specifies the α parameter for Fuller’s modification to the LIML estimation method. See the section “[Fuller’s Modification to LIML](#)” on page 2102 for details.

CORRB

prints the matrix of estimated correlations between the parameter estimates.

COVB

prints the matrix of estimated covariances between the parameter estimates.

DW

prints Durbin-Watson statistics and autocorrelation coefficients for the residuals. If there are missing values, d' is calculated according to Savin and White (1978). Use the DW option only if the data set to be analyzed is an ordinary SAS data set with time series observations sorted in time order. The Durbin-Watson test is not valid for models with lagged dependent regressors.

I

prints the inverse of the crossproducts matrix for the model, $(X'X)^{-1}$. If restrictions are specified, the crossproducts matrix printed is adjusted for the restrictions. See the section “[Computational Details](#)” on page 2100 for details.

K=value

specifies K-class estimation.

NOINT

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

OVERID

prints Basmann’s (1960) test for over identifying restrictions. See the section “[Overidentification Restrictions](#)” on page 2102 for details.

PLOT

plots residual values against regressors. A plot of the residuals for each regressor is printed.

STB

prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a standardized parameter estimate is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the response variable.

UNREST

prints parameter estimates computed before restrictions are applied. The UNREST option is valid only if a RESTRICT statement is specified.

XPX

prints the model crossproducts matrix, $X'X$. See the section “[Computational Details](#)” on page 2100 for details.

OUTPUT Statement

OUTPUT < *PREDICTED=variable* > < *RESIDUAL=variable* > ;

The OUTPUT statement writes predicted values and residuals from the preceding model to the data set specified by the OUT= option in the PROC SYSLIN statement. An OUTPUT statement must come after the MODEL statement to which it applies. The OUT= option must be specified in the PROC SYSLIN statement.

The following options can be specified in the OUTPUT statement:

PREDICTED=*variable*

names a new variable to contain the predicted values for the response variable. The PREDICTED= option can be abbreviated as PREDICT=, PRED=, or P=.

RESIDUAL=*variable*

names a new variable to contain the residual values for the response variable. The RESIDUAL= option can be abbreviated as RESID= or R=.

For example, the following statements create an output data set named B. In addition to the variables in the input data set, the data set B contains the variable YHAT, with values that are predicted values of the response variable Y, and YRESID, with values that are the residual values of Y.

```
proc syslin data=a out=b;
  model y = x1 x2;
  output p=yhat r=yresid;
run;
```

For example, the following statements create an output data set named PRED. In addition to the variables in the input data set, the data set PRED contains the variables Q_DEMAND and Q_SUPPLY, with values that are predicted values of the response variable Q for the demand and supply equations respectively, and R_DEMAND and R_SUPPLY, with values that are the residual values of the demand and supply equations respectively.

```
proc syslin data=in out=pred;
  demand: model q = p y s;
  output p=q_demand r=r_demand;
  supply: model q = p u;
  output p=q_supply r=r_supply;
run;
```

See the section “OUT= Data Set” on page 2102 for details.

RESTRICT Statement

RESTRICT *equation* , . . . , *equation* ;

The RESTRICT statement places restrictions on the parameter estimates for the preceding MODEL statement. Any number of RESTRICT statements can follow a MODEL statement. Each restriction is written as a linear equation. If more than one restriction is specified in a single RESTRICT statement, the restrictions are separated by commas.

Parameters are referred to by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. The keyword INTERCEPT is used to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label : **RESTRICT** ...;

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1.

```
proc syslin data=a;
  model y = x1 x2;
  restrict x1 + x2 = 1;
run;
```

Variable names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Rayner 1971). The estimates of these Lagrangian parameters are printed in the “Parameter Estimates” table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter λ measures the sensitivity of the sum of squared errors (SSE) to the restriction. If the restriction is changed by a small amount ϵ , the SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted.

Any number of restrictions can be specified on a RESTRICT statement, and any number of RESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

NOTE: The RESTRICT statement is not supported for the FIML estimation method.

SRESTRICT Statement

SRESTRICT *equation* , ... , *equation* ;

The SRESTRICT statement imposes linear restrictions that involve parameters in two or more MODEL statements. The SRESTRICT statement is like the RESTRICT statement but is used to impose restrictions across equations, whereas the RESTRICT statement applies only to parameters in the immediately preceding MODEL statement.

Each restriction is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

SRESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label : **SRESTRICT** ...;

The following is an example of the use of the SRESTRICT statement, in which the coefficient for the regressor X2 is constrained to be the same in both models.

```
proc syslin data=a 3sls;
    endogenous y1 y2;
    instruments x1 x2;
    model y1 = y2 x1 x2;
    model y2 = y1 x2;
    srestrict y1.x2 = y2.x2;
run;
```

When no equal sign is used, the linear combination is set equal to 0. Thus, the restriction in the preceding example can also be specified as

```
srestrict y1.x2 - y2.x2;
```

Any number of restrictions can be specified on an SRESTRICT statement, and any number of SRESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

When a system restriction is requested for a single equation estimation method (such as OLS or 2SLS), PROC SYSLIN produces the restricted estimates by actually using a corresponding system method. For example, when SRESTRICT is specified along with OLS, PROC SYSLIN produces the restricted OLS estimates via a two-step process equivalent to using SUR estimation with the SDIAG option. First, the unrestricted OLS results are produced. Then, the GLS (SUR) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals. When SRESTRICT is specified along with 2SLS, PROC SYSLIN produces the restricted 2SLS estimates via a multistep process equivalent to using 3SLS estimation with the SDIAG option. First, the unrestricted 2SLS results are produced. Then, the GLS (3SLS) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals.

The results of the SRESTRICT statements are printed after the parameter estimates for all the models in the system. The format of the SRESTRICT statement output is the same as the “Parameter Estimates” table. In this output the parameter estimate is the Lagrangian parameter λ used to impose the restriction.

The Lagrangian parameter λ measures the sensitivity of the system sum of square errors to the restriction. The system SSE is the system MSE shown in the printed output multiplied by the degrees of freedom. If the restriction is changed by a small amount ϵ , the system SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restriction. If λ is zero, the restricted estimates are the same as the unrestricted estimates.

The model degrees of freedom are not adjusted for the cross-model restrictions imposed by SRESTRICT statements.

NOTE: The SRESTRICT statement is not supported for the LIML and the FIML estimation methods.

STEST Statement

STEST *equation , . . . , equation / options ;*

The STEST statement performs an F test for the joint hypotheses specified in the statement.

The hypothesis is represented in matrix notation as

$$\mathbf{L}\beta = \mathbf{c}$$

and the F test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β , m is the number of restrictions, and $\hat{\sigma}^2$ is the system weighted mean squared error. See the section “[Computational Details](#)” on page 2100 for information about the matrix $\mathbf{X}'\mathbf{X}$.

Each hypothesis to be tested is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

STEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of STEST statements can be specified. Labels are specified as follows:

label : **STEST** ...;

The following is an example of the STEST statement:

```
proc syslin data=a 3sls;
  endogenous y1 y2;
  instruments x1 x2;
  model y1 = y2 x1 x2;
  model y2 = y1 x2;
  stest y1.x2 = y2.x2;
run;
```

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the F test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the STEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The following are examples of STEST statements:

```
stest a.x1 + b.x2 = 1;
stest 2 * b.x2 = c.x3 + c.x4 ,
      a.intercept + b.x2 = 0;
stest a.x1 = c.x2 = b.x3 = 1;
stest 2 * a.x1 - b.x2 = 0;
```

The PRINT option can be specified in the STEST statement after a slash (/):

PRINT

prints intermediate calculations for the hypothesis tests.

NOTE: The STEST statement is not supported for the FIML estimation method.

TEST Statement

TEST *equation* , ... , *equation* / *options* ;

The TEST statement performs F tests of linear hypotheses about the parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Variable names must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT is used to refer to the model intercept.

TEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of TEST statements can be specified. Labels are specified as follows:

label : **TEST** ...;

The following is an example of the use of TEST statement, which tests the hypothesis that the coefficients of X1 and X2 are the same:

```
proc syslin data=a;
  model y = x1 x2;
  test x1 = x2;
run;
```

The following statements perform F tests for the hypothesis that the coefficients of X1 and X2 are equal, for the hypothesis that the sum of the X1 and X2 coefficients is twice the intercept, and for the joint hypothesis.

```
proc syslin data=a;
  model y = x1 x2;
  xleqx2: test x1 = x2;
  sumeq2i: test x1 + x2 = 2 * intercept;
  joint:   test x1 = x2, x1 + x2 = 2 * intercept;
run;
```

The following are additional examples of TEST statements:

```
test x1 + x2 = 1;
test x1 = x2 = x3 = 1;
test 2 * x1 = x2 + x3, intercept + x4 = 0;
test 2 * x1 - x2;
```

The TEST statement performs an F test for the joint hypotheses specified. The hypothesis is represented in matrix notation as follows:

$$L\beta = c$$

The F test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β , m is the number of restrictions, and $\hat{\sigma}^2$ is the model mean squared error. See the section “[Computational Details](#)” on page 2100 for information about the matrix $\mathbf{X}'\mathbf{X}$.

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the F test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the TEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The PRINT option can be specified in the TEST statement after a slash (/):

PRINT

prints intermediate calculations for the hypothesis tests.

NOTE: The TEST statement is not supported for the FIML estimation method.

VAR Statement

VAR *variables* ;

The VAR statement is used to include variables in the crossproducts matrix that are not specified in any MODEL statement. This statement is rarely used with PROC SYSLIN and is used only with the OUTSSCP= option in the PROC SYSLIN statement.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement is used to perform weighted regression. The WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE).

Details: SYSLIN Procedure

Input Data Set

PROC SYSLIN does not compute new values for regressors. For example, if you need a lagged variable, you must create it with a DATA step. No values are computed by IDENTITY statements; all values must be in the input data set.

Special TYPE= Input Data Sets

The input data set for most applications of the SYSLIN procedure contains standard rectangular data. However, PROC SYSLIN can also process input data in the form of a crossproducts, covariance, or correlation matrix. Data sets that contain such matrices are identified by values of the TYPE= data set option.

These special kinds of input data sets can be used to save computer time. It takes nk^2 operations, where n is the number of observations and k is the number of variables, to calculate cross products; the regressions are of the order k^3 . When n is in the thousands and k is much smaller, you can save most of the computer time in later runs of PROC SYSLIN by reusing the SSCP matrix rather than recomputing it.

The SYSLIN procedure can process TYPE=CORR, COV, UCORR, UCOV, or SSCP data sets. TYPE=CORR and TYPE=COV data sets, usually created by the CORR procedure, contain means and standard deviations, and correlations or covariances. TYPE=SSCP data sets, usually created in previous runs of PROC SYSLIN, contain sums of squares and cross products. See the *SAS/STAT User's Guide* for more information about special SAS data sets.

When special SAS data sets are read, you must specify the TYPE= data set option. PROC CORR and PROC SYSLIN automatically set the type for output data sets; however, if you create the data set by some other means, you must specify its type with the TYPE= data set option.

When the special data sets are used, the DW (Durbin-Watson test) and PLOT options in the MODEL statement cannot be performed, and the OUTPUT statements are not valid.

Estimation Methods

A brief description of the methods used by the SYSLIN procedure follows. For more information about these methods, see the references at the end of this chapter.

There are two fundamental methods of estimation for simultaneous equations: least squares and maximum likelihood. There are two approaches within each of these categories: single equation methods (also referred to as limited information methods) and system methods (also referred to as full information methods). System methods take into account cross-equation correlations of the disturbances in estimating parameters, while single equation methods do not.

OLS, 2SLS, MELO, K-class, SUR, ITSUR, 3SLS, and IT3SLS use the least squares method; LIML and FIML use the maximum likelihood method.

OLS, 2SLS, MELO, K-class, and LIML are single equation methods. The system methods are SUR, ITSUR, 3SLS, IT3SLS, and FIML.

Single Equation Estimation Methods

Single equation methods do not take into account correlations of errors across equations. As a result, these estimators are not asymptotically efficient compared to full information methods; however, there are instances in which they may be preferred. (See the section “Choosing a Method for Simultaneous Equations” on page 2098 for details.)

Let y_i be the dependent endogenous variable in equation i , and X_i and Y_i be the matrices of exogenous and endogenous variables appearing as regressors in the same equation.

The 2SLS method owes its name to the fact that, in a first stage, the instrumental variables are used as regressors to obtain a projected value \hat{Y}_i that is uncorrelated with the residual in equation i . In a second stage, \hat{Y}_i replaces Y_i on the right-hand side to obtain consistent least squares estimators.

Normally, the predetermined variables of the system are used as the instruments. It is possible to use variables other than predetermined variables from your system as instruments; however, the estimation might not be as efficient. For consistent estimates, the instruments must be uncorrelated with the residual and correlated with the endogenous variables.

The LIML method results in consistent estimates that are equal to the 2SLS estimates when an equation is exactly identified. LIML can be viewed as a least-variance ratio estimation or as a maximum likelihood estimation. LIML involves minimizing the ratio $\lambda = (rvar_eq)/(rvar_sys)$, where $rvar_eq$ is the residual variance associated with regressing the weighted endogenous variables on all predetermined variables that appear in that equation, and $rvar_sys$ is the residual variance associated with regressing weighted endogenous variables on all predetermined variables in the system.

The MELO method computes the minimum expected loss estimator. MELO estimators “minimize the posterior expectation of generalized quadratic loss functions for structural coefficients of linear structural models” (Judge et al. 1985, p. 635).

K-class estimators are a class of estimators that depends on a user-specified parameter k . A k value less than 1 is recommended but not required. The parameter k can be deterministic or stochastic, but its probability limit must equal 1 for consistent parameter estimates. When all the predetermined variables are listed as instruments, they include all the other single equation estimators supported by PROC SYSLIN. The instance when some of the predetermined variables are not listed among the instruments is not supported by PROC SYSLIN for the general K-class estimation. However, it is supported for the other methods.

For $k = 1$, the K-class estimator is the 2SLS estimator, while for $k = 0$, the K-class estimator is the OLS estimator. The K-class interpretation of LIML is that $k = \lambda$. Note that k is stochastic in the LIML method, unlike for OLS and 2SLS.

MELO is a Bayesian K-class estimator. It yields estimates that can be expressed as a matrix-weighted average of the OLS and 2SLS estimates. MELO estimators have finite second moments and hence finite risk. Other frequently used K-class estimators might not have finite moments under some commonly encountered circumstances, and hence there can be infinite risk relative to quadratic and other loss functions.

One way of comparing K-class estimators is to note that when $k = 1$, the correlation between regressor and the residual is completely corrected for. In all other cases, it is only partially corrected for.

See “[Computational Details](#)” on page 2100 for more details about K-class estimators.

SUR and 3SLS Estimation Methods

SUR might improve the efficiency of parameter estimates when there is contemporaneous correlation of errors across equations. In practice, the contemporaneous correlation matrix is estimated using OLS residuals. Under two sets of circumstances, SUR parameter estimates are the same as those produced by OLS: when there is no contemporaneous correlation of errors across equations (the estimate of the contemporaneous correlation matrix is diagonal) and when the independent variables are the same across equations.

Theoretically, SUR parameter estimates are always at least as efficient as OLS in large samples, provided that your equations are correctly specified. However, in small samples the need to estimate the covariance matrix from the OLS residuals increases the sampling variability of the SUR estimates. This effect can cause SUR to

be less efficient than OLS. If the sample size is small and the cross-equation correlations are small, then OLS is preferred to SUR. The consequences of specification error are also more serious with SUR than with OLS.

The 3SLS method combines the ideas of the 2SLS and SUR methods. Like 2SLS, the 3SLS method uses \hat{Y} instead of Y for endogenous regressors, which results in consistent estimates. Like SUR, the 3SLS method takes the cross-equation error correlations into account to improve large sample efficiency. For 3SLS, the 2SLS residuals are used to estimate the cross-equation error covariance matrix.

The SUR and 3SLS methods can be iterated by recomputing the estimate of the cross-equation covariance matrix from the SUR or 3SLS residuals and then computing new SUR or 3SLS estimates based on this updated covariance matrix estimate. Continuing this iteration until convergence produces ITSUR or IT3SLS estimates.

FIML Estimation Method

The FIML estimator is a system generalization of the LIML estimator. The FIML method involves minimizing the determinant of the covariance matrix associated with residuals of the reduced form of the equation system. From a maximum likelihood standpoint, the LIML method involves assuming that the errors are normally distributed and then maximizing the likelihood function subject to restrictions on a particular equation. FIML is similar, except that the likelihood function is maximized subject to restrictions on all of the parameters in the model, not just those in the equation being estimated.

NOTE: The RESTRICT, SRESTRICT, TEST, and STEST statements are not supported when the FIML method is used.

Choosing a Method for Simultaneous Equations

A number of factors should be taken into account in choosing an estimation method. Although system methods are asymptotically most efficient in the absence of specification error, system methods are more sensitive to specification error than single equation methods.

In practice, models are never perfectly specified. It is a matter of judgment whether the misspecification is serious enough to warrant avoidance of system methods.

Another factor to consider is sample size. With small samples, 2SLS might be preferred to 3SLS. In general, it is difficult to say much about the small sample properties of K-class estimators because the results depend on the regressors used.

LIML and FIML are invariant to the normalization rule imposed but are computationally more expensive than 2SLS or 3SLS.

If the reason for contemporaneous correlation among errors across equations is a common, omitted variable, it is not necessarily best to apply SUR. SUR parameter estimates are more sensitive to specification error than OLS. OLS might produce better parameter estimates under these circumstances. SUR estimates are also affected by the sampling variation of the error covariance matrix. There is some evidence from Monte Carlo studies that SUR is less efficient than OLS in small samples.

ANOVA Table for Instrumental Variables Methods

In the instrumental variables methods (2SLS, LIML, K-class, MELO), first-stage predicted values are substituted for the endogenous regressors. As a result, the regression sum of squares (RSS) and the error

sum of squares (ESS) do not sum to the total corrected sum of squares for the dependent variable (TSS). The analysis-of-variance table included in the second-stage results gives these sums of squares and the mean squares that are used for the F test, but this table is not a variance decomposition in the usual sense.

The F test shown in the instrumental variables case is a valid test of the no-regression hypothesis that the true coefficients of all regressors are 0. However, because of the first-stage projection of the regression mean square, this is a Wald-type test statistic, which is asymptotically F but not exactly F -distributed in finite samples. Thus, for small samples the F test is only approximate when instrumental variables are used.

The R-Square Statistics

As explained in the section “ANOVA Table for Instrumental Variables Methods” on page 2098, when instrumental variables are used, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares. In this case, there are several ways that the R^2 statistic can be defined.

The definition of R^2 used by the SYSLIN procedure is

$$R^2 = \frac{RSS}{RSS + ESS}$$

This definition is consistent with the F test of the null hypothesis that the true coefficients of all regressors are zero. However, this R^2 might not be a good measure of the goodness of fit of the model.

System Weighted R-Square and System Weighted Mean Squared Error

The system weighted R^2 , printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows.

$$R^2 = \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y}/\mathbf{Y}'\mathbf{W}\mathbf{Y}$$

In this equation, the matrix $\mathbf{X}'\mathbf{X}$ is $\mathbf{R}'\mathbf{W}\mathbf{R}$ and \mathbf{W} is the projection matrix of the instruments:

$$\mathbf{W} = \mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$$

The matrix \mathbf{Z} is the instrument set, \mathbf{R} is the regressor set, and \mathbf{S} is the estimated cross-model covariance matrix.

The system weighted MSE, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows:

$$MSE = \frac{1}{tdf}(\mathbf{Y}'\mathbf{W}\mathbf{Y} - \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y})$$

In this equation, tdf is the sum of the error degrees of freedom for the equations in the system.

Computational Details

This section discusses various computational details.

Computation of Least Squares-Based Estimators

Let the system be composed of G equations and let the i th equation be expressed in this form:

$$y_i = Y_i \beta_i + X_i \gamma_i + \mathbf{u}$$

where

y_i is the vector of observations on the dependent variable

Y_i is the matrix of observations on the endogenous variables included in the equation

β_i is the vector of parameters associated with Y_i

X_i is the matrix of observations on the predetermined variables included in the equation

γ_i is the vector of parameters associated with X_i

\mathbf{u} is a vector of errors

Let $\hat{V}_i = Y_i - \hat{Y}_i$, where \hat{Y}_i is the projection of Y_i onto the space spanned by the instruments matrix \mathbf{Z} .

Let

$$\delta_i = \begin{bmatrix} \beta_i \\ \gamma_i \end{bmatrix}$$

be the vector of parameters associated with both the endogenous and exogenous variables.

The K-class of estimators (Theil 1971) is defined by

$$\hat{\delta}_{i,k} = \begin{bmatrix} Y_i' Y_i - k \hat{V}_i' \hat{V}_i & Y_i' X_i \\ X_i' Y_i & X_i' X_i \end{bmatrix}^{-1} \begin{bmatrix} (Y_i - k \hat{V}_i)' y_i \\ X_i' y_i \end{bmatrix}$$

where k is a user-defined value.

Let

$$\mathbf{R} = [Y_i X_i]$$

and

$$\hat{\mathbf{R}} = [\hat{Y}_i X_i]$$

The 2SLS estimator is defined as

$$\hat{\delta}_{i,2SLS} = [\hat{R}_i' \hat{R}_i]^{-1} \hat{R}_i' y_i$$

Let \mathbf{y} and δ be the vectors obtained by stacking the vectors of dependent variables and parameters for all G equations, and let \mathbf{R} and $\hat{\mathbf{R}}$ be the block diagonal matrices formed by R_i and \hat{R}_i , respectively.

The SUR and ITSUR estimators are defined as

$$\hat{\delta}_{(IT)SUR} = \left[\mathbf{R}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \mathbf{R} \right]^{-1} \mathbf{R}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \mathbf{y}$$

while the 3SLS and IT3SLS estimators are defined as

$$\hat{\delta}_{(IT)3SLS} = \left[\hat{\mathbf{R}}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \hat{\mathbf{R}} \right]^{-1} \hat{\mathbf{R}}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \mathbf{y}$$

where \mathbf{I} is the identity matrix, and $\hat{\Sigma}$ is an estimator of the cross-equation correlation matrix. For 3SLS, $\hat{\Sigma}$ is obtained from the 2SLS estimation, while for SUR it is derived from the OLS estimation. For IT3SLS and ITSUR, it is obtained iteratively from the previous estimation step, until convergence.

Computation of Standard Errors

The VARDEF= option in the PROC SYSLIN statement controls the denominator used in calculating the cross-equation covariance estimates and the parameter standard errors and covariances. The values of the VARDEF= option and the resulting denominator are as follows:

N	uses the number of nonmissing observations.
DF	uses the number of nonmissing observations less the degrees of freedom in the model.
WEIGHT	uses the sum of the observation weights given by the WEIGHTS statement.
WDF	uses the sum of the observation weights given by the WEIGHTS statement less the degrees of freedom in the model.

The VARDEF= option does not affect the model mean squared error, root mean squared error, or R^2 statistics. These statistics are always based on the error degrees of freedom, regardless of the VARDEF= option. The VARDEF= option also does not affect the dependent variable coefficient of variation (CV).

Reduced Form Estimates

The REDUCED option in the PROC SYSLIN statement computes estimates of the reduced form coefficients. The REDUCED option requires that the equation system be square. If there are fewer models than endogenous variables, IDENTITY statements can be used to complete the equation system.

The reduced form coefficients are computed as follows. Represent the equation system, with all endogenous variables moved to the left-hand side of the equations and identities, as

$$\mathbf{B}\mathbf{Y} = \mathbf{\Gamma}\mathbf{X}$$

Here \mathbf{B} is the estimated coefficient matrix for the endogenous variables \mathbf{Y} , and $\mathbf{\Gamma}$ is the estimated coefficient matrix for the exogenous (or predetermined) variables \mathbf{X} .

The system can be solved for \mathbf{Y} as follows, provided \mathbf{B} is square and nonsingular:

$$\mathbf{Y} = \mathbf{B}^{-1}\mathbf{\Gamma}\mathbf{X}$$

The reduced form coefficients are the matrix $\mathbf{B}^{-1}\mathbf{\Gamma}$.

Uncorrelated Errors across Equations

The SDIAG option in the PROC SYSLIN statement computes estimates by assuming uncorrelated errors across equations. As a result, when the SDIAG option is used, the 3SLS estimates are identical to 2SLS estimates, and the SUR estimates are the same as the OLS estimates.

Overidentification Restrictions

The OVERID option in the MODEL statement can be used to test for overidentifying restrictions on parameters of each equation. The null hypothesis is that the predetermined variables that do not appear in any equation have zero coefficients. The alternative hypothesis is that at least one of the assumed zero coefficients is nonzero. The test is approximate and rejects the null hypothesis too frequently for small sample sizes.

The formula for the test is given as follows. Let $y_i = \beta_i Y_i + \gamma_i Z_i + e_i$ be the i th equation. Y_i are the endogenous variables that appear as regressors in the i th equation, and Z_i are the instrumental variables that appear as regressors in the i th equation. Let N_i be the number of variables in Y_i and Z_i .

Let $v_i = y_i - Y_i \hat{\beta}_i$. Let Z represent all instrumental variables, T be the total number of observations, and K be the total number of instrumental variables. Define \hat{l} as follows:

$$\hat{l} = \frac{v_i'(\mathbf{I} - \mathbf{Z}_i(\mathbf{Z}_i'\mathbf{Z}_i)^{-1}\mathbf{Z}_i')v_i}{v_i'(\mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}')v_i}$$

Then the test statistic

$$\frac{T - K}{K - N_i}(\hat{l} - 1)$$

is distributed approximately as an F with $K - N_i$ and $T - K$ degrees of freedom. See Basmann (1960) for more information.

Fuller's Modification to LIML

The ALPHA= option in the PROC SYSLIN and MODEL statements parameterizes Fuller's modification to LIML. This modification is $k = \gamma - (\alpha/(n - g))$, where α is the value of the ALPHA= option, γ is the LIML k value, n is the number of observations, and g is the number of predetermined variables. Fuller's modification is not used unless the ALPHA= option is specified. See Fuller (1977) for more information.

Missing Values

Observations that have a missing value for any variable in the analysis are excluded from the computations.

OUT= Data Set

The output SAS data set produced by the OUT= option in the PROC SYSLIN statement contains all the variables in the input data set and the variables that contain predicted values and residuals specified by OUTPUT statements.

The residuals are computed as actual values minus predicted values. Predicted values never use lags of other predicted values, as would be desirable for dynamic simulation. For these applications, PROC SIMLIN is available to predict or simulate values from the estimated equations.

OUTEST= Data Set

The OUTEST= option produces a TYPE=EST output SAS data set that contains estimates from the regressions. The variables in the OUTEST= data set are as follows:

BY variables	identifies the BY statement variables that are included in the OUTEST= data set.
TYPE	identifies the estimation type for the observations. The _TYPE_ value INST indicates first-stage regression estimates. Other values indicate the estimation method used: 2SLS indicates two-stage least squares results, 3SLS indicates three-stage least squares results, LIML indicates limited information maximum likelihood results, and so forth. Observations added by IDENTITY statements have the _TYPE_ value IDENTITY.
STATUS	identifies the convergence status of the estimation. _STATUS_ equals 0 when convergence criteria are met. Otherwise, _STATUS_ equals 1 when the estimation converges with a note, 2 when it converges with a warning, or 3 when it fails to converge.
MODEL	identifies the model label. The model label is the label specified in the MODEL statement or the dependent variable name if no label is specified. For first-stage regression estimates, _MODEL_ has the value FIRST.
DEPVAR	identifies the name of the dependent variable for the model.
NAME	identifies the names of the regressors for the rows of the covariance matrix, if the COVOUT option is specified. _NAME_ has a blank value for the parameter estimates observations. The _NAME_ variable is not included in the OUTEST= data set unless the COVOUT option is used to output the covariance of parameter estimates matrix.
SIGMA	contains the root mean squared error for the model, which is an estimate of the standard deviation of the error term. The _SIGMA_ variable contains the same values reported as Root MSE in the printed output.
INTERCEPT	identifies the intercept parameter estimates.
regressors	identifies the regressor variables from all the MODEL statements that are included in the OUTEST= data set. Variables used in IDENTIFY statements are also included in the OUTEST= data set.

The parameter estimates are stored under the names of the regressor variables. The intercept parameters are stored in the variable INTERCEPT. The dependent variable of the model is given a coefficient of -1 . Variables that are not in a model have missing values for the OUTEST= observations for that model.

Some estimation methods require computation of preliminary estimates. All estimates computed are output to the OUTEST= data set. For each BY group and each estimation, the OUTEST= data set contains one observation for each MODEL or IDENTITY statement. Results for different estimations are identified by the _TYPE_ variable.

For example, consider the following statements:

```
proc syslin data=a outest=est 3sls;
  by b;
  endogenous y1 y2;
  instruments x1-x4;
  model y1 = y2 x1 x2;
  model y2 = y1 x3 x4;
  identity x1 = x3 + x4;
run;
```

The 3SLS method requires both a preliminary 2SLS stage and preliminary first-stage regressions for the endogenous variable. The OUTEST= data set thus contains three different kinds of estimates. The observations for the first-stage regression estimates have the `_TYPE_` value INST. The observations for the 2SLS estimates have the `_TYPE_` value 2SLS. The observations for the final 3SLS estimates have the `_TYPE_` value 3SLS.

Since there are two endogenous variables in this example, there are two first-stage regressions and two `_TYPE_=INST` observations in the OUTEST= data set. Since there are two model statements, there are two OUTEST= observations with `_TYPE_=2SLS` and two observations with `_TYPE_=3SLS`. In addition, the OUTEST= data set contains an observation with the `_TYPE_` value IDENTITY that contains the coefficients specified by the IDENTITY statement. All these observations are repeated for each BY group in the input data set defined by the values of the BY variable B.

When the COVOUT option is specified, the estimated covariance matrix for the parameter estimates is included in the OUTEST= data set. Each observation for parameter estimates is followed by observations that contain the rows of the parameter covariance matrix for that model. The row of the covariance matrix is identified by the variable `_NAME_`. For observations that contain parameter estimates, `_NAME_` is blank. For covariance observations, `_NAME_` contains the regressor name for the row of the covariance matrix and the regressor variables contain the covariances.

See [Example 29.1](#) for an example of the OUTEST= data set.

OUTSSCP= Data Set

The OUTSSCP= option produces a TYPE=SSCP output SAS data set that contains sums of squares and cross products. The data set contains all variables used in the MODEL, IDENTITY, and VAR statements. Observations are identified by the variable `_NAME_`.

The OUTSSCP= data set can be useful when a large number of observations are to be explored in many different SYSLIN runs. The sum-of-squares-and-crossproducts matrix can be saved with the OUTSSCP= option and used as the DATA= data set on subsequent SYSLIN runs. This is much less expensive computationally because PROC SYSLIN never reads the original data again. In the step that creates the OUTSSCP= data set, include in the VAR statement all the variables you expect to use.

Printed Output

The printed output produced by the SYSLIN procedure is as follows:

1. If the SIMPLE option is used, a table of descriptive statistics is printed that shows the sum, mean, sum of squares, variance, and standard deviation for all the variables used in the models.
2. If the FIRST option is specified and an instrumental variables method is used, first-stage regression results are printed. The results show the regression of each endogenous variable on the variables in the INSTRUMENTS list.
3. The results of the second-stage regression are printed for each model. (See the following section “Printed Output for Each Model” on page 2105 for details.)
4. If a systems method like 3SLS, SUR, or FIML is used, the cross-equation error covariance matrix is printed. This matrix is shown four ways: the covariance matrix itself, the correlation matrix form, the inverse of the correlation matrix, and the inverse of the covariance matrix.
5. If a systems method like 3SLS, SUR, or FIML is used, the system weighted mean squared error and system weighted R^2 statistics are printed. The system weighted MSE and R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances.
6. If a systems method like 3SLS, SUR, or FIML is used, the final results are printed for each model.
7. If the REDUCED option is used, the reduced form coefficients are printed. These consist of the structural coefficient matrix for the endogenous variables, the structural coefficient matrix for the exogenous variables, the inverse of the endogenous coefficient matrix, and the reduced form coefficient matrix. The reduced form coefficient matrix is the product of the inverse of the endogenous coefficient matrix and the exogenous structural coefficient matrix.

Printed Output for Each Model

The results printed for each model include the analysis-of-variance table, the “Parameter Estimates” table, and optional items requested by TEST statements or by options in the MODEL statement.

The printed output produced for each model is described in the following.

The analysis-of-variance table includes the following:

- the model degrees of freedom, sum of squares, and mean square
- the error degrees of freedom, sum of squares, and mean square. The error mean square is computed by dividing the error sum of squares by the error degrees of freedom and is not affected by the VARDEF= option.
- the corrected total degrees of freedom and total sum of squares. Note that for instrumental variables methods, the model and error sums of squares do not add to the total sum of squares.
- the F ratio, labeled “F Value,” and its significance, labeled “PROB>F,” for the test of the hypothesis that all the nonintercept parameters are 0
- the root mean squared error. This is the square root of the error mean square.
- the dependent variable mean

- the coefficient of variation (CV) of the dependent variable
- the R^2 statistic. This R^2 is computed consistently with the calculation of the F statistic. It is valid for hypothesis tests but might not be a good measure of fit for models estimated by instrumental variables methods.
- the R^2 statistic adjusted for model degrees of freedom, labeled “Adj R-SQ”

The “Parameter Estimates” table includes the following:

- estimates of parameters for regressors in the model and the Lagrangian parameter for each restriction specified
- a degrees of freedom column labeled DF. Estimated model parameters have 1 degree of freedom. Restrictions have a DF of -1 . Regressors or restrictions dropped from the model due to collinearity have a DF of 0.
- the standard errors of the parameter estimates
- the t statistics, which are the parameter estimates divided by the standard errors
- the significance of the t tests for the hypothesis that the true parameter is 0, labeled “Pr > |t|.” As previously noted, the significance tests are strictly valid in finite samples only for OLS estimates but are asymptotically valid for the other methods.
- the standardized regression coefficients, if the STB option is specified. This is the parameter estimate multiplied by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable.
- the labels of the regressor variables or restriction labels

In addition to the analysis-of-variance table and the “Parameter Estimates” table, the results printed for each model can include the following:

- If TEST statements are specified, the test results are printed.
- If the DW option is specified, the Durbin-Watson statistic and first-order autocorrelation coefficient are printed.
- If the OVERID option is specified, the results of Basman’s test for overidentifying restrictions are printed.
- If the PLOT option is used, plots of residual against each regressor are printed.
- If the COVB or CORRB options are specified, the results for each model also include the covariance or correlation matrix of the parameter estimates. For systems methods like 3SLS and FIML, the COVB and CORB output is printed for the whole system after the output for the last model, instead of separately for each model.

The third-stage output for 3SLS, SUR, IT3SLS, ITSUR, and FIML does not include the analysis-of-variance table. When a systems method is used, the second-stage output does not include the optional output, except for the COVB and CORRB matrices.

ODS Table Names

PROC SYSLIN assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. If the estimation method used is 3SLS, IT3SLS, ITSUR or SUR, you can obtain tables by specifying ODS OUTPUT CorrResiduals, InvCorrResiduals, InvCovResiduals.

Table 29.2 ODS Tables Produced in PROC SYSLIN

ODS Table Name	Description	Option
ANOVA	Summary of the SSE, MSE for the equations	default
AugXPXMat	Model crossproducts	XPX or USSCP
AutoCorrStat	Autocorrelation statistics	DW
ConvergenceStatus	Convergence status	default
CorrB	Correlations of parameters	CORRB
CorrResiduals	Correlations of residuals	
CovB	Covariance of parameters	COVB
CovResiduals	Covariance of residuals	
EndoMat	Endogenous variables	REDUCED
ExogMat	Exogenous variables	REDUCED
FitStatistics	Statistics of fit	default
InvCorrResiduals	Inverse correlations of residuals	
InvCovResiduals	Inverse covariance of residuals	
InvEndoMat	Inverse endogenous variables	REDUCED
InvXPX	$X'X$ inverse for system	I
IterHistory	Iteration printing	ITPRINT
MissingValues	Missing values generated by the program	default
ModelVars	Name and label for the model	default
ParameterEstimates	Parameter estimates	default
RedMat	Reduced form	REDUCED
SimpleStatistics	Descriptive statistics	SIMPLE
SSCP	Model crossproducts	XPX or USSCP
TestResults	Test for overidentifying restrictions	
Weight	Weighted model statistics	

ODS Graphics

This section describes the use of ODS for creating graphics with the SYSLIN procedure.

ODS Graph Names

PROC SYSLIN assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in [Table 29.3](#).

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 29.3 ODS Graphics Produced by PROC SYSLIN

ODS Graph Name	Plot Description
DiagnosticsPanel	All applicable plots listed below
ActualByPredicted	Predicted versus actual plot
QQPlot	Q-Q plot of residuals
ResidualHistogram	Histogram of the residuals
ResidualPlot	Residual plot

Examples: SYSLIN Procedure

Example 29.1: Klein's Model I Estimated with LIML and 3SLS

This example uses PROC SYSLIN to estimate the classic Klein Model I. For a discussion of this model, see Theil (1971). The following statements read the data.

```
*-----Klein's Model I-----*
| By L.R. Klein, Economic Fluctuations in the United States, 1921-1941 |
| (1950), NY: John Wiley.  A macro-economic model of the U.S. with   |
| three behavioral equations, and several identities. See Theil, p.456. |

```

The following statements estimate the Klein model using the limited information maximum likelihood method. In addition, the parameter estimates are written to a SAS data set with the OUTEST= option.

```

proc syslin data=klein outest=b liml;
  endogenous c p w i x wsum k y;
  instruments klag plag xlag wp g t yr;
  consume: model c = p plag wsum;
  invest:  model i = p plag klag;
  labor:   model w = x xlag yr;
run;

proc print data=b;
run;

```

The PROC SYSLIN estimates are shown in [Output 29.1.1](#) through [Output 29.1.3](#).

Example 29.2: Grunfeld's Model Estimated with SUR

The following example was used by Zellner in his classic 1962 paper on seemingly unrelated regressions. Different stock prices often move in the same direction at a given point in time. The SUR technique might provide more efficient estimates than OLS in this situation.

The following statements read the data. (The prefix GE stands for General Electric and WH stands for Westinghouse.)

Example 29.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics. This is a continuation of the section “[Example 29.1: Klein’s Model I Estimated with LIML and 3SLS](#)” on page 2108. These graphical displays are requested by specifying the ODS GRAPHICS statement before running PROC SYSLIN. For information about the graphics available in the SYSLIN procedure, see the section “[ODS Graphics](#)” on page 2107.

The following statements show how to generate ODS graphics plots with the SYSLIN procedure. The plots of residuals for each one of the equations in the model are displayed in [Figure 29.3.1](#) through [Figure 29.3.3](#).

Overview: TIMEDATA Procedure

The TIMEDATA procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format.

After the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple differencing, seasonal differencing, or both. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

The TIMEDATA procedure is very similar to the TIMESERIES procedure. However, unlike the TIMESERIES procedure (which enables you to perform a variety of standard time series analysis techniques), the TIMEDATA procedure enables you to define your own analyses using SAS programming statements.

By default, the TIMEDATA procedure provides no further analyses.

The TIMEDATA procedure forms time series vectors and then provides these vectors as SAS data arrays for subsequent processing by your SAS programming statements. Your programming statements are processed independently for each BY group. The TIMEDATA procedure is like the SAS DATA step for time series data. The SAS DATA step processes data by each row; the TIMEDATA procedure processes time series vectors.

As part of your SAS programming statements, you can include user-defined functions and subroutines created by the FCMP procedure. Additionally, you can use the RUN_MACRO subroutine provided by the FCMP procedure to submit SAS statements that use any SAS procedures.

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

Getting Started: TIMEDATA Procedure

This section outlines the use of the TIMEDATA procedure and gives a cursory description of some of the analysis techniques that you can perform on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMEDATA procedure can form time series as follows:

```
PROC TIMEDATA DATA=<input-data-set>
              OUT=<output-data-set>;
  BY <list-of-BY-variables>;
  ID <time-ID-variable> INTERVAL=<frequency>
    ACCUMULATE=<statistic>;
  VAR <time-series-variables>;
  /* programming statements */
RUN;
```

The TIMEDATA procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS).

Time-stamped transactional data are recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series, such as daily, weekly, or monthly.

Suppose that a bank wants to analyze the transactions that are associated with each of its customers over time. Further, suppose that the data set `Work.Transactions` contains four variables that are related to these transactions: `Customer`, `Date`, `Withdrawals`, and `Deposits`. The following examples illustrate possible ways to analyze these transactions by using the TIMEDATA procedure.

The following TIMEDATA procedure statements accumulate the time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (`Withdrawals` and `Deposits`):

```
proc timedata data=transactions
    out=timeseries
    outarray=arrays;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
  outarrays balance;

  balance[1] = deposits[1] - withdrawals[1];
  do t = 2 to _LENGTH_;
    balance[t] = balance[t-1] + (deposits[t] - withdrawals[t]);
  end;

run;
```

The `OUT=TIMESERIES` option specifies that the resulting time series data for each customer are to be stored in the data set `Work.Transactions`. The `OUTARRAY=ARRAYS` option specifies that the resulting time series data along with a newly created variable, `Balance`, are to be stored in the data set `Work.Arrays`. The `INTERVAL=DAY` option specifies that the transactions are to be accumulated on a daily basis. The `ACCUMULATE=TOTAL` option specifies that the sum of the transactions is to be calculated. After the transactional data are accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the resulting time series data.

For example, the following statements use the ARIMA procedure to model and forecast each customer's balance data by using an $ARIMA(1,0,0)(0,1,0)_s$ model (where the number of seasons is $s=7$ days in a week):

```
proc arima data=arrays;
  by customer;
  identify var=balance(7) noprint;
  estimate p=(1) outest=estimates noprint;
  forecast id=date interval=day out=forecasts;
quit;
```

The `OUTEST=ESTIMATES` data set contains the parameter estimates of the model specified. The `OUT=FORECASTS` data set contains forecasts based on the model specified. See the SAS/ETS ARIMA procedure for more detail.

By default, the TIMEDATA procedure produces no printed output.

Syntax: TIMEDATA Procedure

The following statements are available in the TIMEDATA Procedure:

```

PROC TIMEDATA options ;
  BY variables ;
  ID variable INTERVAL= interval-option ;
  FCMPOPT options ;
  OUTARRAYS array-name-list ;
  OUTSCALARS scalar-name-list ;
  VAR variable-list / options ;
  Programming Statements ;

```

Functional Summary

Table 30.1 summarizes the statements and options that control the TIMEDATA procedure.

Table 30.1 TIMEDATA Functional Summary

Description	Statement	Option

PROC TIMEDATA Statement

PROC TIMEDATA *options* ;

The following *options* can be used in the PROC TIMEDATA statement:

CYCLETYPE=*option*

specifies the indexing of each time series with respect to life-cycle. By default, CYCLETYPE=BOL.

The following CYCLETYPE= *options* are available:

BOL	indexes the time series by the beginning of life. The first time value is 1. The following values are incremented by 1.
MOL	indexes the time series by the middle of life. The middle time value is zero. The preceding values are decremented by 1. The following values are incremented by 1.
EOL	indexes the time series by the end of life. The last time value is 1. The preceding values are incremented by 1.

The CYCLETYPE= option specifies the indexing of the `_CYCLE_` variable contained in the OUTARRAY= data set and the predefined array `_CYCLE_`.

DATA=*SAS-data-set*

names the SAS data set that contains the input data from which the procedure creates the time series. If the DATA= option is not specified, the most recently created SAS data set is used.

LEAD=*n*

specifies the number of periods ahead to forecast (forecast lead or horizon) used to extend the data set. The default is LEAD=0.

The LEAD= value is relative to the last observation in the input data set and not to the last nonmissing observation of a particular series.

MAXERROR=*number*

limits the number of warning and error messages that are produced during the execution of the procedure to the specified *number*. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress recurring messages.

OUT=*SAS-data-set*

names the output data set to contain the time series variables specified in the subsequent VAR statements. If BY variables are specified, they are also included in the OUT= data set. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the INTERVAL= option or the ACCUMULATE= option or both in the ID statement. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTARRAY=*SAS-data-set*

names the output data set to contain the time series vectors listed in the VAR and OUTARRAYS statements.

The OUTARRAY= data set contains the variables specified in the BY, ID, and VAR statements in addition to the arrays that are specified in the OUTARRAYS statements.

OUTSCALAR=SAS-data-set

names the output data set to contain the scalar names listed in the OUTSCALARS statements.

The OUTSCALAR= data set contains the variables specified in the BY statement and the scalars that are specified in the OUTSCALARS statements.

OUTPROCINFO=SAS-data-set

names the output data set to summarize information in the SAS log, specifically the number of notes, errors, and warnings and the number of series processed, analyses requested, and analyses failed.

OUTSUM=SAS-data-set

names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the ACCUMULATE= option, the SETMISSING= option, or both are specified in the ID or VAR statements. The OUTSUM= data set is particularly useful when analyzing large numbers of series and a summary of the results is needed.

PLOTS=option | (options)

specifies the univariate graphical output desired. By default, the TIMEDATA procedure produces no graphical output. The PLOTS= option produces results that are similar to the data sets shown in parentheses next to the following *options*:

ARRAYS plots the time series (OUT= data set).

ALL same as PLOTS=(ARRAYS).

For example, PLOTS=ARRAYS plots the time series. The PLOTS= option produces graphical output for these results by using the Output Delivery System (ODS).

PRINT=option | (options)

specifies the printed output desired. By default, the TIMEDATA procedure produces no printed output. The PRINT= option produces results that are similar to the data sets shown in parentheses next to the following *options*:

ARRAYS prints the arrays table (OUTARRAY= data set).

SCALARS prints the scalars table (OUTSCALAR= data set).

SUMMARY prints the descriptive statistics table for all time series (OUTSUM= data set).

ALL same as PRINT=(ARRAYS SCALARS SUMMARY).

For example, PRINT=SCALARS prints the scalars specified in the OUTSCALARS statement. The PRINT= option produces printed output for these results by using the Output Delivery System (ODS).

SEASONALITY=number

specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is 1 (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

BY Statement

You can include a BY statement with PROC TIMEDATA to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMEDATA procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FCMPOPT Statement

FCMPOPT *options* ;

The FCMPOPT statement specifies the following *options* that are related to user-defined functions and subroutines:

QUIET=ON | OFF

specifies whether the nonfatal errors and warnings that are generated by the user-defined SAS language functions and subroutines are printed to the log. Nonfatal errors are usually associated with operations with missing values. The default is QUIET=ON.

TRACE=ON | OFF

specifies whether the user-defined SAS language functions and subroutines tracings are printed to the log. Tracings are the results of every operation executed. This option is generally used for debugging. The default is TRACE=OFF.

ID Statement

ID *variable* **INTERVAL=***interval* < *options* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement *options* also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The information specified affects all variables listed in subsequent VAR statements. If the ID statement is specified, the INTERVAL= must also be used. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

You can specify following *options* in the ID statement:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default. Observations are accumulated based on the:
TOTAL	total sum of their values.
AVERAGE AVG	average of their values.
MINIMUM MIN	minimum of their values.
MEDIAN MED	median of their values.
MAXIMUM MAX	maximum of their values.
N	number of nonmissing observations.
NMISS	number of missing observations.
NOBS	number of observations.
FIRST	first of their values.
LAST	last of their values.
STDDEV STD	standard deviation of their values.
CSS	corrected sum of squares of their values.
USS	uncorrected sum of squares of their values.

If the `ACCUMULATE=` option is specified, the `SETMISSING=` option is useful for specifying how accumulated missing values are to be treated. If missing values should be interpreted as zero, then `SETMISSING=0` should be used. The section “[Details: TIMEDATA Procedure](#)” on page 2138 describes accumulation in greater detail.

ALIGN=option

controls the alignment of SAS dates that are used to identify output observations. The `ALIGN=` option accepts the following values: `BEGINNING` | `BEG` | `B`, `MIDDLE` | `MID` | `M`, and `ENDING` | `END` | `E`. `BEGINNING` is the default.

END=option

specifies a SAS date or datetime value that represents the end of the data. If the last time ID variable value is less than the `END=` value, the series is extended with missing values. If the last time ID variable value is greater than the `END=` value, the series is truncated. For example, `END=&sysdate` uses the automatic macro variable `SYSDATE` to extend or truncate the series to the current date. You can specify the `START=` and `END=` options to ensure that the data that are associated within each `BY` group contain the same number of observations.

FORMAT=format

specifies the SAS format for the time ID values. If the `FORMAT=` option is not specified, the default format is inferred from the `INTERVAL=` option.

INTERVAL=interval

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then `INTERVAL=QTR` should be used. If the `SEASONALITY=` option is not specified in the `PROC TIMEDATA` statement, the length of the seasonal cycle is implied from the `INTERVAL=` option. For example, `INTERVAL=QTR` implies a seasonal cycle of length 4. If the `ACCUMULATE=` option is also specified, the `INTERVAL=` option determines the time periods for the accumulation of observations. The `INTERVAL=` option is required and must be specified in the `ID` statement.

NOTSORTED

specifies that the time ID values not be in sorted order. The `TIMEDATA` procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING=option | number

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series. If a *number* is specified, missing values are set to the *number*. If a missing value indicates an unknown value, specify `SETMISSING=MISSING`. If a missing value indicates a zero value, specify `SETMISSING=0`. You would typically use `SETMISSING=0` for transactional data because no recorded data usually implies no activity. You can use the following *options* to determine how missing values are assigned. Missing values are set to:

MISSING	a missing value. This is the default.
AVERAGE AVG	the accumulated average value.
MINIMUM MIN	the accumulated minimum value.
MEDIAN MED	the accumulated median value.
MAXIMUM MAX	the accumulated maximum value.

FIRST	the accumulated first nonmissing value.
LAST	the accumulated last nonmissing value.
PREVIOUS PREV	the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START=option

specifies a SAS date or datetime value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, missing values are added at the beginning of the series. If the first time ID variable value is less than the START= value, the series is truncated. You can specify the START= and END= options to ensure that data associated with each BY group contain the same number of observations.

ZEROMISS=option

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series. The following *options* can also be used to determine how beginning and ending zero values are assigned:

NONE	Beginning and ending zeros are unchanged. This is the default.
LEFT	Beginning zeros are set to missing.
RIGHT	Ending zeros are set to missing.
BOTH	Both beginning and ending zeros are set to missing.

If the accumulated series is all missing or zero, the series is not changed.

OUTARRAYS Statements

OUTARRAYS *array-name-list* ;

Each array name listed in an OUTARRAYS statement specifies a numeric output array variable to be stored in the OUTARRAY= data set. You can include any number of OUTARRAYS statements.

Your programming statements can create and use any number of arrays. Only arrays that are listed in the OUTARRAYS statement are predefined and included in your output. The arrays are initialized to missing values.

OUTSCALARS Statements

OUTSCALARS *scalar-name-list* ;

Each scalar name listed in an OUTSCALARS statement specifies a numeric output scalar variable to be stored in the OUTSCALAR= data set. You can include any number of OUTSCALARS statements.

Your programming statements can create and use any number of scalars. Only scalars that are listed in the OUTSCALARS statement are predefined and included in your output. The scalars are initialized to missing values.

VAR Statements

VAR *variable-list* < / *options* > ;

The VAR statements list the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR statement. You can specify any number of VAR statements. You can also specify the following *options* in the VAR statements:

ACCUMULATE=*option*

specifies how the data set observations are to be accumulated within each time period for the variables listed in the VAR statement. If the ACCUMULATE= option is not specified in the VAR statement, accumulation is determined by the ACCUMULATE= option in the ID statement. See the ACCUMULATE= option in the ID statement for more details.

DIF=(*numlist*)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first then third order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option.

SDIF=(*numlist*)

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first then third order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option.

SETMISS=*option* | *number*

SETMISSING= *option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series for variables listed in the VAR statement. If the SETMISSING= option is not specified in the VAR statement, missing values are set based on the SETMISSING= option in the ID statement. See the SETMISSING= option in the ID statement for more details.

TRANSFORM=*option*

specifies the time series transformation to be applied to the accumulated time series. You can specify the following transformation *options*:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation
SQRT	Square-root transformation
LOGISTIC	Logistic transformation
BOXCOX (<i>n</i>)	Box-Cox transformation with parameter number where <i>n</i> is between –5 and 5

When the TRANSFORM= option is specified, the time series must be strictly positive.

ZEROMISS=*option*

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the VAR statement. If the ZEROMISS= option is not specified in the VAR statement, beginning and ending zero values are set based on the ZEROMISS= option of the ID statement. If the ZEROMISS= option is not specified in the ID statement or the VAR statement, no zero value interpretation is performed. See the ID statement ZEROMISS= option for more details.

Program Statements

Program Statements ;

You can use most of the programming statements that are allowed in the SAS DATA step.

Details: TIMEDATA Procedure

The TIMEDATA procedure forms time series data from transactional data. The accumulated time series can then be processed using SAS programming statements. The resulting time series can then be analyzed using time series techniques. The data are analyzed using the following steps (the relevant option is listed to the left):

- | | |
|---------------------------------|---|
| 1. accumulation | ACCUMULATE= option in the ID or VAR statement |
| 2. missing value interpretation | SETMISSING= option in the ID or VAR statement |
| 3. time series transformation | TRANSFORM= option in the VAR statement |
| 4. time series differencing | DIF= and SDIF= options in the VAR statement |
| 5. program execution | SAS programming statements |
| 6. descriptive statistics | OUTSUM= option |

Accumulation

If the ACCUMULATE= option in the ID or VAR statement is specified, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option in the ID statement. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```
19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20
```

If the INTERVAL=MONTH is specified, all of the preceding observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is:

```
01MAR1999    40
01APR1999    .
01MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is:

O1MAR1999	20
O1APR1999	.
O1MAY1999	30

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is:

O1MAR1999	10
O1APR1999	.
O1MAY1999	20

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is:

O1MAR1999	20
O1APR1999	.
O1MAY1999	20

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is:

O1MAR1999	30
O1APR1999	.
O1MAY1999	50

If the ACCUMULATE=FIRST option is specified, the resulting time series is:

O1MAR1999	10
O1APR1999	.
O1MAY1999	50

If the ACCUMULATE=LAST option is specified, the resulting time series is:

O1MAR1999	30
O1APR1999	.
O1MAY1999	20

If the ACCUMULATE=STDDEV option is specified, the resulting time series is:

O1MAR1999	14.14
O1APR1999	.
O1MAY1999	17.32

As you can see from the preceding examples, the accumulated time series can have missing values even though the data set observations contain no missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no value—that is, zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. Specify SETMISSING=0 when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

Four transformations are available for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation.

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation.

$$w_t = \ln(cy_t / (1 - cy_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square root is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed by using the SAS/ETS EXPAND procedure.

Time Series Differencing

After you optionally transform the series, you can simply or seasonally difference the accumulated series by using the VAR statement DIF= and SDIF= options. For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally, when y_t is strictly positive and the TRANSFORM=, DIF=, and SDIF= options are combined in the VAR statements, the transformation operation is performed before the differencing operations.

Summary Statistics

You can compute summary statistics from the working series by specifying the OUTSUM= option or PRINT=SUMMARY.

Programming Statements

You can typically use most of the SAS programming statements and SAS functions that you can use in a DATA step for defining the FCMP functions and subroutines. However, there are a few differences in the capabilities of the DATA step and the FCMP procedure. Refer to the documentation of the FCMP procedure to learn more.

All variables listed in the ID and VAR statements are assigned as predefined arrays for subsequent processing. Additionally, all of the array names listed in the OUTARRAYS statements and all of the scalars names listed in the OUTSCALARS statements are assigned as predefined symbols for subsequent processing.

Predefined Symbols

In addition to both the predefined arrays listed in the OUTARRAYS statements and also the predefined scalars listed in the OUTSCALARS statements, the TIMEDATA procedure creates the following predefined symbols for use in the program statements:

Predefined Scalar Values

<code>_FORMAT_</code>	time format either implied by the INTERVAL= option or specified by the FORMAT= option in the ID statement
<code>_INTERVAL_</code>	time interval specified by the INTERVAL= option in the ID statement
<code>_LEAD_</code>	forecast horizon or lead specified by the LEAD= option in the PROC TIMEDATA statement
<code>_LENGTH_</code>	length of the time series associated with the current BY group
<code>_SERIES_</code>	series index or BY group counter
<code>_SEASONALITY_</code>	length of the seasonal cycle specified by the SEASONALITY= option PROC TIMEDATA statement or implied by the INTERVAL= option in the ID statement

Predefined Array Values

<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	season index values
<code>_CYCLE_</code>	life-cycle index values

Data Set Output

The TIMEDATA procedure can create the OUT=, OUTARRAY=, OUTPROCINFO=, OUTSCALAR=, and OUTSUM= data sets. In general, these data sets contain the variables listed in the BY statement. If an analysis step that is related to an output step fails, the values of this step are not recorded or are set to missing in the related output data set but appropriate error or warning messages (or both) are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, or VAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option.

OUTARRAY= Data Set

The OUTARRAY= data set contains the variables specified in the BY, ID, or VAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option. Additionally, the OUTARRAY= data set contains the variables that are specified in the OUTARRAYS statements and the following variables:

<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>_SERIES_</code>	series index or BY group index
<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	season index values
<code>_CYCLE_</code>	life-cycle index values
Array-Variable-Names	variables listed in the OUTARRAYS statement

The OUTARRAY= data set contains the arrays that are related to the (accumulated) time series.

