Technical Support

Members Paige Daniels, Wen Ji, Kurt Jones, Kathleen Kiernan,
Kevin Meyer, Gina Marie Mondello, David Schlotzhauer,
Donna E. Woodward

Acknowledgments

Hundreds of people have helped the SAS System in many ways since its inception. The following individuals have been especially helpful in the development of the procedures in SAS/ETS software. Acknowledgments for the SAS System generally appear in Base SAS[®] software documentation and SAS/ETS software documentation.

David Amick	Idaho Office of Highway Safety
David M. DeLong	Duke University
David Dickey	North Carolina State University
Douglas J. Drummond	Center for Survey Statistics
William Fortney	Boeing Computer Services
Wayne Fuller	Iowa State University
A. Ronald Gallant	The University North Carolina at Chapel Hill
Phil Hanser	Sacramento Municipal Utilities District
Marvin Jochimsen	Mississippi R&O Center
Jeff Kaplan	Sun Guard
Ken Kraus	Center for Research in Security Prices
George McCollister	San Diego Gas & Electric
Douglas Miller	Purdue University
Brian Monsell	U.S. Census Bureau
Robert Parks	Washington University
Gregory Sali	Idaho Office of Highway Safety
Bob Spatz	Center for Research in Security Prices
Mary Young	Salt River Project

The final responsibility for the SAS System lies with SAS Institute alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

This chapter summarizes the new features available in SAS/ETS software with SAS 9.2. It also describes other new features that were added with SAS 9.1.

What's New in SAS/ETS for SAS 9.2

Overview

Many SAS/ETS procedures now produce graphical output using the SAS Output Delivery System. This output is produced when you turn on ODS graphics with the following ODS statement:

```
ods graphics on;
```

Several procedures now support the PLOTS= option to control the graphical output produced. (See the chapters for individual SAS/ETS procedures for details on the plots supported.)

With SAS 9.2, SAS/ETS offers three new modules:

- The new ESM procedure provides forecasting using exponential smoothing models with optimized smoothing weights.
- The SASEHAVR interface engine is now production and available to Windows users for accessing economic and financial data residing in a HAVER ANALYTICS Data Link Express (DLX) database.
- The new SIMILARITY (experimental) procedure provides similarity analysis of time series data.

New features have been added to the following SAS/ETS components:

- PROC AUTOREG
- PROC COUNTREG
- PROC DATASOURCE
- PROC MODEL
- PROC PANEL
- PROC QLIM
- SASECRSP Interface Engine
- SASEFAME Interface Engine
- SASEHAVR Interface Engine
- PROC UCM
- PROC VARMAX
- PROC X12

AUTOREG Procedure

Two new features have been added to the AUTOREG procedure.

- An alternative test for stationarity, proposed by Kwiatkowski, Phillips, Schmidt, and Shin (KPSS), is implemented. The null hypothesis for this test is a stationary time series, which is a natural choice for many applications. Bartlett and quadratic spectral kernels for estimating long-run variance can be used. Automatic bandwidth selection is an option.

- Corrected Akaike information criterion (AICC) is implemented. This modification of AIC corrects for small-sample bias. Along with the corrected Akaike information criterion, the mean absolute error (MAE) and mean absolute percentage error (MAPE) are now included in the summary statistics.

COUNTREG Procedure

Often the data that is being analyzed take the form of nonnegative integer (count) values. The new **COUNTREG** procedure implements count data models that take this discrete nature of data into consideration. The dependent variable in these models is a count that represents various discrete events (such as number of accidents, number of doctor visits, or number of children). The conditional mean of the dependent variable is a function of various covariates. Typically, you are interested in estimating the probability of the number of event occurrences using maximum likelihood estimation. The **COUNTREG** procedure supports the following types of models:

- Poisson regression
- negative binomial regression with linear (NEGBIN1) and quadratic (NEGBIN2) variance functions (Cameron and Trivedi 1986)
- zero-inflated Poisson (ZIP) model (Lambert 1992)
- zero-inflated negative binomial (ZINB) model

DATASOURCE Procedure

PROC DATASOURCE now supports the newest Compustat Industrial Universal Character Annual and Quarterly data by providing the new filetypes CSAUCY3 for annual data and CSQUCY3 for quarterly data.

New ESM Procedure

The ESM (Exponential Smoothing Models) procedure provides a quick way to generate forecasts for many time series or transactional data in one step. All parameters associated with the forecast model are optimized based on the data.

MODEL Procedure

The t copula and the normal mixture copula have been added to the MODEL procedure. Both copulas support asymmetric parameters. The copula is used to modify the correlation structure of

the model residuals for simulation.

Starting with SAS 9.2, the MODEL procedure stores MODEL files in SAS datasets using an XML-like format instead of in SAS catalogs. This makes MODEL files more readily extendable in the future and enables Java-based applications to read the MODEL files directly. More information is stored in the new format MODEL files; this enables some features that are not available when the catalog format is used.

The MODEL procedure continues to read and write old-style catalog MODEL files, and model files created by previous releases of SAS/ETS continue to work, so you should experience no direct impact from this change.

The CMPMODEL= option can be used in an OPTIONS statement to modify the behavior of the MODEL when reading and writing MODEL files. The values allowed are CMPMODEL= BOTH | XML | CATALOG. For example, the following statements restore the previous behavior:

```
options cmpmodel=catalog;
```

The CMPMODEL= option defaults to BOTH in SAS 9.2; this option is intended for transitional use while customers become accustomed to the new file format. If CMPMODEL=BOTH, the MODEL procedure writes both formats; when loading model files, PROC MODEL attempts to load the XML version first and the CATALOG version second (if the XML version is not found). If CMPMODEL=XML the MODEL procedure reads and writes only the XML format. If CMPMODEL=CATALOG, only the catalog format is used.

PANEL Procedure

The **PANEL** procedure expands the estimation capability of the **TSCSREG** procedure in the time-series cross-sectional framework. The new methods include: between estimators, pooled estimators, and dynamic panel estimators using GMM method. Creating lags of variables in a panel setting is simplified by the LAG statement. Because the presence of heteroscedasticity can result in inefficient and biased estimates of the variance covariance matrix in the OLS framework, several methods that produce heteroscedasticity-corrected covariance matrices (HCCME) are added. The new **RESTRICT** statement specifies linear restrictions on the parameters. New ODS Graphics plots simplify model development by providing visual analytical tools.

QLIM Procedure

Stochastic frontier models are now available in the **QLIM** procedure. Specification of these models allows for random shocks of production or cost along with technological or cost inefficiencies. The nonnegative error-term component that represents technological or cost inefficiencies has half-normal, exponential, or truncated normal distributions.

SASECRSP Engine

The [SASECRSP](#) interface now supports reading of CRSP stock, indices, and combined stock/indices databases by using a variety of keys, not just CRSP's primary key PERMNO.

In addition, SASECRSP can now read the CRSP/Compustat Merged (CCM) database and fully supports cross-database access, enabling you to access the CCM database by CRSP's main identifiers PERMNO and PERMCO, as well as to access the CRSP Stock databases by Compustat's GVKEY identifier.

A list of other new features follows:

- SASECRSP now fully supports access of fiscal CCM data members by both fiscal and calendar date range restrictions. Fiscal to calendar date shifting has been added as well.
- New date fields have been added for CCM fiscal members. Now fiscal members have three different dates: a CRSP date, a fiscal integer date, and a calendar integer date.
- An additional date function has been added which enables you to convert from fiscal to calendar dates.
- Date range restriction for segment members has also been added.

SASEFAME Engine

The [SASEFAME](#) interface enables you to access and process financial and economic time series data that resides in a FAME database. SASEFAME for SAS 9.2 supports Windows, Solaris, AIX, Linux, Linux Opteron, and HP-UX hosts. You can now use the SAS windowing environment to view FAME data and use the SAS viewtable commands to navigate your FAME data base. You can select the time span of data by specifying a range of dates in the RANGE= option. You can use an input SAS data set with a WHERE clause to specify selection of variables based on BY variables, such as tickers or issues stored in a FAME string case series. You can use a FAME crosslist to perform selection based on the crossproduct of two FAME namelists. The new FAMEOUT= option now supports the following classes and types of data series objects: FORMULA, TIME, BOOLEAN, CASE, DATE, and STRING.

It is easy to use a SAS input data set with the INSET= option to create a specific view of your FAME data. Multiple views can be created by using multiple LIBNAME statements with customized options tailored to the unique view that you want to create. See [“Example 34.10: Selecting Time Series Using CROSSLIST= Option with INSET= and WHERE=TICK”](#) on page 2325 in Chapter 34, [“The SASEFAME Interface Engine.”](#)

The INSET variables define the BY variables that enable you to view cross sections or slices of your data. When used in conjunction with the WHERE clause and the CROSSLIST= option, SASEFAME can show any or all of your BY groups in the same view or in multiple views. The INSET= option is invalid without a WHERE that clause specifies the BY variables you want to use in your view, and it must be used with the CROSSLIST=option.

The `CROSSLIST=` option provides a more efficient means of selecting cross sections of financial time series data. This option can be used without using the `INSET=` option. There are two methods for performing the crosslist selection function. The first method uses two FAME namelists, and the second method uses one namelist and one BY group specified in the `WHERE=` clause of the `INSET=` option. See “[Example 34.9: Selecting Time Series Using CROSSLIST= Option with a FAME Namelist of Tickers](#)” on page 2322 in Chapter 34, “[The SASEFAME Interface Engine](#).”

The `FAMEOUT=` option provides efficient selection of the class and type of the FAME data series objects you want in your SAS output data set. The possible values for `fame_data_object_class_type` are `FORMULA`, `TIME`, `BOOLEAN`, `CASE`, `DATE`, and `STRING`. If the `FAMEOUT=` option is not specified, numeric time series are output to the SAS data set. `FAMEOUT=CASE` defaults to case series of numeric type, so if you want another type of case series in your output, then you must specify it. Scalar data objects are not supported. See “[Example 34.6: Reading Other FAME Data Objects with the FAMEOUT= Option](#)” on page 2316 in Chapter 34, “[The SASEFAME Interface Engine](#).”

SASEHAVR Engine

The `SASEHAVR` interface engine is now production, giving Windows users random access to economic and financial data that resides in a Haver Analytics Data Link Express (DLX) database. You can now use the SAS windowing environment to view `HVERDLX` data and use the SAS viewtable commands to navigate your Haver database. You can use the SQL procedure to create a view of your resulting SAS data set. You can limit the range of data that is read from the time series and specify a desired conversion frequency. Start dates are recommended in the `LIBNAME` statement to help you save resources when processing large databases or when processing a large number of observations. You can further subset your data by using the `WHERE`, `KEEP`, or `DROP` statements in your `DATA` step. New options are provided for more efficient subsetting by time series variables, groups, or sources. You can force the aggregation of all variables selected to be of the frequency specified by the `FREQ=` option if you also specify the `FORCE=FREQ` option. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly.

A list of other new features follows:

- You can see the available data sets in the SAS `LIBNAME` window of the SAS windowing environment by selecting the `SASEHAVR` libref in the `LIBNAME` window that you have previously used in your `LIBNAME` statement. You can view your SAS output observations by double clicking on the desired output data set libref in the libname window of the SAS windowing environment. You can type `Viewtable` on the SAS command line to view any of your `SASEHAVR` tables, views, or librefs, both for input and output data sets.
- By default, the `SASEHAVR` engine reads all time series in the Haver database that you reference by using your `SASEHAVR` libref. The `START=` option is specified in the form `YYYYMMDD`, as is the `END=` option. The start and end dates are used to limit the time span of data; they can help you save resources when processing large databases or when processing a large number of observations.

- It is also possible to select specific variables to be included or excluded from the SAS data set by using the KEEP= or the DROP= option. When the KEEP= or the DROP= option is used, the resulting SAS data set keeps or drops the variables that you select in that option. There are three wildcards currently available: '*', '?', and '#'. The '*' wildcard corresponds to any character string and will include any string pattern that corresponds to that position in the matching variable name. The '?' means that any single alphanumeric character is valid. The '#' wildcard corresponds to a single numeric character.
- You can also select time series in your data by using the GROUP= or the SOURCE= option to select on group name or on source name. Alternatively, you can deselect time series by using the DROPGROUP= or the DROPSOURCE= option. These options also support the wildcards '*', '?', and '#'.
- By default, SASEHAVR selects only the variables that are of the specified frequency in the FREQ= option. If this option is not specified, SASEHAVR selects the variables that match the frequency of the first selected variable. If no other selection criteria are specified, the first selected variable is the first physical DLXRecord read from the Haver database. The FORCE=FREQ option can be specified to force the aggregation of all variables selected to be of the frequency specified by the FREQ= option. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. The FORCE= option is ignored if the FREQ= option is not specified.

New SIMILARITY Procedure (Experimental)

The new SIMILARITY procedure provides similarity analysis between two time series and other sequentially ordered numeric data. The SIMILARITY procedure computes similarity measures between an input sequence and target sequence, as well as similarity measures that “slide” the target sequence with respect to the input sequence. The “slides” can be by observation index (sliding-sequence similarity measures) or by seasonal index (seasonal-sliding-sequence similarity measures).

UCM Procedure

The following features are new to the UCM procedure:

- The new RANDOMREG statement enables specification of regressors with time-varying regression coefficients. The coefficients are assumed to follow independent random walks. Multiple RANDOMREG statements can be specified, and each statement can specify multiple regressors. The regression coefficient random walks for regressors specified in the same RANDOMREG statement are assumed to have the same disturbance variance parameter. This arrangement enables a very flexible specification of regressors with time-varying coefficients.

- The new SPLINEREG statement enables specification of a spline regressor that can optionally have time-varying coefficients. The spline specification is useful when the series being forecast depends on a regressor in a nonlinear fashion.
- The new SPLINESEASON statement enables parsimonious modeling of long and complex seasonal patterns using the spline approximation.
- The SEASON statement now has options that enable complete control over the constituent harmonics that make up the trigonometric seasonal model.
- It is now easy to obtain diagnostic test statistics useful for detecting structural breaks such as additive outliers and level shifts.
- As an experimental feature, you can now model the irregular component as an autoregressive moving-average (ARMA) process.
- The memory management and numerical efficiency of the underlying algorithms have been improved.

VARMAX Procedure

The VARMAX procedure now enables independent (exogenous) variables with their distributed lags to influence dependent (endogenous) variables in various models, such as VARMAX, BVARX, VECMX, BVECMX, and GARCH-type multivariate conditional heteroscedasticity models.

Multivariate GARCH Models—New GARCH Statement

Multivariate GARCH modeling is now a production feature of VARMAX.

To enable greater flexibility in specifying multivariate GARCH models, the new GARCH statement has been added to the VARMAX procedure. With the addition of the GARCH statement, the GARCH= option is no longer supported on the MODEL statement.

The OUTHT= option can be specified in the GARCH statement to write the estimated conditional covariance matrix to an output data set. See “[GARCH Statement](#)” on page 1907 in Chapter 30, “[The VARMAX Procedure](#),” for details.

The VARMAX Model

The VARMAX procedure provides modeling of a VARMAX(p, q, s) process which is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \boldsymbol{\Phi}_i \mathbf{y}_{t-i} + \sum_{i=0}^s \boldsymbol{\Theta}_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \boldsymbol{\Theta}_i \boldsymbol{\epsilon}_{t-i}$$

where $\boldsymbol{\Phi}(B) = I_k - \sum_{i=1}^p \boldsymbol{\Phi}_i B^i$, $\boldsymbol{\Theta}^*(B) = \boldsymbol{\Theta}_0^* + \boldsymbol{\Theta}_1^* B + \cdots + \boldsymbol{\Theta}_s^* B^s$, and $\boldsymbol{\Theta}(B) = I_k - \sum_{i=1}^q \boldsymbol{\Theta}_i B^i$.

If the Kalman filtering method is used for the parameter estimation of the VARMAX(p,q,s) model, then the dimension of the state-space vector is large, which takes time and memory for computing. For convenience, the parameter estimation of the VARMAX(p,q,s) model uses the two-stage estimation method, which computes the estimation of deterministic terms and exogenous parameters and then maximizes the log-likelihood function of the VARMA(p,q) model.

Some examples of VARMAX modeling are:

```
model y1 y2 = x1 / q=1;
nloptions tech=qn;
```

```
model y1 y2 = x1 / p=1 q=1 xlag=1 nocurrentx;
nloptions tech=qn;
```

The BVARX Model

Bayesian modeling allows independent (exogenous) variables with their distributed lags. For example:

```
model y1 y2 = x1 / p=2 prior=(theta=0.2 lambda=5);
```

The VECMX Model

Vector error correction modeling now allows independent (exogenous) variables with their distributed lags. For example:

```
model y1 y2 = x1 / p=2 ecm=(rank=1);
```

The BVECMX Model

Bayesian vector error correction modeling allows independent (exogenous) variables with their distributed lags. For example:

```
model y1 y2 = x1 / p=2 prior=(theta=0.2 lambda=5) ecm=(rank=1);
```

The VARMAX-GARCH Model

VARMAX modeling now supports an error term that has a GARCH-type multivariate conditional heteroscedasticity model. For example:

```
model y1 y2 = x1 / p=1 q=1;
garch q=1;
```

New Printing Control Options

The PRINT= option can be used in the MODEL statement to control the results printed. See the description of the PRINT= option in Chapter 30, “The VARMAX Procedure,” for details.

X12 Procedure

The X12 procedure has many new statements and options. Many of the new features are related to the regARIMA modeling, which is used to extend the series to be seasonally adjusted. A new experimental input and output data set has been added which describes the times series model fit to the series.

The following miscellaneous statements and options are new:

- The NOINT option on the AUTOMDL statement suppresses the fitting of a constant term in automatically identified models.
- The following tables are now available through the OUTPUT statement: A7, A9, A10, C20, D1, and D7.
- The TABLES statement enables you to display some tables that represent intermediate calculations in the X11 method and that are not displayed by default.

The following statements and options related to the regression component of regARIMA modeling are new:

- The SPAN= option on the OUTLIER statement can be used to limit automatic outlier detection to a subset of the time series observations.
- The following predefined variables have been added to the PREDEFINED option on the REGRESSION statement: EASTER(*value*), SCEASTER(*value*), LABOR(*value*), THANK(*value*), TDSTOCK(*value*), SINCOS(*value* ...).
- User-defined regression variables can be included on the regression model by specifying them in the USERVAR=(*variables*) option in the REGRESSION statement or the INPUT statement.
- Events can be included as user-defined regression variables in the regression model by specifying them in the EVENT statement. SAS predefined events do not require an INEVENT= data set, but an INEVENT= data set can be specified to define other events.
- You can now supply initial or fixed parameter values for regression variables by using the B=(*value* <F> ...) option in the EVENT statement, the B=(*value* <F> ...) option in the INPUT statement, the B=(*value* <F> ...) option in the REGRESSION statement, or by using the MDLINFOIN= data set in the PROC X12 statement. Some regression variable parameters can be fixed while others are estimated.

- You can now assign user-defined regression variables to a group by the **USERTYPE=** option in the **EVENT** statement, the **USERTYPE=** option in the **INPUT** statement, the **USERTYPE=** option in the **REGRESSION** statement, or by using the **MDLINFOIN=** data set in the **PROC X12** statement. Census Bureau predefined variables are automatically assigned to a regression group, and this cannot be modified. But assigning user-defined regression variables to a regression group allows them to be processed similarly to the predefined variables.
- You can now supply initial or fixed parameters for ARMA coefficients using the **MDLINFOIN=** data set in the **PROC X12** statement. Some ARMA coefficients can be fixed while others are estimated.
- The **INEVENT=** option on the **PROC X12** statement enables you to supply an **EVENT** definition data set so that the events defined in the **EVENT** definition data set can be used as user-defined regressors in the **regARIMA** model.
- User-defined regression variables in the input data set can be identified by specifying them in the **USERDEFINED** statement. User-defined regression variables specified in the **USERVAR=(variables)** option of the **REGRESSION** statement or the **INPUT** statement do not need to be specified in the **USERDEFINED** statement, but user-defined variables specified only in the **MDLINFOIN=** data set need to be identified in the **USERDEFINED** statement.

The following new experimental options specify input and output data sets that describe the times series model:

- The **MDLINFOIN=** and **MDLINFOOUT=** data sets specified in the **PROC X12** statement enable you to store the results of model identification and use the stored information as input when executing the **X12** Procedure.

Overview of SAS/ETS Software

SAS/ETS software, a component of the SAS System, provides SAS procedures for:

- econometric analysis
- time series analysis
- time series forecasting
- systems modeling and simulation
- discrete choice analysis
- analysis of qualitative and limited dependent variable models
- seasonal adjustment of time series data
- financial analysis and reporting
- access to economic and financial databases
- time series data management

In addition to SAS procedures, SAS/ETS software also includes seamless access to economic and financial databases and interactive environments for time series forecasting and investment analysis.

Uses of SAS/ETS Software

SAS/ETS software provides tools for a wide variety of applications in business, government, and academia. Major uses of SAS/ETS procedures are economic analysis, forecasting, economic and financial modeling, time series analysis, financial reporting, and manipulation of time series data.

The common theme relating the many applications of the software is time series data: SAS/ETS software is useful whenever it is necessary to analyze or predict processes that take place over time or to analyze models that involve simultaneous relationships.

Although SAS/ETS software is most closely associated with business, finance and economics, time series data also arise in many other fields. SAS/ETS software is useful whenever time dependencies, simultaneous relationships, or dynamic processes complicate data analysis. For example, an environmental quality study might use SAS/ETS software's time series analysis tools to analyze pollution emissions data. A pharmacokinetic study might use SAS/ETS software's features for nonlinear systems to model the dynamics of drug metabolism in different tissues.

The diversity of problems for which econometrics and time series analysis tools are needed is reflected in the applications reported by SAS users. The following listed items are some applications of SAS/ETS software presented by SAS users at past annual conferences of the SAS Users Group International (SUGI).

- forecasting college enrollment (Calise and Earley 1997)
- fitting a pharmacokinetic model (Morelock et al. 1995)
- testing interaction effect in reducing sudden infant death syndrome (Fleming, Gibson, and Fleming 1996)
- forecasting operational indices to measure productivity changes (McCarty 1994)
- spectral decomposition and reconstruction of nuclear plant signals (Hoyer and Gross 1993)
- estimating parameters for the constant-elasticity-of-substitution translog model (Hisnanick 1993)
- applying econometric analysis for mass appraisal of real property (Amal and Weselowski 1993)
- forecasting telephone usage data (Fishetti, Heathcote, and Perry 1993)
- forecasting demand and utilization of inpatient hospital services (Hisnanick 1992)
- using conditional demand estimation to determine electricity demand (Keshani and Taylor 1992)
- estimating tree biomass for measurement of forestry yields (Parresol and Thomas 1991)
- evaluating the theory of input separability in the production function of U.S. manufacturing (Hisnanick 1991)

- forecasting dairy milk yields and composition (Benseman 1990)
- predicting the gloss of coated aluminum products subject to weathering (Khan 1990)
- learning curve analysis for predicting manufacturing costs of aircraft (Le Bouton 1989)
- analyzing Dow Jones stock index trends (Early, Sweeney, and Zekavat 1989)
- analyzing the usefulness of the composite index of leading economic indicators for forecasting the economy (Lin and Myers 1988)

Contents of SAS/ETS Software

Procedures

SAS/ETS software includes the following SAS procedures:

ARIMA	ARIMA (Box-Jenkins) and ARIMAX (Box-Tiao) modeling and forecasting
AUTOREG	regression analysis with autocorrelated or heteroscedastic errors and ARCH and GARCH modeling
COMPUTAB	spreadsheet calculations and financial report generation
COUNTREG	regression modeling for dependent variables that represent counts
DATASOURCE	access to financial and economic databases
ENTROPY	maximum entropy-based regression
ESM	forecasting by using exponential smoothing models with optimized smoothing weights
EXPAND	time series interpolation, frequency conversion, and transformation of time series
FORECAST	automatic forecasting
LOAN	loan analysis and comparison
MDC	multinomial discrete choice analysis
MODEL	nonlinear simultaneous equations regression and nonlinear systems modeling and simulation
PANEL	panel data models
PDLREG	polynomial distributed lag regression
QLIM	qualitative and limited dependent variable analysis
SIMILARITY	similarity analysis of time series data for time series data mining
SIMLIN	linear systems simulation
SPECTRA	spectral and cross-spectral analysis
STATESPACE	state space modeling and automated forecasting of multivariate time series
SYSLIN	linear simultaneous equations models

TIMESERIES	analysis of time-stamped transactional data
TSCSREG	time series cross-sectional regression analysis
UCM	unobserved components analysis of time series
VARMAX	vector autoregressive and moving-average modeling and forecasting
X11	seasonal adjustment (Census X-11 and X-11 ARIMA)
X12	seasonal adjustment (Census X-12 ARIMA)

Macros

SAS/ETS software includes the following SAS macros:

%AR	generates statements to define autoregressive error models for the MODEL procedure
%BOXCOXAR	investigates Box-Cox transformations useful for modeling and forecasting a time series
%DFPVALUE	computes probabilities for Dickey-Fuller test statistics
%DFTEST	performs Dickey-Fuller tests for unit roots in a time series process
%LOGTEST	tests to determine whether a log transformation is appropriate for modeling and forecasting a time series
%MA	generates statements to define moving-average error models for the MODEL procedure
%PDL	generates statements to define polynomial distributed lag models for the MODEL procedure

These macros are part of the SAS AUTOCALL facility and are automatically available for use in your SAS program. Refer to *SAS Macro Language: Reference* for information about the SAS macro facility.

Access Interfaces to Economic and Financial Databases

In addition to PROC DATASOURCE, these SAS/ETS access interfaces provide seamless access to financial and economic databases:

SASECRSP	LIBNAME engine for accessing time series and event data residing in CRSPAccess database.
SASEFAME	LIBNAME engine for accessing time or case series data residing in a FAME database.
SASEHAVR	LIBNAME engine for accessing time series residing in a HAVER ANALYTICS Data Link Express (DLX) database.

The Time Series Forecasting System

SAS/ETS software includes an interactive forecasting system, described in *Part IV*. This graphical user interface to SAS/ETS forecasting features was developed with SAS/AF software and uses PROC ARIMA and other internal routines to perform time series forecasting. The [Time Series Forecasting System](#) makes it easy to forecast time series and provides many features for graphical data exploration and graphical comparisons of forecasting models and forecasts. (You must have SAS/GRAPH[®] installed to use the graphical features of the system.)

The Investment Analysis System

The [Investment Analysis System](#), described in *Part V*, is an interactive environment for analyzing the time-value of money in a variety of investments. Various analyses are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and break-even analysis.

Experimental Software

Experimental software is sometimes included as part of a production-release product. It is provided to (sometimes targeted) customers in order to obtain feedback. All experimental uses are marked Experimental in this document. Whenever an experimental procedure, statement, or option is used, a message is printed to the SAS log to indicate that it is experimental.

The design and syntax of experimental software might change before any production release. Experimental software has been tested prior to release, but it has not necessarily been tested to production-quality standards, and so should be used with care.

About This Book

This book is a user's guide to SAS/ETS software. Since SAS/ETS software is a part of the SAS System, this book assumes that you are familiar with Base SAS software and have the books *SAS Language Reference: Dictionary* and *Base SAS Procedures Guide* available for reference. It also assumes that you are familiar with SAS data sets, the SAS DATA step, and with basic SAS procedures such as PROC PRINT and PROC SORT. Chapter 3, "[Working with Time Series Data](#)," in this book summarizes the aspects of Base SAS software that are most relevant to the use of SAS/ETS software.

Chapter Organization

Following a brief [What's New](#), this book is divided into five major parts. *Part I* contains general information to aid you in working with SAS/ETS Software. *Part II* explains the SAS procedures of SAS/ETS software. *Part III* describes the available data access interfaces for economic and financial databases. *Part IV* is the reference for the Time Series Forecasting System, an interactive forecasting menu system that uses PROC ARIMA and other routines to perform time series forecasting. Finally, *Part V* is the reference for the [Investment Analysis System](#).

The new features added to SAS/ETS software since the publication of *SAS/ETS Software: Changes and Enhancements for Release 8.2* are summarized in Chapter 1, “[What's New in SAS/ETS](#).” If you have used SAS/ETS software in the past, you may want to skim this chapter to see what's new.

Part I contains the following chapters.

[Chapter 2](#), the current chapter, provides an overview of SAS/ETS software and summarizes related SAS publications, products, and services.

[Chapter 3](#), “[Working with Time Series Data](#),” discusses the use of SAS data management and programming features for time series data.

[Chapter 4](#), “[Date Intervals, Formats, and Functions](#),” summarizes the time intervals, date and datetime informats, date and datetime formats, and date and datetime functions available in the SAS System.

[Chapter 5](#), “[SAS Macros and Functions](#),” documents SAS macros and DATA step financial functions provided with SAS/ETS software. The macros use SAS/ETS procedures to perform Dickey-Fuller tests, test for the need for log transformations, or select optimal Box-Cox transformation parameters for time series data.

[Chapter 6](#), “[Nonlinear Optimization Methods](#),” documents the NonLinear Optimization subsystem used by some ETS procedures to perform nonlinear optimization tasks.

Part II contains chapters that explain the SAS procedures that make up SAS/ETS software. These chapters appear in alphabetical order by procedure name.

Part III contains chapters that document the ETS access interfaces to economic and financial databases.

Each of the chapters that document the SAS/ETS procedures (*Part II*) and the SAS/ETS access interfaces (*Part III*) is organized as follows:

1. The “Overview” section gives a brief description of the procedure.
2. The “Getting Started” section provides a tutorial introduction on how to use the procedure.
3. The “Syntax” section is a reference to the SAS statements and options that control the procedure.
4. The “Details” section discusses various technical details.
5. The “Examples” section contains examples of the use of the procedure.

6. The “References” section contains technical references on methodology.

Part IV contains the chapters that document the features of the [Time Series Forecasting System](#).

Part V contains chapters that document the features of the [Investment Analysis System](#).

Typographical Conventions

This book uses several type styles for presenting information. The following list explains the meaning of the typographical conventions used in this book:

roman	is the standard type style used for most text.
UPPERCASE ROMAN	is used for SAS statements, options, and other SAS language elements when they appear in the text. However, you can enter these elements in your own SAS programs in lowercase, uppercase, or a mixture of the two.
UPPERCASE BOLD	is used in the “Syntax” sections’ initial lists of SAS statements and options.
<i>oblique</i>	is used for user-supplied values for options in the syntax definitions. In the text, these values are written in <i>italic</i> .
helvetica	is used for the names of variables and data sets when they appear in the text.
bold	is used to refer to matrices and vectors and to refer to commands.
<i>italic</i>	is used for terms that are defined in the text, for emphasis, and for references to publications.
bold monospace	is used for example code. In most cases, this book uses lowercase type for SAS statements.

Where to Turn for More Information

This section describes other sources of information about SAS/ETS software.

Accessing the SAS/ETS Sample Library

The SAS/ETS Sample Library includes many examples that illustrate the use of SAS/ETS software, including the examples used in this documentation. To access these sample programs, select **Help** from the menu and then select **SAS Help and Documentation**. From the **Contents** list, select the section **Sample SAS Programs** under **Learning to Use SAS**.

Online Help System

You can access online help information about SAS/ETS software in two ways, depending on whether you are using the SAS windowing environment in the command line mode or the pull-down menu mode.

If you are using a command line, you can access the SAS/ETS help menus by typing **help** on the SAS windowing environment command line. Or you can issue the command **help ARIMA** (or another procedure name) to display the help for that particular procedure.

If you are using the SAS windowing environment pull-down menus, you can pull-down the **Help** menu and make the following selections:

- **SAS Help and Documentation**
- **Learning to Use SAS** in the Contents list
- **SAS Products**
- **SAS/ETS**

The content of the Online Help System follows closely that of this book.

SAS Short Courses

The SAS Education Division offers a number of training courses that might be of interest to SAS/ETS users. Please check the SAS web site for the current list of available training courses.

SAS Technical Support Services

As with all SAS products, the SAS Technical Support staff is available to respond to problems and answer technical questions regarding the use of SAS/ETS software.

Major Features of SAS/ETS Software

The following sections briefly summarize major features of SAS/ETS software. See the chapters on individual procedures for more detailed information.

Discrete Choice and Qualitative and Limited Dependent Variable Analysis

The **MDC** procedure provides maximum likelihood (ML) or simulated maximum likelihood estimates of multinomial discrete choice models in which the choice set consists of unordered multiple alternatives.

The MDC procedure supports the following models and features:

- conditional logit
- nested logit
- heteroscedastic extreme value
- multinomial probit
- mixed logit
- pseudo-random or quasi-random numbers for simulated maximum likelihood estimation
- bounds imposed on the parameter estimates
- linear restrictions imposed on the parameter estimates
- SAS data set containing predicted probabilities and linear predictor ($\mathbf{x}'\boldsymbol{\beta}$) values
- decision tree and nested logit
- model fit and goodness-of-fit measures including
 - likelihood ratio
 - Aldrich-Nelson
 - Cragg-Uhler 1
 - Cragg-Uhler 2
 - Estrella
 - Adjusted Estrella
 - McFadden's LRI
 - Veall-Zimmermann
 - Akaike Information Criterion (AIC)
 - Schwarz Criterion or Bayesian Information Criterion (BIC)

The **QLIM** procedure analyzes univariate and multivariate limited dependent variable models where dependent variables take discrete values or dependent variables are observed only in a limited range of values. This procedure includes logit, probit, Tobit, and general simultaneous equations models. The QLIM procedure supports the following models:

- linear regression model with heteroscedasticity
- probit with heteroscedasticity
- logit with heteroscedasticity
- Tobit (censored and truncated) with heteroscedasticity
- Box-Cox regression with heteroscedasticity
- bivariate probit
- bivariate Tobit
- sample selection models
- multivariate limited dependent models

The **COUNTREG** procedure provides regression models in which the dependent variable takes nonnegative integer count values. The COUNTREG procedure supports the following models:

- Poisson regression
- negative binomial regression with quadratic and linear variance functions
- zero inflated Poisson (ZIP) model
- zero inflated negative binomial (ZINB) model
- fixed and random effect Poisson panel data models
- fixed and random effect NB (negative binomial) panel data models

The **PANEL** procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

The models and methods the PANEL procedure uses to analyze are as follows:

- one-way and two-way models
- fixed and random effects
- autoregressive models
 - the Parks method
 - dynamic panel estimator
 - the Da Silva method for moving-average disturbances

Regression with Autocorrelated and Heteroscedastic Errors

The **AUTOREG** procedure provides regression analysis and forecasting of linear models with autocorrelated or heteroscedastic errors. The **AUTOREG** procedure includes the following features:

- estimation and prediction of linear regression models with autoregressive errors
- any order autoregressive or subset autoregressive process
- optional stepwise selection of autoregressive parameters
- choice of the following estimation methods:
 - exact maximum likelihood
 - exact nonlinear least squares
 - Yule-Walker
 - iterated Yule-Walker
- tests for any linear hypothesis that involves the structural coefficients
- restrictions for any linear combination of the structural coefficients
- forecasts with confidence limits
- estimation and forecasting of ARCH (autoregressive conditional heteroscedasticity), GARCH (generalized autoregressive conditional heteroscedasticity), I-GARCH (integrated GARCH), E-GARCH (exponential GARCH), and GARCH-M (GARCH in mean) models
- combination of ARCH and GARCH models with autoregressive models, with or without regressors
- estimation and testing of general heteroscedasticity models
- variety of model diagnostic information including the following:
 - autocorrelation plots
 - partial autocorrelation plots
 - Durbin-Watson test statistic and generalized Durbin-Watson tests to any order
 - Durbin h and Durbin t statistics
 - Akaike information criterion
 - Schwarz information criterion
 - tests for ARCH errors
 - Ramsey's RESET test
 - Chow and PChow tests
 - Phillips-Perron stationarity test
 - CUSUM and CUMSUMSQ statistics
- exact significance levels (p -values) for the Durbin-Watson statistic
- embedded missing values

Simultaneous Systems Linear Regression

The **SYSLIN** and **ENTROPY** procedures provide regression analysis of a simultaneous system of linear equations.

The **SYSLIN** procedure includes the following features:

- estimation of parameters in simultaneous systems of linear equations
- full range of estimation methods including the following:
 - ordinary least squares (OLS)
 - two-stage least squares (2SLS)
 - three-stage least squares (3SLS)
 - iterated 3SLS (IT3SLS)
 - seemingly unrelated regression (SUR)
 - iterated SUR (ITSUR)
 - limited-information maximum likelihood (LIML)
 - full-information maximum likelihood (FIML)
 - minimum expected loss (MELO)
 - general K-class estimators
- weighted regression
- any number of restrictions for any linear combination of coefficients, within a single model or across equations
- tests for any linear hypothesis, for the parameters of a single model or across equations
- wide range of model diagnostics and statistics including the following:
 - usual ANOVA tables and R-square statistics
 - Durbin-Watson statistics
 - standardized coefficients
 - test for overidentifying restrictions
 - residual plots
 - standard errors and *t* tests
 - covariance and correlation matrices of parameter estimates and equation errors
- predicted values, residuals, parameter estimates, and variance-covariance matrices saved in output SAS data sets
- other features of the **SYSLIN** procedure that enable you to do the following:
 - impose linear restrictions on the parameter estimates

- test linear hypotheses about the parameters
- write predicted and residual values to an output SAS data set
- write parameter estimates to an output SAS data set
- write the crossproducts matrix (SSCP) to an output SAS data set
- use raw data, correlations, covariances, or cross products as input

The **ENTROPY** procedure supports the following models and features:

- generalized maximum entropy (GME) estimation
- generalized cross entropy (GCE) estimation
- normed moment generalized maximum entropy
- maximum entropy-based seemingly unrelated regression (MESUR) estimation
- pure inverse estimation
- estimation of parameters in simultaneous systems of linear equations
- Markov models
- unordered multinomial choice problems
- weighted regression
- any number of restrictions for any linear combination of coefficients, within a single model or across equations
- tests for any linear hypothesis, for the parameters of a single model or across equations

Linear Systems Simulation

The **SIMLIN** procedure performs simulation and multiplier analysis for simultaneous systems of linear regression models. The **SIMLIN** procedure includes the following features:

- reduced form coefficients
- interim multipliers
- total multipliers
- dynamic multipliers
- multipliers for higher order lags
- dynamic forecasts and simulations
- goodness-of-fit statistics
- acceptance of the equation system coefficients estimated by the **SYSLIN** procedure as input

Polynomial Distributed Lag Regression

The **PDLREG** procedure provides regression analysis for linear models with polynomial distributed (Almon) lags. The PDLREG procedure includes the following features:

- entry of any number of regressors as a polynomial lag distribution and the use of any number of covariates
- use of any order lag length and degree polynomial for lag distribution
- optional upper and lower endpoint restrictions
- specification of any number of linear restrictions on covariates
- option to repeat analysis over a range of degrees for the lag distribution polynomials
- support for autoregressive errors to any lag
- forecasts with confidence limits

Nonlinear Systems Regression and Simulation

The **MODEL** procedure provides parameter estimation, simulation, and forecasting of dynamic nonlinear simultaneous equation models. The MODEL procedure includes the following features:

- nonlinear regression analysis for systems of simultaneous equations, including weighted nonlinear regression
- full range of parameter estimation methods including the following:
 - nonlinear ordinary least squares (OLS)
 - nonlinear seemingly unrelated regression (SUR)
 - nonlinear two-stage least squares (2SLS)
 - nonlinear three-stage least squares (3SLS)
 - iterated SUR
 - iterated 3SLS
 - generalized method of moments (GMM)
 - nonlinear full-information maximum likelihood (FIML)
 - simulated method of moments (SMM)
- supports dynamic multi-equation nonlinear models of any size or complexity
- uses the full power of the SAS programming language for model definition, including left-hand-side expressions

- hypothesis tests of nonlinear functions of the parameter estimates
- linear and nonlinear restrictions of the parameter estimates
- bounds imposed on the parameter estimates
- computation of estimates and standard errors of nonlinear functions of the parameter estimates
- estimation and simulation of ordinary differential equations (ODE's)
- vector autoregressive error processes and polynomial lag distributions easily specified for the nonlinear equations
- variance modeling (ARCH, GARCH, and others)
- computation of goal-seeking solutions of nonlinear systems to find input values needed to produce target outputs
- dynamic, static, or n -period-ahead-forecast simulation modes
- simultaneous solution or single equation solution modes
- Monte Carlo simulation using parameter estimate covariance and across-equation residuals covariance matrices or user-specified random functions
- a variety of diagnostic statistics including the following
 - model R-square statistics
 - general Durbin-Watson statistics and exact p -values
 - asymptotic standard errors and t tests
 - first-stage R-square statistics
 - covariance estimates
 - collinearity diagnostics
 - simulation goodness-of-fit statistics
 - Theil inequality coefficient decompositions
 - Theil relative change forecast error measures
 - heteroscedasticity tests
 - Godfrey test for serial correlation
 - Hausman specification test
 - Chow tests
- block structure and dependency structure analysis for the nonlinear system
- listing and cross-reference of fitted model
- automatic calculation of needed derivatives by using exact analytic formula
- efficient sparse matrix methods used for model solution; choice of other solution methods

Model definition, parameter estimation, simulation, and forecasting can be performed interactively in a single SAS session or models can also be stored in files and reused and combined in later runs.

ARIMA (Box-Jenkins) and ARIMAX (Box-Tiao) Modeling and Forecasting

The **ARIMA** procedure provides the identification, parameter estimation, and forecasting of autoregressive integrated moving-average (Box-Jenkins) models, seasonal ARIMA models, transfer function models, and intervention models. The ARIMA procedure includes the following features:

- complete ARIMA (Box-Jenkins) modeling with no limits on the order of autoregressive or moving-average processes
- model identification diagnostics including the following:
 - autocorrelation function
 - partial autocorrelation function
 - inverse autocorrelation function
 - cross-correlation function
 - extended sample autocorrelation function
 - minimum information criterion for model identification
 - squared canonical correlations
- stationarity tests
- outlier detection
- intervention analysis
- regression with ARMA errors
- transfer function modeling with fully general rational transfer functions
- seasonal ARIMA models
- ARIMA model-based interpolation of missing values
- several parameter estimation methods including the following:
 - exact maximum likelihood
 - conditional least squares
 - exact nonlinear unconditional least squares (ELS or ULS)
- prewhitening transformations
- forecasts and confidence limits for all models
- forecasting tied to parameter estimation methods: finite memory forecasts for models estimated by maximum likelihood or exact nonlinear least squares methods and infinite memory forecasts for models estimated by conditional least squares
- diagnostic statistics to help judge the adequacy of the model including the following:

- Akaike’s information criterion (AIC)
- Schwarz’s Bayesian criterion (SBC or BIC)
- Box-Ljung chi-square test statistics for white-noise residuals
- autocorrelation function of residuals
- partial autocorrelation function of residuals
- inverse autocorrelation function of residuals
- automatic outlier detection

Vector Time Series Analysis

The **VARMAX** procedure enables you to model the dynamic relationship both between the dependent variables and between the dependent and independent variables. The VARMAX procedure includes the following features:

- several modeling features:
 - vector autoregressive model
 - vector autoregressive model with exogenous variables
 - vector autoregressive and moving-average model
 - Bayesian vector autoregressive model
 - vector error correction model
 - Bayesian vector error correction model
 - GARCH-type multivariate conditional heteroscedasticity models
- criteria for automatically determining AR and MA orders:
 - Akaike information criterion (AIC)
 - corrected AIC (AICC)
 - Hannan-Quinn (HQ) criterion
 - final prediction error (FPE)
 - Schwarz Bayesian criterion (SBC), also known as Bayesian information criterion (BIC)
- AR order identification aids:
 - partial cross-correlations
 - Yule-Walker estimates
 - partial autoregressive coefficients
 - partial canonical correlations
- testing the presence of unit roots and cointegration:
 - Dickey-Fuller tests

- Johansen cointegration test for nonstationary vector processes of integrated order one
- Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
- Johansen cointegration test for nonstationary vector processes of integrated order two
- model parameter estimation methods:
 - least squares (LS)
 - maximum likelihood (ML)
- model checks and residual analysis using the following tests:
 - Durbin-Watson (DW) statistics
 - F test for autoregressive conditional heteroscedastic (ARCH) disturbance
 - F test for AR disturbance
 - Jarque-Bera normality test
 - Portmanteau test
- seasonal deterministic terms
- subset models
- multiple regression with distributed lags
- dead-start model that does not have present values of the exogenous variables
- Granger-causal relationships between two distinct groups of variables
- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle
- contemporaneous relationships among the components of the vector time series
- forecasts
- conditional covariances for GARCH models

State Space Modeling and Forecasting

The `STATESPACE` procedure provides automatic model selection, parameter estimation, and forecasting of state space models. (*State space models* encompass an alternative general formulation of multivariate ARIMA models.) The `STATESPACE` procedure includes the following features:

- multivariate ARIMA modeling by using the general state space representation of the stochastic process
- automatic model selection using Akaike's information criterion (AIC)
- user-specified state space models including restrictions
- transfer function models with random inputs
- any combination of simple and seasonal differencing; input series can be differenced to any order for any lag lengths
- forecasts with confidence limits
- ability to save selected and fitted model in a data set and reuse for forecasting
- wide range of output options including the ability to print any statistics concerning the data and their covariance structure, the model selection process, and the final model fit

Spectral Analysis

The **SPECTRA** procedure provides spectral analysis and cross-spectral analysis of time series. The **SPECTRA** procedure includes the following features:

- efficient calculation of periodogram and smoothed periodogram using fast finite Fourier transform and Chirp-Z algorithms
- multiple spectral analysis, including raw and smoothed spectral and cross-spectral function estimates, with user-specified window weights
- choice of kernel for smoothing
- output of the following spectral estimates to a SAS data set:
 - Fourier sine and cosine coefficients
 - periodogram
 - smoothed periodogram
 - cospectrum
 - quadrature spectrum
 - amplitude
 - phase spectrum
 - squared coherency
- Fisher's Kappa and Bartlett's Kolmogorov-Smirnov test statistic for testing a null hypothesis of white noise

Seasonal Adjustment

The **X11** procedure provides seasonal adjustment of time series by using the Census X-11 or X-11 ARIMA method. The X11 procedure is based on the U.S. Bureau of the Census X-11 seasonal adjustment program and also supports the X-11 ARIMA method developed by Statistics Canada. The X11 procedure includes the following features:

- decomposition of monthly or quarterly series into seasonal, trend, trading day, and irregular components
- both multiplicative and additive form of the decomposition
- all the features of the Census Bureau program
- support of the X-11 ARIMA method
- support of sliding spans analysis
- processing of any number of variables at once with no maximum length for a series
- computation of tests for stable, moving, and combined seasonality
- optional printing or storing in SAS data sets of the individual X11 tables that show the various components at different stages of the computation; full control over what is printed or output
- ability to project seasonal component one year ahead, which enables reintroduction of seasonal factors for an extrapolated series

The **X12** procedure provides seasonal adjustment of time series using the X-12 ARIMA method. The X12 procedure is based on the U.S. Bureau of the Census X-12 ARIMA seasonal adjustment program (version 0.3). It also supports the X-11 ARIMA method developed by Statistics Canada and the previous X-11 method of the U.S. Census Bureau. The X12 procedure includes the following features:

- decomposition of monthly or quarterly series into seasonal, trend, trading day, and irregular components
- support of multiplicative, additive, pseudo-additive, and log additive forms of decomposition
- support of the X-12 ARIMA method
- support of regARIMA modeling
- automatic identification of outliers
- support of TRAMO-based automatic model selection
- use of regressors to process missing values within the span of the series
- processing of any number of variables at once with no maximum length for a series

- computation of tests for stable, moving, and combined seasonality
- spectral analysis of original, seasonally adjusted, and irregular series
- optional printing or storing in a SAS data set of the individual X11 tables that show the various components at different stages of the decomposition; full control over what is printed or output
- optional projection of seasonal component one year ahead, which enables reintroduction of seasonal factors for an extrapolated series

Structural Time Series Modeling and Forecasting

The **UCM** procedure provides a flexible environment for analyzing time series data using structural time series models, also called unobserved components models (UCM). These models represent the observed series as a sum of suitably chosen components such as trend, seasonal, cyclical, and regression effects. You can use the UCM procedure to formulate comprehensive models that bring out all the salient features of the series under consideration. Structural models are applicable in the same situations where Box-Jenkins ARIMA models are applicable; however, the structural models tend to be more informative about the underlying stochastic structure of the series. The UCM procedure includes the following features:

- general unobserved components modeling where the models can include trend, multiple seasons and cycles, and regression effects
- maximum-likelihood estimation of the model parameters
- model diagnostics that include a variety of goodness-of-fit statistics, and extensive graphical diagnosis of the model residuals
- forecasts and confidence limits for the series and all the model components
- Model-based seasonal decomposition
- extensive plotting capability that includes the following:
 - forecast and confidence interval plots for the series and model components such as trend, cycles, and seasons
 - diagnostic plots such as residual plot, residual autocorrelation plots, and so on
 - seasonal decomposition plots such as trend, trend plus cycles, trend plus cycles plus seasons, and so on
- model-based interpolation of series missing values
- full sample (also called smoothed) estimates of the model components

Time Series Cross-Sectional Regression Analysis

The **TSCSREG** procedure provides combined time series cross-sectional regression analysis. The TSCSREG procedure includes the following features:

- estimation of the regression parameters under several common error structures:
 - Fuller and Battese method (variance component model)
 - Wansbeek-Kapteyn method
 - Parks method (autoregressive model)
 - Da Silva method (mixed variance component moving-average model)
 - one-way fixed effects
 - two-way fixed effects
 - one-way random effects
 - two-way random effects
- any number of model specifications
- unbalanced panel data for the fixed or random-effects models
- variety of estimates and statistics including the following:
 - underlying error components estimates
 - regression parameter estimates
 - standard errors of estimates
 - t -tests
 - R-square statistic
 - correlation matrix of estimates
 - covariance matrix of estimates
 - autoregressive parameter estimate
 - cross-sectional components estimates
 - autocovariance estimates
 - F tests of linear hypotheses about the regression parameters
 - specification tests

Automatic Time Series Forecasting

The **ESM** procedure provides a quick way to generate forecasts for many time series or transactional data in one step by using exponential smoothing methods. All parameters associated with the forecasting model are optimized based on the data.

You can use the following smoothing models:

- simple
- double
- linear
- damped trend
- seasonal
- Winters method (additive and multiplicative)

Additionally, PROC ESM can transform the data before applying the smoothing methods using any of these transformations:

- log
- square root
- logistic
- Box-Cox

In addition to forecasting, the ESM procedure can also produce graphic output.

The ESM procedure can forecast both time series data, whose observations are equally spaced at a specific time interval (for example, monthly, weekly), or transactional data, whose observations are not spaced with respect to any particular time interval. (Internet, inventory, sales, and similar data are typical examples of transactional data. For transactional data, the data are accumulated based on a specified time interval to form a time series.)

The ESM procedure is a replacement for the older FORECAST procedure. ESM is often more convenient to use than PROC FORECAST but it supports only exponential smoothing models.

The **FORECAST** procedure provides forecasting of univariate time series using automatic trend extrapolation. PROC FORECAST is an easy-to-use procedure for automatic forecasting and uses simple popular methods that do not require statistical modeling of the time series, such as exponential smoothing, time trend with autoregressive errors, and the Holt-Winters method.

The FORECAST procedure supplements the powerful forecasting capabilities of the econometric and time series analysis procedures described previously. You can use PROC FORECAST when you have many series to forecast and you want to extrapolate trends without developing a model for each series.

The FORECAST procedure includes the following features:

- choice of the following forecasting methods:
 - EXPO method—exponential smoothing: single, double, triple, or Holt two-parameter smoothing
 - exponential smoothing as an ARIMA Model

- WINTERS method—using updating equations similar to exponential smoothing to fit model parameters
 - ADDWINTERS method—like the WINTERS method except that the seasonal parameters are added to the trend instead of multiplied with the trend
 - STEPAR method—stepwise autoregressive models with constant, linear, or quadratic trend and autoregressive errors to any order
 - Holt-Winters forecasting method with constant, linear, or quadratic trend
 - additive variant of the Holt-Winters method
- support for up to three levels of seasonality for Holt-Winters method: time-of-year, day-of-week, or time-of-day
 - ability to forecast any number of variables at once
 - forecast confidence limits for all methods

Time Series Interpolation and Frequency Conversion

The **EXPAND** procedure provides time interval conversion and missing value interpolation for time series. The EXPAND procedure includes the following features:

- conversion of time series frequency; for example, constructing quarterly estimates from annual series or aggregating quarterly values to annual values
- conversion of irregular observations to periodic observations
- interpolation of missing values in time series
- conversion of observation types; for example, estimate stocks from flows and vice versa. All possible conversions are supported between any of the following:
 - beginning of period
 - end of period
 - period midpoint
 - period total
 - period average
- conversion of time series phase shift; for example, conversion between fiscal years and calendar years
- identifying observations including the following:
 - identification of the time interval of the input values
 - validation of the input data set observations
 - computation of the ID values for the observations in the output data set

- choice of four interpolation methods:
 - cubic splines
 - linear splines
 - step functions
 - simple aggregation
- ability to perform extrapolation by a linear projection of the trend of the cubic spline curve fit to the input data
- ability to transform series before and after interpolation (or without interpolation) by using any of the following:
 - constant shift or scale
 - sign change or absolute value
 - logarithm, exponential, square root, square, logistic, inverse logistic
 - lags, leads, differences
 - classical decomposition
 - bounds, trims, reverse series
 - centered moving, cumulative, or backward moving average
 - centered moving, cumulative, or backward moving range
 - centered moving, cumulative, or backward moving geometric mean
 - centered moving, cumulative, or backward moving maximum
 - centered moving, cumulative, or backward moving median
 - centered moving, cumulative, or backward moving minimum
 - centered moving, cumulative, or backward moving product
 - centered moving, cumulative, or backward moving corrected sum of squares
 - centered moving, cumulative, or backward moving uncorrected sum of squares
 - centered moving, cumulative, or backward moving rank
 - centered moving, cumulative, or backward moving standard deviation
 - centered moving, cumulative, or backward moving sum
 - centered moving, cumulative, or backward moving median
 - centered moving, cumulative, or backward moving t -value
 - centered moving, cumulative, or backward moving variance
- support for a wide range of time series frequencies:
 - YEAR
 - SEMIYEAR
 - QUARTER
 - MONTH
 - SEMIMONTH

- TENDAY
 - WEEK
 - WEEKDAY
 - DAY
 - HOUR
 - MINUTE
 - SECOND
- support for repeating or shifting the basic interval types to define a great variety of different frequencies, such as fiscal years, biennial periods, work shifts, and so forth

Refer to Chapter 3, “[Working with Time Series Data](#),” and Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about time series data transformations.

Trend and Seasonal Analysis on Transaction Databases

The `TIMESERIES` procedure can accumulate transactional data to time series and perform trend and seasonal analysis on the accumulated time series.

Time series analyses performed by the `TIMESERIES` procedure include the follows:

- descriptive statistics relevant for time series data
- seasonal decomposition and seasonal adjustment analysis
- correlation analysis
- cross-correlation analysis

The `TIMESERIES` procedure includes the following features:

- ability to process large amounts of time-stamped transactional data
- statistical methods useful for large-scale time series analysis or (temporal) data mining
- output data sets stored in either a time series format (default) or a coordinate format (transposed)

The `TIMESERIES` procedure is normally used to prepare data for subsequent analysis that uses other SAS/ETS procedures or other parts of the SAS system. The time series format is most useful when the data are to be analyzed with SAS/ETS procedures. The coordinate format is most useful when the data are to be analyzed with SAS/STAT[®] procedures or SAS Enterprise Miner[™]. (For example, clustering time-stamped transactional data can be achieved by using the results of `TIMESERIES` procedure with the clustering procedures of SAS/STAT and the nodes of SAS Enterprise Miner.)

Access to Financial and Economic Databases

The `DATASOURCE` procedure and the SAS/ETS data access interface LIBNAME Engines (`SASECRSP`, `SASEFAME` and `SASEHAVR`) provide seamless, efficient access to time series data from data files supplied by a variety of commercial and governmental data vendors.

The `DATASOURCE` procedure includes the following features:

- support for data files distributed by the following data vendors:
 - DRI/McGraw-Hill
 - FAME Information Services
 - HAVER ANALYTICS
 - Standard & Poors Compustat Service
 - Center for Research in Security Prices (CRSP)
 - International Monetary Fund
 - U.S. Bureau of Labor Statistics
 - U.S. Bureau of Economic Analysis
 - Organization for Economic Cooperation and Development (OECD)
- ability to select the series, frequency, time range, and cross sections of extracted data
- ability to create an output data set containing descriptive information on the series available in the data file
- ability to read EBCDIC data on ASCII systems and vice versa

The `SASECRSP` interface LIBNAME engine includes the following features:

- enables random access to time series data residing in CRSPAccess databases
- provides a seamless interface between CRSP and SAS data processing
- uses the LIBNAME statement to enable you to specify which time series you would like to read from the CRSPAccess database, and how you would like to perform selection
- enables you access to CRSP Stock, CRSP/COMPUSTAT Merged (CCM) or CRSP Indices Data.
- provides convenient formats, informats, and functions for CRSP and SAS datetime conversions

The `SASEFAME` interface LIBNAME engine includes the following features:

- provides SAS and FAME users flexibility in accessing and processing time series data, case series, and formulas that reside in either a FAME database or a SAS data set

- provides a seamless interface between FAME and SAS data processing
- uses the LIBNAME statement to enable you to specify which time series you would like to read from the FAME database
- enables you to convert the selected time series to the same time scale
- works with the SAS DATA step to perform further subsetting and to store the resulting time series into a SAS data set
- performs more analysis if desired either in the same SAS session or in another session at a later time
- supports the FAME CROSSLIST function for subsetting via BYGROUPS using the CROSSLIST= option
 - you can use a FAME namelist that contains your BY variables for selection in the CROSSLIST
 - you can use a SAS input dataset, INSET, that contains the BY selection variables along with the WHERE= option in your SASEFAME libref
- supports the use of FAME in a client/server environment that uses the FAME CHLI capability on your FAME server
- enables access to your FAME remote data when you specify the port number of the TCP/IP service that is defined for your FAME server and the node name of your FAME master server in your SASEFAME libref's physical path

The [SASEHAVR](#) interface LIBNAME engine includes the following features:

- enables Windows users random access to economic and financial data residing in a HAVER ANALYTICS Data Link Express (DLX) database
- the following types of HAVER data sets are available:
 - United States Economic Indicators
 - Specialized Databases
 - Financial Indicators
 - Industry
 - Industrial Countries
 - Emerging Markets
 - International Organizations
 - Forecasts and As Reported Data
 - United States Regional
- enables you to limit the range of data that is read from the time series
- enables you to specify a desired conversion frequency. Start dates are recommended on the LIBNAME statement to help you save resources when processing large databases or when processing a large number of observations.

- enables you to use the WHERE, KEEP, or DROP statements in your DATA step to further subset your data
- supports use of the SQL procedure to create a view of your resulting SAS data set

Spreadsheet Calculations and Financial Report Generation

The **COMPUTAB** procedure generates tabular reports using a programmable data table.

The **COMPUTAB** procedure is especially useful when you need both the power of a programmable spreadsheet and a report-generation system and you want to set up a program to run in batch mode and generate routine reports. The **COMPUTAB** procedure includes the following features:

- report generation facility for creating tabular reports such as income statements, balance sheets, and other row and column reports for analyzing business or time series data
- ability to tailor report format to almost any desired specification
- use of the SAS programming language to provide complete control of the calculation and format of each item of the report
- ability to report definition in terms of a data table on which programming statements operate
- ability for a single reference to a row or column to bring the entire row or column into a calculation
- ability to create new rows and columns (such as totals, subtotals, and ratios) with a single programming statement
- access to individual table values when needed
- built-in features to provide consolidation reports over summarization variables

Loan Analysis, Comparison, and Amortization

The **LOAN** procedure provides analysis and comparison of mortgages and other installment loans; it includes the following features:

- ability to specify contract terms for any number of different loans and ability to analyze and compare various financing alternatives
- analysis of four different types of loan contracts including the following:
 - fixed rate
 - adjustable rate
 - buy-down rate

- balloon payment
- full control over adjustment terms for adjustable rate loans: life caps, adjustment frequency, and maximum and minimum rates
- support for a wide variety of payment and compounding intervals
- ability to incorporate initialization costs, discount points, down payments, and prepayments (uniform or lump-sum) in loan calculations
- analysis of different rate adjustment scenarios for variable rate loans including the following:
 - worst case
 - best case
 - fixed rate case
 - estimated case
- ability to make loan comparisons at different points in time
- ability to make loan comparisons at each analysis date on the basis of five different economic criteria:
 - present worth of cost (net present value of all payments to date)
 - true interest rate (internal rate of return to date)
 - current periodic payment
 - total interest paid to date
 - outstanding balance
- ability to base loan comparisons on either after-tax or before-tax analysis
- report of the best alternative when loans of equal amount are compared
- amortization schedules for each loan contract
- output that shows payment dates, rather than just payment sequence numbers, when starting date is specified
- optional printing or output of the amortization schedules, loan summaries, and loan comparison information to SAS data sets
- ability to specify rounding of payments to any number of decimal places

Time Series Forecasting System

SAS/ETS software includes the [Time Series Forecasting System](#), a point-and-click application for exploring and analyzing univariate time series data. You can use the automatic model selection facility to select the best-fitting model for each time series, or you can use the system's diagnostic features and time series modeling tools interactively to develop forecasting models customized to

best predict your time series. The system provides both graphical and statistical features to help you choose the best forecasting method for each series.

The system can be invoked by selecting **Analysis►Solutions**, by the FORECAST command, and by clicking the **Forecasting** icon in the Data Analysis folder of the SAS Desktop.

The following is a brief summary of the features of the Time Series Forecasting system. With the system you can:

- use a wide variety of forecasting methods, including several kinds of exponential smoothing models, Winters method, and ARIMA (Box-Jenkins) models. You can also produce forecasts by combining the forecasts from several models.
- use predictor variables in forecasting models. Forecasting models can include time trend curves, regressors, intervention effects (dummy variables), adjustments you specify, and dynamic regression (transfer function) models.
- view plots of the data, predicted versus actual values, prediction errors, and forecasts with confidence limits. You can plot changes or transformations of series, zoom in on parts of the graphs, or plot autocorrelations.
- use hold-out samples to select the best forecasting method
- compare goodness-of-fit measures for any two forecasting models side-by-side or list all models sorted by a particular fit statistic
- view the predictions and errors for each model in a spreadsheet or view and compare the forecasts from any two models in a spreadsheet
- examine the fitted parameters of each forecasting model and their statistical significance
- control the automatic model selection process: the set of forecasting models considered, the goodness-of-fit measure used to select the best model, and the time period used to fit and evaluate models
- customize the system by adding forecasting models for the automatic model selection process and for point-and-click manual selection
- save your work in a project catalog
- print an audit trail of the forecasting process
- save and print system output including spreadsheets and graphs

Investment Analysis System

The [Investment Analysis System](#) is an interactive environment for analyzing the time-value of money for a variety of investments:

- loans

- savings
- depreciations
- bonds
- generic cash flows

Various tools are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and breakeven analysis.

These analyses can help answer a number of questions you might have about your investments:

- Which option is more profitable or less costly?
- Is it better to buy or rent?
- Are the extra fees for refinancing at a lower interest rate justified?
- What is the balance of this account after saving this amount periodically for so many years?
- How much is legally tax-deductible?
- Is this a reasonable price?

Investment Analysis can be beneficial to users in many industries for a variety of decisions:

- manufacturing: cost justification of automation or any capital investment, replacement analysis of major equipment, or economic comparison of alternative designs
- government: setting funds for services
- finance: investment analysis and portfolio management for fixed-income securities

ODS Graphics

Many SAS/ETS procedures produce graphical output using the SAS Output Delivery System (ODS). The ODS Graphics system provides several advantages:

- Plots and graphs are output objects in the Output Delivery System (ODS) and can be manipulated with ODS commands.
- There is no need to write SAS/GRAPH statements or use special plotting macros.
- There are multiple formats to choose from: html, gif, and rtf.
- Templates control the appearance of plots.
- Styles control the color scheme.

- You can edit or create templates and styles for all graphs.

To enable graphical output from SAS/ETS procedures, you must use the following statement in your SAS program.

```
ods graphics on;
```

The graphical output produced by many SAS/ETS procedures can be controlled using the PLOTS= option on the PROC statement.

For more information about the features of the ODS Graphics system, including the many ways that you can control or customize the plots produced by SAS procedures, refer to Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*). For more information about the SAS Output Delivery system, refer to the *SAS Output Delivery System: User’s Guide*.

Related SAS Software

Many features not found in SAS/ETS software are available in other parts of the SAS System, such as Base SAS[®], SAS[®] Forecast Server, SAS/STAT[®] software, SAS/OR[®] software, SAS/QC[®] software, SAS[®] Stat Studio, and SAS/IML[®] software.

If you do not find something you need in SAS/ETS software, you might be able to find it in SAS/STAT software and in Base SAS software. If you still do not find it, look in other SAS software products or contact SAS Technical Support staff.

The following subsections summarize the features of other SAS products that might be of interest to users of SAS/ETS software.

Base SAS Software

The features provided by SAS/ETS software are extensions to the features provided by Base SAS software. Many data management and reporting capabilities you need are part of Base SAS software. Refer to *SAS Language Reference: Dictionary* and *Base SAS Procedures Guide* for documentation of Base SAS software. In particular, refer to *Base SAS Procedures Guide: Statistical Procedures* for information about statistical analysis features included with Base SAS.

The following sections summarize Base SAS software features of interest to users of SAS/ETS software. See Chapter 3, “[Working with Time Series Data](#),” for further discussion of some of these topics as they relate to time series data and SAS/ETS software.

SAS DATA Step

The DATA step is your primary tool for reading and processing data in the SAS System. The DATA step provides a powerful general purpose programming language that enables you to perform all kinds of data processing tasks. The DATA step is documented in *SAS Language Reference: Dictionary*.

Base SAS Procedures

Base SAS software includes many useful SAS procedures, which are documented in *Base SAS Procedures Guide* and *Base SAS Procedures Guide: Statistical Procedures*. The following is a list of Base SAS procedures you might find useful:

CATALOG	for managing SAS catalogs
CHART	for printing charts and histograms
COMPARE	for comparing SAS data sets
CONTENTS	for displaying the contents of SAS data sets
COPY	for copying SAS data sets
CORR	for computing correlations
CPORT	for moving SAS data libraries between computer systems
DATASETS	for deleting or renaming SAS data sets
FCMP	for compiling functions for use in SAS programs. The SAS Function Compiler Procedure (FCMP) enables you to create, test, and store SAS functions and subroutines before you use them in other SAS procedures. PROC FCMP accepts slight variations of DATA step statements, and most features of the SAS programming language can be used in functions and subroutines that are processed by PROC FCMP.
FREQ	for computing frequency crosstabulations
MEANS	for computing descriptive statistics and summarizing or collapsing data over cross sections
PLOT	for printing scatter plots
PRINT	for printing SAS data sets
PROTO	for accessing external functions from the SAS system. The PROTO procedure enables you to register external functions that are written in the C or C++ programming languages. You can use these functions in SAS as well as in C-language structures and types. After the C-language functions are registered in PROC PROTO, they can be called from any SAS function or subroutine that is declared in the FCMP procedure, as well as from any SAS function, subroutine, or method block that is declared in the COMPILE procedure.
RANK	for computing rankings or order statistics
SORT	for sorting SAS data sets

SQL	for processing SAS data sets with Structured Query Language
STANDARD	for standardizing variables to a fixed mean and variance
TABULATE	for printing descriptive statistics in tabular format
TIMEPLOT	for plotting variables over time
TRANSPPOSE	for transposing SAS data sets
UNIVARIATE	for computing descriptive statistics

Global Statements

Global statements can be specified anywhere in your SAS program, and they remain in effect until changed. Global statements are documented in *SAS Language Reference: Dictionary*. You may find the following SAS global statements useful:

FILENAME	for accessing data files
FOOTNOTE	for printing footnote lines at the bottom of each page
%INCLUDE	for including files of SAS statements
LIBNAME	for accessing SAS data libraries
OPTIONS	for setting various SAS system options
QUIT	for ending an interactive procedure step
RUN	for executing the preceding SAS statements
TITLE	for printing title lines at the top of each page
X	for issuing host operating system commands from within your SAS session

Some Base SAS statements can be used with any SAS procedure, including SAS/ETS procedures. These statements are not global, and they affect only the SAS procedure they are used with. These statements are documented in *SAS Language Reference: Dictionary*.

The following Base SAS statements are useful with SAS/ETS procedures:

BY	for computing separate analyses for groups of observations
FORMAT	for assigning formats to variables
LABEL	for assigning descriptive labels to variables
WHERE	for subsetting data to restrict the range of data processed or to select or exclude observations from the analysis

SAS Functions

SAS functions can be used in DATA step programs and in the COMPUTAB and MODEL procedures. The following kinds of functions are available:

- character functions for manipulating character strings

- date and time functions for performing date and calendar calculations
- financial functions for performing financial calculations such as depreciation, net present value, periodic savings, and internal rate of return
- lagging and differencing functions for computing lags and differences
- mathematical functions for computing data transformations and other mathematical calculations
- probability functions for computing quantiles of statistical distributions and the significance of test statistics
- random number functions for simulation experiments
- sample statistics functions for computing means, standard deviations, kurtosis, and so forth

SAS functions are documented in *SAS Language Reference: Dictionary*. Chapter 3, “[Working with Time Series Data](#),” discusses the use of date, time, lagging, and differencing functions. Chapter 4, “[Date Intervals, Formats, and Functions](#),” contains a reference list of date and time functions.

Formats, Informats, and Time Intervals

Base SAS software provides formats to control the printing of data values, informats to read data values, and time intervals to define the frequency of time series. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information.

SAS Forecast Studio

SAS Forecast Studio is part of the SAS Forecast Server product. It provides an interactive environment for modeling and forecasting very large collections of hierarchically organized time series, such as SKUs in product lines and sales regions of a retail business. Forecast Studio greatly extends the capabilities provided by the [Time Series Forecasting System](#) included with SAS/ETS and described in *Part IV*.

Forecast Studio is documented in *SAS Forecast Server User's Guide*.

SAS High-Performance Forecasting

SAS High-Performance Forecasting (HPF) software provides a system of SAS procedures for large-scale automatic forecasting in business, government, and academic applications. Major uses of High-Performance Forecasting procedures include: forecasting, forecast scoring, market response modeling, and time series data mining.

The software includes the following automatic forecasting process:

- accumulates the time-stamped data to form a fixed-interval time series
- diagnoses the time series using time series analysis techniques
- creates a list of candidate model specifications based on the diagnostics
- fits each candidate model specification to the time series
- generates forecasts for each candidate fitted model
- selects the most appropriate model specification based on either in-sample or holdout-sample evaluation using a model selection criterion
- refits the selected model specification to the entire range of the time series
- creates a forecast score from the selected fitted model
- generate forecasts from the forecast score
- evaluates the forecast using in-sample analysis
- provides for out-of-sample forecast performance analysis
- performs top-down, middle-out, or bottom-up reconciliations of forecasts in the hierarchy

SAS/GRAPH Software

SAS/GRAPH software includes procedures that create two- and three-dimensional high resolution color graphics plots and charts. You can generate output that graphs the relationship of data values to one another, enhance existing graphs, or simply create graphics output that is not tied to data.

With the addition of ODS Graphics features to SAS/ETS procedures, there is now less need for the use of SAS/GRAPH procedures with SAS/ETS. However, SAS/GRAPH procedures allow you to create additional graphical displays of your results.

SAS/GRAPH software can produce the following types of output:

- charts
- plots
- maps
- text
- three-dimensional graphs

With SAS/GRAPH software you can produce high-resolution color graphics plots of time series data.

SAS/STAT Software

SAS/STAT software is of interest to users of SAS/ETS software because many econometric and other statistical methods not included in SAS/ETS software are provided in SAS/STAT software.

SAS/STAT software includes procedures for a wide range of statistical methodologies including the following:

- logistic regression
- censored regression
- principal component analysis
- structural equation models using covariance structure analysis
- factor analysis
- survival analysis
- discriminant analysis
- cluster analysis
- categorical data analysis; log-linear and conditional logistic models
- general linear models
- mixed linear and nonlinear models
- generalized linear models
- response surface analysis
- kernel density estimation
- LOESS regression
- spline regression
- two-dimensional kriging
- multiple imputation for missing values
- survey data analysis

SAS/IML Software

SAS/IML software gives you access to a powerful and flexible programming language (Interactive Matrix Language) in a dynamic, interactive environment. The fundamental object of the language is a data matrix. You can use SAS/IML software interactively (at the statement level) to see results immediately, or you can store statements in a module and execute them later. The programming is dynamic because necessary activities such as memory allocation and dimensioning of matrices are done automatically.

You can access built-in operators and call routines to perform complex tasks such as matrix inversion or eigenvector generation. You can define your own functions and subroutines using SAS/IML modules. You can perform operations on an entire data matrix. You have access to a wide choice of data management commands. You can read, create, and update SAS data sets from inside SAS/IML software without ever using the DATA step.

SAS/IML software is of interest to users of SAS/ETS software because it enables you to program your own econometric and time series methods in the SAS System. It contains subroutines for time series operators and for general function optimization. If you need to perform a statistical calculation not provided as an automated feature by SAS/ETS or other SAS software, you can use SAS/IML software to program the matrix equations for the calculation.

Kalman Filtering and Time Series Analysis in SAS/IML

SAS/IML software includes CALL routines and functions for Kalman filtering and time series analysis, which perform the following:

- generate univariate, multivariate, and fractional time series
- compute likelihood function of ARMA, VARMA, and ARFIMA models
- compute an autocovariance function of ARMA, VARMA, and ARFIMA models
- check the stationarity of ARMA and VARMA models
- filter and smooth time series models using Kalman method
- fit AR, periodic AR, time-varying coefficient AR, VAR, and ARFIMA models
- handle Bayesian seasonal adjustment models

SAS Stat Studio

SAS Stat Studio is a highly interactive tool for data exploration and analysis. Stat Studio runs on a PC in the Microsoft Windows operating environment. You can use Stat Studio to do the following:

- explore data through graphs linked across multiple windows

- transform data
- subset data
- analyze univariate distributions
- discover structure and features in multivariate data
- fit and evaluate explanatory models
- create your own customized statistical graphics
- add legends, curves, maps, or other custom features to statistical graphics
- develop interactive programs that use dialog boxes
- extend the built-in analyses by calling SAS procedures
- create custom analyses
- repeat an analysis on different data
- extend the results of SAS procedures by using IML
- share analyses with colleagues who also use Stat Studio
- call functions from libraries written in C/C++, FORTRAN, or Java

See [for more information](#).

SAS/OR Software

SAS/OR software provides SAS procedures for operations research and project planning and includes a menu driven system for project management. SAS/OR software has features for the following:

- solving transportation problems
- linear, integer, and mixed-integer programming
- nonlinear programming and optimization
- scheduling projects
- plotting Gantt charts
- drawing network diagrams
- solving optimal assignment problems
- network flow programming

SAS/OR software might be of interest to users of SAS/ETS software for its mathematical programming features. In particular, the NLP and OPTMODEL procedures in SAS/OR software solve nonlinear programming problems and can be used for constrained and unconstrained maximization of user-defined likelihood functions.

See *SAS/OR User's Guide: Mathematical Programming* for more information.

SAS/QC Software

SAS/QC software provides a variety of procedures for statistical quality control and quality improvement. SAS/QC software includes procedures for the following:

- Shewhart control charts
- cumulative sum control charts
- moving average control charts
- process capability analysis
- Ishikawa diagrams
- Pareto charts
- experimental design

SAS/QC software also includes the SQC menu system for interactive application of statistical quality control methods and the ADX Interface for experimental design.

MLE for User-Defined Likelihood Functions

There are several SAS procedures that enable you to do maximum likelihood estimation of parameters in an arbitrary model with a likelihood function that you define: PROC MODEL, PROC NLP, PROC OPTMODEL and PROC IML.

The MODEL procedure in SAS/ETS software enables you to minimize general log-likelihood functions for the error term of a model.

The NLP and OPTMODEL procedures in SAS/OR software are general nonlinear programming procedures that can maximize a general function subject to linear equality or inequality constraints. You can use PROC NLP or OPTMODEL to maximize a user-defined nonlinear likelihood function.

You can use the IML procedure in SAS/IML software for maximum likelihood problems. The optimization routines used by PROC NLP are available through IML subroutines. You can write the likelihood function in the SAS/IML matrix language and call the constrained and unconstrained nonlinear programming subroutines to maximize the likelihood function with respect to the parameter vector.

JMP[®] Software

JMP software uses a flexible graphical interface to display and analyze data. JMP dynamically links statistics and graphics so you can easily explore data, make discoveries, and gain the knowledge you need to make better decisions. JMP provides a comprehensive set of statistical tools as well as design of experiments (DOE) and advanced quality control (QC and SPC) tools for Six Sigma in a single package. JMP is software for interactive statistical graphics and includes:

- a data table window for editing, entering, and manipulating data
- a broad range of graphical and statistical methods for data analysis
- a facility for grouping data and computing summary statistics
- JMP scripting language (JSL)—a scripting language for saving and creating frequently used routines
- JMP automation
- Formula Editor—a formula editor for each table column to compute values as needed
- linear models, correlations, and multivariate
- design of experiments module
- options to highlight and display subsets of data
- statistical quality control and variability charts—special plots, charts, and communication capability for quality-improvement techniques
- survival analysis
- time series analysis, which includes the following:
 - Box-Jenkins ARIMA forecasting
 - seasonal ARIMA forecasting
 - transfer function modeling
 - smoothing models: Winters method, single, double, linear, damped trend linear, and seasonal exponential smoothing
 - diagnostic charts (autocorrelation, partial autocorrelation, and variogram) and statistics of fit
 - a model comparison table to compare all forecasts generated
 - spectral density plots and white noise tests
- tools for printing and for moving analyses results between applications

SAS Enterprise Guide®

SAS Enterprise Guide has the following features:

- integration with the SAS9 platform:
 - open metadata repository (OMR) integration
 - SAS report integration
 - * create report interface
 - * ODS support
 - * Web report studio integration
 - access to information maps
 - ETL studio impact analysis
 - ESRI integration within the OLAP analyzer
 - data mining scoring task
- the user interface and workflow
 - process flow
 - ability to create stored processes from process flows
 - SAS folders window
 - project parameters
 - query builder interface
 - code node
 - OLAP analyzer
 - * ESRI integration
 - * tree-diagram-based OLAP explorer
 - * SAS report snapshots
 - * SAS Web OLAP viewer for .NET ability to create EG projects
 - workspace maximization

With Enterprise Guide, you can perform time series analysis with the following EG procedures:

- prepare time series data—the Prepare Time Series Data task can be used to make data more suitable for analysis by other time series tasks.
- create time series data—the Create Time Series Data wizard helps you convert transactional data into fixed-interval time series. Transactional data are time-stamped data collected over time with irregular or varied frequency.
- ARIMA Modeling and Forecasting task
- Basic Forecasting task
- Regression Analysis with Autoregressive Errors
- Regression Analysis of Panel Data

SAS[®] Add-In for Microsoft Office

The main time series tasks in SAS Add-in for Microsoft Office (AMO) are as follows:

- Prepare Time Series Data
- Basic Forecasting
- ARIMA Modeling and Forecasting
- Regression Analysis with Autoregressive Errors
- Regression Analysis of Panel Data
- Create Time Series Data
- Forecast Studio Create Project
- Forecast Studio Open Project
- Forecast Studio Submit Overrides

SAS Enterprise Miner[™]—Time Series Node

SAS Enterprise Miner[™] is the SAS solution for data mining, streamlining the data mining process to create highly accurate predictive and descriptive models. Enterprise Miner's process flow diagram eliminates the need for manual coding and reduces the model development time for both business analysts and statisticians. The system is customizable and extensible; users can integrate their code and build new nodes for redistribution.

The Time Series node is a method of investigating time series data. It belongs to the Modify category of the SAS SEMMA (sample, explore, modify, model, assess) data mining process. The Time Series node enables you to understand trends and seasonal variation in large amounts of time series and transactional data.

The Time Series node in SAS Enterprise Miner enables you to do the following:

- perform time series analysis
- perform forecasting
- work with transactional data

SAS Risk Products

The SAS Risk products include SAS Risk Dimensions[®], SAS Credit Risk Management for Banking, SAS OpRisk VaR, and SAS OpRisk Monitor.

The analytical methods of SAS Risk Dimensions measure market risk and credit risk. SAS Risk Dimensions creates an environment where market and position data are staged for analysis using SAS data access and warehousing methodologies. SAS Risk Dimensions delivers a full range of modern credit, market and operational risk analysis techniques including:

- mark-to-market
- scenario analysis
- profit/loss curves and surfaces
- sensitivity analysis
- delta normal VaR
- historical simulation VaR
- Monte Carlo VaR
- current exposure
- potential exposure
- credit VaR
- optimization

SAS Credit Risk Management for Banking is a complete end-to-end application for measuring, exploring, managing, and reporting credit risk. SAS Credit Risk Management for Banking integrates data access, mapping, enrichment, and aggregation with advanced analytics and flexible reporting, all in an open, extensible, client-server framework.

SAS Credit Risk Management for Banking enables you to do the following:

- access and aggregate credit risk data across disparate operating systems and sources
- seamlessly integrate credit scoring/internal rating with credit portfolio risk assessment
- accurately measure, monitor, and report potential credit risk exposures within entities of an organization and aggregated across the entire organization, both on the counterparty level and the portfolio level
- evaluate alternative strategies for pricing, hedging, or transferring credit risk
- optimize the allocation of credit risk mitigants or assign the mitigants to lower the regulatory capital requirement

- optimize the allocation of regulatory capital and economic capital
- facilitate regulatory compliance and risk disclosure requirements for a wide variety of regulations such as Basel I, Basel II, and the Capital Requirements Directive (CAD III)

Overview

This chapter discusses working with time series data in the SAS System. The following topics are included:

- dating time series and working with SAS date and datetime values
- subsetting data and selecting observations

- storing time series data in SAS data sets
- specifying time series periodicity and time intervals
- plotting time series
- using calendar and time interval functions
- computing lags and other functions across time
- transforming time series
- transposing time series data sets
- interpolating time series
- reading time series data recorded in different ways

In general, this chapter focuses on using features of the SAS programming language and not on features of SAS/ETS software. However, since SAS/ETS procedures are used to analyze time series, understanding how to use the SAS programming language to work with time series data is important for the effective use of SAS/ETS software.

You do not need to read this chapter to use SAS/ETS procedures. If you are already familiar with SAS programming you might want to skip this chapter, or you can refer to sections of this chapter for help on specific time series data processing questions.

Time Series and SAS Data Sets

Introduction

To analyze data with the SAS System, data values must be stored in a SAS data set. A SAS data set is a matrix (or table) of data values organized into variables and observations.

The *variables* in a SAS data set label the columns of the data matrix, and the *observations* in a SAS data set are the rows of the data matrix. You can also think of a SAS data set as a kind of file, with the observations representing records in the file and the variables representing fields in the records. (See *SAS Language Reference: Concepts* for more information about SAS data sets.)

Usually, each observation represents the measurement of one or more variables for the individual subject or item observed. Often, the values of some of the variables in the data set are used to identify the individual subjects or items that the observations measure. These identifying variables are referred to as *ID variables*.

For many kinds of statistical analysis, only relationships among the variables are of interest, and the identity of the observations does not matter. ID variables might not be relevant in such a case.

However, for time series data the identity and order of the observations are crucial. A time series is a set of observations made at a succession of equally spaced points in time.

For example, if the data are monthly sales of a company's product, the variable measured is sales of the product and the unit observed is the operation of the company during each month. These observations can be identified by year and month. If the data are quarterly gross national product, the variable measured is final goods production and the unit observed is the economy during each quarter. These observations can be identified by year and quarter.

For time series data, the observations are identified and related to each other by their position in time. Since SAS does not assume any particular structure to the observations in a SAS data set, there are some special considerations needed when storing time series in a SAS data set.

The main considerations are how to associate dates with the observations and how to structure the data set so that SAS/ETS procedures and other SAS procedures recognize the observations of the data set as constituting time series. These issues are discussed in following sections.

Reading a Simple Time Series

Time series data can be recorded in many different ways. The section “[Reading Time Series Data](#)” on page 125 discusses some of the possibilities. The example below shows a simple case.

The following SAS statements read monthly values of the U.S. Consumer Price Index for June 1990 through July 1991. The data set USCPI is shown in [Figure 3.1](#).

```
data uscpi;
    input year month cpi;
datalines;
1990 6 129.9
1990 7 130.4

... more lines ...

proc print data=uscpi;
run;
```

Figure 3.1 Time Series Data

Obs	year	month	cpi
1	1990	6	129.9
2	1990	7	130.4
3	1990	8	131.6
4	1990	9	132.7
5	1990	10	133.5
6	1990	11	133.8
7	1990	12	133.8
8	1991	1	134.6
9	1991	2	134.8
10	1991	3	135.0
11	1991	4	135.2
12	1991	5	135.6
13	1991	6	136.0
14	1991	7	136.2

When a time series is stored in the manner shown by this example, the terms *series* and *variable* can be used interchangeably. There is one observation per row and one series/variable per column.

Dating Observations

The SAS System supports special date, datetime, and time values, which make it easy to represent dates, perform calendar calculations, and identify the time period of observations in a data set.

The preceding example uses the ID variables YEAR and MONTH to identify the time periods of the observations. For a quarterly data set, you might use YEAR and QTR as ID variables. A daily data set might have the ID variables YEAR, MONTH, and DAY. Clearly, it would be more convenient to have a single ID variable that could be used to identify the time period of observations, regardless of their frequency.

The following section, “[SAS Date, Datetime, and Time Values](#)” on page 68, discusses how the SAS System represents dates and times internally and how to specify date, datetime, and time values in a SAS program. The section “[Reading Date and Datetime Values with Informats](#)” on page 69 discusses how to read in date and time values from data records and how to control the display of date and datetime values in SAS output. Later sections discuss other issues concerning date and datetime values, specifying time intervals, data periodicity, and calendar calculations.

SAS date and datetime values and the other features discussed in the following sections are also described in *SAS Language Reference: Dictionary*. Reference documentation on these features is also provided in Chapter 4, “[Date Intervals, Formats, and Functions](#).”

SAS Date, Datetime, and Time Values

SAS Date Values

SAS software represents dates as the number of days since a reference date. The reference date, or date zero, used for SAS date values is 1 January 1960. For example, 3 February 1960 is represented by SAS as 33. The SAS date for 17 October 1991 is 11612.

SAS software correctly represents dates from the year 1582 to the year 20,000.

Dates represented in this way are called SAS *date values*. Any numeric variable in a SAS data set whose values represent dates in this way is called a SAS *date variable*.

Representing dates as the number of days from a reference date makes it easy for the computer to store them and perform calendar calculations, but these numbers are not meaningful to users. However, you never have to use SAS date values directly, since SAS automatically converts between this internal representation and ordinary ways of expressing dates, provided that you indicate the format with which you want the date values to be displayed. (Formatting of date values is explained in the section “[Formatting Date and Datetime Values](#)” on page 70.)

Century of Dates Represented with Two-Digit Year Values

SAS software informats, functions, and formats can process dates that are represented with two-digit year values. The century assumed for a two-digit year value can be controlled with the YEARCUTOFF= option in the OPTIONS statement. The YEARCUTOFF= system option controls how dates with two-digit year values are interpreted by specifying the first year of a 100-year span. The default value for the YEARCUTOFF= option is 1920. Thus by default the year ‘17’ is interpreted as 2017, while the year ‘25’ is interpreted as 1925. (See *SAS Language Reference: Dictionary* for more information about YEARCUTOFF=.)

SAS Date Constants

SAS date values are written in a SAS program by placing the dates in single quotes followed by a D. The date is represented by the day of the month, the three letter abbreviation of the month name, and the year.

For example, SAS reads the value ‘17OCT1991’D the same as 11612, the SAS date value for 17 October 1991. Thus, the following SAS statements print DATE=11612:

```
data _null_;
  date = '17oct1991'd;
  put date=;
run;
```

The year value can be given with two or four digits, so ‘17OCT91’D is the same as ‘17OCT1991’D.

SAS Datetime Values and Datetime Constants

To represent both the time of day and the date, SAS uses *datetime values*. SAS datetime values represent the date and time as the number of seconds the time is from a reference time. The reference time, or time zero, used for SAS datetime values is midnight, 1 January 1960. Thus, for example, the SAS datetime value for 17 October 1991 at 2:45 in the afternoon is 1003329900.

To specify datetime constants in a SAS program, write the date and time in single quotes followed by DT. To write the date and time in a SAS datetime constant, write the date part using the same syntax as for date constants, and follow the date part with the hours, the minutes, and the seconds, separating the parts with colons. The seconds are optional.

For example, in a SAS program you would write 17 October 1991 at 2:45 in the afternoon as '17OCT91:14:45'DT. SAS reads this as 1003329900. Table 3.1 shows some other examples of datetime constants.

Table 3.1 Examples of Datetime Constants

Datetime Constant	Time
'17OCT1991:14:45:32'DT	32 seconds past 2:45 p.m., 17 October 1991
'17OCT1991:12:5'DT	12:05 p.m., 17 October 1991
'17OCT1991:2:0'DT	2:00 a.m., 17 October 1991
'17OCT1991:0:0'DT	midnight, 17 October 1991

SAS Time Values

The SAS System also supports *time values*. SAS time values are just like datetime values, except that the date part is not given. To write a time value in a SAS program, write the time the same as for a datetime constant, but use T instead of DT. For example, 2:45:32 p.m. is written '14:45:32'T. Time values are represented by a number of seconds since midnight, so SAS reads '14:45:32'T as 53132.

SAS time values are not very useful for identifying time series, since usually both the date and the time of day are needed. Time values are not discussed further in this book.

Reading Date and Datetime Values with Informats

SAS provides a selection of *informats* for reading SAS date and datetime values from date and time values recorded in ordinary notations.

A SAS informat is an instruction that converts the values from a character-string representation into the internal numerical value of a SAS variable. Date informats convert dates from ordinary notations used to enter them to SAS date values; datetime informats convert date and time from ordinary notation to SAS datetime values.

For example, the following SAS statements read monthly values of the U.S. Consumer Price Index. Since the data are monthly, you could identify the date with the variables YEAR and MONTH, as in the previous example. Instead, in this example the time periods are coded as a three-letter month abbreviation followed by the year. The informat MONYY. is used to read month-year dates coded this way and to express them as SAS date values for the first day of the month, as follows:

```
data uscpi;
  input date : monyy7. cpi;
  format date monyy7.;
  label cpi = "US Consumer Price Index";
datalines;
jun1990 129.9
jul1990 130.4
... more lines ...
```

The SAS System provides informats for most common notations for dates and times. See [Chapter 4](#) for more information about the date and datetime informats available.

Formatting Date and Datetime Values

SAS provides *formats* to convert the internal representation of date and datetime values used by SAS to ordinary notations for dates and times. Several different formats are available for displaying dates and datetime values in most of the commonly used notations.

A SAS format is an instruction that converts the internal numerical value of a SAS variable to a character string that can be printed or displayed. Date formats convert SAS date values to a readable form; datetime formats convert SAS datetime values to a readable form.

In the preceding example, the variable DATE was set to the SAS date value for the first day of the month for each observation. If the data set USCPI were printed or otherwise displayed, the values shown for DATE would be the number of days since 1 January 1960. (See the “DATE with no format” column in [Figure 3.2](#).) To display date values appropriately, use the FORMAT statement.

The following example processes the data set USCPI to make several copies of the variable DATE and uses a FORMAT statement to give different formats to these copies. The format cases shown are the MONYY7. format (for the DATE variable), the DATE9. format (for the DATE1 variable), and no format (for the DATE0 variable). The PROC PRINT output in [Figure 3.2](#) shows the effect of the different formats on how the date values are printed.

```
data fmttest;
  set uscpi;
  date0 = date;
  date1 = date;
  label date = "DATE with MONYY7. format"
        date1 = "DATE with DATE9. format"
        date0 = "DATE with no format";
  format date monyy7. date1 date9.;
```

```
run;

proc print data=fmtest label;
run;
```

Figure 3.2 SAS Date Values Printed with Different Formats

Obs	DATE with	US	DATE with	DATE with
	MONYY7. format	Consumer Price Index	no format	DATE9. format
1	JUN1990	129.9	11109	01JUN1990
2	JUL1990	130.4	11139	01JUL1990
3	AUG1990	131.6	11170	01AUG1990
4	SEP1990	132.7	11201	01SEP1990
5	OCT1990	133.5	11231	01OCT1990
6	NOV1990	133.8	11262	01NOV1990
7	DEC1990	133.8	11292	01DEC1990
8	JAN1991	134.6	11323	01JAN1991
9	FEB1991	134.8	11354	01FEB1991
10	MAR1991	135.0	11382	01MAR1991
11	APR1991	135.2	11413	01APR1991
12	MAY1991	135.6	11443	01MAY1991
13	JUN1991	136.0	11474	01JUN1991
14	JUL1991	136.2	11504	01JUL1991

The appropriate format to use for SAS date or datetime valued ID variables depends on the sampling frequency or periodicity of the time series. Table 3.2 shows recommended formats for common data sampling frequencies and shows how the date '17OCT1991'D or the datetime value '17OCT1991:14:45:32'DT is displayed by these formats.

Table 3.2 Formats for Different Sampling Frequencies

ID values	Periodicity	FORMAT	Example
SAS date	annual	YEAR4.	1991
	quarterly	YYQC6.	1991:4
	monthly	MONYY7.	OCT1991
	weekly	WEEKDATX23.	Thursday, 17 Oct 1991
	daily	DATE9.	17OCT1991
SAS datetime	hourly	DATETIME10.	17OCT91:14
	minutes	DATETIME13.	17OCT91:14:45
	seconds	DATETIME16.	17OCT91:14:45:32

See Chapter 4, “Date Intervals, Formats, and Functions,” for more information about the date and datetime formats available.

The Variables DATE and DATETIME

SAS/ETS procedures enable you to identify time series observations in many different ways to suit your needs. As discussed in preceding sections, you can use a combination of several ID variables, such as YEAR and MONTH for monthly data.

However, using a single SAS date or datetime ID variable is more convenient and enables you to take advantage of some features SAS/ETS procedures provide for processing ID variables. One such feature is automatic extrapolation of the ID variable to identify forecast observations. These features are discussed in following sections.

Thus, it is a good practice to include a SAS date or datetime ID variable in all the time series SAS data sets you create. It is also a good practice to always give the date or datetime ID variable a format appropriate for the data periodicity. (For information about creating SAS date and datetime values from multiple ID variables, see the section “[Computing Dates from Calendar Variables](#)” on page 96.)

You can assign a SAS date- or datetime-valued ID variable any name that conforms to SAS variable name requirements. However, you might find working with time series data in SAS easier and less confusing if you adopt the practice of always using the same name for the SAS date or datetime ID variable.

This book always names the date- or datetime-values ID variable DATE if it contains SAS date values or DATETIME if it contains SAS datetime values. This makes it easy to recognize the ID variable and also makes it easy to recognize whether this ID variable uses SAS date or datetime values.

Sorting by Time

Many SAS/ETS procedures assume the data are in chronological order. If the data are not in time order, you can use the SORT procedure to sort the data set. For example,

```
proc sort data=a;  
    by date;  
run;
```

There are many ways of coding the time ID variable or variables, and some ways do not sort correctly. If you use SAS date or datetime ID values as suggested in the preceding section, you do not need to be concerned with this issue. But if you encode date values in nonstandard ways, you need to consider whether your ID variables will sort.

SAS date and datetime values always sort correctly, as do combinations of numeric variables such as YEAR, MONTH, and DAY used together. Julian dates also sort correctly. (Julian dates are numbers of the form *yyddd*, where *yy* is the year and *ddd* is the day of the year. For example, 17 October 1991 has the Julian date value 91290.)

Calendar dates such as numeric values coded as *mmddy* or *ddmmy* do not sort correctly. Character variables that contain display values of dates, such as dates in the notation produced by SAS date formats, generally do not sort correctly.

Subsetting Data and Selecting Observations

It is often necessary to subset data for analysis. You might need to subset data to do the following:

- restrict the time range. For example, you want to perform a time series analysis using only recent data and ignoring observations from the distant past.
- select cross sections of the data. (See the section “[Cross-Sectional Dimensions and BY Groups](#)” on page 79.) For example, you have a data set with observations over time for each of several states, and you want to analyze the data for a single state.
- select particular kinds of time series from an interleaved-form data set. (See the section “[Interleaved Time Series](#)” on page 80.) For example, you have an output data set produced by the FORECAST procedure that contains both forecast and confidence limits observations, and you want to extract only the forecast observations.
- exclude particular observations. For example, you have an outlier in your time series, and you want to exclude this observation from the analysis.

You can subset data either by using the DATA step to create a subset data set or by using a WHERE statement with the SAS procedure that analyzes the data.

A typical WHERE statement used in a procedure has the following form:

```
proc arima data=full;
  where '31dec1993'd < date < '26mar1994'd;
  identify var=close;
run;
```

For complete reference documentation on the WHERE statement, see *SAS Language Reference: Dictionary*.

Subsetting SAS Data Sets

To create a subset data set, specify the name of the subset data set in the DATA statement, bring in the full data set with a SET statement, and specify the subsetting criteria with either subsetting IF statements or WHERE statements.

For example, suppose you have a data set that contains time series observations for each of several states. The following DATA step uses a WHERE statement to exclude observations with dates before 1970 and uses a subsetting IF statement to select observations for the state NC:

```

data subset;
  set full;
  where date >= '1jan1970'd;
  if state = 'NC';
run;

```

In this case, it makes no difference logically whether the WHERE statement or the IF statement is used, and you can combine several conditions in one subsetting statement. The following statements produce the same results as the previous example:

```

data subset;
  set full;
  if date >= '1jan1970'd & state = 'NC';
run;

```

The WHERE statement acts on the input data sets specified in the SET statement before observations are processed by the DATA step program, whereas the IF statement is executed as part of the DATA step program. If the input data set is indexed, using the WHERE statement can be more efficient than using the IF statement. However, the WHERE statement can refer only to variables in the input data set, not to variables computed by the DATA step program.

To subset the variables of a data set, use KEEP or DROP statements or use KEEP= or DROP= data set options. See *SAS Language Reference: Dictionary* for information about KEEP and DROP statements and SAS data set options.

For example, suppose you want to subset the data set as in the preceding example, but you want to include in the subset data set only the variables DATE, X, and Y. You could use the following statements:

```

data subset;
  set full;
  if date >= '1jan1970'd & state = 'NC';
  keep date x y;
run;

```

Using the WHERE Statement with SAS Procedures

Use the WHERE statement with SAS procedures to process only a subset of the input data set. For example, suppose you have a data set that contains monthly observations for each of several states, and you want to use the AUTOREG procedure to analyze data since 1970 for the state NC. You could use the following statements:

```

proc autoreg data=full;
  where date >= '1jan1970'd & state = 'NC';
  ... additional statements ...
run;

```

You can specify any number of conditions in the WHERE statement. For example, suppose that a strike created an outlier in May 1975, and you want to exclude that observation. You could use the

following statements:

```
proc autoreg data=full;
  where date >= '1jan1970'd & state = 'NC'
    & date ^= '1may1975'd;
  ... additional statements ...
run;
```

Using SAS Data Set Options

You can use the OBS= and FIRSTOBS= data set options to subset the input data set.

For example, the following statements print observations 20 through 25 of the data set FULL:

```
proc print data=full(firstobs=20 obs=25);
run;
```

Figure 3.3 Partial Listing of Data Set FULL

Obs	date	state	i	x	y	close
20	21OCT1993	NC	20	0.44803	0.35302	0.44803
21	22OCT1993	NC	21	0.03186	1.67414	0.03186
22	23OCT1993	NC	22	-0.25232	-1.61289	-0.25232
23	24OCT1993	NC	23	0.42524	0.73112	0.42524
24	25OCT1993	NC	24	0.05494	-0.88664	0.05494
25	26OCT1993	NC	25	-0.29096	-1.17275	-0.29096

You can use KEEP= and DROP= data set options to exclude variables from the input data set. See *SAS Language Reference: Dictionary* for information about SAS data set options.

Storing Time Series in a SAS Data Set

This section discusses aspects of storing time series in SAS data sets. The topics discussed are the standard form of a time series data set, storing several series with different time ranges in the same data set, omitted observations, cross-sectional dimensions and BY groups, and interleaved time series.

Any number of time series can be stored in a SAS data set. Normally, each time series is stored in a separate variable. For example, the following statements augment the USCPI data set read in the previous example with values for the producer price index:

```
data usprice;
  input date : monyy7. cpi ppi;
```

```

format date monyy7.;
label cpi = "Consumer Price Index"
      ppi = "Producer Price Index";
datalines;
jun1990 129.9 114.3
jul1990 130.4 114.5

... more lines ...

proc print data=usprice;
run;

```

13	JUN1991	136.0	116.3
14	JUL1991	136.2	116.0

Standard Form of a Time Series Data Set

The simple way the CPI and PPI time series are stored in the USPRICE data set in the preceding example is termed the *standard form* of a time series data set. A time series data set in standard form has the following characteristics:

- The data set contains one variable for each time series.
- The data set contains exactly one observation for each time period.
- The data set contains an ID variable or variables that identify the time period of each observation.
- The data set is sorted by the ID variables associated with date time values, so the observations are in time sequence.
- The data are equally spaced in time. That is, successive observations are a fixed time interval apart, so the data set can be described by a single sampling interval such as hourly, daily,

monthly, quarterly, yearly, and so forth. This means that time series with different sampling frequencies are not mixed in the same SAS data set.

Most SAS/ETS procedures that process time series expect the input data set to contain time series in this standard form, and this is the simplest way to store time series in SAS data sets. (The [EXPAND](#) and [TIMESERIES](#) procedures can be helpful in converting your data to this standard form.) There are more complex ways to represent time series in SAS data sets.

You can incorporate cross-sectional dimensions with BY groups, so that each BY group is like a standard form time series data set. This method is discussed in the section “[Cross-Sectional Dimensions and BY Groups](#)” on page 79.

You can interleave time series, with several observations for each time period identified by another ID variable. Interleaved time series data sets are used to store several series in the same SAS variable. Interleaved time series data sets are often used to store series of actual values, predicted values, and residuals, or series of forecast values and confidence limits for the forecasts. This is discussed in the section “[Interleaved Time Series](#)” on page 80.

Several Series with Different Ranges

Different time series can have values recorded over different time ranges. Since a SAS data set must have the same observations for all variables, when time series with different ranges are stored in the same data set, missing values must be used for the periods in which a series is not available.

Suppose that in the previous example you did not record values for CPI before August 1990 and did not record values for PPI after June 1991. The USPRICE data set could be read with the following statements:

```
data usprice;
  input date : monyy7. cpi ppi;
  format date monyy7.;
datalines;
jun1990      . 114.3
jul1990      . 114.5
aug1990 131.6 116.5
sep1990 132.7 118.4
oct1990 133.5 120.8
nov1990 133.8 120.1
dec1990 133.8 118.7
jan1991 134.6 119.0
feb1991 134.8 117.2
mar1991 135.0 116.2
apr1991 135.2 116.0
may1991 135.6 116.5
jun1991 136.0 116.3
jul1991 136.2      .
;
```

The decimal points with no digits in the data records represent missing data and are read by SAS as missing value codes.

In this example, the time range of the USPRICE data set is June 1990 through July 1991, but the time range of the CPI variable is August 1990 through July 1991, and the time range of the PPI variable is June 1990 through June 1991.

SAS/ETS procedures ignore missing values at the beginning or end of a series. That is, the series is considered to begin with the first nonmissing value and end with the last nonmissing value.

Missing Values and Omitted Observations

Missing data can also occur within a series. Missing values that appear after the beginning of a time series and before the end of the time series are called *embedded missing values*.

Suppose that in the preceding example you did not record values for CPI for November 1990 and did not record values for PPI for both November 1990 and March 1991. The USPRICE data set could be read with the following statements:

```
data usprice;
  input date : monyy. cpi ppi;
  format date monyy.;
datalines;
jun1990      . 114.3
jul1990      . 114.5
aug1990 131.6 116.5
sep1990 132.7 118.4
oct1990 133.5 120.8
nov1990      .      .
dec1990 133.8 118.7
jan1991 134.6 119.0
feb1991 134.8 117.2
mar1991 135.0      .
apr1991 135.2 116.0
may1991 135.6 116.5
jun1991 136.0 116.3
jul1991 136.2      .
;
```

In this example, the series CPI has one embedded missing value, and the series PPI has two embedded missing values. The ranges of the two series are the same as before.

Note that the observation for November 1990 has missing values for both CPI and PPI; there is no data for this period. This is an example of a *missing observation*.

You might ask why the data record for this period is included in the example at all, since the data record contains no data. However, deleting the data record for November 1990 from the example would cause an *omitted observation* in the USPRICE data set. SAS/ETS procedures expect input data sets to contain observations for a contiguous time sequence. If you omit observations from a time series data set and then try to analyze the data set with SAS/ETS procedures, the omitted

observations will cause errors. When all data are missing for a period, a missing observation should be included in the data set to preserve the time sequence of the series.

If observations are omitted from the data set, the **EXPAND** procedure can be used to fill in the gaps with missing values (or to interpolate nonmissing values) for the time series variables and with the appropriate date or datetime values for the ID variable.

Cross-Sectional Dimensions and BY Groups

Often, time series in a collection are related by a cross sectional dimension. For example, the national average U.S. consumer price index data shown in the previous example can be disaggregated to show price indexes for major cities. In this case, there are several related time series: CPI for New York, CPI for Chicago, CPI for Los Angeles, and so forth. When these time series are considered as one data set, the city whose price level is measured is a cross sectional dimension of the data.

There are two basic ways to store such related time series in a SAS data set. The first way is to use a standard form time series data set with a different variable for each series.

For example, the following statements read CPI series for three major U.S. cities:

```
data citycpi;
  input date : monyy7. cpiny cpichi cpila;
  format date monyy7.;
datalines;
nov1989 133.200 126.700 130.000
dec1989 133.300 126.500 130.600
... more lines ...
```

The second way is to store the data in a time series cross-sectional form. In this form, the series for all cross sections are stored in one variable and a cross section ID variable is used to identify observations for the different series. The observations are sorted by the cross section ID variable and by time within each cross section.

The following statements indicate how to read the CPI series for U.S. cities in time series cross-sectional form:

```
data cpicity;
  length city $11;
  input city $11. date : monyy. cpi;
  format date monyy.;
datalines;
New York      JAN1990    135.100
New York      FEB1990    135.300
... more lines ...
```

```
proc sort data=cpicity;  
  by city date;  
run;
```

When processing a time series cross sectional form data set with most SAS/ETS procedures, use the cross section ID variable in a BY statement to process the time series separately. The data set must be sorted by the cross section ID variable and sorted by date within each cross section. The PROC SORT step in the preceding example ensures that the CPICITY data set is correctly sorted.

When the cross section ID variable is used in a BY statement, each BY group in the data set is like a standard form time series data set. Thus, SAS/ETS procedures that expect a standard form time series data set can process time series cross sectional data sets when a BY statement is used, producing an independent analysis for each cross section.

It is also possible to analyze time series cross-sectional data jointly. The [PANEL](#) procedure (and the older [TSCSREG](#) procedure) expects the input data to be in the time series cross-sectional form described here. See Chapter 19, “[The PANEL Procedure](#),” for more information.

Interleaved Time Series

Normally, a time series data set has only one observation for each time period, or one observation for each time period within a cross section for a time series cross-sectional-form data set. However, it is sometimes useful to store several related time series in the same variable when the different series do not correspond to levels of a cross-sectional dimension of the data.

In this case, the different time series can be interleaved. An interleaved time series data set is similar to a time series cross-sectional data set, except that the observations are sorted differently and the ID variable that distinguishes the different time series does not represent a cross-sectional dimension.

Some SAS/ETS procedures produce interleaved output data sets. The interleaved time series form is a convenient way to store procedure output when the results consist of several different kinds of series for each of several input series. (Interleaved time series are also easy to process with plotting procedures. See the section “[Plotting Time Series](#)” on page 86.)

For example, the [FORECAST](#) procedure fits a model to each input time series and computes predicted values and residuals from the model. The FORECAST procedure then uses the model to compute forecast values beyond the range of the input data and also to compute upper and lower confidence limits for the forecast values.

Thus, the output from PROC FORECAST consists of up to five related time series for each variable forecast. The five resulting time series for each input series are stored in a single output variable with the same name as the series that is being forecast. The observations for the five resulting series are identified by values of the variable `_TYPE_`. These observations are interleaved in the output data set with observations for the same date grouped together.

The following statements show how to use PROC FORECAST to forecast the variable CPI in the US CPI data set. [Figure 3.5](#) shows part of the output data set produced by PROC FORECAST and illustrates the interleaved structure of this data set.

```

proc forecast data=uscpi interval=month lead=12
      out=foreout outfull outresid;
  var cpi;
  id date;
run;

proc print data=foreout (obs=6);
run;

```

Figure 3.5 Partial Listing of Output Data Set Produced by PROC FORECAST

Obs	date	_TYPE_	_LEAD_	cpi
1	JUN1990	ACTUAL	0	129.900
2	JUN1990	FORECAST	0	130.817
3	JUN1990	RESIDUAL	0	-0.917
4	JUL1990	ACTUAL	0	130.400
5	JUL1990	FORECAST	0	130.678
6	JUL1990	RESIDUAL	0	-0.278

Observations with `_TYPE_=ACTUAL` contain the values of CPI read from the input data set. Observations with `_TYPE_=FORECAST` contain one-step-ahead predicted values for observations with dates in the range of the input series and contain forecast values for observations for dates beyond the range of the input series. Observations with `_TYPE_=RESIDUAL` contain the difference between the actual and one-step-ahead predicted values. Observations with `_TYPE_=U95` and `_TYPE_=L95` contain the upper and lower bounds, respectively, of the 95% confidence interval for the forecasts.

Using Interleaved Data Sets as Input to SAS/ETS Procedures

Interleaved time series data sets are not directly accepted as input by SAS/ETS procedures. However, it is easy to use a `WHERE` statement with any procedure to subset the input data and select one of the interleaved time series as the input.

For example, to analyze the residual series contained in the PROC FORECAST output data set with another SAS/ETS procedure, include a `WHERE _TYPE_='RESIDUAL'` statement. The following statements perform a spectral analysis of the residuals produced by PROC FORECAST in the preceding example:

```

proc spectra data=foreout out=spectout;
  var cpi;
  where _type_='RESIDUAL';
run;

```

Combined Cross Sections and Interleaved Time Series Data Sets

Interleaved time series output data sets produced from BY-group processing of time series cross-sectional input data sets have a complex structure that combines a cross-sectional dimension, a time dimension, and the values of the `_TYPE_` variable. For example, consider the PROC FORECAST output data set produced by the following statements:

```

title "FORECAST Output Data Set with BY Groups";

proc forecast data=cpicity interval=month
              method=expo lead=2
              out=foreout outfull outresid;
    var cpi;
    id date;
    by city;
run;

proc print data=foreout (obs=6);
run;

```

The output data set FOREOUT contains many different time series in the single variable CPI. (The first few observations of FOREOUT are shown in [Figure 3.6](#).) BY groups that are identified by the variable CITY contain the result series for the different cities. Within each value of CITY, the actual, forecast, residual, and confidence limits series are stored in interleaved form, with the observations for the different series identified by the values of `_TYPE_`.

Figure 3.6 Combined Cross Sections and Interleaved Time Series Data

FORECAST Output Data Set with BY Groups					
Obs	city	date	_TYPE_	_LEAD_	cpi
1	Chicago	JAN90	ACTUAL	0	128.100
2	Chicago	JAN90	FORECAST	0	128.252
3	Chicago	JAN90	RESIDUAL	0	-0.152
4	Chicago	FEB90	ACTUAL	0	129.200
5	Chicago	FEB90	FORECAST	0	128.896
6	Chicago	FEB90	RESIDUAL	0	0.304

Output Data Sets of SAS/ETS Procedures

Some SAS/ETS procedures (such as PROC FORECAST) produce interleaved output data sets, and other SAS/ETS procedures produce standard form time series data sets. The form a procedure uses depends on whether the procedure is normally used to produce multiple result series for each of many input series in one step (as PROC FORECAST does).

For example, the [ARIMA](#) procedure can output actual series, forecast series, residual series, and confidence limit series just as the FORECAST procedure does. The PROC ARIMA output data set

uses the standard form because PROC ARIMA is designed for the detailed analysis of one series at a time and so forecasts only one series at a time.

The following statements show the use of the ARIMA procedure to produce a forecast of the USCPI data set. [Figure 3.7](#) shows part of the output data set that is produced by the ARIMA procedure's FORECAST statement. (The printed output from PROC ARIMA is not shown.) Compare the PROC ARIMA output data set shown in [Figure 3.7](#) with the PROC FORECAST output data set shown in [Figure 3.6](#).

```

title "PROC ARIMA Output Data Set";

proc arima data=uscpi;
  identify var=cpi(1);
  estimate q=1;
  forecast id=date interval=month
          lead=12 out=arimaout;
run;

proc print data=arimaout(obs=6);
run;

```

Figure 3.7 Partial Listing of Output Data Set Produced by PROC ARIMA

PROC ARIMA Output Data Set							
Obs	date	cpi	FORECAST	STD	L95	U95	RESIDUAL
1	JUN1990	129.9
2	JUL1990	130.4	130.368	0.36160	129.660	131.077	0.03168
3	AUG1990	131.6	130.881	0.36160	130.172	131.590	0.71909
4	SEP1990	132.7	132.354	0.36160	131.645	133.063	0.34584
5	OCT1990	133.5	133.306	0.36160	132.597	134.015	0.19421
6	NOV1990	133.8	134.046	0.36160	133.337	134.754	-0.24552

The output data set produced by the ARIMA procedure's FORECAST statement stores the actual values in a variable with the same name as the response series, stores the forecast series in a variable named FORECAST, stores the residuals in a variable named RESIDUAL, stores the 95% confidence limits in variables named L95 and U95, and stores the standard error of the forecast in the variable STD.

This method of storing several different result series as a standard form time series data set is simple and convenient. However, it works well only for a single input series. The forecast of a single series can be stored in the variable FORECAST. But if two series are forecast, two different FORECAST variables are needed.

The STATESPACE procedure handles this problem by generating forecast variable names FOR1, FOR2, and so forth. The SPECTRA procedure uses a similar method. Names such as FOR1, FOR2, RES1, RES2, and so forth require you to remember the order in which the input series are listed. This is why PROC FORECAST, which is designed to forecast a whole list of input series at once, stores its results in interleaved form.

Other SAS/ETS procedures are often used for a single input series but can also be used to process several series in a single step. Thus, they are not clearly like PROC FORECAST nor clearly like PROC ARIMA in the number of input series they are designed to work with. These procedures use a third method for storing multiple result series in an output data set. These procedures store output time series in standard form (as PROC ARIMA does) but require an OUTPUT statement to give names to the result series.

Time Series Periodicity and Time Intervals

A fundamental characteristic of time series data is how frequently the observations are spaced in time. How often the observations of a time series occur is called the *sampling frequency* or the *periodicity* of the series. For example, a time series with one observation each month has a monthly sampling frequency or monthly periodicity and so is called a monthly time series.

In SAS, data periodicity is described by specifying periodic *time intervals* into which the dates of the observations fall. For example, the SAS time interval MONTH divides time into calendar months.

Many SAS/ETS procedures enable you to specify the periodicity of the input data set with the INTERVAL= option. For example, specifying INTERVAL=MONTH indicates that the procedure should expect the ID variable to contain SAS date values, and that the date value for each observation should fall in a separate calendar month. The EXPAND procedure uses interval name values with the FROM= and TO= options to control the interpolation of time series from one periodicity to another.

SAS also uses time intervals in several other ways. In addition to indicating the periodicity of time series data sets, time intervals are used with the interval functions INTNX and INTCK and for controlling the plot axis and reference lines for plots of data over time.

Specifying Time Intervals

Intervals are specified in SAS by using *interval names* such as YEAR, QTR, MONTH, DAY, and so forth. [Table 3.3](#) summarizes the basic types of intervals.

Table 3.3 Basic Interval Types

Name	Periodicity
YEAR	yearly
SEMIYEAR	semiannual
QTR	quarterly
MONTH	monthly
SEMIMONTH	1st and 16th of each month
TENDAY	1st, 11th, and 21st of each month
WEEK	weekly
WEEKDAY	daily ignoring weekend days
DAY	daily
HOUR	hourly
MINUTE	every minute
SECOND	every second

Interval names can be abbreviated in various ways. For example, you could specify monthly intervals as MONTH, MONTHS, MONTHLY, or just MON. SAS accepts all these forms as equivalent.

Interval names can also be qualified with a multiplier to indicate multi-period intervals. For example, biennial intervals are specified as YEAR2.

Interval names can also be qualified with a shift index to indicate intervals with different starting points. For example, fiscal years starting in July are specified as YEAR.7.

Intervals are classified as either date or datetime intervals. Date intervals are used with SAS date values, while datetime intervals are used with SAS datetime values. The interval types YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, and DAY are date intervals. HOUR, MINUTE, and SECOND are datetime intervals. Date intervals can be turned into datetime intervals for use with datetime values by prefixing the interval name with 'DT'. Thus DTMONTH intervals are like MONTH intervals but are used with datetime ID values instead of date ID values.

See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about specifying time intervals and for a detailed reference to the different kinds of intervals available.

Using Intervals with SAS/ETS Procedures

SAS/ETS procedures use the date or datetime interval and the ID variable in the following ways:

- to validate the data periodicity. The ID variable is used to check the data and verify that successive observations have valid ID values that correspond to successive time intervals.
- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for January 1990 is followed by an observation for April 1990, there is a gap in the input data with two omitted observations.

- to label forecast observations in the output data set. The values of the ID variable for the forecast observations after the end of the input data set are extrapolated according to the frequency specifications of the INTERVAL= option.

Time Intervals, the Time Series Forecasting System, and the Time Series Viewer

Time intervals are used in the Time Series Forecasting System and Time Series Viewer to identify the number of seasonal cycles or seasonality associated with a DATE, DATETIME, or TIME ID variable. For example, monthly time series have a seasonality of 12 because there are 12 months in a year; quarterly time series have a seasonality of 4 because there are four quarters in a year. The seasonality is used to analyze seasonal properties of time series data and to estimate seasonal forecasting methods.

Plotting Time Series

This section discusses SAS procedures that are available for plotting time series data, but it covers only certain aspects of the use of these procedures with time series data.

The Time Series Viewer displays and analyzes time series plots for time series data sets that do not contain cross sections. See Chapter 37, “[Getting Started with Time Series Forecasting](#).”

The SGPLOT procedure produces high resolution color graphics plots. See the *SAS/GRAPH: Statistical Graphics Procedures Guide* and *SAS/GRAPH Software: Reference* for more information.

The PLOT procedure and the TIMEPLOT procedure produce low-resolution line-printer type plots. See the *Base SAS Procedures Guide* for information about these procedures.

Using the Time Series Viewer

The following command starts the Time Series Viewer to display the plot of CPI in the USCPI data set against DATE. (The USCPI data set was shown in the previous example; the time series used in the following example contains more observations than previously shown.)

```
tsview data=uscp1 var=cpi timeid=date
```

The TSVIEW DATA= option specifies the data set to be viewed; the VAR= option specifies the variable that contains the time series observations; the TIMEID= option specifies the time series ID variable.

The Time Series Viewer can also be invoked by selecting **Solutions►Analyze►Time Series Viewer** from the menu in the SAS Display Manager.

Using PROC SGPLOT

The following statements use the SGPLOT procedure to plot CPI in the USCPI data set against DATE. (The USCPI data set was shown in a previous example; the data set plotted in the following example contains more observations than shown previously.)

```
title "Plot of USCPI Data";  
proc sgplot data=uscpi;  
  series x=date y=cpi / markers;  
run;
```

The plot is shown in [Figure 3.8](#).

Figure 3.8 Plot of Monthly CPI Over Time

Controlling the Time Axis: Tick Marks and Reference Lines

It is possible to control the spacing of the tick marks on the time axis. The following statements use the XAXIS statement to tell PROC SGPLOT to mark the axis at the start of each quarter:

```
proc sgplot data=uscpi;
  series x=date y=cpi / markers;
  format date yyqc.;
  xaxis values=('1jan90'd to '1jul91'd by qtr);
run;
```

The plot is shown in [Figure 3.9](#).

Figure 3.9 Plot of Monthly CPI Over Time

Overlay Plots of Different Variables

You can plot two or more series stored in different variables on the same graph by specifying multiple plot requests in one SGPLOT statement.

For example, the following statements plot the CPI, FORECAST, L95, and U95 variables produced by PROC ARIMA in a previous example. A reference line is drawn to mark the start of the forecast

period. Quarterly tick marks with YYQC format date values are used.

```

title "ARIMA Forecasts of CPI";

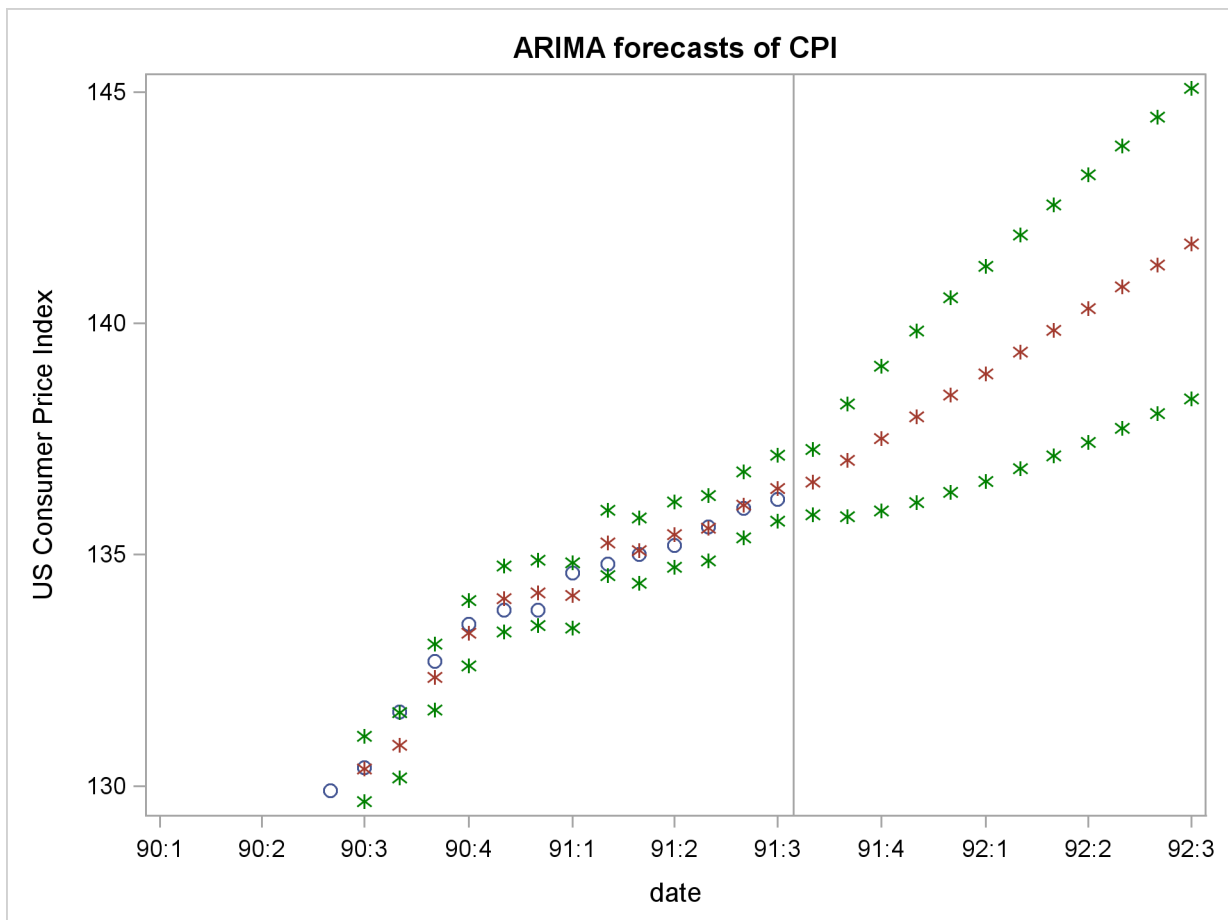

proc arima data=uscpi;
  identify var=cpi(1);
  estimate q=1;
  forecast id=date interval=month lead=12 out=arimaout;
run;

title "ARIMA forecasts of CPI";
proc sgplot data=arimaout noautolegend;
  scatter x=date y=cpi;
  scatter x=date y=forecast / markerattrs=(symbol=asterisk);
  scatter x=date y=195 / markerattrs=(symbol=asterisk color=green);
  scatter x=date y=u95 / markerattrs=(symbol=asterisk color=green);
  format date yyqc4.;
  xaxis values=('1jan90'd to '1jul92'd by qtr);
  refline '15jul91'd / axis=x;
run;

```

The plot is shown in [Figure 3.10](#).

Figure 3.10 Plot of ARIMA Forecast

Overlay Plots of Interleaved Series

You can also plot several series on the same graph when the different series are stored in the same variable in interleaved form. Plot interleaved time series by using the values of the ID variable in GROUP= option to distinguish the different series.

The following example plots the output data set produced by PROC FORECAST in a previous example. Since the residual series has a different scale than the other series, it is excluded from the plot with a WHERE statement.

The `_TYPE_` variable is used in the PLOT statement to identify the different series and to select the SCATTER statements to use for each plot.

```

title "Plot of Forecasts of US CPI Data";

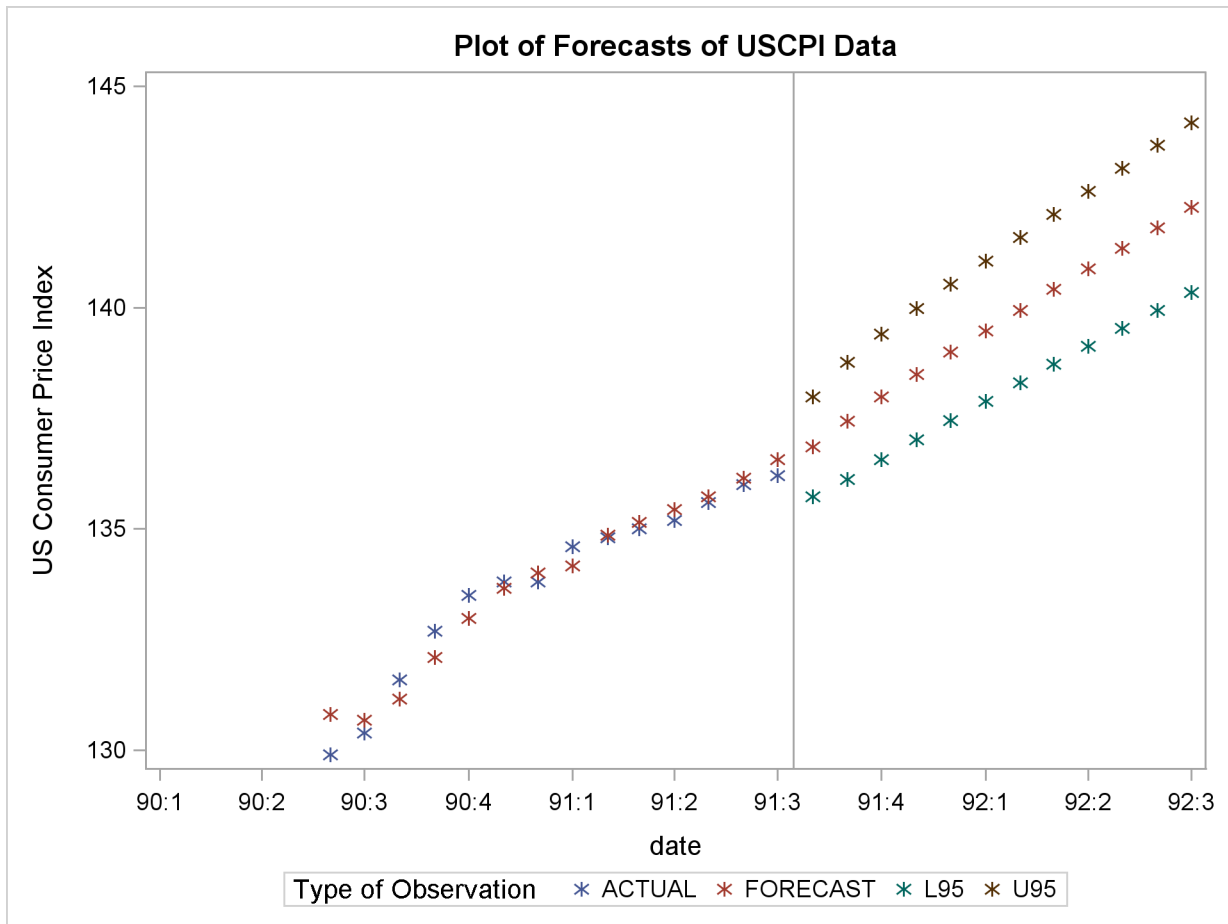

proc forecast data=uscpi interval=month lead=12
              out=foreout outfull outresid;
  var cpi;
  id date;
run;

proc sgplot data=foreout;
  where _type_ ^= 'RESIDUAL';
  scatter x=date y=cpi / group=_type_ markerattrs=(symbol=asterisk);
  format date yyqc4.;
  xaxis values=('1jan90'd to '1jul92'd by qtr);
  refline '15jul91'd / axis=x;
run;

```

The plot is shown in [Figure 3.11](#).

Figure 3.11 Plot of Forecast

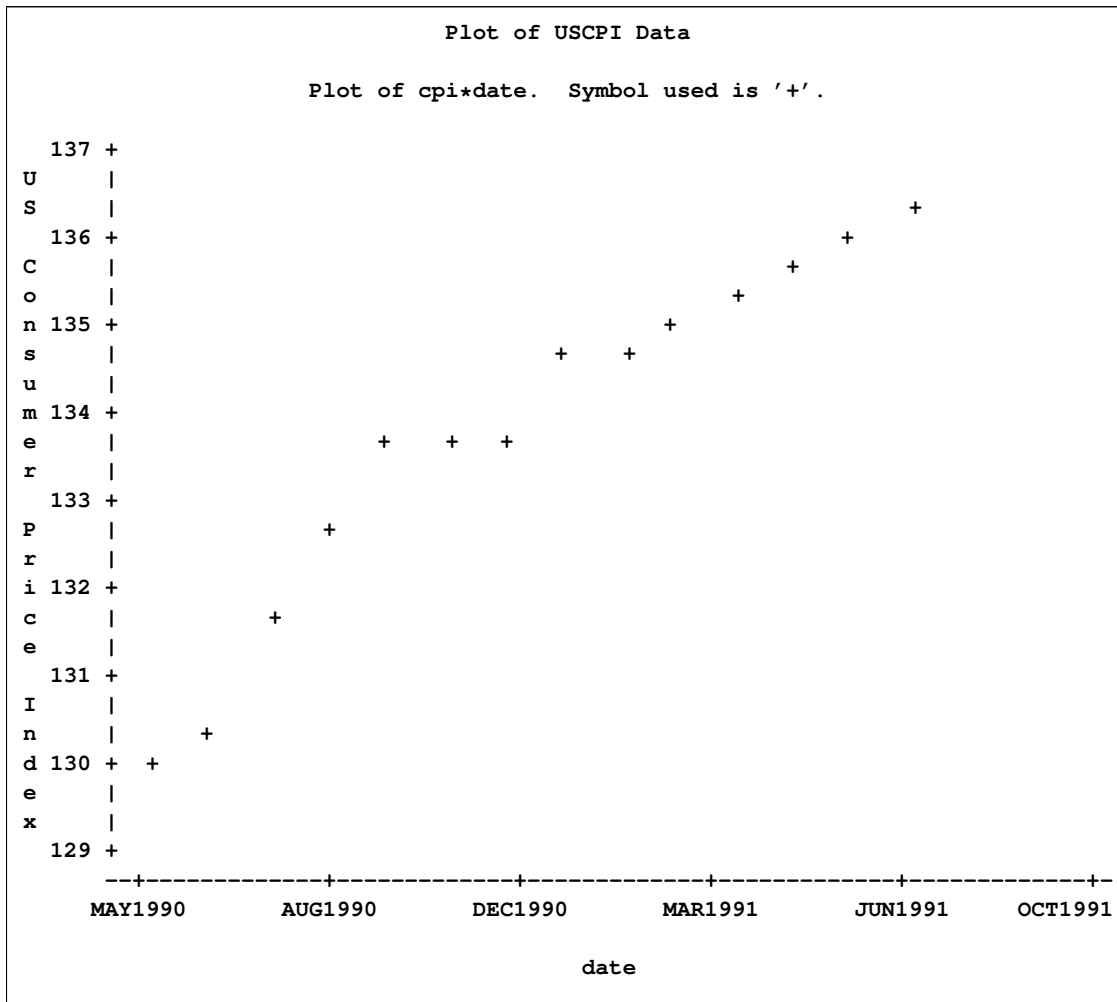

Residual Plots

The following example plots the residuals series that was excluded from the plot in the previous example. The NEEDLE statement specifies a needle plot, so that each residual point is plotted as a vertical line showing deviation from zero.

```
proc sgplot data=foreout;
  where _type_ = 'RESIDUAL';
  needle x=date y=cpi / markers;
  format date yyqc4.;
  xaxis values=('1jan90'd to '1jul91'd by qtr);
run;
```

The plot is shown in [Figure 3.12](#).

Figure 3.13 Plot of Monthly CPI Over Time

Using PROC TIMEPLOT

The TIMEPLOT procedure in Base SAS plots time series data vertically on the page instead of horizontally across the page as the PLOT procedure does. PROC TIMEPLOT can also print the data values as well as plot them.

The following statements use the TIMEPLOT procedure to plot CPI in the USCPI data set. Only the last 14 observations are included in this example. The plot is shown in [Figure 3.14](#).

```

title "Plot of USCPI Data";
proc timeplot data=uscpi;
  plot cpi;
  id date;
  where date >= '1jun90'd;
run;

```

Figure 3.14 Output Produced by PROC TIMEPLOT

The TIMEPLOT procedure has several interesting features not discussed here. See “The TIMEPLOT Procedure” in the *Base SAS Procedures Guide* for more information.

Using PROC GPLOT

The GPLOT procedure in SAS/GRAPH software can also be used to plot time series data, although the newer SGPLOT procedure is easier to use.

The following is an example of how GPLOT can be used to produce a plot similar to the graph produced by PROC SGPLOT in the preceding section.

```

title "Plot of USCPI Data";
proc gplot data=uscpi;
  symbol i=spline v=circle h=2;
  plot cpi * date;
run;

```

The plot is shown in [Figure 3.15](#).

Figure 3.15 Plot of Monthly CPI Over Time

For more information about the GPLOT procedure, see *SAS/GRAPH Software: Reference*.

Calendar and Time Functions

Calendar and time functions convert calendar and time variables such as YEAR, MONTH, DAY, and HOUR, MINUTE, SECOND into SAS date or datetime values, and vice versa.

The SAS calendar and time functions are DATEJUL, DATEPART, DAY, DHMS, HMS, HOUR, JULDATE, MDY, MINUTE, MONTH, QTR, SECOND, TIMEPART, WEEKDAY, YEAR, and YYQ. See *SAS Language Reference: Dictionary* for more details about these functions.

Computing Dates from Calendar Variables

The MDY function converts MONTH, DAY, and YEAR values to a SAS date value. For example, MDY(2010,17,91) returns the SAS date value '17OCT2010'D.

The YYQ function computes the SAS date for the first day of a quarter. For example, YYQ(2010,4) returns the SAS date value '1OCT2010'D.

The DATEJUL function computes the SAS date for a Julian date. For example, DATEJUL(91290) returns the SAS date '17OCT2010'D.

The YYQ and MDY functions are useful for creating SAS date variables when the ID values recorded in the data are year and quarter; year and month; or year, month, and day.

For example, the following statements read quarterly data from records in which dates are coded as separate year and quarter values. The YYQ function is used to compute the variable DATE.

```
data usecon;
    input year qtr gnp;
    date = yyq( year, qtr );
    format date yyqc.;
datalines;
1990 1 5375.4
1990 2 5443.3
... more lines ...
```

The monthly US CPI data shown in a previous example contained time ID values represented in the MONYY format. If the data records instead contain separate year and month values, the data can be read in and the DATE variable computed with the following statements:

```
data uscpi;
    input month year cpi;
    date = mdy( month, 1, year );
    format date monyy.;
datalines;
6 90 129.9
7 90 130.4
... more lines ...
```

Computing Calendar Variables from Dates

The functions YEAR, MONTH, DAY, WEEKDAY, and JULDATE compute calendar variables from SAS date values.

Returning to the example of reading the USCPI data from records that contain date values represented in the MONYY format, you can find the month and year of each observation from the SAS dates of the observations by using the following statements.

```
data uscpi;
  input date monyy7. cpi;
  format date monyy7.;
  year = year( date );
  month = month( date );
datalines;
jun1990 129.9
jul1990 130.4

... more lines ...
```

Converting between Date, Datetime, and Time Values

The DATEPART function computes the SAS date value for the date part of a SAS datetime value. The TIMEPART function computes the SAS time value for the time part of a SAS datetime value.

The HMS function computes SAS time values from HOUR, MINUTE, and SECOND time variables. The DHMS function computes a SAS datetime value from a SAS date value and HOUR, MINUTE, and SECOND time variables.

See the section “[Date, Time, and Datetime Functions](#)” on page 143 for more information about these functions.

Computing Datetime Values

To compute datetime ID values from calendar and time variables, first compute the date and then compute the datetime with DHMS.

For example, suppose you read tri-hourly temperature data with time recorded as YEAR, MONTH, DAY, and HOUR. The following statements show how to compute the ID variable DATETIME:

```
data weather;
  input year month day hour temp;
  datetime = dhms( mdy( month, day, year ), hour, 0, 0 );
  format datetime datetime10.;
datalines;
91 10 16 21 61
91 10 17 0 56
91 10 17 3 53

... more lines ...
```

Computing Calendar and Time Variables

The functions HOUR, MINUTE, and SECOND compute time variables from SAS datetime values. The DATEPART function and the date-to-calendar variables functions can be combined to compute calendar variables from datetime values.

For example, suppose the date and time of the tri-hourly temperature data in the preceding example were recorded as datetime values in the datetime format. The following statements show how to compute the YEAR, MONTH, DAY, and HOUR of each observation and include these variables in the SAS data set:

```
data weather;
  input datetime : datetime13. temp;
  format datetime datetime10.;
  hour = hour( datetime );
  date = datepart( datetime );
  year = year( date );
  month = month( date );
  day = day( date );
datalines;
16oct91:21:00 61
17oct91:00:00 56
17oct91:03:00 53
... more lines ...
```

Interval Functions INTNX and INTCK

The SAS interval functions INTNX and INTCK perform calculations with date values, datetime values, and time intervals. They can be used for calendar calculations with SAS date values to increment date values or datetime values by intervals and to count time intervals between dates.

The INTNX function increments dates by intervals. INTNX computes the date or datetime of the start of the interval a specified number of intervals from the interval that contains a given date or datetime value.

The form of the INTNX function is

```
INTNX ( interval, from, n < , alignment > );
```

The arguments to the INTNX function are as follows:

interval

is a character constant or variable that contains an interval name

from

is a SAS date value (for date intervals) or datetime value (for datetime intervals)

n

is the number of intervals to increment from the interval that contains the *from* value

alignment

controls the alignment of SAS dates, within the interval, used to identify output observations. Allowed values are BEGINNING, MIDDLE, END, and SAMEDAY.

The number of intervals to increment, *n*, can be positive, negative, or zero.

For example, the statement `NEXTMON=INTNX('MONTH',DATE,1)` assigns to the variable `NEXTMON` the date of the first day of the month following the month that contains the value of `DATE`. Thus `INTNX('MONTH','21OCT2007'D,1)` returns the date 1 November 2007.

The `INTCK` function counts the number of interval boundaries between two date values or between two datetime values.

The form of the `INTCK` function is

INTCK (*interval*, *from*, *to*);

The arguments of the `INTCK` function are as follows:

interval

is a character constant or variable that contains an interval name

from

is the starting date value (for date intervals) or datetime value (for datetime intervals)

to

is the ending date value (for date intervals) or datetime value (for datetime intervals)

For example, the statement `NEWYEARS=INTCK('YEAR',DATE1,DATE2)` assigns to the variable `NEWYEARS` the number of New Year's Days between the two dates.

Incrementing Dates by Intervals

Use the `INTNX` function to increment dates by intervals. For example, suppose you want to know the date of the start of the week that is six weeks from the week of 17 October 1991. The function `INTNX('WEEK','17OCT91'D,6)` returns the SAS date value `'24NOV1991'D`.

One practical use of the `INTNX` function is to generate periodic date values. For example, suppose the monthly U.S. Consumer Price Index data in a previous example were recorded without any time identifier on the data records. Given that you know the first observation is for June 1990, the following statements use the `INTNX` function to compute the ID variable `DATE` for each observation:

```

data uscpi;
  input cpi;
  date = intnx( 'month', '1jun1990'd, _n_-1 );
  format date monyy7.;
datalines;
129.9
130.4

... more lines ...

```

The automatic variable `_N_` counts the number of times the DATA step program has executed; in this case `_N_` contains the observation number. Thus `_N_-1` is the increment needed from the first observation date. Alternatively, you could increment from the month before the first observation, in which case the INTNX function in this example would be written `INTNX('MONTH','1MAY1990'D,_N_)`.

Alignment of SAS Dates

Any date within the time interval that corresponds to an observation of a periodic time series can serve as an ID value for the observation. For example, the USCPI data in a previous example might have been recorded with dates at the 15th of each month. The person recording the data might reason that since the CPI values are monthly averages, midpoints of the months might be the appropriate ID values.

However, as far as SAS/ETS procedures are concerned, what is important about monthly data is the month of each observation, not the exact date of the ID value. If you indicate that the data are monthly (with an `INTERVAL=MONTH`) option, SAS/ETS procedures ignore the day of the month in processing the ID variable. The `MONYY` format also ignores the day of the month.

Thus, you could read in the monthly USCPI data with mid-month DATE values by using the following statements:

```

data uscpi;
  input date : date9. cpi;
  format date monyy7.;
datalines;
15jun1990 129.9
15jul1990 130.4

... more lines ...

```

The results of using this version of the USCPI data set for analysis with SAS/ETS procedures would be the same as with first-of-month values for DATE. Although you can use any date within the interval as an ID value for the interval, you might find working with time series in SAS less confusing if you always use date ID values normalized to the start of the interval.

For some applications it might be preferable to use end of period dates, such as 31Jan1994, 28Feb1994, 31Mar1994, ..., 31Dec1994. For other applications, such as plotting time series, it might be more convenient to use interval midpoint dates to identify the observations.

(Some SAS/ETS procedures provide an ALIGN= option to control the alignment of dates for output time series observations. In addition, the INTNX library function supports an optional argument to specify the alignment of the returned date value.)

To normalize date values to the start of intervals, use the INTNX function with a 0 increment. The INTNX function with an increment of 0 computes the date of the first day of the interval (or the first second of the interval for datetime values).

For example, INTNX('MONTH','17OCT1991'D,0,'BEG') returns the date '1OCT1991'D.

The following statements show how the preceding example can be changed to normalize the mid-month DATE values to first-of-month and end-of-month values. For exposition, the first-of-month value is transformed back into a middle-of-month value.

```
data uscpi;
  input date : date9. cpi;
  format date monyy7.;
  monthbeg = intnx( 'month', date, 0, 'beg' );
  midmonth = intnx( 'month', monthbeg, 0, 'mid' );
  monthend = intnx( 'month', date, 0, 'end' );
datalines;
15jun1990 129.9
15jul1990 130.4

... more lines ...
```

If you want to compute the date of a particular day within an interval, you can use calendar functions, or you can increment the starting date of the interval by a number of days. The following example shows three ways to compute the seventh day of the month:

```
data test;
  set uscpi;
  mon07_1 = mdy( month(date), 7, year(date) );
  mon07_2 = intnx( 'month', date, 0, 'beg' ) + 6;
  mon07_3 = intnx( 'day', date, 6 );
run;
```

Computing the Width of a Time Interval

To compute the width of a time interval, subtract the ID value of the start of the next interval from the ID value of the start of the current interval. If the ID values are SAS dates, the width is in days. If the ID values are SAS datetime values, the width is in seconds.

For example, the following statements show how to add a variable WIDTH to the USCPI data set

that contains the number of days in the month for each observation:

```
data uscpi;
  input date : date9. cpi;
  format date monyy7.;
  width = intnx( 'month', date, 1 ) - intnx( 'month', date, 0 );
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6

... more lines ...
```

Computing the Ceiling of an Interval

To shift a date to the start of the next interval if it is not already at the start of an interval, subtract 1 from the date and use INTNX to increment the date by 1 interval.

For example, the following statements add the variable NEWYEAR to the monthly USCPI data set. The variable NEWYEAR contains the date of the next New Year's Day. NEWYEAR contains the same value as DATE when the DATE value is the start of year and otherwise contains the date of the start of the next year.

```
data test;
  set uscpi;
  newyear = intnx( 'year', date - 1, 1 );
  format newyear date.;
run;
```

Counting Time Intervals

Use the INTCK function to count the number of interval boundaries between two dates.

Note that the INTCK function counts the number of times the beginning of an interval is reached in moving from the first date to the second. It does not count the number of complete intervals between two dates. Following are two examples:

- The function INTCK('MONTH', '1JAN1991'D, '31JAN1991'D) returns 0, since the two dates are within the same month.
- The function INTCK('MONTH', '31JAN1991'D, '1FEB1991'D) returns 1, since the two dates lie in different months that are one month apart.

When the first date is later than the second date, INTCK returns a negative count. For example, the function INTCK('MONTH', '1FEB1991'D, '31JAN1991'D) returns -1.

The following example shows how to use the INTCK function with shifted interval specifications to count the number of Sundays, Mondays, Tuesdays, and so forth, in each month. The variables NSUNDAY, NMONDAY, NTUESDAY, and so forth, are added to the USCPI data set.

```
data uscpi;
  set uscpi;
  d0 = intnx( 'month', date, 0 ) - 1;
  d1 = intnx( 'month', date, 1 ) - 1;
  nSunday = intck( 'week.1', d0, d1 );
  nMonday = intck( 'week.2', d0, d1 );
  nTuesday = intck( 'week.3', d0, d1 );
  nWednesday = intck( 'week.4', d0, d1 );
  nThursday = intck( 'week.5', d0, d1 );
  nFriday = intck( 'week.6', d0, d1 );
  nSaturday = intck( 'week.7', d0, d1 );
  drop d0 d1;
run;
```

Since the INTCK function counts the number of interval beginning dates between two dates, the number of Sundays is computed by counting the number of week boundaries between the last day of the previous month and the last day of the current month. To count Mondays, Tuesdays, and so forth, shifted week intervals are used. The interval type WEEK.2 specifies weekly intervals starting on Mondays, WEEK.3 specifies weeks starting on Tuesdays, and so forth.

Checking Data Periodicity

Suppose you have a time series data set and you want to verify that the data periodicity is correct, the observations are dated correctly, and the data set is sorted by date. You can use the INTCK function to compare the date of the current observation with the date of the previous observation and verify that the dates fall into consecutive time intervals.

For example, the following statements verify that the data set USCPI is a correctly dated monthly data set. The RETAIN statement is used to hold the date of the previous observation, and the automatic variable `_N_` is used to start the verification process with the second observation.

```
data _null_;
  set uscpi;
  retain prevdate;
  if _n_ > 1 then
    if intck( 'month', prevdate, date ) ^= 1 then
      put "Bad date sequence at observation number " _n_;
  prevdate = date;
run;
```

Filling In Omitted Observations in a Time Series Data Set

Most SAS/ETS procedures expect input data to be in the standard form, with no omitted observations in the sequence of time periods. When data are missing for a time period, the data set should contain a missing observation, in which all variables except the ID variables have missing values.

You can replace omitted observations in a time series data set with missing observations with the [EXPAND](#) procedure.

The following statements create a monthly data set, `OMITTED`, from data lines that contain records for an intermittent sample of months. (Data values are not shown.) The `OMITTED` data set is sorted to make sure it is in time order.

```
data omitted;
  input date : monyy7. x y z;
  format date monyy7.;
datalines;
jan1991  ...
mar1991  ...
apr1991  ...
jun1991  ...
... etc. ...
;

proc sort data=omitted;
  by date;
run;
```

This data set is converted to a standard form time series data set by the following `PROC EXPAND` step. The `TO=` option specifies that monthly data is to be output, while the `METHOD=NONE` option specifies that no interpolation is to be performed, so that the variables `X`, `Y`, and `Z` in the output data set `STANDARD` will have missing values for the omitted time periods that are filled in by the `EXPAND` procedure.

```
proc expand data=omitted
  out=standard
  to=month
  method=none;
  id date;
run;
```

Using Interval Functions for Calendar Calculations

With a little thought, you can come up with a formula that involves `INTNX` and `INTCK` functions and different interval types to perform almost any calendar calculation.

For example, suppose you want to know the date of the third Wednesday in the month of October 1991. The answer can be computed as

```
intnx( 'week.4', '1oct91'd - 1, 3 )
```

which returns the SAS date value '16OCT91'D.

Consider this more complex example: how many weekdays are there between 17 October 1991 and the second Friday in November 1991, inclusive? The following formula computes the number of weekdays between the date value contained in the variable DATE and the second Friday of the following month (including the ending dates of this period):

```
n = intck( 'weekday', date - 1,
          intnx( 'week.6', intnx( 'month', date, 1 ) - 1, 2 ) + 1 );
```

Setting DATE to '17OCT91'D and applying this formula produces the answer, N=17.

Lags, Leads, Differences, and Summations

When working with time series data, you sometimes need to refer to the values of a series in previous or future periods. For example, the usual interest in the consumer price index series shown in previous examples is how fast the index is changing, rather than the actual level of the index. To compute a percent change, you need both the current and the previous values of the series. When you model a time series, you might want to use the previous values of other series as explanatory variables.

This section discusses how to use the DATA step to perform operations over time: lags, differences, leads, summations over time, and percent changes.

The EXPAND procedure can also be used to perform many of these operations; see Chapter 14, “[The EXPAND Procedure](#),” for more information. See also the section “[Transforming Time Series](#)” on page 115.

The LAG and DIF Functions

The DATA step provides two functions, LAG and DIF, for accessing previous values of a variable or expression. These functions are useful for computing lags and differences of series.

For example, the following statements add the variables CPILAG and CPIDIF to the USCPI data set. The variable CPILAG contains lagged values of the CPI series. The variable CPIDIF contains the changes of the CPI series from the previous period; that is, CPIDIF is CPI minus CPILAG. The new data set is shown in part in [Figure 3.16](#).

```

data uscpi;
  set uscpi;
  cpilag = lag( cpi );
  cpidif = dif( cpi );
run;

proc print data=uscpi;
run;

```

Figure 3.16 USCPI Data Set with Lagged and Differenced Series

Plot of USCPI Data				
Obs	date	cpi	cpilag	cpidif
1	JUN1990	129.9	.	.
2	JUL1990	130.4	129.9	0.5
3	AUG1990	131.6	130.4	1.2
4	SEP1990	132.7	131.6	1.1
5	OCT1990	133.5	132.7	0.8
6	NOV1990	133.8	133.5	0.3
7	DEC1990	133.8	133.8	0.0
8	JAN1991	134.6	133.8	0.8
9	FEB1991	134.8	134.6	0.2
10	MAR1991	135.0	134.8	0.2
11	APR1991	135.2	135.0	0.2
12	MAY1991	135.6	135.2	0.4
13	JUN1991	136.0	135.6	0.4
14	JUL1991	136.2	136.0	0.2

Understanding the DATA Step LAG and DIF Functions

When used in this simple way, LAG and DIF act as lag and difference functions. However, it is important to keep in mind that, despite their names, the LAG and DIF functions available in the DATA step are not true lag and difference functions.

Rather, LAG and DIF are queuing functions that remember and return argument values from previous calls. The LAG function remembers the value you pass to it and returns as its result the value you passed to it on the previous call. The DIF function works the same way but returns the difference between the current argument and the remembered value. (LAG and DIF return a missing value the first time the function is called.)

A true lag function does not return the value of the argument for the “previous call,” as do the DATA step LAG and DIF functions. Instead, a true lag function returns the value of its argument for the “previous observation,” regardless of the sequence of previous calls to the function. Thus, for a true lag function to be possible, it must be clear what the “previous observation” is.

If the data are sorted chronologically, then LAG and DIF act as true lag and difference functions. If in doubt, use PROC SORT to sort your data before using the LAG and DIF functions. Beware of missing observations, which can cause LAG and DIF to return values that are not the actual lag and difference values.

The DATA step is a powerful tool that can read any number of observations from any number of input files or data sets, can create any number of output data sets, and can write any number of output observations to any of the output data sets, all in the same program. Thus, in general, it is not clear what “previous observation” means in a DATA step program. In a DATA step program, the “previous observation” exists only if you write the program in a simple way that makes this concept meaningful.

Since, in general, the previous observation is not clearly defined, it is not possible to make true lag or difference functions for the DATA step. Instead, the DATA step provides queuing functions that make it easy to compute lags and differences.

Pitfalls of DATA Step LAG and DIF Functions

The LAG and DIF functions compute lags and differences provided that the sequence of calls to the function corresponds to the sequence of observations in the output data set. However, any complexity in the DATA step that breaks this correspondence causes the LAG and DIF functions to produce unexpected results.

For example, suppose you want to add the variable CPILAG to the USCPI data set, as in the previous example, and you also want to subset the series to 1991 and later years. You might use the following statements:

```
data subset;
  set uscpi;
  if date >= '1jan1991'd;
  cpilag = lag( cpi ); /* WRONG PLACEMENT! */
run;
```

If the subsetting IF statement comes before the LAG function call, the value of CPILAG will be missing for January 1991, even though a value for December 1990 is available in the USCPI data set. To avoid losing this value, you must rearrange the statements to ensure that the LAG function is actually executed for the December 1990 observation.

```
data subset;
  set uscpi;
  cpilag = lag( cpi );
  if date >= '1jan1991'd;
run;
```

In other cases, the subsetting statement should come before the LAG and DIF functions. For example, the following statements subset the FOREOUT data set shown in a previous example to select only `_TYPE_=RESIDUAL` observations and also to compute the variable LAGRESID:

```
data residual;
  set foreout;
  if _type_ = "RESIDUAL";
  lagresid = lag( cpi );
run;
```

Another pitfall of LAG and DIF functions arises when they are used to process time series cross-sectional data sets. For example, suppose you want to add the variable CPILAG to the CPICITY data set shown in a previous example. You might use the following statements:

```
data cpicity;
  set cpicity;
  cpilag = lag( cpi );
run;
```

However, these statements do not yield the desired result. In the data set produced by these statements, the value of CPILAG for the first observation for the first city is missing (as it should be), but in the first observation for all later cities, CPILAG contains the last value for the previous city. To correct this, set the lagged variable to missing at the start of each cross section, as follows:

```
data cpicity;
  set cpicity;
  by city date;
  cpilag = lag( cpi );
  if first.city then cpilag = .;
run;
```

Alternatives to LAG and DIF Functions

You can also use the [EXPAND](#) procedure to compute lags and differences. For example, the following statements compute lag and difference variables for CPI:

```
proc expand data=uscpi out=uscpi method=none;
  id date;
  convert cpi=cpilag / transform=( lag 1 );
  convert cpi=cpidif / transform=( dif 1 );
run;
```

You can also calculate lags and differences in the DATA step without using LAG and DIF functions. For example, the following statements add the variables CPILAG and CPIDIF to the USCPI data set:

```
data uscpi;
  set uscpi;
  retain cpilag;
  cpidif = cpi - cpilag;
  output;
  cpilag = cpi;
run;
```

The RETAIN statement prevents the DATA step from reinitializing CPILAG to a missing value at the start of each iteration and thus allows CPILAG to retain the value of CPI assigned to it in the last statement. The OUTPUT statement causes the output observation to contain values of the variables before CPILAG is reassigned the current value of CPI in the last statement. This is the approach that must be used if you want to build a variable that is a function of its previous lags.

LAG and DIF Functions in PROC MODEL

The preceding discussion of LAG and DIF functions applies to LAG and DIF functions available in the DATA step. However, LAG and DIF functions are also used in the MODEL procedure.

The **MODEL** procedure LAG and DIF functions do not work like the DATA step LAG and DIF functions. The LAG and DIF functions supported by PROC MODEL are true lag and difference functions, not queuing functions.

Unlike the DATA step, the MODEL procedure processes observations from a single input data set, so the “previous observation” is always clearly defined in a PROC MODEL program. Therefore, PROC MODEL is able to define LAG and DIF as true lagging functions that operate on values from the previous observation. See Chapter 18, “[The MODEL Procedure](#),” for more information about LAG and DIF functions in the MODEL procedure.

Multi-period Lags and Higher-Order Differencing

To compute lags at a lagging period greater than 1, add the lag length to the end of the LAG keyword to specify the lagging function needed. For example, the LAG2 function returns the value of its argument two calls ago, the LAG3 function returns the value of its argument three calls ago, and so forth.

To compute differences at a lagging period greater than 1, add the lag length to the end of the DIF keyword. For example, the DIF2 function computes the differences between the value of its argument and the value of its argument two calls ago. (The maximum lagging period is 100.)

The following statements add the variables CPILAG12 and CPIDIF12 to the USCPI data set. CPI-LAG12 contains the value of CPI from the same month one year ago. CPIDIF12 contains the change in CPI from the same month one year ago. (In this case, the first 12 values of CPILAG12 and CPIDIF12 are missing.)

```
data uscpi;
  set uscpi;
  cpilag12 = lag12( cpi );
  cpidif12 = dif12( cpi );
run;
```

To compute second differences, take the difference of the difference. To compute higher-order differences, nest DIF functions to the order needed. For example, the following statements compute the second difference of CPI:

```
data uscpi;
  set uscpi;
  cpi2dif = dif( dif( cpi ) );
run;
```

Multi-period lags and higher-order differencing can be combined. For example, the following statements compute monthly changes in the inflation rate, with inflation rate computed as percent change

in CPI from the same month one year ago:

```
data uscpi;
  set uscpi;
  infchnng = dif( 100 * dif12( cpi ) / lag12( cpi ) );
run;
```

Percent Change Calculations

There are several common ways to compute the percent change in a time series. This section illustrates the use of LAG and DIF functions by showing SAS statements for various kinds of percent change calculations.

Computing Period-to-Period Change

To compute percent change from the previous period, divide the difference of the series by the lagged value of the series and multiply by 100.

```
data uscpi;
  set uscpi;
  pctchnng = dif( cpi ) / lag( cpi ) * 100;
  label pctchnng = "Monthly Percent Change, At Monthly Rates";
run;
```

Often, changes from the previous period are expressed at annual rates. This is done by exponentiation of the current-to-previous period ratio to the number of periods in a year and expressing the result as a percent change. For example, the following statements compute the month-over-month change in CPI as a percent change at annual rates:

```
data uscpi;
  set uscpi;
  pctchnng = ( ( cpi / lag( cpi ) ) ** 12 - 1 ) * 100;
  label pctchnng = "Monthly Percent Change, At Annual Rates";
run;
```

Computing Year-over-Year Change

To compute percent change from the same period in the previous year, use LAG and DIF functions with a lagging period equal to the number of periods in a year. (For quarterly data, use LAG4 and DIF4. For monthly data, use LAG12 and DIF12.)

For example, the following statements compute monthly percent change in CPI from the same month one year ago:

```
data uscpi;
  set uscpi;
```

```

pctchnng = dif12( cpi ) / lag12( cpi ) * 100;
label pctchnng = "Percent Change from One Year Ago";
run;

```

To compute year-over-year percent change measured at a given period within the year, subset the series of percent changes from the same period in the previous year to form a yearly data set. Use an IF or WHERE statement to select observations for the period within each year on which the year-over-year changes are based.

For example, the following statements compute year-over-year percent change in CPI from December of the previous year to December of the current year:

```

data annual;
  set uscpi;
  pctchnng = dif12( cpi ) / lag12( cpi ) * 100;
  label pctchnng = "Percent Change: December to December";
  if month( date ) = 12;
  format date year4.;
run;

```

Computing Percent Change in Yearly Averages

To compute changes in yearly averages, first aggregate the series to an annual series by using the EXPAND procedure, and then compute the percent change of the annual series. (See Chapter 14, “The EXPAND Procedure,” for more information about PROC EXPAND.)

For example, the following statements compute percent changes in the annual averages of CPI:

```

proc expand data=uscpi out=annual from=month to=year;
  convert cpi / observed=average method=aggregate;
run;

data annual;
  set annual;
  pctchnng = dif( cpi ) / lag( cpi ) * 100;
  label pctchnng = "Percent Change in Yearly Averages";
run;

```

It is also possible to compute percent change in the average over the most recent yearly span. For example, the following statements compute monthly percent change in the average of CPI over the most recent 12 months from the average over the previous 12 months:

```

data uscpi;
  retain sum12 0;
  drop sum12 ave12 cpilag12;
  set uscpi;
  sum12 = sum12 + cpi;
  cpilag12 = lag12( cpi );
  if cpilag12 ^= . then sum12 = sum12 - cpilag12;
  if lag11( cpi ) ^= . then ave12 = sum12 / 12;
  pctchnng = dif12( ave12 ) / lag12( ave12 ) * 100;

```

```

label pctchn = "Percent Change in 12 Month Moving Ave.";
run;

```

This example is a complex use of LAG and DIF functions that requires care in handling the initialization of the moving-window averaging process. The LAG12 of CPI is checked for missing values to determine when more than 12 values have been accumulated, and older values must be removed from the moving sum. The LAG11 of CPI is checked for missing values to determine when at least 12 values have been accumulated; AVE12 will be missing when LAG11 of CPI is missing. The DROP statement prevents temporary variables from being added to the data set.

Note that the DIF and LAG functions must execute for every observation, or the queues of remembered values will not operate correctly. The CPILAG12 calculation must be separate from the IF statement. The PCTCHNG calculation must not be conditional on the IF statement.

The EXPAND procedure provides an alternative way to compute moving averages.

Leading Series

Although the SAS System does not provide a function to look ahead at the “next” value of a series, there are a couple of ways to perform this task.

The most direct way to compute leads is to use the EXPAND procedure. For example:

```

proc expand data=uscpi out=uscpi method=none;
  id date;
  convert cpi=cpilead1 / transform=( lead 1 );
  convert cpi=cpilead2 / transform=( lead 2 );
run;

```

Another way to compute lead series in SAS software is by lagging the time ID variable, renaming the series, and merging the result data set back with the original data set.

For example, the following statements add the variable CPILEAD to the USCPI data set. The variable CPILEAD contains the value of CPI in the following month. (The value of CPILEAD is missing for the last observation, of course.)

```

data temp;
  set uscpi;
  keep date cpi;
  rename cpi = cpilead;
  date = lag( date );
  if date ^= .;
run;

data uscpi;
  merge uscpi temp;
  by date;
run;

```

To compute leads at different lead lengths, you must create one temporary data set for each lead length. For example, the following statements compute CPILEAD1 and CPILEAD2, which contain leads of CPI for 1 and 2 periods, respectively:

```
data temp1(rename=(cpi=cpilead1))
    temp2(rename=(cpi=cpilead2));
    set uscpi;
    keep date cpi;
    date = lag( date );
    if date ^= . then output temp1;
    date = lag( date );
    if date ^= . then output temp2;
run;

data uscpi;
    merge uscpi temp1 temp2;
    by date;
run;
```

Summing Series

Simple cumulative sums are easy to compute using SAS sum statements. The following statements show how to compute the running sum of variable X in data set A, adding XSUM to the data set.

```
data a;
    set a;
    xsum + x;
run;
```

The SAS sum statement automatically retains the variable XSUM and initializes it to 0, and the sum statement treats missing values as 0. The sum statement is equivalent to using a RETAIN statement and the SUM function. The previous example could also be written as follows:

```
data a;
    set a;
    retain xsum;
    xsum = sum( xsum, x );
run;
```

You can also use the EXPAND procedure to compute summations. For example:

```
proc expand data=a out=a method=none;
    convert x=xsum / transform=( sum );
run;
```

Like differencing, summation can be done at different lags and can be repeated to produce higher-order sums. To compute sums over observations separated by lags greater than 1, use the LAG and

SUM functions together, and use a RETAIN statement that initializes the summation variable to zero.

For example, the following statements add the variable XSUM2 to data set A. XSUM2 contains the sum of every other observation, with even-numbered observations containing a cumulative sum of values of X from even observations, and odd-numbered observations containing a cumulative sum of values of X from odd observations.

```
data a;
  set a;
  retain xsum2 0;
  xsum2 = sum( lag( xsum2 ), x );
run;
```

Assuming that A is a quarterly data set, the following statements compute running sums of X for each quarter. XSUM4 contains the cumulative sum of X for all observations for the same quarter as the current quarter. Thus, for a first-quarter observation, XSUM4 contains a cumulative sum of current and past first-quarter values.

```
data a;
  set a;
  retain xsum4 0;
  xsum4 = sum( lag3( xsum4 ), x );
run;
```

To compute higher-order sums, repeat the preceding process and sum the summation variable. For example, the following statements compute the first and second summations of X:

```
data a;
  set a;
  xsum + x;
  x2sum + xsum;
run;
```

The following statements compute the second order four-period sum of X:

```
data a;
  set a;
  retain xsum4 x2sum4 0;
  xsum4 = sum( lag3( xsum4 ), x );
  x2sum4 = sum( lag3( x2sum4 ), xsum4 );
run;
```

You can also use PROC EXPAND to compute cumulative statistics and moving window statistics. See Chapter 14, “[The EXPAND Procedure](#),” for details.

Transforming Time Series

It is often useful to transform time series for analysis or forecasting. Many time series analysis and forecasting methods are most appropriate for time series with an unrestricted range, a linear trend, and a constant variance. Series that do not conform to these assumptions can often be transformed to series for which the methods are appropriate.

Transformations can be useful for the following:

- range restrictions. Many time series cannot have negative values or can be limited to a maximum possible value. You can often create a transformed series with an unbounded range.
- nonlinear trends. Many economic time series grow exponentially. Exponential growth corresponds to linear growth in the logarithms of the series.
- series variability that changes over time. Various transformations can be used to stabilize the variance.
- nonstationarity. The %DFTEST macro can be used to test a series for nonstationarity which can then be removed by differencing.

Log Transformation

The logarithmic transformation is often useful for series that must be greater than zero and that grow exponentially. For example, [Figure 3.17](#) shows a plot of an airline passenger miles series. Notice that the series has exponential growth and the variability of the series increases over time. Airline passenger miles must also be zero or greater.

Figure 3.17 Airline Series

The following statements compute the logarithms of the airline series:

```
data lair;
  set sashelp.air;
  logair = log( air );
run;
```

Figure 3.18 shows a plot of the log-transformed airline series. Notice that the log series has a linear trend and constant variance.

Figure 3.18 Log Airline Series

The %LOGTEST macro can help you decide if a log transformation is appropriate for a series. See Chapter 5, “SAS Macros and Functions,” for more information about the %LOGTEST macro.

Other Transformations

The Box-Cox transformation is a general class of transformations that includes the logarithm as a special case. The %BOXCOXAR macro can be used to find an optimal Box-Cox transformation for a time series. See Chapter 5 for more information about the %BOXCOXAR macro.

The logistic transformation is useful for variables with both an upper and a lower bound, such as market shares. The logistic transformation is useful for proportions, percent values, relative frequencies, or probabilities. The logistic function transforms values between 0 and 1 to values that can range from $-\infty$ to $+\infty$.

For example, the following statements transform the variable SHARE from percent values to an unbounded range:

```
data a;
```

```

set a;
lshare = log( share / ( 100 - share ) );
run;

```

Many other data transformation can be used. You can create virtually any desired data transformation using DATA step statements.

The EXPAND Procedure and Data Transformations

The EXPAND procedure provides a convenient way to transform series. For example, the following statements add variables for the logarithm of AIR and the logistic of SHARE to data set A:

```

proc expand data=a out=a method=none;
  convert air=logair / transform=( log );
  convert share=lshare / transform=( / 100 logit );
run;

```

See [Table 14.2](#) in Chapter 14, “The EXPAND Procedure,” for a complete list of transformations supported by PROC EXPAND.

Manipulating Time Series Data Sets

This section discusses merging, splitting, and transposing time series data sets and interpolating time series data to a higher or lower sampling frequency.

Splitting and Merging Data Sets

In some cases, you might want to separate several time series that are contained in one data set into different data sets. In other cases, you might want to combine time series from different data sets into one data set.

To split a time series data set into two or more data sets that contain subsets of the series, use a DATA step to create the new data sets and use the KEEP= data set option to control which series are included in each new data set. The following statements split the USPRICE data set shown in a previous example into two data sets, USCPI and USPPI:

```

data uscpi(keep=date cpi)
  usppi(keep=date ppi);
  set usprice;
run;

```

If the series have different time ranges, you can subset the time ranges of the output data sets accordingly. For example, if you know that CPI in USPRICE has the range August 1990 through the end of the data set, while PPI has the range from the beginning of the data set through June 1991, you could write the previous example as follows:

```
data uscpi(keep=date cpi)
  usppi(keep=date ppi);
set usprice;
if date >= '1aug1990'd then output uscpi;
if date <= '1jun1991'd then output usppi;
run;
```

To combine time series from different data sets into one data set, list the data sets to be combined in a MERGE statement and specify the dating variable in a BY statement. The following statements show how to combine the USCPI and USPPPI data sets to produce the USPRICE data set. It is important to use the BY DATE statement so that observations are matched by time before merging.

```
data usprice;
  merge uscpi usppi;
  by date;
run;
```

Transposing Data Sets

The TRANSPOSE procedure is used to transpose data sets from one form to another. The TRANSPOSE procedure can transpose variables and observations, or transpose variables and observations within BY groups. This section discusses some applications of the TRANSPOSE procedure relevant to time series data sets. See the *Base SAS Procedures Guide* for more information about PROC TRANSPOSE.

Transposing from Interleaved to Standard Time Series Form

The following statements transpose part of the interleaved-form output data set FOREOUT, produced by PROC FORECAST in a previous example, to a standard form time series data set. To reduce the volume of output produced by the example, a WHERE statement is used to subset the input data set.

Observations with `_TYPE_=ACTUAL` are stored in the new variable ACTUAL; observations with `_TYPE_=FORECAST` are stored in the new variable FORECAST; and so forth. Note that the method used in this example works only for a single variable.

```
title "Original Data Set";
proc print data=foreout(obs=10);
  where date > '1may1991'd & date < '1oct1991'd;
run;

proc transpose data=foreout out=trans(drop=_name_);
```

```

var cpi;
id _type_;
by date;
where date > '1may1991'd & date < '1oct1991'd;
run;

title "Transposed Data Set";
proc print data=trans(obs=10);
run;

```

The TRANSPOSE procedure adds the variables `_NAME_` and `_LABEL_` to the output data set. These variables contain the names and labels of the variables that were transposed. In this example, there is only one transposed variable, so `_NAME_` has the value `CPI` for all observations. Thus, `_NAME_` and `_LABEL_` are of no interest and are dropped from the output data set by using the `DROP=` data set option. (If none of the variables transposed have a label, PROC TRANSPOSE does not output the `_LABEL_` variable and the `DROP=_LABEL_` option produces a warning message. You can ignore this message, or you can prevent the message by omitting `_LABEL_` from the `DROP=` list.)

The original and transposed data sets are shown in [Figure 3.19](#) and [Figure 3.20](#). (The observation numbers shown for the original data set reflect the operation of the WHERE statement.)

Figure 3.19 Original Data Sets

Original Data Set				
Obs	date	_TYPE_	_LEAD_	cpi

2	JUL1991	US Consumer Price Index	136.2	136.566	-0.36635	.	.
3	AUG1991	US Consumer Price Index	.	136.856	.	135.723	137.990
4	SEP1991	US Consumer Price Index	.	137.443	.	136.126	138.761

Transposing Cross-Sectional Dimensions

The following statements transpose the variable CPI in the CPICITY data set shown in a previous example from time series cross-sectional form to a standard form time series data set. (Only a subset of the data shown in the previous example is used here.) Note that the method shown in this example works only for a single variable.

```
title "Original Data Set";
proc print data=cpicity;
run;

proc sort data=cpicity out=temp;
  by date city;
run;

proc transpose data=temp out=citycpi(drop=_name_);
  var cpi;
  id city;
  by date;
run;

title "Transposed Data Set";
proc print data=citycpi;
run;
```

The names of the variables in the transposed data sets are taken from the city names in the ID variable CITY. The original and the transposed data sets are shown in [Figure 3.21](#) and [Figure 3.22](#).

5	MAY90	130.4	134.6	137.2
6	JUN90	131.7	135.0	137.1
7	JUL90	132.0	135.6	138.4

The following statements transpose the CITYCPI data set back to the original form of the CPICITY data set. The variable `_NAME_` is added to the data set to tell PROC TRANSPOSE the name of the variable in which to store the observations in the transposed data set. (If the `(DROP=_NAME_ _LABEL_)` option were omitted from the first PROC TRANSPOSE step, this would not be necessary. PROC TRANSPOSE assumes `ID _NAME_` by default.)

The `NAME=CITY` option in the PROC TRANSPOSE statement causes PROC TRANSPOSE to store the names of the transposed variables in the variable CITY. Because PROC TRANSPOSE recodes the values of the CITY variable to create valid SAS variable names in the transposed data set, the values of the variable CITY in the retransposed data set are not the same as in the original.

The retransposed data set is shown in [Figure 3.23](#).

```

data temp;
  set citycpi;
  _name_ = 'CPI';
run;

proc transpose data=temp out=retrans name=city;
  by date;
run;

proc sort data=retrans;
  by city date;
run;

title "Retransposed Data Set";
proc print data=retrans;
run;

```

Time Series Interpolation

The EXPAND procedure interpolates time series. This section provides a brief summary of the use of PROC EXPAND for different kinds of time series interpolation problems. Most of the issues discussed in this section are explained in greater detail in [Chapter 14](#).

By default, the EXPAND procedure performs interpolation by first fitting cubic spline curves to the available data and then computing needed interpolating values from the fitted spline curves. Other interpolation methods can be requested.

Note that interpolating values of a time series does not add any real information to the data because the interpolation process is not the same process that generated the other (nonmissing) values in the series. While time series interpolation can sometimes be useful, great care is needed in analyzing time series that contain interpolated values.

Interpolating Missing Values

To use the EXPAND procedure to interpolate missing values in a time series, specify the input and output data sets in the PROC EXPAND statement, and specify the time ID variable in an ID statement. For example, the following statements cause PROC EXPAND to interpolate values for missing values of all numeric variables in the data set USPRICE:

```
proc expand data=usprice out=interpl;
  id date;
run;
```

Interpolated values are computed only for embedded missing values in the input time series. Missing values before or after the range of a series are ignored by the EXPAND procedure.

In the preceding example, PROC EXPAND assumes that all series are measured at points in time given by the value of the ID variable. In fact, the series in the USPRICE data set are monthly averages. PROC EXPAND can produce a better interpolation if this is taken into account. The following example uses the FROM=MONTH option to tell PROC EXPAND that the series is monthly and uses the CONVERT statement with the OBSERVED=AVERAGE to specify that the series values are averages over each month:

```
proc expand data=usprice out=interpl
  from=month;
  id date;
  convert cpi ppi / observed=average;
run;
```

Interpolating to a Higher or Lower Frequency

You can use PROC EXPAND to interpolate values of time series at a higher or lower sampling frequency than the input time series. To change the periodicity of time series, specify the time interval of the input data set with the FROM= option, and specify the time interval for the desired output frequency with the TO= option. For example, the following statements compute interpolated weekly values of the monthly CPI and PPI series:

```
proc expand data=usprice out=interpl
           from=month to=week;
  id date;
  convert cpi ppi / observed=average;
run;
```

Interpolating between Stocks and Flows, Levels and Rates

A distinction is made between variables that are measured at points in time and variables that represent totals or averages over an interval. Point-in-time values are often called *stocks* or *levels*. Variables that represent totals or averages over an interval are often called *flows* or *rates*.

For example, the annual series Gross National Product represents the final goods production of over the year and also the yearly average rate of that production. However, the monthly variable Inventory represents the cost of a stock of goods at the end of the month.

The EXPAND procedure can convert between point-in-time values and period average or total values. To convert observation characteristics, specify the input and output characteristics with the OBSERVED= option in the CONVERT statement. For example, the following statements use the monthly average price index values in USPRICE to compute interpolated estimates of the price index levels at the midpoint of each month.

```
proc expand data=usprice out=midpoint
           from=month;
  id date;
  convert cpi ppi / observed=(average,middle);
run;
```

Reading Time Series Data

Time series data can be coded in many different ways. The SAS System can read time series data recorded in almost any form. Earlier sections of this chapter show how to read time series data coded in several commonly used ways. This section shows how to read time series data from data records coded in two other commonly used ways not previously introduced.

Several time series databases distributed by major data vendors can be read into SAS data sets by the DATASOURCE procedure. See Chapter 11, “[The DATASOURCE Procedure](#),” for more information.

The SASECRSP, SASEFAME, and SASEHAVR interface engines enable SAS users to access and process time series data in CRSPAccess data files, FAME databases, and Haver Analytics Data Link Express (DLX) data bases, respectively. See Chapter 33, “[The SASECRSP Interface Engine](#),” Chapter 34, “[The SASEFAME Interface Engine](#),” and Chapter 35, “[The SASEHAVR Interface Engine](#),” for more details.

Reading a Simple List of Values

Time series data can be coded as a simple list of values without dating information and with an arbitrary number of observations on each data record. In this case, the INPUT statement must use the trailing “@@” option to retain the current data record after reading the values for each observation, and the time ID variable must be generated with programming statements.

For example, the following statements read the USPRICE data set from data records that contain pairs of values for CPI and PPI. This example assumes you know that the first pair of values is for June 1990.

```
data usprice;
  input cpi ppi @@;
  date = intnx( 'month', '1jun1990'd, _n_-1 );
  format date monyy7.;
datalines;
129.9 114.3 130.4 114.5 131.6 116.5
132.7 118.4 133.5 120.8 133.8 120.1 133.8 118.7
134.6 119.0 134.8 117.2 135.0 116.2 135.2 116.0
135.6 116.5 136.0 116.3 136.2 116.0
;
```

Reading Fully Described Time Series in Transposed Form

Data for several time series can be coded with separate groups of records for each time series. Data files coded this way are transposed from the form required by SAS procedures. Time series data can also be coded with descriptive information about the series included with the data records.

The following example reads time series data for the USPRICE data set coded with separate groups of records for each series. The data records for each series consist of a series description record and one or more value records. The series description record gives the series name, starting month and year of the series, number of values in the series, and a series label. The value records contain the observations of the time series.

The data are first read into a temporary data set that contains one observation for each value of each series.

```

data temp;
  length _name_ $8 _label_ $40;
  keep _name_ _label_ date value;
  format date monyy.;
  input _name_ month year nval _label_ &;
  date = mdy( month, 1, year );
  do i = 1 to nval;
    input value @;
    output;
    date = intnx( 'month', date, 1 );
  end;
datalines;
cpi      8 90 12 Consumer Price Index
131.6 132.7 133.5 133.8 133.8 134.6 134.8 135.0
135.2 135.6 136.0 136.2
ppi      6 90 13 Producer Price Index
114.3 114.5 116.5 118.4 120.8 120.1 118.7 119.0
117.2 116.2 116.0 116.5 116.3
;

```

The following statements sort the data set by date and series name, and the TRANSPOSE procedure is used to transpose the data into a standard form time series data set.

```

proc sort data=temp;
  by date _name_;
run;

proc transpose data=temp out=usprice(drop=_name_);
  by date;
  var value;
run;

proc contents data=usprice;
run;

proc print data=usprice;
run;

```

The final data set is shown in [Figure 3.25](#).

Overview

This chapter summarizes the time intervals, date and datetime informats, date and datetime formats, and date, time, and datetime functions available in SAS software. The use of these features is explained in Chapter 3, “[Working with Time Series Data](#).” The material in this chapter is also contained in *SAS Language Reference: Concepts* and *SAS Language Reference: Dictionary*. Because these features are useful for work with time series data, documentation of these features is consolidated and repeated here for easy reference.

Time Intervals

This section provides a reference for the different kinds of time intervals supported by SAS but does not cover how they are used. For an introduction to the use of time intervals see [Chapter 3](#).

Some interval names are used with SAS date values, while other interval names are used with SAS datetime values. The interval names used with SAS date values are YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, DAY, YEARV, R445YR, R454YR, R544YR, R445QTR, R454QTR, R544QTR, R445MON, R454MON, R544MON, and WEEKV. The interval names used with SAS datetime or time values are HOUR, MINUTE, and SECOND. Various abbreviations of these names are also allowed, as described in the section “[Summary of Interval Types](#)” on page 132.

Interval names for use with SAS date values can be prefixed with ‘DT’ to construct interval names for use with SAS datetime values. The interval names DTYEAR, DTSEMIYEAR, DTQTR, DTMONTH, DTSEMIMONTH, DTTENDAY, DTWEEK, DTWEEKDAY, DTDAY, DTYEARV, DTR445YR, DTR454YR, DTR544YR, DTR445QTR, DTR454QTR, DTR544QTR, DTR445MON, DTR454MON, DTR544MON, and DTWEEKV are used with SAS datetime or time values.

Constructing Interval Names

Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The general form of an interval name is as follows:

*NAME**n.s*

The three parts of the interval name are shown below:

<i>NAME</i>	the name of the basic interval type. For example, YEAR specifies yearly intervals.
<i>n</i>	an optional multiplier that specifies that the interval is a multiple of the period of the basic interval type. For example, the interval YEAR2 consists of two-year, or biennial, periods.
<i>s</i>	an optional starting subperiod index that specifies that the intervals are shifted to later starting points. For example, YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Both the multiplier *n* and the shift index *s* are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

To test for a valid interval specification, use the INTTEST function:

```
interval = 'MONTH3.2';
valid = INTTEST( interval );
valid = INTTEST( 'YEAR4' );
```

INTTEST returns a value of 0 if the argument is not a valid interval specification and 1 if the argument is a valid interval specification. The INTTEST function can also be used in a DATA step to test an interval before calling an interval function:

```

valid = INTTEST( interval );
if ( valid = 1 ) then do;
    end = INTNX( interval, date, 0, 'E' );
end;

```

For more information about the INTTEST function, see *SAS Language Reference: Dictionary*.

Shifted Intervals

Different kinds of intervals are shifted by different subperiods.

- YEAR, SEMIYEAR, QTR, and MONTH intervals are shifted by calendar months.
- WEEK and DAY intervals are shifted by days.
- SEMIMONTH intervals are shifted by semi-monthly periods.
- TENDAY intervals are shifted by 10-day periods.
- YEARV intervals are shifted by WEEKV intervals.
- R445YR, R445QTR, and R445MON intervals are shifted by R445MON intervals.
- R454YR, R454QTR, and R454MON intervals are shifted by R454MON intervals.
- R544YR, R544QTR, and R544MON intervals are shifted by R544MON intervals.
- WEEKV intervals are shifted by days.
- WEEKDAY intervals are shifted by weekdays.
- HOUR intervals are shifted by hours.
- MINUTE intervals are shifted by minutes.
- SECOND intervals are shifted by seconds.

The INTSHIFT function returns the shift interval:

```

interval = 'MONTH3.2';
shift_interval = INTSHIFT( interval );

```

In this example, the value of shift_interval is 'MONTH'. For more information about the INTSHIFT function see *SAS Language Reference: Dictionary*.

If a subperiod is specified, the shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval. For interval types that shift by subperiods that are the same as the basic interval type, only multiperiod intervals can be shifted.

For example, MONTH type intervals shift by MONTH subintervals; thus, monthly intervals cannot be shifted because there is only one month in MONTH. However, bimonthly intervals can be shifted because there are two MONTH intervals in each MONTH2 interval. The interval name MONTH2.2 specifies bimonthly periods that start on the first day of even-numbered months.

Beginning Dates and Datetimes of Intervals

Intervals that represent divisions of a year begin with the start of the year (1 January). YEARV, R445YR, R454YR, and R544YR intervals begin with the first week of the International Organization for Standardization (ISO) year, the Monday on or immediately preceding January 4th. R445QTR, R454QTR, and R544QTR intervals begin with the 1st, 14th, 27th, and 40th weeks of the ISO year. MONTH2 periods begin with odd-numbered months (January, March, May, and so on).

Likewise, intervals that represent divisions of a day begin with the start of the day (midnight). Thus, HOUR8.7 intervals divide the day into the periods 06:00 to 14:00, 14:00 to 22:00, and 22:00 to 06:00.

Intervals that do not nest within years or days begin relative to the SAS date or datetime value 0. The arbitrary reference time of midnight on January 1, 1960, is used as the origin for nonshifted intervals, and shifted intervals are defined relative to that reference point. For example, MONTH13 defines the intervals January 1, 1960, February 1, 1961, March 1, 1962, and so forth, and the intervals December 1, 1959, November 1, 1958, and so on before the base date January 1, 1960.

Similarly, the WEEK2 interval begins relative to the Sunday of the week of January 1, 1960. The interval specification WEEK6.13 defines six-week periods starting on second Fridays, and the convention of counting relative to the period containing January 1, 1960, indicates the starting date or datetime of the interval closest to January 1, 1960, that corresponds to the second Fridays of six-week intervals.

Intervals always begin on the date or datetime defined by the base interval name, the multiplier, and the shift value. The end of the interval immediately precedes the beginning of the next interval. However, an interval can be identified by any date or datetime value between its starting and ending values, inclusive. See the section “[Alignment of SAS Dates](#)” on page 142 for more information about generating identifying dates for intervals.

Summary of Interval Types

The interval types are summarized as follows.

YEAR

specifies yearly intervals. Abbreviations are YEAR, YEARS, YEARLY, YR, ANNUAL, ANNUALLY, and ANNUALS. The starting subperiod *s* is in months (**MONTH**).

YEARV

specifies ISO 8601 yearly intervals. The ISO 8601 year starts on the Monday on or immediately preceding January 4th. Note that it is possible for the ISO 8601 year to start in December of the preceding year. Also, some ISO 8601 years contain a leap week. For further discussion of ISO weeks, see Technical Committee ISO/TC 154, Documents in Commerce, and Administration (2004). The starting subperiod s is in ISO 8601 weeks ([WEEKV](#)).

R445YR

is the same as YEARV except that the starting subperiod s is in retail 4-4-5 months ([R445MON](#)).

R454YR

is the same as YEARV except that the starting subperiod s is in retail 4-5-4 months ([R454MON](#)). For a discussion of the retail 4-5-4 calendar, see Federation (2007).

R544YR

is the same as YEARV except that the starting subperiod s is in retail 5-4-4 months ([R544MON](#)).

SEMIYEAR

specifies semiannual intervals (every six months). Abbreviations are SEMIYEAR, SEMIYEARS, SEMIYEARLY, SEMIYR, SEMIANNUAL, and SEMIANN.

The starting subperiod s is in months ([MONTH](#)). For example, SEMIYEAR.3 intervals are March–August and September–February.

QTR

specifies quarterly intervals (every three months). Abbreviations are QTR, QUARTER, QUARTERS, QUARTERLY, QTRLY, and QTRS. The starting subperiod s is in months ([MONTH](#)).

R445QTR

specifies retail 4-4-5 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters will contain a leap week. The starting subperiod s is in retail 4-4-5 months ([R445MON](#)).

R454QTR

specifies retail 4-5-4 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters will contain a leap week. For a discussion of the retail 4-5-4 calendar, see Federation (2007). The starting subperiod s is in retail 4-5-4 months ([R454MON](#)).

R544QTR

specifies retail 5-4-4 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters will contain a leap week. The starting subperiod s is in retail 5-4-4 months ([R544MON](#)).

MONTH

specifies monthly intervals. Abbreviations are MONTH, MONTHS, MONTHLY, and MON.

The starting subperiod s is in months ([MONTH](#)). For example, MONTH2.2 intervals are February–March, April–May, June–July, August–September, October–November, and December–January of the following year.

R445MON

specifies retail 4-4-5 monthly intervals. The 3rd, 6th, 9th, and 12th months are five ISO 8601 weeks long with the exception that some 12th months contain leap weeks. All other months are four ISO 8601 weeks long. R445MON intervals begin with the 1st, 5th, 9th, 14th, 18th, 22nd, 27th, 31st, 35th, 40th, 44th, and 48th weeks of the ISO year. The starting subperiod s is in retail 4-4-5 months ([R445MON](#)).

R454MON

specifies retail 4-5-4 monthly intervals. The 2nd, 5th, 8th, and 11th months are five ISO 8601 weeks long. All other months are four ISO 8601 weeks long with the exception that some 12th months contain leap weeks. R454MON intervals begin with the 1st, 5th, 10th, 14th, 18th, 23rd, 27th, 31st, 36th, 40th, 44th, and 49th weeks of the ISO year. For a discussion of the retail 4-5-4 calendar, see Federation (2007). The starting subperiod s is in retail 4-5-4 months ([R454MON](#)).

R544MON

specifies retail 5-4-4 monthly intervals. The 1st, 4th, 7th, and 10th months are five ISO 8601 weeks long. All other months are four ISO 8601 weeks long with the exception that some 12th months contain leap weeks. R544MON intervals begin with the 1st, 6th, 10th, 14th, 19th, 23rd, 27th, 32nd, 36th, 40th, 45th, and 49th weeks of the ISO year. The starting subperiod s is in retail 5-4-4 months ([R544MON](#)).

SEMIMONTH

specifies semimonthly intervals. SEMIMONTH breaks each month into two periods, starting on the 1st and 16th days. Abbreviations are SEMIMONTH, SEMIMONTHS, SEMIMONTHLY, and SEMIMON. The starting subperiod s is in SEMIMONTH periods. For example, SEMIMONTH2.2 specifies intervals from the 16th of one month through the 15th of the next month.

TENDAY

specifies 10-day intervals. TENDAY breaks the month into three periods, the 1st through the 10th day of the month, the 11th through the 20th day of the month, and the remainder of the month. (TENDAY is a special interval typically used for reporting automobile sales data.) The starting subperiod s is in TENDAY periods. For example, TENDAY4.2 defines 40-day periods that start at the second TENDAY period.

WEEK

specifies weekly intervals of seven days. Abbreviations are WEEK, WEEKS, and WEEKLY. The starting subperiod s is in days ([DAY](#)), with the days of the week numbered as 1=Sunday, 2=Monday, 3=Tuesday, 4=Wednesday, 5=Thursday, 6=Friday, and 7=Saturday. For example, WEEK.7 means weekly with Saturday as the first day of the week.

WEEKV

specifies ISO 8601 weekly intervals of seven days. Each week starts on Monday. The starting subperiod s is in days ([DAY](#)). Note that WEEKV differs from WEEK in that WEEKV.1 starts on Monday, WEEKV.2 starts on Tuesday, and so forth.

WEEKDAY**WEEKDAY dW** **WEEKDAY ddW** **WEEKDAY $dddW$**

specifies daily intervals with weekend days included in the preceding weekday. Note that for a five-day work week that starts on Monday, the appropriate interval is WEEKDAY5.2. Abbreviations are WEEKDAY and WEEKDAYS. The starting subperiod s is in weekdays (WEEKDAY).

The WEEKDAY interval is the same as DAY except that weekend days are absorbed into the preceding weekday. Thus there are five WEEKDAY intervals in a calendar week: Monday, Tuesday, Wednesday, Thursday, and the three-day period Friday-Saturday-Sunday.

The default weekend days are Saturday and Sunday, but any one to six weekend days can be listed after the WEEKDAY string and followed by a W. Weekend days are specified as '1' for Sunday, '2' for Monday, and so forth. For example, WEEKDAY67W specifies a Friday-Saturday weekend. WEEKDAY1W specifies a six-day work week with a Sunday weekend. WEEKDAY17W is the same as WEEKDAY.

DAY

specifies daily intervals. Abbreviations are DAY, DAYS, and DAILY. The starting subperiod s is in days (DAY).

HOURLY

specifies hourly intervals. Abbreviations are HOUR, HOURS, HOURLY, and HR. The starting subperiod s is in hours (HOUR).

MINUTE

specifies minute intervals. Abbreviations are MINUTE, MINUTES, and MIN. The starting subperiod s is in minutes (MINUTE).

SECOND

specifies second intervals. Abbreviations are SECOND, SECONDS, and SEC. The starting subperiod s is in seconds (SECOND).

Examples of Interval Specifications

Table 4.1 shows examples of different kinds of interval specifications.

Table 4.1 Examples of Intervals

Name	Kind of Interval
YEAR	years that start in January
YEAR.10	fiscal years that start in October
YEAR2.7	biennial intervals that start in July of even years
YEAR2.19	biennial intervals that start in July of odd years
YEAR4.11	four-year intervals that start in November of leap years (frequency of U.S. presidential elections)
YEAR4.35	four-year intervals that start in November of even years between leap years (frequency of U.S. midterm elections)
WEEK	weekly intervals that start on Sundays
WEEK2	biweekly intervals that start on first Sundays
WEEK1.1	same as WEEK
WEEK.2	weekly intervals that start on Mondays
WEEK6.3	six-week intervals that start on first Tuesdays
WEEK6.11	six-week intervals that start on second Wednesdays
WEEKDAY	daily with Friday-Saturday-Sunday counted as the same day (five-day work week with a Saturday-Sunday weekend)
WEEKDAY17W	same as WEEKDAY
WEEKDAY5.2	five weekdays that start on Monday. If WEEKDAY data are accumulated into weekly data, the interval of the accumulated data is WEEKDAY5.2
WEEKDAY67W	daily with Thursday-Friday-Saturday counted as the same day (five-day work week with a Friday-Saturday weekend)
WEEKDAY1W	daily with Saturday-Sunday counted as the same day (six-day work week with a Sunday weekend)
WEEKDAY3.2	three-weekday intervals (with Friday-Saturday-Sunday counted as one weekday) with the cycle three-weekday periods aligned to Monday 4 Jan 1960
HOUR8.7	eight-hour intervals that start at 6 a.m., 2 p.m., and 10 p.m. (might be used for work shifts)

Date and Datetime Informats

Table 4.2 lists some of the SAS date and datetime informats available in SAS to read date, time, and datetime values. See Chapter 3, “Working with Time Series Data,” for a discussion of the use of date and datetime informats. See *SAS Language Reference: Concepts* for a complete description of these informats.

For each informat, Table 4.2 shows an example of a date or datetime value written in the style that the informat is designed to read. The date 17 October 1991 and the time 2:25:32 p.m. are used for the example in all cases. Table 4.2 shows the width range allowed by the informat and the default width.

Table 4.2 Frequently Used SAS Date and Datetime Informats

Informat Example	Description	Width Range	Default Width
DATE _w . 17oct91	day, month abbreviation, and year: <i>ddmonyy</i>	7–32	7
DATETIME _{w.d} 17oct91:14:45:32	date and time: <i>ddmonyy:hh:mm:ss</i>	13–40	18
DDMMYY _w . 17/10/91	day, month, year: <i>ddmmyy</i> , <i>dd/mm/yy</i> , <i>dd-mm-yy</i> , or <i>dd mm yy</i>	6–32	6
JULIAN _w . 91290	year and day of year (Julian dates): <i>yyddd</i>	5–32	5
MMDDYY _w . 10/17/91	month, day, year: <i>mmddy</i> , <i>mm/dd/yy</i> , <i>mm-dd-yy</i> , or <i>mm dd yy</i>	6–32	6
MONYY _w . Oct91	month abbreviation and year	5–32	5
NENGO _w . H.03/10/17	Japanese Nengo notation	7–32	10
TIME _{w.d} 14:45:32	hours, minutes, seconds: <i>hh:mm:ss</i> or hours, minutes: <i>hh:mm</i> .	5–32	8
WEEKV _w . 1991-W42-04	ISO 8601 year, week, day of week: <i>yyyy-Www-dd</i>	3–200	11
YYMMDD _w . 91/10/17	year, month, day: <i>yymmdd</i> , <i>yy/mm/dd</i> , <i>yy-mm-dd</i> , or <i>yy mm dd</i>	6–32	6
YYQ _w . 91Q4	year and quarter of year: <i>yyQq</i>	4–32	4

Date, Time, and Datetime Formats

Some of the SAS date and datetime formats commonly used to write out SAS date and datetime values are listed in [Table 4.3](#) and [Table 4.4](#). A width value can be specified with each format. The tables list the range of width values allowed and the default width value for each format.

