differenced Series

If dependent (endogenous) variables are differenced, the final forecasts and their prediction error covariances are produced by integrating those of the differenced series. However, if the PRIOR option is specified, the forecasts and their prediction error variances of the differenced series are produced.

Let \mathbf{z}_t be the original series with some appended zero values that correspond to the unobserved past observations. Let $\Delta(B)$ be the $k \times k$ matrix polynomial in the backshift operator that corresponds to the differencing specified by the MODEL statement. The off-diagonal elements of Δ_i are zero, and the diagonal elements can be different. Then $\mathbf{y}_t = \Delta(B)\mathbf{z}_t$.

This gives the relationship

$$\mathbf{z}_t = \Delta^{-1}(B)\mathbf{y}_t = \sum_{j=0}^{\infty} \Lambda_j \mathbf{y}_{t-j}$$

where $\Delta^{-1}(B) = \sum_{j=0}^{\infty} \Lambda_j B^j$ and $\Lambda_0 = I_k$.

The l -step-ahead prediction of \mathbf{z}_{t+l} is

$$\mathbf{z}_{t+l|t} = \sum_{j=0}^{l-1} \Lambda_j \mathbf{y}_{t+l-j|t} + \sum_{j=l}^{\infty} \Lambda_j \mathbf{y}_{t+l-j}$$

The l -step-ahead prediction error of \mathbf{z}_{t+l} is

$$\sum_{j=0}^{l-1} \Lambda_j (\mathbf{y}_{t+l-j} - \mathbf{y}_{t+l-j|t}) = \sum_{j=0}^{l-1} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right) \boldsymbol{\epsilon}_{t+l-j}$$

Letting $\Sigma_{\mathbf{z}}(0) = 0$, the covariance matrix of the l -step-ahead prediction error of \mathbf{z}_{t+l} , $\Sigma_{\mathbf{z}}(l)$, is

$$\begin{aligned} \Sigma_{\mathbf{z}}(l) &= \sum_{j=0}^{l-1} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right) \Sigma_{\boldsymbol{\epsilon}} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right)' \\ &= \Sigma_{\mathbf{z}}(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right) \Sigma_{\boldsymbol{\epsilon}} \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right)' \end{aligned}$$

If there are stochastic exogenous (independent) variables, the covariance matrix of the l -step-ahead prediction error of \mathbf{z}_{t+l} , $\Sigma_{\mathbf{z}}(l)$, is

$$\begin{aligned} \Sigma_{\mathbf{z}}(l) &= \Sigma_{\mathbf{z}}(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right) \Sigma_{\boldsymbol{\epsilon}} \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right)' \\ &\quad + \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j} \right) \Sigma_a \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j} \right)' \end{aligned}$$

Tentative Order Selection

Sample Cross-Covariance and Cross-Correlation Matrices

Given a stationary multivariate time series \mathbf{y}_t , cross-covariance matrices are

$$\Gamma(l) = E[(\mathbf{y}_t - \boldsymbol{\mu})(\mathbf{y}_{t+l} - \boldsymbol{\mu})']$$

where $\boldsymbol{\mu} = E(\mathbf{y}_t)$, and cross-correlation matrices are

$$\rho(l) = D^{-1} \Gamma(l) D^{-1}$$

where D is a diagonal matrix with the standard deviations of the components of \mathbf{y}_t on the diagonal.

The sample cross-covariance matrix at lag l , denoted as $C(l)$, is computed as

$$\hat{\Gamma}(l) = C(l) = \frac{1}{T} \sum_{t=1}^{T-l} \tilde{\mathbf{y}}_t \tilde{\mathbf{y}}_{t+l}'$$

where \tilde{y}_t is the centered data and T is the number of nonmissing observations. Thus, $\hat{\Gamma}(l)$ has (i, j) th element $\hat{\gamma}_{ij}(l) = c_{ij}(l)$. The sample cross-correlation matrix at lag l is computed as

$$\hat{\rho}_{ij}(l) = c_{ij}(l)/[c_{ii}(0)c_{jj}(0)]^{1/2}, \quad i, j = 1, \dots, k$$

The following statements use the CORRY option to compute the sample cross-correlation matrices and their summary indicator plots in terms of +, −, and ·, where + indicates significant positive cross-correlations, − indicates significant negative cross-correlations, and · indicates insignificant cross-correlations.

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3 print=(corry)
             printform=univariate;
run;
```

Figure 30.39 shows the sample cross-correlation matrices of y_{1t} and y_{2t} . As shown, the sample autocorrelation functions for each variable decay quickly, but are significant with respect to two standard errors.

Figure 30.39 Cross-Correlations (CORRY Option)

Partial Autoregressive Matrices

For each $m = 1, 2, \dots, p$ you can define a sequence of matrices Φ_{mm} , which is called the partial autoregression matrices of lag m , as the solution for Φ_{mm} to the Yule-Walker equations of order m ,

$$\Gamma(l) = \sum_{i=1}^m \Gamma(l-i) \Phi'_{im}, \quad l = 1, 2, \dots, m$$

The sequence of the partial autoregression matrices Φ_{mm} of order m has the characteristic property that if the process follows the AR(p), then $\Phi_{pp} = \Phi_p$ and $\Phi_{mm} = 0$ for $m > p$. Hence, the matrices Φ_{mm} have the cutoff property for a VAR(p) model, and so they can be useful in the identification of the order of a pure VAR model.

The following statements use the PARCOEF option to compute the partial autoregression matrices:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
    printform=univariate
    print=(corry parcoef pcorr
      pcancorr roots);
run;
```

Figure 30.40 shows that the model can be obtained by an AR order $m = 1$ since partial autoregression matrices are insignificant after lag 1 with respect to two standard errors. The matrix for lag 1 is the same as the Yule-Walker autoregressive matrix.

Figure 30.40 Partial Autoregression Matrices (PARCOEF Option)

Partial Correlation Matrices

Define the forward autoregression

$$\mathbf{y}_t = \sum_{i=1}^{m-1} \Phi_{i,m-1} \mathbf{y}_{t-i} + \mathbf{u}_{m,t}$$

and the backward autoregression

$$\mathbf{y}_{t-m} = \sum_{i=1}^{m-1} \Phi_{i,m-1}^* \mathbf{y}_{t-m+i} + \mathbf{u}_{m,t-m}^*$$

The matrices $P(m)$ defined by Ansley and Newbold (1979) are given by

$$P(m) = \Sigma_{m-1}^{*1/2} \Phi_{mm}' \Sigma_{m-1}^{-1/2}$$

where

$$\Sigma_{m-1} = \text{Cov}(\mathbf{u}_{m,t}) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(-i) \Phi_{i,m-1}'$$

and

$$\Sigma_{m-1}^* = \text{Cov}(\mathbf{u}_{m,t-m}^*) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(m-i) \Phi_{m-i,m-1}^{*'}$$

$P(m)$ are the partial cross-correlation matrices at lag m between the elements of \mathbf{y}_t and \mathbf{y}_{t-m} , given $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$. The matrices $P(m)$ have the cutoff property for a VAR(p) model, and so they can be useful in the identification of the order of a pure VAR structure.

The following statements use the PCORR option to compute the partial cross-correlation matrices:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
          print=(pcorr)
          printform=univariate;
run;
```

The partial cross-correlation matrices in [Figure 30.41](#) are insignificant after lag 1 with respect to two standard errors. This indicates that an AR order of $m = 1$ can be an appropriate choice.

Figure 30.41 Partial Correlations (PCORR Option)

Partial Canonical Correlation Matrices

The partial canonical correlations at lag m between the vectors \mathbf{y}_t and \mathbf{y}_{t-m} , given $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$, are $1 \geq \rho_1(m) \geq \rho_2(m) \cdots \geq \rho_k(m)$. The partial canonical correlations are the canonical correlations between the residual series $\mathbf{u}_{m,t}$ and $\mathbf{u}_{m,t-m}^*$, where $\mathbf{u}_{m,t}$ and $\mathbf{u}_{m,t-m}^*$ are defined in the previous section. Thus, the squared partial canonical correlations $\rho_i^2(m)$ are the eigenvalues of the matrix

$$\{\text{Cov}(\mathbf{u}_{m,t})\}^{-1} \text{E}(\mathbf{u}_{m,t} \mathbf{u}_{m,t-m}^{*\prime}) \{\text{Cov}(\mathbf{u}_{m,t-m}^*)\}^{-1} \text{E}(\mathbf{u}_{m,t-m}^* \mathbf{u}_{m,t}^{\prime}) = \Phi_{mm}^{*\prime} \Phi_{mm}^{\prime}$$

It follows that the test statistic to test for $\Phi_m = 0$ in the VAR model of order $m > p$ is approximately

$$(T - m) \text{tr} \{\Phi_{mm}^{*\prime} \Phi_{mm}^{\prime}\} \approx (T - m) \sum_{i=1}^k \rho_i^2(m)$$

and has an asymptotic chi-square distribution with k^2 degrees of freedom for $m > p$.

The following statements use the PCANCORR option to compute the partial canonical correlations:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3 print=(pcancorr);
run;
```

Figure 30.42 shows that the partial canonical correlations $\rho_i(m)$ between \mathbf{y}_t and \mathbf{y}_{t-m} are {0.918, 0.773}, {0.092, 0.018}, and {0.109, 0.011} for lags $m = 1$ to 3. After lag $m = 1$, the partial

canonical correlations are insignificant with respect to the 0.05 significance level, indicating that an AR order of $m = 1$ can be an appropriate choice.

Figure 30.42 Partial Canonical Correlations (PCANCORR Option)

The VARMAX Procedure					
Partial Canonical Correlations					
Lag	Correlation1	Correlation2	DF	Chi-Square	Pr > ChiSq

The Minimum Information Criterion (MINIC) Method

The minimum information criterion (MINIC) method can tentatively identify the orders of a VARMA(p, q) process. Note that Spliid (1983), Koreisha and Pukkila (1989), and Quinn (1980) proposed this method. The first step of this method is to obtain estimates of the innovations series, ϵ_t , from the VAR(p_ϵ), where p_ϵ is chosen sufficiently large. The choice of the autoregressive order, p_ϵ , is determined by use of a selection criterion. From the selected VAR(p_ϵ) model, you obtain estimates of residual series

$$\tilde{\epsilon}_t = y_t - \sum_{i=1}^{p_\epsilon} \hat{\Phi}_i^{p_\epsilon} y_{t-i} - \hat{\delta}^{p_\epsilon}, \quad t = p_\epsilon + 1, \dots, T$$

In the second step, you select the order (p, q) of the VARMA model for p in ($p_{min} : p_{max}$) and q in ($q_{min} : q_{max}$)

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} - \sum_{i=1}^q \Theta_i \tilde{\epsilon}_{t-i} + \epsilon_t$$

which minimizes a selection criterion like SBC or HQ.

The following statements use the MINIC= option to compute a table that contains the information criterion associated with various AR and MA orders:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint minic=(p=3 q=3);
run;
```

Figure 30.43 shows the output associated with the MINIC= option. The criterion takes the smallest value at AR order 1.

Figure 30.43 MINIC= Option

The VARMAX Procedure				
Minimum Information Criterion Based on AICC

AR 3	0.7235629	0.8131261	0.8395558	0.9094856

VAR and VARX Modeling

The p th-order VAR process is written as

$$\mathbf{y}_t - \boldsymbol{\mu} = \sum_{i=1}^p \Phi_i (\mathbf{y}_{t-i} - \boldsymbol{\mu}) + \boldsymbol{\epsilon}_t \text{ or } \Phi(B)(\mathbf{y}_t - \boldsymbol{\mu}) = \boldsymbol{\epsilon}_t$$

with $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$.

Equivalently, it can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t \text{ or } \Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

with $\boldsymbol{\delta} = (I_k - \sum_{i=1}^p \Phi_i)\boldsymbol{\mu}$.

Stationarity

For stationarity, the VAR process must be expressible in the convergent causal infinite MA form as

$$\mathbf{y}_t = \boldsymbol{\mu} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1} = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\sum_{j=0}^{\infty} \|\Psi_j\| < \infty$, where $\|A\|$ denotes a norm for the matrix A such as $\|A\|^2 = \text{tr}\{A'A\}$. The matrix Ψ_j can be recursively obtained from the relation $\Phi(B)\Psi(B) = I$; it is

$$\Psi_j = \Phi_1 \Psi_{j-1} + \Phi_2 \Psi_{j-2} + \cdots + \Phi_p \Psi_{j-p}$$

where $\Psi_0 = I_k$ and $\Psi_j = 0$ for $j < 0$.

The stationarity condition is satisfied if all roots of $|\Phi(z)| = 0$ are outside of the unit circle. The stationarity condition is equivalent to the condition in the corresponding VAR(1) representation, $\mathbf{Y}_t = \Phi \mathbf{Y}_{t-1} + \boldsymbol{\varepsilon}_t$, that all eigenvalues of the $kp \times kp$ companion matrix Φ be less than one in absolute value, where $\mathbf{Y}_t = (\mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1})'$, $\boldsymbol{\varepsilon}_t = (\boldsymbol{\varepsilon}'_t, 0', \dots, 0)'$, and

$$\Phi = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

If the stationarity condition is not satisfied, a nonstationary model (a differenced model or an error correction model) might be more appropriate.

The following statements estimate a VAR(1) model and use the ROOTS option to compute the characteristic polynomial roots:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint print=(roots);
run;
```

Figure 30.44 shows the output associated with the ROOTS option, which indicates that the series is stationary since the modulus of the eigenvalue is less than one.

Figure 30.44 Stationarity (ROOTS Option)

The VARMAX Procedure

Index	Real	Imaginary	Modulus	Radian	Degree
1	0.77238	0.35899	0.8517	0.4351	24.9284
2	0.77238	-0.35899	0.8517	-0.4351	-24.9284

Parameter Estimation

Consider the stationary VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\varepsilon}_t$$

where $\mathbf{y}_{-p+1}, \dots, \mathbf{y}_0$ are assumed to be available (for convenience of notation). This can be represented by the general form of the multivariate linear model,

$$\mathbf{Y} = \mathbf{X}\mathbf{B} + \mathbf{E} \quad \text{or} \quad \mathbf{y} = (\mathbf{X} \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned}
 Y &= (\mathbf{y}_1, \dots, \mathbf{y}_T)' \\
 B &= (\boldsymbol{\delta}, \Phi_1, \dots, \Phi_p)' \\
 X &= (X_0, \dots, X_{T-1})' \\
 X_t &= (1, \mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1})' \\
 E &= (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)' \\
 \mathbf{y} &= \text{vec}(Y') \\
 \boldsymbol{\beta} &= \text{vec}(B') \\
 \mathbf{e} &= \text{vec}(E')
 \end{aligned}$$

with vec denoting the column stacking operator.

The conditional least squares estimator of $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = ((X'X)^{-1}X' \otimes I_k)\mathbf{y}$$

and the estimate of Σ is

$$\hat{\Sigma} = (T - (kp + 1))^{-1} \sum_{t=1}^T \hat{\boldsymbol{\epsilon}}_t \hat{\boldsymbol{\epsilon}}_t'$$

where $\hat{\boldsymbol{\epsilon}}_t$ is the residual vectors. Consistency and asymptotic normality of the LS estimator are that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

where $X'X/T$ converges in probability to Γ_p and \xrightarrow{d} denotes convergence in distribution.

The (conditional) maximum likelihood estimator in the VAR(p) model is equal to the (conditional) least squares estimator on the assumption of normality of the error vectors.

Asymptotic Distributions of Impulse Response Functions

As before, vec denotes the column stacking operator and vech is the corresponding operator that stacks the elements on and below the diagonal. For any $k \times k$ matrix A , the commutation matrix K_k is defined as $K_k \text{vec}(A) = \text{vec}(A')$; the duplication matrix D_k is defined as $D_k \text{vech}(A) = \text{vec}(A)$; the elimination matrix L_k is defined as $L_k \text{vec}(A) = \text{vech}(A)$.

The asymptotic distribution of the impulse response function (Lütkepohl 1993) is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G_j') \quad j = 1, 2, \dots$$

where $\Sigma_{\boldsymbol{\beta}} = \Gamma_p^{-1} \otimes \Sigma$ and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{J}(\Phi')^{j-1-i} \otimes \Psi_i$$

where $\mathbf{J} = [I_k, 0, \dots, 0]$ is a $k \times kp$ matrix and Φ is a $kp \times kp$ companion matrix.

The asymptotic distribution of the accumulated impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_l^a - \Psi_l^a) \xrightarrow{d} N(0, F_l \Sigma_{\beta} F_l') \quad l = 1, 2, \dots$$

where $F_l = \sum_{j=1}^l G_j$.

The asymptotic distribution of the orthogonalized impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j^o - \Psi_j^o) \xrightarrow{d} N(0, C_j \Sigma_{\beta} C_j' + \bar{C}_j \Sigma_{\sigma} \bar{C}_j') \quad j = 0, 1, 2, \dots$$

where $C_0 = 0$, $C_j = (\Psi_0^{o'} \otimes I_k) G_j$, $\bar{C}_j = (I_k \otimes \Psi_j) H$,

$$H = \frac{\partial \text{vec}(\Psi_0^o)}{\partial \sigma'} = L_k' \{L_k (I_{k^2} + K_k) (\Psi_0^o \otimes I_k) L_k'\}^{-1}$$

and $\Sigma_{\sigma} = 2D_k^+ (\Sigma \otimes \Sigma) D_k^{+'}$ with $D_k^+ = (D_k' D_k)^{-1} D_k'$ and $\sigma = \text{vech}(E)$.

Granger Causality Test

Let \mathbf{y}_t be arranged and partitioned in subgroups \mathbf{y}_{1t} and \mathbf{y}_{2t} with dimensions k_1 and k_2 , respectively ($k = k_1 + k_2$); that is, $\mathbf{y}_t = (\mathbf{y}'_{1t}, \mathbf{y}'_{2t})'$ with the corresponding white noise process $\boldsymbol{\epsilon}_t = (\boldsymbol{\epsilon}'_{1t}, \boldsymbol{\epsilon}'_{2t})'$. Consider the VAR(p) model with partitioned coefficients $\Phi_{ij}(B)$ for $i, j = 1, 2$ as follows:

$$\begin{bmatrix} \Phi_{11}(B) & \Phi_{12}(B) \\ \Phi_{21}(B) & \Phi_{22}(B) \end{bmatrix} \begin{bmatrix} \mathbf{y}_{1t} \\ \mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\delta}_1 \\ \boldsymbol{\delta}_2 \end{bmatrix} + \begin{bmatrix} \boldsymbol{\epsilon}_{1t} \\ \boldsymbol{\epsilon}_{2t} \end{bmatrix}$$

The variables \mathbf{y}_{1t} are said to cause \mathbf{y}_{2t} , but \mathbf{y}_{2t} do not cause \mathbf{y}_{1t} if $\Phi_{12}(B) = 0$. The implication of this model structure is that future values of the process \mathbf{y}_{1t} are influenced only by its own past and not by the past of \mathbf{y}_{2t} , where future values of \mathbf{y}_{2t} are influenced by the past of both \mathbf{y}_{1t} and \mathbf{y}_{2t} . If the future \mathbf{y}_{1t} are not influenced by the past values of \mathbf{y}_{2t} , then it can be better to model \mathbf{y}_{1t} separately from \mathbf{y}_{2t} .

Consider testing $H_0: C\boldsymbol{\beta} = c$, where C is a $s \times (k^2 p + k)$ matrix of rank s and c is an s -dimensional vector where $s = k_1 k_2 p$. Assuming that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

you get the Wald statistic

$$T(C\hat{\boldsymbol{\beta}} - c)' [C(\hat{\Gamma}_p^{-1} \otimes \hat{\Sigma})C']^{-1} (C\hat{\boldsymbol{\beta}} - c) \xrightarrow{d} \chi^2(s)$$

For the Granger causality test, the matrix C consists of zeros or ones and c is the zero vector. See Lütkepohl(1993) for more details of the Granger causality test.

VARX Modeling

The vector autoregressive model with exogenous variables is called the VARX(p,s) model. The form of the VARX(p,s) model can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$Y = XB + E \text{ or } \mathbf{y} = (X \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned} Y &= (\mathbf{y}_1, \dots, \mathbf{y}_T)' \\ B &= (\boldsymbol{\delta}, \Phi_1, \dots, \Phi_p, \Theta_0^*, \dots, \Theta_s^*)' \\ X &= (X_0, \dots, X_{T-1})' \\ X_t &= (1, \mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1}, \mathbf{x}'_{t+1}, \dots, \mathbf{x}'_{t-s+1})' \\ E &= (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)' \\ \mathbf{y} &= \text{vec}(Y') \\ \boldsymbol{\beta} &= \text{vec}(B') \\ \mathbf{e} &= \text{vec}(E') \end{aligned}$$

The conditional least squares estimator of $\boldsymbol{\beta}$ can be obtained by using the same method in a VAR(p) modeling. If the multivariate linear model has different independent variables that correspond to dependent variables, the SUR (seemingly unrelated regression) method is used to improve the regression estimates.

The following example fits the ordinary regression model:

```
proc varmax data=one;
  model y1-y3 = x1-x5;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:

```
proc reg data=one;
  model y1 = x1-x5;
  model y2 = x1-x5;
  model y3 = x1-x5;
run;
```

The following example fits the second-order lagged regression model:

```
proc varmax data=two;
  model y1 y2 = x / xlag=2;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:

```
data three;
  set two;
  xlag1 = lag1(x);
  xlag2 = lag2(x);
run;

proc reg data=three;
  model y1 = x xlag1 xlag2;
  model y2 = x xlag1 xlag2;
run;
```

The following example fits the ordinary regression model with different regressors:

```
proc varmax data=one;
  model y1 = x1-x3, y2 = x2 x3;
run;
```

This is equivalent to the following SYSLIN procedure statements:

```
proc syslin data=one vardef=df sur;
  endogenous y1 y2;
  model y1 = x1-x3;
  model y2 = x2 x3;
run;
```

From the output in [Figure 30.20](#) in the section “Getting Started: VARMAX Procedure” on page 1858, you can see that the parameters, XL0_1_2, XL0_2_1, XL0_3_1, and XL0_3_2 associated with the exogenous variables, are not significant. The following example fits the VARX(1,0) model with different regressors:

```
proc varmax data=grunfeld;
  model y1 = x1, y2 = x2, y3 / p=1 print=(estimates);
run;
```

Figure 30.45 Parameter Estimates for the VARX(1, 0) Model

The VARMAX Procedure				
XLag				
Lag	Variable	x1	x2	
0	y1	1.83231	-	
	y2	-	2.42110	
	y3	-	-	

As you can see in Figure 30.45, the symbol ‘-’ in the elements of matrix corresponds to endogenous variables that do not take the denoted exogenous variables.

Bayesian VAR and VARX Modeling

Consider the VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \dots + \Phi_p \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

or

$$\mathbf{y} = (X \otimes I_k) \boldsymbol{\beta} + \mathbf{e}$$

When the parameter vector $\boldsymbol{\beta}$ has a prior multivariate normal distribution with known mean $\boldsymbol{\beta}^*$ and covariance matrix V_β , the prior density is written as

$$f(\boldsymbol{\beta}) = \left(\frac{1}{2\pi}\right)^{k^2 p/2} |V_\beta|^{-1/2} \exp\left[-\frac{1}{2}(\boldsymbol{\beta} - \boldsymbol{\beta}^*)' V_\beta^{-1} (\boldsymbol{\beta} - \boldsymbol{\beta}^*)\right]$$

The likelihood function for the Gaussian process becomes

$$\begin{aligned} \ell(\boldsymbol{\beta}|\mathbf{y}) &= \left(\frac{1}{2\pi}\right)^{kT/2} |I_T \otimes \Sigma|^{-1/2} \times \\ &\quad \exp\left[-\frac{1}{2}(\mathbf{y} - (X \otimes I_k)\boldsymbol{\beta})' (I_T \otimes \Sigma^{-1})(\mathbf{y} - (X \otimes I_k)\boldsymbol{\beta})\right] \end{aligned}$$

Therefore, the posterior density is derived as

$$f(\boldsymbol{\beta}|\mathbf{y}) \propto \exp\left[-\frac{1}{2}(\boldsymbol{\beta} - \bar{\boldsymbol{\beta}})' \bar{\Sigma}_\beta^{-1} (\boldsymbol{\beta} - \bar{\boldsymbol{\beta}})\right]$$

where the posterior mean is

$$\bar{\boldsymbol{\beta}} = [V_\beta^{-1} + (X'X \otimes \Sigma^{-1})]^{-1} [V_\beta^{-1} \boldsymbol{\beta}^* + (X' \otimes \Sigma^{-1})\mathbf{y}]$$

and the posterior covariance matrix is

$$\bar{\Sigma}_{\beta} = [V_{\beta}^{-1} + (X'X \otimes \Sigma^{-1})]^{-1}$$

In practice, the prior mean β^* and the prior variance V_{β} need to be specified. If all the parameters are considered to shrink toward zero, the null prior mean should be specified. According to Litterman (1986), the prior variance can be given by

$$v_{ij}(l) = \begin{cases} (\lambda/l)^2 & \text{if } i = j \\ (\lambda\theta\sigma_{ii}/l\sigma_{jj})^2 & \text{if } i \neq j \end{cases}$$

where $v_{ij}(l)$ is the prior variance of the (i, j) th element of Φ_l , λ is the prior standard deviation of the diagonal elements of Φ_l , θ is a constant in the interval $(0, 1)$, and σ_{ii}^2 is the i th diagonal element of Σ . The deterministic terms have diffused prior variance. In practice, you replace the σ_{ii}^2 by the diagonal element of the ML estimator of Σ in the nonconstrained model.

For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + \phi_{1,11}y_{1,t-1} + \phi_{1,12}y_{2,t-1} + \phi_{2,11}y_{1,t-2} + \phi_{2,12}y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + \phi_{1,21}y_{1,t-1} + \phi_{1,22}y_{2,t-1} + \phi_{2,21}y_{1,t-2} + \phi_{2,22}y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

with the prior covariance matrix

$$V_{\beta} = \text{Diag} \left(\begin{array}{cccccc} \infty, \lambda^2, (\lambda\theta\sigma_1/\sigma_2)^2, (\lambda/2)^2, (\lambda\theta\sigma_1/2\sigma_2)^2, \\ \infty, (\lambda\theta\sigma_2/\sigma_1)^2, \lambda^2, (\lambda\theta\sigma_2/2\sigma_1)^2, (\lambda/2)^2 \end{array} \right)$$

For the Bayesian estimation of integrated systems, the prior mean is set to the first lag of each variable equal to one in its own equation and all other coefficients at zero. For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + 1 y_{1,t-1} + 0 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + 0 y_{1,t-1} + 1 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

Forecasting of BVAR Modeling

The mean squared error is used to measure forecast accuracy (Litterman 1986). The MSE of the forecast is

$$MSE = \frac{1}{T} \sum_{t=1}^T (A_t - F_t^s)^2$$

where A_t is the actual value at time t and F_t^s is the forecast made s periods earlier.

Bayesian VARX Modeling

The Bayesian vector autoregressive model with exogenous variables is called the BVARX(p,s) model. The form of the BVARX(p,s) model can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$\mathbf{y} = (X \otimes I_k) \boldsymbol{\beta} + \mathbf{e}$$

The prior means for the AR coefficients are the same as those specified in BVAR(p). The prior means for the exogenous coefficients are set to zero.

Some examples of the Bayesian VARX model are as follows:

```
model y1 y2 = x1 / p=1 xlag=1 prior;
```

```
model y1 y2 = x1 / p=(1 3) xlag=1 nocurrentx
prior=(lambda=0.9 theta=0.1);
```

VARMA and VARMAX Modeling

A VARMA(p, q) process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$ and $\Theta(B) = I_k - \sum_{i=1}^q \Theta_i B^i$.

Stationarity and Invertibility

For stationarity and invertibility of the VARMA process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.

Parameter Estimation

Under the assumption of normality of the ϵ_t with mean vector zero and nonsingular covariance matrix Σ , consider the conditional (approximate) log-likelihood function of a VARMA(p, q) model with mean zero.

Define $Y = (\mathbf{y}_1, \dots, \mathbf{y}_T)'$ and $E = (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)'$ with $B^i Y = (\mathbf{y}_{1-i}, \dots, \mathbf{y}_{T-i})'$ and $B^i E = (\boldsymbol{\epsilon}_{1-i}, \dots, \boldsymbol{\epsilon}_{T-i})'$; define $\mathbf{y} = \text{vec}(Y')$ and $\mathbf{e} = \text{vec}(E')$. Then

$$\mathbf{y} - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i \mathbf{y} = \mathbf{e} - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i \mathbf{e}$$

where $B^i \mathbf{y} = \text{vec}[(B^i Y)']$ and $B^i \mathbf{e} = \text{vec}[(B^i E)']$.

Then, the conditional (approximate) log-likelihood function can be written as follows (Reinsel 1997):

$$\begin{aligned} \ell &= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \sum_{t=1}^T \boldsymbol{\epsilon}_t' \Sigma^{-1} \boldsymbol{\epsilon}_t \\ &= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \mathbf{w}' \Theta^{-1} (I_T \otimes \Sigma^{-1}) \Theta^{-1} \mathbf{w} \end{aligned}$$

where $\mathbf{w} = \mathbf{y} - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i \mathbf{y}$, and Θ is such that $\mathbf{e} - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i \mathbf{e} = \Theta \mathbf{e}$.

For the exact log-likelihood function of a VARMA(p, q) model, the Kalman filtering method is used transforming the VARMA process into the state-space form (Reinsel 1997).

The state-space form of the VARMA(p, q) model consists of a state equation

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + G \boldsymbol{\epsilon}_t$$

and an observation equation

$$\mathbf{y}_t = H \mathbf{z}_t$$

where for $v = \max(p, q + 1)$

$$\mathbf{z}_t = (\mathbf{y}'_t, \mathbf{y}'_{t+1|t}, \dots, \mathbf{y}'_{t+v-1|t})'$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ \Psi_1 \\ \vdots \\ \Psi_{v-1} \end{bmatrix}$$

and

$$H = [I_k, 0, \dots, 0]$$

The Kalman filtering approach is used for evaluation of the likelihood function. The updating equation is

$$\hat{\mathbf{z}}_{t|t} = \hat{\mathbf{z}}_{t|t-1} + K_t \boldsymbol{\epsilon}_{t|t-1}$$

with

$$K_t = P_{t|t-1} H' [H P_{t|t-1} H']^{-1}$$

and the prediction equation is

$$\hat{\mathbf{z}}_{t|t-1} = F \hat{\mathbf{z}}_{t-1|t-1}, \quad P_{t|t-1} = F P_{t-1|t-1} F' + G \Sigma G'$$

with $P_{t|t} = [I - K_t H] P_{t|t-1}$ for $t = 1, 2, \dots, n$.

The log-likelihood function can be expressed as

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |\Sigma_{t|t-1}| - (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})' \Sigma_{t|t-1}^{-1} (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})]$$

where $\hat{\mathbf{y}}_{t|t-1}$ and $\Sigma_{t|t-1}$ are determined recursively from the Kalman filter procedure. To construct the likelihood function from Kalman filtering, you obtain $\hat{\mathbf{y}}_{t|t-1} = H \hat{\mathbf{z}}_{t|t-1}$, $\hat{\boldsymbol{\epsilon}}_{t|t-1} = \mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1}$, and $\Sigma_{t|t-1} = H P_{t|t-1} H'$.

Define the vector $\boldsymbol{\beta}$

$$\boldsymbol{\beta} = (\phi'_1, \dots, \phi'_p, \theta'_1, \dots, \theta'_q, \text{vech}(\Sigma))'$$

where $\phi_i = \text{vec}(\Phi_i)$ and $\theta_i = \text{vec}(\Theta_i)$.

The log-likelihood equations are solved by iterative numerical procedures such as the quasi-Newton optimization. The starting values for the AR and MA parameters are obtained from the least squares estimates.

Asymptotic Distribution of the Parameter Estimates

Under the assumptions of stationarity and invertibility for the VARMA model and the assumption that $\boldsymbol{\epsilon}_t$ is a white noise process, $\hat{\boldsymbol{\beta}}$ is a consistent estimator for $\boldsymbol{\beta}$ and $\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta})$ converges in distribution to the multivariate normal $N(0, V^{-1})$ as $T \rightarrow \infty$, where V is the asymptotic information matrix of $\boldsymbol{\beta}$.

Asymptotic Distributions of Impulse Response Functions

Defining the vector $\boldsymbol{\beta}$

$$\boldsymbol{\beta} = (\phi'_1, \dots, \phi'_p, \theta'_1, \dots, \theta'_q)'$$

the asymptotic distribution of the impulse response function for a VARMA(p, q) model is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G'_j) \quad j = 1, 2, \dots$$

where $\Sigma_{\boldsymbol{\beta}}$ is the covariance matrix of the parameter estimates and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{H}'(\mathbf{A}')^{j-1-i} \otimes \mathbf{J} \mathbf{A}^i \mathbf{J}'$$

where $\mathbf{H} = [I_k, 0, \dots, 0, I_k, 0, \dots, 0]'$ is a $k(p+q) \times k$ matrix with the second I_k following after p block matrices; $\mathbf{J} = [I_k, 0, \dots, 0]$ is a $k \times k(p+q)$ matrix; \mathbf{A} is a $k(p+q) \times k(p+q)$ matrix,

$$\mathbf{A} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

where

$$A_{11} = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix} \quad A_{12} = \begin{bmatrix} -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 \end{bmatrix}$$

A_{21} is a $kq \times kp$ zero matrix, and

$$A_{22} = \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

An Example of a VARMA(1,1) Model

Consider a VARMA(1,1) model with mean zero

$$\mathbf{y}_t = \Phi_1 \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t - \Theta_1 \boldsymbol{\epsilon}_{t-1}$$

where $\boldsymbol{\epsilon}_t$ is the white noise process with a mean zero vector and the positive-definite covariance matrix Σ .

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  theta = {0.5 -0.2, 0.1 0.3};
  /* to simulate the vector time series */
  call varmasim(y,phi,theta) sigma=sig n=100 seed=34657;
  cn = {'y1' 'y2'};
  create simul3 from y[colname=cn];
  append from y;
run;
```

The following statements fit a VARMA(1,1) model to the simulated data. You specify the order of the autoregressive model with the P= option and the order of moving-average model with the Q= option. You specify the quasi-Newton optimization in the NLOPTIONS statement as an optimization method.

```
proc varmax data=simul3;
  nloptions tech=qn;
  model y1 y2 / p=1 q=1 noint print=(estimates);
run;
```

Figure 30.46 shows the initial values of parameters. The initial values were estimated using the least squares method.

The fitted VARMA(1,1) model with estimated standard errors in parentheses is given as

$$\mathbf{y}_t = \begin{pmatrix} 1.01809 & -0.38651 \\ (0.10256) & (0.09644) \\ 0.39147 & 0.55290 \\ (0.10062) & (0.08421) \end{pmatrix} \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t - \begin{pmatrix} 0.32291 & -0.02153 \\ (0.14530) & (0.14199) \\ -0.16566 & 0.58613 \\ (0.15699) & (0.14115) \end{pmatrix} \boldsymbol{\epsilon}_{t-1}$$

VARMAX Modeling

A VARMAX(p, q, s) process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \Theta^*(B)\mathbf{x}_t + \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$, $\Theta^*(B) = \Theta_0^* + \Theta_1^* B + \dots + \Theta_s^* B^s$, and $\Theta(B) = I_k - \sum_{i=1}^q \Theta_i B^i$.

The dimension of the state-space vector of the Kalman filtering method for the parameter estimation of the VARMAX(p, q, s) model is large, which takes time and memory for computing. For convenience, the parameter estimation of the VARMAX(p, q, s) model uses the two-stage estimation method, which first estimates the deterministic terms and exogenous parameters, and then maximizes the log-likelihood function of a VARMA(p, q) model.

Some examples of VARMAX modeling are as follows:

```
model y1 y2 = x1 / q=1;
nloptions tech=qn;
```

```
model y1 y2 = x1 / p=1 q=1 xlag=1 nocurrentx;
nloptions tech=qn;
```

Model Diagnostic Checks

Multivariate Model Diagnostic Checks

- Information Criterion After fitting some candidate models to the data, various model selection criteria (normalized by T) can be used to choose the appropriate model. The following list includes the Akaike information criterion (AIC), the corrected Akaike information criterion

(AICC), the final prediction error criterion (FPE), the Hannan-Quinn criterion (HQC), and the Schwarz Bayesian criterion (SBC, also referred to as BIC):

$$\begin{aligned} \text{AIC} &= \log(|\tilde{\Sigma}|) + 2r/T \\ \text{AICC} &= \log(|\tilde{\Sigma}|) + 2r/(T - r/k) \\ \text{FPE} &= \left(\frac{T + r/k}{T - r/k}\right)^k |\tilde{\Sigma}| \\ \text{HQC} &= \log(|\tilde{\Sigma}|) + 2r \log(\log(T))/T \\ \text{SBC} &= \log(|\tilde{\Sigma}|) + r \log(T)/T \end{aligned}$$

where r denotes the number of parameters estimated, k is the number of dependent variables, T is the number of observations used to estimate the model, and $\tilde{\Sigma}$ is the maximum likelihood estimate of Σ . When comparing models, choose the model with the smallest criterion values.

An example of the output was displayed in [Figure 30.4](#).

- **Portmanteau Q_s statistic** The Portmanteau Q_s statistic is used to test whether correlation remains on the model residuals. The null hypothesis is that the residuals are uncorrelated. Let $C_\epsilon(l)$ be the residual cross-covariance matrices, $\hat{\rho}_\epsilon(l)$ be the residual cross-correlation matrices as

$$C_\epsilon(l) = T^{-1} \sum_{t=1}^{T-l} \epsilon_t \epsilon'_{t+l}$$

and

$$\hat{\rho}_\epsilon(l) = \hat{V}_\epsilon^{-1/2} C_\epsilon(l) \hat{V}_\epsilon^{-1/2} \quad \text{and} \quad \hat{\rho}_\epsilon(-l) = \hat{\rho}_\epsilon(l)'$$

where $\hat{V}_\epsilon = \text{Diag}(\hat{\sigma}_{11}^2, \dots, \hat{\sigma}_{kk}^2)$ and $\hat{\sigma}_{ii}^2$ are the diagonal elements of $\hat{\Sigma}$. The multivariate portmanteau test defined in Hosking (1980) is

$$Q_s = T^2 \sum_{l=1}^s (T-l)^{-1} \text{tr}\{\hat{\rho}_\epsilon(l) \Sigma^{-1} \hat{\rho}_\epsilon(-l) \Sigma^{-1}\}$$

The statistic Q_s has approximately the chi-square distribution with $k^2(s - p - q)$ degrees of freedom. An example of the output is displayed in [Figure 30.7](#).

Univariate Model Diagnostic Checks

There are various ways to perform diagnostic checks for a univariate model. For details, see the section “[Heteroscedasticity and Normality Tests](#)” on page 374 in Chapter 8, “[The AUTOREG Procedure](#).” An example of the output is displayed in [Figure 30.8](#) and [Figure 30.9](#).

- **Durbin-Watson (DW) statistics:** The DW test statistics test for the first order autocorrelation in the residuals.

- Jarque-Bera normality test: This test is helpful in determining whether the model residuals represent a white noise process. This tests the null hypothesis that the residuals have normality.
- F tests for autoregressive conditional heteroscedastic (ARCH) disturbances: F test statistics test for the heteroscedastic disturbances in the residuals. This tests the null hypothesis that the residuals have equal covariances
- F tests for AR disturbance: These test statistics are computed from the residuals of the univariate AR(1), AR(1,2), AR(1,2,3) and AR(1,2,3,4) models to test the null hypothesis that the residuals are uncorrelated.

Cointegration

This section briefly introduces the concepts of cointegration (Johansen 1995b).

Definition 1. (Engle and Granger 1987): *If a series y_t with no deterministic components can be represented by a stationary and invertible ARMA process after differencing d times, the series is integrated of order d , that is, $y_t \sim I(d)$.*

Definition 2. (Engle and Granger 1987): *If all elements of the vector \mathbf{y}_t are $I(d)$ and there exists a cointegrating vector $\boldsymbol{\beta} \neq 0$ such that $\boldsymbol{\beta}'\mathbf{y}_t \sim I(d - b)$ for any $b > 0$, the vector process is said to be cointegrated $CI(d, b)$.*

A simple example of a cointegrated process is the following bivariate system:

$$\begin{aligned} y_{1t} &= \gamma y_{2t} + \epsilon_{1t} \\ y_{2t} &= y_{2,t-1} + \epsilon_{2t} \end{aligned}$$

with ϵ_{1t} and ϵ_{2t} being uncorrelated white noise processes. In the second equation, y_{2t} is a random walk, $\Delta y_{2t} = \epsilon_{2t}$, $\Delta \equiv 1 - B$. Differencing the first equation results in

$$\Delta y_{1t} = \gamma \Delta y_{2t} + \Delta \epsilon_{1t} = \gamma \epsilon_{2t} + \epsilon_{1t} - \epsilon_{1,t-1}$$

Thus, both y_{1t} and y_{2t} are $I(1)$ processes, but the linear combination $y_{1t} - \gamma y_{2t}$ is stationary. Hence $\mathbf{y}_t = (y_{1t}, y_{2t})'$ is cointegrated with a cointegrating vector $\boldsymbol{\beta} = (1, -\gamma)'$.

In general, if the vector process \mathbf{y}_t has k components, then there can be more than one cointegrating vector $\boldsymbol{\beta}'$. It is assumed that there are r linearly independent cointegrating vectors with $r < k$, which make the $k \times r$ matrix $\boldsymbol{\beta}$. The rank of matrix $\boldsymbol{\beta}$ is r , which is called the *cointegration rank* of \mathbf{y}_t .

Common Trends

This section briefly discusses the implication of cointegration for the moving-average representation. Let \mathbf{y}_t be cointegrated $CI(1, 1)$, then $\Delta\mathbf{y}_t$ has the Wold representation:

$$\Delta\mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

where $\boldsymbol{\epsilon}_t$ is $iid(0, \Sigma)$, $\Psi(B) = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\Psi_0 = I_k$, and $\sum_{j=0}^{\infty} j|\Psi_j| < \infty$.

Assume that $\boldsymbol{\epsilon}_t = 0$ if $t \leq 0$ and \mathbf{y}_0 is a nonrandom initial value. Then the difference equation implies that

$$\mathbf{y}_t = \mathbf{y}_0 + \boldsymbol{\delta}t + \Psi(1) \sum_{i=0}^t \boldsymbol{\epsilon}_i + \Psi^*(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = (1 - B)^{-1}(\Psi(B) - \Psi(1))$ and $\Psi^*(B)$ is absolutely summable.

Assume that the rank of $\Psi(1)$ is $m = k - r$. When the process \mathbf{y}_t is cointegrated, there is a cointegrating $k \times r$ matrix $\boldsymbol{\beta}$ such that $\boldsymbol{\beta}'\mathbf{y}_t$ is stationary.

Premultiplying \mathbf{y}_t by $\boldsymbol{\beta}'$ results in

$$\boldsymbol{\beta}'\mathbf{y}_t = \boldsymbol{\beta}'\mathbf{y}_0 + \boldsymbol{\beta}'\Psi^*(B)\boldsymbol{\epsilon}_t$$

because $\boldsymbol{\beta}'\Psi(1) = 0$ and $\boldsymbol{\beta}'\boldsymbol{\delta} = 0$.

Stock and Watson (1988) showed that the cointegrated process \mathbf{y}_t has a common trends representation derived from the moving-average representation. Since the rank of $\Psi(1)$ is $m = k - r$, there is a $k \times r$ matrix H_1 with rank r such that $\Psi(1)H_1 = 0$. Let H_2 be a $k \times m$ matrix with rank m such that $H_2'H_1 = 0$; then $A = C(1)H_2$ has rank m . The $H = (H_1, H_2)$ has rank k . By construction of H ,

$$\Psi(1)H = [0, A] = AS_m$$

where $S_m = (0_{m \times r}, I_m)$. Since $\boldsymbol{\beta}'\Psi(1) = 0$ and $\boldsymbol{\beta}'\boldsymbol{\delta} = 0$, $\boldsymbol{\delta}$ lies in the column space of $\Psi(1)$ and can be written

$$\boldsymbol{\delta} = C(1)\tilde{\boldsymbol{\delta}}$$

where $\tilde{\boldsymbol{\delta}}$ is a k -dimensional vector. The common trends representation is written as

$$\begin{aligned} \mathbf{y}_t &= \mathbf{y}_0 + \Psi(1)[\tilde{\boldsymbol{\delta}}t + \sum_{i=0}^t \boldsymbol{\epsilon}_i] + \Psi^*(B)\boldsymbol{\epsilon}_t \\ &= \mathbf{y}_0 + \Psi(1)H[H^{-1}\tilde{\boldsymbol{\delta}}t + H^{-1}\sum_{i=0}^t \boldsymbol{\epsilon}_i] + \mathbf{a}_t \\ &= \mathbf{y}_0 + A\boldsymbol{\tau}_t + \mathbf{a}_t \end{aligned}$$

and

$$\boldsymbol{\tau}_t = \boldsymbol{\pi} + \boldsymbol{\tau}_{t-1} + \mathbf{v}_t$$

where $\mathbf{a}_t = \Psi^*(B)\boldsymbol{\epsilon}_t$, $\boldsymbol{\pi} = S_m H^{-1} \tilde{\boldsymbol{\delta}}$, $\boldsymbol{\tau}_t = S_m [H^{-1} \tilde{\boldsymbol{\delta}}_t + H^{-1} \sum_{i=0}^t \boldsymbol{\epsilon}_i]$, and $\mathbf{v}_t = S_m H^{-1} \boldsymbol{\epsilon}_t$.

Stock and Watson showed that the common trends representation expresses \mathbf{y}_t as a linear combination of m random walks ($\boldsymbol{\tau}_t$) with drift $\boldsymbol{\pi}$ plus $I(0)$ components (\mathbf{a}_t).

Test for the Common Trends

Stock and Watson (1988) proposed statistics for common trends testing. The null hypothesis is that the k -dimensional time series \mathbf{y}_t has m common stochastic trends, where $m \leq k$ and the alternative is that it has s common trends, where $s < m$. The test procedure of m versus s common stochastic trends is performed based on the first-order serial correlation matrix of \mathbf{y}_t . Let $\boldsymbol{\beta}_\perp$ be a $k \times m$ matrix orthogonal to the cointegrating matrix such that $\boldsymbol{\beta}'_\perp \boldsymbol{\beta} = 0$ and $\boldsymbol{\beta}_\perp \boldsymbol{\beta}'_\perp = I_m$. Let $\mathbf{z}_t = \boldsymbol{\beta}'_\perp \mathbf{y}_t$ and $\mathbf{w}_t = \boldsymbol{\beta}'_\perp \mathbf{y}_t$. Then

$$\mathbf{w}_t = \boldsymbol{\beta}'_\perp \mathbf{y}_0 + \boldsymbol{\beta}'_\perp \boldsymbol{\delta} t + \boldsymbol{\beta}'_\perp \Psi(1) \sum_{i=0}^t \boldsymbol{\epsilon}_i + \boldsymbol{\beta}'_\perp \Psi^*(B) \boldsymbol{\epsilon}_t$$

Combining the expression of \mathbf{z}_t and \mathbf{w}_t ,

$$\begin{bmatrix} \mathbf{z}_t \\ \mathbf{w}_t \end{bmatrix} = \begin{bmatrix} \boldsymbol{\beta}'_\perp \mathbf{y}_0 \\ \boldsymbol{\beta}'_\perp \mathbf{y}_0 \end{bmatrix} + \begin{bmatrix} 0 \\ \boldsymbol{\beta}'_\perp \boldsymbol{\delta} \end{bmatrix} t + \begin{bmatrix} 0 \\ \boldsymbol{\beta}'_\perp \Psi(1) \end{bmatrix} \sum_{i=1}^t \boldsymbol{\epsilon}_i + \begin{bmatrix} \boldsymbol{\beta}'_\perp \Psi^*(B) \\ \boldsymbol{\beta}'_\perp \Psi^*(B) \end{bmatrix} \boldsymbol{\epsilon}_t$$

The Stock-Watson common trends test is performed based on the component \mathbf{w}_t by testing whether $\boldsymbol{\beta}'_\perp \Psi(1)$ has rank m against rank s .

The following statements perform the Stock-Watson test for common trends:

```
proc iml;
  sig = 100*i(2);
  phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
  call varmasim(y,phi) sigma=sig n=100 initial=0
              seed=45876;

  cn = {'y1' 'y2'};
  create simul2 from y[colname=cn];
  append from y;
quit;

data simul2;
  set simul2;
  date = intnx('year', '01jan1900'd, _n_-1 );
  format date year4. ;
run;
```

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(sw);
run;
```

In Figure 30.51, the first column is the null hypothesis that \mathbf{y}_t has $m \leq k$ common trends; the second column is the alternative hypothesis that \mathbf{y}_t has $s < m$ common trends; the third column contains the eigenvalues used for the test statistics; the fourth column contains the test statistics using AR(p) filtering of the data. The table shows the output of the case $p = 2$.

Figure 30.51 Common Trends Test (COINTTEST=(SW) Option)

The VARMAX Procedure						
Common Trend Test						
H0: Rank=m	H1: Rank=s	Eigenvalue	Filter	5% Critical Value	Lag	
1	0	1.000906	0.09	-14.10	2	
2	0	0.996763	-0.32	-8.80		
	1	0.648908	-35.11	-23.00		

The test statistic for testing for 2 versus 1 common trends is more negative (-35.1) than the critical value (-23.0). Therefore, the test rejects the null hypothesis, which means that the series has a single common trend.

Vector Error Correction Modeling

This section discusses the implication of cointegration for the autoregressive representation. Assume that the cointegrated series can be represented by a vector error correction model according to the Granger representation theorem (Engle and Granger 1987). Consider the vector autoregressive process with Gaussian errors defined by

$$\mathbf{y}_t = \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\epsilon}_t$$

where the initial values, $\mathbf{y}_{-p+1}, \dots, \mathbf{y}_0$, are fixed and $\boldsymbol{\epsilon}_t \sim N(0, \Sigma)$. Since the AR operator $\Phi(B)$ can be re-expressed as $\Phi(B) = \Phi^*(B)(1 - B) + \Phi(1)B$, where $\Phi^*(B) = I_k - \sum_{i=1}^{p-1} \Phi_i^* B^i$ with $\Phi_i^* = -\sum_{j=i+1}^p \Phi_j$, the vector error correction model is

$$\Phi^*(B)(1 - B)\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

or

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\boldsymbol{\alpha} \boldsymbol{\beta}' = -\Phi(1) = -I_k + \Phi_1 + \Phi_2 + \dots + \Phi_p$.

One motivation for the VECM(p) form is to consider the relation $\boldsymbol{\beta}' \mathbf{y}_t = \mathbf{c}$ as defining the underlying economic relations and assume that the agents react to the disequilibrium error $\boldsymbol{\beta}' \mathbf{y}_t - \mathbf{c}$ through the adjustment coefficient $\boldsymbol{\alpha}$ to restore equilibrium; that is, they satisfy the economic relations. The cointegrating vector, $\boldsymbol{\beta}$ is sometimes called the *long-run parameters*.

You can consider a vector error correction model with a deterministic term. The deterministic term D_t can contain a constant, a linear trend, and seasonal dummy variables. Exogenous variables can also be included in the model.

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\Pi = \boldsymbol{\alpha} \boldsymbol{\beta}'$.

The alternative vector error correction representation considers the error correction term at lag $t - p$ and is written as

$$\Delta \mathbf{y}_t = \sum_{i=1}^{p-1} \Phi_i^\# \Delta \mathbf{y}_{t-i} + \Pi^\# \mathbf{y}_{t-p} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

If the matrix Π has a full-rank ($r = k$), all components of \mathbf{y}_t are $I(0)$. On the other hand, \mathbf{y}_t are stationary in difference if $\text{rank}(\Pi) = 0$. When the rank of the matrix Π is $r < k$, there are $k - r$ linear combinations that are nonstationary and r stationary cointegrating relations. Note that the linearly independent vector $\mathbf{z}_t = \boldsymbol{\beta}' \mathbf{y}_t$ is stationary and this transformation is not unique unless $r = 1$. There does not exist a unique cointegrating matrix $\boldsymbol{\beta}$ since the coefficient matrix Π can also be decomposed as

$$\Pi = \boldsymbol{\alpha} M M^{-1} \boldsymbol{\beta}' = \boldsymbol{\alpha}^* \boldsymbol{\beta}^{* \prime}$$

where M is an $r \times r$ nonsingular matrix.

Test for the Cointegration

The cointegration rank test determines the linearly independent columns of Π . Johansen (1988, 1995a) and Johansen and Juselius (1990) proposed the cointegration rank test by using the reduced rank regression.

Different Specifications of Deterministic Trends

When you construct the $VECM(p)$ form from the $VAR(p)$ model, the deterministic terms in the $VECM(p)$ form can differ from those in the $VAR(p)$ model. When there are deterministic cointegrated relationships among variables, deterministic terms in the $VAR(p)$ model are not present in the $VECM(p)$ form. On the other hand, if there are stochastic cointegrated relationships in the $VAR(p)$ model, deterministic terms appear in the $VECM(p)$ form via the error correction term or as an independent term in the $VECM(p)$ form. There are five different specifications of deterministic trends in the $VECM(p)$ form.

- **Case 1:** There is no separate drift in the $VECM(p)$ form.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

- **Case 2:** There is no separate drift in the $VECM(p)$ form, but a constant enters only via the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} (\boldsymbol{\beta}', \beta_0) (\mathbf{y}'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

- **Case 3:** There is a separate drift and no separate linear trend in the $VECM(p)$ form.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

- **Case 4:** There is a separate drift and no separate linear trend in the $VECM(p)$ form, but a linear trend enters only via the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} (\boldsymbol{\beta}', \beta_1) (\mathbf{y}'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

- **Case 5:** There is a separate linear trend in the $VECM(p)$ form.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\delta}_1 t + \boldsymbol{\epsilon}_t$$

First, focus on Cases 1, 3, and 5 to test the null hypothesis that there are at most r cointegrating vectors. Let

$$\begin{aligned} Z_{0t} &= \Delta \mathbf{y}_t \\ Z_{1t} &= \mathbf{y}_{t-1} \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+1}, D_t]' \\ Z_0 &= [Z_{01}, \dots, Z_{0T}]' \\ Z_1 &= [Z_{11}, \dots, Z_{1T}]' \\ Z_2 &= [Z_{21}, \dots, Z_{2T}]' \end{aligned}$$

where D_t can be empty for Case 1, 1 for Case 3, and $(1, t)$ for Case 5.

In Case 2, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [\mathbf{y}'_{t-1}, 1]' \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+1}]' \end{aligned}$$

In Case 4, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [\mathbf{y}'_{t-1}, t]' \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+1}, 1]' \end{aligned}$$

Let Ψ be the matrix of parameters consisting of $\Phi_1^*, \dots, \Phi_{p-1}^*$, A , and $\Theta_0^*, \dots, \Theta_s^*$, where parameters A corresponds to regressors D_t . Then the VECM(p) form is rewritten in these variables as

$$Z_{0t} = \alpha \beta' Z_{1t} + \Psi Z_{2t} + \epsilon_t$$

The log-likelihood function is given by

$$\begin{aligned} \ell &= -\frac{kT}{2} \log 2\pi - \frac{T}{2} \log |\Sigma| \\ &\quad - \frac{1}{2} \sum_{t=1}^T (Z_{0t} - \alpha \beta' Z_{1t} - \Psi Z_{2t})' \Sigma^{-1} (Z_{0t} - \alpha \beta' Z_{1t} - \Psi Z_{2t}) \end{aligned}$$

The residuals, R_{0t} and R_{1t} , are obtained by regressing Z_{0t} and Z_{1t} on Z_{2t} , respectively. The regression equation of residuals is

$$R_{0t} = \alpha \beta' R_{1t} + \hat{\epsilon}_t$$

The crossproducts matrices are computed

$$S_{ij} = \frac{1}{T} \sum_{t=1}^T R_{it} R'_{jt}, \quad i, j = 0, 1$$

Then the maximum likelihood estimator for β is obtained from the eigenvectors that correspond to the r largest eigenvalues of the following equation:

$$|\lambda S_{11} - S_{10} S_{00}^{-1} S_{01}| = 0$$

The eigenvalues of the preceding equation are squared canonical correlations between R_{0t} and R_{1t} , and the eigenvectors that correspond to the r largest eigenvalues are the r linear combinations of \mathbf{y}_{t-1} , which have the largest squared partial correlations with the stationary process $\Delta \mathbf{y}_t$ after correcting for lags and deterministic terms. Such an analysis calls for a reduced rank regression of $\Delta \mathbf{y}_t$ on \mathbf{y}_{t-1} corrected for $(\Delta \mathbf{y}_{t-1}, \dots, \Delta \mathbf{y}_{t-p+1}, D_t)$, as discussed by Anderson (1951). Johansen (1988) suggests two test statistics to test the null hypothesis that there are at most r cointegrating vectors

$$H_0 : \lambda_i = 0 \text{ for } i = r + 1, \dots, k$$

Trace Test

The trace statistic for testing the null hypothesis that there are at most r cointegrating vectors is as follows:

$$\lambda_{trace} = -T \sum_{i=r+1}^k \log(1 - \lambda_i)$$

The asymptotic distribution of this statistic is given by

$$tr \left\{ \int_0^1 (dW) \tilde{W}' \left(\int_0^1 \tilde{W} \tilde{W}' dr \right)^{-1} \int_0^1 \tilde{W} (dW)' \right\}$$

where $tr(A)$ is the trace of a matrix A , W is the $k - r$ dimensional Brownian motion, and \tilde{W} is the Brownian motion itself, or the demeaned or detrended Brownian motion according to the different specifications of deterministic trends in the vector error correction model.

Maximum Eigenvalue Test

The maximum eigenvalue statistic for testing the null hypothesis that there are at most r cointegrating vectors is as follows:

$$\lambda_{max} = -T \log(1 - \lambda_{r+1})$$

The asymptotic distribution of this statistic is given by

$$max \left\{ \int_0^1 (dW) \tilde{W}' \left(\int_0^1 \tilde{W} \tilde{W}' dr \right)^{-1} \int_0^1 \tilde{W} (dW)' \right\}$$

where $max(A)$ is the maximum eigenvalue of a matrix A . Osterwald-Lenum (1992) provided detailed tables of the critical values of these statistics.

The following statements use the JOHANSEN option to compute the Johansen cointegration rank trace test of integrated order 1:

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(johansen=(normalize=y1));
run;
```

Figure 30.52 shows the output based on the model specified in the MODEL statement, an intercept term is assumed. In the “Cointegration Rank Test Using Trace” table, the column Drift In ECM means there is no separate drift in the error correction model and the column Drift In Process means the process has a constant drift before differencing. The “Cointegration Rank Test Using Trace” table shows the trace statistics based on Case 3 and the “Cointegration Rank Test Using Trace under Restriction” table shows the trace statistics based on Case 2. The output indicates that the series are cointegrated with rank 1 because the trace statistics are smaller than the critical values in both Case 2 and Case 3.

Figure 30.52 Cointegration Rank Test (COINTTEST=(JOHANSEN=) Option)

The VARMAX Procedure						
Cointegration Rank Test Using Trace						
H0:	H1:	Eigenvalue	Trace	5%	Drift in ECM	Drift in Process
Rank=r	Rank>r			Critical Value		
0	0	0.4644	61.7522	15.34	Constant	Linear
1	1	0.0056	0.5552	3.84		

Cointegration Rank Test Using Trace Under Restriction						
H0:	H1:	Eigenvalue	Trace	5%	Drift in ECM	Drift in Process
Rank=r	Rank>r			Critical Value		
0	0	0.5209	76.3788	19.99	Constant	Constant
1	1	0.0426	4.2680	9.13		

Figure 30.53 shows which result, either Case 2 (the hypothesis H0) or Case 3 (the hypothesis H1), is appropriate depending on the significance level. Since the cointegration rank is chosen to be 1 by the result in Figure 30.52, look at the last row that corresponds to rank=1. Since the *p*-value is 0.054, the Case 2 cannot be rejected at the significance level 5%, but it can be rejected at the significance level 10%. For modeling of the two Case 2 and Case 3, see Figure 30.56 and Figure 30.57.

Figure 30.53 Cointegration Rank Test Continued

Hypothesis of the Restriction			Drift in ECM	Drift in Process
Hypothesis				
H0 (Case 2)			Constant	Constant
H1 (Case 3)			Constant	Linear

Hypothesis Test of the Restriction					
Rank	Eigenvalue	Restricted Eigenvalue	DF	Chi-Square	Pr > ChiSq
0	0.4644	0.5209	2	14.63	0.0007
1	0.0056	0.0426	1	3.71	0.0540

Figure 30.54 shows the estimates of long-run parameter (Beta) and adjustment coefficients (Alpha) based on Case 3.

Figure 30.54 Cointegration Rank Test Continued

Beta		
Variable	1	2
y1	1.00000	1.00000
y2	-2.04869	-0.02854
Alpha		
Variable	1	2
y1	-0.46421	-0.00502
y2	0.17535	-0.01275

Using the NORMALIZE= option, the first row of the “Beta” table has 1. Considering that the cointegration rank is 1, the long-run relationship of the series is

$$\begin{aligned}\beta' y_t &= [1 \quad -2.04869] \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \\ &= y_{1t} - 2.04869y_{2t} \\ y_{1t} &= 2.04869y_{2t}\end{aligned}$$

Figure 30.55 shows the estimates of long-run parameter (Beta) and adjustment coefficients (Alpha) based on Case 2.

Figure 30.55 Cointegration Rank Test Continued

Beta Under Restriction		
Variable	1	2
y1	1.00000	1.00000
y2	-2.04366	-2.75773
1	6.75919	101.37051
Alpha Under Restriction		
Variable	1	2
y1	-0.48015	0.01091
y2	0.12538	0.03722

Considering that the cointegration rank is 1, the long-run relationship of the series is

$$\begin{aligned}\beta' y_t &= \begin{bmatrix} 1 & -2.04366 & 6.75919 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ 1 \end{bmatrix} \\ &= y_{1t} - 2.04366 y_{2t} + 6.75919 \\ y_{1t} &= 2.04366 y_{2t} - 6.75919\end{aligned}$$

Estimation of Vector Error Correction Model

The preceding log-likelihood function is maximized for

$$\begin{aligned}\hat{\beta} &= S_{11}^{-1/2} [v_1, \dots, v_r] \\ \hat{\alpha} &= S_{01} \hat{\beta} (\hat{\beta}' S_{11} \hat{\beta})^{-1} \\ \hat{\Pi} &= \hat{\alpha} \hat{\beta}' \\ \hat{\Psi} &= (Z_2' Z_2)^{-1} Z_2' (Z_0 - Z_1 \hat{\Pi}') \\ \hat{\Sigma} &= (Z_0 - Z_2 \hat{\Psi}' - Z_1 \hat{\Pi}')' (Z_0 - Z_2 \hat{\Psi}' - Z_1 \hat{\Pi}') / T\end{aligned}$$

The estimators of the orthogonal complements of α and β are

$$\hat{\beta}_{\perp} = S_{11} [v_{r+1}, \dots, v_k]$$

and

$$\hat{\alpha}_{\perp} = S_{00}^{-1} S_{01} [v_{r+1}, \dots, v_k]$$

The ML estimators have the following asymptotic properties:

$$\sqrt{T} \text{vec}([\hat{\Pi}, \hat{\Psi}] - [\Pi, \Psi]) \xrightarrow{d} N(0, \Sigma_{co})$$

where

$$\Sigma_{co} = \Sigma \otimes \left(\begin{bmatrix} \beta & 0 \\ 0 & I_k \end{bmatrix} \Omega^{-1} \begin{bmatrix} \beta' & 0 \\ 0 & I_k \end{bmatrix} \right)$$

and

$$\Omega = \text{plim} \frac{1}{T} \begin{bmatrix} \beta' Z_1' Z_1 \beta & \beta' Z_1' Z_2 \\ Z_2' Z_1 \beta & Z_2' Z_2 \end{bmatrix}$$

The following statements are examples of fitting the five different cases of the vector error correction models mentioned in the previous section.

For fitting Case 1,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) noint;
```

For fitting Case 2,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend);
```

For fitting Case 3,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
```

For fitting Case 4,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
trend=linear;
```

For fitting Case 5,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) trend=linear;
```

From [Figure 30.53](#) that uses the COINTTEST=(JOHANSEN) option, you can fit the model by using either Case 2 or Case 3 because the test was not significant at the 0.05 level, but was significant at the 0.10 level. Here both models are fitted to show the difference in output display. [Figure 30.56](#) is for Case 2, and [Figure 30.57](#) is for Case 3.

For Case 2,

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
    print=(estimates);
run;
```

Test for the Linear Restriction on the Parameters

Consider the example with the variables m_t log real money, y_t log real income, i_t^d deposit interest rate, and i_t^b bond interest rate. It seems a natural hypothesis that in the long-run relation, money and income have equal coefficients with opposite signs. This can be formulated as the hypothesis that the cointegrated relation contains only m_t and y_t through $m_t - y_t$. For the analysis, you can express these restrictions in the parameterization of H such that $\boldsymbol{\beta} = H\boldsymbol{\phi}$, where H is a known

$k \times s$ matrix and ψ is the $s \times r$ ($r \leq s < k$) parameter matrix to be estimated. For this example, H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Restriction $H_0: \beta = H\phi$

When the linear restriction $\beta = H\phi$ is given, it implies that the same restrictions are imposed on all cointegrating vectors. You obtain the maximum likelihood estimator of β by reduced rank regression of Δy_t on $H y_{t-1}$ corrected for $(\Delta y_{t-1}, \dots, \Delta y_{t-p+1}, D_t)$, solving the following equation

$$|\rho H' S_{11} H - H' S_{10} S_{00}^{-1} S_{01} H| = 0$$

for the eigenvalues $1 > \rho_1 > \dots > \rho_s > 0$ and eigenvectors (v_1, \dots, v_s) , S_{ij} given in the preceding section. Then choose $\hat{\phi} = (v_1, \dots, v_r)$ that corresponds to the r largest eigenvalues, and the $\hat{\beta}$ is $H\hat{\phi}$.

The test statistic for $H_0: \beta = H\phi$ is given by

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi_{r(k-s)}^2$$

If the series has no deterministic trend, the constant term should be restricted by $\alpha'_{\perp} \delta_0 = 0$ as in Case 2. Then H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The following statements test that $2\beta_1 + \beta_2 = 0$:

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 h=(1,-2);
run;
```

Figure 30.58 shows the results of testing $H_0: 2\beta_1 + \beta_2 = 0$. The input H matrix is $H = (1 - 2)'$. The adjustment coefficient is reestimated under the restriction, and the test indicates that you cannot reject the null hypothesis.

Figure 30.58 Testing of Linear Restriction (H= Option)

Variable		1			
y1		-0.47404			
y2		0.17534			
Hypothesis Test					
Index	Eigenvalue	Restricted Eigenvalue	DF	Chi-Square	Pr > ChiSq
1	0.4644	0.4616	1	0.51	0.4738

Test for the Weak Exogeneity and Restrictions of Alpha

Consider a vector error correction model:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + A D_t + \boldsymbol{\epsilon}_t$$

Divide the process \mathbf{y}_t into $(\mathbf{y}'_{1t}, \mathbf{y}'_{2t})'$ with dimension k_1 and k_2 and the Σ into

$$\Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

Similarly, the parameters can be decomposed as follows:

$$\boldsymbol{\alpha} = \begin{bmatrix} \boldsymbol{\alpha}_1 \\ \boldsymbol{\alpha}_2 \end{bmatrix} \quad \Phi_i^* = \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \quad A = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix}$$

Then the VECM(p) form can be rewritten by using the decomposed parameters and processes:

$$\begin{bmatrix} \Delta \mathbf{y}_{1t} \\ \Delta \mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\alpha}_1 \\ \boldsymbol{\alpha}_2 \end{bmatrix} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \Delta \mathbf{y}_{t-i} + \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} D_t + \begin{bmatrix} \boldsymbol{\epsilon}_{1t} \\ \boldsymbol{\epsilon}_{2t} \end{bmatrix}$$

The conditional model for \mathbf{y}_{1t} given \mathbf{y}_{2t} is

$$\begin{aligned}\Delta \mathbf{y}_{1t} &= \omega \Delta \mathbf{y}_{2t} + (\alpha_1 - \omega \alpha_2) \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} (\Phi_{1i}^* - \omega \Phi_{2i}^*) \Delta \mathbf{y}_{t-i} \\ &\quad + (A_1 - \omega A_2) D_t + \boldsymbol{\epsilon}_{1t} - \omega \boldsymbol{\epsilon}_{2t}\end{aligned}$$

and the marginal model of \mathbf{y}_{2t} is

$$\Delta \mathbf{y}_{2t} = \alpha_2 \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_{2i}^* \Delta \mathbf{y}_{t-i} + A_2 D_t + \boldsymbol{\epsilon}_{2t}$$

where $\omega = \Sigma_{12} \Sigma_{22}^{-1}$.

The test of weak exogeneity of \mathbf{y}_{2t} for the parameters $(\alpha_1, \boldsymbol{\beta})$ determines whether $\alpha_2 = 0$. Weak exogeneity means that there is no information about $\boldsymbol{\beta}$ in the marginal model or that the variables \mathbf{y}_{2t} do not react to a disequilibrium.

Restriction $H_0: \boldsymbol{\alpha} = J\boldsymbol{\psi}$

Consider the null hypothesis $H_0: \boldsymbol{\alpha} = J\boldsymbol{\psi}$, where J is a $k \times m$ matrix with $r \leq m < k$.

From the previous residual regression equation

$$R_{0t} = \boldsymbol{\alpha} \boldsymbol{\beta}' R_{1t} + \hat{\boldsymbol{\epsilon}}_t = J\boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \hat{\boldsymbol{\epsilon}}_t$$

you can obtain

$$\begin{aligned}\bar{J}' R_{0t} &= \boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \bar{J}' \hat{\boldsymbol{\epsilon}}_t \\ J_{\perp}' R_{0t} &= J_{\perp}' \hat{\boldsymbol{\epsilon}}_t\end{aligned}$$

where $\bar{J} = J(J'J)^{-1}$ and J_{\perp} is orthogonal to J such that $J_{\perp}' J = 0$.

Define

$$\Sigma_{JJ_{\perp}} = \bar{J}' \Sigma J_{\perp} \quad \text{and} \quad \Sigma_{J_{\perp} J_{\perp}} = J_{\perp}' \Sigma J_{\perp}$$

and let $\omega = \Sigma_{JJ_{\perp}} \Sigma_{J_{\perp} J_{\perp}}^{-1}$. Then $\bar{J}' R_{0t}$ can be written as

$$\bar{J}' R_{0t} = \boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \omega J_{\perp}' R_{0t} + \bar{J}' \hat{\boldsymbol{\epsilon}}_t - \omega J_{\perp}' \hat{\boldsymbol{\epsilon}}_t$$

Using the marginal distribution of $J_{\perp}' R_{0t}$ and the conditional distribution of $\bar{J}' R_{0t}$, the new residuals are computed as

$$\begin{aligned}\tilde{R}_{Jt} &= \bar{J}' R_{0t} - S_{JJ_{\perp}} S_{J_{\perp} J_{\perp}}^{-1} J_{\perp}' R_{0t} \\ \tilde{R}_{1t} &= R_{1t} - S_{1J_{\perp}} S_{J_{\perp} J_{\perp}}^{-1} J_{\perp}' R_{0t}\end{aligned}$$

where

$$S_{JJ_{\perp}} = \bar{J}' S_{00} J_{\perp}, \quad S_{J_{\perp} J_{\perp}} = J_{\perp}' S_{00} J_{\perp}, \quad \text{and} \quad S_{J_{\perp} 1} = J_{\perp}' S_{01}$$

In terms of \tilde{R}_{Jt} and \tilde{R}_{1t} , the MLE of β is computed by using the reduced rank regression. Let

$$S_{ij.J_{\perp}} = \frac{1}{T} \sum_{t=1}^T \tilde{R}_{it} \tilde{R}'_{jt}, \quad \text{for } i, j = 1, J$$

Under the null hypothesis $H_0: \alpha = J\psi$, the MLE $\tilde{\beta}$ is computed by solving the equation

$$|\rho S_{11.J_{\perp}} - S_{1J.J_{\perp}} S_{JJ.J_{\perp}}^{-1} S_{J1.J_{\perp}}| = 0$$

Then $\tilde{\beta} = (v_1, \dots, v_r)$, where the eigenvectors correspond to the r largest eigenvalues. The likelihood ratio test for $H_0: \alpha = J\psi$ is

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi_{r(k-m)}^2$$

The test of weak exogeneity of y_{2t} is a special case of the test $\alpha = J\psi$, considering $J = (I_{k_1}, 0)'$. Consider the previous example with four variables (m_t, y_t, i_t^b, i_t^d). If $r = 1$, you formulate the weak exogeneity of (y_t, i_t^b, i_t^d) for m_t as $J = [1, 0, 0, 0]'$ and the weak exogeneity of i_t^d for (m_t, y_t, i_t^b) as $J = [I_3, 0]'$.

The following statements test the weak exogeneity of other variables, assuming $r = 1$:

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 exogeneity;
run;
```

Figure 30.59 shows that each variable is not the weak exogeneity of other variable.

Forecasting of the VECM

Consider the cointegrated moving-average representation of the differenced process of \mathbf{y}_t

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

Assume that $\mathbf{y}_0 = 0$. The linear process \mathbf{y}_t can be written as

$$\mathbf{y}_t = \boldsymbol{\delta}t + \sum_{i=1}^t \sum_{j=0}^{t-i} \Psi_j \boldsymbol{\epsilon}_i$$

Therefore, for any $l > 0$,

$$\mathbf{y}_{t+l} = \boldsymbol{\delta}(t+l) + \sum_{i=1}^t \sum_{j=0}^{t+l-i} \Psi_j \boldsymbol{\epsilon}_i + \sum_{i=1}^l \sum_{j=0}^{l-i} \Psi_j \boldsymbol{\epsilon}_{t+i}$$

The l -step-ahead forecast is derived from the preceding equation:

$$\mathbf{y}_{t+l|t} = (t+l)\boldsymbol{\delta} + \sum_{i=1}^t \sum_{j=0}^{t+l-i} \Psi_j \boldsymbol{\epsilon}_i$$

Note that

$$\lim_{l \rightarrow \infty} \boldsymbol{\beta}' \mathbf{y}_{t+l|t} = 0$$

since $\lim_{l \rightarrow \infty} \sum_{j=0}^{t+l-i} \Psi_j = \Psi(1)$ and $\boldsymbol{\beta}'\Psi(1) = 0$. The long-run forecast of the cointegrated system shows that the cointegrated relationship holds, although there might exist some deviations from the equilibrium status in the short-run. The covariance matrix of the predict error $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t}$ is

$$\Sigma(l) = \sum_{i=1}^l [(\sum_{j=0}^{l-i} \Psi_j) \Sigma (\sum_{j=0}^{l-i} \Psi_j)']$$

When the linear process is represented as a VECM(p) model, you can obtain

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{j=1}^{p-1} \Phi_j^* \Delta \mathbf{y}_{t-j} + \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

The transition equation is defined as

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + \mathbf{e}_t$$

where $\mathbf{z}_t = (\mathbf{y}'_{t-1}, \Delta\mathbf{y}'_t, \Delta\mathbf{y}'_{t-1}, \dots, \Delta\mathbf{y}'_{t-p+2})'$ is a state vector and the transition matrix is

$$F = \begin{bmatrix} I_k & I_k & 0 & \cdots & 0 \\ \Pi & (\Pi + \Phi_1^*) & \Phi_2^* & \cdots & \Phi_{p-1}^* \\ 0 & I_k & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

where 0 is a $k \times k$ zero matrix. The observation equation can be written

$$\mathbf{y}_t = \boldsymbol{\delta}t + H\mathbf{z}_t$$

where $H = [I_k, I_k, 0, \dots, 0]$.

The l -step-ahead forecast is computed as

$$\mathbf{y}_{t+l|t} = \boldsymbol{\delta}(t+l) + HF^l\mathbf{z}_t$$

Cointegration with Exogenous Variables

The error correction model with exogenous variables can be written as follows:

$$\Delta\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta\mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The following statements demonstrate how to fit $\text{VECMX}(p, s)$, where $p = 2$ and $s = 1$ from the `P=2` and `XLAG=1` options:

```
proc varmax data=simul3;
  model y1 y2 = x1 / p=2 xlag=1 ecm=(rank=1);
run;
```

The following statements demonstrate how to `BVECMX(2,1)`:

```
proc varmax data=simul3;
  model y1 y2 = x1 / p=2 xlag=1 ecm=(rank=1)
  prior=(lambda=0.9 theta=0.1);
run;
```

I(2) Model

The $\text{VARX}(p, s)$ model can be written in the error correction form:

$$\Delta\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta\mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

Let $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

If α and β have full-rank r , and $rank(\alpha'_\perp \Phi^* \beta_\perp) = k - r$, then y_t is an $I(1)$ process.

If the condition $rank(\alpha'_\perp \Phi^* \beta_\perp) = k - r$ fails and $\alpha'_\perp \Phi^* \beta_\perp$ has reduced-rank $\alpha'_\perp \Phi^* \beta_\perp = \xi \eta'$ where ξ and η are $(k - r) \times s$ matrices with $s \leq k - r$, then α_\perp and β_\perp are defined as $k \times (k - r)$ matrices of full rank such that $\alpha' \alpha_\perp = 0$ and $\beta' \beta_\perp = 0$.

If ξ and η have full-rank s , then the process y_t is $I(2)$, which has the implication of $I(2)$ model for the moving-average representation.

$$y_t = B_0 + B_1 t + C_2 \sum_{j=1}^t \sum_{i=1}^j \epsilon_i + C_1 \sum_{i=1}^t \epsilon_i + C_0(B) \epsilon_t$$

The matrices C_1 , C_2 , and $C_0(B)$ are determined by the cointegration properties of the process, and B_0 and B_1 are determined by the initial values. For details, see Johansen (1995a).

The implication of the $I(2)$ model for the autoregressive representation is given by

$$\Delta^2 y_t = \Pi y_{t-1} - \Phi^* \Delta y_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 y_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j^*$ and $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

Test for $I(2)$

The $I(2)$ cointegrated model is given by the following parameter restrictions:

$$H_{r,s}: \Pi = \alpha \beta' \text{ and } \alpha'_\perp \Phi^* \beta_\perp = \xi \eta'$$

where ξ and η are $(k - r) \times s$ matrices with $0 \leq s \leq k - r$. Let H_r^0 represent the $I(1)$ model where α and β have full-rank r , let $H_{r,s}^0$ represent the $I(2)$ model where ξ and η have full-rank s , and let $H_{r,s}$ represent the $I(2)$ model where ξ and η have rank $\leq s$. The following table shows the relation between the $I(1)$ models and the $I(2)$ models.

Table 30.2 Relation between the $I(1)$ and $I(2)$ Models

		$I(2)$				$I(1)$					
$r \setminus k - r - s$	k	$k-1$...	1							
0	H_{00}	\subset	H_{01}	\subset	...	\subset	$H_{0,k-1}$	\subset	H_{0k}	$=$	H_0^0
1			H_{10}	\subset	...	\subset	$H_{1,k-2}$	\subset	$H_{1,k-1}$	$=$	H_1^0
...						
$k - 1$							$H_{k-1,0}$	\subset	$H_{k-1,1}$	$=$	H_{k-1}^0

Johansen (1995a) proposed the two-step procedure to analyze the $I(2)$ model. In the first step, the values of (r, α, β) are estimated using the reduced rank regression analysis, performing the regression analysis $\Delta^2 \mathbf{y}_t$, $\Delta \mathbf{y}_{t-1}$, and \mathbf{y}_{t-1} on $\Delta^2 \mathbf{y}_{t-1}, \dots, \Delta^2 \mathbf{y}_{t-p+2}$, and D_t . This gives residuals R_{0t} , R_{1t} , and R_{2t} , and residual product moment matrices

$$M_{ij} = \frac{1}{T} \sum_{t=1}^T R_{it} R'_{jt} \text{ for } i, j = 0, 1, 2$$

Perform the reduced rank regression analysis $\Delta^2 \mathbf{y}_t$ on \mathbf{y}_{t-1} corrected for $\Delta \mathbf{y}_{t-1}$, $\Delta^2 \mathbf{y}_{t-1}, \dots, \Delta^2 \mathbf{y}_{t-p+2}$, and D_t , and solve the eigenvalue problem of the equation

$$|\lambda M_{22.1} - M_{20.1} M_{00.1}^{-1} M_{02.1}| = 0$$

where $M_{ij.1} = M_{ij} - M_{i1} M_{11}^{-1} M_{1j}$ for $i, j = 0, 2$.

In the second step, if (r, α, β) are known, the values of (s, ξ, η) are determined using the reduced rank regression analysis, regressing $\hat{\alpha}'_{\perp} \Delta^2 \mathbf{y}_t$ on $\hat{\beta}'_{\perp} \Delta \mathbf{y}_{t-1}$ corrected for $\Delta^2 \mathbf{y}_{t-1}, \dots, \Delta^2 \mathbf{y}_{t-p+2}$, D_t , and $\hat{\beta}' \Delta \mathbf{y}_{t-1}$.

The reduced rank regression analysis reduces to the solution of an eigenvalue problem for the equation

$$|\rho M_{\beta_{\perp} \beta_{\perp} \cdot \beta} - M_{\beta_{\perp} \alpha_{\perp} \cdot \beta} M_{\alpha_{\perp} \alpha_{\perp} \cdot \beta}^{-1} M_{\alpha_{\perp} \beta_{\perp} \cdot \beta}| = 0$$

where

$$\begin{aligned} M_{\beta_{\perp} \beta_{\perp} \cdot \beta} &= \beta'_{\perp} (M_{11} - M_{11} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{11}) \beta_{\perp} \\ M'_{\beta_{\perp} \alpha_{\perp} \cdot \beta} &= M_{\alpha_{\perp} \beta_{\perp} \cdot \beta} = \bar{\alpha}'_{\perp} (M_{01} - M_{01} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{11}) \beta_{\perp} \\ M_{\alpha_{\perp} \alpha_{\perp} \cdot \beta} &= \bar{\alpha}'_{\perp} (M_{00} - M_{01} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{10}) \bar{\alpha}_{\perp} \end{aligned}$$

where $\bar{\alpha} = \alpha (\alpha' \alpha)^{-1}$.

The solution gives eigenvalues $1 > \rho_1 > \dots > \rho_s > 0$ and eigenvectors (v_1, \dots, v_s) . Then, the ML estimators are

$$\begin{aligned} \hat{\eta} &= (v_1, \dots, v_s) \\ \hat{\xi} &= M_{\alpha_{\perp} \beta_{\perp} \cdot \beta} \hat{\eta} \end{aligned}$$

The likelihood ratio test for the reduced rank model $H_{r,s}$ with rank $\leq s$ in the model $H_{r,k-r} = H_r^0$ is given by

$$Q_{r,s} = -T \sum_{i=s+1}^{k-r} \log(1 - \rho_i), \quad s = 0, \dots, k - r - 1$$

The following statements compute the rank test to test for cointegrated order 2:

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(johansen=(iorder=2));
run;
```

The last two columns in Figure 30.60 explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level because the test statistic of 0.5552 is smaller than the critical value of 3.84. Now, look at the row associated with $r = 1$. Compare the test statistic value, 211.84512, to the critical value, 3.84, for the cointegrated order 2. There is no evidence that the series are integrated order 2 at the 0.05 significance level.

Multivariate GARCH Modeling

Stochastic volatility modeling is important in many areas, particularly in finance. To study the volatility of time series, GARCH models are widely used because they provide a good approach to conditional variance modeling.

BEKK Representation

Engle and Kroner (1995) propose a general multivariate GARCH model and call it a *BEKK* representation. Let $\mathcal{F}(t-1)$ be the sigma field generated by the past values of ϵ_t , and let H_t be the conditional covariance matrix of the k -dimensional random vector ϵ_t . Let H_t be measurable with respect to $\mathcal{F}(t-1)$; then the multivariate GARCH model can be written as

$$\begin{aligned} \epsilon_t | \mathcal{F}(t-1) &\sim N(0, H_t) \\ H_t &= C + \sum_{i=1}^q A_i' \epsilon_{t-i} \epsilon_{t-i}' A_i + \sum_{i=1}^p G_i' H_{t-i} G_i \end{aligned}$$

where C , A_i and G_i are $k \times k$ parameter matrices.

Consider a bivariate GARCH(1,1) model as follows:

$$H_t = \begin{bmatrix} c_{11} & c_{12} \\ c_{12} & c_{22} \end{bmatrix} + \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}' \begin{bmatrix} \epsilon_{1,t-1}^2 & \epsilon_{1,t-1}\epsilon_{2,t-1} \\ \epsilon_{2,t-1}\epsilon_{1,t-1} & \epsilon_{2,t-1}^2 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \\ + \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}' H_{t-1} \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}$$

or, representing the univariate model,

$$h_{11,t} = c_{11} + a_{11}^2 \epsilon_{1,t-1}^2 + 2a_{11}a_{21}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}^2 \epsilon_{2,t-1}^2 \\ + g_{11}^2 h_{11,t-1} + 2g_{11}g_{21}h_{12,t-1} + g_{21}^2 h_{22,t-1} \\ h_{12,t} = c_{12} + a_{11}a_{12}\epsilon_{1,t-1}^2 + (a_{21}a_{12} + a_{11}a_{22})\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}a_{22}\epsilon_{2,t-1}^2 \\ + g_{11}g_{12}h_{11,t-1} + (g_{21}g_{12} + g_{11}g_{22})h_{12,t-1} + g_{21}g_{22}h_{22,t-1} \\ h_{22,t} = c_{22} + a_{12}^2 \epsilon_{1,t-1}^2 + 2a_{12}a_{22}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{22}^2 \epsilon_{2,t-1}^2 \\ + g_{12}^2 h_{11,t-1} + 2g_{12}g_{22}h_{12,t-1} + g_{22}^2 h_{22,t-1}$$

For the *BEKK* representation of the bivariate GARCH(1,1) model, the SAS statements are:

```
model y1 y2;
garch q=1 p=1 form=bekk;
```

CCC Representation

Bollerslev (1990) propose a multivariate GARCH model with time-varying conditional variances and covariances but constant conditional correlations.

The conditional covariance matrix H_t consists of

$$H_t = D_t \Gamma D_t$$

where D_t is a $k \times k$ stochastic diagonal matrix with element σ_{it} and Γ is a $k \times k$ time-invariant matrix with the typical element ρ_{ij} .

The elements of H_t are

$$h_{ii,t} = c_i + \sum_{l=1}^q a_{ii,l} \epsilon_{i,t-l}^2 + \sum_{l=1}^p g_{ii,l} h_{ii,t-l} \quad i, j = 1, \dots, k \\ h_{ij,t} = \rho_{ij} (h_{ii,t} h_{jj,t})^{1/2} \quad i \neq j$$

Estimation of GARCH Model

The log-likelihood function of the multivariate GARCH model is written without a constant term

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |H_t| + \boldsymbol{\epsilon}_t' H_t^{-1} \boldsymbol{\epsilon}_t]$$

The log-likelihood function is maximized by an iterative numerical method such as quasi-Newton optimization. The starting values for the regression parameters are obtained from the least squares estimates. The covariance of $\boldsymbol{\epsilon}_t$ is used as the starting values for the GARCH constant parameters, and the starting value used for the other GARCH parameters is either 10^{-6} or 10^{-3} depending on the GARCH models representation. For the identification of the parameters of a *BEKK* representation GARCH model, the diagonal elements of the GARCH constant, the ARCH, and the GARCH parameters are restricted to be positive.

Covariance Stationarity

Define the multivariate GARCH process as

$$\mathbf{h}_t = \sum_{i=1}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\boldsymbol{\eta}_t]$$

where $\mathbf{h}_t = \text{vec}(H_t)$, $\mathbf{c} = \text{vec}(C_0)$, and $\boldsymbol{\eta}_t = \text{vec}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t')$. This representation is equivalent to a GARCH(p, q) model by the following algebra:

$$\begin{aligned} \mathbf{h}_t &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + \sum_{i=2}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\ &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B) \sum_{i=1}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\ &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B)\mathbf{h}_t \end{aligned}$$

Defining $A(B) = \sum_{i=1}^q (A_i \otimes A_i)' B^i$ and $G(B) = \sum_{i=1}^p (G_i \otimes G_i)' B^i$ gives a *BEKK* representation.

The necessary and sufficient conditions for covariance stationarity of the multivariate GARCH process is that all the eigenvalues of $A(1) + G(1)$ are less than one in modulus.

An Example of a VAR(1)–ARCH(1) Model

The following DATA step simulates a bivariate vector time series to provide test data for the multivariate GARCH model:

```
data garch;
  retain seed 16587;
```

```

esq1 = 0; esq2 = 0;
ly1 = 0; ly2 = 0;
do i = 1 to 1000;
  ht = 6.25 + 0.5*esq1;
  call rannor(seed,ehat);
  e1 = sqrt(ht)*ehat;
  ht = 1.25 + 0.7*esq2;
  call rannor(seed,ehat);
  e2 = sqrt(ht)*ehat;
  y1 = 2 + 1.2*ly1 - 0.5*ly2 + e1;
  y2 = 4 + 0.6*ly1 + 0.3*ly2 + e2;
  if i>500 then output;
  esq1 = e1*e1; esq2 = e2*e2;
  ly1 = y1; ly2 = y2;
end;
keep y1 y2;
run;

```

The following statements fit a VAR(1)–ARCH(1) model to the data. For a VAR-ARCH model, you specify the order of the autoregressive model with the P=1 option in the MODEL statement and the Q=1 option in the GARCH statement. In order to produce the initial and final values of parameters, the TECH=QN option is specified in the NLOPTIONS statement.

```

proc varmax data=garch;
  model y1 y2 / p=1
    print=(roots estimates diagnose);
  garch q=1;
  nloptions tech=qn;
run;

```

Figure 30.61 through Figure 30.65 show the details of this example. Figure 30.61 shows the initial values of parameters.

Figure 30.64 shows the AR parameter estimates and their significance.

The fitted VAR(1) model with the previous conditional covariance ARCH model is written as follows:

$$y_t = \begin{bmatrix} 1.94399 \\ 4.07390 \end{bmatrix} + \begin{bmatrix} 1.22094 & -0.52712 \\ 0.60826 & 0.30301 \end{bmatrix} y_{t-1} + \epsilon_t$$

Figure 30.64 VAR(1) Parameter Estimates for the VAR(1)–ARCH(1) Model

Model Parameter Estimates						
Equation	Parameter	Estimate	Standard			
			Error	t Value	Pr > t	Variable
y1	CONST1	1.94399	0.21017	9.25	0.0001	1
	AR1_1_1	1.22095	0.02564	47.63	0.0001	y1 (t-1)
	AR1_1_2	-0.52712	0.02836	-18.59	0.0001	y2 (t-1)
y2	CONST2	4.07390	0.10574	38.53	0.0001	1

Output Data Sets

The VARMAX procedure can create the OUT=, OUTEST=, OUTHT=, and OUTSTAT= data sets. In general, if processing fails, the output is not recorded or is set to missing in the relevant output data set, and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the forecast values produced by the OUTPUT statement. The following output variables can be created:

- the BY variables
- the ID variable
- the MODEL statement dependent (endogenous) variables. These variables contain the actual values from the input data set.
- FOR_i , numeric variables that contain the forecasts. The FOR_i variables contain the forecasts for the i th endogenous variable in the MODEL statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option. Multistep forecasts can be computed after that point based on the LEAD= option.
- RES_i , numeric variables that contain the residual for the forecast of the i th endogenous variable in the MODEL statement list. For multistep forecast observations, the actual values are missing and the RES_i variables contain missing values.
- STD_i , numeric variables that contain the standard deviation for the forecast of the i th endogenous variable in the MODEL statement list. The values of the STD_i variables can be used to construct univariate confidence limits for the corresponding forecasts.
- LCI_i , numeric variables that contain the lower confidence limits for the corresponding forecasts of the i th endogenous variable in the MODEL statement list.
- UCI_i , numeric variables that contain the upper confidence limits for the corresponding forecasts of the i th endogenous variable in the MODEL statement list.

The OUT= data set contains the values shown in [Table 30.3](#) and [Table 30.4](#) for a bivariate case.

Table 30.3 OUT= Data Set

Obs	ID variable	y1	FOR1	RES1	STD1	LCI1	UCI1
1	date	y_{11}	f_{11}	r_{11}	σ_{11}	l_{11}	u_{11}
2	date	y_{12}	f_{12}	r_{12}	σ_{11}	l_{12}	u_{12}
⋮

OUTEST= Data Set

The OUTEST= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created:

- the BY variables
- NAME, a character variable that contains the name of endogenous (dependent) variables or the name of the parameters for the covariance of the matrix of the parameter estimates if the OUTCOV option is specified
- TYPE, a character variable that contains the value EST for parameter estimates, the value STD for standard error of parameter estimates, and the value COV for the covariance of the matrix of the parameter estimates if the OUTCOV option is specified
- CONST, a numeric variable that contains the estimates of constant parameters and their standard errors
- SEASON_*i*, a numeric variable that contains the estimates of seasonal dummy parameters and their standard errors, where $i = 1, \dots, (nseason - 1)$, and *nseason* is based on the NSEASON= option

- LTREND, a numeric variable that contains the estimates of linear trend parameters and their standard errors
- QTREND, a numeric variable that contains the estimates of quadratic trend parameters and their standard errors
- XLl_i , numeric variables that contain the estimates of exogenous parameters and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, r$, where r is the number of exogenous variables
- ARl_i , numeric variables that contain the estimates of autoregressive parameters and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$, where k is the number of endogenous variables
- MAl_i , numeric variables that contain the estimates of moving-average parameters and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$, where k is the number of endogenous variables
- $ACHl_i$ are numeric variables that contain the estimates of the ARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for *BEKK* and *CCC* representations, where k is the number of endogenous variables.
- $GCHl_i$ are numeric variables that contain the estimates of the GARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for *BEKK* and *CCC* representations, where k is the number of endogenous variables.
- $GCHC_i$ are numeric variables that contain the estimates of the constant parameters of the covariance matrix and their standard errors, where $i = 1, \dots, k$ for *BEKK* representation, k is the number of endogenous variables, and $i = 1$ for *CCC* representation.
- CCC_i are numeric variables that contain the estimates of the conditional constant correlation parameters for *CCC* representation where $i = 2, \dots, k$.

The OUTEST= data set contains the values shown [Table 30.5](#) for a bivariate case.

Table 30.5 OUTEST= Data Set

Obs	NAME	TYPE	CONST	AR1_1	AR1_2	AR2_1	AR2_2
1	y1	EST	δ_1	$\phi_{1,11}$	$\phi_{1,12}$	$\phi_{2,11}$	$\phi_{2,12}$

OUTHT= Data Set

The OUTHT= data set contains prediction of the fitted GARCH model produced by the GARCH statement. The following output variables can be created.

- the BY variables
- H_{i_j} , numeric variables that contain the prediction of covariance, where $1 \leq i < j \leq k$, where k is the number of dependent variables

The OUTHT= data set contains the values shown in [Table 30.6](#) for a bivariate case.

Table 30.6 OUTHT= Data Set

OUTSTAT= Data Set

The OUTSTAT= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created. The subindex i is $1, \dots, k$, where k is the number of endogenous variables.

- the BY variables
- NAME, a character variable that contains the name of endogenous (dependent) variables
- SIGMA_ i , numeric variables that contain the estimate of the innovation covariance matrix
- AICC, a numeric variable that contains the corrected Akaike's information criterion value
- HQC, a numeric variable that contains the Hannan-Quinn's information criterion value
- AIC, a numeric variable that contains the Akaike's information criterion value
- SBC, a numeric variable that contains the Schwarz Bayesian's information criterion value
- FPEC, a numeric variable that contains the final prediction error criterion value
- FValue, a numeric variable that contains the F statistics
- PValue, a numeric variable that contains p -value for the F statistics

If the JOHANSEN= option is specified, the following items are added:

- Eigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1
- RestrictedEigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1 when the NOINT option is not specified
- Beta_ i , numeric variables that contain long-run effect parameter estimates, β

- Alpha_{*i*}, numeric variables that contain adjustment parameter estimates, α

If the JOHANSEN=(IORDER=2) option is specified, the following items are added:

- EValueI2_{*i*}, numeric variables that contain eigenvalues for the cointegration rank test of integrated order 2
- EValueI1, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1
- Eta_{*i*}, numeric variables that contain the parameter estimates in integrated order 2, η
- Xi_{*i*}, numeric variables that contain the parameter estimates in integrated order 2, ξ

The OUTSTAT= data set contains the values shown [Table 30.7](#) for a bivariate case.

Table 30.7 OUTSTAT= Data Set

Printed Output

The default printed output produced by the VARMAX procedure is described in the following list:

- descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (STD), their minimums and maximums, the differencing operations used, and the labels of the variables
- a type of model to fit the data and an estimation method
- a table of parameter estimates that shows the following for each parameter: the variable name for the left-hand side of equation, the parameter name, the parameter estimate, the approximate standard error, t value, the approximate probability ($Pr > |t|$), and the variable name for the right-hand side of equations in terms of each parameter
- the innovation covariance matrix
- the information criteria

If PRINT=ESTIMATES is specified, the VARMAX procedure prints the following list with the default printed output:

- the estimates of the constant vector (or seasonal constant matrix), the trend vector, the coefficient matrices of the distributed lags, the AR coefficient matrices, and the MA coefficient matrices
- the ALPHA and BETA parameter estimates for the error correction model
- the schematic representation of parameter estimates

If PRINT=DIAGNOSE is specified, the VARMAX procedure prints the following list with the default printed output:

- the cross-covariance and cross-correlation matrices of the residuals
- the tables of test statistics for the hypothesis that the residuals of the model are white noise:
 - Durbin-Watson (DW) statistics
 - F test for autoregressive conditional heteroscedastic (ARCH) disturbances
 - F test for AR disturbance
 - Jarque-Bera normality test
 - Portmanteau test

ODS Table Names

The VARMAX procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table:

Table 30.8 ODS Tables Produced in the VARMAX Procedure

Forecasts	Forecasts table	without NOPRINT

Note that the ODS table names suffixed by “byVar” can be obtained with the PRINTFORM=UNIVARIATE option.

ODS Graphics

This section describes the use of ODS for creating statistical graphs with the VARMAX procedure.

To request these graphs, you must specify the ODS GRAPHICS ON statement.

When ODS GRAPHICS are in effect, the VARMAX procedure produces a variety of plots for each dependent variable.

The plots available are as follows:

- The procedure displays the following plots for each dependent variable in the MODEL statement with the PLOT= option in the VARMAX statement:
 - impulse response function
 - impulse response of the transfer function
 - time series and predicted series
 - prediction errors
 - distribution of the prediction errors
 - normal quantile of the prediction errors
 - ACF of the prediction errors
 - PACF of the prediction errors
 - IACF of the prediction errors
 - log scaled white noise test of the prediction errors
- The procedure displays forecast plots for each dependent variable in the OUTPUT statement with the PLOT= option in the VARMAX statement.

ODS Graph Names

The VARMAX procedure assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 30.9](#).

Table 30.9 ODS Graphics Produced in the VARMAX Procedure

ODS Table Name	Plot Description	Statement
ErrorACFPlot	Autocorrelation function of prediction errors	MODEL
ErrorIACFPlot	Inverse autocorrelation function of prediction errors	MODEL
ErrorPACFPlot	Partial autocorrelation function of prediction errors	MODEL

Computational Issues

Computational Method

The VARMAX procedure uses numerous linear algebra routines and frequently uses the sweep operator (Goodnight 1979) and the Cholesky root (Golub and Van Loan 1983).

In addition, the VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks for the maximum likelihood estimation. The optimization requires intensive computation.

Convergence Problems

For some data sets, the computation algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data.

If you experience convergence problems, the following points might be helpful:

- Data that contain extreme values can affect results in PROC VARMAX. Rescaling the data can improve stability.
- Changing the TECH=, MAXITER=, and MAXFUNC= options in the [NLOPTIONS](#) statement can improve the stability of the optimization process.
- Specifying a different model that might fit the data more closely and might improve convergence.

Memory

Let T be the length of each series, k be the number of dependent variables, p be the order of autoregressive terms, and q be the order of moving-average terms. The number of parameters to estimate for a VARMA(p, q) model is

$$k + (p + q)k^2 + k * (k + 1)/2$$

As k increases, the number of parameters to estimate increases very quickly. Furthermore the memory requirement for VARMA(p, q) quadratically increases as k and T increase.

For a VARMAX(p, q, s) model and GARCH-type multivariate conditional heteroscedasticity models, the number of parameters to estimate and the memory requirements are considerable.

Computing Time

PROC VARMAX is computationally intensive, and execution times can be long. Extensive CPU time is often required to compute the maximum likelihood estimates.

Examples: VARMAX Procedure

Example 30.1: Analysis of U.S. Economic Variables

Consider the following four-dimensional system of U.S. economic variables. Quarterly data for the years 1954 to 1987 are used (Lütkepohl 1993, Table E.3.).

```

title 'Analysis of U.S. Economic Variables';
data us_money;
    date=intnx( 'qtr', '01jan54'd, _n_-1 );
    format date yyq. ;
    input y1 y2 y3 y4 @@;
    y1=log(y1);
    y2=log(y2);
    label y1='log(real money stock M1)'
          y2='log(GNP in bil. of 1982 dollars)'
          y3='Discount rate on 91-day T-bills'
          y4='Yield on 20-year Treasury bonds';
datalines;
450.9 1406.8  0.010800000  0.026133333
453.0 1401.2  0.0081333333  0.025233333
... more lines ...

```

The following statements plot the series and proceed with the VARMAX procedure.

```
proc timeseries data=us_money vectorplot=series;
  id date interval=qtr;
  var y1 y2;
run;
```

Output 30.1.1 shows the plot of the variables y1 and y2.

Output 30.1.1 Plot of Data

The following statements plot the variables y3 and y4.

```
proc timeseries data=us_money vectorplot=series;
  id date interval=qtr;
  var y3 y4;
run;
```

Output 30.1.2 shows the plot of the variables y3 and y4.

Output 30.1.2 Plot of Data

```
proc varmax data=us_money;
  id date interval=qtr;
  model y1-y4 / p=2 lagmax=6 dftest
          print=(iarr(3) estimates diagnose)
          cointtest=(johansen=(iorder=2))
          ecm=(rank=1 normalize=y1);
  cointeg rank=1 normalize=y1 exogeneity;
run;
```

This example performs the Dickey-Fuller test for stationarity, the Johansen cointegrated test integrated order 2, and the exogeneity test. The VECM(2) is fit to the data. From the outputs shown in [Output 30.1.5](#), you can see that the series has unit roots and is cointegrated in rank 1 with integrated order 1. The fitted VECM(2) is given as

$$\Delta \mathbf{y}_t = \begin{pmatrix} 0.0408 \\ 0.0860 \\ 0.0052 \\ -0.0144 \end{pmatrix} + \begin{pmatrix} -0.0140 & 0.0065 & -0.2026 & 0.1306 \\ -0.0281 & 0.0131 & -0.4080 & 0.2630 \\ -0.0022 & 0.0010 & -0.0312 & 0.0201 \\ 0.0051 & -0.0024 & 0.0741 & -0.0477 \end{pmatrix} \mathbf{y}_{t-1} \\ + \begin{pmatrix} 0.3460 & 0.0913 & -0.3535 & -0.9690 \\ 0.0994 & 0.0379 & 0.2390 & 0.2866 \\ 0.1812 & 0.0786 & 0.0223 & 0.4051 \\ 0.0322 & 0.0496 & -0.0329 & 0.1857 \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The Δ prefixed to a variable name implies differencing.

Output 30.1.3 through Output 30.1.14 show the details. Output 30.1.3 shows the descriptive statistics.

Output 30.1.3 Descriptive Statistics

Analysis of U.S. Economic Variables						
The VARMAX Procedure						
		Number of Observations	136			
		Number of Pairwise Missing	0			
Simple Summary Statistics						
Variable	Type	N	Mean	Standard Deviation	Min	Max

y1	log(real money stock M1)					
y2	log(GNP in bil. of 1982 dollars)					
y3	Discount rate on 91-day T-bills					
y4	Yield on 20-year Treasury bonds					

Output 30.1.4 shows the output for Dickey-Fuller tests for the nonstationarity of each series. The null hypotheses is to test a unit root. All series have a unit root.

Output 30.1.4 Unit Root Tests

Unit Root Test					
Variable	Type	Rho	Pr < Rho	Tau	Pr < Tau
y1	Zero Mean	0.05	0.6934	1.14	0.9343
	Single Mean	-2.97	0.6572	-0.76	0.8260
	Trend	-5.91	0.7454	-1.34	0.8725
y2	Zero Mean	0.13	0.7124	5.14	0.9999
	Single Mean	-0.43	0.9309	-0.79	0.8176
	Trend	-9.21	0.4787	-2.16	0.5063
y3	Zero Mean	-1.28	0.4255	-0.69	0.4182
	Single Mean	-8.86	0.1700	-2.27	0.1842
	Trend	-18.97	0.0742	-2.86	0.1803
y4	Zero Mean	0.40	0.7803	0.45	0.8100
	Single Mean	-2.79	0.6790	-1.29	0.6328
	Trend	-12.12	0.2923	-2.33	0.4170

The Johansen cointegration rank test shows whether the series is integrated order either 1 or 2 as shown in [Output 30.1.5](#). The last two columns in [Output 30.1.5](#) explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level because the test statistic of 20.6542 is smaller than the critical value of 29.38. Now, look at the row associated with $r = 1$. Compare the test statistic value and critical value pairs such as (219.62395, 29.38), (89.21508, 15.34), and (27.32609, 3.84). There is no evidence that the series are integrated order 2 at the 0.05 significance level.

Output 30.1.5 Cointegration Rank Test

Cointegration Rank Test for I(2)

	y4	0.00000	0.00000	0.00000	0.00000	

Output 30.1.14 shows whether each variable is the weak exogeneity of other variables. The variable y_1 is not the weak exogeneity of other variables, y_2 , y_3 , and y_4 ; the variable y_2 is not the weak exogeneity of other variables, y_1 , y_3 , and y_4 ; the variable y_3 and y_4 are the weak exogeneity of other variables.

Output 30.1.14 Weak Exogeneity Test

Testing Weak Exogeneity of Each Variables			
Variable	DF	Chi-Square	Pr > ChiSq
y1	1	6.55	0.0105
y2	1	12.54	0.0004
y3	1	0.09	0.7695
y4	1	1.81	0.1786

Example 30.2: Analysis of German Economic Variables

This example considers a three-dimensional VAR(2) model. The model contains the logarithms of a quarterly, seasonally adjusted West German fixed investment, disposable income, and consumption expenditures. The data used are in Lütkepohl (1993, Table E.1).

```

title 'Analysis of German Economic Variables';
data west;
    date = intnx( 'qtr', '01jan60'd, _n_-1 );
    format date yyq. ;
    input y1 y2 y3 @@;
    y1 = log(y1);
    y2 = log(y2);
    y3 = log(y3);
    label y1 = 'logarithm of investment'
           y2 = 'logarithm of income'
           y3 = 'logarithm of consumption';
datalines;
180 451 415 179 465 421 185 485 434 192 493 448

... more lines ...

data use;
    set west;
    where date < '01jan79'd;
    keep date y1 y2 y3;
run;

proc varmax data=use;
    id date interval=qtr;
    model y1-y3 / p=2 dify=(1)
           print=(decompose(6) impulse=(stderr) estimates diagnose)

```

```

                printform=both lagmax=3;
causal group1=(y1) group2=(y2 y3);
output lead=5;
run;

```

First, the differenced data is modeled as a VAR(2) with the following result:

$$\Delta \mathbf{y}_t = \begin{pmatrix} -0.01672 \\ 0.01577 \\ 0.01293 \end{pmatrix} + \begin{pmatrix} -0.31963 & 0.14599 & 0.96122 \\ 0.04393 & -0.15273 & 0.28850 \\ -0.00242 & 0.22481 & -0.26397 \end{pmatrix} \Delta \mathbf{y}_{t-1} \\ + \begin{pmatrix} -0.16055 & 0.11460 & 0.93439 \\ 0.05003 & 0.01917 & -0.01020 \\ 0.03388 & 0.35491 & -0.02223 \end{pmatrix} \Delta \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

The parameter estimates AR1_1_2, AR1_1_3, AR2_1_2, and AR2_1_3 are insignificant, and the VARX model is fitted in the next step.

The detailed output is shown in [Output 30.2.1](#) through [Output 30.2.8](#).

[Output 30.2.1](#) shows the descriptive statistics.

Output 30.2.1 Descriptive Statistics

[Output 30.2.9](#) shows that you cannot reject Granger noncausality from (y2, y3) to y1 using the 0.05 significance level.

Output 30.2.9 Granger Causality Tests

Granger-Causality Wald Test			
Test	DF	Chi-Square	Pr > ChiSq
1	4	6.37	0.1734
Test 1: Group 1 Variables: y1			
Group 2 Variables: y2 y3			

The following SAS statements show that the variable y_1 is the exogenous variable and fit the VARX(2,1) model to the data.

```
proc varmax data=use;
  id date interval=qtr;
  model y2 y3 = y1 / p=2 dify=(1) difx=(1) xlag=1 lagmax=3
          print=(estimates diagnose);
run;
```

The fitted VARX(2,1) model is written as

$$\begin{pmatrix} \Delta y_{2t} \\ \Delta y_{3t} \end{pmatrix} = \begin{pmatrix} 0.01542 \\ 0.01319 \end{pmatrix} + \begin{pmatrix} 0.02520 \\ 0.05130 \end{pmatrix} \Delta y_{1t} + \begin{pmatrix} 0.03870 \\ 0.00363 \end{pmatrix} \Delta y_{1,t-1} \\ + \begin{pmatrix} -0.12258 & 0.25811 \\ 0.24367 & -0.31809 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-1} \\ \Delta y_{3,t-1} \end{pmatrix} \\ + \begin{pmatrix} 0.01651 & 0.03498 \\ 0.34921 & -0.01664 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-2} \\ \Delta y_{3,t-2} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{pmatrix}$$

The detailed output is shown in [Output 30.2.10](#) through [Output 30.2.13](#).

[Output 30.2.10](#) shows the parameter estimates in terms of the constant, the current and the lag one coefficients of the exogenous variable, and the lag two coefficients of the dependent variables.

Output 30.2.10 Parameter Estimates

Example 30.4: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. The graphical displays are requested by specifying the ODS GRAPHICS ON statement. For information about the graphics available in the VARMAX procedure, see the section “[ODS Graphics](#)” on page 2000.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical

workers and its interaction with the series of masonry workers. The series and predict plots, the residual plot, and the forecast plot are created in [Output 30.4.1](#) through [Output 30.4.3](#). These are a selection of the plots created by the VARMAX procedure.

```

Overview: X11 Procedure

The X11 procedure, an adaptation of the U.S. Bureau of the Census X-11 Seasonal Adjustment program, seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set containing the adjusted time series and intermediate calculations.

The X11 procedure also provides the X-11-ARIMA method developed by Statistics Canada. This method fits an ARIMA model to the original series, then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

The X11 procedure incorporates sliding spans analysis. This type of analysis provides a diagnostic for determining the suitability of seasonal adjustment for an economic series.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t , $t = 1, \dots, n$, and separated from trend cycle, trading-day, and irregular fluctuations. The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated constantly or in an evolving fashion from year to year. The trend cycle component, C_t , includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading-day component, D_t , is the variation that can be attributed to the composition of the calendar. The irregular component, I_t , is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). A seasonally adjusted time series, $C_t I_t$, consists of only the trend cycle and irregular components.

Getting Started: X11 Procedure

The most common use of the X11 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X11 to produce a seasonally adjusted series, $C_t I_t$, from an original series $O_t = S_t C_t D_t I_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t , while S_t , D_t , and I_t vary around 1.0. In all printed tables and in the output data set, these latter components are expressed as percentages, and thus will vary around 100.0 (in the additive case, they vary around 0.0).

The naming convention used in PROC X11 for the tables follows the original U.S. Bureau of the Census X-11 Seasonal Adjustment program specification (Shiskin, Young, and Musgrave 1967). Also, see the section “[Printed Output](#)” on page 2074. This convention is outlined in [Figure 31.1](#).

The tables corresponding to parts A – C are intermediate calculations. The final estimates of the individual components are found in the D tables: table D10 contains the final seasonal factors, table D12 contains the final trend cycle, and table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you only need to look at table D11, the final seasonally adjusted series.

For further details about the X-11-ARIMA tables, see Ladiray and Quenneville (2001).

Basic Seasonal Adjustment

Suppose you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the MONTHLY statement, which associates a SAS date value to each observation. To see the results of the seasonal adjustment, you must request table D11, the final seasonally adjusted series, in a TABLES statement.

```
data sales;
  input sales @@;
  date = intnx( 'month', '01sep1978'd, _n_-1 );
  format date monyy7.;
datalines;

... more lines ...

/*--- X-11 ARIMA ---*/
proc x11 data=sales;
  monthly date=date;
  var sales;
  tables d11;
run;
```

Figure 31.3 Plot of Original and Seasonally Adjusted Data

X-11-ARIMA

An inherent problem with the X-11 method is the revision of the seasonal factor estimates as new data become available. The X-11 method uses a set of centered moving averages to estimate the seasonal components. These moving averages apply symmetric weights to all observations except those at the beginning and end of the series, where asymmetric weights have to be applied. These

asymmetric weights can cause poor estimates of the seasonal factors, which then can cause large revisions when new data become available.

While large revisions to seasonally adjusted values are not common, they can happen. When they do happen, it undermines the credibility of the X-11 seasonal adjustment method.

A method to address this problem was developed at Statistics Canada (Dagum 1980, 1982a). This method, known as X-11-ARIMA, applies an ARIMA model to the original data (after adjustments, if any) to forecast the series one or more years. This extended series is then seasonally adjusted, allowing symmetric weights to be applied to the end of the original data. This method was tested against a large number of Canadian economic series and was found to greatly reduce the amount of revisions as new data were added.

The X-11-ARIMA method is available in PROC X11 through the use of the ARIMA statement. The ARIMA statement extends the original series either with a user-specified ARIMA model or by an automatic selection process in which the best model from a set of five predefined ARIMA models is used.

The following example illustrates the use of the ARIMA statement. The ARIMA statement does not contain a user-specified model, so the best model is chosen by the automatic selection process. Forecasts from this best model are then used to extend the original series by one year. The following partial listing shows parameter estimates and model diagnostics for the ARIMA model chosen by the automatic selection process.

```
proc x11 data=sales;
  monthly date=date;
  var sales;
  arima;
run;
```

Figure 31.4 X-11-ARIMA Model Selection

Monthly Retail Sales Data (in \$1000)

Criteria Summary for Model 2: (0,1,2) (0,1,1)s, Log Transform			
Box-Ljung Chi-square: 22.03 with 21 df Prob= 0.40			
(Criteria prob > 0.05)			
Test for over-differencing: sum of MA parameters = 0.57			
(must be < 0.90)			
MAPE - Last Three Years: 2.84 (Must be < 15.00 %)			
	- Last Year:	3.04	
	- Next to Last Year:	1.96	
	- Third from Last Year:	3.51	

Table D11 (final seasonally adjusted series) is now constructed using symmetric weights on observations at the end of the actual data. This should result in better estimates of the seasonal factors and, thus, smaller revisions in Table D11 as more data become available.

Syntax: X11 Procedure

The X11 procedure uses the following statements:

```

PROC X11 options ;
  ARIMA options ;
  BY variables ;
  ID variables ;
  MACURVES option ;
  MONTHLY options ;
  OUTPUT OUT=dataset options ;
  PDWEIGHTS option ;
  QUARTERLY options ;
  SSPAN options ;
  TABLES tablenames ;
  VAR variables ;

```

Either the MONTHLY or QUARTERLY statement must be specified, depending on the type of time series data you have. The PDWEIGHTS and MACURVES statements can be used only with the MONTHLY statement. The TABLES statement controls the printing of tables, while the OUTPUT statement controls the creation of the OUT= data set.

Functional Summary

The statements and options controlling the X11 procedures are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set	PROC X11	DATA=
write the trading-day regression results to an output data set	PROC X11	OUTTDR=
write the stable seasonality test results to an output data set	PROC X11	OUTSTB=
write table values to an output data set	OUTPUT	OUT=
add extrapolated values to the output data set	PROC X11	OUTEX
add year ahead estimates to the output data set	PROC X11	YRAHEADOUT
write the sliding spans analysis results to an output data set	PROC X11	OUTSPAN=
Printing Control Options		
suppress all printed output	PROC X11	NOPRINT
suppress all printed ARIMA output	ARIMA	NOPRINT
print all ARIMA output	ARIMA	PRINTALL
print selected tables and charts	TABLES	
print selected groups of tables	MONTHLY	PRINTOUT=
	QUARTERLY	PRINTOUT=
print selected groups of charts	MONTHLY	CHARTS=
	QUARTERLY	CHARTS=
print preliminary tables associated with ARIMA processing	ARIMA	PRINTFP
specify number of decimals for printed tables	MONTHLY	NDEC=
	QUARTERLY	NDEC=
suppress all printed SSPAN output	SSPAN	NOPRINT
print all SSPAN output	SSPAN	PRINTALL
Date Information Options		
specify a SAS date variable	MONTHLY	DATE=
	QUARTERLY	DATE=
specify the beginning date	MONTHLY	START=
	QUARTERLY	START=
specify the ending date	MONTHLY	END=
	QUARTERLY	END=
specify beginning year for trading-day regression	MONTHLY	TDCOMPUTE=
Declaring the Role of Variables		
specify BY-group processing	BY	

Description	Statement	Option
specify the variables to be seasonally adjusted	VAR	
specify identifying variables	ID	
specify the prior monthly factor	MONTHLY	PMFACTOR=
Controlling the Table Computations		
use additive adjustment	MONTHLY	ADDITIVE
	QUARTERLY	ADDITIVE
specify seasonal factor moving average length	MACURVES	
specify the extreme value limit for trading-day regression	MONTHLY	EXCLUDE=
specify the lower bound for extreme irregulars	MONTHLY	FULLWEIGHT=
	QUARTERLY	FULLWEIGHT=
specify the upper bound for extreme irregulars	MONTHLY	ZEROWEIGHT=
	QUARTERLY	ZEROWEIGHT=
include the length-of-month in trading-day regression	MONTHLY	LENGTH
specify trading-day regression action	MONTHLY	TDREGR=
compute summary measure only	MONTHLY	SUMMARY
	QUARTERLY	SUMMARY
modify extreme irregulars prior to trend cycle estimation	MONTHLY	TRENDADJ
	QUARTERLY	TRENDADJ
specify moving average length in trend cycle estimation	MONTHLY	TRENDMA=
	QUARTERLY	TRENDMA=
specify weights for prior trading-day factors	PDWEIGHTS	

PROC X11 Statement

PROC X11 *options* ;

The following options can appear in the PROC X11 statement:

DATA= *SAS-data-set*

specifies the input SAS data set used. If it is omitted, the most recently created SAS data set is used.

OUTEXTRAP

adds the extra observations used in ARIMA processing to the output data set.

When ARIMA forecasting/backcasting is requested, extra observations are appended to the ends of the series, and the calculations are carried out on this extended series. The appended observations are not normally written to the OUT= data set. However, if OUTEXTRAP is specified, these extra observations are written to the output data set. If a DATE= variable is specified in the MONTHLY/QUARTERLY statement, the date variable is extrapolated to identify forecasts/backcasts. The OUTEXTRAP option can be abbreviated as OUTEX.

NOPRINT

suppresses any printed output. The NOPRINT option overrides any PRINTOUT=, CHARTS=, or TABLES statement and any output associated with the ARIMA statement.

OUTSPAN= SAS-data-set

specifies the output data set to store the sliding spans analysis results. Tables A1, C18, D10, and D11 for each span are written to this data set. See the section “[The OUTSPAN= Data Set](#)” on page 2071 for details.

OUTSTB= SAS-data-set

specifies the output data set to store the stable seasonality test results (table D8). All the information in the analysis of variance table associated with the stable seasonality test is contained in the variables written to this data set. See the section “[OUTSTB= Data Set](#)” on page 2071 for details.

OUTTDR= SAS-data-set

specifies the output data set to store the trading-day regression results (tables B15 and C15). All the information in the analysis of variance table associated with the trading-day regression is contained in the variables written to this data set. This option is valid only when TDREGR=PRINT, TEST, or ADJUST is specified in the MONTHLY statement. See the section “[OUTTDR= Data Set](#)” on page 2072 for details.

YRAHEADOUT

adds one-year-ahead forecast values to the output data set for tables C16, C18, and D10. The original purpose of this option was to avoid recomputation of the seasonal adjustment factors when new data became available. While computing costs were an important factor when the X-11 method was developed, this is no longer the case and this option is obsolete. See the section “[The YRAHEADOUT Option](#)” on page 2067 for details.

ARIMA Statement

ARIMA options ;

The ARIMA statement applies the X-11-ARIMA method to the series specified in the VAR statement. This method uses an ARIMA model estimated from the original data to extend the series one or more years. The ARIMA statement options control the ARIMA model used and the estimation, forecasting, and printing of this model.

There are two ways of obtaining an ARIMA model to extend the series. A model can be given explicitly with the MODEL= and TRANSFORM= options. Alternatively, the best-fitting model from a set of five predefined models is found automatically whenever the MODEL= option is absent. See the section “[Details of Model Selection](#)” on page 2068 for details.

BACKCAST= n

specifies the number of years to backcast the series. The default is BACKCAST= 0. See the section “[Effect of Backcast and Forecast Length](#)” on page 2067 for details.

CHICR= *value*

specifies the criteria for the significance level for the Box-Ljung chi-square test for lack of fit when testing the five predefined models. The default is CHICR= 0.05. The CHICR= option values must be between 0.01 and 0.90. The hypothesis being tested is that of model adequacy. Nonrejection of the hypothesis is evidence for an adequate model. Making the CHICR= value smaller makes it easier to accept the model. See the section “[Criteria Details](#)” on page 2069 for further details on the CHICR= option.

CONVERGE= *value*

specifies the convergence criterion for the estimation of an ARIMA model. The default value is 0.001. The CONVERGE= value must be positive.

FORECAST= *n*

specifies the number of years to forecast the series. The default is FORECAST= 1. See the section “[Effect of Backcast and Forecast Length](#)” on page 2067 for details.

MAPECR= *value*

specifies the criteria for the mean absolute percent error (MAPE) when testing the five predefined models. A small MAPE value is evidence for an adequate model; a large MAPE value results in the model being rejected. The MAPECR= value is the boundary for acceptance/rejection. Thus a larger MAPECR= value would make it easier for a model to pass the criteria. The default is MAPECR= 15. The MAPECR= option values must be between 1 and 100. See the section “[Criteria Details](#)” on page 2069 for further details on the MAPECR= option.

MAXITER= *n*

specifies the maximum number of iterations in the estimation process. MAXITER must be between 1 and 60; the default value is 15.

METHOD= CLS**METHOD=** ULS**METHOD=** ML

specifies the estimation method. ML requests maximum likelihood, ULS requests unconditional least squares, and CLS requests conditional least squares. METHOD=CLS is the default. The maximum likelihood estimates are more expensive to compute than the conditional least squares estimates. In some cases, however, they can be preferable. For further information on the estimation methods, see “[Estimation Details](#)” on page 248 in Chapter 7, “[The ARIMA Procedure](#).”

MODEL= (P=*n1* Q=*n2* SP=*n3* SQ=*n4* DIF=*n5* SDIF=*n6* < NOINT > < CENTER >)

specifies the ARIMA model. The AR and MA orders are given by P=*n1* and Q=*n2*, respectively, while the seasonal AR and MA orders are given by SP=*n3* and SQ=*n4*, respectively. The lag corresponding to seasonality is determined by the MONTHLY or QUARTERLY statement. Similarly, differencing and seasonal differencing are given by DIF=*n5* and SDIF=*n6*, respectively.

For example

```
arima model=( p=2 q=1 sp=1 dif=1 sdif=1 );
```

specifies a $(2,1,1)(1,1,0)_s$ model, where s , the seasonality, is either 12 (monthly) or 4 (quarterly). More examples of the MODEL= syntax are given in the section “[Details of Model Selection](#)” on page 2068.

NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

CENTER

centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

For example, to fit an AR(1) model on the centered data without an intercept, use the following ARIMA statement:

```
arima model=( p=1 center noint );
```

NOPRINT

suppresses the normal printout generated by the ARIMA statement. Note that the effect of specifying the NOPRINT option in the ARIMA statement is different from the effect of specifying the NOPRINT in the PROC X11 statement, since the former only affects ARIMA output.

OVDIFCR= value

specifies the criteria for the over-differencing test when testing the five predefined models. When the MA parameters in one of these models sum to a number close to 1.0, this is an indication of over-parameterization and the model is rejected. The OVDIFCR= value is the boundary for this rejection; values greater than this value fail the over-differencing test. A larger OVDIFCR= value would make it easier for a model to pass the criteria. The default is OVDIFCR= 0.90. The OVDIFCR= option values must be between 0.80 and 0.99. See the section “[Criteria Details](#)” on page 2069 for further details on the OVDIFCR= option.

PRINTALL

provides the same output as the default printing for all models fit and, in addition, prints an estimation summary and chi-square statistics for each model fit. See “[Printed Output](#)” on page 2074 for details.

PRINTFP

prints the results for the initial pass of X11 made to exclude trading-day effects. This option has an effect only when the TDREGR= option specifies ADJUST, TEST, or PRINT. In these cases, an initial pass of the standard X11 method is required to get rid of calendar effects before doing any ARIMA estimation. Usually this first pass is not of interest, and by default no tables are printed. However, specifying PRINTFP in the ARIMA statement causes any tables printed in the final pass to also be printed for this initial pass.

TRANSFORM= (LOG) | LOG**TRANSFORM= (constant ** power)**

The ARIMA statement in PROC X11 allows certain transformations on the series before estimation. The specified transformation is applied only to a user-specified model. If TRANSFORM= is specified and the MODEL= option is not specified, the transformation request is ignored and a warning is printed.

The LOG transformation requests that the natural log of the series be used for estimation. The resulting forecast values are transformed back to the original scale.

A general power transformation of the form $X_t \rightarrow (X_t + a)^b$ is obtained by specifying

```
transform= ( a ** b )
```

If the constant a is not specified, it is assumed to be zero. The specified ARIMA model is then estimated using the transformed series. The resulting forecast values are transformed back to the original scale.

BY Statement

BY *variables* ;

A BY statement can be used with PROC X11 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

ID Statement

ID *variables* ;

If you are creating an output data set, use the ID statement to put values of the ID variables, in addition to the table values, into the output data set. The ID statement has no effect when an output data set is not created. If the DATE= variable is specified in the MONTHLY or QUARTERLY statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable `_DATE_` is added.

The date variable (or `_DATE_`) values outside the range of the actual data (from ARIMA forecasting or backcasting, or from YRAHEADOUT) are extrapolated, while all other ID variables are missing.

MACURVES Statement

MACURVES *month=option ...* ;

The MACURVES statement specifies the length of the moving-average curves for estimating the seasonal factors for any month. This statement can be used only with monthly time series data.

The *month=option* specifications consist of the month name (or the first three letters of the month name), an equal sign, and one of the following option values:

'3'	specifies a three-term moving average for the month
'3X3'	specifies a three-by-three moving average
'3X5'	specifies a three-by-five moving average
'3X9'	specifies a three-by-nine moving average
STABLE	specifies a stable seasonal factor (average of all values for the month)

For example, the statement

```
macurves jan='3' feb='3x3' march='3x5' april='3x9';
```

uses a three-term moving average to estimate seasonal factors for January, a 3×3 (a three-term moving average of a three-term moving average) for February, a 3×5 (a three-term moving average of a five-term moving average) for March, and a 3×9 (a three-term moving average of a nine-term moving average) for April.

The numeric values used for the weights of the various moving averages and a discussion of the derivation of these weights are given in Shiskin, Young, and Musgrave (1967). A general discussion of moving average weights is given in Dagum (1985).

If the specification for a month is omitted, the X11 procedure uses a three-by-three moving average for the first estimate of each iteration and a three-by-five average for the second estimate.

MONTHLY Statement

MONTHLY options ;

The MONTHLY statement must be used when the input data to PROC X11 are a monthly time series. The MONTHLY statement specifies options that determine the computations performed by PROC X11 and what is included in its output. Either the DATE= or START= option must be used.

The following options can appear in the MONTHLY statement.

ADDITIVE

performs additive adjustments. If the ADDITIVE option is omitted, PROC X11 performs multiplicative adjustments.

CHARTS= STANDARD**CHARTS= FULL****CHARTS= NONE**

specifies the charts produced by the procedure. The default is CHARTS=STANDARD, which specifies 12 monthly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE.

The TABLES statement can also be used to specify particular monthly charts to be printed. If no CHARTS= option is given, and a TABLES statement is given, the TABLES statement overrides the default value of CHARTS=STANDARD; that is, no charts (or tables) are printed except those specified in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. You would specify the following statements:

```
monthly date=date;
tables g1 g4;
```

DATE= variable

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have 12 years of monthly data (144 observations, no missing values) beginning in January 1970 and ending in December 1981, and you wanted to seasonally adjust only six years beginning in January 1974. Specifying

```
monthly date=date start=jan1974 end=dec1979;
```

would seasonally adjust only this subset of the data. If instead you wanted to adjust the last eight years of data, only the START= option is needed:

```
monthly date=date start=jan1974;
```

END= mmmmyyyy

specifies that only the part of the input series ending with the month and year given be adjusted (for example, END=DEC1970). See the DATE=*variable* option for using the START= and END= options to subset a series for processing.

EXCLUDE= value

excludes from the trading-day regression any irregular values that are more than *value* standard deviations from the mean. The EXCLUDE=*value* must be between 0.1 and 9.9, with the default value being 2.5.

FULLWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= *value* (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The FULLWEIGHT=*value* must be between 0.1 and 9.9 but must be less than the ZEROWEIGHT=*value*. The default is FULLWEIGHT=1.5.

LENGTH

includes length-of-month allowance in computing trading-day factors. If this option is omitted, length-of-month allowances are included with the seasonal factors.

NDEC= *n*

specifies the number of decimal places shown in the printed tables in the listing. This option has no effect on the precision of the variable values in the output data set.

PMFACTOR= *variable*

specifies a variable containing the prior monthly factors. Use this option if you have previous knowledge of monthly adjustment factors. The PMFACTOR= option can be used to make the following adjustments:

- adjust the level of all or part of a series with discontinuities
- adjust for the influence of holidays that fall on different dates from year to year, such as the effect of Easter on certain retail sales
- adjust for unreasonable weather influence on series, such as housing starts
- adjust for changing starting dates of fiscal years (for budget series) or model years (for automobiles)
- adjust for temporary dislocating events, such as strikes

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2065 for details and examples using the PMFACTOR= option.

PRINTOUT= STANDARD | LONG | FULL | NONE

specifies the tables to be printed by the procedure. If the PRINTOUT=STANDARD option is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed; however, charts are still printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also be used to specify particular monthly tables to be printed. If no PRINTOUT= option is specified, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT=

option and a TABLES statement are specified, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= *mmmyyyy*

adjusts only the part of the input series starting with the specified month and year. When the DATE= option is not used, the START= option gives the year and month of the first input observation — for example, START=JAN1966. START= must be specified if DATE= is not given. If START= is specified (and no DATE= option is given), and an OUT= data set is requested, a variable named `_DATE_` is added to the data set, giving the date value for each observation. See the DATE= *variable* option for using the START= and END= options to subset a series.

SUMMARY

specifies that the data are already seasonally adjusted and the procedure is to produce summary measures. If the SUMMARY option is omitted, the X11 procedure performs seasonal adjustment of the input data before calculating summary measures.

TD COMPUTE= *year*

uses the part of the input series beginning with January of the specified year to derive trading-day weights. If this option is omitted, the entire series is used.

TDREGR= NONE | PRINT | ADJUST | TEST

specifies the treatment of trading-day regression. TDREG=NONE omits the computation of the trading-day regression. TDREG=PRINT computes and prints the trading-day regressions but does not adjust the series. TDREG=ADJUST computes and prints the trading-day regression and adjusts the irregular components to obtain preliminary weights. TDREG=TEST adjusts the final series if the trading-day regression estimates explain significant variation on the basis of an F test (or residual trading-day variation if prior weights are used). The default is TDREGR=NONE.

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2065 for details and examples using the TDREGR= option.

If ARIMA processing is requested, any value of TDREGR other than the default TDREGR=NONE will cause PROC X11 to perform an initial pass (see the “[Details: X11 Procedure](#)” on page 2056 section and the PRINTFP option).

The significance level reported in Table C15 should be viewed with caution. The dependent variable in the trading-day regression is the irregular component formed by an averaging operation. This induces a correlation in the dependent variable and hence in the residuals from which the F test is computed. Hence the distribution of the trading-day regression F statistics differs from an exact F ; see Cleveland and Devlin (1980) for details.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates in the first iteration. If the TRENDADJ option is omitted, the trend cycle is computed without modifications for extremes.

TRENDMA= 9 | 13 | 23

specifies the number of terms in the moving average to be used by the procedure in estimating

the variable trend cycle component. The value of the TRENDMA= option must be 9, 13, or 23. If the TRENDMA= option is omitted, the procedure selects an appropriate moving average. For information about the number of terms in the moving average, see Shiskin, Young, and Musgrave (1967).

ZEROWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The ZEROWEIGHT= value must be between 0.1 and 9.9 but must be greater than the FULLWEIGHT= value. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See [Example 31.3](#) later in this chapter for an illustration of this use.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set tablename=var1 var2 ... ;*

The OUTPUT statement creates an output data set containing specified tables. The data set is named by the OUT= option.

OUT= *SAS-data-set*

If OUT= is omitted, the SAS System names the new data set by using the DATA n convention.

For each table to be included in the output data set, write the X11 table identification keyword, an equal sign, and a list of new variable names:

tablename = var1 var2 ...

The *tablename* keywords that can be used in the OUTPUT statement are listed in the section “[Printed Output](#)” on page 2074. The following is an example of a VAR statement and an OUTPUT statement:

```
var z1 z2 z3;
output out=out_x11 b1=s d11=w x y;
```

The variable s contains the table B1 values for the variable z1, while the table D11 values for variables z1, z2, and z3 are contained in variables w, x, and y, respectively. As this example shows, the list of variables following a *tablename*= keyword can be shorter than the VAR variable list.

In addition to the variables named by *tablename =var1 var2 ...*, the ID variables, and BY variables, the output data set contains a date identifier variable. If the DATE= option is given

in the MONTHLY or QUARTERLY statement, the DATE= variable is the date identifier. If no DATE= option is given, a variable named `_DATE_` is the date identifier.

PDWEIGHTS Statement

PDWEIGHTS *day=w . . . ;*

The PDWEIGHTS statement can be used to specify one to seven daily weights. The statement can only be used with monthly series that are seasonally adjusted using the multiplicative model. These weights are used to compute prior trading-day factors, which are then used to adjust the original series prior to the seasonal adjustment process. Only relative weights are needed; the X11 procedure adjusts the weights so that they sum to 7.0. The weights can also be corrected by the procedure on the basis of estimates of trading-day variation from the input data.

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2065 for details and examples using the PDWEIGHTS statement.

Each *day=w* option specifies a weight (*w*) for the named day. The *day* can be any day, Sunday through Saturday. The *day* keyword can be the full spelling of the day, or the three-letter abbreviation. For example, SATURDAY=1.0 and SAT=1.0 are both valid. The weights *w* must be a numeric value between 0.0 and 10.0.

The following is an example of a PDWEIGHTS statement:

```
pdweights sun=.2 mon=.9 tue=1 wed=1 thu=1 fri=.8 sat=.3;
```

Any number of days can be specified with one PDWEIGHTS statement. The default weight value for any day that is not specified is 0. If you do not use a PDWEIGHTS statement, the program computes daily weights if TDREGR=ADJUST is specified. See Shiskin, Young, and Musgrave (1967) for details.

QUARTERLY Statement

QUARTERLY *options ;*

The QUARTERLY statement must be used when the input data are quarterly time series. This statement includes options that determine the computations performed by the procedure and what is in the printed output. The DATE= option or the START= option must be used.

The following options can appear in the QUARTERLY statement.

ADDITIVE

performs additive adjustments. If this option is omitted, the procedure performs multiplicative adjustments.

CHARTS= STANDARD**CHARTS= FULL****CHARTS= NONE**

specifies the charts to be produced by the procedure. The default value is CHARTS=STANDARD, which specifies four quarterly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE. The TABLES statement can also be used to specify particular charts to be printed. The presence of a TABLES statement overrides the default value of CHARTS=STANDARD; that is, if a TABLES statement is specified, and no CHARTS=option is specified, no charts (nor tables) are printed except those given in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. This is accomplished by specifying the following statements:

```
quarterly date=date;
tables g1 g4;
```

DATE= variable

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested, and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have a series with 10 years of quarterly data (40 observations, no missing values) beginning in '1970Q1' and ending in '1979Q4', and you want to seasonally adjust only four years beginning in '1974Q1' and ending in '1977Q4'. Specifying

```
quarterly date=variable start='1974q1' end='1977q4';
```

seasonally adjusts only this subset of the data. If instead you wanted to adjust the last six years of data, only the START= option is needed:

```
quarterly date=variable start='1974q1';
```

END= 'yyyyQq'

specifies that only the part of the input series ending with the quarter and year given be adjusted (for example, END='1973Q4'). The specification must be enclosed in quotes and *q* must be 1, 2, 3, or 4. See the DATE= variable option for using the START= and END= options to subset a series.

FULLWEIGHT= value

assigns weights to irregular values based on their distance from the mean in standard deviation

units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= value (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is FULLWEIGHT=1.5.

NDEC= *n*

specifies the number of decimal places shown on the output tables. This option has no effect on the precision of the variables in the output data set.

PRINTOUT= STANDARD

PRINTOUT= LONG

PRINTOUT= FULL

PRINTOUT= NONE

specifies the tables to print. If PRINTOUT=STANDARD is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also specify particular quarterly tables to be printed. If no PRINTOUT= is given, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are given, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= 'yyyyQq'

adjusts only the part of the input series starting with the quarter and year given. When the DATE= option is not used, the START= option gives the year and quarter of the first input observation (for example, START='1967Q1'). The specification must be enclosed in quotes, and *q* must be 1, 2, 3, or 4. START= must be specified if the DATE= option is not given. If START= is specified (and no DATE= is given), and an OUTPUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for a given observation. See the DATE= option for using the START= and END= options to subset a series.

SUMMARY

specifies that the input is already seasonally adjusted and that the procedure is to produce summary measures. If this option is omitted, the procedure performs seasonal adjustment of the input data before calculating summary measures.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates. If this option is omitted, the trend cycle is computed without modification for extremes.

ZEROWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See [Example 31.3](#) later in this chapter for an illustration of this use.

SSPAN Statement

SSPAN *options* ;

The SSPAN statement applies sliding spans analysis to determine the suitability of seasonal adjustment for an economic series.

The following options can appear in the SSPAN statement:

NDEC= *n*

specifies the number of decimal places shown on selected sliding span reports. This option has no effect on the precision of the variables values in the OUTSPAN output data set.

CUTOFF= *value*

gives the percentage value for determining an excessive difference within a span for the seasonal factors, the seasonally adjusted series, and month-to-month and year-to-year differences in the seasonally adjusted series. The default value is 3.0. The use of the CUTOFF=value in determining the maximum percent difference (MPD) is described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2062. Caution should be used in changing the default CUTOFF=value. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when value is changed.

TDCUTOFF= *value*

gives the percentage value for determining an excessive difference within a span for the trading-day factors. The default value is 2.0. The use of the TDCUTOFF=value in determining the maximum percent difference (MPD) is described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2062. Caution should be used in changing the default TDCUTOFF=value. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when the value is changed.

NOPRINT

suppresses all sliding span reports. See “[Computational Details for Sliding Spans Analysis](#)” on page 2062 for more details on sliding span reports.

PRINT

prints the summary sliding span reports S 0 through S 6.E.

PRINTALL

prints the summary sliding spans report S 0 through S 6.E, along with detail reports S 7.A through S 7.E.

TABLES Statement

TABLES *tablenames* ;

The TABLES statement prints the tables specified in addition to the tables that are printed as a result of the PRINTOUT= option in the MONTHLY or QUARTERLY statement. Table names are listed in [Table 31.4](#) later in this chapter.

To print only selected tables, omit the PRINTOUT= option in the MONTHLY or QUARTERLY statement and list the tables to be printed in the TABLES statement. For example, to print only the final seasonal factors and final seasonally adjusted series, use the statement

```
tables d10 d11;
```

VAR Statement

VAR *variables* ;

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those appearing in a BY or ID statement or the variable named in the DATE= option in the MONTHLY or QUARTERLY statement.

Details: X11 Procedure

Historical Development of X-11

This section briefly describes the historical development of the standard X-11 seasonal adjustment method and the later development of the X-11-ARIMA method. Most of the following discussion is based on a comprehensive article by Bell and Hillmer (1984), which describes the history of X-11 and the justification of using seasonal adjustment methods, such as X-11, given the current

availability of time series software. For further discussions about statistical problems associated with the X-11 method, see Ghysels (1990).

Seasonal adjustment methods began to be developed in the 1920s and 1930s, before there were suitable analytic models available and before electronic computing devices were in existence. The lack of any suitable model led to methods that worked the same for any series — that is, methods that were not model-based and that could be applied to any series. Experience with economic series had shown that a given mathematical form could adequately represent a time series only for a fixed length; as more data were added, the model became inadequate. This suggested an approach that used moving averages. For further analysis of the properties of X-11 moving averages, see Cleveland and Tiao (1976).

The basic method was to break up an economic time series into long-term trend, long-term cyclical movements, seasonal movements, and irregular fluctuations.

Early investigators found that it was not possible to uniquely decompose the trend and cycle components. Thus, these two were grouped together; the resulting component is usually referred to as the “trend cycle component.”

It was also found that estimating seasonal components in the presence of trend produced biased estimates of the seasonal components, but, at the same time, estimating trend in the presence of seasonality was difficult. This eventually led to the iterative approach used in the X-11 method.

Two other problems were encountered by early investigators. First, some economic series appear to have changing or evolving seasonality. Secondly, moving averages were very sensitive to extreme values. The estimation method used in the X-11 method allows for evolving seasonal components. For the second problem, the X-11 method uses repeated adjustment of extreme values.

All of these problems encountered in the early investigation of seasonal adjustment methods suggested the use of moving averages in estimating components. Even with the use of moving averages instead of a model-based method, massive amounts of hand calculations were required. Only a small number of series could be adjusted, and little experimentation could be done to evaluate variations on the method.

With the advent of electronic computing in the 1950s, work on seasonal adjustment methods proceeded rapidly. These methods still used the framework previously described; variants of these basic methods could now be easily tested against a large number of series.

Much of the work was done by Julian Shiskin and others at the U.S. Bureau of the Census beginning in 1954 and culminating after a number of variants into the *X-11 Variant of the Census Method II Seasonal Adjustment Program*, which PROC X11 implements.

References for this work during this period include Shiskin and Eisenpress (1957), Shiskin (1958), and Marris (1961). The authoritative documentation for the X-11 Variant is in Shiskin, Young, and Musgrave (1967). This document is not equivalent to a program specification; however, the FORTRAN code that implements the X-11 Variant is in the public domain. A less detailed description of the X-11 Variant is given in U.S. Bureau of the Census (1969).

Development of the X-11-ARIMA Method

The X-11 method uses symmetric moving averages in estimating the various components. At the end of the series, however, these symmetric weights cannot be applied. Either asymmetric weights have to be used, or some method of extending the series must be found.

While various methods of extending a series have been proposed, the most important method to date has been the X-11-ARIMA method developed at Statistics Canada. This method uses Box-Jenkins ARIMA models to extend the series.

The Time Series Research and Analysis Division of Statistics Canada investigated 174 Canadian economic series and found five ARIMA models out of twelve that fit the majority of series well and reduced revisions for the most recent months. References that give details of various aspects of the X-11-ARIMA methodology include Dagum (1980, 1982a, c, 1983, 1988), Laniel (1985), Lothian and Morry (1978a), and Huot et al. (1986).

Differences between X11ARIMA/88 and PROC X11

The original implementation of the X-11-ARIMA method was by Statistics Canada in 1980 (Dagum 1980), with later changes and enhancements made in 1988 (Dagum 1988). The calculations performed by PROC X11 differ from those in X11ARIMA/88, which will result in differences in the final component estimates provided by these implementations.

There are three areas where Statistics Canada made changes to the original X-11 seasonal adjustment method in developing X11ARIMA/80 (Monsell 1984). These are (a) selection of extreme values, (b) replacement of extreme values, and (c) generation of seasonal and trend cycle weights.

These changes have not been implemented in the current version of PROC X11. Thus the procedure produces results identical to those from previous versions of PROC X11 in the absence of an ARIMA statement.

Additional differences can result from the ARIMA estimation. X11ARIMA/88 uses conditional least squares (CLS), while CLS, unconditional least squares (ULS) and maximum likelihood (ML) are all available in PROC X11 by using the METHOD= option in the ARIMA statement. Generally, parameters estimates will differ for the different methods.

Implementation of the X-11 Seasonal Adjustment Method

The following steps describe the analysis of a monthly time series using multiplicative seasonal adjustment. Additional steps used by the X-11-ARIMA method are also indicated. Equivalent descriptions apply for an additive model if you replace *divide* with *subtract* where applicable.

In the multiplicative adjustment, the original series O_t is assumed to be of the form

$$O_t = C_t S_t I_t P_t D_t$$

where C_t is the trend cycle component, S_t is the seasonal component, I_t is the irregular component, P_t is the prior monthly factors component, and D_t is the trading-day component.

The trading-day component can be further factored as

$$D_t = D_{r,t} D_{tr,t},$$

where $D_{tr,t}$ are the trading-day factors derived from the prior daily weights, and $D_{r,t}$ are the residual trading-day factors estimated from the trading-day regression. For further information about estimating trading day variation, see Young (1965).

Additional Steps When Using the X-11-ARIMA Method

The X-11-ARIMA method consists of extending a given series by an ARIMA model and applying the usual X-11 seasonal adjustment method to this extended series. Thus in the simplest case in which there are no prior factors or calendar effects in the series, the ARIMA model selection, estimation, and forecasting are performed first, and the resulting extended series goes through the standard X-11 steps described in the next section.

If prior factor or calendar effects are present, they must be eliminated from the series before the ARIMA estimation is done because these effects are not stochastic.

Prior factors, if present, are removed first. Calendar effects represented by prior daily weights are then removed. If there are no further calendar effects, the adjusted series is extended by the ARIMA model, and this extended series goes through the standard X-11 steps without repeating the removal of prior factors and calendar effects from prior daily weights.

If further calendar effects are present, a trading-day regression must be performed. In this case it is necessary to go through an initial pass of the X-11 steps to obtain a final trading-day adjustment. In this initial pass, the series, adjusted for prior factors and prior daily weights, goes through the standard X-11 steps. At the conclusion of these steps, a final series adjusted for prior factors and all calendar effects is available. This adjusted series is then extended by the ARIMA model, and this extended series goes through the standard X-11 steps again, without repeating the removal of prior factors and calendar effects from prior daily weights and trading-day regression.

The Standard X-11 Seasonal Adjustment Method

The standard X-11 seasonal adjustment method consists of the following steps. These steps are applied to the original data or the original data extended by an ARIMA model.

1. In step 1, the data are read, ignoring missing values until the first nonmissing value is found. If prior monthly factors are present, the procedure reads prior monthly P_t factors and divides them into the original series to obtain $O_t/P_t = C_t S_t I_t D_{tr,t} D_{r,t}$.
Seven daily weights can be specified to develop monthly factors to adjust the series for trading-day variation, $D_{tr,t}$; these factors are then divided into the original or prior adjusted series to obtain $C_t S_t I_t D_{r,t}$.
2. In steps 2, 3, and 4, three iterations are performed, each of which provides estimates of the seasonal S_t , trading-day $D_{r,t}$, trend cycle C_t , and irregular components I_t . Each iteration refines estimates of the extreme values in the irregular components. After extreme values are

identified and modified, final estimates of the seasonal component, seasonally adjusted series, trend cycle, and irregular components are produced. Step 2 consists of three substeps:

- a) During the first iteration, a centered, 12-term moving average is applied to the original series O_t to provide a preliminary estimate \hat{C}_t of the trend cycle curve C_t . This moving average combines 13 (a 2-term moving average of a 12-term moving average) consecutive monthly values, removing the S_t and I_t . Next, it obtains a preliminary estimate $\widehat{S_t I_t}$ by

$$\widehat{S_t I_t} = \frac{O_t}{\hat{C}_t}$$

- b) A moving average is then applied to the $\widehat{S_t I_t}$ to obtain an estimate \hat{S}_t of the seasonal factors. $\widehat{S_t I_t}$ is then divided by this estimate to obtain an estimate \hat{I}_t of the irregular component. Next, a moving standard deviation is calculated from the irregular component and is used in assigning a weight to each monthly value for measuring its degree of extremeness. These weights are used to modify extreme values in $\widehat{S_t I_t}$. New seasonal factors are estimated by applying a moving average to the modified value of $\widehat{S_t I_t}$. A preliminary seasonally adjusted series is obtained by dividing the original series by these new seasonal factors. A second estimate of the trend cycle is obtained by applying a weighted moving average to this seasonally adjusted series.
- c) The same process is used to obtain second estimates of the seasonally adjusted series and improved estimates of the irregular component. This irregular component is again modified for extreme values and then used to provide estimates of trading-day factors and refined weights for the identification of extreme values.
3. Using the same computations, a second iteration is performed on the original series that has been adjusted by the trading-day factors and irregular weights developed in the first iteration. The second iteration produces final estimates of the trading-day factors and irregular weights.
4. A third and final iteration is performed using the original series that has been adjusted for trading-day factors and irregular weights computed during the second iteration. During the third iteration, PROC X11 develops final estimates of seasonal factors, the seasonally adjusted series, the trend cycle, and the irregular components. The procedure computes summary measures of variation and produces a moving average of the final adjusted series.

Sliding Spans Analysis

The motivation for sliding spans analysis is to answer the question, When is a economic series unsuitable for seasonal adjustment? There have been a number of past attempts to answer this question: stable seasonality F test; moving seasonality F test, Q statistics, and others.

Sliding spans analysis attempts to quantify the stability of the seasonal adjustment process, and hence quantify the suitability of seasonal adjustment for a given series.

It is based on a very simple idea: for a stable series, deleting a small number of observations should not result in greatly different component estimates compared with the original, full series. Conversely, if deleting a small number of observations results in drastically different estimates, the series is unstable. For example, a drastic difference in the seasonal factors (Table D10) might result

from a dominating irregular component or sudden changes in the seasonally component. When the seasonal component estimates of a series is unstable in this manner, they have little meaning and the series is likely to be unsuitable for seasonal adjustment.

Sliding spans analysis, developed at the Statistical Research Division of the U.S. Census Bureau (Findley et al. 1990; Findley and Monsell 1986), performs a repeated seasonal adjustment on subsets or spans of the full series. In particular, an initial span of the data, typically eight years in length, is seasonally adjusted, and the Tables C18, the trading-day factors (if trading-day regression performed), D10, the seasonal factors, and D11, the seasonally adjusted series are retained for further processing. Next, one year of data is deleted from the beginning of the initial span and one year of data is added. This new span is seasonally adjusted as before, with the same tables retained. This process continues until the end of the data is reached. The beginning and ending dates of the spans are such that the last observation in the original data is also the last observation in the last span. This is discussed in more detail in the following paragraphs.

The following notation for the components or differences computed in the sliding spans analysis follows Findley et al. (1990). The meaning for the symbol $X_t(k)$ is component X in month (or quarter) t , computed from data in the k th span. These components are now defined.

- Seasonal Factors (Table D10): $S_t(k)$
- Trading-Day Factors (Table C18): $TD_t(k)$
- Seasonally Adjusted Data (Table D11): $SA_t(k)$
- Month-to-Month Changes in the Seasonally Adjusted Data: $MM_t(k)$
- Year-to-Year Changes in the Seasonally Adjusted Data: $YY_t(k)$

The key measure is the maximum percent difference across spans. For example, consider a series that begins in January 1972, ends in December 1984, and has four spans, each of length 8 years (see Figure 1 in Findley et al. (1990), p. 346). Consider $S_t(k)$ the seasonal factor (Table D10) for month t for span k , and let N_t denote the number of spans containing month t ; that is,

$$N_t = \{k : \text{span } k \text{ contains month } t\}$$

In the middle years of the series there is overlap of all four spans, and N_t will be 4. The last year of the series will have only one span, while the beginning can have 1 or 0 spans depending on the original length.

Since we are interested in how much the seasonal factors vary for a given month across the spans, a natural quantity to consider is

$$\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)$$

In the case of the multiplicative model, it is useful to compute a percentage difference; define the maximum percentage difference (MPD) at time t as

$$MPD_t = \frac{\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)}{\min_{k \in N_t} S_t(k)}$$

The seasonal factor for month t is then unreliable if MPD_t is large. While no exact significance level can be computed for this statistic, empirical levels have been established by considering over 500 economic series (Findley et al. 1990; Findley and Monsell 1986). For these series it was found that for four spans, stable series typically had less than 15% of the MPD values exceeding 3.0%, while in marginally stable series, between 15% and 25% of the MPD values exceeded 3.0%. A series in which 25% or more of the MPD values exceeded 3.0% is almost always unstable.

While these empirical values cannot be considered an exact significance level, they provide a useful empirical basis for deciding if a series is suitable for seasonal adjustment. These percentage values are shifted down when fewer than four spans are used.

Computational Details for Sliding Spans Analysis

Length and Number of Spans

The algorithm for determining the length and number of spans for a given series was developed at the U.S. Bureau of the Census, Statistical Research Division. A summary of this algorithm is as follows.

First, an initial length based on the MACURVE *month=option* specification is determined, and then the maximum number of spans possible using this length is determined. If this maximum number exceeds four, set the number of spans to four. If this maximum number is one or zero, there are not enough observations to perform the sliding spans analysis. In this case a note is written to the log and the sliding spans analysis is skipped for this variable.

If the maximum number of spans is two or three, the actual number of spans used is set equal to this maximum. Finally, the length is adjusted so that the spans begin in January (or the first quarter) of the beginning year of the span.

The remainder of this section gives the computation formulas for the maximum percentage difference (MPD) calculations along with the threshold regions.

Seasonal Factors (Table D10)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)}{\min_{k \in N_t} S_t(k)}$$

A series for which less than 15% of the MPD values of D10 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% is unstable. Span reports S 2.A through S 2.C give the various breakdowns for the number of times the MPD exceeded these levels.

Trading Day Factor (Table C18)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} TD_t(k) - \min_{k \in N_t} TD_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{\max_{k \in N_t} TD_t(k) - \min_{k \in N_t} TD_t(k)}{\min_{k \in N_t} TD_t(k)}$$

The U.S. Census Bureau currently gives no recommendation concerning MPD thresholds for the trading-day factors. Span reports S 3.A through S 3.C give the various breakdowns for MPD thresholds. When TDREGR=NONE is specified, no trading-day computations are done, and this table is skipped.

Seasonally Adjusted Data (Table D11)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} SA_t(k) - \min_{k \in N_t} SA_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{\max_{k \in N_t} SA_t(k) - \min_{k \in N_t} SA_t(k)}{\min_{k \in N_t} SA_t(k)}$$

A series for which less than 15% of the MPD values of D11 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% is unstable. Span reports S 4.A through S 4.C give the various breakdowns for the number of times the MPD exceeded these levels.

Month-to-Month Changes in the Seasonally Adjusted Data

Some additional notation is needed for the month-to-month and year-to-year differences. Define $N1_t$ as

$$N1_t = \{k : \text{span } k \text{ contains month } t \text{ and } t - 1\}$$

For the additive model, the month-to-month change for span k is defined as

$$MM_t(k) = SA_t - SA_{t-1}$$

while for the multiplicative model

$$MM_t(k) = \frac{SA_t - SA_{t-1}}{SA_{t-1}}$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined as

$$MPD_t = \max_{k \in N_{1t}} MM_t(k) - \min_{k \in N_{1t}} MM_t(k)$$

The current recommendation of the U.S. Census Bureau is that if 35% or more of the MPD values of the month-to-month differences of D11 exceed 3.0%, then the series is usually not stable; 40% exceeding this level clearly marks an unstable series. Span reports S 5.A.1 through S 5.C give the various breakdowns for the number of times the MPD exceeds these levels.

Year-to-Year Changes in the Seasonally Adjusted Data

First define N_{12t} as

$$N_{12t} = \{k : \text{span } k \text{ contains month } t \text{ and } t - 12\}$$

(Appropriate changes in notation for a quarterly series are obvious.)

For the additive model, the month-to-month change for span k is defined as

$$YY_t(k) = SA_t - SA_{t-12}$$

while for the multiplicative model

$$YY_t(k) = \frac{SA_t - SA_{t-12}}{SA_{t-12}}$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined as

$$MPD_t = \max_{k \in N_{1t}} YY_t(k) - \min_{k \in N_{1t}} YY_t(k)$$

The current recommendation of the U.S. Census Bureau is that if 10% or more of the MPD values of the month-to-month differences of D11 exceed 3.0%, then the series is usually not stable. Span reports S 6.A through S 6.C give the various breakdowns for the number of times the MPD exceeds these levels.

Data Requirements

The input data set must contain either quarterly or monthly time series, and the data must be in chronological order. For the standard X-11 method, there must be at least three years of observations (12 for quarterly time series or 36 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

For the X-11-ARIMA method, there must be at least five years of observations (20 for quarterly time series or 60 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

Missing Values

Missing values at the beginning of a series to be adjusted are skipped. Processing starts with the first nonmissing value and continues until the end of the series or until another missing value is found.

Missing values are not allowed for the DATE= variable. The procedure terminates if missing values are found for this variable.

Missing values found in the PMFACTOR= variable are replaced by 100 for the multiplicative model (default) and by 0 for the additive model.

Missing values can occur in the output data set. If the time series specified in the OUTPUT statement is not computed by the procedure, the values of the corresponding variable are missing. If the time series specified in the OUTPUT statement is a moving average, the values of the corresponding variable are missing for the first n and last n observations, where n depends on the length of the moving average. Additionally, if the time series specified is an irregular component modified for extremes, only the modified values are given, and the remaining values are missing.

Prior Daily Weights and Trading-Day Regression

Suppose that a detailed examination of retail sales at ZXY Company indicates that certain days of the week have higher amounts of sales. In particular, Thursday, Friday, and Saturday have approximately twice the amount of sales as Monday, Tuesday, and Wednesday, and no sales occur on Sunday. This means that months with five Saturdays would have higher amounts of sales than months with only four Saturdays.

This phenomenon is called a calendar effect; it can be handled in PROC X11 by using the PDWEIGHTS (prior daily weights) statement or the TDREGR=option (trading-day regression). The PDWEIGHTS statement and the TDREGR=option can be used separately or together.

If the relative weights are known (as in the preceding) it is appropriate to use the PDWEIGHTS statement. If further residual calendar variation is present, TDREGR=ADJUST should also be used. If you know that a calendar effect is present, but know nothing about the relative weights, use TDREGR=ADJUST without a PDWEIGHTS statement.

In this example, it is assumed that the calendar variation is due to both prior daily weights and residual variation. Thus both a PDWEIGHTS statement and TDREGR=ADJUST are specified.

Note that only the relative weights are needed; in the actual computations, PROC X11 normalizes the weights to sum to 7.0. If a day of the week is not present in the PDWEIGHTS statement, it is given a value of zero. Thus “sun=0” is not needed.