OUTPROCINFO= Data Set

The OUTPROCINFO= data set contains information about the run of the TIMEDATA procedure. The following variables are present:

SOURCE	name of the procedure, in this case TIMEDATA
NAME	name of the item being reported
LABEL	descriptive label for the item in _NAME_
STAGE	current stage of the procedure (for TIMEDATA this is set to ALL)
VALUE	value of the item specified in _NAME_

OUTSCALAR= Data Set

The OUTSCALAR= data set contains the variables specified in the BY statement. Additionally, the OUTSCALAR= data set contains the variables that are specified in the OUTSCALARS statements and following variables:

STATUS	status flag that indicates whether the requested analyses were successful
SERIES	series index or BY group counter
Scalar-Variable-Names	variables listed in the OUTSCALARS statement.

The OUTSCALAR= data set contains the scalars that are related to the (accumulated) time series.

OUTSUM= Data Set

The OUTSUM= data set contains the variables that are specified in the BY statement as and the variables in the following list. The OUTSUM= data set records the descriptive statistics for each variable specified in a VAR statement. Variables related to descriptive statistics are based on the ACCUMULATE= and SETMISSING= options in the ID and VAR statements:

NAME	variable name
STATUS	status flag that indicates whether the requested analyses were successful
SERIES	count of the series processed in each BY group
START	the starting date of each series
END	the ending date of each series
STARTOBS	the beginning observation number of each series
ENDOBS	the ending observation number of each series
NOBS	number of observations
N	number of nonmissing observations

NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
AVG	average value
STDDEV	standard deviation

The OUTSUM= data set contains the descriptive statistics of the (accumulated) time series.

STATUS Variable Values

The `_STATUS_` variable that appears in the OUTSUM= data set contains a value that specifies whether the analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	Analysis was successful.
3000	Accumulation failed.
4000	Missing value interpretation failed.
6000	Series is all missing.
7000	Transformation failed.
8000	Differencing failed.
9000	Descriptive statistics could not be computed.

Printed Output

The TIMEDATA procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= option associated with the PROC TIMEDATA statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error or warning messages or both are recorded in the log. The printed output is similar to the output data set as follows.

PRINT=ARRAYS	prints the arrays similar to the OUTARRAY= data set.
PRINT=SCALARS	prints the scalars similar to the OUTSCALAR= data set.
PRINT=SUMMARY	prints the summary statistics similar to the OUTSUM= data set.

ODS Table Names

Table 30.2 relates the PRINT= options to ODS tables:

Table 30.2 ODS Tables Produced in PROC TIMEDATA

ODS Table Name	Description	Statement	Option
Arrays	Arrays Table	PRINT	ARRAYS
Scalars	Scalars Table	PRINT	SCALARS
StatisticsSummary	Statistics summary	PRINT	SUMMARY

The tables are related to a all series within a BY group.

Arrays Table

The arrays table (Arrays) illustrate the arrays in tabular form with respect to the Time ID values.

Scalars Table

The scalars table (Scalars) illustrate the scalars in tabular form.

Statistics Summary Table

The summary statistics table (StatisticsSummary) illustrate the summary statistics for each array in tabular form.

ODS Graphics Names

This section describes the graphical output produced by the TIMEDATA procedure. PROC TIMEDATA assigns a name to each graph it creates. These names are listed in Table 30.3.

Table 30.3 ODS Graphics Produced by PROC TIMEDATA

ODS Graph Name	Plot Description	Statement	Option
ArrayPlot	Array Plot	PLOTS	ARRAY

The graphs are related to a single series within a BY group.

Array Plots

The array plots (ArrayPlot) illustrate time series associated with each array. The horizontal axis represents the time ID values, and the vertical axis represents the time series values.

Examples: TIMEDATA Procedure

Example 30.1: Accumulating Transactional Data into Time Series Data

This example uses the TIMEDATA procedure to accumulate time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment and decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set `Work.Retail` contains variables `Store` and `Timestamp` and numerous other numeric transaction variables. The BY variable `Store` contains values that break up the transactions into groups (BY groups). The time ID variable `Timestamp` contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables `Store` and `Timestamp`. The following statements form monthly time series from the transactional data based on the median value (`ACCUMULATE=MEDIAN`) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of to missing (`SETMISS=0`) and only transactions recorded between the first day of 1998 (`START='01JAN1998'D`) and last day of 2000 (`END='31JAN2000'D`) are considered and, if needed, extended to include this range.

```
proc timedata data=retail out=mseries;
  by store;
  id timestamp interval=month
      accumulate=median
      setmiss=0
      start='01jan1998'd
      end  ='31dec2000'd;
  var item1-item8;
run;
```

The monthly time series data are stored in the data `Work.Mseries`. Each BY group associated with the BY variable `Store` contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the values `Store`, `Timestamp`, and each of the analysis variables in the input data set.

After each set of transactions has been accumulated to form a corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named `Storeitem`:

```
proc expand data=mseries out=smoothed from=month;
  by store;
  id date;
  convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series are stored in the data set `Work.Smoothed`. The variable `Smooth` contains the smoothed series.

If the time ID variable `Timestamp` contains SAS datetime values instead of SAS date values, the `INTERVAL=`,

START=, and END= options must be changed accordingly and the following statements could be used:

```
proc timedata data=retail out=tseries;
  by store;
  id timestamp interval=dtmonth
      accumulate=median
      setmiss=0
      start='01jan1998:00:00:00'dt
      end  ='31dec2000:00:00:00'dt;
  var _numeric_;
run;
```

The monthly time series data are stored in the data Work.Tseries, and the time ID values use a SAS datetime representation.

Example 30.2: Using User-Defined Functions and Subroutines

This example uses the TIMEDATA procedure with a user-defined function and subroutine created by the FCMP procedure.

The following statements use the FCMP procedure to create a user-defined subroutine and a user-defined function. Mylog is a subroutine that log-transforms a time series. Mymean is a function that compute the mean of a time series. The subroutine and function definitions are stored in the data set Work.Timefnc. The OPTIONS statement loads the subroutine and function definitions.

```
proc fcmp outlib=work.timefnc.funcs;

  subroutine mylog(actual[*], transform[*]);
    outargs transform;
    actlen  = DIM(actual);
    do t = 1 to actlen;
      transform[t] = log(actual[t]);
    end;
  endsub;

  function mymean(actual[*]);
    actlen  = DIM(actual);
    sum = 0;
    do t = 1 to actlen;
      sum = sum + actual[t];
    end;
    return( sum / actlen );
  endsub;

run;
quit;

options cmplib = work.timefnc;
```

The input data set Sashelp.Air contains the variables Air and Date. The time series is recorded monthly.

The following statements form quarterly time series from the monthly series based on the median value (ACCUMULATE=TOTAL) of the transactions recorded with each time period and assign the SAS time format (FORMAT=YYMMDD.). The OUTARRAYS statement specifies the Logair and Myair arrays as output. The OUTSCALARS statement specifies the Mystats scalars as output. The other arrays and scalars are not part of the output. The subsequent programming statements create the output arrays and scalars. The PRINT=(ARRAYS SCALARS) prints the output arrays and scalars.

```
proc timedata data=sashelp.air out=work.air
    print=(scalars arrays);
    id date interval=qtr acc=t format=yyymmdd.;
    vars air;
    outarrays logair myair;
    outscalars mystats;

    call mylog(air,logair);
    do t = 1 to dim(air);
        myair[t] = air[t] - logair[t];
    end;
    mystats= mymean(air);

run;
```

Example 31.3: Examining Multiple BY Groups	2171

Overview: TIMEID Procedure

The TIMEID procedure evaluates a variable in an input data set for its suitability as a time ID variable in SAS procedures and solutions that are used for time series analysis. PROC TIMEID assesses how well a time interval specification fits SAS date or datetime values, or observation numbers used to index a time series. The time interval used in this analysis can be either specified explicitly as input to PROC TIMEID or inferred by the procedure based on values of the time ID variable. The TIMEID procedure produces diagnostic information in the form of data sets and ODS tabular and plotted output. These diagnostic results summarize characteristics of the time ID variable that can help determine its use as an index in other time series procedures and solutions.

PROC TIMEID is intended for use as a tool to either identify the time interval of a variable or prepare problematic data sets for use in subsequent time series analyses. In particular, this procedure can be used to investigate inconsistencies between time ID values and the ID statement options used in other SAS procedures and solutions.

Getting Started: TIMEID Procedure

When a data set contains a time ID variable with corrupted, missing, or duplicate values, PROC TIMEID can help isolate and identify these problematic observations. For a data set with a small number of ID variable anomalies and a known time interval, a graphical depiction of the problem areas can be created using the following statements:

```
proc timeid data=<input-dataset> plot=values;  
  id <time-ID-variable> interval=<frequency>;  
run;
```

For larger data sets whose quality is unknown, it can be useful to get a general overview of the relative number of observations with problematic time ID values. The following statements graphically summarize the prevalence of anomalous time ID values:

```
proc timeid data=<input-dataset> plot=(intervalcounts offsets spans);  
  id <time-ID-variable> interval=<frequency>;  
run;
```

When prior knowledge of the time interval that separates observations is incomplete, PROC TIMEID can be used to infer the interval by omitting the INTERVAL= option from the ID statement as in the following statements:

```
proc timeid data=<input-dataset> outinterval=<output-dataset>;  
  id <time-ID-variable>;  
run;
```

Syntax: TIMEID Procedure

The TIMEID procedure uses the following statements:

```
PROC TIMEID options ;  
  BY variables ;  
  ID variable <options> ;
```

Functional Summary

The statements and options that control the TIMEID procedure are summarized in [Table 31.1](#).

Table 31.1 Syntax Summary

Description	Statement	Option
Statements		
Specifies data sets and options	PROC TIMEID	
Specifies BY-group processing	BY	
Specifies the time ID variable	ID	
Data Set Options		
Specifies the input data set	PROC TIMEID	DATA=
Specifies the maximum number of ID values to analyze	PROC TIMEID	NBYOBS=
Specifies the output frequency count data set	PROC TIMEID	OUTFREQ=
Specifies the output interval data set	PROC TIMEID	OUTINTERVAL=
Specifies the detailed output interval data set	PROC TIMEID	OUTINTERVALDETAILS=
Time ID Options		
Specifies the interval alignment	ID	ALIGN=
Specifies that duplicate time ID values can be present in DATA= data set	ID	DUPLICATES
Specifies the time interval between observations	ID	INTERVAL=
Specifies that time ID variable values are not sorted	ID	NOTSORTED
Printing and Plotting Options		
Specifies the time ID format	ID	FORMAT=
Specifies the types of graphical output	PROC TIMEID	PLOT=
Specifies the types of printed output	PROC TIMEID	PRINT=
Miscellaneous Options		
Limits error and warning messages	PROC TIMEID	MAXERROR=

PROC TIMEID Statement

PROC TIMEID *options* ;

The following options can be used in the PROC TIMEID statement:

DATA=SAS-data-set

names the SAS data set that contains the input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used.

MAXERROR=number

limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress recurring messages.

NBYOBS=number

limits the number of observations that are used to analyze the time ID variable. The NBYOBS= option should be used instead of the OBS= data set option when BY variables are specified. The NBYOBS= option excludes observations from incomplete BY groups in the analysis. This option guarantees that any truncation of the DATA= data set occurs at a BY-group boundary. Only BY groups that are completely contained within the first *number* of observations are processed. When the NBYOBS= option is omitted, all observations are processed.

OUTFREQ=SAS-data-set

names the output data set to contain the frequency counts of each unique value of the time ID variable. The frequency counts are performed on time ID values that are recorded in the DATA= data set. The time ID values are not aligned with respect to an interval prior to computation of the frequency counts. See the section “[OUTFREQ= Data Set](#)” on page 2158 for details.

OUTINTERVAL=SAS-data-set

names the output data set to contain the time ID interval information that is summarized across all BY groups in the DATA= data set. See the section “[OUTINTERVAL= Data Set](#)” on page 2158 for details.

OUTINTERVALDETAILS=SAS-data-set

names the output data set to contain the time ID interval information for each BY group. See the section “[OUTINTERVALDETAILS= Data Set](#)” on page 2159 for details.

PLOT(*global-option*)=*request-option* | (*request-options*)

specifies the graphical output desired. By default, the TIMEID procedure produces no graphical output. The following *global-options* are available:

UNPACK | UNPACKPANELS suppresses paneling.

By default, multiple plots can appear in some output panels. Specify UNPACKPANELS to get each plot in a separate panel. The following plot *request-options* are available:

COUNTS | INTCNTS | INTERVALCOUNTS

plots a histogram of the time ID interval counts.

OFFSETS

plots a histogram of the time offsets for the time ID values.

PERIODS SPANS	plots a histogram of the spans between adjacent time ID values.
VALUES	plots a panel of the counts, offsets, and spans for each of the time ID values.
ALL	is equivalent to specifying PLOT=(INTERVALCOUNTS SPANS OFFSETS VALUES).

See the section “[Time ID Diagnostics](#)” on page 2155 for details.

PRINT=option | (options)

specifies the printed output desired. By default, the TIMEID procedure produces no printed output. The following printing options are available:

COUNTS INTCNTS INTERVALCOUNTS	prints a table that contains the counts of time ID values per interval.
INTERVAL	prints a summary of information about the time interval.
OFFSETS	prints a table that contains the time offsets for the time ID values.
PERIODS SPANS	prints tables that contain statistics on the spans between adjacent time ID values.
VALUES	prints tables that contain offset span and count information for the time ID values.
ALL	is equivalent to specifying PRINT=(INTERVALCOUNTS SPANS INTERVAL OFFSETS VALUES).

See the section “[Time ID Diagnostics](#)” on page 2155 for details.

BY Statement

BY variables ;

A BY statement can be used with PROC TIMEID to obtain separate analyses for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMESERIES procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variable* < *options* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. The ID statement options specify how the time ID values are spaced and aligned relative to a SAS date or datetime interval. The INTERVAL= option specifies the fundamental spacing that is used as the basis for counting intervals, offsets, and spans in the data. Specification of the ID variable in an ID statement is required.

ALIGN=*alignment*

specifies the alignment of the identifying SAS date or datetime that is used to represent intervals. The value of the ALIGN= option is used in the analysis of the time ID variable. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, ENDING | END | E, and INFER. For example, ALIGN=BEGIN specifies that the identifying date for the interval is the beginning date in the interval. If the ALIGN= option is not specified, then the default alignment is BEGIN. ALIGN=INFER specifies that the alignment of values within time intervals be inferred from the time ID values.

DUPLICATES

specifies that multiple observations in the DATA= data set can fall within the same time interval as defined by the time ID variable. When this option is omitted and multiple time ID values are encountered in a single time interval, error messages are written to the SAS log.

FORMAT=*format*

specifies the SAS format used for time ID values in the data sets and in printed and plotted output that is generated by PROC TIMEID. If the FORMAT= option is not specified, the format applied to the input time ID variable is used. If neither of these formats is specified, the format is inferred from the INTERVAL= option.

INTERVAL=*interval*

specifies the proposed time interval and shift that describe the time ID values in the input data set. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about the intervals that can be specified. See the section “[Time ID Diagnostics](#)” on page 2155 for more information about how the INTERVAL= option determines the nature of diagnostic information reported by the TIMEID procedure.

If no interval is specified, the procedure attempts to infer an interval from the input time ID values. See the section “[Inferring Time Intervals and Alignments](#)” on page 2157 for details about how the time interval is inferred.

NOTSORTED

specifies that the observations in the DATA= data set are not sorted by the time ID variable. When this option is omitted, error messages are generated for time ID values that are not sorted in ascending order.

Details: TIMEID Procedure

Time ID Diagnostics

For a specified time interval, PROC TIMEID decomposes the raw time ID values in an input data set into the following three quantities, whose values are represented by nonnegative integers at each unique time ID value in the input series:

interval counts the number of observations that share each time interval in the data set.

offsets the numerical difference between a time ID value and the aligned value for that time interval. The unit of measure used to express this distance is days for date values and seconds for datetime values. The offset is computed for each time ID value, t_i , by using the following SAS expression:

$$\text{offset}_i = t_i - \text{INTNX}(\text{interval}, t_i, 0, \text{alignment})$$

spans the number of intervals between each time ID value and the previous time ID value. The spans value is equivalent to the number returned by the following SAS expression:

$$\text{spans}_i = \text{INTCK}(\text{interval}, t_{i-1}, t_i)$$

Diagnostic Output Representation

The TIMEID procedure produces time ID diagnostics as both time-ID-based and count-based frequency distributions to expose many of the possible problems that can occur in a time ID variable. The time-ID-based frequency distributions that are generated with the PLOT= option provide a detailed view of time ID values that can isolate problems with specific ID values. [Figure 31.1](#) shows a time series that has a span of 10 observations in a weekday series based on the results of the PLOT=(VALUES SPANS) option. The single large bar in the spans plot shows where data are omitted.

Figure 31.1 Time ID Decomposition

The count-based frequency distributions summarize features of the time ID variable. Individual printed and plotted outputs are available to describe the distribution of the number of spans, offsets, and interval counts that occur in the time ID variable. Figure 31.2 illustrates a count-based frequency distribution of the spans within the weekday series.

Figure 31.2 Span Count Distribution

The large bar at the span of 1 shows that most of the observations are correctly separated by one interval. The bar at 11 indicates that one observation is separated by 11 intervals from the preceding value of the time ID variable. This further illustrates a span of 10 omitted observations.

Inferring Time Intervals and Alignments

When the `INTERVAL=` option is not specified in the `ID` statement, a time interval is inferred from the time ID values in the input data set. The technique used to infer a time interval involves searching for the interval that fits the greatest number of time ID values. First, time ID values are sampled from the input data set to generate a set of candidate intervals. Then the candidate interval that is consistent with greatest number of time ID values is chosen to represent the time series.

When the `ALIGN=INFER` option is specified, the convention that is used to specify time interval alignment is inferred from the time ID variable values by using a similar technique. When both the time interval and its alignment are to be inferred, each of the possible alignments, `BEGIN`, `MIDDLE`, and `END`, are considered in the search. Precedence in the search is given to intervals with the `BEGIN` alignment.

Data Set Output

The TIMEID procedure creates the OUTFREQ=, OUTINTERVAL=, and OUTINTERVALDETAILS= data sets. The OUTFREQ= and OUTINTERVALDETAILS= data sets contain the variables that are specified in the BY statement along with variables that characterize the time ID values. The OUTINTERVAL= option creates a data set without BY variables. The information in this data set summarizes time ID diagnostic information across all BY groups in the DATA= data set.

OUTFREQ= Data Set

The OUTFREQ= data set contains a single observation for each value of the time ID variable in the input data set for each BY group. Additionally, the following variables are written to the OUTFREQ= data set:

COUNT	number of the occurrences of the time ID value
PERCENT	percentage of all time ID values

OUTINTERVAL= Data Set

The OUTINTERVAL= data set contains information that is similar to the variables written to the OUTINTERVALDETAILS= data set; however, the OUTINTERVAL= data set summarizes the information across all BY groups into a single observation. The following variables are written to the OUTINTERVAL= data set:

TIMEID	time ID variable
START	smallest time ID interval
END	largest time ID interval
STARTSHARED	largest starting time ID interval
ENDSHARED	smallest ending time ID interval
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
NBY	number of BY groups
NINVALID	number of invalid observations
STATUS	status flag that indicates whether the requested analyses were successful:
0	The analysis completed successfully.
1	interval consistent but data contains gaps
2	interval not consistent with data
10	missing or invalid values found
20	ID values not sorted
21	duplicate ID values detected
30	fewer than 3 values found

	4000	Inference of a time interval from the data set failed.
	5000	Diagnosis of the DATA= data set for the specified time interval failed.
MSG		a message that provides further details when the STATUS variable is not zero
INTERVAL		time interval that is specified or recommended
INTNAME		time interval base name that is specified or recommended
MULTIPLIER		time interval multiplier that is specified or recommended
SHIFT_INDEX		time interval shift index that is specified or recommended
ALIGNMENT		time interval alignment that is specified or recommended
SEASONALITY		seasonality determined from specified or recommended time interval
TOTALSEASONCYCLES		total number of seasonal cycles spanned by all the observations
SEASONCYCLESSHARED		number of seasonal cycles that are shared among all BY groups
FORMAT		format of the time ID variable

The START, END, STARTSHARED, and ENDSHARED variables are reported using the interval and alignment specified in the ID statement or inferred from the time ID values.

OUTINTERVALDETAILS= Data Set

The OUTINTERVALDETAILS= data set contains statistics about the time interval that is specified in the ID statement or inferred from the time ID values for each BY group. The following variables represent these statistics:

TIMEID	time ID variable name
START	starting time ID interval
END	ending time ID interval
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
NINVALID	number of invalid observations
NINTCNTS	number of unique interval count values
PCTINTCNTS	percentage of interval counts greater than one
MININTCNT	minimum of interval counts
MAXINTCNT	maximum of interval counts
MEANINTCNT	mean of interval counts
STDINTCNT	standard deviation of interval counts
MEDINTCNT	median of interval counts
NOFFSETS	number of time ID offset
PCTOFFSETS	percentage of time ID offset

MINOFFSET	minimum of time ID offsets
MAXOFFSET	maximum of time ID offsets
MEANOFFSET	mean of time ID offsets
STDOFFSET	standard deviation of time ID offsets
MEDOFFSET	median of time ID offsets
NSPANS	number of spans between time ID values
PCTSPANS	percentage of spans between time ID values
MINSPAN	maximum of spans between time ID values
MAXSPAN	minimum of spans between time ID values
MEANSPAN	mean of spans between time ID values
STDSPAN	standard deviation of spans between time ID values
MEDSPAN	median of spans between time ID values
STATUS	status flag that indicates whether the requested analyses were successful:
0	The analysis completed successfully.
1	interval consistent but data contains gaps
2	interval not consistent with data
10	missing or invalid values found
20	ID values not sorted
21	duplicate ID values detected
30	fewer than 3 values found
4000	Inference of a time interval from the data set failed .
5000	Diagnosis of the DATA= data set for specified time interval failed.
MSG	a message that provides further details when the STATUS variable is not zero
INTERVAL	time interval specified or recommended
INTNAME	time interval base name specified or recommended
MULTIPLIER	time interval multiplier specified or recommended
SHIFT_INDEX	time interval shift index specified or recommended
ALIGNMENT	time interval alignment specified or recommended
SEASONALITY	seasonality determined from specified or recommended time interval
NSEASONCYCLES	number of seasonal cycles spanned by the time ID values
FORMAT	format of the time ID variable

The START and END variables are reported using the interval and alignment specified in the ID statement or inferred from the time ID values.

Printed Tabular Output

The TIMEID procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. The appearance of the printed tabular output is controlled by the PRINT= option in the PROC TIMEID statement.

Table 31.2 relates the PRINT= options to the names of the ODS tables.

Table 31.2 ODS Tables Produced in PROC TIMEID

ODS Name	Description	PRINT= Option
DataSet	Information about the input data set	ALL
Decomposition	Time ID counts, offsets, and spans	VALUES
Interval	Information about the time interval	INTERVAL
IntervalCountsComponent	Frequency distribution of interval counts	INTERVALCOUNTS
IntervalCountsStatistics	Statistics on interval count frequency distribution	INTERVALCOUNTS
OffsetsComponent	Frequency distribution of offsets	OFFSETS
OffsetStatistics	Statistics on offset frequency distribution	OFFSETS
SpansComponent	Frequency distribution of spans	SPANS
SpanStatistics	Statistics on the span frequency distribution	SPANS
Values	Time ID value counts	VALUES
ValueSummary	Summary of the number of valid observations	VALUES

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

The TIMEID procedure uses ODS Graphics to produce plotted output as specified by the PLOT= option. Table 31.3 relates the PLOT= options to the names of the ODS Graphics objects.

Table 31.3 ODS Graphics Produced by the PLOT= Option in PROC TIMEID

ODS Graph Name	Plot Description	PLOT= Option
DecompositionPlot	Panel of spans, offsets, and counts for each time interval	VALUES
IntervalCountsComponentPlot	Histogram of interval counts	INTERVALCOUNTS
IntervalCountsPlot	Plot of counts for each time interval value	VALUES
OffsetComponentPlot	Histogram of time ID offsets	OFFSETS
OffsetsPlot	Plot of offsets for each time interval value	VALUES
SpanComponentPlot	Histogram of span sizes between time ID values	SPANS
SpansPlot	Plot of spans for each time interval value	VALUES
ValuesPlot	Plot of counts of each time ID value	VALUES

Examples: TIMEID Procedure

Example 31.1: Examining a Weekly Time ID Variable

This example illustrates how problems in a weekly time series can be visualized and quantified using the TIMEID procedure's diagnostic capabilities.

The following DATA step creates a data set that contains time values spaced in three week intervals where some weeks have been skipped or duplicated and some have been recorded on different weekdays.

```
data triweek;
    format date date.;
    input date : date. @@;
datalines;
28DEC48 18JAN49 08FEB49 01MAR49 22MAR49 12APR49 03MAY49 24MAY49
17JUN49 05JUL49 26JUL49 16AUG49 06SEP49 27SEP49 18OCT49 08NOV49
29NOV49 20DEC49 10JAN50 04FEB50 21FEB50 14MAR50 04APR50 25APR50

... more lines ...
```

The following TIMEID procedure statements generate an ODS display of the time series that characterizes interval counts, offsets, and spans in the time ID variable.

```
proc timeid data=triweek print=all plot=all;
  id date interval=week3;
run;
```

The Time ID decomposition listing and plot shown in [Output 31.1.1](#) and [Output 31.1.2](#) summarize how well the WEEK3 interval fits the time ID values by showing the number of counts, offsets, and spans for each time interval that is represented by the DATE variable. The listing in [Output 31.1.1](#) has been truncated to include only the first 10 observations. The Time ID plots in [Output 31.1.2](#) indicate that there are duplicated time ID values for a three-week time interval in the Counts plot. The duplicated time intervals have a Count value of 2. The Offsets plot shows which days in the 21 day cycle have been used to record each time interval in the series. The Spans plot records values of 2 for six time intervals where no observations were recorded in the previous interval. The three component plots are histogram summaries of the diagnostic quantities plotted against individual intervals in the decomposition plots. The component plots can be useful in diagnosing time series that contain many time intervals.

Output 31.1.1 Time ID Decomposition Listing

Time Component					
Value Index	date	Offset	Span	Interval Count	
1	Sun, 12 Dec 1948	16	.	1	
2	Sun, 2 Jan 1949	16	1	1	
3	Sun, 23 Jan 1949	16	1	1	
4	Sun, 13 Feb 1949	16	1	1	
5	Sun, 6 Mar 1949	16	1	1	
6	Sun, 27 Mar 1949	16	1	1	
7	Sun, 17 Apr 1949	16	1	1	
8	Sun, 8 May 1949	16	1	1	
9	Sun, 29 May 1949	19	1	1	
10	Sun, 19 Jun 1949	16	1	1	

Output 31.1.2 Time ID Decomposition Plot

Output 31.1.3 and Output 31.1.4 describe the distribution of counts of duplicated WEEK3 intervals in the TriWeek data set. For this data set there are 134 intervals that contain one DATE value, and 10 intervals that contain two DATE values.

Output 31.1.3 Time ID Interval Counts Listings

The TIMEID Procedure				
Component				
Value	Interval			
Index	Count	Frequency	Percentage	
1	1	132	91.666667	
2	2	12	8.333333	

Output 31.1.3 continued

Statistics Summary			
Minimum	Maximum	Mean	Standard Deviation
1	2	1.0833333	1.3008873

Output 31.1.4 Time ID Interval Counts Histogram

The offsets diagnostics [Output 31.1.5](#) and [Output 31.1.6](#) show the distribution of days in the 21-day WEEK3 interval used to record the time intervals in the series. The observations in the TriWeek data set represent intervals with five different offsets from the beginning of the WEEK3 interval: 0, 16, 18, 19 and 20. The high prevalence of intervals with offset 16 indicates that the TriWeek data set would be represented better using the WEEK3.17 interval.

Output 31.1.5 Time ID Offsets Listings

The TIMEID Procedure				
Component				
Value				
Index	Offset	Frequency	Percentage	
1	0	1	0.694444	
2	16	138	95.833333	
3	18	1	0.694444	
4	19	1	0.694444	
5	20	3	2.083333	
Statistics Summary				
Minimum	Maximum	Mean	Standard Deviation	
0	20	16.006944	1.7006205	

Output 31.1.6 Time ID Offsets Histogram

The span diagnostics [Output 31.1.7](#) and [Output 31.1.8](#) show the distribution of the span sizes between successive DATE values. The TriWeek data set has three different span sizes of widths 0, 1 and 2. Here one span corresponds to the width of a WEEK3 interval.

Output 31.1.7 Time ID Span Listings

The TIMEID Procedure				
Component				
Value Index	Span	Frequency	Percentage	
1	0	1	0.704225	
2	1	135	95.070423	
3	2	6	4.225352	

Output 31.1.7 continued

Statistics Summary			
Minimum	Maximum	Mean	Standard Deviation
0	2	1.0352113	0.6367974

Output 31.1.8 Time ID Span Histogram

Output 31.1.9 and Output 31.1.10 show the distribution of time ID values before alignment to the WEEK3 interval. The listing in Output 31.1.9 has been truncated to include only the first 10 observations.

Output 31.1.9 Unaligned Time ID Listings

Time ID Values for DATE				
Value				
Index	date	Frequency	Percentage	
1	Tue, 28 Dec 1948	1	0.694444	
2	Tue, 18 Jan 1949	1	0.694444	
3	Tue, 8 Feb 1949	1	0.694444	
4	Tue, 1 Mar 1949	1	0.694444	
5	Tue, 22 Mar 1949	1	0.694444

Output 31.1.10 Unaligned Time ID Histogram

Example 31.2: Inferring a Date Interval

This example illustrates how a time ID variable can be inferred from a data set when a sufficient number of observations are present.

```
data workdays;
    format day weekdate.;
    input day : date. @@;
    datalines;
01AUG09 06AUG09 11AUG09 14AUG09 19AUG09 22AUG09
27AUG09 01SEP09 04SEP09 09SEP09 12SEP09 17SEP09
;

proc timeid data=workdays print=interval;
    id day;
run;
```

The 12 observations in the WorkDays data set are enough to determine that the DAY time ID variable is represented by the WEEKDAY12W3 interval. The WEEKDAY12W3 interval corresponds to every third day of the week excluding Sundays and Mondays. Characteristics of this interval are shown in [Output 31.2.1](#).

Output 31.2.1 Inferred Time Interval Information

The TIMEID Procedure	
Time Interval Analysis Summary	
Time ID Variable	day
Time Interval	WEEKDAY12W3
Base Name	WEEKDAY
Multiplier	3
Shift	0
Length of Seasonal Cycle	5
Time ID Format	DATE9.
Start	01AUG2009
End	17SEP2009

Example 31.3: Examining Multiple BY Groups

This example illustrates how a time ID variable can be examined independently over each BY group and summarized over all observations in the DATA= data set.

```
data bygroups;
    format tid date.;
    input tid : date. by @@;
datalines;
24NOV09 1 25NOV09 1 26NOV09 1 27NOV09 1 30NOV09 1 01DEC09 1 02DEC09 1 03DEC09 1

... more lines ...
```

The following TIMEID procedure statements generate two data sets that summarize a data set with four BY groups.

```
proc timeid data=bygroups outintervaldetails=int outinterval=intsum;
    id tid;
    by by;
run;
```

The summarized information in [Output 31.3.1](#) shows that BY groups 2, 3, and 4 in the ByGroups data set contain some duplicate values and spans, and group 1 conforms exactly to the WEEKDAY17W interval. This listing also shows that the date ranges in these two BY groups start and end on different days and that they overlap between December 7, 2009, and December 28, 2009.

Overview: TIMESERIES Procedure

The TIMESERIES procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format. The procedure can perform trend and seasonal analysis on the transactions. After the transactional data are accumulated, time domain and frequency domain analysis can be performed on the accumulated time series.

For seasonal analysis of the transaction data, various statistics can be computed for each season. For trend analysis of the transaction data, various statistics can be computed for each time period. The analysis is similar to applying the MEANS procedure of Base SAS software to each season or time period of concern.

After the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple and/or seasonal differencing. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

Time series analyses performed by the TIMESERIES procedure include:

- descriptive (global) statistics
- seasonal decomposition/adjustment analysis
- correlation analysis
- cross-correlation analysis
- spectral analysis

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

The TIMESERIES procedure can process large amounts of time-stamped transactional data. Therefore, the analysis results are useful for large-scale time series analysis or (temporal) data mining. All of the results can be stored in output data sets in either a time series format (default) or in a coordinate format (transposed). The time series format is useful for preparing the data for subsequent analysis with other SAS/ETS procedures. For example, the working time series can be further analyzed, modeled, and forecast with other SAS/ETS procedures. The coordinate format is useful when using this procedure with SAS/STAT procedures or SAS Enterprise Miner. For example, clustering time-stamped transactional data can be achieved by using the results of this procedure with the clustering procedures of SAS/STAT and the nodes of SAS Enterprise Miner.

The EXPAND procedure can be used for the frequency conversion and transformations of time series output from this procedure.

Getting Started: TIMESERIES Procedure

This section outlines the use of the TIMESERIES procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMESERIES procedure can form time series as follows:

```
PROC TIMESERIES DATA=<input-data-set>
                OUT=<output-data-set>;
  ID <time-ID-variable> INTERVAL=<frequency>
    ACCUMULATE=<statistic>;
  VAR <time-series-variables>;
RUN;
```

The TIMESERIES procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS).

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains four variables that are related to these transactions: CUSTOMER, DATE, WITHDRAWAL, and DEPOSITS. The following examples illustrate possible ways to analyze these transactions by using the TIMESERIES procedure.

To accumulate the time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and DEPOSITS), the following TIMESERIES procedure statements can be used:

```
proc timeseries data=transactions
                out=timeseries;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The OUT=TIMESERIES option specifies that the resulting time series data for each customer is to be stored in the data set WORK.TIMESERIES. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions is to be calculated. After the transactional data is accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the resulting time series data.

For example, the ARIMA procedure can be used to model and forecast each customer's withdrawal data by using an ARIMA(0,1,1)(0,1,1)_s model (where the number of seasons is $s=7$ days in a week) using the following statements:

```
proc arima data=timeseries;
    identify var=withdrawals(1,7) noprint;
    estimate q=(1)(7) outest=estimates noprint;
    forecast id=date interval=day out=forecasts;
quit;
```

The OUTEST=ESTIMATES data set contains the parameter estimates of the model specified. The OUT=FORECASTS data set contains forecasts based on the model specified. See the SAS/ETS ARIMA procedure for more detail.

A single set of transactions can be very large and must be summarized in order to analyze them effectively. Analysts often want to examine transactional data for trends and seasonal variation. To analyze transactional data for trends and seasonality, statistics must be computed for each time period and season of concern. For each observation, the time period and season must be determined and the data must be analyzed based on this determination.

The following statements illustrate how to use the TIMESERIES procedure to perform trend and seasonal analysis of time-stamped transactional data.

```
proc timeseries data=transactions out=out
                outseason=season outtrend=trend;
    by customer;
    id date interval=day accumulate=total;
    var withdrawals deposits;
run;
```

Since the INTERVAL=DAY option is specified, the length of the seasonal cycle is seven (7) where the first season is Sunday and the last season is Saturday. The output data set specified by the OUTSEASON=SEASON option contains the seasonal statistics for each day of the week by each customer. The output data set specified by the OUTTREND=TREND option contains the trend statistics for each day of the calendar by each customer.

Often it is desired to seasonally decompose into seasonal, trend, cycle, and irregular components or to seasonally adjust a time series. The following techniques describe how the changing seasons influence the time series.

The following statements illustrate how to use the TIMESERIES procedure to perform seasonal adjustment/decomposition analysis of time-stamped transactional data.

```
proc timeseries data=transactions
                out=out
                outdecomp=decompose;
    by customer;
    id date interval=day accumulate=total;
    var withdrawals deposits;
run;
```

The output data set specified by the OUTDECOMP=DECOMPOSE data set contains the decomposed/adjusted time series for each customer.

A single time series can be very large. Often, a time series must be summarized with respect to time lags in order to be efficiently analyzed using time domain techniques. These techniques help describe how a current observation is related to the past observations with respect to the time (season) lag.

The following statements illustrate how to use the TIMESERIES procedure to perform time domain analysis of time-stamped transactional data.

```
proc timeseries data=transactions
                out=out
                outcorr=timedomain;
    by customer;
    id date interval=day accumulate=total;
    var withdrawals deposits;
run;
```

The output data set specified by the OUTCORR=TIMEDOMAIN data set contains the time domain statistics, such as sample autocorrelations and partial autocorrelations, by each customer.

Sometimes time series data contain underlying patterns that can be identified using spectral analysis techniques. Two kinds of spectral analyses on univariate data can be performed using the TIMESERIES procedure. They are singular spectrum analysis and Fourier spectral analysis.

Singular spectrum analysis (SSA) is a technique for decomposing a time series into additive components and categorizing these components based on the magnitudes of their contributions. SSA uses a single parameter, the window length, to quantify patterns in a time series without relying on prior information about the series' structure. The window length represents the maximum lag that is considered in the analysis, and it corresponds to the dimensionality of the principle components analysis (PCA) on which SSA is based. The components are combined into groups to categorize their roles in the SSA decomposition.

Fourier spectral analysis decomposes a time series into a sum of harmonics. In the discrete Fourier transform, the contribution of components at evenly spaced frequencies are quantified in a periodogram and summarized in spectral density estimates.

The following statements illustrate how to use the TIMESERIES procedure to analyze time-stamped transactional data without prior information about the series' structure.

```
proc timeseries data=transactions
                outssa=ssa
                outspectra=spectra;
    by customer;
    id date interval=day accumulate=total;
    var withdrawals deposits;
run;
```

The output data set specified by the OUTSSA=SSA data set contains a singular spectrum analysis of the withdrawals and deposits data. The data set specified by OUTSPECTRA=SPECTRA contains a Fourier spectral decomposition of the same data.

By default, the TIMESERIES procedure produces no printed output.

Syntax: TIMESERIES Procedure

The TIMESERIES Procedure uses the following statements:

```

PROC TIMESERIES options ;
  BY variables ;
  CORR statistics-list / options ;
  CROSSCORR statistics-list / options ;
  CROSSVAR variable-list / options ;
  DECOMP component-list / options ;
  ID variable INTERVAL= interval-option ;
  SEASON statistics-list / options ;
  SPECTRA statistics-list / options ;
  SSA / options ;
  TREND statistics-list / options ;
  VAR variable-list / options ;

```

Functional Summary

PROC TIMESERIES Statement

PROC TIMESERIES *options* ;

The following options can be used in the PROC TIMESERIES statement:

DATA= *SAS-data-set*

names the SAS data set that contains the input data for the procedure to create the time series. If the DATA= option is not specified, the most recently created SAS data set is used.

CROSSPLOTS= *option* | (*options*)

specifies the cross-variable graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES plots the time series (OUT= data set).

CCF plots the cross-correlation functions (OUTCROSSCORR= data set).

ALL same as PLOTS=(SERIES CCF).

For example, CROSSPLOTS=SERIES plots the two time series. The CROSSPLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The CROSSPLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

MAXERROR= *number*

limits the number of warning and error messages that are produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

MAXVARLENGTH

specifies that processed variables be set to 8 bytes in length. This option exists principally for use when data storage may be a concern.

OUT= *SAS-data-set*

names the output data set to contain the time series variables specified in the subsequent VAR and CROSSVAR statements. If BY variables are specified, they are also included in the OUT= data set. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= or the ACCUMULATE= option or both. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTCORR= *SAS-data-set*

names the output data set to contain the univariate time domain statistics.

OUTCROSSCORR= *SAS-data-set*

names the output data set to contain the cross-correlation statistics.

OUTDECOMP= *SAS-data-set*

names the output data set to contain the decomposed and/or seasonally adjusted time series.

OUTPROCINFO= *SAS-data-set*

names the output data set to contain information in the SAS log, specifically the number of notes, errors, and warnings and the number of series processed, analyses requested, and analyses failed.

OUTSEASON= *SAS-data-set*

names the output data set to contain the seasonal statistics. The statistics are computed for each season as specified by the ID statement **INTERVAL=** option or the **PROC TIMESERIES** statement **SEASONALITY=** option. The **OUTSEASON=** data set is particularly useful when analyzing transactional data for seasonal variations.

OUTSPECTRA= *SAS-data-set*

names the output data set to contain the univariate frequency domain analysis results.

OUTSSA= *SAS-data-set*

names the output data set to contain the singular spectrum analysis result series.

OUTSUM= *SAS-data-set*

names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the **ACCUMULATE=** and/or **SETMISSING=** options are specified in the **ID** or **VAR** statements. The **OUTSUM=** data set is particularly useful when analyzing large numbers of series and a summary of the results are needed.

OUTTREND= *SAS-data-set*

names the output data set to contain the trend statistics. The statistics are computed for each time period as specified by the ID statement **INTERVAL=** option. The **OUTTREND=** data set is particularly useful when analyzing transactional data for trends.

PLOTS= *option* | (*options*)

specifies the univariate graphical output desired. By default, the **TIMESERIES** procedure produces no graphical output. The following plotting options are available:

SERIES	plots the time series (OUT= data set).
RESIDUAL	plots the residual time series (OUT= data set).
HISTOGRAM	plots a histogram of the time series values
CYCLES	plots the seasonal cycles (OUT= data set).
CORR	plots the correlation panel (OUTCORR= data set).
ACF	plots the autocorrelation function (OUTCORR= data set).
PACF	plots the partial autocorrelation function (OUTCORR= data set).
IACF	plots the inverse autocorrelation function (OUTCORR= data set).
WN	plots the white noise probabilities (OUTCORR= data set).
DECOMP	plots the seasonal adjustment panel (OUTDECOMP= data set).
TCS	plots the trend-cycle-seasonal component (OUTDECOMP= data set).
TCC	plots the trend-cycle component (OUTDECOMP= data set).
SIC	plots the seasonal-irregular component (OUTDECOMP= data set).
SC	plots the seasonal component (OUTDECOMP= data set).

SA	plots the seasonal adjusted component (OUTDECOMP= data set).
PCSA	plots the percent change in the seasonal adjusted component (OUTDECOMP= data set).
IC	plots the irregular component (OUTDECOMP= data set).
TC	plots the trend component (OUTDECOMP= data set).
CC	plots the cycle component (OUTDECOMP= data set).
PERIODOGRAM < (<i>option</i>)>	plots the periodogram (OUTSPECTRA= data set). The available options for modifying the periodogram are
	MAXFREQ= <i>number</i> specifies the maximum frequency in radians to include in the plot
	MINPERIOD= <i>number</i> specifies the minimum period to include in the plot
SPECTRUM < (<i>option</i>)>	plots the spectral density estimate (OUTSPECTRA= data set). The available options for modifying the spectrum plot are
	MAXFREQ= <i>number</i> specifies the maximum frequency in radians to include in the plot
	MINPERIOD= <i>number</i> specifies the minimum period to include in the plot
SSA	plots the singular spectrum analysis results (OUTSSA= data set).
ALL	same as PLOTS=(SERIES HISTOGRAM ACF PACF IACF WN SSA PERIODOGRAM SPECTRUM).
BASIC	same as PLOTS=(SERIES HISTOGRAM CYCLES CORR DECOMP)

For example, PLOTS=SERIES plots the time series. The PLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The PLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINT= *option* | (*options*)

specifies the printed output desired. By default, the TIMESERIES procedure produces no printed output. The following printing options are available:

DECOMP	prints the seasonal decomposition/adjustment table (OUTDECOMP= data set).
SEASONS	prints the seasonal statistics table (OUTSEASON= data set).
DESCSTATS	prints the descriptive statistics for the accumulated time series (OUTSUM= data set).
SUMMARY	prints the descriptive statistics table for all time series (OUTSUM= data set).
TRENDS	prints the trend statistics table (OUTTREND= data set).
SSA	prints the singular spectrum analysis results (OUTSSA= data set).
ALL	same as PRINT=(DESCSTATS SUMMARY).

For example, PRINT=SEASONS prints the seasonal statistics. The PRINT= option produces printed output for these results by using the Output Delivery System (ODS). The PRINT= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINTDETAILS

specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY= *number*

specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES

specifies that the variables specified in the VAR and CROSSVAR statements be processed in sorted order by the variable names. This option allows the output data sets to be presorted by the variable names.

BY Statement

A BY statement can be used with PROC TIMESERIES to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMESERIES procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CORR Statement

CORR *statistics* < / *options* > ;

A CORR statement can be used with the TIMESERIES procedure to specify options related to time domain analysis of the accumulated time series. Only one CORR statement is allowed.

The following time domain statistics are available:

LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	an indicator of whether autocorrelations are less than (-1) , greater than (1) , or within (0) two standard errors of zero
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	an indicator of whether partial autocorrelation are less than (-1) , greater than (1) , or within (0) two standard errors of zero
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	inverse autocorrelation standard errors
IACF2STD	an indicator of whether the inverse autocorrelation is less than (-1) , greater than (1) or within (0) two standard errors of zero
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

If none of the correlation statistics are specified, the default is as follows:

```
corr lag n acov acf acfstd pacf pacfstd iacf iacfstd wn wnprob;
```

The following options can be specified in the CORR statement following the slash (/):

NLAG= *number*

specifies the number of lags to be stored in the OUTCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

LAGS= (*numlist*)

specifies the list of lags to be stored in OUTCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

NPARMS= *number*

specifies the number of parameters used in the model that created the residual time series. The number of parameters determines the degrees of freedom associated with the Ljung-Box statistics. The default is NPARMS=0. This option is useful when analyzing the residuals of a time series model with the number of parameters specified by NPARMS=*number* option.

TRANSPOSE= NO|YES

specifies which values are recorded as column names in the OUTCORR= data set. TRANSPOSE=YES specifies that lags be recorded as the column names instead of correlation statistics as the column names. The TRANSPOSE=NO option is useful for graphing the correlation results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the correlation results with other SAS procedures such as the CLUSTER procedure of SAS/STAT or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

CROSSCORR Statement

CROSSCORR *statistics* < / *options* > ;

A CROSSCORR statement can be used with the TIMESERIES procedure to specify options that are related to cross-correlation analysis of the accumulated time series. Only one CROSSCORR statement is allowed.

The following time domain statistics are available:

LAG	time lag
N	number of variance products
CCOV	cross covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	an indicator of whether cross-correlations are less than (−1), greater than (1), or within (0) two standard errors of zero
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

If none of the cross-correlation statistics are specified, the default is as follows:

```
crosscorr lag n ccov ccf ccfstd;
```

The following options can be specified in the CROSSCORR statement following the slash (/):

NLAG= *number*

specifies the number of lags to be stored in the OUTCROSSCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

LAGS=(*numlist*)

specifies a list of lags to be stored in OUTCROSSCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

TRANSPPOSE= NO|YES

specifies which values are recorded as column names in the OUTCROSSCORR= data set. TRANSPPOSE=YES specifies that the lags be recorded as the column names instead of the cross-correlation statistics. The TRANSPPOSE=NO option is useful for graphing the cross-correlation results with SAS/GRAPH procedures. The TRANSPPOSE=YES option is useful for analyzing the cross-correlation results with other procedures such as the CLUSTER procedure of SAS/STAT or SAS Enterprise Miner software. The default is TRANSPPOSE=NO.

DECOMP Statement

DECOMP *components* < / *options* > ;

A DECOMP statement can be used with the TIMESERIES procedure to specify options related to classical seasonal decomposition of the time series data. Only one DECOMP statement is allowed. The options specified affect all variables listed in the VAR statements. Decomposition can be performed only when the length of the seasonal cycle specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option is greater than one.

The following seasonal decomposition components are available:

ORIG ORIGINAL	original series
TCC TRENDCYCLE	trend-cycle component
SIC SEASONIRREGULAR	seasonal-irregular component
SC SEASONAL	seasonal component
SCSTD	seasonal component standard errors
TCS TRENDCYCLESEASON	trend-cycle-seasonal component
IC IRREGULAR	irregular component
SA ADJUSTED	seasonally adjusted series
PCSA	percent change seasonally adjusted series
TC	trend component
CC CYCLE	cycle component

If none of the components are specified, the default is as follows:

```
decomp orig tcc sc ic sa;
```

The following options can be specified in the DECOMP statement following the slash (/):

MODE= *option*

specifies the type of decomposition to be used to decompose the time series. The following values can be specified for the MODE= option:

ADD ADDITIVE	additive decomposition
MULT MULTIPLICATIVE	multiplicative decomposition
LOGADD LOGADDITIVE	log-additive decomposition
PSEUDOADD PSEUDOADDITIVE	pseudo-additive decomposition
MULTORADD	multiplicative or additive decomposition, depending on data

Multiplicative and log additive decomposition require strictly positive time series. If the accumulated time series contains nonpositive values and the MODE=MULT or MODE=LOGADD option is specified, an error results. Pseudo-additive decomposition requires a nonnegative-valued time series. If the accumulated time series contains negative values and the MODE=PSEUDOADD option is specified, an error results. The MODE=MULTORADD option specifies that multiplicative decomposition be used when the accumulated time series contains only positive values, that pseudo-additive decomposition be used when the accumulated time series contains only nonnegative values, and that additive decomposition be used otherwise. The default is MODE=MULTORADD.

LAMBDA= *number*

specifies the Hodrick-Prescott filter parameter for trend-cycle decomposition. The default is LAMBDA=1600. Filtering applies when the trend component or the cycle component is requested. If filtering is not specified, this option is ignored.

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTDECOMP= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE=NO option is specified, the NPERIODS= option is ignored. If the NPERIODS= option is positive, the first or beginning time periods are recorded. If the NPERIODS= option is negative, the last or ending time periods are recorded. The NPERIODS= option specifies the number of OUTDECOMP= data set variables to contain the seasonal decomposition and is therefore limited to the maximum allowed number of SAS variables. If the number of time periods exceeds this limit, a warning is printed in the log and the number of periods stored is reduced to the limit.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=-5.

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTDECOMP= data set. TRANSPOSE=YES specifies that the time periods be recorded as the column names instead of the statistics.

The first and last time periods stored in the OUTDECOMP= data set correspond to the period of the ID statement START= option and END= option, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for analyzing or displaying the decomposition results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the decomposition results with other SAS procedures or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

ID Statement

ID *variable* **INTERVAL=***interval* **< options >** ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement *options* also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The information specified affects all variables listed in subsequent VAR statements. If the ID statement is specified, the INTERVAL= must also be used. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following *options* can be used with the ID statement:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE AVG	Observations are accumulated based on the average of their values.
MINIMUM MIN	Observations are accumulated based on the minimum of their values.
MEDIAN MED	Observations are accumulated based on the median of their values.
MAXIMUM MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.

NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the `ACCUMULATE=` option is specified, the `SETMISSING=` option is useful for specifying how accumulated missing values are to be treated. If missing values should be interpreted as zero, then `SETMISSING=0` should be used. The section “[Details: TIMESERIES Procedure](#)” on page 2199 describes accumulation in greater detail.

ALIGN= option

controls the alignment of SAS dates used to identify output observations. The `ALIGN=` option accepts the following values: `BEGINNING` | `BEG` | `B`, `MIDDLE` | `MID` | `M`, and `ENDING` | `END` | `E`. `BEGINNING` is the default.

BOUNDARYALIGN= option

controls how the `ACCUMULATE=` option is processed for the two boundary time intervals, which include the `START=` and `END=` time ID values. Some time ID values might fall inside the first and last accumulation intervals but fall outside the `START=` and `END=` boundaries. In these cases the `BOUNDARYALIGN=` option determines which values to include in the accumulation operation. You can specify the following *options*:

NONE	No values outside the <code>START=</code> and <code>END=</code> boundaries are accumulated.
START	All observations in the first time interval are accumulated.
END	All observations in the last time interval are accumulated.
BOTH	All observations in the first and last are accumulated.

If no option is specified, the default value `BOUNDARYALIGN=NONE` is used. The section “[Details: TIMESERIES Procedure](#)” on page 2199 describes the `BOUNDARYALIGN=` accumulation option in greater detail.

END= option

specifies a SAS date or datetime value that represents the end of the data. If the last time ID variable value is less than the `END=` value, the series is extended with missing values. If the last time ID variable value is greater than the `END=` value, the series is truncated. For example, `END=&sysdate` uses the automatic macro variable `SYSDATE` to extend or truncate the series to the current date. The `START=` and `END=` options can be used to ensure that data associated within each `BY` group contains the same number of observations.

FORMAT= *format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied from the INTERVAL= option.

INTERVAL= *interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the PROC TIMESERIES statement SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations. The INTERVAL= option is required and must be the first option specified in the ID statement.

NOTSORTED

specifies that the time ID values not be in sorted order. The TIMESERIES procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING= *option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series. If a number is specified, missing values are set to the number. If a missing value indicates an unknown value, this option should not be used. If a missing value indicates no value, SETMISSING=0 should be used. You would typically use SETMISSING=0 for transactional data because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE AVG	Missing values are set to the accumulated average value.
MINIMUM MIN	Missing values are set to the accumulated minimum value.
MEDIAN MED	Missing values are set to the accumulated median value.
MAXIMUM MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS PREV	Missing values are set to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START= *option*

specifies a SAS date or datetime value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prepended with missing values. If the first time ID variable value is less than the START= value, the series is truncated. The START= and END= options can be used to ensure that data associated with each by group contains the same number of observations.

SEASON Statement

SEASON *statistics* < / *options* > ;

A SEASON statement can be used with the TIMESERIES procedure to specify options that are related to seasonal analysis of the time-stamped transactional data. Only one SEASON statement is allowed. The options specified affect all variables specified in the VAR statements. Seasonal analysis can be performed only when the length of the seasonal cycle specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option is greater than one.

The following seasonal statistics are available:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If none of the season statistics are specified, the default is as follows:

```
season n min max mean std;
```

The following option can be specified in the SEASON statement following the slash (/):

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTSEASON= data set. TRANSPOSE=YES specifies that the seasonal indices be recorded as the column names instead of the statistics. The TRANSPOSE=NO option is useful for graphing the seasonal analysis results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the seasonal analysis results with SAS procedures or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

SPECTRA Statement

SPECTRA *statistics* < / *options* > ;

A SPECTRA statement can be used with the TIMESERIES procedure to specify which statistics appear in the OUTSPECTRA= data set. The SPECTRA statement *options* are used in performing a spectral analysis on the variables listed in the VAR statement. These *options* affect values that are produced in the PROC TIMESERIES statement's OUTSPECTRA= data set, and in the periodogram and spectral density estimate. Only one SPECTRA statement is allowed.

The following univariate frequency domain statistics are available:

FREQ	frequency in radians from 0 to π
PERIOD	period or wavelength
COS	cosine transform
SIN	sine transform
P	periodogram
S	spectral density estimates

If none of the frequency domain statistics are specified, the default is as follows:

```
spectra period p;
```

The following *options* can be specified in the SPECTRA statement following the slash (/):

C=coefficient

specifies the scale coefficient for the kernel function. See the section “[Kernel Option Details](#)” on page 2194 for more information.

E=exponent

EXP=exponent

EXPON=exponent

specifies the exponent for the kernel function. See the section “[Kernel Option Details](#)” on page 2194 for more information.

ADJUSTMEAN=NO | YES

CENTER=NO | YES

specifies whether or not the series should be adjusted by its mean prior to performing the Fourier decomposition. This sets the first periodogram ordinate to 0 rather than to $2n$ times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot. ADJUSTMEAN=YES specifies that the series be transformed by subtracting its mean. ADJUSTMEAN=NO specifies that no adjustment of the series be performed. The default is ADJUSTMEAN=NO.

ALPHA=num

specifies the width of a window that is drawn around the spectral density estimate in a spectral density versus frequency plot. Based on approximations proposed by Brockwell and Davis (1991), periodogram ordinates fall within this window with a confidence level of $1 - num$. The value *num* must be between 0 and 1; the default is 0.5.

DOMAIN=domain

specifies how the smoothing function is interpreted. You can specify the following *domain* values:

FREQUENCY	smooths the periodogram ordinates.
TIME	applies the kernel as a filter to the time series autocovariance function.

By default DOMAIN=FREQUENCY, and smoothing is applied in the same manner as weights are applied when you specify the WEIGHTS= option.

kernel

specifies the smoothing function to use to calculate a spectral density estimate as the moving average of periodogram ordinates. The kernel function is an alternative smoothing method to using the WEIGHTS= option. You can specify the following *kernel* values:

PARZEN	Parzen kernel
BARTLETT	Bartlett kernel
TUKEY	Tukey-Hanning kernel
TRUNC TRUNCAT	truncated kernel
QS QUADR	quadratic spectral kernel

If neither a WEIGHTS= option nor a kernel function is specified, the spectral density estimate is identical to the unmodified periodogram.

WEIGHTS=numlist

specifies the relative weights to use to compute a spectral density estimate as the moving average smoothing of periodogram ordinates. If neither a WEIGHTS= option nor a kernel function is specified, the spectral density estimate is identical to the unmodified periodogram. The following SPECTRA statement uses the WEIGHTS= option to specify equal weighting for each of the three adjacent periodogram ordinates centered on each spectral density estimate:

```
spectra / weights 1 1 1;
```

For information about how the weights are applied, see the section “Using Specification of Weight Constants” on page 2212.

Kernel Option Details

You can further parameterize each of the kernel functions with a kernel scale factor by using the C= and E= options. The default values of the kernel scale parameters, *c* and *e*, that are associated with each of the kernel functions together with their kernel scale factor values, *M*, for a series with 100 periodogram ordinates are listed in Table 32.2. The formula that is used to generate the table entries is $M = cK^e$, where *K* is the number of Fourier component frequencies.

Table 32.2 Default Kernel Scale Factor Parameters

Kernel	<i>c</i>	<i>e</i>	<i>M</i>
Bartlett	1/2	1/3	2.32
Parzen	1	1/5	2.51
Quadratic	1/2	1/5	1.26
Tukey-Hanning	2/3	1/5	1.67
Truncated	1/4	1/5	0.63

For example, to apply the truncated kernel by using default scale factor parameters in the frequency domain, you could use the following SPECTRA statement:

```
spectra / truncat;
```

For more information about the kernel function parameterization and the DOMAIN= option, see the section “Using Kernel Specifications” on page 2210.