The notation used by a format is abbreviated in different ways depending on the width option used.

For example, the format MMDDYY8. writes the date 17 October 1991 as 10/17/91, while the format MMDDYY6. writes this date as 101791. In particular, formats that display the year show two-digit or four-digit year values depending on the width option. The examples shown in the tables are for the default width.

The interval function INTFMT returns a recommended format for time ID values based on the interval that describes the frequency of the values. The following example uses INTFMT to select a format to display the quarterly time ID variable qtrDate. This selected format is stored in a macro variable created by the CALL SYMPUT statement. The macro variable &FMT is then used in the FORMAT statement in the PROC PRINT step.

```
data b(keep=qtrDate);
  interval = 'QTR';
  form = INTFMT( interval, 'long' );
  call symput('fmt', form);
  do i=1 to 4;
    qtrDate = INTNX( interval, '01jan00'd, i-1 );
    output;
  end;
run;

proc print;
  format qtrDate &fmt;
run;
```

The second argument to INTFMT is 'long,' 'l,' 'short,' or 's' and controls the width of the year (2 or 4) for date formats. For more information about the INTFMT function, see *SAS Language Reference: Dictionary*.

See *SAS Language Reference: Concepts* for a complete description of these formats, including the variations of the formats produced by different width options. See Chapter 3, “[Working with Time Series Data](#),” for a discussion of the use of date and datetime formats.

Date Formats

Table 4.3 lists some of the date formats available in SAS. For each format, an example is shown of a date value in the notation produced by the format. The date '17OCT91'D is used as the example.

Table 4.3 Frequently Used SAS Date Formats

Format Example	Description	Width Range	Default Width
DATE _w . 17OCT91	day, month abbreviation, year: <i>ddmomyy</i>	5–9	7
DAY _w . 17	day of month	2–32	2

Table 4.3 continued

Format Example	Description	Width Range	Default Width
DDMMYY _w . 17/10/91	day, month, year: <i>dd/mm/yy</i>	2–8	8
DOWNAME _w . Thursday	name of day of the week	1–32	9
JULDAY _w . 290	day of year	3–32	3
JULIAN _w . 91290	year and day of year: <i>yyddd</i>	5–7	5
MMDDYY _w . 10/17/91	month, day, year: <i>mm/dd/yy</i>	2–8	8
MMYY _w . 10M1991	month and year: <i>mmMyy</i>	5–32	7
MMYYC _w . 10:1991	month and year: <i>mm:yy</i>	5–32	7
MMYYD _w . 10-1991	month and year: <i>mm-yy</i>	5–32	7
MMYYP _w . 10.1991	month and year: <i>mm.yy</i>	5–32	7
MMYYSw. 10/1991	month and year: <i>mm/yy</i>	5–32	7
MMYYN _w . 101991	month and year: <i>mmyy</i>	5–32	6
MONNAME _w . October	name of month	1–32	9
MONTH _w . 10	month of year	1–32	2
MONYY _w . OCT91	month abbreviation and year: <i>monyy</i>	5–7	5

Table 4.3 *continued*

Format Example	Description	Width Range	Default Width
QTR _w . 4	quarter of year	1–32	1
QTRR _w . IV	quarter in roman numerals	3–32	3
NENGO _w . H.03/10/17	Japanese Nengo notation	2–10	10
WEEKDATE _w . Thursday, October 17, 1991	<i>day-of-week, month-name dd, yy</i>	3–37	29
WEEKDATX _w . Thursday, 17 October 1991	<i>day-of-week, dd month-name yy</i>	3–37	29
WEEKDAY _w . 5	day of week	1–32	1
WEEKV _w . 1991-W42-04	ISO 8601 year, week, day of week: <i>yyyy-Www-dd</i>	3–200	11
WORDDATE _w . October 17, 1991	<i>month-name dd, yy</i>	3–32	18
WORDDATX _w . 17 October 1991	<i>dd month-name yy</i>	3–32	18
YEAR _w . 1991	year	2–32	4
YYMM _w . 1991M10	year and month: <i>yyMmm</i>	5–32	7
YYMMC _w . 1991:10	year and month: <i>yy:mm</i>	5–32	7
YYMMD _w . 1991-10	year and month: <i>yy-mm</i>	5–32	7
YYMMP _w . 1991.10	year and month: <i>yy.mm</i>	5–32	7
YYMMS _w . 1991/10	year and month: <i>yy/mm</i>	5–32	7

Table 4.3 *continued*

Format Example	Description	Width Range	Default Width
YYMMN _w . 199110	year and month: <i>yymm</i>	5–32	7
YYMON _w . 1991OCT	year and month abbreviation: <i>yyMON</i>	5–32	7
YYMMDD _w . 91/10/17	year, month, day: <i>yy/mm/dd</i>	2–8	8
YYQ _w . 91Q4	year and quarter: <i>yyQq</i>	4–6	4
YYQC _w . 1991:4	year and quarter: <i>yy:q</i>	4–32	6
YYQD _w . 1991-4	year and quarter: <i>yy-q</i>	4–32	6
YYQP _w . 1991.4	year and quarter: <i>yy.q</i>	4–32	6
YYQS _w . 1991/4	year and quarter: <i>yy/q</i>	4–32	6
YYQN _w . 19914	year and quarter: <i>yyq</i>	3–32	5
YYQR _w . 1991QIV	year and quarter in roman numerals: <i>yyQrr</i>	6–32	8
YYQRC _w . 1991:IV	year and quarter in roman numerals: <i>yy:rr</i>	6–32	8
YYQRD _w . 1991-IV	year and quarter in roman numerals: <i>yy-rr</i>	6–32	8
YYQRP _w . 1991.IV	year and quarter in roman numerals: <i>yy.rr</i>	6–32	8
YYQRS _w . 1991/IV	year and quarter in roman numerals: <i>yy/rr</i>	6–32	8
YYQRN _w .	year and quarter in roman	6–32	8

Datetime and Time Formats

Table 4.4 lists some of the datetime and time formats available in the SAS system. For each format, an example is shown of a datetime value in the notation produced by the format. The datetime value ‘17OCT91:14:25:32’DT is used as the example.

Table 4.4 Frequently Used SAS Datetime and Time Formats

Format		Width	Default
Example	Description	Range	Width
DATETIME $w.d$ 17OCT91:14:25:32	<i>ddMONyy:hh:mm:ss</i>	7–40	16
DTWKDATX $w.$ Thursday, 17 October 1991	<i>day-of-week, dd month yyyy</i>	3–37	29
HHMM $w.d$ 14:25	hour and minute: <i>hh:mm</i>	2–20	5
HOUR $w.d$ 14	hour	2–20	2
MMSS $w.d$ 25:32	minutes and seconds: <i>mm:ss</i>	2–20	5
TIME $w.d$ 14:25:32	time of day: <i>hh:mm:ss</i>	2–20	8
TOD $w.d$ 14:25:32	time of day: <i>hh:mm:ss</i>	2–20	8

Alignment of SAS Dates

SAS date values used to identify time series observations produced by SAS/ETS and SAS High-Performance Forecasting procedures are normally aligned with the beginning of the time intervals

that correspond to the observations. For example, for monthly data for 1994, the date values that identify the observations are 1Jan94, 1Feb94, 1Mar94, . . . , 1Dec94.

However, for some applications it might be preferable to use end-of-period dates, such as 31Jan94, 28Feb94, 31Mar94, . . . , 31Dec94. For other applications, such as plotting time series, it might be more convenient to use interval midpoint dates to identify the observations.

Many SAS/ETS and SAS High-Performance Forecasting procedures provide an ALIGN= option to control the alignment of dates for outputting time series observations. SAS/ETS procedures that support the ALIGN= option are ARIMA, DATASOURCE, ESM, EXPAND, FORECAST, SIMILARITY, TIMESERIES, UCM, and VARMAX. SAS High-Performance Forecasting procedures that support the ALIGN= option are HPFRECONCILE, HPF, HPFDIAGNOSE, HPFENGINE, and HPFEVENTS.

ALIGN=

The ALIGN= option can have the following values:

BEGINNING	specifies that dates be aligned to the start of the interval. This is the default. BEGINNING can be abbreviated as BEGIN, BEG, or B.
MIDDLE	specifies that dates be aligned to the interval midpoint, the average of the beginning and ending values. MIDDLE can be abbreviated as MID or M.
ENDING	specifies that dates be aligned to the end of the interval. ENDING can be abbreviated as END or E.

For information about the calculation of the beginning and ending values of intervals, see the section [“Beginning Dates and Datetimes of Intervals”](#) on page 132.

Date, Time, and Datetime Functions

SAS provides functions to perform calculations with SAS date, time, and datetime values. SAS date, time, and datetime functions are used to perform the following tasks:

- compute date, time, and datetime values from calendar and time-of-day values
- compute calendar and time-of-day values from date and datetime values
- convert between date, time, and datetime values
- perform calculations that involve time intervals
- provide information about time intervals
- provide information about seasonality

SAS date, time, and datetime functions are listed in alphabetical order in the following section. The intervals and other character arguments for interval functions can be supplied either directly as a

quoted string or as a SAS character variable. However, when you use a character variable, you should set the length of the character variable to at least the length of the longest string for that variable used in the DATA step.

Also, to ensure correct results when using interval functions, use date intervals with date values and datetime intervals with datetime values.

See *SAS Language Reference: Dictionary* for a complete description of these functions.

SAS Date, Time, and Datetime Functions

DATE()

returns today's date as a SAS date value.

DATEJUL(*yyddd*)

returns the SAS date value given the Julian date in *yyddd* or *yyyyddd* format. For example, **DATE = DATEJUL(99001)** ; assigns the SAS date value '01JAN99'D to DATE, and **DATE = DATEJUL(1999365)** ; assigns the SAS date value '31DEC1999'D to DATE.

DATEPART(*datetime*)

returns the date part of a SAS datetime value as a date value.

DATETIME()

returns the current date and time of day as a SAS datetime value.

DAY(*date*)

returns the day of the month from a SAS date value.

DHMS(*date, hour, minute, second*)

returns a SAS datetime value for date, hour, minute, and second values.

HMS(*hour, minute, second*)

returns a SAS time value for hour, minute, and second values.

HOLIDAY('*holiday*', *year*)

returns a SAS date value for the holiday and year specified. Valid values for holiday are 'BOXING', 'CANADA', 'CANADAOBSERVED', 'CHRISTMAS', 'COLUMBUS', 'EASTER', 'FATHERS', 'HALLOWEEN', 'LABOR', 'MLK', 'MEMORIAL', 'MOTHERS', 'NEWYEAR', 'THANKSGIVING', 'THANKSGIVINGCANADA', 'USINDEPENDENCE', 'USPRESIDENTS', 'VALENTINES', 'VETERANS', 'VETERANSUSG', 'VETERANSUSPS', and 'VICTORIA'. For example: **EASTER2000 = HOLIDAY('EASTER', 2000)** ;

HOUR(*datetime*)

returns the hour from a SAS datetime or time value.

INTCINDEX(*'date-interval'*, *date*)

INTCINDEX(*'datetime-interval'*, *datetime*)

returns the index of the seasonal cycle given an interval and an appropriate SAS date, date-time, or time value. For example, the seasonal cycle for INTERVAL='DAY' is 'WEEK', so **INTCINDEX**('DAY' , '01SEP78'D); returns 35 since September 1, 1978, is the sixth day of the 35th week of the year. For correct results, date intervals should be used with date values, and datetime intervals should be used with datetime values.

INTCK(*'date-interval'*, *date1*, *date2*)

INTCK(*'datetime-interval'*, *datetime1*, *datetime2*)

returns the number of boundaries of intervals of the given kind that lie between the two date or datetime values.

INTCYCLE(*'interval'*)

returns the interval of the seasonal cycle, given a date, time, or datetime interval. For example, **INTCYCLE**('MONTH') returns 'YEAR' since the months January, February, . . . , December constitute a yearly cycle. **INTCYCLE**('DAY') returns 'WEEK' since Sunday, Monday, . . . , Saturday is a weekly cycle.

INTFIT(*date1*, *date2*, *'D'*)

INTFIT(*datetime1*, *datetime2*, *'DT'*)

INTFIT(*obs1*, *obs2*, *'OBS'*)

returns an interval that fits exactly between two SAS date, datetime, or observation values, in the sense of the **INTNX** function uses **SAMEDAY** alignment. In the following example, *result1* is the same as *date1* and *result2* is the same as *date2*.

```
FitInterval = INTFIT( date1, date2, 'D' );
result1 = INTNX( FitInterval, date1, 0, 'SAMEDAY' );
result2 = INTNX( FitInterval, date1, 1, 'SAMEDAY' );
```

More than one interval can fit the preceding definition. For instance, two SAS date values that are seven days apart could be fit with either 'DAY7' or 'WEEK'. The **INTFIT** algorithm chooses the more common interval, so 'WEEK' is the result when the dates are seven days apart. The **INTFIT** function can be used to detect the possible frequency of the time series or to analyze frequencies of other events in a time series, such as outliers or missing values.

INTFMT(*'interval'* , *'size'*)

returns a recommended format, given a date, time, or datetime interval for displaying the time ID values associated with a time series of the given interval. The valid values of *size* ('long,' '1,' 'short,' 's') specify whether the returned format uses a two-digit or four-digit year to display the SAS date value.

INTGET(*date1*, *date2*, *date3*)

INTGET(*datetime1*, *datetime2*, *datetime3*)

returns an interval that fits three consecutive SAS date or datetime values. The **INTGET** function examines two intervals: the first interval between *date1* and *date2*, and the second interval between *date2* and *date3*. In order for an interval to be detected, either the two intervals must be the same or one interval must be an integer multiple of the other interval. That is, **INTGET** assumes that at least two of the dates are consecutive points in the time series, and that the other two dates are also consecutive or represent the points before and after

missing observations. The INTGET algorithm assumes that large values are SAS datetime values, which are measured in seconds, and that smaller values are SAS date values, which are measured in days. The INTGET function can be used to detect the possible frequency of the time series or to analyze frequencies of other events in a time series, such as outliers or missing values.

INTINDEX(*'date-interval'*, *date*)

INTINDEX(*'datetime-interval'*, *datetime*)

returns the seasonal index, given a date, time, or datetime interval and an appropriate date, time, or datetime value. The seasonal index is a number that represents the position of the date, time, or datetime value in the seasonal cycle of the specified interval. For example, **INTINDEX**(**'MONTH'**,**'01DEC2000'D**); returns 12 because monthly data is yearly periodic and DECEMBER is the 12th month of the year. However, **INTINDEX**(**'DAY'**,**'01DEC2000'D**); returns 6 because daily data is weekly periodic and December 01, 2000, is a Friday, the sixth day of the week. To correctly identify the seasonal index, the interval specification should agree with the date, time, or datetime value. For example, **INTINDEX**(**'DTMONTH'**,**'01DEC2000'D**); and **INTINDEX**(**'MONTH'**,**'01DEC2000:00:00:00'DT**); do not return the expected value of 12. However, both **INTINDEX**(**'MONTH'**,**'01DEC2000'D**); and **INTINDEX**(**'DTMONTH'**,**'01DEC2000:00:00:00'DT**); return the expected value of 12.

INTNX(*'date-interval'*, *date*, *n* <, **'alignment'** >)

INTNX(*'datetime-interval'*, *datetime*, *n* <, **'alignment'** >)

returns the date or datetime value of the beginning of the interval that is *n* intervals from the interval that contains the given date or datetime value. The optional alignment argument specifies that the returned date is aligned to the beginning, middle, or end of the interval. Beginning is the default. In addition, you can specify SAME (or S) alignment. The SAME alignment bases the alignment of the calculated date or datetime value on the alignment of the input date or datetime value. As illustrated in the following example, the SAME alignment can be used to calculate the meaning of “same day next year” or “same day 2 weeks from now.”

```
nextYear = INTNX( 'YEAR', '15Apr2007'D, 1, 'S' );
TwoWeeks = INTNX( 'WEEK', '15Apr2007'D, 2, 'S' );
```

The preceding example returns '15Apr2008'D for nextYear and '29Apr2007'D for TwoWeeks. For all values of alignment, the number of intervals *n* between the input date and the resulting date agrees with the input value.

```
date2 = INTNX( interval, date1, n1, align );
n2 = INTCK( interval, date1, date2 );
```

The result is always that $n2 = n1$.

INTSEAS(*'interval'*)

returns the length of the seasonal cycle, given a date, time, or datetime interval. The length of a seasonal cycle is the number of intervals in a seasonal cycle. For example, when the interval for a time series is described as monthly, many procedures use the option INTERVAL=MONTH to indicate that each observation in the data then corresponds to a particular month. Monthly data are considered to be periodic for a one-year seasonal cycle. There are

12 months in one year, so the number of intervals (months) in a seasonal cycle (year) is 12. For quarterly data, there are 4 quarters in one year, so the number of intervals in a seasonal cycle is 4. The periodicity is not always one year. For example, INTERVAL=DAY is considered to have a seasonal cycle of one week, and because there are 7 days in a week, the number of intervals in a seasonal cycle is 7.

INTSHIFT('interval')

returns the shift interval that applies to the shift index if a subperiod is specified. For example, YEAR intervals are shifted by MONTH, so INTSHIFT('YEAR') returns 'MONTH'.

INTTEST('interval')

returns 1 if the interval name is a valid interval, 0 otherwise. For example, **VALID = INTTEST('MONTH')**; should set VALID to 1, while **VALID = INTTEST('NOTANINTERVAL')**; should set VALID to 0. The INTTEST function can be useful in verifying which values of multiplier *n* and the shift index *s* are valid in constructing an interval name.

JULDATE(date)

returns the Julian date from a SAS date value. The format of the Julian date is either yyddd or yyyyddd depending on the value of the system option YEARCUTOFF=. For example, using the default system option values, **JULDATE('31DEC1999'D)**; returns 99365, while **JULDATE('31DEC1899'D)**; returns 1899365.

MDY(month, day, year)

returns a SAS date value for month, day, and year values.

MINUTE(datetime)

returns the minute from a SAS time or datetime value.

MONTH(date)

returns the numerical value for the month of the year from a SAS date value. For example, **MONTH=MONTH('01JAN2000'D)**; returns 1, the numerical value for January.

NWKDOM(n, weekday, month, year)

returns a SAS date value for the *n*th weekday of the month and year specified. For example, Thanksgiving is always the fourth (*n* = 4) Thursday (*weekday* = 5) in November (*month* = 11). Thus **THANKS2000 = NWKDOM(4, 5, 11, 2000)**; returns the SAS date value for Thanksgiving in the year 2000. The last weekday of a month can be specified using *n* = 5. Memorial Day in the United States is the last (*n* = 5) Monday (*weekday* = 2) in May (*month* = 5), and so **MEMORIAL2002 = NWKDOM(5, 2, 5, 2002)**; returns the SAS date value for Memorial Day in 2002. Because *n* = 5 always specifies the last occurrence of the month and most months have only 4 instances of each day, the result for *n* = 5 is often the same as the result for *n* = 4. NWKDOM is useful for calculating the SAS date values of holidays that are defined in this manner.

QTR(date)

returns the quarter of the year from a SAS date value.

SECOND(date)

returns the second from a SAS time or datetime value.

TIME()

returns the current time of day.

TIMEPART(*datetime*)

returns the time part of a SAS datetime value.

TODAY()

returns the current date as a SAS date value. (TODAY is another name for the DATE function.)

WEEK(*date* <, 'descriptor' >)

returns the week of year from a SAS date value. The algorithm used to calculate the week depends on the descriptor.

If the descriptor is 'U,' weeks start on Sunday and the range is 0 to 53. If weeks 0 and 53 exist, they are only partial weeks. Week 52 can be a partial week.

If the descriptor is 'V', the result is equivalent to the ISO 8601 week of year definition. The range is 1 to 53. Week 53 is a leap week. The first week of the year, Week 1, and the last week of the year, Week 52 or 53, can include days in another Gregorian calendar year.

If the descriptor is 'W', weeks start on Monday and the range is 0 to 53. If weeks 0 and 53 exist, they are only partial weeks. Week 52 can be a partial week.

WEEKDAY(*date*)

returns the day of the week from a SAS date value. For example `WEEKDAY=WEEKDAY('17OCT1991'D)`; returns 5, the numerical value for Thursday.

YEAR(*date*)

returns the year from a SAS date value.

YYQ(*year, quarter*)

returns a SAS date value for year and quarter values.

SAS Macros

This chapter describes several SAS macros and the SAS function PROBDF that are provided with SAS/ETS software. A SAS macro is a program that generates SAS statements. Macros make it easy to produce and execute complex SAS programs that would be time-consuming to write yourself.

SAS/ETS software includes the following macros:

<code>%AR</code>	generates statements to define autoregressive error models for the MODEL procedure.
<code>%BOXCOXAR</code>	investigates Box-Cox transformations useful for modeling and forecasting a time series.
<code>%DFPVALUE</code>	computes probabilities for Dickey-Fuller test statistics.
<code>%DFTEST</code>	performs Dickey-Fuller tests for unit roots in a time series process.
<code>%LOGTEST</code>	tests to see if a log transformation is appropriate for modeling and forecasting a time series.
<code>%MA</code>	generates statements to define moving-average error models for the MODEL procedure.
<code>%PDL</code>	generates statements to define polynomial-distributed lag models for the MODEL procedure.

These macros are part of the SAS AUTOCALL facility and are automatically available for use in your SAS program. See *SAS Macro Language: Reference* for information about the SAS macro facility.

Since the %AR, %MA, and %PDL macros are used only with PROC MODEL, they are documented with the MODEL procedure. See the sections on the %AR, %MA, and %PDL macros in Chapter 18, “The MODEL Procedure,” for more information about these macros. The %BOXCOXAR, %DFPVALUE, %DFTEST, and %LOGTEST macros are described in the following sections.

BOXCOXAR Macro

The %BOXCOXAR macro finds the optimal Box-Cox transformation for a time series.

Transformations of the dependent variable are a useful way of dealing with nonlinear relationships or heteroscedasticity. For example, the logarithmic transformation is often used for modeling and forecasting time series that show exponential growth or that show variability proportional to the level of the series.

The Box-Cox transformation is a general class of power transformations that include the log transformation and no transformation as special cases. The Box-Cox transformation is

$$Y_t = \begin{cases} \frac{(X_t + c)^\lambda - 1}{\lambda} & \text{for } \lambda \neq 0 \\ \ln(X_t + c) & \text{for } \lambda = 0 \end{cases}$$

The parameter λ controls the shape of the transformation. For example, $\lambda=0$ produces a log transformation, while $\lambda=0.5$ results in a square root transformation. When $\lambda=1$, the transformed series differs from the original series by $c - 1$.

The constant c is optional. It can be used when some X_t values are negative or 0. You choose c so that the series X_t is always greater than $-c$.

The %BOXCOXAR macro tries a range of λ values and reports which of the values tried produces the optimal Box-Cox transformation. To evaluate different λ values, the %BOXCOXAR macro transforms the series with each λ value and fits an autoregressive model to the transformed series. It is assumed that this autoregressive model is a reasonably good approximation to the true time series model appropriate for the transformed series. The likelihood of the data under each autoregressive model is computed, and the λ value that produces the maximum likelihood over the values tried is reported as the optimal Box-Cox transformation for the series.

The %BOXCOXAR macro prints and optionally writes to a SAS data set all of the λ values tried, the corresponding log-likelihood value, and related statistics for the autoregressive model.

You can control the range and number of λ values tried. You can also control the order of the autoregressive models fit to the transformed series. You can difference the transformed series before the autoregressive model is fit.

Note that the Box-Cox transformation might be appropriate when the data have a common distribution (apart from heteroscedasticity) but not when groups of observations for the variable are quite

different. Thus the %BOXCOXAR macro is more often appropriate for time series data than for cross-sectional data.

Syntax

The form of the %BOXCOXAR macro is

```
%BOXCOXAR ( SAS-data-set, variable < , options > );
```

The first argument, *SAS-data-set*, specifies the name of the SAS data set that contains the time series to be analyzed. The second argument, *variable*, specifies the time series variable name to be analyzed. The first two arguments are required.

The following options can be used with the %BOXCOXAR macro. Options must follow the required arguments and are separated by commas.

AR=*n*

specifies the order of the autoregressive model fit to the transformed series. The default is AR=5.

CONST=*value*

specifies a constant *c* to be added to the series before transformation. Use the CONST= option when some values of the series are 0 or negative. The default is CONST=0.

DIF=(*differencing-list*)

specifies the degrees of differencing to apply to the transformed series before the autoregressive model is fit. The *differencing-list* is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the transformed series be differenced once at lag 1 and once at lag 12. For more details, see the section “[IDENTIFY Statement](#)” on page 228 in Chapter 7, “[The ARIMA Procedure](#).”

LAMBDAHI=*value*

specifies the maximum value of lambda for the grid search. The default is LAMBDAHI=1. A large (in magnitude) LAMBDAHI= value can result in problems with floating point arithmetic.

LAMBDALO=*value*

specifies the minimum value of lambda for the grid search. The default is LAMBDALO=0. A large (in magnitude) LAMBDALO= value can result in problems with floating point arithmetic.

NLAMBDA=*value*

specifies the number of lambda values considered, including the LAMBDALO= and LAMBDAHI= option values. The default is NLAMBDA=2.

OUT=*SAS-data-set*

writes the results to an output data set. The output data set includes the lambda values tried (LAMBDA), and for each lambda value, the log likelihood (LOGLIK), residual mean squared error (RMSE), Akaike Information Criterion (AIC), and Schwarz’s Bayesian Criterion (SBC).

PRINT=YES | NO

specifies whether results are printed. The default is PRINT=YES. The printed output contains the lambda values, log likelihoods, residual mean square errors, Akaike Information Criterion (AIC), and Schwarz's Bayesian Criterion (SBC).

Results

The value of λ that produces the maximum log likelihood is returned in the macro variable &BOXCOXAR. The value of the variable &BOXCOXAR is "ERROR" if the %BOXCOXAR macro is unable to compute the best transformation due to errors. This might be the result of large lambda values. The Box-Cox transformation parameter involves exponentiation of the data, so that large lambda values can cause floating-point overflow.

Results are printed unless the PRINT=NO option is specified. Results are also stored in SAS data sets when the OUT= option is specified.

Details

Assume that the transformed series Y_t is a stationary p th order autoregressive process generated by independent normally distributed innovations.

$$(1 - \Theta(B))(Y_t - \mu) = \epsilon_t$$

$$\epsilon_t \sim iidN(0, \sigma^2)$$

Given these assumptions, the log-likelihood function of the transformed data Y_t is

$$l_Y(\cdot) = -\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma|) - \frac{n}{2}\ln(\sigma^2) \\ - \frac{1}{2\sigma^2}(\mathbf{Y} - \mathbf{1}\mu)' \Sigma^{-1}(\mathbf{Y} - \mathbf{1}\mu)$$

In this equation, n is the number of observations, μ is the mean of Y_t , $\mathbf{1}$ is the n -dimensional column vector of 1s, σ^2 is the innovation variance, $\mathbf{Y} = (Y_1, \dots, Y_n)'$, and Σ is the covariance matrix of Y .

The log-likelihood function of the original data X_1, \dots, X_n is

$$l_X(\cdot) = l_Y(\cdot) + (\lambda - 1) \sum_{t=1}^n \ln(X_t + c)$$

where c is the value of the CONST= option.

For each value of λ , the maximum log-likelihood of the original data is obtained from the maximum log-likelihood of the transformed data given the maximum likelihood estimate of the autoregressive model.

The maximum log-likelihood values are used to compute the Akaike Information Criterion (AIC) and Schwarz's Bayesian Criterion (SBC) for each λ value. The residual mean squared error based

on the maximum likelihood estimator is also produced. To compute the mean squared error, the predicted values from the model are transformed again to the original scale (Pankratz 1983, pp. 256–258, and Taylor 1986).

After differencing as specified by the DIF= option, the process is assumed to be a stationary autoregressive process. You can check for stationarity of the series with the %DFTEST macro. If the process is not stationary, differencing with the DIF= option is recommended. For a process with moving-average terms, a large value for the AR= option might be appropriate.

DFPVALUE Macro

The %DFPVALUE macro computes the significance of the Dickey-Fuller test. The %DFPVALUE macro evaluates the p -value for the Dickey-Fuller test statistic τ for the test of H_0 : “The time series has a unit root” versus H_a : “The time series is stationary” using tables published by Dickey (1976) and Dickey, Hasza, and Fuller (1984).

The %DFPVALUE macro can compute p -values for tests of a simple unit root with lag 1 or for seasonal unit roots at lags 2, 4, or 12. The %DFPVALUE macro takes into account whether an intercept or deterministic time trend is assumed for the series.

The %DFPVALUE macro is used by the %DFTEST macro described later in this chapter.

Note that the %DFPVALUE macro has been superseded by the PROBDF function described later in this chapter. It remains for compatibility with past releases of SAS/ETS.

Syntax

The %DFPVALUE macro has the following form:

```
%DFPVALUE ( tau, nobs < , options > );
```

The first argument, *tau*, specifies the value of the Dickey-Fuller test statistic.

The second argument, *nobs*, specifies the number of observations on which the test statistic is based.

The first two arguments are required. The following options can be used with the %DFPVALUE macro. Options must follow the required arguments and are separated by commas.

DLAG=1 | 2 | 4 | 12

specifies the lag period of the unit root to be tested. DLAG=1 specifies a one-period unit root test. DLAG=2 specifies a test for a seasonal unit root with lag 2. DLAG=4 specifies a test for a seasonal unit root with lag 4. DLAG=12 specifies a test for a seasonal unit root with lag 12. The default is DLAG=1.

TREND=0 | 1 | 2

specifies the degree of deterministic time trend included in the model. TREND=0 specifies no trend and assumes the series has a zero mean. TREND=1 includes an intercept term.

TREND=2 specifies both an intercept and a deterministic linear time trend term. The default is TREND=1. TREND=2 is not allowed with DLAG=2, 4, or 12.

Results

The computed p -value is returned in the macro variable &DFPVALUE. If the p -value is less than 0.01 or larger than 0.99, the macro variable &DFPVALUE is set to 0.01 or 0.99, respectively.

Minimum Observations

The minimum number of observations required by the %DFPVALUE macro depends on the value of the DLAG= option. The minimum observations are as follows:

DLAG=	Minimum Observations
1	9
2	6
4	4
12	12

DFTEST Macro

The %DFTEST macro performs the Dickey-Fuller unit root test. You can use the %DFTEST macro to decide whether a time series is stationary and to determine the order of differencing required for the time series analysis of a nonstationary series.

Most time series analysis methods require that the series to be analyzed is stationary. However, many economic time series are nonstationary processes. The usual approach to this problem is to difference the series. A time series that can be made stationary by differencing is said to have a *unit root*. For more information, see the discussion of this issue in the section “Getting Started: ARIMA Procedure” on page 191 of Chapter 7, “The ARIMA Procedure.”

The Dickey-Fuller test is a method for testing whether a time series has a unit root. The %DFTEST macro tests the hypothesis H_0 : “The time series has a unit root” versus H_a : “The time series is stationary” based on tables provided in Dickey (1976) and Dickey, Hasza, and Fuller (1984). The test can be applied for a simple unit root with lag 1, or for seasonal unit roots at lag 2, 4, or 12.

Note that the %DFTEST macro has been superseded by the PROC ARIMA stationarity tests. See Chapter 7, “The ARIMA Procedure,” for details.

Syntax

The %DFTEST macro has the following form:

```
%DFTEST ( SAS-data-set, variable < , options > );
```

The first argument, *SAS-data-set*, specifies the name of the SAS data set that contains the time series variable to be analyzed.

The second argument, *variable*, specifies the time series variable name to be analyzed.

The first two arguments are required. The following options can be used with the %DFTEST macro. Options must follow the required arguments and are separated by commas.

AR=*n*

specifies the order of autoregressive model fit after any differencing specified by the DIF= and DLAG= options. The default is AR=3.

DIF=(*differencing-list*)

specifies the degrees of differencing to be applied to the series. The differencing list is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the series be differenced once at lag 1 and once at lag 12. For more details, see the section “**IDENTIFY Statement**” on page 228 in Chapter 7, “**The ARIMA Procedure.**”

If the option DIF=(d_1, \dots, d_k) is specified, the series analyzed is $(1 - B^{d_1}) \dots (1 - B^{d_k}) Y_t$, where Y_t is the variable specified, and B is the backshift operator defined by $BY_t = Y_{t-1}$.

DLAG=1 | 2 | 4 | 12

specifies the lag to be tested for a unit root. The default is DLAG=1.

OUT=*SAS-data-set*

writes residuals to an output data set.

OUTSTAT=*SAS-data-set*

writes the test statistic, parameter estimates, and other statistics to an output data set.

TREND=0 | 1 | 2

specifies the degree of deterministic time trend included in the model. TREND=0 includes no deterministic term and assumes the series has a zero mean. TREND=1 includes an intercept term. TREND=2 specifies an intercept and a linear time trend term. The default is TREND=1. TREND=2 is not allowed with DLAG=2, 4, or 12.

Results

The computed p -value is returned in the macro variable &DFTEST. If the p -value is less than 0.01 or larger than 0.99, the macro variable &DFTEST is set to 0.01 or 0.99, respectively. (The same value is given in the macro variable &DFPVALUE returned by the %DFPVALUE macro, which is used by the %DFTEST macro to compute the p -value.)

Results can be stored in SAS data sets with the OUT= and OUTSTAT= options.

Minimum Observations

The minimum number of observations required by the %DFTEST macro depends on the value of the DLAG= option. Let s be the sum of the differencing orders specified by the DIF= option, let t be

the value of the TREND= option, and let p be the value of the AR= option. The minimum number of observations required is as follows:

DLAG=	Minimum Observations
1	$1 + p + s + \max(9, p + t + 2)$
2	$2 + p + s + \max(6, p + t + 2)$
4	$4 + p + s + \max(4, p + t + 2)$
12	$12 + p + s + \max(12, p + t + 2)$

Observations are not used if they have missing values for the series or for any lag or difference used in the autoregressive model.

LOGTEST Macro

The %LOGTEST macro tests whether a logarithmic transformation is appropriate for modeling and forecasting a time series. The logarithmic transformation is often used for time series that show exponential growth or variability proportional to the level of the series.

The %LOGTEST macro fits an autoregressive model to a series and fits the same model to the log of the series. Both models are estimated by the maximum-likelihood method, and the maximum log-likelihood values for both autoregressive models are computed. These log-likelihood values are then expressed in terms of the original data and compared.

You can control the order of the autoregressive models. You can also difference the series and the log-transformed series before the autoregressive model is fit.

You can print the log-likelihood values and related statistics (AIC, SBC, and MSE) for the autoregressive models for the series and the log-transformed series. You can also output these statistics to a SAS data set.

Syntax

The %LOGTEST macro has the following form:

```
%LOGTEST ( SAS-data-set, variable, < options > );
```

The first argument, *SAS-data-set*, specifies the name of the SAS data set that contains the time series variable to be analyzed. The second argument, *variable*, specifies the time series variable name to be analyzed.

The first two arguments are required. The following options can be used with the %LOGTEST macro. Options must follow the required arguments and are separated by commas.

AR= n

specifies the order of the autoregressive model fit to the series and the log-transformed series. The default is AR=5.

CONST=value

specifies a constant to be added to the series before transformation. Use the CONST= option when some values of the series are 0 or negative. The series analyzed must be greater than the negative of the CONST= value. The default is CONST=0.

DIF=(differencing-list)

specifies the degrees of differencing applied to the original and log-transformed series before fitting the autoregressive model. The *differencing-list* is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the transformed series be differenced once at lag 1 and once at lag 12. For more details, see the section “IDENTIFY Statement” on page 228 in Chapter 7, “The ARIMA Procedure.”

OUT=SAS-data-set

writes the results to an output data set. The output data set includes a variable TRANS that identifies the transformation (LOG or NONE), the log-likelihood value (LOGLIK), residual mean squared error (RMSE), Akaike Information Criterion (AIC), and Schwarz’s Bayesian Criterion (SBC) for the log-transformed and untransformed cases.

PRINT=YES | NO

specifies whether the results are printed. The default is PRINT=NO. The printed output shows the log-likelihood value, residual mean squared error, Akaike Information Criterion (AIC), and Schwarz’s Bayesian Criterion (SBC) for the log-transformed and untransformed cases.

Results

The result of the test is returned in the macro variable &LOGTEST. The value of the &LOGTEST variable is ‘LOG’ if the model fit to the log-transformed data has a larger log likelihood than the model fit to the untransformed series. The value of the &LOGTEST variable is ‘NONE’ if the model fit to the untransformed data has a larger log likelihood. The variable &LOGTEST is set to ‘ERROR’ if the %LOGTEST macro is unable to compute the test due to errors.

Results are printed when the PRINT=YES option is specified. Results are stored in SAS data sets when the OUT= option is specified.

Details

Assume that a time series X_t is a stationary p th order autoregressive process with normally distributed white noise innovations. That is,

$$(1 - \Theta(B))(X_t - \mu_x) = \epsilon_t$$

where μ_x is the mean of X_t .

The log likelihood function of X_t is

$$l_1(\cdot) = -\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma_{xx}|) - \frac{n}{2}\ln(\sigma_e^2) \\ - \frac{1}{2\sigma_e^2}(\mathbf{X} - \mathbf{1}\mu_x)' \Sigma_{xx}^{-1}(\mathbf{X} - \mathbf{1}\mu_x)$$

where n is the number of observations, $\mathbf{1}$ is the n -dimensional column vector of 1s, σ_{ϵ}^2 is the variance of the white noise, $\mathbf{X} = (X_1, \dots, X_n)'$, and $\Sigma_{\mathbf{xx}}$ is the covariance matrix of \mathbf{X} .

On the other hand, if the log-transformed time series $Y_t = \ln(X_t + c)$ is a stationary p th order autoregressive process, the log-likelihood function of X_t is

$$l_0(\cdot) = -\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma_{\mathbf{yy}}|) - \frac{n}{2}\ln(\sigma_{\epsilon}^2) \\ - \frac{1}{2\sigma_{\epsilon}^2}(\mathbf{Y} - \mathbf{1}\mu_y)' \Sigma_{\mathbf{yy}}^{-1}(\mathbf{Y} - \mathbf{1}\mu_y) - \sum_{t=1}^n \ln(X_t + c)$$

where μ_y is the mean of Y_t , $\mathbf{Y} = (Y_1, \dots, Y_n)'$, and $\Sigma_{\mathbf{yy}}$ is the covariance matrix of \mathbf{Y} .

The %LOGTEST macro compares the maximum values of $l_1(\cdot)$ and $l_0(\cdot)$ and determines which is larger.

The %LOGTEST macro also computes the Akaike Information Criterion (AIC), Schwarz's Bayesian Criterion (SBC), and residual mean squared error based on the maximum likelihood estimator for the autoregressive model. For the mean squared error, retransformation of forecasts is based on Pankratz (1983, pp. 256–258).

After differencing as specified by the DIF= option, the process is assumed to be a stationary autoregressive process. You might want to check for stationarity of the series using the %DFTEST macro. If the process is not stationary, differencing with the DIF= option is recommended. For a process with moving average terms, a large value for the AR= option might be appropriate.

Functions

PROBDF Function for Dickey-Fuller Tests

The PROBDF function calculates significance probabilities for Dickey-Fuller tests for unit roots in time series. The PROBDF function can be used wherever SAS library functions can be used, including DATA step programs, SCL programs, and PROC MODEL programs.

Syntax

PROBDF(x , n < , d < , $type$ > >)

- x is the test statistic.
- n is the sample size. The minimum value of n allowed depends on the value specified for the third argument d . For d in the set (1,2,4,6,12), n must be an integer greater than or equal to $\max(2d, 5)$; for other values of d the minimum value of n is 24.

- d* is an optional integer giving the degree of the unit root tested for. Specify $d = 1$ for tests of a simple unit root $(1 - B)$. Specify d equal to the seasonal cycle length for tests for a seasonal unit root $(1 - B^d)$. The default value of d is 1; that is, a test for a simple unit root $(1 - B)$ is assumed if d is not specified. The maximum value of d allowed is 12.
- type* is an optional character argument that specifies the type of test statistic used. The values of *type* are the following:
- SZM studentized test statistic for the zero mean (no intercept) case
 - RZM regression test statistic for the zero mean (no intercept) case
 - SSM studentized test statistic for the single mean (intercept) case
 - RSM regression test statistic for the single mean (intercept) case
 - STR studentized test statistic for the deterministic time trend case
 - RTR regression test statistic for the deterministic time trend case
- The values STR and RTR are allowed only when $d = 1$. The default value of *type* is SZM.

Details

Theoretical Background

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey (1976) and Dickey and Fuller (1979) studied the limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root. Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots.

Consider the $(p + 1)$ th order autoregressive time series

$$Y_t = \alpha_1 Y_{t-1} + \alpha_2 Y_{t-2} + \cdots + \alpha_{p+1} Y_{t-p-1} + e_t$$

and its characteristic equation

$$m^{p+1} - \alpha_1 m^p - \alpha_2 m^{p-1} - \cdots - \alpha_{p+1} = 0$$

If all the characteristic roots are less than 1 in absolute value, Y_t is stationary. Y_t is nonstationary if there is a unit root. If there is a unit root, the sum of the autoregressive parameters is 1, and hence you can test for a unit root by testing whether the sum of the autoregressive parameters is 1 or not. The no-intercept model is parameterized as

$$\nabla Y_t = \delta Y_{t-1} + \theta_1 \nabla Y_{t-1} + \cdots + \theta_p \nabla Y_{t-p} + e_t$$

where $\nabla Y_t = Y_t - Y_{t-1}$ and

$$\delta = \alpha_1 + \cdots + \alpha_{p+1} - 1$$

$$\theta_k = -\alpha_{k+1} - \cdots - \alpha_{p+1}$$

The estimators are obtained by regressing ∇Y_t on $Y_{t-1}, \nabla Y_{t-1}, \dots, \nabla Y_{t-p}$. The t statistic of the ordinary least squares estimator of δ is the test statistic for the unit root test.

If the *type* argument value specifies a test for a nonzero mean (intercept case), the autoregressive model includes a mean term α_0 . If the *type* argument value specifies a test for a time trend, the model also includes a time trend term and the model is as follows:

$$\nabla Y_t = \alpha_0 + \gamma t + \delta Y_{t-1} + \theta_1 \nabla Y_{t-1} + \dots + \theta_p \nabla Y_{t-p} + e_t$$

For testing for a seasonal unit root, consider the multiplicative model

$$(1 - \alpha_d B^d)(1 - \theta_1 B - \dots - \theta_p B^p)Y_t = e_t$$

Let $\nabla^d Y_t \equiv Y_t - Y_{t-d}$. The test statistic is calculated in the following steps:

1. Regress $\nabla^d Y_t$ on $\nabla^d Y_{t-1} \dots \nabla^d Y_{t-p}$ to obtain the initial estimators $\hat{\theta}_i$ and compute residuals \hat{e}_t . Under the null hypothesis that $\alpha_d = 1$, $\hat{\theta}_i$ are consistent estimators of θ_i .
2. Regress \hat{e}_t on $(1 - \hat{\theta}_1 B - \dots - \hat{\theta}_p B^p)Y_{t-d}, \nabla^d Y_{t-1}, \dots, \nabla^d Y_{t-p}$ to obtain estimates of $\delta = \alpha_d - 1$ and $\theta_i - \hat{\theta}_i$.

The t ratio for the estimate of δ produced by the second step is used as a test statistic for testing for a seasonal unit root. The estimates of θ_i are obtained by adding the estimates of $\theta_i - \hat{\theta}_i$ from the second step to $\hat{\theta}_i$ from the first step.

The series $(1 - B^d)Y_t$ is assumed to be stationary, where d is the value of the third argument to the PROBDF function.

If the series is an ARMA process, a large value of p might be desirable in order to obtain a reliable test statistic. To determine an appropriate value for p , see Said and Dickey (1984).

Test Statistics

The Dickey-Fuller test is used to test the null hypothesis that the time series exhibits a lag d unit root against the alternative of stationarity. The PROBDF function computes the probability of observing a test statistic more extreme than x under the assumption that the null hypothesis is true. You should reject the unit root hypothesis when PROBDF returns a small (significant) probability value.

There are several different versions of the Dickey-Fuller test. The PROBDF function supports six versions, as selected by the *type* argument. Specify the *type* value that corresponds to the way that you calculated the test statistic x .

The last two characters of the *type* value specify the kind of regression model used to compute the Dickey-Fuller test statistic. The meaning of the last two characters of the *type* value are as follows:

ZM zero mean or no-intercept case. The test statistic x is assumed to be computed from the regression model

$$y_t = \alpha_d y_{t-d} + e_t$$

SM single mean or intercept case. The test statistic x is assumed to be computed from the regression model

$$y_t = \alpha_0 + \alpha_d y_{t-d} + e_t$$

TR intercept and deterministic time trend case. The test statistic x is assumed to be computed from the regression model

$$y_t = \alpha_0 + \gamma t + \alpha_1 y_{t-1} + e_t$$

The first character of the *type* value specifies whether the regression test statistic or the studentized test statistic is used. Let $\hat{\alpha}_d$ be the estimated regression coefficient for the d th lag of the series, and let $se_{\hat{\alpha}}$ be the standard error of $\hat{\alpha}_d$. The meaning of the first character of the *type* value is as follows:

R the regression-coefficient-based test statistic. The test statistic is

$$x = n(\hat{\alpha}_d - 1)$$

S the studentized test statistic. The test statistic is

$$x = \frac{(\hat{\alpha}_d - 1)}{se_{\hat{\alpha}}}$$

See Dickey and Fuller (1979), Dickey, Hasza, and Fuller (1984), and Hamilton (1994) for more information about the Dickey-Fuller test null distribution. The preceding formulas are for the basic Dickey-Fuller test. The PROBDF function can also be used for the augmented Dickey-Fuller test, in which the error term e_t is modeled as an autoregressive process; however, the test statistic is computed somewhat differently for the augmented Dickey-Fuller test. See Dickey, Hasza, and Fuller (1984) and Hamilton (1994) for information about seasonal and nonseasonal augmented Dickey-Fuller tests.

The PROBDF function is calculated from approximating functions fit to empirical quantiles that are produced by a Monte Carlo simulation that employs 10^8 replications for each simulation. Separate simulations were performed for selected values of n and for $d = 1, 2, 4, 6, 12$ (where n and d are the second and third arguments to the PROBDF function).

The maximum error of the PROBDF function is approximately $\pm 10^{-3}$ for d in the set (1,2,4,6,12) and can be slightly larger for other d values. (Because the number of simulation replications used to produce the PROBDF function is much greater than the 60,000 replications used by Dickey and Fuller (1979) and Dickey, Hasza, and Fuller (1984), the PROBDF function can be expected to produce results that are substantially more accurate than the critical values reported in those papers.)

Examples

Suppose the data set TEST contains 104 observations of the time series variable Y, and you want to test the null hypothesis that there exists a lag 4 seasonal unit root in the Y series. The following statements illustrate how to perform the single-mean Dickey-Fuller regression coefficient test using PROC REG and PROBDF.

```

data test1;
  set test;
  y4 = lag4(y);
run;

proc reg data=test1 outest=alpha;
  model y = y4 / noprint;
run;

data _null_;
  set alpha;
  x = 100 * ( y4 - 1 );
  p = probdf( x, 100, 4, "RSM" );
  put p= pvalue5.3;
run;

```

To perform the augmented Dickey-Fuller test, regress the differences of the series on lagged differences and on the lagged value of the series, and compute the test statistic from the regression coefficient for the lagged series. The following statements illustrate how to perform the single-mean augmented Dickey-Fuller studentized test for a simple unit root using PROC REG and PROBDF:

```

data test1;
  set test;
  y1 = lag(y);
  yd = dif(y);
  yd1 = lag1(yd); yd2 = lag2(yd);
  yd3 = lag3(yd); yd4 = lag4(yd);
run;

proc reg data=test1 outest=alpha covout;
  model yd = y1 yd1-yd4 / noprint;
run;

data _null_;
  set alpha;
  retain a;
  if _type_ = 'PARMS' then a = y1 - 1;
  if _type_ = 'COV' & _NAME_ = 'YL' then do;
    x = a / sqrt(y1);
    p = probdf( x, 99, 1, "SSM" );
    put p= pvalue5.3;
  end;
run;

```

The %DFTEST macro provides an easier way to perform Dickey-Fuller tests. The following statements perform the same tests as the preceding example:

```

%dfctest( test, y, ar=4 );
%put p=&dfctest;

```

Overview

Several SAS/ETS procedures (COUNTREG, ENTROPY, MDC, QLIM, UCM, and VARMAX) use the nonlinear optimization (NLO) subsystem to perform nonlinear optimization. This chapter describes the options of the NLO system and some technical details of the available optimization methods. Note that not all options have been implemented for all procedures that use the NLO subsystem. You should check each procedure chapter for more details about which options are available.

Options

The following table summarizes the options available in the NLO system.

Table 6.1 NLO options

Option	Description
Optimization Specifications	
TECHNIQUE=	minimization technique
UPDATE=	update technique

Table 6.1 continued

Option	Description
LINESEARCH=	line-search method
LSPRECISION=	line-search precision
HESCAL=	type of Hessian scaling
INHESIAN=	start for approximated Hessian
RESTART=	iteration number for update restart
Termination Criteria Specifications	
MAXFUNC=	maximum number of function calls
MAXITER=	maximum number of iterations
MINITER=	minimum number of iterations
MAXTIME=	upper limit seconds of CPU time
ABSCONV=	absolute function convergence criterion
ABSFCNV=	absolute function convergence criterion
ABSGCONV=	absolute gradient convergence criterion
ABSXCONV=	absolute parameter convergence criterion
FCNV=	relative function convergence criterion
FCNV2=	relative function convergence criterion
GCONV=	relative gradient convergence criterion
XCONV=	relative parameter convergence criterion
FSIZE=	used in FCNV, GCONV criterion
XSIZE=	used in XCONV criterion
Step Length Options	
DAMPSTEP=	damped steps in line search
MAXSTEP=	maximum trust region radius
INSTEP=	initial trust region radius
Printed Output Options	
PALL	display (almost) all printed optimization-related output
PHISTORY	display optimization history
PHISTPARMS	display parameter estimates in each iteration
PSHORT	reduce some default optimization-related output
PSUMMARY	reduce most default optimization-related output
NOPRINT	suppress all printed optimization-related output
Remote Monitoring Options	
SOCKET=	specify the fileref for remote monitoring

These options are described in alphabetical order.

ABSCONV= r

ABSTOL= r

specifies an absolute function convergence criterion. For minimization, termination requires $f(\theta^{(k)}) \leq r$. The default value of r is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

ABSFCNV= r [n]**ABSFTOL= r [n]**

specifies an absolute function convergence criterion. For all techniques except NMSIMP, termination requires a small change of the function value in successive iterations:

$$|f(\theta^{(k-1)}) - f(\theta^{(k)})| \leq r$$

The same formula is used for the NMSIMP technique, but $\theta^{(k)}$ is defined as the vertex with the lowest function value, and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is $r = 0$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV= r [n]**ABSGTOL= r [n]**

specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\theta^{(k)})| \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r = 1\text{E} - 5$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSXCONV= r [n]**ABSXTOL= r [n]**

specifies an absolute parameter convergence criterion. For all techniques except NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\|\theta^{(k)} - \theta^{(k-1)}\|_2 \leq r$$

For the NMSIMP technique, termination requires either a small length $\alpha^{(k)}$ of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size $\delta^{(k)}$ is defined as the L1 distance from the simplex vertex $\xi^{(k)}$ with the smallest function value to the other n simplex points $\theta_l^{(k)} \neq \xi^{(k)}$:

$$\delta^{(k)} = \sum_{\theta_l \neq y} \|\theta_l^{(k)} - \xi^{(k)}\|_1$$

The default is $r = 1\text{E} - 8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

DAMPSTEP[=*r*]

specifies that the initial step length value $\alpha^{(0)}$ for each line search (used by the QUANEW, HYQUAN, CONGRA, or NEWRAP technique) cannot be larger than r times the step length value used in the former iteration. If the DAMPSTEP option is specified but r is not specified, the default is $r = 2$. The DAMPSTEP= r option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating point overflows during the computation of objective functions and their derivatives. The DAMPSTEP= r option can save time-costly function calls during the line searches of objective functions that result in very small steps.

FCONV= r [*n*]**FTOL**= r [*n*]

specifies a relative function convergence criterion. For all techniques except NMSIMP, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\theta^{(k)}) - f(\theta^{(k-1)})|}{\max(|f(\theta^{(k-1)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. The same formula is used for the NMSIMP technique, but $\theta^{(k)}$ is defined as the vertex with the lowest function value, and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value may depend on the procedure. In most cases, you can use the PALL option to find it.

FCONV2= r [*n*]**FTOL2**= r [*n*]

specifies another function convergence criterion.

For all techniques except NMSIMP, termination requires a small predicted reduction

$$df^{(k)} \approx f(\theta^{(k)}) - f(\theta^{(k)} + s^{(k)})$$

of the objective function. The predicted reduction

$$\begin{aligned} df^{(k)} &= -g^{(k)T} s^{(k)} - \frac{1}{2} s^{(k)T} H^{(k)} s^{(k)} \\ &= -\frac{1}{2} s^{(k)T} g^{(k)} \\ &\leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step

$$s^{(k)} = -[H^{(k)}]^{-1} g^{(k)}$$

For the NMSIMP technique, termination requires a small standard deviation of the function values of the $n + 1$ simplex vertices $\theta_l^{(k)}$, $l = 0, \dots, n$, $\sqrt{\frac{1}{n+1} \sum_l [f(\theta_l^{(k)}) - \bar{f}(\theta^{(k)})]^2} \leq r$ where $\bar{f}(\theta^{(k)}) = \frac{1}{n+1} \sum_l f(\theta_l^{(k)})$. If there are n_{act} boundary constraints active at $\theta^{(k)}$, the mean and standard deviation are computed only for the $n + 1 - n_{act}$ unconstrained vertices.

The default value is $r = 1E - 6$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FSIZE= r

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. For more details, see the FCONV= and GCONV= options.

GCONV= r [n]**GTOL= r [n]**

specifies a relative gradient convergence criterion. For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction is small,

$$\frac{frac g(\theta^{(k)})^T [H^{(k)}]^{-1} g(\theta^{(k)})}{\max(|f(\theta^{(k)})|, FSIZE)} \leq r$$

where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate H is not available), the following criterion is used:

$$\frac{\|g(\theta^{(k)})\|_2^2 \|s(\theta^{(k)})\|_2}{\|g(\theta^{(k)}) - g(\theta^{(k-1)})\|_2 \max(|f(\theta^{(k)})|, FSIZE)} \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r = 1E - 8$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

HESCAL=0|1|2|3**HS=0|1|2|3**

specifies the scaling version of the Hessian matrix used in NRRIDG, TRUREG, NEWRAP, or DBLDOG optimization.

If HS is not equal to 0, the first iteration and each restart iteration sets the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where $H_{i,i}^{(0)}$ are the diagonal elements of the Hessian. In every other iteration, the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$ is updated depending on the HS option:

HS=0 specifies that no scaling is done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max \left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

HS=2 specifies the Dennis, Gay, & Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max \left[0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

HS=3 specifies that d_i is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update, ϵ is the relative machine precision. The default value is $HS=0$. Scaling of the Hessian can be time consuming in the case where general linear constraints are active.

INHESIAN[= r]

INHES[= r]

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the r specification, the initial estimate of the approximate Hessian is set to the Hessian at $\theta^{(0)}$.
- If you do use the r specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix rI .

By default, if you do not specify the option $INHESIAN=r$, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix rI , where the scalar r is computed from the magnitude of the initial gradient.

INSTEP= r

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of $0 < r < 1$ such as $INSTEP=1E-1$, $INSTEP=1E-2$, $INSTEP=1E-4$, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG), the $INSTEP=$ option specifies a factor $r > 0$ for the initial radius $\Delta^{(0)}$ of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, QUANEW), the $INSTEP=$ option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.
- For the Nelder-Mead simplex algorithm, using $TECH=NMSIMP$, the $INSTEP=r$ option defines the size of the start simplex.

LINESEARCH= i

LIS= i

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. Refer to Fletcher (1987) for an introduction to line-search techniques. The value of i can be $1, \dots, 8$. For CONGRA, QUANEW and NEWRAP, the default value is $i = 2$.

LIS=1 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.

LIS=2 specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the $LSPRECISSION=$ option.

LIS=3	specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.
LIS=4	specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.
LIS=5	specifies a line-search method that is a modified version of LIS=4.
LIS=6	specifies golden section line search (Polak 1971), which uses only function values for linear approximation.
LIS=7	specifies bisection line search (Polak 1971), which uses only function values for linear approximation.
LIS=8	specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION=*r***LSP=*r***

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search may be necessary (Fletcher 1987). The second line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the third line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, you should try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in the following table.

Table 6.2 Line Search Precision Defaults

TECH=	UPDATE=	LSP default
QUANEW	DBFGS, BFGS	$r = 0.4$
QUANEW	DDFP, DFP	$r = 0.06$
CONGRA	all	$r = 0.1$
NEWRAP	no update	$r = 0.9$

For more details, refer to Fletcher (1987).

MAXFUNC=*i***MAXFU=*i***

specifies the maximum number i of function calls in the optimization process. The default values are

- TRUREG, NRRIDG, NEWRAP: 125
- QUANEW, DBLDOG: 500
- CONGRA: 1000
- NMSIMP: 3000

Note that the optimization can terminate only after completing a full iteration. Therefore, the number of function calls that is actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER=*i***MAXIT=*i***

specifies the maximum number *i* of iterations in the optimization process. The default values are

- TRUREG, NRRIDG, NEWRAP: 50
- QUANEW, DBLDOG: 200
- CONGRA: 400
- NMSIMP: 1000

These default values are also valid when *i* is specified as a missing value.

MAXSTEP=*r*[*n*]

specifies an upper bound for the step length of the line-search algorithms during the first *n* iterations. By default, *r* is the largest double-precision value and *n* is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

MAXTIME=*r*

specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. Note that the time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

MINITER=*i***MINIT=*i***

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

NOPRINT

suppresses the output. (See procedure documentation for availability of this option.)

PALL

displays all optional output for optimization. (See procedure documentation for availability of this option.)

PHISTORY

displays the optimization history. (See procedure documentation for availability of this option.)

PHISTPARMS

display parameter estimates in each iteration. (See procedure documentation for availability of this option.)

PINIT

displays the initial values and derivatives (if available). (See procedure documentation for availability of this option.)

PSHORT

restricts the amount of default output. (See procedure documentation for availability of this option.)

PSUMMARY

restricts the amount of default displayed output to a short form of iteration history and notes, warnings, and errors. (See procedure documentation for availability of this option.)

RESTART= $i > 0$ **REST= $i > 0$**

specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after, at most, i iterations. Default values are as follows:

- CONGRA
UPDATE=PB: restart is performed automatically, i is not used.
- CONGRA
UPDATE≠PB: $i = \min(10n, 80)$, where n is the number of parameters.
- QUANEW
 i is the largest integer available.

SOCKET=*fileref*

Specifies the fileref that contains the information needed for remote monitoring. See the section “[Remote Monitoring](#)” on page 181 for more details.

TECHNIQUE=*value***TECH=*value***

specifies the optimization technique. Valid values are as follows:

- CONGRA
performs a conjugate-gradient optimization, which can be more precisely specified with the UPDATE= option and modified with the LINESEARCH= option. When you specify this option, UPDATE=PB by default.
- DBLDOG
performs a version of double-dogleg optimization, which can be more precisely specified with the UPDATE= option. When you specify this option, UPDATE=DBFGS by default.
- NMSIMP
performs a Nelder-Mead simplex optimization.
- NONE
does not perform any optimization. This option can be used as follows:

- to perform a grid search without optimization
- to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques
- NEWRAP
performs a Newton-Raphson optimization that combines a line-search algorithm with ridging. The line-search algorithm LIS=2 is the default method.
- NRRIDG
performs a Newton-Raphson optimization with ridging.
- QUANEW
performs a quasi-Newton optimization, which can be defined more precisely with the UPDATE= option and modified with the LINESEARCH= option. This is the default estimation method.
- TRUREG
performs a trust region optimization.

UPDATE=method

UPD=method

specifies the update method for the QUANEW, DBLDOG, or CONGRA optimization technique. Not every update method can be used with each optimizer.

Valid methods are as follows:

- BFGS
performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
- DBFGS
performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
- DDFP
performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- DFP
performs the original DFP update of the inverse Hessian matrix.
- PB
performs the automatic restart update method of Powell (1977) and Beale (1972).
- FR
performs the Fletcher-Reeves update (Fletcher 1987).
- PR
performs the Polak-Ribiere update (Fletcher 1987).
- CD
performs a conjugate-descent update of Fletcher (1987).

XCONV=*r*[*n*]

XTOL=*r*[*n*]

specifies the relative parameter convergence criterion. For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations.

$$\frac{\max_j |\theta_j^{(k)} - \theta_j^{(k-1)}|}{\max(|\theta_j^{(k)}|, |\theta_j^{(k-1)}|, \text{XSIZE})} \leq r$$

For the NMSIMP technique, the same formula is used, but $\theta_j^{(k)}$ is defined as the vertex with the lowest function value and $\theta_j^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is $r = 1\text{E} - 8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XSIZE=*r* > 0

specifies the XSIZE parameter of the relative parameter termination criterion. The default value is $r = 0$. For more detail, see the XCONV= option.

Details of Optimization Algorithms

Overview

There are several optimization techniques available. You can choose a particular optimizer with the **TECH**=*name* option in the PROC statement or NLOPTIONS statement.

Table 6.3 Optimization Techniques

Algorithm	TECH=
trust region Method	TRUREG
Newton-Raphson method with line search	NEWRAP
Newton-Raphson method with ridging	NRRIDG
quasi-Newton methods (DBFGS, DDFP, BFGS, DFP)	QUANEW
double-dogleg method (DBFGS, DDFP)	DBLDOG
conjugate gradient methods (PB, FR, PR, CD)	CONGRA
Nelder-Mead simplex method	NMSIMP

No algorithm for optimizing general nonlinear functions exists that always finds the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, NLO provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in NLO can find the correct solution. Moreover, nonlinear optimization can

be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem.

All optimization techniques in NLO use $O(n^2)$ memory except the conjugate gradient methods, which use only $O(n)$ of memory and are designed to optimize problems with many parameters. These iterative techniques require repeated computation of the following:

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)

However, since each of the optimizers requires different derivatives, some computational efficiencies can be gained. Table 6.4 shows, for each optimization technique, which derivatives are required. (*FOD* means that first-order derivatives or the gradient is computed; *SOD* means that second-order derivatives or the Hessian is computed.)

Table 6.4 Optimization Computations

Algorithm	FOD	SOD
TRUREG	x	x
NEWRAP	x	x
NRRIDG	x	x
QUANEW	x	-
DBLDOG	x	-
CONGRA	x	-
NMSIMP	-	-

Each optimization method employs one or more convergence criteria that determine when it has converged. The various termination criteria are listed and described in the previous section. An algorithm is considered to have converged when any one of the convergence criterion is satisfied. For example, under the default settings, the QUANEW algorithm will converge if $ABSGCONV < 1E - 5$, $FCONV < 10^{-FDIGITS}$, or $GCONV < 1E - 8$.

Choosing an Optimization Algorithm

The factors that go into choosing a particular optimization technique for a particular problem are complex and might involve trial and error.

For many optimization problems, computing the gradient takes more computer time than computing the function value, and computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and as a result the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be

less reliable. For example, they can more easily terminate at stationary points rather than at global optima.

A few general remarks about the various optimization techniques follow.

- The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with $n(n + 1)/2$ double words; TRUREG and NEWRAP require two such matrices.
- The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. The QUANEW and DBLDOG algorithms, in general, require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with $n(n + 1)/2$ double words). QUANEW is the default optimization method.
- The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. The CONGRA algorithm, in general, requires more iterations than QUANEW or DBLDOG, but each iteration can be much faster. Since CONGRA requires only a factor of n double-word memory, many large applications can be solved only by CONGRA.
- The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

Algorithm Descriptions

Some details about the optimization techniques are as follows.

Trust Region Optimization (TRUREG)

The trust region method uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function $f(\theta)$ have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius Δ that constrains the step size that corresponds to the quality of the quadratic approximation. The trust region method is implemented using Dennis, Gay, and Welsch (1981), Gay (1983), and Moré and Sorensen (1983).

The trust region method performs well for small- to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms may be more efficient.

Newton-Raphson Optimization with Line Search (NEWRAP)

The NEWRAP technique uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method can perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridgeing and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite.

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LIS=2).

Newton-Raphson Ridge Optimization (NRRIDG)

The NRRIDG technique uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small- to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Since the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

Quasi-Newton Optimization (QUANEW)

The (dual) quasi-Newton method uses the gradient $g(\theta_{(k)})$, and it does not need to compute second-order derivatives since they are approximated. It works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian; but, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending upon the value of the UPDATE= option.

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian

- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (default)

You can specify four update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the LIS= option.

The QUANEW algorithm performs its own line-search technique. All options and parameters (except the INSTEP= option) that control the line search in the other algorithms do not apply here. In several applications, large steps in the first iterations are troublesome. You can use the INSTEP= option to impose an upper bound for the step size α during the first five iterations. You can also use the INHESSIAN[=*r*] option to specify a different starting approximation for the Hessian. If you specify only the INHESSIAN option, the Cholesky factor of a (possibly ridged) finite difference approximation of the Hessian is used to initialize the quasi-Newton update process. The values of the LCSINGULAR=, LCEPSILON=, and LCDEACT= options, which control the processing of linear and boundary constraints, are valid only for the quadratic programming subroutine used in each iteration of the QUANEW algorithm.

Double-Dogleg Optimization (DBLDOG)

The double-dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double-dogleg algorithm computes the step $s^{(k)}$ as the linear combination of the steepest descent or ascent search direction $s_1^{(k)}$ and a quasi-Newton search direction $s_2^{(k)}$.

$$s^{(k)} = \alpha_1 s_1^{(k)} + \alpha_2 s_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; see Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double-dogleg optimization technique works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979) and Gay (1983), but it is extended for dealing with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, or NRRIDG technique, which requires second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

Conjugate Gradient Optimization (CONGRA)

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only $O(n)$ memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the UPDATE= option:

- PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default, UPDATE=PB, behaved best in most test examples. You are advised to avoid the option UPDATE=CD, which behaved worst in most test examples.

The CONGRA subroutine should be used for optimization problems with large n . For the unconstrained or boundary constrained case, CONGRA requires only $O(n)$ bytes of working memory, whereas all other optimization methods require order $O(n^2)$ bytes of working memory. During n successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of n conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the LIS= option.

Nelder-Mead Simplex Optimization (NMSIMP)

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it might be unable to generate precise results for n much greater than 40.

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex by adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criteria.

Remote Monitoring

The SAS/EmMonitor is an application for Windows that enables you to monitor and stop from your PC a CPU-intensive application performed by the NLO subsystem that runs on a remote server.

On the server side, a FILENAME statement assigns a fileref to a SOCKET-type device that defines the IP address of the client and the port number for listening. The fileref is then specified in the SOCKET= option in the PROC statement to control the EmMonitor. The following statements show an example of server-side statements for PROC ENTROPY.

```
data one;
  do t = 1 to 10;
    x1 = 5 * ranuni(456);
    x2 = 10 * ranuni( 456);
    x3 = 2 * rannor(1456);
    e1 = rannor(1456);
    e2 = rannor(4560);
    tmp1 = 0.5 * e1 - 0.1 * e2;
    tmp2 = -0.1 * e1 - 0.3 * e2;
    y1 = 7 + 8.5*x1 + 2*x2 + tmp1;
    y2 = -3 + -2*x1 + x2 + 3*x3 + tmp2;
    output;
  end;
run;

filename sock socket 'your.pc.address.com:6943';

proc entropy data=one tech=tr gmenm gconv=2.e-5 socket=sock;
  model y1 = x1 x2 x3;
run;
```

On the client side, the EmMonitor application is started with the following syntax:

EmMonitor *options*

The options are:

- `-p port_number` defines the port number
- `-t title` defines the title of the EmMonitor window
- `-k` keeps the monitor alive when the iteration is completed

The default port number is 6943.

The server does not need to be running when you start the EmMonitor, and you can start or dismiss the server at any time during the iteration process. You only need to remember the port number.

Starting the PC client, or closing it prematurely, does not have any effect on the server side. In other words, the iteration process continues until one of the criteria for termination is met.

Figure 6.1 through Figure 6.4 show screenshots of the application on the client side.

Figure 6.1 Graph Tab Group 0

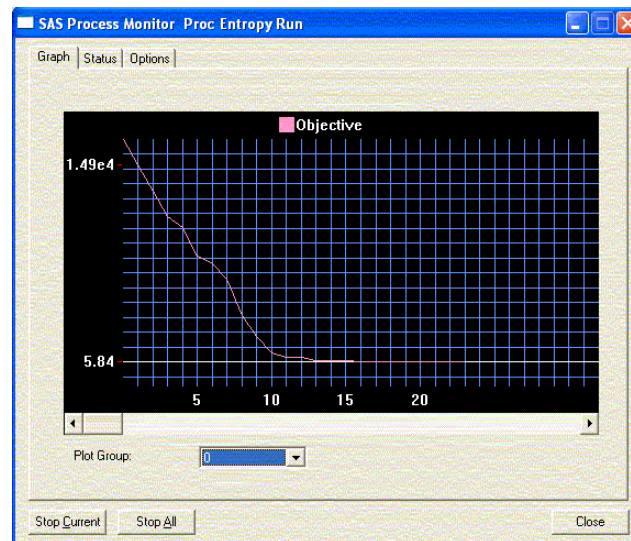

Figure 6.2 Graph Tab Group 1

ODS Table Names

The NLO subsystem assigns a name to each table it creates. You can use these names when using the Output Delivery System (ODS) to select tables and create output data sets. Not all tables are created by all SAS/ETS procedures that use the NLO subsystem. You should check the procedure chapter for more details. The names are listed in the following table.

Table 6.5 ODS Tables Produced by the NLO Subsystem

ODS Table Name	Description
ConvergenceStatus	Convergence status
InputOptions	Input options
IterHist	Iteration history
IterStart	Iteration start
IterStop	Iteration stop
Lagrange	Lagrange multipliers at the solution
LinCon	Linear constraints
LinConDel	Deleted linear constraints
LinConSol	Linear constraints at the solution
ParameterEstimatesResults	Estimates at the results
ParameterEstimatesStart	Estimates at the start of the iterations
ProblemDescription	Problem description
ProjGrad	Projected gradients

Overview: ARIMA Procedure

The ARIMA procedure analyzes and forecasts equally spaced univariate time series data, transfer function data, and intervention data by using the autoregressive integrated moving-average (ARIMA) or autoregressive moving-average (ARMA) model. An ARIMA model predicts a value in a response time series as a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series.

The ARIMA approach was first popularized by Box and Jenkins, and ARIMA models are often referred to as Box-Jenkins models. The general transfer function model employed by the ARIMA procedure was discussed by Box and Tiao (1975). When an ARIMA model includes other time series as input variables, the model is sometimes referred to as an ARIMAX model. Pankratz (1991) refers to the ARIMAX model as *dynamic regression*.

The ARIMA procedure provides a comprehensive set of tools for univariate time series model identification, parameter estimation, and forecasting, and it offers great flexibility in the kinds of ARIMA or ARIMAX models that can be analyzed. The ARIMA procedure supports seasonal, subset, and factored ARIMA models; intervention or interrupted time series models; multiple regression analysis with ARMA errors; and rational transfer function models of any complexity.

The design of PROC ARIMA closely follows the Box-Jenkins strategy for time series modeling with features for the identification, estimation and diagnostic checking, and forecasting steps of the Box-Jenkins method.

Before you use PROC ARIMA, you should be familiar with Box-Jenkins methods, and you should exercise care and judgment when you use the ARIMA procedure. The ARIMA class of time series models is complex and powerful, and some degree of expertise is needed to use them correctly.

Getting Started: ARIMA Procedure

This section outlines the use of the ARIMA procedure and gives a cursory description of the ARIMA modeling process for readers who are less familiar with these methods.

The Three Stages of ARIMA Modeling

The analysis performed by PROC ARIMA is divided into three stages, corresponding to the stages described by Box and Jenkins (1976).

1. In the *identification* stage, you use the IDENTIFY statement to specify the response series and identify candidate ARIMA models for it. The IDENTIFY statement reads time series that are to be used in later statements, possibly differencing them, and computes autocorrelations, inverse autocorrelations, partial autocorrelations, and cross-correlations. Stationarity tests can be performed to determine if differencing is necessary. The analysis of the IDENTIFY statement output usually suggests one or more ARIMA models that could be fit. Options enable you to test for stationarity and tentative ARMA order identification.
2. In the *estimation and diagnostic checking* stage, you use the ESTIMATE statement to specify the ARIMA model to fit to the variable specified in the previous IDENTIFY statement and to estimate the parameters of that model. The ESTIMATE statement also produces diagnostic statistics to help you judge the adequacy of the model.

Significance tests for parameter estimates indicate whether some terms in the model might be unnecessary. Goodness-of-fit statistics aid in comparing this model to others. Tests for white noise residuals indicate whether the residual series contains additional information that might be used by a more complex model. The OUTLIER statement provides another useful tool to check whether the currently estimated model accounts for all the variation in the series. If the diagnostic tests indicate problems with the model, you try another model and then repeat the estimation and diagnostic checking stage.

3. In the *forecasting* stage, you use the FORECAST statement to forecast future values of the time series and to generate confidence intervals for these forecasts from the ARIMA model produced by the preceding ESTIMATE statement.

These three steps are explained further and illustrated through an extended example in the following sections.

Identification Stage

Suppose you have a variable called SALES that you want to forecast. The following example illustrates ARIMA modeling and forecasting by using a simulated data set TEST that contains a time series SALES generated by an ARIMA(1,1,1) model. The output produced by this example is explained in the following sections. The simulated SALES series is shown in [Figure 7.1](#).

```
proc sgplot data=test;
  scatter y=sales x=date;
run;
```

Figure 7.1 Simulated ARIMA(1,1,1) Series SALES

Using the IDENTIFY Statement

You first specify the input data set in the PROC ARIMA statement. Then, you use an IDENTIFY statement to read in the SALES series and analyze its correlation properties. You do this by using the following statements:

```
proc arima data=test ;
    identify var=sales nlag=24;
run;
```

Descriptive Statistics

The IDENTIFY statement first prints descriptive statistics for the SALES series. This part of the IDENTIFY statement output is shown in [Figure 7.2](#).

Figure 7.2 IDENTIFY Statement Descriptive Statistics Output

The ARIMA Procedure	
Name of Variable = sales	
Mean of Working Series	137.3662
Standard Deviation	17.36385
Number of Observations	100

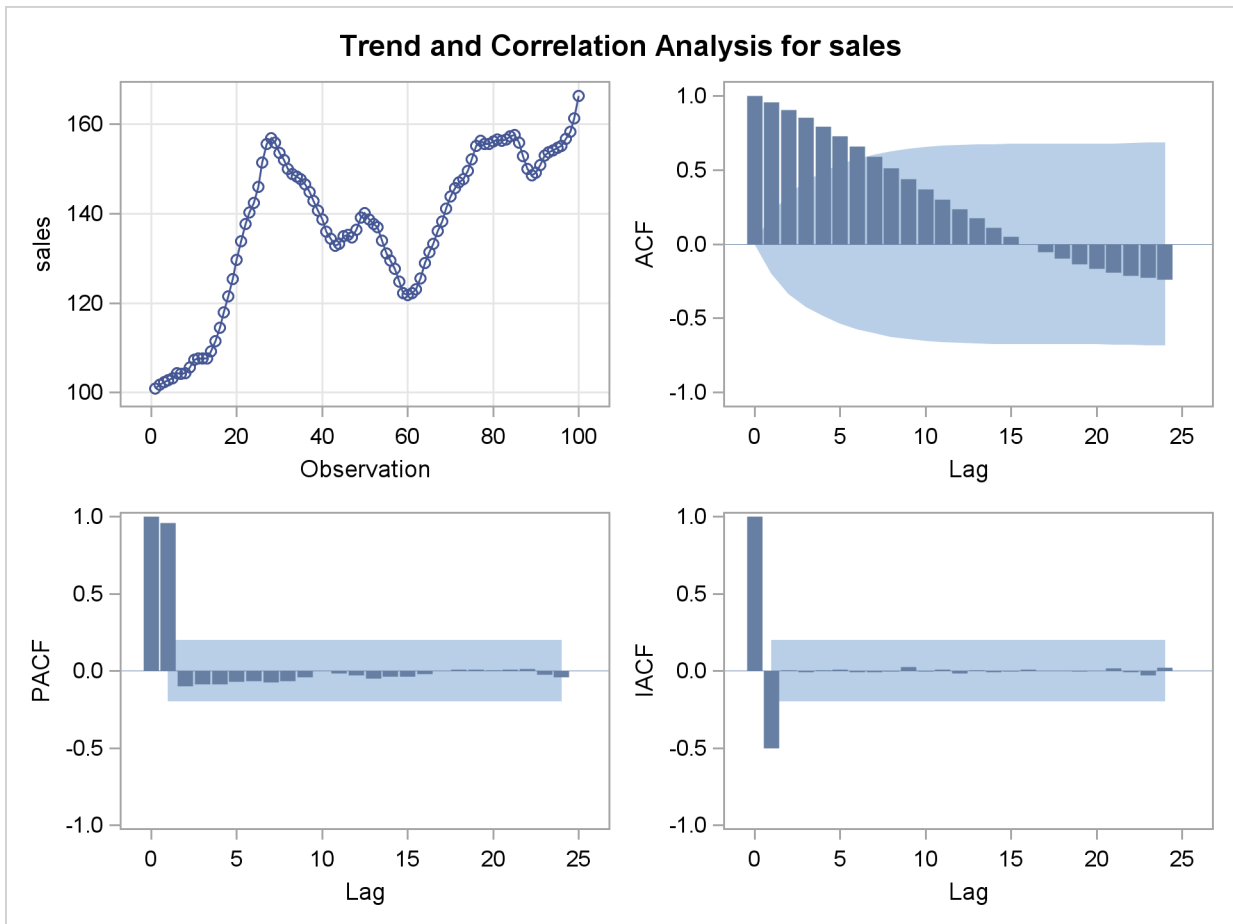

Autocorrelation Function Plots

The IDENTIFY statement next produces a panel of plots used for its autocorrelation and trend analysis. The panel contains the following plots:

- the time series plot of the series
- the sample autocorrelation function plot (ACF)
- the sample inverse autocorrelation function plot (IACF)
- the sample partial autocorrelation function plot (PACF)

This correlation analysis panel is shown in [Figure 7.3](#).

Figure 7.3 Correlation Analysis of SALES

These autocorrelation function plots show the degree of correlation with past values of the series as a function of the number of periods in the past (that is, the lag) at which the correlation is computed.

The `NLAG=` option controls the number of lags for which the autocorrelations are shown. By default, the autocorrelation functions are plotted to lag 24.

Most books on time series analysis explain how to interpret the autocorrelation and the partial autocorrelation plots. See the section “[The Inverse Autocorrelation Function](#)” on page 239 for a discussion of the inverse autocorrelation plots.

By examining these plots, you can judge whether the series is *stationary* or *nonstationary*. In this case, a visual inspection of the autocorrelation function plot indicates that the SALES series is nonstationary, since the ACF decays very slowly. For more formal stationarity tests, use the `STATIONARITY=` option. (See the section “[Stationarity](#)” on page 210.)

White Noise Test

The last part of the default `IDENTIFY` statement output is the check for white noise. This is an approximate statistical test of the hypothesis that none of the autocorrelations of the series up to a

given lag are significantly different from 0. If this is true for all lags, then there is no information in the series to model, and no ARIMA model is needed for the series.

The autocorrelations are checked in groups of six, and the number of lags checked depends on the NLAG= option. The check for white noise output is shown in Figure 7.4.

Figure 7.4 IDENTIFY Statement Check for White Noise

Autocorrelation Check for White Noise									
To Lag	Chi-Square	DF	Pr > ChiSq	-----Autocorrelations-----					
6	426.44	6	<.0001	0.957	0.907	0.852	0.791	0.726	0.659
12	547.82	12	<.0001	0.588	0.514	0.440	0.370	0.303	0.238
18	554.70	18	<.0001	0.174	0.112	0.052	-0.004	-0.054	-0.098
24	585.73	24	<.0001	-0.135	-0.167	-0.192	-0.211	-0.227	-0.240

In this case, the white noise hypothesis is rejected very strongly, which is expected since the series is nonstationary. The *p*-value for the test of the first six autocorrelations is printed as <0.0001, which means the *p*-value is less than 0.0001.

Identification of the Differenced Series

Since the series is nonstationary, the next step is to transform it to a stationary series by differencing. That is, instead of modeling the SALES series itself, you model the change in SALES from one period to the next. To difference the SALES series, use another IDENTIFY statement and specify that the first difference of SALES be analyzed, as shown in the following statements:

```
proc arima data=test;
  identify var=sales(1);
run;
```

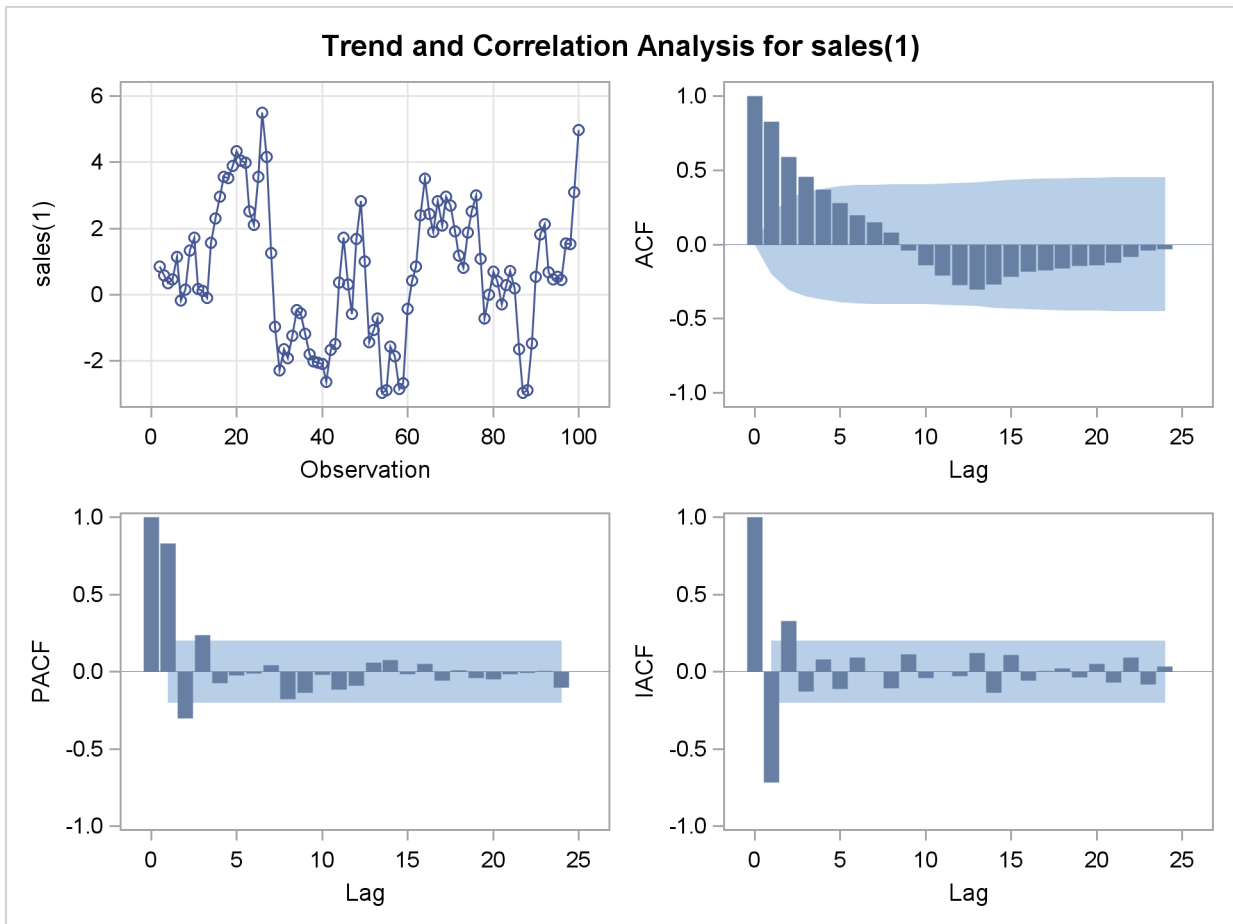

The second IDENTIFY statement produces the same information as the first, but for the change in SALES from one period to the next rather than for the total SALES in each period. The summary statistics output from this IDENTIFY statement is shown in Figure 7.5. Note that the period of differencing is given as 1, and one observation was lost through the differencing operation.

Figure 7.5 IDENTIFY Statement Output for Differenced Series

The ARIMA Procedure	
Name of Variable = sales	
Period(s) of Differencing	1
Mean of Working Series	0.660589
Standard Deviation	2.011543
Number of Observations	99
Observation(s) eliminated by differencing	1

The autocorrelation plots for the differenced series are shown in Figure 7.6.

Figure 7.6 Correlation Analysis of the Change in SALES

The autocorrelations decrease rapidly in this plot, indicating that the change in SALES is a stationary time series.

The next step in the Box-Jenkins methodology is to examine the patterns in the autocorrelation plot to choose candidate ARMA models to the series. The partial and inverse autocorrelation function plots are also useful aids in identifying appropriate ARMA models for the series.

In the usual Box-Jenkins approach to ARIMA modeling, the sample autocorrelation function, inverse autocorrelation function, and partial autocorrelation function are compared with the theoretical correlation functions expected from different kinds of ARMA models. This matching of theoretical autocorrelation functions of different ARMA models to the sample autocorrelation functions computed from the response series is the heart of the identification stage of Box-Jenkins modeling. Most textbooks on time series analysis, such as Pankratz (1983), discuss the theoretical autocorrelation functions for different kinds of ARMA models.

Since the input data are only a limited sample of the series, the sample autocorrelation functions computed from the input series only approximate the true autocorrelation function of the process that generates the series. This means that the sample autocorrelation functions do not exactly match the theoretical autocorrelation functions for any ARMA model and can have a pattern similar to

that of several different ARMA models. If the series is white noise (a purely random process), then there is no need to fit a model. The check for white noise, shown in [Figure 7.7](#), indicates that the change in SALES is highly autocorrelated. Thus, an autocorrelation model, for example an AR(1) model, might be a good candidate model to fit to this process.

Figure 7.7 IDENTIFY Statement Check for White Noise

Autocorrelation Check for White Noise									
To Lag	Chi- Square	DF	Pr > ChiSq	-----Autocorrelations-----					
6	154.44	6	<.0001	0.828	0.591	0.454	0.369	0.281	0.198
12	173.66	12	<.0001	0.151	0.081	-0.039	-0.141	-0.210	-0.274
18	209.64	18	<.0001	-0.305	-0.271	-0.218	-0.183	-0.174	-0.161
24	218.04	24	<.0001	-0.144	-0.141	-0.125	-0.085	-0.040	-0.032

Estimation and Diagnostic Checking Stage

The autocorrelation plots for this series, as shown in the previous section, suggest an AR(1) model for the change in SALES. You should check the diagnostic statistics to see if the AR(1) model is adequate. Other candidate models include an MA(1) model and low-order mixed ARMA models. In this example, the AR(1) model is tried first.

Estimating an AR(1) Model

The following statements fit an AR(1) model (an autoregressive model of order 1), which predicts the change in SALES as an average change, plus some fraction of the previous change, plus a random error. To estimate an AR model, you specify the order of the autoregressive model with the P= option in an ESTIMATE statement:

```
estimate p=1;
run;
```

The ESTIMATE statement fits the model to the data and prints parameter estimates and various diagnostic statistics that indicate how well the model fits the data. The first part of the ESTIMATE statement output, the table of parameter estimates, is shown in [Figure 7.8](#).

Figure 7.8 Parameter Estimates for AR(1) Model

The ARIMA Procedure					
Conditional Least Squares Estimation					
Parameter	Estimate	Standard Error	t Value	Approx Pr > t	Lag
MU	0.90280	0.65984	1.37	0.1744	0
AR1,1	0.86847	0.05485	15.83	<.0001	1

The table of parameter estimates is titled “Conditional Least Squares Estimation,” which indicates the estimation method used. You can request different estimation methods with the `METHOD=` option.

The table of parameter estimates lists the parameters in the model; for each parameter, the table shows the estimated value and the standard error and t value for the estimate. The table also indicates the lag at which the parameter appears in the model.

In this case, there are two parameters in the model. The mean term is labeled MU; its estimated value is 0.90280. The autoregressive parameter is labeled AR1,1; this is the coefficient of the lagged value of the change in SALES, and its estimate is 0.86847.

The t values provide significance tests for the parameter estimates and indicate whether some terms in the model might be unnecessary. In this case, the t value for the autoregressive parameter is 15.83, so this term is highly significant. The t value for MU indicates that the mean term adds little to the model.

The standard error estimates are based on large sample theory. Thus, the standard errors are labeled as approximate, and the standard errors and t values might not be reliable in small samples.

The next part of the ESTIMATE statement output is a table of goodness-of-fit statistics, which aid in comparing this model to other models. This output is shown in [Figure 7.9](#).

Figure 7.9 Goodness-of-Fit Statistics for AR(1) Model

Constant Estimate	0.118749
Variance Estimate	1.15794
Std Error Estimate	1.076076
AIC	297.4469
SBC	302.6372
Number of Residuals	99

The “Constant Estimate” is a function of the mean term MU and the autoregressive parameters. This estimate is computed only for AR or ARMA models, but not for strictly MA models. See the section “[General Notation for ARIMA Models](#)” on page 207 for an explanation of the constant estimate.

The “Variance Estimate” is the variance of the residual series, which estimates the innovation variance. The item labeled “Std Error Estimate” is the square root of the variance estimate. In general,

when you are comparing candidate models, smaller AIC and SBC statistics indicate the better fitting model. The section “[Estimation Details](#)” on page 248 explains the AIC and SBC statistics.

The ESTIMATE statement next prints a table of correlations of the parameter estimates, as shown in [Figure 7.10](#). This table can help you assess the extent to which collinearity might have influenced the results. If two parameter estimates are very highly correlated, you might consider dropping one of them from the model.

Figure 7.10 Correlations of the Estimates for AR(1) Model

Correlations of Parameter Estimates		
Parameter	MU	AR1,1
MU	1.000	0.114
AR1,1	0.114	1.000

The next part of the ESTIMATE statement output is a check of the autocorrelations of the residuals. This output has the same form as the autocorrelation check for white noise that the IDENTIFY statement prints for the response series. The autocorrelation check of residuals is shown in [Figure 7.11](#).

Figure 7.11 Check for White Noise Residuals for AR(1) Model

Autocorrelation Check of Residuals									
To Lag	Chi-Square	DF	Pr > ChiSq	-----Autocorrelations-----					
6	19.09	5	0.0019	0.327	-0.220	-0.128	0.068	-0.002	-0.096
12	22.90	11	0.0183	0.072	0.116	-0.042	-0.066	0.031	-0.091
18	31.63	17	0.0167	-0.233	-0.129	-0.024	0.056	-0.014	-0.008
24	32.83	23	0.0841	0.009	-0.057	-0.057	-0.001	0.049	-0.015

The χ^2 test statistics for the residuals series indicate whether the residuals are uncorrelated (white noise) or contain additional information that might be used by a more complex model. In this case, the test statistics reject the no-autocorrelation hypothesis at a high level of significance ($p = 0.0019$ for the first six lags.) This means that the residuals are not white noise, and so the AR(1) model is not a fully adequate model for this series. The ESTIMATE statement output also includes graphical analysis of the residuals. It is not shown here. The graphical analysis also reveals the inadequacy of the AR(1) model.

The final part of the ESTIMATE statement output is a listing of the estimated model, using the backshift notation. This output is shown in [Figure 7.12](#).

Figure 7.12 Estimated ARIMA(1, 1, 0) Model for SALES

```

Model for variable sales

Estimated Mean           0.902799
Period(s) of Differencing      1

Autoregressive Factors

Factor 1:  1 - 0.86847 B**(1)

```

This listing combines the differencing specification given in the IDENTIFY statement with the parameter estimates of the model for the change in SALES. Since the AR(1) model is for the change in SALES, the final model for SALES is an ARIMA(1,1,0) model. Using B , the backshift operator, the mathematical form of the estimated model shown in this output is as follows:

$$(1 - B)sales_t = 0.902799 + \frac{1}{(1 - 0.86847B)}a_t$$

See the section “[General Notation for ARIMA Models](#)” on page 207 for further explanation of this notation.

Estimating an ARMA(1,1) Model

The IDENTIFY statement plots suggest a mixed autoregressive and moving-average model, and the previous ESTIMATE statement check of residuals indicates that an AR(1) model is not sufficient. You now try estimating an ARMA(1,1) model for the change in SALES.

An ARMA(1,1) model predicts the change in SALES as an average change, plus some fraction of the previous change, plus a random error, plus some fraction of the random error in the preceding period. An ARMA(1,1) model for the change in SALES is the same as an ARIMA(1,1,1) model for the level of SALES.

To estimate a mixed autoregressive moving-average model, you specify the order of the moving-average part of the model with the Q= option in an ESTIMATE statement in addition to specifying the order of the autoregressive part with the P= option. The following statements fit an ARMA(1,1) model to the differenced SALES series:

```

estimate p=1 q=1;
run;

```

The parameter estimates table and goodness-of-fit statistics for this model are shown in [Figure 7.13](#).

Figure 7.13 Estimated ARMA(1, 1) Model for Change in SALES

The ARIMA Procedure					
Conditional Least Squares Estimation					
Parameter	Estimate	Standard Error	t Value	Approx Pr > t	Lag
MU	0.89288	0.49391	1.81	0.0738	0
MA1,1	-0.58935	0.08988	-6.56	<.0001	1
AR1,1	0.74755	0.07785	9.60	<.0001	1
Constant Estimate			0.225409		
Variance Estimate			0.904034		
Std Error Estimate			0.950807		
AIC			273.9155		
SBC			281.7009		
Number of Residuals			99		

The moving-average parameter estimate, labeled “MA1,1”, is -0.58935 . Both the moving-average and the autoregressive parameters have significant t values. Note that the variance estimate, AIC, and SBC are all smaller than they were for the AR(1) model, indicating that the ARMA(1,1) model fits the data better without over-parameterizing.

The graphical check of the residuals from this model is shown in [Figure 7.14](#) and [Figure 7.15](#). The residual correlation and white noise test plots show that you cannot reject the hypothesis that the residuals are uncorrelated. The normality plots also show no departure from normality. Thus, you conclude that the ARMA(1,1) model is adequate for the change in SALES series, and there is no point in trying more complex models.

Figure 7.14 White Noise Check of Residuals for the ARMA(1,1) Model

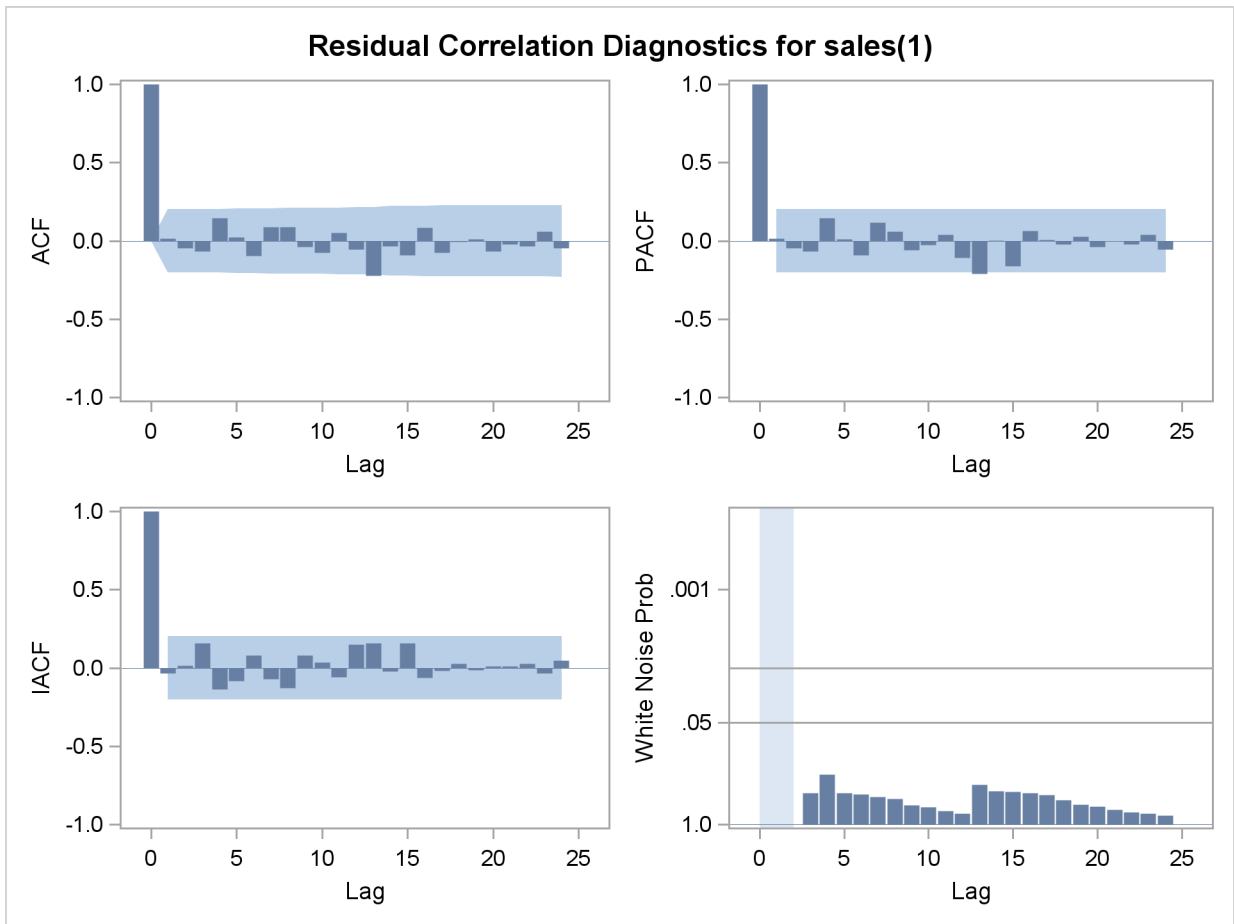

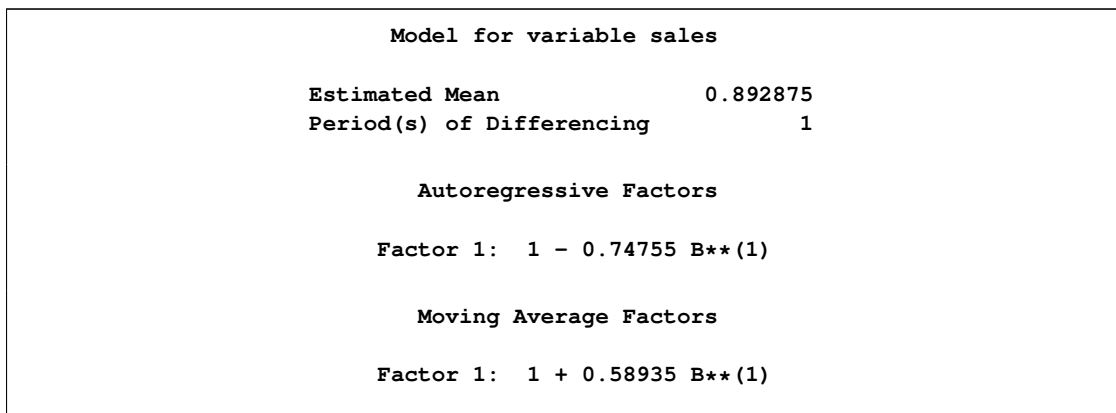

Figure 7.15 Normality Check of Residuals for the ARMA(1,1) Model

The form of the estimated ARIMA(1,1,1) model for SALES is shown in [Figure 7.16](#).

Figure 7.16 Estimated ARIMA(1,1,1) Model for SALES

The estimated model shown in this output is

$$(1 - B)sales_t = 0.892875 + \frac{(1 + 0.58935B)}{(1 - 0.74755B)}a_t$$

In addition to the residual analysis of a model, it is often useful to check whether there are any changes in the time series that are not accounted for by the currently estimated model. The OUTLIER statement enables you to detect such changes. For a long series, this task can be computationally burdensome. Therefore, in general, it is better done after a model that fits the data reasonably well has been found. [Figure 7.17](#) shows the output of the simplest form of the OUTLIER statement:

```
outlier;
run;
```

Two possible outliers have been found for the model in question. See the section “[Detecting Outliers](#)” on page 260, and the examples [Example 7.6](#) and [Example 7.7](#), for more details about modeling in the presence of outliers. In this illustration these outliers are not discussed any further.

Figure 7.17 Outliers for the ARIMA(1,1,1) Model for SALES

Since the model diagnostic tests show that all the parameter estimates are significant and the residual series is white noise, the estimation and diagnostic checking stage is complete. You can now proceed to forecasting the SALES series with this ARIMA(1,1,1) model.

Forecasting Stage

To produce the forecast, use a FORECAST statement after the ESTIMATE statement for the model you decide is best. If the last model fit is not the best, then repeat the ESTIMATE statement for the best model before you use the FORECAST statement.

Suppose that the SALES series is monthly, that you want to forecast one year ahead from the most recently available SALES figure, and that the dates for the observations are given by a variable DATE in the input data set TEST. You use the following FORECAST statement:

```
forecast lead=12 interval=month id=date out=results;
run;
```

The LEAD= option specifies how many periods ahead to forecast (12 months, in this case). The ID= option specifies the ID variable, which is typically a SAS *date*, *time*, or *datetime* variable, used to date the observations of the SALES time series. The INTERVAL= option indicates that data are monthly and enables PROC ARIMA to extrapolate DATE values for forecast periods. The OUT=

option writes the forecasts to the output data set RESULTS. See the section “OUT= Data Set” on page 262 for information about the contents of the output data set.

By default, the FORECAST statement also prints and plots the forecast values, as shown in Figure 7.18 and Figure 7.19. The forecast table shows for each forecast period the observation number, forecast value, standard error estimate for the forecast value, and lower and upper limits for a 95% confidence interval for the forecast.

Figure 7.18 Forecasts for ARIMA(1,1,1) Model for SALES

Figure 7.19 Forecasts for the ARMA(1,1,1) Model

Normally, you want the forecast values stored in an output data set, and you are not interested in seeing this printed list of the forecast. You can use the NOPRINT option in the FORECAST statement to suppress this output.

Using ARIMA Procedure Statements

The IDENTIFY, ESTIMATE, and FORECAST statements are related in a hierarchy. An IDENTIFY statement brings in a time series to be modeled; several ESTIMATE statements can follow to estimate different ARIMA models for the series; for each model estimated, several FORECAST statements can be used. Thus, a FORECAST statement must be preceded at some point by an ESTIMATE statement, and an ESTIMATE statement must be preceded at some point by an IDENTIFY statement. Additional IDENTIFY statements can be used to switch to modeling a different response series or to change the degree of differencing used.

The ARIMA procedure can be used interactively in the sense that all ARIMA procedure statements can be executed any number of times without reinvoking PROC ARIMA. You can execute ARIMA procedure statements singly or in groups by following the single statement or group of statements

with a RUN statement. The output for each statement or group of statements is produced when the RUN statement is entered.

A RUN statement does not terminate the PROC ARIMA step but tells the procedure to execute the statements given so far. You can end PROC ARIMA by submitting a QUIT statement, a DATA step, another PROC step, or an ENDSAS statement.

The example in the preceding section illustrates the interactive use of ARIMA procedure statements. The complete PROC ARIMA program for that example is as follows:

```
proc arima data=test;
  identify var=sales nlag=24;
  run;
  identify var=sales(1);
  run;
  estimate p=1;
  run;
  estimate p=1 q=1;
  run;
  outlier;
  run;
  forecast lead=12 interval=month id=date out=results;
  run;
quit;
```

General Notation for ARIMA Models

The order of an ARIMA (autoregressive integrated moving-average) model is usually denoted by the notation $ARIMA(p,d,q)$, where

- p is the order of the autoregressive part
- d is the order of the differencing
- q is the order of the moving-average process

If no differencing is done ($d = 0$), the models are usually referred to as $ARMA(p, q)$ models. The final model in the preceding example is an $ARIMA(1,1,1)$ model since the IDENTIFY statement specified $d = 1$, and the final ESTIMATE statement specified $p = 1$ and $q = 1$.

Notation for Pure ARIMA Models

Mathematically the pure ARIMA model is written as

$$W_t = \mu + \frac{\theta(B)}{\phi(B)}a_t$$

where

t	indexes time
W_t	is the response series Y_t or a difference of the response series
μ	is the mean term
B	is the backshift operator; that is, $BX_t = X_{t-1}$
$\phi(B)$	is the autoregressive operator, represented as a polynomial in the backshift operator: $\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$
$\theta(B)$	is the moving-average operator, represented as a polynomial in the backshift operator: $\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$
a_t	is the independent disturbance, also called the random error

The series W_t is computed by the IDENTIFY statement and is the series processed by the ESTIMATE statement. Thus, W_t is either the response series Y_t or a difference of Y_t specified by the differencing operators in the IDENTIFY statement.

For simple (nonseasonal) differencing, $W_t = (1 - B)^d Y_t$. For seasonal differencing $W_t = (1 - B)^d (1 - B^s)^D Y_t$, where d is the degree of nonseasonal differencing, D is the degree of seasonal differencing, and s is the length of the seasonal cycle.

For example, the mathematical form of the ARIMA(1,1,1) model estimated in the preceding example is

$$(1 - B)Y_t = \mu + \frac{(1 - \theta_1 B)}{(1 - \phi_1 B)} a_t$$

Model Constant Term

The ARIMA model can also be written as

$$\phi(B)(W_t - \mu) = \theta(B)a_t$$

or

$$\phi(B)W_t = \text{const} + \theta(B)a_t$$

where

$$\text{const} = \phi(B)\mu = \mu - \phi_1\mu - \phi_2\mu - \dots - \phi_p\mu$$

Thus, when an autoregressive operator and a mean term are both included in the model, the constant term for the model can be represented as $\phi(B)\mu$. This value is printed with the label “Constant Estimate” in the ESTIMATE statement output.

Notation for Transfer Function Models

The general ARIMA model with input series, also called the ARIMAX model, is written as

$$W_t = \mu + \sum_i \frac{\omega_i(B)}{\delta_i(B)} B^{k_i} X_{i,t} + \frac{\theta(B)}{\phi(B)} a_t$$

where

$X_{i,t}$	is the i th input time series or a difference of the i th input series at time t
k_i	is the pure time delay for the effect of the i th input series
$\omega_i(B)$	is the numerator polynomial of the transfer function for the i th input series
$\delta_i(B)$	is the denominator polynomial of the transfer function for the i th input series.

The model can also be written more compactly as

$$W_t = \mu + \sum_i \Psi_i(B)X_{i,t} + n_t$$

where

$\Psi_i(B)$	is the transfer function for the i th input series modeled as a ratio of the ω and δ polynomials: $\Psi_i(B) = (\omega_i(B)/\delta_i(B))B^{k_i}$
n_t	is the noise series: $n_t = (\theta(B)/\phi(B))a_t$

This model expresses the response series as a combination of past values of the random shocks and past values of other input series. The response series is also called the *dependent series* or *output series*. An input time series is also referred to as an *independent series* or a *predictor series*. Response variable, dependent variable, independent variable, or predictor variable are other terms often used.

Notation for Factored Models

ARIMA models are sometimes expressed in a factored form. This means that the ϕ , θ , ω , or δ polynomials are expressed as products of simpler polynomials. For example, you could express the pure ARIMA model as

$$W_t = \mu + \frac{\theta_1(B)\theta_2(B)}{\phi_1(B)\phi_2(B)}a_t$$

where $\phi_1(B)\phi_2(B) = \phi(B)$ and $\theta_1(B)\theta_2(B) = \theta(B)$.

When an ARIMA model is expressed in factored form, the order of the model is usually expressed by using a factored notation also. The order of an ARIMA model expressed as the product of two factors is denoted as $\text{ARIMA}(p,d,q) \times (P,D,Q)$.

Notation for Seasonal Models

ARIMA models for time series with regular seasonal fluctuations often use differencing operators and autoregressive and moving-average parameters at lags that are multiples of the length of the seasonal cycle. When all the terms in an ARIMA model factor refer to lags that are a multiple of a constant s , the constant is factored out and suffixed to the $\text{ARIMA}(p,d,q)$ notation.

Thus, the general notation for the order of a seasonal ARIMA model with both seasonal and non-seasonal factors is $\text{ARIMA}(p,d,q) \times (P,D,Q)_s$. The term (p,d,q) gives the order of the nonseasonal part of the ARIMA model; the term $(P,D,Q)_s$ gives the order of the seasonal part. The value of s is

the number of observations in a seasonal cycle: 12 for monthly series, 4 for quarterly series, 7 for daily series with day-of-week effects, and so forth.

For example, the notation $\text{ARIMA}(0,1,2)\times(0,1,1)_{12}$ describes a seasonal ARIMA model for monthly data with the following mathematical form:

$$(1 - B)(1 - B^{12})Y_t = \mu + (1 - \theta_{1,1}B - \theta_{1,2}B^2)(1 - \theta_{2,1}B^{12})a_t$$

Stationarity

The noise (or residual) series for an ARMA model must be *stationary*, which means that both the expected values of the series and its autocovariance function are independent of time.

The standard way to check for nonstationarity is to plot the series and its autocorrelation function. You can visually examine a graph of the series over time to see if it has a visible trend or if its variability changes noticeably over time. If the series is nonstationary, its autocorrelation function will usually decay slowly.

Another way of checking for stationarity is to use the stationarity tests described in the section “[Stationarity Tests](#)” on page 246.

Most time series are nonstationary and must be transformed to a stationary series before the ARIMA modeling process can proceed. If the series has a nonstationary variance, taking the log of the series can help. You can compute the log values in a DATA step and then analyze the log values with PROC ARIMA.

If the series has a trend over time, seasonality, or some other nonstationary pattern, the usual solution is to take the difference of the series from one period to the next and then analyze this differenced series. Sometimes a series might need to be differenced more than once or differenced at lags greater than one period. (If the trend or seasonal effects are very regular, the introduction of explanatory variables can be an appropriate alternative to differencing.)

Differencing

Differencing of the response series is specified with the VAR= option of the IDENTIFY statement by placing a list of differencing periods in parentheses after the variable name. For example, to take a simple first difference of the series SALES, use the statement

```
identify var=sales(1);
```

In this example, the change in SALES from one period to the next is analyzed.

A deterministic seasonal pattern also causes the series to be nonstationary, since the expected value of the series is not the same for all time periods but is higher or lower depending on the season. When the series has a seasonal pattern, you might want to difference the series at a lag that corresponds to the length of the seasonal cycle. For example, if SALES is a monthly series, the statement

```
identify var=sales(12);
```

takes a seasonal difference of SALES, so that the series analyzed is the change in SALES from its value in the same month one year ago.

To take a second difference, add another differencing period to the list. For example, the following statement takes the second difference of SALES:

```
identify var=sales(1,1);
```

That is, SALES is differenced once at lag 1 and then differenced again, also at lag 1. The statement

```
identify var=sales(2);
```

creates a 2-span difference—that is, current period SALES minus SALES from two periods ago. The statement

```
identify var=sales(1,12);
```

takes a second-order difference of SALES, so that the series analyzed is the difference between the current period-to-period change in SALES and the change 12 periods ago. You might want to do this if the series had both a trend over time and a seasonal pattern.

There is no limit to the order of differencing and the degree of lagging for each difference.

Differencing not only affects the series used for the IDENTIFY statement output but also applies to any following ESTIMATE and FORECAST statements. ESTIMATE statements fit ARMA models to the differenced series. FORECAST statements forecast the differences and automatically sum these differences back to undo the differencing operation specified by the IDENTIFY statement, thus producing the final forecast result.

Differencing of input series is specified by the CROSSCORR= option and works just like differencing of the response series. For example, the statement

```
identify var=y(1) crosscorr=(x1(1) x2(1));
```

takes the first difference of Y, the first difference of X1, and the first difference of X2. Whenever X1 and X2 are used in INPUT= options in following ESTIMATE statements, these names refer to the differenced series.

Subset, Seasonal, and Factored ARMA Models

The simplest way to specify an ARMA model is to give the order of the AR and MA parts with the P= and Q= options. When you do this, the model has parameters for the AR and MA parts for all lags through the order specified. However, you can control the form of the ARIMA model exactly as shown in the following section.

Subset Models

You can control which lags have parameters by specifying the P= or Q= option as a list of lags in parentheses. A model that includes parameters for only some lags is sometimes called a *subset* or *additive model*. For example, consider the following two ESTIMATE statements:

```
identify var=sales;
estimate p=4;
estimate p=(1 4);
```

Both specify AR(4) models, but the first has parameters for lags 1, 2, 3, and 4, while the second has parameters for lags 1 and 4, with the coefficients for lags 2 and 3 constrained to 0. The mathematical form of the autoregressive models produced by these two specifications is shown in [Table 7.1](#).

Table 7.1 Saturated versus Subset Models

Option	Autoregressive Operator
P=4	$(1 - \phi_1 B - \phi_2 B^2 - \phi_3 B^3 - \phi_4 B^4)$
P=(1 4)	$(1 - \phi_1 B - \phi_4 B^4)$

Seasonal Models

One particularly useful kind of subset model is a *seasonal model*. When the response series has a seasonal pattern, the values of the series at the same time of year in previous years can be important for modeling the series. For example, if the series SALES is observed monthly, the statements

```
identify var=sales;
estimate p=(12);
```

model SALES as an average value plus some fraction of its deviation from this average value a year ago, plus a random error. Although this is an AR(12) model, it has only one autoregressive parameter.

Factored Models

A factored model (also referred to as a multiplicative model) represents the ARIMA model as a product of simpler ARIMA models. For example, you might model SALES as a combination of an AR(1) process that reflects short term dependencies and an AR(12) model that reflects the seasonal pattern.

It might seem that the way to do this is with the option P=(1 12), but the AR(1) process also operates in past years; you really need autoregressive parameters at lags 1, 12, and 13. You can specify a subset model with separate parameters at these lags, or you can specify a factored model that represents the model as the product of an AR(1) model and an AR(12) model. Consider the following two ESTIMATE statements:

```

identify var=sales;
estimate p=(1 12 13);
estimate p=(1) (12);

```

The mathematical form of the autoregressive models produced by these two specifications are shown in Table 7.2.

Table 7.2 Subset versus Factored Models

Option	Autoregressive Operator
P=(1 12 13)	$(1 - \phi_1 B - \phi_{12} B^{12} - \phi_{13} B^{13})$
P=(1)(12)	$(1 - \phi_1 B)(1 - \phi_{12} B^{12})$

Both models fit by these two ESTIMATE statements predict SALES from its values 1, 12, and 13 periods ago, but they use different parameterizations. The first model has three parameters, whose meanings may be hard to interpret.

The factored specification P=(1)(12) represents the model as the product of two different AR models. It has only two parameters: one that corresponds to recent effects and one that represents seasonal effects. Thus the factored model is more parsimonious, and its parameter estimates are more clearly interpretable.

Input Variables and Regression with ARMA Errors

In addition to past values of the response series and past errors, you can also model the response series using the current and past values of other series, called *input series*.

Several different names are used to describe ARIMA models with input series. *Transfer function model*, *intervention model*, *interrupted time series model*, *regression model with ARMA errors*, *Box-Tiao model*, and *ARIMAX model* are all different names for ARIMA models with input series. Pankratz (1991) refers to these models as *dynamic regression* models.

Using Input Series

To use input series, list the input series in a CROSSCORR= option on the IDENTIFY statement and specify how they enter the model with an INPUT= option on the ESTIMATE statement. For example, you might use a series called PRICE to help model SALES, as shown in the following statements:

```

proc arima data=a;
  identify var=sales crosscorr=price;
  estimate input=price;
run;

```

This example performs a simple linear regression of SALES on PRICE; it produces the same results as PROC REG or another SAS regression procedure. The mathematical form of the model estimated

by these statements is

$$Y_t = \mu + \omega_0 X_t + a_t$$

The parameter estimates table for this example (using simulated data) is shown in [Figure 7.20](#). The intercept parameter is labeled MU. The regression coefficient for PRICE is labeled NUM1. (See the section “[Naming of Model Parameters](#)” on page 256 for information about how parameters for input series are named.)

Figure 7.20 Parameter Estimates Table for Regression Model

The ARIMA Procedure								
Conditional Least Squares Estimation								
Parameter	Estimate	Standard Error	t Value	Approx Pr > t	Lag	Variable	Shift	
MU	199.83602	2.99463	66.73	<.0001	0	sales	0	
NUM1	-9.99299	0.02885	-346.38	<.0001	0	price	0	

Any number of input variables can be used in a model. For example, the following statements fit a multiple regression of SALES on PRICE and INCOME:

```
proc arima data=a;
  identify var=sales crosscorr=(price income);
  estimate input=(price income);
run;
```

The mathematical form of the regression model estimated by these statements is

$$Y_t = \mu + \omega_1 X_{1,t} + \omega_2 X_{2,t} + a_t$$

Lagging and Differencing Input Series

You can also difference and lag the input series. For example, the following statements regress the change in SALES on the change in PRICE lagged by one period. The difference of PRICE is specified with the CROSSCORR= option and the lag of the change in PRICE is specified by the 1 \$ in the INPUT= option.

```
proc arima data=a;
  identify var=sales(1) crosscorr=price(1);
  estimate input=( 1 $ price );
run;
```

These statements estimate the model

$$(1 - B)Y_t = \mu + \omega_0(1 - B)X_{t-1} + a_t$$

Regression with ARMA Errors

You can combine input series with ARMA models for the errors. For example, the following statements regress SALES on INCOME and PRICE but with the error term of the regression model (called the *noise series* in ARIMA modeling terminology) assumed to be an ARMA(1,1) process.

```
proc arima data=a;
  identify var=sales crosscorr=(price income);
  estimate p=1 q=1 input=(price income);
run;
```

These statements estimate the model

$$Y_t = \mu + \omega_1 X_{1,t} + \omega_2 X_{2,t} + \frac{(1 - \theta_1 B)}{(1 - \phi_1 B)} a_t$$

Stationarity and Input Series

Note that the requirement of stationarity applies to the noise series. If there are no input variables, the response series (after differencing and minus the mean term) and the noise series are the same. However, if there are inputs, the noise series is the residual after the effect of the inputs is removed.

There is no requirement that the input series be stationary. If the inputs are nonstationary, the response series will be nonstationary, even though the noise process might be stationary.

When nonstationary input series are used, you can fit the input variables first with no ARMA model for the errors and then consider the stationarity of the residuals before identifying an ARMA model for the noise part.

Identifying Regression Models with ARMA Errors

Previous sections described the ARIMA modeling identification process that uses the autocorrelation function plots produced by the IDENTIFY statement. This identification process does not apply when the response series depends on input variables. This is because it is the noise process for which you need to identify an ARIMA model, and when input series are involved the response series adjusted for the mean is no longer an estimate of the noise series.

However, if the input series are independent of the noise series, you can use the residuals from the regression model as an estimate of the noise series, then apply the ARIMA modeling identification process to this residual series. This assumes that the noise process is stationary.

The PLOT option in the ESTIMATE statement produces similar plots for the model residuals as the IDENTIFY statement produces for the response series. The PLOT option prints an autocorrelation function plot, an inverse autocorrelation function plot, and a partial autocorrelation function plot for the residual series. Note that if ODS Graphics is enabled, then the PLOT option is not needed and these residual correlation plots are produced by default.

The following statements show how the PLOT option is used to identify the ARMA(1,1) model for the noise process used in the preceding example of regression with ARMA errors:

```

proc arima data=a;
  identify var=sales crosscorr=(price income) noprint;
  estimate input=(price income) plot;
  run;
  estimate p=1 q=1 input=(price income);
run;

```

In this example, the IDENTIFY statement includes the NOPRINT option since the autocorrelation plots for the response series are not useful when you know that the response series depends on input series.

The first ESTIMATE statement fits the regression model with no model for the noise process. The PLOT option produces plots of the autocorrelation function, inverse autocorrelation function, and partial autocorrelation function for the residual series of the regression on PRICE and INCOME.

By examining the PLOT option output for the residual series, you verify that the residual series is stationary and identify an ARMA(1,1) model for the noise process. The second ESTIMATE statement fits the final model.

Although this discussion addresses regression models, the same remarks apply to identifying an ARIMA model for the noise process in models that include input series with complex transfer functions.

Intervention Models and Interrupted Time Series

One special kind of ARIMA model with input series is called an *intervention model* or *interrupted time series* model. In an intervention model, the input series is an indicator variable that contains discrete values that flag the occurrence of an event affecting the response series. This event is an intervention in or an interruption of the normal evolution of the response time series, which, in the absence of the intervention, is usually assumed to be a pure ARIMA process.

Intervention models can be used both to model and forecast the response series and also to analyze the impact of the intervention. When the focus is on estimating the effect of the intervention, the process is often called *intervention analysis* or *interrupted time series analysis*.

Impulse Interventions

The intervention can be a one-time event. For example, you might want to study the effect of a short-term advertising campaign on the sales of a product. In this case, the input variable has the value of 1 for the period during which the advertising campaign took place and the value 0 for all other periods. Intervention variables of this kind are sometimes called *impulse functions* or *pulse functions*.

Suppose that SALES is a monthly series, and a special advertising effort was made during the month of March 1992. The following statements estimate the effect of this intervention by assuming an ARMA(1,1) model for SALES. The model is specified just like the regression model, but the

intervention variable AD is constructed in the DATA step as a zero-one indicator for the month of the advertising effort.

```
data a;
  set a;
  ad = (date = '1mar1992'd);
run;

proc arima data=a;
  identify var=sales crosscorr=ad;
  estimate p=1 q=1 input=ad;
run;
```

Continuing Interventions

Other interventions can be continuing, in which case the input variable flags periods before and after the intervention. For example, you might want to study the effect of a change in tax rates on some economic measure. Another example is a study of the effect of a change in speed limits on the rate of traffic fatalities. In this case, the input variable has the value 1 after the new speed limit went into effect and the value 0 before. Intervention variables of this kind are called *step functions*.

Another example is the effect of news on product demand. Suppose it was reported in July 1996 that consumption of the product prevents heart disease (or causes cancer), and SALES is consistently higher (or lower) thereafter. The following statements model the effect of this news intervention:

```
data a;
  set a;
  news = (date >= '1jul1996'd);
run;

proc arima data=a;
  identify var=sales crosscorr=news;
  estimate p=1 q=1 input=news;
run;
```

Interaction Effects

You can include any number of intervention variables in the model. Intervention variables can have any pattern—impulse and continuing interventions are just two possible cases. You can mix discrete valued intervention variables and continuous regressor variables in the same model.

You can also form interaction effects by multiplying input variables and including the product variable as another input. Indeed, as long as the dependent measure is continuous and forms a regular time series, you can use PROC ARIMA to fit any general linear model in conjunction with an ARMA model for the error process by using input variables that correspond to the columns of the design matrix of the linear model.

Rational Transfer Functions and Distributed Lag Models

How an input series enters the model is called its *transfer function*. Thus, ARIMA models with input series are sometimes referred to as transfer function models.

In the preceding regression and intervention model examples, the transfer function is a single scale parameter. However, you can also specify complex transfer functions composed of numerator and denominator polynomials in the backshift operator. These transfer functions operate on the input series in the same way that the ARMA specification operates on the error term.

Numerator Factors

For example, suppose you want to model the effect of PRICE on SALES as taking place gradually with the impact distributed over several past lags of PRICE. This is illustrated by the following statements:

```
proc arima data=a;
  identify var=sales crosscorr=price;
  estimate input=( 1 2 3) price ;
run;
```

These statements estimate the model

$$Y_t = \mu + (\omega_0 - \omega_1 B - \omega_2 B^2 - \omega_3 B^3) X_t + a_t$$

This example models the effect of PRICE on SALES as a linear function of the current and three most recent values of PRICE. It is equivalent to a multiple linear regression of SALES on PRICE, LAG(PRICE), LAG2(PRICE), and LAG3(PRICE).

This is an example of a transfer function with one *numerator factor*. The numerator factors for a transfer function for an input series are like the MA part of the ARMA model for the noise series.

Denominator Factors

You can also use transfer functions with *denominator factors*. The denominator factors for a transfer function for an input series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

To specify transfer functions with denominator factors, place the denominator factors after a slash (/) in the INPUT= option. For example, the following statements estimate the PRICE effect as an infinite distributed lag model with exponentially declining weights:

```
proc arima data=a;
  identify var=sales crosscorr=price;
  estimate input=( / (1) price );
run;
```

The transfer function specified by these statements is as follows:

$$\frac{\omega_0}{(1 - \delta_1 B)} X_t$$

This transfer function also can be written in the following equivalent form:

$$\omega_0 \left(1 + \sum_{i=1}^{\infty} \delta_1^i B^i \right) X_t$$

This transfer function can be used with intervention inputs. When it is used with a pulse function input, the result is an intervention effect that dies out gradually over time. When it is used with a step function input, the result is an intervention effect that increases gradually to a limiting value.

Rational Transfer Functions

By combining various numerator and denominator factors in the INPUT= option, you can specify *rational transfer functions* of any complexity. To specify an input with a general rational transfer function of the form

$$\frac{\omega(B)}{\delta(B)} B^k X_t$$

use an INPUT= option in the ESTIMATE statement of the form

input=(k \$ (ω -lags) / (δ -lags) x)

See the section “[Specifying Inputs and Transfer Functions](#)” on page 253 for more information.

Identifying Transfer Function Models

The CROSSCORR= option of the IDENTIFY statement prints sample cross-correlation functions that show the correlation between the response series and the input series at different lags. The sample cross-correlation function can be used to help identify the form of the transfer function appropriate for an input series. See textbooks on time series analysis for information about using cross-correlation functions to identify transfer function models.

For the cross-correlation function to be meaningful, the input and response series must be filtered with a prewhitening model for the input series. See the section “[Prewhitening](#)” on page 246 for more information about this issue.

Forecasting with Input Variables

To forecast a response series by using an ARIMA model with inputs, you need values of the input series for the forecast periods. You can supply values for the input variables for the forecast periods in the DATA= data set, or you can have PROC ARIMA forecast the input variables.

If you do not have future values of the input variables in the input data set used by the FORECAST statement, the input series must be forecast before the ARIMA procedure can forecast the response series. If you fit an ARIMA model to each of the input series for which you need forecasts before fitting the model for the response series, the FORECAST statement automatically uses the ARIMA models for the input series to generate the needed forecasts of the inputs.

For example, suppose you want to forecast SALES for the next 12 months. In this example, the change in SALES is predicted as a function of the change in PRICE, plus an ARMA(1,1) noise process. To forecast SALES by using PRICE as an input, you also need to fit an ARIMA model for PRICE.

The following statements fit an AR(2) model to the change in PRICE before fitting and forecasting the model for SALES. The FORECAST statement automatically forecasts PRICE using this AR(2) model to get the future inputs needed to produce the forecast of SALES.

```
proc arima data=a;
    identify var=price(1);
    estimate p=2;
    identify var=sales(1) crosscorr=price(1);
    estimate p=1 q=1 input=price;
    forecast lead=12 interval=month id=date out=results;
run;
```

Fitting a model to the input series is also important for identifying transfer functions. (See the section “[Prewhitening](#)” on page 246 for more information.)

Input values from the DATA= data set and input values forecast by PROC ARIMA can be combined. For example, a model for SALES might have three input series: PRICE, INCOME, and TAXRATE. For the forecast, you assume that the tax rate will be unchanged. You have a forecast for INCOME from another source but only for the first few periods of the SALES forecast you want to make. You have no future values for PRICE, which needs to be forecast as in the preceding example.

In this situation, you include observations in the input data set for all forecast periods, with SALES and PRICE set to a missing value, with TAXRATE set to its last actual value, and with INCOME set to forecast values for the periods you have forecasts for and set to missing values for later periods. In the PROC ARIMA step, you estimate ARIMA models for PRICE and INCOME before you estimate the model for SALES, as shown in the following statements:

```
proc arima data=a;
    identify var=price(1);
    estimate p=2;
    identify var=income(1);
    estimate p=2;
    identify var=sales(1) crosscorr=( price(1) income(1) taxrate );
    estimate p=1 q=1 input=( price income taxrate );
    forecast lead=12 interval=month id=date out=results;
run;
```

In forecasting SALES, the ARIMA procedure uses as inputs the value of PRICE forecast by its ARIMA model, the value of TAXRATE found in the DATA= data set, and the value of INCOME found

in the DATA= data set, or, when the INCOME variable is missing, the value of INCOME forecast by its ARIMA model. (Because SALES is missing for future time periods, the estimation of model parameters is not affected by the forecast values for PRICE, INCOME, or TAXRATE.)

Data Requirements

PROC ARIMA can handle time series of moderate size; there should be at least 30 observations. With fewer than 30 observations, the parameter estimates might be poor. With thousands of observations, the method requires considerable computer time and memory.

Syntax: ARIMA Procedure

The ARIMA procedure uses the following statements:

```

PROC ARIMA options ;
  BY variables ;
  IDENTIFY VAR=variable options ;
  ESTIMATE options ;
  OUTLIER options ;
  FORECAST options ;

```

The **PROC ARIMA** and **IDENTIFY** statements are required.

Functional Summary

The statements and options that control the ARIMA procedure are summarized in [Table 7.3](#).

Table 7.3 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	PROC ARIMA IDENTIFY	DATA= DATA=
specify the output data set	PROC ARIMA FORECAST	OUT= OUT=
include only forecasts in the output data set	FORECAST	NOOUTALL
write autocovariances to output data set	IDENTIFY	OUTCOV=
write parameter estimates to an output data set	ESTIMATE	OUTEST=
write correlation of parameter estimates	ESTIMATE	OUTCORR
write covariance of parameter estimates	ESTIMATE	OUTCOV

Table 7.3 continued

Description	Statement	Option
write estimated model to an output data set	ESTIMATE	OUTMODEL=
write statistics of fit to an output data set	ESTIMATE	OUTSTAT=
Options for Identifying the Series		
difference time series and plot autocorrelations	IDENTIFY	
specify response series and differencing	IDENTIFY	VAR=
specify and cross-correlate input series	IDENTIFY	CROSSCORR=
center data by subtracting the mean	IDENTIFY	CENTER
exclude missing values	IDENTIFY	NOMISS
delete previous models and start	IDENTIFY	CLEAR
specify the significance level for tests	IDENTIFY	ALPHA=
perform tentative ARMA order identification by using the ESACF method	IDENTIFY	ESACF
perform tentative ARMA order identification by using the MINIC method	IDENTIFY	MINIC
perform tentative ARMA order identification by using the SCAN method	IDENTIFY	SCAN
specify the range of autoregressive model orders for estimating the error series for the MINIC method	IDENTIFY	PERROR=
determine the AR dimension of the SCAN, ESACF, and MINIC tables	IDENTIFY	P=
determine the MA dimension of the SCAN, ESACF, and MINIC tables	IDENTIFY	Q=
perform stationarity tests	IDENTIFY	STATIONARITY=
selection of white noise test statistic in the presence of missing values	IDENTIFY	WHITENOISE=
Options for Defining and Estimating the Model		
specify and estimate ARIMA models	ESTIMATE	
specify autoregressive part of model	ESTIMATE	P=
specify moving-average part of model	ESTIMATE	Q=
specify input variables and transfer functions	ESTIMATE	INPUT=
drop mean term from the model	ESTIMATE	NOINT
specify the estimation method	ESTIMATE	METHOD=
use alternative form for transfer functions	ESTIMATE	ALTPARM
suppress degrees-of-freedom correction in variance estimates	ESTIMATE	NODF
selection of white noise test statistic in the presence of missing values	ESTIMATE	WHITENOISE=

Table 7.3 continued

Description	Statement	Option
Options for Outlier Detection		
specify the significance level for tests	OUTLIER	ALPHA=
identify detected outliers with variable	OUTLIER	ID=
limit the number of outliers	OUTLIER	MAXNUM=
limit the number of outliers to a percentage of the series	OUTLIER	MAXPCT=
specify the variance estimator used for testing	OUTLIER	SIGMA=
specify the type of level shifts	OUTLIER	TYPE=
Printing Control Options		
limit number of lags shown in correlation plots	IDENTIFY	NLAG=
suppress printed output for identification	IDENTIFY	NOPRINT
plot autocorrelation functions of the residuals	ESTIMATE	PLOT
print log-likelihood around the estimates	ESTIMATE	GRID
control spacing for GRID option	ESTIMATE	GRIDVAL=
print details of the iterative estimation process	ESTIMATE	PRINTALL
suppress printed output for estimation	ESTIMATE	NOPRINT
suppress printing of the forecast values	FORECAST	NOPRINT
print the one-step forecasts and residuals	FORECAST	PRINTALL
Plotting Control Options		
request plots associated with model identification, residual analysis, and forecasting	PROC ARIMA	PLOTS=
Options to Specify Parameter Values		
specify autoregressive starting values	ESTIMATE	AR=
specify moving-average starting values	ESTIMATE	MA=
specify a starting value for the mean parameter	ESTIMATE	MU=
specify starting values for transfer functions	ESTIMATE	INITVAL=
Options to Control the Iterative Estimation Process		
specify convergence criterion	ESTIMATE	CONVERGE=
specify the maximum number of iterations	ESTIMATE	MAXITER=
specify criterion for checking for singularity	ESTIMATE	SINGULAR=
suppress the iterative estimation process	ESTIMATE	NOEST
omit initial observations from objective	ESTIMATE	BACKLIM=
specify perturbation for numerical derivatives	ESTIMATE	DELTA=
omit stationarity and invertibility checks	ESTIMATE	NOSTABLE

Table 7.3 continued

Description	Statement	Option
use preliminary estimates as starting values for ML and ULS	ESTIMATE	NOLS
Options for Forecasting		
forecast the response series	FORECAST	
specify how many periods to forecast	FORECAST	LEAD=
specify the ID variable	FORECAST	ID=
specify the periodicity of the series	FORECAST	INTERVAL=
specify size of forecast confidence limits	FORECAST	ALPHA=
start forecasting before end of the input data	FORECAST	BACK=
specify the variance term used to compute forecast standard errors and confidence limits	FORECAST	SIGSQ=
control the alignment of SAS date values	FORECAST	ALIGN=
BY Groups		
specify BY group processing	BY	

PROC ARIMA Statement

PROC ARIMA *options* ;

The following options can be used in the PROC ARIMA statement.

DATA=*SAS-data-set*

specifies the name of the SAS data set that contains the time series. If different DATA= specifications appear in the PROC ARIMA and IDENTIFY statements, the one in the IDENTIFY statement is used. If the DATA= option is not specified in either the PROC ARIMA or IDENTIFY statement, the most recently created SAS data set is used.

PLOTS<(global-plot-options)> <= plot-request <(options)>>

PLOTS<(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Here are some examples:

```
plots=none
plots=all
plots(unpack)=series(corr crosscorr)
plots(only)=(series(corr crosscorr) residual(normal smooth))
```

You must enable ODS Graphics before requesting plots as shown in the following statements. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*). If you have enabled ODS Graphics but do not specify any specific plot request, then the default plots associated with each of the PROC ARIMA statements used in the program are produced. The old line printer plots are suppressed when ODS Graphics is enabled.

```
ods graphics on;

proc arima;
  identify var=y(1 12);
  estimate q=(1)(12) noint;
run;
```

Since no specific plot is requested in this program, the default plots associated with the identification and estimation stages are produced.

Global Plot Options:

The *global-plot-options* apply to all relevant plots generated by the ARIMA procedure. The following *global-plot-options* are supported:

ONLY

suppresses the default plots. Only the plots specifically requested are produced.

UNPACK

breaks a graphic that is otherwise paneled into individual component plots.

Specific Plot Options:

The following list describes the specific plots and their options.

ALL

produces all plots appropriate for the particular analysis.

NONE

suppresses all plots.

SERIES(< series-plot-options >)

produces plots associated with the identification stage of the modeling. The panel plots corresponding to the CORR and CROSSCORR options are produced by default. The following *series-plot-options* are available:

ACF

produces the plot of autocorrelations.

ALL

produces all the plots associated with the identification stage.

CORR

produces a panel of plots that are useful in the trend and correlation analysis of the series. The panel consists of the following:

- the time series plot
- the series-autocorrelation plot
- the series-partial-autocorrelation plot
- the series-inverse-autocorrelation plot

CROSSCORR

produces panels of cross-correlation plots.

IACF

produces the plot of inverse-autocorrelations.

PACF

produces the plot of partial-autocorrelations.

RESIDUAL(*< residual-plot-options >*)

produces the residuals plots. The residual correlation and normality diagnostic panels are produced by default. The following *residual-plot-options* are available:

ACF

produces the plot of residual autocorrelations.

ALL

produces all the residual diagnostics plots appropriate for the particular analysis.

CORR

produces a summary panel of the residual correlation diagnostics that consists of the following:

- the residual-autocorrelation plot
- the residual-partial-autocorrelation plot
- the residual-inverse-autocorrelation plot
- a plot of Ljung-Box white-noise test p -values at different lags

HIST

produces the histogram of the residuals.

IACF

produces the plot of residual inverse-autocorrelations.

NORMAL

produces a summary panel of the residual normality diagnostics that consists of the following:

- histogram of the residuals
- normal quantile plot of the residuals

PACF

produces the plot of residual partial-autocorrelations.

QQ

produces the normal quantile plot of the residuals.

SMOOTH

produces a scatter plot of the residuals against time, which has an overlaid smooth fit.

WN

produces the plot of Ljung-Box white-noise test p -values at different lags.

FORECAST(< forecast-plot-options >)

produces the forecast plots in the forecasting stage. The forecast-only plot that shows the multistep forecasts in the forecast region is produced by default.

The following *forecast-plot-options* are available:

ALL

produces the forecast-only plot as well as the forecast plot.

FORECAST

produces a plot that shows the one-step-ahead forecasts as well as the multistep-ahead forecasts.

FORECASTONLY

produces a plot that shows only the multistep-ahead forecasts in the forecast region.

OUT=SAS-data-set

specifies a SAS data set to which the forecasts are output. If different OUT= specifications appear in the PROC ARIMA and FORECAST statements, the one in the FORECAST statement is used.

BY Statement

BY variables ;

A BY statement can be used in the ARIMA procedure to process a data set in groups of observations defined by the BY variables. Note that all IDENTIFY, ESTIMATE, and FORECAST statements specified are applied to all BY groups.

Because of the need to make data-based model selections, BY-group processing is not usually done with PROC ARIMA. You usually want to use different models for the different series contained in different BY groups, and the PROC ARIMA BY statement does not let you do this.

Using a BY statement imposes certain restrictions. The BY statement must appear before the first RUN statement. If a BY statement is used, the input data must come from the data set specified in the PROC statement; that is, no input data sets can be specified in IDENTIFY statements.

When a BY statement is used with PROC ARIMA, interactive processing applies only to the first BY group. Once the end of the PROC ARIMA step is reached, all ARIMA statements specified are executed again for each of the remaining BY groups in the input data set.

IDENTIFY Statement

IDENTIFY *VAR=variable options ;*

The IDENTIFY statement specifies the time series to be modeled, differences the series if desired, and computes statistics to help identify models to fit. Use an IDENTIFY statement for each time series that you want to model.

If other time series are to be used as inputs in a subsequent ESTIMATE statement, they must be listed in a CROSSCORR= list in the IDENTIFY statement.

The following options are used in the IDENTIFY statement. The VAR= option is required.

ALPHA=*significance-level*

The ALPHA= option specifies the significance level for tests in the IDENTIFY statement. The default is 0.05.

CENTER

centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

CLEAR

deletes all old models. This option is useful when you want to delete old models so that the input variables are not prewhitened. (See the section “[Prewhitening](#)” on page 246 for more information.)

CROSSCORR=*variable (d11, d12, ..., d1k)*

CROSSCORR= (*variable (d11, d12, ..., d1k)... variable (d21, d22, ..., d2k)*)

names the variables cross-correlated with the response variable given by the VAR= specification.

Each variable name can be followed by a list of differencing lags in parentheses, the same as for the VAR= specification. If differencing is specified for a variable in the CROSSCORR= list, the differenced series is cross-correlated with the VAR= option series, and the differenced series is used when the ESTIMATE statement INPUT= option refers to the variable.

DATA=SAS-data-set

specifies the input SAS data set that contains the time series. If the DATA= option is omitted, the DATA= data set specified in the PROC ARIMA statement is used; if the DATA= option is omitted from the PROC ARIMA statement as well, the most recently created data set is used.

ESACF

computes the extended sample autocorrelation function and uses these estimates to tentatively identify the autoregressive and moving-average orders of mixed models.

The ESACF option generates two tables. The first table displays extended sample autocorrelation estimates, and the second table displays probability values that can be used to test the significance of these estimates. The $P=(p_{min} : p_{max})$ and $Q=(q_{min} : q_{max})$ options determine the size of the table.

The autoregressive and moving-average orders are tentatively identified by finding a triangular pattern in which all values are insignificant. The ARIMA procedure finds these patterns based on the IDENTIFY statement ALPHA= option and displays possible recommendations for the orders.

The following code generates an ESACF table with dimensions of $p=(0:7)$ and $q=(0:8)$.

```
proc arima data=test;
  identify var=x esacf p=(0:7) q=(0:8);
run;
```

See the section “[The ESACF Method](#)” on page 241 for more information.

MINIC

uses information criteria or penalty functions to provide tentative ARMA order identification. The MINIC option generates a table that contains the computed information criterion associated with various ARMA model orders. The $PERROR=(p_{\epsilon,min} : p_{\epsilon,max})$ option determines the range of the autoregressive model orders used to estimate the error series. The $P=(p_{min} : p_{max})$ and $Q=(q_{min} : q_{max})$ options determine the size of the table. The ARMA orders are tentatively identified by those orders that minimize the information criterion.

The following statements generate a MINIC table with default dimensions of $p=(0:5)$ and $q=(0:5)$ and with the error series estimated by an autoregressive model with an order, p_{ϵ} , that minimizes the AIC in the range from 8 to 11.

```
proc arima data=test;
  identify var=x minic perror=(8:11);
run;
```

See the section “[The MINIC Method](#)” on page 243 for more information.

NLAG=number

indicates the number of lags to consider in computing the autocorrelations and cross-correlations. To obtain preliminary estimates of an $ARIMA(p, d, q)$ model, the NLAG= value must be at least $p + q + d$. The number of observations must be greater than or equal to the NLAG= value. The default value for NLAG= is 24 or one-fourth the number of observations, whichever is less. Even though the NLAG= value is specified, the NLAG= value can be changed according to the data set.

NOMISS

uses only the first continuous sequence of data with no missing values. By default, all observations are used.

NOPRINT

suppresses the normal printout (including the correlation plots) generated by the IDENTIFY statement.

OUTCOV=SAS-data-set

writes the autocovariances, autocorrelations, inverse autocorrelations, partial autocorrelations, and cross covariances to an output SAS data set. If the OUTCOV= option is not specified, no covariance output data set is created. See the section “[OUTCOV= Data Set](#)” on page 263 for more information.

P=($p_{min} : p_{max}$)

see the ESACF, MINIC, and SCAN options for details.

PERROR=($p_{\epsilon,min} : p_{\epsilon,max}$)

determines the range of the autoregressive model orders used to estimate the error series in MINIC, a tentative ARMA order identification method. See the section “[The MINIC Method](#)” on page 243 for more information. By default $p_{\epsilon,min}$ is set to p_{max} and $p_{\epsilon,max}$ is set to $p_{max} + q_{max}$, where p_{max} and q_{max} are the maximum settings of the P= and Q= options on the IDENTIFY statement.

Q=($q_{min} : q_{max}$)

see the ESACF, MINIC, and SCAN options for details.

SCAN

computes estimates of the squared canonical correlations and uses these estimates to tentatively identify the autoregressive and moving-average orders of mixed models.

The SCAN option generates two tables. The first table displays squared canonical correlation estimates, and the second table displays probability values that can be used to test the significance of these estimates. The P=($p_{min} : p_{max}$) and Q=($q_{min} : q_{max}$) options determine the size of each table.

The autoregressive and moving-average orders are tentatively identified by finding a rectangular pattern in which all values are insignificant. The ARIMA procedure finds these patterns based on the IDENTIFY statement ALPHA= option and displays possible recommendations for the orders.

The following code generates a SCAN table with default dimensions of p=(0:5) and q=(0:5). The recommended orders are based on a significance level of 0.1.

```
proc arima data=test;
  identify var=x scan alpha=0.1;
run;
```

See the section “[The SCAN Method](#)” on page 244 for more information.

STATIONARITY=

performs stationarity tests. Stationarity tests can be used to determine whether differencing terms should be included in the model specification. In each stationarity test, the autoregressive orders can be specified by a range, $test = ar_{max}$, or as a list of values, $test = (ar_1, \dots, ar_n)$, where $test$ is ADF, PP, or RW. The default is (0,1,2).

See the section “[Stationarity Tests](#)” on page 246 for more information.

STATIONARITY=(ADF= AR orders DLAG= s)**STATIONARITY=(DICKEY= AR orders DLAG= s)**

performs augmented Dickey-Fuller tests. If the DLAG= s option is specified with s is greater than one, seasonal Dickey-Fuller tests are performed. The maximum allowable value of s is 12. The default value of s is 1. The following code performs augmented Dickey-Fuller tests with autoregressive orders 2 and 5.

```
proc arima data=test;
  identify var=x stationarity=(adf=(2,5));
run;
```

STATIONARITY=(PP= AR orders)**STATIONARITY=(PHILLIPS= AR orders)**

performs Phillips-Perron tests. The following statements perform augmented Phillips-Perron tests with autoregressive orders ranging from 0 to 6.

```
proc arima data=test;
  identify var=x stationarity=(pp=6);
run;
```

STATIONARITY=(RW=AR orders)**STATIONARITY=(RANDOMWALK=AR orders)**

performs random-walk-with-drift tests. The following statements perform random-walk-with-drift tests with autoregressive orders ranging from 0 to 2.

```
proc arima data=test;
  identify var=x stationarity=(rw);
run;
```

VAR=variable**VAR= variable (d1, d2, ..., dk)**

names the variable that contains the time series to analyze. The VAR= option is required.

A list of differencing lags can be placed in parentheses after the variable name to request that the series be differenced at these lags. For example, VAR=X(1) takes the first differences of X. VAR=X(1,1) requests that X be differenced twice, both times with lag 1, producing a second difference series, which is

$$(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}.$$

VAR=X(2) differences X once at lag two ($X_t - X_{t-2}$).

If differencing is specified, it is the differenced series that is processed by any subsequent ESTIMATE statement.

WHITENOISE=ST | IGNOREMISS

specifies the type of test statistic that is used in the white noise test of the series when the series contains missing values. If WHITENOISE=IGNOREMISS, the standard Ljung-Box test statistic is used. If WHITENOISE=ST, a modification of this statistic suggested by Stoffer and Toloi (1992) is used. The default is WHITENOISE=ST.

ESTIMATE Statement

<label:>ESTIMATE options ;

The ESTIMATE statement specifies an ARMA model or transfer function model for the response variable specified in the previous IDENTIFY statement, and produces estimates of its parameters. The ESTIMATE statement also prints diagnostic information by which to check the model. The label in the ESTIMATE statement is optional. Include an ESTIMATE statement for each model that you want to estimate.

Options used in the ESTIMATE statement are described in the following sections.

Options for Defining the Model and Controlling Diagnostic Statistics

The following options are used to define the model to be estimated and to control the output that is printed.

ALTPARM

specifies the alternative parameterization of the overall scale of transfer functions in the model. See the section “[Alternative Model Parameterization](#)” on page 253 for details.

INPUT=variable

INPUT=(transfer-function variable ...)

specifies input variables and their transfer functions.

The variables used on the INPUT= option must be included in the CROSSCORR= list in the previous IDENTIFY statement. If any differencing is specified in the CROSSCORR= list, then the differenced series is used as the input to the transfer function.

The transfer function specification for an input variable is optional. If no transfer function is specified, the input variable enters the model as a simple regressor. If specified, the transfer function specification has the following syntax:

$$S$(L_{1,1}, L_{1,2}, \dots)(L_{2,1}, \dots) \dots / (L_{j,1}, \dots) \dots$$

Here, S is a shift or lag of the input variable, the terms before the slash ($/$) are numerator factors, and the terms after the slash ($/$) are denominator factors of the transfer function. All three parts are optional. See the section “[Specifying Inputs and Transfer Functions](#)” on page 253 for details.

METHOD=value

specifies the estimation method to use. METHOD=ML specifies the maximum likelihood

method. METHOD=ULS specifies the unconditional least squares method. METHOD=CLS specifies the conditional least squares method. METHOD=CLS is the default. See the section “[Estimation Details](#)” on page 248 for more information.

NOCONSTANT**NOINT**

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

NODF

estimates the variance by dividing the error sum of squares (SSE) by the number of residuals. The default is to divide the SSE by the number of residuals minus the number of free parameters in the model.

NOPRINT

suppresses the normal printout generated by the ESTIMATE statement. If the NOPRINT option is specified for the ESTIMATE statement, then any error and warning messages are printed to the SAS log.

P=order

P=(lag, ..., lag) ... (lag, ..., lag)

specifies the autoregressive part of the model. By default, no autoregressive parameters are fit.

$P=(l_1, l_2, \dots, l_k)$ defines a model with autoregressive parameters at the specified lags. $P=order$ is equivalent to $P=(1, 2, \dots, order)$.

A concatenation of parenthesized lists specifies a factored model. For example, $P=(1,2,5)(6,12)$ specifies the autoregressive model

$$(1 - \phi_{1,1}B - \phi_{1,2}B^2 - \phi_{1,3}B^5)(1 - \phi_{2,1}B^6 - \phi_{2,2}B^{12})$$

PLOT

plots the residual autocorrelation functions. The sample autocorrelation, the sample inverse autocorrelation, and the sample partial autocorrelation functions of the model residuals are plotted.

Q=order

Q=(lag, ..., lag) ... (lag, ..., lag)

specifies the moving-average part of the model. By default, no moving-average part is included in the model.

$Q=(l_1, l_2, \dots, l_k)$ defines a model with moving-average parameters at the specified lags. $Q=order$ is equivalent to $Q=(1, 2, \dots, order)$. A concatenation of parenthesized lists specifies a factored model. The interpretation of factors and lags is the same as for the P= option.

WHITENOISE=ST | IGNOREMISS

specifies the type of test statistic that is used in the white noise test of the series when the series contains missing values. If WHITENOISE=IGNOREMISS, the standard Ljung-Box test statistic is used. If WHITENOISE=ST, a modification of this statistic suggested by Stoffer and Tolo (1992) is used. The default is WHITENOISE=ST.

Options for Output Data Sets

The following options are used to store results in SAS data sets:

OUTEST=SAS-data-set

writes the parameter estimates to an output data set. If the OUTCORR or OUTCOV option is used, the correlations or covariances of the estimates are also written to the OUTEST= data set. See the section “[OUTEST= Data Set](#)” on page 264 for a description of the OUTEST= output data set.

OUTCORR

writes the correlations of the parameter estimates to the OUTEST= data set.

OUTCOV

writes the covariances of the parameter estimates to the OUTEST= data set.

OUTMODEL=SAS-data-set

writes the model and parameter estimates to an output data set. If OUTMODEL= is not specified, no model output data set is created. See the section “[OUTMODEL= SAS Data Set](#)” on page 267 for a description of the OUTMODEL= output data set.

OUTSTAT=SAS-data-set

writes the model diagnostic statistics to an output data set. If OUTSTAT= is not specified, no statistics output data set is created. See the section “[OUTSTAT= Data Set](#)” on page 268 for a description of the OUTSTAT= output data set.

Options to Specify Parameter Values

The following options enable you to specify values for the model parameters. These options can provide starting values for the estimation process, or you can specify fixed parameters for use in the FORECAST stage and suppress the estimation process with the NOEST option. By default, the ARIMA procedure finds initial parameter estimates and uses these estimates as starting values in the iterative estimation process.

If values for any parameters are specified, values for all parameters should be given. The number of values given must agree with the model specifications.

AR=value ...

lists starting values for the autoregressive parameters. See the section “[Initial Values](#)” on page 254 for more information.

INITVAL=(initializer-spec variable ...)

specifies starting values for the parameters in the transfer function parts of the model. See the section “[Initial Values](#)” on page 254 for more information.

MA=value ...

lists starting values for the moving-average parameters. See the section “[Initial Values](#)” on page 254 for more information.

MU=value

specifies the MU parameter.

NOEST

uses the values specified with the AR=, MA=, INITVAL=, and MU= options as final parameter values. The estimation process is suppressed except for estimation of the residual variance. The specified parameter values are used directly by the next FORECAST statement. When NOEST is specified, standard errors, *t* values, and the correlations between estimates are displayed as 0 or missing. (The NOEST option is useful, for example, when you want to generate forecasts that correspond to a published model.)

Options to Control the Iterative Estimation Process

The following options can be used to control the iterative process of minimizing the error sum of squares or maximizing the log-likelihood function. These tuning options are not usually needed but can be useful if convergence problems arise.

BACKLIM=-*n*

omits the specified number of initial residuals from the sum of squares or likelihood function. Omitting values can be useful for suppressing transients in transfer function models that are sensitive to start-up values.

CONVERGE=value

specifies the convergence criterion. Convergence is assumed when the largest change in the estimate for any parameter is less than the CONVERGE= option value. If the absolute value of the parameter estimate is greater than 0.01, the relative change is used; otherwise, the absolute change in the estimate is used. The default is CONVERGE=0.001.

DELTA=value

specifies the perturbation value for computing numerical derivatives. The default is DELTA=0.001.

GRID

prints the error sum of squares (SSE) or concentrated log-likelihood surface in a small grid of the parameter space around the final estimates. For each pair of parameters, the SSE is printed for the nine parameter-value combinations formed by the grid, with a center at the final estimates and with spacing given by the GRIDVAL= specification. The GRID option can help you judge whether the estimates are truly at the optimum, since the estimation process does not always converge. For models with a large number of parameters, the GRID option produces voluminous output.

GRIDVAL=number

controls the spacing in the grid printed by the GRID option. The default is GRIDVAL=0.005.

MAXITER=*n***MAXIT=*n***

specifies the maximum number of iterations allowed. The default is MAXITER=50.

NOLS

begins the maximum likelihood or unconditional least squares iterations from the preliminary estimates rather than from the conditional least squares estimates that are produced after four iterations. See the section “[Estimation Details](#)” on page 248 for more information.

NOSTABLE

specifies that the autoregressive and moving-average parameter estimates for the noise part of the model not be restricted to the stationary and invertible regions, respectively. See the section “[Stationarity and Invertibility](#)” on page 255 for more information.

PRINTALL

prints preliminary estimation results and the iterations in the final estimation process.

NOTFSTABLE

specifies that the parameter estimates for the denominator polynomial of the transfer function part of the model not be restricted to the stability region. See the section “[Stationarity and Invertibility](#)” on page 255 for more information.

SINGULAR=value

specifies the criterion for checking singularity. If a pivot of a sweep operation is less than the SINGULAR= value, the matrix is deemed singular. Sweep operations are performed on the Jacobian matrix during final estimation and on the covariance matrix when preliminary estimates are obtained. The default is SINGULAR=1E-7.

OUTLIER Statement

OUTLIER options ;

The OUTLIER statement can be used to detect shifts in the level of the response series that are not accounted for by the previously estimated model. An ESTIMATE statement must precede the OUTLIER statement. The following options are used in the OUTLIER statement:

TYPE=ADDITIVE**TYPE=SHIFT****TYPE=TEMP** (d_1, \dots, d_k)**TYPE=(< ADDITIVE > < SHIFT > < TEMP** (d_1, \dots, d_k)) >

specifies the types of level shifts to search for. The default is TYPE=(ADDITIVE SHIFT), which requests searching for additive outliers and permanent level shifts. The option TEMP(d_1, \dots, d_k) requests searching for temporary changes in the level of durations d_1, \dots, d_k . These options can also be abbreviated as AO, LS, and TC.

ALPHA=significance-level

specifies the significance level for tests in the OUTLIER statement. The default is 0.05.

SIGMA=ROBUST | MSE

specifies the type of error variance estimate to use in the statistical tests performed during the outlier detection. SIGMA=MSE corresponds to the usual mean squared error (MSE) estimate,

and SIGMA=ROBUST corresponds to a robust estimate of the error variance. The default is SIGMA=ROBUST.

MAXNUM=number

limits the number of outliers to search. The default is MAXNUM=5.

MAXPCT=number

limits the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=2. When both the MAXNUM= and MAXPCT= options are specified, the minimum of the two search numbers is used.

ID=Date-Time ID variable

specifies a SAS date, time, or datetime identification variable to label the detected outliers. This variable must be present in the input data set.

The following examples illustrate a few possibilities for the OUTLIER statement.

The most basic usage, shown as follows, sets all the options to their default values.

```
outlier;
```

That is, it is equivalent to

```
outlier type=(ao ls) alpha=0.05 sigma=robust maxnum=5 maxpct=2;
```

The following statement requests a search for permanent level shifts and for temporary level changes of durations 6 and 12. The search is limited to at most three changes and the significance level of the underlying tests is 0.001. MSE is used as the estimate of error variance. It also requests labeling of the detected shifts using an ID variable *date*.

```
outlier type=(ls tc(6 12)) alpha=0.001 sigma=mse maxnum=3 ID=date;
```

FORECAST Statement

FORECAST options ;

The FORECAST statement generates forecast values for a time series by using the parameter estimates produced by the previous ESTIMATE statement. See the section “[Forecasting Details](#)” on page 257 for more information about calculating forecasts.

The following options can be used in the FORECAST statement:

ALIGN=option

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING|BEGIB, MIDDLE|MIDIM, and END-INGIENDIE. BEGINNING is the default.

ALPHA=n

sets the size of the forecast confidence limits. The ALPHA= value must be between 0 and

1. When you specify $\text{ALPHA}=\alpha$, the upper and lower confidence limits have a $1 - \alpha$ confidence level. The default is $\text{ALPHA}=0.05$, which produces 95% confidence intervals. ALPHA values are rounded to the nearest hundredth.

BACK=*n*

specifies the number of observations before the end of the data where the multistep forecasts are to begin. The BACK= option value must be less than or equal to the number of observations minus the number of parameters.

The default is $\text{BACK}=0$, which means that the forecast starts at the end of the available data. The end of the data is the last observation for which a noise value can be calculated. If there are no input series, the end of the data is the last nonmissing value of the response time series. If there are input series, this observation can precede the last nonmissing value of the response variable, since there may be missing values for some of the input series.

ID=*variable*

names a variable in the input data set that identifies the time periods associated with the observations. The ID= variable is used in conjunction with the INTERVAL= option to extrapolate ID values from the end of the input data to identify forecast periods in the OUT= data set.

If the INTERVAL= option specifies an interval type, the ID variable must be a SAS date or datetime variable with the spacing between observations indicated by the INTERVAL= value. If the INTERVAL= option is not used, the last input value of the ID= variable is incremented by one for each forecast period to extrapolate the ID values for forecast observations.

INTERVAL=*interval***INTERVAL=*n***

specifies the time interval between observations. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for information about valid INTERVAL= values.

The value of the INTERVAL= option is used by PROC ARIMA to extrapolate the ID values for forecast observations and to check that the input data are in order with no missing periods. See the section “[Specifying Series Periodicity](#)” on page 259 for more details.

LEAD=*n*

specifies the number of multistep forecast values to compute. For example, if $\text{LEAD}=10$, PROC ARIMA forecasts for ten periods beginning with the end of the input series (or earlier if BACK= is specified). It is possible to obtain fewer than the requested number of forecasts if a transfer function model is specified and insufficient data are available to compute the forecast. The default is $\text{LEAD}=24$.

NOOUTALL

includes only the final forecast observations in the OUT= output data set, not the one-step forecasts for the data before the forecast period.

NOPRINT

suppresses the normal printout of the forecast and associated values.

OUT=*SAS-data-set*

writes the forecast (and other values) to an output data set. If OUT= is not specified, the OUT=

data set specified in the PROC ARIMA statement is used. If OUT= is also not specified in the PROC ARIMA statement, no output data set is created. See the section “[OUT= Data Set](#)” on page 262 for more information.

PRINTALL

prints the FORECAST computation throughout the whole data set. The forecast values for the data before the forecast period (specified by the BACK= option) are one-step forecasts.

SIGSQ=*value*

specifies the variance term used in the formula for computing forecast standard errors and confidence limits. The default value is the variance estimate computed by the preceding ESTIMATE statement. This option is useful when you wish to generate forecast standard errors and confidence limits based on a published model. It would often be used in conjunction with the NOEST option in the preceding ESTIMATE statement.

Details: ARIMA Procedure

The Inverse Autocorrelation Function

The sample inverse autocorrelation function (SIACF) plays much the same role in ARIMA modeling as the sample partial autocorrelation function (SPACF), but it generally indicates subset and seasonal autoregressive models better than the SPACF.

Additionally, the SIACF can be useful for detecting over-differencing. If the data come from a nonstationary or nearly nonstationary model, the SIACF has the characteristics of a noninvertible moving-average. Likewise, if the data come from a model with a noninvertible moving average, then the SIACF has nonstationary characteristics and therefore decays slowly. In particular, if the data have been over-differenced, the SIACF looks like a SACF from a nonstationary process.

The inverse autocorrelation function is not often discussed in textbooks, so a brief description is given here. More complete discussions can be found in Cleveland (1972), Chatfield (1980), and Priestly (1981).

Let W_t be generated by the ARMA(p, q) process

$$\phi(B)W_t = \theta(B)a_t$$

where a_t is a white noise sequence. If $\theta(B)$ is invertible (that is, if θ considered as a polynomial in B has no roots less than or equal to 1 in magnitude), then the model

$$\theta(B)Z_t = \phi(B)a_t$$

is also a valid ARMA(q, p) model. This model is sometimes referred to as the dual model. The autocorrelation function (ACF) of this dual model is called the inverse autocorrelation function (IACF) of the original model.

Notice that if the original model is a pure autoregressive model, then the IACF is an ACF that corresponds to a pure moving-average model. Thus, it cuts off sharply when the lag is greater than p ; this behavior is similar to the behavior of the partial autocorrelation function (PACF).

The sample inverse autocorrelation function (SIACF) is estimated in the ARIMA procedure by the following steps. A high-order autoregressive model is fit to the data by means of the Yule-Walker equations. The order of the autoregressive model used to calculate the SIACF is the minimum of the NLAG= value and one-half the number of observations after differencing. The SIACF is then calculated as the autocorrelation function that corresponds to this autoregressive operator when treated as a moving-average operator. That is, the autoregressive coefficients are convolved with themselves and treated as autocovariances.

Under certain conditions, the sampling distribution of the SIACF can be approximated by the sampling distribution of the SACF of the dual model (Bhansali 1980). In the plots generated by ARIMA, the confidence limit marks (.) are located at $\pm 2/\sqrt{n}$. These limits bound an approximate 95% confidence interval for the hypothesis that the data are from a white noise process.

The Partial Autocorrelation Function

The approximation for a standard error for the estimated partial autocorrelation function at lag k is based on a null hypothesis that a pure autoregressive Gaussian process of order $k-1$ generated the time series. This standard error is $1/\sqrt{n}$ and is used to produce the approximate 95% confidence intervals depicted by the dots in the plot.

The Cross-Correlation Function

The autocorrelation and partial and inverse autocorrelation functions described in the preceding sections help when you want to model a series as a function of its past values and past random errors. When you want to include the effects of past and current values of other series in the model, the correlations of the response series and the other series must be considered.

The CROSSCORR= option in the IDENTIFY statement computes cross-correlations of the VAR= series with other series and makes these series available for use as inputs in models specified by later ESTIMATE statements.

When the CROSSCORR= option is used, PROC ARIMA prints a plot of the cross-correlation function for each variable in the CROSSCORR= list. This plot is similar in format to the other correlation plots, but it shows the correlation between the two series at both lags and leads. For example,

```
identify var=y crosscorr=x ...;
```

plots the cross-correlation function of Y and X, $\text{Cor}(y_t, x_{t-s})$, for $s = -L$ to L , where L is the value of the NLAG= option. Study of the cross-correlation functions can indicate the transfer functions through which the input series should enter the model for the response series.

The cross-correlation function is computed after any specified differencing has been done. If differencing is specified for the VAR= variable or for a variable in the CROSSCORR= list, it is the differenced series that is cross-correlated (and the differenced series is processed by any following ESTIMATE statement).

For example,

```
identify var=y(1) crosscorr=x(1);
```

computes the cross-correlations of the changes in Y with the changes in X. When differencing is specified, the subsequent ESTIMATE statement models changes in the variables rather than the variables themselves.

The ESACF Method

The extended sample autocorrelation function (ESACF) method can tentatively identify the orders of a *stationary or nonstationary* ARMA process based on iterated least squares estimates of the autoregressive parameters. Tsay and Tiao (1984) proposed the technique, and Choi (1992) provides useful descriptions of the algorithm.

Given a stationary or nonstationary time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$ with a true autoregressive order of $p + d$ and with a true moving-average order of q , you can use the ESACF method to estimate the unknown orders $p + d$ and q by analyzing the autocorrelation functions associated with filtered series of the form

$$w_t^{(m,j)} = \hat{\Phi}_{(m,j)}(B)\tilde{z}_t = \tilde{z}_t - \sum_{i=1}^m \hat{\phi}_i^{(m,j)} \tilde{z}_{t-i}$$

where B represents the backshift operator, where $m = p_{min}, \dots, p_{max}$ are the autoregressive *test* orders, where $j = q_{min} + 1, \dots, q_{max} + 1$ are the moving-average *test* orders, and where $\hat{\phi}_i^{(m,j)}$ are the autoregressive parameter estimates under the assumption that the series is an ARMA(m, j) process.

For purely autoregressive models ($j = 0$), ordinary least squares (OLS) is used to consistently estimate $\hat{\phi}_i^{(m,0)}$. For ARMA models, consistent estimates are obtained by the iterated least squares recursion formula, which is initiated by the pure autoregressive estimates:

$$\hat{\phi}_i^{(m,j)} = \hat{\phi}_i^{(m+1,j-1)} - \hat{\phi}_{i-1}^{(m,j-1)} \frac{\hat{\phi}_{m+1}^{(m+1,j-1)}}{\hat{\phi}_m^{(m,j-1)}}$$

The j th lag of the sample autocorrelation function of the filtered series $w_t^{(m,j)}$ is the *extended sample autocorrelation function*, and it is denoted as $r_{j(m)} = r_j(w^{(m,j)})$.

The standard errors of $r_{j(m)}$ are computed in the usual way by using Bartlett's approximation of the variance of the sample autocorrelation function, $var(r_{j(m)}) \approx (1 + \sum_{t=1}^{j-1} r_j^2(w^{(m,j)}))$.

If the true model is an ARMA $(p + d, q)$ process, the filtered series $w_t^{(m,j)}$ follows an MA(q) model for $j \geq q$ so that

$$r_{j(p+d)} \approx 0 \quad j > q$$

$$r_{j(p+d)} \neq 0 \quad j = q$$

Additionally, Tsay and Tiao (1984) show that the extended sample autocorrelation satisfies

$$r_{j(m)} \approx 0 \quad j - q > m - p - d \leq 0$$

$$r_{j(m)} \neq c(m - p - d, j - q) \quad 0 \leq j - q \leq m - p - d$$

where $c(m - p - d, j - q)$ is a nonzero constant or a continuous random variable bounded by -1 and 1 .

An ESACF table is then constructed by using the $r_{j(m)}$ for $m = p_{min}, \dots, p_{max}$ and $j = q_{min} + 1, \dots, q_{max} + 1$ to identify the ARMA orders (see Table 7.4). The orders are tentatively identified by finding a right (maximal) triangular pattern with vertices located at $(p + d, q)$ and $(p + d, q_{max})$ and in which all elements are insignificant (based on asymptotic normality of the autocorrelation function). The vertex $(p + d, q)$ identifies the order. Table 7.5 depicts the theoretical pattern associated with an ARMA(1,2) series.

The MINIC Method

The minimum information criterion (MINIC) method can tentatively identify the order of a *stationary and invertible* ARMA process. Note that Hannan and Rissannen (1982) proposed this method, and Box, Jenkins, and Reinsel (1994) and Choi (1992) provide useful descriptions of the algorithm.

Given a stationary and invertible time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$ with a true autoregressive order of p and with a true moving-average order of q , you can use the MINIC method to compute information criteria (or penalty functions) for various autoregressive and moving average orders. The following paragraphs provide a brief description of the algorithm.

If the series is a stationary and invertible ARMA(p, q) process of the form

$$\Phi_{(p,q)}(B)\tilde{z}_t = \Theta_{(p,q)}(B)\epsilon_t$$

the error series can be approximated by a high-order AR process

$$\hat{\epsilon}_t = \hat{\Phi}_{(p_\epsilon, q)}(B)\tilde{z}_t \approx \epsilon_t$$

where the parameter estimates $\hat{\Phi}_{(p_\epsilon, q)}$ are obtained from the Yule-Walker estimates. The choice of the autoregressive order p_ϵ is determined by the order that minimizes the Akaike information criterion (AIC) in the range $p_{\epsilon, \min} \leq p_\epsilon \leq p_{\epsilon, \max}$

$$AIC(p_\epsilon, 0) = \ln(\tilde{\sigma}_{(p_\epsilon, 0)}^2) + 2(p_\epsilon + 0)/n$$

where

$$\tilde{\sigma}_{(p_\epsilon, 0)}^2 = \frac{1}{n} \sum_{t=p_\epsilon+1}^n \hat{\epsilon}_t^2$$

Note that Hannan and Rissannen (1982) use the Bayesian information criterion (BIC) to determine the autoregressive order used to estimate the error series. Box, Jenkins, and Reinsel (1994) and Choi (1992) recommend the AIC.

Once the error series has been estimated for autoregressive test order $m = p_{\min}, \dots, p_{\max}$ and for moving-average test order $j = q_{\min}, \dots, q_{\max}$, the OLS estimates $\hat{\Phi}_{(m,j)}$ and $\hat{\Theta}_{(m,j)}$ are computed from the regression model

$$\tilde{z}_t = \sum_{i=1}^m \phi_i^{(m,j)} \tilde{z}_{t-i} + \sum_{k=1}^j \theta_k^{(m,j)} \hat{\epsilon}_{t-k} + error$$

From the preceding parameter estimates, the BIC is then computed

$$BIC(m, j) = \ln(\tilde{\sigma}_{(m,j)}^2) + 2(m + j)\ln(n)/n$$

where

$$\tilde{\sigma}_{(m,j)}^2 = \frac{1}{n} \sum_{t=t_0}^n \left(\tilde{z}_t - \sum_{i=1}^m \phi_i^{(m,j)} \tilde{z}_{t-i} + \sum_{k=1}^j \theta_k^{(m,j)} \hat{\epsilon}_{t-k} \right)^2$$

where $t_0 = p_\epsilon + \max(m, j)$.

A MINIC table is then constructed using $BIC(m, j)$; see Table 7.6. If $p_{max} > p_{\epsilon, min}$, the preceding regression might fail due to linear dependence on the estimated error series and the mean-corrected series. Values of $BIC(m, j)$ that cannot be computed are set to missing. For large autoregressive and moving-average test orders with relatively few observations, a nearly perfect fit can result. This condition can be identified by a large negative $BIC(m, j)$ value.

The SCAN Method

The smallest canonical (SCAN) correlation method can tentatively identify the orders of a *stationary or nonstationary* ARMA process. Tsay and Tiao (1985) proposed the technique, and Box, Jenkins, and Reinsel (1994) and Choi (1992) provide useful descriptions of the algorithm.

Given a stationary or nonstationary time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$ with a true autoregressive order of $p + d$ and with a true moving-average order of q , you can use the SCAN method to analyze eigenvalues of the correlation matrix of the ARMA process. The following paragraphs provide a brief description of the algorithm.

For autoregressive test order $m = p_{min}, \dots, p_{max}$ and for moving-average test order $j = q_{min}, \dots, q_{max}$, perform the following steps.

1. Let $Y_{m,t} = (\tilde{z}_t, \tilde{z}_{t-1}, \dots, \tilde{z}_{t-m})'$. Compute the following $(m + 1) \times (m + 1)$ matrix

$$\hat{\beta}(m, j + 1) = \left(\sum_t Y_{m,t-j-1} Y'_{m,t-j-1} \right)^{-1} \left(\sum_t Y_{m,t-j-1} Y'_{m,t} \right)$$

$$\hat{\beta}^*(m, j + 1) = \left(\sum_t Y_{m,t} Y'_{m,t} \right)^{-1} \left(\sum_t Y_{m,t} Y'_{m,t-j-1} \right)$$

$$\hat{A}^*(m, j) = \hat{\beta}^*(m, j + 1) \hat{\beta}(m, j + 1)$$

where t ranges from $j + m + 2$ to n .

2. Find the *smallest* eigenvalue, $\hat{\lambda}^*(m, j)$, of $\hat{A}^*(m, j)$ and its corresponding *normalized* eigenvector, $\Phi_{m,j} = (1, -\phi_1^{(m,j)}, -\phi_2^{(m,j)}, \dots, -\phi_m^{(m,j)})$. The squared canonical correlation estimate is $\hat{\lambda}^*(m, j)$.

3. Using the $\Phi_{m,j}$ as AR(m) coefficients, obtain the residuals for $t = j + m + 1$ to n , by following the formula: $w_t^{(m,j)} = \tilde{z}_t - \phi_1^{(m,j)}\tilde{z}_{t-1} - \phi_2^{(m,j)}\tilde{z}_{t-2} - \dots - \phi_m^{(m,j)}\tilde{z}_{t-m}$.
4. From the sample autocorrelations of the residuals, $r_k(w)$, approximate the standard error of the squared canonical correlation estimate by

$$\text{var}(\hat{\lambda}^*(m, j)^{1/2}) \approx d(m, j)/(n - m - j)$$

where $d(m, j) = (1 + 2 \sum_{i=1}^{j-1} r_k(w^{(m,j)}))$.

The test statistic to be used as an identification criterion is

$$c(m, j) = -(n - m - j)\ln(1 - \hat{\lambda}^*(m, j)/d(m, j))$$

which is asymptotically χ_1^2 if $m = p + d$ and $j \geq q$ or if $m \geq p + d$ and $j = q$. For $m > p$ and $j < q$, there is more than one theoretical zero canonical correlation between $Y_{m,t}$ and $Y_{m,t-j-1}$. Since the $\hat{\lambda}^*(m, j)$ are the smallest canonical correlations for each (m, j) , the percentiles of $c(m, j)$ are less than those of a χ_1^2 ; therefore, Tsay and Tiao (1985) state that it is safe to assume a χ_1^2 . For $m < p$ and $j < q$, no conclusions about the distribution of $c(m, j)$ are made.

A SCAN table is then constructed using $c(m, j)$ to determine which of the $\hat{\lambda}^*(m, j)$ are significantly different from zero (see Table 7.7). The ARMA orders are tentatively identified by finding a (maximal) rectangular pattern in which the $\hat{\lambda}^*(m, j)$ are insignificant for all test orders $m \geq p + d$ and $j \geq q$. There may be more than one pair of values $(p + d, q)$ that permit such a rectangular pattern. In this case, parsimony and the number of insignificant items in the rectangular pattern should help determine the model order. Table 7.8 depicts the theoretical pattern associated with an ARMA(2,2) series.

Stationarity Tests

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey (1976) and Dickey and Fuller (1979) studied the limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root. Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots. Hamilton (1994) discusses the various types of unit root testing.

For a description of Dickey-Fuller tests, see the section “[PROBDF Function for Dickey-Fuller Tests](#)” on page 158 in [Chapter 5](#). See [Chapter 8](#), “[The AUTOREG Procedure](#),” for a description of Phillips-Perron tests.

The random-walk-with-drift test recommends whether or not an integrated times series has a drift term. Hamilton (1994) discusses this test.

Prewhitening

If, as is usually the case, an input series is autocorrelated, the direct cross-correlation function between the input and response series gives a misleading indication of the relation between the input and response series.

One solution to this problem is called *prewhitening*. You first fit an ARIMA model for the input series sufficient to reduce the residuals to white noise; then, filter the input series with this model to get the white noise residual series. You then filter the response series with the same model and cross-correlate the filtered response with the filtered input series.

The ARIMA procedure performs this prewhitening process automatically when you precede the IDENTIFY statement for the response series with IDENTIFY and ESTIMATE statements to fit a model for the input series. If a model with no inputs was previously fit to a variable specified by the CROSSCORR= option, then that model is used to prewhiten both the input series and the response series before the cross-correlations are computed for the input series.

For example,

```
proc arima data=in;
  identify var=x;
  estimate p=1 q=1;
  identify var=y crosscorr=x;
run;
```

Both X and Y are filtered by the ARMA(1,1) model fit to X before the cross-correlations are computed.

Note that prewhitening is done to estimate the cross-correlation function; the unfiltered series are used in any subsequent ESTIMATE or FORECAST statements, and the correlation functions of Y with its own lags are computed from the unfiltered Y series. But initial values in the ESTIMATE statement are obtained with prewhitened data; therefore, the result with prewhitening can be different from the result without prewhitening.

To suppress prewhitening for all input variables, use the CLEAR option in the IDENTIFY statement to make PROC ARIMA disregard all previous models.

Prewhitening and Differencing

If the VAR= and CROSSCORR= options specify differencing, the series are differenced before the prewhitening filter is applied. When the differencing lists specified in the VAR= option for an input and in the CROSSCORR= option for that input are not the same, PROC ARIMA combines the two lists so that the differencing operators used for prewhitening include all differences in either list (in the least common multiple sense).

Identifying Transfer Function Models

When identifying a transfer function model with multiple input variables, the cross-correlation functions can be misleading if the input series are correlated with each other. Any dependencies among two or more input series will confound their cross-correlations with the response series.

The prewhitening technique assumes that the input variables do not depend on past values of the response variable. If there is feedback from the response variable to an input variable, as evidenced by significant cross-correlation at negative lags, both the input and the response variables need to be prewhitened before meaningful cross-correlations can be computed.

PROC ARIMA cannot handle feedback models. The STATESPACE and VARMAX procedures are more appropriate for models with feedback.

Missing Values and Autocorrelations

To compute the sample autocorrelation function when missing values are present, PROC ARIMA uses only crossproducts that do not involve missing values and employs divisors that reflect the number of crossproducts used rather than the total length of the series. Sample partial autocorrelations and inverse autocorrelations are then computed by using the sample autocorrelation function. If necessary, a taper is employed to transform the sample autocorrelations into a positive definite sequence before calculating the partial autocorrelation and inverse correlation functions. The confidence intervals produced for these functions might not be valid when there are missing values. The distributional properties for sample correlation functions are not clear for finite samples. See Dunsmuir (1984) for some asymptotic properties of the sample correlation functions.

Estimation Details

The ARIMA procedure primarily uses the computational methods outlined by Box and Jenkins. Marquardt's method is used for the nonlinear least squares iterations. Numerical approximations of the derivatives of the sum-of-squares function are taken by using a fixed delta (controlled by the DELTA= option).

The methods do not always converge successfully for a given set of data, particularly if the starting values for the parameters are not close to the least squares estimates.

Back-Forecasting

The unconditional sum of squares is computed exactly; thus, back-forecasting is not performed. Early versions of SAS/ETS software used the back-forecasting approximation and allowed a positive value of the BACKLIM= option to control the extent of the back-forecasting. In the current version, requesting a positive number of back-forecasting steps with the BACKLIM= option has no effect.

Preliminary Estimation

If an autoregressive or moving-average operator is specified with no missing lags, preliminary estimates of the parameters are computed by using the autocorrelations computed in the IDENTIFY stage. Otherwise, the preliminary estimates are arbitrarily set to values that produce stable polynomials.

When preliminary estimation is not performed by PROC ARIMA, then initial values of the coefficients for any given autoregressive or moving-average factor are set to 0.1 if the degree of the polynomial associated with the factor is 9 or less. Otherwise, the coefficients are determined by expanding the polynomial $(1 - 0.1B)$ to an appropriate power by using a recursive algorithm.

These preliminary estimates are the starting values in an iterative algorithm to compute estimates of the parameters.

Estimation Methods

Maximum Likelihood

The METHOD= ML option produces maximum likelihood estimates. The likelihood function is maximized via nonlinear least squares using Marquardt's method. Maximum likelihood estimates are more expensive to compute than the conditional least squares estimates; however, they may be preferable in some cases (Ansley and Newbold 1980; Davidson 1981).

The maximum likelihood estimates are computed as follows. Let the univariate ARMA model be

$$\phi(B)(W_t - \mu_t) = \theta(B)a_t$$

where a_t is an independent sequence of normally distributed innovations with mean 0 and variance σ^2 . Here μ_t is the mean parameter μ plus the transfer function inputs. The log-likelihood function can be written as follows:

$$-\frac{1}{2\sigma^2} \mathbf{x}' \boldsymbol{\Omega}^{-1} \mathbf{x} - \frac{1}{2} \ln(|\boldsymbol{\Omega}|) - \frac{n}{2} \ln(\sigma^2)$$

In this equation, n is the number of observations, $\sigma^2 \boldsymbol{\Omega}$ is the variance of \mathbf{x} as a function of the ϕ and θ parameters, and $|\boldsymbol{\Omega}|$ denotes the determinant. The vector \mathbf{x} is the time series W_t minus the structural part of the model μ_t , written as a column vector, as follows:

$$\mathbf{x} = \begin{bmatrix} W_1 \\ W_2 \\ \vdots \\ W_n \end{bmatrix} - \begin{bmatrix} \mu_1 \\ \mu_2 \\ \vdots \\ \mu_n \end{bmatrix}$$

The maximum likelihood estimate (MLE) of σ^2 is

$$s^2 = \frac{1}{n} \mathbf{x}' \boldsymbol{\Omega}^{-1} \mathbf{x}$$

Note that the default estimator of the variance divides by $n - r$, where r is the number of parameters in the model, instead of by n . Specifying the NODF option causes a divisor of n to be used.

The log-likelihood concentrated with respect to σ^2 can be taken up to additive constants as

$$-\frac{n}{2} \ln(\mathbf{x}' \boldsymbol{\Omega}^{-1} \mathbf{x}) - \frac{1}{2} \ln(|\boldsymbol{\Omega}|)$$

Let \mathbf{H} be the lower triangular matrix with positive elements on the diagonal such that $\mathbf{H}\mathbf{H}' = \boldsymbol{\Omega}$. Let \mathbf{e} be the vector $\mathbf{H}^{-1} \mathbf{x}$. The concentrated log-likelihood with respect to σ^2 can now be written as

$$-\frac{n}{2} \ln(\mathbf{e}'\mathbf{e}) - \ln(|\mathbf{H}|)$$

or

$$-\frac{n}{2} \ln(|\mathbf{H}|^{1/n} \mathbf{e}' \mathbf{e} |\mathbf{H}|^{1/n})$$

The MLE is produced by using a Marquardt algorithm to minimize the following sum of squares:

$$|\mathbf{H}|^{1/n} \mathbf{e}' \mathbf{e} |\mathbf{H}|^{1/n}$$

The subsequent analysis of the residuals is done by using \mathbf{e} as the vector of residuals.

Unconditional Least Squares

The METHOD=ULS option produces unconditional least squares estimates. The ULS method is also referred to as the *exact least squares* (ELS) method. For METHOD=ULS, the estimates minimize

$$\sum_{t=1}^n \tilde{a}_t^2 = \sum_{t=1}^n (x_t - \mathbf{C}_t \mathbf{V}_t^{-1} (x_1, \dots, x_{t-1})')^2$$

where \mathbf{C}_t is the covariance matrix of x_t and (x_1, \dots, x_{t-1}) , and \mathbf{V}_t is the variance matrix of (x_1, \dots, x_{t-1}) . In fact, $\sum_{t=1}^n \tilde{a}_t^2$ is the same as $\mathbf{x}' \boldsymbol{\Omega}^{-1} \mathbf{x}$, and hence $\mathbf{e}' \mathbf{e}$. Therefore, the unconditional least squares estimates are obtained by minimizing the sum of squared residuals rather than using the log-likelihood as the criterion function.

Conditional Least Squares

The METHOD=CLS option produces conditional least squares estimates. The CLS estimates are conditional on the assumption that the past unobserved errors are equal to 0. The series x_t can be represented in terms of the previous observations, as follows:

$$x_t = a_t + \sum_{i=1}^{\infty} \pi_i x_{t-i}$$

The π weights are computed from the ratio of the ϕ and θ polynomials, as follows:

$$\frac{\phi(B)}{\theta(B)} = 1 - \sum_{i=1}^{\infty} \pi_i B^i$$

The CLS method produces estimates minimizing

$$\sum_{t=1}^n \hat{a}_t^2 = \sum_{t=1}^n (x_t - \sum_{i=1}^{\infty} \hat{\pi}_i x_{t-i})^2$$

where the unobserved past values of x_t are set to 0 and $\hat{\pi}_i$ are computed from the estimates of ϕ and θ at each iteration.

For METHOD=ULS and METHOD=ML, initial estimates are computed using the METHOD=CLS algorithm.

Start-up for Transfer Functions

When computing the noise series for transfer function and intervention models, the start-up for the transferred variable is done by assuming that past values of the input series are equal to the first value of the series. The estimates are then obtained by applying least squares or maximum likelihood to the noise series. Thus, for transfer function models, the ML option does not generate the full (multivariate ARMA) maximum likelihood estimates, but it uses only the univariate likelihood function applied to the noise series.

Because PROC ARIMA uses all of the available data for the input series to generate the noise series, other start-up options for the transferred series can be implemented by prefixing an observation to the beginning of the real data. For example, if you fit a transfer function model to the variable Y with the single input X , then you can employ a start-up using 0 for the past values by prefixing to the actual data an observation with a missing value for Y and a value of 0 for X .

Information Criteria

PROC ARIMA computes and prints two information criteria, Akaike's information criterion (AIC) (Akaike 1974; Harvey 1981) and Schwarz's Bayesian criterion (SBC) (Schwarz 1978). The AIC and SBC are used to compare competing models fit to the same series. The model with the smaller information criteria is said to fit the data better. The AIC is computed as

$$-2\ln(L) + 2k$$

where L is the likelihood function and k is the number of free parameters. The SBC is computed as

$$-2\ln(L) + \ln(n)k$$

where n is the number of residuals that can be computed for the time series. Sometimes Schwarz's Bayesian criterion is called the Bayesian information criterion (BIC).

If METHOD=CLS is used to do the estimation, an approximation value of L is used, where L is based on the conditional sum of squares instead of the exact sum of squares, and a Jacobian factor is left out.

Tests of Residuals

A table of test statistics for the hypothesis that the model residuals are white noise is printed as part of the ESTIMATE statement output. The chi-square statistics used in the test for lack of fit are computed using the Ljung-Box formula

$$\chi_m^2 = n(n+2) \sum_{k=1}^m \frac{r_k^2}{(n-k)}$$

where

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^n a_t^2}$$

and a_t is the residual series.

This formula has been suggested by Ljung and Box (1978) as yielding a better fit to the asymptotic chi-square distribution than the Box-Pierce Q statistic. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977) and by Ljung and Box (1978). When the time series has missing values, Stoffer and Tolo (1992) suggest a modification of this test statistic that has improved distributional properties over the standard Ljung-Box formula given above. When the series contains missing values, this modified test statistic is used by default.

Each chi-square statistic is computed for all lags up to the indicated lag value and is not independent of the preceding chi-square values. The null hypotheses tested is that the current set of autocorrelations is white noise.

***t*-values**

The t values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. When the length of the observed series is short and the number of estimated parameters is large with respect to the series length, the t approximation is usually poor. Probability values that correspond to a t distribution should be interpreted carefully because they may be misleading.

Cautions during Estimation

The ARIMA procedure uses a general nonlinear least squares estimation method that can yield problematic results if your data do not fit the model. Output should be examined carefully. The GRID option can be used to ensure the validity and quality of the results. Problems you might encounter include the following:

- Preliminary moving-average estimates might not converge. If this occurs, preliminary estimates are derived as described previously in “[Preliminary Estimation](#)” on page 248. You can supply your own preliminary estimates with the ESTIMATE statement options.
- The estimates can lead to an unstable time series process, which can cause extreme forecast values or overflows in the forecast.
- The Jacobian matrix of partial derivatives might be singular; usually, this happens because not all the parameters are identifiable. Removing some of the parameters or using a longer time series might help.
- The iterative process might not converge. PROC ARIMA’s estimation method stops after n iterations, where n is the value of the MAXITER= option. If an iteration does not improve the SSE, the Marquardt parameter is increased by a factor of ten until parameters that have a smaller SSE are obtained or until the limit value of the Marquardt parameter is exceeded.
- For METHOD=CLS, the estimates might converge but not to least squares estimates. The estimates might converge to a local minimum, the numerical calculations might be distorted by data whose sum-of-squares surface is not smooth, or the minimum might lie outside the region of invertibility or stationarity.

- If the data are differenced and a moving-average model is fit, the parameter estimates might try to converge exactly on the invertibility boundary. In this case, the standard error estimates that are based on derivatives might be inaccurate.

Specifying Inputs and Transfer Functions

Input variables and transfer functions for them can be specified using the INPUT= option in the ESTIMATE statement. The variables used in the INPUT= option must be included in the CROSS-CORR= list in the previous IDENTIFY statement. If any differencing is specified in the CROSS-CORR= list, then the differenced variable is used as the input to the transfer function.

General Syntax of the INPUT= Option

The general syntax of the INPUT= option is

ESTIMATE ... INPUT=(*transfer-function variable ...*)

The transfer function for an input variable is optional. The name of a variable by itself can be used to specify a pure regression term for the variable.

If specified, the syntax of the transfer function is

$$S \$ (L_{1,1}, L_{1,2}, \dots)(L_{2,1}, \dots) \dots / (L_{i,1}, L_{i,2}, \dots)(L_{i+1,1}, \dots) \dots$$

S is the number of periods of time delay (lag) for this input series. Each term in parentheses specifies a polynomial factor with parameters at the lags specified by the $L_{i,j}$ values. The terms before the slash (/) are numerator factors. The terms after the slash (/) are denominator factors. All three parts are optional.

Commas can optionally be used between input specifications to make the INPUT= option more readable. The \$ sign after the shift is also optional.

Except for the first numerator factor, each of the terms $L_{i,1}, L_{i,2}, \dots, L_{i,k}$ indicates a factor of the form

$$(1 - \omega_{i,1}B^{L_{i,1}} - \omega_{i,2}B^{L_{i,2}} - \dots - \omega_{i,k}B^{L_{i,k}})$$

The form of the first numerator factor depends on the ALTPARM option. By default, the constant 1 in the first numerator factor is replaced with a free parameter ω_0 .

Alternative Model Parameterization

When the ALTPARM option is specified, the ω_0 parameter is factored out so that it multiplies the entire transfer function, and the first numerator factor has the same form as the other factors.

The ALTPARM option does not materially affect the results; it just presents the results differently. Some people prefer to see the model written one way, while others prefer the alternative representation. Table 7.9 illustrates the effect of the ALTPARM option.

Table 7.9 The ALTPARM Option

INPUT= Option	ALTPARM	Model
INPUT=((1 2)(12)(1)X);	No	$(\omega_0 - \omega_1 B - \omega_2 B^2)(1 - \omega_3 B^{12}) / (1 - \delta_1 B) X_t$
	Yes	$\omega_0(1 - \omega_1 B - \omega_2 B^2)(1 - \omega_3 B^{12}) / (1 - \delta_1 B) X_t$

Differencing and Input Variables

If you difference the response series and use input variables, take care that the differencing operations do not change the meaning of the model. For example, if you want to fit the model

$$Y_t = \frac{\omega_0}{(1 - \delta_1 B)} X_t + \frac{(1 - \theta_1 B)}{(1 - B)(1 - B^{12})} a_t$$

then the IDENTIFY statement must read

```
identify var=y(1,12) crosscorr=x(1,12);
estimate q=1 input=(/ (1)x) noconstant;
```

If instead you specify the differencing as

```
identify var=y(1,12) crosscorr=x;
estimate q=1 input=(/ (1)x) noconstant;
```

then the model being requested is

$$Y_t = \frac{\omega_0}{(1 - \delta_1 B)(1 - B)(1 - B^{12})} X_t + \frac{(1 - \theta_1 B)}{(1 - B)(1 - B^{12})} a_t$$

which is a very different model.

The point to remember is that a differencing operation requested for the response variable specified by the VAR= option is applied only to that variable and not to the noise term of the model.

Initial Values

The syntax for giving initial values to transfer function parameters in the INITVAL= option parallels the syntax of the INPUT= option. For each transfer function in the INPUT= option, the INITVAL= option should give an initialization specification followed by the input series name. The initialization specification for each transfer function has the form

$$C \$ (V_{1,1}, V_{1,2}, \dots)(V_{2,1}, \dots) \dots / (V_{i,1}, \dots) \dots$$

where C is the lag 0 term in the first numerator factor of the transfer function (or the overall scale factor if the ALTPARM option is specified) and $V_{i,j}$ is the coefficient of the $L_{i,j}$ element in the transfer function.

To illustrate, suppose you want to fit the model

$$Y_t = \mu + \frac{(\omega_0 - \omega_1 B - \omega_2 B^2)}{(1 - \delta_1 B - \delta_2 B^2 - \delta_3 B^3)} X_{t-3} + \frac{1}{(1 - \phi_1 B - \phi_2 B^3)} a_t$$

and start the estimation process with the initial values $\mu=10$, $\omega_0=1$, $\omega_1=0.5$, $\omega_2=0.03$, $\delta_1=0.8$, $\delta_2=-0.1$, $\delta_3=0.002$, $\phi_1=0.1$, $\phi_2=0.01$. (These are arbitrary values for illustration only.) You would use the following statements:

```
identify var=y crosscorr=x;
estimate p=(1,3) input=(3$(1,2)/(1,2,3)x)
          mu=10 ar=.1 .01
          initval=(1$(.5,.03)/(.8,-.1,.002)x);
```

Note that the lags specified for a particular factor are sorted, so initial values should be given in sorted order. For example, if the P= option had been entered as P=(3,1) instead of P=(1,3), the model would be the same and so would the AR= option. Sorting is done within all factors, including transfer function factors, so initial values should always be given in order of increasing lags.