```
proc x11 data=sales;
  monthly date=date tdregr=adjust;
  var sales;
  tables a1 a4 b15 b16 C14 C15 c18 d11;
  pdweights mon=1 tue=1 wed=1 thu=2 fri=2 sat=2;
```

```

output out=x11out a1=a1 a4=a4 b1=b1 c14=c14
          c16=c16 c18=c18 d11=d11;
run;

```

Tables of interest include A1, A4, B15, B16, C14, C15, C18, and D11. Table A4 contains the adjustment factors derived from the prior daily weights; Table C14 contains the extreme irregular values excluded from trading-day regression; Table C15 contains the trading-day-regression results; Table C16 contains the monthly factors derived from the trading-day regression; and Table C18 contains the final trading-day factors derived from the combined daily weights. Finally, Table D11 contains the final seasonally adjusted series.

Adjustment for Prior Factors

Suppose now that a strike at ZXY Company during July and August of 1988 caused sales to decrease an estimated 50%. Since this is a one-time event with a known cause, it is appropriate to prior adjust the data to reflect the effects of the strike. This is done in PROC X11 through the use of `PMFACTOR=varname` (prior monthly factor) in the `MONTHLY` statement.

In the following example, the `PMFACTOR` variable is named `PMF`. Since the estimate of the decrease in sales is 50%, `PMF` has a value of 50.0 for the observations corresponding to July and August 1988, and a value of 100.0 for the remaining observations.

This prior adjustment on `SALES` is performed by replacing `SALES` with the calculated value $(\text{SALES}/\text{PMF}) * 100.0$. A value of 100.0 for `PMF` leaves `SALES` unchanged, while a value of 50.0 for `PMF` doubles `SALES`. This value is the estimate of what `SALES` would have been without the strike. The following example shows how this prior adjustment is accomplished.

```

data sales2;
  set sales;
  if '01jul1988'd <= date <= '01aug1988'd then pmf = 50;
  else pmf = 100;
run;

proc x11 data=sales2;
  monthly date=date pmfactor=pmf;
  var sales;
  tables a1 a2 a3 d11;
  output out=x11out a1=a1 a2=a2 a3=a3 d11=d11;
run;

```

Table A2 contains the prior monthly factors (the values of `PMF`), and Table A3 contains the prior adjusted series.

The YRAHEADOUT Option

For monthly data, the YRAHEADOUT option affects only Tables C16 (regression trading-day adjustment factors), C18 (trading-day factors from combined daily weights), and D10 (seasonal factors). For quarterly data, only Table D10 is affected. Variables for all other tables have missing values for the forecast observations. The forecast values for a table are included only if that table is specified in the OUTPUT statement.

Tables C16 and C18 are calendar effects that are extrapolated by calendar composition. These factors are independent of the data once trading-day weights have been calculated. Table D10 is extrapolated by a linear combination of past values. If N is the total number of nonmissing observations for the analysis variable, this linear combination is given by

$$D10_t = \frac{1}{2}(3 \times D10_{t-12} - D10_{t-24}), \quad t = N + 1, \dots, N + 12$$

If the input data are monthly time series, 12 extra observations are added to the end of the output data set. (If a BY statement is used, 12 extra observations are added to the end of each BY group.) If the input data are a quarterly time series, four extra observations are added to the end of the output data set. (If a BY statement is used, four extra observations are added to each BY group.)

The DATE= variable (or _DATE_) is extrapolated for the extra observations generated by the YRAHEADOUT option, while all other ID variables will have missing values.

If ARIMA processing is requested, and if both the OUTEXTRAP and YRAHEADOUT options are specified in the PROC X11 statement, an additional 12 (or 4) observations are added to the end of output data set for monthly (or quarterly) data after the ARIMA forecasts, using the same linear combination of past values as before.

Effect of Backcast and Forecast Length

Based on a number of empirical studies (Dagum 1982a, b, c; Dagum and Laniel 1987), one year of forecasts minimize revisions when new data become available. Two and three years of forecasts show only small gains.

Backcasting improves seasonal adjustment but introduces permanent revisions at the beginning of the series and also at the end for series of length 8, 9, or 10 years. For series shorter than 7 years, the advantages of backcasting outweigh the disadvantages (Dagum 1988).

Other studies (Pierce 1980; Bobbit and Otto 1990; Buszuwski 1987) suggest “full forecasting”—that is, using enough forecasts to allow symmetric weights for the seasonal moving averages for the most current data. For example, if a 3×9 seasonal moving average was specified for one or more months by using the MACURVES statement, five years of forecasts would be required. This is because the seasonal moving averages are performed on calendar months separately, and the 3×9 is an 11-term centered moving average, requiring five observations before and after the current observation. Thus

```
macurves dec='3x9' ;
```

would require five additional December values to compute the seasonal moving average.

Details of Model Selection

If an ARIMA statement is present but no MODEL= is given, PROC X11 estimates and forecasts five predefined models and selects the best. This section describes the details of the selection criteria and the selection process.

The five predefined models used by PROC X11 are the same as those used by X11ARIMA/88 from Statistics Canada. These particular models, shown in Table 31.2, were chosen on the basis of testing a large number of economics series (Dagum 1988) and should provide reasonable forecasts for most economic series.

Table 31.2 Five Predefined Models

Model #	Specification	Multiplicative	Additive
1	(0,1,1)(0,1,1)s	log transform	no transform
2	(0,1,2)(0,1,1)s	log transform	no transform
3	(2,1,0)(0,1,1)s	log transform	no transform
4	(0,2,2)(0,1,1)s	log transform	no transform
5	(2,1,2)(0,1,1)s	no transform	no transform

The selection process proceeds as follows. The five models are estimated and one-step-ahead forecasts are produced in the order shown in Table 31.2. As each model is estimated, the following three criteria are checked:

- The mean absolute percent error (MAPE) for the last three years of the series must be less than 15%.
- The significance probability for the Box-Ljung chi-square for up to lag 24 for monthly (8 for quarterly) must be greater than 0.05.
- The over-differencing criteria must not exceed 0.9.

The descriptions of these three criteria are given in the section “Criteria Details” on page 2069. The default values for these criteria are those used by X11ARIMA/88 from Statistics Canada; these defaults can be changed by the MAPECR=, CHICR=, and OVDIFCR= options.

A model that fails any one of these three criteria is excluded from further consideration. In addition, if the ARIMA estimation fails for a given model, a warning is issued, and the model is excluded. The final set of all models considered consists of those that pass all three criteria and are estimated successfully. From this set, the model with the smallest MAPE for the last three years is chosen.

If all five models fail, ARIMA processing is skipped for the variable being processed, and the standard X-11 seasonal adjustment is performed. A note is written to the log with this information.

The chosen model is then used to forecast the series one or more years (determined by the FORECAST= option in the ARIMA statement). These forecasts are appended to the original data (or the prior and calendar-adjusted data).

If a BACKCAST= option is specified, the chosen model form is used, but the parameters are reestimated using the reversed series. Using these parameters, the reversed series is forecast for the number of years specified by the BACKCAST= option. These forecasts are then reversed and appended to the beginning of the original series, or the prior and calendar-adjusted series, to produce the backcasts.

Note that the final selection rule (the smallest MAPE using the last three years) emphasizes the quality of the forecasts at the end of the series. This is consistent with the purpose of the X-11-ARIMA methodology, which is to improve the estimates of seasonal factors and thus minimize revisions to recent past data as new data become available.

Criteria Details

Mean Absolute Percent Error (MAPE)

For the MAPE criteria testing, only the last three years of the original series (or prior and calendar adjusted series) is used in computing the MAPE.

Let y_t , $t = 1, \dots, n$, be the last three years of the series, and denote its one-step-ahead forecast by \hat{y}_t , where $n = 36$ for a monthly series and $n = 12$ for a quarterly series.

With this notation, the MAPE criteria are computed as

$$MAPE = \frac{100}{n} \sum_{t=1}^n \frac{|y_t - \hat{y}_t|}{|y_t|}$$

Box-Ljung Chi-Square

The Box-Ljung chi-square is a lack-of-fit test based on the model residuals. This test statistic is computed using the Ljung-Box formula

$$\chi_m^2 = n(n+2) \sum_{k=1}^m \frac{r_k^2}{(n-k)}$$

where n is the number of residuals that can be computed for the time series, and

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^n a_t^2}$$

where the a_t 's are the residual sequence. This formula has been suggested by Ljung and Box (1978) as yielding a better fit to the asymptotic chi-square distribution. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977) and by Ljung and Box (1978).

For monthly series, $m = 24$, while for quarterly series, $m = 8$.

Over-Differencing Test

From Table 31.2 you can see that all models have a single seasonal MA factor and at most two nonseasonal MA factors. Also, all models have seasonal and nonseasonal differencing. Consider model 2 applied to a monthly series y_t with $E(y_t) = \mu$:

$$(1 - B^1)(1 - B^{12})(y_t - \mu) = (1 - \theta_1 B - \theta_2 B^2)(1 - \theta_3 B^{12})a_t$$

If $\theta_3 = 1.0$, then the factors $(1 - \theta_3 B^{12})$ and $(1 - B^{12})$ will cancel, resulting in a lower-order model.

Similarly, if $\theta_1 + \theta_2 = 1.0$,

$$(1 - \theta_1 B - \theta_2 B^2) = (1 - B)(1 - \alpha B)$$

for some $\alpha \neq 0.0$. Again, this results in cancellation and a lower-order model.

Since the parameters are not exact, it is not reasonable to require that

$$\theta_3 < 1.0 \text{ and } \theta_1 + \theta_2 < 1.0$$

Instead, an approximate test is performed by requiring that

$$\theta_3 \leq 0.9 \text{ and } \theta_1 + \theta_2 \leq 0.9$$

The default value of 0.9 can be changed by the OVDIFCR= option. Similar reasoning applies to the other models.

ARIMA Statement Options for the Five Predefined Models

Table 31.3 lists the five predefined models and gives the equivalent MODEL= parameters in a PROC X11 ARIMA statement.

In all models except the fifth, a log transformation is performed before the ARIMA estimation for the multiplicative case; no transformation is performed for the additive case. For the fifth model, no transformation is done for either case.

The multiplicative case is assumed in the following table. The indicated seasonality s in the specification is either 12 (monthly) or 4 (quarterly). The MODEL statement assumes a monthly series.

Table 31.3 ARIMA Statements Options for Predefined Models

Model	ARIMA Statement Options
(0,1,1)(0,1,1) _s	MODEL=(Q=1 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(0,1,2)(0,1,1) _s	MODEL=(Q=2 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(2,1,0)(0,1,1) _s	MODEL=(P=2 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(0,2,2)(0,1,1) _s	MODEL=(Q=2 SQ=1 DIF=2 SDIF=1) TRANSFORM=LOG
(2,1,2)(0,1,1) _s	MODEL=(P=2 Q=2 SQ=1 DIF=1 SDIF=1)

OUT= Data Set

The OUT= data set specified in the OUTPUT statement contains the BY variables, if any; the ID variables, if any; and the DATE= variable if the DATE= option is given, or `_DATE_` if the DATE= option is not specified.

In addition, the variables specified by the option

tablename =var1 var2 ... varn

are placed in the OUT= data set. A list of tables available for monthly and quarterly series is given later, in [Table 31.4](#).

The OUTSPAN= Data Set

The OUTSPAN= option is specified in the PROC statement, and writes the sliding spans results to the specified output data set. The OUTSPAN= data set contains the following variables:

- A1, a numeric variable that is a copy of the original series truncated to the current span. Note that overlapping spans will contain identical values for this variable.
- C18, a numeric variable that contains the trading-day factors for the seasonal adjustment for the current span
- D10, a numeric variable that contains the seasonal factors for the seasonal adjustment for the current span
- D11, a numeric variable that contains the seasonally adjusted series for the current span
- DATE, a numeric variable that contains the date within the current span
- SPAN, a numeric variable that contains the current span. The first span is the earliest span—that is the one with the earliest starting date.
- VARNAME, a character variable containing the name of each variable in the VAR list. A separate sliding spans analysis is performed on each variable in the VAR list.

OUTSTB= Data Set

The output data set produced by the OUTSTB= option of the PROC X11 statement contains the information in the analysis of variance on table D8 (Final Unmodified S-I Ratios). This analysis of variance, following table D8 in the printed output, tests for stable seasonality (Shiskin, Young, and Musgrave 1967, Appendix A). These data contain the following variables:

- VARNAME, a character variable containing the name of each variable in the VAR list
- TABLE, a character variable specifying the table from which the analysis of variance is performed. When ARIMA processing is requested, and two passes of X11 are required (when TDREGR=PRINT, TEST, or ADJUST), Table D8 and the stable seasonality test are computed twice: once in the initial pass, then again in the final pass. Both of these computations are put in the OUTSTB data set and are identified by D18.1 and D18.2, respectively.
- SOURCE, a character variable corresponding to the “source” column in the analysis of variance table following Table D8
- SS, a numeric variable containing the sum of squares associated with the corresponding source term
- DF, a numeric variable containing the degrees of freedom associated with the corresponding source term
- MS, a numeric variable containing the mean square associated with the corresponding source term. MS is missing for the source term “Total”
- F, a numeric variable containing the F statistic for the “Between” source term. F is missing for all other source terms.
- PROBF, a numeric variable containing the significance level for the F statistic. PROBF is missing for the source terms “Total” and “Error.”

OUTTDR= Data Set

The trading-day regression results (tables B15 and C15) are written to the OUTTDR= data set, which contains the following variables:

- VARNAME, a character variable containing the name of the VAR variable being processed
- TABLE, a character variable containing the name of the table. It can have only the value B15 (Preliminary Trading-Day Regression) or C15 (Final Trading-Day Regression).
- _TYPE_, a character variable whose value distinguishes the three distinct table format types. These types are (a) the regression, (b) the listing of the standard error associated with length-of-month, and (c) the analysis of variance. The first seven observations in the OUTTDR data set correspond to the regression on days of the week; thus the _TYPE_ variable is given the value “REGRESS” (day-of-week regression coefficient). The next four observations correspond to 31-, 30-, 29-, and 28-day months and are given the value _TYPE_=LOM_STD (length-of-month standard errors). Finally, the last three observations correspond to the analysis of variance table, and _TYPE_=ANOVA.
- PARM, a character variable, further identifying the nature of the observation. PARM is set to blank for the three _TYPE_=ANOVA observations.

- SOURCE, a character variable containing the source in the regression. This variable is missing for all `_TYPE_=REGRESS` and `LOM_STD`.
- CWGT, a numeric variable containing the combined trading-day weight (prior weight + weight found from regression). The variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- PRWGT, a numeric variable containing the prior weight. The prior weight is 1.0 if PDWEIGHTS are not specified. This variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- COEFF, a numeric variable containing the calculated regression coefficient for the given day. This variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- STDERR, a numeric variable containing the standard errors. For observations with `_TYPE_=REGRESS`, this is the standard error corresponding to the regression coefficient. For observations with `_TYPE_=LOM_STD`, this is standard error for the corresponding length-of-month. This variable is missing for all `_TYPE_=ANOVA`.
- T1, a numeric variable containing the t statistic corresponding to the test that the combined weight is different from the prior weight. This variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- T2, a numeric variable containing the t statistic corresponding to the test that the combined weight is different from 1.0. This variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- PROBT1, a numeric variable containing the significance level for t statistic T1. The variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- PROBT2, a numeric variable containing the significance level for t statistic T2. The variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- SS, a numeric variable containing the sum of squares associated with the corresponding source term. This variable is missing for all `_TYPE_=REGRESS` and `LOM_STD`.
- DF, a numeric variable containing the degrees of freedom associated with the corresponding source term. This variable is missing for all `_TYPE_=REGRESS` and `LOM_STD`.
- MS, a numeric variable containing the mean square associated with the corresponding source term. This variable is missing for the source term 'Total' and for all `_TYPE_=REGRESS` and `LOM_STD`.
- F, a numeric variable containing the F statistic for the 'Regression' source term. The variable is missing for the source terms 'Total' and 'Error', and for all `_TYPE_=REGRESS` and `LOM_STD`.
- PROBF, a numeric variable containing the significance level for the F statistic. This variable is missing for the source term 'Total' and 'Error' and for all `_TYPE_=REGRESS` and `LOM_STD`.

Printed Output

The output from PROC X11, both printed tables and the series written to the OUT= data set, depends on whether the data are monthly or quarterly. For the printed tables, the output depends further on the value of the PRINTOUT= option and the TABLE statement, along with other options specified.

The printed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X11 procedure are as follows:

A	prior adjustments (optional)
B	preliminary estimates of irregular component weights and regression trading-day factors
C	final estimates of irregular component weights and regression trading-day factors
D	final estimates of seasonal, trend cycle, and irregular components
E	analytical tables
F	summary measures
G	charts

Table 31.4 describes the individual tables and charts. Most tables apply both to quarterly and monthly series. Those that apply only to a monthly time series are indicated by an “M” in the notes section, while “P” indicates the table is not a time series, and is only printed, not output to the OUT= data set.

Table 31.4 Table Names and Descriptions

Table	Description	Notes
A1	original series	M
A2	prior monthly adjustment factors	M
A3	original series adjusted for prior monthly factors	M
A4	prior trading-day adjustments	M
A5	prior adjusted or original series	M
A13	ARIMA forecasts	
A14	ARIMA backcasts	
A15	prior adjusted or original series extended by ARIMA backcasts and forecasts	
B1	prior adjusted or original series	
B2	trend cycle	
B3	unmodified seasonal-irregular (S-I) ratios	
B4	replacement values for extreme S-I ratios	
B5	seasonal factors	
B6	seasonally adjusted series	
B7	trend cycle	
B8	unmodified S-I ratios	
B9	replacement values for extreme S-I ratios

The PRINTOUT= Option

The PRINTOUT= option controls printing for groups of tables. See the “[TABLES Statement](#)” on page 2056 for details on specifying individual tables. The following list gives the tables printed for each value of the PRINTOUT= option:

STANDARD (26 tables)	A1–A4, B1, C13–C19, D8–D13, E1–E6, F1, F2
LONG (40 tables)	A1–A5, A13–A15, B1, B2, B7, B10, B13–B15, C1, C7, C10, C13–C19, D1, D7–D11, D13, E1–E6, F1, F2
FULL (62 tables)	A1–A5, A13–A15, B1–B11, B13–B19, C1–C11, C13–C19, D1, D2, D4–D12, E1–E6, F1, F2

The actual number of tables printed depends on the options and statements specified. If a table is not computed, it is not printed. For example, if TDREGR=NONE is specified, none of the tables associated with the trading-day are printed.

The CHARTS= Option

Of the four charts listed in [Table 31.4](#), G1 and G2 are printed by default (CHARTS=STANDARD). Charts G3 and G4 are printed when CHARTS=FULL is specified. See the “[TABLES Statement](#)” on page 2056 for details on specifying individual charts.

Stable, Moving, and Combined Seasonality Tests on the Final Unmodified SI Ratios (Table D8)

PROC X11 displays four tests used to identify stable seasonality and moving seasonality and to measure identifiable seasonality. These tests are displayed after Table D8. They are “Stable Seasonality Test,” “Moving Seasonality Test,” “Nonparametric Test for the Presence of Seasonality Assuming Stability,” and “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” The motivation, interpretation, and statistical details of all these tests are now given.

Motivation

The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality). If the increase in the seasonal factors from year to year is too large, then the seasonal factors will introduce distortion into the model. It is important to determine if seasonality is identifiable without distorting the series.

To determine if stable seasonality is present in a series, PROC X11 computes a one-way analysis of variance by using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use because the removal of the trend cycle is equivalent to detrending. PROC X11 prints this test, labeled “Stable Seasonality Test,” immediately after the Table D8.

The X11 seasonal adjustment method tests for moving seasonality. Moving seasonality can be a source of distortion when seasonal factors are used in the model. PROC X11 computes and prints a test for moving seasonality. The test is a two-way analysis of variance that uses months (or quarters) and years. As in the “Stable Seasonality Test,” this analysis of variance is performed on the Final Unmodified SI Ratios (Table D8). PROC X11 prints this test, labeled “Moving Seasonality Test,” after the “Stable Seasonality Test.”

PROC X11 next computes a nonparametric Kruskal-Wallis chi-squared test for stable seasonality, “Nonparametric Test for the Presence of Seasonality Assuming Stability.” The Kruskal-Wallis test is performed on the ranks of the Final Unmodified SI Ratios (Table D8). For further details about the Kruskal-Wallis test, see Lehmann (1998, pp. 204–210).

The results of the preceding three tests are combined into a joint test to measure identifiable seasonality, “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” This test combines the two F tests previously described, along with the Kruskal-Wallis chi-squared test for stable seasonality, to determine “identifiable” seasonality. This test is printed after “Nonparametric Test for the Presence of Seasonality Assuming Stability.”

Interpretation and Statistical Details

The “Stable Seasonality Test” is a one-way analysis of variance on the “Final Unmodified SI Ratios” with seasons (months or quarters) as the factor.

To determine whether stable seasonality is present in a series, PROC X11 computes a one-way analysis of variance by using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use because the removal of the trend cycle is similar to detrending.

A large F statistic and a small significance level are evidence that a significant amount of variation in the SI-ratios is due to months or quarters, which in turn is evidence of seasonality; the null hypothesis of no month/quarter effect is rejected.

Conversely, a small F statistic and a large significance level (close to 1.0) are evidence that variation due to month or quarter could be due to random error, and the null hypothesis of no month/quarter effect is not rejected. The interpretation and utility of seasonal adjustment are problematic under such conditions.

The F test for moving seasonality is performed by a two-way analysis of variance. The two factors are seasons (months or quarters) and years. The years effect is tested separately; the null hypothesis is no effect due to years after accounting for variation due to months or quarters. For further details about the moving seasonality test, see Lothian (1984a, b, 1978) and Higginson (1975).

The significance level reported in both the moving and stable seasonality tests are only approximate. Table D8, the Final Unmodified SI Ratios, is constructed from an averaging operation that induces a correlation in the residuals from which the F test is computed. Hence the computed F statistic differs from an exact F statistic; see Cleveland and Devlin (1980) for details.

The test for identifiable seasonality is performed by combining the F tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The following description is based on Lothian and Morry (1978b); other details can be found in Dagum (1988, 1983).

Let F_s and F_m denote the F value for the stable and moving seasonality tests, respectively. The combined test is performed as shown in Table 31.5 and as follows:

1. If the null hypothesis in the stable seasonality test is not rejected at the 0.10% significance level (0.001), this is an indication that the series is not seasonal. PROC X11 displays “Identifiable Seasonality Not Present.”
2. If the null hypothesis in step 1 is rejected, then compute the following quantities:

$$T_1 = \frac{7}{F_m}$$

$$T_2 = \frac{3F_m}{F_s}$$

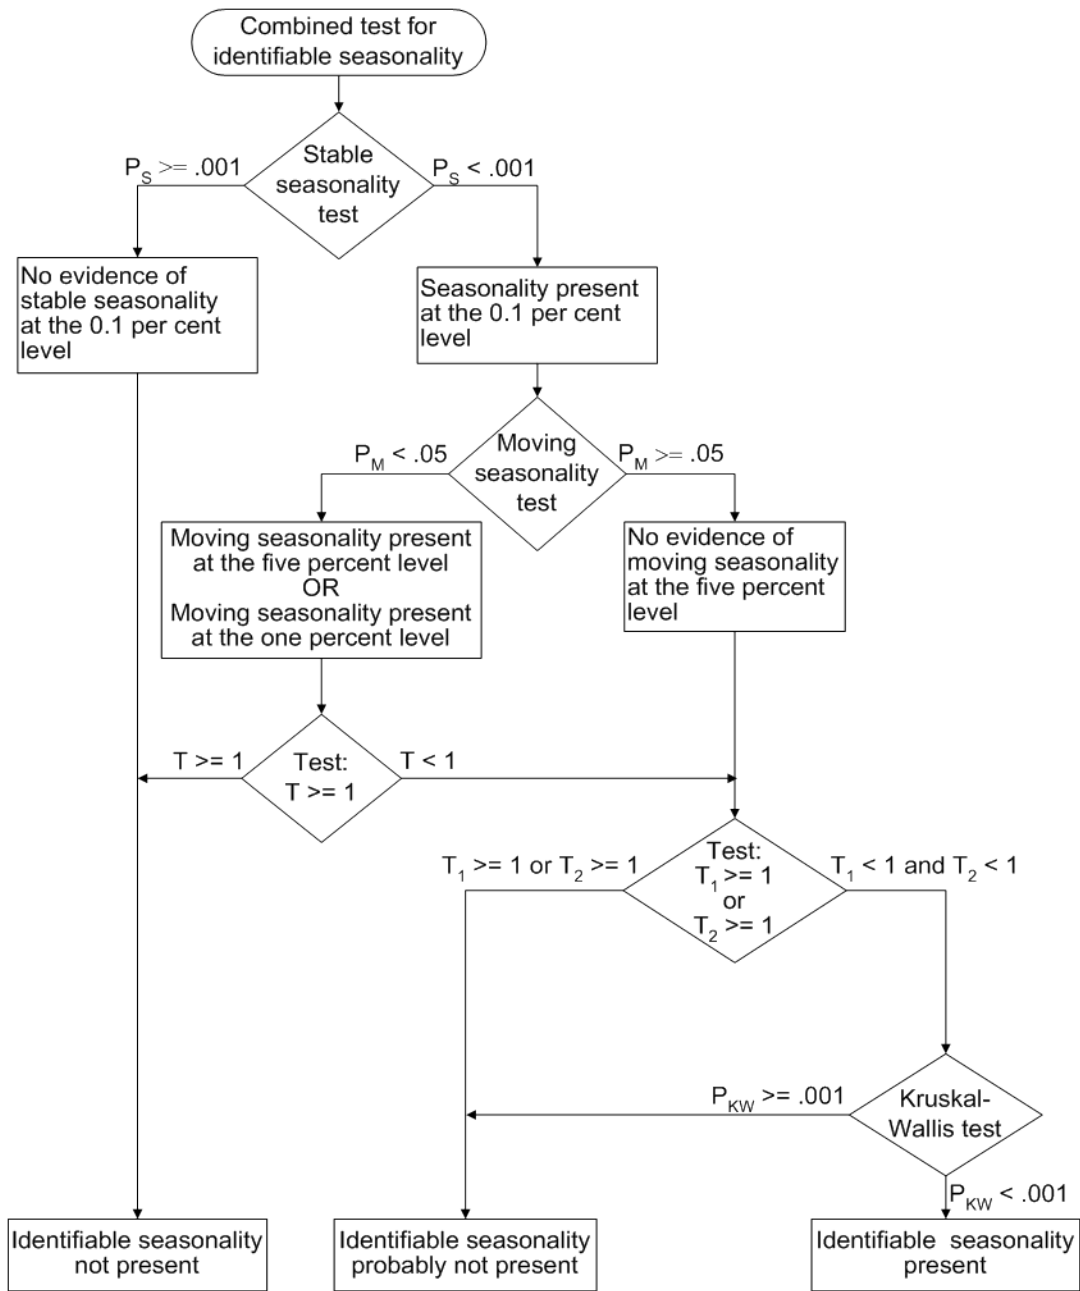

Let T denote the simple average of T_1 and T_2 :

$$T = \frac{(T_1 + T_2)}{2}$$

If the moving seasonality null hypothesis is not rejected at the 5.0% significance level (0.05) and if $T \geq 1.0$, the null hypothesis of identifiable seasonality *not* present is accepted and PROC X11 displays “Identifiable Seasonality Not Present.”

3. If the null hypothesis of identifiable seasonality *not* present has not been accepted, but $T_1 \geq 1.0$, $T_2 \geq 1.0$, or the Kruskal-Wallis chi-squared test fails at the 0.10% significance level (0.001), then PROC X11 displays “Identifiable Seasonality Probably Not Present.”
4. If the F_s and Kruskal-Wallis chi-squared tests pass, and if none of the combined measures described in steps 2 and 3 fail, then the null hypothesis of identifiable seasonality *not* present is rejected, and PROC X11 displays “Identifiable Seasonality Present.”

Figure 31.5 Combined Seasonality Test Flowchart

Tables Written to the OUT= Data Set

All tables that are time series can be written to the OUT= data set. However, depending on the specified options and statements, not all tables are computed. When a table is not computed, but is requested in the OUTPUT statement, the resulting variable has all missing values.

For example, if the PMFACTOR= option is not specified, Table A2 is not computed, and requesting this table in the OUTPUT statement results in the corresponding variable having all missing values.

The trading-day regression results, Tables B15 and C15, although not written to the OUT= data set, can be written to an output data set; see the OUTTDR= option for details.

Printed Output Generated by Sliding Spans Analysis

Table S 0.A

Table S 0.A gives the variable name, the length and number of spans, and the beginning and ending dates of each span.

Table S 0.B

Table S 0.B gives the summary of the two F tests performed during the standard X11 seasonal adjustments for stable and moving seasonality on Table D8, the final SI ratios. These tests are described in the section “Printed Output” on page 2074.

Table S 1.A

Table S 1.A gives the range analysis of seasonal factors. This includes the means for each month (or quarter) within a span, the maximum percentage difference across spans for each month, and the average. The minimum and maximum within a span are also indicated.

For example, for a monthly series and an analysis with four spans, the January row would contain a column for each span, with the value representing the average seasonal factor (Table D10) over all January calendar months occurring within the span. Beside each span column is a character column with either a MIN, MAX, or blank value, indicating which calendar month had the minimum and maximum value over that span.

Denote the average over the j th calendar month in span k , $k = 1, \dots, 4$, by $\bar{S}_j(k)$; then the maximum percent difference (MPD) for month j is defined by

$$MPD_j = \frac{\max_{k=1,\dots,4} \bar{S}_j(k) - \min_{k=1,\dots,4} \bar{S}_j(k)}{\min_{k=1,\dots,4} \bar{S}_j(k)}$$

The last numeric column of Table S 1.A is the average value over all spans for each calendar month, with the minimum and maximum row flagged as in the span columns.

Table S 1.B

Table S 1.B gives a summary of range measures for each span. The first column, Range Means, is calculated by computing the maximum and minimum over all months or quarters in a span, then taking the difference. The next column is the range ratio means, which is simply the ratio of the previously described maximum and minimum. The next two columns are the minimum and maximum seasonal factors over the entire span, while the range sf column is the difference of these. Finally, the last column is the ratio of the Max SF and Min SF columns.

Breakdown Tables

Table S 2.A.1 begins the breakdown analysis for the various series considered in the sliding spans analysis. The key concept here is the MPD described above in the section “Table S 1.A” on page 2080 and in the section “Computational Details for Sliding Spans Analysis” on page 2062. For a month or quarter that appears in two or more spans, the maximum percentage difference is computed and tested against a cutoff level. If it exceeds this cutoff, it is counted as an instance of exceeding the level. It is of interest to see if such instances fall disproportionately in certain months and years. Tables S 2.A.1 through S 6.A.3 display this breakdown for all series considered.

Table S 2.A.1

Table S 2.A.1 gives the monthly (quarterly) breakdown for the seasonal factors (table D10). The first column identifies the month or quarter. The next column is the number of times the MPD for D10 exceeded 3.0%, followed by the total count. The last is the average maximum percentage difference for the corresponding month or quarter.

Table S 2.A.2

Table S 2.A.2 gives the same information as Table S 2.A.1, but on a yearly basis.

Table S 2.A.3

The description of Table S 2.A.3 requires the definition of “Sign Change” and “Turning Point.”

First, some motivation. Recall that for a highly stable series, adding or deleting a small number of observations should not affect the estimation of the various components of a seasonal adjustment procedure.

Consider Table D10, the seasonal factors in a sliding spans analysis that uses four spans. For a given observation t , looking across the four spans, we can easily pick out large differences if they occur. More subtle differences can occur when estimates go from above to below (or vice versa) a base level. In the case of multiplicative model, the seasonal factors have a base level of 100.0. So it is useful to enumerate those instances where both a large change occurs (an MPD value exceeding 3.0%) and a change of sign (with respect to the base) occur.

Let B denote the base value (which in general depends on the component being considered and the model type, multiplicative or additive). If, for span 1, $S_t(1)$ is below B (i.e., $S_t(1) - B$ is negative) and for some subsequent span k , $S_t(k)$ is above B (i.e., $S_t(k) - B$ is positive), then a positive

“Change in Sign” has occurred at observation t . Similarly, if, for span 1, $S_t(1)$ is above B , and for some subsequent span k , $S_t(k)$ is below B , then a negative “Change in Sign” has occurred. Both cases, positive or negative, constitute a “Change in Sign”; the actual direction is indicated in tables S 7.A through S 7.E, which are described below.

Another behavior of interest occurs when component estimates increase then decrease (or vice versa) across spans for a given observation. Using the preceding example, the seasonal factors at observation t could first increase, then decrease across the four spans.

This behavior, combined with an MPD exceeding the level, is of interest in questions of stability.

Again, consider Table D10, the seasonal factors in a sliding spans analysis that uses four spans. For a given observation t (containing at least three spans), note the level of D10 for the first span. Continue across the spans until a difference of 1.0% or greater occurs (or no more spans are left), noting whether the difference is up or down. If the difference is up, continue until a difference of 1.0% or greater occurs downward (or no more spans are left). If such an up-down combination occurs, the observation is counted as an up-down turning point. A similar description occurs for a down-up turning point. Tables S 7.A through S 7.E, described below, show the occurrence of turning points, indicating whether up-down or down-up. Note that it requires at least three spans to test for a turning point. Hence Tables S 2.A.3 through S 6.A.3 show a reduced number in the “Turning Point” row for the “Total Tested” column, and in Tables S 7.A through S 7.E, the turning points symbols can occur only where three or more spans overlap.

With these descriptions of sign change and turning point, we now describe Table S 2.A.3. The first column gives the type or category, the second column gives the total number of observations falling into the category, the third column gives the total number tested, and the last column gives the percentage for the number found in the category.

The first category (row) of the table is for flagged observations—that is, those observations where the MPD exceeded the appropriate cutoff level (3.0% is default for the seasonal factors). The second category is for level changes, while the third category is for turning points. The fourth category is for flagged sign changes—that is, for those observations that are sign changes, how many are also flagged. Note the total tested column for this category equals the number found for sign change, reflecting the definition of the fourth category.

The fifth column is for flagged turning points—that is, for those observations that are turning points, how many are also flagged.

The footnote to Table S 2.A.3 gives the U.S. Census Bureau recommendation for thresholds, as described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2062.

Table S 2.B

Table S 2.B gives the histogram of flagged for seasonal factors (Table D10) using the appropriate cutoff value (default 3.0%). This table looks at the spread of the number of times the MPD exceeded the corresponding level. The range is divided up into four intervals: 3.0%–4.0%, 4.0%–5.0%, 5.0%–6.0%, and greater than 6.0%. The first column shows the symbol used in Table S 7.A, the second column gives the range in interval notation, and the last column gives the number found in the corresponding interval. Note that the sum of the last column should agree with the “Number Found” column of the “Flagged MPD” row in Table S 2.A.3.

Table S 2.C

Table S 2.C gives selected percentiles for the MPD for the seasonal factors (Table D10).

Tables S 3.A.1 through S 3.A.3

These tables relate to the trading-day factors (Table C18) and follow the same format as Tables S 2.A.1 through S 2.A.3. The only difference between these tables and Tables S 2.A.1 through S 2.A.3 is the default cutoff value of 2.0% instead of the 3.0% used for the seasonal factors.

Tables S 3.B, S 3.C

These tables, applied to the trading-day factors (Table C18), are the same format as Tables S 2.B through S 2.C. The default cutoff value is different, with corresponding differences in the intervals in S 3.B.

Tables S 4.A.1 through S 4.A.3

These tables relate to the seasonally adjusted series (Table D11) and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 4.B, S 4.C

These tables, applied to the seasonally adjusted series (Table D11), are the same format as tables S 2.B through S 2.C.

Tables S 5.A.1 through S 5.A.3

These tables relate to the month-to-month (or quarter-to-quarter) differences in the seasonally adjusted series, and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 5.B, S 5.C

These tables, applied to the month-to-month (or quarter-to-quarter) differences in the seasonally adjusted series, are the same format as tables S 2.B through S 2.C. The same default cutoff value of 3.0% is used.

Tables S 6.A.1 through S 6.A.3

These tables relate to the year-to-year differences in the seasonally adjusted series, and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 6.B, S 6.C

These tables, applied to the year-to-year differences in the seasonally adjusted series, are the same format as tables S 2.B through S 2.C. The same default cutoff value of 3.0% is used.

Table S 7.A

Table S 7.A gives the entire listing of the seasonal factors (Table D10) for each span. The first column gives the date for each observation included in the spans. Note that the dates do not cover the entire original data set. Only those observations included in one or more spans are listed.

The next N columns (where N is the number of spans) are the individual spans starting at the earliest span. The span columns are labeled by their beginning and ending dates.

Following the last span is the “Sign Change” column. As explained in the description of Table S 2.A.3, a sign change occurs at a given observation when the seasonal factor estimates go from above to below, or below to above, a base level. For the seasonal factors, 100.0 is the base level for the multiplicative model, 0.0 for the additive model. A blank value indicates no sign change, a “U” indicates a movement “upward” from the base level and a “D” indicates a movement “downward” from the base level.

The next column is the “Turning Point” column. As explained in the description of Table S 2.A.3, a turning point occurs when there is an upward then downward movement, or downward then upward movement, of sufficient magnitude. A blank value indicates no turning point, a “U-D” indicates a movement “upward then downward,” and a “D-U” indicates a movement “downward then upward.”

The next column is the maximum percentage difference (MPD). This quantity, described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2062, is the main computation for sliding spans analysis. A measure of how extreme the MPD value is given in the last column, the “Level of Excess” column. The symbols used and their meaning are described in Table S 2.A.3. If a given observation has exceeded the cutoff, the level of excess column is blank.

Table S 7.B

Table S 7.B gives the entire listing of the trading-day factors (Table C18) for each span. The format of this table is exactly like that of Table S 7.A.

Table S 7.C

Table S 7.C gives the entire listing of the seasonally adjusted data (Table D11) for each span. The format of this table is exactly like that of Table S 7.A except for the “Sign Change” column, which is not printed. The seasonally adjusted data have the same units as the original data; there is no natural base level as in the case of a percentage. Hence the sign change is not appropriate for D11.

Table S 7.D

Table S 7.D gives the entire listing of the month-to-month (or quarter-to-quarter) changes in seasonally adjusted data for each span. The format of this table is exactly like that of Table S 7.A.

Table S 7.E

Table S 7.E gives the entire listing of the year-to-year changes in seasonally adjusted data for each span. The format of this table is exactly like that of Table S 7.A.

Printed Output from the ARIMA Statement

The information printed by default for the ARIMA model includes the parameter estimates, their approximate standard errors, *t* ratios, and variances, the standard deviation of the error term, and the AIC and SBC statistics for the model. In addition, a criteria summary for the chosen model is given that shows the values for each of the three test criteria and the corresponding critical values.

If the PRINTALL option is specified, a summary of the nonlinear estimation optimization and a table of Box-Ljung statistics is also produced. If the automatic model selection is used, this information is printed for each of the five predefined models. Finally, a model selection summary is printed, showing the final model chosen.

ODS Table Names

PROC X11 assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

NOTE: For monthly and quarterly tables, use the ODS names MonthlyTables and QuarterlyTables; For brevity, only the MonthlyTables are listed here; the QuarterlyTables are simply duplicates. Printing of individual tables can be specified by using the TABLES table_name, which is not listed here. Printing groups of tables is specified in the MONTHLY and QUARTERLY statements by specifying the option PRINTOUT=NONE|STANDARD|LONG|FULL. The default is PRINTOUT=STANDARD.

Examples: X11 Procedure

Example 31.1: Component Estimation—Monthly Data

This example computes and plots the final estimates of the individual components for a monthly series. In the first plot ([Output 31.1.1](#)), an overlaid plot of the original and seasonally adjusted data is produced. The trend in the data is more evident in the seasonally adjusted data than in the original data. This trend is even more clear in [Output 31.1.3](#), the plot of Table D12, the trend cycle. Note that both the seasonal factors and the irregular factors vary around 100, while the trend cycle and the seasonally adjusted data are in the scale of the original data.

From [Output 31.1.2](#) the seasonal component appears to be slowly increasing, while no apparent pattern exists for the irregular series in [Output 31.1.4](#).

Example 31.3: Outlier Detection and Removal

PROC X11 can be used to detect and replace outliers in the irregular component of a monthly or quarterly series.

The weighting scheme used in measuring the “extremeness” of the irregulars is developed iteratively; thus the statistical properties of the outlier adjustment method are unknown.

In this example, the data are simulated by generating a trend plus a random error. Two periods in the series were made “extreme” by multiplying one generated value by 2.0 and another by 0.10. The additive model is appropriate based on the way the data were generated. Note that the trend in the generated data was modeled automatically by the trend cycle component estimation.

The detection of outliers is accomplished by considering Table D9, the final replacement values for extreme S-I ratios. This table indicates which observations had irregular component values more than FULLWEIGHT= standard deviation units from 0.0 (1.0 for the multiplicative model). The default value of the FULLWEIGHT= option is 1.5; a larger value would result in fewer observations being declared extreme.

In this example, FULLWEIGHT=3.0 is used to isolate the extreme inflated and deflated values generated in the DATA step. The value of ZEROWEIGHT= must be greater than FULLWEIGHT; it is given a value of 3.5.

A plot of the original and modified series, [Output 31.3.2](#), shows that the deviation from the trend line for the modified series is greatly reduced compared with the original series.

```
data a;
  retain seed 99831;
  do kk = 1 to 48;
    x = kk + 100 + rannor( seed );
    date = intnx( 'month', '01jan1970'd, kk-1 );
    if kk = 20 then x = 2 * x;
    else if kk = 30 then x = x / 10;
    output;
```

```

end;

Overview: X12 Procedure

The X12 procedure, an adaptation of the U.S. Bureau of the Census X-12-ARIMA Seasonal Adjustment program (U.S. Bureau of the Census 2001c), seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set that contains the adjusted time series and intermediate calculations.

The X-12-ARIMA program combines the capabilities of the X-11 program (Shiskin, Young, and Musgrave 1967) and the X-11-ARIMA/88 program (Dagum 1988) and also introduces some new features (Findley et al. 1998). One of the main enhancements involves the use of a regARIMA model, a regression model with ARIMA (autoregressive integrated moving average) errors. Thus, the X-12-ARIMA program contains methods developed by both the U.S. Census Bureau and Statistics Canada. In addition, the X-12-ARIMA automatic modeling routine is based on the TRAMO (time series regression with ARIMA noise, missing values, and outliers) method (Gomez and Maravall 1997a, b). The four major components of the X-12-ARIMA program are regARIMA modeling, model diagnostics, seasonal adjustment that uses enhanced X-11 methodology, and post-adjustment diagnostics. Statistics Canada's X-11 method fits an ARIMA model to the original series, and then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t , $t = 1, \dots, n$, and separated from trend cycle, trading day, and irregular fluctuations. The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated consistently or in an evolving fashion from year to year. The trend cycle component, C_t , includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading day component, D_t , is the variation that can be attributed to the composition of the calendar. The irregular component, I_t , is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). Other economic series are related in an additive fashion ($O_t = S_t + C_t + D_t + I_t$). A seasonally adjusted time series, $C_t I_t$ or $C_t + I_t$, consists of only the trend cycle and irregular components. For more details about seasonal adjustment with the X-11 method, see Ladiray and Quenneville (2001).

Graphics are now available with the X12 procedure. For more information, see the section “[ODS Graphics](#)” on page 2141.

Getting Started: X12 Procedure

The most common use of the X12 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X12 to produce a seasonally adjusted series, $C_t I_t$, from an original series $O_t = S_t C_t D_t I_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t , while S_t , D_t , and I_t vary around 1.0. In all displayed tables, these latter components are expressed as percentages and thus vary around 100.0 (in the additive case, they vary around 0.0). However, in the output data set, the data displayed as percentages in the displayed output are expressed as the decimal equivalent and thus vary around 1.0 in the multiplicative case.

The naming convention used in PROC X12 for the tables follows the convention used in the Census Bureau’s X-12-ARIMA program; see *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2001b) and *X-12-ARIMA Quick Reference for UNIX* (U.S. Bureau of the Census 2001a). Also see the section “[Displayed Output/ODS Table Names/OUTPUT Tablename Keywords](#)” on page 2139. The table names are outlined in [Table 32.8](#).

The tables that correspond to parts A through C are intermediate calculations. The final estimates of the individual components are found in the D tables: Table D10 contains the final seasonal factors, Table D12 contains the final trend cycle, and Table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you need to look only at Table D11, the final seasonally adjusted series. Tables in part E contain information about extreme values and changes in the original and seasonally adjusted series. The tables in part F are seasonal adjustment quality measures. Spectral analysis is performed in part G. For further information about the tables produced by the X11 statement, see Ladiray and Quenneville (2001).

Basic Seasonal Adjustment

Suppose that you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point, you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the PROC X12 statement and request seasonal adjustment in the X11 statement as shown in the following statements:

```
data sales;
  set sashelp.air;
  sales = air;
  date = intnx( 'month', '01sep78'd, _n_-1 );
  format date monyy.;
run;

proc x12 data=sales date=date;
  var sales;
  x11;
  ods select d11;
run ;
```

The results of the seasonal adjustment are in table D11 (the final seasonally adjusted series) in the displayed output as shown in [Figure 32.1](#).

	288.389	291.459	265.807	268.829	268.774	276.446	
Total: 40323			Mean: 280.02	S.D.: 111.31			
			Min: 124.56	Max: 499.2			

You can compare the original series (Table A1) and the final seasonally adjusted series (Table D11) by plotting them together as shown in [Figure 32.2](#). These tables are requested in the OUTPUT statement and are written to the OUT= data set. Note that the default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

```
proc x12 data=sales date=date noprint;
  var sales;
  x11;
  output out=out a1 d11;
run;
```

```

proc sgplot data=out;
  series x=date y=sales_A1 / name = "A1" markers
      markerattrs=(color=red symbol='asterisk')
      lineattrs=(color=red);
  series x=date y=sales_D11 / name= "D11" markers
      markerattrs=(symbol='circle')
      lineattrs=(color=blue);
  yaxis label='Original and Seasonally Adjusted Time Series';
run;

```

Figure 32.2 Plot of Original and Seasonally Adjusted Data

Syntax: X12 Procedure

The X12 procedure uses the following statements:

PROC X12 *options* ;
VAR *variables* ;
BY *variables* ;
ID *variables* ;
EVENT *variables* ;
USERDEFINED *variables* ;
TRANSFORM *options* ;
ADJUST *options* ;
IDENTIFY *options* ;
AUTOMDL *options* ;
OUTLIER *options* ;
REGRESSION *options* ;
INPUT *variables* ;
ARIMA *options* ;
ESTIMATE *options* ;
X11 *options* ;
FORECAST *options* ;
OUTPUT *options* ;
TABLES *options* ;

The PROC X12 statements perform basically the same function as the Census Bureau's X-12-ARIMA specs. *Specs* (specifications) are used in X-12-ARIMA to control the computations and output. The PROC X12 statement performs some of the same functions as the Series spec in the Census Bureau's X-12-ARIMA software. The ADJUST statement performs some of the same functions as the Transform spec. The TRANSFORM, IDENTIFY, AUTOMDL, OUTLIER, REGRESSION, ARIMA, ESTIMATE, X11, and FORECAST statements are designed to perform the same functions as the corresponding X-12-ARIMA specs, although full compatibility is not yet available. The Census Bureau documentation *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2001b) can provide added insight to the functionality of these statements.

Functional Summary

Table 32.1 summarizes the statements and options that control the X12 procedure.

PROC X12 Statement

PROC X12 options ;

The PROC X12 statement provides information about the time series to be processed by PROC X12. Either the `START=` or the `DATE=` option must be specified.

The original series is displayed in Table A1. If there are missing values in the original series and a regARIMA model is specified or automatically selected, then Table MV1 is displayed. Table MV1 contains the original series with missing values replaced by the predicted values from the fitted model. Table B1 is displayed when the original data is altered (for example, through an ARIMA model estimation, prior adjustment factors, or regression) or the series is extended with forecasts.

Although the X-12-ARIMA method handles missing values, there are some restrictions. In order for PROC X12 to process the series, no month or quarter can contain missing values for all years. For instance, if the third quarter contained only missing values for all years, then processing is skipped for that series. In addition, if more than half the values for a month or a quarter are missing, then a warning message is displayed in the log file, and other errors might occur later in processing. If a series contains many missing values, other methods of missing value replacement should be considered prior to seasonally adjusting the series.

The following options can appear in the PROC X12 statement.

DATA=SAS-data-set

specifies the input SAS data set used. If this option is omitted, the most recently created SAS data set is used.

DATE=variable

DATEVAR=variable

specifies a variable that gives the date for each observation. Unless specified in the `SPAN=` option, the starting and ending dates are obtained from the first and last values of the `DATE=` variable, which must contain SAS date or datetime values. The procedure checks values of the `DATE=` variable to ensure that the input observations are sequenced correctly in ascending order. If the `INTERVAL=` option or the `SEASONS=` option is specified, the values of the date variable must be consistent with the specified seasonality or interval. If neither the `INTERVAL=` option nor the `SEASONS=` option is specified, then the procedure tries to determine the type of data from the values of the date variable. This variable is automatically added to the `OUT=` data set if a data set is requested in an `OUTPUT` statement, and the date values for

the variable are extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

START=*mmmyy*

START='yyQq'

STARTDATE=*mmmyy*

STARTDATE='yyQq'

specifies the date of the first observation. Unless the SPAN= option is used, the starting and ending dates are the dates of the first and last observations, respectively. Either this option or the DATE= option is required. When using this option, use either the INTERVAL= option or the SEASONS= option to specify monthly or quarterly data. If neither the INTERVAL= option nor the SEASONS= option is present, monthly data are assumed. Note that for a quarterly date, the specification must be enclosed in quotes. A four-digit year can be specified; if a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies. When using the START= option with BY processing, the start date is applied to the first observation in each BY group.

SPAN=(*mmmyy* ,*mmmyy*)

SPAN=('yyQq' ,'yyQq')

specifies the dates of the first and last observations to define a subset for processing. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use SPAN=(,*mmmyy*). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set is assumed. A four-digit year can be specified; if a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies.

INTERVAL=*interval*

specifies the frequency of the input time series. If the input data consist of quarterly observations, then INTERVAL=QTR should be used. If the input data consist of monthly observations, then INTERVAL=MONTH should be used. If the INTERVAL= option is not specified and SEASONS=4, then INTERVAL=QTR is assumed; likewise, SEASONS=12 implies INTERVAL=MONTH. If both the INTERVAL= option and the SEASONS= option are specified, the values should not be conflicting. If neither the INTERVAL= option nor the SEASONS= option is specified and the START= option is specified, then the data are assumed to be monthly. If a date variable is specified using the DATE= option, it is not necessary to specify the INTERVAL= option or the SEASONS= option; however, if specified, the values of the INTERVAL= option or the SEASONS= option should not be in conflict with the values of the date variable. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more details about intervals.

SEASONS=*number*

specifies the number of observations in a seasonal cycle. If the SEASONS= option is not specified and INTERVAL=QTR, then SEASONS=4 is assumed. If the SEASONS= option is not specified and INTERVAL=MONTH, then SEASONS=12 is assumed. If the SEASONS= option is specified, its value should not conflict with the values of the INTERVAL= option or the values of the date variable. See the preceding descriptions for the START=, DATE=, and INTERVAL= options for more details.

NOTRIMMISS

suppresses the default, by which leading and trailing missing values are trimmed from the series. If NOTRIMMISS is used, PROC X12 automatically generates missing value regressors for any missing value within the span of the series, including leading and trailing missing values.

INEVENT=SAS-data-set

specifies the input data set that defines any user-defined event variables. This option can be omitted if events are not specified or if only SAS predefined events are specified in an EVENT statement. For more information about the format of this data set, see the section “[INEVENT= Data Set](#)” on page 2144 for details.

MDLINFOIN=SAS-data-set

specifies an optional input data set that contains model information that can replace the information contained in the TRANSFORM, REGRESSION, ARIMA, and AUTOMDL statements. The MDLINFOIN= data set can contain BY-group and series names; it is useful for providing specific information about each series to be seasonally adjusted. See the section “[MDLINFOIN= and MDLINFOOUT= Data Sets](#)” on page 2142 for details.

MDLINFOOUT=SAS-data-set

specifies the optional output data set that contains the transformation, regression, and ARIMA information related to each seasonally adjusted series. The data set is sorted by the BY-group variables, if any, and by series names. The MDLINFOOUT= data set can be used as input for the MDLINFOIN= option. See the section “[MDLINFOIN= and MDLINFOOUT= Data Sets](#)” on page 2142 for details.

NOPRINT

suppresses any printed output.

BY Statement

BY variables ;

A BY statement can be used with PROC X12 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

ID Statement

ID variables ;

If you are creating an output data set, use the ID statement to copy values of the ID variables, in addition to the table values, into the output data set. Or, if the VAR statement is omitted, all numeric variables that are not identified as BY variables, ID variables, the DATE= variable, or user-defined regressors are processed as time series. The ID statement has no effect when a VAR statement is

specified and an output data set is not created. If the DATE= variable is specified in the PROC X12 statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from forecasting) are extrapolated, while all other ID variables are missing in the forecast horizon.

EVENT Statement

EVENT *variables* < / *options* > ;

The EVENT statement specifies EVENTS to be included in the regression portion of the regARIMA model. Multiple EVENT statements can be specified. If a MDLINFOIN= data set is not specified, then all variables specified in the EVENT statements are applied to all BY-groups and all time series that are processed. If a MDLINFOIN= data set is specified, then the EVENT statements applies only if no regression information for the BY-group and series is available in the MDLINFOIN= data set. The EVENTS specified in the EVENT statements either must be SAS predefined EVENTS or must be defined in the data set specified in the *INEVENT=SAS-data-set* option of the PROC X12 statement. For a list of SAS predefined EVENTS, see the section “EVENTKEY Statement” in Chapter 6, “The HPFEVENTS Procedure” (*SAS High-Performance Forecasting User’s Guide*).

The EVENT statement can also be used to include outlier, level shift, and temporary change regressors that are available as predefined U.S. Census Bureau variables in the X-12-ARIMA program. For example, the following statements specify an additive outlier in January 1970 and a level shift that begins in July 1971:

```
proc x12 data=ICMETI seasons=12 start=jan1968;
  event AO01JAN1970D CBL01JUL1971D;
```

and the following statements specify an additive outlier in the second quarter 1970 and a temporary change that begins in the fourth quarter 1971:

```
proc x12 data=ICMETI seasons=4 start='1970q1';
  event AO01APR1970D TC01OCT1971D;
```

The following options can appear in the EVENT statement.

B=(value <F> ...)

specifies initial or fixed values for the EVENT parameters. For details about the B= option, see *B=(value <F> ...)* in the section “REGRESSION Statement” on page 2124.

For details about the USERTYPE= option, see the [USERTYPE=](#) option in the section “[REGRESSION Statement](#)” on page 2124.

INPUT Statement

INPUT *variables* < / *options* > ;

The INPUT statement specifies variables in the PROC X12 DATA= data set that are to be used as regressors in the regression portion of the regARIMA model. The variables in the data set should contain the values for each observation that define the regressor. Future values of regression variables should also be included in the DATA= data set if the time series listed in the VAR statement is to be extended with regARIMA forecasts. Multiple INPUT statements can be specified. If a [MDLINFOIN=](#) data set is not specified, then all variables listed in the INPUT statements are applied to all BY-groups and all time series that are processed. If a MDLINFOIN= data set is specified, then the INPUT statements apply only if no regression information for the BY-group and series is available in the MDLINFOIN= data set.

The following options can appear in the INPUT statement.

B=(value <F> ...)

specifies initial or fixed values for the INPUT variable parameters. For details about the B= option, see the [B=\(value <F> ...\)](#) option in the section “[REGRESSION Statement](#)” on page 2124.

ADJUST Statement

ADJUST options ;

The ADJUST statement adjusts the series for leap year and length-of-period factors prior to estimating a regARIMA model. The “Prior Adjustment Factors” table is associated with the ADJUST statement.

The following option can appear in the ADJUST statement.

PREDEFINED=LOM**PREDEFINED=LOQ****PREDEFINED=LPYEAR**

specifies length-of-month adjustment, length-of-quarter adjustment, or leap year adjustment. PREDEFINED=LOM and PREDEFINED=LOQ are equivalent; the actual adjustment is determined by the interval of the time series. Also, since leap year adjustment is a limited form of length-of-period adjustment, only one type of predefined adjustment can be specified. The PREDEFINED= option should not be used in conjunction with PREDEFINED=TD or PREDEFINED=TD1COEF in the REGRESSION statement or MODE=ADD or MODE=PSEUDOADD in the X11 statement. PREDEFINED=LPYEAR cannot be specified unless the series is log transformed.

If the series is to be transformed by using a Box-Cox or logistic transformation, the series is first adjusted according to the ADJUST statement, then transformed.

In the case of a length-of-month adjustment for the series with observations Y_t , each observation is first divided by the number of days in that month, m_t , and then multiplied by the average length of month (30.4375), resulting in $(30.4375 \times Y_t)/m_t$. Length-of-quarter adjustments are performed in a similar manner, resulting in $(91.3125 \times Y_t)/q_t$, where q_t is the length in days of quarter t .

Forecasts of the transformed and adjusted data are transformed and adjusted back to the original scale for output.

ARIMA Statement

ARIMA options ;

The ARIMA statement specifies the ARIMA part of the regARIMA model. This statement defines a pure ARIMA model if no **REGRESSION** statements, **INPUT** statements, or **EVENT** statements are specified. The ARIMA part of the model can include multiplicative seasonal factors.

The following option can appear in the ARIMA statement.

MODEL=(*p d q*) (*P D Q*)*s*

specifies the ARIMA model. The format follows standard Box-Jenkins notation (Box, Jenkins, and Reinsel 1994). The nonseasonal AR and MA orders are given by *p* and *q*, respectively, while the seasonal AR and MA orders are given by *P* and *Q*. The number of differences and seasonal differences are given by *d* and *D*, respectively. The notation (*p d q*) and (*P D Q*) can also be specified as (*p, d, q*) and (*P, D, Q*). The maximum lag of any AR or MA parameter is 36. The maximum value of a difference order, *d* or *D*, is 144. All values for *p*, *d*, *q*, *P*, *D*, and *Q* should be nonnegative integers. The lag that corresponds to seasonality is *s*; *s* should be a positive integer. If *s* is omitted, it is set equal to the value used in the SEASONS= option in the PROC X12 statement.

For example, the following statements specify an ARIMA (2,1,1)(1,1,0)12 model:

```
proc x12 data=ICMETI seasons=12 start=jan1968;
    arima model=((2,1,1) (1,1,0));
```

ESTIMATE Statement

ESTIMATE options ;

The ESTIMATE statement estimates the regARIMA model. The regARIMA model is specified by the REGRESSION, INPUT, EVENT, and ARIMA statements or by the MDLINFOIN= data set. Estimation output includes point estimates and standard errors for all estimated AR, MA, and regression parameters; the maximum likelihood estimate of the variance σ^2 ; *t* statistics for individual regression parameters; χ^2 statistics for assessing the joint significance of the parameters associated with certain regression effects (if included in the model); and likelihood-based model selection statistics (if the exact likelihood function is used). The regression effects for which χ^2 statistics are produced are fixed seasonal effects.

Tables displayed in the output associated with estimation are “Exact ARMA Likelihood Estimation Iteration Tolerances,” “Average Absolute Percentage Error in within-Sample Forecasts,” “ARMA Iteration History,” “AR/MA Roots,” “Exact ARMA Likelihood Estimation Iteration Summary,”

“Regression Model Parameter Estimates,” “Chi-Squared Tests for Groups of Regressors,” “Exact ARMA Maximum Likelihood Estimation,” and “Estimation Summary.”

The following options can appear in the ESTIMATE statement.

MAXITER=*value*

specifies the maximum number of iterations (for estimating the AR and MA parameters) allowed. For models with regression variables, this limit applies to the total number of ARMA iterations over all iterations of the iterative generalized least squares (IGLS) algorithm. For models without regression variables, this is the maximum number of iterations allowed for the set of ARMA iterations. The default is MAXITER=200.

TOL=*value*

specifies the convergence tolerance for the nonlinear estimation. Absolute changes in the log-likelihood are compared to the TOL= value to check convergence of the estimation iterations. For models with regression variables, the TOL= value is used to check convergence of the IGLS iterations (where the regression parameters are reestimated for each new set of AR and MA parameters). For models without regression variables, there are no IGLS iterations, and the TOL= value is then used to check convergence of the nonlinear iterations used to estimate the AR and MA parameters. The default value is TOL=0.00001. The minimum tolerance value is a positive value based on the machine precision and the length of the series. If a tolerance less than the minimum supported value is specified, an error message is displayed and the series is not processed.

ITPRINT

specifies that the “Iterations History” table be displayed. This includes detailed output for estimation iterations (including log-likelihood values and parameters) and counts of function evaluations and iterations. It is useful to examine the “Iterations History” table when errors occur within estimation iterations. By default, only successful iterations are displayed, unless the PRINTERR option is specified. An unsuccessful iteration is an iteration that is restarted due to a problem such as a root inside the unit circle. Successful iterations have a status of 0. If restarted iterations are displayed, a note at the end of the table gives definitions for status codes that indicate a restarted iteration. For restarted iterations, the number of function evaluations and the number of iterations will be –1, which is displayed as missing. If regression parameters are included in the model, then both IGLS and ARMA iterations are included in the table. The number of function evaluations is a cumulative total.

PRINTERR

causes restarted iterations to be included in the “Iterations History” table (if ITPRINT is specified) or creates the “Restarted Iterations” table (if ITPRINT is not specified). Whether or not PRINTERR is specified, a WARNING message is printed to the log file if any iteration is restarted during estimation.

FORECAST Statement

FORECAST *options* ;

The FORECAST statement uses the estimated model to forecast the time series. The output contains point forecast and forecast statistics for the transformed and original series.

The following option can appear in the FORECAST statement.

LEAD=*value*

specifies the number of periods ahead to forecast. The default is the number of periods in a year (4 or 12), and the maximum is 60.

Tables that contain forecasts, standard errors, and confidence limits are displayed in association with the FORECAST statement. If the data is transformed, then two tables are displayed: one table for the original data, and one table for the transformed data.

IDENTIFY Statement

IDENTIFY options ;

The IDENTIFY statement is used to produce plots of the sample autocorrelation function (ACF) and partial autocorrelation function (PACF) for identifying the ARIMA part of a regARIMA model. The sample ACF and PACF are produced for all combinations of the nonseasonal and seasonal differences of the data specified by the DIFF= and SDIFF= options. If the model includes a regression component (specified using the REGRESSION, INPUT, and EVENT statements or the MDLINFOIN= data set), then the ACFs and PACFs are calculated for the specified differences of the regression residuals. If the model does not include a regression component, then the ACFs and PACFs are calculated for the specified differences of the original data.

Tables displayed in association with identification are “Autocorrelation of Model Residuals” and “Partial Autocorrelation of Model Residuals.” If the model includes a regression component (specified using the REGRESSION, INPUT, and EVENT statements or the MDLINFOIN= data set), then the “Regression Model Parameter Estimates” table is also available.

The following options can appear in the IDENTIFY statement.

DIFF=(*order, order, order*)

specifies orders of nonseasonal differencing to use in model identification. The value 0 specifies no differencing; the value 1 specifies one nonseasonal difference $(1 - B)$; the value 2 specifies two nonseasonal differences $(1 - B)^2$; and so forth. The ACFs and PACFs are produced for all orders of nonseasonal differencing specified, in combination with all orders of seasonal differencing specified in the SDIFF= option. The default is DIFF=(0). You can specify up to three values for nonseasonal differences.

SDIFF=(*order, order, order*)

specifies orders of seasonal differencing to use in model identification. The value 0 specifies no seasonal differencing; the value 1 specifies one seasonal difference $(1 - B^s)$; the value 2 specifies two seasonal differences $(1 - B^s)^2$; and so forth. Here the value for s corresponds to the period specified in the SEASONS= option in the PROC X12 statement. The value of the SEASONS= option is supplied explicitly or is implicitly supplied through the INTERVAL= option or the values of the DATE= variable. The ACFs and PACFs are produced for all orders

of seasonal differencing specified, in combination with all orders of nonseasonal differencing specified in the DIFF= option. The default is SDIFF=(0). You can specify up to three values for seasonal differences.

For example, the following statement produces ACFs and PACFs for two levels of differencing: $(1 - B)$ and $(1 - B)(1 - B^s)$:

```
identify diff=(1) sdiff=(0, 1);
```

PRINTREG

causes the “Regression Model Parameter Estimates” table to be printed if the REGRESSION statement is present. By default, the table is not printed.

AUTOMDL Statement

AUTOMDL options ;

The AUTOMDL statement is used to invoke the automatic model selection procedure of the X-12-ARIMA method. This method is based largely on the TRAMO (time series regression with ARIMA noise, missing values, and outliers) method by Gomez and Maravall (1997a, b). If the AUTOMDL statement is used without the OUTLIER statement, then only missing values regressors are included in the regARIMA model. If the AUTOMDL and the OUTLIER statements are used, then both missing values regressors and regressors for automatically identified outliers are included in the regARIMA model.

If both the AUTOMDL statement and the ARIMA statement are present, the ARIMA statement is ignored. The ARIMA statement specifies the model, while the AUTOMDL statement allows the X12 procedure to select the model. If the AUTOMDL statement is specified and a data set is specified in the MDLINFOIN= option of the PROC X12 statement, then the AUTOMDL statement is ignored if the specified data set contains a model specification for the series. If no model for the series is specified in the data set specified in the MDLINFOIN= option, then the AUTOMDL (or ARIMA) statement is used to determine the model. Thus, it is possible to give a specific model for some series and automatically identify the model for other series by using both the MDLINFOIN= option and the AUTOMDL statement.

When AUTOMDL is specified, the X12 procedure compares a model selected using a TRAMO method to a default model. The TRAMO method is implemented first, and involves two parts: identifying the orders of differencing and identifying the ARIMA model. The table “ARIMA Estimates for Unit Root Identification” provides details about the identification of the orders of differencing, while the table “Results of Unit Root Test for Identifying Orders of Differencing” shows the orders of differencing selected by TRAMO. The table “Models Estimated by Automatic ARIMA Model Selection Procedure” provides details regarding the TRAMO automatic model selection, and the table “Best Five ARIMA Models Chosen by Automatic Modeling” ranks the best five models estimated using the TRAMO method. The next available table, “Comparison of Automatically Selected Model and Default Model,” compares the model selected by the TRAMO method to a default model. At this point in the processing, if the default model is selected over the TRAMO model, then PROC X12 displays a note. No note is displayed if the TRAMO model is selected. PROC X12 then performs checks for unit roots, over-differencing, and insignificant ARMA coefficients. If the model

is changed due to any of these tests, a note is displayed. The last table, “Final Automatic Model Selection,” shows the results of the automatic model selection.

The following options can appear in the AUTOMDL statement:

MAXORDER=(*nonseasonal order, seasonal order*)

specifies the maximum orders of nonseasonal and seasonal ARMA polynomials for the automatic ARIMA model identification procedure. The maximum order for the nonseasonal ARMA parameters should be between 1 and 4; the maximum order for the seasonal ARMA should be 1 or 2.

DIFFORDER=(*nonseasonal order, seasonal order*)

specifies the fixed orders of differencing to be used in the automatic ARIMA model identification procedure. When the DIFFORDER= option is used, only the AR and MA orders are automatically identified. Acceptable values for the regular differencing orders are 0, 1, and 2; acceptable values for the seasonal differencing orders are 0 and 1. If the MAXDIFF= option is also specified, then the DIFFORDER= option is ignored. There are no default values for DIFFORDER. If neither the DIFFORDER= option nor the MAXDIFF= option is specified, then the default is MAXDIFF=(2,1).

MAXDIFF=(*nonseasonal order, seasonal order*)

specifies the maximum orders of regular and seasonal differencing for the automatic identification of differencing orders. When MAXDIFF is specified, the differencing orders are identified first, and then the AR and MA orders are identified. Acceptable values for the regular differencing orders are 1 and 2; the only acceptable value for the seasonal differencing order is 1. If both the MAXDIFF= option and the DIFFORDER option= are specified, then the DIFFORDER= option is ignored. If neither the DIFFORDER= nor the MAXDIFF= option is specified, the default is MAXDIFF=(2,1).

NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

PRINT=UNITROOTTEST

PRINT=AUTOCHOICE

PRINT=UNITROOTTESTMDL

PRINT=AUTOCHOICEMDL

PRINT=BEST5MODEL

lists the tables to be displayed in the output.

PRINT=AUTOCHOICE displays the tables titled “Comparison of Automatically Selected Model and Default Model” and “Final Automatic Model Selection.” The “Comparison of Automatically Selected Model and Default Model” table compares a default model to the model chosen by the TRAMO-based automatic modeling method. The “Final Automatic Model Selection” table indicates which model has been chosen automatically. If the PRINT= option is not specified, then PRINT=AUTOCHOICE is displayed by default.

PRINT=UNITROOTTEST causes the table titled “Results of Unit Root Test for Identifying Orders of Differencing” to be printed. This table displays the orders that were automatically

selected by AUTOMDL. Unless the nonseasonal and seasonal differences are specified using the DIFFORDER= option, AUTOMDL automatically identifies the orders of differencing.

PRINT=UNITROOTMDL displays the table titled “ARIMA Estimates for Unit Root Identification.” This table summarizes the various models that were considered by the TRAMO automatic selection method while identifying the orders of differencing and the statistics associated with those models. The unit root identification method first attempts to obtain the coefficients by using the Hannan-Rissanen method. If Hannan-Rissanen estimation cannot be performed, the algorithm attempts to obtain the coefficients by using conditional likelihood estimation.

PRINT=AUTOCHOICEMDL displays the table “Models Estimated by Automatic ARIMA Model Selection Procedure.” This table summarizes the various models that were considered by the TRAMO automatic model selection method and their measures of fit.

PRINT=BEST5MODEL displays the table “Best Five ARIMA Models Chosen by Automatic Modeling.” This table ranks the five best models that were considered by the TRAMO automatic modeling method.

BALANCED

specifies that the automatic modeling procedure prefer balanced models over unbalanced models. A balanced model is one in which the sum of AR, differencing, and seasonal differencing orders equal to the sum of MA and seasonal MA orders. Specifying BALANCED gives the same preference as the TRAMO program. If BALANCED is not specified, all models are given equal consideration.

HRINITIAL

specifies that Hannan-Rissanen estimation be done before exact maximum likelihood estimation to provide initial values. If HRINITIAL is specified, then models for which the Hannan-Rissanen estimation has an unacceptable coefficient are rejected.

ACCEPTDEFAULT

specifies that the default model be chosen if its Ljung-Box Q is acceptable.

LJUNGBOXLIMIT=*value*

specifies acceptance criteria for confidence coefficient of the Ljung-Box Q statistic. If the Ljung-Box Q for a final model is greater than this value, the model is rejected, the outlier critical value is reduced, and outlier identification is redone with the reduced value (see the REDUCECV option). The value specified must be greater than 0 and less than 1. The default value is 0.95.

REDUCECV=*value*

specifies the percentage that the outlier critical value be reduced when a final model is found to have an unacceptable confidence coefficient for the Ljung-Box Q statistic. This value should be between 0 and 1. The default value is 0.14286.

ARMACV=*value*

specifies the threshold value for the t statistics associated with the highest order ARMA coefficients. As a check of model parsimony, the parameter estimates and t statistics of the highest order ARMA coefficients are examined to determine if the coefficient is insignificant.

An ARMA coefficient is considered to be insignificant if the absolute value of the parameter estimate is below 0.15 for 150 or fewer observations, and below 0.1 for more than 150 observations and the t value (displayed in the table “Exact ARMA Maximum Likelihood Estimation”) is below the value specified in the ARMACV= option. If the highest order ARMA coefficient is found to be insignificant then the order of the ARMA model is reduced. For example, if AUTOMDL identifies a (3 1 1)(0 0 1) model and the parameter estimate of the seasonal MA lag of order 1 is -0.9 and its t value is -0.55 , then the ARIMA model is reduced to at least (3 1 1)(0 0 0). After the model is reestimated, the check for insignificant coefficients is performed again. If ARMACV=0.54 is specified in the preceding example, then the coefficient is not found to be insignificant and the model is not reduced.

If a constant regressor is allowed in the model and if the t value (displayed in the table “Regression Model Parameter Estimates”) is below the ARMACV= critical value, then the constant regressor is considered to be insignificant and is removed. Note that if a constant regressor is added to or removed from the model and then the ARIMA model changes, then the t statistic for the constant regressor also changes. Thus, changing the ARMACV= value does not necessarily add or remove a constant term from the model.

The value specified in the ARMACV= option should be greater than zero. The default value is 1.0.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set tablename1 tablename2 ... ;*

The OUTPUT statement creates an output data set that contains specified tables. The data set is named by the OUT= option.

OUT=SAS-data-set

names the data set to contain the specified tables. If the OUT= option is omitted, the SAS System names the new data set by using the default *DATAn* convention.

For each table to be included in the output data set, you must specify the X12 *tablename* keyword. The keyword corresponds to the title label used by the Census Bureau X12-ARIMA software. Currently available tables are A1, A2, A6, A7, A8, A8AO, A8LS, A8TC, A9, A10, B1, C17, C20, D1, D7, D8, D9, D10, D10B, D10D, D11, D11A, D11F, D11R, D12, D13, D16, D16B, D18, E5, E6, E6A, E6R, E7, and MV1. If no table is specified in the OUTPUT statement, Table A1 is output to the OUT= data set by default.

The tablename keywords that can be used in the OUTPUT statement are listed in the section “[Displayed Output/ODS Table Names/OUTPUT Tablename Keywords](#)” on page 2139. The following is an example of a VAR statement and an OUTPUT statement:

```
var sales costs;
output out=out_x12 b1 d11;
```

Note that the default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name. The variable sales_B1 contains

the Table B1 values for the variable sales, the variable costs_B1 contains the Table B1 values for costs, while the Table D11 values for sales are contained in the variable sales_D11, and the variable costs_D11 contains the Table D11 values for costs. If necessary, the variable name is shortened so that the table name can be added. If the DATE= variable is specified in the PROC X12 statement, then that variable is included in the output data set; otherwise, a variable named _DATE_ is written to the OUT= data set as the date identifier.

OUTLIER Statement

OUTLIER *options* ;

The OUTLIER statement specifies that the X12 procedure perform automatic detection of additive (point) outliers, temporary change outliers, level shifts, or any combination of the three when using the specified model. After outliers are identified, the appropriate regression variables are incorporated into the model as “Automatically Identified Outliers,” and the model is reestimated. This procedure is repeated until no additional outliers are found.

The OUTLIER statement also identifies potential outliers and lists them in the table “Potential Outliers” in the displayed output. Potential outliers are identified by decreasing the critical value by 0.5.

In the output, the default initial critical values used for outlier detection in a given analysis are displayed in the table “Critical Values to Use in Outlier Detection.” Outliers that are detected and incorporated into the model are displayed in the output in the table “Regression Model Parameter Estimates,” where the regression variable is listed as “Automatically Identified.”

The following options can appear in the OUTLIER statement.

SPAN=(*mmmyy* ,*mmmyy*)

SPAN=(*'yyQq'* ,*'yyQq'*)

gives the dates of the first and last observations to define a subset for searching for outliers. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use SPAN=(*mmmyy*) or SPAN=(*'yyQq'*). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set is assumed. A four-digit year can be specified; if a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies.

TYPE=NONE

TYPE=(*outlier types*)

lists the outlier types to be detected by the automatic outlier identification method. TYPE=NONE turns off outlier detection. The valid outlier types are AO, LS, and TC. The default is TYPE=(AO LS).

CV=*value*

specifies an initial critical value to use for detection of all types of outliers. The absolute value of the *t* statistic associated with an outlier parameter estimate is compared with the critical value to determine the significance of the outlier. If the CV= option is not specified, then the

default initial critical value is computed using a formula presented by Ljung (1993), which is based on the number of observations or model span used in the analysis. Table 32.2 gives default critical values for various series lengths. Increasing the critical value decreases the sensitivity of the outlier detection routine and can reduce the number of observations treated as outliers. The automatic model identification process might lower the critical value by a certain percentage, if the automatic model identification process fails to identify an acceptable model.

Table 32.2 Default Critical Values for Outlier Identification

Number of Observations	Outlier Critical Value
1	1.96
2	2.24
3	2.44
4	2.62
5	2.74
6	2.84
7	2.92
8	2.99
9	3.04
10	3.09

96	3.80
120	3.85
144	3.89
168	3.92
192	3.95
216	3.97
240	3.99
264	4.01
288	4.03
312	4.04
336	4.05
360	4.07

AOCV=value

specifies a critical value to use for additive (point) outliers. If AOCV is specified, this value overrides any default critical value for AO outliers. See the [CV= option](#) for more details.

LSCV=value

specifies a critical value to use for level shift outliers. If LSCV is specified, this value overrides any default critical value for LS outliers. See the [CV= option](#) for more details.

TCCV=value

specifies a critical value to use for temporary change outliers. If TCCV is specified, this value overrides any default critical value for TC outliers. See the [CV= option](#) for more details.

REGRESSION Statement

REGRESSION PREDEFINED= *variables* < / *options* > ;

REGRESSION USERVAR= *variables* < / *options* > ;

The REGRESSION statement includes regression variables in a regARIMA model or specifies regression variables whose effects are to be removed by the IDENTIFY statement to aid in ARIMA model identification. Predefined regression variables are selected with the PREDEFINED= option. User-defined regression variables are specified with the USERVAR= option. The currently available predefined variables are listed below in [Table 32.3](#). Table A6 in the displayed output generated by the X12 procedure provides information related to trading day effects. Table A7 provides information related to holiday effects. Tables A8, A8AO, A8LS, and A8TC provide information related to outlier factors. Ramps and level shifts are combined in the A8LS table. The A8AO, A8LS and A8TC tables are available only when more than one outlier type is present in the model. Table A9 provides information about user-defined regression effects. Table A10 provides information about the user-defined seasonal component. Missing values in the span of an input series automatically create missing value regressors. See the NOTRIMMISS option of the PROC X12 statement and the section “[Missing Values](#)” on page 2136 for further details about missing values. Combining your model with additional predefined regression variables can result in a singularity problem. If a singularity occurs, then you might need to alter either the model or the choices of the predefined regressors in order to successfully perform the regression.

In order to seasonally adjust a series that uses a regARIMA model, the factors derived from the regression coefficients must be the same type as the factors generated by the seasonal adjustment procedure, so that combined adjustment factors can be derived and adjustment diagnostics can be generated. If the regARIMA model is applied to a log-transformed series, the regression factors are expressed in the form of ratios, which match seasonal factors generated by the multiplicative (or log-additive) adjustment modes. Conversely, if the regARIMA model is fit to the original series, the regression factors are measured on the same scale as the original series, which match seasonal factors generated by the additive adjustment mode. Note that the default transformation (no transformation) and the default seasonal adjustment mode (multiplicative) are in conflict. Thus when you specify the X11 statement and any of the REGRESSION, INPUT, or EVENT statements, it is necessary to also specify either a transform option (using the TRANSFORM statement) or a mode (using the MODE= option of the X11 statement) in order to seasonally adjust the data that uses the regARIMA model.

According to Ladiray and Quenneville (2001), “X-12-ARIMA is based on the same principle [as the X-11 method] but proposes, in addition, a complete module, called Reg-ARIMA, that allows for the initial series to be corrected for all sorts of undesirable effects. These effects are estimated using regression models with ARIMA errors (Findley et al. [23]).” In order to correct the series for effects in this manner, the REGRESSION statement must be specified. The effects that can be corrected in this manner are listed in the PREDEFINED= option below.

Either the PREDEFINED= option or the USERVAR= option can be specified in a single REGRESSION statement, but not both. Multiple REGRESSION statements can be used.

The following options can appear in the REGRESSION statement.

PREDEFINED=CONSTANT < / B= >

PREDEFINED=LOM

PREDEFINED=LOMSTOCK

PREDEFINED=LOQ

PREDEFINED=LPYEAR

PREDEFINED=SEASONAL

PREDEFINED=TD

PREDEFINED=TDNOLPYEAR

PREDEFINED=TD1COEF

PREDEFINED=TD1NOLPYEAR

PREDEFINED=EASTER(*value*)

PREDEFINED=SCEASTER(*value*)

PREDEFINED=LABOR(*value*)

PREDEFINED=THANK(*value*)

PREDEFINED=TDSTOCK(*value*)

PREDEFINED=SINCOS(*value ...*)

lists the predefined regression variables to be included in the model. Data values for these variables are calculated by the program, mostly as functions of the calendar. [Table 32.3](#) gives definitions for the available predefined variables. The values LOM and LOQ are actually equivalent: the actual regression is controlled by the PROC X12 SEASONS= option. Multiple predefined regression variables can be used. The syntax for using both a length-of-month and a seasonal regression can be in one of the following forms:

```
regression predefined=lom seasonal;
```

```
regression predefined=(lom seasonal);
```

```
regression predefined=lom predefined=seasonal;
```

Certain restrictions apply when you use more than one predefined regression variable. Only one of TD, TDNOLPYEAR, TD1COEF, or TD1NOLPYEAR can be specified. LPYEAR cannot be used with TD, TD1COEF, LOM, LOMSTOCK, or LOQ. LOM or LOQ cannot be used with TD or TD1COEF.

The following restriction also applies to the SINCOS predefined regression variable. If SINCOS is specified, then the INTERVAL= option or the SEASONS= option must also be specified because there are restrictions to this regression variable based on the frequency of the data.

The predefined regression variables TDSTOCK, SCEASTER, EASTER, LABOR, THANK, and SINCOS require extra parameters. Only one TDSTOCK regressor can be implemented in the regression model. If multiple TDSTOCK variables are specified, PROC X12 uses

the last TDSTOCK variable specified. For SCEASTER, EASTER, LABOR, THANK, and SINCOS, multiple regressors can be implemented in the model by specifying the variables with different parameters. The syntax for specifying two EASTER regressors with widths 7 and 14 would be:

```
regression predefined=easter(7) easter(14);
```

For SINCOS, specifying a parameter includes both the sine and the cosine regressor except for the highest order allowed (2 for quarterly data and 6 for monthly data.) The most common use of the SINCOS variable for quarterly data would be

```
regression predefined=sincos(1,2);
```

and for monthly data would be

```
regression predefined=sincos(1,2,3,4,5,6);
```

These statements include 3 and 11 regressors in the model, respectively.

Table 32.3 Predefined Regression Variables in X-12-ARIMA

Regression Effect	Variable Definitions
trend constant CONSTANT	$(1 - B)^{-d} (1 - B^s)^{-D} I(t \geq 1)$, where $I(t \geq 1) = \begin{cases} 1 & \text{for } t \geq 1 \\ 0 & \text{for } t < 1 \end{cases}$
length-of-month (monthly flow) LOM	$m_t - \bar{m}$ where $m_t =$ length of month t (in days) and $\bar{m} = 30.4375$ (average length of month)
stock length-of-month LOMSTOCK	$SLOM_t = \begin{cases} m_t - \bar{m} - \mu(l) & \text{for } t = 1 \\ SLOM_{t-1} + m_t - \bar{m} & \text{otherwise} \end{cases}$ where \bar{m} and m_t are defined in LOM and $\mu(l) = \begin{cases} 0.375 & \text{when 1st February in series is a leap year} \\ 0.125 & \text{when 2nd February in series is a leap year} \\ -0.125 & \text{when 3rd February in series is a leap year} \\ -0.375 & \text{when 4th February in series is a leap year} \end{cases}$
length-of-quarter (quarterly flow) LOQ	$q_t - \bar{q}$ where $q_t =$ length of quarter t (in days) and $\bar{q} = 91.3125$ (average length of quarter)
leap year (monthly and quarterly flow) LPYEAR	$LY_t = \begin{cases} 0.75 & \text{in leap year February (first quarter)} \\ -0.25 & \text{in other Februaries (first quarter)} \\ 0 & \text{otherwise} \end{cases}$

Table 32.3 continued

Regression Effect	Variable Definitions
fixed seasonal SEASONAL	$M_{1,t} = \begin{cases} 1 & \text{in January} \\ -1 & \text{in December} \\ 0 & \text{otherwise} \end{cases}$ $, \dots, M_{11,t} = \begin{cases} 1 & \text{in November} \\ -1 & \text{in December} \\ 0 & \text{otherwise} \end{cases}$
fixed seasonal SINCOS(w)	$\sin(w_j t), \cos(w_j t)$, where $w_j = 2\pi j/12, 1 \leq j \leq s/2$ and s is the seasonal period (drop $\sin(w_j t) \equiv 0$ for $j = s/2$)
trading day TD, TDNOLPYEAR	$T_{1,t} = (\text{no. of Mondays}) - (\text{no. of Sundays})$ $, \dots, T_{6,t} = (\text{no. of Saturdays}) - (\text{no. of Sundays})$
one coefficient trading day TD1COEF, TD1NOLPYEAR	$(\text{no. of weekdays}) - \frac{5}{2}(\text{no. of Saturdays and Sundays})$
stock trading day TDSTOCK(w)	$D_{1,t} = \begin{cases} 1 & \tilde{w}^{th} \text{ day of month } t \text{ is a Monday} \\ -1 & \tilde{w}^{th} \text{ day of month } t \text{ is a Sunday} \\ 0 & \text{otherwise} \end{cases}$ $, \dots, D_{6,t} = \begin{cases} 1 & \tilde{w}^{th} \text{ day of month } t \text{ is a Saturday} \\ -1 & \tilde{w}^{th} \text{ day of month } t \text{ is a Sunday} \\ 0 & \text{otherwise} \end{cases}$ <p>where \tilde{w} is the smaller of w and the length of month t. For end-of-month stock series, set w to 31; that is, specify TDSTOCK(31). Restriction: $1 \leq w \leq 31$.</p>
Statistics Canada Easter (monthly or quarterly flow) SCEASTER(w)	<p>If Easter falls before April w, let n_E be the number of the w days on or before Easter that fall in March. Then:</p> $E(w, t) = \begin{cases} n_E/w & \text{in March} \\ -n_E/w & \text{in April} \\ 0 & \text{otherwise} \end{cases}$ <p>If Easter falls on or after April w, then $E(w, t) = 0$. (Note: This variable is 0 except in March and April (or first and second quarter).) Restriction: $1 \leq w \leq 24$.</p>

Table 32.3 continued

Regression Effect	Variable Definitions
Easter holiday EASTER(<i>w</i>)	$E(w, t) = \frac{1}{w} \times n_t$ and n_t is the number of the w days before Easter that fall in month (or quarter) t . (Note: This variable is 0 except in February, March, and April (or first and second quarter). It is nonzero in February only for $w > 22$.) Restriction: $1 \leq w \leq 25$.
Labor Day LABOR(<i>w</i>)	$L(w, t) = \frac{1}{w} \times [\text{no. of the } w \text{ days before Labor Day that fall in month } t]$ (Note: This variable is 0 except in August and September.) Restriction: $1 \leq w \leq 25$.
Thanksgiving THANK(<i>w</i>)	$ThC(w, t) = \text{proportion of days from } w \text{ days before Thanksgiving through December 24 that fall in month } t$ (negative values of w indicate days after Thanksgiving). (Note: This variable is 0 except in November and December.) Restriction: $-8 \leq w \leq 17$.

USERVAR=(variables) < / B=value USERTYPE=option >

specifies variables in the PROC X12 DATA= data set that are to be used as regressors. The variables in the data set should contain the values for each observation that define the regressor; regression variables should also be defined for forecast values if the time series is to be extended with regARIMA forecasts. Missing values are not permitted within the data span, including forecasts, of the user-defined regressors. [Example 32.6](#) shows how you would create an input data set that contains both the series to be seasonally adjusted and a user-defined input variable. Note that all regression variables in the USERVAR= option apply to all time series to be seasonally adjusted unless the MDLINFOIN= data set specifies different regression information.

B=(value <F> ...)

specifies initial or fixed values for the regression parameters in the order in which they appear in the PREDEFINED= and USERVAR= options. Each B= list applies to the PREDEFINED= or USERVAR= variable list that immediately precedes the slash. The PREDEFINED= option and the USERVAR= option cannot be specified in the same REGRESSION statement; however, multiple REGRESSION statements can be specified.

For example, the following statements set an initial value for the user-defined regressor, x, of 1:

```

regression predefined=LOM ;
regression uservar=x / b=1 2 ;

```

In this example, the B= option applies only to the USERVAR= statement. The value 2 is discarded since there is only one variable in the USERVAR= list. To assign an initial value of 1 to the LOM regressor and 2 to the x regressor, use the following statements:

```

regression predefined=LOM / b=1;
regression uservar=x / b=2 ;

```

An F immediately following the numerical value indicates that this is not an initial value, but a fixed value. See [Example 32.8](#) for an example that uses fixed parameters. In PROC X12, individual parameters can be fixed while other parameters in the same model are estimated.

USERTYPE=CONSTANT

USERTYPE=SEASONAL

USERTYPE=TD

USERTYPE=LOM

USERTYPE=LOQ

USERTYPE=LPYEAR

USERTYPE=TDSTOCK

USERTYPE=LOMSTOCK

USERTYPE=EASTER

USERTYPE=LABOR

USERTYPE=THANKS

USERTYPE=AO

USERTYPE=LS

USERTYPE=RP

USERTYPE=HOLIDAY

USERTYPE=SCEASTER

USERTYPE=USER

USERTYPE=TC

enables a user-defined variable to be processed in the same manner as a U.S. Census predefined variable. For instance, the U.S. Census Bureau EASTER(*w*) regression effects are included in the “RegARIMA Holiday Component” table (A7). You should specify USERTYPE=EASTER to include a user-defined variable which would be processed exactly as the U.S. Census predefined EASTER(*w*) variable, including inclusion in the A7 table. Each USERTYPE= list applies to the USERVAR= variable list that immediately precedes the slash. USERTYPE= does not apply to U.S. Census predefined variables. The same rules for assigning B= values to regression variables apply for USERTYPE= options. See the example in [B=\(value <F> ...\)](#).

TABLES Statement

TABLES *tablename1 tablename2 ... options* ;

The TABLES statement enables you to alter the display of the PROC X12 tables. You can specify the display of tables that are not displayed by default by PROC X12, and the NOSUM option enables you to suppress the printing of the period summary line in the time series tables.

tablename1 tablename2 ...

keywords that correspond to the title label used by the Census Bureau X12-ARIMA software. For each table to be included in the displayed output, you must specify the X12 *tablename* keyword. Currently available tables are C20, D1, and D7. Although these tables are not displayed by default, their values are sometimes useful in understanding the X-12-ARIMA method. For further description of the available tables, see the section “[Displayed Output/ODS Table Names/OUTPUT Tablename Keywords](#)” on page 2139.

NOSUM

NOSUMMARY

NOSUMMARYLINE

applies to the tables available for output in the [OUTPUT Statement](#). By default, these tables include a summary line that gives the average, total, or standard deviation for the historical data by period. The NOSUM option suppresses the display of the summary line in the listing. Also, if the tables are output with ODS, the summary line is not an observation in the data set. Thus, the output to the data set is only the time series, both the historical data and the forecast data, if available.

TRANSFORM Statement

TRANSFORM *options* ;

The TRANSFORM statement transforms or adjusts the series prior to estimating a regARIMA model. With this statement, the series can be Box-Cox (power) transformed. The “Prior Adjustment Factors” table is associated with the TRANSFORM statement.

Only one of the following options can appear in the TRANSFORM statement.

POWER=*value*

transforms the input series, Y_t , by using a Box-Cox power transformation,

$$Y_t \rightarrow y_t = \begin{cases} \log(Y_t) & \lambda = 0 \\ \lambda^2 + (Y_t^\lambda - 1)/\lambda & \lambda \neq 0 \end{cases}$$

The power λ must be specified (for example, POWER= 0.33). The default is no transformation ($\lambda = 1$); that is, POWER= 1. The log transformation (POWER= 0), square root transformation (POWER= 0.5), and the inverse transformation (POWER= -1) are equivalent to the corresponding FUNCTION= option.

Table 32.4 Power Values Related to the Census Bureau Function Argument

FUNCTION=	Transformation	Range for Y_t	Equivalent Power Argument
NONE	Y_t	all values	$power = 1$
LOG	$\log(Y_t)$	$Y_t > 0$ for all t	$power = 0$
SQRT	$2(\sqrt{Y_t} - 0.875)$	$Y_t \geq 0$ for all t	$power = 0.5$
INVERSE	$2 - \frac{1}{Y_t}$	$Y_t \neq 0$ for all t	$power = -1$
LOGISTIC	$\log(\frac{Y_t}{1-Y_t})$	$0 < Y_t < 1$ for all t	<i>none equivalent</i>

FUNCTION=NONE**FUNCTION=LOG****FUNCTION=SQRT****FUNCTION=INVERSE****FUNCTION=LOGISTIC****FUNCTION=AUTO****TYPE=NONE | LOG | SQRT | INVERSE | LOGISTIC | AUTO**

the transformation to be applied to the series prior to estimating a regARIMA model. The transformation used by FUNCTION=NONE, LOG, SQRT, INVERSE, and LOGISTIC is related to the POWER= option as shown in [Table 32.4](#). FUNCTION=AUTO uses selection based on Akaike's information criterion (AIC) to decide between a log transformation and no transformation. The default is FUNCTION=NONE.

However, the FUNCTION= and POWER= options are not completely equivalent. In some cases, using the FUNCTION= option causes the program to automatically select other options. For instance, FUNCTION=NONE causes the default mode to be MODE=ADD in the X11 statement. Also, the choice of transformation invoked by the FUNCTION=AUTO option can impact the default mode of the X11 statement.

Note that there are restrictions on the value used in the POWER and FUNCTION options when preadjustment factors for seasonal adjustment are generated from a regARIMA model. When seasonal adjustment is requested with the X11 statement, any value of the POWER option can be used for the purpose of forecasting the series with a regARIMA model. However, this is not the case when factors generated from the regression coefficients are used to adjust either the original series or the final seasonally adjusted series. In this case, the only accepted transformations are the log transformation, which can be specified as POWER=0 (for multiplicative or log-additive seasonal adjustments) and no transformation, which can be specified as POWER=1 (for additive seasonal adjustments). If no seasonal adjustment is performed, any POWER transformation can be used. The preceding restrictions also apply to FUNCTION=NONE and FUNCTION=LOG.

USERDEFINED Statement

USERDEFINED *variables* ;

The USERDEFINED statement is used to identify the variables in the input data set that are available for user-defined regression. Only numeric variables can be specified. Note that specifying variables in the USERDEFINED statement does not include the variables as regressors. If a variable is specified in the INPUT statement or REGRESSION USERVAR= option, it is not necessary to include that variable in the USERDEFINED statement. However, if a variable is specified in the MDLINFOIN= data set and is not specified in an INPUT statement or in the REGRESSION USERVAR= option, then the variable should be specified in the USERDEFINED statement in order to make the variable available for regression.

VAR Statement

VAR *variables* ;

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those that appear in a BY statement, ID statement, INPUT statement, USERDEFINED statement, the USERVAR= option of the REGRESSION statement, or the variable named in the DATE= option in the PROC X12 statement.

X11 Statement

X11 *options* ;

The X11 statement is an optional statement for invoking seasonal adjustment by an enhanced version of the methodology of the Census Bureau X-11 and X-11Q programs. You can control the type of seasonal adjustment decomposition calculated with the MODE= option. The output includes the final tables and diagnostics for the X-11 seasonal adjustment method listed in [Table 32.5](#). Tables C20, D1, and D7 are not displayed by default; you can display these tables by using the [TABLES statement](#).

Table 32.5 Tables Related to X11 Seasonal Adjustment

Table Name	Description
B1	original series, adjusted for prior effects and forecast extended
C17	final weights for the irregular component
C20	final extreme value adjustment factors
D1	modified original data, D iteration
D7	preliminary trend cycle, D iteration
D8	final unmodified SI ratios (differences)
D8A	<i>F</i> tests for stable and moving seasonality, D8
D9	final replacement values for extreme SI ratios (differences), D iteration
D9A	moving seasonality ratios for each period
D10	final seasonal factors
D10B	seasonal factors, adjusted for user-defined seasonal
D10D	final seasonal difference
D11	final seasonally adjusted series
D11A	final seasonally adjusted series with forced yearly totals
D11R	rounded final seasonally adjusted series (with forced yearly totals)
D12	final trend cycle
D13	final irregular component
D16	combined seasonal and trading day factors
D16B	final adjustment differences
D18	combined calendar adjustment factors
E4	ratio of yearly totals of original and seasonally adjusted series
E5	percent changes (differences) in original series
E6	percent changes (differences) in seasonally adjusted series
E6A	percent changes (differences) in seasonally adjusted series with forced yearly totals (D11.A)
E6R	percent changes (differences) in rounded seasonally adjusted series (D11.R)
E7	percent changes (differences) in final trend component series
F2A–F2I	X11 diagnostic summary
F3	monitoring and quality assessment statistics
F4	day of the week trading day component factors
G	spectral plots

For more details about the X-11 seasonal adjustment diagnostics, see Shiskin, Young, and Musgrave (1967), Lothian and Morry (1978a), and Ladiray and Quenneville (2001).

The following options can appear in the X11 statement.

MODE=ADD

MODE=MULT

MODE=LOGADD

MODE=PSEUDOADD

determines the mode of the seasonal adjustment decomposition to be performed. There

are four choices: multiplicative (MODE=MULT), additive (MODE=ADD), pseudo-additive (MODE=PSEUDOADD), and log-additive (MODE=LOGADD) decomposition. If this option is omitted, the procedure performs multiplicative adjustments. Table 32.6 shows the values of the MODE= option and the corresponding models for the original (O) and the seasonally adjusted (SA) series.

Table 32.6 Modes of Seasonal Adjustment and Their Models

Value of Mode Option	Name	Model for O	Model for SA
MULT	multiplicative	$O = C \times S \times I$	$SA = C \times I$
ADD	additive	$O = C + S + I$	$SA = C + I$
PSEUDOADD	pseudo-additive	$O = C \times [S + I - 1]$	$SA = C \times I$
LOGADD	log-additive	$Log(O) = C + S + I$	$SA = exp(C + I)$

OUTFCST

OUTFORECAST

determines whether forecasts are included in certain tables sent to the output data set. If OUTFORECAST is specified, then forecast values are included in the output data set for tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, and D18. The default is not to include forecasts.

SEASONALMA=S3X1

SEASONALMA=S3X3

SEASONALMA=S3X5

SEASONALMA=S3X9

SEASONALMA=S3X15

SEASONALMA=STABLE

SEASONALMA=X11DEFAULT

SEASONALMA=MSR

specifies which seasonal moving average (also called seasonal “filter”) be used to estimate the seasonal factors. These seasonal moving averages are $n \times m$ moving averages, meaning that an n -term simple average is taken of a sequence of consecutive m -term simple averages. X11DEFAULT is the method used by the U.S. Census Bureau’s X-11-ARIMA program. The default for PROC X12 is SEASONALMA=MSR, which is the methodology of Statistic Canada’s X-11-ARIMA/88 program.

Table 32.7 describes the seasonal filter options available for the entire series:

Table 32.7 X-12-ARIMA Seasonal Filter Options and Descriptions

Filter Name	Description of Filter
S3X1	a 3 × 1 moving average
S3X3	a 3 × 3 moving average
S3X5	a 3 × 5 moving average
S3X9	a 3 × 9 moving average
S3X15	a 3 × 15 moving average
STABLE	stable seasonal filter. A single seasonal factor for each calendar month or quarter is generated by calculating the simple average of all the values for each month or quarter (taken after detrending and outlier adjustment).
X11DEFAULT	a 3 × 3 moving average is used to calculate the initial seasonal factors in each iteration, and a 3 × 5 moving average to calculate the final seasonal factors
MSR	filter chosen automatically by using the moving seasonality ratio of X-11-ARIMA/88 (Dagum 1988)

TRENDMA=value

specifies which Henderson moving average be used to estimate the final trend cycle. Any odd number greater than one and less than or equal to 101 can be specified. Example: TRENDMA=23. If no selection is made, the program selects a trend moving average based on statistical characteristics of the data. For monthly series, a 9-, 13-, or 23-term Henderson moving average is selected. For quarterly series, the program chooses either a 5- or a 7-term Henderson moving average.

FINAL=AO**FINAL=LS****FINAL=TC****FINAL=ALL**

lists the types of prior adjustment factors, obtained from the regression and outlier statements, that are to be removed from the final seasonally adjusted series. Additive outliers (FINAL=AO), level change and ramp outliers (FINAL=LS), and temporary change (FINAL=TC) can be removed. If this option is not specified, the final seasonally adjusted series contains these effects.

FORCE=TOTALS**FORCE=ROUND****FORCE=BOTH**

specifies that the seasonally adjusted series be modified to (a) force the yearly totals of the seasonally adjusted series and the original series to be the same (FORCE=TOTALS), (b) adjust the seasonally adjusted values for each calendar year so that the sum of the rounded seasonally adjusted series for any year equals the rounded annual total (FORCE=ROUND), or (c) first force the yearly totals, then round the adjusted series (FORCE=BOTH). When FORCE=TOTALS, the differences between the annual totals is distributed over the seasonally adjusted values in a way that approximately preserves the month-to-month (or quarter-to-quarter) movements of the original series. For more details, see Huot (1975) and Cholette

(1979). This forcing procedure is not recommended if the seasonal pattern is changing or if trading day adjustment is performed. Forcing the seasonally adjusted totals to be the same as the original series annual totals can degrade the quality of the seasonal adjustment, especially when the seasonal pattern is undergoing change. It is not natural if trading day adjustment is performed because the aggregate trading day effect over a year is variable and moderately different from zero.

Details: X12 Procedure

Missing Values

PROC X12 can process a series with missing values. Missing values in a series are considered to be one of two types:

- One type of missing value is a leading or trailing missing value, which occurs before the first nonmissing value or after the last nonmissing value, respectively, in the span of a series. The span of a series can be determined either explicitly by the SPAN= option of the PROC X12 statement or implicitly by the START= or DATE= options. By default, leading and trailing missing values are ignored. The NOTRIMMISS option of the PROC X12 statement causes leading and trailing missing values to also be processed using the X-12-ARIMA missing value method.
- The second type of missing value is an embedded missing value. These missing values occur between the first nonmissing value and the last nonmissing value in the span of the series. Embedded missing values are processed using X-12-ARIMA's missing value method described below.

When the X-12-ARIMA method encounters a missing value, it inserts an additive outlier for that observation into the set of regression variables for the model of the series and then replaces the missing observation with a value large enough to be considered an outlier during model estimation. After the regARIMA model is estimated, the X-12-ARIMA method adjusts the original series by using factors generated from these missing value outlier regressors. The adjusted values are estimates of the missing values, and the adjusted series is displayed in Table MV1.

Combined Test for the Presence of Identifiable Seasonality

The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality). If the increase in the seasonal factors from year to year is too large, then the seasonal factors will introduce distortion into the model. It is important to determine if seasonality is identifiable without distorting the series.

For seasonality to be identifiable, the series should be identified as seasonal by using the “Test for the Presence of Seasonality Assuming Stability” and “Nonparametric Test for the Presence of Seasonality Assuming Stability.” Also, since the presence of moving seasonality can cause distortion, it is important to evaluate the moving seasonality in conjunction with the stable seasonality to determine if the seasonality is identifiable.

The test for identifiable seasonality is performed by combining the F tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The description below is based on Lothian and Morry (1978b); other details can be found in Dagum (1988, 1983).

Let F_s and F_m denote the F value for the stable and moving seasonality tests, respectively. The combined test is performed as shown in Table 32.3 and as follows:

1. If the null hypothesis in the stable seasonality test is not rejected at the 0.10% significance level (0.001), then since the series is not seasonal, PROC X12 displays “Identifiable Seasonality Not Present.”
2. If the null hypothesis in step 1 is rejected, then compute the following quantities:

$$T_1 = \frac{7}{F_m}$$

$$T_2 = \frac{3F_m}{F_s}$$

Let T denote the simple average of T_1 and T_2 :

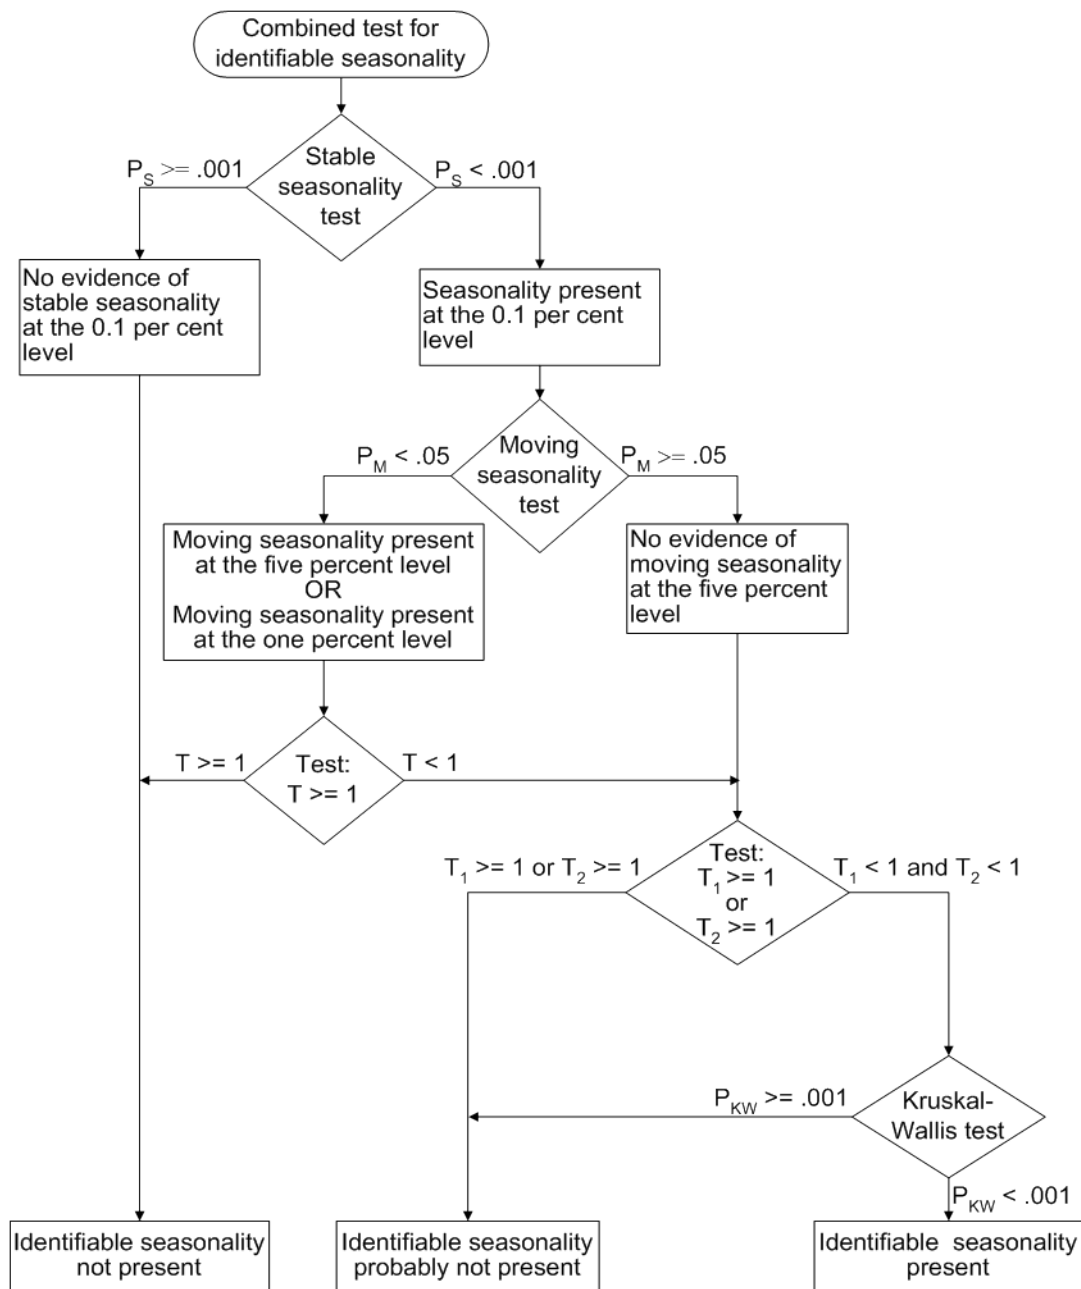

$$T = \frac{(T_1 + T_2)}{2}$$

If the moving seasonality null hypothesis is not rejected at the 5.0% significance level (0.05) and if $T \geq 1.0$, the null hypothesis of identifiable seasonality *not* present is accepted and PROC X12 displays “Identifiable Seasonality Not Present.”

3. If the null hypothesis of identifiable seasonality *not* present has not been accepted, but $T_1 \geq 1.0$, $T_2 \geq 1.0$, or the Kruskal-Wallis chi-squared test fails at the 0.10% significance level (0.001), then PROC X12 displays “Identifiable Seasonality Probably Not Present.”
4. If the F_s and Kruskal-Wallis chi-squared tests pass, and if none of the combined measures described in steps 2 and 3 fail, then the null hypothesis of identifiable seasonality *not* present is rejected, and PROC X12 displays “Identifiable Seasonality Present.”

The “Summary of Results for Combined Test for the Presence of Identifiable Seasonality” table displays the T_1 , T_2 , and T values and the significance levels for the stable seasonality test, the moving seasonality test, and the Kruskal-Wallis test. The last item in the table is the result of the combined test for identifiable seasonality.

Figure 32.3 Combined Seasonality Test Flowchart

Computations

For more details about the computations used in PROC X12, see *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2001b).

For more details about the X-11 method of decomposition, see *Seasonal Adjustment with the X-11 Method* (Ladiray and Quenneville 2001).

Displayed Output/ODS Table Names/OUTPUT Tablename Keywords

The options specified in PROC X12 control both the tables produced by the procedure and the tables available for output to the OUT= data set specified in the OUTPUT statement.

The displayed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X12 procedure are as follows:

- A prior adjustments and regARIMA components (optional)
- B preliminary estimates of irregular component weights and trading day regression factors (X-11 method)
- C final estimates of irregular component weights and trading day regression factors
- D final estimates of seasonal, trend cycle, and irregular components
- E analytical tables
- F summary measures
- G charts

Table 32.8 describes the individual tables and charts. “P” indicates that the table is displayed only and is not available for output to the OUT= data set. Data from displayed tables can be extracted into data sets by using the Output Delivery System (ODS). For more information about the features of the ODS Graphics system, including the many ways that you can control or customize the plots produced by SAS procedures, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*). For more information about the SAS Output Delivery system, see the *SAS Output Delivery System: User’s Guide*.

When tables available through the OUTPUT statement are output using ODS, the summary line is included in the ODS output by default. The summary line gives the average, standard deviation, or total by each period. The value –1 for YEAR indicates that the summary line is a total; the value –2 for YEAR indicates that the summary line is an average; and the value –3 for YEAR indicates that the line is a standard deviation. The value of YEAR for historical and forecast values will be greater than or equal to zero. Thus, a negative value indicates a summary line. You can suppress the summary line altogether by specifying the NOSUM option in the TABLES statement. However, the NOSUM option also suppresses the display of the summary line in the displayed table.

“T” indicates that the table is available using the OUTPUT statement, but is not displayed by default; you must request that these tables be displayed by using the TABLES Statement. The actual number of tables displayed depends on the options and statements specified. If a table is not computed, it is not displayed.

Table 32.8 Table Names and Descriptions

Table	Description	Notes
IDENTIFY Tables		
ACF	autocorrelation factors	P
PACF	partial autocorrelation factors	P

E6R	percent changes (differences) in rounded seasonally adjusted series (D11.R)	
E7	differences in final trend cycle	
F2A-I	summary measures	P
F3	quality assessment statistics	P
F4	day of the week trading day component factors	P
G	spectral analysis	P

ODS Graphics

This section describes the use of ODS for creating graphics with the X12 procedure. To request these graphs, you must specify the ODS GRAPHICS statement.

The graphics available through ODS GRAPHICS are ACF plots, PACF plots, and spectral graphs. ACF and PACF plots are not available unless the IDENTIFY statement is used. A spectral plot of the original series is always available; however additional spectral plots are provided when the X11

statement is used. When the ODS GRAPHICS statement is not used, the plots are integrated into the ACF, PACF, and spectral tables as a column of the table.

ODS Graph Names

PROC X12 assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 32.9](#).

Table 32.9 ODS Graphics Produced by PROC X12

ODS Graph Name	Plot Description
ACFPlot	autocorrelation of model residuals
PACFPlot	partial autocorrelation of model residuals
SpectralPlot	spectral plot of original or adjusted series

Special Data Sets

The X12 procedure can input the MDLINFOIN= and output the MDLINFOOUT= data sets. The structure of both these data sets is the same. The difference is that when the MDLINFOIN= data set is read, only information relative to specifying a model is processed, whereas the MDLINFOOUT= data set contains the results of estimating a model. The X12 procedure can also read data sets that contain EVENT definition data. The structure of these data sets is the same as in the SAS[®] High Performance Forecasting system.

MDLINFOIN= and MDLINFOOUT= Data Sets

The MDLINFOIN= and MDLINFOOUT= data sets can contain the following variables.

- <by-variables> enable the model information to be specified by BY groups. BY variables can be included in this data set that match the BY variables used to process the series. If no BY variables are included, then the models specified by `_NAME_` apply to all BY groups.
- `_NAME_` should match the variable name of the time series to which the model is to be applied. Omit the `_NAME_` variable if you are specifying the same model for all series in the BY group.
- `_MODELTYPE_` specifies whether the observation contains regression or ARIMA information. For PROC X12, `_MODELTYPE_` should either be REG to supply regression information or ARIMA to supply model information. If valid regression information exists in the MDLINFOIN= data set for the BY group and series being processed, then the REGRESSION, INPUT, and EVENT statements are ignored for that BY group and series. Likewise, if valid model information exists in the data set, then the AUTOMDL, ARIMA, and TRANSFORM statements are ignored. Valid values for the other variables in the data set depend on the value of the

`_MODELTYPE_` variable. While other values of `_MODELTYPE_` might be permitted in other SAS procedures, PROC X12 recognizes only REG and ARIMA.

`_MODELPART_` further qualifies the regression or ARIMA information in the observation. For `_MODELTYPE_ = REG`, valid values of `_MODELPART_` are INPUT, EVENT, and PREDEFINED. A value of INPUT indicates that this observation refers to the user-defined variable whose name is given in `_DSVAR_`. Likewise, a value of EVENT indicates that the observation refers to the SAS or user-defined EVENT whose name is given in `_DSVAR_`. PREDEFINED indicates that the name given in `_DSVAR_` is a predefined U.S. Census Bureau variable. If only model information is included in the data set (that is, all observations have `_MODELTYPE_ = ARIMA`) then the `_MODELPART_` variable can be omitted. However, valid values for model information are FORECAST, “?”, or blank.

`_COMPONENT_` further qualifies the regression or ARIMA information in the observation. For `_MODELTYPE_ = REG`, the only valid value of `_COMPONENT_` is SCALE. Other SAS procedures might allow other values. For `_MODELTYPE_ = ARIMA`, the valid values of `_COMPONENT_` are TRANSFORM, CONSTANT, NONSEASONAL, and SEASONAL. TRANSFORM indicates that the observation contains the information that would be supplied in the TRANSFORM statement. CONSTANT is specified to control the constant term in the model. NONSEASONAL and SEASONAL refer to the AR, MA, and differencing terms in the ARIMA model.

`_PARMTYPE_` further qualifies the regression or ARIMA information in the observation. For regression information, the value of `_PARMTYPE_` is the same as the value of the REGRESSION USERTYPE= option. Since the USERTYPE= option applies only to user-defined events and variables, the value of `_PARMTYPE_` does not alter processing in observations where `_MODELPART_ = PREDEFINED`. However, it is consistent to use a value for `_PARMTYPE_` that matches the Census predefined variable. For the constant term in model information, `_PARMTYPE_` should be SCALE. For transformation information, the value of `_PARMTYPE_` should be NONE, LOG, LOGIT, SQRT, or BOXCOX. For ARIMA model information, `_PARMTYPE_` should be AR, MA, or DIF.

`_DSVAR_` specifies the variable name associated with this observation. For regression information, the value of `_DSVAR_` is the name of the user-defined variable, the EVENT, or the Census predefined variable. For model information, `_DSVAR_` should match the name of the series being processed. If the model information applies to more than one series, then `_DSVAR_` can be blank or “?”.

`_VALUE_` contains a numerical value that is used as a parameter for certain types of information. For certain Census predefined variables, `_VALUE_` is the associated parameter value. For example, the REGRESSION statement option PREDEFINED=EASTER(6) would be implemented using `_DSVAR_ = EASTER` and `_VALUE_ = 6`. For a BOXCOX transformation, `_VALUE_` would be the associated parameter value. For `_COMPONENT_ = SEASONAL`, if `_VALUE_` is nonmissing, then `_VALUE_` is used as the seasonal period. If `_VALUE_` is missing for `_COMPONENT_ = SEASONAL`, then the seasonal period is determined by the interval of the series.

<code>_FACTOR_</code>	applies only to AR and MA ARIMA model information. The actual value of <code>_FACTOR_</code> should be the same for all observations related to lags within the same ARIMA factor. So the value of <code>_FACTOR_</code> identifies lags that belong in the same factor.
<code>_LAG_</code>	identifies the degree for differencing and AR and MA lags. If <code>_COMPONENT_=SEASONAL</code> , then the value in <code>_LAG_</code> is multiplied by the seasonal period indicated by the value of <code>_VALUE_</code> .
<code>_SHIFT_</code>	contains the shift value for transfer functions. This value is not processed by PROC X12.
<code>_NOEST_</code>	indicates whether a parameter associated with the observation is to be estimated. For example, the NOINT option would be indicated by constant information with <code>_NOEST_=1</code> and <code>_EST_=0</code> . <code>_NOEST_=1</code> indicates that the value in <code>_EST_</code> is a fixed value. <code>_NOEST_</code> pertains to the constant term, to AR and MA lags, and to regression information.
<code>_EST_</code>	contains an initial or fixed value for a parameter associated with the observation that is to be estimated. <code>_NOEST_=1</code> indicates the value in <code>_EST_</code> is a fixed value. <code>_EST_</code> pertains to the constant term, to AR and MA lags, and to regression information.
<code>_STDERR_</code>	contains output information about estimated parameters.
<code>_TVALUE_</code>	contains output information about estimated parameters.
<code>_PVALUE_</code>	contains output information about estimated parameters.

INEVENT= Data Set

The INEVENT= data set can contain the following variables. When a variable is omitted from the data set, that variable is assumed to have the default value for all observations. The default values are given below.

<code>_NAME_</code>	EVENT variable name. <code>_NAME_</code> is displayed with the case preserved. Since <code>_NAME_</code> is a SAS variable name, the event can be referenced by using any case. The <code>_NAME_</code> variable is required; there is no default.
<code>_CLASS_</code>	class of EVENT: SIMPLE, COMBINATION, PREDEFINED. The default for <code>_CLASS_</code> is SIMPLE.
<code>_KEYNAME_</code>	contains either a date keyword (SIMPLE EVENT), a predefined EVENT variable name (PREDEFINED EVENT), or an EVENT name (COMBINATION event). All <code>_KEYNAME_</code> values are displayed in upper case. However, if the <code>_KEYNAME_</code> value refers to an EVENT name, then the actual name can be of mixed case. The default for <code>_KEYNAME_</code> is no keyname, designated by “.”.
<code>_STARTDATE_</code>	contains either the date timing value or the first date timing value to use in a do-list. The default for <code>_STARTDATE_</code> is no date, designated by a missing value.
<code>_ENDDATE_</code>	contains the last date timing value to use in a do-list. The default for <code>_ENDDATE_</code> is no date, designated by a missing value.

- _DATEINTRVL_** contains the interval for the date do-list. The default for **_DATEINTRVL_** is no interval, designated by “.”.
- _STARTDT_** contains either the datetime timing value or the first datetime timing value to use in a do-list. The default for **_STARTDT_** is no datetime, designated by a missing value.
- _ENDDT_** contains the last datetime timing value to use in a do-list. The default for **_ENDDT_** is no datetime, designated by a missing value.
- _DTINTRVL_** contains the interval for the datetime do-list. The default for **_DTINTRVL_** is no interval, designated by “.”.
- _STARTOBS_** contains either the observation number timing value or the first observation number timing value to use in a do-list. The default for **_STARTOBS_** is no observation number, designated by a missing value.
- _ENDOBS_** contains the last observation number timing value to use in a do-list. The default for **_ENDOBS_** is no observation number, designated by a missing value.
- _OBSINTRVL_** contains the interval length of the observation number do-list. The default for **_OBSINTRVL_** is no interval, designated by “.”.
- _TYPE_** type of EVENT. The default for **_TYPE_** is POINT.
- _VALUE_** value for nonzero observation. The default for **_VALUE_** is 1.0.
- _PULSE_** INTERVAL that defines the units for the DURATION values. The default for **_PULSE_** is no interval, designated by “.”.
- _DUR_BEFORE_** number of durations before the timing value. The default for **_DUR_BEFORE_** is 0.
- _DUR_AFTER_** number of durations after the timing value. The default for **_DUR_AFTER_** is 0.
- _SLOPE_BEFORE_** determines whether the curve is GROWTH or DECAY before the timing value for **_TYPE_=RAMP**, **_TYPE_=RAMPP**, and **_TYPE_=TC**. The default for **_SLOPE_BEFORE_** is GROWTH.
- _SLOPE_AFTER_** determines whether the curve is GROWTH or DECAY after the timing value for **_TYPE_=RAMP**, **_TYPE_=RAMPP**, and **_TYPE_=TC**. The default for **_SLOPE_AFTER_** is GROWTH unless **_TYPE_=TC**; then the default is DECAY.
- _SHIFT_** number of **_PULSE_** intervals to shift the timing value. The shift can be positive (forward in time) or negative (backward in time). If **_PULSE_** is not specified, then the shift is in observations. The default for **_SHIFT_** is 0.
- _TCPARM_** parameter for EVENT of **TYPE=TC**. The default for **_TCPARM_** is 0.5.
- _RULE_** rule to use when combining events or when timing values of an event overlap. The default for **_RULE_** is ADD.
- _PERIOD_** frequency interval at which the event should be repeated. If this value is missing, then the event is not periodic. The default for **_PERIOD_** is no interval, designated by “.”.
- _LABEL_** label or description for the event. If you do not specify a label, then the default label value is displayed as “.”. For events that produce dummy variables, either the user-supplied label or the default label is used. For **COMPLEX** events, the **_LABEL_** value is merely a description of the group of events.

Examples: X12 Procedure

Example 32.1: Model Identification

An example of the statements typically invoked when using PROC X12 for model identification might follow the same format as the following example. This example invokes the X12 procedure and uses the TRANSFORM and IDENTIFY statements. It specifies the time series data, takes the logarithm of the series (TRANSFORM statement), and generates ACFs and PACFs for the specified levels of differencing (IDENTIFY statement). The ACFs and PACFs for Nonseasonal Order=1 and Seasonal Order=1 are shown in [Output 32.1.1](#), [Output 32.1.2](#), [Output 32.1.3](#), and [Output 32.1.4](#). The data set is the same as in the section “[Basic Seasonal Adjustment](#)” on page 2104.

The graphical displays are requested by specifying the ODS GRAPHICS statement. For more information about the graphics available in the X12 procedure, see the section “[ODS Graphics](#)” on page 2141.

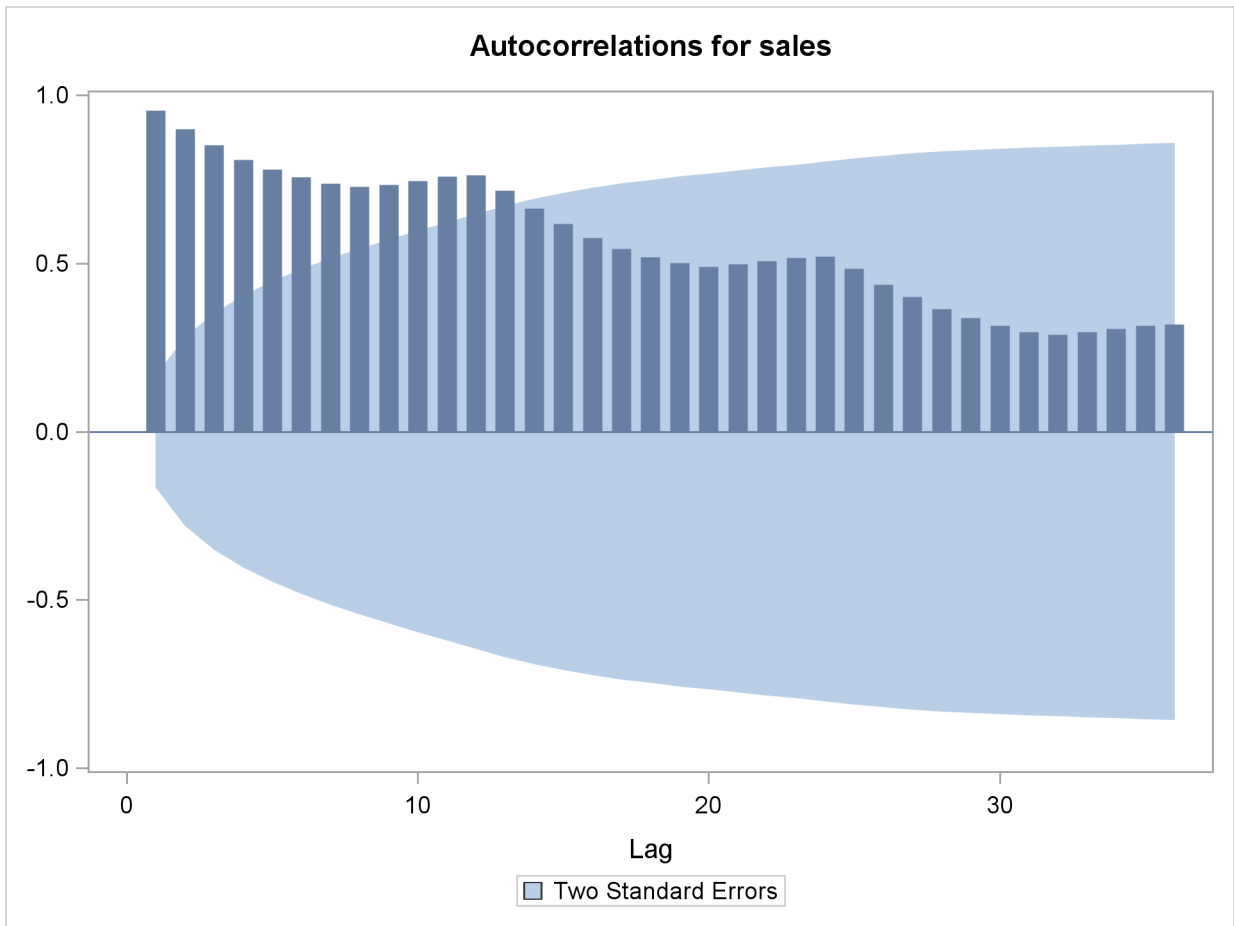

```
ods graphics on;
proc x12 data=sales date=date;
  var sales;
  transform power=0;
  identify diff=(0,1) sdiff=(0,1);
run;
```

Example 32.3: Seasonal Adjustment

Assuming that the model in [Example 32.2](#) is satisfactory, a seasonal adjustment that uses forecast extension can be performed by adding the X11 statement to the procedure. By default, the data is forecast one year ahead at the end of the series. Table D8.A is shown in [Output 32.3.1](#).

```

ods output D8A#1=SalesD8A_1;

T = (T1 + T2)/2		0.04			
Combined Test of Identifiable Seasonality:		Present			

The four ODS statements in the preceding example direct output from the D8A tables into four data sets: SalesD8A_1, SalesD8A_2, SalesD8A_3, and SalesD8A_4. It is best to direct the output to four different data sets because the four tables associated with table D8A have varying formats. The ODS data sets are shown in [Output 32.3.2](#), [Output 32.3.3](#), [Output 32.3.4](#), and [Output 32.3.5](#).

Example 32.4: RegARIMA Automatic Model Selection

This example demonstrates two of the new features available through the X-12-ARIMA method that are not available by using the previous X-11 and X-11-ARIMA methods: regARIMA modeling and TRAMO-based automatic model selection. Assume that the same data set is used as in the previous examples.

run;

```

The automatic model selection output is shown in [Output 32.4.1](#), [Output 32.4.2](#), and [Output 32.4.3](#). The first table, “ARIMA Estimate for Unit Root Identification,” gives details of the method that TRAMO uses to automatically select the orders of differencing. The second table, “Results of Unit Root Test for Identifying Orders of Differencing,” shows that a regular difference order of 1 and a seasonal difference order of 1 has been determined by TRAMO. The third table, “Models estimated by Automatic ARIMA Model Selection procedure,” shows all the models examined by the TRAMO-based method. The fourth table, “Best Five ARIMA Models Chosen by Automatic Modeling,” shows the top five models in order of rank and their BIC2 statistic. The fifth table, “Comparison of Automatically Selected Model and Default Model,” compares the model selected by the TRAMO model to the default X-12-ARIMA model. The sixth table, “Final Automatic Model Selection,” shows which model was actually selected.

Table 32.10 and Output 32.4.4 illustrate the regARIMA modeling method. Table 32.10 shows the relationship between the output variables in PROC X12 that results from a regARIMA model. Note that some of these formulas apply only to this example. Output 32.4.4 shows the values of these variables for the first 23 observations in the example.

Table 32.10 regARIMA Output Variables and Descriptions

Table	Title	Type	Formula
A1	time series data (for the span analyzed)	data	input
A2	prior-adjustment factors leap year (from trading day regression) adjustments	factor	calculated from regression
A6	regARIMA trading day component leap year prior adjustments included from Table A2	factor	calculated from regression
B1	original series (prior adjusted) (adjusted for regARIMA factors)	data	$B1 = A1/A6$ * * because only TD specified
C17	final weights for irregular component	factor	calculated using moving standard deviation
C20	final extreme value adjustment factors	factor	calculated using C16 and C17
D1	modified original data, D iteration	data	$D1 = B1/C20$ ** $D1 = C19/C20$ ** C19=B1 in this example
D7	preliminary trend cycle, D iteration	data	calculated using Henderson moving average
D8	final unmodified SI ratios	factor	$D8 = B1/D7$ *** $D8 = C19/D7$ *** TD specified in regression
D9	final replacement values for SI ratios	factor	if C17 shows extreme values, $D9 = D1/D7$; $D9 = .$ otherwise
D10	final seasonal factors	factor	calculated using moving averages
D11	final seasonally adjusted data (also adjusted for trading day)	data	$D11 = B1/D10$ **** $D11 = C19/D10$ **** $B1 = C19$ for this example
D12	final trend cycle	data	calculated using Henderson moving average
D13	final irregular component	factor	$D13 = D11/D12$
D16	combined adjustment factors (includes seasonal, trading day factors)	factor	$D16 = A1/D11$
D18	combined calendar adjustment factors (includes trading day factors)	factor	$D18 = D16/D10$ $D18 = A6$ ***** ***** regression TD is the only calendar adjustment factor in this example

Example 32.5: Automatic Outlier Detection

This example demonstrates the use of the OUTLIER statement to automatically detect and remove outliers from a time series to be seasonally adjusted. The data set is the same as in the section “[Basic Seasonal Adjustment](#)” on page 2104 and the previous examples. Adding the OUTLIER statement to [Example 32.3](#) requests that outliers be detected by using the default critical value as described in the section “[OUTLIER Statement](#)” on page 2122. The tables associated with outlier detection for this example are shown in [Output 32.5.1](#). The first table shows the critical values; the second table shows that a single potential outlier was identified; the third table shows the estimates for the ARMA parameters. Since no outliers are included in the regression model, the “Regression Model Parameter Estimates” table is not displayed. Because only a potential outlier was identified, and not an actual outlier, in this case the A1 series and the B1 series are identical.

```

title 'Automatic Outlier Identification';
proc x12 data=sales date=date;
  var sales;
  transform function=log;
  arima model=( 0,1,1)(0,1,1) );
  outlier;
  estimate;
  x11;
  output out=nooutlier a1 b1 d10;
run ;

```

Output 32.5.1 PROC X12 Output When Potential Outliers Are Identified

Automatic Outlier Identification				
The X12 Procedure				
Critical Values to use in Outlier Detection				
For variable sales				
Begin		SEP1978		
End		AUG1990		
Observations		144		
Method		Add One		
AO Critical Value		3.889838		
LS Critical Value		3.889838		
NOTE: The following time series values might later be identified as outliers when data are added or revised. They were not identified as outliers in this run either because their test t-statistics were slightly below the critical value or because they were eliminated during the backward deletion step of the identification procedure, when a non-robust t-statistic is used.				
Potential Outliers				
For variable sales				
Type of		t Value	t Value

Output 32.5.1 *continued*

Exact ARMA Maximum Likelihood Estimation For variable sales					
Parameter	Lag	Estimate	Standard Error	t Value	Pr > t
Nonseasonal MA	1	0.40181	0.07887	5.09	<.0001
Seasonal MA	12	0.55695	0.07626	7.30	<.0001

In the next example, reducing the critical value to 3.3 causes the outlier identification routine to more aggressively identify outliers as shown in [Output 32.5.2](#). The first table shows the critical values. The second table shows that three additive outliers and a level shift have been included in the regression model. The third table shows how the inclusion of outliers in the model affects the ARMA parameters.

```
proc x12 data=sales date=date;
  var sales;
  transform function=log;
  arima model=((0,1,1) (0,1,1));
  outlier cv=3.3;
  estimate;
  x11;
  output out=outlier(obs=50) a1 a8 a8ao a8ls b1 d10;
run;
proc print data=outlier(obs=50);
run;
```

The first 50 observations of the A1, A8, A8AO, A8LS, B1, and D10 series are displayed in [Output 32.5.3](#). You can confirm the following relationships from the data.

$$A8 = A8AO \times A8LS$$

$$B1 = A1/A8$$

The seasonal factors are stored in the variable sales_D10.

From the two previous examples, you can examine how outlier detection affects the seasonally adjusted series. [Output 32.5.4](#) shows a plot of A1 versus B1 in the series where outliers are detected. B1 has been adjusted for the additive outliers and the level shift.

```
proc sgplot data=outlier;
  series x=date y=sales_A1 / name='A1' markers
          markerattrs=(color=red symbol='circle')
          lineattrs=(color=red);
  series x=date y=sales_B1 / name='B1' markers
          markerattrs=(color=black symbol='asterisk')
          lineattrs=(color=black);
  yaxis label='Original and Outlier Adjusted Time Series';
run;
```

Output 32.5.4 Original Series and Outlier Adjusted Series

[Output 32.5.5](#) compares the seasonal factors (table D10) of the series unadjusted for outliers to the series adjusted for outliers. The seasonal factors are based on the B1 series.

```
data both;
  merge nooutlier(rename=(sales_D10=unadj_D10)) outlier;
run;

title 'Results of Outlier Identification on Final Seasonal Factors';
proc sgplot data=both;
```

```

series x=date y=unadj_D10 / name='unadjusted' markers
                                markerattrs=(color=red symbol='circle')
                                lineattrs=(color=red)
                                legendlabel='Unadjusted for Outliers';
series x=date y=sales_D10 / name='adjusted' markers
                                markerattrs=(color=blue symbol='asterisk')
                                lineattrs=(color=blue)
                                legendlabel='Adjusted for Outliers';
yaxis label='Final Seasonal Factors';
run;

```

Output 32.5.5 Seasonal Factors Based on Original and Outlier Adjusted Series

Example 32.6: User-Defined Regressors

This example demonstrates the use of the `USERVAR=` option in the `REGRESSION` statement to include user-defined regressors in the `regARIMA` model. The user-defined regressors must be defined as nonmissing values for the span of the series being modeled plus any forecast values. Suppose you have the data set `SALESDATA` with 132 monthly observations beginning in January of 1949.

```

title 'Data Set to be Seasonally Adjusted';

```

```
data salesdata;
  set sashelp.air(obs=132);
run;
```

Since the regARIMA model forecasts one year ahead, the user-defined regressor must be defined for 144 observations that start in January of 1949. You can construct a simple length-of-month regressor by using the following DATA step.

```
title 'User-defined Regressor for Data to be Seasonally Adjusted';
data regressors(keep=date LengthOfMonth);
  set sashelp.air;
  LengthOfMonth = INTNX('MONTH',date,1) - date;
run;
```

The two data sets must be merged in order to use them as input to PROC X12. The BY statement is used to align the regressors with the time series by the time ID variable DATE.

```
title 'Data Set Containing Series and Regressors';
data datain;
  merge regressors salesdata;
  by date;
run;
proc print data=datain(firstobs=121);
run;
```

The last 24 observations of the input data set are displayed in [Output 32.6.1](#). Note that the regressor variable is defined for one year (12 observations) beyond the span of the time series to be seasonally adjusted.

Output 32.6.1 PROC X12 Input Data Set with User-Defined Regressor

Data Set Containing Series and Regressors				
Obs	DATE	Length OfMonth	AIR	
121	JAN59	31	360	
122	FEB59	28	342	
123	MAR59	31	406	
124	APR59	30	396

Suppose that after examining the output from the preceding example, you decide that an Easter regressor should be added to the model. The following statements create a data set with the model identified above and adds a U.S. Census Bureau Predefined Easter(25) regression. The new model data set to be used as input in the MDLINFOIN= option is displayed in the data set shown in [Output 32.7.3](#).

```

data pluseaster;
  _NAME_ = 'y';
  _MODELTYPE_ = 'REG';
  _MODELPART_ = 'PREDEFINED';
  _COMPONENT_ = 'SCALE';
  _PARMTYPE_ = 'EASTER';
  _DSVAR_ = 'EASTER';
  _VALUE_ = 25;
run;

```

```

data mdlpluseaster;
  set mdl;
run;

proc append base=mdlpluseaster data=pluseaster force;
run;

proc print data=mdlpluseaster;
run;

```

Example 32.8: Setting Regression Parameters

This example illustrates the use of fixed regression parameters in PROC X12. Suppose that you have the same data set as in the section “Basic Seasonal Adjustment” on page 2104. You would like to use TRAMO to automatically identify a model with an U.S. Census Bureau Easter(25) regression. The displayed results are shown in [Output 32.8.1](#).

```

title 'Estimate Easter(25) Parameter';
proc x12 data=sales date=date MdlInfoOut=mdlout1;
  var sales;
  regression predefined=easter(25);
  automdl;
run ;

```

Output 32.8.1 Automatic Model ID with Easter(25) Regression

To fix the Easter(25) parameter while adding a regressor that is weighted according to the number of Saturdays in a month, either use the REGRESSION and EVENT statements or create a MDLINFOOUT= data set. The following statements show the method for using the REGRESSION statement to fix the EASTER parameter and the EVENT statement to add the SATURDAY regressor. The output is shown in [Output 32.8.3](#).

```

title 'Use SAS Statements to Alter Model';
proc x12 data=sales date=date MdlInfoOut=mdlout2grm;
  var sales;

```

```

regression predefined=easter(25) / b=-5.029298 F;
event Saturday;
automdl;
run ;

```

The MDLINFOOUT= data set provides a method for comparing the results of the model identification. The data set mdlout3grm that is the result of using the ARIMA MODEL= option can be compared to the data set mdlout2DS that is the result of using the MDLINFOIN= data set with initial values for the AR and MA parameters. The mdlout2DS data set is shown in [Output 32.8.7](#), and the results of the comparison are shown in [Output 32.8.8](#). The slight difference in the estimated parameters can be attributed to the difference in the initial values for the AR and MA parameters.

```
proc print data=mdlout2DS;
run;
```

Example 32.9: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. Using the same data set as in the section “[Basic Seasonal Adjustment](#)” on page 2104 and the previous examples, a spectral plot of the original series is displayed in [Output 32.9.1](#).

The graphical displays are requested by specifying the ODS GRAPHICS statement. For specific information about the graphics available in the X12 procedure, see the section “[ODS Graphics](#)” on page 2141.

```
ods graphics on;
proc x12 data=sales date=date;
    var sales;
run;
```

Output 32.9.1 Spectral Plot for Original Data

Acknowledgments: X12 Procedure

The X-12-ARIMA procedure was developed by the Time Series Staff of the Statistical Research Division, U.S. Census Bureau.

Brian Monsell is the primary programmer for the U.S. Census Bureau's X-12-ARIMA procedure and has been very helpful in the development of PROC X12.

The version of PROC X12 documented here was produced by converting the U.S. Census Bureau's FORTRAN code to the SAS development language and adding typical SAS procedure syntax. This conversion work was performed by SAS and resulted in the X12 procedure. Although several features were added during the conversion, credit for the statistical aspects and general methodology of the X12 procedure belongs to the U.S. Census Bureau.

The X-12-ARIMA seasonal adjustment program contains components developed from Statistics Canada's X-11-ARIMA program.

The X-12-ARIMA automatic modeling method is based on the work of Gomez and Maravall (1997a, b).

Overview: SASECRSP Interface Engine

Introduction

The SASECRSP interface engine enables SAS users to access and process time series, events, portfolios, and group data that reside in CRSPAccess databases. It also provides a seamless interface between CRSP, COMPUSTAT, and SAS data processing. Currently, SASECRSP supports access of CRSP Stock databases, CRSP Indices databases and CRSP/Compustat Merged databases.

Opening a Database

The SASECRSP engine uses the LIBNAME statement to enable you to specify which CRSPAccess database you would like to access and how you would like to perform selection on that database.

To specify the database, you supply the combination of a physical path to indicate the location of the CRSPAccess data files and a set identifier (SETID) to identify the database desired from those available at the physical path. Specify one SETID from [Table 33.1](#). Note that the CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars that provide the time ID variables and enable the LIBNAME to successfully assign.

Table 33.1 CRSPAccess Databases SETIDs

SETID	Data Set
10	CRSP Stock, daily data
20	CRSP Stock, monthly data
200	CRSP/Compustat Merged (CCM) data
400	CRSP Indices data, monthly index groups
420	CRSP Indices data, monthly index series
440	CRSP Indices data, daily index groups
460	CRSP Indices data, daily index series

Usually you do not want to open the entire CRSPAccess database, so for efficiency purposes and ease of use, SASECRSP supports a variety of options for performing data selection on your CRSPAccess database with the LIBNAME statement. These options enable you to open and retrieve data for only the portion of the database you desire. The availability of some of these options depends on the type of database being opened.

CRSP Stock Databases

When accessing the CRSP Stock databases, you can select which securities you want to access by specifying their *PERMNO*s with the *PERMNO=* option. *PERMNO*TM is CRSP's unique permanent issue identification number and the primary key for their stock databases. Alternatively, a number of secondary keys can also be used to select stock data. For example, you could use the *PERMCO=* option to read selected securities based on CRSP's unique permanent company identification number, *PERMCO*TM. A full list of possible keys for accessing CRSP Stock data is shown in [Table 33.2](#).

Table 33.2 Keys for Accessing CRSP Stock Data

Key	Access By
PERMNO	CRSP's unique permanent issue identification number This is the primary key for CRSP Stock databases.
PERMCO	CRSP's unique permanent company identification number
CUSIP	CUSIP number
HCUSIP	historical CUSIP
SICCD	standard industrial classification (SIC) code
TICKER	TICKER symbol (for active companies only)

CRSP/Compustat Merged Databases

When accessing Compustat data via the CCM database, you can select which companies you want to access by specifying their *GVKEY*s. *GVKEY*TM is Compustat's unique identifier and primary key. You can specify a *GVKEY* to include with the *GVKEY=* option. Two secondary keys, *PERMNO* and *PERMCO*, are also supported for access via their respective *PERMNO=* and *PERMCO=* options. A full list of possible keys for accessing CCM data is shown in [Table 33.3](#).

Table 33.3 Keys for Accessing CCM Data

Key	Access By
GVKEY	Compustat's unique identifier and primary key for CCM database
PERMNO	CRSP's unique permanent issue identification number
PERMCO	CRSP's unique permanent company identification number

CRSP Indices Databases

When accessing CRSP Indices data, you can select which indices you want to access by specifying their *INDNO*s. *INDNO*TM is the primary key for CRSP Indices databases. You can specify which *INDNO* to use with the *INDNO=* option. No secondary key access is supported for CRSP Indices. A full list of possible keys for accessing CRSP Indices data is shown in [Table 33.4](#).

Table 33.4 Keys for Accessing Indices Data

Key	Access By
INDNO	CRSP's unique permanent index identifier number. This is the primary key for CRSP Indices databases and enables you to specify which index series or groups you want to select.

Regardless of the database you are accessing, you can always use the INSET= and RANGE= options for subsetting and selection. The RANGE= option subsets the data timewise. The INSET= option enables you to specify which issues or companies you want to select from the CRSP database by using an input SAS data set.

Using Your Opened Database

Once the LIBNAME is assigned, the database is opened. You can retrieve data for any member you want in the opened database. For a complete description of available data sets and their fields, see the section “[Data Elements Reference: SASECRSP Interface Engine](#)” on page 2234. You can also use the SAS DATA Step to perform further subsetting and to store the resulting time series in a SAS data set. Since CRSP and SAS use three different date representations, you can make use of the engine-provided CRSP date formats, informats, and functions for your data processing needs. See the section “[Understanding CRSP Date Formats, Informats, and Functions](#)” on page 2208, as well as [Example 33.6](#) later in this chapter for more information about dates with SASECRSP.

SASECRSP for SAS 9.2 supports Linux, Solaris (SUNOS5.9), and Windows.

Getting Started: SASECRSP Interface Engine

Structure of a SAS Data Set That Contains Time Series Data

SAS requires time series data to be in a specific form that is recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain points in time. The time at which observations are recorded can be included in the data set as a time ID variable. Note that CRSP sets the date to the end of a time period as opposed to the beginning, and SASECRSP follows this convention. For example, the time ID variable for any particular month in a monthly time series occurs on the last trading day of that month.

The SASECRSP engine provides several different time ID variables depending on the data member opened. For most members, a time ID variable called CALDT is provided. CALDT provides a day-

based calendar date and is in a CRSP date format. This means dates are stored as an offset in an array of trading days or a trading day calendar. There are five different CRSP trading day calendars and the one used depends on the frequency of the data member. For example, the CRSP date for a daily time series refers to a daily trading day calendar.

The five trading day calendars are: annual, quarterly, monthly, weekly and daily. For your convenience, the format and informat for this field is set so the CRSP date is automatically converted to an Integer date representation when viewed or printed. For data programming, the SASECRSP engine provides 23 different user functions for date conversions between CRSP, SAS, and integer dates.

The CCM database contains members whose dates are based on the fiscal calendar of the corresponding company, so a comprehensive set of time ID variables are provided. CRSPDT, RCALDT and FISCALDT provide day-based dates, each with its own format.

- CRSPDT This time ID variable provides a date in CRSP date format similar to CALDT. CRSPDT differs only in that its format and informat are not set for automatic conversion to integer dates because this is already provided by FISCALDT and RCALDT. For fiscal members, CRSPDT is one based on the fiscal calendar of the company.
- FISCALDT This time ID variable provides the same date CRSPDT does, but in integer format. It is the result of performing a CRSP-to-Integer date conversion on CRSPDT. Since the date CRSPDT holds is fiscal, FISCALDT is also fiscal.
- RCALDT This time ID variable is also an integer date, just like FISCALDT, but it has been shifted so the date is on calendar time as opposed to being fiscal.

For example, Microsoft's fiscal year ends in June, so if you look at its annual period descriptor for the 2002 fiscal year, its time ID variables are 78 for CRSPDT, 20021231 for its FISCALDT, and 20020628 for RCALDT. In summary, a total of three time ID variables are provided for fiscal time series members. One is in CRSP date format, and the other two are in integer format with the only difference between the two integer formats being that one of them is based on the fiscal calendar of the company while the other is not.