SSA Statement

SSA < / *options* > ;

An SSA statement can be used with the TIMESERIES procedure to specify *options* that are related to singular spectrum analysis (SSA) of the accumulated time series. Only one SSA statement is allowed.

The following *options* can be specified in the SSA statement following the slash (/).

ADJUSTMEAN=NO | YES

CENTER=NO | YES

specifies whether or not the series should be adjusted by its mean prior to performing the singular spectrum analysis. ADJUSTMEAN=YES specifies that the series be transformed by subtracting its mean. ADJUSTMEAN=NO specifies that no adjustment of the series be performed. The default is ADJUSTMEAN=NO.

GROUPS= (*numlist*) . . . (*numlist*)

specifies the lists that categorize window lags into groups. The window lags must be separated by spaces or commas. For example, GROUPS=(1,3) (2,4) specifies that the first and third window lags form the first group and the second and fourth window lags form the second group. If no GROUPS= option is specified, the window lags are divided into two groups based on the THRESHOLDPCT= value.

For example, the following SSA statement specifies three groups:

```
ssa / groups=(1 3) (2 4 5) (6) ;
```

The first group contains the first and third principal components; the second group contains the second, fourth, and fifth principal components; and the third group contains the sixth principal component.

By default, the first group contains the principal components whose contributions to the series sum to greater than the THRESHOLDPCT= value of 90%, and the second group contains the remaining components.

LENGTH = number

specifies the window length to be used in the analysis. It represents the maximum lag used in the SSA autocovariance calculations. The number specified by the LENGTH= option must be greater than one. When the SEASONALITY= option is provided or inferred by the INTERVAL= option in the ID statement the default window length is the smaller of two times the length of the seasonal cycle and one half the length of the time series. When no seasonality value is available the default window length is the smaller of 12 and one half the length of the time series.

For example, the following SSA statement specifies a window length of 10:

```
ssa / length=10;
```

If no window length option is specified and the INTERVAL=MONTH or SEASONALITY=12 options are specified, a window length of 24 is used. If the specified window length is greater than one-half the length of the accumulated time series, the window length is reduced and a warning message is printed to the log.

NPERIODS= number

specifies the number of time periods to be stored in the OUTSSA= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTSSA= data set variables to contain the groups.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=-5.

THRESHOLDPCT= percent

specifies a percentage used to divide the SSA components into two groups based on the cumulative percentage of their singular values. The percentage specified by the THRESHOLDPCT= option must be greater than zero and less than 100. The default is THRESHOLDPCT=90.

For example, the following SSA statement specifies 80%:

```
ssa / THRESHOLDPCT=80;
```

The size of the second group must be at least one, and it must be less than the window length. The percentage is adjusted to achieve this requirement.

For example, the following SSA statement specifies a THRESHOLDPCT= of 0%, which effectively sets the size of the second group to one less than the window length:

```
ssa / THRESHOLDPCT = 0;
```

The following SSA statement specifies a THRESHOLDPCT= of 100%, which implies that the size of the last group is one:

```
ssa / THRESHOLDPCT= 100;
```

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTSSA= data set. TRANSPOSE=YES specifies that the time periods be recorded as the column names instead of the specified groups as the column names. The first and last time period stored in the OUTSSA= data set corresponds to the period of the ID statement START= and END= options, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for displaying the SSA results. The TRANSPOSE=YES option is useful for analyzing the SSA results using SAS Enterprise Miner software. The default is TRANSPOSE=NO.

TREND Statement

TREND *statistics* < / *options* > ;

A TREND statement can be used with the TIMESERIES procedure to specify options related to trend analysis of the time-stamped transactional data. Only one TREND statement is allowed. The options specified affect all variables specified in the VAR statements.

The following trend statistics are available:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If none of the trend statistics are specified, the default is as follows:

```
trend n min max mean std;
```

The following options can be specified in the TREND statement following the slash (/):

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTTREND= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTTREND= data set variables to contain the trend statistics and is therefore limited to the maximum allowed number of SAS variables.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=-5.

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTTREND= data set. TRANSPOSE=YES specifies that the time periods be recorded as the column names instead of the statistics as the column names. The first and last time periods stored in the OUTTREND= data set correspond to the period of the ID statement START= and END= options, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for analyzing or displaying the trend analysis results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the trend analysis results with other SAS procedures or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

VAR and CROSSVAR Statements

```
VAR variable-list < / options > ;
```

```
CROSSVAR variable-list < / options > ;
```

The VAR and CROSSVAR statements list the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR or CROSSVAR statement. Any number of VAR and CROSSVAR statements can be used. The following options can be used with the VAR and CROSSVAR statements:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period for the variables listed in the VAR or CROSSVAR statement. If the ACCUMULATE= option is not specified in the VAR or CROSSVAR statement, accumulation is determined by the ACCUMULATE= option of the ID statement. See the ID statement ACCUMULATE= option for more details.

DIF=(*numlist*)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first then third order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option.

SDIF=(*numlist*)

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first then third order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option.

SETMISS= *option* | *number***SETMISSING=** *option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series for variables listed in the VAR or CROSSVAR statement. If the SETMISSING= option is not specified in the VAR or CROSSVAR statement, missing values are set based on the SETMISSING= option of the ID statement. See the ID statement SETMISSING= option for more details.

TRANSFORM= *option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	logarithmic transformation
SQRT	square-root transformation
LOGISTIC	logistic transformation
BOXCOX (<i>n</i>)	Box-Cox transformation with parameter number where the number is between –5 and 5

When the TRANSFORM= option is specified, the time series must be strictly positive.

Details: TIMESERIES Procedure

The TIMESERIES procedure can be used to perform trend and seasonal analysis on transactional data. For trend analysis, various sample statistics are computed for each time period defined by the time ID variable and INTERVAL= option. For seasonal analysis, various sample statistics are computed for each season defined by the INTERVAL= or the SEASONALITY= option. For example, if the transactional data ranges from June 1990 to January 2000 and the data are to be accumulated on a monthly basis, then the trend statistics are

computed for every month: June 1990, July 1990, . . . , January 2000. The seasonal statistics are computed for each season: January, February, . . . , December.

The TIMESERIES procedure can be used to form time series data from transactional data. The accumulated time series can then be analyzed using time series techniques. The data is analyzed in the following order:

- | | |
|---------------------------------|--|
| 1. accumulation | ACCUMULATE= option in the ID, VAR, or CROSSVAR statement |
| 2. missing value interpretation | SETMISSING= option in the ID, VAR, or CROSSVAR statement |
| 3. time series transformation | TRANSFORM= option in the VAR or CROSSVAR statement |
| 4. time series differencing | DIF= and SDIF= options in the VAR or CROSSVAR statement |
| 5. descriptive statistics | OUTSUM= option and the PRINT=DESCSTATS option |
| 6. seasonal decomposition | DECOMP statement or the OUTDECOMP= option in the PROC TIME-SERIES statement |
| 7. correlation analysis | CORR statement or the OUTCORR= option in the PROC TIME-SERIES statement |
| 8. singular spectrum analysis | SSA statement or the OUTSSA= option in the PROC TIMESERIES statement |
| 9. Fourier spectral analysis | SPECTRA statement or the OUTSPECTRA= option in the PROC TIMESERIES statement |
| 10. cross-correlation analysis | CROSSCORR statement or the OUTCROSSCORR= option in the PROC TIMESERIES statement |

Accumulation

If the ACCUMULATE= option in the ID, VAR, or CROSSVAR statement is specified, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the ID statement INTERVAL= option. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```

19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20

```

If the INTERVAL=MONTH is specified, all of the above observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is:

O1MAR1999	40
O1APR1999	.
O1MAY1999	90

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is:

O1MAR1999	20
O1APR1999	.
O1MAY1999	30

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is:

O1MAR1999	10
O1APR1999	.
O1MAY1999	20

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is:

O1MAR1999	20
O1APR1999	.
O1MAY1999	20

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is:

O1MAR1999	30
O1APR1999	.
O1MAY1999	50

If the ACCUMULATE=FIRST option is specified, the resulting time series is:

O1MAR1999	10
O1APR1999	.
O1MAY1999	50

If the ACCUMULATE=LAST option is specified, the resulting time series is:

O1MAR1999	30
O1APR1999	.
O1MAY1999	20

If the ACCUMULATE=STDDEV option is specified, the resulting time series is:

```
01MAR1999    14.14
01APR1999     .
01MAY1999    17.32
```

As can be seen from the above examples, even though the data set observations contain no missing values, the accumulated time series can have missing values.

Boundary Alignment

When the BOUNDARYALIGN= option is used to qualify the START= or END= options, additional time series values can be incorporated into the accumulation operation. For instance, if a data set contains the following observations

```
01JAN1999    10
01FEB1999    10
01MAR1999    10
01APR1999    10
01MAY1999    10
01JUN1999    10
```

and the options START='/01FEB1999'd, END='/01APR1999'd, INTERVAL=QUARTER, and ACCUMULATE=TOTAL are specified, using the BOUNDARYALIGN= option results in the following accumulated time series:

If BOUNDARYALIGN=START is specified, the accumulated time series is

```
01JAN1999    30
01APR1999    10
```

If BOUNDARYALIGN=END is specified, the accumulated time series is

```
01JAN1999    20
01APR1999    30
```

If BOUNDARYALIGN=BOTH is specified, the accumulated time series is

```
01JAN1999    30
01APR1999    30
```

If BOUNDARYALIGN=NONE is specified, the accumulated time series is

```
01JAN1999    20
01APR1999    10
```

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no value—that is, zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

There are four transformations available for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation.

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation.

$$w_t = \ln(cy_t / (1 - cy_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square root is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed by using the EXPAND procedure of SAS/ETS.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced by using the VAR and CROSSVAR statement DIF= and SDIF= options. For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally, when y_t is strictly positive and the TRANSFORM=, DIF=, and SDIF= options are combined in the VAR and CROSSVAR statements, the transformation operation is performed before the differencing operations.

Descriptive Statistics

Descriptive statistics can be computed from the working series by specifying the OUTSUM= option or PRINT=DESCSTATS.

Seasonal Decomposition

Seasonal decomposition/analysis can be performed on the working series by specifying the OUTDECOMP= option, the PRINT=DECOMP option, or one of the PLOTS= options associated with decomposition in the PROC TIMESERIES statement. The DECOMP statement enables you to specify options related to decomposition. The TIMESERIES procedure uses classical decomposition. More complex seasonal decomposition/adjustment analysis can be performed by using the X11 or the X12 procedure of SAS/ETS.

The DECOMP statement MODE= option determines the mode of the seasonal adjustment decomposition to be performed. There are four modes: multiplicative (MODE=MULT), additive (MODE=ADD), pseudo-additive (MODE=PSEUDOADD), and log-additive (MODE=LOGADD) decomposition. The default is MODE=MULTORADD which specifies MODE=MULT for series that are strictly positive, MODE=PSEUDOADD for series that are nonnegative, and MODE=ADD for series that are not nonnegative.

When MODE=LOGADD is specified, the components are exponentiated to the original metric.

The DECOMP statement LAMBDA= option specifies the Hodrick-Prescott filter parameter (Hodrick and Prescott 1980). The default is LAMBDA=1600. The Hodrick-Prescott filter is used to decompose the trend-cycle component into the trend component and cycle component in an additive fashion. A smaller parameter assigns less significance to the cycle; that is, LAMBDA=0 implies no cycle component.

The notation and keywords associated with seasonal decomposition/adjustment analysis are defined in [Table 32.3](#).

Table 32.3 Seasonal Adjustment Formulas

Component	Keyword	MODE= Option	Formula
original series	ORIGINAL	MULT	$O_t = TC_t S_t I_t$
		ADD	$O_t = TC_t + S_t + I_t$
		LOGADD	$\log(O_t) = TC_t + S_t + I_t$
		PSEUDOADD	$O_t = TC_t(S_t + I_t - 1)$
trend-cycle component	TCC	MULT	centered moving average of O_t
		ADD	centered moving average of O_t
		LOGADD	centered moving average of $\log(O_t)$
		PSEUDOADD	centered moving average of O_t
seasonal-irregular component	SIC	MULT	$SI_t = S_t I_t = O_t / TC_t$
		ADD	$SI_t = S_t + I_t = O_t - TC_t$
		LOGADD	$SI_t = S_t + I_t = \log(O_t) - TC_t$
		PSEUDOADD	$SI_t = S_t + I_t - 1 = O_t / TC_t$
seasonal component	SC	MULT	seasonal Averages of SI_t
		ADD	seasonal Averages of SI_t
		LOGADD	seasonal Averages of SI_t
		PSEUDOADD	seasonal Averages of SI_t
irregular component	IC	MULT	$I_t = SI_t / S_t$
		ADD	$I_t = SI_t - S_t$
		LOGADD	$I_t = SI_t - S_t$
		PSEUDOADD	$I_t = SI_t - S_t + 1$
trend-cycle-seasonal component	TCS	MULT	$TCS_t = TC_t S_t = O_t / I_t$
		ADD	$TCS_t = TC_t + S_t = O_t - I_t$
		LOGADD	$TCS_t = TC_t + S_t = O_t - I_t$
		PSEUDOADD	$TCS_t = TC_t S_t$
trend component	TC	MULT	$T_t = TC_t - C_t$
		ADD	$T_t = TC_t - C_t$
		LOGADD	$T_t = TC_t - C_t$
		PSEUDOADD	$T_t = TC_t - C_t$
cycle component	CC	MULT	$C_t = TC_t - T_t$
		ADD	$C_t = TC_t - T_t$
		LOGADD	$C_t = TC_t - T_t$
		PSEUDOADD	$C_t = TC_t - T_t$
seasonally adjusted series	SA	MULT	$SA_t = O_t / S_t = TC_t I_t$
		ADD	$SA_t = O_t - S_t = TC_t + I_t$
		LOGADD	$SA_t = O_t / \exp(S_t) = \exp(TC_t + I_t)$
		PSEUDOADD	$SA_t = TC_t I_t$

When s is odd the trend-cycle component is computed from the s -period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} y_{t+k}/s$$

When s is even the trend-cycle component is computed from the s -period centered moving average as follows:

$$TC_t = \sum_{k=-s/2}^{s/2-1} (y_{t+k} + y_{t+1+k})/2s$$

The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{T/s}$$

where $0 \leq j \leq T/s$ and $1 \leq k \leq s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

Correlation Analysis

Correlation analysis can be performed on the working series by specifying the OUTCORR= option or one of the PLOTS= options that are associated with correlation. The CORR statement enables you to specify options that are related to correlation analysis.

Autocovariance Statistics

LAGS	$h \in \{0, \dots, H\}$
N	N_h is the number of observed products at lag h , ignoring missing values
ACOV	$\hat{\gamma}(h) = \frac{1}{T} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$
ACOV	$\hat{\gamma}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$ when embedded missing values are present

Autocorrelation Statistics

ACF	$\hat{\rho}(h) = \hat{\gamma}(h)/\hat{\gamma}(0)$
ACFSTD	$Std(\hat{\rho}(h)) = \sqrt{\frac{1}{T} \left(1 + 2 \sum_{j=1}^{h-1} \hat{\rho}(j)^2 \right)}$
ACFNORM	$Norm(\hat{\rho}(h)) = \hat{\rho}(h)/Std(\hat{\rho}(h))$
ACFPROB	$Prob(\hat{\rho}(h)) = 2(1 - \Phi(Norm(\hat{\rho}(h))))$
ACFLPROB	$LogProb(\hat{\rho}(h)) = -\log_{10}(Prob(\hat{\rho}(h)))$
ACF2STD	$Flag(\hat{\rho}(h)) = \begin{cases} 1 & \hat{\rho}(h) > 2Std(\hat{\rho}(h)) \\ 0 & -2Std(\hat{\rho}(h)) < \hat{\rho}(h) < 2Std(\hat{\rho}(h)) \\ -1 & \hat{\rho}(h) < -2Std(\hat{\rho}(h)) \end{cases}$

Partial Autocorrelation Statistics

PACF	$\hat{\phi}(h) = \Gamma_{(0,h-1)}\{\gamma_j\}_{j=1}^h$
PACFSTD	$Std(\hat{\phi}(h)) = 1/\sqrt{N_0}$
PCFNORM	$Norm(\hat{\phi}(h)) = \hat{\phi}(h)/Std(\hat{\phi}(h))$
PACFPROB	$Prob(\hat{\phi}(h)) = 2(1 - \Phi(Norm(\hat{\phi}(h))))$
PACFLPROB	$LogProb(\hat{\phi}(h)) = -\log_{10}(Prob(\hat{\phi}(h)))$
PACF2STD	$Flag(\hat{\phi}(h)) = \begin{cases} 1 & \hat{\phi}(h) > 2Std(\hat{\phi}(h)) \\ 0 & -2Std(\hat{\phi}(h)) < \hat{\phi}(h) < 2Std(\hat{\phi}(h)) \\ -1 & \hat{\phi}(h) < -2Std(\hat{\phi}(h)) \end{cases}$

Inverse Autocorrelation Statistics

IACF	$\hat{\theta}(h)$
IACFSTD	$Std(\hat{\theta}(h)) = 1/\sqrt{N_0}$
IACFNORM	$Norm(\hat{\theta}(h)) = \hat{\theta}(h)/Std(\hat{\theta}(h))$
IACFPROB	$Prob(\hat{\theta}(h)) = 2\left(1 - \Phi\left(Norm(\hat{\theta}(h)) \right)\right)$
IACFLPROB	$LogProb(\hat{\theta}(h)) = -\log_{10}(Prob(\hat{\theta}(h)))$
IACF2STD	$Flag(\hat{\theta}(h)) = \begin{cases} 1 & \hat{\theta}(h) > 2Std(\hat{\theta}(h)) \\ 0 & -2Std(\hat{\theta}(h)) < \hat{\theta}(h) < 2Std(\hat{\theta}(h)) \\ -1 & \hat{\theta}(h) < -2Std(\hat{\theta}(h)) \end{cases}$

White Noise Statistics

WN	$Q(h) = T(T+2) \sum_{j=1}^h \rho(j)^2 / (T-j)$
WN	$Q(h) = \sum_{j=1}^h N_j \rho(j)^2$ when embedded missing values are present
WNPROB	$Prob(Q(h)) = \chi_{\max(1,h-p)}(Q(h))$
WNLPROB	$LogProb(Q(h)) = -\log_{10}(Prob(Q(h)))$

Cross-Correlation Analysis

Cross-correlation analysis can be performed on the working series by specifying the OUTCROSSCORR= option or one of the CROSSPLOTS= options that are associated with cross-correlation. The CROSSCORR statement enables you to specify options that are related to cross-correlation analysis.

Cross-Correlation Statistics

The cross-correlation statistics for the variable x supplied in a VAR statement and variable y supplied in a CROSSVAR statement are:

LAGS	$h \in \{0, \dots, H\}$
N	N_h is the number of observed products at lag h , ignoring missing values
CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{T} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y})$
CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y})$ when embedded missing values are present
CCF	$\hat{\rho}_{x,y}(h) = \hat{\gamma}_{x,y}(h) / \sqrt{\hat{\gamma}_x(0)\hat{\gamma}_y(0)}$
CCFSTD	$Std(\hat{\rho}_{x,y}(h)) = 1/\sqrt{N_0}$
CCFNORM	$Norm(\hat{\rho}_{x,y}(h)) = \hat{\rho}_{x,y}(h) / Std(\hat{\rho}_{x,y}(h))$
CCFPROB	$Prob(\hat{\rho}_{x,y}(h)) = 2(1 - \Phi(Norm(\hat{\rho}_{x,y}(h))))$
CCFLPROB	$LogProb(\hat{\rho}_{x,y}(h)) = -\log_{10}(Prob(\hat{\rho}_{x,y}(h)))$
CCF2STD	$Flag(\hat{\rho}_{x,y}(h)) = \begin{cases} 1 & \hat{\rho}_{x,y}(h) > 2Std(\hat{\rho}_{x,y}(h)) \\ 0 & -2Std(\hat{\rho}_{x,y}(h)) < \hat{\rho}_{x,y}(h) < 2Std(\hat{\rho}_{x,y}(h)) \\ -1 & \hat{\rho}_{x,y}(h) < -2Std(\hat{\rho}_{x,y}(h)) \end{cases}$

Spectral Density Analysis

Spectral analysis can be performed on the working series by specifying the OUTSPECTRA= option or by specifying the PLOTS=PERIODOGRAM or PLOTS=SPECTRUM option in the PROC TIMESERIES statement. PROC TIMESERIES uses the finite Fourier transform to decompose data series into a sum of sine and cosine terms of different amplitudes and wavelengths. The finite Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^{K-1} f_k(a_k \cos \omega_k t + b_k \sin \omega_k t)$$

$$f_k = \begin{cases} 1/2 & \text{if } T \text{ is even and } k = K - 1 \\ 1 & \text{otherwise} \end{cases}$$

where

t	is the time subscript, $t = 0, 1, 2, \dots, T - 1$
x_t	are the equally spaced time series data
T	is the number of observations in the time series
K	is the number of frequencies in the Fourier decomposition: $K = \frac{T+2}{2}$ if T is even, $K = \frac{T+1}{2}$ if T is odd
k	is the frequency subscript, $k = 0, 1, 2, \dots, K - 1$
a_0	is the mean term: $a_0 = 2\bar{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{T}$

The Fourier decomposition is performed after the ACCUMULATE=, DIF=, SDIF= and TRANSFORM= options in the ID and VAR statements have been applied.

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wavelength to form *periodograms*. The amplitude periodogram I_k is defined as follows:

$$I_k = \frac{T}{2}(a_k^2 + b_k^2)$$

Since the Fourier transform is an even, periodic function of frequency which repeats every T ordinates the periodogram is also. Values of I_k for all k therefore can be mapped to the unique values $I_k : k = 0 \dots K-1$ using the equations

$$\begin{aligned} I_k &= I_{-k} && \text{for all } k \\ I_k &= I_{k+nT} && \text{for } n = \pm 1, \pm 2, \pm 3, \dots \\ I_k &= I_{T-k} && \text{for } 0 \leq k \leq K-1 \end{aligned}$$

The periodogram, I_k , is an estimate at the discrete frequencies ω_k of the spectral density function which characterizes the series x_t . By smoothing the periodogram an improved spectral density estimate with reduced variance and bias can be achieved at these points. Smoothing can be accomplished either through use of a spectral window smoothing function or by applying a lag window filter to the series autocovariance function.

When the SPECTRA statement's DOMAIN=FREQUENCY option is in effect spectral density estimates are computed by smoothing the periodogram ordinates using the equation

$$S_k(M) = \sum_{\tau=K-T}^{K-1} w\left(\frac{\tau}{M}\right) I_{k+\tau}$$

where $w(\theta)$ is the spectral window function whose form is specified by either the KERNEL= option or the WEIGHTS option. M is the kernel scale parameter which acts as a frequency scaling factor in the spectral window smoothing function. Values of $I_{k+\tau}$ that fall outside of $0 \leq k + \tau \leq K-1$ are mapped to values inside this range by the equations presented previously.

When the DOMAIN=TIME option is specified spectral density values are estimated by applying a lag window filter, $\lambda(h, M)$, to the series autocovariance function. The spectral density estimate then can be computed from the filtered autocovariance function using the equation

$$S_k(M) = \sum_{h=-(T-1)}^{T-1} \lambda(h, M) \hat{\gamma}(h) \cos h\omega_k.$$

In this case the kernel scale parameter, M , serves as a scale factor for the lag length, h , in the time domain. In the lag window formulation the spectral density estimate is a consistent estimator as $T, M \rightarrow \infty$ under the conditions $\lambda(h, M) = 0$ for $|h| > M$, and $\lim_{T \rightarrow \infty} M/T = 0$. These conditions lead to the following parameterization of M provided by the SPECTRA statement:

$$M = cK^e$$

where the values $c > 0$ and $0 < e < 1$ satisfy the consistency conditions. To specify the kernel scale parameter explicitly, set $c =$ to the desired scale factor and $e = 0$.

For uniformity and computational efficiency all spectral density estimates are calculated using a spectral window weighting function, $w(\theta)$, applied to the periodogram ordinates. In the case where the DOMAIN=TIME option is specified the effective spectral window weighting function is computed by the equation

$$w_{\text{TIME}}(\theta) = \sum_{h=-(T-1)}^{T-1} \lambda(h, M) \cos h\theta.$$

Because the kernel scale parameter, M , serves as a lag scale factor in the time domain and bandwidth scale factor in the frequency domain the impact of M on spectral density estimates depends on the value of the DOMAIN= option. When DOMAIN=FREQUENCY increasing values of M decrease variance and increase bias in the spectral density estimates whereas when DOMAIN=TIME increasing values of M increase variance and decrease bias.

Using Kernel Specifications

You can specify one of ten different kernel smoothing functions in the SPECTRA statement. Five smoothing functions are available as KERNEL= options and five complementary smoothing functions which correspond to lag window filters are available when the KERNEL= option is used in conjunction with the DOMAIN=TIME option.

For example, a Parzen kernel with a support of 11 periodogram ordinates in the frequency domain can be specified using the kernel option:

```
spectra / parzen c=5 expon=0;
```

The TIMESERIES procedure supports the following spectral window kernel functions in the frequency domain where $x = \tau/M$:

BARTLETT: Bartlett kernel

$$w(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

PARZEN: Parzen kernel

$$w(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

QS: quadratic spectral kernel

$$w(x) = \frac{3}{(2\pi x)^2} \left(\frac{\sin 2\pi x}{2\pi x} - \cos 2\pi x \right)$$

TUKEY: Tukey-Hanning kernel

$$w(x) = \begin{cases} (1 + \cos(\pi x))/2 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

TRUNCAT: truncated kernel

$$w(x) = \begin{cases} 1 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

When the DOMAIN=TIME option is specified the five kernel functions above are interpreted as lag window filters on the autocovariance function. The lag window kernel functions correspond to the following spectral window smoothing functions where $\theta = 2\pi\tau/T$:

BARTLETT: Bartlett equivalent lag window filter

$$w(\theta) = \frac{1}{2\pi M} \left(\frac{\sin(M\theta/2)}{\sin(\theta/2)} \right)^2$$

PARZEN: Parzen equivalent lag window filter

$$w(\theta) = \frac{6}{\pi M^3} \left(\frac{\sin(M\theta/4)}{\sin(\theta/2)} \right)^4 \left(1 - \frac{2}{3} \sin^2(\theta/2) \right)$$

QS: quadratic spectral equivalent lag window filter

$$w(\theta) = \begin{cases} \frac{3M}{4\pi} (1 - (M\theta/\pi)^2) & |\theta| \leq \pi/M \\ 0 & |\theta| > \pi/M \end{cases}$$

TUKEY: Tukey-Hanning equivalent lag window filter

$$w(\theta) = \frac{1}{4} D_M(\theta - \pi/M) + \frac{1}{2} D_M(\theta) + \frac{1}{4} D_M(\theta + \pi/M)$$

$$D_M(\theta) = \frac{1}{2\pi} \frac{\sin[(M + 1/2)\theta]}{\sin(\theta/2)}$$

TRUNC: truncated equivalent lag window filter

$$w(\theta) = D_M(\theta)$$

Using Specification of Weight Constants

Any number of weighting constants can be specified. The constants are interpreted symmetrically about the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants is specified) is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS option scaled so that they sum to 1.

The moving average calculation reflects at each end of the periodogram to accommodate the periodicity of the periodogram function.

For example, a simple triangular weighting can be specified using the following WEIGHTS option:

```
spectra / weights 1 2 3 2 1;
```

Computational Method

If the number of observations, T , factors into prime integers that are less than or equal to 23, and the product of the square-free factors of T is less than 210, then the procedure uses the fast Fourier transform developed by Cooley and Tukey (1965) and implemented by Singleton (1969). If T cannot be factored in this way, then the procedure uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1977).

Missing Values

Missing values are replaced with an estimate of the mean to perform spectral analyses. This treatment of a series with missing values is consistent with the approach used by Priestley (1981).

Singular Spectrum Analysis

Given a time series, y_t , for $t = 1, \dots, T$, and a window length, $2 \leq L < T/2$, singular spectrum analysis Golyandina, Nekrutkin, and Zhigljavsky (2001) decompose the time series into spectral groupings using the following steps:

Embedding Step

Using the time series, form a $K \times L$ trajectory matrix, \mathbf{X} , with elements

$$\mathbf{X} = \{x_{k,l}\}_{k=1,l=1}^{K,L}$$

such that $x_{k,l} = y_{k-l+1}$ for $k = 1, \dots, K$ and $l = 1, \dots, L$ and where $K = T - L + 1$. By definition $L \leq K < T$, because $2 \leq L < T/2$.

Decomposition Step

Using the trajectory matrix, \mathbf{X} , apply singular value decomposition to the trajectory matrix

$$\mathbf{X} = \mathbf{U}\mathbf{Q}\mathbf{V}$$

where \mathbf{U} represents the $K \times L$ matrix that contains the left-hand-side (LHS) eigenvectors, where \mathbf{Q} represents the diagonal $L \times L$ matrix that contains the singular values, and where \mathbf{V} represents the $L \times L$ matrix that contains the right-hand-side (RHS) eigenvectors.

Therefore,

$$\mathbf{X} = \sum_{l=1}^L \mathbf{X}^{(l)} = \sum_{l=1}^L \mathbf{u}_l q_l \mathbf{v}_l^T$$

where $\mathbf{X}^{(l)}$ represents the $K \times L$ principal component matrix, \mathbf{u}_l represents the $K \times 1$ left-hand-side (LHS) eigenvector, q_l represents the singular value, and \mathbf{v}_l represents the $L \times 1$ right-hand-side (RHS) eigenvector associated with the l th window index.

Grouping Step

For each group index, $m = 1, \dots, M$, define a group of window indices $I_m \subset \{1, \dots, L\}$. Let

$$\mathbf{X}_{I_m} = \sum_{l \in I_m} \mathbf{X}^{(l)} = \sum_{l \in I_m} \mathbf{u}_l q_l \mathbf{v}_l^T$$

represent the grouped trajectory matrix for group I_m . If groupings represent a spectral partition,

$$\bigcup_{m=1}^M I_m = \{1, \dots, L\} \quad \text{and} \quad I_m \cap I_n = \emptyset \quad \text{for} \quad m \neq n$$

then according to the singular value decomposition theory,

$$\mathbf{X} = \sum_{m=1}^M \mathbf{X}_{I_m}$$

Averaging Step

For each group index, $m = 1, \dots, M$, compute the diagonal average of \mathbf{X}_{I_m} ,

$$\tilde{x}_t^{(m)} = \frac{1}{n_t} \sum_{l=s_t}^{e_t} x_{t-l+1,l}^{(m)}$$

where

$$\begin{aligned} s_t &= 1, & e_t &= t, & n_t &= t & \text{for} & 1 \leq t < L \\ s_t &= 1, & e_t &= L, & n_t &= L & \text{for} & L \leq t \leq T - L + 1 \\ s_t &= T - t - 1, & e_t &= L, & n_t &= T - t + 1 & \text{for} & T - L + 1 < t \leq T \end{aligned}$$

If the groupings represent a spectral partition, then by definition

$$y_t = \sum_{m=1}^M \tilde{x}_t^{(m)}$$

Hence, singular spectrum analysis additively decomposes the original time series, y_t , into m component series $\tilde{x}_t^{(m)}$ for $m = 1, \dots, M$.

Specifying the Window Length

You can explicitly specify the maximum window length, $2 \leq L \leq 1000$, using the `LENGTH=` option or implicitly specify the window length using the `INTERVAL=` option in the `ID` statement or the `SEASONALITY=` option in the `PROC TIMESERIES` statement.

Either way the window length is reduced based on the accumulated time series length, T , to enforce the requirement that $2 \leq L \leq T/2$.

Specifying the Groups

You can use the `GROUPS=` option to explicitly specify the composition and number of groups, $I_m \subset \{1, \dots, L\}$ or use the `THRESHOLDPCT=` option in the `SSA` statement to implicitly specify the grouping. The `THRESHOLDPCT=` option is useful for removing noise or less dominant patterns from the accumulated time series.

Let $0 < \alpha < 1$ be the cumulative percent singular value `THRESHOLDPCT=`. Then the last group, $I_M = \{l_\alpha, \dots, L\}$, is determined by the smallest value such that

$$\left(\sum_{l=1}^{l_\alpha-1} q_l / \sum_{l=1}^L q_l \right) \geq \alpha \quad \text{where } 1 < l_\alpha \leq L$$

Using this rule, the last group, I_M , describes the least dominant patterns in the time series and the size of the last group is at least one and is less than the window length, $L \geq 2$.

The magnitudes of the principal components which are plotted using the `PLOT=SSA` option and selected by the `THRESHOLDPCT=` option are based on the singular values which appear on the diagonal of \mathbf{Q} . Alternatively, each principal component's contribution to variation in the series can be quantified by using the squares of the singular values. The relative contributions of the principal components to variation in the series are included in the printed tabular output produced by the `PRINT=SSA` option.

Data Set Output

The `TIMESERIES` procedure can create the `OUT=`, `OUTCORR=`, `OUTCROSSCORR=`, `OUTDECOMP=`, `OUTSEASON=`, `OUTSPECTRA=`, `OUTSSA=`, `OUTSUM=`, and `OUTTREND=` data sets. In general, these data sets contain the variables listed in the `BY` statement. If an analysis step that is related to an output data step fails, the values of this step are not recorded or are set to missing in the related output data set and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The `OUT=` data set contains the variables specified in the `BY`, `ID`, `VAR`, and `CROSSVAR` statements. If the `ID` statement is specified, the `ID` variable values are aligned and extended based on the `ALIGN=` and `INTERVAL=` options. The values of the variables specified in the `VAR` and `CROSSVAR` statements are accumulated based on the `ACCUMULATE=` option, and missing values are interpreted based on the `SETMISSING=` option.

OUTCORR= Data Set

The OUTCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCORR= data set records the correlations for each variable specified in a VAR statement (not the CROSSVAR statement).

When the CORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to correlation statistics specified in the CORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

NAME	variable name
LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	an indicator of whether autocorrelations are less than (−1), greater than (1), or within (0) two standard errors of zero
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	an indicator of whether partial autocorrelations are less than (−1), greater than (1), or within (0) two standard errors of zero
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	an indicator of whether inverse autocorrelations are less than (−1), greater than (1), or within (0) two standard errors of zero
IACF2STD	two standard errors beyond inverse autocorrelation
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test Statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

The preceding correlation statistics are computed for each specified time lag.

When the CORR statement TRANSPOSE=YES option is specified, the variable *values* are related to correlation statistics specified in the CORR statement and the variable *names* are related to the NLAG= or LAGS= options.

NAME	variable name
STAT	correlation statistic name
LABEL	correlation statistic label
LAG h	correlation statistics for lag h

OUTCROSSCORR= Data Set

The OUTCROSSCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCROSSCORR= data set records the cross-correlations for each variable specified in a VAR and the CROSSVAR statements.

When the CROSSCORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to cross-correlation statistics specified in the CROSSCORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

NAME	variable name
CROSS	cross variable name
LAG	time lag
N	number of variance products
CCOV	cross-covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	an indicator of whether cross-correlations are less than (-1) , greater than (1) , or within (0) two standard errors of zero
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

The preceding cross-correlation statistics are computed for each specified time lag.

When the CROSSCORR statement TRANSPOSE=YES option is specified, the variable *values* are related to cross-correlation statistics specified in the CROSSCORR statement and the variable *names* are related to the NLAG= or LAGS= options.

NAME	variable name
CROSS	cross variable name
STAT	cross-correlation statistic name

<code>_LABEL_</code>	cross-correlation statistic label
<code>LAGh</code>	cross-correlation statistics for lag h

OUTDECOMP= Data Set

The OUTDECOMP= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTDECOMP= data set records the seasonal decomposition/adjustments for each variable specified in a VAR statement (not the CROSSVAR statement).

When the DECOMP statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to decomposition/adjustments specified in the DECOMP statement and the variable *values* are related to the ID statement INTERVAL= option and the PROC TIMESERIES statement SEASONALITY= option.

<code>_NAME_</code>	variable name
<code>_MODE_</code>	mode of decomposition
<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	seasonal index
<code>ORIGINAL</code>	original series values
<code>TCC</code>	trend-cycle component
<code>SIC</code>	seasonal-irregular component
<code>SC</code>	seasonal component
<code>SCSTD</code>	seasonal component standard errors
<code>TCS</code>	trend-cycle-seasonal component
<code>IC</code>	irregular component
<code>SA</code>	seasonally adjusted series
<code>PCSA</code>	percent change seasonally adjusted series
<code>TC</code>	trend component
<code>CC</code>	cycle component

The preceding decomposition components are computed for each time period.

When the DECOMP statement TRANSPOSE=YES option is specified, the variable *values* are related to decomposition/adjustments specified in the DECOMP statement and the variable *names* are related to the ID statement INTERVAL= option, the PROC TIMESERIES statement SEASONALITY= option, and the DECOMP statement NPERIODS= option.

<code>_NAME_</code>	variable name
<code>_MODE_</code>	mode of decomposition name
<code>_COMP_</code>	decomposition component name
<code>_LABEL_</code>	decomposition component label
<code>PERIODt</code>	decomposition component value for time period t

OUTPROCINFO= Data Set

The OUTPROCINFO= data set contains information about the run of the TIMESERIES procedure. The following variables are present:

<code>_SOURCE_</code>	set to the name of the procedure, in this case TIMESERIES
<code>_NAME_</code>	name of the item being reported
<code>_LABEL_</code>	descriptive label for the item in <code>_NAME_</code>
<code>_STAGE_</code>	set to the current stage of the procedure; for TIMESERIES this is set to ALL
<code>_VALUE_</code>	value of the item specified in <code>_NAME_</code>

OUTSEASON= Data Set

The OUTSEASON= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSEASON= data set records the seasonal statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SEASON statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to seasonal statistics specified in the SEASON statement and the variable *values* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

<code>_NAME_</code>	variable name
<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	seasonal index
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

The preceding statistics are computed for each season.

When the SEASON statement TRANSPOSE=YES option is specified, the variable *values* are related to seasonal statistics specified in the SEASON statement and the variable *names* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

<code>_NAME_</code>	variable name
<code>_STAT_</code>	season statistic name
<code>_LABEL_</code>	season statistic name
<code>SEASONs</code>	season statistic value for season s

OUTSPECTRA= Data Set

The OUTSPECTRA= data set contains the variables that are specified in the BY statement in addition to the variables listed below. The OUTSPECTRA= data set records the frequency domain analysis for each variable specified in a VAR statement (not the CROSSVAR statement).

The following variable names are related to correlation statistics specified in the SPECTRA statement options.

<code>_NAME_</code>	variable name
<code>FREQ</code>	frequency in radians from 0 to π
<code>PERIOD</code>	period or wavelength
<code>COS</code>	cosine transform
<code>SIN</code>	sine transform
<code>P</code>	periodogram
<code>S</code>	spectral density estimates

OUTSSA= Data Set

The OUTSSA= data set contains the variables that are specified in the BY statement in addition to the variables listed below. The OUTSSA= data set records the singular spectrum analysis (SSA) for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SSA statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to singular spectrum analysis specified in the SSA statement, and the variable *values* are related to the INTERVAL= option in the ID statement and the SEASONALITY= option in the PROC TIMESERIES statement.

<code>_NAME_</code>	variable name
<code>_TIMEID_</code>	time ID values
<code>_CYCLE_</code>	cycle index
<code>_SEASON_</code>	seasonal index
<code>ORIGINAL</code>	original series values
<code>_GROUPi_</code>	SSA result groups

The `_GROUPi_` decomposition components are computed for each time period.

When the SSA statement `TRANSPPOSE=YES` option is specified, the variable *values* are related to singular spectrum analysis specified in the SSA statement, and the variable *names* are related to the `INTERVAL=` option in the ID statement, the `SEASONALITY=` option in the PROC TIMESERIES statement, or the `NPERIODS=` option in the SSA statement. The following variables are written to a transposed `OUTSSA=` data set:

<code>_NAME_</code>	variable name
<code>_GROUP_</code>	group number
<code>PERIOD_t</code>	SSA group value for time period <i>t</i>

OUTSUM= Data Set

The `OUTSUM=` data set contains the variables specified in the BY statement as well as the variables listed below. The `OUTSUM=` data set records the descriptive statistics for each variable specified in a `VAR` statement (not the `CROSSVAR` statement).

Variables related to descriptive statistics are based on the `ACCUMULATE=` and `SETMISSING=` options in the ID and VAR statements:

<code>_NAME_</code>	variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>NOBS</code>	number of observations
<code>N</code>	number of nonmissing observations
<code>NMISS</code>	number of missing observations
<code>START</code>	the starting date of the time series
<code>END</code>	the ending date of the time series
<code>STARTOBS</code>	the beginning observation of the time series
<code>ENDOBS</code>	the ending observation of the time series
<code>MINIMUM</code>	minimum value
<code>MAXIMUM</code>	maximum value
<code>AVG</code>	average value
<code>STDDEV</code>	standard deviation

The `OUTSUM=` data set contains the descriptive statistics of the (accumulated) time series.

OUTTREND= Data Set

The OUTTREND= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTTREND= data set records the trend statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the TREND statement TRANSPOSE=NO option is omitted or explicitly specified, the variable *names* are related to trend statistics specified in the TREND statement and the variable *values* are related to the INTERVAL= option in the ID statement or the SEASONALITY= option in the PROC TIMESERIES statement.

NAME	variable name
TIMEID	time ID values
SEASON	seasonal index
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

The preceding statistics are computed for each time period.

When the TREND statement TRANSPOSE=YES option is specified, the variable *values* related to trend statistics specified in the TREND statement and the variable *names* are related to the INTERVAL= option in the ID statement, the SEASONALITY= option in the PROC TIMESERIES statement, or the NPERIODS= option in the TREND statement. The following variables are written to the OUTTREND= data set:

NAME	variable name
STAT	trend statistic name
LABEL	trend statistic name
PERIOD t	trend statistic value for time period t

STATUS Variable Values

The `_STATUS_` variable that appears in the `OUTSUM=` data set contains a code that specifies whether the analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	success
1000	transactional trend statistics failure
2000	transactional seasonal statistics failure
3000	accumulation failure
4000	missing value interpretation failure
6000	series is all missing
7000	transformation failure
8000	differencing failure
9000	unable to compute descriptive statistics
10000	seasonal decomposition failure
11000	correlation analysis failure
15000	singular spectrum analysis failure
16000	spectral analysis failure

Printed Output

The TIMESERIES procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the `PRINT=` and `PRINTDETAILS` options associated with the `PROC TIMESERIES` statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error or warning messages or both are recorded in the log. The printed output is similar to the output data set, and these similarities are described below.

<code>PRINT=DECOMP</code>	prints the seasonal decomposition similar to the <code>OUTDECOMP=</code> data set.
<code>PRINT=DESCSTATS</code>	prints a table of descriptive statistics for each variable.
<code>PRINT=SEASONS</code>	prints the seasonal statistics similar to the <code>OUTSEASON=</code> data set.
<code>PRINT=SSA</code>	prints the singular spectrum analysis similar to the <code>OUTSSA=</code> data set.
<code>PRINT=SUMMARY</code>	prints the summary statistics similar to the <code>OUTSUM=</code> data set.
<code>PRINT=TRENDS</code>	prints the trend statistics similar to the <code>OUTTREND=</code> data set.
<code>PRINTDETAILS</code>	prints each table with greater detail.

If `PRINT=SEASONS` and the `PRINTDETAILS` options are both specified, all seasonal statistics are printed.

ODS Table Names

Table 32.4 relates the PRINT= options to ODS tables:

Table 32.4 ODS Tables Produced in PROC TIMESERIES

ODS Table Name	Description	Statement	Option
SeasonalDecomposition	Seasonal decomposition	PRINT	DECOMP
DescStats	Descriptive statistics	PRINT	DESCSTATS
GlobalStatistics	Global statistics	PRINT	SEASONS
SeasonStatistics	Season statistics	PRINT	SEASONS
StatisticsSummary	Statistics summary	PRINT	SUMMARY
TrendStatistics	Trend statistics	PRINT	TRENDS
GlobalStatistics	Global statistics	PRINT	TRENDS
SSASingularValues	SSA singular values	PRINT	SSA
SSAResults	SSA results	PRINT	SSA

The tables are related to a single series within a BY group.

ODS Graphics Names

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

This section describes the graphical output produced by the TIMESERIES procedure. PROC TIMESERIES assigns a name to each graph it creates. These names are listed in Table 32.5.

Table 32.5 ODS Graphics Produced by PROC TIMESERIES

ODS Graph Name	Plot Description	Statement	Option
ACFPlot	Autocorrelation function	PLOTS	ACF
ACFNORMPlot	Normalized autocorrelation function	PLOTS	ACF
CCFNORMPlot	Normalized cross-correlation function	CROSSPLOTS	CCF
CCFPlot	Cross-correlation function	CROSSPLOTS	CCF
CorrelationPlots	Correlation graphics panel	PLOTS	CORR

Examples: TIMESERIES Procedure

Example 32.1: Accumulating Transactional Data into Time Series Data

This example illustrates using the TIMESERIES procedure to accumulate time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment/decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP. The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of to missing (SETMISS=0) and only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31DEC2000'D) are considered and, if needed, extended to include this range.

```
proc timeseries data=retail out=mseries;
  by store;
  id timestamp interval=month
      accumulate=median
      setmiss=0
      start='01jan1998'd
      end  ='31dec2000'd;
  var item1-item8;
run;
```

The monthly time series data are stored in the data WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the variable STORE, TIMESTAMP, and each of the analysis variables in the input data set.

After each set of transactions has been accumulated to form corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM.

```
proc expand data=mseries out=smoothed from=month;
  by store;
  id date;
  convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series are stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options must be changed accordingly and the following statements could be used:

```
proc timeseries data=retail out=tseries;
  by store;
  id timestamp interval=dtmonth
    accumulate=median
    setmiss=0
    start='01jan1998:00:00:00'dt
    end  ='31dec2000:00:00:00'dt;
  var _numeric_;
run;
```

The monthly time series data are stored in the data WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 32.2: Trend and Seasonal Analysis

This example illustrates using the TIMESERIES procedure for trend and seasonal analysis of time-stamped transactional data.

Suppose that the data set SASHELP.AIR contains two variables: DATE and AIR. The variable DATE contains sorted SAS date values recorded at no particular frequency. The variable AIR contains the transaction values to be analyzed.

The following statements accumulate the transactional data on an average basis to form a quarterly time series and perform trend and seasonal analysis on the transactions.

```
proc timeseries data=sashelp.air
  out=series
  outtrend=trend
  outseason=season print=seasons;
  id date interval=qtr accumulate=avg;
  var air;
run;
```

The time series is stored in the data set WORK.SERIES, the trend statistics are stored in the data set WORK.TREND, and the seasonal statistics are stored in the data set WORK.SEASON. Additionally, the seasonal statistics are printed (PRINT=SEASONS) and the results of the seasonal analysis are shown in [Output 32.2.1](#).

Output 32.2.1 Seasonal Statistics Table

The TIMESERIES Procedure						
Season Statistics for Variable AIR						
Season Index	N	Minimum	Maximum	Sum	Mean	Standard Deviation
1	36	112.0000	419.0000	8963.00	248.9722	95.65189
2	36	121.0000	535.0000	10207.00	283.5278	117.61839
3	36	136.0000	622.0000	12058.00	334.9444	143.97935
4	36	104.0000	461.0000	9135.00	253.7500	101.34732

Using the trend statistics stored in the WORK.TREND data set, the following statements plot various trend statistics associated with each time period over time.

```

title1 "Trend Statistics";
proc sgplot data=trend;
  series x=date y=max / lineattrs=(pattern=solid);
  series x=date y=mean / lineattrs=(pattern=solid);
  series x=date y=min / lineattrs=(pattern=solid);
  yaxis display=(nolabel);
  format date year4.;
run;

```

The results of this trend analysis are shown in [Output 32.2.2](#).

Output 32.2.2 Trend Statistics Plot

Using the trend statistics stored in the WORK.TREND data set, the following statements chart the sum of the transactions associated with each time period for the second season over time.

```

title1 "Trend Statistics for 2nd Season";
proc sgplot data=trend;
  where _season_ = 2;
  vbar date / freq=sum;
  format date year4.;
  yaxis label='Sum';
run;

```

The results of this trend analysis are shown in [Output 32.2.3](#).

Output 32.2.3 Trend Statistics Bar Chart

Using the trend statistics stored in the WORK.TREND data set, the following statements plot the mean of the transactions associated with each time period by each year over time.

```
data trend;
  set trend;
  year = year(date);
run;

title1 "Trend Statistics by Year";
proc sgplot data=trend;
  series x=_season_ y=mean / group=year lineattrs=(pattern=solid);
  xaxis values=(1 to 4 by 1);
run;
```

The results of this trend analysis are shown in [Output 32.2.4](#).

Output 32.2.4 Trend Statistics

Using the season statistics stored in the WORK.SEASON data set, the following statements plot various season statistics for each season.

```

title1 "Seasonal Statistics";
proc sgplot data=season;
  series x=_season_ y=max / lineattrs=(pattern=solid);
  series x=_season_ y=mean / lineattrs=(pattern=solid);
  series x=_season_ y=min / lineattrs=(pattern=solid);
  yaxis display=(nolabel);
  xaxis values=(1 to 4 by 1);
run;

```

The results of this seasonal analysis are shown in [Output 32.2.5](#).

Output 32.2.5 Seasonal Statistics Plot

Example 32.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the simply differenced series of masonry workers. The series plot, the correlation panel, the seasonal adjustment panel, and all cross-series plots are requested. [Output 32.3.1](#) through [Output 32.3.4](#) show a selection of the plots created.

The graphical displays are requested by specifying the **PLOTS=** or **CROSSPLOTS=** options in the PROC TIMESERIES statement. For information about the graphics available in the TIMESERIES procedure, see the section “[ODS Graphics Names](#)” on page 2223.

```

title "Illustration of ODS Graphics";
proc timeseries data=sashelp.workers out=_null_
               plots=(series corr decomp)
               crossplots=all;
  id date interval=month;
  var electric;
  crossvar masonry / dif=(1);

```

```
run;
```

Output 32.3.1 Series Plot

Output 32.3.2 Correlation Panel

Output 32.3.3 Seasonal Decomposition Panel

Output 32.3.4 Cross-Correlation Plot

Example 32.4: Illustration of Spectral Analysis

This example illustrates the use of spectral analysis.

The following statements perform a spectral analysis on the SUNSPOT dataset. The periodogram is displayed as a function of the period and frequency in [Output 32.4.1](#). The estimated spectral density together with its 50% confidence limits are displayed in [Output 32.4.2](#).

```
title "Wolfer's Sunspot Data";

proc timeseries data=sunspot plot=(series periodogram spectrum);
  var wolfer;
  id year interval=year;
  spectra freq period p s / adjmean bart c=1.5 expon=0.2;
run;
```

Output 32.4.1 Periodogram

Output 32.4.2 Spectral Density Plot

Example 32.5: Illustration of Singular Spectrum Analysis

This example illustrates the use of singular spectrum analysis.

The following statements extract two additive components from the SASHELP.AIR time series by using the THRESHOLDPCT= option to specify that the first component represent 80% of the variability in the series. The resulting groupings, consisting of the first three and remaining nine singular value components, are presented in [Output 32.5.1](#) through [Output 32.5.3](#).

```
title "SSA of AIR data";

proc timeseries data=sashelp.air plot=ssa;
  id date interval=month;
  var air;
  ssa / length=12 THRESHOLDPCT=80;
run;
```

Output 32.5.1 Singular Value Grouping #1 Plot

Output 32.5.2 Singular Value Grouping #2 Plot

Overview: The TSCSREG Procedure

The TSCSREG (time series cross section regression) procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. The TSCSREG procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

The TSCSREG procedure is very similar to the PANEL procedure; for full description, syntax details, models, and estimation methods, see Chapter 20, “[The PANEL Procedure](#).” The TSCSREG procedure is no longer being updated, and it shares the code base with the PANEL procedure.

The original TSCSREG procedure was developed by Douglas J. Drummond and A. Ronald Gallant, and contributed to the Version 5 SUGI Supplemental Library in 1979. The original code was changed substantially over the years. Additional new methods as well as other new features are currently included in the PANEL PROCEDURE. SAS Institute would like to thank Dr. Drummond and Dr. Gallant for their contribution of the original version of the TSCSREG procedure.

Getting Started: The TSCSREG Procedure

Specifying the Input Data

The input data set used by the TSCSREG procedure must be sorted by cross section and by time within each cross section. Therefore, the first step in using PROC TSCSREG is to make sure that the input data set is sorted. Normally, the input data set contains a variable that identifies the cross section for each observation and a variable that identifies the time period for each observation.

To illustrate, suppose that you have a data set A that contains data over time for each of several states. You want to regress the variable Y on regressors X1 and X2. Cross sections are identified by the variable STATE, and time periods are identified by the variable DATE. The following statements sort the data set A appropriately:

```
proc sort data=a;
  by state date;
run;
```

The next step is to invoke the TSCSREG procedure and specify the cross section and time series variables in an ID statement. List the variables in the ID statement exactly as they are listed in the BY statement.

```
proc tscsreg data=a;
  id state date;
```

Alternatively, you can omit the ID statement and use the CS= and TS= options on the PROC TSCSREG statement to specify the number of cross sections in the data set and the number of time series observations in each cross section.

Unbalanced Data

In the case of fixed-effects and random-effects models, the TSCSREG procedure is capable of processing data with different numbers of time series observations across different cross sections. You must specify the ID statement to estimate models that use unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Specifying the Regression Model

Next, specify the linear regression model with a MODEL statement, as shown in the following statements.

```
proc tscsreg data=a;
  id state date;
  model y = x1 x2;
run;
```

The MODEL statement in PROC TSCSREG is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables.

The reason for using PROC TSCSREG instead of other SAS regression procedures is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the TSCSREG procedure are FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA. See “[Details: The TSCSREG Procedure](#)” on page 2254 for more information about these methods and the error structures they assume.

By default, the two-way random-effects error model structure is used while Fuller-Battese and Wansbeek-Kapteyn methods are used for the estimation of variance components in balanced data and unbalanced data, respectively. Thus, the preceding example is the same as specifying the RANTWO option, as shown in the following statements:

```
proc tscsreg data=a;
  id state date;
  model y = x1 x2 / rantwo;
run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each method specified. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an F statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman m -statistic that provides information about the appropriateness of the random-effects specification. It is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure, which is the most appropriate goodness-of-fit measure for models estimated by using GLS. This number is interpreted as a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.

Estimation Techniques

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is equivalent to best linear unbiased estimation.

The output from TSCSREG is identical to what one would obtain from creating dummy variables to represent the cross-sectional and time (fixed) effects. The output is presented in this manner to facilitate comparisons to the least squares dummy variables estimator (LSDV). As such, the inclusion of an intercept term implies that one dummy variable must be dropped. The actual estimation of the fixed-effects models is not LSDV. LSDV is much too cumbersome to implement. Instead, TSCSREG operates in a two step fashion. In the first step, the following occurs:

- *One-way fixed-effects model:* In the one-way fixed-effects model, the data is transformed by removing the cross-sectional means from the dependent and independent variables. The following is true:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i.$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i.$$

- *Two-way fixed-effects model:* In the two-way fixed-effects model, the data is transformed by removing the cross-sectional and time means and adding back the overall means:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i - \bar{y}_{\cdot t} + \bar{\bar{y}}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{\cdot t} + \bar{\bar{\mathbf{x}}}$$

where the symbols:

y_{it} and \mathbf{x}_{it} are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables not including a constant), respectively

\bar{y}_i and $\bar{\mathbf{x}}_i$ are cross section means

$\bar{y}_{\cdot t}$ and $\bar{\mathbf{x}}_{\cdot t}$ are time means

$\bar{\bar{y}}$ and $\bar{\bar{\mathbf{x}}}$ are the overall means

The second step consists of running OLS on the properly demeaned series, provided that the data are balanced. The unbalanced case is slightly more difficult, because the structure of the missing data must be retained. For this case, PROC TSCSREG uses a slight specialization on Wansbeek and Kapteyn.

The other alternative is to assume that the effects are random. In the one-way case, $E(v_i) = 0$, $E(v_i^2) = \sigma_v^2$, and $E(v_i v_j) = 0$ for $i \neq j$, and v_i is uncorrelated with ϵ_{it} for all i and t . In the two-way case, in addition to all of the preceding, $E(e_t) = 0$, $E(e_t^2) = \sigma_e^2$, and $E(e_t e_s) = 0$ for $t \neq s$, and the e_t are uncorrelated with the v_i and the ϵ_{it} for all i and t . Thus, the model is a variance components model, with the variance components σ_v^2 , σ_e^2 , and σ_ϵ^2 , to be estimated. A crucial implication of such a specification is that the effects are independent of the regressors. For random-effects models, the estimation method is an estimated generalized least squares (EGLS) procedure that involves estimating the variance components in the first stage and using the estimated variance covariance matrix thus obtained to apply generalized least squares (GLS) to the data.

Introductory Example

The following example uses the cost function data from Greene (1990) to estimate the variance components model. The variable OUTPUT is the log of output in millions of kilowatt-hours, and COST is the log of cost in millions of dollars. See to Greene (1990) for details.