Here is another illustration, showing initialization for a factored model with multiple inputs. The model is

$$Y_t = \mu + \frac{\omega_{1,0}}{(1 - \delta_{1,1} B)} W_t + (\omega_{2,0} - \omega_{2,1} B) X_{t-3} + \frac{1}{(1 - \phi_1 B)(1 - \phi_2 B^6 - \phi_3 B^{12})} a_t$$

and the initial values are $\mu=10$, $\omega_{1,0}=5$, $\delta_{1,1}=0.8$, $\omega_{2,0}=1$, $\omega_{2,1}=0.5$, $\phi_1=0.1$, $\phi_2=0.05$, and $\phi_3=0.01$. You would use the following statements:

```
identify var=y crosscorr=(w x);
estimate p=(1)(6,12) input=(/(1)w, 3$(1)x)
          mu=10 ar=.1 .05 .01
          initval=(5$(.8)w 1$(.5)x);
```

Stationarity and Invertibility

By default, PROC ARIMA requires that the parameter estimates for the AR and MA parts of the model always remain in the stationary and invertible regions, respectively. The NOSTABLE option removes this restriction and for high-order models can save some computer time. Note that using the NOSTABLE option does not necessarily result in an unstable model being fit, since the estimates can leave the stable region for some iterations but still ultimately converge to stable values. Similarly, by default, the parameter estimates for the denominator polynomial of the transfer function part of the model are also restricted to be stable. The NOTFSTABLE option can be used to remove this restriction.

Naming of Model Parameters

In the table of parameter estimates produced by the ESTIMATE statement, model parameters are referred to by using the naming convention described in this section.

The parameters in the noise part of the model are named as $AR_{i,j}$ or $MA_{i,j}$, where AR refers to autoregressive parameters and MA to moving-average parameters. The subscript i refers to the particular polynomial factor, and the subscript j refers to the j th term within the i th factor. These terms are sorted in order of increasing lag within factors, so the subscript j refers to the j th term after sorting.

When inputs are used in the model, the parameters of each transfer function are named $NUM_{i,j}$ and $DEN_{i,j}$. The j th term in the i th factor of a numerator polynomial is named $NUM_{i,j}$. The j th term in the i th factor of a denominator polynomial is named $DEN_{i,j}$.

This naming process is repeated for each input variable, so if there are multiple inputs, parameters in transfer functions for different input series have the same name. The table of parameter estimates shows in the “Variable” column the input with which each parameter is associated. The parameter name shown in the “Parameter” column and the input variable name shown in the “Variable” column must be combined to fully identify transfer function parameters.

The lag 0 parameter in the first numerator factor for the first input variable is named NUM1. For subsequent input variables, the lag 0 parameter in the first numerator factor is named NUM_k , where k is the position of the input variable in the INPUT= option list. If the ALTPARM option is specified, the NUM_k parameter is replaced by an overall scale parameter named SCALE k .

For the mean and noise process parameters, the response series name is shown in the “Variable” column. The lag and shift for each parameter are also shown in the table of parameter estimates when inputs are used.

Missing Values and Estimation and Forecasting

Estimation and forecasting are carried out in the presence of missing values by forecasting the missing values with the current set of parameter estimates. The maximum likelihood algorithm employed was suggested by Jones (1980) and is used for both unconditional least squares (ULS) and maximum likelihood (ML) estimation.

The CLS algorithm simply fills in missing values with infinite memory forecast values, computed by forecasting ahead from the nonmissing past values as far as required by the structure of the missing values. These artificial values are then employed in the nonmissing value CLS algorithm. Artificial values are updated at each iteration along with parameter estimates.

For models with input variables, embedded missing values (that is, missing values other than at the beginning or end of the series) are not generally supported. Embedded missing values in input variables are supported for the special case of a multiple regression model that has ARIMA errors. A multiple regression model is specified by an INPUT= option that simply lists the input variables

(possibly with lag shifts) without any numerator or denominator transfer function factors. One-step-ahead forecasts are not available for the response variable when one or more of the input variables have missing values.

When embedded missing values are present for a model with complex transfer functions, PROC ARIMA uses the first continuous nonmissing piece of each series to do the analysis. That is, PROC ARIMA skips observations at the beginning of each series until it encounters a nonmissing value and then uses the data from there until it encounters another missing value or until the end of the data is reached. This makes the current version of PROC ARIMA compatible with earlier releases that did not allow embedded missing values.

Forecasting Details

If the model has input variables, a forecast beyond the end of the data for the input variables is possible only if univariate ARIMA models have previously been fit to the input variables or future values for the input variables are included in the DATA= data set.

If input variables are used, the forecast standard errors and confidence limits of the response depend on the estimated forecast error variance of the predicted inputs. If several input series are used, the forecast errors for the inputs should be independent; otherwise, the standard errors and confidence limits for the response series will not be accurate. If future values for the input variables are included in the DATA= data set, the standard errors of the forecasts will be underestimated since these values are assumed to be known with certainty.

The forecasts are generated using forecasting equations consistent with the method used to estimate the model parameters. Thus, the estimation method specified in the ESTIMATE statement also controls the way forecasts are produced by the FORECAST statement. If METHOD=CLS is used, the forecasts are *infinite memory forecasts*, also called *conditional forecasts*. If METHOD=ULS or METHOD=ML, the forecasts are *finite memory forecasts*, also called *unconditional forecasts*. A complete description of the steps to produce the series forecasts and their standard errors by using either of these methods is quite involved, and only a brief explanation of the algorithm is given in the next two sections. Additional details about the finite and infinite memory forecasts can be found in Brockwell and Davis (1991). The prediction of stationary ARMA processes is explained in Chapter 5, and the prediction of nonstationary ARMA processes is given in Chapter 9 of Brockwell and Davis (1991).

Infinite Memory Forecasts

If METHOD=CLS is used, the forecasts are *infinite memory forecasts*, also called *conditional forecasts*. The term *conditional* is used because the forecasts are computed by assuming that the unknown values of the response series before the start of the data are equal to the mean of the series. Thus, the forecasts are conditional on this assumption.

The series x_t can be represented as

$$x_t = a_t + \sum_{i=1}^{\infty} \pi_i x_{t-i}$$

where $\phi(B)/\theta(B) = 1 - \sum_{i=1}^{\infty} \pi_i B^i$.

The k -step forecast of x_{t+k} is computed as

$$\hat{x}_{t+k} = \sum_{i=1}^{k-1} \hat{\pi}_i \hat{x}_{t+k-i} + \sum_{i=k}^{\infty} \hat{\pi}_i x_{t+k-i}$$

where unobserved past values of x_t are set to zero and $\hat{\pi}_i$ is obtained from the estimated parameters $\hat{\phi}$ and $\hat{\theta}$.

Finite Memory Forecasts

For METHOD=ULS or METHOD=ML, the forecasts are *finite memory forecasts*, also called *unconditional forecasts*. For finite memory forecasts, the covariance function of the ARMA model is used to derive the best linear prediction equation.

That is, the k -step forecast of x_{t+k} , given (x_1, \dots, x_{t-1}) , is

$$\tilde{x}_{t+k} = \mathbf{C}_{k,t} \mathbf{V}_t^{-1} (x_1, \dots, x_{t-1})'$$

where $\mathbf{C}_{k,t}$ is the covariance of x_{t+k} and (x_1, \dots, x_{t-1}) and \mathbf{V}_t is the covariance matrix of the vector (x_1, \dots, x_{t-1}) . $\mathbf{C}_{k,t}$ and \mathbf{V}_t are derived from the estimated parameters.

Finite memory forecasts minimize the mean squared error of prediction if the parameters of the ARMA model are known exactly. (In most cases, the parameters of the ARMA model are estimated, so the predictors are not true best linear forecasts.)

If the response series is differenced, the final forecast is produced by summing the forecast of the differenced series. This summation and the forecast are conditional on the initial values of the series. Thus, when the response series is differenced, the final forecasts are not true finite memory forecasts because they are derived by assuming that the differenced series begins in a steady-state condition. Thus, they fall somewhere between finite memory and infinite memory forecasts. In practice, there is seldom any practical difference between these forecasts and true finite memory forecasts.

Forecasting Log Transformed Data

The log transformation is often used to convert time series that are nonstationary with respect to the innovation variance into stationary time series. The usual approach is to take the log of the series in a DATA step and then apply PROC ARIMA to the transformed data. A DATA step is then used to transform the forecasts of the logs back to the original units of measurement. The confidence limits are also transformed by using the exponential function.

As one alternative, you can simply exponentiate the forecast series. This procedure gives a forecast for the median of the series, but the antilog of the forecast log series underpredicts the mean of the original series. If you want to predict the expected value of the series, you need to take into account the standard error of the forecast, as shown in the following example, which uses an AR(2) model to forecast the log of a series Y:

```

data in;
  set in;
  ylog = log( y );
run;

proc arima data=in;
  identify var=ylog;
  estimate p=2;
  forecast lead=10 out=out;
run;

data out;
  set out;
  y = exp( ylog );
  l95 = exp( l95 );
  u95 = exp( u95 );
  forecast = exp( forecast + std*std/2 );
run;

```

Specifying Series Periodicity

The INTERVAL= option is used together with the ID= variable to describe the observations that make up the time series. For example, INTERVAL=MONTH specifies a monthly time series in which each observation represents one month. See Chapter 4, “Date Intervals, Formats, and Functions,” for details about the interval values supported.

The variable specified by the ID= option in the PROC ARIMA statement identifies the time periods associated with the observations. Usually, SAS date, time, or datetime values are used for this variable. PROC ARIMA uses the ID= variable in the following ways:

- to validate the data periodicity. When the INTERVAL= option is specified, PROC ARIMA uses the ID variable to check the data and verify that successive observations have valid ID values that correspond to successive time intervals. When the INTERVAL= option is not used, PROC ARIMA verifies that the ID values are nonmissing and in ascending order.
- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for April 1970 follows an observation for January 1970, there is a gap in the input data with two omitted observations (namely February and March 1970). A warning message is printed when a gap in the input data is found.
- to label the forecast observations in the output data set. PROC ARIMA extrapolates the values of the ID variable for the forecast observations from the ID value at the end of the input data

according to the frequency specifications of the INTERVAL= option. If the INTERVAL= option is not specified, PROC ARIMA extrapolates the ID variable by incrementing the ID variable value for the last observation in the input data by 1 for each forecast period. Values of the ID variable over the range of the input data are copied to the output data set.

The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

Detecting Outliers

You can use the OUTLIER statement to detect changes in the level of the response series that are not accounted for by the estimated model. The types of changes considered are additive outliers (AO), level shifts (LS), and temporary changes (TC).

Let η_t be a regression variable that describes some type of change in the mean response. In time series literature η_t is called a shock signature. An additive outlier at some time point s corresponds to a shock signature η_t such that $\eta_s = 1.0$ and η_t is 0.0 at all other points. Similarly a permanent level shift that originates at time s has a shock signature such that η_t is 0.0 for $t < s$ and 1.0 for $t \geq s$. A temporary level shift of duration d that originates at time s has η_t equal to 1.0 between s and $s + d$ and 0.0 otherwise.

Suppose that you are estimating the ARIMA model

$$D(B)Y_t = \mu_t + \frac{\theta(B)}{\phi(B)}a_t$$

where Y_t is the response series, $D(B)$ is the differencing polynomial in the backward shift operator B (possibly identity), μ_t is the transfer function input, $\phi(B)$ and $\theta(B)$ are the AR and MA polynomials, respectively, and a_t is the Gaussian white noise series.

The problem of detection of level shifts in the OUTLIER statement is formulated as a problem of sequential selection of shock signatures that improve the model in the ESTIMATE statement. This is similar to the forward selection process in the stepwise regression procedure. The selection process starts with considering shock signatures of the type specified in the TYPE= option, originating at each nonmissing measurement. This involves testing $H_0: \beta = 0$ versus $H_a: \beta \neq 0$ in the model

$$D(B)(Y_t - \beta\eta_t) = \mu_t + \frac{\theta(B)}{\phi(B)}a_t$$

for each of these shock signatures. The most significant shock signature, if it also satisfies the significance criterion in ALPHA= option, is included in the model. If no significant shock signature is found, then the outlier detection process stops; otherwise this augmented model, which incorporates the selected shock signature in its transfer function input, becomes the null model for the subsequent selection process. This iterative process stops if at any stage no more significant shock signatures are found or if the number of iterations exceeds the maximum search number that results due to the MAXNUM= and MAXPCT= settings. In all these iterations, the parameters of the ARIMA model in the ESTIMATE statement are held fixed.

The precise details of the testing procedure for a given shock signature η_t are as follows:

The preceding testing problem is equivalent to testing $H_0: \beta = 0$ versus $H_a: \beta \neq 0$ in the following “regression with ARMA errors” model

$$N_t = \beta \zeta_t + \frac{\theta(B)}{\phi(B)} a_t$$

where $N_t = (D(B)Y_t - \mu_t)$ is the “noise” process and $\zeta_t = D(B)\eta_t$ is the “effective” shock signature.

In this setting, under H_0 , $N = (N_1, N_2, \dots, N_n)^T$ is a mean zero Gaussian vector with variance covariance matrix $\sigma^2 \mathbf{\Omega}$. Here σ^2 is the variance of the white noise process a_t and $\mathbf{\Omega}$ is the variance-covariance matrix associated with the ARMA model. Moreover, under H_a , N has $\beta \zeta$ as the mean vector where $\zeta = (\zeta_1, \zeta_2, \dots, \zeta_n)^T$. Additionally, the generalized least squares estimate of β and its variance is given by

$$\begin{aligned} \hat{\beta} &= \delta / \kappa \\ \text{Var}(\hat{\beta}) &= \sigma^2 / \kappa \end{aligned}$$

where $\delta = \zeta^T \mathbf{\Omega}^{-1} N$ and $\kappa = \zeta^T \mathbf{\Omega}^{-1} \zeta$. The test statistic $\tau^2 = \delta^2 / (\sigma^2 \kappa)$ is used to test the significance of β , which has an approximate chi-squared distribution with 1 degree of freedom under H_0 . The type of estimate of σ^2 used in the calculation of τ^2 can be specified by the SIGMA= option. The default setting is SIGMA=ROBUST, which corresponds to a robust estimate suggested in an outlier detection procedure in X-12-ARIMA, the Census Bureau’s time series analysis program; see Findley et al. (1998) for additional information. The robust estimate of σ^2 is computed by the formula

$$\hat{\sigma}^2 = (1.49 \times \text{Median}(|\hat{a}_t|))^2$$

where \hat{a}_t are the standardized residuals of the null ARIMA model. The setting SIGMA=MSE corresponds to the usual mean squared error estimate (MSE) computed the same way as in the ESTIMATE statement with the NODF option.

The quantities δ and κ are efficiently computed by a method described in de Jong and Penzer (1998); see also Kohn and Ansley (1985).

Modeling in the Presence of Outliers

In practice, modeling and forecasting time series data in the presence of outliers is a difficult problem for several reasons. The presence of outliers can adversely affect the model identification and estimation steps. Their presence close to the end of the observation period can have a serious impact on the forecasting performance of the model. In some cases, level shifts are associated with changes in the mechanism that drives the observation process, and separate models might be appropriate to different sections of the data. In view of all these difficulties, diagnostic tools such as outlier detection and residual analysis are essential in any modeling process.

The following modeling strategy, which incorporates level shift detection in the familiar Box-Jenkins modeling methodology, seems to work in many cases:

1. Proceed with model identification and estimation as usual. Suppose this results in a tentative ARIMA model, say M.
2. Check for additive and permanent level shifts unaccounted for by the model M by using the OUTLIER statement. In this step, unless there is evidence to justify it, the number of level shifts searched should be kept small.
3. Augment the original dataset with the regression variables that correspond to the detected outliers.
4. Include the first few of these regression variables in M, and call this model M1. Reestimate all the parameters of M1. It is important not to include too many of these outlier variables in the model in order to avoid the danger of over-fitting.
5. Check the adequacy of M1 by examining the parameter estimates, residual analysis, and outlier detection. Refine it more if necessary.

OUT= Data Set

The output data set produced by the OUT= option of the PROC ARIMA or FORECAST statements contains the following:

- the BY variables
- the ID variable
- the variable specified by the VAR= option in the IDENTIFY statement, which contains the actual values of the response series
- FORECAST, a numeric variable that contains the one-step-ahead predicted values and the multistep forecasts
- STD, a numeric variable that contains the standard errors of the forecasts
- a numeric variable that contains the lower confidence limits of the forecast. This variable is named L95 by default but has a different name if the ALPHA= option specifies a different size for the confidence limits.
- RESIDUAL, a numeric variable that contains the differences between actual and forecast values
- a numeric variable that contains the upper confidence limits of the forecast. This variable is named U95 by default but has a different name if the ALPHA= option specifies a different size for the confidence limits.

The ID variable, the BY variables, and the response variable are the only ones copied from the input to the output data set. In particular, the input variables are not copied to the OUT= data set.

Unless the NOOUTALL option is specified, the data set contains the whole time series. The FORECAST variable has the one-step forecasts (predicted values) for the input periods, followed by n forecast values, where n is the LEAD= value. The actual and RESIDUAL values are missing beyond the end of the series.

If you specify the same OUT= data set in different FORECAST statements, the latter FORECAST statements overwrite the output from the previous FORECAST statements. If you want to combine the forecasts from different FORECAST statements in the same output data set, specify the OUT= option once in the PROC ARIMA statement and omit the OUT= option in the FORECAST statements.

When a global output data set is created by the OUT= option in the PROC ARIMA statement, the variables in the OUT= data set are defined by the first FORECAST statement that is executed. The results of subsequent FORECAST statements are vertically concatenated onto the OUT= data set. Thus, if no ID variable is specified in the first FORECAST statement that is executed, no ID variable appears in the output data set, even if one is specified in a later FORECAST statement. If an ID variable is specified in the first FORECAST statement that is executed but not in a later FORECAST statement, the value of the ID variable is the same as the last value processed for the ID variable for all observations created by the later FORECAST statement. Furthermore, even if the response variable changes in subsequent FORECAST statements, the response variable name in the output data set is that of the first response variable analyzed.

OUTCOV= Data Set

The output data set produced by the OUTCOV= option of the IDENTIFY statement contains the following variables:

- LAG, a numeric variable that contains the lags that correspond to the values of the covariance variables. The values of LAG range from 0 to N for covariance functions and from $-N$ to N for cross-covariance functions, where N is the value of the NLAG= option.
- VAR, a character variable that contains the name of the variable specified by the VAR= option.
- CROSSVAR, a character variable that contains the name of the variable specified in the CROSSCORR= option, which labels the different cross-covariance functions. The CROSSVAR variable is blank for the autocovariance observations. When there is no CROSSCORR= option, this variable is not created.
- N, a numeric variable that contains the number of observations used to calculate the current value of the covariance or cross-covariance function.
- COV, a numeric variable that contains the autocovariance or cross-covariance function values. COV contains the autocovariances of the VAR= variable when the value of the CROSSVAR variable is blank. Otherwise COV contains the cross covariances between the VAR= variable and the variable named by the CROSSVAR variable.

- **CORR**, a numeric variable that contains the autocorrelation or cross-correlation function values. **CORR** contains the autocorrelations of the **VAR=** variable when the value of the **CROSSVAR** variable is blank. Otherwise **CORR** contains the cross-correlations between the **VAR=** variable and the variable named by the **CROSSVAR** variable.
- **STDERR**, a numeric variable that contains the standard errors of the autocorrelations. The standard error estimate is based on the hypothesis that the process that generates the time series is a pure moving-average process of order **LAG**–1. For the cross-correlations, **STDERR** contains the value $1/\sqrt{n}$, which approximates the standard error under the hypothesis that the two series are uncorrelated.
- **INVCORR**, a numeric variable that contains the inverse autocorrelation function values of the **VAR=** variable. For cross-correlation observations (that is, when the value of the **CROSSVAR** variable is not blank), **INVCORR** contains missing values.
- **PARTCORR**, a numeric variable that contains the partial autocorrelation function values of the **VAR=** variable. For cross-correlation observations (that is, when the value of the **CROSSVAR** variable is not blank), **PARTCORR** contains missing values.

OUTEST= Data Set

PROC ARIMA writes the parameter estimates for a model to an output data set when the **OUTEST=** option is specified in the **ESTIMATE** statement. The **OUTEST=** data set contains the following:

- the **BY** variables
- **_MODLABEL_**, a character variable that contains the model label, if it is provided by using the **label** option in the **ESTIMATE** statement (otherwise this variable is not created).
- **_NAME_**, a character variable that contains the name of the parameter for the covariance or correlation observations or is blank for the observations that contain the parameter estimates. (This variable is not created if neither **OUTCOV** nor **OUTCORR** is specified.)
- **_TYPE_**, a character variable that identifies the type of observation. A description of the **_TYPE_** variable values is given below.
- variables for model parameters

The variables for the model parameters are named as follows:

ERRORVAR	This numeric variable contains the variance estimate. The _TYPE_=EST observation for this variable contains the estimated error variance, and the remaining observations are missing.
MU	This numeric variable contains values for the mean parameter for the model. (This variable is not created if NOCONSTANT is specified.)

MA j _ k	These numeric variables contain values for the moving-average parameters. The variables for moving-average parameters are named MA j _ k , where j is the factor-number and k is the index of the parameter within a factor.
AR j _ k	These numeric variables contain values for the autoregressive parameters. The variables for autoregressive parameters are named AR j _ k , where j is the factor number and k is the index of the parameter within a factor.
I j _ k	These variables contain values for the transfer function parameters. Variables for transfer function parameters are named I j _ k , where j is the number of the INPUT variable associated with the transfer function component and k is the number of the parameter for the particular INPUT variable. INPUT variables are numbered according to the order in which they appear in the INPUT= list.
STATUS	This variable describes the convergence status of the model. A value of 0_CONVERGED indicates that the model converged.

The value of the _TYPE_ variable for each observation indicates the kind of value contained in the variables for model parameters for the observation. The OUTEST= data set contains observations with the following _TYPE_ values:

EST	The observation contains parameter estimates.
STD	The observation contains approximate standard errors of the estimates.
CORR	The observation contains correlations of the estimates. OUTCORR must be specified to get these observations.
COV	The observation contains covariances of the estimates. OUTCOV must be specified to get these observations.
FACTOR	The observation contains values that identify for each parameter the factor that contains it. Negative values indicate denominator factors in transfer function models.
LAG	The observation contains values that identify the lag associated with each parameter.
SHIFT	The observation contains values that identify the shift associated with the input series for the parameter.

The values given for _TYPE_=FACTOR, _TYPE_=LAG, or _TYPE_=SHIFT observations enable you to reconstruct the model employed when provided with only the OUTEST= data set.

OUTEST= Examples

This section clarifies how model parameters are stored in the OUTEST= data set with two examples.

Consider the following example:

```
proc arima data=input;
  identify var=y cross=(x1 x2);
  estimate p=(1) (6) q=(1,3) (12) input=(x1 x2) outest=est;
```

```
run;

proc print data=est;
run;
```

The model specified by these statements is

$$Y_t = \mu + \omega_{1,0}X_{1,t} + \omega_{2,0}X_{2,t} + \frac{(1 - \theta_{11}B - \theta_{12}B^3)(1 - \theta_{21}B^{12})}{(1 - \phi_{11}B)(1 - \phi_{21}B^6)}a_t$$

The OUTEST= data set contains the values shown in [Table 7.10](#).

Table 7.10 OUTEST= Data Set for First Example

Obs	_TYPE_	Y	MU	MA1_1	MA1_2	MA2_1	AR1_1	AR2_1	I1_1	I2_1
1	EST	σ^2	μ	θ_{11}	θ_{12}	θ_{21}	ϕ_{11}	ϕ_{21}	$\omega_{1,0}$	$\omega_{2,0}$
2	STD	.	se μ	se θ_{11}	se θ_{12}	se θ_{21}	se ϕ_{11}	se ϕ_{21}	se $\omega_{1,0}$	se $\omega_{2,0}$
3	FACTOR	.	0	1	1	2	1	2	1	1
4	LAG	.	0	1	3	12	1	6	0	0
5	SHIFT	.	0	0	0	0	0	0	0	0

Note that the symbols in the rows for _TYPE_=EST and _TYPE_=STD in [Table 7.10](#) would be numeric values in a real data set.

Next, consider the following example:

```
proc arima data=input;
  identify var=y cross=(x1 x2);
  estimate p=1 q=1 input=(2 $ (1)/(1,2)x1 1 $ /(1)x2) outest=est;
run;

proc print data=est;
run;
```

The model specified by these statements is

$$Y_t = \mu + \frac{\omega_{10} - \omega_{11}B}{1 - \delta_{11}B - \delta_{12}B^2}X_{1,t-2} + \frac{\omega_{20}}{1 - \delta_{21}B}X_{2,t-1} + \frac{(1 - \theta_1 B)}{(1 - \phi_1 B)}a_t$$

The OUTEST= data set contains the values shown in [Table 7.11](#).

Table 7.11 OUTEST= Data Set for Second Example

Obs	_TYPE_	Y	MU	MA1_1	AR1_1	I1_1	I1_2	I1_3	I1_4	I2_1	I2_2
1	EST	σ^2	μ	θ_1	ϕ_1	ω_{10}	ω_{11}	δ_{11}	δ_{12}	ω_{20}	δ_{21}
2	STD	.	se μ	se θ_1	se ϕ_1	se ω_{10}	se ω_{11}	se δ_{11}	se δ_{12}	se ω_{20}	se δ_{21}
3	FACTOR	.	0	1	1	1	1	-1	-1	1	-1
4	LAG	.	0	1	1	0	1	1	2	0	1
5	SHIFT	.	0	0	0	2	2	2	2	1	1

OUTMODEL= SAS Data Set

The OUTMODEL= option in the ESTIMATE statement writes an output data set that enables you to reconstruct the model. The OUTMODEL= data set contains much the same information as the OUTEST= data set but in a transposed form that might be more useful for some purposes. In addition, the OUTMODEL= data set includes the differencing operators.

The OUTMODEL data set contains the following:

- the BY variables
- `_MODLABEL_`, a character variable that contains the model label, if it is provided by using the label option in the ESTIMATE statement (otherwise this variable is not created).
- `_NAME_`, a character variable that contains the name of the response or input variable for the observation.
- `_TYPE_`, a character variable that contains the estimation method that was employed. The value of `_TYPE_` can be CLS, ULS, or ML.
- `_STATUS_`, a character variable that describes the convergence status of the model. A value of 0 `_CONVERGED` indicates that the model converged.
- `_PARAM_`, a character variable that contains the name of the parameter given by the observation. `_PARAM_` takes on the values ERRORVAR, MU, AR, MA, NUM, DEN, and DIF.
- `_VALUE_`, a numeric variable that contains the value of the estimate defined by the `_PARAM_` variable.
- `_STD_`, a numeric variable that contains the standard error of the estimate.
- `_FACTOR_`, a numeric variable that indicates the number of the factor to which the parameter belongs.
- `_LAG_`, a numeric variable that contains the number of the term within the factor that contains the parameter.
- `_SHIFT_`, a numeric variable that contains the shift value for the input variable associated with the current parameter.

The values of `_FACTOR_` and `_LAG_` identify which particular MA, AR, NUM, or DEN parameter estimate is given by the `_VALUE_` variable. The `_NAME_` variable contains the response variable name for the MU, AR, or MA parameters. Otherwise, `_NAME_` contains the input variable name associated with NUM or DEN parameter estimates. The `_NAME_` variable contains the appropriate variable name associated with the current DIF observation as well. The `_VALUE_` variable is 1 for all DIF observations, and the `_LAG_` variable indicates the degree of differencing employed.

The observations contained in the OUTMODEL= data set are identified by the `_PARAM_` variable. A description of the values of the `_PARAM_` variable follows:

NUMRESID	_VALUE_ contains the number of residuals.
NPARMS	_VALUE_ contains the number of parameters in the model.
NDIFS	_VALUE_ contains the sum of the differencing lags employed for the response variable.
ERRORVAR	_VALUE_ contains the estimate of the innovation variance.
MU	_VALUE_ contains the estimate of the mean term.
AR	_VALUE_ contains the estimate of the autoregressive parameter indexed by the _FACTOR_ and _LAG_ variable values.
MA	_VALUE_ contains the estimate of a moving-average parameter indexed by the _FACTOR_ and _LAG_ variable values.
NUM	_VALUE_ contains the estimate of the parameter in the numerator factor of the transfer function of the input variable indexed by the _FACTOR_, _LAG_, and _SHIFT_ variable values.
DEN	_VALUE_ contains the estimate of the parameter in the denominator factor of the transfer function of the input variable indexed by the _FACTOR_, _LAG_, and _SHIFT_ variable values.
DIF	_VALUE_ contains the difference operator defined by the difference lag given by the value in the _LAG_ variable.

OUTSTAT= Data Set

PROC ARIMA writes the diagnostic statistics for a model to an output data set when the OUTSTAT= option is specified in the ESTIMATE statement. The OUTSTAT data set contains the following:

- the BY variables.
- `_MODLABEL_`, a character variable that contains the model label, if it is provided by using the label option in the ESTIMATE statement (otherwise this variable is not created).
- `_TYPE_`, a character variable that contains the estimation method used. `_TYPE_` can have the value CLS, ULS, or ML.
- `_STAT_`, a character variable that contains the name of the statistic given by the `_VALUE_` variable in this observation. `_STAT_` takes on the values AIC, SBC, LOGLIK, SSE, NUMRESID, NPARMS, NDIFS, ERRORVAR, MU, CONV, and NITER.
- `_VALUE_`, a numeric variable that contains the value of the statistic named by the `_STAT_` variable.

The observations contained in the OUTSTAT= data set are identified by the `_STAT_` variable. A description of the values of the `_STAT_` variable follows:

AIC	Akaike's information criterion
SBC	Schwarz's Bayesian criterion
LOGLIK	the log-likelihood, if METHOD=ML or METHOD=ULS is specified
SSE	the sum of the squared residuals
NUMRESID	the number of residuals
NPARMS	the number of parameters in the model
NDIFS	the sum of the differencing lags employed for the response variable
ERRORVAR	the estimate of the innovation variance
MU	the estimate of the mean term
CONV	tells if the estimation converged. The value of 0 signifies that estimation converged. Nonzero values reflect convergence problems.
NITER	the number of iterations

Remark. CONV takes an integer value that corresponds to the error condition of the parameter estimation process. The value of 0 signifies that estimation process has converged. The higher values signify convergence problems of increasing severity. Specifically:

- CONV = 0 indicates that the estimation process has converged.
- CONV = 1 or 2 indicates that the estimation process has run into numerical problems (such as encountering an unstable model or a ridge) during the iterations.
- CONV \geq 3 indicates that the estimation process has failed to converge.

Printed Output

The ARIMA procedure produces printed output for each of the IDENTIFY, ESTIMATE, and FORECAST statements. The output produced by each ARIMA statement is described in the following sections. If ODS Graphics is enabled, the line printer plots mentioned below are replaced by the corresponding ODS plots.

IDENTIFY Statement Printed Output

The printed output of the IDENTIFY statement consists of the following:

- a table of summary statistics, including the name of the response variable, any specified periods of differencing, the mean and standard deviation of the response series after differencing, and the number of observations after differencing
- a plot of the sample autocorrelation function for lags up to and including the NLAG= option value. Standard errors of the autocorrelations also appear to the right of the autocorrelation

plot if the value of `LINESIZE=` option is sufficiently large. The standard errors are derived using Bartlett's approximation (Box and Jenkins 1976, p. 177). The approximation for a standard error for the estimated autocorrelation function at lag k is based on a null hypothesis that a pure moving-average Gaussian process of order $k-1$ generated the time series. The relative position of an approximate 95% confidence interval under this null hypothesis is indicated by the dots in the plot, while the asterisks represent the relative magnitude of the autocorrelation value.

- a plot of the sample inverse autocorrelation function. See the section “[The Inverse Autocorrelation Function](#)” on page 239 for more information about the inverse autocorrelation function.
- a plot of the sample partial autocorrelation function
- a table of test statistics for the hypothesis that the series is white noise. These test statistics are the same as the tests for white noise residuals produced by the `ESTIMATE` statement and are described in the section “[Estimation Details](#)” on page 248.
- a plot of the sample cross-correlation function for each series specified in the `CROSSCORR=` option. If a model was previously estimated for a variable in the `CROSSCORR=` list, the cross-correlations for that series are computed for the prewhitened input and response series. For each input variable with a prewhitening filter, the cross-correlation report for the input series includes the following:
 - a table of test statistics for the hypothesis of no cross-correlation between the input and response series
 - the prewhitening filter used for the prewhitening transformation of the predictor and response variables
- ESACF tables if the `ESACF` option is used
- MINIC table if the `MINIC` option is used
- SCAN table if the `SCAN` option is used
- `STATIONARITY` test results if the `STATIONARITY` option is used

ESTIMATE Statement Printed Output

The printed output of the `ESTIMATE` statement consists of the following:

- if the `PRINTALL` option is specified, the preliminary parameter estimates and an iteration history that shows the sequence of parameter estimates tried during the fitting process
- a table of parameter estimates that show the following for each parameter: the parameter name, the parameter estimate, the approximate standard error, t value, approximate probability ($Pr > |t|$), the lag for the parameter, the input variable name for the parameter, and the lag or “Shift” for the input variable

- the estimates of the constant term, the innovation variance (variance estimate), the innovation standard deviation (Std Error Estimate), Akaike's information criterion (AIC), Schwarz's Bayesian criterion (SBC), and the number of residuals
- the correlation matrix of the parameter estimates
- a table of test statistics for hypothesis that the residuals of the model are white noise. The table is titled "Autocorrelation Check of Residuals."
- if the PLOT option is specified, autocorrelation, inverse autocorrelation, and partial autocorrelation function plots of the residuals
- if an INPUT variable has been modeled in such a way that prewhitening is performed in the IDENTIFY step, a table of test statistics titled "Crosscorrelation Check of Residuals." The test statistic is based on the chi-square approximation suggested by Box and Jenkins (1976, pp. 395–396). The cross-correlation function is computed by using the residuals from the model as one series and the prewhitened input variable as the other series.
- if the GRID option is specified, the sum-of-squares or likelihood surface over a grid of parameter values near the final estimates
- a summary of the estimated model that shows the autoregressive factors, moving-average factors, and transfer function factors in backshift notation with the estimated parameter values.

OUTLIER Statement Printed Output

The printed output of the OUTLIER statement consists of the following:

- a summary that contains the information about the maximum number of outliers searched, the number of outliers actually detected, and the significance level used in the outlier detection.
- a table that contains the results of the outlier detection process. The outliers are listed in the order in which they are found. This table contains the following columns:
 - The Obs column contains the observation number of the start of the level shift.
 - If an ID= option is specified, then the Time ID column contains the time identification labels of the start of the outlier.
 - The Type column lists the type of the outlier.
 - The Estimate column contains $\hat{\beta}$, the estimate of the regression coefficient of the shock signature.
 - The Chi-Square column lists the value of the test statistic τ^2 .
 - The Approx Prob > ChiSq column lists the approximate p -value of the test statistic.

FORECAST Statement Printed Output

The printed output of the FORECAST statement consists of the following:

- a summary of the estimated model
- a table of forecasts with following columns:
 - The Obs column contains the observation number.
 - The Forecast column contains the forecast values.
 - The Std Error column contains the forecast standard errors.
 - The Lower and Uppers columns contain the approximate 95% confidence limits. The ALPHA= option can be used to change the confidence interval for forecasts.
 - If the PRINTALL option is specified, the forecast table also includes columns for the actual values of the response series (Actual) and the residual values (Residual).

ODS Table Names

PROC ARIMA assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 7.12](#).

Table 7.12 ODS Tables Produced by PROC ARIMA

ODS Table Name	Description	Statement	Option
ChiSqAuto	chi-square statistics table for autocorrelation	IDENTIFY	
ChiSqCross	chi-square statistics table for cross-correlations	IDENTIFY	CROSSCORR
CorrGraph	Correlations graph	IDENTIFY	
DescStats	Descriptive statistics	IDENTIFY	
ESACF	Extended sample autocorrelation function	IDENTIFY	ESACF
ESACFPValues	ESACF probability values	IDENTIFY	ESACF
IACFGraph	Inverse autocorrelations graph	IDENTIFY	
InputDescStats	Input descriptive statistics	IDENTIFY	
MINIC	Minimum information criterion	IDENTIFY	MINIC
PACFGraph	Partial autocorrelations graph	IDENTIFY	
SCAN	Squared canonical correlation estimates	IDENTIFY	SCAN
SCANPValues	SCAN chi-square probability values	IDENTIFY	SCAN
StationarityTests	Stationarity tests	IDENTIFY	STATIONARITY
TentativeOrders	Tentative order selection	IDENTIFY	MINIC, ESACF, or SCAN
ARPolynomial	Filter equations	ESTIMATE	

Table 7.12 *continued*

ODS Table Name	Description	Statement	Option

Statistical Graphics

This section provides information about the basic ODS statistical graphics produced by the ARIMA procedure. To request graphics with PROC ARIMA, you must first enable ODS Graphics by specifying the `ODS GRAPHICS ON;` statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for more information. The main types of plots available are as follows:

- plots useful in the trend and correlation analysis of the dependent and input series
- plots useful for the residual analysis of an estimated model
- forecast plots

You can obtain most plots relevant to the specified model by default if ODS Graphics is enabled. For finer control of the graphics, you can use the **PLOTS=** option in the PROC ARIMA statement. The following example is a simple illustration of how to use the **PLOTS=** option.

Airline Series: Illustration of ODS Graphics

The series in this example, the monthly airline passenger series, is also discussed later, in [Example 7.2](#).

The following statements specify an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model without a mean term to the logarithms of the airline passengers series, `xlog`. Notice the use of the global plot option **ONLY** in the **PLOTS=** option of the PROC ARIMA statement. It suppresses the production of default graphics and produces only the plots specified by the subsequent **RESIDUAL** and **FORECAST** plot options. The **RESIDUAL (SMOOTH)** plot specification produces a time series plot of residuals that has an overlaid loess fit; see [Figure 7.21](#). The **FORECAST (FORECAST)** option produces a plot that shows the one-step-ahead forecasts, as well as the multistep-ahead forecasts; see [Figure 7.22](#).

```
proc arima data=seriesg
  plots(only)=(residual(smooth) forecast(forecasts));
  identify var=xlog(1,12);
  estimate q=(1)(12) noint method=ml;
  forecast id=date interval=month;
run;
```

ODS Graph Names

PROC ARIMA assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in [Table 7.13](#).

Table 7.13 ODS Graphics Produced by PROC ARIMA

ODS Graph Name	Plot Description	Option
SeriesPlot	Time series plot of the dependent series	PLOTS(UNPACK)
SeriesACFPlot	Autocorrelation plot of the dependent series	PLOTS(UNPACK)
SeriesPACFPlot	Partial-autocorrelation plot of the dependent series	PLOTS(UNPACK)
SeriesIACFPlot	Inverse-autocorrelation plot of the dependent series	PLOTS(UNPACK)
SeriesCorrPanel	Series trend and correlation analysis panel	Default

Table 7.13 continued

ODS Graph Name	Plot Description	Option
CrossCorrPanel	Cross-correlation plots, either individual or paneled. They are numbered 1, 2, and so on as needed.	Default
ResidualACFPlot	Residual-autocorrelation plot	PLOTS(UNPACK)
ResidualPACFPlot	Residual-partial-autocorrelation plot	PLOTS(UNPACK)
ResidualIACFPlot	Residual-inverse-autocorrelation plot	PLOTS(UNPACK)
ResidualWNPlot	Residual-white-noise-probability plot	PLOTS(UNPACK)
ResidualHistogram	Residual histogram	PLOTS(UNPACK)
ResidualQQPlot	Residual normal Q-Q Plot	PLOTS(UNPACK)
ResidualPlot	Time series plot of residuals with a superimposed smoother	PLOTS=RESIDUAL(SMOOTH)
ForecastsOnlyPlot	Time series plot of multistep forecasts	Default
ForecastsPlot	Time series plot of one-step-ahead as well as multistep forecasts	PLOTS=FORECAST(FORCAST)

Examples: ARIMA Procedure

Example 7.1: Simulated IMA Model

This example illustrates the ARIMA procedure results for a case where the true model is known. An integrated moving-average model is used for this illustration.

The following DATA step generates a pseudo-random sample of 100 periods from the ARIMA(0,1,1) process $u_t = u_{t-1} + a_t - 0.8a_{t-1}$, a_t iid $N(0, 1)$:

```

title1 'Simulated IMA(1,1) Series';
data a;
  u1 = 0.9; a1 = 0;
  do i = -50 to 100;

```

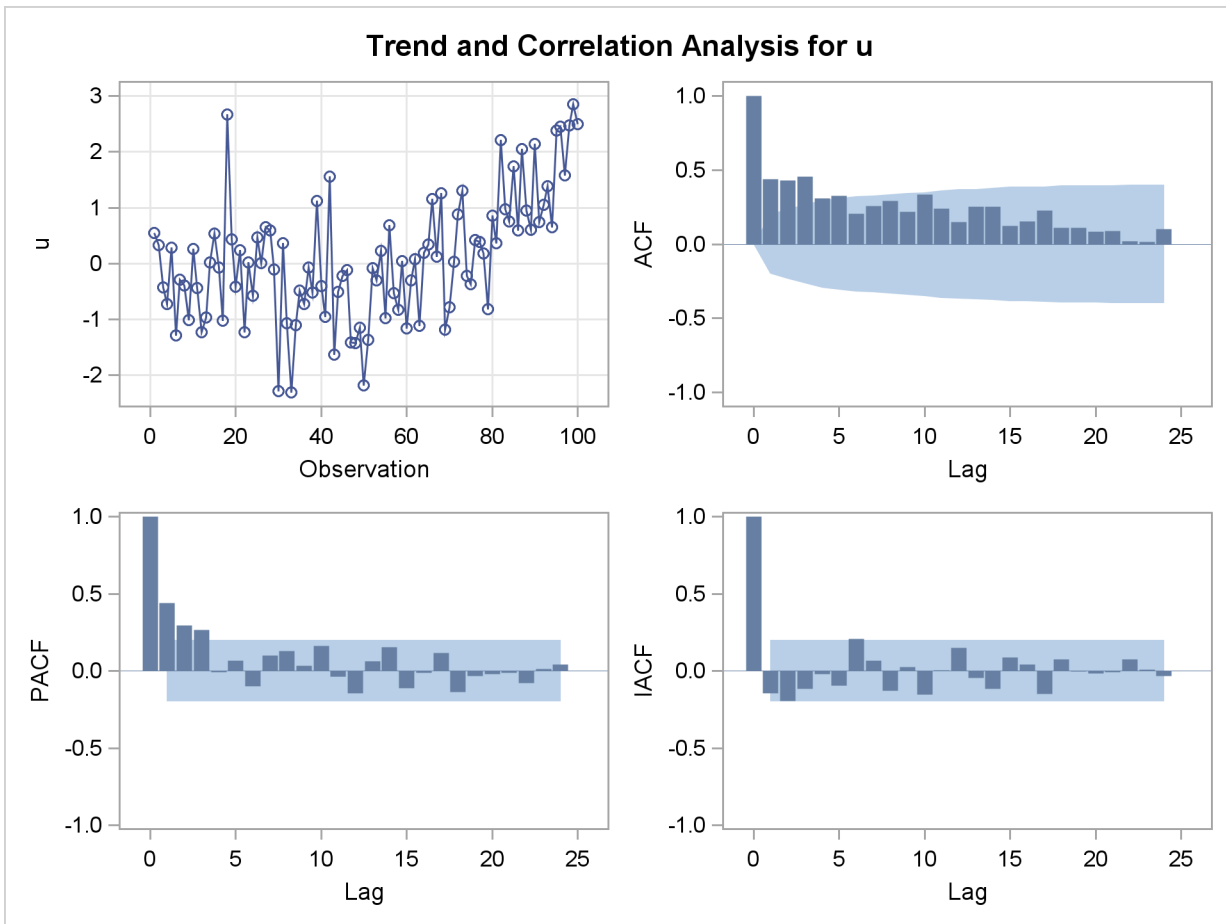

```
      a = rannor( 32565 );
      u = u1 + a - .8 * a1;
      if i > 0 then output;
      a1 = a;
      u1 = u;
    end;
  run;
```

The following ARIMA procedure statements identify and estimate the model:

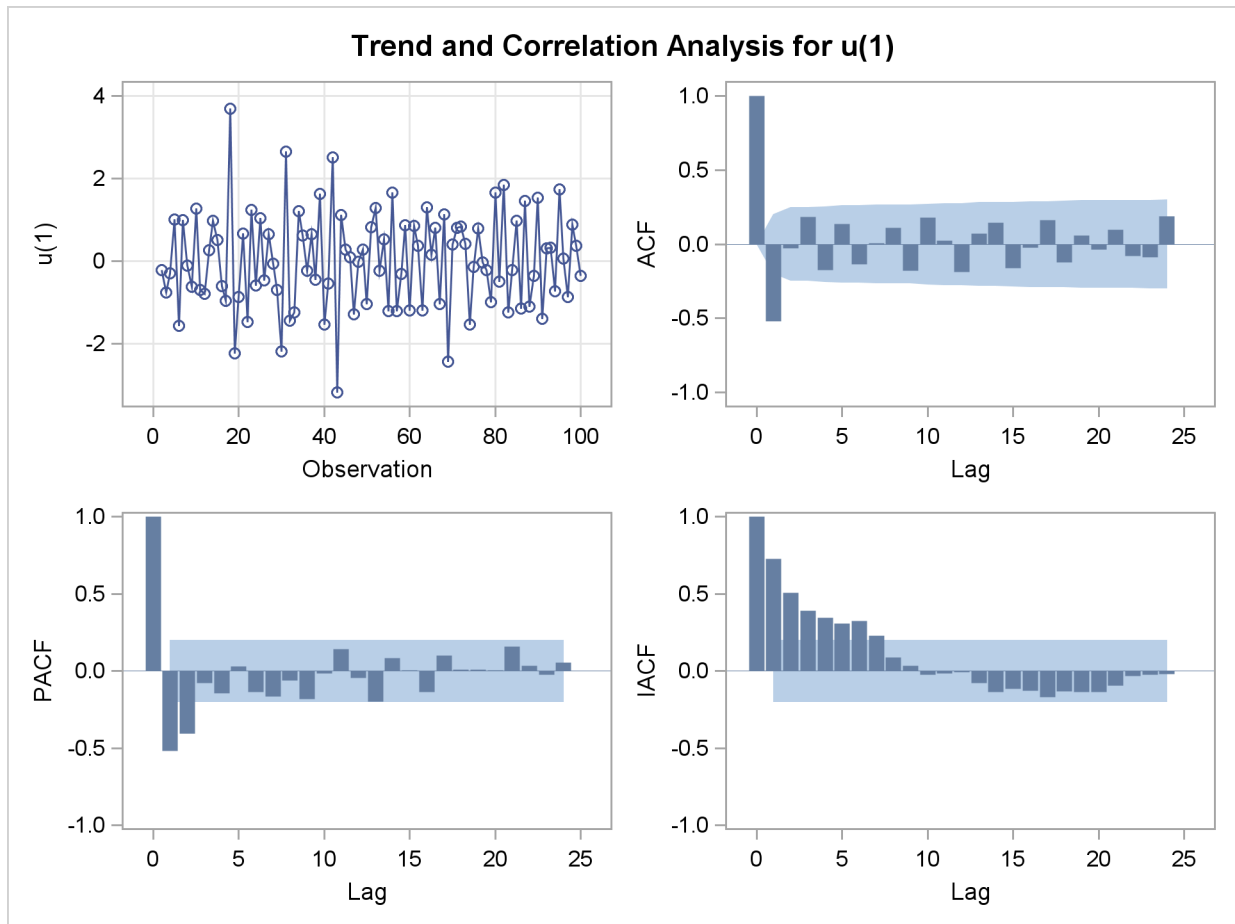

```
/*-- Simulated IMA Model --*/
proc arima data=a;
  identify var=u;
  run;
  identify var=u(1);
  run;
  estimate q=1 ;
  run;
quit;
```

The graphical series correlation analysis output of the first IDENTIFY statement is shown in [Output 7.1.1](#). The output shows the behavior of the sample autocorrelation function when the process is nonstationary. Note that in this case the estimated autocorrelations are not very high, even at small lags. Nonstationarity is reflected in a pattern of significant autocorrelations that do not decline quickly with increasing lag, not in the size of the autocorrelations.

Output 7.1.1 Correlation Analysis from the First IDENTIFY Statement

The second IDENTIFY statement differences the series. The results of the second IDENTIFY statement are shown in [Output 7.1.2](#). This output shows autocorrelation, inverse autocorrelation, and partial autocorrelation functions typical of MA(1) processes.

Output 7.1.2 Correlation Analysis from the Second IDENTIFY Statement

The ESTIMATE statement fits an ARIMA(0,1,1) model to the simulated data. Note that in this case the parameter estimates are reasonably close to the values used to generate the simulated data. ($\mu = 0$, $\hat{\mu} = 0.02$; $\theta_1 = 0.8$, $\hat{\theta}_1 = 0.79$; $\sigma^2 = 1$, $\hat{\sigma}^2 = 0.82$.) Moreover, the graphical analysis of the residuals shows no model inadequacies (see [Output 7.1.4](#) and [Output 7.1.5](#)).

The ESTIMATE statement results are shown in [Output 7.1.3](#).

Output 7.1.3 Output from Fitting ARIMA(0,1,1) Model

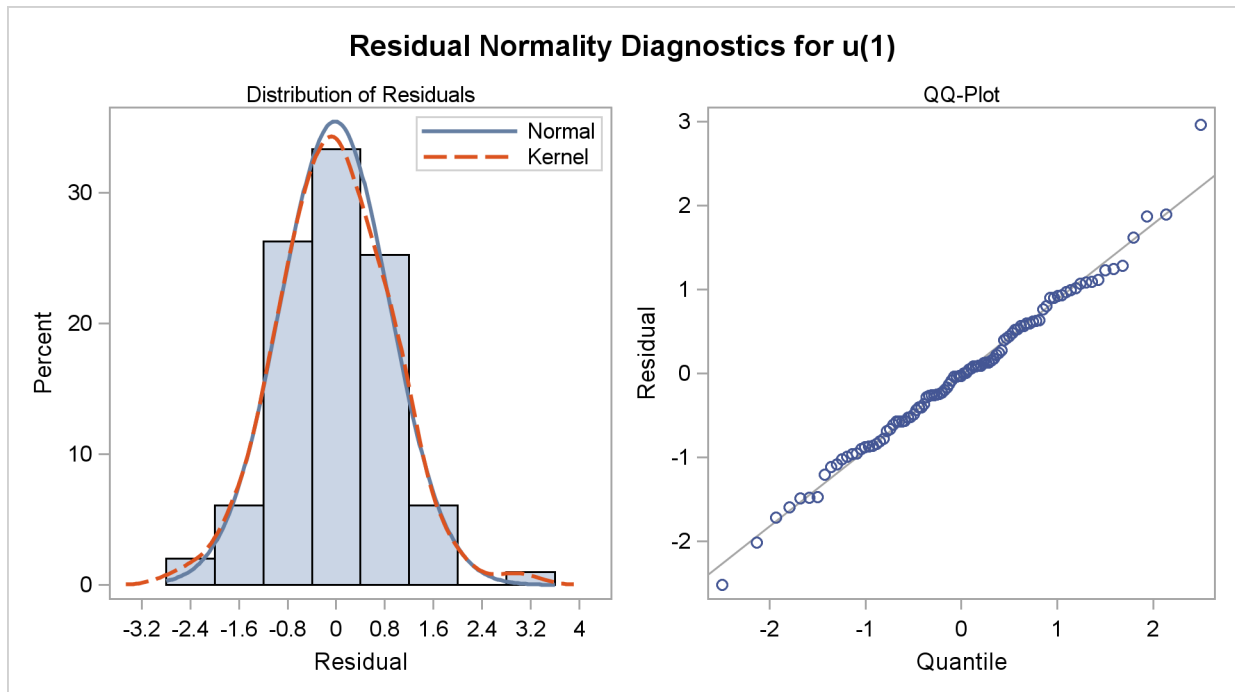

Conditional Least Squares Estimation

Output 7.1.4 Residual Correlation Analysis of the ARIMA(0,1,1) Model

Output 7.1.5 Residual Normality Analysis of the ARIMA(0,1,1) Model**Example 7.2: Seasonal Model for the Airline Series**

The airline passenger data, given as Series G in Box and Jenkins (1976), have been used in time series analysis literature as an example of a nonstationary seasonal time series. This example uses PROC ARIMA to fit the airline model, $ARIMA(0,1,1) \times (0,1,1)_{12}$, to Box and Jenkins' Series G. The following statements read the data and log-transform the series:

```

title1 'International Airline Passengers';
title2 '(Box and Jenkins Series-G)';
data seriesg;
  input x @@;
  xlog = log( x );
  date = intnx( 'month', '31dec1948'd, _n_ );
  format date monyy.;
datalines;

... more lines ...

```

The following PROC TIMESERIES step plots the series, as shown in [Output 7.2.1](#):

```

proc timeseries data=seriesg plot=series;
  id date interval=month;
  var x;
run;

```

Output 7.2.1 Time Series Plot of the Airline Passenger Series

The following statements specify an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model without a mean term to the logarithms of the airline passengers series, `xlog`. The model is forecast, and the results are stored in the data set `B`.

```

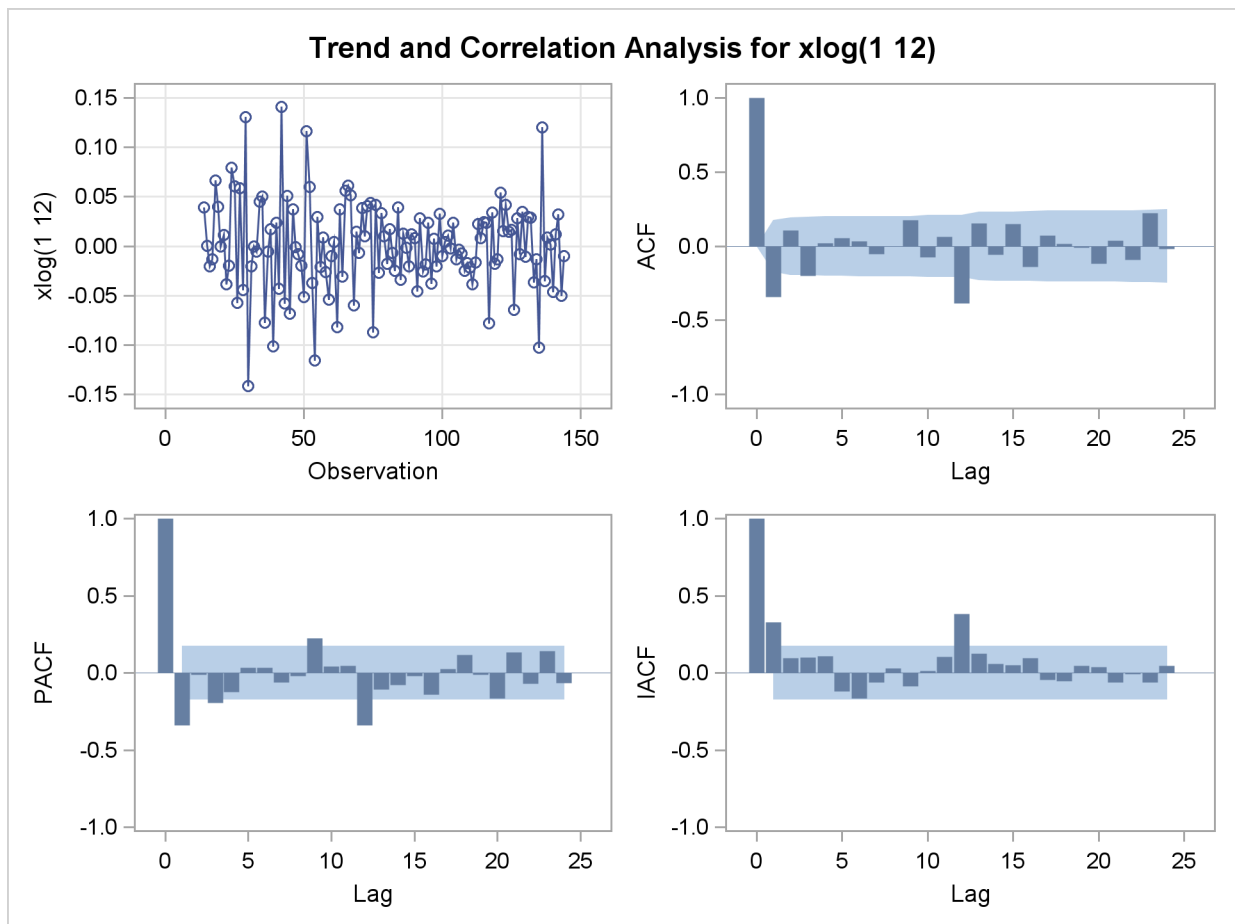

/*-- Seasonal Model for the Airline Series --*/
proc arima data=seriesg;
  identify var=xlog(1,12);
  estimate q=(1)(12) noint method=ml;
  forecast id=date interval=month printall out=b;
run;

```

The output from the `IDENTIFY` statement is shown in [Output 7.2.2](#). The autocorrelation plots shown are for the twice differenced series $(1 - B)(1 - B^{12})XLOG$. Note that the autocorrelation functions have the pattern characteristic of a first-order moving-average process combined with a seasonal moving-average process with lag 12.

Output 7.2.2 IDENTIFY Statement Output

Output 7.2.5 Residual Analysis of the Airline Model: Correlation

Output 7.2.6 Residual Analysis of the Airline Model: Normality

The forecasts and their confidence limits for the transformed series are shown in [Output 7.2.7](#).

Output 7.2.7 Forecast Plot for the Transformed Series

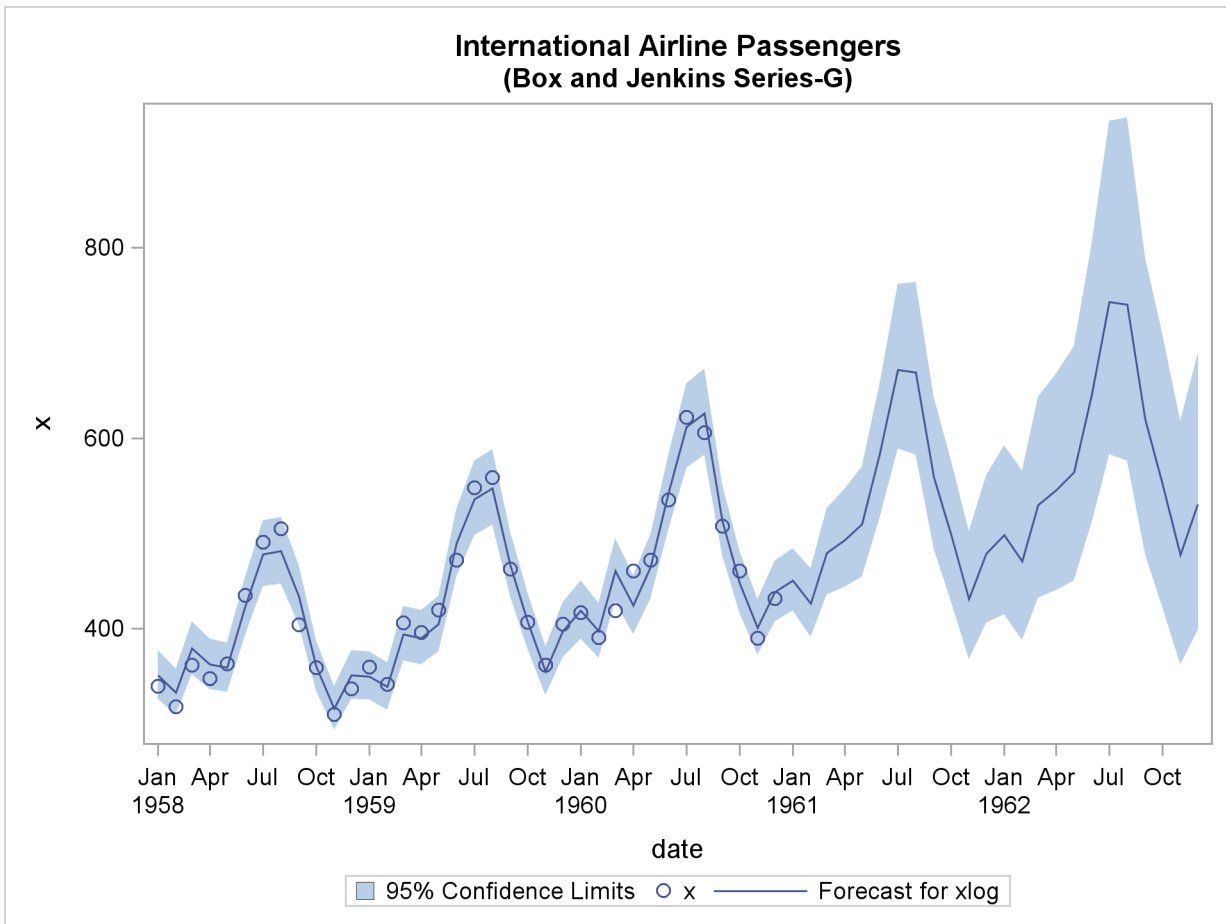

The following statements retransform the forecast values to get forecasts in the original scales. See the section “[Forecasting Log Transformed Data](#)” on page 258 for more information.

```
data c;
  set b;
  x      = exp( xlog );
  forecast = exp( forecast + std*std/2 );
  l95    = exp( l95 );
  u95    = exp( u95 );
run;
```

The forecasts and their confidence limits are plotted by using the following PROC SGPLOT step. The plot is shown in [Output 7.2.8](#).

```
proc sgplot data=c;
  where date >= '1jan58'd;
  band Upper=u95 Lower=l95 x=date
    / LegendLabel="95% Confidence Limits";
  scatter x=date y=x;
  series x=date y=forecast;
run;
```

Output 7.2.8 Plot of the Forecast for the Original Series**Example 7.3: Model for Series J Data from Box and Jenkins**

This example uses the Series J data from Box and Jenkins (1976). First, the input series X is modeled with a univariate ARMA model. Next, the dependent series Y is cross-correlated with the input series. Since a model has been fit to X , both Y and X are prewhitened by this model before the sample cross-correlations are computed. Next, a transfer function model is fit with no structure on the noise term. The residuals from this model are analyzed; then, the full model, transfer function and noise, is fit to the data.

The following statements read 'Input Gas Rate' and 'Output CO₂' from a gas furnace. (Data values are not shown. The full example including data is in the SAS/ETS sample library.)

```

title1 'Gas Furnace Data';
title2 '(Box and Jenkins, Series J)';
data seriesj;
  input x y @@;
  label x = 'Input Gas Rate'
        y = 'Output CO2';
datalines;

```

```
... more lines ...
```

The following statements produce [Output 7.3.1](#) through [Output 7.3.11](#):

```
proc arima data=seriesj;

  /*--- Look at the input process -----*/
  identify var=x;
  run;

  /*--- Fit a model for the input -----*/
  estimate p=3 plot;
  run;

  /*--- Crosscorrelation of prewhitened series -----*/
  identify var=y crosscorr=(x) nlag=12;
  run;

  /*- Fit a simple transfer function - look at residuals -*/
  estimate input=( 3 $ (1,2)/(1) x );
  run;

  /*--- Final Model - look at residuals ---*/
  estimate p=2 input=( 3 $ (1,2)/(1) x );
  run;

quit;
```

The results of the first IDENTIFY statement for the input series X are shown in [Output 7.3.1](#). The correlation analysis suggests an AR(3) model.

Example 7.4: An Intervention Model for Ozone Data

This example fits an intervention model to ozone data as suggested by Box and Tiao (1975). Notice that the response variable, OZONE, and the innovation, X1, are seasonally differenced. The final model for the differenced data is a multiple regression model with a moving-average structure assumed for the residuals.

The model is fit by maximum likelihood. The seasonal moving-average parameter and its standard error are fairly sensitive to which method is chosen to fit the model, in agreement with the observations of Davidson (1981) and Ansley and Newbold (1980); thus, fitting the model by the unconditional or conditional least squares method produces somewhat different estimates for these parameters.

Some missing values are appended to the end of the input data to generate additional values for the independent variables. Since the independent variables are not modeled, values for them must be available for any times at which predicted values are desired. In this case, predicted values are requested for 12 periods beyond the end of the data. Thus, values for X1, WINTER, and SUMMER must be given for 12 periods ahead.

The following statements read in the data and compute dummy variables for use as intervention inputs:

```

title1 'Intervention Data for Ozone Concentration';
title2 '(Box and Tiao, JASA 1975 P.70)';
data air;
  input ozone @@;
  label ozone = 'Ozone Concentration'
        x1     = 'Intervention for post 1960 period'
        summer = 'Summer Months Intervention'
        winter = 'Winter Months Intervention';
  date = intnx( 'month', '31dec1954'd, _n_ );
  format date monyy.;
  month = month( date );
  year  = year( date );
  x1    = year >= 1960;
  summer = ( 5 < month < 11 ) * ( year > 1965 );
  winter = ( year > 1965 ) - summer;
datalines;
2.7  2.0  3.6  5.0  6.5  6.1  5.9  5.0  6.4  7.4  8.2  3.9

Example 7.5: Using Diagnostics to Identify ARIMA Models

Fitting ARIMA models is as much an art as it is a science. The ARIMA procedure has diagnostic options to help tentatively identify the orders of both stationary and nonstationary ARIMA processes.

Consider the Series A in Box, Jenkins, and Reinsel (1994), which consists of 197 concentration readings taken every two hours from a chemical process. Let Series A be a data set that contains these readings in a variable named X. The following SAS statements use the SCAN option of the IDENTIFY statement to generate [Output 7.5.1](#) and [Output 7.5.2](#). See “[The SCAN Method](#)” on page 244 for details of the SCAN method.

```

/*-- Order Identification Diagnostic with SCAN Method --*/
proc arima data=SeriesA;
  identify var=x scan;
run;

```

Output 7.5.1 Example of SCAN Tables

```

In [Output 7.5.3](#), there are three right-triangular regions in which all elements are insignificant at the 5% level. The triangles have vertices (1,1), (3,1), and (4,1). Since the triangle at (1,1) covers more insignificant terms, it is recommended first. Similarly, the remaining recommendations are ordered by the number of insignificant terms contained in the triangle. [Output 7.5.4](#) gives recommendations based on the significance level specified by the ALPHA=*siglevel* option.

Order Selection Tests			
---SCAN---		--ESACF--	
p+d	q	p+d	q
1	1	1	1
		3	1
		4	1
(5% Significance Level)			

From Output 7.5.5, the autoregressive and moving-average orders are tentatively identified by both SCAN and ESACF tables to be $(p + d, q) = (1, 1)$. Because both the SCAN and ESACF indicate a $p + d$ term of 1, a unit root test should be used to determine whether this autoregressive term is a unit root. Since a moving-average term appears to be present, a large autoregressive term is appropriate for the augmented Dickey-Fuller test for a unit root.

Submitting the following statements generates Output 7.5.6:

```
/*-- Augmented Dickey-Fuller Unit Root Tests --*/
proc arima data=SeriesA;
    identify var=x stationarity=(adf=(5, 6, 7, 8));
run;
```

Output 7.5.6 Example of STATIONARITY Option Output

	8	-10.0370	0.4236	-1.79	0.7081	1.74	0.8293

The preceding test results show that a unit root is very likely given that none of the p -values are small enough to cause you to reject the null hypothesis that the series has a unit root. Based on this test and the previous results, the series should be differenced, and an ARIMA(0,1,1) would be a good choice for a tentative model for Series A.

Using the recommendation that the series be differenced, the following statements generate [Output 7.5.7](#):

```

/*-- Minimum Information Criterion --*/
proc arima data=SeriesA;
  identify var=x(1) minic;
run;

```

Output 7.5.7 Example of MINIC Table

SERIES A: Chemical Process Concentration Readings						
The ARIMA Procedure						
Minimum Information Criterion						
Lags	MA 0	MA 1	MA 2	MA 3	MA 4	MA 5
AR 0	-2.05761	-2.3497	-2.32358	-2.31298	-2.30967	-2.28528
AR 1	-2.23291	-2.32345	-2.29665	-2.28644	-2.28356	-2.26011
AR 2	-2.23947	-2.30313	-2.28084	-2.26065	-2.25685	-2.23458
AR 3	-2.25092	-2.28088	-2.25567	-2.23455	-2.22997	-2.20769
AR 4	-2.25934	-2.2778	-2.25363	-2.22983	-2.20312	-2.19531
AR 5	-2.2751	-2.26805	-2.24249	-2.21789	-2.19667	-2.17426

The error series is estimated by using an AR(7) model, and the minimum of this MINIC table is $BIC(0, 1)$. This diagnostic confirms the previous result which indicates that an ARIMA(0,1,1) is a tentative model for Series A.

If you also specify the SCAN or MINIC option in the same IDENTIFY statement as follows, the BIC associated with the SCAN table and ESACF table recommendations is listed. [Output 7.5.8](#) shows the results.

```

/*-- Combination of MINIC, SCAN, and ESACF Options --*/
proc arima data=SeriesA;
  identify var=x(1) minic scan esacf;
run;

```

Output 7.5.8 Example of SCAN, ESACF, MINIC Options Combined

Example 7.6: Detection of Level Changes in the Nile River Data

This example shows how to use the OUTLIER statement to detect changes in the dynamics of the time series being modeled. The time series used here is discussed in de Jong and Penzer (1998). The data consist of readings of the annual flow volume of the Nile River at Aswan from 1871 to 1970. These data have also been studied by Cobb (1978). These studies indicate that river flow levels in the years 1877 and 1913 are strong candidates for additive outliers and that there was a shift in the flow levels starting from the year 1899. This shift in 1899 is attributed partly to the weather changes and partly to the start of construction work for a new dam at Aswan. The following DATA step statements create the input data set.

```

data nile;
  input level @@;
  year = intnx('year', '1jan1871'd, _n_-1 );
  format year year4.;
datalines;
1120 1160 963 1210 1160 1160 813 1230 1370 1140
995 935 1110 994 1020 960 1180 799 958 1140
... more lines ...

```

The following program fits an ARIMA model, ARIMA(0,1,1), similar to the structural model suggested in de Jong and Penzer (1998). This model is also suggested by the usual correlation analysis of the series. By default, the OUTLIER statement requests detection of additive outliers and level shifts, assuming that the series follows the estimated model.

```

/*-- ARIMA(0, 1, 1) Model --*/
proc arima data=nile;
  identify var=level(1);
  estimate q=1 noint method=ml;
  outlier maxnum= 5 id=year;
run;

```

The outlier detection output is shown in [Output 7.6.1](#).

Output 7.6.1 ARIMA(0, 1, 1) Model

SERIES A: Chemical Process Concentration Readings						
The ARIMA Procedure						
Outlier Detection Summary						
Maximum number searched						5
Number found						5
Significance used						0.05
Outlier Details						
Obs	Time ID	Type	Estimate	Chi-Square	Approx Prob>	ChiSq
29	1899	Shift	-315.75346	13.13	0.0003	
43	1913	Additive	-403.97105	11.83	0.0006	
7	1877	Additive	-335.49351	7.69	0.0055	
94	1964	Additive	305.03568	6.16	0.0131	
18	1888	Additive	-287.81484	6.00	0.0143	

Note that the first three outliers detected are indeed the ones discussed earlier. You can include the shock signatures that correspond to these three outliers in the Nile data set as follows:

```

data nile;
  set nile;
  AO1877 = ( year = '1jan1877'd );
  AO1913 = ( year = '1jan1913'd );
  LS1899 = ( year >= '1jan1899'd );
run;

```

Now you can refine the earlier model by including these outliers. After examining the parameter estimates and residuals (not shown) of the ARIMA(0,1,1) model with these regressors, the following stationary MA1 model (with regressors) appears to fit the data well:

```

/*-- MA1 Model with Outliers --*/
proc arima data=nile;
  identify var=level
           crosscorr=( AO1877 AO1913 LS1899 );
  estimate q=1
           input=( AO1877 AO1913 LS1899 )
           method=ml;
  outlier maxnum=5 alpha=0.01 id=year;
run;

```

The relevant outlier detection process output is shown in [Output 7.6.2](#). No outliers, at significance level 0.01, were detected.

Output 7.6.2 MA1 Model with Outliers

SERIES A: Chemical Process Concentration Readings	
The ARIMA Procedure	
Outlier Detection Summary	
Maximum number searched	5
Number found	0
Significance used	0.01

Example 7.7: Iterative Outlier Detection

This example illustrates the iterative nature of the outlier detection process. This is done by using a simple test example where an additive outlier at observation number 50 and a level shift at observation number 100 are artificially introduced in the international airline passenger data used in [Example 7.2](#). The following DATA step shows the modifications introduced in the data set:

```

data airline;
  set sashelp.air;
  logair = log(air);
  if _n_ = 50 then logair = logair - 0.25;
  if _n_ >= 100 then logair = logair + 0.5;
run;

```

In [Example 7.2](#) the airline model, $ARIMA(0, 1, 1) \times (0, 1, 1)_{12}$, was seen to be a good fit to the unmodified log-transformed airline passenger series. The preliminary identification steps (not shown) again suggest the airline model as a suitable initial model for the modified data. The following statements specify the airline model and request an outlier search.

```

/*-- Outlier Detection --*/
proc arima data=airline;
  identify var=logair( 1, 12 ) noprint;
  estimate q= (1)(12) noint method= ml;

```

```

outlier maxnum=3 alpha=0.01;
run;

```

The outlier detection output is shown in [Output 7.7.1](#).

Output 7.7.1 Initial Model

SERIES A: Chemical Process Concentration Readings				
The ARIMA Procedure				
Outlier Detection Summary				
Maximum number searched		3		
Number found		3		
Significance used		0.01		
Outlier Details				
Obs	Type	Estimate	Chi-Square	Approx Prob> ChiSq
100	Shift	0.49325	199.36	<.0001
50	Additive	-0.27508	104.78	<.0001
135	Additive	-0.10488	13.08	0.0003

Clearly the level shift at observation number 100 and the additive outlier at observation number 50 are the dominant outliers. Moreover, the corresponding regression coefficients seem to correctly estimate the size and sign of the change. You can augment the airline data with these two regressors, as follows:

```

data airline;
  set airline;
  if _n_ = 50 then AO = 1;
  else AO = 0.0;
  if _n_ >= 100 then LS = 1;
  else LS = 0.0;
run;

```

You can now refine the previous model by including these regressors, as follows. Note that the differencing order of the dependent series is matched to the differencing orders of the outlier regressors to get the correct “effective” outlier signatures.

```

/*-- Airline Model with Outliers --*/
proc arima data=airline;
  identify var=logair(1, 12)
           crosscorr=( AO(1, 12) LS(1, 12) )
           noprint;
  estimate q= (1)(12) noint
           input=( AO LS )
           method=ml plot;
  outlier maxnum=3 alpha=0.01;

```

```
run;
```

The outlier detection results are shown in [Output 7.7.2](#).

Output 7.7.2 Airline Model with Outliers

SERIES A: Chemical Process Concentration Readings				
The ARIMA Procedure				
Outlier Detection Summary				
Maximum number searched		3		
Number found		3		
Significance used		0.01		
Outlier Details				
Obs	Type	Estimate	Chi-Square	Approx Prob> ChiSq
135	Additive	-0.10310	12.63	0.0004
62	Additive	-0.08872	12.33	0.0004
29	Additive	0.08686	11.66	0.0006

The output shows that a few outliers still remain to be accounted for and that the model could be refined further.

Overview: AUTOREG Procedure

The AUTOREG procedure estimates and forecasts linear regression models for time series data when the errors are autocorrelated or heteroscedastic. The autoregressive error model is used to correct for autocorrelation, and the generalized autoregressive conditional heteroscedasticity (GARCH) model and its variants are used to model and correct for heteroscedasticity.

When time series data are used in regression analysis, often the error term is not independent through time. Instead, the errors are *serially correlated* or *autocorrelated*. If the error term is autocorrelated, the efficiency of ordinary least squares (OLS) parameter estimates is adversely affected and standard error estimates are biased.

The autoregressive error model corrects for serial correlation. The AUTOREG procedure can fit autoregressive error models of any order and can fit subset autoregressive models. You can also specify stepwise autoregression to select the autoregressive error model automatically.

To diagnose autocorrelation, the AUTOREG procedure produces generalized Durbin-Watson (DW) statistics and their marginal probabilities. Exact p -values are reported for generalized DW tests to any specified order. For models with lagged dependent regressors, PROC AUTOREG performs the Durbin t test and the Durbin h test for first-order autocorrelation and reports their marginal significance levels.

Ordinary regression analysis assumes that the error variance is the same for all observations. When the error variance is not constant, the data are said to be *heteroscedastic*, and ordinary least squares estimates are inefficient. Heteroscedasticity also affects the accuracy of forecast confidence limits. More efficient use of the data and more accurate prediction error estimates can be made by models that take the heteroscedasticity into account.

To test for heteroscedasticity, the AUTOREG procedure uses the portmanteau test statistics and the Engle Lagrange multiplier tests. Test statistics and significance p -values are reported for conditional heteroscedasticity at lags 1 through 12. The Bera-Jarque normality test statistic and its significance level are also reported to test for conditional nonnormality of residuals.

The family of GARCH models provides a means of estimating and correcting for the changing variability of the data. The GARCH process assumes that the errors, although uncorrelated, are not independent and models the conditional error variance as a function of the past realizations of the series.

The AUTOREG procedure supports the following variations of the GARCH models:

- generalized ARCH (GARCH)
- integrated GARCH (IGARCH)
- exponential GARCH (EGARCH)
- GARCH-in-mean (GARCH-M)

For GARCH-type models, the AUTOREG procedure produces the conditional prediction error variances as well as parameter and covariance estimates.

The AUTOREG procedure can also analyze models that combine autoregressive errors and GARCH-type heteroscedasticity. PROC AUTOREG can output predictions of the conditional mean and variance for models with autocorrelated disturbances and changing conditional error variances over time.

Four estimation methods are supported for the autoregressive error model:

- Yule-Walker
- iterated Yule-Walker
- unconditional least squares
- exact maximum likelihood

The maximum likelihood method is used for GARCH models and for mixed AR-GARCH models.

The AUTOREG procedure produces forecasts and forecast confidence limits when future values of the independent variables are included in the input data set. PROC AUTOREG is a useful tool for forecasting because it uses the time series part of the model as well as the systematic part in generating predicted values. The autoregressive error model takes into account recent departures from the trend in producing forecasts.

The AUTOREG procedure permits embedded missing values for the independent or dependent variables. The procedure should be used only for ordered and equally spaced time series data.

Getting Started: AUTOREG Procedure

Regression with Autocorrelated Errors

Ordinary regression analysis is based on several statistical assumptions. One key assumption is that the errors are independent of each other. However, with time series data, the ordinary regression residuals usually are correlated over time. It is not desirable to use ordinary regression analysis for

time series data since the assumptions on which the classical linear regression model is based will usually be violated.

Violation of the independent errors assumption has three important consequences for ordinary regression. First, statistical tests of the significance of the parameters and the confidence limits for the predicted values are not correct. Second, the estimates of the regression coefficients are not as efficient as they would be if the autocorrelation were taken into account. Third, since the ordinary regression residuals are not independent, they contain information that can be used to improve the prediction of future values.

The AUTOREG procedure solves this problem by augmenting the regression model with an autoregressive model for the random error, thereby accounting for the autocorrelation of the errors. Instead of the usual regression model, the following autoregressive error model is used:

$$y_t = \mathbf{x}'_t \boldsymbol{\beta} + v_t$$

$$v_t = -\varphi_1 v_{t-1} - \varphi_2 v_{t-2} - \dots - \varphi_m v_{t-m} + \epsilon_t$$

$$\epsilon_t \sim \text{IN}(0, \sigma^2)$$

The notation $\epsilon_t \sim \text{IN}(0, \sigma^2)$ indicates that each ϵ_t is normally and independently distributed with mean 0 and variance σ^2 .

By simultaneously estimating the regression coefficients $\boldsymbol{\beta}$ and the autoregressive error model parameters φ_i , the AUTOREG procedure corrects the regression estimates for autocorrelation. Thus, this kind of regression analysis is often called *autoregressive error correction* or *serial correlation correction*.

Example of Autocorrelated Data

A simulated time series is used to introduce the AUTOREG procedure. The following statements generate a simulated time series Y with second-order autocorrelation:

```
/* Regression with Autocorrelated Errors */
data a;
  ul = 0; ull = 0;
  do time = -10 to 36;
    u = + 1.3 * ul - .5 * ull + 2*rannor(12346);
    y = 10 + .5 * time + u;
    if time > 0 then output;
    ull = ul; ul = u;
  end;
run;
```

The series Y is a time trend plus a second-order autoregressive error. The model simulated is

$$y_t = 10 + 0.5t + v_t$$

$$v_t = 1.3v_{t-1} - 0.5v_{t-2} + \epsilon_t$$

$$\epsilon_t \sim \text{IN}(0, 4)$$

The following statements plot the simulated time series Y. A linear regression trend line is shown for reference.

```
title 'Autocorrelated Time Series';
proc sgplot data=a noautolegend;
```

```

series x=time y=y / markers;
reg x=time y=y/ lineattrs=(color=black);
run;

```

The plot of series Y and the regression line are shown in [Figure 8.1](#).

Figure 8.1 Autocorrelated Time Series

Note that when the series is above (or below) the OLS regression trend line, it tends to remain above (below) the trend for several periods. This pattern is an example of *positive autocorrelation*.

Time series regression usually involves independent variables other than a time trend. However, the simple time trend model is convenient for illustrating regression with autocorrelated errors, and the series Y shown in [Figure 8.1](#) is used in the following introductory examples.

Ordinary Least Squares Regression

To use the AUTOREG procedure, specify the input data set in the PROC AUTOREG statement and specify the regression model in a MODEL statement. Specify the model by first naming the dependent variable and then listing the regressors after an equal sign, as is done in other SAS regression procedures. The following statements regress Y on TIME by using ordinary least squares:

```
proc autoreg data=a;
  model y = time;
run;
```

The AUTOREG procedure output is shown in Figure 8.2.

Figure 8.2 PROC AUTOREG Results for OLS Estimation

Autocorrelated Time Series

Intercept	1	8.2308	0.8559	9.62	<.0001
time	1	0.5021	0.0403	12.45	<.0001

The output first shows statistics for the model residuals. The model root mean square error (Root MSE) is 2.51, and the model R^2 is 0.82. Notice that two R^2 statistics are shown, one for the regression model (Reg Rsq) and one for the full model (Total Rsq) that includes the autoregressive error process, if any. In this case, an autoregressive error model is not used, so the two R^2 statistics are the same.

Other statistics shown are the sum of square errors (SSE), mean square error (MSE), mean absolute error (MAE), mean absolute percentage error (MAPE), error degrees of freedom (DFE, the number of observations minus the number of parameters), the information criteria SBC, AIC, and AICC, and the Durbin-Watson statistic. (Durbin-Watson statistics, MAE, MAPE, SBC, AIC, and AICC are discussed in the section “R-Square Statistics and Other Measures of Fit” on page 367 later in this chapter.)

The output then shows a table of regression coefficients, with standard errors and t tests. The estimated model is

$$y_t = 8.23 + 0.502t + \epsilon_t$$

$$Est. Var(\epsilon_t) = 6.32$$

Figure 8.3 continued

AR1	1	-1.2464	0.1385	-9.00	<.0001
AR2	1	0.6283	0.1366	4.60	<.0001
Autoregressive parameters assumed given.					
Variable	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	7.8833	1.1678	6.75	<.0001
time	1	0.5096	0.0551	9.26	<.0001

The diagnostic statistics and parameter estimates tables in Figure 8.4 have the same form as in the OLS output, but the values shown are for the autoregressive error model. The MSE for the autoregressive model is 1.71, which is much smaller than the true value of 4. In small samples, the

autoregressive error model tends to underestimate σ^2 , while the OLS MSE overestimates σ^2 .

Notice that the total R^2 statistic computed from the autoregressive model residuals is 0.954, reflecting the improved fit from the use of past residuals to help predict the next Y value. The Reg Rsq value 0.728 is the R^2 statistic for a regression of transformed variables adjusted for the estimated autocorrelation. (This is not the R^2 for the estimated trend line. For details, see the section “R-Square Statistics and Other Measures of Fit” on page 367 later in this chapter.)

The parameter estimates table shows the ML estimates of the regression coefficients and includes two additional rows for the estimates of the autoregressive parameters, labeled AR(1) and AR(2).

The estimated model is

$$y_t = 7.88 + 0.5096t + v_t$$

$$v_t = 1.25v_{t-1} - 0.628v_{t-2} + \epsilon_t$$

$$Est. Var(\epsilon_t) = 1.71$$

Note that the signs of the autoregressive parameters shown in this equation for v_t are the reverse of the estimates shown in the AUTOREG procedure output. [Figure 8.4](#) also shows the estimates of the regression coefficients with the standard errors recomputed on the assumption that the autoregressive parameter estimates equal the true values.

Predicted Values and Residuals

The AUTOREG procedure can produce two kinds of predicted values and corresponding residuals and confidence limits. The first kind of predicted value is obtained from only the structural part of the model, $\mathbf{x}'_t\mathbf{b}$. This is an estimate of the unconditional mean of the response variable at time t . For the time trend model, these predicted values trace the estimated trend. The second kind of predicted value includes both the structural part of the model and the predicted values of the autoregressive error process. The full model (conditional) predictions are used to forecast future values.

Use the OUTPUT statement to store predicted values and residuals in a SAS data set and to output other values such as confidence limits and variance estimates. The P= option specifies an output variable to contain the full model predicted values. The PM= option names an output variable for the predicted mean. The R= and RM= options specify output variables for the corresponding residuals, computed as the actual value minus the predicted value.

The following statements store both kinds of predicted values in the output data set. (The printed output is the same as previously shown in [Figure 8.3](#) and [Figure 8.4](#).)

```
proc autoreg data=a;
  model y = time / nlag=2 method=ml;
  output out=p p=yhat pm=trendhat;
run;
```

The following statements plot the predicted values from the regression trend line and from the full model together with the actual values:

```
title 'Predictions for Autocorrelation Model';
proc sgplot data=p;
```

```

scatter x=time y=y / markerattrs=(color=blue);
series x=time y=yhat / lineattrs=(color=blue);
series x=time y=trendhat / lineattrs=(color=black);
run;

```

The plot of predicted values is shown in [Figure 8.5](#).

Figure 8.5 PROC AUTOREG Predictions

In [Figure 8.5](#) the straight line is the autocorrelation corrected regression line, traced out by the structural predicted values TRENDHAT. The jagged line traces the full model prediction values. The actual values are marked by asterisks. This plot graphically illustrates the improvement in fit provided by the autoregressive error process for highly autocorrelated data.

Forecasting Autoregressive Error Models

To produce forecasts for future periods, include observations for the forecast periods in the input data set. The forecast observations must provide values for the independent variables and have missing values for the response variable.

For the time trend model, the only regressor is time. The following statements add observations for time periods 37 through 46 to the data set A to produce an augmented data set B:

```
data b;
  y = .;
  do time = 37 to 46; output; end;
run;

data b;
  merge a b;
  by time;
run;
```

To produce the forecast, use the augmented data set as input to PROC AUTOREG, and specify the appropriate options in the OUTPUT statement. The following statements produce forecasts for the time trend with autoregressive error model. The output data set includes all the variables in the input data set, the forecast values (YHAT), the predicted trend (YTREND), and the upper (UCL) and lower (LCL) 95% confidence limits.

```
proc autoreg data=b;
  model y = time / nlag=2 method=ml;
  output out=p p=yhat pm=ytrend
         lcl=lcl ucl=ucl;
run;
```

The following statements plot the predicted values and confidence limits, and they also plot the trend line for reference. The actual observations are shown for periods 16 through 36, and a reference line is drawn at the start of the out-of-sample forecasts.

```
title 'Forecasting Autocorrelated Time Series';
proc sgplot data=p;
  band x=time upper=ucl lower=lcl;
  scatter x=time y=y;
  series x=time y=yhat;
  series x=time y=ytrend / lineattrs=(color=black);
run;
```

The plot is shown in [Figure 8.6](#). Notice that the forecasts take into account the recent departures from the trend but converge back to the trend line for longer forecast horizons.

Figure 8.6 PROC AUTOREG Forecasts

Testing for Autocorrelation

In the preceding section, it is assumed that the order of the autoregressive process is known. In practice, you need to test for the presence of autocorrelation.

The Durbin-Watson test is a widely used method of testing for autocorrelation. The first-order Durbin-Watson statistic is printed by default. This statistic can be used to test for first-order autocorrelation. Use the DWPROB option to print the significance level (p -values) for the Durbin-Watson tests. (Since the Durbin-Watson p -values are computationally expensive, they are not reported by default.)

You can use the DW= option to request higher-order Durbin-Watson statistics. Since the ordinary Durbin-Watson statistic tests only for first-order autocorrelation, the Durbin-Watson statistics for higher-order autocorrelation are called *generalized Durbin-Watson statistics*.

The following statements perform the Durbin-Watson test for autocorrelation in the OLS residuals for orders 1 through 4. The DWPROB option prints the marginal significance levels (p -values) for the Durbin-Watson statistics.

```

/*-- Durbin-Watson test for autocorrelation --*/
proc autoreg data=a;
  model y = time / dw=4 dwprob;
run;

```

The AUTOREG procedure output is shown in Figure 8.7. In this case, the first-order Durbin-Watson test is highly significant, with $p < .0001$ for the hypothesis of no first-order autocorrelation. Thus, autocorrelation correction is needed.

Figure 8.7 Durbin-Watson Test Results for OLS Residuals

3	2.0694	0.6545	0.3455		
4	2.5544	0.9818	0.0182		
NOTE: Pr<DW is the p-value for testing positive autocorrelation, and Pr>DW is the p-value for testing negative autocorrelation.					
Variable	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	8.2308	0.8559	9.62	<.0001
time	1	0.5021	0.0403	12.45	<.0001

Using the Durbin-Watson test, you can decide if autocorrelation correction is needed. However, generalized Durbin-Watson tests should not be used to decide on the autoregressive order. The higher-order tests assume the absence of lower-order autocorrelation. If the ordinary Durbin-Watson test indicates no first-order autocorrelation, you can use the second-order test to check for second-order autocorrelation. Once autocorrelation is detected, further tests at higher orders are not appropriate.

In [Figure 8.7](#), since the first-order Durbin-Watson test is significant, the order 2, 3, and 4 tests can be ignored.

When using Durbin-Watson tests to check for autocorrelation, you should specify an order at least as large as the order of any potential seasonality, since seasonality produces autocorrelation at the seasonal lag. For example, for quarterly data use $DW=4$, and for monthly data use $DW=12$.

Lagged Dependent Variables

The Durbin-Watson tests are not valid when the lagged dependent variable is used in the regression model. In this case, the Durbin h test or Durbin t test can be used to test for first-order autocorrelation.

For the Durbin h test, specify the name of the lagged dependent variable in the LAGDEP= option. For the Durbin t test, specify the LAGDEP option without giving the name of the lagged dependent variable.

For example, the following statements add the variable YLAG to the data set A and regress Y on YLAG instead of TIME:

```
data b;
  set a;
  ylag = lag1( y );
run;

proc autoreg data=b;
  model y = ylag / lagdep=ylag;
run;
```

The results are shown in [Figure 8.8](#). The Durbin h statistic 2.78 is significant with a p -value of 0.0027, indicating autocorrelation.

Stepwise Autoregression

Once you determine that autocorrelation correction is needed, you must select the order of the autoregressive error model to use. One way to select the order of the autoregressive error model is *stepwise autoregression*. The stepwise autoregression method initially fits a high-order model with many autoregressive lags and then sequentially removes autoregressive parameters until all remaining autoregressive parameters have significant *t* tests.

To use stepwise autoregression, specify the BACKSTEP option, and specify a large order with the NLAG= option. The following statements show the stepwise feature, using an initial order of 5:

```
/*-- stepwise autoregression --*/
proc autoreg data=a;
  model y = time / method=ml nlag=5 backstep;
run;
```

The results are shown in Figure 8.9.

5	0.131734	1.21	0.2340																					

The estimates of the autocorrelations are shown for 5 lags. The backward elimination of autoregressive terms report shows that the autoregressive parameters at lags 3, 4, and 5 were insignificant and eliminated, resulting in the second-order model shown previously in Figure 8.4. By default, retained autoregressive parameters must be significant at the 0.05 level, but you can control this with the SLSTAY= option. The remainder of the output from this example is the same as that in Figure 8.3 and Figure 8.4, and it is not repeated here.

The stepwise autoregressive process is performed using the Yule-Walker method. The maximum likelihood estimates are produced after the order of the model is determined from the significance tests of the preliminary Yule-Walker estimates.

When using stepwise autoregression, it is a good idea to specify an NLAG= option value larger than the order of any potential seasonality, since seasonality produces autocorrelation at the seasonal lag.

For example, for monthly data use NLAG=13, and for quarterly data use NLAG=5.

Subset and Factored Models

In the previous example, the BACKSTEP option dropped lags 3, 4, and 5, leaving a second-order model. However, in other cases a parameter at a longer lag may be kept while some smaller lags are dropped. For example, the stepwise autoregression method might drop lags 2, 3, and 5 but keep lags 1 and 4. This is called a *subset model*, since the number of estimated autoregressive parameters is lower than the order of the model.

Subset models are common for seasonal data and often correspond to *factored* autoregressive models. A factored model is the product of simpler autoregressive models. For example, the best model for seasonal monthly data may be the combination of a first-order model for recent effects with a 12th-order subset model for the seasonality, with a single parameter at lag 12. This results in a 13th-order subset model with nonzero parameters at lags 1, 12, and 13. See Chapter 7, “[The ARIMA Procedure](#),” for further discussion of subset and factored autoregressive models.

You can specify subset models with the NLAG= option. List the lags to include in the autoregressive model within parentheses. The following statements show an example of specifying the subset model resulting from the combination of a first-order process for recent effects with a fourth-order seasonal process:

```
/*-- specifying the lags --*/
proc autoreg data=a;
  model y = time / nlag=(1 4 5);
run;
```

The MODEL statement specifies the following fifth-order autoregressive error model:

$$y_t = a + bt + v_t$$

$$v_t = -\phi_1 v_{t-1} - \phi_4 v_{t-4} - \phi_5 v_{t-5} + \epsilon_t$$

Testing for Heteroscedasticity

One of the key assumptions of the ordinary regression model is that the errors have the same variance throughout the sample. This is also called the *homoscedasticity* model. If the error variance is not constant, the data are said to be *heteroscedastic*.

Since ordinary least squares regression assumes constant error variance, heteroscedasticity causes the OLS estimates to be inefficient. Models that take into account the changing variance can make more efficient use of the data. Also, heteroscedasticity can make the OLS forecast error variance inaccurate since the predicted forecast variance is based on the average variance instead of the variability at the end of the series.

To illustrate heteroscedastic time series, the following statements re-create the simulated series Y. The variable Y has an error variance that changes from 1 to 4 in the middle part of the series. The length of the series is also extended 120 observations.

```

data a;
  ul = 0; ull = 0;
  do time = -10 to 120;
    s = 1 + (time >= 60 & time < 90);
    u = + 1.3 * ul - .5 * ull + s*rannor(12346);
    y = 10 + .5 * time + u;
    if time > 0 then output;
    ull = ul; ul = u;
  end;
run;

title 'Heteroscedastic Autocorrelated Time Series';
proc sgplot data=a noautolegend;
  series x=time y=y / markers;
  reg x=time y=y / lineattrs=(color=black);
run;

```

The simulated series is plotted in [Figure 8.10](#).

Figure 8.10 Heteroscedastic and Autocorrelated Series

To test for heteroscedasticity with PROC AUTOREG, specify the ARCHTEST option. The following statements regress Y on TIME and use the ARCHTEST option to test for heteroscedastic OLS

residuals. The DWPROB option is also used to test for autocorrelation.

```

/*-- test for heteroscedastic OLS residuals --*/
proc autoreg data=a;
  model y = time / nlag=2 archtest dwprob;
  output out=r r=yresid;
run;

```

The PROC AUTOREG output is shown in Figure 8.11. The Q statistics test for changes in variance across time by using lag windows ranging from 1 through 12. (See the section “Heteroscedasticity and Normality Tests” on page 374 for details.) The p -values for the test statistics are given in parentheses. These tests strongly indicate heteroscedasticity, with $p < 0.0001$ for all lag windows.

The Lagrange multiplier (LM) tests also indicate heteroscedasticity. These tests can also help determine the order of the ARCH model appropriate for modeling the heteroscedasticity, assuming that the changing variance follows an autoregressive conditional heteroscedasticity model.

Heteroscedasticity and GARCH Models

There are several approaches to dealing with heteroscedasticity. If the error variance at different times is known, weighted regression is a good method. If, as is usually the case, the error variance is unknown and must be estimated from the data, you can model the changing error variance.

The *generalized autoregressive conditional heteroscedasticity* (GARCH) model is one approach to modeling time series with heteroscedastic errors. The GARCH regression model with autoregressive errors is

$$\begin{aligned}
 y_t &= \mathbf{x}_t' \boldsymbol{\beta} + v_t \\
 v_t &= \epsilon_t - \phi_1 v_{t-1} - \dots - \phi_m v_{t-m} \\
 \epsilon_t &= \sqrt{h_t} e_t \\
 h_t &= \omega + \sum_{i=1}^q \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^p \gamma_j h_{t-j} \\
 e_t &\sim \text{IN}(0, 1)
 \end{aligned}$$

This model combines the m th-order autoregressive error model with the GARCH(p, q) variance model. It is denoted as the AR(m)-GARCH(p, q) regression model.

The Lagrange multiplier (LM) tests shown in Figure 8.11 can help determine the order of the ARCH model appropriate for the data. The tests are significant ($p < .0001$) through order 12, which indicates that a very high-order ARCH model is needed to model the heteroscedasticity.

The basic ARCH(q) model ($p = 0$) is a *short memory* process in that only the most recent q squared residuals are used to estimate the changing variance. The GARCH model ($p > 0$) allows *long memory* processes, which use all the past squared residuals to estimate the current variance. The LM tests in Figure 8.11 suggest the use of the GARCH model ($p > 0$) instead of the ARCH model.

The GARCH(p, q) model is specified with the GARCH=(P= p , Q= q) option in the MODEL statement. The basic ARCH(q) model is the same as the GARCH(0, q) model and is specified with the GARCH=(Q= q) option.

The following statements fit an AR(2)-GARCH(1, 1) model for the Y series regressed on TIME. The GARCH=(P=1, Q=1) option specifies the GARCH(1, 1) conditional variance model. The

NLAG=2 option specifies the AR(2) error process. Only the maximum likelihood method is supported for GARCH models; therefore, the METHOD= option is not needed. The CEV= option in the OUTPUT statement stores the estimated conditional error variance at each time period in the variable VHAT in an output data set named OUT. The data set is the same as in the section “Testing for Heteroscedasticity” on page 329.

```

/*-- AR(2)-GARCH(1,1) model for the Y series regressed on TIME --*/
proc autoreg data=a;
  model y = time / nlag=2 garch=(q=1,p=1) maxit=50;
  output out=out cev=vhat;
run;

```

The results for the GARCH model are shown in Figure 8.12. (The preliminary estimates are not shown.)

Figure 8.12 AR(2)-GARCH(1, 1) Model

Heteroscedastic Autocorrelated Time Series					
The AUTOREG Procedure					
GARCH Estimates

SBC	408.392693	AIC	388.88025		
MAE	0.97051351	AICC	389.88025		
MAPE	2.75945185	Normality Test	0.0839		
		Pr > ChiSq	0.9589		
Variable	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	8.9301	0.7235	12.34	<.0001
time	1	0.5075	0.0107	47.30	<.0001
AR1	1	-1.2301	0.1078	-11.41	<.0001
AR2	1	0.5023	0.1057	4.75	<.0001
ARCH0	1	0.0850	0.0757	1.12	0.2614
ARCH1	1	0.2103	0.0847	2.48	0.0130
GARCH1	1	0.7376	0.0960	7.68	<.0001

The normality test is not significant ($p = 0.959$), which is consistent with the hypothesis that the residuals from the GARCH model, $\epsilon_t/\sqrt{h_t}$, are normally distributed. The parameter estimates table includes rows for the GARCH parameters. ARCH0 represents the estimate for the parameter ω , ARCH1 represents α_1 , and GARCH1 represents γ_1 .

The following statements transform the estimated conditional error variance series VHAT to the estimated standard deviation series SHAT. Then, they plot SHAT together with the true standard deviation S used to generate the simulated data.

```
data out;
```

```

set out;
shat = sqrt( vhat );
run;

title 'Predicted and Actual Standard Deviations';
proc sgplot data=out noautolegend;
scatter x=time y=s;
series x=time y=shat/ lineattrs=(color=black);
run;

```

The plot is shown in [Figure 8.13](#).

Figure 8.13 Estimated and Actual Error Standard Deviation Series

Note that in this example the form of heteroscedasticity used in generating the simulated series Y does not fit the GARCH model. The GARCH model assumes *conditional* heteroscedasticity, with homoscedastic unconditional error variance. That is, the GARCH model assumes that the changes in variance are a function of the realizations of preceding errors and that these changes represent temporary and random departures from a constant unconditional variance. The data-generating process used to simulate series Y , contrary to the GARCH model, has exogenous unconditional heteroscedasticity that is independent of past errors.

Nonetheless, as shown in [Figure 8.13](#), the GARCH model does a reasonably good job of approxi-

mating the error variance in this example, and some improvement in the efficiency of the estimator of the regression parameters can be expected.

The GARCH model may perform better in cases where theory suggests that the data-generating process produces true autoregressive conditional heteroscedasticity. This is the case in some economic theories of asset returns, and GARCH-type models are often used for analysis of financial market data.

EGARCH, IGARCH, and GARCH-M Models

The AUTOREG procedure supports several variations of the generalized conditional heteroscedasticity model.

Using the TYPE= suboption of the GARCH= option, you can control the constraints placed on the estimated GARCH parameters. You can specify unconstrained, nonnegativity constrained (default), stationarity constrained, or integration constrained. The integration constraint produces the integrated GARCH, or IGARCH, model.

You can also use the TYPE= option to specify the exponential form of the GARCH model, called the EGARCH model. The MEAN suboption of the GARCH= option specifies the GARCH-in-mean, or GARCH-M, model.

The following statements illustrate the use of the TYPE= option to fit an AR(2)-EGARCH(1, 1) model to the series Y. (Output is not shown.)

```
/*-- AR(2)-EGARCH(1,1) model --*/
proc autoreg data=a;
  model y = time / nlag=2 garch=(p=1,q=1,type=exp);
run;
```

See the section “GARCH, IGARCH, EGARCH, and GARCH-M Models” on page 362 later in this chapter for details.

Syntax: AUTOREG Procedure

The AUTOREG procedure is controlled by the following statements:

```
PROC AUTOREG options ;
  BY variables ;
  MODEL dependent = regressors / options ;
  HETERO variables / options ;
  RESTRICT equation , . . . , equation ;
  TEST equation , . . . , equation / option ;
  OUTPUT OUT = SAS data set options ;
```

At least one MODEL statement must be specified. One OUTPUT statement can follow each MODEL statement. One HETERO statement can follow each MODEL statement.

Functional Summary

The statements and options used with the AUTOREG procedure are summarized in the following table.

Table 8.1 AUTOREG Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	AUTOREG	DATA=
write parameter estimates to an output data set	AUTOREG	OUTEST=
include covariances in the OUTEST= data set	AUTOREG	COVOUT
requests that the procedure produce graphics via the Output Delivery System	AUTOREG	PLOTS=
write predictions, residuals, and confidence limits to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify BY-group processing	BY	
Printing Control Options		
request all printing options	MODEL	ALL
print transformed coefficients	MODEL	COEF
print correlation matrix of the estimates	MODEL	CORRB
print covariance matrix of the estimates	MODEL	COVB
print DW statistics up to order j	MODEL	DW= j
print marginal probability of the generalized Durbin-Watson test statistics for large sample sizes	MODEL	DWPROB
print the p -values for the Durbin-Watson test be computed using a linearized approximation of the design matrix	MODEL	LDW
print inverse of Toeplitz matrix	MODEL	GINV
print the Godfrey LM serial correlation test	MODEL	GODFREY=
print details at each iteration step	MODEL	ITPRINT
print the Durbin t statistic	MODEL	LAGDEP
print the Durbin h statistic	MODEL	LAGDEP=
print the log likelihood value of the regression model	MODEL	LOGLIKL
print the Jarque-Bera normality test	MODEL	NORMAL
print tests for ARCH process	MODEL	ARCHTEST
print the Lagrange multiplier test	HETERO	TEST=LM
print the Chow test	MODEL	CHOW=
print the predictive Chow test	MODEL	PCHOW=
suppress printed output	MODEL	NOPRINT
print partial autocorrelations	MODEL	PARTIAL
print Ramsey's RESET test	MODEL	RESET

Table 8.1 continued

Description	Statement	Option
print Phillips-Perron tests for stationarity or unit roots	MODEL	STATIONARITY=(PHILLIPS=)
print KPSS tests for stationarity or unit roots	MODEL	STATIONARITY=(KPSS=)
print tests of linear hypotheses	TEST	
specify the test statistics to use	TEST	TYPE=
prints the uncentered regression R^2	MODEL	URSQ
Model Estimation Options		
specify the order of autoregressive process	MODEL	NLAG=
center the dependent variable	MODEL	CENTER
suppress the intercept parameter	MODEL	NOINT
remove nonsignificant AR parameters	MODEL	BACKSTEP
specify significance level for BACKSTEP	MODEL	SLSTAY=
specify the convergence criterion	MODEL	CONVERGE=
specify the type of covariance matrix	MODEL	COVEST=
set the initial values of parameters used by the iterative optimization algorithm	MODEL	INITIAL=
specify iterative Yule-Walker method	MODEL	ITER
specify maximum number of iterations	MODEL	MAXITER=
specify the estimation method	MODEL	METHOD=
use only first sequence of nonmissing data	MODEL	NOMISS
specify the optimization technique	MODEL	OPTMETHOD=
imposes restrictions on the regression estimates	RESTRICT	
estimate and test heteroscedasticity models	HETERO	
GARCH Related Options		
specify order of GARCH process	MODEL	GARCH=(Q,P=)
specify type of GARCH model	MODEL	GARCH=(. . .,TYPE=)
specify various forms of the GARCH-M model	MODEL	GARCH=(. . .,MEAN=)
suppress GARCH intercept parameter	MODEL	GARCH=(. . .,NOINT)
specify the trust region method	MODEL	GARCH=(. . .,TR)
estimate the GARCH model for the conditional t distribution	MODEL	GARCH=(. . .) DIST=
estimates the start-up values for the conditional variance equation	MODEL	GARCH=(. . .,STARTUP=)
specify the functional form of the heteroscedasticity model	HETERO	LINK=
specify that the heteroscedasticity model does not include the unit term	HETERO	NOCONST
impose constraints on the estimated parameters the heteroscedasticity model	HETERO	COEF=
impose constraints on the estimated standard deviation of the heteroscedasticity model	HETERO	STD=
output conditional error variance	OUTPUT	CEV=

Table 8.1 continued

Description	Statement	Option
output conditional prediction error variance	OUTPUT	CPEV=
specify the flexible conditional variance form of the GARCH model	HETERO	
Output Control Options		
specify confidence limit size	OUTPUT	ALPHACLI=
specify confidence limit size for structural predicted values	OUTPUT	ALPHACLM=
specify the significance level for the upper and lower bounds of the CUSUM and CUSUMSQ statistics	OUTPUT	ALPHACSM=
specify the name of a variable to contain the values of the Theil's BLUS residuals	OUTPUT	BLUS=
output the value of the error variance σ_t^2	OUTPUT	CEV=
output transformed intercept variable	OUTPUT	CONSTANT=
specify the name of a variable to contain the CUSUM statistics	OUTPUT	CUSUM=
specify the name of a variable to contain the CUSUMSQ statistics	OUTPUT	CUSUMSQ=
specify the name of a variable to contain the upper confidence bound for the CUSUM statistic	OUTPUT	CUSUMUB=
specify the name of a variable to contain the lower confidence bound for the CUSUM statistic	OUTPUT	CUSUMLB=
specify the name of a variable to contain the upper confidence bound for the CUSUMSQ statistic	OUTPUT	CUSUMSQUB=
option specify the name of a variable to contain the lower confidence bound for the CUSUMSQ statistic	OUTPUT	CUSUMSQLB=
output lower confidence limit	OUTPUT	LCL=
output lower confidence limit for structural predicted values	OUTPUT	LCLM=
output predicted values	OUTPUT	P=
output predicted values of structural part	OUTPUT	PM=
output residuals	OUTPUT	R=
output residuals from structural predictions	OUTPUT	RM=
specify the name of a variable to contain the part of the predictive error variance (v_t)	OUTPUT	RECPEV=
specify the name of a variable to contain recursive residuals	OUTPUT	RECRES=
output transformed variables	OUTPUT	TRANSFORM=
output upper confidence limit	OUTPUT	UCL=
output upper confidence limit for structural predicted values	OUTPUT	UCLM=

PROC AUTOREG Statement

PROC AUTOREG *options* ;

The following options can be used in the PROC AUTOREG statement:

DATA= *SAS-data-set*

specifies the input SAS data set. If the DATA= option is not specified, PROC AUTOREG uses the most recently created SAS data set.

OUTEST= *SAS-data-set*

writes the parameter estimates to an output data set. See the section “**OUTEST= Data Set**” on page 384 later in this chapter for information on the contents of these data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

PLOTS<(Global-Plot-Options)> <= (Specific Plot Options)>

requests that the AUTOREG procedure produce statistical graphics via the Output Delivery System, provided that the ODS GRAPHICS statement has been specified. For general information about ODS Graphics, see Chapter 21, “**Statistical Graphics Using ODS**” (*SAS/STAT User’s Guide*). The *global-plot-options* apply to all relevant plots generated by the AUTOREG procedure. The *global-plot-options* supported by the AUTOREG procedure follow.

Global Plot Options

- | | |
|-------------|---|
| ONLY | suppresses the default plots. Only the plots specifically requested are produced. |
| UNPACKPANEL | breaks a graphic that is otherwise paneled into individual component plots. |

Specific Plot Options

- | | |
|----------------|--|
| ALL | requests that all plots appropriate for the particular analysis be produced. |
| ACF | produces the autocorrelation function plot. |
| IACF | produces the inverse autocorrelation function plot of residuals. |
| PACF | produces the partial autocorrelation function plot of residuals. |
| FITPLOT | plots the predicted and actual values. |
| COOKSD | produces the Cook’s <i>D</i> plot. |
| QQ | Q-Q plot of residuals. |
| RESIDUAL RES | plots the residuals. |

STUDENTRESIDUAL plots the studentized residuals. For the models with the **NLAG=** or **GARCH=** options in the **MODEL** statement or with the **HETERO** statement, this option is replaced by the **STANDARDRESIDUAL** option.

STANDARDRESIDUAL plots the standardized residuals.

WHITENOISE plots the white noise probabilities.

RESIDUALHISTOGRAM | **RESIDHISTOGRAM** plots the histogram of residuals.

NONE suppresses all plots.

In addition, any of the following **MODEL** statement options can be specified in the **PROC AUTOREG** statement, which is equivalent to specifying the option for every **MODEL** statement: **ALL**, **ARCHTEST**, **BACKSTEP**, **CENTER**, **COEF**, **CONVERGE=**, **CORRB**, **COVB**, **DW=**, **DWPROB**, **GINV**, **ITER**, **ITPRINT**, **MAXITER=**, **METHOD=**, **NOINT**, **NOMISS**, **NOPRINT**, and **PARTIAL**.

BY Statement

BY *variables* ;

A **BY** statement can be used with **PROC AUTOREG** to obtain separate analyses on observations in groups defined by the **BY** variables.

MODEL Statement

MODEL *dependent = regressors / options* ;

The **MODEL** statement specifies the dependent variable and independent regressor variables for the regression model. If no independent variables are specified in the **MODEL** statement, only the mean is fitted. (This is a way to obtain autocorrelations of a series.)

Models can be given labels of up to eight characters. Model labels are used in the printed output to identify the results for different models. The model label is specified as follows:

label : **MODEL** ... ;

The following options can be used in the **MODEL** statement after a slash (/).

CENTER

centers the dependent variable by subtracting its mean and suppresses the intercept parameter from the model. This option is valid only when the model does not have regressors (explanatory variables).

NOINT

suppresses the intercept parameter.

Autoregressive Error Options

NLAG= *number*

NLAG= (*number-list*)

specifies the order of the autoregressive error process or the subset of autoregressive error lags to be fitted. Note that NLAG=3 is the same as NLAG=(1 2 3). If the NLAG= option is not specified, PROC AUTOREG does not fit an autoregressive model.

GARCH Estimation Options

DIST= *value*

specifies the distribution assumed for the error term in GARCH-type estimation. If no GARCH= option is specified, the option is ignored. If EGARCH is specified, the distribution is always normal distribution. The values of the DIST= option are as follows:

T specifies Student's *t* distribution.

NORMAL specifies the standard normal distribution. The default is DIST=NORMAL.

GARCH= (*option-list*)

specifies a GARCH-type conditional heteroscedasticity model. The GARCH= option in the MODEL statement specifies the family of ARCH models to be estimated. The GARCH(1, 1) regression model is specified in the following statement:

```
model y = x1 x2 / garch=(q=1,p=1);
```

When you want to estimate the subset of ARCH terms, such as ARCH(1, 3), you can write the SAS statement as follows:

```
model y = x1 x2 / garch=(q=(1 3));
```

With the TYPE= option, you can specify various GARCH models. The IGARCH(2, 1) model without trend in variance is estimated as follows:

```
model y = / garch=(q=2,p=1,type=integ,noint);
```

The following options can be used in the GARCH=() option. The options are listed within parentheses and separated by commas.

Q= *number*

Q= (*number-list*)

specifies the order of the process or the subset of ARCH terms to be fitted.

P= *number*

P= (*number-list*)

specifies the order of the process or the subset of GARCH terms to be fitted. If only the P= option is specified, Q=1 is assumed.

TYPE= *value*

specifies the type of GARCH model. The values of the TYPE= option are as follows:

EXP	specifies the exponential GARCH or EGARCH model.
INTEGRATED	specifies the integrated GARCH or IGARCH model.
NELSON NELSONCAO	specifies the Nelson-Cao inequality constraints.
NONNEG	specifies the GARCH model with nonnegativity constraints.
STATIONARY	constrains the sum of GARCH coefficients to be less than 1.

The default is TYPE=NELSON.

MEAN= *value*

specifies the functional form of the GARCH-M model. The values of the MEAN= option are as follows:

LINEAR specifies the linear function:

$$y_t = \mathbf{x}'_t \boldsymbol{\beta} + \delta h_t + \epsilon_t$$

LOG specifies the log function:

$$y_t = \mathbf{x}'_t \boldsymbol{\beta} + \delta \ln(h_t) + \epsilon_t$$

SQRT specifies the square root function:

$$y_t = \mathbf{x}'_t \boldsymbol{\beta} + \delta \sqrt{h_t} + \epsilon_t$$

NOINT

suppresses the intercept parameter in the conditional variance model. This option is valid only with the TYPE=INTEG option.

STARTUP= *MSE | ESTIMATE*

requests that the positive constant c for the start-up values of the GARCH conditional error variance process be estimated. By default or if STARTUP=MSE is specified, the value of the mean squared error is used as the default constant.

TR

uses the trust region method for GARCH estimation. This algorithm is numerically stable, though computation is expensive. The double quasi-Newton method is the default.

Printing Options

ALL

requests all printing options.

ARCHTEST

requests the Q and LM statistics testing for the absence of ARCH effects.

CHOW= (*obs*₁ ... *obs*_{*n*})

computes Chow tests to evaluate the stability of the regression coefficient. The Chow test is also called the analysis-of-variance test.

Each value *obs*_{*i*} listed on the CHOW= option specifies a break point of the sample. The sample is divided into parts at the specified break point, with observations before *obs*_{*i*} in the first part and *obs*_{*i*} and later observations in the second part, and the fits of the model in the two parts are compared to whether both parts of the sample are consistent with the same model.

The break points *obs*_{*i*} refer to observations within the time range of the dependent variable, ignoring missing values before the start of the dependent series. Thus, CHOW=20 specifies the 20th observation after the first nonmissing observation for the dependent variable. For example, if the dependent variable Y contains 10 missing values before the first observation with a nonmissing Y value, then CHOW=20 actually refers to the 30th observation in the data set.

When you specify the break point, you should note the number of presample missing values.

COEF

prints the transformation coefficients for the first *p* observations. These coefficients are formed from a scalar multiplied by the inverse of the Cholesky root of the Toeplitz matrix of autocovariances.

CORRB

prints the estimated correlations of the parameter estimates.

COVB

prints the estimated covariances of the parameter estimates.

COVEST= *OP* | *HESSIAN* | *QML*

specifies the type of covariance matrix for the GARCH or heteroscedasticity model. When COVEST=OP is specified, the outer product matrix is used to compute the covariance matrix of the parameter estimates. The COVEST=HESSIAN option produces the covariance matrix by using the Hessian matrix. The quasi-maximum likelihood estimates are computed with COVEST=QML. The default is COVEST=OP.

DW= *n*

prints Durbin-Watson statistics up to the order *n*. The default is DW=1. When the LAGDEP option is specified, the Durbin-Watson statistic is not printed unless the DW= option is explicitly specified.

DWPROB

now produces *p*-values for the generalized Durbin-Watson test statistics for large sample sizes. Previously, the Durbin-Watson probabilities were calculated only for small sample sizes. The new method of calculating Durbin-Watson probabilities is based on the algorithm of Ansley, Kohn, and Shively (1992).

GINV

prints the inverse of the Toeplitz matrix of autocovariances for the Yule-Walker solution. See the section “[Computational Methods](#)” on page 359 later in this chapter for details.

GODFREY**GODFREY=** *r*

produces Godfrey's general Lagrange multiplier test against ARMA errors.

ITPRINT

prints the objective function and parameter estimates at each iteration. The objective function is the full log likelihood function for the maximum likelihood method, while the error sum of squares is produced as the objective function of unconditional least squares. For the ML method, the ITPRINT option prints the value of the full log likelihood function, not the concentrated likelihood.

LAGDEP**LAGDV**

prints the Durbin *t* statistic, which is used to detect residual autocorrelation in the presence of lagged dependent variables. See the section “[Generalized Durbin-Watson Tests](#)” on page 370 later in this chapter for details.

LAGDEP= *name***LAGDV=** *name*

prints the Durbin *h* statistic for testing the presence of first-order autocorrelation when regressors contain the lagged dependent variable whose name is specified as LAGDEP=*name*. If the Durbin *h* statistic cannot be computed, the asymptotically equivalent *t* statistic is printed instead. See the section “[Generalized Durbin-Watson Tests](#)” on page 370 for details.

When the regression model contains several lags of the dependent variable, specify the lagged dependent variable for the smallest lag in the LAGDEP= option. For example:

```
model y = x1 x2 ylag2 ylag3 / lagdep=ylag2;
```

LOGLIKL

prints the log likelihood value of the regression model, assuming normally distributed errors.

NOPRINT

suppresses all printed output.

NORMAL

specifies the Jarque-Bera's normality test statistic for regression residuals.

PARTIAL

prints partial autocorrelations.

PCHOW= (*obs*₁ . . . *obs*_{*n*})

computes the predictive Chow test. The form of the PCHOW= option is the same as the CHOW= option; see the discussion of the CHOW= option earlier in this chapter.

RESET

produces Ramsey's RESET test statistics. The RESET option tests the null model

$$y_t = \mathbf{x}_t \boldsymbol{\beta} + u_t$$

against the alternative

$$y_t = \mathbf{x}_t \beta + \sum_{j=2}^p \phi_j \hat{y}_t^j + u_t$$

where \hat{y}_t is the predicted value from the OLS estimation of the null model. The RESET option produces three RESET test statistics for $p = 2, 3,$ and 4 .

STATIONARITY= (PHILLIPS)

STATIONARITY= (PHILLIPS=(value ... value))

STATIONARITY= (KPSS)

STATIONARITY= (KPSS=(KERNEL=TYPE))

STATIONARITY= (KPSS=(KERNEL=TYPE TRUNCPOINTMETHOD))

STATIONARITY= (PHILLIPS<=(...)>, KPSS<=(...)>)

specifies tests of stationarity or unit roots. The STATIONARITY= option provides Phillips-Perron, Phillips-Ouliaris, and KPSS tests.

The PHILLIPS or PHILLIPS= suboption of the STATIONARITY= option produces the Phillips-Perron unit root test when there are no regressors in the MODEL statement. When the model includes regressors, the PHILLIPS option produces the Phillips-Ouliaris cointegration test. The PHILLIPS option can be abbreviated as PP.

The PHILLIPS option performs the Phillips-Perron test for three null hypothesis cases: zero mean, single mean, and deterministic trend. For each case, the PHILLIPS option computes two test statistics, \hat{Z}_ρ and \hat{Z}_t (in the original paper they are referred to as \hat{Z}_α and \hat{Z}_t), and reports their p -values. These test statistics have the same limiting distributions as the corresponding Dickey-Fuller tests.

The three types of the Phillips-Perron unit root test reported by the PHILLIPS option are as follows.

Zero mean computes the Phillips-Perron test statistic based on the zero mean autoregressive model:

$$y_t = \rho y_{t-1} + u_t$$

Single mean computes the Phillips-Perron test statistic based on the autoregressive model with a constant term:

$$y_t = \mu + \rho y_{t-1} + u_t$$

Trend computes the Phillips-Perron test statistic based on the autoregressive model with constant and time trend terms:

$$y_t = \mu + \rho y_{t-1} + \delta t + u_t$$

You can specify several truncation points l for weighted variance estimators by using the PHILLIPS=($l_1 \dots l_n$) specification. The statistic for each truncation point l is computed as

$$\sigma_{Tl}^2 = \frac{1}{T} \sum_{i=1}^T \hat{u}_i^2 + \frac{2}{T} \sum_{s=1}^l w_{sl} \sum_{t=s+1}^T \hat{u}_t \hat{u}_{t-s}$$

where $w_{sl} = 1 - s/(l + 1)$ and \hat{u}_t are OLS residuals. If you specify the PHILLIPS option without specifying truncation points, the default truncation point is $\max(1, \sqrt{T}/5)$, where T is the number of observations.

The Phillips-Perron test can be used in general time series models since its limiting distribution is derived in the context of a class of weakly dependent and heterogeneously distributed data. The marginal probability for the Phillips-Perron test is computed assuming that error disturbances are normally distributed.

When there are regressors in the MODEL statement, the PHILLIPS option computes the Phillips-Ouliaris cointegration test statistic by using the least squares residuals. The normalized cointegrating vector is estimated using OLS regression. Therefore, the cointegrating vector estimates might vary with the regressand (normalized element) unless the regression R-square is 1.

The marginal probabilities for cointegration testing are not produced. You can refer to Phillips and Ouliaris (1990) tables Ia–Ic for the \hat{Z}_α test and tables IIa–IIc for the \hat{Z}_t test. The standard residual-based cointegration test can be obtained using the NOINT option in the MODEL statement, while the demeaned test is computed by including the intercept term. To obtain the demeaned and detrended cointegration tests, you should include the time trend variable in the regressors. Refer to Phillips and Ouliaris (1990) or Hamilton (1994, Tbl. 19.1) for information about the Phillips-Ouliaris cointegration test. Note that Hamilton (1994, Tbl. 19.1) uses Z_ρ and Z_t instead of the original Phillips and Ouliaris (1990) notation. We adopt the notation introduced in Hamilton. To distinguish from Student's t distribu-

tion, these two statistics are named accordingly as ρ (rho) and τ (tau).

The KPSS, KPSS=(KERNEL=TYPE), or KPSS=(KERNEL=TYPE TRUNCPOINT=METHOD) specifications of the STATIONARITY= option produce the Kwiatkowski, Phillips, Schmidt, and Shin (1992) (KPSS) unit root test.

Unlike the null hypothesis of the Dickey-Fuller and Phillips-Perron tests, the null hypothesis of the KPSS states that the time series is stationary. As a result, it tends to reject a random walk more often. If the model does not have an intercept, the KPSS option performs the KPSS test for three null hypothesis cases: zero mean, single mean, and deterministic trend. Otherwise, it reports single mean and deterministic trend only. It computes a test statistic and tabulated p -values (see Hobijn, Franses, and Ooms (2004)) for the hypothesis that the random walk component of the time series is equal to zero in the following cases (for details, see “Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test” on page 378):

Zero mean computes the KPSS test statistic based on the zero mean autoregressive model. The p -value reported is used from Hobijn, Franses, and Ooms (2004).

$$y_t = u_t$$

Single mean computes the KPSS test statistic based on the autoregressive model with a constant term. The p -value reported is used from Kwiatkowski et al. (1992).

$$y_t = \mu + u_t$$

Trend computes the KPSS test statistic based on the autoregressive model with constant and time trend terms. The p -value reported is from Kwiatkowski et al. (1992).

$$y_t = \mu + \delta t + u_t$$

This test depends on the long-run variance of the series being defined as

$$\sigma_{Tl}^2 = \frac{1}{T} \sum_{i=1}^T \hat{u}_i^2 + \frac{2}{T} \sum_{s=1}^l w_{sl} \sum_{t=s+1}^T \hat{u}_t \hat{u}_{t-s}$$

where w_{sl} is a kernel, s is a maximum lag (truncation point), and \hat{u}_t are OLS residuals or original data series. You can specify two types of the kernel:

KERNEL=NWIBART Newey-West (or Bartlett) kernel

$$w(s, l) = 1 - \frac{s}{l + 1}$$

KERNEL=QS Quadratic spectral kernel

$$w(s/l) = w(x) = \frac{25}{12\pi^2 x^2} \left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5) \right)$$

You can set the truncation point s by using three different methods:

SCHW=c Schwert maximum lag formula

$$s = \max \left\{ 1, \text{floor} \left[c \left(\frac{T}{100} \right)^{1/4} \right] \right\}$$

LAG=s LAG=s manually defined number of lags.

AUTO Automatic bandwidth selection (Hobijn, Franses, and Ooms 2004) (for details, see “Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test” on page 378).

If STATIONARITY=KPSS is defined without additional parameters, the Newey-West kernel is used. For the Newey-West kernel the default is the Schwert truncation point method with $c = 4$. For the quadratic spectral kernel the default is AUTO.

The KPSS test can be used in general time series models since its limiting distribution is derived in the context of a class of weakly dependent and heterogeneously distributed data. The limiting probability for the KPSS test is computed assuming that error disturbances are normally distributed.

The asymptotic distribution of the test does not depend on the presence of regressors in the MODEL statement.

The marginal probabilities for the test are reported. They are copied from Kwiatkowski et al. (1992) and Hobijn, Franses, and Ooms (2004). When there is an intercept in the model, results for mean and trend tests statistics are provided.

Examples: To test for stationarity of regression residuals, using default KERNEL= NW and SCHW= 4, you can use the following code:

```

/*-- test for stationarity of regression residuals --*/
proc autoreg data=a;
    model y= / stationarity = (KPSS);
run;

```

To test for stationarity of regression residuals, using quadratic spectral kernel and automatic bandwidth selection, you can use:

```

/*-- test for stationarity using quadratic
    spectral kernel and automatic bandwidth selection --*/
proc autoreg data=a;
    model y= /
        stationarity = (KPSS=(KERNEL=QS AUTO));
run;

```

URSQ

prints the uncentered regression R^2 . The uncentered regression R^2 is useful to compute Lagrange multiplier test statistics, since most LM test statistics are computed as $T * \text{URSQ}$, where T is the number of observations used in estimation.

Stepwise Selection Options

BACKSTEP

removes insignificant autoregressive parameters. The parameters are removed in order of least significance. This backward elimination is done only once on the Yule-Walker estimates computed after the initial ordinary least squares estimation. The BACKSTEP option can be used with all estimation methods since the initial parameter values for other estimation methods are estimated using the Yule-Walker method.

SLSTAY= *value*

specifies the significance level criterion to be used by the BACKSTEP option. The default is SLSTAY=.05.

Estimation Control Options

CONVERGE= *value*

specifies the convergence criterion. If the maximum absolute value of the change in the autoregressive parameter estimates between iterations is less than this amount, then convergence is assumed. The default is CONVERGE=.001.

If the GARCH= option and/or the HETERO statement is specified, convergence is assumed when the absolute maximum gradient is smaller than the value specified by the CONVERGE= option or when the relative gradient is smaller than $1E-8$. By default, CONVERGE= $1E-5$.

INITIAL= (*initial-values*)

START= (*initial-values*)

specifies initial values for some or all of the parameter estimates. The values specified are

assigned to model parameters in the same order as the parameter estimates are printed in the AUTOREG procedure output. The order of values in the INITIAL= or START= option is as follows: the intercept, the regressor coefficients, the autoregressive parameters, the ARCH parameters, the GARCH parameters, the inverted degrees of freedom for Student's t distribution, the start-up value for conditional variance, and the heteroscedasticity model parameters η specified by the HETERO statement.

The following is an example of specifying initial values for an AR(1)-GARCH(1, 1) model with regressors X1 and X2:

```
/*-- specifying initial values --*/
model y = w x / nlag=1 garch=(p=1,q=1)
           initial=(1 1 1 .5 .8 .1 .6);
```

The model specified by this MODEL statement is

$$y_t = \beta_0 + \beta_1 w_t + \beta_2 x_t + v_t$$

$$v_t = \epsilon_t - \phi_1 v_{t-1}$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \alpha_1 \epsilon_{t-1}^2 + \gamma_1 h_{t-1}$$

$$\epsilon_t \sim N(0, \sigma_t^2)$$

The initial values for the regression parameters, INTERCEPT (β_0), X1 (β_1), and X2 (β_2), are specified as 1. The initial value of the AR(1) coefficient (ϕ_1) is specified as 0.5. The initial value of ARCH0 (ω) is 0.8, the initial value of ARCH1 (α_1) is 0.1, and the initial value of GARCH1 (γ_1) is 0.6.

When you use the RESTRICT statement, the initial values specified by the INITIAL= option should satisfy the restrictions specified for the parameter estimates. If they do not, the initial values you specify are adjusted to satisfy the restrictions.

LDW

specifies that p -values for the Durbin-Watson test be computed using a linearized approximation of the design matrix when the model is nonlinear due to the presence of an autoregressive error process. (The Durbin-Watson tests of the OLS linear regression model residuals are not affected by the LDW option.) Refer to White (1992) for Durbin-Watson testing of nonlinear models.

MAXITER= *number*

sets the maximum number of iterations allowed. The default is MAXITER=50.

METHOD= *value*

requests the type of estimates to be computed. The values of the METHOD= option are as follows:

METHOD=ML specifies maximum likelihood estimates.

METHOD=ULS specifies unconditional least squares estimates.

METHOD=YW specifies Yule-Walker estimates.

METHOD=ITYW specifies iterative Yule-Walker estimates.

If the GARCH= or LAGDEP option is specified, the default is METHOD=ML. Otherwise, the default is METHOD=YW.

NOMISS

requests the estimation to the first contiguous sequence of data with no missing values. Otherwise, all complete observations are used.

OPTMETHOD= QN | TR

specifies the optimization technique when the GARCH or heteroscedasticity model is estimated. The OPTMETHOD=QN option specifies the quasi-Newton method. The OPTMETHOD=TR option specifies the trust region method. The default is OPTMETHOD=QN.

HETERO Statement

The HETERO statement specifies variables that are related to the heteroscedasticity of the residuals and the way these variables are used to model the error variance of the regression.

The syntax of the HETERO statement is

HETERO *variables / options* ;

The heteroscedastic regression model supported by the HETERO statement is

$$y_t = \mathbf{x}_t \beta + \epsilon_t$$

$$\epsilon_t \sim N(0, \sigma_t^2)$$

$$\sigma_t^2 = \sigma^2 h_t$$

$$h_t = l(\mathbf{z}'_t \eta)$$

The HETERO statement specifies a model for the conditional variance h_t . The vector \mathbf{z}_t is composed of the variables listed in the HETERO statement, η is a parameter vector, and $l(\cdot)$ is a link function that depends on the value of the LINK= option. In the printed output, *HET0* represents the estimate of sigma, while *HET1* - *HETn* are the estimates of parameters in the η vector.

The keyword XBETA can be used in the *variables* list to refer to the model predicted value $\mathbf{x}'_t \beta$. If XBETA is specified in the *variables* list, other variables in the HETERO statement will be ignored. In addition, XBETA cannot be specified in the GARCH process.

For heteroscedastic regression models without GARCH effects, the errors ϵ_t are assumed to be uncorrelated — the heteroscedasticity models specified by the HETERO statement cannot be combined with an autoregressive model for the errors. Thus, when a HETERO statement is used, the NLAG= option cannot be specified unless the GARCH= option is also specified.

You can specify the following options in the HETERO statement.

LINK= *value*

specifies the functional form of the heteroscedasticity model. By default, LINK=EXP. If you specify a GARCH model with the HETERO statement, the model is estimated using LINK=LINEAR only. For details, see the section “Using the HETERO Statement with GARCH Models” on page 364. Values of the LINK= option are as follows:

EXP specifies the exponential link function. The following model is estimated when you specify LINK=EXP:

$$h_t = \exp(\mathbf{z}'_t \eta)$$

SQUARE specifies the square link function. The following model is estimated when you specify LINK=SQUARE:

$$h_t = (1 + \mathbf{z}'_t \eta)^2$$

LINEAR specifies the linear function; that is, the HETERO statement variables predict the error variance linearly. The following model is estimated when you specify LINK=LINEAR:

$$h_t = (1 + \mathbf{z}'_t \eta)$$

COEF= *value*

imposes constraints on the estimated parameters η of the heteroscedasticity model. The values of the COEF= option are as follows:

NONNEG specifies that the estimated heteroscedasticity parameters η must be non-negative. When the HETERO statement is used in conjunction with the GARCH= option, the default is COEF=NONNEG.

UNIT constrains all heteroscedasticity parameters η to equal 1.

ZERO constrains all heteroscedasticity parameters η to equal 0.

UNREST specifies unrestricted estimation of η . When the GARCH= option is not specified, the default is COEF=UNREST.

STD= *value*

imposes constraints on the estimated standard deviation σ of the heteroscedasticity model. The values of the STD= option are as follows:

NONNEG specifies that the estimated standard deviation parameter σ must be non-negative.

UNIT constrains the standard deviation parameter σ to equal 1.

UNREST specifies unrestricted estimation of σ . This is the default.

TEST= *LM*

produces a Lagrange multiplier test for heteroscedasticity. The null hypothesis is homoscedasticity; the alternative hypothesis is heteroscedasticity of the form specified by the

HETERO statement. The power of the test depends on the variables specified in the HETERO statement.

The test may give different results depending on the functional form specified by the LINK= option. However, in many cases the test does not depend on the LINK= option. The test is invariant to the form of h_t when $h_t(0) = 1$ and $h'_t(0) \neq 0$. (The condition $h_t(0) = 1$ is satisfied except when the NOCONST option is specified with LINK=SQUARE or LINK=LINEAR.)

NOCONST

specifies that the heteroscedasticity model does not include the unit term for the LINK=SQUARE and LINK=LINEAR options. For example, the following model is estimated when you specify the options LINK=SQUARE NOCONST:

$$h_t = (\mathbf{z}'_t \boldsymbol{\eta})^2$$

RESTRICT Statement

The RESTRICT statement provides constrained estimation. The syntax of the RESTRICT statement is

```
RESTRICT equation , ... , equation ;
```

The RESTRICT statement places restrictions on the parameter estimates for covariates in the preceding MODEL statement. Any number of RESTRICT statements can follow a MODEL statement. Several restrictions can be specified in a single RESTRICT statement by separating the individual restrictions with commas.

Each restriction is written as a linear equation composed of constants and parameter names. Refer to model parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model.

The following is an example of a RESTRICT statement:

```
model y = a b c d ;  
restrict a+b=0, 2*d-c=0 ;
```

When restricting a linear combination of parameters to be 0, you can omit the equal sign. For example, the following RESTRICT statement is equivalent to the preceding example:

```
restrict a+b, 2*d-c ;
```

The following RESTRICT statement constrains the parameters estimates for three regressors (X1, X2, and X3) to be equal:

```
restrict x1 = x2, x2 = x3 ;
```

The preceding restriction can be abbreviated as follows.

```
restrict x1 = x2 = x3;
```

Only simple linear combinations of parameters can be specified in RESTRICT statement expressions; complex expressions involving parentheses, division, functions, or complex products are not allowed.

TEST Statement

The AUTOREG procedure now supports a TEST statement for linear hypothesis tests. The syntax of the TEST statement is

```
TEST equation , ... , equation / option ;
```

The TEST statement tests hypotheses about the covariates in the model estimated by the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Each test is written as a linear equation composed of constants and parameter names. Refer to parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model.

You can specify the following option in the TEST statement:

TYPE= value

specifies the test statistics to use, F or Wald. TYPE=F produces an F test. TYPE=WALD produces a Wald test. The default is TYPE=F.

The following example of a TEST statement tests the hypothesis that the coefficients of two regressors A and B are equal:

```
model y = a b c d;
test a = b;
```

To test separate null hypotheses, use separate TEST statements. To test a joint hypothesis, specify the component hypotheses on the same TEST statement, separated by commas.

For example, consider the following linear model:

$$y_t = \beta_0 + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t$$

The following statements test the two hypotheses $H_0 : \beta_0 = 1$ and $H_0 : \beta_1 + \beta_2 = 0$:

```
model y = x1 x2;
test intercept = 1;
test x1 + x2 = 0;
```

The following statements test the joint hypothesis $H_0 : \beta_0 = 1$ and $\beta_1 + \beta_2 = 0$:

```

model y = x1 x2;
test intercept = 1, x1 + x2 = 0;

```

OUTPUT Statement

OUTPUT *OUT=SAS-data-set keyword = options ...;*

The OUTPUT statement creates an output SAS data set as specified by the following options.

OUT= *SAS-data-set*

names the output SAS data set containing the predicted and transformed values. If the OUT= option is not specified, the new data set is named according to the DATA*n* convention.

ALPHACLI= *number*

sets the confidence limit size for the estimates of future values of the response time series. The ALPHACLI= value must be between 0 and 1. The resulting confidence interval has 1-*number* confidence. The default is ALPHACLI=.05, corresponding to a 95% confidence interval.

ALPHACLM= *number*

sets the confidence limit size for the estimates of the structural or regression part of the model. The ALPHACLI= value must be between 0 and 1. The resulting confidence interval has 1-*number* confidence. The default is ALPHACLM=.05, corresponding to a 95% confidence interval.

ALPHACSM= *.01 | .05 | .10*

specifies the significance level for the upper and lower bounds of the CUSUM and CUSUMSQ statistics output by the CUSUMLB=, CUSUMUB=, CUSUMSQLB=, and CUSUMSQUB= options. The significance level specified by the ALPHACSM= option can be .01, .05, or .10. Other values are not supported.

The following options are of the form *KEYWORD=name*, where *KEYWORD* specifies the statistic to include in the output data set and *name* gives the name of the variable in the OUT= data set containing the statistic.

BLUS= *variable*

specifies the name of a variable to contain the values of the Theil's BLUS residuals. Refer to Theil (1971) for more information on BLUS residuals.

CEV= *variable*

HT= *variable*

writes to the output data set the value of the error variance σ_t^2 from the heteroscedasticity model specified by the HETERO statement or the value of the conditional error variance h_t by the GARCH= option in the MODEL statement.

CPEV= *variable*

writes the conditional prediction error variance to the output data set. The value of conditional prediction error variance is equal to that of the conditional error variance when there are no

autoregressive parameters. For the exponential GARCH model, conditional prediction error variance cannot be calculated. See the section “[Predicted Values](#)” on page 381 later in this chapter for details.

CONSTANT= *variable*

writes the transformed intercept to the output data set. The details of the transformation are described in “[Computational Methods](#)” on page 359 later in this chapter.

CUSUM= *variable*

specifies the name of a variable to contain the CUSUM statistics.

CUSUMSQ= *variable*

specifies the name of a variable to contain the CUSUMSQ statistics.

CUSUMUB= *variable*

specifies the name of a variable to contain the upper confidence bound for the CUSUM statistic.

CUSUMLB= *variable*

specifies the name of a variable to contain the lower confidence bound for the CUSUM statistic.

CUSUMSQUB= *variable*

specifies the name of a variable to contain the upper confidence bound for the CUSUMSQ statistic.

CUSUMSQLB= *variable*

specifies the name of a variable to contain the lower confidence bound for the CUSUMSQ statistic.

LCL= *name*

writes the lower confidence limit for the predicted value (specified in the PREDICTED= option) to the output data set. The size of the confidence interval is set by the ALPHACLI= option. When a GARCH model is estimated, the lower confidence limit is calculated assuming that the disturbances have homoscedastic conditional variance. See the section “[Predicted Values](#)” on page 381 later in this chapter for details.

LCLM= *name*

writes the lower confidence limit for the structural predicted value (specified in the PREDICTEDM= option) to the output data set under the name given. The size of the confidence interval is set by the ALPHACLM= option.

PREDICTED= *name*

P= *name*

writes the predicted values to the output data set. These values are formed from both the structural and autoregressive parts of the model. See the section “[Predicted Values](#)” on page 381 later in this chapter for details.

PREDICTEDM= *name*

PM= *name*

writes the structural predicted values to the output data set. These values are formed from only the structural part of the model. See the section “[Predicted Values](#)” on page 381 later in this chapter for details.

RECPEV= *variable*

specifies the name of a variable to contain the part of the predictive error variance (v_t) that is used to compute the recursive residuals.

RECRES= *variable*

specifies the name of a variable to contain recursive residuals. The recursive residuals are used to compute the CUSUM and CUSUMSQ statistics.

RESIDUAL= *name*

R= *name*

writes the residuals from the predicted values based on both the structural and time series parts of the model to the output data set.

RESIDUALM= *name*

RM= *name*

writes the residuals from the structural prediction to the output data set.

TRANSFORM= *variables*

transforms the specified variables from the input data set by the autoregressive model and writes the transformed variables to the output data set. The details of the transformation are described in “[Computational Methods](#)” on page 359 later in this chapter. If you need to reproduce the data suitable for reestimation, you must also transform an intercept variable. To do this, transform a variable that is all 1s or use the **CONSTANT=** option.

UCL= *name*

writes the upper confidence limit for the predicted value (specified in the **PREDICTED=** option) to the output data set. The size of the confidence interval is set by the **ALPHACLI=** option. When the GARCH model is estimated, the upper confidence limit is calculated assuming that the disturbances have homoscedastic conditional variance. See the section “[Predicted Values](#)” on page 381 later in this chapter for details.

UCLM= *name*

writes the upper confidence limit for the structural predicted value (specified in the **PREDICTEDM=** option) to the output data set. The size of the confidence interval is set by the **ALPHACLIM=** option.

Details: AUTOREG Procedure

Missing Values

PROC AUTOREG skips any missing values at the beginning of the data set. If the NOMISS option is specified, the first contiguous set of data with no missing values is used; otherwise, all data with nonmissing values for the independent and dependent variables are used. Note, however, that the observations containing missing values are still needed to maintain the correct spacing in the time series. PROC AUTOREG can generate predicted values when the dependent variable is missing.

Autoregressive Error Model

The regression model with autocorrelated disturbances is as follows:

$$y_t = \mathbf{x}_t' \boldsymbol{\beta} + v_t$$

$$v_t = \epsilon_t - \varphi_1 v_{t-1} - \dots - \varphi_m v_{t-m}$$

$$\epsilon_t \sim N(0, \sigma^2)$$

In these equations, y_t are the dependent values, \mathbf{x}_t is a column vector of regressor variables, $\boldsymbol{\beta}$ is a column vector of structural parameters, and ϵ_t is normally and independently distributed with a mean of 0 and a variance of σ^2 . Note that in this parameterization, the signs of the autoregressive parameters are reversed from the parameterization documented in most of the literature.

PROC AUTOREG offers four estimation methods for the autoregressive error model. The default method, Yule-Walker (YW) estimation, is the fastest computationally. The Yule-Walker method used by PROC AUTOREG is described in Gallant and Goebel (1976). Harvey (1981) calls this method the *two-step full transform method*. The other methods are iterated YW, unconditional least squares (ULS), and maximum likelihood (ML). The ULS method is also referred to as nonlinear least squares (NLS) or exact least squares (ELS).

You can use all of the methods with data containing missing values, but you should use ML estimation if the missing values are plentiful. See the section “[Alternative Autocorrelation Correction Methods](#)” on page 361 later in this chapter for further discussion of the advantages of different methods.

The Yule-Walker Method

Let $\boldsymbol{\varphi}$ represent the vector of autoregressive parameters,

$$\boldsymbol{\varphi} = (\varphi_1, \varphi_2, \dots, \varphi_m)'$$

and let the variance matrix of the error vector $\mathbf{v} = (v_1, \dots, v_N)'$ be Σ ,

$$E(\mathbf{v}\mathbf{v}') = \Sigma = \sigma^2\mathbf{V}$$

If the vector of autoregressive parameters $\boldsymbol{\varphi}$ is known, the matrix \mathbf{V} can be computed from the autoregressive parameters. Σ is then $\sigma^2\mathbf{V}$. Given Σ , the efficient estimates of regression parameters β can be computed using generalized least squares (GLS). The GLS estimates then yield the unbiased estimate of the variance σ^2 ,

The Yule-Walker method alternates estimation of β using generalized least squares with estimation of $\boldsymbol{\varphi}$ using the Yule-Walker equations applied to the sample autocorrelation function. The YW method starts by forming the OLS estimate of β . Next, $\boldsymbol{\varphi}$ is estimated from the sample autocorrelation function of the OLS residuals by using the Yule-Walker equations. Then \mathbf{V} is estimated from the estimate of $\boldsymbol{\varphi}$, and Σ is estimated from \mathbf{V} and the OLS estimate of σ^2 . The autocorrelation corrected estimates of the regression parameters β are then computed by GLS, using the estimated Σ matrix. These are the Yule-Walker estimates.

If the ITER option is specified, the Yule-Walker residuals are used to form a new sample autocorrelation function, the new autocorrelation function is used to form a new estimate of $\boldsymbol{\varphi}$ and \mathbf{V} , and the GLS estimates are recomputed using the new variance matrix. This alternation of estimates continues until either the maximum change in the $\hat{\boldsymbol{\varphi}}$ estimate between iterations is less than the value specified by the CONVERGE= option or the maximum number of allowed iterations is reached. This produces the iterated Yule-Walker estimates. Iteration of the estimates may not yield much improvement.

The Yule-Walker equations, solved to obtain $\hat{\boldsymbol{\varphi}}$ and a preliminary estimate of σ^2 , are

$$\mathbf{R}\hat{\boldsymbol{\varphi}} = -\mathbf{r}$$

Here $\mathbf{r} = (r_1, \dots, r_m)'$, where r_i is the lag i sample autocorrelation. The matrix \mathbf{R} is the Toeplitz matrix whose i, j th element is $r_{|i-j|}$. If you specify a subset model, then only the rows and columns of \mathbf{R} and \mathbf{r} corresponding to the subset of lags specified are used.

If the BACKSTEP option is specified, for purposes of significance testing, the matrix $[\mathbf{R} \ \mathbf{r}]$ is treated as a sum-of-squares-and-crossproducts matrix arising from a simple regression with $N - k$ observations, where k is the number of estimated parameters.

The Unconditional Least Squares and Maximum Likelihood Methods

Define the transformed error, \mathbf{e} , as

$$\mathbf{e} = \mathbf{L}^{-1}\mathbf{n}$$

where $\mathbf{n} = \mathbf{y} - \mathbf{X}\boldsymbol{\beta}$.

The unconditional sum of squares for the model, S , is

$$S = \mathbf{n}'\mathbf{V}^{-1}\mathbf{n} = \mathbf{e}'\mathbf{e}$$

The ULS estimates are computed by minimizing S with respect to the parameters β and φ_i .

The full log likelihood function for the autoregressive error model is

$$l = -\frac{N}{2}\ln(2\pi) - \frac{N}{2}\ln(\sigma^2) - \frac{1}{2}\ln(|\mathbf{V}|) - \frac{S}{2\sigma^2}$$

where $|\mathbf{V}|$ denotes determinant of \mathbf{V} . For the ML method, the likelihood function is maximized by minimizing an equivalent sum-of-squares function.

Maximizing l with respect to σ^2 (and concentrating σ^2 out of the likelihood) and dropping the constant term $-\frac{N}{2}\ln(2\pi) + 1 - \ln(N)$ produces the concentrated log likelihood function

$$l_c = -\frac{N}{2}\ln(S|\mathbf{V}|^{1/N})$$

Rewriting the variable term within the logarithm gives

$$S_{ml} = |\mathbf{L}|^{1/N} \mathbf{e}'\mathbf{e}|\mathbf{L}|^{1/N}$$

PROC AUTOREG computes the ML estimates by minimizing the objective function $S_{ml} = |\mathbf{L}|^{1/N} \mathbf{e}'\mathbf{e}|\mathbf{L}|^{1/N}$.

The maximum likelihood estimates may not exist for some data sets (Anderson and Mentz 1980). This is the case for very regular data sets, such as an exact linear trend.

Computational Methods

Sample Autocorrelation Function

The sample autocorrelation function is computed from the structural residuals or noise $\mathbf{n}_t = y_t - \mathbf{x}'_t\mathbf{b}$, where \mathbf{b} is the current estimate of β . The sample autocorrelation function is the sum of all available lagged products of \mathbf{n}_t of order j divided by $\ell + j$, where ℓ is the number of such products.

If there are no missing values, then $\ell + j = N$, the number of observations. In this case, the Toeplitz matrix of autocorrelations, \mathbf{R} , is at least positive semidefinite. If there are missing values, these autocorrelation estimates of r can yield an \mathbf{R} matrix that is not positive semidefinite. If such estimates occur, a warning message is printed, and the estimates are tapered by exponentially declining weights until \mathbf{R} is positive definite.

Data Transformation and the Kalman Filter

The calculation of \mathbf{V} from ϕ for the general AR(m) model is complicated, and the size of \mathbf{V} depends on the number of observations. Instead of actually calculating \mathbf{V} and performing GLS in the usual way, in practice a Kalman filter algorithm is used to transform the data and compute the GLS results through a recursive process.

In all of the estimation methods, the original data are transformed by the inverse of the Cholesky root of \mathbf{V} . Let \mathbf{L} denote the Cholesky root of \mathbf{V} — that is, $\mathbf{V} = \mathbf{L}\mathbf{L}'$ with \mathbf{L} lower triangular. For an AR(m) model, \mathbf{L}^{-1} is a band diagonal matrix with m anomalous rows at the beginning and the

autoregressive parameters along the remaining rows. Thus, if there are no missing values, after the first $m - 1$ observations the data are transformed as

$$z_t = x_t + \hat{\varphi}_1 x_{t-1} + \dots + \hat{\varphi}_m x_{t-m}$$

The transformation is carried out using a Kalman filter, and the lower triangular matrix \mathbf{L} is never directly computed. The Kalman filter algorithm, as it applies here, is described in Harvey and Phillips (1979) and Jones (1980). Although \mathbf{L} is not computed explicitly, for ease of presentation the remaining discussion is in terms of \mathbf{L} . If there are missing values, then the submatrix of \mathbf{L} consisting of the rows and columns with nonmissing values is used to generate the transformations.

Gauss-Newton Algorithms

The ULS and ML estimates employ a Gauss-Newton algorithm to minimize the sum of squares and maximize the log likelihood, respectively. The relevant optimization is performed simultaneously for both the regression and AR parameters. The OLS estimates of β and the Yule-Walker estimates of φ are used as starting values for these methods.

The Gauss-Newton algorithm requires the derivatives of \mathbf{e} or $|\mathbf{L}|^{1/N} \mathbf{e}$ with respect to the parameters. The derivatives with respect to the parameter vector β are

$$\frac{\partial \mathbf{e}}{\partial \beta'} = -\mathbf{L}^{-1} \mathbf{X}$$

$$\frac{\partial |\mathbf{L}|^{1/N} \mathbf{e}}{\partial \beta'} = -|\mathbf{L}|^{1/N} \mathbf{L}^{-1} \mathbf{X}$$

These derivatives are computed by the transformation described previously. The derivatives with respect to φ are computed by differentiating the Kalman filter recurrences and the equations for the initial conditions.

Variance Estimates and Standard Errors

For the Yule-Walker method, the estimate of the error variance, s^2 , is the error sum of squares from the last application of GLS, divided by the error degrees of freedom (number of observations N minus the number of free parameters).

The variance-covariance matrix for the components of \mathbf{b} is taken as $s^2(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$ for the Yule-Walker method. For the ULS and ML methods, the variance-covariance matrix of the parameter estimates is computed as $s^2(\mathbf{J}'\mathbf{J})^{-1}$. For the ULS method, \mathbf{J} is the matrix of derivatives of \mathbf{e} with respect to the parameters. For the ML method, \mathbf{J} is the matrix of derivatives of $|\mathbf{L}|^{1/N} \mathbf{e}$ divided by $|\mathbf{L}|^{1/N}$. The estimate of the variance-covariance matrix of \mathbf{b} assuming that φ is known is $s^2(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$.

Park and Mitchell (1980) investigated the small sample performance of the standard error estimates obtained from some of these methods. In particular, simulating an AR(1) model for the noise term, they found that the standard errors calculated using GLS with an estimated autoregressive parameter underestimated the true standard errors. These estimates of standard errors are the ones calculated by PROC AUTOREG with the Yule-Walker method.

The estimates of the standard errors calculated with the ULS or ML method take into account the joint estimation of the AR and the regression parameters and may give more accurate standard-error values than the YW method. At the same values of the autoregressive parameters, the ULS and ML standard errors will always be larger than those computed from Yule-Walker. However, simulations of the models used by Park and Mitchell (1980) suggest that the ULS and ML standard error estimates can also be underestimates. Caution is advised, especially when the estimated autocorrelation is high and the sample size is small.

High autocorrelation in the residuals is a symptom of lack of fit. An autoregressive error model should not be used as a nostrum for models that simply do not fit. It is often the case that time series variables tend to move as a random walk. This means that an AR(1) process with a parameter near one absorbs a great deal of the variation. See [Example 8.3](#) later in this chapter, which fits a linear trend to a sine wave.

For ULS or ML estimation, the joint variance-covariance matrix of all the regression and autoregression parameters is computed. For the Yule-Walker method, the variance-covariance matrix is computed only for the regression parameters.

Lagged Dependent Variables

The Yule-Walker estimation method is not directly appropriate for estimating models that include lagged dependent variables among the regressors. Therefore, the maximum likelihood method is the default when the LAGDEP or LAGDEP= option is specified in the MODEL statement. However, when lagged dependent variables are used, the maximum likelihood estimator is not exact maximum likelihood but is conditional on the first few values of the dependent variable.

Alternative Autocorrelation Correction Methods

Autocorrelation correction in regression analysis has a long history, and various approaches have been suggested. Moreover, the same method may be referred to by different names.

Pioneering work in the field was done by Cochrane and Orcutt (1949). The *Cochrane-Orcutt method* refers to a more primitive version of the Yule-Walker method that drops the first observation. The Cochrane-Orcutt method is like the Yule-Walker method for first-order autoregression, except that the Yule-Walker method retains information from the first observation. The iterative Cochrane-Orcutt method is also in use.

The Yule-Walker method used by PROC AUTOREG is also known by other names. Harvey (1981) refers to the Yule-Walker method as the *two-step full transform method*. The Yule-Walker method can be considered as generalized least squares using the OLS residuals to estimate the covariances across observations, and Judge et al. (1985) use the term *estimated generalized least squares* (EGLS) for this method. For a first-order AR process, the Yule-Walker estimates are often termed *Prais-Winsten estimates* (Prais and Winsten 1954). There are variations to these methods that use different estimators of the autocorrelations or the autoregressive parameters.

The unconditional least squares (ULS) method, which minimizes the error sum of squares for all observations, is referred to as the nonlinear least squares (NLS) method by Spitzer (1979).

The *Hildreth-Lu* method (Hildreth and Lu 1960) uses nonlinear least squares to jointly estimate the parameters with an AR(1) model, but it omits the first transformed residual from the sum of squares. Thus, the Hildreth-Lu method is a more primitive version of the ULS method supported by PROC AUTOREG in the same way Cochrane-Orcutt is a more primitive version of Yule-Walker.

The maximum likelihood method is also widely cited in the literature. Although the maximum likelihood method is well defined, some early literature refers to estimators that are called maximum likelihood but are not full unconditional maximum likelihood estimates. The AUTOREG procedure produces full unconditional maximum likelihood estimates.

Harvey (1981) and Judge et al. (1985) summarize the literature on various estimators for the autoregressive error model. Although asymptotically efficient, the various methods have different small sample properties. Several Monte Carlo experiments have been conducted, although usually for the AR(1) model.

Harvey and McAvinchey (1978) found that for a one-variable model, when the independent variable is trending, methods similar to Cochrane-Orcutt are inefficient in estimating the structural parameter. This is not surprising since a pure trend model is well modeled by an autoregressive process with a parameter close to 1.

Harvey and McAvinchey (1978) also made the following conclusions:

- The Yule-Walker method appears to be about as efficient as the maximum likelihood method. Although Spitzer (1979) recommended ML and NLS, the Yule-Walker method (labeled Prais-Winsten) did as well or better in estimating the structural parameter in Spitzer's Monte Carlo study (table A2 in their article) when the autoregressive parameter was not too large. Maximum likelihood tends to do better when the autoregressive parameter is large.
- For small samples, it is important to use a full transformation (Yule-Walker) rather than the Cochrane-Orcutt method, which loses the first observation. This was also demonstrated by Maeshiro (1976), Chipman (1979), and Park and Mitchell (1980).
- For large samples (Harvey and McAvinchey used 100), losing the first few observations does not make much difference.

GARCH, IGARCH, EGARCH, and GARCH-M Models

Consider the series y_t , which follows the GARCH process. The conditional distribution of the series Y for time t is written

$$y_t | \Psi_{t-1} \sim N(0, h_t)$$

where Ψ_{t-1} denotes all available information at time $t - 1$. The conditional variance h_t is

$$h_t = \omega + \sum_{i=1}^q \alpha_i y_{t-i}^2 + \sum_{j=1}^p \gamma_j h_{t-j}$$

where

$$p \geq 0, q > 0$$

$$\omega > 0, \alpha_i \geq 0, \gamma_j \geq 0$$

The GARCH(p, q) model reduces to the ARCH(q) process when $p = 0$. At least one of the ARCH parameters must be nonzero ($q > 0$). The GARCH regression model can be written

$$y_t = \mathbf{x}_t' \beta + \epsilon_t$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \sum_{i=1}^q \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^p \gamma_j h_{t-j}$$

where $e_t \sim \text{IN}(0, 1)$.

In addition, you can consider the model with disturbances following an autoregressive process and with the GARCH errors. The AR(m)-GARCH(p, q) regression model is denoted

$$y_t = \mathbf{x}_t' \beta + v_t$$

$$v_t = \epsilon_t - \phi_1 v_{t-1} - \dots - \phi_m v_{t-m}$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \sum_{i=1}^q \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^p \gamma_j h_{t-j}$$

GARCH Estimation with Nelson-Cao Inequality Constraints

The GARCH(p, q) model is written in ARCH(∞) form as

$$\begin{aligned} h_t &= \left(1 - \sum_{j=1}^p \gamma_j B^j \right)^{-1} \left[\omega + \sum_{i=1}^q \alpha_i \epsilon_{t-i}^2 \right] \\ &= \omega^* + \sum_{i=1}^{\infty} \phi_i \epsilon_{t-i}^2 \end{aligned}$$

where B is a backshift operator. Therefore, $h_t \geq 0$ if $\omega^* \geq 0$ and $\phi_i \geq 0, \forall i$. Assume that the roots of the following polynomial equation are inside the unit circle:

$$\sum_{j=0}^p -\gamma_j Z^{p-j}$$

where $\gamma_0 = -1$ and Z is a complex scalar. $-\sum_{j=0}^p \gamma_j Z^{p-j}$ and $\sum_{i=1}^q \alpha_i Z^{q-i}$ do not share common factors. Under these conditions, $|\omega^*| < \infty, |\phi_i| < \infty$, and these coefficients of the ARCH(∞) process are well defined.

Define $n = \max(p, q)$. The coefficient ϕ_i is written

$$\begin{aligned}\phi_0 &= \alpha_1 \\ \phi_1 &= \gamma_1\phi_0 + \alpha_2 \\ &\dots \\ \phi_{n-1} &= \gamma_1\phi_{n-2} + \gamma_2\phi_{n-3} + \dots + \gamma_{n-1}\phi_0 + \alpha_n \\ \phi_k &= \gamma_1\phi_{k-1} + \gamma_2\phi_{k-2} + \dots + \gamma_n\phi_{k-n} \text{ for } k \geq n\end{aligned}$$

where $\alpha_i = 0$ for $i > q$ and $\gamma_j = 0$ for $j > p$.

Nelson and Cao (1992) proposed the finite inequality constraints for GARCH(1, q) and GARCH(2, q) cases. However, it is not straightforward to derive the finite inequality constraints for the general GARCH(p , q) model.

For the GARCH(1, q) model, the nonlinear inequality constraints are

$$\begin{aligned}\omega &\geq 0 \\ \gamma_1 &\geq 0 \\ \phi_k &\geq 0 \text{ for } k = 0, 1, \dots, q-1\end{aligned}$$

For the GARCH(2, q) model, the nonlinear inequality constraints are

$$\begin{aligned}\Delta_i &\in R \text{ for } i = 1, 2 \\ \omega^* &\geq 0 \\ \Delta_1 &> 0 \\ \sum_{j=0}^{q-1} \Delta_1^{-j} \alpha_{j+1} &> 0 \\ \phi_k &\geq 0 \text{ for } k = 0, 1, \dots, q\end{aligned}$$

where Δ_1 and Δ_2 are the roots of $(Z^2 - \gamma_1 Z - \gamma_2)$.

For the GARCH(p , q) model with $p > 2$, only $\max(q-1, p) + 1$ nonlinear inequality constraints ($\phi_k \geq 0$ for $k = 0$ to $\max(q-1, p)$) are imposed, together with the in-sample positivity constraints of the conditional variance h_t .

Using the HETERO Statement with GARCH Models

The HETERO statement can be combined with the GARCH= option in the MODEL statement to include input variables in the GARCH conditional variance model. For example, the GARCH(1, 1) variance model with two dummy input variables D1 and D2 is

$$\begin{aligned}\epsilon_t &= \sqrt{h_t} e_t \\ h_t &= \omega + \alpha_1 \epsilon_{t-1}^2 + \gamma_1 h_{t-1} + \eta_1 D1_t + \eta_2 D2_t\end{aligned}$$

The following statements estimate this GARCH model:

```
proc autoreg data=one;
  model y = x z / garch=(p=1,q=1);
  hetero d1 d2;
run;
```

The parameters for the variables D1 and D2 can be constrained using the COEF= option. For example, the constraints $\eta_1 = \eta_2 = 1$ are imposed by the following statements:

```
proc autoreg data=one;
  model y = x z / garch=(p=1,q=1);
  hetero d1 d2 / coef=unit;
run;
```

Limitations of GARCH and Heteroscedasticity Specifications

When you specify both the GARCH= option and the HETERO statement, the GARCH=(TYPE=EXP) option is not valid. The COVEST= option is not applicable to the EGARCH model.

IGARCH and Stationary GARCH Model

The condition $\sum_{i=1}^q \alpha_i + \sum_{j=1}^p \gamma_j < 1$ implies that the GARCH process is weakly stationary since the mean, variance, and autocovariance are finite and constant over time. However, this condition is not sufficient for weak stationarity in the presence of autocorrelation. For example, the stationarity condition for an AR(1)-GARCH(p, q) process is

$$\frac{1}{1 - \phi_1^2} \sum_{i=1}^q \alpha_i + \sum_{j=1}^p \gamma_j < 1$$

When the GARCH process is stationary, the unconditional variance of ϵ_t is computed as

$$\mathbf{V}(\epsilon_t) = \frac{\omega}{(1 - \sum_{i=1}^q \alpha_i - \sum_{j=1}^p \gamma_j)}$$

where $\epsilon_t = \sqrt{h_t} e_t$ and h_t is the GARCH(p, q) conditional variance.

Sometimes the multistep forecasts of the variance do not approach the unconditional variance when the model is integrated in variance; that is, $\sum_{i=1}^q \alpha_i + \sum_{j=1}^p \gamma_j = 1$.

The unconditional variance for the IGARCH model does not exist. However, it is interesting that the IGARCH model can be strongly stationary even though it is not weakly stationary. Refer to Nelson (1990) for details.

EGARCH Model

The EGARCH model was proposed by Nelson (1991). Nelson and Cao (1992) argue that the non-negativity constraints in the linear GARCH model are too restrictive. The GARCH model imposes

the nonnegative constraints on the parameters, α_i and γ_j , while there are no restrictions on these parameters in the EGARCH model. In the EGARCH model, the conditional variance, h_t , is an asymmetric function of lagged disturbances ϵ_{t-i} :

$$\ln(h_t) = \omega + \sum_{i=1}^q \alpha_i g(z_{t-i}) + \sum_{j=1}^p \gamma_j \ln(h_{t-j})$$

where

$$g(z_t) = \theta z_t + \gamma[|z_t| - E|z_t|]$$

$$z_t = \epsilon_t / \sqrt{h_t}$$

The coefficient of the second term in $g(z_t)$ is set to be 1 ($\gamma=1$) in our formulation. Note that $E|z_t| = (2/\pi)^{1/2}$ if $z_t \sim N(0, 1)$. The properties of the EGARCH model are summarized as follows:

- The function $g(z_t)$ is linear in z_t with slope coefficient $\theta + 1$ if z_t is positive while $g(z_t)$ is linear in z_t with slope coefficient $\theta - 1$ if z_t is negative.
- Suppose that $\theta = 0$. Large innovations increase the conditional variance if $|z_t| - E|z_t| > 0$ and decrease.
- the conditional variance if $|z_t| - E|z_t| < 0$
- Suppose that $\theta < 1$. The innovation in variance, $g(z_t)$, is positive if the innovations z_t are less than $(2/\pi)^{1/2}/(\theta - 1)$. Therefore, the negative innovations in returns, ϵ_t , cause the innovation to the conditional variance to be positive if θ is much less than 1.

GARCH-in-Mean

The GARCH-M model has the added regressor that is the conditional standard deviation:

$$y_t = \mathbf{x}'_t \beta + \delta \sqrt{h_t} + \epsilon_t$$

$$\epsilon_t = \sqrt{h_t} e_t$$

where h_t follows the ARCH or GARCH process.

Maximum Likelihood Estimation

The family of GARCH models are estimated using the maximum likelihood method. The log-likelihood function is computed from the product of all conditional densities of the prediction errors.

When e_t is assumed to have a standard normal distribution ($e_t \sim N(0, 1)$), the log-likelihood function is given by

$$l = \sum_{t=1}^N \frac{1}{2} \left[-\ln(2\pi) - \ln(h_t) - \frac{\epsilon_t^2}{h_t} \right]$$

where $\epsilon_t = y_t - \mathbf{x}'_t \beta$ and h_t is the conditional variance. When the GARCH(p, q)-M model is estimated, $\epsilon_t = y_t - \mathbf{x}'_t \beta - \delta \sqrt{h_t}$. When there are no regressors, the residuals ϵ_t are denoted as y_t or $y_t - \delta \sqrt{h_t}$.

If e_t has the standardized Student's t distribution, the log-likelihood function for the conditional t distribution is

$$\ell = \sum_{t=1}^N \left[\ln \left(\Gamma \left(\frac{\nu+1}{2} \right) \right) - \ln \left(\Gamma \left(\frac{\nu}{2} \right) \right) - \frac{1}{2} \ln((\nu-2)h_t) - \frac{1}{2} (\nu+1) \ln \left(1 + \frac{\epsilon_t^2}{h_t(\nu-2)} \right) \right]$$

where $\Gamma(\cdot)$ is the gamma function and ν is the degree of freedom ($\nu > 2$). Under the conditional t distribution, the additional parameter $1/\nu$ is estimated. The log-likelihood function for the conditional t distribution converges to the log-likelihood function of the conditional normal GARCH model as $1/\nu \rightarrow 0$.

The likelihood function is maximized via either the dual quasi-Newton or trust region algorithm. The default is the dual quasi-Newton algorithm. The starting values for the regression parameters β are obtained from the OLS estimates. When there are autoregressive parameters in the model, the initial values are obtained from the Yule-Walker estimates. The starting value 1.0^{-6} is used for the GARCH process parameters.

The variance-covariance matrix is computed using the Hessian matrix. The dual quasi-Newton method approximates the Hessian matrix while the quasi-Newton method gets an approximation of the inverse of Hessian. The trust region method uses the Hessian matrix obtained using numerical differentiation. When there are active constraints, that is, $\mathbf{q}(\theta) = \mathbf{0}$, the variance-covariance matrix is given by

$$\mathbf{V}(\hat{\theta}) = \mathbf{H}^{-1} [\mathbf{I} - \mathbf{Q}'(\mathbf{Q}\mathbf{H}^{-1}\mathbf{Q}')^{-1}\mathbf{Q}\mathbf{H}^{-1}]$$

where $\mathbf{H} = -\partial^2 l / \partial \theta \partial \theta'$ and $\mathbf{Q} = \partial \mathbf{q}(\theta) / \partial \theta'$. Therefore, the variance-covariance matrix without active constraints reduces to $\mathbf{V}(\hat{\theta}) = \mathbf{H}^{-1}$.

R-Square Statistics and Other Measures of Fit

This section discusses various goodness-of-fit statistics produced by the AUTOREG procedure.

Total R-Square

The total R^2 statistic (Total Rsq) is computed as

$$R_{\text{tot}}^2 = 1 - \frac{SSE}{SST}$$

where SST is the sum of squares for the original response variable corrected for the mean and SSE is the final error sum of squares. The Total Rsq is a measure of how well the next value can be predicted using the structural part of the model and the past values of the residuals. If the NOINT option is specified, SST is the uncorrected sum of squares.

Regression R-Square

The regression R^2 (Reg RSQ) is computed as

$$R_{\text{reg}}^2 = 1 - \frac{TSSE}{TSST}$$

where $TSST$ is the total sum of squares of the transformed response variable corrected for the transformed intercept, and $TSSE$ is the error sum of squares for this transformed regression problem. If the NOINT option is requested, no correction for the transformed intercept is made. The Reg RSQ is a measure of the fit of the structural part of the model after transforming for the autocorrelation and is the R^2 for the transformed regression.

The regression R^2 and the total R^2 should be the same when there is no autocorrelation correction (OLS regression).

Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE)

The mean absolute error (MAE) is computed as

$$\text{MAE} = \frac{1}{T} \sum_{t=1}^T |e_t|$$

where e_t are the estimated model residuals and T is the number of observations.

The mean absolute percentage error (MAPE) is computed as

$$\text{MAPE} = \frac{1}{T'} \sum_{t=1}^T \delta_{y_t \neq 0} \frac{|e_t|}{|y_t|}$$

where e_t are the estimated model residuals, y_t are the original response variable observations, $\delta_{y_t \neq 0} = 1$ if $y_t \neq 0$, $\delta_{y_t \neq 0} |e_t/y_t| = 0$ if $y_t = 0$, and T' is the number of nonzero original response variable observations.

Calculation of Recursive Residuals and CUSUM Statistics

The recursive residuals w_t are computed as

$$w_t = \frac{e_t}{\sqrt{v_t}}$$

$$e_t = y_t - \mathbf{x}'_t \boldsymbol{\beta}^{(t)}$$

$$\boldsymbol{\beta}^{(t)} = \left[\sum_{i=1}^{t-1} \mathbf{x}_i \mathbf{x}'_i \right]^{-1} \left(\sum_{i=1}^{t-1} \mathbf{x}_i y_i \right)$$

$$v_t = 1 + \mathbf{x}'_t \left[\sum_{i=1}^{t-1} \mathbf{x}_i \mathbf{x}'_i \right]^{-1} \mathbf{x}_t$$

Note that the first $\beta^{(t)}$ can be computed for $t = p + 1$, where p is the number of regression coefficients. As a result, first p recursive residuals are not defined. Note also that the forecast error variance of e_t is the scalar multiple of v_t such that $V(e_t) = \sigma^2 v_t$.

The CUSUM and CUSUMSQ statistics are computed using the preceding recursive residuals.

$$\text{CUSUM}_t = \sum_{i=k+1}^t \frac{w_i}{\sigma_w}$$

$$\text{CUSUMSQ}_t = \frac{\sum_{i=k+1}^t w_i^2}{\sum_{i=k+1}^T w_i^2}$$

where w_i are the recursive residuals,

$$\sigma_w = \sqrt{\frac{\sum_{i=k+1}^T (w_i - \hat{w})^2}{(T - k - 1)}}$$

$$\hat{w} = \frac{1}{T - k} \sum_{i=k+1}^T w_i$$

and k is the number of regressors.

The CUSUM statistics can be used to test for misspecification of the model. The upper and lower critical values for CUSUM_t are

$$\pm a \left[\sqrt{T - k} + 2 \frac{(t - k)}{(T - k)^{\frac{1}{2}}} \right]$$

where $a = 1.143$ for a significance level 0.01, 0.948 for 0.05, and 0.850 for 0.10. These critical values are output by the CUSUMLB= and CUSUMUB= options for the significance level specified by the ALPHACSM= option.

The upper and lower critical values of CUSUMSQ_t are given by

$$\pm a + \frac{(t - k)}{T - k}$$

where the value of a is obtained from the table by Durbin (1969) if the $\frac{1}{2}(T - k) - 1 \leq 60$. Edgerton and Wells (1994) provided the method of obtaining the value of a for large samples.

These critical values are output by the CUSUMSQLB= and CUSUMSQUB= options for the significance level specified by the ALPHACSM= option.

Information Criteria AIC, AICC, and SBC

Akaike's information criterion (AIC), the corrected Akaike's information criterion (AICC) and Schwarz's Bayesian information criterion (SBC) are computed as follows:

$$\begin{aligned} \text{AIC} &= -2\ln(L) + 2k \\ \text{AICC} &= \text{AIC} + 2\frac{k(k+1)}{N-k-1} \\ \text{SBC} &= -2\ln(L) + \ln(N)k \end{aligned}$$

In these formulas, L is the value of the likelihood function evaluated at the parameter estimates, N is the number of observations, and k is the number of estimated parameters. Refer to Judge et al. (1985), Hurvich and Tsai (1989) and Schwarz (1978) for additional details.

Generalized Durbin-Watson Tests

Consider the following linear regression model:

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\nu}$$

where \mathbf{X} is an $N \times k$ data matrix, $\boldsymbol{\beta}$ is a $k \times 1$ coefficient vector, and $\boldsymbol{\nu}$ is a $N \times 1$ disturbance vector. The error term $\boldsymbol{\nu}$ is assumed to be generated by the j th-order autoregressive process $\nu_t = \epsilon_t - \varphi_j \nu_{t-j}$ where $|\varphi_j| < 1$, ϵ_t is a sequence of independent normal error terms with mean 0 and variance σ^2 . Usually, the Durbin-Watson statistic is used to test the null hypothesis $H_0 : \varphi_1 = 0$ against $H_1 : -\varphi_1 > 0$. Vinod (1973) generalized the Durbin-Watson statistic:

$$d_j = \frac{\sum_{t=j+1}^N (\hat{\nu}_t - \hat{\nu}_{t-j})^2}{\sum_{t=1}^N \hat{\nu}_t^2}$$

where $\hat{\nu}$ are OLS residuals. Using the matrix notation,

$$d_j = \frac{\mathbf{Y}'\mathbf{M}\mathbf{A}'_j\mathbf{A}_j\mathbf{M}\mathbf{Y}}{\mathbf{Y}'\mathbf{M}\mathbf{Y}}$$

where $\mathbf{M} = \mathbf{I}_N - \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$ and \mathbf{A}_j is a $(N-j) \times N$ matrix:

$$\mathbf{A}_j = \begin{bmatrix} -1 & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 0 & -1 & 0 & \cdots & 0 & 1 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & -1 & 0 & \cdots & 0 & 1 \end{bmatrix}$$

and there are $j-1$ zeros between -1 and 1 in each row of matrix \mathbf{A}_j .

The QR factorization of the design matrix \mathbf{X} yields a $N \times N$ orthogonal matrix \mathbf{Q} :

$$\mathbf{X} = \mathbf{Q}\mathbf{R}$$

where \mathbf{R} is an $N \times k$ upper triangular matrix. There exists an $N \times (N - k)$ submatrix of \mathbf{Q} such that $\mathbf{Q}_1 \mathbf{Q}'_1 = \mathbf{M}$ and $\mathbf{Q}'_1 \mathbf{Q}_1 = \mathbf{I}_{N-k}$. Consequently, the generalized Durbin-Watson statistic is stated as a ratio of two quadratic forms:

$$d_j = \frac{\sum_{l=1}^n \lambda_{jl} \xi_l^2}{\sum_{l=1}^n \xi_l^2}$$

where $\lambda_{j1} \dots \lambda_{jn}$ are upper n eigenvalues of $\mathbf{M} \mathbf{A}'_j \mathbf{A}_j \mathbf{M}$ and ξ_l is a standard normal variate, and $n = \min(N - k, N - j)$. These eigenvalues are obtained by a singular value decomposition of $\mathbf{Q}'_1 \mathbf{A}'_j$ (Golub and Van Loan 1989; Savin and White 1978).

The marginal probability (or p -value) for d_j given c_0 is

$$\text{Prob}\left(\frac{\sum_{l=1}^n \lambda_{jl} \xi_l^2}{\sum_{l=1}^n \xi_l^2} < c_0\right) = \text{Prob}(q_j < 0)$$

where

$$q_j = \sum_{l=1}^n (\lambda_{jl} - c_0) \xi_l^2$$

When the null hypothesis $H_0 : \varphi_j = 0$ holds, the quadratic form q_j has the characteristic function

$$\phi_j(t) = \prod_{l=1}^n (1 - 2(\lambda_{jl} - c_0)it)^{-1/2}$$

The distribution function is uniquely determined by this characteristic function:

$$F(x) = \frac{1}{2} + \frac{1}{2\pi} \int_0^\infty \frac{e^{itx} \phi_j(-t) - e^{-itx} \phi_j(t)}{it} dt$$

For example, to test $H_0 : \varphi_4 = 0$ given $\varphi_1 = \varphi_2 = \varphi_3 = 0$ against $H_1 : -\varphi_4 > 0$, the marginal probability (p -value) can be used:

$$F(0) = \frac{1}{2} + \frac{1}{2\pi} \int_0^\infty \frac{(\phi_4(-t) - \phi_4(t))}{it} dt$$

where

$$\phi_4(t) = \prod_{l=1}^n (1 - 2(\lambda_{4l} - \hat{d}_4)it)^{-1/2}$$

and \hat{d}_4 is the calculated value of the fourth-order Durbin-Watson statistic.

In the Durbin-Watson test, the marginal probability indicates positive autocorrelation ($-\varphi_j > 0$) if it is less than the level of significance (α), while you can conclude that a negative autocorrelation ($-\varphi_j < 0$) exists if the marginal probability based on the computed Durbin-Watson statistic is greater than $1 - \alpha$. Wallis (1972) presented tables for bounds tests of fourth-order autocorrelation, and Vinod (1973) has given tables for a 5% significance level for orders two to four. Using the

AUTOREG procedure, you can calculate the exact p -values for the general order of Durbin-Watson test statistics. Tests for the absence of autocorrelation of order p can be performed sequentially; at the j th step, test $H_0 : \varphi_j = 0$ given $\varphi_1 = \dots = \varphi_{j-1} = 0$ against $\varphi_j \neq 0$. However, the size of the sequential test is not known.

The Durbin-Watson statistic is computed from the OLS residuals, while that of the autoregressive error model uses residuals that are the difference between the predicted values and the actual values. When you use the Durbin-Watson test from the residuals of the autoregressive error model, you must be aware that this test is only an approximation. See “Autoregressive Error Model” on page 357 earlier in this chapter. If there are missing values, the Durbin-Watson statistic is computed using all the nonmissing values and ignoring the gaps caused by missing residuals. This does not affect the significance level of the resulting test, although the power of the test against certain alternatives may be adversely affected. Savin and White (1978) have examined the use of the Durbin-Watson statistic with missing values.

Enhanced Durbin-Watson Probability Computation

The Durbin-Watson probability calculations have been enhanced to compute the p -value of the generalized Durbin-Watson statistic for large sample sizes. Previously, the Durbin-Watson probabilities were only calculated for small sample sizes.

Consider the following linear regression model:

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$u_t + \varphi_j u_{t-j} = \epsilon_t, \quad t = 1, \dots, N$$

where \mathbf{X} is an $N \times k$ data matrix, $\boldsymbol{\beta}$ is a $k \times 1$ coefficient vector, \mathbf{u} is a $N \times 1$ disturbance vector, and ϵ_t is a sequence of independent normal error terms with mean 0 and variance σ^2 .

The generalized Durbin-Watson statistic is written as

$$DW_j = \frac{\hat{\mathbf{u}}' \mathbf{A}'_j \mathbf{A}_j \hat{\mathbf{u}}}{\hat{\mathbf{u}}' \hat{\mathbf{u}}}$$

where $\hat{\mathbf{u}}$ is a vector of OLS residuals and \mathbf{A}_j is a $(T-j) \times T$ matrix. The generalized Durbin-Watson statistic DW_j can be rewritten as

$$DW_j = \frac{\mathbf{Y}' \mathbf{M} \mathbf{A}'_j \mathbf{A}_j \mathbf{M} \mathbf{Y}}{\mathbf{Y}' \mathbf{M} \mathbf{Y}} = \frac{\boldsymbol{\eta}' (\mathbf{Q}'_1 \mathbf{A}'_j \mathbf{A}_j \mathbf{Q}_1) \boldsymbol{\eta}}{\boldsymbol{\eta}' \boldsymbol{\eta}}$$

where $\mathbf{Q}'_1 \mathbf{Q}_1 = \mathbf{I}_{T-k}$, $\mathbf{Q}'_1 \mathbf{X} = 0$, and $\boldsymbol{\eta} = \mathbf{Q}'_1 \mathbf{u}$.

The marginal probability for the Durbin-Watson statistic is

$$\Pr(DW_j < c) = \Pr(h < 0)$$

where $h = \boldsymbol{\eta}' (\mathbf{Q}'_1 \mathbf{A}'_j \mathbf{A}_j \mathbf{Q}_1 - c \mathbf{I}) \boldsymbol{\eta}$.

The p -value or the marginal probability for the generalized Durbin-Watson statistic is computed by numerical inversion of the characteristic function $\phi(u)$ of the quadratic form $h = \boldsymbol{\eta}' (\mathbf{Q}'_1 \mathbf{A}'_j \mathbf{A}_j \mathbf{Q}_1 -$

$c\mathbf{I}\eta$. The trapezoidal rule approximation to the marginal probability $\Pr(h < 0)$ is

$$\Pr(h < 0) = \frac{1}{2} - \sum_{k=0}^K \frac{\text{Im}[\phi((k + \frac{1}{2})\Delta)]}{\pi(k + \frac{1}{2})} + E_I(\Delta) + E_T(K)$$

where $\text{Im}[\phi(\cdot)]$ is the imaginary part of the characteristic function, $E_I(\Delta)$ and $E_T(K)$ are integration and truncation errors, respectively. Refer to Davies (1973) for numerical inversion of the characteristic function.

Ansley, Kohn, and Shively (1992) proposed a numerically efficient algorithm that requires $O(N)$ operations for evaluation of the characteristic function $\phi(u)$. The characteristic function is denoted as

$$\begin{aligned} \phi(u) &= \left| \mathbf{I} - 2iu(\mathbf{Q}'_1 \mathbf{A}'_j \mathbf{A}_j \mathbf{Q}_1 - c\mathbf{I}_{N-k}) \right|^{-1/2} \\ &= |\mathbf{V}|^{-1/2} |\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}|^{-1/2} |\mathbf{X}'\mathbf{X}|^{1/2} \end{aligned}$$

where $\mathbf{V} = (1 + 2iuc)\mathbf{I} - 2iu\mathbf{A}'_j \mathbf{A}_j$ and $i = \sqrt{-1}$. By applying the Cholesky decomposition to the complex matrix \mathbf{V} , you can obtain the lower triangular matrix \mathbf{G} that satisfies $\mathbf{V} = \mathbf{G}\mathbf{G}'$. Therefore, the characteristic function can be evaluated in $O(N)$ operations by using the following formula:

$$\phi(u) = |\mathbf{G}|^{-1} |\mathbf{X}^* \mathbf{X}^*|^{-1/2} |\mathbf{X}'\mathbf{X}|^{1/2}$$

where $\mathbf{X}^* = \mathbf{G}^{-1}\mathbf{X}$. Refer to Ansley, Kohn, and Shively (1992) for more information on evaluation of the characteristic function.

Tests for Serial Correlation with Lagged Dependent Variables

When regressors contain lagged dependent variables, the Durbin-Watson statistic (d_1) for the first-order autocorrelation is biased toward 2 and has reduced power. Wallis (1972) shows that the bias in the Durbin-Watson statistic (d_4) for the fourth-order autocorrelation is smaller than the bias in d_1 in the presence of a first-order lagged dependent variable. Durbin (1970) proposes two alternative statistics (Durbin h and t) that are asymptotically equivalent. The h statistic is written as

$$h = \hat{\rho} \sqrt{N/(1 - N\hat{V})}$$

where $\hat{\rho} = \sum_{t=2}^N \hat{v}_t \hat{v}_{t-1} / \sum_{t=1}^N \hat{v}_t^2$ and \hat{V} is the least squares variance estimate for the coefficient of the lagged dependent variable. Durbin's t test consists of regressing the OLS residuals \hat{v}_t on explanatory variables and \hat{v}_{t-1} and testing the significance of the estimate for coefficient of \hat{v}_{t-1} .

Inder (1984) shows that the Durbin-Watson test for the absence of first-order autocorrelation is generally more powerful than the h test in finite samples. Refer to Inder (1986) and King and Wu (1991) for the Durbin-Watson test in the presence of lagged dependent variables.

Testing

Heteroscedasticity and Normality Tests

Portmanteau Q Test

For nonlinear time series models, the portmanteau test statistic based on squared residuals is used to test for independence of the series (McLeod and Li 1983):

$$Q(q) = N(N + 2) \sum_{i=1}^q \frac{r(i; \hat{v}_t^2)}{(N - i)}$$

where

$$r(i; \hat{v}_t^2) = \frac{\sum_{t=i+1}^N (\hat{v}_t^2 - \hat{\sigma}^2)(\hat{v}_{t-i}^2 - \hat{\sigma}^2)}{\sum_{t=1}^N (\hat{v}_t^2 - \hat{\sigma}^2)^2}$$

$$\hat{\sigma}^2 = \frac{1}{N} \sum_{t=1}^N \hat{v}_t^2$$

This Q statistic is used to test the nonlinear effects (for example, GARCH effects) present in the residuals. The GARCH(p, q) process can be considered as an ARMA(max(p, q), p) process. See the section “[Predicting the Conditional Variance](#)” on page 383 later in this chapter. Therefore, the Q statistic calculated from the squared residuals can be used to identify the order of the GARCH process.

Lagrange Multiplier Test for ARCH Disturbances

Engle (1982) proposed a Lagrange multiplier test for ARCH disturbances. The test statistic is asymptotically equivalent to the test used by Breusch and Pagan (1979). Engle’s Lagrange multiplier test for the q th order ARCH process is written

$$LM(q) = \frac{N\mathbf{W}'\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'\mathbf{W}}{\mathbf{W}'\mathbf{W}}$$

where

$$\mathbf{W} = \left(\frac{\hat{v}_1^2}{\hat{\sigma}^2}, \dots, \frac{\hat{v}_N^2}{\hat{\sigma}^2} \right)'$$

and

$$\mathbf{Z} = \begin{bmatrix} 1 & \hat{v}_0^2 & \cdots & \hat{v}_{-q+1}^2 \\ \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ 1 & \hat{v}_{N-1}^2 & \cdots & \hat{v}_{N-q}^2 \end{bmatrix}$$

The presample values (v_0^2, \dots, v_{-q+1}^2) have been set to 0. Note that the LM(q) tests may have different finite-sample properties depending on the presample values, though they are asymptotically equivalent regardless of the presample values. The LM and Q statistics are computed from the OLS residuals assuming that disturbances are white noise. The Q and LM statistics have an approximate $\chi_{(q)}^2$ distribution under the white-noise null hypothesis.

Normality Test

Based on skewness and kurtosis, Jarque and Bera (1980) calculated the test statistic

$$T_N = \left[\frac{N}{6} b_1^2 + \frac{N}{24} (b_2 - 3)^2 \right]$$

where

$$b_1 = \frac{\sqrt{N} \sum_{t=1}^N \hat{u}_t^3}{\left(\sum_{t=1}^N \hat{u}_t^2 \right)^{\frac{3}{2}}}$$

$$b_2 = \frac{N \sum_{t=1}^N \hat{u}_t^4}{\left(\sum_{t=1}^N \hat{u}_t^2 \right)^2}$$

The $\chi^2(2)$ distribution gives an approximation to the normality test T_N .

When the GARCH model is estimated, the normality test is obtained using the standardized residuals $\hat{u}_t = \hat{\varepsilon}_t / \sqrt{h_t}$. The normality test can be used to detect misspecification of the family of ARCH models.

Computation of the Chow Test

Consider the linear regression model

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

where the parameter vector $\boldsymbol{\beta}$ contains k elements.

Split the observations for this model into two subsets at the break point specified by the CHOW= option, so that

$$\mathbf{y} = (\mathbf{y}'_1, \mathbf{y}'_2)'$$

$$\mathbf{X} = (\mathbf{X}'_1, \mathbf{X}'_2)'$$

$$\mathbf{u} = (\mathbf{u}'_1, \mathbf{u}'_2)'$$

Now consider the two linear regressions for the two subsets of the data modeled separately,

$$\mathbf{y}_1 = \mathbf{X}_1\boldsymbol{\beta}_1 + \mathbf{u}_1$$

$$\mathbf{y}_2 = \mathbf{X}_2\beta_2 + \mathbf{u}_2$$

where the number of observations from the first set is n_1 and the number of observations from the second set is n_2 .

The Chow test statistic is used to test the null hypothesis $H_0 : \beta_1 = \beta_2$ conditional on the same error variance $V(\mathbf{u}_1) = V(\mathbf{u}_2)$. The Chow test is computed using three sums of square errors:

$$F_{chow} = \frac{(\hat{\mathbf{u}}'\hat{\mathbf{u}} - \hat{\mathbf{u}}_1'\hat{\mathbf{u}}_1 - \hat{\mathbf{u}}_2'\hat{\mathbf{u}}_2)/k}{(\hat{\mathbf{u}}_1'\hat{\mathbf{u}}_1 + \hat{\mathbf{u}}_2'\hat{\mathbf{u}}_2)/(n_1 + n_2 - 2k)}$$

where $\hat{\mathbf{u}}$ is the regression residual vector from the full set model, $\hat{\mathbf{u}}_1$ is the regression residual vector from the first set model, and $\hat{\mathbf{u}}_2$ is the regression residual vector from the second set model. Under the null hypothesis, the Chow test statistic has an F distribution with k and $(n_1 + n_2 - 2k)$ degrees of freedom, where k is the number of elements in β .

Chow (1960) suggested another test statistic that tests the hypothesis that the mean of prediction errors is 0. The predictive Chow test can also be used when $n_2 < k$.

The PCHOW= option computes the predictive Chow test statistic

$$F_{pchow} = \frac{(\hat{\mathbf{u}}'\hat{\mathbf{u}} - \hat{\mathbf{u}}_1'\hat{\mathbf{u}}_1)/n_2}{\hat{\mathbf{u}}_1'\hat{\mathbf{u}}_1/(n_1 + k)}$$

The predictive Chow test has an F distribution with n_2 and $(n_1 - k)$ degrees of freedom.

Phillips-Perron Unit Root and Cointegration Testing

Consider the random walk process

$$y_t = y_{t-1} + u_t$$

where the disturbances might be serially correlated with possible heteroscedasticity. Phillips and Perron (1988) proposed the unit root test of the OLS regression model,

$$y_t = \rho y_{t-1} + u_t$$

Let $s^2 = \frac{1}{T-k} \sum_{t=1}^T \hat{u}_t^2$ and let $\hat{\sigma}^2$ be the variance estimate of the OLS estimator $\hat{\rho}$, where \hat{u}_t is the OLS residual. You can estimate the asymptotic variance of $\frac{1}{T} \sum_{t=1}^T \hat{u}_t^2$ by using the truncation lag l .

$$\hat{\lambda} = \sum_{j=0}^l \kappa_j [1 - j/(l+1)] \hat{\gamma}_j$$

where $\kappa_0 = 1$, $\kappa_j = 2$ for $j > 0$, and $\hat{\gamma}_j = \frac{1}{T} \sum_{t=j+1}^T \hat{u}_t \hat{u}_{t-j}$.

Then the Phillips-Perron \hat{Z}_α (defined here as \hat{Z}_ρ) test (zero mean case) is written

$$\hat{Z}_\rho = T(\hat{\rho} - 1) - \frac{1}{2} T^2 \hat{\sigma}^2 (\hat{\lambda} - \hat{\gamma}_0) / s^2$$

and has the following limiting distribution:

$$\frac{\frac{1}{2}\{B(1)^2 - 1\}}{\int_0^1 [B(x)]^2 dx}$$

where $B(\cdot)$ is a standard Brownian motion. Note that the realization z from the stochastic process $B(x)$ is distributed as $N(0, x)$ and thus $B(1)^2 \sim \chi_1^2$.

Note that $P(\hat{\rho} < 1) \approx 0.68$ as $T \rightarrow \infty$, which shows that the limiting distribution is skewed to the left.

Let τ_ρ be the τ statistic for $\hat{\rho}$. The Phillips-Perron \hat{Z}_τ (defined here as \hat{Z}_τ) test is written

$$\hat{Z}_\tau = (\hat{\gamma}_0/\hat{\lambda})^{1/2} t_{\hat{\rho}} - \frac{1}{2} T \hat{\sigma} (\hat{\lambda} - \hat{\gamma}_0) / (s \hat{\lambda}^{1/2})$$

and its limiting distribution is derived as

$$\frac{\frac{1}{2}\{[B(1)]^2 - 1\}}{\{\int_0^1 [B(x)]^2 dx\}^{1/2}}$$

When you test the regression model $y_t = \mu + \rho y_{t-1} + u_t$ for the true random walk process (single mean case), the limiting distribution of the statistic \hat{Z}_ρ is written

$$\frac{\frac{1}{2}\{[B(1)]^2 - 1\} - B(1) \int_0^1 B(x) dx}{\int_0^1 [B(x)]^2 dx - \left[\int_0^1 B(x) dx \right]^2}$$

while the limiting distribution of the statistic \hat{Z}_τ is given by

$$\frac{\frac{1}{2}\{[B(1)]^2 - 1\} - B(1) \int_0^1 B(x) dx}{\{\int_0^1 [B(x)]^2 dx - \left[\int_0^1 B(x) dx \right]^2\}^{1/2}}$$

Finally, the limiting distribution of the Phillips-Perron test for the random walk with drift process $y_t = \mu + y_{t-1} + u_t$ (trend case) can be derived as

$$[0 \quad c \quad 0] V^{-1} \begin{bmatrix} B(1) \\ \frac{B(1)^2 - 1}{2} \\ B(1) - \int_0^1 B(x) dx \end{bmatrix}$$

where $c = 1$ for \hat{Z}_ρ and $c = \frac{1}{\sqrt{Q}}$ for \hat{Z}_τ ,

$$V = \begin{bmatrix} 1 & \int_0^1 B(x) dx & \frac{1}{2} \\ \int_0^1 B(x) dx & \int_0^1 [B(x)]^2 dx & \int_0^1 x B(x) dx \\ \frac{1}{2} & \int_0^1 x B(x) dx & \frac{1}{3} \end{bmatrix}$$

$$Q = [0 \quad c \quad 0] V^{-1} \begin{bmatrix} 0 \\ c \\ 0 \end{bmatrix}$$

When several variables $\mathbf{z}_t = (z_{1t}, \dots, z_{kt})'$ are cointegrated, there exists a $(k \times 1)$ cointegrating vector \mathbf{c} such that $\mathbf{c}'\mathbf{z}_t$ is stationary and \mathbf{c} is a nonzero vector. The residual based cointegration test assumes the following regression model:

$$y_t = \beta_1 + \mathbf{x}_t' \boldsymbol{\beta} + u_t$$

where $y_t = z_{1t}$, $\mathbf{x}_t = (z_{2t}, \dots, z_{kt})'$, and $\boldsymbol{\beta} = (\beta_2, \dots, \beta_k)'$. You can estimate the consistent cointegrating vector by using OLS if all variables are difference stationary — that is, $I(1)$. The Phillips-Ouliaris test is computed using the OLS residuals from the preceding regression model, and it performs the test for the null hypothesis of no cointegration. The estimated cointegrating vector is $\hat{\mathbf{c}} = (1, -\hat{\beta}_2, \dots, -\hat{\beta}_k)'$.