For more information about how CALDT, CRSPDT, and date conversions are handled, see the section [“Understanding CRSP Date Formats, Informats, and Functions”](#) on page 2208.

The CCM database also contains fiscal array members, which are all the segment data members. They are unlike the fiscal time series in that they are not associated with a calendar and also have their time ID variables embedded in the data as a data field. Generally both fiscal and calendar time ID variables are embedded. However, segment members *segsr*, *segcur*, and *segitm* have only one fiscal time ID variable embedded. For your convenience, SASECRSP calculates and provides CALYR, the calendar version of the embedded fiscal time ID variable for these three segment members. Note that due to limitations of the data, all segment member time ID variables are year-based.

Reading CRSP Data Files

The SASECRSP engine supports reading time series, events, portfolios and group data from CRSPAccess databases. The SETID you specify determines the database that is read. See [Table 33.1](#) for a list of possible databases. The CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars that provide the time ID variables and enable the LIBNAME to successfully assign.

Using the SAS DATA Step

If desired, you can store the selected series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. Once the data is in a SAS data set you can use it as you would any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure, and you can report information concerning the contents of your data set by using the CONTENTS procedure.

You can also create a view of the CRSPAccess database by using the SQL procedure in conjunction with a SASECRSP *libref*. See [Example 33.11](#) later in this chapter for an example with PROC SQL.

Viewtable enables you to view your data by double-clicking on a SASECRSP *libref* in the LIBNAME window of the SAS Display Manager.

Using CRSP Date Formats, Informats, and Functions

Historically, CRSP has used two different methods to represent dates, and SAS has used a third. The SASECRSP engine provides 23 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. See the section “[Understanding CRSP Date Formats, Informats, and Functions](#)” on page 2208 for details.

Syntax: SASECRSP Interface Engine

The SASECRSP engine uses standard engine syntax. Options used by SASECRSP are summarized in [Table 33.5](#).

Table 33.5 Summary of LIBNAME libref

Option	Description
SETID=	specifies which CRSP database subset to open This option is required. See Table 33.1 for complete list of supported SETIDs.
PERMNO=	specifies a CRSP PERMNO to be selected for access
PERMCO=	specifies a CRSP PERMCO to be selected for access
CUSIP=	specifies a current CUSIP to be selected for access
HCUSIP=	specifies a historic CUSIP to be selected for access
TICKER=	specifies a TICKER to be selected for access (for active companies only)
SICCD=	specifies a SIC Code to be selected for access
GVKEY=	specifies a Compustat GVKEY to be selected for access
INDNO=	specifies a CRSP INDNO to be selected for access
RANGE=	specifies the range of data to keep in format 'YYYYMMDD-YYYYMMDD'
INSET=	uses a SAS data set named <i>setname</i> as input for issues
CRSPLINKPATH=	specifies location of the CRSP link history. This option is required for accessing CRSP data with Compustat's GVKEY.

The LIBNAME libref SASECRSP Statement

LIBNAME libref SASECRSP 'physical name' options ;

The physical name required by the LIBNAME statement should point to the directory of CRSPAccess data files where the CRSP database you want to open is located. Note that the physical name **must** end in a slash for UNIX environments and a backslash for Windows environments.

The CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars. The CRSP environment variable CRSPDB_SASCAL is necessary for the SASECRSP LIBNAME to assign successfully. This necessary environment variable should be defined automatically by either the CRSP software installation or, in later versions, the CRSP data installation. Since occasional instances occur where the variable is not set properly, always check to ensure the CRSPDB_SASCAL environment variable is set to the location where your most recent CRSP data resides. Remember to include the final slash or backslash required.

After the LIBNAME is assigned, you can access any of the available data sets/members within the opened database. For a complete description of available data sets and their fields, see the section "[Data Elements Reference: SASECRSP Interface Engine](#)" on page 2234.

The following options can be used in the LIBNAME libref SASECRSP statement:

SETID=*crsp_setidnumber*

Specifies the CRSP database you want to read from. SETID is a required option. Choose one

SETID from seven possible values in Table 33.1. The SETID limits the frequency selection of time series that are included in the SAS data set.

As an example, to access monthly CRSP Stock data, you would use the following statements:

```
LIBNAME myLib sasecrsp 'physical-name'
          SETID=20;
```

PERMNO=*crsp_permnumber*

By default, the SASECRSP engine reads all keys for the CRSPAccess database that you specified in your SASECRSP *libref*. The PERMNO= option enables you to select data from your CRSP database by the PERMNO(s) (or other keys) you specify. PERMNOs are CRSP's unique permanent issue identification number. There is no limit to the number of *crsp_permnumber* options that you can use.

From a performance standpoint, the PERMNO= option does efficient random access and reads *only* the data for the PERMNOs specified.

The following LIBNAME statement reads data only for Microsoft Corporation (PERMNO=10107) and International Business Machines Corporation (PERMNO=12490) using the primary PERMNO key, and thus is very efficient.

```
LIBNAME myLib sasecrsp 'physical-name'
          SETID=20
          PERMNO=10107
          PERMNO=12490;
```

The PERMCO=, CUSIP=, HCUSIP=, SICCD=, TICKER=, GVKEY=, and INDNO= options behave similarly and you can use them in conjunction with or in place of the PERMNO= option. For example you could have used the following statement to access monthly data for Microsoft and IBM:

```
LIBNAME myLib sasecrsp 'physical-name'
          SETID=20
          TICKER='MSFT'
          CUSIP=59491810;
```

Details on the use of other key selection options are described separately later.

PERMNOs specified by this option can select the companies or issues to keep for CRSP Stock or for CRSP/Compustat Merged databases, but PERMNO is not a supported option for CRSP Indices databases. Use the INDNO= option for the CRSP Indices database and use the PERMNO= option with CRSP US Stock and with CRSP/Compustat Merged databases. Details on the use of key selection options for each type of database follows.

STK Databases

PERMNO is the primary key for CRSP Stock databases. Every valid PERMNO you specify with the PERMNO= option keeps exactly one issue.

CCM Databases

PERMNO can be used as a secondary key for the CCM database through CRSPLink™. Linking between the CRSP and Compustat databases is a complex, many-to-many relationship

between *PERMNO*/*PERMCO*s and *GVKEY*s. When accessing CCM data by *PERMNO*, all *GVKEY*s that link to the given *PERMNO* are amalgamated to provide seamless access to all linked data. However, note that accessing CCM data by *PERMNO* is logically different than accessing it by its linked *GVKEY*(s).

In particular, when the *PERMNO* you specify is linked to several different *GVKEY*s, one link is designated as the primary link. This designation is set by CRSP and its researchers, and serves in a specific role for the link information in the CCM database. Only data for the primary link is retrieved for the header. For other members, including all time series members, all links are examined, but data is extracted only for the active period of the links and only if the data is within any possible user-specified date restriction. If two or more *GVKEY*-to-*PERMNO* links overlap in time, data from the later (more recent) *GVKEY* is used. For more information about CRSP links, see “Link Used Array” in the *CRSP/Compustat Merged Database Guide*.

For example, *PERMNO*=10083 is CRSP’s unique issue identifier for Teknowledge Incorporated, and later (due to a name change) Cimflex Teknowledge Corporation. To access CCM data for IBM Corporation, Teknowledge Inc., and Cimflex Teknowledge Corp., you can use the following statement:

```
LIBNAME myLib1 sasecrsp 'physical-name'
      SETID=200
      GVKEY=6066      /* IBM */
      PERMNO=10083;  /* Teknowledge and Cimflex */
```

Teknowledge Inc. and Cimflex Corp. have separate *GVKEY*s in the CCM database, so the previous statement is actually an example of using one *PERMNO* to access data for several (linked) *GVKEY*s. The first link to *GVKEY*=11947 spans March 5, 1986, to December 31, 1988, and the second link to *GVKEY*=15495 spans February 2, 1989, to September 9, 1993.

An alternate way of accessing the data is by using the linked *GVKEY*s directly as seen in this statement.

```
LIBNAME myLib2 sasecrsp 'physical-name'
      SETID=200
      GVKEY=6066
      GVKEY=11947
      GVKEY=15495;
```

These two LIBNAME statements look similar, but do not perform the same operation. **myLib1** assumes you are selecting the issue data for *PERMNO*=10083, so only observations from the CCM database that are **within** the time period of the used links are accessed. In the previous example for **myLib1**, only data ranging from March 5, 1986, to December 31, 1988, are extracted for *GVKEY*=11947 and only data ranging from February 28, 1989, to September 9, 1993, are extracted for *GVKEY*=15496.

Furthermore, while both *GVKEY*s 11947 and 15495 are linked to the *PERMNO*, *GVKEY* 15495 is the primary link, and when accessing the header, only 15495 is used. If the two links overlap, the data from the later (more recent) *GVKEY* of 15495 is used.

In contrast, **myLib2** uses an open range for all three specified keys. If there are data overlapping in time between *GVKEY* 11947 and 15495, data for both are reported. Similarly, when accessing the header, data for both 11947 and 15497 are retrieved.

IND Databases

INDNO is the primary key for accessing CRSP Indices databases. *PERMNO* is not available as a key for the IND (CRSP Indices) database; use *INDNO* for efficient access of IND database.

GVKEY=*crsp_gvkey*

The *GVKEY=* option is similar to the *PERMNO=* option. It enables you to use the Compustat's Permanent SPC Identifier key (*GVKEY*) to select the companies or issues to keep. There is no limit to the number of *crsp_gvkey* options that you can use.

STK Databases

GVKEY can serve as a secondary key for accessing CRSP Stock databases. This requires the additional use of the *CRSPLINKPATH=* option. Linking between the Compustat and CRSP databases is a complex, many-to-many relationship between *GVKEYs* and *PERMNO/PERMCOs*. When accessing CRSP data by *GVKEY*, all links of the specified *GVKEY* are followed and processed. No additional logic is applied, and link ranges are ignored. Accessing CRSP data by *GVKEY* is identical to accessing CRSP data by all of its linked *PERMNOs*.

For example, Wolverine Exploration Co. and Amerac Energy Corp have different *PERMNOs* but the same *GVKEY*, and there are two *identical* ways of accessing CRSP Stock data on these two entities.

```
LIBNAME myLib1 sasacrsp 'physical-name'
          SETID=10
          PERMNO=13638 /* Wolverine Exploration */
          PERMNO=84641; /* Amerac Energy */

LIBNAME myLib2 sasacrsp 'physical-name'
          SETID=10
          CRSPLINKPATH='physical-name'
          GVKEY=1544;
```

The *CRSPLINKPATH=* option is required when accessing CRSP Stock databases by *GVKEY*. See the discussion later in this section on the *CRSPLINKPATH=* option.

CCM Databases

GVKEY is the primary key for accessing the CCM database. Every valid *GVKEY* you specify keeps exactly one company.

IND Databases

INDNO is the primary key for accessing CRSP Indices databases; use *INDNO* instead of *GVKEY* for IND databases. *GVKEY* is not available as a key for accessing CRSP Indices databases.

PERMCO=*crsp_permcompany*

The PERMCO= option is similar to the PERMNO= option. It enables you to use the CRSP's unique permanent company identification key (*PERMCO*) to select the companies or issues to keep. There is no limit to the number of *crsp_permcompany* options that you can use.

STK Databases

PERMCO is a secondary key for accessing CRSP Stock databases. One *PERMCO* can map to multiple *PERMNOs*. Access by *PERMCO* is equivalent to access by all mapped *PERMNOs*.

CCM Databases

PERMCO can also be used as a secondary key for accessing the CCM database. Linking between the CRSP and CCM databases is a complex, many-to-many relationship. When accessing CCM data by *PERMCO*, all linking *GVKEYs* are amalgamated and processed. Link active ranges are respected. Only data for the primary link is returned for the header. In cases when the active ranges of various links overlap, the most recent link is used. See PERMNO= option for more details.

IND Databases

Use *INDNO* for accessing CRSP Indices databases. *PERMCO* is not available as a key for accessing CRSP Indices databases; use *INDNO* instead.

CUSIP=*crsp_cusip*

The CUSIP= option is similar to the PERMNO= option. It enables you to use the *CUSIP* key to select the companies or issues to keep. There is no limit to the number of *crsp_cusip* options that you can use.

STK Databases

CUSIP is a secondary key for accessing CRSP Stock databases. One *CUSIP* maps to one *PERMNO*.

CCM Databases

CUSIP is not available as a key for accessing CCM databases.

IND Databases

Use *INDNO* for accessing CRSP Indices databases. *CUSIP* is not available as a key for accessing CRSP Indices databases; use *INDNO* instead.

HCUSIP=*crsp_hcusip*

The HCUSIP= option is similar to the PERMNO= option. It enables you to use the historical CUSIP key, *HCUSIP*, to select the companies or issues to keep. There is no limit to the number of *crsp_hcusip* options that you can use.

STK Databases

HCUSIP is a secondary key for accessing CRSP Stock databases. One *HCUSIP* maps to one *PERMNO*.

CCM Databases

HCUSIP is not available as a key for accessing CCM databases.

IND Databases

Use *INDNO* for accessing CRSP Indices databases. *HCUSIP* is not available as a key for accessing CRSP Indices databases; use *INDNO* instead.

TICKER=*crsp_ticker*

The *TICKER=* option is similar to the *PERMNO=* option. It enables you to use the *TICKER* key to select the companies or issues to keep. There is no limit to the number of *crsp_ticker* options that you can use.

STK Databases

TICKER is a secondary key for accessing CRSP Stock databases. One *TICKER* maps to one *PERMNO*. Note that some *PERMNO*s are inaccessible by *TICKER*.

CCM Databases

TICKER is not available as a key for accessing CCM databases.

IND Databases

Use *INDNO* for accessing CRSP Indices databases. *TICKER* is not available as a key for accessing CRSP Indices databases; use *INDNO* instead.

SICCD=*crsp_siccd*

The *SICCD=* option is similar to the *PERMNO=* option. It enables you to use the Standard Industrial Classification (SIC) Code (*SICCD*) to select the companies or issues to keep. There is no limit to the number of *crsp_siccd* options that you can use.

STK Databases

SICCD is a secondary key for accessing CRSP Stock databases. One *SICCD* can map to multiple *PERMNO*s. All *PERMNO*s that have been classified once under the specified *SICCD* are mapped and data for them is retrieved. Access by *SICCD* is equivalent to access by all *PERMNO*s that have ever been classified under the specified *SICCD*.

CCM Databases

SICCD is not available as a key for accessing CCM databases.

IND Databases

Use *INDNO* for accessing CRSP Indices databases. *SICCD* is not available as a key for accessing CRSP Indices databases; use *INDNO* instead.

INDNO=*crsp_indno*

The *INDNO=* option is similar to the *PERMNO=* option. It enables you to use CRSP's permanent index number *INDNO* to select the companies or issues to keep. There is no limit to the number of *crsp_indno* options that you can use.

STK Databases

INDNO is not available as a key for accessing CRSP Stock databases, but it can be used in the combined CRSP Stock and Indices databases.

CCM Databases

INDNO is not available as a key for accessing CCM databases; use *GVKEY* instead.

IND Databases

INDNO is the primary key for accessing CRSP Indices databases. Every *INDNO* you specify keeps exactly one index series or group.

For example, you can use the following statement to access the CRSP NYSE Value-Weighted and Equal-Weighted daily market indices:

```
LIBNAME myLib3 sasecrsp 'physical-name'
                    SETID=460
                    INDNO=1000000 /* Value-Weighted */
                    INDNO=1000001; /* Equal-Weighted */
```

CRSPLINKPATH='crsp_linkpath'

To access CRSP Stock data with *GVKEY*s, use the *CRSPLINKPATH=* option. *CRSPLINKPATH=* specifies the physical location where your CCM database resides.

NOTE: The physical name must end in a slash for UNIX environments and a backslash for Windows environments.

RANGE='crsp_begdt-crsp_enddt'

To limit the time range of data read from your CRSPAccess database, specify the *RANGE=* option in your *SASECRSP libref*, where *crsp_begdt* is the beginning date in YYYYMMDD format and *crsp_enddt* is the ending date of the range in YYYYMMDD format.

As an example, to access monthly stock data for Microsoft Corporation and for International Business Machines Corporation for the first quarter of 1999, you can use the following statement:

```
LIBNAME myLib sasecrsp 'physical-name'
                    SETID=20
                    PERMNO=10107
                    PERMNO=12490
                    RANGE='19990101-19990331' ;
```

The given beginning and ending dates are interpreted as calendar dates by default. If you want these dates to be interpreted as fiscal dates, you must prepend the character 'f' to the range.

For example, the following statement extracts data for the 1994 fiscal year of both Microsoft and IBM.

```
LIBNAME myLib sasecrsp 'physical-name'
                    SETID=20
                    PERMNO=10107
```

```

PERMNO=12490
RANGE=' f19940101-19941231' ;

```

The result of the previous statement is that data from actual calendar date July 1,1993, to June 30,1994, is extracted for Microsoft because its fiscal year end month is June. Data from January 1,1994, to December 31,1994, is extracted for IBM because its fiscal year end month is December. See [Example 33.10](#) for a more detailed example.

The RANGE= option can be used on all CRSP Stock, Indices, and CCM members. When this option is applied to segment data members however, the behavior is slightly different in the following ways.

- Dates associated with segment member data records are in years and can resolve only to years. This is unique to segment members. All other CRSP data members have a date resolution to the day. For example, monthly time series, though monthly, resolve to the last trading day of the month. However, segment members have a maximum resolution of years because they are not mapped to a calendar in the CRSP/Compustat database. Hence, when range restrictions are applied to segment members, only the 'YYYY' year portion of the range is considered.
- Multiple dates are sometimes associated with a particular segment member record. In such cases, the preferred date for use in determining the date range restriction is the data year as opposed to the source year. This multiple date behavior is unique only to segment members. All other CRSP data members are associated with only one date.

INSET='setname[,keyfieldname,keyfieldtype,date1field,date2field,datatype]'

When you specify a SAS data set named *setname* as input for issues, the SASECRSP engine assumes that a default PERMNO field that contains selected CRSP PERMNOs is present in the data set. If optional parameters are used, they must all be specified. The only acceptable shorthand for dropping the parameters is to drop those at the very end, assuming they are all being omitted. Dropped parameters use their defaults.

The optional parameters are explained below:

- | | |
|--------------|--|
| keyfieldname | label of the field that contains the keys to be selected. If unspecified, the default is "PERMNO". |
| keyfieldtype | specifies the CRSPAccess key type of the provided keys. Possible key types are: <i>PERMNO</i> , <i>PERMCO</i> , <i>CUSIP</i> , <i>HCUSIP</i> , <i>TICKER</i> , <i>SICCD</i> , <i>GVKEY</i> or <i>INDNO</i> . If unspecified, the default is "PERMNO". |
| date1field | beginning date of the specific date range restriction being applied to this key. If either <i>date1field</i> or <i>date2field</i> is omitted, the default is for there to be no date range restriction. |
| date2field | ending date of the specific date range restriction being applied to this key. If either <i>date1field</i> or <i>date2field</i> is omitted, the default is for there to be no date range restriction. |
| datatype | indicates whether the provided beginning and ending dates are calendar dates or fiscal dates. A fiscal date type means the dates given are based on the fiscal calendar of the respective company or GVKEY. A calendar date means the dates are based on the standard Julian calendar. |
- The strings 'calendar' and 'fiscal' are used to indicate the respective date types. If unspecified, the default type is calendar.

It is important to note that fiscal dates are applicable only to members with fiscal data. Fiscal members consists of all period descriptors, items, and segment members of the CCM database. If a fiscal date range is applied to nonfiscal members, it is ignored.

Individual date range restrictions specified by the inset can be used in combination with the RANGE= option on the LIBNAME. In such a case, only data from the intersection of the individual date restriction and the global RANGE= option date restriction are read.

Details: SASECRSP Interface Engine

Using the Inset Option

To better illustrate the use of the INSET= option, some examples follow:

Basic Inset Use: Providing a List of PERMNOs

This example uses the INSET= option to extract monthly data for a portfolio of three companies. No date range restriction is used.

```
data testin1;
  permno = 10107; output;
  permno = 12490; output;
  permno = 14322; output;
run;

LIBNAME mstk sasecrsp 'physical-name'
          SETID=20
          INSET='testin1';

proc print data=mstk.stkhead (keep=permno permco begdt enddt hcomnam htick);
run;
```

General Use of Inset for Specifying Lists of Keys

The following example illustrates the use of the INSET= option to select a few Index Series from the Indices database, companies from the CCM database, and securities from the Stock database. Libref `ind2` is used for accessing the Indices database with the two specified INDNOs. Libref `comp2` is used to access the CCM database with the two specified PERMCOs. Libref `sec3` is used to access the Stock database with the three specified TICKERs. Note the use of shorthand in specifying the INSET= option. The *date1field*, *date2field*, and *datetype* fields are all omitted, thereby using the default of no range restriction (though the range restriction set by the RANGE= on the LIBNAME statement still applies). For details including sample output, see [Example 33.4](#)

```
data indices;
```

```

indno=1000000; output; /* NYSE Value-Weighted Market Index */
indno=1000001; output; /* NYSE Equal-Weighted Market Index */
run;

libname ind2 sasecrsp "%sysget(CRSP_MSTK)" setid=420
    inset='indices,INDNO,INDNO' range='19990101-19990401';

title2 'Total Returns for NYSE Value and Equal Weighted Market Indices';
proc print data=ind2.tret label;
run;

data companies;
    permco=8045; output; /* Oracle */
    permco=20483; output; /* Citigroup */
run;

libname comp2 sasecrsp "%sysget(CRSP_CST)" setid=200
    inset='companies,PERMCO,PERMCO'
    range='20040101-20040531';

title2 'Link Info of Selected PERMCOs';
proc print data=comp2.link label; run;

title3 'Dividends Per Share for Oracle and Citigroup';
proc print data=comp2.div label; run;

data securities;
    ticker='BAC'; output; /* Bank of America */
    ticker='DUK'; output; /* Duke Energy */
    ticker='GSK'; output; /* GlaxoSmithKline */
run;

libname sec3 sasecrsp "%sysget(CRSP_MSTK)" setid=20
    inset='securities,TICKER,TICKER'
    range='19970820-19970920';

title2 'PERMNOs and General Header Info of Selected TICKERs';
proc print data=sec3.stkhead (keep=permno htick htsymbol) label;
run;

title3 'Average Price for Bank of America, Duke and GlaxoSmithKline';
proc print data=sec3.prc label; run;

```

Key-Specific Date Range Restriction with Insets

Suppose you not only want to select keys with your inset, but also want to specify a date range restriction for each key individually. The following example shows how to do this. Again, shorthand enables you to omit the datatype field. The provided dates default to a calendar interpretation. For details including the sample output, see [Example 33.5](#).

```

title2 'INSET=testin2 uses date ranges along with PERMNOs:';
title3 '10107, 12490, 14322, 25788';
title4 'Begin dates and end dates for each permno are used in the INSET';

```

```

data testin2;
    permno = 10107; date1 = 19980731; date2 = 19981231; output;
    permno = 12490; date1 = 19970101; date2 = 19971231; output;
    permno = 14322; date1 = 19950731; date2 = 19960131; output;
    permno = 25778; date1 = 19950101; date2 = 19950331; output;
run;

libname mstk2 sasexrsp "%sysget (CRSP_MSTK) " setid=20
    inset='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
    set mstk2.prc;
run;

proc print data=b;
run;

```

Fiscal Date Range Restrictions with Insets

You can use fiscal dates on the date range restrictions inside insets by specifying the date type. The following example shows two identical accesses, except one inset uses the date range restriction in fiscal terms, and the other inset uses the date range restriction in calendar terms. For details including sample output, see [Example 33.10](#).

```

data comp_fiscal;

    /* Crude Petroleum & Natural Gas */
    compkey=2416;
    begdate=19860101; enddate=19861231;
    datatype='fiscal';
    output;

    /* Commercial Intertech */
    compkey=3248;
    begdate=19940101; enddate=19941231;
    datatype='fiscal';
    output;
run;

data comp_calendar;

    /* Crude Petroleum & Natural Gas */
    compkey=2416;
    begdate=19860101; enddate=19861231;
    datatype='calendar';
    output;

    /* Commercial Intertech */
    compkey=3248;
    begdate=19940101; enddate=19941231;
    datatype='calendar';
    output;

```

```

run;

libname fisclib sasecrsp "%sysget (CRSP_CST) "
      SETID=200
      INSET=' comp_fiscal, compkey, gvkey, begdate, enddate, datetype' ;

libname callib sasecrsp "%sysget (CRSP_CST) "
      SETID=200
      INSET=' comp_calendar, compkey, gvkey, begdate, enddate, datetype' ;

title2 'Quarterly Period Descriptors with Fiscal Date Range' ;
proc print data=fisclib.qperdes(drop = peftnt1 peftnt2 peftnt3 peftnt4
      peftnt5 peftnt6 peftnt7 peftnt8 candxc flowcd spbond spdebt sppaper) ;
run;

title2 'Quarterly Period Descriptors with Calendar Date Range' ;
proc print data=callib.qperdes(drop = peftnt1 peftnt2 peftnt3 peftnt4
      peftnt5 peftnt6 peftnt7 peftnt8 candxc flowcd spbond spdebt sppaper) ;
run;

```

Inset Ranges in Conjunction with the LIBNAME Range

Suppose you want to specify individual date restrictions but also impose a common range. This example demonstrates two companies, each with its own date range restriction, but both companies are also subject to a common range set in the LIBNAME by the RANGE= option. As a result, data from August 1, 1999, to February 1, 2000, is retrieved for IBM, and data from January 1, 2001, to April 21, 2002, is retrieved for Microsoft. For details including sample output see [Example 33.11](#).

```

data two_companies;
  gvkey=6066; date1=19800101; date2=20000201; output;
  gvkey=12141; date1=20010101; date2=20051231; output;
run;

libname mylib sasecrsp "%sysget (CRSP_CST) "
      SETID=200
      INSET='two_companies, gvkey, gvkey, date1, date2'
      RANGE='19990801-20020421' ;

proc sql;
  select prcc.gvkey, prcc.caldt, prcc, ern
  from mylib.prcc as prcc, mylib.ern as ern
  where prcc.caldt = ern.caldt and
        prcc.gvkey = ern.gvkey;
quit;

```

The SAS Output Data Set

You can use the SAS DATA step to write the selected CRSP or Compustat data to a SAS data set. This enables you to easily analyze the data using SAS. When you specify the name of the output

data set on the DATA statement, it causes the engine supervisor to create a SAS data set using the specified name in either the SAS WORK library or, if specified, the USER library.

The contents of the SAS data set include the DATE of each observation, the series name of each series read from the CRSPAccess database, event variables, and the label or description of each series/event or array.

You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in the SAS Explorer. You can also use PROC SQL with your SASECRSP libref to create a custom view of your data.

In general, CRSP missing values are represented as ‘.’ in the SAS data set. When accessing the CRSP STOCK data, SASECRSP uses the mapping shown in [Table 33.6](#) for converting CRSP missing values into SAS missing codes.

Table 33.6 Mapping of CRSP Stock Missing Values to SAS Missing Codes

CRSP Stock	SAS	Condition
-99	.	No valid price
-88	.A	Out of range
-77	.B	Off-exchange
-66	.C	No valid previous price
-55	.D	No delisting information
-44	.E	No valid comparison for an excess return

When accessing the CCM database, CRSP uses certain Compustat missing codes which SASECRSP then converts into SAS missing codes. [Table 33.7](#) shows the mapping of Compustat missing codes for the CCM database.

Table 33.7 Mapping of Compustat and SAS Missing Codes

Compustat	SAS	Condition
0.0001	.	No data for data item
0.0002	.S	Data is only on a semi-annual basis
0.0003	.A	Data is only on an annual basis
0.0004	.C	Combined into other item
0.0007	.N	Data is not meaningful
0.0008	.I	Reported as insignificant

Missing value codes conform with Compustat’s Strategic Insight and binary conventions for missing values. See *Notes on Missing Values* in the second chapter of the *CRSP/Compustat Merged Database Guide* for more information about how CRSP handles Compustat missing codes.

Understanding CRSP Date Formats, Informats, and Functions

CRSP has historically used two different methods to represent dates, while SAS has used a third. The three formats are SAS dates, CRSP dates, and integer dates. The SASECRSP engine provides 23 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. A SASECRSP LIBNAME assign must be active to use these date access methods. See [Example 33.6](#), “Converting Dates Using the CRSP Date Functions.”

SAS dates are stored internally as the number of days since January 1, 1960. The SAS method is an industry standard and provides a great deal of flexibility, including a wide variety of informats, formats, and functions.

CRSP dates are designed to ease time series storage and access. Internally, the dates are stored as an offset into an array of trading days or trading day calendar. Note that there are five different CRSP trading day calendars: Annual, Quarterly, Monthly, Weekly, and Daily. In this sense, there are five different types of CRSP dates, one for each frequency of calendar it references. The CRSP method provides fewer missing values and makes trading period calculations very easy. However, there are also many valid calendar dates that are not available in the CRSP trading calendars, and care must be taken when using other dates.

Integer dates are a way to represent dates that are platform independent and maintain the correct sort order. However, the distance between dates is not maintained.

The best way to illustrate these formats is with some sample data. [Table 33.8](#) shows date representations for CRSP daily and monthly data.

Table 33.8 Date Representations for Daily and Monthly Data

Date	SAS Date	CRSP Date (Daily)	CRSP Date (Monthly)	Integer Date
July 31, 1962	942	21	440	19620731
August 31, 1962	973	44	441	19620831
Dec. 30, 1998	14,243	9190	NA*	19981230
Dec. 31, 1998	14,244	9191	877	19981231

* Not available if an exact match is requested.

Having an understanding of the internal differences in representing SAS dates, CRSP dates, and CRSP integer dates helps you use the SASECRSP formats, informats, and functions effectively. Always keep in mind the frequency of the CRSP calendar that you are accessing when you specify a CRSP date.

The CRSP Date Formats

There are two types of formats for CRSP dates, and five frequencies are available for each of the two types. The two types are exact dates (CRSPDT*) and range dates (CRSPDR*), where the ‘*’ can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The ten

types are: CRSPDTA, CRSPDTQ, CRSPDTM, CRSPDTW, CRSPDTD, CRSPDRA, CRSPDRQ, CRSPDRM, CRSPDRW, and CRSPDRD.

Table 33.9 shows some samples that use the monthly and daily calendar as examples. The Annual (CRSPDTA and CRSPDRA), Quarterly (CRSPDTQ and CRSPDRQ), and the Weekly (CRSPDTW and CRSPDRW) formats work analogously.

Table 33.9 Sample CRSPDT Formats for Daily and Monthly Data

Date	CRSP Date Daily, Monthly	CRSPDTD Daily Date	CRSPDRD Daily Range	CRSPDTM Monthly Date	CRSPDRM Monthly Range
July 31,1962	21, 440	19620731	19620731 +	19620731	19620630, 19620731
August 31,1962	44, 441	19620831	19620831 +	19620831	19620801, 19620831
Dec. 30,1998	9190, NA *	19981230	19981230 +	NA*	NA*
Dec. 31,1998	9191, 877	19981231	19981231 +	19981231	19981201, 19981231

+ Daily ranges look similar to Monthly Ranges if they are Mondays or immediately following a trading holiday.

* When working with exact matches, no CRSP monthly date exists for December 30, 1998.

The @CRSP Date Informats

There are three types of informats for CRSP dates, and five frequencies are available for each of the three types. The three types are exact (@CRSPDT*), range (@CRSPDR*), and backward (@CRSPDB*) dates, where the '*' can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The fifteen formats are: @CRSPDTA, @CRSPDTQ, @CRSPDTM, @CRSPDTW, @CRSPDTD, @CRSPDRA, @CRSPDRQ, @CRSPDRM, @CRSPDRW, @CRSPDRD, @CRSPDBA, @CRSPDBQ, @CRSPDBM, @CRSPDBW, and @CRSPDBD.

The five CRSPDT* informats find exact matches only. The five CRSPDR* informats look for an exact match, and if an exact match is not found, they go forward, matching the CRSPDR* formats. The five CRSPDB* informats look for an exact match, and if an exact match is not found, they go backward.

Table 33.10 shows a sample that uses only the CRSP monthly calendar as an example. The daily, weekly, quarterly, and annual frequencies work analogously.

Table 33.10 Sample @CRSP Date Informat Using Monthly Data

Input Date (Integer Date)	CRSP Date CRSPDTM	CRSP Date CRSPDRM	CRSP Date CRSPDBM	CRSPDTM Monthly Date	CRSPDRM Monthly Range
19620731	440	440	440	19620731	19620630 to 19620731
19620815	.(missing)	441	440	See below+	See below*
19620831	441	441	441	19620831	19620801 to 19620831

+ If missing, then missing. If 441, then 19620831. If 440, then 19620731.

* If missing, then missing. If 441, then 19620801 to 19620831. If 440, then 19620630 to 19620731.

The CRSP Date Functions

Table 33.11 shows the 23 date functions provided with the SASECRSP engine. These functions are used internally by the engine, but also are available to the end users. There are seven groups of functions. The first four have five functions each, one for each CRSP calendar frequency. The next two are for converting between SAS and Integer date formats. The last function does not convert between formats, but is a shifting function for shifting integer dates based on a fiscal calendar to normal calendar time. In this shift function, the second argument holds the fiscal year-end month of the fiscal calendar used.

Table 33.11 CRSP Date Functions

Function Group	Function Name	Argument One	Argument Two	Return Value
CRSP dates to integer dates for December 31, 1998				
Annual	crspdcia	74	None	19981231
Quarterly	crspdciq	293	None	19981231
Monthly	crspdcim	877	None	19981231
Weekly	crspdciw	1905	None	19981231
Daily	crspdcid	9191	None	19981231
CRSP dates to SAS dates for December 31, 1998				
Annual	crspdcsa	74	None	14,244
Quarterly	crspdcsq	293	None	14,244
Monthly	crspdcsm	877	None	14,244
Weekly	crspdcsw	1905	None	14,244
Daily	crspdcsd	9191	None	14,244
Integer dates to CRSP dates exact is illustrated, but can be forward or backward				
Annual	crspdica	19981231	0	74
Quarterly	crspdicq	19981231	0	293
Monthly	crspdicm	19981231	0	877
Weekly	crspdicw	19981231	0	1905
Daily	crspdicd	19981231	0	9191
SAS dates to CRSP dates exact is illustrated, but can be forward or backward				
Annual	crspdsca	14,244	0	74

Monthly	crspdsclm	14,244	0	877
Weekly	crspdsclw	14,244	0	1905
Daily	crspdscl	14,244	0	9191
Integer dates to SAS dates for December 31, 1998				
Integer to SAS	crspdi2s	19981231	None	14,244
SAS dates to integer dates for December 31, 1998				
SAS to Integer	crspds2i	14,244	None	19981231
Fiscal to calendar shifting of integer dates for December 31, 1998				
Fiscal to Calendar Shift	crspdf2c	20021231	8	20020831

Examples: SASECRSP Interface Engine

Example 33.1: Specifying PERMNOs and RANGE on the LIBNAME Statement

The following statements show how to set up a LIBNAME statement for extracting data for certain selected PERMNOs during a specific time period. The result is shown in [Output 33.1.1](#).

```
title2 'Define a range inside the data range';
title3 'My range is ( 19950101-19960630 )';

libname _all_ clear;
libname testit1 sasecrsp "%sysget(CRSP_MSTK)"
    setid=20
    permno=81871    /* Desired PERMNOs are selected */
    permno=82200    /* via the libname PERMNO= option */
    permno=82224
    permno=83435
    permno=83696
    permno=83776
    permno=84788
    range='19950101-19960630';

proc print data=testit1.ask;
run;
```

Output 33.1.1 ASK Monthly Time Series Data with RANGE

```

Define a range inside the data range
My range is ( 19950101-19960630 )

```

Obs	PERMNO	CALDT	ASK
1	81871	19950731	18.25000
2	81871	19950831	19.25000
3	81871	19950929	26.00000
4	81871	19951031	26.00000
5	81871	19951130	25.50000
6	81871	19951229	24.25000
7	81871	19960131	22.00000
8	81871	19960229	32.50000
9	81871	19960329	30.25000
10	81871	19960430	33.75000
11	81871	19960531	27.50000
12	81871	19960628	30.50000
13	82200	19950831	49.50000
14	82200	19950929	62.75000
15	82200	19951031	88.00000

Example 33.2: Using the LIBNAME Statement to Access All Keys

To set up the libref to access all keys, no key options such as PERMNO=, TICKER=, or GVKEY= are specified on the LIBNAME statement, and no INSET= option is used. Use of any of these options causes the engine to limit access to only specified keys or specified insets. When no such options are specified, the engine correctly defaults to selecting all keys in the database. Other LIBNAME options such as the RANGE= option can still be used normally to limit the time span of the data, in other words, to define the date range of observations.

In this example, no key-specifying options are used. This forces the engine to default to all PERMNOs in the monthly STK database. The range given on the LIBNAME behaves normally, and data is limited to the first two months of 1995.

```
title2 'Define a range inside the data range ';
title3 'My range is ( 19950101-19950228 )';

libname _all_ clear;
libname testit2 sasecrsp "%sysget(CRSP_MSTK) "
    setid=20
    range='19950101-19950228';
data a;
    set testit2.ask(obs=30);
run;

proc print data=a;
run;
```

The result is shown in [Output 33.2.1](#).

Output 33.2.1 All PERMNOs of ASK Monthly with RANGE

```

Define a range inside the data range
My range is ( 19950101-19950228 )

```

Example 33.4: Specifying Keys Using the INSET= Option

The INSET= option enables you to select any companies and/or issues you want data for. This example selects two CRSP Index Series from the Indices database, two companies from the CCM

database, and four securities from the Stock database for data extraction. Note that because each CRSP database might be in a different location and has to be opened separately, a total of three different librefs are used, one for each database.

```

data indices;
  indno=1000000; output; /* NYSE Value-Weighted Market Index */
  indno=1000001; output; /* NYSE Equal-Weighted Market Index */
run;

libname _all_ clear;
libname ind2 sasecrsp "%sysget (CRSP_MSTK) "
  setid=420
  inset='indices,INDNO,INDNO'
  range='19990101-19990401';

title2 'Total Returns for NYSE Value and Equal Weighted Market Indices';
proc print data=ind2.tret label;
run;

```

Output 33.4.1 shows the result of selecting two CRSP Index Series from the Indices database.

Output 33.4.1 IND Data Extracted Using INSET= Option

Total Returns for NYSE Value and Equal Weighted Market Indices

Example 33.7: Comparing Different Ways of Accessing CCM Data

You can use three different ways to select CCM data: by the primary key, *GVKEY*, or by either of the two secondary keys *PERMNO* and *PERMCO*. This section demonstrate the three different ways.

This example retrieves data on Cimflex Teknowledge Corporation which was previously known as Teknowledge Inc. This company is considered a single entity by the CRSP Stock database and is identified by *PERMNO*=10083 and *PERMCO*=8026. The Compustat database, however, considers Teknowledge Inc. and Cimflex Teknowledge Corporation as two separate entities, and each has its own *GVKEY*. Thus, *PERMNO*=10083 maps to *GVKEYS* 11947 and 15495, and *PERMCO*=8026 has the identical relationship. Access by *PERMNO* and *PERMCO* are equivalent in this case, but differ from access by *GVKEY*. *PERMNO/PERMCO* access retrieves data only within the active period of the links, and only the primary linked *GVKEY* is used for header access. In contrast, *GVKEY* access provides wide-open, full data for both *GVKEYS*. See *PERMNO*= option for more details.

Example 33.8: Comparing PERMNO and GVKEY Access of CRSP Stock Data

You can access CRSP data using *GVKEYs*. Access in this manner requires the use of the `CRSPLINKPATH=` option, and is identical to access by its corresponding *PERMNO(s)*. Links between *PERMNOs* and *GVKEYs* are used without reference to their active period. Link information is used solely for finding corresponding *GVKEYs*. This example shows two ways of accessing CRSP Stock data: one by *PERMNOs* and the other by its corresponding *GVKEY*. Several members are compared, showing they are equivalent.

Example 33.9: Using Fiscal Date Range Restriction

Fiscal date ranges give you the flexibility of selecting company data by using fiscal year range specifications instead of calendar year range specifications. This example shows how to use this feature to extract data such as the 'Earnings Per Share' time series for several companies for the 1994 fiscal year.

```
title 'Extract data for fiscal year 1994 for several companies';

libname _all_ clear;
libname crsp1 sasecrsp "%sysget (CRSP_CST) "
    setid=200
    gvkey=6066 gvkey=12141 gvkey=10107
    range=' f19940101-19941231';

data rnd_eps (keep = gvkey rcaldt fiscaldt iq4 iq9 iq19 iq69);
    set crsp1.iqitems;
run;

proc print data=rnd_eps label;
run;
```

Output 33.9.1 shows Earnings Per Share for several companies for the 1994 fiscal year.

Note how two time ID variables are kept. Raw Calendar Trading Date provides the actual calendar date. Fiscal Trading Date provides the date according to the company's fiscal calendar which is dependent upon when its fiscal year-end month is. For example, Observation 8 is Microsoft's fourth fiscal quarter, hence a Fiscal Trading Date of December 30,1994. Since Microsoft's fiscal year ends in June, its fourth fiscal quarter corresponds to the second calendar quarter of the year, so the Raw Calendar Trading Date shows June 30,1994. The shift calculation of six months (in this case) required to compute the Raw Calendar Trading Date is done automatically by the SASECRSP engine.

Keep in mind that fiscal date ranges are applicable only to fiscal members. When fiscal date range restrictions are applied to nonfiscal members, they are ignored.

The missing value '.A' seen in observations 9 through 12 indicate that the data is reported only on an annual basis.

Example 33.10: Using Different Types of Range Restrictions in the INSET

You can specify both calendar and fiscal date range restrictions with the INSET= option. This example shows how to use both types of date range restrictions.

Two *INSETs*, nearly identical except for the type of their date range restriction, are used for accessing the same database. Despite the many similarities, the different date range restriction types result in dissimilar output.

Note that the specification of the datatype in the INSET= option for *comp_calendar* is not required. The datatype default is the calendar type.

```

data comp_fiscal;

    /* Crude Petroleum & Natural Gas */
    compkey=2416;
    begdate=19860101; enddate=19861231;
    datatype='fiscal';
    output;

    /* Commercial Intertech */
    compkey=3248;
    begdate=19940101; enddate=19941231;
    datatype='fiscal';
    output;
run;

data comp_calendar;

    /* Crude Petroleum & Natural Gas */
    compkey=2416;
    begdate=19860101; enddate=19861231;
    datatype='calendar';    output;

    /* Commercial Intertech */
    compkey=3248;
    begdate=19940101; enddate=19941231;
    datatype='calendar';
    output;
run;

libname _all_ clear;
libname fisclib sasecrsp "%sysget (CRSP_CST) "
    SETID=200
    INSET='comp_fiscal, compkey, gvkey, begdate, enddate, datatype' ;

libname callib sasecrsp "%sysget (CRSP_CST) "
    SETID=200
    INSET='comp_calendar, compkey, gvkey, begdate, enddate, datatype' ;

```

```

title1 'Quarterly Period Descriptors';
title2 'Using the Fiscal Date Range';
proc print data=fisclib.qperdes(drop = peftnt1 peftnt2 peftnt3 peftnt4
                             peftnt5 peftnt6 peftnt7 peftnt8

The next PRINT procedure uses the calendar datatype in its INSET= option instead of the fiscal datatype, producing different results for the Crude Petroleum and Natural Gas Company when the report is based on calendar dates instead of fiscal dates. The differences shown in observations 1 through 4 are due to Crude Petroleum and Natural Gas Company's fiscal year ending in March instead of December.

option or the RANGE= option. Use calendar date ranges for nonfiscal members. **NOTE:** Fiscal date ranges are ignored when used with nonfiscal members.

Example 33.11: Using INSET Ranges with the LIBNAME RANGE Option

It is possible to specify both individual range restrictions with an INSET and a global date range restriction via the RANGE= option on the LIBNAME statement. In such cases, only observations that satisfy *both* date range restrictions are returned. The effective range restriction becomes the intersection of the two specified range restrictions. If this intersection is empty, no observations are returned.

This example extracts data for two companies, IBM and Microsoft. Each company has an individual range restriction specified in the inset. Furthermore, a global range restriction is set by the RANGE= option on the LIBNAME statement. As a result the effective date range restriction for IBM becomes August 1, 1999, to February 1, 2000, and the effective date range restriction for Microsoft becomes January 1, 2001, to April 21, 2002.

```
data two_companies;
  gvkey=6066;  date1=19800101; date2=20000201; output;
  gvkey=12141; date1=20010101; date2=20051231; output;
run;

libname _all_ clear;
libname mylib sasecrsp "%sysget(CRSP_CST) "
  SETID=200
  INSET='two_companies,gvkey,gvkey,date1,date2'
  RANGE='19990801-20020421';

title1 'Two Companies, Two Range Selections';

For more about using the SQL procedure, see the chapter on SQL in *Base SAS Procedures Guide*.

Data Elements Reference: SASECRSP Interface Engine

Data sets are made available based on the type of CRSP database opened. [Table 33.12](#), [Table 33.13](#), and [Table 33.14](#) show summary views of the three types of CRSP databases (Stock, CCM, and Indices) and the data sets they make available. Details on the data sets including their specific fields can be found in sections immediately following the summary tables. You can also see the available data sets for an opened database via the SAS Explorer by opening a SASECRSP libref that you have previously assigned.

Acknowledgments

Many people have been instrumental in the development of the ETS Interface engine. The individuals listed here have been especially helpful.

Janet Eder, Center for Research in Security Prices, University of Chicago Graduate School of Business.

Ken Kraus, Center for Research in Security Prices, University of Chicago Graduate School of Business.

Bob Spatz, Center for Research in Security Prices, University of Chicago Graduate School of Business.

Rick Langston, SAS Institute, Cary, NC.

Kelly Fellingham, SAS Institute, Cary, NC.

Peng Zang, SAS Institute, Atlanta, GA.

The final responsibility for the SAS System lies with SAS Institute alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

Overview: SASEFAME Interface Engine

The SASEFAME interface engine enables SAS users to access and process time series, case series, and formulas residing in a FAME database, and provides a seamless interface between FAME and SAS data processing.

FAME (Financial Analytic Modeling Environment) is an integrated, front-to-back market data and historical database solution for storing and managing real-time and high-volume time series data that is used by leading institutions in the financial, energy, and public sectors, as well as third-party content aggregators, software vendors, and individual investors. FAME provides real-time market data feeds, a Web-based desktop solution, application hosting, data delivery components, and tools for performing analytic modeling.

The SASEFAME engine uses the LIBNAME statement to enable you to specify which time series you would like to read from the FAME database, and how you would like to convert the selected time series to the same time scale. The SAS DATA step can then be used to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis if desired either in the same SAS session or in another session at a later time.

SASEFAME for SAS 8.2 supports Windows, Solaris, AIX, and HP-UX hosts.

SASEFAME for SAS 9.2 supports Windows, Solaris, AIX, Linux, Linux Opteron, and HP-UX hosts.

Getting Started: SASEFAME Interface Engine

Structure of a SAS Data Set Containing Time Series Data

SAS requires time series data to be in a specific form recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASEFAME engine provides a time ID variable named DATE.

Reading and Converting FAME Database Time Series

The SASEFAME engine supports reading and converting time series stored in FAME databases. The SASEFAME engine uses the FAME WORK database to temporarily store the converted time series. All series specified by the FAME wildcard are written to the FAME WORK database. For

conversion of very large databases, you may want to define the FAME_TEMP environment variable to point to a location where there is ample space for FAME WORK.

SASEFAME provides seamless access to FAME databases via FAME's C Host Language Interface (CHLI). The FAME CHLI does not support writing more than 2 gigabytes to the FAME WORK area, and when this happens SASEFAME will terminate with a system error. The SASEFAME engine finishes the CHLI whenever a fatal error occurs. To restart the engine after a fatal error, terminate the current SAS session and bring up a new SAS session.

Using the SAS DATA Step

If desired, you can store the converted series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. Once your data is stored in a SAS data set you can use it as you would any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure and report information concerning the contents of your data set by using the CONTENTS procedure, as in [Example 34.1](#). You can create a view of the FAME database by using the SQL procedure to create your view using the SASEFAME engine in your *libref*, along with the using clause. See [Example 34.5](#).

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEFAME libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking on the desired output data set libref in the LIBNAME window of the SAS windowing environment. You can type **Viewtable** on the SAS command line to view any of your SASEFAME tables, views, or librefs both for input and output data sets.

Using Remote FAME Data Access

The remote access feature of the SASEFAME interface uses the FAME CHLI to communicate with your remote FAME server, and it is available to licensed CHLI customers who have FAME CHLI on both the remote and client machines.

As shown in [Example 34.7](#), you simply provide the frdb_m port number and node name of your FAME master server in your libref. For more details, refer to “Starting the Master Server” in the *Guide to FAME Database Servers*.

Creating Views of Time Series Using SASEFAME LIBNAME Options

You can perform selection based on names of your time series simply by using FAME wildcard specifications in your SASEFAME WILDCARD= option.

You can limit the time span of time series data by specifying a begin and end date range in your SASEFAME RANGE= option.

It is also easy to use the SAS input data set INSET= option to create a specific view of your FAME data. Multiple views can be created by using multiple LIBNAME statements with customized options tailored to the unique view that you want to create.

The INSET variables define the BY variables that enable you to view cross sections or slices of your data. When used in conjunction with the WHERE clause and the CROSSLIST= option, SASEFAME can show any or all of your BY groups in the same view or in multiple views. The INSET= option is invalid without a WHERE clause specifying the BY variables you want to use in your view, and it must be used with the CROSSLIST= option, as shown in [Example 34.10](#). The CROSSLIST= option can be used without using the INSET= option as shown in [Example 34.8](#) and [Example 34.9](#).

Syntax: SASEFAME Interface Engine

The SASEFAME engine uses standard engine syntax. Options used by SASEFAME are summarized in [Table 34.1](#).

Table 34.1 Summary of LIBNAME *libref* SASEFAME Statement

Option	Description
CONVERT=	specifies the FAME frequency and the FAME technique
WILDCARD=	specifies a FAME wildcard to match data object series names within the FAME database, which limits the selection of time series that are included in the SAS data set
RANGE=	specifies the range of data to keep in format 'ddmonyyy'd - 'ddmonyyy'd
INSET=	uses a SAS data set named <i>setname</i> and/or WHERE= FAME <i>namelist</i> as selection input for BY variables such as tickers or issues stored in a FAME string case series
CROSSLIST=	specifies a FAME crosslist <i>namelist</i> to perform selection based on the crossproduct of two FAME namelists
FAMEOUT=	specifies the FAME data object class/type you want output to the SAS data set

The LIBNAME *libref* SASEFAME Statement

LIBNAME *libref* SASEFAME '*physical name*' options ;

Since *physical name* specifies the location of the folder where your FAME database resides, it should end in a backslash if you are in a Windows environment, or a forward slash if you are in a UNIX environment.

If you are accessing a remote FAME database by using FAME CHLI, you can use the following syntax for *physical name*:

```
'#port_number@hostname physical_path_name'
```

The following options can be used in the LIBNAME *libref* SASEFAME statement.

CONVERT=(FREQ=*fame_frequency* TECH=*fame_technique*)

specifies the FAME frequency and the FAME technique just as you would in the FAME CONVERT function. There are four possible values for *fame_technique*: CONSTANT (default), CUBIC, DISCRETE, or LINEAR. All FAME frequencies except PPY and YPP are supported by the SASEFAME engine.

For a more complete discussion of FAME frequencies and SAS time intervals, see the section “[Mapping FAME Frequencies to SAS Time Intervals](#)” on page 2298. For all possible *fame_frequency* values, refer to “Understanding Frequencies” in the *User’s Guide to FAME*. For example:

```
LIBNAME libref sasefame 'physical-name'
      CONVERT=(TECH=CONSTANT FREQ=TWICEMONTHLY);
```

WILDCARD="fame_wildcard"

By default, the SASEFAME engine reads all time series in the FAME database that you name in your SASEFAME libref. You can limit the time series read from the FAME database by specifying the WILDCARD= option in your LIBNAME statement. The *fame_wildcard* is a quoted string containing the FAME wildcard you want to use. The wildcard is used for matching against the data object names of series you want to select from the FAME database that resides in the library you are assigning.

For more information about wildcarding, see “Specifying Wildcards” in the *User’s Guide to FAME*.

For example, to read all time series in the TEST library being accessed by the SASEFAME engine, you would specify

```
LIBNAME test sasefame 'physical name of test database'
WILDCARD="?";
```

To read series with names such as A_DATA, B_DATA, or C_DATA, you could specify

```
LIBNAME test sasefame 'physical name of test database'
WILDCARD="^_DATA";
```

When you use the WILDCARD= option, you are limiting the number of series that are read and converted to the desired frequency. This option can help you save resources when processing large databases or when processing a large number of observations, such as daily or hourly frequencies. Since the SASEFAME engine uses the FAME WORK database to store the converted time series, using wildcards is recommended to prevent your WORK space from getting too large. When the FAMEOUT= option is also specified, the wildcard is applied to the type of data object series you specify in the FAMEOUT= option.

RANGE='fame_begdt'd-'fame_enddt'd

To limit the time range of data read from your FAME database, specify the RANGE= option in your SASEFAME libref, where *fame_begdt* is the beginning date in ddmonyyyy format and *fame_enddt* is the ending date of the range in ddmonyyyy format.

As an example, to read a series with a date range that spans the first quarter of 1999, you could use the following statement:

```
LIBNAME test sasefame 'physical name of test database'
RANGE='01jan1999'd - '31mar1999'd;
```

INSET=(setname WHERE=fame_bygroup)

When you specify a SAS data set named *setname* as input for a BY group such as tickers, the SASEFAME engine uses the *fame_bygroup* to select time series that are named using the following convention. Selected variable names are glued together by the ticker name concatenated with the glue character (such as DOT) to the series name that is specified in the CROSSLIST= option or the *fame_namelist*. See the following example that uses both the CROSSLIST= option and the INSET= option with the WHERE= clause.

CROSSLIST=([fame_namelist1] , fame_namelist2)

There are two methods for performing the crosslist selection function. The first method uses two FAME namelists, and the second method uses one namelist and one BY group specified in the WHERE= clause of the INSET= option.

Using the CROSSLIST= option with the optional *fame_namelist1* causes the SASEFAME engine to perform a crossproduct of the first namelist's members with the second namelist's members, using a glue symbol "." to join the two.

For example, if your FAME database has a namelist named TICKER defined by

```
Ticker = {AOL, C, CVX, F, GM, HPQ, IBM, INDUA, INTC, SPX, SUNW, XOM}
```

and your time series are named in *fame_namelist2* as adjust, close, high, low, open, volume, uclose, uhigh, ulow, uopen, uvolume when you specify

```
LIBNAME test sasefame 'physical name of test database'
RANGE='01jan1999'd - '31mar1999'd
CROSSLIST=(nl(ticker),
            {adjust, close, high, low, open, volume,
             uclose, uhigh, ulow, uopen, uvolume})
;
```

then the 132 variables shown in [Table 34.2](#) are selected by the CROSSLIST= option.

Table 34.2 SAS Variables Selected by CROSSLIST= Option

AOL.ADJUST	C.ADJUST	CVX.ADJUST	F.ADJUST
AOL.CLOSE	C.CLOSE	CVX.CLOSE	F.CLOSE
AOL.HIGH	C.HIGH	CVX.HIGH	F.HIGH

GM.UOPEN	HPQ.UOPEN	IBM.UOPEN	INDUA.UOPEN
GM.UVOLUME	HPQ.UVOLUME	IBM.UVOLUME	INDUA.UVOLUME
GM.VOLUME	HPQ.VOLUME	IBM.VOLUME	INDUA.VOLUME

Table 34.2 continued

INTC.ADJUST	SPX.ADJUST	SUNW.ADJUST	XOM.ADJUST
INTC.CLOSE	SPX.CLOSE	SUNW.CLOSE	XOM.CLOSE
INTC.HIGH	SPX.HIGH	SUNW.HIGH	XOM.HIGH
INTC.LOW	SPX.LOW	SUNW.LOW	XOM.LOW
INTC.OPEN	SPX.OPEN	SUNW.OPEN	XOM.OPEN
INTC.UCLOSE	SPX.UCLOSE	SUNW.UCLOSE	XOM.UCLOSE
INTC.UHIGH	SPX.UHIGH	SUNW.UHIGH	XOM.UHIGH
INTC.ULOW	SPX.ULOW	SUNW.ULOW	XOM.ULOW
INTC.UOPEN	SPX.UOPEN	SUNW.UOPEN	XOM.UOPEN
INTC.UVOLUME	SPX.UVOLUME	SUNW.UVOLUME	XOM.UVOLUME
INTC.VOLUME	SPX.VOLUME	SUNW.VOLUME	XOM.VOLUME

Instead of using two namelists, you can use the WHERE= clause from your INSET= option to perform the crossproduct of the BY variables specified in your INSET via the WHERE= clause, with the members named in your namelist. Suppose you have defined a SAS input dataset named INSETA and you want to use it as input for your CROSSLIST= option instead of using the FAME namelist:

```

DATA INSETA;
  LENGTH tick $5;
  /* AOL, C, CVX, F, GM, HPQ, IBM, INDUA, INTC, SPX, SUNW, XOM */
  tick='AOL'; output;
  tick='C'; output;
  tick='CVX'; output;
  tick='F'; output;
  tick='GM'; output;
  tick='HPQ'; output;
  tick='IBM'; output;
  tick='INDUA'; output;
  tick='INTC'; output;
  tick='SPX'; output;
  tick='SUNW'; output;
  tick='XOM'; output;
RUN;

LIBNAME test sasefame 'physical name of test database'
  RANGE='01jan1999'd - '31mar1999'd
  INSET=(inseta, where=tick)
  CROSSLIST=(
    {adjust, close, high, low, open, volume,
    uclose, uhigh, ulow, uopen, uvolume})
  ;

```

Whether you use a SAS INSET with a WHERE clause or you use a FAME namelist for your CROSSLIST= selection, the two methods are equivalent ways of performing the same selection function. In the preceding example, the FAME ticker namelist corresponds to the SAS INSET's BY variable named TICK.

Note that the WHERE= *fame_bygroup* must match your BY variable name used in your INSET= in order for the CROSSLIST= option to perform the desired selection. If one of the time series listed in your *fame_namelist2* does not exist, the SASEFAME engine stops processing the remainder of the namelist. For complete results you should make sure that your *fame_namelist2* is accurate and does not name unknown variables. The same holds true for *fame_namelist1* and the BY variable values named in your INSET= option and used in your WHERE= clause.

FAMEOUT=fame_data_object_class_type

specifies the class and type of the FAME data series objects you want in your SAS output data set. The possible values for *fame_data_object_class_type* are FORMULA, TIME, BOOLEAN, CASE, DATE, and STRING. If the FAMEOUT= option is not specified, numeric time series are output to the SAS data set. FAMEOUT=CASE defaults to case series of numeric type, so if you want another type of case series in your output, then you must specify it. Scalar data objects are not supported.

Details: SASEFAME Interface Engine

The SAS Output Data Set

You can use the SAS DATA step to write the selected time series from your FAME database to a SAS data set. This enables you to easily analyze the data by using SAS. You can specify the name of the output data set in the DATA statement. This causes the engine supervisor to create a SAS data set by using the specified name in either the SAS WORK library or, if specified, the USER library. For more about naming your SAS data set, see the section “Characteristics of SAS Data Libraries” in *SAS Language Reference: Dictionary*.

The contents of the SAS data set containing time series include the date of each observation, the name of each series read from the FAME database as specified by the WILDCARD option, and the label or FAME description of each series. Missing values are represented as ‘.’ in the SAS data set. You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEFAME libref in the LIBNAME window that you have previously used in your LIBNAME statement. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can use PROC SQL along with the SASEFAME engine to create a view of your SAS data set. You can view your SAS output observations by double-clicking on the desired output data set libref in the LIBNAME window of the SAS windowing environment.

The DATE variable in the SAS data set contains the date of the observation. For FAME weekly intervals that end on a Friday, FAME reports the date on the Friday that ends the week, whereas SAS reports the date on the Saturday that begins the week.

A more detailed discussion of how to map FAME frequencies to SAS time intervals follows. For other types of data such as string case series, date case series, boolean case series, and formulas, see [Example 34.11](#).

Mapping FAME Frequencies to SAS Time Intervals

Table 34.3 summarizes the mapping of FAME frequencies to SAS time intervals. It is important to note that FAME frequencies often have a sample unit in parentheses following the keyword frequency. This sample unit is an end-of-interval unit. SAS dates are represented using beginning-of-interval notation. For more on SAS time intervals, see Chapter 4, “[Date Intervals, Formats, and Functions](#).” For more on FAME frequencies, see the section “[Understanding Frequencies](#)” in the *User’s Guide to FAME*.

Examples: SASEFAME Interface Engine

In this section, the examples were run on Windows, so the physical names used in the LIBNAME *libref* SASEFAME statement reflect the syntax necessary for that platform. In general, the Windows environments use backslashes in their pathname, and the UNIX environments use forward slashes.

Example 34.1: Converting an Entire FAME Database

To enable conversion of all time series no wildcard is specified, so the default “?” wildcard is used. Always consider both the number of time series and the number of observations generated by the conversion process. The converted series are stored in the FAME WORK database during the SAS DATA step. You can further limit your resulting SAS data set by using KEEP, DROP, or WHERE statements inside your DATA step.

The following statements convert a FAME database and print out its contents:

```
options pagesize=60 linesize=80 validvarname=any ;
%let FAME=%sysget (FAME) ;
%put (&FAME) ;
%let FAMETEMP=%sysget (FAME_TEMP) ;
%put (&FAMETEMP) ;

libname famedir sasefame "%sysget (FAME_DATA) "
        convert=(freq=annual technique=constant) ;

libname mydir "%sysget (FAME_TEMP) " ;

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* Read in oecd1.db data from the Organization */
    /* For Economic Cooperation and Development */
    where date between '01jan88'd and '31dec93'd;
run;

proc print data=mydir.a;
run;
```

In the preceding example, the FAME database is called oecd1.db and it resides in the famedir directory. The DATA statement names the SAS output data set 'a', which will reside in mydir. All time series in the FAME oecd1.db database will be converted to an annual frequency and stored in the mydir.a SAS data set. Since the time series variable names contain the special glue symbol '.', the SAS option statement specifies VALIDVARNAME=ANY. Refer to the *SAS Language Reference: Dictionary* for more about this option. The FAME environment variable is the location of the FAME installation, and on Windows, the log would look like this:

```
1          options validvarname=any;
2          %let FAME=%sysget (FAME) ;
3          %put (&FAME) ;
(C:\PROGRA~1\FAME)
4          %let FAMETEMP=%sysget (FAME_TEMP) ;
5          %put (&FAMETEMP) ;
(\\ge\U11\saskff\fametemp\ )
6
7          libname famedir sasefame "&FAME\util"
8          convert=(freq=annual technique=constant) ;
```

NOTE: Libref FAMEDIR was successfully assigned as follows:

Engine: FAMECHLI
Physical Name: C:\PROGRA~1\FAME\util

9

10 libname mydir '\\dntsrc\usrtmp\saskff';

NOTE: Libref MYDIR was successfully assigned as follows:

Engine: V9
Physical Name: \\dntsrc\usrtmp\saskff

11

12 data mydir.a; /* add data set to mydir */

13 set famedir.oecd1;

AUS.DIRDES -- SERIES (NUMERIC by ANNUAL)

AUS.DIRDES copied to work data base as AUS.DIRDES.

For more about the glue DOT character, refer to “Glueing Names Together” in the *User’s Guide to FAME*. In the preceding log, the variable name AUS.DIRDES uses the glue DOT between AUS and DIRDES.

The PROC PRINT statement creates [Output 34.1.1](#) showing all of the observations in the mydir.a SAS data set.

Output 34.1.1 Listing of OUT=MYDIR.A of the OECD1 FAME Data

Example 34.2: Reading Time Series from the FAME Database

Use the FAME wildcard option to limit the number of series converted. For example, suppose you want to read only series starting with “WSPCA”. [Output 34.2.1](#) and [Output 34.2.2](#) show the results of the following sample code.

```
options validvarname=any;

%let FAME=%sysget (FAME) ;
%put (&FAME) ;
%let FAMETEMP=%sysget (FAME_TEMP) ;
%put (&FAMETEMP) ;

libname lib1 sasefame "%sysget (FAME_DATA) "
      wildcard="wspca?"
      convert=(technique=constant freq=twicemonthly ) ;

libname lib2 "%sysget (FAME_TEMP) " ;

data lib2.twild(label='Annual Series from the FAMEECON.db') ;
  set lib1.subecon ;
  where date between '01jan93'd and '31dec93'd ;
  /* keep only */
  keep date wspca ;
run ;

proc contents data=lib2.twild ;
run ;

proc print data=lib2.twild ;
run ;
```

Output 34.2.1 Contents of OUT=LIB2.TWILD of the SUBECON FAME Data

The CONTENTS Procedure					
Alphabetic List of Variables and Attributes					
#	Variable	Type	Len	Format	Informat Label
1	DATE	Num	8	DATE9.	9. Date of Observation
2	WSPCA	Num	8		STANDARD & POOR'S WEEKLY BOND YIELD: COMPOSITE, A

The WILDCARD=“WSPCA?” option limits reading only those series whose names begin with WSPCA. The KEEP statement further restricts the SAS data set to include only the series named WSPCA and the DATE variable. The time interval used for the conversion is TWICEMONTHLY.

Output 34.2.2 Listing of OUT=LIB2.TWILD of the SUBECON FAME Data

Obs	DATE	WSPCA
1	01JAN1993	8.59400
2	16JAN1993	8.50562
3	01FEB1993	8.47000

16	16AUG1993	7.91600

Example 34.3: Writing Time Series to the SAS Data Set

You can use the KEEP or DROP statement to include or exclude certain series names from the SAS data set as shown in [Output 34.3.1](#).

```
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);

libname famedir sasefame "%sysget(FAME_DATA)"
        convert=(freq=annual technique=constant);

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    drop 'ita.dirdes'n--'jpn.herd'n 'tur.dirdes'n--'usa.herd'n;
    where date between '01jan88'd and '31dec93'd;
run;

title2 "OECD1: TECH=constant, FREQ=annual";
title3 "drop using n-literals";

proc print data=mydir.a;
run;
```

Output 34.3.1 Listing of OUT=MYDIR.A of the OECD1 FAME Data

Note that the SAS option VALIDVARNAME=ANY was used at the beginning of this example due to special characters being present in the time series names. SAS variables that contain certain special characters are called *n-literals* and are referenced in SAS code as shown in this example.

You can rename your SAS variables by using the RENAME statement as follows. [Output 34.3.2](#) shows how to use *n-literals* when selecting variables you want to keep, and how to rename some of your kept variables.

```
options validvarname=any;
```

```

%let FAME=%sysget (FAME);
%put (&FAME);
%let FAMETEMP=%sysget (FAME_TEMP);
%put (&FAMETEMP);

libname famedir sasefame "%sysget (FAME_DATA)"
        convert=(freq=annual technique=constant);

libname mydir "%sysget (FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* keep and rename */
    keep date 'ita.dirdes'n--'jpn.herd'n 'tur.dirdes'n--'usa.herd'n;
    rename 'ita.dirdes'n='italy.dirdes'n
           'jpn.dirdes'n='japan.dirdes'n
           'tur.dirdes'n='turkey.dirdes'n
           'usa.dirdes'n='united.states.of.america.dirdes'n ;
run;

title3 "keep statement using n-literals";
title4 "rename statement using n-literals";

proc print data=mydir.a;
run;

```

Example 34.4: Limiting the Time Range of Data

You can also limit the time range of the data in the SAS data set by using the RANGE= option in the LIBNAME statement or the WHERE statement in the DATA step to process the time ID variable DATE only when it falls in the range you are interested in.

All data for 1988, 1989, and 1990 are included in the SAS data set generated by using the RANGE='01JAN1988'D - '31DEC1990'D option or the WHERE DATE BETWEEN '01JAN88'D AND '31DEC90'D statement. The difference is that the range option uses less space in your FAME WORK database. If you have a very large database and want to use less space in your FAME WORK database while you are processing the oecd1 database, you should instead use the RANGE= option as shown in [Output 34.4.1](#).

```
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAME_TEMP=%sysget(FAME_TEMP);
%put(&FAME_TEMP);

libname famedir SASEFAME "%sysget(FAME_DATA)"
      convert=(freq=annual technique=constant)
      range='01jan1988'd - '31dec1990'd;

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
  set famedir.oecd1;
  /* range on the libref restricts the dates *
   * read from famedir's oecd1 database */
run;

proc print data=mydir.a;
run;
```

Output 34.4.1 Listing of OUT=MYDIR.A of the OECD1 FAME Data Using RANGE= Option

```

OECD1: TECH=constant, FREQ=annual
keep statement using n-literals
rename statement using n-literals

  create view fameview as
    select date, husts
    from lib1.driecon
    using libname lib1 sasefame "%sysget(FAME_DATA)";
```

```

convert=(tech=constant freq=annual)
range='01jan1980'd - '01jan2006'd ,
libname temp "%sysget(FAME_TEMP)";
quit;

title2 'DRIECON: Print of View from Embedded Library with FAME Option';
proc print data=fameview;
run;

```

Note that the SAS option VALIDVARNAME=ANY was used at the beginning of this example due to special characters being present in the time series names. The output from this example shows how each FAME view is the output of the SASEFAME engine's processing. Note that different engine options could have been used in the USING LIBNAME clause if desired.

Output 34.5.4 Printout of the FAME View of DRI Basic Economic Data

famesql5: PROC SQL Dual Embedded Libraries w/ FAME option

19	1998	1.56250	

Example 34.6: Reading Other FAME Data Objects with the FAMEOUT= Option

Suppose you want to see the source for your formulas or you are interested in string case series instead of numeric time series. You can designate the data objects that are output to your SAS data set using the FAMEOUT= option. In this example, the FAMEOUT=FORMULA option selects the formulas and their source definitions to be output as shown in [Output 34.6.1](#). Note that the RANGE= option is ignored since no time series are selected when FAMEOUT=FORMULA is specified.

```

options validvarname=any ls=90;

%let FAME=%sysget (FAME);
%put (&FAME);
%let FAMETEMP=%sysget (FAME_TEMP);
%put (&FAMETEMP);

libname lib6 sasefame "%sysget (FAME_DATA) "
      fameout=formula
      convert=(frequency=business technique=constant)
      range='02jan1995'd - '25jul1997'd
      wildcard="?YIELD?" ;

data crout;
  set lib6.training;
  keep 'S.GM.YIELD.A'n -- 'S.XON.YIELD.A'n ;
run;

title2 'Contents of OUT=CROUT from the FAMEOUT=FORMULA Option';
title3 'Using WILDCARD="?YIELD?"';
proc contents
  data=crout;
run;

```

Output 34.6.1 Contents of OUT=CROUT from the FAMEOUT=FORMULA Option of the TRAINING FAME Data

```

famesql5: PROC SQL Dual Embedded Libraries w/ FAME option
  Contents of OUT=CROUT from the FAMEOUT=FORMULA Option
    Using WILDCARD="?YIELD?"

      The CONTENTS Procedure

    Alphabetic List of Variables and Attributes

          #   Variable              Type      Len
          1   S.GM.YIELD.A           Char      82
          2   S.GM_PP.YIELD.A        Char      82
          3   S.HWP.YIELD.A          Char      82
          4   S.IBM.YIELD.A          Char      82
          5   S.INDUT.YIELD.A        Char      82
          6   S.SPAL.YIELD.A         Char      82
          7   S.SPALN.YIELD.A        Char      82
          8   S.SUNW.YIELD.A         Char      82
          9   S.XOM.YIELD.A          Char      82
          10  S.XON.YIELD.A          Char      82

```

The FAMEOUT=FORMULA option restricts the SAS data set to include only formulas. The WILDCARD="?YIELD?" option further limits reading only those formulas whose names "YIELD" in them. This output is shown in [Output 34.6.2](#).

Example 34.7: Remote FAME Access Using FAME CHLI

Suppose you are running FAME in a client/server environment and have FAME CHLI capability allowing you access to your FAME server. You could access your FAME remote data by specifying the port number of the tcpip service that is defined for your `frdb_m` and the node name of your FAME master server in your physical path. In this example, the FAME server node name is `STONES`, and the port number is `5555`, which was designated in the FAME master command. Refer to “Starting the Master Server” in the *Guide to FAME Database Servers* for more information about starting your FAME master server. This output is shown in [Output 34.7.1](#).

```
options ls=78;
title1 "DRIECON Database, Using FAME with REMOTE ACCESS VIA CHLI";

libname test1 sasefame '#5555@stones $FAME/util';

data a;
  set test1.driecon;
  keep YP ZA ZB;
  where date between '01jan98'd and '31dec03'd;
run;

proc means data=a n;
run;
```

Output 34.7.1 Summary Statistics for the Remote FAME Data

Variable	Label	N
YP	PERSONAL INCOME	5
ZA	CORPORATE PROFITS AFTER TAX EXCLUDING IVA	4
ZB	CORPORATE PROFITS BEFORE TAX EXCLUDING IVA	4

Example 34.8: Selecting Time Series Using `CROSSLIST=` Option and `KEEP` Statement

This example shows how to use two FAME namelists to perform selection. Note that `fame_namelist1` could be easily generated using the FAME `WILDLIST` function. For more about `WILDLIST`, refer to “The `WILDLIST` Function” in the *FAME Command Reference Volume 2, Functions*. In the following statements, 11 tickers are selected in `fame_namelist1`, but when you use the `KEEP` statement, the resulting data set contains only the desired IBM ticker shown in [Output 34.8.1](#) and [Output 34.8.2](#).

```

libname lib8 sasefame "%sysget (FAME_DATA) "
      convert=(frequency=business technique=constant)
      crosslist=(
        { IBM, SPALN, SUNW, XOM },
        { adjust, close, high, low, open, volume,
          uclose, uhigh, ulow, uopen, uvolume }
      );

data trout;
  /* eleven companies, keep only the IBM ticker this time */
  set lib8.training;
  where date between '01mar02'd and '20mar02'd;
  keep IBM: ;
run;

Example 34.10: Selecting Time Series Using `CROSSLIST=` Option with `INSET=` and `WHERE=TICK`

Suppose instead of having a FAME namelist with the Tickers for companies whose data you are interested in, you have an input SAS data set (`INSET`) that specifies the tickers to select. You can specify your selection by using the `WHERE` statement as in the following statements. The results are shown in [Output 34.10.1](#) and [Output 34.10.2](#).

```
data inseta;
  length tick $5;
  /* need $5 so SPALN is not truncated */

  tick='AOL';   output;
  tick='C';     output;
  tick='CPQ';   output;
  tick='CVX';   output;
  tick='F';     output;
  tick='GM';    output;
  tick='HWP';   output;
  tick='IBM';   output;
  tick='SPALN'; output;
  tick='SUNW';  output;
  tick='XOM';   output;
run;

libname lib10 sasefame "%sysget(FAME_DATA)"
  convert=(frequency=business technique=constant)
  range='07jul1997'd - '25jul1997'd
  inset=( inseta where=tick )
  crosslist=
    ( {adjust, close, high, low, open, volume,
      uclose, uhigh, ulow, uopen, uvolume} );

data trout;
  /* eleven companies with unique TICKs specified in INSETA */
  set lib10.training;
  keep IBM: ;
run;

title2 'TRAINING DB, Pricing Timeseries for eleven Tickers in CROSSLIST=';
title3 'OUT=TROUT from the PRINT Procedure';
proc print data=trout;

Example 34.11: Selecting Series Using FAMEOUT= Option

This example shows how to read case series instead of time series. Case series can be numeric, boolean, string, date, or formulas that resolve to series. SASEFAME resolves all formulas that belong to the type of series data object that you specify in your FAMEOUT= option. If these object types are not specified, the FAMEOUT= option defaults to time series.

The first case shows writing of all boolean case series to your SAS data set, while the second shows selection of numeric case series; the third shows writing all date case series to your SAS data set, while the fourth shows selection of all the string case series. The last case shows output of the SOURCE for all the formula case series in the ALLTYPES data base.

In the first example, suppose you prefer to extract all boolean case series from your FAME data base. The following statements write all boolean case series to your SAS data set. The results are shown in [Output 34.11.1](#) and [Output 34.11.2](#).

```

title1 '***famallt: FAMEOUT option, Different Type Values***';
options validvarname=any;

%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);

Overview: SASEHAVR Interface Engine

The SASEHAVR interface engine is a seamless interface between HAVER and SAS data processing that enables SAS users to read economic and financial time series data residing in a HAVER ANALYTICS DLX (Data Link Express) database. The HAVER ANALYTICS DLX economic and financial database offerings include United States Economic Indicators, Specialized Databases, Financial Indicators, Industry, Industrial Countries, Emerging Markets, International Organizations, Forecasts and As Reported Data, and United States Regional. For more details, see “[Data Elements Reference: SASEHAVR Interface Engine](#)” on page 2369.

The SASEHAVR engine uses the LIBNAME statement to enable you to specify how you would like to subset your HAVER data and how you would like to aggregate the selected time series to the same frequency. The SAS DATA step can then be used to perform further subsetting and to store the resulting time series into a SAS data set. You can perform more analysis if desired either in the same SAS session or in another session at a later time.

Getting Started: SASEHAVR Interface Engine

Structure of a SAS Data Set Containing Time Series Data

SAS represents time series data in a two-dimensional array called a SAS data set whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASEHAVR engine provides a time ID variable called DATE. The DATE variable can be represented in any of the time intervals shown in the section “[Mapping HAVER Frequencies to SAS Time Intervals](#)” on page 2346.

Reading and Converting HAVER DLX Time Series

The SASEHAVR engine supports reading and converting time series stored in HAVER DLX databases. The SASEHAVR engine enables you to limit the range of data with the START= and END= libname options. Start dates and end dates are recommended on the libname statement to help you save resources when processing large databases or when processing a large number of observations.

The SASEHAVR engine enables you to convert or aggregate all selected time series to a desired frequency. By default, SASEHAVR selects the time series variables that match the frequency of the first selected variable. To select variables of one specific frequency, use the FREQ= option. If no selection criteria are specified, the first selected variable is the first physical DLXRecord read

from the HAVER database. To force aggregation of all selected variables to the frequency specified by the `FREQ=` option, the `FORCE= FREQ` option can be used. Aggregation is only supported from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. If a conversion to a more frequent frequency is attempted, all missing values are returned by the HAVER DLX API (application programming interface). See “[Aggregating to Quarterly Frequency Using the FORCE= FREQ Option](#)” on page 2350. The `FORCE=` option is ignored if the `FREQ=` option is not specified.

Using the SAS DATA Step

If desired, you can store your selected time series in a SAS data set by using the SAS DATA step. You can further subset your data by using the `WHERE`, `KEEP`, or `DROP` statements in your DATA step.

For more efficient subsetting of time series by HAVER variables, by HAVER groups, or by HAVER sources, you can use the corresponding `KEEP=`, `GROUP=`, and `SOURCE=` option on the `LIBNAME libref SASEHAVR` statement. For your convenience, wildcarding is supported in these options.

There are three wildcard symbols: `'*'`, `'?'` and `'#'`. The `'*'` wildcard corresponds to any character string and will include any string pattern that corresponds to that position in the matching variable name. The `'?'` stands for any single alphanumeric character. Lastly, the `'#'` wildcard corresponds to a single numeric character.

You can also deselect time series by HAVER variables, by HAVER groups, or by HAVER sources, by using the corresponding `DROP=`, `DROPGROUP=` or the `DROPSOURCE=` option. These options also support wildcarding to facilitate deselection based on variable names, group names, or source names.

Once your selected data is stored in a SAS data set, you can use it as you would any other SAS data set.

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEHAVR libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking on the desired output data set libref in the LIBNAME window of the SAS windowing environment. You can type **Viewtable** on the SAS command line to view your SASEHAVR tables, views, or librefs. It is recommended that Viewtable be used for output data set viewing by storing your output data sets in a separate physical folder/library from your input data bases. When this guideline is followed, the default location for output data sets is SASWORK. When this guideline is not followed, it is expected that the following errors are likely to be encountered for some of your input databases being viewed:

ERROR: No variable selected with current options.

ERROR: No variable selected with current options.

ERROR: No variable selected with current options.

ERROR: No variable selected with current options.

ERROR: No variable selected with current options.

When this happens, you will notice that you get one error message for each input data base that does not have the selected options on the sasehavr libref that you have double-clicked on.

Syntax: SASEHAVR Interface Engine

The SASEHAVR engine uses standard engine syntax. Options used by SASEHAVR are summarized in the following table.

Table 35.1 Summary of LIBNAME *libref* SASEHAVR statement Options

Option	Description
FREQ=	specifies the HAVER frequency
FREQUENCY=	specifies the HAVER frequency
INTERVAL=	specifies the HAVER frequency
START=	specifies a HAVER start date to limit the selection of time series that begins with the specified date
STARTDATE=	specifies a HAVER start date to limit the selection of time series that begins with the specified date
STDATE=	specifies a HAVER start date to limit the selection of time series that begins with the specified date
BEGIN=	specifies a HAVER start date to limit the selection of time series that begins with the specified date
END=	specifies a HAVER end date to limit the selection of time series that ends with the specified date
ENDDATE=	specifies a HAVER end date to limit the selection of time series that ends with the specified date
ENDATE=	specifies a HAVER end date to limit the selection of time series that ends with the specified date
KEEP=	specifies a list of comma-delimited HAVER variables to keep in the output SAS data set
DROP=	specifies a list of comma-delimited HAVER variables to drop in the output SAS data set
GROUP=	specifies a list of comma-delimited HAVER groups to keep in the output SAS data set
KEEPGROUP=	specifies a list of comma-delimited HAVER groups to keep in the output SAS data set
DROPGROUP=	specifies a list of comma-delimited HAVER groups to drop in the output SAS data set
SOURCE=	specifies a list of comma-delimited HAVER sources to keep in the output SAS data set
KEEPSOURCE=	specifies a list of comma-delimited HAVER sources to keep in the output SAS data set
DROPSOURCE=	specifies a list of comma-delimited HAVER sources to drop in the output SAS data set
FORCE= FREQ	specifies that all selected variables should be aggregated to the frequency specified in the FREQ= option

The LIBNAME *libref* SASEHAVR Statement

LIBNAME *libref* sasehavr 'physical name' options ;

The *physical name* specifies the location of the folder where your HAVER DLX database resides.

The following options can be used in the LIBNAME libref SASEHAVR statement:

FREQ=*haver_frequency*

specifies the HAVER frequency. All HAVER frequencies are supported by the SASEHAVR engine. Accepted frequency values are annual, year, yearly, quarter, quarterly, qtr, monthly, month, mon, week.1, week.2, week.3, week.4, week.5, week.6, week.7, weekly, week, daily, day.

START=*start_date*

specifies the start date for the time series in the form YYYYMMDD.

END=*end_date*

specifies the end date for the time series in the form YYYYMMDD.

KEEP=*haver_variables*

specifies the list of HAVER variables to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROP=*haver_variables*

specifies the list of HAVER variables to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

GROUP=*haver_groups*

specifies the list of HAVER groups to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROPGROUP=*haver_groups*

specifies the list of HAVER groups to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

SOURCE=*haver_sources*

specifies the list of HAVER sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROPSOURCE=*haver_sources*

specifies the list of HAVER sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

FORCE= **FREQ**

specifies that the selected variables are to be aggregated to the frequency in the FREQ= option. Aggregation is only supported from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. See [“Aggregating to Quarterly Frequency Using the FORCE= FREQ Option”](#) on page 2350 for sample output and suggested error recovery from attempting a conversion that yields missing values when specifying a higher frequency conversion. This option is ignored if the FREQ= option is not set.

For a more complete discussion of HAVER frequencies and SAS time intervals see the section [“Mapping HAVER Frequencies to SAS Time Intervals”](#) on page 2346. As an example,

```
LIBNAME libref sasehavr 'physical-name'
      FREQ=MONTHLY;
```

By default, the SASEHAVR engine reads all time series in the HAVER database that you reference when using your SASEHAVR libref. The *haver_startdate* is specified in the form YYYYMMDD. The start date is used to delimit the data to a specified start date.

For example, to read the time series in the TEST library starting on July 4, 1996, you would specify

```
LIBNAME test sasehavr 'physical-name'
      STARTDATE=19960704;
```

When you use the START= option, you are limiting the range of observations that are read from the time series and that are converted to the desired frequency. Start dates can help you save resources when processing large databases or when processing a large number of observations. It is also possible to select specific variables to be included or excluded from the SAS data set by using the KEEP= or the DROP= option.

```
LIBNAME test sasehavr 'physical-name'
      KEEP="ABC*, XYZ??";
```

```
LIBNAME test sasehavr 'physical-name'
      DROP="*SC*, #T#";
```

When the KEEP= or the DROP= option is used the resulting SAS data set will keep or drop the variables that you select in that option. There are three wildcards currently available: '*', '?' and '#'. The '*' wildcard corresponds to any character string and will include any string pattern that corresponds to that position in the matching variable name. The '?' means that any single alphanumeric character is valid. And finally, the '#' wildcard corresponds to a single numeric character. You can also select time series in your data by using the GROUP= or the SOURCE= option to select on GROUP name or on SOURCE name. Alternatively, you can deselect time series by using the DROPGROUP= or the DROPSOURCE= option.

```
LIBNAME test sasehavr 'physical-name'
      GROUP="CBA, *ZYX";
```

```
LIBNAME test sasehavr 'physical-name'
      DROPGROUP="TKN*, XCZ?";
```

```
LIBNAME test sasehavr 'physical-name'
      SOURCE="FRB";
```

```
LIBNAME test sasehavr 'physical-name'
      DROPSOURCE="NYSE";
```

SASEHAVR selects only the variables that are of the specified frequency in the **FREQ=** option. If this option is not specified, SASEHAVR selects the variables that match the frequency of the first selected variable. If no other selection criterion are specified, by default, the first selected variable is the first physical DLXRecord read from the HAVER database. The **FORCE= FREQ** option can be specified to force the aggregation of all variables selected to be of the frequency specified in the **FREQ=** option. Aggregation is only supported from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. See [“Aggregating to Quarterly Frequency Using the FORCE= FREQ Option”](#) on page 2350 for suggested recovery from using a frequency that does not aggregate the data appropriately. The **FORCE=** option is ignored if the **FREQ=** option is not specified.

Details: SASEHAVR Interface Engine

The SAS Output Data Set

You can use the SAS DATA step to write the HAVER converted series to a SAS data set. This enables the user to easily analyze the data using SAS. You can specify the name of the output data set on the DATA statement. This causes the engine supervisor to create a SAS data set using the specified name in either the SAS WORK library, or if specified, the USER library. For more about naming your SAS data set see the section “Characteristics of SAS Data Libraries” in *SAS Language Reference: Dictionary*.

The contents of the SAS data set include the DATE of each observation, the name of each series read from the HAVER database, and the label or HAVER description of each series. Missing values are represented as ‘.’ in the SAS data set. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can use PROC SQL along with the SASEHAVR engine to create a view of your SAS data set.

The DATE variable in the SAS data set contains the date of the observation. The SASEHAVR engine automatically maps the HAVER intervals to the appropriate corresponding SAS interval.

A more detailed discussion of how to map HAVER frequencies to SAS time intervals follows.

Mapping HAVER Frequencies to SAS Time Intervals

Table 35.2 summarizes the mapping of HAVER frequencies to SAS time intervals. For more information refer to “Date Intervals, Formats, and Functions” in *SAS/ETS User’s Guide*.

Table 35.2 Mapping HAVER Frequencies to SAS Time Intervals

HAVER Frequency	SAS Time Interval	FREQ=
ANNUAL	YEAR	YEARLY
QUARTERLY	QTR	QTRLY
MONTHLY	MONTH	MON
WEEKLY (SUNDAY)	WEEK.1	WEEK.1
WEEKLY (MONDAY)	WEEK.2	WEEK.2
WEEKLY (TUESDAY)	WEEK.3	WEEK.3
WEEKLY (WEDNESDAY)	WEEK.4	WEEK.4
WEEKLY (THURSDAY)	WEEK.5	WEEK.5
WEEKLY (FRIDAY)	WEEK.6	WEEK.6
WEEKLY (SATURDAY)	WEEK.7	WEEK.7
WEEKLY WEEK.1-WEEK.7	WEEKLY	WEEKLY
DAILY	WEEKDAY17W	DAY

Error Recovery for SASEHAVR

Common errors are easy to avoid by noting the valid dates that are specified in the warning messages in your SAS log. Often you can get rid of errors by removing either your date restriction (START= and END= options), by removing your FORCE= FREQ option, or by letting the *haver_frequency* default to the original frequency rather than attempting a conversion.

Here are some common error scenarios and how to handle them.

Using the Optimum Range for Best Output Results

Suppose you see the following warnings in your SAS log:

```
libname kgs2 sasehavr "%sysget(HAVER_DATA) "
      start= 19550101 end=19600105
      keep="FCSEED, FCSEEI, FCSEEM, BGSX, BGSM, FXDUSBC"
      group="I01, F56, M02, R30"
      source="JPM,CEN,OMB" ;

NOTE: Libref KGS2 was successfully assigned as follows:
      Engine:          HAVERDLX
      Physical Name:  C:\haver

data kgse9;
  set kgs2.haver;
NOTE: Defaulting to MONTHLY frequency.
WARNING: Start date (19550101) is not a valid date.
      Engine is ignoring your start date and using
      default. Setting the default Haver start date to 7001.
WARNING: End date (19600105) is not a valid date.
      Engine is ignoring your end date and using
      default. Setting the default Haver end date to 10103.

run;

NOTE: There were 375 observations read from the data set KGS2.HAVER.
NOTE: The data set WORK.KGSE9 has 375 observations and 4 variables.
```

The important diagnostic to note here is the warning message which tells you that the data starts in January of 1970 (HAVER date 7001), and ends in March, 2001 (HAVER date 10103). Since the specified range falls outside the range of data, no observations are in range so the engine uses the default range stated in the warning messages. Changing the START= and END= options to overlap the results in data spanning from JAN1970 to MAR2001. To view the entire range of selected data, remove the START= and END= options from your LIBNAME statement:

```
libname kgs sasehavr "%sysget(HAVER_DATA) "
      keep="FCSEED, FCSEEI, FCSEEM, BGSX, BGSM, FXDUSBC"
      group="I01, F56, M02, R30"
      source="JPM,CEN,OMB" ;
```

```
NOTE: Libref KGS was successfully assigned as follows:
      Engine:          HAVERDLX
      Physical Name: C:\haver
```

```
data kgse5;
  set kgs.haver;
NOTE: Defaulting to MONTHLY frequency.
run;
```

```
NOTE: There were 375 observations read from the data set KGS.HAVER.
NOTE: The data set WORK.KGSE5 has 375 observations and 4 variables.
```

Using a Valid Range of Data With START= and END= Options

In this example, an error about an invalid range is issued:

```
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Weekly
  start=20060301 end=20060531;
NOTE: Libref LIB1 was successfully assigned as follows:
      Engine:          HAVERDLX
      Physical Name: C:\haver
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
      Engine:          V9
      Physical Name: \\dntsrc\usrtmp\saskff
data lib2.wweek;
  set lib1.intwkly;
ERROR: No observations found inside RANGE.
      The valid range for HAVER dates is (610104-1050318).
ERROR: No observations found in specified range.
      keep date m11: ;
run;

WARNING: The variable date in the DROP, KEEP, or RENAME list
has never been referenced.
WARNING: The variable m11: in the DROP, KEEP, or RENAME list
has never been referenced.
NOTE: The SAS System stopped processing this step because of errors.
WARNING: The data set LIB2.WWEEK may be incomplete.
      When this step was stopped there were 0
      observations and 0 variables.
WARNING: Data set LIB2.WWEEK was not replaced because this step was stopped.
```

In the preceding example, the important diagnostic message is the first error statement which tells you that the RANGE of HAVER dates is invalid for the specified frequency. A valid range is one that overlaps the dates (610104-1050318). Removing the range altogether will cause the engine to output the entire range of data.

```
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Weekly;
```

```
NOTE: Libref LIB1 was successfully assigned as follows:
      Engine:          HAVERDLX
      Physical Name:  C:\haver
```

```
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
      Engine:          V9
      Physical Name:  \\dntsrc\usrtmp\saskff
```

```
data lib2.wweek;
      set lib1.intwkly;
      keep date m11: ;
run;
```

```
NOTE: There were 2307 observations read from the data set LIB1.INTWKLY.
NOTE: The data set LIB2.WWEEK has 2307 observations and 35 variables.
```

When giving a range of dates, since the START=, END= options give day-based dates, its important to use dates that correspond to the FREQ= option, especially with weekly frequencies, such as week.1-week.7. Since the FREQ=week.4 selects weeks that begin on Wednesday, the start and end dates need to be specified as Wednesday dates.

```
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Week.4
      start=20050302 end=20050309;
NOTE: Libref LIB1 was successfully assigned as follows:
      Engine:          HAVERDLX
      Physical Name:  \\tappan\crsp1\haver
title2 'Weekly dataset with freq=week.4 range is small';
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
      Engine:          V9
      Physical Name:  \\dntsrc\usrtmp\saskff
```

```
data lib2.wweek;
      set lib1.intwkly;
      keep date m11: ;
run;
```

```
NOTE: There were 2 observations read from the data set LIB1.INTWKLY.
NOTE: The data set LIB2.WWEEK has 2 observations and 25 variables.
```

Giving bad dates (i.e., Tuesday dates) for a Wednesday FREQ=week.4 will result in the following error.

```
ERROR: Fatal error in GetDate routine.
      Remove the range statement or change the START= date to
      be consistent with the freq=option.
ERROR: No observations found in specified range.
```

Aggregating to Quarterly Frequency Using the FORCE= FREQ Option

In the next example, 6 time series are selected by the KEEP=option, but their frequencies are annual, monthly, quarterly, so when the FREQ= weekly and FORCE= freq options are used, a diagnostic appears in the log stating that the engine is forcing the frequency to QUARTERLY for better date alignment of observations. The first selected variable is BALO which is a quarterly time series, which causes the default choice of freq to be quarterly:

```

title1 '***HAVKWC.SAS: KEEP= option tests with wildcards***';

%setup( ets );

/*-----*/
/* Wildcard: * */
/*-----*/

title2 "keep=B*, G*, I*";
title3 "6 valid variables are: BALO BGSM BGSX BPBCA G IUM";
libname lib1 sasehavr 'C:\haver\' keep="B*, G*, I*"
    freq=weekly force=freq;
NOTE: Libref LIB1 was successfully assigned as follows:
      Engine:          HAVERDLX
      Physical Name: C:\haver\

data wc;
    set lib1.haver;
WARNING: Earliest Start Date in DLX Database matches QUARTERLY frequency
        better than the specified WEEKLY frequency.
        Engine is forcing the frequency to QUARTERLY for better date
        alignment of observations.

run;

NOTE: There were 221 observations read from the data set LIB1.HAVER.
NOTE: The data set WORK.WC has 221 observations and 7 variables.

```

Note that the time series IUM is an annual frequency, so the attempt to convert to a quarterly frequency produces all missing values in the output range because aggregation produces only missing values when going from a lower frequency to a higher (forced) frequency.

Examples: SASEHAVR Interface Engine

Before running the following sample code, set your HAVER_DATA environment variable to point to the ETS SASMISC folder containing sample HAVER databases. The provided sample data files are HAVERD.DAT, HAVERD.IDX, HAVERW.IDX, and HAVERW.DAT.

Example 35.1: Examining the Contents of a HAVER Database

To see which time series are in your HAVER database, use PROC CONTENTS with the SASE-HAVR LIBNAME statement to read the contents.

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=yearly start=19920101
      end=20041231
      force=freq;

data hwouty;
  set lib1.haverw;
run;

  title1 'Haver Analytics Database, HAVERW.DAT';
  title2 'PROC CONTENTS for Time Series converted to yearly frequency';
proc contents data=hwouty;
run;
```

In the preceding example, the HAVER database is called haverw and it resides in the directory referenced in lib1. The DATA statement names the SAS output data set hwouty, which will reside in saswork. All time series in the HAVER haverw database are listed alphabetically in [Output 35.1.1](#).

Output 35.1.1 Examining the Contents of HAVER Analytics Database, haverw.dat

Haver Analytics Database, HAVERW.DAT				
PROC CONTENTS for Time Series converted to yearly frequency				
The CONTENTS Procedure				
Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Format Label
1	DATE	Num	8	YEAR4. Date of Observation
2	FA	Num	8	Total Assets: All Commercial Banks (SA, Bil.\$)
3	FCM1M	Num	8	1-Month Treasury Bill Market Bid Yield at Constant Maturity (%)
4	FM1	Num	8	Money Stock: M1 (SA, Bil.\$)
5	FTA1MA	Num	8	Treasury 4-Week Bill: Total Amount Accepted (Bil\$)
6	FTB3	Num	8	3-Month Treasury Bills, Auction (% p.a.)
7	LICN	Num	8	Unemployment Insurance: Initial Claims, State Programs (NSA, Thous)

You could use the following SAS statements to create a SAS data set named hwouty and to print its contents.

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=yearly
      start=19920101
      end=20041231
      force=freq;
```

```

data hwouty;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=yearly, infile=haverw.dat';
title2 'Define a range inside the data range for OUT= dataset,';
title3 'Using the START=19920101 END=20041231 LIBNAME options.';

proc print data=hwouty;
run;

```

The preceding LIBNAME lib1 statement specifies that all time series in the haverw database be converted to yearly frequency but to only select the range of data from January 1, 1992, to December 31, 2004. The resulting SAS data set hwouty is shown in [Output 35.1.2](#).

Output 35.1.2 Defining a Range Inside the Data Range for Yearly Time Series

Haver Analytics Database, Frequency=yearly, infile=haverw.dat Define a range inside the data range for OUT= dataset, Using the START=19920101 END=20041231 LIBNAME options.							
Obs	DATE	FA	FCM1M	FM1	FTA1MA	FTB3	LICN
1	1992	3466.3	.	965.31	.	3.45415	407.340
2	1993	3624.6	.	1077.69	.	3.01654	344.934

12	2003	7302.9	1.02346	1268.40	16.089	1.01413	399.137
13	2004	7950.5	1.26642	1337.89	13.019	1.37557	345.109

Example 35.2: Viewing Quarterly Time Series from a HAVER Database

Consider the following statements for quarterly frequency conversion of all time series for the period spanning April 1, 2001, to December 31, 2004.

```

libname lib1 sasehavr "%sysget (HAVER_DATA) "
  freq=quarterly
  start=20010401
  end=20041231
  force=freq;

data hwoutq;

```

```

set lib1.haverw;
run;

title1 'HAVER Analytics Database, Frequency=quarterly, infile=haverw.dat';
title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20010401 END=20041231 LIBNAME options.';

proc print data=hwoutq;
run;

```

The resulting SAS data set hwoutq is shown in [Output 35.2.1](#).

Output 35.2.1 Defining a Range Inside the Data Range for Quarterly Time Series

HAVER Analytics Database, Frequency=quarterly, infile=haverw.dat Define a range inside the data range for OUT= dataset Using the START=20010401 END=20041231 LIBNAME options.							
Obs	DATE	FA	FCM1M	FM1	FTA1MA	FTB3	LICN
1	2001Q2	6225.4	.	1115.75	.	3.68308	356.577

10	2003Q3	7238.6	0.92000	1286.21	16.472	0.92885	361.346
11	2003Q4	7302.9	0.91538	1293.76	16.089	0.91846	390.269
12	2004Q1	7637.3	0.90231	1312.43	21.818	0.91308	400.585
13	2004Q2	7769.8	0.94692	1332.75	12.547	1.06885	310.508
14	2004Q3	7949.5	1.34923	1343.79	21.549	1.49393	305.862
15	2004Q4	7950.5	1.82429	1362.60	13.019	2.01731	362.171

Example 35.3: Viewing Monthly Time Series from a HAVER Database

Suppose you want to convert your time series to a monthly frequency like this:

```

libname lib1 sasehavr "%sysget (HAVER_DATA) "
      freq=monthly
      start=20040401
      end=20041231
      force=freq;

data hwoutm;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=monthly, infile=haverw.dat';

```

```

title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20040401 END=20041231 LIBNAME options.';

proc print data=hwoutm;
run;

```

The result from using the range of April 1, 2004, to December 31, 2004, is shown in [Output 35.3.1](#).

Output 35.3.1 Defining a Range Inside the Data Range for Monthly Time Series

Haver Analytics Database, Frequency=monthly, infile=haverw.dat							
Define a range inside the data range for OUT= dataset							
Using the START=20040401 END=20041231 LIBNAME options.

Example 35.4: Viewing Weekly Time Series from a HAVER Database

An example of weekly data spanning September 1, 2004, to December 31, 2004, is shown in [Output 35.4.1](#).

```

libname lib1 sasehavr "%sysget (HAVER_DATA) "
freq=weekly
start=20040901
end=20041231;

data hwoutw;
set lib1.haverw;
run;

title1 'HAVER Analytics Database, Frequency=weekly, infile=haverw.dat';
title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20040901 END=20041231 LIBNAME options.';

proc print data=hwoutw;
run;

```

Output 35.4.1 Defining a Range Inside the Data Range for Weekly Time Series

HAVER Analytics Database, Frequency=weekly, infile=haverw.dat Define a range inside the data range for OUT= dataset Using the START=20040901 END=20041231 LIBNAME options.

Example 35.5: Viewing Daily Time Series from a HAVER Database

Consider viewing the HAVER Analytics daily database named `haverd`. The contents of this database can be seen by submitting the following DATA step.

```
libname lib1 sasehavr "%sysget (HAVER_DATA) "
      freq=daily
      start=20041201
      end=20041231;

data hwoutd;
  set lib1.haverd;
run;

title1 'HAVER Analytics Database, HAVERD.DAT';
title2 'PROC CONTENTS for Time Series converted to daily frequency';
proc contents data=hwoutd;
run;
```

Output 35.5.1 shows the output of PROC CONTENTS with the time id variable DATE followed by the time series variables FCM10, FCM1M, FFED, FFP1D, FXAUS, and TCC with their corresponding attributes such as type, length, format, and label.

Output 35.5.1 Examining the Contents of a Daily HAVER Analytics Database, haverd.dat

HAVER Analytics Database, HAVERD.DAT				
PROC CONTENTS for Time Series converted to daily frequency				
The CONTENTS Procedure				
Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Format Label
1	DATE	Num	8	DATE9. Date of Observation
2	FCM10	Num	8	10-Year Treasury Note Yield at Constant Maturity (Avg, % p.a.)
3	FCM1M	Num	8	1-Month Treasury Bill Market Bid Yield at Constant Maturity (%)
4	FFED	Num	8	Federal Funds [Effective] Rate (% p.a.)
5	FFP1D	Num	8	1-Day AA Financial Commercial Paper (% per annum)
6	FXAUS	Num	8	Foreign Exchange Rate: Australia (US\$/Australian\$)
7	TCC	Num	8	Treasury: Closing Operating Cash Balance (Today, Mil.\$)

Example 35.6: Limiting the Range of Time Series from a HAVER Database

Suppose you limit the range of data to the month of December:

```
libname lib1 sasehavr "%sysget (HAVER_DATA) "
      freq=daily
      start=20041201
      end=20041231;

data hwoutd;
  set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20041201 END=20041231 LIBNAME options.';

proc print data=hwoutd;
run;
```

Note that [Output 35.6.1](#) for daily conversion shows the frequency as the SAS time interval for WEEKDAY.

Output 35.6.1 Defining a Range Inside the Data Range for Daily Time Series

Haver Analytics Database, Frequency=daily, infile=haverd.dat							
Define a range inside the data range for OUT= dataset							
Using the START=20041201 END=20041231 LIBNAME options.

21	29DEC2004	4.33	1.76	2.23	2.23	0.7709	34754
22	30DEC2004	4.27	1.68	2.24	2.18	0.7785	20045
23	31DEC2004	4.24	1.89	1.97	2.18	0.7805	24690

Example 35.7: Using the WHERE Statement to Subset Time Series from a HAVER Database

Using a WHERE statement in the DATA step can be useful for further subsetting.

```
libname lib1 sasehavr "%sysget (HAVER_DATA) "
      freq=daily start=20041101 end=20041231;

data hwoutd;
  set lib1.haverd;
  where date between '01nov2004'd and '01dec2004'd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20041101 END=20041231 LIBNAME options.';
title4 'Subset further: where date between 01nov2004 and 31dec2004.';
proc print data=hwoutd;
run;
```

Output 35.7.1 shows that the time slice of November 1, 2004, to December 31, 2004, is narrowed further by the DATE test on the WHERE statement to stop at December 1, 2004.

Output 35.7.1 Defining a Range Using START=20041101 END=20041231 along with the WHERE statement

```

Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041231 LIBNAME options.
Subset further: where date between 01nov2004 and 31dec2004.

```

Example 35.8: Using the KEEP Option to Subset Time Series from a HAVER Database

To select specific time series, the KEEP= or DROP= option can also be used as follows.

```
libname lib1 sasehavr "%sysget (HAVER_DATA) "  
    freq=daily  
    start=20041101  
    end=20041231  
    keep="FCM*";  
  
data hwoutd;  
    set lib1.haverd;  
run;  
  
title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';  
title2 '    Define a range inside the data range for OUT= dataset';  
title3 '    Using the START=20041101 END=20041231 LIBNAME options.';  
title4 '    Subset further: Using keep="FCM*" LIBNAME option ';  
proc print data=hwoutd;  
run;
```

[Output 35.8.1](#) shows two series that are selected by using KEEP="FCM*" on the LIBNAME statement.

Output 35.8.1 Using the KEEP Option along with Defining a Range Using START=20041101
END=20041231

```
Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041231 LIBNAME options.
Subset further: Using keep="FCM*" LIBNAME option
```

The DROP option can be used to drop specific variables from a HAVER database. To specify this option, use DROP= instead of KEEP=.

Example 35.9: Using the SOURCE Option to Subset Time Series from a HAVER Database

To select specific variables that belong to a certain source, the SOURCE= or DROPSOURCE= option can be used, similar to the way you use the KEEP= or DROP= option.

```
libname lib1 sasehavr "%sysget (HAVER_DATA) "  
    freq=daily  
    start=20041101  
    end=20041223  
    source="FRB";  
  
data hwoutd;  
    set lib1.haverd;  
run;  
  
title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';  
title2 '    Define a range inside the data range for OUT= dataset';  
title3 '    Using the START=20041101 END=20041223 LIBNAME options.';  
title4 '    Subset further: Using source="FRB" LIBNAME option';  
proc print data=hwoutd;  
run;
```

Output 35.9.1 shows two series that are selected by using SOURCE="FRB" on the LIBNAME statement.

Output 35.9.1 Using the SOURCE Option along with Defining a Range Using START=20041101
END=20041213

```
Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041223 LIBNAME options.
Subset further: Using source="FRB" LIBNAME option
```

Example 35.10: Using the GROUP Option to Subset Time Series from a HAVER Database

To select specific variables that belong to a certain group, the GROUP= or DROPGROUP= option can also be used, similar to the way you use the KEEP= or DROP= option.

Output 35.10.1, Output 35.10.2, and Output 35.10.3 show 3 different cross sections of the same database, haverw, by specifying 3 unique GROUP= options: GROUP="F*" on LIBNAME lib1, GROUP="M*" on LIBNAME lib2, and GROUP="E*" on LIBNAME lib3.

```
libname lib1 sasehavr "%sysget (HAVER_DATA) "  
    freq=week.6  
    force=freq  
    start=20040102  
    end=20041001  
    group="F*";  
  
data hwoutw;  
    set lib1.haverw;  
run;  
  
title1 'Haver Analytics Database, Frequency=week.6, infile=haverw.dat';  
title2 '    Define a range inside the data range for OUT= dataset';  
title3 '    Using the START=20040102 END=20041001 LIBNAME options.';  
title4 '    Subset further: Using group="F*" LIBNAME option';  
proc print data=hwoutw;  
run;
```

Output 35.10.1 Using the GROUP=F* Option along with Defining a Range