```

title1;
data greene;
    input firm year output cost @@;
    df1 = firm = 1;
    df2 = firm = 2;
    df3 = firm = 3;
    df4 = firm = 4;
    df5 = firm = 5;
    d60 = year = 1960;
    d65 = year = 1965;
    d70 = year = 1970;
datalines;
    1 1955    5.36598    1.14867    1 1960    6.03787    1.45185
... more lines ...

```

Usually you cannot explicitly specify all the explanatory variables that affect the dependent variable. The omitted or unobservable variables are summarized in the error disturbances. The TSCSREG procedure used with the RANTWO option specifies the two-way random-effects error model where the variance components are estimated by the Fuller-Battese method, because the data are balanced and the parameters are efficiently estimated by using the GLS method. The variance components model used by the Fuller-Battese method is

$$y_{it} = \sum_{k=1}^K X_{itk} \beta_k + v_i + e_t + \epsilon_{it} \quad i = 1, \dots, N; t = 1, \dots, T$$

The following statements fit this model.

```

proc sort data=greene;
    by firm year;
run;

proc tscsreg data=greene;
    model cost = output / rantwo;
    id firm year;
run;

```

The TSCSREG procedure output is shown in [Figure 33.1](#). A model description is printed first; it reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and t tests.

Syntax: The TSCSREG Procedure

The following statements are used with the TSCSREG procedure.

```
PROC TSCSREG options ;
  BY variables ;
  ID cross-section-id-variable time-series-id-variable ;
  MODEL dependent = regressor-variables / options ;
  TEST equation1 < ,equation2... > ;
```

Functional Summary

The statements and options used with the TSCSREG procedure are summarized in the following table.

Table 33.1 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	TSCSREG	DATA=
write parameter estimates to an output data set	TSCSREG	OUTEST=
include correlations in the OUTEST= data set	TSCSREG	CORROUT
include covariances in the OUTEST= data set	TSCSREG	COVOUT
specify number of time series observations	TSCSREG	TS=
specify number of cross sections	TSCSREG	CS=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the cross section and time ID variables	ID	
Printing Control Options		
print correlations of the estimates	MODEL	CORRB
print covariances of the estimates	MODEL	COVB
suppress printed output	MODEL	NOPRINT
perform tests of linear hypotheses	TEST	
Model Estimation Options		
specify the one-way fixed-effects model	MODEL	FIXONE
specify the two-way fixed-effects model	MODEL	FIXTWO
specify the one-way random-effects model	MODEL	RANONE
specify the two-way random-effects model	MODEL	RANTWO
specify Fuller-Battese method	MODEL	FULLER
specify PARKS	MODEL	PARKS
specify Da Silva method	MODEL	DASILVA
specify order of the moving-average error process for Da Silva method	MODEL	M=

Description	Statement	Option
print Φ matrix for Parks method	MODEL	PHI
print autocorrelation coefficients for Parks method	MODEL	RHO
suppress the intercept term	MODEL	NOINT
control check for singularity	MODEL	SINGULAR=

PROC TSCSREG Statement

PROC TSCSREG *options* ;

The following options can be specified in the PROC TSCSREG statement.

DATA=SAS-data-set

names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

TS=number

specifies the number of observations in the time series for each cross section. The TS= option value must be greater than 1. The TS= option is required unless an ID statement is used. Note that the number of observations for each time series must be the same for each cross section and must cover the same time period.

CS=number

specifies the number of cross sections. The CS= option value must be greater than 1. The CS= option is required unless an ID statement is used.

OUTEST=SAS-data-set

the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set.

OUTCORR

CORROUT

writes the correlation matrix of the parameter estimates to the OUTEST= data set.

In addition, any of the following MODEL statement options can be specified in the PROC TSCSREG statement: CORRB, COVB, FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, and SINGULAR=. When specified in the PROC TSCSREG statement, these options are equivalent to specifying the options for every MODEL statement.

BY Statement

BY *variables* ;

A BY statement can be used with PROC TSCSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

When both an ID statement and a BY statement are specified, the input data set must be sorted first with respect to BY variables and then with respect to the cross section and time series ID variables. For example,

```
proc sort data=a;
    by byvar1 byvar2 csid tsid;
run;

proc tscsreg data=a;
    by byvar1 byvar2;
    id csid tsid;
    ...
run;
```

When both a BY statement and an ID statement are used, the data set might have a different number of cross sections or a different number of time periods in each BY group. If no ID statement is used, the CS= N and TS= T options must be specified and each BY group must contain $N \times T$ observations.

ID Statement

ID *cross-section-id-variable time-series-id-variable* ;

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the TSCSREG procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The TSCSREG procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT with a BY statement with the variables listed exactly as they are listed in the ID statement to sort the input data set. For example,

```
proc sort data=a;
    by csid tsid;
run;

proc tscsreg data=a;
    id csid tsid;
    ... etc. ...
run;
```

If the ID statement is not used, the TS= and CS= options must be specified on the PROC TSCSREG statement. Note that the input data must be sorted by time within cross section, regardless of whether the cross section structure is given by an ID statement or by the options TS= and CS=.

If an ID statement is specified, the time series length T is set to the minimum number of observations for any cross section, and only the first T observations in each cross section are used. If both the ID statement and the TS= and CS= options are specified, the TS= and CS= options are ignored.

MODEL Statement

MODEL *response = regressors / options ;*

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels up to 32 characters in length. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label: **MODEL** *response = regressors / options ;*

The following options can be specified on the MODEL statement after a slash (/).

CORRB

CORR

prints the matrix of estimated correlations between the parameter estimates.

COVB

VAR

prints the matrix of estimated covariances between the parameter estimates.

FIXONE

specifies that a one-way fixed-effects model be estimated with the one-way model that corresponds to group effects only.

FIXTWO

specifies that a two-way fixed-effects model be estimated.

RANONE

specifies that a one-way random-effects model be estimated.

RANTWO

specifies that a two-way random-effects model be estimated.

FULLER

specifies that the model be estimated by using the Fuller-Battese method, which assumes a variance components model for the error structure.

PARKS

specifies that the model be estimated by using the Parks method, which assumes a first-order autoregressive model for the error structure.

DASILVA

specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure.

M=number

specifies the order of the moving-average process in the Da Silva method. The M= value must be less than $T - 1$. The default is M=1.

PHI

prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used.

RHO

prints the estimated autocorrelation coefficients for the Parks method.

NOINT**NOMEAN**

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

SINGULAR=number

specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TEST Statement

TEST *equation* < , *equation* ... > < / *options* > ;

The TEST statement performs F tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following statements illustrate the use of the TEST statement:

```
proc tscsreg;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0;
  test_int: test intercept=0, x3 = 0;
```

Note that a test of the following form is not permitted:

```
test_bad: test x2 / 2 + 2 * x3 = 0;
```

Do not use the division sign in test/restrict statements.

Details: The TSCSREG Procedure

Models, estimators, and methods are covered in detail in Chapter 20, “The PANEL Procedure.”

ODS Table Names

PROC TSCSREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 33.2 ODS Tables Produced in PROC TSCSREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ModelDescription	Model description	default
FitStatistics	Fit statistics	default
FixedEffectsTest	<i>F</i> test for no fixed effects	FIXONE, FIXTWO, RA- NONE, RANTWO
ParameterEstimates	Parameter estimates	default
CovB	Covariance of parameter estimates	COVB
CorrB	Correlations of parameter estimates	CORRB
VarianceComponents	Variance component estimates	FULLER, DASILVA, M=, RANONE, RANTWO
RandomEffectsTest	Hausman test for random effects	FULLER, DASILVA, M=, RANONE, RANTWO
AR1Estimates	First order autoregressive parameter estimates	PARKS, RHO
EstimatedPhiMatrix	Estimated phi matrix	PARKS
EstimatedAutocovariances	Estimates of autocovariances	DASILVA, M=
ODS Tables Created by the TEST Statement		
TestResults	Test results	

Examples: The TSCSREG Procedure

For examples of analysis of panel data, see Chapter 20, “[The PANEL Procedure](#).”

Overview: UCM Procedure

The UCM procedure analyzes and forecasts equally spaced univariate time series data by using an unobserved components model (UCM). The UCMs are also called *structural models* in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in explaining and predicting its behavior. Harvey (1989) is a good reference for time series modeling that uses the UCMs. Harvey calls the components in a UCM the “stylized facts” about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the exponential smoothing models have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of UCM and ARIMA modeling, is given in Harvey (1989). The UCMs are also very similar to another set of models, called the *dynamic models*, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS/ETS, you can use PROC SSM for multivariate (and more general univariate) UCMs (see Chapter 27, “[The SSM Procedure](#)”), PROC ARIMA for ARIMA modeling (see Chapter 7, “[The ARIMA Procedure](#)”), PROC ESM for exponential smoothing modeling (see Chapter 14, “[The ESM Procedure](#)”), and the Time Series Forecasting System for a point-and-click interface to ARIMA and exponential smoothing modeling.

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of time series analysis using the UCMs. Once a suitable UCM is found for the series under consideration, it can be used for a variety of purposes. For example, it can be used for the following:

- forecasting the values of the response series and the component series in the model
- obtaining a model-based seasonal decomposition of the series
- obtaining a “denoised” version and interpolating the missing values of the response series in the historical period
- obtaining the full sample or “smoothed” estimates of the component series in the model

Getting Started: UCM Procedure

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for estimating and forecasting the commonly observed features in time series. These models are discussed in detail later in the section “[An Introduction to Unobserved Component Models](#)” on page 2296. First the procedure is illustrated using an example.

A Seasonal Series with Linear Trend

The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a steady rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. The following DATA step prepares the log-transformed passenger series analyzed in this example:

```
data seriesG;
    set sashelp.air;
    logair = log( air );
run;
```

The following statements produce a time series plot of the series by using the TIMESERIES procedure (see Chapter 32, “[The TIMESERIES Procedure](#)”). The trend and seasonal features of the series are apparent in the plot in [Figure 34.1](#).

```
proc timeseries data=seriesG plot=series;
    id date interval=month;
    var logair;
run;
```

Figure 34.1 Series Plot of Log-Transformed Airline Passenger Series

In this example this series is modeled using an unobserved component model called the basic structural model (BSM). The BSM models a time series as a sum of three stochastic components: a trend component μ_t , a seasonal component γ_t , and random error ϵ_t . Formally, a BSM for a response series y_t can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error ϵ_t , also called the *irregular component*, is modeled simply as a sequence of independent, identically distributed (i.i.d.) zero-mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a *locally linear time trend*. This trend model can be written as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2)\end{aligned}$$

These equations specify a trend where the level μ_t as well as the slope β_t is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms η_t and ξ_t in their respective equations. Some interesting special cases of this model arise when you manipulate these disturbance variances. For example, if the variance of ξ_t is zero, the slope will be constant (equal to β_0); if the variance of η_t is also zero, μ_t will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model used in this example is called a trigonometric seasonal. The stochastic equations governing a trigonometric seasonal are explained later (see the section “[Modeling Seasons](#)” on page 2298). However, it is interesting to note here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is equal to zero. The following statements specify a BSM with these three components:

```
proc ucm data=seriesG;
    id date interval=month;
    model logair;
    irregular;
    level;
    slope;
    season length=12 type=trig print=smooth;
    estimate;
    forecast lead=24 print=decomp;
run;
```

The PROC UCM statement signifies the start of the UCM procedure, and the input data set, `seriesG`, containing the dependent series is specified there. The optional **ID** statement is used to specify a date, datetime, or time identification variable, `date` in this example, to label the observations. The `INTERVAL=MONTH` option in the ID statement indicates that the measurements were collected on a monthly basis. The model specification begins with the **MODEL** statement, where the response series is specified (`logair` in this case). After this the components in the model are specified using separate statements that enable you to control their individual properties. The irregular component ϵ_t is specified using the **IRREGULAR** statement and the trend component μ_t is specified using the **LEVEL** and **SLOPE** statements. The seasonal component γ_t is specified using the **SEASON** statement. The specifics of the seasonal characteristics such as the season length, its stochastic evolution properties, etc., are specified using the options in the **SEASON** statement. The seasonal component used in this example has a season length of 12, corresponding to the monthly seasonality, and is of the *trigonometric* type. Different types of seasonals are explained later (see the section “[Modeling Seasons](#)” on page 2298).

The parameters of this model are the variances of the disturbance terms in the evolution equations of μ_t , β_t , and γ_t and the variance of the irregular component ϵ_t . These parameters are estimated by maximizing the likelihood of the data. The **ESTIMATE** statement options can be used to specify the span of data used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts—for example, **PRINT=SMOOTH** option in the **SEASON** statement requests the displaying of smoothed forecasts of the seasonal component γ_t . The series forecasts and forecasts of the sum of components can be requested using the **FORECAST** statement. The option **PRINT=DECOMP** in the **FORECAST** statement requests the printing of the smoothed trend μ_t and the trend plus seasonal component ($\mu_t + \gamma_t$).

The parameter estimates for this model are displayed in [Figure 34.2](#).

Figure 34.2 BSM for the Logair Series

The UCM Procedure					
Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00023436	0.0001079	2.17	0.0298
Level	Error Variance	0.00029828	0.0001057	2.82	0.0048
Slope	Error Variance	8.47916E-13	6.2271E-10	0.00	0.9989
Season	Error Variance	0.00000356	1.32347E-6	2.69	0.0072

The estimates suggest that except for the slope component, the disturbance variances of all the components are significant—that is, all these components are *stochastic*. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It might then be useful to check if the slope component can be dropped from the model—that is, if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in [Figure 34.3](#).

Figure 34.3 Component Significance Analysis for the Logair Series

Significance Analysis of Components (Based on the Final State)			
Component	DF	Chi-Square	Pr > ChiSq
Irregular	1	0.08	0.7747
Level	1	117867	<.0001
Slope	1	43.78	<.0001
Season	11	507.75	<.0001

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic, then this analysis pertains only to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component's contribution appears insignificant toward the end of the estimation span; however, since it is a stochastic component, it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at zero. This is done by modifying the SLOPE statement as follows:

```
slope variance=0 noest;
```

After a tentative model is fit, its adequacy can be checked by examining different goodness-of-fit measures and other diagnostic tests and plots that are based on the model residuals. Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components in the model. The plots of component forecasts can be useful in understanding their contributions to the series. The following statements illustrate some of these features:

```
proc ucm data=seriesG;
  id date interval = month;
  model logair;
  irregular;
  level plot=smooth;
  slope variance=0 noest;
  season length=12 type=trig
    plot=smooth;
  estimate;
  forecast lead=24 plot=decomp;
run;
```

The table given in [Figure 34.4](#) shows the goodness-of-fit statistics that are computed by using the one-step-ahead prediction errors (see the section “[Statistics of Fit](#)” on page 2334). These measures indicate a good agreement between the model and the data. Additional diagnostic measures are also printed by default but are not shown here.

Figure 34.4 Fit Statistics for the Logair Series

The UCM Procedure	
Fit Statistics Based on Residuals	
Mean Squared Error	0.00147
Root Mean Squared Error	0.03830
Mean Absolute Percentage Error	0.54132
Maximum Percent Error	2.19097
R-Square	0.99061
Adjusted R-Square	0.99046
Random Walk R-Square	0.87288
Amemiya's Adjusted R-Square	0.99017
Number of non-missing residuals used for computing the fit statistics = 131	

The first plot, shown in [Figure 34.5](#), is produced by the PLOT=SMOOTH option in the LEVEL statement, it shows the smoothed level of the series.

Figure 34.5 Smoothed Trend in the Logair Series

The second plot (Figure 34.6), produced by the PLOT=SMOOTH option in the SEASON statement, shows the smoothed seasonal component by itself.

Figure 34.6 Smoothed Seasonal in the Logair Series

The plot of the sum of the trend and seasonal component, produced by the PLOT=DECOMP option in the FORECAST statement, is shown in [Figure 34.7](#). You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future based on the LEAD=24 option specified in the FORECAST statement.

Figure 34.7 Smoothed Trend plus Seasonal in the Logair Series

Syntax: UCM Procedure

The UCM procedure uses the following statements:

```

PROC UCM < options > ;
  AUTOREG < options > ;
  BLOCKSEASON options ;
  BY variables ;
  CYCLE < options > ;
  DEPLAG options ;
  ESTIMATE < options > ;
  FORECAST < options > ;
  ID variable options ;
  IRREGULAR < options > ;
  LEVEL < options > ;
  MODEL dependent variable < = regressors > ;
  NLOPTIONS options ;
  PERFORMANCE options ;
  OUTLIER options ;
  RANDOMREG regressors < / options > ;
  SEASON options ;
  SLOPE < options > ;
  SPLINEREG regressor < options > ;
  SPLINESEASON options ;

```

The **PROC UCM** and **MODEL** statements are required. In addition, the model must contain at least one component with nonzero disturbance variance.

Functional Summary

The statements and options controlling the UCM procedure are summarized in the following table. Most commonly needed scenarios are listed; see the individual statements for additional details. You can use the **PRINT=** and **PLOT=** options in the individual component statements for printing and plotting the corresponding component forecasts.

Table 34.1 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	PROC UCM	DATA=
write parameter estimates to an output data set	ESTIMATE	OUTEST=
write series and component forecasts to an output data set	FORECAST	OUTFOR=

Table 34.1 *continued*

Description	Statement	Option
Model Specification		
specify the dependent variable and simple predictors	MODEL	
specify predictors with time-varying coefficients	RANDOMREG	
specify a nonlinear predictor	SPLINEREG	
specify the irregular component	IRREGULAR	
specify the random walk trend	LEVEL	
specify the locally linear trend	LEVEL and SLOPE	
specify a cycle component	CYCLE	
specify a dummy seasonal component	SEASON	TYPE=DUMMY
specify a trigonometric seasonal component	SEASON	TYPE=TRIG
drop some harmonics from a trigonometric seasonal component	SEASON	DROPH=
specify a list of harmonics to keep in a trigonometric seasonal component	SEASON	KEEPH=
specify a spline-season component	SPLINESEASON	
specify a block-season component	BLOCKSEASON	
specify an autoreg component	AUTOREG	
specify the lags of the dependent variable	DEPLAG	
Controlling the Likelihood Optimization Process		
request optimization of the profile likelihood	ESTIMATE	PROFILE
request optimization of the usual likelihood	ESTIMATE	NOPROFILE
specify the optimization technique	NLOPTIONS	TECH=
limit the number of iterations	NLOPTIONS	MAXITER=
Outlier Detection		
turn on the search for additive outliers		Default
turn on the search for level shifts	LEVEL	CHECKBREAK
specify the significance level for outlier tests	OUTLIER	ALPHA=
limit the number of outliers	OUTLIER	MAXNUM=
limit the number of outliers to a percentage of the series length	OUTLIER	MAXPCT=
Controlling the Series Span		
exclude some initial observations from analysis during the parameter estimation	ESTIMATE	SKIPFIRST=
exclude some observations at the end from analysis during the parameter estimation	ESTIMATE	BACK=
exclude some initial observations from analysis during forecasting	FORECAST	SKIPFIRST=

Table 34.1 *continued*

Description	Statement	Option
exclude some observations at the end from analysis during forecasting	FORECAST	BACK=
Graphical Residual Analysis		
get a panel of plots consisting of residual autocorrelation plots and residual normality plots	ESTIMATE	PLOT=PANEL
get the residual CUSUM plot	ESTIMATE	PLOT=CUSUM
get the residual cumulative sum of squares plot	ESTIMATE	PLOT=CUSUMSQ
get a plot of p -values for the portmanteau white noise test	ESTIMATE	PLOT=WN
get a time series plot of residuals with overlaid LOESS smoother	ESTIMATE	PLOT=LOESS
Series Decomposition and Forecasting		
specify the number of periods to forecast in the future	FORECAST	LEAD=
specify the significance level of the forecast confidence interval	FORECAST	ALPHA=
request printing of smoothed series decomposition	FORECAST	PRINT=DECOMP
request printing of one-step-ahead and multistep-ahead forecasts	FORECAST	PRINT=FORECASTS
request plotting of smoothed series decomposition	FORECAST	PLOT=DECOMP
request plotting of one-step-ahead and multistep-ahead forecasts	FORECAST	PLOT=FORECASTS
request bootstrap standard errors	FORECAST	BOOTSTRAP
BY Groups		
specify BY-group processing	BY	
Global Printing and Plotting Options		
turn off all the printing for the procedure	PROC UCM	NOPRINT
turn on all the printing options for the procedure	PROC UCM	PRINTALL
turn off all the plotting for the procedure	PROC UCM	PLOTS=NONE
turn on all the plotting options for the procedure	PROC UCM	PLOTS=ALL
turn on a variety of plotting options for the procedure	PROC UCM	PLOTS=
ID		
specify a variable that provides the time index for the series values	ID	

PROC UCM Statement

PROC UCM < options > ;

The PROC UCM statement is required. The following options can be used in the PROC UCM statement:

DATA=SAS-data-set

specifies the name of the SAS data set containing the time series. If the DATA= option is not specified in the PROC UCM statement, the most recently created SAS data set is used.

NOPRINT

turns off all the printing for the procedure. The subsequent print options in the procedure are ignored.

PLOTS< (global-plot-options) > < = plot-request < (options) > >

PLOTS< (global-plot-options) > < = (plot-request < (options) > < ... plot-request < (options) > > >

controls the plots produced with ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Here are some examples:

```
plots=none
plots=all
plots=residuals(acf loess)
plots(noclm)=(smooth(decomp) residual(panel loess))
```

For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

```
proc ucm;
  model y = x;
  irregular;
  level;
run;

proc ucm plots=all;
  model y = x;
  irregular;
  level;
run;
```

The first PROC UCM step does not specify the PLOTS= option, so the default plot that displays the series forecasts in the forecast region is produced. The PLOTS=ALL option in the second PROC UCM step produces all the plots that are appropriate for the specified model.

In addition to the PLOTS= option in the PROC UCM statement, you can request plots by using the PLOT= option in other statements of the UCM procedure. This way of requesting plots provides finer

control over the plot production. If you do not specify any specific plot request, then PROC UCM produces the plot of series forecasts in the forecast horizon by default.

Global Plot Options:

The *global-plot-options* apply to all relevant plots generated by the UCM procedure. The following *global-plot-option* is supported:

NOCLM

suppresses the confidence limits in all the component and forecast plots.

Specific Plot Options:

The following list describes the specific plots and their options:

ALL

produces all plots appropriate for the particular analysis.

NONE

suppresses all plots.

FILTER (< *filter-plot-options* >)

produces time series plots of the filtered component estimates. The following *filter-plot-options* are available:

ALL

produces all the filtered component estimate plots appropriate for the particular analysis.

LEVEL

produces a time series plot of the filtered level component estimate, provided the model contains the level component.

SLOPE

produces a time series plot of the filtered slope component estimate, provided the model contains the slope component.

CYCLE

produces time series plots of the filtered cycle component estimates for all cycle components in the model, if there are any.

SEASON

produces time series plots of the filtered season component estimates for all seasonal components in the model, if there are any.

DECOMP

produces time series plots of the filtered estimates of the series decomposition.

RESIDUAL (< *residual-plot-options* >)

produces the residuals plots. The following *residual-plot-options* are available:

ALL

produces all the residual diagnostics plots appropriate for the particular analysis.

ACF

produces the autocorrelation plot of residuals.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF

produces the partial-autocorrelation plot of residuals.

PANEL

produces a summary panel of the residual diagnostics consisting of the following:

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces the plot of Ljung-Box white-noise test p -values at different lags (in log scale).

SMOOTH (< smooth-plot-options >)

produces time series plots of the smoothed component estimates. The following *smooth-plot-options* are available:

ALL

produces all the smoothed component estimate plots appropriate for the particular analysis.

LEVEL

produces time series plot of the smoothed level component estimate, provided the model contains the level component.

SLOPE

produces time series plot of the smoothed slope component estimate, provided the model contains the slope component.

CYCLE

produces time series plots of the smoothed cycle component estimates for all cycle components in the model, if there are any.

SEASON

produces time series plots of the smoothed season component estimates for all season components in the model, if there are any.

DECOMP

produces time series plots of the smoothed estimates of the series decomposition.

PRINTALL

turns on all the printing options for the procedure. The subsequent NOPRINT options in the procedure are ignored.

AUTOREG Statement

AUTOREG < options > ;

The AUTOREG statement specifies an autoregressive component in the model. An autoregressive component is a special case of cycle that corresponds to the frequency of zero or π . It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component r_t can be written as follows:

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim i.i.d. \ N(0, \sigma_v^2)$$

The damping factor ρ can take any value in the interval $(-1, 1)$, including -1 but excluding 1 . If $\rho = 1$, the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$, the autoregressive component corresponds to a seasonal component with a season length of 2, or a nonstationary cycle with period 2. If $|\rho| < 1$, then the autoregressive component is stationary. The following example illustrates the AUTOREG statement. This statement includes an autoregressive component in the model. The damping factor ρ and the disturbance variance σ_v^2 are estimated from the data.

```
autoreg;
```

NOEST=RHO

NOEST=VARIANCE

NOEST=(RHO VARIANCE)

fixes the values of ρ and σ_v^2 to those specified in the **RHO=** and **VARIANCE=** options.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of the filtered or smoothed estimate of the autoreg component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of the filtered or smoothed estimate of the autoreg component.

RHO=valuespecifies an initial value for the damping factor ρ during the parameter estimation process. The value of ρ must be in the interval $(-1, 1)$, including -1 but excluding 1 .**VARIANCE=value**specifies an initial value for the disturbance variance σ_v^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BLOCKSEASON Statement

BLOCKSEASON *NBLOCKS* = integer *BLOCKSIZE* = integer < options > ;

The **BLOCKSEASON** or **BLOCKSEASONAL** statement is used to specify a seasonal component γ_t that has a special block structure. The seasonal γ_t is called a *block seasonal* of block size m and number of blocks k if its season length, s , can be factored as $s = m * k$ and its seasonal effects have a block form—that is, the first m seasonal effects are all equal to some number τ_1 , the next m effects are all equal to some number τ_2 , and so on.

This type of seasonal structure can be appropriate in some cases; for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the hour-of-the-day effect and the day-of-the-week effect are additive. In this situation the hour-of-the-week seasonality, having a season length of 168, can be modeled as a sum of two components. The hour-of-the-day effect is modeled using a simple seasonal of season length 24, while the day-of-the-week is modeled as a block seasonal component that has the days of the week as blocks. This day-of-the-week block seasonal component has seven blocks, each of size 24.

A block seasonal specification requires, at the minimum, the block size m and the number of blocks in the seasonal k . These are specified using the **BLOCKSIZE=** and **NBLOCKS=** option, respectively. In addition, you might need to specify the position of the first observation of the series by using the **OFFSET=** option if it is not at the beginning of one of the blocks. In the example just considered, this corresponds to a situation where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as **OFFSET=7**.

The other options in this statement are very similar to the options in the **SEASON** statement; for example, a block seasonal can also be of one of the two types, **DUMMY** and **TRIG**. There can be more than one block seasonal component in the model, each specified using a separate **BLOCKSEASON** statement. No two block seasonals in the model can have the same **NBLOCKS=** and **BLOCKSIZE=** specifications. The following

example illustrates the use of the BLOCKSEASON statement to specify the additive, hour-of-the-week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```

BLOCKSIZE=integer

specifies the block size, m . This is a required option in this statement. The block size can be any integer larger than or equal to two. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, etc.

NBLOCKS=integer

specifies the number of blocks, k . This is a required option in this statement. The number of blocks can be any integer greater than or equal to two.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the **VARIANCE=** option.

OFFSET=integer

specifies the position of the first measurement within the block, if the first measurement is not at the start of a block. The **OFFSET=** value must be between one and the block size. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ ANNUAL

PLOT=S_ ANNUAL

PLOT=(< plot request > ... < plot request >)

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component γ_t . You can use the **F_ ANNUAL** and **S_ ANNUAL** options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years. The first period in each block is plotted over the years.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests the printing of the filtered or smoothed estimate of the block seasonal component γ_t .

TYPE=DUMMY | TRIG

specifies the type of the block seasonal component. The default type is DUMMY.

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BY Statement

BY *variables* ;

A BY statement can be used in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model specified using the MODEL and other component statements is applied to all the groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

CYCLE Statement

CYCLE *< options >* ;

The CYCLE statement is used to specify a cycle component, ψ_t , in the model. The stochastic equation governing a cycle component of period p and damping factor ρ is as follows

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} v_t \\ v_t^* \end{bmatrix}$$

where v_t and v_t^* are independent, zero-mean, Gaussian disturbances with variance σ_v^2 and $\lambda = 2 * \pi / p$ is the angular frequency of the cycle. Any p strictly greater than two is an admissible value for the period, and the damping factor ρ can be any value in the interval (0, 1), including one but excluding zero. The cycles with frequency zero and π , which correspond to the periods equal to infinity and two, respectively, can be specified using the AUTOREG statement. The values of ρ less than one give rise to a stationary cycle, while $\rho = 1$ gives rise to a nonstationary cycle. As a default, values of ρ , p , and σ_v^2 are estimated from the data. However, if necessary, you can fix the values of some or all of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. The examples that follow illustrate the use of the CYCLE statement.

The following statements request including two cycles in the model. The parameters of each of these cycles are estimated from the data.

```
cycle;
cycle;
```

The following statement requests inclusion of a nonstationary cycle in the model. The cycle period p and the disturbance variance σ_v^2 are estimated from the data.

```
cycle rho=1 noest=rho;
```

In the following statement a nonstationary cycle with a fixed period of 12 is specified. Moreover, a starting value is supplied for σ_v^2 .

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```

NOEST=PERIOD

NOEST=RHO

NOEST=VARIANCE

NOEST=(< RHO > < PERIOD > < VARIANCE >)

fixes the values of the component parameters to those specified in the **RHO=**, **PERIOD=**, and **VARIANCE=** options. This option enables you to fix any combination of parameter values.

PERIOD=value

specifies an initial value for the cycle period during the parameter estimation process. Period value must be strictly greater than 2.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the cycle component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests the printing of a filtered or smoothed estimate of the cycle component ψ_t .

RHO=value

specifies an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including one but excluding zero, is an acceptable initial value for the damping factor.

VARIANCE=value

specifies an initial value for the disturbance variance parameter, σ_v^2 , to be used during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

DEPLAG Statement

DEPLAG LAGS = order < PHI = value ... > < NOEST > ;

The DEPLAG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of DEPLAG statement.

If the dependent series is denoted by y_t , the following statement specifies the inclusion of $\phi_1 y_{t-1} + \phi_2 y_{t-2}$ in the model. The parameters ϕ_1 and ϕ_2 are estimated from the data.

```
deplag lags=2;
```

The following statement requests including $\phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1 \phi_2 y_{t-5}$ in the model. The values of ϕ_1 and ϕ_2 are fixed at 0.8 and -1.2.

```
deplag lags=(1) (4) phi=0.8 -1.2 noest;
```

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an irregular component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLAG statement, if an initial value is supplied for any one of the parameters, the initial values must also be supplied for all other parameters.

LAGS=order

LAGS=(lag, ..., lag) ... (lag, ..., lag)

is a required option in this statement. $\text{LAGS}=(l_1, l_2, \dots, l_k)$ defines a model with specified lags of the dependent variable included as predictors. **LAGS=order** is equivalent to $\text{LAGS}=(1, 2, \dots, \text{order})$.

A concatenation of parenthesized lists specifies a factored model. For example, $\text{LAGS}=(1)(12)$ specifies that the lag values, 1, 12, and 13, corresponding to the following polynomial in the backward shift operator, be included in the model

$$(1 - \phi_{1,1}B)(1 - \phi_{2,1}B^{12})$$

Note that, in this case, the coefficient of the thirteenth lag is constrained to be the product of the coefficients of the first and twelfth lags.

NOEST

fixes the values of the parameters to those specified in **PHI=** option.

PHI=value ...

lists starting values for the coefficients of the lagged dependent variable. The order of the values listed corresponds with the order of the lags specified in the **LAGS=** option.

ESTIMATE Statement

ESTIMATE <options>;

The **ESTIMATE** statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model by using the **SKIPFIRST=** and **BACK=** options. This can be useful in model diagnostics. You can request a variety of goodness-of-fit statistics and other model diagnostic information including different residual diagnostic plots. Note that the **ESTIMATE** statement is not used to control the nonlinear optimization process itself. That is done using the **NLOPTIONS** statement, where you can control the number of iterations, choose between the different optimization techniques, and so on. You can save the estimated parameters and other related information in a data set by using the **OUTEST=** option. You can request the optimization of the profile likelihood, the likelihood obtained by concentrating out a disturbance variance, for parameter estimation by using the **PROFILE** option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the model-fitting process. The actual observation span used to fit the model is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the measurements between observation numbers $n_0 + 12$ and $n_1 - 24$ form the estimation span. Of course, the model fitting might not take place if there are insufficient data in the resulting span. The model fitting does not take place if there are regressors in the model that have missing values in the estimation span.

BACK=integer

SKIPLAST=integer

indicates that some ending part of the data needs to be ignored during the parameter estimation. This can be useful when you want to study the forecasting performance of a model on the observed data. BACK=10 results in skipping the last 10 measurements of the response series during the parameter estimation. The default is BACK=0.

EXTRADIFFUSE=k

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead residuals are produced only after the diffuse state is initialized. Delaying the initialization leads to a reduction in the number of one-step-ahead residuals available for computing the residual diagnostic measures. This option is useful when you want to ignore the first few one-step-ahead residuals that often have large variance.

NOPROFILE

requests that the usual likelihood be optimized for parameter estimation. For more information, see the section [“Parameter Estimation by Profile Likelihood Optimization”](#) on page 2312.

OUTEST=SAS-data-set

specifies an output data set for the estimated parameters.

In the ESTIMATE statement, the PLOT= option is used to obtain different residual diagnostic plots. The different possibilities are as follows:

PLOT=ACF

PLOT=MODEL

PLOT=LOESS

PLOT=HISTOGRAM

PLOT=PACF

PLOT=PANEL

PLOT=QQ

PLOT=RESIDUAL

PLOT=WN

PLOT=(<plot request> ... <plot request>)

requests different residual diagnostic plots. The different options are as follows:

ACF

produces the residual-autocorrelation plot.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

MODEL

produces the plot of one-step-ahead forecasts in the estimation span.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF

produces the residual-partial-autocorrelation plot.

PANEL

produces a summary panel of the residual diagnostics consisting of

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces a plot of p -values, in log-scale, at different lags for the Ljung-Box portmanteau white noise test statistics.

PRINT=NONE

suppresses all the printed output related to the model fitting, such as the parameter estimates, the goodness-of-fit statistics, and so on.

PROFILE

requests that the profile likelihood, obtained by concentrating out one of the disturbance variances from the likelihood, be optimized for parameter estimation. By default, the profile likelihood is not optimized if any of the disturbance variance parameters is held fixed to a nonzero value. For more information see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 2312.

SKIPFIRST=integer

indicates that some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the parameter estimation. The default is SKIPFIRST=0.

FORECAST Statement

FORECAST < options > ;

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to use to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, is specified using the LEAD= and ALPHA= options. You can request one-step-ahead series and component forecasts by using the PRINT= option. You can save the series forecasts, and the model-based decomposition of the series, in a data set by using the OUTFOR= option. You can use the BOOTSTRAP option to request the computation of bootstrap prediction standard errors and the associated confidence intervals. The following example illustrates the use of this statement:

```
forecast skipfirst=12 back=24 lead=30;
```

This statement requests that the initial 12 and the last 24 response values be excluded during the forecast computations. The forecast horizon, specified using the LEAD= option, is 30 periods; that is, multistep forecasting begins at the end of the historical period and continues for 30 periods. The actual observation span used to compute the multistep forecasting is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the historical period, or the forecast span, begins at $n_0 + 12$ and ends at $n_1 - 24$. Multistep forecasts are produced for the next 30 periods—that is, for the observation numbers $n_1 - 23$ to $n_1 + 6$. Of course, the forecast computations can fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon—that is, between the observations $n_1 - 23$ and $n_1 + 6$ —the forecast horizon is reduced accordingly.

ALPHA=value

specifies the significance level of the forecast confidence intervals; for example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

BACK=integer**SKIPLAST=integer**

specifies the holdout sample for the evaluation of the forecasting performance of the model. For example, BACK=10 results in treating the last 10 observed values of the response series as unobserved. A post-sample-prediction-analysis table is produced for comparing the predicted values with the actual values in the holdout period. The default is BACK=0.

BOOTSTRAP(NREP=integer < SEED=integer >) (Experimental)

enables the computation of bootstrap prediction standard errors based on the specified number of replications (NREP). The value of NREP must be at least 2. Optionally, you can specify the random

number seed that is associated with the first replication by using the SEED= option. The seeds for the subsequent replications are assigned sequentially. The default seed value that is associated with the first replication is 123. The BOOTSTRAP option has no effect if the number of parameters to be estimated is zero (that is, all the model parameters are known). Note that this option is computationally expensive. The computational cost of NREP replications is comparable to the cost of estimating parameters NREP times.

EXTRADIFFUSE=*k*

enables continuation of the diffuse filtering iterations for *k* additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified *k* is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead forecasts are produced only after the diffuse state is initialized. Delaying the initialization leads to reduction in the number of one-step-ahead forecasts. This option is useful when you want to ignore the first few one-step-ahead forecasts that often have large variance.

LEAD=*integer*

specifies the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and BACK= options; for example, LEAD=10 results in the forecasting of 10 future values of the response series. The default is LEAD=12.

OUTFOR=*SAS-data-set*

specifies an output data set for the forecasts. The output data set contains the ID variable (if specified), the response and predictor series, the one-step-ahead and out-of-sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series, and the smoothed forecasts produced as a result of the model-based decomposition of the series.

PLOT=DECOMP

PLOT=DECOMPVAR

PLOT=FDECOMP

PLOT=FDECOMPVAR

PLOT=FORECASTS

PLOT=TREND

PLOT=(<plot request> ... <plot request>)

requests forecast and model decomposition plots. The FORECASTS option provides the plot of the series forecasts, the TREND and DECOMP options provide the plots of the smoothed trend and other decompositions, the DECOMPVAR option can be used to plot the variance of these components, and the FDECOMP and FDECOMPVAR options provide the same plots for the filtered decomposition estimates and their variances.

PRINT=DECOMP

PRINT=FDECOMP

PRINT=FORECASTS

PRINT=NONE

PRINT=(<print request> ... <print request>)

controls the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon specified by the LEAD= option; that is, the one-step-ahead predicted values are not printed. You can request forecasts for the entire

forecast span by specifying the PRINT=FORECASTS option. Using PRINT=DECOMP, you can get smoothed estimates of the following effects: trend, trend plus regression, trend plus regression plus cycle, and sum of all components except the irregular. If some of these effects are absent in the model, then they are ignored. Similarly you can get filtered estimates of these effects by using PRINT=FDECOMP. You can use PRINT=NONE to suppress the printing of all the forecast output.

SKIPFIRST=integer

indicates that some early part of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model being used for forecasting is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the forecast calculations. The default is SKIPFIRST=0.

ID Statement

ID variable *INTERVAL*=value < *ALIGN*=value > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the frequency associated with the time series. The ID statement options also specify how the observations are aligned to form the time series. If the ID statement is specified, the INTERVAL= option must also be specified. If the ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

ALIGN=value

controls the alignment of SAS dates used to identify output observations. The ALIGN= option has the following possible values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable with the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL=value

specifies the time interval between observations. This option is required in the ID statement. INTERVAL=value is used in conjunction with the ID variable to check that the input data are in order and have no gaps. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. For a complete discussion of the intervals supported, please see Chapter 4, “[Date Intervals, Formats, and Functions](#).”

IRREGULAR Statement

IRREGULAR < options > ;

The IRREGULAR statement includes an irregular component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error ϵ_t in the model. By default the irregular component is modeled as white noise—that is, as a sequence of independent, identically distributed, zero-mean, Gaussian random variables. However, you can also model it as an autoregressive moving average (ARMA) process. The options for specifying an ARMA model for the irregular component are given in a separate subsection: “[ARMA Specification](#)” on page 2284.

The options in this statement enable you to specify the model for the irregular component and to output its estimates. Two examples of the **IRREGULAR** statement are given next. In the first example the statement is in its simplest form, resulting in the inclusion of an irregular component that is white noise with unknown variance:

```
irregular;
```

The following statement provides a starting value for the white noise variance σ_ϵ^2 to be used in the nonlinear parameter estimation process. It also requests the printing of smoothed estimates of ϵ_t . The smoothed irregulars are useful in model diagnostics.

```
irregular variance=4 print=smooth;
```

NOEST

fixes the value of σ_ϵ^2 to the value specified in the **VARIANCE=** option. Also see the **NOEST=** option in the subsection “**ARMA Specification**” on page 2284.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the irregular component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the irregular component.

VARIANCE=value

specifies an initial value for σ_ϵ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

ARMA Specification

This section details the options for specifying an ARMA model for the irregular component. The specification of ARMA models requires some notation, which is explained first.

Let B denote the backshift operator—that is, for any sequence ϵ_t , $B\epsilon_t = \epsilon_{t-1}$. The higher powers of B represent larger shifts (for example, $B^3\epsilon_t = \epsilon_{t-3}$). A random sequence ϵ_t follows a zero-mean $\text{ARMA}(p,q) \times (P,Q)_s$ model with nonseasonal autoregressive order p , seasonal autoregressive order P , nonseasonal moving average order q , and seasonal moving average order Q , if it satisfies the following difference equation specified in terms of the polynomials in the backshift operator where a_t is a white noise sequence and s is the season length:

$$\phi(B)\Phi(B^s)\epsilon_t = \theta(B)\Theta(B^s)a_t$$

The polynomials ϕ , Φ , θ , and Θ are of orders p , P , q , and Q , respectively, which can be any nonnegative integers. The season length s must be a positive integer. For example, ϵ_t satisfies an $\text{ARMA}(1,1)$ model (that is, $p = 1, q = 1, P = 0$, and $Q = 0$) if

$$\epsilon_t = \phi_1\epsilon_{t-1} + a_t - \theta_1a_{t-1}$$

for some coefficients ϕ_1 and θ_1 and a white noise sequence a_t . Similarly ϵ_t satisfies an $\text{ARMA}(1,1) \times (1,1)_{12}$ model if

$$\epsilon_t = \phi_1 \epsilon_{t-1} + \Phi_1 \epsilon_{t-12} - \phi_1 \Phi_1 \epsilon_{t-13} + a_t - \theta_1 a_{t-1} - \Theta_1 a_{t-12} + \theta_1 \Theta_1 a_{t-13}$$

for some coefficients ϕ_1 , Φ_1 , θ_1 , and Θ_1 and a white noise sequence a_t . The ARMA process is stationary and invertible if the defining polynomials ϕ , Φ , θ , and Θ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the ARMA model specified for the irregular component is stationary and invertible—that is, the coefficients of the polynomials ϕ , Φ , θ , and Θ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated using the data.

The notation for a closely related class of models, autoregressive integrated moving average (ARIMA) models, is also given here. A random sequence y_t is said to follow an $\text{ARIMA}(p,d,q) \times (P,D,Q)_s$ model if, for some nonnegative integers d and D , the differenced series $\epsilon_t = (1 - B)^d (1 - B^s)^D y_t$ follows an $\text{ARMA}(p,q) \times (P,Q)_s$ model. The integers d and D are called nonseasonal and seasonal differencing orders, respectively. You can specify ARIMA models by using the **DEPLAG** statement for specifying the differencing orders and by using the **IRREGULAR** statement for the ARMA specification. See [Example 34.8](#) for an example of $\text{ARIMA}(0,1,1) \times (0,1,1)_{12}$ model specification. Brockwell and Davis (1991) can be consulted for additional information about ARIMA models.

You can use options of the **IRREGULAR** statement to specify the desired ARMA model and to request printed and graphical output. A few examples of the **IRREGULAR** statement are given next.

The following statement specifies an irregular component that is modeled as an $\text{ARMA}(1,1)$ process. It also requests plotting its smoothed estimate.

```
irregular p=1 q=1 plot=smooth;
```

The following statement specifies an $\text{ARMA}(1,1) \times (1,1)_{12}$ model. It also fixes the coefficient of the first-order seasonal moving average polynomial to 0.1. The other coefficients and the white noise variance are estimated using the data.

```
irregular p=1 sp=1 q=1 sq=1 s=12 sma=0.1 noest=(sma);
```

AR= $\phi_1 \phi_2 \dots \phi_p$

lists the starting values of the coefficients of the nonseasonal autoregressive polynomial

$$\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$$

where the order p is specified in the **P=** option. The coefficients ϕ_i must define a stationary autoregressive polynomial.

MA= $\theta_1 \theta_2 \dots \theta_q$

lists the starting values of the coefficients of the nonseasonal moving average polynomial

$$\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$$

where the order q is specified in the **Q=** option. The coefficients θ_i must define an invertible moving average polynomial.

NOEST=<VARIANCE> <AR> <SAR> <MA> <SMA>)

fixes the values of the ARMA parameters and the value of the white noise variance to those specified in the **AR=**, **SAR=**, **MA=**, **SMA=**, or **VARIANCE=** options.

P=integer

specifies the order of the nonseasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

Q=integer

specifies the order of the nonseasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

S=integer

specifies the season length used during the specification of the seasonal autoregressive or seasonal moving average polynomial. The season length can be any positive integer; for example, S=4 might be an appropriate value for a quarterly series. The default value is S=1.

SAR= $\Phi_1 \Phi_2 \dots \Phi_P$

lists the starting values of the coefficients of the seasonal autoregressive polynomial

$$\Phi(B^s) = 1 - \Phi_1 B^s - \dots - \Phi_P B^{sP}$$

where the order P is specified in the **SP=** option and the season length s is specified in the **S=** option. The coefficients Φ_i must define a stationary autoregressive polynomial.

SMA= $\Theta_1 \Theta_2 \dots \Theta_Q$

lists the starting values of the coefficients of the seasonal moving average polynomial

$$\Theta(B^s) = 1 - \Theta_1 B^s - \dots - \Theta_Q B^{sQ}$$

where the order Q is specified in the **SQ=** option and the season length s is specified in the **S=** option. The coefficients Θ_i must define an invertible moving average polynomial.

SP=integer

specifies the order of the seasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

SQ=integer

specifies the order of the seasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

LEVEL Statement

LEVEL <options> ;

The LEVEL statement is used to include a level component in the model. The level component, either by itself or together with a slope component (see the **SLOPE** statement), forms the trend component, μ_t , of

the model. If the slope component is absent, the resulting trend is a random walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. \ N(0, \sigma_\eta^2)$$

If the slope component is present, signified by the presence of a **SLOPE** statement, a locally linear trend (LLT) is obtained. The equations of LLT are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. \ N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. \ N(0, \sigma_\xi^2) \end{aligned}$$

In either case, the options in the **LEVEL** statement are used to specify the value of σ_η^2 and to request forecasts of μ_t . The **SLOPE** statement is used for similar purposes in the case of slope β_t . The following examples illustrate the use of the **LEVEL** statement. Assuming that a **SLOPE** statement is not added subsequently, a simple random walk trend is specified by the following statement:

```
level;
```

The following statements specify a locally linear trend with value of σ_η^2 fixed at 4. It also requests printing of filtered values of μ_t . The value of σ_ξ^2 , the disturbance variance in the slope equation, is estimated from the data.

```
level variance=4 noest print=filter;  
slope;
```

CHECKBREAK

turns on the checking of breaks in the level component.

NOEST

fixes the value of σ_η^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the level component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the level component.

VARIANCE=*value*

specifies an initial value for σ_{η}^2 , the disturbance variance in the μ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

MODEL Statement

MODEL *dependent* < = *regressors* > ;

The MODEL statement specifies the response variable and, optionally, the predictor or regressor variables for the UCM model. This is a required statement in the UCM procedure. The predictors specified in the MODEL statement are assumed to have a linear and time-invariant relationship with the response. The predictors that have time-varying regression coefficients are specified separately in the [RANDOMREG](#) statement. Similarly, the predictors that have a nonlinear effect on the response variable are specified separately in the [SPLINEREG](#) statement. Only one MODEL statement can be specified.

NLOPTIONS Statement

NLOPTIONS < *options* > ;

PROC UCM uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. This can be done by using the TECH= and MAXITER= options in the NLOPTIONS statement as follows:

```
nloptions tech=dbldog maxiter=200;
```

This sets the maximum number of iterations to 200 and changes the optimization technique to DBLDOG rather than the default technique, TRUREG, used in PROC UCM. A discussion of the full range of options that can be used with the NLOPTIONS statement is given in Chapter 6, “[Nonlinear Optimization Methods](#).” In PROC UCM all these options are available except the options related to the printing of the optimization history. In this version of PROC UCM all the printed output from the NLO subsystem is suppressed.

OUTLIER Statement

OUTLIER < *options* > ;

The OUTLIER statement enables you to control the reporting of the additive outliers (AO) and level shifts (LS) in the response series. The AOs are searched by default. You can turn on the search for LSs by using the [CHECKBREAK](#) option in the LEVEL statement.

ALPHA=*significance-level*

specifies the significance level for reporting the outliers. The default is 0.05.

MAXNUM=number

limits the number of outliers to search. The default is MAXNUM=5.

MAXPCT=number

is similar to the MAXNUM= option. In the MAXPCT= option you can limit the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=1. When both of these options are specified, the minimum of the two search numbers is used.

PRINT=SHORT | DETAIL

enables you to control the printed output of the outlier search. The PRINT=SHORT option, which is the default, produces an outlier summary table containing the most significant outliers, either AO or LS, discovered in the outlier search. The PRINT=DETAIL option produces, in addition to the outlier summary table, separate tables containing the AO and LS structural break chi-square statistics computed at each time point in the estimation span.

PERFORMANCE Statement (Experimental)

PERFORMANCE options ;

The PERFORMANCE statement defines performance parameters for distributed and multithreaded computing and passes variables that describe the distributed computing environment. In the UCM procedure, this statement is applicable only if you specify the **BOOTSTRAP** option in the FORECAST statement. In addition, the number of nodes that you specify in the **NODES=** option in the PERFORMANCE statement must be strictly smaller than the number of bootstrap replications that you specify in the **BOOTSTRAP** option. The following statements illustrate how you can use this statement to perform bootstrap computations that use 10 nodes on a grid named *hpa.sas.com*:

```
proc ucm data=seriesG;
  id date interval=month;
  model logair;
  irregular;
  level;
  forecast lead=24 bootstrap(nrep=50 seed=1234);
  performance nodes=10 host="hpa.sas.com";
run;
```

For more information about the PERFORMANCE statement, see the section “PERFORMANCE Statement” (Chapter 3, *SAS/ETS User’s Guide: High-Performance Procedures*).

RANDOMREG Statement

RANDOMREG regressors </ options > ;

The RANDOMREG statement is used to specify regressors with time-varying regression coefficients. Each regression coefficient—say, β_t —is assumed to evolve as a random walk:

$$\beta_t = \beta_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. \ N(0, \sigma^2)$$

Of course, if the random walk disturbance variance σ^2 is zero, then the regression coefficient is not time varying, and it reduces to the standard regression setting. There can be multiple RANDOMREG statements,

and each statement can contain one or more regressors. The regressors in a given RANDOMREG statement form a group that is assumed to share the same disturbance variance parameter. The random walks associated with different regressors are assumed to be independent. For an example of using this statement see [Example 34.4](#). See the section “[Reporting Parameter Estimates for Random Regressors](#)” on page 2309 for additional information about the way parameter estimates are reported for this type of regressors.

NOEST

fixes the value of σ^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of the filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=value

specifies an initial value for σ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SEASON Statement

SEASON LENGTH = integer < options > ;

The SEASON or SEASONAL statement is used to specify a seasonal component, γ_t , in the model. A seasonal component can be one of the two types, DUMMY or TRIG. A DUMMY seasonal with season length s satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim i.i.d. \ N(0, \sigma_\omega^2)$$

The equations for a TRIG (short for trigonometric) seasonal component are as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The sinusoids, also called *harmonics*, $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

In the TRIG seasonal case, the option **KEEPH=** or **DROPH=** can be used to obtain *subset trigonometric* seasonals that contain only a subset of the full set of harmonics $\gamma_{j,t}$, $j = 1, 2, \dots, [s/2]$. This is particularly useful when the season length s is large and the seasonal pattern is relatively smooth.

Note that whether the seasonal type is DUMMY or TRIG, there is only one parameter, the disturbance variance σ_ω^2 , in the seasonal model.

There can be more than one seasonal component in the model, necessarily with different season lengths if the seasons are full. You can have multiple *subset* season components with the same season length, if you need to use separate disturbance variances for different sets of harmonics. Each seasonal component is specified using a separate SEASON statement. A model with multiple seasonal components can easily become quite complex and might need a large amount of data and computing resources for its estimation and forecasting. The examples that follow illustrate the use of SEASON statement.

The following statement specifies a DUMMY type (default) seasonal component with a season length of four, corresponding to the quarterly seasonality. The disturbance variance σ_ω^2 is estimated from the data.

```
season length=4;
```

The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for σ_ω^2 .