You need to refer to the tables by Phillips and Ouliaris (1990) to obtain the p -value of the cointegration test. Before you apply the cointegration test, you may want to perform the unit root test for each variable (see the option `STATIONARITY=(PHILLIPS)`).

Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test

The KPSS test was introduced in Kwiatkowski et al. (1992) to test the null hypothesis that an observable series is stationary around a deterministic trend. Please note, that for consistency reasons, the notation used here is different from the notation used in the original paper. The setup of the problem is as follows: it is assumed that the series is expressed as the sum of the deterministic trend, random walk r_t , and stationary error u_t ; that is,

$$y_t = \mu + \delta t + r_t + u_t$$

with $r_t = r_{t-1} + e_t$, $e_t \sim \text{iid}(0, \sigma_e^2)$, and an intercept μ (in the original paper, the authors use r_0 instead of μ .) Under stronger assumptions of normality and iid of u_t and e_t , a one-sided LM test of the null that there is no random walk ($e_t = 0, \forall t$) can be constructed as follows:

$$\begin{aligned} \widehat{LM} &= \frac{1}{T^2} \sum_{t=1}^T \frac{S_t^2}{s^2(l)} \\ s^2(l) &= \frac{1}{T} \sum_{t=1}^T u_t^2 + \frac{2}{T} \sum_{s=1}^l w(s, l) \sum_{t=s+1}^T u_t u_{t-s} \\ S_t &= \sum_{\tau=1}^t u_\tau \end{aligned}$$

Following the original work of Kwiatkowski, Phillips, Schmidt, and Shin, under the null ($\sigma_e^2 = 0$), \widehat{LM} statistic converges asymptotically to three different distributions depending on whether the model is trend-stationary, level-stationary ($\delta = 0$), or zero-mean stationary ($\delta = 0, \mu = 0$). The trend-stationary model is denoted by subscript τ and the level-stationary model is denoted by subscript μ . The case when there is no trend and zero intercept denoted as 0. The last case is

considered in Hobijn, Franses, and Ooms (2004).

$$\begin{aligned}
 y_t = u_t : \quad \widehat{LM}_0 &\xrightarrow{D} \int_0^1 B^2(r) dr \\
 y_t = \mu + u_t : \quad \widehat{LM}_\mu &\xrightarrow{D} \int_0^1 V^2(r) dr \\
 y_t = \mu + \delta t + u_t : \quad \widehat{LM}_\tau &\xrightarrow{D} \int_0^1 V_2^2(r) dr \\
 \text{with:} \quad V(r) &= B(r) - rB(1) \\
 V_2(r) &= B(r) + (2r - 3r^2)B(1) + (-6r + 6r^2) \int_0^1 B(s) ds
 \end{aligned}$$

where $V(r)$ is a standard Brownian bridge, $V_2(r)$ is a Brownian bridge of a second-level, $B(r)$ is a Brownian motion (Wiener process), and \xrightarrow{D} is convergence in distribution.

Using the notation of Kwiatkowski et al. (1992) the \widehat{LM} statistic is named as $\hat{\eta}$. This test depends on the computational method used to compute the long-run variance $s(l)$ — that is, the window width l and the kernel type $w(\cdot)$. You can specify the kernel used in the test, using the KERNEL option:

- Newey-West/Bartlett (KERNEL=NW | BART), default

$$w(s, l) = 1 - \frac{s}{l + 1}$$

- Quadratic spectral (KERNEL=QS)

$$w(s/l) = w(x) = \frac{25}{12\pi^2 x^2} \left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5) \right)$$

You can specify the number of lags, l , in three different ways:

- Schwert (SCHW = c) (default for NW, c=4)

$$l = \text{floor} \left\{ c \left(\frac{T}{100} \right)^{1/4} \right\}$$

- Manual (LAG = l)
- Automatic selection (AUTO) (default for QS) Hobijn, Franses, and Ooms (2004)

The last option (AUTO) needs more explanation, summarized in the following table.

NW Kernel	QS Kernel
$l = \min(T, \text{floor}(\hat{\gamma}T^{1/3}))$ where T – number of observations,	$l = \min(T, \text{floor}(\hat{\gamma}T^{1/5}))$
$\hat{\gamma} = 1.1447 \left\{ \left(\frac{\hat{s}^{(1)}}{\hat{s}^{(0)}} \right)^2 \right\}^{1/3}$	$\hat{\gamma} = 1.3221 \left\{ \left(\frac{\hat{s}^{(2)}}{\hat{s}^{(0)}} \right)^2 \right\}^{1/5}$
$\hat{s}^{(j)} = \delta_{0,j} \hat{\gamma}_0 + 2 \sum_{i=1}^n i^j \hat{\gamma}_i$	
$n = \text{floor}(T^{2/9})$	$n = \text{floor}(T^{2/25})$

$$\delta_{0,j} = \begin{cases} 1 & j = 0 \\ 0 & \text{otherwise} \end{cases}$$

$$\hat{\gamma}_i = \frac{1}{T} \sum_{t=1}^{T-i} u_t u_{t+i}$$

Ramsey's Reset Test

Ramsey's reset test is a misspecification test associated with the functional form of models to check whether power transforms need to be added to a model. The original linear model, henceforth called the restricted model, is

$$y_t = \mathbf{x}_t \boldsymbol{\beta} + u_t$$

To test for misspecification in the functional form, the unrestricted model is

$$y_t = \mathbf{x}_t \boldsymbol{\beta} + \sum_{j=2}^p \phi_j \hat{y}_t^j + u_t$$

where \hat{y}_t is the predicted value from the linear model and p is the power of \hat{y}_t in the unrestricted model equation starting from 2. The number of higher-ordered terms to be chosen depends on the discretion of the analyst. The RESET opti

on produces test results for $p = 2, 3$, and 4.

The reset test is an F statistic for testing $H_0 : \phi_j = 0, \forall j = 2, \dots, p$, against $H_1 : \phi_j \neq 0$ for at least one $j = 2, \dots, p$ in the unrestricted model and is computed as follows:

$$F_{(p-1, n-k-p+1)} = \frac{(SSE_R - SSE_U)/(p-1)}{SSE_U/(n-k-p+1)}$$

where SSE_R is the sum of squared errors due to the restricted model, SSE_U is the sum of squared errors due to the unrestricted model, n is the total number of observations, and k is the number of parameters in the original linear model.

Ramsey's test can be viewed as a linearity test that checks whether any nonlinear transformation of the specified independent variables has been omitted, but it need not help in identifying a new relevant variable other than those already specified in the current model.

Predicted Values

The AUTOREG procedure can produce two kinds of predicted values for the response series and corresponding residuals and confidence limits. The residuals in both cases are computed as the actual value minus the predicted value. In addition, when GARCH models are estimated, the AUTOREG procedure can output predictions of the conditional error variance.

Predicting the Unconditional Mean

The first type of predicted value is obtained from only the structural part of the model, $\mathbf{x}'_t \mathbf{b}$. These are useful in predicting values of new response time series, which are assumed to be described by the same model as the current response time series. The predicted values, residuals, and upper and lower confidence limits for the structural predictions are requested by specifying the PREDICTEDM=, RESIDUALM=, UCLM=, or LCLM= option in the OUTPUT statement. The ALPHACL M= option controls the confidence level for UCLM= and LCLM=. These confidence limits are for estimation of the mean of the dependent variable, $\mathbf{x}'_t \mathbf{b}$, where \mathbf{x}_t is the column vector of independent variables at observation t .

The predicted values are computed as

$$\hat{y}_t = \mathbf{x}'_t \mathbf{b}$$

and the upper and lower confidence limits as

$$\hat{u}_t = \hat{y}_t + t_{\alpha/2} v$$

$$\hat{l}_t = \hat{y}_t - t_{\alpha/2} v$$

where v^2 is an estimate of the variance of \hat{y}_t and $t_{\alpha/2}$ is the upper $\alpha/2$ percentage point of the t distribution.

$$\text{Prob}(T > t_{\alpha/2}) = \alpha/2$$

where T is an observation from a t distribution with q degrees of freedom. The value of α can be set with the ALPHACL M= option. The degrees of freedom parameter, q , is taken to be the number of observations minus the number of free parameters in the regression and autoregression parts of the model. For the YW estimation method, the value of v is calculated as

$$v = \sqrt{s^2 \mathbf{x}'_t (\mathbf{X}' \mathbf{V}^{-1} \mathbf{X})^{-1} \mathbf{x}_t}$$

where s^2 is the error sum of squares divided by q . For the ULS and ML methods, it is calculated as

$$v = \sqrt{s^2 \mathbf{x}'_t \mathbf{W} \mathbf{x}_t}$$

where \mathbf{W} is the $k \times k$ submatrix of $(\mathbf{J}' \mathbf{J})^{-1}$ that corresponds to the regression parameters. For details, see the section “Computational Methods” on page 359 earlier in this chapter.

Predicting Future Series Realizations

The other predicted values use both the structural part of the model and the predicted values of the error process. These conditional mean values are useful in predicting future values of the current response time series. The predicted values, residuals, and upper and lower confidence limits for future observations conditional on past values are requested by the PREDICTED=, RESIDUAL=, UCL=, or LCL= option in the OUTPUT statement. The ALPHACLI= option controls the confidence level for UCL= and LCL=. These confidence limits are for the predicted value,

$$\tilde{y}_t = \mathbf{x}'_t \mathbf{b} + v_{t|t-1}$$

where \mathbf{x}_t is the vector of independent variables and $v_{t|t-1}$ is the minimum variance linear predictor of the error term given the available past values of v_{t-j} , $j = 1, 2, \dots, t-1$, and the autoregressive model for v_t . If the m previous values of the structural residuals are available, then

$$v_{t|t-1} = -\hat{\phi}_1 v_{t-1} - \dots - \hat{\phi}_m v_{t-m}$$

where $\hat{\phi}_1, \dots, \hat{\phi}_m$ are the estimated AR parameters. The upper and lower confidence limits are computed as

$$\tilde{u}_t = \tilde{y}_t + t_{\alpha/2} v$$

$$\tilde{l}_t = \tilde{y}_t - t_{\alpha/2} v$$

where v , in this case, is computed as

$$v = \sqrt{s^2(\mathbf{x}'_t(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{x}_t + r)}$$

where the value rs^2 is the estimate of the variance of $v_{t|t-1}$. At the start of the series, and after missing values, r is generally greater than 1. See the section “[Predicting the Conditional Variance](#)” on page 383 for computational details of r . The plot of residuals and confidence limits in [Example 8.4](#) later in this chapter illustrates this behavior.

Except to adjust the degrees of freedom for the error sum of squares, the preceding formulas do not account for the fact that the autoregressive parameters are estimated. In particular, the confidence limits are likely to be somewhat too narrow. In large samples, this is probably not an important effect, but it may be appreciable in small samples. Refer to Harvey (1981) for some discussion of this problem for AR(1) models.

Note that at the beginning of the series (the first m observations, where m is the value of the NLAG= option) and after missing values, these residuals do not match the residuals obtained by using OLS on the transformed variables. This is because, in these cases, the predicted noise values must be based on less than a complete set of past noise values and, thus, have larger variance. The GLS transformation for these observations includes a scale factor as well as a linear combination of past values. Put another way, the \mathbf{L}^{-1} matrix defined in the section “[Computational Methods](#)” on page 359 has the value 1 along the diagonal, except for the first m observations and after missing values.

Predicting the Conditional Variance

The GARCH process can be written

$$\epsilon_t^2 = \omega + \sum_{i=1}^n (\alpha_i + \gamma_i) \epsilon_{t-i}^2 - \sum_{j=1}^p \gamma_j \eta_{t-j} + \eta_t$$

where $\eta_t = \epsilon_t^2 - h_t$ and $n = \max(p, q)$. This representation shows that the squared residual ϵ_t^2 follows an ARMA(n, p) process. Then for any $d > 0$, the conditional expectations are as follows:

$$\mathbf{E}(\epsilon_{t+d}^2 | \Psi_t) = \omega + \sum_{i=1}^n (\alpha_i + \gamma_i) \mathbf{E}(\epsilon_{t+d-i}^2 | \Psi_t) - \sum_{j=1}^p \gamma_j \mathbf{E}(\eta_{t+d-j} | \Psi_t)$$

The d -step-ahead prediction error, $\xi_{t+d} = y_{t+d} - y_{t+d|t}$, has the conditional variance

$$\mathbf{V}(\xi_{t+d} | \Psi_t) = \sum_{j=0}^{d-1} g_j^2 \sigma_{t+d-j|t}^2$$

where

$$\sigma_{t+d-j|t}^2 = \mathbf{E}(\epsilon_{t+d-j}^2 | \Psi_t)$$

Coefficients in the conditional d -step prediction error variance are calculated recursively using the following formula:

$$g_j = -\varphi_1 g_{j-1} - \dots - \varphi_m g_{j-m}$$

where $g_0 = 1$ and $g_j = 0$ if $j < 0$; $\varphi_1, \dots, \varphi_m$ are autoregressive parameters. Since the parameters are not known, the conditional variance is computed using the estimated autoregressive parameters. The d -step-ahead prediction error variance is simplified when there are no autoregressive terms:

$$\mathbf{V}(\xi_{t+d} | \Psi_t) = \sigma_{t+d|t}^2$$

Therefore, the one-step-ahead prediction error variance is equivalent to the conditional error variance defined in the GARCH process:

$$h_t = \mathbf{E}(\epsilon_t^2 | \Psi_{t-1}) = \sigma_{t|t-1}^2$$

Note that the conditional prediction error variance of the EGARCH and GARCH-M models cannot be calculated using the preceding formula. Therefore, the confidence intervals for the predicted values are computed assuming the homoscedastic conditional error variance. That is, the conditional prediction error variance is identical to the unconditional prediction error variance:

$$\mathbf{V}(\xi_{t+d} | \Psi_t) = \mathbf{V}(\xi_{t+d}) = \sigma^2 \sum_{j=0}^{d-1} g_j^2$$

since $\sigma_{t+d-j|t}^2 = \sigma^2$. You can compute s^2r , which is the second term of the variance for the predicted value \tilde{y}_t explained previously in the section “[Predicting Future Series Realizations](#)” on page 382 using the formula $\sigma^2 \sum_{j=0}^{d-1} g_j^2$; r is estimated from $\sum_{j=0}^{d-1} g_j^2$ by using the estimated autoregressive parameters.

Consider the following conditional prediction error variance:

$$V(\xi_{t+d}|\Psi_t) = \sigma^2 \sum_{j=0}^{d-1} g_j^2 + \sum_{j=0}^{d-1} g_j^2 (\sigma_{t+d-j|t}^2 - \sigma^2)$$

The second term in the preceding equation can be interpreted as the noise from using the homoscedastic conditional variance when the errors follow the GARCH process. However, it is expected that if the GARCH process is covariance stationary, the difference between the conditional prediction error variance and the unconditional prediction error variance disappears as the forecast horizon d increases.

OUT= Data Set

The output SAS data set produced by the OUTPUT statement contains all the variables in the input data set and the new variables specified by the OUTPUT statement options. See the section “[OUTPUT Statement](#)” on page 354 earlier in this chapter for information on the output variables that can be created. The output data set contains one observation for each observation in the input data set.

OUTEST= Data Set

The OUTEST= data set contains all the variables used in any MODEL statement. Each regressor variable contains the estimate for the corresponding regression parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

<code>_A_i</code>	the i th order autoregressive parameter estimate. There are m such variables <code>_A_1</code> through <code>_A_m</code> , where m is the value of the NLAG= option.
<code>_AH_i</code>	the i th order ARCH parameter estimate, if the GARCH= option is specified. There are q such variables <code>_AH_1</code> through <code>_AH_q</code> , where q is the value of the Q= option. The variable <code>_AH_0</code> contains the estimate of ω .
<code>_DELTA_</code>	the estimated mean parameter for the GARCH-M model, if a GARCH-in-mean model is specified
<code>_DEPVAR_</code>	the name of the dependent variable
<code>_GH_i</code>	the i th order GARCH parameter estimate, if the GARCH= option is specified. There are p such variables <code>_GH_1</code> through <code>_GH_p</code> , where p is the value of the P= option.

INTERCEPT	the intercept estimate. INTERCEP contains a missing value for models for which the NOINT option is specified.
METHOD	the estimation method that is specified in the METHOD= option
MODEL	the label of the MODEL statement if one is given, or blank otherwise
MSE	the value of the mean square error for the model
NAME	the name of the row of covariance matrix for the parameter estimate, if the COVOUT option is specified
LIKLHD	the log-likelihood value of the GARCH model
SSE	the value of the error sum of squares
STATUS	This variable indicates the optimization status. <code>_STATUS_ = 0</code> indicates that there were no errors during the optimization and the algorithm converged. <code>_STATUS_ = 1</code> indicates that the optimization could not improve the function value and means that the results should be interpreted with caution. <code>_STATUS_ = 2</code> indicates that the optimization failed due to the number of iterations exceeding either the maximum default or the specified number of iterations or the number of function calls allowed. <code>_STATUS_ = 3</code> indicates that an error occurred during the optimization process. For example, this error message is obtained when a function or its derivatives cannot be calculated at the initial values or during the iteration process, when an optimization step is outside of the feasible region or when active constraints are linearly dependent.
STDERR	standard error of the parameter estimate, if the COVOUT option is specified
THETA	the estimate of the θ parameter in the EGARCH model, if an EGARCH model is specified
TYPE	OLS for observations containing parameter estimates, or COV for observations containing covariance matrix elements.

The OUTEST= data set contains one observation for each MODEL statement giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for each MODEL statement giving the rows of the covariance of parameter estimates matrix. For covariance observations, the value of the `_TYPE_` variable is COV, and the `_NAME_` variable identifies the parameter associated with that row of the covariance matrix.

Printed Output

The AUTOREG procedure prints the following items:

1. the name of the dependent variable
2. the ordinary least squares estimates
3. Estimates of autocorrelations, which include the estimates of the autocovariances, the autocorrelations, and (if there is sufficient space) a graph of the autocorrelation at each LAG

4. if the PARTIAL option is specified, the partial autocorrelations
5. the preliminary MSE, which results from solving the Yule-Walker equations. This is an estimate of the final MSE.
6. the estimates of the autoregressive parameters (Coefficient), their standard errors (Std Error), and the ratio of estimate to standard error (*t* Ratio)
7. the statistics of fit for the final model. These include the error sum of squares (SSE), the degrees of freedom for error (DFE), the mean square error (MSE), the mean absolute error (MAE), the mean absolute percentage error (MAPE), the root mean square error (Root MSE), the Schwarz information criterion (SBC), the Akaike information criterion (AIC), the corrected Akaike information criterion (AICC), the regression R^2 (Reg Rsq), and the total R^2 (Total Rsq). For GARCH models, the following additional items are printed:
 - the value of the log-likelihood function
 - the number of observations that are used in estimation (OBS)
 - the unconditional variance (UVAR)
 - the normality test statistic and its *p*-value
8. the parameter estimates for the structural model (B Value), a standard error estimate (Std Error), the ratio of estimate to standard error (*t* Ratio), and an approximation to the significance probability for the parameter being 0 (Approx Prob)
9. If the NLAG= option is specified with METHOD=ULS or METHOD=ML, the regression parameter estimates are printed again, assuming that the autoregressive parameter estimates are known. In this case, the Std Error and related statistics for the regression estimates will, in general, be different from the case when they are estimated. Note that from a standpoint of estimation, Yule-Walker and iterated Yule-Walker methods (NLAG= with METHOD=YW, ITYW) generate only one table, assuming AR parameters are given.
10. If you specify the NORMAL option, the Bera-Jarque normality test statistics are printed. If you specify the LAGDEP option, Durbin's *h* or Durbin's *t* is printed.

ODS Table Names

PROC AUTOREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the [Table 8.2](#).

Table 8.2 ODS Tables Produced in PROC AUTOREG

ODS Graphics

This section describes the use of ODS for creating graphics with the AUTOREG procedure.

To request these graphs, you must specify the ODS GRAPHICS statement. By default, only the residual, predicted versus actual, and autocorrelation of residuals plots are produced. If, in addition to the ODS GRAPHICS statement, you also specify the ALL option in either the PROC AUTOREG statement or MODEL statement, all plots are created. For HETERO, GARCH, and AR models studentized residuals are replaced by standardized residuals. For the autoregressive models, the conditional variance of the residuals is computed as described in the section “[Predicting Future Series Realizations](#)” on page 382. For the GA

RCH and HETERO models, residuals are assumed to have h_t conditional variance invoked by the HT= option of the OUTPUT statement. For all these cases, the Cook’s *D* plot is not produced.

ODS Graph Names

PROC AUTOREG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 8.3](#).

Table 8.3 ODS Graphics Produced by PROC AUTOREG

ODS Graph Name	Plot Description	Option
ACFPlot	Autocorrelation of residuals	ACF
FitPlot	Predicted versus actual plot	Default
CooksD	Cook’s <i>D</i> plot	ALL (no NLAG=)
IACFPlot	Inverse autocorrelation of residuals	ALL
QQPlot	Q-Q plot of residuals	ALL
PACFPlot	Partial autocorrelation of residuals	ALL
ResidualHistogram	Histogram of the residuals	ALL
ResidualPlot	Residual plot	Default
StudentResidualPlot	Studentized residual plot	ALL (no NLAG=/HETERO=/GARCH=)
StandardResidualPlot	Standardized residual plot	ALL
WhiteNoiseLogProbPlot	Tests for white noise residuals	ALL

Examples: AUTOREG Procedure

Example 8.1: Analysis of Real Output Series

In this example, the annual real output series is analyzed over the period 1901 to 1983 (Balke and Gordon 1986, pp. 581–583). With the following DATA step, the original data are transformed using the natural logarithm, and the differenced series DY is created for further analysis. The log of real output is plotted in [Output 8.1.1](#).

```
title 'Analysis of Real GNP';
data gnp;
  date = intnx( 'year', '01jan1901'd, _n_-1 );
  format date year4.;
  input x @@;
  y = log(x);
  dy = dif(y);
  t = _n_;
  label y = 'Real GNP'
        dy = 'First Difference of Y'
        t = 'Time Trend';
datalines;

... more lines ...

proc sgplot data=gnp noautolegend;
  scatter x=date y=y;
  xaxis grid values=('01jan1901'd '01jan1911'd '01jan1921'd '01jan1931'd
                    '01jan1941'd '01jan1951'd '01jan1961'd '01jan1971'd
                    '01jan1981'd '01jan1991'd);
run;
```

Output 8.1.1 Real Output Series: 1901 – 1983

The (linear) trend-stationary process is estimated using the following form:

$$y_t = \beta_0 + \beta_1 t + v_t$$

where

$$v_t = \epsilon_t - \varphi_1 v_{t-1} - \varphi_2 v_{t-2}$$

$$\epsilon_t \sim \text{IN}(0, \sigma_\epsilon)$$

The preceding trend-stationary model assumes that uncertainty over future horizons is bounded since the error term, v_t , has a finite variance. The maximum likelihood AR estimates from the statements that follow are shown in [Output 8.1.2](#):

```
proc autoreg data=gnp;
  model y = t / nlag=2 method=ml;
run;
```

t	1	0.0302	0.001346	22.45	<.0001	Time Trend

Nelson and Plosser (1982) failed to reject the hypothesis that macroeconomic time series are non-stationary and have no tendency to return to a trend line. In this context, the simple random walk process can be used as an alternative process:

$$y_t = \beta_0 + y_{t-1} + v_t$$

where $v_t = \epsilon_t$ and $y_0 = 0$. In general, the difference-stationary process is written as

$$\phi(L)(1 - L)y_t = \beta_0\phi(1) + \theta(L)\epsilon_t$$

where L is the lag operator. You can observe that the class of a difference-stationary process should have at least one unit root in the AR polynomial $\phi(L)(1 - L)$.

The Dickey-Fuller procedure is used to test the null hypothesis that the series has a unit root in the AR polynomial. Consider the following equation for the augmented Dickey-Fuller test:

$$\Delta y_t = \beta_0 + \delta t + \beta_1 y_{t-1} + \sum_{i=1}^m \gamma_i \Delta y_{t-i} + \epsilon_t$$

where $\Delta = 1 - L$. The test statistic τ_τ is the usual t ratio for the parameter estimate $\hat{\beta}_1$, but the τ_τ does not follow a t distribution.

The %DFTEST macro in the following statements computes the test statistic τ_τ and its p -value to perform the Dickey-Fuller test. The default value of m is 3, but you can specify m with the AR= option. The option TREND=2 implies that the Dickey-Fuller test equation contains linear time trend. See Chapter 5, “SAS Macros and Functions,” for details.

```
%dfctest (gnp, y, trend=2, outstat=stat1);

proc print data=stat1;
run;
```

The augmented Dickey-Fuller test indicates that the output series may have a difference-stationary process. The statistic `_TAU_` has a value of -2.61903 and its p -value is 0.29104 . (See [Output 8.1.3](#).)

The AR(1) model for the differenced series DY is estimated using the maximum likelihood method for the period 1902 to 1983. The difference-stationary process is written

$$\Delta y_t = \beta_0 + v_t$$

$$v_t = \epsilon_t - \phi_1 v_{t-1}$$

The estimated value of ϕ_1 is -0.297 and that of β_0 is 0.0293 . All estimated values are statistically significant. The PROC step follows:

```
proc autoreg data=gnp;
  model dy = / nlag=1 method=ml;
run;
```

The printed output produced by the PROC step is shown in [Output 8.1.4](#).

Example 8.2: Comparing Estimates and Models

In this example, the Grunfeld series are estimated using different estimation methods. Refer to Maddala (1977) for details of the Grunfeld investment data set. For comparison, the Yule-Walker method, ULS method, and maximum likelihood method estimates are shown. With the DWPROB

option, the p -value of the Durbin-Watson statistic is printed. The Durbin-Watson test indicates the positive autocorrelation of the regression residuals. The DATA and PROC steps follow:

```

title 'Grunfeld's Investment Models Fit with Autoregressive Errors';
data grunfeld;
  input year gei gef gec;
  label gei = 'Gross investment GE'
        gec = 'Lagged Capital Stock GE'
        gef = 'Lagged Value of GE shares';
datalines;

... more lines ...

proc autoreg data=grunfeld;
  model gei = gef gec / nlag=1 dwprob;
  model gei = gef gec / nlag=1 method=uls;
  model gei = gef gec / nlag=1 method=ml;
run;

```

The printed output produced by each of the MODEL statements is shown in [Output 8.2.1](#) through [Output 8.2.4](#).

Example 8.3: Lack-of-Fit Study

Many time series exhibit high positive autocorrelation, having the smooth appearance of a random walk. This behavior can be explained by the partial adjustment and adaptive expectation hypotheses.

Short-term forecasting applications often use autoregressive models because these models absorb the behavior of this kind of data. In the case of a first-order AR process where the autoregressive parameter is exactly 1 (a *random walk*), the best prediction of the future is the immediate past.

PROC AUTOREG can often greatly improve the fit of models, not only by adding additional parameters but also by capturing the random walk tendencies. Thus, PROC AUTOREG can be expected to provide good short-term forecast predictions.

However, good forecasts do not necessarily mean that your structural model contributes anything worthwhile to the fit. In the following example, random noise is fit to part of a sine wave. Notice that the structural model does not fit at all, but the autoregressive process does quite well and is very nearly a first difference ($AR(1) = -0.976$). The DATA step, PROC AUTOREG step, and PROC SGPLOT step follow:

```

title1 'Lack of Fit Study';
title2 'Fitting White Noise Plus Autoregressive Errors to a Sine Wave';

data a;
  pi=3.14159;
  do time = 1 to 75;
    if time > 75 then y = .;
    else y = sin( pi * ( time / 50 ) );
    x = ranuni( 1234567 );
    output;
  end;
run;

```

```

proc autoreg data=a plots;
  model y = x / nlag=1;
  output out=b p=pred pm=xbeta;
run;

proc sgplot data=b;
  scatter y=y x=time / markerattrs=(color=black);
  series y=pred x=time / lineattrs=(color=blue);
  series y=xbeta x=time / lineattrs=(color=red);
run;

```

The printed output produced by PROC AUTOREG is shown in [Output 8.3.1](#) and [Output 8.3.2](#). Plots of observed and predicted values are shown in [Output 8.3.3](#) and [Output 8.3.4](#). Note: the plot [Output 8.3.3](#) can be viewed in the Autoreg.Model.FitDiagnosticPlots category by selecting **View►Results**.

Example 8.4: Missing Values

In this example, a pure autoregressive error model with no regressors is used to generate 50 values of a time series. Approximately 15% of the values are randomly chosen and set to missing. The following statements generate the data:

```

title 'Simulated Time Series with Roots: ';
title2 ' (X-1.25) (X**4-1.25) ';
title3 'With 15% Missing Values';
data ar;
  do i=1 to 550;
    e = rannor(12345);
    n = sum( e, .8*n1, .8*n4, -.64*n5 ); /* ar process */
    y = n;
    if ranuni(12345) > .85 then y = .; /* 15% missing */
    n5=n4; n4=n3; n3=n2; n2=n1; n1=n; /* set lags */
    if i>500 then output;
  end;
run;

```

The model is estimated using maximum likelihood, and the residuals are plotted with 99% confidence limits. The PARTIAL option prints the partial autocorrelations. The following statements fit the model:

```

proc autoreg data=ar partial;
  model y = / nlag=(1 4 5) method=ml;
  output out=a predicted=p residual=r ucl=u lcl=l alphacli=.01;
run;

```

The printed output produced by the AUTOREG procedure is shown in [Output 8.4.1](#) and [Output 8.4.2](#). Note: the plot [Output 8.4.2](#) can be viewed in the Autoreg.Model.FitDiagnosticPlots category by selecting **View►Results**.

The following statements plot the residuals and confidence limits:

```

data reshape1;
  set a;
  miss = .;
  if r=. then do;
    miss = p;
    p = .;
  end;
run;

title 'Predicted Values and Confidence Limits';

proc sgplot data=reshape1 NOAUTOLEGEND;
  band x=i upper=u lower=l;
  scatter y=miss x=i/ MARKERATTRS =(symbol=x color=red);
  series y=p x=i/markers MARKERATTRS =(color=blue) lineattrs=(color=blue);
run;

```

The plot of the predicted values and the upper and lower confidence limits is shown in [Output 8.4.3](#). Note that the confidence interval is wider at the beginning of the series (when there are no past noise values to use in the forecast equation) and after missing values where, again, there is an incomplete set of past residuals.

Output 8.4.3 Plot of Predicted Values and Confidence Interval

Example 8.5: Money Demand Model

This example estimates the log-log money demand equation by using the maximum likelihood method. The money demand model contains four explanatory variables. The lagged nominal money stock M1 is divided by the current price level GDF to calculate a new variable M1CP since the money stock is assumed to follow the partial adjustment process. The variable M1CP is then used to estimate the coefficient of adjustment. All variables are transformed using the natural logarithm with a DATA step. Refer to Balke and Gordon (1986) for a data description.

The first eight observations are printed using the PRINT procedure and are shown in [Output 8.5.1](#). Note that the first observation of the variables M1CP and INFR are missing. Therefore, the money demand equation is estimated for the period 1968:2 to 1983:4 since PROC AUTOREG ignores the first missing observation. The DATA step that follows generates the transformed variables.

```
data money;
  date = intnx( 'qtr', '01jan1968'd, _n_-1 );
  format date yyqc6.;
  input m1 gnp gdf ycb @@;
  m = log( 100 * m1 / gdf );
  mlcp = log( 100 * lag(m1) / gdf );
  y = log( gnp );
  intr = log( ycb );
  infr = 100 * log( gdf / lag(gdf) );
  label m      = 'Real Money Stock (M1)'
        mlcp   = 'Lagged M1/Current GDF'
        y      = 'Real GNP'
        intr   = 'Yield on Corporate Bonds'
        infr   = 'Rate of Prices Changes';
datalines;

... more lines ...
```

Output 8.5.1 Money Demand Data Series – First 8 Observations

The money demand equation is first estimated using OLS. The DW=4 option produces generalized Durbin-Watson statistics up to the fourth order. Their exact marginal probabilities (p -values) are also calculated with the DWPROB option. The Durbin-Watson test indicates positive first-order

autocorrelation at, say, the 10% confidence level. You can use the Durbin-Watson table, which is available only for 1% and 5% significance points. The relevant upper (d_U) and lower (d_L) bounds are $d_U = 1.731$ and $d_L = 1.471$, respectively, at 5% significance level. However, the bounds test is inconvenient, since sometimes you may get the statistic in the inconclusive region while the interval between the upper and lower bounds becomes smaller with the increasing sample size. The PROC step follows:

```

title 'Partial Adjustment Money Demand Equation';
title2 'Quarterly Data - 1968:2 to 1983:4';

proc autoreg data=money outest=est covout;
  model m = mlcp y intr infr / dw=4 dwprob;
run;

```

Output 8.5.2 *continued*

Variable	DF	Estimate	Standard Error	t Value	Pr > t	Approx Variable Label
Intercept	1	0.3084	0.2359	1.31	0.1963	
m1cp	1	0.8952	0.0439	20.38	<.0001	Lagged M1/Current GDF
y	1	0.0476	0.0122	3.89	0.0003	Real GNP
intr	1	-0.0238	0.007933	-3.00	0.0040	Yield on Corporate Bonds
infr	1	-0.005646	0.001584	-3.56	0.0007	Rate of Prices Changes

The autoregressive model is estimated using the maximum likelihood method. Though the Durbin-Watson test statistic is calculated after correcting the autocorrelation, it should be used with care since the test based on this statistic is not justified theoretically. The PROC step follows:

```
proc autoreg data=money;
  model m = m1cp y intr infr / nlag=1 method=ml maxit=50;
  output out=a p=p pm=pm r=r rm=rm ucl=ucl lcl=lcl
         uclm=uclm lclm=lclm;
run;

proc print data=a(obs=8);
  var p pm r rm ucl lcl uclm lclm;
run;
```

A difference is shown between the OLS estimates in [Output 8.5.2](#) and the AR(1)-ML estimates in [Output 8.5.3](#). The estimated autocorrelation coefficient is significantly negative (-0.88345). Note that the negative coefficient of AR(1) should be interpreted as a positive autocorrelation.

Two predicted values are produced: predicted values computed for the structural model and predicted values computed for the full model. The full model includes both the structural and error-process parts. The predicted values and residuals are stored in the output data set A, as are the upper and lower 95% confidence limits for the predicted values. Part of the data set A is shown in [Output 8.5.4](#). The first observation is missing since the explanatory variables, M1CP and INFR, are missing for the corresponding observation.

Example 8.6: Estimation of ARCH(2) Process

Stock returns show a tendency for small changes to be followed by small changes while large changes are followed by large changes. The plot of daily price changes of IBM common stock (Box and Jenkins 1976, p. 527) is shown in [Output 8.6.1](#). The time series look serially uncorrelated, but the plot makes us skeptical of their independence.

With the following DATA step, the stock (capital) returns are computed from the closing prices. To forecast the conditional variance, an additional 46 observations with missing values are generated.

```

title 'IBM Stock Returns (daily)';
title2 '29jun1959 - 30jun1960';

data ibm;
  infile datalines eof=last;
  input x @@;
  r = dif( log( x ) );
  time = _n_-1;
  output;
  return;
last:
  do i = 1 to 46;
    r = .;
    time + 1;
    output;
  end;
  return;
datalines;

... more lines ...

proc sgplot data=ibm;
  series y=r x=time/lineattrs=(color=blue);
  refline 0/ axis = y LINEATTRS = (pattern=ShortDash);
run;

```

Output 8.6.1 IBM Stock Returns: Daily

The simple ARCH(2) model is estimated using the AUTOREG procedure. The MODEL statement option GARCH=(Q=2) specifies the ARCH(2) model. The OUTPUT statement with the CEV= option produces the conditional variances V. The conditional variance and its forecast are calculated using parameter estimates:

$$h_t = \hat{\omega} + \hat{\alpha}_1 \epsilon_{t-1}^2 + \hat{\alpha}_2 \epsilon_{t-2}^2$$

$$\mathbf{E}(\epsilon_{t+d}^2 | \Psi_t) = \hat{\omega} + \sum_{i=1}^2 \hat{\alpha}_i \mathbf{E}(\epsilon_{t+d-i}^2 | \Psi_t)$$

where $d > 1$. This model can be estimated as follows:

```
proc autoreg data=ibm maxit=50;
  model r = / noint garch=(q=2);
  output out=a cev=v;
run;
```

The parameter estimates for ω , α_1 , and α_2 are 0.00011, 0.04136, and 0.06976, respectively. The normality test indicates that the conditional normal distribution may not fully explain the leptokurtosis in the stock returns (Bollerslev 1987).

The ARCH model estimates are shown in [Output 8.6.2](#), and conditional variances are also shown in [Output 8.6.3](#). The code that generates [Output 8.6.3](#) is shown below.

```
data b; set a;
  length type $ 8.;
  if r ^= . then do;
    type = 'ESTIMATE'; output; end;
  else do;
    type = 'FORECAST'; output; end;
run;
proc sgplot data=b;
  series x=time y=v/group=type;
  refline 254/ axis = x LINEATTRS = (pattern=ShortDash);
run;
```

Overview: COMPUTAB Procedure

The COMPUTAB (computing and tabular reporting) procedure produces tabular reports generated using a programmable data table.

The COMPUTAB procedure is especially useful when you need both the power of a programmable spreadsheet and a report generation system, but you want to set up a program to run in a batch mode and generate routine reports.

With PROC COMPUTAB, you can select a subset of observations from the input data set, define the format of a table, operate on its row and column values, and create new columns and rows. Access to individual table values is available when needed.

The COMPUTAB procedure can tailor reports to almost any desired specification and provide consolidation reports over summarization variables. The generated report values can be stored in an output data set. PROC COMPUTAB is especially useful in creating tabular reports such as income statements, balance sheets, and other row and column reports.

Getting Started: COMPUTAB Procedure

The following example shows the different types of reports that can be generated by PROC COMPUTAB.

Suppose a company has monthly expense data on three of its divisions and wants to produce the year-to-date expense report shown in [Figure 9.1](#). This section starts out with the default report produced by the COMPUTAB procedure and modifies it until the desired report is achieved.

Figure 9.1 Year-to-Date Expense Report

Year to Date Expenses				
	Division	Division	Division	All
	A	B	C	Divisions
Travel Expenses within U.S.	18700	211000	12800	\$242,500
Advertising	18500	176000	34500	\$229,000
Permanent Staff Salaries	186000	1270000	201000	\$1,657,000
Benefits Including Insurance	3900	11100	17500	\$32,500
	=====	=====	=====	=====
Total	227100	1668100	265800	\$2,161,000

Producing a Simple Report

Without any specifications, the COMPUTAB procedure transposes and prints the input data set. The variables in the input data set become rows in the report, and the observations in the input data set become columns. The variable names are used as the row titles. The column headings default to COL1 through COLn. For example, the following input data set contains the monthly expenses reported by different divisions of the company:

```
data report;
  length compdiv $ 1;
  input compdiv $ date:date7. salary travel insure advrtise;
  format date date7.;
  label travel    = 'Travel Expenses within U.S.'
        advrtise = 'Advertising'
        salary    = 'Permanent Staff Salaries'
        insure    = 'Benefits Including Insurance';
datalines;
A 31JAN1989 95000 10500 2000 6500
B 31JAN1989 668000 112000 5600 90000
C 31JAN1989 105000 6800 9000 18500
A 28FEB1989 91000 8200 1900 12000
B 28FEB1989 602000 99000 5500 86000
C 28FEB1989 96000 6000 8500 16000
;
```

You can get a listing of the data set by using the PRINT procedure, as follows:

```
title 'Listing of Monthly Divisional Expense Data';
proc print data=report;
run;
```

Figure 9.2 Listing of Data Set by PROC PRINT

Listing of Monthly Divisional Expense Data						
Obs	compdiv	date	salary	travel	insure	advrtise
1	A	31JAN89	95000	10500	2000	6500
2	B	31JAN89	668000	112000	5600	90000
3	C	31JAN89	105000	6800	9000	18500
4	A	28FEB89	91000	8200	1900	12000
5	B	28FEB89	602000	99000	5500	86000
6	C	28FEB89	96000	6000	8500	16000

To get a simple, transposed report of the same data set, use the following PROC COMPUTAB statement:

```
title 'Monthly Divisional Expense Report';
proc computab data=report;
run;
```

Figure 9.3 Listing of Data Set by PROC COMPUTAB

Monthly Divisional Expense Report						
	COL1	COL2	COL3	COL4	COL5	COL6
compdiv	A	B	C	A	B	C
date	31JAN89	31JAN89	31JAN89	28FEB89	28FEB89	28FEB89
salary	95000.00	668000.00	105000.00	91000.00	602000.00	96000.00
travel	10500.00	112000.00	6800.00	8200.00	99000.00	6000.00
insure	2000.00	5600.00	9000.00	1900.00	5500.00	8500.00
advrtise	6500.00	90000.00	18500.00	12000.00	86000.00	16000.00

Using PROC COMPUTAB

The COMPUTAB procedure is best understood by examining the following features:

- definition of the report layout with ROWS and COLUMNS statements
- input block
- row blocks
- column blocks

PROC COMPUTAB builds a table according to the specifications in the ROWS and COLUMNS statements. Row names and column names define the rows and columns of the table. Options in the ROWS and COLUMNS statements control titles, spacing, and formatting.

The input block places input observations into the appropriate columns of the report. It consists of programming statements used to select observations to be included in the report, to determine the column into which the observation should be placed, and to calculate row and column values that are not in the input data set.

Row blocks and column blocks perform operations on the values of rows and columns of the report after the input block has executed. Row blocks are a block of programming statements labeled ROWxxxx: that create or modify row values; column blocks are a block of programming statements labeled COLxxxx: that create or modify column values. Row and column blocks can make multiple passes through the report for final calculations.

For most reports, these features are sufficient. More complicated applications might require knowledge of the program data vector and the COMPUTAB data table. These topics are discussed in the section “[Details: COMPUTAB Procedure](#)” on page 448.

Defining Report Layout

ROWS and COLUMNS statements define the rows and columns of the report. The order of row and column names in these statements determines the order of rows and columns in the report. Additional ROWS and COLUMNS statements can be used to specify row and column formatting options.

The following statements select and order the variables from the input data set and produce the report in [Figure 9.4](#):

```
proc computab data=report;
  rows travel advrtise salary;
run;
```

Figure 9.4 Report Produced Using a ROWS Statement

Monthly Divisional Expense Report						
	COL1	COL2	COL3	COL4	COL5	COL6
TRAVEL	10500.00	112000.00	6800.00	8200.00	99000.00	6000.00
ADVRTISE	6500.00	90000.00	18500.00	12000.00	86000.00	16000.00
SALARY	95000.00	668000.00	105000.00	91000.00	602000.00	96000.00

When a COLUMNS statement is not specified, each observation becomes a new column. If you use a COLUMNS statement, you must specify to which column each observation belongs by using program statements for column selection. When more than one observation is selected for the same column, values are summed.

The following statements produce [Figure 9.5](#):

```
proc computab data= report;
  rows travel advrtise salary insure;
  columns a b c;
  *----select column for company division,
    based on value of compdiv----*;
  a = compdiv = 'A';
  b = compdiv = 'B';
  c = compdiv = 'C';
run;
```

The statement `A=COMPDIV='A'`; illustrates the use of logical operators as a selection technique. If `COMPDIV='A'`, then the current observation is added to the A column. See *SAS Language: Reference, Version 6, First Edition* for more information about logical operators.

Figure 9.5 Report Produced Using ROWS and COLUMNS Statements

Monthly Divisional Expense Report			
	A	B	C
TRAVEL	18700.00	211000.00	12800.00
ADVERTISE	18500.00	176000.00	34500.00
SALARY	186000.00	1270000.0	201000.00
INSURE	3900.00	11100.00	17500.00

Adding Computed Rows and Columns

In addition to the variables and observations in the input data set, you can create additional rows or columns by using SAS programming statements in PROC COMPUTAB. You can do the following:

- modify input data and select columns in the input block
- create or modify columns in column blocks
- create or modify rows in row blocks

The following statements add one computed row (SUM) and one computed column (TOTAL) to the report in [Figure 9.5](#). In the input block the logical operators indicate the observations that correspond to each column of the report. After the input block reads in the values from the input data set, the column block creates the column variable TOTAL by summing the columns A, B, and C. The additional row variable, SUM, is calculated as the sum of the other rows. The result is shown in [Figure 9.6](#).

```
proc computab data= report;
  rows travel advertise salary insure sum;
  columns a b c total;
  a = compdiv = 'A';
  b = compdiv = 'B';
  c = compdiv = 'C';
  colblk: total = a + b + c;
  rowblk: sum   = travel + advertise + salary + insure;
run;
```

Figure 9.6 Report Produced Using Row and Column Blocks

Monthly Divisional Expense Report				
	A	B	C	TOTAL
TRAVEL	18700.00	211000.00	12800.00	242500.00
ADVERTISE	18500.00	176000.00	34500.00	229000.00
SALARY	186000.00	1270000.0	201000.00	1657000.0
INSURE	3900.00	11100.00	17500.00	32500.00
SUM	227100.00	1668100.0	265800.00	2161000.0

Enhancing the Report

To enhance the appearance of the final report, you can use the following:

- TITLE and LABEL statements
- column headings
- row titles
- row and column spacing control
- overlining and underlining
- formats

The following example enhances the report in the previous example. The enhanced report is shown in [Figure 9.7](#).

The TITLE statement assigns the report title. The column headings in [Figure 9.7](#) (Division A, Division B, and Division C) are assigned in the first COLUMNS statement by “Division” `_name_` specification. The second COLUMNS statement assigns the column heading (“All” “Divisions”), sets the spacing (+4), and formats the values in the TOTAL column.

Similarly, the first ROWS statement uses previously assigned variable labels for row labels by specifying the `_LABEL_` option. The DUL option in the second ROWS statement double-underlines the INSURE row. The third ROWS statement assigns the row label TOTAL to the SUM row.

```

title 'Year to Date Expenses';

proc computab cwidth=8 cdec=0;

  columns a b c / 'Division' _name_;
  columns total / 'All' 'Divisions' +4 f=dollar10.0;

  rows travel advertise salary insure / _label_;
  rows insure / dul;

```

```

rows sum / 'Total';

a = compdiv = 'A';
b = compdiv = 'B';
c = compdiv = 'C';

colblk: total = a + b + c;
rowblk: sum   = travel + advrtise + salary + insure;
run;

```

Figure 9.7 Report Produced by PROC COMPUTAB Using Enhancements

Year to Date Expenses				
	Division A	Division B	Division C	All Divisions
Travel Expenses within U.S.	18700	211000	12800	\$242,500
Advertising	18500	176000	34500	\$229,000
Permanent Staff Salaries	186000	1270000	201000	\$1,657,000
Benefits Including Insurance	3900	11100	17500	\$32,500
	=====	=====	=====	=====
Total	227100	1668100	265800	\$2,161,000

Syntax: COMPUTAB Procedure

The following statements are used with the COMPUTAB procedure:

```

PROC COMPUTAB options ;
  BY variables ;
  COLUMNS names / options ;
  ROWS names / options ;
  CELL names / FORMAT= format ;
  INIT anchor-name locator-name values locator-name values ;
  programming statements ;
  SUMBY variables ;

```

The PROC COMPUTAB statement is the only required statement. The COLUMNS, ROWS, and CELL statements define the COMPUTAB table. The INIT statement initializes the COMPUTAB table values. Programming statements process COMPUTAB table values. The BY and SUMBY statements provide BY-group processing and consolidation (roll up) tables.

Functional Summary

Table 9.1 summarizes the COMPUTAB procedure statements and options.

Table 9.1 COMPUTAB Functional Summary

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify the format for printing a particular cell	CELL	
define columns of the report	COLUMNS	
initialize values in the COMPUTAB data table	INIT	
define rows of the report	ROWS	
produce consolidation tables	SUMBY	
Data Set Options		
specify the input data set	COMPUTAB	DATA=
specify an output data set	COMPUTAB	OUT=
Input Options		
specify a value to use when testing for 0	COMPUTAB	FUZZ=
initialize the data table to missing	COMPUTAB	INITMISS
prevent the transposition of the input data set	COMPUTAB	NOTRANS
Printing Control Options		
suppress printing of the listed columns	COLUMNS	NOPRINT
suppress all printed output	COMPUTAB	NOPRINT
suppress printing of the listed rows	ROWS	NOPRINT
suppress columns with all 0 or missing values	COLUMNS	NOZERO
suppress rows with all 0 or missing values	ROWS	NOZERO
list option values	COMPUTAB	OPTIONS
overprint titles, values, overlining, and underlining associated with listed rows	ROWS	OVERPRINT
print only consolidation tables	COMPUTAB	SUMONLY
Report Formatting Options		
specify number of decimal places to print	COMPUTAB	CDEC=
specify number of spaces between columns	COMPUTAB	CSPACE=
specify column width for the report	COMPUTAB	CWIDTH=
overline the listed rows with double lines	ROWS	DOL
underline the listed rows with double lines	ROWS	DUL
specify a format for printing the cell values	CELL	FORMAT=
specify a format for printing column values	COLUMNS	FORMAT=
specify a format for printing the row values	ROWS	FORMAT=
left-align the column headings	COLUMNS	LJC
left-justify character rows in each column	ROWS	LJC
specify indentation from the margin	ROWS	+n
suppress printing of row titles on later pages	COMPUTAB	NORTR
overline the listed rows with a single line	ROWS	OL
start a new page before printing the listed rows	ROWS	_PAGE_
specify number of spaces before row titles	COMPUTAB	RTS=

Description	Statement	Option
print a blank row	ROWS	SKIP
underline the listed rows with a single line	ROWS	UL
specify text to print if column is 0 or missing	COLUMNS	ZERO=
specify text to print if row is 0 or missing	ROWS	ZERO=
Row and Column Type Options		
specify that columns contain character data	COLUMNS	CHAR
specify that rows contain character data	ROWS	CHAR
Options for Column Headings		
specify literal column headings	COLUMNS	'column heading'
use variable labels in column headings	COLUMNS	_LABEL_
specify a master title centered over columns	COLUMNS	MTITLE=
use column names in column headings	COLUMNS	_NAME_
Options for Row Titling		
use labels in row titles	ROWS	_LABEL_
use row names in row titles	ROWS	_NAME_
specify literal row titles	ROWS	'row title'

PROC COMPUTAB Statement

PROC COMPUTAB *options* ;

The following options can be used in the PROC COMPUTAB statement.

Input Options

DATA=SAS-data-set

names the SAS data set that contains the input data. If this option is not specified, the last created data set is used. If you are not reading a data set, use DATA=_NULL_.

FUZZ=value

specifies the criterion to use when testing for 0. If a number is within the FUZZ= value of 0, the number is set to 0.

INITMISS

initializes the COMPUTAB data table to missing rather than to 0. The COMPUTAB data table is discussed further in the section “[Details: COMPUTAB Procedure](#)” on page 448.

NOTRANSPOSE

NOTRANS

prevents the transposition of the input data set in building the COMPUTAB report tables. The NOTRANS option causes input data set variables to appear among the columns of the report rather than among the rows.

Report Formatting Options

The formatting options specify default values. Many of the formatting options can be modified for specific columns in COLUMNS statements and for rows in ROWS statements.

CDEC=*d*

specifies the default number of decimal places for printing. The default is CDEC=2. See the FORMAT= option in the sections on COLUMN, ROWS, and CELL statements later in this chapter.

CSPACE=*n*

specifies the default number of spaces to insert between columns. The value of the CSPACE= option is used as the default value for the +*n* option in the COLUMNS statement. The default is CSPACE=2.

CWIDTH=*w*

specifies a default column width for the report. The default is CWIDTH=9. The width must be in the range of 1–32.

NORTR

suppresses the printing of row titles on each page. The NORTR (no row-title repeat) option is useful to suppress row titles when report pages are to be joined together in a larger report.

RTS=*n*

specifies the default number of spaces to be inserted before row titles when row titles appear after the first printed column. The default row-title spacing is RTS=2.

Output Options**NOPRINT**

suppresses all printed output. Use the NOPRINT option with the OUT= option to produce an output data set but no printed reports.

OPTIONS

lists PROC COMPUTAB option values. The option values appear on a separate page preceding the procedure's normal output.

OUT=*SAS-data-set*

names the SAS data set to contain the output data. See the section “[Details: COMPUTAB Procedure](#)” on page 448 for a description of the structure of the output data set.

SUMONLY

suppresses printing of detailed reports. When the SUMONLY option is used, PROC COMPUTAB generates and prints only consolidation tables as specified in the SUMBY statement.

COLUMNS Statement

COLUMNS *column-list / options ;*

COLUMNS statements define the columns of the report. The COLUMNS statement can be abbreviated COLUMN, COLS, or COL.

The specified column names must be valid SAS names. Abbreviated lists, as described in *SAS Language: Reference*, can also be used.

You can use as many COLUMNS statements as you need. A COLUMNS statement can describe more than one column, and one column of the report can be described with several different COLUMNS statements. The order of the columns on the report is determined by the order of appearance of column names in COLUMNS statements. The first occurrence of the name determines where in the sequence of columns a particular column is located.

The following options can be used in the COLUMNS statement.

Option for Column Type

CHAR

indicates that the columns contain character data.

Options for Column Headings

You can specify as many lines of column headings as needed. If no options are specified, the column names from the COLUMNS statement are used as column headings. Any or all of the following options can be used in a column heading:

“column heading”

specifies that the characters enclosed in quotes are to be used in the column heading for the variable or variables listed in the COLUMNS statement. Each quoted string appears on a separate line of the heading.

LABEL

uses labels, if provided, in the heading for the column or columns listed in the COLUMNS statement. If a label has not been provided, the name of the column is used. See *SAS Language: Reference* for information about the LABEL statement.

MTITLE=*“text”*

specifies that the string of characters enclosed in quotes is a master title to be centered over all the columns listed in the COLUMNS statement. The list of columns must be consecutive. Special characters (“+”, “*”, “=”, and so forth) placed on either side of the text expand to fill the space. The MTITLE= option can be abbreviated M=.

NAME

uses column names in column headings for the columns listed in the COLUMNS statement. This option allows headings (“*text*”) and names to be combined in a heading.

Options for Column Print Control**+n**

inserts *n* spaces before each column listed in the COLUMNS statement. The default spacing is given by the CSPACE= option in the PROC COMPUTAB statement.

NOPRINT

suppresses printing of columns listed in the COLUMNS statement. This option enables you to create columns to be used for intermediate calculations without having those columns printed.

NOZERO

suppresses printing of columns when all the values in a column are 0 or missing. Numbers within the FUZZ= value of 0 are treated as 0.

PAGE

starts a new page of the report before printing each of the columns in the list that follows.

TITLES

prints row titles before each column in the list. The _TITLES_ option can be abbreviated as _TITLE_.

Options for Column Formatting

Column formats override row formats for particular table cells only when the input data set is not transposed (when the NOTRANS option is specified).

FORMAT=*format*

specifies a format for printing the values of the columns listed in the COLUMNS statement. The FORMAT= option can be abbreviated F=.

LJC

left-justifies the column headings for the columns listed. By default, columns are right-justified. When the LJC (left-justify character) option is used, any character row values in the column are also left-justified rather than right-justified.

ZERO=*“text”*

substitutes “*text*” when the value in the column is 0 or missing.

ROWS Statement

ROWS *row-list / options ;*

ROWS statements define the rows of the report. The ROWS statement can be abbreviated ROW.

The specified row names must be valid SAS names. Abbreviated lists, as described in *SAS Language: Reference*, can also be used.

You can use as many ROWS statements as you need. A ROWS statement can describe more than one row, and one row of the report can be described with several different ROWS statements. The order of the rows in the report is determined by the order of appearance of row names in ROWS statements. The first occurrence of the name determines where the row is located.

The following options can be used in the ROWS statement.

Option for Row Type

CHAR

indicates that the rows contain character data.

Options for Row Titling

You can specify as many lines of row titles as needed. If no options are specified, the names from the ROWS statement are used as row titles. Any or all of the following options can be used in a row title:

LABEL

uses labels as row titles for the row or rows listed in the ROWS statement. If a label is not provided, the name of the row is substituted. See *SAS Language: Reference* for more information about the LABEL statement.

NAME

uses row names in row titles for the row or rows listed in the ROWS statement.

“row title”

specifies that the string of characters enclosed in quotes is to be used in the row title for the row or rows listed in the ROWS statement. Each quoted string appears on a separate line of the heading.

Options for Row Print Control

+n

indents *n* spaces from the margin for the rows in the ROWS statement.

DOL

overlines the rows listed in the ROWS statement with double lines. Overlines are printed on the line before any row titles or data for the row.

DUL

underlines the rows listed in the ROWS statement with double lines. Underlines are printed on the line after the data for the row. A row can have both an underline and an overline option.

NOPRINT

suppresses printing of the rows listed in the ROWS statement. This option enables you to create rows to be used for intermediate calculations without having those rows printed.

NOZERO

suppresses the printing of a row when all the values are 0 or missing.

OL

overlines the rows listed in the ROWS statement with a single line. Overlines are printed on the line before any row titles or data for the row.

OVERPRINT

overprints titles, values, overlining, and underlining associated with rows listed in the ROWS statement. The OVERPRINT option can be abbreviated OVP. This option is valid only when the system option OVP is in effect. See *SAS Language: Reference* for more information about the OVP option.

PAGE

starts a new page of the report before printing these rows.

SKIP

prints a blank line after the data lines for these rows.

UL

underlines the rows listed in the ROWS statement with a single line. Underlines are printed on the line after the data for the row. A row can have both an underline and an overline option.

Options for Row Formatting

Row formatting options take precedence over column-formatting options when the input data set is transposed. Row print width can never be wider than column width. Character values are truncated on the right.

FORMAT= *format*

specifies a format for printing the values of the rows listed in the ROWS statement. The FORMAT= option can be abbreviated as F=.

LJC

left-justifies character rows in each column.

ZERO= *“text”*

substitutes *text* when the value in the row is 0 or missing.

CELL Statement

CELL *cell_names* / **FORMAT=** *format* ;

The CELL statement specifies the format for printing a particular cell in the COMPUTAB data table. Cell variable names are compound SAS names of the form *name1.name2*, where *name1* is the name of a row variable and *name2* is the name of a column variable. Formats specified with the FORMAT= option in CELL statements override formats specified in ROWS and COLUMNS statements.

INIT Statement

INIT *anchor-name* [*locator-name*] *values* [*locator-name values*] ;

The INIT statement initializes values in the COMPUTAB data table at the beginning of each execution of the procedure and at the beginning of each BY group if a BY statement is present.

The INIT statement in the COMPUTAB procedure is similar in function to the RETAIN statement in the DATA step, which initializes values in the program data vector. The INIT statement can be used at any point after the variable to which it refers has been defined in COLUMNS or ROWS statements. Each INIT statement initializes one row or column. Any number of INIT statements can be used.

The first term after the keyword INIT, *anchor-name*, anchors initialization to a row or column. If *anchor-name* is a row name, then all *locator-name* values in the statement are columns of that row. If *anchor-name* is a column name, then all *locator-name* values in the statement are rows of that column.

The following terms appear in the INIT statement:

anchor-name names the row or column in which values are to be initialized. This term is required.

locator-name identifies the starting column in the row (or starting row in the column) into which values are to be placed. For example, in a table with a row SALES and a column for each month of the year, the following statement initializes values for columns JAN, FEB, and JUN:

```
init sales jan 500 feb 600 jun 800;
```

If you do not specify *locator-name* values, the first value is placed into the first row or column, the second value into the second row or column, and so on. For example, the following statement assigns 500 to column JAN, 600 to FEB, and 450 to MAR:

```
init sales 500 600 450;
```

+n specifies the number of columns in a row (or rows in a column) that are to be skipped when initializing values. For example, the following statement assigns 500 to JAN and 900 to JUL:

```
init sales jan 500 +5 900;
```

`n*value` assigns *value* to *n* columns in the row (or rows in the column). For example, both of the following statements assign 500 to columns JAN through JUN and 1000 to JUL through DEC:

```
init sales jan 6*500 jul 6*1000;
init sales 6*500 6*1000;
```

Programming Statements

You can use most SAS programming statements the same way you use them in the DATA step. Also, all DATA step functions can be used in the COMPUTAB procedure.

Lines written by the PUT statement are not integrated with the COMPUTAB report. PUT statement output is written to the SAS log.

The automatic variable `_N_` can be used; its value is the number of observations read or the number read in the current BY group, if a BY statement is used. `FIRST.variable` and `LAST.variable` references cannot be used.

The following statements are also available in PROC COMPUTAB:

ABORT	FORMAT
ARRAY	GOTO
ATTRIB	IF-THEN/ELSE
assignment statement	LABEL
CALL	LINK
DELETE	PUT
DO	RETAIN
iterative DO	SELECT
DO UNTIL	STOP
DO WHILE	sum statement
END	TITLE
FOOTNOTE	

The programming statements can be assigned labels `ROWxxxx:` or `COLxxxx:` to indicate the start of a row and column block, respectively. Statements in a row block create or change values in all the columns in the specified rows. Similarly, statements in a column block create or change values in all the rows in the specified columns.

There is an implied RETURN statement before each new row or column block. Thus, the flow of execution does not leave the current row (column) block before the block repeats for all columns (rows.) Row and column variables and nonretained variables are initialized prior to each execution of the block.

The next `COLxxxx:` label, `ROWxxxx:` label, or the end of the PROC COMPUTAB step signals the end of a row (column) block. Column blocks and row blocks can be mixed in any order. In some cases, performing calculations in different orders can lead to different results.

See the sections “[Program Flow Example](#)” on page 448, “[Order of Calculations](#)” on page 451, and “[Controlling Execution within Row and Column Blocks](#)” on page 453 for more information.

BY Statement

BY variables ;

A BY statement can be used with PROC COMPUTAB to obtain separate reports for observations in groups defined by the BY variables. At the beginning of each BY group, before PROC COMPUTAB reads any observations, all table values are set to 0 unless the INITMISS option or an INIT statement is specified.

SUMBY Statement

SUMBY variables ;

The SUMBY statement produces consolidation tables for variables whose names are in the SUMBY list. Only one SUMBY statement can be used.

To use a SUMBY statement, you must use a BY statement. The SUMBY and BY variables must be in the same relative order in both statements. For example:

```
by a b c;
sumby a b;
```

This SUMBY statement produces tables that consolidate over values of C within levels of B and over values of B within levels of A. Suppose A has values 1, 2; B has values 1, 2; and C has values 1, 2, 3. [Table 9.2](#) indicates the consolidation tables produced by the SUMBY statement.

Table 9.2 Consolidation Tables Produced by the SUMBY Statement

SUMBY Consolidations	Consolidated BY Groups		
A=1, B=1	C=1	C=2	C=3
A=1, B=2	C=1	C=2	C=3
A=1	B=1, C=1 B=2, C=1	B=1, C=2 B=2, C=2	B=1, C=3 B=2, C=3
A=2, B=1	C=1	C=2	C=3
A=2, B=2	C=1	C=2	C=3
A=2	B=1, C=1 B=2, C=1	B=1, C=2 B=2, C=2	B=1, C=3 B=2, C=3

Two consolidation tables for B are produced for each value of A. The first table consolidates the three tables produced for the values of C while B is 1; the second table consolidates the three tables produced for C while B is 2.

Tables are similarly produced for values of A. Nested consolidation tables are produced for B (as described previously) for each value of A. Thus, this SUMBY statement produces a total of six consolidation tables in addition to the tables produced for each BY group.

To produce a table that consolidates the entire data set (the equivalent of using PROC COMPUTAB with neither BY nor SUMBY statements), use the special name `_TOTAL_` as the first entry in the SUMBY variable list. For example,

```
sumby _total_ a b;
```

PROC COMPUTAB then produces consolidation tables for SUMBY variables as well as a consolidation table for all observations.

To produce only consolidation tables, use the SUMONLY option in the PROC COMPUTAB statement.

NOTRANS Option

The NOTRANS option in the PROC COMPUTAB statement prevents the transposition of the input data set. NOTRANS affects the input block, the precedence of row and column options, and the structure of the output data set if the OUT= option is specified.

When the input data set is transposed, input variables are among the rows of the COMPUTAB report, and observations compose columns. The reverse is true if the data set is not transposed; therefore, the input block must select rows to receive data values, and input variables are among the columns.

Variables from the input data set dominate the format specification and data type. When the input data set is transposed, input variables are among the rows of the report, and row options take precedence over column options. When the input data set is not transposed, input variables are among the columns, and column options take precedence over row options.

Variables for the output data set are taken from the dimension (row or column) that contains variables from the input data set. When the input data set is transposed, this dimension is the row dimension; otherwise, the output variables come from the column dimension.

Details: COMPUTAB Procedure

Program Flow Example

This example shows how the COMPUTAB procedure processes observations in the program working storage and the COMPUTAB data table (CDT).

Assume you have three years of figures for sales and cost of goods sold (CGS), and you want to determine total sales and cost of goods sold and calculate gross profit and the profit margin.

```
data example;
    input year sales cgs;
datalines;
1988    83    52
1989   106    85
1990   120   114
;

proc computab data=example;

    columns c88 c89 c90 total;
    rows sales cgs gprofit pctmarg;

    /* calculate gross profit */
    gprofit = sales - cgs;

    /* select a column */
    c88 = year = 1988;
    c89 = year = 1989;
    c90 = year = 1990;

    /* calculate row totals for sales */
    /* and cost of goods sold */
    col: total = c88 + c89 + c90;

    /* calculate profit margin */
    row: pctmarg = gprofit / cgs * 100;
run;
```

Table 9.3 shows the CDT before any observation is read in. All the columns and rows are defined with the values initialized to 0.

Table 9.3 CDT before Any Input

	C88	C89	C90	TOTAL
SALES	0	0	0	0
CGS	0	0	0	0
GPROFIT	0	0	0	0
PCTMARG	0	0	0	0

When the first input is read in (year=1988, sales=83, and cgs=52), the input block puts the values for SALES and CGS in the C88 column since year=1988. Also the value for the gross profit for that year (GPROFIT) is calculated as indicated in the following statements:

```

gprofit = sales-cgs;
c88 = year = 1988;
c89 = year = 1989;
c90 = year = 1990;

```

Table 9.4 shows the CDT after the first observation is input.

Table 9.4 CDT after First Observation Input (C88=1)

	C88	C89	C90	TOTAL
SALES	83	0	0	0
CGS	52	0	0	0
GPROFIT	31	0	0	0
PCTMARG	0	0	0	0

Similarly, the second observation (year=1989, sales=106, cgs=85) is put in the second column, and the GPROFIT is calculated to be 21. The third observation (year=1990, sales=120, cgs=114) is put in the third column, and the GPROFIT is calculated to be 6. Table 9.5 shows the CDT after all observations are input.

Table 9.5 CDT after All Observations Input

	C88	C89	C90	TOTAL
SALES	83	106	120	0
CGS	52	85	114	0
GPROFIT	31	21	6	0
PCTMARG	0	0	0	0

After the input block is executed for each observation in the input data set, the first row or column block is processed. In this case, the column block is

```
col: total = c88 + c89 + c90;
```

The column block executes for each row, calculating the TOTAL column for each row. Table 9.6 shows the CDT after the column block has executed for the first row (total=83 + 106 + 120). The total sales for the three years is 309.

Table 9.6 CDT after Column Block Executed for First Row

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	0
GPROFIT	31	21	6	0
PCTMARG	0	0	0	0

Table 9.7 shows the CDT after the column block has executed for all rows and the values for total cost of goods sold and total gross profit have been calculated.

Table 9.7 CDT after Column Block Executed for All Rows

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	251
GPROFIT	31	21	6	58
PCTMARG	0	0	0	0

After the column block has been executed for all rows, the next block is processed. The row block is

```
row: pctmarg = gprofit / cgs * 100;
```

The row block executes for each column, calculating the PCTMARG for each year and the total (TOTAL column) for three years. Table 9.8 shows the CDT after the row block has executed for all columns.

Table 9.8 CDT after Row Block Executed for All Columns

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	251
GPROFIT	31	21	6	58
PCTMARG	59.62	24.71	5.26	23.11

Order of Calculations

The COMPUTAB procedure provides alternative programming methods for performing most calculations. New column and row values are formed by adding values from the input data set, directly or with modification, into existing columns or rows. New columns can be formed in the input block or in column blocks. New rows can be formed in the input block or in row blocks.

This example illustrates the different ways to collect totals. [Table 9.9](#) is the total sales report for two products, SALES1 and SALES2, during the years 1988–1990. The values for SALES1 and SALES2 in columns C88, C89, and C90 come from the input data set.

Table 9.9 Total Sales Report

	C88	C89	C90	SALESTOT
SALES1	15	45	80	140
SALES2	30	40	50	120
YRTOT	45	85	130	260

The new column SALESTOT, which is the total sales for each product over three years, can be computed in several different ways:

- in the input block by selecting SALESTOT for each observation:

```
salestot = 1;
```

- in a column block:

```
coltot: salestot = c88 + c89 + c90;
```

In a similar fashion, the new row YRTOT, which is the total sales for each year, can be formed as follows:

- in the input block:

```
yrtot = sales1 + sales2;
```

- in a row block:

```
rowtot: yrtot = sales1 + sales2;
```

Performing some calculations in PROC COMPUTAB in different orders can yield different results, because many operations are not commutative. Be sure to perform calculations in the proper sequence. It might take several column and row blocks to produce the desired report values.

Notice that in the previous example, the grand total for all rows and columns is 260 and is the same whether it is calculated from row subtotals or column subtotals. It makes no difference in this case whether you compute the row block or the column block first.

However, consider the following example where a new column and a new row are formed:

Table 9.10 Report Sensitive to Order of Calculations

	STORE1	STORE2	STORE3	MAX
PRODUCT1	12	13	27	27
PRODUCT2	11	15	14	15
TOTAL	23	28	41	?

The new column MAX contains the maximum value in each row, and the new row TOTAL contains the column totals. MAX is calculated in a column block:

```
col: max = max(store1, store2, store3);
```

TOTAL is calculated in a row block:

```
row: total = product1 + product2;
```

Notice that either of two values, 41 or 42, is possible for the element in column MAX and row TOTAL. If the row block is first, the value is the maximum of the column totals (41). If the column block is first, the value is the sum of the MAX values (42). Whether to compute a column block before a row block can be a critical decision.

Column Selection

The following discussion assumes that the NOTRANS option has not been specified. When NOTRANS is specified, this section applies to rows rather than columns.

If a COLUMNS statement appears in PROC COMPUTAB, a target column must be selected for the incoming observation. If there is no COLUMNS statement, a new column is added for each observation. When a COLUMNS statement is present and the selection criteria fail to designate a column, the current observation is ignored. Faulty column selection can result in columns or entire tables of 0s (or missing values if the INITMISS option is specified).

During execution of the input block, when an observation is read, its values are copied into row variables in the program data vector (PDV).

To select columns, use either the column variable names themselves or the special variable `_COL_`. Use the column names by setting a column variable equal to some nonzero value. The example in the section “[Getting Started: COMPUTAB Procedure](#)” on page 430 uses the logical expression `COMPDIV= value`, and the result is assigned to the corresponding column variable.

```
a = compdiv = 'A';
b = compdiv = 'B';
c = compdiv = 'C';
```

IF statements can also be used to select columns. The following statements are equivalent to the preceding example:

```
if      compdiv = 'A' then a = 1;
else if compdiv = 'B' then b = 1;
else if compdiv = 'C' then c = 1;
```

At the end of the input block for each observation, PROC COMPUTAB multiplies numeric input values by any nonzero selector values and adds the result to selected columns. Character values simply overwrite the contents already in the table. If more than one column is selected, the values are added to each of the selected columns.

Use the `_COL_` variable to select a column by assigning the column number to it. The COMPUTAB procedure automatically initializes column variables and sets the `_COL_` variable to 0 at the start of each execution of the input block. At the end of the input block for each observation, PROC COMPUTAB examines the value of `_COL_`. If the value is nonzero and within range, the row variable values are added to the CDT cells of the `_COL_`th column, for example,

```
data rept;
  input div sales cgs;
datalines;
2  106    85
3  120   114
1   83    52
;

proc computab data=rept;
  row div sales cgs;
  columns div1 div2 div3;
  _col_ = div;
run;
```

The code in this example places the first observation (DIV=2) in column 2 (DIV2), the second observation (DIV=3) in column 3 (DIV3), and the third observation (DIV=1) in column 1 (DIV1).

Controlling Execution within Row and Column Blocks

Row names, column names, and the special variables `_ROW_` and `_COL_` can be used to limit the execution of programming statements to selected rows or columns. A row block operates on all

columns of the table for a specified row unless restricted in some way. Likewise, a column block operates on all rows for a specified column. Use column names or `_COL_` in a row block to execute programming statements conditionally; use row names or `_ROW_` in a column block.

For example, consider a simple column block that consists of only one statement:

```
col: total = qtr1 + qtr2 + qtr3 + qtr4;
```

This column block assigns a value to each row in the TOTAL column. As each row participates in the execution of a column block, the following changes occur:

- Its row variable in the program data vector is set to 1.
- The value of `_ROW_` is the number of the participating row.
- The value from each column of the row is copied from the COMPUTAB data table to the program data vector.

To avoid calculating TOTAL on particular rows, use row names or `_ROW_`. For example,

```
col: if sales|cost then total = qtr1 + qtr2 + qtr3 + qtr4;
```

or

```
col: if _row_ < 3 then total = qtr1 + qtr2 + qtr3 + qtr4;
```

Row and column blocks can appear in any order, and rows and columns can be selected in each block.

Program Flow

This section describes in detail the different steps in PROC COMPUTAB execution.

Step 1: Define Report Organization and Set Up the COMPUTAB Data Table

Before the COMPUTAB procedure reads in data or executes programming statements, the columns list from the COLUMNS statements and the rows list from the ROWS statements are used to set up a matrix of all columns and rows in the report. This matrix is called the COMPUTAB data table (CDT). When you define columns and rows of the CDT, the COMPUTAB procedure also sets up corresponding variables in working storage called the program data vector (PDV) for programming statements. Data values reside in the CDT but are copied into the program data vector as they are needed for calculations.

Step 2: Select Input Data with Input Block Programming Statements

The input block copies input observations into rows or columns of the CDT. By default, observations go to columns; if the data set is not transposed (the NOTRANS option is specified), observations go to rows of the report table. The input block consists of all executable statements before any ROWxxxx: or COLxxxx: statement label. Use programming statements to perform calculations and select a given observation to be added into the report.

Input Block

The input block is executed once for each observation in the input data set. If there is no input data set, the input block is not executed. The program logic of the input block is as follows:

1. Determine which variables, row or column, are selector variables and which are data variables. Selector variables determine which rows or columns receive values at the end of the block. Data variables contain the values that the selected rows or columns receive. By default, column variables are selector variables and row variables are data variables. If the input data set is not transposed (the NOTRANS option is specified), the roles are reversed.
2. Initialize nonretained program variables (including selector variables) to 0 (or missing if the INITMISS option is specified). Selector variables are temporarily associated with a numeric data item supplied by the procedure. Using these variables to control row and column selection does not affect any other data values.
3. Transfer data from an observation in the data set to data variables in the PDV.
4. Execute the programming statements in the input block by using values from the PDV and storing results in the PDV.
5. Transfer data values from the PDV into the appropriate columns of the CDT. If a selector variable for a row or column has a nonmissing and nonzero value, multiply each PDV value for variables used in the report by the selector variable and add the results to the selected row or column of the CDT.

Step 3: Calculate Final Values by Using Column Blocks and Row Blocks

Column Blocks

A column block is executed once for each row of the CDT. The program logic of a column block is as follows:

1. Indicate the current row by setting the corresponding row variable in the PDV to 1 and the other row variables to missing. Assign the current row number to the special variable `_ROW_`.
2. Move values from the current row of the CDT to the respective column variables in the PDV.
3. Execute programming statements in the column block by using the column values in the PDV. Here new columns can be calculated and old ones adjusted.
4. Move the values back from the PDV to the current row of the CDT.

Row Blocks

A row block is executed once for each column of the CDT. The program logic of a row block is as follows:

1. Indicate the current column by setting the corresponding column variable in the PDV to 1 and the other column variables to missing. Assign the current column number to the special variable `_COL_`.
2. Move values from the current column of the CDT to the respective row variables in the PDV.
3. Execute programming statements in the row block by using the row values in the PDV. Here new rows can be calculated and old ones adjusted.
4. Move the values back from the PDV to the current column of the CDT.

See the section “Controlling Execution within Row and Column Blocks” on page 453.

Any number of column blocks and row blocks can be used. Each can include any number of programming statements.

The values of row variables and column variables are determined by the order in which different row-block and column-block programming statements are processed. These values can be modified throughout the COMPUTAB procedure, and final values are printed in the report.

Direct Access to Table Cells

You can insert or retrieve numeric values from specific table cells by using the special reserved name `TABLE` with row and column subscripts. References to the `TABLE` have the form

```
TABLE[ row-index, column-index ]
```

where *row-index* and *column-index* can be numbers, character literals, numeric variables, character variables, or expressions that produce a number or a name. If an index is numeric, it must be within range; if it is character, it must name a row or column.

References to `TABLE` elements can appear on either side of an equal sign in an assignment statement and can be used in a SAS expression.

Reserved Words

Certain words are reserved for special use by the COMPUTAB procedure, and using these words as variable names can lead to syntax errors or warnings. They are:

- COLUMN
- COLUMNS
- COL
- COLS
- _COL_
- ROW
- ROWS
- _ROW_
- INIT
- _N_
- TABLE

Missing Values

Missing values for variables in programming statements are treated in the same way that missing values are treated in the DATA step; that is, missing values used in expressions propagate missing values to the result. See *SAS Language: Reference* for more information about missing values.

Missing values in the input data are treated as follows in the COMPUTAB report table. At the end of the input block, either one or more rows or one or more columns can have been selected to receive values from the program data vector (PDV). Numeric data values from variables in the PDV are added into selected report table rows or columns. If a PDV value is missing, the values already in the selected rows or columns for that variable are unchanged by the current observation. Other values from the current observation are added to table values as usual.

OUT= Data Set

The output data set contains the following variables:

- BY variables
- a numeric variable _TYPE_
- a character variable _NAME_
- the column variables from the COMPUTAB data table

The BY variables contain values for the current BY group. For observations in the output data set from consolidation tables, the consolidated BY variables have missing values.

The special variable `_TYPE_` is a numeric variable that can have one of three values: 1, 2, or 3. `_TYPE_ = 1` indicates observations from the normal report table produced for each BY group; `_TYPE_ = 2` indicates observations from the `_TOTAL_` consolidation table; `_TYPE_ = 3` indicates observations from other consolidation tables. `_TYPE_ = 2` and `_TYPE_ = 3` observations have one or more BY variables with missing values.

The special variable `_NAME_` is a character variable of length 8 that contains the row or column name associated with the observation from the report table. If the input data set is transposed, `_NAME_` contains column names; otherwise, `_NAME_` contains row names.

If the input data set is transposed, the remaining variables in the output data set are row variables from the report table. They are column variables if the input data set is not transposed.

Examples: COMPUTAB Procedure

Example 9.1: Using Programming Statements

This example illustrates two ways of operating on the same input variables and producing the same tabular report. To simplify the example, no report enhancements are shown.

The manager of a hotel chain wants a report that shows the number of bookings at its hotels in each of four cities, the total number of bookings in the current quarter, and the percentage of the total coming from each location for each quarter of the year. Input observations contain the following variables: `REPTDATE` (report date), `LA` (number of bookings in Los Angeles), `ATL` (number of bookings in Atlanta), `CH` (number of bookings in Chicago), and `NY` (number of bookings in New York).

The following `DATA` step creates the SAS data set `BOOKINGS`:

```
data bookings;
  input reptdate date9. la atl ch ny;
datalines;
01JAN1989 100 110 120 130
01FEB1989 140 150 160 170
01MAR1989 180 190 200 210
01APR1989 220 230 240 250
01MAY1989 260 270 280 290
01JUN1989 300 310 320 330
01JUL1989 340 350 360 370
01AUG1989 380 390 400 410
01SEP1989 420 430 440 450
01OCT1989 460 470 480 490
01NOV1989 500 510 520 530
```

```
01DEC1989 540 550 560 570
;
```

The following PROC COMPUTAB statements select columns by setting `_COL_` to an appropriate value. The PCT1, PCT2, PCT3, and PCT4 columns represent the percentage contributed by each city to the total for the quarter. These statements produce [Output 9.1.1](#).

```
proc computab data=bookings cspace=1 cwidth=6;

  columns qtr1 pct1 qtr2 pct2 qtr3 pct3 qtr4 pct4;
  columns qtr1-qtr4 / format=6.;
  columns pct1-pct4 / format=6.2;
  rows la atl ch ny total;

  /* column selection */
  _col_ = qtr( reptdate ) * 2 - 1;

  /* copy qtr column values temporarily into pct columns */
  colcopy:
    pct1 = qtr1;
    pct2 = qtr2;
    pct3 = qtr3;
    pct4 = qtr4;

  /* calculate total row for all columns */
  /* calculate percentages for all rows in pct columns only */
  rowcalc:
    total = la + atl + ch + ny;
    if mod( _col_, 2 ) = 0 then do;
      la = la / total * 100;
      atl = atl / total * 100;
      ch = ch / total * 100;
      ny = ny / total * 100;
      total = 100;
    end;

run;
```

Output 9.1.1 Quarterly Report of Hotel Bookings

Year to Date Expenses								
	QTR1	PCT1	QTR2	PCT2	QTR3	PCT3	QTR4	PCT4
LA	420	22.58	780	23.64	1140	24.05	1500	24.27
ATL	450	24.19	810	24.55	1170	24.68	1530	24.76
CH	480	25.81	840	25.45	1200	25.32	1560	25.24
NY	510	27.42	870	26.36	1230	25.95	1590	25.73
TOTAL	1860	100.00	3300	100.00	4740	100.00	6180	100.00

Using the same input data, the next set of statements shows the usefulness of arrays in allowing PROC COMPUTAB to work in two directions at once. Arrays in larger programs can both reduce the amount of program source code and simplify otherwise complex methods of referring to rows and columns. The same report as in [Output 9.1.1](#) is produced.

```
proc computab data=bookings cspace=1 cwidth=6;

    columns qtr1 pct1 qtr2 pct2 qtr3 pct3 qtr4 pct4;
    columns qtr1-qtr4 / format=6.;
    columns pct1-pct4 / format=6.2;
    rows la atl ch ny total;

    array pct[4] pct1-pct4;
    array qt[4] qtr1-qtr4;
    array rowlist[5] la atl ch ny total;

    /* column selection */
    _col_ = qtr(reptdate) * 2 - 1;

    /* copy qtr column values temporarily into pct columns */
    colcopy:
        do i = 1 to 4;
            pct[i] = qt[i];
        end;

    /* calculate total row for all columns */
    /* calculate percentages for all rows in pct columns only */

    rowcalc:
        total = la + atl + ch + ny;
        if mod(_col_,2) = 0 then
            do i = 1 to 5;
                rowlist[i] = rowlist[i] / total * 100;
            end;
run;
```

Example 9.2: Enhancing a Report

The following example shows how a report can be enhanced from a simple listing to a complex report. The simplest COMPUTAB report is a transposed listing of the data in the SAS data set INCOMREP shown in [Output 9.2.1](#). To produce this output, nothing is specified except the PROC COMPUTAB statement and a TITLE statement.

```
data incomrep;
    length type $ 8;
    input type :$8. date :monyy7.
           sales retdis tcos selling randd
           general admin deprec other taxes;
    format date monyy7.;
```

```

datalines;
BUDGET JAN1989 4600 300 2200 480 110 500 210 14 -8 510
BUDGET FEB1989 4700 330 2300 500 110 500 200 14 0 480
BUDGET MAR1989 4800 360 2600 500 120 600 250 15 2 520
ACTUAL JAN1989 4900 505 2100 430 130 410 200 14 -8 500
ACTUAL FEB1989 5100 480 2400 510 110 390 230 15 2 490
;

title 'Computab Report without Any Specifications';
proc computab data=incomrep;
run;

```

Output 9.2.1 Simple Report

Computab Report without Any Specifications					
	COL1	COL2	COL3	COL4	COL5
type	BUDGET	BUDGET	BUDGET	ACTUAL	ACTUAL
date	JAN1989	FEB1989	MAR1989	JAN1989	FEB1989
sales	4600.00	4700.00	4800.00	4900.00	5100.00
retdis	300.00	330.00	360.00	505.00	480.00
tcos	2200.00	2300.00	2600.00	2100.00	2400.00
selling	480.00	500.00	500.00	430.00	510.00
randd	110.00	110.00	120.00	130.00	110.00
general	500.00	500.00	600.00	410.00	390.00
admin	210.00	200.00	250.00	200.00	230.00
deprec	14.00	14.00	15.00	14.00	15.00
other	-8.00	0.00	2.00	-8.00	2.00
taxes	510.00	480.00	520.00	500.00	490.00

To exclude the budgeted values from your report, select columns for ACTUAL observations only. To remove unwanted variables, specify the variables you want in a ROWS statement.

```

title 'Column Selection by Month';

proc computab data=incomrep;
  rows sales--other;
  columns jana feba mara;
  mnth = month(date);
  if type = 'ACTUAL';
    jana = mnth = 1;
    feba = mnth = 2;
    mara = mnth = 3;
run;

```

The report is shown in [Output 9.2.2](#).

Output 9.2.2 Report That Uses Column Selection Techniques

Column Selection by Month			
	JANA	FEBA	MARA

general	410.00	390.00	0.00
admin	200.00	230.00	0.00
deprec	14.00	15.00	0.00
other	-8.00	2.00	0.00

To complete the report, compute new rows from existing rows. This is done in a row block (although it can also be done in the input block). Add a new column (QTR1) that accumulates all the actual data. The NOZERO option suppresses the zero column for March. The output produced by these statements is shown in [Output 9.2.3](#).

```
proc computab data=incomrep;

    /* add a new column to be selected */
    /* qtr1 column will be selected several times */
    columns actual1-actual3 qtr1 / nozero;
    array collist[3] actual1-actual3;
    rows sales retdis netsales tcos grosspft selling randd general
          admin deprec operexp operinc other taxblinc taxes netincom;

    if type='ACTUAL';
    i = month(date);
    if i <= 3 then qtr1 = 1;
    collist[i]=1;

    rowcalc:
        if sales = . then return;
        netsales = sales - retdis;
        grosspft = netsales - tcos;
        operexp = selling + randd + general + admin + deprec;
        operinc = grosspft - operexp;
        taxblinc = operinc + other;
        netincom = taxblinc - taxes;

run;
```

Output 9.2.3 Report That Uses Techniques to Compute New Rows

Column Selection by Month			
	ACTUAL1	ACTUAL2	QTR1
SALES	4900.00	5100.00	10000.00
RETDIS	505.00	480.00	985.00
NETSALES	4395.00	4620.00	9015.00
TCOS	2100.00	2400.00	4500.00

Example 9.3: Comparison of Actual and Budget

This example shows a more complex report that compares the actual data with the budgeted values. The same input data as in the previous example is used.

The report produced by these statements is shown in [Output 9.3.1](#). The report shows the values for the current month and the year-to-date totals for budgeted amounts, actual amounts, and the actuals as a percentage of the budgeted amounts. The data have the values for January and February. Therefore, the CURMO variable (current month) in the RETAIN statement is set to 2. The values for the observations where the month of the year is 2 (February) are accumulated for the current month values. The year-to-date values are accumulated from those observations where the month of the year is less than or equal to 2 (January and February).

Example 9.5: Creating an Output Data Set

This example uses data and reports similar to those in [Example 9.3](#) to illustrate the creation of an output data set.

```

data product;
  input pcode div region month sold revenue recd cost;
datalines;
1 1 1 1 56 5600 29 2465
1 1 1 2 13 1300 30 2550
1 1 1 3 17 1700 65 5525
2 1 1 1 2 240 50 4900
2 1 1 2 82 9840 17 1666

... more lines ...

proc sort data=product out=sorted;
  by div region;
run;

```

```

/* create data set, profit */
proc computab data=sorted notrans out=profit noprint;
  by div region;
  sumby div;

  /* specify order of rows and row titles */
  row    jan feb mar qtr1;
  row    apr may jun qtr2;
  row    jul aug sep qtr3;
  row    oct nov dec qtr4;

  /* specify order of columns and column titles */
  columns sold revenue recd cost profit pctmarg;

  /* select row for appropriate month */
  _row_ = month + ceil( month / 3 ) - 1;

  /* calculate quarterly summary rows */
  rowcalc:
    qtr1 = jan + feb + mar;
    qtr2 = apr + may + jun;
    qtr3 = jul + aug + sep;
    qtr4 = oct + nov + dec;

  /* calculate profit columns */
  colcalc:
    profit = revenue - cost;
    if cost > 0 then pctmarg = profit / cost * 100;
run;

/* make a partial listing of the output data set */
options linesize=96;
proc print data=profit(obs=10) noobs;
run;

```

Because the NOTRANS option is specified, column names become variables in the data set. REGION has missing values in the output data set for observations associated with consolidation tables. The output data set PROFIT, in conjunction with the option NOPRINT, illustrates how you can use the computational features of PROC COMPUTAB for creating additional rows and columns as in a spreadsheet without producing a report. [Output 9.5.1](#) shows a partial listing of the output data set PROFIT.

Output 9.5.1 Partial Listing of the PROFIT Data Set

Example 9.6: A What-If Market Analysis

PROC COMPUTAB can be used with other SAS/ETS procedures and with macros to implement commonly needed decision support tools for financial and marketing analysis.

The following input data set reads quarterly sales figures:

```
data market;
  input date :yyq6. units @@;
datalines;

... more lines ...
```

The following statements illustrate how PROC FORECAST makes a total market forecast for the next four quarters:

```
/* forecast the total number of units to be */
/* sold in the next four quarters */
proc forecast out=outcome trend=2
  interval=qtr lead=4;
  id date;
  var units;
run;
```

The macros WHATIF and SHOW build a report table and provide the flexibility of examining alternate what-if situations. The row and column calculations of PROC COMPUTAB compute the income statement. With macros stored in a macro library, the only statements required with PROC COMPUTAB are macro invocations and TITLE statements.

```

/* set up rows and columns of report and initialize */
/* market share and program constants */
%macro whatif(mktshr=,price=,ucost=,taxrate=,numshar=,overhead=);

Overview: COUNTREG Procedure

The COUNTREG (count regression) procedure analyzes regression models in which the dependent variable takes nonnegative integer or count values. The dependent variable is usually an *event count*, which refers to the number of times an event occurs. For example, an event count might represent the number of ship accidents per year for a given fleet. In count regression, the conditional mean $E(y_i | \mathbf{x}_i)$ of the dependent variable, y_i , is assumed to be a function of a vector of covariates, \mathbf{x}_i .

The Poisson (log-linear) regression model is the most basic model that explicitly takes into account the nonnegative integer-valued aspect of the outcome. With this model, the probability of an event count is determined by a Poisson distribution, where the conditional mean of the distribution is a function of a vector of covariates. However, the basic Poisson regression model is limited because it forces the conditional mean of the outcome to equal the conditional variance. This assumption is often violated in real-life data. Negative binomial regression is an extension of Poisson regression in which the conditional variance may exceed the conditional mean. Also, an often encountered characteristic of count data is that the number of zeros in the sample exceeds the number of zeros predicted by either the Poisson or negative binomial model. Zero-inflated Poisson (ZIP) and zero-inflated negative binomial (ZINB) models explicitly model the production of zero counts to account for excess zeros and also enable the conditional variance of the outcome to differ from the conditional mean.

Under zero-inflated models, additional zeros occur with probability φ_i , which is determined by a separate model, $\varphi_i = F(\mathbf{z}'_i \boldsymbol{\gamma})$, where F is the normal or logistic distribution function resulting in a probit or logistic model, and \mathbf{z}_i is a set of covariates.

PROC COUNTREG supports the following models for count data:

- Poisson regression
- negative binomial regression with quadratic (NEGBIN2) and linear (NEGBIN1) variance functions (Cameron and Trivedi 1986)
- zero-inflated Poisson (ZIP) model (Lambert 1992)
- zero-inflated negative binomial (ZINB) model

In recent years, count data models have been used extensively in economics, political science, and sociology. For example, Hausman, Hall, and Griliches (1984) examine the effects of R&D expenditures on the number of patents received by U.S. companies. Cameron and Trivedi (1986) study factors affecting the number of doctor visits. Greene (1994) studies the number of derogatory reports to a credit reporting agency for a group of credit card applicants. As a final example, Long (1997) analyzes the number of doctoral publications in the final three years of Ph.D. studies.

The COUNTREG procedure uses maximum likelihood estimation. When a model with a dependent count variable is estimated using linear ordinary least squares (OLS) regression, the count nature of the dependent variable is ignored. This leads to negative predicted counts and to parameter estimates with undesirable properties in terms of statistical efficiency, consistency, and unbiasedness unless

the mean of the counts is high, in which case the Gaussian approximation and linear regression may be satisfactory.

Getting Started: COUNTREG Procedure

The COUNTREG procedure is similar in use to other regression model procedures in the SAS System. For example, the following statements are used to estimate a Poisson regression model:

```
proc countreg data=one ;
    model y = x / dist=poisson ;
run;
```

The response variable y is numeric and has nonnegative integer values. To allow for variance greater than the mean, specify the `dist=negbin` option to fit the negative binomial model instead of the Poisson.

The following example illustrates the use of PROC COUNTREG. The data are taken from Long (1997). This study examines how factors such as gender (`fem`), marital status (`mar`), number of young children (`kid5`), prestige of the graduate program (`phd`), and number of articles published by a scientist's mentor (`ment`) affect the number of articles (`art`) published by the scientist.

The first 10 observations are shown in [Figure 10.1](#).

Figure 10.1 Article Count Data

Obs	art	fem	mar	kid5	phd	ment
1	3	0	1	2	1.38000	8.0000
2	0	0	0	0	4.29000	7.0000
3	4	0	0	0	3.85000	47.0000
4	1	0	1	1	3.59000	19.0000
5	1	0	1	0	1.81000	0.0000
6	1	0	1	1	3.59000	6.0000
7	0	0	1	1	2.12000	10.0000
8	0	0	1	0	4.29000	2.0000
9	3	0	1	2	2.58000	2.0000
10	3	0	1	1	1.80000	4.0000

The following SAS statements estimate the Poisson regression model:

```
/*-- Poisson Regression --*/
proc countreg data=long97data;
    model art = fem mar kid5 phd ment / dist=poisson method=quanew;
run;
```

The Model Fit Summary, shown in [Figure 10.2](#), lists several details about the model. By default, the COUNTREG procedure uses the Newton-Raphson optimization technique. The maximum log-

likelihood value is shown, as well as two information measures, Akaike's information criterion (AIC) and Schwarz's Bayesian information criterion (SBC), which can be used to compare competing Poisson models. Smaller values of these criteria indicate better models.

Figure 10.2 Estimation Summary Table for a Poisson Regression

The COUNTREG Procedure	
Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	Poisson
Log Likelihood	-1651
Maximum Absolute Gradient	0.00181
Number of Iterations	13
Optimization Method	Quasi-Newton
AIC	3314
SBC	3343

The parameter estimates of the model and their standard errors are shown in [Figure 10.3](#). All covariates are significant predictors of the number of articles, except for the prestige of the program (phd), which has a p -value of 0.6271.

Figure 10.3 Parameter Estimates of Poisson Regression

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.304617	0.102982	2.96	0.0031
fem	1	-0.224594	0.054614	-4.11	<.0001
mar	1	0.155243	0.061375	2.53	0.0114
kid5	1	-0.184883	0.040127	-4.61	<.0001
phd	1	0.012823	0.026397	0.49	0.6271
ment	1	0.025543	0.002006	12.73	<.0001

The following statements fit the negative binomial model. While the Poisson model requires that the conditional mean and conditional variance be equal, the negative binomial model allows for overdispersion; that is, the conditional variance may exceed the conditional mean.

```

/*-- Negative Binomial Regression --*/
proc countreg data=long97data;
  model art = fem mar kid5 phd ment / dist=negbin(p=2) method=quanew;
run;

```

The fit summary is shown in [Figure 10.4](#), and parameter estimates are listed in [Figure 10.5](#).

Figure 10.4 Estimation Summary Table for a Negative Binomial Regression

The COUNTREG Procedure	
Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	NegBin
Log Likelihood	-1561
Maximum Absolute Gradient	1.75584E-6
Number of Iterations	16
Optimization Method	Quasi-Newton
AIC	3136
SBC	3170

Figure 10.5 Parameter Estimates of Negative Binomial Regression

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.256144	0.138560	1.85	0.0645
fem	1	-0.216418	0.072672	-2.98	0.0029
mar	1	0.150489	0.082106	1.83	0.0668
kid5	1	-0.176415	0.053060	-3.32	0.0009
phd	1	0.015271	0.036040	0.42	0.6718
ment	1	0.029082	0.003470	8.38	<.0001
_Alpha	1	0.441620	0.052967	8.34	<.0001

The parameter estimate for `_Alpha` of 0.4416 is an estimate of the dispersion parameter in the negative binomial distribution. A t test for the hypothesis $H_0 : \alpha = 0$ is provided. It is highly significant, indicating overdispersion ($p < 0.0001$).

The null hypothesis $H_0 : \alpha = 0$ can be also tested against the alternative $\alpha > 0$ by using the likelihood ratio test, as described by Cameron and Trivedi (1998, pp. 45, 77–78). The likelihood ratio test statistic is equal to $-2(\mathcal{L}_P - \mathcal{L}_{NB}) = -2(-1651 + 1561) = 180$, which is highly significant, providing strong evidence of overdispersion.

Syntax: COUNTREG Procedure

The COUNTREG procedure is controlled by the following statements:

```

PROC COUNTREG options ;
  BOUNDS bound1 [ , bound2 ... ] ;
  BY variables ;
  INIT initvalue1 [ , initvalue2 ... ] ;
  MODEL dependent variable = regressors / options ;
  OUTPUT options ;
  RESTRICT restriction1 [ , restriction2 ... ] ;
  ZEROMODEL dependent variable ~ zero-inflated regressors / options ;

```

There can only be one MODEL statement. The ZEROMODEL statement, if used, must appear after the MODEL statement.

Functional Summary

The statements and options used with the COUNTREG procedure are summarized in the following table.

Table 10.1 COUNTREG Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	COUNTREG	DATA=
write parameter estimates to an output data set	COUNTREG	OUTEST=
write estimates of $\mathbf{x}'_i\boldsymbol{\beta}$ and $\mathbf{z}'_i\boldsymbol{\gamma}$ to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify BY-group processing	BY	
Printing Control Options		
print the correlation matrix of the estimates	MODEL	CORRB
print the covariance matrix of the estimates	MODEL	COVB
print a summary iteration listing	MODEL	ITPRINT
suppress the normal printed output	COUNTREG	NOPRINT
request all printing options	MODEL	PRINTALL
Options to Control the Optimization Process		
specify maximum number of iterations allowed	MODEL	MAXITER=
select the iterative minimization method to use	COUNTREG	METHOD=
set boundary restrictions on parameters	BOUNDS	
set initial values for parameters	INIT	
set linear restrictions on parameters	RESTRICT	
specify other optimization options	COUNTREG	see Chapter 6, “Nonlinear Optimization Methods,”

Description	Statement	Option

specify the type of model	MODEL	DIST=
specify the type of model	COUNTREG	DIST=
specify the type of covariance matrix	MODEL	COVEST=
suppress the intercept parameter	MODEL	NOINT
specify the offset variable	MODEL	OFFSET=
specify the zero-inflated offset variable	ZEROMODEL	OFFSET=
specify the zero-inflated link function	ZEROMODEL	LINK=
Output Control Options		
include covariances in the OUTEST= data set	COUNTREG	COVOUT
output probability of response variable taking the current value	OUTPUT	PROB=
output expected value of response variable	OUTPUT	PRED=
output estimates of $X\beta = \mathbf{x}'_i\boldsymbol{\beta}$	OUTPUT	XBETA=
output estimates of $Z\gamma = \mathbf{z}'_i\boldsymbol{\gamma}$	OUTPUT	ZGAMMA=
output probability of response variable taking a zero value as a result of the zero-generating process	OUTPUT	PROBZERO=

PROC COUNTREG Statement

PROC COUNTREG *options* ;

The following options can be used in the PROC COUNTREG statement:

Data Set Options

DATA=*SAS-data-set*

specifies the input SAS data set. If the DATA= option is not specified, PROC COUNTREG uses the most recently created SAS data set.

Output Data Set Options

OUTEST=*SAS-data-set*

writes the parameter estimates to an output data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This

option is valid only if the OUTEST= option is specified.

Printing Options

NOPRINT

suppresses all printed output.

Estimation Control Options

COVEST=*value*

The COVEST= option specifies the type of covariance matrix of the parameter estimates. The quasi-maximum likelihood estimates are computed with COVEST=QML. The default is COVEST=HESSIAN. The supported covariance types are as follows:

OP	specifies the covariance from the outer product matrix.
HESSIAN	specifies the covariance from the Hessian matrix.
QML	specifies the covariance from the outer product and Hessian matrices.

Options to Control the Optimization Process

PROC COUNTREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. All the NLO options are available. For details, see Chapter 6, “[Nonlinear Optimization Methods](#).” In addition, the following option is supported on the PROC COUNTREG statement:

METHOD=*value*

specifies the iterative minimization method to use. The default is METHOD=NRA.

QN	specifies the quasi-Newton method.
NRA	specifies the Newton-Raphson method.
TR	specifies the trust region method.

BOUNDS Statement

BOUNDS *bound1* [, *bound2* ...] ;

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the COUNTREG procedure. You can specify any number of BOUNDS statements.

Each *bound* is composed of parameter names, constants, and inequality operators:

item operator item [operator item [operator item ...]]

Each *item* is a constant, a parameter name, or a list of parameter names. Each *operator* is '<', '>', '<=', or '>='. Parameter names are as shown in the ESTIMATE column of the “Parameter Estimates” table.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the section “[RESTRICT Statement](#)” on page 493 as well.

The following BOUNDS statement constrains the estimates of the parameter for *z* to be negative, the parameters for *x1* through *x10* to be between zero and one, and the parameter for *x1* in the zero-inflation model to be less than one. The following example illustrates the use of parameter lists to specify boundary constraints:

```
bounds z < 0,
       0 < x1-x10 < 1,
       Inf_x1 < 1;
```

BY Statement

BY *variables* ;

A BY statement can be used with PROC COUNTREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set should be sorted in order of the BY variables.

INIT Statement

INIT *initvalue1* [, *initvalue2* ...] ;

The INIT statement is used to set initial values for parameters in the optimization.

Each *initvalue* is written as a parameter or parameter list, followed by an optional equal sign (=), followed by a number:

parameter [=] **number**

Parameter names are as shown in the ESTIMATE column of the “Parameter Estimates” table.

MODEL Statement

MODEL *dependent* = *regressors* / *options* ;

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. The dependent count variable should take on only nonnegative integer values in

the input data set. PROC COUNTREG rounds any positive noninteger count values to the nearest integer. PROC COUNTREG discards any observations with a negative count.

Only one MODEL statement can be specified. The following options can be used in the MODEL statement after a slash (/).

DIST=value, D=value

specifies a type of model to be analyzed. If you specify this option in both the MODEL statement and the PROC COUNTREG statement, then only the value in the MODEL statement is used. The supported model types as follows:

POISSON | P Poisson regression model

NEGBIN(P=1) negative binomial regression model with a linear variance function

NEGBIN(P=2) | NEGBIN negative binomial regression model with a quadratic variance function

ZIPOISSON | ZIP zero-inflated Poisson regression

ZINEGBIN | ZINB zero-inflated negative binomial regression

NOINT

suppresses the intercept parameter.

OFFSET=variable

specifies a variable in the input data set to be used as an offset variable. The offset variable appears as a covariate in the model with its parameter restricted to 1. The offset variable cannot be the response variable, the zero-inflation offset variable (if any), or one of the explanatory variables. The Model Fit Summary gives the name of the data set variable used as the offset variable; it is labeled as “Offset.”

Printing Options

CORRB

prints the correlation matrix of the parameter estimates. It can also be specified in the PROC COUNTREG statement.

COVB

prints the covariance matrix of the parameter estimates. It can also be specified in the PROC COUNTREG statement.

ITPRINT

prints the objective function and parameter estimates at each iteration. The objective function is the negative log-likelihood function. It can also be specified in the PROC COUNTREG statement.

PRINTALL

requests all printing options. It can also be specified in the PROC COUNTREG statement.

OUTPUT Statement

OUTPUT < *OUT=SAS-data-set* > < *output-options* > ;

The OUTPUT statement creates a new SAS data set containing all the variables in the input data set and, optionally, the estimates of $\mathbf{x}'_i \boldsymbol{\beta}$, the expected value of the response variable, and the probability that the response variable will take on the current value. Furthermore, if a zero-inflated model was fit, you can request that the output data set contain the estimates of $\mathbf{z}'_i \boldsymbol{\gamma}$, and the probability that the response is zero as a result of the zero-generating process. These statistics can be computed for all observations in which the regressors are not missing, even if the response is missing. By adding observations with missing response values to the input data set, you can compute these statistics for new observations or for settings of the regressors not present in the data without affecting the model fit.

You can only specify one OUTPUT statement. OUTPUT statement options as follows:

OUT=SAS-data-set

names the output data set.

XBETA=name

names the variable containing estimates of $\mathbf{x}'_i \boldsymbol{\beta}$.

PRED=name

names the variable containing the predicted value of the response variable.

PROB=name

names the variable containing the probability of the response variable taking the current value, $\Pr(Y = y_i)$.

ZGAMMA=name

names the variable containing estimates of $\mathbf{z}'_i \boldsymbol{\gamma}$.

PROBZERO=name

names the variable containing the value that of φ_i , the probability that the response variable will take on the value of zero as a result of the zero-generating process. It is written to the output file only if the model is zero-inflated.

RESTRICT Statement

RESTRICT *restriction1* [, *restriction2* ...] ;

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <=, or >=.

Restriction expressions can be composed of parameter names, constants, and the operators times (*), plus (+), and minus (-). Parameter names are as shown in the ESTIMATE column of the “Parameter Estimates” table. The restriction expressions must be a linear function of the variables.

Lagrange multipliers are reported in the “Parameter Estimates” table for all the active linear constraints. They are identified with the names Restrict1, Restrict2, and so on. The probabilities of these Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive, or nonbinding, restrictions have no effect on the estimation results and are not noted in the output.

The following RESTRICT statement constrains the negative binomial dispersion parameter, α , to 1, which restricts the conditional variance to be $\mu + \mu^2$:

```
restrict _Alpha = 1;
```

ZEROMODEL Statement

ZEROMODEL *dependent variable* ~ *zero-inflated regressors / options* ;

The ZEROMODEL statement is required if either ZIP or ZINB is specified in the DIST= option in the MODEL statement. If ZIP or ZINB is specified, then the ZEROMODEL statement must follow immediately after the MODEL statement. The dependent variable in the ZEROMODEL statement must be the same as the dependent variable in the MODEL statement.

The zero-inflated (ZI) regressors appear in the equation that determines the probability (φ_i) of a zero count. Each of these q variables has a parameter to be estimated in the regression. For example, let \mathbf{z}'_i be the i th observation's $1 \times (q + 1)$ vector of values of the q ZI explanatory variables (w_0 is set to 1 for the intercept term). Then φ_i will be a function of $\mathbf{z}'_i \boldsymbol{\gamma}$, where $\boldsymbol{\gamma}$ is the $(q + 1) \times 1$ vector of parameters to be estimated. (The zero-inflated intercept is γ_0 ; the coefficients for the q zero-inflated covariates are $\gamma_1, \dots, \gamma_q$.) If this option is omitted, then only the intercept term γ_0 is estimated. The “Parameter Estimates” table in the displayed output gives the estimates for the ZI intercept and ZI explanatory variables; they are labeled with the prefix “Inf_”. For example, the ZI intercept is labeled “Inf_intercept”. If you specify “Age” (a variable in your data set) as a ZI explanatory variable, then the “Parameter Estimates” table labels the corresponding parameter estimate “Inf_Age”.

The following options can be specified in the ZEROMODEL statement following a slash (/):

LINK=value

specifies the distribution function used to compute probability of zeros. The supported distribution functions are as follows:

- | | |
|----------|---|
| LOGISTIC | specifies logistic distribution. |
| NORMAL | specifies standard normal distribution. |

If this option is omitted, then the default ZI link function is logistic.

OFFSET=*variable*

specifies a variable in the input data set to be used as a zero-inflated (ZI) offset variable. The ZI offset variable is included as a term, with coefficient restricted to 1, in the equation that determines the probability (φ_i) of a zero count. The ZI offset variable cannot be the response variable, the offset variable (if any), or one of the explanatory variables. The name of the data set variable used as the ZI offset variable is displayed in the “Model Fit Summary” output, where it is labeled as “Inf_offset”.

Details: COUNTREG Procedure

Missing Values

Any observation in the input data set with a missing value for one or more of the regressors is ignored by PROC COUNTREG and not used in the model fit. PROC COUNTREG rounds any positive noninteger count values to the nearest integer. PROC COUNTREG ignores any observations with a negative count.

If there are observations in the input data set with missing response values but with nonmissing regressors, PROC COUNTREG can compute several statistics and store them in an output data set by using the OUTPUT statement. For example, you can request that the output data set contain the estimates of $\mathbf{x}'_i\boldsymbol{\beta}$, the expected value of the response variable, and the probability of the response variable taking on the current value. Furthermore, if a zero-inflated model was fit, you can request that the output data set contain the estimates of $\mathbf{z}'_i\boldsymbol{\gamma}$, and the probability that the response is zero as a result of the zero-generating process. Note that the presence of such observations (with missing response values) does not affect the model fit.

Poisson Regression

The most widely used model for count data analysis is Poisson regression. This assumes that y_i , given the vector of covariates \mathbf{x}_i , is independently Poisson distributed with

$$P(Y_i = y_i | \mathbf{x}_i) = \frac{e^{-\mu_i} \mu_i^{y_i}}{y_i!}, \quad y_i = 0, 1, 2, \dots$$

and the mean parameter — that is, the mean number of events per period — is given by

$$\mu_i = \exp(\mathbf{x}'_i\boldsymbol{\beta})$$

where $\boldsymbol{\beta}$ is a $(k + 1) \times 1$ parameter vector. (The intercept is β_0 ; the coefficients for the k regressors are β_1, \dots, β_k .) Taking the exponential of $\mathbf{x}'_i\boldsymbol{\beta}$ ensures that the mean parameter μ_i is nonnegative.

It can be shown that the conditional mean is given by

$$E(y_i | \mathbf{x}_i) = \mu_i = \exp(\mathbf{x}_i' \boldsymbol{\beta})$$

The name *log-linear model* is also used for the Poisson regression model since the logarithm of the conditional mean is linear in the parameters:

$$\ln[E(y_i | \mathbf{x}_i)] = \ln(\mu_i) = \mathbf{x}_i' \boldsymbol{\beta}$$

Note that the conditional variance of the count random variable is equal to the conditional mean in the Poisson regression model:

$$V(y_i | \mathbf{x}_i) = E(y_i | \mathbf{x}_i) = \mu_i$$

The equality of the conditional mean and variance of y_i is known as *equidispersion*.

The marginal effect of a regressor is given by

$$\frac{\partial E(y_i | \mathbf{x}_i)}{\partial x_{ji}} = \exp(\mathbf{x}_i' \boldsymbol{\beta}) \beta_j = E(y_i | \mathbf{x}_i) \beta_j$$

Thus, a one-unit change in the j th regressor leads to a *proportional* change in the conditional mean $E(y_i | \mathbf{x}_i)$ of β_j .

The standard estimator for the Poisson model is the maximum likelihood estimator (MLE). Since the observations are independent, the log-likelihood function is written as

$$\mathcal{L} = \sum_{i=1}^N (-\mu_i + y_i \ln \mu_i - \ln y_i!) = \sum_{i=1}^N (-e^{\mathbf{x}_i' \boldsymbol{\beta}} + y_i \mathbf{x}_i' \boldsymbol{\beta} - \ln y_i!)$$

The gradient and the Hessian are, respectively,

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{i=1}^N (y_i - \mu_i) \mathbf{x}_i = \sum_{i=1}^N (y_i - e^{\mathbf{x}_i' \boldsymbol{\beta}}) \mathbf{x}_i \\ \frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}'} &= - \sum_{i=1}^N \mu_i \mathbf{x}_i \mathbf{x}_i' = - \sum_{i=1}^N e^{\mathbf{x}_i' \boldsymbol{\beta}} \mathbf{x}_i \mathbf{x}_i' \end{aligned}$$

The Poisson model has been criticized for its restrictive property that the conditional variance equals the conditional mean. Real-life data are often characterized by *overdispersion* — that is, the variance exceeds the mean. Allowing for overdispersion can improve model predictions since the Poisson restriction of equal mean and variance results in the underprediction of zeros when overdispersion exists. The most commonly used model that accounts for overdispersion is the negative binomial model.

Negative Binomial Regression

The Poisson regression model can be generalized by introducing an unobserved heterogeneity term for observation i . Thus, the individuals are assumed to differ randomly in a manner that is not fully accounted for by the observed covariates. This is formulated as

$$E(y_i | \mathbf{x}_i, \tau_i) = \mu_i \tau_i = e^{\mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i}$$

where the unobserved heterogeneity term $\tau_i = e^{\epsilon_i}$ is independent of the vector of regressors \mathbf{x}_i . Then the distribution of y_i conditional on \mathbf{x}_i and τ_i is Poisson with conditional mean and conditional variance $\mu_i \tau_i$:

$$f(y_i | \mathbf{x}_i, \tau_i) = \frac{\exp(-\mu_i \tau_i) (\mu_i \tau_i)^{y_i}}{y_i!}$$

Let $g(\tau_i)$ be the probability density function of τ_i . Then, the distribution $f(y_i | \mathbf{x}_i)$ (no longer conditional on τ_i) is obtained by integrating $f(y_i | \mathbf{x}_i, \tau_i)$ with respect to τ_i :

$$f(y_i | \mathbf{x}_i) = \int_0^\infty f(y_i | \mathbf{x}_i, \tau_i) g(\tau_i) d\tau_i$$

An analytical solution to this integral exists when τ_i is assumed to follow a gamma distribution. This solution is the negative binomial distribution. When the model contains a constant term, it is necessary to assume that $E(e^{\epsilon_i}) = E(\tau_i) = 1$, in order to identify the mean of the distribution. Thus, it is assumed that τ_i follows a gamma(θ, θ) distribution with $E(\tau_i) = 1$ and $V(\tau_i) = 1/\theta$:

$$g(\tau_i) = \frac{\theta^\theta}{\Gamma(\theta)} \tau_i^{\theta-1} \exp(-\theta \tau_i)$$

where $\Gamma(x) = \int_0^\infty z^{x-1} \exp(-z) dz$ is the gamma function and θ is a positive parameter. Then, the density of y_i given \mathbf{x}_i is derived as

$$\begin{aligned} f(y_i | \mathbf{x}_i) &= \int_0^\infty f(y_i | \mathbf{x}_i, \tau_i) g(\tau_i) d\tau_i \\ &= \frac{\theta^\theta \mu_i^{y_i}}{y_i! \Gamma(\theta)} \int_0^\infty e^{-(\mu_i + \theta)\tau_i} \tau_i^{\theta + y_i - 1} d\tau_i \\ &= \frac{\theta^\theta \mu_i^{y_i} \Gamma(y_i + \theta)}{y_i! \Gamma(\theta) (\theta + \mu_i)^{\theta + y_i}} \\ &= \frac{\Gamma(y_i + \theta)}{y_i! \Gamma(\theta)} \left(\frac{\theta}{\theta + \mu_i} \right)^\theta \left(\frac{\mu_i}{\theta + \mu_i} \right)^{y_i} \end{aligned}$$

Making the substitution $\alpha = \frac{1}{\theta}$ ($\alpha > 0$), the negative binomial distribution can then be rewritten as

$$f(y_i | \mathbf{x}_i) = \frac{\Gamma(y_i + \alpha^{-1})}{y_i! \Gamma(\alpha^{-1})} \left(\frac{\alpha^{-1}}{\alpha^{-1} + \mu_i} \right)^{\alpha^{-1}} \left(\frac{\mu_i}{\alpha^{-1} + \mu_i} \right)^{y_i}, \quad y_i = 0, 1, 2, \dots$$

Thus, the negative binomial distribution is derived as a gamma mixture of Poisson random variables. It has conditional mean

$$E(y_i | \mathbf{x}_i) = \mu_i = e^{\mathbf{x}_i' \boldsymbol{\beta}}$$

and conditional variance

$$V(y_i | \mathbf{x}_i) = \mu_i \left[1 + \frac{1}{\theta} \mu_i \right] = \mu_i [1 + \alpha \mu_i] > E(y_i | \mathbf{x}_i)$$

The conditional variance of the negative binomial distribution exceeds the conditional mean. Overdispersion results from neglected unobserved heterogeneity. The negative binomial model with

variance function $V(y_i | \mathbf{x}_i) = \mu_i + \alpha \mu_i^2$, which is quadratic in the mean, is referred to as the NEGBIN2 model (Cameron and Trivedi 1986). To estimate this model, specify `DIST=NEGBIN(p=2)` in the `MODEL` statement. The Poisson distribution is a special case of the negative binomial distribution where $\alpha = 0$. A test of the Poisson distribution can be carried out by testing the hypothesis that $\alpha = \frac{1}{\theta_i} = 0$. A Wald test of this hypothesis is provided (it is the reported t statistic for the estimated α in the negative binomial model).

The log-likelihood function of the negative binomial regression model (NEGBIN2) is given by

$$\mathcal{L} = \sum_{i=1}^N \left\{ \sum_{j=0}^{y_i-1} \ln(j + \alpha^{-1}) - \ln(y_i!) \right. \\ \left. - (y_i + \alpha^{-1}) \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) + y_i \ln(\alpha) + y_i \mathbf{x}'_i \boldsymbol{\beta} \right\}$$

where use of the following fact is made:

$$\Gamma(y + a) / \Gamma(a) = \prod_{j=0}^{y-1} (j + a)$$

if y is an integer.

The gradient is

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N \frac{y_i - \mu_i}{1 + \alpha \mu_i} \mathbf{x}_i$$

and

$$\frac{\partial \mathcal{L}}{\partial \alpha} = \sum_{i=1}^N \left\{ -\alpha^{-2} \sum_{j=0}^{y_i-1} \frac{1}{(j + \alpha^{-1})} + \alpha^{-2} \ln(1 + \alpha \mu_i) + \frac{y_i - \mu_i}{\alpha(1 + \alpha \mu_i)} \right\}$$

Cameron and Trivedi (1986) consider a general class of negative binomial models with mean μ_i and variance function $\mu_i + \alpha \mu_i^p$. The NEGBIN2 model, with $p = 2$, is the standard formulation of the negative binomial model. Models with other values of p , $-\infty < p < \infty$, have the same density $f(y_i | \mathbf{x}_i)$ except that α^{-1} is replaced everywhere by $\alpha^{-1} \mu_i^{2-p}$. The negative binomial model NEGBIN1, which sets $p = 1$, has variance function $V(y_i | \mathbf{x}_i) = \mu_i + \alpha \mu_i$, which is linear in the mean. To estimate this model, specify `DIST=NEGBIN(p=1)` in the `MODEL` statement.

The log-likelihood function of the NEGBIN1 regression model is given by

$$\mathcal{L} = \sum_{i=1}^N \left\{ \sum_{j=0}^{y_i-1} \ln(j + \alpha^{-1} \exp(\mathbf{x}'_i \boldsymbol{\beta})) \right. \\ \left. - \ln(y_i!) - (y_i + \alpha^{-1} \exp(\mathbf{x}'_i \boldsymbol{\beta})) \ln(1 + \alpha) + y_i \ln(\alpha) \right\}$$

The gradient is

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N \left\{ \left(\sum_{j=0}^{y_i-1} \frac{\mu_i}{(j\alpha + \mu_i)} \right) \mathbf{x}_i - \alpha^{-1} \ln(1 + \alpha) \mu_i \mathbf{x}_i \right\}$$

and

$$\frac{\partial \mathcal{L}}{\partial \alpha} = \sum_{i=1}^N \left\{ - \left(\sum_{j=0}^{y_i-1} \frac{\alpha^{-1} \mu_i}{(j\alpha + \mu_i)} \right) - \alpha^{-2} \mu_i \ln(1 + \alpha) - \frac{(y_i + \alpha^{-1} \mu_i)}{1 + \alpha} + \frac{y_i}{\alpha} \right\}$$

Zero-Inflated Count Regression Overview

The main motivation for zero-inflated count models is that real-life data frequently display overdispersion and excess zeros. Zero-inflated count models provide a way of modeling the excess zeros as well as allowing for overdispersion. In particular, for each observation, there are two possible data generation processes. The result of a Bernoulli trial is used to determine which of the two processes is used. For observation i , Process 1 is chosen with probability φ_i and Process 2 with probability $1 - \varphi_i$. Process 1 generates only zero counts. Process 2 generates counts from either a Poisson or a negative binomial model. In general,

$$y_i \sim \begin{cases} 0 & \text{with probability } \varphi_i \\ g(y_i) & \text{with probability } 1 - \varphi_i \end{cases}$$

Therefore, the probability of $\{Y_i = y_i\}$ can be described as

$$\begin{aligned} P(y_i = 0 | \mathbf{x}_i) &= \varphi_i + (1 - \varphi_i)g(0) \\ P(y_i | \mathbf{x}_i) &= (1 - \varphi_i)g(y_i), \quad y_i > 0 \end{aligned}$$

where $g(y_i)$ follows either the Poisson or the negative binomial distribution.

When the probability φ_i depends on the characteristics of observation i , φ_i is written as a function of $\mathbf{z}'_i \boldsymbol{\gamma}$, where \mathbf{z}'_i is the $1 \times (q + 1)$ vector of zero-inflated covariates and $\boldsymbol{\gamma}$ is the $(q + 1) \times 1$ vector of zero-inflated coefficients to be estimated. (The zero-inflated intercept is γ_0 ; the coefficients for the q zero-inflated covariates are $\gamma_1, \dots, \gamma_q$.) The function F relating the product $\mathbf{z}'_i \boldsymbol{\gamma}$ (which is a scalar) to the probability φ_i is called the zero-inflated link function,

$$\varphi_i = F_i = F(\mathbf{z}'_i \boldsymbol{\gamma})$$

In the COUNTREG procedure, the zero-inflated covariates are indicated in the ZEROMODEL statement. Furthermore, the zero-inflated link function F can be specified as either the logistic function,

$$F(\mathbf{z}'_i \boldsymbol{\gamma}) = \Lambda(\mathbf{z}'_i \boldsymbol{\gamma}) = \frac{\exp(\mathbf{z}'_i \boldsymbol{\gamma})}{1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma})}$$

or the standard normal cumulative distribution function (also called the probit function),

$$F(\mathbf{z}'_i \boldsymbol{\gamma}) = \Phi(\mathbf{z}'_i \boldsymbol{\gamma}) = \int_0^{\mathbf{z}'_i \boldsymbol{\gamma}} \frac{1}{\sqrt{2\pi}} \exp(-u^2/2) du$$

The zero-inflated link function is indicated in the ZEROMODEL statement, using the LINK= option. The default ZI link function is the logistic function.

Zero-Inflated Poisson Regression

In the zero-inflated Poisson (ZIP) regression model, the data generation process referred to earlier as Process 2 is

$$g(y_i) = \frac{\exp(-\mu_i)\mu_i^{y_i}}{y_i!}$$

where $\mu_i = e^{\mathbf{x}_i'\boldsymbol{\beta}}$. Thus the ZIP model is defined as

$$\begin{aligned} P(y_i = 0 | \mathbf{x}_i, \mathbf{z}_i) &= F_i + (1 - F_i) \exp(-\mu_i) \\ P(y_i | \mathbf{x}_i, \mathbf{z}_i) &= (1 - F_i) \frac{\exp(-\mu_i)\mu_i^{y_i}}{y_i!}, \quad y_i > 0 \end{aligned}$$

The conditional expectation and conditional variance of y_i are given by

$$\begin{aligned} E(y_i | \mathbf{x}_i, \mathbf{z}_i) &= \mu_i(1 - F_i) \\ V(y_i | \mathbf{x}_i, \mathbf{z}_i) &= E(y_i | \mathbf{x}_i, \mathbf{z}_i)(1 + \mu_i F_i) \end{aligned}$$

Note that the ZIP model (as well as the ZINB model) exhibits overdispersion since $V(y_i | \mathbf{x}_i, \mathbf{z}_i) > E(y_i | \mathbf{x}_i, \mathbf{z}_i)$.

In general, the log-likelihood function of the ZIP model is

$$\mathcal{L} = \sum_{i=1}^N \ln [P(y_i | \mathbf{x}_i, \mathbf{z}_i)]$$

Once a specific link function (either logistic or standard normal) for the probability φ_i is chosen, it is possible to write the exact expressions for the log-likelihood function and the gradient.

ZIP Model with Logistic Link Function

First, consider the ZIP model in which the probability φ_i is expressed with a logistic link function, namely

$$\varphi_i = \frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma})}$$

The log-likelihood function is

$$\begin{aligned} \mathcal{L} &= \sum_{\{i: y_i=0\}} \ln [\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))] \\ &\quad + \sum_{\{i: y_i>0\}} \left[y_i \mathbf{x}_i'\boldsymbol{\beta} - \exp(\mathbf{x}_i'\boldsymbol{\beta}) - \sum_{k=2}^{y_i} \ln(k) \right] \\ &\quad - \sum_{i=1}^N \ln [1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma})] \end{aligned}$$

The gradient for this model is given by

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\gamma}} = \sum_{\{i:y_i=0\}} \left[\frac{\exp(\mathbf{z}'_i \boldsymbol{\gamma})}{\exp(\mathbf{z}'_i \boldsymbol{\gamma}) + \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))} \right] \mathbf{z}_i - \sum_{i=1}^N \left[\frac{\exp(\mathbf{z}'_i \boldsymbol{\gamma})}{1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma})} \right] \mathbf{z}_i$$

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{\{i:y_i=0\}} \left[\frac{-\exp(\mathbf{x}'_i \boldsymbol{\beta}) \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))}{\exp(\mathbf{z}'_i \boldsymbol{\gamma}) + \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))} \right] \mathbf{x}_i + \sum_{\{i:y_i>0\}} [y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})] \mathbf{x}_i$$

ZIP Model with Standard Normal Link Function

Next, consider the ZIP model in which the probability φ_i is expressed with a standard normal link function: $\varphi_i = \Phi(\mathbf{z}'_i \boldsymbol{\gamma})$. The log-likelihood function is

$$\mathcal{L} = \sum_{\{i:y_i=0\}} \ln \{ \Phi(\mathbf{z}'_i \boldsymbol{\gamma}) + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta})) \}$$

$$+ \sum_{\{i:y_i>0\}} \left\{ \ln [(1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma}))] - \exp(\mathbf{x}'_i \boldsymbol{\beta}) + y_i \mathbf{x}'_i \boldsymbol{\beta} - \sum_{k=2}^{y_i} \ln(k) \right\}$$

The gradient for this model is given by

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\gamma}} = \sum_{\{i:y_i=0\}} \frac{\varphi(\mathbf{z}'_i \boldsymbol{\gamma}) [1 - \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))]}{\Phi(\mathbf{z}'_i \boldsymbol{\gamma}) + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))} \mathbf{z}_i$$

$$- \sum_{\{i:y_i>0\}} \frac{\varphi(\mathbf{z}'_i \boldsymbol{\gamma})}{[1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})]} \mathbf{z}_i$$

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{\{i:y_i=0\}} \frac{-[1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \exp(\mathbf{x}'_i \boldsymbol{\beta}) \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))}{\Phi(\mathbf{z}'_i \boldsymbol{\gamma}) + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \exp(-\exp(\mathbf{x}'_i \boldsymbol{\beta}))} \mathbf{x}_i$$

$$+ \sum_{\{i:y_i>0\}} [y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})] \mathbf{x}_i$$

Zero-Inflated Negative Binomial Regression

The zero-inflated negative binomial (ZINB) model in PROC COUNTREG is based on the negative binomial model with quadratic variance function ($p=2$). The ZINB model is obtained by specifying a negative binomial distribution for the data generation process referred to earlier as Process 2:

$$g(y_i) = \frac{\Gamma(y_i + \alpha^{-1})}{y_i! \Gamma(\alpha^{-1})} \left(\frac{\alpha^{-1}}{\alpha^{-1} + \mu_i} \right)^{\alpha^{-1}} \left(\frac{\mu_i}{\alpha^{-1} + \mu_i} \right)^{y_i}$$

Thus the ZINB model is defined to be

$$\begin{aligned}
 P(y_i = 0 | \mathbf{x}_i, \mathbf{z}_i) &= F_i + (1 - F_i) (1 + \alpha \mu_i)^{-\alpha^{-1}} \\
 P(y_i | \mathbf{x}_i, \mathbf{z}_i) &= (1 - F_i) \frac{\Gamma(y_i + \alpha^{-1})}{y_i! \Gamma(\alpha^{-1})} \left(\frac{\alpha^{-1}}{\alpha^{-1} + \mu_i} \right)^{\alpha^{-1}} \\
 &\quad \times \left(\frac{\mu_i}{\alpha^{-1} + \mu_i} \right)^{y_i}, \quad y_i > 0
 \end{aligned}$$

In this case, the conditional expectation and conditional variance of y_i are

$$\begin{aligned}
 E(y_i | \mathbf{x}_i, \mathbf{z}_i) &= \mu_i (1 - F_i) \\
 V(y_i | \mathbf{x}_i, \mathbf{z}_i) &= E(y_i | \mathbf{x}_i, \mathbf{z}_i) [1 + \mu_i (F_i + \alpha)]
 \end{aligned}$$

As with the ZIP model, the ZINB model exhibits overdispersion because the conditional variance exceeds the conditional mean.

ZINB Model with Logistic Link Function

In this model, the probability φ_i is given by the logistic function, namely

$$\varphi_i = \frac{\exp(\mathbf{z}'_i \boldsymbol{\gamma})}{1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma})}$$

The log-likelihood function is

$$\begin{aligned}
 \mathcal{L} &= \sum_{\{i: y_i=0\}} \ln \left[\exp(\mathbf{z}'_i \boldsymbol{\gamma}) + (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}} \right] \\
 &+ \sum_{\{i: y_i>0\}} \sum_{j=0}^{y_i-1} \ln(j + \alpha^{-1}) \\
 &+ \sum_{\{i: y_i>0\}} \{ -\ln(y_i!) - (y_i + \alpha^{-1}) \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) + y_i \ln(\alpha) + y_i \mathbf{x}'_i \boldsymbol{\beta} \} \\
 &- \sum_{i=1}^N \ln [1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma})]
 \end{aligned}$$

The gradient for this model is given by

$$\begin{aligned}
 \frac{\partial \mathcal{L}}{\partial \boldsymbol{\gamma}} &= \sum_{\{i: y_i=0\}} \left[\frac{\exp(\mathbf{z}'_i \boldsymbol{\gamma})}{\exp(\mathbf{z}'_i \boldsymbol{\gamma}) + (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}}} \right] \mathbf{z}_i \\
 &- \sum_{i=1}^N \left[\frac{\exp(\mathbf{z}'_i \boldsymbol{\gamma})}{1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma})} \right] \mathbf{z}_i
 \end{aligned}$$

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{\{i:y_i=0\}} \left[\frac{-\exp(\mathbf{x}'_i \boldsymbol{\beta})(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}-1}}{\exp(\mathbf{z}'_i \boldsymbol{\gamma}) + (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}}} \right] \mathbf{x}_i \\
&+ \sum_{\{i:y_i>0\}} \left[\frac{y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})}{1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})} \right] \mathbf{x}_i \\
\frac{\partial \mathcal{L}}{\partial \alpha} &= \sum_{\{i:y_i=0\}} \frac{\alpha^{-2} [(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) - \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})]}{\exp(\mathbf{z}'_i \boldsymbol{\gamma})(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{(1+\alpha)/\alpha} + (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))} \\
&+ \sum_{\{i:y_i>0\}} \left\{ -\alpha^{-2} \sum_{j=0}^{y_i-1} \frac{1}{(j + \alpha^{-1})} + \alpha^{-2} \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) + \frac{y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})}{\alpha(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))} \right\}
\end{aligned}$$

ZINB Model with Standard Normal Link Function

For this model, the probability φ_i is specified with the standard normal distribution function (probit function): $\varphi_i = \Phi(\mathbf{z}'_i \boldsymbol{\gamma})$. The log-likelihood function is

$$\begin{aligned}
\mathcal{L} &= \sum_{\{i:y_i=0\}} \ln \left\{ \Phi(\mathbf{z}'_i \boldsymbol{\gamma}) + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}} \right\} \\
&+ \sum_{\{i:y_i>0\}} \ln [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \\
&+ \sum_{\{i:y_i>0\}} \sum_{j=0}^{y_i-1} \{ \ln(j + \alpha^{-1}) \} \\
&- \sum_{\{i:y_i>0\}} \ln(y_i!) \\
&- \sum_{\{i:y_i>0\}} (y_i + \alpha^{-1}) \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) \\
&+ \sum_{\{i:y_i>0\}} y_i \ln(\alpha) \\
&+ \sum_{\{i:y_i>0\}} y_i \mathbf{x}'_i \boldsymbol{\beta}
\end{aligned}$$

The gradient for this model is given by

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\gamma}} = \sum_{\{i:y_i=0\}} \left[\frac{\varphi(\mathbf{z}'_i \boldsymbol{\gamma}) [1 - (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}}]}{\Phi(\mathbf{z}'_i \boldsymbol{\gamma}) + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}}} \right] \mathbf{z}_i$$

$$\begin{aligned}
& - \sum_{\{i:y_i>0\}} \left[\frac{\varphi(\mathbf{z}'_i \boldsymbol{\gamma})}{1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})} \right] \mathbf{z}_i \\
\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{\{i:y_i=0\}} \frac{-[1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \exp(\mathbf{x}'_i \boldsymbol{\beta}) (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-(1+\alpha)/\alpha}}{\Phi(\mathbf{z}'_i \boldsymbol{\gamma}) + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{-\alpha^{-1}}} \mathbf{x}_i \\
& + \sum_{\{i:y_i>0\}} \left[\frac{y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})}{1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})} \right] \mathbf{x}_i \\
\frac{\partial \mathcal{L}}{\partial \alpha} &= \sum_{\{i:y_i=0\}} \frac{[1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] \alpha^{-2} [(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) - \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})]}{\Phi(\mathbf{z}'_i \boldsymbol{\gamma}) (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))^{(1+\alpha)/\alpha} + [1 - \Phi(\mathbf{z}'_i \boldsymbol{\gamma})] (1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))} \\
& + \sum_{\{i:y_i>0\}} \left\{ -\alpha^{-2} \sum_{j=0}^{y_i-1} \frac{1}{(j + \alpha^{-1})} + \alpha^{-2} \ln(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta})) + \frac{y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})}{\alpha(1 + \alpha \exp(\mathbf{x}'_i \boldsymbol{\beta}))} \right\}
\end{aligned}$$

Computational Resources

The time and memory required by PROC COUNTREG are proportional to the number of parameters in the model and the number of observations in the data set being analyzed. Less time and memory will be required for smaller models and fewer observations. Also affecting these resources are the method chosen to calculate the variance-covariance matrix and the optimization method. All optimization methods available through the METHOD= option have similar memory use requirements. The processing time might differ for each method depending on the number of iterations and functional calls needed. The data set is read into memory to save processing time. If there is not enough memory available to hold the data, the COUNTREG procedure stores the data in a utility file on disk and rereads the data as needed from this file. When this occurs, the execution time of the procedure increases substantially. The gradient and the variance-covariance matrix must be held in memory. If the model has p parameters including the intercept, then at least $8 * (p + p * (p + 1)/2)$ bytes will be needed. Time is also a function of the number of iterations needed to converge to a solution for the model parameters. The number of iterations needed cannot be known in advance. The MAXITER= option can be used to limit the number of iterations that PROC COUNTREG will do. The convergence criteria can be altered by nonlinear optimization options available in the PROC COUNTREG statement. For a list of all the nonlinear optimization options, see Chapter 6, “Nonlinear Optimization Methods.”

Nonlinear Optimization Options

PROC COUNTREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. In the PROC COUNTREG statement, you can specify nonlinear optimization options that are then passed to the NLO subsystem. For a list of all the nonlinear optimization options, see Chapter 6, “[Nonlinear Optimization Methods](#).”

Covariance Matrix Types

The COUNTREG procedure allows the user to specify the estimation method for the covariance matrix. COVEST=HESSIAN option estimates the covariance matrix based on the inverse of the Hessian matrix; COVEST=OP uses the outer product of gradients; and COVEST=QML produces the covariance matrix based on both the Hessian and outer product matrices. While all three methods produce asymptotically equivalent results, they differ in computational intensity and produce results that might differ in finite samples. The COVEST=OP option provides the covariance matrix that is typically the easiest to compute. In some cases, the OP approximation is considered more efficient than the Hessian or QML approximations because it contains fewer random elements. The QML approximation is computationally the most complex because both outer product of gradients and Hessian matrix are required. In most cases, OP or Hessian approximations are preferred to QML. The need to use QML approximation arises in some cases when the model is misspecified and the information matrix equality does not hold. The default is COVEST=HESSIAN.

Displayed Output

PROC COUNTREG produces the following displayed output.

Iteration History for Parameter Estimates

If you specify the ITPRINT or PRINTALL options in the PROC COUNTREG statement, PROC COUNTREG displays a table containing the following for each iteration. Note that some information is specific to the model fitting procedure chosen (for example, Newton-Raphson, trust region, quasi-Newton).

- iteration number
- number of restarts since the fitting began
- number of function calls
- number of active constraints at the current solution

- value of the objective function (negative one times the log-likelihood value) at the current solution
- change in the objective function from previous iteration
- value of the maximum absolute gradient element
- step size (for Newton-Raphson and quasi-Newton methods)
- slope of the current search direction (for Newton-Raphson and quasi-Newton methods)
- lambda (for trust region method)
- radius value at current iteration (for trust region method)

Model Fit Summary

The Model Fit Summary output contains the following information:

- dependent (count) variable name
- number of observations used
- number of missing values in data set, if any
- data set name
- type of model that was fit
- offset variable name, if any
- zero-inflated link function, if any
- zero-inflated offset variable name, if any
- log-likelihood value at solution
- maximum absolute gradient at solution
- number of iterations
- AIC value at solution. Smaller value indicates better fit.
- SBC value at solution. Smaller value indicates better fit.

Under the Model Fit Summary is a statement about whether or not the algorithm successfully converged.

Parameter Estimates

The “Parameter Estimates” table in the displayed output gives the estimates for the ZI intercept and ZI explanatory variables; they are labeled with the prefix “Inf_”. For example, the ZI intercept is labeled “Inf_intercept”. If you specify “Age” (a variable in your data set) as a ZI explanatory variable, then the “Parameter Estimates” table labels the corresponding parameter estimate “Inf_Age”. If you do not list any ZI explanatory variables (for the ZI option VAR=), then only the intercept term is estimated.

“_Alpha” is the negative binomial dispersion parameter. The t statistic given for “_Alpha” is a test of overdispersion.

Last Evaluation of the Gradient

If you specify the model option ITPRINT, the COUNTREG procedure displays the last evaluation of the gradient vector.

Covariance of Parameter Estimates

If you specify the COVB option in the MODEL statement, the COUNTREG procedure displays the estimated covariance matrix, defined as the inverse of the information matrix at the final iteration.

Correlation of Parameter Estimates

If you specify the CORRB option in the MODEL statement, PROC COUNTREG displays the estimated correlation matrix. It is based on the Hessian matrix used at the final iteration.

OUTPUT OUT= Data Set

The OUTPUT statement creates a new SAS data set containing all the variables in the input data set and, optionally, the estimates of $\mathbf{x}'_i\boldsymbol{\beta}$, the expected value of the response variable, and the probability of the response variable taking on the current value. Furthermore, if a zero-inflated model was fit, you can request that the output data set contain the estimates of $\mathbf{z}'_i\boldsymbol{\gamma}$, and the probability that the response is zero as a result of the zero-generating process. These statistics can be computed for all observations in which the regressors are not missing, even if the response is missing. By adding observations with missing response values to the input data set, you can compute these statistics for new observations or for settings of the regressors not present in the data without affecting the model fit.

OUTEST= Data Set

The OUTEST= data set is made up of one row (with `_TYPE_='PARM'`) containing each of the parameter estimates in the model. The second row (with `_TYPE_='STD'`) contains the standard errors for the parameter estimates in the model.

If you use the COVOUT option in the PROC COUNTREG statement, the OUTEST= data set also contains the covariance matrix for the parameter estimates. The covariance matrix appears in the observations with `_TYPE_='COV'`, and the `_NAME_` variable labels the rows with the parameter names.

ODS Table Names

PROC COUNTREG assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 10.2](#).

Table 10.2 ODS Tables Produced in PROC COUNTREG

ODS Table Name	Description	Option

Examples: COUNTREG Procedure

Example 10.1: Basic Models

Data Description and Objective

The data set `docvisit` contains information for approximately 5,000 Australian individuals about the number and possible determinants of doctor visits that were made during a two-week interval. This data set contains a subset of variables taken from the `Raccd3` data set used by Cameron and Trivedi (1998).

The variable `doctorco` represents doctor visits. Additional variables in the data set that you want to evaluate as determinants of doctor visits include `sex` (coded 0=male, 1=female), `age` (age in years divided by 100, with more than 70 coded as 72), `illness` (number of illnesses during the two-week interval, with five or more coded as five), `income` (annual income in Australian dollars divided by 1,000), and `hscore` (a general health questionnaire score, where a high score indicates bad health). Summary statistics for these variables are computed in the following statements and presented in [Output 10.1.1](#). In the rest of this example some possible applications of the COUNTREG procedure in this context are presented.

```
proc means data=docvisit;
  var doctorco sex age illness income hscore;
run;
```

Output 10.1.1 Summary Statistics

The MEANS Procedure					
Variable	N	Mean	Std Dev	Minimum	Maximum
<code>doctorco</code>	5190	0.3017341	0.7981338	0	9.0000000
<code>sex</code>	5190	0.5206166	0.4996229	0	1.0000000
<code>age</code>	5190	0.4063854	0.2047818	0.1900000	0.7200000
<code>illness</code>	5190	1.4319846	1.3841524	0	5.0000000
<code>income</code>	5190	0.5831599	0.3689067	0	1.5000000
<code>hscore</code>	5190	1.2175337	2.1242665	0	12.0000000

Poisson Models

These statements fit a Poisson model to the data by using the covariates `SEX`, `ILLNESS`, `INCOME`, and `HSCORE`:

```
/*-- Poisson Model --*/
proc countreg data=docvisit;
```

```

model doctorco=sex illness income hscore / dist=poisson printall;
run;

```

In this example, the DIST= option in the MODEL statement specifies the POISSON distribution. In addition, the PRINTALL option displays the correlation and covariance matrices for the parameters, log-likelihood values, and convergence information in addition to the parameter estimates. The parameter estimates for this model are shown in [Output 10.1.2](#).

Output 10.1.2 Parameter Estimates of Poisson Model

The COUNTREG Procedure					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	-1.855552	0.074545	-24.89	<.0001
sex	1	0.235583	0.054362	4.33	<.0001
illness	1	0.270326	0.017080	15.83	<.0001
income	1	-0.242095	0.077829	-3.11	0.0019
hscore	1	0.096313	0.009089	10.60	<.0001

Suppose that you suspect that the population of individuals can be viewed as two distinct groups: a low-risk group, comprising individuals who never go to the doctor, and a high-risk group, comprising individuals who do go to the doctor. You might suspect that the data have this structure both because the sample variance of DOCTORCO (0.64) exceeds its sample mean (0.30), which suggests overdispersion, and because a large fraction of the DOCTORCO observations (80%) have the value zero. Estimating a zero-inflated model is one way to deal with overdispersion that results from excess zeros.

Suppose also that you suspect that the covariate AGE has an impact on whether an individual belongs to the low-risk group. For example, younger individuals might have illnesses of much lower severity when they do get sick and be less likely to visit a doctor, all else being equal. The following statements estimate a zero-inflated Poisson regression with AGE as a covariate in the zero-generation process:

```

/*-- Zero-Inflated Poisson Model --*/
proc countreg data=docvisit;
  model doctorco=sex illness income hscore / dist=zip;
  zeromodel doctorco ~ age;
run;

```

In this case, the ZEROMODEL statement following the MODEL statement specifies that both an intercept and the variable AGE be used to estimate the likelihood of zero doctor visits. [Output 10.1.3](#) shows the resulting parameter estimates.

Output 10.1.3 Parameter Estimates for ZIP Model

The COUNTREG Procedure					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	-1.033387	0.096973	-10.66	<.0001
sex	1	0.122511	0.062566	1.96	0.0502
illness	1	0.237478	0.019997	11.88	<.0001
income	1	-0.143945	0.087810	-1.64	0.1012
hscore	1	0.088386	0.010043	8.80	<.0001
Inf_Intercept	1	0.986557	0.131339	7.51	<.0001
Inf_age	1	-2.090923	0.270580	-7.73	<.0001

The estimates of the zero-inflated intercept (Inf_Intercept) and the zero-inflated regression coefficient for AGE (Inf_age) are approximately 0.99 and -2.09, respectively. Therefore, you can estimate the probabilities for individuals of ages 20, 50, and 70 as follows:

$$\begin{aligned}
 \text{20 years: } & \frac{e^{(0.99-2.09*.20)}}{1 + e^{(0.99-2.09*.20)}} = 0.64 \\
 \text{50 years: } & \frac{e^{(0.99-2.09*.50)}}{1 + e^{(0.99-2.09*.50)}} = 0.49 \\
 \text{70 years: } & \frac{e^{(0.99-2.09*.70)}}{1 + e^{(0.99-2.09*.70)}} = 0.38
 \end{aligned}$$

That is, the estimated probability of belonging to the low-risk group is about 0.64 for a 20-year-old individual, 0.49 for a 50-year-old individual, and only 0.38 for a 70-year-old individual. This supports the suspicion that older individuals are more likely to have a positive number of doctor visits.

Alternative models to account for the overdispersion are the negative binomial and the zero-inflated negative binomial models, which can be fit using the DIST=NEGBIN and DIST=ZINB option, respectively.

Example 10.2: ZIP and ZINB Models for Data Exhibiting Extra Zeros

In the study by Long (1997) of the number of published articles by scientists (see the section “Getting Started: COUNTREG Procedure” on page 485), the observed proportion of scientists publishing no articles is 0.3005. The following statements use PROC FREQ to compute the proportion of scientists publishing each observed number of articles. [Output 10.2.1](#) shows the results.

```
proc freq data=long97data;
  table art / out=obs;
run;
```

Output 10.2.1 Proportion of Scientists Publishing a Certain Number of Articles

The FREQ Procedure				
art	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	275	30.05	275	30.05
1	246	26.89	521	56.94
2	178	19.45	699	76.39
3	84	9.18	783	85.57
4	67	7.32	850	92.90
5	27	2.95	877	95.85
6	17	1.86	894	97.70
7	12	1.31	906	99.02
8	1	0.11	907	99.13
9	2	0.22	909	99.34
10	1	0.11	910	99.45
11	1	0.11	911	99.56
12	2	0.22	913	99.78
16	1	0.11	914	99.89
19	1	0.11	915	100.00

PROC COUNTREG is then used to fit Poisson and negative binomial models to the data. For each model, the PROBCOUNTS macro computes the probability that the number of published articles is m , where m is a value in a list of nonnegative integers specified in the COUNTS= option. The computations require the parameter estimates of the fitted model. These are saved using the ODS OUTPUT statement as shown and passed to the PROBCOUNTS macro by using the INMODEL= option. Variables containing the probabilities are created with names beginning with the PREFIX= string followed by the COUNTS= values and are saved in the OUT= data set. For the Poisson model, the variables poi0, poi1, ..., poi10 are created and saved in the data set predpoi, which also contains all of the variables in the DATA= data set. The PROBCOUNTS macro is available from the Samples section at <http://support.sas.com>. The following statements compute the estimates for Poisson and negative binomial models.

```
/*-- Poisson Model --*/
proc countreg data=long97data;
  model art=fem mar kid5 phd ment / dist=poisson;
  ods output ParameterEstimates=pe;
run;

%include probcounts;
%probcounts (data=long97data,
             inmodel=pe,
             counts=0 to 10,
             prefix=poi, out=predpoi)

/*-- Negative Binomial Model --*/
```

```

proc countreg data=long97data;
  model art=fem mar kid5 phd ment / dist=negbin(p=2);
  ods output ParameterEstimates=pe;
run;

%probcounts (data=predpoi,
             inmodel=pe,
             counts=0 to 10,
             prefix=nb, out=prednb)

```

Parameter estimates for these two models are shown in the section “[Getting Started: COUNTREG Procedure](#)” on page 485. For each model, the predicted proportion of zero articles can be calculated as the average predicted probability of zero articles across all scientists as shown in the macro probcounts in the following program. Under the Poisson model, the predicted proportion of zero articles is 0.2092, which considerably underestimates the observed proportion. The negative binomial more closely estimates the proportion of zeros (0.3036). Also, the test of the dispersion parameter, $_Alpha$, in the negative binomial model indicates significant overdispersion ($p < 0.0001$). As a result, the negative binomial model is preferred to the Poisson model.

Another way to account for the large number of zeros in this data set is to fit a zero-inflated Poisson (ZIP) or a zero-inflated negative binomial (ZINB) model. In the following statements, `DIST=ZIP` requests the ZIP model. In the `ZEROMODEL` statement, you can specify the predictors, \mathbf{z} , for the process that generated the additional zeros. The `ZEROMODEL` statement also specifies the model for the probability φ . By default, a logistic model is used for φ . The default can be changed using the `LINK=` option. In this particular ZIP model, all variables used to model the article counts are also used to model φ .

```

proc countreg data=long97data;
  model art = fem mar kid5 phd ment / dist=zip;
  zeromodel art ~ fem mar kid5 phd ment;
  ods output ParameterEstimates=pe;
run;

%probcounts (data=prednb,
             inmodel=pe,
             counts=0 to 10,
             prefix=zip, out=predzip)

```

The parameters of the ZIP model are displayed in [Output 10.2.2](#). The first set of parameters gives the estimates of β in the model for the Poisson process mean. Parameters with the prefix “`Inf_`” are the estimates of γ in the logistic model for φ .

Output 10.2.2 ZIP Model Estimation

The COUNTREG Procedure					
Model Fit Summary					
Dependent Variable					art

Inf_mar	1	-0.354013	0.317611	-1.11	0.2650
Inf_kid5	1	0.217101	0.196481	1.10	0.2692
Inf_phd	1	0.001272	0.145262	0.01	0.9930
Inf_ment	1	-0.134114	0.045244	-2.96	0.0030

The proportion of zeros predicted by the ZIP model is 0.2986, which is much closer to the observed proportion than the Poisson model. But [Output 10.2.4](#) shows that both models deviate from the observed proportions at one, two, and three articles.

The ZINB model is specified by the DIST=ZINB option. All variables are again used to model both the number of articles and φ . The METHOD=QN option specifies that the quasi-Newton method be used to fit the model rather than the default Newton-Raphson method. These options are implemented in the following program.

```
proc countreg data=long97data;
  model art=fem mar kid5 phd ment / dist=zinb method=qn;
  zeromodel art ~ fem mar kid5 phd ment;
  ods output ParameterEstimates=pe;
run;

%probcunts (data=predzip,
            inmodel=pe,
            counts=0 to 10,
            prefix=zinb, out=predzinb)
```

The estimated parameters of the ZINB model are shown in [Output 10.2.3](#). The test for overdispersion again indicates a preference for the negative binomial version of the zero-inflated model ($p < 0.0001$). The ZINB model also does a good job of estimating the proportion of zeros (0.3119), and it follows the observed proportions well, though possibly not as well as the negative binomial model.

Output 10.2.3 ZINB Model Estimation

The following statements compute the average predicted count probability across all scientists for each count 0, 1, . . . , 10. The averages for each model, along with the observed proportions, are then arranged for plotting by PROC SGPLOT.

```
proc summary data=predzinb;
  var poi0-poi10 nb0-nb10 zip0-zip10 zinb0-zinb10;
  output out=mnpoi  mean(poi0-poi10)  =mn0-mn10;
  output out=mnnb   mean(nb0-nb10)    =mn0-mn10;
  output out=mnzip  mean(zip0-zip10)   =mn0-mn10;
  output out=mnzinb mean(zinb0-zinb10)=mn0-mn10;
run;

data means;
  set mnpoi mnnb mnzip mnzinb;
  drop _type_ _freq_;
run;

proc transpose data=means out=tmeans;
run;

data allpred;
  merge obs(where=(art<=10)) tmeans;
  obs=percent/100;
run;

proc sgplot;
  yaxis label='Probability';
  xaxis label='Number of Articles';
  series y=obs x=art / name='obs' legendlabel='Observed'
    lineattrs=(color=black thickness=4px);
  series y=col1 x=art / name='poi' legendlabel='Poisson'
    lineattrs=(color=blue);
  series y=col2 x=art / name='nb' legendlabel='Negative Binomial'
    lineattrs=(color=red);
  series y=col3 x=art / name='zip' legendlabel='ZIP'
    lineattrs=(color=blue pattern=2);
  series y=col4 x=art / name='zinb' legendlabel='ZINB'
    lineattrs=(color=red pattern=2);
  discretelegend 'poi' 'zip' 'nb' 'zinb' 'obs' / title='Models:'
    location=inside position=ne across=2 down=3;
run;
```

For each of the four fitted models, [Output 10.2.4](#) shows the average predicted count probability for each article count across all scientists. The Poisson model clearly underestimates the proportion of zero articles published, while the other three models are quite accurate at zero. All of the models do well at the larger numbers of articles.

Output 10.2.4 Average Predicted Count Probability

Overview: DATASOURCE Procedure

The DATASOURCE procedure extracts time series and event data from many different kinds of data files distributed by various data vendors and stores them in a SAS data set. Once stored in a SAS data set, the time series and event variables can be processed by other SAS procedures.

The DATASOURCE procedure has statements and options to extract only a subset of time series data from an input data file. It gives you control over the frequency of data to be extracted, time series variables to be selected, cross sections to be included, and time range of data to be output.

The DATASOURCE procedure can create auxiliary data sets containing descriptive information on the time series variables and cross sections. More specifically, the OUTCONT= option names a data set containing information on time series variables, the OUTBY= option names a data set that reports information on cross-sectional variables, and the OUTALL= option names a data set that combines both time series variables and cross-sectional information.

In addition to the auxiliary data sets, two types of primary output data sets are the OUT= and OUTEVENT= data sets. The OUTEVENT= data set contains event variables but excludes periodic time series data. The OUT= data set contains periodic time series data and any event variables referenced in the KEEP statement.

The output variables in the output and auxiliary data sets can be assigned various attributes by the DATASOURCE procedure. These attributes are labels, formats, new names, and lengths. While the

first three attributes in this list are used to enhance the output, the length attribute is used to control the memory and disk-space usage of the DATASOURCE procedure.

Data files currently supported by the DATASOURCE procedure include the following:

- U.S. Bureau of Economic Analysis data files:
 - National Income and Product Accounts
 - National Income and Product Accounts PC format
 - S-pages
- U.S. Bureau of Labor Statistics data files:
 - Consumer Price Index Surveys
 - Producer Price Index Survey
 - National Employment, Hours, and Earnings Survey
 - State and Area Employment, Hours, and Earnings Survey
- Standard & Poor's Compustat Services Financial Database Files:
 - COMPUSTAT Annual
 - COMPUSTAT 48 Quarter
 - COMPUSTAT Full Coverage Annual
 - COMPUSTAT Full Coverage 48 Quarter
- Center for Research in Security Prices (CRSP) data files:
 - Daily Binary Format Files
 - Monthly Binary Format Files
 - Daily Character Format Files
 - Monthly Character Format Files
- Global Insight, formerly DRI/McGraw-Hill data files:
 - Basic Economics Data (formerly CITIBASE)
 - DRI Data Delivery Service files
 - CITIBASE Data Files
 - DRI Data Delivery Service Time Series
 - PC Format CITIBASE Databases
- FAME Information Services Databases
- Haver Analytics data files
 - United States Economic Indicators

- Specialized Databases
 - Financial Indicators
 - Industry
 - Industrial Countries
 - Emerging Markets
 - International Organizations
 - Forecasts and As Reported Data
 - United States Regional
- International Monetary Fund’s Economic Information System data files:
 - International Financial Statistics
 - Direction of Trade Statistics
 - Balance of Payment Statistics
 - Government Finance Statistics
 - Organization for Economic Cooperation and Development:
 - Annual National Accounts
 - Quarterly National Accounts
 - Main Economic Indicators

Getting Started: DATASOURCE Procedure

Structure of a SAS Data Set Containing Time Series Data

SAS procedures require time series data to be in a specific form recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods.

The time periods at which observations are recorded can be included in the data set as a time ID variable. The DATASOURCE procedure does include a time ID variable by the name of DATE.

For example, the following data set in [Table 11.1](#), extracted from a DRIBASIC data file, gives the foreign exchange rates for Japan, Switzerland, and the United Kingdom, respectively.

Table 11.1 The Form of SAS Data Sets Required by Most SAS/ETS Procedures

Time ID Variable	Time Series Variables		
DATE	EXRJAN	EXRSW	EXRUK
SEP1987	143.290	1.50290	164.460
OCT1987	143.320	1.49400	166.200
NOV1987	135.400	1.38250	177.540
DEC1987	128.240	1.33040	182.880
JAN1988	127.690	1.34660	180.090
FEB1988	129.170	1.39160	175.820

Reading Data Files

The DATASOURCE procedure is designed to read data from many different files and to place them in a SAS data set. For example, if you have a DRI Basic Economics data file you want to read, use the following statements:

```
proc datasource filetype=dribasic infile=citifile out=dataset;
run;
```

Here, the FILETYPE= option indicates that you want to read DRI's Basic Economics data file, the INFILE= option specifies the fileref CITIFILE of the external file you want to read, and the OUT= option names the SAS data set to contain the time series data.

Subsetting Input Data Files

When only a subset of a data file is needed, it is inefficient to extract all the data and then subset it in a subsequent DATA step. Instead, you can use the DATASOURCE procedure options and statements to extract only needed information from the data file.

The DATASOURCE procedure offers the following subsetting capabilities:

- the INTERVAL= option controls the frequency of data output
- the KEEP or DROP statement selects a subset of time series variables
- the RANGE statement restricts the time range of data
- the WHERE statement selects a subset of cross sections

Controlling the Frequency of Data – The INTERVAL= Option

The OUT= data set contains only data with the same frequency. If the data file you want to read contains time series data with several frequencies, you can indicate the frequency of data you want to extract with the INTERVAL= option. For example, the following statements extract all monthly time series from the DRIBASIC file CITIFILE:

```
proc datasource filetype=dribasic infile=citifile
                interval=month out=dataset;
run;
```

When the INTERVAL= option is not given, the default frequency defined for the FILETYPE= type file is used. For example, the statements in the previous section extract yearly series since INTERVAL=YEAR is the default frequency for DRI's Basic Economic Data files.

To extract data for several frequencies, you need to execute the DATASOURCE procedure once for each frequency.

Selecting Time Series Variables – The KEEP and DROP Statements

If you want to include specific series in the OUT= data set, list them in a KEEP statement. If, on the other hand, you want to exclude some variables from the OUT= data set, list them in a DROP statement. For example, the following statements extract monthly foreign exchange rates for Japan (EXRJAN), Switzerland (EXRSW), and the United Kingdom (EXRUK) from a DRIBASIC file CITIFILE:

```
proc datasource filetype=dribasic infile=citifile
                interval=month out=dataset;
    keep  exrjan exrsw exruk;
run;
```

The KEEP statement also allows input names to be quoted strings. If the name of a series in the input file contains blanks or special characters that are not valid SAS name syntax, put the series name in quotes to select it. Another way to allow the use of special characters in your SAS variable names is to use the SAS options statement to designate VALIDVARNAME=ANY. This option will allow PROC DATASOURCE to include special characters in your SAS variable names. The following is an example of extracting series from a FAME database by using the DATASOURCE procedure.

```
proc datasource filetype=fame dbname='fame_nys /disk1/prc/prc'
                interval=weekday out=outds outcont=attrds;
    range '1jan90'd to '1feb90'd;
    keep cci.close
        '{ibm.high,ibm.low,ibm.close}'
        'mave(ibm.close,30)'
```

```

        'crosslist({gm,f,c},{volume})'
        'cci.close+ibm.close';
rename 'mave(ibm.close,30)' = ibm30day
        'cci.close+ibm.close' = cci_ibm;
run;

```

The resulting output data set OUTDS contains the following series: DATE, CCI_CLOS, IBM_HIGH, IBM_LOW, IBM_CLOS, IBM30DAY, GM_VOLUM, F_VOLUME, C_VOLUME, CCI_IBM.

Obviously, to be able to use KEEP and DROP statements, you need to know the name of time series variables available in the data file. The OUTCONT= option gives you this information. More specifically, the OUTCONT= option creates a data set containing descriptive information on the same frequency time series. This descriptive information includes series names, a flag indicating if the series is selected for output, series variable types, lengths, position of series in the OUT= data set, labels, format names, format lengths, format decimals, and a set of FILETYPE= specific descriptor variables.

For example, the following statements list some of the monthly series available in the CITIFILE and are shown in [Figure 11.1](#).

```

/*-- Selecting Time Series Variables -- The KEEP and DROP Statements --*/
filename citifile "citiaf.dat" RECFM=F LRECL=80;
proc datasource filetype=dribasic infile=citifile
        interval=month outcont=vars;
        drop e: ;
run;

title1 'Some Time Series Variables Available in CITIFILE';
proc print data=vars;
run;

```

Controlling the Time Range of Data – The RANGE Statement

The RANGE statement is used to control the time range of observations included in the output data set. [Figure 11.2](#) shows an example extracting the foreign exchange rates from September 1985 to

February 1987, you can use the following statements:

```

/*-- Controlling the Time Range of Data - The RANGE Statement ---*/
filename citifile "citiaf.dat" RECFM=F LRECL=80;
proc datasource filetype=dribasic infile=citifile
    interval=month out=dataset;
    keep  exrjan exrsw exruk;
    range from 1985:9 to 1987:2;
run;

title1 'Printout of the OUT= Data Set';
proc print data=dataset;
run;

```

18	FEB1987	153.410	1.54030	152.800

Reading in Data Files Containing Cross Sections

Some data files group time series data with respect to cross-section identifiers; for example, International Financial Statistics files, distributed by IMF, group data with respect to countries (COUNTRY). Within each country, data are further grouped by Control Source Code (CSC), Partner Country Code (PARTNER), and Version Code (VERSION).

If a data file contains cross-section identifiers, the DATASOURCE procedure adds them to the output data set as BY variables. For example, the data set in [Table 11.2](#) contains three cross sections:

- Cross-section one is identified by (COUNTRY='112' CSC='F' PARTNER=' ' VERSION='Z').
- Cross-section two is identified by (COUNTRY='146' CSC='F' PARTNER=' ' VERSION='Z').
- Cross-section three is identified by (COUNTRY='158' CSC='F' PARTNER=' ' VERSION='Z').

Table 11.2 The Form of a SAS Data Set Containing BY Variables

COUNTRY	BY Variables			Time ID Variable	Time Series Variables	
	CSC	PARTNER	VERSION	DATE	EFFEXR	EXRINDEX
112	F		Z	SEP1987	9326	12685
112	F		Z	OCT1987	9393	12813
112	F		Z	NOV1987	9626	13694
112	F		Z	DEC1987	9675	14099
112	F		Z	JAN1988	9581	13910
112	F		Z	FEB1988	9493	13549
146	F		Z	SEP1987	12046	16192
146	F		Z	OCT1987	12067	16266
146	F		Z	NOV1987	12558	17596
146	F		Z	DEC1987	12759	18301
146	F		Z	JAN1988	12642	18082
146	F		Z	FEB1988	12409	17470
158	F		Z	SEP1987	13841	16558
158	F		Z	OCT1987	13754	16499
158	F		Z	NOV1987	14222	17505
158	F		Z	DEC1987	14768	18423
158	F		Z	JAN1988	14933	18565
158	F		Z	FEB1988	14915	18331

Note that the data sets in [Table 11.1](#) and [Table 11.2](#) use two different ways of representing time series data for three different countries: the United Kingdom (COUNTRY='112'), Switzerland (COUNTRY='146'), and Japan (COUNTRY='158'). The first representation ([Table 11.1](#)) incorporates each country's name into the series names, while the second representation ([Table 11.2](#)) represents countries as different cross sections by using the BY variable named COUNTRY. See "Time Series and SAS Data Sets" in Chapter 3, "[Working with Time Series Data](#)."

Obtaining Descriptive Information on Cross Sections

If you want to know the unique set of values BY variables assume for each cross section in the data file, use the OUTBY= option. For example, the following statements list some of the cross sections available for an IFS file, and are shown in Figure 11.3.

```
filename ifsfile "imfifs1.dat" RECFM=F LRECL=88;
proc datasource
  filetype=imfifsp infile=ifsfile
  outselect=on ebclic
  interval=month
  outby=xsection;
run;

title 'Some Cross Sections Available in IFSFILE';
proc print data=xsection;
run;
```

Figure 11.3 Listing of the OUTBY= Data Set

Some Cross Sections Available in IFSFILE											
	C	P	V	S	E		N	N	N	C	
	O	A	E	T	D		S	S	T		
	U	R	R	—	—	N	E	E	Y		
	N	T	S	D	D	T	N	R	L	N

1	111	F	Z	JAN1957	SEP1986	357	357	6	3	UNITED STATES	
2	112	F	Z	JAN1957	SEP1986	357	357	6	3	UNITED KINGDOM	
3	146	F	Z	JAN1957	SEP1986	357	357	6	3	SWITZERLAND	
4	158	F	Z	JAN1957	SEP1986	357	357	6	3	JAPAN	
5	186	F	Z	JAN1957	SEP1986	357	357	6	3	TURKEY	

The OUTBY= data set reports the total number of series, NSERIES, defined in each cross section, NSELECT of which represent the selected variables. If you want to see the descriptive information on each of these NSELECT variables for each cross section, specify the OUTALL= option. For example, the following statements print descriptive information on all monthly series defined for all cross sections (COUNTRY='111', COUNTRY='112', COUNTRY='146', COUNTRY='158', and COUNTRY='186') which are shown in [Figure 11.4](#).

```
filename datafile "imfifs1.dat" RECFM=F LRECL=88;

title3 'Time Series Defined in Cross Section';
proc datasource filetype=imfifsp
  outselect=on ebcdic
  interval=month
  outall=ifsall;
run;

title4 'Cross Sections Available in OUTALL=IFSALL Data Set';
proc print
  data=ifsall;
run;
```

14	0	JAN1957	SEP1986	357	357	TURKEY			S	F	U
15	0	JAN1957	SEP1986	357	357	TURKEY			S	A	U

The OUTCONT= data set contains one observation for each time series variable with the descriptive information summarized over BY groups. When the data file contains no cross sections, the OUTCONT= and OUTALL= data sets are equivalent, except that the OUTALL= data set also reports time ranges of available data. The OUTBY= data set in this case contains a single observation reporting the number of series and time ranges for the whole data file.

Subsetting a Data File Containing Cross Sections

Data files containing cross sections can be subsetted by controlling which cross sections to include in the output data set. Selecting a subset of cross sections is accomplished using the WHERE statement. The WHERE statement gives a condition that the BY variables must satisfy for a cross section to be selected. For example, the following statements extract the monthly market rate conversion factors for the United Kingdom (COUNTRY='112') and Switzerland (COUNTRY='146') for the period from September 1985 to February 1986.

```
filename datafile "imfifs1.dat" RECFM=F LRECL=88;

title3 'Time Series Defined in Selected Cross Sections';
proc datasource filetype=imfifsp
  outselect=on ebcdic
  interval=month
  out=ifs;

  where country in ('146', '112') and partner=' ';
  keep F__AA F__AC;
  range from '01sep85'd to '01feb86'd;
run;

title4 'OUTALL=IFS Data Set';
proc print
  data=ifs;
run;
```

Renaming Time Series Variables

Sometimes the time series variable names as given by data vendors are not descriptive enough, or you may prefer a different naming convention. In such cases, you can use the RENAME statement to assign more meaningful names to time series variables. You can also use LABEL statements to associate descriptive labels with your series variables.

For example, the series names for market rate conversion factor (F__AA) and market rate conversion factor (F__AC) used by IMF can be given more descriptive names and labels by the following statements and are shown in [Figure 11.5](#) and [Figure 11.6](#).

```
filename ifsfile "imfifs1.dat" RECFM=F LRECL=88;
```

```

proc datasource filetype=imfifsp infile=ifsfile
      interval=month
      out=market outcont=mrktvars;
  where country in ('112','146','158') and partner=' ';
  keep f__aa f__ac;
  range from '01jun85'd to '01feb86'd;
  rename f__aa=alphmkt f__ac=charmkt;
  label f__aa='F__AA: Market Rate Conversion Factor Used in Alpha Test'
        f__ac='F__AC: Market Rate Conversion Used in Charlie Test';
run;

titlel 'Printout of OUTCONT= Showing New NAMEs and LABELs';
proc print data=mrktvars ;
  var name label length;
run;

titlel 'Contents of OUT= Showing New NAMEs and LABELs';
proc contents data=market;
run;

```

The RENAME statement allows input names to be quoted strings. If the name of a series in the input file contains blanks or special characters that are not in valid SAS name syntax, use the SAS option VALIDVARNAME=ANY or put the series name in quotes to rename it. See the FAME example using rename in the “[Selecting Time Series Variables – The KEEP and DROP Statements](#)” on page 524 section.

Figure 11.6 Renaming and Labeling Variables

Contents of OUT= Showing New NAMES and LABELS				
The CONTENTS Procedure				
Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Format Label
1	COUNTRY	Char	3	COUNTRY CODE
2	CSC	Char	1	CONTROL SOURCE CODE
5	DATE	Num	4	MONYY7. Date of Observation
3	PARTNER	Char	3	PARTNER COUNTRY CODE
4	VERSION	Char	1	VERSION CODE
6	alphmkt	Num	5	F__AA: Market Rate Conversion Factor Used in Alpha Test
7	charmkt	Num	5	F__AC: Market Rate Conversion Used in Charlie Test

Notice that even though you changed the names of F__AA and F__AC to alphmkt and charmkt, respectively, you still use their old names in the KEEP and LABEL statements because renaming takes place at the output stage.

Changing the Lengths of Numeric Variables

The length attribute indicates the number of bytes the SAS System uses for storing the values of variables in output data sets. Therefore, the shorter the variable lengths, the more efficient the disk-space usage. However, there is a trade-off. The lengths of numeric variables are closely tied to their precision, and reducing their lengths arbitrarily can cause precision loss.

The DATASOURCE procedure uses default lengths for series variables appropriate to each file type. For example, the default lengths for numeric variables are 5 for IMFIFSP type files. In some cases, however, you may want to assign different lengths. Assigning lengths less than the defaults reduces memory and disk-space usage at the expense of precision. Specifying lengths longer than the defaults increases the precision but causes the DATASOURCE procedure to use more memory and disk space. The following statements define a default length of 4 for all numeric variables in the IFSFILE and then assign a length of 6 to the exchange rate index. Output is shown in [Figure 11.7](#) and [Figure 11.8](#).

```
filename ifsfile "imfifs1.dat" RECFM=F LRECL=88;

proc datasource filetype=imfifsp infile=ifsfile
    interval=month
    out=market outcont=mrktvars;
    where country in ('112','146','158') and partner=' ';
    keep f__aa f__ac;
    range from '01jun85'd to '01feb86'd;
    rename f__aa=alphmkt f__ac=charmkt;
```

```

label   f__aa='F__AA: Market Rate Conversion Factor Used in Alpha Test'
        f__ac='F__AC: Market Rate Conversion Used in Charlie Test';
length _numeric_ 4;
length f__aa 6;
run;

titlel 'Printout of OUTCONT= Showing New NAMEs and LABELs';
proc print data=mrktvars ;
    var name label length;
run;

titlel 'Contents of OUT= Showing New NAMEs and LABELs';
proc contents data=market;
run;

```

Figure 11.7 Changing the Lengths of Numeric Variables

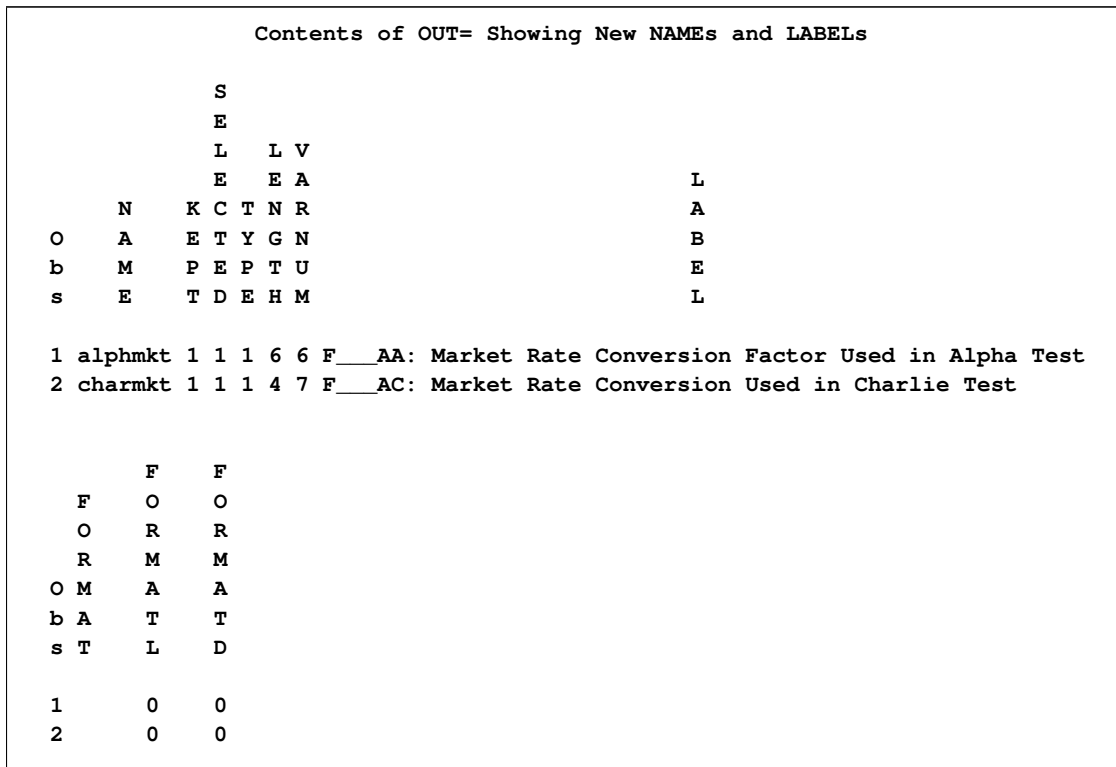

Figure 11.8 Changing the Lengths of Numeric Variables

Contents of OUT= Showing New NAMES and LABELS				
The CONTENTS Procedure				
Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Format Label
1	COUNTRY	Char	3	COUNTRY CODE
2	CSC	Char	1	CONTROL SOURCE CODE
5	DATE	Num	4	MONYY7. Date of Observation
3	PARTNER	Char	3	PARTNER COUNTRY CODE
4	VERSION	Char	1	VERSION CODE
6	alphmkt	Num	6	F__AA: Market Rate Conversion Factor Used in Alpha Test
7	charmkt	Num	4	F__AC: Market Rate Conversion Used in Charlie Test

The default lengths of the character variables are set to the minimum number of characters that can hold the longest possible value.

Syntax: DATASOURCE Procedure

The DATASOURCE procedure uses the following statements:

```

PROC DATASOURCE options ;
  KEEP variable-list ;
  DROP variable-list ;
  KEEPEVENT event-list ;
  DROPEVENT event-list ;
  WHERE where-expression ;
  RANGE FROM from TO to ;
  ATTRIBUTE variable-list attribute-list ... ;
  FORMAT variable-list format ... ;
  LABEL variable="label" ... ;
  LENGTH variable-list length ... ;
  RENAME old-name=new-name ... ;

```

The PROC DATASOURCE statement is required. All the rest of the statements are optional.

The DATASOURCE procedure uses two kinds of statements, subsetting statements and attribute statements. Subsetting statements provide selection of time series data over selected time periods and cross sections from the input data file. Attribute statements control the attributes of the variables in the output SAS data set.

The subsetting statements are the KEEP, DROP, KEEPEVENT, and DROPEVENT statements (which select output variables); the RANGE statement (which selects time ranges); and the WHERE

statement (which selects cross sections). The attribute statements are the ATTRIBUTE, FORMAT, LABEL, LENGTH, and RENAME statements.

The statements and options used by PROC DATASOURCE are summarized in [Table 11.3](#).

Table 11.3 Summary of Syntax

Option	Description
Input Data File Options	
FILETYPE=	type of input data file to read
INFILE=	fileref(s) of the input data
LRECL=	lrecl(s) of the input data
RECFM=	recfm(s) of the input data
ASCII	character set of the incoming data
EBCDIC	character set of the incoming data
Output Data Set Options	
OUT=	write the extracted time series data
OUTALL=	information on time series and cross sections
OUTBY=	information on only cross sections
OUTCONT=	information on only time series variables
OUTEVENT=	write event-oriented data
OUTSELECT=	control reporting of all or only selected series and cross sections
INDEX	create single indexes from BY variables for the OUT= data set
ALIGN=	control the alignment of SAS date values
Subsetting Option and Statements	
INTERVAL=	select periodicity of series to extract
KEEP	time series to include in the OUT= data set
DROP	time series to exclude from the OUT= data set
KEEP EVENT	events to include in the OUTEVENT= data set
DROPEVENT	events to exclude from the OUTEVENT= data set
WHERE	select cross sections for output
RANGE	time range of observations to be output
Assigning Attributes Options and Statements	
FORMAT	assign formats to variables in the output data sets
ATTRIBUTE FORMAT=	assign formats to variables in the output data sets
LABEL	assign labels to variables in the output data sets
ATTRIBUTE LABEL=	assign labels to variables in the output data sets
LENGTH	control the lengths of variables in the output data sets
ATTRIBUTE LENGTH=	control the lengths of variables in the output data sets
RENAME	assign new names to variables in the output data sets

PROC DATASOURCE Statement

PROC DATASOURCE *options* ;

The following options can be used in the PROC DATASOURCE statement:

ALIGN= *option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

ASCII

specifies the incoming data is ASCII. This option is used when the native character set of your host machine is EBCDIC.

DBNAME= '*database name*'

specifies the FAME database to access. Only use this option with the filetype=FAME option. The character string you specify in the DBNAME= option is passed through to FAME. Specify the value of this option as you would in accessing the database from within FAME software.

EBCDIC

specifies the incoming data is ebcdic. This option is needed when the native character set of your host machine is ASCII.

FAMEPRINT

prints the FAME command file generated by PROC DATASOURCE and the log file produced by the FAME component of the interface system. Only use this option with the filetype=FAME option.

FILETYPE= *entry*

DBTYPE= *dbtype*

specifies the kind of input data file to process. See “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586 for a list of supported file types. The FILETYPE= option is required.

INDEX

creates a set of single indexes from BY variables for the OUT= data set. Under some circumstances, creating indexes for a SAS data set may increase the efficiency in locating observations when BY or WHERE statements are used in subsequent steps. Refer to *SAS Language Reference: Concepts* for more information on SAS indexes. The INDEX option is ignored when no OUT= data set is created or when the data file does not contain any BY variables. The INDEX= data set option can be used to override the index variable definitions.

INFILE= *fileref*

INFILE= (*fileref1 fileref2 ... filerefn*)

specifies the *fileref* assigned to the input data file. The default value is DATAFILE. The fileref used in the INFILE= option (or if no INFILE= option is specified, the fileref DATAFILE) must be associated with the physical data file in a FILENAME statement. (On some operating systems, the fileref assignment can be made with the system’s control language, and a FILENAME statement may not be needed. Refer to *SAS Language Reference: Dictionary* for more details on the FILENAME statement. Physical data files can reside on DVD, CD-ROM, or other media.

For some file types, the data are distributed over several files. In this case, the INFILE= option is required, and it lists in parentheses the filerefs for each of the files making up the database. The order in which these FILEREFS are listed is important and must conform to the specifics of each file type as explained in “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586.

LRECL= *lrecl*

LRECL= (*lrecl1 lrecl2 ... lrecln*)

The logical record length in bytes of the infile. Only use this if you need to override the default LRECL of the file. For some file types, the data are distributed over several files. In this case, the LRECL= option lists in parentheses the LRECLs for each of the files making up the database. The order in which these LRECLs are listed is important and must conform to the specifics of each file type as explained in “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586.

RECFM= *recfm*

RECFM= (*recfm1 recfm2 ... recfmn*)

The record format of the infile. Only use this if you need to override the default record format of the file. For some file types, the data are distributed over several files. In this case, the RECFM= option lists in parentheses the RECFMs for each of the files making up the database. The order in which these RECFMs are listed is important and must conform to the specifics of each file type as explained in “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586. The possible values of RECFM are

- F or FIXED for fixed length records
- N or BIN for binary records
- D or VAR for varying length records
- U or DEF for host default record format
- DOM_V or DOMAIN_VAR or BIN_V or BIN_VAR for UNIX binary record format

INTERVAL= *interval*

FREQUENCY= *interval*

TYPE= *interval*

specifies the periodicity of series selected for output to the OUT= data set. The OUT= data set created by PROC DATASOURCE can contain only time series with the same periodicity. Some data files contain time series with different periodicities; for example, a file can contain both monthly series and quarterly series. Use the INTERVAL= option to indicate which periodicity you want. If you want to extract series with different periodicities, use different PROC DATASOURCE invocations with the desired INTERVAL= options.

Common values for INTERVAL= are YEAR, QUARTER, MONTH, WEEK, and DAY. The values allowed, as well as the default value of the INTERVAL= option, depend on the file type. See “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586 for the INTERVAL= values appropriate to the data file type you are reading.

OUT= *SAS-data-set*

names the output data set for the time series extracted from the data file. If none of the output

data set options are specified, including the OUT= data set itself, an OUT= data set is created and named according to the DATA n convention. However, when you create any of the other output data sets, such as OUTCONT=, OUTBY=, OUTALL=, or OUTEVENT=, you must explicitly specify the OUT= data set; otherwise, it will not be created. See “[OUT= Data Set](#)” on page 548 for further details.

OUTALL= *SAS-data-set*

writes information on the contents of the input data file to an output data set. The OUTALL= data set includes descriptive information, time ranges, and observation counts for all the time series within each BY group. By default, no OUTALL= data set is created.

The OUTALL= data set contains the Cartesian product of the information output by the OUTCONT= and OUTBY= options. In data files for which there are no cross sections, the OUTALL= and OUTCONT= data sets are almost equivalent, except that OUTALL= data set also reports time ranges and observation counts of series. See “[OUTALL= Data Set](#)” on page 552 for further details.

OUTBY= *SAS-data-set*

writes information on the BY variables to an output data set. The OUTBY= data set contains the list of cross sections in the database delimited by the unique set of values that the BY variables assume. Unless the OUTSELECT=OFF option is present, only the selected BY groups are written to the OUTBY= data set. If you omit the OUTBY= option, no OUTBY= data set is created. See “[OUTBY= Data Set](#)” on page 551 for further details.

OUTCONT= *SAS-data-set*

writes information on the contents of the input data file to an output data set. By default, the OUTCONT= data set includes descriptive information on all of the unique series of the selected periodicity in the data file. When the OUTSELECT=OFF option is omitted, the OUTCONT= data set includes observations only for the series selected for output to the OUT= data set. By default, no OUTCONT= data set is created. See “[OUTCONT= Data Set](#)” on page 550 for further details.

OUTEVENT= *SAS-data-set*

names the output data set to output event-oriented time series data. This option can only be used when CRSP stock files are being processed. For all other file types, it will be ignored. See “[OUTEVENT= Data Set](#)” on page 553 for further details.

OUTSELECT= ON | OFF

determines whether to output all observations (OUTSELECT=OFF) or only those corresponding to the selected time series and selected BY groups (OUTSELECT=ON) to OUTCONT=, OUTBY=, and OUTALL= data sets. The default is OUTSELECT=ON. The OUTSELECT= option is only relevant when any one of the auxiliary data sets is specified. The option writes observations to OUTCONT=, OUTBY=, and OUTALL= data sets for only the selected time series and selected BY groups if it is set ON. The OUTSELECT= option is only relevant when any one of the OUTCONT=, OUTBY=, and OUTALL= options is specified. The default is OUTSELECT=ON.

KEEP Statement

KEEP *variable-list* ;

The KEEP statement specifies which variables in the data file are to be included in the OUT= data set. Only the time series and event variables can be specified in a KEEP statement. All the BY variables and the time ID variable DATE are always included in the OUT= data set; they cannot be referenced in a KEEP statement. If they are referenced, a warning message is given and the reference is ignored.

The variable list can contain variable names or name range specifications. See “[Variable Lists](#)” on page 547 for details.

There is a default KEEP list for each file type. Usually, descriptor type variables, like footnotes, are not included in the default KEEP list. If you give a KEEP statement, the default list becomes undefined.

Only one KEEP or one DROP statement can be used. KEEP and DROP are mutually exclusive.

You can also use the KEEP= data set option to control which variables to include in the OUT= data set. However, the KEEP statement differs from the KEEP= data set option in several respects:

- The KEEP statement selection is applied before variables are read from the data file, while the KEEP= data set option selection is applied after variables are read and as they are written to the OUT= data set. Therefore, using the KEEP statement instead of the KEEP= data set option is much more efficient.
- If the KEEP statement causes no series variables to be selected, then no observations are output to the OUT= data set.
- The KEEP statement variable specifications are applied to each cross section independently. This behavior may produce variables different from those produced by the KEEP= data set option when order-range variable list specifications are used.

DROP Statement

DROP *variable-list* ;

The DROP statement specifies that some variables be excluded from the OUT= data set. Only the time series and event variables can be specified in a DROP statement. None of the BY variables or the time ID variable DATE can be excluded from the OUT= data set. If they are referenced in a DROP statement, a warning message is given and the reference is ignored. Use the WHERE statement for selection based on BY variables, and use the RANGE statement for date selections.

The variable list can contain variable names or name range specifications. See “[Variable Lists](#)” on page 547 for details.

Only one DROP or one KEEP statement can be used. KEEP and DROP are mutually exclusive.

There is a default DROP or KEEP list for each file type. Usually, descriptor type variables, like footnotes, are not included in the default KEEP list. If you specify a DROP statement, the default list becomes undefined.

You can also use the DROP= data set option to control which variables to exclude from the OUT= data set. However, the DROP statement differs from the DROP= data set option in several aspects:

- The DROP statement selection is applied before variables are read from the data file, while the DROP= data set option selection is applied after variables are read and as they are written to the OUT= data set. Therefore, using the DROP statement instead of the DROP= data set option is much more efficient.
- If the DROP statement causes all series variables to be excluded, then no observations are output to the OUT= data set.
- The DROP statement variable specifications are applied to each cross section independently. This behavior may produce variables different from those produced by the DROP= data set option when order-range variable list specifications are used.

KEEPEVENT Statement

KEEPEVENT *variable-list* ;

The KEEPEVENT statement specifies which event variables in the data file are to be included in the OUTEVENT= data set. As a result, the KEEPEVENT statement is valid only for data files containing event-oriented time series data. All the BY variables, the time ID variable DATE, and the event-grouping variable EVENT are always included in the OUTEVENT= data set. These variables cannot be referenced in the KEEPEVENT statement. If any of these variables are referenced, a warning message is given and the reference is ignored.

The variable list can contain variable names or name range specifications. See “[Variable Lists](#)” on page 547 for details.

Only one KEEPEVENT or one DROPEVENT statement can be used. KEEPEVENT and DROPEVENT are mutually exclusive.

You can also use the KEEP= data set option to control which event variables to include in the OUTEVENT= data set. However, the KEEPEVENT statement differs from the KEEP= data set option in several respects:

- The KEEPEVENT statement selection is applied before variables are read from the data file, while the KEEP= data set option selection is applied after variables are read and as they are written to the OUTEVENT= data set. Therefore, using the KEEPEVENT statement instead of the KEEP= data set option is much more efficient.
- If the KEEPEVENT statement causes no event variables to be selected, then no observations are output to the OUTEVENT= data set.

DROPEVENT Statement

DROPEVENT *variable-list* ;

The DROPEVENT statement specifies that some event variables be excluded from the OUTEVENT= data set. As a result, the DROPEVENT statement is valid only for data files containing event-oriented time series data. All the BY variables, the time ID variable DATE, and the event-grouping variable EVENT are always included in the OUTEVENT= data set. These variables cannot be referenced in the DROPEVENT statement. If any of these variables are referenced, a warning message is given and the reference is ignored.

The variable list can contain variable names or name range specifications. See “[Variable Lists](#)” on page 547 for details.

Only one DROPEVENT or one KEEPEVENT statement can be used. DROPEVENT and KEEPEVENT are mutually exclusive.

You can also use the DROP= data set option to control which event variables to exclude from the OUTEVENT= data set. However, the DROPEVENT statement differs from the DROP= data set option in several respects:

- The DROPEVENT statement selection is applied before variables are read from the data file, while the DROP= data set option selection is applied after variables are read and as they are written to the OUTEVENT= data set. Therefore, using the DROPEVENT statement instead of the DROP= data set option is much more efficient.
- If the DROPEVENT statement causes all series variables to be excluded, then no observations are output to the OUTEVENT= data set.

WHERE Statement

WHERE *where-expression* ;

The WHERE statement specifies conditions that BY variables must satisfy in order for a cross section to be included in the OUT= and OUTEVENT= data sets. By default, all BY groups are selected.

The *where-expression* must refer only to BY variables defined for the file type you are reading. The “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586 lists the names of the BY variables for each file type.

For example, DOTS (Direction of Trade Statistics) files, distributed by the International Monetary Fund, have four BY variables: COUNTRY, CSC, PARTNER, and VERSION. Both COUNTRY and PARTNER are three-digit country codes. To select the direction of trade statistics of the United States (COUNTRY='111') with Turkey (COUNTRY='186'), Japan (COUNTRY='158'), and the oil exporting countries group (COUNTRY='985'), you should specify

```
where country='111' and partner in ('186','158','985');
```

You can use any SAS language operators and special WHERE expression operators in the WHERE statement condition. Refer to *SAS Language Reference: Concepts* for a more detailed discussion of WHERE expressions.

If you want to see the names of the BY variables and the values they assume for each cross section, you can first run PROC DATASOURCE with only the OUTBY= option. The information contained in the OUTBY= data set will aid you in selecting the appropriate BY groups for subsequent PROC DATASOURCE steps.

RANGE Statement

RANGE FROM *from* *TO* to ;

The RANGE statement selects the time range of observations written to the OUT= and OUTEVENT= data sets. The *from* and *to* values can be SAS date, time, or datetime constants, or they can be specified as *year* or *year : period*, where *year* is a two-digit or four-digit year, and *period* (when specified) is a period within the year corresponding to the INTERVAL= option. (For example, if INTERVAL=QTR, then *period* refers to quarters.) When *period* is omitted, the beginning of the year is assumed for the *from* value, and the end of the year is assumed for the *to* value.

If a two-digit year is specified, PROC DATASOURCE uses the current value of the YEARCUTOFF option to determine the century of your data. Warnings are issued in the SAS log whenever DATASOURCE needs to determine the century from a two-digit year specification.

The default YEARCUTOFF value is 1920. To use a different YEARCUTOFF value, specify

```
options yearcutoff=yyyy;
```

where YYYY is the YEARCUTOFF value you want to use. See *SAS Language Reference: Dictionary* for a more detailed discussion of the YEARCUTOFF option.

Both the FROM and TO specifications are optional, and both the FROM and TO keywords are optional. If the FROM limit is omitted, the output observations start with the minimum date for which data are available for any selected series. Similarly, if the TO limit is omitted, the output observations end with the maximum date for which data are available.

The following are some examples of RANGE statements:

```
range from 1980 to 1990;
range 1980 - 1990;
range from 1980;
range 1980;
range to 1990;
range to 1990:2;
range from '31aug89'd to '28feb1990'd;
```

The RANGE statement applies to each BY group independently. If all the selected series contain no data in the specified range for a given BY group, then there will be no observations for that BY group in the OUT= and OUTEVENT= data sets.

If you want to know the time ranges for which periodic time series data are available, you can first run PROC DATASOURCE with the OUTBY= or OUTALL= option. The OUTBY= data set reports the union of the time ranges over all the series within each BY group, while the OUTALL= data set gives time ranges for each series separately in each BY group.

ATTRIBUTE Statement

ATTRIBUTE *variable-list attribute-list . . . ;*

The ATTRIBUTE statement assigns formats, labels, and lengths to variables in the output data sets.

The *variable-list* can contain variable names and variable name range specifications. See “[Variable Lists](#)” on page 547 for details. The attributes specified in the following attribute list apply to all variables in the variable list.

An *attribute-list* consists of one or more of the following options:

FORMAT= *format*

associates a format with variables in *variable-list*. The *format* can be either a standard SAS format or a format defined with the FORMAT procedure. The default formats for variables depend on the file type.

LABEL= *"label"*

assigns a label to the variables in the variable list. The default labels for variables depend on the file type. Labels can be up to 256 bytes in length.

LENGTH= *length*

specifies the number of bytes used to store the values of variables in the variable list. The default lengths for numeric variables depend on the file type. Usually default lengths are set to 5 bytes.

The length specification also controls the amount of memory that PROC DATASOURCE uses to hold variable values while processing the input data file. Thus, specifying a LENGTH= value smaller than the default will reduce both the disk space taken up by the output data sets and the amount of memory used by the PROC DATASOURCE step, at the cost of precision of output data values.

FORMAT Statement

FORMAT *variable-list format . . . ;*

The FORMAT statement assigns formats to variables in output data sets. The *variable-list* can contain variable names and variable name range specifications. See “[Variable Lists](#)” on page 547 for details. The format specified applies to all variables in the variable list.

A single FORMAT statement can assign the same format to several variables or different formats to different variables. The FORMAT statement can use standard SAS formats or formats defined using the FORMAT procedure.

Any later format specification for a variable, using either the FORMAT statement or the FORMAT= option in the ATTRIBUTE statement, always overrides the previous one.

LABEL Statement

```
LABEL variable = "label" ... ;
```

The LABEL statement assigns SAS variable labels to variables in the output data sets. You can give labels for any number of variables in a single LABEL statement. The default labels for variables depend on the file type. Extra-long labels (> 256 bytes) reside in the OUTCONT data set as the DESCRIPT variable.

Any later label specification for a variable, using either the LABEL statement or the LABEL= option in the ATTRIBUTE statement, always overrides the previous one.

LENGTH Statement

```
LENGTH variable-list length ... ;
```

The LENGTH statement, like the LENGTH= option in the ATTRIBUTE statement, specifies the number of bytes used to store values of variables in output data sets. The default lengths for numeric variables depend on the file type. Usually default lengths are set to 5 bytes.

The default lengths of character variables are defined as the minimum number of characters that can hold the longest possible value.

For some file types, the LENGTH statement also controls the amount of memory used to store values of numeric variables while processing the input data file. Thus, specifying LENGTH values smaller than the default will reduce both the disk space taken up by the output data sets and the amount of memory used by the PROC DATASOURCE step, at the cost of precision of output data values.

Any later length specification for a variable, using either the LENGTH statement or the LENGTH= option in the ATTRIBUTE statement, always overrides the previous one.

RENAME Statement

RENAME *old-name* = *new-name* ... ;

The RENAME statement is used to change the names of variables in the output data sets. Any number of variables can be renamed in a single RENAME statement. The most recent RENAME specification overrides any previous ones for a given variable. The *new-name* is limited to 32 characters.

Renaming of variables is done at the output stage. Therefore, you need to use the old variable names in all other PROC DATASOURCE statements. For example, the series variable names DATA1-DATA350 used with annual COMPUSTAT files are not very descriptive, so you may choose to rename them to reflect the financial aspect they represent. You may rename “DATA51” as “INVESTTAX” with the RENAME statement

```
rename data51=investtax;
```

since it contains investment tax credit data. However, in all other DATASOURCE statements, you must use the old name, DATA51.

Details: DATASOURCE Procedure

Variable Lists

Variable lists used in PROC DATASOURCE statements can consist of any combination of variable names and name range specifications. Items in variable lists can have the following forms:

- a name, such as PZU.
- an alphabetic range *name1-name2*. For example, A-DZZZZZZZ specifies all variables with names starting with A, B, C, or D.
- a prefix range *prefix* :. For example, IP: selects all variables with names starting with the letters IP.
- an order range *name1-name2*. For example, GLR72–GLRD72 specifies all variables in the input data file between GLR72 and GRLD72 inclusive.
- a numeric order range *name1-NUMERIC-name2*. For example, GLR72-NUMERIC-GLRD72 specifies all numeric variables between GLR72 and GRLD72 inclusive.
- a character order range *name1-CHARACTER-name2*. For example, GLR72-CHARACTER-GLRD72 specifies all character variables between GLR72 and GRLD72 inclusive.

- one of the keywords `_NUMERIC_`, `_CHARACTER_`, or `_ALL_`. The keyword `_NUMERIC_` specifies all numeric variables, `_CHARACTER_` specifies all character variables, and `_ALL_` specifies all variables.

To determine the order of series in a data file, run PROC DATASOURCE with the `OUTCONT=` option, and print the output data set. Note that order and alphabetic range specifications are inclusive, meaning that the beginning and ending names of the range are also included in the variable list.

For order ranges, the names used to define the range must actually name variables in the input data file. For alphabetic ranges, however, the names used to define the range need not be present in the data file.

Note that variable specifications are applied to each cross section independently. This may cause the order-range variable list specification to behave differently than its DATA step and data set option counterparts. This is because PROC DATASOURCE knows which variables are defined for which cross sections, while the DATA step applies order range specification to the whole collection of time series variables.

If the ending variable name in an order range specification is not in the current cross section, all variables starting from the beginning variable to the last variable defined in that cross section get selected. If the first variable is not in the current cross section, then order range specification has no effect for that cross section.

The variable names used in variable list specifications can refer either to series names appearing in the input data file or to the SAS names assigned to series data fields internally if the series names are not recorded to the `INFILE=` file. When the latter is the case, internally defined variable names are listed in “[Data Elements Reference: DATASOURCE Procedure](#)” on page 586 later in this chapter.

The following are examples of the use of variable lists:

```
keep ip: pw112-pw117 pzu;
drop data1-data99 data151-data350;
length data1-numeric-aftnt350 ucode 4;
```

The first statement keeps all the variables starting with `IP:`, all the variables between `PW112` and `PW117` including `PW112` and `PW117` themselves, and a single variable `PZU`. The second statement drops all the variables that fall alphabetically between `DATA1` and `DATA99`, and between `DATA151` and `DATA350`. Finally, the third statement assigns a length of 4 bytes to all the numeric variables defined between `DATA1` and `AFTNT350`, and `UCODE`. Variable lists can not exceed 200 characters in length.

OUT= Data Set

The `OUT=` data set can contain the following variables:

- the `BY` variables, which identify cross-sectional dimensions when the input data file contains time series replicated for different values of the `BY` variables. Use the `BY` variables in a

WHERE statement to process the OUT= data set by cross sections. The order in which BY variables are defined in the OUT= data set corresponds to the order in which the data file is sorted.

- DATE, a SAS date-, time-, or datetime-valued variable that reports the time period of each observation. The values of the DATE variable may span different time ranges for different BY groups. The format of the DATE variable depends on the INTERVAL= option.
- the periodic time series variables, which are included in the OUT= data set only if they have data in at least one selected BY group and they are not discarded by a KEEP or DROP statement
- the event variables, which are included in the OUT= data set if they are not discarded by a KEEP or DROP statement. By default, these variables are not output to OUT= data set.

The values of BY variables remain constant in each cross section. Observations within each BY group correspond to the sampling of the series variables at the time periods indicated by the DATE variable.

You can create a set of single indexes for the OUT= data set by using the INDEX option, provided there are BY variables. Under some circumstances, this may increase the efficiency of subsequent PROC and DATA steps that use BY and WHERE statements. However, there is a cost associated with creation and maintenance of indexes. The *SAS Language Reference: Concepts* lists the conditions under which the benefits of indexes outweigh the cost.

With data files containing cross sections, there can be various degrees of overlap among the series variables. One extreme is when all the series variables contain data for all the cross sections. In this case, the output data set is very compact. In the other extreme case, however, the set of time series variables are unique for each cross section, making the output data set very sparse, as depicted in Table 11.4.

Table 11.4 The OUT= Data Set Containing Unique Series for Each BY Group

BY Variables BY1 ... BYP	Series in first BY group F1 F2 F3 ... FN	Series in second BY group S1 S2 S3 ... SM	...	Series in last BY group T1 T2 T3 ... TK
BY group 1	DATA is here			
BY group 2		DATA is here		data is missing everywhere except on diagonal
⋮			DATA is here	
BY group N				DATA is here

The data in Table 11.4 can be represented more compactly if cross-sectional information is incorporated into series variable names.

OUTCONT= Data Set

The OUTCONT= data set contains descriptive information for the time series variables. This descriptive information includes various attributes of the time series variables. The OUTCONT= data set contains the following variables:

- NAME, a character variable that contains the series name
- KEPT, a numeric variable that indicates whether the series was selected for output by the DROP or KEEP statements. KEPT is usually the same as SELECTED, but can differ if a WHERE statement is used.
- SELECTED, a numeric variable that indicates whether the series is selected for output to the OUT= data set. The series is included in the OUT= data set (SELECTED=1) if it is kept (KEPT=1) and it has data for at least one selected BY group.
- TYPE, a numeric variable that indicates the type of the time series variable. TYPE=1 for numeric series; TYPE=2 for character series.
- LENGTH, a numeric variable that gives the number of bytes allocated for the series variable in the OUT= data set
- VARNUM, a numeric variable that gives the variable number of the series in the OUT= data set. If the series variable is not selected for output (SELECTED=0), then VARNUM has a missing value. Likewise, if no OUT= option is given, VARNUM has all missing values.
- LABEL, a character variable that contains the label of the series variable. LABEL contains only the first 256 characters of the labels. If they are longer than 256 characters, then the variable, DESCRIPT, is defined to hold the whole length of series labels. Note that if a data file assigns different labels to the same series variable within different cross sections, only the first occurrence of labels will be transferred to the LABEL column.
- the variables FORMAT, FORMATL, and FORMATD, which give the format name, length, and number of format decimals, respectively
- the GENERIC variables, whose values may vary from one series to another, but whose values remain constant across BY groups for the same series

By default, the OUTCONT= data set contains observations for only the selected series where SELECTED=1. If the OUTSELECT=OFF option is specified, the OUTCONT= data set contains one observation for each unique series of the specified periodicity contained in the input data file.

If you do not know what series are in the data file, you can run PROC DATASOURCE with the OUTCONT= option and OUTSELECT=OFF. The information contained in the OUTCONT= data set can then help you to determine which time series data you want to extract.

OUTBY= Data Set

The OUTBY= data set contains information on the cross sections contained in the input data file. These cross sections are represented as BY groups in the OUT= data set. The OUTBY= data set contains the following variables:

- the BY variables, whose values identify the different cross sections in the data file. The BY variables depend on the file type.
- BYSELECT, a numeric variable that reports the outcome of the WHERE statement condition for the BY variable values for this observation. The value of BYSELECT is 1 for BY groups selected by the WHERE statement for output to the OUT= data set and is 0 for BY groups that are excluded by the WHERE statement. BYSELECT is added to the data set only if a WHERE statement is given. When there is no WHERE statement, then all the BY groups are selected.
- ST_DATE, a numeric variable that gives the starting date for the BY group. The starting date is the earliest of the starting dates of all the series that have data for the current BY group.
- END_DATE, a numeric variable that gives the ending date for the BY group. The ending date is the latest of the ending dates of all the series that have data for the BY group.
- NTIME, a numeric variable that gives the number of time periods between ST_DATE and END_DATE, inclusive. Usually, this is the same as NOBS, but they differ when time periods are not equally spaced and when the OUT= data set is not specified. NTIME is a maximum limit on NOBS.
- NOBS, a numeric variable that gives the number of time series observations in the OUT= data set between ST_DATE and END_DATE inclusive. When a given BY group is discarded by a WHERE statement, the NOBS variable corresponding to this BY group becomes 0, since the OUT= data set does not contain any observations for this BY group. Note that BYSELECT=0 for every discarded BY group.
- NINRANGE, a numeric variable that gives the number of observations in the range (*from,to*) defined by the RANGE statement. This variable is only added to the OUTBY= data set when the RANGE statement is specified.
- NSERIES, a numeric variable that gives the total number of unique time series variables having data for the BY group
- NSELECT, a numeric variable that gives the total number of selected time series variables having data for the BY group
- the generic variables, whose values remain constant for all the series in the current BY group

In this list, you can only control the attributes of the BY and GENERIC variables.

The variables NOBS, NTIME, and NINRANGE give observation counts, while the variables NSERIES and NSELECT give series counts.

By default, observations for only the selected BY groups (where BYSELECT=1) are output to the OUTBY= data set, and the date and time range variables are computed over only the selected time series variables. If the OUTSELECT=OFF option is specified, the OUTBY= data set contains an observation for each BY group, and the date and time range variables are computed over all the time series variables.

For file types that have no BY variables, the OUTBY= data set contains one observation giving ST_DATE, END_DATE, NTIME, NOBS, NINRANGE, NSERIES, and NSELECT for all the series in the file.

If you do not know the BY variable names or their possible values, you can do an initial run of PROC DATASOURCE with the OUTBY= option. The information contained in the OUTBY= data set can help you design your WHERE expression and RANGE statement for the subsequent executions of PROC DATASOURCE to obtain different subsets of the same data file.

OUTALL= Data Set

The OUTALL= data set combines and expands the information provided by the OUTCONT= and OUTBY= data sets. That is, the OUTALL= data set not only reports the OUTCONT= information separately for each BY group, but also reports the OUTBY= information separately for each series. Each observation in the OUTBY= data set gets expanded to NSERIES or NSELECT observations in the OUTALL= data set, depending on whether the OUTSELECT=OFF option is specified.

By default, only the selected BY groups and series are included in the OUTALL= data set. If the OUTSELECT=OFF option is specified, then all the series within all the BY groups are reported.

The OUTALL= data set contains all the variables defined in the OUTBY= and OUTCONT= data sets and also contains the GENERIC variables (whose values can vary from one series to another and from one BY group to another). Another additional variable is BLKNUM, which gives the data block number in the data file containing the series variable.

The OUTALL= data set is useful when BY groups do not contain the same time series variables or when the time ranges for series change across BY groups.

You should be careful in using the OUTALL= option, since the OUTALL= data set can get very large for many file types. Some file types have the same series and time ranges for each BY group; the OUTALL= option should not be used with these file types. For example, you should not specify the OUTALL= option with COMPUSTAT files, since all the BY groups contain the same series variables.

The OUTALL= and OUTCONT= data sets are equivalent when there are no BY variables, except that the OUTALL= data set contains extra information about the time ranges and observation counts of the series variables.

OUTEVENT= Data Set

The OUTEVENT= data set is used to output event-oriented time series data. Events occurring at discrete points in time are recorded along with the date they occurred. Only CRSP stock files contain event-oriented time series data. For all other types of files, the OUTEVENT= option is ignored.

The OUTEVENT= data set contains the following variables:

- the BY variables, which identify cross-sectional dimensions when the input data file contains time series replicated for different values of the BY variables. Use the BY variables in a WHERE statement to process the OUTEVENT= data set by cross sections. The order in which BY variables are defined in the OUTEVENT= data set corresponds to the order in which the data file is sorted.
- DATE, a SAS date-, time- or datetime-valued variable that reports the discrete time periods at which events occurred. The format of the DATE variable depends on the INTERVAL= option, and should accurately report the date based on the SAS YEARCUTOFF option. The default value for YEARCUTOFF is 1920. The dates used can span up to 250 years.
- EVENT, a character variable that contains the event group name. The EVENT variable is another cross-sectional variable.
- the event variables, which are included in the OUTEVENT= data set only if they have data in at least one selected BY group, and are not discarded by a KEEPEVENT or DROPEVENT statement

Note that each event group contains a nonoverlapping set of event variables; therefore, the OUTEVENT= data set is very sparse. You should exercise care when selecting event variables to be included in the OUTEVENT= data set.

Also note that even though the OUTEVENT= data set cannot contain any periodic time series variables, the OUT= data set can contain event variables if they are explicitly specified in a KEEP statement. In summary, you can specify event variables in a KEEP statement, but you cannot specify periodic time series variables in a KEEPEVENT statement.

While variable selection for OUT= and OUTEVENT= data sets are controlled by a different set of statements (KEEP versus KEEPEVENT or DROP versus DROPEVENT), cross-section and range selections are controlled by the same statements, so in summary, the WHERE and the RANGE statements are effective for both output data sets.

Examples: DATASOURCE Procedure

Example 11.1: BEA National Income and Product Accounts

In this example, exports and imports of goods and services are extracted to demonstrate how to work with a National Income and Product Accounts (NIPA) file.

From the “Statistical Tables” published by the United States Department of Commerce, Bureau of Economic Analysis, the relation of foreign transactions in the Balance of Payments Accounts (BPA) are given in the fifth table (TABNUM='05') of the “Foreign Transactions” section (PARTNO='4'). Moreover, the first line in the table gives BPAs, while the eighth gives exports of goods and services. The series names __00100 and __00800, are constructed by two underscores followed by three digits as the line numbers, and then two digits as the column numbers.

The following statements put this information together to extract quarterly BPAs and exports from a BEANIPA type file:

```
/*- assign fileref to the external file to be processed -----*/

filename ascifile 'beanipa.data' recfm=v lrecl=108;

title1 'Relation of Foreign Transactions to Balance of Payment Accounts';
title2 'Range from 1984 to 1989';

title3 'Annual';
proc datasource filetype=beanipa infile=ascifile
               interval=year
               outselect=off
               outkey=byfor4;

    range from 1984 to 1989;
    keep __00100 __00800;

    label __00100='Balance of Payment Accounts';
    label __00800='Exports of Goods and Services';

    rename __00100=BPAs __00800=exports;
run;

proc print data=byfor4;
run;

/*- assign fileref to the external file to be processed -----*/

filename ascifile 'beanipa.data' recfm=v lrecl=108;

title1 'Relation of Foreign Transactions to Balance of Payment Accounts';
title2 'Range from 1984 to 1989';
```

```
title3 'Annual';
proc datasource filetype=beanipa infile=ascifile
      interval=year
      outselect=off
      outkey=byfor4
      out=foreign4;

      range from 1984 to 1989;
      keep __00100 __00800;

      label __00100='Balance of Payment Accounts';
      label __00800='Exports of Goods and Services';

      rename __00100=BPAs __00800=exports;

run;

proc contents data=foreign4;
run;
proc print data=foreign4;
run;
```

The results are shown in [Output 11.1.1](#), [Output 11.1.2](#), and [Output 11.1.3](#).

This example illustrates the following features:

- You need to know the series variables names used by a particular vendor in order to construct the KEEP statement.
- You need to know the BY-variable names and their values for the required cross sections.
- You can use RENAME and LABEL statements to associate more meaningful names and labels with your selected series variables.

Example 11.2: BLS Consumer Price Index Surveys

This example compares changes of the prices in medical care services with respect to different regions for all urban consumers (SURVEY='CU') since May 1975. The source of the data is the Consumer Price Index Surveys distributed by the U.S. Department of Labor, Bureau of Labor Statistics.

An initial run of PROC DATASOURCE gives the descriptive information on different regions available (the OUTBY= data set), as well as the series variable name corresponding to medical care services (the OUTCONT= data set).