```

Haver Analytics Database, Frequency=week.6, infile=haverw.dat
Define a range inside the data range for OUT= dataset
Using the START=20040102 END=20041001 LIBNAME options.
Subset further: Using group="F*" LIBNAME option

```

HAVER ANALYTICS DLX Database Profile

The HAVER DLX economic and financial database offerings include United States Economic Indicators, Specialized Databases, Financial Indicators, Industry, Industrial Countries, Emerging Markets, International Organizations, Forecasts and As Reported Data, and United States Regional. [Table 35.3](#) is a list of available databases and the corresponding description of each.

Table 35.3 Available Data Offerings

Database Name	Offering Type	Description
USECON	U.S. Economic Indicators	HAVER Analytics' primary database of US Economic, Financial data
USNA	U.S. Economic Indicators	Complete US National Income and Product Accounts from the Bureau of Economic Analysis
SURVEYS	U.S. Economic Indicators	Business and Consumer Expectations, surveys
SURVEYW	U.S. Economic Indicators	Business and Consumer Expectations, weekly surveys
CPIDATA	U.S. Economic Indicators	Consumer Price Indexes, monthly in CPI Detailed Report
PPI	U.S. Economic Indicators	Producer Price Indexes by Bureau of Labor Statistics
PPIR	U.S. Economic Indicators	Producer Price Indexes by Bureau of Labor Statistics
LABOR	U.S. Economic Indicators	Employment and Earnings by Bureau of Labor Statistics
EMPL	U.S. Economic Indicators	Household Employment Survey, monthly by Bureau of Labor Statistics
CEW	U.S. Economic Indicators	Covered Employment and Wages, monthly, quarterly
IP	U.S. Economic Indicators	Industrial Production and Capacity Utilization by Federal Reserve Board
FFUNDS	U.S. Economic Indicators	Flow of Funds Data by Federal Reserve Board
CAPSTOCK	U.S. Economic Indicators	Capital Stock by Bureau of Economic Analysis
USINT	U.S. Economic Indicators	U.S. International Trade (TIC) data by Country and Product
CBDB	Specialized Databases	Conference Board Database, monthly

Table 35.3 *continued*

Database Name	Offering Type		Description
BCI	Specialized Databases		US Business Cycle Indicators
UMSCA	Specialized Databases		Consumer Sentiment Survey from The University of Michigan Surveys of Consumers
FIBER	Specialized Databases		Fiber Business Cycle Indicators from the Foundation of International Business and Economic Research
ECRI	Specialized Databases		Cyclical Indicators from Economic Cycle Research Institute, weekly and monthly
DAILY	Financial Indicators		U.S. Daily Statistics Data
INTDAILY	Financial Indicators		Country Daily Statistics
WEEKLY	Financial Indicators		U.S. Weekly Statistics
INTWKLY	Financial Indicators		Country Weekly Statistics
SPD	Financial Indicators		Standard and Poor's Industry Groups, daily
SPW	Financial Indicators		Standard and Poor's Industry Groups, weekly
SPM	Financial Indicators		Standard and Poor's Industry Groups, monthly
SPAH	Financial Indicators		Standard and Poor's Analysts' Annual Handbook, yearly
MSCID	Financial Indicators		Morgan Stanley Capital International, daily
MSCIW	Financial Indicators		Morgan Stanley Capital International, weekly
MSCIM	Financial Indicators		Morgan Stanley Capital International, monthly
BONDINDEX	Financial Indicators		U.S. Bond Indexes
BONDS	Financial Indicators		CITIGROUP Bond Performance Indexes by CITIGROUP Global Markets, formerly Salomon Smith Barney
ICI	Financial Indicators		Mutual Fund Activity from the Investment Company Institute
QFR	Financial Indicators		Quarterly Financial Report Capacity Utilization by Federal Reserve Board
MBAMTG	Financial Indicators		Mortgage Delinquency Rates by Mortgage Bankers Association
DLINQ	Financial Indicators		Consumer Delinquency Rates by American Bankers Association, monthly

Table 35.3 *continued*

Database Name	Offering Type	Description
FDIC	Financial Indicators	FDIC Banking Statistics TIC data by Country and Product
GOVFIN	Financial Indicators	U.S. Government Financial Statistics by U.S. Treasury
INDUSTRY	Industry	U.S. Industry Statistics
REALTOR	Industry	Home Sales from National Association of Realtors
OGJ	Industry	U.S. and International Energy Statistics, from Pennwell Publishing's Oil and Gas Journal
OGJANN	Industry	U.S. and International Energy Statistics, from Pennwell Publishing's Oil and Gas Journal, annual
OILWKLY	Industry	Weekly Oil Statistics
EEI	Industry	U.S. Electric Output from the Edison Electric Institute, weekly
ASM	Industry	Annual Survey of Manufactures
RAILSHAR	Industry	Railcar Loadings from Association of American Railroads and Atlantic Systems
CHEMWEEK	Industry	Weekly Chemical Prices from the Chemical Division of Access Intelligence
BALTIC	Industry	Baltic Freight Indexes, from the Baltic Exchange in London
G10+	Industrial Countries	International Macroeconomic Data
PMI	Industrial Countries	Purchasing Managers Surveys by NTC Research
INTSRVYS	Industrial Countries	Country Surveys
JAPAN	Industrial Countries	Japan from Nomura Research Institute
JAPANW	Industrial Countries	Japan from Nomura Research Institute, weekly
CANSIM	Industrial Countries	Canada from Statistics Canada and the Bank of Canada
CANSIMR	Industrial Countries	Canada from Statistics Canada and the Bank of Canada
UK	Industrial Countries	United Kingdom
UKSRVYS	Industrial Countries	United Kingdom Surveys, by NTC Research
GERMANY	Industrial Countries	Germany from the Deutsche Bundesbank and Statistics Bundesamt
FRANCE	Industrial Countries	France, Statistics from INSEE, the Bank of France and the Ministry of France

Table 35.3 *continued*

Database Name	Offering Type	Description
ITALY	Industrial Countries	Italy, from Istituto Nazionale di Statistica and Banca d'Italia
SPAIN	Industrial Countries	Spain, from the Instituto Nacional de Estadística and the Banco de España
IRELAND	Industrial Countries	Ireland, from the Central Statistics Office and Central Bank
NORDIC	Industrial Countries	Norway, Sweden, Denmark, Finland
ALPMED	Industrial Countries	Austria, Switzerland, Greece, Portugal
BENELUX	Industrial Countries	Belgium, Netherlands, Luxembourg, monthly
ANZ	Industrial Countries	Australia and New Zealand
EMERGELA	Emerging Markets	Latin American Macroeconomic Data
EMERGEPR	Emerging Markets	Asia/Pacific RIm Emerging Markets
CHINA	Emerging Markets	CEIC Premium China Database, from CEIC
EMERGECW	Emerging Markets	Central and Eastern Europe and Western Asia
EMERGEMA	Emerging Markets	Middle East and African Emerging Markets
EUROSTAT	International Organizations	European Union Data from EUROSTAT and OECD
OECDMEI	International Organizations	OECD Main Economic Indicators
OECDNAQ	International Organizations	OECD Quarterly National Accounts
OECDNA	International Organizations	OECD Annual National Accounts
OECDLFS	International Organizations	OECD Quarterly Labor Force
OUTLOOK	International Organizations	OECD Economic Outlook
IFS	International Organizations	International Financial Statistics from International Monetary Fund
IFSANN	International Organizations	International Financial Statistics, annual from International Monetary Fund
IMFDOTM	International Organizations	Direction of Trade Statistics, monthly from International Monetary Fund
IMFDOT	International Organizations	Direction of Trade Statistics from International Monetary Fund

Table 35.3 *continued*

Database Name	Offering Type	Description
WBPRICES	International Organizations	World Commodity Prices from World Development Prospects Group (Pinksheets)
WBDEBT	International Organizations	Global Development Finance from World Bank Debt Tables
UNPOP	International Organizations	United Nations Population Projections
INTCOMP	International Organizations	International Comparisons from Bureau of Labor Statistics
MA4CAST	Forecasts and As Reported Data	Short Term U.S. Economic Forecasts from Macroeconomic Advisors
MA4CSTL	Forecasts and As Reported Data	Long Term U.S. Economic Forecasts from Macroeconomic Advisors
CQM	Forecasts and As Reported Data	Canadian Quarterly Model from Centre for Spatial Economics
CPM	Forecasts and As Reported Data	Canadian Provincial Model from Centre for Spatial Economics
OEFQMACR	Forecasts and As Reported Data	OEF Global Macroeconomic Forecasts from Oxford Economic Forecasting
OEFMAJOR	Forecasts and As Reported Data	OEF Global Macroeconomic Forecasts from Oxford Economic Forecasting
OEFINTER	Forecasts and As Reported Data	OEF Global Macroeconomic Forecasts from Oxford Economic Forecasting
OEFMINOR	Forecasts and As Reported Data	OEF Global Macroeconomic Forecasts from Oxford Economic Forecasting
OEFQIND	Forecasts and As Reported Data	OEF Global Industry from Oxford Economic Forecasting
EIUIAMER	Forecasts and As Reported Data	EIU Market Indicators and Forecasts from the Economist Intelligence Unit
EIUIASIA	Forecasts and As Reported Data	EIU Market Indicators and Forecasts from the Economist Intelligence Unit
EIUIEEUR	Forecasts and As Reported Data	EIU Market Indicators and Forecasts from the Economist Intelligence Unit

Acknowledgments

Many people have been instrumental in the development of the ETS Interface engine. The individuals listed here have been especially helpful.

Maurine Haver, HAVER ANALYTICS, New York, NY.

Lai Cheng, HAVER ANALYTICS, New York, NY.

Rick Langston, SAS Institute, Cary, NC.

The final responsibility for the SAS System lies with SAS Institute alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

Part IV

Time Series Forecasting System

Chapter 36

Overview of the Time Series Forecasting System

Contents

Introduction	2379
Using the Time Series Forecasting System	2380
SAS Software Products Needed	2381

Introduction

The Time Series Forecasting system forecasts future values of time series variables by extrapolating trends and patterns in the past values of the series or by extrapolating the effect of other variables on the series. The system provides convenient point-and-click windows to control the time series analysis and forecasting tools of SAS/ETS software.

You can use the system in a fully automatic mode, or you can use the system's diagnostic features and time series modeling tools interactively to develop forecasting models customized to best predict your time series. The system provides both graphical and statistical features to help you choose the best forecasting method for each series.

The following is a brief summary of the features of the Time Series Forecasting system. You can use the system in the following ways:

- use a wide variety of forecasting methods, including several kinds of exponential smoothing models, Winters method, and ARIMA (Box-Jenkins) models. You can also produce forecasts by combining the forecasts from several models.
- use predictor variables in forecasting models. Forecasting models can include time trend curves, regressors, intervention effects (dummy variables), adjustments you specify, and dynamic regression (transfer function) models.
- view plots of the data, predicted versus actual values, prediction errors, and forecasts with confidence limits, as well as autocorrelations and results of white noise and stationarity tests. Any of these plots can be zoomed and can represent raw or transformed series.
- use hold-out samples to select the best forecasting method

- compare goodness-of-fit measures for any two forecasting models side by side or list all models sorted by a particular fit statistic
- view the predictions and errors for each model in a spreadsheet or compare the fit of any two models in a spreadsheet
- examine the fitted parameters of each forecasting model and their statistical significance
- control the automatic model selection process: the set of forecasting models considered, the goodness-of-fit measure used to select the best model, and the time period used to fit and evaluate models
- customize the system by adding forecasting models for the automatic model selection process and for point-and-click manual selection
- save your work in a project catalog
- print an audit trail of the forecasting process
- show source statements for PROC ARIMA code
- save and print system output including spreadsheets and graphs

Using the Time Series Forecasting System

Chapters starting from Chapter 37, “[Getting Started with Time Series Forecasting](#),” through Chapter 41, “[Using Predictor Variables](#),” contain a series of example sessions that show the major features of the system. Chapters from Chapter 42, “[Command Reference](#),” through Chapter 44, “[Forecasting Process Details](#),” serve as reference and provide more details about how the system operates. The reference chapters contain a complete list of system features.

To get started using the Time Series Forecasting system, it is a good idea to work through a few of the example sessions. Start with Chapter 37, “[Getting Started with Time Series Forecasting](#),” and use the system to reproduce the steps shown in the examples. Continue with the other chapters when you feel comfortable using the system.

The example sessions make use of time series data sets contained in the SASHELP library: `air`, `citimon`, `citiqtr`, `citiyr`, `citiwk`, `citiday`, `gnp`, `retail`, `usecon`, and `workers`. You can use these data sets to work through the example sessions or to experiment further with the system.

Once you are familiar with how the system operates, start working with your own data to build your own forecasting models. When you have questions, consult the reference chapters mentioned above for more information about particular features.

The Time Series Forecasting system forecasts *time series*, that is, variables that consist of ordered observations taken at regular intervals over time. Since the Time Series Forecasting system is a part of the SAS software system, time series values must be stored as variables in a SAS data set or data

view, with the observations representing the time periods. The data can also be stored in an external spreadsheet or data base if you license SAS/ACCESS software.

The Time Series Forecasting System chapters refer to *series* and *variables*. Since time series are stored as variables in SAS data sets or data views, these terms are used interchangeably. However, the term *series* is preferred when attention is focused on the sequence of data values, and the term *variable* is preferred when attention is focused on the data set.

SAS Software Products Needed

The Time Series Forecasting system is part of SAS/ETS software. To use it, you must have a license for SAS/ETS. To use the graphical display features of the system, you must also license SAS/GRAPH software.

This chapter outlines the forecasting process and introduces the major windows of the system through three example sessions.

The first example, beginning with the section “The Time Series Forecasting Window,” shows how to use the system for fully automated forecasting of a set of time series. This example also introduces the system’s features for viewing data and forecasts through tables and interactive graphs. It also shows how to save and restore forecasting work in SAS catalogs.

The second example, beginning with the section “Develop Models Window,” introduces the features for developing the best forecasting models for individual time series. The chapter concludes with an example showing how to create dating variables for your data in the form expected by the system.

After working through the examples in this chapter, you should be able to do the following:

- select a data set of time series to work with and specify its periodicity and time ID variable
- use the automatic forecasting model selection feature to create forecasting models for the variables in a data set
- produce and save forecasts of variables in a data set
- examine your data and forecasts as tables of values and through interactive graphs
- save and restore your forecasting models by using project files in a SAS catalog and edit project information
- use some of the model development features to fit and select forecasting models for individual time series variables

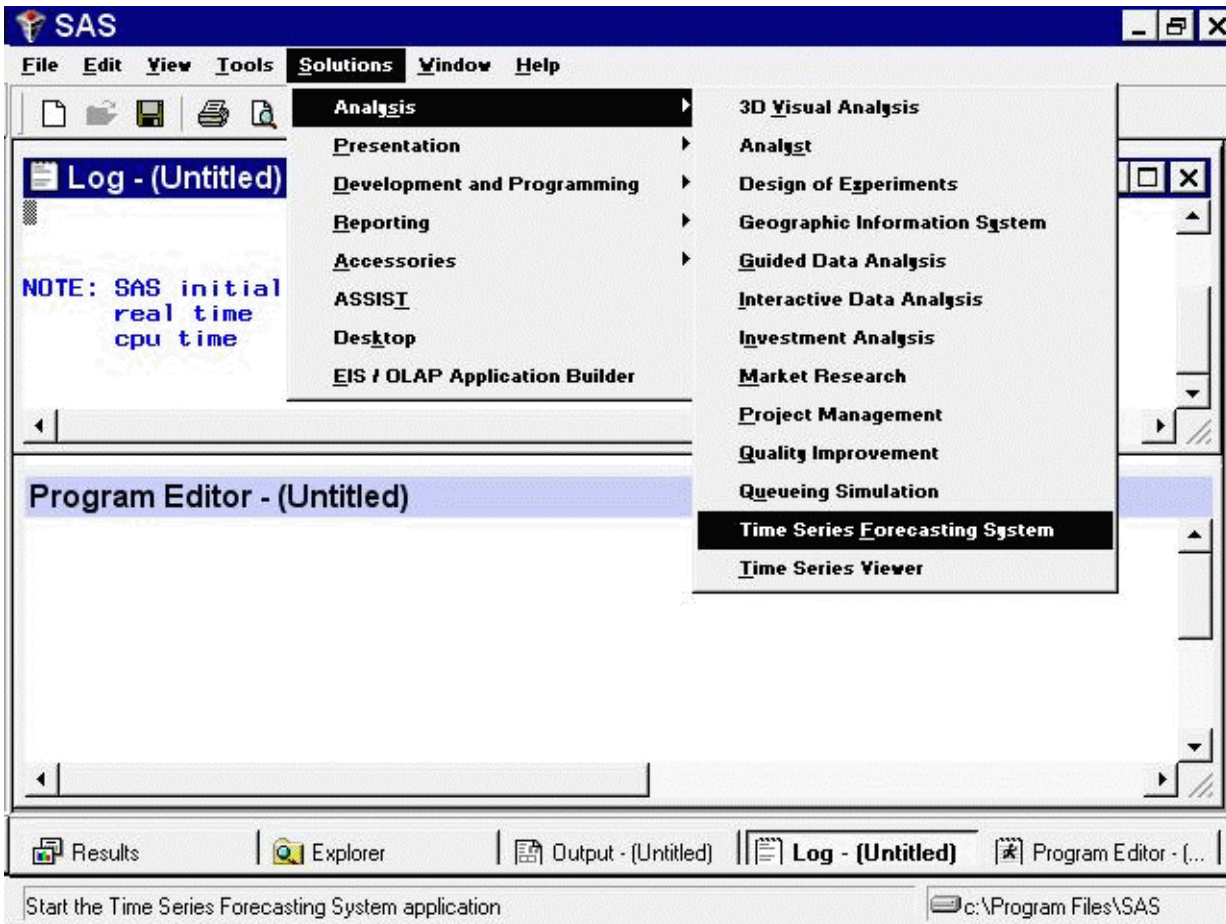

This chapter introduces these topics and helps you get started using the system. Later chapters present these topics in greater detail and document more advanced features and options.

The Time Series Forecasting Window

There are several ways to get to the Time Series Forecasting System. If you prefer to use commands, invoke the system by entering `forecast` on the command line. You can optionally specify additional information on the command line; see Chapter 42, “[Command Reference](#),” for details.

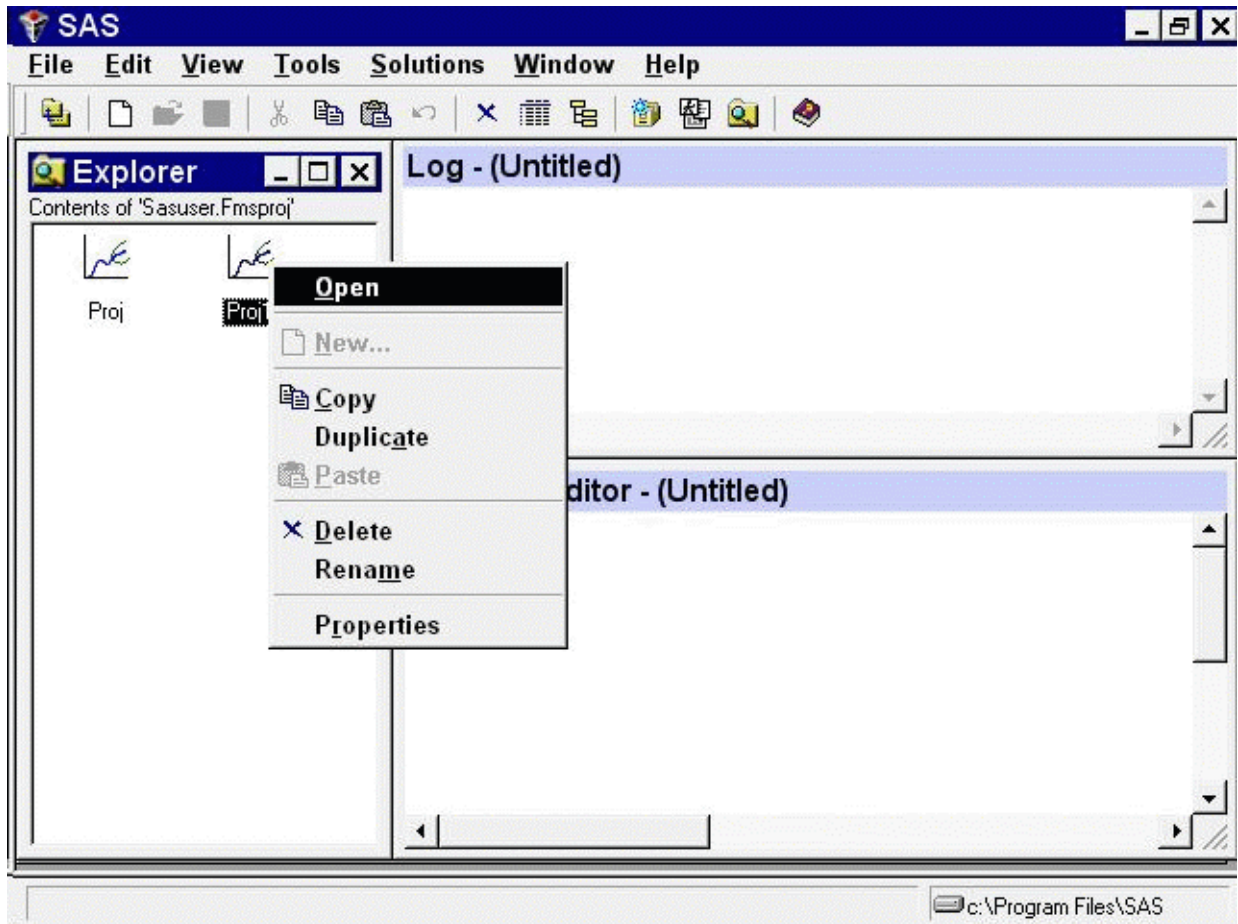

If you are using the SAS windowing environment with pull-down menus, select the Solutions menu from the menu bar, select the Analysis item, and then select `Time Series Forecasting System`, as shown in [Figure 37.1](#).

Figure 37.1 Time Series Forecasting System Menu Selection

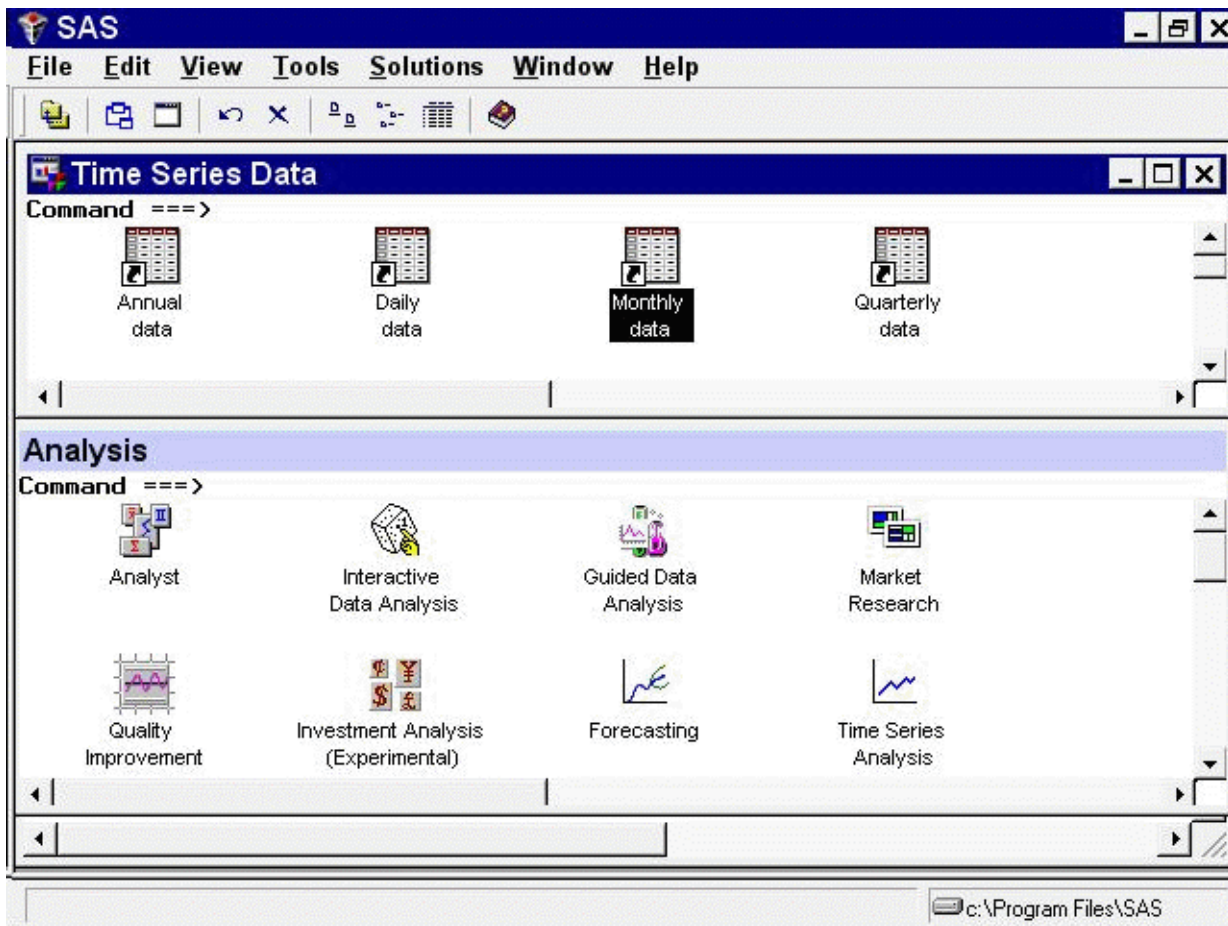

You can invoke the Forecasting System from the SAS Explorer window by opening an existing forecasting project. By default these projects are stored in the FMSPROJ catalog in the SASUSER library. Select SASUSER in the Explorer to display its contents. Then select FMSPROJ. This catalog is created the first time you use the Forecasting System. If you have saved projects, they appear in the Explorer with the forecasting graph icon, as shown in [Figure 37.2](#). Double-click one of the projects, or select it with the right mouse button and then select Open from the pop-up menu, as shown in the figure. This opens the Forecasting System and opens the selected project.

Figure 37.2 Opening a Project from the Explorer

To invoke the Forecasting System in the SAS desktop environment, select the Solutions menu from the menu bar, select *Desktop*, and then open the Analysis folder. You can run the Time Series Forecasting System or the Time Series Viewer directly, or you can drag and drop. Figure 37.3 illustrates dragging a data set (known as a table in the Desktop environment) and dropping it on the Forecasting icon. In this example, the tables reside in a user-defined folder called *Time Series Data*.

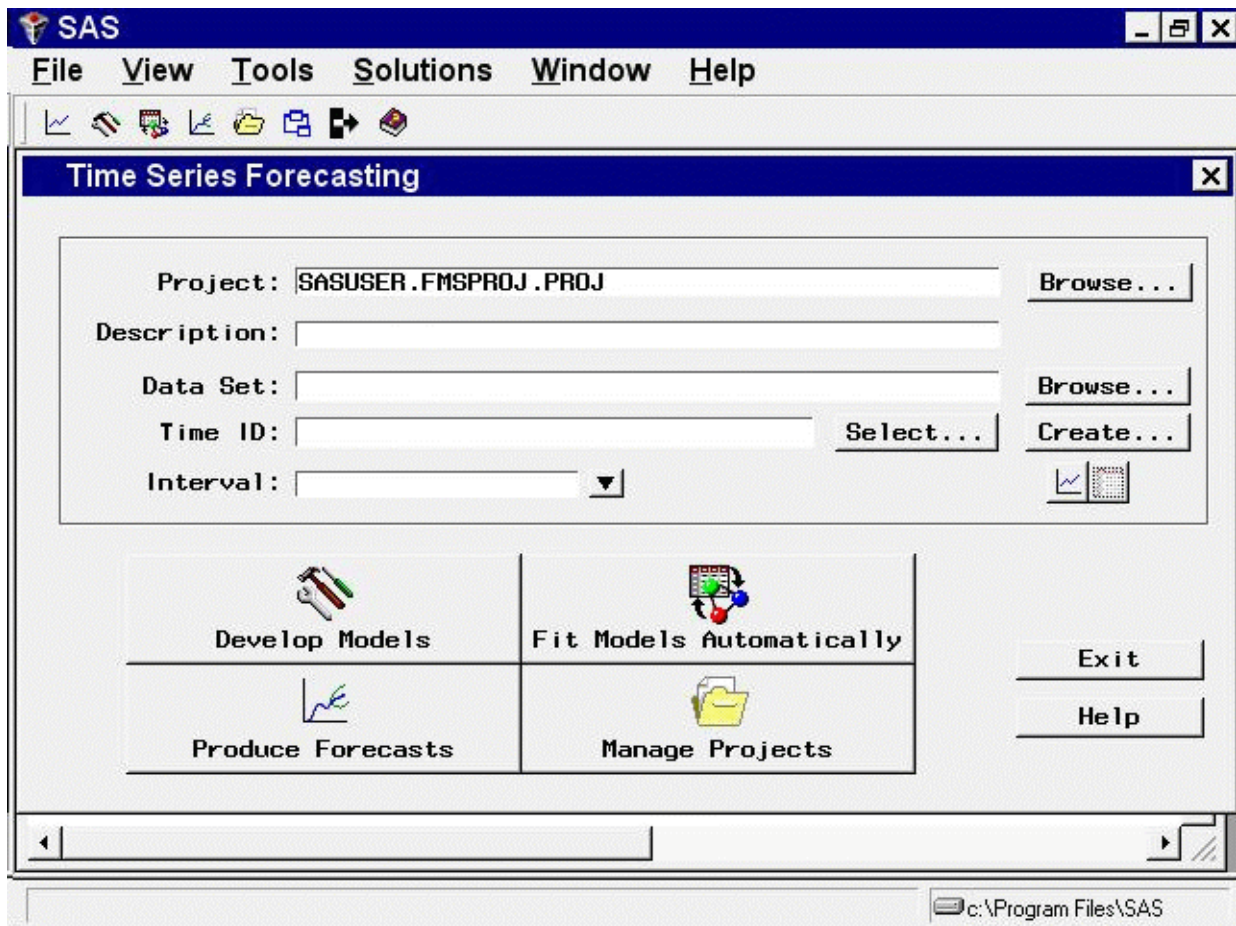

Figure 37.3 Drag and Drop on the SAS Desktop

If you are using SAS/ASSIST software, select the Planning button and then select `Forecasting` from the pop-up menu.

Any of these methods takes you to the Time Series Forecasting window, as shown in [Figure 37.4](#).

Figure 37.4 Time Series Forecasting Window

At the top of the window is a data selection area for specifying a project file and the input data set containing historical data (the known past values) for the time series variables that you want to forecast. This area also contains buttons for opening viewers to explore your input data either graphically, one series at a time, or as a table, one data set at a time.

The Project and Description fields are used to specify a project file for saving and restoring forecasting models created by the system. Using project files is discussed later, and these fields are ignored for now.

The lower part of the window contains six buttons:

Develop Models

opens the Develop Models window, which you use to develop and fit forecasting models interactively for individual time series.

Fit Models Automatically

opens the Automatic Model Fitting window, which you use to search automatically for the best forecasting model for multiple series in the input data set.

Produce Forecasts

opens the Produce Forecasts window, which you use to compute forecasts for all

the variables in the input data set for which forecasting models have been fit.

Manage Projects

opens the Manage Forecasting Project window, which lists the time series for which you have fit forecasting models. You can drill down on a series to see the models that have been fit. You can delete series or models from the project, re-evaluate or refit models, and explore models and forecasts graphically or in tabular form.

Exit

exits the Forecasting System.

Help

displays information about the Forecasting System.

Outline of the Forecasting Process

The examples shown in the following sections illustrate the basic process you use with the Forecasting System.

Specify the Input Data Set

Suppose you have a number of *time series*, variables recorded over time, for which you want to forecast future values. The past values of these time series are stored as variables in a SAS data set or data view. The observations of this data set correspond to regular time periods, such as days, weeks, or months. The first step in the forecasting process is to tell the system to use this data set by setting the Data Set field.

If your time series are not in a SAS data set, you must provide a way for the SAS System to access the data. You can use SAS features to read your data into a SAS data set; refer to *SAS Language Reference*. You can use a SAS/ACCESS product to establish a view of data in a database management system; refer to SAS/ACCESS documentation. You can use PROC SQL to create a SAS data view. You can use PROC DATASOURCE to read data from files supplied by supported data vendors; refer to Chapter 11, “[The DATASOURCE Procedure](#),” for more details.

Provide a Valid Time ID Variable

To use the Forecasting System, your data set must be dated: the data set must contain a *time ID variable* that gives the date of each observation. The time ID variable must represent the observation dates with *SAS date values* or with *SAS datetime values* (for hourly data or other frequencies less than a day), or you can use a simple time index.

When SAS date values are used, the ID variable contains dates within the time periods corresponding to the observations. For example, for monthly data, the values for the time ID variable can be the date of the first day of the month corresponding to each observation, or the time ID variable can contain the date of the last day in the month. (Any date within the period serves as the time ID for the observation.)

If your data set already contains a valid time ID variable with SAS date or datetime values, the next step is to specify this time ID variable in the Time ID field. If the time ID variable is named DATE, the system fills in the Time ID field automatically.

If your data set does not contain a time ID, you must add a valid time ID variable before beginning the forecasting process. The Forecasting System provides features that make this easy to do. See Chapter 38, “[Creating Time ID Variables](#),” for details.

Select and Fit a Forecasting Model for Each Series

If you are using the automated model selection feature, the system performs this step for you and chooses a forecasting model for each series automatically. All you need to do is select the Fit Models Automatically button and then select the variables to fit models for.

If you want more control over forecasting model selection, you can select the Develop Models button, select the series you want to forecast, and use the Develop Models window to specify a forecasting model. As part of this process, you can use the Time Series Viewer and Model Viewer graphical tools. Once you have selected a model for the first series, you can select a different series to work with and repeat the model development process until you have created forecasting models for all the series you want to forecast.

The system provides many features to help you choose the best forecasting model for each series. The features of the Develop Models window and graphical viewer tools are introduced in later sections.

Produce the Forecasts

Once a forecasting model has been fit for each series, select the Produce Forecasts button and use the Produce Forecasts window to compute forecast values and store them in a SAS data set.

Save Your Work

If you want only a single forecast, your task is now complete. But you might want to produce updated forecasts later, as more data becomes available. In this case, you want to save the forecasting models you have created, so that you do not need to repeat the model selection and fitting process.

To save your work, fill in the Project field with the name of a SAS catalog member in which the system will store the model information when you exit the system. Later, you will select the same catalog member name when you first enter the Forecasting System, and the model information will be reloaded.

Note that any number of people can work with the same project file. If you are working on a forecasting project as part of a team, you should take care to avoid conflicting updates to the project file by different team members.

Summary

This is the basic outline of how the Forecasting System works. The system offers many other features and options that you might need to use (for example, the time range of the data used to fit models and how far into the future to forecast). These options will become apparent as you work with the Forecasting System.

As an introductory example, the following sections use the Automatic Model Fitting and Produce Forecasts windows to perform automated forecasting of the series in an example data set.

The Input Data Set

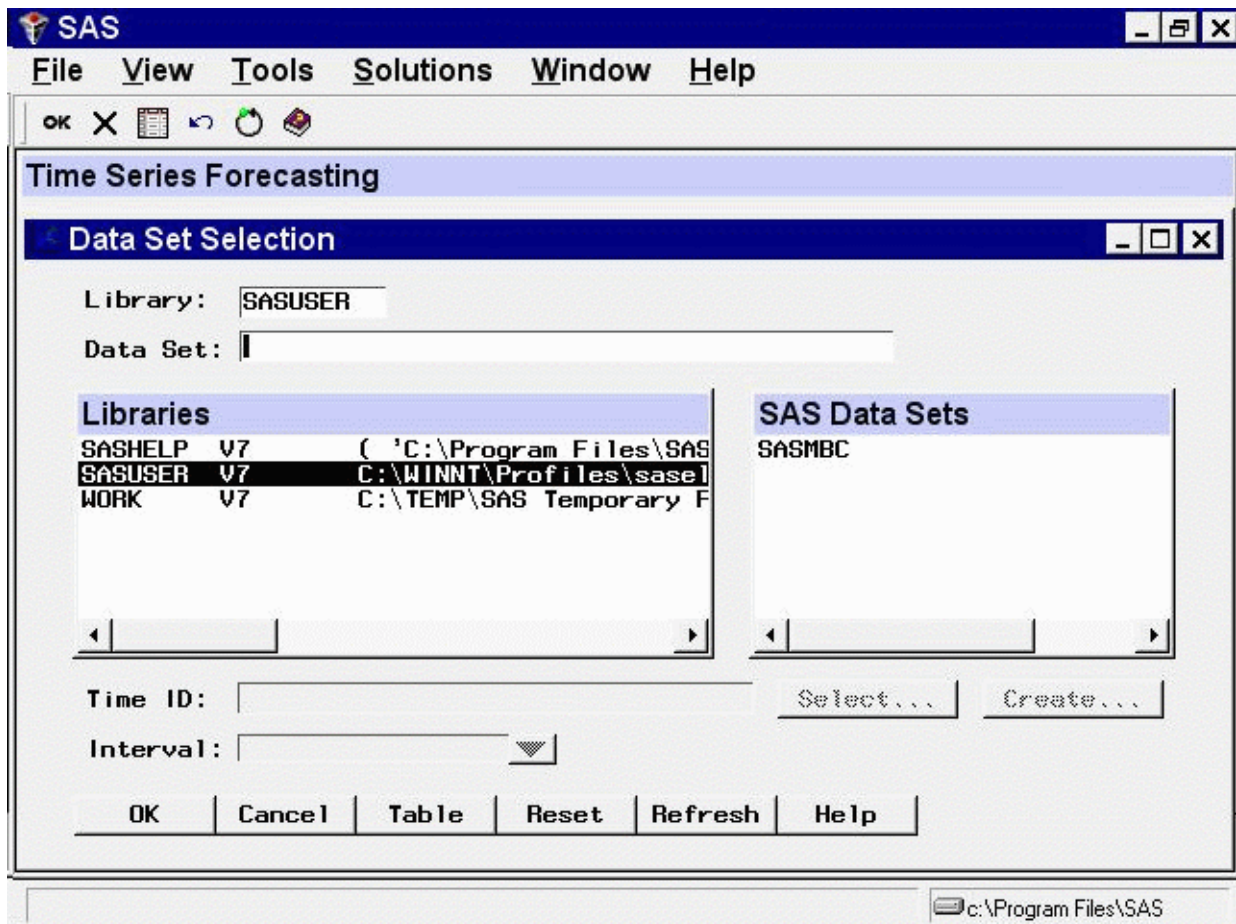

As the first step, you must specify the input data set.

The Data Set field in the Time Series Forecasting window gives the name of the input data set containing the time series to forecast. Initially, this field is blank. You can specify the input data set by typing the data set name in this field. Alternatively, you can select the Browse button at the right of the Data Set field to select the data set from a list, as shown in the following section.

The Data Set Selection Window

Select the Browse button to the right of the Data Set field. This opens the Data Set Selection window, as shown in [Figure 37.5](#).

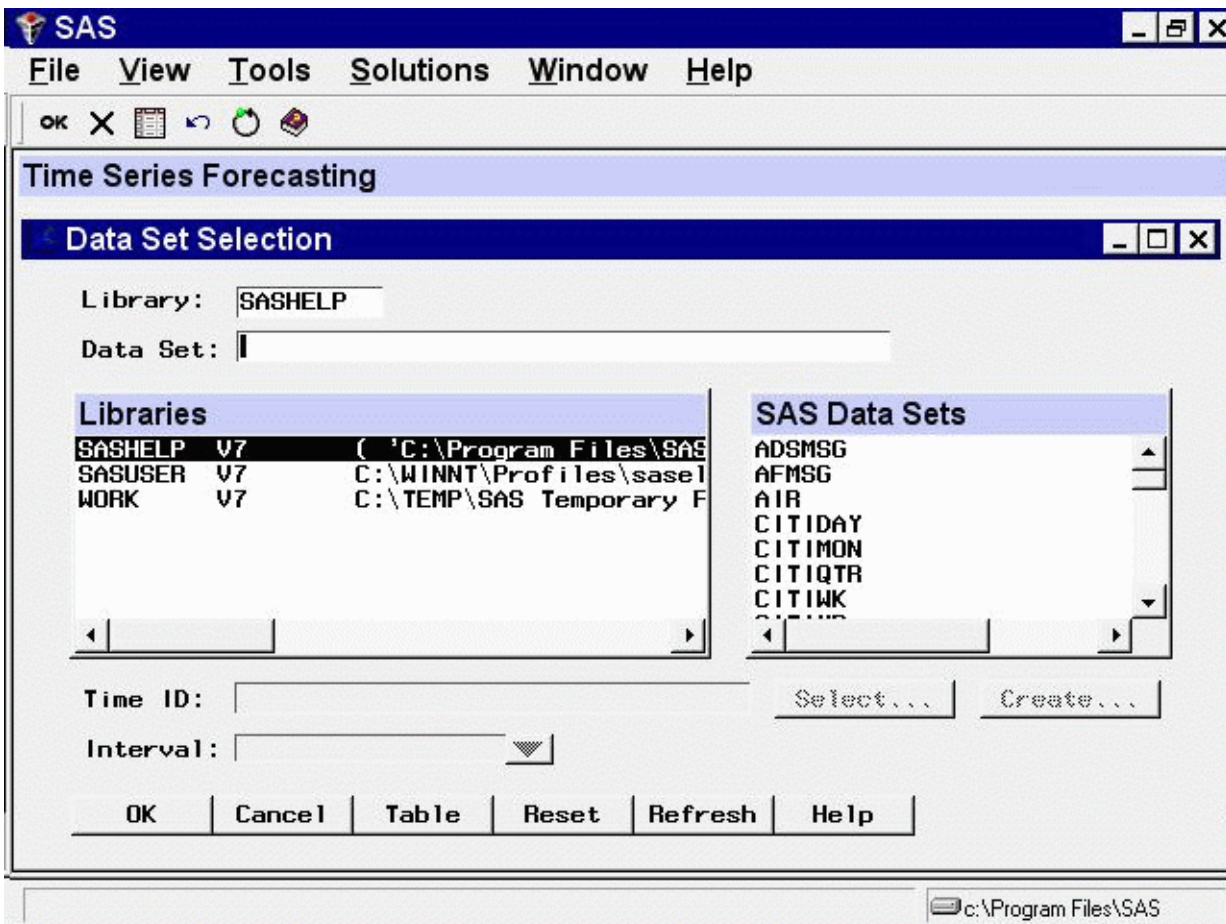

Figure 37.5 Data Set Selection Window

The `Libraries` list shows the SAS librefs that are currently allocated in your SAS session. Initially, the `SASUSER` library is selected, and the `SAS Data Sets` list shows the data sets available in your `SASUSER` library.

In the `Libraries` list, select the row that starts with `SASHELP`. The Data Set Selection window now lists the data sets in the `SASHELP` library, as shown in [Figure 37.6](#).

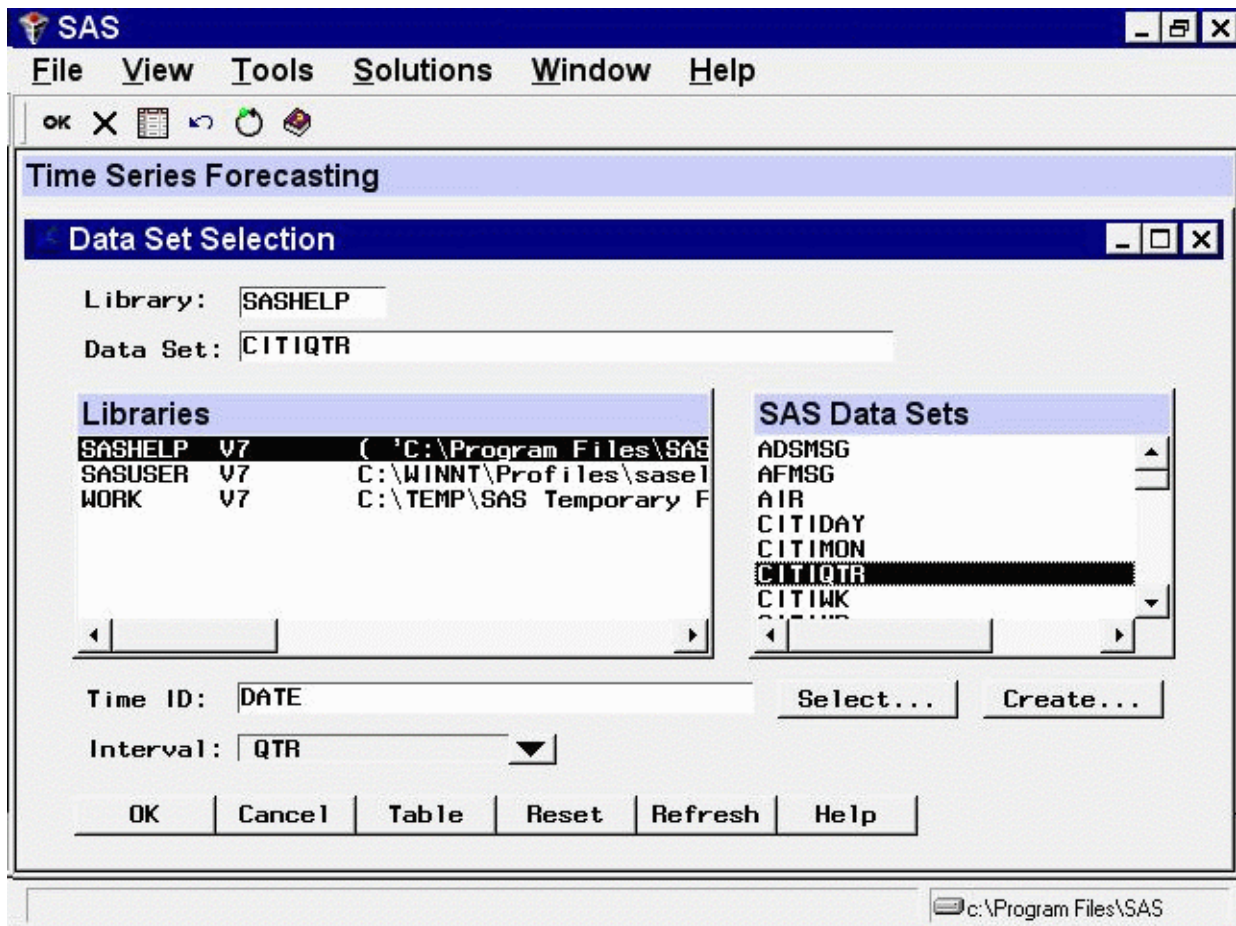

Figure 37.6 SASHELP Library

Use the vertical scroll bar on the SAS Data Sets list to scroll down the list until the data set CITIQTR appears. Then select the CITIQTR row. This selects the data set SASHELP.CITIQTR as the input data set.

Figure 37.7 shows the Data Set Selection window after selection of CITIQTR from the SAS Data Sets list.

Figure 37.7 CITIQTR Data Set Selected

Note that the Time ID field is now set to DATE and the Interval field is set to QTR. These fields are explained in the following section.

Now select the OK button to complete selection of the CITIQTR data set. This closes the Data Set Selection window and returns to the Time Series Forecasting window, as shown in [Figure 37.8](#).

Figure 37.8 Time Series Forecasting Window

Time Series Data Sets, ID Variables, and Time Intervals

Before you continue with the example, it is worthwhile to consider how the system determined the values for the Time ID and Interval fields in the Data Set Selection window.

The Forecasting System requires that the input data set contain time series observations, with one observation for each time period. The observations must be sorted in increasing time order, and there must be no gaps in the sequence of observations. The time period of each observation must be identified by an ID variable, which is shown in the Time ID field.

If the data set contains a variable named DATE, TIME, or DATETIME, the system assumes that this variable is the SAS date or datetime valued ID variable, and the Time ID field is filled in automatically. The time ID variable for the SASHELP.CITIQTR data set is named DATE, and therefore the system set the Time ID field to DATE.

If the time ID variable for a data set is not named DATE, TIME, or DATETIME, you must specify the time ID variable name. You can specify the time ID variable either by typing the ID variable name in the Time ID field or by clicking the Select button.

If your data set does not contain a time ID variable with SAS date values, you can add a time ID variable using one of the windows described in Chapter 38, “[Creating Time ID Variables](#).”

Once the time ID variable is known, the Forecasting System examines the ID values to determine the time interval between observations. The data set SASHELP.CITIQTR contains quarterly observations. Therefore, the system determined that the data have a quarterly interval, and set the Interval field to QTR.

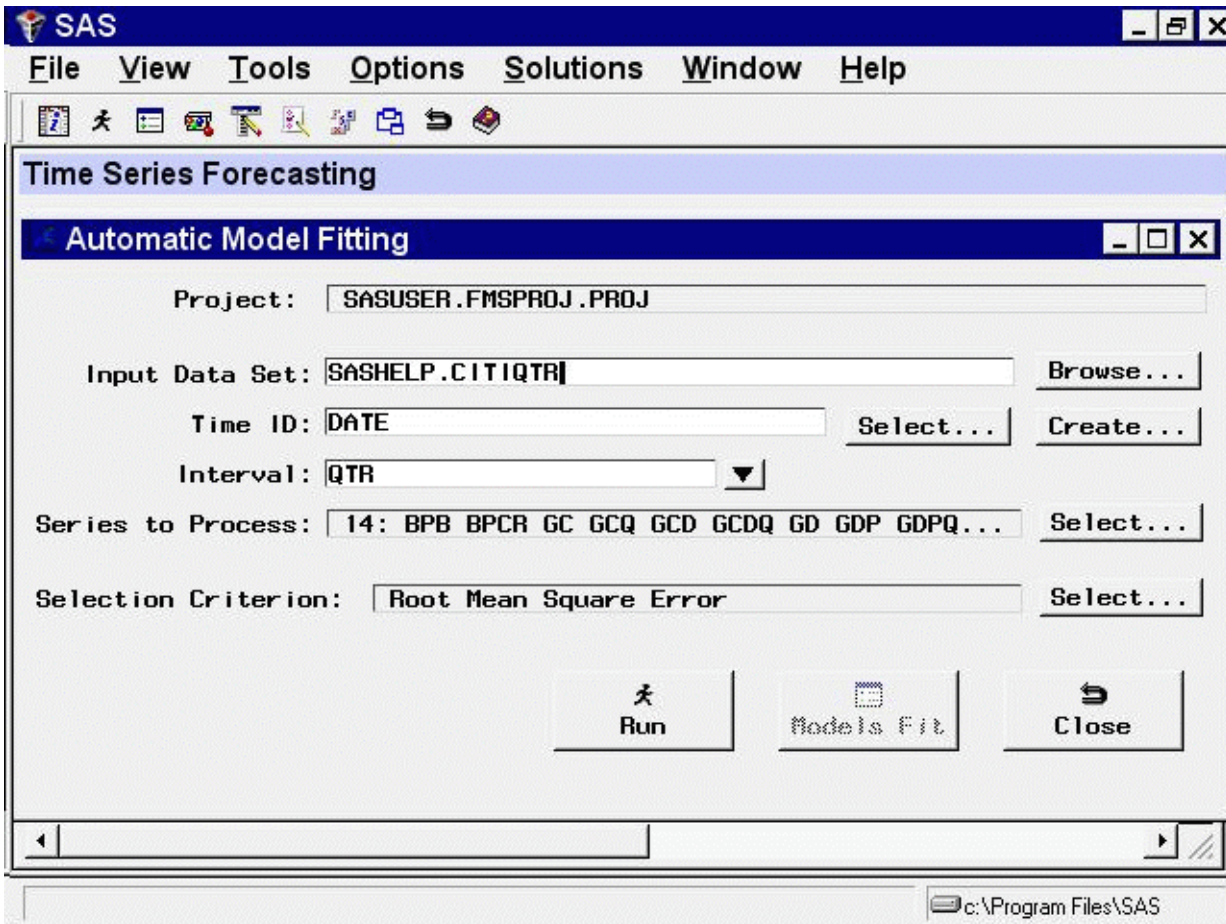

If the system cannot determine the data frequency from the values of the time ID variable, you must specify the time interval between observations. You can specify the time interval by using the `Interval` combo box. In addition to the interval names provided in the pop-up list, you can type in more complex interval names to specify an interval that is a multiple of other intervals or that has date values in the middle of the interval (such as monthly data with time ID values falling on the 10th day of the month).

See Chapter 3, “[Working with Time Series Data](#),” and Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about time intervals, SAS date values, and ID variables for time series data sets.

Automatic Model Fitting Window

Before you can produce forecasts, you must fit forecasting models to the time series. Select the `Fit Models Automatically` button. This opens the Automatic Model Fitting window, as shown in [Figure 37.9](#).

Figure 37.9 Automatic Model Fitting Window

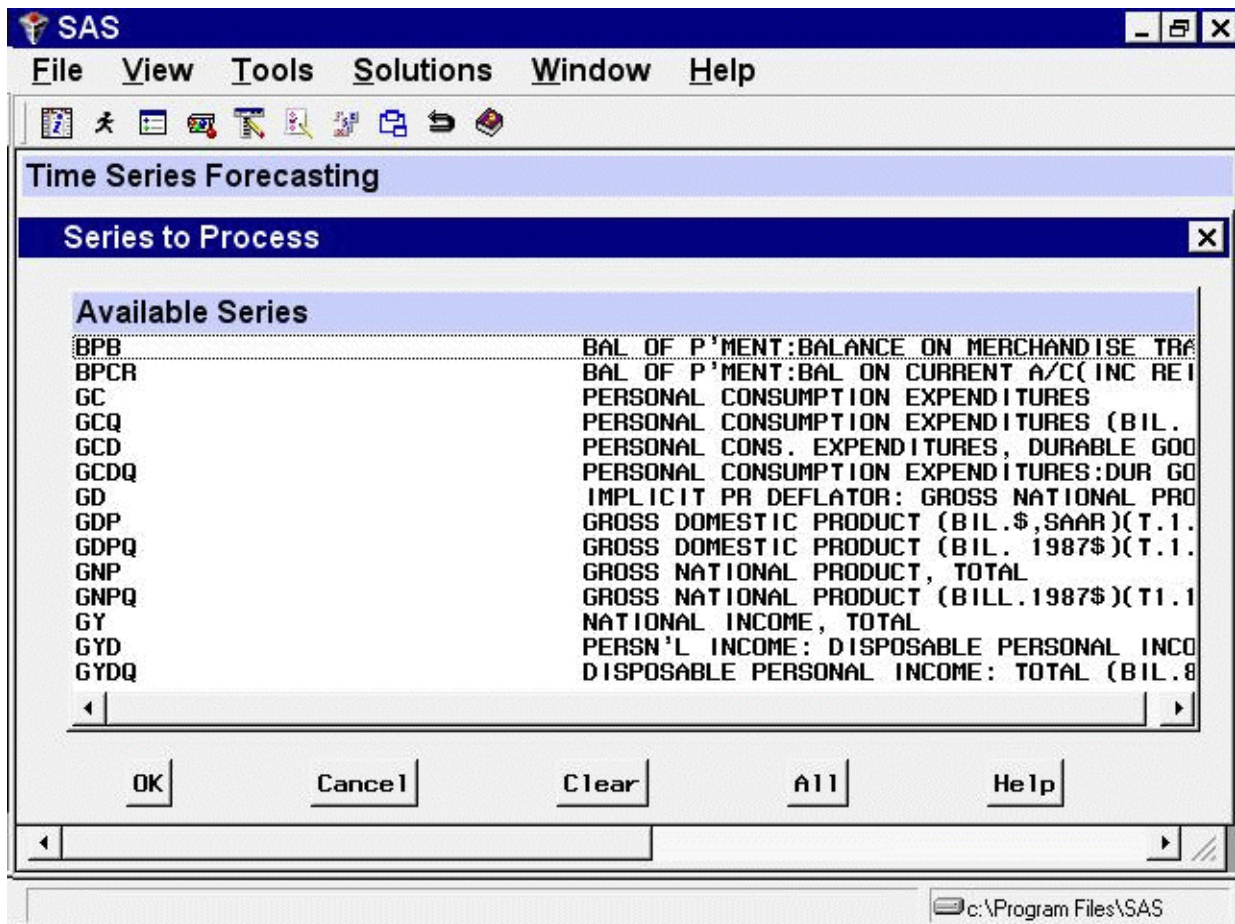

The first part of the Automatic Model Fitting window confirms the project filename and the input data set name.

The Series to Process field shows the number and lists the names of the variables in the input data set to which the Automatic Model Fitting process will be applied. By default, all numeric variables (except the time ID variable) are processed. However, you can specify that models be generated for only a select subset of these variables.

Click the Select button to the right of the Series to Process field. This opens the Series to Process window, as shown in [Figure 37.10](#).

Figure 37.10 Series to Process Window

Use the mouse and the CTRL key to select the personal consumption expenditures series (GC), the personal consumption expenditures for durable goods series (GCD), and the disposable personal income series (GYD), as shown in Figure 37.11. (Remember to hold down the CTRL key as you make the selections; otherwise, selecting a second series will deselect the first.)

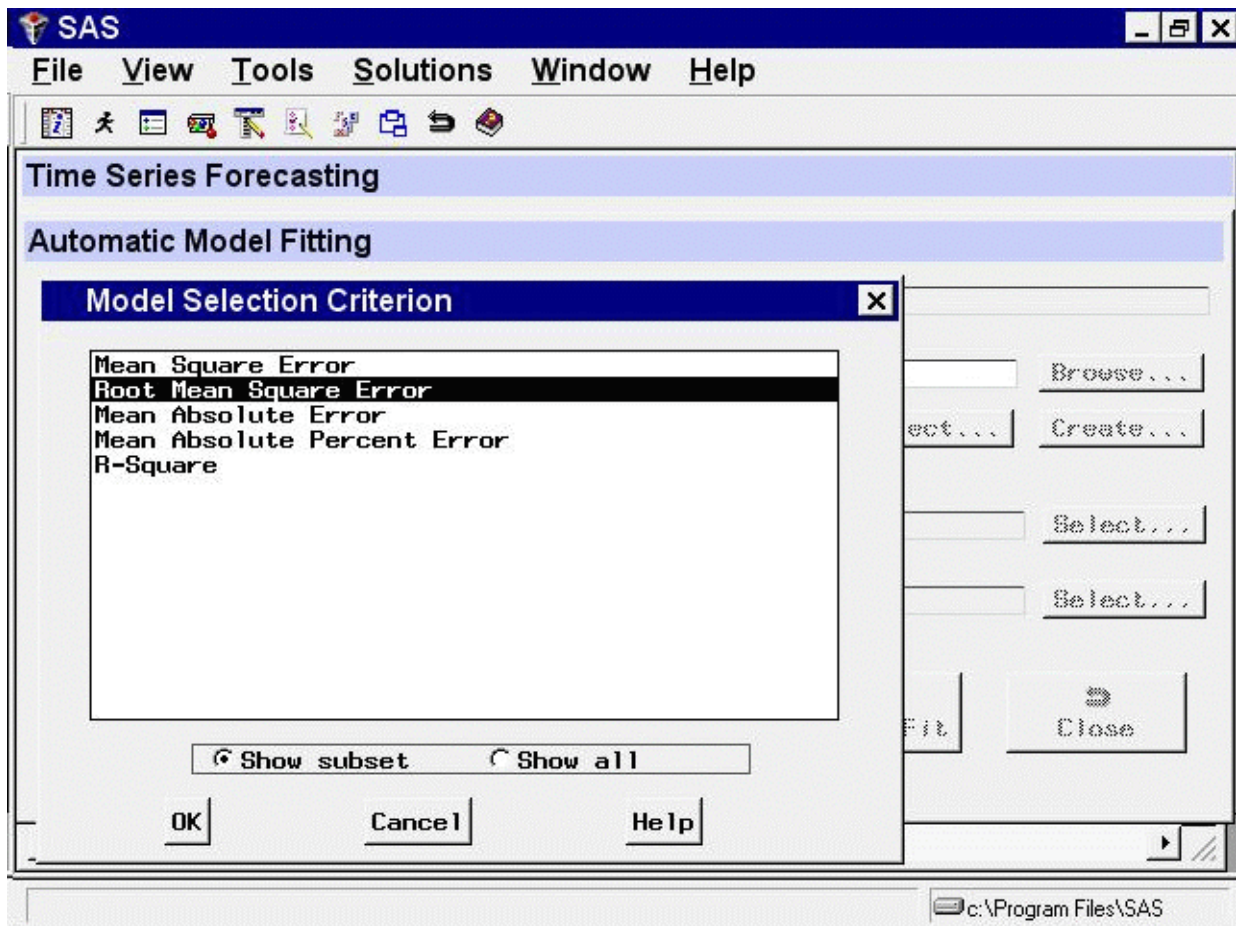

Figure 37.11 Selecting Series for Automatic Model Fitting

Now select the OK button. This returns you to the Automatic Model Fitting window. The Series to Process field now shows the selected variables.

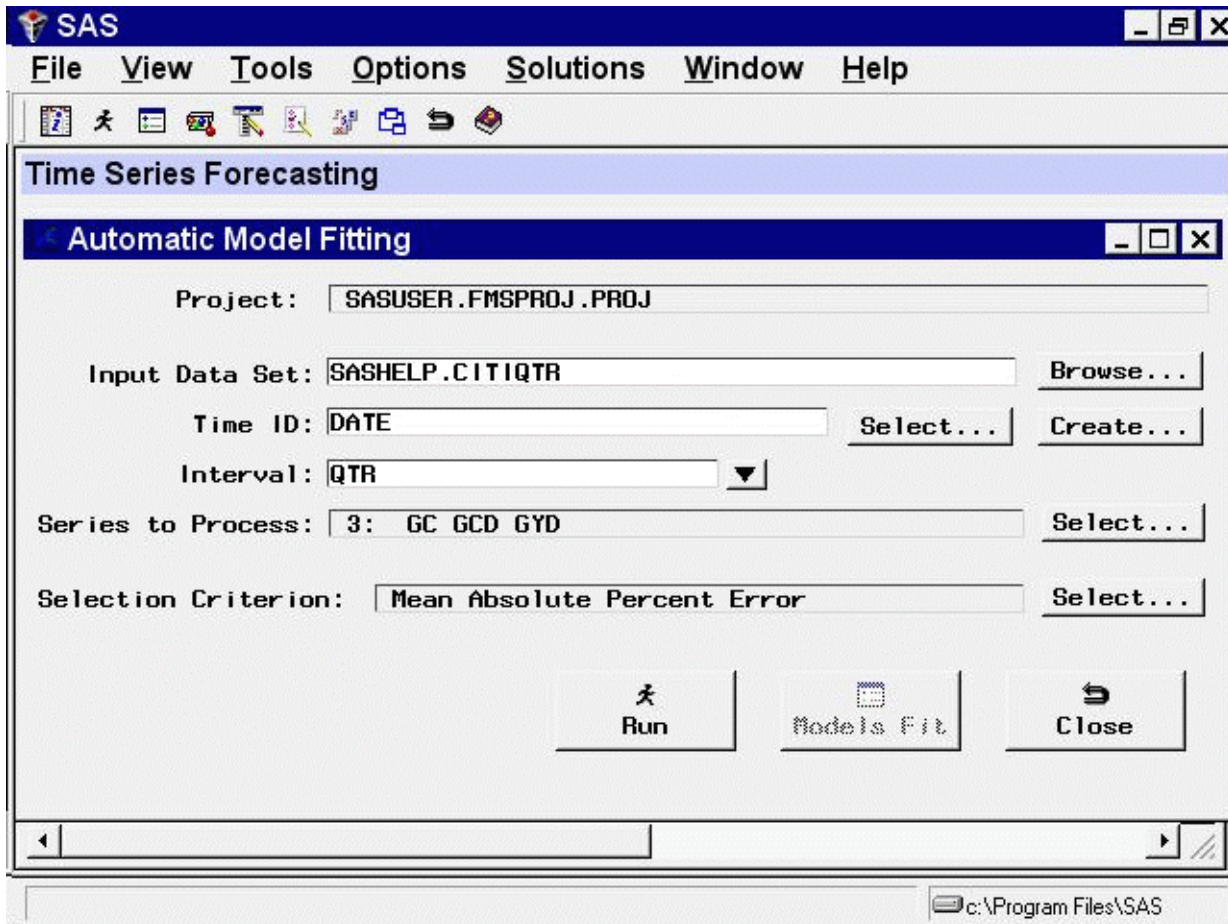

The Selection Criterion field shows the goodness-of-fit measure that the Forecasting System will use to select the best fitting model for each series. By default, the selection criterion is the root mean squared error. To illustrate how you can control the selection criterion, this example uses the mean absolute percent error to select the best fitting models.

Click the Select button to the right of the Selection Criterion field. This opens a list of statistics of fit, as shown in [Figure 37.12](#).

Figure 37.12 Choosing the Model Selection Criterion

Select *Mean Absolute Percent Error* and then select the OK button. The Automatic Model Fitting window now appears as shown in [Figure 37.13](#).

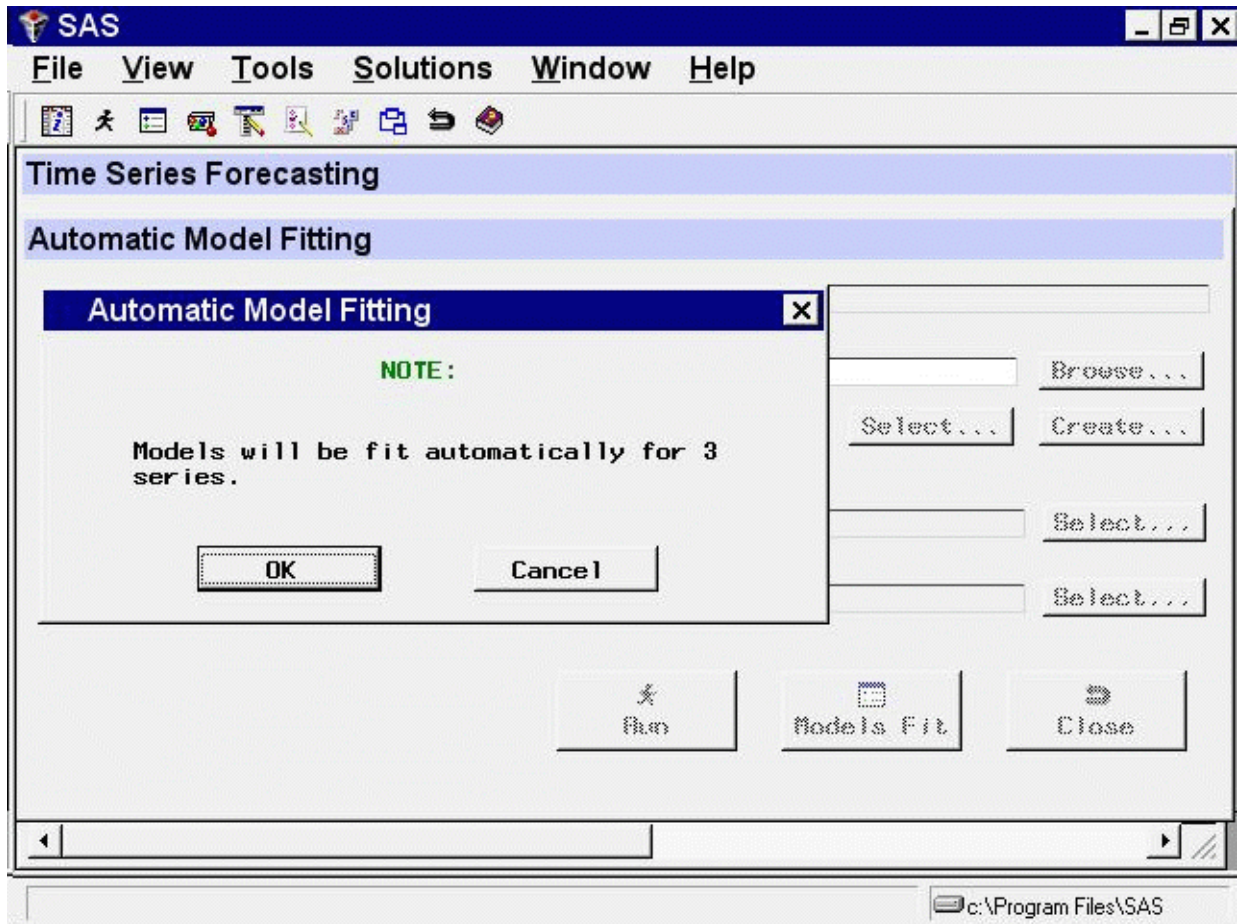

Figure 37.13 Automatic Model Fitting Window

Now that all the options are set appropriately, select the Run button.

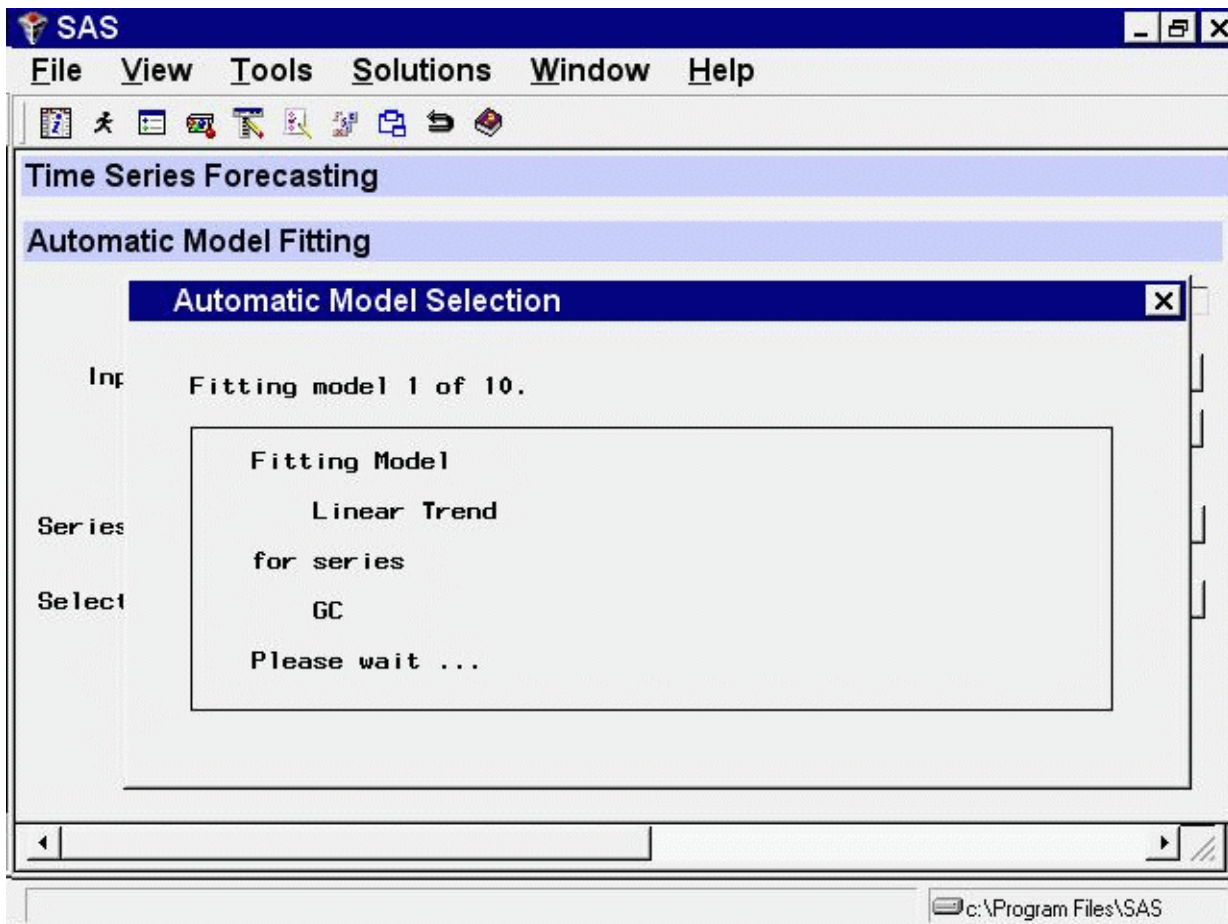

The Forecasting System now displays a notice, shown in [Figure 37.14](#), confirming that models will be fit for three series using the automatic forecasting model search feature. This prompt is displayed because it is possible to fit models for a large number of series at once, which might take a lot of time. So the system gives you a chance to cancel if you accidentally ask to fit models for more series than you intended. Select the OK button.

Figure 37.14 Automatic Model Fitting Note

The system now fits several forecasting models to each of the three series you selected. While the models are being fit, the Forecasting System displays notices indicating what it is doing so that you can observe its progress, as shown in [Figure 37.15](#).

Figure 37.15 “Working” Notice

For each series, the system saves the model that produces the smallest mean absolute percent error. You can have the system save all the models fit by selecting *Automatic Fit* from the Options menu.

After the Automatic Model Fitting process has completed, the results are displayed in the Automatic Model Fitting Results window, as shown in [Figure 37.16](#).

Figure 37.16 Automatic Model Fitting Results

This resizable window shows the list of series names and descriptive labels for the forecasting models chosen for them, as well as the values of the model selection criterion and other statistics of fit. Select the Close button.

This returns you to the Automatic Model Fitting window. You can now fit models for other series in this data set or change to a different data set and fit models for series in the new data set.

Select the Close button to return to the Time Series Forecasting window.

Produce Forecasts Window

Now that you have forecasting models for these three series, you are ready to produce forecasts. Select the Produce Forecasts button. This opens the Produce Forecasts window, as shown in Figure 37.17.

Figure 37.17 Produce Forecasts Window

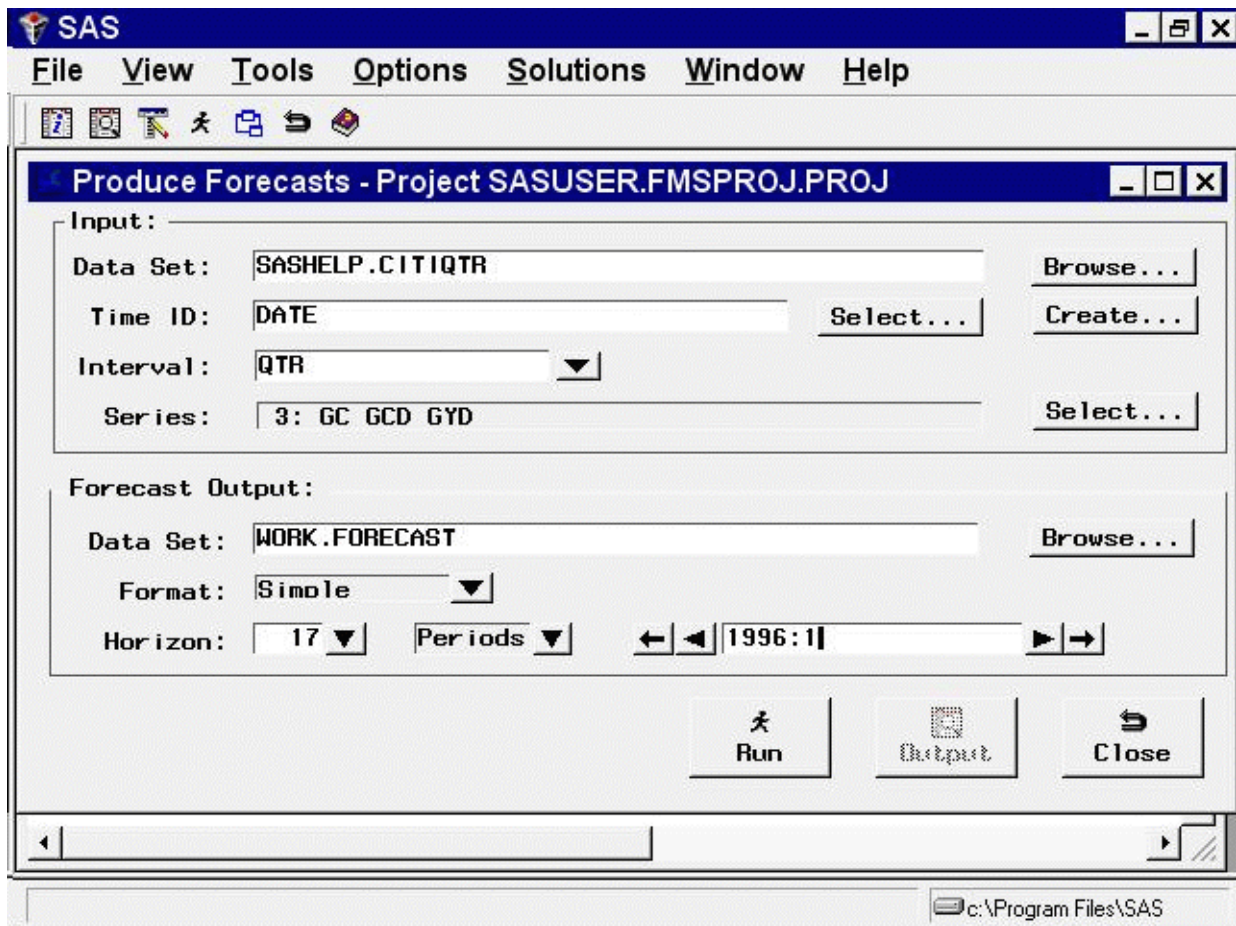

The Produce Forecasts window shows the input data set information and indicates the variables in the input data set for which forecasting models exist. Forecasts will be produced for these series. If you want to produce forecasts for only some of these series, use the Select button at the right of the Series field to select the series to forecast. The Data Set field in the Forecast Output box contains the name of the SAS data set in which the system will store the forecasts. The default output data set is WORK.FORECAST.

You can set the forecast horizon by using the controls on the line labeled Horizon. The default horizon is 12 periods. You can change it by specifying the number of periods, number of years, or the date of the last forecast period. Position the cursor in the date field and change the forecast ending date to 1 January 1996 by typing `jan1996` and pressing the ENTER key.

The window now appears as shown in [Figure 37.18](#).

Figure 37.18 Produce Forecasts Window

Now select the Run button to produce the forecasts. The system indicates that the forecasts have been stored in the output data set. Select OK to dismiss the notice.

The Forecast Data Set

The Forecasting System can save the forecasts to a SAS data set in three different formats. Depending on your needs, you might find one of these output formats more convenient. The output data set format is controlled by the `Format` combo box. You can select the following output formats. The simple format is the default.

Simple	The data set contains time ID variables and the forecast variables, and it contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.
Interleaved	The data set contains time ID variables, the variable <code>TYPE</code> , and the forecast variables. There are several observations per time period, with the meaning of

each observation identified by the TYPE variable.

Concatenated The data set contains the variable SERIES, time ID variables, and the variables ACTUAL, PREDICT, ERROR, UPPER, LOWER, and STD. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

Simple Format Forecast Data Set

To see the simple format forecast data set that the system created, select the Output button. This opens a VIEWTABLE window to display the data set, as shown in Figure 37.19.

Figure 37.19 Forecast Data Set—Simple Format

The screenshot shows the SAS VIEWTABLE: WORK.FORECAST window. The table contains the following data:

	Date of Observation	YEAR	QTR	GC	GCD	GYD
1	1980:1	1980	1	1702	218.7000	1894
2	1980:2	1980	2	1705	198.2000	1901
3	1980:3	1980	3	1762	211.3000	1966
4	1980:4	1980	4	1824	221.8000	2051
5	1981:1	1981	1	1876	230.8000	2107
6	1981:2	1981	2	1909	225.5000	2142
7	1981:3	1981	3	1952	236.3000	2209
8	1981:4	1981	4	1968	221.4000	2241
9	1982:1	1982	1	2005	230.9000	2259
10	1982:2	1982	2	2029	232.9000	2303
11	1982:3	1982	3	2073	235.2000	2343
12	1982:4	1982	4	2129	246.9000	2374
13	1983:1	1983	1	2163	251.2000	2406
14	1983:2	1983	2	2232	270.1000	2457
15	1983:3	1983	3	2289	281.0000	2518
16	1983:4	1983	4	2347	297.7000	2594
17	1984:1	1984	1	2397	307.0000	2694

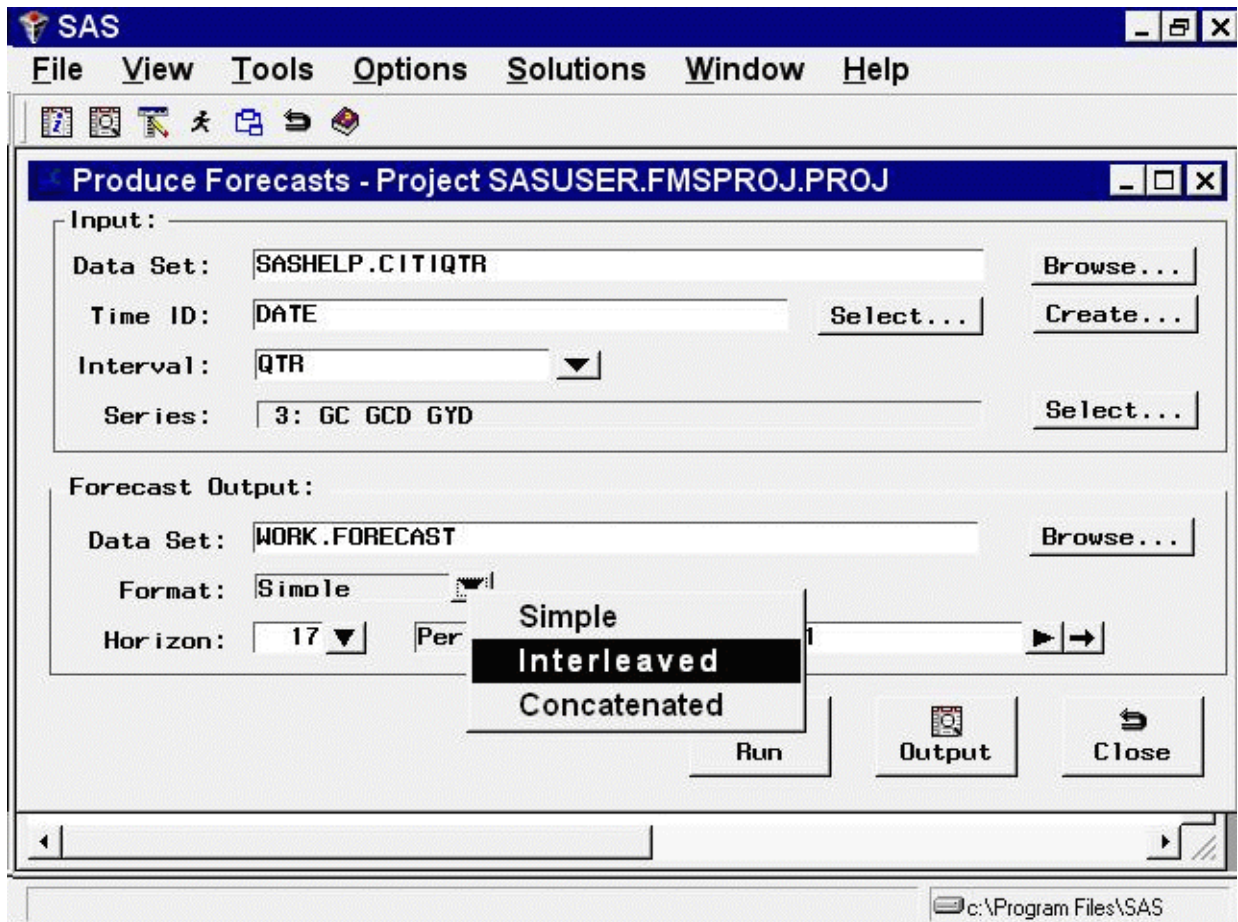

Figure 37.19 shows the default simple format. This form of the forecast data set contains time ID variables and the variables that you forecast. The forecast variables contain actual values or predicted values, depending on whether the date of the observation is within the range of data supplied in the input data set.

Select **File** and **Close** to close the Viewtable window.

Interleaved Format Forecast Data Set

From the Produce Forecasts window, use the list to select the *Interleaved* format, as shown in Figure 37.20.

Figure 37.20 Forecast Data Set Options

Now select the Run button again. The system presents a warning notice reminding you that the data set WORK.FORECAST already exists and asking if you want to replace it. Select *Replace*.

The forecasts are stored in the data set WORK.FORECAST again, this time in the *Interleaved* format. Dismiss the notice that the forecast was stored.

Now select the Output button again. This opens a Viewtable window to display the data set, as shown in Figure 37.21.

Figure 37.21 Forecast Data Set—Interleaved Format

	Date of Observation	YEAR	QTR	Type of Observation	GC	GCD	GYD
1	1980:1	1980	1	ACTUAL	1702	218.7000	1894
2	1980:1	1980	1	ERROR	.	8.3333	0.2423
3	1980:1	1980	1	LOWER	.	185.7776	1843
4	1980:1	1980	1	PREDICT	.	210.3667	1893
5	1980:1	1980	1	STD	.	12.5457	25.9165
6	1980:1	1980	1	UPPER	.	234.9558	1944
7	1980:2	1980	2	ACTUAL	1705	198.2000	1901
8	1980:2	1980	2	ERROR	-44.1085	-21.5633	-44.2337
9	1980:2	1980	2	LOWER	1715	195.1742	1895
10	1980:2	1980	2	PREDICT	1749	219.7633	1945
11	1980:2	1980	2	STD	17.5899	12.5457	25.9165
12	1980:2	1980	2	UPPER	1783	244.3524	1996
13	1980:3	1980	3	ACTUAL	1762	211.3000	1966
14	1980:3	1980	3	ERROR	9.8915	3.2521	13.1664
15	1980:3	1980	3	LOWER	1718	183.4588	1902
16	1980:3	1980	3	PREDICT	1752	208.0479	1953
17	1980:3	1980	3	STD	17.5899	12.5457	25.9165

NOTE: Table has been opened in browse mode. c:\Program Files\SAS

In the interleaved format, there are several output observations for each input observation, identified by the TYPE variable. The values of the forecast variables for observations with different TYPE values are as follows.

ACTUAL	actual values copied from the input data set
ERROR	the difference between the actual and predicted values
LOWER	the lower confidence limits
PREDICT	the predicted values from the forecasting model. These are within-sample, one-step-ahead predictions for observations within the historical period, or multistep predictions for observations within the forecast period.
STD	the estimated standard deviations of the prediction errors
UPPER	the upper confidence limits

Select **File** and **Close** to close the VIEWTABLE window.

Concatenated Format Forecast Data Set

Use the list to select the `Concatenated` format. Create the forecast data set again, and then select the `Output` button.

The Viewtable window showing the concatenated format of the forecast data set appears, as shown in Figure 37.22.

Figure 37.22 Forecast Data Set—Concatenated Format

	series	Date of Observation	YEAR	QTR	Actual value	Predicted value	Prediction error	Upper 95% Confidence Limit	Lower 95% Confidence Limit	Prediction standard error
1	GC	1980:1	1980	1	1702					
2	GC	1980:2	1980	2	1705	1749	-44.1085	1783	1715	17.5899
3	GC	1980:3	1980	3	1762	1752	9.8915	1787	1718	17.5899
4	GC	1980:4	1980	4	1824	1810	13.7915	1844	1775	17.5899
5	GC	1981:1	1981	1	1876	1871	4.8915	1906	1837	17.5899
6	GC	1981:2	1981	2	1909	1924	-14.6085	1958	1889	17.5899
7	GC	1981:3	1981	3	1952	1956	-4.3085	1991	1922	17.5899
8	GC	1981:4	1981	4	1968	2000	-31.6085	2034	1965	17.5899
9	GC	1982:1	1982	1	2005	2016	-10.1085	2050	1981	17.5899
10	GC	1982:2	1982	2	2029	2053	-23.5085	2087	2018	17.5899
11	GC	1982:3	1982	3	2073	2077	-3.8085	2111	2042	17.5899
12	GC	1982:4	1982	4	2129	2121	8.0915	2155	2086	17.5899
13	GC	1983:1	1983	1	2163	2176	-13.3085	2211	2142	17.5899
14	GC	1983:2	1983	2	2232	2210	21.4915	2245	2176	17.5899
15	GC	1983:3	1983	3	2289	2279	9.2915	2314	2245	17.5899
16	GC	1983:4	1983	4	2347	2336	10.5915	2371	2302	17.5899

This completes the example of how to use the Produce Forecasts window. Select `File` and `Close` to close the Viewtable window. Select the `Close` button to return to the Time Series Forecasting window.

Forecasting Projects

The system collects all the forecasting models you create, together with the options you set, into a package called a *forecasting project*. You can save this information in a SAS catalog entry and

restore your work in later forecasting sessions. You can store any number of forecasting projects under different catalog entry names.

To see how this works, select the Manage Projects button. This opens the Manage Forecasting Project window, as shown in [Figure 37.23](#).

Figure 37.23 Manage Forecasting Project Window

The table in this window lists the series for which forecasting models have been fit, and it shows for each series the forecasting model used to produce the forecasts. This window provides several features that allow you to manage the information in your forecasting project.

You can select a row of the table to drill down to the list of models fit to the series. Select the GYD row of the table, either by double-clicking with the mouse or by clicking once to highlight the table row and then selecting *List Models* from the toolbar or from the Tools menu. This opens the Model List window for this series, as shown in [Figure 37.24](#).

Figure 37.24 Model List Window

Because the Automatic Model Fitting process kept only the best fitting model, only one model appears in the model list. You can fit and retain any number of models for each series, and all the models fit and kept will appear in the series' model list.

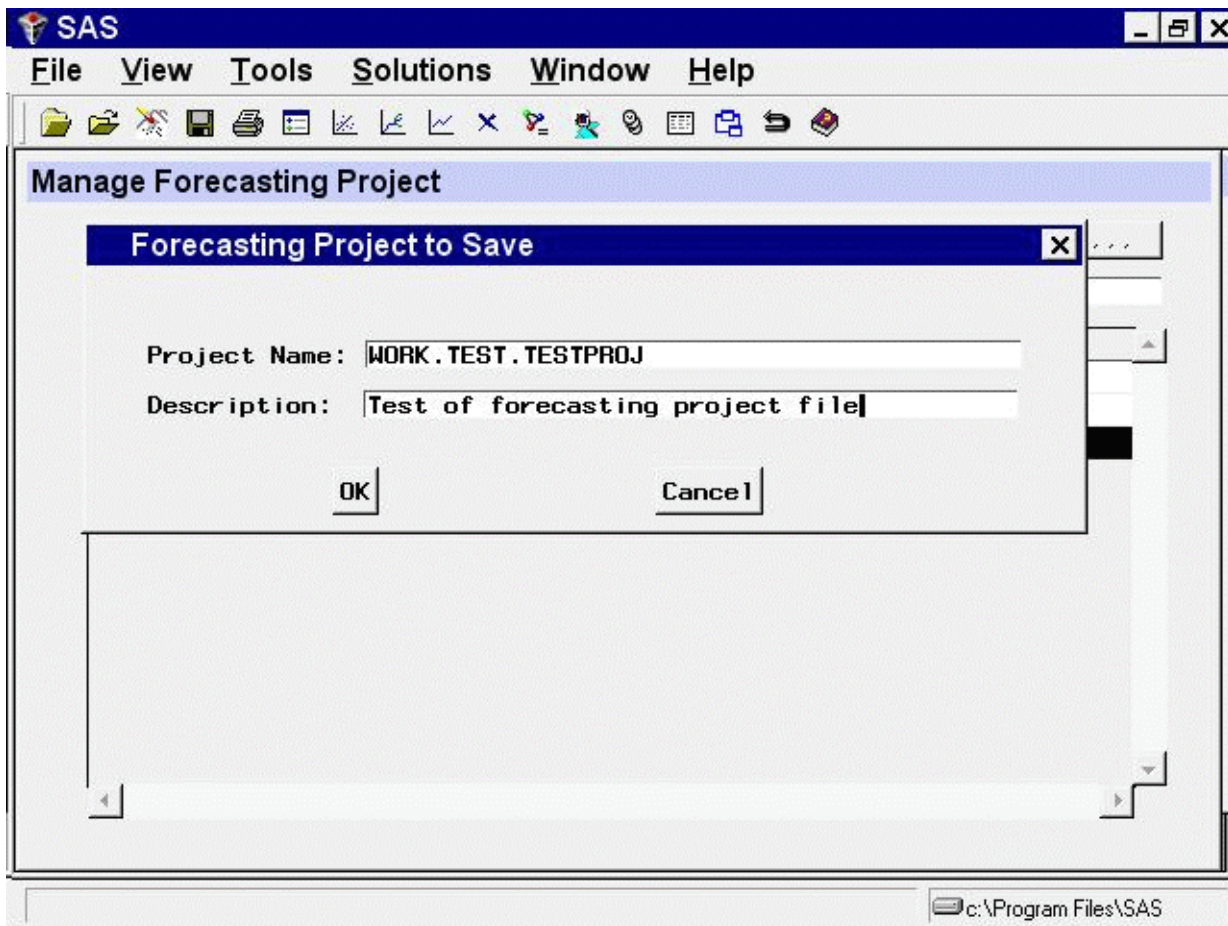

Select **Close** from the toolbar or from the **File** menu to return to the Manage Forecasting Project window.

Saving and Restoring Project Information

To illustrate how you can save your work between sessions, in this section you will exit and then re-enter the Forecasting System.

From the Manage Forecasting Project window, select **File** and **Save as**. This opens the Forecasting Project to Save window. In the Project Name field, type the name **WORK.TEST.TESTPROJ**. In the Description field, type "Test of forecasting project file." The window should now appear as shown in Figure 37.25.

Figure 37.25 Project to Save Name and Description

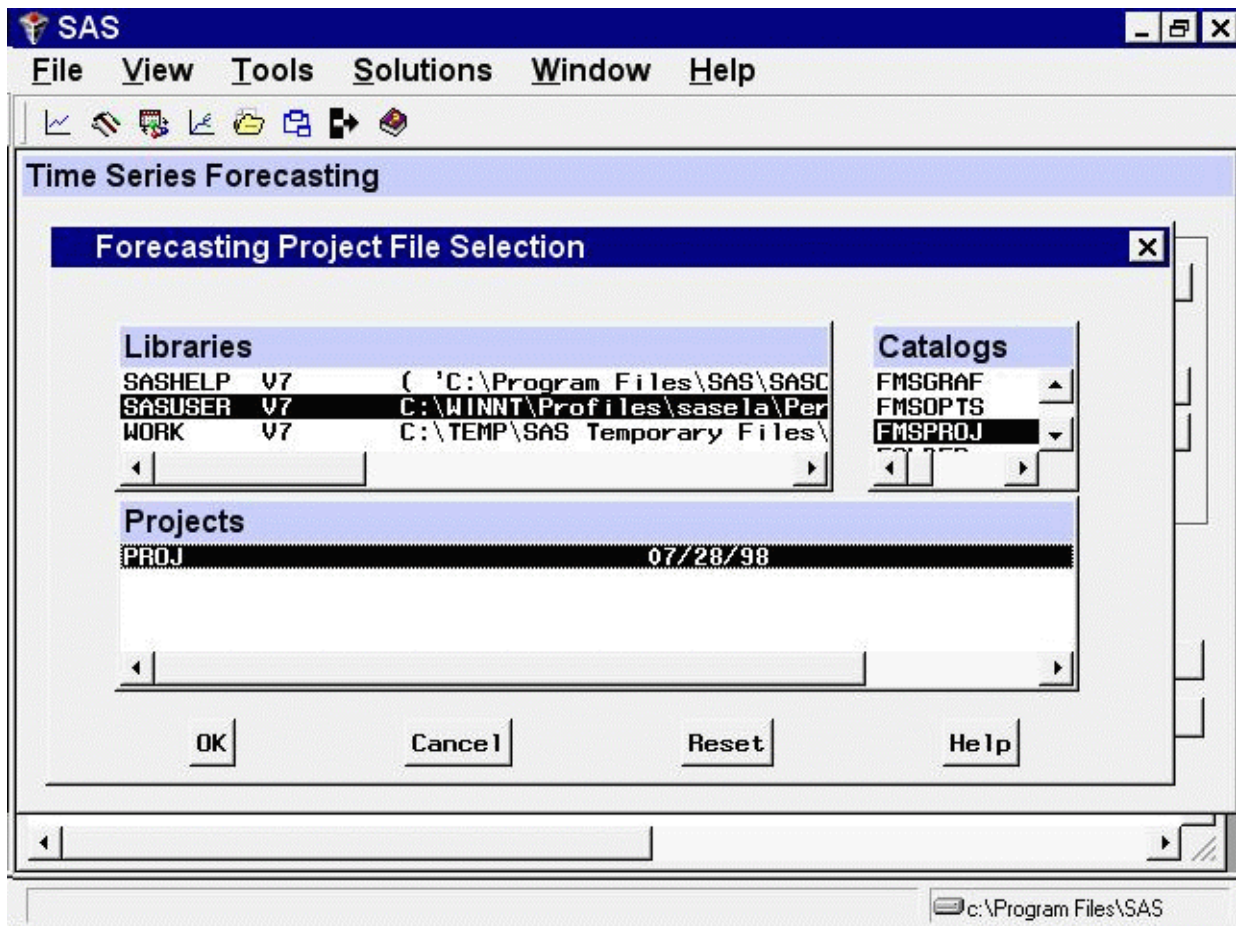

Select the OK button. This returns you to the Project Management window and displays a message indicating that the project was saved.

Select **C**lose from the toolbar or from the File menu to return to the Time Series Forecasting window. Now select the Exit button. The system asks if you are sure you want to exit the system; select **Y**es. The forecasting application now terminates.

Open the forecasting application again. A new project name is displayed by default.

Now restore the forecasting project you saved previously. Select the Browse button to the right of the Project field. This opens the Forecasting Project File Selection window, as shown in [Figure 37.26](#).

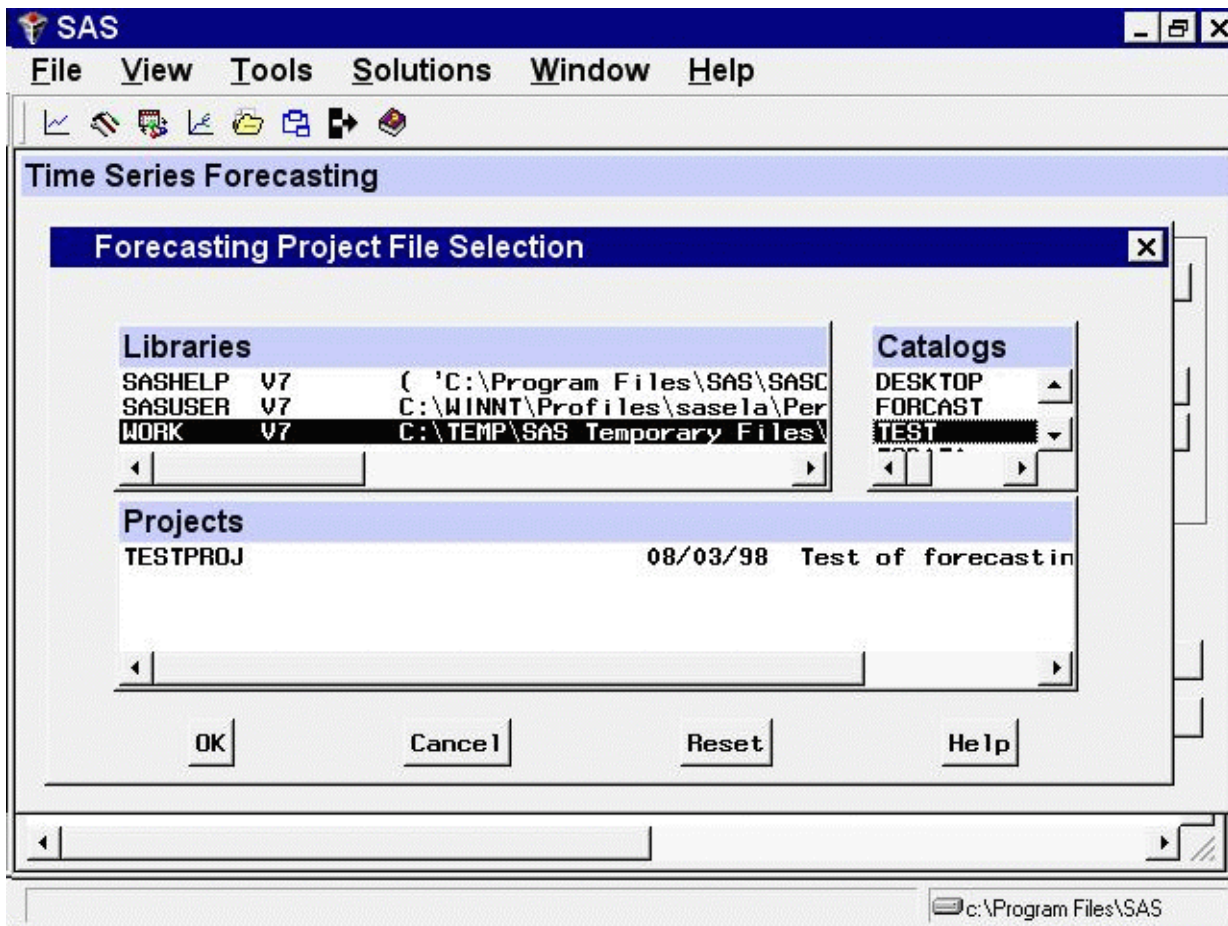

Figure 37.26 Forecasting Project File Selection Window

Select the WORK library from the Libraries list. The Catalogs list now shows all the SAS catalogs in the WORK library.

Select the TEST catalog. The Projects list now shows the list of forecasting projects in the catalog TEST. So far, you have created only one project file, TESTPROJ; so TESTPROJ is the only entry in the Projects list, as shown in [Figure 37.27](#).

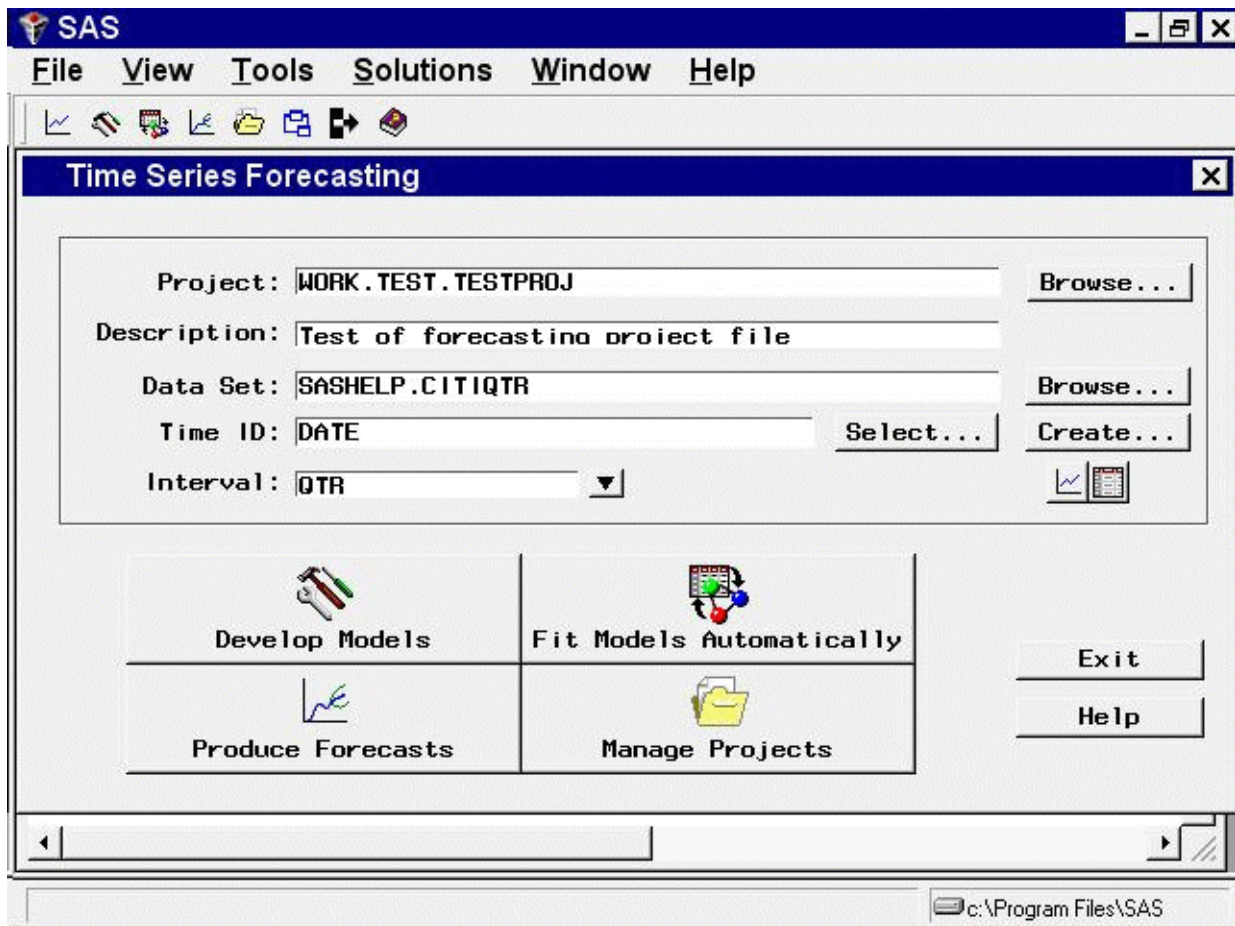

Figure 37.27 Forecasting Projects List

Select TESTPROJ from the Projects list and then select the OK button. This returns you to the Time Series Forecasting window.

The system loads the project information you saved in TESTPROJ and displays a message indicating this. The Project field is now set to WORK.TEST.TESTPROJ, and the description is the description you previously gave to TESTPROJ, as shown in [Figure 37.28](#).

Figure 37.28 Time Series Forecasting Window after Loading Project

If you now select the Manage Projects button, you will see the list of series and forecasting models you created in the previous forecasting session.

Sharing Projects

If you plan to work with others on a forecasting project, you might need to consider how project information can be shared. The series, models, and results of your project are stored in a forecasting project (FMSPROJ) catalog entry in the location you specify, as illustrated in the previous section. You need only read access to the catalog to work with it, but you must have write access to save the project. Multiple users cannot open a project for update at the same time, but they can do so at different times if they all have write access to the catalog where it is stored.

Project options settings such as the *model selection criterion* and *number of models to keep* are stored in an SLIST catalog entry in the SASUSER or TSFSUSER library. Write access to this catalog is required. If you have only read access to the SASUSER library, you can use the -RSASUSER option when starting SAS. You will be prompted for a location for the TSFSUSER library, if it is not already assigned. If you want to use TSFSUSER routinely, assign it before you start the Time

Series Forecasting System. Select New from the SAS Explorer file menu. In the New Library window, type TSFSUSER for the name. Click the Browse button and select the directory or folder you want to use. Turn on the *enable at startup* option so this library will be assigned automatically in subsequent sessions.

The SASUSER library is typically used for private settings saved by individual users. This is the default location for project options. If a work group shares a single options catalog (SASUSER or TSFSUSER points to the same location for all users), then only one user can use the system at a time.

Develop Models Window

In the first forecasting example, you used the Automatic Model Fitting window to fit and select the forecasting model for each series automatically. In addition to this automatic forecasting process, you can also work with time series one at a time to fit forecasting models and apply your own judgment to choose the best forecasting model for each series.

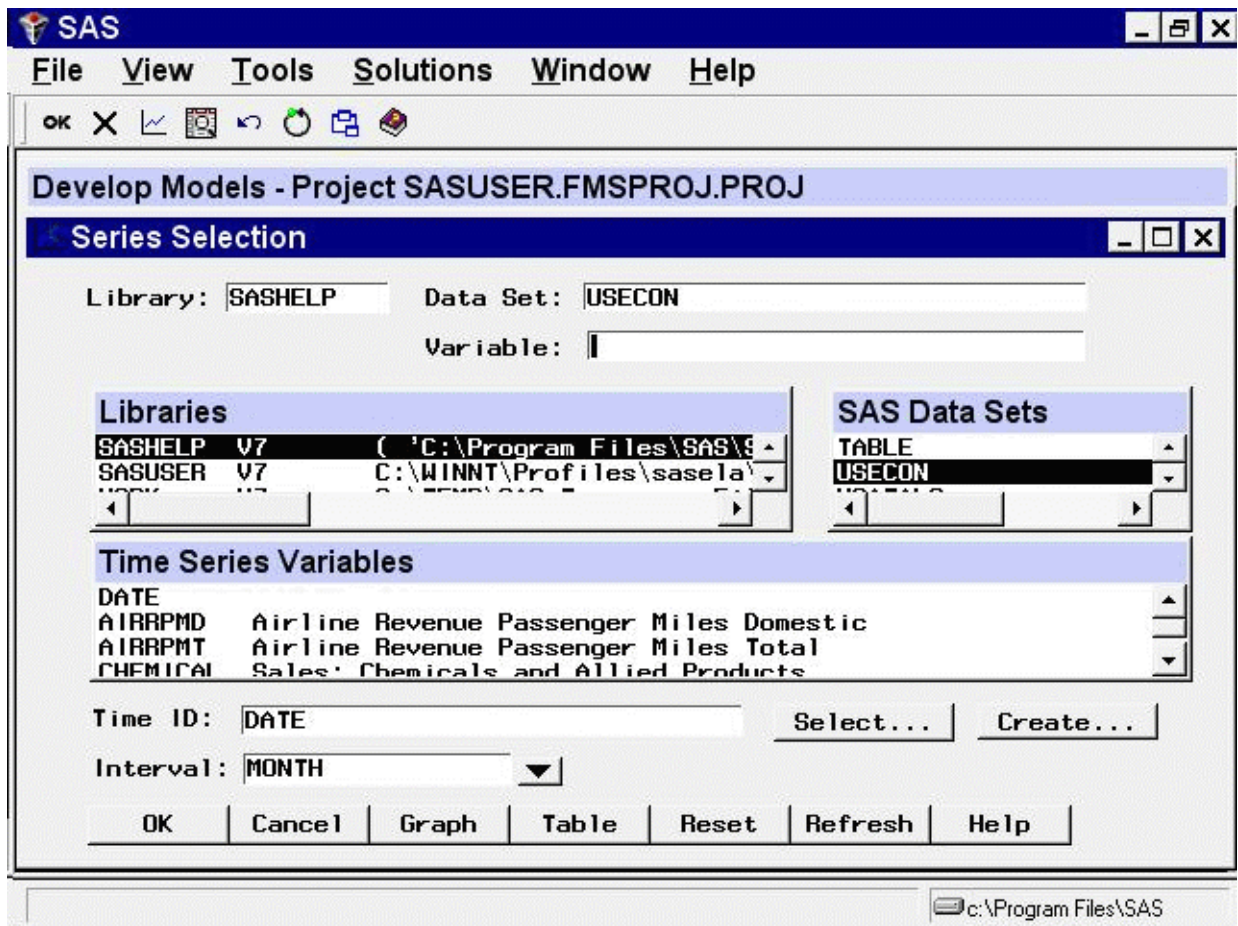

Using the Automatic Model Fitting feature, the system acts like a “black box.” This section goes inside the black box to look at the kinds of forecasting methods that the system provides and introduces some of the tools the system offers to help you find the best forecasting model.

Introduction

From the Time Series Forecasting window, select the Browse button to the right of the Data Set field to open the Data Set Selection window. Select the USECON data set from the SASHELP library. This data set contains monthly data on the U.S. economy.

Select OK to close the selection window. Now select the Develop Models button. This opens the Series Selection window, as shown in [Figure 37.29](#). You can enlarge this window for easier viewing of lists of data sets and series.

Figure 37.29 Series Selection Window

Select the series CHEMICAL: Sales of Chemicals and Allied Products, and then select the OK button.

This opens the Develop Models window, as shown in [Figure 37.30](#).

Figure 37.30 Develop Models Window

The Data Set, Interval, and Series fields in the upper part of the Develop Models window indicate the series with which you are currently working. You can change the settings of these fields by selecting the Browse button.

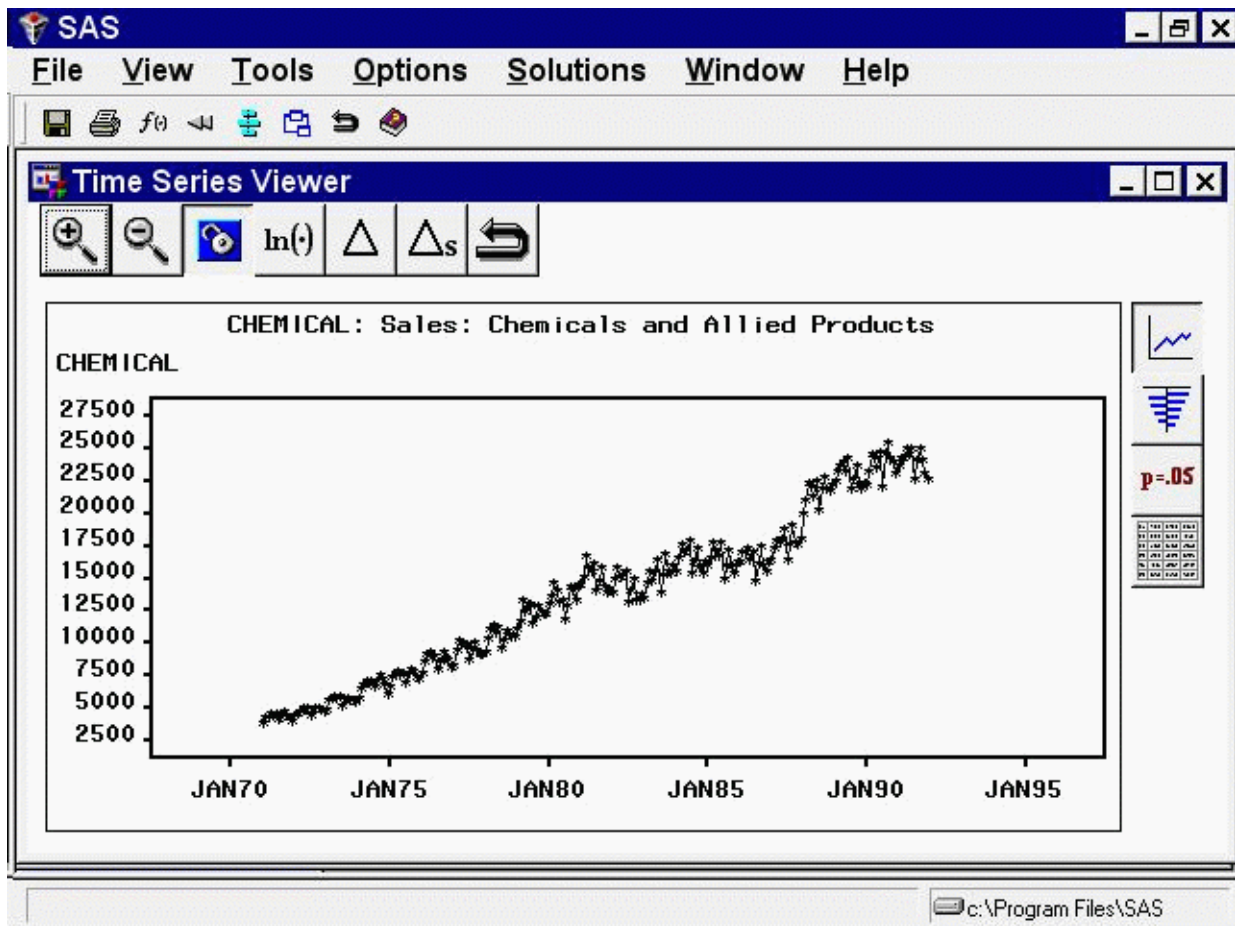

The Data Range, Fit Range, and Evaluation Range fields show the time period over which data are available for the current series, and what parts of that time period are used to fit forecasting models to the series and to evaluate how well the models fit the data. You can change the settings of these fields by selecting the Set Ranges button.

The bottom part of the Develop Models window consists of a table of forecasting models fit to the series. Initially, the list is empty, as indicated by the message “No models.” You can fit any number of forecasting models to each series and designate which one you want to use to produce forecasts.

Graphical tools are available for exploring time series and fitted models. The two icons below the Browse button access the Time Series Viewer and the Model Viewer.

Select the left icon. This opens the Time Series Viewer window, as shown in [Figure 37.31](#).

Figure 37.31 Chemical and Allied Product Series

The Time Series Viewer displays a plot of the CHEMICAL series. The Time Series Viewer offers many useful features, which are explored in later sections.

The Time Series Viewer appears in a separate resizable window. You can switch back and forth between the Time Series Viewer window and other windows. For now, return to the Develop Models window. You can close the Time Series Viewer window or leave it open. (To close the Time Series Viewer window, select `Close` from the toolbar or from the File menu.)

Fitting Models

To open a menu of model fitting choices, select `Edit` from the menu bar and then select `Fit Model`, or select `Fit Models` from `List` in the toolbar, or simply select a blank line in the table as shown in Figure 37.32.

Figure 37.32 Menu of Model Fitting Choices

The Forecasting System provides several ways to specify forecasting models. The eight choices given by the menu shown in Figure 37.32 are as follows:

Fit Models Automatically

performs for the current series the same automatic model selection process that the Automatic Model Fitting window applies to a set of series.

Fit Models from List

presents a list of commonly used forecasting models for convenient point-and-click selection.

Fit Smoothing Model

displays the Smoothing Model Specification window, which enables you to specify several kinds of exponential smoothing and Winters method forecasting models.

Fit ARIMA Model

displays the ARIMA Model Specification window, which enables you to specify many kinds of autoregressive integrated moving average (ARIMA) models, including seasonal ARIMA models and ARIMA models with regressors, transfer functions, and other predictors.

Fit Factored ARIMA Model

displays the Factored ARIMA Model Specification window, which enables you to specify more general ARIMA models, including subset models and models with unusual and/or multiple seasonal cycles. It also supports regressors, transfer functions, and other predictors.

Fit Custom Model

displays the Custom Model Specification window, which enables you to construct a forecasting model by specifying separate options for transforming the data, modeling the trend, modeling seasonality, modeling autocorrelation of the errors, and modeling the effect of regressors and other independent predictors.

Combine Forecasts

displays the Forecast Combination Model Specification window, which enables you to specify models that produce forecasts by combining, or averaging, the forecasts from other models. (This option is not available unless you have fit at least two models.)

Use External Forecasts

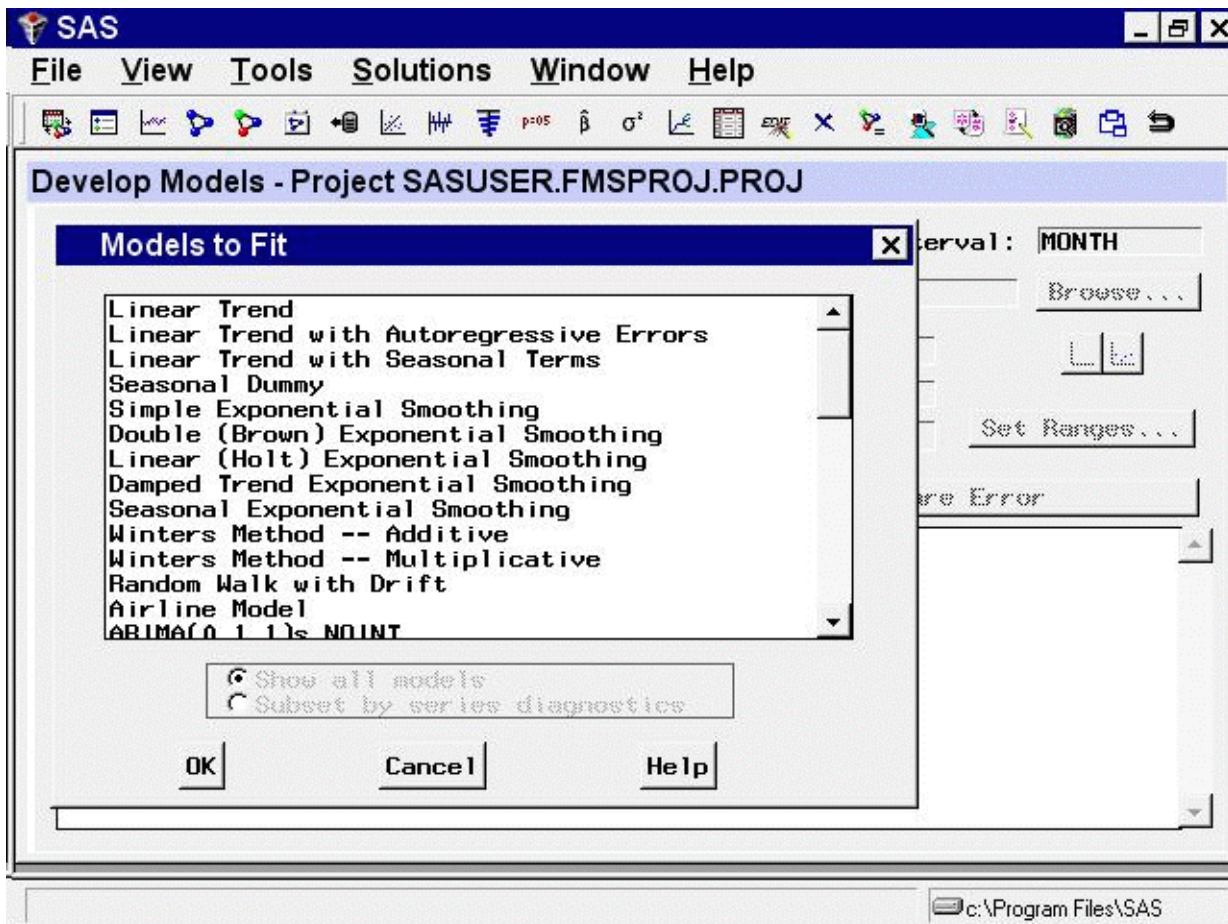

displays the External Forecast Model Specification window, which enables you to use judgmental or externally produced forecasts that have been saved in a separate series in the data set.

All of the forecasting models used by the system are ultimately specified through one of the four windows: Smoothing Method Specification, ARIMA Model Specification, Factored ARIMA Model Specification, or Custom Model Specification. You can specify the same models with either the ARIMA Model Specification window or the Custom Model Specification window, but the Custom Model Specification window can provide a more natural way to specify models for those who are less familiar with the Box-Jenkins style of time series model specification.

The Automatic Model feature, the Models to Fit window, and the Forecast Combination Model Specification window all deal with lists of forecasting models previously defined through the Smoothing Model, ARIMA Model, or Custom Model specification windows. These windows are discussed in detail in later sections.

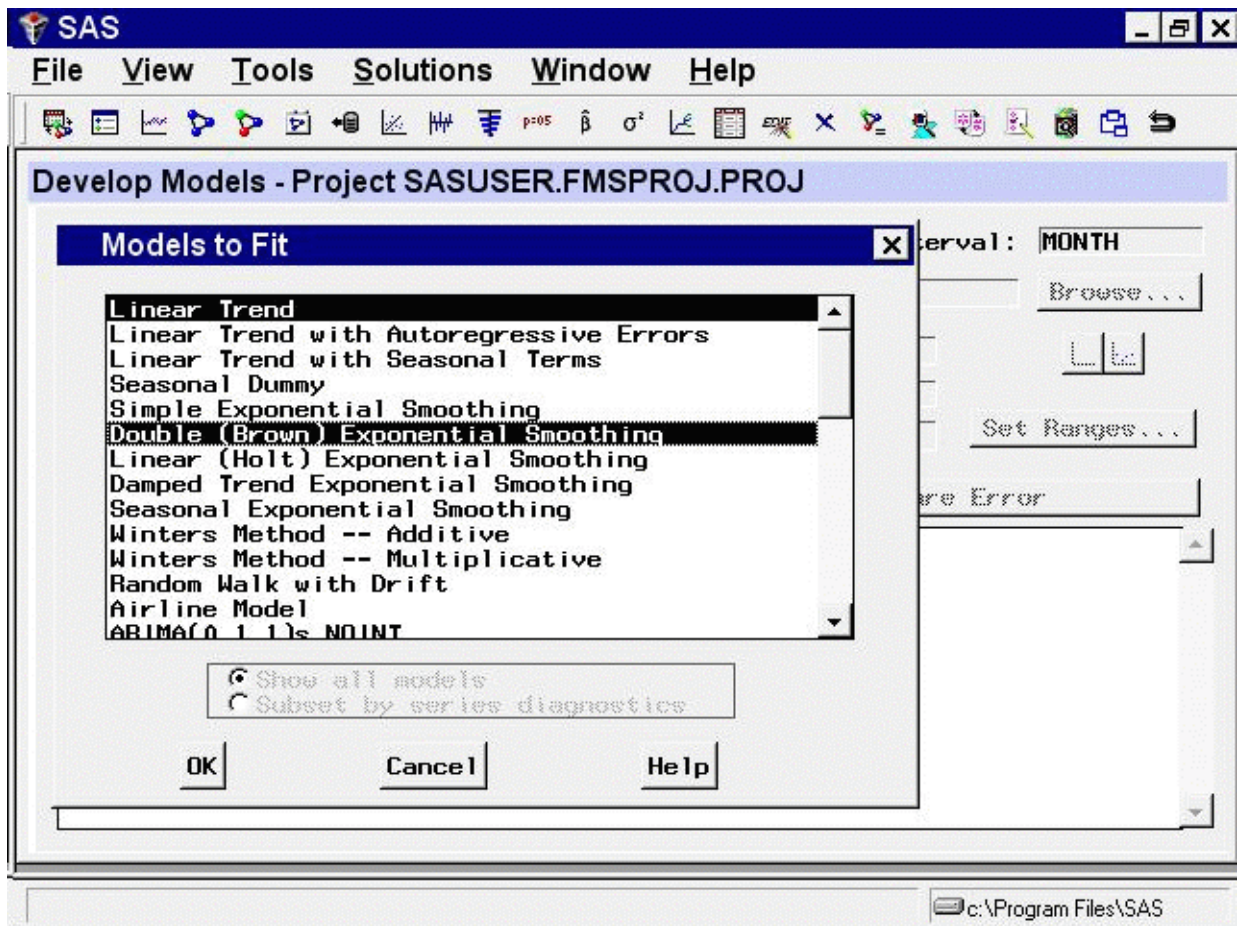

To get started using the Develop Models window, select the Fit Models from List item from the menu shown in [Figure 37.32](#). This opens the Models to Fit window, as shown in [Figure 37.33](#).

Figure 37.33 Models to Fit Window

You can select several models to fit at once by holding down the CTRL key as you make the selections. Select **Linear Trend** and **Double (Brown) Exponential Smoothing**, as shown in [Figure 37.34](#), and then select the **OK** button.

Figure 37.34 Selecting Models to Fit

The system fits the two models you selected. After the models are fit, the labels of the two models and their goodness-of-fit statistic are added to the model table, as shown in Figure 37.35.

Figure 37.35 Fitted Models List

The screenshot shows the SAS 'Develop Models' window. The window title is 'Develop Models - Project SASUSER.FMSPROJ.PROJ'. The interface includes a menu bar (File, Edit, View, Tools, Options, Solutions, Window, Help) and a toolbar with various icons. The main area contains the following settings:

- Data Set: SASHELP.usecon
- Interval: MONTH
- Series: CHEMICAL: Sales: Chemicals and Allied Products
- Data Range: JAN1971 to DEC1991
- Fit Range: JAN1971 to DEC1991
- Evaluation Range: JAN1971 to DEC1991

Below the settings is a table with the following columns: Forecast Model, Model Title, and Root Mean Square Error.

Forecast Model	Model Title	Root Mean Square Error
<input type="checkbox"/>	Linear Trend	1203.2
<input checked="" type="checkbox"/>	Double (Brown) Exponential Smoothing	868.69919

Model List and Statistics of Fit

In the model list, the *Model Title* column shows the descriptive labels for the two fitted models, in this case Linear Trend and Double Exponential Smoothing.

The column labeled *Root Mean Square Error* (or labeled *Mean Absolute Percent Error* if you continued from the example in the previous section) shows the goodness-of-fit criterion used to decide which model fits better. By default, the criterion used is the root mean square error, but you can choose a different measure of fit. The linear trend model has a root mean square error of 1203, while the double exponential smoothing model fits better, with a RMSE of only 869.

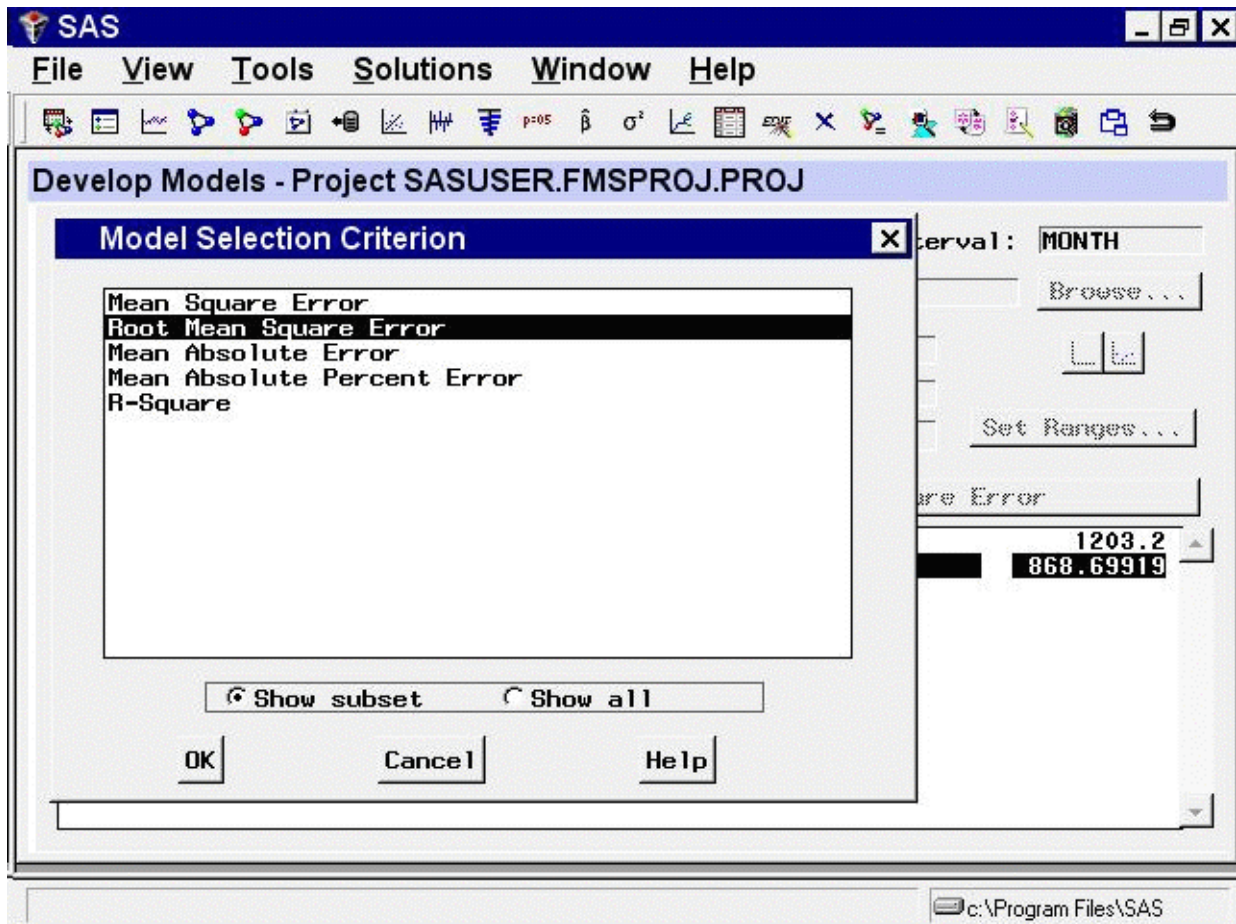

The left column labeled *Forecast Model* consists of check boxes that indicate which one of the models in the list has been selected as the model to use to produce the forecasts for the series. When new models are fit and added to the model list, the system sets the Forecast Model flags to designate the one model with the best fit—as measured by the selected goodness-of-fit statistic—as the forecast model. (In the case of ties, the first model with the best fit is selected.)

Because the Double Exponential Smoothing model has the smaller RMSE of the two models in the list, its Forecast Model check box is set. If you would rather produce forecasts by using the Linear

Trend model, choose it by selecting the corresponding check box in the Forecast Model column.

To use a different goodness-of-fit criterion, select the button with the current criterion name on it (Root Mean Square Error or Mean Absolute Percent Error). This opens the Model Selection Criterion window, as shown in [Figure 37.36](#).

Figure 37.36 Model Selection Criterion Window

The system provides many measures of fit that you can use as the model selection criterion. To avoid confusion, only the most popular of the available fit statistics are shown in this window by default. To display the complete list, you can select the `Show all` option. You can control the subset of statistics listed in this window through the `Statistics of Fit` item in the `Options` menu on the `Develop Models` window.

Initially, `Root Mean Square Error` is selected. Select `R-Square` and then select the `OK` button. This changes the fit statistic displayed in the model list, as shown in [Figure 37.37](#).

Figure 37.37 Model List with R-Square Statistics

The screenshot shows the SAS Model Viewer window titled "Develop Models - Project SASUSER.FMSPROJ.PROJ". The window displays the following settings:

- Data Set: SASHELP.usecon
- Interval: MONTH
- Series: CHEMICAL: Sales: Chemicals and Allied Products
- Data Range: JAN1971 to DEC1991
- Fit Range: JAN1971 to DEC1991
- Evaluation Range: JAN1971 to DEC1991

The "Forecast" section contains a table with the following data:

Model	Model Title	R-Square
<input type="checkbox"/>	Linear Trend	0.961
<input checked="" type="checkbox"/>	Double (Brown) Exponential Smoothing	0.980

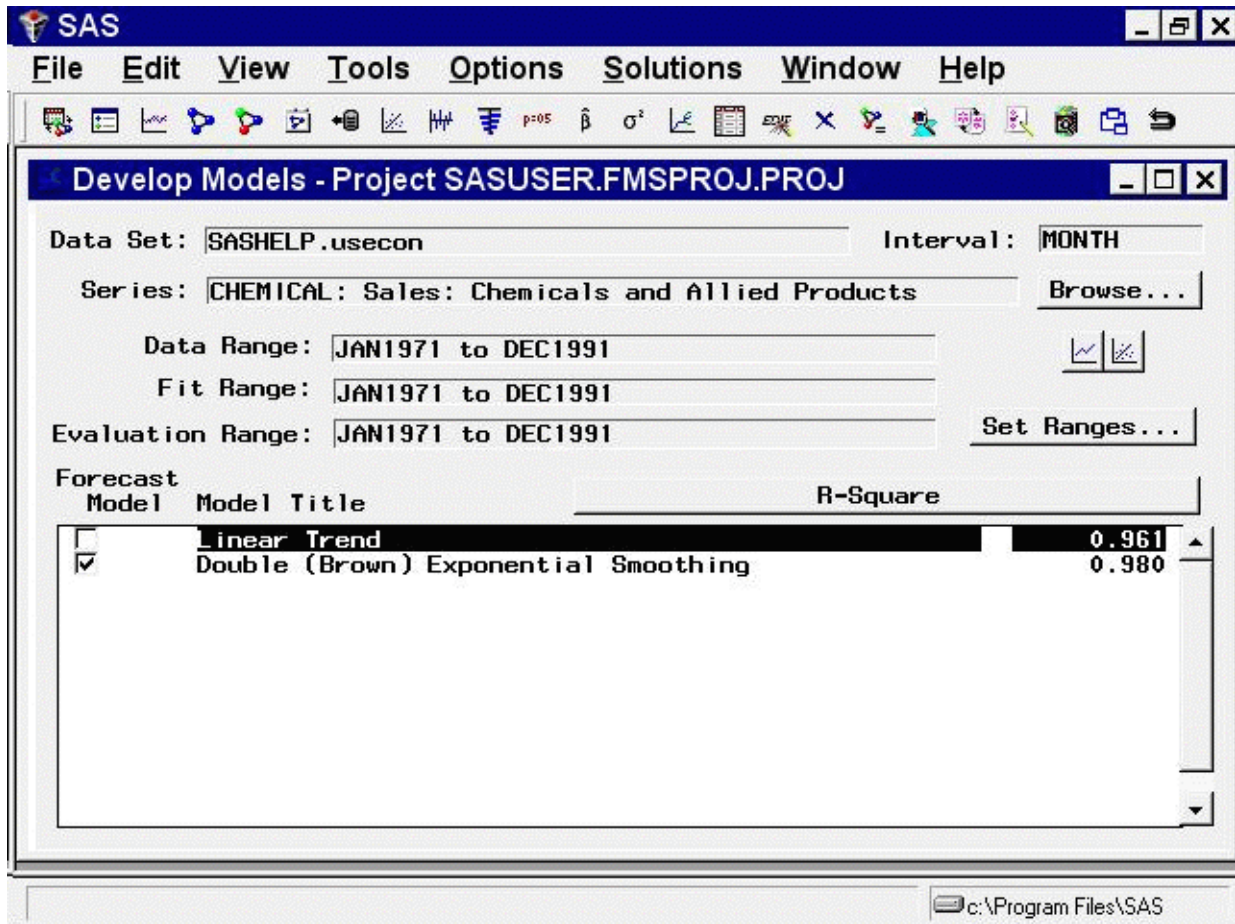

The "Double (Brown) Exponential Smoothing" model is highlighted in the table. The window title bar shows the path "c:\Program Files\SAS".

Now that you have fit some models to the series, you can use the Model Viewer button to take a closer look at the predictions of these models.

Model Viewer

In the Develop Models window, select the row in the table containing the Linear Trend model so that this model is highlighted. The model list should now appear as shown in [Figure 37.38](#).

Figure 37.38 Selecting a Model to View

Note that the Linear Trend model is now highlighted, but the Forecast Model column still shows the Double Exponential Smoothing model as the model chosen to produce the final forecasts for the series. Selecting a model in the list means that this is the model that menu items such as View Model, Delete, Edit, and Refit will act upon. Choosing a model by selecting its check box in the Forecast Model column means that this model will be used by the Produce Forecasts process to generate forecasts.

Now open the Model Viewer by selecting the right-hand icon under the Browse button, or by selecting Model Predictions in the toolbar or from the View menu. The Model Viewer displays the Linear Trend model, as shown in Figure 37.39.

Figure 37.39 Model Viewer: Actual and Predicted Values Plot

This graph shows the linear trend line representing the model predicted values together with a plot of the actual data values, which fluctuate about the trend line.

Prediction Error Plots

Select the second icon from the top in the vertical toolbar in the Model Viewer window. This switches the Viewer to display a plot of the model prediction errors (actual data values minus the predicted values), as shown in [Figure 37.40](#).

Figure 37.40 Model Viewer: Prediction Errors Plot

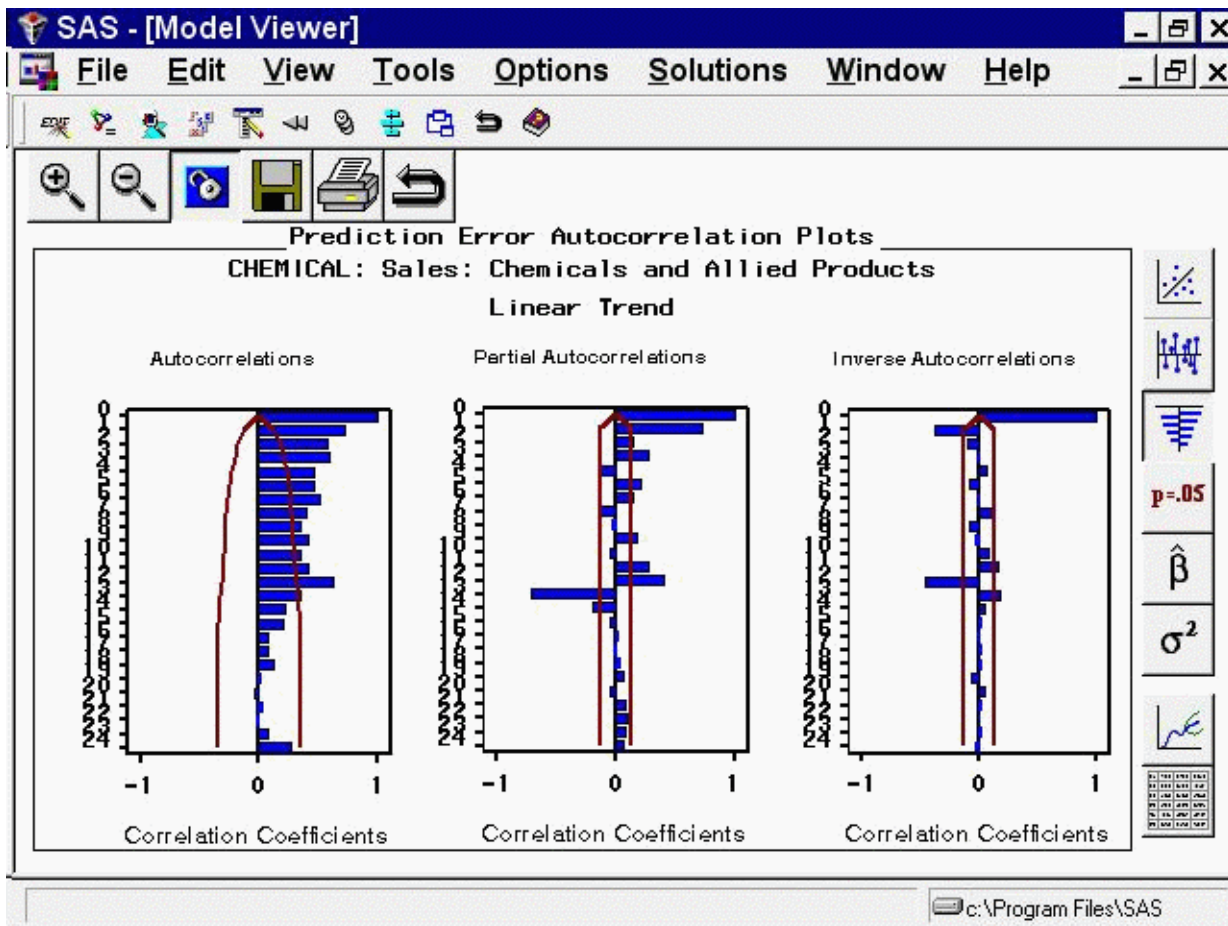

If the model being viewed includes a transformation, prediction errors are defined as the difference between the transformed series actual values and model predictions. You can choose to graph instead the difference between the untransformed series values and untransformed model predictions, which are called *model residuals*. You can also graph normalized prediction errors or normalized model residuals. Use the Residual Plot Options submenu under the Options menu.

Autocorrelation Plots

Select the third icon from the top in the vertical toolbar. This switches the Viewer to display a plot of autocorrelations of the model prediction errors at different lags, as shown in Figure 37.41. Autocorrelations, partial autocorrelations, and inverse autocorrelations are displayed, with lines overlaid at plus and minus two standard errors. You can switch the graphs so that the bars represent significance probabilities by selecting the Correlation Probabilities item on the toolbar or from the View menu. For more information about the meaning and use of autocorrelation plots, see Chapter 7, “The ARIMA Procedure.”

Figure 37.41 Model Viewer: Autocorrelations Plot

White Noise and Stationarity Plots

Select the fourth icon from the top in the vertical toolbar. This switches the Viewer to display a plot of white noise and stationarity tests on the model prediction errors, as shown in [Figure 37.42](#).

Figure 37.42 Model Viewer: White Noise and Stationarity Plot

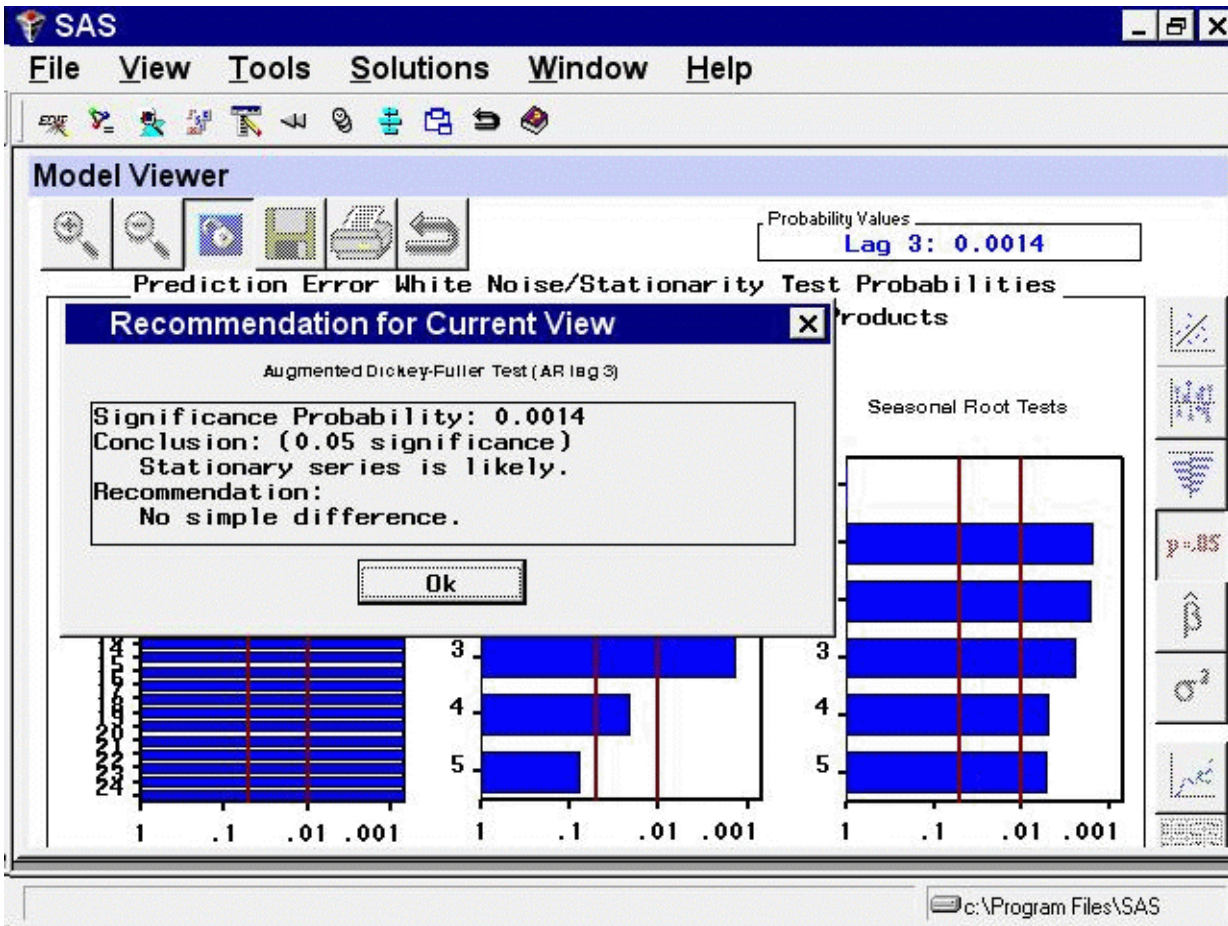

The white noise test bar chart shows significance probabilities of the Ljung-Box chi square statistic. Each bar shows the probability computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the prediction errors represent white noise. In this example, they are all significant beyond the 0.001 probability level, so that you reject the null hypothesis. In other words, the high level of significance at all lags makes it clear that the linear trend model is inadequate for this series.

The second bar chart shows significance probabilities of the augmented Dickey-Fuller test for unit roots. For example, the bar at lag three indicates a probability of 0.0014, so that you reject the null hypothesis that the series is nonstationary. The third bar chart is similar to the second except that it represents the seasonal lags. Since this series has a yearly seasonal cycle, the bars represent yearly intervals.

You can select any of the bars to display an interpretation. Select the fourth bar of the middle chart. This displays the `Recommendation for Current View`, as shown in Figure 37.43. This window gives an interpretation of the test represented by the bar that was selected; it is significant, therefore a stationary series is likely. It also gives a recommendation: You do not need to perform a simple difference to make the series stationary.

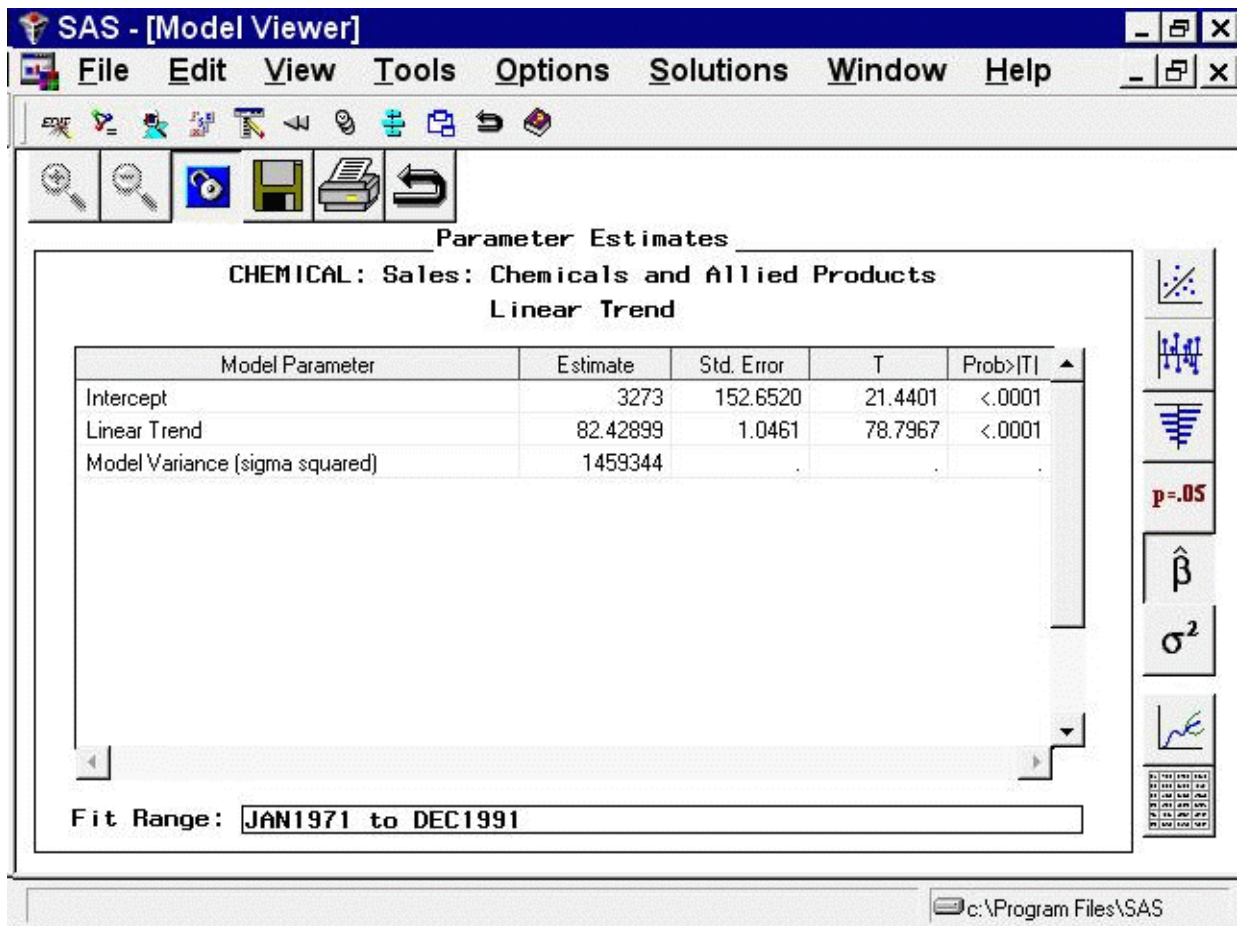

Figure 37.43 Model Viewer: Recommendation for Current View

Parameter Estimates Table

Select the fifth icon from the top in the vertical toolbar to the right of the graph. This switches the Viewer to display a table of parameter estimates for the fitted model, as shown in Figure 37.44.

Figure 37.44 Model Viewer: Parameter Estimates Table

For the linear trend model, the parameters are the intercept and slope coefficients. The table shows the values of the fitted coefficients together with standard errors and t tests for the statistical significance of the estimates. The model residual variance is also shown.

Statistics of Fit Table

Select the sixth icon from the top in the vertical toolbar to the right of the table. This switches the Viewer to display a table of statistics of fit computed from the model prediction errors, as shown in Figure 37.45. The list of statistics displayed is controlled by selecting `Statistics of Fit` from the Options menu.

Figure 37.45 Model Viewer: Statistics of Fit Table

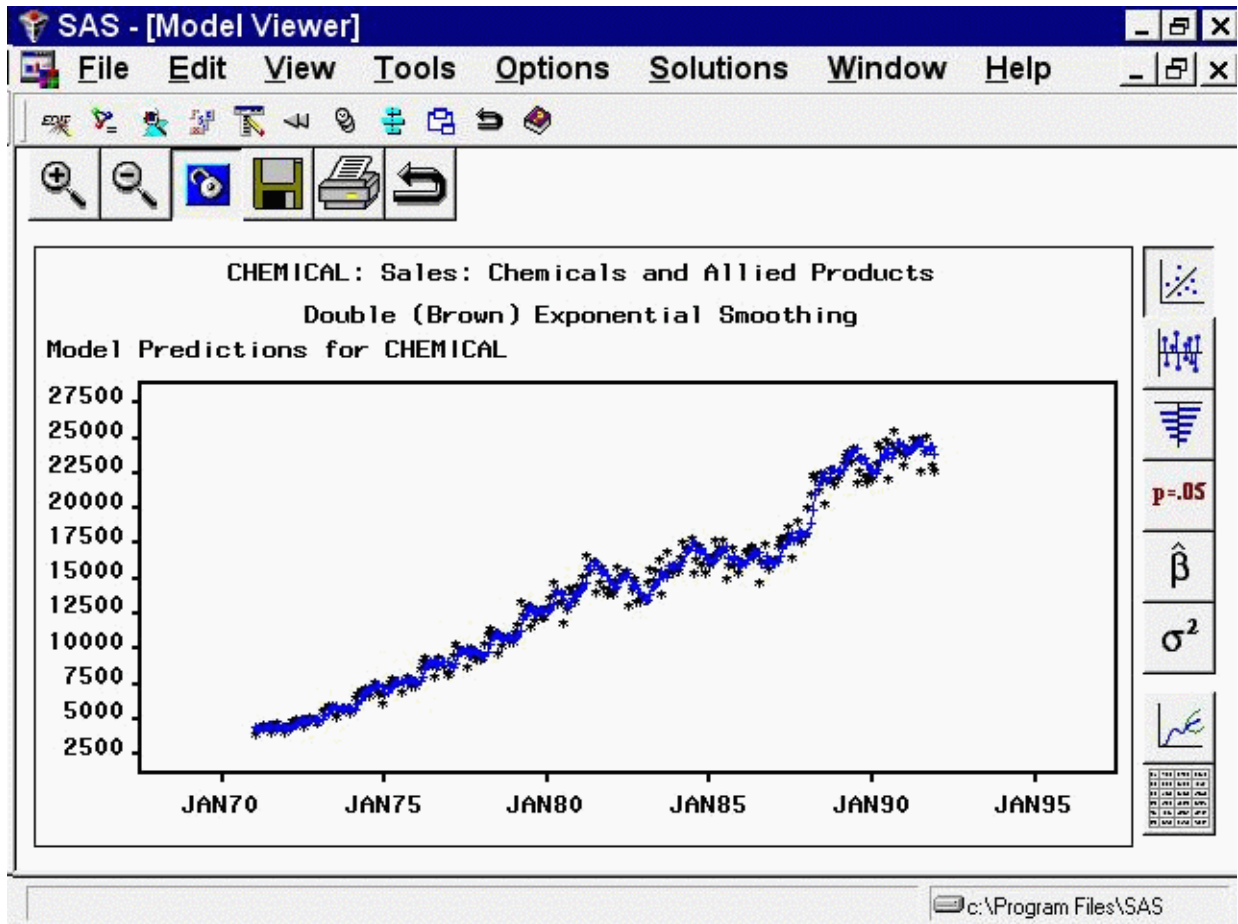

Changing to a Different Model

Select the first icon in the vertical toolbar to the right of the table to return the display to the predicted and actual values plots (Figure 37.39).

Now return to the Develop Models window, but do not close the Model Viewer window. You can use the Next Viewer icon in the toolbar or your system's window manager controls to switch windows. You can resize the windows to make them both visible.

Select the Double Exponential Smoothing model so that this line of the model list is highlighted. The Model Viewer window is now updated to display a plot of the predicted values for the Double Exponential Smoothing model, as shown in Figure 37.46. The Model Viewer is automatically updated to display the currently selected model, unless you specify `Unlink` (the third icon in the window's horizontal toolbar).

Figure 37.46 Model Viewer Plot for Exponential Smoothing Model

Forecasts and Confidence Limits Plots

Select the seventh icon from the top in the vertical toolbar to the right of the graph. This switches the Viewer to display a plot of forecast values and confidence limits, together with actual values and one-step-ahead within-sample predictions, as shown in [Figure 37.47](#).

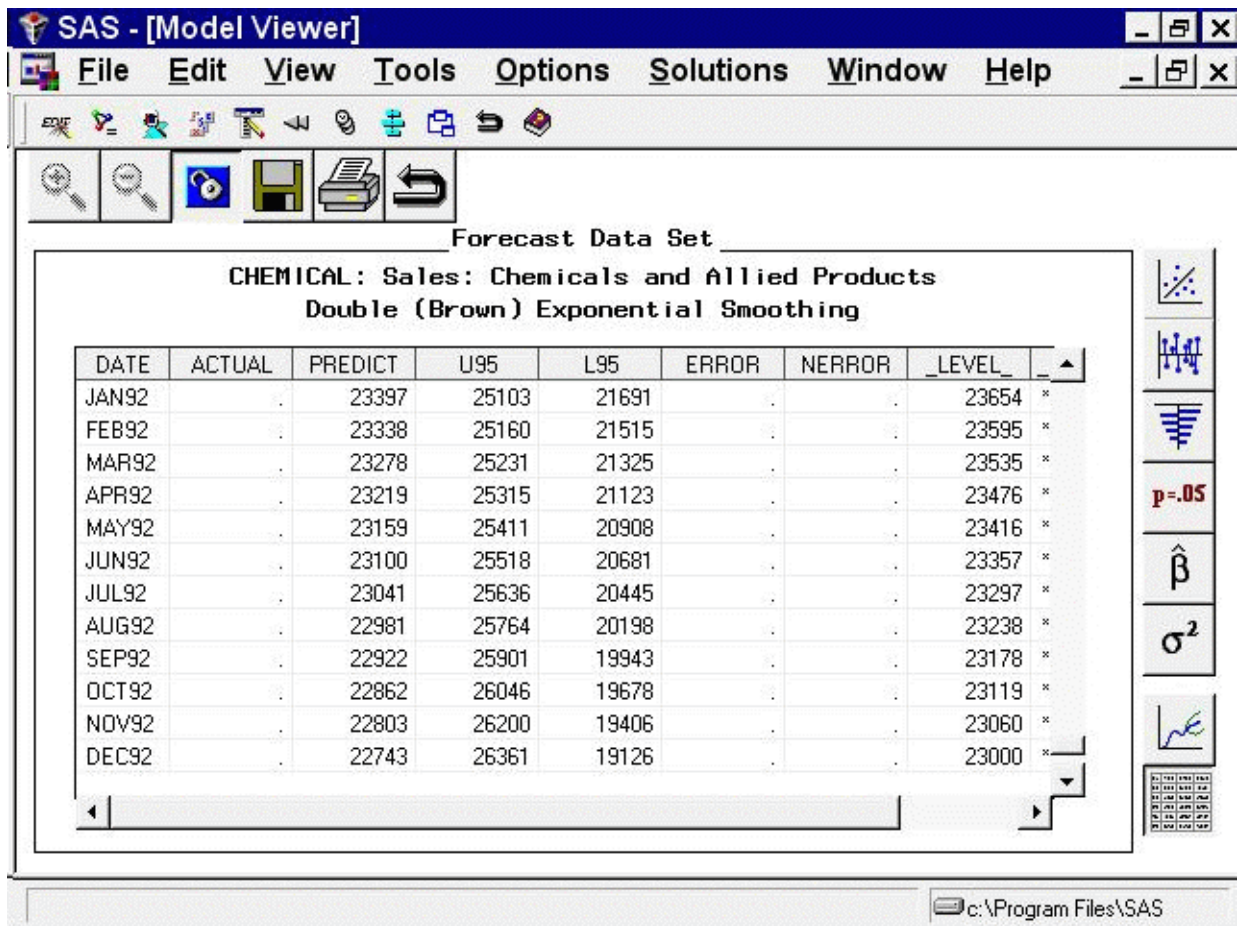

Figure 37.47 Model Viewer: Forecasts and Confidence Limits

Data Table

Select the last icon at the bottom of the vertical toolbar to the right of the graph. This switches the Viewer to display the forecast data set as a table, as shown in [Figure 37.48](#).

Figure 37.48 Model Viewer: Forecast Data Table

To view the full data set, use the vertical and horizontal scroll bars on the data table or enlarge the window.

Closing the Model Viewer

Other features of the Model Viewer and Develop Models window are discussed later in this book. For now, close the Model Viewer window and return to the Time Series Forecasting window.

To close the Model Viewer window, select **C**lose from the window's horizontal toolbar or from the File menu.

Chapter 38

Creating Time ID Variables

Contents

Creating a Time ID Value from a Starting Date and Frequency	2439
Using Observation Numbers as the Time ID	2443
Creating a Time ID from Other Dating Variables	2446

The Forecasting System requires that the input data set contain a time ID variable. If the data you want to forecast are not in this form, you can use features of the Forecasting System to help you add time ID variables to your data set. This chapter shows examples of how to use these features.

Creating a Time ID Value from a Starting Date and Frequency

As a first example of adding a time ID variable, use the SAS data set created by the following statements. (Or use your own data set if you prefer.)

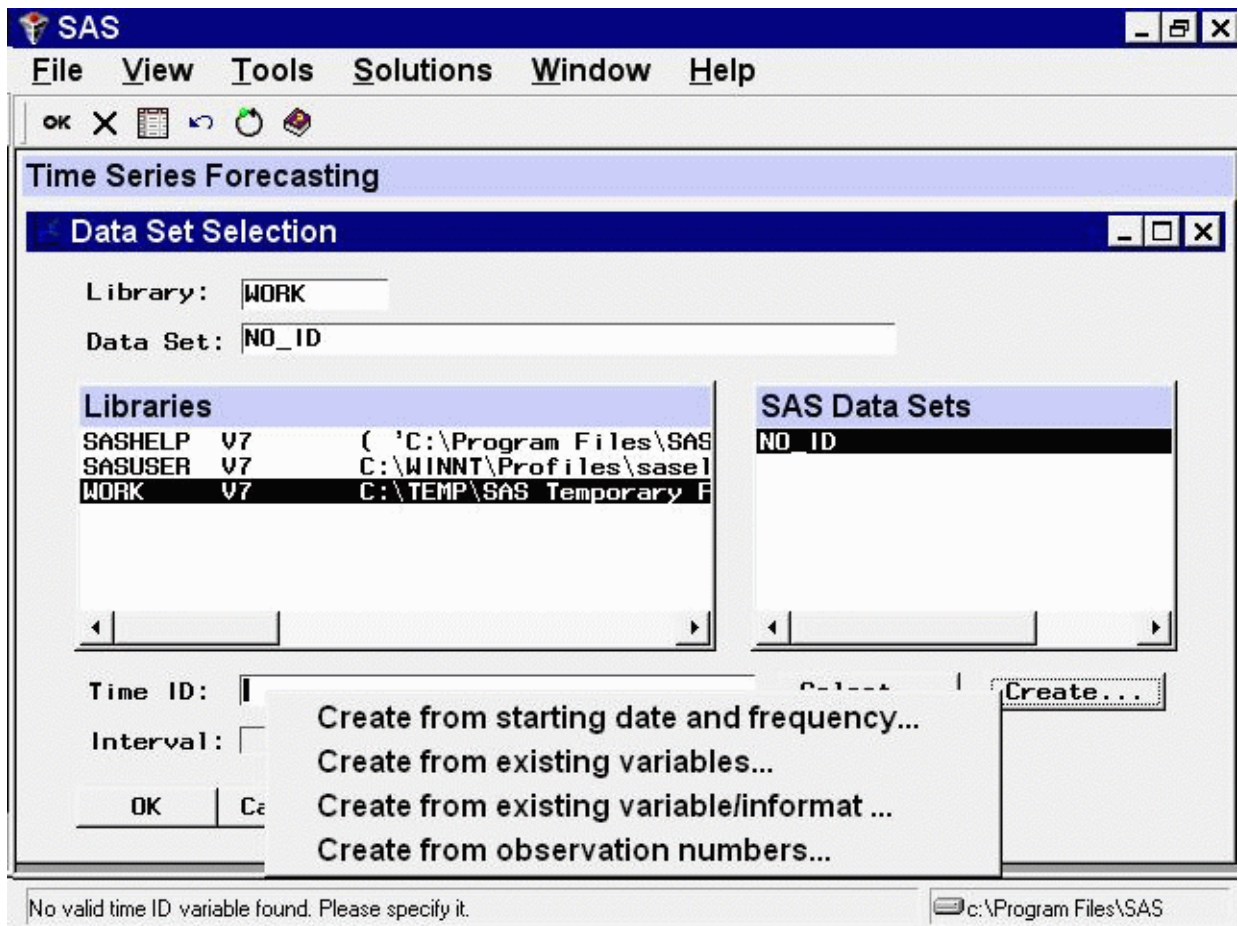

```
data no_id;
  input y @@;
datalines;
  10 15 20 25 30 35 40 45
  50 55 60 65 70 75 80 85
run;
```

Submit these SAS statements to create the data set NO_ID. This data set contains the single variable Y. Assume that Y is a quarterly series and starts in the first quarter of 1991.

In the *Time Series Forecasting* window, use the *Browse* button to the right of the *Data set* field to bring up the *Data Set Selection* window. Select the *WORK* library, and then select the *NO_ID* data set.

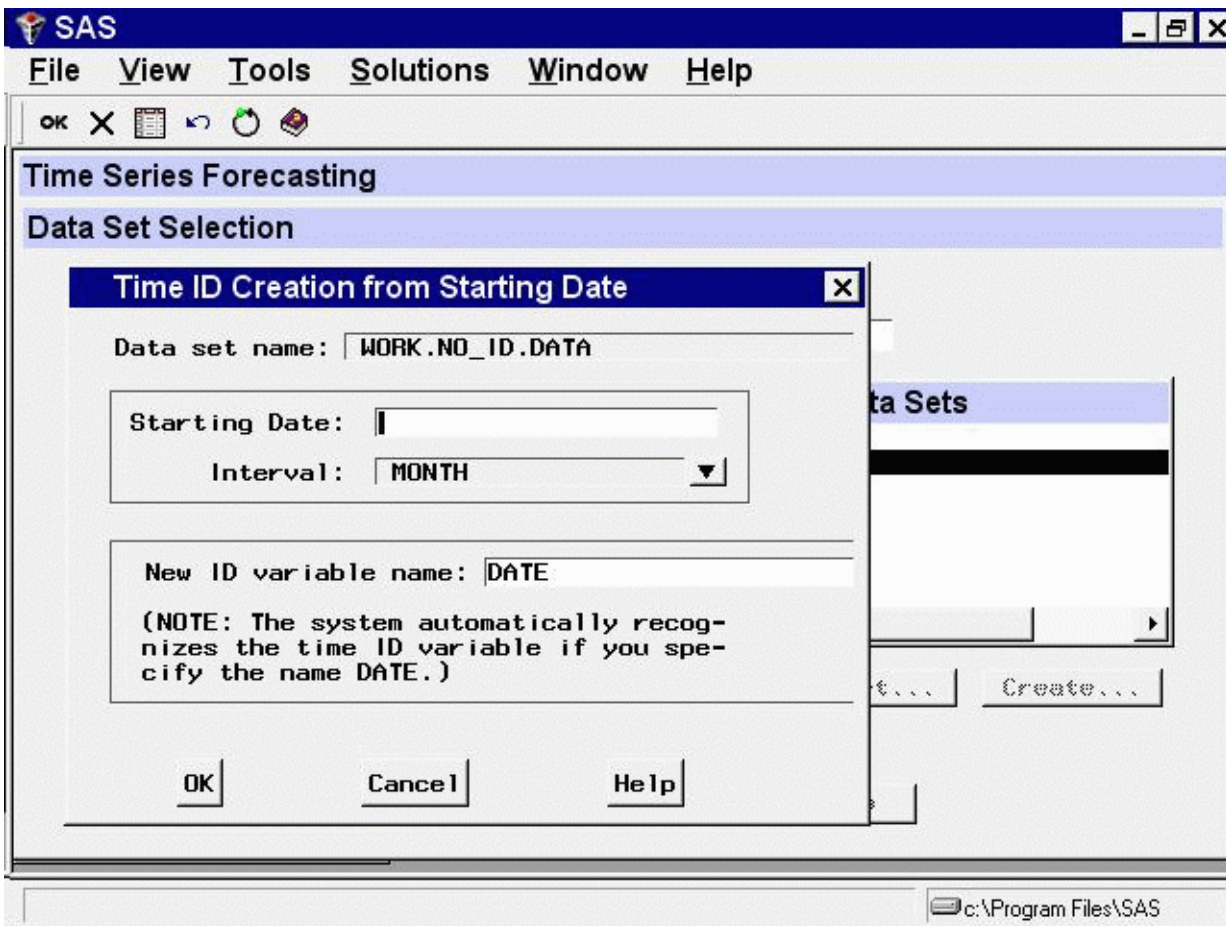

You must create a time ID variable for the data set. Click the *Create* button to the right of the *Time ID* field. This opens a menu of choices for creating the Time ID variable, as shown in [Figure 38.1](#).

Figure 38.1 Time ID Creation Popup Menu

Select the first choice, Create from starting date and frequency. This opens the Time ID Creation from Starting Date window shown in Figure 38.2.

Figure 38.2 Time ID Creation from Starting Date Window

Enter the starting date, 1991:1, in the `Starting Date` field.

Select the `Interval` list arrow and select `QTR`. The `Interval` value `QTR` means that the time interval between successive observations is a quarter of a year; that is, the data frequency is quarterly.

Now select the `OK` button. The system prompts you for the name of the new data set. If you want to create a new copy of the input data set with the `DATE` variable added, enter a name for the new data set. If you want to replace the `NO_ID` data set with the new copy containing `DATE`, just select the `OK` button without changing the name.

For this example, change the `New name` field to `WITH_ID` and select the `OK` button. The data set `WITH_ID` is created containing the series `Y` from `NO_ID` and the added ID variable `DATE`. The system returns to the `Data Set Selection` window, which now appears as shown in [Figure 38.3](#).

Figure 38.3 Data Set Selection Window after Creating Time ID

Select the **Table** button to see the new data set WITH_ID. This opens a VIEWTABLE window for the data set WITH_ID, as shown in [Figure 38.4](#). Select **File** and **Close** to close the VIEWTABLE window.

Figure 38.4 Viewtable Display of Data Set with Time ID Added

	DATE	y
1	1991:1	10
2	1991:2	15
3	1991:3	20
4	1991:4	25
5	1992:1	30
6	1992:2	35
7	1992:3	40
8	1992:4	45
9	1993:1	50
10	1993:2	55
11	1993:3	60
12	1993:4	65
13	1994:1	70
14	1994:2	75
15	1994:3	80
16	1994:4	85

NOTE: Table has been opened in browse mode. c:\Program Files\SAS

Using Observation Numbers as the Time ID

Normally, the time ID variable contains date values. If you do not want to have dates associated with your forecasts, you can also use observation numbers as time ID variables. However, you still must have an ID variable. This can be illustrated by adding an observation index time ID variable to the data set NO_ID.

In the Data Set Selection window, select the data set NO_ID again. Select the Create button to the right of the Time ID field. Select the fourth choice, Create from observation numbers. This opens the Time ID Variable Creation window shown in [Figure 38.5](#).

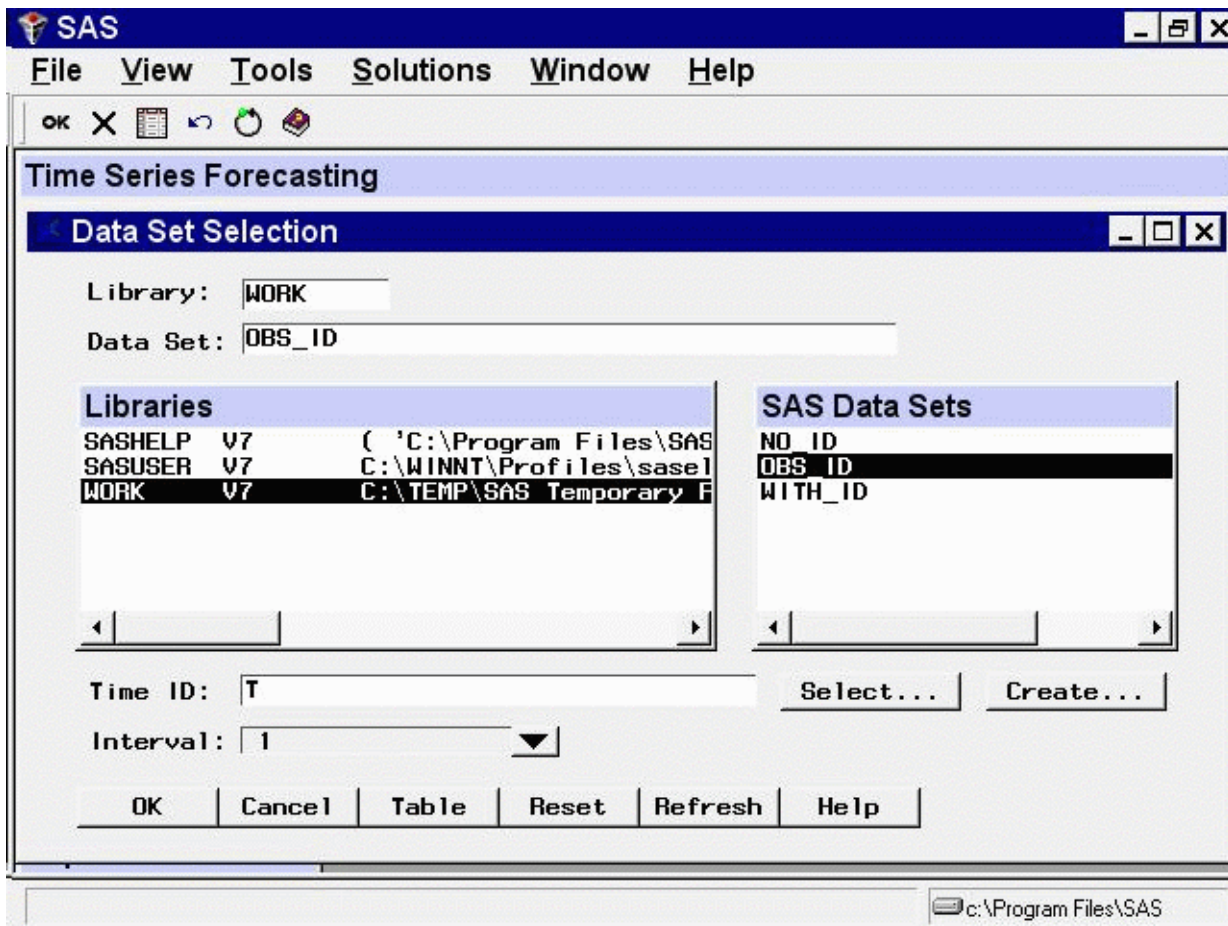

Figure 38.5 Create Time ID Variable Window

Select the **OK** button. This opens the **New Data Set Name** window. Enter "OBS_ID" in the **New data set name** field. Enter "T" in the **New ID variable name** field.

Now select the **OK** button. The new data set **OBS_ID** is created, and the system returns to the **Data Set Selection** window, which now appears as shown in [Figure 38.6](#).

Figure 38.6 Data Set Selection Window after Creating Time ID

The `Interval` field for `OBS_ID` has the value '1'. This means that the values of the time ID variable `T` increment by one between successive observations.

Select the `Table` button to look at the `OBS_ID` data set, as shown in [Figure 38.7](#).

Figure 38.7 VIEWTABLE of Data Set with Observation Index ID

The screenshot shows the SAS VIEWTABLE window for the data set WORK.OBS_ID. The window title is 'VIEWTABLE: WORK.OBS_ID'. The table displayed has three columns: 'T', 'y', and an unlabeled column. The data is as follows:

	T	y	
1	1	10	
2	2	15	
3	3	20	
4	4	25	
5	5	30	
6	6	35	
7	7	40	
8	8	45	
9	9	50	
10	10	55	
11	11	60	
12	12	65	
13	13	70	
14	14	75	
15	15	80	
16	16	85	

At the bottom of the window, there is a note: 'NOTE: Table has been opened in browse mode.' and the file path 'c:\Program Files\SAS'.

Select **File** and **Close** to close the VIEWTABLE window. Select the **OK** button from the Data Set Selection window to return to the Time Series Forecasting window.

Creating a Time ID from Other Dating Variables

Your data set might contain ID variables that date the observations in a different way than the SAS date valued ID variable expected by the forecasting system. For example, for monthly data, the data set might contain the ID variables YEAR and MONTH, which together date the observations.

In these cases, you can use the Forecasting System's Create Time ID features to compute a time ID variable with SAS date values from the existing dating variables. As an example of this, use the SAS data set read in by the following SAS statements:

```
data id_parts;
  input yr qtr y;
datalines;
```

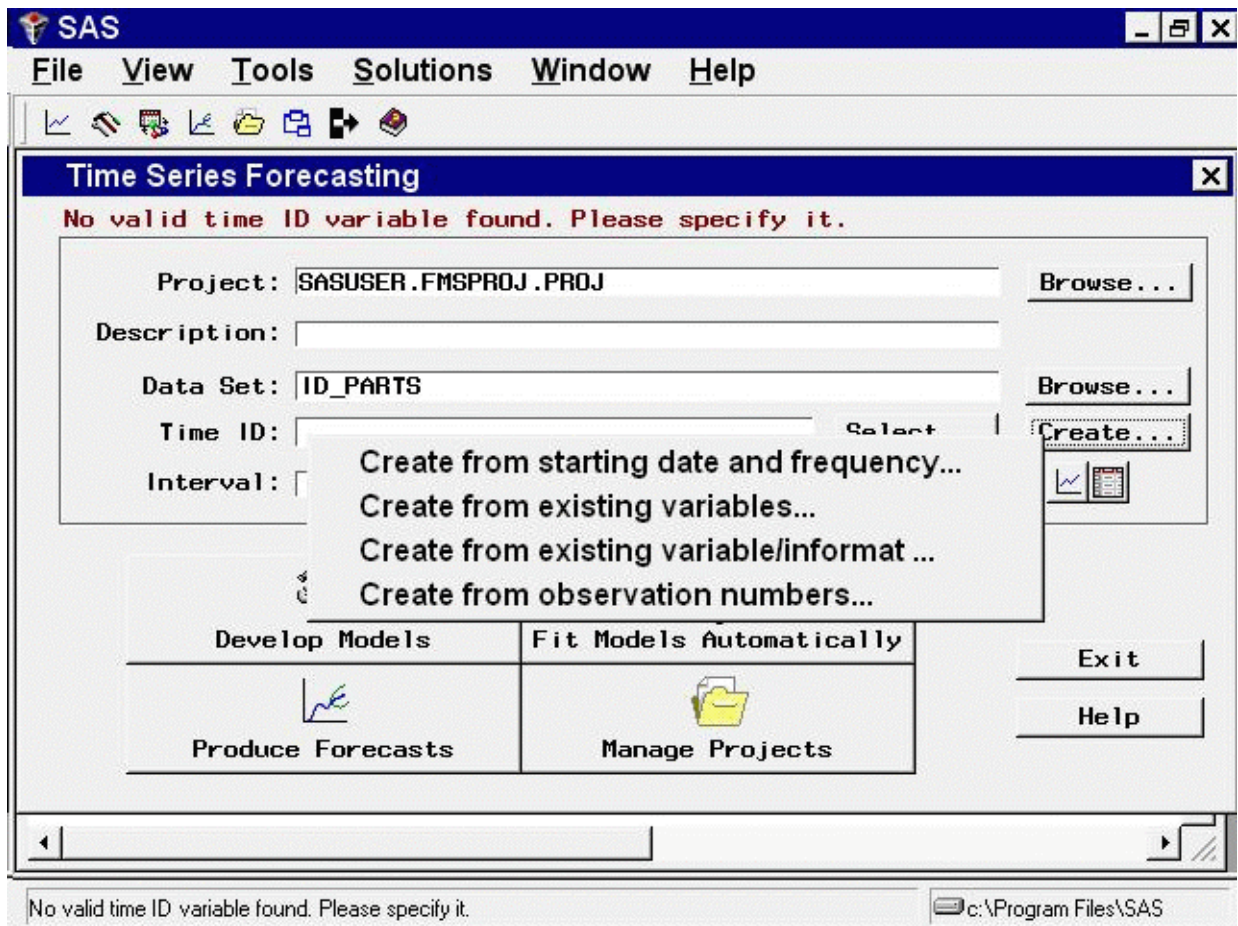