```
season length=12 type=trig variance=4;
```

DROPHARMONICS|DROPH=number-list | n TO m BY p

enables you to drop some harmonics $\gamma_{j,t}$ from the full set of harmonics used to obtain a trigonometric seasonal. The drop list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length 12 that consists of only the first four harmonics $\gamma_{j,t}$, $j = 1, 2, 3, 4$:

```
season length=12 type=trig DROPH=5 6;
```

The last two *high* frequency harmonics are dropped. The **DROPH=** option cannot be used with the **KEEPH=** option.

KEEPHARMONICS|KEEPH=number-list | n TO m BY p

enables you to keep only the harmonics $\gamma_{j,t}$ listed in the option to obtain a trigonometric seasonal. The keep list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length of 12 that consists of all the six harmonics $\gamma_{j,t}$, $j = 1, \dots, 6$:

```
season length=12 type=trig KEEPH=1 to 3;
season length=12 type=trig KEEPH=4 to 6;
```

However, these six harmonics are grouped into two groups, each having its own disturbance variance parameter. The **DROPH=** option cannot be used with the **KEEPH=** option.

LENGTH=integer

specifies the season length, s . This is a required option in this statement. The season length can be any integer greater than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=F_ANNUAL****PLOT=S_ANNUAL****PLOT=(<plot request> ... <plot request>)**

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component γ_t . You can use the **F_ANNUAL** and **S_ANNUAL** options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

PRINT=HARMONICS

requests printing of the summary of harmonics present in the seasonal component. This option is valid only for the trigonometric seasonal component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(<print request> ... <print request>)**

requests printing of the filtered or smoothed estimate of the seasonal component γ_t .

TYPE=DUMMY | TRIG

specifies the type of the seasonal component. The default type is **DUMMY**.

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SLOPE Statement

SLOPE <options> ;

The **SLOPE** statement is used to include a slope component in the model. The slope component cannot be used without the level component (see the **LEVEL** statement). The level and slope specifications jointly

define the trend component of the model. A SLOPE statement without the accompanying LEVEL statement is ignored. The equations of the trend, defined jointly by the level μ_t and slope β_t , are as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2)\end{aligned}$$

The SLOPE statement is used to specify the value of the disturbance variance, σ_ξ^2 , in the slope equation, and to request forecasts of β_t . The following examples illustrate this statement:

```
level;
slope;
```

The preceding statements fit a model with a locally linear trend. The disturbance variances σ_η^2 and σ_ξ^2 are estimated from the data. You can request a locally linear trend with fixed slope by using the following statements:

```
level;
slope variance=0 noest;
```

NOEST

fixes the value of the disturbance variance, σ_ξ^2 , to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the slope component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the slope component β_t .

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ξ^2 , in the β_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINEREG Statement

SPLINEREG *regressor* < options > ;

The SPLINEREG statement is used to specify a regressor that has a nonlinear relationship with the dependent series that can be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it is known that it can be written as a linear combination of $(n + d + 1)$ regressors that are derived from the original regressor. The span of these $(n + d + 1)$ derived regressors includes constant; therefore, to avoid multicollinearity with the level component, one of these regressors is dropped. Specifying the SPLINEREG statement is equivalent to specifying a RANDOMREG statement with these

derived regressors. There can be multiple `SPLINEREG` statements. You must specify at least one interior knot, either using the `NKNOTS=` option or the `KNOTS=` option. For additional information about splines, see Chapter 101, “The TRANSREG Procedure” (*SAS/STAT User’s Guide*). For an example of using this statement, see [Example 34.6](#). See the section “[Reporting Parameter Estimates for Random Regressors](#)” on page 2309 for additional information about the way parameter estimates are reported for this type of regressors.

DEGREE=integer

specifies the degree of the spline. It can be any integer larger than or equal to zero. The default value is 3. The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

KNOTS=number-list | n TO m BY p

specifies the interior knots or break points. The values in the knot list must be nondecreasing and must lie between the minimum and the maximum of the spline regressor values in the input data set. The first time you specify a value in the knot list, it indicates a discontinuity in the n th (from `DEGREE=n`) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n - 1)$ th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the `KNOTS=` option with the `NKNOTS=` option. You should keep the number of knots small.

NKNOTS=m

creates m knots, the first at the $100/(m + 1)$ percentile, the second at the $200/(m + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if `NKNOTS=3`, knots are placed at the 25th percentile, the median, and the 75th percentile. The value specified for the `NKNOTS=` option must be ≥ 1 . You cannot use the `NKNOTS=` option with the `KNOTS=` option.

NOTE: Specifying knots by using the `NKNOTS=` option can result in different sets of knots in the estimation and forecast stages if the distributions of regressor values in the estimation and forecast spans differ. The estimation span is based on the `BACK=` and `SKIPFIRST=` options in the [ESTIMATE](#) statement, and the forecast span is based on the `BACK=` and `SKIPFIRST=` options in the [FORECAST](#) statement.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the [VARIANCE=](#) option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINESEASON Statement

SPLINESEASON *LENGTH* = *integer* *KNOTS* = *integer*₁ *integer*₂ ... *< options >* ;

The SPLINESEASON statement is used to specify a seasonal pattern that is to be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it can be written as a linear combination of $(n + d)$ regressors that are derived from the seasonal dummy regressors. The SPLINESEASON specification is equivalent to specifying a RANDOMREG specification with these derived regressors. Such approximation is useful only if the season length is relatively large, at least larger than $(n + d)$. For additional information about splines, see Chapter 101, “The TRANSREG Procedure” (*SAS/STAT User’s Guide*). For an example of using this statement, see [Example 34.3](#).

DEGREE=*integer*

specifies the degree of the spline. It can be any integer greater than or equal to zero. The default value is 3.

KNOTS=*integer*₁ *integer*₂ ...

lists the *internal* knots. This list of values must be a nondecreasing sequence of integers within the range of 2 to $(s - 1)$, where s is the season length specified in the **LENGTH=** option. This is a required option in this statement.

LENGTH=*integer*

specifies the season length, s . This is a required option in this statement. The length can be any integer greater than or equal to three.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the **VARIANCE=** option.

OFFSET=*integer*

specifies the position of the first measurement within the season, if the first measurement is not at the start of the season. The OFFSET= value must be between one and the season length. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the season length.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests the printing of the filtered or smoothed estimate of the spline season component.

RKNOTS=(knot, ..., knot) ... (knot, ..., knot) (Experimental)

specifies a grouping of knots such that the knots within the same group have identical seasonal values. The knots specified in this option must already be present in the list specified by the KNOTS= option. The knot groups must be non-overlapping and without any repeated knots.

VARIANCE=value

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

Details: UCM Procedure

An Introduction to Unobserved Component Models

A UCM decomposes the response series into components such as trend, seasons, cycles, and the regression effects due to predictor series. The following model shows a possible scenario:

$$y_t = \mu_t + \gamma_t + \psi_t + \sum_{j=1}^m \beta_j x_{jt} + \epsilon_t$$

$$\epsilon_t \sim i.i.d. N(0, \sigma_\epsilon^2)$$

The terms μ_t , γ_t , and ψ_t represent the trend, seasonal, and cyclical components, respectively. In fact the model can contain multiple seasons and cycles, and the seasons can be of different types. For simplicity of discussion the preceding model contains only one of each of these components. The regression term, $\sum_{j=1}^m \beta_j x_{jt}$, includes contribution of regression variables with *fixed* regression coefficients. A model can also contain regression variables that have *time varying* regression coefficients or that have a nonlinear relationship with the dependent series (see “[Incorporating Predictors of Different Kinds](#)” on page 2308). The disturbance term ϵ_t , also called the *irregular* component, is usually assumed to be Gaussian white noise. In some cases it is useful to model the irregular component as a stationary ARMA process. See the section “[Modeling the Irregular Component](#)” on page 2300 for additional information.

By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as *log* and *difference*.

The components μ_t , γ_t , and ψ_t model structurally different aspects of the time series. For example, the trend μ_t models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables, while the seasonal component γ_t models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component

models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

Modeling the Trend

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component μ_t . The first model, called the random walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The RW model can be described as

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma_\eta^2)$$

Note that if $\sigma_\eta^2 = 0$, then the model becomes $\mu_t = \text{constant}$. In the LLT model the trend is locally linear, consisting of both the *level* and *slope*. The LLT model is

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

The disturbances η_t and ξ_t are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances σ_η^2 and σ_ξ^2 equal to zero. If σ_ξ^2 is set equal to zero, then you get a linear trend model with fixed slope. If σ_η^2 is set to zero, then the resulting model usually has a smoother trend. If both the variances are set to zero, then the resulting model is the deterministic linear time trend: $\mu_t = \mu_0 + \beta_0 t$.

You can incorporate these trend patterns in your model by using the **LEVEL** and **SLOPE** statements.

Modeling a Cycle

A deterministic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, can be written as

$$\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)$$

If the argument t is measured on a continuous scale, then ψ_t is a periodic function with period $2\pi/\lambda$, amplitude $\gamma = (\alpha^2 + \beta^2)^{1/2}$, and phase $\phi = \tan^{-1}(\beta/\alpha)$. Equivalently, the cycle can be written in terms of the amplitude and phase as

$$\psi_t = \gamma \cos(\lambda t - \phi)$$

Note that when ψ_t is measured only at the integer values, it is not exactly periodic, unless $\lambda = (2\pi j)/k$ for some integers j and k . The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed period but time-varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing ψ_t :

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix}$$

starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that ψ_t and ψ_t^* satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle ψ_t can be obtained by adding random noise to this recursion and by introducing a damping factor, ρ , for additional modeling flexibility. This model can be described as follows

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} v_t \\ v_t^* \end{bmatrix}$$

where $0 \leq \rho \leq 1$, and the disturbances v_t and v_t^* are independent $N(0, \sigma_v^2)$ variables. The resulting stochastic cycle has a fixed period but time-varying amplitude and phase. The stationarity properties of the random sequence ψ_t depend on the damping factor ρ . If $\rho < 1$, ψ_t has a stationary distribution with mean zero and variance $\sigma_v^2/(1 - \rho^2)$. If $\rho = 1$, ψ_t is nonstationary.

You can incorporate a cycle in a UCM by specifying a **CYCLE** statement. You can include multiple cycles in the model by using separate **CYCLE** statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonal components is considered next.

Modeling Seasons

The seasonal fluctuations are a common source of variation in time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to zero when summed over the full season cycle. Therefore the seasonal component γ_t is modeled as a stochastic periodic pattern of an integer period s such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always zero in the mean. The period s is called the season length. Two different models for the seasonal component are considered here. The first model is called the *dummy* variable form of the seasonal component. It is described by the equation

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim i.i.d. \ N(0, \sigma_\omega^2)$$

The other model is called the *trigonometric* form of the seasonal component. In this case γ_t is modeled as a sum of cycles of different frequencies. This model is given as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called *harmonics*. If the seasonal component is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high-frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals, the situation might not be so transparent; however, similar considerations still apply. Note that if the disturbance variance $\sigma_\omega^2 = 0$, then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

In the UCM procedure you can specify a seasonal component in a variety of ways, the **SEASON** statement being the simplest of these. The dummy and the trigonometric seasonal components discussed so far can be considered as *saturated* seasonal components that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal might be more appropriate. This is particularly useful for seasonal components with large season lengths. In the UCM procedure you can obtain parsimonious representations of the seasonal components by one of the following ways:

- Use a *subset* trigonometric seasonal component obtained by deleting a few of the $[s/2]$ harmonics used in its sum. For example, a slightly smoother seasonal component of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest-frequency harmonic of period 2. That is, such a seasonal component will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. You can specify such subset seasonal components by using the **KEEPH=** or **DROPH=** option in the **SEASON** statement.
- Approximate the seasonal pattern by a suitable spline approximation. You can do this by using the **SPLINESEASON** statement.
- A *block-seasonal* pattern is a seasonal pattern where the pattern is divided into a few blocks of equal length such that the season values within a block are the same—for example, a monthly seasonal pattern that has only four different values, one for each quarter. In some situations a long seasonal pattern can be approximated by the sum of block season and a simple season, the length of the simple season being equal to the block length of the block season. You can obtain such approximation by using a combination of **BLOCKSEASON** and **SEASON** statements.
- Consider a seasonal component of a large season length as a sum of two or more seasonal components that are each of much smaller season lengths. This can be done by specifying more than one **SEASON** statements.

Note that the preceding techniques of obtaining parsimonious seasonal components can also enable you to specify seasonal components that are more *general* than the simple saturated seasonal components. For example, you can specify a saturated trigonometric seasonal component that has some of its harmonics evolving according to one disturbance variance parameter while the others evolve with another disturbance variance parameter.

Modeling an Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency λ is either 0 or π . Modeling this special case separately helps interpretation and parameter estimation. The autoregression component r_t is modeled as follows

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim i.i.d. \ N(0, \sigma_v^2)$$

where $-1 \leq \rho < 1$. An autoregression can also provide an alternative to the **IRREGULAR** component when the model errors show some autocorrelation. You can incorporate an autoregression in your model by using the **AUTOREG** statement.

Modeling Regression Effects

A predictor variable can affect the response variable in a variety of ways. The UCM procedure enables you to model several different types of predictor-response relationships:

- The predictor-response relationship is *linear*, and the regression coefficient does not change with time. This is the simplest kind of relationship and such predictors are specified in the **MODEL** statement.
- The predictor-response relationship is *linear*, but the regression coefficient does change with time. Such predictors are specified in the **RANDOMREG** statement. Here the regression coefficient is assumed to evolve as a random walk.
- The predictor-response relationship is *nonlinear* and the relationship can change with time. This type of relationship can be approximated by an appropriate time-varying spline. Such predictors are specified in the **SPLINEREG** statement.

A response variable can depend on its own past values—that is, lagged dependent values. Such a relationship can be specified in the **DEPLAG** statement.

Modeling the Irregular Component

The components—such as trend, seasonal and regression effects, and nonstationary cycles—are used to capture the structural dynamics of a response series. In contrast, the stationary cycles and the autoregression are used to capture the transient aspects of the response series that are important for its short-range prediction but have little impact on its long-term forecasts. The irregular component represents the residual variation remaining in the response series that is modeled using an appropriate selection of structural and transient effects. In most cases, the irregular component can be assumed to be simply Gaussian white noise. In some other cases, however, the residual variation can be more complicated. In such situations, it might be necessary to model the irregular component as a stationary ARMA process. Moreover, you can use the ARMA irregular component together with the dependent lag specification (see the **DEPLAG** statement) to specify an $\text{ARIMA}(p,d,q) \times (P,D,Q)_s$ model for the response series. See the **IRREGULAR** statement for the explanation of the ARIMA notation. See [Example 34.8](#) for an example of modeling a series by using an $\text{ARIMA}(0,1,1) \times (0,1,1)_{12}$ model.

The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user-specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

consisting of the irregular, level, slope, and seasonal components. This model is called the basic structural model (BSM) by Harvey (1989). The syntax for a BSM with monthly seasonality of trigonometric type is as follows:

```
model y;
irregular;
level;
slope;
season length=12 type=trig;
```

Similarly the following syntax specifies a BSM with a response variable y , a regressor x , and dummy-type monthly seasonality:

```
model y = x;
irregular;
level;
slope variance=0 noest;
season length=12 type=dummy;
```

Moreover, the disturbance variance of the slope component is restricted to zero, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for a model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
irregular;
level;
cycle;
cycle;
```

The UCMs as State Space Models

The UCMs considered in PROC UCM can be thought of as special cases of more general models, called (linear) Gaussian state space models (GSSM). A GSSM can be described as follows:

$$\begin{aligned} y_t &= Z_t \alpha_t \\ \alpha_{t+1} &= T_t \alpha_t + \zeta_{t+1}, \quad \zeta_t \sim N(0, Q_t) \\ \alpha_1 &\sim N(0, P) \end{aligned}$$

The first equation, called the *observation equation*, relates the response series y_t to a state vector α_t that is usually unobserved. The second equation, called the *state equation*, describes the evolution of the state vector in time. The system matrices Z_t and T_t are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series ζ_t consists of independent, zero-mean, Gaussian vectors with covariance matrices Q_t . For most of the UCMs considered here, the system matrices Z_t and T_t , and the noise covariances Q_t , are time invariant—that is, they do not depend on time. In a few cases, however, some or all of them can depend on time. The initial state vector α_1 is assumed to be independent of the noise series, and its covariance matrix P can be partially diffuse. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite—that is, you have no prior information about this part of the vector. The covariance of the initial state α_1 is assumed to have the following form:

$$P = P_* + \kappa P_\infty$$

where P_* and P_∞ are nonnegative definite, symmetric matrices and κ is a constant that is assumed to be close to ∞ . In the case of UCMs considered here, P_∞ is always a diagonal matrix that consists of zeros and ones, and, if a particular diagonal element of P_∞ is one, then the corresponding row and column in P_* are zero.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states $\{\alpha_t\}$ by using the observed series $\{y_t\}$. These algorithms also yield the in-sample and out-of-sample forecasts and the likelihood of $\{y_t\}$. The state space representation of a UCM does not need to be unique. In the representation used here, the unobserved components in the UCM often appear as elements of the state vector. This makes the elements of the state interpretable and, more important, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information about the computational aspects of the state space modeling, see Durbin and Koopman (2001). Next, some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let $\{y_t, t = 1, \dots, n\}$ be the observed sample from a series that satisfies a state space model. Next, for $1 \leq t \leq n$, let the one-step-ahead forecasts of the series, the states, and their variances be defined as follows, using the usual notation to denote the conditional expectation and conditional variance:

$$\begin{aligned} \hat{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \Gamma_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \hat{y}_t &= E(y_t | y_1, y_2, \dots, y_{t-1}) \\ F_t &= \text{Var}(y_t | y_1, y_2, \dots, y_{t-1}) \end{aligned}$$

These are also called the *filtered* estimates of the series and the states. Similarly, for $t \geq 1$, let the following denote the full-sample estimates of the series and the state values at time t :

$$\begin{aligned}\tilde{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_n) \\ \Delta_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_n) \\ \tilde{y}_t &= E(y_t | y_1, y_2, \dots, y_n) \\ G_t &= \text{Var}(y_t | y_1, y_2, \dots, y_n)\end{aligned}$$

If the time t is in the historical period—that is, if $1 \leq t \leq n$ —then the full-sample estimates are called the *smoothed* estimates, and if t lies in the future then they are called out-of-sample forecasts. Note that if $1 \leq t \leq n$, then $\tilde{y}_t = y_t$ and $G_t = 0$, unless y_t is missing.

All the filtered and smoothed estimates ($\hat{\alpha}_t, \tilde{\alpha}_t, \dots, G_t$, and so on) are computed by using the Kalman filtering and smoothing (KFS) algorithm, which is an iterative process. If the initial state is diffuse, as is often the case for the UCMs, its treatment requires modification of the traditional KFS, which is called the diffuse KFS (DKFS). The details of DKFS implemented in the UCM procedure can be found in de Jong and Chu-Chun-Lin (2003). Additional information on the state space models can be found in Durbin and Koopman (2001). The likelihood formulas described in this section are taken from the latter reference.

In the case of diffuse initial condition, the effect of the improper prior distribution of α_1 manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse; that is, during these iterations the one-step-ahead series and state forecast variances F_t and Γ_t have the following form:

$$\begin{aligned}F_t &= F_{*t} + \kappa F_{\infty t} \\ \Gamma_t &= \Gamma_{*t} + \kappa \Gamma_{\infty t}\end{aligned}$$

The actual number of iterations—say, I —affected by this improper prior depends on the nature of the vectors Z_t , the number of nonzero diagonal elements of P_∞ , and the pattern of missing values in the dependent series. After I iterations, $\Gamma_{\infty t}$ and $F_{\infty t}$ become zero and the one-step-ahead series and state forecasts have proper distributions. These first I iterations constitute the *initialization* phase of the DKFS algorithm. The post-initialization phase of the DKFS and the traditional KFS is the same. In the state space modeling literature the pre-initialization and post-initialization phases are sometimes called *pre-collapse* and *post-collapse* phases of the diffuse Kalman filtering. In certain missing value patterns it is possible for I to exceed the sample size; that is, the sample information can be insufficient to create a proper prior for the filtering process. In these cases, parameter estimation and forecasting is done on the basis of this improper prior, and some or all of the series and component forecasts can have infinite variances (or zero precision). The forecasts that have infinite variance are set to missing. The same situation can occur if the specified model contains components that are essentially multicollinear. In these situations no residual analysis is possible; in particular, no residuals-based goodness-of-fit statistics are produced.

The log likelihood of the sample (L_∞), which takes account of this diffuse initialization step, is computed by using the one-step-ahead series forecasts as follows

$$L_\infty(y_1, \dots, y_n) = -\frac{(n-d)}{2} \log 2\pi - \frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \left(\log F_t + \frac{v_t^2}{F_t} \right)$$

where d is the number of diffuse elements in the initial state α_1 , $v_t = y_t - Z_t \hat{\alpha}_t$ are the one-step-ahead residuals, and

$$\begin{aligned} w_t &= \log F_{\infty t} && \text{if } F_{\infty t} > 0 \\ &= \log F_{*t} + \frac{v_t^2}{F_{*t}} && \text{if } F_{\infty t} = 0 \end{aligned}$$

If y_t is missing at some time t , then the corresponding summand in the log likelihood expression is deleted, and the constant term is adjusted suitably. Moreover, if the initialization step does not complete—that is, if I exceeds the sample size—then the value of d is reduced to the number of diffuse states that are successfully initialized.

The portion of the log likelihood that corresponds to the post-initialization period is called the nondiffuse log likelihood (L_0). The nondiffuse log likelihood is given by

$$L_0(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=I+1}^n (\log F_t + \frac{v_t^2}{F_t})$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^I w_t$, does not depend on the model parameters, and in these cases the maximization of nondiffuse and diffuse likelihoods is equivalent. However, in some cases, such as when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and nondiffuse likelihood can produce different parameter estimates.

In some situations it is convenient to reparameterize the nondiffuse initial state covariance P_* as $\sigma^2 P_*$ and the state noise covariance Q_t as $\sigma^2 Q_t$ for some common scalar parameter σ^2 . In this case the preceding log-likelihood expression, up to a constant, can be written as

$$L_\infty(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \log F_t - \frac{1}{2\sigma^2} \sum_{t=I+1}^n \frac{v_t^2}{F_t} - \frac{(n-d)}{2} \log \sigma^2$$

Solving analytically for the optimum, the maximum likelihood estimate of σ^2 can be shown to be

$$\hat{\sigma}^2 = \frac{1}{(n-d)} \sum_{t=I+1}^n \frac{v_t^2}{F_t}$$

When this expression of σ^2 is substituted back into the likelihood formula, an expression called the *profile likelihood* ($L_{profile}$) of the data is obtained:

$$-2L_{profile}(y_1, \dots, y_n) = \sum_{t=1}^I w_t + \sum_{t=I+1}^n \log F_t + (n-d) \log \left(\sum_{t=I+1}^n \frac{v_t^2}{F_t} \right)$$

In some situations the parameter estimation is done by optimizing the profile likelihood (see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 2312 and the **PROFILE** option in the ESTIMATE statement).

In the remainder of this section the state space formulation of UCMs is further explained by using some particular UCMs as examples. The examples show that the state space formulation of the UCMs depends

on the components in the model in a simple fashion; for example, the system matrix T is usually a block diagonal matrix with blocks that correspond to the components in the model. The only exception to this pattern is the UCMs that consist of the lags of dependent variable. This case is considered at the end of the section.

In what follows, $Diag[a, b, \dots]$ denotes a diagonal matrix with diagonal entries $[a, b, \dots]$, and the transpose of a matrix T is denoted as T' .

Locally Linear Trend Model

Recall that the dynamics of the locally linear trend model are

$$\begin{aligned} y_t &= \mu_t + \epsilon_t \\ \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t \\ \beta_t &= \beta_{t-1} + \xi_t \end{aligned}$$

Here y_t is the response series and ϵ_t , η_t , and ξ_t are independent, zero-mean Gaussian disturbance sequences with variances σ_ϵ^2 , σ_η^2 , and σ_ξ^2 , respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [\epsilon_t \mu_t \beta_t]'$ and the state noise $\zeta_t = [\epsilon_t \eta_t \xi_t]'$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices T and Z and the noise covariance Q corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$Z = [1 \ 1 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad Q = Diag[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2]$$

The distribution of the initial state vector α_1 is diffuse, with $P_* = Diag[\sigma_\epsilon^2, 0, 0]$ and $P_\infty = Diag[0, 1, 1]$. The parameter vector θ consists of all the disturbance variances—that is, $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2)$.

Basic Structural Model

The basic structural model (BSM) is obtained by adding a seasonal component, γ_t , to the local level model. In order to economize on the space, the state space formulation of a BSM with a relatively short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t 0 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

and $Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag} [\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag} [0, 1, 1, 1, 1, 1]$.

In the case of the trigonometric type of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

and $Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag} [\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag} [0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Seasons with Blocked Seasonal Values

Block seasons are special seasonal components that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure—that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal component is a block seasonal with block size m equal to 3 and the number of blocks k equal to 4. The state space structure for such a model with dummy-type seasonality is as follows: The state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t \ 0 \ 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag m and $\gamma_{3,t}$ to lag $2m$. All the system matrices are time invariant, except the matrix T . They can be seen to be $Z = [1 \ 1 \ 0 \ 1 \ 0 \ 0]$, $Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. Note that when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$.

Similarly in the case of the trigonometric form of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . $Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1]$, $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. As before, when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Cycles and Autoregression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There you can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, and damping coefficient ρ can be modeled as

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} v_t \\ v_t^* \end{bmatrix}$$

where v_t and v_t^* are independent, zero-mean, Gaussian disturbances with variance σ_v^2 . In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = [\epsilon_t \psi_t \psi_t^*]'$, and the state noise vector $\zeta_t = [\epsilon_t v_t v_t^*]'$. The system matrices are

$$Z = [1 \ 1 \ 0] \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \rho \cos \lambda & \rho \sin \lambda \\ 0 & -\rho \sin \lambda & \rho \cos \lambda \end{bmatrix} \quad Q = \text{Diag}[\sigma_\epsilon^2, \sigma_v^2, \sigma_v^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag} [\sigma_\epsilon^2, \sigma_\psi^2, \sigma_\psi^2]$, where $\sigma_\psi^2 = \sigma_v^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \lambda, \sigma_v^2)$.

An autoregression r_t can be considered as a special case of cycle with frequency λ equal to 0 or π . In this case the equation for ψ_t^* is not needed. Therefore, for a UCM consisting of an autoregressive component and an irregular component, the state space model simplifies to the following form.

The state vector $\alpha_t = [\epsilon_t \ r_t]'$, and the state noise vector $\zeta_t = [\epsilon_t \ v_t]'$. The system matrices are

$$Z = [1 \ 1], \quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \quad \text{and} \quad Q = \text{Diag} [\sigma_\epsilon^2, \sigma_v^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag} [\sigma_\epsilon^2, \sigma_r^2]$, where $\sigma_r^2 = \sigma_v^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \sigma_v^2)$.

Incorporating Predictors of Different Kinds

In the UCM procedure, predictors can be incorporated in a UCM in a variety of ways: simple time-invariant linear predictors are specified in the **MODEL** statement, predictors with time-varying coefficients can be specified in the **RANDOMREG** statement, and predictors that have a nonlinear relationship with the response variable can be specified in the **SPLINEREG** statement. As with earlier examples, how to obtain a state space form of a UCM consisting of such variety of predictors is illustrated using a simple special case. Consider a random walk trend model with predictors x , u_1 , u_2 , and v . Let us assume that x is a simple regressor specified in the **MODEL** statement, u_1 and u_2 are random regressors with time-varying regression coefficients that are specified in the same **RANDOMREG** statement, and v is a nonlinear regressor specified on a **SPLINEREG** statement. Let us further assume that the spline associated with v has degree one and is based on two internal knots. As explained in the section “**SPLINEREG Statement**” on page 2293, using v is equivalent to using $(nknots + degree) = (2 + 1) = 3$ derived (random) regressors: say, s_1, s_2, s_3 . In all there are $(1 + 2 + 3) = 6$ regressors, the first one being a simple regressor and the others being time-varying coefficient regressors. The time-varying regressors are in two groups, the first consisting of u_1 and u_2 and the other consisting of s_1, s_2 , and s_3 . The dynamics of this model are as follows:

$$\begin{aligned} y_t &= \mu_t + \beta x_t + \kappa_{1t} u_{1t} + \kappa_{2t} u_{2t} + \sum_{i=1}^3 \gamma_{it} s_{it} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \\ \kappa_{1t} &= \kappa_{1(t-1)} + \xi_{1t} \\ \kappa_{2t} &= \kappa_{2(t-1)} + \xi_{2t} \\ \gamma_{1t} &= \gamma_{1(t-1)} + \zeta_{1t} \\ \gamma_{2t} &= \gamma_{2(t-1)} + \zeta_{2t} \\ \gamma_{3t} &= \gamma_{3(t-1)} + \zeta_{3t} \end{aligned}$$

All the disturbances $\epsilon_t, \eta_t, \xi_{1t}, \xi_{2t}, \zeta_{1t}, \zeta_{2t}$, and ζ_{3t} are independent, zero-mean, Gaussian variables, where ξ_{1t}, ξ_{2t} share a common variance parameter σ_ξ^2 and $\zeta_{1t}, \zeta_{2t}, \zeta_{3t}$ share a common variance σ_ζ^2 . These dynamics can be captured in the state space form by taking state $\alpha_t = [\epsilon_t \ \mu_t \ \beta \ \kappa_{1t} \ \kappa_{2t} \ \gamma_{1t} \ \gamma_{2t} \ \gamma_{3t}]'$, state

disturbance $\zeta_t = [\epsilon_t \eta_t 0 \xi_{1t} \xi_{2t} \zeta_{1t} \zeta_{2t} \zeta_{3t}]'$, and the system matrices

$$\begin{aligned} Z_t &= [1 \ 1 \ x_t \ u_{1t} \ u_{2t} \ s_{1t} \ s_{2t} \ s_{3t}] \\ T &= \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1] \\ Q &= \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, 0, \sigma_\xi^2, \sigma_\xi^2, \sigma_\xi^2, \sigma_\xi^2, \sigma_\xi^2] \end{aligned}$$

Note that the regression coefficients are elements of the state vector and that the system vector Z_t is not time invariant. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1]$. The parameters of this model are the disturbance variances, $\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2$, and σ_ξ^2 , which get estimated by maximizing the likelihood. The regression coefficients, time-invariant β and time-varying $\kappa_{1t}, \kappa_{2t}, \gamma_{1t}, \gamma_{2t}$ and γ_{3t} , get implicitly estimated during the state estimation (smoothing).

Reporting Parameter Estimates for Random Regressors

If the random walk disturbance variance associated with a random regressor is held fixed at zero, then its coefficient is no longer time-varying. In the UCM procedure the random regressor parameter estimates are reported differently if the random walk disturbance variance associated with a random regressor is held fixed at zero. The following points explain how the parameter estimates are reported in the parameter estimates table and in the OUTEST= data set.

- If the random walk disturbance variance associated with a random regressor is not held fixed, then its estimate is reported in the parameter estimates table and in the OUTEST= data set.
- If more than one random regressor is specified in a **RANDOMREG** statement, then the first regressor in the list is used as a representative of the list while reporting the corresponding common variance parameter estimate.
- If the random walk disturbance variance is held fixed at zero, then the parameter estimates table and the OUTEST= data set contain the corresponding regression parameter estimate rather than the variance parameter estimate.
- Similar considerations apply in the case of the derived random regressors associated with a spline-regressor.

ARMA Irregular Component

The state space form for the irregular component that follows an $\text{ARMA}(p,q) \times (P,Q)_s$ model is described in this section. The notation for ARMA models is explained in the **IRREGULAR** statement. A number of alternate state space forms are possible in this case; the one given here is based on Jones (1980). With slight abuse of notation, let $p = p + sP$ denote the effective autoregressive order and $q = q + sQ$ denote the effective moving average order of the model. Similarly, let ϕ be the effective autoregressive polynomial and θ be the effective moving average polynomial in the backshift operator with coefficients ϕ_1, \dots, ϕ_p and $\theta_1, \dots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence ϵ_t that follows an $\text{ARMA}(p,q) \times (P,Q)_s$ model with a white noise sequence a_t has a state space form with state vector of size $m = \max(p, q + 1)$. The system matrices, which are time invariant, are as follows: $Z = [1 \ 0 \ \dots \ 0]$. The state transition matrix T , in a blocked form, is given by

$$T = \begin{bmatrix} 0 & I_{m-1} \\ \phi_m & \dots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and I_{m-1} is an $(m-1)$ dimensional identity matrix. The covariance of the state disturbance matrix $Q = \sigma^2 \psi \psi'$ where σ^2 is the variance of the white noise sequence a_t and the vector $\psi = [\psi_0 \dots \psi_{m-1}]'$ contains the first m values of the impulse response function—that is, the first m coefficients in the expansion of the ratio θ/ϕ . Since ϵ_t is a stationary sequence, the initial state is nondiffuse and $P_\infty = 0$. The description of P_* , the covariance matrix of the initial state, is a little involved; the details are given in Jones (1980).

Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Consider a model that has random walk trend, two simple time-invariant regressors, and that also includes a few—say, k —lags of the dependent variable. That is,

$$\begin{aligned} y_t &= \sum_{i=1}^k \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \end{aligned}$$

The state space form of this augmented model can be described in terms of the state space form of a model that has random walk trend with two simple time-invariant regressors. A superscript dagger (\dagger) has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha_t^\dagger = [\alpha_t' y_t y_{t-1} \dots y_{t-k+1}]'$ and the new state noise vector $\zeta_t^\dagger = [\zeta_t' u_t 0 \dots 0]'$, where u_t is the matrix product $Z_t' \zeta_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in block form, are

$$Z_t^\dagger = [0 \ 0 \ 0 \ 0 \ 1 \ \dots \ 0], \quad T_t^\dagger = \begin{bmatrix} T_t & 0 & \dots & 0 \\ Z_{t+1}' T_t & \phi_1 & \dots & \phi_k \\ 0 & I_{k-1, k-1} & & 0 \end{bmatrix}$$

where $I_{k-1, k-1}$ is the $k-1$ dimensional identity matrix and

$$Q_t^\dagger = \begin{bmatrix} Q_t & Q_t Z_t' & 0 \\ Z_t Q_t & Z_t Q_t Z_t' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Note that the T and Q matrices of the random walk with predictors model are time invariant, and in the expressions above their time indices are kept because they illustrate the pattern for more general models. The initial state vector is diffuse, with

$$P_*^\dagger = \begin{bmatrix} P_* & 0 \\ 0 & 0 \end{bmatrix}, \quad P_\infty^\dagger = \begin{bmatrix} P_\infty & 0 \\ 0 & I_{k, k} \end{bmatrix}$$

The parameters of this model are the disturbance variances σ_ϵ^2 and σ_η^2 , the lag coefficients $\phi_1, \phi_2, \dots, \phi_k$, and the regression coefficients β_1 and β_2 . As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

Outlier Detection

In time series analysis it is often useful to detect changes over time in the characteristics of the response series. In the UCM procedure you can search for two types of changes, additive outliers (AO) and level shifts (LS). An additive outlier is an unusual value in the series, the cause of which might be a data recording error or a temporary shock to the series generation process. A level shift represents a permanent shift, either up or down, in the level of the series. You can control different aspects of the outlier search, such as the significance level of the reported outliers, by choosing different options in the **OUTLIER** statement. The search for AOs is done by default, whereas the **CHECKBREAK** option in the **LEVEL** statement must be used to turn on the search for LSs.

The outlier detection process implemented in the UCM procedure is based on de Jong and Penzer (1998). In this approach the fitted model is taken to be the *null* model, and the series values and level shifts that are not adequately accounted for by the null model are flagged as outliers. The unusualness of a response series value at a particular time point t_0 , with respect to the fitted model, can be judged by estimating its value based on the rest of the data (that is, the series obtained by *deleting* the series value at t_0) and comparing the estimated value to the observed value. If the difference between the estimated and observed values is statistically significant, then such value can be regarded as an AO. Note that this difference between the estimated and observed values is also the regression coefficient of a *dummy* regressor that takes the value 1.0 at t_0 and is 0.0 elsewhere, assuming such a regressor is added to the null model. In this way the series value at t_0 is regarded as AO if the regression coefficient of this dummy regressor is significant. Similarly, you can say that a level shift has occurred at a time point t_0 if the regression coefficient of a regressor, which is 0.0 before t_0 and 1.0 at t_0 and thereafter, is statistically significant. de Jong and Penzer (1998) provide an efficient way to compute such AO and LS regression coefficients and their standard errors at all time points in the series. The outlier summary table, which is produced by default, simply lists the most statistically significant candidates among these.

Missing Values

Embedded missing values in the dependent variable usually cause no problems in UCM modeling. However, no embedded missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can lead to failure of the initialization step of the diffuse Kalman filtering for some models. For example, if in a monthly series all values are missing for a certain month—say, May—then a BSM with monthly seasonality leads to such a situation. However, in this case the initialization step can complete successfully for a nonseasonal model such as local linear model.

Parameter Estimation

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the nondiffuse likelihood. The decision to use the full diffuse likelihood or the nondiffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any

dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the nondiffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients, the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either full or nondiffuse, is carried out using one of several nonlinear optimization algorithms. The user can control many aspects of the optimization process by using the **NLOPTIONS** statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

Parameter Estimation by Profile Likelihood Optimization

If a disturbance variance, such as the disturbance variance of the irregular component, is a part of the UCM and is a free parameter, then it can be profiled out of the likelihood. This means solving analytically for its optimum and plugging this expression back into the likelihood formula, giving rise to the so-called *profile* likelihood. The expression of the profile likelihood and the MLE of the profiled variance are given earlier in the section “The UCMs as State Space Models” on page 2302, where the computation of the likelihood of the state space model is also discussed.

In some situations the optimization of the profile likelihood can be more efficient because the number of parameters to optimize is reduced by one; however, for a variety of reasons such gains might not always be observed. Moreover, in theory the estimates obtained by optimizing the profile likelihood and the usual likelihood should be the same, but in practice this might not hold because of numerical rounding and other conditions.

In the UCM procedure, by default the usual likelihood is optimized if any of the disturbance variance parameters is held fixed to a nonzero value by using the **NOEST** option in the corresponding component statement. In other cases the decision whether to optimize the profile likelihood or the usual likelihood is based on several factors that are difficult to document. You can choose which likelihood to optimize during parameter estimation by specifying the **PROFILE** option for the profile likelihood optimization or the **NOPROFILE** option for the usual likelihood optimization. In the presence of the **PROFILE** option, the disturbance variance to profile is checked in a specific order, so that if the irregular component disturbance variance is free then it is always chosen. The situation in other cases is more complicated.

Profiling in the Presence of Fixed Variance Parameters

Note that when the parameter estimation is done by optimizing the profile likelihood, the interpretation of the variance parameters that are held fixed to nonzero values changes. In the presence of the **PROFILE** option, the disturbance variances that are held at a fixed value by using the **NOEST** option in their respective component statements are interpreted as being restricted to be that fixed multiple of the profiled variance rather than being fixed at that nominal value. That is, implicitly, the parameter estimation is done under the restriction of holding the disturbance variance *ratio* fixed at a given value rather than the disturbance variance itself. See [Example 34.5](#) for an example of this type of restriction to obtain a UC model that is equivalent to the famous Hodrick-Prescott filter.

***t* values**

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully; therefore the probability values that correspond to a *t* distribution should be interpreted carefully, as they can be misleading. This is particularly true if the parameters in question are close to the boundary of the parameter space. The two sources by Harvey (1989, 2001) are good references for information about this topic. For some parameters, such as, the cycle period, the reported *t* values are uninformative because comparison of the estimated parameter with zero is never needed. In such cases the *t* values and the corresponding probability values should be ignored.

Bootstrap Prediction Intervals (Experimental)

By default, the UCM procedure computes the standard errors of the series and component forecasts (both the filtered and smoothed estimates) by assuming that the estimated parameters are in fact the true parameters. Rodriguez and Ruiz (2010) describe a bootstrap-based procedure to compute the standard errors of the series and component forecasts that takes into account the uncertainty of parameter estimation. As an experimental feature in this release, you can request the computation of standard errors based on this bootstrap-based procedure by specifying the **BOOTSTRAP** option in the FORECAST statement. Subsequently, the confidence intervals for the series and component forecasts are based on these bootstrap standard errors. The algorithm that PROC UCM uses closely follows the first procedure described in Section 3 of Rodriguez and Ruiz (2010). Note that this bootstrap algorithm is computationally expensive. The computational burden increases with the number of bootstrap replications and is comparable to the computational burden of fitting the specified model as many times as the number of replications. Fortunately, these replications can be executed in parallel, and the UCM procedure can use multiple cores and multiple grid nodes (if they are available) to complete these calculations faster. For a single machine with multiple cores, the procedure automatically detects and uses all the cores. If a grid environment with multiple machines is available (with the appropriate SAS license), you must use the **PERFORMANCE** statement to supply the necessary information to the UCM procedure.

Computational Issues

Convergence Problems

As explained in the section “[Parameter Estimation](#)” on page 2311, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, the following points might be helpful:

- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.

- Examine your model for redundancies in the included components and regressors. If some of the included components or regressors are nearly collinear to each other, then the optimization process can become unstable.
- Experimenting with different options offered by the **NLOPTIONS** statement can help.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement for the smoothing stage of the Kalman filter is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed then the memory requirement is of the order of $6 \times 8 \times (m^2 + n)$ bytes. Besides m and n , the computing time for the parameter estimation depends on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Displayed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set, including the data set name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, including the names of the variables in the model, their categorization as dependent or predictor, the index of the beginning and ending observations in the spans, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation
- information about the model parameters at the start of the model-fitting stage, including the fixed parameters in the model and the initial estimates of the free parameters in the model
- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting-stage, including the parameter estimates, their approximate standard errors, t statistics, and the approximate p -value
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
- the fit statistics that are based on the raw residuals (observed minus predicted), including the mean squared error (MSE), the root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R square, the adjusted R square, the random walk R square, and Amemiya's R square

- the significance analysis of the components included in the model that is based on the estimation span
- brief information about the components included in the model
- additive outliers in the series, if any are detected
- the multistep series forecasts
- post-sample-prediction analysis table that compares the multistep forecasts with the observed series values, if the `BACK=` option is used in the `FORECAST` statement

Statistical Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

This section provides information about the basic ODS statistical graphics produced by the UCM procedure.

You can obtain most plots relevant to the specified model by using the global `PLOTS=` option in the `PROC UCM` statement. The plot of series forecasts in the forecast horizon is produced by default. You can further control the production of individual plots by using the `PLOT=` options in the different statements.

The main types of plots available are as follows:

- Time series plots of the component estimates, either filtered or smoothed, can be requested by using the `PLOT=` option in the respective component statements. For example, the use of `PLOT=SMOOTH` option in a `CYCLE` statement produces a plot of smoothed estimate of that cycle.
- Residual plots for model diagnostics can be obtained by using the `PLOT=` option in the `ESTIMATE` statement.
- Plots of series forecasts and model decompositions can be obtained by using the `PLOT=` option in the `FORECAST` statement.

The following example is a simple illustration of the available plot options.

Analysis of Sunspot Data: Illustration of ODS Graphics

In this example a well-known series, Wolfer’s sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with a period of about eleven years. The following `DATA` step creates the input data set:

```

data sunspot;
  input year wolfer @@;
  year = mdy(1,1, year);
  format year year4.;
datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755   96
1756  102 1757  324 1758  476 1759  540 1760  629 1761  859 1762  612
1763  451 1764  364 1765  209 1766  114 1767  378 1768  698 1769 1061

... more lines ...

```

The following statements specify a UCM that includes a cycle component and a random walk trend component:

```

proc ucm data=sunspot;
  id year interval=year;
  model wolfer;
  irregular;
  level ;
  cycle plot=(filter smooth);
  estimate back=24 plot=(loess panel cusum wn);
  forecast back=24 lead=24 plot=(forecasts decomp);
run;

```

The following subsections explain the graphics produced by the above statements.

Component Plots

The plots in Figure 34.8 and Figure 34.9, produced by specifying PLOT=(FILTER SMOOTH) in the CYCLE statement, show the filtered and smoothed estimates, respectively, of the cycle component in the model. Note that the smoothed estimate appears smoother than the filtered estimate. This is always true because the filtered estimate of a component at time t is based on the observations prior to time t —that is, it uses measurements from the first observation up to the $(t - 1)$ th observation. On the other hand, the corresponding smoothed estimate uses all the available observations—that is, all the measurements from the first observation to the last. This makes the smoothed estimate of the component more precise than the filtered estimate for the time points within historical period. In the forecast horizon, both filtered and smoothed estimates are identical, being based on the same set of observations.

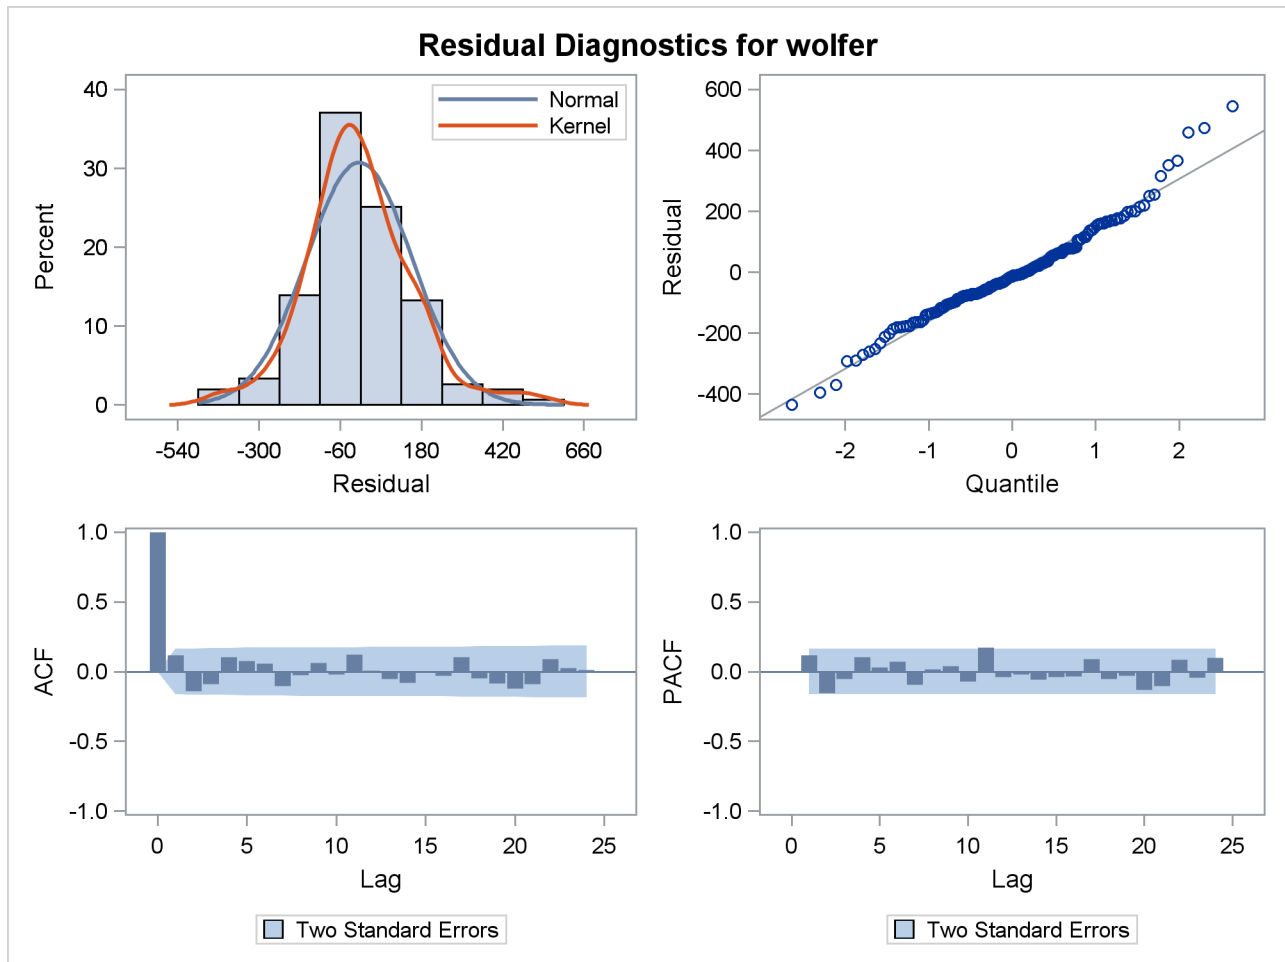

Figure 34.8 Sunspots Series: Filtered Cycle

Figure 34.9 Sunspots Series: Smoothed Cycle**Residual Diagnostics**

If the fitted model is appropriate for the given data, then the corresponding one-step-ahead residuals should be approximately *white*—that is, uncorrelated—and approximately normal. Moreover, the residuals should not display any discernible pattern. You can detect departures from these conditions graphically. Different residual diagnostic plots can be requested by using the PLOT= option in the ESTIMATE statement.

The normality can be checked by examining the histogram and the normal quantile plot of residuals. The whiteness can be checked by examining the ACF and PACF plots that show the sample autocorrelation and sample partial-autocorrelation at different lags. The diagnostic panel shown in Figure 34.10, produced by specifying PLOT=PANEL, contains these four plots.

Figure 34.10 Sunspots Series: Residual Diagnostics

The residual histogram and Q-Q plot show no serious violation of normality. The histogram appears reasonably symmetric and follows the overlaid normal density curve reasonably closely. Similarly in the Q-Q plot the residuals follow the reference line fairly closely. The ACF and PACF plots also do not exhibit any violation of the whiteness assumption; the correlations at all nonzero lags seem to be insignificant.

The residual whiteness can also be formally tested by using the Ljung-Box portmanteau test. The plot in [Figure 34.11](#), produced by specifying `PLOT=WN`, shows the p -values of the Ljung-Box test statistics at different lags. In these plots the p -values for the first few lags, equal to the number of estimated parameters in the model, are not shown because they are always missing. This portion of the plot is shaded blue to indicate this fact. In the case of this model, five parameters are estimated so the p -values for the first five lags are not shown. The p -values are displayed on a log scale in such a way that higher bars imply more extreme test statistics. In this plot some early p -values appear extreme. However, these p -values are based on large sample theory, which suggests that these statistics should be examined for lags larger than the square root of sample size. In this example it means that the p -values for the first $\sqrt{154} \approx 12$ lags can be ignored. With this consideration, the plot shows no violation of whiteness since the p -values after the 12th lag do not appear extreme.

Figure 34.11 Sunspots Series: Ljung-Box Portmanteau Test

The plot in [Figure 34.12](#), produced by specifying PLOT=LOESS, shows the residuals plotted against time with an overlaid LOESS curve. This plot is useful for checking whether any discernible pattern remains in the residuals. Here again, no significant pattern appears to be present.

Figure 34.12 Sunspots Series: Residual Loess Plot

The plot in [Figure 34.13](#), produced by specifying `PLOT=CUSUM`, shows the cumulative residuals plotted against time. This plot is useful for checking structural breaks. Here, there appears to be no evidence of structural break since the cumulative residuals remain within the confidence band throughout the sample period. Similarly you can request a plot of the squared cumulative residuals by specifying `PLOT=CUSUMSQ`.

Figure 34.13 Sunspots Series: CUSUM Plot

Brockwell and Davis (1991) can be consulted for additional information on diagnosing residuals. For more information on CUSUM and CUSUMSQ plots, you can consult Harvey (1989).

Forecast and Series Decomposition Plots

You can use the PLOT= option in the FORECAST statement to obtain the series forecast plot and the series decomposition plots. The series decomposition plots show the result of successively adding different components in the model starting with the trend component. The IRREGULAR component is left out of this process. The following two plots, produced by specifying PLOT=DECOMP, show the results of successive component addition for this example. The first plot, shown in Figure 34.14, shows the smoothed trend component and the second plot, shown in Figure 34.15, shows the sum of smoothed trend and cycle.

Figure 34.14 Sunspots Series: Smoothed Trend

Figure 34.15 Sunspots Series: Smoothed Trend plus Cycle

Finally, Figure 34.16 shows the forecast plot.

Figure 34.16 Sunspots Series: Series Forecasts

ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 34.2](#).

Table 34.2 ODS Tables Produced by PROC UCM

ODS Table Name	Description	Statement	Option
Tables Summarizing the Estimation and Forecast Spans			
EstimationSpan	Estimation span summary information		default
ForecastSpan	Forecast span summary information		default

Table 34.2 continued

ODS Table Name	Description	Statement	Option
Tables Related to Model Parameters			
ConvergenceStatus	Convergence status of the estimation process		default
FixedParameters	Fixed parameters in the model		default
InitialParameters	Initial estimates of the free parameters		default
ParameterEstimates	Final estimates of the free parameters		default
Tables Related to Model Information and Diagnostics			
BlockSeasonDescription	Information about the block seasonals in the model		default
ComponentSignificance	Significance analysis of the components in the model		default
CycleDescription	Information about the cycles in the model		default
FitStatistics	Fit statistics based on the one-step-ahead predictions		default
FitSummary	Likelihood-based fit statistics		default
OutlierSummary	Summary table of the detected outliers		default
SeasonDescription	Information about the seasonals in the model		default
SeasonHarmonics	Summary of harmonics in a trigonometric seasonal component	SEASON	PRINT=HARMONICS
SplineSeasonDescription	Information about the spline-seasonals in the model		default
TrendInformation	Summary information of the level and slope components		default
Tables Related to Filtered Component Estimates			
FilteredAutoReg	Filtered estimate of an autoreg component	AUTOREG	PRINT=FILTER
FilteredBlockSeason	Filtered estimate of a block seasonal component	BLOCKSEASON	PRINT=FILTER
FilteredCycle	Filtered estimate of a cycle component	CYCLE	PRINT=FILTER
FilteredIrregular	Filtered estimate of the irregular component	IRREGULAR	PRINT=FILTER
FilteredLevel	Filtered estimate of the level component	LEVEL	PRINT=FILTER

Table 34.2 *continued*

ODS Table Name	Description	Statement	Option
FilteredRandomReg	Filtered estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=FILTER
FilteredSeason	Filtered estimate of a seasonal component	SEASON	PRINT=FILTER
FilteredSlope	Filtered estimate of the slope component	SLOPE	PRINT=FILTER
FilteredSplineReg	Filtered estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=FILTER
FilteredSplineSeason	Filtered estimate of a spline-seasonal component	SPLINESEASON	PRINT=FILTER
Tables Related to Smoothed Component Estimates			
SmoothedAutoReg	Smoothed estimate of an autoreg component	AUTOREG	PRINT=SMOOTH
SmoothedBlockSeason	Smoothed estimate of a block seasonal component	BLOCKSEASON	PRINT=SMOOTH
SmoothedCycle	Smoothed estimate of the cycle component	CYCLE	PRINT=SMOOTH
SmoothedIrregular	Smoothed estimate of the irregular component	IRREGULAR	PRINT=SMOOTH
SmoothedLevel	Smoothed estimate of the level component	LEVEL	PRINT=SMOOTH
SmoothedRandomReg	Smoothed estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=SMOOTH
SmoothedSeason	Smoothed estimate of a seasonal component	SEASON	PRINT=SMOOTH
SmoothedSlope	Smoothed estimate of the slope component	SLOPE	PRINT=SMOOTH
SmoothedSplineReg	Smoothed estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=SMOOTH
SmoothedSplineSeason	Smoothed estimate of a spline-seasonal component	SPLINESEASON	PRINT=SMOOTH
Tables Related to Series Decomposition and Forecasting			
FilteredAllExceptIrreg	Filtered estimate of sum of all components except the irregular component	FORECAST	PRINT=FDECOMP
FilteredTrend	Filtered estimate of trend	FORECAST	PRINT= FDECOMP
FilteredTrendReg	Filtered estimate of trend plus regression	FORECAST	PRINT=FDECOMP

Table 34.2 continued

ODS Table Name	Description	Statement	Option
FilteredTrendRegCyc	Filtered estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=FDECOMP
Forecasts	Dependent series forecasts		default
PostSamplePrediction	Forecasting performance in the holdout period	FORECAST	BACK=
SmoothedAllExceptIrreg	Smoothed estimate of sum of all components except the irregular component	FORECAST	PRINT=DECOMP
SmoothedTrend	Smoothed estimate of trend	FORECAST	PRINT= DECOMP
SmoothedTrendReg	Smoothed estimate of trend plus regression	FORECAST	PRINT=DECOMP
SmoothedTrendRegCyc	Smoothed estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=DECOMP

NOTE: The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonal components, or block seasonal components, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal component and the PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal component. There are some exceptions to this numbering rule: the tables, FilteredRandomReg, SmoothedRandomReg, FilteredSplineReg, and SmoothedSplineReg, are always numbered starting with zero.

ODS Graph Names

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC UCM generates are listed in Table 34.3, along with the required statements and options.

Table 34.3 ODS Graphics Produced by PROC UCM

ODS Graph Name	Description	Statement	Option
Plots Related to Residual Analysis			
ErrorACFPlot	Prediction error autocorrelation plot	ESTIMATE	PLOT=ACF
ErrorPACFPlot	Prediction error partial-autocorrelation plot	ESTIMATE	PLOT=PACF
ErrorHistogram	Prediction error histogram	ESTIMATE	PLOT=NORMAL
ErrorQQPlot	Prediction error normal quantile plot	ESTIMATE	PLOT=QQ
ErrorPlot	Plot of prediction errors	ESTIMATE	PLOT=RESIDUAL

OUTFOR= Data Set

You can use the `OUTFOR=` option in the `FORECAST` statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified, then a numerical variable, `_ID_`, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- `FORECAST`, a numerical variable containing the one-step-ahead predicted values and the multistep forecasts
- `RESIDUAL`, a numerical variable containing the difference between the actual and forecast values
- `STD`, a numerical variable containing the standard error of prediction
- `LCL` and `UCL`, numerical variables containing the lower and upper forecast confidence limits
- `S_SERIES` and `VS_SERIES`, numerical variables containing the smoothed values of the dependent series and their variances
- `S_IRREG` and `VS_IRREG`, numerical variables containing the smoothed values of the irregular component and their variances. These variables are present only if the model has an irregular component.
- `F_LEVEL`, `VF_LEVEL`, `S_LEVEL`, and `VS_LEVEL`, numerical variables containing the filtered and smoothed values of the level component and the respective variances. These variables are present only if the model has a level component.
- `F_SLOPE`, `VF_SLOPE`, `S_SLOPE`, and `VS_SLOPE`, numerical variables containing the filtered and smoothed values of the slope component and the respective variances. These variables are present only if the model has a slope component.
- `F_AUTOREG`, `VF_AUTOREG`, `S_AUTOREG`, and `VS_AUTOREG`, numerical variables containing the filtered and smoothed values of the autoreg component and the respective variances. These variables are present only if the model has an autoreg component.
- `F_CYCLE`, `VF_CYCLE`, `S_CYCLE`, and `VS_CYCLE`, numerical variables containing the filtered and smoothed values of the cycle component and the respective variances. If there are multiple cycles in the model, these variables are sequentially numbered as `F_CYCLE1`, `F_CYCLE2`, etc. These variables are present only if the model has at least one cycle component.
- `F_SEASON`, `VF_SEASON`, `S_SEASON`, and `VS_SEASON`, numerical variables containing the filtered and smoothed values of the season component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as `F_SEASON1`, `F_SEASON2`, etc. These variables are present only if the model has at least one season component.
- `F_BLKSEAS`, `VF_BLKSEAS`, `S_BLKSEAS`, and `VS_BLKSEAS`, numerical variables containing the filtered and smoothed values of the blockseason component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as `F_BLKSEAS1`, `F_BLKSEAS2`, etc.

- F_SPLSEAS, VF_SPLSEAS, S_SPLSEAS, and VS_SPLSEAS, numerical variables containing the filtered and smoothed values of the splinseason component and the respective variances. If there are multiple spline seasons in the model, these variables are sequentially numbered as F_SPLSEAS1, F_SPLSEAS2, etc. These variables are present only if the model has at least one splinseason component.
- Filtered and smoothed estimates, and their variances, of the time-varying regression coefficients of the variables specified in the RANDOMREG and SPLINEREG statements. A variable is not included if its coefficient is time-invariant, that is, if the associated disturbance variance is zero.
- S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.
- S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.
- S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one seasonal or block seasonal component.

OUTEST= Data Set

You can use the OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was fixed by the user or estimated
- _STATUS_, a character variable indicating whether the parameter estimation process converged or failed or there was an error of some other kind
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This has a missing value if the parameter value is fixed.
- TVALUE, a numerical variable containing the t -statistic. This has a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the p -value. This has a missing value if the parameter value is fixed.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, $y_t - \hat{y}_t$, are considered. In these formulas, n is the number of nonmissing prediction errors and k is the number of fitted parameters in the model. Moreover, the sum of squared errors, $SSE = \sum (y_t - \hat{y}_t)^2$, and the total sum of squares for the series corrected for the mean, $SST = \sum (y_t - \bar{y})^2$, where \bar{y} is the series mean, and the sums are over all the nonmissing prediction errors.

Mean Squared Error

The mean squared prediction error, $MSE = \frac{1}{n} SSE$

Root Mean Squared Error

The root mean square error, $RMSE = \sqrt{MSE}$

Mean Absolute Percent Error

The mean absolute percent prediction error, $MAPE = \frac{100}{n} \sum_{t=1}^n |(y_t - \hat{y}_t)/y_t|$.

The summation ignores observations where $y_t = 0$.

R-square

The R-square statistic, $R^2 = 1 - SSE/SST$.

If the model fits the series badly, the model error sum of squares, SSE , might be larger than SST and the R-square statistic will be negative.

Adjusted R-square

The adjusted R-square statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$

Amemiya's Adjusted R-square

Amemiya's adjusted R-square, $1 - (\frac{n+k}{n-k})(1 - R^2)$

Random Walk R-square

The random walk R-square statistic (Harvey's R-square statistic that uses the random walk model for comparison), $1 - (\frac{n-1}{n})SSE/RWSSE$, where $RWSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$

Maximum Percent Error

The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. In this computation the observations where $y_t = 0$ are ignored.