```

options yearcutoff = 1900;

The OUTBY= data set in [Output 11.2.1](#) lists all cross sections available for the four geographical regions: Northeast (AREA='0100'), North Central (AREA='0200'), Southern (AREA='0300'), and Western (AREA='0400'). The OUTCONT= data set in [Output 11.2.2](#) gives the variable names for medical care related series.

The OUTALL= data set in [Output 11.2.3](#) indicates that data values are stored with one decimal place (see the NDEC variable). Therefore, they need to be rescaled, as follows:

```
data medical;
  set medical;
  medcare = medcare * 0.1;
run;
```

This example illustrates the following features:

- Descriptive information needed to write KEEP and WHERE statements can be obtained with an initial run of the DATASOURCE procedure.
- The OUTCONT= and OUTALL= data sets contain information on how data values are stored, such as the precision, the units, and so on.
- The OUTCONT= and OUTALL= data sets report the new series names assigned by the RE-NAME statement, not the old names (see the NAME variable in [Output 11.2.3](#)).
- You can use PROC FORMAT to define formats for series or BY variables to enhance your output. Note that PROC DATASOURCE associates a permanent format, \$AREAFMT., with the BY variable AREA. As a result, the formatted values are displayed in the printout of the OUTALL=MEDINFO data set (see [Output 11.2.3](#)).

Example 11.3: BLS State and Area Employment, Hours, and Earnings Surveys

This example illustrates how to extract specific series from a State and Area Employment, Hours, and Earnings Survey. The series to be extracted is total employment in real estate and construction industries with respect to states from March 1989 to March 1990.

The State and Area, Employment, Hours and Earnings survey designates the totals for statewide figures by AREA='0000'.

The data type code for total employment is reported to be 1. Therefore, the series name for this variable is SA1, since series names are constructed by adding an SA prefix to the data type codes given by BLS.

[Output 11.3.1](#) and [Output 11.3.2](#) show statewide figures for total employment (SA1) in many industries from March 1989 through March 1990.

```
filename ascifile "blseesa.dat" RECFM=F LRECL=152;

13	5	2580	7	0000	1	MAR1990	15

Note the following for this example:

- When the INFILE= option is omitted, the fileref assigned to the BLSEESA file is the default value DATAFILE.
- The FROM and TO values in the RANGE statement correspond to monthly data points since the INTERVAL= option defaults to MONTH for the BLSEESA filetype.

Example 11.4: DRI/McGraw-Hill Format CITIBASE Files

Output 11.4.1 and Output 11.4.2 illustrate how to extract weekly series from a sample CITIBASE file. They also demonstrate how the OUTSELECT= option affects the contents of the auxiliary data sets.

The weekly series contained in the sample data file CITIDEMO are listed by the following statements:

```
options yearcutoff=1920;
```

```

filename datafile "citidem.dat" RECFM=D LRECL=80;

proc datasource filetype=citibase interval=week
                outall=citiall outby=citikey;
run;

title1 'Summary Information on Weekly Data for CITIDEMO File';
proc print data=citikey;
run;

title1 'Weekly Series Available in CITIDEMO File';
proc print data=citiall( drop=label );
run;

```

Note the following from [Output 11.4.2](#):

- The OUTALL= data set reports the time ranges of variables.
- There are six observations in the OUTALL= data set, the same number as reported by NSERIES and NSELECT variables in the OUTBY= data set.
- The VARNUM variable contains all MISSING values, since no OUT= data set is created.

[Output 11.4.3](#) and [Output 11.4.4](#) demonstrate how the OUTSELECT= option affects the contents of the OUTBY= and OUTALL= data sets when a KEEP statement is present. First, set the OUTSELECT= option to OFF.

```

filename citidemo "citidem.dat" RECFM=D LRECL=80;

Comparison of [Output 11.4.4](#) and [Output 11.4.6](#) reveals the following:

- The OUTALL= data set contains 10 (NSERIES) observations when OUTSELECT=OFF, and three (NSELECT) observations when OUTSELECT=ON.
- The observations in OUTALL=ALLON are those for which SELECTED=1 in OUTALL=ALLOFF.
- The time ranges in the OUTBY= data set are computed over all the variables (selected or not) for OUTSELECT=OFF, but only computed over the selected variables for OUTSELECT=ON. This corresponds to computing time ranges over all the series reported in the OUTALL= data set.
- The variable NTIME is the number of time periods between ST_DATE and END_DATE, while NOBS is the number of observations the OUT= data set is to contain. Thus, NTIME is

different depending on whether the OUTSELECT= option is set to ON or OFF, while NOBS stays the same.

The KEEP statement in the last two examples illustrates the use of an additional variable, KEPT, in the OUTALL= data sets of [Output 11.4.4](#) and [Output 11.4.6](#). KEPT, which reports the outcome of the KEEP statement, is only added to the OUTALL= data set when there is KEEP statement.

Adding the RANGE statement to the last example generates the data sets in [Output 11.4.7](#) and [Output 11.4.8](#):

```
filename citidemo "citidem.dat" RECFM=D LRECL=80;
proc datasource filetype=citibase infile=citidemo interval=week
              outby=keyrange out=citiout outselect=on;
  keep WSP;;
  range from '01dec1990'd;
run;

title 'Summary Information on Weekly Data for CITIDEMO File';
proc print data=keyrange;
run;

title 'Weekly Data in CITIDEMO File';
proc print data=citiout;
run;
```

Output 11.4.7 Listing of the OUTBY=KEYRANGE Data Set for FILETYPE=CITIBASE

Daily Data in CITIDEMO File				
Obs	DATE	DSIUSNYSECM	DCP05	DCD1M
1	02DEC2019	142.900	6.81000	6.89000
2	03DEC2019	144.540	6.84000	6.85000
3	04DEC2019	144.820	6.79000	6.87000
4	05DEC2019	145.890	6.77000	6.88000
5	06DEC2019	137.030	6.73000	6.88000
6	09DEC2019	138.810	6.81000	6.89000
7	10DEC2019	137.740	6.73000	6.83000
8	11DEC2019	137.950	6.65000	6.80000
9	12DEC2019	137.970	6.67000	6.81000

The OUTBY= data set in this last example contains an additional variable NINRANGE. This variable is added since there is a RANGE statement. Its value, 15, is the number of observations in the OUT= data set. In this case, NOBS gives the number of observations the OUT= data set would contain if there were not a RANGE statement.

Example 11.5: DRI Data Delivery Service Database

This example demonstrates the DRIDDS filetype for the daily Federal Reserve Series fxrates_dds. Use VALIDVARNAME=ANY in your SAS options statement to allow special characters such as @, \$, and % to be in the series name. Note the use of long variable names in the OUT= data set in [Output 11.5.2](#) and long labels in the OUTCONT= data set in [Output 11.5.1](#).

The following statements extract daily series starting in January 1,1997:

```
options validvarname=any;
filename datafile "drifxrat.dat" RECFM=F LRECL=80;
proc format;
    value distekfm 0 = 'Unspecified'

Example 11.6: PC Format CITIBASE Database

This example uses a PC format CITIBASE database (FILETYPE=CITIDISK) to extract annual population estimates for females and males with respect to various age groups.

Population estimate series for all ages of females including those in the armed forces overseas are given by PANF, while PANM gives the population estimate for all ages of males including those in armed forces overseas. More population estimate time series are described in [Output 11.6.1](#) and are output in [Output 11.6.2](#).

The following statements extract the required population estimates series:

```
filename keyfile "basekey.dat" RECFM=V LRECL=22;
```

```

filename indfile "baseind.dat" RECFM=F LRECL=84;
filename dbfile "basedb.dat" RECFM=F LRECL=4;

proc datasource filetype=citidisk infile=( keyfile indfile dbfile )
      out=popest outall=popinfo;

run;

proc print data=popinfo;
run;
proc print data=popest;
run;

```

Output 11.6.1 Listing of the OUTALL=POPINFO Data Set for FILETYPE=CITIDISK

10	1989	248762	191570	153695	127317	121445

This example demonstrates the following:

- The INFILE= options lists the filerefs of the key, index, and database files, in that order.
- The INTERVAL= option is omitted since the default interval for CITIDISK type files is YEAR.

Example 11.7: Quarterly COMPUSTAT Data Files

This example shows how to extract data from a 48-quarter Compustat Database File. For COMPUSTAT data files, the series variable names are constructed by concatenating the name of the data array DATA and the column number containing the required information. For example, for quarterly files the common stock data is in column 56. Therefore, the variable name for this series is DATA56. Similarly, the series variable names for quarterly footnotes are constructed by adding the column number to the array name, QFTNT. For example, the variable name for common stock footnotes is QFTNT14 since the 14th column of the QFTNT array contains this information.

The following example extracts common stock series (DATA56) and its footnote (QFTNT14) for companies whose stocks are traded over-the-counter and not in the S&P 500 Index (ZLIST=06) and whose data reside in the over-the-counter file (FILE=06).

```
filename compstat "csqibm.dat" recfm=s370v lrecl=4820 blksize=14476;
proc datasource filetype=cs48qibm infile=compstat
    out=stocks outby=company;
    keep data56 qftnt14;
    rename data56=comstock qftnt14=ftcomstk;
    label data56='Common Stock'
          qftnt14='Footnote for Common Stock';
    range from 1990:4;

run;
```

```
/*- add company name to the out= data set */
data stocks;
  merge stocks company( keep=dnum cnum cic coname );
  by dnum cnum cic;
run;

title1 'Common Stocks for Last Quarter of 1990';
proc print data=stocks ;
run;
```

Output 11.7.1 contains a listing of the STOCKS data set.

Output 11.7.1 Listing of the OUT=STOCKS Data Set

Note that quarterly Compustat data are also available in Universal Character format. If you have this type of file instead of IBM 360/370 General format, use the FILETYPE=CS48QUC option instead.

Example 11.8: Annual COMPUSTAT Data Files, V9.2 New Filetype CSAUC3

Annual COMPUSTAT data in Universal Character format is read for PRICES since the year 2002, so that the desired output show the PRICE (HIGH), PRICE (LOW), and PRICE (CLOSE) for each company.

```
filename datafile "csaucy3.dat" RECFM=F LRECL=13612;
/*-----*
 * create OUT=csaucy3 data set with ASCII 2003 Industrial Data *
 * compare it with the OUT=csauc data set created by DATA STEP *
 *-----*/

proc datasource filetype=csaucy3 ascii
               infile=datafile
               interval=year
               outselect=on
               outkey=y3key
               out=csaucy3;

               keep data197-data199 label;
               range from 2002;
run;

Note that annual COMPUSTAT data are available in either IBM 360/370 General format or Universal Character format. The first example expects an IBM 360/370 General format file since the FILETYPE= is set to CSAIBM, while the second example uses a Universal Character format file (FILETYPE=CSAUC).

Example 11.9: CRSP Daily NYSE/AMEX Combined Stocks

This sample code reads all the data on a three-volume daily NYSE/AMEX combined character data set. Assume that the following filerefs are assigned to the calendar/indices file and security files that this database comprises:

Fileref	VOLSER	File Type
calfile	DXAA1	calendar/indices file on volume 1
secfile1	DXAA1	security file on volume 1
secfile2	DXAA2	security file on volume 2
secfile3	DXAA3	security file on volume 3

The data set CALDATA is created by the following statements to contain the calendar/indices file:

```
proc datasource filetype=crspdci infile=calfile out=caldata;
run;
```

Here the FILETYPE=CRSPDCI indicates that you are reading a character format (indicated by a C in the 6th position) daily (indicated by a D in the 5th position) calendar/indices file (indicated by an I in the 7th position).

The annual data in security files can be obtained by the following statements:

```
proc datasource filetype=crspdca
      infile=( secfile1 secfile2 secfile3 )
      out=annual;
run;
```

Similarly, the data sets to contain the daily security data (the OUT= data set) and the event data (the OUTEVENT= data set) are obtained by the following statements:

```
proc datasource filetype=crspdcs
      infile=( calfile secfile1 secfile2 secfile3 )
      out=periodic index outevent=events;
run;
```

Note that the FILETYPE= has an S in the 7th position, since you are reading the security files. Also, the INFILE= option first expects the fileref of the calendar/indices file since the dating variable (CALDT) is contained in that file. Following the fileref of calendar/indices file, you give the list of security files in the order in which you want to read them. When data span more than one physical volume, the filerefs of the security files residing on each volume must be given following the fileref of the calendar/indices file. The DATASOURCE procedure reads each of these files in the order in which they are specified. Therefore, you can request that all three volumes be mounted to the same drive, if you choose to do so.

This sample code illustrates the following points:

- The INDEX option in the second PROC DATASOURCE run creates an index file for the OUT=PERIODIC data set. This index file provides random access to the OUT= data set

and may increase the efficiency of the subsequent PROC and DATA steps that use BY and WHERE statements. The index variables are CUSIP, CRSP permanent number (PERMNO), NASDAQ company number (COMPNO), NASDAQ issue number (ISSUNO), header exchange code (HEXCD), and header SIC code (HSICCD). Each one of these variables forms a different key which is a single index. If you want to form keys from a combination of variables (composite indexes) or use some other variables as indexes, you should use the INDEX= data set option for the OUT= data set.

- The OUTEVENT=EVENTS data set is sparse. In fact, for each EVENT type, a unique set of event variables are defined. For example, for EVENT='SHARES', only the variables SHROUT and SHRFLG are defined, and they have missing values for all other EVENT types. Pictorially, this structure is similar to the data set shown in [Figure 11.4](#). Because of this sparse representation, you should create the OUTEVENT= data set only when you need a subset of securities and events.

By default, the OUT= data set contains only the periodic data. However, you may also want to include the event-oriented data in the OUT= data set. This is accomplished by listing the event variables together with periodic variables in a KEEP statement. For example, if you want to extract the historical CUSIP (NCUSIP), number of shares outstanding (SHROUT), and dividend cash amount (DIVAMT) together with all the periodic series, use the following statements.

```
proc datasource filetype=crspdc
    infile=( calfile secfile1 secfile2 secfile3 )
    out=both outevent=events;
    where cusip='09523220';
    keep bidlo askhi prc vol ret sxret bxret ncusip shrou t divamt;
run;
```

The KEEP statement has no effect on the event variables output to the OUTEVENT= data set. If you want to extract only a subset of event variables, you need to use the KEEPEVENT statement. For example, the following sample code outputs only NCUSIP and SHROUT to the OUTEVENT= data set for CUSIP='09523220':

```
proc datasource filetype=crspdc
    infile=( calfile secfile)
    outevent=subevts;
    where cusip='09523220';
    keepevent ncusip shrou t;
run;
```

[Output 11.9.1](#), [Output 11.9.2](#), [Output 11.9.3](#), and [Output 11.9.4](#) show how to read the CRSP Daily NYSE/AMEX Combined ASCII Character Files.

```
filename dxci "dxcca195.dat" RECFM=F LRECL=130;
filename dxc "dxcsu95.dat" RECFM=F LRECL=400;

/*--- create output data sets from character format DX files ---*/
/* create securities output data sets using DATASOURCE -----*/
/* statements                                                    -*/
proc datasource filetype=crspdc ascii
    infile=( dxci dxc )
```

```

Note in Output 11.9.4 that there were no events in range for cusip 35614220. See Chapter 33, “The SASECRSP Interface Engine,” for more on CRSPAccess Data access.

Data Elements Reference: DATASOURCE Procedure

PROC DATASOURCE can process only certain kinds of data files. For certain time series databases, the DATASOURCE procedure has built-in information on the layout of files composing the database. PROC DATASOURCE knows how to read only these kinds of data files. To access these databases, you must indicate the data file type in the FILETYPE= option. For more detailed information, see the corresponding document for each filetype. (See “References” on page 612.) The currently supported file types are summarized in Table 11.5.

Table 11.5 Supported File Types

Supplier	FILETYPE=	Description
BEA	BEANIPA	National Income and Product Accounts

Data supplier abbreviations used in [Table 11.5](#) are summarized in [Table 11.6](#).

Table 11.6 Data Supplier Abbreviations

Abbreviation	Supplier
BEA	Bureau of Economic Analysis, U.S. Department of Commerce
BLS	Bureau of Labor Statistics, U.S. Department of Labor
CRSP	Center for Research in Security Prices
DRI	Global Insight (formerly DRI/McGraw-Hill)
FAME	FAME Information Services, Inc.
GLOBAL INSIGHT	Global Insight, Inc.
HAYER	Haver Analytics Inc.
IMF	International Monetary Fund
OECD	Organization for Economic Cooperation and Development
S&P	Standard & Poor's Compustat Services Inc.

BEA Data Files

The Bureau of Economic Analysis, U.S. Department of Commerce, supplies national income, product accounting, and various other macroeconomic data at the regional, national, and international levels in the form of data files with various formats and on various media.

The following BEA data file types are supported.

FILETYPE=BEANIPA–National Income and Product Accounts Format

Table 11.7 FILETYPE=BEANIPA–National Income and Product Accounts Format

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	PARTNO	Part Number of Publication, Integer Portion of the Table Number, 1–9 (character)
	TABNUM	Table Number Within Part, Decimal Portion of the Table Number, 1–24 (character)
Series Variables	Series variable names are constructed by concatenating table number suffix, line and column numbers within each table. An underscore (_) prefix is also added for readability.	

FILETYPE=BEANIPAD–National Income and Product Accounts PC Format

The PC format National Income and Product Accounts files contain the same information as the BEANIPA files described previously.

Table 11.8 FILETYPE=BEANIPAD–National Income and Product Accounts PC Format

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	PARTNO	Part Number of Publication, Integer Portion of the Table Number, 1–9 (character)
	TABNUM	Table Number Within Part, Decimal Portion of the Table Number, 1–24 (character)

Table 11.8 (BEANIPAD–National Income and Product Accounts PC Format continued)

Metadata Field Types	Metadata Fields	Metadata Labels
Series Variables	Series variable names are constructed by concatenating table number suffix, line and column numbers within each table. An underscore (_) prefix is also added for readability.	

BLS Data Files

The Bureau of Labor Statistics, U.S. Department of Labor, compiles and distributes data on employment, expenditures, prices, productivity, injuries and illnesses, and wages.

The following BLS file types are supported.

FILETYPE=BLSCPI–Consumer Price Index Surveys (=CU,CW)

Table 11.9 FILETYPE=BLSCPI–Consumer Price Index Surveys (=CU,CW)

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR, SEMIYEAR1.6, MONTH (default)	
BY Variables	SURVEY	Survey type: CU=All Urban Consumers, CW=Urban Wage Earners and Clerical Workers (character)
	SEASON	Seasonality: S=Seasonally adjusted, U=Unadjusted (character)
	AREA	Geographic Area (character)
	BASPTYPE	Index Base Period Type, S=Standard, A=Alternate Reference (character)
	BASEPER	Index Base Period (character)
Series Variables	Series variable names are the same as consumer item codes listed in the Series Directory shipped with the data.	
Missing Codes	A data value of 0 is interpreted as MISSING.	

FILETYPE=BLSWPI–Producer Price Index Survey (WP)

Table 11.10 FILETYPE=BLSWPI–Producer Price Index Survey (WP)

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.

BY Variables	SEASON	Seasonality: S=Seasonally adjusted, U=Unadjusted (character)
	DIVISION	Major Industrial Division (character)
	INDUSTRY	Industry Code (character)
Sorting Order	BY SEASON DIVISION INDUSTRY	
Series Variables	Series variable names are the same as data type codes prefixed by EE.	
	EE01	Total Employment
	EE02	Employment of Women
	EE03	Employment of Production or Nonsupervisory Workers
	EE04	Average Weekly Earnings of Production Workers
	EE05	Average Weekly Hours of Production Workers
	EE06	Average Hourly Earnings of Production Workers
	EE07	Average Weekly Overtime Hours of Production Workers
	EE40	Index of Aggregate Weekly Hours
	EE41	Index of Aggregate Weekly Payrolls
	EE47	Hourly Earnings Index; 1977 Weights; Current Dollars
	EE48	Hourly Earnings Index; 1977 Weights; Base 1977 Dollars
	EE49	Average Hourly Earnings; Base 1977 Dollars
	EE50	Gross Average Weekly Earnings; Current Dollars
	EE51	Gross Average Weekly Earnings; Base 1977 Dollars
	EE52	Spendable Average Weekly Earnings; No Dependents; Current Dollars

Table 11.11 (BLSEENA–National Employment, Hours, and Earnings Survey Format continued)

Metadata Field Types	Metadata Fields	Metadata Labels
	EE53	Spendable Average Weekly Earnings; No Dependents; Base 1977 Dollars
	EE54	Spendable Average Weekly Earnings; 3 Dependents; Current Dollars
	EE55	Spendable Average Weekly Earnings; 3 Dependents; Base 1977 Dollars
	EE60	Average Hourly Earnings Excluding Overtime
	EE61	Index of Diffusion; 1-month Span; Base 1977
	EE62	Index of Diffusion; 3-month Span; Base 1977
	EE63	Index of Diffusion; 6-month Span; Base 1977
	EE64	Index of Diffusion; 12-month Span; Base 1977
Missing Codes	Series data values are set to MISSING when their status codes are 1.	

FILETYPE=BLSEESA–State and Area Employment, Hours, and Earnings Survey

Table 11.12 FILETYPE=BLSEESA–State and Area Employment, Hours, and Earnings Survey

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR, MONTH (default)	
BY Variables	STATE	State FIPS codes (numeric)
	AREA	Area codes (character)
	DIVISION	Major industrial division (character)
	INDUSTRY	Industry code (character)
	DETAIL	Private/Government detail
Sorting Order	BY STATE AREA DIVISION INDUSTRY DETAIL	
Series Variables	Series variable names are the same as data type codes prefixed by SA.	
	SA1	All employees
	SA2	Women workers
	SA3	Production workers
	SA4	Average weekly earnings
	SA5	Average weekly hours
Missing Codes	Series data values are set to MISSING when their status codes are 1.	

Global Insight DRI Data Files

The DRIBASIC (formerly CITIBASE) database contains economic and financial indicators of the U.S. and international economies gathered from various government and private sources by DRI/McGraw-Hill, Inc. There are over 8000 yearly, quarterly, monthly, weekly, and daily time

series.

Global Insight, formerly DRI/McGraw-Hill, distributes Basic Economic data files on various media. Old DRIDDS data files can be read by DATASOURCE using the DRIDDS filetype.

The following DRI file types are supported.

FILETYPE=DRIBASIC—Global Insight DRI Basic Economic Data Files

Table 11.13 FILETYPE=DRIBASIC—Global Insight DRI Basic Economic Data Files

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH, WEEK, WEEK1.1, WEEK1.2, WEEK1.3, WEEK1.4, WEEK1.5, WEEK1.6, WEEK1.7, WEEKDAY	
BY Variables	None	
Series Variables	Variable names are taken from the series descriptor records in the data file. Note that series codes can be 20 bytes.	
Missing Codes	MISSING=('1.000000E9'=, 'NA'-'ND'=,)	

Note that when you specify the INTERVAL=WEEK option, all the weekly series will be aggregated, and the DATE variable in the OUT= data set will be set to the date of Sundays. The date of first observation for each series is the Sunday marking the beginning of the week that contains the starting date of that variable.

FILETYPE=DRIDDS—Global Insight DRI Data Delivery Service Data Files

Table 11.14 FILETYPE=DRIDDS—Global Insight DRI Data Delivery Service Data Files

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), SEMIYEAR, QUARTER, MONTH, SEMI-MONTH, TENDAY, WEEK, WEEK1.1, WEEK1.2, WEEK1.3, WEEK1.4, WEEK1.5, WEEK1.6, WEEK1.7, WEEKDAY, DAY	
BY Variables	None	
Series Variables	Variable names are taken from the series descriptor records in the data file. Note that series names can be 24 bytes.	
Missing Codes	MISSING=('NA'-'ND'=,)	

FILETYPE=CITIOLD—Old Format CITIBASE Data Files

This file type is used for CITIBASE data distributed prior to May 1987.

Table 11.15 FILETYPE=CITIOLD—Old Format CITIBASE Data Files

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	None	
Series Variables	Variable names are taken from the series descriptor records in the data file and are the same as the series codes reported in the <i>CITIBASE Directory</i> .	
Missing Codes	1.0E9=.	

FILETYPE=CITIDISK—PC Format CITIBASE Databases

Table 11.16 FILETYPE=CITIDISK—PC Format CITIBASE Databases

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in groups of three associated files having the same filename but different extensions: KEY, IND, or DB. The INFILE= option should contain three filerefs in the following order: INFILE=(<i>keyfile indfile dbfile</i>).	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	None	
Series Variables	Series variable names are the same as series codes reported in the <i>CITIBASE Directory</i> .	
Missing Codes	1.0E9=.	

COMPUSTAT Data Files

COMPUSTAT data files, distributed by Standard & Poor's Compustat Services, Inc., consist of a collection of financial, statistical, and market information covering several thousand industrial and nonindustrial companies. Data are available in both an IBM 360/370 format and a "Universal Character" format, both of which further subdivide into annual and quarterly formats.

The BY variables are used to select individual companies or a group of companies. Individual companies can be selected by their unique six-digit CUSIP issuer code (CNUM). A number of specific groups of companies can be extracted by the following key fields:

FILE	specifies the file identification code used to group companies by files.
ZLIST	specifies the exchange listing code that can be used to group companies by exchange.
DNUM	is used to extract companies in a specific SIC industry group.

Series names are internally constructed from the data array names documented in the COMPUSTAT manual. Each column of data array is treated as a SAS variable. The names of these variables are generated by concatenating the corresponding column numbers to the array name.

Missing values use four codes. Missing code '.C' represents a combined figure where the data item has been combined into another data item, '.I' reports an insignificant figure, '.S' represents a semi-annual figure in the second and fourth quarters, '.A' represents an annual figure in the fourth quarter, and '.' indicates that the data item is not available. The missing codes '.C' and '.I' are not used for Aggregate or Prices, Dividends, and Earnings (PDE) files. The missing codes '.S' and '.A' are used only on the Industrial Quarterly File and not on the Aggregate Quarterly, Business Information, or PDE files.

CRSP Stock Files

The Center for Research in Security Prices provides comprehensive security price data through two primary stock files, the NYSE/AMEX file and the NASDAQ file. These files contain master and return components, available separately or combined. CRSP stock files are further differentiated by the frequency at which prices and returns are reported, daily or monthly. Both daily and monthly

files contain annual data fields.

CRSP data files are distributed in CRSPAccess format. See Chapter 33, “[The SASECRSP Interface Engine](#),” for more about accessing your CRSPAccess database. You can convert your CRSPAccess data to binary format (SFA format) by using the CRSP-supplied utility (STK_DUMP_BIN). Use the DATASOURCE procedure for SFA format access and use SASECRSP Interface for CRSPAccess.

CRSP stock data (in SFA format) are provided in two files, a main data file containing security information and a calendar/indices file containing a list of trading dates and market information associated with those trading dates.

The file types for CRSP stock files are constructed by concatenating CRSP with a D or M to indicate the frequency of data, followed by B, C, or I to indicate file formats. B is for host binary, C is for character, and I is for IBM binary formats. The last character in the file type indicates if you are reading the Calendar/Indices file (I), or if you are extracting the security (S) or annual data (A). For example, the file type for the daily NYSE/AMEX combined data in IBM binary format is CRSPDIS. Its calendar/indices file can be read by CRSPDII, and its annual data can be extracted by CRSPDIA.

Starting in 1995, binary data used split records (RICFAC=2), so the 1995 filetypes (CR95*) should be used for 1995 and 1996 binary data. If you use utility routines supplied by CRSP to convert a character format file to a binary format file on a given host, then you need to use host binary file types (RIDFAC=1) to read those files in. Note that you cannot do the conversion on one host and transfer and read the file on another host.

If you are using the CRSPAccess Database, you will need to use the utility routine (stk_dump_bin) supplied by CRSP to generate the UNIX binary format of the data. You can access the UNIX (or SUN) binary data by using PROC DATASOURCE with the CRSPDUS for daily or CRSPMUS for monthly stock data.

For the four-digit year data, use the Y2K-compliant filetypes for that data type.

For CRSP file types, the INFILE= option must be of the form

```
INFILE=( calfile security1 < security2 ... > )
```

where *calfile* is the fileref assigned to the calendar/indices file, and *security1 < security2 ... >* are the filerefs given to the security files, in the order in which they should be read.

FAME Information Services Databases

The DATASOURCE procedure provides access to FAME Information Services databases for UNIX-based systems only. For a more flexible FAME database access use the SASEFAME interface engine discussed in Chapter 34, “[The SASEFAME Interface Engine](#),” which is supported

for SAS 8.2 on Windows, Solaris2, AIX, and HP-UX hosts. SASEFAME for SAS 9 supports Windows, Solaris, AIX, and Linux.

The DATASOURCE interface to FAME requires a component supplied by FAME Information Services, Inc. Once this FAME component is installed on your system, you can use the DATASOURCE procedure to extract data from your FAME databases by giving the following specifications.

Specify FILETYPE=FAME in the PROC DATASOURCE statement and give the FAME database name to access with a DBNAME=*'fame-database'* option. The character string you specify in the DBNAME= option is passed through to FAME; specify the value of this option as you would in accessing the database from within FAME software.

Specify the output SAS data set to be created, the frequency of the series to be extracted, and other usual DATASOURCE procedure options as appropriate.

Specify the time range to extract with a RANGE statement. The RANGE statement is required when extracting series from FAME databases.

Name the FAME series to be extracted with a KEEP statement. The items in the KEEP statement are passed through to FAME software; therefore, you can use any valid FAME expression to specify the series to be extracted. Enclose in quotes any FAME series name or expression that is not a valid SAS name.

Name the SAS variable names you want to use for the extracted series in a RENAME statement. Give the FAME series name or expression (in quotes if needed) followed by an equal sign and the SAS name. The RENAME statement is not required; however, if the FAME series name is not a valid SAS variable name, the DATASOURCE procedure will construct a SAS name by translating and truncating the FAME series name. This process might not produce the desired name for the variable in the output SAS data set, so a rename statement could be used to produce a more appropriate variable name. The VALIDVARNAME=ANY option in your SAS options statement can be used to allow special characters in the SAS variable name.

For an alternative solution to PROC DATASOURCE's access to FAME, see "The SASEFAME Interface Engine" in Chapter 34, "[The SASEFAME Interface Engine](#)."

Haver Analytics Data Files

Haver Analytics offers a broad range of economic, financial, and industrial data for the United States and other countries. See “The SASEHAVR Interface Engine” in Chapter 35, “[The SASEHAVR Interface Engine](#),” for information about accessing your HAVR DLX database. SASEHAVR is supported on most Windows environments. Use the DATASOURCE procedure for serial access of

your data. The format of Haver Analytics data files is similar to the CITIBASE/DRIBASIC formats.

IMF Data Files

The International Monetary Fund's Economic Information System (EIS) offers subscriptions for their International Financial Statistics (IFS), Direction of Trade Statistics (DOTS), Balance of Payment Statistics (BOPS), and Government Finance Statistics (GFS) databases. The first three contain annual, quarterly, and monthly data, while the GFS file has only annual data.

PROC DATASOURCE supports only the packed format IMF data.

FILETYPE=IMFIFSP—International Financial Statistics, Packed Format

The IFS data files contain over 23,000 time series including interest and exchange rates, national income and product accounts, price and production indexes, money and banking, export commodity prices, and balance of payments for nearly 200 countries and regional aggregates.

Overview: ENTROPY Procedure

The ENTROPY procedure implements a parametric method of linear estimation based on generalized maximum entropy. The ENTROPY procedure is suitable when there are outliers in the data and robustness is required, when the model is ill-posed or under-determined for the observed data, or for regressions that involve small data sets.

The main features of the ENTROPY procedure are as follows:

- estimation of simultaneous systems of linear regression models
- estimation of Markov models
- estimation of seemingly unrelated regression (SUR) models
- estimation of unordered multinomial discrete Choice models
- solution of pure inverse problems
- allowance of bounds and restrictions on parameters
- performance of tests on parameters
- allowance of data and moment constrained generalized cross entropy

It is often the case that the statistical/economic model of interest is ill-posed or under-determined for the observed data. For the general linear model, this can imply that high degrees of collinearity exist among explanatory variables or that there are more parameters to estimate than observations available to estimate them. These conditions lead to high variances or non-estimability for traditional generalized least squares (GLS) estimates.

Under these situations it might be in the researcher's or practitioner's best interest to consider a nontraditional technique for model fitting. The principle of maximum entropy is the foundation for an estimation methodology that is characterized by its robustness to ill-conditioned designs and its ability to fit over-parameterized models. See Mittelhammer, Judge, and Miller (2000) and Golan, Judge, and Miller (1996) for a discussion of Shannon's maximum entropy measure and the related Kullback-Leibler information.

Generalized maximum entropy (GME) is a means of selecting among probability distributions to choose the distribution that maximizes uncertainty or uniformity remaining in the distribution, subject to information already known about the distribution. Information takes the form of data or moment constraints in the estimation procedure. PROC ENTROPY creates a GME distribution for each parameter in the linear model, based upon support points supplied by the user. The mean of each distribution is used as the estimate of the parameter. Estimates tend to be biased, as they are a type of shrinkage estimate, but typically portray smaller variances than ordinary least squares (OLS) counterparts, making them more desirable from a mean squared error viewpoint (see [Figure 12.1](#)).

Figure 12.1 Distribution of Maximum Entropy Estimates versus OLS

Maximum entropy techniques are most widely used in the econometric and time series fields. Some important uses of maximum entropy include the following:

- size distribution of firms
- stationary Markov Process
- social accounting matrix (SAM)
- consumer brand preference
- exchange rate regimes

- wage-dependent firm relocation
- oil market dynamics

Getting Started: ENTROPY Procedure

This section introduces the ENTROPY procedure and shows how to use PROC ENTROPY for several kinds of statistical analyses.

Simple Regression Analysis

The ENTROPY procedure is similar in syntax to the other regression procedures in SAS. To demonstrate the similarity, suppose the endogenous/dependent variable is y , and x_1 and x_2 are two exogenous/independent variables of interest. To estimate the parameters in this single equation model using PROC ENTROPY, use the following SAS statements:

```
proc entropy;
  model y = x1 x2;
run;
```

Test Scores Data Set

Consider the following test score data compiled by Coleman et al. (1966):

```
title "Test Scores compiled by Coleman et al. (1966)";
data coleman;
  input test_score 6.2 teach_sal 6.2 prcnt_prof 8.2
        socio_stat 9.2 teach_score 8.2 mom_ed 7.2;
  label test_score="Average sixth grade test scores in observed district";
  label teach_sal="Average teacher salaries per student (1000s of dollars)";
  label prcnt_prof="Percent of students' fathers with professional employment";
  label socio_stat="Composite measure of socio-economic status in the district";
  label teach_score="Average verbal score for teachers";
  label mom_ed="Average level of education (years) of the students' mothers";
datalines;

... more lines ...
```

This data set contains outliers, and the condition number of the matrix of regressors, \mathbf{X} , is large, which indicates collinearity among the regressors. Since the maximum entropy estimates are both robust with respect to the outliers and also less sensitive to a high condition number of the \mathbf{X} matrix, maximum entropy estimation is a good choice for this problem.

To fit a simple linear model to this data by using PROC ENTROPY, use the following statements:

```
proc entropy data=coleman;
  model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

This requests the estimation of a linear model for TEST_SCORE with the following form:

$$\text{test_score} = \text{intercept} + a * \text{teach_sal} + b * \text{prcnt_prof} + c * \text{socio_stat} \\ + d * \text{teach_score} + e * \text{mom_ed} + \epsilon;$$

This estimation produces the “Model Summary” table in [Figure 12.2](#), which shows the equation variables used in the estimation.

Figure 12.2 Model Summary Table

Test Scores compiled by Coleman et al. (1966)	
The ENTROPY Procedure	
Variables (Supports (Weights))	teach_sal prcnt_prof socio_stat teach_score mom_ed Intercept
Equations (Supports (Weights))	test_score

Since support points and prior weights are not specified in this example, they are not shown in the “Model Summary” table. The next four pieces of information displayed in [Figure 12.3](#) are: the “Data Set Options,” the “Minimization Summary,” the “Final Information Measures,” and the “Observations Processed.”

Figure 12.3 Estimation Summary Tables

Normed Entropy (Noise)	0.999786
Parameter Information Index	0.009024
Error Information Index	0.000214
Observations Processed	
Read	20
Used	20

The item labeled “Objective Function Value” is the value of the entropy estimation criterion for this estimation problem. This measure is analogous to the log-likelihood value in a maximum likelihood estimation. The “Parameter Information Index” and the “Error Information Index” are normalized entropy values that measure the proximity of the solution to the prior or target distributions.

The next table displayed is the ANOVA table, shown in Figure 12.4. This is in the same form as the ANOVA table for the MODEL procedure, since this is also a multivariate procedure.

Figure 12.4 Summary of Residual Errors

GME-NM Summary of Residual Errors							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj RSq
test_score	6	14	175.8	8.7881	2.9645	0.7266	0.6290

The last table displayed is the “Parameter Estimates” table, shown in Figure 12.5. The difference between this parameter estimates table and the parameter estimates table produced by other regression procedures is that the standard error and the probabilities are labeled as approximate.

Figure 12.5 Parameter Estimates

GME-NM Variable Estimates				
Variable	Estimate	Approx Std Err	t Value	Approx Pr > t
teach_sal	0.287979	0.00551	52.26	<.0001
prcnt_prof	0.02266	0.00323	7.01	<.0001
socio_stat	0.199777	0.0308	6.48	<.0001
teach_score	0.497137	0.0180	27.61	<.0001
mom_ed	1.644472	0.0921	17.85	<.0001
Intercept	10.5021	0.3958	26.53	<.0001

The parameter estimates produced by the REG procedure for this same model are shown in [Figure 12.6](#). Note that the parameters and standard errors from PROC REG are much different than estimates produced by PROC ENTROPY.

```
symbol v=dot h=1 c=green;

proc reg data=coleman;
  model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
  plot rstudent.*obs.
  / vref= -1.714 1.714 cvref=blue lvref=1
    HREF=0 to 30 by 5 cHREF=red cframe=ligr;
run;
```

Figure 12.6 REG Procedure Parameter Estimates

Test Scores compiled by Coleman et al. (1966)					
The REG Procedure					
Model: MODEL1					
Dependent Variable: test_score					
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	19.94857	13.62755	1.46	0.1653
teach_sal	1	-1.79333	1.23340	-1.45	0.1680
prcnt_prof	1	0.04360	0.05326	0.82	0.4267
socio_stat	1	0.55576	0.09296	5.98	<.0001
teach_score	1	1.11017	0.43377	2.56	0.0227
mom_ed	1	-1.81092	2.02739	-0.89	0.3868

This data set contains two outliers, observations 3 and 18. These can be seen in a plot of the residuals shown in [Figure 12.7](#)

Figure 12.7 PROC REG Residuals with Outliers

The presence of outliers suggests that a robust estimator such as M -estimator in the ROBUSTREG procedure should be used. The following statements use the ROBUSTREG procedure to estimate the model.

```
proc robustreg data=coleman;
  model test_score = teach_sal prcnt_prof
                socio_stat teach_score mom_ed;
run;
```

The results of the estimation are shown in Figure 12.8.

Figure 12.8 *M*-Estimation Results

Test Scores compiled by Coleman et al. (1966)							
The ROBUSTREG Procedure							
Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	29.3416	6.0381	17.5072	41.1761	23.61	<.0001
teach_sal	1	-1.6329	0.5465	-2.7040	-0.5618	8.93	0.0028
prcnt_prof	1	0.0823	0.0236	0.0361	0.1286	12.17	0.0005
socio_stat	1	0.6653	0.0412	0.5846	0.7461	260.95	<.0001
teach_score	1	1.1744	0.1922	0.7977	1.5510	37.34	<.0001
mom_ed	1	-3.9706	0.8983	-5.7312	-2.2100	19.54	<.0001
Scale	1	0.6966					

Note that TEACH_SAL(VAR1) and MOM_ED(VAR5) change greatly when the robust estimation is used. Unfortunately, these two coefficients are negative, which implies that the test scores increase with decreasing teacher salaries and decreasing levels of the mother's education. Since ROBUSTREG is robust to outliers, they are not causing the counterintuitive parameter estimates.

The condition number of the regressor matrix \mathbf{X} also plays an important role in parameter estimation. The condition number of the matrix can be obtained by specifying the COLLIN option in the PROC ENTROPY statement.

```
proc entropy data=coleman collin;
  model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

The output produced by the COLLIN option is shown in [Figure 12.9](#).

Figure 12.9 Collinearity Diagnostics

3	0.066023	8.6833	0.0202	0.3529	0.6159	0.0011
4	0.016036	17.6191	0.7961	0.0317	0.0534	0.0059
5	0.001364	60.4112	0.1619	0.3242	0.0053	0.7987
6	0.000691	84.8501	0.0205	0.2874	0.1096	0.1942

Collinearity Diagnostics					
Number	Eigenvalue	Condition Number	-Proportion of Variation-		
			mom_ed	Intercept	
1	4.978128	1.0000	0.0001	0.0000	
2	0.937758	2.3040	0.0000	0.0001	
3	0.066023	8.6833	0.0000	0.0003	
4	0.016036	17.6191	0.0083	0.0099	
5	0.001364	60.4112	0.3309	0.0282	
6	0.000691	84.8501	0.6607	0.9614	

The condition number of the \mathbf{X} matrix is reported to be 84.85. This means that the condition number of $\mathbf{X}'\mathbf{X}$ is $84.85^2 = 7199.5$, which is very large.

Ridge regression can be used to offset some of the problems associated with ill-conditioned \mathbf{X} matrices. Using the formula for the ridge value as

$$\lambda_R = \frac{kS^2}{\hat{\beta}'\hat{\beta}} \approx 0.9$$

where $\hat{\beta}$ and S^2 are the least squares estimators of β and σ^2 and $k = 6$. A ridge regression of the test score model was performed by using the data set with the outliers removed. The following PROC REG code performs the ridge regression:

```
data coleman;
  set coleman;
  if _n_ = 3 or _n_ = 18 then delete;
run;

proc reg data=coleman ridge=0.9 outest=t noprint;
  model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

```
proc print data=t;
run;
```

The results of the estimation are shown in Figure 12.10.

Figure 12.10 Ridge Regression Estimates

Test Scores compiled by Coleman et al. (1966)							
Obs	_MODEL_	_TYPE_	_DEPVAR_	_RIDGE_	_PCOMIT_	_RMSE_	Intercept
1	MODEL1	PARMS	test_score	.	.	0.78236	29.7577
2	MODEL1	RIDGE	test_score	0.9	.	3.19679	9.6698
Obs	teach_	prcnt_	socio_	teach_		test_	
	sal	prof	stat	score	mom_ed	score	
1	-1.69854	0.085118	0.66617	1.18400	-4.06675	-1	
2	-0.08892	0.041889	0.23223	0.60041	1.32168	-1	

Note that the ridge regression estimates are much closer to the estimates produced by the ENTROPY procedure that uses the original data set. Ridge regressions are not robust to outliers as maximum entropy estimates are. This might explain why the estimates still differ for TEACH_SAL.

Using Prior Information

You can use prior information about the parameters or the residuals to improve the efficiency of the estimates. Some authors prefer the terms *pre-sample* or *pre-data* over the term *prior* when used with maximum entropy to avoid confusion with Bayesian methods. The maximum entropy method described here does not use Bayes' rule when including prior information in the estimation.

To perform regression, the ENTROPY procedure uses a generalization of maximum entropy called *generalized maximum entropy*. In maximum entropy estimation, the unknowns are probabilities. Generalized maximum entropy expands the set of problems that can be solved by introducing the concept of *support points*. Generalized maximum entropy still estimates probabilities, but these are the probabilities of a support point. Support points are used to map the (0, 1) domain of the maximum entropy to the any finite range of values.

Prior information, such as expected ranges for the parameters or the residuals, is added by specifying support points for the parameters or the residuals. Support points are points in one dimension that specify the expected domain of the parameter or the residual. The wider the domain specified, the less efficient your parameter estimates are (the more variance they have). Specifying more support points in the same width interval also improves the efficiency of the parameter estimates at the cost of more computation. Golan, Judge, and Miller (1996) show that the gains in efficiency fall off for adding more than five support points. You can specify between 2 to 256 support points in the ENTROPY procedure.

If you have only a small amount of data, the estimates are very sensitive to your selection of support points and weights. For larger data sets, incorrect priors are discounted if they are not supported by the data.

Consider the data set generated by the following SAS statements:

```
data prior;
  do by = 1 to 100;
    do t = 1 to 10;
      y = 2*t + 5 * rannor(456);
      output;
    end;
  end;
run;
```

The PRIOR data set contains 100 samples of 10 observations each from the population

$$y = 2 * t + \epsilon$$

$$\epsilon \sim N(0, 5)$$

You can estimate these samples using PROC ENTROPY as

```
proc entropy data=prior outest=parml noprint;
  model y = t ;
  by by;
run;
```

The 100 estimates are summarized by using the following SAS statements:

```
proc univariate data=parml;
  var t;
run;
```

The summary statistics from PROC UNIVARIATE are shown in [Output 12.11](#). The true value of the coefficient T is 2.0, demonstrating that maximum entropy estimates tend to be biased.

Figure 12.11 No Prior Information Monte Carlo Summary

Test Scores compiled by Coleman et al. (1966)			
The UNIVARIATE Procedure			
Variable: t			
Basic Statistical Measures			
Location		Variability	
Mean	1.674802	Std Deviation	0.32418
Median	1.708554	Variance	0.10509
Mode	.	Range	1.80200
		Interquartile Range	0.34135

Now assume that you have prior information about the slope and the intercept for this model. You

are reasonably confident that the slope is 2 and you are less confident that intercept is zero. To specify prior information about the parameters, use the PRIORS statement.

There are two parts to the prior information specified in the PRIORS statement. The first part is the support points for a parameter. The support points specify the domain of the parameter. For example, the following statement sets the support points -1000 and 1000 for the parameter associated with variable T:

```
priors t -1000 1000;
```

This means that the coefficient lies in the interval $[-1000, 1000]$. If the estimated value of the coefficient is actually outside of this interval, the estimation will not converge. In the previous PRIORS statement, no weights were specified for the support points, so uniform weights are assumed. This implies that the coefficient has a uniform probability of being in the interval $[-1000, 1000]$.

The second part of the prior information is the weights on the support points. For example, the following statements sets the support points 10, 15, 20, and 25 with weights 1, 5, 5, and 1 respectively for the coefficient of T:

```
priors t 10(1) 15(5) 20(5) 25(1);
```

This creates the prior distribution on the coefficient shown in [Figure 12.12](#). The weights are automatically normalized so that they sum to one.

Figure 12.12 Prior Distribution of Parameter T

For the PRIOR data set created previously, the expected value of the coefficient of T is 2. The following SAS statements reestimate the parameters with a prior weight specified for each one.

```
proc entropy data=prior outest=parm2 noprint;
  priors t 0(1) 2(3) 4(1)
         intercept -100(.5) -10(1.5) 0(2) 10(1.5) 100(0.5);
  model y = t;
  by by;
run;
```

The priors on the coefficient of T express a confident view of the value of the coefficient. The priors on INTERCEPT express a more diffuse view on the value of the intercept. The following PROC UNIVARIATE statement computes summary statistics from the estimations:

```
proc univariate data=parm2;
  var t;
run;
```

The summary statistics for the distribution of the estimates of T are shown in [Figure 12.13](#).

Figure 12.13 Prior Information Monte Carlo Summary

Prior Distribution of Parameter T			
The UNIVARIATE Procedure			
Variable: t			
Basic Statistical Measures			
Location		Variability	
Mean	1.999872	Std Deviation	0.01404
Median	2.000952	Variance	0.0001972
Mode	.	Range	0.06807
		Interquartile Range	0.01641

The prior information improves the estimation of the coefficient of T dramatically. The downside of specifying priors comes when they are incorrect. For example, say the priors for this model were specified as

```
priors t -2(1) 0(3) 2(1);
```

to indicate a prior centered on zero instead of two.

The resulting summary statistics shown in [Figure 12.14](#) indicate how the estimation is biased away from the solution.

Figure 12.14 Incorrect Prior Information Monte Carlo Summary

Prior Distribution of Parameter T			
The UNIVARIATE Procedure			
Variable: t			
Basic Statistical Measures			
Location		Variability	
Mean	0.061016	Std Deviation	0.00942
Median	0.060133	Variance	0.0000888
Mode	.	Range	0.05650
		Interquartile Range	0.01158

The more data available for estimation, the less sensitive the parameters are to the priors. If the number of observations in each sample is 50 instead of 10, then the summary statistics shown in [Figure 12.15](#) are produced. The prior information is not supported by the data, so it is discounted.

Median	0.653486	Variance	0.0000870
Mode	.	Range	0.04351
		Interquartile Range	0.01498

Pure Inverse Problems

A special case of systems of equations estimation is the pure inverse problem. A pure problem is one that contains an exact relationship between the dependent variable and the independent variables and does not have an error component. A pure inverse problem can be written as

$$\mathbf{y} = \mathbf{X}\beta$$

where \mathbf{y} is a n -dimensional vector of observations, \mathbf{X} is a $n \times k$ matrix of regressors, and β is a k -dimensional vector of unknowns. Notice that there is no error term.

A classic example is a dice problem (Jaynes 1963). Given a six-sided die that can take on the values $x = 1, 2, 3, 4, 5, 6$ and the average outcome of the die $y = A$, compute the probabilities $\beta = (p_1, p_2, \dots, p_6)'$ of rolling each number. This infers six values from two pieces of information. The data points are the expected value of y , and the sum of the probabilities is one. Given $E(y) = 4.0$, this problem is solved by using the following SAS code:

```
data one;
  array x[6] ( 1 2 3 4 5 6 );
  y=4.0;
run;

proc entropy data=one pure;
  priors x1 0 1 x2 0 1 x3 0 1 x4 0 1 x5 0 1 x6 0 1;
  model y = x1-x6/ noint;
  restrict x1 + x2 +x3 +x4 + x5 + x6 =1;
run;
```

The probabilities are given in [Figure 12.16](#).

Figure 12.16 Jaynes' Dice Pure Inverse Problem

Prior Distribution of Parameter T			
The ENTROPY Procedure			
GME Variable Estimates			
Variable	Estimate	Information Index	Label
x1	0.101763	0.5254	
x2	0.122658	0.4630	
x3	0.147141	0.3974	
x4	0.175533	0.3298	
x5	0.208066	0.2622	
x6	0.244839	0.1970	
Restrict0	2.388082	.	x1 + x2 + x3 + x4 + x5 + x6 = 1

Note how the probabilities are skewed to the higher values because of the high average roll provided in the input data.

First-Order Markov Process Estimation

A more useful inverse problem is the first-order markov process. Companies have a share of the marketplace where they do business. Generally, customers for a specific market space can move from company to company. The movement of customers can be visualized graphically as a flow diagram, as in [Figure 12.17](#). The arrows represent movements of customers from one company to another.

Figure 12.17 Markov Transition Diagram

You can model the probability that a customer moves from one company to another using a first-order Markov model. Mathematically the model is:

$$y_t = P y_{t-1}$$

where y_t is a vector of k market shares at time t and P is a $k \times k$ matrix of unknown transition probabilities. The value p_{ij} represents the probability that a customer who is currently using company j at time $t - 1$ moves to company i at time t . The diagonal elements then represent the probability that a customer stays with the current company. The columns in P sum to one.

Given market share information over time, you can estimate the transition probabilities P . In order to estimate P using traditional methods, you need at least k observations. If you have fewer than k transitions, you can use the ENTROPY procedure to estimate the probabilities.

Suppose you are studying the market share for four companies. If you want to estimate the transition probabilities for these four companies, you need a time series with four observations of the shares. Assume the current transition probability matrix is as follows:

$$\begin{bmatrix} 0.7 & 0.4 & 0.0 & 0.1 \\ 0.1 & 0.5 & 0.4 & 0.0 \\ 0.0 & 0.1 & 0.6 & 0.0 \\ 0.2 & 0.0 & 0.0 & 0.9 \end{bmatrix}$$

The following SAS DATA step statements generate a series of market shares from this probability matrix. A transition is represented as the current period shares, y , and the previous period shares, x .

```

data m;
    /* Known Transition matrix */
    array p[4,4] (0.7 .4 .0 .1
                 0.1 .5 .4 .0
                 0.0 .1 .6 .0
                 0.2 .0 .0 .9 ) ;
    /* Initial Market shares */
    array y[4] y1-y4 ( .4 .3 .2 .1 );
    array x[4] x1-x4;
    drop p1-p16 i;
    do i = 1 to 3;
        x[1] = y[1]; x[2] = y[2];
        x[3] = y[3]; x[4] = y[4];
        y[1] = p[1,1] * x1 + p[1,2] * x2 + p[1,3] * x3 + p[1,4] * x4;
        y[2] = p[2,1] * x1 + p[2,2] * x2 + p[2,3] * x3 + p[2,4] * x4;
        y[3] = p[3,1] * x1 + p[3,2] * x2 + p[3,3] * x3 + p[3,4] * x4;
        y[4] = p[4,1] * x1 + p[4,2] * x2 + p[4,3] * x3 + p[4,4] * x4;
        output;
    end;
run;

```

The following SAS statements estimate the transition matrix by using only the first transition.

```

proc entropy markov pure data=m(obs=1);
    model y1-y4 = x1-x4;
run;

```

The MARKOV option implies NOINT for each model, that the sum of the parameters in each column is one, and chooses support points of 0 and 1. This model can be expressed equivalently as

```

proc entropy pure data=m(obs=1) ;
    priors y1.x1 0 1 y1.x2 0 1 y1.x3 0 1 y1.x4 0 1 ;
    priors y2.x1 0 1 y2.x2 0 1 y2.x3 0 1 y2.x4 0 1 ;
    priors y3.x1 0 1 y3.x2 0 1 y3.x3 0 1 y3.x4 0 1 ;
    priors y4.x1 0 1 y4.x2 0 1 y4.x3 0 1 y4.x4 0 1 ;

    model y1 = x1-x4 / noint;
    model y2 = x1-x4 / noint;
    model y3 = x1-x4 / noint;
    model y4 = x1-x4 / noint;

    restrict y1.x1 + y2.x1 + y3.x1 + y4.x1 = 1;
    restrict y1.x2 + y2.x2 + y3.x2 + y4.x2 = 1;
    restrict y1.x3 + y2.x3 + y3.x3 + y4.x3 = 1;
    restrict y1.x4 + y2.x4 + y3.x4 + y4.x4 = 1;
run;

```

The transition matrix is given in [Figure 12.18](#).

Figure 12.18 Estimate of P by Using One Transition

Prior Distribution of Parameter T		
The ENTROPY Procedure		
GME Variable Estimates		
Variable	Estimate	Information Index
y1.x1	0.463407	0.0039
y1.x2	0.41055	0.0232
y1.x3	0.356272	0.0605
y1.x4	0.302163	0.1161
y2.x1	0.272755	0.1546
y2.x2	0.271459	0.1564
y2.x3	0.267252	0.1625
y2.x4	0.260084	0.1731
y3.x1	0.119926	0.4709
y3.x2	0.148481	0.3940
y3.x3	0.180224	0.3194
y3.x4	0.214394	0.2502
y4.x1	0.143903	0.4056
y4.x2	0.169504	0.3434
y4.x3	0.196252	0.2856
y4.x4	0.223364	0.2337

Note that P varies greatly from the true solution.

If two transitions are used instead (OBS=2), the resulting transition matrix is shown in [Figure 12.19](#).

```
proc entropy markov pure data=m(obs=2);
  model y1-y4 = x1-x4;
run;
```

Figure 12.19 Estimate of P by Using Two Transitions

Prior Distribution of Parameter T		
The ENTROPY Procedure		
GME Variable Estimates		
Variable	Estimate	Information Index
y1.x1	0.721012	0.1459
y1.x2	0.355703	0.0609
y1.x3	0.026095	0.8256
y1.x4	0.096654	0.5417
y2.x1	0.083987	0.5839
y2.x2	0.53886	0.0044
y2.x3	0.373668	0.0466
y2.x4	0.000133	0.9981
y3.x1	0.000062	0.9990
y3.x2	0.099848	0.5315
y3.x3	0.600104	0.0291
y3.x4	7.871E-8	1.0000
y4.x1	0.194938	0.2883
y4.x2	0.00559	0.9501
y4.x3	0.000133	0.9981
y4.x4	0.903214	0.5413

This transition matrix is much closer to the actual transition matrix.

If, in addition to the transitions, you had other information about the transition matrix, such as your own company's transition values, that information can be added as restrictions to the parameter estimates. For noisy data, the PURE option should be dropped. Note that this example has six zero probabilities in the transition matrix; the accurate estimation of transition matrices with fewer zero probabilities generally requires more transition observations.

Analyzing Multinomial Response Data

Multinomial discrete choice models suffer the same problems with collinearity of the regressors and small sample sizes as linear models. Unordered multinomial discrete choice models can be estimated using a variant of GME for discrete models called GME-D.

Consider the model shown in Golan, Judge, and Perloff (1996). In this model, there are five occupational categories, and the categories are considered a function of four individual characteristics. The sample contains 337 individuals.

```
data kpdata;
  input job x1 x2 x3 x4;
datalines;

... more lines ...
```

The dependent variable in this data, job, takes on values 0 through 4. Support points are used only for the error terms; so error supports are specified on the MODEL statement.

```
proc entropy data=kpdata gmed tech=nra;
  model job = x1 x2 x3 x4 / noint
        esupports=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 );
run;
```

Figure 12.20 Estimate of Jobs Model by Using GME-D

Prior Distribution of Parameter T				
The ENTROPY Procedure				
GME-D Variable Estimates				
Variable	Estimate	Approx Std Err	t Value	Approx Pr > t
x1_1	1.885831	1.3463	1.40	0.1622
x2_1	-0.00308	0.0152	-0.20	0.8400
x3_1	-0.17823	0.0872	-2.04	0.0418
x4_1	1.03477	0.6952	1.49	0.1376
x1_2	0.187073	1.2612	0.15	0.8822
x2_2	0.019307	0.0144	1.34	0.1804
x3_2	0.003994	0.0817	0.05	0.9611
x4_2	0.269913	0.5747	0.47	0.6389
x1_3	-4.47704	1.6245	-2.76	0.0062
x2_3	0.025457	0.0164	1.55	0.1214
x3_3	0.235925	0.0969	2.43	0.0155
x4_3	1.25614	0.8294	1.51	0.1308
x1_4	-9.56275	1.5573	-6.14	<.0001
x2_4	0.026694	0.0154	1.73	0.0840
x3_4	0.650215	0.0930	6.99	<.0001
x4_4	1.444471	0.6912	2.09	0.0374

Note there are five estimates of the parameters produced for each regressor, one for each choice. The first choice is restricted to zero for normalization purposes. PROC ENTROPY drops the zeroed regressors. PROC ENTROPY also generates tables of marginal effects for each regressor. The following statements generate the marginal effects table for the previous analysis at the means of the variables.

```
proc entropy data=kpdata gmed tech=nra;
  model job = x1 x2 x3 x4 / noint
        esupports=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 )
        marginals;
run;
```

Figure 12.21 Estimate of Jobs Model by Using GME-D (Marginals)

Prior Distribution of Parameter T		
The ENTROPY Procedure		
GME-D Variable Marginal Effects Table		
Variable	Marginal Effect	Mean
x1_0	0.331414	1
x2_0	-0.00186	20.50148
x3_0	-0.02079	13.09496
x4_0	-0.09815	0.916914
x1_1	0.853981	1
x2_1	-0.00343	20.50148
x3_1	-0.0644	13.09496
x4_1	0.034867	0.916914
x1_2	0.853874	1
x2_2	0.000952	20.50148
x3_2	-0.04913	13.09496
x4_2	-0.16118	0.916914
x1_3	-0.25376	1
x2_3	0.001479	20.50148
x3_3	0.008944	13.09496
x4_3	0.064326	0.916914
x1_4	-1.78551	1
x2_4	0.00286	20.50148
x3_4	0.125377	13.09496
x4_4	0.160136	0.916914

The marginals are derivatives of the probabilities with respect to each variable and so summarize how a small change in each variable affects the overall probability.

PROC ENTROPY also enables the user to specify where the derivative is evaluated, as shown below:

```
proc entropy data=kpdata gmed tech=nra;
  model job = x1 x2 x3 x4 / noint
    esupports=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 )
    marginals=( x2=.4 x3=10 x4=0);
run;
```

Figure 12.22 Estimate of Jobs Model by Using GME-D (Marginals)

Prior Distribution of Parameter T				
The ENTROPY Procedure				
GME-D Variable Marginal Effects Table				
Variable	Marginal Effect	Mean	Marginal Effect at User Supplied Values	User Supplied Values
x1_0	0.331414	1	-0.10594	1
x2_0	-0.00186	20.50148	-0.00202	0.4
x3_0	-0.02079	13.09496	0.010599	10
x4_0	-0.09815	0.916914	-0.13625	0
x1_1	0.853981	1	0.472546	1
x2_1	-0.00343	20.50148	-0.0032	0.4
x3_1	-0.0644	13.09496	-0.04401	10
x4_1	0.034867	0.916914	0.172753	0
x1_2	0.853874	1	-0.06716	1
x2_2	0.000952	20.50148	0.004337	0.4
x3_2	-0.04913	13.09496	0.014829	10
x4_2	-0.16118	0.916914	-0.07592	0
x1_3	-0.25376	1	-0.16652	1
x2_3	0.001479	20.50148	0.000628	0.4
x3_3	0.008944	13.09496	0.009385	10
x4_3	0.064326	0.916914	0.026551	0
x1_4	-1.78551	1	-0.13292	1
x2_4	0.00286	20.50148	0.000261	0.4
x3_4	0.125377	13.09496	0.009199	10
x4_4	0.160136	0.916914	0.012866	0

In this example, you evaluate the derivative when $x1=1$, $x2=0.4$, $x3=10$, and $x4=0$. If the user neglects a variable, PROC ENTROPY uses its mean value.

Syntax: ENTROPY Procedure

The following statements can be used with the ENTROPY procedure:

```

PROC ENTROPY options ;
  BOUNDS bound1 < , bound2, ... > ;
  BY variable < variable ... > ;
  ID variable < variable ... > ;
  MODEL variable = variable < variable > ... < / options > ;
  PRIORS variable < support points > variable < value > ... ;
  RESTRICT restriction1 < , restriction2 ... > ;
  TEST < "name" > test1 < , test2 ... > < / options > ;
  WEIGHT variable ;

```

Functional Summary

The statements and options in the ENTROPY procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set for the variables	ENTROPY	DATA=
specify the input data set for support points and priors	ENTROPY	PDATA=
specify the output data set for residual, predicted, and actual values	ENTROPY	OUT=
specify the output data set for the support points and priors	ENTROPY	OUTP=
write the covariance matrix of the estimates to OUTEST= data set	ENTROPY	OUTCOV
write the parameter estimates to a data set	ENTROPY	OUTEST=
write the Lagrange multiplier estimates to a data set	ENTROPY	OUTL=
write the covariance matrix of the equation errors to a data set	ENTROPY	OUTS=
write the S matrix used in the objective function definition to a data set	ENTROPY	OUTSUSED=
read the covariance matrix of the equation errors	ENTROPY	SDATA=
Printing Options		
request that the procedure produce graphics via the Output Delivery System	ENTROPY	PLOTS=
print collinearity diagnostics	ENTROPY	COLLIN
suppress the normal printed output	ENTROPY	NOPRINT
Options to Control Iteration Output		
print a summary iteration listing	ENTROPY	ITPRINT

Description	Statement	Option
Options to Control the Minimization Process		
specify the convergence criteria	ENTROPY	CONVERGE=
specify the maximum number of iterations allowed	ENTROPY	MAXITER=
specify the maximum number of subiterations allowed	ENTROPY	MAXSUBITER=
select the iterative minimization method to use	ENTROPY	METHOD=
Statements That Declare Variables		
specify BY-group processing	BY	
specify a weight variable	WEIGHT	
specify identifying variables	ID	
General PROC ENTROPY Statement Options		
specify seemingly unrelated regression	ENTROPY	SUR
specify iterated seemingly unrelated regression	ENTROPY	ITSUR
specify data-constrained generalized maximum entropy	ENTROPY	GME
specify normed moment generalized maximum entropy	ENTROPY	GMENM
specify the denominator for computing variances and covariances	ENTROPY	VARDEF=
General TEST Statement Options		
specify that a Wald test be computed	TEST	WALD
specify that a Lagrange multiplier test be computed	TEST	LM
specify that a likelihood ratio test be computed	TEST	LR
request all three types of tests	TEST	ALL

PROC ENTROPY Statement

PROC ENTROPY *options* ;

The following options can be specified in the PROC ENTROPY statement.

General Options

COLLIN

requests that the collinearity diagnostics of the $X'X$ matrix be printed.

COVBEST=CROSS | GME | GMENM

specifies the method for producing the covariance matrix of parameters for output and for standard error calculations. GMENM and GME are aliases and are the default.

GME | GCE

requests generalized maximum entropy or generalized cross entropy. This is the default estimation method.

GMENM | GCENM

requests normed moment maximum entropy or the normed moment cross entropy.

GMED

requests a variant of GME suitable for multinomial discrete choice models.

MARKOV

specifies that the model is a first-order Markov model.

PURE

specifies a regression without an error term.

SUR | ITSUR

specifies seemingly unrelated regression or iterated seemingly unrelated regression.

VARDEF=N | WGT | DF | WDF

specifies the denominator to be used in computing variances and covariances. VARDEF=N specifies that the number of nonmissing observations be used. VARDEF=WGT specifies that the sum of the weights be used. VARDEF=DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used. VARDEF=WDF specifies that the sum of the weights minus the model degrees of freedom be used. The default is VARDEF=DF.

Data Set Options

DATA=SAS-data-set

specifies the input data set. Values for the variables in the model are read from this data set.

PDATA=SAS-data-set

names the SAS data set that contains the data about priors and supports.

OUT=SAS-data-set

names the SAS data set to contain the residuals from each estimation.

OUTCOV**COVOUT**

writes the covariance matrix of the estimates to the OUTEST= data set in addition to the parameter estimates. The OUTCOV option is applicable only if the OUTEST= option is also specified.

OUTEST=SAS-data-set

names the SAS data set to contain the parameter estimates and optionally the covariance of the estimates.

OUTL=SAS-data-set

names the SAS data set to contain the estimated Lagrange multipliers for the models.

OUTP=SAS-data-set

names the SAS data set to contain the support points and estimated probabilities.

OUTS=SAS-data-set

names the SAS data set to contain the estimated covariance matrix of the equation errors. This is the covariance of the residuals computed from the parameter estimates.

OUTSUSED=SAS-data-set

names the SAS data set to contain the **S** matrix used in the objective function definition. The OUTSUSED= data set is the same as the OUTS= data set for the methods that iterate the **S** matrix.

SDATA=SAS-data-set

specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation error covariance matrix (**S** matrix) in the estimation. The SDATA= matrix is used to provide only the initial estimate of **S** for the methods that iterate the **S** matrix.

Printing Options

ITPRINT

prints the parameter estimates, objective function value, and convergence criteria at each iteration.

NOPRINT

suppresses the normal printed output but does not suppress error listings. Using any other print option turns the NOPRINT option off.

PLOTS=global-plot-options | plot-request

requests that the ENTROPY procedure produce statistical graphics via the Output Delivery System, provided that the ODS GRAPHICS statement has been specified. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*). The *global-plot-options* apply to all relevant plots generated by the ENTROPY procedure.

The *global-plot-options* supported by the ENTROPY procedure are as follows:

ONLY	suppresses the default plots. Only the plots specifically requested are produced.
UNPACKPANEL	breaks a graphic that is otherwise paneled into individual component plots.

The specific *plot-request* values supported by the ENTROPY procedure are as follows:

ALL	requests that all plots appropriate for the particular analysis be produced. ALL is equivalent to specifying FITPLOT, COOKSD, QQ, RESIDUALHISTOGRAM, and STUDENTRESIDUAL.
FITPLOT	plots the predicted and actual values.
COOKSD	produces the Cook's <i>D</i> plot.
QQ	produces a Q-Q plot of residuals.
RESIDUALHISTOGRAM	plots the histogram of residuals.
STUDENTRESIDUAL	plots the studentized residuals.
NONE	suppresses all plots.

When ODS graphics are enabled, the default behavior is to plot all plots appropriate for the particular analysis (ALL) in a panel.

Options to Control the Minimization Process

The following options can be helpful if a convergence problem occurs for a given model and set of data. The ENTROPY procedure uses the nonlinear optimization subsystem (NLO) to perform the model optimizations. In addition to the options listed below, all options supported in the NLO subsystem can be specified on the ENTROPY procedure statement. See Chapter 6, “[Nonlinear Optimization Methods](#),” for more details.

CONVERGE=*value*

GCONV=*value*

specifies the convergence criteria for *S*-iterated methods. The convergence measure computed during model estimation must be less than *value* before convergence is assumed. The default value is CONVERGE=0.001.

DUAL | PRIMAL

specifies whether the optimization problem is solved using the dual or primal form. The dual form is the default.

MAXITER=*n*

specifies the maximum number of iterations allowed. The default is MAXITER=100.

MAXSUBITER=*n*

specifies the maximum number of subiterations allowed for an iteration. The MAXSUBITER= option limits the number of step halvings. The default is MAXSUBITER=30.

METHOD=TR | NEWRAP | NRR | QN | CONGR | NSIMP | DBLDOG | LEVMAR

TECHNIQUE=TR | NEWRAP | NRR | QN | CONGR | NSIMP | DBLDOG | LEVMAR

TECH=TR | NEWRAP | NRR | QN | CONGR | NSIMP | DBLDOG | LEVMAR

specifies the iterative minimization method to use. METHOD=TR specifies the trust region method, METHOD=NEWRAP specifies the Newton-Raphson method, METHOD=NRR specifies the Newton-Raphson ridge method, and METHOD=QN specifies the quasi-Newton method. See Chapter 6, “[Nonlinear Optimization Methods](#),” for more details about optimization methods. The default is METHOD=QN for the dual form and METHOD=NEWRAP for the primal form.

BOUNDS Statement

BOUNDS *bound1* <, *bound2* ... > ;

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the ENTROPY procedure. You can specify any number of BOUNDS statements.

Each *boundary constraint* is composed of variables, constants, and inequality operators in the following form:

item operator item <, **operator item** <, **operator item** ... > >

Each *item* is a constant, the name of a regressor variable, or a list of regressor names. Each *operator* is <, >, <=, or >=.

You can use either the BOUNDS statement or the RESTRICT statement to impose boundary constraints; the BOUNDS statement provides a simpler syntax for specifying inequality constraints. See section “[RESTRICT Statement](#)” on page 648 for more information about the computational details of estimation with inequality restrictions.

Lagrange multipliers are reported for all the active boundary constraints. In the printed output and in the OUTEST= data set, the Lagrange multiplier estimates are identified with the names BOUND1, BOUND2, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive or nonbinding bounds have no effect on the estimation results and are not noted in the output. To give the constraints more descriptive names, use the RESTRICT statement instead of the BOUNDS statement.

The following BOUNDS statement constrains the estimates of the coefficients of WAGE and TARGET and the 10 coefficients of x_1 through x_{10} to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < wage target x1-x10 < 1;
```

The following is an example of the use of the BOUNDS statement to impose boundary constraints on the variables X1, X2, and X3:

```

proc entropy data=zero;
  bounds .1 <= x1 <= 100,
         0 <= x2 <= 25.6,
         0 <= x3 <= 5;

  model y = x1 x2 x3;
run;

```

The parameter estimates from this run are shown in [Figure 12.23](#).

Figure 12.23 Output from Bounded Estimation

```

x1	0.1	0	.	.	
x2	0	0	.	.	
x3	3.33E-16	0	.	.	
Intercept	-0.00432	3.406E-6	-1269.3	<.0001	
	1.25731	9130.3	0.00	0.9999	0.1 <= x1
	0.009384	0	.	.	0 <= x2
	0.000025	0	.	.	0 <= x3

BY Statement

BY *variables* ;

A BY statement is used to obtain separate estimates for observations in groups defined by the BY variables. To save parameter estimates for each BY group, use the OUTEST= option.

ID Statement

ID *variables* ;

The ID statement specifies variables to identify observations in error messages or other listings and in the OUT= data set. The ID variables are normally SAS date or datetime variables. If more than one ID variable is used, the first variable is used to identify the observations and the remaining variables are added to the OUT= data set.

MODEL Statement

MODEL *dependent = regressors < / options >* ;

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. If no independent variables are specified in the MODEL statement, only the mean

(intercept) is estimated. To model a system of equations, specify more than one MODEL statement.

The following options can be used in the MODEL statement after a slash (/).

ESUPPORTS=(*support (prior) . . .*)

specifies the support points and prior weights on the residuals for the specified equation. The default is the following five support values:

$$-10 * value, -value, 0, value, 10 * value$$

where *value* is computed as

$$value = (max(y) - \bar{y}) * multiplier$$

for GME, where *y* is the dependent variable, and

$$value = (max(y) - \bar{y}) * multiplier * nobs * max(X) * 0.1$$

for generalized maximum entropy—normed moments (GME-NM), where **X** is the information matrix, and *nobs* is the number of observations. The *multiplier* depends on the MULTIPLIER= option. The MULTIPLIER= option defaults to 2 for unrestricted models and to 4 for restricted models. The prior probabilities default to the following:

$$0.0005, 0.333, 0.333, 0.333, 0.0005$$

The support points and prior weights are selected so that hypothesis tests can be performed without adding significant bias to the estimation. These prior probability values are ad hoc.

NOINT

suppresses the intercept parameter.

MARGINALS = (*variable = value, . . . , variable = value*)

requests that the marginal effects of each variable be calculated for GME-D. Specifying the MARGINALS option with an optional list of values calculates the marginals at that vector of values. For example, if *x1–x4* are explanatory variables, then including

$$MARGINALS = (x1 = 2, x2 = 4, x3 = -1, x4 = 5)$$

calculates the marginal effects at that vector. A skipped variable implies that its mean value is to be used.

CENSORED ((*UB | LB*) = (*variable | value*), **ESUPPORTS** = (*support (prior) . . .*))

specifies that the dependent variable be observed with censoring and specifies the censoring thresholds and the supports of the censored observations.

CATEGORY= *variable*

specifies the variable that keeps track of the categories the dependent variable is in when there is range censoring. When the actual value is observed, this variable should be set to MISSING.

RANGE (ID = (QS | INT) L = (NUMBER) R = (NUMBER) , ESUPPORTS=(support < (prior) > ...))

specifies that the dependent variable be range bound. The RANGE option defines the range and the key (RANGE) that is used to identify the observation as being range bound. The RANGE = value should be some value in the CATEGORY= variable. The L and R define, respectively, the left endpoint of the range and the right endpoint of the range. ESUPPORTS sets the error supports on the variable.

PRIORS Statement

PRIORS *variable* < support points < (priors) >> *variable* < support points < (priors) >> ... ;

The PRIORS statement specifies the support points and prior weights for the coefficients on the variables.

Support points for coefficients default to five points, determined as follows:

$$-2 * value, -value, 0, value, 2 * value$$

where *value* is computed as

$$value = (\|mean\| + 3 * stderr) * multiplier$$

where the *mean* and the *stderr* are obtained from OLS and the *multiplier* depends on the MULTIPLIER= option. The MULTIPLIER= option defaults to 2 for unrestricted models and to 4 for restricted models. The prior probabilities for each support point default to the uniform distribution.

The number of support points must be at least two. If priors are specified, they must be positive and there must be the same number of priors as there are support points. Priors and support points can also be specified through the PDATA= data set.

RESTRICT Statement

RESTRICT *restriction1* < , *restriction2* ... > ;

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an optional name, followed by an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

<"name" > **expression operator expression**

The optional "name" is a string used to identify the restriction in the printed output and in the OUTEST= data set. The *operator* can be =, <, >, <=, or >=. The operator and second expression are optional, as in the TEST statement, where they default to = 0.

Restriction expressions can be composed of variable names, multiplication (*), and addition (+) operators, and constants. Variable names in restriction expressions must be among the variables whose coefficients are estimated by the model. The restriction expressions must be a linear function of the variables.

The following is an example of the use of the RESTRICT statement:

```
proc entropy data=one;
  restrict y1.x1*2 <= x2 + y2.x1;
  model y1 = x1 x2;
  model y2 = x1 x3;
run;
```

This example illustrates the use of compound names, `y1.x1`, to specify coefficients of specific equations.

TEST Statement

TEST < "name" > *test1* < , *test2* ... > < ,/ options > ;

The TEST statement performs tests of linear hypotheses on the model parameters.

The TEST statement applies only to parameters estimated in the model. You can specify any number of TEST statements.

Each *test* is written as an expression optionally followed by an equal sign (=) and a second expression:

expression <= **expression**>

Test expressions can be composed of variable names, multiplication (*), addition (+), and subtraction (−) operators, and constants. Variables named in test expressions must be among the variables estimated by the model.

If you specify only one expression in a TEST statement, that expression is tested against zero. For example, the following two TEST statements are equivalent:

```
test a + b;

test a + b = 0;
```

When you specify multiple tests on the same TEST statement, a joint test is performed. For example, the following TEST statement tests the joint hypothesis that both of the coefficients on *a* and *b* are equal to zero:

```
test a, b;
```

To perform separate tests rather than a joint test, use separate TEST statements. For example, the following TEST statements test the two separate hypotheses that a is equal to zero and that b is equal to zero:

```
test a;
test b;
```

You can use the following options in the TEST statement:

WALD

specifies that a Wald test be computed. WALD is the default.

LM

RAO

LAGRANGE

specifies that a Lagrange multiplier test be computed.

LR

LIKE

specifies that a pseudo-likelihood ratio test be computed.

ALL

requests all three types of tests.

OUT=

specifies the name of an output SAS data set that contains the test results. The format of the OUT= data set produced by the TEST statement is similar to that of the OUTEST= data set.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters.

If the weight of an observation is nonpositive, that observation is not used for the estimation. *Variable* must be a numeric variable in the input data set. The regressors and the dependent variables are multiplied by the square root of the weight variable to form the weighted **X** matrix and the weighted dependent variable. The same weight is used for all MODEL statements.

Details: ENTROPY Procedure

Shannon's measure of entropy for a distribution is given by

$$\begin{aligned} \text{maximize} \quad & -\sum_{i=1}^n p_i \ln(p_i) \\ \text{subject to} \quad & \sum_{i=1}^n p_i = 1 \end{aligned}$$

where p_i is the probability associated with the i th support point. Properties that characterize the entropy measure are set forth by Kapur and Kesavan (1992).

The objective is to maximize the entropy of the distribution with respect to the probabilities p_i and subject to constraints that reflect any other known information about the distribution (Jaynes 1957). This measure, in the absence of additional information, reaches a maximum when the probabilities are uniform. A distribution other than the uniform distribution arises from information already known.

Generalized Maximum Entropy

Reparameterization of the errors in a regression equation is the process of specifying a support for the errors, observation by observation. If a two-point support is used, the error for the t th observation is reparameterized by setting $e_t = w_{t1} v_{t1} + w_{t2} v_{t2}$, where v_{t1} and v_{t2} are the upper and lower bounds for the t th error e_t , and w_{t1} and w_{t2} represent the weight associated with the point v_{t1} and v_{t2} . The error distribution is usually chosen to be symmetric, centered around zero, and the same across observations so that $v_{t1} = -v_{t2} = R$, where R is the support value chosen for the problem (Golan, Judge, and Miller 1996).

The generalized maximum entropy (GME) formulation was proposed for the ill-posed or underdetermined case where there is insufficient data to estimate the model with traditional methods. β is reparameterized by defining a support for β (and a set of weights in the cross entropy case), which defines a prior distribution for β .

In the simplest case, each β_k is reparameterized as $\beta_k = p_{k1} z_{k1} + p_{k2} z_{k2}$, where p_{k1} and p_{k2} represent the probabilities ranging from $[0,1]$ for each β , and z_{k1} and z_{k2} represent the lower and upper bounds placed on β_k . The support points, z_{k1} and z_{k2} , are usually distributed symmetrically around the most likely value for β_k based on some prior knowledge.

With these reparameterizations, the GME estimation problem is

$$\begin{aligned} &\text{maximize} && H(p, w) = -p' \ln(p) - w' \ln(w) \\ &\text{subject to} && y = X Z p + V w \\ &&& 1_K = (I_K \otimes 1'_L) p \\ &&& 1_T = (I_T \otimes 1'_L) w \end{aligned}$$

where y denotes the column vector of length T of the dependent variable; X denotes the $(T \times K)$ matrix of observations of the independent variables; p denotes the LK column vector of weights associated with the points in Z ; w denotes the LT column vector of weights associated with the points in V ; 1_K , 1_L , and 1_T are K -, L -, and T -dimensional column vectors, respectively, of ones; and I_K and I_T are $(K \times K)$ and $(T \times T)$ dimensional identity matrices.

These equations can be rewritten using set notation as follows:

$$\begin{aligned} &\text{maximize} && H(p, w) = - \sum_{l=1}^L \sum_{k=1}^K p_{kl} \ln(p_{kl}) - \sum_{l=1}^L \sum_{t=1}^T w_{tl} \ln(w_{tl}) \\ &\text{subject to} && y_t = \sum_{l=1}^L \left[\sum_{k=1}^K (X_{kt} Z_{kl} p_{kl}) + V_{tl} w_{tl} \right] \\ &&& \sum_{l=1}^L p_{kl} = 1 \quad \text{and} \quad \sum_{l=1}^L w_{tl} = 1 \end{aligned}$$

The subscript l denotes the support point ($l=1, 2, \dots, L$), k denotes the parameter ($k=1, 2, \dots, K$), and t denotes the observation ($t=1, 2, \dots, T$).

The GME objective is strictly concave; therefore, a unique solution exists. The optimal estimated probabilities, p and w , and the prior supports, Z and V , can be used to form the point estimates of the unknown parameters, β , and the unknown errors, e .

Generalized Cross Entropy

Kullback and Leibler (1951) cross entropy measures the “discrepancy” between one distribution and another. Cross entropy is called a measure of discrepancy rather than distance because it does not satisfy some of the properties one would expect of a distance measure. (See Kapur and Kesavan (1992) for a discussion of cross entropy as a measure of discrepancy.) Mathematically, cross entropy is written as

$$\begin{aligned} &\text{minimize} && \sum_{i=1}^n p_i \ln(p_i / q_i) \\ &\text{subject to} && \sum_{i=1}^n p_i = 1, \end{aligned}$$

where q_i is the probability associated with the i th point in the distribution from which the discrepancy is measured. The q_i (in conjunction with the support) are often referred to as the prior distribution. The measure is nonnegative and is equal to zero when p_i equals q_i . The properties of the cross entropy measure are examined by Kapur and Kesavan (1992).

The principle of minimum cross entropy (Kullback 1959; Good 1963) states that one should choose probabilities that are as close as possible to the prior probabilities. That is, out of all probability distributions that satisfy a given set of constraints which reflect known information about the distribution, choose the distribution that is closest (as measured by $p(\ln(p) - \ln(q))$) to the prior distribution. When the prior distribution is uniform, maximum entropy and minimum cross entropy produce the same results (Kapur and Kesavan 1992), where the higher values for entropy correspond exactly with the lower values for cross entropy.

If the prior distributions are nonuniform, the problem can be stated as a generalized cross entropy (GCE) formulation. The cross entropy terminology specifies weights, q_i and u_i , for the points Z and V , respectively. Given informative prior distributions on Z and V , the GCE problem is

$$\begin{aligned} \text{minimize } & I(p, q, w, u) = p' \ln(p/q) + w' \ln(w/u) \\ \text{subject to } & y = X Z p + V w \\ & 1_K = (I_K \otimes 1'_L) p \\ & 1_T = (I_T \otimes 1'_L) w \end{aligned}$$

where y denotes the T column vector of observations of the dependent variables; \mathbf{X} denotes the $(T \times K)$ matrix of observations of the independent variables; q and p denote LK column vectors of prior and posterior weights, respectively, associated with the points in Z ; u and w denote the LT column vectors of prior and posterior weights, respectively, associated with the points in V ; 1_K , 1_L , and 1_T are K -, L -, and T -dimensional column vectors, respectively, of ones; and \mathbf{I}_K and \mathbf{I}_T are $(K \times K)$ and $(T \times T)$ dimensional identity matrices.

The optimization problem can be rewritten using set notation as follows

$$\begin{aligned} \text{minimize } & I(p, q, w, u) = \sum_{l=1}^L \sum_{k=1}^K p_{kl} \ln(p_{kl}/q_{kl}) + \sum_{l=1}^L \sum_{t=1}^T w_{tl} \ln(w_{tl}/u_{tl}) \\ \text{subject to } & y_t = \sum_{l=1}^L \left[\sum_{k=1}^K (X_{kt} Z_{kl} p_{kl}) + V_{tl} w_{tl} \right] \\ & \sum_{l=1}^L p_{kl} = 1 \text{ and } \sum_{l=1}^L w_{tl} = 1 \end{aligned}$$

The subscript l denotes the support point ($l=1, 2, \dots, L$), k denotes the parameter ($k=1, 2, \dots, K$), and t denotes the observation ($t=1, 2, \dots, T$).

The objective function is strictly convex; therefore, there is a unique global minimum for the problem (Golan, Judge, and Miller 1996). The optimal estimated weights, p and w , and the prior supports, Z and V , can be used to form the point estimates of the unknown parameters, β , and the unknown errors, e , by using

$$\beta = Z p = \begin{bmatrix} z_{11} & \cdots & z_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & z_{12} & \cdots & z_{L2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1K} & \cdots & z_{LK} \end{bmatrix} \begin{bmatrix} p_{11} \\ \vdots \\ p_{L1} \\ p_{12} \\ \vdots \\ p_{L2} \\ \vdots \\ p_{1K} \\ \vdots \\ p_{LK} \end{bmatrix}$$

$$e = V w = \begin{bmatrix} v_{11} & \cdots & v_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & v_{12} & \cdots & v_{L2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{1T} & \cdots & v_{LT} \end{bmatrix} \begin{bmatrix} w_{11} \\ \vdots \\ w_{L1} \\ w_{12} \\ \vdots \\ w_{L2} \\ \vdots \\ w_{1T} \\ \vdots \\ w_{LT} \end{bmatrix}$$

Computational Details

This constrained estimation problem can be solved either directly (primal) or by using the dual form. Either way, it is prudent to factor out one probability for each parameter and each observation as the sum of the other probabilities. This factoring reduces the computational complexity significantly. If the primal formalization is used and two support points are used for the parameters and the errors, the resulting GME problem is $O((nparams + nobs)^3)$. For the dual form, the problem is $O((nobs)^3)$. Therefore for large data sets, GME-NM should be used instead of GME.

Normed Moment Generalized Maximum Entropy

The default estimation technique is normed moment generalized maximum entropy (GME-NM). This is simply GME with the data constraints modified by multiplying both sides by X' . GME-NM then becomes

$$\begin{aligned}
&\text{maximize} && H(p, w) = -p' \ln(p) - w' \ln(w) \\
&\text{subject to} && X'y = X'X Z p + X'V w \\
&&& 1_K = (I_K \otimes 1'_L) p \\
&&& 1_T = (I_T \otimes 1'_L) w
\end{aligned}$$

There is also the cross entropy version of GME-NM, which has the same form as GCE but with the normed constraints.

GME versus GME-NM

GME-NM is more computationally attractive than GME for large data sets because the computational complexity of the estimation problem depends primarily on the number of parameters and not on the number of observations. GME-NM is based on the first moment of the data, whereas GME is based on the data itself. If the distribution of the residuals is well defined by its first moment, then GME-NM is a good choice. So if the residuals are normally distributed or exponentially distributed, then GME-NM should be used. On the other hand if the distribution is Cauchy, lognormal, or some other distribution where the first moment does not describe the distribution, then use GME. See [Example 12.1](#) for an illustration of this point.

Maximum Entropy-Based Seemingly Unrelated Regression

In a multivariate regression model, the errors in different equations might be correlated. In this case, the efficiency of the estimation can be improved by taking these cross-equation correlations into account. Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems.

Like SUR in the least squares setting, the generalized maximum entropy SUR (GME-SUR) method assumes that all the regressors are independent variables and uses the correlations among the errors in different equations to improve the regression estimates. The GME-SUR method requires an initial entropy regression to compute residuals. The entropy residuals are used to estimate the cross-equation covariance matrix.

In the iterative GME-SUR (ITGME-SUR) case, the preceding process is repeated by using the residuals from the GME-SUR estimation to estimate a new cross-equation covariance matrix. ITGME-SUR method alternates between estimating the system coefficients and estimating the cross-equation covariance matrix until the estimated coefficients and covariance matrix converge.

The estimation problem becomes the generalized maximum entropy system adapted for multi-equations as follows:

$$\begin{aligned}
 &\text{maximize } H(p, w) = -p' \ln(p) - w' \ln(w) \\
 &\text{subject to } y = X Z p + V w \\
 &\quad 1_{KM} = (I_{KM} \otimes 1'_L) p \\
 &\quad 1_{MT} = (I_{MT} \otimes 1'_L) w
 \end{aligned}$$

where

$$\beta = Z p$$

$$Z = \begin{bmatrix}
 z_{11}^1 & \cdots & z_{L1}^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & z_{11}^K & \cdots & z_{L1}^K & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1M}^1 & \cdots & z_{LM}^1 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1M}^K & \cdots & z_{LM}^K
 \end{bmatrix}$$

$$p = [p_{11}^1 \cdot p_{L1}^1 \cdot p_{11}^K \cdot p_{L1}^K \cdot p_{1M}^1 \cdot p_{LM}^1 \cdot p_{1M}^K \cdot p_{LM}^K]'$$

$$e = V w$$

$$V = \begin{bmatrix}
 v_{11}^1 & \cdots & v_{11}^L & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & v_{1T}^1 & \cdots & v_{1T}^L & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{M1}^1 & \cdots & v_{M1}^L & 0 & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{MT}^1 & \cdots & v_{MT}^L
 \end{bmatrix}$$

$$w = [w_{11}^1 \cdot w_{11}^L \cdot w_{1T}^1 \cdot w_{1T}^L \cdot w_{M1}^1 \cdot w_{M1}^L \cdot w_{MT}^1 \cdot w_{MT}^L]'$$

y denotes the MT column vector of observations of the dependent variables; \mathbf{X} denotes the $(MT \times KM)$ matrix of observations for the independent variables; p denotes the LKM column vector of weights associated with the points in Z ; w denotes the LMT column vector of weights associated with the points in V ; 1_L , 1_{KM} , and 1_{MT} are L -, KM -, and MT -dimensional column vectors, respectively, of ones; and \mathbf{I}_{KM} and \mathbf{I}_{MT} are $(KM \times KM)$ and $(MT \times MT)$ dimensional identity matrices. The subscript l denotes the support point ($l = 1, 2, \dots, L$), k denotes the parameter ($k = 1, 2, \dots, K$), m denotes the equation ($m = 1, 2, \dots, M$), and t denotes the observation ($t = 1, 2, \dots, T$).

Using this notation, the maximum entropy problem that is analogous to the OLS problem used as the initial step of the traditional SUR approach is

$$\begin{aligned} &\text{maximize} && H(p, w) = -p' \ln(p) - w' \ln(w) \\ &\text{subject to} && (y - X Z p) = \sqrt{\hat{\Sigma}} V w \\ &&& 1_{KM} = (I_{KM} \otimes 1'_L) p \\ &&& 1_{MT} = (I_{MT} \otimes 1'_L) w \end{aligned}$$

The results are GME-SUR estimates with independent errors, the analog of OLS. The covariance matrix $\hat{\Sigma}$ is computed based on the residual of the equations, $Vw = e$. An $L'L$ factorization of the $\hat{\Sigma}$ is used to compute the square root of the matrix.

After solving this problem, these entropy-based estimates are analogous to the Aitken two-step estimator. For iterative GME-SUR, the covariance matrix of the errors is recomputed, and a new $\hat{\Sigma}$ is computed and factored. As in traditional ITSUR, this process repeats until the covariance matrix and the parameter estimates converge.

The estimation of the parameters for the normed-moment version of SUR (GME-SUR-NM) uses an identical process. The constraints for GME-SUR-NM is defined as:

$$X'y = X'(\mathbf{S}^{-1} \otimes \mathbf{I})X Z p + X'(\mathbf{S}^{-1} \otimes \mathbf{I})V w$$

The estimation of the parameters for GME-SUR-NM uses an identical process as outlined previously for GME-SUR.

Generalized Maximum Entropy for Multinomial Discrete Choice Models

Multinomial discrete choice models take the form of an experiment that consists of n trials. On each trial, one of k alternatives is observed. If y_{ij} is the random variable that takes on the value 1 when alternative j is selected for the i th trial and 0 otherwise, then the probability that y_{ij} is 1, conditional on a vector of regressors X_i and unknown parameter vector β_j , is

$$\Pr(y_{ij} = 1 | X_i, \beta_j) = G(X_i' \beta_j)$$

where $G()$ is a link function. For noisy data the model becomes:

$$y_{ij} = G(X_i' \beta_j) + \epsilon_{ij} = p_{ij} + \epsilon_{ij}$$

The standard maximum likelihood approach for multinomial logit is equivalent to the maximum entropy solution for discrete choice models. The generalized maximum entropy approach avoids an assumption of the form of the link function $G()$.

The generalized maximum entropy for discrete choice models (GME-D) is written in primal form as

$$\begin{aligned} \text{maximize } H(p, w) &= -p' \ln(p) - w' \ln(w) \\ \text{subject to } (I_j \otimes X' y) &= (I_j \otimes X') p + (I_j \otimes X') V w \\ \sum_j^k p_{ij} &= 1 \text{ for } i = 1 \text{ to } N \\ \sum_m^L w_{ijm} &= 1 \text{ for } i = 1 \text{ to } N \text{ and } j = 1 \text{ to } k \end{aligned}$$

Golan, Judge, and Miller (1996) have shown that the dual unconstrained formulation of the GME-D can be viewed as a general class of logit models. Additionally, as the sample size increases, the solution of the dual problem approaches the maximum likelihood solution. Because of these characteristics, only the dual approach is available for the GME-D estimation method.

The parameters β_j are the Lagrange multipliers of the constraints. The covariance matrix of the parameter estimates is computed as the inverse of the Hessian of the dual form of the objective function.

Censored or Truncated Dependent Variables

In practice, you might find that variables are not always measured throughout their natural ranges. A given variable might be recorded continuously in a range, but, outside of that range, only the endpoint is denoted. In other words, say that the data generating process is:

$$y_i = \mathbf{x}_{i\epsilon} + \epsilon.$$

However, you observe the following:

$$y_i^* = \begin{cases} ub & : y_i \geq ub \\ \mathbf{x}_{i\epsilon} + \epsilon & : lb < y_i < ub \\ lb & : y_i \leq lb \end{cases}$$

The primal problem is simply a slight modification of the primal formulation for GME-GCE. You specify different supports for the errors in the truncated or censored region, perhaps reflecting some nonsample information. Then the data constraints are modified. The constraints that arise in the censored areas are changed to inequality constraints (Golan, Judge, and Perloff 1997). Let the variable \mathbf{X}^u denote the observations of the explanatory variable where censoring occurs from the top, \mathbf{X}^l from the bottom, and \mathbf{X}^a in the middle region (no censoring). Let, \mathbf{V}^u be the supports for the observations at the upper bound, \mathbf{V}^l lower bound, and \mathbf{V}^a in the middle.

You have:

$$\begin{bmatrix} \mathbf{y}^u \geq ub \\ \mathbf{y}^a \\ \mathbf{y}^l \leq lb \end{bmatrix} = \begin{bmatrix} \mathbf{X}^u \\ \mathbf{X}^a \\ \mathbf{X}^l \end{bmatrix} \mathbf{Zp} + \begin{bmatrix} \mathbf{V}^u \mathbf{w}^u \\ \mathbf{V}^a \mathbf{w}^a \\ \mathbf{V}^l \mathbf{w}^l \end{bmatrix}$$

The primal problem then becomes

$$\begin{aligned} \text{maximize } & H(p, w) = -p' \ln(p) - w' \ln(w) \\ \text{subject to } & \mathbf{y}^a = \mathbf{X}^a \mathbf{V}^a p + \mathbf{V}^a \mathbf{w}^a \\ & \mathbf{y}^u \geq \mathbf{X}^u \mathbf{V}^u p + \mathbf{V}^u \mathbf{w}^u \\ & \mathbf{y}^l \leq \mathbf{X}^l \mathbf{V}^l p + \mathbf{V}^l \mathbf{w}^l \\ & \mathbf{1}_K = (\mathbf{I}_K \otimes \mathbf{1}'_L) p \\ & \mathbf{1}_T = (\mathbf{I}_T \otimes \mathbf{1}'_L) w \end{aligned}$$

PROC ENTROPY requires that the number of supports be identical for all three regions.

Alternatively, you can think of cases where the dependent variable is observed continuously for most of its range. However, the variable's range is reported for some observations. Such data is often found in highly disaggregated state level employment measures.

$$y_i^* = \begin{cases} \text{missing} & : l_1 \leq y \leq r_1 \\ \vdots & : \vdots \\ \text{missing} & : l_k \leq y \leq r_k \\ \mathbf{x}_{i,c} + \epsilon & : \text{otherwise} \end{cases}$$

Just as in the censored case, each range yields two inequality constraints for each observation in that range.

Information Measures

PROC ENTROPY returns several measures of fit. First, the value of the objective function is returned. Next, the signal entropy is provided followed by the noise entropy. The sum of the noise and signal entropies should equal the value of the objective function. The next two metrics that follow are the normed entropies of both the signal and the noise.

Normalized entropy (NE) measures the relative informational content of both the signal and noise components through p and w , respectively (Golan, Judge, and Miller 1996). Let S denote the normalized entropy of the signal, $X\beta$, defined as:

$$S(\tilde{p}) = \frac{-\tilde{p}' \ln(\tilde{p})}{-q' \ln(q)}$$

where $S(\tilde{p}) \in [0, 1]$. In the case of GME, where uniform priors are assumed, S can be written as:

$$S(\tilde{p}) = \frac{-\tilde{p}' \ln(\tilde{p})}{\sum_i \ln(M_i)}$$

where M_i is the number of support points for parameter i . A value of 0 for S implies that there is no uncertainty regarding the parameters; hence, it is a degenerate situation. However, a value of 1 implies that the posterior distributions equal the priors, which indicates total uncertainty if the priors are uniform.

Because NE is relative, it can be used for comparing various situations. Consider adding a data point to the model. If $S_{T+1} = S_T$, then there is no additional information contained within that data constraint. However, if $S_{T+1} < S_T$, then the data point gives a more informed set of parameter estimates.

NE can be used for determining the importance of particular variables with regard to the reduction of the uncertainty they bring to the model. Each of the k parameters that is estimated has an associated NE defined as

$$S(\tilde{p}_k) = \frac{-\tilde{p}'_k \ln(\tilde{p}_k)}{-\ln(q_k)}$$

or, in the GME case,

$$S(\tilde{p}_k) = \frac{-\tilde{p}'_k \ln(\tilde{p}_k)}{\ln(M)}$$

where \tilde{p}_k is the vector of supports for parameter β_k and M is the corresponding number of support points. Since a value of 1 implies no relative information for that particular sample, Golan, Judge, and Miller (1996) suggest an exclusion criteria of $S(\tilde{p}_k) > 0.99$ as an acceptable means of selecting noninformative variables. See Golan, Judge, and Miller (1996) for some simulation results.

The final set of measures of fit are the parameter information index and error information index. These measures can be best summarized as 1 – the appropriate normed entropy.

Parameter Covariance For GCE

For the cross-entropy problem, the estimate of the asymptotic variance of the signal parameter is given by:

$$\widehat{Var}(\hat{\beta}) = \frac{\hat{\sigma}_y^2(\hat{\beta})}{\hat{\psi}^2(\hat{\beta})} (X'X)^{-1}$$

where

$$\hat{\sigma}_y^2(\hat{\beta}) = \frac{1}{N} \sum_{i=1}^N \gamma_i^2$$

and γ_i is the Lagrange multiplier associated with the i th row of the Vw constraint matrix. Also,

$$\hat{\psi}^2(\hat{\beta}) = \left[\frac{1}{N} \sum_{i=1}^N \left(\sum_{j=1}^J v_{ij}^2 w_{ij} - \left(\sum_{j=1}^J v_{ij} w_{ij} \right)^2 \right) \right]^{-1} \right]^2$$

Parameter Covariance For GCE-NM

Golan, Judge, and Miller (1996) give the finite approximation to the asymptotic variance matrix of the normed moment formulation as:

$$\widehat{Var}(\hat{\beta}) = \Sigma_z X' X C^{-1} D C^{-1} X' X \Sigma_z$$

where

$$C = X' X \Sigma_z X' X + \Sigma_v$$

and

$$D = X' \Sigma_e X$$

Recall that in the normed moment formulation, V is the support of $\frac{X'e}{T}$, which implies that Σ_v is a K -dimensional variance matrix. Σ_z and Σ_v are both diagonal matrices with the form

$$\Sigma_z = \begin{bmatrix} \sum_{l=1}^L z_{1l}^2 p_{1l} - \left(\sum_{l=1}^L z_{1l} p_{1l} \right)^2 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \sum_{l=1}^L z_{Kl}^2 p_{Kl} - \left(\sum_{l=1}^L z_{Kl} p_{Kl} \right)^2 \end{bmatrix}$$

and

$$\Sigma_v = \begin{bmatrix} \sum_{j=1}^J v_{1j}^2 w_{1j} - \left(\sum_{j=1}^J v_{1j} w_{1j} \right)^2 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \sum_{j=1}^J v_{Kj}^2 w_{Kj} - \left(\sum_{j=1}^J v_{Kj} w_{Kj} \right)^2 \end{bmatrix}$$

Statistical Tests

Since the GME estimates have been shown to be asymptotically normally distributed, the classical Wald, Lagrange multiplier, and likelihood ratio statistics can be used for testing linear restrictions on the parameters.

Wald Tests

Let $H_0 : L\beta = m$, where L is a set of linearly independent combinations of the elements of β . Then under the null hypothesis, the Wald test statistic,

$$T_W = (L\hat{\beta} - m)' \left(L(\hat{Var}(\hat{\beta}))L' \right)^{-1} (L\hat{\beta} - m)$$

has a central χ^2 limiting distribution with degrees of freedom equal to the rank of L .

Pseudo-Likelihood Ratio Tests

Using the conditionally maximized entropy function as a pseudo-likelihood, F , Mittelhammer and Cardell (2000) state that:

$$\frac{2\hat{\psi}(\hat{\beta})}{\hat{\sigma}_y^2(\hat{\beta})} \left(F(\hat{\beta}) - F(\tilde{\beta}) \right)$$

has the limiting distribution of the Wald statistic when testing the same hypothesis. Note that $F(\hat{\beta})$ and $F(\tilde{\beta})$ are the maximum values of the entropy objective function over the full and restricted parameter spaces, respectively.

Lagrange Multiplier Tests

Again using the GME function as a pseudo-likelihood, Mittelhammer and Cardell (2000) define the Lagrange multiplier statistic as:

$$\frac{1}{\hat{\sigma}_y^2(\tilde{\beta})} G(\tilde{\beta})'(X'X)^{-1}G(\tilde{\beta})$$

where G is the gradient of F , which is being evaluated at the optimum point for the restricted parameters. This test statistic shares the same limiting distribution as the Wald and pseudo-likelihood ratio tests.

Missing Values

If an observation in the input data set contains a missing value for any of the regressors or dependent values, that observation is dropped from the analysis.

Input Data Sets

DATA= Data Set

The DATA= data set specified in the PROC ENTROPY statement is the data set that contains the data to be analyzed.

PDATA= Data Set

The PDATA= data set specified in the PROC ENTROPY statement specifies the support points and prior probabilities to be used in the estimation. The PDATA= can be used in lieu of a PRIORS statement, but is intended for use in conjunction with the OUTF= option. Once priors are entered through a PRIORS statement, they can be reused in subsequent estimations by specifying the PDATA= option.

The variables in the data set are as follows:

- BY variables (if any)
- `_TYPE_`, a character variable of length 8 that identifies the estimation method: GME or GMENM. This is an optional column.
- `variable`, a character variable of length 32 that indicates the name of the regressor. The regressor name and the equation name identify a unique coefficient. This is required.
- `_OBS_`, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The `_OBS_` and the equation name identify which residual the probability is associated with. This is an optional column.
- `equation`, a character variable of length 32 indicating the name of the dependent variable. This is a required column.
- `NSupport`, a numeric variable that indicates the number of support points for each basis. This variable is required.
- `support`, a numeric variable that is the support value the probability is associated with. This is a required column.
- `prior`, a numeric variable that is the prior probability associated with the probability. This is a required column.
- `Prb`, a numeric variable that is the estimated probability. This is optional.

SDATA= Data Set

The SDATA= data set specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation covariance matrix (**S** matrix) in the estimation. (The SDATA= **S** matrix is used to provide only the initial estimate of **S** for the methods that iterate the **S** matrix.)

Output Data Sets

OUT= Data Set

The OUT= data set specified in the PROC ENTROPY statement contains residuals of the dependent variables computed from the parameter estimates. The ID and BY variables are also added to this data set.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates and, if requested via the COVOUT option, estimates of the covariance of the parameter estimates.

The variables in the data set are as follows:

- BY variables
- `_NAME_`, a character variable of length 32, blank for observations that contain parameter estimates or a parameter name for observations that contain covariances
- `_TYPE_`, a character variable of length 8 that identifies the estimation method: GME or GMENM
- the parameters estimated

If the COVOUT option is specified, an additional observation is written for each row of the estimate of the covariance matrix of parameter estimates, with the `_NAME_` values containing the parameter names for the rows.

OUTP= Data Set

The OUTP= data set specified in the PROC ENTROPY statement contains the probabilities estimated for each support point, as well as the support points and prior probabilities used in the estimation.

The variables in the data set are as follows:

- BY variables (if any)
- `_TYPE_`, a character variable of length 8 that identifies the estimation method: GME or GMENM.
- `variable`, a character variable of length 32 that indicates the name of the regressor. The regressor name and the equation name identify a unique coefficient.
- `_OBS_`, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The `_OBS_` and the equation name identify which residual the probability is associated with.
- `equation`, a character variable of length 32 that indicates the name of the dependent variable
- `NSupport`, a numeric variable that indicates the number of support points for each basis
- `support`, a numeric variable that is the support value the probability is associated with
- `prior`, a numeric variable that is the prior probability associated with the probability
- `Prb`, a numeric variable that is the estimated probability

OUTL= Data Set

The OUTL= data set specified in the PROC ENTROPY statement contains the Lagrange multiplier values for the underlying maximum entropy problem.

The variables in the data set are as follows:

- BY variables
- `equation`, a character variable of length 32 that indicates the name of the dependent variable
- `variable`, a character variable of length 32 that indicates the name of the regressor. The regressor name and the equation name identify a unique coefficient.
- `_OBS_`, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The `_OBS_` and the equation name identify which residual the Lagrange multiplier is associated with
- `LagrangeMult`, a numeric variable that contains the Lagrange multipliers

ODS Table Names

PROC ENTROPY assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 12.2 ODS Tables Produced in PROC ENTROPY

ODS Table Name	Description	Option
ConvCrit	Convergence criteria for estimation	default
ConvergenceStatus	Convergence status	default
DatasetOptions	Data sets used	default
MinSummary	Number of parameters, estimation kind	default
ObsUsed	Observations read, used, and missing	default
ParameterEstimates	Parameter estimates	default
ResidSummary	Summary of the SSE, MSE for the equations	default
TestResults	Test statement table	TEST statement

ODS Graphics

This section describes the use of ODS for creating graphics with the ENTROPY procedure.

ODS Graph Names

PROC ENTROPY assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 12.3](#).

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 12.3 ODS Graphics Produced by PROC ENTROPY

ODS Graph Name	Plot Description
DiagnosticsPanel	Includes all the plots listed below
FitPlot	Predicted versus actual plot
CooksD	Cook's D plot
QQPlot	Q-Q plot of residuals
StudentResidualPlot	Studentized residual plot
ResidualHistogram	Histogram of the residuals

Examples: ENTROPY Procedure

Example 12.1: Nonnormal Error Estimation

This example illustrates the difference between GME-NM and GME. One of the basic assumptions of OLS estimation is that the errors in the estimation are normally distributed. If this assumption is violated, the estimated parameters are biased. For GME-NM, the story is similar. If the first moment of the distribution of the errors and a scale factor cannot be used to describe the distribution, then the parameter estimates from GME-MN are more biased. GME is much less sensitive to the underlying distribution of the errors than GME-NM.

To illustrate this, data for the following model is simulated with three different error distributions:

$$y = a * x_1 + b * x_2 + \epsilon.$$

For the first simulation, ϵ is distributed normally, then a chi-squared distribution with six degrees of freedom is assumed for the second simulation, and finally ϵ is assumed to have a Cauchy distribution in the third simulation.

In each of the three simulations, 100 samples of 10 observations each were simulated. The data for the model with the Cauchy error distribution is generated using the following DATA step code:

```
data one;
  call streaminit(156789);
  do by = 1 to 100;
    do x2 = 1 to 10;
      x1 = 10 * ranuni( 512);
      y = x1 + 2*x2 + rand('cauchy');
      output;
    end;
  end;
run;
```

The statements for the other distributions are identical except for the argument to the RAND() function.

The parameters to the model were estimated by using maximum entropy with the following programming statements:

```
proc entropy data=one gme outest=parml;
  model y = x1 x2;
  by by;
run;
```

The estimation by using moment-constrained maximum entropy was performed by changing the GME option to GMENM. For comparison, the same model was estimated by using OLS with the following PROC REG statements:

```
proc reg data=one outest=parm3;
  model y = x1 x2;
  by by;
run;
```

The 100 estimations of the coefficient on variable x1 are then summarized for each of the three error distributions by using PROC UNIVARIATE, as follows:

```
proc univariate data=parm1;
  var x1;
run;
```

The following table summarizes the results from the estimations. The true value for the coefficient on x1 is 1.0.

Estimation Method	Normal		Chi-Squared		Cauchy	
	Mean	Std Deviation	Mean	Std Deviation	Mean	Std Deviation
GME	0.418	0.117	0.626	.330	0.818	3.36
GME-NM	0.878	0.116	0.948	0.427	3.03	13.62
OLS	0.973	0.142	1.023	0.467	5.54	26.83

For normally distributed or nearly normally distributed data, moment-constrained maximum entropy is a good choice. For distributions not well described by a normal distribution, data-constrained maximum entropy is a good choice.

Example 12.2: Unreplicated Factorial Experiments

Factorial experiments are useful for studying the effects of various factors on a response. For the practitioner constrained to the use of OLS regression, there must be replication to estimate all of the possible main and interaction effects in a factorial experiment. Using OLS regression to analyze unreplicated experimental data results in zero degrees of freedom for error in the ANOVA table, since there are as many parameters as observations. This situation leaves the experimenter unable to compute confidence intervals or perform hypothesis testing on the parameter estimates.

Several options are available when replication is impossible. The higher-order interactions can be assumed to have negligible effects, and their degrees of freedom can be pooled to create the error degrees of freedom used to perform inference on the lower-order estimates. Or, if a preliminary experiment is being run, a normal probability plot of all effects can provide insight as to which effects are significant, and therefore focused, in a later, more complete experiment.

The following example illustrates the probability plot methodology and the alternative by using PROC ENTROPY. Consider a 2^4 factorial model with no replication. The data are taken from Myers and Montgomery (1995).

```

data rate;
  do a=-1,1; do b=-1,1; do c=-1,1; do d=-1,1;
    input y @@;
    ab=a*b; ac=a*c; ad=a*d; bc=b*c; bd=b*d; cd=c*d;
    abc=a*b*c; abd=a*b*d; acd=a*c*d; bcd=b*c*d;
    abcd=a*b*c*d;
    output;
  end; end; end; end;
datalines;
45 71 48 65 68 60 80 65 43 100 45 104 75 86 70 96
;
run;

```

Analyze the data by using PROC REG, then output the resulting estimates.

```

proc reg data=rate outest=regout;
  model y=a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
run;

proc transpose data=regout out=ploteff name=effect prefix=est;
  var a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
run;

```

Now the normal scores for the estimates can be computed with the rank procedure as follows:

```

proc rank data=ploteff normal=blom out=qqplot;
  var est1;
  ranks normalq;
run;

```

To create the probability plot, simply plot the estimates versus their normal scores by using PROC SGPLOT as follows:

```

title "Unreplicated Factorial Experiments";
proc sgplot data=qqplot;
  scatter x=est1 y=normalq / markerchar=effect
          markercharattrs=(size=10pt);
  xaxis label="Estimate";
  yaxis label="Normal Quantile";
run;

```

Output 12.2.1 Normal Probability Plot of Effects

The plot shown in [Output 12.2.1](#) displays evidence that the a, b, d, ad, and bd estimates do not fit into the purely random normal model, which suggests that they may have some significant effect on the response variable. To verify this, fit a reduced model that contains only these effects.

```
proc reg data=rate;
  model y=a b d ad bd;
run;
```

The estimates for the reduced model are shown in [Output 12.2.2](#).

Output 12.2.2 Reduced Model OLS Estimates

Unreplicated Factorial Experiments					
The REG Procedure					
Model: MODEL1					
Dependent Variable: y					
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	70.06250	1.10432	63.44	<.0001
a	1	7.31250	1.10432	6.62	<.0001
b	1	4.93750	1.10432	4.47	0.0012
d	1	10.81250	1.10432	9.79	<.0001
ad	1	8.31250	1.10432	7.53	<.0001
bd	1	-9.06250	1.10432	-8.21	<.0001

These results support the probability plot methodology.

PROC ENTROPY can directly estimate the full model without having to rely upon the probability plot for insight into which effects can be significant. To illustrate this, PROC ENTROPY is run by using default parameter and error supports in the following statements:

```
proc entropy data=rate;
  model y=a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
run;
```

The resulting GME estimates are shown in [Output 12.2.3](#). Note that the parameter estimates associated with the a, b, d, ad, and bd effects are all significant.

Output 12.2.3 Full Model Entropy Results

Unreplicated Factorial Experiments

Intercept	69.87294	1.1403	61.28	<.0001

Example 12.3: Censored Data Models in PROC ENTROPY

Data available to an analyst might sometimes be censored, where only part of the actual series is observed. Consider the case in which only observations greater than some lower bound are recorded, as defined by the following process:

$$y = \max(\mathbf{X}\boldsymbol{\beta} + \epsilon, lb).$$

Running ordinary least squares estimation on data generated by the preceding process is not optimal because the estimates are likely to be biased and inefficient. One alternative to estimating models with censored data is the tobit estimator. This model is supported in the QLIM procedure in SAS/ETS and in the LIFEREG procedure in SAS/STAT. PROC ENTROPY provides another alternative which can make it very easy to estimate such a model correctly.

The following DATA step generates censored data in which any negative values of the dependent variable, *y*, are set to a lower bound of 0.

```
data cens;
  do t = 1 to 100;
    x1 = 5 * ranuni(456);
    x2 = 10 * ranuni( 457);
    y = 4.5*x1 + 2*x2 + 15 * rannor(458);
    if( y<0 ) then y = 0;
    output;
  end;
run;
```

To illustrate the effect of the censored option in PROC ENTROPY, the model is initially estimated without accounting for censoring in the following statements:

```
title "Censored Data Estimation";
proc entropy data = cens gme primal;
  priors intercept -32 32
        x1      -15 15
        x2      -15 15;
  model y = x1 x2 /
        esupports = (-25 1 25);
run;
```

Output 12.3.1 GME Estimates

Censored Data Estimation				
The ENTROPY Procedure				
GME Variable Estimates				
Variable	Estimate	Approx Std Err	t Value	Approx Pr > t
x1	2.377609	0.000503	4725.98	<.0001
x2	2.353014	0.000255	9244.87	<.0001
intercept	5.478121	0.00188	2906.41	<.0001

The previous model is reestimated by using the CENSORED option in the following statements:

```
proc entropy data = cens gme primal;
  priors intercept -32 32
        x1      -15 15
        x2      -15 15;
  model y = x1 x2 /
        esupports = (-25 1 25)
        censored(lb = 0, esupports=(-15 1 15) );
run;
```

Output 12.3.2 Entropy Estimates

Censored Data Estimation				
The ENTROPY Procedure				
GME Variable Estimates				
Variable	Estimate	Approx Std Err	t Value	Approx Pr > t
x1	4.429697	0.00690	641.85	<.0001
x2	1.46858	0.00349	420.61	<.0001
intercept	8.261412	0.0259	319.51	<.0001

The second set of entropy estimates are much closer to the true parameter estimates of 4.5 and 2. Since another alternative available for fitting a model of censored data is a tobit model, PROC QLIM is used in the following statements to fit a tobit model to the data:

```
proc qlim data=cens;
  model y = x1 x2;
  endogenous y ~ censored(lb=0);
run;
```

Output 12.3.3 QLIM Estimates

Censored Data Estimation					
The QLIM Procedure					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	2.979455	3.824252	0.78	0.4359
x1	1	4.882284	1.019913	4.79	<.0001
x2	1	1.374006	0.513000	2.68	0.0074
_Sigma	1	13.723213	1.032911	13.29	<.0001

For this data and code, PROC ENTROPY produces estimates that are closer to the true parameter values than those computed by PROC QLIM.

Example 12.4: Use of the PDATA= Option

It is sometimes useful to specify priors and supports by using the PDATA= option. This example illustrates how to create a PDATA= data set which contains the priors and support points for use in a subsequent PROC ENTROPY step. In order to have a model to estimate in PROC ENTROPY, you must first have data to analyze. The following DATA step generates the data used in this analysis:

```

title "Using a PDATA= data set";
data a;
  retain seed1 55371 seed2 97335;
  array x[4];
  do t = 1 to 100;
    ys = -5;
    do k = 1 to 4;
      x[k] = rannor( seed1 + k ) ;
      ys = ys + x[k] * k;
    end;
    ys = ys + rannor( seed2 );
    output;
  end;
run;

```

Next you fit this data with some arbitrary parameter support points and priors by using the following PROC ENTROPY statements:

```

proc entropy data = a gme primal;
  priors      x1  -10(2) 30(1)
             x2  -20(3) 30(2)
             x3  -15(4) 30(4)
             x4  -25(3) 30(2)
             intercept -13(4) 30(2) ;
  model ys = x1 x2 x3 x4 / esupports=(-25 0 25);
run;

```

These statements produce the output shown in [Output 12.4.1](#).

Output 12.4.1 Output From PROC ENTROPY

Using a PDATA= data set				
The ENTROPY Procedure				
GME Variable Estimates				
Variable	Estimate	Approx Std Err	t Value	Approx Pr > t
x1	1.195688	0.1078	11.09	<.0001
x2	1.844903	0.1018	18.12	<.0001
x3	3.268396	0.1136	28.77	<.0001
x4	3.908194	0.0934	41.83	<.0001
intercept	-4.94319	0.1005	-49.21	<.0001

You can estimate the same model by first creating a PDATA= data set, which includes the same information as the PRIORS statement in the preceding PROC ENTROPY step.

A data set that defines the supports and priors for the model parameters is shown in the following statements:

```
data test;
  length Variable $ 12 Equation $ 12;
  input Variable $ Equation $ Nsupport Support Prior ;
datalines;
  Intercept . 2 -13 0.66667
  Intercept . 2 30 0.33333
  x1 . 2 -10 0.66667
  x1 . 2 30 0.33333
  x2 . 2 -20 0.60000
  x2 . 2 30 0.40000
  x3 . 2 -15 0.50000
  x3 . 2 30 0.50000
  x4 . 2 -25 0.60000
  x4 . 2 30 0.40000
;
```

The following statements reestimate the model by using these support points.

```
proc entropy data=a gme primal pdata=test;
  model ys = x1 x2 x3 x4 / esupports=(-25 0 25);
run;
```

These statements produce the output shown in [Output 12.4.2](#).

Output 12.4.2 Output From PROC ENTROPY with PDATA= option

Using a PDATA= data set				
The ENTROPY Procedure				
GME Variable Estimates				
Variable	Estimate	Approx Std Err	t Value	Approx Pr > t
x1	1.195686	0.1078	11.09	<.0001
x2	1.844902	0.1018	18.12	<.0001
x3	3.268395	0.1136	28.77	<.0001
x4	3.908194	0.0934	41.83	<.0001
Intercept	-4.94319	0.1005	-49.21	<.0001

These results are identical to the ones produced by the previous PROC ENTROPY step.

Example 12.5: Illustration of ODS Graphics

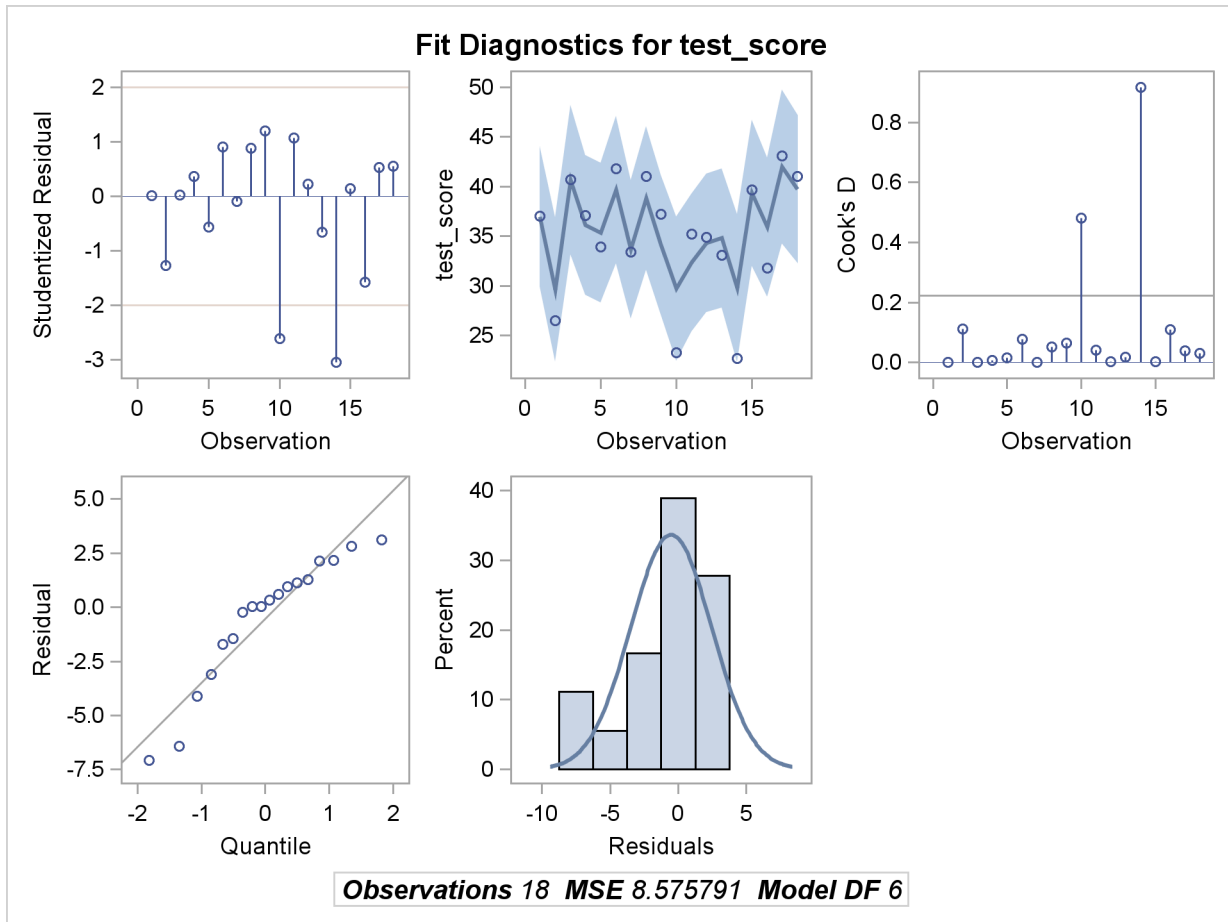

This example illustrates how to use ODS graphics in the ENTROPY procedure. This example is a continuation of the example in the section “[Simple Regression Analysis](#)” on page 618. Graphical

displays are requested by specifying the ODS GRAPHICS statement. For information about the graphics available in the ENTROPY procedure, see the section “ODS Graphics” on page 666.

The following statements show how to generate ODS graphics plots with the ENTROPY procedure. The plots are displayed in [Output 12.5.1](#).

```
proc entropy data=coleman;
  model test_score = teach_sal prcnt_prof socio_stat
    teach_score mom_ed;
run;
```

Output 12.5.1 Model Diagnostics Plots

Overview: ESM Procedure

The ESM procedure generates forecasts by using exponential smoothing models with optimized smoothing weights for many time series or transactional data.

- For typical time series, you can use the following smoothing models:
 - simple
 - double
 - linear
 - damped trend
 - seasonal
 - Winters method (additive and multiplicative)
- Additionally, transformed versions of these models are provided:
 - log
 - square root
 - logistic
 - Box-Cox

Graphics are available with the ESM procedure. For more information, see the section “[ODS Graphics](#)” on page 705.

The exponential smoothing models supported in PROC ESM differ from those supported in PROC FORECAST since all parameters associated with the forecasting model are optimized by PROC ESM based on the data.

The ESM procedure writes the time series extrapolated by the forecasts, the series summary statistics, the forecasts and confidence limits, the parameter estimates, and the fit statistics to output data sets. The ESM procedure optionally produces printed output for these results by using the Output Delivery System (ODS).

The ESM procedure can forecast both time series data, whose observations are equally spaced by a specific time interval (for example, monthly, weekly), or transactional data, whose observations are not spaced with respect to any particular time interval. Internet, inventory, sales, and similar data are typical examples of transactional data. For transactional data, the data is accumulated based on a specified time interval to form a time series prior to modeling and forecasting.

Getting Started: ESM Procedure

The ESM procedure is simple to use and does not require in-depth knowledge of forecasting methods. It can provide results in output data sets or in other output formats by using the Output Delivery

System (ODS). The following examples are more fully illustrated in “[Example 13.2: Forecasting of Transactional Data](#)” on page 709.

Given an input data set that contains numerous time series variables recorded at a specific frequency, the ESM procedure can forecast the series as follows:

```
proc esm data=<input-data-set> out=<output-data-set>;
  id <time-ID-variable> interval=<frequency>;
  forecast <time-series-variables>;
run;
```

For example, suppose that the input data set SALES contains sales data recorded monthly, the variable that represents time is DATE, and the forecasts are to be recorded in the output data set NEXTYEAR. The ESM procedure could be used as follows:

```
proc esm data=sales out=nextyear;
  id date interval=month;
  forecast _numeric_;
run;
```

The preceding statements generate forecasts for every numeric variable in the input data set SALES for the next twelve months and store these forecasts in the output data set NEXTYEAR. Other output data sets can be specified to store the parameter estimates, forecasts, statistics of fit, and summary data.

By default, PROC ESM generates no printed output. If you want to print the forecasts by using the Output Delivery System (ODS), then you need to add the PRINT=FORECASTS option to the PROC ESM statement, as shown in the following example:

```
proc esm data=sales out=nextyear print=forecasts;
  id date interval=month;
  forecast _numeric_;
run;
```

Other PRINT= options can be specified to print the parameter estimates, statistics of fit, and summary data.

The ESM procedure can forecast both time series data, whose observations are equally spaced by a specific time interval (for example, monthly, weekly), or transactional data, whose observations are not spaced with respect to any particular time interval.

Given an input data set that contains transactional variables not recorded at any specific frequency, the ESM procedure accumulates the data to a specific time interval and forecasts the accumulated series as follows:

```
proc esm data=<input-data-set> out=<output-data-set>;
  id <time-ID-variable> interval=<frequency>
    accumulate=<accumulation>;
  forecast <time-series-variables> / model=<esm>;
run;
```

For example, suppose that the input data set WEBSITES contains three variables (BOATS, CARS, PLANES) that are Internet data recorded on no particular time interval, and the variable that represents time is TIME, which records the time of the Web hit. The forecasts for the total daily values are to be recorded in the output data set NEXTWEEK. The ESM procedure could be used as follows:

```
proc esm data=websites out=nextweek lead=7;
  id time interval=dtday accumulate=total;
  forecast boats cars planes;
run;
```

The preceding statements accumulate the data into a daily time series, generate forecasts for the BOATS, CARS, and PLANES variables in the input data set (WEBSITES) for the next seven days, and store the forecasts in the output data set (NEXTWEEK). Because the MODEL= option is not specified in the FORECAST statement, a simple exponential smoothing model is fit to each series.

Syntax: ESM Procedure

The following statements are used with the ESM procedure:

```
PROC ESM options ;
  BY variables ;
  ID variable INTERVAL= interval options ;
  FORECAST variable-list / options ;
```

Functional Summary

The statements and options that control the ESM procedure are summarized in the following table.

Table 13.1 Syntax Summary

Description	Statement	Option
Statements		
specify data sets and options	PROC ESM	
specify BY-group processing	BY	
specify variables to forecast	FORECAST	
specify the time ID variable	ID	
Data Set Options		
specify the input data set	PROC ESM	DATA=
specify to output forecasts only	PROC ESM	NOOUTALL
specify the output data set	PROC ESM	OUT=
specify parameter output data set	PROC ESM	OUTEST=

Description	Statement	Option
specify forecast output data set	PROC ESM	OUTFOR=
specify the forecast procedure information output data set	PROC ESM	OUTPROCINFO=
specify statistics output data set	PROC ESM	OUTSTAT=
specify summary output data set	PROC ESM	OUTSUM=
replace actual values held back	FORECAST	REPLACEBACK
replace missing values	FORECAST	REPLACEMISSING
use forecast value to append	FORECAST	USE=
Accumulation and Seasonality Options		
specify accumulation frequency	ID	INTERVAL=
specify length of seasonal cycle	PROC ESM	SEASONALITY=
specify interval alignment	ID	ALIGN=
specify that time ID variable values are not sorted	ID	NOTSORTED
specify starting time ID value	ID	START=
specify ending time ID value	ID	END=
specify accumulation statistic	ID, FORECAST	ACCUMULATE=
specify missing value interpretation	ID, FORECAST	SETMISSING=
specify zero value interpretation	ID, FORECAST	ZEROMISS=
Forecasting Horizon, Holdback Options		
specify data to hold back	PROC ESM	BACK=
specify forecast horizon or lead	PROC ESM	LEAD=
specify horizon to start summation	PROC ESM	STARTSUM=
Forecasting Model Options		
specify confidence limit width	FORECAST	ALPHA=
specify forecast model	FORECAST	MODEL=
specify median forecasts	FORECAST	MEDIAN
specify backcast initialization	FORECAST	NBACKCAST=
specify model transformation	FORECAST	TRANSFORM=
Printing and Plotting Control Options		
specify time ID format	ID	FORMAT=
specify graphical output	PROC ESM	PLOT=
specify printed output	PROC ESM	PRINT=
specify detailed printed output	PROC ESM	PRINTDETAILS
Miscellaneous Options		
specify that analysis variables are processed in sorted order	PROC ESM	SORTNAMES
limit error and warning messages	PROC ESM	MAXERROR=

PROC ESM Statement

PROC ESM *options* ;

The following options can be used in the PROC ESM statement.

BACK=*n*

specifies the number of observations before the end of the data where the multistep forecasts are to begin. The default is BACK=0.

DATA=*SAS-data-set*

names the SAS data set that contains the input data for the procedure to forecast. If the DATA= option is not specified, the most recently created SAS data set is used.

LEAD=*n*

specifies the number of periods ahead to forecast (forecast lead or horizon). The default is LEAD=12.

The LEAD= value is relative to the BACK= option specification and to the last observation in the input data set or the accumulated series, and not to the last nonmissing observation of a particular series. Thus, if a series has missing values at the end, the actual number of forecasts computed for that series is greater than the LEAD= value.

MAXERROR=*number*

limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

NOOUTALL

specifies that only forecasts are written to the OUT= and OUTFOR= data sets. The NOOUTALL option includes only the final forecast observations in the output data sets; it does not include the one-step forecasts for the data before the forecast period.

The OUT= and OUTFOR= data set will only contain the forecast results starting at the next period following the last observation and ending with the forecast horizon specified by the LEAD= option.

OUT=*SAS-data-set*

names the output data set to contain the forecasts of the variables specified in the subsequent FORECAST statements. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the ACCUMULATE= option, and forecasts are appended to these values based on the FORECAST statement USE= option. The OUT= data set is particularly useful in extending the independent variables. The OUT= data set can be used as the input data set in a subsequent PROC step to forecast a dependent series by using a regression modeling procedure. If the OUT= option is not specified, a default output data set is created by using the DATA*n* convention. If you do not want the OUT= data set created, use OUT=_NULL_.

OUTEST=SAS-data-set

names the output data set to contain the model parameter estimates and the associated test statistics and probability values. The OUTEST= data set is useful for evaluating the significance of the model parameters and understanding the model dynamics.

OUTFOR=SAS-data-set

names the output data set to contain the forecast time series components (actual, predicted, lower confidence limit, upper confidence limit, prediction error, prediction standard error). The OUTFOR= data set is useful for displaying the forecasts in tabular or graphical form.

OUTPROCINFO=SAS-data-set

names the output data set to contain information in the SAS log, specifically the number of notes, errors, and warnings and the number of series processed, forecasts requested, and forecasts failed.

OUTSTAT=SAS-data-set

names the output data set to contain the statistics of fit (or goodness-of-fit statistics). The OUTSTAT= data set is useful for evaluating how well the model fits the series.

OUTSUM=SAS-data-set

names the output data set to contain the summary statistics and the forecast summation. The summary statistics are based on the accumulated time series when the ACCUMULATE= or SETMISSING= options are specified. The forecast summations are based on the LEAD=, STARTSUM=, and USE= options. The OUTSUM= data set is useful when forecasting large numbers of series and a summary of the results are needed.

PLOT=option | (options)

specifies the graphical output desired. By default, the ESM procedure produces no graphical output. The following plotting options are available:

ERRORS	plots prediction error time series graphics.
ACF	plots prediction error autocorrelation function graphics.
PACF	plots prediction error partial autocorrelation function graphics.
IACF	plots prediction error inverse autocorrelation function graphics.
WN	plots white noise graphics.
MODELS	plots model graphics.
FORECASTS	plots forecast graphics.
MODELFORECASTSONLY	plots forecast graphics with confidence limits in the data range.
FORECASTSONLY	plots the forecast in the forecast horizon only.
LEVELS	plots smoothed level component graphics.
SEASONS	plots smoothed seasonal component graphics.
TRENDS	plots smoothed trend (slope) component graphics.
ALL	is the same as specifying all of the above PLOT= options.

For example, PLOT=FORECASTS plots the forecasts for each series. The PLOT= option produces printed output for these results by using the Output Delivery System (ODS).

PRINT=option | (options)

specifies the printed output desired. By default, the ESM procedure produces no printed output. The following printing options are available:

ESTIMATES	prints the results of parameter estimation.
FORECASTS	prints the forecasts.
PERFORMANCE	prints the performance statistics for each forecast.
PERFORMANCE SUMMARY	prints the performance summary for each BY group.
PERFORMANCE OVERALL	prints the performance summary for all of the BY groups.
STATISTICS	prints the statistics of fit.
STATES	prints the backcast, initial, and final states.
SUMMARY	prints the summary statistics for the accumulated time series.
ALL	Same as PRINT=(ESTIMATES FORECASTS STATISTICS SUMMARY).

For example, PRINT=FORECASTS prints the forecasts, PRINT=(ESTIMATES FORECASTS) prints the parameter estimates and the forecasts, and PRINT=ALL prints all of the output.

PRINTDETAILS

specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY=number

specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three observations forms a seasonal cycle. The SEASONALITY= option is applicable only for seasonal forecasting models. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is twelve.

SORTNAMES

specifies that the variables specified in the FORECAST statements are processed in sorted order.

STARTSUM=n

specifies the starting forecast lead (or horizon) for which to begin summation of the forecasts specified by the LEAD= option. The STARTSUM= value must be less than the LEAD= value. The default is STARTSUM=1; that is, the sum from the one-step ahead forecast (which is the first forecast in the forecast horizon) to the multistep forecast specified by the LEAD= option.

The prediction standard errors of the summation of forecasts take into account the correlation between the multistep forecasts. The section “[Forecast Summation](#)” on page 698 describes the STARTSUM= option in more detail.

BY Statement

BY *variables* ;

A BY statement can be used with PROC ESM to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the ESM procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FORECAST Statement

FORECAST *variable-list / options* ;

The FORECAST statement lists the numeric variables in the DATA= data set whose accumulated values represent time series to be modeled and forecast. The options specify which forecast model is to be used.

A data set variable can be specified in only one FORECAST statement. Any number of FORECAST statements can be used. The following options can be used with the FORECAST statement.

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period for the variables listed in the FORECAST statement. If the ACCUMULATE= option is not specified in the FORECAST statement, accumulation is determined by the ACCUMULATE= option of the ID statement. Use the ACCUMULATE= option with multiple FORECAST statements when you want different accumulation specifications for different variables. See the ID statement [ACCUMULATE=](#) option for more details.

ALPHA=*number*

specifies the significance level to use in computing the confidence limits of the forecast. The ALPHA= value must be between 0 and 1. The default is ALPHA=0.05, which produces 95% confidence intervals.

MEDIAN

specifies that the median forecast values are to be estimated. Forecasts can be based on the mean or median. By default, the mean value is provided. If no transformation is applied to the time series by using the TRANSFORM= option, the mean and median forecast values are identical.

MODEL=*model-name*

specifies the forecasting model to be used to forecast the time series. The default is MODEL=SIMPLE, which performs simple exponential smoothing. The following forecasting models are provided:

NONE	no forecast
SIMPLE	simple (single) exponential smoothing. This is the default.
DOUBLE	double (Brown) exponential smoothing
LINEAR	linear (Holt) exponential smoothing
DAMPTREND	damped trend exponential smoothing
ADDSEASONALISEASONAL	additive seasonal exponential smoothing
MULTSEASONAL	multiplicative seasonal exponential smoothing
WINTERS	Winters multiplicative method
ADDWINTERS	Winters additive method

When the option MODEL=NONE is specified, the time series is appended with missing values in the OUT= data set. This option is useful when the results stored in the OUT= data set are used in a subsequent analysis where forecasts of the independent variables are needed to forecast the dependent variable.

NBACKCAST=*n*

specifies the number of observations used to initialize the backcast states. The default is the entire series.

REPLACEBACK

specifies that actual values excluded by the BACK= option are replaced with one-step-ahead forecasts in the OUT= data set.

REPLACEMISSING

specifies that embedded missing values are replaced with one-step-ahead forecasts in the OUT= data set.

SETMISSING=*option* | *number*

specifies how missing values (either input or accumulated) are assigned in the accumulated time series for variables listed in the FORECAST statement. If the SETMISSING= option is not specified in the FORECAST statement, missing values are set based on the SETMISSING= option of the ID statement. See the ID statement SETMISSING= option for more details.

TRANSFORM=option

specifies the time series transformation to be applied to the input or accumulated time series. The following transformations are provided:

NONE	no transformation. This is the default.
LOG	logarithmic transformation
SQRT	square-root transformation
LOGISTIC	logistic transformation
BOXCOX(<i>n</i>)	Box-Cox transformation with parameter number where number is between -5 and 5

When the TRANSFORM= option is specified, the time series must be strictly positive. After the time series is transformed, the model parameters are estimated by using the transformed series. The forecasts of the transformed series are then computed, and finally the transformed series forecasts are inverse transformed. The inverse transform produces either mean or median forecasts depending on whether the MEDIAN option is specified. The sections “[Transformations](#)” on page 697 and “[Inverse Transformations](#)” on page 698 describe this in more detail.

USE=option

specifies which forecast values are appended to the actual values in the OUT= and OUTSUM= data sets. The following USE= options are provided:

PREDICT	The predicted values are appended to the actual values. This option is the default.
LOWER	The lower confidence limit values are appended to the actual values.
UPPER	The upper confidence limit values are appended to the actual values.

Thus, the USE= option enables the OUT= and OUTSUM= data sets to be used for worst-case, best-case, average-case, and median-case decisions.

ZEROMISS=option

specifies how beginning or ending zero values (either input or accumulated) are interpreted in the accumulated time series for variables listed in the FORECAST statement. If the ZEROMISS= option is not specified in the FORECAST statement, beginning or ending zero values are set to missing values based on the ZEROMISS= option of the ID statement. See the ID statement [ZEROMISS=](#) option for more details.

ID Statement

ID variable *INTERVAL= interval < options > ;*

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable’s values are assumed to be SAS date or datetime values. In addition, the

ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series to be forecast. The information specified affects all variables specified in subsequent FORECAST statements. If the ID statement is specified, the INTERVAL= option must be specified. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. The following options can be used with the ID statement.

ACCUMULATE=option

specifies how the data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent model fitting and forecasting.

The ACCUMULATE= option is particularly useful when there are gaps in the input data or when there are multiple input observations that coincide with a particular time period (for example, transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following options determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE AVG	Observations are accumulated based on the average of their values.
MINIMUM MIN	Observations are accumulated based on the minimum of their values.
MEDIAN MED	Observations are accumulated based on the median of their values.
MAXIMUM MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.

USS Observations are accumulated based on the uncorrected sum of squares of their values.

If the **ACCUMULATE=** option is specified, the **SETMISSING=** option is useful for specifying how accumulated missing values are treated. If missing values should be interpreted as zero, then **SETMISSING=0** should be used. The section “[Accumulation](#)” on page 695 describes accumulation in greater detail.

ALIGN=option

controls the alignment of SAS dates used to identify output observations. The **ALIGN=** option accepts the following values: **BEGINNING** | **BEG** | **B**, **MIDDLE** | **MID** | **M**, and **ENDING** | **END** | **E**. **BEGINNING** is the default.

END=date | datetime

specifies a SAS date or datetime literal value that represents the end of the data. If the last time ID variable value is less than the **END=** value, the series is extended with missing values. If the last time ID variable value is greater than the **END=** value, the series is truncated. For example, **END= '1jan2008' D** specifies that data for time periods after the first of January 2008 not be used. The option **END="&sysdate" D** uses the automatic macro variable **SYSDATE** to extend or truncate the series to the current date. This option and the **START=** option can be used to ensure that data associated with each **BY** group contains the same number of observations.

FORMAT=format

specifies the SAS format for the time ID values. If the **FORMAT=** option is not specified, the default format is implied from the **INTERVAL=** option.

INTERVAL=interval

specifies the frequency of the input time series or for the time series to be accumulated from the input data. For example, if the input data set consists of quarterly observations, then **INTERVAL=QTR** should be used. If the **SEASONALITY=** option is not specified, the length of the seasonal cycle is implied by the **INTERVAL=** option. For example, **INTERVAL=QTR** implies a seasonal cycle of length 4. If the **ACCUMULATE=** option is also specified, the **INTERVAL=** option determines the time periods for the accumulation of observations.

The basic intervals are **YEAR**, **SEMIYEAR**, **QTR**, **MONTH**, **SEMIMONTH**, **TENDAY**, **WEEK**, **WEEKDAY**, **DAY**, **HOUR**, **MINUTE**, **SECOND**. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about the intervals that can be specified.

NOTSORTED

specifies that the time ID values are not in sorted order. The **ESM** procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING=option | number

specifies how missing values (either input or accumulated) are assigned in the accumulated time series. If a number is specified, missing values are set to that number. If a missing value on the input data set indicates an unknown value, the **SETMISSING=** option should not be used. If a missing value indicates no value, **SETMISSING=0** should be used. You

typically use SETMISSING=0 for transactional data, because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE AVG	Missing values are set to the accumulated average value.
MINIMUM MIN	Missing values are set to the accumulated minimum value.
MEDIAN MED	Missing values are set to the accumulated median value.
MAXIMUM MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS PREV	Missing values are set to the previous accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

If SETMISSING=MISSING is specified, the missing observations are replaced with predicted values computed from the exponential smoothing model.

START=*date | datetime*

specifies a SAS date or datetime literal value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prefixed with missing values. If the first time ID variable value is less than the START= value, the series is truncated. This option and the END= option can be used to ensure that data associated with each BY group contains the same number of observations.

ZEROMISS=*option*

specifies how beginning and/or ending zero values (either input or accumulated) are interpreted in the accumulated time series. The following values can be specified for the ZEROMISS= option:

NONE	Beginning and/or ending zeros are unchanged. This is the default.
LEFT	Beginning zeros are set to missing.
RIGHT	Ending zeros are set to missing.
BOTH	Both beginning and ending zeros are set to missing.

If the accumulated series is all missing and/or zero the series is not changed.

Details: ESM Procedure

The ESM procedure can be used to forecast time series data as well as transactional data. If the data is transactional, then the procedure must first accumulate the data into a time series before it can be forecast. The procedure uses the following sequential steps to produce forecasts, with the options that control the step listed to the right:

Table 13.2 ESM Processing Steps and Control Options

Step	Operation	Option	Statement
1	accumulation	ACCUMULATE=	ID
2	missing value interpretation	SETMISSING=	ID, FORECAST
3	transformations	TRANSFORM=	FORECAST
4	parameter estimation	MODEL=	FORECAST
5	forecasting	MODEL=, LEAD=	FORECAST, PROC ESM
6	inverse transformation	TRANSFORM, MEDIAN	FORECAST
7	summation of forecasts	LEAD=, STARTSUM=	PROC ESM

Each of the steps shown in [Table 13.2](#) is described in the following sections.

Accumulation

If the ACCUMULATE= option is specified in the ID statement, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option, and the ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is particularly useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series that is used in subsequent analyses by the ESM procedure.

For example, suppose a data set contains the following observations:

```

19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20

```

If the INTERVAL=MONTH option is specified on the ID statement, all of the preceding observations fall within three time periods: March 1999, April 1999, and May 1999. The observations are accumulated within each time period as follows.

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is:

```
O1MAR1999    40
O1APR1999    .
O1MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is:

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is:

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the resulting time series is:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the resulting time series is:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the resulting time series is:

```
O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32
```

As can be seen from the preceding examples, even though the data set observations contained no missing values, the accumulated time series can have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as truly unknown values and retained as missing values in the data set. The forecasting models used by the ESM procedure can effectively handle missing values (see the section “[Missing Value Modeling Issues](#)” on page 697). However, sometimes missing values are known, such as when missing values are created from accumulation and represent no observed values for the variable. In this case, the value for the period should be interpreted as zero (no values), and the SETMISSING=0 option should be used to cause PROC ESM to recode missing values as zero. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and missing-value-recoded time series is used in subsequent analyses in PROC ESM.

Transformations

If the TRANSFORM= option is specified in the FORECAST statement, the time series is transformed prior to model parameter estimation and forecasting. Only strictly positive series can be transformed. An error is generated when the TRANSFORM= option is used with a nonpositive series. (See Chapter 44, “[Forecasting Process Details](#),” for more details about forecasting transformed time series.)

Parameter Estimation

All the parameters (smoothing weights) associated with the exponential smoothing model used to forecast the time series (as specified by the MODEL= option) are optimized based on the data, with the default parameter restrictions imposed. If the TRANSFORM= option is specified, the transformed time series data are used to estimate the model parameters.

The techniques used in the ESM procedure are identical to those used for exponential smoothing models in the Time Series Forecasting System of SAS/ETS software. See Chapter 36, “[Overview of the Time Series Forecasting System](#),” for more information.

Missing Value Modeling Issues

The treatment of missing values varies with the forecasting model. Missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted values are used in the smoothing equations.

The treatment of missing values can also be specified with the SETMISSING= option, which changes the missing values prior to modeling.

NOTE: Even if all of the observed data are nonmissing, the `ACCUMULATE=` option can create missing values in the accumulated series (when the data contain no observations for some of the time periods specified by the `INTERVAL=` option).

Forecasting

Once the model parameters are estimated, one-step-ahead forecasts are generated for the full range of the accumulated and optionally transformed time series data, and multistep forecasts are generated from the end of the time series to the future time period specified by the `LEAD=` option. If there are missing values at the end of the time series, the forecast horizon will be greater than that specified by the `LEAD=` option.

Inverse Transformations

If the `TRANSFORM=` option is specified in the `FORECAST` statement, the forecasts of the transformed time series are inverse transformed. By default, forecasts of the mean (expected value) are generated. If the `MEDIAN` option is specified, median forecasts are generated. (See Chapter 44, “[Forecasting Process Details](#),” for more details about forecasting transformed time series.)

Statistics of Fit

The statistics of fit are computed by comparing the time series data (after accumulation and missing value recoding, if specified) with the generated forecasts. If the `TRANSFORM=` option is specified, the statistics of fit are based on the inverse transformed forecasts. (See Chapter 44, “[Forecasting Process Details](#),” for more details about statistics of fit for forecasting models.)

Forecast Summation

The multistep forecasts generated by the preceding steps can optionally be summed from the `STARTSUM=` value to the `LEAD=` value. For example, if the options `STARTSUM=4` and `LEAD=6` are specified on the `PROC ESM` statement, the four-step through six-step ahead forecasts are summed.

The forecasts are simply summed; however, the prediction error variance of this sum is computed by taking into account the correlation between the individual predictions. (These variance-related computations are performed only when no transformation is specified; that is, when `TRANSFORM=NONE`.) The upper and lower confidence limits for the sum of the predictions is then computed based on the prediction error variance of the sum.

The forecast summation is particularly useful when it is desirable to model in one frequency but the forecast of interest is another frequency. For example, if a time series has a monthly frequency (INTERVAL=MONTH) and you want a forecast for the third and fourth future months, a forecast summation for the third and fourth month can be obtained by specifying STARTSUM=3 and LEAD=4.

Data Set Output

The ESM procedure can create the OUT=, OUTEST=, OUTFOR=, OUTSTAT=, and OUTSUM= data sets. These data sets contain the variables listed in the BY statement and statistics related to the variables listing in the FORECAST statement. In general, if a forecasting step related to an output data set fails, the values of this step are not recorded or are set to missing in the related output data set and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, and FORECAST statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the FORECAST statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option. If the REPLACEMISSING option is specified, embedded missing values are replaced by the one-step-ahead predicted values.

These FORECAST variables are then extrapolated based on the forecasts from the fitted models, or extended with missing values when the MODEL=NONE option is specified. If USE=LOWER is specified, the variable is extrapolated with the lower confidence limits; if USE=UPPER, the variable is extrapolated using the upper confidence limits; otherwise, the variable values are extrapolated with the predicted values. If the TRANSFORM= option is specified, the predicted values contain either mean or median forecasts depending on whether or not the MEDIAN option is specified.

If any of the forecasting steps fail for a particular variable, the variable is extended by missing values.

OUTEST= Data Set

The OUTEST= data set contains the variables specified in the BY statement as well as the variables listed below. For variables listed in FORECAST statements where the option MODEL=NONE is specified, no observations are recorded in the OUTEST= data set. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the following variables in the OUTEST= data set contain observations related to the parameter estimation step:

<code>_NAME_</code>	variable name
<code>_MODEL_</code>	forecasting model
<code>_TRANSFORM_</code>	transformation

<code>_PARM_</code>	parameter name
<code>_EST_</code>	parameter estimate
<code>_STDERR_</code>	standard errors
<code>_TVALUE_</code>	<i>t</i> values
<code>_PVALUE_</code>	probability values

If the parameter estimation step fails for a particular variable, no observations are output to the `OUTEST=` data set for that variable.

OUTFOR= Data Set

The `OUTFOR=` data set contains the variables specified in the `BY` statement as well as the variables listed below. For variables listed in `FORECAST` statements where the option `MODEL=NONE` is specified, no observations are recorded in the `OUTFOR=` data set for these variables. For variables listed in `FORECAST` statements where the option `MODEL=NONE` is not specified, the following variables in the `OUTFOR=` data set contain observations related to the forecasting step:

<code>_NAME_</code>	variable name
<code>_TIMEID_</code>	time ID values
<code>ACTUAL</code>	actual values
<code>PREDICT</code>	predicted values
<code>STD</code>	prediction standard errors
<code>LOWER</code>	lower confidence limits
<code>UPPER</code>	upper confidence limits
<code>ERROR</code>	prediction errors

If the forecasting step fails for a particular variable, no observations are recorded in the `OUTFOR=` data set for that variable. If the `TRANSFORM=` option is specified, the values in the preceding variables are the inverse transform forecasts. If the `MEDIAN` option is specified, the median forecasts are stored; otherwise, the mean forecasts are stored.

OUTPROCINFO= Data Set

The `OUTPROCINFO=` data set contains information about the run of the ESM procedure. The following variables are present:

<code>_SOURCE_</code>	set to the name of the procedure, in this case ESM
<code>_NAME_</code>	name of an item being reported; can be the number of errors, notes, or warnings, number of forecasts requested, and so on
<code>_LABEL_</code>	descriptive label for the item in <code>_NAME_</code>
<code>_STAGE_</code>	set to the current stage of the procedure, for ESM this is set to ALL
<code>_VALUE_</code>	value of the item specified in <code>_NAME_</code>

OUTSTAT= Data Set

The OUTSTAT= data set contains the variables specified in the BY statement as well as the variables listed below. For variables listed in FORECAST statements where the option MODEL=NONE is specified, no observations are recorded for these variables in the OUTSTAT= data set. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the following variables in the OUTSTAT= data set contain observations related to the statistics of fit:

<u>_NAME_</u>	variable name
<u>_REGION_</u>	the region in which the statistics are calculated. Statistics calculated in the fit region are indicated by FIT. Statistics calculated in the forecast region, which happens only if the BACK= option is greater than zero, are indicated by FORECAST.
DFE	degrees of freedom error
N	number of observations
NOBS	number of observations used
NMISSA	number of missing actuals
NMISSP	number of missing predicted values
NPARMS	number of parameters
TSS	total sum of squares
SST	corrected total sum of squares
SSE	sum of square error
MSE	mean square error
UMSE	unbiased mean square error
RMSE	root mean square error
URMSE	unbiased root mean square error
MAPE	mean absolute percent error
MAE	mean absolute error
MASE	mean absolute scaled error
RSQUARE	R square
ADJRSQ	adjusted R square
AADJRSQ	Amemiya's adjusted R square
RWRSQ	random walk R square
AIC	Akaike information criterion
AICC	finite sample corrected AIC
SBC	Schwarz Bayesian information criterion
APC	Amemiya's prediction criterion
MAXERR	maximum error

MINERR	minimum error
MINPE	minimum percent error
MAXPE	maximum percent error
ME	mean error
MPE	mean percent error
MDAPE	median absolute percent error
GMAPE	geometric mean absolute percent error
MINPPE	minimum predictive percent error
MAXPPE	maximum predictive percent error
MSPPE	mean predictive percent error
MAPPE	symmetric mean absolute predictive percent error
MDAPPE	median absolute predictive percent error
GMAPPE	geometric mean absolute predictive percent error
MINSPE	minimum symmetric percent error
MAXSPE	maximum symmetric percent error
MSPE	mean symmetric percent error
SMAPE	symmetric mean absolute percent error
MDASPE	median absolute symmetric percent error
GMASPE	geometric mean absolute symmetric percent error
MINRE	minimum relative error
MAXRE	maximum relative error
MRE	mean relative error
MRAE	mean relative absolute error
MDRAE	median relative absolute error
GMRAE	geometric mean relative absolute error
MINAPES	minimum absolute error percent of standard deviation
MAXAPES	maximum absolute error percent of standard deviation
MAPES	mean absolute error percent of standard deviation
MDAPES	median absolute error percent of standard deviation
GMAPES	geometric mean absolute error percent of standard deviation

If the statistics of fit cannot be computed for a particular variable, no observations are recorded in the OUTSTAT= data set for that variable. If the TRANSFORM= option is specified, the values in the preceding variables are computed based on the inverse transform forecasts. If the MEDIAN option is specified, the median forecasts are the basis; otherwise, the mean forecasts are the basis.

See Chapter 44, “[Forecasting Process Details](#),” for more information about the calculation of forecasting statistics of fit.

OUTSUM= Data Set

The OUTSUM= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSUM= data set records the summary statistics for each variable specified in a FORECAST statement. For variables listed in FORECAST statements where the option MODEL=NONE is specified, the values related to forecasts are set to missing for those variables in the OUTSUM= data set. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the forecast values are set based on the USE= option.

The following variables related to summary statistics are based on the ACCUMULATE= and SET-MISSING= options:

<code>_NAME_</code>	variable name
<code>_STATUS_</code>	forecasting status. Nonzero values imply that no forecast was generated for the series.
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MIN	minimum value
MAX	maximum value
MEAN	mean value
STDDEV	standard deviation

The following variables related to forecast summation are based on the LEAD= and STARTSUM= options:

PREDICT	forecast summation predicted values
STD	forecast summation prediction standard errors
LOWER	forecast summation lower confidence limits
UPPER	forecast summation upper confidence limits

Variance-related computations are computed only when no transformation is specified (TRANSFORM=NONE).

The following variables related to multistep forecast are based on the LEAD= and USE= options:

<code>_LEADn_</code>	multistep forecast (n ranges from one to the value of the LEAD= option). If USE=LOWER, this variable contains the lower confidence limits; if USE=UPPER, this variable contains the upper confidence limits; otherwise, this variable contains the predicted values.
-----------------------------------	---

If the forecast step fails for a particular variable, the variables that are related to forecasting are set to missing for that variable. The OUTSUM= data set contains both a summary of the (accumulated) time series and optionally its forecasts for all series.

Printed Output

The ESM procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= and PRINTDETAILS options in the PROC ESM statement. In general, if a forecasting step that is related to printed output fails, the values of this step are not printed and appropriate error or warning messages are recorded in the log. The printed output is similar to the output data sets.

The printed output produced by the PRINT= option values is described as follows:

SUMMARY	prints the summary statistics and forecast summaries similar to the OUTSUM= data set.
ESTIMATES	prints the parameter estimates similar to the OUTEST= data set.
FORECASTS	prints the forecasts similar to the OUTFOR= data set.
PERFORMANCE	prints the performance statistics.
PERFORMANCESUMMARY	prints the performance summary for each BY group.
PERFORMANCEOVERALL	prints the performance summary for all BY groups.
STATES	prints the backcast, initial, and final smoothed states.
STATISTICS	prints the statistics of fit similar to the OUTSTAT= data set.

The PRINTDETAILS option is the opposite of the NOOUTALL option. Specifically, if PRINT=FORECASTS and the PRINTDETAILS options are specified in the PROC ESM statement, the one-step-ahead forecasts through the range of the data are printed in addition to the information related to a specific forecasting model, such as the smoothing states. If the PRINTDETAILS option is not specified, only the multistep forecasts are printed.

ODS Table Names

Table 13.3 relates the PRINT= options to ODS tables:

Table 13.3 ODS Tables Produced in PROC ESM

ODS Table Name	Description	PRINT= Option
DescStats	descriptive statistics	SUMMARY
ForecastSummary	forecast summary	SUMMARY
ForecastSummation	forecast summation	SUMMARY
ParameterEstimates	parameter estimates	ESTIMATES
Forecasts	forecasts	FORECASTS
Performance	performance statistics	PERFORMANCE
PerformanceSummary	performance summary	PERFORMANCESUMMARY
PerformanceOverall	performance overall	PERFORMANCEOVERALL
SmoothedStates	smoothed states	STATES
FitStatistics	evaluation statistics of fit	STATISTICS
PerformanceStatistics	performance (out-of-sample) statistics of fit	STATISTICS

The ODS table “ForecastSummary” is related to all time series within a BY group. The other tables are related to a single series within a BY group.

ODS Graphics

This section describes the use of ODS for creating graphics with the ESM procedure.

To request these graphs, you must specify the statement `ods graphics on` in your SAS program before the PROC ESM statement. In addition, you must specify the PLOT= option in the PROC ESM statement.

ODS Graph Names

PROC ESM assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 13.4](#).

Table 13.4 ODS Graphics Produced by the PLOT= Option in PROC ESM

ODS Graph Name	Plot Description	PLOT= Option
ErrorACFNORMPlot	standardized autocorrelation of prediction errors	ACF
ErrorACFPlot	autocorrelation of prediction errors	ACF
ErrorHistogram	prediction error histogram	ERRORS
ErrorIACFNORMPlot	standardized inverse autocorrelation of prediction errors	IACF
ErrorIACFPlot	inverse autocorrelation of prediction errors	IACF
ErrorPACFNORMPlot	standardized partial autocorrelation of prediction errors	PACF
ErrorPACFPlot	partial autocorrelation of prediction errors	PACF
ErrorPlot	plot of prediction errors	ERRORS
ErrorWhiteNoiseLogProbPlot	white noise log probability plot of prediction errors	WN
ErrorWhiteNoiseProbPlot	white noise probability plot of prediction errors	WN
ForecastsOnlyPlot	forecasts only plot	FORECASTSONLY
ForecastsPlot	forecasts plot	FORECASTS
LevelStatePlot	smoothed level state plot	LEVELS
ModelForecastsPlot	model and forecasts plot	MODELFORECASTS
ModelPlot	model plot	MODELS
SeasonStatePlot	smoothed season state plot	SEASONS
TrendStatePlot	smoothed trend state plot	TRENDS

Examples: ESM Procedure

Example 13.1: Forecasting of Time Series Data

This example uses retail sales data to illustrate how the ESM procedure can be used to forecast time series data.

The following DATA step creates a data set from data recorded monthly at numerous points of sales. The data set, SALES, contains a variable DATE that represents time and a variable for each sales item. Each value of the DATE variable is recorded in ascending order, and the values of each of the other variables represent a single time series:

```

data sales;
  format date date9.;
  input date : date9. shoes socks laces dresses
        coats shirts ties belts hats blouses;
datalines;

... more lines ...

```

The following ESM procedure statements forecast each of the monthly time series:

```

proc esm data=sales out=nextyear;
  id date interval=month;
  forecast _numeric_;
run;

```

The preceding statements generate forecasts for every numeric variable in the input data set SALES for the next twelve months and store these forecasts in the output data set NEXTYEAR.

The following statements plot the forecasts:

```

title1 "Shoe Department Sales";
proc sgplot data=nextyear;
  series x=date y=shoes / markers
        markerattrs=(symbol=circlefilled color=red)
        lineattrs=(color=red);
  series x=date y=socks / markers
        markerattrs=(symbol=asterisk color=blue)
        lineattrs=(color=blue);
  series x=date y=laces / markers
        markerattrs=(symbol=circle color=styg)
        lineattrs=(color=styg);
  refline '01JAN1999'd / axis=x;
  xaxis values=('01JAN1994'd to '01DEC2000'd by year);
  yaxis values=(2000 to 10000 by 1000) minor label='Websites';
run;

```

The plots are shown in [Output 13.1.1](#). The historical data is shown to the left of the reference line and the forecasts for the next twelve monthly periods is shown to the right.

Output 13.1.1 Retail Sales Forecast Plots

The default simple exponential smoothing model is used because the `MODEL=` option is omitted on the `FORECAST` statement. Note that for simple exponential smoothing the forecasts are constant.

The following ESM procedure statements are identical to the preceding statements except that the `PRINT=FORECASTS` option is specified:

```
proc esm data=sales out=nextyear print=forecasts;
  id date interval=month;
  forecast _numeric_;
run;
```

In addition to forecasting each of the monthly time series, the preceding statements print the forecasts by using the Output Delivery System (ODS); the forecasts are partially shown in [Output 13.1.2](#). This output shows the predictions, prediction standard errors, and the upper and lower confidence limits for the next twelve monthly periods.

Output 13.1.2 Forecast Tables

Shoe Department Sales

Example 13.2: Forecasting of Transactional Data

This example illustrates how the ESM procedure can be used to forecast transactional data.

The following DATA step creates a data set from data recorded at several Internet Web sites. The data set WEBSITES contains a variable TIME that represents time and the variables ENGINE, BOATS, CARS, and PLANES that represent Internet Web site data. Each value of the TIME variable is recorded in ascending order, and the values of each of the other variables represent a transactional data series.

The following ESM procedure statements forecast each of the transactional data series:

```
proc esm data=websites out=nextweek lead=7;
  id time interval=dtday accumulate=total;
  forecast boats cars planes;
run;
```

The preceding statements accumulate the data into a daily time series, generate forecasts for the BOATS, CARS, and PLANES variables in the input data set WEBSITES for the next week, and the forecasts are stored in the OUT= data set NEXTWEEK.

The following statements plot the forecasts related to the Internet data:

```

title1 "Website Data";
proc sgplot data=nextweek;
series x=time y=boats / markers
      markerattrs=(symbol=circlefilled color=red)
      lineattrs=(color=red);
series x=time y=cars / markers
      markerattrs=(symbol=asterisk color=blue)
      lineattrs=(color=blue);
series x=time y=planes / markers
      markerattrs=(symbol=circle color=styg)
      lineattrs=(color=styg);
refline '11APR2000:00:00:00' dt / axis=x;
xaxis values=('13MAR2000:00:00:00' dt to '18APR2000:00:00:00' dt by dtweek);
yaxis label='Websites' minor;
run;

```

The plots are shown in [Output 13.2.1](#). The historical data is shown to the left of the reference line and the forecasts for the next seven days are shown to the right.

Output 13.2.1 Internet Data Forecast Plots

Example 13.3: Specifying the Forecasting Model

This example illustrates how the ESM procedure can be used to specify different models for different series. Internet data from the previous example are used for this illustration.

This example, forecasts the BOATS variable by using the seasonal exponential smoothing model (SEASONAL), the CARS variable by using the Winters (multiplicative) model (MULTWINTERS), and the PLANES variable by using the Log Winters (additive) model. The following ESM procedure statements forecast each of the transactional data series based on these requirements:

```
proc esm data=websites out=nextweek lead=7;
  id time interval=dtday accumulate=total;
  forecast boats / model=seasonal;
  forecast cars / model=multwinters;
  forecast planes / model=addwinters transform=log;
run;
```

Example 13.4: Extending the Independent Variables for Multivariate Forecasts

In the previous example, the ESM procedure was used to forecast several transactional series variables by using univariate models. This example illustrates how the ESM procedure can be used to extend the independent variables that are associated with a multiple regression forecasting problem.

This example accumulates and forecasts the BOATS, CARS, and PLANES variables that were illustrated in the previous example. In addition, this example accumulates the ENGINES variable to form a time series that is then extended with missing values within the forecast horizon with the specification of MODEL=NONE.

```
proc esm data=websites out=nextweek lead=7;
  id time interval=dtday accumulate=total;
  forecast engines / model=none;
  forecast boats / model=seasonal;
  forecast cars / model=multwinters;
  forecast planes / model=addwinters transform=log;
run;
```

The following AUTOREG procedure statements are used to forecast the ENGINES variable by regressing on the independent variables (BOATS, CARS, and PLANES).

```
proc autoreg data= nextweek;
  model engines = boats cars planes / noprint;
  output out=enginehits p=predicted;
run;
```

The NEXTWEEK data set created by PROC ESM is used as an input data set to PROC AUTOREG. The output data set from PROC AUTOREG contains the forecast of the variable ENGINES based on

the regression model with the variables BOATS, CARS, and PLANES as regressors. See Chapter 8, “[The AUTOREG Procedure](#),” for details about autoregression models.

The following statements plot the forecasts related to the ENGINES variable:

```

title1 "Website Data";
proc sgplot data=enginehits;
  series x=time y=boats / markers
          markerattrs=(symbol=circlefilled color=red)
          lineattrs=(color=red);
  series x=time y=cars / markers
          markerattrs=(symbol=asterisk color=blue)
          lineattrs=(color=blue);
  series x=time y=planes / markers
          markerattrs=(symbol=circle color=styg)
          lineattrs=(color=styg);
  scatter x=time y=predicted / markerattrs=(symbol=plus color=black);
  refline '11APR2000:00:00:00'dt / axis=x;
  xaxis values=('13MAR2000:00:00:00'dt to '18APR2000:00:00:00'dt by dtweek);
  yaxis label='Websites' minor;
run;

```

The plots are shown in [Output 13.4.1](#). The historical data is shown to the left of the reference line and the forecasts for the next seven daily periods are shown to the right.

Output 13.4.1 Internet Data Forecast Plots

Example 13.5: Illustration of ODS Graphics

This example illustrates the use of ODS graphics in the ESM procedure and uses the SASHELP.PAIR data set to forecast the time series of international airline travel.

The graphical displays are requested by specifying the `ods graphics on` statement and the `PLOTS=` option in the PROC ESM statement. In this case, all plots are requested. [Output 13.5.1](#) through [Output 13.5.4](#) show a selection of the plots created.

For information about the graphics available in the ESM procedure, see the section “[ODS Graphics](#)” on page 705.

```
proc esm data=sashelp.air out=_null_  
    lead=20  
    back=20  
    print=all  
    plots=all;  
    id date interval=month;  
    forecast air / model=addwinters transform=log;  
run;
```

Output 13.5.1 Smoothed Trend Plot

Output 13.5.2 Prediction Error Plot

Output 13.5.3 Prediction Error Standardized ACF Plot

Output 13.5.4 Forecast Plot

Overview: EXPAND Procedure

The EXPAND procedure converts time series from one sampling interval or frequency to another and interpolates missing values in time series. A wide array of data transformations is also supported. Using PROC EXPAND, you can collapse time series data from higher frequency intervals to lower frequency intervals, or expand data from lower frequency intervals to higher frequency intervals. For example, quarterly values can be aggregated to produce an annual series, or quarterly estimates can be interpolated from an annual series.

Time series frequency conversion is useful when you need to combine series with different sampling intervals into a single data set. For example, if you need as input to a monthly model a series that is only available quarterly, you might use PROC EXPAND to interpolate the needed monthly values.

You can also interpolate missing values in time series, either without changing series frequency or in conjunction with expanding or collapsing the series.

You can convert between any combination of input and output frequencies that can be specified by SAS time interval names. (See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for a complete description of SAS interval names.) When the FROM= and TO= options are used to specify *from* and *to* intervals, PROC EXPAND automatically accounts for calendar effects such as the differing number of days in each month and leap years.

The EXPAND procedure also handles conversions of frequencies that cannot be defined by standard interval names. Using the FACTOR= option, you can interpolate any number of output observations for each group of a specified number of input observations. For example, if you specify the option FACTOR=(13:2), 13 equally spaced output observations are interpolated from each pair of input observations.

You can also convert aperiodic series, observed at arbitrary points in time, into periodic estimates. For example, a series of randomly timed quality control spot-check results might be interpolated to form estimates of monthly average defect rates.

The EXPAND procedure can also change the observation characteristics of time series. Time series observations can measure beginning-of-period values, end-of-period values, midpoint values, or period averages or totals. PROC EXPAND can convert between these cases. You can construct estimates of interval averages from end-of-period values of a variable, estimate beginning-of-period or midpoint values from interval averages, or compute averages from interval totals, and so forth.

By default, the EXPAND procedure fits cubic spline curves to the nonmissing values of variables to form continuous-time approximations of the input series. Output series are then generated from the spline approximations. Several alternate conversion methods are described in the section “[Conversion Methods](#)” on page 739. You can also interpolate estimates of the rate of change of time series by differentiating the interpolating spline curve.

Various transformations can be applied to the input series prior to interpolation and to the interpolated output series. For example, the interpolation process can be modified by transforming the input series, interpolating the transformed series, and applying the inverse of the input transformation to the output series. PROC EXPAND can also be used to apply transformations to time series without interpolation or frequency conversion.

The results of the EXPAND procedure are stored in a SAS data set. No printed output is produced.

Getting Started: EXPAND Procedure

Converting to Higher Frequency Series

To create higher frequency estimates, specify the input and output intervals with the FROM= and TO= options, and list the variables to be converted in a CONVERT statement. For example, suppose variables X, Y, and Z in the data set ANNUAL are annual time series, and you want monthly estimates. You can interpolate monthly estimates by using the following statements:

```
proc expand data=annual out=monthly from=year to=month;
  convert x y z;
run;
```

Note that interpolating values of a time series does not add any real information to the data as the interpolation process is not the same process that generated the other (nonmissing) values in the series. While time series interpolation can sometimes be useful, great care is needed in analyzing time series containing interpolated values.

Aggregating to Lower Frequency Series

PROC EXPAND provides two ways to convert from a higher frequency to a lower frequency. When a curve fitting method is used, converting to a lower frequency is no different than converting to a higher frequency—you just specify the desired output frequency with the TO= option. This provides for interpolation of missing values and allows conversion from non-nested intervals, such as converting from weekly to monthly values.

Alternatively, you can specify simple aggregation or selection without interpolation of missing values. This might be useful, for example, if you want to add up monthly values to produce annual totals, but want the annual output data set to contain values only for complete years.

To perform simple aggregation, use the METHOD=AGGREGATE option in the CONVERT statement. For example, the following statements aggregate monthly values to yearly values:

```
proc expand data=monthly out=annual
  from=month to=year;
  convert x y z / method=aggregate;
  convert a b c / method=aggregate observed=total;
  id date;
run;
```

This example assumes that the variables X, Y, and Z represent point-in-time values observed at the beginning of each month, and that the desired results are point-in-time values observed at the beginning of each year. (The default value of the OBSERVED= option is OBSERVED=(BEGINNING,BEGINNING).) The variables A, B, and C are assumed to represent monthly totals, and that the desired results are annual totals; therefor the option OBSERVED=TOTAL is specified. See the section “[Specifying Observation Characteristics](#)” on page 724 for more information on the OBSERVED= option.

Note that the AGGREGATE method can be used only if the input intervals are nested within the output intervals, as when converting from daily to monthly or from monthly to yearly frequency.

Combining Time Series with Different Frequencies

One important use of PROC EXPAND is to combine time series measured at different sampling frequencies. For example, suppose you have data on monthly money stocks (M1), quarterly gross domestic product (GDP), and weekly interest rates (INTEREST), and you want to perform an analysis of a model that uses all these variables. To perform the analysis, you first need to convert the series to a common frequency and then combine the variables into one data set.

The following statements illustrate this process for the three data sets QUARTER, MONTHLY, and WEEKLY. The data sets QUARTER and WEEKLY are converted to monthly frequency using two PROC EXPAND steps, and the three data sets are then merged using a DATA step MERGE statement to produce the data set COMBINED. The quarterly GDP data are interpolated as the total GDP over each month (OBSERVED=TOTAL) while the weekly INTEREST data are converted to average rates over each month (OBSERVED=AVERAGE).

```
proc expand data=quarter out=temp1
           from=qtr to=month;
  id date;
  convert gdp / observed=totals;
run;

proc expand data=weekly out=temp2
           from=week to=month;
  id date;
  convert interest / observed=average;
run;

data combined;
  merge monthly temp1 temp2;
  by date;
run;
```

See Chapter 3, “[Working with Time Series Data](#),” for further discussion of time series periodicity, time series dating, and time series interpolation. See the section “[Specifying Observation Characteristics](#)” on page 724 for more information on the OBSERVED= option.

Interpolating Missing Values

To interpolate missing values in time series without converting the observation frequency, leave off the `TO=` option on the `PROC EXPAND` statement. For example, the following statements interpolate any missing values in the time series in the data set `ANNUAL`.

```
proc expand data=annual out=new from=year;
  id date;
  convert x y z;
  convert a b c / observed=total;
run;
```

This example assumes that the variables `X`, `Y`, and `Z` represent point-in-time values observed at the beginning of each year. (The default value of the `OBSERVED=` option is `OBSERVED=BEGINNING`.) The variables `A`, `B`, and `C` are assumed to represent annual totals.

To interpolate missing values in variables observed at specific points in time, omit both the `FROM=` and `TO=` options and use the `ID` statement to supply time values for the observations. The observations do not need to be periodic or form regular time series, but the data set must be sorted by the `ID` variable. For example, the following statements interpolate any missing values in the numeric variables in the data set `A`.

```
proc expand data=a out=b;
  id date;
run;
```

If the observations are equally spaced in time, and all the series are observed as beginning-of-period values, only the input and output data sets need to be specified. For example, the following statements interpolate any missing values in the numeric variables in the data set `A` using a cubic spline function, assuming that the observations are at equally spaced points in time.

```
proc expand data=a out=b;
run;
```

Refer to the section “[Missing Values](#)” on page 748 for further information.

Requesting Different Interpolation Methods

By default, a cubic spline curve is fit to the input series, and the output is computed from this interpolating curve. Other interpolation methods can be specified with the `METHOD=` option on the `CONVERT` statement. The section “[Conversion Methods](#)” on page 739 explains the available methods.

For example, the following statements convert annual series to monthly series using linear interpolation instead of cubic spline interpolation.

```
proc expand data=annual out=monthly from=year to=month;
  id date;
  convert x y z / method=join;
run;
```

Using the ID Statement

An ID statement is normally used with PROC EXPAND to specify a SAS date or datetime variable to identify the time of each input observation. An ID variable allows PROC EXPAND to do the following:

- identify the observations in the output data set
- determine the time span between observations and detect gaps in the input series caused by omitted observations
- account for calendar effects such as the number of days in each month and leap years

If you do not specify an ID variable with SAS date or datetime values, PROC EXPAND makes default assumptions that may not be what you want. See the section “[ID Statement](#)” on page 733 for details.

Specifying Observation Characteristics

It is important to distinguish between variables that are measured at points in time and variables that represent totals or averages over an interval. Point-in-time values are often called *stocks* or *levels*. Variables that represent totals or averages over an interval are often called *flows* or *rates*.

For example, the annual series *U.S. Gross Domestic Product* represents the total value of production over the year and also the yearly average rate of production in dollars per year. However, a monthly variable *inventory* may represent the cost of a stock of goods as of the end of the month.

When the data represent periodic totals or averages, the process of interpolation to a higher frequency is sometimes called *distribution*, and the total values of the larger intervals are said to be *distributed* to the smaller intervals. The process of interpolating periodic total or average values to lower frequency estimates is sometimes called *aggregation*.

By default, PROC EXPAND assumes that all time series represent beginning-of-period point-in-time values. If a series does not measure beginning of period point-in-time values, interpolation of the data values using this assumption is not appropriate, and you should specify the correct observation characteristics of the series. The observation characteristics of the series are specified with the [OBSERVED=](#) option on the CONVERT statement.

For example, suppose that the data set ANNUAL contains variables A, B, and C that measure yearly totals, while the variables X, Y, and Z measure first-of-year values. The following statements

estimate the contribution of each month to the annual totals in A, B, and C, and interpolate first-of-month estimates of X, Y, and Z.

```
proc expand data=annual out=monthly
    from=year to=month;
    id date;
    convert x y z;
    convert a b c / observed=total;
run;
```

The EXPAND procedure supports five different observation characteristics. The **OBSERVED=** *value* options for these five observation characteristics are:

BEGINNING	beginning-of-period values
MIDDLE	period midpoint values
END	end-of-period values
TOTAL	period totals
AVERAGE	period averages

The interpolation of each series is adjusted appropriately for its observation characteristics. When **OBSERVED=TOTAL** or **AVERAGE** is specified, the interpolating curve is fit to the data values so that the area under the curve within each input interval equals the value of the series. For **OBSERVED=MIDDLE** or **END**, the curve is fit through the data points, with the time position of each data value placed at the specified offset from the start of the interval.

See the section “**OBSERVED= Option**” on page 737 for details.

Converting Observation Characteristics

The EXPAND procedure can be used to interpolate values for output series with different observation characteristics than the input series. To change observation characteristics, specify two values in the **OBSERVED=** option. The first value specifies the observation characteristics of the input series; the second value specifies the observation characteristics of the output series.

For example, the following statements convert the period total variable A in the data set **ANNUAL** to yearly midpoint estimates. This example does not change the series frequency, and the other variables in the data set are copied to the output data set unchanged.