```
91 1 10
91 2 15
91 3 20
91 4 25
92 1 30
92 2 35
92 3 40
92 4 45
93 1 50
93 2 55
93 3 60
93 4 65
94 1 70
94 2 75
94 3 80
94 4 85
run;
```

Submit these SAS statements to create the data set `ID_PARTS`. This data set contains the three variables `YR`, `QTR`, and `Y`. `YR` and `QTR` are ID variables that together date the observations, but each variable provides only part of the date information. Because the forecasting system requires a single dating variable containing SAS date values, you need to combine `YR` and `QTR` to create a single variable `DATE`.

Type “`ID_PARTS`” in the `Data Set` field and press the `ENTER` key. (You could also use the `Browse` button to open the `Data Set Selection` window, as in the previous example, and complete this example from there.)

Select the `Create` button at the right of the `Time ID` field. This opens the menu of `Create Time ID` choices, as shown in [Figure 38.8](#).

Figure 38.8 Adding a Time ID Variable

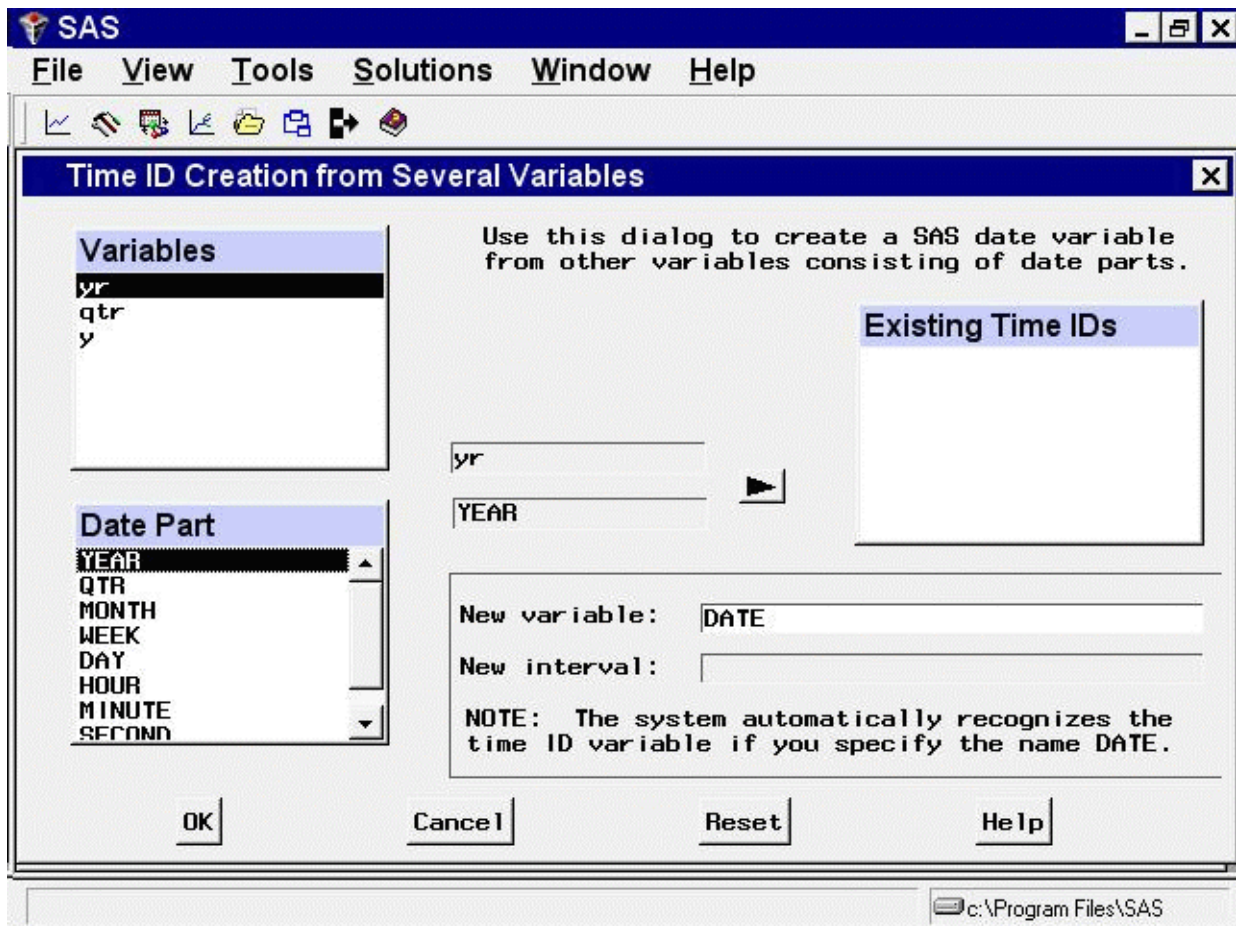

Select the second choice, *Create from existing variables*. This opens the window shown in [Figure 38.9](#).

Figure 38.9 Creating a Time ID Variable from Date Parts

In the Variables list, select YR. In the Date Part list, select YEAR as shown in Figure 38.10.

Figure 38.10 Specifying the ID Variable for Years

Now click the right-pointing arrow button. The variable YR and the part code YEAR are added to the Existing Time IDs list.

Next select QTR from the Variables list, select QTR from the Date Part list, and click the arrow button. This adds the variable QTR and the part code QTR to the Existing Time IDs list, as shown in Figure 38.11.

Figure 38.11 Creating a Time ID Variable from Date Parts

Now select the **OK** button. This opens the **New Data Set Name** window. Change the **New data set name** field to **NEWDATE**, and then select the **OK** button.

The data set **NEWDATE** is created, and the system returns to the **Time Series Forecasting** window with **NEWDATE** as the selected Data Set. The **Time ID** field is set to **DATE**, and the **Interval** field is set to **QTR**.

Incorporating Forecasts from Other Sources	2485

This chapter explores the tools available through the Develop Models window for investigating the properties of time series and for specifying and fitting models. The first section shows you how to diagnose time series properties in order to determine the class of models appropriate for forecasting series with such properties. Later sections show you how to specify and fit different kinds of forecasting models.

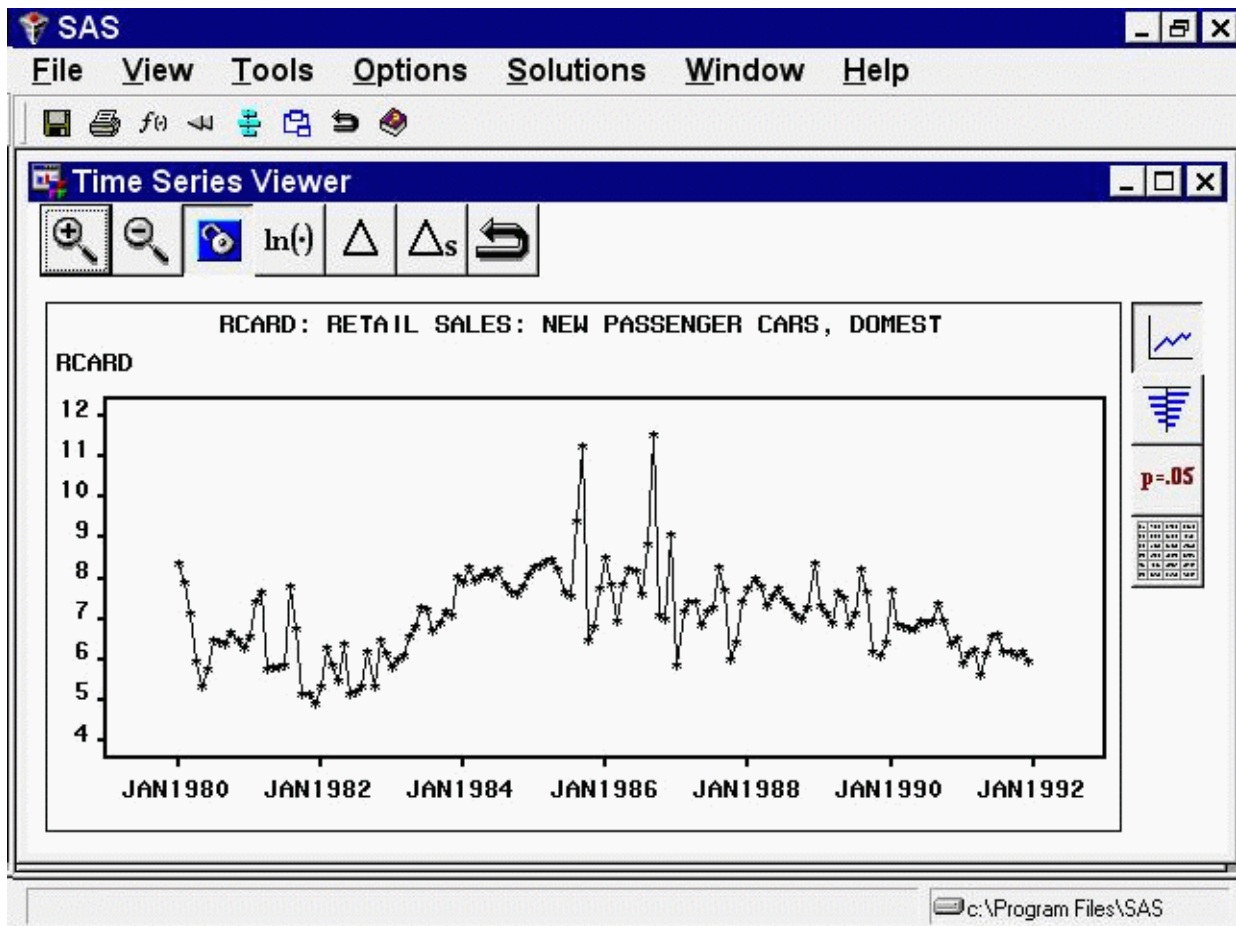

Series Diagnostics

The series diagnostics tool helps you determine the kinds of forecasting models that are appropriate for the data series so that you can limit the search for the best forecasting model. The series diagnostics address these three questions: Is a log transformation needed to stabilize the variance? Is a time trend present in the data? Is there a seasonal pattern to the data?

The automatic model fitting process, which you used in the previous chapter through the Automatic Model Fitting window, performs series diagnostics and selects trial models from a list according to the results. You can also look at the diagnostic information and make your own decisions as to the kinds of models appropriate for the series. The following example illustrates the series diagnostics features.

Select “Develop Models” from the Time Series Forecasting window. Select the library SASHELP, the data set CITIMON, and the series RCARD. This series represents domestic retail sales of passenger cars. To look at this series, select “View Series” from the Develop Models window. This opens the Time Series Viewer window, as shown in [Figure 39.1](#).

Figure 39.1 Automobile Sales Series

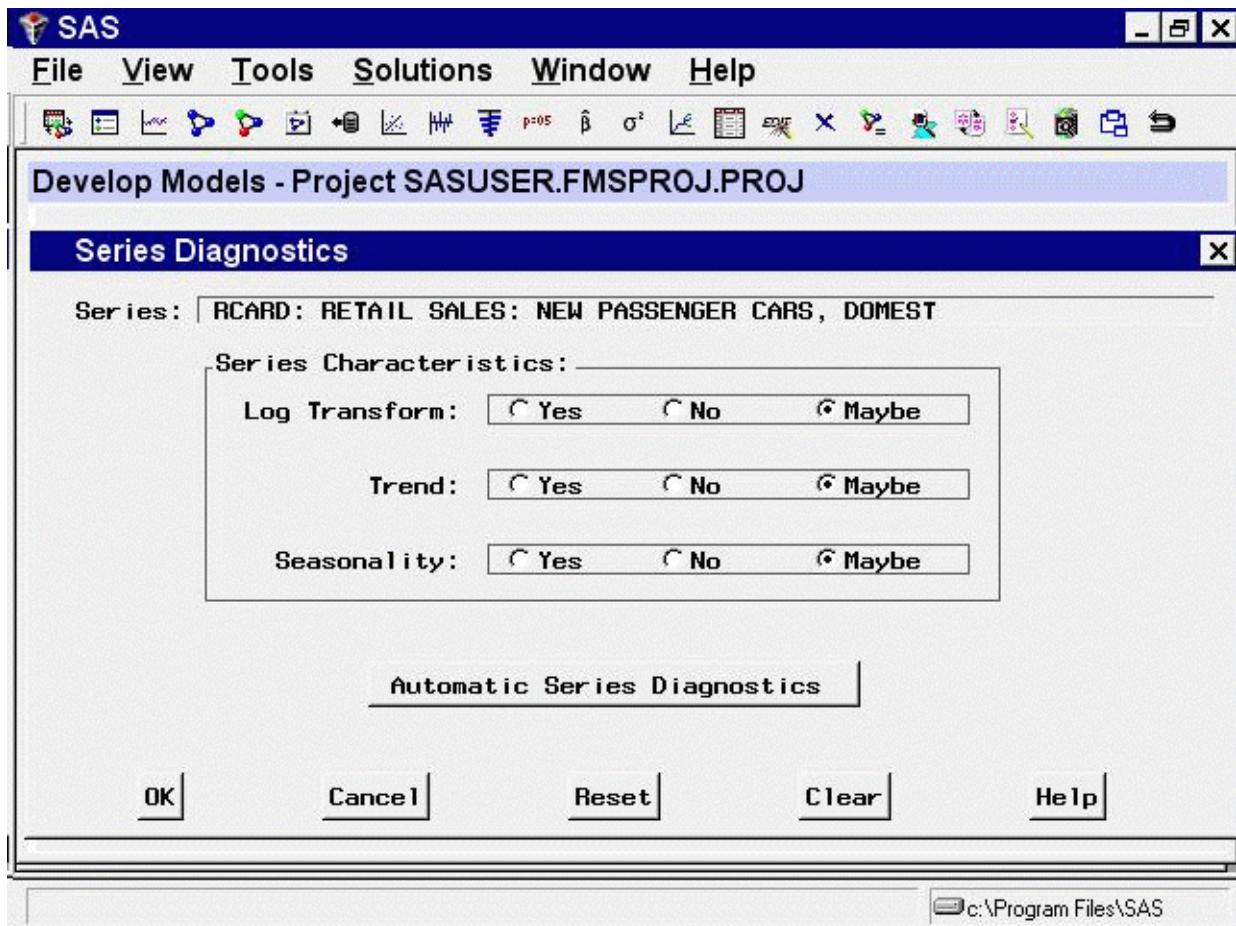

Select "Diagnose Series" from the Tools menu. You can do this from the Develop Models window or from the Time Series Viewer window. Figure 39.2 shows this from the Develop Models window.

Figure 39.2 Selecting Series Diagnostics

This opens the Series Diagnostics window, as shown in [Figure 39.3](#).

Figure 39.3 Series Diagnostics Window

Each of the three series characteristics—need for log transformation, presence of a trend, and seasonality—has a set of options for *Yes*, *No*, and *Maybe*. *Yes* indicates that the series has the characteristic and that forecasting models fit to the series should be able to model and predict this behavior. *No* indicates that you do not need to consider forecasting models designed to predict series with this characteristic. *Maybe* indicates that models with and without the characteristic should be considered. Initially, all these values are set to *Maybe*.

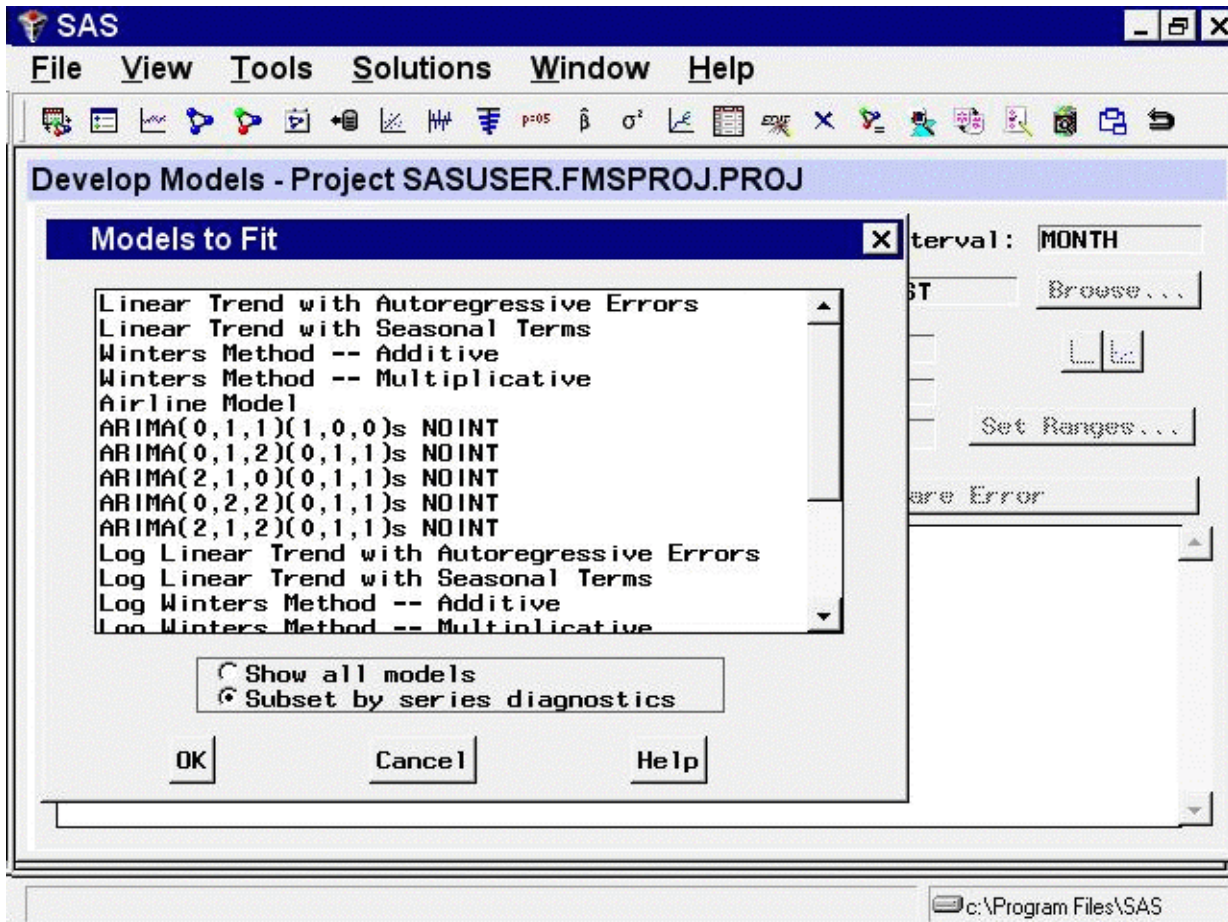

To have the system diagnose the series characteristics, select the **Automatic Series Diagnostics** button. This runs the diagnostic routines described in Chapter 44, “[Forecasting Process Details](#),” and sets the options according to the results. In this example, *Trend* and *Seasonality* are changed from *Maybe* to *Yes*, while *Log Transform* remains set to *Maybe*.

These diagnostic criteria affect the models displayed when you use the **Models to Fit** window or the **Automatic Model Selection** model-fitting options described in the following section. You can set the criteria manually, according to your judgment, by selecting any of the options, whether you have used the **Automatic Series Diagnostics** button or not. For this exercise, leave them as set by the automatic diagnostics. Select the **OK** button to close the **Series Diagnostics** window.

Models to Fit Window

As you saw in the previous chapter, you can select models from a list. Invoke the Models to Fit window by clicking the middle of the table and selecting “Fit Models from List” from the menu. This can also be selected from the tool bar or the Fit Model submenu of the Edit menu. The Models to Fit window comes up, as shown in [Figure 39.4](#).

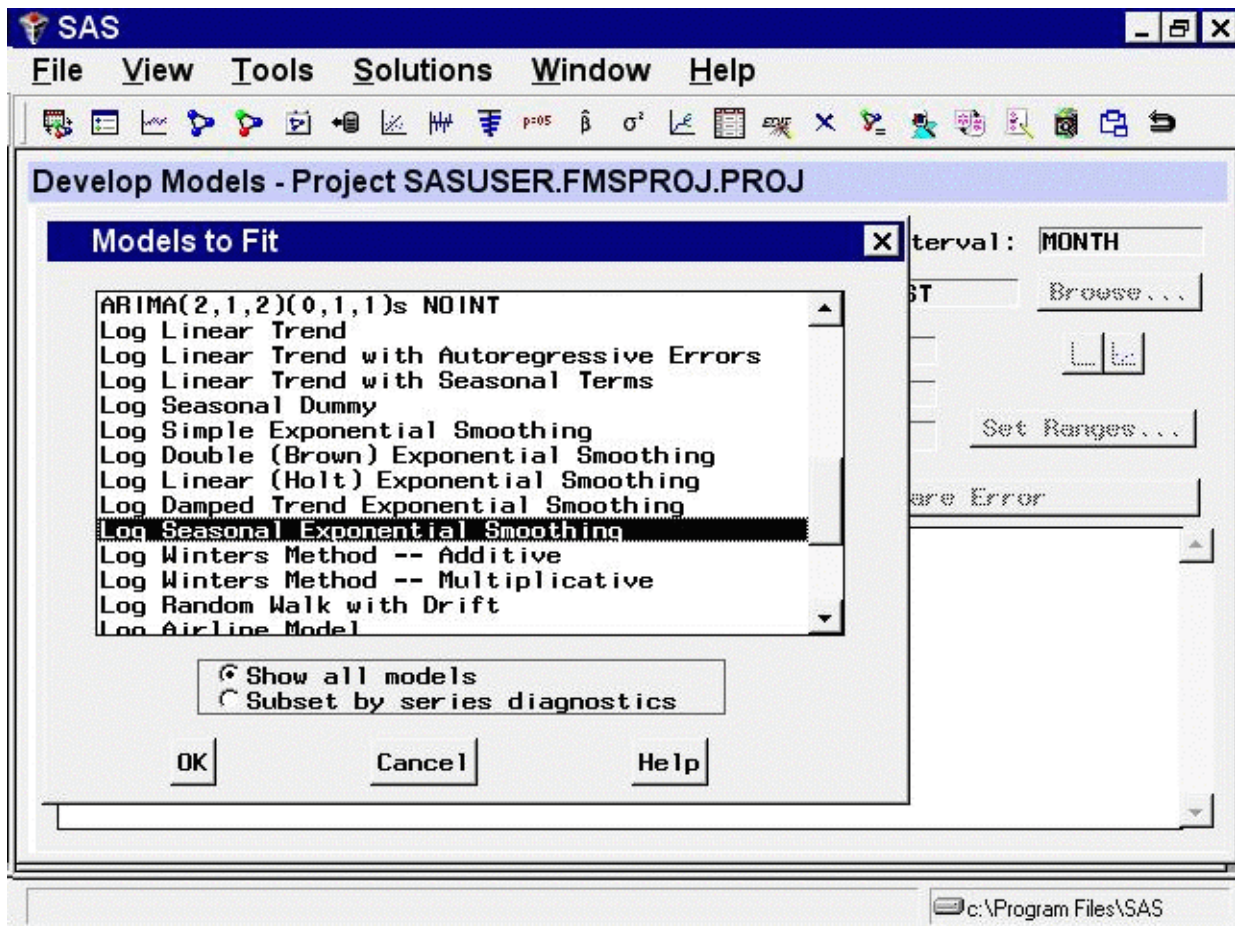

Figure 39.4 Models to Fit Window

Since you have performed series diagnostics, the models shown are the subset that fits the diagnostic criteria.

Suppose you want to consider models other than those in this subset because you are undecided about including a trend in the model. Select the Show all models option. Now the entire model selection list is shown. Scroll through the list until you find Log Seasonal Exponential Smoothing, as shown in [Figure 39.5](#).

Figure 39.5 Selecting a Model from List

This is a nontrended model, which seems a good candidate. Select this model, and then select the OK button. The model is fit to the series and then appears in the table with the value of the selected fit criterion, as shown in [Figure 39.6](#).

Figure 39.6 Develop Models Window Showing Model Fit

You can edit the model list that appears in the Models to Fit window by selecting “Options” and “Model Selection List” from the menu bar or by selecting the Edit Model List toolbar icon. You can then delete models you are not interested in from the default list and add models using any of the model specification methods described in this chapter. When you save your project, the edited model selection list is saved in the project file. In this way, you can use the Select from List item and the Automatic Model Selection item to select models from a customized search set.

Automatic Model Selection

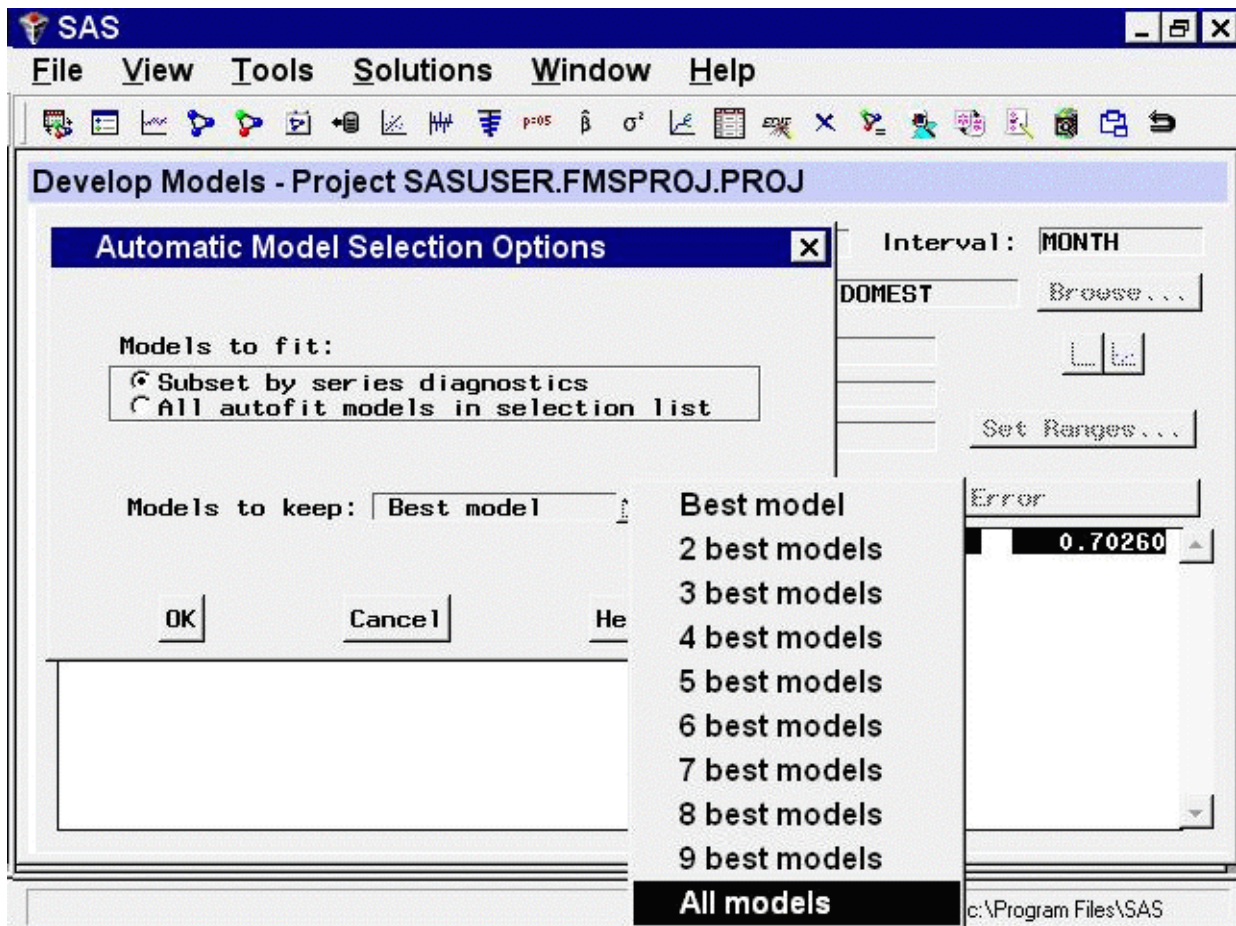

Automatic model selection is equivalent to choosing Select from List, as you did in the preceding section, fitting all the models in the subset list and then deleting all except the best fitting of the models. If series diagnostics have not yet been done, they are performed automatically to determine the model subset to fit. If you set the series diagnostics for log, trend, or seasonal criteria manually using the radio buttons, these choices are honored by the automatic fitting process.

Using automatic selection, the system does not pause to warn you of model fitting errors, such as failure of the estimates to converge (you can track these using the audit trail feature).

By default, only the best fitting model is kept. However, you can control the number of automatically fit models retained in the Develop Models list, and the following example shows how to do this.

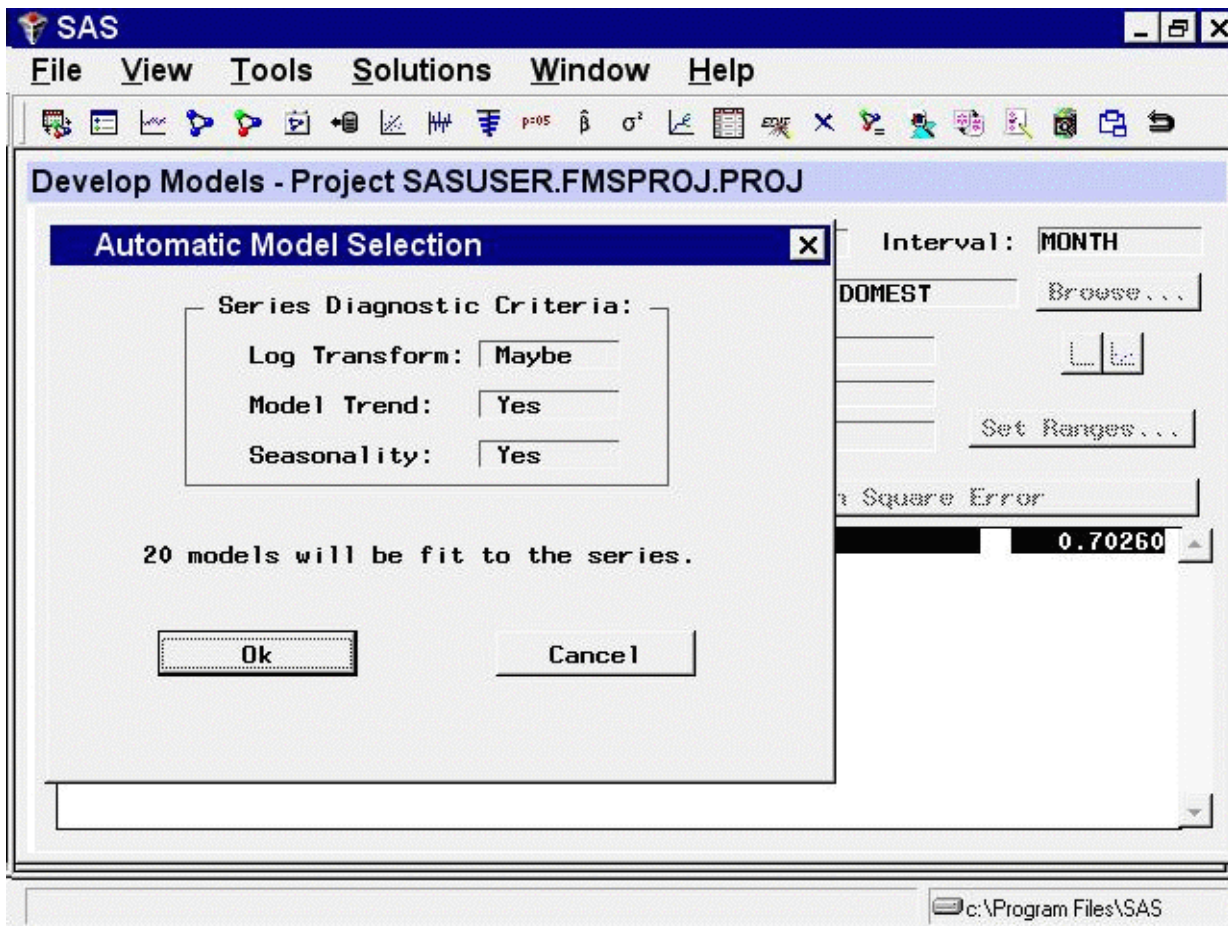

From the menu bar, choose “Options” and “Automatic Fit.” This opens the Automatic Model Selection Options window. Click the Models to Keep list arrow, and select “All models”, as shown in Figure 39.7. Now select OK.

Figure 39.7 Selecting Number of Automatic Fit Models to Keep

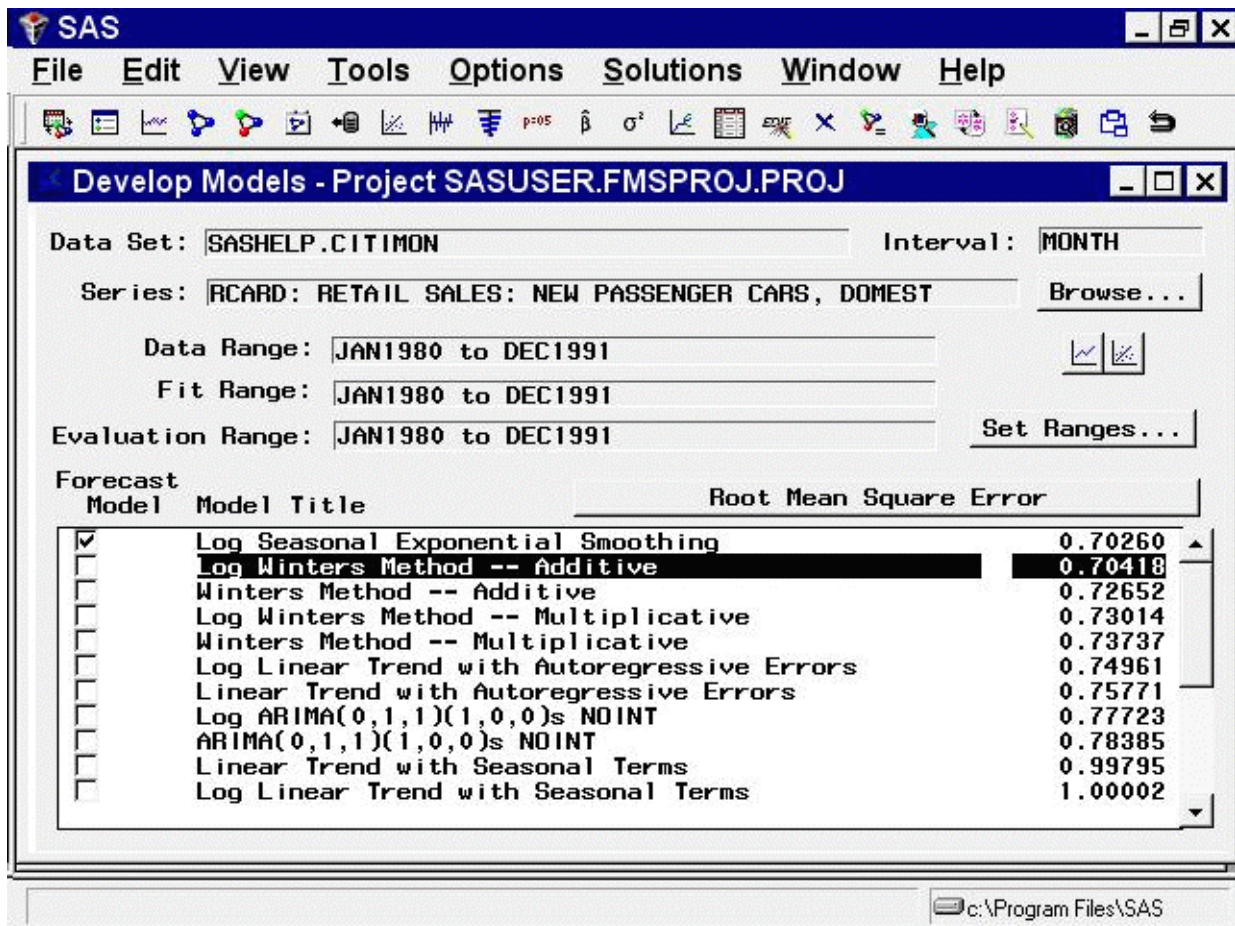

Next, select “Fit Models Automatically” by clicking the middle of the table or using the toolbar or Edit menu. The Automatic Model Selection window appears, showing the diagnostic criteria in effect and the number of models to be fit, as shown in Figure 39.8.

Figure 39.8 Automatic Model Selection Window

Select the OK button. After the models have been fit, all of them appear in the table, in addition to the model which you fit earlier, as shown in [Figure 39.9](#).

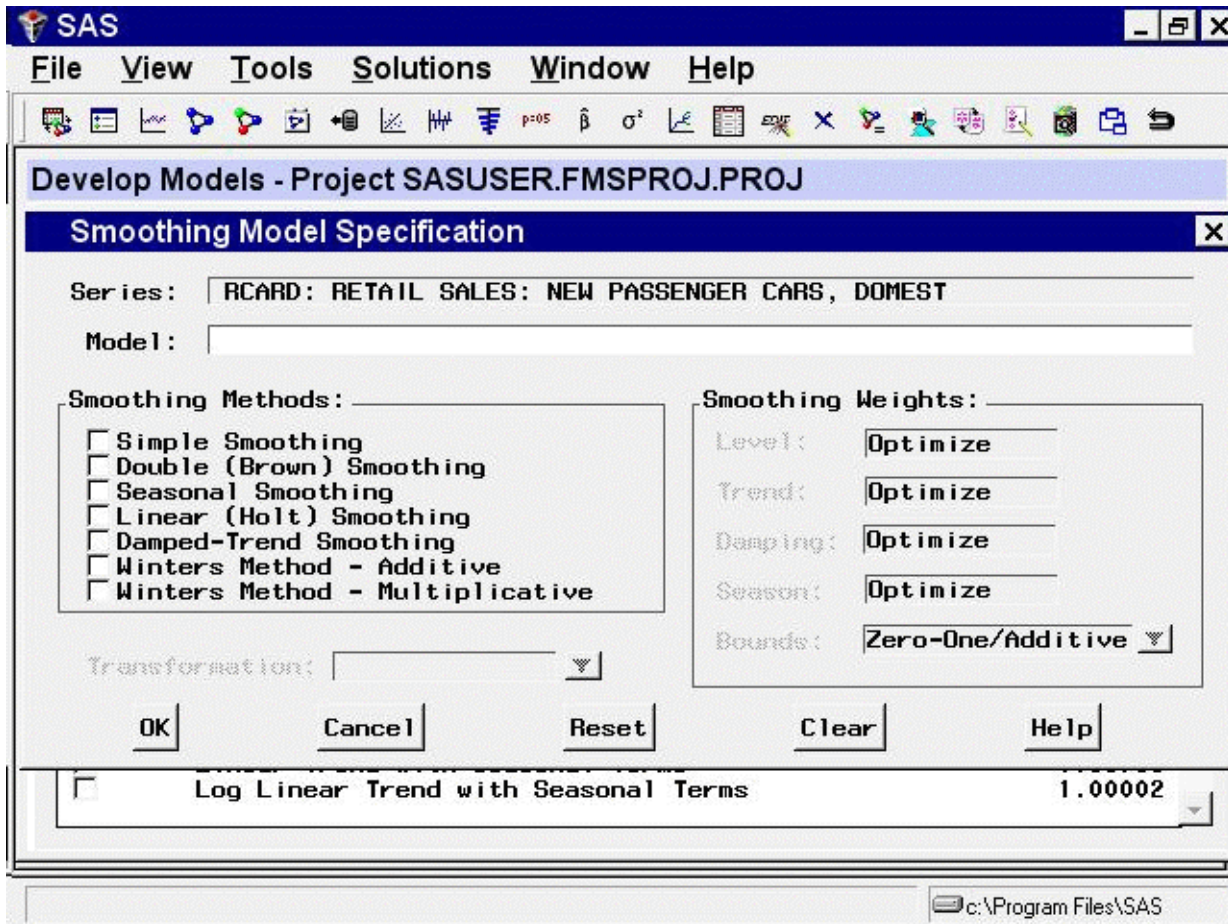

Figure 39.9 Automatically Fit Models

Smoothing Model Specification Window

To fit exponential smoothing and Winters models not already provided in the Models to Fit window, select “Fit Smoothing Model” from the pop-up menu or toolbar or select “Smoothing Model” from the Fit Model submenu of the Edit menu. This opens the Smoothing Model Specification window, as shown in [Figure 39.10](#).

Figure 39.10 Smoothing Model Specification Window

The Smoothing Model Specification window consists of several parts. At the top is the series name and a field for the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

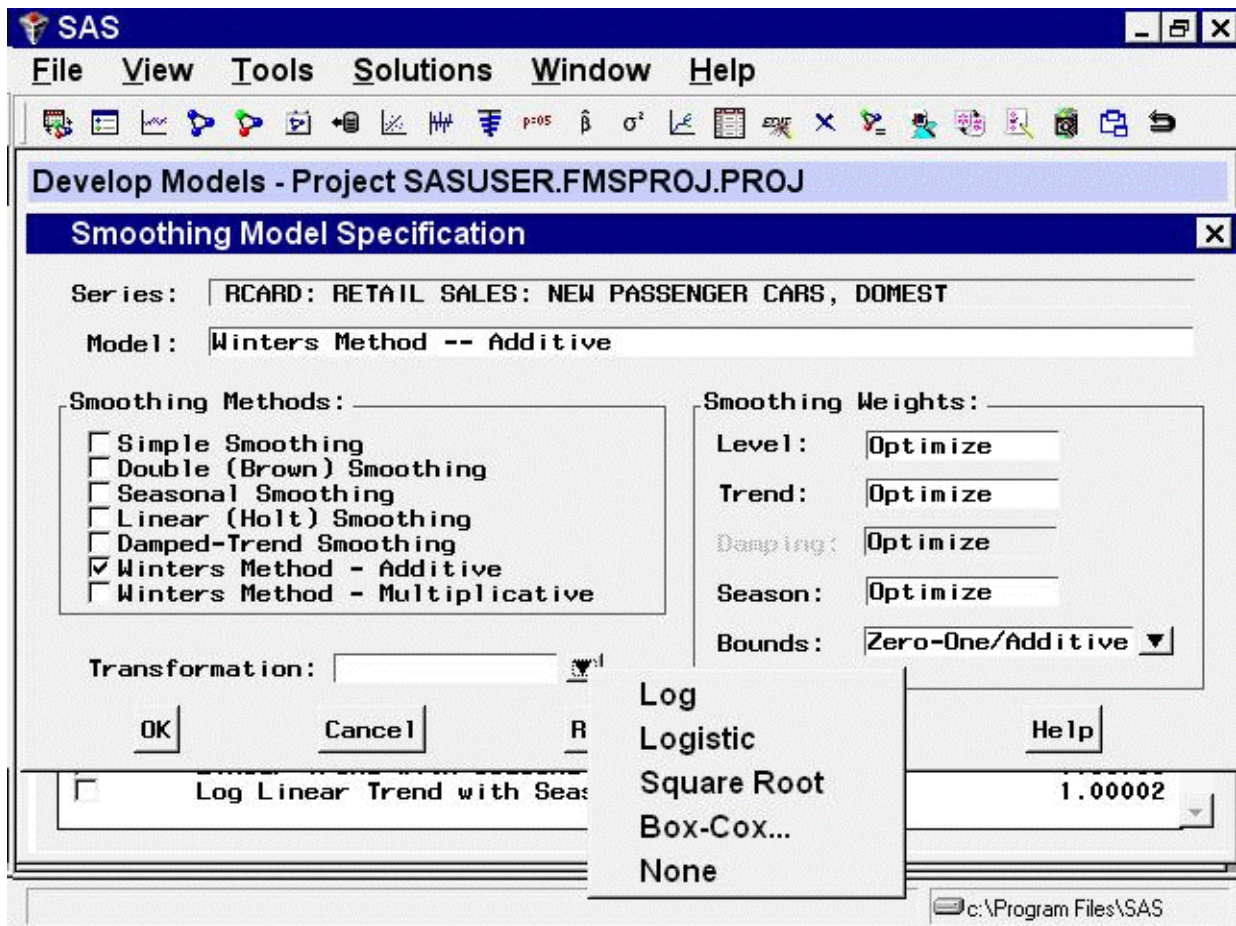

The Smoothing Methods box lists the different methods available. Below the Smoothing Methods box is the Transformation field, which is used to apply the smoothing method to transformed series values.

The Smoothing Weights box specifies how the smoothing weights are determined. By default, the smoothing weights are automatically set to optimize the fit of the model to the data. See Chapter 44, “Forecasting Process Details,” for more information about how the smoothing weights are fit.

Under smoothing methods, select “Winters Method – Additive.” Notice the smoothing weights box to the right. The third item, Damping, is grayed out, while the other items, Level, Trend, and Season, show the word Optimize. This tells you that these three smoothing weights are applicable to the smoothing method that you selected and that the system is currently set to optimize these weights for you.

Next, specify a transformation using the Transformation list. A menu of transformation choices pops up, as shown in Figure 39.11.

Figure 39.11 Transformation Options

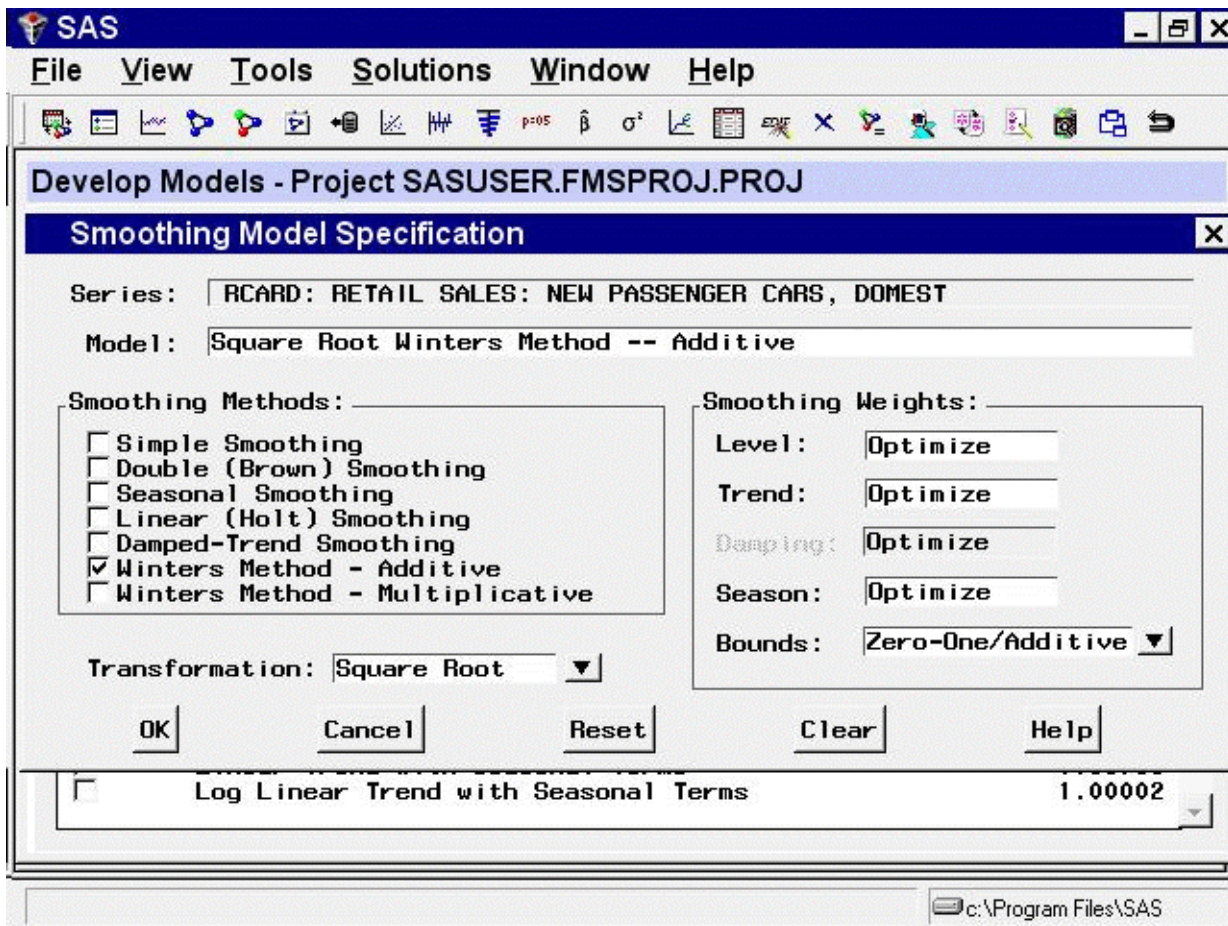

You can specify a logarithmic, logistic, square root, or Box-Cox transformation. For this example, select “Square Root” from the list. The Transformation field is now set to Square Root.

This means that the system will first take the square roots of the series values, apply the additive version of the Winters method to the square root series, and then produce the predictions for the original series by squaring the Winters method predictions (and multiplying by a variance factor if the Mean Prediction option is set in the Forecast Options window). See Chapter 44, “[Forecasting Process Details](#),” for more information about predictions from transformed models.

The Smoothing Model Specification window should now appear as shown in [Figure 39.12](#). Select the OK button to fit the model. The model is added to the table of fitted models in the Develop Models window.

Figure 39.12 Winter's Method Applied to Square Root Series

ARIMA Model Specification Window

To fit ARIMA or Box-Jenkins models not already provided in the Models to Fit window, select the ARIMA model item from the pop-up menu, toolbar, or Edit menu. This opens the ARIMA Model Specification window, as shown in [Figure 39.13](#).

Figure 39.13 ARIMA Model Specification Window

This ARIMA Model Specification window is structured according to the Box and Jenkins approach to time series modeling. You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you may find one more convenient than the other.

At the top of the ARIMA Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

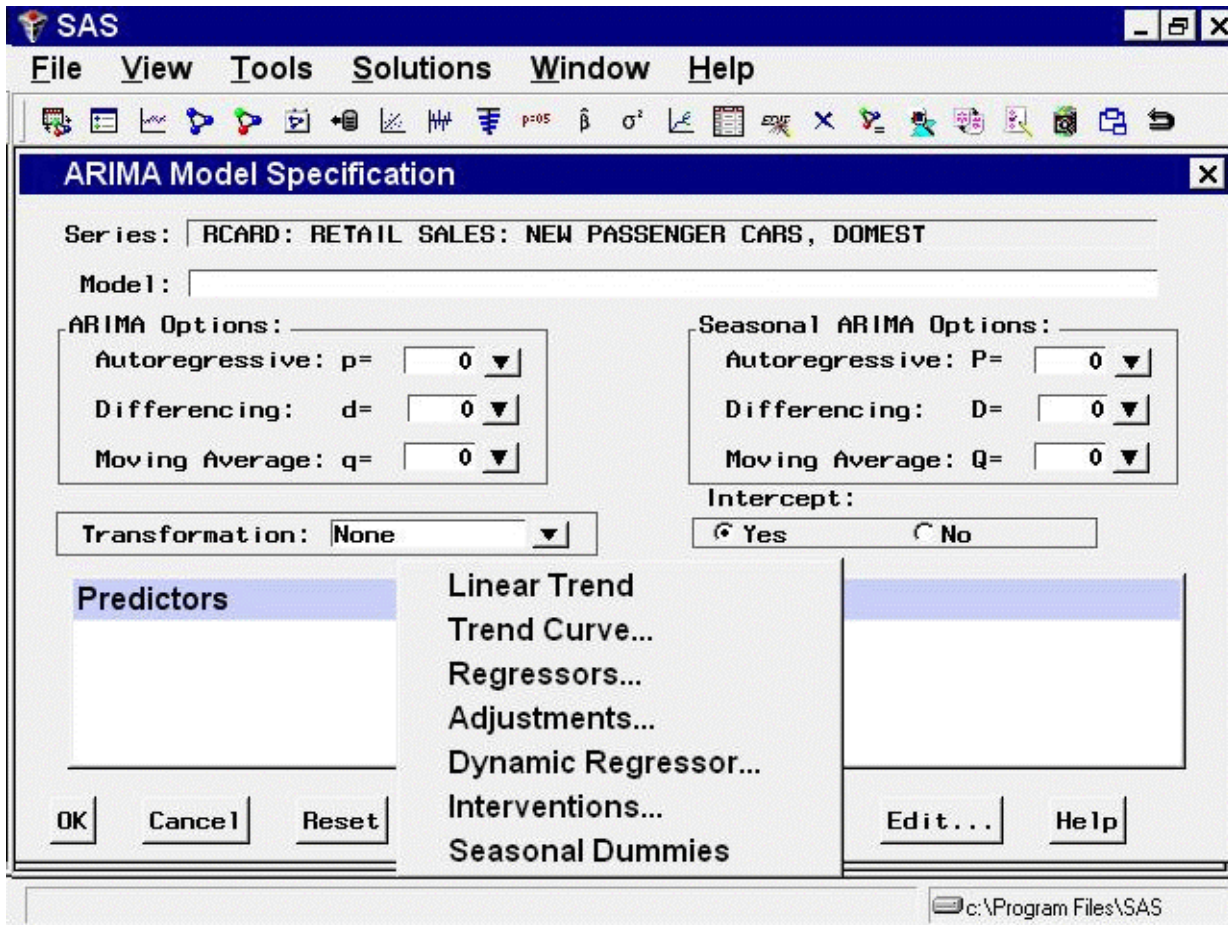

Using the ARIMA Model Specification window, you can specify autoregressive (p), differencing (d), and moving average (q) orders for both simple and seasonal factors. You can specify transformations with the `Transformation` list. You can also specify whether an intercept is included in the ARIMA model.

In addition to specifying seasonal and nonseasonal ARIMA processes, you can also specify predictor variables and other terms as inputs to the model. ARIMA models with inputs are sometimes called ARIMAX models or Box-Tiao models. Another term for this kind of model is *dynamic regression*.

In the lower part of the ARIMA Model Specification window is the list of *predictors* to the model

(initially empty). You can specify predictors by using the Add button. This opens a menu of different kinds of independent effects, as shown in [Figure 39.14](#).

Figure 39.14 Add Predictors Menu

The kinds of predictor effects allowed include time trends, regressors, adjustments, dynamic regression (transfer functions), intervention effects, and seasonal dummy variables. How to use different kinds of predictors is explained in Chapter 41, “[Using Predictor Variables](#).”

As an example, in the `ARIMA Options` box, set the order of differencing d to 1 and the moving average order q to 2. You can either type in these values or click the arrows and select the values from pop-up lists.

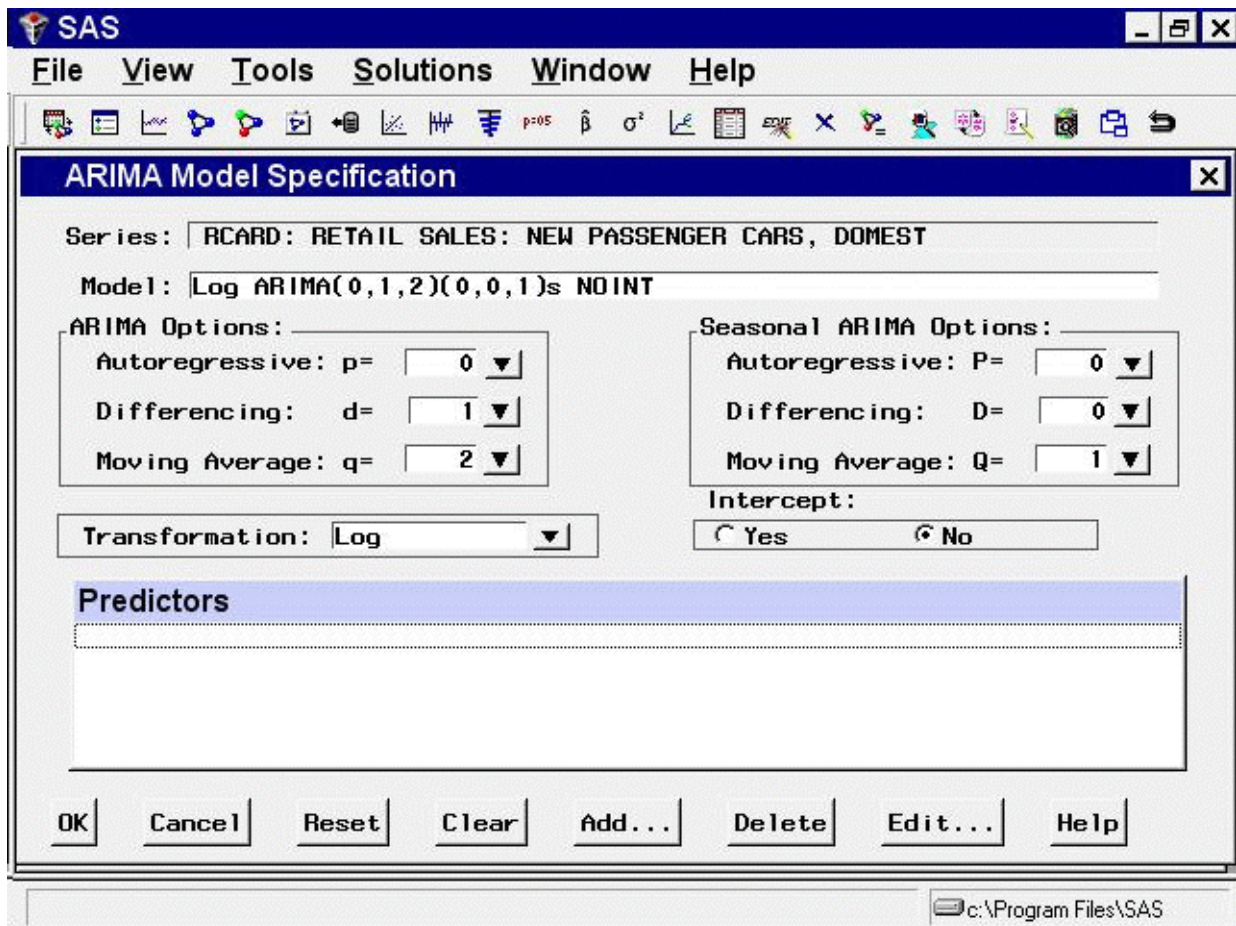

These selections specify an `ARIMA(0,1,2)` or `IMA(1,2)` model. (See Chapter 7, “[The ARIMA Procedure](#),” for more information about the notation used for ARIMA models.) Notice that the model label at the top is now `IMA(1,2) NOINT`, meaning that the data are differenced once and a second-order moving-average term is included with no intercept.

In the `Seasonal ARIMA Options` box, set the seasonal moving-average order Q to 1. This adds a first-order moving-average term at the seasonal (12 month) lag. Finally, select “Log” in the Transformation combo box.

The model label is now `Log ARIMA(0,1,2)(0,0,1)s NOINT`, and the window appears as shown

in Figure 39.15.

Figure 39.15 Log ARIMA(0,1,2)(0,0,1)_s Specified

Select the OK button to fit the model. The model is fit and added to the Develop Models table.

Factored ARIMA Model Specification Window

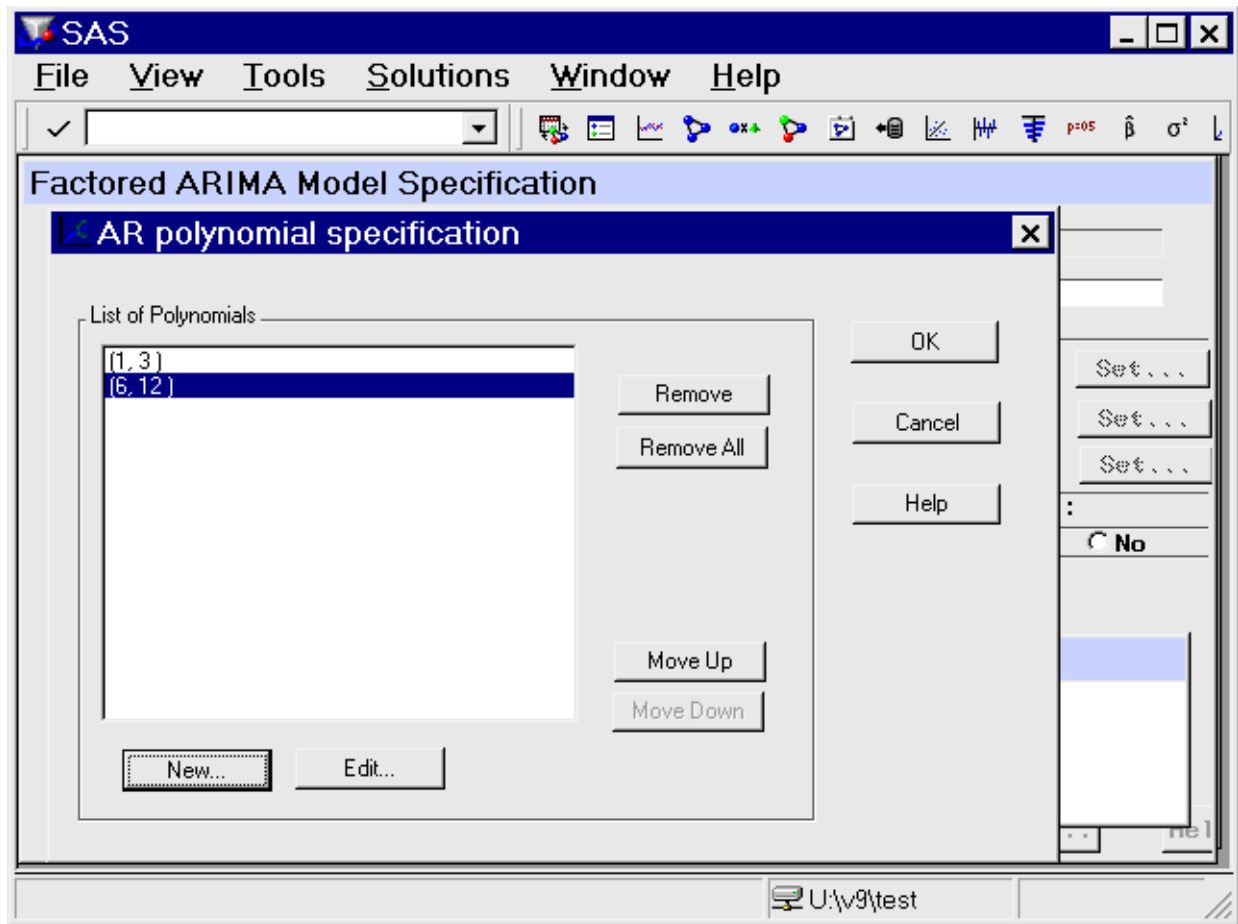

To fit a factored ARIMA model, select the Factored ARIMA model item from the pop-up menu, toolbar, or Edit menu. This brings up the Factored ARIMA Model Specification window, shown in Figure 39.16.

Figure 39.16 Factored ARIMA Model Specification Window

The Factored ARIMA Model Specification window is similar to the ARIMA Model Specification window and has the same features, but it uses a more general specification of the autoregressive (p), differencing (d), and moving-average (q) terms. To specify these terms, select the corresponding Set button, as shown in Figure 39.16. For example, to specify autoregressive terms, select the first Set button. This opens the AR Polynomial Specification Window, shown in Figure 39.17.

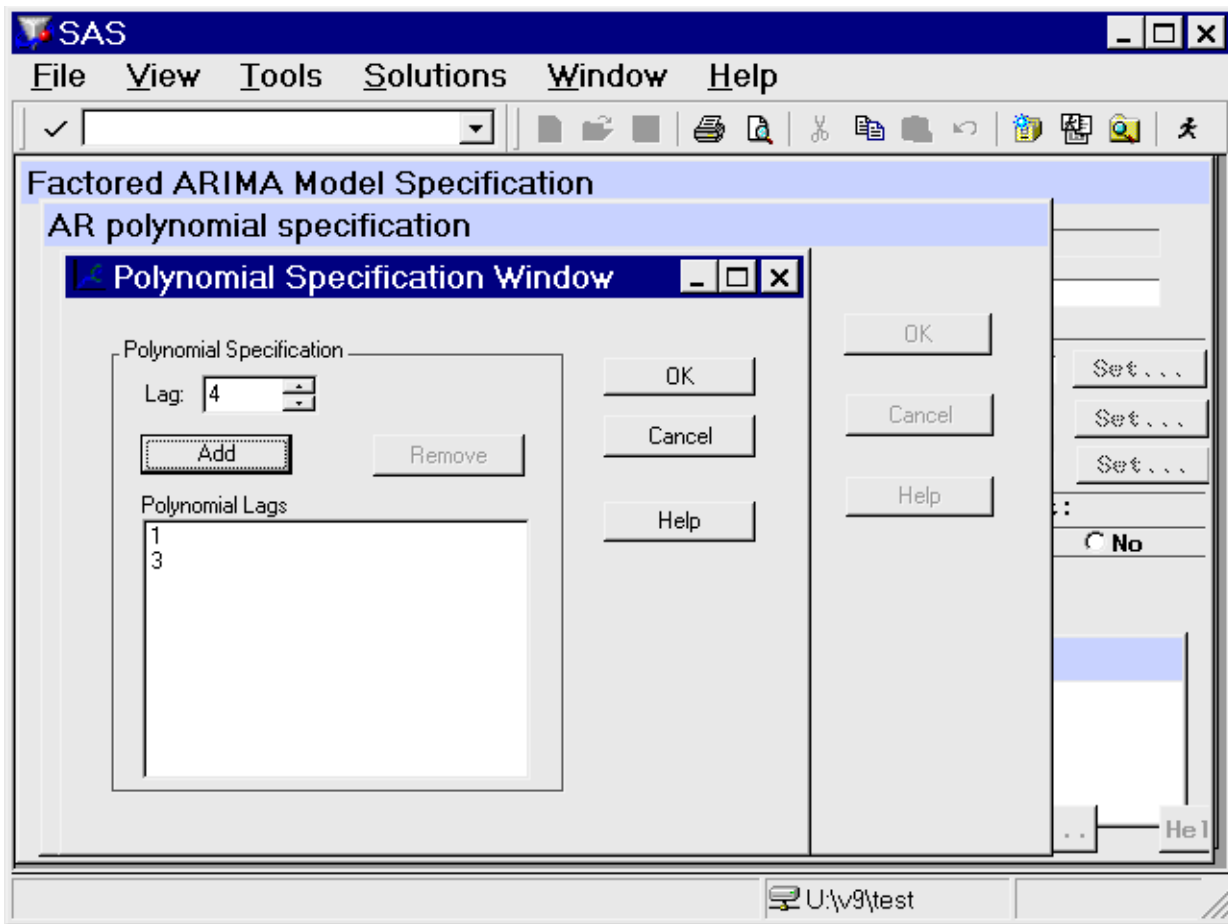

Figure 39.17 AR Polynomial Specification Window

To add AR polynomial terms, select the New button. This opens the Polynomial Specification Window, shown in Figure 39.18. Specify the first lag you want to include by using the Lag spin box, then select the Add button. Repeat this process, adding each lag you want to include in the current list. All lags must be specified. For example, if you add only lag 3, the model contains only lag 3, not 1 through 3.

As an example, add lags 1 and 3, then select the OK button. The AR Polynomial Specification Window now shows (1,3) in the list of polynomials. Now select “New” again. Add lags 6 and 12 and select “OK”. Now the AR Polynomial Specification Window shows (1,3) and (6,12) as shown in Figure 39.17. Select “OK” to close this window. The Factored ARIMA Model Specification Window now shows the factored model $p=(1, 3) (6, 12)$. Use the same technique to specify the q terms, or moving-average part of the model. There is no limit to the number of lags or the number of factors you can include in the model.

Figure 39.18 Polynomial Specification Window

To specify differencing lags, select the middle Set button to open the Differencing Specification window. Specify lags using the spin box and add them to the list with the Add button. When you select “OK” to close the window, the differencing lags appear after $d=$ in the Factored ARIMA Specification Window, within a single pair of parentheses.

You can use the Factored ARIMA Model Specification Window to specify any model that you can specify with the ARIMA Model and Custom Model windows, but the notation is more similar to that of the ARIMA procedure (see Chapter 7, “[The ARIMA Procedure](#)”). Consider as an example the classic Airline model fit to the International Airline Travel series, `SASHELP.AIR`. This is a factored model with one moving-average term at lag one and one moving-average term at the seasonal lag, with first-order differencing at the simple and seasonal lags. Using the ARIMA Model Specification Window, you specify the value 1 for the q and d terms and also for the Q and D terms, which represent the seasonal lags. For monthly data, the seasonal lags represent lag 12, since a yearly seasonal cycle is assumed.

By contrast, the Factored ARIMA Model Specification Window makes no assumptions about seasonal cycles. The Airline model is written as `IMA d=(1,12) q=(1)(12) NOINT`. To specify the differencing terms, add the values 1 and 12 in the Differencing Specification Window and select OK. Then select “New” in the MA Polynomial Specification Window, add the value 1, and select OK. To add the factored term, select “New” again, add the value 12, and select OK. Remember to

select “No” in the Intercept radio box, since it is not selected by default. Select OK to close the Factored ARIMA Model Specification Window and fit the model.

You can show that the results are the same as they are when you specify the model by using the ARIMA Model Specification Window and when you select Airline Model from the default model list. If you are familiar with the ARIMA Procedure (Chapter 7, “[The ARIMA Procedure](#)”), you might want to turn on the `Show Source Statements` option before fitting the model, then examine the procedure source statements in the log window after fitting the model.

The strength of the Factored ARIMA Specification approach lies in its ability to construct unusual ARIMA models, such as:

Subset models

These are models of order n , where fewer than n lags are specified. For example, an AR order 3 model might include lags 1 and 3 but not lag 2.

Unusual seasonal cycles

For example, a monthly series might cycle two or four times per year instead of just once.

Multiple cycles

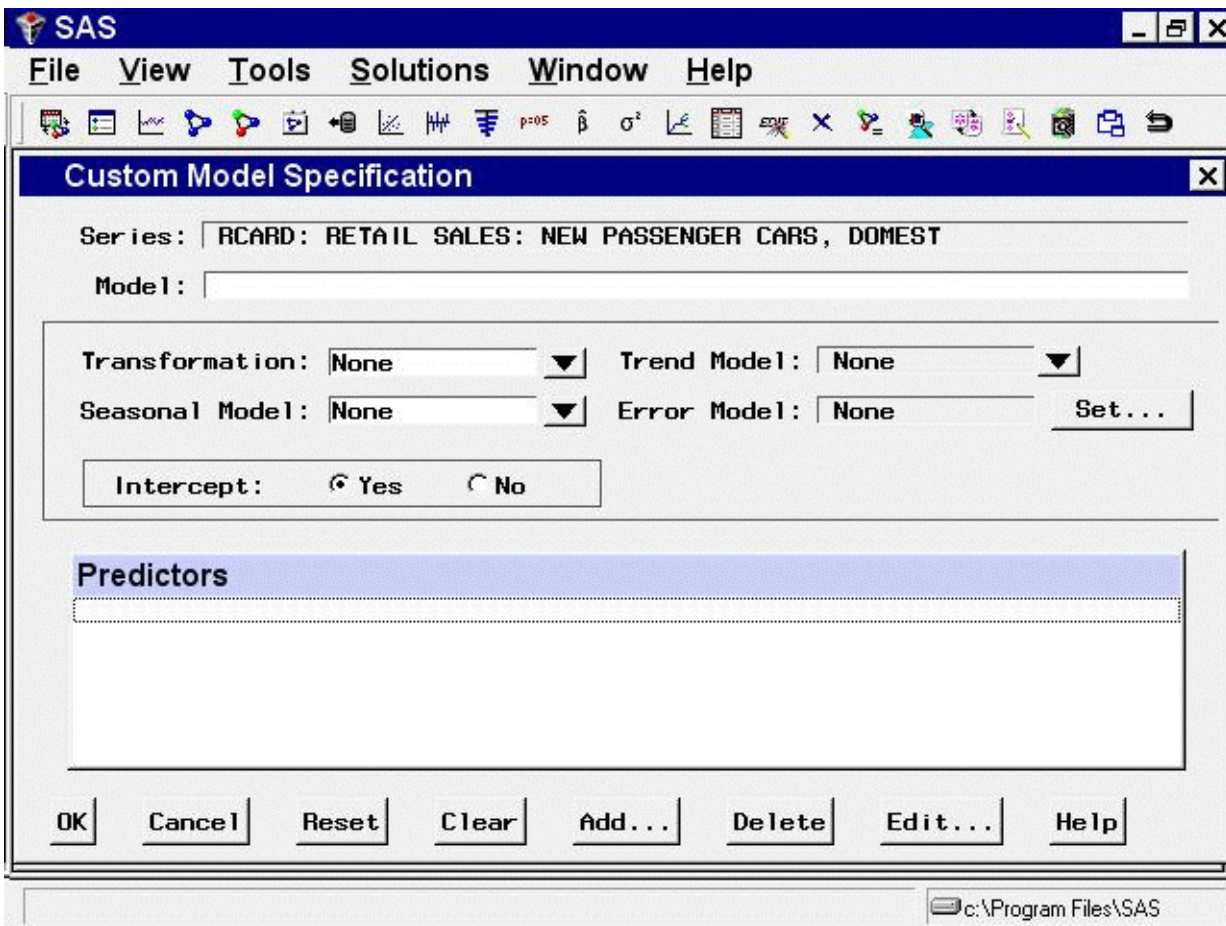

For example, a daily sales series might peak on a certain day each week and also once a year at the Christmas season. Given sufficient data, you can fit a three-factor model, such as $IMA\ d=(1)\ q=(1)\ (7)\ (365)$.

Models with high order lags take longer to fit and often fail to converge. To save time, select the Conditional Least Squares or Unconditional Least Squares estimation method (see [Figure 39.16](#)). Once you have narrowed down the list of candidate models, change to the Maximum Likelihood estimation method.

Custom Model Specification Window

To fit a custom time series model not already provided in the Models to Fit window, select the Custom Model item from the pop-up menu, toolbar, or Edit menu. This opens the Custom Model Specification window, as shown in [Figure 39.19](#).

Figure 39.19 Custom Model Specification Window

You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you might find one more convenient than the other.

At the top of the Custom Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Custom Model Specification window consists of four fields: Transformation, Trend Model, Seasonal Model, and Error Model. These fields allow you to specify the model in four parts. Each part specifies how a different aspect of the pattern of the time series is modeled and predicted.

The Predictors list at the bottom of the Custom Model Specification window allows you to include different kinds of predictor variables in the forecasting model. The Predictors feature for the Custom Model Specification window is like the Predictors feature for the ARIMA Model Specification window, except that time trend predictors are provided through the Trend Model field and seasonal dummy variable predictors are provided through the Seasonal Model field.

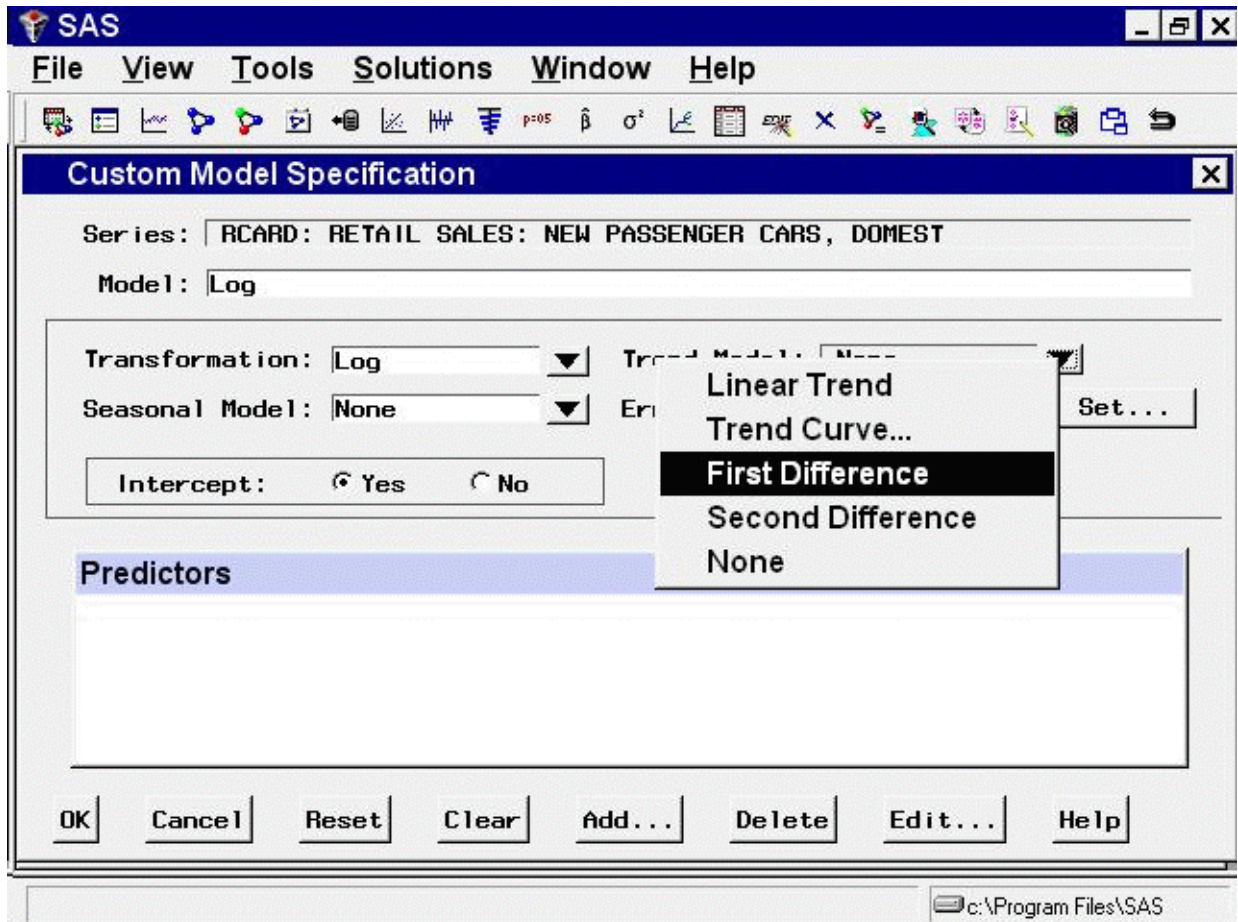

To illustrate how to use the Custom Model Specification window, the following example specifies

the same model you fit by using the ARIMA Model Specification window.

First, specify the data transformation to use. Select “Log” using the Transformation combo box.

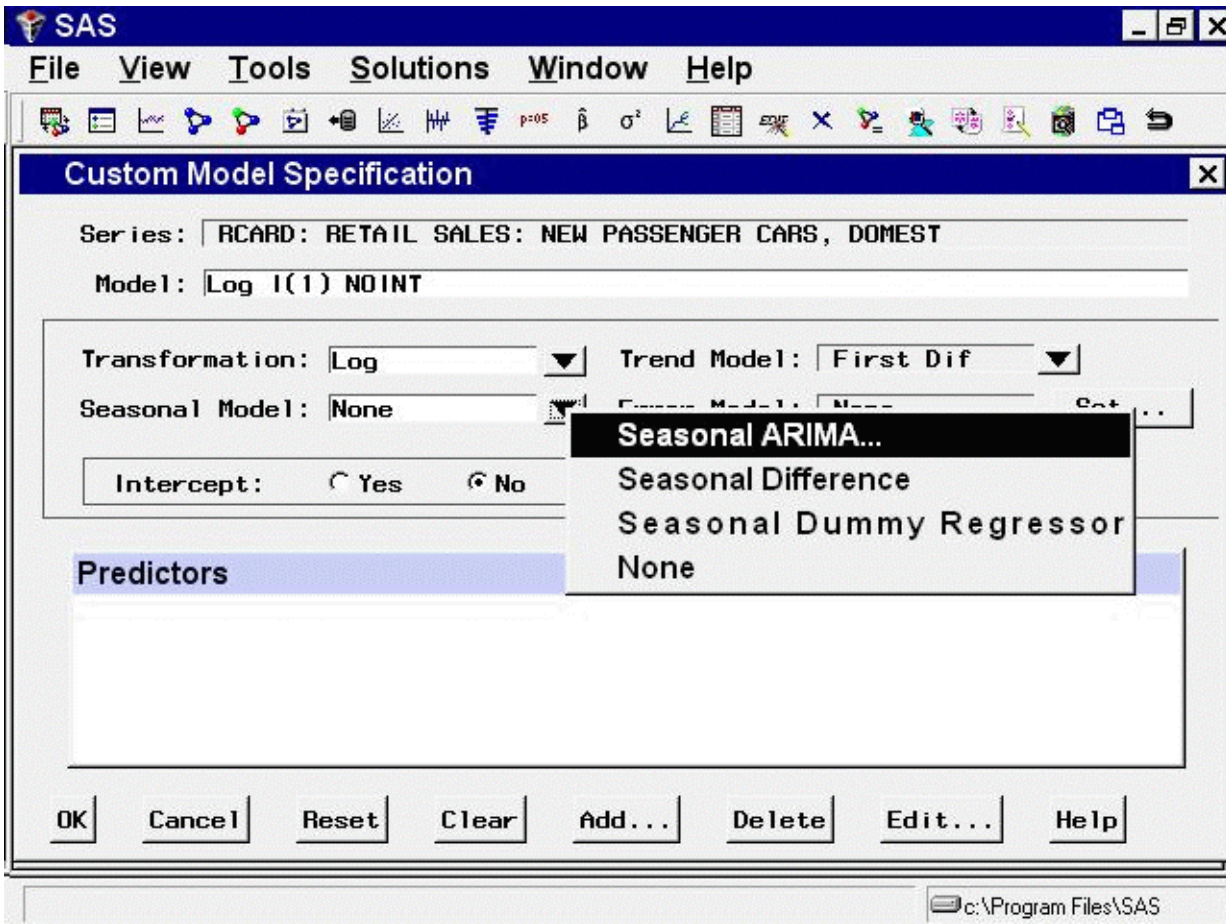

Second, specify how to model the trend in the series. Select **First Difference in the Trend Model** combo box, as shown in [Figure 39.20](#).

Figure 39.20 Trend Model Options

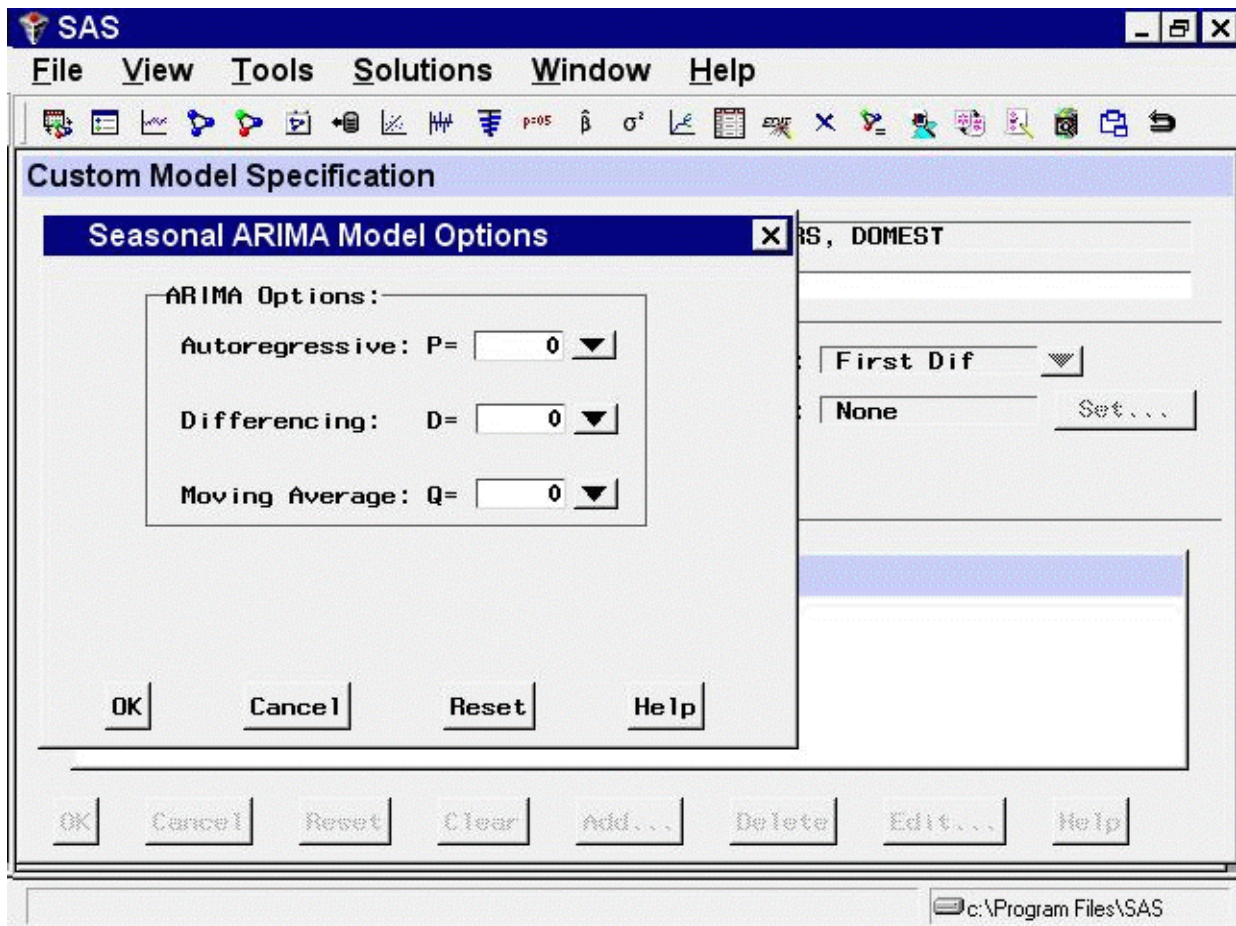

Next, specify how to model the seasonal pattern in the series. Select “Seasonal ARIMA” in the Seasonal Model combo box, as shown in [Figure 39.21](#).

Figure 39.21 Seasonal Model Options

This opens the Seasonal ARIMA Model Options window, as shown in [Figure 39.22](#).

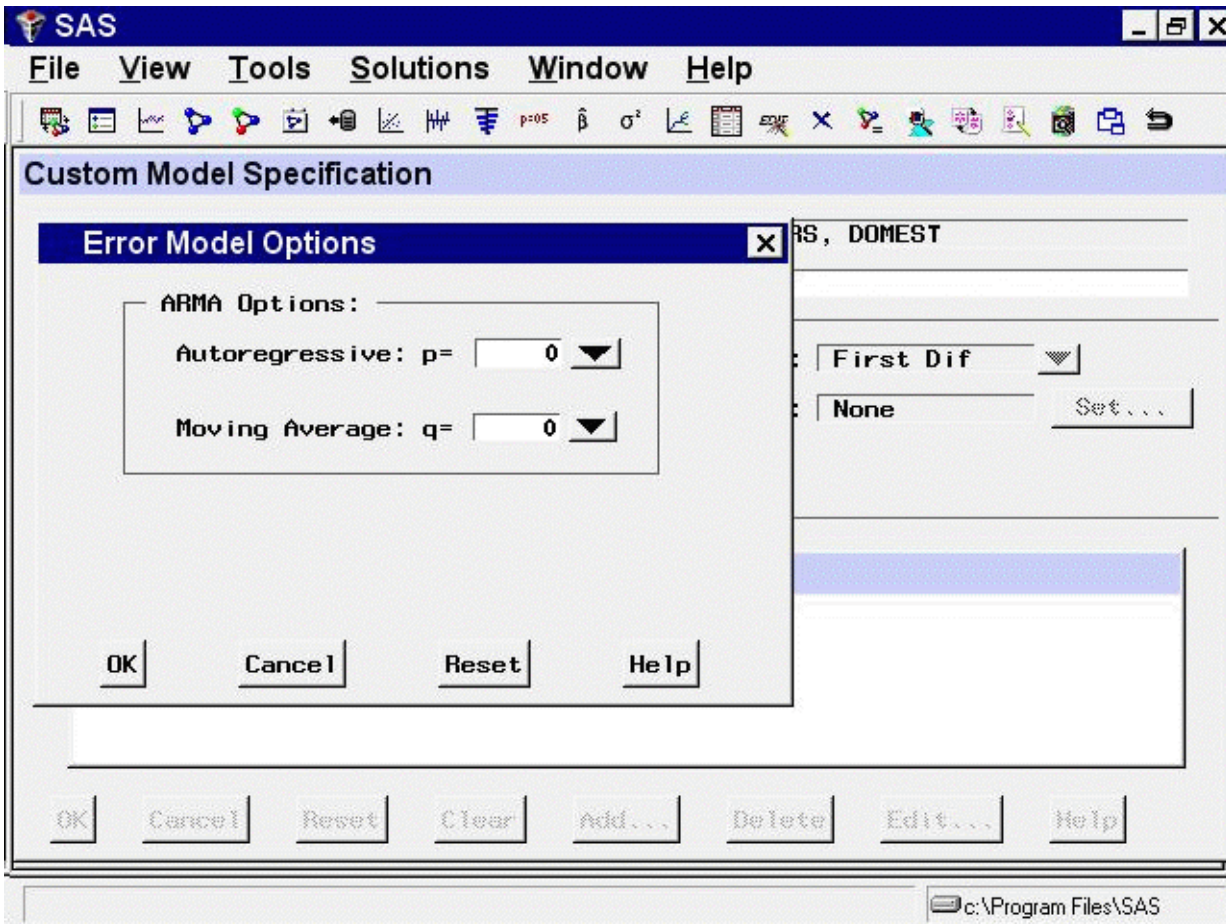

Figure 39.22 Seasonal ARIMA Model Options

Specify a first-order seasonal moving-average term by typing 1 or by selecting “1” from the Moving Average: Q= combo box pop-up menu, and then select the OK button.

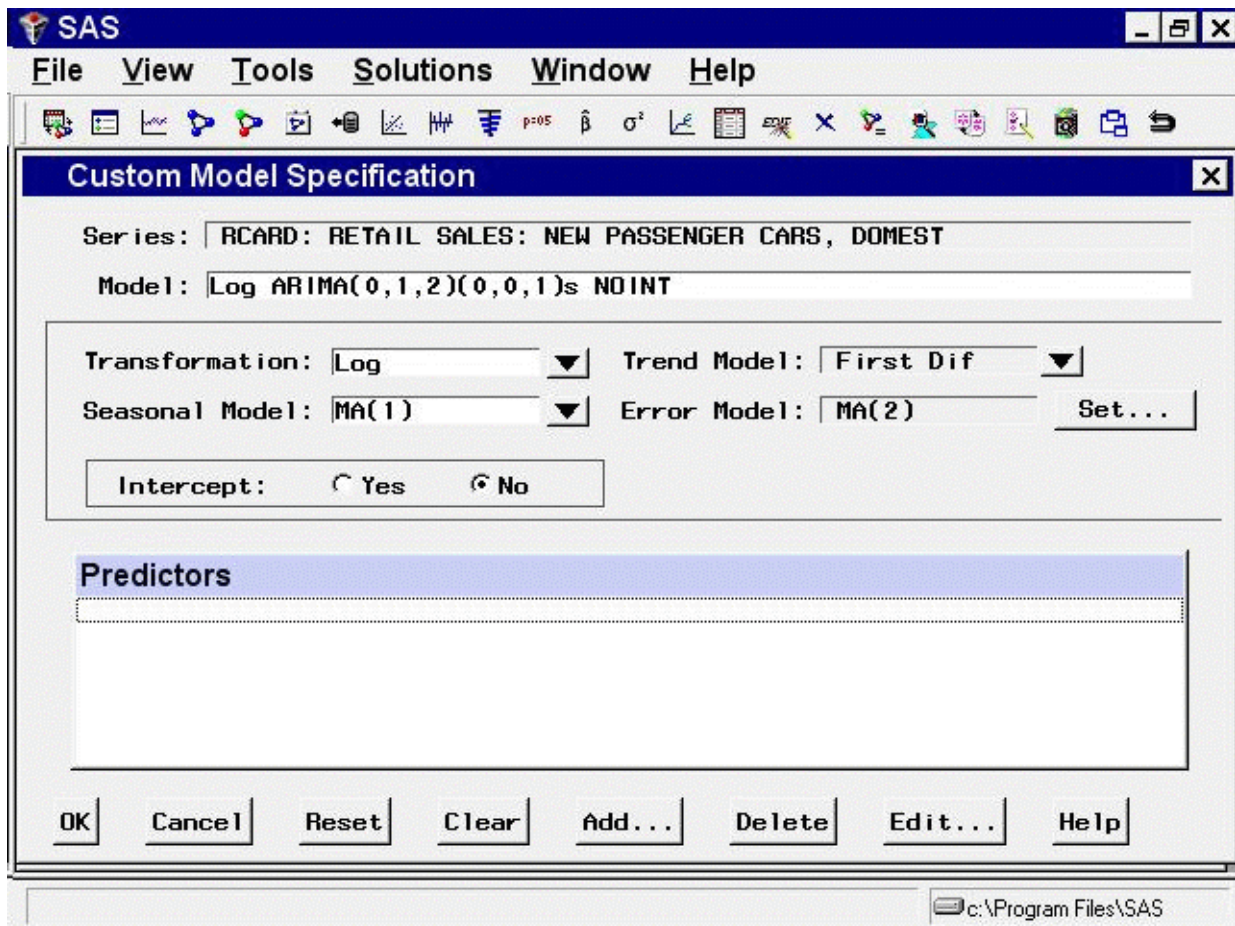

Finally, specify how to model the autocorrelation pattern in the model prediction errors. Select the Set button to the right of the Error Model field. This opens the Error Model Options window, as shown in Figure 39.23. This window allows you to specify an ARMA error process. Set the Moving Average order q to 2, and then select the OK button.

Figure 39.23 Error Model Options

The Custom Model Specification window should now appear as shown in [Figure 39.24](#). The model label at the top of the Custom Model Specification window should now read `Log ARIMA(0,1,2)(0,0,1)s NOINT`, just as it did when you used the ARIMA Model Specification window.

Figure 39.24 Log ARIMA(0,1,2)(0,0,1)s Specified

Now that you have seen how the Custom Model Specification window works, select “Cancel” to exit the window without fitting the model. This should return you to the Develop Models window.

Editing the Model Selection List

Now that you know how to specify new models that are not included in the system default model selection list, you can edit the model selection list to add models that you expect to use in the future or to delete models that you do not expect to use. When you save the forecasting project to a SAS catalog, the edited model selection list is saved with the project file, and the list is restored when you load the project.

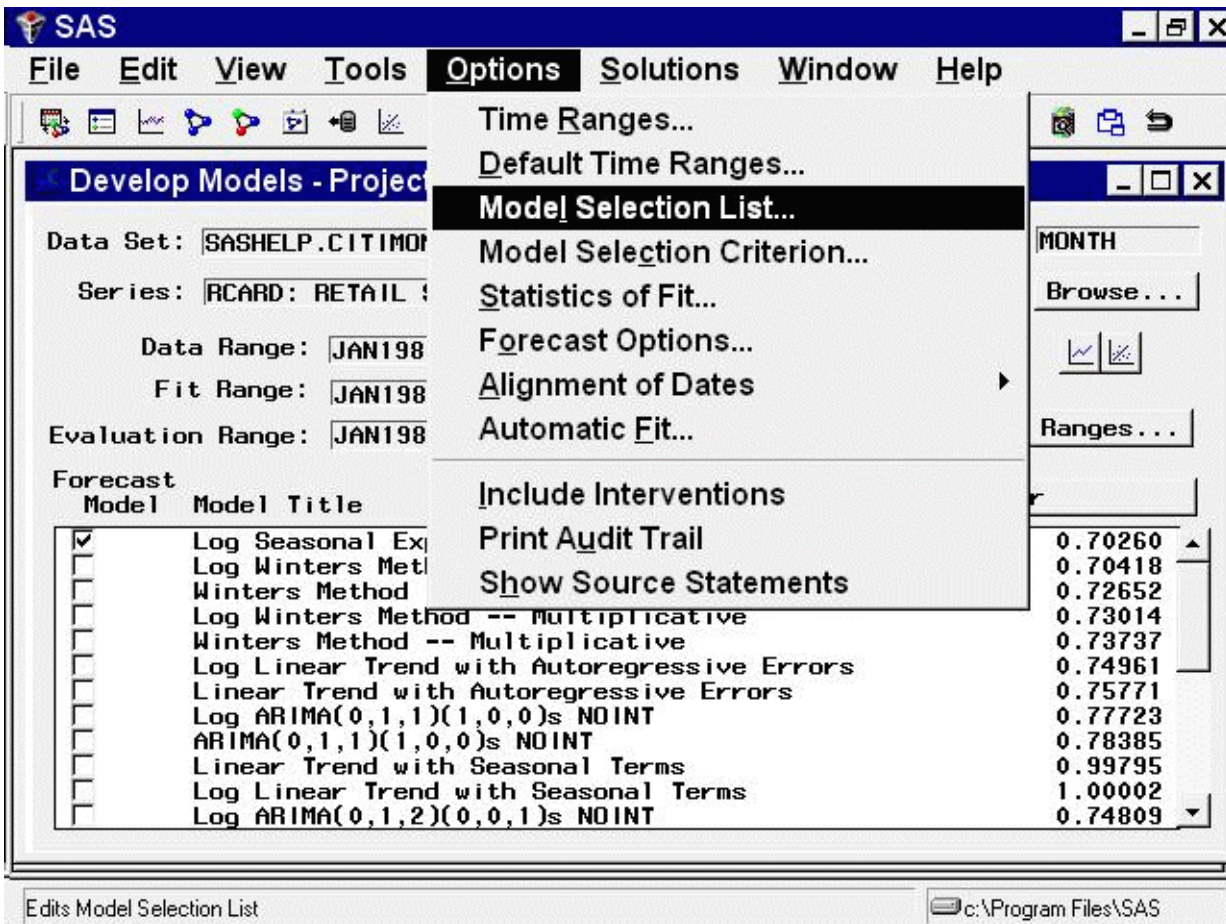

There are two reasons why you would add a model to the model selection list. First, by adding the model to the list, you can fit the model to different time series by selecting it through the `Fit Models from List` action. You do not need to specify the model again every time you use it.

Second, once the model is added to the model selection list, it is available to the automatic model

selection process. The model is then considered automatically whenever you use the automatic model selection feature for any series.

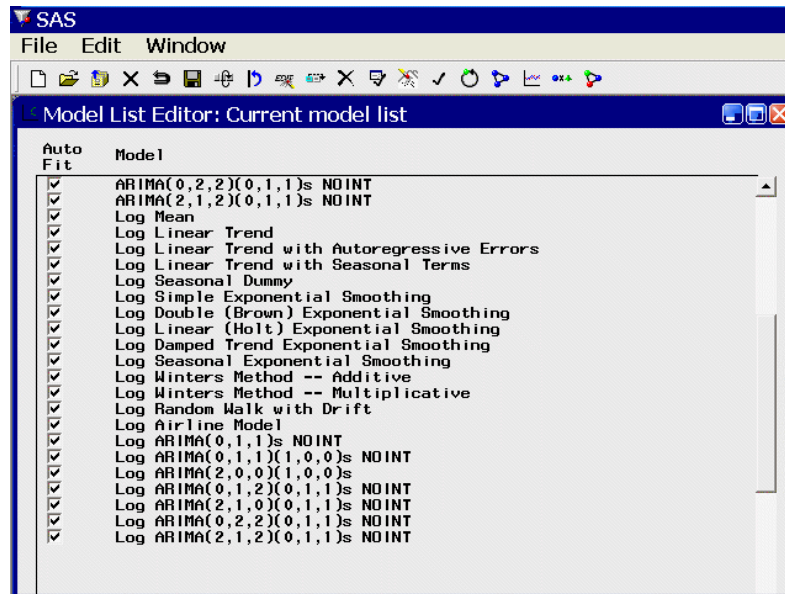

To edit the model selection list, select “Model Selection List” from the Options menu as shown in Figure 39.25, or select the Edit Model List toolbar icon.

Figure 39.25 Model Selection List Option

This selection brings up the Model Selection List editor window, as shown in Figure 39.26. This window consists of the model selection list and an “Auto Fit” column, which controls for each model whether the model is included in the list of models used by the automatic model selection process.

Figure 39.26 Model Selection List Window

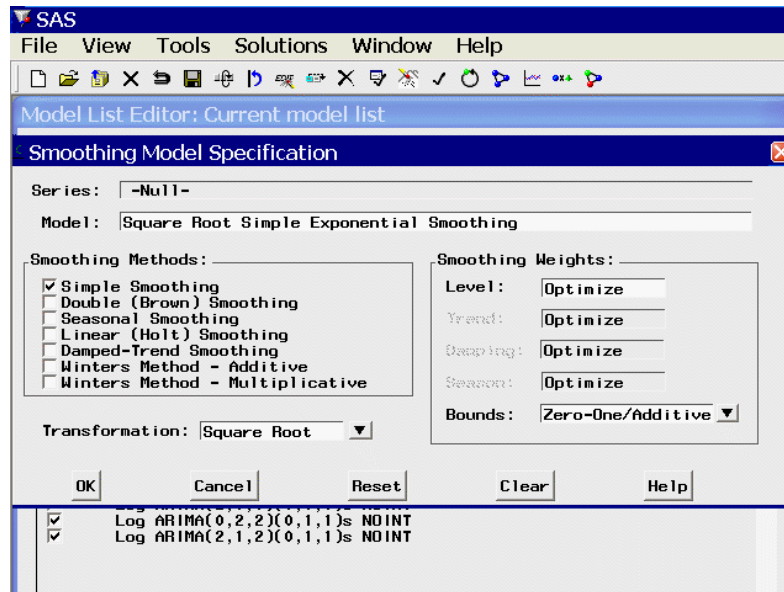

To add a model to the list, select “Add Model” from the Edit menu and then select “Smoothing Model,” “ARIMA Model,” “Factored ARIMA Model,” or “Custom Model” from the submenu. Alternatively, click the corresponding icon on the toolbar.

As an example, select “Smoothing Model.” This brings up the Smoothing Model Specification window. Note that the series name is “-Null-.” This means that you are not specifying a model to be fit to a particular series, but are specifying a model to be added to the selection list for later reference.

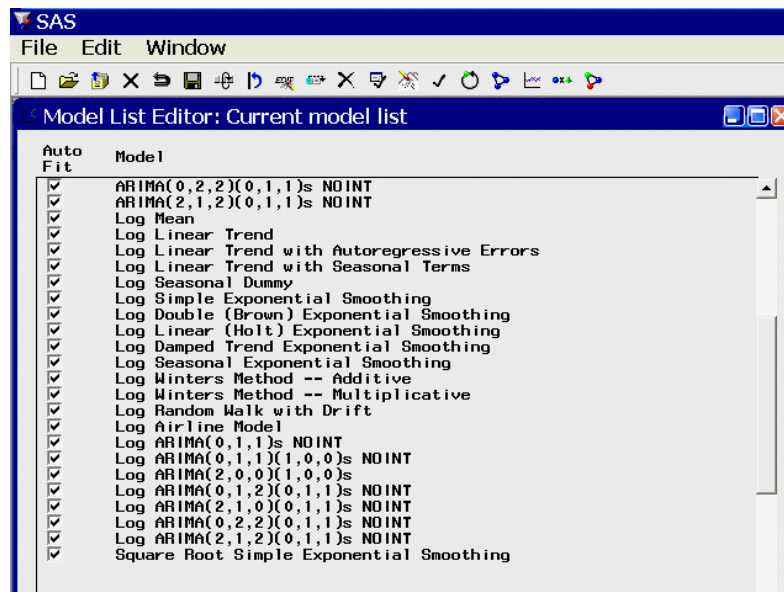

Specify a smoothing model. For example, select “Simple Smoothing” and then select the Square Root transformation. The window appears as shown in [Figure 39.27](#).

Figure 39.27 Adding a Model Specification

Select the OK button to add the model to the end of the model selection list and return you to the Model Selection List window, as shown in Figure 39.28. You can now select the Fit Models from List model-fitting option to use the edited selection list.

Figure 39.28 Model Added to Selection List

If you want to delete one or more models from the list, select the model labels to highlight them in the list. Click a second time to clear a selected model. Then select “Delete” from the Edit pull-down menu, or the corresponding toolbar icon. As an example, delete the Square Root Simple Exponential Smoothing model that you just added.

The Model Selection List editor window gives you a lot of flexibility for managing multiple model lists, as explained in the section “[Model Selection List Editor Window](#)” on page 2611. For example, you can create your own model lists from scratch or modify or combine previously saved model lists and those provided with the software, and you can save them and designate one as the default for future projects.

Now select “Close” from the File menu (or the Close icon) to close the Model Selection List editor window.

Forecast Combination Model Specification Window

Once you have fit several forecasting models to a series, you face the question of which model to use to produce the final forecasts. One possible answer is to combine or average the forecasts from several models. Combining the predictions from several different forecasting methods is a popular approach to forecasting.

The way that you produce forecast combinations with the Time Series Forecasting System is to use the Forecast Combination Model Specification window to specify a new forecasting model that performs the averaging of forecasts from the models you want to combine. This new model is added to the list of fitted models just like other models. You can then use the Model Viewer window features and Model Fit Comparison window features to examine the fit of the combined model.

To specify a forecast combination model, select “Combine Forecasts” from the pop-up menu or toolbar, or select “Edit” and “Fit Model” from the menu bar. This brings up the Forecast Combination Model Specification window, as shown in [Figure 39.29](#).

Figure 39.29 Forecast Combination Window

At the top of the Forecast Combination window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Forecast Combination window consists of the list of models that you have fit to the series. This table shows the label and goodness-of-fit measure for each model and the combining weight assigned to the model.

The `Weight` column controls how much weight is given to each model in the combined forecasts. A missing weight means that the model is not used. Initially, all the models have missing weight values.

You can enter the weight values you want to use in the `Weight` column. Alternatively, you can select models from the `Model Description` column, and weight values for the models you select are set automatically. To remove a model from the combination, select it again. This resets its weight value to missing.

At the bottom of the Forecast Combination window are two buttons: `Normalize Weights` and `Fit Regression Weights`. The `Normalize Weights` button adjusts the nonmissing weight values so that they sum to one. The `Fit Regression Weights` button uses linear regression to compute the

weight values that produce the combination of model predictions with the best fit to the series.

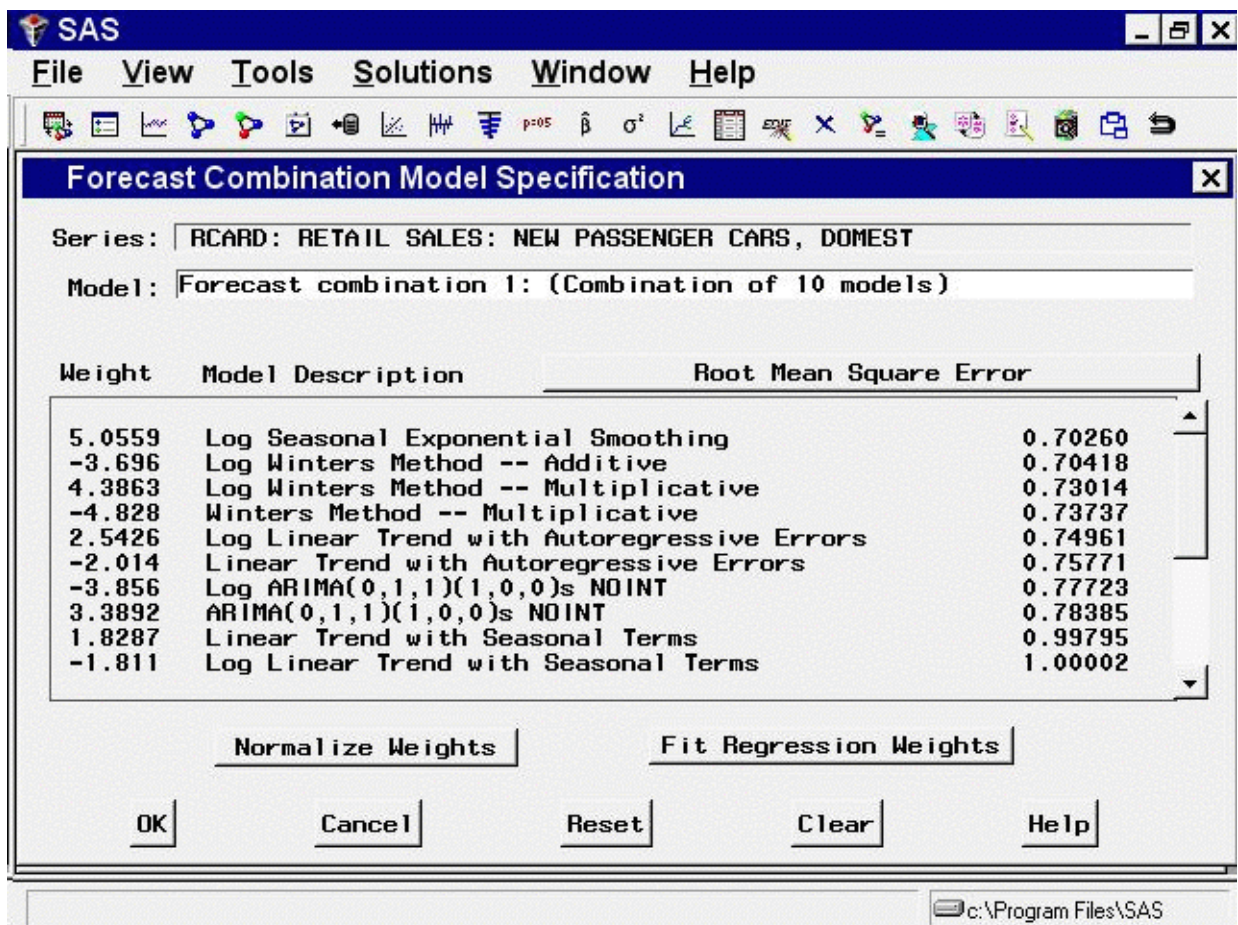

If no models are selected, the Fit Regression Weights button fits weights for all the models in the list. You can compute regression weights for only some of the models by first selecting the models you want to combine and then selecting Fit Regression Weights. In this case, only the nonmissing Weight values are replaced with regression weights.

As an example of how to combine forecasting models, select all the models in the list. After you have finished selecting the models, all the models in the list should now have equal weight values, which implies a simple average of the forecasts.

Now select the Fit Regression Weights button. The system performs a linear regression of the series on the predictions from the models with nonmissing weight values and replaces the weight values with the estimated regression coefficients. These are the combining weights that produce the smallest mean square prediction error within the sample.

The Forecast Combination window should now appear as shown in [Figure 39.30](#). (Note that some of the regression weight values are negative.)

Figure 39.30 Combining Models

Select the OK button to fit the combined model. Now the Develop Models window shows this model to be the best fitting according to the root mean square error, as shown in [Figure 39.31](#).

Figure 39.31 Develop Models Window Showing All Models Fit

Notice that the combined model has a smaller root mean square error than any one of the models included in the combination. The confidence limits for forecast combinations are produced by taking a weighted average of the mean square prediction errors for the component forecasts, ignoring the covariance between the prediction errors.

Incorporating Forecasts from Other Sources

You might have forecasts from other sources that you want to include in the forecasting process. Examples of other forecasts you might want to use are “best guess” forecasts based on personal judgments, forecasts produced by government agencies or commercial forecasting services, planning scenarios, and reference or “base line” projections. Because such forecasts are produced externally to the Time Series Forecasting System, they are referred to as external forecasts.

You can include external forecasts in combination models to produce compromise forecasts that split the difference between the external forecast and forecasting models that you fit. You can use external forecasts to compare them to the forecasts from models that are fit by the system.

To include external forecasts in the Time Series Forecasting process, you must first supply the external forecast as a variable in the input data set. You then specify a special kind of forecasting “model” whose predictions are identical to the external forecast recorded in the data set.

As an example, suppose you have 12 months of sales data and five months of sales forecasts based on a consensus opinion of the sales staff. The following statements create a SAS data set containing made-up numbers for this situation.

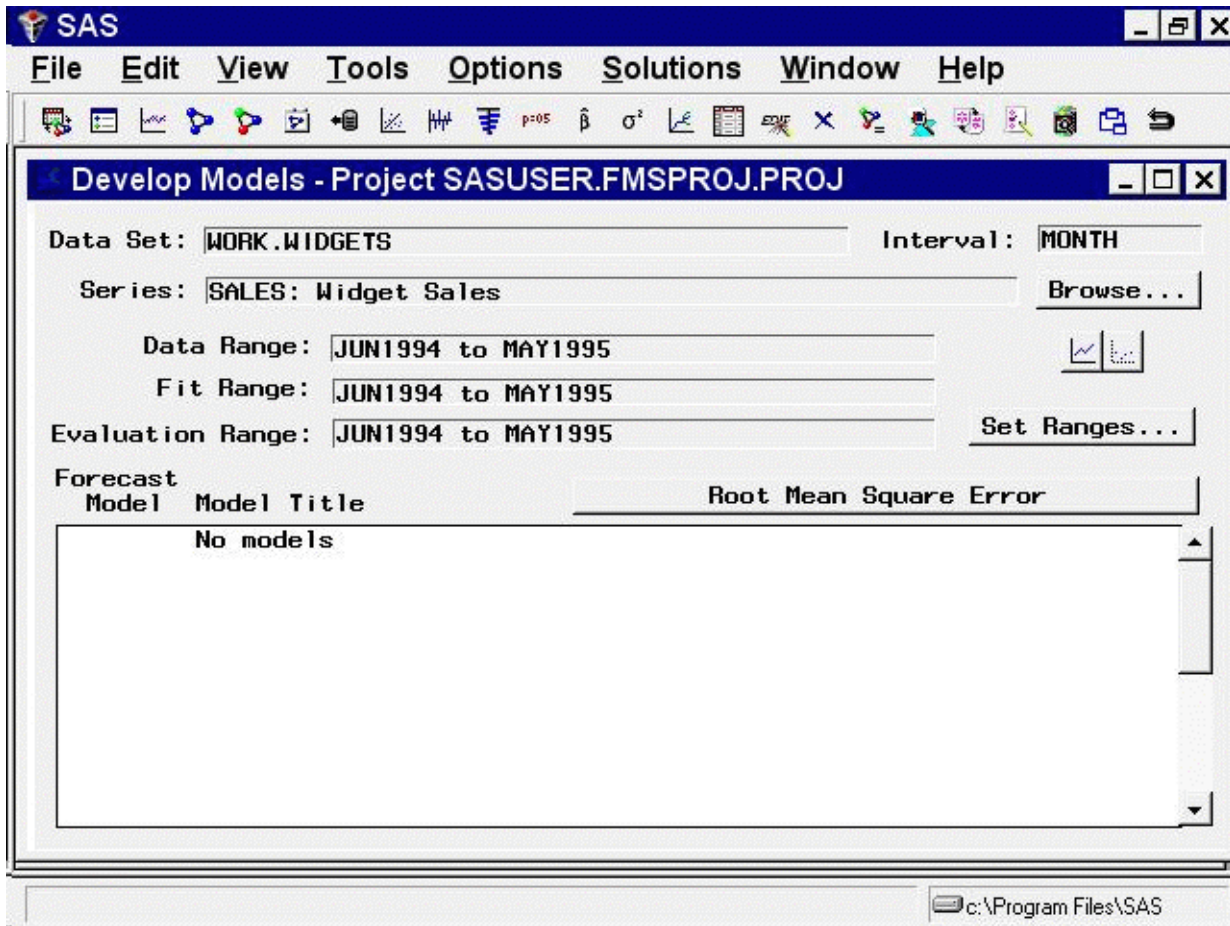