The likelihood-based fit statistics are reported separately (see the section “[The UCMs as State Space Models](#)” on page 2302). They include the full log likelihood (L_∞), the diffuse part of the log likelihood, the normalized residual sum of squares, and several information criteria: AIC, AICC, HQIC, BIC, and CAIC. Let q denote the number of estimated parameters, n be the number of nonmissing measurements in the estimation span, and d be the number of diffuse elements in the initial state vector that are successfully initialized during the Kalman filtering process. Moreover, let $n^* = (n - d)$. The reported information criteria, all in smaller-is-better form, are described in [Table 34.4](#):

Table 34.4 Information Criteria

Criterion	Formula	Reference
AIC	$-2L_\infty + 2q$	Akaike (1974)

Table 34.4 *continued*

Criterion	Formula	Reference
AICC	$-2L_{\infty} + 2qn^{*}/(n^{*} - q - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
HQIC	$-2L_{\infty} + 2q \log \log(n^{*})$	Hannan and Quinn (1979)
BIC	$-2L_{\infty} + q \log(n^{*})$	Schwarz (1978)
CAIC	$-2L_{\infty} + q(\log(n^{*}) + 1)$	Bozdogan (1987)

Examples: UCM Procedure

Example 34.1: The Airline Series Revisited

The series in this example, the monthly airline passenger series, has already been discussed earlier; see the section “A Seasonal Series with Linear Trend” on page 2259. Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here additional output features of the UCM procedure are illustrated, such as how to use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following statements fit a BSM to the logarithm of the airline passenger numbers. The disturbance variance for the slope component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data, some of the observed data are withheld during parameter estimation and forecast computations. The observations in the last two years, years 1959 and 1960, are not used in parameter estimation, while the observations in the last year, year 1960, are not used in the forecasting computations. This is done using the BACK= option in the ESTIMATE and FORECAST statements. In addition, a panel of residual diagnostic plots is obtained using the PLOT= PANEL option in the ESTIMATE statement.

```
data seriesG;
    set sashelp.air;
    logair = log(air);
run;

proc ucm data = seriesG;
    id date interval = month;
    model logair;
    irregular;
    level;
    slope var = 0 noest;
    season length = 12 type=trig;
    estimate back=24 plot=panel;
    forecast back=12 lead=24 print=forecasts;
run;
```

The following tables display the summary of data used in estimation and forecasting (Output 34.1.1 and Output 34.1.2). These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the beginning and ending dates of the span, the number of nonmissing values, etc.

Output 34.1.1 Observation Span Used in Parameter Estimation (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1958	120	5.43035

Output 34.1.2 Observation Span Used in Forecasting (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1959	132	5.48654

The following tables display the fixed parameters in the model, the preliminary estimates of the free parameters, and the final estimates of the free parameters ([Output 34.1.3](#), [Output 34.1.4](#), and [Output 34.1.5](#)).

Output 34.1.3 Fixed Parameters in the Model

The UCM Procedure		
Fixed Parameters in the Model		
Component	Parameter	Value
Slope	Error Variance	0

Output 34.1.4 Starting Values for the Parameters to Be Estimated

Preliminary Estimates of the Free Parameters		
Component	Parameter	Estimate
Irregular	Error Variance	6.64120
Level	Error Variance	2.49045
Season	Error Variance	1.26676

Output 34.1.5 Maximum Likelihood Estimates of the Free Parameters

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00018686	0.0001212	1.54	0.1233
Level	Error Variance	0.00040314	0.0001566	2.57	0.0100
Season	Error Variance	0.00000350	1.66319E-6	2.10	0.0354

Two types of goodness-of-fit statistics are reported after a model is fit to the series (see [Output 34.1.6](#) and [Output 34.1.7](#)). The first type is the likelihood-based goodness-of-fit statistics, which include the full likelihood of the data, the diffuse portion of the likelihood (see the section “[Details: UCM Procedure](#)” on page 2296), and the information criteria. The second type of statistics is based on the raw residuals, residual = observed – predicted. If the model is nonstationary, then one-step-ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

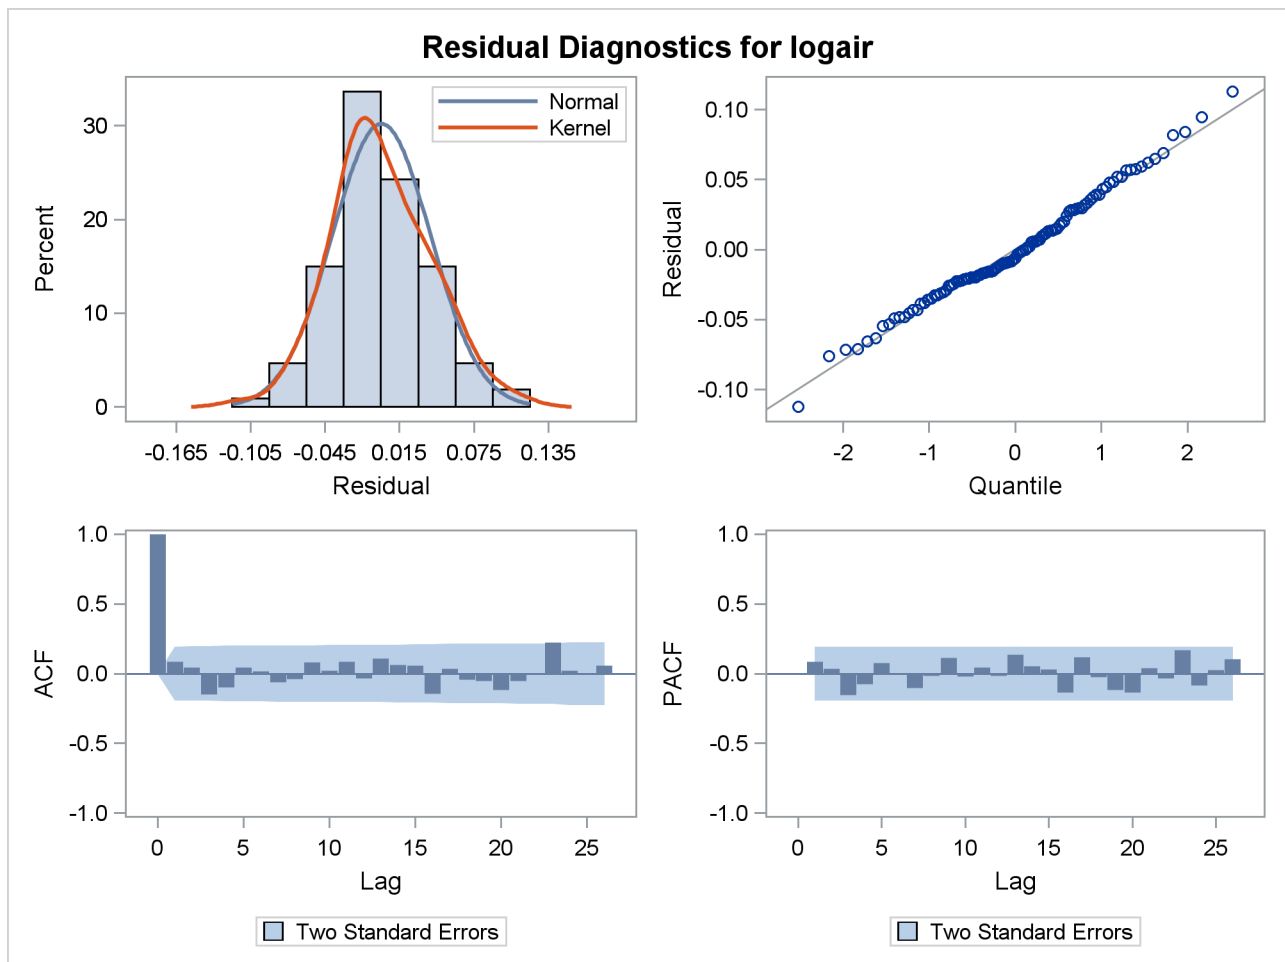

Output 34.1.6 Likelihood-Based Fit Statistics for the Airline Data

Likelihood Based Fit Statistics	
Statistic	Value
Full Log Likelihood	180.63
Diffuse Part of Log Likelihood	-13.93
Non-Missing Observations Used	120
Estimated Parameters	3
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	107
AIC (smaller is better)	-355.3
BIC (smaller is better)	-347.2
AICC (smaller is better)	-355
HQIC (smaller is better)	-352
CAIC (smaller is better)	-344.2

Output 34.1.7 Residuals-Based Fit Statistics for the Airline Data

Fit Statistics Based on Residuals	
Mean Squared Error	0.00156
Root Mean Squared Error	0.03944
Mean Absolute Percentage Error	0.57677
Maximum Percent Error	2.19396
R-Square	0.98705
Adjusted R-Square	0.98680
Random Walk R-Square	0.86370
Amemiya's Adjusted R-Square	0.98630
Number of non-missing residuals used for computing the fit statistics = 107	

The diagnostic plots based on the one-step-ahead residuals are shown in [Output 34.1.8](#). The residual histogram and the Q-Q plot show no reasons to question the approximate normality of the residual distribution. The remaining plots check for the *whiteness* of the residuals. The sample correlation plots, the autocorrelation function (ACF) and the partial autocorrelation function (PACF), also do not show any significant violations of the whiteness of the residuals. Therefore, on the whole, the model seems to fit the data well.

Output 34.1.8 Residual Diagnostics for the Airline Series Using a BSM

The forecasts are given in [Output 34.1.9](#). In order to save the space, the upper and lower confidence limit columns are dropped from the output, and only the rows corresponding to the year 1960 are shown. Recall that the actual measurements in the years 1959 and 1960 were withheld during the parameter estimation, and the ones in 1960 were not used in the forecast computations.

Output 34.1.9 Forecasts for the Airline Data

Obs	date	Forecast	StdErr	logair	Residual
133	JAN60	6.050	0.038	6.033	-0.017
134	FEB60	5.996	0.044	5.969	-0.027
135	MAR60	6.156	0.049	6.038	-0.118

142	OCT60	6.138	0.073	6.133	-0.005
143	NOV60	6.015	0.075	5.966	-0.049
144	DEC60	6.121	0.077	6.068	-0.053

The figure [Output 34.1.10](#) shows the forecast plot. The forecasts in the year 1960 show that the model predictions were quite good.

Output 34.1.10 Forecast Plot of the Airline Series Using a BSM

Example 34.2: Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (<http://www.york.ac.uk/depts/math/data/ts/welcome.htm> (series number 26)). The following DATA step statements read the data in a SAS data set.

```
data star;
    input magnitude @@;
    day = _n_;
datalines;
  25  28  31  32  33  33  32  31  28  25  22  18
  14  10   7   4   2   0   0   0   2   4   8  11
  15  19  23  26  29  32  33  34  33  32  30  27
  24  20  17  13  10   7   5   3   3   3   4   5
    7  10  13  16  19  22  24  26  27  28  29  28
  27  25  24  21  19  17  15  13  12  11  11  10
  10  11  12  12  13  14  15  16  17  18  19  19

    ... more lines ...
```

The following statements use the TIMESERIES procedure to get a timeseries plot of the series (see [Output 34.2.1](#)).

```
proc timeseries data=star plot=series;
    var magnitude;
run;
```

Output 34.2.1 Plot of Star Brightness on Successive Days

The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also mentions the difficulty involved in estimating the periods from the data (Bloomfield 2000, Chapter 3). In his case the cycle periods are estimated by least squares, and the sum of squares surface has multiple local optima and ridges. The following statements show how to use the UCM procedure to fit this two-cycle model to the series. The constant term in the model is specified by holding the variance parameter of the level component to zero.

```
proc ucm data=star;
  model magnitude;
  irregular;
  level var=0 noest;
  cycle;
  cycle;
  estimate;
run;
```

The final parameter estimates and the goodness-of-fit statistics are shown in [Output 34.2.2](#) and [Output 34.2.3](#), respectively. The model fit appears to be good.

Output 34.2.2 Two-Cycle Model: Parameter Estimates

The UCM Procedure					
Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.09257	0.0053845	17.19	<.0001
Cycle_1	Damping Factor	1.00000	1.81175E-7	5519514	<.0001
Cycle_1	Period	29.00036	0.0022709	12770.4	<.0001
Cycle_1	Error Variance	0.00000882	5.27213E-6	1.67	0.0944
Cycle_2	Damping Factor	1.00000	2.11939E-7	4718334	<.0001
Cycle_2	Period	24.00011	0.0019128	12547.2	<.0001
Cycle_2	Error Variance	0.00000535	3.56374E-6	1.50	0.1330

Output 34.2.3 Two-Cycle Model: Goodness of Fit

Fit Statistics Based on Residuals	
Mean Squared Error	0.12072
Root Mean Squared Error	0.34745
Mean Absolute Percentage Error	2.65141
Maximum Percent Error	36.38991
R-Square	0.99850
Adjusted R-Square	0.99849
Random Walk R-Square	0.97281
Amemiya's Adjusted R-Square	0.99847
Number of non-missing residuals used for computing the fit statistics = 599	

A summary of the cycles in the model is given in [Output 34.2.4](#).

Output 34.2.4 Two-Cycle Model: Summary

Name	Type	period	Rho	ErrorVar
Cycle_1	Stationary	29.00036	1.00000	0.00000882
Cycle_2	Stationary	24.00011	1.00000	0.00000535

Note that the estimated periods are the same as in Bloomfield's model, the damping factors are nearly equal to 1.0, and the disturbance variances are very close to zero, implying persistent deterministic cycles. In fact, this model is identical to Bloomfield's model.

Example 34.3: Modeling Long Seasonal Patterns

This example illustrates some of the techniques you can use to model long seasonal patterns in a series. If the seasonal pattern is of moderate length and the underlying dynamics are simple, then it is easily modeled by using the basic settings of the SEASON statement and these additional techniques are not needed. However, if the seasonal pattern has a long season length and/or has a complex stochastic dynamics, then the techniques discussed here can be useful. You can obtain parsimonious models for a long seasonal pattern by using an appropriate subset of trigonometric harmonics, or by using a suitable spline function, or by using a block-season pattern in combination with a seasonal component of much smaller length. You can also vary the disturbance variances of the subcomponents that combine to form the seasonal component.

The time series used in this example consists of number of calls received per shift at a call center. Each shift is six hours long, and the first shift of the day begins at midnight, resulting in four shifts per day. The observations are available from December 15, 1999, to April 30, 2000. This series is seasonal with season length 28, which is moderate, and in fact there is no particular need to use pattern approximation techniques in this case. However, it is adequate for demonstration purposes. The plan of this example is as follows. First an initial model with a full seasonal component is created. This model is used as a baseline for comparing alternate models created by the techniques that are being illustrated. In practice any candidate model is first checked for adequacy by using various diagnostic procedures. In this illustration the main focus is on the different ways a long seasonal pattern can be modeled and no model diagnostics are done for the models being entertained. The alternate models are compared by using the sum of absolute prediction errors in the holdout region.

The following DATA step statements create the input data set used in this example.

```
data callCenter;
  input calls @@;
  label calls= "Number of Calls Received in a 6 Hour Shift";
  start = '15dec99:00:00'dt;
  datetime = INTNX( 'dthour6', start, _n_-1 );
  format datetime datetime10.;
datalines;
  18    122    244    128    19    113    230    119    17    112
  219    93    14    73    139    53    11    32    74    56
  15    137    289    153    20    125    227    106    16    101
  201    92    14    94    187    69    11    59    94    21
  ... more lines ...
```

Initial exploration of the series clearly indicates that the series does not show any significant trend, and time of day and day of the week have a significant influence on the number of calls received. These considerations suggest a simple random walk trend model along with a seasonal component of season length 28, the total number of shifts in a week. The following statements specify this model. Note the PRINT=HARMONICS option in the SEASON statement, which produces a table that lists the full set of harmonics contributing to the seasonal along with the significance of their contribution. This table will be useful later in choosing a subset trigonometric model. The BACK=28 and the LEAD=28 specifications in the FORECAST statement create a holdout region of 28 observations. The sum of absolute prediction errors (SAE) in this holdout region are used to compare the different models.

```

proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig
    print=(harmonics);
  estimate back=28;
  forecast back=28 lead=28;
run;

```

The forecasting performance of this model in the holdout region is shown in [Output 34.3.1](#). The sum of absolute prediction errors $SAE = 516.22$, which appears in the last row of the holdout analysis table.

Output 34.3.1 Predictions in the Holdout Region: Baseline Model

Now that a baseline model is created, the exploration for alternate models can begin. The review of the harmonic table in [Output 34.3.2](#) shows that all but the last three harmonics are significant, and deleting any of them to form a subset trigonometric seasonal component will lead to a poorer model. The last three harmonics, 12th, 13th and 14th, with periods of 2.333, 2.15 and 2.0, respectively, do appear to be possible

choices for deletion. Note that the disturbance variance of the seasonal component is not very insignificant (see [Output 34.3.3](#)); therefore the seasonal component is stochastic and the preceding logic, which is based on the final state estimate, provides only a rough guideline.

Output 34.3.2 Harmonic Analysis of the Season: Initial Model

The UCM Procedure						
Harmonic Analysis of Trigonometric Seasons (Based on the Final State)						
Name	Season Length	Harmonic	Period	Chi-Square	DF	Pr > ChiSq
Season	28	1	28.00000	234.19	2	<.0001
Season	28	2	14.00000	264.19	2	<.0001

Output 34.3.3 Parameter Estimates: Initial Model

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	92.14591	13.10986	7.03	<.0001
Level	Error Variance	44.83595	10.65465	4.21	<.0001
Season	Error Variance	0.01250	0.0065153	1.92	0.0551

The following statements fit a subset trigonometric model formed by dropping the last three harmonics by specifying the DROPH= option in the SEASON statement:

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig droph=12 13 14;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The last row of the holdout region prediction analysis table for the preceding model is shown in [Output 34.3.4](#). It shows that the subset trigonometric model has better prediction performance in the holdout region than the full trigonometric model, its SAE = 471.53 compared to the SAE = 516.22 for the full model.

Output 34.3.4 SAE for the Subset Trigonometric Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	40.836	20.164	471.534

The following statements illustrate a spline approximation to this seasonal component. In the spline specification the knot placement is quite important, and usually some experimentation is needed. In the following model the knots are placed at the beginning and the middle of each day. Note that the knots at the beginning and end of the season, 1 and 28 in this case, should not be listed in the knot list because knots are always placed there anyway.

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  splinesseason length=28
    knots=3 5 7 9 11 13 15 17 19 21 23 25 27
    degree=3;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The spline season model takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 34.3.5](#), which shows that the spline season model performs even better than the previous two models in the holdout region, its SAE = 313.79 compared to SAE = 471.53 for the previous model.

Output 34.3.5 SAE for the Spline Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	23.350	37.650	313.792

The following statements illustrate yet another way to approximate a long seasonal component. Here a combination of BLOCKSEASON and SEASON statements results in a seasonal component that is a sum of two seasonal patterns: one seasonal pattern is simply a regular season with season length 4 that captures the *within-day* seasonal pattern, and the other seasonal pattern is a block seasonal pattern that remains constant during the day but varies from day to day within a week. Note the use of NLOPTIONS statement to change the optimization technique during the parameter estimation to DBLDOG, which in this case performs better than the default technique, TRUREG.

```

proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=4 type=trig;
  blockseason nblocks=7 blocksize=4
    type=trig;
  estimate back=28;
  forecast back=28 lead=28;
  nloptions tech=dbldog;
run;

```

This model also takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 34.3.6](#), which shows that the block season model does slightly better than the baseline model but not as good as the other two models, its SAE = 508.52 compared to the SAE = 516.22 of the baseline model.

Output 34.3.6 SAE for the Block Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	39.339	21.661	508.522

This example showed a few different ways to model a long seasonal pattern. It showed that parsimonious models for long seasonal patterns can be useful, and in some cases even more effective than the full model. Moreover, for very long seasonal patterns the high memory requirements and long computing times might make full models impractical.

Example 34.4: Modeling Time-Varying Regression Effects

In April 1979 the Albuquerque Police Department began a special enforcement program aimed at reducing the number of DWI (driving while intoxicated) accidents. The program was administered by a squad of police officers, who used breath alcohol testing (BAT) devices and a van that houses a BAT device (Batmobile). These data were collected by the Division of Governmental Research of the University of New Mexico, under a contract with the National Highway Traffic Safety Administration of the U.S. Department of Transportation, to evaluate the Batmobile program. The first 29 observations are for a control period, and the next 23 observations are for the experimental (Batmobile) period. The data, freely available at <http://lib.stat.cmu.edu/DASL/Datafiles/batdat.html>, consist of two variables: ACC, which represents injuries and fatalities from Wednesday to Saturday nighttime accidents, and FUEL, which represents fuel consumption (millions of gallons) in Albuquerque. The variables are measured quarterly starting from the first quarter of 1972 up to the last quarter of 1984, covering the span of 13 years. The following DATA step statements create the input data set.

```

data bat;
  input ACC FUEL @@;
  batProgram = 0;
  if _n_ > 29 then batProgram = 1;
  date = INTNX( 'qtr', '1jan1972'd, _n_- 1 );
  format date qtr8.;
datalines;
192    32.592    238    37.250    232    40.032
246    35.852    185    38.226    274    38.711
266    43.139    196    40.434    170    35.898
234    37.111    272    38.944    234    37.717
210    37.861    280    42.524    246    43.965
248    41.976    269    42.918    326    49.789
342    48.454    257    45.056    280    49.385
290    42.524    356    51.224    295    48.562
279    48.167    330    51.362    354    54.646
331    53.398    291    50.584    377    51.320
327    50.810    301    46.272    269    48.664
314    48.122    318    47.483    288    44.732
242    46.143    268    44.129    327    46.258
253    48.230    215    46.459    263    50.686

286    51.717    323    51.824    306    49.380
230    47.961    304    46.039    311    55.683
292    52.263
;

```

There are a number of ways to study these data and the question of the effectiveness of the BAT program. One possibility is to study the *before-after* difference in the injuries and fatalities per million gallons of fuel consumed, by regressing ACC on the FUEL and the dummy variable BATPROGRAM, which is zero before the program began and one while the program is in place. However, it is possible that the effect of the Batmobiles might well be cumulative, because as awareness of the program becomes dispersed, its effectiveness as a deterrent to driving while intoxicated increases. This suggests that the regression coefficient of the BATPROGRAM variable might be *time varying*. The following program fits a model that incorporates these considerations. A seasonal component is included in the model since it is easy to see that the data show strong quarterly seasonality.

```

proc ucm data=bat;
  model acc = fuel;
  id date interval=qtr;
  irregular;
  level var=0 noest;
  randomreg batProgram / plot=smooth;
  season length=4 var=0 noest plot=smooth;
  estimate plot=(panel residual);
  forecast plot=forecasts lead=0;
run;

```

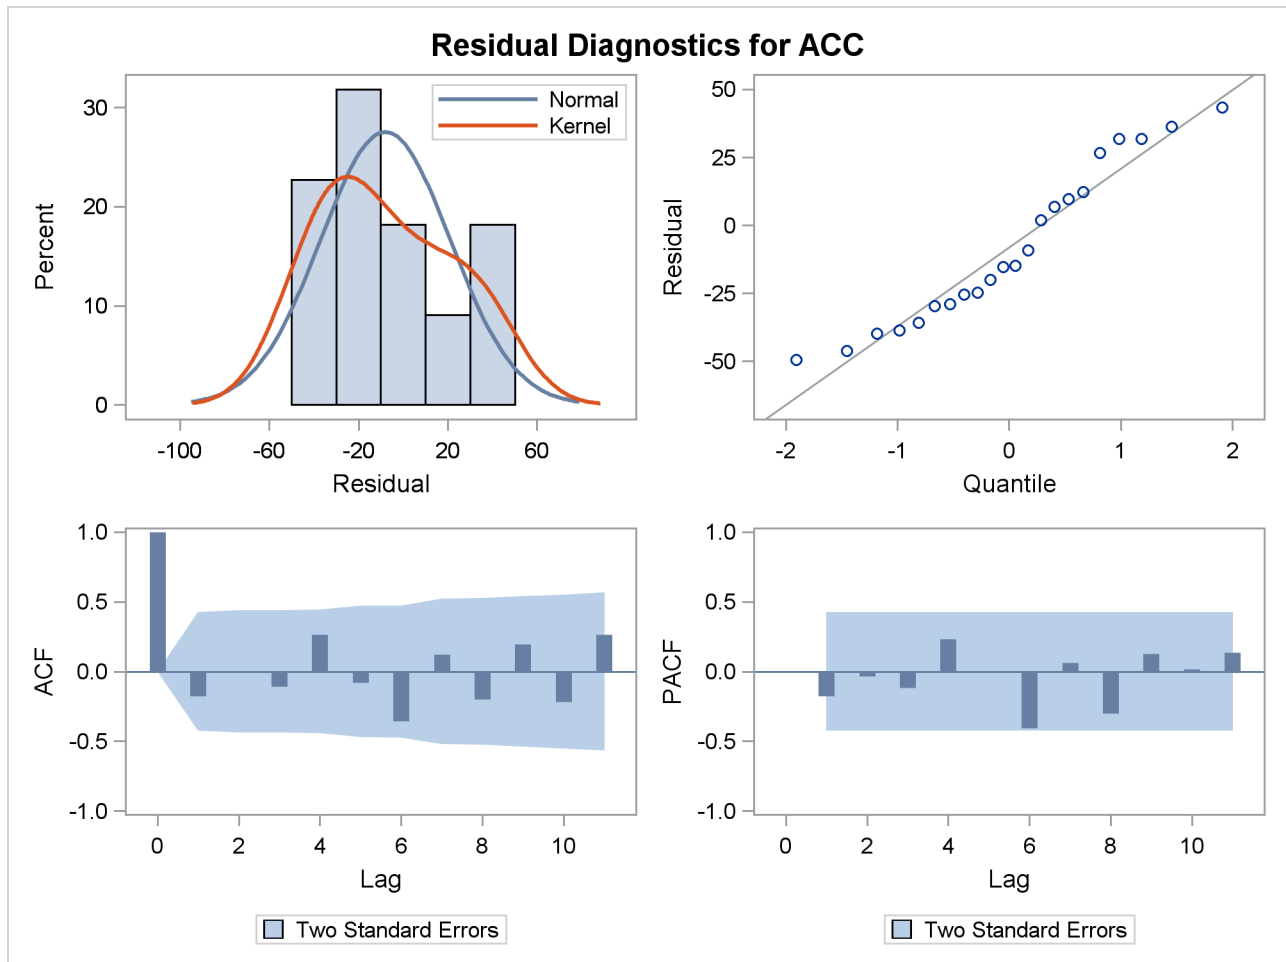

The model seems to fit the data adequately. No data are withheld for model validation because the series is relatively short. The plot of the time-varying coefficient of BATPROGRAM is shown in [Output 34.4.1](#). As expected, it shows that the effectiveness of the program increases as awareness of the program becomes dispersed. The effectiveness eventually seems to level off. The residual diagnostic plots are shown in [Output 34.4.2](#) and [Output 34.4.3](#), the forecast plot is in [Output 34.4.4](#), the goodness-of-fit statistics are in [Output 34.4.5](#), and the parameter estimates are in [Output 34.4.6](#).

Example 34.5: Trend Removal Using the Hodrick-Prescott Filter

Hodrick-Prescott filter (Hodrick and Prescott 1997) is a popular tool in macroeconomics for fitting smooth trend to time series. It is well known that the trend computation according to this filter is equivalent to fitting the local linear trend plus irregular model with the level disturbance variance restricted to zero and the slope disturbance variance restricted to be a suitable multiple of the irregular component variance. The multiple used depends on the frequency of the series; for example, for quarterly series the commonly recommended multiple is $1/1600 = 0.000625$. For other intervals there is no consensus, but a frequently suggested value for monthly series is $1/14400$ and the value for an annual series can range from $1/400 = 0.0025$ to $1/7 = 0.15$. The data set considered in this example consists of quarterly GNP values for the United States from 1960 to 1991. In the UCM procedure statements that follow, the presence of the **PROFILE** option in the **ESTIMATE** statement implies that the restriction that the disturbance variance of the slope component be fixed at 0.000625 is interpreted differently: it implies that the disturbance variance of the slope component be restricted to be 0.000625 *times* the estimated irregular component variance, as needed for the Hodrick-Prescott filter. The plot of the fitted trend is shown in [Output 34.5.1](#), and the plot of the smoothed irregular component, which corresponds to the detrended series, is given in [Output 34.5.2](#). The detrended series can be further analyzed for business cycles.

```
proc ucm data=sashelp.gnp;
  id date interval=qtr;
  model gnp;
  irregular plot=smooth;
  level var=0 noest plot=smooth;
  slope var=0.000625 noest;
  estimate PROFILE;
  forecast plot=(decomp);
run;
```

Output 34.5.1 Smoothed Trend for the GNP Series as per the Hodrick-Prescott Filter

Output 34.5.2 Detrended GNP Series**Example 34.6: Using Splines to Incorporate Nonlinear Effects**

The data in this example are created to mirror the electricity demand and temperature data recorded at a utility company in the midwest region of the United States. The data set (not shown), `utility`, has three variables: `load`, `temp`, and `date`. The `load` column contains the daily electricity demand, the `temp` column has the average daily temperature readings, and the `date` column records the observation date.

The following statements produce a plot, shown in [Output 34.6.1](#), of electricity load versus temperature. Clearly the relationship is smooth but nonlinear: the load generally increases when the temperatures are away from the comfortable sixties.

```
proc sgplot data=utility;
  loess x=temp y=load / smooth=0.4;
run;
```

Output 34.6.1 Load versus Temperature Plot

The time series plot of the load (not shown) also shows that, apart from a day-of-the-week seasonal effect, there are no additional easily identifiable patterns in the series. The series has no apparent upward or downward trend. The following statements fit a UCM to the series that takes into account these observations. The particular choice of the model is a result of a little modeling exercise that compared a small number of competing models. The chosen model is adequate but by no means the best possible. The temperature effect is modeled by a deterministic three-degree spline with knots at 30, 40, 50, 60, and 75. The knot locations and the degree were chosen by visual inspection of the plot (Output 34.6.1). An autoreg component is used in place of the simple irregular component, which improved the residual analysis. The last 60 days of data are withheld for out-of-sample forecast evaluation (note the BACK= option in both the ESTIMATE and FORECAST statements). The OUTLIER statement is used to increase the number of outliers reported to 10. Since no CHECKBREAK option is used in the LEVEL statement, only the additive outliers are searched. In this example the use of the EXTRADIFFUSE= option in the ESTIMATE and FORECAST statements is useful for discarding some early one-step-ahead forecasts and residuals with large variance.

```
proc ucm data=utility;
  id date interval=day;
  model load;
  autoreg;
  level plot=smooth;
```

```

splinereg temp knots=30 40 50 65 75 degree=3
      variance=0 noest;
season length=7 var=0 noest;
      estimate plot=panel back=60
      extradiffuse=50;
outlier maxnum=10;
forecast back=60 lead=60
      extradiffuse=50;
run;

```

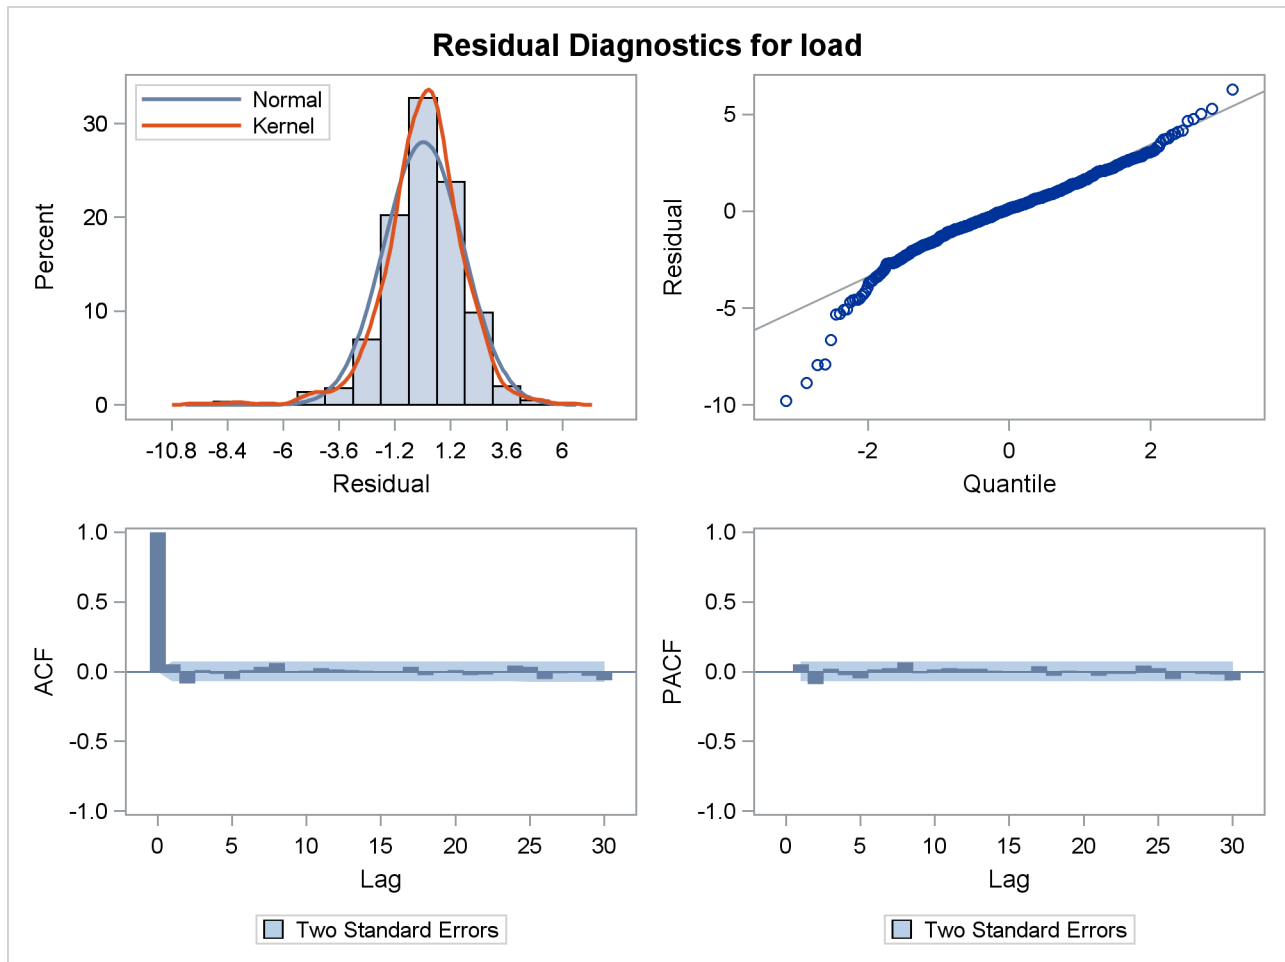

The parameter estimates are given in [Output 34.6.2](#), and the residual goodness-of-fit statistics are shown in [Output 34.6.3](#). The residual diagnostic plots are shown in [Output 34.6.4](#). The ACF and PACF plots appear satisfactory, but the normality plots, particularly the Q-Q plot, show possible violations. It appears that, at least in part, this nonNormal behavior of the residuals might be attributable to the outliers in the series. The outlier summary table, [Output 34.6.5](#), shows the most likely outlying observations. Notice that most of these outliers are holidays, like July 4th, when the electricity load is lower than usual for that day of the week.

Output 34.6.2 Electricity Load: Parameter Estimates

Output 34.6.6 Electricity Load: Forecast Evaluation of the Withheld Data

Example 34.7: Detection of Level Shift

The series in this example consists of the yearly water level readings of the Nile River recorded at Aswan, Egypt (Cobb 1978; de Jong and Penzer 1998). The readings are from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the water level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in [Output 34.7.1](#). The following DATA step statements create the input data set.

```
data nile;
  input waterlevel @@;
  year = intnx( 'year', '1jan1871'd, _n_-1 );
  format year year4.;
datalines;
1120 1160 963 1210 1160 1160 813 1230 1370 1140

;

proc timeseries data=nile plot=series;
  id year interval=year;
  var waterlevel;
run;

```

Output 34.7.1 Nile Water Level

In this situation it is known that a shift in the water level occurred within the span of the series, and its effect can be easily taken into account by including an appropriate indicator variable as a regressor. However, in many situation such prior information is not available, and it is useful to detect such a shift in a data analytic fashion. You can check for breaks in the level by using the [CHECKBREAK](#) option in the `LEVEL` statement. The following statements fit a simple locally constant level plus error model to the series:

```

proc ucm data=nile;
  id year interval=year;
  model waterlevel;
  irregular;
  level plot=smooth checkbreak;
  estimate;
  forecast plot=decomp;
run;

```

The plot in [Output 34.7.2](#) shows a noticeable drop in the smoothed water level around 1899.

Output 34.7.2 Smoothed Trend without the Shift of 1899

The “Outlier Summary” table in [Output 34.7.3](#) shows the most likely types of breaks and their locations within the series span. The shift of 1899 is easily detected.

Output 34.7.3 Detection of Structural Breaks in the Nile River Level

Outlier Summary					
Obs	year	Break Type	Estimate	Standard Error	Chi-Square
					DF Pr > ChiSq
29	1899	Level	-315.73791	97.639753	10.46
					1 0.0012

The following statements specify a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (SHIFT1899):

```
data nile;
  set nile;
  shift1899 = ( year >= '1jan1899'd );
run;

proc ucm data=nile;
  id year interval=year;
  model waterlevel = shift1899;
  irregular;
  level;
  estimate;
  forecast plot=decomp;
run;
```

The plot in [Output 34.7.4](#) shows the smoothed trend, including the correction due to the shift in the year 1899. Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

Output 34.7.4 Smoothed Trend plus Shift of 1899

Example 34.8: ARIMA Modeling

This example shows how you can use the UCM procedure for ARIMA modeling. The parameter estimates and predictions for ARIMA models obtained by using PROC UCM will be close to those obtained by using PROC ARIMA (in the presence of the ML option in its ESTIMATE statement) if the model is stationary or if the model is nonstationary and there are no missing values in the data. See Chapter 7, “[The ARIMA Procedure](#),” for additional details about the ARIMA procedure. However, if there are missing values in the data and the model is nonstationary, then the UCM and ARIMA procedures can produce significantly different parameter estimates and predictions. An article by Kohn and Ansley (1986) suggests a statistically sound method of estimation, prediction, and interpolation for nonstationary ARIMA models with missing data. This method is based on an algorithm that is equivalent to the Kalman filtering and smoothing algorithm used in the UCM procedure. The results of an illustrative example in their article are reproduced here using the UCM procedure. In this example an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model is applied to the logarithm of the air series in the `sashelp.air` data set. Four different missing value patterns are considered to highlight different aspects of the problem:

- *Data1*. The full data set of 144 observations.
- *Data2*. The set of 78 observations that omit January through November in each of the last 6 years.
- *Data3*. The data set with the 5 observations July 1949, June, July, and August 1957, and July 1960 missing.
- *Data4*. The data set with all July observations missing and June and August 1957 also missing.

The following DATA steps create these data sets:

```
data Data1;
    set sashelp.air;
    logair = log(air);
run;

data Data2;
    set data1;
    if year(date) >= 1955 and month(date) < 12 then logair = .;
run;

data Data3;
    set data1;
    if (year(date) = 1949 and month(date) = 7) then logair = .;
    if (year(date) = 1957 and
        (month(date) = 6 or month(date) = 7 or month(date) = 8))
        then logair = .;
    if (year(date) = 1960 and month(date) = 7) then logair = .;
run;

data Data4;
    set data1;
    if month(date) = 7 then logair = .;
    if year(date) = 1957 and (month(date) = 6 or month(date) = 8)
        then logair = .;
run;
```

The following statements specify the $ARIMA(0, 1, 1) \times (0, 1, 1)_{12}$ model for the logair series in the first data set (Data1):

```
proc ucm data=Data1;
  id date interval=month;
  model logair;
  irregular q=1 sq=1 s=12;
  deplag lags=(1)(12) phi=1 1 noest;
  estimate outest=est1;
  forecast outfor=for1;
run;
```

Note that the moving average part of the model is specified by using the Q=, SQ=, and S= options in the IRREGULAR statement and the differencing operator, $(1 - B)(1 - B^{12})$, is specified by using the DEPLAG statement. The model does not contain an intercept term; therefore no LEVEL statement is needed. The parameter estimates are saved in a data set EST1 by using the OUTEST= option in the ESTIMATE statement and the forecasts and the component estimates are saved in a data set FOR1 by using the OUTFOR= option in the FORECAST statement. The same analysis is performed on the other three data sets, but is not shown here.

Output 34.8.1 resembles Table 1 in Kohn and Ansley (1986). This table is generated by merging the parameter estimates from the four analyses. Only the moving average parameter estimates and their standard errors are reported. The columns EST1 and STD1 correspond to the estimates for Data1. The parameter estimates and their standard errors for other three data sets are similarly named. Note that the parameter estimates closely match the parameter estimates in the article. However, their standard errors differ slightly. This difference could be the result of different ways of computing the Hessian at the optimum. The white noise error variance estimates are not reported here, but they agree quite closely with those in the article.

Output 34.8.1 Data Sets 1–4: Parameter Estimates and Standard Errors

P A R A M E T E R	e s t i m a t e	s t a n d a r d	e s t i m a t e	s t a n d a r d	e s t i m a t e	s t a n d a r d	e s t i m a t e	s t a n d a r d
	1	1	2	2	3	3	4	4
MA_1	0.402	0.090	0.457	0.121	0.408	0.092	0.431	0.091
SMA_1	0.557	0.073	0.758	0.236	0.566	0.075	0.573	0.074

Output 34.8.2 resembles Table 2 in Kohn and Ansley (1986). It contains forecasts and their standard errors for the four data sets. The numbers are very close to those in the article.

Output 34.8.2 Data Sets 1–4: Forecasts and Standard Errors

DATE	for1	std1	for2	std2	for3	std3	for4	std4
JAN61	6.110	0.037	6.084	0.052	6.110	0.037	6.111	0.037

OCT61	6.209	0.075	6.174	0.087	6.209	0.076	6.209	0.074
NOV61	6.063	0.079	6.043	0.089	6.064	0.079	6.064	0.077
DEC61	6.168	0.082	6.174	0.086	6.168	0.082	6.169	0.080

Output 34.8.3 is based on Data2. It resembles Table 3 in Kohn and Ansley (1986). The columns S_SERIES and VS_SERIES in the **OUTFOR=** data set contain the interpolated values of logair and their variances. The estimate column in **Output 34.8.3** reports interpolated values (which are the same as S_SERIES), and the std column reports their standard errors (which are computed as square root of VS_SERIES) for January–November 1957. The actual logair values for these months, which are missing in Data2, are also provided for comparison. The numbers are very close to those in the article.

Output 34.8.3 Data Set 2: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JAN57	5.753	5.733	0.045
FEB57	5.707	5.738	0.049
MAR57	5.875	5.893	0.052
APR57	5.852	5.850	0.054
MAY57	5.872	5.843	0.055
JUN57	6.045	5.951	0.055
JUL57	6.142	6.051	0.055
AUG57	6.146	6.055	0.054
SEP57	6.001	5.938	0.052
OCT57	5.849	5.812	0.049
NOV57	5.720	5.680	0.045

Output 34.8.4 resembles Table 4 in Kohn and Ansley (1986). These numbers are based on Data3, and they also are very close to those in the article.

Output 34.8.4 Data Set 3: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUL49	4.997	5.013	0.031
JUN57	6.045	6.024	0.030
JUL57	6.142	6.147	0.031
AUG57	6.146	6.148	0.030
JUL60	6.433	6.409	0.031

Output 34.8.5 resembles Table 5 in Kohn and Ansley (1986). As before, the numbers are very close to those in the article.

Output 34.8.5 Data Set 4: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUN57	6.045	6.023	0.030
AUG57	6.146	6.147	0.030

The similarity between the outputs in this example and the results shown in Kohn and Ansley (1986) demonstrate that PROC UCM can be effectively used for nonstationary ARIMA models with missing data.

Overview: VARMAX Procedure

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts associated with vector autoregressive moving-average processes with exogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated to each other, they are also correlated to each other's past values. The VARMAX procedure can be used to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables). The VARMAX procedure enables you to model the dynamic relationship both between the dependent variables and also between the dependent and independent variables.

VARMAX models are defined in terms of the orders of the autoregressive or moving-average process (or both). When you use the VARMAX procedure, these orders can be specified by options or they can be automatically determined. Criteria for automatically determining these orders include the following:

- Akaike information criterion (AIC)
- corrected AIC (AICC)
- Hannan-Quinn (HQ) criterion
- final prediction error (FPE)
- Schwarz Bayesian criterion (SBC), also known as Bayesian information criterion (BIC)

If you do not want to use the automatic order selection, the VARMAX procedure provides autoregressive order identification aids:

- partial cross-correlations
- Yule-Walker estimates
- partial autoregressive coefficients
- partial canonical correlations

For situations where the stationarity of the time series is in question, the VARMAX procedure provides tests to aid in determining the presence of unit roots and cointegration. These tests include the following:

- Dickey-Fuller tests
- Johansen cointegration test for nonstationary vector processes of integrated order one
- Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
- Johansen cointegration test for nonstationary vector processes of integrated order two

For stationary vector times series (or nonstationary series made stationary by appropriate differencing), the VARMAX procedure provides for vector autoregressive and moving-average (VARMA) and Bayesian vector autoregressive (BVAR) models. To cope with the problem of high dimensionality in the parameters of the VAR model, the VARMAX procedure provides both vector error correction model (VECM) and Bayesian vector error correction model (BVECM). Bayesian models are used when prior information about the model parameters is available. The VARMAX procedure also allows independent (exogenous) variables with their distributed lags to influence dependent (endogenous) variables in various models such as VARMAX, BVARX, VECMX, and BVECMX models.

Forecasting is one of the main objectives of multivariate time series analysis. After successfully fitting the VARMAX, BVARX, VECMX, and BVECMX models, the VARMAX procedure computes predicted values based on the parameter estimates and the past values of the vector time series.

The model parameter estimation methods are the following:

- least squares (LS)
- maximum likelihood (ML)

The VARMAX procedure provides various hypothesis tests of long-run effects and adjustment coefficients by using the likelihood ratio test based on Johansen cointegration analysis. The VARMAX procedure offers the likelihood ratio test of the weak exogeneity for each variable.

After fitting the model parameters, the VARMAX procedure provides for model checks and residual analysis by using the following tests:

- Durbin-Watson (DW) statistics
- F test for autoregressive conditional heteroscedastic (ARCH) disturbance
- F test for AR disturbance
- Jarque-Bera normality test
- Portmanteau test

The VARMAX procedure supports several modeling features, including the following:

- seasonal deterministic terms
- subset models
- multiple regression with distributed lags
- dead-start model that does not have present values of the exogenous variables
- GARCH-type multivariate conditional heteroscedasticity models

The VARMAX procedure provides a Granger causality test to determine the Granger-causal relationships between two distinct groups of variables. It also provides the following:

- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle
- contemporaneous relationships among the components of the vector time series

Getting Started: VARMAX Procedure

This section outlines the use of the VARMAX procedure and gives five different examples of the kinds of models supported.

Vector Autoregressive Process

Let $y_t = (y_{1t}, \dots, y_{kt})'$, $t = 1, 2, \dots$, denote a k -dimensional time series vector of random variables of interest. The p th-order VAR process is written as

$$y_t = \delta + \Phi_1 y_{t-1} + \dots + \Phi_p y_{t-p} + \epsilon_t$$

where the ϵ_t is a vector white noise process with $\epsilon_t = (\epsilon_{1t}, \dots, \epsilon_{kt})'$ such that $E(\epsilon_t) = 0$, $E(\epsilon_t \epsilon_t') = \Sigma$, and $E(\epsilon_t \epsilon_s') = 0$ for $t \neq s$; $\delta = (\delta_1, \dots, \delta_k)'$ is a constant vector and Φ_i is a $k \times k$ matrix.

Analyzing and modeling the series jointly enables you to understand the dynamic relationships over time among the series and to improve the accuracy of forecasts for individual series by using the additional information available from the related series and their forecasts.

Example of Vector Autoregressive Model

Consider the first-order stationary bivariate vector autoregressive model

$$y_t = \begin{pmatrix} 1.2 & -0.5 \\ 0.6 & 0.3 \end{pmatrix} y_{t-1} + \epsilon_t, \quad \text{with } \Sigma = \begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 1.25 \end{pmatrix}$$

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  /* simulate the vector time series */
  call varmasim(y, phi) sigma = sig n = 100 seed = 34657;
  cn = {'y1' 'y2'};
  create simu11 from y[colname=cn];
  append from y;
quit;
```

The following statements plot the simulated vector time series y_t shown in [Figure 35.1](#):

```
data simu11;
  set simu11;
  date = intnx('year', '01jan1900'd, _n_-1);
  format date year4.;
run;

ods graphics on;
proc timeseries data=simu11 vectorplot=series;
  id date interval=year;
  var y1 y2;
run;
```

Figure 35.1 Plot of Generated Data Process

The following statements fit a VAR(1) model to the simulated data. First, you specify the input data set in the PROC VARMAX statement. Then, you use the MODEL statement to designate the dependent variables, y_1 and y_2 . To estimate a VAR model with mean zero, you specify the order of the autoregressive model with the P= option and the NOINT option. The MODEL statement fits the model to the data and prints parameter estimates and their significance. The PRINT=ESTIMATES option prints the matrix form of parameter estimates, and the PRINT=DIAGNOSE option prints various diagnostic tests. The LAGMAX=3 option is used to print the output for the residual diagnostic checks.

To output the forecasts to a data set, you specify the OUTPUT statement with the OUT= option. If you want to forecast five steps ahead, you use the LEAD=5 option. The ID statement specifies the yearly interval between observations and provides the Time column in the forecast output.

The VARMAX procedure output is shown in Figure 35.2 through Figure 35.10.

```

/*--- Vector Autoregressive Model ---*/

proc varmax data=simul1;
  id date interval=year;
  model y1 y2 / p=1 noint lagmax=3
              print=(estimates diagnose);
  output out=for lead=5;
run;

```

Figure 35.2 Descriptive Statistics

The VARMAX Procedure						
		Number of Observations		100		
		Number of Pairwise Missing		0		
Simple Summary Statistics						
Variable Type		N	Mean	Standard Deviation	Min	Max
y1	Dependent	100	-0.21653	2.78210	-4.75826	8.37032
y2	Dependent	100	0.16905	2.58184	-6.04718	9.58487

The VARMAX procedure first displays descriptive statistics. The Type column specifies that the variables are dependent variables. The column N stands for the number of nonmissing observations.

Figure 35.3 shows the type and the estimation method of the fitted model for the simulated data. It also shows the AR coefficient matrix in terms of lag 1, the parameter estimates, and their significance, which can indicate how well the model fits the data.

The second table schematically represents the parameter estimates and allows for easy verification of their significance in matrix form.

In the last table, the first column gives the left-hand-side variable of the equation; the second column is the parameter name ARl_i_j , which indicates the (i, j) th element of the lag l autoregressive coefficient; the last column is the regressor that corresponds to the displayed parameter.

Figure 35.3 Model Type and Parameter Estimates

The VARMAX Procedure						
Type of Model			VAR(1)			
Estimation Method			Least Squares Estimation			
AR						
Lag	Variable	y1	y2			
1	y1	1.15977	-0.51058			
	y2	0.54634	0.38499			
Schematic Representation						
Variable/ Lag		AR1				
y1		+-				
y2		++				
+ is > 2*std error, - is < -2*std error, . is between, * is N/A						
Model Parameter Estimates						
Equation Parameter		Estimate	Standard Error	t Value	Pr > t	Variable
y1	AR1_1_1	1.15977	0.05508	21.06	0.0001	y1(t-1)
	AR1_1_2	-0.51058	0.05898	-8.66	0.0001	y2(t-1)
y2	AR1_2_1	0.54634	0.05779	9.45	0.0001	y1(t-1)
	AR1_2_2	0.38499	0.06188	6.22	0.0001	y2(t-1)

The fitted VAR(1) model with estimated standard errors in parentheses is given as

$$y_t = \begin{pmatrix} 1.160 & -0.511 \\ (0.055) & (0.059) \\ 0.546 & 0.385 \\ (0.058) & (0.062) \end{pmatrix} y_{t-1} + \epsilon_t$$

Clearly, all parameter estimates in the coefficient matrix Φ_1 are significant.

The model can also be written as two univariate regression equations.

$$\begin{aligned}y_{1t} &= 1.160 y_{1,t-1} - 0.511 y_{2,t-1} + \epsilon_{1t} \\y_{2t} &= 0.546 y_{1,t-1} + 0.385 y_{2,t-1} + \epsilon_{2t}\end{aligned}$$

The table in [Figure 35.4](#) shows the innovation covariance matrix estimates and the various information criteria results. The smaller value of information criteria fits the data better when it is compared to other models. The variable names in the covariance matrix are printed for convenience; y_1 means the innovation for y_1 , and y_2 means the innovation for y_2 .

The VARMAX procedure provides diagnostic checks for the univariate form of the equations. The table in Figure 35.8 describes how well each univariate equation fits the data. From two univariate regression equations in Figure 35.3, the values of R^2 in the second column are 0.84 and 0.80 for each equation. The standard deviations in the third column are the square roots of the diagonal elements of the covariance matrix from Figure 35.4. The F statistics are in the fourth column for hypotheses to test $\phi_{11} = \phi_{12} = 0$ and $\phi_{21} = \phi_{22} = 0$, respectively, where ϕ_{ij} is the (i, j) th element of the matrix Φ_1 . The last column shows the p -values of the F statistics. The results show that each univariate model is significant.

Figure 35.8 Univariate Diagnostic Checks

Univariate Model ANOVA Diagnostics				
Variable	R-Square	Standard Deviation	F Value	Pr > F
y1	0.8351	1.13523	491.25	<.0001
y2	0.7906	1.19096	366.29	<.0001

The check for white noise residuals in terms of the univariate equation is shown in [Figure 35.9](#). This output contains information that indicates whether the residuals are correlated and heteroscedastic. In the first table, the second column contains the Durbin-Watson test statistics to test the null hypothesis that the residuals are uncorrelated. The third and fourth columns show the Jarque-Bera normality test statistics and their p -values to test the null hypothesis that the residuals have normality. The last two columns show F statistics and their p -values for ARCH(1) disturbances to test the null hypothesis that the residuals have equal covariances. The second table includes F statistics and their p -values for AR(1), AR(1,2), AR(1,2,3) and AR(1,2,3,4) models of residuals to test the null hypothesis that the residuals are uncorrelated.

Bayesian Vector Autoregressive Process

The Bayesian vector autoregressive (BVAR) model is used to avoid problems of collinearity and overparameterization that often occur with the use of VAR models. BVAR models do this by imposing priors on the AR parameters.

The following statements fit a BVAR(1) model to the simulated data. You specify the PRIOR= option with the hyperparameters. The LAMBDA=0.9 and THETA=0.1 options are hyperparameters controlling the prior covariance. Part of the VARMAX procedure output is shown in [Figure 35.11](#).

```

/*--- Bayesian Vector Autoregressive Process ---*/

proc varmax data=simul1;
  model y1 y2 / p=1 noint
           prior=(lambda=0.9 theta=0.1);
run;

```

The output in [Figure 35.11](#) shows that parameter estimates are slightly different from those in [Figure 35.3](#). By choosing the appropriate priors, you might be able to get more accurate forecasts by using a BVAR model rather than by using an unconstrained VAR model. See the section “[Bayesian VAR and VARX Modeling](#)” on page 2470 for details.

Vector Error Correction Model

A vector error correction model (VECM) can lead to a better understanding of the nature of any nonstationarity among the different component series and can also improve longer term forecasting over an unconstrained model.

The VECM(p) form with the cointegration rank $r(\leq k)$ is written as

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where Δ is the differencing operator, such that $\Delta \mathbf{y}_t = \mathbf{y}_t - \mathbf{y}_{t-1}$; $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$, where $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are $k \times r$ matrices; Φ_i^* is a $k \times k$ matrix.

It has an equivalent VAR(p) representation as described in the preceding section.

$$\mathbf{y}_t = \boldsymbol{\delta} + (I_k + \Pi + \Phi_1^*)\mathbf{y}_{t-1} + \sum_{i=2}^{p-1} (\Phi_i^* - \Phi_{i-1}^*)\mathbf{y}_{t-i} - \Phi_{p-1}^*\mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where I_k is a $k \times k$ identity matrix.

Example of Vector Error Correction Model

An example of the second-order nonstationary vector autoregressive model is

$$y_t = \begin{pmatrix} -0.2 & 0.1 \\ 0.5 & 0.2 \end{pmatrix} y_{t-1} + \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} y_{t-2} + \epsilon_t$$

with

$$\Sigma = \begin{pmatrix} 100 & 0 \\ 0 & 100 \end{pmatrix} \text{ and } y_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

This process can be given the following VECM(2) representation with the cointegration rank one:

$$\Delta y_t = \begin{pmatrix} -0.4 \\ 0.1 \end{pmatrix} (1, -2) y_{t-1} - \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \Delta y_{t-1} + \epsilon_t$$

The following PROC IML statements generate simulated data for the VECM(2) form specified above and plot the data as shown in [Figure 35.12](#):

```
proc iml;
  sig = 100*i(2);
  phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
  call varmasim(y,phi) sigma=sig n=100 initial=0
               seed=45876;

  cn = {'y1' 'y2'};
  create simul2 from y[colname=cn];
  append from y;
quit;

data simul2;
  set simul2;
  date = intnx( 'year', '01jan1900'd, _n_-1 );
  format date year4. ;
run;

proc timeseries data=simul2 vectorplot=series;
  id date interval=year;
  var y1 y2;
run;
```

Figure 35.12 Plot of Generated Data Process

Cointegration Testing

The following statements use the Johansen cointegration rank test. The COINTTEST=(JOHANSEN) option does the Johansen trace test and is equivalent to specifying COINTTEST with no additional options or the COINTTEST=(JOHANSEN=(TYPE=TRACE)) option.