```
proc expand data=annual out=new from=year;
    id date;
    convert a / observed=(total,middle);
run;
```

Creating New Variables

You can use the CONVERT statement to name a new variable to contain the results of the conversion. Using this feature, you can create several different versions of a series in a single PROC EXPAND step. Specify the new name after the input variable name and an equal sign:

```
convert variable=newname ... ;
```

For example, suppose you are converting quarterly data to monthly and you want both first-of-month and midmonth estimates for a beginning-of-period variable X. The following statements perform this task:

```
proc expand data=a out=b
           from=qtr to=month;
  id date;
  convert x=x_begin / observed=beginning;
  convert x=x_mid   / observed=(beginning,middle);
run;
```

Transforming Series

The interpolation methods used by PROC EXPAND assume that there are no restrictions on the range of values that series can have. This assumption can sometimes cause problems if the series must be within a certain range.

For example, suppose you are converting monthly sales figures to weekly estimates. Sales estimates should never be less than zero, but since the spline curve ignores this restriction some interpolated values may be negative. One way to deal with this problem is to transform the input series before fitting the interpolating spline and then reverse transform the output series.

You can apply various transformations to the input series using the **TRANSFORMIN=** option on the CONVERT statement. (The TRANSFORMIN= option can be abbreviated as TRANSFORM= or TIN=.) You can apply transformations to the output series using the **TRANSFORMOUT=** option. (The TRANSFORMOUT= option can be abbreviated as TOUT=.)

For example, you might use a logarithmic transformation of the input sales series and exponentiate the interpolated output series. The following statements fit a spline curve to the log of SALES and then exponentiate the output series.

```
proc expand data=a out=b from=month to=week;
  id date;
  convert sales / observed=total
              transformin=(log)
              transformout=(exp);
run;
```

Note that the transformations specified by the TRANSFORMIN= option are applied before the data are interpolated; the cubic spline curve or other interpolation method is fitted to transformed input data. The transformations specified by the TRANSFORMOUT= option are applied to interpolated values computed from the curves fit to the transformed input data.

As another example, suppose you are interpolating missing values in a series of market share estimates. Market shares must be between 0% and 100%, but applying a spline interpolation to the raw series can produce estimates outside of this range.

The following statements use the logistic transformation to transform proportions in the range 0 to 1 to values in the range $-\infty$ to $+\infty$. The TIN= option first divides the market shares by 100 to rescale percent values to proportions and then applies the LOGIT function. The TOUT= option applies the inverse logistic function ILOGIT to the interpolated values to convert back to proportions and then multiplies by 100 to rescale back to percentages.

```
proc expand data=a out=b;
  id date;
  convert mshare / tin=( / 100 logit )
          tout=( ilogit * 100 );
run;
```

When more than one transformation is specified in the TRANSFORMIN= or TRANSFORMOUT= option, the transformations are applied in the order in which they are listed. Thus in the above example the complete input transformation is $\text{logit}(mshare/100)$ (and not $\text{logit}(mshare)/100$) because the division operation is listed first in the TIN= option.

You can also use the TRANSFORM= (or TRANSFORMOUT=) option as a convenient way to do calculations normally performed with the SAS DATA step. For example, the following statements add the lead of X to the data set A. The METHOD=NONE option is used to suppress interpolation.

```
proc expand data=a method=none;
  id date;
  convert x=xlead / transform=(lead);
run;
```

Any number of operations can be listed in the TRANSFORMIN= and TRANSFORMOUT= options. See [Table 14.2](#) for a list of the operations supported.

Syntax: EXPAND Procedure

The EXPAND procedure uses the following statements:

```
PROC EXPAND options ;
  BY variables ;
  CONVERT variables / options ;
  ID variable ;
```

Functional Summary

The statements and options controlling the EXPAND procedure are summarized in the following table.

Description	Statement	Option
Statements		
specify options	PROC EXPAND	
specify BY-group processing	BY	
specify conversion options	CONVERT	
specify the ID variable	ID	
Data Set Options		
specify the input data set	PROC EXPAND	DATA=
extrapolate values before or after input series	PROC EXPAND	EXTRAPOLATE
specify the output data set	PROC EXPAND	OUT=
write interpolating functions to a data set	PROC EXPAND	OUTEST=
Input and Output Frequencies		
control the alignment of SAS Date values	PROC EXPAND	ALIGN=
specify frequency conversion factor	PROC EXPAND	FACTOR=
specify input frequency	PROC EXPAND	FROM=
specify output frequency	PROC EXPAND	TO=
Interpolation Control Options		
specify interpolation method for all series	PROC EXPAND	METHOD=
specify interpolation method for series	CONVERT	METHOD=
specify observation characteristics for series	PROC EXPAND	OBSERVED=
specify observation characteristics for series	CONVERT	OBSERVED=
specify transformations of the input series	CONVERT	TRANSFORMIN=
specify transformations of the output series	CONVERT	TRANSFORMOUT=
Graphical Output Control Options		
specify graphical output	PROC EXPAND	PLOTS=

PROC EXPAND Statement

PROC EXPAND *options* ;

The following options can be used with the PROC EXPAND statement:

Data Set Options

DATA= *SAS-data-set*

names the input data set. If the DATA= option is omitted, the most recently created SAS data set is used.

OUT= *SAS-data-set*

names the output data set containing the resulting time series. If OUT= is not specified, the data set is named using the DATA n convention. See the section “[OUT= Data Set](#)” on page 756 for details.

OUTEST= *SAS-data-set*

names an output data set containing the coefficients of the spline curves fit to the input series. If the OUTEST= option is not specified, the spline coefficients are not output. See the section “[OUTEST= Data Set](#)” on page 756 for details.

Options That Define Input and Output Frequencies

ALIGN= *option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

FACTOR= *n*

FACTOR=(*n : m* **)**

specifies the number of output observations to be created from the input observations. FACTOR= n specifies that n output observations are to be produced for each input observation. FACTOR=($n : m$) specifies that n output observations are to be produced for each group of m input observations. FACTOR= n is the same as FACTOR=($n : 1$).

In the FACTOR=($n : m$) option, a comma can be used instead of a colon or the delimiter can be omitted. Thus FACTOR=(n, m) or FACTOR=($n m$) is the same as FACTOR=($n : m$).

The FACTOR= option cannot be used if the TO= option is used. The default value is FACTOR=(1:1). For more information, see the section “[Frequency Conversion](#)” on page 733.

FROM= *interval*

specifies the time interval between observations in the input data set. Examples of FROM= values are YEAR, QTR, MONTH, DAY, and HOUR. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for a complete description and examples of interval specifications.

TO= *interval*

specifies the time interval between observations in the output data set. By default, the TO= interval is generated from the combination of the FROM= and the FACTOR= values or is set to be the same as the FROM= value if FACTOR= is not specified. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for a description of interval specifications.

Options to Control the Interpolation

EXTRAPOLATE

specifies that missing values at the beginning or end of input series be replaced with values produced by a linear extrapolation of the interpolating curve fit to the input series. See the section “[Extrapolation](#)” on page 736 later in this chapter for details.

By default, PROC EXPAND avoids extrapolating values beyond the first or last input value for a series and only interpolates values within the range of the nonmissing input values. Note that the extrapolated values are often not very accurate and for the SPLINE method the EXTRAPOLATE option results may be very unreasonable. The EXTRAPOLATE option is rarely used.

METHOD= *option*

METHOD=SPLINE(*constraint* < , *constraint* >)

specifies the method used to convert the data series. The methods supported are SPLINE, JOIN, STEP, AGGREGATE, and NONE. The METHOD= option specified on the PROC EXPAND statement can be overridden for particular series by the METHOD= option on the CONVERT statement. The default is METHOD=SPLINE. The *constraint* specifications for METHOD=SPLINE can have the values NOTAKNOT (the default), NATURAL, SLOPE=*value*, and/or CURVATURE=*value*. See the section “[Conversion Methods](#)” on page 739 for more information about these methods.

OBSERVED= *value*

OBSERVED=(*from-value* , *to-value*)

indicates the observation characteristics of the input time series and of the output series. Specifying the OBSERVED= option on the PROC EXPAND statement sets the default OBSERVED= value for subsequent CONVERT statements. See the sections “[CONVERT Statement](#)” on page 732 and “[OBSERVED= Option](#)” on page 737 later in this chapter for details. The default is OBSERVED=BEGINNING.

Options to Control Graphical Output

PLOTS= *option* | (*options*)

specifies the graphical output desired. If the PLOTS= option is used, the specified graphical output is produced for each output variable specified by a CONVERT statement. By default, the EXPAND procedure produces no graphical output. The following PLOTS= options are available. Required options are listed in parentheses in the plot descriptions when necessary.

INPUT	plots the input series
TRANSFORMIN	plots the transformed input series (TRANSFORMIN= option)
CROSSINPUT	plots both the input series and the transformed input series on one plot with two Y axis. The input and transformed series are shown on separate scales. (TRANSFORMIN= option)
JOINTINPUT	plots both the input series and the transformed input series on one plot with one Y axis. The input and transformed series are shown on the same scale. (TRANSFORMIN= option)

CONVERTED	plots the converted series, after input transformations and interpolation but before any TRANSFORMOUT= transformations are applied (METHOD= option)
TRANSFORMOUT	plots the transformed output series (TRANSFORMOUT= option)
CROSSOUTPUT	plots both the converted series and the transformed output series on one plot with two Y axis. The converted and transformed output series are shown on separate scales. (TRANSFORMOUT= option)
JOINTOUTPUT	plots both the converted series and the transformed output series on one plot with one Y axis. The converted and transformed output series are shown on the same scale. (TRANSFORMOUT= option)
OUTPUT	plots the series stored in the OUT= data set (combination of TRANSFORMIN=, METHOD=, and TRANSFORMOUT= options)
ALL	produces all plots except the Joint and Cross plots. (Same as PLOTS=(INPUT TRANSFORMIN CONVERTED TRANSFORMOUT).)

The PLOTS= option produces results associated with each CONVERT statement output variable and the options listed in the PLOTS= specification. See the section “[PLOTS= Option Details](#)” on page 758 for more information.

BY Statement

BY variables ;

A BY statement can be used with PROC EXPAND to obtain separate analyses on observations in groups defined by the BY variables. The input data set must be sorted by the BY variables and be sorted by the ID variable within each BY group.

Use a BY statement when you want to interpolate or convert time series within levels of a cross-sectional variable. For example, suppose you have a data set STATE containing annual estimates of average disposable personal income per capita (DPI) by state and you want quarterly estimates by state. These statements convert the DPI series within each state:

```
proc sort data=state;
  by state date;
run;

proc expand data=state out=stateqtr from=year to=qtr;
  convert dpi;
  by state;
  id date;
run;
```

CONVERT Statement

CONVERT *variable = newname ... < / options >* ;

The CONVERT statement lists the variables to be processed. Only numeric variables can be processed.

For each of the variables listed, a new variable name can be specified after an equal sign to name the variable in the output data set that contains the converted values. If a name for the output series is not given, the variable in the output data set has the same name as the input variable. Variable lists may be used only when no name is given for the output series.

For example, variable lists can be specified as follows:

```
convert y1-y25 / observed=(beginning, end) ;
convert x--a / observed=average;
convert x-numeric-a / observed=average;
```

Any number of CONVERT statements can be used. If no CONVERT statement is used, all the numeric variables in the input data set except those appearing in the BY and ID statements are processed.

The following options can be used with the CONVERT statement.

METHOD= *option*

METHOD=SPLINE(*constraint < , constraint >*)

specifies the method used to convert the data series. (The method specified by the METHOD= option is applied to the input data series after applying any transformations specified by the TRANSFORMIN= option.) The methods supported are SPLINE, JOIN, STEP, AGGREGATE, and NONE. The METHOD= option specified on the PROC EXPAND statement can be overridden for particular series by the METHOD= option on the CONVERT statement. The default is METHOD=SPLINE. The *constraint* specifications for METHOD=SPLINE can have the values NOTAKNOT (the default), NATURAL, SLOPE=*value*, and/or CURVATURE=*value*. See the section “[Conversion Methods](#)” on page 739 section for more information about these methods.

OBSERVED= *value*

OBSERVED=(*from-value , to-value*)

indicates the observation characteristics of the input time series and of the output series. The values supported are TOTAL, AVERAGE, BEGINNING, MIDDLE, and END. In addition, DERIVATIVE can be specified as the *to-value* when the SPLINE method is used.

When only one values is specified, that value specifies both the *from-value* and the *to-value*. (That is, OBSERVED=*value* is equivalent to OBSERVED=(*value,value*.) If the OBSERVED= option is omitted from both the PROC EXPAND and the CONVERT statements, the default is OBSERVED=(BEGINNING,BEGINNING). See the section “[OBSERVED= Option](#)” on page 737 later in this chapter for details.

TRANSFORMIN=(operation . . .)

specifies a list of transformations to be applied to the input series before the interpolating function is fit. The operations are applied in the order listed. See the section “[Transformation Operations](#)” on page 742 later in this chapter for the operations that can be specified. The TRANSFORMIN= option can be abbreviated as TRANSIN=, TIN=, or TRANSFORM=.

TRANSFORMOUT=(operation . . .)

specifies a list of transformations to be applied to the output series. The operations are applied in the order listed. See the section “[Transformation Operations](#)” on page 742 later in this chapter for the operations that can be specified. The TRANSFORMOUT= option can be abbreviated as TRANSOUT=, or TOUT=.

ID Statement

ID variable ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable’s values are assumed to be SAS date or datetime values.

The input data must form time series. This means that the observations in the input data set must be sorted by the ID variable (within the BY variables, if any). Moreover, there should be no duplicate observations, and no two observations should have ID values within the same time interval as defined by the FROM= option.

If the ID statement is omitted, SAS date or datetime values are generated to label the input observations. These ID values are generated by assuming that the input data set starts at a SAS date value of 0, that is, 1 January 1960. This default starting date is then incremented for each observation by the FROM= interval (using the same logic as DATA step INTNX function). If the FROM= option is not specified, the ID values are generated as the observation count minus 1. When the ID statement is not used, an ID variable is added to the output data set named either DATE or DATETIME, depending on the value specified in the TO= option. If neither the TO= option nor the FROM= option is given, the ID variable in the output data set is named TIME.

Details: EXPAND Procedure

Frequency Conversion

Frequency conversion is controlled by the FROM=, TO=, and FACTOR= options. The possible combinations of these options are explained in the following:

None Used

If FROM=, TO=, and FACTOR= are not specified, no frequency conversion is done. The data are

processed to interpolate any missing values and perform any specified transformations. Each input observation produces one output observation.

FACTOR=(n:m)

FACTOR=(n:m) specifies that n output observations are produced for each group of m input observations. The fraction m/n is reduced first: thus **FACTOR=(10:6)** is equivalent to **FACTOR=(5:3)**. Note that if $m/n=1$, the result is the same as the case given previously under “None Used”.

FROM=interval

The **FROM=** option used alone establishes the frequency and interval widths of the input observations. Missing values are interpolated, and any specified transformations are performed, but no frequency conversion is done.

TO=interval

When the **TO=** option is used without the **FROM=** option, output observations with the **TO=** frequency are generated over the range of input ID values. The first output observation is for the **TO=** interval containing the ID value of the first input observation; the last output observation is for the **TO=** interval containing the ID value of the last input observation. The input observations are not assumed to form regular time series and may represent aperiodic points in time. An ID variable is required to give the date or datetime of the input observations.

FROM=interval TO=interval

When both the **FROM=** and **TO=** options are used, the input observations have the frequency given by the **FROM=** interval, and the output observations have the frequency given by the **TO=** interval.

FROM=interval FACTOR=(n:m)

When both the **FROM=** and **FACTOR=** options are used, a **TO=** interval is inferred from the combination of the **FROM=interval** and the **FACTOR=(n:m)** values specified. For example, **FROM=YEAR FACTOR=4** is the same as **FROM=YEAR TO=QTR**. Also, **FROM=YEAR FACTOR=(3:2)** is the same as **FROM=YEAR** used with **TO=MONTH8**. Once the implied **TO=** interval is determined, this combination operates the same as if **FROM=** and **TO=** had been specified. If no valid **TO=** interval can be constructed from the combination of the **FROM=** and **FACTOR=** options, an error is produced.

TO=interval FACTOR=(n:m)

The combination of the **TO=** option and the **FACTOR=** option is not allowed and produces an error.

ALIGN= option

Controls the alignment of SAS dates used to identify output observations. The **ALIGN=** option allows the following values: **BEGINNING | BEG | B**, **MIDDLE | MID | M**, and **ENDING | END | E**. **BEGINNING** is the default.

Converting to a Lower Frequency

When converting to a lower frequency, the results are either exact or approximate, depending on whether or not the input interval nests within the output interval and depending on the need to interpolate missing values within the series. If the **TO=** interval is nested within the **FROM=** interval (as when converting from monthly to yearly), and if there are no missing input values or partial periods, the results are exact.

When values are missing or the FROM= interval is not nested within the TO= interval (as when aggregating from weekly to monthly), the results depend on an interpolation. The METHOD=AGGREGATE option always produces exact results, never an interpolation. However, this method can only be used if the FROM= interval is nested within the TO= interval.

Identifying Observations

The variable specified in the ID statement is used to identify the observations. Usually, SAS date or datetime values are used for this variable. PROC EXPAND uses the ID variable to do the following:

- identify the time interval of the input values
- validate the input data set observations
- compute the ID values for the observations in the output data set

Identifying the Input Time Intervals

When the FROM= option is specified, observations are understood to refer to the whole time interval and not to a single time point. The ID values are interpreted as identifying the FROM= time interval containing the value. In addition, the widths of these input intervals are used by the OBSERVED= values TOTAL, AVERAGE, MIDDLE, and END.

For example, if FROM=MONTH is specified, then each observation is for the whole calendar month containing the ID value for the observation, and the width of the time interval covered by the observation is the number of days in that month. Therefore, if FROM=MONTH, the ID value '31MAR92'D is equivalent to the ID value '1MAR92'D—both of these ID values identify the same interval, March of 1992.

Widths of Input Time Intervals

When the FROM= option is not specified, the ID variable values are usually interpreted as referring to points in time. However, if an OBSERVED= option value is specified that assumes the observations refer to whole intervals and also requires interval widths (TOTAL or AVERAGE), then, in the absence of the FROM= specification, interval widths are assumed to be the time span between ID values. For the last observation, the interval width is assumed to be the same as for the next to last observation. (If neither the FROM= option nor the ID statement are specified, interval widths are assumed to be 1.0.) A note is printed in the SAS log warning that this assumption is made.

Validating the Input Data Set Observations

The ID variable is used to verify that successive observations read from the input data set correspond to sequential FROM= intervals. When the FROM= option is not used, PROC EXPAND verifies

that the ID values are nonmissing and in ascending order. An error message is produced and the observation is ignored when an invalid ID value is found in the input data set.

ID values for Observations in the Output Data Set

The time unit used for the ID variable in the output data set is controlled by the interval value specified by the TO= option. If you specify a date interval for the TO= value, the ID variable values in the output data set are SAS date values. If you specify a datetime interval for the TO= value, the ID variable values in the output data set are SAS datetime values.

The date or datetime values for the ID variable for output observations is the first date or datetime of the TO= interval, unless the ALIGN= option is used to specify a different alignment. (For example, if TO=WEEK is specified, then the output dates are Sundays. If TO=WEEK.2 is specified, then the output date are Mondays.) See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information on interval specifications.

Range of Output Observations

If no frequency conversion is done, the range of output observations is the same as in the input data set.

When frequency conversion is done, the observations in the output data set range from the earliest start of any result series to the latest end of any result series. Observations at the beginning or end of the input range for which all result values are missing are not written to the OUT= data set.

When the EXTRAPOLATE option is not used, the range of the nonmissing output results for each series is as follows. The first result value is for the TO= interval that contains the ID value of the start of the FROM= interval containing the ID value of the first nonmissing input observation for the series. The last result value is for the TO= interval that contains the end of the FROM= interval containing the ID value of the last nonmissing input observation for the series.

When the EXTRAPOLATE option is used, result values for all series are computed for the full time range covered by the input data set.

Extrapolation

The spline functions fit by the EXPAND procedure are very good at approximating continuous curves within the time range of the input data but poor at extrapolating beyond the range of the data. The accuracy of the results produced by PROC EXPAND may be somewhat less at the ends of the output series than at time periods for which there are several input values at both earlier and later times. The curves fit by PROC EXPAND should not be used for forecasting.

PROC EXPAND normally avoids extrapolation of values beyond the time range of the nonmissing input data for a series, unless the EXTRAPOLATE option is used. However, if the start or end of

the input series does not correspond to the start or end of an output interval, some output values may depend in part on an extrapolation.

For example, if FROM=YEAR, TO=WEEK, and OBSERVED=BEGINNING are specified, then the first observation output for a series is for the week of 1 January of the first nonmissing input year. If 1 January of that year is not a Sunday, the beginning of this week falls before the date of the first input value, and therefore a beginning-of-period output value for this week is extrapolated.

This extrapolation is made only to the extent needed to complete the terminal output intervals that overlap the endpoints of the input series and is limited to no more than the width of one FROM= interval or one TO= interval, whichever is less. This restriction of the extrapolation to complete terminal output intervals is applied to each series separately, and it takes into account the OBSERVED= option for the input and output series.

When the EXTRAPOLATE option is used, the normal restriction on extrapolation is overridden. Output values are computed for the full time range covered by the input data set.

For the SPLINE method, extrapolation is performed by a linear projection of the trend of the cubic spline curve fit to the input data, not by extrapolation of the first and last cubic segments.

The EXTRAPLOTE option should be used with caution.

OBSERVED= Option

The values of the CONVERT statement OBSERVED= option are as follows:

BEGINNING	indicates that the data are beginning-of-period values. OBSERVED=BEGINNING is the default.
MIDDLE	indicates that the data are period midpoint values.
ENDING	indicates that the data represent end-of-period values.
TOTAL	indicates that the data values represent period totals for the time interval corresponding to the observation.
AVERAGE	indicates that the data values represent period averages.
DERIVATIVE	requests that the output series be the derivatives of the cubic spline curve fit to the input data by the SPLINE method.

If only one value is specified in the OBSERVED= option, that value applies to both the input and the output series. For example, OBSERVED=TOTAL is the same as OBSERVED=(TOTAL,TOTAL), which indicates that the input values represent totals over the time intervals corresponding to the input observations, and the converted output values also represent period totals. The value DERIVATIVE can be used only as the second OBSERVED= option value, and it can be used only when METHOD=SPLINE is specified or is the default method.

Since the TOTAL, AVERAGE, MIDDLE, and END cases require that the width of each input interval be known, both the FROM= option and an ID statement are normally required if one of these observation characteristics is specified for any series. However, if the FROM= option is not

specified, each input interval is assumed to extend from the ID value for the observation to the ID value of the next observation, and the width of the interval for the last observation is assumed to be the same as the width for the next to last observation.

Scale of OBSERVED=AVERAGE Values

The average values are assumed to be expressed in the time units defined by the FROM= or TO= option. That is, the product of the average value for an interval and the width of the interval is assumed to equal the total value for the interval. For purposes of interpolation, OBSERVED=AVERAGE values are first converted to OBSERVED=TOTAL values using this assumption, and then the interpolated totals are converted back to averages by dividing by the widths of the output intervals.

For example, suppose the options FROM=MONTH, TO=HOUR, and OBSERVED=AVERAGE are specified. Since FROM=MONTH is specified, each input value is assumed to represent an average rate per day such that the product of the value and the number of days in the month is equal to the total for the month. The input values are assumed to represent a per-day rate because FROM=MONTH implies SAS date ID values that measure time in days, and therefore the widths of MONTH intervals are measured in days. If FROM=DTMONTH is used instead, the values are assumed to represent a per-second rate, because the widths of DTMONTH intervals are measured in seconds.

Since TO=HOUR is specified, the output values are scaled as an average rate per second such that the product of each output value and the number of seconds in an hour (3600) is equal to the interpolated hourly total. A per-second rate is used because TO=HOUR implies SAS datetime ID values that measure time in seconds, and therefore the widths of HOUR intervals are measured in seconds.

Note that the scale assumed for OBSERVED=AVERAGE data is important only when converting between AVERAGE and another OBSERVED= option, or when converting between SAS date and SAS datetime ID values. When both the input and the output series are AVERAGE values, and the units for the ID values are not changed, the scale assumed does not matter.

For example, suppose you are converting gross domestic product (GDP) from quarterly to monthly. The GDP values are quarterly averages measured at annual rates. If you want the interpolated monthly values to also be measured at annual rates, then the option OBSERVED=AVERAGE works fine. Since there is no change of scale involved in this problem, it makes no difference that PROC EXPAND assumes daily rates instead of annual rates.

However, suppose you want to convert GDP from quarterly to monthly and also convert from annual rates to monthly rates, so that the result is total gross domestic product for the month. Using the option OBSERVED=(AVERAGE,TOTAL) would fail, because PROC EXPAND assumes the average is scaled to daily, not annual, rates.

One solution is to rescale to quarterly totals and treat the data as totals. You could use the options TRANSFORMIN=(/ 4) OBSERVED=TOTAL. Alternatively, you could treat the data as averages but first convert to daily rates. In this case you would use the options TRANSFORMIN=(/ 365.25) OBSERVED=AVERAGE.

Results of the OBSERVED=DERIVATIVE Option

If the first value of the OBSERVED= option is BEGINNING, TOTAL, or AVERAGE, the result is the derivative of the spline curve evaluated at first-of-period ID values for the output observation. For OBSERVED=(MIDDLE,DERIVATIVE), the derivative of the function is evaluated at output interval midpoints. For OBSERVED=(END,DERIVATIVE), the derivative is evaluated at end-of-period ID values.

Conversion Methods

The SPLINE Method

The SPLINE method fits a cubic spline curve to the input values. A cubic spline is a segmented function consisting of third-degree (cubic) polynomial functions joined together so that the whole curve and its first and second derivatives are continuous.

For point-in-time input data, the spline curve is constrained to pass through the given data points. For interval total or average data, the definite integrals of the spline over the input intervals are constrained to equal the given interval totals.

For boundary constraints, the *not-a-knot* condition is used by default. This means that the first two spline pieces are constrained to be part of the same cubic curve, as are the last two pieces. Thus the spline used by PROC EXPAND by default is not the same as the commonly used natural spline, which uses zero second-derivative endpoint constraints. While DeBoor (1981) recommends the *not-a-knot* constraint for cubic spline interpolation, using this constraint can sometimes produce anomalous results at the ends of the interpolated series. PROC EXPAND provides options to specify other endpoint constraints for spline curves.

To specify endpoint constraints, use the following form of the METHOD= option.

METHOD=SPLINE(*constraint* < , *constraint* >)

The first constraint specification applies to the lower endpoint, and the second constraint specification applies to the upper endpoint. If only one constraint is specified, it applies to both the lower and upper endpoints.

The *constraint* specifications can have the following values:

NOTAKNOT

specifies the not-a-knot constraint. This is the default.

NATURAL

specifies the *natural spline* constraint. The second derivative of the spline curve is constrained to be zero at the endpoint.

SLOPE= value

specifies the first derivative of the spline curve at the endpoint. The value specified can be any positive or negative number, but extreme values may produce unreasonable results.

CURVATURE= value

specifies the second derivative of the spline curve at the endpoint. The value specified can be any positive or negative number, but extreme values may produce unreasonable results. Specifying `CURVATURE=0` is equivalent to specifying the `NATURAL` option.

For example, to specify natural spline interpolation, use the following option in the `CONVERT` or `PROC EXPAND` statement:

```
method=spline(natural)
```

For `OBSERVED=BEGINNING`, `MIDDLE`, and `END` series, the spline knots are placed at the beginning, middle, and end of each input interval, respectively. For total or averaged series, the spline knots are set at the start of the first interval, at the end of the last interval, and at the interval midpoints, except that there are no knots for the first two and last two midpoints.

Once the cubic spline curve is fit to the data, the spline is extended by adding linear segments at the beginning and end. These linear segments are used for extrapolating values beyond the range of the input data.

For point-in-time output series, the spline function is evaluated at the appropriate points. For interval total or average output series, the spline function is integrated over the output intervals.

The JOIN Method

The `JOIN` method fits a continuous curve to the data by connecting successive straight line segments. For point-in-time data, the `JOIN` method connects successive nonmissing input values with straight lines. For interval total or average data, interval midpoints are used as the break points, and ordinates are chosen so that the integrals of the piecewise linear curve agree with the input totals.

For point-in-time output series, the `JOIN` function is evaluated at the appropriate points. For interval total or average output series, the `JOIN` function is integrated over the output intervals.

The STEP Method

The `STEP` method fits a discontinuous piecewise constant curve. For point-in-time input data, the resulting step function is equal to the most recent input value. For interval total or average data, the step function is equal to the average value for the interval.

For point-in-time output series, the step function is evaluated at the appropriate points. For interval total or average output series, the step function is integrated over the output intervals.

The AGGREGATE Method

The `AGGREGATE` method performs simple aggregation of time series without interpolation of missing values.

If the input data are totals or averages, the results are the sums or averages, respectively, of the input values for observations corresponding to the output observations. That is, if either `TOTAL` or `AVERAGE` is specified for the `OBSERVED=` option, the `METHOD=AGGREGATE` result is the sum or mean of the input values corresponding to the output observation. For example, suppose `METHOD=AGGREGATE`, `FROM=MONTH`, and `TO=YEAR` are specified. For `OBSERVED=TOTAL` series, the result for each output year is the sum of the input values over the months of that year. If any input value is missing, the corresponding sum or mean is also a missing value.

If the input data are point-in-time values, the result value of each output observation equals the input value for a selected input observation determined by the `OBSERVED=` attribute. For example, suppose `METHOD=AGGREGATE`, `FROM=MONTH`, and `TO=YEAR` are specified. For `OBSERVED=BEGINNING` series, January observations are selected as the annual values. For `OBSERVED=MIDDLE` series, July observations are selected as the annual values. For `OBSERVED=END` series, December observations are selected as the annual values. If the selected value is missing, the output annual value is missing.

The `AGGREGATE` method can be used only when the `FROM=` intervals are nested within the `TO=` intervals. For example, you can use `METHOD=AGGREGATE` when `FROM=MONTH` and `TO=QTR` because months are nested within quarters. You cannot use `METHOD=AGGREGATE` when `FROM=WEEK` and `TO=QTR` because weeks are not nested within quarters.

In addition, the `AGGREGATE` method cannot convert between point-in-time data and interval total or average data. Conversions between `TOTAL` and `AVERAGE` data are allowed, but conversions between `BEGINNING`, `MIDDLE`, and `END` are not.

Missing input values produce missing result values for `METHOD=AGGREGATE`. However, gaps in the sequence of input observations are not allowed. For example, if `FROM=MONTH`, you may have a missing value for a variable in an observation for a given February. But if an observation for January is followed by an observation for March, there is a gap in the data, and `METHOD=AGGREGATE` cannot be used.

When the `AGGREGATE` method is used, there is no interpolating curve, and therefore the `EXTRAPOLATE` option is not allowed.

Alternate methods for aggregating or accumulating time series data are supported by the `TIME-SERIES` procedure. See Chapter 27, “[The TIMESERIES Procedure](#),” for more information.

METHOD=NONE

The option `METHOD=NONE` specifies that no interpolation be performed. This option is normally used in conjunction with the `TRANSFORMIN=` or `TRANSFORMOUT=` option.

When `METHOD=NONE` is specified, there is no difference between the `TRANSFORMIN=` and `TRANSFORMOUT=` options; if both are specified, the `TRANSFORMIN=` operations are performed first, followed by the `TRANSFORMOUT=` operations. `TRANSFORM=` can be used as an abbreviation for `TRANSFORMIN=`. `METHOD=NONE` cannot be used when frequency conversion is specified.

Transformation Operations

The operations that can be used in the TRANSFORMIN= and TRANSFORMOUT= options are shown in Table 14.2. Operations are applied to each value of the series. Each value of the series is replaced by the result of the operation.

In Table 14.2, x_t or x represents the value of the series at a particular time period t before the transformation is applied, y_t represents the value of the result series, and N represents the total number of observations.

The notation $[n]$ indicates that the argument n is optional; the default is 1. The notation *window* is used as the argument for the moving statistics operators, and it indicates that you can specify either an integer number of periods n or a list of n weights in parentheses. The notation *sequence* is used as the argument for the sequence operators, and it indicates that you must specify a sequence of numbers. The notation s indicates the length of seasonality, and it is a required argument.

Table 14.2 Transformation Operations

Syntax	Result
+ <i>number</i>	adds the specified <i>number</i> : $x + \textit{number}$
- <i>number</i>	subtracts the specified <i>number</i> : $x - \textit{number}$

TRIMRIGHT n	sets x_t to missing a value if $t \geq N - n + 1$

Moving Time Window Operators

Some operators compute statistics for a set of values within a moving time window; these are called *moving time window operators*. There are centered and backward versions of these operators.

The centered moving time window operators are CMOVAVE, CMOVCSS, CMOVGMEAN, CMOVMAX, CMOVMEAN, CMOVMIN, CMOVPROD, CMOV RANGE, CMOVRANK, CMOVSTD, CMOVSUM, CMOVTVALUE, CMOVUSS, and CMOVVAR. These operators compute statistics of the n values x_i for observations $t - (n - 1)/2 \leq i \leq t + (n - 1)/2$.

The backward moving time window operators are MOVAVE, MOVCSS, MOVGMEAN, MOVMAX, MOVMEAN, MOVMIN, MOVPROD, MOV RANGE, MOV RANK, MOVSTD, MOVSUM, MOVTVALUE, MOVUSS, and MOVVAR. These operators compute statistics of the n values $x_t, x_{t-1}, \dots, x_{t-n+1}$.

All the moving time window operators accept an argument n specifying the number of periods to include in the time window. For example, the following statement computes a five-period backward moving average of X .

```
convert x=y / transformout=( movave 5 );
```

In this example, the resulting transformation is

$$y_t = (x_t + x_{t-1} + x_{t-2} + x_{t-3} + x_{t-4})/5$$

The following statement computes a five-period centered moving average of X .

```
convert x=y / transformout=( cmovave 5 );
```

In this example, the resulting transformation is

$$y_t = (x_{t-2} + x_{t-1} + x_t + x_{t+1} + x_{t+2})/5$$

If the window with a centered moving time window operator is not an odd number, one more lagged value than lead value is included in the time window. For example, the result of the CMOVAVE 4 operator is

$$y_t = (x_{t+1} + x_t + x_{t-1} + x_{t-2})/4$$

You can compute a forward moving time window operation by combining a backward moving time window operator with the REVERSE operator. For example, the following statement computes a five-period forward moving average of X .

```
convert x=y / transformout=( reverse movave 5 reverse );
```

In this example, the resulting transformation is

$$y_t = (x_t + x_{t+1} + x_{t+2} + x_{t+3} + x_{t+4})/5$$

Some of the moving time window operators enable you to specify a list of weight values to compute weighted statistics. These are CMOVAVE, CMOVCSS, CMOVGMEAN, CMOVPROD, CMOVSTD, CMOVTVALUE, CMOVUSS, CMOVVAR, MOVAVE, MOVCSS, MOVGMEAN, MOVPROD, MOVSTD, MOVTVALUE, MOVUSS, and MOVVAR.

To specify a weighted moving time window operator, enter the weight values in parentheses after the operator name. The window width n is equal to the number of weights that you specify; do not specify n .

For example, the following statement computes a weighted five-period centered moving average of X .

```
convert x=y / transformout=( cmovave( .1 .2 .4 .2 .1 ) );
```

In this example, the resulting transformation is

$$y_t = .1x_{t-2} + .2x_{t-1} + .4x_t + .2x_{t+1} + .1x_{t+2}$$

The weight values must be greater than zero. If the weights do not sum to 1, the weights specified are divided by their sum to produce the weights used to compute the statistic.

A complete time window is not available at the beginning of the series. For the centered operators a complete window is also not available at the end of the series. The computation of the moving time window operators is adjusted for these boundary conditions as follows.

For backward moving window operators, the width of the time window is shortened at the beginning of the series. For example, the results of the MOVSUM 3 operator are

$$\begin{aligned} y_1 &= x_1 \\ y_2 &= x_1 + x_2 \\ y_3 &= x_1 + x_2 + x_3 \\ y_4 &= x_2 + x_3 + x_4 \\ y_5 &= x_3 + x_4 + x_5 \\ &\dots \end{aligned}$$

For centered moving window operators, the width of the time window is shortened at the beginning and the end of the series due to unavailable observations. For example, the results of the

CMOVSUM 5 operator are

$$\begin{aligned}
 y_1 &= x_1 + x_2 + x_3 \\
 y_2 &= x_1 + x_2 + x_3 + x_4 \\
 y_3 &= x_1 + x_2 + x_3 + x_4 + x_5 \\
 y_4 &= x_2 + x_3 + x_4 + x_5 + x_6 \\
 &\dots \\
 y_{N-2} &= x_{N-4} + x_{N-3} + x_{N-2} + x_{N-1} + x_N \\
 y_{N-1} &= x_{N-3} + x_{N-2} + x_{N-1} + x_N \\
 y_N &= x_{N-2} + x_{N-1} + x_N
 \end{aligned}$$

For weighted moving time window operators, the weights for the unavailable or unused observations are ignored and the remaining weights renormalized to sum to 1.

Cumulative Statistics Operators

Some operators compute cumulative statistics for a set of current and previous values of the series. The cumulative statistics operators are CUAVE, CUCSS, CUMAX, CUMED, CUMIN, CURANGE, CUSTD, CUSUM, CUUSS, and CUVAR.

By default, the cumulative statistics operators compute the statistics from all previous values of the series, so that y_t is based on the set of values x_t, x_{t-1}, \dots, x_1 . For example, the following statement computes y_t as the cumulative sum of nonmissing x_i values for $i \leq t$.

```
convert x=y / transformout=( csum );
```

You can specify a lag increment argument n for the cumulative statistics operators. In this case, the statistic is computed from the current and every n^{th} previous value. When n is specified these operators compute statistics of the values $x_t, x_{t-n}, x_{t-2n}, \dots, x_{t-in}$ for $t - in > 0$.

For example, the following statement computes y_t as the cumulative sum of nonmissing x_i values for odd i when t is odd and for even i when t is even.

```
convert x=y / transformout=( csum 2 );
```

The results of this example are

$$\begin{aligned}
 y_1 &= x_1 \\
 y_2 &= x_2 \\
 y_3 &= x_1 + x_3 \\
 y_4 &= x_2 + x_4 \\
 y_5 &= x_1 + x_3 + x_5 \\
 y_6 &= x_2 + x_4 + x_6 \\
 &\dots
 \end{aligned}$$

Missing Values

You can truncate the length of the result series by using the TRIM, TRIMLEFT, and TRIMRIGHT operators to set values to missing at the beginning or end of the series.

You can use these functions to trim the results of moving time window operators so that the result series contains only values computed from a full width time window. For example, the following statements compute a centered five-period moving average of X , and they set to missing values at the ends of the series that are averages of fewer than five values.

```
convert x=y / transformout=( cmovave 5 trim 2 );
```

Normally, the moving time window and cumulative statistics operators ignore missing values and compute their results for the nonmissing values. When preceded by the NOMISS operator, these functions produce a missing result if any value within the time window is missing.

The NOMISS operator does not perform any calculations, but serves to modify the operation of the moving time window operator that follows it. The NOMISS operator has no effect unless it is followed by a moving time window operator.

For example, the following statement computes a five-period moving average of the variable X but produces a missing value when any of the five values are missing.

```
convert x=y / transformout=( nomiss movave 5 );
```

The following statement computes the cumulative sum of the variable X but produces a missing value for all periods after the first missing X value.

```
convert x=y / transformout=( nomiss cusum );
```

Similar to the NOMISS operator, the MISSONLY operator does not perform any calculations (unless followed by the MEAN option), but it serves to modify the operation of the moving time window operator that follows it. When preceded by the MISSONLY operator, these moving time window operators replace any missing values with the moving statistic and leave nonmissing values unchanged.

For example, the following statement replaces any missing values of the variable X with an exponentially weighted moving average of the past values of X and leaves nonmissing values unchanged. The missing values are interpolated using the specified exponentially weighted moving average. (This is also called simple exponential smoothing.)

```
convert x=y / transformout=( missonly ewma 0.3 );
```

The following statement replaces any missing values of the variable X with the overall mean of X .

```
convert x=y / transformout=( missonly mean );
```

You can use the SETMISS operator to replace missing values with a specified number. For example, the following statement replaces any missing values of the variable X with the number 8.77.

```
convert x=y / transformout=( setmiss 8.77 );
```

Classical Decomposition Operators

If x_t is a seasonal time series with s observations per season, *classical decomposition* methods “break down” the time series into four components: trend, cycle, seasonal, and irregular components. The trend and cycle components are often combined to form the trend-cycle component. There are two basic forms of classical decomposition: multiplicative and additive, which are shown below.

$$\begin{aligned}x_t &= TC_t S_t I_t \\x_t &= TC_t + S_t + I_t\end{aligned}$$

where

TC_t	is the trend-cycle component
S_t	is the seasonal component or seasonal factors that are periodic with period s and with mean one (multiplicative) or zero (additive)
I_t	is the irregular or random component that is assumed to have mean one (multiplicative) or zero (additive)

For multiplicative decomposition, all of the x_t values should be positive.

The CD_TC operator computes the trend-cycle component for both the multiplicative and additive models. When s is odd, this operator computes an s -period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} x_{t+k} / s$$

For example, in the case where $s=5$, the CD_TC s operator

```
convert x=tc / transformout=( cd_tc 5 );
```

is equivalent to the following CMOVAVE operator:

```
convert x=tc / transformout=( cmovave 5 trim 2 );
```

When s is even, the CD_TC s operator computes the average of two adjacent s -period centered moving averages as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor - 1} (x_{t+k} + x_{t+1+k}) / 2s$$

For example, in the case where $s=12$, the CD_TC s operator

```
convert x=tc / transformout=( cd_tc 12 );
```

is equivalent to the following CMOVAVE operator:

```
convert x=tc / transformout=(cmovave 12 movave 2 trim 6);
```

The CD_S and CDA_S operators compute the seasonal components for the multiplicative and additive models, respectively. First, the trend-cycle component is computed as shown previously. Second, the seasonal-irregular component is computed by $SI_t = x_t/TC_t$ for the multiplicative model and by $SI_t = x_t - TC_t$ for the additive model. The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{n/s}$$

where $0 \leq j \leq n/s$ and $1 \leq k \leq s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

The CD_I and CDA_I operators compute the irregular component for the multiplicative and additive models respectively. First, the seasonal component is computed as shown previously. Next, the irregular component is determined from the seasonal-irregular and seasonal components as appropriate.

$$\begin{aligned} I_t &= SI_t/S_t \\ I_t &= SI_t - S_t \end{aligned}$$

The CD_SA and CDA_SA operators compute the seasonally adjusted time series for the multiplicative and additive models, respectively. After decomposition, the original time series can be seasonally adjusted as appropriate.

$$\begin{aligned} \tilde{x}_t &= x_t/S_t = TC_t I_t \\ \tilde{x}_t &= x_t - S_t = TC_t + I_t \end{aligned}$$

The following statements compute all the multiplicative classical decomposition components for the variable X for $s=12$.

```
convert x=tc / transformout=( cd_tc 12 );
convert x=s / transformout=( cd_s 12 );
convert x=i / transformout=( cd_i 12 );
convert x=sa / transformout=( cd_sa 12 );
```

The following statements compute all the additive classical decomposition components for the variable X for $s=4$.

```

convert x=tc / transformout=( cd_tc 4 );
convert x=s / transformout=( cda_s 4 );
convert x=i / transformout=( cda_i 4 );
convert x=sa / transformout=( cda_sa 4 );

```

The X12 and X11 procedures provides other methods for seasonal decomposition. See Chapter 32, “The X12 Procedure,” and Chapter 31, “The X11 Procedure.”

Fractional Operators

For fractional operators, the parameter, d , represents the order of fractional differencing. Fractional summation is the inverse operation of fractional differencing.

Examples of Usage

Suppose that X is a fractionally integrated time series variable of order $d=0.25$. Fractionally differencing X forms a time series variable Y which is not integrated.

```

convert x=y / transformout=(fdif 0.25);

```

Suppose that Z is a non-integrated time series variable. Fractionally summing Z forms a time series W which is fractionally integrated of order $d = 0.25$.

```

convert z=w / transformout=(fsum 0.25);

```

Moving Rank Operators

For the rank operators, the ranks are computed based on the current value with respect to the cumulative, centered, or moving window values. If the current value is missing, the transformed current value is set to missing. If the NOMISS option was previously specified and if any missing values are present in the moving window, the transformed current value is set to missing. Otherwise, redundant values from the moving window are removed and the rank of the current value is computed among the unique values of the moving window.

Examples of Usage

The trades of a particular security are recorded for each weekday in a variable named PRICE. Given the historical daily trades, the ranking of the price of this security for each trading day, considering its entire past history, can be computed as follows:

```

convert price=history / transformout=( curank );

```

The ranking of the price of this security for each trading day considering the previous week’s history can be computed as follows:

```
convert price=lastweek / transformout=( movrank 5 );
```

The ranking of the price of this security for each trading day considering the previous two week's history can be computed as follows:

```
convert price=twoweek / transformout=( movrank 10 );
```

Moving Product Operators

For the product operators, the current transformed value is computed based on the (weighted) product of the cumulative, centered, or moving window values. If missing values are present in the moving window and the NOMISS operator is previously specified, the current transformed value is set to missing. Otherwise, the current transformed value is set to the (weighted) product of the nonmissing values of the moving window. If the geometric mean is desired, the exponents of each product are normalized to one.

Examples of Usage

The interest rates for a savings account are recorded for each month in the data set variable RATES. The cumulative interest rate for each month considering the entire account past history can be computed as follows:

```
convert rates=history / transformout=( + 1 cuprod - 1);
```

The interest rate for each quarter considering the previous quarter's history can be computed as follows:

```
convert rates=lastqtr / transformout=( + 1 movprod 3 - 1);
```

Sequence Operators

For the sequence operators, the sequence values are used to compute the transformed values from the original values in a sequential fashion. You can add to or subtract from the original series or you can multiply or divide by the sequence values. The first sequence value is applied to the first observation of the series, the second sequence value is applied to the second observation of the series, and so on until the end of the sequence is reached. At this point, the first sequence value is applied to the next observation of the series and the second sequence value on the next observation and so on.

Let v_1, \dots, v_m be the sequence values and let $x_t, t = 1, \dots, N$, be the original time series. The transformed series, y_t , is computed as follows:

$$\begin{aligned}
 y_1 &= x_1 \text{ op } v_1 \\
 y_2 &= x_2 \text{ op } v_2 \\
 &\dots \\
 y_m &= x_m \text{ op } v_m \\
 y_{m+1} &= x_{m+1} \text{ op } v_1 \\
 y_{m+2} &= x_{m+2} \text{ op } v_2 \\
 &\dots \\
 y_{2m} &= x_{2m} \text{ op } v_m \\
 y_{2m+1} &= x_{2m+1} \text{ op } v_1 \\
 y_{2m+2} &= x_{2m+2} \text{ op } v_2 \\
 &\dots
 \end{aligned}$$

where $op = +, -, *, \text{ or } /$.

Examples of Usage

The multiplicative seasonal indices are 0.9, 1.2, 0.8, and 1.1 for the four quarters. Let SEASADJ be a quarterly time series variable that has been seasonally adjusted in a multiplicative fashion. To restore the seasonality to SEASADJ use the following transformation:

```
convert seasadj=seasonal /
transformout=(seqmult (0.9 1.2 0.8 1.1));
```

The additive seasonal indices are 4.4, -1.1, -2.1, and -1.2 for the four quarters. Let SEASADJ be a quarterly time series variable that has been seasonally adjusted in additive fashion. To restore the seasonality to SEASADJ use the following transformation:

```
convert seasadj=seasonal /
transformout=(seqadd (4.4 -1.1 -2.1 -1.2));
```

Set Operators

For the set operators, the first parameter, n_1 , represents the value to be replaced and the second parameter, n_2 , represents the replacement value. The replacement can be localized to the beginning, middle, or end of the series.

Examples of Usage

Suppose that a store opened recently and that the sales history is stored in a database that does not recognize missing values. Even though demand may have existed prior to the stores opening, this

database assigns the value of zero. Modeling the sales history may be problematic because the sales history is mostly zero. To compensate for this deficiency, the leading zero values should be set to missing with the remaining zero values unchanged (representing no demand).

```
convert sales=demand / transformout=(setleft 0 .);
```

Likewise, suppose a store is closed recently. The demand may still be present and hence a recorded value of zero does not accurately reflect actual demand.

```
convert sales=demand / transformout=(setright 0 .);
```

Scale Operator

For the scale operator, the first parameter, n_1 , represents the value associated with the minimum value (x_{min}) and the second parameter, n_2 , represents the value associated with the maximum value (x_{max}) of the original series (x_t). The scale operator rescales the original data to be between the parameters n_1 and n_2 as follows:

$$y_t = ((n_2 - n_1)/(x_{max} - x_{min}))(x_t - x_{min}) + n_1$$

Examples of Usage

Suppose that two new product sales histories are stored in variables X and Y and you wish to determine their adoption rates. In order to compare their adoption histories the variables must be scaled for comparison.

```
convert x=w / transformout=(scale 0 1);
convert y=z / transformout=(scale 0 1);
```

Adjust Operator

For the moving summation and product window operators, the window widths at the beginning and end of the series are smaller than those in the middle of the series. Likewise, if there are embedded missing values, the window width is smaller than specified. When preceded by the ADJUST operator, the moving summation (MOVSUM CMOVSUM) and moving product operators (MOVPROD CMOVPROD) are adjusted by the window width.

For example, suppose the variable X has 10 values and the moving summation operator of width 3 is applied to X to create the variable Y with window width adjustment and the variable Z without adjustment.

```
convert x=y / transformout=(adjust movsum 3);
convert x=z / transformout=(movsum 3);
```

The above transformations result in the following relationship between Y and Z : $y_1 = 3z_1$, $y_2 = \frac{3}{2}z_2$, $y_t = z_t$ for $t > 2$ because the first two window widths are smaller than 3.

For example, suppose the variable X has 10 values and the moving multiplicative operator of width 3 is applied to X to create the variable Y with window width adjustment and the variable Z without adjustment.

```
convert x=y / transformout=(adjust movprod 3);
convert x=z / transformout=(movprod 3);
```

The above transformation result in the following: $y_1 = z_1^3$, $y_2 = z_2^{3/2}$, $y_t = z_t$ for $t > 2$ because the first two window widths are smaller than 3.

Moving T-Value Operators

The moving t -value operators (CUTVALUE, MOVTVALUE, CMOVTVALUE) compute the t -value of the cumulative series or moving window. They can be viewed as combinations of the moving average (CUAVE, MOVAVE, CMOVAVE) and the moving standard deviation (CUSTD, MOVSTD, CMOVSTD), respectively.

Percent Operators

The percentage operators compute the percent summation and the percent difference of the current value and the lag(n). The percent summation operator (PCTSUM) computes $y_t = 100x_t/\text{cusum}(x_{t-n})$. If any of the values of the preceding equation are missing or the cumulative summation is zero, the result is set to missing. The percent difference operator (PCTDIF) computes $y_t = 100(x_t - x_{t-n})/x_{t-n}$. If any of the values of the preceding equation are missing or the lag value is zero, the result is set to missing.

For example, suppose variable X contains the series. The percent summation of lag 4 is applied to X to create the variable Y . The percent difference of lag 4 is applied to X to create the variable Z .

```
convert x=y / transformout=(pctsum 4);
convert x=z / transformout=(pctdif 4);
```

Ratio Operators

The ratio operator computes the ratio of the current value and the lag(n) value. The ratio operator (RATIO) computes $y_t = x_t/x_{t-n}$. If any of the values of the preceding equation are missing or the lag value is zero, the result is set to missing.

For example, suppose variable X contains the series. The ratio of the current value and the lag 4 value of X assigned to the variable Y . The percent ratio of the current value and lag 4 value of X is assigned to the variable Z .

```
convert x=y / transformout=(ratio 4);
convert x=z / transformout=(ratio 4 * 100);
```

OUT= Data Set

The OUT= output data set contains the following variables:

- the BY variables, if any
- an ID variable that identifies the time period for each output observation
- the result variables
- if no frequency conversion is performed (so that there is one output observation corresponding to each input observation), all the other variables in the input data set are copied to the output data set

The ID variable in the output data set is named as follows:

- If an ID statement is used, the new ID variable has the same name as the variable used in the ID statement.
- If no ID statement is used, but the FROM= option is used, then the name of the ID variable is either DATE or DATETIME, depending on whether the TO= option indicates SAS date or SAS datetime values.
- If neither an ID statement nor the TO= option is used, the ID variable is named TIME.

OUTEST= Data Set

The OUTEST= data set contains the coefficients of the spline curves fit to the input series. The OUTEST= data set is of interest if you want to verify the interpolating curve PROC EXPAND uses, or if you want to use this function in another context, (for example, in a SAS/IML program).

The OUTEST= data set contains the following variables:

- the BY variables, if any
- VARNAME, a character variable containing the name of the input variable to which the coefficients apply
- METHOD, a character variable containing the value of the METHOD= option used to fit the series
- OBSERVED, a character variable containing the first letter of the OBSERVED= option name for the input series

- the ID variable that contains the lower breakpoint (or “knot”) of the spline segment to which the coefficients apply. The ID variable has the same name as the variable used in the ID statement. If an ID statement is not used, but the FROM= option is used, then the name of the ID variable is DATE or DATETIME, depending on whether the FROM= option indicates SAS date or SAS datetime values. If neither an ID statement nor the FROM= option is used, the ID variable is named TIME.
- CONSTANT, the constant coefficient for the spline segment
- LINEAR, the linear coefficient for the spline segment
- QUAD, the quadratic coefficient for the spline segment
- CUBIC, the cubic coefficient for the spline segment

For each BY group, the OUTEST= data set contains observations for each polynomial segment of the spline curve fit to each input series. To obtain the observations defining the spline curve used for a series, select the observations where the value of VARNAME equals the name of the series.

The observations for a series in the OUTEST= data set encode the spline function fit to the series as follows. Let a_i , b_i , c_i , and d_i be the values of the variables CUBIC, QUAD, LINEAR, and CONSTANT, respectively, for the i th observation for the series. Let x_i be the value of the ID variable for the i th observation for the series. Let n be the number of observations in the OUTEST= data set for the series. The value of the spline function evaluated at a point x is

$$f(x) = a_i(x - x_i)^3 + b_i(x - x_i)^2 + c_i(x - x_i) + d_i$$

where the segment number i is selected as follows:

$$i = \begin{cases} i & x_i \leq x < x_{i+1}, 1 \leq i < n \\ 1 & x < x_1 \\ n & x \geq x_n \end{cases}$$

In other words, if x is between the first and last ID values ($x_1 \leq x < x_n$), use the observation from the OUTEST= data set with the largest ID value less than or equal to x . If x is less than the first ID value x_1 , then $i = 1$. If x is greater than or equal to the last ID value ($x \geq x_n$), then $i = n$.

For METHOD=JOIN, the curve is a linear spline, and the values of CUBIC and QUAD are 0. For METHOD=STEP, the curve is a constant spline, and the values of CUBIC, QUAD, and LINEAR are 0. For METHOD=AGGREGATE, no coefficients are output.

ODS Graphics

This section describes the use of ODS for creating graphics with the EXPAND procedure. To request these graphs, you must specify the statement `ods graphics on;` in your SAS program prior to the PROC EXPAND step and specify the `PLOTS=` option in the PROC EXPAND statement.

ODS Graph Names

PROC EXPAND assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 14.3](#).

To request these graphs, you must specify the ODS GRAPHICS statement and the **PLOTS=** option in the EXPAND statement.

Table 14.3 ODS Graphics Produced by PROC EXPAND

ODS Graph Name	Plot Description	PLOTS= Options
ConvertedSeriesPlot	Converted Series Plot	CONVERTED OUTPUT ALL
CrossInputSeriesPlot	Cross Input Series Plot	CROSSINPUT
CrossOutputSeriesPlot	Cross Output Series Plot	CROSSOUTPUT
InputSeriesPlot	Input Series Plot	INPUT JOINTINPUT ALL
JointInputSeriesPlot	Joint Input Series Plot	JOINTINPUT
JointOutputSeriesPlot	Joint Output Series Plot	JOINTOUTPUT
OutputSeriesPlot	Output Series Plot	SERIESOUTPUT
TransformedInputSeriesPlot	Transformed Input Series Plot	TRANSFORMIN OUTPUT ALL
TransformedOutputSeriesPlot	Transformed Output Series Plot	TRANSFORMOUT OUTPUT ALL

PLOTS= Option Details

Some plots will only be produced for a series if the relevant options are also specified. For example, if **PLOTS=TRANSFORMIN** specified, the **TRANSFORMIN** plot will not be produced for a variable unless the **TRANSFORMIN=** option is specified on a **CONVERT** statement for that variable.

The **PLOTS=TRANSFORMIN** option plots the series after the input transformation (**TRANSFORMIN=** option) is applied. If the **TRANSFORMIN=** option is not specified in the **CONVERT** statement for an output variable, the input transformation plot is not produced.

The **PLOTS=CONVERTED** option plots the series after the input transformation (**TRANSFORMIN=** option) is applied and after frequency conversion (**METHOD=** option). If there is no frequency conversion for an output variable, the converted series plot is not produced.

The **PLOTS=TRANSFORMOUT** option plots the series after the output transformation (**TRANSFORMOUT=** option) is applied. If the **TRANSFORMOUT=** option is not specified in the **CONVERT** statement for an output variable, the output transformation plot is not produced.

The **PLOTS=OUTPUT** option plots the series after it has undergone input transformation (**TRANSFORMIN=** option), frequency conversion (**METHOD=** option), and output transformation (**TRANSFORMOUT=** option) if these **CONVERT** statement options were specified.

Cross and Joint Plots

The PLOTS= option values CROSSINPUT and CROSSOUTPUT produce graphs that overlay plots of two series using two Y axis and with each of the two plots show at a separate scale. The PLOTS= option values JOINTINPUT and JOINTOUTPUT produce graphs that overly plots of two series using a single Y axis and with both of the plots shown on the same scale.

Note that because the joint graphics options (PLOTS=JOINTINPUT or PLOTS=JOINTOUTPUT) plot the (input or converted) series and the transformed series on the same scale, if the transformation changes the range of the series these plots may be hard to visualize.

The PLOTS=CROSSINPUT option plots both the input series and the series after the input transformation (TRANSFORMIN= option) is applied. The left side vertical axis refers to the input series, while the right side vertical axis refers to the series after the transformation. If the TRANSFORMIN= option is not specified in the CONVERT statement for an output variable, the cross input plot is not produced for that variable.

The PLOTS=JOINTINPUT option jointly plots both the input series and the series after the input transformation (TRANSFORMIN= option) is applied. If the TRANSFORMIN= option is not specified in the CONVERT statement for an output variable, the joint input plot is not produced for that variable.

The PLOTS=CROSSOUTPUT option plots both the converted series and the converted series after the output transformation (TRANSFORMOUT= option) is applied. The left side vertical axis refers to the input series, while the right side vertical axis refers to the series after the transformation. If the TRANSFORMOUT= option is not specified in the CONVERT statement for an output variable, the cross output plot is not produced for that variable.

The PLOTS=JOINTOUTPUT jointly plots both the converted series and the converted series after the output transformation (TRANSFORMOUT= option) is applied. If the TRANSFORMOUT= option is not specified in the CONVERT statement for an output variable, the joint output plot is not produced for that variable.

Requesting All Plots

The PLOTS=ALL option is a convenient way to specify all the plots except the OUTPUT plots and the joint and cross plots. The option PLOTS=(ALL OUTPUT JOINTINPUT JOINTOUTPUT CROSSINPUT CROSSOUTPUT) request that all possible plots be produced.

Examples: EXPAND Procedure

Example 14.1: Combining Monthly and Quarterly Data

This example combines monthly and quarterly data sets by interpolating monthly values for the quarterly series. The series are extracted from two small sample data sets stored in the SASHELP library. These data sets were contributed by Citicorp Data Base services and contain selected U.S. macro economic series.

The quarterly series gross domestic product (GDP) and implicit price deflator (GD) are extracted from SASHELP.CITIQTR. The monthly series industrial production index (IP) and unemployment rate (LHUR) are extracted from SASHELP.CITIMON. Only observations for the years 1990 and 1991 are selected. PROC EXPAND is then used to interpolate monthly estimates for the quarterly series, and the interpolated series are merged with the monthly data.

The following statements extract and print the quarterly data, shown in [Output 14.1.1](#).

```
data qtrly;
  set sashelp.citiqtr;
  where date >= '1jan1990'd &
        date < '1jan1992'd ;
  keep date gdp gd;
run;

title "Quarterly Data";
proc print data=qtrly;
run;
```

Output 14.1.1 Quarterly Data Set

Quarterly Data				
Obs	DATE	GD	GDP	
1	1990:1	111.100	5422.40	
2	1990:2	112.300	5504.70	
3	1990:3	113.600	5570.50	
4	1990:4	114.500	5557.50	
5	1991:1	115.900	5589.00	
6	1991:2	116.800	5652.60	
7	1991:3	117.400	5709.20	
8	1991:4	.	5736.60	

The following statements extract and print the monthly data, shown in [Output 14.1.2](#).

```
data monthly;
  set sashelp.citimom;
```

```

where date >= '1jan1990'd &
      date < '1jan1992'd ;
keep date ip lhur;
run;

title "Monthly Data";
proc print data=monthly;
run;

```

Output 14.1.2 Monthly Data Set

Monthly Data

Example 14.2: Illustration of ODS Graphics

This example illustrates the use of ODS graphics with PROC EXPAND.

The graphical displays are requested by specifying the `ods graphics on;` statement and specifying the `PLOTS=` option in the PROC EXPAND statement. For information about the graphics available in the EXPAND procedure, see the section “[ODS Graphics](#)” on page 757.

The following statements utilize the SASHELP.WORKERS data set to convert the time series of electrical workers from monthly to quarterly frequency and display ODS graphics plots. The `PLOTS=ALL` option is specified to request the plots of the input series, the transformed input series, the converted series, and the transformed output series. [Figure 14.2.1](#) through [Figure 14.2.4](#) show these plots.

```

proc expand data=sashelp.workers out=out
          from=month to=qtr

```

```

plots=all;
id date;
convert electric=out / method=spline
transformin=(movmed 4)
transformout=(movave 3);
run;

```

Output 14.2.1 Input Series Plot

Output 14.2.2 Transformed Input Series Plot – 4-Period Moving Median

Output 14.2.3 Converted Series Plot

Output 14.2.4 Transformed Output Series Plot – 3-Period Moving Average**Example 14.3: Interpolating Irregular Observations**

This example shows the interpolation of a series of values measured at irregular points in time. The data are hypothetical. Assume that a series of randomly timed quality control inspections are made and defect rates for a process are measured. The problem is to produce two reports: estimates of monthly average defect rates for the months within the period covered by the samples, and a plot of the interpolated defect rate curve over time.

The following statements read and print the input data, as shown in [Output 14.3.1](#).

```
data samples;
  input date : date9. defects @@;
  label defects = "Defects per 1000 units";
  format date date9.;
datalines;

... more lines ...
```

```

title "Sampled Defect Rates";
proc print data=samples;
run;

```

Output 14.3.1 Measured Defect Rates

Sampled Defect Rates		
Obs	date	defects
1	13JAN1992	55
2	27JAN1992	73

13	15AUG1992	112
14	29AUG1992	89
15	10SEP1992	77
16	27SEP1992	82

To compute the monthly estimates, use PROC EXPAND with the TO=MONTH option and specify OBSERVED=(BEGINNING,AVERAGE). The following statements interpolate the monthly estimates.

```

proc expand data=samples
  out=monthly
  to=month
  plots=(input output);
  id date;
  convert defects / observed=(beginning,average);
run;

```

The following PROC PRINT step prints the results, as shown in [Output 14.3.2](#).

```

title "Estimated Monthly Average Defect Rates";
proc print data=monthly;
run;

```

Output 14.3.2 Monthly Average Estimates

Estimated Monthly Average Defect Rates		
Obs	date	defects
1	JAN1992	59.323
2	FEB1992	82.000
3	MAR1992	66.909
4	APR1992	70.205
5	MAY1992	82.762
6	JUN1992	99.701
7	JUL1992	101.564
8	AUG1992	105.491
9	SEP1992	79.206

The plots produced by PROC EXPAND are shown in [Output 14.3.3](#).

Output 14.3.3 Interpolated Defects Rate Curve

Output 14.3.3 continued

Example 14.4: Using Transformations

This example shows the use of PROC EXPAND to perform various transformations of time series. The following statements read in monthly values for a variable X.

```

data test;
  input year qtr x;
  date = yyq( year, qtr );
  format date yyqc.;
datalines;
1989 3 5238
1989 4 5289
1990 1 5375
1990 2 5443
1990 3 5514
1990 4 5527
1991 1 5557
1991 2 5615
;

```

The following statements use PROC EXPAND to compute lags and leads and a 3-period moving average of the X series.

```
proc expand data=test out=out method=none;
  id date;
  convert x = x_lag2 / transformout=(lag 2);
  convert x = x_lag1 / transformout=(lag 1);
  convert x;
  convert x = x_lead1 / transformout=(lead 1);
  convert x = x_lead2 / transformout=(lead 2);
  convert x = x_movave / transformout=(movave 3);
run;

title "Transformed Series";
proc print data=out;
run;
```

Because there are no missing values to interpolate and no frequency conversion, the METHOD=NONE option is used to prevent PROC EXPAND from performing unnecessary computations. Because no frequency conversion is done, all variables in the input data set are copied to the output data set. The CONVERT X; statement is included to control the position of X in the output data set. This statement can be omitted, in which case X is copied to the output data set following the new variables computed by PROC EXPAND.

The results are shown in [Output 14.4.1](#).

Output 14.4.1 Output Data Set with Transformed Variables

Overview: FORECAST Procedure

The FORECAST procedure provides a quick and automatic way to generate forecasts for many time series in one step. The procedure can forecast hundreds of series at a time, with the series organized into separate variables or across BY groups. PROC FORECAST uses extrapolative forecasting methods where the forecasts for a series are functions only of time and past values of the series, not of other variables.

You can use the following forecasting methods. For each of these methods, you can specify linear, quadratic, or no trend.

- The stepwise autoregressive method is used by default. This method combines time trend regression with an autoregressive model and uses a stepwise method to select the lags to use for the autoregressive process.
- The exponential smoothing method produces a time trend forecast. However, in fitting the trend, the parameters are allowed to change gradually over time, and earlier observations are given exponentially declining weights. Single, double, and triple exponential smoothing are supported, depending on whether no trend, linear trend, or quadratic trend, respectively, is specified. Holt two-parameter linear exponential smoothing is supported as a special case of the Holt-Winters method without seasons.
- The Winters method (also called Holt-Winters) combines a time trend with multiplicative seasonal factors to account for regular seasonal fluctuations in a series. Like the exponential smoothing method, the Winters method allows the parameters to change gradually over time, with earlier observations given exponentially declining weights. You can also specify the additive version of the Winters method, which uses additive instead of multiplicative seasonal factors. When seasonal factors are omitted, the Winters method reduces to the Holt two-parameter version of double exponential smoothing.

The FORECAST procedure writes the forecasts and confidence limits to an output data set. It can also write parameter estimates and fit statistics to an output data set. The FORECAST procedure does not produce printed output.

PROC FORECAST is an extrapolation procedure useful for producing practical results efficiently. However, in the interest of speed, PROC FORECAST uses some shortcuts that cause some statistical results (such as confidence limits) to be only approximate. For many time series, the FORECAST procedure, with appropriately chosen methods and weights, can yield satisfactory results. Other SAS/ETS procedures can produce better forecasts but at greater computational expense.

You can perform the stepwise autoregressive forecasting method with the [AUTOREG](#) procedure. You can perform forecasting by exponential smoothing with statistically optimal weights with the [ESM](#) procedure. Seasonal [ARIMA](#) models can be used for forecasting seasonal series for which the Winters and additive Winters methods might be used.

Additionally, the Time Series Forecasting System can be used to develop forecasting models, estimate the model parameters, evaluate the models' ability to forecast and display the results graphically. See Chapter 37, "[Getting Started with Time Series Forecasting](#)," for more details.

Getting Started: FORECAST Procedure

To use PROC FORECAST, specify the input and output data sets and the number of periods to forecast in the PROC FORECAST statement, and then list the variables to forecast in a VAR statement.

For example, suppose you have monthly data on the sales of some product in a data set named PAST, as shown in [Figure 15.1](#), and you want to forecast sales for the next 10 months.

Figure 15.1 Example Data Set PAST

Obs	date	sales
1	JUL89	9.5161
2	AUG89	9.6994
3	SEP89	9.2644
4	OCT89	9.6837
5	NOV89	10.0784
6	DEC89	9.9005
7	JAN90	10.2375
8	FEB90	10.6940
9	MAR90	10.6290
10	APR90	11.0332

13	JUL90	11.2918
14	AUG90	11.3475
15	SEP90	11.2913
16	OCT90	11.3771
17	NOV90	11.5457
18	DEC90	11.6433
19	JAN91	11.9293
20	FEB91	11.9752
21	MAR91	11.9283
22	APR91	11.8985
23	MAY91	12.0419
24	JUN91	12.3537
25	JUL91	12.4546

The following statements forecast 10 observations for the variable SALES by using the default STEPAR method and write the results to the output data set PRED:

```
proc forecast data=past lead=10 out=pred;  
  var sales;  
run;
```

The following statements use the PRINT procedure to print the data set PRED:

```
proc print data=pred;  
run;
```

The PROC PRINT listing of the forecast data set PRED is shown in [Figure 15.2](#).

Figure 15.2 Forecast Data Set PRED

Obs	_TYPE_	_LEAD_	sales

5	FORECAST	5	13.1595
6	FORECAST	6	13.2854
7	FORECAST	7	13.4105
8	FORECAST	8	13.5351
9	FORECAST	9	13.6596
10	FORECAST	10	13.7840

Giving Dates to Forecast Values

Normally, your input data set has an ID variable that gives dates to the observations, and you want the forecast observations to have dates also. Usually, the ID variable has SAS date values. (See Chapter 3, “[Working with Time Series Data](#),” for information about using SAS date and datetime values.) The ID statement specifies the identifying variable.

If the ID variable contains SAS date or datetime values, the INTERVAL= option should be used on the PROC FORECAST statement to specify the time interval between observations. (See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about time intervals.) The FORECAST procedure uses the INTERVAL= option to generate correct dates for forecast observations.

The data set PAST, shown in [Figure 15.1](#), has monthly observations and contains an ID variable DATE with SAS date values identifying each observation. The following statements produce the same forecast as the preceding example and also include the ID variable DATE in the output data set. Monthly SAS date values are extrapolated for the forecast observations.

```
proc forecast data=past interval=month lead=10 out=pred;
  var sales;
  id date;
run;
```

Computing Confidence Limits

Depending on the output options specified, multiple observations are written to the OUT= data set for each time period. The different parts of the results are contained in the VAR statement variables in observations identified by the character variable _TYPE_ and by the ID variable.

For example, the following statements use the OUTLIMIT option to write forecasts and 95% confidence limits for the variable SALES to the output data set PRED. This data set is printed with the PRINT procedure.

```

proc forecast data=past interval=month lead=10
      out=pred outlimit;
  var sales;
  id date;
run;

proc print data=pred;
run;

```

The output data set PRED is shown in [Figure 15.3](#).

29	MAY92	L95	10	13.2380
30	MAY92	U95	10	14.3301

Form of the OUT= Data Set

The OUT= data set PRED, shown in [Figure 15.3](#), contains three observations for each of the 10 forecast periods. Each of these three observations has the same value of the ID variable DATE, the SAS date value for the month and year of the forecast.

The three observations for each forecast period have different values of the variable `_TYPE_`. For the `_TYPE_=FORECAST` observation, the value of the variable `SALES` is the forecast value for the period indicated by the `DATE` value. For the `_TYPE_=L95` observation, the value of the variable `SALES` is the lower limit of the 95% confidence interval for the forecast. For the `_TYPE_=U95` observation, the value of the variable `SALES` is the upper limit of the 95% confidence interval.

You can control the types of observations written to the `OUT=` data set with the `PROC FORECAST` statement options `OUTLIMIT`, `OUTRESID`, `OUTACTUAL`, `OUT1STEP`, `OUTSTD`, `OUTFULL`, and `OUTALL`. For example, the `OUTFULL` option outputs the confidence limit values, the one-step-ahead predictions, and the actual data, in addition to the forecast values. See the sections “[Syntax: FORECAST Procedure](#)” on page 788 and “[OUTEST= Data Set](#)” on page 808 for more information.

Plotting Forecasts

The forecasts, confidence limits, and actual values can be plotted on the same graph with the `SGPLOT` procedure. Use the appropriate output control options in the `PROC FORECAST` statement to include in the `OUT=` data set the series you want to plot. Use the `_TYPE_` variable in the `SGPLOT` procedure `GROUP` option to separate the observations for the different plots.

The `OUTFULL` option is used in the following statements. The resulting output data set contains the actual and predicted values, as well as the upper and lower 95% confidence limits.

```
proc forecast data=past interval=month lead=10
              out=pred outfull;
  id date;
  var sales;
run;

proc sgplot data=pred;
  series x=date y=sales / group=_type_ lineattrs=(pattern=1);
  xaxis values=('1jan90'd to '1jan93'd by qtr);
  reftime '15jul91'd / axis=x;
run;
```

The `_TYPE_` variable is used in the `SGPLOT` procedure’s `PLOT` statement to make separate plots over time for each type of value. A reference line marks the start of the forecast period. (See *SAS/GRAPH Software: Reference* for more information about using `PROC SGPLOT`.) The `WHERE` statement restricts the range of the actual data shown in the plot. In this example, the variable `SALES` has monthly data from July 1989 through July 1991, but only the data for 1990 and 1991 are shown in [Figure 15.4](#).

Figure 15.4 Plot of Forecast with Confidence Limits

Plotting Residuals

You can plot the residuals from the forecasting model by using PROC SGPLOT and a WHERE statement.

1. Use the OUTRESID option or the OUTALL option in the PROC FORECAST statement to include the residuals in the output data set.
2. Use a WHERE statement to specify the observation type of 'RESIDUAL' in the PROC GPLOT code.

The following statements add the OUTRESID option to the preceding example and plot the residuals:

```
proc forecast data=past interval=month lead=10
              out=pred outfull outresid;
  id date;
  var sales;
```

```

run;

proc sgplot data=pred;
  where _type_='RESIDUAL';
  needle x=date y=sales / markers;
  xaxis values=('1jan89'd to '1oct91'd by qtr);
run;

```

The plot of residuals is shown in [Figure 15.5](#).

Figure 15.5 Plot of Residuals

Model Parameters and Goodness-of-Fit Statistics

You can write the parameters of the forecasting models used, as well as statistics that measure how well the forecasting models fit the data, to an output SAS data set by using the `OUTEST=` option. The options `OUTFITSTATS`, `OUTESTTHEIL`, and `OUTESTALL` control what goodness-of-fit statistics are added to the `OUTEST=` data set.

For example, the following statements add the `OUTEST=` and `OUTFITSTATS` options to the previous example to create the output statistics data set `EST` for the results of the default stepwise

autoregressive forecasting method:

```
proc forecast data=past interval=month lead=10
    out=pred outfull outresid
    outest=est outfitstats;
    id date;
    var sales;
run;

proc print data=est;
run;
```

The PRINT procedure prints the OUTEST= data set, as shown in [Figure 15.6](#).

Figure 15.6 The OUTEST= Data Set for STEPAR Method

In the OUTEST= data set, the DATE variable contains the ID value of the last observation in the data set used to fit the forecasting model. The variable SALES contains the statistic indicated

by the value of the `_TYPE_` variable. The `_TYPE_=N`, `NRESID`, and `DF` observations contain, respectively, the number of observations read from the data set, the number of nonmissing residuals used to compute the goodness-of-fit statistics, and the number of nonmissing observations minus the number of parameters used in the forecasting model.

The observation that has `_TYPE_=SIGMA` contains the estimate of the standard deviation of the one-step prediction error computed from the residuals. The `_TYPE_=CONSTANT` and `_TYPE_=LINEAR` observations contain the coefficients of the time trend regression. The `_TYPE_=AR1`, `AR2`, ..., `AR8` observations contain the estimated autoregressive parameters. A missing autoregressive parameter indicates that the autoregressive term at that lag was not retained in the model by the stepwise model selection method. (See the section “[STEPAR Method](#)” on page 797 for more information.)

The other observations in the `OUTEST=` data set contain various goodness-of-fit statistics that measure how well the forecasting model used fits the given data. See the section “[OUTEST= Data Set](#)” on page 808 for details.

Controlling the Forecasting Method

The `METHOD=` option controls which forecasting method is used. The `TREND=` option controls the degree of the time trend model used. For example, the following statements produce forecasts of `SALES` as in the preceding example but use the double exponential smoothing method instead of the default `STEPAR` method:

```
proc forecast data=past interval=month lead=10
              method=expo trend=2
              out=pred outfull outresid
              outest=est outfitstats;
  var sales;
  id date;
run;

proc print data=est;
run;
```

The `PRINT` procedure prints the `OUTEST=` data set for the `EXPO` method, as shown in [Figure 15.7](#).

See the section “[Syntax: FORECAST Procedure](#)” on page 788 for other options that control the forecasting method. See the section “[Introduction to Forecasting Methods](#)” on page 783 and the section “[Forecasting Methods](#)” on page 796 for an explanation of the different forecasting methods.

Introduction to Forecasting Methods

This section briefly introduces the forecasting methods used by the FORECAST procedure. See textbooks on forecasting and see the section “[Forecasting Methods](#)” on page 796 for more detailed discussions of forecasting methods.

The FORECAST procedure combines three basic models to fit time series:

- time trend models for long-term, deterministic change
- autoregressive models for short-term fluctuations
- seasonal models for regular seasonal fluctuations

Two approaches to time series modeling and forecasting are *time trend models* and *time series methods*.

Time Trend Models

Time trend models assume that there is some permanent deterministic pattern across time. These models are best suited to data that are not dominated by random fluctuations.

Examining a graphical plot of the time series you want to forecast is often very useful in choosing an appropriate model. The simplest case of a time trend model is one in which you assume the series is a constant plus purely random fluctuations that are independent from one time period to the next. Figure 15.8 shows how such a time series might look.

Figure 15.8 Time Series without Trend

The x_t values are generated according to the equation

$$x_t = b_0 + \epsilon_t$$

where ϵ_t is an independent, zero-mean, random error and b_0 is the true series mean.

Suppose that the series exhibits growth over time, as shown in Figure 15.9.

Figure 15.9 Time Series with Linear Trend

A linear model is appropriate for this data. For the linear model, assume the x_t values are generated according to the equation

$$x_t = b_0 + b_1t + \epsilon_t$$

The linear model has two parameters. The predicted values for the future are the points on the estimated line. The extension of the polynomial model to three parameters is the quadratic (which forms a parabola). This allows for a constantly changing slope, where the x_t values are generated according to the equation

$$x_t = b_0 + b_1t + b_2t^2 + \epsilon_t$$

PROC FORECAST can fit three types of time trend models: constant, linear, and quadratic. For other kinds of trend models, other SAS procedures can be used.

Exponential smoothing fits a time trend model by using a smoothing scheme in which the weights decline geometrically as you go backward in time. The forecasts from exponential smoothing are a time trend, but the trend is based mostly on the recent observations instead of on all the observations

equally. How well exponential smoothing works as a forecasting method depends on choosing a good smoothing weight for the series.

To specify the exponential smoothing method, use the `METHOD=EXPO` option. Single exponential smoothing produces forecasts with a constant trend (that is, no trend). Double exponential smoothing produces forecasts with a linear trend, and triple exponential smoothing produces a quadratic trend. Use the `TREND=` option with the `METHOD=EXPO` option to select single, double, or triple exponential smoothing.

The time trend model can be modified to account for regular seasonal fluctuations of the series about the trend. To capture seasonality, the trend model includes a seasonal parameter for each season. Seasonal models can be additive or multiplicative.

$$x_t = b_0 + b_1t + s(t) + \epsilon_t \quad (\text{additive})$$

$$x_t = (b_0 + b_1t)s(t) + \epsilon_t \quad (\text{multiplicative})$$

where $s(t)$ is the seasonal parameter for the season that corresponds to time t .

The Winters method is similar to exponential smoothing, but it includes seasonal factors. The Winters method can use either additive or multiplicative seasonal factors. Like exponential smoothing, good results with the Winters method depend on choosing good smoothing weights for the series to be forecast.

To specify the multiplicative or additive versions of the Winters method, use the `METHOD=WINTERS` or `METHOD=ADDWINTERS` options, respectively. To specify seasonal factors to include in the model, use the `SEASONS=` option.

Many observed time series do not behave like constant, linear, or quadratic time trends. However, you can partially compensate for the inadequacies of the trend models by fitting time series models to the departures from the time trend, as described in the following sections.

Time Series Methods

Time series models assume the future value of a variable to be a linear function of past values. If the model is a function of past values for a finite number of periods, it is an *autoregressive model* and is written as follows:

$$x_t = a_0 + a_1x_{t-1} + a_2x_{t-2} + \dots + a_px_{t-p} + \epsilon_t$$

The coefficients a_i are *autoregressive parameters*. One of the simplest cases of this model is the random walk, where the series dances around in purely random jumps. This is illustrated in [Figure 15.10](#).

Figure 15.10 Random Walk Series

The x_t values are generated by the equation

$$x_t = x_{t-1} + \epsilon_t$$

In this type of model, the best forecast of a future value is the present value. However, with other autoregressive models, the best forecast is a weighted sum of recent values. Pure autoregressive forecasts always damp down to a constant (assuming the process is stationary).

Autoregressive time series models can also be used to predict seasonal fluctuations.

Combining Time Trend with Autoregressive Models

Trend models are suitable for capturing long-term behavior, whereas autoregressive models are more appropriate for capturing short-term fluctuations. One approach to forecasting is to combine a deterministic time trend model with an autoregressive model.

The *stepwise autoregressive method* (STEPAR method) combines a time trend regression with an autoregressive model for departures from trend. The combined time trend and autoregressive model

is written as follows:

$$x_t = b_0 + b_1t + b_2t^2 + u_t$$

$$u_t = a_1u_{t-1} + a_2u_{t-2} + \dots + a_pu_{t-p} + \epsilon_t$$

The autoregressive parameters included in the model for each series are selected by a stepwise regression procedure, so that autoregressive parameters are included only at those lags at which they are statistically significant.

The stepwise autoregressive method is fully automatic. Unlike the exponential smoothing and Winters methods, it does not depend on choosing smoothing weights. However, the STEPARG method assumes that the long-term trend is stable; that is, the time trend regression is fit to the whole series with equal weights for the observations.

The stepwise autoregressive model is used when you specify the METHOD=STEPARG option or do not specify any METHOD= option. To select a constant, linear, or quadratic trend for the time-trend part of the model, use the TREND= option.

Syntax: FORECAST Procedure

The following statements are used with PROC FORECAST:

```
PROC FORECAST options ;
  BY variables ;
  ID variables ;
  VAR variables ;
```

Functional Summary

Table 15.1 summarizes the statements and options that control the FORECAST procedure.

Table 15.1 FORECAST Functional Summary

Description	Statement	Option
Statements		
specify model and data set options	PROC FORECAST	
specify BY-group processing	BY	
identify observations	ID	
specify the variables to forecast	VAR	
Input Data Set Options		
specify the input SAS data set	PROC FORECAST	DATA=
specify frequency of the input time series	PROC FORECAST	INTERVAL=

Description	Statement	Option
Initializing Smoothed Values		
specify number of beginning values to use in calculating starting values	PROC FORECAST	NSTART=
specify number of beginning values to use in calculating initial seasonal parameters	PROC FORECAST	NSSTART=
specify starting values for constant term	PROC FORECAST	ASTART=
specify starting values for linear trend	PROC FORECAST	BSTART=
specify starting values for the quadratic trend	PROC FORECAST	CSTART=

PROC FORECAST Statement

PROC FORECAST *options* ;

The following options can be specified in the PROC FORECAST statement:

ALIGN=*option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

ALPHA=*value*

specifies the significance level to use in computing the confidence limits of the forecast. The value of the ALPHA= option must be between 0.01 and 0.99. You should use only two digits for the ALPHA= option because PROC FORECAST rounds the value to the nearest percent (ALPHA=0.101 is the same as ALPHA=0.10). The default is ALPHA=0.05, which produces 95% confidence limits.

AR=*n*

NLAGS=*n*

specifies the maximum order of the autoregressive model. The AR= option is valid only for METHOD=STEPAR. The default value of *n* depends on the INTERVAL= option and on the number of observations in the DATA= data set. See the section “[STEPAR Method](#)” on page 797 for details.

ASTART=*value*

ASTART=(*value* . . .)

specifies starting values for the constant term for the exponential smoothing, Winters, and additive Winters methods. This option is ignored if METHOD=STEPAR. The values specified are associated with the variables in the VAR statement in the order in which the variables are listed. See the section “[Starting Values for EXPO, WINTERS, and ADDWINTERS Methods](#)” on page 804 for details.

BSTART=*value*

BSTART=(value ...)

specifies starting values for the linear trend for the exponential smoothing, Winters, and additive Winters methods. The values specified are associated with the variables in the VAR statement in the order in which the variables are listed. This option is ignored if METHOD=STEPAR or TREND=1. See the section “[Starting Values for EXPO, WINTERS, and ADDWINTERS Methods](#)” on page 804 for details.

CSTART=value**CSTART=(value ...)**

specifies starting values for the quadratic trend for the exponential smoothing, Winters, and additive Winters methods. The values specified are associated with the variables in the VAR statement in the order in which the variables are listed. This option is ignored if METHOD=STEPAR or TREND=1 or 2. See the section “[Starting Values for EXPO, WINTERS, and ADDWINTERS Methods](#)” on page 804 for details.

DATA=SAS-data-set

names the SAS data set that contains the input time series for the procedure to forecast. If the DATA= option is not specified, the most recently created SAS data set is used.

INTERVAL=interval

specifies the frequency of the input time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more details about the intervals available.

INTPER=n

when the INTERVAL= option is not used, specifies an increment (other than 1) to use in generating the values of the ID variable for the forecast observations in the output data set.

LEAD=n

specifies the number of periods ahead to forecast. The default is LEAD=12.

The LEAD= value is relative to the last observation in the input data set and not to the end of a particular series. Thus, if a series has missing values at the end, the actual number of forecasts computed for that series will be greater than the LEAD= value.

MAXERRORS=n

limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50.

This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

METHOD=method-name

specifies the method to use to model the series and generate the forecasts.

METHOD=STEPAR specifies the stepwise autoregressive method.

METHOD=EXPO specifies the exponential smoothing method.

METHOD=WINTERS specifies the Holt-Winters exponentially smoothed trend-seasonal method.

METHOD=ADDWINTERS specifies the additive seasonal factors variant of the Winters method.

For more information, see the section “[Forecasting Methods](#)” on page 796. The default is **METHOD=STEPAR**.

NSTART=*n*

NSTART=MAX

specifies the number of beginning values of the series to use in calculating starting values for the trend parameters in the exponential smoothing, Winters, and additive Winters methods. This option is ignored if **METHOD=STEPAR**.

For **METHOD=EXPO**, *n* beginning values of the series are used in forming the exponentially smoothed values *S*1, *S*2, and *S*3, where *n* is the value of the **NSTART=** option. The parameters are initialized by fitting a time trend regression to the first *n* nonmissing values of the series.

For **METHOD=WINTERS** or **METHOD=ADDWINTERS**, *n* beginning complete seasonal cycles are used to compute starting values for the trend parameters. For example, for monthly data the seasonal cycle is one year, and **NSTART=2** specifies that the first 24 observations at the beginning of each series are used for the time trend regression used to calculate starting values.

When **NSTART=MAX** is specified, all the observations are used. The default for **METHOD=EXPO** is **NSTART=8**; the default for **METHOD=WINTERS** or **METHOD=ADDWINTERS** is **NSTART=2**. See the section “[Starting Values for EXPO, WINTERS, and ADDWINTERS Methods](#)” on page 804 for details.

NSSTART=*n*

NSSTART=MAX

specifies the number of beginning values of the series to use in calculating starting values for seasonal parameters for **METHOD=WINTERS** or **METHOD=ADDWINTERS**. The seasonal parameters are initialized by averaging over the first *n* values of the series for each season, where *n* is the value of the **NSSTART=** option. When **NSSTART=MAX** is specified, all the observations are used.

If **NSTART=** is specified, but **NSSTART=** is not, **NSSTART=** defaults to the value specified for **NSTART=**. If neither **NSTART=** nor **NSSTART=** is specified, then the default is **NSSTART=2**. This option is ignored if **METHOD=STEPAR** or **METHOD=EXPO**. See the section “[Starting Values for EXPO, WINTERS, and ADDWINTERS Methods](#)” on page 804 for details.

OUT=SAS-data-set

names the output data set to contain the forecasts. If the **OUT=** option is not specified, the data set is named by using the **DATA*n*** convention. See the section “[OUTEST= Data Set](#)” on page 808 for details.

OUTACTUAL

writes the actual values to the **OUT=** data set.

OUTALL

provides all the output control options (OUTLIMIT, OUT1STEP, OUTACTUAL, OUTRESID, and OUTSTD).

OUTEST=SAS-data-set

names an output data set to contain the parameter estimates and goodness-of-fit statistics. When the OUTEST= option is not specified, the parameters and goodness-of-fit statistics are not stored. See the section “[OUTEST= Data Set](#)” on page 808 for details.

OUTESTALL

writes additional statistics to the OUTEST= data set. This option is the same as specifying both OUTESTTHEIL and OUTFITSTATS.

OUTESTTHEIL

writes Theil forecast accuracy statistics to the OUTEST= data set.

OUTFITSTATS

writes various R-square-type forecast accuracy statistics to the OUTEST= data set.

OUTFULL

provides OUTACTUAL, OUT1STEP, and OUTLIMIT output control options in addition to the forecast values.

OUTLIMIT

writes the forecast confidence limits to the OUT= data set.

OUTRESID

writes the residuals (when available) to the OUT= data set.

OUTSTD

writes the standard errors of the forecasts to the OUT= data set.

OUT1STEP

writes the one-step-ahead predicted values to the OUT= data set.

SEASONS=interval

SEASONS= (*interval1* [*interval2* [*interval3*]])

SEASONS=n

SEASONS= (*n1* [*n2* [*n3*]])

specifies the seasonality for seasonal models. The *interval* can be QTR, MONTH, DAY, or HOUR, or multiples of these (for example, QTR2, MONTH2, MONTH3, MONTH4, MONTH6, HOUR2, HOUR3, HOUR4, HOUR6, HOUR8, and HOUR12).

Alternatively, seasonality can be specified by giving the length of the seasonal cycles. For example, SEASONS=3 means that every group of three observations forms a seasonal cycle. The SEASONS= option is valid only for METHOD=WINTERS or METHOD=ADDWINTERS. See the section “[Specifying Seasonality](#)” on page 805 for details.

SINGULAR=value

gives the criterion for judging singularity. The default depends on the precision of the computer that you run SAS programs on.

SINTPER=m**SINTPER= (m1 [m2 [m3]])**

specifies the number of periods to combine in forming a season. For example, SEASONS=3 SINTPER=2 specifies that each group of two observations forms a season and that the seasonal cycle repeats every six observations. The SINTPER= option is valid only when the SEASONS= option is used. See the section “[Specifying Seasonality](#)” on page 805 for details.

SLENTRY=value

controls the significance levels for entry of autoregressive parameters in the STEPAR method. The value of the SLENTRY= option must be between 0 and 1. The default is SLENTRY=0.2. See the section “[STEPAR Method](#)” on page 797 for details.

SLSTAY=value

controls the significance levels for removal of autoregressive parameters in the STEPAR method. The value of the SLSTAY= option must be between 0 and 1. The default is SLSTAY=0.05. See the section “[STEPAR Method](#)” on page 797 for details.

START=n

uses the first n observations to fit the model and begins forecasting with the $n + 1$ observation.

TREND=n

specifies the degree of the time trend model. The value of the TREND= option must be 1, 2, or 3. TREND=1 selects the constant trend model; TREND=2 selects the linear trend model; and TREND=3 selects the quadratic trend model. The default is TREND=2, except for METHOD=EXPO, for which the default is TREND=3.

WEIGHT=w**WEIGHT= (w1 [w2 [w3]])**

specifies the smoothing weights for the EXPO, WINTERS, and ADDWINTERS methods. For the EXPO method, only one weight can be specified. For the WINTERS or ADDWINTERS method, $w1$ gives the weight for updating the constant component, $w2$ gives the weight for updating the linear and quadratic trend components, and $w3$ gives the weight for updating the seasonal component. The $w2$ and $w3$ values are optional. Each value in the WEIGHT= option must be between 0 and 1. For default values, see the section “[EXPO Method](#)” on page 798 and the section “[WINTERS Method](#)” on page 799.

ZEROMISS

treats zeros at the beginning of a series as missing values. For example, a product can be introduced at a date after the date of the first observation in the data set, and the sales variable for the product can be recorded as zero for the observations prior to the introduction date. The ZEROMISS option says to treat these initial zeros as missing values.

BY Statement

BY variables ;

A BY statement can be used with PROC FORECAST to obtain separate analyses on observations in groups defined by the BY variables.

ID Statement

ID variables ;

The first variable listed in the ID statement identifies observations in the input and output data sets. Usually, the first ID variable is a SAS date or datetime variable. Its values are interpreted and extrapolated according to the values of the INTERVAL= option. See the section “[Data Periodicity and Time Intervals](#)” on page 796 for details.

If more than one ID variable is specified in the ID statement, only the first is used to identify the observations; the rest are just copied to the OUT= data set and will have missing values for forecast observations.

VAR Statement

VAR variables ;

The VAR statement specifies the variables in the input data set that you want to forecast. If no VAR statement is specified, the procedure forecasts all numeric variables except the ID and BY variables.

Details: FORECAST Procedure

Missing Values

The treatment of missing values varies by method. For METHOD=STEPAR, missing values are tolerated in the series; the autocorrelations are estimated from the available data and tapered, if necessary. For the EXPO, WINTERS, and ADDWINTERS methods, missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted values are applied to the smoothing equations. For the WINTERS method, negative or zero values are treated as missing.

Data Periodicity and Time Intervals

The INTERVAL= option is used to establish the frequency of the time series. For example, INTERVAL=MONTH specifies that each observation in the input data set represents one month. If INTERVAL=MONTH2, each observation represents two months. Thus, there is a two-month time interval between each pair of successive observations, and the data frequency is bimonthly.

See Chapter 4, “Date Intervals, Formats, and Functions,” for details about the interval values supported.

The INTERVAL= option is used together with the ID statement to fully describe the observations that make up the time series. The first variable specified in the ID statement is used to identify the observations. Usually, SAS date or datetime values are used for this variable. PROC FORECAST uses the ID variable in the following ways:

- to validate the data periodicity. When the INTERVAL= option is specified, the ID variable is used to check the data and verify that successive observations have valid ID values that correspond to successive time intervals. When the INTERVAL= option is not used, PROC FORECAST verifies that the ID values are nonmissing and in ascending order. A warning message is printed when an invalid ID value is found in the input data set.
- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for January 1970 is followed by an observation for April 1970, there is a gap in the input data, with two observations omitted. When a gap in the input data is found, a warning message is printed, and PROC FORECAST processes missing values for each omitted input observation.
- to label the forecast observations in the output data set. The values of the ID variable for the forecast observations after the end of the input data set are extrapolated according to the frequency specifications of the INTERVAL= option. If the INTERVAL= option is not specified, the ID variable is extrapolated by incrementing the ID variable value for the last observation in the input data set by the INTPER= value, if specified, or by one.

The ALIGN= option controls the alignment of SAS dates. See Chapter 4, “Date Intervals, Formats, and Functions,” for more information.

Forecasting Methods

This section explains the forecasting methods used by PROC FORECAST.

STEPAR Method

In the STEPAR method, PROC FORECAST first fits a time trend model to the series and takes the difference between each value and the estimated trend. (This process is called *detrending*.) Then, the remaining variation is fit by using an autoregressive model.

The STEPAR method fits the autoregressive process to the residuals of the trend model by using a backwards-stepping method to select parameters. Because the trend and autoregressive parameters are fit in sequence rather than simultaneously, the parameter estimates are not optimal in a statistical sense. However, the estimates are usually close to optimal, and the method is computationally inexpensive.

The STEPAR Algorithm

The STEPAR method consists of the following computational steps:

1. Fit the trend model as specified by the TREND= option by using ordinary least-squares regression. This step detrends the data. The default trend model for the STEPAR method is TREND=2, a linear trend model.
2. Take the residuals from step 1 and compute the autocovariances to the number of lags specified by the NLAGS= option.
3. Regress the current values against the lags, using the autocovariances from step 2 in a Yule-Walker framework. Do not bring in any autoregressive parameter that is not significant at the level specified by the SLENTY= option. (The default is SLENTY=0.20.) Do not bring in any autoregressive parameter that results in a nonpositive-definite Toeplitz matrix.
4. Find the autoregressive parameter that is least significant. If the significance level is greater than the SLSTAY= value, remove the parameter from the model. (The default is SLSTAY=0.05.) Continue this process until only significant autoregressive parameters remain. If the OUTEST= option is specified, write the estimates to the OUTEST= data set.
5. Generate the forecasts by using the estimated model and output to the OUT= data set. Form the confidence limits by combining the trend variances with the autoregressive variances.

Missing values are tolerated in the series; the autocorrelations are estimated from the available data and tapered if necessary.

This method requires at least three passes through the data: two passes to fit the model and a third pass to initialize the autoregressive process and write to the output data set.

Default Value of the NLAGS= Option

If the NLAGS= option is not specified, the default value of the NLAGS= option is chosen based on the data frequency specified by the INTERVAL= option and on the number of observations in the input data set, if this can be determined in advance. (PROC FORECAST cannot determine the number of input observations before reading the data when a BY statement or a WHERE statement

is used or if the data are from a tape format SAS data set or external database. The NLAGS= value must be fixed before the data are processed.)

If the INTERVAL= option is specified, the default NLAGS= value includes lags for up to three years plus one, subject to the maximum of 13 lags or one-third of the number of observations in your data set, whichever is less. If the number of observations in the input data set cannot be determined, the maximum NLAGS= default value is 13. If the INTERVAL= option is not specified, the default is NLAGS=13 or one-third the number of input observations, whichever is less.

If the Toeplitz matrix formed by the autocovariance matrix at a given step is not positive definite, the maximal number of autoregressive lags is reduced.

For example, for INTERVAL=QTR, the default is NLAGS=13 (that is, $4 \times 3 + 1$) provided that there are at least 39 observations. The NLAGS= option default is always at least 3.

EXPO Method

Exponential smoothing is used when the METHOD=EXPO option is specified. The term *exponential smoothing* is derived from the computational scheme developed by Brown and others (Brown and Meyers 1961; Brown 1962). Estimates are computed with updating formulas that are developed across time series in a manner similar to smoothing.

The EXPO method fits a trend model such that the most recent data are weighted more heavily than data in the early part of the series. The weight of an observation is a geometric (exponential) function of the number of periods that the observation extends into the past relative to the current period. The weight function is

$$w_{\tau} = \omega(1 - \omega)^{t-\tau}$$

where τ is the observation number of the past observation, t is the current observation number, and ω is the weighting constant specified with the WEIGHT= option.

You specify the model with the TREND= option as follows:

- TREND=1 specifies single exponential smoothing (a constant model)
- TREND=2 specifies double exponential smoothing (a linear trend model)
- TREND=3 specifies triple exponential smoothing (a quadratic trend model)

Updating Equations

The single exponential smoothing operation is expressed by the formula

$$S_t = \omega x_t + (1 - \omega)S_{t-1}$$

where S_t is the smoothed value at the current period, t is the time index of the current period, and x_t is the current actual value of the series. The smoothed value S_t is the forecast of x_{t+1} and is calculated as the smoothing constant ω times the value of the series, x_t , in the current period plus $(1 - \omega)$ times the previous smoothed value S_{t-1} , which is the forecast of x_t computed at time $t - 1$.

Double and triple exponential smoothing are derived by applying exponential smoothing to the smoothed series, obtaining smoothed values as follows:

$$S_t^{[2]} = \omega S_t + (1 - \omega) S_{t-1}^{[2]}$$

$$S_t^{[3]} = \omega S_t^{[2]} + (1 - \omega) S_{t-1}^{[3]}$$

Missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted value is then applied to the smoothing equations.

The polynomial time trend parameters CONSTANT, LINEAR, and QUAD in the OUTEST= data set are computed from S_T , $S_T^{[2]}$, and $S_T^{[3]}$, the final smoothed values at observation T , the last observation used to fit the model. In the OUTEST= data set, the values of S_T , $S_T^{[2]}$, and $S_T^{[3]}$ are identified by _TYPE_=S1, _TYPE_=S2, and _TYPE_=S3, respectively.

Smoothing Weights

Exponential smoothing forecasts are forecasts for an integrated moving-average process; however, the weighting parameter is specified by the user rather than estimated from the data. Experience has shown that good values for the WEIGHT= option are between 0.05 and 0.3. As a general rule, smaller smoothing weights are appropriate for series with a slowly changing trend, while larger weights are appropriate for volatile series with a rapidly changing trend. If unspecified, the weight defaults to $(1 - 0.8^{1/trend})$, where *trend* is the value of the TREND= option. This produces defaults of WEIGHT=0.2 for TREND=1, WEIGHT=0.10557 for TREND=2, and WEIGHT=0.07168 for TREND=3.

The [ESM](#) procedure can be used to forecast time series by using exponential smoothing with smoothing weights that are optimized automatically. See Chapter 13, “[The ESM Procedure](#).”

The [Time Series Forecasting System](#) provides for exponential smoothing models and enables you to either specify or optimize the smoothing weights. See Chapter 37, “[Getting Started with Time Series Forecasting](#),” for details.

Confidence Limits

The confidence limits for exponential smoothing forecasts are calculated as they would be for an exponentially weighted time trend regression, using the simplifying assumption of an infinite number of observations. The variance estimate is computed by using the mean square of the unweighted one-step-ahead forecast residuals.

More detailed descriptions of the forecast computations can be found in Montgomery and Johnson (1976) and Brown (1962).

WINTERS Method

The WINTERS method uses updating equations similar to exponential smoothing to fit parameters for the model

$$x_t = (a + bt)s(t) + \epsilon_t$$

where a and b are the trend parameters and the function $s(t)$ selects the seasonal parameter for the season that corresponds to time t .

The WINTERS method assumes that the series values are positive. If negative or zero values are found in the series, a warning is printed and the values are treated as missing.

The preceding standard WINTERS model uses a linear trend. However, PROC FORECAST can also fit a version of the WINTERS method that uses a quadratic trend. When TREND=3 is specified for METHOD=WINTERS, PROC FORECAST fits the following model:

$$x_t = (a + bt + ct^2)s(t) + \epsilon_t$$

The quadratic trend version of the Winters method is often unstable, and its use is not recommended.

When TREND=1 is specified, the following constant trend version is fit:

$$x_t = as(t) + \epsilon_t$$

The default for the WINTERS method is TREND=2, which produces the standard linear trend model.

Seasonal Factors

The notation $s(t)$ represents the selection of the seasonal factor used for different time periods. For example, if INTERVAL=DAY and SEASONS=MONTH, there are 12 seasonal factors, one for each month in the year, and the time index t is measured in days. For any observation, t is determined by the ID variable and $s(t)$ selects the seasonal factor for the month that t falls in. For example, if t is 9 February 1993 then $s(t)$ is the seasonal parameter for February.

When there are multiple seasons specified, $s(t)$ is the product of the parameters for the seasons. For example, if SEASONS=(MONTH DAY), then $s(t)$ is the product of the seasonal parameter for the month that corresponds to the period t and the seasonal parameter for the day of the week that corresponds to period t . When the SEASONS= option is not specified, the seasonal factors $s(t)$ are not included in the model. See the section “[Specifying Seasonality](#)” on page 805 for more information about specifying multiple seasonal factors.

Updating Equations

This section shows the updating equations for the Winters method. In the following formula, x_t is the actual value of the series at time t ; a_t is the smoothed value of the series at time t ; b_t is the smoothed trend at time t ; c_t is the smoothed quadratic trend at time t ; $s_{t-1}(t)$ selects the old value of the seasonal factor that corresponds to time t before the seasonal factors are updated.

The estimates of the constant, linear, and quadratic trend parameters are updated by using the following equations:

For TREND=3,

$$a_t = \omega_1 \frac{x_t}{s_{t-1}(t)} + (1 - \omega_1)(a_{t-1} + b_{t-1} + c_{t-1})$$

$$b_t = \omega_2(a_t - a_{t-1} + c_{t-1}) + (1 - \omega_2)(b_{t-1} + 2c_{t-1})$$

$$c_t = \omega_2 \frac{1}{2}(b_t - b_{t-1}) + (1 - \omega_2)c_{t-1}$$

For TREND=2,

$$a_t = \omega_1 \frac{x_t}{s_{t-1}(t)} + (1 - \omega_1)(a_{t-1} + b_{t-1})$$

$$b_t = \omega_2(a_t - a_{t-1}) + (1 - \omega_2)b_{t-1}$$

For TREND=1,

$$a_t = \omega_1 \frac{x_t}{s_{t-1}(t)} + (1 - \omega_1)a_{t-1}$$

In this updating system, the trend polynomial is always centered at the current period so that the intercept parameter of the trend polynomial for predicted values at times after t is always the updated intercept parameter a_t . The predicted value for τ periods ahead is

$$x_{t+\tau} = (a_t + b_t \tau)s_t(t + \tau)$$

The seasonal parameters are updated when the season changes in the data, using the mean of the ratios of the actual to the predicted values for the season. For example, if SEASONS=MONTH and INTERVAL=DAY, then when the observation for the first of February is encountered, the seasonal parameter for January is updated by using the formula

$$s_t(t-1) = \omega_3 \frac{1}{31} \sum_{i=t-31}^{t-1} \frac{x_i}{a_i} + (1 - \omega_3)s_{t-1}(t-1)$$

where t is February 1 of the current year, $s_t(t-1)$ is the seasonal parameter for January updated with the data available at time t , and $s_{t-1}(t-1)$ is the seasonal parameter for January of the previous year.

When multiple seasons are used, $s_t(t)$ is a product of seasonal factors. For example, if SEASONS=(MONTH DAY) then $s_t(t)$ is the product of the seasonal factors for the month and for the day of the week: $s_t(t) = s_t^m(t)s_t^d(t)$.

The factor $s_t^m(t)$ is updated at the start of each month by using a modification of the preceding formula that adjusts for the presence of the other seasonal by dividing the summands $\frac{x_i}{a_i}$ by the that corresponds to day of the week effect $s_i^d(i)$.

Similarly, the factor $s_t^d(t)$ is updated by using the following formula:

$$s_t^d(t) = \omega_3 \frac{x_t}{a_t s_t^m(t)} + (1 - \omega_3)s_{t-1}^d(t)$$

where $s_{t-1}^d(t)$ is the seasonal factor for the same day of the previous week.

Missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted value is substituted for x_i and applied to the updating equations.

Normalization

The parameters are normalized so that the seasonal factors for each cycle have a mean of 1.0. This normalization is performed after each complete cycle and at the end of the data. Thus, if INTERVAL=MONTH and SEASONS=MONTH are specified and a series begins with a July value, then the seasonal factors for the series are normalized at each observation for July and at the last observation in the data set. The normalization is performed by dividing each of the seasonal parameters, and multiplying each of the trend parameters, by the mean of the unnormalized seasonal parameters.

Smoothing Weights

The weight for updating the seasonal factors, ω_3 , is given by the third value specified in the WEIGHT= option. If the WEIGHT= option is not used, then ω_3 defaults to 0.25; if the WEIGHT= option is used but does not specify a third value, then ω_3 defaults to ω_2 . The weight for updating the linear and quadratic trend parameters, ω_2 , is given by the second value specified in the WEIGHT= option; if the WEIGHT= option does not specify a second value, then ω_2 defaults to ω_1 . The updating weight for the constant parameter, ω_1 , is given by the first value specified in the WEIGHT= option. As a general rule, smaller smoothing weights are appropriate for series with a slowly changing trend, while larger weights are appropriate for volatile series with a rapidly changing trend.

If the WEIGHT= option is not used, then ω_1 defaults to $(1 - 0.8^{1/trend})$, where *trend* is the value of the TREND= option. This produces defaults of WEIGHT=0.2 for TREND=1, WEIGHT=0.10557 for TREND=2, and WEIGHT=0.07168 for TREND=3.

The **ESM** procedure and the **Time Series Forecasting System** provide for generating forecast models that use Winters Method and enable you to specify or optimize the weights. (See Chapter 13, “**The ESM Procedure**,” and Chapter 37, “**Getting Started with Time Series Forecasting**,” for details.)

Confidence Limits

A method for calculating exact forecast confidence limits for the WINTERS method is not available. Therefore, the approach taken in PROC FORECAST is to assume that the true seasonal factors have small variability about a set of fixed seasonal factors and that the remaining variation of the series is small relative to the mean level of the series. The equations are written

$$s_t(t) = I(t)(1 + \delta_t)$$

$$x_t = \mu I(t)(1 + \gamma_t)$$

$$a_t = \xi(1 + \alpha_t)$$

where μ is the mean level and $I(t)$ are the fixed seasonal factors. Assuming that α_t and δ_t are small, the forecast equations can be linearized and only first-order terms in δ_t and α_t kept. In terms of forecasts for γ_t , this linearized system is equivalent to a seasonal ARIMA model. Confidence limits for γ_t are based on this ARIMA model and converted into confidence limits for x_t using $s_t(t)$ as estimates of $I(t)$.

The exponential smoothing confidence limits are based on an approximation to a weighted regression model, whereas the preceding Winters confidence limits are based on an approximation to an ARIMA model. You can use METHOD=WINTERS without the SEASONS= option to do exponential smoothing and get confidence limits for the EXPO forecasts based on the ARIMA model

approximation. These are generally more pessimistic than the weighted regression confidence limits produced by METHOD=EXPO.

ADDWINTERS Method

The ADDWINTERS method is like the WINTERS method except that the seasonal parameters are added to the trend instead of multiplied with the trend. The default TREND=2 model is as follows:

$$x_t = a + bt + s(t) + \epsilon_t$$

The WINTERS method for updating equation and confidence limits calculations described in the preceding section are modified accordingly for the additive version.

Holt Two-Parameter Exponential Smoothing

If the seasonal factors are omitted (that is, if the SEASONS= option is not specified), the WINTERS (and ADDWINTERS) method reduces to the Holt two-parameter version of exponential smoothing. Thus, the WINTERS method is often referred to as the Holt-Winters method.

Double exponential smoothing is a special case of the Holt two-parameter smoother. The double exponential smoothing results can be duplicated with METHOD=WINTERS by omitting the SEASONS= option and appropriately setting the WEIGHT= option. Letting $\alpha = \omega(2 - \omega)$ and $\beta = \omega/(2 - \omega)$, the following statements produce the same forecasts:

```
proc forecast method=expo trend=2 weight= $\omega$  ...;
proc forecast method=winters trend=2 weight=( $\alpha, \beta$ ) ...;
```

Although the forecasts are the same, the confidence limits are computed differently.

Choice of Weights for EXPO, WINTERS, and ADDWINTERS Methods

For the EXPO, WINTERS, and ADDWINTERS methods, properly chosen smoothing weights are of critical importance in generating reasonable results. There are several factors to consider in choosing the weights.

The noisier the data, the lower should be the weight given to the most recent observation. Another factor to consider is how quickly the mean of the time series is changing. If the mean of the series is changing rapidly, relatively more weight should be given to the most recent observation. The more stable the series over time, the lower should be the weight given to the most recent observation.

Note that the smoothing weights should be set separately for each series; weights that produce good results for one series might be poor for another series. Since PROC FORECAST does not have a feature to use different weights for different series, when forecasting multiple series with the EXPO, WINTERS, or ADDWINTERS method it might be desirable to use different PROC FORECAST steps with different WEIGHT= options.

For the Winters method, many combinations of weight values might produce unstable *noninvertible* models, even though all three weights are between 0 and 1. When the model is noninvertible, the forecasts depend strongly on values in the distant past, and predictions are determined largely by the starting values. Unstable models usually produce poor forecasts. The Winters model can be unstable even if the weights are optimally chosen to minimize the in-sample MSE. See Archibald (1990) for a detailed discussion of the unstable region of the parameter space of the Winters model.

Optimal weights and forecasts for exponential smoothing models can be computed by using the [ESM](#) and [ARIMA](#) procedures and by the [Time Series Forecasting System](#).

Starting Values for EXPO, WINTERS, and ADDWINTERS Methods

The exponential smoothing method requires starting values for the smoothed values S_0 , $S_0^{[2]}$, and $S_0^{[3]}$. The Winters and additive Winters methods require starting values for the trend coefficients and seasonal factors.

By default, starting values for the trend parameters are computed by a time trend regression over the first few observations for the series. Alternatively, you can specify the starting value for the trend parameters with the `ASTART=`, `BSTART=`, and `CSTART=` options.

The number of observations used in the time trend regression for starting values depends on the `NSTART=` option. For `METHOD=EXPO`, `NSTART=` beginning values of the series are used, and the coefficients of the time trend regression are then used to form the initial smoothed values S_0 , $S_0^{[2]}$, and $S_0^{[3]}$.

For `METHOD=WINTERS` or `METHOD=ADDWINTERS`, n complete seasonal cycles are used to compute starting values for the trend parameter, where n is the value of the `NSTART=` option. For example, for monthly data the seasonal cycle is one year, so `NSTART=2` specifies that the first 24 observations at the beginning of each series are used for the time trend regression used to calculate starting values.

The starting values for the seasonal factors for the `WINTERS` and `ADDWINTERS` methods are computed from seasonal averages over the first few complete seasonal cycles at the beginning of the series. The number of seasonal cycles averaged to compute starting seasonal factors is controlled by the `NSSTART=` option. For example, for monthly data with `SEASONS=12` or `SEASONS=MONTH`, the first n January values are averaged to get the starting value for the January seasonal parameter, where n is the value of the `NSSTART=` option.

The $s_0(i)$ seasonal parameters are set to the ratio (for `WINTERS`) or difference (for `ADDWINTERS`) of the mean for the season to the overall mean for the observations used to compute seasonal starting values.

For example, if `METHOD=WINTERS`, `INTERVAL=DAY`, `SEASON=(MONTH DAY)`, and `NSTART=2` (the default), the initial seasonal parameter for January is the ratio of the mean value over days in the first two Januarys after the start of the series (that is, after the first nonmissing value) to the mean value for all days read for initialization of the seasonal factors. Likewise, the initial factor for Sundays is the ratio of the mean value for Sundays to the mean of all days read.

For the `ASTART=`, `BSTART=`, and `CSTART=` options, the values specified are associated with the

variables in the VAR statement in the order in which the variables are listed (the first value with the first variable, the second value with the second variable, and so on). If there are fewer values than variables, default starting values are used for the later variables. If there are more values than variables, the extra values are ignored.

Specifying Seasonality

Seasonality of a time series is a regular fluctuation about a trend. This is called seasonality because the time of year is the most common source of periodic variation. For example, sales of home heating oil are regularly greater in winter than during other times of the year.

Seasonality can be caused by many things other than weather. In the United States, sales of non-durable goods are greater in December than in other months because of the Christmas shopping season. The term seasonality is also used for cyclical fluctuation at periods other than a year. Often, certain days of the week cause regular fluctuation in daily time series, such as increased spending on leisure activities during weekends.

Three kinds of seasonality are supported in PROC FORECAST: time-of-year, day-of-week, and time-of-day. The seasonal part of the model is specified by using the SEASONS= option. The values for the SEASONS= option are listed in [Table 15.2](#).

Table 15.2 The SEASONS= Option

SEASONS= Value	Cycle Length	Type of Seasonality
QTR	yearly	time of year
MONTH	yearly	time of year
DAY	weekly	day of week
HOUR	daily	time of day

The three kinds of seasonality can be combined. For example, SEASONS=(MONTH DAY HOUR) specifies that 24 hour-of-day seasons are nested within 7 day-of-week seasons, which in turn are nested within 12 month-of-year seasons. The different kinds of intervals can be listed in the SEASONS= option in any order. Thus, SEASONS=(HOUR DAY MONTH) is the same as SEASONS=(MONTH DAY HOUR). Note that the Winters method smoothing equations might be less stable when multiple seasonal factors are used.

Multiple period seasons can also be used. For example, SEASONS=QTR2 specifies two semiannual time-of-year seasons. The grouping of observations into multiple period seasons starts with the first interval in the seasonal cycle. Thus, MONTH2 seasons are January–February, March–April, and so on. (There is no provision for shifting seasonal intervals; thus, there is no way to specify seasons December–January, February–March, April–May, and so on.)

For multiple period seasons, the number of intervals combined to form the seasons must evenly divide and be less than the basic cycle length. For example, with SEASONS=MONTH n , the basic cycle length is 12, so MONTH2, MONTH3, MONTH4, and MONTH6 are valid SEASONS= values (because 2, 3, 4, and 6 evenly divide 12 and are less than 12), but MONTH5 and MONTH12 are not valid SEASONS= values.

The frequency of the seasons must not be greater than the frequency of the input data. For example, you cannot specify SEASONS=MONTH if INTERVAL=QTR or SEASONS=MONTH if INTERVAL=MONTH2. You also cannot specify two seasons of the same basic cycle. For example, SEASONS=(MONTH QTR) or SEASONS=(MONTH2 MONTH4) is not allowed.

Alternatively, the seasonality can be specified by giving the number of seasons in the SEASONS= option. SEASONS= n specifies that there are n seasons, with observations 1, $n + 1$, $2n + 1$, and so on in the first season, observations 2, $n + 2$, $2n + 2$, and so on in the second season, and so forth.

The options SEASONS= n and SINTPER= m cause PROC FORECAST to group the input observations into n seasons, with m observations to a season, which repeat every nm observations. The options SEASONS=($n_1 n_2$) and SINTPER=($m_1 m_2$) produce n_1 seasons with m_1 observations to a season nested within n_2 seasons with $n_1 m_1 m_2$ observations to a season.

If the SINTPER= m option is used with the SEASONS= option, the SEASONS= interval is multiplied by the SINTPER= value. For example, specifying both SEASONS=(QTR HOUR) and SINTPER=(2 3) is the same as specifying SEASONS=(QTR2 HOUR3) and also the same as specifying SEASONS=(HOUR3 QTR2).

Data Requirements

You should have ample data for the series that you forecast by using PROC FORECAST. However, the results might be poor unless you have a good deal more than the minimum amount of data the procedure allows. The minimum number of observations required for the different methods is as follows:

- If METHOD=STEPAR is used, the minimum number of nonmissing observations required for each series forecast is the TREND= option value plus the value of the NLAGS= option. For example, using NLAGS=13 and TREND=2, at least 15 nonmissing observations are needed.
- If METHOD=EXPO is used, the minimum is the TREND= option value.
- If METHOD=WINTERS or ADDWINTERS is used, the minimum number of observations is either the number of observations in a complete seasonal cycle or the TREND= option value, whichever is greater. (However, there should be data for several complete seasonal cycles, or the seasonal factor estimates might be poor.) For example, for the seasonal specifications SEASONS=MONTH, SEASONS=(QTR DAY), or SEASONS=(MONTH DAY HOUR), the longest cycle length is one year, so at least one year of data is required. At least two years of data is recommended.

OUT= Data Set

The FORECAST procedure writes the forecast to the output data set named by the OUT= option. The OUT= data set contains the following variables:

- the BY variables
- `_TYPE_`, a character variable that identifies the type of observation
- `_LEAD_`, a numeric variable that indicates the number of steps ahead in the forecast. The value of `_LEAD_` is 0 for the one-step-ahead forecasts before the start of the forecast period.
- the ID statement variables
- the VAR statement variables, which contain the result values as indicated by the `_TYPE_` variable value for the observation

The FORECAST procedure processes each of the input variables listed in the VAR statement and writes several observations for each forecast period to the OUT= data set. The observations are identified by the value of the `_TYPE_` variable. The options OUTACTUAL, OUTALL, OUTLIMIT, OUTRESID, OUT1STEP, OUTFULL, and OUTSTD control which types of observations are included in the OUT= data set.

The values of the variable `_TYPE_` are as follows:

ACTUAL	The VAR statement variables contain actual values from the input data set. The OUTACTUAL option writes the actual values. By default, only the observations for the forecast period are output.
FORECAST	The VAR statement variables contain forecast values. The OUT1STEP option writes the one-step-ahead predicted values for the observations used to fit the model.
RESIDUAL	The VAR statement variables contain residuals. The residuals are computed by subtracting the forecast value from the actual value ($residual = actual - forecast$). The OUTRESID option writes observations for the residuals.
Lnn	The VAR statement variables contain lower <i>nn</i> % confidence limits for the forecast values for the future observations specified by the LEAD= option. The value of <i>nn</i> depends on the ALPHA= option; with the default ALPHA=0.05, the <code>_TYPE_</code> value is L95 for the lower confidence limit observations. The OUTLIMIT option writes observations for the upper and lower confidence limits.
Unn	The VAR statement variables contain upper <i>nn</i> % confidence limits for the forecast values for the future observations specified by the LEAD= option. The value of <i>nn</i> depends on the ALPHA= option; with the default ALPHA=0.05, the <code>_TYPE_</code> value is U95 for the upper confidence limit observations. The OUTLIMIT option writes observations for the upper and lower confidence limits.
STD	The VAR statement variables contain standard errors of the forecast values. The OUTSTD option writes observations for the standard errors of the forecast.

If no output control options are specified, PROC FORECAST outputs only the forecast values for the forecast periods.

The `_TYPE_` variable can be used to subset the OUT= data set. For example, the following data step splits the OUT= data set into two data sets, one that contains the forecast series and the other that contains the residual series. For example

```

proc forecast out=out outresid ...;
    ...
run;

data fore resid;
    set out;
    if _TYPE_='FORECAST' then output fore;
    if _TYPE_='RESIDUAL' then output resid;
run;

```

See Chapter 3, “[Working with Time Series Data](#),” for more information about processing time series data sets in this format.

OUTEST= Data Set

The FORECAST procedure writes the parameter estimates and goodness-of-fit statistics to an output data set when the OUTEST= option is specified. The OUTEST= data set contains the following variables:

- the BY variables
- the first ID variable, which contains the value of the ID variable for the last observation in the input data set used to fit the model
- `_TYPE_`, a character variable that identifies the type of each observation
- the VAR statement variables, which contain statistics and parameter estimates for the input series. The values contained in the VAR statement variables depend on the `_TYPE_` variable value for the observation.

The observations contained in the OUTEST= data set are identified by the `_TYPE_` variable. The OUTEST= data set might contain observations with the following `_TYPE_` values:

AR1–AR n	The observation contains estimates of the autoregressive parameters for the series. Two-digit lag numbers are used if the value of the NLAGS= option is 10 or more; in that case these <code>_TYPE_</code> values are AR01–AR n . These observations are output for the STEPAR method only.
CONSTANT	The observation contains the estimate of the constant or intercept parameter for the time trend model for the series. For the exponential smoothing and the Winters’ methods, the trend model is centered (that is, $t = 0$) at the last observation used for the fit.
LINEAR	The observation contains the estimate of the linear or slope parameter for the time trend model for the series. This observation is output only if you specify TREND=2 or TREND=3.

N	The observation contains the number of nonmissing observations used to fit the model for the series.
QUAD	The observation contains the estimate of the quadratic parameter for the time trend model for the series. This observation is output only if you specify TREND=3.
SIGMA	The observation contains the estimate of the standard deviation of the error term for the series.
S1–S3	The observations contain exponentially smoothed values at the last observation. <code>_TYPE_=S1</code> is the final smoothed value of the single exponential smooth. <code>_TYPE_=S2</code> is the final smoothed value of the double exponential smooth. <code>_TYPE_=S3</code> is the final smoothed value of the triple exponential smooth. These observations are output for METHOD=EXPO only.
<i>S_name</i>	<p>The observation contains estimates of the seasonal parameters. For example, if SEASONS=MONTH, the OUTEST= data set contains observations with <code>_TYPE_=S_JAN</code>, <code>_TYPE_=S_FEB</code>, <code>_TYPE_=S_MAR</code>, and so forth.</p> <p>For multiple-period seasons, the names of the first and last interval of the season are concatenated to form the season name. Thus, for SEASONS=MONTH4, the OUTEST= data set contains observations with <code>_TYPE_=S_JANAPR</code>, <code>_TYPE_=S_MAYAUG</code>, and <code>_TYPE_=S_SEPDEC</code>.</p> <p>When the SEASONS= option specifies numbers, the seasonal factors are labeled <code>_TYPE_=S_i_j</code>. For example, SEASONS=(2 3) produces observations with <code>_TYPE_</code> values of <code>S_1_1</code>, <code>S_1_2</code>, <code>S_2_1</code>, <code>S_2_2</code>, and <code>S_2_3</code>. The observation with <code>_TYPE_=S_i_j</code> contains the seasonal parameters for the <i>j</i>th season of the <i>i</i>th seasonal cycle.</p> <p>These observations are output only for METHOD=WINTERS or METHOD=ADDWINTERS.</p>
WEIGHT	The observation contains the smoothing weight used for exponential smoothing. This is the value of the WEIGHT= option. This observation is output for METHOD=EXPO only.
WEIGHT1	
WEIGHT2	
WEIGHT3	The observations contain the weights used for smoothing the WINTERS or ADDWINTERS method parameters (specified by the WEIGHT= option). <code>_TYPE_=WEIGHT1</code> is the weight used to smooth the CONSTANT parameter. <code>_TYPE_=WEIGHT2</code> is the weight used to smooth the LINEAR and QUAD parameters. <code>_TYPE_=WEIGHT3</code> is the weight used to smooth the seasonal parameters. These observations are output only for the WINTERS and ADDWINTERS methods.
NRESID	The observation contains the number of nonmissing residuals, <i>n</i> , used to compute the goodness-of-fit statistics. The residuals are obtained by subtracting the one-step-ahead predicted values from the observed values.
SST	The observation contains the total sum of squares for the series, corrected for the mean. $SST = \sum_{t=1}^n (y_t - \bar{y})^2$, where \bar{y} is the series mean.

SSE	The observation contains the sum of the squared residuals, uncorrected for the mean. $SSE = \sum_{t=1}^n (y_t - \hat{y}_t)^2$, where \hat{y} is the one-step predicted value for the series.
MSE	The observation contains the mean squared error, calculated from one-step-ahead forecasts. $MSE = \frac{1}{n-k} SSE$, where k is the number of parameters in the model.
RMSE	The observation contains the root mean squared error. $RMSE = \sqrt{MSE}$.
MAPE	The observation contains the mean absolute percent error. $MAPE = \frac{100}{n} \sum_{t=1}^n (y_t - \hat{y}_t)/y_t $.
MPE	The observation contains the mean percent error. $MPE = \frac{100}{n} \sum_{t=1}^n (y_t - \hat{y}_t)/y_t$.
MAE	The observation contains the mean absolute error. $MAE = \frac{1}{n} \sum_{t=1}^n y_t - \hat{y}_t $.
ME	The observation contains the mean error. $MAE = \frac{1}{n} \sum_{t=1}^n (y_t - \hat{y}_t)$.
MAXE	The observation contains the maximum error (the largest residual).
MINE	The observation contains the minimum error (the smallest residual).
MAXPE	The observation contains the maximum percent error.
MINPE	The observation contains the minimum percent error.
RSQUARE	The observation contains the R square statistic, $R^2 = 1 - SSE/SST$. If the model fits the series badly, the model error sum of squares SSE might be larger than SST and the R square statistic will be negative.
ADJRSQ	The observation contains the adjusted R square statistic. $ADJRSQ = 1 - (\frac{n-1}{n-k})(1 - R^2)$.
ARSQ	The observation contains Amemiya's adjusted R square statistic. $ARSQ = 1 - (\frac{n+k}{n-k})(1 - R^2)$.
RW_RSQ	The observation contains the random walk R square statistic (Harvey's R_D^2 statistic that uses the random walk model for comparison). $RW_RSQ = 1 - (\frac{n-1}{n})SSE/RWSSSE$, where $RWSSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$ and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$.
AIC	The observation contains Akaike's information criterion. $AIC = n \ln(SSE/n) + 2k$.
SBC	The observation contains Schwarz's Bayesian criterion. $SBC = n \ln(SSE/n) + k \ln(n)$.
APC	The observation contains Amemiya's prediction criterion. $APC = \frac{1}{n} SST (\frac{n+k}{n-k})(1 - R^2) = (\frac{n+k}{n-k}) \frac{1}{n} SSE$.
CORR	The observation contains the correlation coefficient between the actual values and the one-step-ahead predicted values.
THEILU	The observation contains Theil's U statistic that uses original units. See Maddala (1977, pp. 344–345), and Pindyck and Rubinfeld (1981, pp. 364–365) for more information about Theil statistics.

RTHEILU	The observation contains Theil's U statistic calculated using relative changes.
THEILUM	The observation contains the bias proportion of Theil's U statistic.
THEILUS	The observation contains the variance proportion of Theil's U statistic.
THEILUC	The observation contains the covariance proportion of Theil's U statistic.
THEILUR	The observation contains the regression proportion of Theil's U statistic.
THEILUD	The observation contains the disturbance proportion of Theil's U statistic.
RTHEILUM	The observation contains the bias proportion of Theil's U statistic, calculated by using relative changes.
RTHEILUS	The observation contains the variance proportion of Theil's U statistic, calculated by using relative changes.
RTHEILUC	The observation contains the covariance proportion of Theil's U statistic, calculated by using relative changes.
RTHEILUR	The observation contains the regression proportion of Theil's U statistic, calculated by using relative changes.
RTHEILUD	The observation contains the disturbance proportion of Theil's U statistic, calculated by using relative changes.

Examples: FORECAST Procedure

Example 15.1: Forecasting Auto Sales

This example uses the Winters method to forecast the monthly U. S. sales of passenger cars series (VEHICLES) from the data set SASHELP.USECON. These data are taken from *Business Statistics*, published by the U. S. Bureau of Economic Analysis.

The following statements plot the series. The plot is shown in [Output 15.1.1](#).

```

title1 "Sales of Passenger Cars";

symbol1 i=spline v=dot;
axis2 label=(a=-90 r=90 "Vehicles and Parts" )
      order=(6000 to 24000 by 3000);

title1 "Sales of Passenger Cars";
proc sgplot data=sashelp.usecon;
  series x=date y=vehicles / markers;
  xaxis values=('1jan80'd to '1jan92'd by year);
  yaxis values=(6000 to 24000 by 3000);
  format date year4.;
run;

```

Output 15.1.1 Monthly Passenger Car Sales

The following statements produce the forecast:

```
proc forecast data=sashelp.usecon interval=month
            method=winters seasons=month lead=12
            out=out outfull outresid outest=est;
    id date;
    var vehicles;
    where date >= '1jan80'd;
run;
```

The INTERVAL=MONTH option indicates that the data are monthly, and the ID DATE statement gives the dating variable. The METHOD=WINTERS specifies the Winters smoothing method. The LEAD=12 option forecasts 12 months ahead. The OUT=OUT option specifies the output data set, while the OUTFULL and OUTRESID options include in the OUT= data set the predicted and residual values for the historical period and the confidence limits for the forecast period. The OUTEST= option stores various statistics in an output data set. The WHERE statement is used to include only data from 1980 on.

The following statements print the OUT= data set (first 20 observations):

```
proc print data=out (obs=20) noobs;
run;
```

The listing of the output data set produced by PROC PRINT is shown in part in [Output 15.1.2](#).

Output 15.1.2 The OUT= Data Set Produced by PROC FORECAST (First 20 Observations)

Sales of Passenger Cars			
DATE	_TYPE_	_LEAD_	VEHICLES

Overview: LOAN Procedure

The LOAN procedure analyzes and compares fixed rate, adjustable rate, buydown, and balloon payment loans. The LOAN procedure computes the loan parameters and outputs the loan summary information for each loan.

Multiple loan specifications can be processed and compared in terms of economic criteria such as after-tax or before-tax present worth of cost and true interest rate, breakeven of periodic payment and of interest paid, and outstanding balance at different periods in time. PROC LOAN selects the best alternative in terms of the specified economic criterion for each loan comparison period.

The LOAN procedure allows various payment and compounding intervals (including continuous compounding) and uniform or lump sum prepayments for a loan. Down payments, discount points, and other initialization costs can be included in the loan analysis and comparison.

The LOAN procedure does not support an input data set. All loans analyzed are specified with statements in the PROC LOAN step. The SAS DATA step provides a function MORT that can be used for data-driven analysis of many fixed-rate mortgage or installment loans. However, the MORT function supports only simple fixed rate loans.

Getting Started: LOAN Procedure

PROC LOAN supports four types of loans. You specify each type of loan with the corresponding statement: FIXED, BALLOON, ARM, and BUYDOWN.

- **FIXED**—Fixed rate loans have a constant interest rate and periodic payment throughout the life of the loan.
- **BALLOON**—Balloon payment loans are fixed rate loans with lump sum payments in certain payment periods in addition to the constant periodic payment.
- **ARM**—Adjustable rate loans are those in which the interest rate and periodic payment vary over the life of the loan. The future interest rates of an adjustable rate loan are not known with certainty, but they will vary within specified limits according to terms stated in the loan agreement. In practice, the rate adjustment terms vary. PROC LOAN offers a flexible set of options to capture a wide variety of rate adjustment terms.
- **BUYDOWN**—Buydown rate loans are similar to adjustable rate loans, but the interest rate adjustments are predetermined at the initialization of the loan, usually by paying interest points at the time of loan initialization.

Analyzing Fixed Rate Loans

The most common loan analysis is the calculation of the periodic payment when the loan amount, life, and interest rate are known. The following PROC LOAN statements analyze a 15-year (180 monthly payments) fixed rate loan for \$100,000 with an annual nominal interest rate of 7.5%:

```
proc loan;
  fixed amount=100000 rate=7.5 life=180;
run;
```

Another parameter the PROC LOAN statement can compute is the maximum amount you can borrow given the periodic payment you can afford and the rates available in the market. The following SAS statements analyze a loan for 180 monthly payments of \$900, with a nominal annual rate of 7.5%, and compute the maximum amount that can be borrowed:

```
proc loan;
  fixed payment=900 rate=7.5 life=180;
run;
```

Assume that you want to borrow \$100,000 and can pay \$900 a month. You know that the lender charges a 7.5% nominal interest rate compounded monthly. To determine how long it will take you to pay off your debt, use the following statements:

```
proc loan;
  fixed amount=100000 payment=900 rate=7.5;
run;
```

Sometimes, a loan is expressed in terms of the amount borrowed and the amount and number of periodic payments. In this case, you want to calculate the annual nominal rate charged on the loan to compare it to other alternatives. The following statements analyze a loan of \$100,000 paid in 180 monthly payments of \$800:

```
proc loan;
  fixed amount=100000 payment=800 life=180;
run;
```

There are four basic parameters that define a loan: life (number of periodic payments), principal amount, interest rate, and the periodic payment amount. PROC LOAN calculates the missing parameter among these four. Loan analysis output includes a loan summary table and an amortization schedule.

You can use the START= and LABEL= options to enhance your output. The START= option specifies the date of loan initialization and dates all the output accordingly. The LABEL= specification is used to label all output that corresponds to a particular loan; it is especially useful when multiple loans are analyzed. For example, the preceding statements for the first fixed rate loan are revised to include the START= and LABEL= options as follows:

```

proc loan start=1998:12;
    fixed amount=100000 rate=7.5 life=180
        label='BANK1, Fixed Rate';
run;

```

Loan Summary Table

The loan summary table is produced by default and contains loan analysis information. It shows the principal amount, the costs at the time of loan initialization (down payment, discount points, and other loan initialization costs), the total payment and interest, the initial nominal and effective interest rates, payment and compounding intervals, the length of the loan in the time units specified, the start and end dates (if specified), a list of nominal and effective interest rates, and periodic payments throughout the life of the loan.

Figure 16.1 shows the loan summary table for the fixed rate loan labeled “BANK1, Fixed Rate.”

Figure 16.1 Fixed Rate Loan Summary

The LOAN Procedure			
Fixed Rate Loan Summary			
BANK1, Fixed Rate			
Downpayment	0.00	Principal Amount	100000.00
Initialization	0.00	Points	0.00
Total Interest	66862.61	Nominal Rate	7.5000%
Total Payment	166862.61	Effective Rate	7.7633%
Pay Interval	MONTHLY	Compounding	MONTHLY
No. of Payments	180	No. of Compoundings	180
Start Date	DEC1998	End Date	DEC2013
Rates and Payments for BANK1, Fixed Rate			
Date	Nominal Rate	Effective Rate	Payment
DEC1998	7.5000%	7.7633%	927.01

The loan is initialized in December 1998 and paid off in December 2013. The monthly payment is calculated to be \$927.01, and the effective interest rate is 7.7633%. Over the 15 years, \$66,862.61 is paid for interest charges on the loan.

Analyzing Balloon Payment Loans

You specify balloon payment loans like fixed rate loans, with the additional specification of the balloon payments. Assume you have an alternative to finance the \$100,000 investment with a 15-year balloon payment loan. The annual nominal rate is 7.5%, as in the fixed rate loan. The terms of

the loan require two balloon payments of \$2000 and \$1000 at the 15th and 48th payment periods, respectively. These balloon payments keep the periodic payment lower than that of the fixed rate loan. The balloon payment loan is defined by the following BALLOON statement:

```
proc loan start=1998:12;
  balloon amount=100000 rate=7.5 life=180
    balloonpayment=(15=2000 48=1000)
    label = 'BANK2, with Balloon Payment';
run;
```

List of Balloon Payments

In addition to the information for the fixed rate loan, the “Loan Summary Table” for the balloon payment loan includes a list of balloon payments in the list of rates and payments. For example, the balloon payment loan described previously includes two balloon payments, as shown in [Figure 16.2](#).

Figure 16.2 List of Rates and Payments for a Balloon Payment Loan

The LOAN Procedure			
Rates and Payments for BANK2, with Balloon Payment			
Date	Nominal Rate	Effective Rate	Payment
DEC1998	7.5000%	7.7633%	903.25
	Balloon Period	Payment	
	MAR2000	2000.00	
	DEC2002	1000.00	

The periodic payment for the balloon payment loan is \$23.76 less than that of the fixed rate loan.

Analyzing Adjustable Rate Loans

In addition to specifying the basic loan parameters, you need to specify the terms of the rate adjustments for an adjustable rate loan. There are many ways of stating the rate adjustment terms, and PROC LOAN facilitates all of them. For details, see the section “[Rate Adjustment Terms Options](#)” on page 846.

Assume that you have an alternative to finance the \$100,000 investment with a 15-year adjustable rate loan with an initial annual nominal interest rate of 5.5%. The rate adjustment terms specify a 0.5% annual cap, a 2.5% life cap, and a rate adjustment every 12 months. *Annual cap* refers to the maximum increase in interest rate per adjustment period, and *life cap* refers to the maximum increase over the life of the loan. The following ARM statement specifies this adjustable rate loan by assuming the interest rate adjustments will always increase by the maximum allowed by the

terms of the loan. These assumptions are specified by the WORSTCASE and CAPS= options, as shown in the following statements:

```
proc loan start=1998:12;
  arm amount=100000 rate=5.5 life=180 worstcase
  caps=(0.5, 2.5)
  label='BANK3, Adjustable Rate';
run;
```

List of Rates and Payments for Adjustable Rate Loans

The list of rates and payments in the loan summary table for the adjustable rate loans reflects the changes in the interest rates and payments and the dates these changes become effective. For the adjustable rate loan described previously, Figure 16.3 shows the list of rates and payments that indicate five annual rate adjustments in addition to the initial rate and payment.

Figure 16.3 List of Rates and Payments for an Adjustable Rate Loan

The LOAN Procedure			
Rates and Payments for BANK3, Adjustable Rate			
Date	Nominal Rate	Effective Rate	Payment
DEC1998	5.5000%	5.6408%	817.08
JAN2000	6.0000%	6.1678%	842.33
JAN2001	6.5000%	6.6972%	866.44
JAN2002	7.0000%	7.2290%	889.32
JAN2003	7.5000%	7.7633%	910.88
JAN2004	8.0000%	8.3000%	931.03

Notice that the periodic payment of the adjustable rate loan as of January 2004 (\$931.03) exceeds that of the fixed rate loan (\$927.01).

Analyzing Buydown Rate Loans

A 15-year buydown rate loan is another alternative to finance the \$100,000 investment. The nominal annual interest rate is 6.5% initially and will increase to 8% and 9% as of the 24th and 48th payment periods, respectively. The nominal annual interest rate is lower than that of the fixed rate alternative, at the cost of a 1% discount point (\$1000) paid at the initialization of the loan. The following BUYDOWN statement represents this loan alternative:

```
proc loan start=1998:12;
  buydown amount=100000 rate=6.5 life=180
  buydownrates=(24=8 48=9) pointpct=1
  label='BANK4, Buydown';
run;
```

List of Rates and Payments for Buydown Rate Loans

Figure 16.4 shows the list of rates and payments in the loan summary table. It reflects the two rate adjustments and the corresponding monthly payments as well as the initial values for these parameters. As of December 2000, the periodic payment of the buydown loan exceeds the periodic payment for any of the other alternatives.

Figure 16.4 List of Rates and Payments for a Buydown Rate Loan

The LOAN Procedure			
Rates and Payments for BANK4, Buydown			
Date	Nominal Rate	Effective Rate	Payment
DEC1998	6.5000%	6.6972%	871.11
DEC2000	8.0000%	8.3000%	946.50
DEC2002	9.0000%	9.3807%	992.01

Loan Repayment Schedule

In addition to the loan summary, you can print a loan repayment (amortization) schedule for each loan. For each payment period, this schedule contains the year and period within the year (or date, if the START= option is specified), the principal balance at the beginning of the period, the total payment, interest payment, principal repayment for the period, and the principal balance at the end of the period.

To print the first year of the amortization schedule for the fixed rate loan shown in Figure 16.5, use the following statements:

```
proc loan start=1998:12;
  fixed amount=100000 rate=7.5 life=180
  schedule=1
  label='BANK1, Fixed Rate';
run;
```

Figure 16.5 Loan Repayment Schedule for the First Year

The LOAN Procedure					
Loan Repayment Schedule					
BANK1, Fixed Rate					
Date	Beginning Outstanding	Payment	Interest Payment	Principal Repayment	Ending Outstanding
DEC1998	100000.00	0.00	0.00	0.00	100000.00
DEC1998	100000.00	0.00	0.00	0.00	100000.00
JAN1999	100000.00	927.01	625.00	302.01	99697.99
FEB1999	99697.99	927.01	623.11	303.90	99394.09
MAR1999	99394.09	927.01	621.21	305.80	99088.29
APR1999	99088.29	927.01	619.30	307.71	98780.58
MAY1999	98780.58	927.01	617.38	309.63	98470.95
JUN1999	98470.95	927.01	615.44	311.57	98159.38
JUL1999	98159.38	927.01	613.50	313.51	97845.87
AUG1999	97845.87	927.01	611.54	315.47	97530.40
SEP1999	97530.40	927.01	609.57	317.44	97212.96
OCT1999	97212.96	927.01	607.58	319.43	96893.53
NOV1999	96893.53	927.01	605.58	321.43	96572.10
DEC1999	96572.10	927.01	603.58	323.43	96248.67
DEC1999	100000.00	11124.12	7372.79	3751.33	96248.67

The principal balance at the end of one year is \$96,248.67. The total payment for the year is \$11,124.12, of which \$3,751.33 went toward principal repayment.

You can also print the amortization schedule with annual summary information or for a specified number of years. The SCHEDULE=YEARLY option produces an annual summary loan amortization schedule, which is useful for loans with a long life. For example, to print the annual summary loan repayment schedule for the buydown loan shown in [Figure 16.6](#), use the following statements:

```
proc loan start=1998:12;
  buydown amount=100000 rate=6.5 life=180
    buydownrates=(24=8 48=9) pointpct=1
    schedule=yearly
    label='BANK4, Buydown';
run;
```

Figure 16.6 Annual Summary Loan Repayment Schedule

The LOAN Procedure

2013	11343.53	11904.09	560.56	11343.53	0.00

Loan Comparison

The LOAN procedure can compare alternative loans on the basis of different economic criteria and help select the most desirable loan. You can compare alternative loans through different points in time. The economic criteria offered by PROC LOAN are:

- outstanding principal balance—that is, the unpaid balance of the loan
- present worth of cost—that is, before-tax or after-tax net value of the loan cash flow through the comparison period. The cash flow includes all payments, discount points, initialization costs, down payment, and the outstanding principal balance at the comparison period.
- true interest rate—that is, before-tax or after-tax effective annual interest rate charged on the loan. The cash flow includes all payments, discount points, initialization costs, and the outstanding principal balance at the specified comparison period.
- periodic payment
- the total interest paid on the loan

The figures for present worth of cost, true interest rate, and interest paid are reported on the cash flow through the comparison period. The reported outstanding principal balance and the periodic payment are the values as of the comparison period.

The COMPARE statement specifies the type of comparison and the periods of comparison. For each period specified in the COMPARE statement, a loan comparison report is printed that also indicates the best alternative. Different criteria can lead to selection of different alternatives. Also, the period of comparison might change the desirable alternative. See the section “[Loan Comparison Details](#)” on page 852 for further information.

Comparison of 15-Year versus 30-Year Loan Alternatives

An issue that arises in the purchase of a house is the length of the loan life. Residential home loans are often for 15 or 30 years. Ordinarily, 15-year loans have a lower interest rate but higher periodic payments than 30-year loans. A comparison of both loans might identify the better loan for your means and needs. The following SAS statements compare two such loans:

```
proc loan start=1998:12 amount=120000;
  fixed rate=7.5 life=360 label='30 year loan';
  fixed rate=6.5 life=180 label='15 year loan';
  compare;
run;
```

Default Loan Comparison Report

The default loan comparison report in [Figure 16.7](#) shows the ending outstanding balance, periodic payment, interest paid, and before-tax true rate at the end of 30 years. In the case of the default loan comparison, the selection of the best alternative is based on minimization of the true rate.

Figure 16.7 Default Loan Comparison Report

The LOAN Procedure				
Loan Comparison Report				
Analysis through DEC2028				
Loan Label	Ending Outstanding	Payment	Interest Paid	True Rate
30 year loan	0.00	835.48	182058.02	7.76
15 year loan	0.00	1044.95	68159.02	6.70
NOTE: "15 year loan" is the best alternative based on true rate analysis through DEC2028.				

Based on true rate, the best alternative is the 15-year loan. However, if the objective were to minimize the periodic payment, the 30-year loan would be the more desirable.

Comparison of Fixed Rate and Adjustable Rate Loans

Suppose you want to compare a fixed rate loan to an adjustable rate alternative. The nominal interest rate on the adjustable rate loan is initially 1.5% lower than the fixed rate loan. The future rates of the adjustable rate loan are calculated using the worst case scenario.

The interest paid on a loan might be deductible for tax purposes, depending on the purpose of the loan and applicable laws. In the following example, the TAXRATE=28 (income tax rate) option in the COMPARE statement bases the calculations of true interest rate on the after-tax cash flow. Assume, also, that you are uncertain as to how long you will keep this property. The AT=(60 120) option, as shown in the following example, produces two loan comparison reports through the end of the 5th and the 10th years, respectively:

```
proc loan start=1998:12 amount=120000 life=360;
  fixed rate=7.5 label='BANK1, Fixed Rate';
  arm rate=6.0 worstcase caps=(0.5 2.5)
    label='BANK3, Adjustable Rate';
  compare taxrate=28 at=(60 120);
run;
```

After-Tax Loan Comparison Reports

The two loan comparison reports in [Figure 16.8](#) and [Figure 16.9](#) show the ending outstanding balance, periodic payment, interest paid, and after-tax true rate at the end of five years and ten years, respectively.

Figure 16.8 Loan Comparison Report as of December 2003

The LOAN Procedure				
Loan Comparison Report				
Analysis through DEC2003				
Loan Label	Ending Outstanding	Payment	Interest Paid	True Rate
BANK1, Fixed Rate	113540.74	839.06	43884.34	5.54
BANK3, Adjustable Rate	112958.49	871.83	40701.93	5.11

NOTE: "BANK3, Adjustable Rate" is the best alternative based on true rate analysis through DEC2003.

Figure 16.9 Loan Comparison Report as of December 2008

Loan Comparison Report				
Analysis through DEC2008				
Loan Label	Ending Outstanding	Payment	Interest Paid	True Rate
BANK1, Fixed Rate	104153.49	839.06	84840.69	5.54
BANK3, Adjustable Rate	104810.98	909.57	87128.62	5.60
NOTE: "BANK1, Fixed Rate" is the best alternative based on true rate analysis through DEC2008.				

The loan comparison report through December 2003 picks the adjustable rate loan as the best alternative, whereas the report through December 2008 shows the fixed rate loan as the better alternative. This implies that if you intend to keep the loan for 10 years or longer, the best alternative is the fixed rate alternative. Otherwise, the adjustable rate loan is the better alternative in spite of the worst-case scenario. Further analysis shows that the actual breakeven of true interest rate occurs at August 2008. That is, the desirable alternative switches from the adjustable rate loan to the fixed rate loan in August 2008.

Note that, under the assumption of worst-case scenario for the rate adjustments, the periodic payment for the adjustable rate loan already exceeds that of the fixed rate loan on December 2003 (as of the rate adjustment on January 2003 to be exact). If the objective were to minimize the periodic payment, the fixed rate loan would have been more desirable as of December 2003. However, all of the other criteria at that point still favor the adjustable rate loan.

Syntax: LOAN Procedure

The following statements are used with PROC LOAN:

```

PROC LOAN options ;
  FIXED options ;
  BALLOON options ;
  ARM options ;
  BUYDOWN options ;
  COMPARE options ;

```

Functional Summary

Table 16.1 summarizes the statements and options that control the LOAN procedure. Many of the loan specification options can be used on all of the statements except the COMPARE statement.

For these options, the statement column is left blank. Options specific to a type of loan indicate the statement name.

PROC LOAN Statement

PROC LOAN *options* ;

The OUTSUM= option can be used in the PROC LOAN statement. In addition, the following loan specification options can be specified in the PROC LOAN statement to be used as defaults for all loans unless otherwise specified for a given loan:

AMOUNT=	INTERVAL=	POINTPCT=
AMOUNTPCT=	LABEL=	PREPAYMENTS=
COMPOUND=	LIFE=	PRICE=
DOWNPAYMENT=	NOSUMMARYPRINT	RATE=
DOWNPAYPCT=	NOPRINT	ROUND=
INITIAL=	PAYMENT=	START=
INITIALPCT=	POINTS=	SCHEDULE=

Output Option

OUTSUM= *SAS-data-set*

creates an output data set that contains loan summary information for all loans other than those for which a different OUTSUM= output data set is specified.

FIXED Statement

FIXED *options* ;

The FIXED statement specifies a fixed rate and periodic payment loan. It can be specified using the options that are common to all loan statements. The FIXED statement options are listed in this section.

You must specify three of the following options in each loan statement: AMOUNT=, LIFE=, RATE=, and PAYMENT=. The LOAN procedure calculates the fourth parameter based on the values you give the other three. If you specify all four of the options, the PAYMENT= specification is ignored, and the periodic payment is recalculated for consistency.

As an alternative to specifying the AMOUNT= option, you can specify the PRICE= option along with one of the following options to facilitate the calculation of the loan amount: AMOUNTPCT=, DOWNPAYMENT=, or DOWNPAYPCT=.

Required Specifications

AMOUNT=*amount*

A=*amount*

specifies the loan amount (the outstanding principal balance at the initialization of the loan).

LIFE=*n*

L=*n*

gives the life of the loan in number of payments. (The payment frequency is specified by the INTERVAL= option.) For example, if the life of the loan is 10 years with monthly payments, use LIFE=120 and INTERVAL=MONTH (default) to indicate a 10-year loan in which 120 monthly payments are made.

PAYMENT=amount**P=amount**

specifies the periodic payment. For ARM and BUYDOWN loans where the periodic payment might change, the PAYMENT= option specifies the initial amount of the periodic payment.

RATE=rate**R=rate**

specifies the initial annual (nominal) interest rate in percent notation. The rate specified must be in the range 0% to 120%. For example, use RATE=12.75 for a 12.75% loan. For ARM and BUYDOWN loans, where the rate might change over the life of the loan, the RATE= option specifies the initial annual interest rate.

Specification Options

AMOUNTPCT=value**APCT=value**

specifies the loan amount as a percentage of the purchase price (PRICE= option). The AMOUNTPCT= specification is used to calculate the loan amount if the AMOUNT= option is not specified. The value specified must be in the range 1% to 100%.

If both the AMOUNTPCT= and DOWNPAYPCT= options are specified and the sum of their values is not equal to 100, the value of the downpayment percentage is set equal to 100 minus the value of the amount percentage.

COMPOUND=time-unit

specifies the time interval between compoundings. The default is the time unit given by the INTERVAL= option. If the INTERVAL= option is not used, then the default is COMPOUND=MONTH. The following time units are valid COMPOUND= values: CONTINUOUS, DAY, SEMIMONTH, MONTH, QUARTER, SEMIYEAR, and YEAR. The compounding interval is used to calculate the simple interest rate per payment period from the nominal annual interest rate or vice versa.

DOWNPAYMENT=amount**DP=amount**

specifies the down payment at the initialization of the loan. The down payment is included in the calculation of the present worth of cost but not in the calculation of the true interest rate. The after-tax analysis assumes that the down payment is not tax-deductible. (Specify after-tax analysis with the TAXRATE= option in the COMPARE statement.)

DOWNPAYPCT=value**DPCT=value**

specifies the down payment as a percentage of the purchase price (PRICE= option). The DOWNPAYPCT= specification is used to calculate the down payment amount if you do not specify the DOWNPAYMENT= option. The value you specify must be in the range 0% to 99%.

If you specified both the AMOUNTPCT= and DOWNPAYPCT= options and the sum of their values is not equal to 100, the value of the downpayment percentage is set equal to 100 minus the value of the amount percentage.

INITIAL=amount

INIT=amount

specifies the amount paid for loan initialization other than the discount points and down payment. This amount is included in the calculation of the present worth of cost and the true interest rate. The after-tax analysis assumes that the initial amount is not tax-deductible. (After-tax analysis is specified by the TAXRATE= option in the COMPARE statement.)

INITIALPCT=value

INITPCT=value

specifies the initialization costs as a percentage of the loan amount (AMOUNT= option). The INITIALPCT= specification is used to calculate the amount paid for loan initialization if you do not specify the INITIAL= option. The value you specify must be in the range of 0% to 100%.

INTERVAL=time-unit

gives the time interval between periodic payments. The default is INTERVAL=MONTH. The following time units are valid INTERVAL values: SEMIMONTH, MONTH, QUARTER, SEMIYEAR, and YEAR.

LABEL='loan-label'

specifies a label for the loan. If you specify the LABEL= option, all output related to the loan is labeled accordingly. If you do not specify the LABEL= option, the loan is labeled by sequence number.

POINTS=amount

PNT=amount

specifies the amount paid for discount points at the initialization of the loan. This amount is included in the calculation of the present worth of cost and true interest rate. The amount paid for discount points is assumed to be tax-deductible in after-tax analysis (that is, if the TAXRATE= option is specified in the COMPARE statement).

POINTPCT=value

PNTPCT=value

specifies the discount points as a percentage of the loan amount (AMOUNT= option). The POINTPCT= specification is used to calculate the amount paid for discount points if you do not specify the POINTS= option. The value you specify must be in the range of 0% to 100%.

PREPAYMENTS=amount

PREPAYMENTS=(date1=prepayment1 date2=prepayment2 ...)

PREPAYMENTS=(period1=prepayment1 period2=prepayment2 ...)

PREP=

specifies either a uniform prepayment p throughout the life of the loan or lump sum prepayments. A uniform prepayment p is assumed to be paid with each periodic payment. Specify lump sum prepayments by pairs of periods (or dates) and respective prepayment amounts.

You can specify the prepayment periods as dates if you specify the START= option. Prepayment periods or dates and the respective prepayment amounts must be in time sequence. The prepayments are treated as principal payments, and the outstanding principal balance is

adjusted accordingly. In the adjustable rate and buydown rate loans, if there is a rate adjustment after prepayments, the adjusted periodic payment is calculated based on the outstanding principal balance. The prepayments do not result in periodic payment amount adjustments in fixed rate and balloon payment loans.

PRICE=*amount*

PRC=*amount*

specifies the purchase price, which is the loan amount plus the down payment. If you specify the **PRICE=** option along with the loan amount (**AMOUNT=** option) or the down payment (**DOWNPAYMENT=** option), the value of the other one is calculated.

If you specify the **PRICE=** option with the **AMOUNTPCT=** or **DOWNPAYPCT=** options, the loan amount and the downpayment are calculated.

ROUND=*n*

ROUND=NONE

specifies the number of decimal places to which the monetary amounts are rounded for the loan. Valid values for *n* are integers from 0 to 6. If you specify **ROUND=NONE**, the values are not rounded off internally, but the printed output is rounded off to two decimal places. The default is **ROUND=2**.

START=*SAS-date-literal*

START=*yyyy:period*

S=

gives the date of loan initialization. The first payment is assumed to be one payment interval after the start date. For example, you can specify the **START=** option as **START='1APR2010'D** or as **START=2010:3**, where 3 is the third payment interval within the year 2010. If **INTERVAL=QUARTER**, 3 refers to the third quarter. If you specify the **START=** option, all output for the particular loan is dated accordingly.

Output Options

NOSUMMARYPRINT

NOSUMPR

suppresses the printing of the loan summary report. The **NOSUMMARYPRINT** option is usually used when an **OUTSUM=** data set is created to store loan summary information.

NOPRINT

NOP

suppresses all printed output for the loan.

OUT=*SAS-data-set*

writes the loan amortization schedule to an output data set.

OUTSUM=*SAS-data-set*

writes the loan summary for the individual loan to an output data set.

SCHEDULE**SCHEDULE=nyears****SCHEDULE=YEARLY****SCHED**

prints the amortization schedule for the loan. **SCHEDULE=nyears** specifies the number of years the printed amortization table covers. If you omit the number of years or specify a period longer than the loan life, the schedule is printed for the full term of the loan. **SCHEDULE=YEARLY** prints yearly summary information in the amortization schedule rather than the full amortization schedule. **SCHEDULE=YEARLY** is useful for long-term loans.

BALLOON Statement**BALLOON options ;**

The **BALLOON** statement specifies a fixed rate loan with scheduled balloon payments in addition to the periodic payment. The following option is used in the **BALLOON** statement, in addition to the required options listed under the **FIXED** statement:

BALLOONPAYMENT=(date1=payment1 date2=payment2 ...)**BALLOONPAYMENT=(period1=payment1 period2=payment2 ...)****BPAY=(date1=payment1 date2=payment2 ...)****BPAY=(period1=payment1 period2=payment2 ...)**

specifies pairs of periods and amounts of balloon (lump sum) payments in excess of the periodic payment during the life of the loan. You can also specify the balloon periods as dates if you specify the **START=** option. The dates are specified as SAS date literals. For example, **BALLOONPAYMENT=('1MAR2011'D=1000)** specifies a payment of 1000 in March of 2011.

If you do not specify this option, the calculations are identical to a loan specified in a **FIXED** statement. Balloon periods (or dates) and the respective balloon payments must be in time sequence.

ARM Statement**ARM options ;**

The **ARM** statement specifies an adjustable rate loan where the future interest rates are not known with certainty but will vary within specified limits according to the terms stated in the loan agreement. In practice, the adjustment terms vary. Adjustments in the interest rate can be captured using the **ARM** statement options.

In addition to the required specifications and options listed under the **FIXED** statement, you can use the following options with the **ARM** statement.

Rate Adjustment Terms Options

ADJUSTFREQ=*n*

ADF=*n*

specifies the number of periods, in terms of the INTERVAL= specification, between rate adjustments. INTERVAL=MONTH ADJUSTFREQ=6 indicates that the nominal interest rate can be adjusted every six months until the life cap or maximum rate (whichever is specified) is reached. The default is ADJUSTFREQ=12. The periodic payment is adjusted every adjustment period even if there is no rate change; therefore, if prepayments are made (as specified with the PREPAYMENTS= option), the periodic payment might change even if the nominal rate does not.

CAPS=(*periodic-cap*, *life-cap*)

specifies the maximum interest rate adjustment, in percent notation, allowed by the loan agreement. The *periodic cap* specifies the maximum adjustment allowed at each adjustment period. The *life cap* specifies the maximum total adjustment over the life of the loan. For example, a loan specified with CAPS=(0.5, 2) indicates that the nominal interest rate can change by 0.5% each adjustment period, and the annual nominal interest rate throughout the life of the loan will be within a 2% range of the initial annual nominal rate.

MAXADJUST=*rate*

MAXAD=*rate*

specifies the maximum rate adjustment, in percent notation, allowed at each adjustment period. Use the MAXADJUST= option with the MAXRATE= and MINRATE= options. The initial nominal rate plus the maximum adjustment should not exceed the specified MAXRATE= value. The initial nominal rate minus the maximum adjustment should not be less than the specified MINRATE= value.

MAXRATE=*rate*

MAXR=*rate*

specifies the maximum annual nominal rate, in percent notation, that might be charged on the loan. The maximum annual nominal rate should be greater than or equal to the initial annual nominal rate specified with the RATE= option.

MINRATE=*rate*

MINR=*rate*

specifies the minimum annual nominal rate, in percent notation, that might be charged on the loan. The minimum annual nominal rate should be less than or equal to the initial annual nominal rate specified with the RATE= option.

Rate Adjustment Case Options

PROC LOAN supports four rate adjustment scenarios for analysis of adjustable rate loans: pessimistic (WORSTCASE), optimistic (BESTCASE), no-change (FIXEDCASE), and estimated (ESTIMATEDCASE). The estimated case enables you to analyze the adjustable rate loan with your predictions of future interest rates. The default is worst-case analysis. If more than one case is

specified, worst-case analysis is performed. You can specify options for adjustable rate loans as follows:

BESTCASE

B

specifies a best-case analysis. The best-case analysis assumes that the interest rate charged on the loan will reach its minimum allowed limits at each adjustment period and over the life of the loan. If you use the BESTCASE option, you must specify either the CAPS= option or the MINRATE= and MAXADJUST= options.

ESTIMATEDCASE=(*date1=rate1 date2=rate2 ...*)

ESTIMATEDCASE=(*period1=rate1 period2=rate2 ...*)

ESTC=

specifies an estimated case analysis that indicates the rate adjustments will follow the rates you predict. This option specifies pairs of periods and estimated nominal interest rates.

The ESTIMATEDCASE= option can specify adjustments that cannot fit into the BESTCASE, WORSTCASE, or FIXEDCASE specifications, or “what-if” type analysis. If you specify the START= option, you can also specify the estimation periods as dates, in the form of SAS date literals. Estimated rates and the respective periods must be in time sequence.

If the estimated period falls between two adjustment periods (determined by ADJUSTFREQ= option), the rate is adjusted in the next adjustment period. The nominal interest rate charged on the loan is constant between two adjustment periods.

If any of the MAXRATE=, MINRATE=, CAPS=, and MAXADJUST= options are specified to indicate the rate adjustment terms of the loan agreement, these specifications are used to bound the rate adjustments. By using the ESTIMATEDCASE= option, you are predicting what the annual nominal rates in the market will be at different points in time, not necessarily the interest rate on your particular loan. For example, if the initial nominal rate (RATE= option) is 6.0, ADJUSTFREQ=6, MAXADJUST=0.5, and the ESTIMATEDCASE=(6=6.5, 12=7.5), the actual nominal rates charged on the loan would be 6.0% initially, 6.5% for the sixth through the eleventh periods, and 7.5% for the twelfth period onward.

FIXEDCASE

FIXCASE

specifies a fixed case analysis that assumes the rate will stay constant. The FIXEDCASE option calculates the ARM loan values similar to a fixed rate loan, but the payments are updated every adjustment period even if the rate does not change, leading to minor differences between the two methods. One such difference is in the way prepayments are handled. In a fixed rate loan, the rate and the payments are never adjusted; therefore, the payment stays the same over the life of the loan even when prepayments are made (instead, the life of the loan is shortened). In an ARM loan with the FIXEDCASE option, on the other hand, if prepayments are made, the payment is adjusted in the following adjustment period, leaving the life of the loan constant.

WORSTCASE

W

specifies a worst-case analysis. The worst-case analysis assumes that the interest rate charged

on the loan will reach its maximum allowed limits at each rate adjustment period and over the life of the loan. If the WORSTCASE option is used, either the CAPS= option or the MAXRATE= and MAXADJUST= options must be specified.

BUYDOWN Statement

BUYDOWN options ;

The BUYDOWN statement specifies a buydown rate loan. The buydown rate loans are similar to ARM loans, but the interest rate adjustments are predetermined at the initialization of the loan, usually by paying interest points at the time of loan initialization.

You must use all the required specifications and options listed under the FIXED statement with the BUYDOWN statement. The following option is specific to the BUYDOWN statement and is required:

BUYDOWNRATES=(*date1=rate1 date2=rate2 ...*)

BUYDOWNRATES=(*period1=rate1 period2=rate2 ...*)

BDR=

specifies pairs of periods and the predetermined nominal interest rates that will be charged on the loan starting at the corresponding time periods.

You can also specify the buydown periods as dates in the form of SAS date literals if you also specify the date of the initial payment by using a date value in the START= option. Buydown periods (or dates) and the respective buydown rates must be in time sequence.

COMPARE Statement

COMPARE options ;

The COMPARE statement compares multiple loans, or it can be used with a single loan. You can use only one COMPARE statement. COMPARE statement options specify the periods and desired types of analysis for loan comparison. The default analysis reports the outstanding principal balance, breakeven of payment, breakeven of interest paid, and before-tax true interest rate. The default comparison period corresponds to the first LIFE= option specification. If the LIFE= option is not specified for any loan, the loan comparison period defaults to the first calculated life.

You can use the following options with the COMPARE statement. For more detailed information on loan comparison, see the section “[Loan Comparison Details](#)” on page 852.

Analysis Options

ALL

is equivalent to specifying the BREAKINTEREST, BREAKPAYMENT, PWOF COST, and

TRUEINTEREST options. The loan comparison report includes all the criteria. You need to specify the MARR= option for present worth of cost calculation.

AT=(date1 date2 ...)

AT=(period1 period2 ...)

specifies the periods for loan comparison reports. If you specify the START= option in the PROC LOAN statement, you can specify the AT= option as a list of dates expressed as SAS date literals instead of periods. The comparison periods do not need to be in time sequence. If you do not specify the AT= option, the comparison period defaults to the first LIFE= option specification. If you do not specify the LIFE= option for any of the loans, the loan comparison period defaults to the first calculated life.

BREAKINTEREST

BI

specifies breakeven analysis of the interest paid. The loan comparison report includes the interest paid for each loan through the specified comparison period (AT= option).

BREAKPAYMENT

BP

specifies breakeven analysis of payment. The periodic payment for each loan is reported for every comparison period specified in the AT=option.

MARR=rate

specifies the MARR (minimum attractive rate of return) in percent notation. The MARR reflects the cost of capital or the opportunity cost of money. The MARR= option is used in calculating the present worth of cost.

PWFOCOST

PWC

calculates the present worth of cost (net present value of costs) for each loan based on the cash flow through the specified comparison periods. The calculations account for down payment, initialization costs, and discount points, as well as the payments and outstanding principal balance at the comparison period. If you specify the TAXRATE= option, the present worth of cost is based on after-tax cash flow. Otherwise, before-tax present worth of cost is calculated. You need to specify the MARR= option for present worth of cost calculations.

TAXRATE=rate

TAX=rate

specifies income tax rate in percent notation for the after-tax calculations of the true interest rate and present worth of cost for those assets that qualify for tax deduction. If you specify this option, the amount specified in the POINTS= option and the interest paid on the loan are assumed to be tax-deductible. Otherwise, it is assumed that the asset does not qualify for tax deductions, and the cash flow is not adjusted for tax savings.

TRUEINTEREST

TI

calculates the true interest rate (effective interest rate based on the cash flow of all payments,

initialization costs, discount points, and the outstanding principal balance at the comparison period) for all the specified loans through each comparison period. If you specify the `TAXRATE=` option, the true interest rate is based on after-tax cash flow. Otherwise, the before-tax true interest rate is calculated.

Output Options

NOCOMPRINT

NOCP

suppresses the printing of the loan comparison report. The `NOCOMPRINT` option is usually used when an `OUTCOMP=` data set is created to store loan comparison information.

OUTCOMP=SAS-data-set

writes the loan comparison report to an output data set.

Details: LOAN Procedure

Computational Details

These terms are used in the formulas that follow:

p	periodic payment
a	principal amount
r_a	nominal annual rate
f	compounding frequency (per year)
f'	payment frequency (per year)
r	periodic rate
r_e	effective interest rate
n	total number of payments

The periodic rate, or the simple interest applied during a payment period, is given by

$$r = \left(1 + \frac{r_a}{f}\right)^{f/f'} - 1$$

Note that the interest calculation is performed at each payment period rather than at the compound period. This is done by adjusting the nominal rate. See Muksian (1984) for details.

Note that when $f = f'$ (that is, when the payment and compounding frequency coincide), the preceding expression reduces to the familiar form:

$$r = \frac{ra}{f}$$

The periodic rate for continuous compounding can be obtained from this general expression by taking the limit as the compounding frequency f goes to infinity. The resulting expression is

$$r = \exp\left(\frac{ra}{f'}\right) - 1$$

The effective interest rate, or annualized percentage rate (APR), is that rate which, if compounded once per year, is equivalent to the nominal annual rate compounded f times per year. Thus,

$$(1 + r_e) = (1 + r)^f = \left(1 + \frac{ra}{f}\right)^f$$

or

$$r_e = \left(1 + \frac{ra}{f}\right)^f - 1$$

For continuous compounding, the effective interest rate is given by

$$r_e = \exp(ra) - 1$$

See Muksian (1984) for details.

The payment is calculated as

$$p = \frac{ar}{1 - \frac{1}{(1+r)^n}}$$

The amount is calculated as

$$a = \frac{p}{r} \left(1 - \frac{1}{(1+r)^n}\right)$$

Both the payment and amount are rounded to the nearest hundredth (cent) unless the ROUND= specification is different than the default, 2.

The total number of payments n is calculated as

$$n = \frac{-\ln\left(1 - \frac{ar}{p}\right)}{\ln(1+r)}$$

The total number of payments is rounded up to the nearest integer.

The nominal annual rate is calculated using the bisection method, with a as the objective and r starting in the interval between $8 * 10^{-6}$ and 0.1 with an initial midpoint 0.01 and successive midpoints bisecting.

Loan Comparison Details

In order to compare the costs of different alternatives, the input cash flow for the alternatives must be represented in equivalent values. The equivalent value of a cash flow accounts for the time-value of money. That is, it is preferable to pay the same amount of money later than to pay it now, since the money can earn interest while you keep it. The MARR (minimum attractive rate of return) reflects the cost of capital or the opportunity cost of money—that is, the interest that would have been earned on the savings that is foregone by making the investment. The MARR is used to discount the cash flow of alternatives into equivalent values at a fixed point in time. The MARR can vary for each investor and for each investment. Therefore, the MARR= option must be specified in the COMPARE statement if present worth of cost (PWOF COST option) comparison is specified.

Present worth of cost reflects the equivalent amount at loan initialization of the loan cash flow discounted at MARR, not accounting for inflation. Present worth of cost accounts for the down payment, initialization costs, discount points, periodic payments, and the principal balance at the end of the report period. Therefore, it reflects the present worth of cost of the asset, not the loan. It is meaningful to use minimization of present worth of cost as a selection criterion only if the assets (down payment plus loan amount) are of the same value.

Another economic selection criterion is the rate of return (internal rate of return) of the alternatives. If interest is being earned by an alternative, the objective is to maximize the rate of return. If interest is being paid, as in loan alternatives, the best alternative is the one that minimizes the rate of return. The true interest rate reflects the effective annual rate charged on the loan based on the cash flow, including the initialization cost and the discount points.

The effects of taxes on different alternatives must be accounted for when these vary among different alternatives. Since interest costs on certain loans are tax-deductible, the comparisons for those loans are made based on the after-tax cash flows. The cost of the loan is reduced by the tax benefits it offers through the loan life if the TAXRATE= option is specified. The present worth of cost and true interest rate are calculated based on the after-tax cash flow of the loan. The down payment on the loan and initialization costs are assumed to be not tax-deductible in after-tax analysis. Discount points and the interest paid in each periodic payment are assumed to be tax-deductible if the TAXRATE= option is specified. If the TAXRATE= option is not specified, the present worth of cost and the true interest rate are based on before-tax cash flow, assuming that the interest paid on the specified loan does not qualify for tax benefits.

The other two selection criteria are breakeven analysis of periodic payment and interest paid. If the objective is to minimize the periodic payment, the best alternative is the one with the minimum periodic payment. If the objective is to minimize the interest paid on the principal, then the best alternative is the one with the least interest paid.

Another criterion might be the minimization of the outstanding balance of the loan at a particular point in time. For example, if you plan to sell a house before the end of the loan life (which is often the case), you might want to select the loan with the minimum principal balance at the time of the sale, since this balance must be paid at that time. The outstanding balance of the alternative loans is calculated for each loan comparison period by default.

If you specified the START= option in the PROC LOAN statement, the present worth of cost reflects

the equivalent amount for each loan at that point in time. Any loan that has a `START=` specification different from the one in the `PROC LOAN` statement is not processed in the loan comparison.

The loan comparison report for each comparison period contains for each loan the loan label, outstanding balance, and any of the following measures if requested in the `COMPARE` statement: periodic payment (`BREAKPAYMENT` option), total interest paid to date (`BREAKINTEREST` option), present worth of cost (`PWOF COST` option), and true interest rate (`TRUEINTEREST` option). The best loan is selected on the basis of present worth of cost or true interest rate. If both `PWOF COST` and `TRUEINTEREST` options are specified, present worth of cost is the basis for the selection of the best loan.

You can use the `OUTCOMP=` option in the `COMPARE` statement to write the loan comparison report to a data set. The `NOCOMPRINT` option suppresses the printing of a loan comparison report.

OUT= Data Set

The `OUT=` option writes the loan amortization schedule to an output data set. The `OUT=` data set contains one observation for each payment period (or one observation for each year if you specified the `SCHEDULE=YEARLY` option). If you specified the `START=` option, the `DATE` variable denotes the date of the payment. Otherwise, `YEAR` and period variable (`SEMIMONTH`, `MONTH`, `QUARTER`, or `SEMIYEAR`) denote the payment year and period within the year.

The `OUT=` data set contains the following variables:

- `DATE`, date of the payment. `DATE` is included in the `OUT=` data set only when you specify the `START=` option.
- `YEAR`, year of the payment period. `YEAR` is included in the `OUT=` data set only when you do not specify the `START=` option.
- `PERIOD`, period within the year of the payment period. The name of the period variable matches the `INTERVAL=` specification (`SEMIMONTH`, `MONTH`, `QUARTER`, or `SEMIYEAR`.) The `PERIOD` variable is included in the `OUT=` data set only when you do not specify the `START=` option.
- `BEGPRIN`, beginning principal balance
- `PAYMENT`, payment
- `INTEREST`, interest payment
- `PRIN`, principal repayment
- `ENDPRIN`, ending principal balance

OUTCOMP= Data Set

The OUTCOMP= option in the COMPARE statement writes the loan comparison analysis results to an output data set. If you specified the START= option, the DATE variable identifies the date of the loan comparison. Otherwise, the PERIOD variable identifies the comparison period.

The OUTCOMP= data set contains one observation for each loan and for each loan comparison period. The OUTCOMP= data set contains the following variables.

- DATE, date of loan comparison report. The DATE variable is included in the OUTCOMP= data set only when you specify the START= option.
- PERIOD, period of the loan comparison for the observation. The PERIOD variable is included in the OUTCOMP= data set only when you do not specify the START= option.
- LABEL, label string for the loan
- TYPE, type of the loan
- PAYMENT, periodic payment at the time of report. The PAYMENT is included in the OUTCOMP= data set if you specified the BREAKPAYMENT or ALL option or if you used default criteria.
- INTPAY, interest paid through the time of report. The INTPAY variable is included in the OUTCOMP= data set if you specified the BREAKINTEREST or ALL option or if you used default criteria.
- TRUERATE, true interest rate charged on the loan. The TRUERATE variable is included in the OUTCOMP= data set if you specified the TRUERATE or ALL option or if you used default criteria.
- PWOFPCOST, present worth of cost. The PWOFPCOST variable is included in the OUTCOMP= data set only if you specified the PWOFPCOST or ALL option.
- BALANCE, outstanding principal balance at the time of report

OUTSUM= Data Set

The OUTSUM= option writes the loan summary to an output data set. If you specified this option in the PROC LOAN statement, the loan summary information for all loans is written to the specified data set, except for those loans for which you specified a different OUTSUM= data set in the ARM, BALLOON, BUYDOWN, or FIXED statement.

The OUTSUM= data set contains one observation for each loan and contains the following variables:

- TYPE, type of loan

- LABEL, loan label
- PAYMENT, periodic payment
- AMOUNT, loan principal
- DOWNPAY, down payment. DOWNPAY is included in the OUTSUM= data set only when you specify a down payment.
- INITIAL, loan initialization costs. INITIAL is included in the OUTSUM= data set only when you specify initialization costs.
- POINTS, discount points. POINTS is included in the OUTSUM= data set only when you specify discount points.
- TOTAL, total payment
- INTEREST, total interest paid
- RATE, nominal annual interest rate
- EFFRATE, effective interest rate
- INTERVAL, payment interval
- COMPOUND, compounding interval
- LIFE, loan life (that is, the number of payment intervals)
- NCOMPND, number of compounding intervals
- COMPUTE, computed loan parameter: life, amount, payment, or rate

If you specified the START= option either in the PROC LOAN statement or for the individual loan, the OUTSUM= data set also contains the following variables:

- BEGIN, start date
- END, loan termination date

Printed Output

The output from PROC LOAN consists of the loan summary table, loan amortization schedule, and loan comparison report.

Loan Summary Table

The loan summary table shows the total payment and interest, the initial nominal annual and effective interest rates, payment and compounding intervals, the length of the loan in the time units specified, the start and end dates if specified, a list of nominal and effective interest rates, and periodic payments throughout the life of the loan.

A list of balloon payments for balloon payment loans and a list of prepayments if specified are printed with their respective periods or dates.

The loan summary table is printed for each loan by default. The NOSUMMARYPRINT option specified in the PROC LOAN statement suppresses the printing of the loan summary table for all loans. The NOSUMMARYPRINT option can be specified in individual loan statements to selectively suppress the printing of the loan summary table.

Loan Repayment Schedule

The amortization schedule contains for each payment period: the year and period within the year (or date, if you specified the START= option); principal balance at the beginning of the period; total payment, interest payment and principal payment for the period; and the principal balance at the end of the period. If you specified the SCHEDULE=YEARLY option, the amortization contains a summary for each year instead of for each payment period.

The amortization schedule is not printed by default. The SCHEDULE option in the PROC LOAN statement requests the printing of amortization tables for all loans. You can specify the SCHEDULE option in individual loan statements to selectively request the printing of the amortization schedule.

Loan Comparison Report

The loan comparison report is processed for each report period and contains the results of economic analysis of the loans. The quantities reported can include the outstanding principal balance, after-tax or before-tax present worth of cost and true interest rate, periodic payment, and the interest paid through the report period for each loan. The best alternative is identified if the asset value (down payment plus loan amount) is the same for each alternative.

The loan comparison report is printed by default. The NOCOMPRINT option specified in the COMPARE statement suppresses the printing of the loan comparison report.

ODS Table Names

PROC LOAN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 16.2](#).

Table 16.2 ODS Tables Produced in PROC LOAN

ODS Table Name	Description	Option
ODS Tables Created by the PROC LOAN, FIXED, ARM, BALLOON, and BUYDOWN Statements		
Repayment	loan repayment schedule	SCHEDULE
ODS Tables Created by the FIXED, ARM, BALLOON, and BUYDOWN Statements		
LoanSummary	loan summary	default
RateList	rates and payments	default

Examples: LOAN Procedure

Example 16.1: Discount Points for Lower Interest Rates

This example illustrates the comparison of two \$100,000 loans. The major difference between the two loans is that the nominal interest rate in the second loan is lower than the first with the added expense of paying discount points at the time of initialization.

Both alternatives are 30-year loans. The first loan is labeled “8.25% - no discount points” and the second one is labeled “8% - 1 discount point.”

Assume that the interest paid qualifies for a tax deduction and you are in the 33% tax bracket. Also, your minimum attractive rate of return (MARR) for an alternative investment is 4% (adjusted for tax rate).

You use the following statements to find the breakeven point in the life of the loan for your preference between the loans:

```

proc loan start=1992:1 nosummaryprint amount=100000 life=360;
  fixed rate=8.25 label='8.25% - no discount points';
  fixed rate=8 points=1000 label='8% - 1 discount point';
  compare at=(48 54 60) all taxrate=33 marr=4;
run;

```

Output 16.1.1 shows the loan comparison reports as of January 1996 (48th period), July 1996 (54th period), and January 1997 (60th period).

Output 16.1.1 Loan Comparison Reports for Discount Point Breakeven

The LOAN Procedure				
Loan Comparison Report				
Analysis through JAN1996				
Loan Label	Ending Outstanding	Present Worth of Cost	Payment	Interest Paid
8.25% - no discount points	96388.09	105546.17	751.27	32449.05
8% - 1 discount point	96219.32	105604.05	733.76	31439.80
Loan Comparison Report				
Analysis through JAN1996				
Loan Label			True Rate	
8.25% - no discount points			5.67	
8% - 1 discount point			5.69	
NOTE: "8.25% - no discount points" is the best alternative based on present worth of cost analysis through JAN1996.				

Output 16.1.1 continued

Loan Comparison Report				
Analysis through JUL1996				
Loan Label	Ending Outstanding	Present Worth of Cost	Payment	Interest Paid
8.25% - no discount points	95847.27	106164.97	751.27	36415.85
8% - 1 discount point	95656.22	106153.97	733.76	35279.26
Loan Comparison Report				
Analysis through JUL1996				
Loan Label				True Rate
8.25% - no discount points				5.67
8% - 1 discount point				5.67
NOTE: "8% - 1 discount point" is the best alternative based on present worth of cost analysis through JUL1996.				
Loan Comparison Report				
Analysis through JAN1997				
Loan Label	Ending Outstanding	Present Worth of Cost	Payment	Interest Paid
8.25% - no discount points	95283.74	106768.07	751.27	40359.94
8% - 1 discount point	95070.21	106689.80	733.76	39095.81
Loan Comparison Report				
Analysis through JAN1997				
Loan Label				True Rate
8.25% - no discount points				5.67
8% - 1 discount point				5.66
NOTE: "8% - 1 discount point" is the best alternative based on present worth of cost analysis through JAN1997.				

Notice that the breakeven point for present worth of cost and true rate both happen on July 1996. This indicates that if you intend to keep the loan for 4.5 years or more, it is better to pay the discount points for the lower rate. If your objective is to minimize the interest paid or the periodic payment, the "8% - 1 discount point" loan is the preferred choice.

Example 16.2: Refinancing a Loan

Assume that you obtained a fixed rate 15-year loan in June 1995 for \$78,500 with a nominal annual rate of 9%. By early 1998, the market offers a 6.5% interest rate, and you are considering whether to refinance your loan.

Use the following statements to find out the status of the loan on February 1998. [Output 16.2.1](#) shows the results:

```
proc loan start=1995:6;
  fixed life=180 rate=9 amount=78500 noprint
    label='Original Loan';
  compare at=('10FEB1998'd);
run;
```

Output 16.2.1 Loan Comparison Report for Original Loan

The LOAN Procedure				
Loan Comparison Report				
Analysis through FEB1998				
Loan Label	Ending Outstanding	Payment	Interest Paid	True Rate
Original Loan	71028.75	796.20	18007.15	9.38

The monthly payment on the original loan is \$796.20. The ending outstanding principal balance as of February is \$71,028.75. At this point, you might want to refinance your loan with another 15-year loan. The alternate loan has a 6.5% nominal annual rate. The initialization costs are \$1,419.00. Use the following statements to compare your alternatives:

```
proc loan start=1998:2 amount=71028.75;
  fixed rate=9 payment=796.20
    label='Keep the original loan' noprint;
  fixed life=180 rate=6.5 init=1419
    label='Refinance at 6.5%' noprint;
  compare at=(15 16) taxrate=33 marr=4 all;
run;
```

The comparison reports of May 1999 and June 1999 in [Output 16.2.2](#) illustrate the break even between the two alternatives. If you intend to keep the loan through June 1999 or longer, your initialization costs for the refinancing are justified. The periodic payment of the refinanced loan is \$618.74.

Output 16.2.2 Loan Comparison Report for Refinancing Decision

The LOAN Procedure				
Loan Comparison Report				
Analysis through MAY1999				
Loan Label	Ending Outstanding	Present Worth of Cost	Payment	Interest Paid
Keep the original loan	66862.10	72737.27	796.20	7776.35

NOTE: "Refinance at 6.5%" is the best alternative based on present worth of cost analysis through JUN1999.				

Example 16.3: Prepayments on a Loan

This example compares a 30-year loan with and without prepayments. Assume the \$240,000 30-year loan has an 8.25% nominal annual rate. Use the following statements to see the effect of making uniform prepayments of \$500 with periodic payment:

```
proc loan start=1992:12 rate=8.25 amount=240000 life=360;
  fixed label='No prepayments';
  fixed label='With Prepayments' prepay=500;
  compare at=(120) taxrate=33 marr=4 all;
run;
```

Output 16.3.1 Loan Summary Reports without Prepayments

The LOAN Procedure

Loan Comparison Report

Analysis through DEC2002

Loan Label          True Rate
No prepayments      5.67
With Prepayments    5.67

NOTE: "With Prepayments" is the best alternative based on present worth of cost
analysis through DEC2002.
    
```

Output 16.3.1 through Output 16.3.3 illustrate the Loan Summary Reports and the Loan Comparison report. Notice that with prepayments you pay off the loan in slightly more than 15 years. Also, the total payments and total interest are considerably lower with the prepayments. If you can afford the prepayments of \$500 each month, another alternative you should consider is using a 15-year loan, which is generally offered at a lower nominal interest rate.

Example 16.4: Output Data Sets

This example shows the analysis and comparison of five alternative loans. Initialization cost, discount points, and both lump sum and periodic payments are included in the specification of these loans. Although no printed output is produced, the loan summary and loan comparison information is stored in the OUTSUM= and OUTCOMP= data sets.

```
proc loan start=1998:12 noprint outsum=loans

Example 16.5: Piggyback Loans

The *piggyback* loan is becoming a widely available alternative. Borrowers like to avoid the PMI (private mortgage insurance) required with loans where the borrower has a down payment of less than 20% of the price. The piggyback allows a secondary home equity loan to be packaged with a primary loan with less than 20% down payment. The secondary loan usually has a shorter life and higher interest rate. The interest paid on both loans are tax-deductible whereas PMI does not qualify for a tax deduction.

The following example compares a conventional fixed rate loan with 20% down as opposed to a piggyback loan: one primary fixed rate with 10% down payment and a secondary, home equity loan for 10% of the original price. All loans have monthly payments.

The conventional loan alternative is a 30-year loan with a fixed annual rate of 7.5%. The primary loan in the piggyback loan setup is also a 30-year loan with a fixed annual rate of 7.75%. The secondary loan is a 15-year loan with a fixed annual interest rate of 8.25%.

The comparison output for the two loans comprising the piggyback loan is aggregated using the TIMESERIES procedure with a minimum of specified options:

- The INTERVAL= option requests that the data be aggregated into periods of length 5 years beginning on the 25th month, resulting in appropriately identified periods.
- The ACC=TOTAL option specifies that the output should reflect accumulated totals as opposed to, say, averages.
- The NOTSORTED option indicates that the input data set has not been sorted by the ID variable.

See Chapter 27, “[The TIMESERIES Procedure](#),” for more information about this procedure.

Use the following statements to analyze the conventional loan, as well as the piggyback alternative, and compare them on the basis of their present worth of cost, outstanding balance, and interest payment amounts at the end of 5, 10, and 15 years into the loan life.

```

title1 'LOAN: Piggyback loan example';

title2 'LOAN: Conventional loan';

proc loan start=2002:1 noprint;

    fixed price=200000 dp=40000 rate=7.5 life=360
          label='20 percent down: Conventional Fixed Rate' ;

    compare at=(60 120 180) pwofcost taxrate=30 marr=12
           breakpay breakint outcomp=comploans;

run;

title2 'LOAN: Piggyback: Primary Loan';

```

```

proc loan start=2002:1 noprint;

    fixed amount=160000 dp=20000 rate=7.75 life=360
        label='Piggyback: Primary loan' out=loan1;

    compare at=(60 120 180 ) pwofcost taxrate=30 marr=12
        breakpay breakint outcomp=cloan1;

Overview: MDC Procedure

The MDC (multinomial discrete choice) procedure analyzes models where the choice set consists of multiple alternatives. This procedure supports conditional logit, mixed logit, heteroscedastic extreme value, nested logit, and multinomial probit models. The MDC procedure uses the maximum likelihood (ML) or simulated maximum likelihood method for model estimation. The term *multinomial logit* is often used in the econometrics literature to refer to the *conditional logit* model of McFadden (1974). Here, the term *conditional logit* refers to McFadden's conditional logit model, and the term *multinomial logit* refers to a model that differs slightly. Schmidt and Strauss (1975) and Theil (1969) are early applications of the multinomial logit model in the econometrics literature. The main difference between McFadden's conditional logit model and the multinomial logit model is that the multinomial logit model makes the choice probabilities depend on the characteristics of the individuals only, whereas the conditional logit model considers the effects of choice attributes on choice probabilities as well.

Unordered multiple choices are observed in many settings in different areas of application. For example, choices of housing location, occupation, political party affiliation, type of automobile, and mode of transportation are all unordered multiple choices. Economics and psychology models often explain observed choices by using the *random utility* function. The utility of a specific choice can be interpreted as the relative pleasure or happiness that the decision maker derives from that choice with respect to other alternatives in a finite choice set. It is assumed that the individual chooses the alternative for which the associated utility is highest. However, the utilities are not known to the analyst with certainty and are therefore treated by the analyst as random variables. When the utility function contains a random component, the individual choice behavior becomes a probabilistic process.

The random utility function of individual i for choice j can be decomposed into deterministic and stochastic components:

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where V_{ij} is a deterministic utility function, assumed to be linear in the explanatory variables, and ϵ_{ij} is an unobserved random variable that captures the factors that affect utility that are not included in V_{ij} . Different assumptions on the distribution of the errors, ϵ_{ij} , give rise to different classes of models.

The features of discrete choice models available in the MDC procedure are summarized in [Table 17.1](#).

Table 17.1 Summary of Models Supported by PROC MDC

Model Type	Utility Function	Distribution of ϵ_{ij}
Conditional Logit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	IEV independent and identical
HEV	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	HEV independent and nonidentical
Nested Logit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	GEV correlated and identical
Mixed Logit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \xi_{ij} + \epsilon_{ij}$	IEV independent and identical
Multinomial Probit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	MVN correlated and nonidentical

IEV stands for type I extreme-value (or Gumbel) distribution with the probability density function and the cumulative distribution function of the random error given by $f(\epsilon_{ij}) = \exp(-\epsilon_{ij}) \exp(-\exp(-\epsilon_{ij}))$ and $F(\epsilon_{ij}) = \exp(-\exp(-\epsilon_{ij}))$; HEV stands for heteroscedastic extreme-value distribution with the probability density function and the cumulative distribution function of the random error given by $f(\epsilon_{ij}) = \frac{1}{\theta_j} \exp(\frac{\epsilon_{ij}}{\theta_j}) \exp[-\exp(-\frac{\epsilon_{ij}}{\theta_j})]$ and $F(\epsilon_{ij}) = \exp[-\exp(-\frac{\epsilon_{ij}}{\theta_j})]$, where θ_j is a scale parameter for the random component of the j th alternative; GEV stands for generalized extreme-value distribution; MVN represents multivariate normal distribution; and ξ_{ij} is an error component. See the “[Mixed Logit Model](#)” on page 907 section for more information about ξ_{ij} .

Getting Started: MDC Procedure

Conditional Logit: Estimation and Prediction

The MDC procedure is similar in use to the other regression model procedures in the SAS System. However, the MDC procedure requires identification and choice variables. For example, consider a random utility function

$$U_{ij} = x_{1,ij}\beta_1 + x_{2,ij}\beta_2 + \epsilon_{ij} \quad j = 1, \dots, 3$$

where the cumulative distribution function of the stochastic component is type I extreme value, $F(\epsilon_{ij}) = \exp(-\exp(-\epsilon_{ij}))$. You can estimate this conditional logit model with the following statements:

```
proc mdc;
  model decision = x1 x2 / type=clogit
    choice=(mode 1 2 3);
```

```

    id pid;
run;

```

Note that the MDC procedure, unlike other regression procedures, does not include the intercept term automatically. The dependent variable `decision` takes the value 1 when a specific alternative is chosen; otherwise it takes the value 0. Each individual is allowed to choose one and only one of the possible alternatives. In other words, the variable `decision` takes the value 1 one time only for each individual. If each individual has three elements (1, 2, and 3) in the choice set, the `NCHOICE=3` option can be specified instead of `CHOICE=(mode 1 2 3)`.

Consider the following trinomial data from Daganzo (1979). The original data (`origdata`) contain travel time (`ttime1-ttime3`) and choice (`choice`) variables. `ttime1-ttime3` are the travel times for three different modes of transportation, and `choice` indicates which one of the three modes is chosen. The choice variable must have integer values.

```

data origdata;
  input ttime1 ttime2 ttime3 choice @@;
datalines;
16.481 16.196 23.89 2 15.123 11.373 14.182 2
19.469 8.822 20.819 2 18.847 15.649 21.28 2
12.578 10.671 18.335 2 11.513 20.582 27.838 1
... more lines ...

```

A new data set (`newdata`) is created since PROC MDC requires that each individual decision maker has one case for each alternative in his choice set. Note that the ID statement is required for all MDC models. In the following example, there are two public transportation modes, 1 and 2, and one private transportation mode, 3, and all individuals share the same choice set.

The first nine observations of the raw data set are shown in [Figure 17.1](#).

Figure 17.1 Initial Choice Data

Obs	ttime1	ttime2	ttime3	choice
1	16.481	16.196	23.890	2
2	15.123	11.373	14.182	2
3	19.469	8.822	20.819	2
4	18.847	15.649	21.280	2
5	12.578	10.671	18.335	2
6	11.513	20.582	27.838	1
7	10.651	15.537	17.418	1
8	8.359	15.675	21.050	1
9	11.679	12.668	23.104	1

The following statements transform the data according to MDC procedure requirements.

```

data newdata(keep=pid decision mode ttime);
  set origdata;
  array tvec{3} ttime1 - ttime3;

```

```

retain pid 0;
pid + 1;
do i = 1 to 3;
  mode = i;
  ttime = tvec{i};
  decision = ( choice = i );
  output;
end;
run;

```

The first nine observations of the transformed data set are shown in [Figure 17.2](#).