```

data widgets;
  input date monyy5. sales staff;
  format date monyy5.;
  label sales = "Widget Sales"
        staff = "Sales Staff Consensus Forecast";
  datalines;
jun94  142.1  .
jul94   139.6  .
aug94   145.0  .
sep94   150.2  .
oct94   151.1  .
nov94   154.3  .
dec94   158.7  .
jan95   155.9  .
feb95   159.2  .
mar95   160.8  .
apr95   162.0  .
may95   163.3  .
jun95    . 166.
jul95    . 168.
aug95    . 170.
sep95    . 171.
oct95    . 177.
run;

```

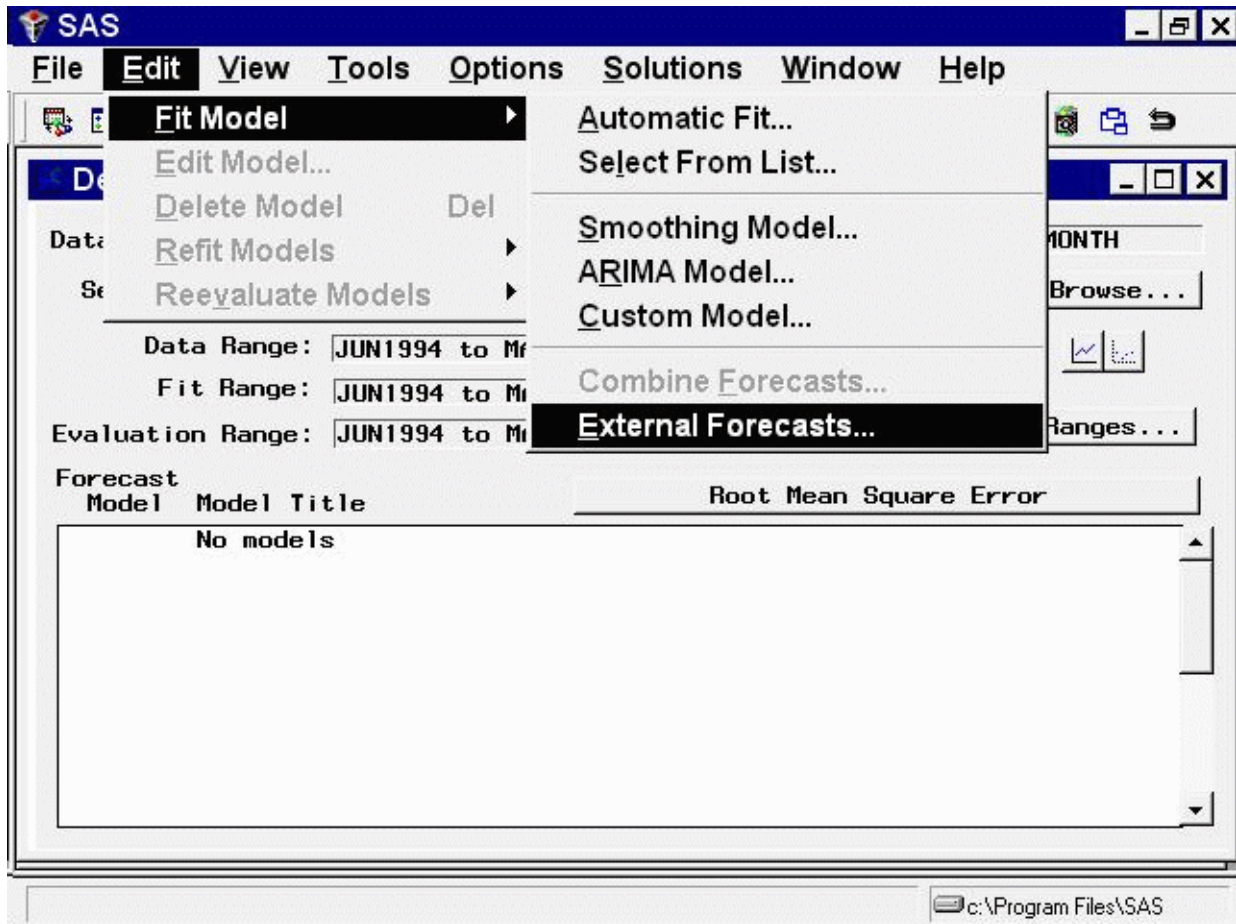

Submit the preceding statements in the SAS Program Editor window. From the Time Series Forecasting window, select “Develop Models.” In the Series Selection window, select the data set WORK.WIDGETS and the variable SALES. The Develop Models window should now appear as shown in [Figure 39.32](#).

Figure 39.32 Develop Models Window

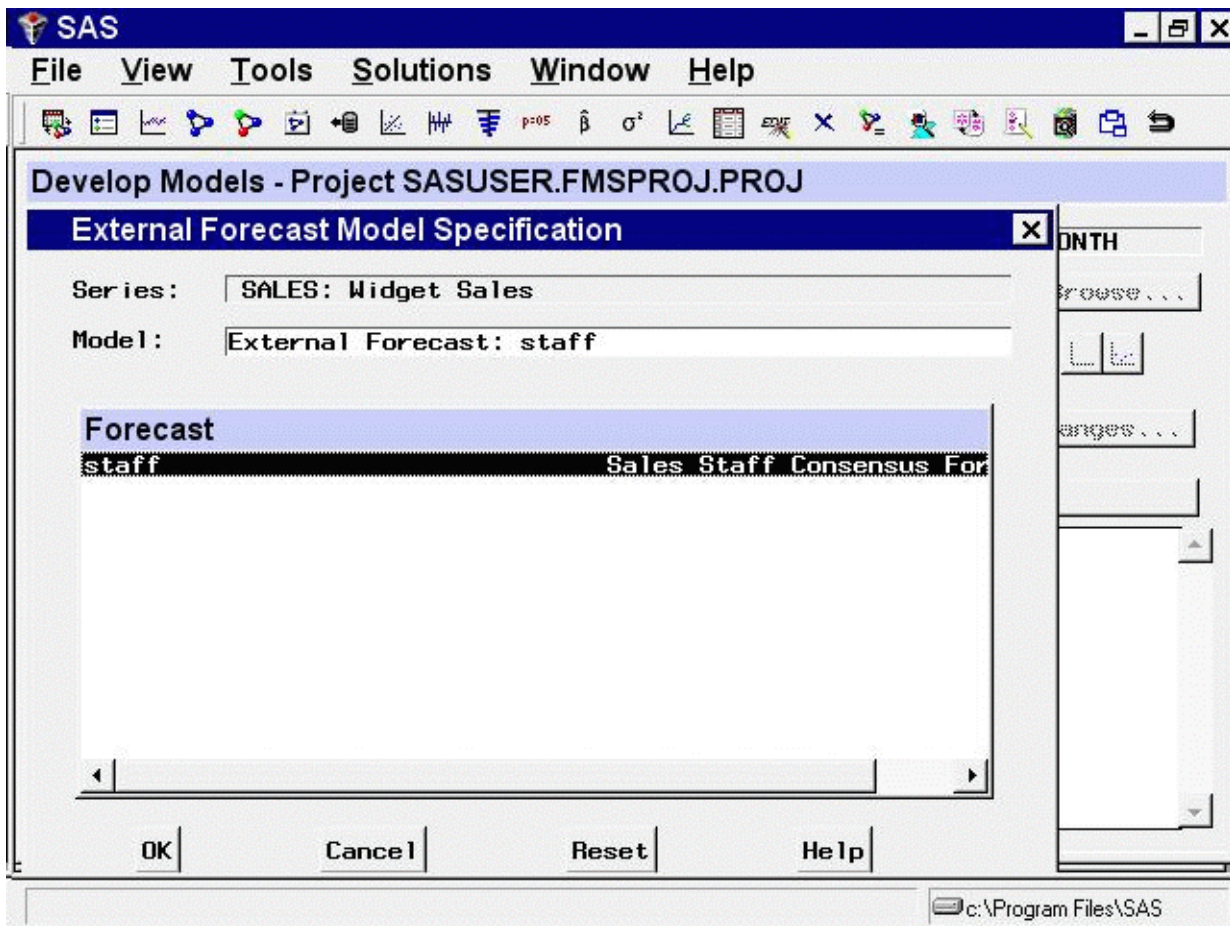

Now select “Edit,” “Fit Model,” and “External Forecasts” from the menu bar of the Develop Models window, as shown in [Figure 39.33](#), or the Use External Forecasts toolbar icon.

Figure 39.33 Adding a Model for an External Forecast Series

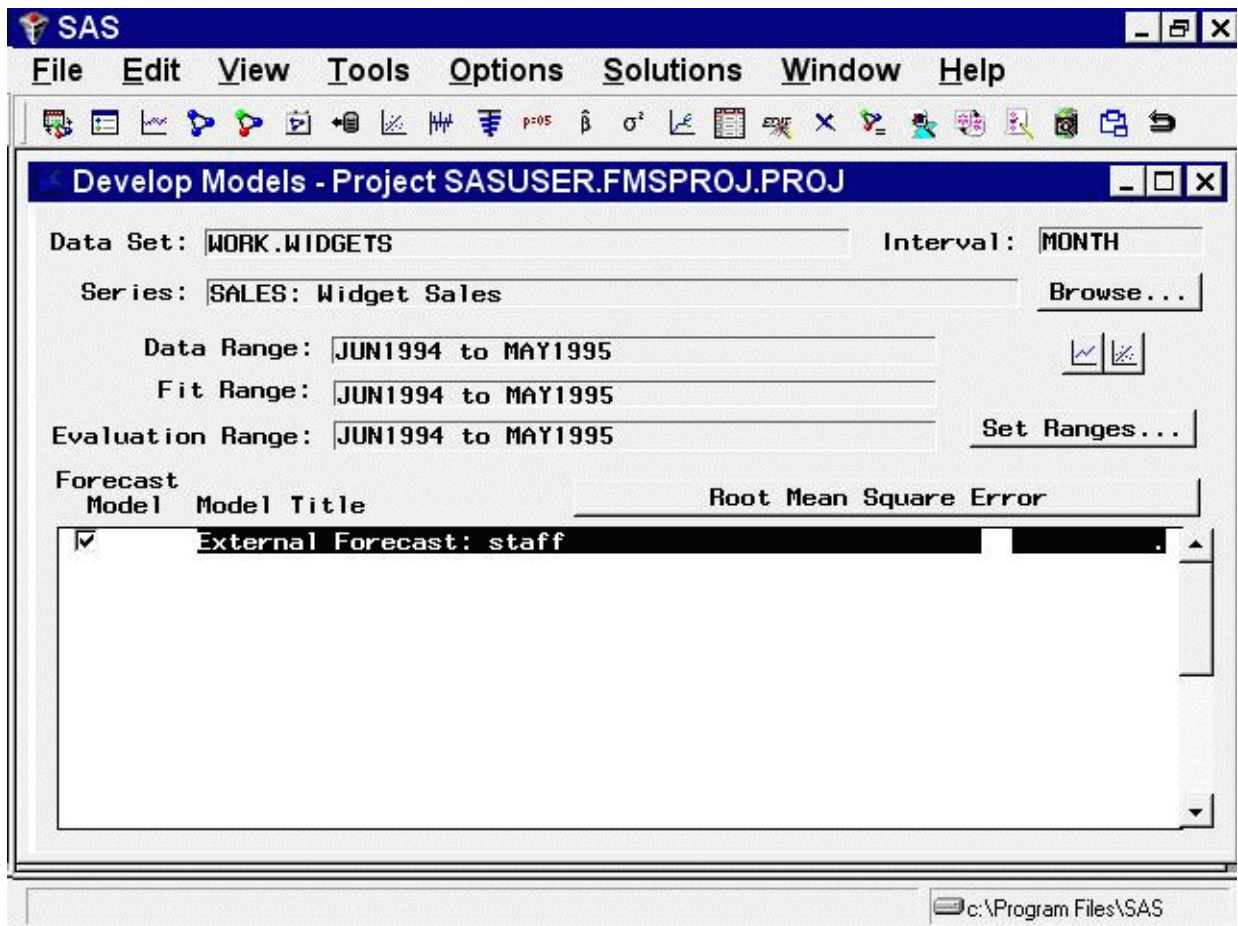

This selection opens the External Forecast Model Specification window. Select the STAFF variable as shown in Figure 39.34.

Figure 39.34 External Forecast Series Selected

Select the OK button. The external forecast model is now “fit” and added to the Develop Models list, as shown in Figure 39.35.

Figure 39.35 Model for External Forecast

You can now use this model for comparison with the predictions from other forecasting models that you fit, or you can include it in a forecast combination model.

Note that no fitting is actually performed for an external forecast model. The predictions of the external forecast model are simply the values of the external forecast series read from the input data set. The goodness-of-fit statistics for such models will depend on the values that the external forecast series contains for observations within the period of fit. In this case, no STAFF values are given for past periods, and therefore the fit statistics for the model are missing.

Chapter 40

Choosing the Best Forecasting Model

Using Hold-out Samples	2508

The Time Series Forecasting System provides a variety of tools for identifying potential forecasting models and for choosing the best fitting model. It allows you to decide how much control you want to have over the process, from a hands-on approach to one that is completely automated. This chapter begins with an exploration of the tools available through the Series Viewer and Model Viewer. It presents an example of identifying models graphically and exercising your knowledge of model properties. The remainder of the chapter shows you how to compare models by using a variety of statistics and by controlling the fit and evaluation time ranges. It concludes by showing you how to refit existing models and how to compare models using hold-out samples.

Time Series Viewer Features

The `Time Series Viewer` is a graphical tool for viewing and analyzing time series. It can be used separately from the `Time Series Forecasting System` by using the `TSVIEW` command or by selecting `Time Series Viewer` from the `Analysis` pull-down menu under `Solutions`.

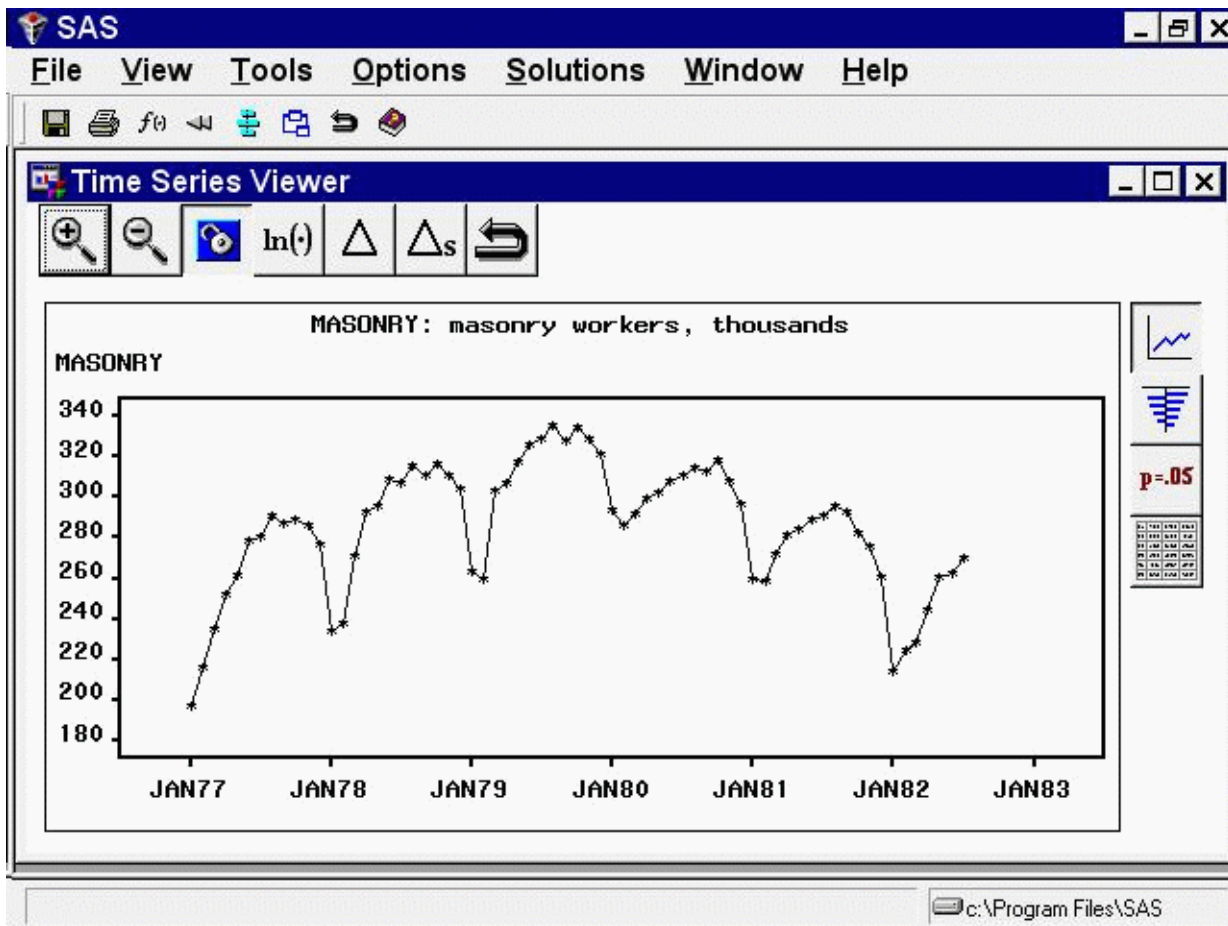

In this chapter you will use the `Time Series Viewer` to examine plots of your series before fitting models. Begin this example by invoking the Forecasting system and selecting the `View Series Graphically` button, as shown in [Figure 40.1](#), or the `View Series` toolbar icon.

Figure 40.1 Invoking the Time Series Viewer

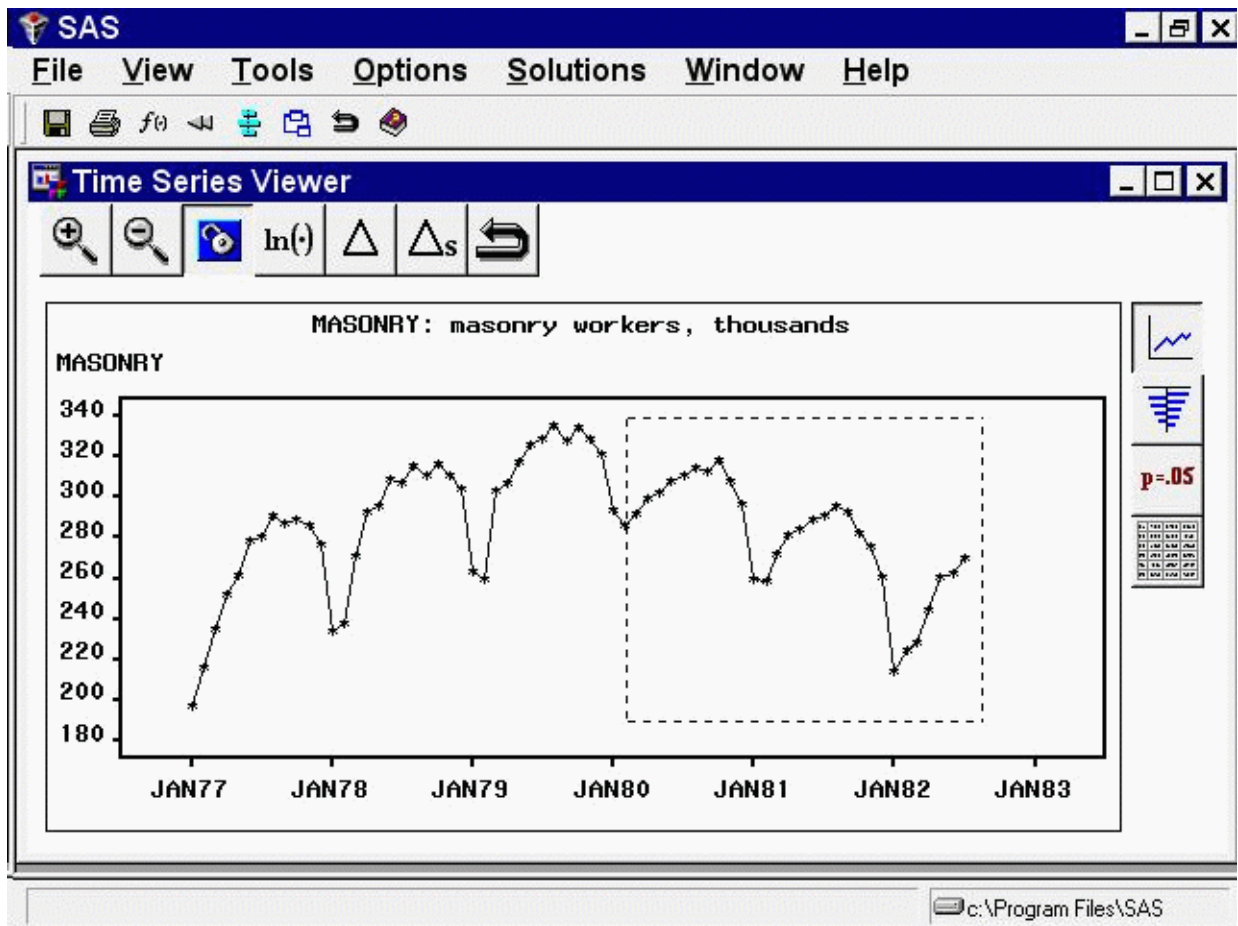

From the Series Selection window, select SASHELP as the library, WORKERS as the data set, and MASONRY as the time series, and then click the **Graph** button. The Time Series Viewer displays a plot of the series, as shown in [Figure 40.2](#).

Figure 40.2 Series Plot

Select the Zoom In icon, the first one on the window's horizontal toolbar. Notice that the mouse cursor changes shape and that "Note: Click on a corner of the region, then drag to the other corner" appears on the message line. Outline an area, as shown in Figure 40.3, by clicking the mouse at the upper-left corner, holding the button down, dragging to the lower-right corner, and releasing the button.

Figure 40.3 Selecting an Area for Zoom

The zoomed plot should appear as shown in [Figure 40.4](#).

Figure 40.4 Zoomed Plot

You can repeat the process to zoom in still further. To return to the previous view, select the Zoom Out icon, the second icon on the window's horizontal toolbar.

The third icon on the horizontal toolbar is used to link or unlink the viewer window. By default, the viewer is linked, meaning that it is automatically updated to reflect selection of a different time series. To see this, return to the Series Selection window by clicking on it or using the Window menu or Next Viewer toolbar icon. Select the Electric series in the Time Series Variables list box. Notice that the Time Series Viewer window is updated to show a plot of the ELECTRIC series. Select the Link/Unlink icon if you prefer to unlink the viewer so that it is not automatically updated in this way. Successive selections toggle between the linked and unlinked state. A note on the message line informs you of the state of the Time Series Viewer window.

When a Time Series Viewer window is linked, selecting View Series again makes the linked Viewer window active. When no Time Series Viewer window is linked, selecting View Series opens an additional Time Series Viewer window. You can bring up as many Time Series Viewer windows as you want.

Having seen the plot in Figure 40.2, you might suspect that the series is nonstationary and seasonal. You can gain further insight into this by examining the sample autocorrelation function (ACF), partial autocorrelation function (PACF), and inverse autocorrelation function (IACF) plots. To switch

the display to the autocorrelation plots, select the second icon from the top on the vertical toolbar at the right side of the Time Series Viewer. The plot appears as shown in [Figure 40.5](#).

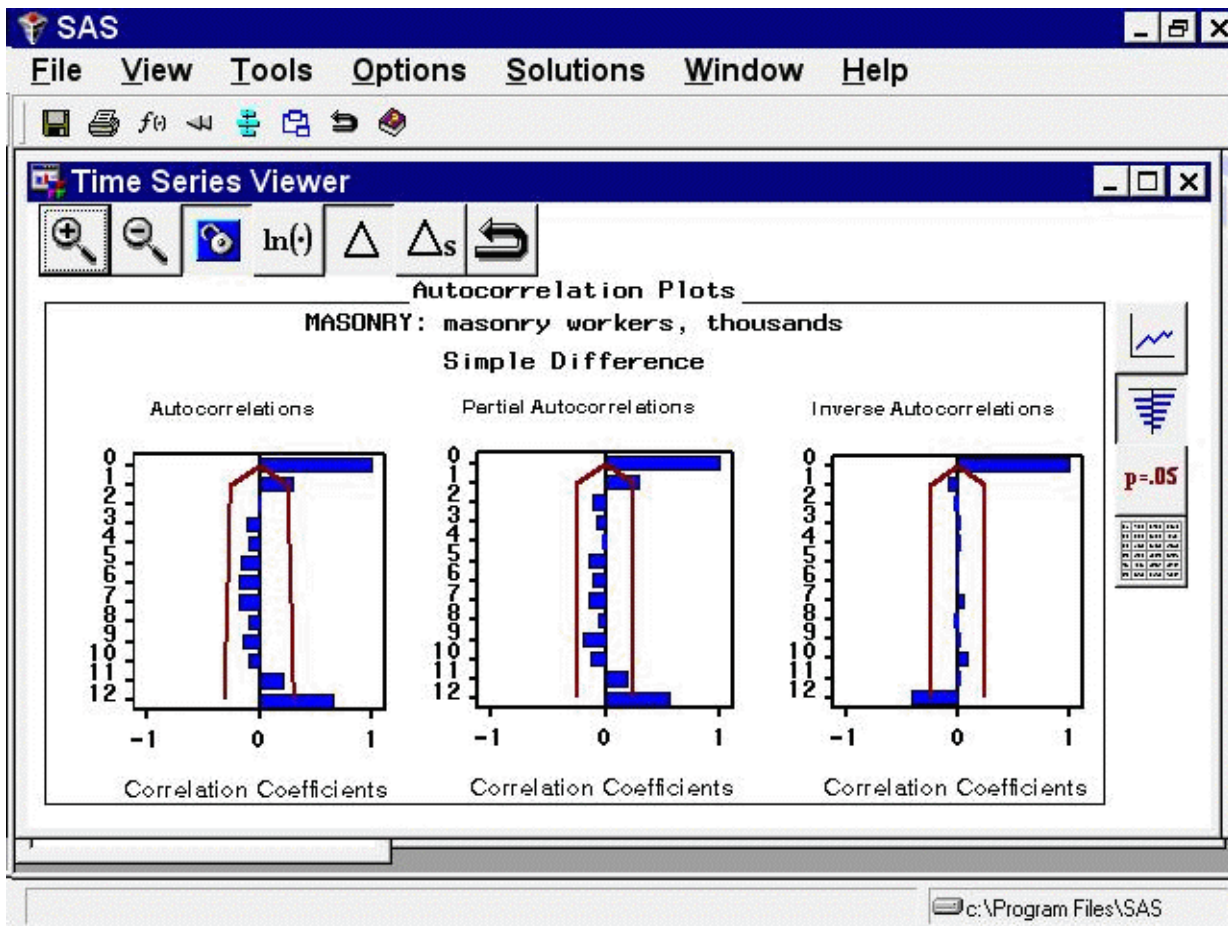

Figure 40.5 Sample Autocorrelation Plots

Each bar represents the value of the correlation coefficient at the given lag. The overlaid lines represent confidence limits computed at plus and minus two standard errors. You can switch the graphs to show significance probabilities by selecting *Correlation Probabilities* under the *Options* pull-down menu, or by selecting the *Toggle ACF Probabilities* toolbar icon.

The slow decline of the ACF suggests that first differencing might be warranted. To see the effect of first differencing, select the simple difference icon, the fifth icon from the left on the window's horizontal toolbar. The plot now appears as shown in [Figure 40.6](#).

Figure 40.6 ACF Plots with First Difference Applied

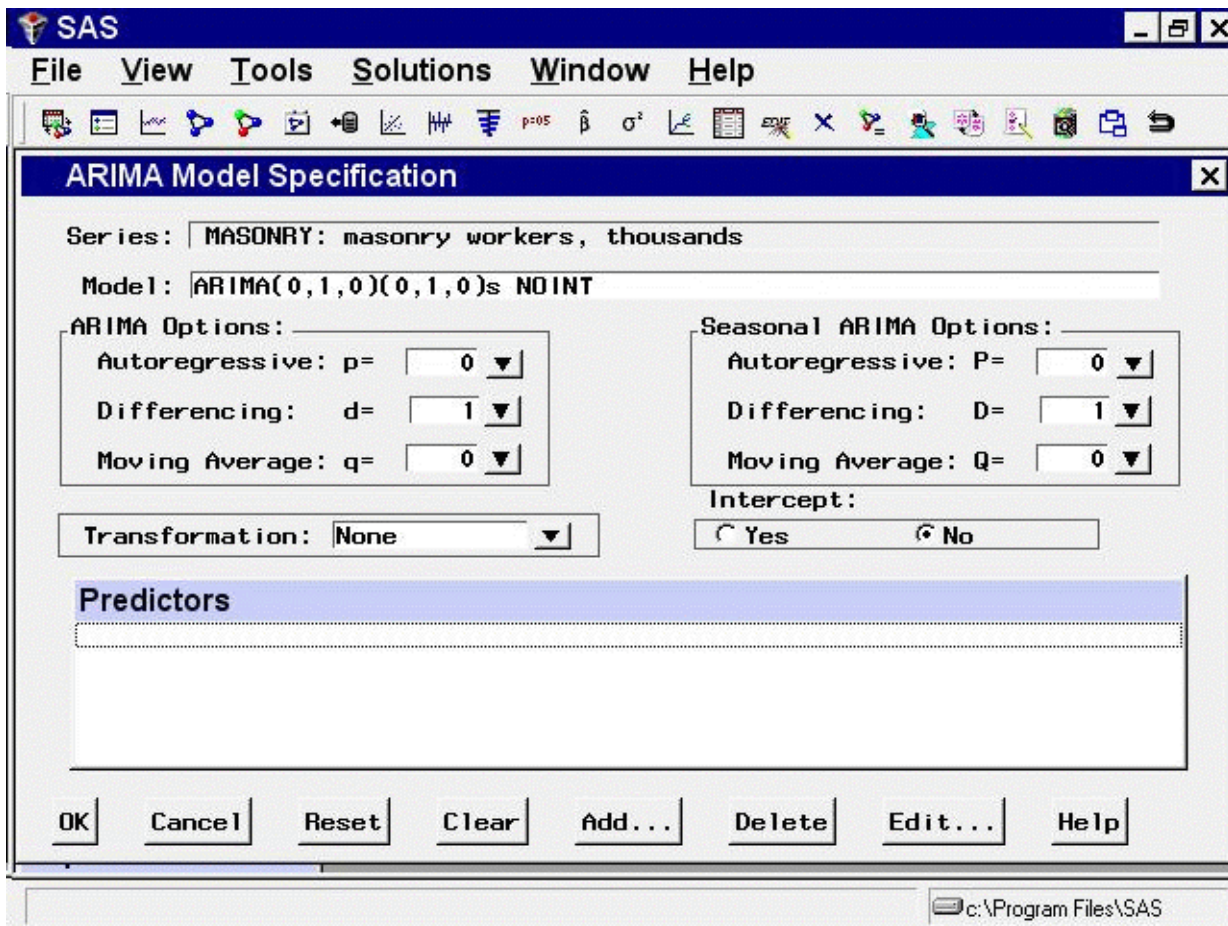

Since the ACF still displays slow decline at seasonal lags, seasonal differencing is appropriate (in addition to the first differencing already applied). Select the *Seasonal Difference* icon, the sixth icon from the left on the horizontal toolbar. The plot now appears as shown in Figure 40.7.

Figure 40.7 ACF Plot with Simple and Seasonal Differencing

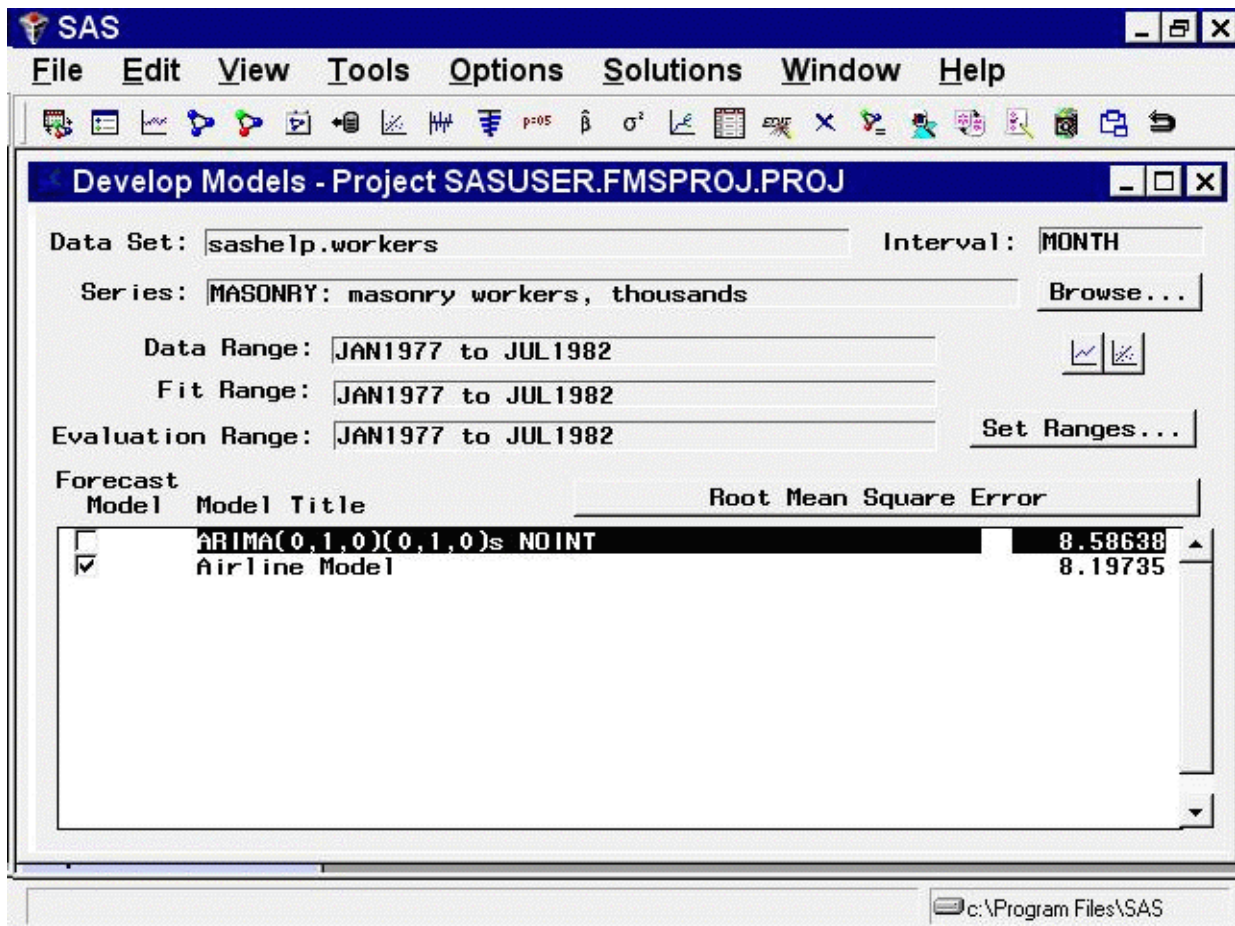

Model Viewer Prediction Error Analysis

Leave the Time Series Viewer open for the remainder of this exercise. Drag it out of the way or push it to the background so that you can return to the Time Series Forecasting window. Select **Develop Models**, then click an empty part of the table to bring up the pop-up menu, and select **Fit ARIMA Model**. Define the ARIMA(0,1,0)(0,1,0)_s model by selecting 1 for Differencing under ARIMA Options, 1 for Differencing under Seasonal ARIMA Options, and No for Intercept, as shown in Figure 40.8.

Figure 40.8 Specifying the ARIMA(0,1,0)(0,1,0)_s Model

When you select the **OK** button, the model is fit and you are returned to the Develop Models window. Click on an empty part of the table and choose **Fit Models** from **List** from the pop-up menu. Select **Airline Model** from the window. (Airline Model is a common name for the ARIMA(0,1,1)(0,1,1)_s model, which is often used for seasonal data with a linear trend.) Select the **OK** button. Once the model has been fit, the table shows the two models and their root mean square errors. Notice that the Airline Model provides only a slight improvement over the differencing model, ARIMA(0,1,0)(0,1,0)_s. Select the first row to highlight the differencing model, as shown in Figure 40.9.

Figure 40.9 Selecting a Model

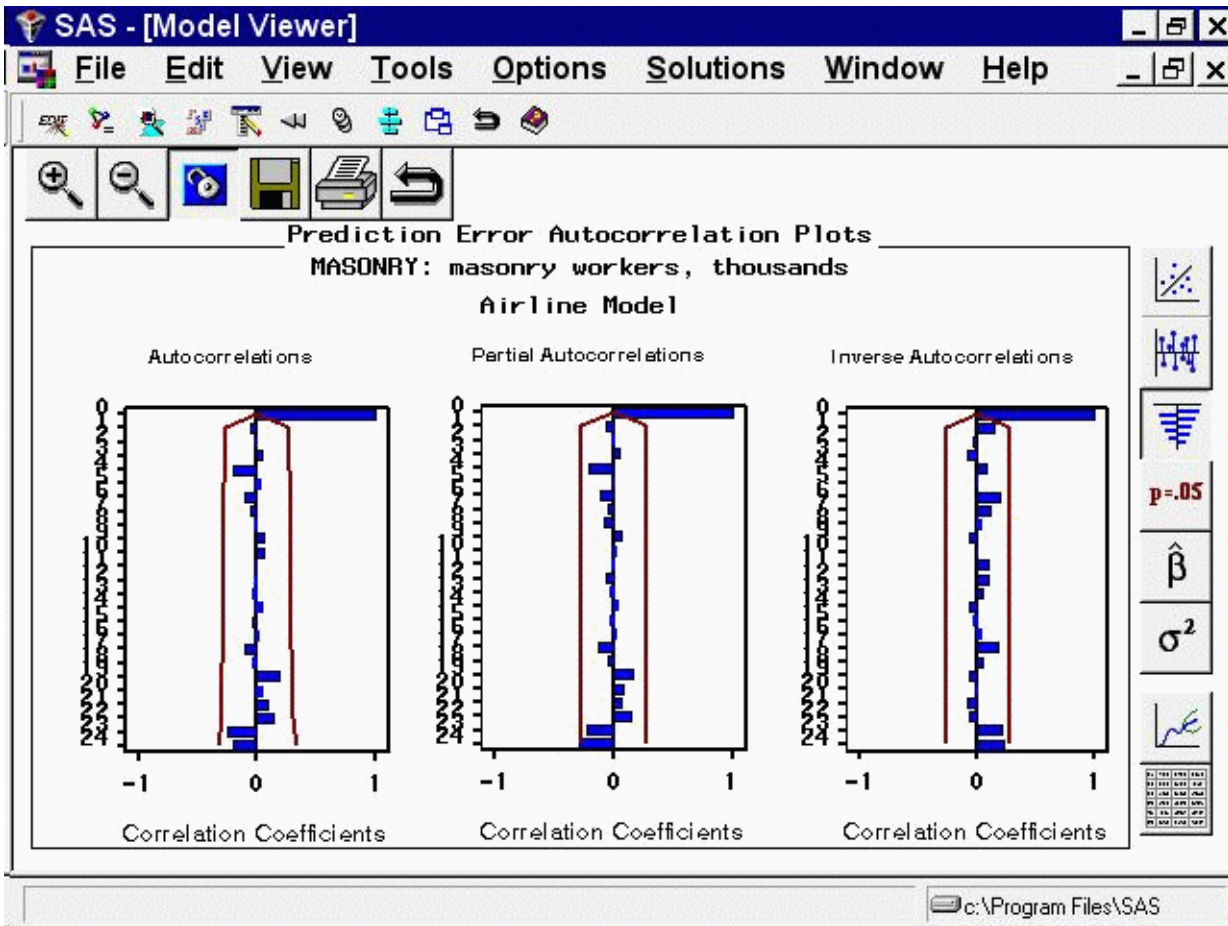

Now select the **View Selected Model Graphically** button, below the **Browse** button at the right side of the **Develop Models** window. The **Model Viewer** window appears, showing the actual data and model predictions for the **MASONRY** series. (Note that predicted values are missing for the first 13 observations due to simple and seasonal differencing.)

To examine the ACF plot for the model prediction errors, select the third icon from the top on the vertical toolbar. For this model, the prediction error ACF is the same as the ACF of the original data with first differencing and seasonal differencing applied. This differencing is apparent if you bring the **Time Series Viewer** back into view for comparison.

Return to the **Develop Models** Window by clicking on it or using the window pull-down menu or the **Next Viewer** toolbar icon. Select the second row of the table in the **Develop Models** window to highlight the **Airline Model**. The **Model Viewer** is automatically updated to show the prediction error ACF of the newly selected model, as shown in [Figure 40.10](#).

Figure 40.10 Prediction Error ACF Plot for the Airline Model

Another helpful tool available within the Model Viewer is the parameter estimates table. Select the fifth icon from the top of the vertical toolbar. The table gives the parameter estimates for the two moving-average terms in the Airline Model, as well as the model residual variance, as shown in Figure 40.11.

Figure 40.11 Parameter Estimates for the Airline Model

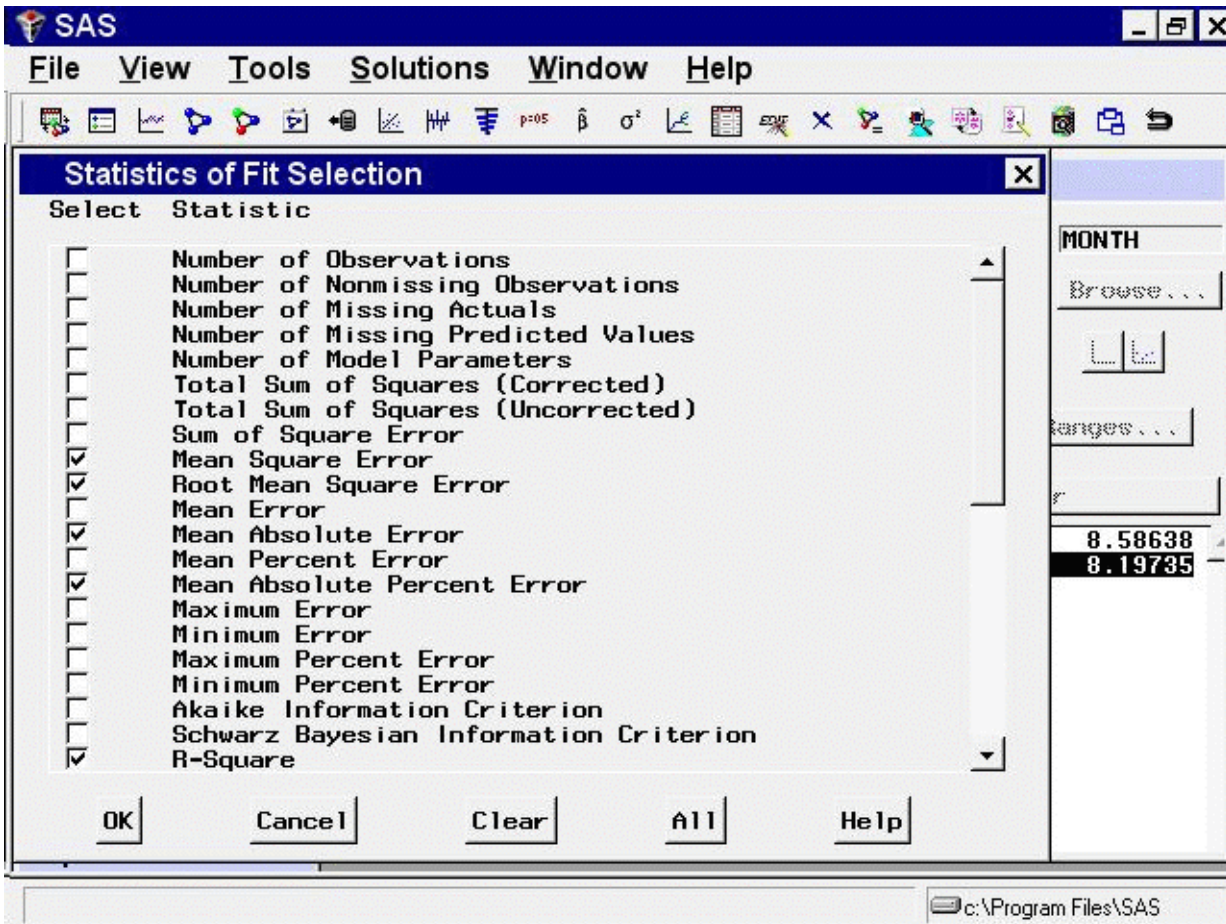

You can adjust the column widths in the table by dragging the vertical borders of the column titles with the mouse. Notice that neither of the parameter estimates is significantly different from zero at the 0.05 level of significance, since $\text{Prob}>|t|$ is greater than 0.05. This suggests that the Airline Model should be discarded in favor of the more parsimonious differencing model, which has no parameters to estimate.

The Model Selection Criterion

Return to the Develop Models window (Figure 40.9) and notice the Root Mean Square Error button at the right side of the table banner. This is the model selection criterion—the statistic used by the system to select the best fitting model. So far in this example you have fit two models and have left the default criterion, root mean square error (RMSE), in effect. Because the Airline Model has the smaller value of this criterion and because smaller values of the RMSE indicate better fit, the system has chosen this model as the forecasting model, indicated by the check box in the Forecast Model column.

The statistics available as model selection criteria are a subset of the statistics available for informational purposes. To access the entire set, select *Options* from the menu bar, and then select *Statistics of Fit*. The *Statistics of Fit Selection* window appears, as shown in Figure 40.12.

Figure 40.12 Statistics of Fit

By default, five of the more well known statistics are selected. You can select and deselect statistics by clicking the check boxes in the left column. For this exercise, select *All*, and notice that all the check boxes become checked. Select the *OK* button to close the window. Now if you choose *Statistics of Fit* in the *Model Viewer* window, all of the statistics will be shown for the selected model.

To change the model selection criterion, click the *Root Mean Square Error* button or select *Options* from the menu bar and then select *Model Selection Criterion*. Notice that most of the statistics of fit are shown, but those which are not relevant to model selection, such as number of observations, are not shown. Select *Schwarz Bayesian Information Criterion* and click *OK*. Since this statistic puts a high penalty on models with larger numbers of parameters, the *ARIMA(0,1,0)(0,1,0)*s model comes out with the better fit.

Notice that changing the selection criterion does not automatically select the model that is best according to that criterion. You can always choose the model you want to use for forecasts by

selecting its check box in the `Forecast Model` column.

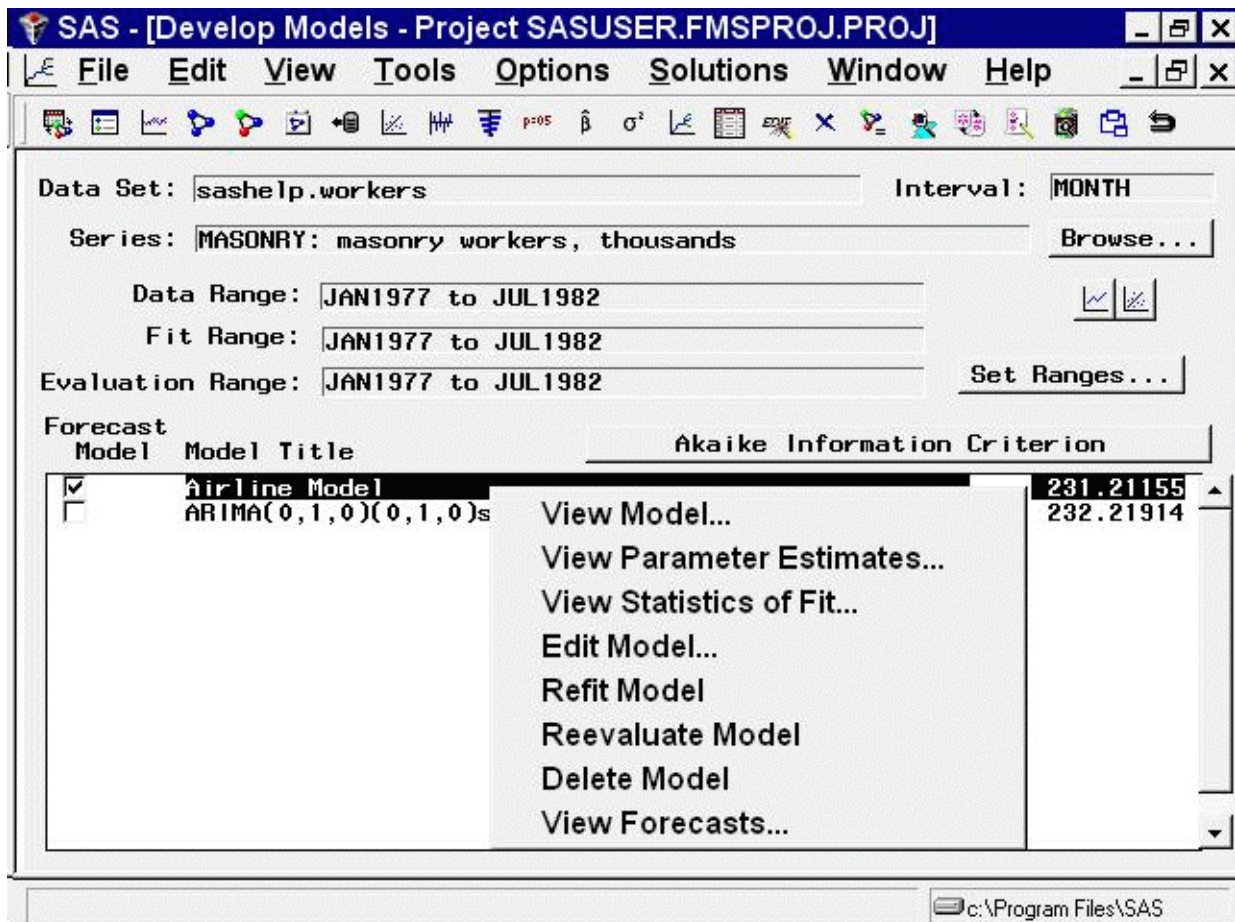

Now bring up the Model Selection Criterion window again and select `Akaike Information Criterion`. This statistic puts a lesser penalty on number of parameters, and the Airline Model comes out as the better fitting model.

Sorting and Selecting Models

Select `Sort Models` on the `Tools` menu or from the toolbar. This sorts the current list of fitted models by the current selection criterion. Although some selection criteria assign larger values to better fitting models (for example, R-square) while others assign smaller values to better fitting models, `Sort Models` always orders models with the best fitting model—in this case, the Airline Model—at the top of the list.

When you select a model in the table, its name and criterion value become highlighted, and actions that apply to that model become available. If your system supports a right mouse button, you can click it to invoke a pop-up menu, as shown in [Figure 40.13](#).

Figure 40.13 Right Mouse Button Pop-up Menu

Whether or not you have a right mouse button, the same choices are available under `Edit` and `View` from the menu bar. If the model viewer has been invoked, it is automatically updated to show the selected model, unless you have unlinked the viewer by using the `Link/Unlink` toolbar button.

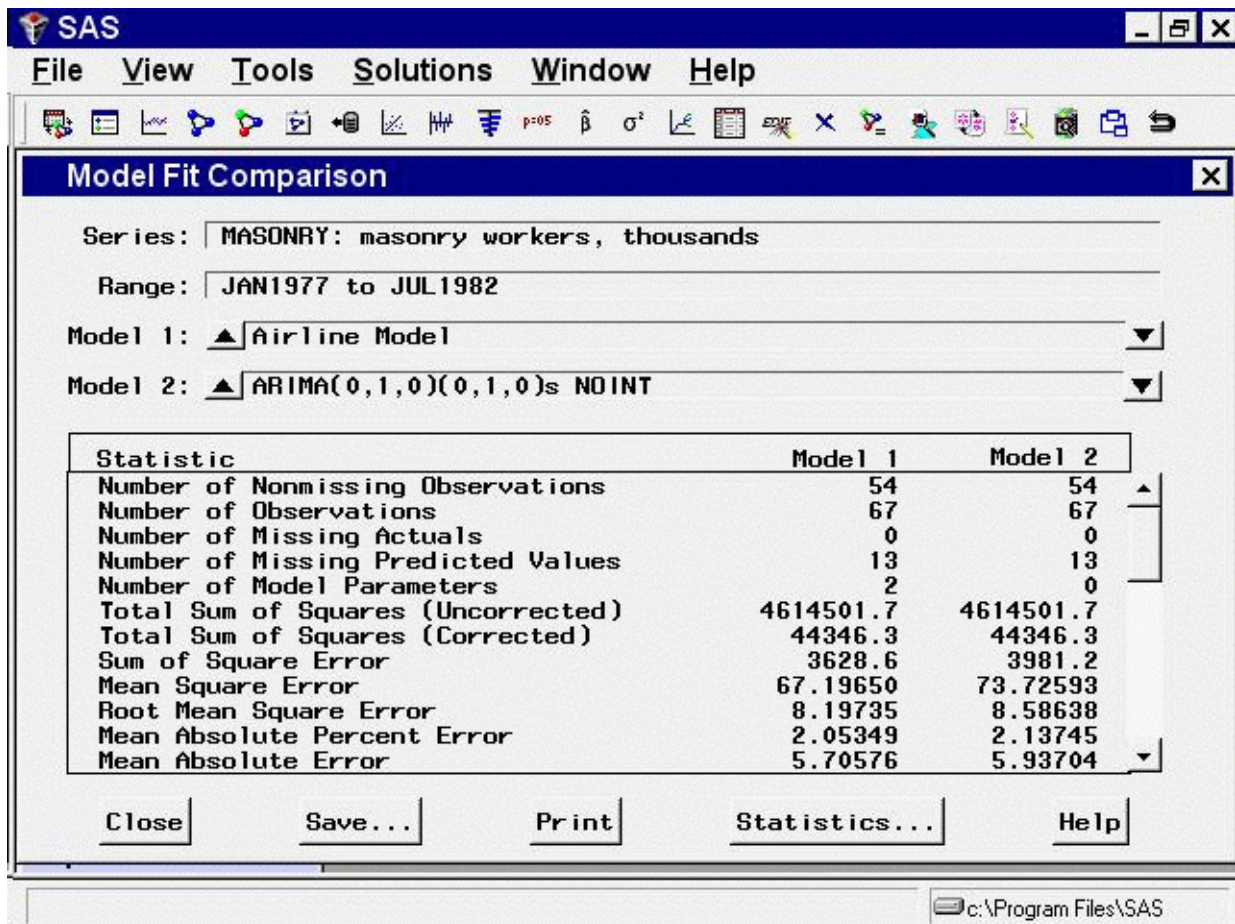

Select the highlighted model in the table again. Notice that it is no longer highlighted. When no models are highlighted, the right mouse button pop-up menu changes, and items on the menu bar that apply to a selected model become unavailable. For example, you can choose `Edit` from the menu bar, but you can't choose the `Edit Model` or `Delete Model` selections unless you have highlighted a model in the table.

When you select the check box in the `Forecast Model` column of the table, the model in that row becomes the forecasting model. This is the model that will be used the next time forecasts are generated by choosing `View Forecasts` or by using the `Produce Forecasts` window. Note that this forecasting model flag is automatically set when you use `Fit Automatic Model` or when you fit an individual model that fits better, using the current selection criterion, than the current forecasting model.

Comparing Models

Select `Tools` and `Compare Models` from the menu bar. This displays the `Model Fit Comparison` table, as shown in [Figure 40.14](#).

Figure 40.14 Model Comparison Window

The two models you have fit are shown as Model 1 and Model 2. When there are more than two models, you can bring any two of them into the table by selecting the up and down arrows. In this way, it is easy to do pairwise comparisons on any number of models, looking at as many statistics of fit as you like. Since you previously chose to display all statistics of fit, all of them are shown in the comparison table. Use the vertical scroll bar to move through the list.

After you have examined the model comparison table, select the `Close` button to return to the Develop Models window.

Controlling the Period of Evaluation and Fit

Notice the three time ranges shown on the Develop Models window (Figure 40.9). The data range shows the beginning and ending dates of the MASONRY time series. The period of fit shows the beginning and ending dates of data used to fit the models. The period of evaluation shows the beginning and ending dates of data used to compute statistics of fit. By default, the fit and evaluate ranges are the same as the data range. To change these ranges, select the `Set Ranges`

button, or select **Options** and **Time Ranges** from the menu bar. This brings up the **Time Ranges Specification** window, as shown in [Figure 40.15](#).

Figure 40.15 Time Ranges Specification Window

For this example, suppose the early data in the series is unreliable, and you want to use the range June 1978 to the latest available for both model fitting and model evaluation. You can either type JUN1978 in the **From** column for **Period of Fit** and **Period of Evaluation**, or you can advance these dates by clicking the right pointing arrows. The outer arrow advances the date by a large amount (in this case, by a year), and the inner arrow advances it by a single period (in this case, by a month). Once you have changed the **Period of Fit** and the **Period of Evaluation** to JUN1978 in the **From** column, select the **OK** button to return to the **Develop Models** window. Notice that these time ranges are updated at the top of the window, but the models already fit have not been affected. Your changes to the time ranges affect *subsequently fit* models.

Refitting and Reevaluating Models

If you fit the ARIMA(0,1,0)(0,1,0)s and Airline models again in the same way as before, they will be added to the model list, with the same names but with different values of the model selection criterion. Parameter estimates will be different, due to the new fit range, and statistics of fit will be different, due to the new evaluation range.

For this exercise, instead of specifying the models again, refit the existing models by selecting `Edit` from the menu bar and then selecting `Refit Models` and `All Models`. After the models have been refit, you should see the same two models listed in the table but with slightly different values for the selection criterion. The ARIMA (0,1,0)(0,1,0)s and Airline models have now been fit to the MASONRY series by using data from June 1978 to July 1982, since this is the period of fit you specified. The statistics of fit have been computed for the period of evaluation, which was the same as the period of fit. If you had specified a period of evaluation different from the period of fit, the statistics would have been computed accordingly.

In practice, another common reason for refitting models is the availability of new data. For example, when data for a new month become available for a monthly series, you might add them to the input data set, then invoke the forecasting system, open the project containing models fit previously, and refit the models prior to generating new forecasts. Unless you specify the period of fit and period of evaluation in the `Time Ranges Specification` window, they default to the full data range of the series found in the input data set at the time of refitting.

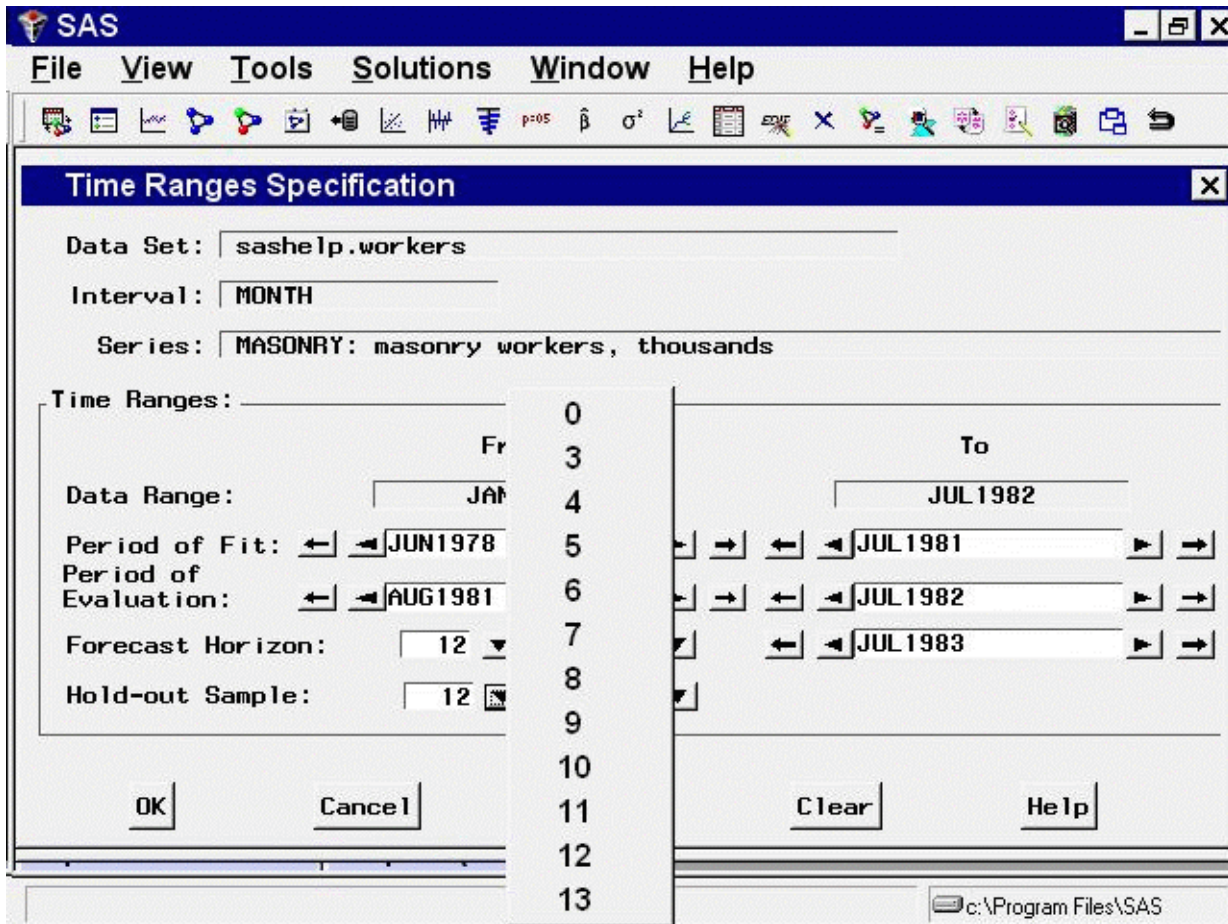

If you prefer to apply previously fit models to revised data without refitting, use `Reevaluate Models` instead of `Refit Models`. This recomputes the statistics of fit by using the current evaluation range, but does not re-estimate the model parameters.

Using Hold-out Samples

One important application of model fitting where the period of fit is different from the period of evaluation is the use of hold-out samples. With this technique of model evaluation, the period of fit ends at a time point before the end of the data series, and the remainder of the data are held out as a nonoverlapping period of evaluation. With respect to the period of fit, the hold-out sample is a period in the future, used to compare the forecasting accuracy of models fit to past data.

For this exercise, use a hold-out sample of 12 months. Bring up the `Time Ranges Specification` window again by selecting the `Set Ranges` button. Set `Hold-out Sample` to 12 using the combo box, as shown in [Figure 40.16](#). You can also type in a value. To specify a hold-out sample period in different units, you can use the `Periods` combo box. In this case, it allows you to select years as the unit, instead of periods.

Figure 40.16 Specifying the Hold-out Sample Size

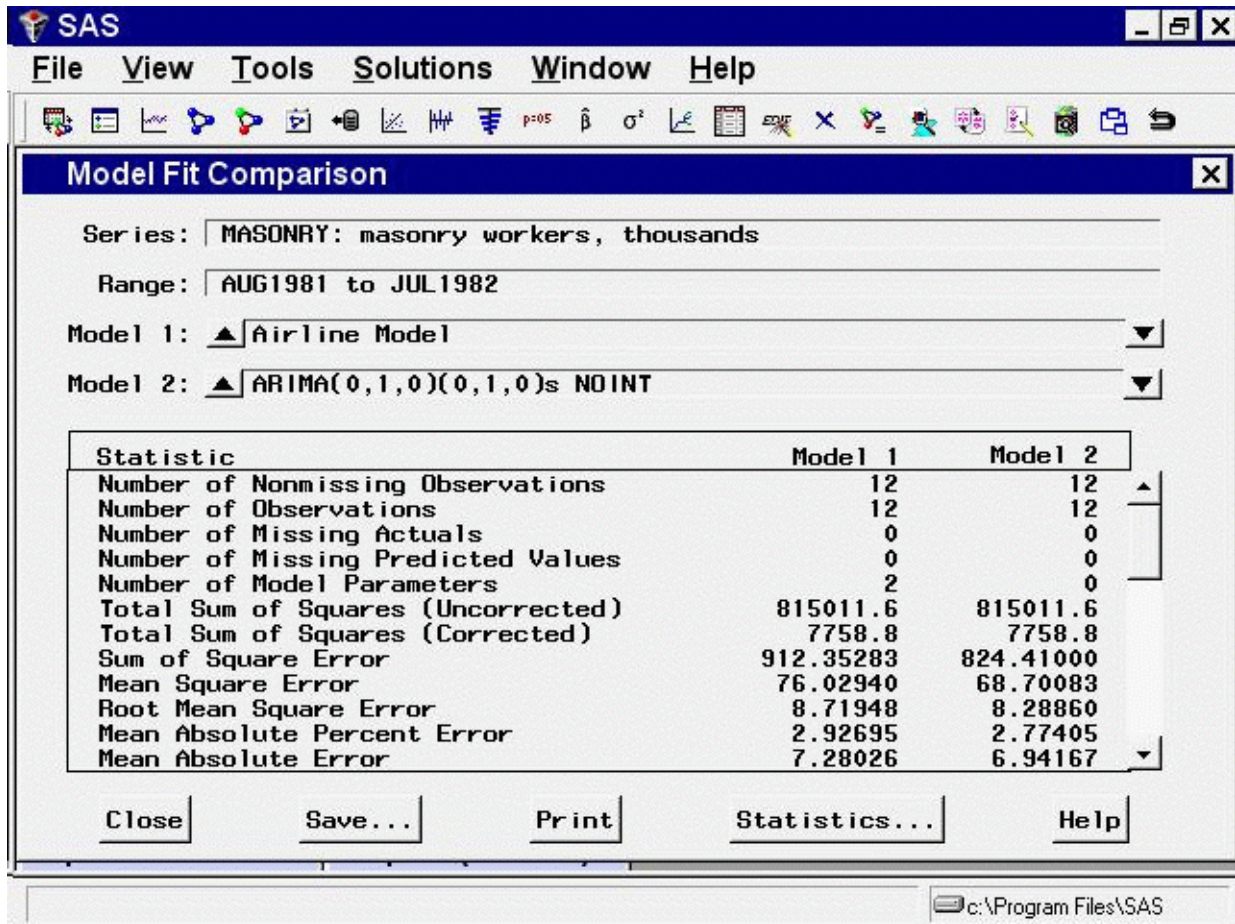

Notice that setting the hold-out sample to 12 automatically sets the fit range to JUN1978–JUL1981 and the evaluation range to AUG1981–JUL1982. If you had set the period of fit and period of evaluation to these ranges, the hold-out sample would have been automatically set to 12 periods.

Select the OK button to return to the `Develop Models` window. Now refit the models again. Select `Tools` and `Compare Models` to compare the models now that they have been fit to the period June 1978 through July 1981 and evaluated for the hold-out sample period August 1981 through July 1982. Note that the fit statistics for the hold-out sample are based on one-step-ahead forecasts. (See *Statistics of Fit* in Chapter 44, “[Forecasting Process Details](#).”)

As shown in [Figure 40.17](#), the ARIMA (0,1,0)(0,1,0)_s model now seems to provide a better fit to the data than does the Airline model. It should be noted that the results can be quite different if you choose a different size hold-out sample.

Figure 40.17 Using 12 Month Hold-out Sample

Forecasting models predict the future values of a series by using two sources of information: the past values of the series and the values of other time series variables. Other variables used to predict a series are called *predictor variables*.

Predictor variables that are used to predict the dependent series can be variables in the input data set, such as regressors and adjustment variables, or they can be special variables computed by the system as functions of time, such as trend curves, intervention variables, and seasonal dummies.

You can specify seven different types of predictors in forecasting models by using the ARIMA Model or Custom Model Specification windows. You cannot specify predictor variables with the Smoothing Model Specification window.

Figure 41.1 shows the menu of options for adding predictors to an ARIMA model that is opened by clicking the Add button. The Add menu for the Custom Model Specification menu is similar.

Figure 41.1 Add Predictors Menu

These types of predictors are as follows.

- | | |
|-------------------|--|
| Linear Trend | adds a variable that indexes time as a predictor series. A straight line time trend is fit to the series by regression when you specify a linear trend. |
| Trend Curve | provides a menu of various functions of time that you can add to the model to fit nonlinear time trends. The Linear Trend option is a special case of the Trend Curve option for which the trend curve is a straight line. |
| Regressors | allows you to predict the series by regressing it on other variables in the data set. |
| Adjustments | allows you to specify other variables in the data set that supply adjustments to the forecast. |
| Dynamic Regressor | allows you to select a predictor variable from the input data set and specify a complex model for the way that the predictor variable affects the dependent series. |
| Interventions | allows you to model the effect of special events that “intervene” to change the pattern of the dependent series. Examples of intervention effects are strikes, tax increases, and special sales promotions. |

Seasonal Dummies adds seasonal indicator or “dummy” variables as regressors to model seasonal effects.

You can add any number of predictors to a forecasting model, and you can combine predictor variables with other model options.

The following sections explain these seven kinds of predictors in greater detail and provide examples of their use. The examples illustrate these different kinds of predictors by using series in the SASHELP.USECON data set.

Select the `Develop Models` button from the main window. Select the data set `SASHELP.USECON` and select the series `PETROL`. Then select the `View Series Graphically` button from the `Develop Models` window. The plot of the example series `PETROL` appears as shown in [Figure 41.2](#).

Figure 41.2 Sales of Petroleum and Coal

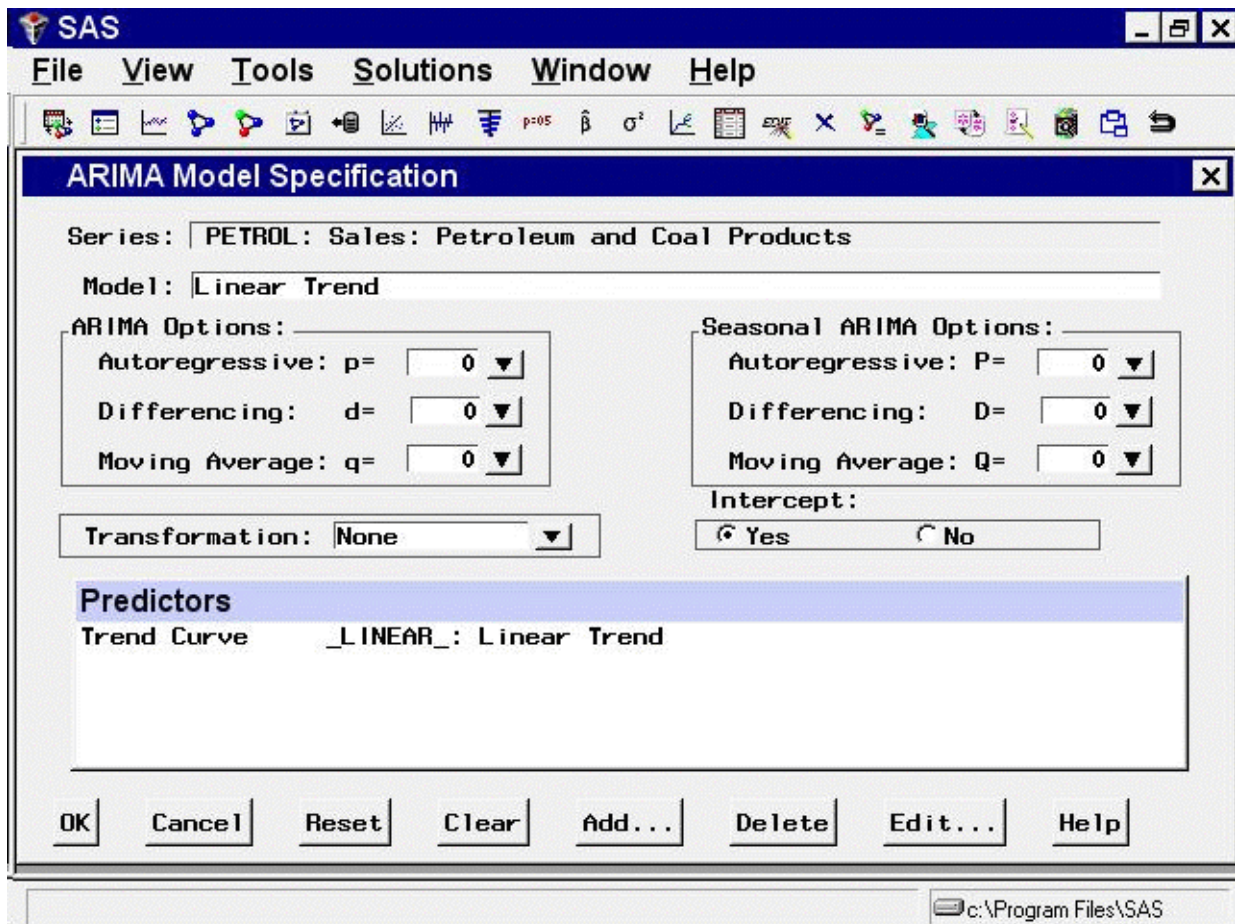

Linear Trend

From the `Develop Models` window, select `Fit ARIMA Model`. From the `ARIMA Model Specification` window, select `Add` and then select `Linear Trend` from the menu (shown in [Figure 41.1](#)).

A linear trend is added to the Predictors list, as shown in [Figure 41.3](#).

Figure 41.3 Linear Trend Predictor Specified

The description for the linear trend item shown in the Predictors list has the following meaning. The first part of the description, Trend Curve, describes the type of predictor. The second part, `_LINEAR_`, gives the variable name of the predictor series. In this case, the variable is a time index that the system computes. This variable is included in the output forecast data set. The final part, Linear Trend, describes the predictor.

Notice that the model you have specified consists only of the time index regressor `_LINEAR_` and an intercept. Although this window is normally used to specify ARIMA models, in this case no ARIMA model options are specified, and the model is a simple regression on time.

Select the **OK** button. The Linear Trend model is fit and added to the model list in the Develop Models window.

Now open the Model Viewer by using the *View Model Graphically* icon or the *Model Predictions* item under the *View* pull-down menu or toolbar. This displays a plot of the model predictions and actual series values, as shown in [Figure 41.4](#). The predicted values lie along the least squares trend line.

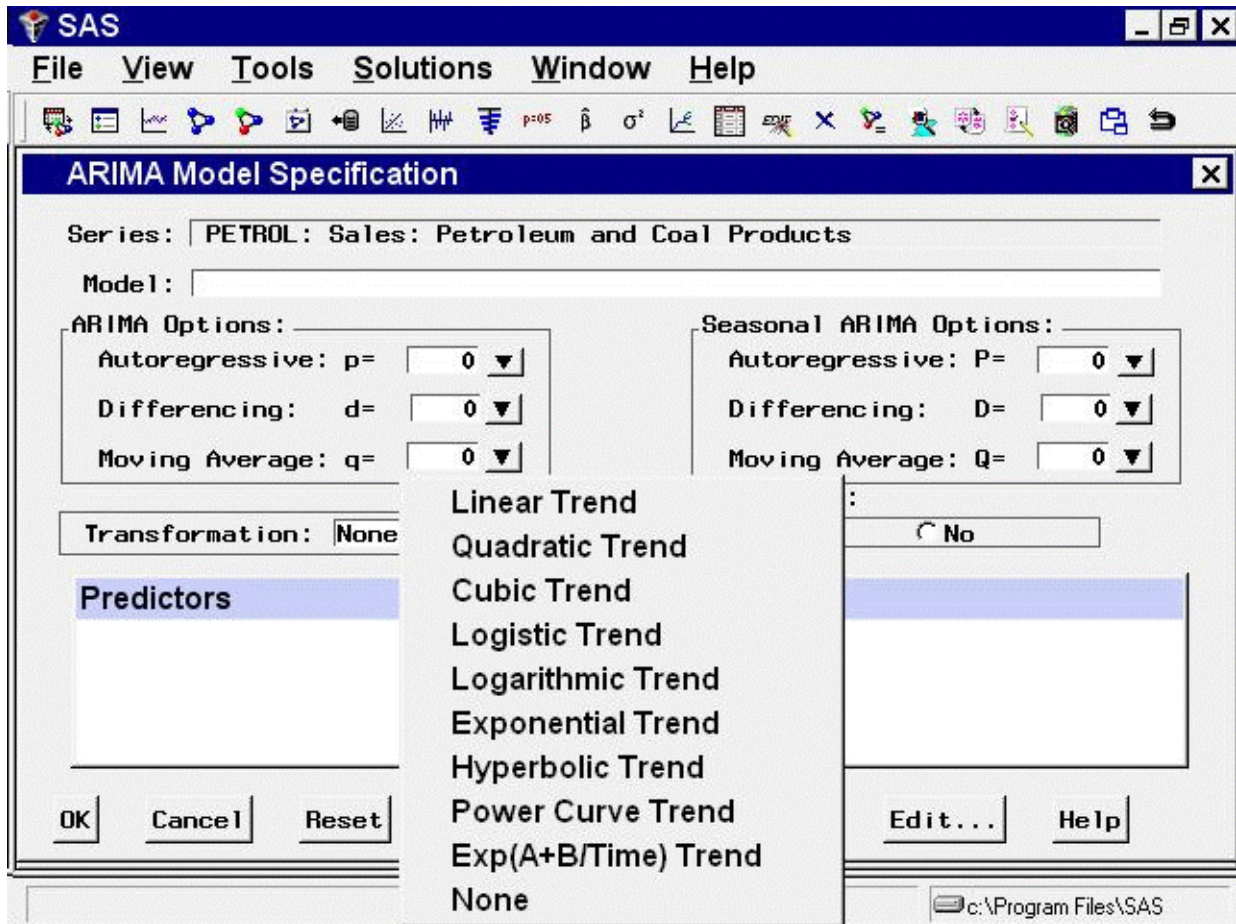

Figure 41.4 Linear Trend Model

Time Trend Curves

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select `Add` and then select `Trend Curve` from the menu (shown in Figure 41.1). A menu of different kinds of trend curves is displayed, as shown in Figure 41.5.

Figure 41.5 Time Trend Curves Menu

These trend curves work in a similar way as the Linear Trend option (which is a special case of a trend curve and one of the choices on the menu), but with the Trend Curve menu you have a choice of various nonlinear time trends.

Select `Quadratic Trend`. This adds a quadratic time trend to the Predictors list, as shown in [Figure 41.6](#).

Figure 41.6 Quadratic Trend Specified

Now select the **OK** button. The quadratic trend model is fit and added to the list of models in the Develop Models window. The Model Viewer displays a plot of the quadratic trend model, as shown in Figure 41.7.

Figure 41.7 Quadratic Trend Model

This curve does not fit the PETROL series very well, but the View Model plot illustrates how time trend models work. You might want to experiment with different trend models to see what the different trend curves look like.

Some of the trend curves require transforming the dependent series. When you specify one of these curves, a notice is displayed reminding you that a transformation is needed, and the Transformation field is automatically filled in. Therefore, you cannot control the Transformation specification when some kinds of trend curves are specified.

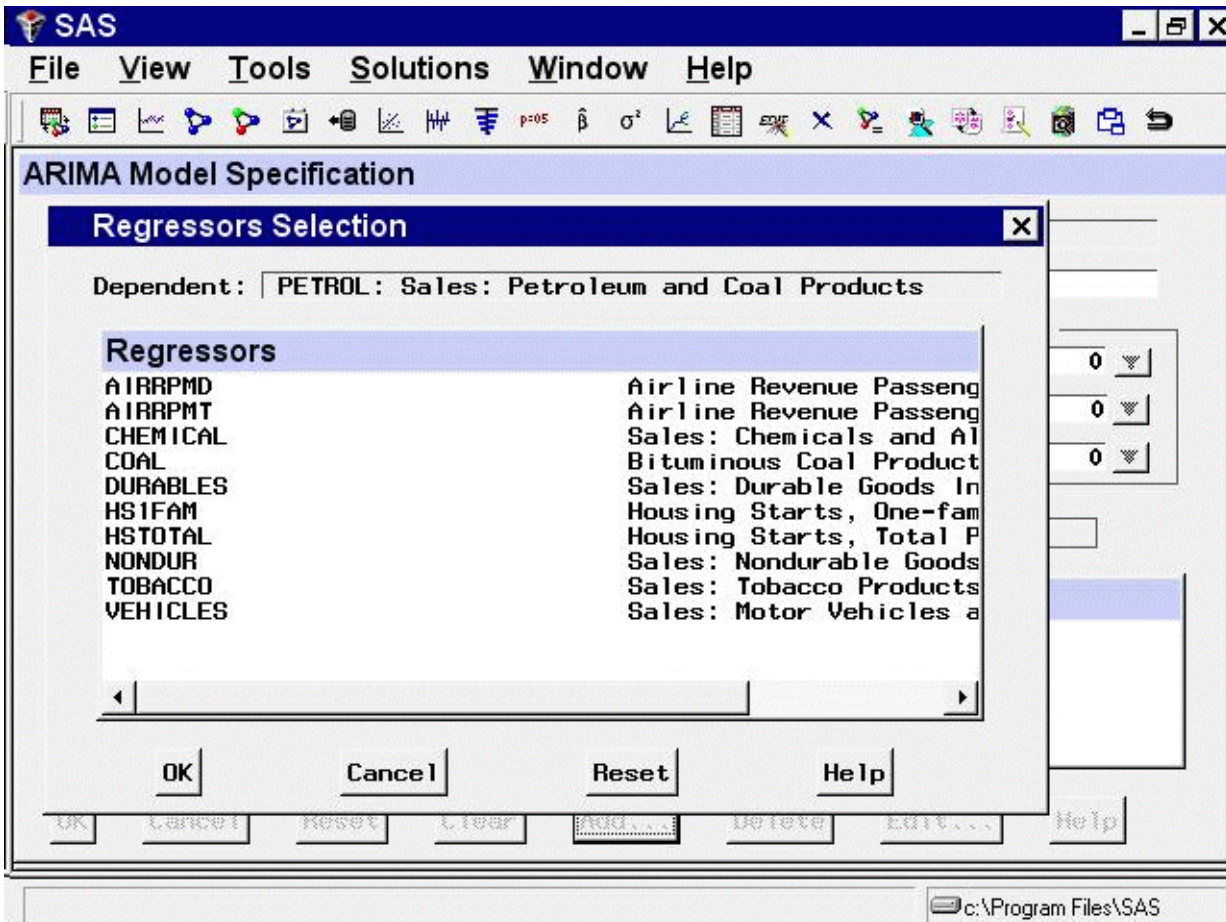

See the section “[Time Trend Curves](#)” on page 2515 in Chapter 44, “[Forecasting Process Details](#),” for more information about the different trend curves.

Regressors

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select `Add` and then select `Regressors` from the menu (shown in [Figure 41.1](#)).

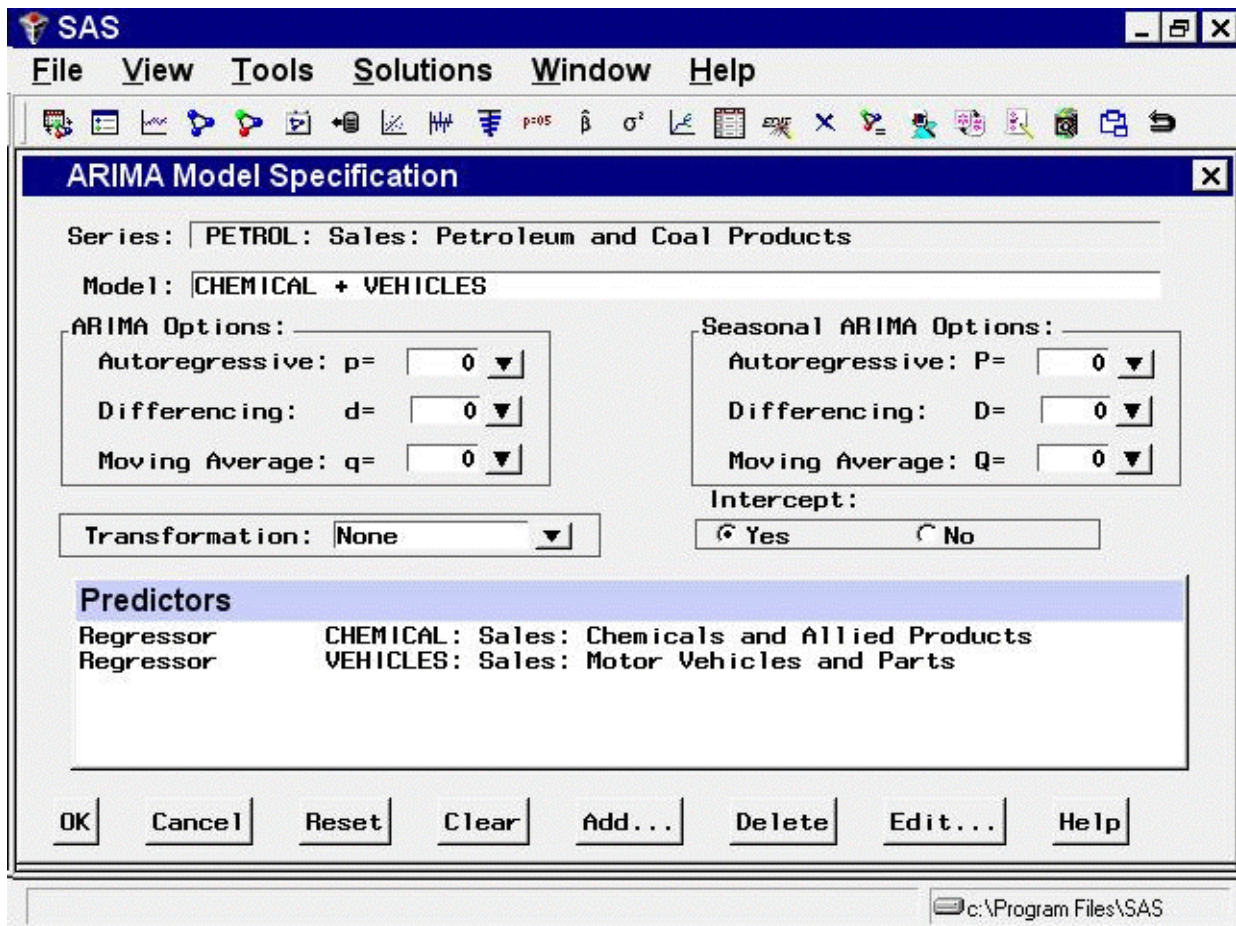

This displays the `Regressors Selection` window, as shown in [Figure 41.8](#). This window allows you to select any number of other series in the input data set as regressors to predict the dependent series.

Figure 41.8 Regressors Selection Window

For this example, select `CHEMICAL`, `Sales: Chemicals and Allied Products`, and `VEHICLES`, `Sales: Motor Vehicles and Parts`. (Note: You do not need to use the `CTRL` key when selecting more than one regressor.) Then select the `OK` button. The two variables you selected are added to the Predictors list as regressor type predictors, as shown in [Figure 41.9](#).

Figure 41.9 Regressors Selected

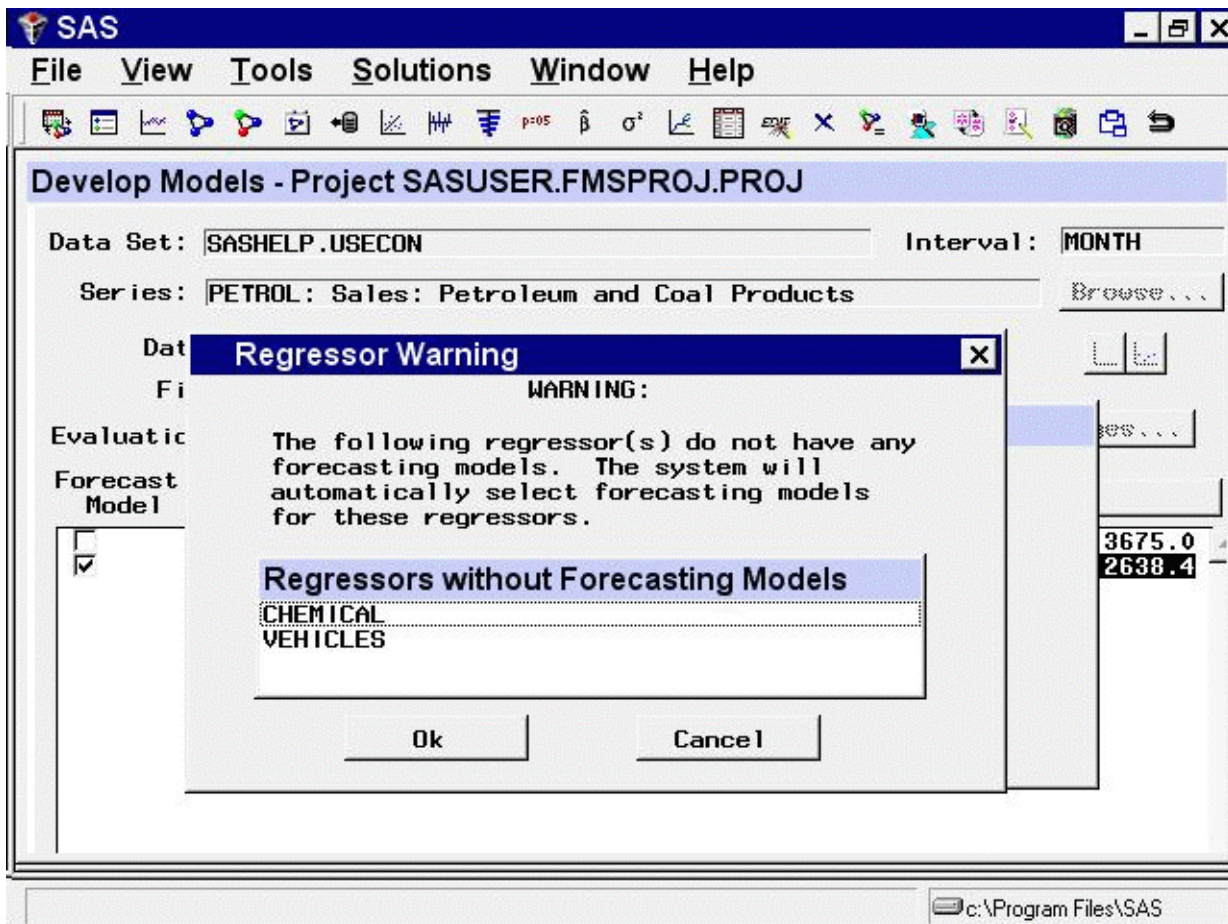

You must have forecasts of the future values of the regressor variables in order to use them as predictors. To do this, you can specify a forecasting model for each regressor, have the system automatically select forecasting models for the regressors, or supply predicted future values for the regressors in the input data set.

Even if you have supplied future values for a regressor variable, the system requires a forecasting model for the regressor. Future values that you supply in the input data set take precedence over predicted values from the regressor's forecasting model when the system computes the forecasts for the dependent series.

Select the **OK** button. The system starts to fit the regression model but then stops and displays a warning that the regressors that you selected do not have forecasting models, as shown in [Figure 41.10](#).

Figure 41.10 Regressors Needing Models Warning

If you want the system to create forecasting models automatically for the regressor variables by using the automatic model selection process, select the **OK** button. If not, you can select the **Cancel** button to abort fitting the regression model.

For this example, select the **OK** button. The system now performs the automatic model selection process for **CHEMICAL** and **VEHICLES**. The selected forecasting models for **CHEMICAL** and **VEHICLES** are added to the model lists for those series. If you switch the current time series in the **Develop Models** window to **CHEMICAL** or **VEHICLES**, you will see the model that the system selected for that series.

Once forecasting models have been fit for all regressors, the system proceeds to fit the regression model for **PETROL**. The fitted regression model is added to the model list displayed in the **Develop Models** window.

Adjustments

An *adjustment* predictor is a variable in the input data set that is used to adjust the forecast values produced by the forecasting model. Unlike a regressor, an adjustment variable does not have a regression coefficient. No model fitting is performed for adjustments. Nonmissing values of the adjustment series are simply added to the model prediction for the corresponding period. Missing adjustment values are ignored. If you supply adjustment values for observations within the period of fit, the adjustment values are subtracted from the actual values, and the model is fit to these adjusted values.

To add adjustments, select **Add** and then select **Adjustments** from the pop-up menu (shown in [Figure 41.1](#)). This displays the **Adjustments Selection** window. The **Adjustments Selection** window functions the same as the **Regressor Selection** window (which is shown in [Figure 41.8](#)). You can select any number of adjustment variables as predictors.

Unlike regressors, adjustments do not require forecasting models for the adjustment variables. If a variable that is used as an adjustment does have a forecasting model fit to it, the adjustment variable's forecasting model is ignored when the variable is used as an adjustment.

You can use forecast adjustments to account for expected future events that have no precedent in the past and so cannot be modeled by regression. For example, suppose you are trying to forecast the sales of a product, and you know that a special promotional campaign for the product is planned during part of the period you want to forecast. If such sales promotion programs have been frequent in the past, then you can record the past and expected future level of promotional efforts in a variable in the data set and use that variable as a regressor in the forecasting model.

However, if this is the first sales promotion of its kind for this product, you have no way to estimate the effect of the promotion from past data. In this case, the best you can do is to make an educated guess at the effect the promotion will have and add that guess to what your forecasting model would predict in the absence of the special sales campaign.

Adjustments are also useful for making judgmental alterations to forecasts. For example, suppose you have produced forecast sales data for the next 12 months. Your supervisor believes that the forecasts are too optimistic near the end and asks you to prepare a forecast graph in which the numbers that you have forecast are reduced by 1000 in the last three months. You can accomplish this task by editing the input data set so that it contains observations for the actual data range of sales plus 12 additional observations for the forecast period, and a new variable called, for example, **ADJUSTMENT**. The variable **ADJUSTMENT** contains the value 1000 for the last three observations and is missing for all other observations. You fit the same model previously selected for forecasting by using the **ARIMA Model Specification** or **Custom Model Specification** window, but with an adjustment added that uses the variable **ADJUSTMENT**. Now when you graph the forecasts by using the **Model Viewer**, the last three periods of the forecast are reduced by 1000. The confidence limits are unchanged, which helps draw attention to the fact that the adjustments to the forecast deviate from what would be expected statistically.

Dynamic Regressor

Selecting `Dynamic Regressor` from the `Add Predictors` menu (shown in [Figure 41.1](#)) allows you to specify a complex time series model of the way that a predictor variable influences the series that you are forecasting.

When you specify a predictor variable as a simple regressor, only the current period value of the predictor affects the forecast for the period. By specifying the predictor with the `Dynamic Regression` option, you can use past values of the predictor series, and you can model effects that take place gradually.

Dynamic regression models are an advanced feature that you are unlikely to find useful unless you have studied the theory of statistical time series analysis. You might want to skip this section if you are not trained in time series modeling.

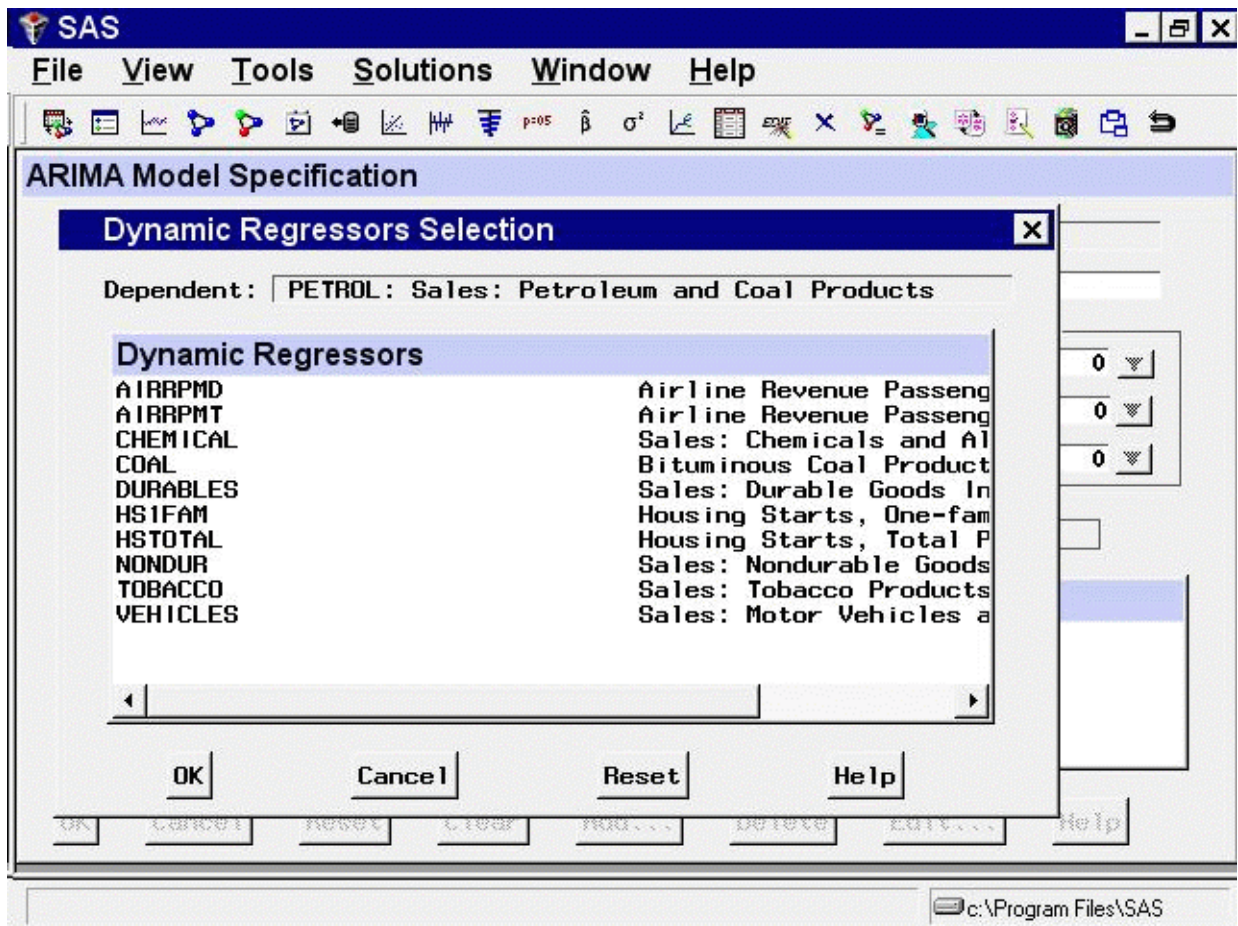

The term *dynamic regression* was introduced by Pankratz (1991) and refers to what Box and Jenkins (1976) named *transfer function models*. In dynamic regression, you have a time series model, similar to an ARIMA model, that predicts how changes in the predictor series affect the dependent series over time.

The dynamic regression model relates the predictor variable to the expected value of the dependent series in the same way that an ARIMA model relates the fluctuations of the dependent series about its conditional mean to the random error term (which is also called the innovation series). Refer to Pankratz (1991) and Box and Jenkins (1976) for more information about dynamic regression or transfer function models. See also Chapter 7, “[The ARIMA Procedure](#).”

From the `Develop Models` window, select `Fit ARIMA Model`. From the `ARIMA Model Specification` window, select `Add` and then select `Linear Trend` from the menu (shown in [Figure 41.1](#)).

Now select `Add` and select `Dynamic Regressor`. This displays the `Dynamic Regressors Selection` window, as shown in [Figure 41.11](#).

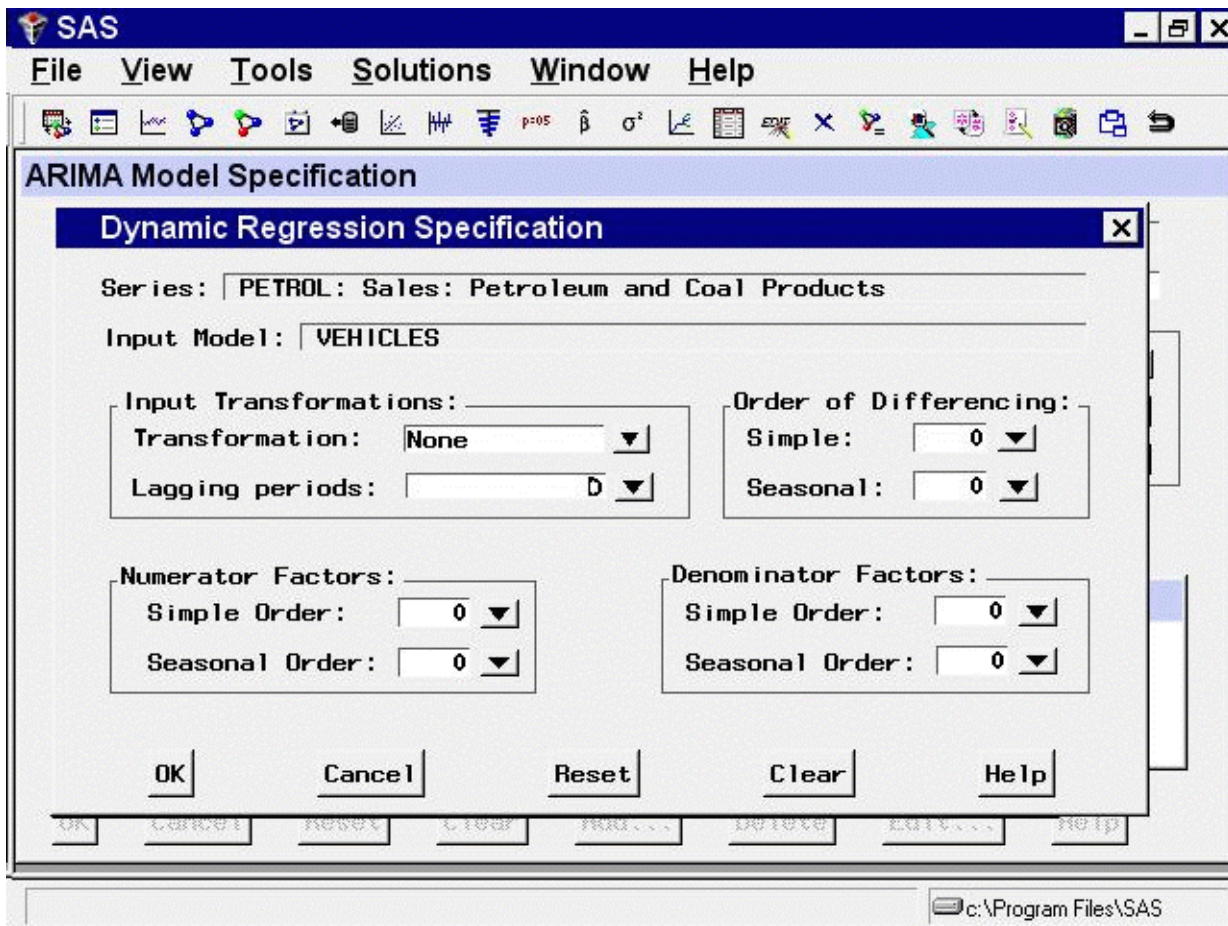

Figure 41.11 Dynamic Regressors Selection Window

You can select only one predictor series when specifying a dynamic regression model. For this example, select `VEHICLES`, Sales: Motor Vehicles and Parts. Then select the OK button.

This displays the Dynamic Regression Specification window, as shown in [Figure 41.12](#).

Figure 41.12 Dynamic Regression Specification Window

This window consists of four parts. The `Input Transformations` fields enable you to transform or lag the predictor variable. For example, you might use the lagged logarithm of the variable as the predictor series.

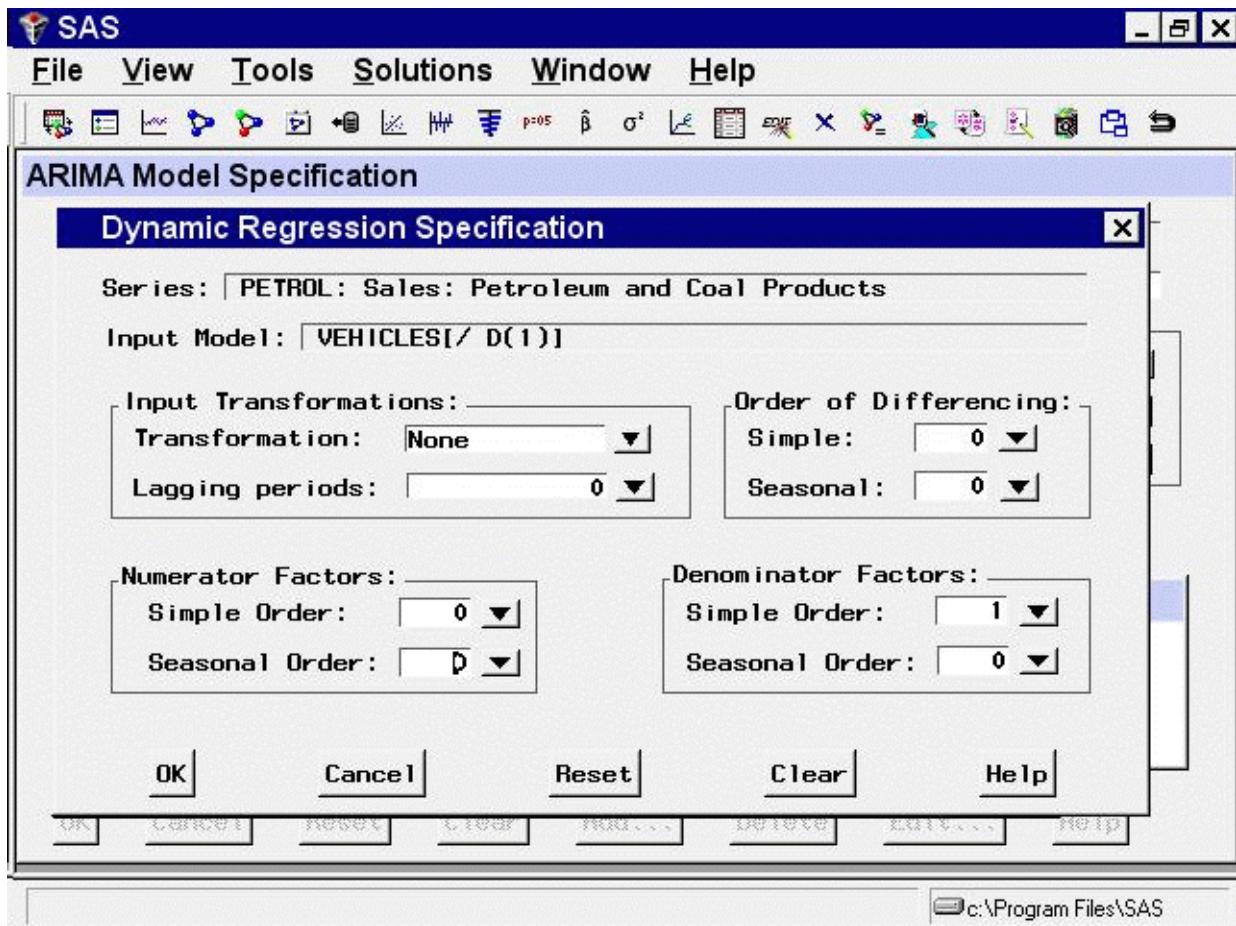

The `Order of Differencing` fields enable you to specify simple and seasonal differencing of the predictor series. For example, you might use changes in the predictor variable instead of the variable itself as the predictor series.

The `Numerator Factors` and `Denominator Factors` fields enable you to specify the orders of simple and seasonal numerator and denominator factors of the transfer function.

Simple regression is a special case of dynamic regression in which the dynamic regression model consists of only a single regression coefficient for the current value of the predictor series. If you select the `OK` button without specifying any options in the `Dynamic Regression Specification` window, a simple regressor will be added to the model.

For this example, use the `Simple Order` combo box for `Denominator Factors` and set its value to 1. The window now appears as shown in [Figure 41.13](#).

Figure 41.13 Distributed Lag Regression Specified

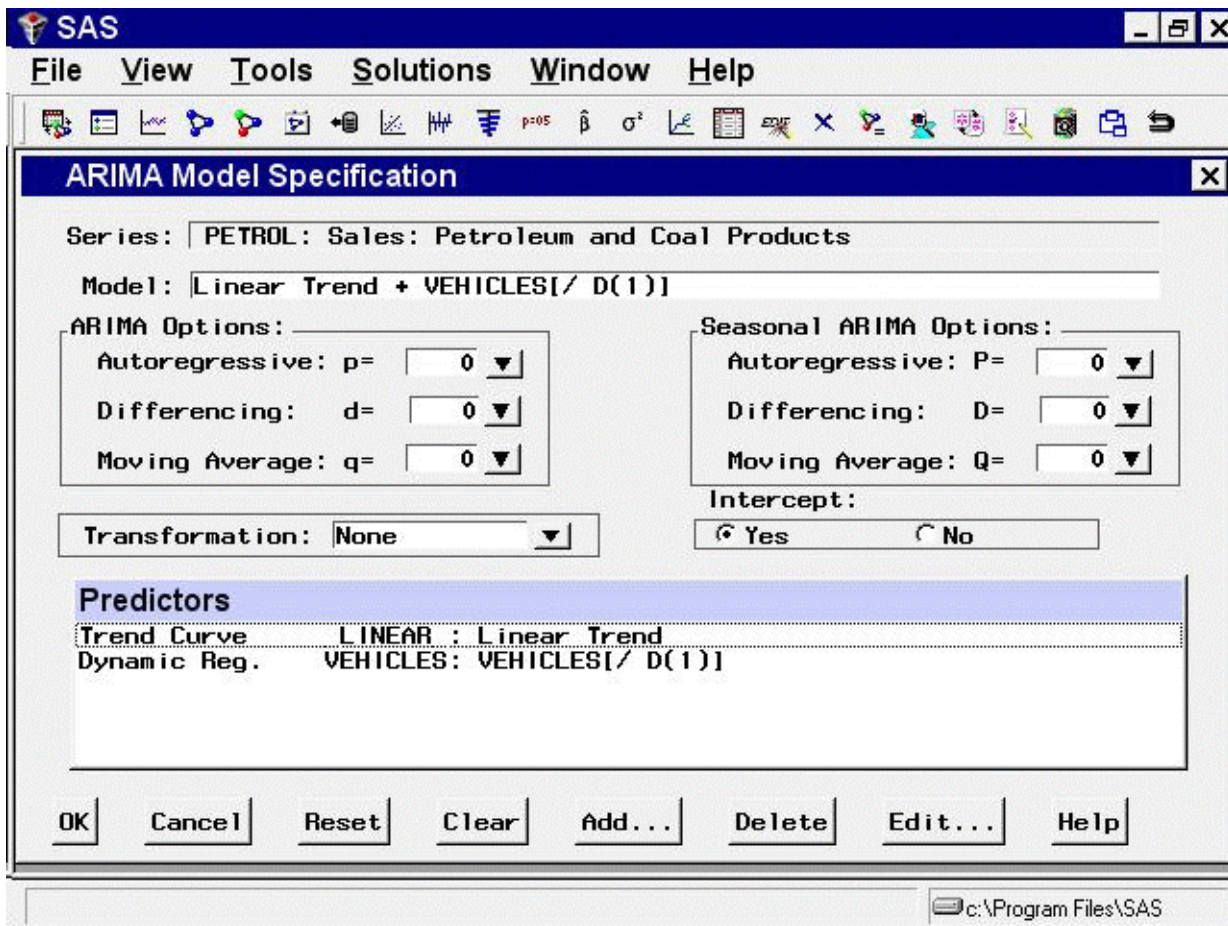

This model is equivalent to regression on an exponentially weighted infinite distributed lag of VEHICLES (in the same way an MA(1) model is equivalent to single exponential smoothing).

Select the **OK** button to add the dynamic regressor to the model predictors list.

In the ARIMA Model Specification window, the Predictors list should now contain two items, a linear trend and a dynamic regressor for VEHICLES, as shown in [Figure 41.14](#).

Figure 41.14 Dynamic Regression Model

This model is a multiple regression of PETROL on a time trend variable and an infinite distributed lag of VEHICLES. Select the **OK** button to fit the model.

As with simple regressors, if VEHICLES does not already have a forecasting model, an automatic model selection process is performed to find a forecasting model for VEHICLES before the dynamic regression model for PETROL is fit.

Interventions

An *intervention* is a special indicator variable, computed automatically by the system, that identifies time periods affected by unusual events that influence or intervene in the normal path of the time series you are forecasting. When you add an intervention predictor, the indicator variable of the intervention is used as a regressor, and the impact of the intervention event is estimated by regression analysis.

To add an intervention to the Predictors list, you must use the Intervention Specification window to specify the time or times that the intervening event took place and to specify the type of intervention.

You can add interventions either through the `Interventions` item of the `Add` action or by selecting `Tools` from the menu bar and then selecting `Define Interventions`.

Intervention specifications are associated with the series. You can specify any number of interventions for each series, and once you define interventions you can select them for inclusion in forecasting models. If you select the `Include Interventions` option in the `Options` menu, any interventions that you have previously specified for a series are automatically added as predictors to forecasting models for the series.

From the `Develop Models` window, invoke the series viewer by selecting the `View Series Graphically` icon or `Series` under the `View` menu. This displays the `Time Series Viewer`, as was shown in [Figure 41.2](#).

Note that the trend in the `PETROL` series shows several clear changes in direction. The upward trend in the first part of the series reverses in 1981. There is a sharp drop in the series towards the end of 1985, after which the trend is again upwardly sloped. Finally, in 1991 the series takes a sharp upward excursion but quickly returns to the trend line.

You might have no idea what events caused these changes in the trend of the series, but you can use these patterns to illustrate the use of intervention predictors. To do this, you fit a linear trend model to the series, but modify that trend line by adding intervention effects to model the changes in trend you observe in the series plot.

The Intervention Specification Window

From the `Develop Models` window, select `Fit ARIMA model`. From the `ARIMA Model Specification` window, select `Add` and then select `Linear Trend` from the menu (shown in [Figure 41.1](#)).

Select `Add` again and then select `Interventions`. If you have any interventions already defined for the series, this selection displays the `Interventions for Series` window. However, since you have not previously defined any interventions, this list is empty. Therefore, the system assumes that you want to add an intervention and displays the `Intervention Specification` window instead, as shown in [Figure 41.15](#).

Figure 41.15 Interventions Specification Window

The top of the Intervention Specification window shows the current series and the label for the new intervention (initially blank). At the right side of the window is a scrollable table showing the values of the series. This table helps you locate the dates of the events you want to model.

At the left of the window is an area titled *Intervention Specification* that contains the options for defining the intervention predictor. The *Date* field specifies the time that the intervention occurs. You can type a date value in the *Date* field, or you can set the *Date* value by selecting a row from the table of series values at the right side of the window.

The area titled *Type of Intervention* controls the kind of indicator variable constructed to model the intervention effect. You can specify the following kinds of interventions:

- Point** is used to indicate an event that occurs in a single time period. An example of a point event is a strike that shuts down production for part of a time period. The value of the intervention's indicator variable is zero except for the date specified.
- Step** is used to indicate a continuing event that changes the level of the series. An example of a step event is a change in the law, such as a tax rate increase. The value of the intervention's indicator variable is zero before the date specified and 1 thereafter.

Ramp is used to indicate a continuing event that changes the trend of the series. The value of the intervention's indicator variable is zero before the date specified, and it increases linearly with time thereafter.

The areas titled *Effect Time Window* and *Effect Decay Pattern* specify how to model the effect that the intervention has on the dependent series. These options are not used for simple interventions, they will be discussed later in this chapter.

Specifying a Trend Change Intervention

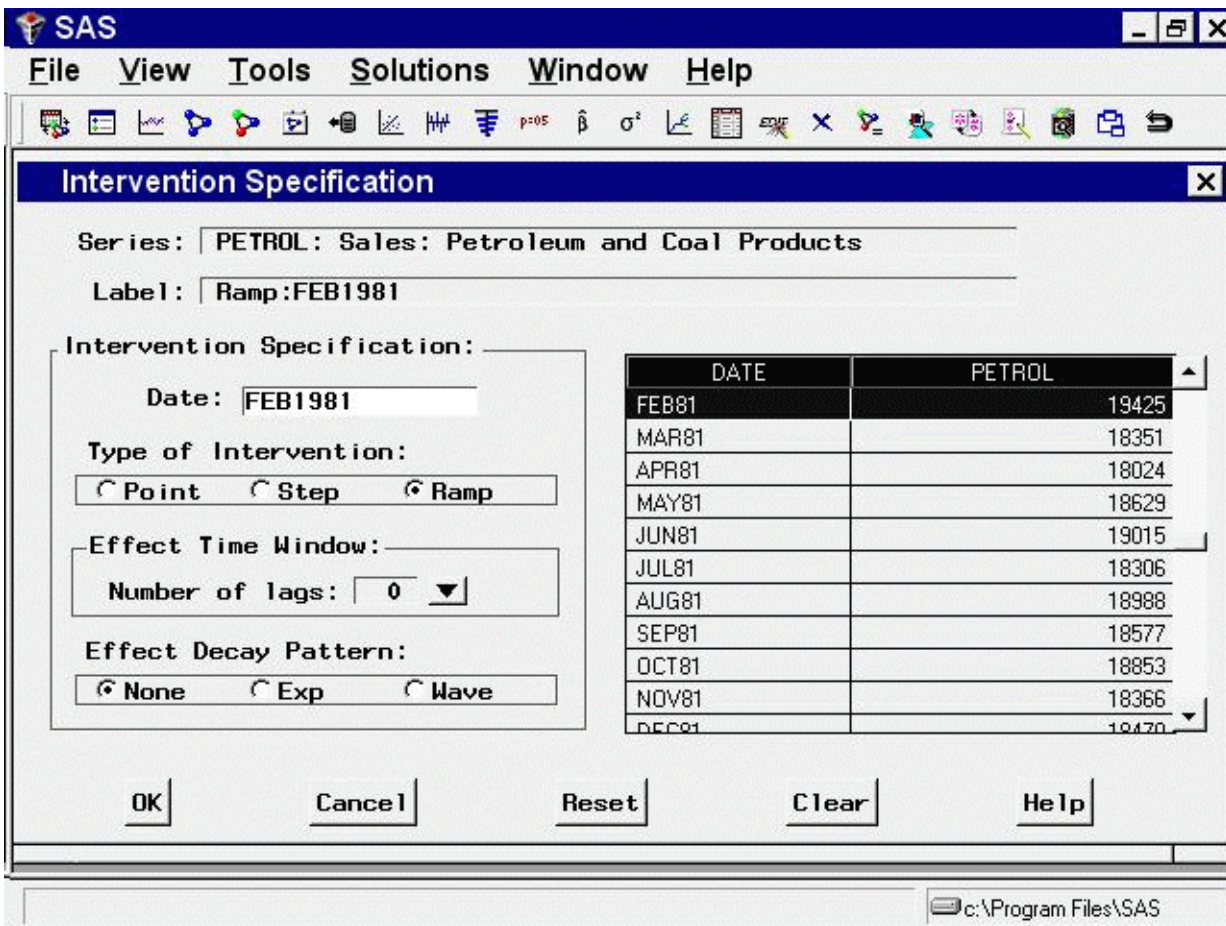

In the Time Series Viewer window position the mouse over the highest point in 1981 and select the point. This displays the data value, 19425, and date, February 1981, of that point in the upper-right corner of the Time Series Viewer, as shown in [Figure 41.16](#).

Figure 41.16 Identifying the Turning Point

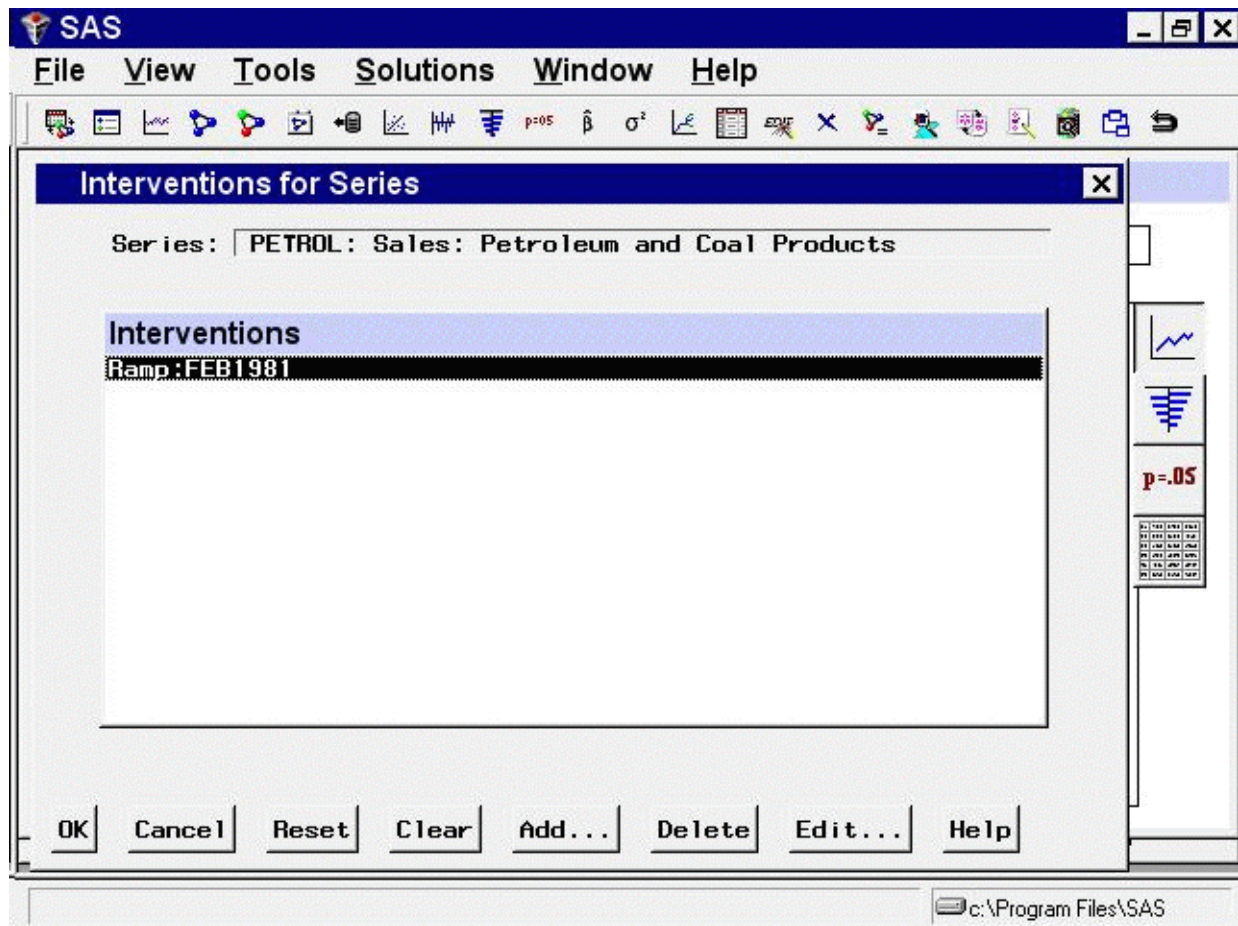

Now that you know the date that the trend reversal occurred, enter that date in the *Date* field of the Intervention Specification window. Select *Ramp* as the type of intervention. The window should now appear as shown in [Figure 41.17](#).

Figure 41.17 Ramp Intervention Specified

Select the **OK** button. This adds the intervention to the list of interventions for the **PETROL** series, and returns you to the **Interventions for Series** window, as shown in [Figure 41.18](#).

Figure 41.18 Interventions for Series Window

This window allows you to select interventions for inclusion in the forecasting model. Since you need to define other interventions, select the **Add** button. This returns you to the Intervention Specification window (shown in Figure 41.15).

Specifying a Level Change Intervention

Now add an intervention to account for the drop in the series in late 1985. You can locate the date of this event by selecting points in the Time Series Viewer plot or by scrolling through the data values table in the Interventions Specification window. Use the latter method so that you can see how this works.

Scrolling through the table, you see that the drop was from 15262 in December 1985, to 13937 in January 1986, to 12002 in February, to 10834 in March. Since the drop took place over several periods, you could use another ramp type intervention. However, this example represents the drop as a sudden event by using a step intervention and uses February 1986 as the approximate time of the drop.

Select the table row for February 1986 to set the `Date` field. Select `Step` as the intervention type. The window should now appear as shown in [Figure 41.19](#).

Figure 41.19 Step Intervention Specified

Select the `OK` button to add this intervention to the list for the series.

Since the trend reverses again after the drop, add a ramp intervention for the same date as the step intervention. Select `Add` from the Interventions for Series window. Enter `FEB86` in the `Date` field, select `Ramp`, and then select the `OK` button.

Modeling Complex Intervention Effects

You have now defined three interventions to model the changes in trend and level. The excursion near the end of the series remains to be dealt with.

Select `Add` from the Interventions for Series window. Scroll through the data values and select the date on which the excursion began, August 1990. Leave the intervention type as `Point`.

The pattern of the series from August 1990 through January 1991 is more complex than a simple

shift in level or trend. For this pattern, you need a complex intervention model for an event that causes a sharp rise followed by a rapid return to the previous trend line. To specify this model, use the `Effect Time Window` and `Effect Decay Rate` options.

The `Effect Time Window` option controls the number of lags of the intervention's indicator variable used to model the effect of the intervention on the dependent series. For a simple intervention, the number of lags is zero, which means that the effect of the intervention is modeled by fitting a single regression coefficient to the intervention's indicator variable.

When you set the number of lags greater than zero, regression coefficients are fit to lags of the indicator variable. This allows you to model interventions whose effects take place gradually, or to model rebound effects. For example, severe weather might reduce production during one period but cause an increase in production in the following period as producers struggle to catch up. You could model this by using a point intervention with an effect time window of 1 lag. This would fit two coefficients for the intervention, one for the immediate effect and one for the delayed effect.

The `Effect Decay Pattern` option controls how the effect of the intervention dissipates over time. `None` specifies that there is no gradual decay: for point interventions, the effect ends immediately; for step and ramp interventions, the effect continues indefinitely. `Exp` specifies that the effect declines at an exponential rate. `Wave` specifies that the effect declines like an exponentially damped sine wave (or as the sum of two exponentials, depending on the fit to the data).

If you are familiar with time series analysis, these options might be clearer if you note that together the `Effect Time Window` and `Effect Decay Pattern` options define the numerator and denominator orders of a transfer function or dynamic regression model for the indicator variable of the intervention. See the section “[Dynamic Regressor](#)” on page 2523 for more information.

For this example, select 2 lags as the value of the `Event Time Window` option, and select `Exp` as the `Effect Decay Pattern` option. The window should now appear as shown in [Figure 41.20](#).

Figure 41.20 Complex Intervention Model

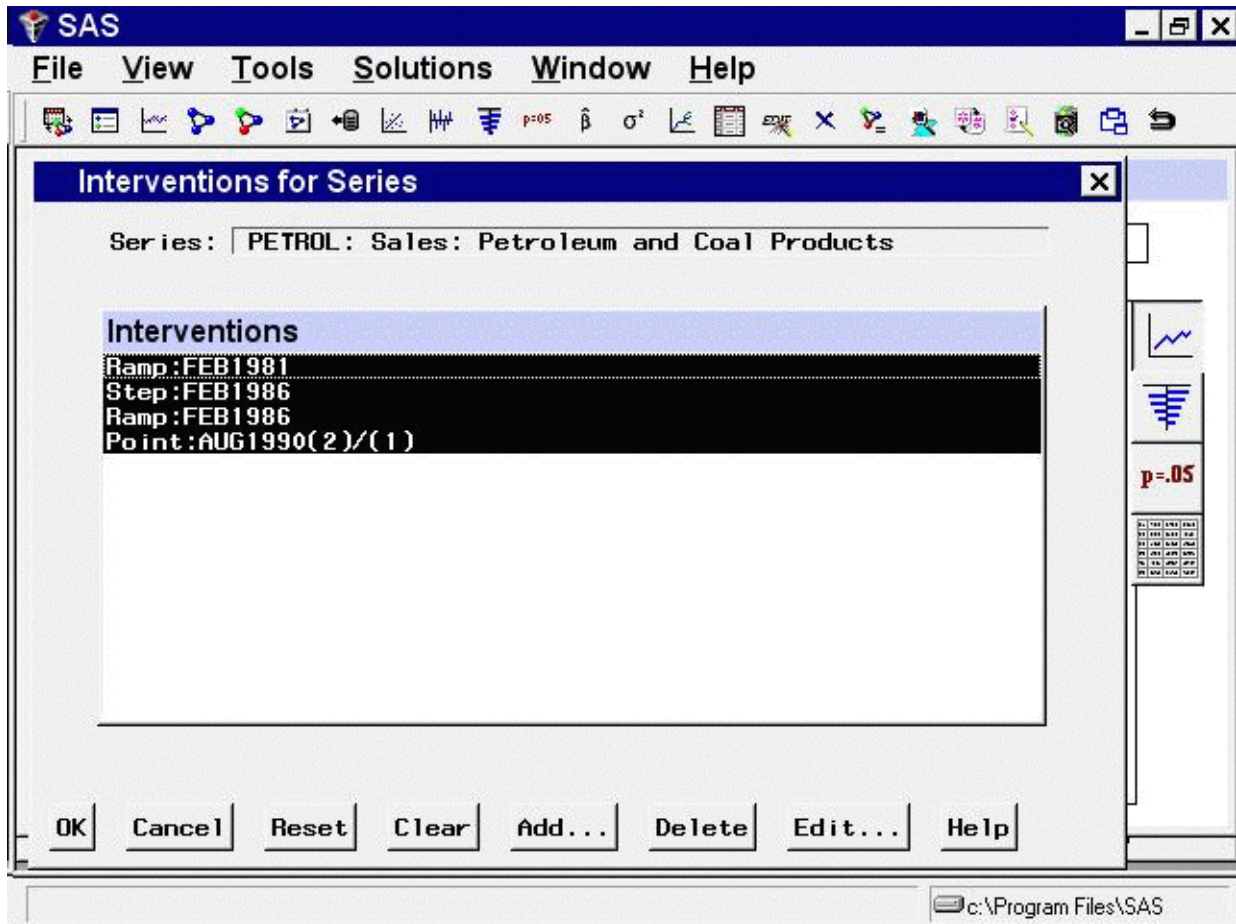

Select the OK button to add the intervention to the list.

Fitting the Intervention Model

The Interventions for Series window now contains definitions for four intervention predictors. Select all four interventions, as shown in Figure 41.21.

Figure 41.21 Interventions for Series Window

Select the **OK** button. This returns you to the ARIMA Model Specification window, which now lists items in the Predictors list, as shown in [Figure 41.22](#).

Figure 41.22 Linear Trend with Interventions Specified

Select the **OK** button to fit this model. After the model is fit, bring up the Model Viewer. You will see a plot of the model predictions, as shown in [Figure 41.23](#).

Figure 41.23 Linear Trend with Interventions Model

You can use the Zoom In feature to take a closer look at how the complex intervention effect fits the excursion in the series starting in August 1990.

Limitations of Intervention Predictors

Note that the model you have just fit is intended only to illustrate the specification of interventions. It is not intended as an example of good forecasting practice.

The use of continuing (step and ramp type) interventions as predictors has some limitations that you should consider. If you model a change in trend with a simple ramp intervention, then the trend in the data before the date of the intervention has no influence on the forecasts. Likewise, when you use a step intervention, the average level of the series before the intervention has no influence on the forecasts.

Only the final trend and level at the end of the series are extrapolated into the forecast period. If a linear trend is the only pattern of interest, then instead of specifying step or ramp interventions, it would be simpler to adjust the period of fit so that the model ignores the data before the final trend

or level change.

Step and ramp interventions are valuable when there are other patterns in the data—such as seasonality, autocorrelated errors, and error variance—that are stable across the changes in level or trend. Step and ramp interventions enable you to fit seasonal and error autocorrelation patterns to the whole series while fitting the trend only to the latter part of the series.

Point interventions are a useful tool for dealing with outliers in the data. A point intervention will fit the series value at the specified date exactly, and it has the effect of removing that point from the analysis. When you specify an effect time window, a point intervention will exactly fit as many additional points as the number of lags specified.

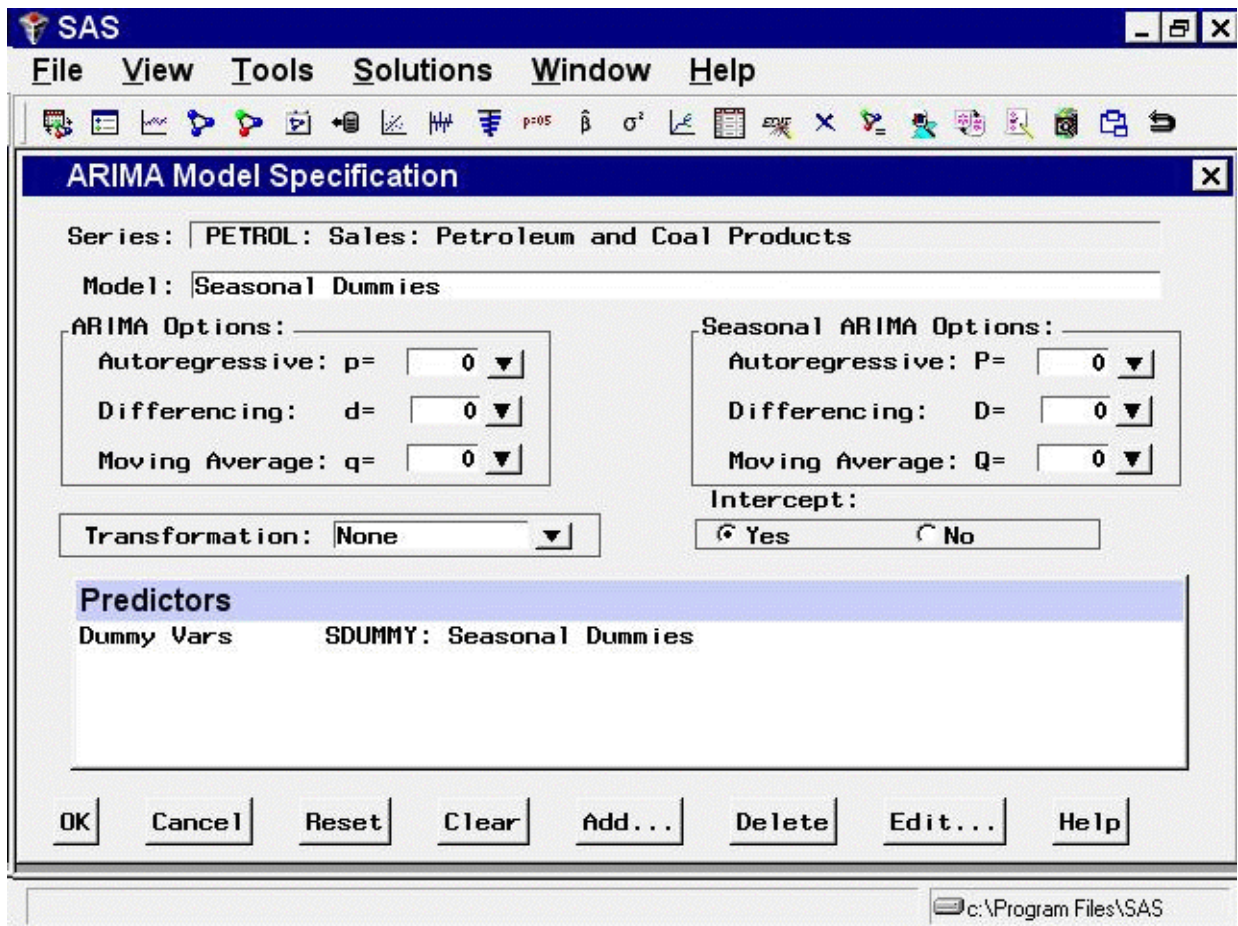

Seasonal Dummies

A *Seasonal Dummies* predictor is a special feature that adds to the model seasonal indicator or “dummy” variables to serve as regressors for seasonal effects.

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select `Add` and then select `Seasonal Dummies` from the menu (shown in [Figure 41.1](#)).

A `Seasonal Dummies` input is added to the Predictors list, as shown in [Figure 41.24](#).

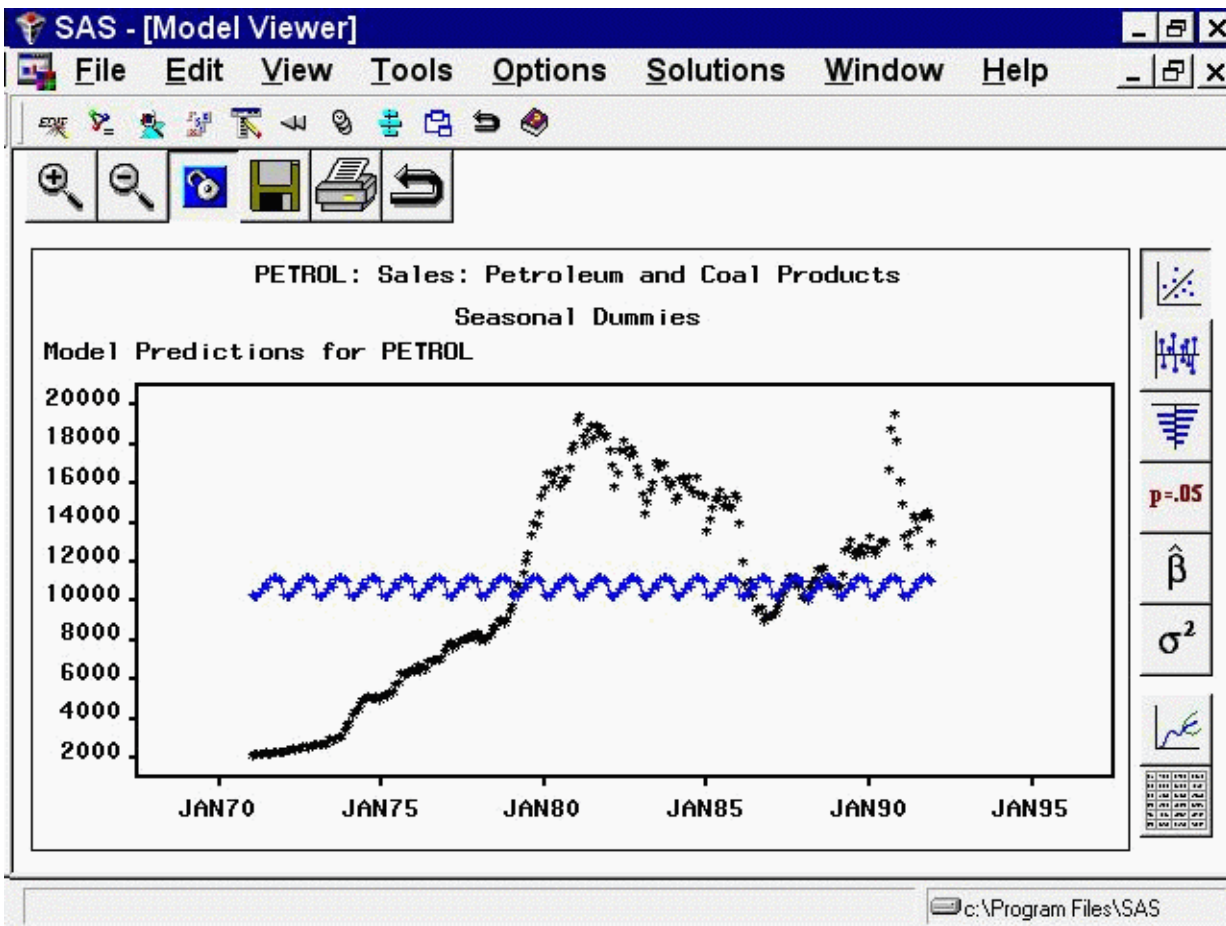

Figure 41.24 Seasonal Dummies Specified

Select the **OK** button. A model consisting of an intercept and 11 seasonal dummy variables is fit and added to the model list in the Develop Models window. This is effectively a mean model with a separate mean for each month.

Now return to the Model Viewer, which displays a plot of the model predictions and actual series values, as shown in [Figure 41.25](#). This is obviously a poor model for this series, but it serves to illustrate how seasonal dummy variables work.

Figure 41.25 Seasonal Dummies Model

Now select the parameter estimates icon, the fifth from the top on the vertical toolbar. This displays the Parameter Estimates table, as shown in Figure 41.26.

Figure 41.26 Parameter Estimates for Seasonal Dummies Model

Since the data for this example are monthly, the Seasonal Dummies option added 11 seasonal dummy variables. These include a dummy regressor variable that is 1.0 for January and 0 for other months, a regressor that is 1.0 only for February, and so forth through November.

Because the model includes an intercept, no dummy variable is added for December. The December effect is measured by the intercept, while the effect of other seasons is measured by the difference between the intercept and the estimated regression coefficient for the season's dummy variable.

The same principle applies for other data frequencies: the "Seasonal Dummy 1" parameter always refers to the first period in the seasonal cycle; and, when an intercept is present in the model, there is no seasonal dummy parameter for the last period in the seasonal cycle.

TSVIEW Command and Macro	2545
Syntax	2545
Examples	2546
FORECAST Command and Macro	2546
Syntax	2547
Examples	2550

TSVIEW Command and Macro

The TSVIEW command invokes the Time Series Viewer. This is a component of the Time Series Forecasting System that can also be used as a standalone graphical viewer for any time series data set or view. See the section “Time Series Viewer Window” in Chapter 43, “[Window Reference](#),” for more information.

The TSVIEW command must be specified from the command line or an SCL program. If you need to submit from the program editor, use the %TSVIEW macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the TSVIEW command or %TSVIEW macro is issued without arguments, the Series Selection window appears to enable you to select an input data set and series. This is equivalent to selecting “Time Series Viewer” from the Analysis submenu of the Solutions menu. By specifying the DATA= and VAR= arguments, you can bring up the Time Series Viewer window directly. The ID= and INTERVAL= arguments are useful when the system cannot determine them automatically from the data.

Syntax

The TSVIEW command has the following form:

```
TSVIEW [options] ;
```

The %TSVIEW macro has the following form:

```
%TSVIEW [(option, ..., option) ] ;
```

The following options can be specified for the command and the macro.

DATA=*data set name*

specifies the name of the SAS data set containing the input data.

VAR=*time series variable name*

specifies the series variable name. It must be a numeric variable contained in the data set.

ID=*time id variable name*

specifies the time ID variable name for the data set. If the ID= option is not specified, the system attempts to locate the variables named DATE, DATETIME, and TIME in the data set specified by the DATA= option.

INTERVAL=*interval name*

specifies the time ID interval between observations in the data set.

Examples

TSVIEW Command

```
tsview data=sashelp.air var=air
tsview data=dept.prod var=units id=period interval=qtr
```

%TSVIEW Macro

```
%tsview( data=sashelp.air, var=air);
%tsview( data=dept.prod, var=units, id=period, interval=qtr);
```

FORECAST Command and Macro

The FORECAST command invokes the Time Series Forecasting System. The command must be specified from the command line or an SCL program. If you need to submit from the program editor, use the %FORECAST macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the FORECAST command or %FORECAST macro is issued without arguments, the Time Series Forecasting window appears. This is equivalent to selecting “Time Series Forecasting System” from the Analysis submenu of the Solutions menu.

Using the arguments, it is possible to do the following:

- Bring up the system with information already filled into some of the fields

- Bring up the system starting at a different window than the default Time Series Forecasting window
- Run the system in unattended mode so that a task such as creating a forecast data set is accomplished without any user interaction. By submitting such commands repeatedly from a SAS/AF or SAS/EIS application, it is possible to do “batch” processing for many data sets or by-group processing for many subsets of a data set. You can create a project in unattended mode and later open it for inspection interactively. You can also create a project interactively in order to set options, fit a model, or edit the list of models, and then use this project later in unattended mode.

The `Forecast Command Builder`, a point-and-click SAS/AF application, makes it easy to specify, run, save, and rerun forecasting jobs by using the `FORECAST` command. To use it, enter the following on the command line (not the program editor):

```
%FCB
```

or

```
AF C=SASHELP.FORCAST.FORCCMD.FRAME.
```

Syntax

The `FORECAST` command has the following form:

```
FORECAST [options] ;
```

The `%FORECAST` macro has the following form:

```
%FORECAST [(option, ..., option) ] ;
```

The following options can be specified for the command and the macro.

PROJECT=*project name*

specifies the name of the SAS catalog entry in which forecasting models and other results are stored and from which previously stored results are loaded into the forecasting system.

DATA=*data set name*

specifies the name of the SAS data set containing the input data.

VAR=*time series variable name*

specifies the series variable name. It must be a numeric variable contained in the data set.

ID=*time id variable name*

specifies the time ID variable name for the data set. If the `ID=` option is not specified, the system attempts to locate the variables named `DATE`, `DATETIME`, and `TIME` in the data set specified by the `DATA=` option. However, it is recommended that you specify the time ID variable whenever you are using the `ENTRY=` argument.

INTERVAL=*interval name*

specifies the time ID interval between observations in the data set. Commonly used intervals are `year`, `semyear`, `qtr`, `month`, `semimonth`, `week`, `weekday`, `day`, `hour`, `minute`, and `second`. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for information about more complex interval specifications. If the `INTERVAL=` option is not specified, the system attempts to determine the interval based on the time ID variable. However, it is recommended that you specify the interval whenever you are using the `ENTRY=` argument.

STAT=*statistic*

specifies the name of the goodness-of-fit statistic to be used as the model selection criterion. The default is `RMSE`. Valid names are

<code>sse</code>	sum of square error
<code>mse</code>	mean square error
<code>rmse</code>	root mean square error
<code>mae</code>	mean absolute error
<code>mape</code>	mean absolute percent error
<code>aic</code>	Akaike information criterion
<code>sbc</code>	Schwarz Bayesian information criterion
<code>rsquare</code>	R-square
<code>adjrsq</code>	adjusted R-square
<code>rwrsg</code>	random walk R-square
<code>arsq</code>	Amemiya’s adjusted R-square
<code>apc</code>	Amemiya’s prediction criterion

CLIMIT=*integer*

specifies the level of the confidence limits to be computed for the forecast. This integer represents a percentage; for example, `925` indicates 92.5% confidence limits. The default is `95`—that is, 95% confidence limits.

HORIZON=*integer*

specifies the number of periods into the future for which forecasts are computed. The default is 12 periods. The maximum is 9999.

ENTRY=*name*

The name of an entry point into the system. Valid names are

<code>main</code>	starts the system at the Time Series Forecasting window (default).
<code>devmod</code>	starts the system at the Develop Models window.
<code>viewmod</code>	starts the system at the Model Viewer window. Specify a project that contains a forecasting model by using the <code>PROJECT=</code> option. If a project containing a model is not specified, the message “No forecasting model to view” appears.

<code>viewer</code>	starts the system at the Time Series Viewer window.
<code>autofit</code>	runs the system in unattended mode, fitting a forecasting model automatically and saving it in a project. If <code>PROJECT=</code> is not specified, the default project name <code>SASUSER.FMSPROJ.PROJ</code> is used.
<code>forecast</code>	runs the system in unattended mode to generate a forecast data set. The name of this data set is specified by the <code>OUT=</code> parameter. If <code>OUT=</code> is not specified, a window appears to prompt for the name and label of the output data set. If <code>PROJECT=</code> is not specified, the default project name <code>SASUSER.FMSPROJ.PROJ</code> is used. If the project does not exist or does not contain a forecasting model for the specified series, automatic model fitting is performed and the forecast is computed by using the automatically selected model. If the project exists and contains a forecasting model for the specified series, the forecast is computed by using this model. If the series covers a different time range than it did when the project was created, use the <code>REFIT</code> or <code>REEVAL</code> keyword to reset the time ranges.

OUT=argument

specifies one or two-level name of a SAS data set in which forecasts are saved. Use in conjunction with `ENTRY=FORECAST`. If omitted, the system prompts for the name of the forecast data set.

KEEP=argument

specifies the number of models to keep in the project when automatic model fitting is performed. This corresponds to `Models to Keep` in the Automatic Model Selection Options window. A value greater than 9 indicates that all models are kept. The default is 1.

DIAG=YES|NO

specifies which models to search with regard to series diagnostics. `DIAG= YES` causes the automatic model selection process to search only over those models that are consistent with the series diagnostics. `DIAG= NO` causes the automatic model selection process to search over all models in the selection list, without regard for the series diagnostics. This corresponds to `Models to Fit` in the Automatic Model Selection Options window. The default is `YES`.

REFIT=keyword

(for macro usage) refits a previously saved forecasting model by using the current fit range; that is, it reestimates the model parameters. Refitting also causes the model to be reevaluated (statistics of fit recomputed), and it causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). This keyword has no effect if you do not use the `PROJECT=` argument to reference an existing project containing a forecasting model. Use the `REFIT` keyword if you have added new data to the input series and you want to refit the forecasting model and update the forecast by using the new time ranges. Be sure to use the same project, data set, and series names that you used previously.

REEVAL=keyword

(for macro usage) reevaluates a previously saved forecasting model by using the current evaluation range; that is, it recomputes the statistics of fit. Reevaluating also causes the time ranges to be reset if the data range has changed (for example, if new observations have been

added to the series). It does not refit the model parameters. This keyword has no effect if you also specify REFIT, or if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REEVAL keyword if you have added new data to the input series and want to update your forecast by using a previously fit forecasting model and the same project, data set, and series names that you used previously.

Examples

FORECAST Command

The following command opens the Time Series Forecasting window with the data set name and series name filled in. The time ID variable is also filled in since the data set contains the variable DATE. The interval is filled in because the system recognizes that the observations are monthly.

```
forecast data=sashelp.air var=air
```

The following command opens the Time Series Forecasting window with the project, data set name, series, time ID, and interval fields filled in, assuming that the project SAMPROJ was previously saved either interactively or by using unattended mode as depicted below. Previously fit models appear when the Develop Models or Manage Projects window is opened.

```
forecast project=samproj
```

The following command runs the system in unattended mode, fitting a model automatically, storing it in the project SAMPROJ in the default catalog SASUSER.FMSPROJ, and placing the forecasts in the data set WORK.SAMPOUT.

```
forecast data=sashelp.workers var=electric id=date interval=month
project=samproj entry=forecast out=sampout
```

The following command assumes that a new month's data have been added to the data set from the previous example and that an updated forecast is needed that uses the previously fit model. Time ranges are automatically updated to include the new data since the REEVAL keyword is included. Substitute REFIT for REEVAL if you want the system to reestimate the model parameters.

```
forecast data=sashelp.workers var=electric id=date interval=month
project=samproj entry=forecast out=sampout reeval
```

The following command opens the model viewer with the project created in the previous example and with 99 percent confidence limits in the forecast graph.

```
forecast data=sashelp.workers var=electric id=date interval=month
project=samproj entry=viewmod climit=99
```

The final example illustrates using unattended mode with an existing project that has been defined interactively. In this example, the goal is to add a model to the model selection list, to specify that all models in that list be fit, and that all models which are fit successfully be retained.

First open the Time Series Forecasting window and specify a new project name, WORKPROJ. Then select `Develop Models`, choosing SASHELP.WORKERS as the data set and MASONRY as the series. Now select “Model Selection List” from the Options menu. In the Model Selection List window, click `Actions`, then `Add`, and then `ARIMA Model`. Define the model `ARIMA(0,1,0)(0,1,0)SNOINT` by setting the differencing value to 1 under both `ARIMA Options` and `Seasonal ARIMA Options`. Select `OK` to save the model and `OK` to close the Model Selection List window. Now select “Automatic Fit” from the Options menu. In the Automatic Model Selection Options window, select “All autofit models in selection list” in the Models to fit radio box, select “All models” from the Models to keep combo box, and then click `OK` to close the window. Select “Save Project” from the File menu, and then close the Develop Models window and the Time Series Forecasting window. You now have a project with a new model added to the selection list, options set for automatic model fitting, and one series selected but no models fit.

Now enter the command:

```
forecast data=sashelp.workers var=electric id=date interval=month
project=workproj entry=forecast out=workforc
```

The system runs in unattended mode to update the project and create the forecast data set WORKFORC. Check the messages in the Log window to find out if the run was successful and which model was selected for forecasting. To see the forecast data set, issue the command `viewtable WORKFORC`. To see the contents of the project, open the Time Series Forecasting window, open the project WORKPROJ, and select “Manage Projects.” You will see that the variable ELECTRIC was added to the project and has a forecasting model. Select this row in the table and then select `List Models` from the Tools menu. You will see that all of the models in the selection list which fit successfully are there, including the new model you added to the selection list.

%FORECAST Macro

This example demonstrates the use of the %FORECAST macro to start the Time Series Forecasting System from a SAS program submitted from the Editor window. The SQL procedure is used to create a view of a subset of a products data set. Then the %FORECAST macro is used to produce forecasts.

```
proc sql;
  create view selprod as
  select * from products
  where type eq 'A'
  order by date;
run;