```
/*--- Cointegration Test ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint dfctest cointtest=(johansen);
run;
```

Figure 35.13 shows the output for Dickey-Fuller tests for the nonstationarity of each series and Johansen cointegration rank test between series.

Figure 35.13 Dickey-Fuller Tests and Cointegration Rank Test

The VARMAX Procedure						
Unit Root Test						
Variable	Type	Rho	Pr < Rho	Tau	Pr < Tau	
y1	Zero Mean	1.47	0.9628	1.65	0.9755	
	Single Mean	-0.80	0.9016	-0.47	0.8916	
	Trend	-10.88	0.3573	-2.20	0.4815	
y2	Zero Mean	-0.05	0.6692	-0.03	0.6707	
	Single Mean	-6.03	0.3358	-1.72	0.4204	
	Trend	-50.49	0.0003	-4.92	0.0006	
Cointegration Rank Test Using Trace						
H0:	H1:	5%				
Rank=r	Rank>r	Eigenvalue	Trace	Critical Value	Drift in ECM	Drift in Process
0	0	0.5086	70.7279	12.21	NOINT	Constant
1	1	0.0111	1.0921	4.14		

In Dickey-Fuller tests, the second column specifies three types of models, which are zero mean, single mean, or trend. The third column (Rho) and the fifth column (Tau) are the test statistics for unit root testing. Other columns are their p -values. You can see that both series have unit roots. For a description of Dickey-Fuller tests, see the section “[PROBDF Function for Dickey-Fuller Tests](#)” on page 157 in Chapter 5, “[SAS Macros and Functions](#).”

In the cointegration rank test, the last two columns explain the drift in the model or process. Since the NOINT option is specified, the model is

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \Phi_1^* \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The column Drift In ECM means there is no separate drift in the error correction model, and the column Drift In Process means the process has a constant drift before differencing.

H0 is the null hypothesis, and H1 is the alternative hypothesis. The first row tests $r = 0$ against $r > 0$; the second row tests $r = 1$ against $r > 1$. The Trace test statistics in the fourth column are computed by $-T \sum_{i=r+1}^k \log(1 - \lambda_i)$ where T is the available number of observations and λ_i is the eigenvalue in the third column. By default, the critical values at 5% significance level are used for testing. You can compare the test statistics and critical values in each row. There is one cointegrated process in this example since the Trace statistic for testing $r = 0$ against $r > 0$ is greater than the critical value, but the Trace statistic for testing $r = 1$ against $r > 1$ is not greater than the critical value.

The following statements fit a VECM(2) form to the simulated data. From the result in [Figure 35.13](#), the time series are cointegrated with rank=1. You specify the ECM= option with the RANK=1 option. For normalizing the value of the cointegrated vector, you specify the normalized variable with the NORMALIZE= option. The PRINT=(IARR) option provides the VAR(2) representation. The VARMAX procedure output is shown in [Figure 35.14](#) through [Figure 35.16](#).

```

/*--- Vector Error-Correction Model ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint lagmax=3
           ecm=(rank=1 normalize=y1)
           print=(iarr estimates);
run;

```

The ECM= option produces the estimates of the long-run parameter, β , and the adjustment coefficient, α . In Figure 35.14, “1” indicates the first column of the α and β matrices. Since the cointegration rank is 1 in the bivariate system, α and β are two-dimensional vectors. The estimated cointegrating vector is $\hat{\beta} = (1, -1.96)'$. Therefore, the long-run relationship between y_{1t} and y_{2t} is $y_{1t} = 1.96y_{2t}$. The first element of $\hat{\beta}$ is 1 since y_1 is specified as the normalized variable.

Figure 35.14 Parameter Estimates for the VECM(2) Form

The VARMAX Procedure		
Type of Model	VECM(2)

y2	0.10667	

Figure 35.15 shows the parameter estimates in terms of lag one coefficients, y_{t-1} , and lag one first differenced coefficients, Δy_{t-1} , and their significance. “Alpha * Beta” indicates the coefficients of y_{t-1} and is obtained by multiplying the “Alpha” and “Beta” estimates in Figure 35.14. The parameter AR1_i_j corresponds to the elements in the “Alpha * Beta” matrix. The t values and p -values corresponding to the parameters AR1_i_j are missing since the parameters AR1_i_j have non-Gaussian distributions. The parameter AR2_i_j corresponds to the elements in the differenced lagged AR coefficient matrix. The “D_” prefixed to a variable name in Figure 35.15 implies differencing.

Figure 35.15 Parameter Estimates for the VECM(2) Form

D_y2	AR1_2_1	0.10667	0.05146			y1(t-1)
	AR1_2_2	-0.20862	0.10064			y2(t-1)
	AR2_2_1	0.40493	0.04867	8.32	0.0001	D_y1(t-1)
	AR2_2_2	-0.57157	0.05128	-11.15	0.0001	D_y2(t-1)

The fitted model is given as

$$\Delta \mathbf{y}_t = \begin{pmatrix} -0.467 & 0.913 \\ (0.048) & (0.094) \\ 0.107 & -0.209 \\ (0.051) & (0.100) \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} -0.743 & -0.746 \\ (0.045) & (0.048) \\ 0.405 & -0.572 \\ (0.049) & (0.051) \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

Figure 35.16 Change the VECM(2) Form to the VAR(2) Model

Infinite Order AR Representation				
Lag	Variable	y1	y2	
1	y1	-0.21013	0.16674	
	y2	0.51160	0.21980	
2	y1	0.74332	0.74621	
	y2	-0.40493	0.57157	
3	y1	0.00000	0.00000	
	y2	0.00000	0.00000	

The PRINT=(IARR) option in the previous SAS statements prints the reparameterized coefficient estimates. For the LAGMAX=3 in the SAS statements, the coefficient matrix of lag 3 is zero.

The VECM(2) form in Figure 35.16 can be rewritten as the following second-order vector autoregressive model:

$$y_t = \begin{pmatrix} -0.210 & 0.167 \\ 0.512 & 0.220 \end{pmatrix} y_{t-1} + \begin{pmatrix} 0.743 & 0.746 \\ -0.405 & 0.572 \end{pmatrix} y_{t-2} + \epsilon_t$$

Bayesian Vector Error Correction Model

Bayesian inference on a cointegrated system begins by using the priors of β obtained from the VECM(p) form. Bayesian vector error correction models can improve forecast accuracy for cointegrated processes.

The following statements fit a BVECM(2) form to the simulated data. You specify both the PRIOR= and ECM= options for the Bayesian vector error correction model. The VARMAX procedure output is shown in Figure 35.17.

```
/*--- Bayesian Vector Error-Correction Model ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint
    prior=( lambda=0.5 theta=0.2 )
    ecm=( rank=1 normalize=y1 )
    print=(estimates);
run;
```

Figure 35.17 shows the model type fitted to the data, the estimates of the adjustment coefficient (α), the parameter estimates in terms of lag one coefficients (y_{t-1}), and lag one first differenced coefficients (Δy_{t-1}).

Vector Autoregressive Process with Exogenous Variables

A VAR process can be affected by other observable variables that are determined outside the system of interest. Such variables are called exogenous (independent) variables. Exogenous variables can be stochastic or nonstochastic. The process can also be affected by the lags of exogenous variables. A model used to describe this process is called a VARX(p,s) model.

The VARX(p,s) model is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\mathbf{x}_t = (x_{1t}, \dots, x_{rt})'$ is an r -dimensional time series vector and Θ_i^* is a $k \times r$ matrix.

For example, a VARX(1,0) model is

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \Theta_0^* \mathbf{x}_t + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_t = (y_{1t}, y_{2t}, y_{3t})'$ and $\mathbf{x}_t = (x_{1t}, x_{2t})'$.

The following statements fit the VARX(1,0) model to the given data:

```
data grunfeld;
  input year y1 y2 y3 x1 x2 x3;
  label y1='Gross Investment GE'
        y2='Capital Stock Lagged GE'
        y3='Value of Outstanding Shares GE Lagged'

Figure 35.19 shows the parameter estimates for the constant, the lag zero coefficients of exogenous variables, and the lag one AR coefficients. From the schematic representation of parameter estimates, the significance of the parameter estimates can be easily verified. The symbol “C” means the constant and “XL0” means the lag zero coefficients of exogenous variables.

	AR1_3_3	0.93801	0.01821	51.50	0.0001	y3(t-1)

The fitted model is given as

$$\begin{pmatrix} y_{1t} \\ y_{2t} \\ y_{3t} \end{pmatrix} = \begin{pmatrix} -12.013 \\ (27.471) \\ 702.086 \\ (256.480) \\ -22.421 \\ (10.312) \end{pmatrix} + \begin{pmatrix} 1.693 & -0.009 \\ (0.544) & (0.054) \\ -6.099 & 2.580 \\ (5.078) & (0.501) \\ -0.023 & -0.013 \\ (0.204) & (0.020) \end{pmatrix} \begin{pmatrix} x_{1t} \\ x_{2t} \end{pmatrix} \\
 + \begin{pmatrix} 0.237 & 0.008 & 0.029 \\ (0.207) & (0.016) & (0.049) \\ -2.467 & 0.164 & -0.841 \\ (1.930) & (0.152) & (0.453) \\ 0.951 & 0.002 & 0.938 \\ (0.078) & (0.006) & (0.018) \end{pmatrix} \begin{pmatrix} y_{1,t-1} \\ y_{2,t-1} \\ y_{3,t-1} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \\ \epsilon_{3t} \end{pmatrix}$$

Parameter Estimation and Testing on Restrictions

In the previous example, the VARX(1,0) model is written as

$$y_t = \delta + \Theta_0^* x_t + \Phi_1 y_{t-1} + \epsilon_t$$

with

$$\Theta_0^* = \begin{pmatrix} \theta_{11}^* & \theta_{12}^* \\ \theta_{21}^* & \theta_{22}^* \\ \theta_{31}^* & \theta_{32}^* \end{pmatrix} \quad \Phi_1 = \begin{pmatrix} \phi_{11} & \phi_{12} & \phi_{13} \\ \phi_{21} & \phi_{22} & \phi_{23} \\ \phi_{31} & \phi_{32} & \phi_{33} \end{pmatrix}$$

In [Figure 35.20](#) of the preceding section, you can see several insignificant parameters. For example, the coefficients XL0_1_2, AR1_1_2, and AR1_3_2 are insignificant.

The following statements restrict the coefficients of $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model.

```
/*--- Models with Restrictions and Tests ---*/

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 print=(estimates);
  restrict XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;
```

The output in [Figure 35.21](#) shows that three parameters θ_{12}^* , ϕ_{12} , and ϕ_{32} are replaced by the restricted values, zeros. In the schematic representation of parameter estimates, the three restricted parameters θ_{12}^* , ϕ_{12} , and ϕ_{32} are replaced by *.

Figure 35.21 Parameter Estimation with Restrictions

y1	.	++	...	
y2	+	+.	..-	
y3	-	..	+++	
+ is > 2*std error, -				
is < -2*std error, .				
is between, * is N/A				

The output in Figure 35.22 shows the estimates of the Lagrangian parameters and their significance. Based on the p -values associated with the Lagrangian parameters, you cannot reject the null hypotheses $\theta_{12}^* = 0$, $\phi_{12} = 0$, and $\phi_{32} = 0$ with the 0.05 significance level.

Figure 35.22 RESTRICT Statement Results

Testing of the Restricted Parameters				
Parameter	Estimate	Standard Error	t Value	Pr > t
Restrict0	1.74969	21.44026	0.08	0.9389
Restrict1	30.36254	70.74347	0.43	0.6899
Restrict2	55.42191	164.03075	0.34	0.7524
Testing of the Restricted Parameters				
Parameter	Equation			
Restrict0	XL0_1_2 = 0			
Restrict1	AR1_1_2 = 0			
Restrict2	AR1_3_2 = 0			

The TEST statement in the following example tests $\phi_{31} = 0$ and $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model:

```
proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1;
  test AR(1,3,1)=0;
  test XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;
```

The output in Figure 35.23 shows that the first column in the output is the index corresponding to each TEST statement. You can reject the hypothesis test $\phi_{31} = 0$ at the 0.05 significance level, but you cannot reject the joint hypothesis test $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ at the 0.05 significance level.

Figure 35.23 TEST Statement Results

The VARMAX Procedure			
Testing of the Parameters			
Test	DF	Chi-Square	Pr > ChiSq
1	1	150.31	<.0001
2	3	0.34	0.9522

Causality Testing

The following statements use the CAUSAL statement to compute the Granger causality test for a VAR(1) model. For the Granger causality tests, the autoregressive order should be defined by the P= option in the MODEL statement. The variable groups are defined in the MODEL statement as well. Regardless of whether the variables specified in the GROUP1= and GROUP2= options are designated as dependent or exogenous (independent) variables in the MODEL statement, the CAUSAL statement fits the VAR(p) model by considering the variables in the two groups as dependent variables.

```
/*--- Causality Testing ---*/

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 noprint;
  causal group1=(x1) group2=(y1-y3);
  causal group1=(y3) group2=(y1 y2);
run;
```

The output in Figure 35.24 is associated with the CAUSAL statement. The first CAUSAL statement fits the VAR(1) model by using the variables y1, y2, y3, and x1. The second CAUSAL statement fits the VAR(1) model by using the variables y1, y3, and y2.

Figure 35.24 CAUSAL Statement Results

The VARMAX Procedure			
Granger-Causality Wald Test			
Test	DF	Chi-Square	Pr > ChiSq
1	3	2.40	0.4946
2	2	262.88	<.0001
Test 1: Group 1 Variables: x1			
Group 2 Variables: y1 y2 y3			
Test 2: Group 1 Variables: y3			
Group 2 Variables: y1 y2			

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2.

The first column in the output is the index corresponding to each CAUSAL statement. The output shows that you cannot reject that x1 is influenced by itself and not by (y1, y2, y3) at the 0.05 significance level for Test 1. You can reject that y3 is influenced by itself and not by (y1, y2) for Test 2. See the section “[VAR and VARX Modeling](#)” on page 2465 for details.

Functional Summary

The statements and options used with the VARMAX procedure are summarized in the following table:

Table 35.1 VARMAX Functional Summary

Description	Statement	Option
Data Set Options		
Specifies the input data set	VARMAX	DATA=
Writes parameter estimates to an output data set	VARMAX	OUTEST=
include covariances in the OUTEST= data set	VARMAX	OUTCOV
Writes the diagnostic checking tests for a model and the cointegration test results to an output data set	VARMAX	OUTSTAT=
Writes actuals, predictions, residuals, and confidence limits to an output data set	OUTPUT	OUT=
Writes the conditional covariance matrix to an output data set	GARCH	OUTHT=
BY Groups		
Specifies BY-group processing	BY	
ID Variable		
Specifies the identifying variable	ID	
Specifies the time interval between observations	ID	INTERVAL=
Controls the alignment of SAS date values	ID	ALIGN=
Options to Control the Optimization Process		
Specifies the optimization options	NOPTIONS	

Table 35.1 *continued*

Description	Statement	Option
Printing Control Options		
Specifies how many lags to print results	MODEL	LAGMAX=
Suppresses the printed output	MODEL	NOPRINT
Requests all printing options	MODEL	PRINTALL
Requests the printing format	MODEL	PRINTFORM=
Controls plots produced through ODS GRAPHICS	VARMAX	PLOTS=
PRINT= Option		
Prints the correlation matrix of parameter estimates	MODEL	CORRB
Prints the cross-correlation matrices of independent variables	MODEL	CORRX
Prints the cross-correlation matrices of dependent variables	MODEL	CORRY
Prints the covariance matrices of prediction errors	MODEL	COVPE
Prints the cross-covariance matrices of the independent variables	MODEL	COVX
Prints the cross-covariance matrices of the dependent variables	MODEL	COVY
Prints the covariance matrix of parameter estimates	MODEL	COVB
Prints the decomposition of the prediction error covariance matrix	MODEL	DECOMPOSE
Prints the residual diagnostics	MODEL	DIAGNOSE
Prints the contemporaneous relationships among the components of the vector time series	MODEL	DYNAMIC
Prints the parameter estimates	MODEL	ESTIMATES
Prints the infinite order AR representation	MODEL	IARR
Prints the impulse response function	MODEL	IMPULSE=
Prints the impulse response function in the transfer function	MODEL	IMPULSX=
Prints the partial autoregressive coefficient matrices	MODEL	PARCOEF
Prints the partial canonical correlation matrices	MODEL	PCANCORR
Prints the partial correlation matrices	MODEL	PCORR
Prints the eigenvalues of the companion matrix	MODEL	ROOTS
Prints the Yule-Walker estimates	MODEL	YW
Model Estimation and Order Selection Options		
Centers the dependent variables	MODEL	CENTER
Specifies the degrees of differencing for the specified model variables	MODEL	DIF=
Specifies the degrees of differencing for all independent variables	MODEL	DIFX=
Specifies the degrees of differencing for all dependent variables	MODEL	DIFY=
Specifies the vector error correction model	MODEL	ECM=
Specifies the estimation method	MODEL	METHOD=

Table 35.1 *continued*

Description	Statement	Option
Selects the tentative order	MODEL	MINIC=
Suppresses the current values of independent variables	MODEL	NOCURRENTX
Suppresses the intercept parameters	MODEL	NOINT
Specifies the number of seasonal periods	MODEL	NSEASON=
Specifies the order of autoregressive polynomial	MODEL	P=
Specifies the Bayesian prior model	MODEL	PRIOR=
Specifies the order of moving-average polynomial	MODEL	Q=
Centers the seasonal dummies	MODEL	SCENTER
Specifies the degree of time trend polynomial	MODEL	TREND=
Specifies the denominator for error covariance matrix estimates	MODEL	VARDEF=
Specifies the lag order of independent variables	MODEL	XLAG=
GARCH-Related Options		
Specifies how to calculate the constant (unconditional) correlation matrix in the CCC (DCC) GARCH model	GARCH	CORRCONSTANT=
Specifies the type of the multivariate GARCH model	GARCH	FORM=
Specifies the order of the GARCH polynomial	GARCH	P=
Specifies the order of the ARCH polynomial	GARCH	Q=
Specifies the type of the univariate GARCH model for each innovation in the CCC or DCC GARCH model	GARCH	SUBFORM=
Cointegration-Related Options		
Prints the results from the weak exogeneity test of the long-run parameters	COINTEG	EXOGENEITY
Specifies the restriction on the cointegrated coefficient matrix	COINTEG	H=
Specifies the restriction on the adjustment coefficient matrix	COINTEG	J=
Specifies the variable name whose cointegrating vectors are normalized	COINTEG	NORMALIZE=
Specifies a cointegration rank	COINTEG	RANK=
Prints the Johansen cointegration rank test	MODEL	COINTTEST= (JOHANSEN=)
Prints the Stock-Watson common trends test	MODEL	COINTTEST=(SW=)
Prints the Dickey-Fuller unit root test	MODEL	DFTEST=
Tests and Restrictions on Parameters		
Tests the Granger causality	CAUSAL	GROUP1= GROUP2=
Places and tests restrictions on parameter estimates	RESTRICT	
Tests hypotheses on parameter estimates	TEST	

Table 35.1 *continued*

Description	Statement	Option
Forecasting Control Options		
Specifies the size of confidence limits for forecasting	OUTPUT	ALPHA=
Starts forecasting before end of the input data	OUTPUT	BACK=
Specifies how many periods to forecast	OUTPUT	LEAD=
Suppresses the printed forecasts	OUTPUT	NOPRINT

PROC VARMAX Statement

PROC VARMAX *options* ;

The following options can be used in the PROC VARMAX statement:

DATA=SAS-data-set

specifies the input SAS data set. If the DATA= option is not specified, the PROC VARMAX statement uses the most recently created SAS data set.

OUTEST=SAS-data-set

writes the parameter estimates to the output data set.

COVOUT

OUTCOV

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

OUTSTAT=SAS-data-set

writes residual diagnostic results to an output data set. If the COINTTEST=(JOHANSEN) option is specified, the results of this option are also written to the output data set.

The following statements are the examples of these options in the PROC VARMAX statement:

```
proc varmax data=one outest=est outcov outstat=stat;
  model y1-y3 / p=1;
run;
```

```
proc varmax data=one outest=est outstat=stat;
  model y1-y3 / p=1 cointtest=(johansen);
run;
```

PLOTS< (*global-plot-option*) > = *plot-request-option* < (*options*) >

PLOTS< (*global-plot-option*) > = (*plot-request-option* < (*options*) > ... *plot-request-option* < (*options*) >)

controls the plots produced through ODS Graphics. When you specify only one plot, you can omit the parentheses around the plot request. Some examples follow:

```

plots=none
plots=all
plots(unpack)=residual(residual normal)
plots=(forecasts model)

```

For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

```

proc varmax data=one plots=impulse(simple);
    model y1-y3 / p=1;
run;

proc varmax data=one plots=(model residual);
    model y1-y3 / p=1;
run;

proc varmax data=one plots=forecasts;
    model y1-y3 / p=1;
    output lead=12;
run;

```

The first VARMAX program produces the simple response impulse plots. The second VARMAX program produces the plots associated with the model and prediction errors. The plots associated with prediction errors are the ACF, PACF, IACF, distribution, white-noise, and Normal quantile plots and the prediction error plot. The third VARMAX program produces the FORECASTS and FORECASTSONLY plots.

The *global-plot-option* applies to the impulse and prediction error analysis plots generated by the VARMAX procedure. The following *global-plot-option* is available:

UNPACK	displays each graph separately. (By default, some graphs can appear together in a single panel.)
--------	--

The following *plot-request-options* are available:

ALL	produces all plots appropriate for the particular analysis.
-----	---

FORECASTS <(forecasts-plot-options)>	produces plots of the forecasts. The forecasts-only plot that shows the multistep forecasts in the forecast region is produced by default. The following <i>forecasts-plot-options</i> are available:
--------------------------------------	---

ALL	produces the FORECASTSONLY and the FORECASTS plots. This is the default.
-----	--

FORECASTS	produces a plot that shows the one-step-ahead as well as the multistep forecasts.
-----------	---

FORECASTSONLY	produces a plot that shows only the multistep forecasts.
---------------	--

IMPULSE <(impulse-plot-options)>	produces the plots of impulse response function and the impulse response of the transfer function.
----------------------------------	--

	ALL	produces all impulse plots. This is the default.
	ACCUM	produces the accumulated impulse plot.
	ORTH	produces the orthogonalized impulse plot.
	SIMPLE	produces the simple impulse plot.
MODEL		produces plots of dependent variables listed in the MODEL statement and plots of the one-step-ahead predicted values for each dependent variables.
NONE		suppresses all plots.
RESIDUAL	<(residual-plot-options)> produces plots associated with the prediction errors obtained after modeling the data. The following <i>residual-plot-options</i> are available:	
	ALL	produces all plots associated with the analysis of the prediction errors. This is the default.
	RESIDUAL	produces prediction error plot.
	DIAGNOSTICS	produces a panel of plots useful in assessing the autocorrelations and white-noise of the prediction errors. The panel consists of the following: <ul style="list-style-type: none"> • the autocorrelation plot of the prediction errors • the partial autocorrelation plot of the prediction errors • the inverse autocorrelation plot of the prediction errors • the log scaled white noise plot of the prediction errors
	NORMAL	produces a panel of plots useful in assessing normality of the prediction errors. The panel consists of the following: <ul style="list-style-type: none"> • distribution of the prediction errors with overlaid the normal curve • normal quantile plot of the prediction errors

Other Options

In addition, any of the following MODEL statement options can be specified in the PROC VARMAX statement, which is equivalent to specifying the option for every MODEL statement: CENTER, DFTEST=, DIF=, DIFX=, DIFY=, LAGMAX=, METHOD=, MINIC=, NOCURRENTX, NOINT, NOPRINT, NSEASON=, P=, PRINT=, PRINTALL, PRINTFORM=, Q=, SCENTER, TREND=, VARDEF=, and XLAG= options.

The following is an example of the options in the PROC VARMAX statement:

```
proc varmax data=one lagmax=3 method=ml;
  model y1-y3 / p=1;
run;
```

BOUND Statement

BOUND *restriction, . . . , restriction ;*

The BOUND statement sets up linear bounds for parameters when the maximum likelihood method is applied to the estimation of VARMAX or VARMAX-GARCH models. Only one BOUND statement is allowed. If you specify more than one *restriction*, separate them with commas. The *restrictions* are specified in the same manner as the *restrictions* in the RESTRICT statement. For information about how to define restrictions by using matrix expressions, operators, and functions, see the section “[RESTRICT Statement](#)” on page 2425. Both equality and inequality constraints are allowed in the BOUND statement, although in general, the equality constraints are specified in the RESTRICT statement, and the inequality constraints are specified in the BOUND statement.

To use the BOUND statement, you need to know the form of the model. If you do not specify the P=, Q=, or XLAG= option or the GARCH statement, then the BOUND statement is not applicable. If you specify the PRIOR=, ECM=, or METHOD=LS option or the COINTEG statement, the BOUND statement is ignored. Nonlinear restrictions on parameters are not supported.

The following is an example of the BOUND statement for a bivariate ($k=2$) zero-mean VARMA(1,1) model, which is by default estimated by maximum likelihood method because the MA term is present:

```
proc varmax data=one;
  model y1 y2 / noint p=1 q=1;
  bound -1<=AR<=1, 0<MA;
run;
```

This BOUND statement specifies that all AR parameters must be between -1 and 1 and that all MA parameters must be positive.

You can use the BOUND statement together with the RESTRICT statement, as in the following bivariate ($k=2$) zero-mean VARMA(1,1) model:

```
proc varmax data=one;
  model y1 y2 / noint p=1 q=1;
  bound AR+MA>=0.001;
  restrict AR(1,1,2) = 0.5;
run;
```

BY Statement

BY *variables ;*

A BY statement can be used with PROC VARMAX to obtain separate analyses on observations in groups defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARMAX procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information about the BY statement, see in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

The following is an example of the BY statement:

```
proc varmax data=one;
  by region;
  model y1-y3 / p=1;
run;
```

CAUSAL Statement

CAUSAL GROUP1=(variables) GROUP2=(variables) ;

A CAUSAL statement prints the Granger causality test by fitting the VAR(p) model by using all variables defined in GROUP1 and GROUP2. Any number of CAUSAL statements can be specified. The CAUSAL statement proceeds with the MODEL statement and uses the variables and the autoregressive order, p , specified in the MODEL statement. Variables in the GROUP1= and GROUP2= options should be defined in the MODEL statement. If the P=0 option is specified in the MODEL statement, the CAUSAL statement is not applicable.

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2. If the hypothesis fails to reject the null, then the variables listed in GROUP1 might be considered as independent variables.

See the section “[VAR and VARX Modeling](#)” on page 2465 for details.

The following is an example of the CAUSAL statement. You specify the CAUSAL statement with the GROUP1= and GROUP2= options.

```
proc varmax data=one;
  model y1-y3 = x1 / p=1;
  causal group1=(x1) group2=(y1-y3);
  causal group1=(y2) group2=(y1 y3);
run;
```

The first CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_2 , y_3 , and x_1 and tests the null hypothesis that x_1 causes the other variables, y_1 , y_2 , and y_3 , but the other variables do not cause x_1 . The second CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_3 , and y_2 and tests the null hypothesis that y_2 causes the other variables, y_1 and y_3 , but the other variables do not cause y_2 .

COINTEG Statement

COINTEG **RANK=number** **<H=(matrix)>** **<J=(matrix)>**
<EXOGENEITY> **<NORMALIZE=variable>** ;

The COINTEG statement fits the vector error correction model to the data, tests the restrictions of the long-run parameters and the adjustment parameters, and tests for the weak exogeneity in the long-run parameters. The cointegrated system uses the maximum likelihood analysis proposed by Johansen and Juselius (1990); Johansen (1995a, b). Only one COINTEG statement is allowed.

You specify the ECM= option in the MODEL statement or the COINTEG statement to fit the VECM(p). The P= option in the MODEL statement is used to specify the autoregressive order of the VECM.

The following statements are equivalent for fitting a VECM(2).

```
proc varmax data=one;
  model y1-y3 / p=2 ecm=(rank=1);
run;
```

```
proc varmax data=one;
  model y1-y3 / p=2;
  cointeg rank=1;
run;
```

To test restrictions of either α or β or both, you specify either J= or H= or both, respectively. You specify the EXOGENEITY option in the COINTEG statement for tests of the weak exogeneity in the long-run parameters.

The following is an example of the COINTEG statement.

```
proc varmax data=one;
  model y1-y3 / p=2;
  cointeg rank=1 h=(1 0, -1 0, 0 1)
              j=(1 0, 0 0, 0 1) exogeneity;
run;
```

The following options can be used in the COINTEG statement:

EXOGENEITY

formulates the likelihood ratio tests for testing weak exogeneity in the long-run parameters. The null hypothesis is that one variable is weakly exogenous for the others.

H=(matrix)

specifies the restrictions H on the $k \times r$ or $(k + 1) \times r$ cointegrated coefficient matrix β such that $\beta = H\phi$, where H is known and ϕ is unknown. If the VECM(p) is specified with the COINTEG statement or with the ECM= option in the MODEL statement and the ECTREND option is not included with the ECM= specification, then the H matrix has dimension $k \times m$. If the VECM(p) is specified with the COINTEG statement or with the ECM= option in the MODEL statement and the ECTREND option is also used, then the H matrix has dimension $(k + 1) \times m$. Here k is the number of dependent variables, and m is $r \leq m < k$ where r is defined with the RANK= r option.

For example, consider a system that contains four variables and the RANK=1 option with $\beta = (\beta_1, \beta_2, \beta_3, \beta_4)'$. The restriction matrix for the test of $\beta_1 + \beta_2 = 0$ can be specified as

```
cointeg rank=1 h=(1 0 0, -1 0 0, 0 1 0, 0 0 1);
```

Here the matrix H is 4×3 where $k = 4$ and $m = 3$, and each row of the matrix H is separated by commas.

When the series has no separate deterministic trend, the constant term should be restricted by $\alpha'_1 \delta = 0$. In the preceding example, the β can be either $\beta = (\beta_1, \beta_2, \beta_3, \beta_4, 1)'$ or $\beta = (\beta_1, \beta_2, \beta_3, \beta_4, t)'$. You can specify the restriction matrix for the previous test of $\beta_1 + \beta_2 = 0$ as follows:

```
cointeg rank=1
h=(1 0 0 0, -1 0 0 0, 0 1 0 0, 0 0 1 0, 0 0 0 1);
```

When the cointegrated system contains three dependent variables and the RANK=2 option, you can specify the restriction matrix for the test of $\beta_{1j} = -\beta_{2j}$ for $j = 1, 2$ as follows:

```
cointeg rank=2 h=(1 0, -1 0, 0 1);
```

J=(matrix)

specifies the restrictions J on the $k \times r$ adjustment matrix α such that $\alpha = J\psi$, where J is known and ψ is unknown. The $k \times m$ matrix J is specified by using this option, where k is the number of dependent variables, m is $r \leq m < k$, and r is defined with the RANK= r option.

For example, when the system contains four variables and the RANK=1 option is used, you can specify the restriction matrix for the test of $\alpha_j = 0$ for $j = 2, 3, 4$ as follows:

```
cointeg rank=1 j=(1, 0, 0, 0);
```

When the system contains three variables and the RANK=2 option, you can specify the restriction matrix for the test of $\alpha_{2j} = 0$ for $j = 1, 2$ as follows:

```
cointeg rank=2 j=(1 0, 0 0, 0 1);
```

NORMALIZE=variable

specifies a single dependent (endogenous) variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTTEST=(JOHANSEN=) or ECM= option in the MODEL statement, the variable name specified in the COINTEG statement is used. If the normalized variable is not specified, cointegrating vectors are not normalized.

RANK=number

specifies the cointegration rank of the cointegrated system. This option is required in the COINTEG statement. The rank of cointegration should be greater than zero and less than the number of dependent (endogenous) variables. If the value of the RANK= option in the COINTEG statement is different from that specified in the ECM= option, the rank specified in the COINTEG statement is used.

GARCH Statement

GARCH *options* ;

The GARCH statement specifies a GARCH-type multivariate conditional heteroscedasticity model.

You can specify the following options:

CORRCONSTANT=ESTIMATE | EXPECT

specifies how to calculate the constant (unconditional) correlation matrix in the CCC (DCC) GARCH model. If you specify CORRCONSTANT=EXPECT, the constant conditional correlation matrix in the CCC GARCH model or the unconditional correlation matrix in the DCC GARCH model is calculated through the standardized residuals, given the other parameters. After parameter estimates are output, the constant (unconditional) correlation matrix for the CCC (DCC) GARCH model is output in the ODS table CCCCorrConstant (DCCCorrConstant). If you specify CORRCONSTANT=ESTIMATE, the correlation matrix is estimated like all other parameters in the model. By default, CORRCONSTANT=ESTIMATE.

FORM=value

specifies the representation for a GARCH model. Valid values are as follows:

- BEKK specifies a BEKK representation. This is the default.
- CCC specifies a constant conditional correlation representation.
- DCC specifies a dynamic conditional correlation representation.

OUTHT=SAS-data-set

writes the conditional covariance matrix to an output data set.

P=number

P=(number-list)

specifies the order of the process or the subset of GARCH terms to be fitted. For example, you can specify the P=(1,3) option. The P=3 option is equivalent to the P=(1,2,3) option. By default, P=0.

Q=number

Q=(number-list)

specifies the order of the process or the subset of ARCH terms to be fitted. This option is required in the GARCH statement. For example, you can specify the Q=(2) option. The Q=2 option is equivalent to the Q=(1,2) option.

SUBFORM=value

specifies the type of the univariate GARCH model for each innovation in the CCC or DCC GARCH model. The values of the SUBFORM= option are as follows:

- EGARCH specifies the exponential GARCH, or EGARCH, model.
- GARCH specifies the GARCH model with no constraints.
- GJR | TGARCH specifies the GJR GARCH (also called threshold GARCH, or TGARCH) model.
- PGARCH specifies the power GARCH, or PGARCH, model.

QGARCH specifies the quadratic GARCH, or QGARCH, model.

By default, SUBFORM=GARCH.

For the VAR(1)–ARCH(1) model,

```
model y1 y2 / p=1;
garch q=1 form=bekk;
```

For the multivariate GARCH(1,1) model,

```
model y1 y2;
garch q=1 p=1 form=ccc;
```

Other multivariate GARCH-type models are

```
model y1 y2 = x1 / xlag=1;
garch q=1;
```

```
model y1 y2 / q=1;
garch q=1 p=1;
```

For more information, see the section “[Multivariate GARCH Modeling](#)” on page 2504.

ID Statement

ID *variable* **INTERVAL=***value* < **ALIGN=***value* > ;

The ID statement specifies a variable that identifies observations in the input data set. The datetime variable specified in the ID statement is included in the OUT= data set if the OUTPUT statement is specified. The ID *variable* is usually a SAS datetime variable. The values of the ID variable are extrapolated for the forecast observations based on the value of the INTERVAL= option.

ALIGN= *value*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL= *value*

specifies the time interval between observations. This option is required in the ID statement. The INTERVAL= option is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data when the OUTPUT statement is specified.

The following is an example of the ID statement:

```
proc varmax data=one;
  id date interval=qtr align=mid;
  model y1-y3 / p=1;
run;
```

INITIAL Statement

INITIAL *equation, . . . , equation ;*

The INITIAL statement sets up the initial parameter values for nonlinear optimization when the maximum likelihood method is applied to the estimation of VARMAX or VARMAX-GARCH models. Only one INITIAL statement is allowed. If you specify more than one *equation*, separate them with commas. The initial parameter values are the solution of the specified linear equations. The *equations* are specified in the same manner as the *restrictions* in the RESTRICT statement. For information about how to define equations by using matrix expressions, operators, and functions, see the section “RESTRICT Statement” on page 2425.

To use the INITIAL statement, you need to know the form of the model. If you do not specify the P=, Q=, or XLAG= option or the GARCH statement, then the INITIAL statement is not applicable. If you specify the PRIOR=, ECM=, or METHOD=LS option or the COINTEG statement, the INITIAL statement is ignored. Nonlinear equations on parameters are not supported.

The following is an example of the INITIAL statement for a bivariate ($k=2$) zero-mean VARMA(1,1) model, which is by default estimated by maximum likelihood method because the MA term is present:

```
proc varmax data=one;
  model y1 y2 / noint p=1 q=1;
  initial AR = 0, MA = 0,
          COV={1 0.5, 0.5 4};
run;
```

Like the RESTRICT statement, the preceding INITIAL statement can be abbreviated as follows:

```
initial AR = MA = 0,
        COV={1 0.5, 0.5 4};
```

or

```
initial AR, MA, COV={1 0.5, 0.5 4};
```

MODEL Statement

MODEL *dependents < = regressors >*
 < , dependents < = regressors > ... >
 < / options > ;

The MODEL statement specifies dependent (endogenous) variables and independent (exogenous) variables for the VARMAX model. The multivariate model can have the same or different independent variables corresponding to the dependent variables. As a special case, the VARMAX procedure allows you to analyze one dependent variable. Only one MODEL statement is allowed.

For example, the following statements are equivalent ways of specifying the multivariate model for the vector (y_1, y_2, y_3) :

```
model y1 y2 y3 </options>;
model y1-y3 </options>;
```

The following statements are equivalent ways of specifying the multivariate model with independent variables, where y_1, y_2, y_3 , and y_4 are the dependent variables and x_1, x_2, x_3, x_4 , and x_5 are the independent variables:

```
model y1 y2 y3 y4 = x1 x2 x3 x4 x5 </options>;
model y1 y2 y3 y4 = x1-x5 </options>;
model y1 = x1-x5, y2 = x1-x5, y3 y4 = x1-x5 </options>;
model y1-y4 = x1-x5 </options>;
```

When the multivariate model has different independent variables that correspond to each of the dependent variables, equations are separated by commas (,) and the model can be specified as illustrated by the following MODEL statement:

```
model y1 = x1-x3, y2 = x3-x5, y3 y4 = x1-x5 </options>;
```

The following options can be used in the MODEL statement after a forward slash (/):

CENTER

centers the dependent (endogenous) variables by subtracting their means. Note that centering is done after differencing when the DIF= or DIFY= option is specified. If there are exogenous (independent) variables, this option is not applicable.

```
model y1 y2 / p=1 center;
```

DIF(*variable (number-list) <... variable (number-list)>*)

DIFY(*variable (number-list) <... variable (number-list)>*)

specifies the degrees of differencing to be applied to the specified dependent or independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. The differencing can be the same for all variables, or it can vary among variables. For example, the DIF=($y_1(1,4)$ $y_3(1)$ $x_2(2)$) option specifies that the series y_1 is differenced at lag 1 and at lag 4, which is

$$(1 - B^4)(1 - B)y_{1t} = (y_{1t} - y_{1,t-1}) - (y_{1,t-4} - y_{1,t-5})$$

the series y_3 is differenced at lag 1, which is $(y_{3t} - y_{3,t-1})$; and the series x_2 is differenced at lag 2, which is $(x_{2t} - x_{2,t-2})$.

The following uses the data dy_1 , y_2 , x_1 , and dx_2 , where $dy_1 = (1 - B)y_{1t}$ and $dx_2 = (1 - B)^2x_{2t}$.

```
model y1 y2 = x1 x2 / p=1 dif=(y1(1) x2(2));
```

DIFX(*number-list*)**DIFX=**(*number-list*)

specifies the degrees of differencing to be applied to all independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For example, the DIFX=(1) option specifies that all of the independent series are differenced once at lag 1. The DIFX=(1,4) option specifies that all of the independent series are differenced at lag 1 and at lag 4. If independent variables are specified in the DIF= option, then the DIFX= option is ignored.

The following statement uses the data y_1 , y_2 , dx_1 , and dx_2 , where $dx_1 = (1 - B)x_{1t}$ and $dx_2 = (1 - B)x_{2t}$.

```
model y1 y2 = x1 x2 / p=1 difx(1);
```

DIFY(*number-list*)**DIFY=**(*number-list*)

specifies the degrees of differencing to be applied to all dependent (endogenous) variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For details, see the DIFX= option. If dependent variables are specified in the DIF= option, then the DIFY= option is ignored.

```
model y1 y2 / p=1 dify(1);
```

METHOD=*value*

requests the type of estimates to be computed. The possible values of the METHOD= option are as follows:

LS	specifies least squares estimates.
ML	specifies maximum likelihood estimates.

When the ECM=, PRIOR=, and Q= options and the GARCH statement are specified, the default ML method is used regardless of the method given by the METHOD= option.

```
model y1 y2 / p=1 method=ml;
```

NOCURRENTX

suppresses the current values x_t of the independent variables. In general, the VARX(p, s) model is

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where p is the number of lags of the dependent variables included in the model, and s is the number of lags of the independent variables included in the model, including the contemporaneous values of x_t .

A VARX(1,2) model can be specified as:

```
model y1 y2 = x1 x2 / p=1 xlag=2;
```

If the NOCURRENTX option is specified, it suppresses the current values \mathbf{x}_t and starts with \mathbf{x}_{t-1} . The VARX(p, s) model is redefined as:

$$\mathbf{y}_t = \delta + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=1}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

This model with $p = 1$ and $s = 2$ can be specified as:

```
model y1 y2 = x1 x2 / p=1 xlag=2 nocurrentx;
```

NOINT

suppresses the intercept parameter δ .

```
model y1 y2 / p=1 noint;
```

NSEASON=*number*

specifies the number of seasonal periods. When the NSEASON=*number* option is specified, (*number* – 1) seasonal dummies are added to the regressors. If the NOINT option is specified, the NSEASON= option is not applicable.

```
model y1 y2 / p=1 nseason=4;
```

SCENTER

centers seasonal dummies specified by the NSEASON= option. The centered seasonal dummies are generated by $c - (1/s)$, where c is a seasonal dummy generated by the NSEASON= s option.

```
model y1 y2 / p=1 nseason=4 scenter;
```

TREND=*value*

specifies the degree of deterministic time trend included in the model. Valid values are as follows:

LINEAR	includes a linear time trend as a regressor.
QUAD	includes linear and quadratic time trends as regressors.

The TREND=QUAD option is not applicable for a cointegration analysis.

```
model y1 y2 / p=1 trend=linear;
```

VARDEF=*value*

corrects for the degrees of freedom of the denominator for computing an error covariance matrix for the METHOD=LS option. If the METHOD=ML option is specified, the VARDEF=N option is always used. Valid values are as follows:

DF	specifies that the number of nonmissing observation minus the number of regressors be used.
N	specifies that the number of nonmissing observation be used.

```
model y1 y2 / p=1 vardef=n;
```

Printing Control Options

LAGMAX=*number*

specifies the maximum number of lags for which results are computed and displayed by the PRINT=(CORRX CORRY COVX COVY IARR IMPULSE= IMPULSX= PARCOEF PCANCORR PCORR) options. This option is also used to limit the printed results for the cross covariances and cross-correlations of residuals. The default is LAGMAX=min(12, $T-2$), where T is the number of nonmissing observations.

```
model y1 y2 / p=1 lagmax=6;
```

NOPRINT

suppresses all printed output.

```
model y1 y2 / p=1 noprint;
```

PRINTALL

requests all printing control options. The options set by the option PRINTALL are DFTEST=, MINIC=, PRINTFORM=BOTH, and PRINT=(CORRB CORRX CORRY COVB COVPE COVX COVY DECOMPOSE DYNAMIC IARR IMPULSE=(ALL) IMPULSX=(ALL) PARCOEF PCANCORR PCORR ROOTS YW).

You can also specify this option as the option ALL.

```
model y1 y2 / p=1 printall;
```

PRINTFORM=*value*

requests the printing format of the output generated by the PRINT= option and cross covariances and cross-correlations of residuals. Valid values are as follows:

BOTH	prints output in both MATRIX and UNIVARIATE forms.
MATRIX	prints output in matrix form. This is the default.
UNIVARIATE	prints output by variables.

```
model y1 y2 / p=1 print=(impulse) printform=univariate;
```

Printing Options

PRINT=(*options*)

The following options can be used in the PRINT=() option. The options are listed within parentheses. If a number in parentheses follows an option listed below, then the option prints the number of lags specified by *number* in parentheses. The default is the number of lags specified by the LAGMAX=*number* option.

CORRB

prints the estimated correlations of the parameter estimates.

CORRX**CORRX(*number*)**

prints the cross-correlation matrices of exogenous (independent) variables. The *number* should be greater than zero.

CORRY**CORRY(*number*)**

prints the cross-correlation matrices of dependent (endogenous) variables. The *number* should be greater than zero.

COVB

prints the estimated covariances of the parameter estimates.

COVPE**COVPE(*number*)**

prints the covariance matrices of *number*-ahead prediction errors for the VARMAX(*p,q,s*) model. The *number* should be greater than zero. If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the section “[Forecasting](#)” on page 2454 for details.

COVX**COVX(*number*)**

prints the cross-covariance matrices of exogenous (independent) variables. The *number* should be greater than zero.

COVY**COVY(*number*)**

prints the cross-covariance matrices of dependent (endogenous) variables. The *number* should be greater than zero.

DECOMPOSE**DECOMPOSE(*number*)**

prints the decomposition of the prediction error covariances using up to the number of lags specified by *number* in parentheses for the VARMA(*p,q*) model. The *number* should be greater than zero. It can be interpreted as the contribution of innovations in one variable to the mean squared error of the multistep forecast of another variable. The DECOMPOSE option also prints proportions of the forecast error variance.

If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the section “[Forecasting](#)” on page 2454 for details.

DIAGNOSE

prints the residual diagnostics and model diagnostics.

DYNAMIC

prints the contemporaneous relationships among the components of the vector time series.

ESTIMATES

prints the coefficient estimates and a schematic representation of the significance and sign of the parameter estimates.

IARR**IARR(*number*)**

prints the infinite order AR representation of a VARMA process. The *number* should be greater than zero. If the ECM= option and the COINTEG statement are specified, then the reparameterized AR coefficient matrices are printed.

IMPULSE**IMPULSE(*number*)****IMPULSE=(SIMPLE ACCUM ORTH STDERR ALL)****IMPULSE(*number*)=(SIMPLE ACCUM ORTH STDERR ALL)**

prints the impulse response function. The *number* should be greater than zero. It investigates the response of one variable to an impulse in another variable in a system that involves a number of other variables as well. It is an infinite order MA representation of a VARMA process. See the section [“Impulse Response Function”](#) on page 2444 for details.

The following options can be used in the IMPULSE=() option. The options are specified within parentheses.

ACCUM	prints the accumulated impulse response function.
ALL	is equivalent to specifying all of SIMPLE, ACCUM, ORTH, and STDERR.
ORTH	prints the orthogonalized impulse response function.
SIMPLE	prints the impulse response function. This is the default.
STDERR	prints the standard errors of the impulse response function, the accumulated impulse response function, or the orthogonalized impulse response function.

If the exogenous variables are used to fit the model, then the STDERR option is ignored.

IMPULSX**IMPULSX(*number*)****IMPULSX=(SIMPLE ACCUM ALL)****IMPULSX(*number*)=(SIMPLE ACCUM ALL)**

prints the impulse response function related to exogenous (independent) variables. The *number* should be greater than zero. See the section [“Impulse Response Function”](#) on page 2444 for details.

The following options can be used in the IMPULSX=() option. The options are specified within parentheses.

ACCUM	prints the accumulated impulse response matrices for the transfer function.
ALL	is equivalent to specifying both SIMPLE and ACCUM.
SIMPLE	prints the impulse response matrices for the transfer function. This is the default.

PARCOEF**PARCOEF**(*number*)

prints the partial autoregression coefficient matrices, Φ_{mm} up to the lag *number*. The *number* should be greater than zero. With a VAR process, this option is useful for the identification of the order since the Φ_{mm} have the property that they equal zero for $m > p$ under the hypothetical assumption of a VAR(*p*) model. See the section “[Tentative Order Selection](#)” on page 2459 for details.

PCANCORR**PCANCORR**(*number*)

prints the partial canonical correlations of the process at lag *m* and the test for testing $\Phi_m=0$ for $m > p$ up to the lag *number*. The *number* should be greater than zero. The lag *m* partial canonical correlations are the canonical correlations between y_t and y_{t-m} , after adjustment for the dependence of these variables on the intervening values $y_{t-1}, \dots, y_{t-m+1}$. See the section “[Tentative Order Selection](#)” on page 2459 for details.

PCORR**PCORR**(*number*)

prints the partial correlation matrices. The *number* should be greater than zero. With a VAR process, this option is useful for a tentative order selection by the same property as the partial autoregression coefficient matrices, as described in the PRINT=(PARCOEF) option. See the section “[Tentative Order Selection](#)” on page 2459 for details.

ROOTS

prints the eigenvalues of the $kp \times kp$ companion matrix associated with the AR characteristic function $\Phi(B)$, where *k* is the number of dependent (endogenous) variables, and $\Phi(B)$ is the finite order matrix polynomial in the backshift operator *B*, such that $B^i y_t = y_{t-i}$. These eigenvalues indicate the stationary condition of the process since the stationary condition on the roots of $|\Phi(B)| = 0$ in the VAR(*p*) model is equivalent to the condition in the corresponding VAR(1) representation that all eigenvalues of the companion matrix be less than one in absolute value. Similarly, you can use this option to check the invertibility of the MA process. In addition, when the GARCH statement is specified, this option prints the roots of the GARCH characteristic polynomials to check covariance stationarity for the GARCH process.

YW

prints Yule-Walker estimates of the preliminary autoregressive model for the dependent (endogenous) variables. The coefficient matrices are printed using the maximum order of the autoregressive process.

Some examples of the PRINT= option are as follows:

```
model y1 y2 / p=1 print=(covy(10) corry(10));
model y1 y2 / p=1 print=(parcoef pcancorr pcorr);
model y1 y2 / p=1 print=(impulse(8) decompose(6) covpe(6));
model y1 y2 / p=1 print=(dynamic roots yw);
```

Lag Specification Options

P=number

P=(number-list)

specifies the order of the vector autoregressive process. Subset models of vector autoregressive orders can be specified by listing the desired set of lags. For example, you can specify the P=(1,3,4) option. The P=3 option is equivalent to the P=(1,2,3) option. The default is P=0.

If P=0 and there are no exogenous (independent) variables, then the AR polynomial order is automatically determined by minimizing an information criterion. If P=0 and the PRIOR= or ECM= option or both are specified, then the AR polynomial order is determined automatically.

If the ECM= option is specified, then subset models of vector autoregressive orders are not allowed and the AR maximum order specified is used.

Examples illustrating the P= option follow:

```
model y1 y2 / p=3;
model y1 y2 / p=(1,3);
model y1 y2 / p=(1,3) prior;
```

Q=number

Q=(number-list)

specifies the order of the moving-average error process. Subset models of moving-average orders can be specified by listing the desired set of lags. For example, you can specify the Q=(1,5) option. The default is Q=0.

```
model y1 y2 / p=1 q=1;
model y1 y2 / q=(2);
```

XLAG=number

XLAG=(number-list)

specifies the lags of exogenous (independent) variables. Subset models of distributed lags can be specified by listing the desired set of lags. For example, XLAG=(2) selects only a lag 2 of the exogenous variables. The default is XLAG=0. To exclude the present values of exogenous variables from the model, the NOCURRENTX option must be used.

```
model y1 y2 = x1-x3 / xlag=2 nocurrentx;
model y1 y2 = x1-x3 / p=1 xlag=(2);
```

Tentative Order Selection Options

MINIC

MINIC=(TYPE=value P=number Q=number PERROR=number)

prints the information criterion for the appropriate AR and MA tentative order selection and for the diagnostic checks of the fitted model.

If the MINIC= option is not specified, all types of information criteria are printed for diagnostic checks of the fitted model.

The following options can be used in the MINIC=() option. The options are specified within parentheses.

P=number

P=(p_{min} : p_{max})

specifies the range of AR orders to be considered in the tentative order selection. The default is $P=(0:5)$. The $P=3$ option is equivalent to the $P=(0:3)$ option.

PERROR=number

PERROR=($p_{\epsilon,min}$: $p_{\epsilon,max}$)

specifies the range of AR orders for obtaining the error series. The default is $PERROR=(p_{max} : p_{max} + q_{max})$.

Q=number

Q=(q_{min} : q_{max})

specifies the range of MA orders to be considered in the tentative order selection. The default is $Q=(0:5)$.

TYPE=value

specifies the criterion for the model order selection. Valid criteria are as follows:

AIC	specifies the Akaike information criterion.
AICC	specifies the corrected Akaike information criterion. This is the default criterion.
FPE	specifies the final prediction error criterion.
HQC	specifies the Hanna-Quinn criterion.
SBC	specifies the Schwarz Bayesian criterion. You can also specify this value as $TYPE=BIC$.

```
model y1 y2 / minic;
model y1 y2 / minic=(type=aic p=5);
```

Cointegration Related Options

Two options are related to integrated time series; one is the DFTEST option to test for a unit root and the other is the COINTTEST option to test for cointegration.

DFTEST

DFTEST=(DLAG=number)

DFTEST=(DLAG=(number) ... (number))

prints the Dickey-Fuller unit root tests. The $DLAG=(number) \dots (number)$ option specifies the regular or seasonal unit root test. Supported values of *number* are in 1, 2, 4, 12. If the *number* is greater than one, a seasonal Dickey-Fuller test is performed. If the TREND= option is specified, the seasonal unit root test is not available. The default is $DLAG=1$.

For example, the $DFTEST=(DLAG=(1)(12))$ option produces two tables: the Dickey-Fuller regular unit root test and the seasonal unit root test.

Some examples of the $DFTEST=$ option follow:

```
model y1 y2 / p=2 dftest;
model y1 y2 / p=2 dftest=(dlag=4);
model y1 y2 / p=2 dftest=(dlag=(1) (12));
model y1 y2 / p=2 dftest cointtest;
```

COINTTEST

COINTTEST=(**JOHANSEN** <(*=options*)> **SW** <(*=options*)> **SIGLEVEL**=*number*)

The following *options* can be used with the COINTTEST=() option. The *options* are specified within parentheses.

JOHANSEN

JOHANSEN=(**TYPE**=*value* **IORDER**=*number* **NORMALIZE**=*variable*)

prints the cointegration rank test for multivariate time series based on Johansen's method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 11. See the section “[Vector Error Correction Modeling](#)” on page 2486 for details.

The VARX(*p,s*) model can be written as the error correction model

$$\Delta y_t = \Pi y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where Π , Φ_i^* , A , and Θ_i^* are coefficient parameters; D_t is a deterministic term such as a constant, a linear trend, or seasonal dummies.

The $I(1)$ model is defined by one reduced-rank condition. If the cointegration rank is $r < k$, then there exist $k \times r$ matrices α and β of rank r such that $\Pi = \alpha\beta'$.

The $I(1)$ model is rewritten as the $I(2)$ model

$$\Delta^2 y_t = \Pi y_{t-1} - \Psi \Delta y_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 y_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where $\Psi = I_k - \sum_{i=1}^{p-1} \Phi_i^*$ and $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j^*$.

The $I(2)$ model is defined by two reduced-rank conditions. One is that $\Pi = \alpha\beta'$, where α and β are $k \times r$ matrices of full-rank r . The other is that $\alpha'_\perp \Psi \beta_\perp = \xi \eta'$ where ξ and η are $(k-r) \times s$ matrices with $s \leq k-r$; α_\perp and β_\perp are $k \times (k-r)$ matrices of full-rank $k-r$ such that $\alpha'_\perp \alpha_\perp = 0$ and $\beta'_\perp \beta_\perp = 0$.

The following options can be used in the JOHANSEN=() option. The options are specified within parentheses.

IORDER=*number* specifies the integrated order.

IORDER =1	prints the cointegration rank test for an integrated order 1 and prints the long-run parameter, β , and the adjustment coefficient, α . This is the default. If the IORDER =1 option is specified, then the AR order should be greater than or equal to 1. When the P =0 option, the value of P is set to 1 for the Johansen test.
IORDER =2	prints the cointegration rank test for integrated orders 1 and 2. If the IORDER =2 option is specified, then the AR order should be greater than or equal to 2. If the P =1 option with the IORDER =2 option, then the value of IORDER is set to 1; if the P =0 option with the IORDER =2 option, then the value of P is set to 2.

NORMALIZE=variable specifies the dependent (endogenous) variable name whose cointegration vectors are to be normalized. If the normalized variable is different from that specified in the ECM= option or the COINTEG statement, then the value specified in the COINTEG statement is used.

TYPE=value specifies the type of cointegration rank test to be printed. Valid values are as follows:

MAX prints the cointegration maximum eigenvalue test.

TRACE prints the cointegration trace test. This is the default.

If the NOINT option is not specified, the procedure prints two different cointegration rank tests in the presence of the unrestricted and restricted deterministic terms (constant or linear trend) models. If the IORDER=2 option is specified, the procedure automatically determines that the TYPE=TRACE option.

Some examples that illustrate the COINTTEST= option follow:

```
model y1 y2 / p=2 cointtest=(johansen=(type=max normalize=y1));
model y1 y2 / p=2 cointtest=(johansen=(iorder=2 normalize=y1));
```

SIGLEVEL=value

sets the size of cointegration rank tests and common trends tests.

The SIGLEVEL=value can be set to 0.1, 0.05, or 0.01. The default is SIGLEVEL=0.05.

```
model y1 y2 / p=2 cointtest=(johansen siglevel=0.1);
model y1 y2 / p=2 cointtest=(sw siglevel=0.1);
```

SW

SW=(TYPE=value LAG=number)

prints common trends tests for a multivariate time series based on the Stock-Watson method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 6. See the section “[Common Trends](#)” on page 2484 for details.

The following options can be used in the SW=() option. The options are listed within parentheses.

LAG=number specifies the number of lags. The default is $LAG=\max(1, p)$ for the TYPE=FILTDIF or TYPE=FILTRES option, where p is the AR maximum order specified by the P= option; $LAG=T^{1/4}$ for the TYPE=KERNEL option, where T is the number of nonmissing observations. If the specified LAG=number exceeds the default, then it is replaced by the default.

TYPE=value specifies the type of common trends test to be printed. Valid values are as follows:

FILTDIF prints the common trends test based on the filtering method applied to the differenced series. This is the default.

FILTRES prints the common trends test based on the filtering method applied to the residual series.