Figure 17.2 Transformed Modal Choice Data

Obs	pid	mode	ttime	decision
1	1	1	16.481	0
2	1	2	16.196	1
3	1	3	23.890	0
4	2	1	15.123	0
5	2	2	11.373	1
6	2	3	14.182	0
7	3	1	19.469	0
8	3	2	8.822	1
9	3	3	20.819	0

The decision variable, decision, must have one nonzero value for each decision maker corresponding to the actual choice. When the RANK option is specified, the decision variable must contain rank data. For more details, see the section “[MODEL Statement](#)” on page 892. The following SAS statements estimate the conditional logit model by using maximum likelihood:

```

proc mdc data=newdata;
  model decision = ttime /
    type=clogit
    nchoice=3
    optmethod=qn
    covest=hess;
  id pid;
run;

```

The MDC procedure enables different individuals to face different choice sets. When all individuals have the same choice set, the NCHOICE= option can be used instead of the CHOICE= option. However, the NCHOICE= option is not allowed when a nested logit model is estimated. When the NCHOICE=*number* option is specified, the choices are generated as 1, . . . , *number*. For more flexible alternatives (e.g., 1 3 6 8), you need to use the CHOICE= option. The choice variable must have integer values.

The OPTMETHOD=QN option specifies the quasi-Newton optimization technique. The covariance matrix of the parameter estimates is obtained from the Hessian matrix since COVEST=HESS is specified. You can also specify COVEST=OP or COVEST=QML. See the section “[MODEL Statement](#)” on page 892 for more details.

The MDC procedure produces a summary of model estimation displayed in [Figure 17.3](#). Since there are multiple observations for each individual, the “Number of Cases” (150)—that is, the total number of choices faced by all individuals—is larger than the number of individuals, “Number of Observations” (50). [Figure 17.4](#) shows the frequency distribution of the three choice alternatives. In this example, mode 2 is most frequently chosen.

Figure 17.3 Estimation Summary Table

The MDC Procedure

2	3	7	14.00

The MDC procedure computes nine goodness-of-fit measures for the discrete choice model. Seven of them are pseudo- R^2 measures based on the null hypothesis that all coefficients except for an intercept term are zero ([Figure 17.5](#)). McFadden’s likelihood ratio index (LRI) is the smallest in value. For more details see the section “[Model Fit and Goodness-of-Fit Statistics](#)” on page 915.

Figure 17.5 Likelihood Ratio Test and R² Measures

Goodness-of-Fit Measures		
Measure	Value	Formula
Likelihood Ratio (R)	43.219	$2 * (\text{LogL} - \text{LogL0})$
Upper Bound of R (U)	109.86	$- 2 * \text{LogL0}$
Aldrich-Nelson	0.4636	$R / (R+N)$
Cragg-Uhler 1	0.5787	$1 - \exp(-R/N)$
Cragg-Uhler 2	0.651	$(1 - \exp(-R/N)) / (1 - \exp(-U/N))$
Estrella	0.6666	$1 - (1 - R/U)^{(U/N)}$
Adjusted Estrella	0.6442	$1 - ((\text{LogL} - K) / \text{LogL0})^{(-2/N * \text{LogL0})}$
McFadden's LRI	0.3934	R / U
Veall-Zimmermann	0.6746	$(R * (U+N)) / (U * (R+N))$

N = # of observations, K = # of regressors

Finally, the parameter estimate is displayed in [Figure 17.6](#).

Figure 17.6 Parameter Estimate of Conditional Logit

The MDC Procedure					
Conditional Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime	1	-0.3572	0.0776	-4.60	<.0001

The predicted choice probabilities are produced using the OUTPUT statement:

```
output out=probdata pred=p;
```

The parameter estimates can be used to forecast the choice probability of individuals that are not in the input data set. To do so, you need to append to the input data set extra observations whose values of the dependent variable decision are missing, since these extra observations are not supposed to be used in the estimation stage. The identification variable pid must have values that are not used in the existing observations. The output data set, probdata, contains a new variable, p, in addition to input variables in the data set, extdata.

The following statements forecast the choice probability of individuals that are not in the input data set.

```
data extra;
  input pid mode decision ttime;
datalines;
51 1 . 5.0
```

```

51 2 . 15.0
51 3 . 14.0
;

data extdata;
  set newdata extra;
run;

proc mdc data=extdata;
  model decision = ttime /
        type=clogit
        covest=hess
        nchoice=3;

  id pid;
  output out=probdata pred=p;
run;

proc print data=probdata( where=( pid >= 49 ) );
  var mode decision p ttime;
  id pid;
run;

```

The last nine observations from the forecast data set (probdata) are displayed in [Figure 17.7](#). It is expected that the decision maker will choose mode “1” based on predicted probabilities for all modes.

51	3	.	0.03759	14.000

Nested Logit Modeling

A more general model can be specified using the nested logit model.

Consider, for example, the following random utility function:

$$U_{ij} = x_{ij}\beta + \epsilon_{ij} \quad j = 1, \dots, 3$$

Suppose the set of all alternatives indexed by j is partitioned into K nests, B_1, \dots, B_K . The nested logit model is obtained by assuming that the error term in the utility function has the GEV

cumulative distribution function:

$$\exp \left(- \sum_{k=1}^K \left(\sum_{j \in B_k} \exp \{ -\epsilon_{ij} / \lambda_k \} \right)^{\lambda_k} \right)$$

where λ_k is a measure of a degree of independence among the alternatives in nest k . When $\lambda_k = 1$ for all k , the model reduces to the standard logit model.

Since the public transportation modes, 1 and 2, tend to be correlated, these two choices can be grouped together. The decision tree displayed in Figure 17.8 is constructed.

Figure 17.8 Decision Tree for Model Choice

The two-level decision tree is specified in the NEST statement. The NCHOICE= option is not allowed for nested logit estimation. Instead, the CHOICE= option needs to be specified, as in the following statements:

```

/*-- nested logit estimation ---*/
proc mdc data=newdata;
  model decision = ttime /
    type=nlogit
    choice=(mode 1 2 3)
    covest=hess;
  id pid;
  utility u(1,) = ttime;
  nest level(1) = (1 2 @ 1, 3 @ 2),
    level(2) = (1 2 @ 1);
run;

```

In Figure 17.9, estimates of the inclusive value parameters, INC_L2G1C1 and INC_L2G1C2, are indicative of a nested model structure. See the section “Nested Logit” on page 910 and the section “Decision Tree and Nested Logit” on page 912 for more details on inclusive values.

Figure 17.9 Two-Level Nested Logit Estimates

The MDC Procedure					
Nested Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime_L1	1	-0.4040	0.1241	-3.25	0.0011
INC_L2G1C1	1	0.8016	0.4352	1.84	0.0655
INC_L2G1C2	1	0.8087	0.3591	2.25	0.0243

The nested logit model is estimated with the restriction $INC_L2G1C1 = INC_L2G1C2$ by specifying the `SAMESCALE` option, as in the following statements. The estimation result is displayed in Figure 17.10.

```

/*-- nlogit with samescale option --*/
proc mdc data=newdata;
  model decision = ttime /
    type=nlogit
    choice=(mode 1 2 3)
    samescale
    covest=hess;
  id pid;
  utility u(1,) = ttime;
  nest level(1) = (1 2 @ 1, 3 @ 2),
    level(2) = (1 2 @ 1);
run;

```

Figure 17.10 Nested Logit Estimates with One Dissimilarity Parameter

The MDC Procedure					
Nested Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime_L1	1	-0.4025	0.1217	-3.31	0.0009
INC_L2G1	1	0.8209	0.3019	2.72	0.0066

The nested logit model is equivalent to the conditional logit model if $INC_L2G1C1 = INC_L2G1C2 = 1$. You can verify this relationship by estimating a constrained nested logit model. (See the section “[RESTRICT Statement](#)” on page 901 for details on imposing linear restrictions on parameter estimates.) The parameter estimates and the active linear constraints for the following constrained nested logit model are displayed in Figure 17.11.

```

/*-- constrained nested logit estimation --*/
proc mdc data=newdata;
  model decision = ttime /
    type=nlogit
    choice=(mode 1 2 3)
    covest=hess;
  id pid;
  utility u(1,) = ttime;
  nest level(1) = (1 2 @ 1, 3 @ 2),
    level(2) = (1 2 @ 1);
  restrict INC_L2G1C1 = 1, INC_L2G1C2 =1;
run;

```

Multivariate Normal Utility Function

Consider the following random utility function:

$$U_{ij} = \text{time}_{ij}\beta + \epsilon_{ij}, \quad j = 1, 2, 3$$

where

$$\begin{bmatrix} \epsilon_{i1} \\ \epsilon_{i2} \\ \epsilon_{i3} \end{bmatrix} \sim N \left(\mathbf{0}, \begin{bmatrix} 1 & \rho_{21} & 0 \\ \rho_{21} & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right)$$

The correlation coefficient (ρ_{21}) between U_{i1} and U_{i2} represents common neglected attributes of public transportation modes, 1 and 2. The following SAS statements estimate this trinomial probit model:

```

/*-- homoscedastic mprobit --*/
proc mdc data=newdata;
  model decision = ttime /
    type=mprobit
    nchoice=3
    unitvariance=(1 2 3)
    covest=hess;
  id pid;
run;

```

The UNITVARIANCE=(1 2 3) option specifies that the random component of utility for each of these choices have unit variance. If the UNITVARIANCE= option is specified, it needs to include at least two choices. The results of this constrained multinomial probit model estimation are displayed in [Figure 17.12](#) and [Figure 17.13](#). The test for $\text{time} = 0$ is rejected at the 1% significance level.

HEV and Multinomial Probit: Heteroscedastic Utility Function

When the stochastic components of utility are heteroscedastic and independent, you can model the data by using an HEV or a multinomial probit model. The HEV model assumes that the utility of alternative j for each individual i has heteroscedastic random components,

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where the cumulative distribution function of the Gumbel distributed ϵ_{ij} is

$$F(\epsilon_{ij}) = \exp(-\exp(-\epsilon_{ij}/\theta_j))$$

Note that the variance of ϵ_{ij} is $\frac{1}{6}\pi^2\theta_j^2$. Therefore, the error variance is proportional to the square of the scale parameter θ_j . For model identification, at least one of the scale parameters must be normalized to 1. The following SAS statements estimate an HEV model under a unit scale restriction for mode “1” ($\theta_1 = 1$). The results of computation are presented in [Output 17.14](#) and [Output 17.15](#).

```

/*-- hev with gauss-laguerre method --*/
proc mdc data=newdata;
  model decision = ttime /
    type=hev
    nchoice=3
    hev=(unitscale=1, integrate=laguerre)
    covest=hess;
  id pid;
run;

```

Maximum Absolute Gradient	0.0000218
Number of Iterations	11
Optimization Method	Dual Quasi-Newton
AIC	72.82765
Schwarz Criterion	78.56372

Figure 17.15 HEV Parameter Estimates

The MDC Procedure					
Heteroscedastic Extreme Value Model Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime	1	-0.4407	0.1798	-2.45	0.0143
SCALE2	1	0.7765	0.4348	1.79	0.0741
SCALE3	1	0.5753	0.2752	2.09	0.0366

The parameters SCALE2 and SCALE3 in the output correspond to the estimates of the scale parameters θ_2 and θ_3 , respectively.

Note that the estimate of the HEV model is not always stable since computation of the log-likelihood function requires numerical integration. Bhat (1995) proposed the Gauss-Laguerre method. In general, the log-likelihood function value of HEV should be larger than that of conditional logit since HEV models include the conditional logit as a special case, but in this example the reverse is true (-33.414 for the HEV model, which is less than -33.321 for the conditional logit model). (See Figure 17.14 and Figure 17.3.) This indicates that the Gauss-Laguerre approximation to the true probability is too coarse. You can see how well the Gauss-Laguerre method works by specifying a unit scale restriction for all modes, as in the following statements, since the HEV model with the unit variance for all modes reduces to the conditional logit model:

```

/*-- hev with gauss-laguerre and unit scale --*/
proc mdc data=newdata;
  model decision = ttime /
    type=hev
    nchoice=3

```

```

      hev=(unitscale=1 2 3, integrate=laguerre)
      covest=hess;
    id pid;
  run;

```

Figure 17.16 shows that the time coefficient is not close to that of the conditional logit model.

Figure 17.16 HEV Estimates with All Unit Scale Parameters

The MDC Procedure					
Heteroscedastic Extreme Value Model Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime	1	-0.2926	0.0438	-6.68	<.0001

There is another option of specifying the integration method. The INTEGRATE=HARDY option uses the adaptive Romberg-type integration method. The adaptive integration produces much more accurate probability and log-likelihood function values, but often it is not practical to use this method of analyzing the HEV model since it requires excessive CPU time. The following SAS statements produce the HEV estimates by using the adaptive Romberg-type integration method. The results are displayed in Figure 17.17 and Figure 17.18.

```

/*-- hev with adaptive integration --*/
proc mdc data=newdata;
  model decision = ttime /
    type=hev
    nchoice=3
    hev=(unitscale=1, integrate=hardy)
    covest=hess;
  id pid;
run;

```

Figure 17.17 HEV Estimation Summary Using Alternative Integration Method

The MDC Procedure

Model Fit Summary	
Dependent Variable	decision
Number of Observations	50
Number of Cases	150
Log Likelihood	-33.02598
Maximum Absolute Gradient	0.0001202
Number of Iterations	8
Optimization Method	Dual Quasi-Newton
AIC	72.05197
Schwarz Criterion	77.78803

Figure 17.18 HEV Estimates Using Alternative Integration Method

The MDC Procedure					
Heteroscedastic Extreme Value Model Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime	1	-0.4580	0.1861	-2.46	0.0139
SCALE2	1	0.7757	0.4283	1.81	0.0701
SCALE3	1	0.6908	0.3384	2.04	0.0412

With the INTEGRATE=HARDY option, the log-likelihood function value of the HEV model, -33.026, is greater than that of the conditional logit model, -33.321. (See [Figure 17.17](#) and [Figure 17.3](#).)

When you impose unit scale restrictions on all choices, as in the following statements, the HEV model gives the same estimates as the conditional logit model. (See [Figure 17.19](#) and [Figure 17.6](#).)

```

/*-- hev with adaptive integration and unit scale --*/
proc mdc data=newdata;
  model decision = ttime /
    type=hev
    nchoice=3
    hev=(unitscale=1 2 3, integrate=hardy)
    covest=hess;
  id pid;
run;

```

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime	1	-0.3572	0.0776	-4.60	<.0001

For comparison, we estimate a heteroscedastic multinomial probit model by imposing a zero restriction on the correlation parameter, $\rho_{31} = 0$. The MDC procedure requires normalization of at least two of the error variances in the multinomial probit model. Also, for identification, the correlation parameters associated with a unit normalized variance are restricted to be zero. When the UNITVARIANCE= option is specified, the zero restriction on correlation coefficients applies to the last choice of the list. In the following statements, the variances of the first and second choices are normalized. The UNITVARIANCE=(1 2) option imposes additional restrictions that $\rho_{32} = \rho_{21} = 0$. The default for the UNITVARIANCE= option is the last two choices (which would have been equivalent to UNITVARIANCE=(2 3) for this example). The result is presented in Figure 17.20.

The utility function can be defined as

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where

$$\epsilon_i \sim N \left(\mathbf{0}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \sigma_3^2 \end{bmatrix} \right)$$

```

/*-- mprobit estimation --*/
proc mdc data=newdata;
  model decision = ttime /
    type=mprobit
    nchoice=3
    unitvariance=(1 2)
    covest=hess;

  id pid;
  restrict RHO_31 = 0;
run;

```

Figure 17.20 Heteroscedastic Multinomial Probit Estimates

ttime	
STD_3	
RHO_31	
Restrict1	Linear EC [1]

* Probability computed using beta distribution.

Note that in the output the estimates of standard errors and correlations are denoted by STD_i and RHO_{ij} , respectively. In this particular case the first two variances (STD_1 , STD_2) are normalized to one, and corresponding correlations (RHO_{21} , RHO_{32}) are set to zero, so they are not listed among parameter estimates.

Parameter Heterogeneity: Mixed Logit

One way of modeling unobserved heterogeneity across individuals in their sensitivity to observed exogenous variables is to use the mixed logit model with a random parameters or random coefficients specification. The probability of choosing alternative j is written as

$$P_i(j) = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})}{\sum_{k=1}^J \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}$$

where $\boldsymbol{\beta}$ is a vector of coefficients that varies across individuals, and \mathbf{x}_{ij} is a vector of exogenous attributes.

For example, you can specify the distribution of the parameter $\boldsymbol{\beta}$ to be the normal distribution.

The mixed logit model uses a Monte Carlo simulation method to estimate the probabilities of choice. There are two simulation methods available. When the `RANDNUM=PSEUDO` option is given in the `MODEL` statement, pseudo-random numbers are generated, while the `RANDNUM=HALTON` option uses Halton quasi-random sequences. The default value is `RANDNUM=HALTON`.

You can estimate the model with normally distributed random coefficients of *ttime* with the following SAS statements:

```

/*-- mixed logit estimation --*/
proc mdc data=newdata type=mixedlogit;
  model decision = ttime /
        nchoice=3
        mixed=(normalparm=ttime);
  id pid;
run;

```

Let β^m and β^s be mean and scale parameters, respectively, for the random coefficient, β . The relevant utility function is

$$U_{ij} = \text{ttime}_{ij} \beta + \epsilon_{ij}$$

where $\beta = \beta^m + \beta^s \eta$; β^m and β^s are fixed mean and scale parameters, respectively. The stochastic component, η , is assumed to be standard normal since the NORMALPARM= option is given. Alternatively, the UNIFORMPARM= or LOGNORMALPARM= option can be specified. The LOGNORMALPARM= option is useful when nonnegative parameters are being estimated. The NORMALPARM=, UNIFORMPARM=, and LOGNORMALPARM= variables must be included on the right-hand side of the MODEL statement. See the section “Mixed Logit Model” on page 907 for more details. To estimate a mixed logit model by using the transportation mode choice data, the MDC procedure requires the MIXED= option for random components. Results of the mixed logit estimation are displayed in [Figure 17.21](#).

Figure 17.21 Mixed Logit Model Parameter Estimates

The MDC Procedure					
Mixed Multinomial Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
ttime_M	1	-0.5342	0.2184	-2.45	0.0144
ttime_S	1	0.2843	0.1911	1.49	0.1368

Note that the parameter *ttime_M* corresponds to the constant mean parameter β^m and the parameter *ttime_S* corresponds to the constant scale parameter β^s of the random coefficient β .

Syntax: MDC Procedure

The MDC procedure is controlled by the following statements:

```

PROC MDC options ;
  MDCDATA options ;
  BOUNDS bound1 < , bound2 ... > ;
  BY variables ;
  ID variable ;
  MODEL dependent variables = regressors / options ;
  NEST LEVEL(value) = ((values)@(value),..., (values)@(value)) ;
  NLOPTIONS options ;
  OUTPUT options ;
  RESTRICT restriction1 < , restriction2 ... > ;
  UTILITY U() = variables, ..., U() = variables ;

```

Functional Summary

The statements and options used with the MDC procedure are summarized in the following table:

Table 17.2 MDC Functional Summary

Description	Statement	Option
Data Set Options		
formats the data for use by PROC MDC	MDCDATA	
specify the input data set	MDC	DATA=
write parameter estimates to an output data set	MDC	OUTEST=
include covariances in the OUTEST= data set	MDC	COVOUT
write linear predictors and predicted probabilities to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify the ID variable	ID	
specify BY-group processing variables	BY	
Printing Control Options		
request all printing options	MODEL	ALL
display correlation matrix of the estimates	MODEL	CORRB
display covariance matrix of the estimates	MODEL	COVB
display detailed information about optimization iterations	MODEL	ITPRINT
suppress all displayed output	MODEL	NOPRINT
Model Estimation Options		
specify the choice variables	MODEL	CHOICE=()
specify the convergence criterion	MODEL	CONVERGE=
specify the type of covariance matrix	MODEL	COVEST=
specify the starting point of the Halton sequence	MODEL	HALTONSTART=
specify options specific to the HEV model	MODEL	HEV=()
set the initial values of parameters used by the iterative optimization algorithm	MODEL	INITIAL=()

Description	Statement	Option
specify the maximum number of iterations	MODEL	MAXITER=
specify the options specific to mixed logit	MODEL	MIXED=()
specify the number of choices for each person	MODEL	NCHOICE=
specify the number of simulations	MODEL	NSIMUL=
specify the optimization technique	MODEL	OPTMETHOD=
specify the type of random number generators	MODEL	RANDNUM=
specify that initial values are generated using random numbers	MODEL	RANDINIT
specify the rank dependent variable	MODEL	RANK
specify optimization restart options	MODEL	RESTART=()
specify a restriction on inclusive parameters	MODEL	SAMESCALE
specify a seed for pseudo-random number generation	MODEL	SEED=
specify a stated preference data restriction on inclusive parameters	MODEL	SPSCALE
specify the type of the model	MODEL	TYPE=
specify normalization restrictions on multinomial probit error variances	MODEL	UNITVARIANCE=()
Controlling the Optimization Process		
specify upper and lower bounds for the parameter estimates	BOUNDS	
specify linear restrictions on the parameter estimates	RESTRICT	
specify nonlinear optimization options	NLOPTIONS	
NESTED Logit Related Options		
specify the tree structure	NEST	LEVEL()=
specify the type of utility function	UTILITY	U()=
Output Control Options		
output predicted probabilities	OUTPUT	P=
output estimated linear predictor	OUTPUT	XBETA=

PROC MDC Statement

PROC MDC *options* ;

The following options can be used in the PROC MDC statement.

DATA=SAS-data-set

specifies the input SAS data set. If the DATA= option is not specified, PROC MDC uses the most recently created SAS data set.

OUTEST=SAS-data-set

names the SAS data set that the parameter estimates are written to. See “OUTEST= Data Set” later in this chapter for information about the contents of this data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

In addition, any of the following MODEL statement options can be specified in the PROC MDC statement, which is equivalent to specifying the option for the MODEL statement: ALL, CONVERGE=, CORRB, COVB, COVEST=, HALTONSTART=, ITPRINT, MAXITER=, NOPRINT, NSIMUL=, OPTMETHOD=, RANDINIT, RANK, RESTART=, SAMESCALE, SEED=, SPSCALE, TYPE=, and UNITVARIANCE=.

MDCDATA Statement

MDCDATA *options* < / OUT= SAS-data-set > ;

The MDCDATA statement prepares data for use by PROC MDC when the choice-specific information is stored in multiple variables (see [Output 17.1](#)).

VARLIST (**name1** = (var1 var2 ...) **name2** = (var1 var2 ...) ...)

creates *name* variables from a multiple variable list of choice alternatives in parentheses. The choice-specific dummy variables are created for the first set of multiple variables. At least one set of multiple variables must be specified.

SELECT=(*variable*)

specifies a variable that contains choices for each individual.

ID=(*name*)

creates a variable that identifies each individual.

ALT=(*name*)

identifies selection alternatives for each individual.

DECVAR=(*name*)

creates a 0-1 variable indicating the choice made for each individual.

OUT=SAS-data-set

specifies a SAS data set where modified data are outputted.

BOUNDS Statement

BOUNDS *bound1* < , *bound2* ... > ;

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the MDC procedure. You can specify any number of BOUNDS statements.

Each *bound* is composed of parameters, constants, and inequality operators:

item operator item < operator item < operator item ... > >

Each *item* is a constant, parameter, or list of parameters. Parameters associated with a regressor variable are referred to by the name of the corresponding regressor variable. Each *operator* is '<', '>', '<=', or '>='.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the section “[RESTRICT Statement](#)” on page 901 as well.

Lagrange multipliers are reported for all the active boundary constraints. In the displayed output, the Lagrange multiplier estimates are identified with the names Restrict1, Restrict2, and so forth. The probability of the Lagrange multipliers is computed using a beta distribution (LaMotte 1994). Nonactive, or nonbinding, bounds have no effect on the estimation results and are not noted in the output.

The following BOUNDS statement constrains the estimates of the coefficient of *time* to be negative and the coefficients of *x1* through *x10* to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds ttime < 0,
       0 < x1-x10 < 1;
```

BY Statement

BY *variables* ;

A BY statement can be used with PROC MDC to obtain separate analyses on observations in groups defined by the BY variables.

ID Statement

ID *variable* ;

The ID statement must be used with PROC MDC to specify the identification variable that controls multiple choice-specific cases. The MDC procedure requires only one ID statement even with multiple MODEL statements.

MODEL Statement

MODEL *dependent = regressors < / options > ;*

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. When the nested logit model is estimated, regressors in the UTILITY statement are used for estimation.

The following options can be used in the MODEL statement after a slash (/).

CHOICE=(*variables*)

CHOICE=(*variable numbers*)

specifies the variables that contain possible choices for each individual. Choice variables must have integer values. Multiple choice variables are allowed only for nested logit models. If all possible alternatives are written with the variable name, the MDC procedure checks all values of the choice variable. The CHOICE=(X 1 2 3) specification implies that the value of X should be 1, 2, or 3. On the other hand, the CHOICE=(X) specification considers all distinctive nonmissing values of X as elements of the choice set.

CONVERGE=*number*

specifies the convergence criterion. The CONVERGE= option is the same as the ABSGCONV= option in the NLOPTIONS statement. The ABSGCONV= option in the NLOPTIONS statement overrides the CONVERGE= option. The default value is 1E-5.

HALTONSTART=*number*

specifies the starting point of the Halton sequence. The specified number must be a positive integer. The default is HALTONSTART=11.

HEV=(*option-list*)

specifies options that are used to estimate the HEV model. The HEV model with a unit scale for the alternative 1 is estimated using the following SAS statement:

```
model y = x1 x2 x3 / hev=(unitscale=1);
```

The following options can be used in the HEV=() option. These options are listed within parentheses and separated by commas.

INTORDER=*number*

specifies the number of summation terms for Gaussian quadrature integration. The default is INTORDER=40. The maximum order is limited to 45. This option applies only to the INTEGRATION=LAGUERRE method.

UNITSCALE=*number-list*

specifies restrictions on scale parameters of stochastic utility components.

INTEGRATE=LAGUERRE | HARDY

specifies the integration method. The INTEGRATE=HARDY option specifies an adaptive integration method, while the INTEGRATE=LAGUERRE option specifies the Gauss-Laguerre approximation method. The default is INTEGRATE=LAGUERRE.

MIXED=(option-list)

specifies options that are used for mixed logit estimation. The mixed logit model with normally distributed random parameters is specified as follows:

```
model y = x1 x2 x3 / mixed=(normalparm=x1);
```

The following options can be used in the MIXED=() option. The options are listed within parentheses and separated by commas.

LOGNORMALPARM=variables

specifies the variables whose random coefficients are lognormally distributed. LOGNORMALPARM= variables must be included on the right-hand side of the MODEL statement.

NORMALEC=variables

specifies the error component variables whose coefficients have a normal distribution $N(0, \sigma^2)$.

NORMALPARM=variables

specifies the variables whose random coefficients are normally distributed. NORMALPARM= variables must be included on the right-hand side of the MODEL statement.

UNIFORMEC=variables

specifies the error component variables whose coefficients have a uniform distribution $U(-\sqrt{3}\sigma, \sqrt{3}\sigma)$.

UNIFORMPARM=variables

specifies the variables whose random coefficients are uniformly distributed. UNIFORMPARM= variables must be included on the right-hand side of the MODEL statement.

NCHOICE=number

specifies the number of choices for multinomial choice models when all individuals have the same choice set. When individuals have different number of choices, NCHOICE= option is not allowed, and CHOICE= option should be used. The NCHOICE= and CHOICE= options must not be used simultaneously, and the NCHOICE= option cannot be used for nested logit models.

NSIMUL=number

specifies the number of simulations when the mixed logit or multinomial probit model is estimated. The default is NSIMUL=100. In general, you need a smaller number of simulations with RANDNUM=HALTON than with RANDNUM=PSEUDO.

RANDNUM=value

specifies the type of the random number generator used for simulation. RANDNUM=HALTON is the default. The following option values are allowed:

PSEUDO	specifies pseudo-random number generation.
HALTON	specifies Halton sequence generation.

RANDINIT**RANDINIT=number**

specifies that initial parameter values be perturbed by uniform pseudo-random numbers for numerical optimization of the objective function. The default is $U(-1, 1)$. When the **RANDINIT=r** option is specified, $U(-r, r)$ pseudo-random numbers are generated. The value r should be positive. With a **RANDINIT** or **RANDINIT=** option, there are pure random searches for a given number of trials (1000 for conditional or nested logit, and 500 for other models) to get a maximum (or minimum) value of the objective function. For example, when there is a parameter estimate with an initial value of 1, the **RANDINIT** option will add a generated random number u to the initial value and compute an objective function value by using $1 + u$. This option is helpful in finding the initial value automatically if there is no guidance in setting the initial estimate.

RANK

specifies that the dependent variable contain ranks. The numbers must be positive integers starting from 1. When the dependent variable has value 1, the corresponding alternative is chosen. This option is provided only as a convenience to the user: the extra information contained in the ranks is not currently used for estimation purposes.

RESTART=(option-list)

specifies options that are used for reiteration of the optimization problem. When the **ADDRANDOM** option is specified, the initial value of reiteration is computed using random grid searches around the initial solution, as follows:

```
model y = x1 x2 / type=clogit
      restart=(addvalue=(.01 .01));
```

The preceding SAS statement reestimates a conditional logit model by adding **ADDVALUE=** values. If the **ADDVALUE=** option contains missing values, the **RESTART=** option uses the corresponding estimate from the initial stage. If no **ADDVALUE=** value is specified for an estimate, a default value equal to $(\text{lestimate1} * 1e-3)$ is added to the corresponding estimate from the initial stage. If both the **ADDVALUE=** and **ADDRANDOM(=)** options are specified, **ADDVALUE=** is ignored.

The following options can be used in the **RESTART=()** option. The options are listed within parentheses.

ADDMAXIT=number

specifies the maximum number of iterations for the second stage of the estimation. The default is **ADDMAXIT=100**.

ADDRANDOM**ADDRANDOM=value**

specifies random added values to the estimates from the initial stage. With the **ADDRANDOM** option, $U(-1, 1)$ random numbers are created and added to the estimates obtained in the initial stage. When the **ADDRANDOM=r** option is specified, $U(-r, r)$ random numbers are generated. The restart initial value is determined based on the given number of random searches (1000 for conditional or nested logit, and 500 for other models).

ADDVALUE=(*value-list*)

specifies values added to the estimates from the initial stage. A missing value in the list is considered as a zero value for the corresponding estimate. When the ADDVALUE= option is not specified, default values equal to (lestimate1 * 1e-3) are added.

SAMESCALE

specifies that the parameters of the inclusive values be the same within a group at each level when the nested logit is estimated.

SEED=*number*

specifies an initial seed for pseudo-random number generation. The SEED= value must be less than $2^{31} - 1$. If the SEED= value is negative or zero, the time of day from the computer's clock is used to obtain the initial seed. The default is SEED=0.

SPSCALE

specifies that the parameters of the inclusive values be the same for any choice with only one nested choice within a group, for each level in a nested logit model. This option is useful in analyzing stated preference data.

TYPE=*value*

specifies the type of model to be analyzed. The supported model types are as follows:

CONDITIONLOGIT CLOGIT CL	specifies a conditional logit model.
HEV	specifies a heteroscedastic extreme-value model.
MIXEDLOGIT MXL	specifies a mixed logit model.
MULTINOMPROBIT MPROBIT MP	specifies a multinomial probit model.
NESTEDLOGIT NLOGIT NL	specifies a nested logit model.

UNITVARIANCE=(*number-list*)

specifies normalization restrictions on error variances of multinomial probit for the choices whose numbers are given in the list. If the UNITVARIANCE= option is specified, it must include at least two choices. Also, for identification, additional zero restrictions are placed on the correlation coefficients for the last choice in the list.

COVEST=*value*

The COVEST= option specifies the type of covariance matrix. Possible values are OP, HESSIAN, and QML.

OP	specifies the covariance from the outer product matrix.
HESSIAN	specifies the covariance from the Hessian matrix.
QML	specifies the covariance from the outer product and Hessian matrices.

When COVEST=OP is specified, the outer product matrix is used to compute the covariance matrix of the parameter estimates. The COVEST=HESSIAN option produces the covariance matrix by using the inverse Hessian matrix. The quasi-maximum likelihood estimates

are computed with COVEST=QML. The default is COVEST=HESSIAN when the Newton-Raphson method is used. COVEST=OP is the default when the OPTMETHOD=QN option is specified.

Printing Options

ALL

requests all printing options.

COVB

displays the estimated covariances of the parameter estimates.

CORRB

displays the estimated correlation matrix of the parameter estimates.

ITPRINT

displays the initial parameter estimates, convergence criteria, and constraints of the optimization. At each iteration, objective function value, maximum absolute gradient element, step size, and slope of search direction are printed as well. The objective function is the full negative log-likelihood function for the maximum likelihood method. When the ITPRINT option is specified in the presence of the NLOPTIONS statement, all printing options in the NLOPTIONS statement are ignored.

NOPRINT

suppresses all displayed output.

Estimation Control Options

You can also specify detailed optimization options in the NLOPTIONS statement. The OPTMETHOD= option overrides the TECHNIQUE= option in the NLOPTIONS statement. Note that the NLOPTIONS statement is ignored if the OPTMETHOD= option is specified.

INITIAL=(*initial-values*)

START=(*initial-values*)

specifies initial values for some or all of the parameter estimates. The values specified are assigned to model parameters in the same order in which the parameter estimates are displayed in the MDC procedure output.

When you use the INITIAL= option, the initial values in the INITIAL= option must satisfy the restrictions specified for the parameter estimates. If they do not, the initial values you specify are adjusted to satisfy the restrictions.

MAXITER=*number*

sets the maximum number of iterations allowed. The MAXITER= option overrides the MAXITER= option in the NLOPTIONS statement. The default is MAXITER=100.

OPTMETHOD=*value*

The OPTMETHOD= option specifies the optimization technique when the estimation method uses nonlinear optimization.

QN	specifies the quasi-Newton method.
NR	specifies the Newton-Raphson method.
TR	specifies the trust region method.

The OPTMETHOD=NR option is the same as the TECHNIQUE=NEWRAP option in the NLOPTIONS statement. For the conditional and nested logit models the default is OPTMETHOD=NR. For other models the default is OPTMETHOD=QN.

NEST Statement

NEST *LEVEL*(*level-number*)= (*choices@choice*, ...) ;

The NEST statement is used when one choice variable contains all possible alternatives and the TYPE=NLOGIT option is specified. The decision tree is constructed based on the NEST statement. When the choice set is specified using multiple CHOICE= variables in the MODEL statement, the NEST statement is ignored.

Consider the following eight choices that are nested in a three-level tree structure.

Level 1	Level 2	Level 3	top
1	1	1	1
2	1	1	1
3	1	1	1
4	2	1	1
5	2	1	1
6	2	1	1
7	3	2	1
8	3	2	1

You can use the following NEST statement to specify the tree structure displayed in [Figure 17.22](#):

```
nest level(1) = (1 2 3 @ 1, 4 5 6 @ 2, 7 8 @ 3),
      level(2) = (1 2 @ 1, 3 @ 2),
      level(3) = (1 2 @ 1);
```

Figure 17.22 A Three-Level Tree

Note that the decision tree is constructed based on the sequence of first-level choice set specification. Therefore, specifying another order at Level 1 builds a different tree. The following NEST statement builds the tree displayed in [Figure 17.23](#):

```

nest level(1) = (4 5 6 @ 2, 1 2 3 @ 1, 7 8 @ 3),
level(2) = (1 2 @ 1, 3 @ 2),
level(3) = (1 2 @ 1);
  
```

Figure 17.23 An Alternative Three-Level Tree

However, the NEST statement with a different sequence of choice specification at higher levels builds the same tree as displayed in [Figure 17.22](#) if the sequence at the first level is the same:

```

nest level(1) = (1 2 3 @ 1, 4 5 6 @ 2, 7 8 @ 3),
level(2) = (3 @ 2, 1 2 @ 1),
level(3) = (1 2 @ 1);

```

The following specifications are equivalent:

```

nest level(2) = (3 @ 2, 1 2 @ 1)

nest level(2) = (3 @ 2, 1 @ 1, 2 @ 1)

nest level(2) = (1 @ 1, 2 @ 1, 3 @ 2)

```

Since the MDC procedure contains multiple cases for each individual, it is important to keep the data sequence in the proper order. Consider the four-choice multinomial model with one explanatory variable cost:

pid	choice	y	cost
1	1	1	10
1	2	0	25
1	3	0	20
1	4	0	30
2	1	0	15
2	2	0	22
2	3	1	16
2	4	0	25

The order of data needs to correspond to the value of choice. Therefore, the following data set is equivalent to the preceding data:

pid	choice	y	cost
1	2	0	25
1	3	0	20
1	1	1	10
1	4	0	30
2	3	1	16
2	4	0	25
2	1	0	15
2	2	0	22

The two-level nested model is estimated with a NEST statement, as follows:

```

proc mdc data=one type=nlogit;
  model y = cost / choice=(choice);
  id pid;
  utility(1,) = cost;
  nest level(1) = (1 2 3 @ 1, 4 @ 2),
    level(2) = (1 2 @ 1);
run;

```

The tree is constructed as in [Figure 17.24](#).

Figure 17.24 A Two-Level Tree

Another model is estimated if you specify the decision tree as in Figure 17.25. The different nested tree structure is specified in the following SAS statements:

```

proc mdc data=one type=nlogit;
  model y = cost / choice=(choice);
  id pid;
  utility u(1,) = cost;
  nest level(1) = (1 @ 1, 2 3 4 @ 2),
    level(2) = (1 2 @ 1);
run;

```

Figure 17.25 An Alternate Two-Level Tree

NLOPTIONS Statement

NLOPTIONS *options* ;

PROC MDC uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. The NLOPTIONS statement specifies nonlinear optimization options. The NLOPTIONS statement must follow the MODEL statement. For a list of all the options of the NLOPTIONS statement, see Chapter 6, “Nonlinear Optimization Methods.”

OUTPUT Statement

OUTPUT *options* ;

The MDC procedure supports the OUTPUT statement. The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors (XBETA) and predicted probabilities (P). The input data set must be sorted by the choice variable(s) within each ID.

OUT=*SAS-data-set*

specifies the name of the output data set.

PRED=*variable name*

P=*variable name*

requests the predicted probabilities by naming the variable that contains the predicted probabilities in the output data set.

XBETA=*variable name*

names the variable that contains the linear predictor ($\mathbf{x}'\boldsymbol{\beta}$) values. However, the XBETA= option is not supported in the nested logit model.

RESTRICT Statement

RESTRICT *restriction1* < , *restriction2* ... > ;

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <=, or >=.

Restriction expressions can be composed of parameters; multiplication (*), summation (+), and subtraction (−) operators; and constants. Parameters named in restriction expressions must be among the parameters estimated by the model. Parameters associated with a regressor variable are referred to by the name of the corresponding regressor variable. The restriction expressions must be a linear function of the parameters.

Lagrange multipliers are reported for all the active linear constraints. In the displayed output, the Lagrange multiplier estimates are identified with the names Restrict1, Restrict2, and so forth. The probability of the Lagrange multipliers is computed using a beta distribution (LaMotte 1994).

The following are examples of using the RESTRICT statement:

```
proc mdc data=one;
```

```

model y = x1-x10 /
      type=clogit
      choice=(mode 1 2 3);
id pid;
restrict x1*2 <= x2 + x3, ;
run;

proc mdc data=newdata;
model decision = ttime /
      type=mprobit
      nchoice=3
      unitvariance=(1 2)
      covest=hess;
id pid;
restrict RHO_31 = 0, STD_3<=1;
run;

```

UTILITY Statement

UTILITY $U(\text{level} < , \text{choices} >) = \text{variables} ;$

The **UTILITY** statement can be used in estimating a nested logit model. The $U()$ option can have two arguments. The first argument contains level information, while the second argument is related to choice information. The second argument can be omitted for the first level when all the choices at the first level share the same variables and the same parameters. However, for any level above the first, the second argument must be provided. The **UTILITY** statement specifies a utility function while the **NEST** statement constructs the decision tree.

Consider a two-level nested logit model that has one explanatory variable at level 1. This model can be specified as follows:

```

proc mdc data=one type=nlogit;
  model y = cost / choice=(choice);
  id pid;
  utility u(1,2 3 4) = cost;
  nest level(1) = (1 @ 1, 2 3 4 @ 2),
    level(2) = (1 2 @ 1);
run;

```

You also can specify the following statement, since all the variables at the first level share the same explanatory variable, *cost*:

```
utility u(1,) = cost;
```

The variable, *cost*, should be listed in the **MODEL** statement. When the additional explanatory variable, *dummy*, is included at level 2, another $U()$ option needs to be specified. Note that the $U()$ option must specify choices within any level above the first. Thus, it is specified as $U(2, 1\ 2)$ in the following statements:

```

proc mdc data=one type=nlogit;
  model y = cost dummy / choice=(choice);
  id pid;
  utility u(1,) = cost,
         u(2,1 2) = dummy;
  nest level(1) = (1 @ 1, 2 3 4 @ 2),
        level(2) = (1 2 @ 1);
run;

```

Details: MDC Procedure

Multinomial Discrete Choice Modeling

When the dependent variable takes multiple discrete values, you can use multinomial discrete choice modeling to analyze the data. We consider models for unordered multinomial data. Let the random utility function be defined by

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where the subscript i is an index for the individual, the subscript j is an index for the alternative, V_{ij} is a nonstochastic utility function, and ϵ_{ij} is a random component, or error, which captures unobserved characteristics of alternatives and/or individuals. In multinomial discrete choice models, the utility function is assumed to be linear, so that $V_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta}$. In the conditional logit model, each ϵ_{ij} for all $j \in C_i$ is distributed independently and identically (iid) with the type I extreme-value distribution, $\exp(-\exp(-\epsilon_{ij}))$, also known as the Gumbel distribution. The iid assumption on the random components of the utilities of the different alternatives can be relaxed to overcome the well-known and restrictive *Independence from Irrelevant Alternatives* (IIA) property of the conditional logit model. This allows for more flexible substitution patterns among alternatives than the one imposed by the conditional logit model. See the section “[Independence from Irrelevant Alternatives \(IIA\)](#)” on page 905. The nested logit model is derived by allowing the random components to be identical but nonindependent. Instead of independent type I extreme-value errors, the errors are assumed to have a generalized extreme-value distribution. This model generalizes the conditional logit model to allow for particular patterns of correlation in unobserved utility (McFadden 1978). Another generalization of the conditional logit model, the heteroscedastic extreme-value (HEV) model, is obtained by allowing independent but nonidentical errors distributed with a type I extreme-value distribution (Bhat 1995). It permits different variances on the random components of utility across the alternatives. Mixed logit models are also generalizations of the conditional logit model that can represent very general patterns of substitution among alternatives. See the “[Mixed Logit Model](#)” on page 907 section for details. The multinomial probit (MNP) model is derived when the errors, $(\epsilon_{i1}, \epsilon_{i2}, \dots, \epsilon_{iJ})$, have a multivariate normal (MVN) distribution. Thus, this model accommodates a very general error structure.

The multinomial probit model requires burdensome computation compared to a family of multinomial choice models derived from the Gumbel distributed utility function, since it involves multi-

dimensional integration (with dimension $J - 1$) in the estimation process. In addition, the multinomial probit model requires more parameters than other multinomial choice models. As a result, conditional and nested logit models are used more frequently, even though they are derived from a utility function whose random component is more restrictively defined than the multinomial probit model.

The event of a choice being made, $\{y_i = j\}$, can be expressed using a random utility function as follows:

$$U_{ij} \geq \max_{k \in C_i, k \neq j} U_{ik}$$

where C_i is the choice set of individual i . Individual i chooses alternative j if and only if it provides a level of utility that is greater than or equal to that of any other alternative in his choice set. Then, the probability that individual i chooses alternative j (from among the n_i choices in his choice set C_i) is

$$P_i(j) = P_{ij} = P[\mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij} \geq \max_{k \in C_i} (\mathbf{x}'_{ik}\boldsymbol{\beta} + \epsilon_{ik})]$$

Multinomial Logit and Conditional Logit

When explanatory variables contain only individual characteristics, the multinomial logit model is defined as

$$P(y_i = j) = P_{ij} = \frac{\exp(\mathbf{x}'_i \boldsymbol{\beta}_j)}{\sum_{k=0}^J \exp(\mathbf{x}'_i \boldsymbol{\beta}_k)} \text{ for } j = 0, \dots, J$$

where y_i is a random variable that indicates the choice made, x_i is a vector of characteristics specific to the i th individual, and $\boldsymbol{\beta}_j$ is a vector of coefficients specific to the j th alternative. Thus, this model involves choice-specific coefficients and only individual specific regressors. For model identification, one often assumes that $\boldsymbol{\beta}_0 = 0$. The multinomial logit model reduces to the binary logit model if $J = 1$.

The ratio of the choice probabilities for alternatives j and l , or the *odds ratio* of alternatives j and l , is

$$\frac{P_{ij}}{P_{il}} = \frac{\exp(\mathbf{x}'_i \boldsymbol{\beta}_j) / \sum_{k=0}^J \exp(\mathbf{x}'_i \boldsymbol{\beta}_k)}{\exp(\mathbf{x}'_i \boldsymbol{\beta}_l) / \sum_{k=0}^J \exp(\mathbf{x}'_i \boldsymbol{\beta}_k)} = \exp[\mathbf{x}'_i (\boldsymbol{\beta}_j - \boldsymbol{\beta}_l)]$$

Note that the odds ratio of alternatives j and l does not depend on any alternatives other than j and l . For more on this, see the section “[Independence from Irrelevant Alternatives \(IIA\)](#)” on page 905.

The log-likelihood function of the multinomial logit model is

$$\mathcal{L} = \sum_{i=1}^N \sum_{j=0}^J d_{ij} \ln P(y_i = j)$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

This type of multinomial choice modeling has a couple of weaknesses: it has too many parameters (the number of individual characteristics times J) and it is difficult to interpret. The multinomial logit model can be used to predict the choice probabilities, among a given set of $J + 1$ alternatives, of an individual with known vector of characteristics \mathbf{x}_i .

The parameters of the multinomial logit model can be estimated with the TYPE=CLOGIT option in the MODEL statement; however, this requires modification of the conditional logit model to allow individual specific effects.

The conditional logit model, sometimes also called the multinomial logit model, is similarly defined when choice-specific data are available. Using properties of type I extreme-value (or Gumbel) distribution, the probability that individual i chooses alternative j from among the choices in his choice set C_i is

$$P(y_i = j) = P_{ij} = P[\mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij} \geq \max_{k \in C_i, k \neq j} (\mathbf{x}'_{ik}\boldsymbol{\beta} + \epsilon_{ik})] = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})}{\sum_{k \in C_i} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}$$

where \mathbf{x}_{ij} is a vector of attributes specific to the j th alternative as perceived by the i th individual. It is assumed that there are n_i choices in each individual's choice set, C_i .

The log-likelihood function of the conditional logit model is

$$\mathcal{L} = \sum_{i=1}^N \sum_{j \in C_i} d_{ij} \ln P(y_i = j)$$

The conditional logit model can be used to predict the probability that an individual will choose a previously unavailable alternative, given knowledge of $\boldsymbol{\beta}$ and the vector \mathbf{x}_{ij} of choice-specific characteristics.

Independence from Irrelevant Alternatives (IIA)

The problematic aspect of the conditional logit (and the multinomial logit) model lies in the property of independence from irrelevant alternatives (IIA). The IIA property can be derived from the probability ratio of any two choices. For the conditional logit model,

$$\frac{P_{ij}}{P_{il}} = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta}) / \sum_{k \in C_i} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}{\exp(\mathbf{x}'_{il}\boldsymbol{\beta}) / \sum_{k \in C_i} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})} = \exp[(\mathbf{x}_{ij} - \mathbf{x}_{il})'\boldsymbol{\beta}]$$

It is evident that the ratio of the probabilities for alternatives j and l does not depend on any alternatives other than j and l . This was also shown to be the case for the multinomial logit model. Thus, for the conditional and multinomial logit models, the ratio of probabilities of any two alternatives is necessarily the same regardless of what other alternatives are in the choice set or what the characteristics of the other alternatives are. This is referred to as the IIA property.

The IIA property is useful from the point of view of estimation and forecasting. For example, it allows the prediction of demand for currently unavailable alternatives. If the IIA property is appropriate for the choice situation being considered, then estimation can be based on the set of currently available alternatives and then the estimated model can be used to calculate the probability that an individual would choose a new alternative not considered in the estimation procedure. However,

the IIA property is restrictive from the point of view of choice behavior. Models that display the IIA property predict that a change in the attributes of one alternative changes the probabilities of the other alternatives proportionately such that the ratios of probabilities remain constant. Thus, cross elasticities due to a change in the attributes of an alternative j are equal for all alternatives $k \neq j$. This particular substitution pattern might be too restrictive in some choice settings.

The IIA property of the conditional logit model follows from the assumption that the random components of utility are identically and independently distributed. The other models in PROC MDC, namely, nested logit, HEV, mixed logit, and multinomial probit, relax the IIA property in different ways.

For an example of Hausman's specification test of IIA assumption, see "Example 17.6: Hausman's Specification and Likelihood Ratio Tests" on page 936.

Heteroscedastic Extreme-Value Model

The heteroscedastic extreme-value (HEV) model (Bhat 1995) allows the random components of the utility function to be nonidentical. Specifically, the HEV model assumes independent but non-identical error terms distributed with the type I extreme-value distribution. The HEV model allows the variances of the random components of utility to differ across alternatives. Bhat (1995) argues that the HEV model does not have the IIA property. The HEV model contains the conditional logit model as a special case. The probability that an individual i will choose alternative j from the set C_i of available alternatives is

$$P_i(j) = \int_{-\infty}^{\infty} \prod_{k \in C_i, k \neq j} \Gamma \left[\frac{\mathbf{x}'_{ij} \boldsymbol{\beta} - \mathbf{x}'_{ik} \boldsymbol{\beta} + \theta_j w}{\theta_k} \right] \gamma(w) dw$$

where the choice set C_i has n_i elements and

$$\Gamma(x) = \exp(-\exp(-x))$$

$$\gamma(x) = \exp(-x)\Gamma(x)$$

are the cumulative distribution function and probability density function of the type I extreme-value distribution. The variance of the error term for the j th alternative is $\frac{1}{6}\pi^2\theta_j^2$. If the scale parameters, θ_j , of the random components of utility of all alternatives are equal, then this choice probability is the same as that of the conditional logit model. The log-likelihood function of the HEV model can be written as

$$\mathcal{L} = \sum_{i=1}^N \sum_{j \in C_i} d_{ij} \ln[P_i(j)]$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

Since the log-likelihood function contains an improper integral function, it is computationally difficult to get a stable estimate. With the transformation $u = \exp(-w)$, the probability can be written

$$\begin{aligned} P_i(j) &= \int_0^\infty \prod_{k \in C_i, k \neq j} \Gamma \left[\frac{\mathbf{x}'_{ij} \boldsymbol{\beta} - \mathbf{x}'_{ik} \boldsymbol{\beta} - \theta_j \ln(u)}{\theta_k} \right] \exp(-u) du \\ &= \int_0^\infty G_{ij}(u) \exp(-u) du \end{aligned}$$

Using the Gauss-Laguerre weight function, $W(x) = \exp(-u)$, the integration of the log-likelihood function can be replaced with a summation as follows:

$$\int_0^\infty G_{ij}(u) \exp(-u) du = \sum_{k=1}^K w_k G_{ij}(x_k)$$

Weights (w_k) and abscissas (x_k) are tabulated by Abramowitz and Stegun (1970).

Mixed Logit Model

In mixed logit models, an individual's utility from any alternative can be decomposed into a deterministic component, $\mathbf{x}'_{ij} \boldsymbol{\beta}$, which is a linear combination of observed variables, and a stochastic component, $\xi_{ij} + \epsilon_{ij}$:

$$U_{ij} = \mathbf{x}'_{ij} \boldsymbol{\beta} + \xi_{ij} + \epsilon_{ij}$$

where \mathbf{x}_{ij} is a vector of observed variables relating to individual i and alternative j , $\boldsymbol{\beta}$ is a vector of parameters, ξ_{ij} is an error component that can be correlated among alternatives and heteroscedastic for each individual, and ϵ_{ij} is a random term with zero mean that is independently and identically distributed over alternatives and individuals. The conditional logit model is derived if you assume ϵ_{ij} has an iid Gumbel distribution and $V(\xi_{ij}) = 0$.

The mixed logit model assumes a general distribution for ξ_{ij} and an iid Gumbel distribution for ϵ_{ij} . Denote the density function of the error component ξ_{ij} as $f(\xi_{ij} | \boldsymbol{\gamma})$, where $\boldsymbol{\gamma}$ is a parameter vector of the distribution of ξ_{ij} . The choice probability of alternative j for individual i is written as

$$P_i(j) = \int Q_i(j | \xi_{ij}) f(\xi_{ij} | \boldsymbol{\gamma}) d\xi_{ij}$$

where the conditional choice probability for a given value of ξ_{ij} is the logit

$$Q_i(j | \xi_{ij}) = \frac{\exp(\mathbf{x}'_{ij} \boldsymbol{\beta} + \xi_{ij})}{\sum_{k \in C_i} \exp(\mathbf{x}'_{ik} \boldsymbol{\beta} + \xi_{ik})}$$

Since ξ_{ij} is not given, the unconditional choice probability, $P_i(j)$, is the integral of the conditional choice probability, $Q_i(j | \xi_{ij})$, over the distribution of ξ_{ij} . This model is called "mixed logit" since the choice probability is a mixture of logits with $f(\xi_{ij} | \boldsymbol{\gamma})$ as the mixing distribution.

In general, the mixed logit model does not have an exact likelihood function since the probability $P_i(j)$ does not always have a closed form solution. Therefore, a simulation method is used for computing the approximate probability:

$$\tilde{P}_i(j) = 1/S \sum_{s=1}^S \tilde{Q}_i(j|\xi_{ij}^s)$$

where S is the number of simulation replications and $\tilde{P}_i(j)$ is a simulated probability. The simulated log-likelihood function is computed as

$$\tilde{\mathcal{L}} = \sum_{i=1}^N \sum_{j=1}^{n_i} d_{ij} \ln(\tilde{P}_i(j))$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

For simulation purposes, assume that the error component has a specific structure,

$$\xi_{ij} = \mathbf{z}'_{ij} \boldsymbol{\mu} + \mathbf{w}'_{ij} \boldsymbol{\beta}^*$$

where \mathbf{z}_{ij} is a vector of observed data and $\boldsymbol{\mu}$ is a random vector with zero mean and density function $\psi(\boldsymbol{\mu}|\boldsymbol{\gamma})$. The observed data vector (\mathbf{z}_{ij}) of the error component can contain some or all elements of \mathbf{x}_{ij} . The component $\mathbf{z}'_{ij} \boldsymbol{\mu}$ induces heteroscedasticity and correlation across unobserved utility components of the alternatives. This allows flexible substitution patterns among the alternatives. The k th element of vector $\boldsymbol{\mu}$ is distributed as

$$\mu_k \sim (0, \sigma_k^2)$$

Therefore, μ_k can be specified as

$$\mu_k = \sigma_k \epsilon_\mu$$

where

$$\epsilon_\mu \sim N(0, 1)$$

or

$$\epsilon_\mu \sim U(-\sqrt{3}, \sqrt{3})$$

In addition, $\boldsymbol{\beta}^*$ is a vector of random parameters (or random coefficients). Random coefficients allow heterogeneity across individuals in their sensitivity to observed exogenous variables. The observed data vector, \mathbf{w}_{ij} , is a subset of \mathbf{x}_{ij} . Three types of distributions for the random coefficients are supported. Denote the m th element of $\boldsymbol{\beta}^*$ as β_m^* .

- Normally distributed coefficient with the mean b_m and spread s_m being estimated.

$$\beta_m^* = b_m + s_m \epsilon_\beta \quad \text{and} \quad \epsilon_\beta \sim N(0, 1)$$

- Uniformly distributed coefficient with the mean b_m and spread s_m being estimated. A uniform distribution with mean b and spread s is $U(b - s, b + s)$.

$$\beta_m^* = b_m + s_m \epsilon_\beta \quad \text{and} \quad \epsilon_\beta \sim U(-1, 1)$$

- Lognormally distributed coefficient. The coefficient is calculated as

$$\beta_m^* = \exp(b_m + s_m \epsilon_\beta) \quad \text{and} \quad \epsilon_\beta \sim N(0, 1)$$

where b_m and s_m are parameters that are estimated.

The estimate of spread for normally, uniformly, and lognormally distributed coefficients can be negative. The absolute value of the estimated spread can be interpreted as an estimate of standard deviation for normally distributed coefficients.

A detailed description of mixed logit models can be found, for example, in Brownstone and Train (1999).

Multinomial Probit

The multinomial probit model allows the random components of the utility of the different alternatives to be nonindependent and nonidentical. Thus, it does not have the IIA property. The increase in the flexibility of the error structure comes at the expense of introducing several additional parameters in the covariance matrix of the errors.

Consider the random utility function

$$U_{ij} = \mathbf{x}'_{ij} \boldsymbol{\beta} + \epsilon_{ij}$$

where the joint distribution of $(\epsilon_{i1}, \epsilon_{i2}, \dots, \epsilon_{iJ})$ is multivariate normal:

$$\begin{bmatrix} \epsilon_{i1} \\ \epsilon_{i2} \\ \vdots \\ \epsilon_{iJ} \end{bmatrix} \sim N(\mathbf{0}, \boldsymbol{\Sigma})$$

$$\boldsymbol{\Sigma} = [\sigma_{jk}]_{j,k=1,\dots,J}$$

The dimension of the error covariance matrix is determined by the number of alternatives J . Given $(\mathbf{x}_{i1}, \mathbf{x}_{i2}, \dots, \mathbf{x}_{iJ})$, the j th alternative is chosen if and only if $U_{ij} \geq U_{ik}$ for all $k \neq j$. Thus, the probability that the j th alternative is chosen is

$$P(y_i = j) = P_{ij} = P[\epsilon_{i1} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{i1})' \boldsymbol{\beta}, \dots, \epsilon_{iJ} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{iJ})' \boldsymbol{\beta}]$$

where y_i is a random variable that indicates the choice made. This is a cumulative probability from a $(J - 1)$ -variate normal distribution. Since evaluation of this probability involves multidimensional integration, it is practical to use a simulation method to estimate the model. Many studies have shown that the simulators proposed by Geweke (1989), Hajivassiliou (1993), and Keane (1994)

(GHK) perform well. For example, Hajivassiliou, McFadden, and Ruud (1996) compare 13 simulators using 11 different simulation methods and conclude that the GHK simulation method is the most reliable. To compute the probability of the multivariate normal distribution, the recursive simulation method is used. Refer to Hajivassiliou (1993) for more details on GHK simulators.

The log-likelihood function for the multinomial probit model can be written as

$$\mathcal{L} = \sum_{i=1}^N \sum_{j=1}^J d_{ij} \ln P(y_i = j)$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

For identification of the multinomial probit model, two of the diagonal elements of Σ are normalized to 1, and it is assumed that for one of the choices whose error variance is normalized to 1 (say, k), it is also true that $\sigma_{jk} = \sigma_{kj} = 0$ for $j = 1, \dots, J$ and $j \neq k$. Thus, a model with J alternatives has at most $J(J-1)/2 - 1$ covariance parameters after normalization.

Let D and R be defined as

$$D = \begin{bmatrix} \sigma_1 & 0 & \cdots & 0 \\ 0 & \sigma_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_J \end{bmatrix}$$

$$R = \begin{bmatrix} 1 & \rho_{12} & \cdots & \rho_{1J} \\ \rho_{21} & 1 & \cdots & \rho_{2J} \\ \vdots & \vdots & \ddots & \vdots \\ \rho_{J1} & \rho_{J2} & \cdots & 1 \end{bmatrix}$$

where $\sigma_j^2 = \sigma_{jj}$ and $\rho_{jk} = \frac{\sigma_{jk}}{\sigma_j \sigma_k}$. Then, for identification, $\sigma_{J-1} = \sigma_J = 1$ and $\rho_{kJ} = \rho_{Jk} = 0$, for all $k \neq J$ can be imposed, and the error covariance matrix is $\Sigma = DRD$.

In the standard MDC output, the parameter estimates STD_j and RHO_jk correspond to σ_j and ρ_{jk} .

In principle, the multinomial probit model is fully identified with the preceding normalizations. However, in practice, convergence in applications of the model with more than three alternatives often requires additional restrictions on the elements of Σ .

It must also be noted that the unrestricted structure of the error covariance matrix makes it impossible to forecast demand for a new alternative without knowledge of the new $(J+1)$ by $(J+1)$ error covariance matrix.

Nested Logit

The nested logit model (McFadden 1978, 1981) allows partial relaxation of the assumption of independence of the stochastic components of utility of alternatives. In some choice situations, the IIA

property holds for some pairs of alternatives but not all. In these situations, the nested logit model can be used if the set of alternatives faced by an individual can be partitioned into subsets such that the IIA property holds within subsets but not across subsets.

In the nested logit model, the joint distribution of the errors is generalized extreme value (GEV). This is a generalization of the type I extreme-value distribution that gives rise to the conditional logit model. Note that all ϵ_{ij} within each subset are correlated with each other. Refer to McFadden (1978, 1981) for details.

Nested logit models can be described analytically following the notation of McFadden (1981). Assume that there are L levels, with 1 representing the lowest and L representing the highest level of the tree. The index of a node at level h in the tree is a pair (j_h, π_h) , where $\pi_h = (j_{h+1}, \dots, j_L)$ is the index of the adjacent node at level $h + 1$. Thus, the primitive alternatives, at level 1 in the tree, are indexed by vectors (j_1, \dots, j_L) , while the alternative nodes at level L are indexed by integers j_L . The choice set C_{π_h} is the set of primitive alternatives (at level 1) that belong to branches below the node π_h . The notation C_{π_h} is also used to denote a set of indices j_h such that (j_h, π_h) is a node immediately below π_h . Note that C_{π_0} is a set with a single element, while C_{π_L} represents a choice set containing all possible alternatives. As an example, consider the circled node at level 1 in Figure 17.26. Since it stems from node 11, $\pi_h = 11$, and since it is the second node stemming from 11, $j_h = 2$, so that its index is $\pi_{h-1} = \pi_0 = (j_h, \pi_h) = 211$. Similarly, $C_{11} = \{111, 211, 311\}$ contains all the possible choices below 11.

Note that while this notation is useful for writing closed-form solutions for probabilities, the MDC procedure allows a more flexible definition of indices. See the NEST statement in the section “Syntax” for more details on how to describe decision trees within the MDC procedure.

Figure 17.26 Node Indices for a Three-Level Tree

Let $\mathbf{x}_{i;j_h\pi_h}^{(h)}$ denote the vector of observed variables for individual i common to the alternatives below node $j_h\pi_h$. The probability of choice at level h has a closed-form solution and is written

$$P_i(j_h|\pi_h) = \frac{\exp \left[\mathbf{x}_{i;j_h\pi_h}^{(h)'} \boldsymbol{\beta}^{(h)} + \sum_{k \in C_{i;j_h\pi_h}} I_{k,j_h\pi_h} \theta_{k,j_h\pi_h} \right]}{\sum_{j \in C_{i;\pi_h}} \exp \left[\mathbf{x}_{i;j\pi_h}^{(h)'} \boldsymbol{\beta}^{(h)} + \sum_{k \in C_{i;j\pi_h}} I_{k,j\pi_h} \theta_{k,j\pi_h} \right]}, h = 2, \dots, L$$

where I_{π_h} is the *inclusive value* (at level $h + 1$) of the branch below node π_h and is defined recursively as follows:

$$I_{\pi_h} = \ln \left\{ \sum_{j \in C_{i;\pi_h}} \exp \left[\mathbf{x}_{i;j\pi_h}^{(h)'} \boldsymbol{\beta}^{(h)} + \sum_{k \in C_{i;j\pi_h}} I_{k,j\pi_h} \theta_{k,j\pi_h} \right] \right\}$$

$$0 \leq \theta_{k,\pi_1} \leq \dots \leq \theta_{k,\pi_{L-1}}$$

The inclusive value I_{π_h} denotes the average utility that the individual can expect from the branch below π_h . The *dissimilarity parameters* or *inclusive value parameters* ($\theta_{k,j\pi_h}$) are the coefficients of the inclusive values and have values between 0 and 1 if nested logit is the correct model specification. When they all take value 1, the nested logit model is equivalent to the conditional logit model.

At decision level 1, there is no inclusive value; i.e., $I_{\pi_0} = 0$. Therefore, the conditional probability is

$$P_i(j_1|\pi_1) = \frac{\exp \left[\mathbf{x}_{i;j_1\pi_1}^{(1)'} \boldsymbol{\beta}^{(1)} \right]}{\sum_{j \in C_{i;\pi_1}} \exp \left[\mathbf{x}_{i;j\pi_1}^{(1)'} \boldsymbol{\beta}^{(1)} \right]}$$

The log-likelihood function at level h can then be written

$$\mathcal{L}^{(h)} = \sum_{i=1}^N \sum_{\pi_{h'} \in C_{i,\pi_{h+1}}} \sum_{j \in C_{i,\pi_{h'}}} y_{i,j\pi_{h'}} \ln P(C_{i,j\pi_{h'}} | C_{i,\pi_{h'}})$$

where $y_{i,j\pi_{h'}}$ is an indicator variable that has the value of 1 for the selected choice. The full log-likelihood function of the nested logit model is obtained by adding the conditional log-likelihood functions at each level:

$$\mathcal{L} = \sum_{h=1}^L \mathcal{L}^{(h)}$$

Note that the log-likelihood functions are computed from conditional probabilities when $h < L$. The nested logit model is estimated using the full information maximum likelihood method.

Decision Tree and Nested Logit

You can view choices as a decision tree and model the decision tree by using the nested logit model. You need to use either the NEST statement or the CHOICE= option of the MODEL statement to specify the nested tree structure. Additionally, you need to identify which explanatory variables are used at each level of the decision tree. These explanatory variables are arguments for what is called a *utility function*. The utility function is specified using UTILITY statements. For example, consider a two-level decision tree. The tree structure is displayed in [Figure 17.27](#).

Figure 17.27 Two-Level Decision Tree

A nested logit model with two levels can be specified using the following SAS statements:

```

proc mdc data=one type=nlogit;
  model decision = x1 x2 x3 x4 x5 /
    choice=(upmode 1 2, mode 1 2 3 4 5);
  id pid;
  utility u(1, 3 4 5 @ 2) = x1 x2,
    u(1, 1 2 @ 1) = x3 x4,
    u(2, 1 2) = x5;
run;

```

The DATA=one data set should be arranged as follows:

obs	pid	upmode	mode	x1	x2	x3	x4	x5	decision
1	1	1	1	#	#	#	#	#	1
2	1	1	2	#	#	#	#	#	0
3	1	2	3	#	#	#	#	#	0
4	1	2	4	#	#	#	#	#	0
5	1	2	5	#	#	#	#	#	0
6	2	1	1	#	#	#	#	#	0
7	2	1	2	#	#	#	#	#	0
8	2	2	3	#	#	#	#	#	0
9	2	2	4	#	#	#	#	#	0
10	2	2	5	#	#	#	#	#	1

All model variables, x_1 through x_5 , are specified in the UTILITY statement. It is required that entries denoted as # have values for model estimation and prediction. The values of the level 2 utility variable x_5 should be the same for all the primitive (level 1) alternatives below node 1 at level 2 and, similarly, for all the primitive alternatives below node 2 at level 2. In other words, x_5 should have the same value for primitive alternatives 1 and 2 and, similarly, it should have the same value for primitive alternatives 3, 4, and 5. More generally, the values of any level 2 or higher utility function variables should be constant across primitive alternatives under each node for which the utility function applies. Since PROC MDC expects this to be the case, it will use the values of x_5 only for the primitive alternatives 1 and 3, ignoring the values for the primitive alternatives 2, 4, and 5. Thus, PROC MDC uses the values of the utility function variable only

for the primitive alternatives that come first under each node for which the utility function applies. This behavior applies to any utility function variables that are specified above the first level. The choice variable for level 2 (upmode) should be placed before the first-level choice variable (mode) when the CHOICE= option is given. Alternatively, the NEST statement can be used to specify the decision tree. The following SAS statements fit the same nested logit model:

```
proc mdc data=a type=nlogit;
  model decision = x1 x2 x3 x4 x5 /
    choice=(mode 1 2 3 4 5);
  id pid;
  utility u(1, 3 4 5 @ 2) = x1 x2,
    u(1, 1 2 @ 1) = x3 x4,
    u(2, 1 2) = x5;
  nest level(1) = (1 2 @ 1, 3 4 5 @ 2),
    level(2) = (1 2 @ 1);
run;
```

The U(1, 3 4 5 @ 2)= option specifies three choices, 3, 4, and 5, at level 1 of the decision tree. They are connected to the upper branch 2. The specified variables (x1 and x2) are used to model this utility function. The bottom level of the decision tree is level 1. All variables in the UTILITY statement must be included in the MODEL statement. When all choices at the first level share the same variables, you can omit the second argument of the U()= option for that level. However, U(1,) = x1 x2 is not equivalent to the following statements:

```
u(1, 3 4 5 @ 2) = x1 x2;
u(1, 1 2 @ 1) = x1 x2;
```

The CHOICE= variables need to be specified from the top to the bottom level. To forecast demand for new products, stated preference data are widely used. Stated preference data are attractive for market researchers since attribute variations can be controlled. Hensher (1993) explores the advantage of combining revealed preference (market data) and stated preference data. The scale factor (V_{rp}/V_{sp}) can be estimated using the nested logit model with the decision tree structure displayed in Figure 17.28.

Figure 17.28 Decision Tree for Revealed and Stated Preference Data

Example SAS statements are as follows:

```
proc mdc data=a type=nlogit;
  model decision = x1 x2 x3 /
    spscale
    choice=(mode 1 2 3 4 5 6);
  id pid;
  utility u(1,) = x1 x2 x3;
  nest level(1) = (1 2 3 @ 1, 4 @ 2, 5 @ 3, 6 @ 4),
    level(2) = (1 2 3 4 @ 1);
run;
```

The SPSCALE option specifies that parameters of inclusive values for nodes 2, 3, and 4 at level 2 be the same. When you specify the SAMESCALE option, the MDC procedure imposes the same coefficient of inclusive values for choices 1–4.

Model Fit and Goodness-of-Fit Statistics

McFadden (1974) suggests a likelihood ratio index that is analogous to the R^2 in the linear regression model:

$$R_M^2 = 1 - \frac{\ln L}{\ln L_0}$$

where L is the maximum of the log-likelihood function and L_0 is the maximum of the log-likelihood function when all coefficients, except for an intercept term, are zero. McFadden's likelihood ratio index is bounded by 0 and 1.

Estrella (1998) proposes the following requirements for a goodness-of-fit measure to be desirable in discrete choice modeling:

- The measure must take values in $[0, 1]$, where 0 represents no fit and 1 corresponds to perfect fit.
- The measure should be directly related to the valid test statistic for the significance of all slope coefficients.
- The derivative of the measure with respect to the test statistic should comply with corresponding derivatives in a linear regression.

Estrella's measure is written as

$$R_{E1}^2 = 1 - \left(\frac{\ln L}{\ln L_0} \right)^{-(2/N) \ln L_0}$$

Estrella suggests an alternative measure,

$$R_{E2}^2 = 1 - [(\ln L - K) / \ln L_0]^{-(2/N) \ln L_0}$$

where $\ln L_0$ is computed with null parameter values, N is the number of observations used, and K represents the number of estimated parameters.

Other goodness-of-fit measures are summarized as follows:

$$R_{CU1}^2 = 1 - \left(\frac{L_0}{L}\right)^{\frac{2}{N}} \quad (\text{Cragg-Uhler 1})$$

$$R_{CU2}^2 = \frac{1 - (L_0/L)^{\frac{2}{N}}}{1 - L_0^{\frac{2}{N}}} \quad (\text{Cragg-Uhler 2})$$

$$R_A^2 = \frac{2(\ln L - \ln L_0)}{2(\ln L - \ln L_0) + N} \quad (\text{Aldrich-Nelson})$$

$$R_{VZ}^2 = R_A^2 \frac{2 \ln L_0 - N}{2 \ln L_0} \quad (\text{Veall-Zimmermann})$$

The AIC and SBC are computed as follows:

$$AIC = -2 \ln(L) + 2k$$

$$SBC = -2 \ln(L) + \ln(n)k$$

where

$\ln(L)$ is the log likelihood value for the model, k is the number of parameters estimated, and n is the number of observations (i.e., the number of respondents).

OUTEST= Data Set

The OUTEST= data set contains all the parameters estimated in a MODEL statement. The OUTEST= option can be used when the PROC MDC call contains one MODEL statement. There are additional restrictions. For the HEV and multinomial probit models, you need to specify exactly all possible elements of the choice set, since additional parameters (e.g., SCALE1 or STD1) are generated automatically in the MDC procedure. Therefore, the following SAS statements are not valid when the OUTEST= option is given:

```
proc mdc data=a outest=e;
  model y = x / type=hev choice=(alter);
run;
```

You need to specify all possible choices in the CHOICE= option since the OUTEST= option is specified:

```
proc mdc data=a outest=e;
  model y = x / type=hev choice=(alter 1 2 3);
run;
```

When the NCHOICE= option is given, no additional information about possible choices is required. Therefore, the following are correct SAS statements:

```
proc mdc data=a outest=e;
  model y = x / type=mprobit nchoice=3;
run;
```

The nested logit model does not produce the OUTEST= data set unless the NEST statement is specified.

Each parameter contains the estimate for the corresponding parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

<code>_DEPVAR_</code>	the name of the dependent variable
<code>_METHOD_</code>	the estimation method
<code>_MODEL_</code>	the label of the MODEL statement if one is given, or blank otherwise
<code>_STATUS_</code>	a character variable indicating whether the optimization process reached convergence or failed to converge; 0 indicates that the convergence was reached, 1 indicates that the maximum number of iterations allowed was exceeded, 2 indicates a failure to improve the function value, and 3 indicates a failure to converge because objective function or its derivatives could not be evaluated, or improved, or linear constraints were dependent, or the algorithm failed to return to feasible region, or the number of iterations was greater than prespecified.
<code>_NAME_</code>	the name of the row of the covariance matrix for the parameter estimate, if the COVOUT option is specified, or blank otherwise
<code>_LIKLHD_</code>	the log-likelihood value
<code>_STDERR_</code>	standard error of the parameter estimate, if the COVOUT option is specified
<code>_TYPE_</code>	PARMS for observations containing parameter estimates, or COV for observations containing covariance matrix elements

The OUTEST= data set contains one observation for the MODEL statement giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement giving the rows of the covariance matrix of parameter estimates. For covariance observations, the value of the `_TYPE_` variable is COV, and the `_NAME_` variable identifies the parameter associated with that row of the covariance matrix.

ODS Table Names

PROC MDC assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the [Table 17.3](#).

Table 17.3 ODS Tables Produced in PROC MDC

Examples: MDC Procedure

Example 17.1: Binary Data Modeling

The MDC procedure supports various multinomial choice models. However, binary choice models such as binary logit and probit can also be estimated using PROC MDC since these models are special cases of multinomial models.

Spector and Mazzeo (1980) studied the effectiveness of a new teaching method on students' performance in an economics course. They reported grade point average (*gpa*), previous knowledge of the material (*tuce*), a dummy variable for the new teaching method (*psi*), and the final course grade (*grade*). *grade* is recorded as 1 if a student earned the letter grade "A," and 0 otherwise.

The binary logit can be estimated using the conditional logit model. In order to use the MDC procedure, the data are converted as follows so that each possible choice corresponds to one observation:

```

data smdata;
  input gpa tuce psi grade;
datalines;
2.66      20      0      0
2.89      22      0      0
3.28      24      0      0
... more lines ...

```

```

data smdata1;
  set smdata;
  retain id 0;
  id + 1;

  /*-- first choice --*/
  choice1 = 1;
  choice2 = 0;
  decision = (grade = 0);
  gpa_2 = 0;
  tuce_2 = 0;
  psi_2 = 0;
  output;

  /*-- second choice --*/
  choice1 = 0;
  choice2 = 1;
  decision = (grade = 1);
  gpa_2 = gpa;
  tuce_2 = tuce;
  psi_2 = psi;
  output;
run;

```

The first 10 observations are displayed in [Output 17.1.1](#). The variables related to grade =0 are omitted since these are not used for binary choice model estimation.

Output 17.1.1 Converted Binary Data

	id	decision	choice2	gpa_2	tuce_2	psi_2
	1	1	0	0.00	0	0
	1	0	1	2.66	20	0
	2	1	0	0.00	0	0
	2	0	1	2.89	22	0
	3	1	0	0.00	0	0
	3	0	1	3.28	24	0
	4	1	0	0.00	0	0
	4	0	1	2.92	12	0
	5	0	0	0.00	0	0
	5	1	1	4.00	21	0

Consider the choice probability of the conditional logit model for binary choice:

$$P_i(j) = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})}{\sum_{k=1}^2 \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}, \quad j = 1, 2$$

The choice probability of the binary logit model is computed based on normalization. The preceding conditional logit model can be converted as

$$P_i(1) = \frac{1}{1 + \exp((\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta})}$$

$$P_i(2) = \frac{\exp((\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta})}{1 + \exp((\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta})}$$

Therefore, you can interpret the binary choice data as the difference between the first and second choice characteristics. In the following statements, it is assumed that $\mathbf{x}_{i1} = \mathbf{0}$. The binary logit model is estimated and displayed in [Output 17.1.2](#).

```

/*-- Conditional Logit --*/
proc mdc data=smdatal;
  model decision = choice2 gpa_2 tuce_2 psi_2 /
    type=clogit
    nchoice=2
    covest=hess;
  id id;
run;

```

Output 17.1.2 Binary Logit Estimates

The MDC Procedure					
Conditional Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
choice2	1	-13.0213	4.9313	-2.64	0.0083
gpa_2	1	2.8261	1.2629	2.24	0.0252
tuce_2	1	0.0952	0.1416	0.67	0.5014
psi_2	1	2.3787	1.0646	2.23	0.0255

Consider the choice probability of the multinomial probit model:

$$P_i(j) = P[\epsilon_{i1} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{i1})'\boldsymbol{\beta}, \dots, \epsilon_{iJ} - \epsilon_{ij} < (\mathbf{x}_{iJ} - \mathbf{x}_{ij})'\boldsymbol{\beta}]$$

The probabilities of choice of the two alternatives can be written as

$$P_i(1) = P[\epsilon_{i2} - \epsilon_{i1} < (\mathbf{x}_{i1} - \mathbf{x}_{i2})'\boldsymbol{\beta}]$$

$$P_i(2) = P[\epsilon_{i1} - \epsilon_{i2} < (\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta}]$$

where $\begin{bmatrix} \epsilon_{i1} \\ \epsilon_{i2} \end{bmatrix} \sim N\left(\mathbf{0}, \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{12} & \sigma_2^2 \end{bmatrix}\right)$. Assume that $\mathbf{x}_{i1} = 0$ and $\sigma_{12} = 0$. The binary probit model is estimated and displayed in [Output 17.1.3](#). You do not get the same estimates as that of the usual binary probit model. The probabilities of choice in the binary probit model are

$$P_i(2) = P[\epsilon_i < \mathbf{x}'_i \boldsymbol{\beta}]$$

$$P_i(1) = 1 - P[\epsilon_i < \mathbf{x}'_i \boldsymbol{\beta}]$$

where $\epsilon_i \sim N(0, 1)$. However, the multinomial probit model has the error variance $\text{Var}(\epsilon_{i2} - \epsilon_{i1}) = \sigma_1^2 + \sigma_2^2$ if ϵ_{i1} and ϵ_{i2} are independent ($\sigma_{12} = 0$). In the following statements, unit variance restrictions are imposed on choices 1 and 2 ($\sigma_1^2 = \sigma_2^2 = 1$). Therefore, the usual binary probit estimates (and standard errors) can be obtained by multiplying the multinomial probit estimates (and standard errors) in [Output 17.1.3](#) by $1/\sqrt{2}$.

```

/*-- Multinomial Probit --*/
proc mdc data=smdatal;
  model decision = choice2 gpa_2 tuce_2 psi_2 /
    type=mprobit
    nchoice=2
    covest=hess
    unitvariance=(1 2);
  id id;
run;

```

Output 17.1.3 Binary Probit Estimates

The MDC Procedure					
Multinomial Probit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
choice2	1	-10.5392	3.5956	-2.93	0.0034
gpa_2	1	2.2992	0.9813	2.34	0.0191
tuce_2	1	0.0732	0.1186	0.62	0.5375
psi_2	1	2.0171	0.8415	2.40	0.0165

Example 17.2: Conditional Logit and Data Conversion

In this example, data are prepared for use by the MDCDATA statement. Sometimes, choice-specific information is stored in multiple variables. Since the MDC procedure requires multiple observations for each decision maker, you need to arrange the data so that there is an observation for each subject-alternative (or individual-choice) combination. Simple binary choice data are obtained from Ben-Akiva and Lerman (1985). The following statements create the SAS data set:

```

data travel;
  length mode $ 8;
  input auto transit mode $;
datalines;
52.9  4.4 Transit
4.1   28.5 Transit
4.1   86.9 Auto
56.2  31.6 Transit
51.8  20.2 Transit
0.2   91.2 Auto
27.6  79.7 Auto
89.9  2.2  Transit
41.5  24.5 Transit
95.0  43.5 Transit

... more lines ...

```

The travel time is stored in two variables, auto and transit. In addition, the chosen alternatives are stored in a character variable, mode. The choice variable, mode, is converted to a numeric variable, decision, since the MDC procedure supports only numeric variables. The following statements convert the original data set, travel, and estimate the binary logit model. The first 10 observations of a relevant subset of the new data set and the parameter estimates are displayed in [Output 17.2.1](#) and [Output 17.2.2](#), respectively.

```

data new;
  set travel;
  retain id 0;
  id+1;
  /*-- create auto variable --*/
  decision = (upcase(mode) = 'AUTO');
  ttime = auto;
  autodum = 1;
  trandum = 0;
  output;
  /*-- create transit variable --*/
  decision = (upcase(mode) = 'TRANSIT');
  ttime = transit;
  autodum = 0;
  trandum = 1;
  output;
run;
proc print data=new(obs=10);
  var decision autodum trandum ttime;
  id id;
run;

```

Output 17.2.1 Converted Data

id	decision	autodum	trandum	ttime
1	0	1	0	52.9
1	1	0	1	4.4
2	0	1	0	4.1
2	1	0	1	28.5
3	1	1	0	4.1
3	0	0	1	86.9
4	0	1	0	56.2
4	1	0	1	31.6
5	0	1	0	51.8
5	1	0	1	20.2

The following statements perform the binary logit estimation.

```
proc mdc data=new;
  model decision = autodum ttime /
    type=clogit
    nchoice=2;
  id id;
run;
```

Output 17.2.2 Binary Logit Estimation of Modal Choice Data

The MDC Procedure					
Conditional Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
autodum	1	-0.2376	0.7505	-0.32	0.7516
ttime	1	-0.0531	0.0206	-2.57	0.0101

In order to handle more general cases, you can use the MDCDATA statement. Choice-specific dummy variables are generated and multiple observations for each individual are created. The following example converts the original data set travel by using the MDCDATA statement and performs conditional logit analysis. Interleaved data are output into the new data set new3. This data set has twice as many observations as the original travel data set.

```
proc mdc data=travel;
  mdcdata varlist( x1 = (auto transit) )
    select=mode
    id=id
    alt=alternative
    decvar=Decision / out=new3;
  model decision = auto x1 /
    nchoice=2
```

```

                                type=clogit;
    id id;
run;

```

The first nine observations of the modified data set are shown in [Output 17.2.3](#). The result of the preceding program is listed in [Output 17.2.4](#).

Output 17.2.3 Transformed Model Choice Data

Obs	MODE	AUTO	TRANSIT	X1	ID	ALTERNATIVE	DECISION
1	TRANSIT	1	0	52.9	1	1	0
2	TRANSIT	0	1	4.4	1	2	1
3	TRANSIT	1	0	4.1	2	1	0
4	TRANSIT	0	1	28.5	2	2	1
5	AUTO	1	0	4.1	3	1	1
6	AUTO	0	1	86.9	3	2	0
7	TRANSIT	1	0	56.2	4	1	0
8	TRANSIT	0	1	31.6	4	2	1
9	TRANSIT	1	0	51.8	5	1	0

Output 17.2.4 Results Using MDCDATA Statement

The MDC Procedure					
Conditional Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t

X1	1	-0.0531	0.0206	-2.57	0.0101

Example 17.3: Correlated Choice Modeling

Often, it is not realistic to assume that the random components of utility for all choices are independent. This example shows the solution to the problem of correlated random components by using multinomial probit and nested logit.

To analyze correlated data, trinomial choice data (1000 observations) are created using a pseudo-random number generator by using the following statements. The random utility function is

$$U_{ij} = V_{ij} + \epsilon_{ij}, \quad j = 1, 2, 3$$

where

$$\epsilon_{ij} \sim N \left(0, \begin{bmatrix} 2 & .6 & 0 \\ .6 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right)$$

```

/*-- generate simulated series --*/
%let ndim = 3;
%let nobs = 1000;

data trichoice;
  array error{&ndim} e1-e3;
  array vtemp{&ndim} _temporary_;
  array lm{6} _temporary_ (1.4142136 0.4242641 0.9055385 0 0 1);
  retain nseed 345678 useed 223344;

  do id = 1 to &nobs;
    index = 0;
    /* generate independent normal variate */
    do i = 1 to &ndim;
      /* index of diagonal element */
      vtemp{i} = rannor(nseed);
    end;
    /* get multivariate normal variate */
    index = 0;
    do i = 1 to &ndim;
      error{i} = 0;
      do j = 1 to i;
        error{i} = error{i} + lm{index+j}*vtemp{j};
      end;
      index = index + i;
    end;
    x1 = 1.0 + 2.0 * ranuni(useed);
    x2 = 1.2 + 2.0 * ranuni(useed);
    x3 = 1.5 + 1.2 * ranuni(useed);
    util1 = 2.0 * x1 + e1;
    util2 = 2.0 * x2 + e2;
    util3 = 2.0 * x3 + e3;
    do i = 1 to &ndim;
      vtemp{i} = 0;
    end;
    if ( util1 > util2 & util1 > util3 ) then
      vtemp{1} = 1;
    else if ( util2 > util1 & util2 > util3 ) then
      vtemp{2} = 1;
    else if ( util3 > util1 & util3 > util2 ) then
      vtemp{3} = 1;
    else continue;
    /*-- first choice --*/
    x = x1;
    mode = 1;
    decision = vtemp{1};
    output;
    /*-- second choice --*/

```

```

x = x2;
mode = 2;
decision = vtemp{2};
output;
/*-- third choice --*/
x = x3;
mode = 3;
decision = vtemp{3};
output;
end;
run;

```

First, the multinomial probit model is estimated (see the following program). Results show that standard deviation, correlation, and slope estimates are close to the parameter values. Note that $\rho_{12} = \frac{\sigma_{12}}{\sqrt{(\sigma_1^2)(\sigma_2^2)}} = \frac{0.6}{\sqrt{(2)(1)}} = 0.42$, $\sigma_1 = \sqrt{2} = 1.41$, $\sigma_2 = \sqrt{1} = 1$, and the parameter value for the variable x is 2.0. (See [Output 17.3.1](#).)

```

/*-- Trinomial Probit --*/
proc mdc data=trichoice randnum=halton nsimul=100;
  model decision = x /
    type=mprobit
    choice=(mode 1 2 3)
    covest=op
    optmethod=qn;
  id id;
run;

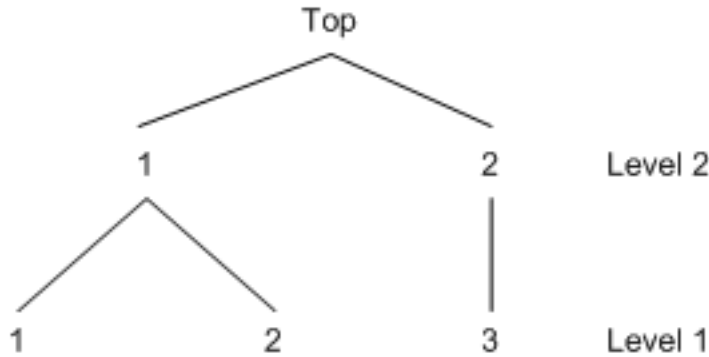

```

Output 17.3.1 Trinomial Probit Model Estimation

The MDC Procedure					
Multinomial Probit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
x	1	1.7987	0.1202	14.97	<.0001
STD_1	1	1.2824	0.1468	8.74	<.0001
RHO_21	1	0.4233	0.1041	4.06	<.0001

The nested model is also estimated based on a two-level decision tree (see the following program). (See [Output 17.3.2](#).) The estimated result (see [Output 17.3.3](#)) shows that the data support the nested tree model since the estimates of the inclusive value parameters are significant and are less than 1.

Output 17.3.2 Nested Tree Structure

```

/*-- Two-Level Nested Logit --*/
proc mdc data=trichoice;
  model decision = x /
    type=nlogit
    choice=(mode 1 2 3)
    covest=op
    optmethod=qn;

  id id;
  utility u(1,) = x;
  nest level(1) = (1 2 @ 1, 3 @ 2),
    level(2) = (1 2 @ 1);
run;

```

Output 17.3.3 Two-Level Nested Logit

The MDC Procedure					
Nested Logit Estimates					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
x_L1	1	2.6672	0.1978	13.48	<.0001
INC_L2G1C1	1	0.7911	0.0832	9.51	<.0001
INC_L2G1C2	1	0.7965	0.0921	8.65	<.0001

Example 17.4: Testing for Homoscedasticity of the Utility Function

The conditional logit model imposes equal variances on random components of utility of all alternatives. This assumption can often be too restrictive and the calculated results misleading. This example shows several approaches to testing the homoscedasticity assumption.

The section “Getting Started: MDC Procedure” on page 871 analyzes an HEV model by using

Daganzo's trinomial choice data and displays the HEV parameter estimates in [Figure 17.15](#). The inverted scale estimates for mode "2" and mode "3" suggest that the conditional logit model (which imposes equal variances on random components of utility of all alternatives) might be misleading. The HEV estimation summary from that analysis is repeated in [Output 17.4.1](#).

Output 17.4.1 HEV Estimation Summary ($\theta_1 = 1$)

Model Fit Summary	
Dependent Variable	decision
Number of Observations	50
Number of Cases	150
Log Likelihood	-33.41383
Maximum Absolute Gradient	0.0000218
Number of Iterations	11
Optimization Method	Dual Quasi-Newton
AIC	72.82765
Schwarz Criterion	78.56372

You can estimate the HEV model with unit scale restrictions on all three alternatives ($\theta_1 = \theta_2 = \theta_3 = 1$) with the following statements. [Output 17.4.2](#) displays the estimation summary.

```

/*-- HEV Estimation --*/
proc mdc data=newdata;
  model decision = ttime /
    type=hev
    nchoice=3
    hev=(unitscale=1 2 3, integrate=laguerre)
    covest=hess;
  id pid;
run;

```

Output 17.4.2 HEV Estimation Summary ($\theta_1 = \theta_2 = \theta_3 = 1$)

The MDC Procedure	
Heteroscedastic Extreme Value Model Estimates	
Model Fit Summary

Optimization Method	Dual Quasi-Newton
AIC	70.25512
Schwarz Criterion	72.16714

The test for scale equivalence (SCALE2=SCALE3=1) is performed using a likelihood ratio test statis-

tic. The following SAS statements compute the test statistic (1.4276) and its p -value (0.4898) from the log-likelihood values in [Figure 17.4.1](#) and [Figure 17.4.2](#):

```
data _null_;
  /*-- test for H0: scale2 = scale3 = 1 --*/
  /* ln L(max) = -34.1276 */
  /* ln L(0) = -33.4138 */
  stat = -2 * ( - 34.1276 + 33.4138 );
  df = 2;
  p_value = 1 - probchi(stat, df);
  put stat= p_value=;
run;
```

The test statistic fails to reject the null hypothesis of equal scale parameters, which implies that the random utility function is homoscedastic.

A multinomial probit model also allows heteroscedasticity of the random components of utility for different alternatives. Consider the following utility function:

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where

$$\epsilon_i \sim N \left(\mathbf{0}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \sigma_3^2 \end{bmatrix} \right)$$

This multinomial probit model is estimated by using the following program. The estimation summary is displayed in [Output 17.4.3](#).

```
/*-- Heteroscedastic Multinomial Probit --*/
proc mdc data=newdata;
  model decision = ttime /
    type=mprobit
    nchoice=3
    unitvariance=(1 2)
    covest=hess;
  id pid;
  restrict RHO_31 = 0;
run;
```

The test for homoscedasticity ($\sigma_3 = 1$) under $\sigma_1 = \sigma_2 = 1$ shows that the error variance is not heteroscedastic since the test statistic (1.313) is less than $\chi_{0.05,1}^2 = 3.84$. The marginal probability or p -value computed in the following program from the PROBCHI function is 0.2519.

```
data _null_;
  /*-- test for H0: sigma3 = 1 --*/
  /* ln L(max) = -33.8860 */
  /* ln L(0) = -34.5425 */
  stat = -2 * ( -34.5425 + 33.8860 );
  df = 1;
  p_value = 1 - probchi(stat, df);
  put stat= p_value=;
run;
```

Example 17.5: Choice of Time for Work Trips: Nested Logit Analysis

This example uses sample data of 527 automobile commuters in the San Francisco Bay Area to demonstrate the use of nested logit model.

Brownstone and Small (1989) analyzed a two-level nested logit model displayed in [Output 17.5.1](#). The probability of choosing j at level 2 is written as

$$P_i(j) = \frac{\exp(\tau_j I_j)}{\sum_{j'=1}^3 \exp(\tau_{j'} I_{j'})}$$

where $I_{j'}$ is an inclusive value and is computed as

$$I_{j'} = \ln \left[\sum_{k' \in C_{j'}} \exp(\mathbf{x}'_{ik'} \boldsymbol{\beta}) \right]$$

The probability of choosing an alternative k is denoted as

$$P_i(k|j) = \frac{\exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}{\sum_{k' \in C_j} \exp(\mathbf{x}'_{ik'}\boldsymbol{\beta})}$$

The full information maximum likelihood (FIML) method maximizes the following log-likelihood function:

$$\mathcal{L} = \sum_{i=1}^N \sum_{j=1}^J d_{ij} [\ln(P_i(k|j)) + \ln(P_i(j))]$$

where $d_{ij} = 1$ if a decision maker i chooses j , and 0 otherwise.

Output 17.5.1 Decision Tree for Two-Level Nested Logit

Sample data of 527 automobile commuters in the San Francisco Bay Area have been analyzed by Small (1982) and Brownstone and Small (1989). The regular time of arrival is recorded as between 42.5 minutes early and 17.5 minutes late, and indexed by 12 alternatives, using five-minute interval groups. Refer to Small (1982) for more details on these data.

The following statements estimate the two-level nested logit model:

```

/*-- Two-level Nested Logit --*/
proc mdc data=small maxit=200 outest=a;
  model decision = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21 /
  type=nlogit
  choice=(alt);

  id id;
  utility u(1, ) = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21;
  nest level(1) = (1 2 3 4 5 6 7 8 @ 1, 9 @ 2, 10 11 12 @ 3),
                 level(2) = (1 2 3 @ 1);
run;
  
```

The estimation summary, discrete response profile, and the FIML estimates are displayed in [Output 17.5.2](#) through [Output 17.5.4](#).

  df = 2;
  p_value = 1 - probchi(stat, df);
  put stat= p_value=;
```

```
run;
```

Example 17.6: Hausman's Specification and Likelihood Ratio Tests

Hausman's Specification Test

As discussed under multinomial and conditional logits (see the section “[Multinomial Logit and Conditional Logit](#)” on page 904), the odds ratios in the multinomial or conditional logits are independent of the other alternatives. This property of the logit models is often viewed as rather restrictive and provides substitution patterns that do not represent the actual relationship among choice alternatives.

This independence assumption, called Independence of Irrelevant Alternatives (IIA), can be tested with Hausman's specification test. According to Hausman and McFadden (1984), if a subset of choice alternatives is irrelevant, it can be omitted from the sample without changing the remaining parameters systematically.

Under the null hypothesis (IIA holds), omitting the irrelevant alternatives will lead to consistent and efficient parameter estimates β_R , while parameter estimates β_U from the unrestricted model will be consistent but inefficient. Under the alternative, only the parameter estimates β_U obtained from the unrestricted model will be consistent.

This example demonstrates the use of Hausman's specification test to analyze the IIA assumption and decide on an appropriate model providing less restrictive substitution patterns (nested logit, multinomial probit). A sample data set of 527 automobile commuters in the San Francisco Bay Area is used (Small 1982). The regular time of arrival is recorded as between 42.5 minutes early and 17.5 minutes late, and indexed by 12 alternatives, using five-minute interval groups. Refer to Small (1982) for more details on these data.

Naturally, the data can be divided into three groups: commuters arriving early (alternatives 1 – 8), commuters arriving on time (alternative 9), and commuters arriving late (alternatives 10 – 12). Suppose that we want to test whether the IIA assumption holds for commuters who arrived on time (alternative 9).

Hausman's specification test is distributed as χ^2 with k degrees of freedom (equal to the number of independent variables) and can be written as

$$\chi^2 = (\hat{\beta}_U - \hat{\beta}_R)'[\hat{V}_U - \hat{V}_R]^{-1}(\hat{\beta}_U - \hat{\beta}_R)$$

where $\hat{\beta}_R$ and \hat{V}_R represent parameter estimates and variance-covariance matrix from the model where the ninth alternative was omitted, and $\hat{\beta}_U$ and \hat{V}_U represent parameter estimates and variance-covariance matrix from the full model. The following macro can be used to perform the IIA test for the ninth alternative.

```
/*-----
* name: %IIA
* note: This macro test the IIA hypothesis using the Hausman's
*       specification test. Inputs into the macro are as follows:
```

```

*      indata:    input data set
*      varlist:   list of RHS variables
*      nchoice:  number of choices for each individual
*      choice:    list of choices
*      nvar:      number of dependent variables
*      nIIA:      number of choice alternatives used to test IIA
*      IIA:       choice alternatives used to test IIA
*      id:        ID variable
*      decision:  0-1 LHS variable representing nchoice choices
* purpose: Hausman's specification test
*-----*/

%macro IIA(indata=, varlist=, nchoice=, choice= , nvar= , IIA= ,
          nIIA=, id= , decision=);

  %let n=%eval(&nchoice-&nIIA);

  proc mdc data=&indata outest=cov covout ;
    model &decision = &varlist /
          type=clogit
          nchoice=&nchoice;
    id &id;
    run;

  data two;
    set &indata;
    if &choice in &IIA and &decision=1 then output;
  run;

  data two;
    set two;
    keep &id ind;
    ind=1;
  run;

  data merged;
    merge &indata two;
    by &id;
    if ind=1 or &choice in &IIA then delete;
  run;

  proc mdc data=merged outest=cov2 covout ;
    model &decision = &varlist /
          type=clogit
          nchoice=&n;

    id &id;
    run;

  proc IML;
    use cov var{&_TYPE_ &varlist};
    read first into BetaU;
    read all into CovVarU where(&_TYPE_='COV');
    close cov;

```

```

use cov2 var{ _TYPE_ &varlist };
  read first into BetaR;
  read all into CovVarR where( _TYPE_='COV' );
close cov;

tmp = BetaU-BetaR;
ChiSq=tmp*ginv(CovVarR-CovVarU)*tmp`;
if ChiSq<0 then ChiSq=0;
Prob=1-Probchi(ChiSq, &nvar);
Print "Hausman Test for IIA for Variable &IIA";
Print ChiSq Prob;
run; quit;

%mend IIA;

```

The following statement invokes the %IIA macro to test IIA for commuters arriving on time:

```

%IIA( indata=small,
      varlist=r15 r10 ttime ttime_cp sde sde_cp sdl sdlx d21,
      nchoice=12,
      choice=alt,
      nvar=9,
      nIIA=1,
      IIA=(9),
      id=id,
      decision=decision );

```

The obtained χ^2 of 7.9 and the p -value of 0.54 indicate that IIA does not hold for commuters arriving on time (alternative 9). In this case the following model (nested logit), which reserves a subcategory for alternative 9, might be more appropriate ([Output 17.5.1](#)):

```

proc mdc data=small maxit=200 outest=a;
  model decision = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21 /
         type=nlogit
         choice=(alt);
  id id;
  utility u(1, ) = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21;
  nest level(1) = (1 2 3 4 5 6 7 8 @ 1, 9 @ 2, 10 11 12 @ 3),
        level(2) = (1 2 3 @ 1);
run;

```

Similarly, IIA could be tested for commuters arriving approximately on time (alternative 8, 9, 10), as follows:

```

%IIA( indata=small,
      varlist=r15 r10 ttime ttime_cp sde sde_cp sdl sdlx d21,
      nchoice=12,
      choice=alt,
      nvar=9,
      nIIA=3,
      IIA=(8 9 10),

```

```
id=id,
decision=decision );
```

Based on this test, independence of irrelevant alternatives is rejected for this subgroup ($\chi^2 = 10.3$), and it is concluded that these three alternatives are not independent from the other nine alternatives. This finding provides a partial justification for another nested logit model, with commuters arriving approximately on time being in one subcategory.

Likelihood Ratio Test

Another specification test that can be performed is the likelihood ratio test (LR). Suppose we are interested in testing whether the nested logit model (Output 17.5.1) with three subgroups representing commuters arriving early, on time, and late is more appropriate than the standard multinomial logit. This can be done by running two logit models and calculating the LR test as follows. First, run the unrestricted nested logit model.

```
/*-- Unrestricted Nested Logit --*/
proc mdc data=small maxit=200 outest=a;
  model decision = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21 /
         type=nlogit
         choice=(alt);
  id id;
  utility u(1, ) = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21;
  nest level(1) = (1 2 3 4 5 6 7 8 @ 1, 9 @ 2, 10 11 12 @ 3),
        level(2) = (1 2 3 @ 1);
run;
```

Second, run the restricted model with inclusive value parameters constrained to one. This model, with a restriction on inclusive value parameters, is equal to the standard multinomial logit.

```
/*-- Restricted Model with Inclusive Value Parameters
   Constrained to One --*/
proc mdc data=small maxit=200 outest=a;
  model decision = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21 /
         type=nlogit
         choice=(alt);
  id id;
  utility u(1, ) = r15 r10 ttime ttime_cp sde sde_cp
                 sdl sdlx d21;
  nest level(1) = (1 2 3 4 5 6 7 8 @ 1, 9 @ 2, 10 11 12 @ 3),
        level(2) = (1 2 3 @ 1);
  restrict INC_L2G1C1=1, INC_L2G1C2=1, INC_L2G1C3=1;
run;
```

The likelihood ratio test is distributed as χ^2 with degrees of freedom equal to number of restrictions imposed:

$$\chi^2 = 2 * (\text{Log} \hat{L}_U - \text{Log} \hat{L}_R)$$

where $\text{Log}\hat{L}_U$ represents the log of unrestricted likelihood and $\text{Log}\hat{L}_R$ is the log of restricted likelihood at the optimized solution. Unrestricted and restricted log-likelihood values can be found in the “Model Fit Summary” table (see [Output 17.5.5](#)). Calculating the LR, test we conclude that nested logit is a more appropriate model. The LR test can be used to test other types of restrictions in the nested logit setting as long as one model can be nested within another.

Acknowledgments: MDC Procedure

Professor Kenneth Small provided the work trip data that are used in the “Examples” section. These data were collected for the urban travel demand forecasting project, which was carried out by McFadden, Talvitie, and Associates (1977). The project was supported by the National Science Foundation, Research Applied to National Needs Program through grants GI-43740 and APR74-20392, and the Alfred P. Sloan Foundation, through grant 74-21-8.

Overview: MODEL Procedure

The MODEL procedure analyzes models in which the relationships among the variables comprise a system of one or more nonlinear equations. Primary uses of the MODEL procedure are estimation, simulation, and forecasting of nonlinear simultaneous equation models.

PROC MODEL features include the following:

- SAS programming statements to define simultaneous systems of nonlinear equations
- tools to analyze the structure of the simultaneous equation system
- ARIMA, PDL, and other dynamic modeling capabilities
- tools to specify and estimate the error covariance structure
- tools to estimate and solve ordinary differential equations

- the following methods for parameter estimation:
 - ordinary least squares (OLS)
 - two-stage least squares (2SLS)
 - seemingly unrelated regression (SUR) and iterative SUR (ITSUR)
 - three-stage least squares (3SLS) and iterative 3SLS (IT3SLS)
 - generalized method of moments (GMM)
 - simulated method of moments (SMM)
 - full information maximum likelihood (FIML)
 - general log-likelihood maximization
- simulation and forecasting capabilities
- Monte Carlo simulation
- goal-seeking solutions

ODS Graphics is now available with the MODEL procedure. For more information, see the section “[ODS Graphics](#)” on page 1115.

A system of equations can be nonlinear in the parameters, nonlinear in the observed variables, or nonlinear in both the parameters and the variables. *Nonlinear* in the parameters means that the mathematical relationship between the variables and parameters is not required to have a linear form. (A linear model is a special case of a nonlinear model.) A general nonlinear system of equations can be written as

$$\begin{aligned}
 q_1(y_{1,t}, y_{2,t}, \dots, y_{g,t}, x_{1,t}, x_{2,t}, \dots, x_{m,t}, \theta_1, \theta_2, \dots, \theta_p) &= \epsilon_{1,t} \\
 q_2(y_{1,t}, y_{2,t}, \dots, y_{g,t}, x_{1,t}, x_{2,t}, \dots, x_{m,t}, \theta_1, \theta_2, \dots, \theta_p) &= \epsilon_{2,t} \\
 &\vdots \\
 q_g(y_{1,t}, y_{2,t}, \dots, y_{g,t}, x_{1,t}, x_{2,t}, \dots, x_{m,t}, \theta_1, \theta_2, \dots, \theta_p) &= \epsilon_{g,t}
 \end{aligned}$$

where $y_{i,t}$ is an endogenous variable, $x_{i,t}$ is an exogenous variable, θ_i is a parameter, and ϵ_i is the unknown error. The subscript t represents time or some index to the data.

In econometrics literature, the observed variables are either *endogenous* (dependent) variables or *exogenous* (independent) variables. This system can be written more succinctly in vector form as

$$\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) = \boldsymbol{\epsilon}_t$$

This system of equations is in *general form* because the error term is by itself on one side of the equality. Systems can also be written in *normalized form* by placing the endogenous variable on one side of the equality, with each equation defining a predicted value for a unique endogenous variable. A normalized form equation system can be written in vector notation as

$$\mathbf{y}_t = \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) + \boldsymbol{\epsilon}_t.$$

PROC MODEL handles equations written in both forms.

Econometric models often explain the current values of the endogenous variables as functions of past values of exogenous and endogenous variables. These past values are referred to as *lagged* values, and the variable x_{t-i} is called lag i of the variable x_t . Using lagged variables, you can create a *dynamic*, or time-dependent, model. In the preceding model systems, the lagged exogenous and endogenous variables are included as part of the exogenous variables.

If the data are time series, so that t indexes time (see Chapter 3, “[Working with Time Series Data](#),” for more information on time series), it is possible that ϵ_t depends on ϵ_{t-i} or, more generally, the ϵ_t 's are not identically and independently distributed. If the errors of a model system are autocorrelated, the standard error of the estimates of the parameters of the system will be inflated.

Sometimes the ϵ_i 's are not identically distributed because the variance of ϵ is not constant. This is known as *heteroscedasticity*. Heteroscedasticity in an estimated model can also inflate the standard error of the estimates of the parameters. Using a weighted estimation can sometimes eliminate this problem. Alternately, a variance model such as GARCH or EGARCH can be estimated to correct for heteroscedasticity. If the proper weighting scheme and the form of the error model is difficult to determine, generalized methods of moments (GMM) estimation can be used to determine parameter estimates with very few assumptions about the form of the error process.

Other problems can also arise when estimating systems of equations. Consider the following system of equations, which is nonlinear in its parameters and cannot be estimated with linear regression:

$$\begin{aligned} y_{1,t} &= \theta_1 + (\theta_2 + \theta_3\theta_4^t)^{-1} + \theta_5 y_{2,t} + \epsilon_{1,t} \\ y_{2,t} &= \theta_6 + (\theta_7 + \theta_8\theta_9^t)^{-1} + \theta_{10} y_{1,t} + \epsilon_{2,t} \end{aligned}$$

This system of equations represents a rudimentary predator-prey process with y_1 as the prey and y_2 as the predator (the second term in both equations is a logistics curve). The two equations must be estimated simultaneously because of the cross-dependency of y 's. This cross-dependency makes ϵ_1 and ϵ_2 violate the assumption of independence. Nonlinear ordinary least squares estimation of these equations produce biased and inconsistent parameter estimates. This is called *simultaneous equation bias*.

One method to remove simultaneous equation bias, in the linear case, is to replace the endogenous variables on the right-hand side of the equations with predicted values that are uncorrelated with the error terms. These predicted values can be obtained through a preliminary, or “first-stage,” *instrumental variable regression*. *Instrumental variables*, which are uncorrelated with the error term, are used as regressors to model the predicted values. The parameter estimates are obtained by a second regression by using the predicted values of the regressors. This process is called *two-stage least squares*.

In the nonlinear case, nonlinear ordinary least squares estimation is performed iteratively by using a linearization of the model with respect to the parameters. The instrumental solution to simultaneous equation bias in the nonlinear case is the same as the linear case, except the linearization of the model with respect to the parameters is predicted by the instrumental regression. Nonlinear two-stage least squares is one of several instrumental variables methods available in the MODEL procedure to handle simultaneous equation bias.

When you have a system of several regression equations, the random errors of the equations can

be correlated. In this case, the large-sample efficiency of the estimation can be improved by using a joint generalized least squares method that takes the cross-equation correlations into account. If the equations are not simultaneous (no dependent regressors), then *seemingly unrelated regression* (SUR) can be used. The SUR method requires an estimate of the cross-equation error covariance matrix, Σ . The usual approach is to first fit the equations by using OLS, compute an estimate $\hat{\Sigma}$ from the OLS residuals, and then perform the SUR estimation based on $\hat{\Sigma}$. The MODEL procedure estimates Σ by default, or you can supply your own estimate of Σ .

If the equation system is simultaneous, you can combine the 2SLS and SUR methods to take into account both simultaneous equation bias and cross-equation correlation of the errors. This is called *three-stage least squares* or 3SLS.

A different approach to the simultaneous equation bias problem is the full information maximum likelihood (FIML) estimation method. FIML does not require instrumental variables, but it assumes that the equation errors have a multivariate normal distribution. 2SLS and 3SLS estimation do not assume a particular distribution for the errors.

Other nonnormal error distribution models can be estimated as well. The centered t distribution with estimated degrees of freedom and nonconstant variance is an additional built-in likelihood function. If the distribution of the equation errors is not normal or t but known, then the log likelihood can be specified by using the ERRORMODEL statement.

Once a nonlinear model has been estimated, it can be used to obtain forecasts. If the model is linear in the variables you want to forecast, a simple linear solve can generate the forecasts. If the system is nonlinear, an iterative procedure must be used. The preceding example system is linear in its endogenous variables. The MODEL procedure's SOLVE statement is used to forecast nonlinear models.

One of the main purposes of creating models is to obtain an understanding of the relationship among the variables. There are usually only a few variables in a model you can control (for example, the amount of money spent on advertising). Often you want to determine how to change the variables under your control to obtain some target goal. This process is called *goal seeking*. PROC MODEL allows you to solve for any subset of the variables in a system of equations given values for the remaining variables.

The nonlinearity of a model creates two problems with the forecasts: the forecast errors are not normally distributed with zero mean, and no formula exists to calculate the forecast confidence intervals. PROC MODEL provides Monte Carlo techniques, which, when used with the covariance of the parameters and error covariance matrix, can produce approximate error bounds on the forecasts. The following distributions on the errors are supported for multivariate Monte Carlo simulation:

- Cauchy
- chi-squared
- empirical
- F
- Poisson
- t

- uniform

A transformation technique is used to create a covariance matrix for generating the correct innovations in a Monte Carlo simulation.

Getting Started: MODEL Procedure

This section introduces the MODEL procedure and shows how to use PROC MODEL for several kinds of nonlinear regression analysis and nonlinear systems simulation problems.

Nonlinear Regression Analysis

One of the most important uses of PROC MODEL is to estimate unknown parameters in a nonlinear model. A simple nonlinear model has the form:

$$y = f(\mathbf{x}, \boldsymbol{\theta}) + \epsilon$$

where \mathbf{x} is a vector of exogenous variables. To estimate unknown parameters by using PROC MODEL, do the following:

1. Use the DATA= option in a PROC MODEL statement to specify the input SAS data set that contains \mathbf{y} and \mathbf{x} , the observed values of the variables.
2. Write the equation for the model by using SAS programming statements, including all parameters and arithmetic operators but leaving off the unobserved error component, ϵ .
3. Use a FIT statement to fit the model equation to the input data to determine the unknown parameters, $\boldsymbol{\theta}$.

An Example

The SASHELP library contains the data set CITIMON, which contains the variable LHUR, the monthly unemployment figures, and the variable IP, the monthly industrial production index. You suspect that the unemployment rates are inversely proportional to the industrial production index. Assume that these variables are related by the following nonlinear equation:

$$lhur = \frac{1}{a \cdot ip + b} + c + \epsilon$$

In this equation a , b , and c are unknown coefficients and ϵ is an unobserved random error.

The following statements illustrate how to use PROC MODEL to estimate values for a , b , and c from the data in SASHELP.CITIMON.

```

proc model data=sashelp.citimon;
  lhur = 1/(a * ip + b) + c;
  fit lhur;
run;

```

Notice that the model equation is written as a SAS assignment statement. The variable LHUR is assumed to be the dependent variable because it is named in the FIT statement and is on the left-hand side of the assignment.

PROC MODEL determines that LHUR and IP are observed variables because they are in the input data set. A, B, and C are treated as unknown parameters to be estimated from the data because they are not in the input data set. If the data set contained a variable named A, B, or C, you would need to explicitly declare the parameters with a PARMS statement.

In response to the FIT statement, PROC MODEL estimates values for A, B, and C by using non-linear least squares and prints the results. The first part of the output is a “Model Summary” table, shown in [Figure 18.1](#).

Figure 18.1 Model Summary Report

The MODEL Procedure	
Model Summary	
Model Variables	1
Parameters	3
Equations	1
Number of Statements	1
Model Variables	LHUR
Parameters	a b c
Equations	LHUR

This table details the size of the model, including the number of programming statements that define the model, and lists the dependent variables (LHUR in this case), the unknown parameters (A, B, and C), and the model equations. In this case the equation is named for the dependent variable, LHUR.

PROC MODEL then prints a summary of the estimation problem, as shown in [Figure 18.2](#).

Figure 18.2 Estimation Problem Report

The Equation to Estimate is
LHUR = F(a, b, c(1))

The notation used in the summary of the estimation problem indicates that LHUR is a function of A, B, and C, which are to be estimated by fitting the function to the data. If the partial derivative of the equation with respect to a parameter is a simple variable or constant, the derivative is shown in

parentheses after the parameter name. In this case, the derivative with respect to the intercept C is 1. The derivatives with respect to A and B are complex expressions and so are not shown.

Next, PROC MODEL prints an estimation summary as shown in [Figure 18.3](#).

Figure 18.3 Estimation Summary Report

The MODEL Procedure	
OLS Estimation Summary	
Data Set Options	
DATA=	SASHELP.CITIMON
Minimization Summary	
Parameters Estimated	3
Method	Gauss
Iterations	10
Final Convergence Criteria	
R	0.000737
PPC (b)	0.003943
RPC (b)	0.00968
Object	4.784E-6
Trace (S)	0.533325
Objective Value	0.522214
Observations Processed	
Read	145
Solved	145
Used	144
Missing	1

The estimation summary provides information on the iterative process used to compute the estimates. The heading “OLS Estimation Summary” indicates that the nonlinear ordinary least squares (OLS) estimation method is used. This table indicates that all three parameters were estimated successfully by using 144 nonmissing observations from the data set SASHELP.CITIMON. Calculating the estimates required 10 iterations of the GAUSS method. Various measures of how well the iterative process converged are also shown. For example, the “RPC(B)” value 0.00968 means that on the final iteration the largest relative change in any estimate was for parameter B, which changed by 0.968 percent. See the section “[Convergence Criteria](#)” on page 1028 for details.

PROC MODEL then prints the estimation results. The first part of this table is the summary of residual errors, shown in [Figure 18.4](#).

Figure 18.4 Summary of Residual Errors Report

The MODEL Procedure						
Nonlinear OLS Summary of Residual Errors						
Equation	DF Model	DF Error	SSE	MSE	R-Square	Adj R-Sq
LHUR	3	141	75.1989	0.5333	0.7472	0.7436

This table lists the sum of squared errors (SSE), the mean squared error (MSE), the root mean squared error (root MSE), and the R^2 and adjusted R^2 statistics. The R^2 value of 0.7472 means that the estimated model explains approximately 75 percent more of the variability in LHUR than a mean model explains.

Following the summary of residual errors is the parameter estimates table, shown in [Figure 18.5](#).

Figure 18.5 Parameter Estimates

Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
a	0.009046	0.00343	2.63	0.0094
b	-0.57059	0.2617	-2.18	0.0309
c	3.337151	0.7297	4.57	<.0001

Because the model is nonlinear, the standard error of the estimate, the t value, and its significance level are only approximate. These values are computed using asymptotic formulas that are correct for large sample sizes but only approximately correct for smaller samples. Thus, you should use caution in interpreting these statistics for nonlinear models, especially for small sample sizes. For linear models, these results are exact and are the same as standard linear regression.

The last part of the output produced by the FIT statement is shown in [Figure 18.6](#).

Figure 18.6 System Summary Statistics

Number of Observations		Statistics for System	
Used	144	Objective	0.5222
Missing	1	Objective*N	75.1989

This table lists the objective value for the estimation of the nonlinear system. Since there is only a single equation in this case, the objective value is the same as the residual MSE for LHUR except that the objective value does not include a degrees-of-freedom correction. This can be seen in the fact that “Objective*N” equals the residual SSE, 75.1989. N is 144, the number of observations used.

Convergence and Starting Values

Computing parameter estimates for nonlinear equations requires an iterative process. Starting with an initial guess for the parameter values, PROC MODEL tries different parameter values until the objective function of the estimation method is minimized. (The objective function of the estimation method is sometimes called the *fitting function*.) This process does not always succeed, and whether it does succeed depends greatly on the starting values used. By default, PROC MODEL uses the starting value 0.0001 for all parameters.

Consequently, in order to use PROC MODEL to achieve convergence of parameter estimates, you need to know two things: how to recognize convergence failure by interpreting diagnostic output, and how to specify reasonable starting values. The MODEL procedure includes alternate iterative techniques and grid search capabilities to aid in finding estimates. See the section “[Troubleshooting Convergence Problems](#)” on page 1030 for more details.

Nonlinear Systems Regression

If a model has more than one endogenous variable, several facts need to be considered in the choice of an estimation method. If the model has endogenous regressors, then an instrumental variables method such as 2SLS or 3SLS can be used to avoid simultaneous equation bias. Instrumental variables must be provided to use these methods. A discussion of possible choices for instrumental variables is provided in the section “[Choice of Instruments](#)” on page 1084 in this chapter.

The following is an example of the use of 2SLS and the INSTRUMENTS statement:

```
proc model data=test2;
  exogenous x1 x2;
  parms a1 a2 b2 2.5 c2 55 d1;

  y1 = a1 * y2 + b2 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / 2s1s;
  instruments b2 c2 _exog_;
run;
```

The estimation method selected is added after the slash (/) on the FIT statement. The INSTRUMENTS statement follows the FIT statement and in this case selects all the exogenous variables as instruments with the `_EXOG_` keyword. The parameters B2 and C2 in the instruments list request that the derivatives with respect to B2 and C2 be additional instruments.

Full information maximum likelihood (FIML) can also be used to avoid simultaneous equation bias. FIML is computationally more expensive than an instrumental variables method and assumes that the errors are normally distributed. On the other hand, FIML does not require the specification of instruments. FIML is selected with the FIML option on the FIT statement.

The preceding example is estimated with FIML by using the following statements:

```

proc model data=test2;
  exogenous x1 x2;
  parms a1 a2 b2 2.5 c2 55 d1;

  y1 = a1 * y2 + b2 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / fiml;
run;

```

General Form Models

The single equation example shown in the preceding section was written in normalized form and specified as an assignment of the regression function to the dependent variable LHUR. However, sometimes it is impossible or inconvenient to write a nonlinear model in normalized form.

To write a general form equation, give the equation a name with the prefix “EQ.”. This EQ.-prefixed variable represents the equation error. Write the equation as an assignment to this variable.

For example, suppose you have the following nonlinear model that relates the variables x and y :

$$\epsilon = a + b \ln(cy + dx)$$

Naming this equation ‘one’, you can fit this model with the following statements:

```

proc model data=xydata;
  eq.one = a + b * log( c * y + d * x );
  fit one;
run;

```

The use of the EQ. prefix tells PROC MODEL that the variable is an error term and that it should not expect actual values for the variable ONE in the input data set.

Supply and Demand Models

General form specifications are often useful when you have several equations for the same dependent variable. This is common in supply and demand models, where both the supply equation and the demand equation are written as predictions for quantity as functions of price.

For example, consider the following supply and demand system:

$$\begin{aligned} \text{(supply)} \quad & \text{quantity} = \alpha_1 + \alpha_2 \text{ price} + \epsilon_1 \\ \text{(demand)} \quad & \text{quantity} = \beta_1 + \beta_2 \text{ price} + \beta_3 \text{ income} + \epsilon_2 \end{aligned}$$

Assume the *quantity* of interest is the amount of energy consumed in the U.S., the *price* is the price of gasoline, and the *income* variable is the consumer debt. When the market is at equilibrium, these

equations determine the market price and the equilibrium quantity. These equations are written in general form as

$$\epsilon_1 = \text{quantity} - (\alpha_1 + \alpha_2 \text{ price})$$

$$\epsilon_2 = \text{quantity} - (\beta_1 + \beta_2 \text{ price} + \beta_3 \text{ income})$$

Note that the endogenous variables *quantity* and *price* depend on two error terms so that OLS should not be used. The following example uses three-stage least squares estimation.

Data for this model is obtained from the SASHELP.CITIMON data set.

```

title1 'Supply-Demand Model using General-form Equations';
proc model data=sashelp.citimon;
  endogenous eegp eec;
  exogenous exvus cciutc;
  parameters a1 a2 b1 b2 b3 ;
  label eegp   = 'Gasoline Retail Price'
         eec    = 'Energy Consumption'
         cciutc = 'Consumer Debt';

  /* ----- Supply equation ----- */
  eq.supply = eec - (a1 + a2 * eegp );

  /* ----- Demand equation ----- */
  eq.demand = eec - (b1 + b2 * eegp + b3 * cciutc);

  /* ----- Instrumental variables -----*/
  lageegp = lag(eegp); lag2eegp=lag2(eegp);

  /* ----- Estimate parameters ----- */
  fit supply demand / n3sls fsrsq;
  instruments _EXOG_ lageegp lag2eegp;
run;

```

The FIT statement specifies the two equations to estimate and the method of estimation, N3SLS. Note that '3SLS' is an alias for N3SLS. The option FSRSQ is selected to get a report of the first stage R^2 to determine the acceptability of the selected instruments.

Since three-stage least squares is an instrumental variables method, instruments are specified with the INSTRUMENTS statement. The instruments selected are all the exogenous variables, selected with the _EXOG_ option, and two lags of the variable EEGP: LAGEEGP and LAG2EEGP.

The data set CITIMON has four observations that generate missing values because values for EEGP, EEC, or CCIUTC are missing. This is revealed in the "Observations Processed" output shown in [Figure 18.7](#). Missing values are also generated when the equations cannot be computed for a given observation. Missing observations are not used in the estimation.

Figure 18.7 Supply-Demand Observations Processed

Supply-Demand Model using General-form Equations	
The MODEL Procedure	
3SLS Estimation Summary	
Observations Processed	
Read	145
Solved	143
First	3
Last	145
Used	139
Missing	4
Lagged	2

The lags used to create the instruments also reduce the number of observations used. In this case, the first two observations were used to fill the lags of EEGP.

The data set has a total of 145 observations, of which four generated missing values and two were used to fill lags, which left 139 observations for the estimation. In the estimation summary, in [Figure 18.8](#), the total degrees of freedom for the model and error is 139.

Figure 18.8 Supply-Demand Parameter Estimates

Supply-Demand Model using General-form Equations							
The MODEL Procedure							
Nonlinear 3SLS Summary of Residual Errors							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj R-Sq
supply	2	137	43.2677	0.3158	0.5620		
demand	3	136	39.5791	0.2910	0.5395		
Nonlinear 3SLS Parameter Estimates							
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	1st Stage R-Square		
a1	7.30952	0.3799	19.24	<.0001	1.0000		
a2	-0.00853	0.00328	-2.60	0.0103	0.9617		
b1	6.82196	0.3788	18.01	<.0001	1.0000		
b2	-0.00614	0.00303	-2.02	0.0450	0.9617		
b3	9E-7	3.165E-7	2.84	0.0051	1.0000		

One disadvantage of specifying equations in general form is that there are no actual values associated with the equation, so the R^2 statistic cannot be computed.

Solving Simultaneous Nonlinear Equation Systems

You can use a SOLVE statement to solve the nonlinear equation system for some variables when the values of other variables are given.

Consider the supply and demand model shown in the preceding example. The following statement computes equilibrium price (EEGP) and quantity (EEC) values for given observed cost (CCIUTC) values and stores them in the output data set EQUILIB.

```

title1 'Supply-Demand Model using General-form Equations';
proc model data=sashelp.citimon;
  endogenous eegp eec;
  exogenous exvus cciutc;
  parameters a1 a2 a3 b1 b2 ;
  label eegp   = 'Gasoline Retail Price'
         eec   = 'Energy Consumption'
         cciutc = 'Consumer Debt';

  /* ----- Supply equation ----- */
  eq.supply = eec - (a1 + a2 * eegp + a3 * cciutc);

  /* ----- Demand equation ----- */
  eq.demand = eec - (b1 + b2 * eegp );

  /* ----- Instrumental variables -----*/
  lageegp = lag(eegp); lag2eegp=lag2(eegp);

  /* ----- Estimate parameters ----- */
  instruments _EXOG_ lageegp lag2eegp;
  fit supply demand / n3sls ;
  solve eegp eec / out=equilib;
run;

```

As a second example, suppose you want to compute points of intersection between the square root function and hyperbolas of the form $a + b/x$. That is, you want to solve the system:

$$\text{(square root)} \quad y = \sqrt{x}$$

$$\text{(hyperbola)} \quad y = a + \frac{b}{x}$$

The following statements read parameters for several hyperbolas in the input data set TEST and solve the nonlinear equations. The SOLVEPRINT option in the SOLVE statement prints the solution values. The ID statement is used to include the values of A and B in the output of the SOLVEPRINT option.

```

title1 'Solving a Simultaneous System';
data test;
  input a b @@;
datalines;
  0 1   1 1   1 2

```

```

;

proc model data=test;
  eq.sqrt      = sqrt(x) - y;
  eq.hyperbola = a + b / x - y;
  solve x y / solveprint;
  id a b;
run;

```

The printed output produced by this example consists of a model summary report, a listing of the solution values for each observation, and a solution summary report. The model summary for this example is shown in [Figure 18.9](#).

		Iterations	4	CC	0.000000	
Solution Values						
		x	y			
		2.875130	1.695621			

For each observation, a heading line is printed that lists the values of the ID variables for the observation and information about the iterative process used to compute the solution. The number of iterations required, and the convergence measure (labeled CC) are printed. This convergence measure indicates the maximum error by which solution values fail to satisfy the equations. When this error is small enough (as determined by the CONVERGE= option), the iterations terminate. The equation with the largest error is indicated. For example, for observation 3 the HYPERBOLA equation has an error of 4.42×10^{-13} while the error of the SQRT equation is even smaller. Following the heading line for the observation, the solution values are printed.

The last part of the SOLVE statement output is the solution summary report shown in Figure 18.11. This report summarizes the solution method used (Newton's method by default), the iteration history, and the observations processed.

Monte Carlo Simulation

The `RANDOM=` option is used to request Monte Carlo (or stochastic) simulation to generate confidence intervals for a forecast. The confidence intervals are implied by the model's relationship to implicit random error term ϵ and the parameters.

The Monte Carlo simulation generates a random set of additive error values, one for each observation and each equation, and computes one set of perturbations of the parameters. These new parameters, along with the additive error terms, are then used to compute a new forecast that satisfies this new simultaneous system. Then a new set of additive error values and parameter perturbations is computed, and the process is repeated the requested number of times.

Consider the following exchange rate model for the U.S. dollar with the German mark and the Japanese yen:

$$rate_jp = a_1 + b_1 im_jp + c_1 di_jp;$$

$$rate_wg = a_2 + b_2 im_wg + c_1 di_wg;$$

where $rate_jp$ and $rate_wg$ are the exchange rate of the Japanese yen and the German mark versus the U.S. dollar, respectively; im_jp and im_wg are the imports from Japan and Germany in 1984 dollars, respectively; and di_jp and di_wg are the differences in inflation rate of Japan and the U.S., and Germany and the U.S., respectively. The Monte Carlo capabilities of the MODEL procedure are used to generate error bounds on a forecast by using this model.

```
proc model data=exchange;
  endo im_jp im_wg;
  exo di_jp di_wg;
  parms a1 a2 b1 b2 c1 c2;
  label rate_jp = 'Exchange Rate of Yen/$'
        rate_wg = 'Exchange Rate of Gm/$'
        im_jp = 'Imports to US from Japan in 1984 $'
        im_wg = 'Imports to US from WG in 1984 $'
        di_jp = 'Difference in Inflation Rates US-JP'
        di_wg = 'Difference in Inflation Rates US-WG';

  rate_jp = a1 + b1*im_jp + c1*di_jp;
  rate_wg = a2 + b2*im_wg + c2*di_wg;
```

```

        /* Fit the EXCHANGE data */
fit rate_jp rate_wg / sur outest=xch_est outcov outs=s;

        /* Solve using the WHATIF data set */
solve rate_jp rate_wg / data=whatif estdata=xch_est sdata=s
        random=100 seed=123 out=monte forecast;
id yr;
range yr=1986;
run;

```

Data for the EXCHANGE data set was obtained from the Department of Commerce and the yearly “Economic Report of the President.”

First, the parameters are estimated using SUR selected by the SUR option in the FIT statement. The OUTEST= option is used to create the XCH_EST data set which contains the estimates of the parameters. The OUTCOV option adds the covariance matrix of the parameters to the XCH_EST data set. The OUTS= option is used to save the covariance of the equation error in the data set S.

Next, Monte Carlo simulation is requested by using the RANDOM= option in the SOLVE statement. The data set WHATIF is used to drive the forecasts. The ESTDATA= option reads in the XCH_EST data set which contains the parameter estimates and covariance matrix. Because the parameter covariance matrix is included, perturbations of the parameters are performed. The SDATA= option causes the Monte Carlo simulation to use the equation error covariance in the S data set to perturb the equation errors. The SEED= option selects the number 123 as a seed value for the random number generator. The output of the Monte Carlo simulation is written to the data set MONTE selected by the OUT= option.

To generate a confidence interval plot for the forecast, use PROC UNIVARIATE to generate percentile bounds and use PROC SGPLOT to plot the graph. The following SAS statements produce the graph in [Figure 18.12](#).

```

proc sort data=monte;
    by yr;
run;

proc univariate data=monte noprint;
    by yr;
    var rate_jp rate_wg;
    output out=bounds mean=mean p5=p5 p95=p95;
run;

title "Monte Carlo Generated Confidence Intervals on a Forecast";
proc sgplot data=bounds noautolegend;
    series x=yr y=mean / markers;
    series x=yr y=p5 / markers;
    series x=yr y=p95 / markers;
run;

```

Functional Summary

The statements and options in the MODEL procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set for the variables	FIT, SOLVE	DATA=
specify the input data set for parameters	FIT, SOLVE	ESTDATA=
specify the method for handling missing values	FIT	MISSING=
specify the input data set for parameters	MODEL	PARMSDATA=
request that the procedure produce graphics via the Output Delivery System	MODEL	PLOTS=
specify the output data set for residual, predicted, or actual values	FIT	OUT=
specify the output data set for solution mode results	SOLVE	OUT=
write the actual values to OUT= data set	FIT	OUTACTUAL
select all output options	FIT	OUTALL
write the covariance matrix of the estimates	FIT	OUTCOV
write the parameter estimates to a data set	FIT	OUTEST=
write the parameter estimates to a data set	MODEL	OUTPARMS=
write the observations used to start the lags	SOLVE	OUTLAGS
write the predicted values to the OUT= data set	FIT	OUTPREDICT
write the residual values to the OUT= data set	FIT	OUTRESID
write the covariance matrix of the equation errors to a data set	FIT	OUTS=
write the S matrix used in the objective function definition to a data set	FIT	OUTSUSED=
write the estimate of the variance matrix of the moment generating function	FIT	OUTV=
read the covariance matrix of the equation errors	FIT, SOLVE	SDATA=
read the covariance matrix for GMM and IT-GMM	FIT	VDATA=
specify the name of the time variable	FIT, SOLVE, MODEL	TIME=
select the estimation type to read	FIT, SOLVE	TYPE=
General ESTIMATE Statement Options		
specify the name of the data set in which the estimate of the functions of the parameters are to be written	ESTIMATE	OUTEST=

Description	Statement	Option
write the covariance matrix of the functions of the parameters to the OUTEST= data set	ESTIMATE	OUTCOV
print the covariance matrix of the functions of the parameters	ESTIMATE	COVB
print the correlation matrix of the functions of the parameters	ESTIMATE	CORRB
Printing Options for FIT Tasks		
print the modified Breusch-Pagan test for heteroscedasticity	FIT	BREUSCH
print the Chow test for structural breaks	FIT	CHOW=
print collinearity diagnostics	FIT	COLLIN
print the correlation matrices	FIT	CORR
print the correlation matrix of the parameters	FIT	CORRB
print the correlation matrix of the residuals	FIT	CORRS
print the covariance matrices	FIT	COV
print the covariance matrix of the parameters	FIT	COVB
print the covariance matrix of the residuals	FIT	COVS
print Durbin-Watson d statistics	FIT	DW
print first-stage R^2 statistics	FIT	FSRSQ
print Godfrey's tests for autocorrelated residuals for each equation	FIT	GODFREY
print Hausman's specification test	FIT	HAUSMAN
print tests of normality of the model residuals	FIT	NORMAL
print the predictive Chow test for structural breaks	FIT	PCHOW=
specify all the printing options	FIT	PRINTALL
print White's test for heteroscedasticity	FIT	WHITE
Options to Control FIT Iteration Output		
print the inverse of the crossproducts Jacobian matrix	FIT	I
print a summary iteration listing	FIT	ITPRINT
print a detailed iteration listing	FIT	ITDETAILS
print the crossproduct Jacobian matrix	FIT	XPX
specify all the iteration printing-control options	FIT	ITALL
Options to Control the Minimization Process		
specify the convergence criteria	FIT	CONVERGE=
select the Hessian approximation used for FIML	FIT	HESSIAN=

Description	Statement	Option
specify the local truncation error bound for the integration	FIT, SOLVE, MODEL	LTEBOUND=
specify the maximum number of iterations allowed	FIT	MAXITER=
specify the maximum number of subiterations allowed	FIT	MAXSUBITER=
select the iterative minimization method to use	FIT	METHOD=
specify the smallest allowed time step to be used in the integration	FIT, SOLVE, MODEL	MINTIMESTEP=
modify the iterations for estimation methods that iterate the S matrix or the V matrix	FIT	NESTIT
specify the smallest pivot value	MODEL, FIT, SOLVE	SINGULAR
specify the number of minimization iterations to perform at each grid point	FIT	STARTITER=
specify a weight variable	WEIGHT	
Options to Read and Write Model Files		
read a model from one or more input model files	INCLUDE	MODEL=
suppress the default output of the model file	MODEL, RESET	NOSTORE
specify the name of an output model file	MODEL, RESET	OUTMODEL=
delete the current model	RESET	PURGE
Options to List or Analyze the Structure of the Model		
print a dependency structure of a model	MODEL	BLOCK
print a graph of the dependency structure of a model	MODEL	GRAPH
print the model program and variable lists	MODEL	LIST
print the derivative tables and compiled model program code	MODEL	LISTCODE
print a dependency list	MODEL	LISTDEP
print a table of derivatives	MODEL	LISTDER
print a cross-reference of the variables	MODEL	XREF
General Printing Control Options		
expand parts of the printed output	FIT, SOLVE	DETAILS
print a message for each statement as it is executed	FIT, SOLVE	FLOW
select the maximum number of execution errors that can be printed	FIT, SOLVE	MAXERRORS=
select the number of decimal places shown in the printed output	FIT, SOLVE	NDEC=
suppress the normal printed output	FIT, SOLVE	NOPRINT

Description	Statement	Option
specify all the noniteration printing options	FIT, SOLVE	PRINTALL
print the result of each operation as it is executed	FIT, SOLVE	TRACE
request a comprehensive memory usage summary	FIT, SOLVE, MODEL, RESET	MEMORYUSE
turn off the NOPRINT option	RESET	PRINT
Statements that Declare Variables		
associate a name with a list of variables and constants	ARRAY	
declare a variable to have a fixed value	CONTROL	
declare a variable to be a dependent or endogenous variable	ENDOGENOUS	
declare a variable to be an independent or exogenous variable	EXOGENOUS	
specify identifying variables	ID	
assign a label to a variable	LABEL	
select additional variables to be output	OUTVARS	
declare a variable to be a parameter	PARAMETERS	
force a variable to hold its value from a previous observation	RETAIN	
declare a model variable	VAR	
declare an instrumental variable	INSTRUMENTS	
omit the default intercept term in the instruments list	INSTRUMENTS	NOINT
General FIT Statement Options		
omit parameters from the estimation	FIT	DROP=
associate a variable with an initial value as a parameter or a constant	FIT	INITIAL=
bypass OLS to get initial parameter estimates for GMM, ITGMM, or FIML	FIT	NOOLS
bypass 2SLS to get initial parameter estimates for GMM, ITGMM, or FIML	FIT	NO2SLS
specify the parameters to estimate	FIT	PARMS=
request confidence intervals on estimated parameters	FIT	PRL=
select a grid search	FIT	START=
Options to Control the Estimation Method Used		
specify nonlinear ordinary least squares	FIT	OLS
specify iterated nonlinear ordinary least squares	FIT	ITOLS

Description	Statement	Option
specify seemingly unrelated regression	FIT	SUR
specify iterated seemingly unrelated regression	FIT	ITSUR
specify two-stage least squares	FIT	2SLS
specify iterated two-stage least squares	FIT	IT2SLS
specify three-stage least squares	FIT	3SLS
specify iterated three-stage least squares	FIT	IT3SLS
specify full information maximum likelihood	FIT	FIML
specify simulated method of moments	FIT	NDRAW
specify number of draws for the V matrix	FIT	NDRAWV
specify number of initial observations for SMM	FIT	NPREOBS
select the variance-covariance estimator used for FIML	FIT	COVBEST=
specify generalized method of moments	FIT	GMM
specify the kernel for GMM and ITGMM	FIT	KERNEL=
specify iterated generalized method of moments	FIT	ITGMM
specify the type of generalized inverse used for the covariance matrix	FIT	GINV=
specify the denominator for computing variances and covariances	FIT	VARDEF=
specify adding the variance adjustment for SMM	FIT	ADJSMMV
specify variance correction for heteroscedasticity	FIT	HCCME=
specify GMM variance under arbitrary weighting matrix	FIT	GENGMMV
specify GMM variance under optimal weighting matrix	FIT	NOGENGMMV
Solution Mode Options		
select a subset of the model equations	SOLVE	SATISFY=
solve only for missing variables	SOLVE	FORECAST
solve for all solution variables	SOLVE	SIMULATE
Solution Mode Options: Lag Processing		
use solved values in the lag functions	SOLVE	DYNAMIC
use actual values in the lag functions	SOLVE	STATIC
produce successive forecasts to a fixed forecast horizon	SOLVE	NAHEAD=
select the observation to start dynamic solutions	SOLVE	START=

Description	Statement	Option
Solution Mode Options: Numerical Methods		
specify the maximum number of iterations allowed	SOLVE	MAXITER=
specify the maximum number of subiterations allowed	SOLVE	MAXSUBITER=
specify the convergence criteria	SOLVE	CONVERGE=
compute a simultaneous solution using a Jacobi-like iteration	SOLVE	JACOBI
compute a simultaneous solution using a Gauss-Seidel-like iteration	SOLVE	SEIDEL
compute a simultaneous solution using Newton's method	SOLVE	NEWTON
compute a nonsimultaneous solution	SOLVE	SINGLE
Monte Carlo Simulation Options		
specify quasi-random number generator	SOLVE	QUASI=
specify pseudo-random number generator	SOLVE	PSUEDO=
repeat the solution multiple times	SOLVE	RANDOM=
initialize the pseudo-random number generator	SOLVE	SEED=
specify copula options	SOLVE	COPULA=
Solution Mode Printing Options		
print between data points integration values for the DERT. variables and the auxiliary variables	FIT, SOLVE, MODEL	INTGPRINT
print the solution approximation and equation errors	SOLVE	ITPRINT
print the solution values and residuals at each observation	SOLVE	SOLVEPRINT
print various summary statistics	SOLVE	STATS
print tables of Theil inequality coefficients	SOLVE	THEIL
specify all printing control options	SOLVE	PRINTALL
General TEST Statement Options		
specify that a Wald test be computed	TEST	WALD
specify that a Lagrange multiplier test be computed	TEST	LM
specify that a likelihood ratio test be computed	TEST	LR
request all three types of tests	TEST	ALL
specify the name of an output SAS data set that contains the test results	TEST	OUT=

Description	Statement	Option
Miscellaneous Statements		
specify the range of observations to be used	RANGE	
subset the data set with BY variables	BY	

PROC MODEL Statement

PROC MODEL *options* ;

The following options can be specified in the PROC MODEL statement. All of the nonassignment options (the options that do not accept a value after an equal sign) can have NO prefixed to the option name in the RESET statement to turn the option off. The default case is not explicitly indicated in the discussion that follows. Thus, for example, the option DETAILS is documented in the following, but NODETAILS is not documented since it is the default. Also, the NOSTORE option is documented because STORE is the default.

Data Set Options

DATA=*SAS-data-set*

names the input data set. Variables in the model program are looked up in the DATA= data set and, if found, their attributes (type, length, label, format) are set to be the same as those in the input data set (if not previously defined otherwise). The values for the variables in the program are read from the input data set when the model is estimated or simulated by FIT and SOLVE statements.

OUTPARMS=*SAS-data-set*

writes the parameter estimates to a SAS data set. See the section “[Output Data Sets](#)” on page 1110 for details.

PARMSDATA=*SAS-data-set*

names the SAS data set that contains the parameter estimates. In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used. See the section “[Input Data Sets](#)” on page 1104 for details.

PLOTS=*global-plot-options | plot-request*

requests that the MODEL procedure produce statistical graphics via the Output Delivery System, provided that the ODS GRAPHICS statement has been specified. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT*

User's Guide). The *global-plot-options* apply to all relevant plots generated by the MODEL procedure. The *global-plot-options* supported by the MODEL procedure follow.

Global Plot Options

ONLY	suppresses the default plots. Only the plots specifically requested are produced.
UNPACKPANEL	breaks a graphic that is otherwise paneled into individual component plots.

Specific Plot Options

ALL	requests that all plots appropriate for the particular analysis be produced.
ACF	produces the autocorrelation function plot.
IACF	produces the inverse autocorrelation function plot of residuals.
PACF	produces the partial autocorrelation function plot of residuals.
FITPLOT	plots the predicted and actual values.
COOKSD	produces the Cook's D plot.
QQ	produces a QQ plot of residuals.
RESIDUAL RES	plots the residuals.
STUDENTRESIDUAL	plots the studentized residuals.
RESIDUALHISTOGRAM RESIDHISTOGRAM	plots the histogram of residuals.
NONE	suppresses all plots.

Options to Read and Write Model Files

MODEL=*model-name*

MODEL=(*model-list*)

reads the model from one or more input model files created by previous PROC MODEL executions. Model files are written by the OUTMODEL= option.

NOSTORE

suppresses the default output of the model file. This option is applicable only when FIT or SOLVE statements are not used, the MODEL= option is not used, and when a model is specified.

OUTMODEL=*model-name*

specifies the name of an output model file to which the model is to be written. Starting with SAS 9.2, model files are being stored as XML-based SAS data sets instead of being stored as members of a SAS catalog as in earlier releases. This makes MODEL files more readily extendable in the future and enables Java-based applications to read the MODEL files directly. To change this behavior, use the SAS *global-CMPMODEL-options*. You can choose the format in which the output model file is stored and read by using the *CMPMODEL=global-CMPMODEL-options* in an OPTIONS statement as follows.

OPTIONS CMPMODEL=*global-CMPMODEL-options*;

The global CMPMODEL options are:

CATALOG	specifies that model files be written and read from SAS catalogs only.
XML	specifies that model files be written and read from XML datasets only.
BOTH	specifies that model files be written to both XML and CATALOG formats. When BOTH is specified, model files are read from the data set first and read from the SAS catalog only if the data set is not found. This is the default option.

Options to List or Analyze the Structure of the Model

These options produce reports on the structure of the model or list the programming statements that define the models. These options are automatically reset (turned off) after the reports are printed. To turn these options back on after a RUN statement has been entered, use the RESET statement or specify the options on a FIT or SOLVE statement.

BLOCK

prints an analysis of the structure of the model given by the assignments to model variables appearing in the model program. This analysis includes a classification of model variables into endogenous (dependent) and exogenous (independent) groups based on the presence of the variable on the left-hand side of an assignment statement. The endogenous variables are grouped into simultaneously determined blocks. The dependency structure of the simultaneous blocks and exogenous variables is also printed. The BLOCK option cannot analyze dependencies implied by general form equations.

GRAPH

prints the graph of the dependency structure of the model. The GRAPH option also invokes the BLOCK option and produces a graphical display of the information listed by the BLOCK option.

LIST

prints the model program and variable lists, including the statements added by PROC MODEL and macros.

LISTALL

selects the LIST, LISTDEP, LISTDER, and LISTCODE options.

LISTCODE

prints the derivative tables and compiled model program code. LISTCODE is a debugging feature and is not normally needed.

LISTDEP

prints a report that lists for each variable in the model program the variables that depend on it and that it depends on. These lists are given separately for current-period values and for lagged values of the variables.

The information displayed is the same as that used to construct the BLOCK report but differs in that the information is listed for all variables (including parameters, control variables, and program variables), not just for the model variables. Classification into endogenous and exogenous groups and analysis of simultaneous structure is not done by the LISTDEP report.

LISTDER

prints a table of derivatives for FIT and SOLVE tasks. (The LISTDER option is applicable only for the default NEWTON method for SOLVE tasks.) The derivatives table shows each nonzero derivative computed for the problem. The derivative listed can be a constant, a variable in the model program, or a special derivative variable created to hold the result of the derivative expression. This option is turned on by the LISTCODE and PRINTALL options.

XREF

prints a cross-reference of the variables in the model program that shows where each variable was referenced or given a value. The XREF option is normally used in conjunction with the LIST option. A more detailed description is given in the section “[Diagnostics and Debugging](#)” on page 1168.

General Printing Control Options

DETAILS

specifies the detailed printout. Parts of the printed output are expanded when the DETAILS option is specified. If ODS GRAPHICS ON is specified, the following additional graphs of the residuals are produced: ACF, PACF, IACF, white noise, and QQ plot versus the normal.

FLOW

prints a message for each statement in the model program as it is executed. This debugging option is needed very rarely and produces voluminous output.

MAXERRORS=*n*

specifies the maximum number of execution errors that can be printed. The default is MAXERRORS=50.

NDEC=*n*

specifies the precision of the format that PROC MODEL uses when printing various numbers. The default is NDEC=3, which means that PROC MODEL attempts to print values by using the D format but ensures that at least three significant digits are shown. If the NDEC= value is greater than nine, the BEST. format is used. The smallest value allowed is NDEC=2.

The NDEC= option affects the format of most, but not all, of the floating point numbers that PROC MODEL can print. For some values (such as parameter estimates), a precision limit one or two digits greater than the NDEC= value is used. This option does not apply to the precision of the variables in the output data set.

NOPRINT

suppresses the normal printed output but does not suppress error listings. Using any other print option turns the NOPRINT option off. The PRINT option can be used with the RESET statement to turn off NOPRINT.

PRINTALL

turns on all the printing-control options. The options set by PRINTALL are DETAILS; the model information options LIST, LISTDEP, LISTDER, XREF, BLOCK, and GRAPH; the FIT task printing options FRSQ, COVB, CORRB, COVS, CORRS, DW, and COLLIN; and the SOLVE task printing options STATS, THEIL, SOLVEPRINT, and ITPRINT.

TRACE

prints the result of each operation in each statement in the model program as it is executed, in addition to the information printed by the FLOW option. This debugging option is needed very rarely and produces voluminous output.

MEMORYUSE

prints a report of the memory required for the various parts of the analysis.

FIT Task Options

The following options are used in the FIT statement (parameter estimation) and can also be used in the PROC MODEL statement: COLLIN, CONVERGE=, CORR, CORRB, CORRS, COVB, COVBEST=, COVS, DW, FIML, FRSQ, GMM, HESSIAN=, I, INTGPRINT, ITALL, ITDETAILS, ITGMM, ITPRINT, ITOLS, ITSUR, IT2SLS, IT3SLS, KERNEL=, LTEBOUND=, MAXITER=, MAXSUBITER=, METHOD=, MINTIMESTEP=, NESTIT, N2SLS, N3SLS, OLS, OUTPREDICT, OUTRESID, OUTACTUAL, OUTLAGS, OUTALL, OUTCOV, SINGULAR=, STARTITER=, SUR, TIME=, VARDEF, and XPX. See the section “[FIT Statement](#)” on page 984 for a description of these options.

When used in the PROC MODEL or RESET statement, these are default options for subsequent FIT statements. For example, the statement

```
proc model n2s1s ... ;
```

makes two-stage least squares the default parameter estimation method for FIT statements that do not specify an estimation method.

SOLVE Task Options

The following options used in the SOLVE statement can also be used in the PROC MODEL statement: CONVERGE=, DYNAMIC, FORECAST, INTGPRINT, ITPRINT, JACOBI, LTEBOUND=, MAXITER=, MAXSUBITER=, MINTIMESTEP=, NAHEAD=, NEWTON, OUTPREDICT, OUTRESID, OUTACTUAL, OUTLAGS, OUTERRORS, OUTALL, SEED=, SEIDEL, SIMULATE, SINGLE, SINGULAR=, SOLVEPRINT, START=, STATIC, STATS, THEIL, TIME=, and TYPE=. See the section “[SOLVE Statement](#)” on page 1000 for a description of these options.

When used in the PROC MODEL or RESET statement, these options provide default values for subsequent SOLVE statements.

BOUNDS Statement

```
BOUNDS bound1 <, bound2 ... >;
```

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the associated FIT statement (that is, to either the preceding FIT statement or, in the absence of a preceding FIT statement, to the following FIT statement). You can specify any number of BOUNDS statements.

Each *bound* is composed of parameters and constants and inequality operators:

```
item operator item < operator item < operator item ... > >
```

Each *item* is a constant, the name of an estimated parameter, or a list of parameter names. Each *operator* is <, >, <=, or >=.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the section “[RESTRICT Statement](#)” on page 999 for more information about the computational details of estimation with inequality restrictions.

Lagrange multipliers are reported for all the active boundary constraints. In the printed output and in the OUTEST= data set, the Lagrange multiplier estimates are identified with the names BOUND0, BOUND1, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994). To give the constraints more descriptive names, use the RESTRICT statement instead of the BOUNDS statement.

The following BOUNDS statement constrains the estimates of the parameters A and B and the ten parameters P1 through P10 to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < a b p1-p10 < 1;
```

The following statements are an example of the use of the BOUNDS statement and they produce the output shown in [Figure 18.13](#):

```
title 'Holzman Function (1969), Himmelblau No. 21, N=3';
data zero;
  do i = 1 to 99;
    output;
  end;
run;

proc model data=zero;
  parms x1= 100 x2= 12.5 x3= 3;
  bounds .1 <= x1 <= 100,
          0 <= x2 <= 25.6,
          0 <= x3 <= 5;

  t = 2 / 3;
```

```

u = 25 + (-50 * log(0.01 * i )) ** t;
v = (u - x2) ** x3;
w = exp(-v / x1);
eq.foo = -.01 * i + w;

fit foo / method=marquardt;
run;

```

x1	49.99999	0	.	.
x2	25	0	.	.
x3	1.5	0	.	.

BY Statement

BY variables ;

A BY statement is used with the FIT statement to obtain separate estimates for observations in groups defined by the BY variables. Note that if an output model file is written, using the OUTMODEL= option, the parameter values stored are those from the last BY group processed. To save parameter estimates for each BY group, use the OUTEST= option in the FIT statement.

A BY statement is used with the SOLVE statement to obtain solutions for observations in groups defined by the BY variables. If the BY variables are identical in the DATA= data set and the ESTDATA= data set, then the two data sets are synchronized and the calculations are performed by using the data and parameters for each BY group. This holds for BY variables in the SDATA= data set as well. If the BY variables do not match, BY group processing is abandoned in either the ESTDATA= data set or the SDATA= data set, whichever has the missing BY value. If the DATA= data set does not contain BY variables and the ESTDATA= data set or the SDATA= data set does, then BY processing is performed for the ESTDATA= data set and the SDATA= data set by reusing the data in the DATA= data set for each BY group.

If both FIT and SOLVE tasks require BY group processing, then two separate BY statements are needed. If parameters for each BY group in the OUTEST = data set obtained from the FIT task are to be used for the corresponding BY group for the SOLVE task, then one of the two BY statements must appear after the SOLVE statement.

The following linear regression example illustrates the use of BY group processing. Both the datasets A and D to be used for fitting and solving, respectively, have three groups.

```

/*----- data set for fit task----- */
data a ;
  do group = 1 to 3 ;
    do i = 1 to 100 ;
      x = normal(1);
      y = 2 + 3*x + rannor(3535) ;
      output ;
    end ;
  end ;
run ;

/*----- data set for solve task----- */
data d ;
  do group = 1 to 3 ;
    x = normal(1) ;
    output ;
  end ;
run ;

/* ----- 2 BY statements, one of them appear after SOLVE statement ----- */
proc model data = a ;
  by group ;
  y = a0 + a1*x ;
  fit y / outest = b1 ;
  solve y / data = d estdata = b1 out = c1 ;
  by group ;
run;

proc print data = b1 ;run;
proc print data = c1 ; run;

```

Each of the parameter estimates obtained from the BY group processing in the FIT statement shown in [Figure 18.14](#) is used in the corresponding BY group variables in the SOLVE statement. The output dataset is shown in [Figure 18.15](#).

Figure 18.14 Listing of OUTEST= Data Set Created in the FIT Statement with Two BY Statements

Obs	group	_NAME_	_TYPE_	_STATUS_	_NUSED_	a0	a1
1	1		OLS	0 Converged	100	2.00338	3.00298
2	2		OLS	0 Converged	100	2.05091	3.08808
3	3		OLS	0 Converged	100	2.15528	3.04290

Figure 18.15 Listing of OUT= Data Set Created in the SOLVE Statement with Two BY Statements

Obs	group	_TYPE_	_MODE_	_ERRORS_	y	x
1	1	PREDICT	SIMULATE	0	7.42322	1.80482
2	2	PREDICT	SIMULATE	0	1.80413	-0.07992
3	3	PREDICT	SIMULATE	0	3.36202	0.39658

If only one BY statement is used and it appears before the SOLVE statement, then parameters for the last BY group in the OUTEST = data set are used for all BY groups for the SOLVE task.

```

/*----- 1 BY statement that appears before SOLVE statement----- */
proc model data = a ;
  by group ;
  y = a0 + a1*x ;
  fit y / outest = b2 ;
  solve y / data = d estdata = b2 out = c2 ;
run;

proc print data = b2 ; run;
proc print data = c2 ; run;

```

The estimates of the parameters are shown in [Figure 18.16](#), and the output data set of the SOLVE statement is shown in [Figure 18.17](#). Hence, the estimates and the predicted values obtained in the last BY group variable of both DATA C1 and C2 are the same while the others do not match.

Figure 18.16 Listing of OUTEST= Data Set Created in the FIT Statement with One BY Statement That Appears before the SOLVE Statement

Obs	group	_NAME_	_TYPE_	_STATUS_	_NUSED_	a0	a1
1	1		OLS	0 Converged	100	2.00338	3.00298
2	2		OLS	0 Converged	100	2.05091	3.08808
3	3		OLS	0 Converged	100	2.15528	3.04290

Figure 18.17 Listing of OUT= Data Set Created in the SOLVE Statement with One BY Statement That Appears before the SOLVE Statement

Obs	_TYPE_	_MODE_	_ERRORS_	y	x
1	PREDICT	SIMULATE	0	7.64717	1.80482
2	PREDICT	SIMULATE	0	1.91211	-0.07992
3	PREDICT	SIMULATE	0	3.36202	0.39658

If only one BY statement is used and it appears after the SOLVE statement, then BY group processing does not apply to the FIT task. In this case, the OUTEST=data set does not contain the BY variable, and the single set of parameter estimates obtained from the FIT task are used for all BY groups during the SOLVE task.

```

/*----- 1 BY statement that appears after SOLVE statement-----*/
proc model data = a ;
  y = a0 + a1*x ;
  fit y / outest = b3 ;
  solve y / data = d estdata = b3 out = c3 ;
  by group ;
run;

proc print data = b3 ; run;
proc print data = c3 ; run;

```

The output data B3 and C3 are listed in [Figure 18.18](#) and [Figure 18.19](#), respectively.

Figure 18.18 Listing of OUTEST= Data Set Created in the FIT Statement with One BY Statement That Appears after the SOLVE Statement

Obs	_NAME_	_TYPE_	_STATUS_	_NUSED_	a0	a1
1		OLS	0 Converged	300	2.06624	3.04219

Obs	group	_TYPE_	_MODE_	_ERRORS_	y	x
1	1	PREDICT	SIMULATE	0	7.55686	1.80482
2	2	PREDICT	SIMULATE	0	1.82312	-0.07992
3	3	PREDICT	SIMULATE	0	3.27270	0.39658

CONTROL Statement

CONTROL *variable* < *value* > ... ;

The CONTROL statement declares control variables and specifies their values. A control variable is like a parameter except that it has a fixed value and is not estimated from the data. You can use control variables for constants in model equations that you might want to change in different solution cases. You can use control variables to vary the program logic. Unlike the retained variables, these values are fixed across iterations.

ENDOGENOUS Statement

ENDOGENOUS *variable* < *initial-values* > ... ;

The ENDOGENOUS statement declares model variables and identifies them as endogenous. You can declare model variables with an ENDOGENOUS statement instead of with a VAR statement

to help document the model or to indicate the default solution variables. The variables declared endogenous are solved when a SOLVE statement does not indicate which variables to solve. Valid abbreviations for the ENDOGENOUS statement are ENDOG and ENDO.

The DEPENDENT statement is equivalent to the ENDOGENOUS statement and is provided for the convenience of non-econometric practitioners.

The ENDOGENOUS statement optionally provides initial values for lagged dependent variables. See the section “Lag Logic” on page 1161 for more information.

ERRORMODEL Statement

ERRORMODEL *equation-name* ~ *distribution* < CDF= CDF(*options*) > ;

The ERRORMODEL statement is the mechanism for specifying the distribution of the residuals. You must specify the dependent/endogenous variables or general-form model name, a tilde (~), and then a distribution with its parameters. The following options are used in the ERRORMODEL statement:

Options to Specify the Distribution

CAUCHY(< *location*, *scale* >)

specifies the Cauchy distribution. This option is supported only for simulation. The arguments correspond to the arguments of the SAS CDF function which computes the cumulative distribution function (ignoring the random variable argument).

CHISQUARED (*df* < , *nc* >)

specifies the χ^2 distribution. This option is supported only for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

GENERAL(*Likelihood* < , *parm1*, *parm2*, ... *parmn* >)

specifies the negative of a general log-likelihood function that you construct by using SAS programming statements. The procedure minimizes the negative log-likelihood function specified. *parm1*, *parm2*, ... *parmn* are optional parameters for this distribution and are used for documentation purposes only.

F(*ndf*, *ddf* < , *nc* >)

specifies the *F* distribution. This option is supported only for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

NORMAL(*v*₁ *v*₂ ... *v*_{*n*})

specifies a multivariate normal (Gaussian) distribution with mean 0 and variances *v*₁ through *v*_{*n*}.

POISSON(*mean*)

specifies the Poisson distribution. This option is supported only for simulation. The argu-

ments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

T($v_1 v_2 \cdots v_n, df$)

specifies a multivariate t distribution with noncentrality 0, variance v_1 through v_n , and common degrees of freedom df .

UNIFORM($< left, right >$)

specifies the uniform distribution. This option is supported only for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

Options to Specify the CDF for Simulation

CDF=($CDF(options)$)

specifies the univariate distribution that is used for simulation so that the estimation can be done for one set of distributional assumptions and the simulation for another. The CDF can be any of the distributions from the previous section with the exception of the general likelihood. In addition, you can specify the empirical distribution of the residuals.

EMPIRICAL= ($< TAILS=(options)>$)

uses the sorted residual data to create an empirical CDF.

TAILS=($tail-options$)

specifies how to handle the tails in computing the inverse CDF from an empirical distribution, where $tail-options$ are:

NORMAL specifies the normal distribution to extrapolate the tails.

T(df) specifies the t distribution to extrapolate the tails.

PERCENT= p specifies the percentage of the observations to use in constructing each tail. The default for the **PERCENT=** option is 10. A normal distribution or a t distribution is used to extrapolate the tails to infinity. The variance for the tail distribution is obtained from the data so that the empirical CDF is continuous.

ESTIMATE Statement

ESTIMATE $item < , item \dots > < ,/ options > ;$

The **ESTIMATE** statement computes estimates of functions of the parameters.

The **ESTIMATE** statement refers to the parameters estimated by the associated **FIT** statement (that is, to either the preceding **FIT** statement or, in the absence of a preceding **FIT** statement, to the following **FIT** statement). You can use any number of **ESTIMATE** statements.

Let $\mathbf{h}(\theta)$ denote the function of parameters that needs to be estimated. Let $\hat{\theta}$ denote the unconstrained estimate of the parameter of interest, θ . Let $\hat{\mathbf{V}}$ be the estimate of the covariance matrix of θ . Denote

$$\mathbf{A}(\theta) = \partial h(\theta) / \partial \theta |_{\hat{\theta}}$$

Then the standard error of the parameter function estimate is computed by obtaining the square root of $\mathbf{A}(\hat{\theta})\hat{\mathbf{V}}\mathbf{A}'(\hat{\theta})$. This is the same as the variance needed for a Wald type test statistic with null hypothesis $h(\theta) = 0$.

If the expression of the function in the ESTIMATE statement includes a variable, then the value used in computing the function estimate is the last observation of the variable in the DATA= data set.

If you specify options on the ESTIMATE statement, a comma is required before the “/” character that separates the test expressions from the options, since the “/” character can also be used within test expressions to indicate division. Each *item* is written as an optional name followed by an expression,

< "name" > expression

where “name” is a string used to identify the estimate in the printed output and in the OUTEST= data set.

Expressions can be composed of parameter names, arithmetic operators, functions, and constants. Comparison operators (such as = or <) and logical operators (such as &) cannot be used in ESTIMATE statement expressions. Parameters named in ESTIMATE expressions must be among the parameters estimated by the associated FIT statement.

You can use the following options in the ESTIMATE statement:

OUTEST=

specifies the name of the data set in which the estimate of the functions of the parameters are to be written. The format for this data set is identical to the OUTEST= data set for the FIT statement.

If you specify a *name* in the ESTIMATE statement, that name is used as the parameter name for the estimate in the OUTEST= data set. If no *name* is provided and the expression is just a symbol, the symbol name is used; otherwise, the string “_Estimate #” is used, where “#” is the variable number in the OUTEST= data set.

OUTCOV

writes the covariance matrix of the functions of the parameters to the OUTEST= data set in addition to the parameter estimates.

COVB

prints the covariance matrix of the functions of the parameters.

CORRB

prints the correlation matrix of the functions of the parameters.

The following statements are an example of the use of the ESTIMATE statement in a segmented model and produce the output shown in [Figure 18.20](#):

```

data a;
  input y x @@;
datalines;
  .46 1 .47 2 .57 3 .61 4 .62 5 .68 6 .69 7
  .78 8 .70 9 .74 10 .77 11 .78 12 .74 13 .80 13
  .80 15 .78 16
;

title 'Segmented Model -- Quadratic with Plateau';
proc model data=a;

  x0 = -.5 * b / c;

  if x < x0 then y = a + b*x + c*x*x;
  else          y = a + b*x0 + c*x0*x0;

  fit y start=( a .45 b .5 c -.0025 );

  estimate 'Join point' x0 ,
           'plateau' a + b*x0 + c*x0**2 ;
run;

```

Figure 18.20 ESTIMATE Statement Output

Segmented Model -- Quadratic with Plateau					
The MODEL Procedure					
Nonlinear OLS Estimates					
Term	Estimate	Approx Std Err	t Value	Approx Pr > t	Label
Join point	12.7504	1.2785	9.97	<.0001	x0
plateau	0.777516	0.0123	63.10	<.0001	a + b*x0 + c*x0**2

EXOGENOUS Statement

EXOGENOUS *variable* < *initial-values* > ... ;

The EXOGENOUS statement declares model variables and identifies them as exogenous. You can declare model variables with an EXOGENOUS statement instead of with a VAR statement to help document the model or to indicate the default instrumental variables. The variables declared exogenous are used as instruments when an instrumental variables estimation method is requested (such as N2SLS or N3SLS) and an INSTRUMENTS statement is not used. Valid abbreviations for the EXOGENOUS statement are EXOG and EXO.

The INDEPENDENT statement is equivalent to the EXOGENOUS statement and is provided for

the convenience of non-econometric practitioners.

The EXOGENOUS statement optionally provides initial values for lagged exogenous variables. See the section “[Lag Logic](#)” on page 1161 for more information.

FIT Statement

```
FIT < equations > < PARMs=( parameter < values > ... ) > < START=( parameter values
... ) > < DROP=( parameter ... ) > < INITIAL=( variable < = parameter | constant > ... )
> < / options > ;
```

The FIT statement estimates model parameters by fitting the model equations to input data and optionally selects the equations to be fit. If the list of equations is omitted, all model equations that contain parameters are fitted.

The following options can be used in the FIT statement.

DROP= (parameters ...)

specifies that the named parameters not be estimated. All the parameters in the equations fit are estimated except those listed in the DROP= option. The dropped parameters retain their previous values and are not changed by the estimation.

INITIAL= (variable = < parameter | constant > ...)

associates a *variable* with an initial value as a *parameter* or a *constant*. This option applies only to ordinary differential equations. See the section “[Ordinary Differential Equations](#)” on page 1066 for more information.

PARMS= (parameters [values] ...)

selects a subset of the parameters for estimation. When the PARMS= option is used, only the named parameters are estimated. Any parameters not specified in the PARMS= list retain their previous values and are not changed by the estimation.

In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used.

PRL= WALD | LR | BOTH

requests confidence intervals on estimated parameters. By default, the PRL option produces 95% likelihood ratio confidence limits. The coverage of the confidence interval is controlled by the ALPHA= option in the FIT statement.

START= (parameter values ...)

supplies starting values for the parameter estimates. In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from

highest to lowest): the START= option, the PARMS statement initialization value, the EST-DATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used. If the START= option specifies more than one starting value for one or more parameters, a grid search is performed over all combinations of the values, and the best combination is used to start the iterations. For more information, see the STARTITER= option.

Options to Control the Estimation Method Used

ADJSMMV

specifies adding the variance adjustment from simulating the moments to the variance-covariance matrix of the parameter estimators. By default, no adjustment is made.

COVBEST=GLS | CROSS | FDA

specifies the variance-covariance estimator used for FIML. COVBEST=GLS selects the generalized least squares estimator. COVBEST=CROSS selects the crossproducts estimator. COVBEST=FDA selects the inverse of the finite difference approximation to the Hessian. The default is COVBEST=CROSS.

DYNAMIC

specifies dynamic estimation of ordinary differential equations. See the section “[Ordinary Differential Equations](#)” on page 1066 for more details.

FIML

specifies full information maximum likelihood estimation.

GINV=G2 | G4

specifies the type of generalized inverse to be used when computing the covariance matrix. G4 selects the Moore-Penrose generalized inverse. The default is GINV=G2.

Rather than deleting linearly related rows and columns of the covariance matrix, the Moore-Penrose generalized inverse averages the variance effects between collinear rows. When the option GINV=G4 is used, the Moore-Penrose generalized inverse is used to calculate standard errors and the covariance matrix of the parameters as well as the change vector for the optimization problem. For singular systems, a normal G2 inverse is used to determine the singular rows so that the parameters can be marked in the parameter estimates table. A G2 inverse is calculated by satisfying the first two properties of the Moore-Penrose generalized inverse; that is, $\mathbf{AA}^+\mathbf{A} = \mathbf{A}$ and $\mathbf{A}^+\mathbf{AA}^+ = \mathbf{A}^+$. Whether or not you use a G4 inverse, if the covariance matrix is singular, the parameter estimates are not unique. Refer to Noble and Daniel (1977, pp. 337–340) for more details about generalized inverses.

GENGMMV

specify GMM variance under arbitrary weighting matrix. See the section “[Estimation Methods](#)” on page 1007 for more details.

This is the default method for GMM estimation.

GMM

specifies generalized method of moments estimation.

HCCME= 0 | 1 | 2 | 3 | NO

specifies the type of heteroscedasticity-consistent covariance matrix estimator to use for OLS, 2SLS, 3SLS, SUR, and the iterated versions of these estimation methods. The number corresponds to the type of covariance matrix estimator to use as

$$\begin{aligned} HC_0 &: \hat{\epsilon}_t^2 \\ HC_1 &: \frac{n}{n-df} \hat{\epsilon}_t^2 \\ HC_2 &: \hat{\epsilon}_t^2 / (1 - \hat{h}_t) \\ HC_3 &: \hat{\epsilon}_t^2 / (1 - \hat{h}_t)^2 \end{aligned}$$

The default is NO.

ITGMM

specifies iterated generalized method of moments estimation.

ITOLS

specifies iterated ordinary least squares estimation. This is the same as OLS unless there are cross-equation parameter restrictions.

ITSUR

specifies iterated seemingly unrelated regression estimation

IT2SLS

specifies iterated two-stage least squares estimation. This is the same as 2SLS unless there are cross-equation parameter restrictions.

IT3SLS

specifies iterated three-stage least squares estimation.

KERNEL=(PARZEN | BART | QS, <c> , <e>)**KERNEL=PARZEN | BART | QS**

specifies the kernel to be used for GMM and ITGMM. PARZEN selects the Parzen kernel, BART selects the Bartlett kernel, and QS selects the quadratic spectral kernel. $e \geq 0$ and $c \geq 0$ are used to compute the bandwidth parameter. The default is KERNEL=(PARZEN, 1, 0.2). See the section “[Estimation Methods](#)” on page 1007 for more details.

N2SLS | 2SLS

specifies nonlinear two-stage least squares estimation. This is the default when an INSTRUMENTS statement is used.

N3SLS | 3SLS

specifies nonlinear three-stage least squares estimation.

NDRAW <=number of draws>

requests the simulation method for estimation. H is the *number of draws*. If *number of draws* is not specified, the default H is set to 10.

NOOLS**NO2SLS**

specifies bypassing OLS or 2SLS to get initial parameter estimates for GMM, ITGMM, or FIML. This is important for certain models that are poorly defined in OLS or 2SLS, or if good initial parameter values are already provided. Note that for GMM, the V matrix is created by using the initial values specified and this might not be consistently estimated.

NO3SLS

specifies not to use 3SLS automatically for FIML initial parameter starting values.

NOGENGMMV

specifies not to use GMM variance under arbitrary weighting matrix. Use GMM variance under optimal weighting matrix instead. See the section “[Estimation Methods](#)” on page 1007 for more details.

NPREOBS =number of obs to initialize

specifies the initial number of observations to run the simulation before the simulated values are compared to observed variables. This option is most useful in cases where the program statements involve lag operations. Use this option to avoid the effect of the starting point on the simulation.

NVDRAW =number of draws for V matrix

specifies H' , the number of draws for V matrix. If this option is not specified, the default H' is set to 20.

OLS

specifies ordinary least squares estimation. This is the default.

SUR

specifies seemingly unrelated regression estimation.

VARDEF=N | WGT | DF | WDF

specifies the denominator to be used in computing variances and covariances, MSE, root MSE measures, and so on. VARDEF=N specifies that the number of nonmissing observations be used. VARDEF=WGT specifies that the sum of the weights be used. VARDEF=DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used. VARDEF=WDF specifies that the sum of the weights minus the model degrees of freedom be used. The default is VARDEF=DF. VARDEF=N is the only option used for FIML estimation regardless of any option specified.

Data Set Options**DATA=SAS-data-set**

specifies the input data set. Values for the variables in the program are read from this data set. If the DATA= option is not specified on the FIT statement, the data set specified by the DATA= option on the PROC MODEL statement is used.

ESTDATA=SAS-data-set

specifies a data set whose first observation provides initial values for some or all of the parameters.

MISSING=PAIRWISE | DELETE

The option **MISSING=PAIRWISE** specifies that missing values are tracked on an equation-by-equation basis. The **MISSING=DELETE** option specifies that the entire observation is omitted from the analysis when any equation has a missing predicted or actual value for the equation. The default is **MISSING=DELETE**.

OUT=SAS-data-set

names the SAS data set to contain the residuals, predicted values, or actual values from each estimation. The residual values written to the **OUT=** data set are defined as the *actual – predicted*, which is the negative of *RESID.variable* as defined in the section “[Equation Translations](#)” on page 1155. Only the residuals are output by default.

OUTACTUAL

writes the actual values of the endogenous variables of the estimation to the **OUT=** data set. This option is applicable only if the **OUT=** option is specified.

OUTALL

selects the **OUTACTUAL**, **OUTERRORS**, **OUTLAGS**, **OUTPREDICT**, and **OUTRESID** options.

OUTCOV**COVOUT**

writes the covariance matrix of the estimates to the **OUTEST=** data set in addition to the parameter estimates. The **OUTCOV** option is applicable only if the **OUTEST=** option is also specified.

OUTEST=SAS-data-set

names the SAS data set to contain the parameter estimates and optionally the covariance of the estimates.

OUTLAGS

writes the observations used to start the lags to the **OUT=** data set. This option is applicable only if the **OUT=** option is specified.

OUTPREDICT

writes the predicted values to the **OUT=** data set. This option is applicable only if **OUT=** is specified.

OUTRESID

writes the residual values computed from the parameter estimates to the **OUT=** data set. The **OUTRESID** option is the default if neither **OUTPREDICT** nor **OUTACTUAL** is specified. This option is applicable only if the **OUT=** option is specified. If the *h.var* equation is specified, the residual values written to the **OUT=** data set are the normalized residuals, defined as *actual – predicted*, divided by the square root of the *h.var* value. If the **WEIGHT** statement is used, the residual values are calculated as *actual – predicted* multiplied by the square root of the **WEIGHT** variable.

OUTS=SAS-data-set

names the SAS data set to contain the estimated covariance matrix of the equation errors. This is the covariance of the residuals computed from the parameter estimates.

OUTSN=SAS-data-set

names the SAS data set to contain the estimated normalized covariance matrix of the equation errors. This is valid for multivariate t distribution estimation.

OUTSUSED=SAS-data-set

names the SAS data set to contain the **S** matrix used in the objective function definition. The OUTSUSED= data set is the same as the OUTS= data set for the methods that iterate the **S** matrix.

OUTUNWGTRESID

writes the unweighted residual values computed from the parameter estimates to the OUT= data set. These are residuals computed as *actual* – *predicted* with no accounting for the WEIGHT statement, the `_WEIGHT_` variable, or any variance expressions. This option is applicable only if the OUT= option is specified.

OUTV=SAS-data-set

names the SAS data set to contain the estimate of the variance matrix for GMM and ITGMM.

SDATA=SAS-data-set

specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation covariance matrix (**S** matrix) in the estimation. (The SDATA= **S** matrix is used to provide only the initial estimate of **S** for the methods that iterate the **S** matrix.)

TIME=name

specifies the name of the time variable. This variable must be in the data set.

TYPE=name

specifies the estimation type to read from the SDATA= and ESTDATA= data sets. The name specified in the TYPE= option is compared to the `_TYPE_` variable in the ESTDATA= and SDATA= data sets to select observations to use in constructing the covariance matrices. When the TYPE= option is omitted, the last estimation type in the data set is used. Valid values are the estimation methods used in PROC MODEL.

VDATA=SAS-data-set

specifies a data set that contains a variance matrix for GMM and ITGMM estimation. See the section “[Output Data Sets](#)” on page 1110 for details.

Printing Options for FIT Tasks

BREUSCH=(variable-list)

specifies the modified Breusch-Pagan test, where *variable-list* is a list of variables used to model the error variance.

CHOW=obs**CHOW=(obs1 obs2 . . . obsn)**

prints the Chow test for break points or structural changes in a model. The argument is the number of observations in the first sample or a parenthesized list of first sample sizes. If the size of the one of the two groups in which the sample is partitioned is less than the number of parameters, then a [predictive Chow](#) test is automatically used. See the section “[Chow Tests](#)” on page 1081 for details.

COLLIN

prints collinearity diagnostics for the Jacobian crossproducts matrix (**XPX**) after the parameters have converged. Collinearity diagnostics are also automatically printed if the estimation fails to converge.

CORR

prints the correlation matrices of the residuals and parameters. Using CORR is the same as using both CORRB and CORRS.

CORRB

prints the correlation matrix of the parameter estimates.

CORRS

prints the correlation matrix of the residuals.

COV

prints the covariance matrices of the residuals and parameters. Specifying COV is the same as specifying both COVB and COVS.

COVB

prints the covariance matrix of the parameter estimates.

COVS

prints the covariance matrix of the residuals.

DW <=>

prints Durbin-Watson d statistics, which measure autocorrelation of the residuals. When the residual series is interrupted by missing observations, the Durbin-Watson statistic calculated is d' as suggested by Savin and White (1978). This is the usual Durbin-Watson computed by ignoring the gaps. Savin and White show that it has the same null distribution as the DW with no gaps in the series and can be used to test for autocorrelation using the standard tables. The Durbin-Watson statistic is not valid for models that contain lagged endogenous variables.

You can use the DW= option to request higher-order Durbin-Watson statistics. Since the ordinary Durbin-Watson statistic tests only for first-order autocorrelation, the Durbin-Watson statistics for higher-order autocorrelation are called *generalized Durbin-Watson* statistics.

DWPROB

prints the significance level (p -values) for the Durbin-Watson tests. Since the Durbin-Watson p -values are computationally expensive, they are not reported by default. In the Durbin-Watson test, the null hypothesis is that there is autocorrelation at a specific lag.

See the section “Generalized Durbin-Watson Tests” for limitations of the statistic in the Chapter 8, “[The AUTOREG Procedure](#).”

FSRSQ

prints the first-stage R^2 statistics for instrumental estimation methods. These R^2 statistics measure the proportion of the variance retained when the Jacobian columns associated with the parameters are projected through the instruments space.

GODFREY**GODFREY=*n***

performs Godfrey’s tests for autocorrelated residuals for each equation, where n is the maximum autoregressive order, and specifies that Godfrey’s tests be computed for lags 1 through n . The default number of lags is one.

HAUSMAN

performs Hausman’s specification test, or m -statistics.

NORMAL

performs tests of normality of the model residuals.

PCHOW=*obs***PCHOW=(*obs1 obs2 . . . obsn*)**

prints the predictive Chow test for break points or structural changes in a model. The argument is the number of observations in the first sample or a parenthesized list of first sample sizes. See the section “[Chow Tests](#)” on page 1081 for details.

PRINTALL

specifies the printing options COLLIN, CORRB, CORRS, COVB, COVS, DETAILS, DW, and FSRSQ.

WHITE

specifies White’s test.

Options to Control Iteration Output

Details of the output produced are discussed in the section “[Iteration History](#)” on page 1042.

I

prints the inverse of the crossproducts Jacobian matrix at each iteration.

ITALL

specifies all iteration printing-control options (I, ITDETAILS, ITPRINT, and XPX). ITALL also prints the crossproducts matrix (labeled CROSS), the parameter change vector, and the estimate of the cross-equation covariance of residuals matrix at each iteration.

ITDETAILS

prints a detailed iteration listing. This includes the ITPRINT information and additional statistics.

ITPRINT

prints the parameter estimates, objective function value, and convergence criteria at each iteration.

XPX

prints the crossproducts Jacobian matrix at each iteration.

Options to Control the Minimization Process

The following options can be helpful when you experience a convergence problem:

CONVERGE=*value1***CONVERGE=(*value1*, *value2*)**

specifies the convergence criteria. The convergence measure must be less than *value1* before convergence is assumed. *value2* is the convergence criterion for the **S** and **V** matrices for **S** and **V** iterated methods. *value2* defaults to *value1*. See the section “[Convergence Criteria](#)” on page 1028 for details. The default value is CONVERGE=0.001.

HESSIAN=CROSS | GLS | FDA

specifies the Hessian approximation used for FIML. HESSIAN=CROSS selects the crossproducts approximation to the Hessian, HESSIAN=GLS selects the generalized least squares approximation to the Hessian, and HESSIAN=FDA selects the finite difference approximation to the Hessian. HESSIAN=GLS is the default.

LTEBOUND=*n*

specifies the local truncation error bound for the integration. This option is ignored if no ordinary differential equations (ODEs) are specified.

EPSILON =*value*

specifies the tolerance value used to transform strict inequalities into inequalities when restrictions on parameters are imposed. By default, EPSILON=1E-8. See the section “[Restrictions and Bounds on Parameters](#)” on page 1076 for details.

MAXITER=*n*

specifies the maximum number of iterations allowed. The default is MAXITER=100.

MAXSUBITER=*n*

specifies the maximum number of subiterations allowed for an iteration. For the GAUSS method, the MAXSUBITER= option limits the number of step halvings. For the MARQUARDT method, the MAXSUBITER= option limits the number of times λ can be increased. The default is MAXSUBITER=30. See the section “[Minimization Methods](#)” on page 1027 for details.

METHOD=GAUSS | MARQUARDT

specifies the iterative minimization method to use. METHOD=GAUSS specifies the Gauss-Newton method, and METHOD=MARQUARDT specifies the Marquardt-Levenberg method. The default is METHOD=GAUSS. If the default GAUSS method fails to converge, the procedure switches to the MARQUARDT method. See the section “[Minimization Methods](#)” on page 1027 for details.

MINTIMESTEP=*n*

specifies the smallest allowed time step to be used in the integration. This option is ignored if no ODEs are specified.

NESTIT

changes the way the iterations are performed for estimation methods that iterate the estimate of the equation covariance (**S** matrix). The NESTIT option is relevant only for the methods that iterate the estimate of the covariance matrix (ITGMM, ITOLS, ITSUR, IT2SLS, and IT3SLS). See the section “[Details on the Covariance of Equation Errors](#)” on page 1026 for an explanation of NESTIT.

SINGULAR=*value*

specifies the smallest pivot value allowed. The default 1.0E–12.

STARTITER=*n*

specifies the number of minimization iterations to perform at each grid point. The default is STARTITER=0, which implies that no minimization is performed at the grid points. See the section “[Using the STARTITER Option](#)” on page 1035 for more details.

Other Options

Other options that can be used on the FIT statement include the following that list and analyze the model: BLOCK, GRAPH, LIST, LISTCODE, LISTDEP, LISTDER, and XREF. The following printing control options are also available: DETAILS, FLOW, INTGPRINT, MAXERRORS=, NO-PRINT, PRINTALL, and TRACE. For complete descriptions of these options, see the discussion of the PROC MODEL statement options earlier in this chapter.

ID Statement

ID *variables* ;

The ID statement specifies variables to identify observations in error messages or other listings and in the OUT= data set. The ID variables are normally SAS date or datetime variables. If more than one ID variable is used, the first variable is used to identify the observations; the remaining variables are added to the OUT= data set.

INCLUDE Statement

INCLUDE *model-names ...* ;

The INCLUDE statement reads model files and inserts their contents into the current model. However, instead of replacing the current model as the RESET MODEL= option does, the contents of included model files are inserted into the model program at the position that the INCLUDE statement appears.

INSTRUMENTS Statement

```
INSTRUMENTS variables < _EXOG_ > ;
```

```
INSTRUMENTS < variables-list > < _EXOG_ > < EXCLUDE =( parameters ) > < / options >  
;
```

```
INSTRUMENTS (equation, variables) (equation, variables) ... ;
```

The INSTRUMENTS statement specifies the instrumental variables to be used in the N2SLS, N3SLS, IT2SLS, IT3SLS, GMM, and ITGMM estimation methods.

There are three ways of specifying the INSTRUMENTS statement. The first form of the INSTRUMENTS statement is declared before a FIT statement and defines the default instruments list. The items specified as instruments can be variables or the special keyword `_EXOG_`. The keyword `_EXOG_` indicates that all the model variables declared EXOGENOUS are to be added to the instruments list. If a single INSTRUMENTS statement of the first form is declared before multiple FIT statements, then it serves as the default instruments list for each of the FIT statements. However, if any of these FIT statements are followed by separate INSTRUMENTS statement, then the latter take precedence over the default list. Hence, in the case of multiple FIT statements, the INSTRUMENTS statement for a particular FIT statement is written below the FIT statement if instruments other than the default are required. For a single FIT statement, you can declare the INSTRUMENTS statement of the first form either preceding or following the FIT statement.

The second form of the INSTRUMENTS statement is used only after the FIT statement and before the next RUN statement. The items specified as instruments for the second form can be variables, names of parameters to be estimated, or the special keyword `_EXOG_`. If you specify the name of a parameter in the instruments list, the partial derivatives of the equations with respect to the parameter (that is, the columns of the Jacobian matrix associated with the parameter) are used as instruments. The parameter itself is not used as an instrument. These partial derivatives should not depend on any of the parameters to be estimated. Only the names of parameters to be estimated can be specified.

Note that an INSTRUMENTS statement of only the first form declared before multiple FIT statements serves as the default instruments list. Hence, in the cases of multiple as well as single FIT statements, you can declare the second form of INSTRUMENTS statements only following the FIT statements.

In the case where a FIT statement is preceded by an INSTRUMENTS statement of the second form in error and not followed by any INSTRUMENTS statement, then the default list is used. This default list is given by the INSTRUMENTS statement of the first form as explained above. If such a list is not declared, all the model variables declared EXOGENOUS comprise the default.

A third form of the INSTRUMENTS statement is used to specify instruments for each equation. No explicit intercept is added, parameters cannot be specified to represent instruments, and the `_EXOG_` keyword is not allowed. Equations not explicitly assigned instruments use all the instruments specified for the other equations as well as instruments not assigned specific equations. In the following statements, `z1`, `z2`, and `z3` are instruments used with equation `y1`, and `z2`, `z3`, and `z4` are instruments used with equation `y2`.

```

proc model data=data_sim;
  exogenous x1 x2;
  parms a b c d e f;

  y1 =a*x1**2 + b*x2**2 + c*x1*x2   ;
  y2 =d*x1**2 + e*x2**2 + f*x1*x2**2;

  fit y1 y2 / 3sls ;
  instruments (y1, z1 z2 z3) (y2, z2 z3 z4);
run;

```

EXCLUDE=(parameters)

specifies that the derivatives of the equations with respect to all of the parameters to be estimated (except the parameters listed in the EXCLUDE list) be used as instruments, in addition to the other instruments specified. If you use the EXCLUDE= option, you should be sure that the derivatives with respect to the nonexcluded parameters in the estimation are independent of the endogenous variables and not functions of the parameters estimated.

The following options can be specified on the INSTRUMENTS statement following a slash (/):

NOINTERCEPT**NOINT**

excludes the constant of 1.0 (intercept) from the instruments list. An intercept is included as an instrument while using the first or second form of the INSTRUMENTS statement unless NOINTERCEPT is specified.

When a FIT statement specifies an instrumental variables estimation method and no INSTRUMENTS statement accompanies the FIT statement, the default instruments are used. If no default instruments list has been specified, all the model variables declared EXOGENOUS are used as instruments. See the section “[Choice of Instruments](#)” on page 1084 for more details.

INTONLY

specifies that only the intercept be used as an instrument. This option is used for GMM estimation where the moments have been specified explicitly.

LABEL Statement

LABEL *variable='label' ... ;*

The LABEL statement specifies a label of up to 255 characters for parameters and other variables used in the model program. Labels are used to identify parts of the printout of FIT and SOLVE tasks. The labels are displayed in the output if the LINESIZE= option is large enough.

MOMENT Statement

MOMENT *variables = moment specification ;*

In many scenarios, endogenous variables are observed from data. From the models, you can simulate these endogenous variables based on a fixed set of parameters. The goal of simulated method of moments (SMM) is to find a set of parameters such that the moments of the simulated data match the moments of the observed variables. If there are many moments to match, the code might be tedious. The following MOMENT statement provides a way to generate some commonly used moments automatically. Multiple MOMENT statements can be used.

variables can be one or more endogenous variables.

moment specification can have the following four types:

- (*number list*) specifies that the endogenous variable is raised to the power specified by each number in *number list*. For example,

```
moment y = (2 3);
```

adds the following two equations to be estimated:

```
eq._moment_1 = y**2 - pred.y**2;
eq._moment_2 = y**3 - pred.y**3;
```

- ABS(*number list*) specifies that the absolute value of the endogenous variable is raised to the power specified by each number in *number list*. For example,

```
moment y = ABS(3);
```

adds the following equation to be estimated:

```
eq._moment_2 = abs(y)**3 - abs(pred.y)**3;
```

- LAGnum (*number list*) specifies that the endogenous variable is multiplied by the *num*th lag of the endogenous variable, and this product is raised to the power specified by each number in *number list*. For example,

```
moment y = LAG4(3);
```

adds the following equation to be estimated:

```
eq._moment_3 = (y*lag4(y))**3 - (pred.y*lag4(pred.y))**3;
```

- ABS_LAGnum (*number list*) specifies that the endogenous variable is multiplied by the *num*th lag of the endogenous variable, and the absolute value of this product is raised to the power specified by each number in *number list*. For example,

```
moment y = ABS_LAG4(3);
```

adds the following equation to be estimated:

$$\text{eq.}_\text{moment}_4 = \text{abs}(y*\text{lag4}(y))^{**3} - \text{abs}(\text{pred.}y*\text{lag4}(\text{pred.}y))^{**3};$$

The following PROC MODEL statements use the MOMENT statement to generate 24 moments and fit these moments using SMM.