%forecast(data=selprod, var=amount, id=date, interval=day,
  entry=forecast, out=typea, proj=proda, refit= );
```

Overview

This chapter provides a reference to the various windows of the Time Series Forecasting System. The windows are presented in alphabetical order by name. Each section describes the purpose of the window, how to open it, its controls, fields, and menus. For windows that have their own menus, there is a description of each menu item under the heading “Menu Bar.” These windows also have a toolbar with icons that duplicate the more commonly used menu items. Each icon has a *screen tip*: a brief description that appears when you hover the mouse cursor over the icon. If you don’t see the screen tips, open the SAS Preferences window, under the Options submenu of the Tools menu. Select the View tab and make sure the “Screen tips” check box is checked.

Adjustments Selection Window

Use the Adjustments Selection window to select input variables for use as adjustments to the forecasts and add them to the Predictors list. Invoke this window from the pop-up menu that appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window. For more information, see the “Adjustments” section in Chapter 41, “Using Predictor Variables.”

Controls and Fields

Dependent

is the name and variable label of the current series.

Adjustments

is a table that lists the names and labels in the input data set available for selection as adjustments. The variables you select are highlighted. Selecting a highlighted row again deselects that variable.

OK

closes the Adjustments Selection window and adds the selected variables as adjustments in the model.

Cancel

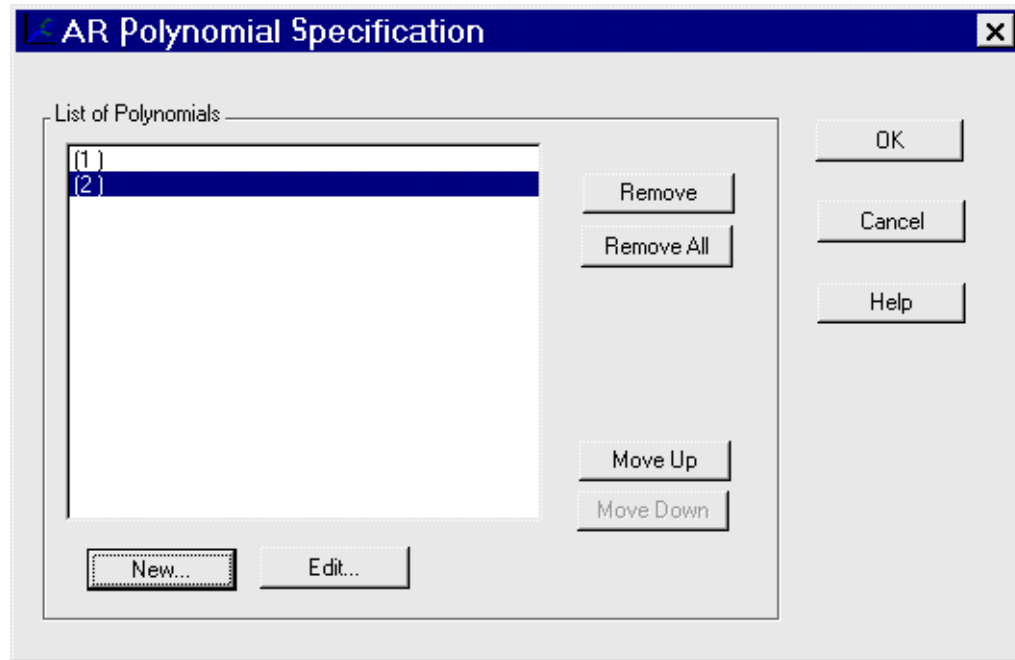

closes the window without adding any adjustments.

Reset

resets all selections to their initial values upon entry to the window.

AR/MA Polynomial Specification Window

Use these windows to specify the autoregressive and moving-average terms in a factored ARIMA model. Access the AR Polynomial Specification window from the Set button next to the Autoregressive term in the Factored ARIMA Model Specification window. Access the MA Polynomial Specification window from the Set button next to the Moving Average term.

Controls and Fields

List of Polynomials

Lists the polynomials that have been specified. Each polynomial is represented by a comma-delimited list of lag values enclosed in parentheses.

New

Opens the Polynomial Specification window to add a new polynomial to the model.

Edit

Opens the Polynomial Specification window to edit a polynomial that has been selected. If no polynomial is selected, this button is unavailable.

Remove

Removes a selected polynomial from the list. If none are selected, this button is unavailable.

Remove All

Clears the list of polynomials.

Move Up

Moves a selected polynomial up one position in the list. If no polynomial is selected, or the first one is selected, this button is unavailable.

Move Down

Moves a selected polynomial down one position in the list. If no polynomial is selected, or the last one is selected, this button is unavailable.

OK

Closes the window and returns the specified list of polynomials to the Factored ARIMA Model Specification window.

Cancel

Closes the window and discards any changes made to the list of polynomials.

ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit in the menu bar, or from the pop-up menu when you click an empty area of the model table.

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

ARIMA Options

specify the orders of the ARIMA model. You can either type in a value or click the arrow to select from a list.

Autoregressive

defines the order of the autoregressive part of the model.

Differencing

defines the order of simple differencing—for example, first difference or second difference.

Moving Average

defines the order of the moving-average part of the model.

Seasonal ARIMA Options

specify the orders of the seasonal part of the ARIMA model. You can either type in a value or click the arrow to select from a list.

Autoregressive

defines the order of the seasonal autoregressive part of the model.

Differencing

defines the order of seasonal differencing—for example, first difference or second difference at the seasonal lags.

Moving Average

defines the order of the seasonal moving-average part of the model.

Transformation

defines the series transformation for the model. When a transformation is specified, the ARIMA model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the ARIMA model predictions. The available transformations are: Log, Logistic, Square Root, Box-Cox, and None.

Intercept

specify whether a mean or intercept parameter is included in the ARIMA model. By default, the Intercept option is set to No when the model includes differencing and Yes when there is no differencing.

Predictors

lists the predictor effects included as inputs in the model.

OK

closes the ARIMA Model Specification window and fits the model.

Cancel

closes the ARIMA Model Specification window without fitting the model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the ARIMA Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Add

opens a menu of types of predictors to add to the Predictors list.

Delete

deletes the selected (highlighted) entry from the Predictors list.

Edit

edits the selected (highlighted) entry in the Predictors list.

Mouse Button Actions

You can select or deselect entries in the Predictors list by clicking them. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you right-click an entry in the Predictors list, the system displays the following menu of actions that encompass the features of the Add, Delete, and Edit buttons.

Add Linear Trend

adds a Linear Trend item to the Predictors list.

Add Trend Curve

opens a menu of different time trend curves and adds the curve you select to the Predictors list. Certain trend curve specifications also set the Transformation field.

Add Regressors

opens the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

Add Adjustments

opens the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

Add Dynamic Regressor

opens the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

Add Interventions

opens the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

Add Seasonal Dummies

adds a Seasonal Dummies predictor item to the Predictors list.

Edit Predictor

edits the selected (highlighted) entry in the Predictors list.

Delete Predictors

deletes the selected (highlighted) entry from the Predictors list.

ARIMA Process Specification Window

Use the ARIMA Process Specification window to define ARIMA processes for simulation. Invoke this window from the Add Series button in the Time Series Simulation window.

ARIMA Process Specification

Series Name:

Series Label:

Series Mean: Simple Differencing: ▼

Transformation: ▼ Seasonal Differencing: ▼

AR Parameters

Factor	Lao	Value
1	1	0.3000
1	2	0.1500
1	3	-0.4000
		.
		.
		.
		.

MA Parameters

Factor	Lao	Value
		.
		.
		.
		.
		.

Controls and Fields

Series Name

is the variable name for the series to be simulated.

Series Label

is the variable label for the series to be simulated.

Series Mean

is the mean of the simulated series.

Transformation

defines the series transformation.

Simple Differencing

is the order of simple differencing for the series.

Seasonal Differencing

is the order of seasonal differencing for the series.

AR Parameters

is a table of autoregressive terms for the simulated ARIMA process. Enter a value for Factor,

Lag, and Value for each term of the AR part of the process you want to simulate. For a non-factored AR model, make the Factor values the same for all terms. For a factored AR model, use different Factor values to group the terms into the factors.

MA Parameters

is a table of moving-average terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the MA part of the process you want to simulate. For a non-factored MA model, make the Factor values the same for all terms. For a factored MA model, use different Factor values to group the terms into the factors.

OK

closes the ARIMA Process Specification window and adds the specified process to the Series to Generate list in the Time Series Simulation window.

Cancel

closes the window without adding to the Series to Generate list. Any options you specified are lost.

Reset

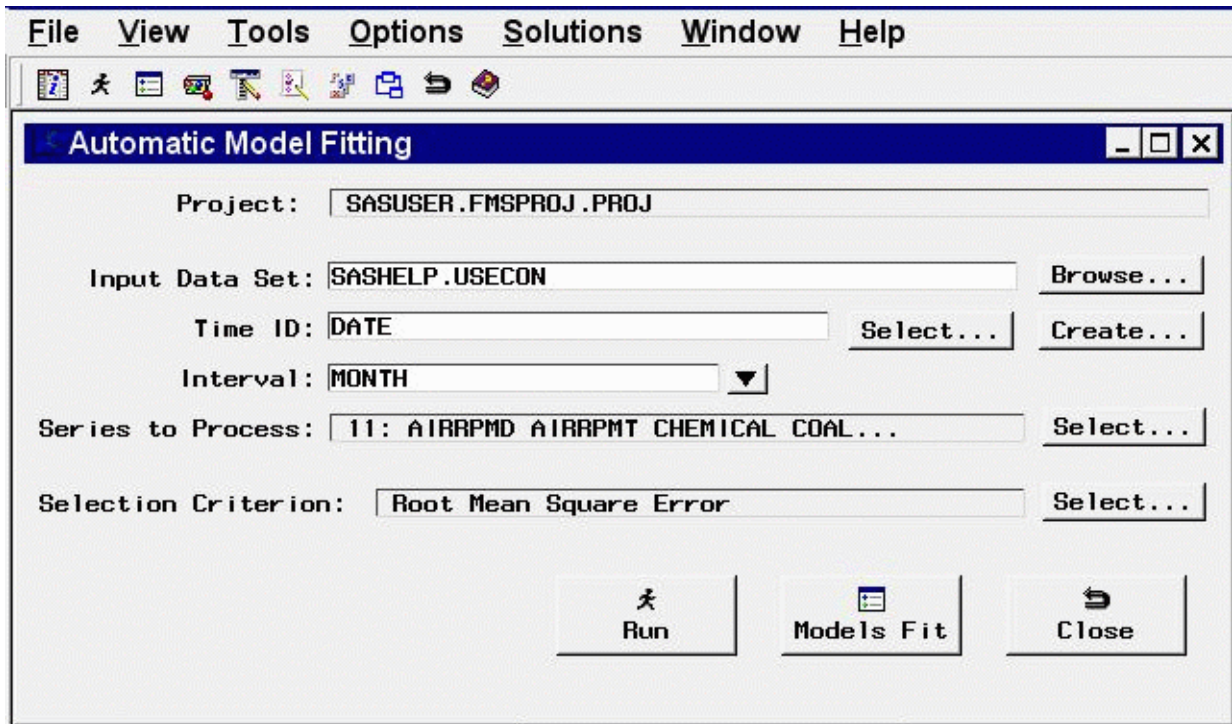

resets all the fields to their initial values upon entry to the window.

Clear

resets all the fields to their default values.

Automatic Model Fitting Window

Use the Automatic Model Fitting window to perform automatic model selection on all series or selected series in an input data set. Invoke this window by using the Fit Models Automatically button on the Time Series Forecasting window. Note that you can also perform automatic model fitting, one series at a time, from the Develop Models window.

Controls and Fields

Project

the name of the SAS catalog entry in which the results of the model search process are stored.

Input Data Set

is the name of the current input data set. You can type in a one-level or two-level data set name here.

Browse button

opens the Data Set Selection window for selecting an input data set.

Time ID

is the name of the ID variable for the input data set. You can type in the variable name here or use the Select or Create button.

time ID Select button

opens the Time ID Variable Specification window.

time ID Create button

opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the current input data set. You can type in an interval name or select one by using the combo box pop-up menu.

Series to Process

indicates the number and names of time series variables for which forecasting model selection will be applied.

Series to Process *Select* button

opens the Series to Process window to let you select the series for which you want to fit models.

Selection Criterion

shows the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

Selection Criterion *Select* button

opens the Model Selection Criterion window to enable you to select the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

Run button

begins the automatic model fitting process.

Models Fit button

opens the Automatic Model Fitting Results window to display the models fit during the current invocation of the Automatic Model Fitting window. The results appear automatically when model fitting is complete, but this button enables you to redisplay the results window.

Close button

Closes the Automatic Model Fitting window.

Menu Bar

File

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the Automatic Model Fitting window.

View

Input Data Set

opens a Viewtable window to browse the current input data set.

Models Fit

opens Automatic Model Fitting Results window to show the forecasting models fit during the current invocation of the Automatic Model Fitting window. This is the same as the Models Fit button.

Tools

Fit Models

performs the automatic model selection process for the selected series. This is the same as the Run button.

Options

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series.

Model Selection List

opens the Model Selection List editor window. Use this action to control the forecasting models considered by the automatic model selection process and displayed in the Models to Fit window.

Model Selection Criterion

opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This action is the same as the Selection Criterion Select button.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion menu.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Forecast Data Set

see Produce Forecasts window.

Alignment of Dates

Beginning

aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle

aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End

aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the

number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Tool Bar Type

Image Only

displays the toolbar items as icons without text.

Label Only

displays the toolbar items as text without icon images.

Both

displays the toolbar items with both text and icon images.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Automatic Model Fitting Results Window

This resizable window displays the models fit by the most recent invocation of the Automatic Model Fitting window. It appears automatically after Automatic Model Fitting runs, and can be opened repeatedly from that window by using the Models Fit button or by selecting Models Fit from the View menu. Once you exit the Automatic Model Fitting window, the Automatic Model Fitting Results window cannot be opened again until you fit additional models by using Automatic Model Fitting.

Series Name	Model Label	Root Mean Square Error
AIRRPMD	Log ARIMA(2,1,2)(0,1,1)s NOINT	0.63290
AIRRPMD	Log ARIMA(0,1,2)(0,1,1)s NOINT	0.63390
AIRRPMT	Log ARIMA(0,1,2)(0,1,1)s NOINT	0.74226
AIRRPMT	Log ARIMA(2,1,0)(0,1,1)s NOINT	0.74883
CHEMICAL	Log ARIMA(2,1,2)(0,1,1)s NOINT	386.25
CHEMICAL	Log Winters Method -- Additive	397.96
COAL	Linear Trend with Autoregressive Errors	6972.17
COAL	Winters Method -- Additive	7244.40
DURABLES	Log Winters Method -- Multiplicative	2157.29
DURABLES	Log Winters Method -- Additive	2161.37
HS1FAM	Log Seasonal Exponential Smoothing	7.22149

Table Contents The results table displays the series name in the first column and the model label in the second column. If you have chosen to retain more than one model by using the Automatic Model Selection Options window, more than one row appears in the table for each series; that is, there is a row for each model fit. If you have already fit models to the same series before invoking the Automatic Model Fitting window, those models do not appear here, since the Automatic Model Fitting Results window is intended to show the results of the current operation of Automatic Model Fitting. To see all models that have been fit, use the Manage Projects window.

The third column of the table shows the values of the current model selection criterion statistic. Additional columns show the values of other fit statistics. The set of statistics shown are selectable by using the Statistics of Fit Selection window.

The table can be sorted by any column other than Series Name by clicking on the column heading.

Controls and Fields

Graph

opens the Model Viewer window on the model currently selected in the table.

Stats

opens the Statistics of Fit Selection window. This controls the set of goodness-of-fit statistics displayed in the table and in other parts of the Time Series Forecasting System.

Compare

opens the Model Fit Comparison window for the series currently selected in the table. This button is unavailable if the currently selected row in the table represents a series for which fewer than two models have been fit.

Save

opens an output data set dialog, enabling you to specify a SAS data set to which the contents of the table is saved. Note that this operation saves what you see in the table. If you want to save the models themselves for use in a future session, use the Manage Projects window.

Print

prints the contents of the table.

Close

closes the window and returns to the Automatic Model Fitting window.

Menu Bar

File**Save**

opens an output data set dialog, enabling you to specify a SAS data set to which the contents of the table is saved. This is the same as the Save button.

Print

prints the contents of the table. This is the same as the Print button.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the window and returns to the Automatic Model Fitting window.

View**Model Predictions**

opens the Model Viewer to display a predicted and actual plot for the currently highlighted model.

Prediction Errors

opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations

opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests

opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit

opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph

opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table

opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Tools**Compare Models**

opens the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This item is unavailable until you select a series in the table for which the automatic model fitting run selected two or more models.

Options**Statistics of Fit**

opens the Statistics of Fit Selection window. This is the same as the Stats button.

Column Labels

selects long or short column labels for the table. Long column labels are used by default.

ID Columns

freezes or unfreezes the series and model columns. By default they are frozen so that they remain visible when you scroll the table horizontally to view other columns.

Automatic Model Selection Options Window

Use the Automatic Model Selection Options window to control the automatic selection process. This window is available from the Automatic Fit item of the Options menu in the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.

Controls and Fields

Models to fit

Subset by series diagnostics

when selected, causes the automatic model selection process to search only over those models consistent with the series diagnostics.

All models in selection list

when selected, causes the automatic model selection process to search over all models in the search list, without regard for the series diagnostics.

Models to keep

specifies how many of the models tried by the automatic model selection process are retained and added to the model list for the series. You can specify the best fitting model only, the best n models, where n can be 1 through 9, or all models tried.

OK

closes the window and saves the automatic model selection options you specified.

Cancel

closes the window without changing the automatic model selection options.

Custom Model Specification Window

Use the Custom Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models window, where it is invoked from the Fit Model item under the Edit menu, or from the pop-up menu when you click an empty area of the model table.

Custom Model Specification

Series:

Model:

Transformation: Trend Model:

Seasonal Model: Error Model:

Intercept: Yes No

Predictors

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Transformation

defines the series transformation for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the resulting forecasts. The following transformations are available:

Log

specifies a logarithmic transformation.

Logistic

specifies a logistic transformation.

Square Root

specifies a square root transformation.

Box-Cox

specifies a Box-Cox transform and opens a window to specify the Box-Cox λ parameter.

None

specifies no series transformation.

Trend Model

controls the model options to model and forecast the series trend. Select from the following:

Linear Trend

adds a Linear Trend item to the Predictors list.

Trend Curve

brings of a menu of different time trend curves and adds the curve you select to the Predictors list.

First Difference

specifies differencing the series.

Second Difference

specifies second-order differencing of the series.

None

specifies no model for the series trend.

Seasonal Model

controls the model options to model and forecast the series seasonality. Select from the following:

Seasonal ARIMA

opens the Seasonal ARIMA Model Options window to enable you to specify an ARIMA model for the seasonal pattern in the series.

Seasonal Difference

specifies differencing the series at the seasonal lag.

Seasonal Dummy Regressors

adds a Seasonal Dummies predictor item to the Predictors list.

None

specifies no seasonal model.

Error Model

displays the current settings of the autoregressive and moving-average terms, if any, for modeling the prediction error autocorrelation pattern in the series.

Set button

opens the Error Model Options window to enable you to set the autoregressive and moving-average terms for modeling the prediction error autocorrelation pattern in the series.

Intercept

specifies whether a mean or intercept parameter is included in the model. By default, the Intercept option is set to No when the model includes differencing and set to Yes when there is no differencing.

Predictors

is a list of the predictor effects included as inputs in the model.

OK

closes the Custom Model Specification window and fits the model.

Cancel

closes the Custom Model Specification window without fitting the model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the Custom Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Add

opens a menu of types of predictors to add to the Predictors list. Select from the following:

Linear Trend

adds a Linear Trend item to the Predictors list.

Trend Curve

opens a menu of different time trend curves and adds the curve you select to the Predictors list.

Regressors

opens the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

Adjustments

opens the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

Dynamic Regressor

opens the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

Interventions

opens the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

Seasonal Dummies

adds a Seasonal Dummies predictor item to the Predictors list. This is unavailable if the series interval is not one which has a seasonal cycle.

Delete

deletes the selected (highlighted) entry from the Predictors list.

Edit

edits the selected (highlighted) entry in the Predictors list.

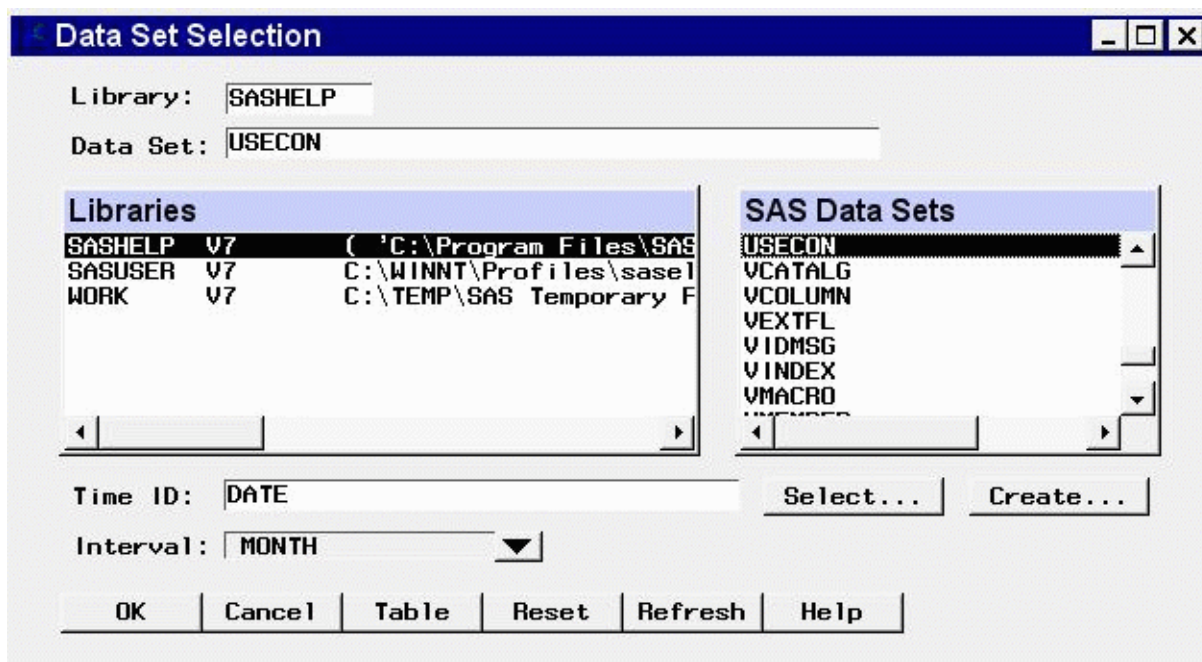

Mouse Button Actions

You can select or deselect entries in the Predictors list by clicking them. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you right-click an entry in the Predictors list and press the right mouse button, the system displays a menu of actions that encompass the features of the Add, Delete, and Edit buttons.

Data Set Selection Window

Use this resizable window to select a data set to process by specifying a library and a SAS data set or view. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set.

Access this window by using the Browse button to the right of the Data Set field in the Time Series Forecasting, Automatic Model Fitting, and Produce Forecasts windows. It functions in the same way as the Series Selection window, except that it does not allow you to select or view a time series variable.

Controls and Fields

Library

is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname. See also Libraries under Selection Lists.

Data Set

is the name of a SAS data set (data file or data view) that resides under the selected libname.

If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted.

Time ID

is the name of the ID variable for the selected input data set. To specify the ID variable, you can type the ID variable name in this field or select the control arrows to the right of the field.

Time ID Select button

opens the Time ID Variable Specification window.

Time ID Create button

opens a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically identified by the system, you can type in the interval name or select it from a list by clicking the combo box arrow. For more information about intervals, see Chapter 4, “[Date Intervals, Formats, and Functions](#),” in this book.

OK

closes the Data Set Selection window and makes the selected data set the current input data set.

Cancel

closes the window without applying any selections made.

Table

opens a Viewtable window for browsing the selected data set.

Reset

resets the fields to their initial values upon entry to the window.

Refresh

updates all fields and lists in the window. If you assign a new libname without exiting the Data Set Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname.

Selection Lists

Libraries

displays a list of currently assigned libnames. You can select a libname by clicking it with the left mouse button, which is equivalent to typing its name in the Library field.

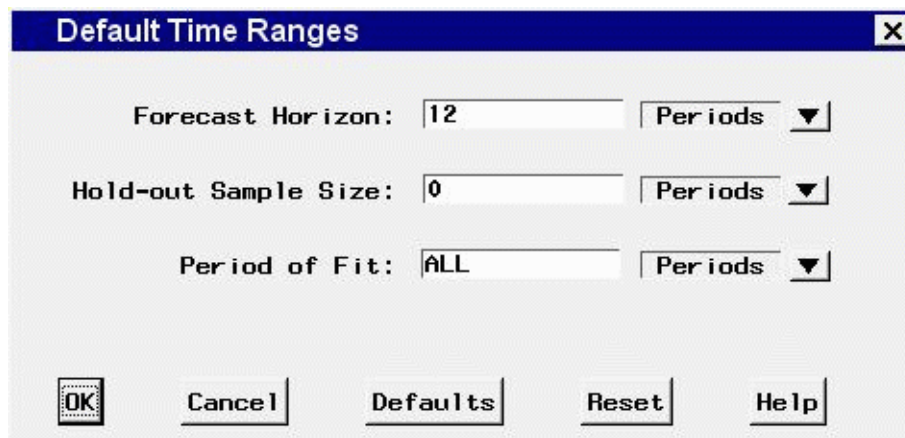

If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File menu, then select “Library” and “OK.” This opens the New Library window. You also assign a libname by submitting a libname statement from the Editor window. Select the Refresh button to make the new libname available in the libraries list.

SAS Data Sets

displays a list of the SAS data sets (data files or data views) contained in the selected library. You can select one of these by clicking with the left mouse button, which is equivalent to typing its name in the Data set field. You can double-click a data set name to select it and exit the window.

Default Time Ranges Window

Use the Default Time Ranges window to control how the period of fit and evaluation and the forecasting horizon are determined for each series when you do not explicitly set these ranges for a particular series. Invoke this window from the Options menu of the Develop Models, Automatic Model Fitting, Produce Forecasts, and Manage Forecasting Project windows. The settings you make in this window affect subsequently selected series; they do not alter the time ranges of series you have already selected.

Controls and Fields

Forecast Horizon

specifies the forecast horizon as either a number of periods or years from the last nonmissing data value or as a fixed date. You can type a number or date value in this field. Date value must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.)

Forecast Horizon Units

indicates whether the value in the forecast horizon field represents periods or years or a date. Click the arrow and select one from the pop-up list.

Hold-out Sample Size

specifies that a number of observations, number of years, or percent of the data at the end of the data range be used for the period of evaluation with the remainder of data used as the period of fit.

Hold-out Sample Size Units

indicates whether the hold-out sample size represents periods or years or percent of data range.

Period of Fit

specifies how much of the data range for a series is to be used as the period of fit for models fit to the series. ALL indicates that all the available data is used. You can specify a number of periods, number of years, or a fixed date, depending on the value of the units field to the right. When you specify a date, the start of the period of fit is the specified date or the first nonmissing series value, whichever is more recent. Date value must be entered in a form

recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) When you specify the number of periods or years, the start of the period of fit is computed as the date that number of periods or years from the end of the data.

Period of Fit Units

indicates whether the period-of-fit value represents periods or years or a date.

OK

closes the window and stores the specified changes.

Cancel

closes the window without saving changes. Any options you specified are lost.

Defaults

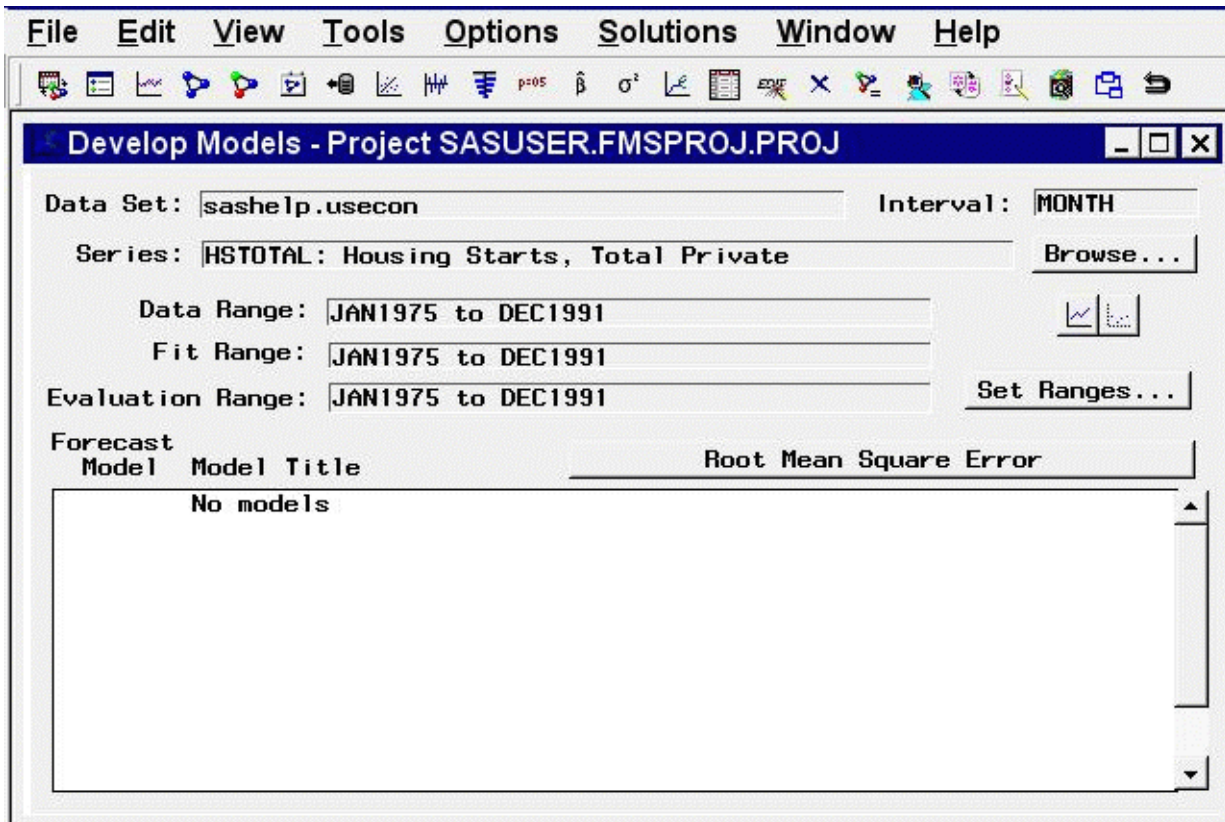

resets all options to their default values.

Reset

resets the options to their initial values upon entry to the window.

Develop Models Window

This resizable window provides access to all of the Forecasting System's interactive model fitting and graphical tools. Use it to fit forecasting models to an individual time series and choose the best model to use to produce the final forecasts of the series. Invoke this window by using the Develop Models button on the Time Series Forecasting window.

Controls and Fields

Data Set

is the name of the current input data set.

Interval

is the time interval (data frequency) for the input data set.

Series

is the variable name and label of the current time series.

Browse button

opens the Series Selection window to enable you to change the current input data set or series.

Data Range

is the date of the first and last nonmissing data values available for the current series in the input data set.

Fit Range

is the current period of fit setting. This is the range of data that will be used to fit models to the series.

Evaluation Range

is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series.

Set Ranges button

opens the Time Ranges Specification window to enable you to change the fit range or evalua-

tion range. Note: A new fit range is applied when new models are fit or when existing models are refit. A new evaluation range is applied when new models are fit or when existing models are refit or reevaluated. Changing the ranges does not automatically refit or reevaluate any models in the table: Use the Refit Models or Reevaluate Models items under the Edit menu.

View Series Graphically icon

opens the Time Series Viewer window to display plots of the current series.

View Selected Model Graphically icon

opens the Model Viewer to display graphs and tables for the currently highlighted model.

Forecast Model

is the column of the model table that contains check boxes to select which model is used to produce the final forecasts for the current series.

Model Title

is the column of the model table that contains the descriptive labels of the forecasting models fit to the current series.

Root Mean Square Error (or other statistic name) button

is the button above the right side of the table. It displays the name of the current model selection criterion: a statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button opens the Model Selection Criterion window to let you to select a different statistic. When you select a statistic, the model table the Develop Models window is updated to show current values of that statistic.

Menu Bar

File

New Project

opens a dialog that lets you create a new project, assign it a name and description, and make it the active project.

Open Project

opens a dialog that lets you select and load a previously saved project.

Save Project

saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

Save Project as

saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

Clear Project

clears the system, deleting all the models for all series.

Save Forecast

writes forecasts from the currently highlighted model to an output data set.

Save Forecast As

prompts for an output data set name and saves the forecasts from the currently highlighted model.

Output Forecast Data Set

opens a dialog for specifying the default data set used when you select “Save Forecast.”

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which enables you to access your operating system print setup.

Close

closes the Develop Models window and returns to the main window.

Edit**Fit Model****Automatic Fit**

invokes the automatic model selection process.

Select From List

opens the Models to Fit window.

Smoothing Model

opens the Smoothing Model Specification window.

ARIMA Model

opens the ARIMA Model Specification window.

Custom Model

opens the Custom Model Specification window.

Combine Forecasts

opens the Forecast Combination Model Specification window.

External Forecasts

opens the External Forecast Model Specification window.

Edit Model

enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

Delete Model

deletes the currently highlighted model from the model table.

Refit Models

All Models

refits all models in the table by using data within the current fit range.

Selected Model

refits the currently highlighted model by using data within the current fit range.

Reevaluate Models

All Models

recomputes statistics of fit for all models in the table by using data within the current evaluation range.

Selected Model

recomputes statistics of fit for the currently highlighted model by using data within the current evaluation range.

View

Project

opens the Manage Forecasting Project window.

Data Set

opens a Viewtable window to display the current input data set.

Series

opens the Time Series Viewer window to display plots of the current series. This is the same as the View Series Graphically icon.

Model Predictions

opens the Model Viewer to display a predicted versus actual plot for the currently highlighted model. This is the same as the View Selected Model Graphically icon.

Prediction Errors

opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations

opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests

opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit

opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph

opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table

opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Tools**Diagnose Series**

opens the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

Define Interventions

opens the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

Sort Models

sorts the models in the table by the values of the currently displayed fit statistic.

Compare Models

opens the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This is unavailable if there are fewer than two models in the table.

Generate Data

opens the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

Options**Time Ranges**

opens the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon. This action is the same as the Set Ranges button.

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made by using this window do not affect series you are already working with; they take effect when you select a new series.

Model Selection List

opens the Model Selection List editor window. Use this action to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Model Selection Criterion

opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This action is the same as clicking the button above the table which displays the name of the current model selection criterion.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Alignment of Dates**Beginning**

aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle

aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End

aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Models to Fit window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

Controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions for the Model Table

When the cursor is over the description of a model in the table, the left mouse button selects (highlights) or deselects that model. On some computer systems, you can double-click to open the Model Viewer window for the selected model.

When the cursor is over an empty part of the model table, the left mouse button opens a menu of model fitting choices. These choices are the same as those in the Fit Model submenu of the Edit menu.

Right Mouse Button Actions for the Model Table

When a model in the table is selected, the right mouse opens a menu of actions that apply to the highlighted model. The actions available in this menu are as follows.

`View Model`

opens the Model Viewer for the selected model. This action is the same as the View Model Graphically icon.

`View Parameter Estimates`

opens the Model Viewer to display the parameter estimates table for the currently highlighted model. This is the same as the Parameter Estimates item in the View menu.

`View Statistics of Fit`

opens the Model Viewer to display a table of goodness-of-fit statistics for the currently highlighted model. This is the same as the Statistics of Fit item in the View menu.

`Edit Model`

enables you to modify the specification of the currently highlighted model in the table and fit the modified model. This is the same as the Edit Model item in the Edit menu.

`Refit Model`

refits the highlighted model by using data within the current fit range. This is the same as the Selected Model item under the Refit Models submenu of the Edit menu.

`Reevaluate Model`

reevaluates the highlighted model by using data within the evaluation fit range. This is the same as the Selected Model item under the Reevaluate Models submenu of the Edit menu.

`Delete Model`

deletes the currently highlighted model from the model table. This is the same as the Delete Model item under the Edit menu.

`View Forecasts`

opens the Model Viewer to display the forecasts for the currently highlighted model. This is the same as the Forecast Graph item under the View menu.

When the model list is empty or when no model is selected, the right mouse button opens the same menu of model fitting actions as the left mouse button.

Differencing Specification Window

Use the Differencing Specification window to specify the list of differencing lags $d = (\text{lag}, \dots, \text{lag})$ in a factored ARIMA model. To specify a first difference, add the value 1 ($d = (1)$). To specify a second difference (difference twice at lag 1), add the value 1 again ($d = (1, 1)$). For first differencing at lags 1 and 12, use the values 1 and 12 ($d = (1, 12)$).

Controls and Fields

Lag

specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows. Duplicates are allowed.

Add

adds the value in the Lag spin box to the list of differencing lags.

Remove

deletes a selected lag from the list of differencing lags.

OK

closes the window and returns the specified list to the Factored ARIMA Model Specification window.

Cancel

closes the window and discards any lags added to the list.

Dynamic Regression Specification Window

Use the Dynamic Regression Specification window to specify a dynamic regression or transfer function model for the effect of the predictor variable. It is invoked from the Dynamic Regressors Selection window.

The screenshot shows the 'Dynamic Regression Specification' dialog box. The 'Series' field contains 'HSTOTAL: Housing Starts, Total Private'. The 'Input Model' field contains 'VEHICLES'. The 'Input Transformations' section has a 'Transformation' dropdown set to 'None' and a 'Lagging periods' spinner set to '0'. The 'Order of Differencing' section has 'Simple' and 'Seasonal' spinners both set to '0'. The 'Numerator Factors' section has 'Simple Order' and 'Seasonal Order' spinners both set to '0'. The 'Denominator Factors' section has 'Simple Order' and 'Seasonal Order' spinners both set to '0'. At the bottom, there are five buttons: 'OK', 'Cancel', 'Reset', 'Clear', and 'Help'.

Controls and Fields

Series

is the name and variable label of the current series.

Input Model

is a descriptive label for the dynamic regression model. You can type a label in this field or allow the system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify. When no options are specified, the label is the name and variable label of the predictor variable.

Input Transformation

displays the transformation specified for the predictor variable. When a transformation is specified, the transfer function model is fit to the transformed input variable.

Lagging periods

is the pure delay in the effect of the predictor, l .

Simple Order of Differencing

is the order of differencing, d . Set this field to 1 to use the changes in the predictor variable.

Seasonal Order of Differencing

is the order of seasonal differencing, D . Set this field to 1 to difference the predictor variable at the seasonal lags—for example, to use the year-over-year or week-over-week changes in the predictor variable.

Simple Order Numerator Factors

is the order of the numerator factor of the transfer function, p .

Seasonal Order Numerator Factors

is the order of the seasonal numerator factor of the transfer function, P .

Simple Order Denominator Factors

is the order of the denominator factor of the transfer function, q .

Seasonal Order Denominator Factors

is the order of the seasonal denominator factor of the transfer function, Q .

OK

closes the window and adds the dynamic regression model specified to the model predictors list.

Cancel

closes the window without adding the dynamic regression model. Any options you specified are lost.

Reset

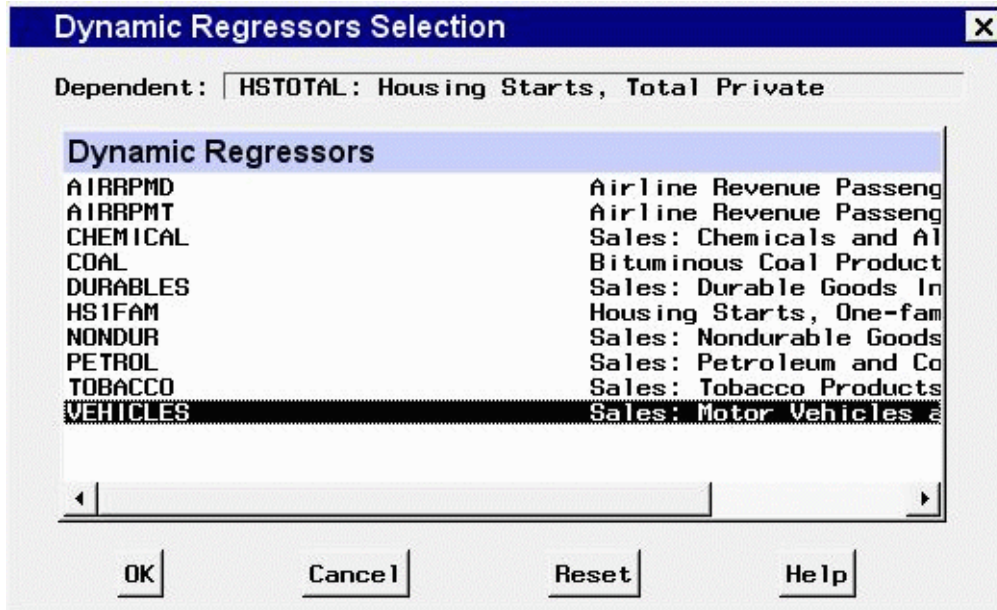

resets all options to their initial values upon entry to the window. This might be useful when editing a predictor specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Dynamic Regressors Selection Window

Use the Dynamic Regressors Selection window to select an input variable as a dynamic regressor. Access this window from the pop-up menu which appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window.

Controls and Fields

Dependent

is the name and variable label of the current series.

Dynamic Regressors

is a table listing the variables in the input data set. Select one variable in this list as the predictor series.

OK

opens the Dynamic Regression Specification window for you to specify the form of the dynamic regression for the selected predictor series, and then closes the Dynamic Regressors Selection window and adds the specified dynamic regression to the model predictors list.

Cancel

closes the window without adding the dynamic regression model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the window.

Error Model Options Window

Use the Error Model Options window to specify the autoregressive and moving-average orders for the residual autocorrelation part of a model defined by using the Custom Model Specification window. Access it by using the Set button of that window.

Controls and Fields

ARIMA Options

Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a pop-up list.

Autoregressive

defines the order of the autoregressive part of the model.

Moving Average

defines the order of the moving-average term.

OK

closes the Error Model Options window and returns to the Custom Model Specification window.

Cancel

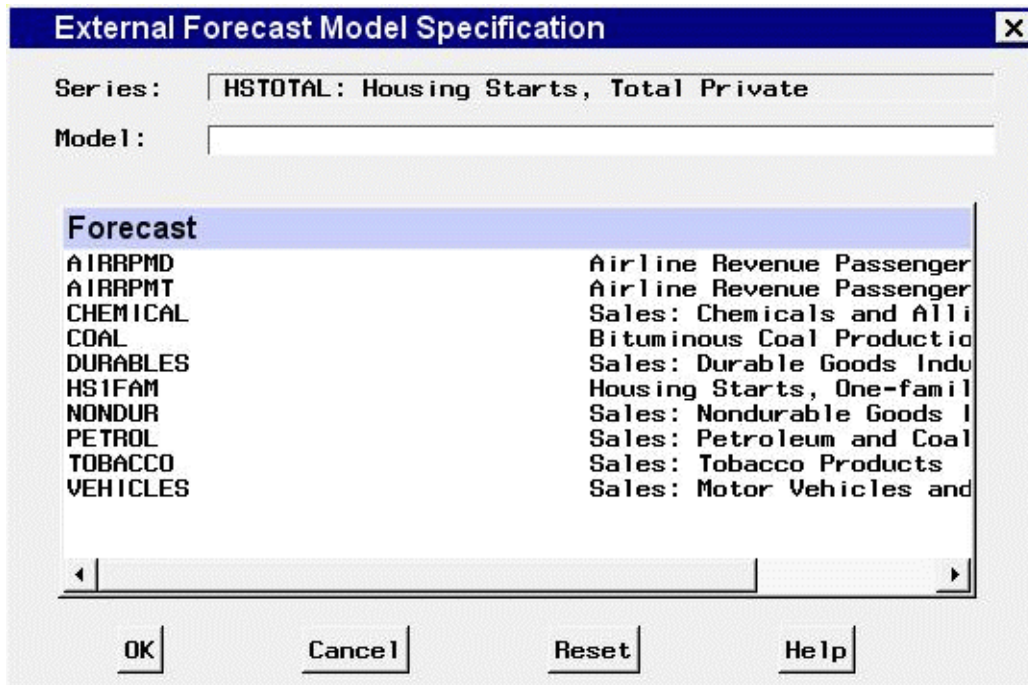

closes the Error Model Options window and returns to the Custom Model Specification window, discarding any changes made.

Reset

resets all options to their initial values upon entry to the window.

External Forecast Model Specification Window

Use the External Forecast Model Specification window to add to the current project forecasts produced externally to the Time Series Forecasting System. To add an external forecast, select a variable from the selection list and choose the OK button. The name of the selected variable will be added to the list of models fit, and the values of this variable will be used as the forecast. For more information, see “Incorporating Forecasts from Other Sources” in the “Specifying Forecasting Models” chapter.

Controls and Fields

OK

closes the window and adds the external forecast to the project.

Cancel

closes the window without adding an external forecast to the project.

Reset

deselects any selection made in the selection list.

Factored ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify an ARIMA model by using the notation:

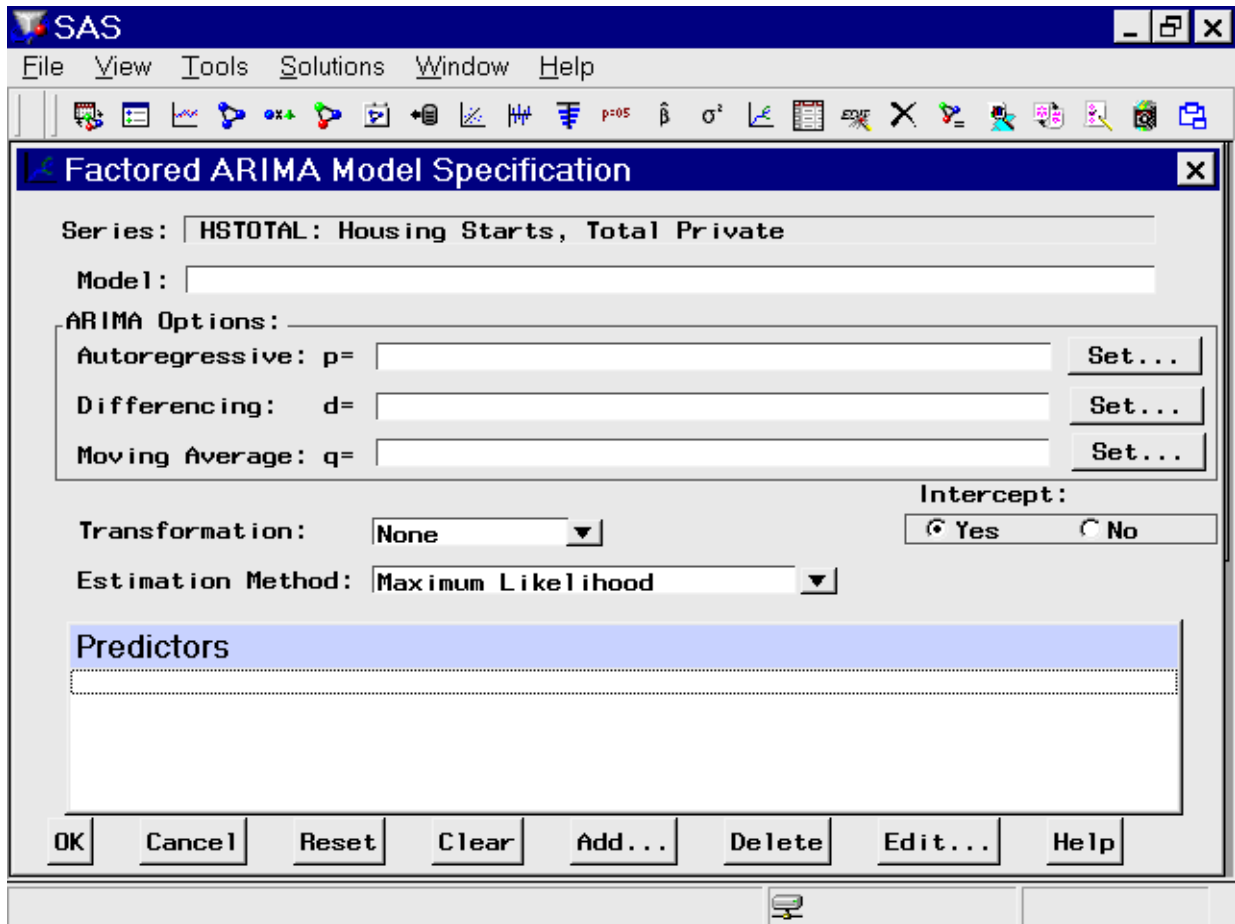

$$p = (\text{lag}, \dots, \text{lag}) \dots (\text{lag}, \dots, \text{lag})$$

$$d = (\text{lag}, \dots, \text{lag})$$

$$q = (\text{lag}, \dots, \text{lag}) \dots (\text{lag}, \dots, \text{lag})$$

where p, d, and q represent autoregressive, differencing, and moving-average terms, respectively.

Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit in the menu bar, or from the pop-up menu when you click an empty area of the model table.

The Factored ARIMA Model Specification window is identical to the ARIMA Model Specification window, except that the p , d , and q terms are specified in a more general and less limited way. Only those controls and fields that differ from the ARIMA Model Specification window are described here.

Controls and Fields

Model

is a descriptive label for the model. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the p , d , and q terms that you specify. For example, if you specify $p=(1, 2, 3)$, $d=(1)$, $q=(12)$ and no intercept, the model label is `ARIMA p=(1,2,3) d=(1) q=(12) NOINT`. For monthly data, this is equivalent to the model `ARIMA(3,1,0)(0,0,1)s NOINT` as specified in the ARIMA Model Specification window or the Custom Model Specification window.

ARIMA Options

Specifies the ARIMA model in terms of the autoregressive lags (p), differencing lags (d), and moving-average lags (q).

Autoregressive

defines the autoregressive part of the model. Select the Set button to open the AR Polynomial

Specification window, where you can add any set of autoregressive lags grouped into any number of factors.

Differencing

specifies differencing to be applied to the input data. Select the Set button to open the Differencing Specification window, where you can specify any set of differencing lags.

Moving Average

defines the moving-average part of the model. Select the Set button to open the MA Polynomial Specification window, where you can add any set of moving-average lags grouped into any number of factors.

Estimation Method

specifies the method used to estimate the model parameters. The Conditional Least Squares and Unconditional Least Squares methods generally require fewer computing resources and are more likely to succeed in fitting complex models. The Maximum Likelihood method requires more resources but provides a better fit in some cases. See also Estimation Details in Chapter 7, “[The ARIMA Procedure](#).”

Forecast Combination Model Specification Window

Use the Forecast Combination Model Specification window to produce forecasts by averaging the forecasts of two or more forecasting models. The specified combination of models is added to the model list for the series. Access this window from the Develop Models window whenever two or more models have been fit to the current series. It is invoked by selecting Combine Forecasts from the Fit Model submenu of the Edit menu, or from the pop-up menu which appears when you click an empty part of the model table.

Forecast Combination Model Specification

Series:

Model:

Weight	Model Description	Root Mean Square Error
.	Linear Trend	37.01371
.	Linear Trend with Autoregressive Errors	14.13055

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Weight

is a column of the forecasting model table that contains the weight values for each model. The forecasts for the combined model are computed as a weighted average of the predictions from the models in the table that use these weights. Models with missing weight values are not included in the forecast combination. You can type weight values in these fields or you can use other features of the window to set the weights.

Model Description

is a column of the forecasting model table that contains the descriptive labels of the forecasting models fit to the current series that are available for combination.

Root Mean Square Error (or other statistic name) button

is the button above the right side of the table. It displays the name of the current model selection criterion: a statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button opens the Model Selection Criterion window to enable you to select a different statistic.

Normalize Weights button

replaces each nonmissing value in the Weights column with the current value divided by the sum of the weights. The resulting weights are proportional to original weights and sum to 1.

Fit Regression Weights button

computes weight values for the models in the table by regressing the series on the predictions from the models. The values in the Weights column are replaced by the estimated coefficients produced by this linear regression. If some weight values are nonmissing and some are missing, only models with nonmissing weight values are included in the regression. If all weights are missing, all models are used.

OK

closes the Forecast Combination Model Specification window and fits the model.

Cancel

closes the Forecast Combination Model Specification window without fitting the model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the Forecast Combination Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

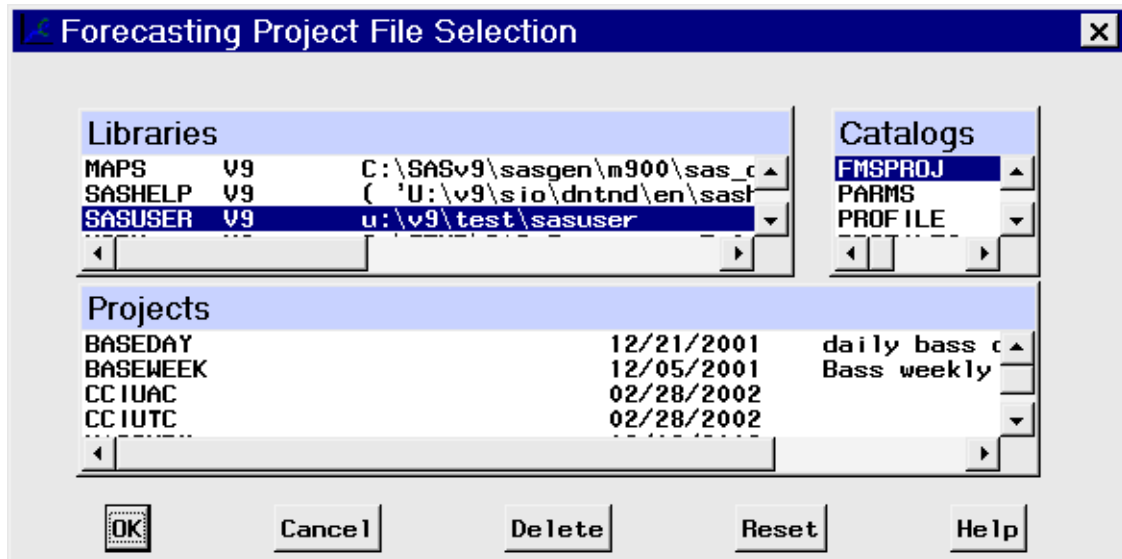

Mouse Button Actions

You can select or deselect models for inclusion in the combination model by positioning the mouse cursor over the model description and pressing the left mouse button. When you select a model in this way, the weights are automatically updated.

The newly selected model is given a weight equal to the average weight of the previously selected models, and all the nonmissing weights are normalized to sum to 1. When you use the mouse to remove a model from the combination, the weight of the deselected model is set to missing and the remaining nonmissing weights are normalized to sum to 1.

Forecasting Project File Selection Window

Use the Forecasting Project File Selection window to locate and load a previously stored forecasting project. Access it from the project Browse button of the Manage Forecasting Project window or the Time Series Forecasting window or from the Open Project item under the File menu of the Develop Models window.

Selection Lists

Libraries

is a list of currently assigned libraries. When you select a library from this list, the catalogs in that library are shown in the catalog selection list.

Catalogs

is a list of catalogs contained in the currently selected library. When you select a catalog from this list, any forecasting project entries stored in that catalog are shown in the projects selection list.

Projects

is a list of forecasting project entries contained in the currently selected catalog.

Controls and Fields

OK

closes the window and opens the selected project.

Cancel

closes the window without selecting a project.

Delete

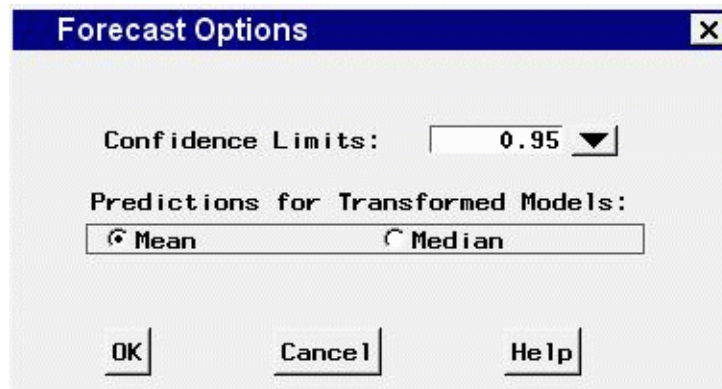

deletes the selected project file.

Reset

restores selections to those which were set before the window was opened.

Forecast Options Window

Use the Forecast Options window to set options to control how forecasts and confidence limits are computed. It is available from the Forecast Options item in the Options menu of the Develop Models window, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

Controls and Fields

Confidence Limits

specifies the size of the confidence limits for the forecast values. For example, a value of 0.95 specifies 95% confidence intervals. You can type in a number or select from the pop-up list.

Predictions for transformed models

controls how forecast values are computed for models that employ a series transformation. See the section [Predictions for Transformed Models](#) in Chapter 44, “[Forecasting Process Details](#),” for more information. The values are as follows.

Mean

specifies that forecast values be predictions of the conditional mean of the series.

Median

specifies that forecast values be predictions of the conditional median of the series.

OK

closes the window and saves the option settings you specified.

Cancel

closes the window without changing the forecast options. Any options you specified are lost.

Intervention Specification Window

Use the Intervention Specification window to specify intervention effects to model the impact on the series of unusual events. Access it from the Intervention for Series window. For more information,

see the section “Interventions” on page 2527.

Intervention Specification

Series:

Label:

Intervention Specification:

Date:

Type of Intervention:

Point Step Ramp

Effect Time Window:

Number of lags: ▼

Effect Decay Pattern:

None Exp Wave

DATE	HSTOTAL
JAN75	56.1000
FEB75	54.7000
MAR75	80.2000
APR75	97.9000
MAY75	116.1000
JUN75	110.3000
JUL75	119.3000
AUG75	117.3000
SEP75	111.9000
OCT75	123.6000
NOV75	96.9000

OK Cancel Reset Clear Help

Controls and Fields

Series

is the name and variable label of the current series.

Label

is a descriptive label for the intervention effect that you specify. You can type a label in this field or allow the system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify.

Date

is the date that the intervention occurs. You can type a date value in this field, or you can set the date by selecting a row of the data table on the right side of the window.

Type of Intervention

Point

specifies that the intervention variable is zero except for the specified date.

Step

specifies that the intervention variable is zero before the specified date and a constant 1.0 after the date.

Ramp

specifies that the intervention variable is an increasing linear function of time after the date of the intervention and zero before the intervention date.

Number of lags

specifies the numerator order for the transfer function model for the intervention effect. Select a value from the pop-up list.

Effect Decay Pattern

specifies the denominator order for the transfer function model for the intervention effect. The value “Exp” specifies a single lag denominator factor; the value “Wave” specifies a two-lag denominator factor.

OK

closes the window and adds the intervention effect specified to the series interventions list.

Cancel

closes the window without adding the intervention. Any options you specified are lost.

Reset

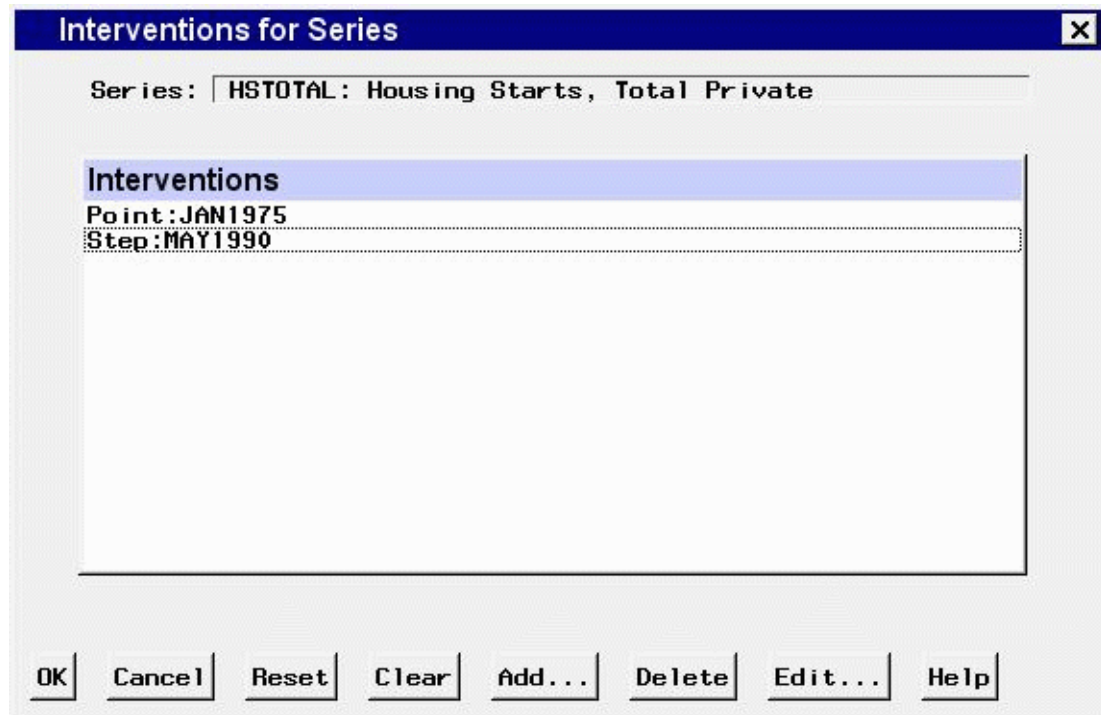

resets all options to their initial values upon entry to the window. This might be useful when editing an intervention specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Interventions for Series Window

Use the Interventions for Series window to create and edit a list of intervention effects to model the impact on the series of unusual events and to select intervention effects as predictors for forecasting models. Access it from the Add button pop-up menu of the ARIMA Model Specification or Custom Model Specification window, or by selecting Define Interventions from the Tools in the Develop Models window. For more information, see the section “[Interventions](#)” on page 2527.

Controls and Fields

Series

is the name and variable label of the current series.

OK

closes the window. If you access this window from the ARIMA Model Specification window or the Custom Model Specification window, any interventions that are selected (highlighted) in the list are added to the model. If you access this window from the Tools menu, all interventions in the list are saved for the current series.

Cancel

closes the window without returning a selection or changing the interventions list. Any options you specified are lost.

Reset

resets the list as it was on entry to the window.

Clear

deletes all interventions from the list.

Add

opens the Intervention Specification window to specify a new intervention effect and add it to the list.

Delete

deletes the currently selected (highlighted) entries from the list.

Edit

opens the Intervention Specification window to edit the currently selected (highlighted) intervention.

Mouse Button Actions

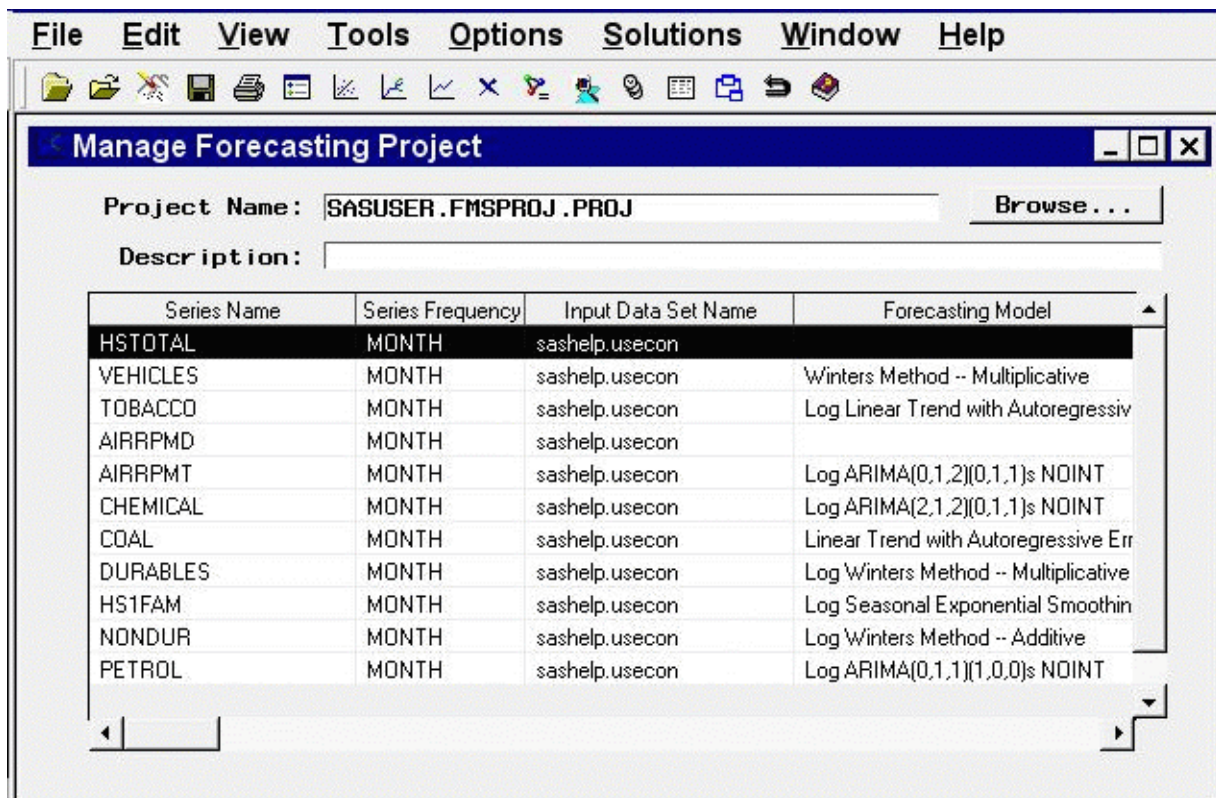

To select or deselect interventions, position the mouse cursor over the intervention's label in the Interventions list and press the left mouse button.

When you position the mouse cursor in the Interventions list and press the right mouse button, a menu containing the actions Add, Delete, and Edit appears. These actions are the same as the Add, Delete, and Edit buttons.

Double-clicking on an intervention in the list invokes an Edit action for that intervention specification.

Manage Forecasting Project Window

Use this resizable window to work with collections of series, models, and options called *projects*. The window contains a project name, a description field, and a table of information about all the series for which you have fit forecasting models. Access it by using the Manage Projects button on the Time Series Forecasting window.

Controls and Fields

Project Name

is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project by typing a SAS catalog entry name in this field or by selecting the Browse button to the right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one-level name, it is assumed to be the name of a project in the “fmsproj” catalog in the “sasuser” library. For example, typing `samproj` is equivalent to typing `sasuser.fmsproj.samproj`.

project Browse button

opens the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored project files.

Description

is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field if you save the project.

Series List Table

The table of series for which forecasting models have been fit contains the following columns.

Series Name

is the name of the time series variable represented in the given row of the table.

Series Frequency

is the time interval (data frequency) for the time series.

Input Data Set Name

is the input data set that provided the data for the series.

Forecasting Model

is the descriptive label for the forecasting model selected for the series.

Statistic Name

is the statistic of fit for the forecasting model selected for the series.

Number of Models

is the total number of forecasting models fit to the series. If there is more than one model for a series, use the Model List window to see a list of models.

Series Label

is the variable label for the series.

Time ID Variable Name

is the time ID variable for the input data set for the series.

Series Data Range

is the time range of the nonmissing values of the series.

Model Fit Range

is the period of fit used for the series.

Model Evaluation Range
is the evaluation period used for the series.

Forecast Range
is the forecast period set for the series.

Menu Bar

File

New

opens a dialog which lets you create a new project, assign it a name and description, and make it the active project.

Open

opens a dialog that lets you select and load a previously saved project.

Close

closes the Manage Forecasting Project window and returns to the main window.

Save

saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

Save As

saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

Save to Data Set

saves the current project file information in a SAS data set. The contents of the data set are the same as the information displayed in the series list table.

Delete

deletes the current project file.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print

prints the current project file information.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Edit

Delete Series

deletes all models for the selected (highlighted) row of the table and removes the series from the project.

Clear

resets the system, deleting all series and models from the project.

Reset

restores the Manage Forecasting Project window to its initial state.

View

Data Set

opens a Viewtable window to display the input data set for the selected (highlighted) series.

Series

opens the Time Series Viewer window to display plots of the selected (highlighted) series.

Model

opens the Model Viewer window to show the current forecasting model for the selected series.

Forecast

opens the Model Viewer to display plots of the forecasts produced by the forecasting model for the selected (highlighted) series.

Tools

Diagnose Series

opens the Series Diagnostics window to perform the automatic series diagnostic process to determine the kinds of forecasting models appropriate for the selected (highlighted) series.

List Models

opens the Model List window for the selected (highlighted) series, which displays a list of all the models that you fit for the series. This action is the same as double-clicking the mouse on the table row.

Generate Data

opens the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

Refit Models

All Series

refits all the models for all the series in the project by using data within the current fit range.

Selected Series

refits all the models for the currently highlighted series by using data within the current fit range.

Reevaluate Models**All Series**

reevaluates all the models for all the series in the project by using data within the current evaluation fit range.

Selected Series

reevaluates all the models for the currently highlighted series by using data within the current evaluation range.

Options**Time Ranges**

opens the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon.

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made by using this window do not affect series you are already working with; they take effect when you select a new series.

Model Selection List

opens the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Statistics of Fit

opens the Statistics of Fit Selection window, which controls which of the available statistics will be displayed.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Column Labels

enables you to set long or short column labels. Long labels are used by default.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Model Selection List editor window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions

If you select a series in the table by positioning the cursor over the table row and clicking with the left mouse button once, that row of the table is highlighted. Menu bar actions such as Delete Series will apply to the highlighted row of the table.

If you select a series in the table by positioning the cursor over the table row and double-clicking with the left mouse button, the system opens the Model List window for that series, which displays a list of all the models that you fit for the series. This is the same as the List Models action under Tools in the menu bar.

Right Mouse Button Actions

Clicking the right mouse button invokes a pop-up menu of actions applicable to the highlighted series. The actions in this menu are as follows.

Delete Series

deletes the highlighted series and its models from the project. This is the same as Delete Series in the Edit menu.

Refit All Models

refits all models attached to the highlighted series by using data within the current fit range. This is the same as the Selected Series item under Refit Models in the Tools menu.

Reevaluate All Models

reevaluates all models attached to the highlighted series by using data within the current evaluation range. This is the same as the Selected Series item under Reevaluate Models in the Tools menu.

List Models

invokes the Model List window. This is the same as List Models under the Tools menu.

View Series

opens the Time Series Viewer window to display plots of the highlighted series. This is the same as the Series item under the View menu.

View Forecasting Model

invokes the Model Viewer window to display the forecasting model for the highlighted series. This is the same as the Model item under the View menu.

View Forecast

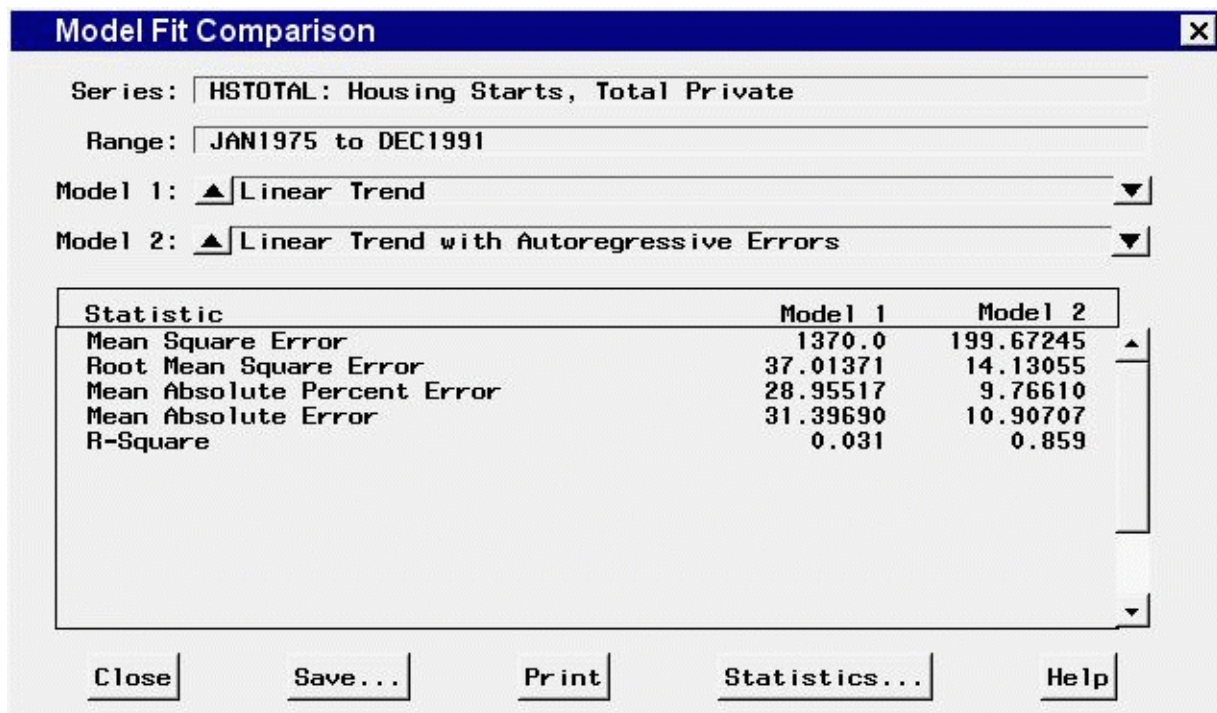

opens the Model Viewer window to display the forecasts for the highlighted series. This is the same as the Forecast item under the View menu.

Refresh

updates information shown in the Manage Forecasting Project window.

Model Fit Comparison Window

Use the Model Fit Comparison window to compare goodness-of-fit statistics for any two models fit to the current series. Access it from the Tools menu of the Develop Models window and the Automatic Model Fitting Results window whenever two or more models have been fit to the series.

Controls and Fields

Series

identifies the current time series variable.

Range

displays the starting and ending dates of the series data range.

Model 1

shows the model currently identified as Model 1.

Model 1 upward arrow button

enables you to change the model identified as Model 1 if it is not already the first model in the

list of models associated with the series. Select this button to cycle upward through the list of models.

Model 1 downward arrow button

enables you to change the model identified as Model 1 if it is not already the last model in the list of models. Select this button to cycle downward through the list of models.

Model 2

shows the model currently identified as Model 2.

Model 2 upward arrow button

enables you to change the model identified as Model 2 if it is not already the first model in the list of models associated with the series. Select this button to cycle upward through the list of models.

Model 2 downward arrow button

enables you to change the model identified as Model 2 if it is not already the last model in the list of models. Select this button to cycle downward through the list of models.

Close

closes the Model Fit Comparison window.

Save

opens a dialog for specifying the name and label of a SAS data set to which the statistics will be saved. The data set will contain all available statistics and their values for Model 1 and Model 2, as well as a flag variable that is set to 1 for those statistics that were displayed.

Print

prints the contents of the table to the SAS Output window. If you find that the contents do not appear immediately in the Output window, you need to set scrolling options. Select “Preferences” under the Options submenu of the Tools menu. In the Preferences window, select the Advanced tab, then set output scroll lines to a number greater than zero.

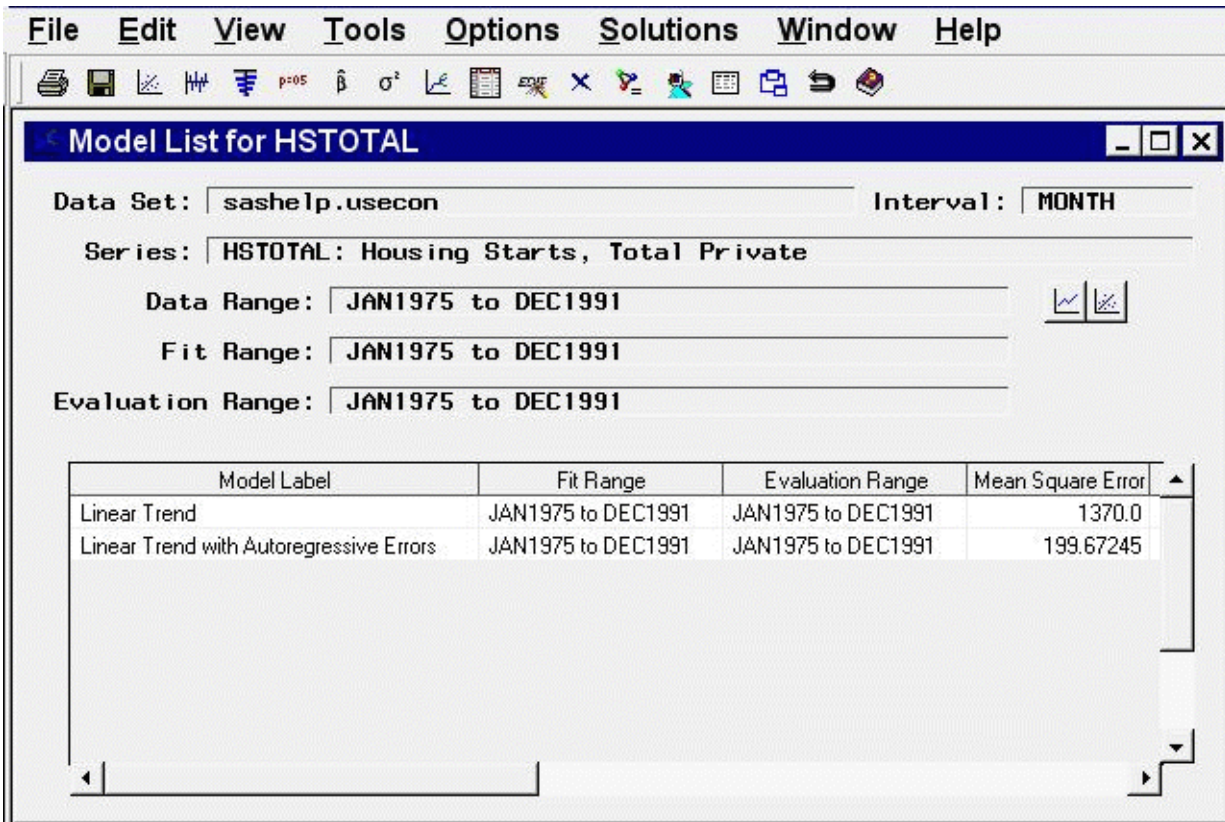

If you want to route the contents to a printer, go to the Output window and select “Print” from the File menu.

Statistics

opens the Statistics of Fit Selection window for controlling which statistics are displayed.

Model List Window

This resizable window shows all of the models that have been fit to a particular series in a project. Access it from the Manage Forecasting Project window by selecting a series in the series list table and choosing “List Models” from the Tools menu or by double-clicking the series.

Controls and Fields

Data Set

is the name of the current input data set.

Interval

is the time interval (data frequency) for the input data set.

Series

is the variable name and label of the current time series.

Data Range

is the date of the first and last nonmissing data values available for the current series in the input data set.

Fit Range

is the current period of fit setting. This is the range of data that will be used to fit models to the series. It might be different from the fit ranges shown in the table, which were in effect when the models were fit.

Evaluation Range

is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series. It might be different from the evaluation ranges shown in the table, which were in effect when the models were fit.

View Series Graphically icon

opens the Time Series Viewer window to display plots of the current series.

View Model Graphically icon

opens the Model Viewer to display graphs and tables for the currently highlighted model.

Model List Table

The table of models fit to the series contains columns that show the model label, the fit range and evaluation range used to fit the models, and all of the currently selected fit statistics. You can change the selection of fit statistics by using the Statistics of Fit Selection window.

Click on column headings to sort the table by a particular column. If a model is highlighted, clicking with the right mouse button invokes a pop-up menu that provides actions applicable to the highlighted model. It includes the following items.

View Model

opens the Model Viewer on the selected model. This is the same as “Model Predictions” under the View menu.

View Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model. This is the same as “Parameter Estimates” under the View menu.

View Statistics of Fit

opens the Model Viewer to display the statistics of fit table for the currently highlighted model. This is the same as “Statistics of Fit” under the View menu.

Edit Model

opens the appropriate model specification window for changing the attributes of the highlighted model and fitting the modified model.

Refit Model

refits the highlighted model using the current fit range.

Reevaluate Model

reevaluates the highlighted model using the current evaluation range.

Delete Model

deletes the highlighted model from the project.

View Forecasts

opens the Model Viewer to show the forecasts for the highlighted model. This is the same as “Forecast Graph” under the View menu.

Menu Bar

File

Save

opens a dialog which lets you save the contents of the table to a specified SAS data set.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you

can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print

sends the contents of the table to a printer as defined through Print Setup.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the window and returns to the Manage Forecasting Projects window.

Edit

Edit Model

enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

Refit Model

refits the currently highlighted model using data within the current fit range.

Reevaluate Model

recomputes statistics of fit for the currently highlighted model using data within the current evaluation range.

Delete Model

deletes the currently highlighted model from the model table.

Reset

restores the contents of the Model List window to the state initially displayed.

View

Series

opens the Time Series Viewer window to display plots of the current series. This is the same as the View Series Graphically icon.

Model Predictions

opens the Model Viewer to display a predicted and actual plot for the currently highlighted model. This is the same as the View Model Graphically icon.

Prediction Errors

opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations

opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests

opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit

opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph

opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table

opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Options

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

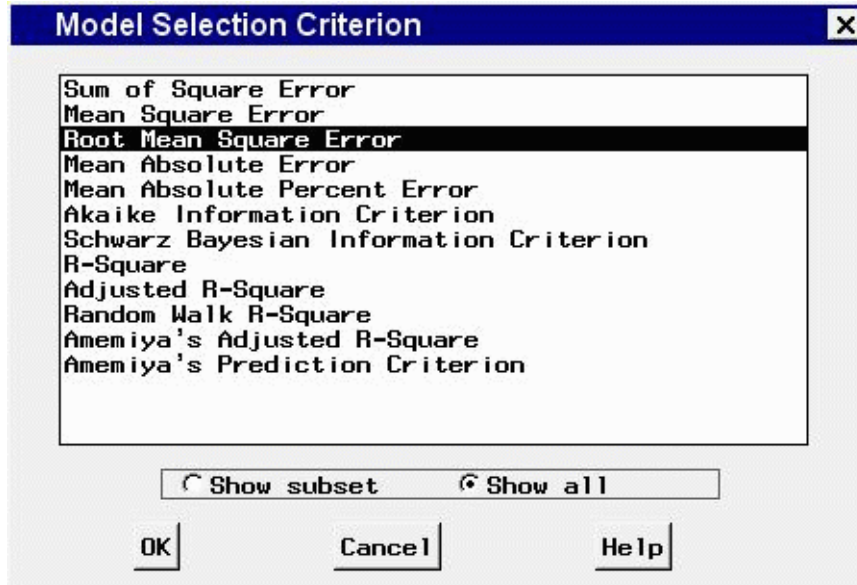

Column Labels

enables you to set long or short column labels. Long labels are used by default.

Model Selection Criterion Window

Use the Model Selection Criterion window to select the model selection criterion statistic used by the automatic selection process to determine the best fitting forecasting model. Model selection criterion statistics are a subset of those shown in the Statistics of Fit Selection window, since some statistics of fit, such as number of observations, are not useful for model selection.

This window is available from the Model Selection Criterion item of the Options menu of the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.

Controls and Fields

Show subset

when selected, lists only those model selection criterion statistics that are selected in the Statistics of Fit Selection window.

Show all

when selected, lists all available model selection criterion statistics.

OK

closes the window and sets the model selection criterion to the statistic you specified.

Cancel

closes the window without changing the model selection criterion.

Model Selection List Editor Window

Use the Model Selection List Editor window to edit the model selection list, including adding your own custom models, and to specify which models in the list are to be used in the automatic fitting process. Access it from the Options menu in the Develop Models, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

The window initially displays the current model list for your project. You can modify this set of models in several ways:

- Open one or more alternate model lists to replace or append to the current model list. These can be either model lists included with the software or model lists previously saved by you or other users.

- Turn the autofit option on or off for individual models. Those that are not flagged for autofit will be available by using the Models to Fit window but not by using automatic model fitting.
- Delete models from the list that are not needed for your project.
- Reorder the models in the list.
- Edit models in the list.
- Create a new empty list.
- Add new models to the list.

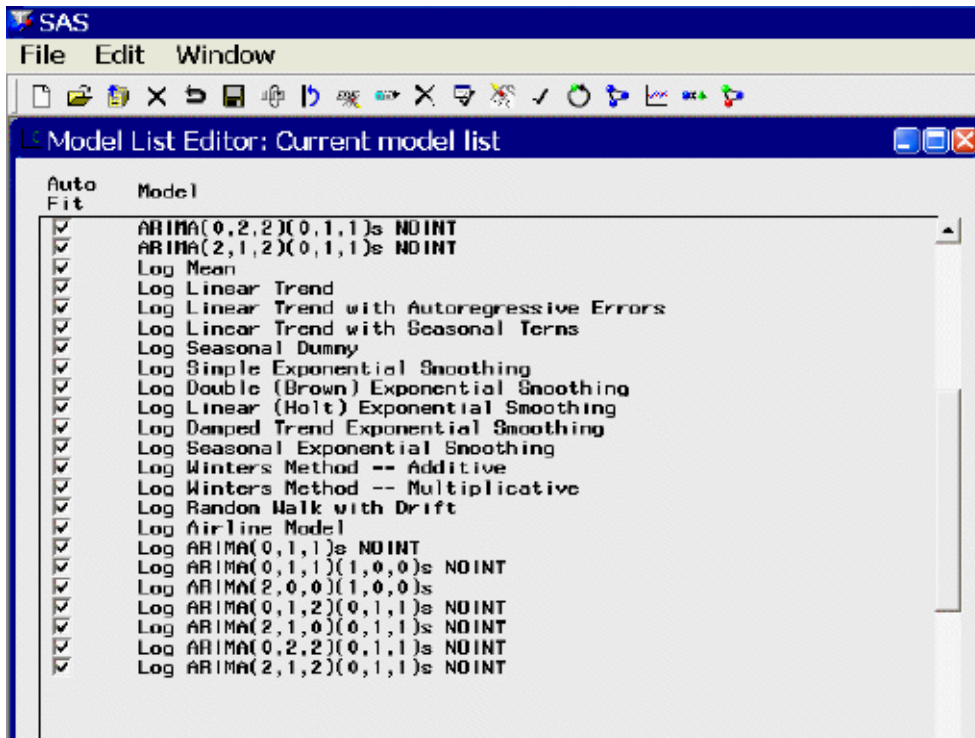

Having modified the current model list, you can save it for future use in several ways:

- Save it in a catalog so it can be opened later in the Model Selection List Editor.
- Save it as the user default to be used automatically when new projects are created.
- Select *close* to close the Model Selection List Editor and attach the modified model selection list to the current project.
- Select *cancel* to close the Model Selection List Editor without changing the current project's model selection list.

Since model selection lists are not bound to specific data sources, care must be taken when including data-specific features such as interventions and regressors. When you add an ARIMA, Factored ARIMA, or Custom model to the list, you can add regressors by selecting from the variables in the current data set. If there is no current data set, you will be prompted to specify a data set so you can select regressors from the series it contains.

If you use a model list that has models with a particular regressor name on a data set that does not contain a series of that name, model fitting will fail. However, you can make global changes to the regressor names in the model list by using *Set regressor names*. For example, you might use the list of dynamic regression models found in the `sashelp.forecast` catalog. It uses the regressor name "price." If your regressor series is named "x," you can specify "price" as the current regressor name and "x" as the "change to" name. The change will be applied to all models in the list that contain the specified regressor name.

Interventions cannot be defined for models defined from the Model Selection List Editor. However, you can define interventions by using the Intervention Specification Window and apply them to your models by turning on the Include Interventions option.

Auto Fit

The auto fit column of check boxes enables you to eliminate some of the models from being used in the automatic fitting process without having to delete them from the list. By default, all models are checked, meaning that they are all used for automatic fitting.

Model

This column displays the descriptions of all models in the model selection list. You can select one or more models by clicking them. Selected models are highlighted and become the object of the actions Edit, Move, and Delete.

Menu Bar

File

New

creates a new empty model selection list.

Open

opens a dialog for selecting one or more existing model selection lists to open. If you select multiple lists, they are all opened at once as a concatenated list. This helps you build large specialized model lists quickly by mixing and matching various existing lists such as the various ARIMA model lists included in SASHELP.FORCAST. By default,

the lists you open replace the current model list. Select the “append” radio button if you want to append them to the current model list.

Open System Default

opens the default model list supplied with the product.

Cancel

exits the window without applying any changes to the current project’s model selection list.

Close

closes the window and applies any changes made to the project’s model selection list.

Save

opens a dialog for saving the edited model selection list in a catalog of your choice.

Save as User Default

saves your edited model list as a default list for new projects. The location of this saved list is shown on the message line. When you create new projects, the system searches for this model list and uses it if it is found. If it is not found, the system uses the original default model list supplied with the product.

Edit

Reset

restores the list to its initial state when the window was invoked.

Add Model

enables you to add new models to the selection list. You can use the Smoothing Model Specification window, the ARIMA Model Specification window, the Factored ARIMA Model Specification window, or the Custom Model Specification window.

Edit Selected

opens the appropriate model specification window for changing the attributes of the highlighted model and adding the modified model to the selection list. The original model is not deleted.

Move Selected

enables you to reorder the models in the list. Select one or more models, then select Move Selected from the menu or toolbar. A note appears on the message line: “Select the row after which the selected models are to be moved.” Then select any unhighlighted row in the table. The selected models will be moved after this row.

Delete

deletes any highlighted models from the list. This item is not available if no models are selected.

Set Regressor Names

opens a dialog for changing all occurrences of a given regressor name in the models of the current model selection list to a name that you specify.

Select All

selects all models in the list.

Clear Selections

deselects all models in the list.

Select All for Autofit

checks the autofit check boxes of all models in the list.

Clear Autofit Selections

deselects the autofit check boxes of all models in the list.

Mouse Button Actions

Clicking any model description in the table selects (highlights) that model. Clicking the same model again deselects it. Multiple selections are allowed.

Clicking the auto fit check box in any row toggles the associated model's eligibility for use in automatic model fitting.

Right-clicking the right mouse button opens a pop-up menu.

Model Viewer Window

This resizable window provides plots and tables of actual values, model predictions, forecasts, and related statistics. The various plots and tables available are referred to as *views*. The section “[View Selection Icons](#)” on page 2617 explains how to change the view.

You can access Model Viewer in a number of ways, including the View Model Graphically icon of the Develop Models and Model List windows, the Graph button of the Automatic Model Fitting Results window, and the Model item under the View menu in the Manage Forecasting Project window. In addition, you can go directly to a selected view in the Model Viewer window by selecting Model Predictions, Prediction Errors, Statistics of Fit, Prediction Error Autocorrelations, Prediction Error Tests, Parameter Estimates, Forecast Graph, or Forecast Table from the View menu or corresponding toolbar icon or pop-up menu item in the Develop Models, Model List, or Automatic Model Fitting Results windows.

The state of the Model Viewer window is controlled by the current model and the currently selected view. You can resize this window, and you can use other windows without closing the Model Viewer window. By default, the Model Viewer window is automatically updated to display the new model when you switch to working with another model (that is, when you highlight a different model). You can unlink the Model Viewer window from the current model selection by selecting the Link/Unlink icon from the window's horizontal toolbar. See "Link/Unlink" in the section "[Toolbar Icons](#)" on page 2616.

For more information, see the section "[Model Viewer](#)" on page 2427.

Toolbar Icons

The Model Viewer window contains a horizontal row of icons called the Toolbar. Corresponding menu items appear under various menus. The function of each icon is explained in the following list.

Zoom in

In the Model Predictions, Prediction Errors, and Forecast Graph views, the Zoom In action changes the mouse cursor into cross hairs that you can use with the left mouse button to define a region of the graph to zoom in on. In the Prediction Error Autocorrelations and Prediction Error Tests views, Zoom In reduces the number of lags displayed.

Zoom out

reverses the previous Zoom In action.

Link/Unlink viewer

disconnects or connects the Model Viewer window to the model table (Develop Models window, Model List window, or Automatic Model Fitting Results window). When the viewer is linked, selecting another model in the model table causes the model viewer to be updated to show the selected model. When the Viewer is unlinked, selecting another model does not affect the viewer. This feature is useful for comparing two or more models graphically. You can display a model of interest in the Model Viewer, unlink it, then select another model and open another Model Viewer window for that model. Position the viewer windows side by side for convenient comparisons of models, or use the Next Viewer icon or F12 function key to switch between them.

Save

saves the contents of the Model Viewer window. By default, an HTML page is created. This enables you to display graphs and tables by using the Results Viewer or publish them on the Web or your intranet. See also "Save Graph As" and "Save Data As" under "Menu Bar" below.

Print

prints the contents of the viewer window.

Close

closes the Model Viewer window and returns to the window from which it was invoked.

View Selection Icons

At the right hand side of the Model Viewer window is a vertical toolbar to select the view—that is, the kind of plot or table that the viewer displays. Corresponding menu items appear under View in the menu bar. The function of each icon is explained in the following list.

Model Predictions

displays a plot of actual series values and model predictions over time. Click individual points in the graph to get a display of the type (actual or predicted), ID value, and data value in the upper right corner of the window.

Prediction Errors

displays a plot of model prediction errors (residuals) over time. Click individual points in the graph to get a display of the prediction error value in the upper right corner of the window.

Prediction Error Autocorrelations

displays horizontal bar charts of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the model prediction errors. Overlaid line plots represent confidence limits computed at plus and minus two standard errors. Click any of the bars to display its value.

Prediction Error Tests

displays horizontal bar charts that represent results of white noise and stationarity tests on the model prediction errors. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click any of the bars to display an interpretation.

The second bar chart shows tests of stationarity of the model prediction errors, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click on any of the bars to display an interpretation.

Parameter Estimates

displays a table showing model parameter estimates along with standard errors and t tests for the null hypothesis that the parameter is zero.

Statistics of Fit

displays a table of statistics of fit for the selected model. The set of statistics shown can be changed by using the Statistics of Fit item under Options in the menu bar.

Forecast Graph

displays a plot of actual and predicted values for the series data range, followed by a horizontal reference line and forecasted values with confidence limits. Click individual points in the

graph to get a display of the type, date/time, and value of the data point in the upper right corner of the window.

Forecast Table

displays a data table with columns containing the date/time, actual, predicted, error (residual), lower confidence limit, and upper confidence limit values, together with any predictor series.

Menu Bar

File

Save Graph

saves the plot displayed in viewer window as a SAS/GRAPH grseg catalog entry. When the current view is a table, this menu item is not available. See also “Save” in the section “[Toolbar Icons](#)” on page 2616. If a graphics catalog entry name has not already been specified, this action functions like “Save Graph As.”

Save Graph As

saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the graph embedded as a gif image.

Save Data

saves the data displayed in the viewer window in a SAS data set, where applicable.

Save Data As

saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the data displayed as a table.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Graph

prints the contents of the viewer window if the current view is a graph. This is the same as the Print toolbar icon. If the current view is a table, this menu item is not available.

Print Data

prints the data displayed in the viewer window, where applicable.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Print Preview

opens a preview window to show how your plots will appear when printed.

Close

closes the Model Viewer window and returns to the window from which it was invoked.

Edit**Edit Model**

enables you to modify the specification of the current model and to fit the modified model, which is then displayed in the viewer.

Refit Model

refits the current model by using data within the current fit range. This action also causes the ranges to be reset if the data range has changed.

Reevaluate Model

reevaluates the current model by using data within the current evaluation range. This action also causes the ranges to be reset if the data range has changed.

View

See “[View Selection Icons](#)” on page 2617. It describes each of the items available under “View,” except “Zoom Way Out.”

Zoom Way Out

zooms the plot out as far as it will go, undoing all prior zoom in operations.

Tools**Link Viewer**

See “[Link/Unlink](#)” in the section “[Toolbar Icons](#)” on page 2616.

Options**Time Ranges**

opens the Time Ranges Specification window to enable you to change the period of fit, period of evaluation, or forecast horizon to be applied to subsequently fit models.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the statistics of fit table and available for selection in the Model Selection Criterion menu.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Residual Plot Options

Provides a choice of four methods of computing prediction errors for models which include a data transformation.

Prediction Errors

computes the difference between the transformed series actual values and model predictions.

Normalized Prediction Errors

computes prediction errors in normalized form.

Model Residuals

computes the difference between the untransformed series values and the untransformed model predictions.

Normalized Model Residuals

computes model residuals in normalized form.

Number of Lags

opens a window to enable you to specify the number of lags shown in the Prediction Error Autocorrelations and Prediction Error Tests views. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

Correlation Probabilities

controls whether the bar charts in the Prediction Error Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Mouse Button Actions

You can examine the data values of individual points in the Model Predictions, Model Prediction Errors, and Forecast Graph views of the Model Viewer by clicking the point. The date/time and data values as well as the type (actual, predicted, and so forth) are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

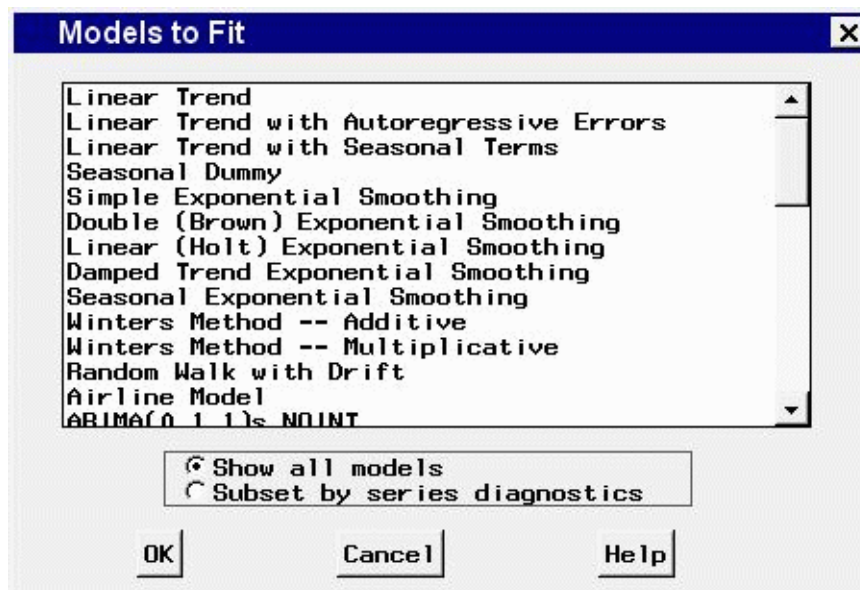

Similarly, you can display values in the Prediction Error Autocorrelations view by clicking any of the bars. Clicking bars in the Prediction Error Tests view displays a Recommendation for Current View window which explains the test represented by the bar.

When you select the Zoom In action in the Predicted Values, Model Prediction Errors, and Forecasted Values views, you can use the mouse to define a region of the graph to zoom. Position the

mouse cursor at one corner of the region, press the left mouse button, and move the mouse cursor to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

Models to Fit Window

Use the Models to Fit window to fit models by choosing them from the current model selection list. Access it by using “Fit Models from List” under the Fit Model submenu of the Edit menu in the Develop Models window, or the pop-up menu that appears when you click an empty area of the model table in the Develop Models window. If you want to alter the list of models that appears here, use the Model Selection List editor window.

To select a model to be fit, use the left mouse button. To select more than one model to fit, drag with the mouse, or select the first model, then press the shift key while selecting the last model. For noncontiguous selections, press the control key while selecting with the mouse. To begin fitting the models, double-click the last selection or select the OK button.

If series diagnostics have been performed, the radio box is available. If the Subset by series diagnostics radio button is selected, only those models in the selection list that fit the diagnostic criteria will be shown for selection. If you want to choose models that do not fit the diagnostic criteria, select the Show all models button.

Controls and Fields

Show all models

when selected, lists all available models, regardless of the setting of the series diagnostics options.

Subset by series diagnostics

when selected, lists only the available models that are consistent with the series diagnostics options.

OK

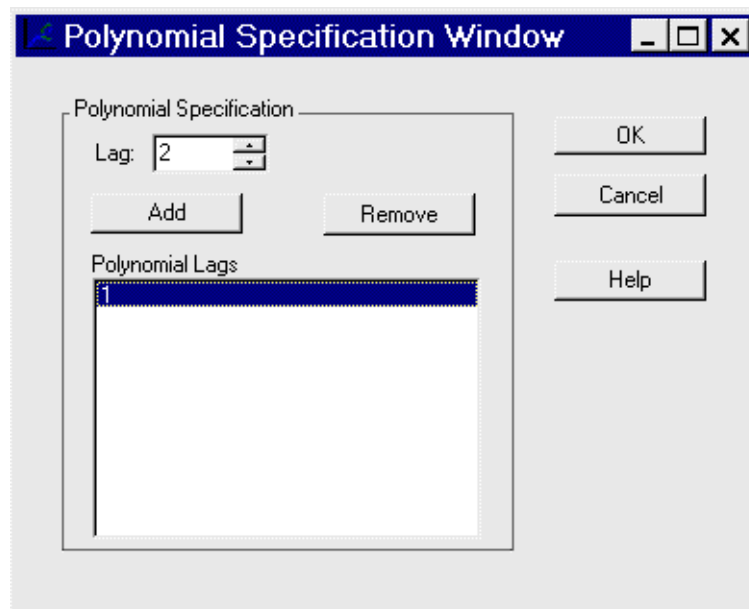

closes the Models to Fit window and fits the selected models.

Cancel

closes the window without fitting any models. Any selections you made are lost.

Polynomial Specification Window

Use the Polynomial Specification window to add a polynomial to an ARIMA model. The set of lags defined here become a polynomial factor, denoted by a list of lags in parentheses, when you select “OK.” If you accessed this window from the AR Polynomial Specification window, then it is added to the autoregressive part of the model. If you accessed it from the MA Polynomial Specification window, it is added to the moving-average part of the model.

Controls and Fields

Lag

specifies a lag value to add to the list. Type in a positive integer or select one by clicking the

spin box arrows.

Add

adds the value in the Lag spin box to the list of polynomial lags. Duplicate values are not allowed.

Remove

deletes a selected lag from the list of polynomial lags.

Polynomial Lags

is a list of unique integers that represent lags to be added to the model.

OK

closes the window and returns the specified polynomial to the AR or MA polynomial specification window.

Cancel

closes the window and discards any polynomial lags added to the list.

Produce Forecasts Window

Use the Produce Forecasts window to produce forecasts for the series in the current input data set for which you have fit forecasting models. Access it by using the Produce Forecasts button of the Time Series Forecasting window.

The screenshot shows the SAS 'Produce Forecasts' dialog box. The title bar reads 'Produce Forecasts - Project SASUSER.FMSPROJ.PROJ'. The menu bar includes 'File', 'View', 'Tools', 'Options', 'Solutions', 'Window', and 'Help'. A toolbar contains icons for help, print, run, save, undo, redo, and delete. The dialog is organized into two main sections: 'Input:' and 'Forecast Output:'.
 In the 'Input:' section:
 - 'Data Set' is 'SASHELP.usecon' with a 'Browse...' button.
 - 'Time ID' is 'DATE' with a 'Select...' button.
 - 'Interval' is 'MONTH' with a dropdown arrow.
 - 'Series' is '1: HSTOTAL' with a 'Select...' button.
 In the 'Forecast Output:' section:
 - 'Data Set' is 'WORK.FORECAST' with a 'Browse...' button.
 - 'Format' is 'Simple' with a dropdown arrow.
 - 'Horizon' is '12' with a dropdown arrow.
 - 'Periods' is a dropdown arrow.
 - A date field shows 'DEC 1992' with navigation arrows.
 At the bottom of the dialog are three buttons: 'Run', 'Output', and 'Close'.

Controls and Fields

Input Data Set

is the name of the current input data set. To specify the input data set, you can type a one-level or two-level SAS data set name in this field or select the Browse button to the right of the field.

Input data set Browse button

opens the Data Set Selection window to enable you to select the input data set.

Time ID

is the name of the time ID variable for the input data set. To specify this variable, you can type the ID variable name in this field or use the Select button.

Time ID Select button

opens the Time ID Variable Specification window.

Create button

opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in by the system, you can type in an interval name here, or select one from the pop-up list.

Series

indicates the number and names of time series variables for which forecasts will be produced.

Series Select button

opens the Series to Process window to let you select the series for which you want to produce forecasts.

Forecast Output Data Set

is the name of the output data set that will contain the forecasts. Type the name of the output data set in this field or click the Browse button.

Forecast Output Browse button

opens a dialog to let you locate an existing data set to which to save the forecasts.

Format

enables you to select one of three formats for the forecast data set:

Simple

specifies the simple format for the output data set. The data set contains the time ID variable and the forecast variables and contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.

Interleaved

specifies the interleaved format for the output data set. The data set contains the time ID variable, the variable TYPE, and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the TYPE variable.

Concatenated

specifies the concatenated format for the output data set. The data set contains the variable SERIES, the time ID variable, and the variables ACTUAL, PREDICT, ERROR,

LOWER, and UPPER. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

Horizon

is the number of periods or years to forecast beyond the end of the input data range. To specify the forecast horizon, you can type a value in this field or select one from the pop-up list.

Horizon periods

selects the units to apply to the horizon. By default, the horizon value represents number of periods. For example, if the interval is month, the horizon represents the number of months to forecast. Depending on the interval, you can also select weeks or years, so that the horizon is measured in those units.

Horizon date

is the ending date of the forecast horizon. You can type in a date that uses a form recognized by a SAS date informat, or you can increment or decrement the date shown by using the left and right arrows. The outer arrows change the date by a larger amount than the inner arrows. The date field and the horizon field reset each other, so you can use either one to specify the forecasting horizon.

Run button

produces forecasts for the selected series and stores the forecasts in the specified output SAS data set.

Output button

opens a Viewtable window to display the output data set. This button becomes available once the forecasts have been written to the data set.

Close button

closes the Produce Forecasts window and returns to the Time Series Forecasting window.

Menu Bar

File

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the Produce Forecasts window and returns to the Time Series Forecasting window.

View

Input Data Set

opens a Viewtable window to browse the current input data set.

Output Data Set

opens a Viewtable window to browse the output data set. This is the same as the Output button.

Tools

Produce Forecasts

produces forecasts for the selected series and stores the forecasts in the specified output SAS data set. This is the same as the Run button.

Options

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges when new series are selected.

Model Selection List

opens the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Model Selection Criterion

opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion window.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Forecast Data Set

enables you to select one of three formats for the forecast data set. See `Format`, which is described previously in this section.

Alignment of Dates

Beginning

aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle

aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End

aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Set Toolbar Type**Image Only**

displays the toolbar items as icons without text.

Label Only

displays the toolbar items as text without icon images.

Both

displays the toolbar items as both text and icon images.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

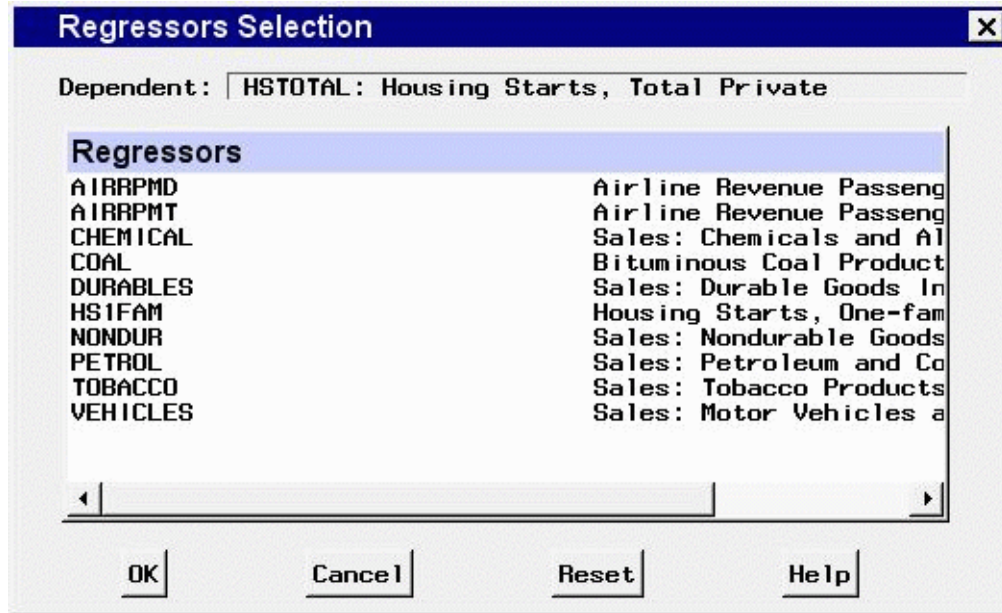

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Regressors Selection Window

Use the Regressors Selection window to select one or more time series variables in the input data set to include as regressors in the forecasting model to predict the dependent series. Access it from the pop-up menu that appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window.

Controls and Fields

Dependent

is the name and variable label of the current series.

Regressors

is a table listing the names and labels of the variables in the input data set available for selection as regressors. The variables that you select are highlighted. Selecting a highlighted row again deselects that variable.

OK

closes the Regressors Selection window and adds the selected variables as regressors in the model.

Cancel

closes the window without adding any regressors. Any selections you made are lost.

Reset

resets all options to their initial values upon entry to the window.

Save Data As

Use Save Data As from the Time Series Viewer Window or the Model Viewer Window to save data displayed in a table to a SAS data set or external file.

Use Save Forecast As from the Develop Models Window to save forecasts and related data including the series name, model, and interval. It supports append mode, enabling you to accumulate the forecasts of multiple series in a single data set.

The screenshot shows the 'Save Data as' dialog box with the following details:

- SAS Library Output:**
 - Library: - Data Set:
 - Label:
- External File Output:**
 - Save External File - Title 1:
 - Title 2:
 - Title 3:
- Buttons:

To save your data in a SAS data set, provide a library name or assign one by using the Browse button, then provide a data set name or accept the default. Enter a descriptive label for the data set in the Label field. Click OK to save the data set. If you specify an existing data set, it will be overwritten, except in the case of Save Forecast As.

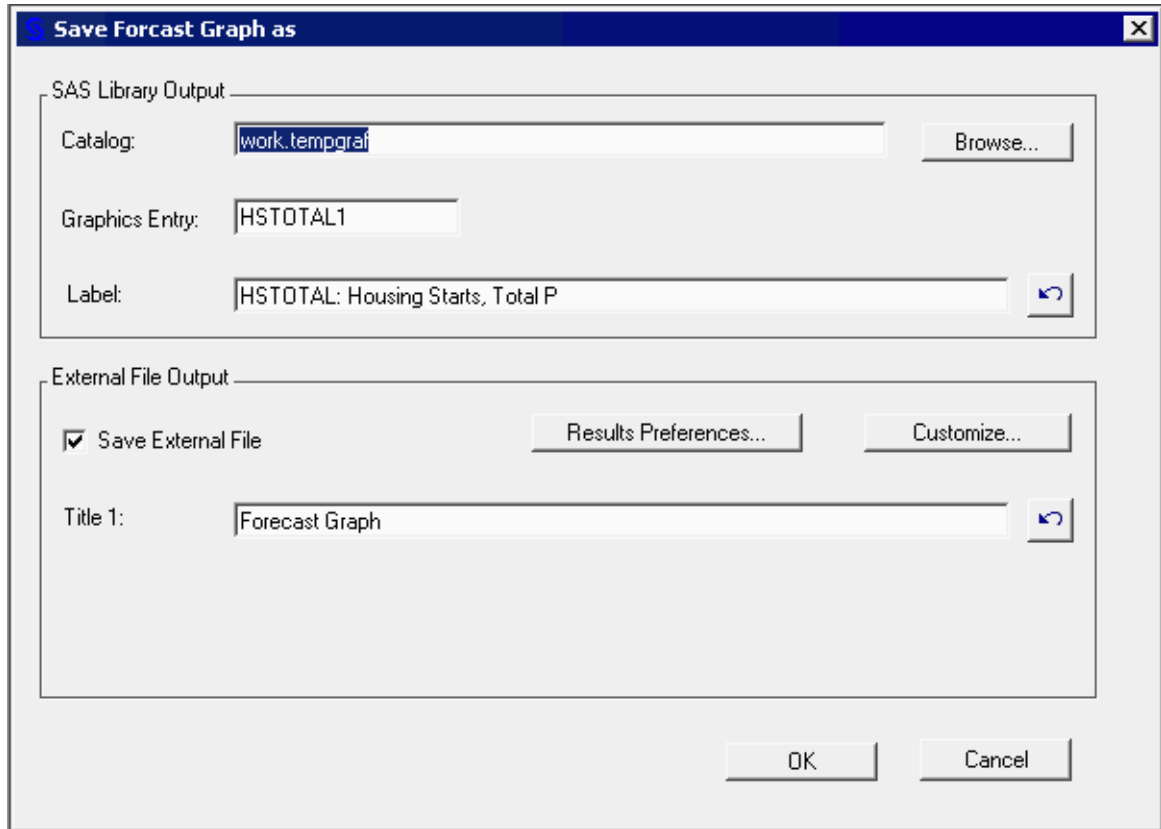

External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating HTML tables for Web reporting. You can build a set of Web pages quickly and use the ODS Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, then select the Results tab in the Preferences dialog.

If you have previously saved data of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro that contains ODS statements. The default macro simply runs the PRINT procedure. A custom macro can be used to add PRINT procedure and/or ODS statements to customize the type and organization of output files produced.

Save Graph As

Use Save Graph As from the Time Series Viewer Window or the Model Viewer Window to save any of the graphs in a catalog or external file.

To save your graph as a grseg catalog entry, enter a two level name for the catalog or select Browse to open an Open dialog. Use it to select an existing library or assign a new one and then select a catalog to contain the graph. Click the Open button to open the catalog and close the dialog. Then enter a graphics entry name (eight characters or less) and a label or accept the defaults and click the OK button to save the graph.

External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating gif images and HTML for Web reporting. You can build a set of Web pages that contain graphs and use the Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, then select the Results tab in the Preferences dialog.

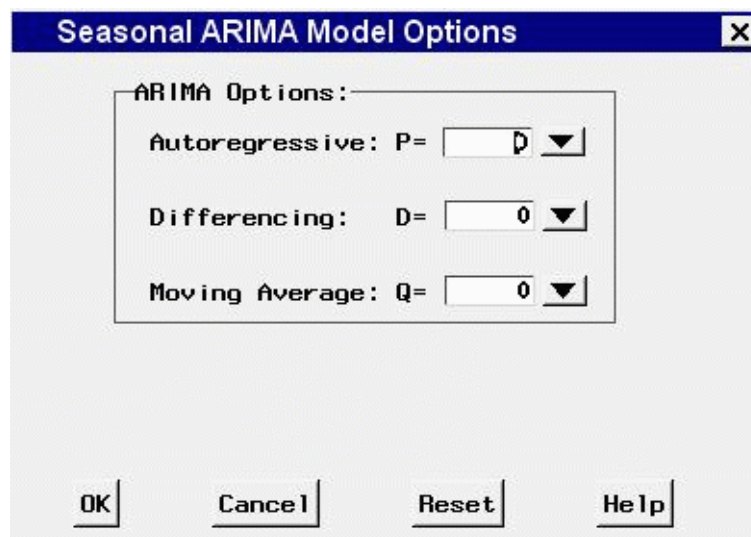

If you have previously saved graphs of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro that contains ODS statements. The default macro simply runs the GREPLAY procedure. Users familiar with ODS

might want to add statements to the macro to customize the type and organization of output files produced.

Seasonal ARIMA Model Options Window

Use the Seasonal ARIMA Model Options window to specify the autoregressive, differencing, and moving-average orders for the seasonal part of a model defined by using the Custom Model Specification window. Access it by selecting “Seasonal ARIMA...” from the Seasonal Model combo box of that window.

Controls and Fields

ARIMA Options

Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a pop-up list.

Autoregressive

defines the order of the seasonal autoregressive part of the model.

Differencing

defines the order of seasonal differencing.

Moving Average

defines the order of the seasonal moving-average term.

OK

closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window.

Cancel

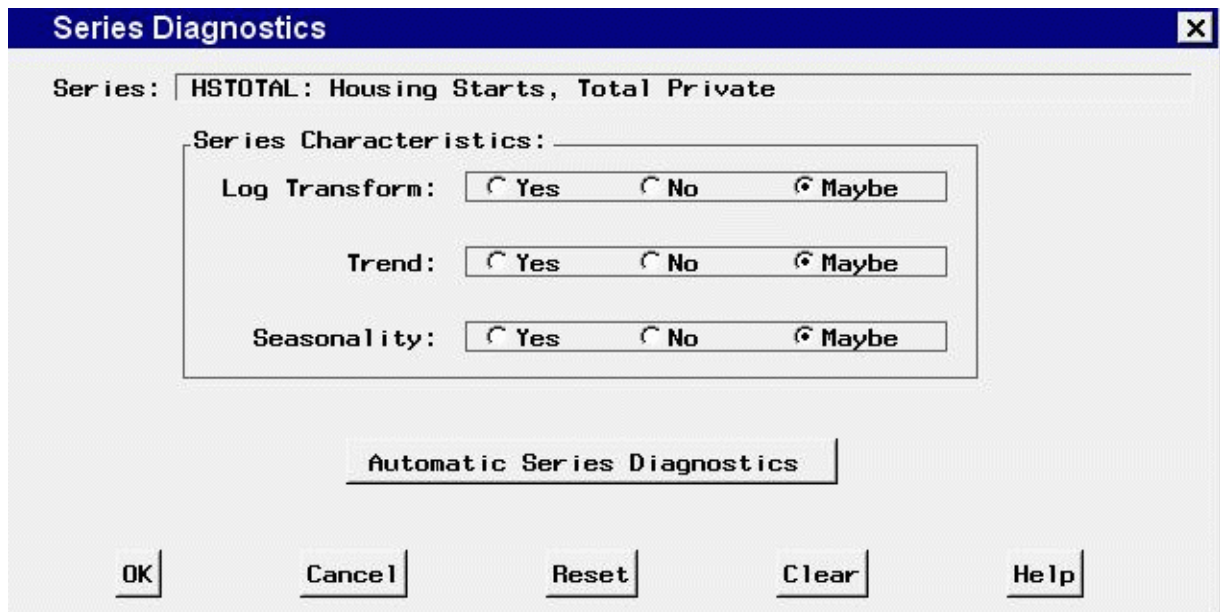

closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window, discarding any changes made.

Reset

resets all options to their initial values upon entry to the window.

Series Diagnostics Window

Use the Series Diagnostics window to set options to limit the kinds of forecasting models considered for the series according to series characteristics. Access it by selecting “Diagnose Series” from the Tools menu in the Develop Models, Manage Project, and Time Series Viewer window menu bars. You can let the system diagnose the series characteristics automatically or you can specify series characteristics according to your judgment by using the radio buttons.

For each of the options Log Transform, Trend, and Seasonality, the value “Yes” means that only models appropriate for series with that characteristic should be considered. The value “No” means that only models appropriate for series without that characteristic should be considered. The value “Maybe” means that models should be considered without regard for that characteristic.

Controls and Fields

Series

is the name and variable label of the current series.

Series Characteristics

Log Transform

specifies whether forecasting models with or without a logarithmic series transformation are appropriate for the series.

Trend

specifies whether forecasting models with or without a trend component are appropriate for the series.

Seasonality

specifies whether forecasting models with or without a seasonal component are appropriate for the series.

Automatic Series Diagnostics

performs the automatic series diagnostic process. The options Log Transform, Trend, and Seasonality are set according to the results of statistical tests.

OK

closes the Series Diagnostics window.

Cancel

closes the Series Diagnostics window without changing the series diagnostics options. Any options you specified are lost.

Reset

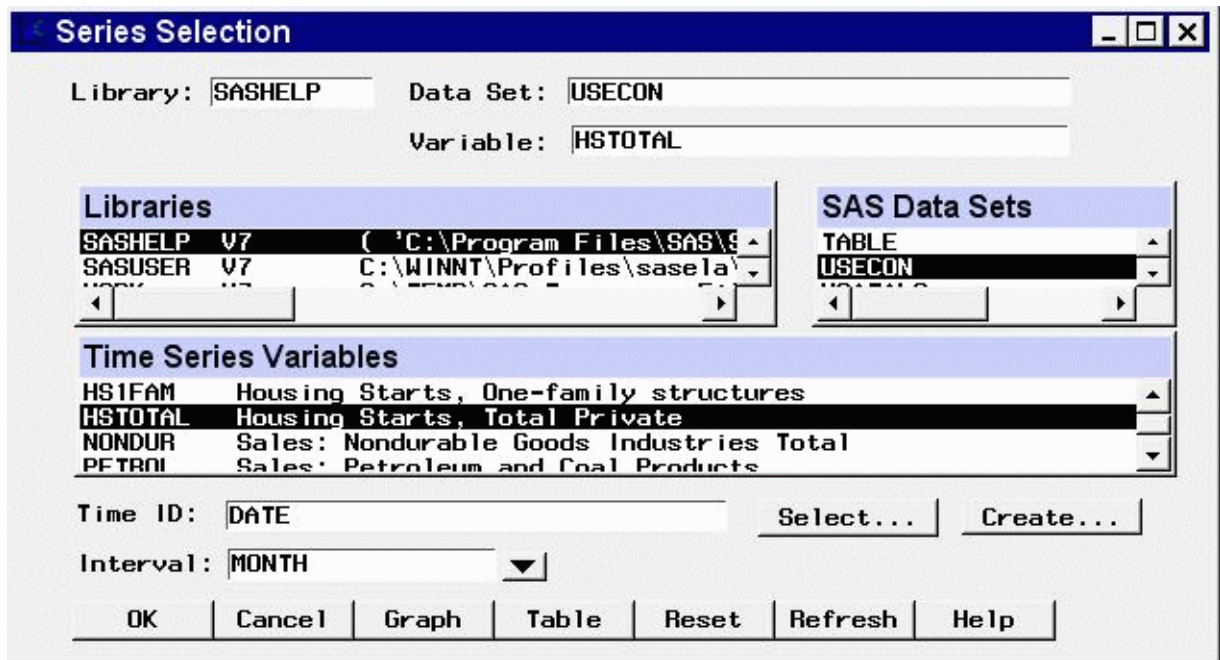

resets all options to their initial values upon entry to the Series Diagnostics window.

Clear

resets all options to their default values.

Series Selection Window

Use this resizable window to select a time series variable by specifying a library, a SAS data set or view, and a variable. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set or view plots of the series from this window.

This window appears automatically when you select the View Series Graphically or Develop Models buttons in the Time Series Forecasting window and no series has been selected, and when you open the Time Series Viewer as a standalone tool. It is also invoked by using the Browse button in the Develop Models window.

The system requires that series names be unique for each frequency (interval) within the forecasting project. If you select a series from the current input data set that already exists in the project with the same interval but a different input data set name, the system warns you and gives you the option to cancel the selection, to refit all models associated with the series by using the data from the current input data set, to delete the models for the series, or to inherit the existing models.

Controls and Fields

Library

is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field and press Return. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname.

Data Set

is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted, and the Time Series Variables list will be populated with the numeric variables in the data set.

Variable

is the name of a numeric variable contained in the selected data set. You can type the variable name in this field or you can select the variable with the mouse from the Time Series Variables list.

Time ID

is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or click the Select button.

Select button

opens the Time ID Variable Specification window to let you select an existing variable in the data set as the Time ID.

Create button

opens a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically filled in by the system, you can type in an interval name or select one from the pop-up list. For more information about intervals, see Chapter 4, “[Date Intervals, Formats, and Functions](#),” in this book.

OK

This button is present when you have selected “Develop Models” from the Time Series Forecasting window. It closes the Series Selection window and makes the selected series the current series.

Close

If you have selected the View Series Graphically icon from the Time Series Forecasting window, this button returns you to that window. If you have selected a series, it remains selected as the current series.

If you are using the Time Series Viewer as a standalone application, this button closes the application.

Cancel

This button is present when you have selected “Develop Models” from the Time Series Forecasting window. It closes the Series Selection window without applying any selections made.

Reset

resets the fields to their initial values at entry to the window.

Table

opens a Viewtable window for browsing the selected data set. This can assist you in locating the variable containing data you are looking for.

Graph

opens the Time Series Viewer window to display the selected time series variable. You can switch to a different series in the Series Selection window without closing the Time Series Viewer window. Position the windows so they are both visible, or use the Next Viewer toolbar icon or F12 function key to switch between windows.

Refresh

updates all fields and lists on the window. If you assign a new libname without exiting the Series Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname. Also use the Refresh action to update the variables list if the input data set is changed.

Selection Lists

Libraries

displays a list of currently assigned libnames. You can select a libname by clicking it, which is equivalent to typing its name in the Library field. If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File menu, then select “Library” and “OK.” This opens the New Library dialog window. You also assign a libname by submitting a libname statement from the Editor window. Select the Refresh button to make the new libname available in the libraries list.

SAS Data Sets

displays a list of the SAS data sets (data files or data views) located under the selected libname. You can select one of these by clicking it, which is equivalent to typing its name in the Data Set field.

Time Series Variables

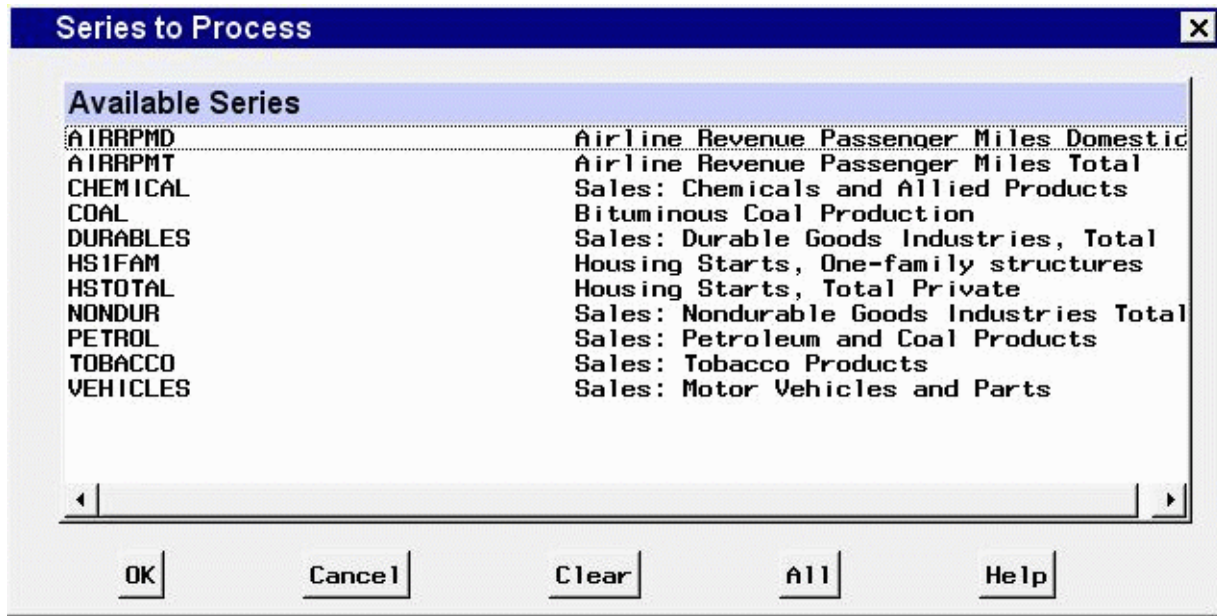

displays a list of numeric variables contained within the selected data set. You can select one of these by clicking it, which is equivalent to typing its name in the Variable field. You can double-click a series to select it and exit the window.

Series to Process Window

Use the Series to Process window to select series for model fitting or forecasting. Access it by using the Select button in the Automatic Model Fitting and Produce Forecasts windows. Hold down the shift key or drag with the left mouse button for multiple selections. Use the control key for noncontiguous multiple selections. Once you make selections and select OK, the number of selected series and their names are listed in the Series to Process field of the calling window (with ellipses if not all the names will fit).

When invoked from Automatic Model Fitting, the Series to Process window shows all the numeric variables in the input data set except the time ID variable. These are the series which are currently available for model fitting.

When invoked from Produce Forecasts, the Series to Process window shows all the series in the input data set for which models have been fit. These are the series which are currently available for forecasting.

Controls and Fields

OK

closes the window and applies the series selection(s) which have been made. At least one series must be selected.

Cancel

closes the window, ignoring series selections which have been made, if any.

Clear

deselects all series in the selection list.

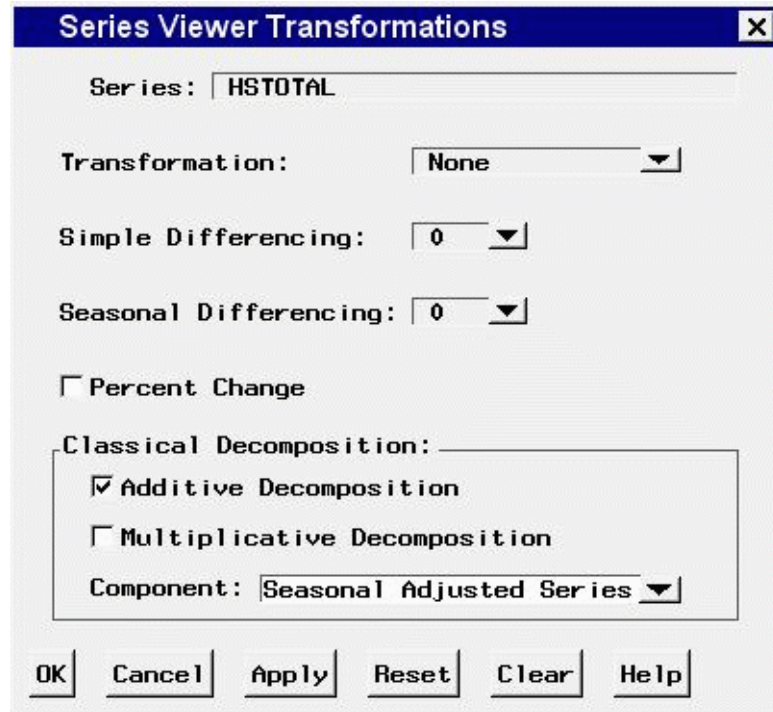

All

selects all series in the selection list.

Series Viewer Transformations Window

Use the Series Viewer Transformations window to view plots of transformations of the current series in the Time Series Viewer window. It provides a larger set of transformations than those available from the viewer window's toolbar. It is invoked by using "Other Transformations" under the Tools menu of the Time Series Viewer window. The options that you specify in this window are applied to the series displayed in the Time Series Viewer window when you select "OK" or "Apply."

Use the Apply button if you want to make repeated transformations to a series without having to close and reopen the Series Viewer Transformations window each time.

Controls and Fields

Series

is the variable name for the current time series.

Transformation

is the transformation applied to the time series displayed in the Time Series Viewer window. Select Log, Logistic, Square Root, Box-Cox, or none from the pop-up list.

Simple Differencing

is the order of differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 5 from the pop-up list.

Seasonal Differencing

is the order of seasonal differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 3 from the pop-up list.

Percent Change

is a check box that if selected displays the series in terms of percent change from the previous period.

Additive Decomposition

is a check box that produces a display of a selected series component derived by using additive decomposition.

Multiplicative Decomposition

is a check box that produces a display of a selected series component derived using multiplicative decomposition.

Component

selects a series component to display when either additive or multiplicative decomposition is

turned on. You can display the seasonally adjusted component, the trend-cycle component, the seasonal component, or the irregular component—that is, the residual that remains after removal of the other components. The heading in the viewer window shows which component is currently displayed.

OK

applies the transformation options you selected to the series displayed in the Time Series Viewer window and closes the Series Viewer Transformations window.

Cancel

closes the Series Viewer Transformations window without changing the series displayed by the Time Series Viewer window.

Apply

applies the transformation options you selected to the series displayed in the Time Series Viewer window without closing the Series Viewer Transformations window.

Reset

resets the transformation options to their initial values upon entry to the Series Viewer Transformations window.

Clear

resets the transformation options to their default values (no transformations).

Smoothing Model Specification Window

Use the Smoothing Model Specification window to specify and fit exponential smoothing and Winters method models. Access it from the Develop Models window by using the Fit Model submenu of the Edit menu or from the pop-up menu when you click an empty area of the model table.

Smoothing Model Specification [X]

Series:

Model:

Smoothing Methods:

- Simple Smoothing
- Double (Brown) Smoothing
- Seasonal Smoothing
- Linear (Holt) Smoothing
- Damped-Trend Smoothing
- Winters Method - Additive
- Winters Method - Multiplicative

Smoothing Weights:

Level:

Trend:

Damping:

Season:

Bounds: ▼

Transformation: ▼

OK Cancel Reset Clear Help

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Smoothing Methods

Simple Smoothing

specifies simple (single) exponential smoothing.

Double (Brown) Smoothing

specifies double exponential smoothing by using Brown's one parameter model (single exponential smoothing applied twice).

Seasonal Smoothing

specifies seasonal exponential smoothing. (This is like Winters method with the trend term omitted.)

Linear (Holt) Smoothing

specifies exponential smoothing of both the series level and trend (Holt's two parameter model).

Damped-Trend Smoothing

specifies exponential smoothing of both the series level and trend with a trend damping weight.

Winters Method - Additive

specifies Winters method with additive seasonal factors.

Winters Method - Multiplicative

specifies Winters method with multiplicative seasonal factors.

Smoothing Weights

displays the values used for the smoothing weights. By default, the Smoothing Weights fields are set to "optimize," which means that the system will compute the weight values that best fit the data. You can also type smoothing weight values in these fields.

Level

is the smoothing weight used for the level of the series.

Trend

is the smoothing weight used for the trend of the series.

Damping

is the smoothing weight used by the damped-trend method to damp the forecasted trend towards zero as the forecast horizon increases.

Season

is the smoothing weight used for the seasonal factors in Winters method and seasonal exponential smoothing.

Transformation

displays the series transformation specified for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the model predictions. Select *Log*, *Logistic*, *Square Root*, *Box-Cox*, or *None* from the pop-up list.

Bounds

displays the constraints imposed on the fitted smoothing weights. Select one of the following from the pop-up list:

Zero-One/Additive

sets the smoothing weight optimization region to the intersection of the region bounded by the intervals from zero (0.001) to one (0.999) and the additive invertible region. This is the default.

Zero-One Boundaries

sets the smoothing weight optimization region to the region bounded by the intervals from zero (0.001) to one (0.999).

Additive Invertible

sets the smoothing weight optimization region to the additive invertible region.

Unrestricted

sets the smoothing weight optimization region to be unbounded.

Custom

opens the *Smoothing Weights* window to enable you to customize the constraints for smoothing weights optimization.

OK

closes the *Smoothing Model Specification* window and fits the model you specified.

Cancel

closes the *Smoothing Model Specification* window without fitting the model. Any options you specified are lost.

Reset

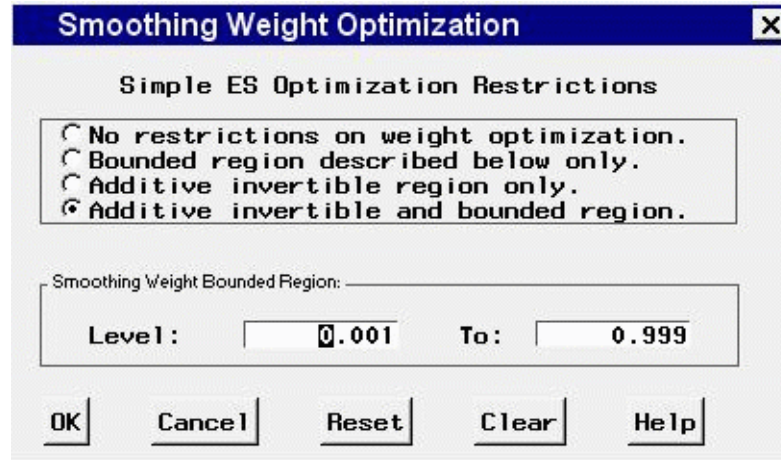

resets all options to their initial values upon entry to the window. This might be useful when editing an existing model specification; otherwise, *Reset* has the same function as *Clear*.

Clear

resets all options to their default values.

Smoothing Weight Optimization Window

Use the *Smoothing Weight Optimization* window to specify constraints for the automatic fitting of smoothing weights for exponential smoothing and Winters method models. Access it from the *Smoothing Models Specification* window when you select “*Custom*” in the “*Bounds*” combo box.

Controls and Fields

No restrictions

when selected, specifies unrestricted smoothing weights.

Bounded region

when selected, restricts the fitted smoothing weights to be within the bounds that you specify with the “Smoothing Weight Bounded Region” options.

Additive invertible region

when selected, restricts the fitted smoothing weights to be within the additive invertible region of the parameter space of the ARIMA model equivalent to the smoothing model. (See the section “[Smoothing Models](#)” on page 2669 for details.)

Additive invertible and bounded region

when selected, restricts the fitted smoothing weights to be both within the additive invertible region and within bounds that you specify.

Smoothing Weight Bounded Region

is a group of numeric entry fields that enable you to specify lower and upper limits on the fitted value of each smoothing weight. The fields that appear in this part of the window depend on the kind of smoothing model that you specified.

OK

closes the window and sets the options that you specified.

Cancel

closes the window without changing any options. Any values you specified are lost.

Reset

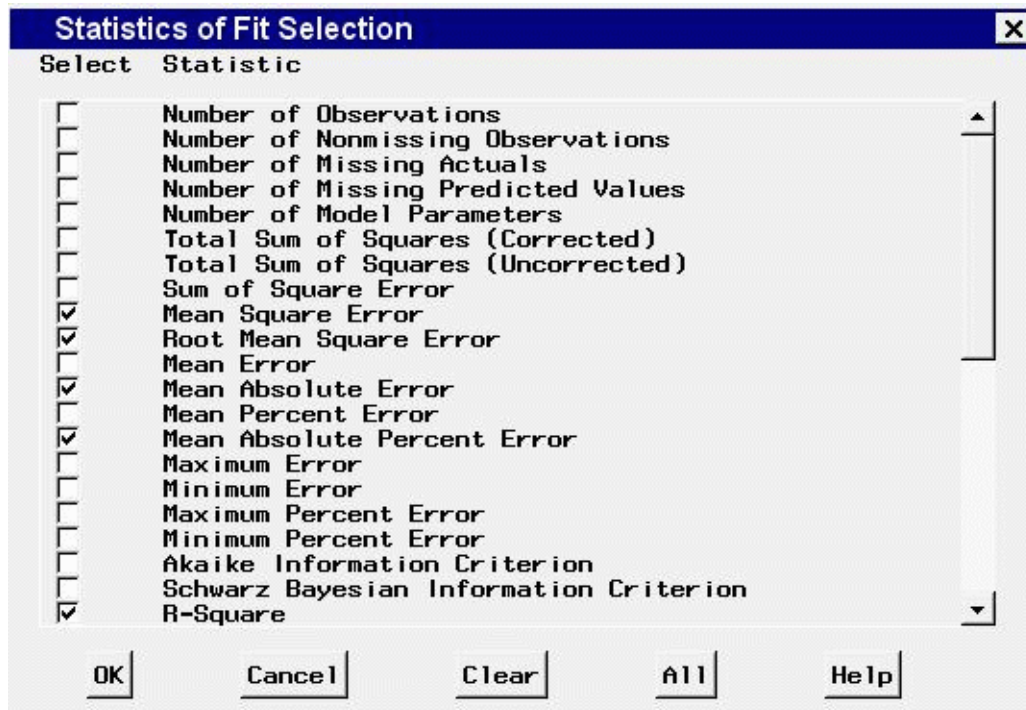

resets all options to their initial values upon entry to the window.

Clear

resets all options to their default values.

Statistics of Fit Selection Window

Use the Statistics of Fit Selection window to specify which of the available goodness-of-fit statistics are reported for models you fit and are available for selection as the model selection criterion used by the automatic selection process. This window is available under the Options menu in the Develop Models, Automatic Model Fitting, Produce Forecasts, and Model List windows, and from the Statistics button of the Model Fit Comparison window and Automatic Model Fitting results windows.

Controls and Fields

Select Statistics Table

list the available statistics. Select a row of the table to select or deselect the statistic shown in that row.

OK

closes the window and applies the selections made.

Cancel

closes the window without applying any selections.

Clear

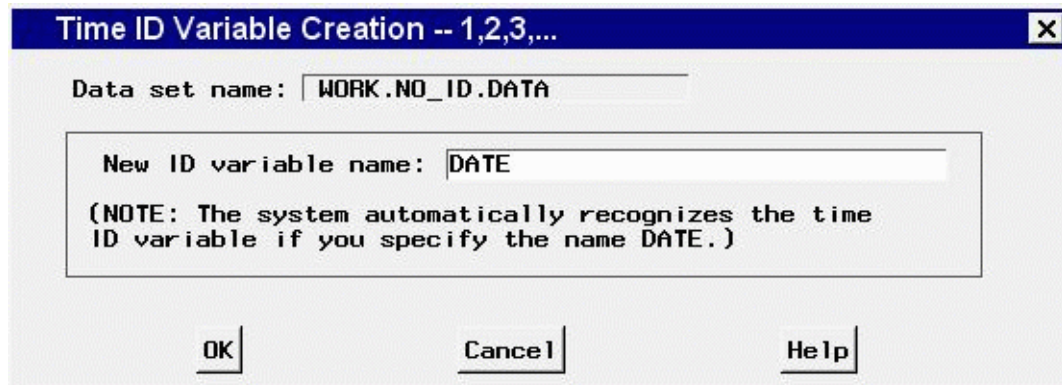

deselects all statistics.

All

selects all statistics.

Time ID Creation – 1,2,3 Window

Use the Time ID Creation – 1,2,3 window to add a time ID variable to an input data set with observation numbers as the ID values. The interval for the series will be 1. Use this approach if the data frequency does not match any of the system’s date or date-time intervals, or if other methods of assigning a time ID do not work. To access this window, select “Create from observation numbers” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 4, “Date Intervals, Formats, and Functions,” in this book.

Controls and Fields

Data set name

is the name of the input data set.

New ID variable name

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK

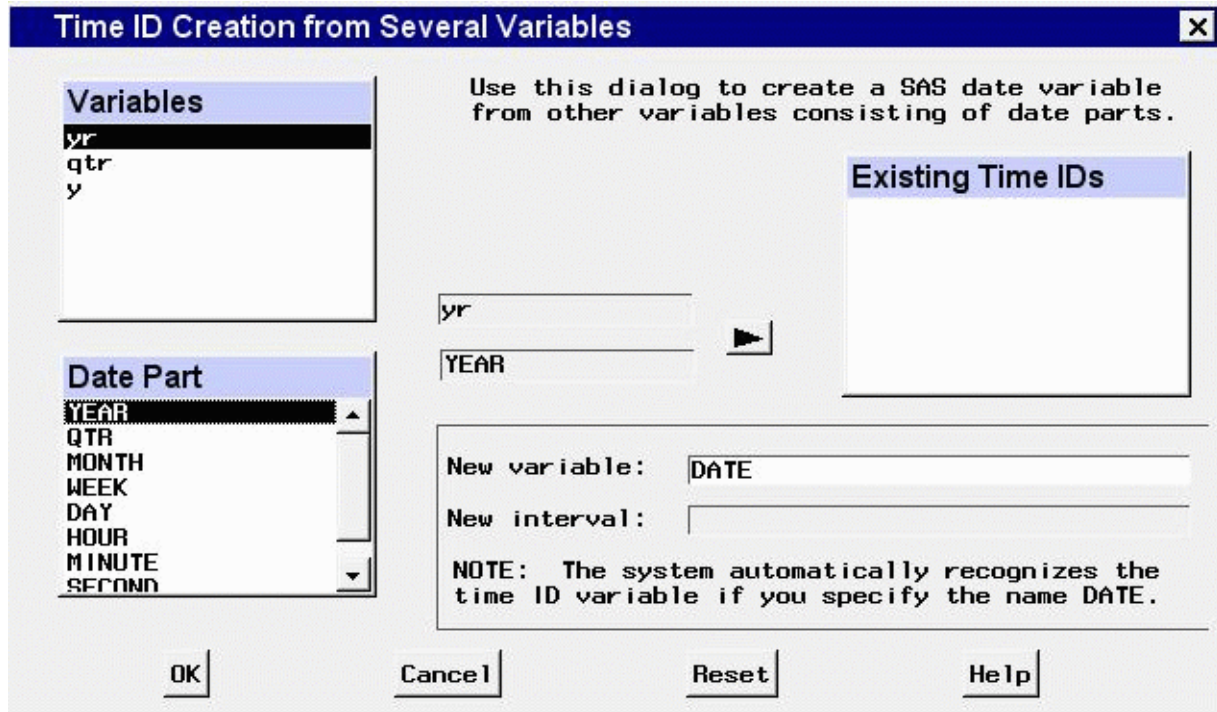

closes the window and proceeds to the next step in the time ID creation process.

Cancel

closes the window without creating a Time ID variable. Any options you specified are lost.

Time ID Creation from Several Variables Window

Use the Time ID Creation from Several Variables window to add a SAS date valued time ID variable to an input data set when the input data set already contains several dating variables, such as day, month, and year. To access this window, select “Create from existing variables” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 38, “Creating Time ID Variables.”

Controls and Fields

Variables

is a list of variables in the input data set. Select existing ID variables from this list.

Date Part

is a list of date parts that you can specify for the selected ID variable. For each ID variable that you select from the Variables list, select the Date Part value that describes what the values of the ID variable represent.

arrow button

moves the selected existing ID variable and date part specification to the “Existing Time IDs” list. Once you have done this, you can select another ID variable from the Variables list.

New variable

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

New interval

is the time interval between observations in the input data set implied by the date part ID variables you have selected.

OK

closes the window and proceeds to the next step in the time ID creation process.

Cancel

closes the window without creating a time ID. Any options you specified are lost.

Reset

resets the options to their initial values upon entry to the window.

Time ID Creation from Starting Date Window

Use the Time ID Creation from Starting Date window to add a SAS date valued time ID variable to an input data set. This is a convenient way to add a time ID of any interval as long as you know the starting date of the series. To access this window, select “Create from starting date and frequency” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 38, “Creating Time ID Variables.”

Time ID Creation from Starting Date

Data set name:

Starting Date:

Interval:

New ID variable name:

(NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.)

Controls and Fields

Data set name

is the name of the input data set.

Starting Date

is the starting date for the time series in the data set. Enter a date value in this field, using a form recognizable by a SAS date informat, for example, 1998:1, feb1997, or 03mar1998.

Interval

is the time interval between observations in the data set. Select an interval from the pop-up list.

New ID variable name

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK

closes the window and proceeds to the next step in the time ID creation process.

Cancel

closes the window without changing the input data set. Any options you specified are lost.

Time ID Creation Using Informat Window

Use the Time ID Creation using Informat window to add a SAS date valued time ID variable to an input data set. Use this window if your data set contains a date variable that is stored as a character string. Using the appropriate SAS date informat, the date string is read in and used to create a date or date-time variable. To access this window, select “Create from existing variable/informat” from the Create pop-up list in any window where you can select a Time ID variable.

Time Id Creation using Informat

Existing Variable and Informat: _____

Variable Name: **Select...**

Informat: ▼

First obs:

Date Value:

New ID variable name:

NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.

OK **Cancel** **Reset** **Help**

Controls and Fields

Variable Name

is the name of an existing ID variable in the input data set. Click the Select button to select a variable.

Select button

opens a list of variables in the input data set for you to select from.

Informat

is a SAS date or datetime informat for reading date or datetime value from the values of the specified existing ID variable. You can type in an informat or select one from the pop-up list.

First Obs

is the value of the variable you selected from the first observation in the data set, displayed here for convenience.

Date Value

is the SAS date or datetime value read from the first observation value that uses the informat that you specified.

New ID variable name

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK

closes the window and proceeds to the next step in the time ID creation process.

Cancel

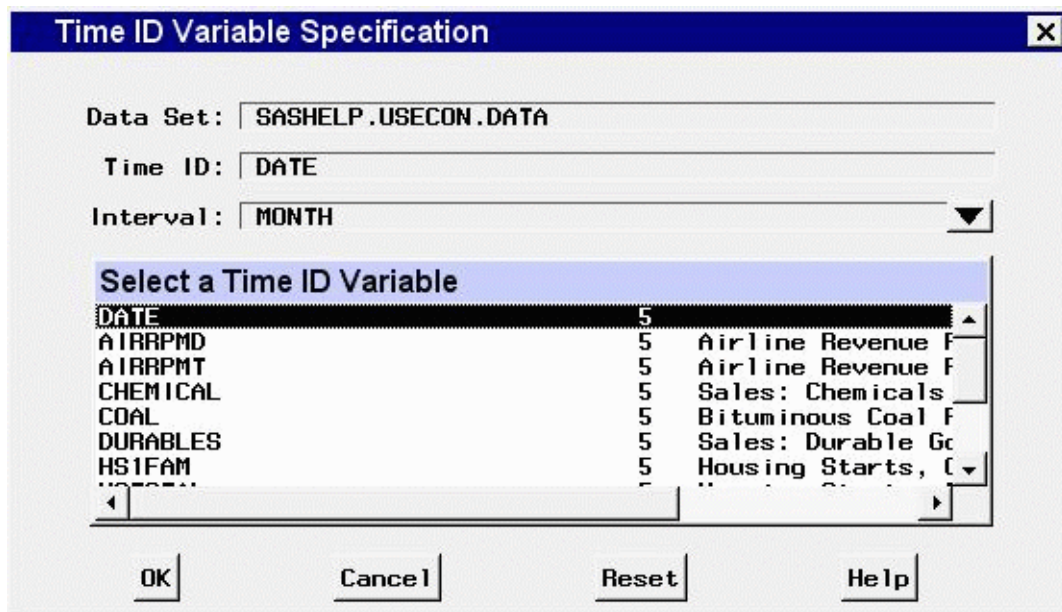

closes the window without changing the input data set. Any options you specified are lost.

Reset

resets the options to their initial values upon entry to the window.

Time ID Variable Specification Window

Use the Time ID Variable Specification window to specify a variable in the input data set that contains the SAS date or datetime value of each observation. You do not need to use this window if your time ID variable is named `date`, `time`, or `datetime`, since these are picked up automatically. Invoke the window from the Select button to the right of the Time ID field in the Data Set Selection, Automatic Model Fitting, Produce Forecasts, Series Selection, and Time Series Forecasting windows.

Controls and Fields

Data Set

is the name of the current input data set.

Time ID

is the name of the currently selected Time ID variable, if any.

Interval

is the time interval between observations (data frequency) in the input data set.

Select a Time ID Variable

is a selection list of variables in the input set. Select one variable to assign it as the Time ID variable.

OK

closes the window and retains the selection made, if it is a valid time ID.

Cancel

closes the window and ignores any selection made.

Reset

restores the time ID variable to the one assigned when the window was initially opened, if any.

Time Ranges Specification Window

Use the Time Ranges Specification window to control the period of fit and evaluation and the forecasting horizon. Invoke this window from the Options menu in the Develop Models, Manage Forecasting Project, and Model Viewer windows or the Set Ranges button in the Develop Models window.

Time Ranges Specification

Data Set:

Interval:

Series:

Time Ranges:

	From	To
Data Range:	<input type="text" value="JAN1975"/>	<input type="text" value="DEC1991"/>
Period of Fit:	<input type="text" value="JAN1975"/>	<input type="text" value="DEC1991"/>
Period of Evaluation:	<input type="text" value="JAN1975"/>	<input type="text" value="DEC1991"/>
Forecast Horizon:	<input type="text" value="12"/> <input type="text" value="Periods"/>	<input type="text" value="DEC1992"/>
Hold-out Sample:	<input type="text" value="0"/> <input type="text" value="Periods"/>	

OK Cancel Reset Clear Help

Controls and Fields

Data Set

is the name of the current input data set.

Interval

is the time interval (data frequency) for the input data set.

Series

is the variable name and label of the current time series.

Data Range

gives the date of the first and last nonmissing data values available for the current series in the input data set.

Period of Fit

gives the starting and ending dates of the period of fit. This is the time range used for estimating model parameters. By default, it is the same as the data range. You can type dates in these fields, or you can use the arrow buttons to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

Period of Evaluation

gives the starting and ending dates of the period of evaluation. This is the time range used for evaluating models in terms of statistics of fit. By default, it is the same as the data range. You can type dates in these fields, or you can use the control arrows to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

Forecast Horizon

is the forecasting horizon expressed as a number of forecast periods or number of years (or number of weeks for daily data). You can type a number or select one from the pop-up list. The ending date for the forecast period is automatically updated when you change the number of forecasts periods.

Forecast Horizon - Units

indicates whether the Forecast Horizon value represents periods or years (or weeks for daily data).

Forecast Horizon Date Value

is the date of the last forecast observation. You can type a date in this field, or you can use the arrow buttons to the left and right of the date field to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) The Forecast Horizon is automatically updated when you change the ending date for the forecast period.

Hold-out Sample

specifies that a number of observations or years (or weeks) of data at the end of the data range are used for the period of evaluation with the remainder of data used as the period of fit. You can type a number in this field or select one from the pop-up list. When the hold-out sample

value is changed, the Period of Fit and Period of Evaluation ranges are changed to reflect the hold-out sample specification.

Hold-out Sample - Units

indicates whether the hold-out sample field represents periods or years (or weeks for daily data).

OK

closes the window and stores the specified changes.

Cancel

closes the window without saving changes. Any options you specified are lost.

Reset

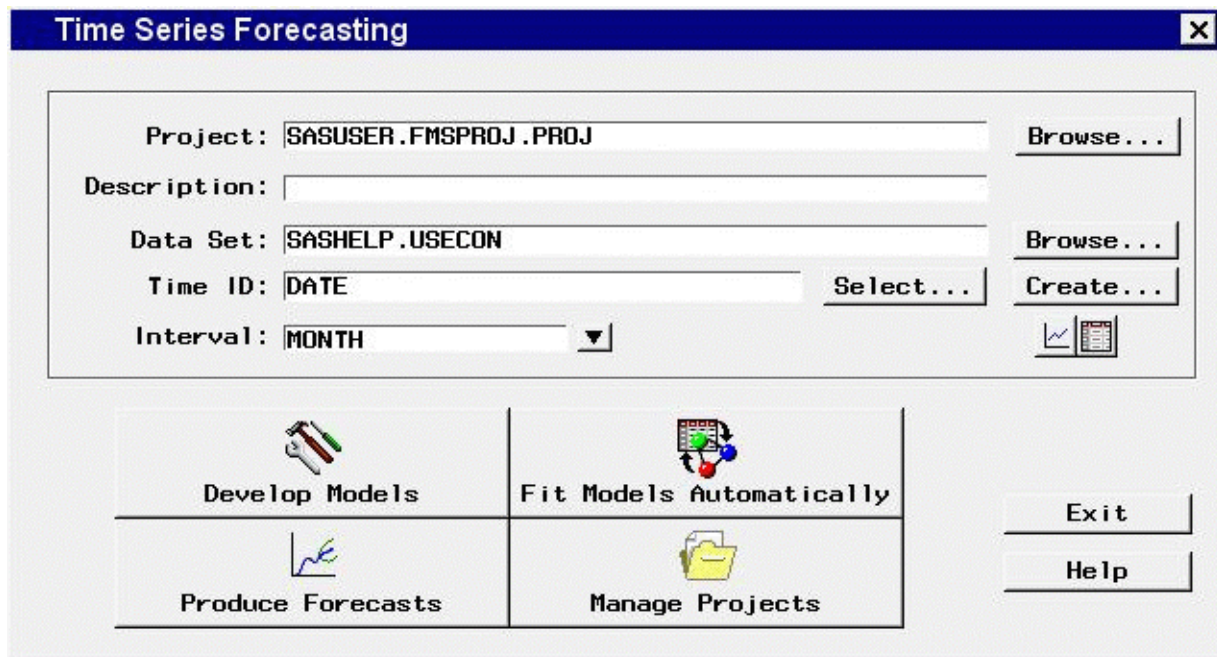

resets the options to their initial values upon entry to the window.

Clear

resets all options to their default values.

Time Series Forecasting Window

The Time Series Forecasting window is the main application window that appears when you invoke the Time Series Forecasting System. It enables you to specify a project file and an input data set and provides access to the other windows described in this chapter.

Controls and Fields

Project

is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project by typing a SAS catalog entry name in this field or by selecting the Browse button to right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one-level name, the catalog name is assumed to be `fmsproj` and the library is assumed to be `sasuser`. For example, `samproj` is equivalent to `sasuser.fmsproj.samproj`.

Project Browse button

opens the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored projects.

Description

is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field.

Data Set

is the name of the current input data set. To specify the input data set, you can type the data set name in this field or use the Browse button to the right of the field.

Data set Browse button

opens the Data Set Selection window to enable you to select the input data set.

Time ID

is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or use the Select button. If the time ID variable is named `date`, `time`, or `datetime`, it is automatically picked up by the system.

Select button

opens the Time ID Variable Specification window.

Create button

opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in, you can type an interval name or select one from the pop-up list. For more information about intervals, see the section “[Time Series Data Sets, ID Variables, and Time Intervals](#)” on page 2395.

View Series Graphically icon

opens the Time Series Viewer window to display plots of series in the current input data set.

View Data as a Table

opens a Viewtable window for browsing the selected input data set.

Develop Models

opens the Develop Models window to enable you to fit forecasting models to individual time series and choose the best models to use to produce the final forecasts of each series.

Fit Models Automatically

opens the Automatic Model Fitting window for applying the automatic model selection process to all series or to selected series in an input data set.

Produce Forecast

opens the Produce Forecasts window for producing forecasts for the series in the current input data set for which you have fit forecasting models.

Manage Projects

opens the Manage Forecasting Project window for viewing or editing information stored in projects.

Exit

closes the Time Series Forecasting system.

Help

accesses the help system.

Time Series Simulation Window

Use the Time Series Simulation window to create a data set of simulated series generated by ARIMA processes. Access this window from the Tools menu in the Develop Models and Manage Forecasting Project windows.

Time Series Simulation [X]

Output Data Set:

Interval: <input type="text" value="WEEKDAY"/>	N Observations: <input type="text" value="60"/>
ID Name: <input type="text" value="DATE"/>	Starting Date: <input type="text" value="Mon, 1 Jan 90"/>
Seed: <input type="text" value="123456789"/>	Ending Date: <input type="text" value="Fri, 23 Mar 90"/>

Series to Generate

Controls and Fields

Output Data Set

is the name of the data set to be created. Type in a one-level or two-level SAS data set name.

Interval

is the time interval between observations (data frequency) in the simulated data set. Type in an interval name or select one from the pop-up list.

Seed

is the seed for the random number generator used to produce the simulated time series.

N Observations

is the number of time periods to simulate.

Starting Date

is the starting date for the simulated observations. Type in a date in a form recognizable by a SAS data informat, for example, 1998:1, feb1997, or 03mar1998.

Ending Date

is the ending date for the simulated observations. Type in a date in a form recognizable by a SAS data informat.

Series to Generate

is the list of variable names and ARIMA processes to simulate.

Add Series

opens the ARIMA Process Specification window to enable you to add entries to the Series to Generate list.

Delete Series

deletes selected (highlighted) entries from the Series to Generate list.

OK

closes the Time Series Simulation window and performs the specified simulations and creates the specified data set.

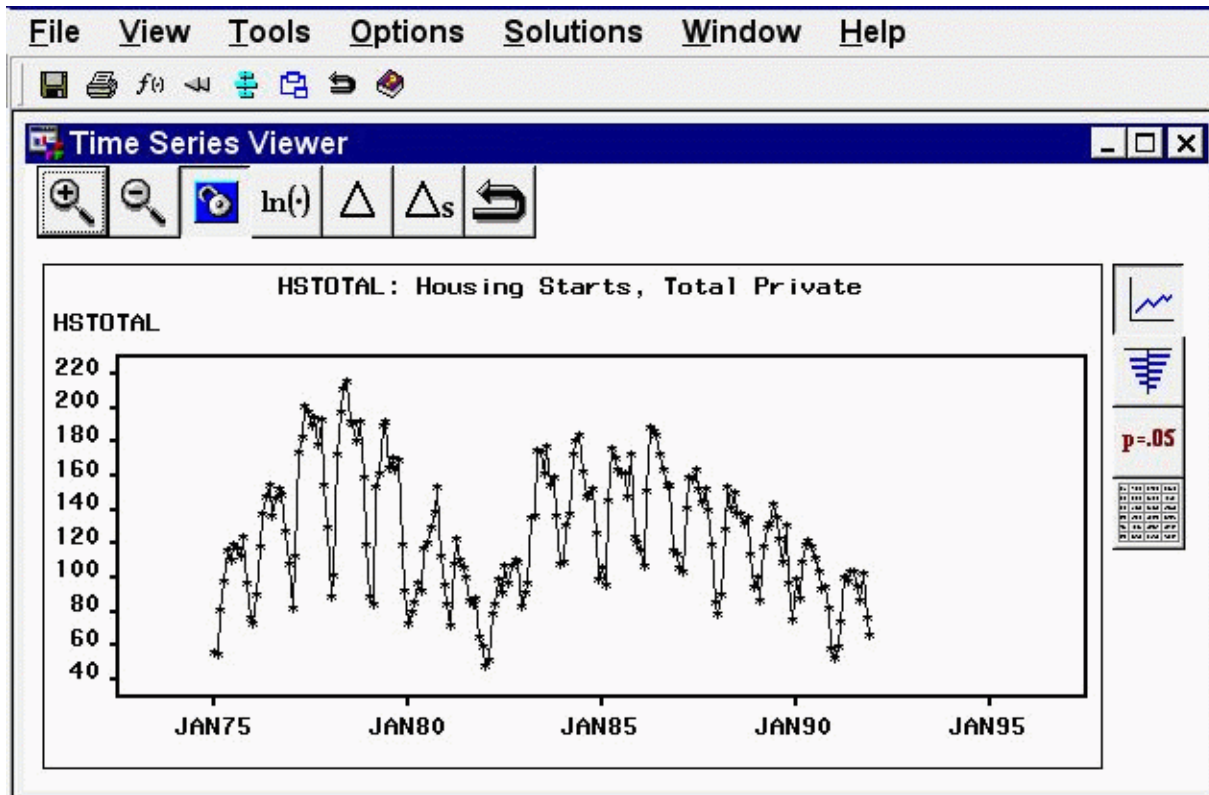

Cancel

closes the window without creating a simulated data set. Any options you specified are lost.

Time Series Viewer Window

Use the Time Series Viewer window to explore time series data using plots, transformations, statistical tests, and tables. It is available as a standalone application and as part of the Time Series Forecasting System. To use it as a standalone application, select it from the Analysis submenu of the Solutions menu, or use the `tsview` command (see Chapter 42, “[Command Reference](#),” in this book). To use it within the Time Series Forecasting System, select the View Series Graphically icon in the Time Series Forecasting, Develop Models, or Model List window, or select “Series” from the View menu of the Develop Models, Manage Project, or Model List window.

The various plots and tables available are referred to as *views*. The section “[View Selection Icons](#)” on page 2617 explains how to change the view.

The state of the Time Series Viewer window is controlled by the current series, the current series transformation specification, and the currently selected view. You can resize this window, and you can use other windows without closing the Time Series Viewer window. You can explore a number of series conveniently by keeping the Series Selection window open. Each time you make a selection, the viewer window is updated to show the selected series. Keep both windows visible, or switch between them by using the Next Viewer toolbar icon or the F12 function key.

You can open multiple Time Series Viewer windows. This enables you to “freeze” a plot so you can come back to it later, or compare two plots side by side on your screen. To do this, unlink the viewer by using the Link/Unlink icon on the window’s toolbar or the corresponding item in the Tools menu. While the viewer window remains unlinked, it is not updated when other selections are made in the Series Selection window. Instead, when you select a series and click the Graph button, a new Time Series Viewer window is invoked. You can continue this process to open as many viewer windows as you want. The Next Viewer icon and corresponding F12 function key are useful for navigating between windows when they are not simultaneously visible on your screen.

A wide range of series transformations is available. Basic transformations are available from the window’s horizontal toolbar, and others are available by selecting “Other Transformations” from the Tools menu.

Horizontal Tool Bar

The Time Series Viewer window contains a horizontal toolbar with the following icons:

Zoom in

changes the mouse cursor into cross hairs that you can use with the left mouse button to drag out a region of the time series plot to zoom in on. In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom In reduces the number of lags displayed.

Zoom out

reverses the previous Zoom In action and expands the time range of the plot to show more of the series. In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom Out increases the number of lags displayed.

Link/Unlink viewer

disconnects or connects the Time Series Viewer window to the window in which the series was selected. When the Viewer is linked, it always shows the current series. If you select another series, linked Viewers are updated. Unlinking a Viewer freezes its current state, and changing the current series has no effect on the Viewer's display. The View Series action creates a new Series Viewer window if there is no linked Viewer. By using the unlink feature, you can open several Time Series Viewer windows and display several different series simultaneously.

Log Transform

applies a log transform to the current view. This can be combined with other transformations; the current transformations are shown in the title.

Difference

applies a simple difference to the current view. This can be combined with other transformations; the current transformations are shown in the title.

Seasonal Difference

applies a seasonal difference to the current view. For example, if the data are monthly, the seasonal cycle is one year. Each value has subtracted from it the value from one year previous. This can be combined with other transformations; the current transformations are shown in the title.

Close

closes the Time Series Viewer window and returns to the window from which it was invoked.

Vertical Toolbar View Selection Icons

At the right-hand side of the Time Series Viewer window is a vertical toolbar used to select the kind of plot or table that the Viewer displays.

Series

displays a plot of series values over time.

Autocorrelations

displays plots of the sample autocorrelations, partial autocorrelation, and inverse autocorrelation functions for the series, with lines overlaid at plus and minus two standard errors.

White Noise and Stationarity Tests

displays horizontal bar charts that represent results of white noise and stationarity tests. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click any of the bars to display an interpretation.

The second bar chart shows tests of stationarity, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click any of the bars to display an interpretation.

Data Table

displays a data table containing the values in the input data set.

Menu Bar

File

Save Graph

saves the current plot as a SAS/GRAPH grseg catalog entry in a default or most recently specified catalog. This item is unavailable in the Data Table view.

Save Graph as

saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the graph embedded as a gif image. This item is unavailable in the Data Table view.

Save Data

saves the data displayed in the viewer window to an output SAS data set. This item is unavailable in the Series view.

Save Data as

saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the data displayed as a table.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Graph

prints the plot displayed in the viewer window. This item is unavailable in the Data Table view.

Print Data

prints the data displayed in the viewer window. This item is unavailable in the Series view.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Print Preview

opens a preview window to show how your plots will look when printed.

Close

closes the Time Series Viewer window and returns to the window from which it was invoked.

View**Series**

displays a plot of series values over time. This is the same as the Series icon in the vertical toolbar.

Autocorrelations

displays plots of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the series. This is the same as the Autocorrelations icon in the vertical toolbar.

White Noise and Stationarity Tests

displays horizontal bar charts representing results of white noise and stationarity tests. This is the same as the White Noise and Stationarity Tests icon in the vertical toolbar.

Data Table

displays a data table containing the values in the input data set. This is the same as the Data Table icon in the vertical toolbar.

Zoom In

zooms the display. This is the same as the Zoom In icon in the window's horizontal toolbar.

Zoom Out

undoes the last zoom in action. This is the same as the Zoom Out icon in the window's horizontal toolbar.

Zoom Way Out

reverses all previous Zoom In actions and expands the time range of the plot to show all of the series, or shows the maximum number of lags in the Autocorrelations View or the White Noise and Stationarity Tests view.

Tools**Log Transform**

applies a log transformation. This is the same as the Log Transform icon in the window's horizontal toolbar.

Difference

applies simple differencing. This is the same as the Difference icon in the window's horizontal toolbar.

Seasonal Difference

applies seasonal differencing. This is the same as the Seasonal Difference icon in the window's horizontal toolbar.

Other Transformations

opens the Series Viewer Transformations window to enable you to apply a wide range of transformations.

Diagnose Series

opens the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

Define Interventions

opens the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

Link Viewer

connects or disconnects the Time Series Viewer window to the window from which series are selected. This is the same as the Link item in the window's horizontal toolbar.

Options**Number of Lags**

opens a window to let you specify the number of lags shown in the Autocorrelations view and the White Noise and Stationarity Tests view. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

Correlation Probabilities

controls whether the bar charts in the Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

Mouse Button Actions

You can examine the data value and date of individual points in the Series view by clicking them. The date and value are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

You can examine the values of the bars and confidence limits at different lags in the Autocorrelations view by clicking individual bars in the vertical bar charts.

You can display an interpretation of the tests in the White Noise and Stationarity Tests view by clicking the bars.

When you select the Zoom In action, you can use the mouse to define a region of the graph to take a closer look at. Position the mouse cursor at one corner of the region, press the left mouse button, and move the mouse cursor to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

This chapter provides computational details on several aspects of the Time Series Forecasting System.

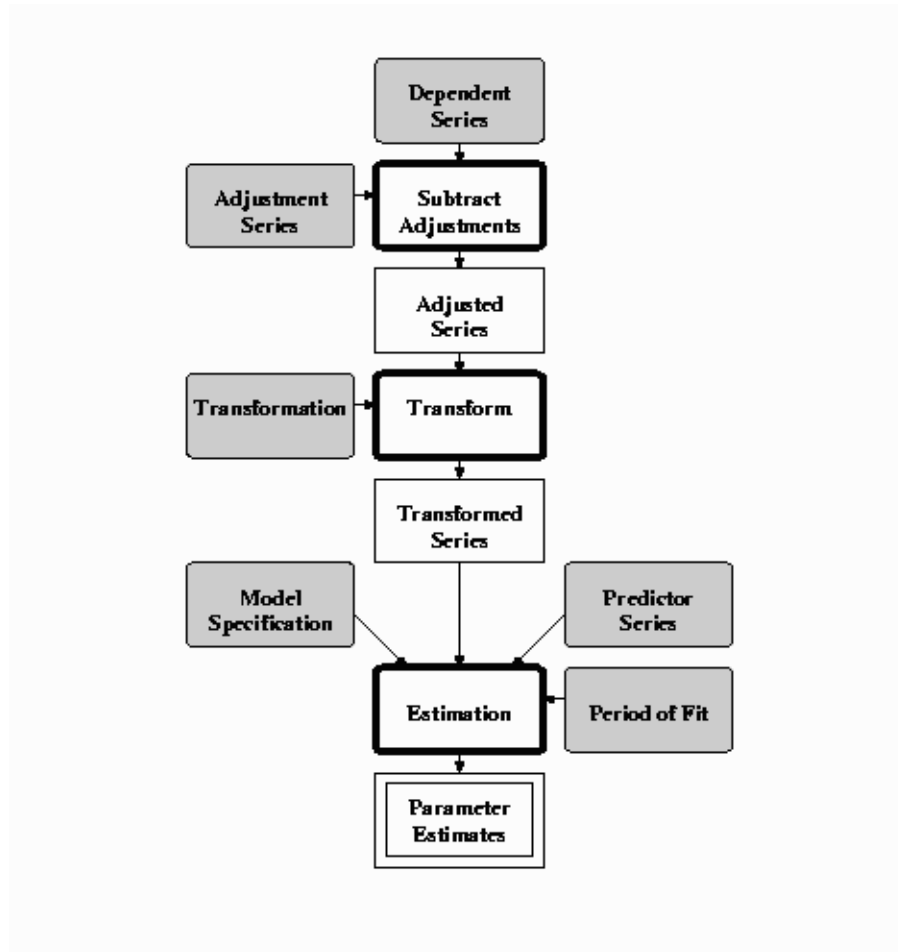

Forecasting Process Summary

This section summarizes the forecasting process.

Parameter Estimation

The parameter estimation process for ARIMA and smoothing models is described graphically in Figure 44.1.

Figure 44.1 Model Fitting Flow Diagram

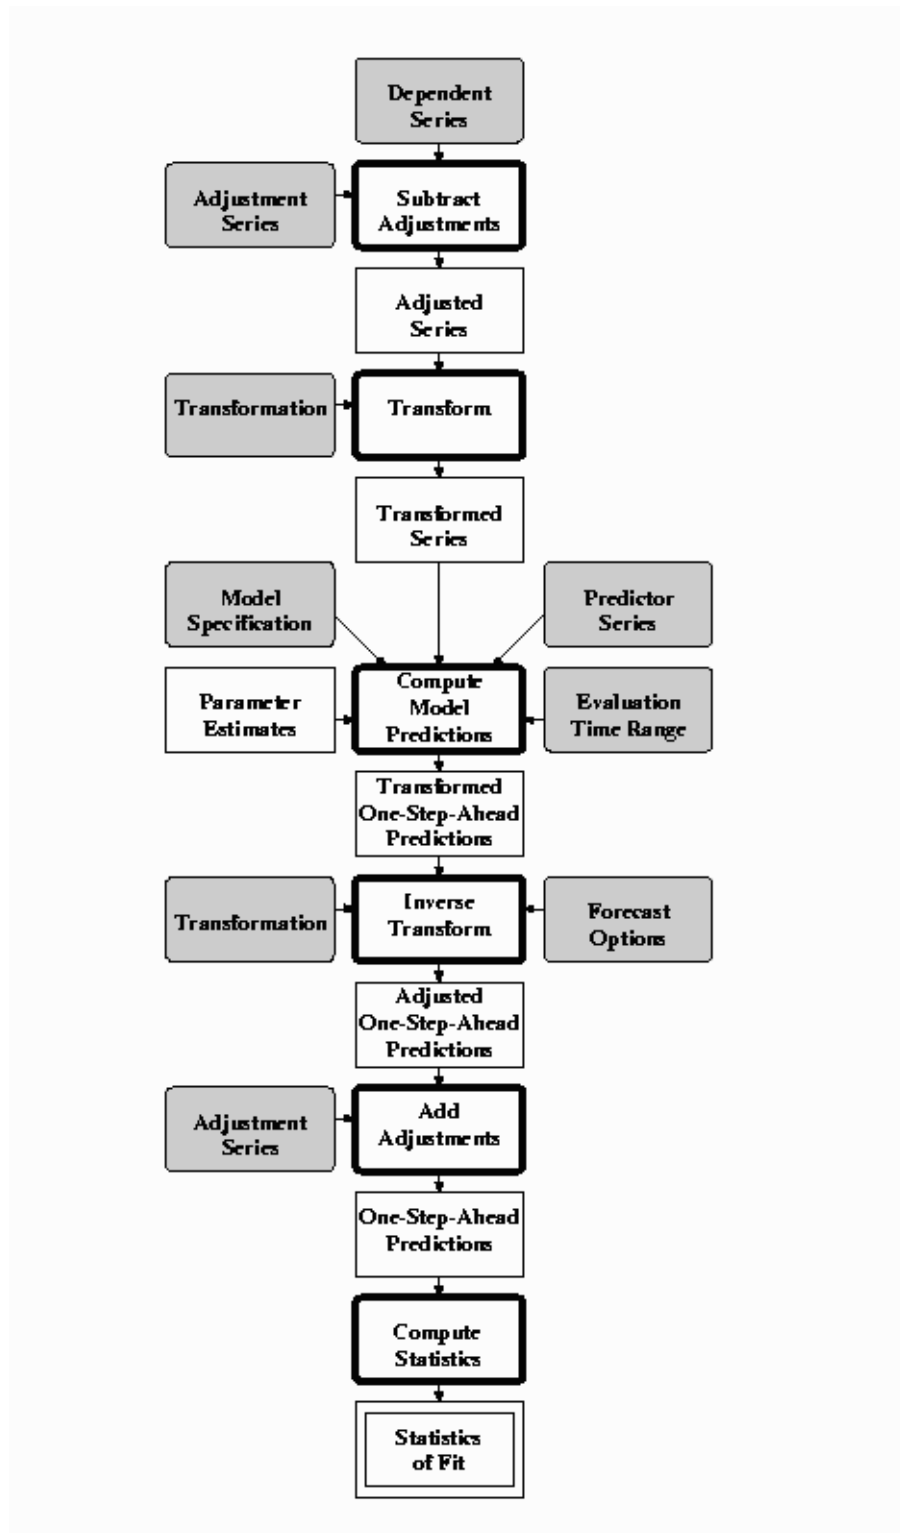

The specification of smoothing and ARIMA models is described in Chapter 39, “[Specifying Forecasting Models](#).” Computational details for these kinds of models are provided in the following sections “[Smoothing Models](#)” on page 2669 and “[ARIMA Models](#)” on page 2680. The results of the parameter estimation process are displayed in the Parameter Estimates table of the Model Viewer windows along with the estimate of the model variance and the final smoothing state.

Model Evaluation

The model evaluation process is described graphically in [Figure 44.2](#).

Figure 44.2 Model Evaluation Flow Diagram

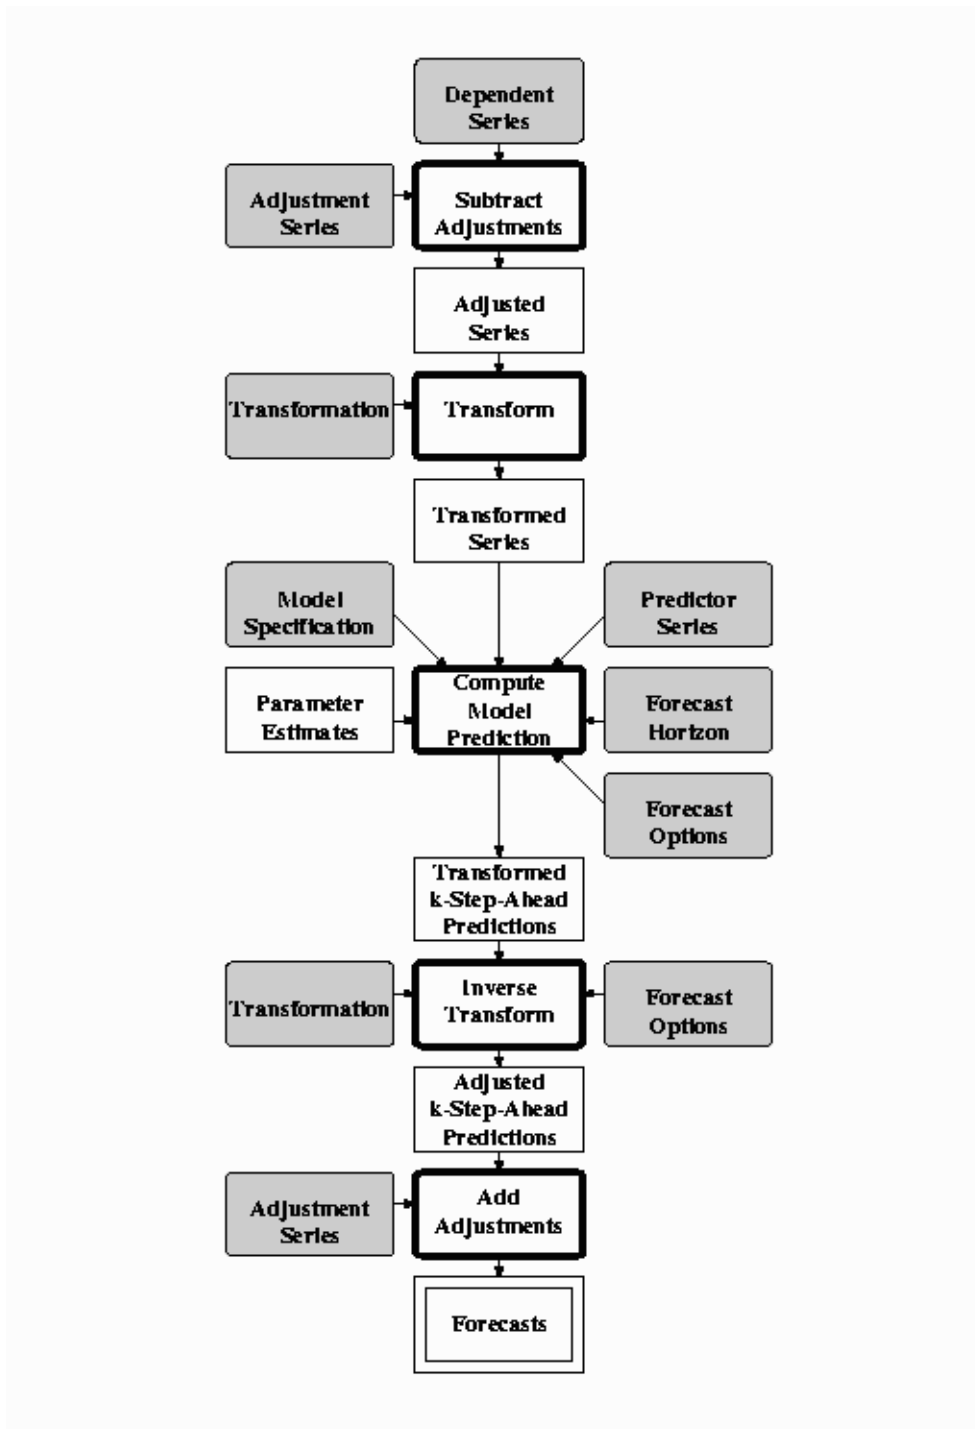

Model evaluation is based on the one-step-ahead prediction errors for observations within the period of evaluation. The one-step-ahead predictions are generated from the model specification and

parameter estimates. The predictions are inverse transformed (median or mean) and adjustments are removed. The prediction errors (the difference of the dependent series and the predictions) are used to compute the statistics of fit, which are described in the section “[Series Diagnostic Tests](#)” on page 2687. The results generated by the evaluation process are displayed in the Statistics of Fit table of the Model Viewer window.

Forecasting

The forecasting generation process is described graphically in [Figure 44.3](#).

Figure 44.3 Forecasting Flow Diagram

The forecasting process is similar to the model evaluation process described in the preceding section, except that k -step-ahead predictions are made from the end of the data through the specified forecast horizon, and prediction standard errors and confidence limits are calculated. The forecasts and confidence limits are displayed in the Forecast plot or table of the Model Viewer window.

Forecast Combination Models

This section discusses the computation of predicted values and confidence limits for forecast combination models. See Chapter 39, “Specifying Forecasting Models,” for information about how to specify forecast combination models and their combining weights.

Given the response time series $\{y_t : 1 \leq t \leq n\}$ with previously generated forecasts for the m component models, a combined forecast is created from the component forecasts as follows:

$$\begin{aligned} \text{Predictions:} \quad & \hat{y}_t = \sum_{i=1}^m w_i \hat{y}_{i,t} \\ \text{Prediction Errors:} \quad & \hat{e}_t = y_t - \hat{y}_t \end{aligned}$$

where $\hat{y}_{i,t}$ are the forecasts of the component models and w_i are the combining weights.

The estimate of the root mean square prediction error and forecast confidence limits for the combined forecast are computed by assuming independence of the prediction errors of the component forecasts, as follows:

$$\begin{aligned} \text{Standard Errors:} \quad & \hat{\sigma}_t = \sqrt{\sum_{i=1}^m w_i^2 \hat{\sigma}_{i,t}^2} \\ \text{Confidence Limits:} \quad & \pm \hat{\sigma}_t Z_{\alpha/2} \end{aligned}$$

where $\hat{\sigma}_{i,t}$ are the estimated root mean square prediction errors for the component models, α is the confidence limit width, $1 - \alpha$ is the confidence level, and $Z_{\alpha/2}$ is the $\frac{\alpha}{2}$ quantile of the standard normal distribution.

Since, in practice, there might be positive correlation between the prediction errors of the component forecasts, these confidence limits may be too narrow.

External or User-Supplied Forecasts

This section discusses the computation of predicted values and confidence limits for external forecast models.

Given a response time series y_t and external forecast series \hat{y}_t , the prediction errors are computed as $\hat{e}_t = y_t - \hat{y}_t$ for those t for which both y_t and \hat{y}_t are nonmissing. The mean squared error (MSE) is computed from the prediction errors.

The variance of the k -step-ahead prediction errors is set to k times the MSE. From these variances, the standard errors and confidence limits are computed in the usual way. If the supplied predictions contain so many missing values within the time range of the response series that the MSE estimate cannot be computed, the confidence limits, standard errors, and statistics of fit are set to missing.

Adjustments

Adjustment predictors are subtracted from the response time series prior to model parameter estimation, evaluation, and forecasting. After the predictions of the adjusted response time series are obtained from the forecasting model, the adjustments are added back to produce the forecasts.

If y_t is the response time series and $X_{i,t}$, $1 \leq i \leq m$ are m adjustment predictor series, then the adjusted response series w_t is

$$w_t = y_t - \sum_{i=1}^m X_{i,t}$$

Parameter estimation for the model is performed by using the adjusted response time series w_t . The forecasts \hat{w}_t of w_t are adjusted to obtain the forecasts \hat{y}_t of y_t .

$$\hat{y}_t = \hat{w}_t + \sum_{i=1}^m X_{i,t}$$

Missing values in an adjustment series are ignored in these computations.

Series Transformations

For pure ARIMA models, transforming the response time series can aid in obtaining stationary noise series. For general ARIMA models with inputs, transforming the response time series or one or more of the input time series can provide a better model fit. Similarly, the fit of smoothing models can improve when the response series is transformed.

There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation,

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation,

$$w_t = \ln(cy_t/(1 - cy_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square Root is the square root transformation,

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation,

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

Parameter estimation is performed by using the transformed series. The transformed model predictions and confidence limits are then obtained from the transformed time series and these parameter estimates.

The transformed model predictions \hat{w}_t are used to obtain either the minimum mean absolute error (MMAE) or minimum mean squared error (MMSE) predictions \hat{y}_t , depending on the setting of the forecast options. The model is then evaluated based on the residuals of the original time series and these predictions. The transformed model confidence limits are inverse-transformed to obtain the forecast confidence limits.

Predictions for Transformed Models

Since the transformations described in the previous section are monotonic, applying the inverse-transformation to the transformed model predictions results in the *median* of the conditional probability density function at each point in time. This is the minimum mean absolute error (MMAE) prediction.

If $w_t = F(y_t)$ is the transform with inverse-transform $y_t = F^{-1}(w_t)$, then

$$\text{median}(\hat{y}_t) = F^{-1}(E[w_t]) = F^{-1}(\hat{w}_t)$$

The minimum mean squared error (MMSE) predictions are the *mean* of the conditional probability density function at each point in time. Assuming that the prediction errors are normally distributed with variance σ_t^2 , the MMSE predictions for each of the transformations are as follows:

Log is the conditional expectation of inverse-logarithmic transformation,

$$\hat{y}_t = E[e^{w_t}] = \exp(\hat{w}_t + \sigma_t^2/2)$$

Logistic is the conditional expectation of inverse-logistic transformation,

$$\hat{y}_t = E\left[\frac{1}{c(1 + \exp(-w_t))}\right]$$

where the scaling factor $c = (1 - e^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$.

Square Root is the conditional expectation of the inverse-square root transformation,

$$\hat{y}_t = E[w_t^2] = \hat{w}_t^2 + \sigma_t^2$$

Box Cox is the conditional expectation of the inverse Box-Cox transformation,

$$\hat{y}_t = \begin{cases} E\left[(\lambda w_t + 1)^{1/\lambda}\right], & \lambda \neq 0 \\ E[e^{w_t}] = \exp(\hat{w}_t + \frac{1}{2}\sigma_t^2), & \lambda = 0 \end{cases}$$

The expectations of the inverse logistic and Box-Cox ($\lambda \neq 0$) transformations do not generally have explicit solutions and are computed by using numerical integration.

Smoothing Models

This section details the computations performed for the exponential smoothing and Winters method forecasting models.

Smoothing Model Calculations

The descriptions and properties of various smoothing methods can be found in Gardner (1985), Chatfield (1978), and Bowerman and O'Connell (1979). The following section summarizes the smoothing model computations.

Given a time series $\{Y_t : 1 \leq t \leq n\}$, the underlying model assumed by the smoothing models has the following (additive seasonal) form:

$$Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t$$

where

- μ_t represents the time-varying mean term.
- β_t represents the time-varying slope.
- $s_p(t)$ represents the time-varying seasonal contribution for one of the p seasons.
- ϵ_t are disturbances.

For smoothing models without trend terms, $\beta_t = 0$; and for smoothing models without seasonal terms, $s_p(t) = 0$. Each smoothing model is described in the following sections.

At each time t , the smoothing models estimate the time-varying components described above with the *smoothing state*. After initialization, the smoothing state is updated for each observation using the *smoothing equations*. The smoothing state at the last nonmissing observation is used for predictions.

Smoothing State and Smoothing Equations

Depending on the smoothing model, the *smoothing state* at time t consists of the following:

- L_t is a smoothed level that estimates μ_t .
- T_t is a smoothed trend that estimates β_t .
- S_{t-j} , $j = 0, \dots, p - 1$, are seasonal factors that estimate $s_p(t)$.

The smoothing process starts with an initial estimate of the smoothing state, which is subsequently updated for each observation by using the *smoothing equations*.

The smoothing equations determine how the smoothing state changes as time progresses. Knowledge of the smoothing state at time $t - 1$ and that of the time series value at time t uniquely determine the smoothing state at time t . The *smoothing weights* determine the contribution of the previous smoothing state to the current smoothing state. The smoothing equations for each smoothing model are listed in the following sections.

Smoothing State Initialization

Given a time series $\{Y_t : 1 \leq t \leq n\}$, the smoothing process first computes the smoothing state for time $t = 1$. However, this computation requires an initial estimate of the smoothing state at time $t = 0$, even though no data exists at or before time $t = 0$.

An appropriate choice for the initial smoothing state is made by backcasting from time $t = n$ to $t = 1$ to obtain a prediction at $t = 0$. The initialization for the backcast is obtained by regression with constant and linear terms and seasonal dummies (additive or multiplicative) as appropriate for the smoothing model. For models with linear or seasonal terms, the estimates obtained by the regression are used for initial smoothed trend and seasonal factors; however, the initial smoothed level for backcasting is always set to the last observation, Y_n .

The smoothing state at time $t = 0$ obtained from the backcast is used to initialize the smoothing process from time $t = 1$ to $t = n$ (Chatfield and Yar 1988).

For models with seasonal terms, the smoothing state is normalized so that the seasonal factors S_{t-j} for $j = 0, \dots, p - 1$ sum to zero for models that assume additive seasonality and average to one for models (such as Winters method) that assume multiplicative seasonality.

Missing Values

When a missing value is encountered at time t , the smoothed values are updated using the *error-correction form* of the smoothing equations with the one-step-ahead prediction error, e_t , set to zero. The missing value is estimated using the one-step-ahead prediction at time $t - 1$, that is $\hat{Y}_{t-1}(1)$ (Aldrin 1989). The error-correction forms of each of the smoothing models are listed in the following sections.

Predictions and Prediction Errors

Predictions are made based on the last known smoothing state. Predictions made at time t for k steps ahead are denoted $\hat{Y}_t(k)$ and the associated prediction errors are denoted $e_t(k) = Y_{t+k} - \hat{Y}_t(k)$. The *prediction equation* for each smoothing model is listed in the following sections.

The *one-step-ahead predictions* refer to predictions made at time $t - 1$ for one time unit into the future—that is, $\hat{Y}_{t-1}(1)$. The *one-step-ahead prediction errors* are more simply denoted $e_t = e_{t-1}(1) = Y_t - \hat{Y}_{t-1}(1)$. The one-step-ahead prediction errors are also the model residuals,

and the sum of squares of the one-step-ahead prediction errors is the objective function used in smoothing weight optimization.

The *variance of the prediction errors* are used to calculate the confidence limits (Sweet 1985, McKenzie 1986, Yar and Chatfield 1990, and Chatfield and Yar 1991). The equations for the variance of the prediction errors for each smoothing model are listed in the following sections.

Note: $var(\epsilon_t)$ is estimated by the mean square of the one-step-ahead prediction errors.

Smoothing Weights

Depending on the smoothing model, the smoothing weights consist of the following:

- α is a level smoothing weight.
- γ is a trend smoothing weight.
- δ is a seasonal smoothing weight.
- ϕ is a trend damping weight.

Larger smoothing weights (less damping) permit the more recent data to have a greater influence on the predictions. Smaller smoothing weights (more damping) give less weight to recent data.

Specifying the Smoothing Weights

Typically the smoothing weights are chosen to be from zero to one. (This is intuitive because the weights associated with the past smoothing state and the value of current observation would normally sum to one.) However, each smoothing model (except Winters Method—Multiplicative Version) has an ARIMA equivalent. Weights chosen to be within the ARIMA additive-invertible region will guarantee stable predictions (Archibald 1990 and Gardner 1985). The ARIMA equivalent and the additive-invertible region for each smoothing model are listed in the following sections.

Optimizing the Smoothing Weights

Smoothing weights are determined so as to minimize the sum of squared, one-step-ahead prediction errors. The optimization is initialized by choosing from a predetermined grid the initial smoothing weights that result in the smallest sum of squared, one-step-ahead prediction errors. The optimization process is highly dependent on this initialization. It is possible that the optimization process will fail due to the inability to obtain stable initial values for the smoothing weights (Greene 1993 and Judge et al. 1980), and it is possible for the optimization to result in a local minima.

The optimization process can result in weights to be chosen outside both the zero-to-one range and the ARIMA additive-invertible region. By restricting weight optimization to additive-invertible region, you can obtain a local minimum with stable predictions. Likewise, weight optimization can be restricted to the zero-to-one range or other ranges. It is also possible to fix certain weights to a specific value and optimize the remaining weights.

Standard Errors

The standard errors associated with the smoothing weights are calculated from the Hessian matrix of the sum of squared, one-step-ahead prediction errors with respect to the smoothing weights used in the optimization process.

Weights Near Zero or One

Sometimes the optimization process results in weights near zero or one.

For simple or double (Brown) exponential smoothing, a level weight near zero implies that simple differencing of the time series might be appropriate.

For linear (Holt) exponential smoothing, a level weight near zero implies that the smoothed trend is constant and that an ARIMA model with deterministic trend might be a more appropriate model.

For damped-trend linear exponential smoothing, a damping weight near one implies that linear (Holt) exponential smoothing might be a more appropriate model.

For Winters method and seasonal exponential smoothing, a seasonal weight near one implies that a nonseasonal model might be more appropriate and a seasonal weight near zero implies that deterministic seasonal factors might be present.

Equations for the Smoothing Models

Simple Exponential Smoothing

The model equation for simple exponential smoothing is

$$Y_t = \mu_t + \epsilon_t$$

The smoothing equation is

$$L_t = \alpha Y_t + (1 - \alpha)L_{t-1}$$

The error-correction form of the smoothing equation is

$$L_t = L_{t-1} + \alpha e_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t$$

The ARIMA model equivalency to simple exponential smoothing is the ARIMA(0,1,1) model

$$(1 - B)Y_t = (1 - \theta B)\epsilon_t$$

$$\theta = 1 - \alpha$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \alpha \epsilon_{t-j}$$

For simple exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \alpha^2 \right] = \text{var}(\epsilon_t)(1 + (k-1)\alpha^2)$$

Double (Brown) Exponential Smoothing

The model equation for double exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha Y_t + (1 - \alpha)L_{t-1} \\ T_t &= \alpha(L_t - L_{t-1}) + (1 - \alpha)T_{t-1} \end{aligned}$$

This method can be equivalently described in terms of two successive applications of simple exponential smoothing:

$$\begin{aligned} S_t^{[1]} &= \alpha Y_t + (1 - \alpha)S_{t-1}^{[1]} \\ S_t^{[2]} &= \alpha S_t^{[1]} + (1 - \alpha)S_{t-1}^{[2]} \end{aligned}$$

where $S_t^{[1]}$ are the smoothed values of Y_t , and $S_t^{[2]}$ are the smoothed values of $S_t^{[1]}$. The prediction equation then takes the form:

$$\hat{Y}_t(k) = (2 + \alpha k / (1 - \alpha))S_t^{[1]} - (1 + \alpha k / (1 - \alpha))S_t^{[2]}$$

The error-correction forms of the smoothing equations are

$$\begin{aligned} L_t &= L_{t-1} + T_{t-1} + \alpha e_t \\ T_t &= T_{t-1} + \alpha^2 e_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + ((k-1) + 1/\alpha)T_t$$

The ARIMA model equivalency to double exponential smoothing is the ARIMA(0,2,2) model,

$$(1 - B)^2 Y_t = (1 - \theta B)^2 \epsilon_t$$

$$\theta = 1 - \alpha$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (2\alpha + (j-1)\alpha^2) \epsilon_{t-j}$$

For double exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (2\alpha + (j-1)\alpha^2)^2 \right]$$

Linear (Holt) Exponential Smoothing

The model equation for linear exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha Y_t + (1 - \alpha)(L_{t-1} + T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t$$

$$T_t = T_{t-1} + \alpha \gamma e_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + kT_t$$

The ARIMA model equivalency to linear exponential smoothing is the ARIMA(0,2,2) model,

$$(1 - B)^2 Y_t = (1 - \theta_1 B - \theta_2 B^2) \epsilon_t$$

$$\theta_1 = 2 - \alpha - \alpha \gamma$$

$$\theta_2 = \alpha - 1$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + j\alpha\gamma)\epsilon_{t-j}$$

For linear exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

$$\{0 < \gamma < 4/\alpha - 2\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (\alpha + j\alpha\gamma)^2 \right]$$

Damped-Trend Linear Exponential Smoothing

The model equation for damped-trend linear exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha Y_t + (1 - \alpha)(L_{t-1} + \phi T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1 - \gamma)\phi T_{t-1}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + \phi T_{t-1} + \alpha e_t \quad T_t = \phi T_{t-1} + \alpha \gamma e_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + \sum_{i=1}^k \phi^i T_t$$

The ARIMA model equivalency to damped-trend linear exponential smoothing is the ARIMA(1,1,2) model,

$$(1 - \phi B)(1 - B)Y_t = (1 - \theta_1 B - \theta_2 B^2)\epsilon_t$$

$$\theta_1 = 1 + \phi - \alpha - \alpha\gamma\phi$$

$$\theta_2 = (\alpha - 1)\phi$$

The moving-average form of the equation (assuming $|\phi| < 1$) is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + \alpha\gamma\phi(\phi^j - 1)/(\phi - 1))\epsilon_{t-j}$$

For damped-trend linear exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

$$\{0 < \phi\gamma < 4/\alpha - 2\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (\alpha + \alpha\gamma\phi(\phi^j - 1)/(\phi - 1))^2 \right]$$

Seasonal Exponential Smoothing

The model equation for seasonal exponential smoothing is

$$Y_t = \mu_t + s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t - S_{t-p}) + (1 - \alpha)L_{t-1}$$

$$S_t = \delta(Y_t - L_t) + (1 - \delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + \alpha e_t$$

$$S_t = S_{t-p} + \delta(1 - \alpha)e_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + S_{t-p+k}$$

The ARIMA model equivalency to seasonal exponential smoothing is the ARIMA(0,1,p+1)(0,1,0)_p model,

$$(1 - B)(1 - B^p)Y_t = (1 - \theta_1 B - \theta_2 B^p - \theta_3 B^{p+1})\epsilon_t$$

$$\theta_1 = 1 - \alpha$$

$$\theta_2 = 1 - \delta(1 - \alpha)$$

$$\theta_3 = (1 - \alpha)(\delta - 1)$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j}$$

$$\psi_j = \begin{cases} \alpha & \text{for } j \bmod p \neq 0 \\ \alpha + \delta(1 - \alpha) & \text{for } j \bmod p = 0 \end{cases}$$

For seasonal exponential smoothing, the additive-invertible region is

$$\{\max(-p\alpha, 0) < \delta(1 - \alpha) < (2 - \alpha)\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \psi_j^2 \right]$$

Multiplicative Seasonal Smoothing

In order to use the multiplicative version of seasonal smoothing, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of seasonal smoothing is

$$Y_t = \mu_t s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t/S_{t-p}) + (1 - \alpha)L_{t-1}$$

$$S_t = \delta(Y_t/L_t) + (1 - \delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + \alpha e_t/S_{t-p}$$

$$S_t = S_{t-p} + \delta(1 - \alpha)e_t/L_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t S_{t-p+k}$$

The multiplicative version of seasonal smoothing does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of seasonal described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[\sum_{i=0}^{\infty} \sum_{j=0}^{p-1} (\psi_{j+ip} S_{t+k}/S_{t+k-j})^2 \right]$$

where ψ_j are as described for the additive version of seasonal method, and $\psi_j = 0$ for $j \geq k$.

Winters Method—Additive Version

The model equation for the additive version of Winters method is

$$Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha(Y_t - S_{t-p}) + (1 - \alpha)(L_{t-1} + T_{t-1}) \\ T_t &= \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1} \\ S_t &= \delta(Y_t - L_t) + (1 - \delta)S_{t-p} \end{aligned}$$

The error-correction form of the smoothing equations is

$$\begin{aligned} L_t &= L_{t-1} + T_{t-1} + \alpha e_t \\ T_t &= T_{t-1} + \alpha \gamma e_t \\ S_t &= S_{t-p} + \delta(1 - \alpha)e_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + kT_t + S_{t-p+k}$$

The ARIMA model equivalency to the additive version of Winters method is the ARIMA(0,1,p+1)(0,1,0)_p model,

$$(1 - B)(1 - B^p)Y_t = \left[1 - \sum_{i=1}^{p+1} \theta_i B^i \right] \epsilon_t$$

$$\theta_j = \begin{cases} 1 - \alpha - \alpha\gamma & j = 1 \\ -\alpha\gamma & 2 \leq j \leq p - 1 \\ 1 - \alpha\gamma - \delta(1 - \alpha) & j = p \\ (1 - \alpha)(\delta - 1) & j = p + 1 \end{cases}$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j}$$

$$\psi_j = \begin{cases} \alpha + j\alpha\gamma & \text{for } j \bmod p \neq 0 \\ \alpha + j\alpha\gamma + \delta(1 - \alpha), & \text{for } j \bmod p = 0 \end{cases}$$

For the additive version of Winters method (see Archibald 1990), the additive-invertible region is

$$\begin{aligned} &\{\max(-p\alpha, 0) < \delta(1 - \alpha) < (2 - \alpha)\} \\ &\{0 < \alpha\gamma < 2 - \alpha - \delta(1 - \alpha)(1 - \cos(\vartheta))\} \end{aligned}$$

where ϑ is the smallest nonnegative solution to the equations listed in Archibald (1990).

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \psi_j^2 \right]$$

Winters Method—Multiplicative Version

In order to use the multiplicative version of Winters method, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of Winters method is

$$Y_t = (\mu_t + \beta_t t) s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t/S_{t-p}) + (1 - \alpha)(L_{t-1} + T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1}$$

$$S_t = \delta(Y_t/L_t) + (1 - \delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t / S_{t-p}$$

$$T_t = T_{t-1} + \alpha \gamma e_t / S_{t-p}$$

$$S_t = S_{t-p} + \delta(1 - \alpha) e_t / L_t$$

NOTE: For missing values, $e_t = 0$.

The k -step prediction equation is

$$\hat{Y}_t(k) = (L_t + kT_t)S_{t-p+k}$$

The multiplicative version of Winters method does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of Winters method described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[\sum_{i=0}^{\infty} \sum_{j=0}^{p-1} (\psi_{j+ip} S_{t+k} / S_{t+k-j})^2 \right]$$

where ψ_j are as described for the additive version of Winters method and $\psi_j = 0$ for $j \geq k$.

ARIMA Models

Autoregressive integrated moving-average (ARIMA) models predict values of a dependent time series with a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series (predictor time series).

The Time Series Forecasting System uses the ARIMA procedure of SAS/ETS software to fit and forecast ARIMA models. The maximum likelihood method is used for parameter estimation. Refer to Chapter 7, “[The ARIMA Procedure](#),” for details of ARIMA model estimation and forecasting.

This section summarizes the notation used for ARIMA models.

Notation for ARIMA Models

A dependent time series that is modeled as a linear combination of its own past values and past values of an error series is known as a (pure) ARIMA model.

Nonseasonal ARIMA Model Notation

The order of an ARIMA model is usually denoted by the notation $ARIMA(p,d,q)$, where

- p is the order of the autoregressive part.
- d is the order of the differencing (rarely should $d > 2$ be needed).
- q is the order of the moving-average process.

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA model is written as

$$(1 - B)^d Y_t = \mu + \frac{\theta(B)}{\phi(B)} a_t$$

where

- t indexes time.
- μ is the mean term.
- B is the backshift operator; that is, $BX_t = X_{t-1}$.
- $\phi(B)$ is the autoregressive operator, represented as a polynomial in the back shift operator: $\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$.
- $\theta(B)$ is the moving-average operator, represented as a polynomial in the back shift operator: $\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$.
- a_t is the independent disturbance, also called the random error.

For example, the mathematical form of the ARIMA(1,1,2) model is

$$(1 - B)Y_t = \mu + \frac{(1 - \theta_1 B - \theta_2 B^2)}{(1 - \phi_1 B)} a_t$$

Seasonal ARIMA Model Notation

Seasonal ARIMA models are expressed in factored form by the notation ARIMA(p,d,q)(P,D,Q) $_s$, where

- P is the order of the seasonal autoregressive part.
- D is the order of the seasonal differencing (rarely should $D > 1$ be needed).
- Q is the order of the seasonal moving-average process.
- s is the length of the seasonal cycle.

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA seasonal model is written as

$$(1 - B)^d (1 - B^s)^D Y_t = \mu + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)} a_t$$

where

- $\phi_s(B^s)$ is the seasonal autoregressive operator, represented as a polynomial in the back shift operator:
 $\phi_s(B^s) = 1 - \phi_{s,1} B^s - \dots - \phi_{s,P} B^{sP}$
- $\theta_s(B^s)$ is the seasonal moving-average operator, represented as a polynomial in the back shift operator: $\theta_s(B^s) = 1 - \theta_{s,1} B^s - \dots - \theta_{s,Q} B^{sQ}$

For example, the mathematical form of the ARIMA(1,0,1)(1,1,2) $_{12}$ model is

$$(1 - B^{12})Y_t = \mu + \frac{(1 - \theta_1 B)(1 - \theta_{s,1} B^{12} - \theta_{s,2} B^{24})}{(1 - \phi_1 B)(1 - \phi_{s,1} B^{12})} a_t$$

Abbreviated Notation for ARIMA Models

If the differencing order, autoregressive order, or moving-average order is zero, the notation is further abbreviated as

- I(d)(D) $_s$ integrated model or ARIMA($0,d,0$)($0,D,0$)
- AR(p)(P) $_s$ autoregressive model or ARIMA($p,0,0$)($P,0,0$)
- IAR(p,d)(P,D) $_s$ integrated autoregressive model or ARIMA($p,d,0$)($P,D,0$) $_s$
- MA(q)(Q) $_s$ moving average model or ARIMA($0,0,q$)($0,0,Q$) $_s$
- IMA(d,q)(D,Q) $_s$ integrated moving average model or ARIMA($0,d,q$)($0,D,Q$) $_s$
- ARMA(p,q)(P,Q) $_s$ autoregressive moving-average model or ARIMA($p,0,q$)($P,0,Q$) $_s$.

Notation for Transfer Functions

A transfer function can be used to filter a predictor time series to form a dynamic regression model.

Let Y_t be the dependent series, let X_t be the predictor series, and let $\Psi(B)$ be a linear filter or transfer function for the effect of X_t on Y_t . The ARIMA model is then

$$(1 - B)^d (1 - B^s)^D Y_t = \mu + \Psi(B) (1 - B)^d (1 - B^s)^D X_t + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)} a_t$$

This model is called a *dynamic regression* of Y_t on X_t .

Nonseasonal Transfer Function Notation

Given the i th predictor time series $\{X_{i,t} : 1 \leq t \leq n\}$, the transfer function is written as

$$\text{Dif}(d_i)\text{Lag}(k_i)\text{N}(q_i)/\text{D}(p_i)$$

where

d_i	is the simple order of the differencing for the i th predictor time series, $(1 - B)^{d_i} X_{i,t}$ (rarely should $d_i > 2$ be needed).
k_i	is the pure time delay (lag) for the effect of the i th predictor time series, $X_{i,t} B^{k_i} = X_{i,t-k_i}$.
p_i	is the simple order of the denominator for the i th predictor time series.
q_i	is the simple order of the numerator for the i th predictor time series.

The mathematical notation used to describe a transfer function is

$$\Psi_i(B) = \frac{\omega_i(B)}{\delta_i(B)} (1 - B)^{d_i} B^{k_i}$$

where

B	is the backshift operator; that is, $BX_t = X_{t-1}$.
$\delta_i(B)$	is the denominator polynomial of the transfer function for the i th predictor time series: $\delta_i(B) = 1 - \delta_{i,1}B - \dots - \delta_{i,p_i}B^{p_i}$.
$\omega_i(B)$	is the numerator polynomial of the transfer function for the i th predictor time series: $\omega_i(B) = 1 - \omega_{i,1}B - \dots - \omega_{i,q_i}B^{q_i}$.

The numerator factors for a transfer function for a predictor series are like the MA part of the ARMA model for the noise series. The denominator factors for a transfer function for a predictor series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

For example, the transfer function for the i th predictor time series with

$k_i = 3$	time lag is 3
$d_i = 1$	simple order of differencing is one
$p_i = 1$	simple order of the denominator is one
$q_i = 2$	simple order of the numerator is two

would be written as [Dif(1)Lag(3)N(2)/D(1)]. The mathematical notation for the transfer function in this example is

$$\Psi_i(B) = \frac{(1 - \omega_{i,1}B - \omega_{i,2}B^2)}{(1 - \delta_{i,1}B)}(1 - B)B^3$$

Seasonal Transfer Function Notation

The general transfer function notation for the i th predictor time series $X_{i,t}$ with seasonal factors is [Dif(d_i)(D_i) $_s$ Lag(k_i) N(q_i)(Q_i) $_s$ / D(p_i)(P_i) $_s$] where

D_i	is the seasonal order of the differencing for the i th predictor time series (rarely should $D_i > 1$ be needed).
P_i	is the seasonal order of the denominator for the i th predictor time series (rarely should $P_i > 2$ be needed).
Q_i	is the seasonal order of the numerator for the i th predictor time series, (rarely should $Q_i > 2$ be needed).
s	is the length of the seasonal cycle.

The mathematical notation used to describe a seasonal transfer function is

$$\Psi_i(B) = \frac{\omega_i(B)\omega_{s,i}(B^s)}{\delta_i(B)\delta_{s,i}(B^s)}(1 - B)^{d_i}(1 - B^s)^{D_i}B^{k_i}$$

where

$\delta_{s,i}(B^s)$	is the denominator seasonal polynomial of the transfer function for the i th predictor time series: $\delta_{s,i}(B) = 1 - \delta_{s,i,1}B - \dots - \delta_{s,i,P_i}B^{sP_i}$
$\omega_{s,i}(B^s)$	is the numerator seasonal polynomial of the transfer function for the i th predictor time series: $\omega_{s,i}(B) = 1 - \omega_{s,i,1}B - \dots - \omega_{s,i,Q_i}B^{sQ_i}$

For example, the transfer function for the i th predictor time series $X_{i,t}$ whose seasonal cycle $s = 12$ with

$d_i = 2$	simple order of differencing is two
$D_i = 1$	seasonal order of differencing is one
$q_i = 2$	simple order of the numerator is two
$Q_i = 1$	seasonal order of the numerator is one

would be written as $[\text{Dif}(2)(1)_s \text{N}(2)(1)_s]$. The mathematical notation for the transfer function in this example is

$$\Psi_i(B) = (1 - \omega_{i,1}B - \omega_{i,2}B^2)(1 - \omega_{s,i,1}B^{12})(1 - B)^2(1 - B^{12})$$

Note: In this case, $[\text{Dif}(2)(1)_s \text{N}(2)(1)_s] = [\text{Dif}(2)(1)_s \text{Lag}(0)\text{N}(2)(1)_s/\text{D}(0)(0)_s]$.

Predictor Series

This section discusses time trend curves, seasonal dummies, interventions, and adjustments.

Time Trend Curves

When you specify a time trend curve as a predictor in a forecasting model, the system computes a predictor series that is a deterministic function of time. This variable is then included in the model as a regressor, and the trend curve is fit to the dependent series by linear regression, in addition to other predictor series.

Some kinds of nonlinear trend curves are fit by transforming the dependent series. For example, the exponential trend curve is actually a linear time trend fit to the logarithm of the series. For these trend curve specifications, the series transformation option is set automatically, and you cannot independently control both the time trend curve and transformation option.

The computed time trend variable is included in the output data set in a variable named in accordance with the trend curve type. Let t represent the observation count from the start of the period of fit for the model, and let X_t represent the value of the time trend variable at observation t within the period of fit. The names and definitions of these variables are as follows. (Note: These deterministic variables are reserved variable names.)

Linear trend	variable name <code>_LINEAR_</code> , with $X_t = t - c$
Quadratic trend	variable name <code>_QUAD_</code> , with $X_t = (t - c)^2$. Note that a quadratic trend implies a linear trend as a special case and results in two regressors: <code>_QUAD_</code> and <code>_LINEAR_</code> .
Cubic trend	variable name <code>_CUBE_</code> , with $X_t = (t - c)^3$. Note that a cubic trend implies a quadratic trend as a special case and results in three regressors: <code>_CUBE_</code> , <code>_QUAD_</code> , and <code>_LINEAR_</code> .
Logistic trend	variable name <code>_LOGIT_</code> , with $X_t = t$. The model is a linear time trend applied to the logistic transform of the dependent series. Thus, specifying a logistic trend is equivalent to specifying the logistic series transformation and a linear time trend. A logistic trend predictor can be used only in conjunction with the logistic transformation, which is set automatically when you specify logistic trend.

Logarithmic trend	variable name <code>_LOG_</code> , with $X_t = \ln(t)$
Exponential trend	variable name <code>_EXP_</code> , with $X_t = t$. The model is a linear time trend applied to the logarithms of the dependent series. Thus, specifying an exponential trend is equivalent to specifying the log series transformation and a linear time trend. An exponential trend predictor can be used only in conjunction with the log transformation, which is set automatically when you specify exponential trend.
Hyperbolic trend	variable name <code>_HYP_</code> , with $X_t = 1/t$
Power curve trend	variable name <code>_POW_</code> , with $X_t = \ln(t)$. The model is a logarithmic time trend applied to the logarithms of the dependent series. Thus, specifying a power curve is equivalent to specifying the log series transformation and a logarithmic time trend. A power curve predictor can be used only in conjunction with the log transformation, which is set automatically when you specify a power curve trend.
EXP(A+B/TIME) trend	variable name <code>_ERT_</code> , with $X_t = 1/t$. The model is a hyperbolic time trend applied to the logarithms of the dependent series. Thus, specifying this trend curve is equivalent to specifying the log series transformation and a hyperbolic time trend. This trend curve can be used only in conjunction with the log transformation, which is set automatically when you specify this trend.

Intervention Effects

Interventions are used for modeling events that occur at specific times. That is, they are known changes that affect the dependent series or outliers.

The i th intervention series is included in the output data set with variable name `_INTVi_`, which is a reserved variable name.

Point Interventions

The point intervention is a one-time event. The i th intervention series $X_{i,t}$ has a point intervention at time t_{int} when the series is nonzero only at time t_{int} —that is,

$$X_{i,t} = \begin{cases} 1, & t = t_{int} \\ 0, & \text{otherwise} \end{cases}$$

Step Interventions

Step interventions are continuing, and the input time series flags periods after the intervention. For a step intervention, before time t_{int} , the i th intervention series $X_{i,t}$ is zero and then steps to a constant level thereafter—that is,

$$X_{i,t} = \begin{cases} 1, & t \geq t_{int} \\ 0, & \text{otherwise} \end{cases}$$

Ramp Interventions

A ramp intervention is a continuing intervention that increases linearly after the intervention time. For a ramp intervention, before time t_{int} , the i th intervention series $X_{i,t}$ is zero and increases linearly thereafter—that is, proportional to time.

$$X_{i,t} = \begin{cases} t - t_{int}, & t \geq t_{int} \\ 0, & \text{otherwise} \end{cases}$$

Intervention Effect

Given the i th intervention series $X_{i,t}$, you can define how the intervention takes effect by filters (transfer functions) of the form

$$\Psi_i(B) = \frac{1 - \omega_{i,1}B - \dots - \omega_{i,q_i}B^{q_i}}{1 - \delta_{i,1}B - \dots - \delta_{i,p_i}B^{p_i}}$$

where B is the backshift operator $By_t = y_{t-1}$.

The denominator of the transfer function determines the decay pattern of the intervention effect, whereas the numerator terms determine the size of the intervention effect time window.

For example, the following intervention effects are associated with the respective transfer functions.

Immediately	$\Psi_i(B) = 1$
Gradually	$\Psi_i(B) = 1/(1 - \delta_{i,1}B)$
1 lag window	$\Psi_i(B) = 1 - \omega_{i,1}B$
3 lag window	$\Psi_i(B) = 1 - \omega_{i,1}B - \omega_{i,2}B^2 - \omega_{i,3}B^3$

Intervention Notation

The notation used to describe intervention effects has the form $type : t_{int} (q_i)/(p_i)$, where $type$ is point, step, or ramp; t_{int} is the time of the intervention (for example, OCT87); q_i is the transfer function numerator order; and p_i is the transfer function denominator order. If $q_i = 0$, the part “ (q_i) ” is omitted; if $p_i = 0$, the part “ $/(p_i)$ ” is omitted.

In the Intervention Specification window, the `Number of Lags` option specifies the transfer function numerator order q_i , and the `Effect Decay Pattern` option specifies the transfer function denominator order p_i . In the `Effect Decay Pattern` options, values and resulting p_i are: `None`, $p_i = 0$; `Exp`, $p_i = 1$; `Wave`, $p_i = 2$.

For example, a step intervention with date 08MAR90 and effect pattern `Exp` is denoted “Step:08MAR90/(1)” and has a transfer function filter $\Psi_i(B) = 1/(1 - \delta_1 B)$. A ramp intervention immediately applied on 08MAR90 is denoted “Ramp:08MAR90” and has a transfer function filter $\Psi_i(B) = 1$.

Seasonal Dummy Inputs

For a seasonal cycle of length s , the seasonal dummy regressors include

$$\{X_{i,t} : 1 \leq i \leq (s - 1), 1 \leq t \leq n\}$$

for models that include an intercept term and

$$\{X_{i,t} : 1 \leq i \leq s, 1 \leq t \leq n\}$$

for models that exclude an intercept term. Each element of a seasonal dummy regressor is either zero or one, based on the following rule:

$$X_{i,t} = \begin{cases} 1, & \text{when } i = t \pmod{s} \\ 0, & \text{otherwise} \end{cases}$$

Note that if the model includes an intercept term, the number of seasonal dummy regressors is one less than s to ensure that the linear system is full rank.

The seasonal dummy variables are included in the output data set with variable names prefixed with “SDUMMY i ” and sequentially numbered. They are reserved variable names.

Series Diagnostic Tests

This section describes the diagnostic tests that are used to determine the kinds of forecasting models appropriate for a series.

The series diagnostics are a set of heuristics that provide recommendations on whether or not the forecasting model should contain a log transform, trend terms, and seasonal terms. These recommendations are used by the automatic model selection process to restrict the model search to a subset of the model selection list. (You can disable this behavior by using the Automatic Model Selection Options window.)

The tests that are used by the series diagnostics do not always produce the correct classification of the series. They are intended to accelerate the process of searching for a good forecasting model for the series, but you should not rely on them if finding the very best model is important to you.

If you have information about the appropriate kinds of forecasting models (perhaps from studying the plots and autocorrelations shown in the Series Viewer window), you can set the series diagnostic flags in the Series Diagnostics window. Select the YES, NO, or MAYBE values for the `Log Transform`, `Trend`, and `Seasonality` options in the Series Diagnostics window as you think appropriate.

The series diagnostics tests are intended as a heuristic tool only, and no statistical validity is claimed for them. These tests might be modified and enhanced in future releases of the Time Series Forecasting System. The testing strategy is as follows:

1. **Log transform test.** The log test fits a high-order autoregressive model to the series and to the log of the series and compares goodness-of-fit measures for the prediction errors of the two models. If this test finds that log transforming the series is suitable, the `Log Transform` option is set to YES, and the subsequent diagnostic tests are performed on the log transformed series.
2. **Trend test.** The resultant series is tested for presence of a trend by using an augmented Dickey-Fuller test and a random walk with drift test. If either test finds that the series appears to have a trend, the `Trend` option is set to YES, and the subsequent diagnostic tests are performed on the differenced series.
3. **Seasonality test.** The resultant series is tested for seasonality. A seasonal dummy model with AR(1) errors is fit and the joint significance of the seasonal dummy estimates is tested. If the seasonal dummies are significant, the AIC statistic for this model is compared to the AIC for an AR(1) model without seasonal dummies. If the AIC for the seasonal model is lower than that of the nonseasonal model, the `Seasonal` option is set to YES.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well different models fit the data. The statistics of fit for the various forecasting models can be viewed or stored in a data set by using the Model Viewer window.

Statistics of fit are computed by using the actual and forecasted values for observations in the period of evaluation. One-step forecasted values are used whenever possible, including the case when a hold-out sample contains no missing values. If a one-step forecast for an observation cannot be computed due to missing values for previous series observations, a multi-step forecast is computed, using the minimum number of steps as the previous nonmissing values in the data range permit.

The various statistics of fit reported are as follows. In these formulas, n is the number of nonmissing observations and k is the number of fitted parameters in the model.

Number of Nonmissing Observations.

The number of nonmissing observations used to fit the model.

Number of Observations.

The total number of observations used to fit the model, including both missing and nonmissing observations.

Number of Missing Actuals.

The number of missing actual values.

Number of Missing Predicted Values.

The number of missing predicted values.

Number of Model Parameters.

The number of parameters fit to the data. For combined forecast, this is the number of forecast components.

Total Sum of Squares (Uncorrected).

The total sum of squares for the series, SST, uncorrected for the mean: $\sum_{t=1}^n y_t^2$.

Total Sum of Squares (Corrected).

The total sum of squares for the series, SST, corrected for the mean: $\sum_{t=1}^n (y_t - \bar{y})^2$, where \bar{y} is the series mean.

Sum of Square Errors.

The sum of the squared prediction errors, SSE. $SSE = \sum_{t=1}^n (y_t - \hat{y}_t)^2$, where \hat{y} is the one-step predicted value.

Mean Squared Error.

The mean squared prediction error, MSE, calculated from the one-step-ahead forecasts. $MSE = \frac{1}{n}SSE$. This formula enables you to evaluate small hold-out samples.

Root Mean Squared Error.

The root mean square error (RMSE), \sqrt{MSE} .

Mean Absolute Percent Error.

The mean absolute percent prediction error (MAPE), $\frac{100}{n} \sum_{t=1}^n |(y_t - \hat{y}_t)/y_t|$.

The summation ignores observations where $y_t = 0$.

Mean Absolute Error.

The mean absolute prediction error, $\frac{1}{n} \sum_{t=1}^n |y_t - \hat{y}_t|$.

R-Square.

The R^2 statistic, $R^2 = 1 - SSE/SST$. If the model fits the series badly, the model error sum of squares, SSE, can be larger than SST and the R^2 statistic will be negative.

Adjusted R-Square.

The adjusted R^2 statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$.

Amemiya's Adjusted R-Square.

Amemiya's adjusted R^2 , $1 - (\frac{n+k}{n-k})(1 - R^2)$.

Random Walk R-Square.

The random walk R^2 statistic (Harvey's R^2 statistic by using the random walk model for comparison), $1 - (\frac{n-1}{n})SSE/RWSSE$, where $RWSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$.

Akaike's Information Criterion.

Akaike's information criterion (AIC), $n \ln(MSE) + 2k$.

Schwarz Bayesian Information Criterion.

Schwarz Bayesian information criterion (SBC or BIC), $n \ln(MSE) + k \ln(n)$.

Amemiya's Prediction Criterion.

Amemiya's prediction criterion, $\frac{1}{n}SST(\frac{n+k}{n-k})(1 - R^2) = (\frac{n+k}{n-k})\frac{1}{n}SSE$.

Maximum Error.

The largest prediction error.

Minimum Error.

The smallest prediction error.

Maximum Percent Error.

The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

Minimum Percent Error.

The smallest percent prediction error, $100 \min((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

Mean Error.

The mean prediction error, $\frac{1}{n} \sum_{t=1}^n (y_t - \hat{y}_t)$.

Mean Percent Error.

The mean percent prediction error, $\frac{100}{n} \sum_{t=1}^n \frac{(y_t - \hat{y}_t)}{y_t}$. The summation ignores observations where $y_t = 0$.

About Investment Analysis

The Investment Analysis system is an interactive environment for the time-value of money of a variety of investments:

- loans
- savings
- depreciations
- bonds
- generic cashflows

Various analyses are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and breakeven analysis.

These analyses can help answer a number of questions you may have about your investments:

- Which option is more profitable or less costly?
- Is it better to buy or rent?
- Are the extra fees for refinancing at a lower interest rate justified?
- What is the balance of this account after saving this amount periodically for so many years?
- How much is legally tax-deductible?

- Is this a reasonable price?

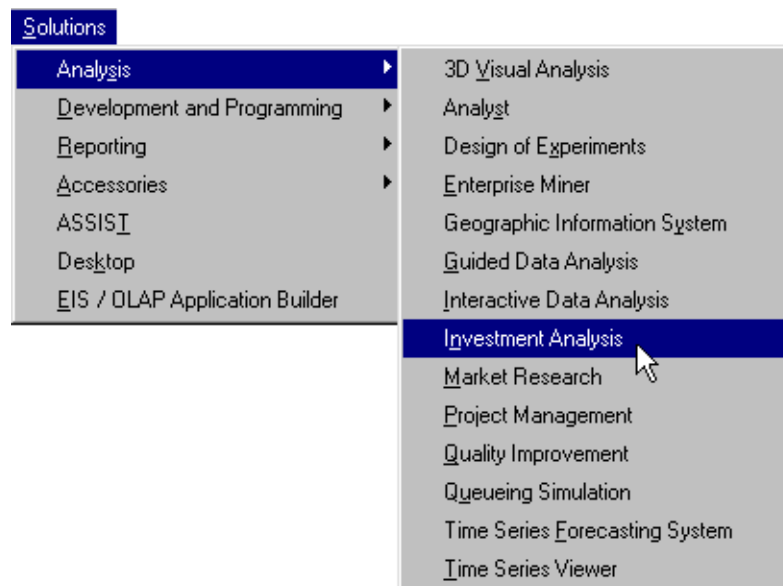

Investment Analysis can be beneficial to users in many industries for a variety of decisions:

- manufacturing: cost justification of automation or any capital investment, replacement analysis of major equipment, or economic comparison of alternative designs
- government: setting funds for services
- finance: investment analysis and portfolio management for fixed-income securities

Starting Investment Analysis

There are two ways to invoke Investment Analysis from the main SAS window. One way is to select **Solutions** → **Analysis** → **Investment Analysis** from the main SAS menu, as displayed in Figure 45.1.

Figure 45.1 Initializing Investment Analysis with the Menu Bar

The other way is to type **INVEST** into the toolbar's command prompt, as displayed in Figure 45.2.

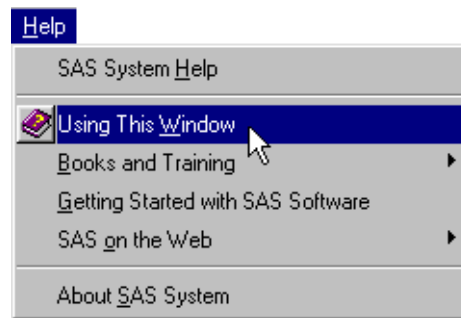

Figure 45.2 Initializing Investment Analysis with the Toolbar

Getting Help

You can get help in Investment Analysis in three ways. One way is to use the Help Menu, as displayed in [Figure 45.3](#). This is the right-most menu item on the menu bar.

Figure 45.3 The Help Menu

Help buttons, as in [Figure 45.4](#), provide another way to access help. Most dialog boxes provide help buttons in their lower-right corners.

Figure 45.4 A Help Button

Also, the toolbar has a button (see [Figure 45.5](#)) that invokes the help system. This is the right-most icon on the toolbar.

Figure 45.5 The Help Icon

Each of these methods invokes a browser that gives specific help for the active window.

Using Help

The chapters pertaining to Investment Analysis in this document typically have a section that introduces you to a menu and summarizes the options available through the menu. Such chapters then have sections titled Task and Dialog Box Guides. The Task section provides a description of how to perform many useful tasks. The Dialog Box Guide lists all dialog boxes pertinent to those tasks and gives a brief description of each element of each dialog box.

Software Requirements

Investment Analysis uses the following SAS software:

- Base SAS
- SAS/ETS
- SAS/GRAPH (optional, to view bond pricing and breakeven graphs)

The File Menu

Investment Analysis stores portfolios as catalog entries. Portfolios contain a collection of investments, providing a structure to collect investments with a common purpose or goal (like a retirement or building fund portfolio). It may be advantageous also to collect investments into a common portfolio if they are competing investments you want to perform a comparative analysis upon. Within this structure you can perform computations and analyses on a collection of investments in a portfolio, just as you would perform them on a single investment.

Investment Analysis provides many tools to aid in your manipulation of portfolios through the **File** menu, shown in [Figure 46.1](#).

Figure 46.1 File Menu

The **File** menu offers the following items:

New Portfolio creates an empty portfolio with a new name.

Open Portfolio opens the standard SAS Open dialog box where you select a portfolio to open.

Save Portfolio saves the current portfolio to its current name.

Save Portfolio As opens the standard SAS Save As dialog box where you supply a new portfolio name for the current portfolio.

Close closes Investment Analysis.

Exit closes SAS (Windows only).

Tasks

Creating a New Portfolio

From the Investment Analysis dialog box, select **File** → **New Portfolio**.

Figure 46.2 Creating a New Portfolio

The **Portfolio Name** is WORK.INVEST.INVEST1 as displayed in [Figure 46.2](#), unless you have saved a portfolio to that name in the past. In that case, some other unused portfolio name is given to the new portfolio.

Saving a Portfolio

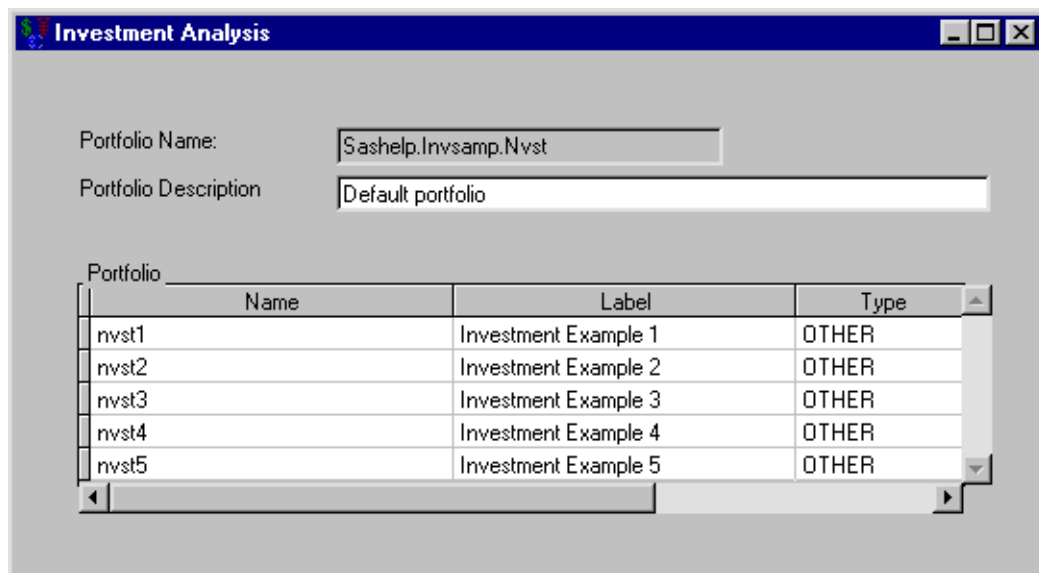

From the Investment Analysis dialog box, select **File** → **Save Portfolio**. The portfolio is saved to a catalog-entry with the name in the **Portfolio Name** box.

Opening an Existing Portfolio

From the Investment Analysis dialog box, select **File** → **Open Portfolio**. This opens the standard SAS Open dialog box. You enter the name of a SAS portfolio to open in the **Entry Name** box. For example, enter SASHELP.INVSAMP.NVST as displayed in [Figure 46.3](#).

Figure 46.3 Opening an Existing Portfolio

Click **Open** to load the portfolio. The portfolio should look like [Figure 46.4](#).

Figure 46.4 The Opened Portfolio

Saving a Portfolio to a Different Name

From the Investment Analysis dialog box, select **File** → **Save Portfolio As**.

This opens the standard SAS Save As dialog box. You can enter the name of a SAS portfolio into the **Entry Name** box. For example, enter SASUSER.MY_PORTS.PORT1, as in [Figure 46.5](#).

Figure 46.5 Saving a Portfolio to a Different Name

Click **Save** to save the portfolio.

Selecting Investments within a Portfolio

To select a single investment in an opened portfolio, click the investment in the Portfolio area within the Investment Analysis dialog box.

To select a list of adjacent investments, do the following: click the first investment, hold down SHIFT, and click the final investment. After the list of investments is selected, you can release the SHIFT key. The selected investments will appear highlighted as in [Figure 46.6](#).

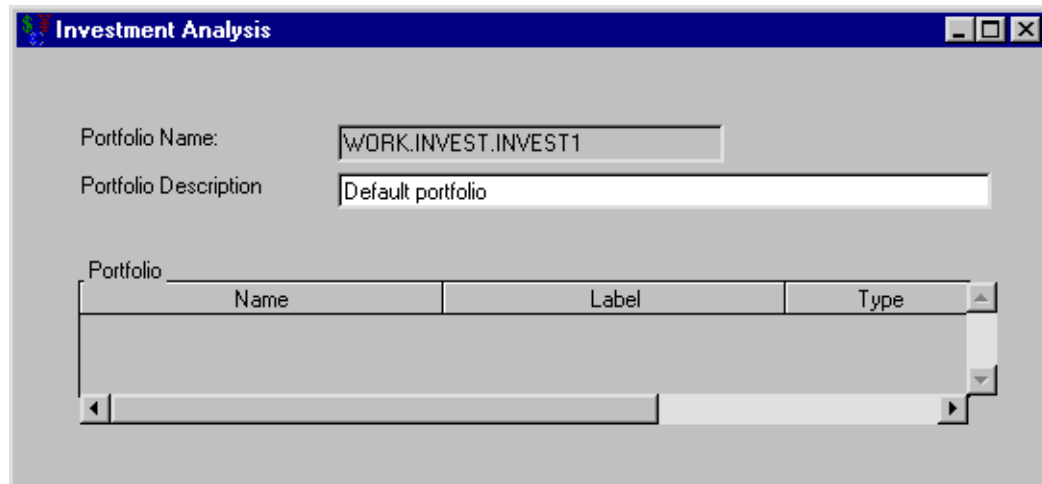

Figure 46.6 Selecting Investments within a Portfolio

Dialog and Utility Guide

Investment Analysis

Figure 46.7 Investment Analysis Dialog Box

Investment Portfolio Name holds the name of the portfolio. The name is of the form `library.catalog_entry.portfolio`. The default portfolio name is `work.invest.invest1`, as in [Figure 46.7](#).

Portfolio Description provides a more descriptive explanation of the portfolio's contents. You can edit this description any time this dialog box is active.

The **Portfolio** area contains the list of investments comprising the particular portfolio. Each investment in the **Portfolio** area displays the following attributes:

Name is the name of the investment. It must be a valid SAS name. It is used to distinguish investments when performing analyses and computations.

Label is a place where you can provide a more descriptive explanation of the investment.

Type is the type of investment, which is fixed when you create the investment. It is one of the following: LOAN, SAVINGS, DEPRECIATION, BOND, or OTHER.

Additional tools to aid in the management of your portfolio are available by selecting from the [menu bar](#) or by [right-clicking](#) within the **Portfolio** area.

Menu Bar Options

Figure 46.8 The Menu Bar

The menu bar (shown in [Figure 46.8](#)) provides many tools to aid in the management of portfolios and the investments that comprise them. The following menu items provide functionality particular to Investment Analysis:

File opens and saves portfolios.

Investment creates new investments within the portfolio.

Compute performs constant dollar, after tax, and currency conversion computations on generic cashflows.

Analyze analyzes investments to aid in decision-making.

Tools sets default values of inflation and income tax rates.

Right-Clicking within the Portfolio Area

Figure 46.9 Right-Clicking

After selecting an investment, right-clicking in the **Portfolio** area pops up a menu (see [Figure 46.9](#)) that offers the following options:

Edit opens the selected investment within the portfolio.

Duplicate creates a duplicate of the selected investment within the portfolio.

Delete removes the selected investment from the portfolio.

If you wish to perform one of these actions on a collection of investments, you must select a collection of investments (as described in the section “[Selecting Investments within a Portfolio](#)” on page 2705) before right-clicking.

The Investment Menu

Because there are many types of investments, a tool that manages and analyzes collections of investments must be robust and flexible. Providing specifications for four specific investment types and one generic type, Investment Analysis can model almost any real-world investment.

Figure 47.1 Investment Menu

The **Investment** menu, shown in [Figure 47.1](#), offers the following items:

New → **Loan** opens the [Loan](#) dialog box. Loans are useful for acquiring capital to pursue various interests. Available terms include rate adjustments for variable rate loans, initialization costs, prepayments, and balloon payments.

New → **Savings** opens the [Savings](#) dialog box. Savings are necessary when planning for the future, whether for business or personal purposes. Account summary calculations available per deposit include starting balance, deposits, interest earned, and ending balance.

New → **Depreciation** opens the [Depreciation](#) dialog box. Depreciations are relevant in tax calculation. The available depreciation methods are Straight Line, Sum-of-years Digits, Depreciation Table, and Declining Balance. Depreciation Tables are necessary when depreciation calculations must conform to set yearly percentages. Declining Balance with conversion to Straight Line is also provided.

New → **Bond** opens the [Bond](#) dialog box. Bonds have widely varying terms depending on the issuer. Because bond issuers frequently auction their bonds, the ability to price a bond between the issue date and maturity date is desirable. Fixed-coupon bonds may be analyzed for the following: price versus yield-to-maturity, duration, and convexity. These are available at different times in the bond's life.

New → **Generic Cashflow** opens the [Generic Cashflow](#) dialog box. Generic cashflows are the most flexible investments. Only a sequence of date-amount pairs is necessary for specification. You can enter date-amount pairs and load values from SAS data sets to specify any type of investment. You can generate uniform, arithmetic, and geometric cashflows with ease. SAS's forecasting ability is available to forecast future cashflows as well. The new graphical display aids in visualization of the cashflow and enables the user to change the frequency of the cashflow view to aggregate and disaggregate the view.

Edit opens the specification dialog box for an investment selected within the portfolio.

Duplicate creates a duplicate of an investment selected within the portfolio.

Delete removes an investment selected from the portfolio.

If you want to edit, duplicate, or delete a collection of investments, you must select a collection of investments as described in the section "[Selecting Investments within a Portfolio](#)" on page 2705 before performing the menu-option.

Tasks

Loan Tasks

Suppose you want to buy a home that costs \$100,000. You can make a down payment of \$20,000. Hence, you need a loan of \$80,000. You are able to acquire a 30-year loan at 7% interest starting January 1, 2000. Let's use Investment Analysis to specify and analyze this loan.

In the Investment Analysis dialog box, select **Investment** → **New** → **Loan** from the menu bar to open the Loan dialog box.

Specifying Loan Terms to Create an Amortization Schedule

You must specify the loan before generating the amortization table. To specify the loan, follow these steps:

1. Enter MORTGAGE for the **Name**.
2. Enter 80000 for the **Loan Amount**.
3. Enter 7 for the **Initial Rate**.
4. Enter 360 for the **Number of Payments**.
5. Enter 01JAN2000 for the **Start Date**.

After you have specified the loan, click **Create Amortization Schedule** to generate the amortization schedule displayed in [Figure 47.2](#).

Figure 47.2 Creating an Amortization Schedule

The screenshot shows a 'Loan' dialog box with the following fields and options:

- Name: MORTGAGE
- Loan Specification:
 - Loan Amount: 80000
 - Initial Rate: 7.00
 - Periodic Payment: (empty)
 - Start Date: 01JAN2000
 - Number of Payments: 360
 - Payment Interval: MONTH
 - Compounding Interval: MONTH
- Buttons: Initialization..., Prepayments..., Balloon Payments..., Rate Adjustments..., Rounding Off...
- Create Amortization Schedule button
- Amortization Schedule Table:

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Rep
JAN2000	80000.00	0.00	0.00	0.00
FEB2000	80000.00	532.24	466.67	65.57
MAR2000	79934.43	532.24	466.28	65.96
APR2000	79868.47	532.24	465.90	66.34
- Buttons: Save Data As..., OK, Cancel, Help

Storing Other Loan Terms

Let's include information concerning the purchase price and downpayment. These terms are not necessary to specify the loan, but it may be advantageous to store such information with the loan.

Consider the loan described in the section “[Loan Tasks](#)” on page 2711. In the Loan dialog box ([Figure 47.2](#)) click **Initialization** to open the Loan Initialization Options dialog box, where you can specify the down payment, initialization costs, and discount points. To specify the down payment, enter 100000 for the **Purchase Price**, as shown in [Figure 47.3](#).

Figure 47.3 Including the Purchase Price

Loan Initialization Options

Downpayment: % of Price:

Initialization Costs and Discount Points

Loan Amount:

Initialization Costs: % of Amount:

Discount Points: % of Amount:

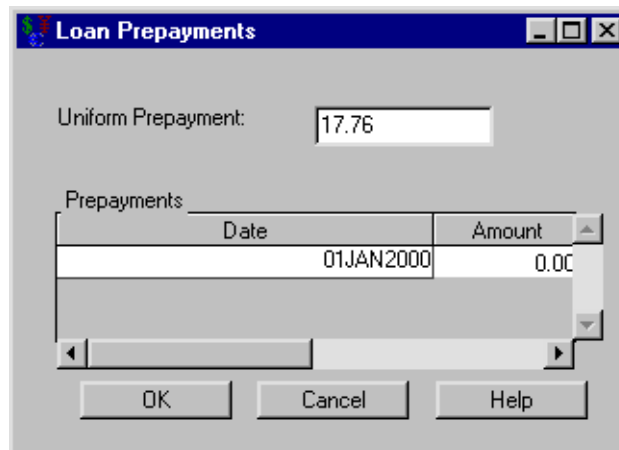

OK Cancel Help

Click **OK** to return to the Loan dialog box.

Adding Prepayments

Now let's observe the effect of prepayments on the loan. Consider the loan described in the section "Loan Tasks" on page 2711. You must pay a minimum of \$532.24 each month to keep up with payments. However, let's say you dislike entering this amount in your checkbook. You would rather pay \$550.00 to keep the arithmetic simpler. This would constitute a uniform prepayment of \$17.76 each month.

In the Loan dialog box, click **Prepayments**, which opens the Loan Prepayments dialog box shown in Figure 47.4.

Figure 47.4 Specifying the Loan Prepayments

The screenshot shows a dialog box titled "Loan Prepayments". It has a "Uniform Prepayment:" label followed by a text box containing "17.76". Below this is a "Prepayments" section containing a table with two columns: "Date" and "Amount". The table has one row with "01JAN2000" in the "Date" column and "0.00" in the "Amount" column. At the bottom of the dialog are three buttons: "OK", "Cancel", and "Help".

Date	Amount
01JAN2000	0.00

You can specify an arbitrary sequence of prepayments in the **Prepayments** area. If you want a uniform prepayment, clear the **Prepayments** area and enter the uniform payment amount in the **Uniform Prepayment** text box. That amount will be added to each payment until the loan is paid off.

To specify this uniform prepayment, follow these steps:

1. Enter 17.76 for the **Uniform Prepayment**.
2. Click **OK** to return to the Loan dialog box.
3. Click **Create Amortization Schedule**, and the amortization schedule is updated, as displayed in [Figure 47.5](#).

Figure 47.5 The Amortization Schedule with Loan Prepayments

The screenshot shows the 'Loan' dialog box with the following fields and values:

- Name: MORTGAGE
- Loan Specification:
 - Loan Amount: 80000
 - Initial Rate: 7.00
 - Periodic Payment: (empty)
 - Start Date: 01JAN2000
 - Number of Payments: 360
 - Payment Interval: MONTH
 - Compounding Interval: MONTH
- Buttons: Initialization..., Prepayments..., Balloon Payments..., Rate Adjustments..., Rounding Off...
- Amortization Schedule: Create Amortization Schedule

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Rep
JAN2000	80000.00	0.00	0.00	0.00
FEB2000	80000.00	550.00	466.67	83.33
MAR2000	79916.67	550.00	466.18	83.82
APR2000	79832.85	550.00	465.69	84.31

Buttons at the bottom: Save Data As..., OK, Cancel, Help

The last payment is on January 2030 without prepayments and February 2027 with prepayment; you would pay the loan off almost three years earlier with the \$17.76 prepayments.

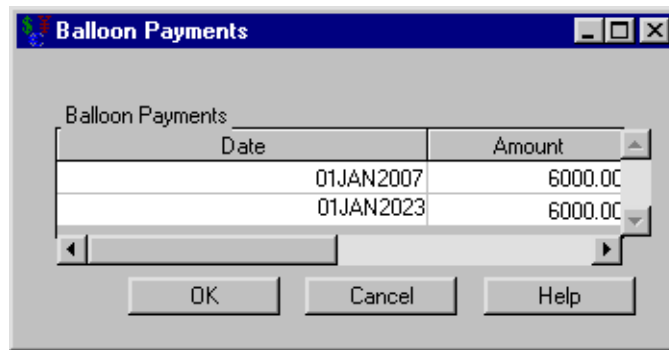

To continue this example you must remove the prepayments from the loan specification, following these steps:

1. Reopen the Loan Prepayments dialog box from the Loan dialog box by clicking **Prepayments**.
2. Enter 0 for **Uniform Prepayment**.
3. Click **OK** to return to the Loan dialog box.

Adding Balloon Payments

Consider the loan described in the section “[Loan Tasks](#)” on page 2711. Suppose you cannot afford the payments of \$532.24 each month. To lessen your monthly payment, you could pay balloon payments of \$6,000 at the end of 2007 and 2023. You wonder how this would affect your monthly payment. (Note that Investment Analysis does not allow both balloon payments and rate adjustments to be specified for a loan.)

In the Loan dialog box, click **Balloon Payments**, which opens the Balloon Payments dialog box shown in [Figure 47.6](#).

Figure 47.6 Defining Loan Balloon Payments

You can specify an arbitrary sequence of balloon payments by adding date-amount pairs to the **Balloon Payments** area.

To specify these balloon payments, follow these steps:

1. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **New**.
2. Set the pair's **Date** to 01JAN2007.
3. Set **Amount** to 6000.
4. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **New**.
5. Set the new pair's **Date** to 01JAN2023.
6. Set its **Amount** to 6000.

Click **OK** to return to the Loan dialog box. Click **Create Amortization Schedule**, and the amortization schedule is updated. Your monthly payment is now \$500.30, a difference of approximately \$32 each month.

To continue this example you must remove the balloon payments from the loan specification, following these steps:

1. Reopen the Balloon Payments dialog box.
2. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **Clear**.
3. Click **OK** to return to the Loan dialog box.

Handling Rate Adjustments

Consider the loan described in the section “[Loan Tasks](#)” on page 2711. Another option for lowering your payments is to get a variable rate loan. You can acquire a three-year adjustable rate mortgage (ARM) at 6% with a periodic cap of 1% with a maximum of 9%. (Note that Investment Analysis does not allow both rate adjustments and balloon payments to be specified for a loan.)

In the Loan dialog box, click **Rate Adjustments** to open the Rate Adjustment Terms dialog box shown in [Figure 47.7](#).

Figure 47.7 Setting the Rate Adjustments

Rate Adjustment Terms

Rate Adjustment Terms:

Life Cap:

Periodic Cap:

Adjustment Frequency: months

Rate Adjustment Assumption

Worst Case

Best Case

Fixed Case

Estimated Case

Estimated Rates

Date	Rate
------	------

OK Cancel Help

To specify these loan adjustment terms, follow these steps:

1. Enter 3 for the **Life Cap**. The **Life Cap** is the maximum deviation from the Initial Rate.
2. Enter 1 for the **Periodic Cap**.
3. Enter 36 for the **Adjustment Frequency**.
4. Confirm that **Worst Case** is selected from the Rate Adjustment Assumption options.
5. Click **OK** to return to the Loan dialog box.
6. Enter 6 for the **Initial Rate**.
7. Click **Create Amortization Schedule**, and the amortization schedule is updated.

Your monthly payment drops to \$479.64 each month. However, if the worst-case scenario plays out, the payments will increase to \$636.84 in nine years. [Figure 47.8](#) displays amortization table information for the final few months under this scenario.

Figure 47.8 The Amortization Schedule with Rate Adjustments

The screenshot shows a 'Loan' dialog box with the following fields and buttons:

- Name: untitled_loan
- Loan Specification:
 - Loan Amount: 80000
 - Initial Rate: 6.00
 - Periodic Payment: (empty)
 - Start Date: 01JAN2000
 - Number of Payments: 360
 - Payment Interval: MONTH
 - Compounding Interval: MONTH
- Buttons: Initialization..., Prepayments..., Balloon Payments..., Rate Adjustments..., Rounding Off...
- Create Amortization Schedule button
- Amortization Schedule table:

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Repay
AUG2029	3722.76	636.84	27.92	608.92
SEP2029	3113.84	636.84	23.35	613.49
OCT2029	2500.35	636.84	18.75	618.09
NOV2029	1882.26	636.84	14.12	622.72
DEC2029	1259.54	636.84	9.45	627.39
JAN2030	632.15	636.89	4.74	632.15

Buttons at the bottom: Save Data As..., OK, Cancel, Help

Click **OK** to return to the Investment Analysis dialog box.

Specifying Savings Terms to Create an Account Summary

Suppose you put \$500 each month into an account that earns 6% interest for 20 years. What is the balance of the account after those 20 years?

In the Investment Analysis dialog box, select **Investment** → **New** → **Savings** from the menu bar to open the Savings dialog box.

To specify the savings, follow these steps:

1. Enter RETIREMENT for the **Name**.
2. Enter 500 for the **Periodic Deposit**.
3. Enter 240 for the **Number of Deposits**.
4. Enter 6 for the **Initial Rate**.

You must specify the savings before generating the account summary. After you have specified the savings, click **Create Account Summary** to compute the ending date and balance and to generate the account summary displayed in [Figure 47.9](#).

Figure 47.9 Creating an Account Summary

The screenshot shows a 'Savings' dialog box with the following fields and values:

- Name: RETIREMENT
- Savings Specification:
 - Periodic Deposit: 500
 - Start Date: 01JAN2000
 - Number of Deposits: 240
 - Deposit Interval: MONTH
 - Initial Rate: 6.00
 - Compounding Interval: MONTH
- Ending Date: 01JAN2020
- Balance: 232175.54982
- Buttons: Create Account Summary, Save Data As..., OK, Cancel, Help

The 'Account Summary' table is as follows:

Date	StartingBalance	Deposits	InterestEarned	EndingBalance
01JAN2000	0.00	500.00	0.00	500.00
01FEB2000	500.00	500.00	2.50	1002.50
01MAR2000	1002.50	500.00	5.01	1507.51

Click **OK** to return to the Investment Analysis dialog box.

Depreciation Tasks

Commercial assets are considered to lose value as time passes. For tax purposes, you want to quantify this loss. This investment structure helps calculate appropriate values.

Suppose you spend \$50,000 for a commercial fishing boat that is considered to have a ten-year useful life. How would you depreciate it?

In the Investment Analysis dialog box, select **Investment** → **New** → **Depreciation** from the menu bar to open the Depreciation dialog box.

Specifying Depreciation Terms to Create a Depreciation Table

To specify the depreciation, follow these steps:

1. Enter FISHING_BOAT for the **Name**.

2. Enter 50000 for the **Cost**.
3. Enter 2000 for the **Year of Purchase**.
4. Enter 10 for the **Useful Life**.
5. Enter 0 for the **Salvage Value**.

You must specify the depreciation before generating the depreciation schedule. After you have specified the depreciation, click **Create Depreciation Schedule** to generate a depreciation schedule like the one displayed in [Figure 47.10](#).

Figure 47.10 Creating a Depreciation Schedule

The screenshot shows a dialog box titled "Depreciation" with the following fields and options:

- Name: FISHING_BOAT
- Depreciable Asset Specification:
 - Cost: 50000
 - Year of Purchase: 2000
 - Useful Life: 10
 - Salvage Value: 0
- Depreciation Method:
 - Straight Line (SL)
 - Sum-of-years-digits
 - Depreciation Table...
 - Declining Balance (DB)
- DB Factor: 2 1.5 1
- Conversion to SL: Yes No

Below the settings is a "Create Depreciation Schedule" button and a table showing the schedule:

Year	StartBookValue	Depreciation	EndBookValue
2000	50000.00	10000.00	40000.00
2001	40000.00	8000.00	32000.00
2002	32000.00	6400.00	25600.00
2003	25600.00	5120.00	20480.00
2004	20480.00	4096.00	16384.00

At the bottom of the dialog are buttons for "Save Data As...", "OK", "Cancel", and "Help".

The default depreciation method is Declining Balance (with Conversion to Straight Line). Try the following methods to see how they each affect the schedule:

- Straight Line
- Sum-of-years Digits
- Declining Balance (without conversion to Straight Line)

It might be useful to compare the value of the boat at 5 years for each method.

A description of these methods is available in the section "[Depreciation Methods](#)" on page 2785.

Using the Depreciation Table

Sometimes you want to force the depreciation rates to be certain percentages each year. This option is particularly useful for calculating modified accelerated cost recovery system (MACRS) depreciations. The United States' Tax Reform Act of 1986 set depreciation rates for an asset based on an assumed lifetime for that asset. Since these lists of rates are important to many people, Investment Analysis provides SAS data sets for situations with yearly rates (using the “half-year convention”). Find them at SASHELP.MACRS* where * refers to the class of the property. For example, use SASHELP.MACRS15 for a fifteen-year property. (When using the MACRS with the Tax Reform Act tables, you must set the **Salvage Value** to zero.)

Suppose you want to compute the depreciation schedule for the commercial fishing boat described in the section “[Depreciation Tasks](#)” on page 2719. The boat is a ten-year property according to the Tax Reform Act of 1986.

To employ the MACRS depreciation from the Depreciation dialog box, follow these steps:

1. Select the **Depreciation Table** option within the **Depreciation Method** area and click **OK**. This opens the Depreciation Table dialog box.
2. Right-click within the **Depreciation** area (which pops up a menu) and select **Load**.
3. Enter SASHELP.MACRS10 for the **Dataset Name**. The dialog box should look like [Figure 47.11](#).

Figure 47.11 MACRS Percentages for a Ten-Year Property

Year	Rate
1	10.0000
2	18.0000
3	14.4000
4	11.5200
5	9.2200
6	7.3700
7	6.5500
8	6.5500
9	6.5600
10	6.5500
11	3.2800

Click **OK** to return to the Depreciation dialog box. Click **Create Depreciation Schedule** and the depreciation schedule fills (see [Figure 47.12](#)).

Note there are eleven entries in this depreciation schedule. This is because of the half-year convention that enables you to deduct one half of a year the first year which leaves a half year to deduct after the useful life is over.

Figure 47.12 Depreciation Table with MACRS10

The screenshot shows a 'Depreciation' dialog box with the following fields and options:

- Name:** FISHING_BOAT
- Depreciable Asset Specification:**
 - Cost: 50000
 - Year of Purchase: 2000
 - Useful Life: 10
 - Salvage Value: 0
- Depreciation Method:**
 - Straight Line (SL)
 - Sum-of-years-digits
 - Depreciation Table...
 - Declining Balance (DB)
- DB Factor:** 2 1.5 1
- Conversion to SL:** Yes No
- Create Depreciation Schedule** (button)
- Depreciation Schedule Table:**

Year	StartBookValue	Depreciation	EndBookValue
2000	50000.00	5000.00	45000.00
2001	45000.00	9000.00	36000.00
2002	36000.00	7200.00	28800.00
2003	28800.00	5760.00	23040.00
2004	23040.00	4608.00	18432.00
- Buttons:** Save Data As..., OK, Cancel, Help

Click **OK** to return to the Investment Analysis dialog box.

Bond Tasks

Suppose someone offers to sell you a 20-year utility bond that was issued six years ago. It has a \$1,000 face value and pays semi-year coupons at 2%. You can purchase it for \$780. Would you be satisfied with this bond if you expect an 8% minimum attractive rate of return (MARR)?

In the Investment Analysis dialog box, select **Investment** → **New** → **Bond** from the menu bar to open the Bond dialog box.

Specifying Bond Terms

To specify the bond, follow these steps:

1. Enter UTILITY_BOND for the **Name**.

2. Enter 1000 for the **Face Value**.
3. Enter 2 for the **Coupon Rate**. The **Coupon Payment** updates to 20.
4. Select SEMIYEAR for **Coupon Interval**.
5. Enter 28 for the **Number of Coupons**. Because 14 years remain before the bond matures, the bond still has 28 semiyear coupons to pay. The **Maturity Date** updates.

Computing the Price from Yield

Enter 8 for **Yield** within the **Valuation** area. You see the bond's value would be \$666.72 as in Figure 47.13.

Figure 47.13 Bond Value

The screenshot shows a Windows-style dialog box titled "Bond". It contains the following fields and controls:

- Name:** A text box containing "UTILITY_BOND".
- Bond Specification:** A bordered area containing:
 - Face Value:** Text box with "1000".
 - Coupon Interval:** Dropdown menu set to "SEMIYEAR".
 - Coupon Payment:** Text box with "20".
 - Number of Coupons:** Text box with "28".
 - Coupon Rate:** Text box with "2.00".
 - Maturity Date:** Text box with "01JAN2014".
- Valuation:** A bordered area containing:
 - Value:** Text box with "666.73873564".
 - Yield:** Text box with "8.00".
- Buttons:** "Analyze...", "OK", "Cancel", and "Help".

Computing the Yield from Price

Now enter 780 for **Value** within the **Valuation** area. You see the yield is only 6.5%, as in Figure 47.14. This is not acceptable if you desire an 8% MARR.

Figure 47.14 Bond Yield

The screenshot shows a 'Bond' dialog box with the following fields and controls:

- Name:** UTILITY_BOND
- Bond Specification:**
 - Face Value: 1000
 - Coupon Interval: SEMIYEAR (dropdown)
 - Coupon Payment: 20
 - Number of Coupons: 28
 - Coupon Rate: 2.00
 - Maturity Date: 01JAN2014
- Valuation:**
 - Value: 780
 - Yield: 6.51
- Buttons:** Analyze..., OK, Cancel, Help

Performing Bond Analysis

To perform bond-pricing analysis, follow these steps:

1. Click **Analyze** to open the Bond Analysis dialog box.
2. Enter 8.0 as the **Yield to Maturity**.
3. Enter 4.0 as the **+/-**.
4. Enter 0.5 as the **Increment by**.
5. Enter 780 as the **Reference Price**.
6. Click **Create Bond Valuation Summary**.

The **Bond Valuation Summary** area fills and shows you the different values for various yields as in Figure 47.15.

Creating a Price versus Yield-to-Maturity Graph

Click **Graphics** to open the Bond Price dialog box. This contains the price versus yield-to-maturity graph shown in Figure 47.16.

Figure 47.16 Bond Price Graph

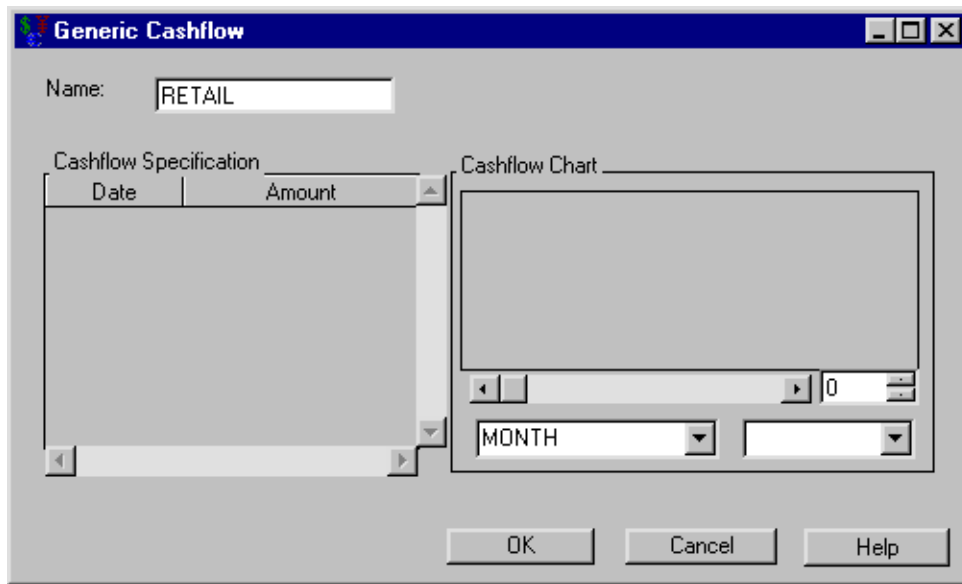

Click **Return** to return to the Bond Analysis dialog box. In the Bond Analysis dialog box, click **OK** to return to the Bond dialog box. In the Bond dialog box, click **OK** to return to the Investment Analysis dialog box.

Generic Cashflow Tasks

To specify a generic cashflow, you merely define any sequence of date-amount pairs. The flexibility of generic cashflows enables the user to represent economic alternatives or investments that do not fit into loan, savings, depreciation, or bond specifications.

In the Investment Analysis dialog box, select **Investment** → **New** → **Generic Cashflow** from the menu bar to open the **Generic Cashflow** dialog box. Enter RETAIL for the **Name** as in Figure 47.17.

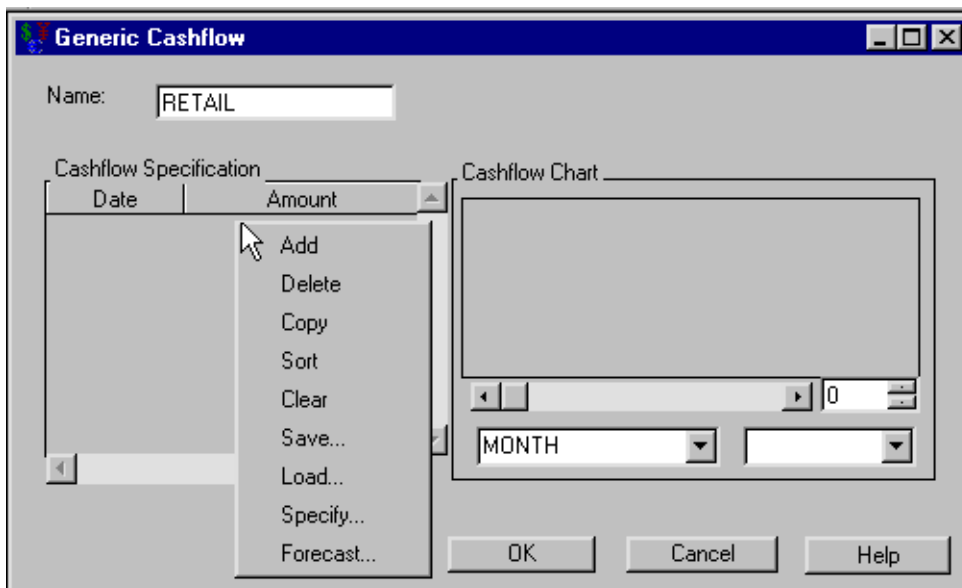

Figure 47.17 Introducing the Generic Cashflow

Right-Clicking within the Cashflow Specification Area

Right-clicking within Generic Cashflow's **Cashflow Specification** area reveals the pop-up menu displayed in [Figure 47.18](#). The menu provides many useful tools to assist you in creating these date-amount pairs.

Figure 47.18 Right-Clicking within the Cashflow Specification Area

The following sections describe how to use most of these right-click options. The **Specify** and **Forecast** menu items are described in the sections “[Including a Generated Cashflow](#)” on page 2729 and “[Including a Forecasted Cashflow](#)” on page 2731.

Adding a New Date-Amount Pair

To add a new date-amount pair manually, follow these steps:

1. Right-click in the **Cashflow Specification** area as shown in [Figure 47.18](#), and release on **Add**.
2. Enter 01JAN01 for the date.
3. Enter 100 for the amount.

Copying a Date-Amount Pair

To copy a selected date-amount pair, follow these steps:

1. Select the pair you just created.
2. Right-click in the **Cashflow Specification** area as shown in [Figure 47.18](#), but this time release on **Copy**.

Sorting All of the Date-Amount Pairs

Change the second date to 01JAN00. Now the dates are unsorted. Right-click in the **Cashflow Specification** area as shown in [Figure 47.18](#), and release on **Sort**.

Deleting a Date-Amount Pair

To delete a selected date-amount pair, follow these steps:

1. Select a date-amount pair.
2. Right-click in the **Cashflow Specification** area as shown in [Figure 47.18](#), and release on **Delete**.

Clearing All of the Date-Amount Pairs

To clear all date-amount pairs, right-click in the **Cashflow Specification** area as shown in [Figure 47.18](#), and release on **Clear**.

Loading Date-Amount Pairs from a Data Set

To load date-amount pairs from a SAS data set into the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area, and release on **Load**. This opens the Load Dataset dialog box.
2. Enter SASHELP.RETAIL for **Dataset Name**.

3. Click **OK** to return to the Generic Cashflow dialog box.

If there is a **Date** variable in the SAS data set, Investment Analysis loads it into the list. If there is no date-time-formatted variable, it loads the first available date or date-time-formatted variable. Investment Analysis then searches the SAS data set for an **Amount** variable to use. If none exists, it takes the first numeric variable that is not used by the **Date** variable.

Saving Date-Amount Pairs to a Data Set

To save date-amount pairs from the **Cashflow Specification** area to a SAS data set, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Save**. This opens the Save Dataset dialog box.
2. Enter the name of the SAS data set for **Dataset Name**.
3. Click **OK** to return to the Generic Cashflow dialog box.

Including a Generated Cashflow

To generate date-amount pairs for the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Specify**. This opens the Flow Specification dialog box.
2. Select YEAR for the **Time Interval**.
3. Enter today's date for the **Starting Date**.
4. Enter 10 for the **Number of Periods**. The **Ending Date** updates.
5. Enter 100 for the level. You can visualize the specification in the Cashflow Chart area (see [Figure 47.19](#)).
6. Click **Add** to add the specified cashflow to the list in the Generic Cashflow dialog box. Clicking **Add** also returns you to the Generic Cashflow dialog box.

Figure 47.19 Uniform Cashflow Specification

Clicking **Subtract** subtracts the current cashflow from the Generic Cashflow dialog box, and it returns you to the Generic Cashflow dialog box.

You can generate arithmetic and geometric specifications by clicking them within the **Series Flow Type** area. However, you must enter a value for the **Gradient**. In both cases the **Level** value is the value of the list at the **Starting Date**. With an arithmetic flow type, entries increase by the value **Gradient** for each **Time Interval**. With a geometric flow type, entries increase by the factor **Gradient** for each **Time Interval**. Figure 47.20 displays an arithmetic cashflow with a **Level** of 100 and a **Gradient** of 12.

Figure 47.20 Arithmetic Cashflow Specification

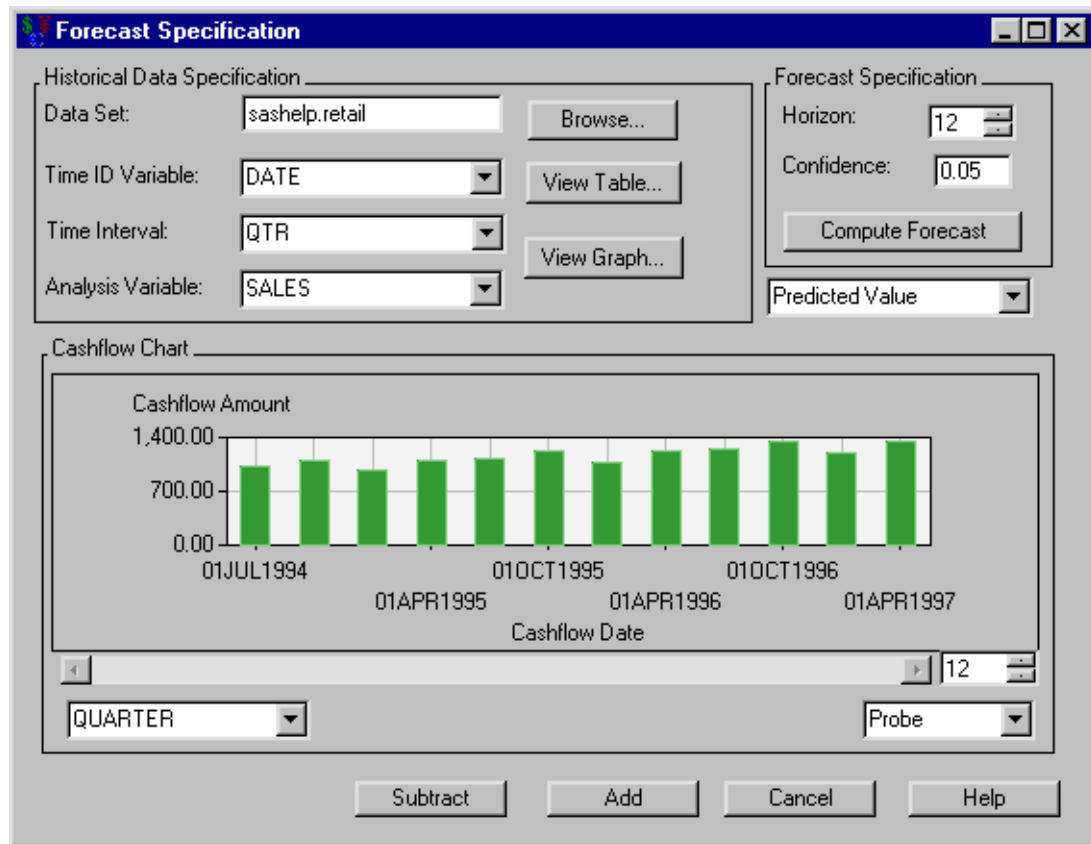

Including a Forecasted Cashflow

To generate date-amount pairs for the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Forecast** to open the **Forecast Specification** dialog box.
2. Enter sashelp.retail as the **Data Set**.
3. Select SALES for the **Analysis Variable**.
4. Click **Compute Forecast** to generate the forecast. You can visualize the forecast in the Cashflow Chart area (see Figure 47.21).
5. Click **Add** to add the forecast to the list in the Generic Cashflow dialog box. Clicking **Add** also returns you to the Generic Cashflow dialog box.

Figure 47.21 Cashflow Forecast

Clicking **Subtract** subtracts the current forecast from the Generic Cashflow dialog box, and it returns you to the Generic Cashflow dialog box.

To review the values from the SAS data set you forecast, click **View Table** or **View Graph**.

You can adjust the following values for the SAS data set you forecast: **Time ID Variable**, **Time Interval**, and **Analysis Variable**.

You can adjust the following values for the forecast: the **Horizon**, the **Confidence**, and choice of predicted value, lower confidence limit, and upper confidence limit.

Using the Cashflow Chart

Three dialog boxes contain the Cashflow Chart to aide in your visualization of cashflows: Generic Cashflow, Flow Specification, and Forecast Specification. Within this chart, you possess the following tools:

You can click on a bar in the plot and view its **Cashflow Date** and **Cashflow Amount**.

You can change the aggregation period of the view with the box in the lower-left corner of the Cashflow Chart. You can take the quarterly sales figures from the previous example, select **YEAR** as the value for this box, and view the annual sales figures. You can change the number in the

box to the right of the horizontal scroll bar to alter the number of entries you want to view. The number in that box must be no greater than the number of entries in the cashflow list. Lessening this number has the effect of zooming in upon a portion of the cashflow. When the number is less than the number of entries in the cashflow list, you can use the scroll bar at the bottom of the chart to scroll through the chart.

Dialog Box Guide

Loan

Selecting **Investment** → **New** → **Loan** from the Investment Analysis dialog box's menu bar opens the Loan dialog box displayed in [Figure 47.22](#).

Figure 47.22 Loan Dialog Box

The following items are displayed:

Name holds the name you assign to the loan. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

The **Loan Specification** area gives access to the values that define the loan.

Loan Amount holds the borrowed amount.

Periodic Payment holds the value of the periodic payments.

Number of Payments holds the number of payments in loan terms.

Payment Interval holds the frequency of the Periodic Payment.

Compounding Interval holds the compounding frequency.

Initial Rate holds the interest rate (a nominal percentage between 0 and 120) you pay on the loan.

Start Date holds the SAS date when the loan is initialized. The first payment is due one Payment Interval after this time.

Initialization opens the [Loan Initialization Options](#) dialog box where you can define initialization costs and down-payments relevant to the loan.

Prepayments opens the [Loan Prepayments](#) dialog box where you can specify the SAS dates and amounts of any prepayments.

Balloon Payments opens the [Balloon Payments](#) dialog box where you can specify the SAS dates and amounts of any balloon payments.

Rate Adjustments opens the [Rate Adjustment Terms](#) dialog box where you can specify terms for a variable-rate loan.

Rounding Off opens the [Rounding Off](#) dialog box where you can select the number of decimal places for calculations.

Create Amortization Schedule becomes available when you adequately define the loan within the **Loan Specification** area. Clicking it generates the amortization schedule.

Amortization Schedule fills when you click **Create Amortization Schedule**. The schedule contains a row for the loan's start-date and each payment-date with information about the following:

Date is a SAS date, either the loan's start-date or a payment-date.

Beginning Principal Amount is the balance at that date.

Periodic Payment Amount is the expected payment at that date.

Interest Payment is zero for the loan's start-date; otherwise it holds the interest since the previous date.

Principal Repayment is the amount of the payment that went toward the principal.

Ending Principal is the balance at the end of the payment interval.

Print becomes available when you generate the amortization schedule. Clicking it sends the contents of the amortization schedule to the SAS session print device.

Save Data As becomes available when you generate the amortization schedule. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the amortization table (or portions thereof) as a SAS Dataset.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new loan specification, clicking **OK** appends the current loan specification to the portfolio. If this is an existing loan specification, clicking **OK** returns the altered loan specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new loan specification, clicking **Cancel** discards the current loan specification. If this is an existing loan specification, clicking **Cancel** discards the current changes.

Loan Initialization Options

Clicking **Initialization** in the Loan dialog box opens the Loan Initialization Options dialog box displayed in Figure 47.23.

Figure 47.23 Loan Initialization Options Dialog Box

The following items are displayed:

The **Price, Loan Amount and Downpayment** area contains the following information:

Purchase Price holds the actual price of the asset. This value equals the loan amount plus the downpayment.

Loan Amount holds the loan amount.

% of Price (to the right of **Loan Amount**) updates when you enter the **Purchase Price** and either the **Loan Amount** or **Downpayment**. This holds the percentage of the **Purchase Price** that comprises the **Loan Amount**. Setting the percentage manually causes the **Loan Amount** and **Downpayment** to update.

Downpayment holds any downpayment paid for the asset.

% of Price (to the right of **Downpayment**) updates when you enter the **Purchase Price** and either the **Loan Amount** or **Downpayment**. This holds the percentage of the **Purchase Price** that comprises the **Downpayment**. Setting the percentage manually causes the **Loan Amount** and **Downpayment** to update.

Initialization Costs and Discount Points area

Loan Amount holds a copy of the **Loan Amount** above.

Initialization Costs holds the value of any initialization costs.

% of Amount (to the right of **Initialization Costs**) updates when you enter the **Purchase Price** and either the **Initialization Costs** or **Discount Points**. This holds the percentage of the **Loan Amount** that comprises the **Initialization Costs**. Setting the percentage manually causes the **Initialization Costs** to update.

Discount Points holds the value of any discount points.

% of Amount (to the right of **Discount Points**) updates when you enter the **Purchase Price** and either the **Initialization Costs** or **Discount Points**. This holds the percentage of the **Loan Amount** that comprises the **Discount Points**. Setting the percentage manually causes the **Discount Points** to update.

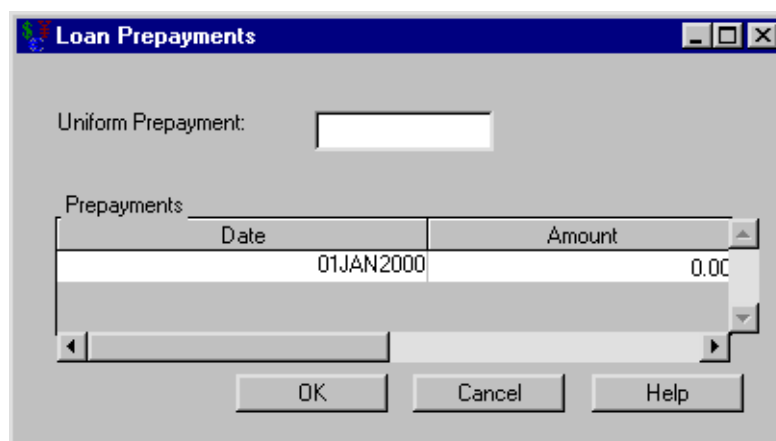

OK returns you to the **Loan** dialog box, saving the information that is entered.

Cancel returns you to the **Loan** dialog box, discarding any changes made since you opened the dialog box.

Loan Prepayments

Clicking **Prepayments** in the **Loan** dialog box opens the **Loan Prepayments** dialog box displayed in [Figure 47.24](#).

Figure 47.24 Loan Prepayments Dialog Box

The following items are displayed:

Uniform Prepayment holds the value of a regular prepayment concurrent to the usual periodic payment.

Prepayments holds a list of date-amount pairs to accommodate any prepayments. [Right-clicking](#) within the **Prepayments** area reveals many helpful tools for managing date-amount pairs.

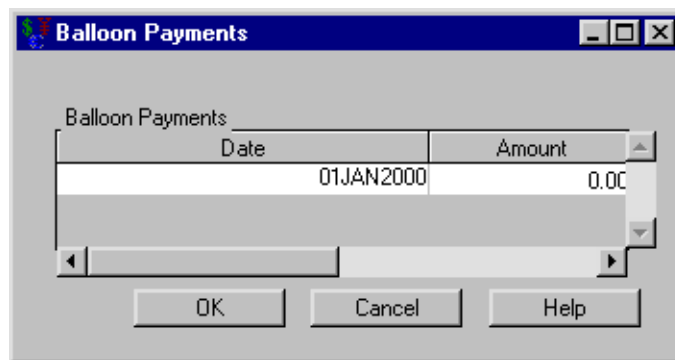

OK returns you to the [Loan](#) dialog box, storing the information entered on the prepayments.

Cancel returns you to the [Loan](#) dialog box, discarding any prepayments entered since you opened the dialog box.

Balloon Payments

Clicking **Balloon Payments** in the Loan dialog box opens the Balloon Payments dialog box displayed in [Figure 47.25](#).

Figure 47.25 Balloon Payments Dialog Box

The following items are displayed:

Balloon Payments holds a list of date-amount pairs to accommodate any balloon payments. [Right-clicking](#) within the **Balloon Payments** area reveals many helpful tools for managing date-amount pairs.

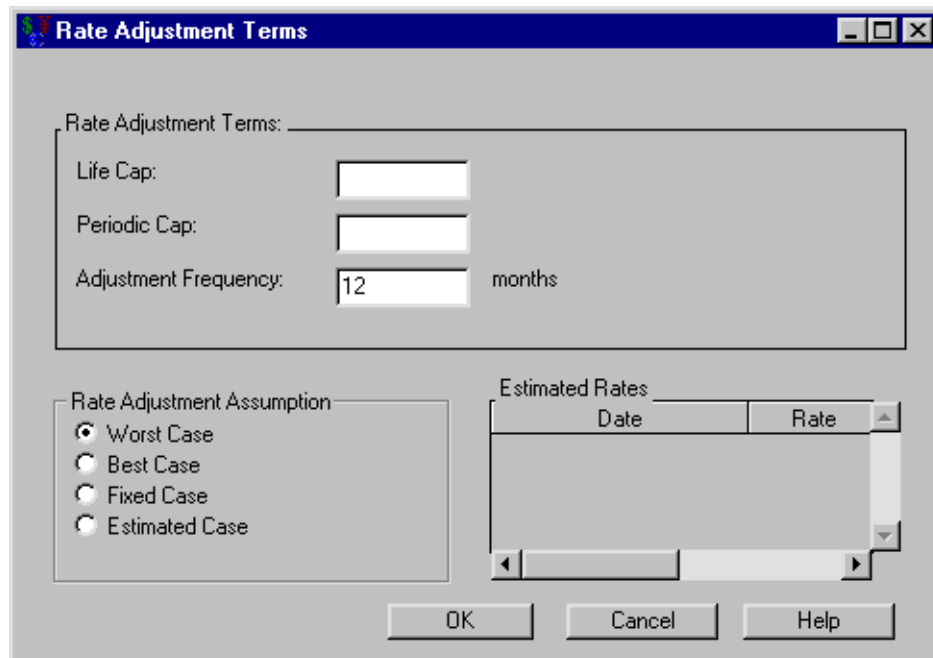

OK returns you to the [Loan](#) dialog box, storing the information entered on the balloon payments.

Cancel returns you to the [Loan](#) dialog box, discarding any balloon payments entered since you opened the dialog box.

Rate Adjustment Terms

Clicking **Rate Adjustments** in the Loan dialog box opens the Rate Adjustment Terms dialog box displayed in [Figure 47.26](#).

Figure 47.26 Rate Adjustment Terms Dialog Box

The following items are displayed:

The **Rate Adjustment Terms** area

Life Cap holds the maximum deviation from the **Initial Rate** allowed over the life of the loan.

Periodic Cap holds the maximum adjustment allowed per adjustment.

Adjustment Frequency holds how often (in months) the lender can adjust the interest rate.

The **Rate Adjustment Assumption** determines the scenario the adjustments will take.

Worst Case uses information from the **Rate Adjustment Terms** area to forecast a worst-case scenario.

Best Case uses information from the **Rate Adjustment Terms** area to forecast a best-case scenario.

Fixed Case specifies a fixed-rate loan.

Estimated Case uses information from the **Rate Adjustment Terms** and **Estimated Rate** area to forecast a best-case scenario.

Estimated Rates holds a list of date-rate pairs, where each date is a SAS date and the rate is a nominal percentage between 0 and 120. The **Estimated Case** assumption uses these rates for its calculations. [Right-clicking](#) within the **Estimated Rates** area reveals many helpful tools for managing date-rate pairs.

OK returns you to the [Loan](#) dialog box, taking rate adjustment information into account.

Cancel returns you to the [Loan](#) dialog box, discarding any rate adjustment information provided since opening the dialog box.

Rounding Off

Clicking **Rounding Off** in the Loan dialog box opens the Rounding Off dialog box displayed in [Figure 47.27](#).

Figure 47.27 Rounding Off Dialog Box

The following items are displayed:

Decimal Places fixes the number of decimal places your results will display.

OK returns you to the [Loan](#) dialog box. Numeric values will then be represented with the number of decimals specified in **Decimal Places**.

Cancel returns you to the [Loan](#) dialog box. Numeric values will be represented with the number of decimals specified prior to opening this dialog box.

Savings

Selecting **Investment** → **New** → **Savings** from the Investment Analysis dialog box's menu bar opens the Savings dialog box displayed in [Figure 47.28](#).

Figure 47.28 Savings Dialog Box

The following items are displayed:

Name holds the name you assign to the savings. You can set the name here or within the **Portfolio** area of the **Investment Analysis** dialog box. This must be a valid SAS name.

The **Savings Specification** area

Periodic Deposit holds the value of your regular deposits.

Number of Deposits holds the number of deposits into the account.

Initial Rate holds the interest rate (a nominal percentage between 0 and 120) the savings account earns.

Start Date holds the SAS date when deposits begin.

Deposit Interval holds the frequency of your **Periodic Deposit**.

Compounding Interval holds how often the interest compounds.

Create Account Summary becomes available when you adequately define the savings within the **Savings Specification** area. Clicking it generates the account summary.

Account Summary fills when you click **Create Account Summary**. The schedule contains a row for each deposit-date with information about the following:

Date is the SAS date of a deposit.

Starting Balance is the balance at that date.

Deposits is the deposit at that date.

Interest Earned is the interest earned since the previous date.

Ending Balance is the balance after the payment.

Print becomes available when you generate an account summary. Clicking it sends the contents of the account summary to the SAS session print device.

Save Data As becomes available when you generate an account summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the account summary (or portions thereof) as a SAS Dataset.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new savings, clicking **OK** appends the current savings specification to the portfolio. If this is an existing savings specification, clicking **OK** returns the altered savings to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new savings, clicking **Cancel** discards the current savings specification. If this is an existing savings, clicking **Cancel** discards the current changes.

Depreciation

Selecting **Investment** → **New** → **Depreciation** from the Investment Analysis dialog box's menu bar opens the Depreciation dialog box displayed in [Figure 47.29](#).

Figure 47.29 Depreciation Dialog Box

The screenshot shows the 'Depreciation' dialog box with the following details:

- Name:** untitled_depreciation
- Depreciable Asset Specification:**
 - Cost: []
 - Year of Purchase: 2000
 - Useful Life: []
 - Salvage Value: 0
- Depreciation Method:**
 - Straight Line (SL)
 - Sum-of-years-digits
 - Depreciation Table...
 - Declining Balance (DB)
- DB Factor:** 2 1.5 1
- Conversion to SL:** Yes No
- Buttons:** Create Depreciation Schedule, Save Data As..., OK, Cancel, Help
- Depreciation Schedule:** []

The following items are displayed:

Name holds the name you assign to the depreciation. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

Depreciable Asset Specification

Cost holds the asset's original cost.

Year of Purchase holds the asset's year of purchase.

Useful Life holds the asset's useful life (in years).

Salvage Value holds the asset's value at the end of its **Useful Life**.

The **Depreciation Method** area holds the depreciation methods available:

- Straight Line
- Sum-of-years Digits
- [Depreciation Table](#)
- Declining Balance
 - DB Factor: choice of 2, 1.5, or 1
 - Conversion to SL: choice of Yes or No

Create Depreciation Schedule becomes available when you adequately define the depreciation within the **Depreciation Asset Specification** area. Clicking the **Create Depreciation Schedule** button then fills the **Depreciation Schedule** area.

Depreciation Schedule fills when you click **Create Depreciation Schedule**. The schedule contains a row for each year. Each row holds:

Year is a year.

Start Book Value is the starting book value for that year.

Depreciation is the depreciation value for that year.

End Book Value is the ending book value for that year.

Print becomes available when you generate the depreciation schedule. Clicking it sends the contents of the depreciation schedule to the SAS session print device.

Save Data As becomes available when you generate the depreciation schedule. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the depreciation table (or portions thereof) as a SAS Dataset.

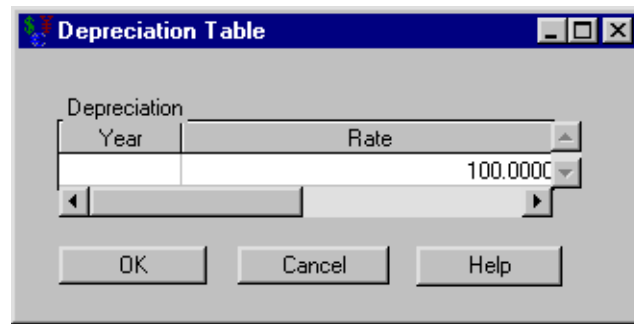

OK returns you to the [Investment Analysis](#) dialog box. If this is a new depreciation specification, clicking **OK** appends the current depreciation specification to the portfolio. If this is an existing depreciation specification, clicking **OK** returns the altered depreciation specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new depreciation specification, clicking **Cancel** discards the current depreciation specification. If this is an existing depreciation specification, clicking **Cancel** discards the current changes.

Depreciation Table

Clicking **Depreciation Table** from **Depreciation Method** area of the Depreciation dialog box opens the Depreciation Table dialog box displayed in [Figure 47.30](#).

Figure 47.30 Depreciation Table Dialog Box

The following items are displayed:

The **Depreciation** area holds a list of year-rate pairs where the rate is an annual depreciation rate (a percentage between 0% and 100%). **Right-clicking** within the **Depreciation** area reveals many helpful tools for managing year-rate pairs.

OK returns you to the [Depreciation](#) dialog box with the current list of depreciation rates from the **Depreciation** area.

Cancel returns you to the [Depreciation](#) dialog box, discarding any editions to the **Depreciation** area since you opened the dialog box.

Bond

Selecting **Investment** → **New** → **Bond** from the Investment Analysis dialog box's menu bar opens the Bond dialog box displayed in [Figure 47.31](#).

Figure 47.31 Bond

The screenshot shows a dialog box titled "Bond" with the following fields and controls:

- Name:** A text input field containing "untitled_bond".
- Bond Specification:** A group box containing:
 - Face Value:** An empty text input field.
 - Coupon Interval:** A dropdown menu currently showing "SEMIYEAR".
 - Coupon Payment:** An empty text input field.
 - Number of Coupons:** An empty text input field.
 - Coupon Rate:** An empty text input field.
 - Maturity Date:** An empty text input field.
- Valuation:** A group box containing:
 - Value:** An empty text input field.
 - Yield:** An empty text input field.
- Buttons:** "Analyze...", "OK", "Cancel", and "Help".

The following items are displayed:

Name holds the name you assign to the bond. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

Bond Specification

Face Value holds the bond's value at maturity.

Coupon Payment holds the amount of money you receive periodically as the bond matures.

Coupon Rate holds the rate (a nominal percentage between 0% and 120%) of the **Face Value** that defines the **Coupon Payment**.

Coupon Interval holds how often the bond pays its coupons.

Number of Coupons holds the number of coupons before maturity.

Maturity Date holds the SAS date when you can redeem the bond for its **Face Value**.

The **Valuation** area becomes available when you adequately define the bond within the **Bond Specification** area. Entering either the **Value** or the **Yield** causes the calculation of the other. If you respecify the bond after performing a calculation here, you must reenter the **Value** or **Yield** value to update the calculation.

Value holds the bond's value if expecting the specified **Yield**.

Yield holds the bond's yield if the bond is valued at the amount of **Value**.

You must specify the bond before analyzing it. After you have specified the bond, clicking **Analyze** opens the [Bond Analysis](#) dialog box where you can compare various values and yields.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new bond specification, clicking **OK** appends the current bond specification to the portfolio. If this is an existing bond specification, clicking **OK** returns the altered bond specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new bond specification, clicking **Cancel** discards the current bond specification. If this is an existing bond specification, clicking **Cancel** discards the current changes.

Bond Analysis

Clicking **Analyze** from the Bond dialog box opens the Bond Analysis dialog box displayed in [Figure 47.32](#).

Figure 47.32 Bond Analysis

The following items are displayed:

Analysis Specifications

Yield-to-maturity holds the percentage yield upon which to center the analysis.

+/- holds the maximum deviation percentage to consider from the **Yield-to-maturity**.

Increment by holds the percentage increment by which the analysis is calculated.

Reference Price holds the reference price.

Analysis Dates holds a list of SAS dates for which you perform the bond analysis.

You must specify the analysis before valuing the bond for the various yields. After you adequately specify the analysis, click **Create Bond Valuation Summary** to generate the bond valuation summary.

Bond Valuation Summary fills when you click **Create Bond Valuation Summary**. The schedule contains a row for each rate with information concerning the following:

Date is the SAS date when the **Value** gives the particular **Yield**.

Yield is the percent yield that corresponds to the **Value** at the given **Date**.

Value is the value of the bond at **Date** for the given **Yield**.

Percent Change is the percent change if the **Reference Price** is specified.

Duration is the duration.

Convexity is the convexity.

Graphics opens the [Bond Price](#) graph that represents the price versus yield-to-maturity.

Print becomes available when you generate the **Bond Valuation Summary**. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you fill the **Bond Valuation Summary** area. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the valuation summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Bond](#) dialog box.

Bond Price

Clicking **Graphics** from the Bond dialog box opens the Bond Price dialog box displayed in [Figure 47.33](#).

Figure 47.33 Bond Price Graph

It possesses the following item:

Return takes you back to the [Bond Analysis](#) dialog box.

Generic Cashflow

Selecting **Investment** → **New** → **Generic Cashflow** from the Investment Analysis dialog box's menu bar opens the Generic Cashflow dialog box displayed in [Figure 47.34](#).

Figure 47.34 Generic Cashflow

The Generic Cashflow dialog box contains the following elements:

- Name:** untitled_cashflow
- Cashflow Specification:** A table with columns for Date and Amount.
- Cashflow Chart:** A chart area with a numerical input field set to 0 and a dropdown menu currently showing MONTH.
- Buttons:** OK, Cancel, and Help.

The following items are displayed:

Name holds the name you assign to the generic cashflow. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

Cashflow Specification holds date-amount pairs that correspond to deposits and withdrawals (or benefits and costs) for the cashflow. Each date is a SAS date. [Right-clicking](#) within the **Cashflow Specification** area reveals many helpful tools for managing date-amount pairs.

The **Cashflow Chart** fills with a graph representing the cashflow when the **Cashflow Specification** area is nonempty. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency for drilling purposes.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new generic cashflow specification, clicking **OK** appends the current cashflow specification to the portfolio. If this is an existing cashflow specification, clicking **OK** returns the altered cashflow specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new cashflow specification, clicking **Cancel** discards the current cashflow specification. If this is an existing cashflow specification, clicking **Cancel** discards the current changes.

Right-Clicking within Generic Cashflow's Cashflow Specification Area

Right-click within the **Cashflow Specification** area of the Generic Cashflow dialog box pops up the menu displayed in [Figure 47.35](#).

Figure 47.35 Right-Clicking

Add creates a blank pair.

Delete removes the currently highlighted pair.

Copy duplicates the currently selected pair.

Sort arranges the entered pairs in chronological order.

Clear empties the area of all pairs.

Save opens the [Save Dataset](#) dialog box where you can save the entered pairs as a SAS Dataset for later use.

Load opens the [Load Dataset](#) dialog box where you select a SAS Dataset to populate the area.

Specify opens the [Flow Specification](#) dialog box where you can generate date-rate pairs to include in your cashflow.

Forecast opens the [Forecast Specification](#) dialog box where you can generate the forecast of a SAS data set to include in your cashflow.

If you want to perform one of these actions on a collection of pairs, you must select a collection of pairs before right-clicking. To select an adjacent list of pairs, do the following: click the first pair, hold down the SHIFT key, and click the final pair. After the list of pairs is selected, you can release the SHIFT key.

Flow Specification

Figure 47.36 Flow Specification

The following items are displayed:

Flow Time Specification

Time Interval holds the uniform frequency of the entries.

You can set the **Starting Date** when you set the **Time Interval**. It holds the SAS date the entries will start.

You can set the **Ending Date** when you set the **Time Interval**. It holds the SAS date the entries will end.

Number of Periods holds the number of entries.

Flow Value Specification

Series Flow Type describes the movement the entries can assume:

- **Uniform** assumes all entries are equal.
- **Arithmetic** assumes the entries begin at **Level** and increase by the value of **Gradient** per entry.
- **Geometric** assumes the entries begin at **Level** and increase by a factor of **Gradient** per entry.

Level holds the starting amount for all flow types.

You can set the **Gradient** when you select either **Arithmetic** or **Geometric** series flow type. It holds the arithmetic and geometric gradients, respectively, for the **Arithmetic** and **Geometric** flow types.

When the cashflow entries are adequately defined, the **Cashflow Chart** fills with a graph displaying the dates and values of the entries. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency.

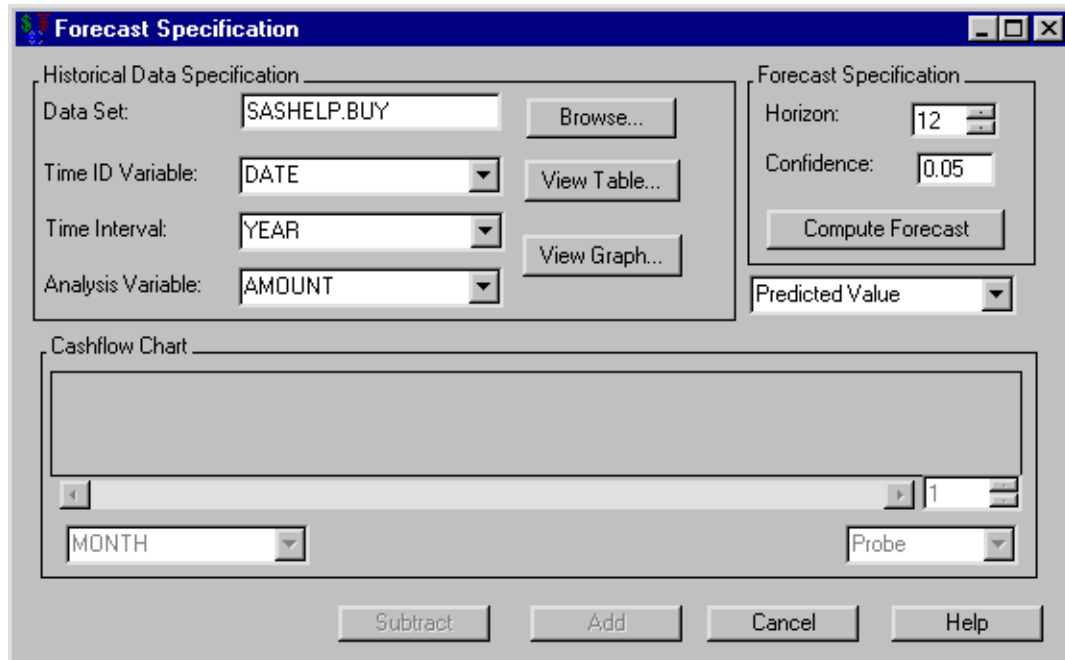

Subtract becomes available when the collection of entries is adequately specified. Clicking **Subtract** then returns you to the [Generic Cashflow](#) dialog box and subtracts the entries from the current cashflow.

Add becomes available when the collection of entries is adequately specified. Clicking **Add** then returns you to the [Generic Cashflow](#) dialog box and adds the entries to the current cashflow.

Cancel returns you to [Generic Cashflow](#) dialog box without changing the cashflow.

Forecast Specification

Figure 47.37 Forecast Specification

The following items are displayed:

Historical Data Specification

Data Set holds the name of the SAS data set to forecast.

Browse opens the standard SAS **Open** dialog box to help select a SAS data set to forecast.

Time ID Variable holds the time ID variable to forecast over.

Time Interval fixes the time interval for the **Time ID Variable**.

Analysis Variable holds the data variable upon which to forecast.

View Table opens a table that displays the contents of the specified SAS data set.

View Graph opens the Time Series Viewer that graphically displays the contents of the specified SAS data set.

Forecast Specification

Horizon holds the number of periods into the future you want to forecast.

Confidence holds the confidence limit for applicable forecasts.

Compute Forecast fills the **Cashflow Chart** with the forecast.

The box below **Forecast Specification** holds the type of forecast you want to generate:

- Predicted Value
- Lower Confidence Limit
- Upper Confidence Limit

The **Cashflow Chart** fills when you click **Compute Forecast**. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency.

Subtract becomes available when the collection of entries is adequately specified. Clicking **Subtract** then returns you to the [Generic Cashflow](#) dialog box subtracting the forecast from the current cashflow.

Add becomes available when the collection of entries is adequately specified. Clicking **Add** then returns you to the [Generic Cashflow](#) adding the forecast to the current cashflow.

Cancel returns to [Generic Cashflow](#) dialog box without changing the cashflow.

Chapter 48

Computations

Contents

The Compute Menu	2753
Tasks	2754
Taxing a Cashflow	2754
Converting Currency	2756
Deflating Cashflows	2758
Dialog Box Guide	2760
After Tax Cashflow Calculation	2760
Currency Conversion	2761
Constant Dollar Calculation	2763

The Compute Menu

Figure 48.1 shows the **Compute** menu.

Figure 48.1 The Compute Menu

The **Compute** menu offers the following options that apply to generic cashflows.

After Tax Cashflow opens the [After Tax Cashflow Calculation](#) dialog box. Computing an after tax cashflow is useful when taxes affect investment alternatives differently. Comparing after tax cashflows provides a more accurate determination of the cashflows' profitabilities. You can set default values for income tax rates by selecting **Tools** → **Define Rate** → **Income Tax Rate** from the Investment Analysis dialog box. This opens the [Income Tax Specification](#) dialog box where you can enter the tax rates.

Currency Conversion opens the **Currency Conversion** dialog box. Currency conversion is necessary when investments are in different currencies. For data concerning currency conversion rates, see <http://dsbb.imf.org/>, the International Monetary Fund’s Dissemination Standards Bulletin Board.

Constant Dollars opens the **Constant Dollar Calculation** dialog box. A constant dollar (inflation adjusted monetary value) calculation takes cashflow and inflation information and discounts the cashflow to a level where the buying power of the monetary unit is constant over time. Groups quantify inflation (in the form of price indices and inflation rates) for countries and industries by averaging the growth of prices for various products and sectors of the economy. For data concerning price indices, see the United States Department of Labor at <http://www.dol.gov/> and the International Monetary Fund’s Dissemination Standards Bulletin Board at <http://dsbb.imf.org/>. You can set default values for inflation rates by clicking **Tools** → **Define Rate** → **Inflation** from the Investment Analysis dialog box. This opens the **Inflation Specification** dialog box where you can enter the inflation rates.

Tasks

The next few sections show how to perform computations for the following situation. Suppose you buy a \$10,000 certificate of deposit that pays 12% interest a year for five years. Your earnings are taxed at a rate of 30% federally and 7% locally. Also, you want to transfer all the money to an account in England. British pounds convert to American dollars at an exchange rate of \$1.00 to £0.60. The inflation rate in England is 3%. The instructions in this example assume familiarity with the following:

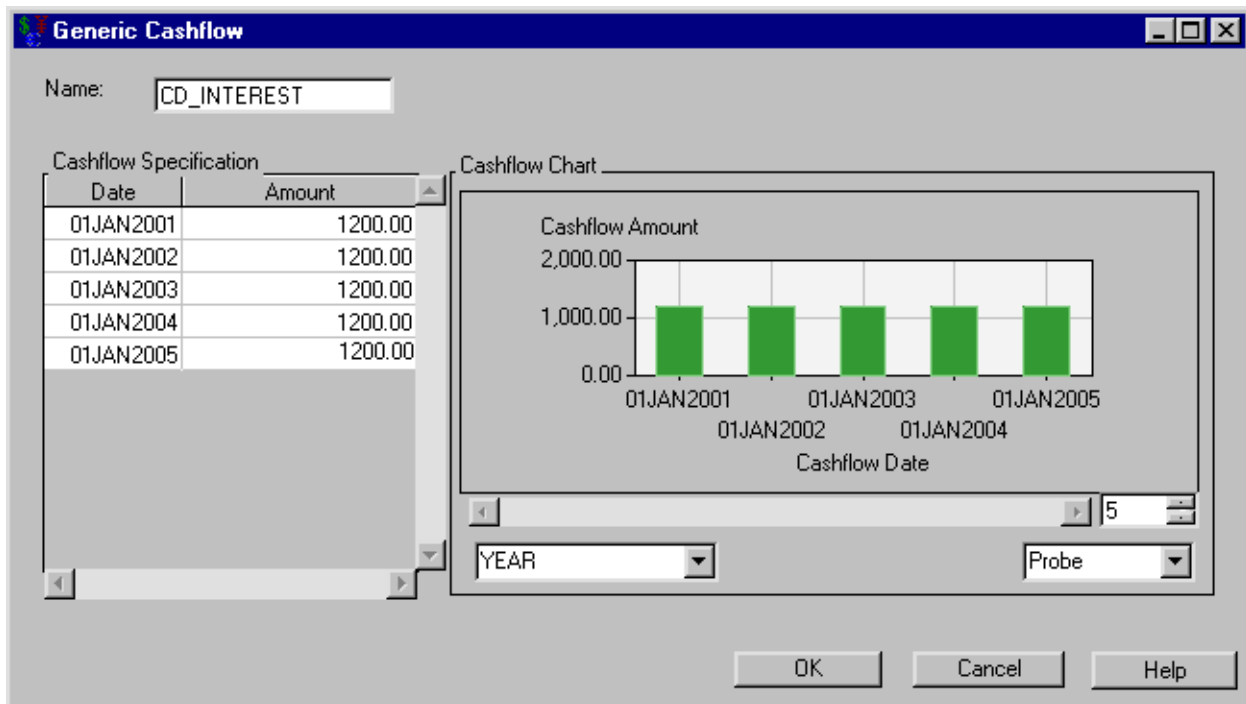

- The right-clicking options of the **Cashflow Specification** area in the Generic Cashflow dialog box (described in the section “**Right-Clicking within Generic Cashflow’s Cashflow Specification Area**” on page 2748.)
- The **Save Data As** button located in many dialog boxes (described in the section “**Saving Output to SAS Data Sets**” on page 2781.)

Taxing a Cashflow

Consider the example described in the section “**The Compute Menu**” on page 2753. To create the earnings, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to create a generic cashflow.
2. Enter CD_INTEREST for the **Name**.
3. Enter 1200 for each of the five years starting one year from today as displayed in [Figure 48.2](#).
4. Click **OK** to return to the Investment Analysis dialog box.

Figure 48.2 Computing the Interest on the CD

To compute the tax on the earnings, follow these steps:

1. Select CD_INTEREST from the **Portfolio** area.
2. Select **Compute** → **After Tax Cashflow** from the pull-down menu.
3. Enter 30 for **Federal Tax**.
4. Enter 7 for **Local Tax**. Note that **Combined Tax** updates.
5. Click **Create After Tax Cashflow**. The **After Tax Cashflow** area fills, as displayed in [Figure 48.3](#).

Figure 48.3 Computing the Interest After Taxes

After Tax Cashflow Calculation

Name:

Local Tax:

Combined Tax:

After Tax Cashflow

Date	Amount
01JAN2001	781.20
01JAN2002	781.20
01JAN2003	781.20
01JAN2004	781.20
01JAN2005	781.20

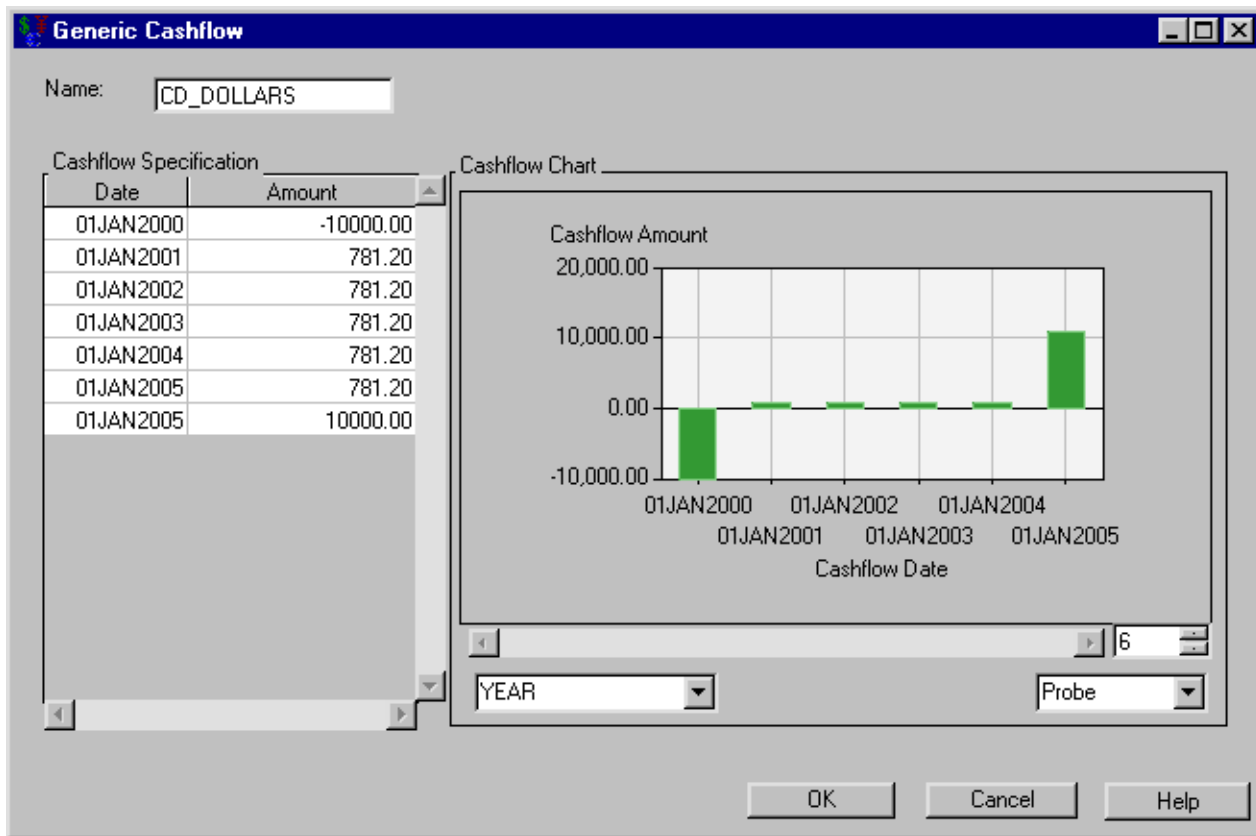

Save the taxed earnings to a SAS data set named WORK.CD_AFTERTAX. Click **Return** to return to the Investment Analysis dialog box.

Converting Currency

Consider the example described in the section “[The Compute Menu](#)” on page 2753. To create the cashflow to convert, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to open a new generic cashflow.
2. Enter CD_DOLLARS for the **Name**.
3. Load WORK.CD_AFTERTAX into its **Cashflow Specification**.
4. Add –10,000 for today and +10,000 for five years from today to the cashflow as displayed in [Figure 48.4](#).
5. Sort the transactions by date to aid your reading.
6. Click **OK** to return to the Investment Analysis dialog box.

Figure 48.4 The CD in Dollars

To convert from British pounds to American dollars, follow these steps:

1. Select CD_DOLLARS from the portfolio.
2. Select **Compute** → **Currency Conversion** from the pull-down menu. This opens the Currency Conversion dialog box.
3. Select USD for the **From Currency**.
4. Select GBP for the **To Currency**.
5. Enter 0.60 for the **Exchange Rate**.
6. Click **Apply Currency Conversion** to fill the **Currency Conversion** area as displayed in Figure 48.5.

Figure 48.5 Converting the CD to Pounds

The screenshot shows a 'Currency Conversion' dialog box with the following fields and values:

- Name: CD_DOLLARS
- From Currency: USD
- To Currency: GBP
- Exchange Rate: 0.60

Below the input fields is a table titled 'Currency Conversion' with the following data:

Date	CD_DOLLARS	GBP
01JAN2000	-10000.00	-6000.00
01JAN2001	781.20	468.72
01JAN2002	781.20	468.72
01JAN2003	781.20	468.72
01JAN2004	781.20	468.72
01JAN2005	781.20	468.72
01JAN2005	10000.00	6000.00

Buttons at the bottom include 'Apply Currency Conversion', 'Save Data As...', 'Return', and 'Help'.

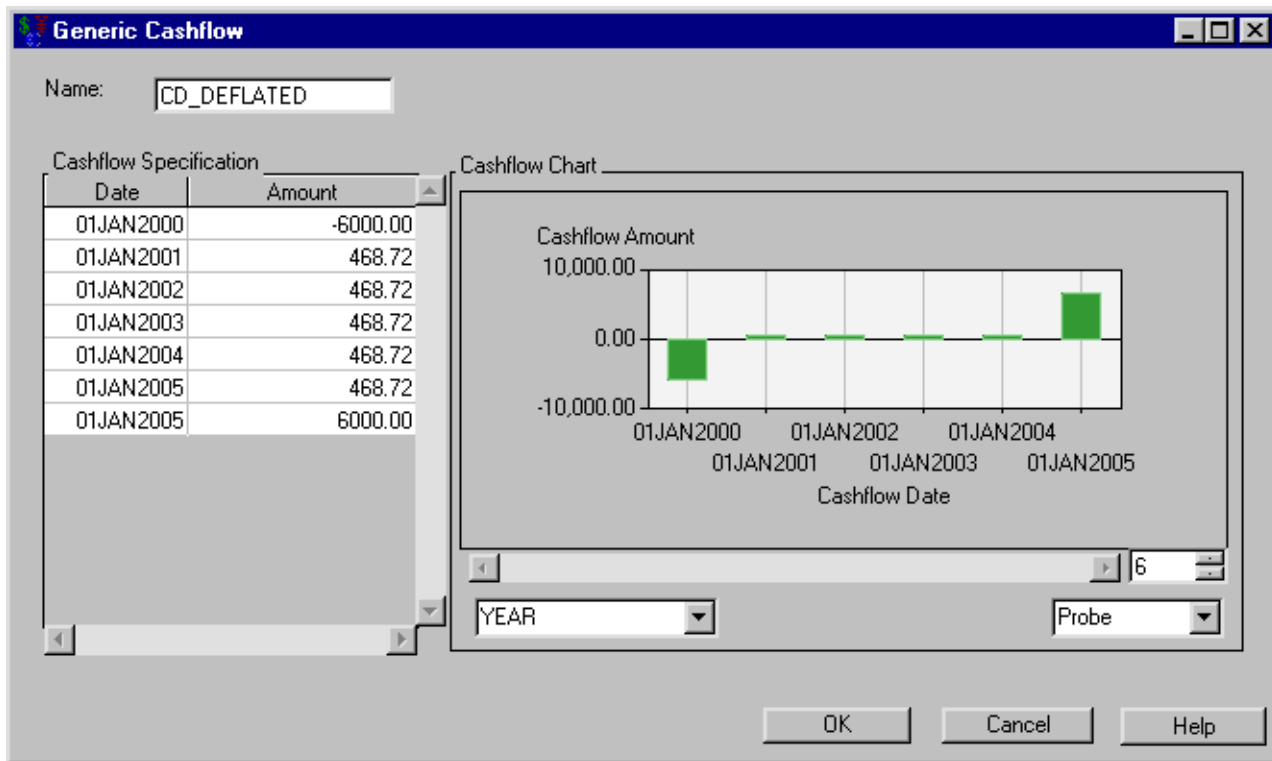

Save the converted values to a SAS data set named `WORK.CD_POUNDS`. Click **Return** to return to the Investment Analysis dialog box.

Deflating Cashflows

Consider the example described in the section “[The Compute Menu](#)” on page 2753. To create the cashflow to deflate, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to open a new generic cashflow.
2. Enter `CD_DEFLATED` for **Name**.
3. Load `WORK.CD_POUNDS` into its **Cashflow Specification** (see [Figure 48.6](#)).
4. Click **OK** to return to the Investment Analysis dialog box.

Figure 48.6 The CD before Deflation

To deflate the values, follow these steps:

1. Select CD_DEFLATED from the portfolio.
2. Select **Compute** → **Constant Dollars** from the menu. This opens the Constant Dollar Calculation dialog box.
3. Clear the **Variable Inflation List** area.
4. Enter 3 for the **Constant Inflation Rate**.
5. Click **Create Constant Dollar Equivalent** to generate a constant dollar equivalent summary (see [Figure 48.7](#)).

Figure 48.7 CD Values after Deflation

Constant Dollar Calculation

Name:

Constant Inflation Rate:

Variable Inflation List

Date	Rate

Dates

Date
01JAN2000

Constant Dollar Equivalent Summary

Date	JAN2000
01JAN2000	-6000.00
01JAN2001	455.07
01JAN2002	441.81
01JAN2003	428.95
01JAN2004	416.45
01JAN2005	404.32
01JAN2005	5175.65

You can save the deflated cashflow to a SAS data set for use in an internal rate of return analysis or breakeven analysis.

Click **Return** to return to the Investment Analysis dialog box.

Dialog Box Guide

After Tax Cashflow Calculation

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an after tax calculation, select **Compute** → **After Tax** from the Investment Analysis dialog box's menu bar. This opens the After Tax Cashflow Calculation dialog box displayed in Figure 48.8.

Figure 48.8 After Tax Cashflow Calculation Dialog Box

The following items are displayed:

Name holds the name of the investment for which you are computing the after-tax cashflow.

Federal Tax holds the federal tax rate (a percentage between 0% and 100%).

Local Tax holds the local tax rate (a percentage between 0% and 100%).

Combined Tax holds the effective tax rate from federal and local income taxes.

Create After Tax Cashflow becomes available when **Combined Tax** is not empty. Clicking **Create After Tax Cashflow** then fills the **After Tax Cashflow** area.

After Tax Cashflow fills when you click **Create After Tax Cashflow**. It holds a list of date-amount pairs where the amount is the amount retained after taxes for that date.

Print becomes available when you fill the after-tax cashflow. Clicking it sends the contents of the after tax cashflow to the SAS session print device.

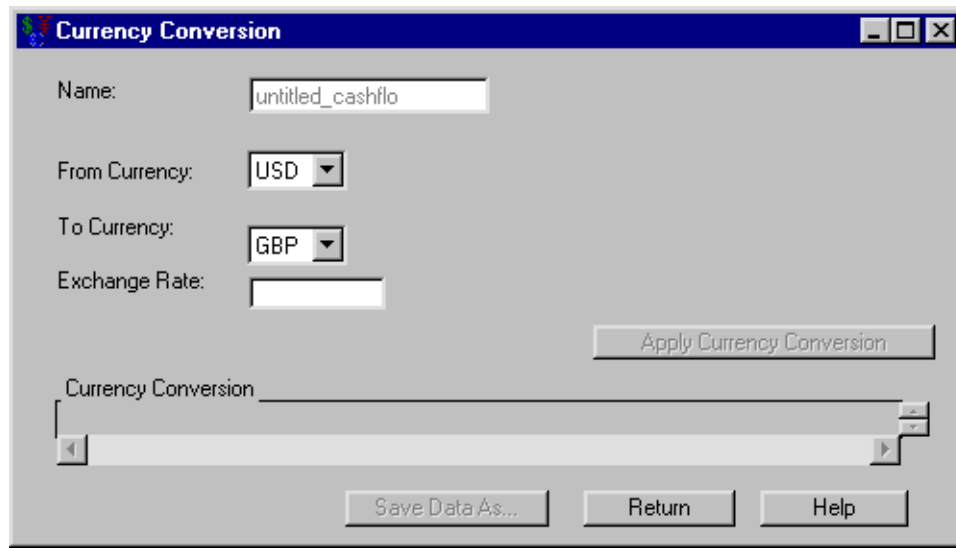

Save Data As becomes available when you fill the after tax cashflow. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the resulting cashflow (or portions thereof) as a SAS Dataset.

Return returns you to the [Investment Analysis](#) dialog box.

Currency Conversion

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a currency conversion, select **Compute** → **Currency Conversion** from the Investment Analysis dialog box's menu bar. This opens the Currency Conversion dialog box displayed in [Figure 48.9](#).

Figure 48.9 Currency Conversion Dialog Box

The following items are displayed:

Name holds the name of the investment to which you are applying the currency conversion.

From Currency holds the name of the currency the cashflow currently represents.

To Currency holds the name of the currency to which you wish to convert.

Exchange Rate holds the rate of exchange between the **From Currency** and the **To Currency**.

Apply Currency Conversion becomes available when you fill **Exchange Rate**. Clicking **Apply Currency Conversion** fills the **Currency Conversion** area.

Currency Conversion fills when you click **Apply Currency Conversion**. The schedule contains a row for each cashflow item with the following information:

- **Date** is a SAS date within the cashflow.
- The **From Currency** value is the amount in the original currency at that date.
- The **To Currency** value is the amount in the new currency at that date.

Print becomes available when you fill the **Currency Conversion** area. Clicking it sends the contents of the conversion table to the SAS session print device.

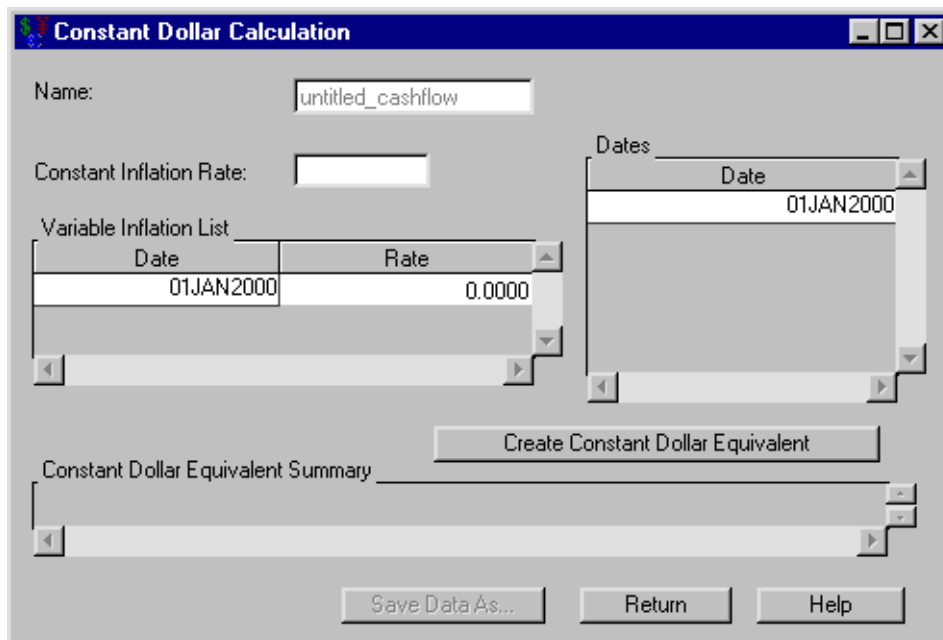

Save Data As becomes available when you fill the **Currency Conversion** area. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the conversion table (or portions thereof) as a SAS Dataset.

Return returns you to the [Investment Analysis](#) dialog box.

Constant Dollar Calculation

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a constant dollar calculation, select **Compute** → **Constant Dollars** from the Investment Analysis dialog box's menu bar. This opens the Constant Dollar Calculation dialog box displayed in [Figure 48.10](#).

Figure 48.10 Constant Dollar Calculation Dialog Box

The following items are displayed:

Name holds the name of the investment for which you are computing the constant dollars value.

Constant Inflation Rate holds the constant inflation rate (a percentage between 0% and 120%). This value is used if the **Variable Inflation List** area is empty.

Variable Inflation List holds date-rate pairs that describe how inflation varies over time. Each date is a SAS date, and the rate is a percentage between 0% and 120%. Each date refers to when that inflation rate begins. Right-clicking within the **Variable Inflation** area reveals many helpful tools for managing date-rate pairs. If you assume a fixed inflation rate, just insert that rate in **Constant Rate**.

Dates holds the SAS date(s) at which you wish to compute the constant dollar equivalent. Right-clicking within the **Dates** area reveals many helpful tools for managing date lists.

Create Constant Dollar Equivalent becomes available when you enter inflation rate information. Clicking it fills the constant dollar equivalent summary with the computed constant dollar values.

Constant Dollar Equivalent Summary fills with a summary when you click **Create Constant Dollar Equivalent**. The first column lists the dates of the generic cashflow. The second column contains the constant dollar equivalent of the original generic cashflow item of that date.

Print becomes available when you fill the constant dollar equivalent summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you fill the constant dollar equivalent summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return returns you to the [Investment Analysis](#) dialog box.

The Analyze Menu

Figure 49.1 shows the **Analyze** menu.

Figure 49.1 Analyze Menu

The **Analyze** menu offers the following options for use on applicable investments.

Time Value opens the **Time Value Analysis** dialog box. Time value analysis involves moving money through time across a defined minimum attractive rate of return (MARR) so that you can

compare value at a consistent date. The MARR can be constant or variable over time.

Periodic Equivalent opens the [Uniform Periodic Equivalent](#) dialog box. Uniform periodic equivalent analysis determines the payment needed to convert a cashflow to uniform amounts over time, given a periodicity, a number of periods, and a MARR. This option helps when making comparisons where one alternative is uniform (such as renting) and another is not (such as buying).

Internal Rate of Return opens the [Internal Rate of Return](#) dialog box. The internal rate of return of a cashflow is the interest rate that makes the time value equal to 0. This calculation assumes uniform periodicity of the cashflow. It is particularly applicable where the choice of MARR would be difficult.

Benefit-Cost Ratio opens the [Benefit-Cost Ratio Analysis](#) dialog box. The benefit-cost ratio divides the time value of the benefits by the time value of the costs. For example, governments often use this analysis when deciding whether to commit to a public works project.

Breakeven Analysis opens the [Breakeven Analysis](#) dialog box. Breakeven analysis computes time values at various MARRs to compare, which can be advantageous when it is difficult to determine a MARR. This analysis can help you determine how the cashflow's profitability varies with your choice of MARR. A graph displaying the relationships between time value and MARR is also available.

Tasks

Performing Time Value Analysis

Suppose a rock quarry needs equipment to use the next five years. It has two alternatives:

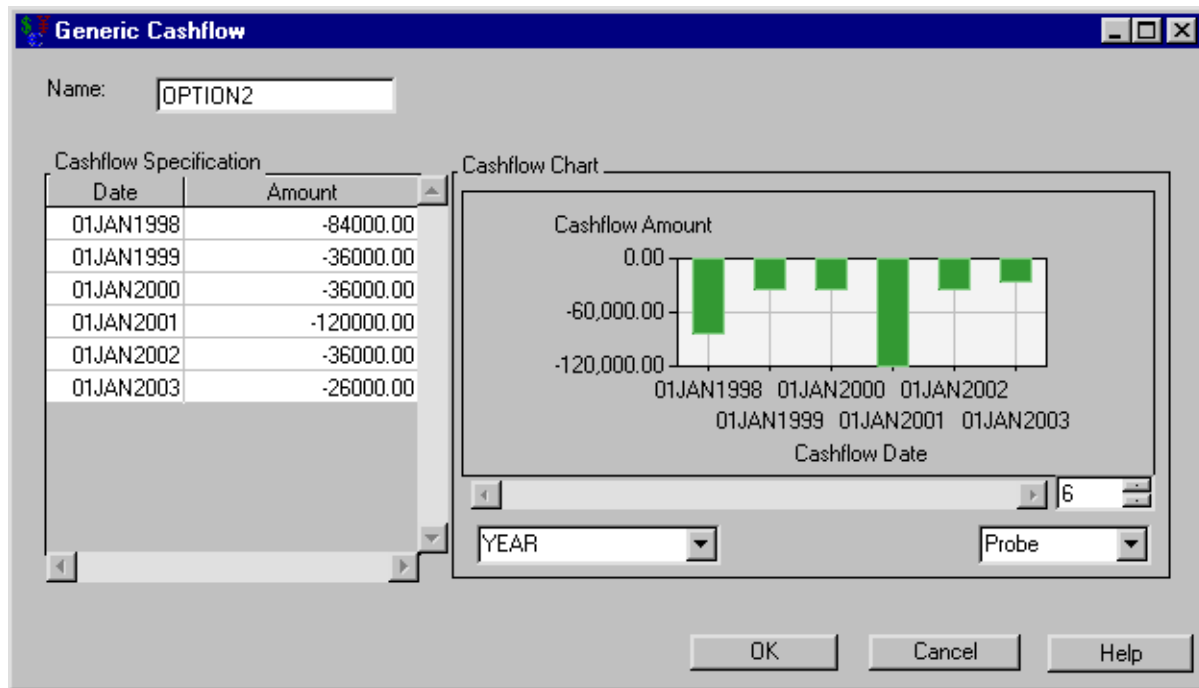

- a box loader and conveyer system that has a one-time cost of \$264,000
- a two-shovel loader, which costs \$84,000 but has a yearly operating cost of \$36,000. This loader has a service life of three years, which necessitates the purchase of a new loader for the final two years of the rock quarry project. Assume the second loader also costs \$84,000 and its salvage value after its two-year service is \$10,000. A SAS data set that describes this is available at SASHELP.ROCKPIT

You expect a 13% MARR. Which is the better alternative?

To create the cashflows, follow these steps:

1. Create a cashflow with the single amount $-264,000$. Date the amount 01JAN1998 to be consistent with the SAS data set you load.
2. Load SASHELP.ROCKPIT into a second cashflow, as displayed in [Figure 49.2](#).

Figure 49.2 The contents of SASHELP.ROCKPIT

To compute the time values of these investments, follow these steps:

1. Select both cashflows.
2. Select **Analyze** → **Time Value**. This opens the Time Value Analysis dialog box.
3. Enter the date 01JAN1998 into the **Dates** area.
4. Enter 13 for the **Constant MARR**.
5. Click **Create Time Value Summary**.

Figure 49.3 Performing the Time Value Analysis

As shown in [Figure 49.3](#), option 1 has a time value of $-\$264,000.00$ naturally on 01JAN1998. However, option 2 has a time value of $-\$263,408.94$, which is slightly less expensive.

Computing an Internal Rate of Return

You are choosing between five investments. A portfolio containing these investments is available at SASHELP.INVSAMP.NVST. Which investments are acceptable if you expect a MARR of 9%?

Open the portfolio SASHELP.INVSAMP.NVST and compare the investments. Note that Internal Rate of Return computations assume regular periodicity of the cashflow. To compute the internal rates of return, follow these steps:

1. Select all five investments.
2. Select **Analyze** → **Internal Rate of Return**.

Figure 49.4 Computing an Internal Rate of Return

The screenshot shows a window titled "Internal Rate of Return" with a table of results. The table has three columns: "Name", "IRR", and "interval". There are five rows of data, labeled "nvst1" through "nvst5". Below the table are three buttons: "Save Data As...", "Return", and "Help".

Name	IRR	interval
nvst1	7.9308	YEAR
nvst2	9.0009	YEAR
nvst3	7.9308	YEAR
nvst4	13.5526	YEAR
nvst5	11.8410	YEAR

The results displayed in [Figure 49.4](#) indicate that the internal rates of return for investments 2, 4, and 5 are greater than 9%. Hence, each of these is acceptable.

Performing a Benefit-Cost Ratio Analysis

Suppose a municipality has excess funds to invest. It is choosing between the same investments described in the previous example. Government agencies often compute benefit-cost ratios to decide which investment to pursue. Which is best in this case?

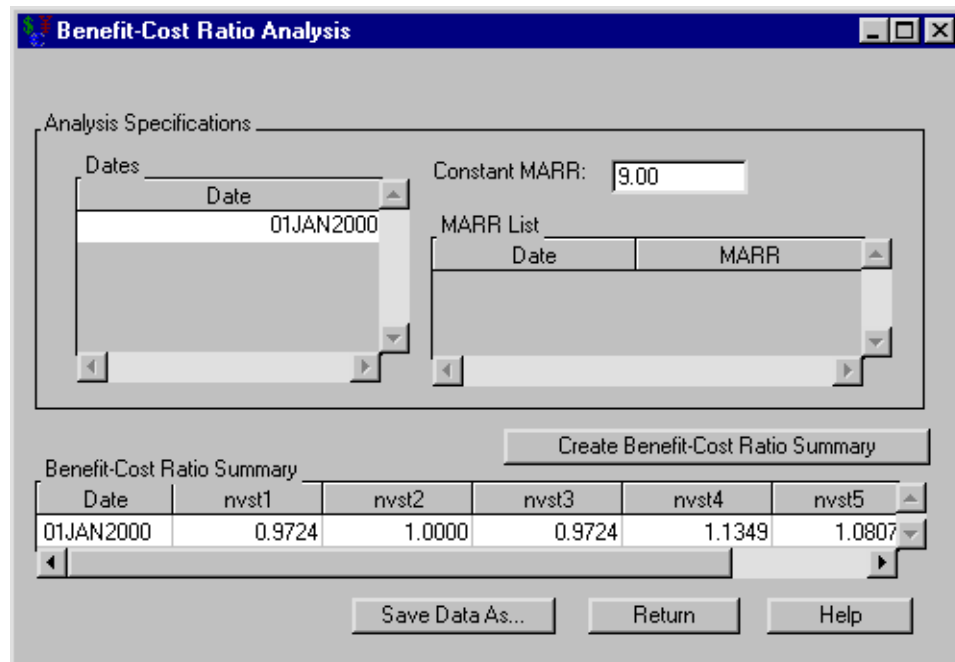

Open the portfolio SASHELP.INVSAMP.NVST and compare the investments.

To compute the benefit-cost ratios, follow these steps:

1. Select all five investments.
2. Select **Analyze** → **Benefit-Cost Ratio**.
3. Enter 01JAN1996 for the **Date**.
4. Enter 9 for **Constant MARR**.
5. Click **Create Benefit-Cost Ratio Summary** to fill the **Benefit-Cost Ratio Summary** area.

The results displayed in [Figure 49.5](#) indicate that investments 2, 4, and 5 have ratios greater than 1. Therefore, each is profitable with a MARR of 9%.

Figure 49.5 Performing a Benefit-Cost Ratio Analysis

Computing a Uniform Periodic Equivalent

Suppose you need a warehouse for ten years. You have two options:

- pay rent for ten years at \$23,000 per year
- build a two-stage facility that you will maintain and which you intend to sell at the end of those ten years

Data sets describing these scenarios are available in the portfolio SASHELP.INVSAMP.BUYRENT. Which option is more financially sound if you desire a 12% MARR?

Open the portfolio SASHELP.INVSAMP.BUYRENT and compare the options.

To perform the periodic equivalent, follow these steps:

1. Load the portfolio SASHELP.INVSAMP.BUYRENT.
2. Select both cashflows.
3. Select **Analyze** → **Periodic Equivalent**.
This opens the Uniform Periodic Equivalent dialog box.
4. Enter 01JAN1996 for the **Start Date**.
5. Enter 10 for the **Number of Periods**.
6. Select YEAR for the **Interval**.

7. Enter 12 for the **Constant MARR**.
8. Click **Create Time Value Summary**.

Figure 49.6 Computing a Uniform Periodic Equivalent

Uniform Periodic Equivalent

Analysis Specifications

Start Date: 01JAN1996 Interval: YEAR

Number of Periods: 10 Constant MARR: 12.00

Create Periodic Equivalent Summary

Periodic Equivalent Summary

Name	Amount
buy	-21868.44
rent	-20535.71

Save Data As... Return Help

Figure 49.6 indicates that renting costs about \$1,300 less each year. Hence, renting is more financially sound. Notice the periodic equivalent for renting is not \$23,000. This is because the \$23,000 per year does not account for the MARR.

Performing a Breakeven Analysis

In the previous example you computed the uniform periodic equivalent for a rent-buy scenario. Now let's perform a breakeven analysis to see how the MARR affects the time values.

To perform the breakeven analysis, follow these steps:

1. Select both options.
2. Select **Analyze** → **Breakeven Analysis**.
3. Enter 01JAN1996 for the **Date**.
4. Enter 12.0 for **Value**.
5. Enter 4.0 for (+/-).
6. Enter 0.5 for **Increment by**.

- Click **Create Breakeven Analysis Summary** to fill the **Breakeven Analysis Summary** area as displayed in [Figure 49.7](#).

Figure 49.7 Performing a Breakeven Analysis

Analysis Specifications

Analysis: Variable:

Date: Value:

+/-:

Increment by:

Date	buy	rent	MARR
01JAN1996	-138119.27	-111164.23	16.0000
01JAN1996	-138200.93	-113265.33	15.5000
01JAN1996	-138270.89	-115431.68	15.0000
01JAN1996	-138328.24	-117665.87	14.5000
01JAN1996	-138371.98	-119970.66	14.0000

Click **Graphics** to view a plot displaying the relationship between time value and MARR.

Figure 49.8 Viewing a Breakeven Graph

As shown in [Figure 49.8](#), renting is better if you want a MARR of 12%. However, if your MARR should drop to 10.5%, buying would be better.

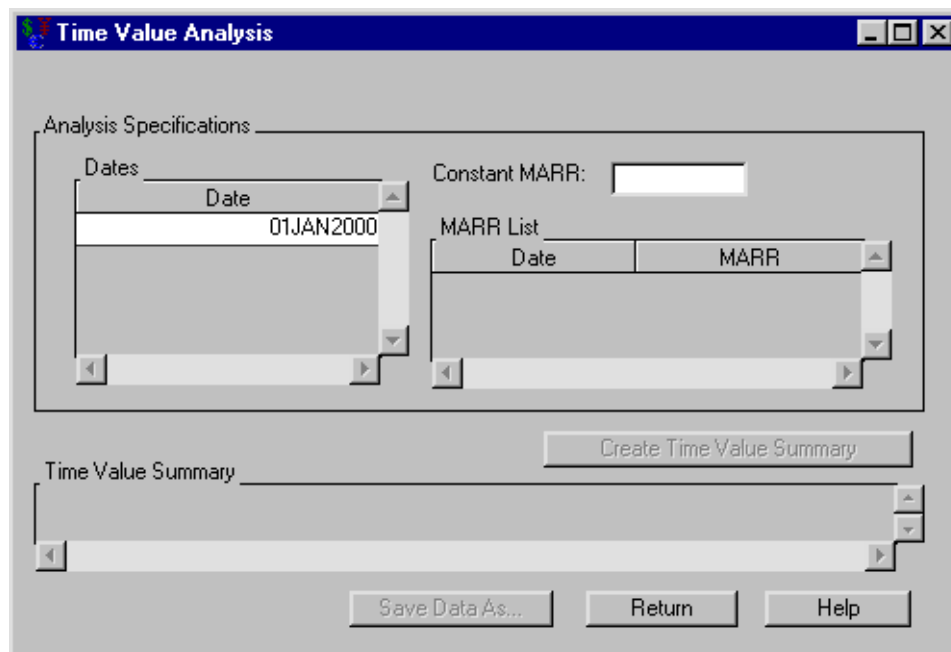

With a single investment, knowing where the graph has a time value of 0 tells the MARR when a venture switches from being profitable to being a loss. With multiple investments, knowing where the graphs for the various investments cross each other tells at what MARR a particular investment becomes more profitable than another.

Dialog Box Guide

Time Value Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an time value analysis, select **Analyze** → **Time Value** from the Investment Analysis dialog box's menu bar. This opens the Time Value Analysis dialog box displayed in [Figure 49.9](#).

Figure 49.9 Time Value Analysis Dialog Box

The following items are displayed:

Analysis Specifications

Dates holds the list of dates as of which to perform the time value analysis. [Right-clicking](#) within the **Dates** area reveals many helpful tools for managing date lists.

Constant MARR holds the desired MARR for the time value analysis. This value is used if the **MARR List** area is empty.

MARR List holds date-rate pairs that express your desired MARR as it changes over time. Each date refers to when that expected MARR begins. [Right-clicking](#) within the **MARR List** area reveals many helpful tools for managing date-rate pairs.

Create Time Value Summary becomes available when you adequately specify the analysis within the **Analysis Specifications** area. Clicking **Create Time Value Summary** then fills the **Time Value Summary** area.

Time Value Summary fills when you click **Create Time Value Summary**. The table contains a row for each date in the **Dates** area. The remainder of each row holds the time values at that date, one value for each investment selected.

Print becomes available when you fill the time value summary. Clicking it sends the contents of the summary to the SAS session print device.

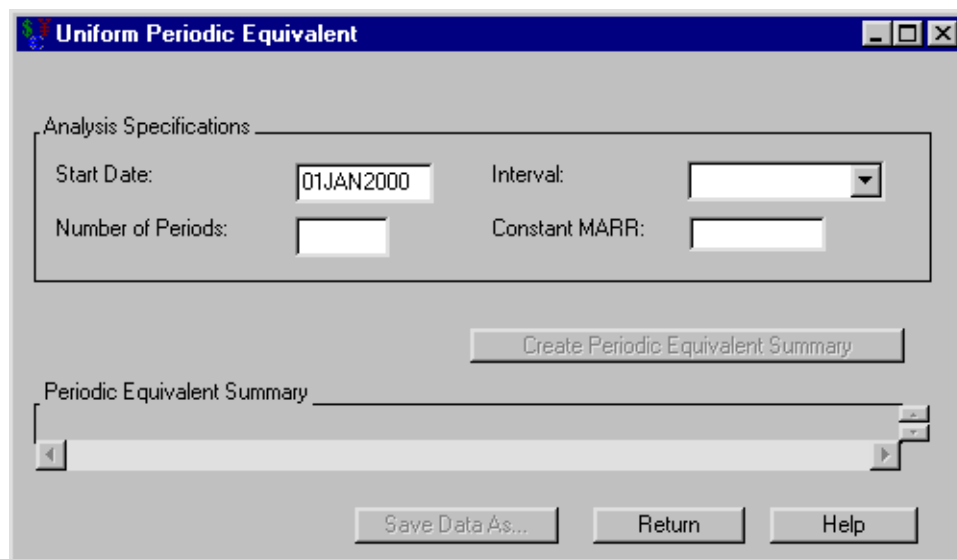

Save Data As becomes available when you fill the time value summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Investment Analysis](#) dialog box.

Uniform Periodic Equivalent

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a uniform periodic equivalent, select **Analyze** → **Periodic Equivalent** from the Investment Analysis dialog box's menu bar. This opens the Uniform Periodic Equivalent dialog box displayed in [Figure 49.10](#).

Figure 49.10 Uniform Periodic Equivalent Dialog Box

The following items are displayed:

Analysis Specifications

Start Date holds the date the uniform periodic equivalents begin.

Number of Periods holds the number of uniform periodic equivalents.

Interval holds how often the uniform periodic equivalents occur.

Constant MARR holds the Minimum Attractive Rate of Return.

Create Periodic Equivalent Summary becomes available when you adequately fill the **Analysis Specification** area. Clicking **Create Periodic Equivalent Summary** then fills the periodic equivalent summary.

Periodic Equivalent Summary fills with two columns when you click **Create Periodic Equivalent Summary**. The first column lists the investments selected. The second column lists the computed periodic equivalent amount.

Print becomes available when you fill the periodic equivalent summary. Clicking it sends the contents of the summary to the SAS session print device.

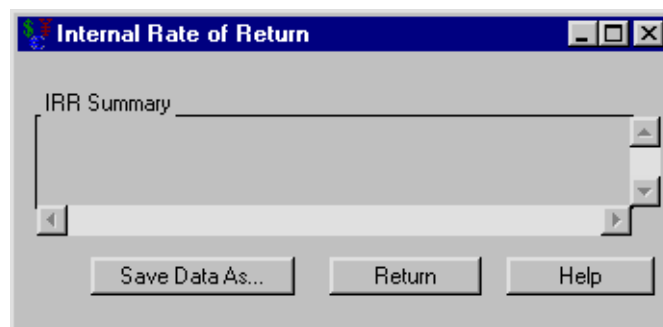

Save Data As becomes available when you generate the periodic equivalent summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Investment Analysis](#) dialog box.

Internal Rate of Return

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an internal rate of return calculation, select **Analyze** → **Internal Rate of Return** from the Investment Analysis dialog box's menu bar. This opens the Internal Rate of Return dialog box displayed in [Figure 49.11](#).

Figure 49.11 Internal Rate of Return Dialog Box

The following items are displayed:

IRR Summary contains a row for each deposit. Each row holds:

Name holds the name of the investment.

IRR holds the internal rate of return for that investment.

interval holds the interest rate interval for that **IRR**.

Print becomes available when you fill the IRR summary. Clicking it sends the contents of the summary to the SAS session print device.

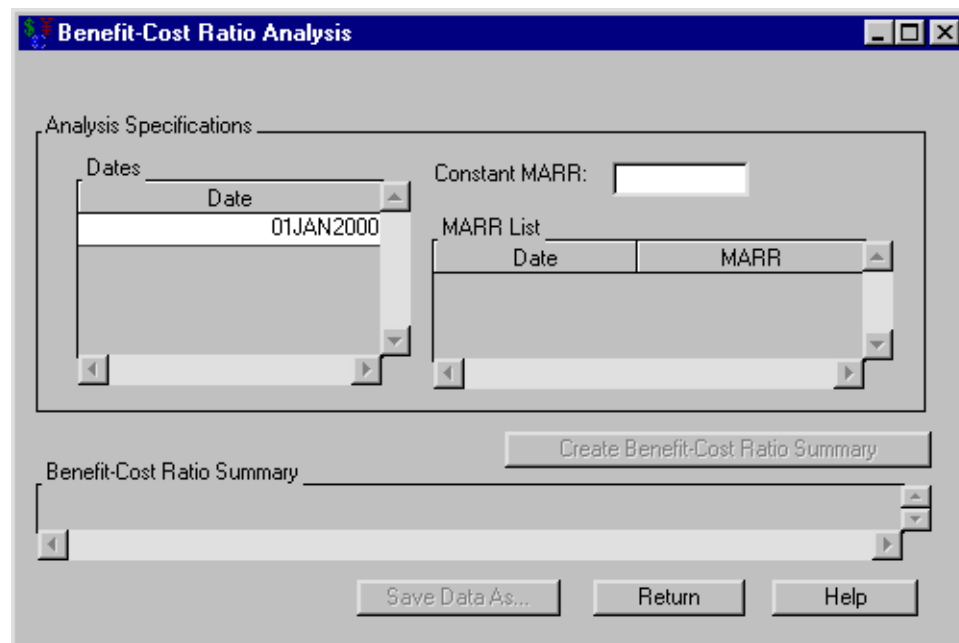

Save Data As opens the [Save Output Dataset](#) dialog box where you can save the IRR summary (or portions thereof) as a SAS data set.

Return takes you back to the [Investment Analysis](#) dialog box.

Benefit-Cost Ratio Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to compute a benefit-cost ratio, select **Analyze** → **Benefit-Cost Ratio** from the Investment Analysis dialog box's menu bar. This opens the Benefit-Cost Ratio Analysis dialog box displayed in [Figure 49.12](#).

Figure 49.12 Benefit-Cost Ratio Analysis Dialog Box

The following items are displayed:

Analysis Specifications

Dates holds the dates as of which to compute the Benefit-Cost ratios.

Constant MARR holds the desired MARR. This value is used if the **MARR List** area is empty.

MARR List holds date-rate pairs that express your desired MARR as it changes over time. Each date refers to when that expected MARR begins. [Right-clicking](#) within the **MARR List** area reveals many helpful tools for managing date-rate pairs.

Create Benefit-Cost Ratio Summary becomes available when you adequately specify the analysis. Clicking **Create Benefit-Cost Ratio Summary** fills the benefit-cost ratio summary.

Benefit-Cost Ratio Summary fills when you click **Exchange the Rates**. The area contains a row for each date in the **Dates** area. The remainder of each row holds the benefit-cost ratios at that date, one value for each investment selected.

Print becomes available when you fill the benefit-cost ratio summary. Clicking it sends the contents of the summary to the SAS session print device.

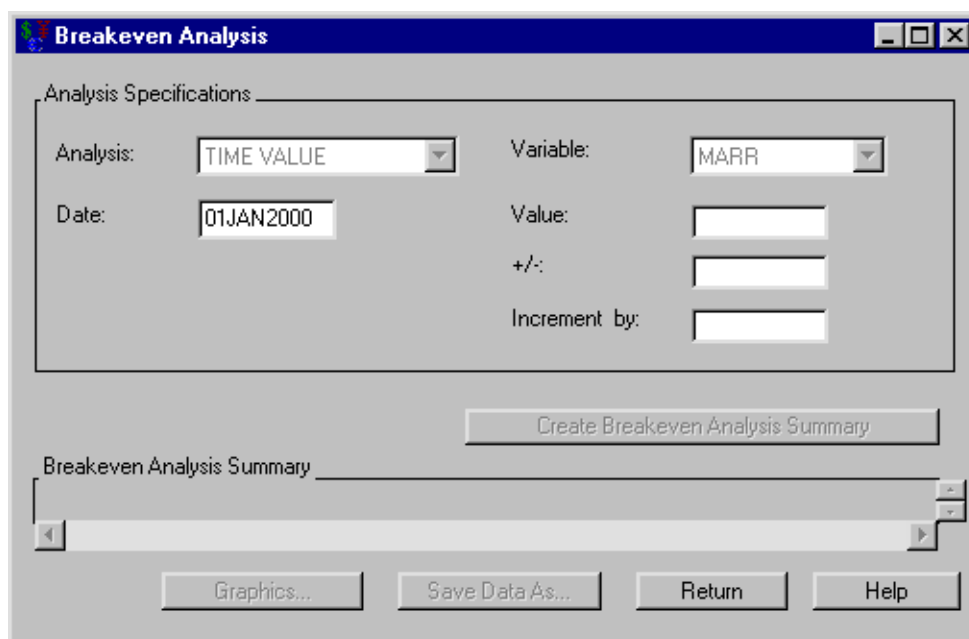

Save Data As becomes available when you generate the benefit-cost ratio summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Investment Analysis](#) dialog box.

Breakeven Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a breakeven analysis, select **Analyze** → **Breakeven Analysis** from the Investment Analysis dialog box's menu bar. This opens the Breakeven Analysis dialog box displayed in [Figure 49.13](#).

Figure 49.13 Breakeven Analysis Dialog Box

The following items are displayed:

Analysis Specification

Analysis holds the analysis type. Only Time Value is currently available.

Date holds the date for which you perform this analysis.

Variable holds the variable upon which the breakeven analysis will vary. Only MARR is currently available.

Value holds the desired rate upon which to center the analysis.

+/- holds the maximum deviation from the **Value** to consider.

Increment by holds the increment by which the analysis is calculated.

Create Breakeven Analysis Summary becomes available when you adequately specify the analysis. Clicking **Create Breakeven Analysis Summary** then fills the **Breakeven Analysis Summary** area.

Breakeven Analysis Summary fills when you click **Create Breakeven Analysis Summary**. The schedule contains a row for each MARR and date.

Graphics becomes available when you fill the **Breakeven Analysis Summary** area. Clicking it opens the [Breakeven Graph](#) graph representing the time value versus MARR.

Print becomes available when you fill the breakeven analysis summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you generate the breakeven analysis summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Investment Analysis](#) dialog box.

Breakeven Graph

Suppose you perform a breakeven analysis in the Breakeven Analysis dialog box. Once you create the breakeven analysis summary, you can click the **Graphics** button to open the Breakeven Graph dialog box displayed in [Figure 49.14](#).

Figure 49.14 Breakeven Graph Dialog Box

The following item is displayed:

Return takes you back to the [Breakeven Analysis](#) dialog box.

Investments and Data Sets

Investment Analysis provides tools to assist you in moving data between SAS data sets and lists you can use within Investment Analysis.

Saving Output to SAS Data Sets

Many investment specifications have a button that reads **Save Data As**. Clicking that button opens the Save Output Dataset dialog box (see [Figure 50.1](#)). This dialog box enables you to save all or part of the area generated by the specification.

Figure 50.1 Saving to a Dataset

The following items are displayed:

Dataset Name holds the SAS data set name to which you want to save.

Browse opens the standard SAS **Open** dialog box, which enables you to select an existing SAS data set to overwrite.

Dataset Label holds the SAS data set's label.

Dataset Variables organizes variables. The variables listed in the **Selected** area will be included in the SAS data set.

- You can select variables one at a time, by clicking the single right-arrow after each selection to move it to the **Selected** area.
- If the desired SAS data set has many variables you want to save, it may be simpler to follow these steps:
 1. Click the double right-arrow to select all available variables.
 2. Remove any unwanted variable by selecting it from the **Selected** area and clicking the single left-arrow.
- The double left-arrow removes all selected variables from the proposed SAS data set.
- The up and down arrows below the **Available** and **Selected** boxes enable you to scroll up and down the list of variables in their respective boxes.

Save Dataset attempts to save the SAS data set. If the SAS data set name exists, you are asked if you want to replace the existing SAS data set, append to the existing SAS data set, or cancel the current save attempt. You then return to this dialog box ready to create another SAS data set to save.

Return takes you back to the specification dialog box.

Loading a SAS Data Set into a List

Right-click in the area that you want to load the list and release on **Load**. This opens the Load Dataset dialog box (see [Figure 50.2](#)).

Figure 50.2 Load Dataset Dialog Box

The following items are displayed:

Dataset Name holds the name of the SAS data set that you want to load.

Browse opens the standard SAS **Open** dialog box, which aids in finding a SAS data set to load. If there is a **Date** variable in the SAS data set, Investment Analysis loads it into the list. If there is no **Date** variable, it loads the first available time-formatted variable. If an amount or rate variable is needed, Investment Analysis searches the SAS data set for a **Amount** or **Rate** variable to use. Otherwise it takes the first numeric variable that is not used by the **Date** variable.

Dataset Label holds a SAS data set label.

OK attempts to load the SAS data set specified in **Dataset Name**. If the specified SAS data set exists, clicking **OK** returns you to the calling dialog box with the selected SAS data set filling the list. If the specified SAS data set does not exist and you click **OK**, you receive an error message and no SAS data set is loaded.

Cancel returns you to the calling dialog box without loading a SAS data set.

Saving Data from a List to a SAS Data Set

Right-click in the area you want to hold the list, and release on **Save**. This opens the Save Dataset dialog box.

Figure 50.3 Save Dataset Dialog Box

The following items are displayed:

Dataset Name holds the SAS data set name to which you want to save.

Browse opens the standard SAS **Save As** dialog box, which enables you to find an existing SAS data set to overwrite.

Dataset Label holds a user-defined description to be saved as the label of the SAS data set.

OK saves the current data to the SAS data set specified in **Dataset Name**. If the specified SAS data set does not already exist, clicking **OK** saves the SAS data set and returns you to the calling dialog box. If the specified SAS data set does already exist, clicking **OK** warns you and enables you to replace the old SAS data set with the new SAS data set or cancel the save attempt.

Cancel aborts the save process. Clicking **Cancel** returns you to the calling dialog box without attempting to save.

Right Mouse Button Options

A pop-up menu often appears when you right-click within table editors. The menus offer tools to aid in the management of the table's entries. Most table editors provide the following options.

Figure 50.4 Right-Clicking Options

Add creates a blank row.

Delete removes any currently selected row.

Copy duplicates the currently selected row.

Sort arranges the rows in chronological order according to the date variable.

Clear empties the table of all rows.

Save opens the [Save Dataset](#) dialog box where you can save the all rows to a SAS Dataset for later use.

Load opens the [Load Dataset](#) dialog box where you select a SAS Dataset to fill the rows.

If you want to perform one of these actions on a collection of rows, you must select a collection of rows before right-clicking. To select an adjacent list of rows, do the following: click the first pair, hold down SHIFT, and click the final pair. After the list of rows is selected, you may release the SHIFT key.

Depreciation Methods

Suppose an asset's price is \$20,000 and it has a salvage value of \$5,000 in five years. The following sections describe various methods to quantify the depreciation.

Straight Line (SL)

This method assumes a constant depreciation value per year.

Assuming that the price of a depreciating asset is P and its salvage value after N years is S , the annual depreciation is:

$$\frac{P - S}{N}$$

For our example, the annual depreciation would be

$$\frac{\$20,000 - \$5,000}{5} = \$3,000$$

Sum-of-Years Digits

An asset often loses more of its value early in its lifetime. A method that exhibits this dynamic is desirable.

Assume an asset depreciates from price P to salvage value S in N years. First compute the sum-of-years as $T = 1 + 2 + \cdots + N$. The depreciation for the years after the asset's purchase is:

Table 50.1 Sum-of-Years General Example

Year Number	Annual Depreciation
first	$\frac{N}{T}(P - S)$
second	$\frac{N-1}{T}(P - S)$
third	$\frac{N-2}{T}(P - S)$
⋮	⋮
final	$\frac{1}{T}(P - S)$

For the i th year of the asset's use, the annual depreciation is:

$$\frac{N + 1 - i}{T}(P - S)$$

For our example, $N = 5$ and the sum of years is $T = 1 + 2 + 3 + 4 + 5 = 15$. The depreciation during the first year is

$$(\$20,000 - \$5,000)\frac{5}{15} = \$5,000$$

Table 50.2 describes how Declining Balance would depreciate the asset.

Table 50.2 Sum-of-Years Example

Year	Depreciation	Year-End Value
1	$(\$20,000 - \$5,000)\frac{5}{15} = \$5,000$	\$15,000.00
2	$(\$20,000 - \$5,000)\frac{4}{15} = \$4,000$	\$11,000.00
3	$(\$20,000 - \$5,000)\frac{3}{15} = \$3,000$	\$8,000.00
4	$(\$20,000 - \$5,000)\frac{2}{15} = \$2,000$	\$6,000.00
5	$(\$20,000 - \$5,000)\frac{1}{15} = \$1,000$	\$5,000.00

As expected, the value after N years is S .

$$\begin{aligned} S &= P - (5 \text{ years' depreciation}) \\ &= P - \left(\frac{5}{15}(P - S) + \frac{4}{15}(P - S) + \frac{3}{15}(P - S) + \frac{2}{15}(P - S) + \frac{1}{15}(P - S) \right) \\ &= P - (P - S) \end{aligned}$$

Declining Balance (DB)

Recall that the straight line method assumes a constant depreciation value. Conversely, the declining balance method assumes a constant depreciation rate per year. And like the sum-of-years method, more depreciation tends to occur earlier in the asset's life.

Assume the price of a depreciating asset is P and its salvage value after N years is S . You could assume the asset depreciates by a factor of $\frac{1}{N}$ (or a rate of $\frac{100}{N}\%$). This method is known as single declining balance. The annual depreciation is:

$$\frac{1}{N}(\text{previous year's value})$$

So for our example, the depreciation during the first year is $\frac{\$20,000}{5} = \$4,000$. [Table 50.3](#) describes how declining balance would depreciate the asset.

Table 50.3 Declining Balance Example

Year	Depreciation	Year-End Value
1	$\frac{\$20,000.00}{5} = \$4,000.00$	\$16,000.00
2	$\frac{\$16,000.00}{5} = \$3,200.00$	\$12,800.00
3	$\frac{\$12,800.00}{5} = \$2,560.00$	\$10,240.00
4	$\frac{\$10,240.00}{5} = \$2,048.00$	\$8,192.00
5	$\frac{\$12,800.00}{5} = \$1,638.40$	\$6,553.60

DB Factor

You could also accelerate the depreciation by increasing the factor (and hence the rate) at which depreciation occurs. Other commonly accepted depreciation rates are $\frac{200}{N}\%$ (called double declining balance as the depreciation factor becomes $\frac{2}{N}$) and $\frac{150}{N}\%$. Investment Analysis enables you to choose between these three types for declining balance: 2 (with $\frac{200}{N}\%$ depreciation), 1.5 (with $\frac{150}{N}\%$), and 1 (with $\frac{100}{N}\%$).

Declining Balance and the Salvage Value

The declining balance method assumes that depreciation is faster earlier in an asset's life; this is what you wanted. But notice the final value is greater than the salvage value. Even if the salvage value were greater than \$6,553.60, the final year-end value would not change. The salvage value never enters the calculation, so there is no way for the salvage value to force the depreciation to assume its value. [Newnan and Lavelle \(1998\)](#) describe two ways to adapt the declining balance method to assume the salvage value at the final time. One way is as follows:

Suppose you call the depreciated value after i years $V(i)$. This sets $V(0) = P$ and $V(N) = S$.

- If $V(N) > S$ according to the usual calculation for $V(N)$, redefine $V(N)$ to equal S .
- If $V(i) < S$ according to the usual calculation for $V(i)$ for some i (and hence for all subsequent $V(i)$ values), you can redefine all such $V(i)$ to equal S .

This alteration to declining balance forces the depreciated value of the asset after N years to be S and keeps $V(i)$ no less than S .

Conversion to SL

The second (and preferred) way to force declining balance to assume the salvage value is by conversion to straight line. If $V(N) > S$, the first way redefines $V(N)$ to equal S ; you can think of this as converting to the straight line method for the last timestep.

If the $V(N)$ value supplied by DB is appreciably larger than S , then the depreciation in the final year would be unrealistically large. An alternate way is to compute the DB and SL step at each timestep and take whichever step gives a larger depreciation (unless DB drops below the salvage value).

After SL assumes a larger depreciation, it continues to be larger over the life of the asset. SL forces the value at the final time to equal the salvage value. As an algorithm, this looks like the following statements:

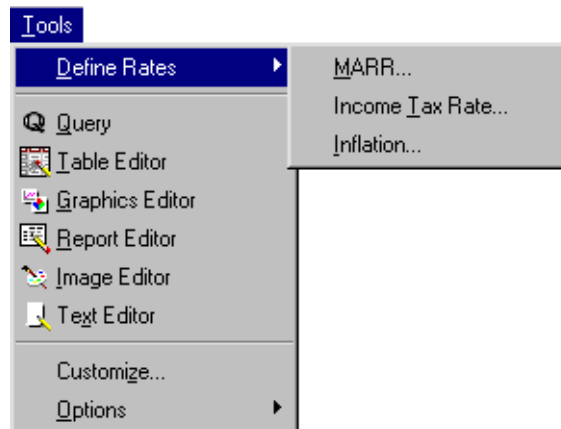

```
V(0) = P;
for i=1 to N
  if DB step > SL step from (i,V(i))
    take a DB step to make V(i);
  else
    break;
for j = i to N
  take a SL step to make V(j);
```

The MACRS, which is discussed in the section that describes the [Depreciation Table](#) window, is actually a variation on the declining balance method with conversion to the straight line method.

Rate Information

The Tools Menu

Figure 50.5 shows the **Tools** menu.

Figure 50.5 The Tools Menu

The **Tools** → **Define Rates** menu offers the following options.

MARR opens the [Minimum Attractive Rate of Return \(MARR\)](#) dialog box.

Income Tax Rate opens the [Income Tax Specification](#) dialog box.

Inflation opens the [Inflation Specification](#) dialog box.

Dialog Box Guide

Minimum Attractive Rate of Return (MARR)

Selecting **Tools** → **Define Rates** → **MARR** from the Investment Analysis dialog box menu bar opens the MARR dialog box that is displayed in [Figure 50.6](#).

Figure 50.6 MARR Dialog Box

The dialog box is titled "Minimum Attractive Rate of Return (MARR)". It features three input fields: "Name:", "Constant MARR:", and "MARR List". The "MARR List" field is a table editor with two columns: "Date" and "MARR". Below the table are three buttons: "OK", "Cancel", and "Help".

Name holds the name that you assign to the MARR specification. This must be a valid SAS name.

Constant MARR holds the numeric value that you choose to be the constant MARR. This value is used if the **MARR List** table editor is empty.

MARR List holds date-MARR pairs where the date refers to when the particular MARR value begins. Each date is a SAS date.

OK returns you to the [Investment Analysis](#) dialog box. Clicking it causes the preceding MARR specification to be assumed when you do not specify MARR rates in a dialog box that needs MARR rates.

Cancel returns you to the [Investment Analysis](#) dialog box, discarding any work that was done in the MARR dialog box.

Income Tax Specification

Selecting **Tools** → **Define Rates** → **Income Tax Rate** from the Investment Analysis dialog box menu bar opens the Income Tax Specification dialog box displayed in [Figure 50.7](#).

Figure 50.7 Income Tax Specification Dialog Box

Date	Federal	Local

Name holds the name you assign to the Income Tax specification. This must be a valid SAS name.

Federal Tax holds the numeric value that you want to be the constant Federal Tax.

Local Tax holds the numeric value that you want to be the constant Local Tax.

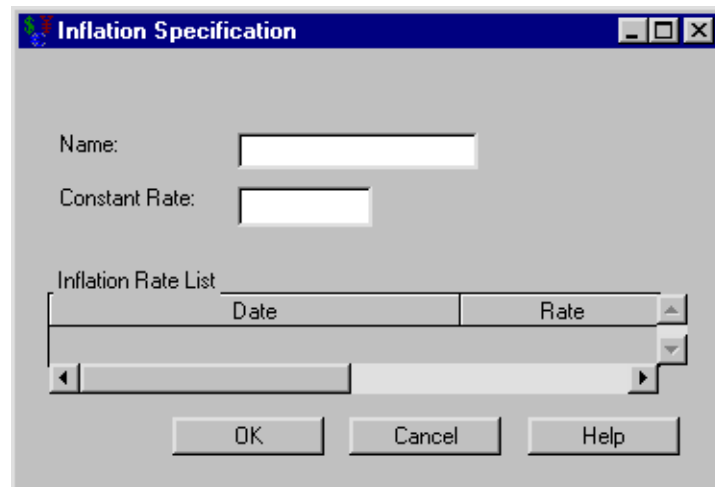

Taxrate List holds date-Income Tax triples where the date refers to when the particular Income Tax value begins. Each date is a SAS date, and the value is a percentage between 0% and 100%.

OK returns you to the [Investment Analysis](#) dialog box. Clicking it causes the preceding income tax specification to be the default income tax rates when using the [After Tax Cashflow Calculation](#) dialog box.

Cancel returns you to the [Investment Analysis](#) dialog box, discarding any changes that were made since this dialog box was opened.

Inflation Specification

Selecting **Tools** → **Define Rates** → **Inflation** from the Investment Analysis dialog box menu bar opens the Inflation Specification dialog box displayed in [Figure 50.8](#).

Figure 50.8 Inflation Specification Dialog Box

Name holds the name that you assign to the Inflation specification. This must be a valid SAS name.

Constant Rate holds the numeric value that you want to be the constant inflation rate. This value is used if the **Inflation Rate List** table editor is empty.

Inflation Rate List holds date-rate pairs where the date refers to when the particular inflation rate begins. Each date is a SAS date and the rate is a percentage between 0% and 120%.

OK returns you to the [Investment Analysis](#) dialog box. Clicking it causes the preceding inflation specification to be assumed when you use the [Constant Dollar Calculation](#) dialog box and do not specify inflation rates.

Cancel returns you to the [Investment Analysis](#) dialog box, discarding any changes that were made since this dialog box was opened.

- If you have comments about the software, please send them to **suggest@sas.com**.

SAS® Publishing Delivers!

Whether you are new to the work force or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS® Publishing provides you with a wide range of resources to help you set yourself apart. Visit us online at support.sas.com/bookstore.

SAS® Press

Need to learn the basics? Struggling with a programming problem? You'll find the expert answers that you need in example-rich books from SAS Press. Written by experienced SAS professionals from around the world, SAS Press books deliver real-world insights on a broad range of topics for all skill levels.

support.sas.com/saspress

SAS® Documentation

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information: SAS documentation. We currently produce the following types of reference documentation to improve your work experience:

- Online help that is built into the software.
- Tutorials that are integrated into the product.
- Reference documentation delivered in HTML and PDF – free on the Web.
- Hard-copy books.