```
proc model data=_tmpdata list;
  parms a b .5 s 1;
  instrument _exog_ / intonly;

  u = rannor( 10091 );
  z = rannor( 97631 );

  lsigmasq = xlag(sigmasq,exp(a));

  lnsigmasq = a + b * log(lsigmasq) + s * u;
  sigmasq = exp( lnsigmasq );

  y = sqrt(sigmasq) * z;

  moment y = (2 4) abs(1 3) abs_lag1(1 2) abs_lag2(1 2);
  moment y = abs_lag3(1 2) abs_lag4(1 2)
             abs_lag5(1 2) abs_lag6(1 2)
             abs_lag7(1 2) abs_lag8(1 2)
             abs_lag9(1 2) abs_lag10(1 2);

  fit y / gmm npreobs=20 ndraw=10;
  bound s > 0, 1>b>0;

run;
```

OUTVARS Statement

OUTVARS *variables* ;

The OUTVARS statement specifies additional variables defined in the model program to be output to the OUT= data sets. The OUTVARS statement is not needed unless the variables to be added to the output data set are not referred to by the model, or unless you want to include parameters or other special variables in the OUT= data set. The OUTVARS statement includes additional variables, whereas the KEEP statement excludes variables.

PARAMETERS Statement

PARAMETERS *variable* < *value* > < *variable* < *value* > > ... ;

The PARAMETERS statement declares the parameters of a model and optionally sets their initial values. Valid abbreviations are PARMS and PARM.

Each parameter has a single value associated with it, which is the same for all observations. Lagging is not relevant for parameters. If a value is not specified in the PARMS statement (or by the PARMS= option of a FIT statement), the value defaults to 0.0001 for FIT tasks and to a missing value for SOLVE tasks.

Programming Statements

To define the model, you can use most of the programming statements that are allowed in the SAS DATA step. See the *SAS Language Reference: Dictionary* for more information.

RANGE Statement

RANGE *variable* < = *first* > < TO *last* > ;

The RANGE statement specifies the range of observations to be read from the DATA= data set. For FIT tasks, the RANGE statement controls the period of fit for the estimation. For SOLVE tasks, the RANGE statement controls the simulation period or forecast horizon.

The RANGE variable must be a numeric variable in the DATA= data set that identifies the observations, and the data set must be sorted by the RANGE variable. The first observation in the range is identified by *first*, and the last observation is identified by *last*.

PROC MODEL uses the first *l* observations prior to *first* to initialize the lags, where *l* is the maximum number of lags needed to evaluate any of the equations to be fit or solved, or the maximum number of lags needed to compute any of the instruments when an instrumental variables estimation method is used. There should be at least *l* observations in the data set before *first*. If *last* is not specified, all the nonmissing observations starting with *first* are used.

If *first* is omitted, the first *l* observations are used to initialize the lags, and the rest of the data, until *last*, is used. If a RANGE statement is used but both *first* and *last* are omitted, the RANGE statement variable is used to report the range of observations processed.

The RANGE variable should be nonmissing for all observations. Observations that contain missing RANGE values are deleted.

The following are examples of RANGE statements:

```
range year = 1971 to 1988;           /* yearly data */
range date = '1feb73'd to '1nov82'd; /* monthly data */
range time = 60.5;                 /* time in years */
range year to 1977;                /* use all years through 1977 */
range date; /* use values of date to report period-of-fit */
```

If no RANGE statements follow multiple FIT statements and a single RANGE statement is declared before all the FIT statements, estimation in each of the multiple FIT statements is based on the data specified in the single RANGE statement. A single RANGE statement following multiple FIT statements affects only the fit immediately preceding it.

If the FIT statement is both followed by and preceded by RANGE statements, the following RANGE statement takes precedence over the preceding RANGE statement.

In the case where a range of data is to be used for a particular SOLVE task, the RANGE statement should be specified following the SOLVE statement in the case of either single or multiple SOLVE statements.

RESET Statement

RESET *options* ;

All of the options of the PROC MODEL statement can be reset by the RESET statement. In addition, the RESET statement supports one additional option:

PURGE

deletes the current model so that a new model can be defined.

When the MODEL= option is used in the RESET statement, the current model is deleted before the new model is read.

RESTRICT Statement

RESTRICT *restriction1* < , *restriction2* ... > ;

The RESTRICT statement is used to impose linear and nonlinear restrictions on the parameter estimates.

RESTRICT statements refer to the parameters estimated by the associated FIT statement (that is, to either the preceding FIT statement or, in the absence of a preceding FIT statement, to the following FIT statement). You can specify any number of RESTRICT statements.

Each *restriction* is written as an optional name, followed by an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

< "name" > expression operator expression

The optional "name" is a string used to identify the restriction in the printed output and in the OUTEST= data set. The *operator* can be =, <, >, <=, or >=. The operator and second expression are optional.

Restriction expressions can be composed of parameter names, arithmetic operators, functions, and constants. Comparison operators (such as = or <) and logical operators (such as &) cannot be used

in RESTRICT statement expressions. Parameters named in restriction expressions must be among the parameters estimated by the associated FIT statement. Expressions can refer to variables defined in the program.

The restriction expressions can be linear or nonlinear functions of the parameters.

The following is an example of the use of the RESTRICT statement:

```
proc model data=one;
  endogenous y1 y2;
  exogenous x1 x2;
  parms a b c;
  restrict b*(b+c) <= a;

  eq.one = -y1/c + a/x2 + b * x1**2 + c * x2**2;
  eq.two = -y2 * y1 + b * x2**2 - c/(2 * x1);

  fit one two / fml;
run;
```

SOLVE Statement

SOLVE *variables* < *SATISFY= equations* > < /*options* > ;

The SOLVE statement specifies that the model be simulated or forecast for input data values and, optionally, selects the variables to be solved. If the list of variables is omitted, all of the model variables declared ENDOGENOUS are solved. If no model variables are declared ENDOGENOUS, then all model variables are solved.

The following specification can be used in the SOLVE statement:

SATISFY=*equation*

SATISFY=(*equations*)

specifies a subset of the model equations that the solution values are to satisfy. If the SATISFY= option is not used, the solution is computed to satisfy all the model equations. Note that the number of equations must equal the number of variables solved.

Data Set Options

DATA=*SAS-data-set*

names the input data set. The model is solved for each observation read from the DATA= data set. If the DATA= option is not specified on the SOLVE statement, the data set specified by the DATA= option in the PROC MODEL statement is used.

ESTDATA=*SAS-data-set*

names a data set whose first observation provides values for some or all of the parameters and whose additional observations (if any) give the covariance matrix of the parameter estimates.

The covariance matrix read from the ESTDATA= data set is used to generate multivariate normal pseudo-random shocks to the model parameters when the RANDOM= option requests Monte Carlo simulation.

OUT=SAS-data-set

outputs the predicted (solution) values, residual values, actual values, or equation errors from the solution to a data set. The residual values are the *actual – predicted* values, which is the negative of RESID.variable as defined in the section “[Equation Translations](#)” on page 1155. Only the solution values are output by default.

OUTACTUAL

outputs the actual values of the solved variables read from the input data set to the OUT= data set. This option is applicable only if the OUT= option is specified.

OUTALL

specifies the OUTACTUAL, OUTERRORS, OUTLAGS, OUTPREDICT, and OUTRESID options.

OUTERRORS

writes the equation errors to the OUT= data set. These values are normally very close to zero when a simultaneous solution is computed; they can be used to double-check the accuracy of the solution process. It is applicable only if the OUT= option is specified.

OUTLAGS

writes the observations used to start the lags to the OUT= data set. This option is applicable only if the OUT= option is specified.

OUTPREDICT

writes the solution values to the OUT= data set. This option is relevant only if the OUT= option is specified.

The OUTPREDICT option is the default unless one of the other output options is used.

OUTRESID

writes the residual values computed as the *actual – predicted* values and is not the same as the RESID.variable values. This option is applicable only if the OUT= option is specified.

PARMSDATA=SAS-data-set

specifies a data set that contains the parameter estimates. See the section “[Input Data Sets](#)” on page 1104 for more details.

RESIDDATA=SAS-data-set

specifies a data set that contains the residuals that are to be used in the empirical distribution. This data set can be created using the OUT= option on the FIT statement.

SDATA=SAS-data-set

specifies a data set that provides the covariance matrix of the equation errors. The covariance matrix read from the SDATA= data set is used to generate multivariate normal pseudo-random shocks to the equations when the RANDOM= option requests Monte Carlo simulation.

TYPE=*name*

specifies the estimation type. The name specified in the TYPE= option is compared to the `_TYPE_` variable in the ESTDATA= and SDATA= data sets to select observations to use in constructing the covariance matrices. When TYPE= is omitted, the last estimation type in the data set is used.

Solution Mode Options: Lag Processing

DYNAMIC

specifies a dynamic solution. In the dynamic solution mode, solved values are used by the lagging functions. DYNAMIC is the default.

NAHEAD=*n*

specifies a simulation of *n*-period-ahead dynamic forecasting. The NAHEAD= option is used to simulate the process of using the model to produce successive forecasts to a fixed forecast horizon, in which each forecast uses the historical data available at the time the forecast is made.

Note that NAHEAD=1 produces a static (one-step-ahead) solution. NAHEAD=2 produces a solution that uses one-step-ahead solutions for the first lag (LAG1 functions return static predicted values) and actual values for longer lags. NAHEAD=3 produces a solution that uses NAHEAD=2 solutions for the first lags, NAHEAD=1 solutions for the second lags, and actual values for longer lags. In general, NAHEAD=*n* solutions use NAHEAD=*n*−1 solutions for LAG1, NAHEAD=*n*−2 solutions for LAG2, and so forth.

START=*s*

specifies static solutions until the *s*th observation and then changes to dynamic solutions. If the START=*s* option is specified, the first observation in the range in which LAG n delivers solved predicted values is *s*+*n*, while LAG n returns actual values for earlier observations.

STATIC

specifies a static solution. In static solution mode, actual values of the solved variables from the input data set are used by the lagging functions.

Solution Mode Options: Use of Available Data

FORECAST

specifies that the actual value of a solved variable is used as the solution value (instead of the predicted value from the model equations) whenever nonmissing data are available in the input data set. That is, in FORECAST mode, PROC MODEL solves only for those variables that are missing in the input data set.

SIMULATE

specifies that PROC MODEL always solves for all solution variables as a function of the input values of the other variables, even when actual data for some of the solution variables are available in the input data set. SIMULATE is the default.

Solution Mode Options: Numerical Solution Method

JACOBI

computes a simultaneous solution using a Jacobi iteration.

NEWTON

computes a simultaneous solution by using Newton's method. When the NEWTON option is selected, the analytic derivatives of the equation errors with respect to the solution variables are computed, and memory-efficient sparse matrix techniques are used for factoring the Jacobian matrix.

The NEWTON option can be used to solve both normalized-form and general-form equations and can compute goal-seeking solutions. NEWTON is the default.

SEIDEL

computes a simultaneous solution by using a Gauss-Seidel method.

SINGLE

ONEPASS

specifies a single-equation (nonsimultaneous) solution. The model is executed once to compute predicted values for the variables from the actual values of the other endogenous variables. The SINGLE option can be used only for normalized-form equations and cannot be used for goal-seeking solutions.

For more information on these options, see the section “[Solution Modes](#)” on page 1117.

Monte Carlo Simulation Options

COPULA=(NORMAL | NORMALMIX($n, p_1 \dots p_n, v_1 \dots v_n$) | T(df) < ASYM >)

specifies copula to be used in the simulation. The normal (Gaussian) copula is the default. The copula applies to covariance of equation errors.

PSEUDO=DEFAULT | TWISTER

specifies which pseudo-number generator is to be used in generating draws for Monte Carlo simulation. The two pseudo-random number generators supported by the MODEL procedure are a default congruential generator which has period $2^{31} - 1$ and Mersenne-Twister pseudo-random number generator which has an extraordinarily long period $2^{19937} - 1$.

QUASI=NONE|SOBOL|FAURE

specifies a pseudo- or quasi-random number generator. Two quasi-random number generators are supported by the MODEL procedure: the Sobol sequence (QUASI=SOBOL) and the Faure sequence (QUASI=FAURE). The default is QUASI=NONE, which is the pseudo-random number generator.

RANDOM= n

repeats the solution n times for each BY group, with different random perturbations of the equation errors if the SDATA= option is used; with different random perturbations of the parameters if the ESTDATA= option is used and the ESTDATA= data set contains a parameter covariance matrix; and with different values returned from the random number generator

functions, if any are used in the model program. If `RANDOM=0`, the random number generator functions always return zero. See the section “[Monte Carlo Simulation](#)” on page 1120 for details. The default is `RANDOM=0`.

SEED=*n*

specifies an integer to use as the seed in generating pseudo-random numbers to shock the parameters and equations when the `ESTDATA=` or the `SDATA=` options are specified. If *n* is negative or zero, the time of day from the computer’s clock is used as the seed. The `SEED=` option is relevant only if the `RANDOM=` option is used. The default is `SEED=0`.

WISHART=*df*

specifies that a Wishart distribution with degrees of freedom *df* be used in place of the normal error covariance matrix. This option is used to model the variance of the error covariance matrix when Monte Carlo simulation is selected.

Options for Controlling the Numerical Solution Process

The following options are useful when you have difficulty converging to the simultaneous solution.

CONVERGE=*value*

specifies the convergence criterion for the simultaneous solution. Convergence of the solution is judged by comparing the `CONVERGE=` value to the maximum over the equations of

$$\frac{|\epsilon_i|}{|y_i| + 1E - 6}$$

if they are computable, otherwise

$$|\epsilon_i|$$

where ϵ_i represents the equation error and y_i represents the solution variable that corresponds to the *i*th equation for normalized-form equations. The default is `CONVERGE=1E-8`.

MAXITER=*n*

specifies the maximum number of iterations allowed for computing the simultaneous solution for any observation. The default is `MAXITER=50`.

MAXSUBITER=*n*

specifies the maximum number of damping subiterations that are performed in solving a nonlinear system when using the `NEWTON` solution method. Damping is disabled by setting `MAXSUBITER=0`. The default is `MAXSUBITER=10`.

Printing Options

INTGPRINT

prints between data points integration values for the `DETRT.` variables and the auxiliary variables. If you specify the `DETAILS` option, the integrated derivative variables are printed as well.

ITPRINT

prints the solution approximation and equation errors at each iteration for each observation. This option can produce voluminous output.

PRINTALL

specifies the printing control options DETAILS, ITPRINT, SOLVEPRINT, STATS, and THEIL.

SOLVEPRINT

prints the solution values and residuals at each observation.

STATS

prints various summary statistics for the solution values.

THEIL

prints tables of Theil inequality coefficients and Theil relative change forecast error measures for the solution values. See the section “[Summary Statistics](#)” on page 1135 for more information.

Other Options

Other options that can be used on the SOLVE statement include the following that list and analyze the model: BLOCK, GRAPH, LIST, LISTCODE, LISTDEP, LISTDER, and XREF. The LTEBOUND= and MINTIMESTEP= options can be used to control the integration process. The following printing-control options are also available: DETAILS, FLOW, MAXERRORS=, NO-PRINT, and TRACE. For complete descriptions of these options, see the PROC MODEL and FIT statement options described earlier in this chapter.

TEST Statement

```
TEST < "name" > test1 < , test2 ... > < , / options > ;
```

The TEST statement performs tests of nonlinear hypotheses on the model parameters.

The TEST statement applies to the parameters estimated by the associated FIT statement (that is, either the preceding FIT statement or, in the absence of a preceding FIT statement, the following FIT statement). You can specify any number of TEST statements.

If you specify options on the TEST statement, a comma is required before the “/” character that separates the test expressions from the options, because the “/” character can also be used within test expressions to indicate division.

The label lengths for tests and estimate statements are 256 characters. If the labels exceed this length, the label is truncated to 256 characters with a note printed to the log.

Each test is written as an expression optionally followed by an equal sign (=) and a second expression:

< expression > <= expression >

Test expressions can be composed of parameter names, arithmetic operators, functions, and constants. Comparison operators (such as =) and logical operators (such as &) cannot be used in TEST statement expressions. Parameters named in test expressions must be among the parameters estimated by the associated FIT statement.

If you specify only one expression in a test, that expression is tested against zero. For example, the following two TEST statements are equivalent:

```
test a + b;

test a + b = 0;
```

When you specify multiple tests in the same TEST statement, a joint test is performed. For example, the following TEST statement tests the joint hypothesis that both A and B are equal to zero.

```
test a, b;
```

To perform separate tests rather than a joint test, use separate TEST statements. For example, the following TEST statements test the two separate hypotheses that A is equal to zero and that B is equal to zero.

```
test a;
test b;
```

You can use the following options in the TEST statement.

WALD

specifies that a Wald test be computed. WALD is the default.

LM**RAO****LAGRANGE**

specifies that a Lagrange multiplier test be computed.

LR**LIKE**

specifies that a likelihood ratio test be computed.

ALL

requests all three types of tests.

OUT=SAS-data-set

specifies the name of an output SAS data set that contains the test results. The format of the OUT= data set produced by the TEST statement is similar to that of the OUTEST= data set produced by the FIT statement.

VAR Statement

VAR *variables* < *initial-values* > ... ;

The VAR statement declares model variables and optionally provides initial values for the lags of the variables. See the section “[Lag Logic](#)” on page 1161 for more information.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters.

If the weight of an observation is nonpositive, that observation is not used for the estimation. *variable* must be a numeric variable in the input data set.

An alternative weighting method is to use an assignment statement to give values to the special variable `_WEIGHT_`. The `_WEIGHT_` variable must not depend on the parameters being estimated. If both weighting specifications are given, the weights are multiplied together.

Details: Estimation by the MODEL Procedure

Estimation Methods

Consider the general nonlinear model:

$$\begin{aligned}\epsilon_t &= \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta}) \\ \mathbf{z}_t &= Z(\mathbf{x}_t)\end{aligned}$$

where $\mathbf{q} \in R^g$ is a real vector valued function of $y_t \in R^g$, $\mathbf{x}_t \in R^l$, $\boldsymbol{\theta} \in R^p$, where g is the number of equations, l is the number of exogenous variables (lagged endogenous variables are considered exogenous here), p is the number of parameters, and t ranges from 1 to n . $\mathbf{z}_t \in R^k$ is a vector of instruments. ϵ_t is an unobservable disturbance vector with the following properties:

$$\begin{aligned}E(\epsilon_t) &= 0 \\ E(\epsilon_t \epsilon_t') &= \Sigma\end{aligned}$$

All of the methods implemented in PROC MODEL aim to minimize an *objective function*. The following table summarizes the objective functions that define the estimators and

the corresponding estimator of the covariance of the parameter estimates for each method.

Table 18.2 Summary of PROC MODEL Estimation Methods

Method	Instruments	Objective Function	Covariance of θ
OLS	no	$\mathbf{r}'\mathbf{r}/n$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
ITOLS	no	$\mathbf{r}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{r}/n$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
SUR	no	$\mathbf{r}'(\mathbf{S}_{\text{OLS}}^{-1} \otimes \mathbf{I})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
ITSUR	no	$\mathbf{r}'(\mathbf{S}^{-1} \otimes \mathbf{I})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
N2SLS	yes	$\mathbf{r}'(\mathbf{I} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
IT2SLS	yes	$\mathbf{r}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
N3SLS	yes	$\mathbf{r}'(\mathbf{S}_{\text{N2SLS}}^{-1} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
IT3SLS	yes	$\mathbf{r}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
GMM	yes	$[\mathbf{n}\mathbf{m}_n(\theta)]'\hat{\mathbf{V}}_{\text{N2SLS}}^{-1}[\mathbf{n}\mathbf{m}_n(\theta)]/n$	$[(\mathbf{Y}\mathbf{X})'\hat{\mathbf{V}}^{-1}(\mathbf{Y}\mathbf{X})]^{-1}$
ITGMM	yes	$[\mathbf{n}\mathbf{m}_n(\theta)]'\hat{\mathbf{V}}^{-1}[\mathbf{n}\mathbf{m}_n(\theta)]/n$	$[(\mathbf{Y}\mathbf{X})'\hat{\mathbf{V}}^{-1}(\mathbf{Y}\mathbf{X})]^{-1}$
FIML	no	$\text{constant} + \frac{n}{2}\ln(\det(\mathbf{S})) - \sum_1^n \ln (\mathbf{J}_t) $	$[\hat{\mathbf{Z}}'(\mathbf{S}^{-1} \otimes \mathbf{I})\hat{\mathbf{Z}}]^{-1}$

The column labeled “Instruments” identifies the estimation methods that require instruments. The variables used in this table and the remainder of this chapter are defined as follows:

n = is the number of nonmissing observations.

g = is the number of equations.

k = is the number of instrumental variables.

$\mathbf{r} = \begin{bmatrix} r_1 \\ r_2 \\ \vdots \\ r_g \end{bmatrix}$ is the $ng \times 1$ vector of residuals for the g equations stacked together.

$\mathbf{r}_i = \begin{bmatrix} q_i(\mathbf{y}_1, \mathbf{x}_1, \boldsymbol{\theta}) \\ q_i(\mathbf{y}_2, \mathbf{x}_2, \boldsymbol{\theta}) \\ \vdots \\ q_i(\mathbf{y}_n, \mathbf{x}_n, \boldsymbol{\theta}) \end{bmatrix}$ is the $n \times 1$ column vector of residuals for the i th equation.

\mathbf{S} is a $g \times g$ matrix that estimates $\boldsymbol{\Sigma}$, the covariances of the errors across equations (referred to as the \mathbf{S} matrix).

\mathbf{X} is an $ng \times p$ matrix of partial derivatives of the residual with respect to the parameters.

\mathbf{W} is an $n \times n$ matrix, $\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$.

\mathbf{Z} is an $n \times k$ matrix of instruments.

\mathbf{Y} is a $gk \times ng$ matrix of instruments. $\mathbf{Y} = \mathbf{I}_g \otimes \mathbf{Z}'$.

$\hat{\mathbf{Z}}$ $\hat{\mathbf{Z}} = (\hat{\mathbf{Z}}_1, \hat{\mathbf{Z}}_2, \dots, \hat{\mathbf{Z}}_p)$ is an $ng \times p$ matrix. $\hat{\mathbf{Z}}_i$ is a $ng \times 1$ column vector obtained

from stacking the columns of

$$\mathbf{U} \frac{1}{n} \sum_{t=1}^n \left(\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})'}{\partial \mathbf{y}_t} \right)^{-1} \frac{\partial^2 \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})'}{\partial \mathbf{y}_t \partial \boldsymbol{\theta}_i} - \mathbf{Q}_i$$

\mathbf{U}	is an $n \times g$ matrix of residual errors. $\mathbf{U} = \boldsymbol{\epsilon}_1, \boldsymbol{\epsilon}_2, \dots, \boldsymbol{\epsilon}_n'$.
\mathbf{Q}	is the $n \times g$ matrix $\mathbf{q}(\mathbf{y}_1, \mathbf{x}_1, \boldsymbol{\theta}), \mathbf{q}(\mathbf{y}_2, \mathbf{x}_2, \boldsymbol{\theta}), \dots, \mathbf{q}(\mathbf{y}_n, \mathbf{x}_n, \boldsymbol{\theta})$.
\mathbf{Q}_i	is an $n \times g$ matrix $\frac{\partial \mathbf{Q}}{\partial \boldsymbol{\theta}_i}$.
\mathbf{I}	is an $n \times n$ identity matrix.
\mathbf{J}_t	is $\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})}{\partial \mathbf{y}_t}$, which is a $g \times g$ Jacobian matrix.
\mathbf{m}_n	is first moment of the crossproduct $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t$, $m_n = \frac{1}{n} \sum_{t=1}^n \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t$
\mathbf{z}_t	is a k column vector of instruments for observation t . \mathbf{z}_t' is also the t th row of \mathbf{Z} .
$\hat{\mathbf{V}}$	is the $gk \times gk$ matrix that represents the variance of the moment functions.
k	is the number of instrumental variables used.
<i>constant</i>	is the constant $\frac{ng}{2}(1 + \ln(2\pi))$.
\otimes	is the notation for a Kronecker product.

All vectors are column vectors unless otherwise noted. Other estimates of the covariance matrix for FIML are also available.

Dependent Regressors and Two-Stage Least Squares

Ordinary regression analysis is based on several assumptions. A key assumption is that the independent variables are in fact statistically independent of the unobserved error component of the model. If this assumption is not true (if the regressor varies systematically with the error), then ordinary regression produces inconsistent results. The parameter estimates are *biased*.

Regressors might fail to be independent variables because they are dependent variables in a larger simultaneous system. For this reason, the problem of dependent regressors is often called *simultaneous equation bias*. For example, consider the following two-equation system:

$$y_1 = a_1 + b_1 y_2 + c_1 x_1 + \epsilon_1$$

$$y_2 = a_2 + b_2 y_1 + c_2 x_2 + \epsilon_2$$

In the first equation, y_2 is a dependent, or *endogenous*, variable. As shown by the second equation, y_2 is a function of y_1 , which by the first equation is a function of ϵ_1 , and therefore y_2 depends on ϵ_1 . Likewise, y_1 depends on ϵ_2 and is a dependent regressor in the second equation. This is an example of a *simultaneous equation* system; y_1 and y_2 are a function of all the variables in the system.

Using the ordinary least squares (OLS) estimation method to estimate these equations produces biased estimates. One solution to this problem is to replace y_1 and y_2 on the right-hand side of the equations with predicted values, thus changing the regression problem to the following:

$$y_1 = a_1 + b_1 \hat{y}_2 + c_1 x_1 + \epsilon_1$$

$$y_2 = a_2 + b_2\hat{y}_1 + c_2x_2 + \epsilon_2$$

This method requires estimating the predicted values \hat{y}_1 and \hat{y}_2 through a preliminary, or “first stage,” *instrumental regression*. An instrumental regression is a regression of the dependent regressors on a set of *instrumental variables*, which can be any independent variables useful for predicting the dependent regressors. In this example, the equations are linear and the exogenous variables for the whole system are known. Thus, the best choice for instruments (of the variables in the model) are the variables x_1 and x_2 .

This method is known as *two-stage least squares* or 2SLS, or more generally as the *instrumental variables method*. The 2SLS method for linear models is discussed in Pindyck (1981, p. 191–192). For nonlinear models this situation is more complex, but the idea is the same. In nonlinear 2SLS, the derivatives of the model with respect to the parameters are replaced with predicted values. See the section “[Choice of Instruments](#)” on page 1084 for further discussion of the use of instrumental variables in nonlinear regression.

To perform nonlinear 2SLS estimation with PROC MODEL, specify the instrumental variables with an INSTRUMENTS statement and specify the 2SLS or N2SLS option in the FIT statement. The following statements show how to estimate the first equation in the preceding example with PROC MODEL:

```
proc model data=in;
  y1 = a1 + b1 * y2 + c1 * x1;
  fit y1 / 2s1s;
  instruments x1 x2;
run;
```

The 2SLS or instrumental variables estimator can be computed by using a first-stage regression on the instrumental variables as described previously. However, PROC MODEL actually uses the equivalent but computationally more appropriate technique of projecting the regression problem into the linear space defined by the instruments. Thus, PROC MODEL does not produce any “first stage” results when you use 2SLS. If you specify the FRSQ option in the FIT statement, PROC MODEL prints “First-Stage R²” statistic for each parameter estimate.

Formally, the $\hat{\theta}$ that minimizes

$$\hat{S}_n = \frac{1}{n} \left(\sum_{t=1}^n (\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t) \right)' \left(\sum_{t=1}^n I \otimes \mathbf{z}_t \mathbf{z}_t' \right)^{-1} \left(\sum_{t=1}^n (\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t) \right)$$

is the N2SLS estimator of the parameters. The estimate of Σ at the final iteration is used in the covariance of the parameters given in [Table 18.2](#). See Amemiya (1985, p. 250) for details on the properties of nonlinear two-stage least squares.

Seemingly Unrelated Regression

If the regression equations are not simultaneous (so there are no dependent regressors), *seemingly unrelated regression* (SUR) can be used to estimate systems of equations with correlated random

errors. The large-sample efficiency of an estimation can be improved if these cross-equation correlations are taken into account. SUR is also known as *joint generalized least squares* or *Zellner regression*. Formally, the $\hat{\theta}$ that minimizes

$$\hat{S}_n = \frac{1}{n} \sum_{t=1}^n \mathbf{q}(y_t, \mathbf{x}_t, \theta)' \hat{\Sigma}^{-1} \mathbf{q}(y_t, \mathbf{x}_t, \theta)$$

is the SUR estimator of the parameters.

The SUR method requires an estimate of the cross-equation covariance matrix, Σ . PROC MODEL first performs an OLS estimation, computes an estimate, $\hat{\Sigma}$, from the OLS residuals, and then performs the SUR estimation based on $\hat{\Sigma}$. The OLS results are not printed unless you specify the OLS option in addition to the SUR option.

You can specify the $\hat{\Sigma}$ to use for SUR by storing the matrix in a SAS data set and naming that data set in the SDATA= option. You can also feed the $\hat{\Sigma}$ computed from the SUR residuals back into the SUR estimation process by specifying the ITSUR option. You can print the estimated covariance matrix $\hat{\Sigma}$ by using the COVS option in the FIT statement.

The SUR method requires estimation of the Σ matrix, and this increases the sampling variability of the estimator for small sample sizes. The efficiency gain that SUR has over OLS is a large sample property, and you must have a reasonable amount of data to realize this gain. For a more detailed discussion of SUR, see Pindyck and Rubinfeld (1981, p. 331-333).

Three-Stage Least Squares Estimation

If the equation system is simultaneous, you can combine the 2SLS and SUR methods to take into account both dependent regressors and cross-equation correlation of the errors. This is called *three-stage least squares* (3SLS).

Formally, the $\hat{\theta}$ that minimizes

$$\hat{S}_n = \frac{1}{n} \left(\sum_{t=1}^n (\mathbf{q}(y_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t) \right)' \left(\sum_{t=1}^n (\hat{\Sigma} \otimes \mathbf{z}_t \mathbf{z}_t') \right)^{-1} \left(\sum_{t=1}^n (\mathbf{q}(y_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t) \right)$$

is the 3SLS estimator of the parameters. For more details on 3SLS, see Gallant (1987, p. 435).

Residuals from the 2SLS method are used to estimate the Σ matrix required for 3SLS. The results of the preliminary 2SLS step are not printed unless the 2SLS option is also specified.

To use the three-stage least squares method, specify an INSTRUMENTS statement and use the 3SLS or N3SLS option in either the PROC MODEL statement or a FIT statement.

Generalized Method of Moments (GMM)

For systems of equations with heteroscedastic errors, generalized method of moments (GMM) can be used to obtain efficient estimates of the parameters. See the section “[Heteroscedasticity](#)” on page 1050 for alternatives to GMM.

Consider the nonlinear model

$$\begin{aligned}\boldsymbol{\epsilon}_t &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \\ \mathbf{z}_t &= \mathbf{Z}(\mathbf{x}_t)\end{aligned}$$

where \mathbf{z}_t is a vector of instruments and $\boldsymbol{\epsilon}_t$ is an unobservable disturbance vector that can be serially correlated and nonstationary.

In general, the following orthogonality condition is desired:

$$E(\boldsymbol{\epsilon}_t \otimes \mathbf{z}_t) = 0$$

This condition states that the expected crossproducts of the unobservable disturbances, $\boldsymbol{\epsilon}_t$, and functions of the observable variables are set to 0. The first moment of the crossproducts is

$$\begin{aligned}\mathbf{m}_n &= \frac{1}{n} \sum_{t=1}^n \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \\ \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t\end{aligned}$$

where $\mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \in R^{gk}$.

The case where $gk > p$ is considered here, where p is the number of parameters.

Estimate the true parameter vector $\boldsymbol{\theta}^0$ by the value of $\hat{\boldsymbol{\theta}}$ that minimizes

$$S(\boldsymbol{\theta}, \mathbf{V}) = [n\mathbf{m}_n(\boldsymbol{\theta})]' \mathbf{V}^{-1} [n\mathbf{m}_n(\boldsymbol{\theta})] / n$$

where

$$\mathbf{V} = \text{Cov}([n\mathbf{m}_n(\boldsymbol{\theta}^0)], [n\mathbf{m}_n(\boldsymbol{\theta}^0)]')$$

The parameter vector that minimizes this objective function is the GMM estimator. GMM estimation is requested in the FIT statement with the GMM option.

The variance of the moment functions, \mathbf{V} , can be expressed as

$$\begin{aligned}\mathbf{V} &= E \left(\sum_{t=1}^n \boldsymbol{\epsilon}_t \otimes \mathbf{z}_t \right) \left(\sum_{s=1}^n \boldsymbol{\epsilon}_s \otimes \mathbf{z}_s \right)' \\ &= \sum_{t=1}^n \sum_{s=1}^n E [(\boldsymbol{\epsilon}_t \otimes \mathbf{z}_t)(\boldsymbol{\epsilon}_s \otimes \mathbf{z}_s)'] \\ &= n\mathbf{S}_n^0\end{aligned}$$

where \mathbf{S}_n^0 is estimated as

$$\hat{\mathbf{S}}_n = \frac{1}{n} \sum_{t=1}^n \sum_{s=1}^n (\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t)(\mathbf{q}(\mathbf{y}_s, \mathbf{x}_s, \boldsymbol{\theta}) \otimes \mathbf{z}_s)'$$

Note that $\hat{\mathbf{S}}_n$ is a $gk \times gk$ matrix. Because $\text{Var}(\hat{\mathbf{S}}_n)$ does not decrease with increasing n , you consider estimators of \mathbf{S}_n^0 of the form:

$$\hat{\mathbf{S}}_n(l(n)) = \sum_{\tau=-n+1}^{n-1} w\left(\frac{\tau}{l(n)}\right) \mathbf{D} \hat{\mathbf{S}}_{n,\tau} \mathbf{D}$$

$$\hat{\mathbf{S}}_{n,\tau} = \begin{cases} \sum_{t=1+\tau}^n [\mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta}^\#) \otimes \mathbf{z}_t][\mathbf{q}(y_{t-\tau}, \mathbf{x}_{t-\tau}, \boldsymbol{\theta}^\#) \otimes \mathbf{z}_{t-\tau}]' & \tau \geq 0 \\ (\hat{\mathbf{S}}_{n,-\tau})' & \tau < 0 \end{cases}$$

where $l(n)$ is a scalar function that computes the bandwidth parameter, $w(\cdot)$ is a scalar valued kernel, and the diagonal matrix \mathbf{D} is used for a small sample degrees of freedom correction (Gallant 1987). The initial $\boldsymbol{\theta}^\#$ used for the estimation of $\hat{\mathbf{S}}_n$ is obtained from a 2SLS estimation of the system. The degrees of freedom correction is handled by the VARDEF= option as it is for the \mathbf{S} matrix estimation.

The following kernels are supported by PROC MODEL. They are listed with their default bandwidth functions.

Bartlett: KERNEL=BART

$$w(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(n) = \frac{1}{2}n^{1/3}$$

Parzen: KERNEL=PARZEN

$$w(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(n) = n^{1/5}$$

Quadratic spectral: KERNEL=QS

$$w(x) = \frac{25}{12\pi^2 x^2} \left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5) \right)$$

$$l(n) = \frac{1}{2}n^{1/5}$$

Figure 18.21 Kernels for Smoothing

Details of the properties of these and other kernels are given in Andrews (1991). Kernels are selected with the `KERNEL=` option; `KERNEL=PARZEN` is the default. The general form of the `KERNEL=` option is

```
KERNEL=( PARZEN | QS | BART, c, e )
```

where the $e \geq 0$ and $c \geq 0$ are used to compute the bandwidth parameter as

$$l(n) = cn^e$$

The bias of the standard error estimates increases for large bandwidth parameters. A warning message is produced for bandwidth parameters greater than $n^{1/3}$. For a discussion of the computation of the optimal $l(n)$, refer to Andrews (1991).

The “Newey-West” kernel (Newey and West 1987) corresponds to the Bartlett kernel with bandwidth parameter $l(n) = L + 1$. That is, if the “lag length” for the Newey-West kernel is L , then the corresponding MODEL procedure syntax is `KERNEL=(bart, L+1, 0)`.

Andrews and Monahan (1992) show that using prewhitening in combination with GMM can improve confidence interval coverage and reduce over rejection of t statistics at the cost of inflating the variance and MSE of the estimator. Prewhitening can be performed by using the `%AR` macros.

For the special case that the errors are not serially correlated—that is,

$$E(e_t \otimes \mathbf{z}_t)(e_s \otimes \mathbf{z}_s) = 0 \quad t \neq s$$

the estimate for \mathbf{S}_n^0 reduces to

$$\hat{\mathbf{S}}_n = \frac{1}{n} \sum_{t=1}^n [\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t][\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t]'$$

The option `KERNEL=(kernel,0,)` is used to select this type of estimation when using GMM.

Covariance of GMM estimators

The covariance of GMM estimators, given a general weighting matrix \mathbf{V}_G^{-1} , is

$$[(\mathbf{YX})' \mathbf{V}_G^{-1} (\mathbf{YX})]^{-1} (\mathbf{YX})' \mathbf{V}_G^{-1} \hat{\mathbf{V}} \mathbf{V}_G^{-1} (\mathbf{YX}) [(\mathbf{YX})' \mathbf{V}_G^{-1} (\mathbf{YX})]^{-1}$$

By default or when `GENGMMV` is specified, this is the covariance of GMM estimators.

If the weighting matrix is the same as $\hat{\mathbf{V}}$, then the covariance of GMM estimators becomes

$$[(\mathbf{YX})' \hat{\mathbf{V}}^{-1} (\mathbf{YX})]^{-1}$$

If `NOGENGMMV` is specified, this is used as the covariance estimators.

Testing Over-Identifying Restrictions

Let r be the number of unique instruments times the number of equations. The value r represents the number of orthogonality conditions imposed by the GMM method. Under the assumptions of the GMM method, $r - p$ linearly independent combinations of the orthogonality should be close to zero. The GMM estimates are computed by setting these combinations to zero. When r exceeds the number of parameters to be estimated, the `OBJECTIVE*N`, reported at the end of the estimation, is an asymptotically valid statistic to test the null hypothesis that the over-identifying restrictions of the model are valid. The `OBJECTIVE*N` is distributed as a chi-square with $r - p$ degrees of freedom (Hansen 1982, p. 1049).

Iterated Generalized Method of Moments (ITGMM)

Iterated generalized method of moments is similar to the iterated versions of 2SLS, SUR, and 3SLS. The variance matrix for GMM estimation is reestimated at each iteration with the parameters determined by the GMM estimation. The iteration terminates when the variance matrix for the equation errors change less than the `CONVERGE=` value. Iterated generalized method of moments is selected by the `ITGMM` option on the `FIT` statement. For some indication of the small sample properties of ITGMM, see Ferson and Foerster (1993).

Simulated Method of Moments (SMM)

The SMM method uses simulation techniques in model inference and estimation. It is appropriate for estimating models in which integrals appear in the objective function, and these integrals can be approximated by simulation. There might be various reasons for integrals to appear in an objective function (for example, transformation of a latent model into an observable model, missing data, random coefficients, heterogeneity, and so on).

This simulation method can be used with all the estimation methods except full information maximum likelihood (FIML) in PROC MODEL. SMM, also known as simulated generalized method of moments (SGMM), is the default estimation method because of its nice properties.

Estimation Details

A general nonlinear model can be described as

$$\boldsymbol{\epsilon}_t = \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})$$

where $\mathbf{q} \in R^g$ is a real vector valued function of $\mathbf{y}_t \in R^g$, $\mathbf{x}_t \in R^l$, $\boldsymbol{\theta} \in R^p$; g is the number of equations; l is the number of exogenous variables (lagged endogenous variables are considered exogenous here); p is the number of parameters; and t ranges from 1 to n . $\boldsymbol{\epsilon}_t$ is an unobservable disturbance vector with the following properties:

$$\begin{aligned} E(\boldsymbol{\epsilon}_t) &= \mathbf{0} \\ E(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t') &= \boldsymbol{\Sigma} \end{aligned}$$

In many cases, it is not possible to write $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})$ in a closed form. Instead \mathbf{q} is expressed as an integral of a function \mathbf{f} ; that is,

$$\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) = \int \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}, \mathbf{u}_t) dP(\mathbf{u})$$

where $\mathbf{f} \in R^g$ is a real vector valued function of $\mathbf{y}_t \in R^g$, $\mathbf{x}_t \in R^l$, $\boldsymbol{\theta} \in R^p$, and $\mathbf{u}_t \in R^m$, m is the number of stochastic variables with a known distribution $P(\mathbf{u})$. Since the distribution of \mathbf{u} is completely known, it is possible to simulate artificial draws from this distribution. Using such independent draws \mathbf{u}_{ht} , $h = 1, \dots, H$, and the strong law of large numbers, \mathbf{q} can be approximated by

$$\frac{1}{H} \sum_{h=1}^H \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}, \mathbf{u}_{ht}).$$

Simulated Generalized Method of Moments (SGMM)

Generalized method of moments (GMM) is widely used to obtain efficient estimates for general model systems. When the moment conditions are not readily available in closed forms but can be approximated by simulation, simulated generalized method of moments (SGMM) can be used. The SGMM estimators have the nice property of being asymptotically consistent and normally distributed even if the number of draws H is fixed (see McFadden 1989; Pakes and Pollard 1989).

Consider the nonlinear model

$$\begin{aligned}\boldsymbol{\epsilon}_t &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) = \frac{1}{H} \sum_{h=1}^H \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}, \mathbf{u}_{ht}) \\ \mathbf{z}_t &= \mathbf{Z}(\mathbf{x}_t)\end{aligned}$$

where $\mathbf{z}_t \in R^k$ is a vector of k instruments and $\boldsymbol{\epsilon}_t$ is an unobservable disturbance vector that can be serially correlated and nonstationary. In the case of no instrumental variables, \mathbf{z}_t is 1. $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})$ is the vector of moment conditions, and it is approximated by simulation.

In general, theory suggests the following orthogonality condition

$$E(\boldsymbol{\epsilon}_t \otimes \mathbf{z}_t) = 0$$

which states that the expected crossproducts of the unobservable disturbances, $\boldsymbol{\epsilon}_t$, and functions of the observable variables are set to 0. The sample means of the crossproducts are

$$\begin{aligned}\mathbf{m}_n &= \frac{1}{n} \sum_{t=1}^n \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \\ \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \otimes \mathbf{z}_t\end{aligned}$$

where $\mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \in R^{gk}$. The case where $gk > p$, where p is the number of parameters, is considered here. An estimate of the true parameter vector $\boldsymbol{\theta}^0$ is the value of $\hat{\boldsymbol{\theta}}$ that minimizes

$$S(\boldsymbol{\theta}, \mathbf{V}) = [n\mathbf{m}_n(\boldsymbol{\theta})]' \mathbf{V}^{-1} [n\mathbf{m}_n(\boldsymbol{\theta})] / n$$

where

$$\mathbf{V} = \text{Cov}(\mathbf{m}(\boldsymbol{\theta}^0), \mathbf{m}(\boldsymbol{\theta}^0)').$$

The steps for SGMM are as follows:

1. Start with a positive definite $\hat{\mathbf{V}}$ matrix. This $\hat{\mathbf{V}}$ matrix can be estimated from a consistent estimator of $\boldsymbol{\theta}$. If $\hat{\boldsymbol{\theta}}$ is a consistent estimator, then \mathbf{u}_t for $t = 1, \dots, n$ can be simulated H' number of times. A consistent estimator of \mathbf{V} is obtained as

$$\hat{\mathbf{V}} = \frac{1}{n} \sum_{t=1}^n \left[\frac{1}{H'} \sum_{h=1}^{H'} \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \hat{\boldsymbol{\theta}}, \mathbf{u}_{ht}) \otimes \mathbf{z}_t \right] \left[\frac{1}{H'} \sum_{h=1}^{H'} \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \hat{\boldsymbol{\theta}}, \mathbf{u}_{ht}) \otimes \mathbf{z}_t \right]'$$

H' must be large so that this is an consistent estimator of \mathbf{V} .

2. Simulate H number of \mathbf{u}_t for $t = 1, \dots, n$. As shown by Gourieroux and Monfort (1993), the number of simulations H does not need to be very large. For $H = 10$, the SGMM estimator achieves 90% of the efficiency of the corresponding GMM estimator. Find $\hat{\boldsymbol{\theta}}$ that minimizes the quadratic product of the moment conditions again with the weight matrix being $\hat{\mathbf{V}}^{-1}$.

$$\min_{\boldsymbol{\theta}} [n\mathbf{m}_n(\boldsymbol{\theta})]' \hat{\mathbf{V}}^{-1} [n\mathbf{m}_n(\boldsymbol{\theta})] / n$$

3. The covariance matrix of $\sqrt{n}\theta$ is given as (Gourieroux and Monfort 1993)

$$\Sigma_1^{-1} \mathbf{D} \hat{\mathbf{V}}^{-1} \mathbf{V}(\hat{\theta}) \hat{\mathbf{V}}^{-1} \mathbf{D}' \Sigma_1^{-1} + \frac{1}{H} \Sigma_1^{-1} \mathbf{D} \hat{\mathbf{V}}^{-1} E[\mathbf{z} \otimes \text{Var}(\mathbf{f}|\mathbf{x}) \otimes \mathbf{z}] \hat{\mathbf{V}}^{-1} \mathbf{D}' \Sigma_1^{-1}$$

where $\Sigma_1 = \mathbf{D} \hat{\mathbf{V}}^{-1} \mathbf{D}$, \mathbf{D} is the matrix of partial derivatives of the residuals with respect to the parameters, $\mathbf{V}(\hat{\theta})$ is the covariance of moments from estimated parameters $\hat{\theta}$, and $\text{Var}(\mathbf{f}|\mathbf{x})$ is the covariance of moments for each observation from simulation. The first term is the variance-covariance matrix of the exact GMM estimator, and the second term accounts for the variation contributed by simulating the moments.

Implementation in PROC MODEL

In PROC MODEL, if the user specifies the GMM and NDRAW options in the FIT statement, PROC MODEL first fits the model by using N2SLS and computes $\hat{\mathbf{V}}$ by using the estimates from N2SLS and H' simulation. If NO2SLS is specified in the FIT statement, $\hat{\mathbf{V}}$ is read from VDATA= data set. If the user does not provide a $\hat{\mathbf{V}}$ matrix, the initial starting value of θ is used as the estimator for computing the $\hat{\mathbf{V}}$ matrix in step 1. If ITGMM option is specified instead of GMM, then PROC MODEL iterates from step 1 to step 3 until the \mathbf{V} matrix converges.

The consistency of the parameter estimates is not affected by the variance correction shown in the second term in step 3. The correction on the variance of parameter estimates is not computed by default. To add the adjustment, use ADJSMMV option on the FIT statement. This correction is of the order of $\frac{1}{H}$ and is small even for moderate H .

The following example illustrates how to use SMM to estimate a simple regression model. Suppose the model is

$$y = a + bx + u, u \sim iid N(0, s^2).$$

First, consider the problem in a GMM context. The first two moments of y are easily derived:

$$\begin{aligned} E(y) &= a + bx \\ E(y^2) &= (a + bx)^2 + s^2 \end{aligned}$$

Rewrite the moment conditions in the form similar to the discussion above:

$$\begin{aligned} \epsilon_{1t} &= y_t - (a + bx_t) \\ \epsilon_{2t} &= y_t^2 - (a + bx_t)^2 - s^2 \end{aligned}$$

Then you can estimate this model by using GMM with following statements:

```
proc model data=a;
  parms a b s;
  instrument x;
  eq.m1 = y-(a+b*x);
  eq.m2 = y*y - (a+b*x)**2 - s*s;
  bound s > 0;
  fit m1 m2 / gmm;
run;
```

Now suppose you do not have the closed form for the moment conditions. Instead you can simulate the moment conditions by generating H number of simulated samples based on the parameters. Then the simulated moment conditions are

$$\begin{aligned}\epsilon_{1t} &= \frac{1}{H} \sum_{h=1}^H \{y_t - (a + bx_t + su_{t,h})\} \\ \epsilon_{2t} &= \frac{1}{H} \sum_{h=1}^H \{y_t^2 - (a + bx_t + su_{t,h})^2\}\end{aligned}$$

This model can be estimated by using SGMM with the following statements:

```
proc model data=_tmpdata;
  parms a b s;
  instrument x;
  ysim = (a+b*x) + s * rannor( 98711 );
  eq.m1 = y-ysim;
  eq.m2 = y*y - ysim*ysim;
  bound s > 0;
  fit m1 m2 / gmm ndraw=10;
run;
```

You can use the following MOMENT statement instead of specifying the two moment equations above:

```
moment ysim=(1, 2);
```

In cases where you require a large number of moment equations, using the MOMENT statement to specify them is more efficient.

Note that the NDRAW= option tells PROC MODEL that this is a simulation-based estimation. Thus, the random number function RANNOR returns random numbers in estimation process. During the simulation, 10 draws of $m1$ and $m2$ are generated for each observation, and the averages enter the objective functions just as the equations specified previously.

Other Estimation Methods

The simulation method can be used not only with GMM and ITGMM, but also with OLS, ITOLS, SUR, ITSUR, N2SLS, IT2SLS, N3SLS, and IT3SLS. These simulation-based methods are similar to the corresponding methods in PROC MODEL; the only difference is that the objective functions include the average of the H simulations.

Full Information Maximum Likelihood Estimation (FIML)

A different approach to the simultaneous equation bias problem is the full information maximum likelihood (FIML) estimation method (Amemiya 1977).

Compared to the instrumental variables methods (2SLS and 3SLS), the FIML method has these advantages and disadvantages:

- FIML does not require instrumental variables.
- FIML requires that the model include the full equation system, with as many equations as there are endogenous variables. With 2SLS or 3SLS, you can estimate some of the equations without specifying the complete system.
- FIML assumes that the equations errors have a multivariate normal distribution. If the errors are not normally distributed, the FIML method might produce poor results. 2SLS and 3SLS do not assume a specific distribution for the errors.
- The FIML method is computationally expensive.

The full information maximum likelihood estimators of θ and σ are the $\hat{\theta}$ and $\hat{\sigma}$ that minimize the negative log-likelihood function:

$$\begin{aligned} \mathbf{l}_n(\theta, \sigma) = & \frac{ng}{2} \ln(2\pi) - \sum_{t=1}^n \ln \left(\left| \frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}'_t} \right| \right) + \frac{n}{2} \ln(|\Sigma(\sigma)|) \\ & + \frac{1}{2} \text{tr} \left(\Sigma(\sigma)^{-1} \sum_{t=1}^n \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \mathbf{q}'(\mathbf{y}_t, \mathbf{x}_t, \theta) \right) \end{aligned}$$

The option FIML requests full information maximum likelihood estimation. If the errors are distributed normally, FIML produces efficient estimators of the parameters. If instrumental variables are not provided, the starting values for the estimation are obtained from a SUR estimation. If instrumental variables are provided, then the starting values are obtained from a 3SLS estimation. The log-likelihood value and the l_2 norm of the gradient of the negative log-likelihood function are shown in the estimation summary.

FIML Details

To compute the minimum of $\mathbf{l}_n(\theta, \sigma)$, this function is *concentrated* using the relation

$$\Sigma(\theta) = \frac{1}{n} \sum_{t=1}^n \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \mathbf{q}'(\mathbf{y}_t, \mathbf{x}_t, \theta)$$

This results in the concentrated negative log-likelihood function:

$$\mathbf{l}_n(\theta) = \frac{ng}{2} (1 + \ln(2\pi)) - \sum_{t=1}^n \ln \left| \frac{\partial}{\partial \mathbf{y}'_t} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \right| + \frac{n}{2} \ln |\Sigma(\theta)|$$

The gradient of the negative log-likelihood function is

$$\frac{\partial}{\partial \theta_i} \mathbf{l}_n(\theta) = \sum_{t=1}^n \nabla_i(t)$$

$$\begin{aligned} \nabla_i(t) &= -\text{tr} \left(\left(\frac{\partial \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})}{\partial \mathbf{y}'_t} \right)^{-1} \frac{\partial^2 \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})}{\partial \mathbf{y}'_t \partial \theta_i} \right) \\ &+ \frac{1}{2} \text{tr} \left(\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1} \frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \theta_i} \right. \\ &\quad \left. [I - \boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1} \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta}) \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})'] \right) \\ &+ \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta}') \boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1} \frac{\partial \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})}{\partial \theta_i} \end{aligned}$$

where

$$\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \theta_i} = \frac{2}{n} \sum_{t=1}^n \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta}) \frac{\partial \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})'}{\partial \theta_i}$$

The estimator of the variance-covariance of $\hat{\boldsymbol{\theta}}$ (COVB) for FIML can be selected with the COVBEST= option with the following arguments:

CROSS selects the crossproducts estimator of the covariance matrix (Gallant 1987, p. 473):

$$C = \left(\frac{1}{n} \sum_{t=1}^n \nabla(t) \nabla'(t) \right)^{-1}$$

where $\nabla(t) = [\nabla_1(t), \nabla_2(t), \dots, \nabla_p(t)]'$. This is the default.

GLS selects the generalized least squares estimator of the covariance matrix. This is computed as (Dagenais 1978)

$$C = [\hat{\mathbf{Z}}' (\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1} \otimes I) \hat{\mathbf{Z}}]^{-1}$$

where $\hat{\mathbf{Z}} = (\hat{Z}_1, \hat{Z}_2, \dots, \hat{Z}_p)$ is $ng \times p$ and each \hat{Z}_i column vector is obtained from stacking the columns of

$$\mathbf{U} \frac{1}{n} \sum_{t=1}^n \left(\frac{\partial \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})'}{\partial \mathbf{y}} \right)^{-1} \frac{\partial^2 \mathbf{q}(y_t, \mathbf{x}_t, \boldsymbol{\theta})'}{\partial \mathbf{y}'_n \partial \theta_i} - Q_i$$

\mathbf{U} is an $n \times g$ matrix of residuals and q_i is an $n \times g$ matrix $\frac{\partial \mathbf{Q}}{\partial \theta_i}$.

FDA selects the inverse of concentrated likelihood Hessian as an estimator of the covariance matrix. The Hessian is computed numerically, so for a large problem this is computationally expensive.

The HESSIAN= option controls which approximation to the Hessian is used in the minimization procedure. Alternate approximations are used to improve convergence and execution time. The choices are as follows:

CROSS The crossproducts approximation is used.

GLS The generalized least squares approximation is used (default).

FDA The Hessian is computed numerically by finite differences.

HESSIAN=GLS has better convergence properties in general, but COVBEST=CROSS produces the most pessimistic standard error bounds. When the HESSIAN= option is used, the default estimator of the variance-covariance of $\hat{\theta}$ is the inverse of the Hessian selected.

Multivariate t Distribution Estimation

The multivariate t distribution is specified by using the ERRORMODEL statement with the T option. Other method specifications (FIML and OLS, for example) are ignored when the ERRORMODEL statement is used for a distribution other than normal.

The probability density function for the multivariate t distribution is

$$P_q = \frac{\Gamma(\frac{df+m}{2})}{(\pi * df)^{\frac{m}{2}} * \Gamma(\frac{df}{2}) |\Sigma(\sigma)|^{\frac{1}{2}}} * \left(1 + \frac{\mathbf{q}'(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \Sigma(\sigma)^{-1} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})}{df} \right)^{-\frac{df+m}{2}}$$

where m is the number of equations and df is the degrees of freedom.

The maximum likelihood estimators of θ and σ are the $\hat{\theta}$ and $\hat{\sigma}$ that minimize the negative log-likelihood function:

$$\begin{aligned} \mathbf{l}_n(\boldsymbol{\theta}, \sigma) = & - \sum_{t=1}^n \ln \left(\frac{\Gamma(\frac{df+m}{2})}{(\pi * df)^{\frac{m}{2}} * \Gamma(\frac{df}{2})} * \left(1 + \frac{q_t' \Sigma^{-1} q_t}{df} \right)^{-\frac{df+m}{2}} \right) \\ & + \frac{n}{2} * \ln(|\Sigma|) - \sum_{t=1}^n \ln \left(\left| \frac{\partial q_t}{\partial \mathbf{y}_t'} \right| \right) \end{aligned}$$

The ERRORMODEL statement is used to request the t distribution maximum likelihood estimation. An OLS estimation is done to obtain initial parameter estimates and MSE.var estimates. Use NOOLS to turn off this initial estimation. If the errors are distributed normally, t distribution estimation produces results similar to FIML.

The multivariate model has a single shared degrees-of-freedom parameter, which is estimated. The degrees-of-freedom parameter can also be set to a fixed value. The log-likelihood value and the l_2 norm of the gradient of the negative log-likelihood function are shown in the estimation summary.

t Distribution Details

Since a variance term is explicitly specified by using the ERRORMODEL statement, $\Sigma(\theta)$ is estimated as a correlation matrix and $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})$ is normalized by the variance. The gradient of the negative log-likelihood function with respect to the degrees of freedom is

$$\begin{aligned} \frac{\partial l_n}{\partial df} = & \frac{nm}{2 df} - \frac{n}{2} \frac{\Gamma'(\frac{df+m}{2})}{\Gamma(\frac{df+m}{2})} + \frac{n}{2} \frac{\Gamma'(\frac{df}{2})}{\Gamma(\frac{df}{2})} + \\ & 0.5 \log \left(1 + \frac{\mathbf{q}' \Sigma^{-1} \mathbf{q}}{df} \right) - \frac{0.5(df+m) \mathbf{q}' \Sigma^{-1} \mathbf{q}}{(1 + \frac{\mathbf{q}' \Sigma^{-1} \mathbf{q}}{df}) df^2} \end{aligned}$$

The gradient of the negative log-likelihood function with respect to the parameters is

$$\frac{\partial l_n}{\partial \theta_i} = \frac{0.5(df + m)}{(1 + \mathbf{q}'\boldsymbol{\Sigma}^{-1}\mathbf{q}/df)} \left[\frac{(2 \mathbf{q}'\boldsymbol{\Sigma}^{-1} \frac{\partial \mathbf{q}}{\partial \theta_i})}{df} + \mathbf{q}'\boldsymbol{\Sigma}^{-1} \frac{\partial \boldsymbol{\Sigma}}{\partial \theta_i} \boldsymbol{\Sigma}^{-1} \mathbf{q} \right] - \frac{n}{2} \text{trace}(\boldsymbol{\Sigma}^{-1} \frac{\partial \boldsymbol{\Sigma}}{\partial \theta_i})$$

where

$$\frac{\partial \boldsymbol{\Sigma}(\theta)}{\partial \theta_i} = \frac{2}{n} \sum_{t=1}^n \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) \frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta})'}{\partial \theta_i}$$

and

$$\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \boldsymbol{\theta}) = \frac{\epsilon(\theta)}{\sqrt{h(\theta)}} \in R^{m \times n}$$

The estimator of the variance-covariance of $\hat{\theta}$ (COVB) for the t distribution is the inverse of the likelihood Hessian. The gradient is computed analytically, and the Hessian is computed numerically.

Empirical Distribution Estimation and Simulation

The following SAS statements fit a model that uses least squares as the likelihood function, but represent the distribution of the residuals with an empirical cumulative distribution function (CDF). The plot of the empirical probability distribution is shown in [Figure 18.22](#).

```
data t;
  format date monyy.;
  do t = 0 to 9.9 by 0.1;
    date = intnx('month', '1jun90'd, (t*10)-1 );
    y = 0.1 * (rannor(123)-10) +
        .5 * (rannor(456)+10);
  output;
end;
run;

ods select Model.Likelihood.ResidSummary
           Model.Likelihood.ParameterEstimates;

proc model data=t time=t itprint;
  dependent y;
  parm a 5;

  y = a;
  obj = resid.y * resid.y;
  errormodel y ~ general( obj )
  cdf=(empirical=(tails=( normal percent=10)));

  fit y / outsn=s out=r;
  id date;
```

```

solve y / data=t(where=(date='1aug98'd))
      residdata=r sdata=s
      random=200 seed=6789 out=monte ;
run;

proc kde data=monte;
  univar y / plots=density;
run;
ods graphics off;

```

Figure 18.22 Empirical PDF Plot

For simulation, if the CDF for the model is not built in to the procedure, you can use the `CDF=EMPIRICAL()` option. This uses the sorted residual data to create an empirical CDF. For computing the inverse CDF, the program needs to know how to handle the tails. For continuous data, the tail distribution is generally poorly determined. To counter this, the `PERCENT=` option specifies the percentage of the observations to use in constructing each tail. The default for the `PERCENT=` option is 10.

A normal distribution or a t distribution is used to extrapolate the tails to infinity. The standard errors for this extrapolation are obtained from the data so that the empirical CDF is continuous.

Properties of the Estimates

All of the methods are consistent. Small sample properties might not be good for nonlinear models. The tests and standard errors reported are based on the convergence of the distribution of the estimates to a normal distribution in large samples.

These nonlinear estimation methods reduce to the corresponding linear systems regression methods if the model is linear. If this is the case, PROC MODEL produces the same estimates as PROC SYSLIN.

Except for GMM, the estimation methods assume that the equation errors for each observation are identically and independently distributed with a 0 mean vector and positive definite covariance matrix Σ consistently estimated by S . For FIML, the errors need to be normally distributed. There are no other assumptions concerning the distribution of the errors for the other estimation methods.

The consistency of the parameter estimates relies on the assumption that the S matrix is a consistent estimate of Σ . These standard error estimates are asymptotically valid, but for nonlinear models they might not be reliable for small samples.

The S matrix used for the calculation of the covariance of the parameter estimates is the best estimate available for the estimation method selected. For S -iterated methods, this is the most recent estimation of Σ . For OLS and 2SLS, an estimate of the S matrix is computed from OLS or 2SLS residuals and used for the calculation of the covariance matrix. For a complete list of the S matrix used for the calculation of the covariance of the parameter estimates, see [Table 18.2](#).

Missing Values

An observation is excluded from the estimation if any variable used for FIT tasks is missing, if the weight for the observation is not greater than 0 when weights are used, or if a DELETE statement is executed by the model program. Variables used for FIT tasks include the equation errors for each equation, the instruments, if any, and the derivatives of the equation errors with respect to the parameters estimated. Note that variables can become missing as a result of computational errors or calculations with missing values.

The number of usable observations can change when different parameter values are used; some parameter values can be invalid and cause execution errors for some observations. PROC MODEL keeps track of the number of usable and missing observations at each pass through the data, and if the number of missing observations counted during a pass exceeds the number that was obtained using the previous parameter vector, the pass is terminated and the new parameter vector is considered infeasible. PROC MODEL never takes a step that produces more missing observations than the current estimate does.

The values used to compute the Durbin-Watson, R^2 , and other statistics of fit are from the observations used in calculating the objective function and do not include any observation for which any needed variable was missing (residuals, derivatives, and instruments).

Details on the Covariance of Equation Errors

There are several \mathbf{S} matrices that can be involved in the various estimation methods and in forming the estimate of the covariance of parameter estimates. These \mathbf{S} matrices are estimates of $\mathbf{\Sigma}$, the true covariance of the equation errors. Apart from the choice of instrumental or noninstrumental methods, many of the methods provided by PROC MODEL differ in the way the various \mathbf{S} matrices are formed and used.

All of the estimation methods result in a final estimate of $\mathbf{\Sigma}$, which is included in the output if the COVS option is specified. The final \mathbf{S} matrix of each method provides the initial \mathbf{S} matrix for any subsequent estimation.

This estimate of the covariance of equation errors is defined as

$$\mathbf{S} = \mathbf{D}(\mathbf{R}'\mathbf{R})\mathbf{D}$$

where $\mathbf{R} = (\mathbf{r}_1, \dots, \mathbf{r}_g)$ is composed of the equation residuals computed from the current parameter estimates in an $n \times g$ matrix and \mathbf{D} is a diagonal matrix that depends on the VARDEF= option.

For VARDEF=N, the diagonal elements of \mathbf{D} are $1/\sqrt{n}$, where n is the number of nonmissing observations. For VARDEF=WGT, n is replaced with the sum of the weights. For VARDEF=WDF, n is replaced with the sum of the weights minus the model degrees of freedom. For the default VARDEF=DF, the i th diagonal element of \mathbf{D} is $1/\sqrt{n - df_i}$, where df_i is the degrees of freedom (number of parameters) for the i th equation. Binkley and Nelson (1984) show the importance of using a degrees-of-freedom correction in estimating $\mathbf{\Sigma}$. Their results indicate that the DF method produces more accurate confidence intervals for N3SLS parameter estimates in the linear case than the alternative approach they tested. VARDEF=N is always used for the computation of the FIML estimates.

For the fixed \mathbf{S} methods, the OUTSUSED= option writes the \mathbf{S} matrix used in the estimation to a data set. This \mathbf{S} matrix is either the estimate of the covariance of equation errors matrix from the preceding estimation, or a prior $\mathbf{\Sigma}$ estimate read in from a data set when the SDATA= option is specified. For the diagonal \mathbf{S} methods, all of the off-diagonal elements of the \mathbf{S} matrix are set to 0 for the estimation of the parameters and for the OUTSUSED= data set, but the output data set produced by the OUTS= option contains the off-diagonal elements. For the OLS and N2SLS methods, there is no previous estimate of the covariance of equation errors matrix, and the option OUTSUSED= saves an identity matrix unless a prior $\mathbf{\Sigma}$ estimate is supplied by the SDATA= option. For FIML, the OUTSUSED= data set contains the \mathbf{S} matrix computed with VARDEF=N. The OUTS= data set contains the \mathbf{S} matrix computed with the selected VARDEF= option.

If the COVS option is used, the method is not \mathbf{S} -iterated, \mathbf{S} is not an identity, and the OUTSUSED= matrix is included in the printed output.

For the methods that iterate the covariance of equation errors matrix, the \mathbf{S} matrix is iteratively re-estimated from the residuals produced by the current parameter estimates. This \mathbf{S} matrix estimate iteratively replaces the previous estimate until both the parameter estimates and the estimate of the covariance of equation errors matrix converge. The final OUTS= matrix and OUTSUSED= matrix are thus identical for the \mathbf{S} -iterated methods.

Nested Iterations

By default, for **S**-iterated methods, the **S** matrix is held constant until the parameters converge once. Then the **S** matrix is reestimated. One iteration of the parameter estimation algorithm is performed, and the **S** matrix is again reestimated. This latter process is repeated until convergence of both the parameters and the **S** matrix. Since the objective of the minimization depends on the **S** matrix, this has the effect of chasing a moving target.

When the NESTIT option is specified, iterations are performed to convergence for the structural parameters with a fixed **S** matrix. The **S** matrix is then reestimated, the parameter iterations are repeated to convergence, and so on until both the parameters and the **S** matrix converge. This has the effect of fixing the objective function for the inner parameter iterations. It is more reliable, but usually more expensive, to nest the iterations.

R-Square Statistic

For unrestricted linear models with an intercept successfully estimated by OLS, R^2 is always between 0 and 1. However, nonlinear models do not necessarily encompass the dependent mean as a special case and can produce negative R^2 statistics. Negative R^2 statistics can also be produced even for linear models when an estimation method other than OLS is used and no intercept term is in the model.

R^2 is defined for normalized equations as

$$R^2 = 1 - \frac{SSE}{SSA - \bar{y}^2 \times n}$$

where SSA is the sum of the squares of the actual y 's and \bar{y} are the actual means. R^2 cannot be computed for models in general form because of the need for an actual Y .

Minimization Methods

PROC MODEL currently supports two methods for minimizing the objective function. These methods are described in the following sections.

GAUSS

The Gauss-Newton parameter-change vector for a system with g equations, n nonmissing observations, and p unknown parameters is

$$\mathbf{\Delta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r}$$

where $\mathbf{\Delta}$ is the change vector, \mathbf{X} is the stacked $ng \times p$ Jacobian matrix of partial derivatives of the residuals with respect to the parameters, and \mathbf{r} is an $ng \times 1$ vector of the stacked residuals. The components of \mathbf{X} and \mathbf{r} are weighted by the \mathbf{S}^{-1} matrix. When instrumental methods are used, \mathbf{X}

and \mathbf{r} are the projections of the Jacobian matrix and residuals vector in the instruments space and not the Jacobian and residuals themselves. In the preceding formula, \mathbf{S} and \mathbf{W} are suppressed. If instrumental variables are used, then the change vector becomes:

$$\mathbf{\Delta} = (\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X})^{-1} \mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{r}$$

This vector is computed at the end of each iteration. The objective function is then computed at the changed parameter values at the start of the next iteration. If the objective function is not improved by the change, the $\mathbf{\Delta}$ vector is reduced by one-half and the objective function is reevaluated. The change vector will be halved up to MAXSUBITER= times until the objective function is improved. If the objective function cannot be improved after MAXSUBITER= times, the procedure switches to the MARQUARDT method described in the next section to further improve the objective function.

For FIML, the $\mathbf{X}'\mathbf{X}$ matrix is substituted with one of three choices for approximations to the Hessian. See the section “[Full Information Maximum Likelihood Estimation \(FIML\)](#)” on page 1019 in this chapter.

MARQUARDT

The Marquardt-Levenberg parameter change vector is

$$\mathbf{\Delta} = (\mathbf{X}'\mathbf{X} + \lambda \text{diag}(\mathbf{X}'\mathbf{X}))^{-1} \mathbf{X}'\mathbf{r}$$

where $\mathbf{\Delta}$ is the change vector, and \mathbf{X} and \mathbf{r} are the same as for the Gauss-Newton method, described in the preceding section. Before the iterations start, λ is set to a small value (1E–6). At each iteration, the objective function is evaluated at the parameters changed by $\mathbf{\Delta}$. If the objective function is not improved, λ is increased to 10λ and the step is tried again. λ can be increased up to MAXSUBITER= times to a maximum of 1E15 (whichever comes first) until the objective function is improved. For the start of the next iteration, λ is reduced to $\max(\lambda/10, 1E-10)$.

Convergence Criteria

There are a number of measures that could be used as convergence or stopping criteria. PROC MODEL computes five convergence measures labeled R, S, PPC, RPC, and OBJECT.

When an estimation technique that iterates estimates of $\mathbf{\Sigma}$ is used (that is, IT3SLS), two convergence criteria are used. The termination values can be specified with the CONVERGE=(p,s) option in the FIT statement. If the second value, s , is not specified, it defaults to p . The criterion labeled S (described later in the section) controls the convergence of the \mathbf{S} matrix. When S is less than s , the \mathbf{S} matrix has converged. The criterion labeled R is compared to the p -value to test convergence of the parameters.

The R convergence measure cannot be computed accurately in the special case of singular residuals (when all the residuals are close to 0) or in the case of a 0 objective value. When either the trace of the \mathbf{S} matrix computed from the current residuals (trace(S)) or the objective value is less than the value of the SINGULAR= option, convergence is assumed.

The various convergence measures are explained in the following:

R is the primary convergence measure for the parameters. It measures the degree to which the residuals are orthogonal to the Jacobian columns, and it approaches 0 as the gradient of the objective function becomes small. R is defined as the square root of

$$\frac{(r'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X}(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})r)}{(r'(\mathbf{S}^{-1} \otimes \mathbf{W})r)}$$

where \mathbf{X} is the Jacobian matrix and \mathbf{r} is the residuals vector. R is similar to the relative offset orthogonality convergence criterion proposed by Bates and Watts (1981).

In the univariate case, the R measure has several equivalent interpretations:

- the cosine of the angle between the residuals vector and the column space of the Jacobian matrix. When this cosine is 0, the residuals are orthogonal to the partial derivatives of the predicted values with respect to the parameters, and the gradient of the objective function is 0.
- the square root of the R^2 for the current linear pseudo-model in the residuals
- a norm of the gradient of the objective function, where the norming matrix is proportional to the current estimate of the covariance of the parameter estimates. Thus, using R, convergence is judged when the gradient becomes small in this norm.
- the prospective relative change in the objective function value expected from the next GAUSS step, assuming that the current linearization of the model is a good local approximation

In the multivariate case, R is somewhat more complicated but is designed to go to 0 as the gradient of the objective becomes small and can still be given the previous interpretations for the aggregation of the equations weighted by \mathbf{S}^{-1} .

PPC is the prospective parameter change measure. PPC measures the maximum relative change in the parameters implied by the parameter-change vector computed for the next iteration. At the k th iteration, PPC is the maximum over the parameters

$$\frac{|\theta_i^{k+1} - \theta_i^k|}{|\theta_i^k + 1.0e^{-6}|}$$

where θ_i^k is the current value of the i th parameter and θ_i^{k+1} is the prospective value of this parameter after adding the change vector computed for the next iteration. The parameter with the maximum prospective relative change is printed with the value of PPC, unless the PPC is nearly 0.

RPC is the retrospective parameter change measure. RPC measures the maximum relative change in the parameters from the previous iteration. At the k th iteration,

RPC is the maximum over i of

$$\frac{|\theta_i^k - \theta_i^{k-1}|}{|\theta_i^{k-1} + 1.0e^{-6}|}$$

where θ_i^k is the current value of the i th parameter and θ_i^{k-1} is the previous value of this parameter. The name of the parameter with the maximum retrospective relative change is printed with the value of RPC, unless the RPC is nearly 0.

OBJECT measures the relative change in the objective function value between iterations:

$$\frac{|O^k - O^{k-1}|}{|O^{k-1} + 1.0e^{-6}|}$$

where O^{k-1} is the value of the objective function (O^k) from the previous iteration.

S measures the relative change in the **S** matrix. **S** is computed as the maximum over i, j of

$$\frac{|S_{ij}^k - S_{ij}^{k-1}|}{|S_{ij}^{k-1} + 1.0e^{-6}|}$$

where S^{k-1} is the previous **S** matrix. The **S** measure is relevant only for estimation methods that iterate the **S** matrix.

An example of the convergence criteria output is shown in [Figure 18.23](#).

Figure 18.23 Convergence Criteria Output

Final Convergence Criteria	
R	0.000737
PPC (b)	0.003943
RPC (b)	0.00968
Object	4.784E-6
Trace (S)	0.533325
Objective Value	0.522214

The Trace(S) is the trace (the sum of the diagonal elements) of the **S** matrix computed from the current residuals. This row is labeled MSE if there is only one equation.

Troubleshooting Convergence Problems

As with any nonlinear estimation routine, there is no guarantee that the estimation will be successful for a given model and data. If the equations are linear with respect to the parameters, the parameter

estimates always converge in one iteration. The methods that iterate the **S** matrix must iterate further for the **S** matrix to converge. Nonlinear models might not necessarily converge.

Convergence can be expected only with fully identified parameters, adequate data, and starting values sufficiently close to solution estimates.

Convergence and the rate of convergence might depend primarily on the choice of starting values for the estimates. This does not mean that a great deal of effort should be invested in choosing starting values. First, try the default values. If the estimation fails with these starting values, examine the model and data and rerun the estimation using reasonable starting values. It is usually not necessary that the starting values be very good, just that they not be very bad; choose values that seem plausible for the model and data.

An Example of Requiring Starting Values

Suppose you want to regress a variable *Y* on a variable *X*, assuming that the variables are related by the following nonlinear equation:

$$y = a + bx^c + \epsilon$$

In this equation, *Y* is linearly related to a power transformation of *X*. The unknown parameters are *a*, *b*, and *c*. ϵ is an unobserved random error. The following SAS statements generate simulated data. In this simulation, $a = 10$, $b = 2$, and the use of the `SQRT` function corresponds to $c = .5$.

```
data test;
  do i = 1 to 20;
    x = 5 * ranuni(1234);
    y = 10 + 2 * sqrt(x) + .5 * rannor(2345);
    output;
  end;
run;
```

The following statements specify the model and give descriptive labels to the model parameters. Then the `FIT` statement attempts to estimate *a*, *b*, and *c* by using the default starting value 0.0001.

```
proc model data=test;
  y = a + b * x ** c;
  label a = "Intercept"
        b = "Coefficient of Transformed X"
        c = "Power Transformation Parameter";
  fit y;
run;
```

`PROC MODEL` prints model summary and estimation problem summary reports and then prints the output shown in [Figure 18.24](#).

Figure 18.24 Diagnostics for Convergence Failure

```

By using the default starting values, PROC MODEL is unable to take even the first step in iterating to the solution. The change in the parameters that the Gauss-Newton method computes is very extreme and makes the objective values worse instead of better. Even when this step is shortened by a factor of a million, the objective function is still worse, and PROC MODEL is unable to estimate the model parameters.

The problem is caused by the starting value of C. Using the default starting value $C=0.0001$, the first iteration attempts to compute better values of A and B by what is, in effect, a linear regression of Y on the 10,000th root of X, which is almost the same as the constant 1. Thus the matrix that is inverted to compute the changes is nearly singular and affects the accuracy of the computed parameter changes.

This is also illustrated by the next part of the output, which displays collinearity diagnostics for the crossproducts matrix of the partial derivatives with respect to the parameters, shown in [Figure 18.25](#).

Figure 18.25 Collinearity Diagnostics

```

Collinearity Diagnostics

Number      Eigenvalue      Condition Number      -----Proportion of Variation-----
      a      b      c
1          2.376793          1.0000          0.0000          0.0000          0.0000
2          0.623207          1.9529          0.0000          0.0000          0.0000
3          1.68475E-12          1187758          1.0000          1.0000          1.0000

```

This output shows that the matrix is singular and that the partials of A, B, and C with respect to the residual are collinear at the point (0.0001, 0.0001, 0.0001) in the parameter space. See the section “[Linear Dependencies](#)” on page 1041 for a full explanation of the collinearity diagnostics.

The MODEL procedure next prints the note shown in [Figure 18.26](#), which suggests that you try different starting values.

Figure 18.26 Estimation Failure Note

```
NOTE: The parameter estimation is abandoned. Check your model and data. If the
      model is correct and the input data are appropriate, try rerunning the
      parameter estimation using different starting values for the parameter
      estimates.
PROC MODEL continues as if the parameter estimates had converged.
```

PROC MODEL then produces the usual printout of results for the nonconverged parameter values. The estimation summary is shown in [Figure 18.27](#). The heading includes the reminder “(Not Converged)”.

The nonconverged estimation results are shown in [Figure 18.28](#).

Figure 18.28 Nonconverged Results

The MODEL Procedure							
Nonlinear OLS Summary of Residual Errors (Not Converged)							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj R-Sq
y	3	17	79.3551	4.6679	2.1605	-1.6812	-1.9966
Nonlinear OLS Parameter Estimates (Not Converged)							
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label		
a	137.3822	263349	0.00	0.9996	Intercept		
b	-126.533	263349	-0.00	0.9996	Coefficient of Transformed X		
c	-0.00213	4.4373	-0.00	0.9996	Power Transformation Parameter		

Note that the R^2 statistic is negative. An $R^2 < 0$ results when the residual mean squared error for the model is larger than the variance of the dependent variable. Negative R^2 statistics might be produced when either the parameter estimates fail to converge correctly, as in this case, or when the correctly estimated model fits the data very poorly.

Controlling Starting Values

To fit the preceding model you must specify a better starting value for C. Avoid starting values of C that are either very large or close to 0. For starting values of A and B, you can specify values, use the default, or have PROC MODEL fit starting values for them conditional on the starting value for C.

Starting values are specified with the START= option of the FIT statement or in a PARMS statement. In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. When no starting values for the parameter estimates are specified with BY group processing, the default start value 0.0001 is used for each by group. Again, when no starting values are specified, and a model with a FIT statement is stored by the OUTMODEL=*outmodel-filename* option in a previous step, the *outmodel-filename* can be invoked in a subsequent PROC MODEL step by using the MODEL=*outmodel-filename* option with multiple estimation methods in the second step. In such a case, the parameter estimates from the *outmodel-filename* are used directly as starting values for OLS, and OLS results from the second step provide starting values for the subsequent estimation method such as 2SLS or SUR, provided that NOOLS is not specified.

For example, the following statements estimate the model parameters by using the starting values A=0.0001, B=0.0001, and C=5.

```
proc model data=test;
  y = a + b * x ** c;
  label a = "Intercept"
        b = "Coefficient of Transformed X"
        c = "Power Transformation Parameter";
  fit y start=(c=5);
run;
```

Using these starting values, the estimates converge in 16 iterations. The results are shown in Figure 18.29. Note that since the START= option explicitly declares parameters, the parameter C is placed first in the table.

Figure 18.29 Converged Results

The MODEL Procedure							
Nonlinear OLS Summary of Residual Errors							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj R-Sq
y	3	17	5.7359	0.3374	0.5809	0.8062	0.7834
Nonlinear OLS Parameter Estimates							
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label		
c	0.327079	0.2892	1.13	0.2738	Power Transformation Parameter		
a	8.384311	3.3775	2.48	0.0238	Intercept		
b	3.505391	3.4858	1.01	0.3287	Coefficient of Transformed X		

Using the STARTITER Option

PROC MODEL can compute starting values for some parameters conditional on starting values you specify for the other parameters. You supply starting values for some parameters and specify the STARTITER option on the FIT statement.

For example, the following statements set C to 1 and compute starting values for A and B by estimating these parameters conditional on the fixed value of C. With C=1, this is equivalent to computing A and B by linear regression on X. A PARMS statement is used to declare the parameters in alphabetical order. The ITPRINT option is used to print the parameter values at each iteration.

```
proc model data=test;
  parms a b c;
  y = a + b * x ** c;
  label a = "Intercept"
        b = "Coefficient of Transformed X"
```

```

c = "Power Transformation Parameter";
fit y start=(c=1) / starttiter itprint;
run;

```

With better starting values, the estimates converge in only eight iterations. Counting the iteration required to compute the starting values for A and B, this is seven fewer than the 16 iterations required without the STARTTITER option. The iteration history listing is shown in [Figure 18.30](#).

Figure 18.30 ITPRINT Listing

The MODEL Procedure

OLS	6	20	0.0612		0.2879	0	8.51825	3.36746	0.33201
OLS	7	20	0.0022		0.2868	0	8.39485	3.49449	0.32776
OLS	8	20	0.0001		0.2868	0	8.38467	3.50502	0.32711

NOTE: At OLS Iteration 8 CONVERGE=0.001 Criteria Met.

The results produced in this case are almost the same as the results shown in [Figure 18.29](#), except that the PARMS statement causes the parameter estimates table to be ordered A, B, C instead of C, A, B. They are not exactly the same because the different starting values caused the iterations to converge at a slightly different place. This effect is controlled by changing the convergence criterion with the CONVERGE= option.

By default, the STARTTITER option performs one iteration to find starting values for the parameters that are not given values. In this case, the model is linear in A and B, so only one iteration is needed. If A or B were nonlinear, you could specify more than one “starting values” iteration by specifying a number for the STARTTITER= option.

Finding Starting Values by Grid Search

PROC MODEL can try various combinations of parameter values and use the combination that produces the smallest objective function value as starting values. (For OLS the objective function is the residual mean square.) This is known as a preliminary *grid search*. You can combine the STARTTITER option with a grid search.

For example, the following statements try five different starting values for C: 1, 0.7, 0.5, 0.3, and 0. For each value of C, values for A and B are estimated. The combination of A, B, and C values that produce the smallest residual mean square is then used to start the iterative process.

```
proc model data=test;
  parms a b c;
  y = a + b * x ** c;
  label a = "Intercept"
        b = "Coefficient of Transformed X"
        c = "Power Transformation Parameter";
  fit y start=(c=1 .7 .5 .3 0) / startiter itprint;
run;
```

The iteration history listing is shown in Figure 18.31. Using the best starting values found by the grid search, the OLS estimation only requires two iterations. However, since the grid search required nine iterations, the total iterations in this case is 11.

NOTE: At OLS Iteration 2 CONVERGE=0.001 Criteria Met.

Because no initial values for A or B were provided in the PARAMETERS statement or were read in with a PARMSDATA= or ESTDATA= option, A and B were given the default value of 0.0001 for the first iteration. At the second grid point, C=5, the values of A and B obtained from the previous iterations are used for the initial iteration. If initial values are provided for parameters, the parameters start at those initial values at each grid point.

Guessing Starting Values from the Logic of the Model

Example 18.1, which uses a logistic growth curve model of the U.S. population, illustrates the need for reasonable starting values. This model can be written

$$pop = \frac{a}{1 + \exp(b - c(t - 1790))}$$

where t is time in years. The model is estimated by using decennial census data of the U.S. population in millions. If this simple but highly nonlinear model is estimated by using the default starting values, the estimation fails to converge.

To find reasonable starting values, first consider the meaning of a and c . Taking the limit as time increases, a is the limiting or maximum possible population. So, as a starting value for a , several times the most recent population known can be used—for example, one billion (1000 million).

Dividing the time derivative by the function to find the growth rate and taking the limit as t moves into the past, you can determine that c is the initial growth rate. You can examine the data and compute an estimate of the growth rate for the first few decades, or you can pick a number that sounds like a plausible population growth rate figure, such as 2%.

To find a starting value for b , let t equal the base year used, 1790, which causes c to drop out of the formula for that year, and then solve for the value of b that is consistent with the known population in 1790 and with the starting value of a . This yields $b = \ln(a/3.9 - 1)$ or about 5.5, where a is 1000 and 3.9 is roughly the population for 1790 given in the data. The estimates converge using these starting values.

Convergence Problems

When estimating nonlinear models, you might encounter some of the following convergence problems.

Unable to Improve

The optimization algorithm might be unable to find a step that improves the objective function. If this happens in the Gauss-Newton method, the step size is halved to find a change vector for which the objective improves. In the Marquardt method, λ is increased to find a change vector for which the objective improves. If, after MAXSUBITER= step-size halvings or increases in λ , the change vector still does not produce a better objective value, the iterations are stopped and an error message is printed.

Failure of the algorithm to improve the objective value can be caused by a CONVERGE= value that is too small. Look at the convergence measures reported at the point of failure. If the estimates appear to be approximately converged, you can accept the NOT CONVERGED results reported, or you can try rerunning the FIT task with a larger CONVERGE= value.

If the procedure fails to converge because it is unable to find a change vector that improves the objective value, check your model and data to ensure that all parameters are identified and data values are reasonably scaled. Then, rerun the model with different starting values. Also, consider

using the Marquardt method if the Gauss-Newton method fails; the Gauss-Newton method can get into trouble if the Jacobian matrix is nearly singular or ill-conditioned. Keep in mind that a nonlinear model may be well-identified and well-conditioned for parameter values close to the solution values but unidentified or numerically ill-conditioned for other parameter values. The choice of starting values can make a big difference.

Nonconvergence

The estimates might diverge into areas where the program overflows or the estimates might go into areas where function values are illegal or too badly scaled for accurate calculation. The estimation might also take steps that are too small or that make only marginal improvement in the objective function and thus fail to converge within the iteration limit.

When the estimates fail to converge, collinearity diagnostics for the Jacobian crossproducts matrix are printed if there are 20 or fewer parameters estimated. See the section “[Linear Dependencies](#)” on page 1041 for an explanation of these diagnostics.

Inadequate Convergence Criterion

If convergence is obtained, the resulting estimates approximate only a minimum point of the objective function. The statistical validity of the results is based on the exact minimization of the objective function, and for nonlinear models the quality of the results depends on the accuracy of the approximation of the minimum. This is controlled by the convergence criterion used.

There are many nonlinear functions for which the objective function is quite flat in a large region around the minimum point so that many quite different parameter vectors might satisfy a weak convergence criterion. By using different starting values, different convergence criteria, or different minimization methods, you can produce very different estimates for such models.

You can guard against this by running the estimation with different starting values and different convergence criteria and checking that the estimates produced are essentially the same. If they are not, use a smaller CONVERGE= value.

Local Minimum

You might have converged to a local minimum rather than a global one. This problem is difficult to detect because the procedure appears to have succeeded. You can guard against this by running the estimation with different starting values or with a different minimization technique. The START= option can be used to automatically perform a grid search to aid in the search for a global minimum.

Discontinuities

The computational methods assume that the model is a continuous and smooth function of the parameters. If this is not the case, the methods might not work.

If the model equations or their derivatives contain discontinuities, the estimation usually succeeds, provided that the final parameter estimates lie in a continuous interval and that the iterations do not produce parameter values at points of discontinuity or parameter values that try to cross asymptotes.

One common case of discontinuities causing estimation failure is that of an asymptotic discontinuity between the final estimates and the initial values. For example, consider the following model, which is basically linear but is written with one parameter in reciprocal form:

$$y = a + b * x1 + x2 / c;$$

By placing the parameter C in the denominator, a singularity is introduced into the parameter space at C=0. This is not necessarily a problem, but if the correct estimate of C is negative while the starting value is positive (or vice versa), the asymptotic discontinuity at 0 will lie between the estimate and the starting value. This means that the iterations have to pass through the singularity to get to the correct estimates. The situation is shown in [Figure 18.32](#).

Figure 18.32 Asymptotic Discontinuity

Because of the incorrect sign of the starting value, the C estimate goes off towards positive infinity in a vain effort to get past the asymptote and onto the correct arm of the hyperbola. As the computer is required to work with ever closer approximations to infinity, the numerical calculations break down and an “objective function was not improved” convergence failure message is printed. At this point, the iterations terminate with an extremely large positive value for C. When the sign of the starting value for C is changed, the estimates converge quickly to the correct values.

Linear Dependencies

In some cases, the Jacobian matrix might not be of full rank; parameters might not be fully identified for the current parameter values with the current data. When linear dependencies occur among the derivatives of the model, some parameters appear with a standard error of 0 and with the word BIASED printed in place of the *t* statistic. When this happens, collinearity diagnostics for the Jacobian crossproducts matrix are printed if the DETAILS option is specified and there are twenty or fewer parameters estimated. Collinearity diagnostics are also printed out automatically when a minimization method fails, or when the COLLIN option is specified.

For each parameter, the proportion of the variance of the estimate accounted for by each *principal component* is printed. The principal components are constructed from the eigenvalues and eigenvectors of the correlation matrix (scaled covariance matrix). When collinearity exists, a principal component is associated with proportion of the variance of more than one parameter. The numbers reported are proportions so they remain between 0 and 1. If two or more parameters have large proportion values associated with the same principal component, then two problems can occur: the computation of the parameter estimates are slow or nonconvergent; and the parameter estimates have inflated variances (Belsley, Kuh, and Welsch 1980, p. 105–117).

For example, the following cubic model is fit to a quadratic data set:

```
proc model data=test3;
  exogenous x1;
  parms b1 a1 c1 ;
  y1 = a1 * x1 + b1 * x1 * x1 + c1 * x1 * x1 *x1;
  fit y1 / collin;
run;
```

The collinearity diagnostics are shown in [Figure 18.33](#).

Figure 18.33 Collinearity Diagnostics

The MODEL Procedure					
Collinearity Diagnostics					
Number	Eigenvalue	Condition Number	-----Proportion of Variation-----		
			b1	a1	c1
1	2.942920	1.0000	0.0001	0.0004	0.0002
2	0.056638	7.2084	0.0001	0.0357	0.0148
3	0.000442	81.5801	0.9999	0.9639	0.9850

Notice that the proportions associated with the smallest eigenvalue are almost 1. For this model, removing any of the parameters decreases the variances of the remaining parameters.

In many models, the collinearity might not be clear cut. Collinearity is not necessarily something you remove. A model might need to be reformulated to remove the redundant parameterization, or the limitations on the estimability of the model can be accepted. The GINV=G4 option can be helpful to avoid problems with convergence for models containing collinearities.

Collinearity diagnostics are also useful when an estimation does not converge. The diagnostics provide insight into the numerical problems and can suggest which parameters need better starting values. These diagnostics are based on the approach of Belsley, Kuh, and Welsch (1980).

Iteration History

The options ITPRINT, ITDETAILS, XPX, I, and ITALL specify a detailed listing of each iteration of the minimization process.

ITPRINT Option

The ITPRINT information is selected whenever any iteration information is requested.

The following information is displayed for each iteration:

N	is the number of usable observations.
Objective	is the corrected objective function value.
Trace(S)	is the trace of the S matrix.
subit	is the number of subiterations required to find a λ or a damping factor that reduces the objective function.
R	is the R convergence measure.

The estimates for the parameters at each iteration are also printed.

ITDETAILS Option

The additional values printed for the ITDETAILS option are:

Theta	is the angle in degrees between Δ , the parameter change vector, and the negative gradient of the objective function.
Phi	is the directional derivative of the objective function in the Δ direction scaled by the objective function.
Stepsize	is the value of the damping factor used to reduce Δ if the Gauss-Newton method is used.
Lambda	is the value of λ if the Marquardt method is used.
Rank(XPX)	is the rank of the $\mathbf{X}'\mathbf{X}$ matrix (output if the projected Jacobian crossproducts matrix is singular).

The definitions of PPC and R are explained in the section “[Convergence Criteria](#)” on page 1028. When the values of PPC are large, the parameter associated with the criteria is displayed in parentheses after the value.

XPX and I Options

The XPX and the I options select the printing of the augmented $\mathbf{X}'\mathbf{X}$ matrix and the augmented $\mathbf{X}'\mathbf{X}$ matrix after a *sweep* operation (Goodnight 1979) has been performed on it. An example of the output from the following statements is shown in Figure 18.34.

```
proc model data=test2;
  y1 = a1 * x2 * x2 - exp( d1*x1);
  y2 = a2 * x1 * x1 + b2 * exp( d2*x2);
  fit y1 y2 / itall XPX I ;
run;
```

Figure 18.34 XPX and I Options Output

The MODEL Procedure						
OLS Estimation						
Cross Products for System At OLS Iteration 0						
	a1	d1	a2	b2	d2	Residual
a1	1839468	-33818.35	0.0	0.00	0.000000	3879959
d1	-33818	1276.45	0.0	0.00	0.000000	-76928
a2	0	0.00	42925.0	1275.15	0.154739	470686
b2	0	0.00	1275.2	50.01	0.003867	16055
d2	0	0.00	0.2	0.00	0.000064	2
Residual	3879959	-76928.14	470686.3	16055.07	2.329718	24576144
XPX Inverse for System At OLS Iteration 0						
	a1	d1	a2	b2	d2	Residual
a1	0.000001	0.000028	0.000000	0.0000	0.00	2
d1	0.000028	0.001527	0.000000	0.0000	0.00	-9
a2	0.000000	0.000000	0.000097	-0.0025	-0.08	6
b2	0.000000	0.000000	-0.002455	0.0825	0.95	172
d2	0.000000	0.000000	-0.084915	0.9476	15746.71	11931
Residual	1.952150	-8.546875	5.823969	171.6234	11930.89	10819902

The first matrix, labeled “Cross Products,” for OLS estimation is

$$\begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{r} \\ \mathbf{r}'\mathbf{X} & \mathbf{r}'\mathbf{r} \end{bmatrix}$$

The column labeled Residual in the output is the vector $\mathbf{X}'\mathbf{r}$, which is the gradient of the objective function. The diagonal scalar value $\mathbf{r}'\mathbf{r}$ is the objective function uncorrected for degrees of freedom. The second matrix, labeled “XPX Inverse,” is created through a sweep operation on the augmented $\mathbf{X}'\mathbf{X}$ matrix to get:

$$\begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-1} & (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r} \\ (\mathbf{X}'\mathbf{r})'(\mathbf{X}'\mathbf{X})^{-1} & \mathbf{r}'\mathbf{r} - (\mathbf{X}'\mathbf{r})'(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r} \end{bmatrix}$$

Note that the residual column is the change vector used to update the parameter estimates at each iteration. The corner scalar element is used to compute the R convergence criteria.

ITALL Option

The ITALL option, in addition to causing the output of all of the preceding options, outputs the **S** matrix, the inverse of the **S** matrix, the **CROSS** matrix, and the swept **CROSS** matrix. An example of a portion of the **CROSS** matrix for the preceding example is shown in [Figure 18.35](#).

Computer Resource Requirements

If you are estimating large systems, you need to be aware of how PROC MODEL uses computer resources (such as memory and the CPU) so they can be used most efficiently.

Saving Time with Large Data Sets

If your input data set has many observations, the FIT statement performs a large number of model program executions. A pass through the data is made at least once for each iteration and the model program is executed once for each observation in each pass. If you refine the starting estimates by using a smaller data set, the final estimation with the full data set might require fewer iterations.

For example, you could use

```
proc model;
  /* Model goes here */
  fit / data=a(obs=25);
  fit / data=a;
```

where OBS=25 selects the first 25 observations in A. The second FIT statement produces the final estimates using the full data set and starting values from the first run.

Fitting the Model in Sections to Save Space and Time

If you have a very large model (with several hundred parameters, for example), the procedure uses considerable space and time. You might be able to save resources by breaking the estimation process into several steps and estimating the parameters in subsets.

You can use the FIT statement to select for estimation only the parameters for selected equations. Do not break the estimation into too many small steps; the total computer time required is minimized by compromising between the number of FIT statements that are executed and the size of the crossproducts matrices that must be processed.

When the parameters are estimated for selected equations, the entire model program must be executed even though only a part of the model program might be needed to compute the residuals for the equations selected for estimation. If the model itself can be broken into sections for estimation (and later combined for simulation and forecasting), then more resources can be saved.

For example, to estimate the following four equation model in two steps, you could use

```
proc model data=a outmodel=part1;
  parms a0-a2 b0-b2 c0-c3 d0-d3;
  y1 = a0 + a1*y2 + a2*x1;
  y2 = b0 + b1*y1 + b2*x2;
  y3 = c0 + c1*y1 + c2*y4 + c3*x3;
  y4 = d0 + d1*y1 + d2*y3 + d3*x4;
  fit y1 y2;
  fit y3 y4;
  fit y1 y2 y3 y4;
run;
```

You should try estimating the model in pieces to save time only if there are more than 14 parameters; the preceding example takes more time, not less, and the difference in memory required is trivial.

Memory Requirements for Parameter Estimation

PROC MODEL is a large program, and it requires much memory. Memory is also required for the SAS System, various data areas, the model program and associated tables and data vectors, and a few crossproducts matrices. For most models, the memory required for PROC MODEL itself is much larger than that required for the model program, and the memory required for the model program is larger than that required for the crossproducts matrices.

The number of bytes needed for two crossproducts matrices, four **S** matrices, and three parameter covariance matrices is

$$8 \times (2 + k + m + g)^2 + 16 \times g^2 + 12 \times (p + 1)^2$$

plus lower-order terms, where m is the number of unique nonzero derivatives of each residual with respect to each parameter, g is the number of equations, k is the number of instruments, and p is the number of parameters. This formula is for the memory required for 3SLS. If you are using OLS, a reasonable estimate of the memory required for large problems (greater than 100 parameters) is to divide the value obtained from the formula in half.

Consider the following model program.

```
proc model data=test2 details;
  exogenous x1 x2;
  parms b1 100 a1 a2 b2 2.5 c2 55;
  y1 = a1 * y2 + b1 * x1 * x1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2;
  fit y1 y2 / n3sls memoryuse;
  inst b1 b2 c2 x1 ;
run;
```

The DETAILS option prints the storage requirements information shown in [Figure 18.36](#).

Figure 18.36 Storage Requirements Information

The MODEL Procedure	
Storage Requirements for this Problem	
Order of XPX Matrix	6
Order of S Matrix	2
Order of Cross Matrix	13
Total Nonzero Derivatives	5
Distinct Variable Derivatives	5
Size of Cross matrix	728

The matrix $\mathbf{X}'\mathbf{X}$ augmented by the residual vector is called the XPX matrix in the output, and it has the size $m + 1$. The order of the **S** matrix, 2 for this example, is the value of g . The CROSS matrix is made up of the k unique instruments, a constant column that represents the intercept terms, followed by the m unique Jacobian variables plus a constant column that represents the parameters with constant derivatives, followed by the g residuals.

The size of two CROSS matrices in bytes is

$$8 \times (2 + k + m + g)^2 + 2 + k + m + g$$

Note that the CROSS matrix is symmetric, so only the diagonal and the upper triangular part of the matrix is stored. For examples of the CROSS and XPX matrices see the section “[Iteration History](#)” on page 1042.

The MEMORYUSE Option

The MEMORYUSE option in the FIT, SOLVE, MODEL, or RESET statement can be used to request a comprehensive memory usage summary.

Figure 18.37 shows an example of the output produced by the MEMORYUSE option.

Figure 18.37 MEMORYUSE Option Output for FIT Task

Memory Usage Summary (in bytes)	
Symbols	11088
Strings	1051
Lists	3392
Arrays	1848
Statements	2432
Opcodes	800
Parsing	576
Executable	7296
Block option	0
Cross reference	0
Flow analysis	336
Derivatives	13920
Data vector	320
Cross matrix	1480
X'X matrix	590
S matrix	144
GMM memory	0
Jacobian	0
Work vectors	702
Overhead	13094
-----	-----
Total	59069

Definitions of the memory components follow:

symbols	memory used to store information about variables in the model
strings	memory used to store the variable names and labels
lists	space used to hold lists of variables
arrays	memory used by ARRAY statements
statements	memory used for the list of programming statements in the model
opcodes	memory used to store the code compiled to evaluate the expression in the model program
parsing	memory used in parsing the SAS statements
executable	the compiled model program size
block option	memory used by the BLOCK option
cross ref.	memory used by the XREF option
flow analysis	memory used to compute the interdependencies of the variables
derivatives	memory used to compute and store the analytical derivatives
data vector	memory used for the program data vector
cross matrix	memory used for one or more copies of the CROSS matrix
$X'X$ matrix	memory used for one or more copies of the $X'X$ matrix
S matrix	memory used for the covariance matrix
GMM memory	additional memory used for the GMM and ITGMM methods
Jacobian	memory used for the Jacobian matrix for SOLVE and FIML
work vectors	memory used for miscellaneous work vectors
overhead	other miscellaneous memory

Testing for Normality

The NORMAL option in the FIT statement performs multivariate and univariate tests of normality.

The three multivariate tests provided are Mardia's skewness test and kurtosis test (Mardia 1970) and the Henze-Zirkler $T_{n,\beta}$ test (Henze and Zirkler 1990). The two univariate tests provided are the Shapiro-Wilk W test and the Kolmogorov-Smirnov test. (For details on the univariate tests, refer to "Goodness-of-Fit Tests" section in "The UNIVARIATE Procedure" chapter in the *Base SAS Procedures Guide*.) The null hypothesis for all these tests is that the residuals are normally distributed.

For a random sample X_1, \dots, X_n , $X_i \in \mathbb{R}^d$, where d is the dimension of X_i and n is the number of observations, a measure of multivariate skewness is

$$b_{1,d} = \frac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n [(X_i - \mu)' \mathbf{S}^{-1} (X_j - \mu)]^3$$

where \mathbf{S} is the sample covariance matrix of \mathbf{X} . For weighted regression, both \mathbf{S} and $(X_i - \mu)$ are computed by using the weights supplied by the WEIGHT statement or the `_WEIGHT_` variable.

Mardia showed that under the null hypothesis $\frac{n}{6} b_{1,d}$ is asymptotically distributed as $\chi^2(d(d+1)(d+2)/6)$. For small samples, Mardia's skewness test statistic is calculated with a small sample correction formula, given by $\frac{nk}{6} b_{1,d}$ where the correction factor k is given by $k = (d+1)(n+1)(n+3)/n(((n+1)(d+1)) - 6)$. Mardia's skewness test statistic in PROC MODEL uses this small sample corrected formula.

A measure of multivariate kurtosis is given by

$$b_{2,d} = \frac{1}{n} \sum_{i=1}^n [(X_i - \mu)' \mathbf{S}^{-1} (X_i - \mu)]^2$$

Mardia showed that under the null hypothesis, $b_{2,d}$ is asymptotically normally distributed with mean $d(d+2)$ and variance $8d(d+2)/n$.

The Henze-Zirkler test is based on a nonnegative functional $D(.,.)$ that measures the distance between two distribution functions and has the property that

$$D(N_d(0, I_d), Q) = 0$$

if and only if

$$Q = N_d(0, I_d)$$

where $N_d(\mu, \Sigma_d)$ is a d -dimensional normal distribution.

The distance measure $D(.,.)$ can be written as

$$D_\beta(P, Q) = \int_{\mathbb{R}^d} |\hat{P}(t) - \hat{Q}(t)|^2 \varphi_\beta(t) dt$$

where $\hat{P}(t)$ and $\hat{Q}(t)$ are the Fourier transforms of P and Q , and $\varphi_\beta(t)$ is a weight or a kernel function. The density of the normal distribution $N_d(0, \beta^2 I_d)$ is used as $\varphi_\beta(t)$

$$\varphi_\beta(t) = (2\pi\beta^2)^{-\frac{d}{2}} \exp\left(-\frac{|t|^2}{2\beta^2}\right), t \in \mathbb{R}^d$$

where $|t| = (t't)^{0.5}$.

The parameter β depends on n as

$$\beta_d(n) = \frac{1}{\sqrt{2}} \left(\frac{2d+1}{4}\right)^{1/(d+4)} n^{1/(d+4)}$$

The test statistic computed is called $T_\beta(d)$ and is approximately distributed as a lognormal. The lognormal distribution is used to compute the null hypothesis probability.

$$\begin{aligned} T_\beta(d) &= \frac{1}{n^2} \sum_{j=1}^n \sum_{k=1}^n \exp\left(-\frac{\beta^2}{2} |Y_j - Y_k|^2\right) \\ &\quad - 2(1 + \beta^2)^{-d/2} \frac{1}{n} \sum_{j=1}^n \exp\left(-\frac{\beta^2}{2(1 + \beta^2)} |Y_j|^2\right) + (1 + 2\beta^2)^{-d/2} \end{aligned}$$

where

$$|Y_j - Y_k|^2 = (X_j - X_k)' \mathbf{S}^{-1} (X_j - X_k)$$

$$|Y_j|^2 = (X_j - \bar{X})'S^{-1}(X_j - \bar{X})$$

Monte Carlo simulations suggest that $T_\beta(d)$ has good power against distributions with heavy tails.

The Shapiro-Wilk W test is computed only when the number of observations (n) is less than 2000 while computation of the Kolmogorov-Smirnov test statistic requires at least 2000 observations.

The following is an example of the output produced by the NORMAL option.

```
proc model data=test2;
  y1 = a1 * x2 * x2 - exp( d1*x1);
  y2 = a2 * x1 * x1 + b2 * exp( d2*x2);
  fit y1 y2 / normal ;
run;
```

Figure 18.38 Normality Test Output

The MODEL Procedure			
Normality Test			
Equation	Test Statistic	Value	Prob
y1	Shapiro-Wilk W	0.37	<.0001
y2	Shapiro-Wilk W	0.84	<.0001
System	Mardia Skewness	286.4	<.0001
	Mardia Kurtosis	31.28	<.0001
	Henze-Zirkler T	7.09	<.0001

Heteroscedasticity

One of the key assumptions of regression is that the variance of the errors is constant across observations. If the errors have constant variance, the errors are called *homoscedastic*. Typically, residuals are plotted to assess this assumption. Standard estimation methods are inefficient when the errors are *heteroscedastic* or have nonconstant variance.

Heteroscedasticity Tests

The MODEL procedure provides two tests for heteroscedasticity of the errors: White's test and the modified Breusch-Pagan test.

Both White's test and the Breusch-Pagan are based on the residuals of the fitted model. For systems of equations, these tests are computed separately for the residuals of each equation.

The residuals of an estimation are used to investigate the heteroscedasticity of the true disturbances.

The WHITE option tests the null hypothesis

$$H_0 : \sigma_i^2 = \sigma^2 \text{ for all } i$$

White's test is general because it makes no assumptions about the form of the heteroscedasticity (White 1980). Because of its generality, White's test might identify specification errors other than heteroscedasticity (Thursby 1982). Thus, White's test might be significant when the errors are homoscedastic but the model is misspecified in other ways.

White's test is equivalent to obtaining the error sum of squares for the regression of squared residuals on a constant and all the unique variables in $\mathbf{J} \otimes \mathbf{J}$, where the matrix \mathbf{J} is composed of the partial derivatives of the equation residual with respect to the estimated parameters. White's test statistic W is computed as follows:

$$W = nR^2$$

where R^2 is the correlation coefficient obtained from the above regression. The statistic is asymptotically distributed as chi-squared with $P-1$ degrees of freedom, where P is the number of regressors in the regression, including the constant and n is the total number of observations. In the example given below, the regressors are constant, income, income*income, income*income*income, and income*income*income*income. income*income occurs twice and one is dropped. Hence, $P=5$ with degrees of freedom, $P-1=4$.

Note that White's test in the MODEL procedure is different than White's test in the REG procedure requested by the SPEC option. The SPEC option produces the test from Theorem 2 on page 823 of White (1980). The WHITE option, on the other hand, produces the statistic discussed in Greene (1993).

The null hypothesis for the modified Breusch-Pagan test is homoscedasticity. The alternate hypothesis is that the error variance varies with a set of regressors, which are listed in the BREUSCH= option.

Define the matrix \mathbf{Z} to be composed of the values of the variables listed in the BREUSCH= option, such that $z_{i,j}$ is the value of the j th variable in the BREUSCH= option for the i th observation. The null hypothesis of the Breusch-Pagan test is

$$\sigma_i^2 = \sigma^2(\alpha_0 + \boldsymbol{\alpha}' \mathbf{z}_i) \quad H_0 : \boldsymbol{\alpha} = \mathbf{0}$$

where σ_i^2 is the error variance for the i th observation and α_0 and $\boldsymbol{\alpha}$ are regression coefficients.

The test statistic for the Breusch-Pagan test is

$$bp = \frac{1}{v} (\mathbf{u} - \bar{u}\mathbf{i})' \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}' (\mathbf{u} - \bar{u}\mathbf{i})$$

where $\mathbf{u} = (e_1^2, e_2^2, \dots, e_n^2)$, \mathbf{i} is a $n \times 1$ vector of ones, and

$$v = \frac{1}{n} \sum_{i=1}^n \left(e_i^2 - \frac{\mathbf{e}'\mathbf{e}}{n} \right)^2$$

This is a modified version of the Breusch-Pagan test, which is less sensitive to the assumption of normality than the original test (Greene 1993, p. 395).

The statements in the following example produce the output in [Figure 18.39](#):

```

proc model data=schools;
  parms const inc inc2;

  exp = const + inc * income + inc2 * income * income;
  incsq = income * income;

  fit exp / white breusch=(1 income incsq);
run;

```

Figure 18.39 Output for Heteroscedasticity Tests

The MODEL Procedure					
Heteroscedasticity Test					
Equation	Test	Statistic	DF	Pr > ChiSq	Variables
exp	White's Test	21.16	4	0.0003	Cross of all vars
	Breusch-Pagan	15.83	2	0.0004	1, income, incsq

Correcting for Heteroscedasticity

There are two methods for improving the efficiency of the parameter estimation in the presence of heteroscedastic errors. If the error variance relationships are known, weighted regression can be used or an error model can be estimated. For details about error model estimation, see the section “[Error Covariance Structure Specification](#)” on page 1062. If the error variance relationship is unknown, GMM estimation can be used.

Weighted Regression

The WEIGHT statement can be used to correct for the heteroscedasticity. Consider the following model, which has a heteroscedastic error term:

$$y_t = 250(e^{-0.2t} - e^{-0.8t}) + \sqrt{(9/t)}\epsilon_t$$

The data for this model is generated with the following SAS statements.

```

data test;
  do t=1 to 25;
    y = 250 * (exp( -0.2 * t ) - exp( -0.8 * t )) +
      sqrt( 9 / t ) * rannor(1);
    output;
  end;
run;

```

If this model is estimated with OLS, as shown in the following statements, the estimates shown in [Figure 18.40](#) are obtained for the parameters.

```

proc model data=test;

```

```

parms b1 0.1 b2 0.9;
y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
fit y;
run;

```

Figure 18.40 Unweighted OLS Estimates

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
b1	0.200977	0.00101	198.60	<.0001
b2	0.826236	0.00853	96.82	<.0001

If both sides of the model equation are multiplied by \sqrt{t} , the model has a homoscedastic error term. This multiplication or weighting is done through the WEIGHT statement. The WEIGHT statement variable operates on the squared residuals as

$$\epsilon'_t \epsilon_t = \text{weight} \times \mathbf{q}'_t \mathbf{q}_t$$

so that the WEIGHT statement variable represents the square of the model multiplier. The following PROC MODEL statements corrects the heteroscedasticity with a WEIGHT statement:

```

proc model data=test;
parms b1 0.1 b2 0.9;
y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
fit y;
weight t;
run;

```

Note that the WEIGHT statement follows the FIT statement. The weighted estimates are shown in Figure 18.41.

Figure 18.41 Weighted OLS Estimates

Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
b1	0.200977	0.00101	198.60	<.0001
b2	0.826236	0.00853	96.82	<.0001

The weighted OLS estimates are identical to the output produced by the following PROC MODEL example:

```

proc model data=test;

```

```

    parms b1 0.1 b2 0.9;
    y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
    _weight_ = t;
    fit y;
run;

```

If the WEIGHT statement is used in conjunction with the `_WEIGHT_` variable, the two values are multiplied together to obtain the weight used.

The WEIGHT statement and the `_WEIGHT_` variable operate on all the residuals in a system of equations. If a subset of the equations needs to be weighted, the residuals for each equation can be modified through the `RESID.` variable for each equation. The following example demonstrates the use of the `RESID.` variable to make a homoscedastic error term:

```

proc model data=test;
  parms b1 0.1 b2 0.9;
  y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
  resid.y = resid.y * sqrt(t);
  fit y;
run;

```

These statements produce estimates of the parameters and standard errors that are identical to the weighted OLS estimates. The reassignment of the `RESID.Y` variable must be done after `Y` is assigned; otherwise it would have no effect. Also, note that the residual (`RESID.Y`) is multiplied by \sqrt{t} . Here the multiplier is acting on the residual before it is squared.

GMM Estimation

If the form of the heteroscedasticity is unknown, generalized method of moments estimation (GMM) can be used. The following PROC MODEL statements use GMM to estimate the example model used in the preceding section:

```

proc model data=test;
  parms b1 0.1 b2 0.9;
  y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
  fit y / gmm;
  instruments b1 b2;
run;

```

GMM is an instrumental method, so instrument variables must be provided.

GMM estimation generates estimates for the parameters shown in [Figure 18.42](#).

Figure 18.42 GMM Estimation for Heteroscedasticity

The MODEL Procedure				
Nonlinear GMM Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
b1	0.200487	0.000800	250.69	<.0001
b2	0.822148	0.0148	55.39	<.0001

Heteroscedasticity-Consistent Covariance Matrix Estimation

Homoscedasticity is required for ordinary least squares regression estimates to be efficient. A non-constant error variance, heteroscedasticity, causes the OLS estimates to be inefficient, and the usual OLS covariance matrix, $\hat{\Sigma}$, is generally invalid:

$$\hat{\Sigma} = \sigma^2(\mathbf{X}'\mathbf{X})^{-1}$$

When the variance of the errors of a classical linear model

$$Y = \mathbf{X}\beta + \epsilon$$

is not constant across observations (heteroscedastic), so that $\sigma_i^2 \neq \sigma_j^2$ for some $j > 1$, the OLS estimator

$$\hat{\beta}_{OLS} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'Y$$

is unbiased but it is inefficient. Models that take into account the changing variance can make more efficient use of the data. When the variances, σ_i^2 , are known, generalized least squares (GLS) can be used and the estimator

$$\hat{\beta}_{GLS} = (\mathbf{X}'\mathbf{\Omega}\mathbf{X})^{-1}\mathbf{X}'\mathbf{\Omega}^{-1}Y$$

where

$$\mathbf{\Omega} = \begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \sigma_T^2 \end{bmatrix}$$

is unbiased and efficient. However, GLS is unavailable when the variances, σ_i^2 , are unknown.

To solve this problem White (1980) proposed a heteroscedastic consistent-covariance matrix estimator (HCCME)

$$\hat{\Sigma} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\hat{\mathbf{\Omega}}\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}$$

that is consistent as well as unbiased, where

$$\hat{\mathbf{\Omega}}_0 = \begin{bmatrix} \epsilon_1^2 & 0 & 0 & 0 \\ 0 & \epsilon_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \epsilon_T^2 \end{bmatrix}$$

and $\epsilon_t = Y_t - \mathbf{X}_t \beta_{OLS}$.

This estimator is considered somewhat unreliable in finite samples. Therefore, Davidson and MacKinnon (1993) propose three different modifications to estimating $\hat{\mathbf{\Omega}}$. The first solution is to simply multiply ϵ_t^2 by $\frac{n}{n-df}$, where n is the number of observations and df is the number of explanatory variables, so that

$$\hat{\mathbf{\Omega}}_1 = \begin{bmatrix} \frac{n}{n-df} \epsilon_1^2 & 0 & 0 & 0 \\ 0 & \frac{n}{n-df} \epsilon_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{n}{n-df} \epsilon_n^2 \end{bmatrix}$$

The second solution is to define

$$\hat{\mathbf{\Omega}}_2 = \begin{bmatrix} \frac{\epsilon_1^2}{1-\hat{h}_1} & 0 & 0 & 0 \\ 0 & \frac{\epsilon_2^2}{1-\hat{h}_2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{\epsilon_n^2}{1-\hat{h}_n} \end{bmatrix}$$

where $\hat{h}_t = \mathbf{X}_t(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}_t'$.

The third solution, called the “jackknife,” is to define

$$\hat{\mathbf{\Omega}}_3 = \begin{bmatrix} \frac{\epsilon_1^2}{(1-\hat{h}_1)^2} & 0 & 0 & 0 \\ 0 & \frac{\epsilon_2^2}{(1-\hat{h}_2)^2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{\epsilon_n^2}{(1-\hat{h}_n)^2} \end{bmatrix}$$

MacKinnon and White (1985) investigated these three modified HCCMEs, including the original HCCME, based on finite-sample performance of pseudo- t statistics. The original HCCME performed the worst. The first modification performed better. The second modification performed even better than the first, and the third modification performed the best. They concluded that the original HCCME should never be used in finite sample estimation, and that the second and third modifications should be used over the first modification if the diagonals of $\hat{\mathbf{\Omega}}$ are available.

Seemingly Unrelated Regression HCCME

Extending the discussion to systems of g equations, the HCCME for SUR estimation is

$$(\tilde{\mathbf{X}}'\tilde{\mathbf{X}})^{-1}\tilde{\mathbf{X}}'\hat{\mathbf{\Omega}}\tilde{\mathbf{X}}(\tilde{\mathbf{X}}'\tilde{\mathbf{X}})^{-1}$$

where $\tilde{\mathbf{X}}$ is a $ng \times k$ matrix with the first g rows representing the first observation, the next g rows representing the second observation, and so on. $\hat{\mathbf{\Omega}}$ is now a $ng \times ng$ block diagonal matrix with typical block $g \times g$

$$\hat{\mathbf{\Omega}}_i = \begin{bmatrix} \psi_{1,i} & \psi_{1,i} & \psi_{1,i} & \psi_{2,i} & \cdots & \psi_{1,i} & \psi_{g,i} \\ \psi_{2,i} & \psi_{1,i} & \psi_{2,i} & \psi_{2,i} & \cdots & \psi_{2,i} & \psi_{g,i} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \psi_{g,i} & \psi_{1,i} & \psi_{g,i} & \psi_{2,i} & \cdots & \psi_{g,i} & \psi_{g,i} \end{bmatrix}$$

where

$$\psi_{j,i} = \epsilon_{j,i} \quad HC_0$$

or

$$\psi_{j,i} = \sqrt{\frac{n}{n-df}} \epsilon_{j,i} \quad HC_1$$

or

$$\psi_{j,i} = \epsilon_{j,i} / \sqrt{1 - \hat{h}_i} \quad HC_2$$

or

$$\psi_{j,i} = \epsilon_{j,i} / (1 - \hat{h}_i) \quad HC_3$$

Two- and Three-Stage Least Squares HCCME

For two- and three-stage least squares, the HCCME for a g equation system is

$$\text{Cov}F(\hat{\mathbf{\Omega}})\text{Cov}$$

where

$$\text{Cov} = \left(\frac{1}{n} \mathbf{X}'(\mathbf{I} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}')\mathbf{X} \right)^{-1}$$

is the normal covariance matrix without the \mathbf{S} matrix and

$$F(\mathbf{\Omega}) = \frac{1}{n} \sum_i^g \sum_j^g \mathbf{X}'_i \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}' \hat{\mathbf{\Omega}}_{ij} \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}' \mathbf{X}_j$$

where \mathbf{X}_j is a $n \times p$ matrix with the j th equations regressors in the appropriate columns and zeros everywhere else.

$$\hat{\mathbf{\Omega}}_{ij} = \begin{bmatrix} \psi_{i,1}\psi_{j,1} & 0 & 0 & 0 \\ 0 & \psi_{i,2}\psi_{j,2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \psi_{i,n}\psi_{j,n} \end{bmatrix}$$

For 2SLS $\hat{\mathbf{\Omega}}_{ij} = 0$ when $i \neq j$. The ϵ_t used in $\hat{\mathbf{\Omega}}$ is computed by using the parameter estimates obtained from the instrumental variables estimation.

The leverage value for the i th equation used in the HCCME=2 and HCCME=3 methods is computed as conditional on the first stage as

$$h_{ii} = \mathbf{Z}_i(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{X}_i(\mathbf{X}'(\mathbf{I} \otimes \mathbf{Z}(\mathbf{Z}' * \mathbf{Z})^{-1}\mathbf{Z}')\mathbf{X})^{-1}\mathbf{X}'_i\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'_i$$

for 2SLS and

$$h_{ii} = \mathbf{Z}_i(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{X}_i(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}' * \mathbf{Z})^{-1}\mathbf{Z}')\mathbf{X})^{-1}\mathbf{X}'_i\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'_i/\mathbf{S}_{ii}$$

for 3SLS.

Testing for Autocorrelation

The GODFREY= option in the FIT statement produces the Godfrey Lagrange multiplier test for serially correlated residuals for each equation (Godfrey 1978a and 1978b). n is the maximum autoregressive order, and specifies that Godfrey's tests be computed for lags 1 through n . The default number of lags is four.

The tests are performed separately for each equation estimated by the FIT statement. When a nonlinear model is estimated, the test is computed by using a linearized model.

The following is an example of the output produced by the GODFREY=3 option:

Figure 18.43 Autocorrelation Test Output

Godfrey Test Output			
The MODEL Procedure			
Godfrey's Serial Correlation Test			
Equation	Alternative	LM	Pr > LM
y	1	6.63	0.0100
	2	6.89	0.0319
	3	6.96	0.0732

The three variations of the test reported by the GODFREY=3 option are designed to have power

against different alternative hypothesis. Thus, if the residuals in fact have only first-order autocorrelation, the lag 1 test has the most power for rejecting the null hypothesis of uncorrelated residuals. If the residuals have second- but not higher-order autocorrelation, the lag 2 test might be more likely to reject; the same is true for third-order autocorrelation and the lag 3 test.

The null hypothesis of Godfrey's tests is that the equation residuals are white noise. However, if the equation includes autoregressive error model of order p (AR(p)), then the lag i test, when considered in terms of the structural error, is for the null hypothesis that the structural errors are from an AR(p) process versus the alternative hypothesis that the errors are from an AR($p + i$) process.

The alternative ARMA(p, i) process is locally equivalent to the alternative AR($p + i$) process with respect to the null model AR(p). Thus, the GODFREY= option results are also a test of AR(p) errors against the alternative hypothesis of ARMA(p, i) errors. See Godfrey (1978a and 1978b) for more detailed information.

Transformation of Error Terms

In PROC MODEL you can control the form of the error term. By default, the error term is assumed to be additive. This section demonstrates how to specify nonadditive error terms and discusses the effects of these transformations.

Models with Nonadditive Errors

The estimation methods used by PROC MODEL assume that the error terms of the equations are independently and identically distributed with zero means and finite variances. Furthermore, the methods assume that the RESID.*name* equation variable for normalized form equations or the EQ.*name* equation variable for general form equations contains an estimate of the error term of the true stochastic model whose parameters are being estimated. Details on RESID.*name* and EQ.*name* equation variables are in the section “[Equation Translations](#)” on page 1155.

To illustrate these points, consider the common loglinear model

$$y = \alpha x^\beta \tag{1}$$

$$\ln y = a + b \ln(x) \tag{2}$$

where $a = \log(\alpha)$ and $b = \beta$. Equation (2) is called the *log form* of the equation in contrast to equation (1), which is called the *level form* of the equation. Using the SYSLIN procedure, you can estimate equation (2) by specifying

```
proc syslin data=in;
  model logy=logx;
run;
```

where LOGY and LOGX are the logs of Y and X computed in a preceding DATA step. The resulting values for INTERCEPT and LOGX correspond to a and b in equation (2).

Using the MODEL procedure, you can try to estimate the parameters in the level form (and avoid the DATA step) by specifying

```
proc model data=in;
  parms alpha beta;
  y = alpha * x ** beta;
  fit y;
run;
```

where ALPHA and BETA are the parameters in equation (1).

Unfortunately, at least one of the preceding is wrong; an ambiguity results because equations (1) and (2) contain no explicit error term. The SYSLIN and MODEL procedures both deal with additive errors; the residual used (the estimate of the error term in the equation) is the difference between the predicted and actual values (of LOGY for PROC SYSLIN and of Y for PROC MODEL in this example). If you perform the regressions discussed previously, PROC SYSLIN estimates equation (3) while PROC MODEL estimates equation (4).

$$\ln y = a + b \ln(x) + \epsilon \quad (3)$$

$$y = \alpha x^\beta + \xi \quad (4)$$

These are different statistical models. Equation (3) is the log form of equation (5)

$$y = \alpha x^\beta \mu \quad (5) \quad \text{where } \mu = e^\epsilon.$$

Equation (4), on the other hand, cannot be linearized because the error term ξ (different from μ) is additive in the level form.

You must decide whether your model is equation (4) or (5). If the model is equation (4), you should use PROC MODEL. If you linearize equation (1) without considering the error term and apply SYSLIN to MODEL LOGY=LOGX, the results will be wrong. On the other hand, if your model is equation (5) (in practice it usually is), and you want to use PROC MODEL to estimate the parameters in the *level* form, you must do something to account for the multiplicative error.

PROC MODEL estimates parameters by minimizing an objective function. The objective function is computed using either the RESID.-prefixed equation variable or the EQ.-prefixed equation variable. You must make sure that these prefixed equation variables are assigned an appropriate error term. If the model has additive errors that satisfy the assumptions, nothing needs to be done. In the case of equation (5), the error is nonadditive and the equation is in normalized form, so you must alter the value of RESID.Y.

The following assigns a valid estimate of μ to RESID.Y:

```
y = alpha * x ** beta;
resid.y = actual.y / pred.y;
```

However, $\mu = e^\epsilon$, and therefore μ , cannot have a mean of zero, and you cannot consistently estimate α and β by minimizing the sum of squares of an estimate of μ . Instead, you use $\epsilon = \ln \mu$.

```
proc model data=in;
```

```

parms alpha beta;
y = alpha * x ** beta;
resid.y = log( actual.y / pred.y );
fit y;
run;

```

If the model was expressed in general form, this transformation becomes

```

proc model data=in;
  parms alpha beta;
  EQ.trans = log( y / (alpha * x ** beta));
  fit trans;
run;

```

Both examples produce estimates of α and β of the level form that match the estimates of a and b of the log form. That is, ALPHA=exp(INTERCEPT) and BETA=LOGX, where INTERCEPT and LOGX are the PROC SYSLIN parameter estimates from the MODEL LOGY=LOGX. The standard error reported for ALPHA is different from that for the INTERCEPT in the log form.

The preceding example is not intended to suggest that loglinear models should be estimated in level form but, rather, to make the following points:

- Nonlinear transformations of equations involve the error term of the equation, and this should be taken into account when transforming models.
- The RESID.-prefixed and the EQ.-prefixed equation variables for models estimated by the MODEL procedure must represent additive errors with zero means.
- You can use assignments to RESID.-prefixed and EQ.-prefixed equation variables to transform error terms.
- Some models do not have additive errors or zero means, and many such models can be estimated using the MODEL procedure. The preceding approach applies not only to multiplicative models but to any model that can be manipulated to isolate the error term.

Predicted Values of Transformed Models

Nonadditive or transformed errors affect the distribution of the predicted values, as well as the estimates. For the preceding loglinear example, the MODEL procedure produces consistent parameter estimates. However, the predicted values for Y computed by PROC MODEL are not unbiased estimates of the expected values of Y, although they do estimate the conditional median Y values.

In general, the predicted values produced for a model with nonadditive errors are not unbiased estimates of the conditional means of the endogenous value. If the model can be transformed to a model with additive errors by using a *monotonic* transformation, the predicted values estimate the conditional medians of the endogenous variable.

For transformed models in which the biasing factor is known, you can use programming statements to correct for the bias in the predicted values as estimates of the endogenous means. In the preceding log-linear case, the predicted values are biased by the factor $\exp(\sigma^2/2)$. You can produce approximately unbiased predicted values in this case by writing the model as

```
proc model data=in;
  parms alpha beta;
  y=alpha * x ** beta;
  resid.y = log( actual.y / pred.y );
  fit y;
run;
```

See Miller (1984) for a discussion of bias factors for predicted values of transformed models.

Note that models with transformed errors are not appropriate for Monte Carlo simulation that uses the SDATA= option. PROC MODEL computes the OUTS= matrix from the transformed RESID.-prefixed equation variables, while it uses the SDATA= matrix to generate multivariate normal errors, which are added to the predicted values. This method of computing errors is inconsistent when the equation variables have been transformed.

Error Covariance Structure Specification

One of the key assumptions of regression is that the variance of the errors is constant across observations. Correcting for heteroscedasticity improves the efficiency of the estimates.

Consider the following general form for models:

$$\begin{aligned} \mathbf{q}(y_t, \mathbf{x}_t, \theta) &= \boldsymbol{\varepsilon}_t \\ \boldsymbol{\varepsilon}_t &= H_t * \boldsymbol{\epsilon}_t \\ H_t &= \begin{bmatrix} \sqrt{h_{t,1}} & 0 & \dots & 0 \\ 0 & \sqrt{h_{t,2}} & \dots & 0 \\ & & \ddots & \\ 0 & 0 & \dots & \sqrt{h_{t,g}} \end{bmatrix} \\ \mathbf{h}_t &= \mathbf{g}(y_t, \mathbf{x}_t, \phi) \end{aligned}$$

where $\boldsymbol{\epsilon}_t \sim N(0, \Sigma)$.

For models that are homoscedastic,

$$h_t = 1$$

If you have a model that is heteroscedastic with known form, you can improve the efficiency of the estimates by performing a weighted regression. The weight variable, using this notation, would be $1/\sqrt{h_t}$.

If the errors for a model are heteroscedastic and the functional form of the variance is known, the model for the variance can be estimated along with the regression function.

To specify a functional form for the variance, assign the function to an `H.var` variable where `var` is the equation variable. For example, if you want to estimate the scale parameter for the variance of a simple regression model

$$y = a * x + b$$

you can specify

```
proc model data=s;
  y = a * x + b;
  h.y = sigma**2;
fit y;
```

Consider the same model with the following functional form for the variance:

$$h_t = \sigma^2 * x^{2*\alpha}$$

This would be written as

```
proc model data=s;
  y = a * x + b;
  h.y = sigma**2 * x**(2*alpha);
fit y;
```

There are three ways to model the variance in the `MODEL` procedure: feasible generalized least squares, generalized method of moments, and full information maximum likelihood.

Feasible GLS

A simple approach to estimating a variance function is to estimate the mean parameters θ by using some auxiliary method, such as OLS, and then use the residuals of that estimation to estimate the parameters ϕ of the variance function. This scheme is called *feasible GLS*. It is possible to use the residuals from an auxiliary method for the purpose of estimating ϕ because in many cases the residuals consistently estimate the error terms.

For all estimation methods except GMM and FIML, using the `H.var` syntax specifies that feasible GLS is used in the estimation. For feasible GLS, the mean function is estimated by the usual method. The variance function is then estimated using pseudo-likelihood (PL) function of the generated residuals. The objective function for the PL estimation is

$$p_n(\sigma, \theta) = \sum_{i=1}^n \left(\frac{(y_i - f(x_i, \hat{\beta}))^2}{\sigma^2 h(z_i, \theta)} + \log[\sigma^2 h(z_i, \theta)] \right)$$

Once the variance function has been estimated, the mean function is reestimated by using the variance function as weights. If an S-iterated method is selected, this process is repeated until convergence (iterated feasible GLS).

Note that feasible GLS does not yield consistent estimates when one of the following is true:

- The variance is unbounded.
- There is too much serial dependence in the errors (the dependence does not fade with time).
- There is a combination of serial dependence and lag dependent variables.

The first two cases are unusual, but the third is much more common. Whether iterated feasible GLS avoids consistency problems with the last case is an unanswered research question. For more information see Davidson and MacKinnon (1993, pp. 298–301) or Gallant (1987, pp. 124–125) and Amemiya (1985, pp. 202–203).

One limitation is that parameters cannot be shared between the mean equation and the variance equation. This implies that certain GARCH models, cross-equation restrictions of parameters, or testing of combinations of parameters in the mean and variance component are not allowed.

Generalized Method of Moments

In GMM, normally the first moment of the mean function is used in the objective function.

$$\begin{aligned} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) &= \epsilon_t \\ \mathbf{E}(\epsilon_t) &= 0 \end{aligned}$$

To add the second moment conditions to the estimation, add the equation

$$\mathbf{E}(\epsilon_t * \epsilon_t - h_t) = 0$$

to the model. For example, if you want to estimate σ for linear example above, you can write

```
proc model data=s;
  y = a * x + b;
  eq.two = resid.y**2 - sigma**2;
  fit y two/ gmm;
  instruments x;
run;
```

This is a popular way to estimate a continuous-time interest rate processes (see Chan et al. 1992). The H.var syntax automatically generates this system of equations.

To further take advantage of the information obtained about the variance, the moment equations can be modified to

$$\begin{aligned} \mathbf{E}(\epsilon_t / \sqrt{h_t}) &= 0 \\ \mathbf{E}(\epsilon_t * \epsilon_t - h_t) &= 0 \end{aligned}$$

For the above example, this can be written as

```

proc model data=s;
  y = a * x + b;
  eq.two = resid.y**2 - sigma**2;
  resid.y = resid.y / sigma;
fit y two/ gmm;
instruments x;
run;

```

Note that, if the error model is misspecified in this form of the GMM model, the parameter estimates might be inconsistent.

Full Information Maximum Likelihood

For FIML estimation of variance functions, the concentrated likelihood below is used as the objective function. That is, the mean function is coupled with the variance function and the system is solved simultaneously.

$$\begin{aligned}
 l_n(\phi) = & \frac{ng}{2}(1 + \ln(2\pi)) - \sum_{t=1}^n \ln \left(\left| \frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t} \right| \right) \\
 & + \frac{1}{2} \sum_{t=1}^n \sum_{i=1}^g (\ln(h_{t,i}) + \mathbf{q}_i(\mathbf{y}_t, \mathbf{x}_t, \theta)^2 / h_{t,i})
 \end{aligned}$$

where g is the number of equations in the system.

The HESSIAN=GLS option is not available for FIML estimation that involves variance functions. The matrix used when HESSIAN=CROSS is specified is a crossproducts matrix that has been enhanced by the dual quasi-Newton approximation.

Examples

You can specify a GARCH(1,1) model as follows:

```

proc model data=modloc.usd_jpy;

      /* Mean model -----*/
  jpyret = intercept ;

      /* Variance model -----*/
  h.jpyret = arch0
            + arch1 * xlag( resid.jpyret ** 2, mse.jpyret )
            + garch1 * xlag(h.jpyret, mse.jpyret) ;

  bounds arch0 arch1 garch1 >= 0;

fit jpyret / method=marquardt fiml;
run;

```

Note that the BOUNDS statement is used to ensure that the parameters are positive, a requirement for GARCH models.

EGARCH models are used because there are no restrictions on the parameters. You can specify a EGARCH(1,1) model as follows:

```
proc model data=sasuser.usd_dem ;

    /* Mean model -----*/
    demret = intercept ;

    /* Variance model -----*/
    if ( _OBS_ =1 ) then
        h.demret = exp( earch0 + egarch1 * log(mse.demret) );
    else
        h.demret = exp( earch0 + earch1 * zlag( g )
                        + egarch1 * log(zlag(h.demret)) );
    g = - theta * nresid.demret + abs( nresid.demret ) - sqrt(2/3.1415);

fit demret / method=marquardt fiml maxiter=100 converge=1.0e-6;
run;
```

Ordinary Differential Equations

Ordinary differential equations (ODEs) are also called *initial value problems* because a time zero value for each first-order differential equation is needed. The following is an example of a first-order system of ODEs:

$$\begin{aligned} y' &= -0.1y + 2.5z^2 \\ z' &= -z \\ y_0 &= 0 \\ z_0 &= 1 \end{aligned}$$

Note that you must provide an initial value for each ODE.

As a reminder, any n -order differential equation can be modeled as a system of first-order differential equations. For example, consider the differential equations

$$\begin{aligned} y'' &= by' + cy \\ y_0 &= 0 \\ y'_0 &= 1 \end{aligned}$$

which can be written as the system of differential equations

$$\begin{aligned} y' &= z \\ z' &= by' + cy \\ y_0 &= 0 \\ z_0 &= 1 \end{aligned}$$

This differential system can be simulated as follows:

```
data t;
  time=0; output;
  time=1; output;
  time=2; output;
run;

proc model data=t ;
  dependent y z ;
  parm b -2 c -4;
  dert.y = z;
  dert.z = b * dert.y + c * y;

  solve y z / dynamic solveprint;
run;
```

The preceding statements produce the output shown in [Figure 18.44](#). These statements produce additional output, which is not shown.

Figure 18.44 continued

Solution Values	
y	z
-.0247649	-.1035929

The differential variables are distinguished by the derivative with respect to time (DERT.) prefix. Once you define the DERT. variable, you can use it on the right-hand side of another equation. The differential equations must be expressed in normal form; implicit differential equations are not allowed, and other terms on the left-hand side are not allowed.

The TIME variable is the *implied with respect to* variable for all DERT. variables. The TIME variable is also the only variable that must be in the input data set.

You can provide initial values for the differential equations in the data set, in the declaration statement (as in the previous example), or in statements in the program. Using the previous example, you can specify the initial values as

```
proc model data=t ;
  dependent y z ;
  parm b -2 c -4;

  if ( time=0 ) then
    do;
      y=0;
      z=1;
    end;
  else
    do;
      dert.y = z;
      dert.z = b * dert.y + c * y;
    end;
  end;

  solve y z / dynamic solveprint;
run;
```

If you do not provide an initial value, 0 is used.

DYNAMIC and STATIC Simulation

Note that, in the previous example, the DYNAMIC option is specified in the SOLVE statement. The DYNAMIC and STATIC options work the same for differential equations as they do for dynamic systems. In the differential equation case, the DYNAMIC option makes the initial value needed at each observation the computed value from the previous iteration. For a static simulation, the data set must contain values for the integrated variables. For example, if DERT.Y and DERT.Z are the

differential variables, you must include Y and Z in the input data set in order to do a static simulation of the model.

If the simulation is dynamic, the initial values for the differential equations are obtained from the data set, if they are available. If the variable is not in the data set, you can specify the initial value in a declaration statement. If you do not specify an initial value, the value of 0.0 is used.

A dynamic solution is obtained by solving one initial value problem for all the data. A graph of a simple dynamic simulation is shown in [Figure 18.45](#). If the time variable for the current observation is less than the time variable for the previous observation, the integration is restarted from this point. This allows for multiple samples in one data file.

Figure 18.45 Dynamic Solution

In a static solution, $n-1$ initial value problems are solved using the first $n-1$ data values as initial values. The equations are integrated using the i th data value as an initial value to the $i+1$ data value. [Figure 18.46](#) displays a static simulation of noisy data from a simple differential equation. The static solution does not propagate errors in initial values as the dynamic solution does.

Figure 18.46 Static Solution

For estimation, the DYNAMIC and STATIC options in the FIT statement perform the same functions as they do in the SOLVE statement. Components of differential systems that have missing values or are not in the data set are simulated dynamically. For example, often in multiple compartment kinetic models, only one compartment is monitored. The differential equations that describe the unmonitored compartments are simulated dynamically.

For estimation, it is important to have accurate initial values for ODEs that are not in the data set. If an accurate initial value is not known, the initial value can be made an unknown parameter and estimated. This allows for errors in the initial values but increases the number of parameters to estimate by the number of equations.

Estimation of Differential Equations

Consider the kinetic model for the accumulation of mercury (Hg) in mosquito fish (Matis, Miller, and Allen 1991, p. 177). The model for this process is the one-compartment constant infusion model shown in [Figure 18.47](#).

Figure 18.47 One-Compartment Constant Infusion Model

The differential equation that models this process is

$$\begin{aligned} \frac{dconc}{dt} &= k_u - k_e conc \\ conc_0 &= 0 \end{aligned}$$

The analytical solution to the model is

$$conc = (k_u/k_e)(1 - \exp(-k_e t))$$

The data for the model are

```
data fish;
  input day conc;
datalines;
0.0    0.0
1.0    0.15
2.0    0.2
3.0    0.26
4.0    0.32
6.0    0.33
;
```

To fit this model in differential form, use the following statements:

```
proc model data=fish;
  parm ku ke;

  dert.conc = ku - ke * conc;

  fit conc / time=day;
run;
```

The results from this estimation are shown in [Figure 18.48](#).

Figure 18.48 Static Estimation Results for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.180159	0.0312	5.78	0.0044
ke	0.524661	0.1181	4.44	0.0113

To perform a dynamic estimation of the differential equation, add the DYNAMIC option to the FIT statement.

```
proc model data=fish;
  parm ku .3 ke .3;

  dert.conc = ku - ke * conc;

  fit conc / time = day dynamic;
run;
```

The equation DERT.CONC is integrated from $conc(0) = 0$. The results from this estimation are shown in [Figure 18.49](#).

Figure 18.49 Dynamic Estimation Results for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.167109	0.0170	9.84	0.0006
ke	0.469033	0.0731	6.42	0.0030

To perform a dynamic estimation of the differential equation and estimate the initial value, use the following statements:

```
proc model data=fish;
  parm ku .3 ke .3 conc0 0;

  dert.conc = ku - ke * conc;

  fit conc initial=(conc = conc0) / time = day dynamic;
run;
```

The INITIAL= option in the FIT statement is used to associate the initial value of a differential equation with a parameter. The results from this estimation are shown in [Figure 18.50](#).

Figure 18.50 Dynamic Estimation with Initial Value for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.164408	0.0230	7.14	0.0057
ke	0.45949	0.0943	4.87	0.0165
conc0	0.003798	0.0174	0.22	0.8414

Finally, to estimate the fish model by using the analytical solution, use the following statements:

```
proc model data=fish;
  parm ku .3 ke .3;

  conc = (ku/ ke)*( 1 -exp(-ke * day));

  fit conc;
run;
```

The results from this estimation are shown in [Figure 18.51](#).

Figure 18.51 Analytical Estimation Results for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.167109	0.0170	9.84	0.0006
ke	0.469033	0.0731	6.42	0.0030

A comparison of the results among the four estimations reveals that the two dynamic estimations and the analytical estimation give nearly identical results (identical to the default precision). The two dynamic estimations are identical because the estimated initial value (0.00013071) is very close to the initial value used in the first dynamic estimation (0). Note also that the static model did not require an initial guess for the parameter values. Static estimation, in general, is more forgiving of bad initial values.

The form of the estimation that is preferred depends mostly on the model and data. If a very accurate initial value is known, then a dynamic estimation makes sense. If, additionally, the model can be written analytically, then the analytical estimation is computationally simpler. If only an approximate initial value is known and not modeled as an unknown parameter, the static estimation is less sensitive to errors in the initial value.

The form of the error in the model is also an important factor in choosing the form of the estimation.

If the error term is additive and independent of previous error, then the dynamic mode is appropriate. If, on the other hand, the errors are cumulative, a static estimation is more appropriate. See the section “[Monte Carlo Simulation](#)” on page 1120 for an example.

Auxiliary Equations

Auxiliary equations can be used with differential equations. These are equations that need to be satisfied with the differential equations at each point between each data value. They are automatically added to the system, so you do not need to specify them in the SOLVE or FIT statement.

Consider the following example.

The Michaelis-Menten equations describe the kinetics of an enzyme-catalyzed reaction. The enzyme is E, and S is called the *substrate*. The enzyme first reacts with the substrate to form the enzyme-substrate complex ES, which then breaks down in a second step to form enzyme and products P.

The reaction rates are described by the following system of differential equations:

$$\begin{aligned}\frac{d[ES]}{dt} &= k_1([E] - [ES])[S] - k_2[ES] - k_3[ES] \\ \frac{d[S]}{dt} &= -k_1([E] - [ES])[S] + k_2[ES] \\ [E] &= [E]_{tot} - [ES]\end{aligned}$$

The first equation describes the rate of formation of ES from E + S. The rate of formation of ES from E + P is very small and can be ignored. The enzyme is in either the complexed or the uncomplexed form. So if the total ($[E]_{tot}$) concentration of enzyme and the amount bound to the substrate is known, $[E]$ can be obtained by conservation.

In this example, the conservation equation is an auxiliary equation and is coupled with the differential equations for integration.

Time Variable

You must provide a time variable in the data set. The name of the time variable defaults to TIME. You can use other variables as the time variable by specifying the TIME= option in the FIT or SOLVE statement. The time intervals need not be evenly spaced. If the time variable for the current observation is less than the time variable for the previous observation, the integration is restarted.

Differential Equations and Goal Seeking

Consider the following differential equation

$$y' = a*x$$

and the data set

```

data t2;
  y=0; time=0; output;
  y=2; time=1; output;
  y=3; time=2; output;
run;

```

The problem is to find values for X that satisfy the differential equation and the data in the data set. Problems of this kind are sometimes referred to as *goal-seeking problems* because they require you to search for values of X that satisfy the goal of Y.

This problem is solved with the following statements:

```

proc model data=t2;
  independent x 0;
  dependent y;
  parm a 5;
  dert.y = a * x;
  solve x / out=goaldata;
run;

proc print data=goaldata;
run;

```

The output from the PROC PRINT statement is shown in [Figure 18.52](#).

Figure 18.52 Dynamic Solution

Obs	_TYPE_	_MODE_	_ERRORS_	x	y	time
1	PREDICT	SIMULATE	0	0.00000	0.00000	0
2	PREDICT	SIMULATE	0	0.80000	2.00000	1
3	PREDICT	SIMULATE	0	-0.40000	3.00000	2

Note that an initial value of 0 is provided for the X variable because it is undetermined at TIME = 0.

In the preceding goal-seeking example, X is treated as a linear function between each set of data points (see [Figure 18.53](#)).

Figure 18.53 Form of X Used for Integration in Goal Seeking

If you integrate $y' = ax$ manually, you have

$$\begin{aligned}
 x(t) &= \frac{t_f - t}{t_f - t_0}x_0 + \frac{t - t_0}{t_f - t_0}x_f \\
 y &= \int_{t_0}^{t_f} ax(t)dt \\
 &= a \frac{1}{t_f - t_0} (t(t_f x_0 - t_0 x_f) + \frac{1}{2}t^2(x_f - x_0)) \Big|_{t_0}^{t_f}
 \end{aligned}$$

For observation 2, this reduces to

$$\begin{aligned}
 y &= \frac{1}{2}a*x_f \\
 2 &= 2.5*x_f
 \end{aligned}$$

So $x = 0.8$ for this observation.

Goal seeking for the TIME variable is not allowed.

Restrictions and Bounds on Parameters

Using the BOUNDS and RESTRICT statements, PROC MODEL can compute optimal estimates subject to equality or inequality constraints on the parameter estimates.

Equality restrictions can be written as a vector function:

$$\mathbf{h}(\theta) = 0$$

Inequality restrictions are either active or inactive. When an inequality restriction is active, it is treated as an equality restriction. All inactive inequality restrictions can be written as a vector function:

$$F(\theta) \geq 0$$

Strict inequalities, such as $(f(\theta) > 0)$, are transformed into inequalities as $f(\theta) \times (1 - \epsilon) - \epsilon \geq 0$, where the tolerance ϵ is controlled by the EPSILON= option in the FIT statement and defaults to 10^{-8} . The i th inequality restriction becomes active if $F_i < 0$ and remains active until its Lagrange multiplier becomes negative. Lagrange multipliers are computed for all the nonredundant equality restrictions and all the active inequality restrictions.

For the following, assume the vector $\mathbf{h}(\theta)$ contains all the current active restrictions. The constraint matrix \mathbf{A} is

$$\mathbf{A}(\hat{\theta}) = \frac{\partial \mathbf{h}(\hat{\theta})}{\partial \hat{\theta}}$$

The covariance matrix for the restricted parameter estimates is computed as

$$\mathbf{Z}(\mathbf{Z}'\mathbf{H}\mathbf{Z})^{-1}\mathbf{Z}'$$

where \mathbf{H} is Hessian or approximation to the Hessian of the objective function $((\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{X})$ for OLS), and \mathbf{Z} is the last $(np - nc)$ columns of \mathbf{Q} . \mathbf{Q} is from an LQ factorization of the constraint matrix, nc is the number of active constraints, and np is the number of parameters. See Gill, Murray, and Wright (1981) for more details on LQ factorization. The covariance column in Table 18.2 summarizes the Hessian approximation used for each estimation method.

The covariance matrix for the Lagrange multipliers is computed as

$$(\mathbf{A}\mathbf{H}^{-1}\mathbf{A}')^{-1}$$

The p -value reported for a restriction is computed from a beta distribution rather than a t distribution because the numerator and the denominator of the t ratio for an estimated Lagrange multiplier are not independent.

The Lagrange multipliers for the active restrictions are printed with the parameter estimates. The Lagrange multiplier estimates are computed using the relationship

$$\mathbf{A}'\lambda = \mathbf{g}$$

where the dimensions of the constraint matrix \mathbf{A} are the number of constraints by the number of parameters, λ is the vector of Lagrange multipliers, and \mathbf{g} is the gradient of the objective function at the final estimates.

The final gradient includes the effects of the estimated \mathbf{S} matrix. For example, for OLS the final gradient would be:

$$\mathbf{g} = \mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{r}$$

where \mathbf{r} is the residual vector. Note that when nonlinear restrictions are imposed, the convergence measure R might have values greater than one for some iterations.

Tests on Parameters

In general, the hypothesis tested can be written as

$$H_0 : \mathbf{h}(\theta) = 0$$

where $\mathbf{h}(\theta)$ is a vector-valued function of the parameters θ given by the r expressions specified on the TEST statement.

Let $\hat{\mathbf{V}}$ be the estimate of the covariance matrix of $\hat{\theta}$. Let $\hat{\theta}$ be the unconstrained estimate of θ and $\tilde{\theta}$ be the constrained estimate of θ such that $h(\tilde{\theta}) = 0$. Let

$$\mathbf{A}(\theta) = \partial h(\theta) / \partial \theta \big|_{\hat{\theta}}$$

Let r be the dimension of $h(\theta)$ and n be the number of observations. Using this notation, the test statistics for the three kinds of tests are computed as follows.

The Wald test statistic is defined as

$$W = h'(\hat{\theta}) \left(\mathbf{A}(\hat{\theta}) \hat{\mathbf{V}} \mathbf{A}'(\hat{\theta}) \right)^{-1} h(\hat{\theta})$$

The Wald test is not invariant to reparameterization of the model (Gregory and Veall 1985; Gallant 1987, p. 219). For more information about the theoretical properties of the Wald test, see Phillips and Park (1988).

The Lagrange multiplier test statistic is

$$R = \lambda' \mathbf{A}(\tilde{\theta}) \tilde{\mathbf{V}} \mathbf{A}'(\tilde{\theta}) \lambda$$

where λ is the vector of Lagrange multipliers from the computation of the restricted estimate $\tilde{\theta}$.

The Lagrange multiplier test statistic is equivalent to Rao's efficient score test statistic:

$$R = (\partial L(\tilde{\theta}) / \partial \theta)' \tilde{\mathbf{V}} (\partial L(\tilde{\theta}) / \partial \theta)$$

where L is the log-likelihood function for the estimation method used. For SUR, 3SLS, GMM, and iterated versions of these methods, the likelihood function is computed as

$$L = \text{Objective} \times \text{Nobs} / 2$$

For OLS and 2SLS, the Lagrange multiplier test statistic is computed as:

$$R = [(\partial \hat{S}(\tilde{\theta}) / \partial \theta)' \tilde{\mathbf{V}} (\partial \hat{S}(\tilde{\theta}) / \partial \theta)] / \hat{S}(\tilde{\theta})$$

where $\hat{S}(\tilde{\theta})$ is the corresponding objective function value at the constrained estimate.

The likelihood ratio test statistic is

$$T = 2 \left(L(\hat{\theta}) - L(\tilde{\theta}) \right)$$

where $\tilde{\theta}$ represents the constrained estimate of θ and L is the concentrated log-likelihood value.

For OLS and 2SLS, the likelihood ratio test statistic is computed as:

$$T = (n - nparms) \times (\hat{S}(\tilde{\theta}) - \hat{S}(\hat{\theta})) / \hat{S}(\hat{\theta})$$

This test statistic is an approximation from

$$T = n \times \log \left(1 + \frac{rF}{n - nparms} \right)$$

when the value of $rF/(n - nparms)$ is small (Greene 2004, p. 421).

The likelihood ratio test is not appropriate for models with nonstationary serially correlated errors (Gallant 1987, p. 139). The likelihood ratio test should not be used for dynamic systems, for systems with lagged dependent variables, or with the FIML estimation method unless certain conditions are met (see Gallant 1987, p. 479).

For each kind of test, under the null hypothesis the test statistic is asymptotically distributed as a χ^2 random variable with r degrees of freedom, where r is the number of expressions in the TEST statement. The p -values reported for the tests are computed from the $\chi^2(r)$ distribution and are only asymptotically valid. When both RESTRICT and TEST statements are used in a PROC MODEL step, test statistics are computed by taking into account the constraints imposed by the RESTRICT statement.

Monte Carlo simulations suggest that the asymptotic distribution of the Wald test is a poorer approximation to its small sample distribution than the other two tests. However, the Wald test has the least computational cost, since it does not require computation of the constrained estimate $\tilde{\theta}$.

The following is an example of using the TEST statement to perform a likelihood ratio test for a compound hypothesis.

```
test a*exp(-k) = 1-k, d = 0 ,/ 1r;
```

It is important to keep in mind that although individual t tests for each parameter are printed by default into the parameter estimates table, they are only asymptotically valid for nonlinear models. You should be cautious in drawing any inferences from these t tests for small samples.

Hausman Specification Test

Hausman's specification test, or m -statistic, can be used to test hypotheses in terms of bias or inconsistency of an estimator. This test was also proposed by Wu (1973). Hausman's m -statistic is as follows.

Given two estimators, $\hat{\beta}_0$ and $\hat{\beta}_1$, where under the null hypothesis both estimators are consistent but only $\hat{\beta}_0$ is asymptotically efficient and under the alternative hypothesis only $\hat{\beta}_1$ is consistent, the m -statistic is

$$m = \hat{q}'(\hat{V}_1 - \hat{V}_0)^{-1}\hat{q}$$

where $\hat{\mathbf{V}}_1$ and $\hat{\mathbf{V}}_0$ represent consistent estimates of the asymptotic covariance matrices of $\hat{\beta}_1$ and $\hat{\beta}_0$ respectively, and

$$q = \hat{\beta}_1 - \hat{\beta}_0$$

The m -statistic is then distributed χ^2 with k degrees of freedom, where k is the rank of the matrix $(\hat{\mathbf{V}}_1 - \hat{\mathbf{V}}_0)$. A generalized inverse is used, as recommended by Hausman and Taylor (1982).

In the MODEL procedure, Hausman's m -statistic can be used to determine if it is necessary to use an instrumental variables method rather than a more efficient OLS estimation. Hausman's m -statistic can also be used to compare 2SLS with 3SLS for a class of estimators for which 3SLS is asymptotically efficient (similarly for OLS and SUR).

Hausman's m -statistic can also be used, in principle, to test the null hypothesis of normality when comparing 3SLS to FIML. Because of the poor performance of this form of the test, it is not offered in the MODEL procedure. See Fair (1984, pp. 246–247) for a discussion of why Hausman's test fails for common econometric models.

To perform a Hausman's specification test, specify the HAUSMAN option in the FIT statement. The selected estimation methods are compared using Hausman's m -statistic.

In the following example, Hausman's test is used to check the presence of measurement error. Under H_0 of no measurement error, OLS is efficient, while under H_1 , 2SLS is consistent. In the following code, OLS and 2SLS are used to estimate the model, and Hausman's test is requested.

```
proc model data=one out=fiml2;
  endogenous y1 y2;

  y1 = py2 * y2 + px1 * x1 + interc;
  y2 = py1* y1 + pz1 * z1 + d2;

  fit y1 y2 / ols 2sls hausman;
  instruments x1 z1;
run;
```

The output specified by the HAUSMAN option produces the results shown in [Figure 18.54](#).

Figure 18.54 Hausman's Specification Test Results

The MODEL Procedure				
Hausman's Specification Test Results				
Efficient under H0	Consistent under H1	DF	Statistic	Pr > ChiSq
OLS	2SLS	6	13.86	0.0313

[Figure 18.54](#) indicates that 2SLS is preferred over OLS at 5% level of significance. In this case, the null hypothesis of no measurement error is rejected. Hence, the instrumental variable estimator is required for this example due to the presence of measurement error.

Chow Tests

The Chow test is used to test for break points or structural changes in a model. The problem is posed as a partitioning of the data into two parts of size n_1 and n_2 . The null hypothesis to be tested is

$$H_0 : \beta_1 = \beta_2 = \beta$$

where β_1 is estimated by using the first part of the data and β_2 is estimated by using the second part.

The test is performed as follows (see Davidson and MacKinnon 1993, p. 380).

1. The p parameters of the model are estimated.
2. A second linear regression is performed on the residuals, \hat{u} , from the nonlinear estimation in step one.

$$\hat{u} = \hat{\mathbf{X}}b + \text{residuals}$$

where $\hat{\mathbf{X}}$ is Jacobian columns that are evaluated at the parameter estimates. If the estimation is an instrumental variables estimation with matrix of instruments \mathbf{W} , then the following regression is performed:

$$\hat{u} = \mathbf{P}_{\mathbf{W}^*} \hat{\mathbf{X}}b + \text{residuals}$$

where $\mathbf{P}_{\mathbf{W}^*}$ is the projection matrix.

3. The restricted SSE (RSSE) from this regression is obtained. An SSE for each subsample is then obtained by using the same linear regression.
4. The F statistic is then

$$f = \frac{(RSSE - SSE_1 - SSE_2)/p}{(SSE_1 + SSE_2)/(n - 2p)}$$

This test has p and $n - 2p$ degrees of freedom.

Chow's test is not applicable if $\min(n_1, n_2) < p$, since one of the two subsamples does not contain enough data to estimate β . In this instance, the *predictive Chow test* can be used. The predictive Chow test is defined as

$$f = \frac{(RSSE - SSE_1) \times (n_1 - p)}{SSE_1 * n_2}$$

where $n_1 > p$. This test can be derived from the Chow test by noting that the $SSE_2 = 0$ when $n_2 \leq p$ and by adjusting the degrees of freedom appropriately.

You can select the Chow test and the predictive Chow test by specifying the `CHOW=arg` and the `PCHOW=arg` options in the FIT statement, where `arg` is either the number of observations in the first sample or a parenthesized list of first sample sizes. If the size of the one of the two groups in which the sample is partitioned is less than the number of parameters, then a predictive Chow test is automatically used. These tests statistics are not produced for GMM and FIML estimations.

The following is an example of the use of the Chow test.

```

data exp;
  x=0;
  do time=1 to 100;
    if time=50 then x=1;
    y = 35 * exp( 0.01 * time ) + rannor( 123 ) + x * 5;
    output;
  end;
run;

proc model data=exp;
  parm zo 35 b;
  dert.z = b * z;
  y=z;
  fit y init=(z=zo) / chow =(40 50 60) pchow=90;
run;

```

The data set introduces an artificial structural change into the model (the structural change effects the intercept parameter). The output from the requested Chow tests are shown in [Figure 18.55](#).

Figure 18.55 Chow's Test Results

The MODEL Procedure					
Structural Change Test

Chow	40	2	96	12.95	<.0001
Chow	50	2	96	101.37	<.0001
Chow	60	2	96	26.43	<.0001
Predictive Chow	90	11	87	1.86	0.0566

Profile Likelihood Confidence Intervals

Wald-based and likelihood-ratio-based confidence intervals are available in the MODEL procedure for computing a confidence interval on an estimated parameter. A confidence interval on a parameter θ can be constructed by inverting a Wald-based or a likelihood-ratio-based test.

The approximate $100(1 - \alpha)\%$ Wald confidence interval for a parameter θ is

$$\hat{\theta} \pm z_{1-\alpha/2} \hat{\sigma}$$

where z_p is the $100p$ th percentile of the standard normal distribution, $\hat{\theta}$ is the maximum likelihood estimate of θ , and $\hat{\sigma}$ is the standard error estimate of $\hat{\theta}$.

A likelihood-ratio-based confidence interval is derived from the χ^2 distribution of the generalized likelihood ratio test. The approximate $1 - \alpha$ confidence interval for a parameter θ is

$$\theta : 2[l(\hat{\theta}) - l(\theta)] \leq q_{1,1-\alpha} = 2l^*$$

where $q_{1,1-\alpha}$ is the $(1 - \alpha)$ quantile of the χ^2 with one degree of freedom, and $l(\theta)$ is the log likelihood as a function of one parameter. The endpoints of a confidence interval are the zeros of the function $l(\theta) - l^*$. Computing a likelihood-ratio-based confidence interval is an iterative process. This process must be performed twice for each parameter, so the computational cost is considerable. Using a modified form of the algorithm recommended by Venzon and Moolgavkar (1988), you can determine that the cost of each endpoint computation is approximately the cost of estimating the original system.

To request confidence intervals on estimated parameters, specify the PRL= option in the FIT statement. By default, the PRL option produces 95% likelihood ratio confidence limits. The coverage of the confidence interval is controlled by the ALPHA= option in the FIT statement.

The following is an example of the use of the confidence interval options.

```
data exp;
  do time = 1 to 20;
    y = 35 * exp( 0.01 * time ) + 5*rannor( 123 );
  output;
  end;
run;

proc model data=exp;
  parm zo 35 b;
  dert.z = b * z;
  y=z;
  fit y init=(z=zo) / prl=both;
  test zo = 40.475437 , / lr;
run;
```

The output from the requested confidence intervals and the TEST statement are shown in Figure 18.56

Figure 18.56 Confidence Interval Estimation

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
zo	36.58933	1.9471	18.79	<.0001
b	0.006497	0.00464	1.40	0.1780
Test Results				
Test	Type	Statistic	Pr > ChiSq	Label
Test0	L.R.	3.81	0.0509	zo = 40.475437

Figure 18.56 continued

Parameter Wald			
95% Confidence Intervals			
Parameter	Value	Lower	Upper
zo	36.5893	32.7730	40.4056
b	0.00650	-0.00259	0.0156
Parameter Likelihood Ratio			
95% Confidence Intervals			
Parameter	Value	Lower	Upper
zo	36.5893	32.8381	40.4921
b	0.00650	-0.00264	0.0157

Note that the likelihood ratio test reported the probability that $z_o = 40.47543$ is 5% but $z_o = 40.47543$ is the upper bound of a 95% confidence interval. To understand this conundrum, note that the TEST statement is using the likelihood ratio statistic to test the null hypothesis $H_0 : z_o = 40.47543$ with the alternate that $H_a : z_o \neq 40.47543$. The upper confidence interval can be viewed as a test with the null hypothesis $H_0 : z_o \leq 40.47543$.

Choice of Instruments

Several of the estimation methods supported by PROC MODEL are instrumental variables methods. There is no standard method for choosing instruments for nonlinear regression. Few econometric textbooks discuss the selection of instruments for nonlinear models. See Bowden and Turkington (1984, pp. 180–182) for more information.

The purpose of the instrumental projection is to purge the regressors of their correlation with the residual. For nonlinear systems, the regressors are the partials of the residuals with respect to the parameters.

Possible instrumental variables include the following:

- any variable in the model that is independent of the errors
- lags of variables in the system
- derivatives with respect to the parameters, if the derivatives are independent of the errors
- low-degree polynomials in the exogenous variables
- variables from the data set or functions of variables from the data set

Selected instruments must not have any of the following characteristics:

- depend on any variable endogenous with respect to the equations estimated

- depend on any of the parameters estimated
- be lags of endogenous variables if there is serial correlation of the errors

If the preceding rules are satisfied and there are enough observations to support the number of instruments used, the results should be consistent and the efficiency loss held to a minimum.

You need at least as many instruments as the maximum number of parameters in any equation, or some of the parameters cannot be estimated. Note that *number of instruments* means linearly independent instruments. If you add an instrument that is a linear combination of other instruments, it has no effect and does not increase the effective number of instruments.

You can, however, use too many instruments. In order to get the benefit of instrumental variables, you must have more observations than instruments. Thus, there is a trade-off; the instrumental variables technique completely eliminates the simultaneous equation bias only in large samples. In finite samples, the larger the excess of observations over instruments, the more the bias is reduced. Adding more instruments might improve the efficiency, but after some point efficiency declines as the excess of observations over instruments becomes smaller and the bias grows.

The instruments used in an estimation are printed out at the beginning of the estimation. For example, the following statements produce the instruments list shown in [Figure 18.57](#).

```
proc model data=test2;
  exogenous x1 x2;
  parms b1 a1 a2 b2 2.5 c2 55;
  y1 = a1 * y2 + b1 * exp(x1);
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2;
  fit y1 y2 / n2s1s;
  inst b1 b2 c2 x1 ;
run;
```

Figure 18.57 Instruments Used Message

```

                                The MODEL Procedure

                                The 2 Equations to Estimate

                                y1 = F(b1, a1(y2))
                                y2 = F(a2(y1), b2, c2)
                                Instruments 1 x1 @y1/@b1 @y2/@b2 @y2/@c2
```

This states that an intercept term, the exogenous variable X1, and the partial derivatives of the equations with respect to B1, B2, and C2, were used as instruments for the estimation.

Examples

Suppose that Y1 and Y2 are endogenous variables, that X1 and X2 are exogenous variables, and that A, B, C, D, E, F, and G are parameters. Consider the following model:

```

y1 = a + b * x1 + c * y2 + d * lag(y1);
y2 = e + f * x2 + g * y1;
fit y1 y2;
instruments exclude=(c g);

```

The INSTRUMENTS statement produces X1, X2, LAG(Y1), and an intercept as instruments.

In order to estimate the Y1 equation by itself, it is necessary to include X2 explicitly in the instruments since F, in this case, is not included in the following estimation:

```

y1 = a + b * x1 + c * y2 + d * lag(y1);
y2 = e + f * x2 + g * y1;
fit y1;
instruments x2 exclude=(c);

```

This produces the same instruments as before. You can list the parameter associated with the lagged variable as an instrument instead of using the EXCLUDE= option. Thus, the following is equivalent to the previous example:

```

y1 = a + b * x1 + c * y2 + d * lag(y1);
y2 = e + f * x2 + g * y1;
fit y1;
instruments x1 x2 d;

```

For an example of declaring instruments when estimating a model involving identities, consider Klein's Model I:

```

proc model data=klien;
  endogenous c p w i x wsum k y;
  exogenous wp g t year;
  parms c0-c3 i0-i3 w0-w3;
  a: c = c0 + c1 * p + c2 * lag(p) + c3 * wsum;
  b: i = i0 + i1 * p + i2 * lag(p) + i3 * lag(k);
  c: w = w0 + w1 * x + w2 * lag(x) + w3 * year;
  x = c + i + g;
  y = c + i + g-t;
  p = x-w-t;
  k = lag(k) + i;
  wsum = w + wp;
run;

```

The three equations to estimate are identified by the labels A, B, and C. The parameters associated with the predetermined terms are C2, I2, I3, W2, and W3 (and the intercepts, which are automatically added to the instruments). In addition, the system includes five identities that contain the predetermined variables G, T, LAG(K), and WP. Thus, the INSTRUMENTS statement can be written as

```

lagk = lag(k);
instruments c2 i2 i3 w2 w3 g t wp lagk;

```

where LAGK is a program variable used to hold LAG(K). However, this is more complicated than it needs to be. Except for LAG(K), all the predetermined terms in the identities are exogenous variables, and LAG(K) is already included as the coefficient of I3. There are also more parameters for predetermined terms than for endogenous terms, so you might prefer to use the EXCLUDE= option. Thus, you can specify the same instruments list with the simpler statement

```
instruments _exog_ exclude=(c1 c3 i1 w1);
```

To illustrate the use of polynomial terms as instrumental variables, consider the following model:

$$y_1 = a + b * \exp(c * x_1) + d * \log(x_2) + e * \exp(f * y_2);$$

The parameters are A, B, C, D, E, and F, and the right-hand-side variables are X1, X2, and Y2. Assume that X1 and X2 are exogenous (independent of the error), while Y2 is endogenous. The equation for Y2 is not specified, but assume that it includes the variables X1, X3, and Y1, with X3 exogenous, so the exogenous variables of the full system are X1, X2, and X3. Using as instruments quadratic terms in the exogenous variables, the model is specified to PROC MODEL as follows:

```
proc model;
  parms a b c d e f;
  y1 = a + b * exp(c * x1) + d * log(x2) + e * exp(f * y2);
  instruments inst1-inst9;
  inst1 = x1; inst2 = x2; inst3 = x3;
  inst4 = x1 * x1; inst5 = x1 * x2; inst6 = x1 * x3;
  inst7 = x2 * x2; inst8 = x2 * x3; inst9 = x3 * x3;
  fit y1 / 2s1s;
run;
```

It is not clear what degree polynomial should be used. There is no way to know how good the approximation is for any degree chosen, although the first-stage R^2 s might help the assessment.

First-Stage R-Squares

When the FSRSQ option is used on the FIT statement, the MODEL procedure prints a column of first-stage R^2 (FSRSQ) statistics along with the parameter estimates. The FSRSQ measures the fraction of the variation of the derivative column associated with the parameter that remains after projection through the instruments.

Ideally, the FSRSQ should be very close to 1.00 for exogenous derivatives. If the FSRSQ is small for an endogenous derivative, it is unclear whether this reflects a poor choice of instruments or a large influence of the errors in the endogenous right-hand-side variables. When the FSRSQ for one or more parameters is small, the standard errors of the parameter estimates are likely to be large.

Note that you can make all the FSRSQs larger (or 1.00) by including more instruments, because of the disadvantage discussed previously. The FSRSQ statistics reported are unadjusted R^2 s and do not include a degrees-of-freedom correction.

Autoregressive Moving-Average Error Processes

Autoregressive moving-average error processes (ARMA errors) and other models that involve lags of error terms can be estimated by using FIT statements and simulated or forecast by using SOLVE statements. ARMA models for the error process are often used for models with autocorrelated residuals. The %AR macro can be used to specify models with autoregressive error processes. The %MA macro can be used to specify models with moving-average error processes.

Autoregressive Errors

A model with first-order autoregressive errors, AR(1), has the form

$$y_t = f(x_t, \theta) + \mu_t$$

$$\mu_t = \phi\mu_{t-1} + \epsilon_t$$

while an AR(2) error process has the form

$$\mu_t = \phi_1\mu_{t-1} + \phi_2\mu_{t-2} + \epsilon_t$$

and so forth for higher-order processes. Note that the ϵ_t 's are independent and identically distributed and have an expected value of 0.

An example of a model with an AR(2) component is

$$y = \alpha + \beta x_1 + \mu_t$$

$$\mu_t = \phi_1\mu_{t-1} + \phi_2\mu_{t-2} + \epsilon_t$$

You would write this model as

```
proc model data=in;
  parms a b p1 p2;
  y = a + b * x1 + p1 * zlag1(y - (a + b * x1)) +
      p2 * zlag2(y - (a + b * x1));
  fit y;
run;
```

or equivalently using the %AR macro as

```
proc model data=in;
  parms a b;
  y = a + b * x1;
  %ar( y, 2 );
  fit y;
run;
```

Moving-Average Models

A model with first-order moving-average errors, MA(1), has the form

$$y_t = f(x_t) + \mu_t$$

$$\mu_t = \epsilon_t - \theta_1 \epsilon_{t-1}$$

where ϵ_t is identically and independently distributed with mean zero. An MA(2) error process has the form

$$\mu_t = \epsilon_t - \theta_1 \epsilon_{t-1} - \theta_2 \epsilon_{t-2}$$

and so forth for higher-order processes.

For example, you can write a simple linear regression model with MA(2) moving-average errors as

```
proc model data=inma2;
  parms a b ma1 ma2;
  y = a + b * x + ma1 * zlag1( resid.y ) +
      ma2 * zlag2( resid.y );
  fit;
run;
```

where MA1 and MA2 are the moving-average parameters.

Note that RESID.Y is automatically defined by PROC MODEL as

```
pred.y = a + b * x + ma1 * zlag1( resid.y ) +
      ma2 * zlag2( resid.y );
resid.y = pred.y - actual.y;
```

Note that RESID.Y is negative of ϵ_t .

The ZLAG function must be used for MA models to truncate the recursion of the lags. This ensures that the lagged errors start at zero in the lag-priming phase and do not propagate missing values when lag-priming period variables are missing, and it ensures that the future errors are zero rather than missing during simulation or forecasting. For details about the lag functions, see the section “[Lag Logic](#)” on page 1161.

This model written using the %MA macro is as follows:

```
proc model data=inma2;
  parms a b;
  y = a + b * x;
  %ma(y, 2);
  fit;
run;
```

General Form for ARMA Models

The general ARMA(p,q) process has the following form

$$\mu_t = \phi_1\mu_{t-1} + \dots + \phi_p\mu_{t-p} + \epsilon_t - \theta_1\epsilon_{t-1} - \dots - \theta_q\epsilon_{t-q}$$

An ARMA(p,q) model can be specified as follows:

```
yhat = ... compute structural predicted value here ... ;
yarma = ar1 * zlag1( y - yhat ) + ... /* ar part */
        + ar(p) * zlag(p)( y - yhat )
        + ma1 * zlag1( resid.y ) + ... /* ma part */
        + ma(q) * zlag(q)( resid.y );
y = yhat + yarma;
```

where AR i and MA j represent the autoregressive and moving-average parameters for the various lags. You can use any names you want for these variables, and there are many equivalent ways that the specification could be written.

Vector ARMA processes can also be estimated with PROC MODEL. For example, a two-variable AR(1) process for the errors of the two endogenous variables Y1 and Y2 can be specified as follows:

```
y1hat = ... compute structural predicted value here ... ;

y1      = y1hat + ar1_1 * zlag1( y1 - y1hat ) /* ar part y1,y1 */
          + ar1_2 * zlag1( y2 - y2hat ); /* ar part y1,y2 */

y21hat = ... compute structural predicted value here ... ;

y2      = y2hat + ar2_2 * zlag1( y2 - y2hat ) /* ar part y2,y2 */
          + ar2_1 * zlag1( y1 - y1hat ); /* ar part y2,y1 */
```

Convergence Problems with ARMA Models

ARMA models can be difficult to estimate. If the parameter estimates are not within the appropriate range, a moving-average model's residual terms grow exponentially. The calculated residuals for later observations can be very large or can overflow. This can happen either because improper starting values were used or because the iterations moved away from reasonable values.

Care should be used in choosing starting values for ARMA parameters. Starting values of 0.001 for ARMA parameters usually work if the model fits the data well and the problem is well-conditioned. Note that an MA model can often be approximated by a high-order AR model, and vice versa. This can result in high collinearity in mixed ARMA models, which in turn can cause serious ill-conditioning in the calculations and instability of the parameter estimates.

If you have convergence problems while estimating a model with ARMA error processes, try to estimate in steps. First, use a FIT statement to estimate only the structural parameters with the ARMA parameters held to zero (or to reasonable prior estimates if available). Next, use another FIT

statement to estimate the ARMA parameters only, using the structural parameter values from the first run. Since the values of the structural parameters are likely to be close to their final estimates, the ARMA parameter estimates might now converge. Finally, use another FIT statement to produce simultaneous estimates of all the parameters. Since the initial values of the parameters are now likely to be quite close to their final joint estimates, the estimates should converge quickly if the model is appropriate for the data.

AR Initial Conditions

The initial lags of the error terms of AR(p) models can be modeled in different ways. The autoregressive error startup methods supported by SAS/ETS procedures are the following:

CLS	conditional least squares (ARIMA and MODEL procedures)
ULS	unconditional least squares (AUTOREG, ARIMA, and MODEL procedures)
ML	maximum likelihood (AUTOREG, ARIMA, and MODEL procedures)
YW	Yule-Walker (AUTOREG procedure only)
HL	Hildreth-Lu, which deletes the first p observations (MODEL procedure only)

See Chapter 8, “[The AUTOREG Procedure](#),” for an explanation and discussion of the merits of various AR(p) startup methods.

The CLS, ULS, ML, and HL initializations can be performed by PROC MODEL. For AR(1) errors, these initializations can be produced as shown in [Table 18.3](#). These methods are equivalent in large samples.

Table 18.3 Initializations Performed by PROC MODEL: AR(1) ERRORS

Method	Formula
conditional least squares	$Y = \text{YHAT} + \text{AR1} * \text{ZLAG1}(Y - \text{YHAT});$
unconditional least squares	$Y = \text{YHAT} + \text{AR1} * \text{ZLAG1}(Y - \text{YHAT});$ IF _OBS_=1 THEN $\text{RESID.Y} = \text{SQRT}(1 - \text{AR1}^{**2}) * \text{RESID.Y};$
maximum likelihood	$Y = \text{YHAT} + \text{AR1} * \text{ZLAG1}(Y - \text{YHAT});$ $W = (1 - \text{AR1}^{**2})^{**(-1/(2 * _NUSED_))};$ IF _OBS_=1 THEN $W = W * \text{SQRT}(1 - \text{AR1}^{**2});$ $\text{RESID.Y} = W * \text{RESID.Y};$
Hildreth-Lu	$Y = \text{YHAT} + \text{AR1} * \text{LAG1}(Y - \text{YHAT});$

MA Initial Conditions

The initial lags of the error terms of MA(q) models can also be modeled in different ways. The following moving-average error start-up paradigms are supported by the ARIMA and MODEL procedures:

ULS	unconditional least squares
CLS	conditional least squares
ML	maximum likelihood

The conditional least squares method of estimating moving-average error terms is not optimal because it ignores the start-up problem. This reduces the efficiency of the estimates, although they remain unbiased. The initial lagged residuals, extending before the start of the data, are assumed to be 0, their unconditional expected value. This introduces a difference between these residuals and the generalized least squares residuals for the moving-average covariance, which, unlike the autoregressive model, persists through the data set. Usually this difference converges quickly to 0, but for nearly noninvertible moving-average processes the convergence is quite slow. To minimize this problem, you should have plenty of data, and the moving-average parameter estimates should be well within the invertible range.

This problem can be corrected at the expense of writing a more complex program. Unconditional least squares estimates for the MA(1) process can be produced by specifying the model as follows:

```

yhat = ... compute structural predicted value here ... ;
if _obs_ = 1 then do;
  h = sqrt( 1 + ma1 ** 2 );
  y = yhat;
  resid.y = ( y - yhat ) / h;
end;
else do;
  g = ma1 / zlag1( h );
  h = sqrt( 1 + ma1 ** 2 - g ** 2 );
  y = yhat + g * zlag1( resid.y );
  resid.y = ( ( y - yhat ) - g * zlag1( resid.y ) ) / h;
end;

```

Moving-average errors can be difficult to estimate. You should consider using an AR(p) approximation to the moving-average process. A moving-average process can usually be well-approximated by an autoregressive process if the data have not been smoothed or differenced.

The %AR Macro

The SAS macro %AR generates programming statements for PROC MODEL for autoregressive models. The %AR macro is part of SAS/ETS software, and no special options need to be set to use the macro. The autoregressive process can be applied to the structural equation errors or to the endogenous series themselves.

The %AR macro can be used for the following types of autoregression:

- univariate autoregression
- unrestricted vector autoregression
- restricted vector autoregression

Univariate Autoregression

To model the error term of an equation as an autoregressive process, use the following statement after the equation:

```
%ar( varname, nlags )
```

For example, suppose that Y is a linear function of X1, X2, and an AR(2) error. You would write this model as follows:

```
proc model data=in;
  parms a b c;
  y = a + b * x1 + c * x2;
  %ar( y, 2 )
  fit y / list;
run;
```

The calls to %AR must come *after* all of the equations that the process applies to.

The preceding macro invocation, %AR(y,2), produces the statements shown in the LIST output in Figure 18.58.

Figure 18.58 LIST Option Output for an AR(2) Model

The MODEL Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	1940:4	PRED.y = a + b * x1 + c * x2;
1	1940:4	RESID.y = PRED.y - ACTUAL.y;
1	1940:4	ERROR.y = PRED.y - y;
2	1941:14	_PRED__y = PRED.y;
3	1941:15	_OLD_PRED.y = PRED.y + y_l1
		* ZLAG1(y - _PRED__y) + y_l2
		* ZLAG2(y - _PRED__y);
3	1941:15	PRED.y = _OLD_PRED.y;
3	1941:15	RESID.y = PRED.y - ACTUAL.y;
3	1941:15	ERROR.y = PRED.y - y;

The _PRED__ prefixed variables are temporary program variables used so that the lags of the residuals are the correct residuals and not the ones redefined by this equation. Note that this is equivalent to the statements explicitly written in the section “[General Form for ARMA Models](#)” on page 1090.

You can also restrict the autoregressive parameters to zero at selected lags. For example, if you wanted autoregressive parameters at lags 1, 12, and 13, you can use the following statements:

```
proc model data=in;
  parms a b c;
  y = a + b * x1 + c * x2;
  %ar( y, 13, , 1 12 13 )
  fit y / list;
run;
```

These statements generate the output shown in [Figure 18.59](#).

Figure 18.59 LIST Option Output for an AR Model with Lags at 1, 12, and 13

The MODEL Procedure		
Listing of Compiled Program Code		
Stmnt	Line:Col	Statement as Parsed
1	1949:4	PRED.y = a + b * x1 + c * x2;
1	1949:4	RESID.y = PRED.y - ACTUAL.y;
1	1949:4	ERROR.y = PRED.y - y;
2	1950:14	_PRED_y = PRED.y;
3	1950:15	_OLD_PRED.y = PRED.y + y_l1 * ZLAG1(y - _PRED_y) + y_l12 * ZLAG12(y - _PRED_y) + y_l13 * ZLAG13(y - _PRED_y);
3	1950:15	PRED.y = _OLD_PRED.y;
3	1950:15	RESID.y = PRED.y - ACTUAL.y;
3	1950:15	ERROR.y = PRED.y - y;

There are variations on the conditional least squares method, depending on whether observations at the start of the series are used to “warm up” the AR process. By default, the %AR conditional least squares method uses all the observations and assumes zeros for the initial lags of autoregressive terms. By using the M= option, you can request that %AR use the unconditional least squares (ULS) or maximum-likelihood (ML) method instead. For example,

```
proc model data=in;
  y = a + b * x1 + c * x2;
  %ar( y, 2, m=uls )
  fit y;
run;
```

Discussions of these methods is provided in the section “[AR Initial Conditions](#)” on page 1091.

By using the M=CLS*n* option, you can request that the first *n* observations be used to compute estimates of the initial autoregressive lags. In this case, the analysis starts with observation *n* + 1. For example:

```
proc model data=in;
  y = a + b * x1 + c * x2;
  %ar( y, 2, m=cls2 )
```

```
fit y;
run;
```

You can use the %AR macro to apply an autoregressive model to the endogenous variable, instead of to the error term, by using the TYPE=V option. For example, if you want to add the five past lags of Y to the equation in the previous example, you could use %AR to generate the parameters and lags by using the following statements:

```
proc model data=in;
  parms a b c;
  y = a + b * x1 + c * x2;
  %ar( y, 5, type=v )
  fit y / list;
run;
```

The preceding statements generate the output shown in [Figure 18.60](#).

Figure 18.60 LIST Option Output for an AR model of Y

The MODEL Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	1972:4	PRED.y = a + b * x1 + c * x2;
1	1972:4	RESID.y = PRED.y - ACTUAL.y;
1	1972:4	ERROR.y = PRED.y - y;
2	1973:15	_OLD_PRED.y = PRED.y + y_11 * ZLAG1(y) + y_12 * ZLAG2(y) + y_13 * ZLAG3(y) + y_14 * ZLAG4(y) + y_15 * ZLAG5(y);
2	1973:15	PRED.y = _OLD_PRED.y;
2	1973:15	RESID.y = PRED.y - ACTUAL.y;
2	1973:15	ERROR.y = PRED.y - y;

This model predicts Y as a linear combination of X1, X2, an intercept, and the values of Y in the most recent five periods.

Unrestricted Vector Autoregression

To model the error terms of a set of equations as a vector autoregressive process, use the following form of the %AR macro after the equations:

```
%ar( process_name, nlags, variable_list )
```

The *process_name* value is any name that you supply for %AR to use in making names for the autoregressive parameters. You can use the %AR macro to model several different AR processes for different sets of equations by using different process names for each set. The process name ensures that the variable names used are unique. Use a short *process_name* value for the process if parameter estimates are to be written to an output data set. The %AR macro tries to construct parameter names

less than or equal to eight characters, but this is limited by the length of *process_name*, which is used as a prefix for the AR parameter names.

The *variable_list* value is the list of endogenous variables for the equations.

For example, suppose that errors for equations Y1, Y2, and Y3 are generated by a second-order vector autoregressive process. You can use the following statements:

```
proc model data=in;
  y1 = ... equation for y1 ...;
  y2 = ... equation for y2 ...;
  y3 = ... equation for y3 ...;
  %ar( name, 2, y1 y2 y3 )
  fit y1 y2 y3;
run;
```

which generate the following for Y1 and similar code for Y2 and Y3:

```
y1 = pred.y1 + name1_1_1*zlag1(y1-name_y1) +
      name1_1_2*zlag1(y2-name_y2) +
      name1_1_3*zlag1(y3-name_y3) +
      name2_1_1*zlag2(y1-name_y1) +
      name2_1_2*zlag2(y2-name_y2) +
      name2_1_3*zlag2(y3-name_y3) ;
```

Only the conditional least squares (M=CLS or M=CLSn) method can be used for vector processes.

You can also use the same form with restrictions that the coefficient matrix be 0 at selected lags. For example, the following statements apply a third-order vector process to the equation errors with all the coefficients at lag 2 restricted to 0 and with the coefficients at lags 1 and 3 unrestricted:

```
proc model data=in;
  y1 = ... equation for y1 ...;
  y2 = ... equation for y2 ...;
  y3 = ... equation for y3 ...;
  %ar( name, 3, y1 y2 y3, 1 3 )
  fit y1 y2 y3;
```

You can model the three series Y1–Y3 as a vector autoregressive process in the variables instead of in the errors by using the TYPE=V option. If you want to model Y1–Y3 as a function of past values of Y1–Y3 and some exogenous variables or constants, you can use %AR to generate the statements for the lag terms. Write an equation for each variable for the nonautoregressive part of the model, and then call %AR with the TYPE=V option. For example,

```
proc model data=in;
  parms a1-a3 b1-b3;
  y1 = a1 + b1 * x;
  y2 = a2 + b2 * x;
  y3 = a3 + b3 * x;
```

```

%ar( name, 2, y1 y2 y3, type=v )
fit y1 y2 y3;
run;

```

The nonautoregressive part of the model can be a function of exogenous variables, or it can be intercept parameters. If there are no exogenous components to the vector autoregression model, including no intercepts, then assign zero to each of the variables. There must be an assignment to each of the variables before %AR is called.

```

proc model data=in;
  y1=0;
  y2=0;
  y3=0;
  %ar( name, 2, y1 y2 y3, type=v )
  fit y1 y2 y3;
run;

```

This example models the vector $Y=(Y1 Y2 Y3)'$ as a linear function only of its value in the previous two periods and a white noise error vector. The model has $18=(3 \times 3 + 3 \times 3)$ parameters.

Syntax of the %AR Macro

There are two cases of the syntax of the %AR macro. When restrictions on a vector AR process are not needed, the syntax of the %AR macro has the general form

```
%AR ( name , nlag < ,endolist < , laglist >> < ,M= method > < ,TYPE= V> ) ;
```

where

name specifies a prefix for %AR to use in constructing names of variables needed to define the AR process. If the *endolist* is not specified, the endogenous list defaults to *name*, which must be the name of the equation to which the AR error process is to be applied. The *name* value cannot exceed 32 characters.

nlag is the order of the AR process.

endolist specifies the list of equations to which the AR process is to be applied. If more than one name is given, an unrestricted vector process is created with the structural residuals of all the equations included as regressors in each of the equations. If not specified, *endolist* defaults to *name*.

laglist specifies the list of lags at which the AR terms are to be added. The coefficients of the terms at lags not listed are set to 0. All of the listed lags must be less than or equal to *nlag*, and there must be no duplicates. If not specified, the *laglist* defaults to all lags 1 through *nlag*.

M=method specifies the estimation method to implement. Valid values of *M=* are CLS (conditional least squares estimates), ULS (unconditional least squares estimates), and ML (maximum likelihood estimates). *M=CLS* is the default. Only *M=CLS* is allowed when more than one equation is specified. The ULS and ML methods are not supported for vector AR models by %AR.

TYPE=V specifies that the AR process is to be applied to the endogenous variables themselves instead of to the structural residuals of the equations.

Restricted Vector Autoregression

You can control which parameters are included in the process, restricting to 0 those parameters that you do not include. First, use %AR with the DEFER option to declare the variable list and define the dimension of the process. Then, use additional %AR calls to generate terms for selected equations with selected variables at selected lags. For example,

```
proc model data=d;
  y1 = ... equation for y1 ...;
  y2 = ... equation for y2 ...;
  y3 = ... equation for y3 ...;
  %ar( name, 2, y1 y2 y3, defer )
  %ar( name, y1, y1 y2 )
  %ar( name, y2 y3, , 1 )
  fit y1 y2 y3;
run;
```

The error equations produced are as follows:

```
y1 = pred.y1 + name1_1_1*zlag1(y1-name_y1) +
      name1_1_2*zlag1(y2-name_y2) + name2_1_1*zlag2(y1-name_y1) +
      name2_1_2*zlag2(y2-name_y2) ;
y2 = pred.y2 + name1_2_1*zlag1(y1-name_y1) +
      name1_2_2*zlag1(y2-name_y2) + name1_2_3*zlag1(y3-name_y3) ;
y3 = pred.y3 + name1_3_1*zlag1(y1-name_y1) +
      name1_3_2*zlag1(y2-name_y2) + name1_3_3*zlag1(y3-name_y3) ;
```

This model states that the errors for Y1 depend on the errors of both Y1 and Y2 (but not Y3) at both lags 1 and 2, and that the errors for Y2 and Y3 depend on the previous errors for all three variables, but only at lag 1.

%AR Macro Syntax for Restricted Vector AR

An alternative use of %AR is allowed to impose restrictions on a vector AR process by calling %AR several times to specify different AR terms and lags for different equations.

The first call has the general form

```
%AR( name, nlag, endolist , DEFER ) ;
```

where

name specifies a prefix for %AR to use in constructing names of variables needed to define the vector AR process.

<i>nlag</i>	specifies the order of the AR process.
<i>endolist</i>	specifies the list of equations to which the AR process is to be applied.
DEFER	specifies that %AR is not to generate the AR process but is to wait for further information specified in later %AR calls for the same <i>name</i> value.

The subsequent calls have the general form

```
%AR( name, eqlist, varlist, laglist, TYPE= )
```

where

<i>name</i>	is the same as in the first call.
<i>eqlist</i>	specifies the list of equations to which the specifications in this %AR call are to be applied. Only names specified in the <i>endolist</i> value of the first call for the <i>name</i> value can appear in the list of equations in <i>eqlist</i> .
<i>varlist</i>	specifies the list of equations whose lagged structural residuals are to be included as regressors in the equations in <i>eqlist</i> . Only names in the <i>endolist</i> of the first call for the <i>name</i> value can appear in <i>varlist</i> . If not specified, <i>varlist</i> defaults to <i>endolist</i> .
<i>laglist</i>	specifies the list of lags at which the AR terms are to be added. The coefficients of the terms at lags not listed are set to 0. All of the listed lags must be less than or equal to the value of <i>nlag</i> , and there must be no duplicates. If not specified, <i>laglist</i> defaults to all lags 1 through <i>nlag</i> .

The %MA Macro

The SAS macro %MA generates programming statements for PROC MODEL for moving-average models. The %MA macro is part of SAS/ETS software, and no special options are needed to use the macro. The moving-average error process can be applied to the structural equation errors. The syntax of the %MA macro is the same as the %AR macro except there is no TYPE= argument.

When you are using the %MA and %AR macros combined, the %MA macro must follow the %AR macro. The following SAS/IML statements produce an ARMA(1, (1 3)) error process and save it in the data set MADAT2.

```
/* use IML module to simulate a MA process */
proc iml;
  phi = { 1 .2 };
  theta = { 1 .3 0 .5 };
  y = armasim( phi, theta, 0, .1, 200, 32565 );
  create madat2 from y[colname='y'];
  append from y;
quit;
```

The following PROC MODEL statements are used to estimate the parameters of this model by using maximum likelihood error structure:

```

title 'Maximum Likelihood ARMA(1, (1 3))';
proc model data=madat2;
  y=0;
  %ar( y, 1, , M=ml )
  %ma( y, 3, , 1 3, M=ml ) /* %MA always after %AR */
  fit y;
run;
title;

```

The estimates of the parameters produced by this run are shown in [Figure 18.61](#).

Figure 18.61 Estimates from an ARMA(1, (1 3)) Process

Maximum Likelihood ARMA(1, (1 3))							
The MODEL Procedure							
Nonlinear OLS Summary of Residual Errors							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj R-Sq
y	3	197	2.6383	0.0134	0.1157	-0.0067	-0.0169
RESID.y		197	1.9957	0.0101	0.1007		
Nonlinear OLS Parameter Estimates							
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label		
y_l1	-0.10067	0.1187	-0.85	0.3973	AR(y) y lag1 parameter		
y_m1	-0.1934	0.0939	-2.06	0.0408	MA(y) y lag1 parameter		
y_m3	-0.59384	0.0601	-9.88	<.0001	MA(y) y lag3 parameter		

Syntax of the %MA Macro

There are two cases of the syntax for the %MA macro. When restrictions on a vector MA process are not needed, the syntax of the %MA macro has the general form

```
%MA ( name , nlag < , endolist < , laglist >> < , M= method > );
```

where

name specifies a prefix for %MA to use in constructing names of variables needed to define the MA process and is the default *endolist*.

nlag is the order of the MA process.

<i>endolist</i>	specifies the equations to which the MA process is to be applied. If more than one name is given, CLS estimation is used for the vector process.
<i>laglist</i>	specifies the lags at which the MA terms are to be added. All of the listed lags must be less than or equal to <i>nlag</i> , and there must be no duplicates. If not specified, the <i>laglist</i> defaults to all lags 1 through <i>nlag</i> .
<i>M=method</i>	specifies the estimation method to implement. Valid values of <i>M=</i> are CLS (conditional least squares estimates), ULS (unconditional least squares estimates), and ML (maximum likelihood estimates). <i>M=CLS</i> is the default. Only <i>M=CLS</i> is allowed when more than one equation is specified in the <i>endolist</i> .

%MA Macro Syntax for Restricted Vector Moving-Average

An alternative use of *%MA* is allowed to impose restrictions on a vector MA process by calling *%MA* several times to specify different MA terms and lags for different equations.

The first call has the general form

```
%MA( name , nlag , endolist , DEFER ) ;
```

where

<i>name</i>	specifies a prefix for <i>%MA</i> to use in constructing names of variables needed to define the vector MA process.
<i>nlag</i>	specifies the order of the MA process.
<i>endolist</i>	specifies the list of equations to which the MA process is to be applied.
DEFER	specifies that <i>%MA</i> is not to generate the MA process but is to wait for further information specified in later <i>%MA</i> calls for the same <i>name</i> value.

The subsequent calls have the general form

```
%MA( name, eqlist, varlist, laglist )
```

where

<i>name</i>	is the same as in the first call.
<i>eqlist</i>	specifies the list of equations to which the specifications in this <i>%MA</i> call are to be applied.
<i>varlist</i>	specifies the list of equations whose lagged structural residuals are to be included as regressors in the equations in <i>eqlist</i> .
<i>laglist</i>	specifies the list of lags at which the MA terms are to be added.

Distributed Lag Models and the %PDL Macro

In the following example, the variable y is modeled as a linear function of x , the first lag of x , the second lag of x , and so forth:

$$y_t = a + b_0x_t + b_1x_{t-1} + b_2x_{t-2} + b_3x_{t-3} + \dots + b_nx_{t-n}$$

Models of this sort can introduce a great many parameters for the lags, and there may not be enough data to compute accurate independent estimates for them all. Often, the number of parameters is reduced by assuming that the lag coefficients follow some pattern. One common assumption is that the lag coefficients follow a polynomial in the lag length

$$b_i = \sum_{j=0}^d \alpha_j (i)^j$$

where d is the degree of the polynomial used. Models of this kind are called *Almon lag models*, *polynomial distributed lag models*, or *PDLs* for short. For example, [Figure 18.62](#) shows the lag distribution that can be modeled with a low-order polynomial. Endpoint restrictions can be imposed on a PDL to require that the lag coefficients be 0 at the 0th lag, or at the final lag, or at both.

Figure 18.62 Polynomial Distributed Lags

For linear single-equation models, SAS/ETS software includes the PDLREG procedure for estimating PDL models. See Chapter 20, “[The PDLREG Procedure](#),” for a more detailed discussion of

polynomial distributed lags and an explanation of endpoint restrictions.

Polynomial and other distributed lag models can be estimated and simulated or forecast with PROC MODEL. For polynomial distributed lags, the %PDL macro can generate the needed programming statements automatically.

The %PDL Macro

The SAS macro %PDL generates the programming statements to compute the lag coefficients of polynomial distributed lag models and to apply them to the lags of variables or expressions.

To use the %PDL macro in a model program, you first call it to declare the lag distribution; later, you call it again to apply the PDL to a variable or expression. The first call generates a PARMS statement for the polynomial parameters and assignment statements to compute the lag coefficients. The second call generates an expression that applies the lag coefficients to the lags of the specified variable or expression. A PDL can be declared only once, but it can be used any number of times (that is, the second call can be repeated).

The initial declaratory call has the general form

```
%PDL ( pdlname, nlags, degree , R=code , OUTEST=dataset ) ;
```

where *pdlname* is a name (up to 32 characters) that you give to identify the PDL, *nlags* is the lag length, and *degree* is the degree of the polynomial for the distribution. The *R=code* is optional for endpoint restrictions. The value of *code* can be FIRST (for upper), LAST (for lower), or BOTH (for both upper and lower endpoints). See Chapter 20, “The PDLREG Procedure,” for a discussion of endpoint restrictions. The option *OUTEST=dataset* creates a data set that contains the estimates of the parameters and their covariance matrix.

The later calls to apply the PDL have the general form

```
%PDL( pdlname, expression )
```

where *pdlname* is the name of the PDL and *expression* is the variable or expression to which the PDL is to be applied. The *pdlname* given must be the same as the name used to declare the PDL.

The following statements produce the output in [Figure 18.63](#):

```
proc model data=in list;
  parms int pz;
  %pdl(xpdl,5,2);
  y = int + pz * z + %pdl(xpdl,x);
  %ar(y,2,M=ULS);
  id i;
fit y / out=modell outresid converge=1e-6;
run;
```

Figure 18.63 %PDL Macro Estimates

The MODEL Procedure					
Nonlinear OLS Estimates					
Term	Estimate	Approx Std Err	t Value	Approx Pr > t	Label
XPDL_L0	1.568788	0.0935	16.77	<.0001	PDL(XPDL,5,2) coefficient for lag0
XPDL_L1	0.564917	0.0328	17.22	<.0001	PDL(XPDL,5,2) coefficient for lag1
XPDL_L2	-0.05063	0.0593	-0.85	0.4155	PDL(XPDL,5,2) coefficient for lag2
XPDL_L3	-0.27785	0.0517	-5.37	0.0004	PDL(XPDL,5,2) coefficient for lag3
XPDL_L4	-0.11675	0.0368	-3.17	0.0113	PDL(XPDL,5,2) coefficient for lag4
XPDL_L5	0.43267	0.1362	3.18	0.0113	PDL(XPDL,5,2) coefficient for lag5

This second example models two variables, Y1 and Y2, and uses two PDLs:

```
proc model data=in;
  parms int1 int2;
  %pdl( logxpdl, 5, 3 )
  %pdl( zpd1, 6, 4 )
  y1 = int1 + %pdl( logxpdl, log(x) ) + %pdl( zpd1, z );
  y2 = int2 + %pdl( zpd1, z );
  fit y1 y2;
run;
```

A (5,3) PDL of the log of X is used in the equation for Y1. A (6,4) PDL of Z is used in the equations for both Y1 and Y2. Since the same ZPDL is used in both equations, the lag coefficients for Z are the same for the Y1 and Y2 equations, and the polynomial parameters for ZPDL are shared by the two equations. See [Example 18.5](#) for a complete example and comparison with PDLREG.

Input Data Sets

DATA= Input Data Set