KERNEL prints the common trends test based on the kernel method.

```

model y1 y2 / p=2 cointtest=(sw);
model y1 y2 / p=2 cointtest=(sw=(type=kernel));
model y1 y2 / p=2 cointtest=(sw=(type=kernel lag=3));

```

Bayesian VARX Estimation Options

PRIOR

PRIOR=(prior-options)

specifies the prior value of parameters for the BVARX(p, s) model. The BVARX model allows for a subset model specification. If the ECM= option is specified with the PRIOR option, the BVECMX(p, s) form is fitted. See the section “[Bayesian VAR and VARX Modeling](#)” on page 2470 for details.

The following options can be used with the PRIOR=(prior-options) option. The *prior-options* are listed within parentheses.

IVAR

IVAR=(variables)

specifies an integrated BVAR(p) model. The *variables* should be specified in the MODEL statement as dependent variables. If you use the IVAR option without *variables*, then it sets the overall prior mean of the first lag of each variable equal to one in its own equation and sets all other coefficients to zero. If *variables* are specified, it sets the prior mean of the first lag of the specified variables equal to one in its own equation and sets all other coefficients to zero. When the series $\mathbf{y}_t = (y_1, y_2)'$ follows a bivariate BVAR(2) process, the IVAR or IVAR=($y_1 \ y_2$) option is equivalent to specifying MEAN=(1 0 0 0 0 1 0 0).

If the PRIOR=(MEAN=) or ECM= option is specified, the IVAR= option is ignored.

LAMBDA=value

specifies the prior standard deviation of the AR coefficient parameter matrices. It should be a positive number. The default is LAMBDA=1. As the value of the LAMBDA= option is increased, the BVAR(p) model becomes closer to a VAR(p) model.

MEAN=(vector)

specifies the mean vector in the prior distribution for the AR coefficients. If the vector is not specified, the prior value is assumed to be a zero vector. See the section “[Bayesian VAR and VARX Modeling](#)” on page 2470 for details.

You can specify the mean vector by order of the equation. Let $(\delta, \Phi_1, \dots, \Phi_p)$ be the parameter sets to be estimated and $\Phi = (\Phi_1, \dots, \Phi_p)$ be the AR parameter sets. The mean vector is specified by row-wise from Φ ; that is, the MEAN=(vec(Φ')) option.

For the PRIOR=(mean) option in the BVAR(2),

$$\Phi = \begin{pmatrix} \phi_{1,11} & \phi_{1,12} & \phi_{2,11} & \phi_{2,12} \\ \phi_{1,21} & \phi_{1,22} & \phi_{2,21} & \phi_{2,22} \end{pmatrix} = \begin{pmatrix} 2 & 0.1 & 1 & 0 \\ 0.5 & 3 & 0 & -1 \end{pmatrix}$$

where $\phi_{l,i,j}$ is an element of Φ , l is a lag, i is associated with the first dependent variable, and j is associated with the second dependent variable.

```

model y1 y2 / p=2 prior=(mean=(2 0.1 1 0 0.5 3 0 -1));

```

The deterministic terms and exogenous variables are considered to shrink toward zero; you must omit prior means of exogenous variables and deterministic terms such as a constant, seasonal dummies, or trends.

For a Bayesian error correction model estimated when both the ECM= and PRIOR= options are used, a mean vector for only lagged AR coefficients, Φ_i^* , in terms of regressors Δy_{t-i} , for $i = 1, \dots, (p-1)$ is used in the VECM(p) representation. The diffused prior variance of α is used, since β is replaced by $\hat{\beta}$ estimated in a nonconstrained VECM(p) form.

$$\Delta y_t = \alpha z_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where $z_t = \beta' y_t$.

For example, in the case of a bivariate ($k = 2$) BVECM(2) form, the option

$$\text{MEAN} = (\phi_{1,11}^* \phi_{1,12}^* \phi_{1,21}^* \phi_{1,22}^*)$$

where $\phi_{1,ij}^*$ is the (i, j) th element of the matrix Φ_1^* .

NREP=number

determines the number of repetitions that are used to compute the measure of forecast accuracy. See the equation in the section “[Forecasting of BVAR Modeling](#)” on page 2472 for details. The default is $\text{NREP}=0.5T$, where T is the number of observations. If NREP is above $0.5T$, it is decreased to $0.5T$; if NREP is below the value of the LEAD= option, it is increased to the value of the LEAD= option.

THETA=value

specifies the prior standard deviation of the AR coefficient parameter matrices. The *value* is in the interval (0,1). The default is THETA=0.1. As the value of the THETA= option approaches 1, the specified BVAR(p) model approaches a VAR(p) model.

Some examples of the PRIOR= option follow:

```
model y1 y2 / p=2 prior;
model y1 y2 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2
    prior=(theta=0.2 lambda=5 mean=(2 0.1 1 0 0.5 3 0 -1));
```

See the section “[Bayesian VAR and VARX Modeling](#)” on page 2470 for details.

Vector Error Correction Model Options

ECM=(RANK=number NORMALIZE=variable ECTREND)

specifies a vector error correction model.

The following options can be used in the ECM=() option. The options are specified within parentheses.

NORMALIZE=variable

specifies a single dependent variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTEG statement, then the value specified in the COINTEG statement is used.

RANK=number

specifies the cointegration rank. This option is required in the ECM= option. The value of the RANK= option should be greater than zero and less than or equal to the number of dependent (endogenous) variables, k . If the rank is different from that specified in the COINTEG statement, then the value specified in the COINTEG statement is used.

ECTREND

specifies the restriction on the drift in the VECM(p) form.

- There is no separate drift in the VECM(p) form, but a constant enters only through the error correction term.

$$\Delta y_t = \alpha(\beta', \beta_0)(y'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t$$

An example of the ECTREND option follows:

```
model y1 y2 / p=2 ecm=(rank=1 ectrend);
```

- There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only through the error correction term.

$$\Delta y_t = \alpha(\beta', \beta_1)(y'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \epsilon_t$$

An example of the ECTREND option with the TREND= option follows:

```
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

If the NSEASON option is specified, then the NSEASON option is ignored; if the NOINT option is specified, then the ECTREND option is ignored.

Some examples of the ECM= option follow:

```
model y1 y2 / p=2 ecm=(rank=1 normalized=y1);
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

See the section “[Vector Error Correction Modeling](#)” on page 2486 for details.

NLOPTIONS Statement

NLOPTIONS options ;

The VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 6, “[Nonlinear Optimization Methods](#).”

An example of the NLOPTIONS statement follows:

```
proc varmax data=one;
  nloptions tech=qn;
  model y1 y2 / p=2;
run;
```

The VARMAX procedure uses the dual quasi-Newton optimization method by default when no NLOPTIONS statement is specified. However, it uses Newton-Raphson ridge optimization when the NLOPTIONS statement is specified.

The following example uses the TECH=QUANEW by default.

```
proc varmax data=one;
    model y1 y2 / p=2 method=ml;
run;
```

The next example uses the TECH=NRRIDG by default.

```
proc varmax data=one;
    nloptions maxiter=500 maxfunc=5000;
    model y1 y2 / p=2 method=ml;
run;
```

OUTPUT Statement

OUTPUT < options > ;

The OUTPUT statement generates and prints forecasts based on the model estimated in the previous MODEL statement and, optionally, creates an output SAS data set that contains these forecasts.

When the GARCH model is estimated, the upper and lower confidence limits of forecasts are calculated by assuming that the error covariance has homoscedastic conditional covariance.

ALPHA=number

sets the forecast confidence limit size, where *number* is between 0 and 1. When you specify the ALPHA=*number* option, the upper and lower confidence limits define the $100(1 - \alpha)\%$ confidence interval. The default is ALPHA=0.05, which produces 95% confidence intervals.

BACK=number

specifies the number of observations before the end of the data at which the multistep forecasts begin. The BACK= option value must be less than or equal to the number of observations minus the number of lagged regressors in the model. The default is BACK=0, which means that the forecasts start at the end of the available data.

LEAD=number

specifies the number of multistep forecast values to compute. The default is LEAD=12.

NOPRINT

suppresses the printed forecast values of each dependent (endogenous) variable.

OUT=SAS-data-set

writes the forecast values to an output data set.

Some examples of the OUTPUT statements follow:

```

proc varmax data=one;
  model y1 y2 / p=2;
  output lead=6 back=2;
run;

proc varmax data=one;
  model y1 y2 / p=2;
  output out=for noprint;
run;

```

RESTRICT Statement

RESTRICT *restriction, ..., restriction* ;

The RESTRICT statement places linear restrictions on the parameters and provides constrained estimation. Only one RESTRICT statement is allowed. If you specify more than one *restriction* in a RESTRICT statement, separate them with commas. Both equality and inequality constraints are allowed in the RESTRICT statement, although in general, the equality constraints are specified in the RESTRICT statement, and the inequality constraints are specified in the BOUND statement. If the least squares method is used, the inequality constraints are not applicable.

To use the RESTRICT statement, you need to know the form of the model. If you do not specify the P=, Q=, or XLAG= option or the GARCH statement, then the RESTRICT statement is not applicable. Nonlinear restrictions on parameters are not supported.

You compute restricted parameter estimates by introducing a Lagrangian parameter for each restriction (Pringle and Rayner 1971). The Lagrangian parameter measures the sensitivity of the sum of squared errors to the restriction. The estimates of these Lagrangian parameters and their significance are printed in the Restrict ODS table.

Matrix Expression

The RESTRICT statement operates on matrices. That is, you can specify the parameter matrices or constant matrices through the RESTRICT statement's built-in operators and functions. You can add elements of the matrices **A** and **B** with the expression **A+B**, and you can perform matrix multiplication with the expression **A*B** and elementwise multiplication with the expression **A#B**. You can get the diagonal elements of the matrix **A** through the function **DIAG(A)**, and you can get the $n \times n$ identity matrix through the function **I(n)**.

Each restriction is written as a matrix expression composed of constants, operators, and functions.

Constants

Constants are either scalar constants, such as -1.2, 0.3, ..., or matrix constants enclosed in braces, such as 2×2 matrix {1 2, 3 4}, 1×3 matrix (or called row vector) {-0.2 5.3 12}, and so on. Constants also include the dependent variable names and exogenous variable names that represent their index values and are mostly used in the subscripts or function arguments. For example, in the following statement, according to the order of the dependent and exogenous variables in the MODEL statement, GDP is equal to 1, CPI to 2, M2 to 3, FFR to 1, and CP to 2. Hence, the function call **AR(2, GDP, {CPI M2})** is equivalent to **AR(2,1,{2 3})**, and **XL(0, CPI, {FFR CP})** is equivalent to **XL(0,2,{1 2})**. The use of **AR** and **XL** functions to access parameters is discussed in the section “[Functions](#)” on page 2427.

```
proc varmax data=macrodata;
  model GDP CPI M2 = FFR CP / p=12 xlag=12;
  restrict AR(2, GDP, {CPI M2}) = 0,
           XL(0, CPI, {FFR CP}) = 0;
run;
```

The matrix constant cannot be the first item in the RESTRICT statement. For example, you cannot specify the following statement:

```
restrict {-0.1 -0.2, -0.3 -0.4} <= AR <= {0.1 0.2, 0.3 0.4};
```

You can put the first matrix constant in parentheses and specify the preceding example in the following way:

```
restrict ({-0.1 -0.2, -0.3 -0.4}) <= AR <= {0.1 0.2, 0.3 0.4};
```

Operators

Operators define the operations on operands. [Table 35.2](#) lists all built-in operators supported by the RESTRICT statement.

Table 35.2 Operators

Operator Name		Description
+	Addition	Adds corresponding matrix elements
=	Comparison, equal	Compares matrix elements
<	Comparison, less than	Compares matrix elements
<=	Comparison, not greater than	Compares matrix elements
>	Comparison, greater than	Compares matrix elements
>=	Comparison, not less than	Compares matrix elements
	Concatenation, horizontal	Concatenates matrices horizontally
//	Concatenation, vertical	Concatenates matrices vertically
@	Direct product	Takes the direct product of two matrices
:	Index creation	Creates an index vector
#	Multiplication, elementwise	Performs elementwise multiplication
*	Multiplication, matrix	Performs matrix multiplication
—	Sign reverse	Reverses the signs of elements
[]	Subscripts	Selects submatrices
—	Subtraction	Subtracts corresponding matrix elements
`	Transpose	Transposes a matrix

For more information about each operator, see the section “[Details of Operators](#)” on page 2431.

[Table 35.3](#) shows the precedence of matrix operators in the RESTRICT statement.

Table 35.3 Operator Precedence

Priority Group	Operators
I (highest)	[] (subscripts) `
II	− (sign reverse)
III	* # @
IV	− (subtraction) +
V	// :
VI (lowest)	= < <= > >=

Each restriction can be a compound expression that involves several matrix operators and operands. The rules for evaluating compound expressions are as follows:

- Evaluation follows the order of operator precedence, as described in [Table 35.3](#). Group I has the highest priority; that is, Group I operators are evaluated first. Group II operators are evaluated after Group I operators, and so on. For example, $1 + 2 * 3$ returns 7.
- If neighboring operators in an expression have equal precedence, the expression is evaluated from left to right, except for the Group I operators. For example, $1 - 2 - 3$ returns -4 .
- All expressions in parentheses are evaluated first, following the two preceding rules. For example, $3 * (2 + 1)$ returns 9.

Functions

Functions are mainly divided into two categories: one type of function refers to parameters to be estimated, such as **AR**(**L**, **I**, **J**) and **CCC**(**I**, **J**); the other type does not, such as **I**(**n**) and **DIAG**(**A**).

Functions that refer to the parameters are listed in [Table 35.4](#). The arguments for functions can be matrices. The simplest case, scalar arguments, is discussed first. For convenience, the scalar indices **i** and **j** refer to the position of the element in the coefficient matrix, and scalar **l** refers to the lag value.

Table 35.4 Functions Referring to Parameters

Function	Description
ACH (l , i , j)	ARCH parameter of the lag <i>l</i> value of $\epsilon_t \epsilon_t'$ in a GARCH model
AR (l , i , j)	Autoregressive parameter of the lag <i>l</i> value of the <i>j</i> th dependent (endogenous) variable, $y_{j,t-l}$, to the <i>i</i> th dependent variable at time <i>t</i> , y_{it}
CCC (i , j)	Constant conditional correlation parameter between <i>i</i> th and <i>j</i> th standardized error processes for the CCC GARCH model
CONST (i)	Intercept parameter of the <i>i</i> th time series, y_{it}
COV (i , j)	Covariance of innovations parameter between <i>i</i> th and <i>j</i> th error processes when the maximum likelihood method is used for the fitted non-GARCH model
DCCA ()	Parameter α in the correlation equation for the DCC GARCH model
DCCB ()	Parameter β in the correlation equation for the DCC GARCH model
DCCS (i , j)	Unconditional correlation parameter between <i>i</i> th and <i>j</i> th standardized error processes for the DCC GARCH model

Table 35.4 continued

Function	Description
EACH (1, <i>i</i> , <i>j</i>)	Exponential ARCH parameter of the lag <i>l</i> value of $\epsilon_{it}/\sigma_{it}$ in the CCC or DCC GARCH model when SUBFORM=EGARCH is specified if $i = j$; if $i \neq j$, the value is set to 0.
GCH (1, <i>i</i> , <i>j</i>)	GARCH parameter of the lag <i>l</i> value of the covariance matrix, H_t , in a GARCH model
GCHC (<i>i</i> , <i>j</i>)	Constant parameter of the covariance matrix, H_t , in a GARCH model
LAMBDA (<i>i</i>)	Power parameter for the <i>i</i> th error process in the CCC or DCC GARCH model when SUBFORM=PGARCH is specified
LTREND (<i>i</i>)	Linear trend parameter of the <i>i</i> th time series, y_{it}
MA (1, <i>i</i> , <i>j</i>)	Moving-average parameter of the lag <i>l</i> value of the <i>j</i> th error process, $\epsilon_{j,t-l}$, to the <i>i</i> th dependent variable at time <i>t</i> , y_{it}
PACH (1, <i>i</i> , <i>j</i>)	Power ARCH parameter of the lag <i>l</i> value of ϵ_{it} in the CCC or DCC GARCH model when SUBFORM=PGARCH is specified if $i = j$; if $i \neq j$, the value is set to 0.
QACH (1, <i>i</i> , <i>j</i>)	Quadratic ARCH center parameter of the lag <i>l</i> value of ϵ_{it} in the CCC or DCC GARCH model when SUBFORM=QGARCH is specified if $i = j$; if $i \neq j$, the value is set to 0.
QTREND (<i>i</i>)	Quadratic trend parameter of the <i>i</i> th time series, y_{it}
SD (<i>i</i> , <i>j</i>)	Same as SDUMMY (<i>i</i> , <i>j</i>)
SDUMMY (<i>i</i> , <i>j</i>)	<i>j</i> th seasonal dummy of the <i>i</i> th time series at time <i>t</i> , y_{it} , where $j = 1, \dots, (nseason-1)$, where <i>nseason</i> is based on the NSEASON= option in the MODEL statement
TACH (1, <i>i</i> , <i>j</i>)	Threshold ARCH parameter of the lag <i>l</i> value of $1_{\epsilon_{it} < 0} \epsilon_{it}^2$ in the CCC or DCC GARCH model when SUBFORM=GJR is specified if $i = j$; if $i \neq j$, the value is set to 0.
XL (1, <i>i</i> , <i>j</i>)	Exogenous parameter of the lag <i>l</i> value of the <i>j</i> th exogenous (independent) variable, $x_{j,t-l}$, to the <i>i</i> th dependent variable at time <i>t</i> , y_{it}

The functions that refer to parameters, as shown in Table 35.4, accept vector arguments and return the matrix constructed by the corresponding parameters. According to the number of arguments, the following list shows what matrix a function returns when the arguments are vectors:

- A function **FUNC0**, namely **DCCA** and **DCCB**, with zero arguments, always returns the corresponding scalar parameter.
- A function **FUNC1**, namely **CONST**, **LAMBDA**, **LTREND**, and **QTREND**, with one vector argument *I*, where $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$, returns a vector $R = (r_1 \ r_2 \ \dots \ r_{n_I})'$, where $r_k = \text{FUNC1}(i_k)$, $k = 1, \dots, n_I$.
- A function **FUNC2**, namely **CCC**, **COV**, **DCCS**, **GCHC**, **SD**, and **SDUMMY**, with two vector arguments *I* and *J*, where $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$ and $J = (j_1 \ j_2 \ \dots \ j_{n_J})'$, returns a matrix

$$R = \begin{pmatrix} r_{1,1} & r_{1,2} & \cdots & r_{1,n_J} \\ r_{2,1} & r_{2,2} & \cdots & r_{2,n_J} \\ \cdots & & & \\ r_{n_I,1} & r_{n_I,2} & \cdots & r_{n_I,n_J} \end{pmatrix}$$

where $r_{k,m} = \text{FUNC2}(i_k, j_m)$, $k = 1, \dots, n_I$, $m = 1, \dots, n_J$.

- A function **FUNC3**, namely **ACH**, **AR**, **EACH**, **GCH**, **MA**, **PACH**, **QACH**, **TACH**, and **XL**, with three vector arguments L , I , and J , where $L = (l_1 \ l_2 \ \dots \ l_{n_L})'$, $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$, and $J = (j_1 \ j_2 \ \dots \ j_{n_J})'$, returns a matrix

$$R = \begin{pmatrix} r_{1,1} & r_{1,2} & \cdots & r_{1,n_L n_J} \\ r_{2,1} & r_{2,2} & \cdots & r_{2,n_L n_J} \\ \cdots & & & \\ r_{n_I,1} & r_{n_I,2} & \cdots & r_{n_I,n_L n_J} \end{pmatrix}$$

where $r_{k,m} = \text{FUNC3}(l_m, i_k, j_m)$, $k = 1, \dots, n_I$, $m = 1, \dots, n_L n_J$, and l_m and j_m are the quotient and remainder of m divided by n_J , respectively.

The functions that refer to parameters can accept empty arguments or omit any number of last arguments. The empty or omitted arguments are replaced with all possible values for those arguments. For example, in a bivariate ($k=2$) VARX(1,1) model with three exogenous variables,

```
model y1 y2 = x1 x2 x3 / p=1 xlag=3;
```

in order to restrict the third exogenous variable from having an effect on the first dependent variable, and to restrict the first exogenous variable from having an effect on the second dependent variable, you can use the following statement:

```
restrict XL({0 1 2 3}, 1, 3) = 0,
          XL({0 1 2 3}, 2, 1) = 0;
```

Taking advantage of empty arguments, you can specify the preceding example as follows:

```
restrict XL( , 1, 3) = 0,
          XL( , 2, 1) = 0;
```

To get all coefficients of the first lag exogenous variables on dependent variables, you can use **XL(1, {1 2}, {1 2 3})** or **XL(1, ,)** or **XL(1)**. To get all coefficients of exogenous variables on dependent variables, you can use **XL({0 1 2 3}, {1 2}, {1 2 3})**, or **XL(, ,)** or **XL()** or even just **XL**.

Another type of function does not refer to parameters but generates useful matrices. [Table 35.5](#) lists all built-in functions supported by the RESTRICT statement.

Table 35.5 Functions Not Referring to Parameters

Function	Description
DIAG (A)	Creates a diagonal matrix from a vector or extracts the diagonal elements of a matrix
I (n)	Creates an $n \times n$ identity matrix
J (m, n, elem)	Creates an $m \times n$ matrix with all elements equal to elem
SHAPE (A, m, n)	Creates a $m \times n$ matrix with elements of matrix A

For more information about each function in [Table 35.5](#), see the section “[Details of Functions](#)” on page 2435.

Examples

The following examples show how to use the RESTRICT statement.

This example shows a bivariate ($k=2$) VAR(2) model:

```
proc varmax data=one;
  model y1 y2 / p=2;
  restrict AR(1,1,2)=0, AR(2,1,2)=0.3;
run;
```

The $\text{AR}(1,1,2)$ and $\text{AR}(2,1,2)$ parameters are fixed as $\text{AR}(1,1,2)=0$ and $\text{AR}(2,1,2)=0.3$, respectively, and other parameters are to be estimated.

The following example shows a bivariate ($k=2$) VAR(1) model, estimated using the ML method:

```
proc varmax data=two;
  model y1 y2 = / p=1 method=ml;
  restrict cov(1,1)=cov(2,2), cov(1,2)=0;
run;
```

The $\text{COV}(1,1)$ and $\text{COV}(2,2)$ parameters are equal, and the correlation between the two series is fixed at 0. You can also express the preceding restrictions in matrix expressions as follows; this approach is very convenient when the number of dependent variables is large:

```
proc varmax data=two;
  model y1 y2 = / p=1 method=ml;
  restrict cov = cov(1,1)*I(2);
run;
```

When restricting a linear combination of parameters to be 0, you can omit the equal sign. For example, the following two RESTRICT statements are equivalent:

```
restrict AR(1)[1,1]-AR(1)[2,2], 2*MA(1)[1,2]-MA(1)[2,1];

restrict AR(1)[1,1]-AR(1)[2,2] = 0, 2*MA(1)[1,2]-MA(1)[2,1] = 0;
```

The following RESTRICT statement constrains four parameter estimates to be equal:

```
restrict AR(1)[1,1] = AR(1)[1,2],
        AR(1)[1,2] = AR(1)[2,1],
        AR(1)[2,1] = AR(1)[2,2];
```

This restriction can be abbreviated as follows:

```
restrict AR(1)[1,1] = AR(1)[1,2] = AR(1)[2,1] = AR(1)[2,2];
```

Or, in matrix expressions,

```
restrict AR(1,1:2,1:2) = J(2,2,AR(1,1,1));
```

The VARMA representation $A(L)y_t = \Theta(L)\varepsilon_t$, where $A(L) = I_k - A_1L - \dots - A_pL^p$ and $\Theta(L) = I_k - \Theta_1L - \dots - \Theta_qL^q$, is said to be in final equation form if $A(L) = a(L)I_k$, where $a(L) = 1 - a_1L - \dots - a_pL^p$ is a scalar operator with $a_p \neq 0$. If p and k are large, it would be difficult and inconvenient to restrict AR parameters element by element in standard form to estimate the VARMA model in final equation form. However, when you use matrix expressions, the restrictions become very simple, as shown in the following statement for a trivariate ($k = 3$) VARMA(p, q) model, where p might be any positive integer:

```
restrict AR = AR(,1,1) @ I(3);
```

Details of Operators

This section describes all operators that are available in the RESTRICT statement. Each subsection shows how the operator is used, followed by a description of the operator.

Addition Operator: +

```
matrix1 + matrix2
```

```
matrix + scalar
```

```
matrix + vector
```

The addition operator (+) computes a new matrix whose elements are the sums of the corresponding elements of **matrix1** and **matrix2**. If **matrix1** and **matrix2** are both $n \times p$ matrices, then the addition operator adds the element in the i th row and j th column of the first matrix to the element in the i th row and j th column of the second matrix, for $i = 1, \dots, n, j = 1, \dots, p$. For example, $\{1 \ 2 \ 3, \ 4 \ 5 \ 6\} + \{7 \ 8 \ 9, \ 10 \ 11 \ 12\}$ results in $\{8 \ 10 \ 12, \ 14 \ 16 \ 18\}$.

You can also use the addition operator as follows to conveniently add a value to each element of a matrix, to each column of a matrix, or to each row of a matrix:

- When you use the **matrix + scalar** form, the scalar value is added to each element of the matrix.
- When you use the **matrix + vector** form, the vector is added to each row or column of the $n \times p$ matrix.
 - If you add an $n \times 1$ column vector, each row of the vector is added to each row of the matrix.
 - If you add a $1 \times p$ row vector, each column of the vector is added to each column of the matrix.

For example, you can obtain $\{2 \ 3 \ 4, \ 5 \ 6 \ 7\}$ from $\{1 \ 2 \ 3, \ 4 \ 5 \ 6\} + 1$ or $\{1 \ 2 \ 3, \ 4 \ 5 \ 6\} + \{1 \ 1 \ 1\}$ or $\{1 \ 2 \ 3, \ 4 \ 5 \ 6\} + \{1, \ 1\}$.

Comparison Operators: =, <, <=, >, >=

```
matrix1 = matrix2
```

```
matrix1 < matrix2
```

```
matrix1 <= matrix2
```

```
matrix1 > matrix2
```

```
matrix1 >= matrix2
```

The comparison operators (=, <, <=, >, >=) compare two matrices element by element and return a list of equivalent restrictions on only scalar constants and parameters.

For example, the RESTRICT statement with matrix expressions

```
restrict AR(1,{1,2},{1,2}) = MA(2,{3,4},{3,4});
```

is transformed into the following equivalent RESTRICT statement with scalar parameters:

```
restrict AR(1,1,1) = MA(2,3,3),
        AR(1,1,2) = MA(2,3,4),
        AR(1,2,1) = MA(2,4,3),
        AR(1,2,2) = MA(2,4,4);
```

You can also use the comparison operators to conveniently compare all elements of a matrix with a scalar:

- If either argument is a scalar, then the VARMAX procedure performs an elementwise comparison between each element of the matrix and the scalar.

You can also compare an $n \times p$ matrix with a row or column vector:

- If the comparison is with an $n \times 1$ column vector, the VARMAX procedure compares each row of the vector to each row of the matrix.
- If the comparison is with a $1 \times p$ row vector, the VARMAX procedure compares each column of the vector to each column of the matrix.

For example, the following statements are equivalent:

```
restrict AR(1,1:2,1:3) >= 0.2;

restrict AR(1,1:2,1:3) >= {0.2, 0.2};

restrict AR(1,1:2,1:3) >= {0.2 0.2 0.2};
```

Concatenation Operator, Horizontal: ||

```
matrix1 || matrix2
```

The horizontal concatenation operator (||) produces a new matrix by horizontally joining **matrix1** and **matrix2**. The matrices must have the same number of rows, which is also the number of rows in the new matrix. The number of columns in the new matrix is the number of columns in **matrix1** plus the number of columns in **matrix2**.

For example, {1 1 1, 7 7 7} || {0 0 0, 8 8 8} returns {1 1 1 0 0 0, 7 7 7 8 8 8}.

Concatenation Operator, Vertical: //

```
matrix1 // matrix2
```

The vertical concatenation operator (//) produces a new matrix by vertically joining **matrix1** and **matrix2**. The matrices must have the same number of columns, which is also the number of columns in the new matrix. The number of rows in the new matrix is the number of rows in **matrix1** plus the number of rows in **matrix2**.

For example, {1 1 1} // {0 0 0, 8 8 8} returns {1 1 1, 0 0 0, 8 8 8}.

Direct Product Operator: @**matrix1 @ matrix2**

The direct product operator (@) computes a new matrix that is the direct product (also called the *Kronecker product*) of **matrix1** and **matrix2**. For matrices **A** and **B**, the direct product is denoted by $A \otimes B$. The number of rows in the new matrix equals the product of the number of rows in **matrix1** and the number of rows in **matrix2**; the number of columns in the new matrix equals the product of the number of columns in **matrix1** and the number of columns in **matrix2**.

Specifically, if **A** is an $n \times p$ matrix and **B** is a $m \times q$ matrix, then the Kronecker product $A \otimes B$ is the following $nm \times pq$ block matrix:

$$A \otimes B = \begin{bmatrix} A_{11}B & \cdots & A_{1p}B \\ \vdots & \ddots & \vdots \\ A_{n1}B & \cdots & A_{np}B \end{bmatrix}$$

For example, {1 2, 3 4} @ {0 2} returns {0 2 0 4, 0 6 0 8}, and {0 2} @ {1 2, 3 4} returns {0 0 2 4, 0 0 6 8}. Note that the direct product of two matrices is not commutative.

Index Creation Operator: :**value1 : value2**

The index creation operator (:) creates a column vector whose first element is **value1**, whose second element is **value1+1**, and so on, until the last element, which is less than or equal to **value2**.

For example, 3 : 6 returns {3 4 5 6}.

If **value1** is greater than **value2**, a reverse-order index is created. For example, 6 : 3 returns {6 5 4 3}.

Neither **value1** nor **value2** is required to be an integer.

Multiplication Operator, Elementwise: #**matrix1 # matrix2****matrix # scalar****matrix # vector**

The elementwise multiplication operator (#) computes a new matrix whose elements are the products of the corresponding elements of **matrix1** and **matrix2**.

For example, {1 2, 3 4} # {4 8, 0 5} returns {4 16, 0 20}.

In addition to multiplying matrices that have the same dimensions, you can use the elementwise multiplication operator to multiply a matrix and a scalar:

- When either argument is a scalar, each element in **matrix** is multiplied by the scalar value.

When you use the **matrix # vector** form, each row or column of the $n \times p$ matrix is multiplied by a corresponding element of the vector:

- If you multiply by an $n \times 1$ column vector, each row of the matrix is multiplied by the corresponding row of the vector.

- If you multiply by a $1 \times p$ row vector, each column of the matrix is multiplied by the corresponding column of the vector.

For example, a 2×3 matrix can be multiplied on either side by a 2×3 , 1×3 , 2×1 , or 1×1 scalar.

The product of elementwise multiplication is also known as the Schur or Hadamard product. Elementwise multiplication (which uses the `#` operator) should not be confused with matrix multiplication (which uses the `*` operator).

Multiplication Operator, Matrix: *

matrix1 * matrix2

The matrix multiplication operator (`*`) computes a new matrix by performing matrix multiplication. The first matrix must have the same number of columns as the second matrix has rows. The new matrix has the same number of rows as the first matrix and the same number of columns as the second matrix. That is, if A is an $n \times p$ matrix and B is a $p \times m$ matrix, then the product $A * B$ is an $n \times m$ matrix. The ij th element of the product is the sum $\sum_{k=1}^p A_{ik} B_{kj}$.

For example, `{1 2, 3 4} * {1, 2}` returns `{5, 11}`.

Sign Reversal Operator: -

- matrix

The sign reversal operator (`-`) computes a new matrix whose elements are formed by reversing the sign of each element in **matrix**. The sign reversal operator is also called the *unary minus* operator.

For example, `-{-1 7 6, 2 0 -8}` returns `{1 -7 -6, -2 0 8}`.

Subscripts: []

matrix[rows, columns]

matrix[elements]

Subscripts are used with matrices to select submatrices, where **rows**, **columns**, and **elements** are expressions that evaluate to scalars or vectors. If these expressions are numeric, they must contain valid subscript values of rows and columns, or the indices, in the argument matrix.

For example, `{1 2 3, 4 5 6, 7 8 9}[2,3]` returns `6`, `{1 2 3, 4 5 6, 7 8 9}[2,1:3]` returns `{4 5 6}`, and `{1 2 3, 4 5 6, 7 8 9}[,3]` returns `{3, 6, 9}`. Because the VARMAX procedure stores matrices in row-major order, `{11 22 33, 44 55 66, 77 88 99} [{3 5 9}]` returns `{33, 55, 99}`.

Subtraction Operator: -

matrix1 - matrix2

matrix - scalar

matrix - vector

The subtraction operator (`-`) computes a new matrix whose elements are formed by subtracting the corresponding elements of **matrix2** from those of **matrix1**.

In addition to subtracting conformable matrices, you can also use the subtraction operator to subtract a scalar from a matrix or subtract a vector from a matrix:

- When either argument is a scalar, the VARMAX procedure performs the subtraction between the scalar and each element of the matrix argument. For example, when you use the **matrix** - **scalar** form, the scalar value is subtracted from each element of the matrix.
- When you use the **matrix** - **vector** form, the vector is subtracted from each row or column of the $n \times p$ matrix.
 - If you subtract an $n \times 1$ column vector, each row of the vector is subtracted from each row of the matrix.
 - If you subtract a $1 \times p$ row vector, each column of the vector is subtracted from each column of the matrix.

For example, $\{1\ 2\ 3,\ 4\ 5\ 6\} - \{1\ 1\ 1,\ 1\ 1\ 1\}$ returns $\{0\ 1\ 2,\ 3\ 4\ 5\}$. The same results can be obtained by $\{1\ 2\ 3,\ 4\ 5\ 6\} - 1$ or $\{1\ 2\ 3,\ 4\ 5\ 6\} - \{1\ 1\ 1\}$ or $\{1\ 2\ 3,\ 4\ 5\ 6\} - \{1,\ 1\}$.

Transpose Operator: `

matrix`

The transpose operator, denoted by the backquote character (`), exchanges the rows and columns of **matrix**, producing the transpose of **matrix**. If v is the value in the i th row and j th column of **matrix**, then the transpose of **matrix** contains v in the j th row and i th column. If **matrix** contains n rows and p columns, the transpose has p rows and n columns.

For example, $\{1\ 2,\ 3\ 4,\ 5\ 6\}`$ returns $\{1\ 3\ 5,\ 2\ 4\ 6\}$.

Details of Functions

DIAG Function

DIAG(matrix)

The **DIAG** function creates a diagonal matrix from a vector or extracts the diagonal elements of a matrix. The **matrix** argument can be either a square matrix or a vector.

If **matrix** is a vector, the **DIAG** function creates a matrix whose diagonal elements are the values in the vector. All off-diagonal elements are zeros.

If **matrix** is a square matrix, the **DIAG** function creates a vector from the diagonal elements of the matrix.

For example, **DIAG**($\{1\ 2\ 3,\ 4\ 5\ 6,\ 7\ 8\ 9\}$) returns $\{1,\ 5,\ 9\}$. Also, **DIAG**($\{1\ 5\ 9\}$) or **DIAG**($\{1,\ 5,\ 9\}$) or **DIAG**(**DIAG**($\{1\ 2\ 3,\ 4\ 5\ 6,\ 7\ 8\ 9\}$)) returns $\{1\ 0\ 0,\ 0\ 5\ 0,\ 0\ 0\ 9\}$.

I Function

I(dim)

The **I** function creates an identity matrix that contains **dim** rows and columns. The diagonal elements of an identity matrix are ones; all other elements are zeros. The value of **dim** must be an integer greater than or equal to 1. Noninteger operands are rounded to the nearest integer.

For example, **I**(3) returns $\{1\ 0\ 0,\ 0\ 1\ 0,\ 0\ 0\ 1\}$.

J Function**J**(*nrow*, *ncol*, *value*)

The **J** function creates a matrix that contains **nrow** rows and **ncol** columns, in which all elements are equal to **value**.

The arguments **nrow** and **ncol** are both integers; **value** can be any expression that returns a linear combination of scalar constants and parameters.

For example, **J**(2, 3, 1) returns {1 1 1, 1 1 1}. **J**(2, 3, 5+2***AR**(1,1,1)) returns the same result as **J**(2, 3, 1) * (5+2***AR**(1,1,1)).

SHAPE Function**SHAPE**(*matrix*, *nrow*, *ncol*)

The **SHAPE** function creates a new matrix from data in **matrix**. The values **nrow** and **ncol** specify the number of rows and columns, respectively, in the new matrix. The **SHAPE** function produces the result matrix by traversing the argument matrix in row-major order until it reaches the specified number of elements. If necessary, the **SHAPE** function reuses elements.

For example, **SHAPE**({1 2 3, 4 5 6}, 3, 2) returns {1 2, 3 4, 5 6}; **SHAPE**({1 2 3, 4 5 6}, 5, 2) returns {1 2, 3 4, 5 6, 1 2, 3 4}; and **SHAPE**({1 2 3, 4 5 6}, 1, 4) returns {1 2 3 4}.

TEST Statement
TEST *restriction*, ..., *restriction* ;

The **TEST** statement performs the Wald test for the joint linear hypothesis that is specified in the statement. Each restriction specifies a linear hypothesis to be tested. If you specify more than one *restriction*, separate them with commas. Specify the *restrictions* in the same manner as in the **RESTRICT** statement. For information about how to define restriction by using matrix expressions, operators, and functions, see the section “**RESTRICT Statement**” on page 2425. You can specify any number of **TEST** statements.

To use the **TEST** statement, you need to know the form of the model. If you do not specify the **P=**, **Q=**, or **XLAG=** option or the **GARCH** statement, then the **TEST** statement is not applicable.

For information about the Wald test, see the section “**Granger Causality Test**” on page 2468.

The following is an example of the **TEST** statement for a bivariate ($k=2$) VAR(2) model:

```
proc varmax data=one;
  model y1 y2 / p=2;
  test AR(1,1,2) = 0, AR(2,1,2) = 0;
run;
```

After estimating the parameters, the **TEST** statement tests the null hypothesis that **AR**(1,1,2)=0 and **AR**(2,1,2)=0. Like the **RESTRICT** statement, the preceding **TEST** statement can be abbreviated as follows:

```
test AR(1,1,2) = AR(2,1,2) = 0;
```

or

```
test AR(1,1,2), AR(2,1,2);
```

Note that the following statements are different from the preceding statement:

```
test AR(1,1,2);
test AR(2,1,2);
```

These two TEST statements are to test two null hypotheses separately: one is $\mathbf{AR}(1,1,2)=0$, and the other is $\mathbf{AR}(2,1,2)=0$.

Details: VARMAX Procedure

Missing Values

The VARMAX procedure currently does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the MODEL statement variables. Observations at the beginning of the data set with missing values for any MODEL statement variables are not used or included in the output data set. At the end of the data set, observations can have dependent (endogenous) variables with missing values and independent (exogenous) variables with nonmissing values.

VARMAX Model

The vector autoregressive moving-average model with exogenous variables is called the VARMAX(p,q,s) model. The form of the model can be written as

$$\mathbf{y}_t = \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

where the output variables of interest, $\mathbf{y}_t = (y_{1t}, \dots, y_{kt})'$, can be influenced by other input variables, $\mathbf{x}_t = (x_{1t}, \dots, x_{rt})'$, which are determined outside of the system of interest. The variables \mathbf{y}_t are referred to as dependent, response, or endogenous variables, and the variables \mathbf{x}_t are referred to as independent, input, predictor, regressor, or exogenous variables. The unobserved noise variables, $\boldsymbol{\epsilon}_t = (\epsilon_{1t}, \dots, \epsilon_{kt})'$, are a vector white noise process.

The VARMAX(p,q,s) model can be written

$$\Phi(B)\mathbf{y}_t = \Theta^*(B)\mathbf{x}_t + \Theta(B)\boldsymbol{\epsilon}_t$$

where

$$\begin{aligned}\Phi(B) &= I_k - \Phi_1 B - \dots - \Phi_p B^p \\ \Theta^*(B) &= \Theta_0^* + \Theta_1^* B + \dots + \Theta_s^* B^s \\ \Theta(B) &= I_k - \Theta_1 B - \dots - \Theta_q B^q\end{aligned}$$

are matrix polynomials in B in the backshift operator, such that $B^i y_t = y_{t-i}$, the Φ_i and Θ_i are $k \times k$ matrices, and the Θ_i^* are $k \times r$ matrices.

The following assumptions are made:

- $E(\epsilon_t) = 0$, $E(\epsilon_t \epsilon_t') = \Sigma$, which is positive-definite, and $E(\epsilon_t \epsilon_s') = 0$ for $t \neq s$.
- For stationarity and invertibility of the VARMAX process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.
- The exogenous (independent) variables x_t are not correlated with residuals ϵ_t , $E(x_t \epsilon_t') = 0$. The exogenous variables can be stochastic or nonstochastic. When the exogenous variables are stochastic and their future values are unknown, forecasts of these future values are needed to forecast the future values of the endogenous (dependent) variables. On occasion, future values of the exogenous variables can be assumed to be known because they are deterministic variables. The VARMAX procedure assumes that the exogenous variables are nonstochastic if future values are available in the input data set. Otherwise, the exogenous variables are assumed to be stochastic and their future values are forecasted by assuming that they follow the VARMA(p, q) model, prior to forecasting the endogenous variables, where p and q are the same as in the VARMAX(p, q, s) model.

State-Space Representation

Another representation of the VARMAX(p, q, s) model is in the form of a state-variable or a state-space model, which consists of a state equation

$$z_t = F z_{t-1} + K x_t + G \epsilon_t$$

and an observation equation

$$y_t = H z_t$$

where

$$z_t = \begin{bmatrix} y_t \\ \vdots \\ y_{t-p+1} \\ x_t \\ \vdots \\ x_{t-s+1} \\ \epsilon_t \\ \vdots \\ \epsilon_{t-q+1} \end{bmatrix}, \quad K = \begin{bmatrix} \Theta_0^* \\ 0_{k \times r} \\ \vdots \\ 0_{k \times r} \\ I_r \\ 0_{r \times r} \\ \vdots \\ 0_{r \times r} \\ 0_{k \times r} \\ \vdots \\ 0_{k \times r} \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ 0_{k \times k} \\ \vdots \\ 0_{k \times k} \\ 0_{r \times k} \\ \vdots \\ 0_{r \times k} \\ I_{k \times k} \\ 0_{k \times k} \\ \vdots \\ 0_{k \times k} \end{bmatrix}$$

$$F = \begin{bmatrix} \Phi_1 & \cdots & \Phi_{p-1} & \Phi_p & \Theta_1^* & \cdots & \Theta_{s-1}^* & \Theta_s^* & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & I_r & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & I_r & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \dots, 0_{k \times k}, 0_{k \times r}, \dots, 0_{k \times r}, 0_{k \times k}, \dots, 0_{k \times k}]$$

On the other hand, it is assumed that \mathbf{x}_t follows a VARMA(p, q) model

$$\mathbf{x}_t = \sum_{i=1}^p A_i \mathbf{x}_{t-i} + \mathbf{a}_t - \sum_{i=1}^q C_i \mathbf{a}_{t-i}$$

The model can also be expressed as

$$A(B)\mathbf{x}_t = C(B)\mathbf{a}_t$$

where $A(B) = I_r - A_1 B - \cdots - A_p B^p$ and $C(B) = I_r - C_1 B - \cdots - C_q B^q$ are matrix polynomials in B , and the A_i and C_i are $r \times r$ matrices. Without loss of generality, the AR and MA orders can be taken to be the same as the VARMAX(p, q, s) model, and \mathbf{a}_t and ϵ_t are independent white noise processes.

Under suitable conditions such as stationarity, \mathbf{x}_t is represented by an infinite order moving-average process

$$\mathbf{x}_t = A(B)^{-1} C(B) \mathbf{a}_t = \Psi^x(B) \mathbf{a}_t = \sum_{j=0}^{\infty} \Psi_j^x \mathbf{a}_{t-j}$$

where $\Psi^x(B) = A(B)^{-1} C(B) = \sum_{j=0}^{\infty} \Psi_j^x B^j$.

The optimal minimum mean squared error (minimum MSE) i -step-ahead forecast of \mathbf{x}_{t+i} is

$$\begin{aligned} \mathbf{x}_{t+i|t} &= \sum_{j=i}^{\infty} \Psi_j^x \mathbf{a}_{t+i-j} \\ \mathbf{x}_{t+i|t+1} &= \mathbf{x}_{t+i|t} + \Psi_{i-1}^x \mathbf{a}_{t+1} \end{aligned}$$

For $i > q$,

$$\mathbf{x}_{t+i|t} = \sum_{j=1}^p A_j \mathbf{x}_{t+i-j|t}$$

The VARMAX(p, q, s) model has an absolutely convergent representation as

$$\begin{aligned} \mathbf{y}_t &= \Phi(B)^{-1} \Theta^*(B) \mathbf{x}_t + \Phi(B)^{-1} \Theta(B) \boldsymbol{\epsilon}_t \\ &= \Psi^*(B) \Psi^x(B) \mathbf{a}_t + \Phi(B)^{-1} \Theta(B) \boldsymbol{\epsilon}_t \\ &= V(B) \mathbf{a}_t + \Psi(B) \boldsymbol{\epsilon}_t \end{aligned}$$

or

$$\mathbf{y}_t = \sum_{j=0}^{\infty} V_j \mathbf{a}_{t-j} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1} \Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$, $\Psi^*(B) = \Phi(B)^{-1} \Theta^*(B)$, and $V(B) = \Psi^*(B) \Psi^x(B) = \sum_{j=0}^{\infty} V_j B^j$.

The optimal (minimum MSE) i -step-ahead forecast of \mathbf{y}_{t+i} is

$$\begin{aligned} \mathbf{y}_{t+i|t} &= \sum_{j=i}^{\infty} V_j \mathbf{a}_{t+i-j} + \sum_{j=i}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+i-j} \\ \mathbf{y}_{t+i|t+1} &= \mathbf{y}_{t+i|t} + V_{i-1} \mathbf{a}_{t+1} + \Psi_{i-1} \boldsymbol{\epsilon}_{t+1} \end{aligned}$$

for $i = 1, \dots, v$ with $v = \max(p, q + 1)$. For $i > q$,

$$\begin{aligned} \mathbf{y}_{t+i|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \mathbf{x}_{t+i|t} + \sum_{j=1}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \sum_{j=1}^p A_j \mathbf{x}_{t+i-j|t} + \sum_{j=1}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=1}^u (\Theta_0^* A_j + \Theta_j^*) \mathbf{x}_{t+i-j|t} \end{aligned}$$

where $u = \max(p, s)$.

Define $\Pi_j = \Theta_0^* A_j + \Theta_j^*$. For $i = v > q$ with $v = \max(p, q + 1)$, you obtain

$$\begin{aligned} \mathbf{y}_{t+v|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^u \Pi_j \mathbf{x}_{t+v-j|t} \quad \text{for } u \leq v \\ \mathbf{y}_{t+v|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^r \Pi_j \mathbf{x}_{t+v-j|t} \quad \text{for } u > v \end{aligned}$$

From the preceding relations, a state equation is

$$\mathbf{z}_{t+1} = F \mathbf{z}_t + K \mathbf{x}_t^* + G \boldsymbol{\epsilon}_{t+1}$$

and an observation equation is

$$y_t = H z_t$$

where

$$z_t = \begin{bmatrix} y_t \\ y_{t+1|t} \\ \vdots \\ y_{t+v-1|t} \\ x_t \\ x_{t+1|t} \\ \vdots \\ x_{t+v-1|t} \end{bmatrix}, \quad x_t^* = \begin{bmatrix} x_{t+v-u} \\ x_{t+v-u+1} \\ \vdots \\ x_{t-1} \end{bmatrix}, \quad e_{t+1} = \begin{bmatrix} a_{t+1} \\ \epsilon_{t+1} \end{bmatrix}$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 & \Pi_v & \Pi_{v-1} & \Pi_{v-2} & \cdots & \Pi_1 \\ 0 & 0 & 0 & \cdots & 0 & 0 & I_r & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & I_r & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & A_v & A_{v-1} & A_{v-2} & \cdots & A_1 \end{bmatrix}$$

$$K = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \Pi_u & \Pi_{u-1} & \cdots & \Pi_{v+1} \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}, \quad G = \begin{bmatrix} V_0 & I_k \\ V_1 & \Psi_1 \\ \vdots & \vdots \\ V_{v-1} & \Psi_{v-1} \\ I_r & 0_{r \times k} \\ \Psi_1^x & 0_{r \times k} \\ \vdots & \vdots \\ \Psi_{v-1}^x & 0_{r \times k} \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \dots, 0_{k \times k}, 0_{k \times r}, \dots, 0_{k \times r}]$$

Note that the matrix K and the input vector x_t^* are defined only when $u > v$.

Dynamic Simultaneous Equations Modeling

In the econometrics literature, the VARMAX(p, q, s) model is sometimes written in a form that is slightly different than the one shown in the previous section. This alternative form is referred to as a *dynamic simultaneous equations* model or a *dynamic structural equations* model.

Since $E(\epsilon_t \epsilon_t') = \Sigma$ is assumed to be positive-definite, there exists a lower triangular matrix A_0 with ones on the diagonals such that $A_0 \Sigma A_0' = \Sigma^d$, where Σ^d is a diagonal matrix with positive diagonal elements.

$$A_0 y_t = \sum_{i=1}^p A_i y_{t-i} + \sum_{i=0}^s C_i^* x_{t-i} + C_0 \epsilon_t - \sum_{i=1}^q C_i \epsilon_{t-i}$$

where $A_i = A_0 \Phi_i$, $C_i^* = A_0 \Theta_i^*$, $C_0 = A_0$, and $C_i = A_0 \Theta_i$.

As an alternative form,

$$A_0 y_t = \sum_{i=1}^p A_i y_{t-i} + \sum_{i=0}^s C_i^* x_{t-i} + a_t - \sum_{i=1}^q C_i a_{t-i}$$

where $A_i = A_0 \Phi_i$, $C_i^* = A_0 \Theta_i^*$, $C_i = A_0 \Theta_i A_0^{-1}$, and $a_t = C_0 \epsilon_t$ has a diagonal covariance matrix Σ^d . The PRINT=(DYNAMIC) option returns the parameter estimates that result from estimating the model in this form.

A dynamic simultaneous equations model involves a leading (lower triangular) coefficient matrix for y_t at lag 0 or a leading coefficient matrix for ϵ_t at lag 0. Such a representation of the VARMAX(p, q, s) model can be more useful in certain circumstances than the standard representation. From the linear combination of the dependent variables obtained by $A_0 y_t$, you can easily see the relationship between the dependent variables in the current time.

The following statements provide the dynamic simultaneous equations of the VAR(1) model.

```
proc iml;
    sig = {1.0  0.5, 0.5 1.25};
    phi = {1.2 -0.5, 0.6 0.3};
    /* simulate the vector time series */
    call varmasim(y, phi) sigma = sig n = 100 seed = 34657;
    cn = {'y1' 'y2'};
    create simull from y[colname=cn];
    append from y;
quit;

data simull;
    set simull;
    date = intnx('year', '01jan1900'd, _n_-1 );
    format date year4.;
run;

proc varmax data=simull;
    model y1 y2 / p=1 noint print=(dynamic);
run;
```

This is the same data set and model used in the section “[Getting Started: VARMAX Procedure](#)” on page 2372. You can compare the results of the VARMA model form and the dynamic simultaneous equations model form.

Figure 35.25 Dynamic Simultaneous Equations (DYNAMIC Option)

The VARMAX Procedure

Equation	Parameter	Estimate	Standard Error	t Value	Pr > t	Variable
y1	AR1_1_1	1.15977	0.05508	21.06	0.0001	y1(t-1)
	AR1_1_2	-0.51058	0.07140	-7.15	0.0001	y2(t-1)
y2	AR0_2_1	0.30845				y1(t)
	AR1_2_1	0.18861	0.05779	3.26	0.0015	y1(t-1)
	AR1_2_2	0.54247	0.07491	7.24	0.0001	y2(t-1)

In Figure 35.4 in the section “Getting Started: VARMAX Procedure” on page 2372, the covariance of ϵ_t estimated from the VARMAX model form is

$$\Sigma_{\epsilon} = \begin{pmatrix} 1.28875 & 0.39751 \\ 0.39751 & 1.41839 \end{pmatrix}$$

Figure 35.25 shows the results from estimating the model as a dynamic simultaneous equations model. By the decomposition of Σ_{ϵ} , you get a diagonal matrix (Σ_a) and a lower triangular matrix (A_0) such as $\Sigma_a = A_0 \Sigma_{\epsilon} A_0'$ where

$$\Sigma_a = \begin{pmatrix} 1.28875 & 0 \\ 0 & 1.29578 \end{pmatrix} \text{ and } A_0 = \begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix}$$

The lower triangular matrix (A_0) is shown in the left side of the simultaneous equations model. The parameter estimates in equations system are shown in the right side of the two-equations system.

The simultaneous equations model is written as

$$\begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix} y_t = \begin{pmatrix} 1.15977 & -0.51058 \\ 0.18861 & 0.54247 \end{pmatrix} y_{t-1} + a_t$$

The resulting two-equation system can be written as

$$\begin{aligned}y_{1t} &= 1.15977y_{1,t-1} - 0.51058y_{2,t-1} + a_{1t} \\y_{2t} &= 0.30845y_{1t} + 0.18861y_{1,t-1} + 0.54247y_{2,t-1} + a_{2t}\end{aligned}$$

Impulse Response Function

Simple Impulse Response Function (IMPULSE=SIMPLE Option)

The VARMAX(p,q,s) model has a convergent representation

$$\mathbf{y}_t = \Psi^*(B)\mathbf{x}_t + \Psi(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B) = \sum_{j=0}^{\infty} \Psi_j^* B^j$ and $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$.

The elements of the matrices Ψ_j from the operator $\Psi(B)$, called the impulse response, can be interpreted as the impact that a shock in one variable has on another variable. Let $\psi_{j,in}$ be the in^{th} element of Ψ_j at lag j , where i is the index for the impulse variable, and n is the index for the response variable (impulse \rightarrow response). For instance, $\psi_{j,11}$ is an impulse response to $y_{1t} \rightarrow y_{1t}$, and $\psi_{j,12}$ is an impulse response to $y_{1t} \rightarrow y_{2t}$.

Accumulated Impulse Response Function (IMPULSE=ACCUM Option)

The accumulated impulse response function is the cumulative sum of the impulse response function, $\Psi_l^a = \sum_{j=0}^l \Psi_j$.

Orthogonalized Impulse Response Function (IMPULSE=ORTH Option)

The MA representation of a VARMA(p,q) model with a standardized white noise innovation process offers another way to interpret a VARMA(p,q) model. Since Σ is positive-definite, there is a lower triangular matrix P such that $\Sigma = PP'$. The alternate MA representation of a VARMA(p,q) model is written as

$$\mathbf{y}_t = \Psi^o(B)\mathbf{u}_t$$

where $\Psi^o(B) = \sum_{j=0}^{\infty} \Psi_j^o B^j$, $\Psi_j^o = \Psi_j P$, and $\mathbf{u}_t = P^{-1}\boldsymbol{\epsilon}_t$.

The elements of the matrices Ψ_j^o , called the *orthogonal impulse response*, can be interpreted as the effects of the components of the standardized shock process \mathbf{u}_t on the process \mathbf{y}_t at lag j .

Impulse Response of Transfer Function (IMPULSX=SIMPLE Option)

The coefficient matrix Ψ_j^* from the transfer function operator $\Psi^*(B)$ can be interpreted as the effects that changes in the exogenous variables \mathbf{x}_t have on the output variable \mathbf{y}_t at lag j ; it is called an impulse response matrix in the transfer function.

Impulse Response of Transfer Function (IMPULSX=ACCUM Option)

The accumulated impulse response in the transfer function is the cumulative sum of the impulse response in the transfer function, $\Psi_l^{*a} = \sum_{j=0}^l \Psi_j^*$.

The asymptotic distributions of the impulse functions can be seen in the section “VAR and VARX Modeling” on page 2465.

The following statements provide the impulse response and the accumulated impulse response in the transfer function for a VARX(1,0) model.

```
proc varmax data=grunfeld plot=impulse;
  model y1-y3 = x1 x2 / p=1 lagmax=5
          printform=univariate
          print=(impulsx=(all) estimates);
run;
```

In Figure 35.26, the variables x_1 and x_2 are impulses and the variables y_1 , y_2 , and y_3 are responses. You can read the table matching the pairs of *impulse* \rightarrow *response* such as $x_1 \rightarrow y_1$, $x_1 \rightarrow y_2$, $x_1 \rightarrow y_3$, $x_2 \rightarrow y_1$, $x_2 \rightarrow y_2$, and $x_2 \rightarrow y_3$. In the pair of $x_1 \rightarrow y_1$, you can see the long-run responses of y_1 to an impulse in x_1 (the values are 1.69281, 0.35399, 0.09090, and so on for lag 0, lag 1, lag 2, and so on, respectively).

Figure 35.26 Impulse Response in Transfer Function (IMPULSX= Option)

Figure 35.29 shows the accumulated responses of y_1 , y_2 , and y_3 to a forecast error impulse in x_1 .

Figure 35.29 Plot of Accumulated Impulse Response in Transfer Function

The following statements provide the impulse response function, the accumulated impulse response function, and the orthogonalized impulse response function with their standard errors for a VAR(1) model. Parts of the VARMAX procedure output are shown in Figure 35.30, Figure 35.32, and Figure 35.34.

```
proc varmax data=simul1 plot=impulse;
  model y1 y2 / p=1 noint lagmax=5
           print=(impulse=(all))
           printform=univariate;
run;
```

Figure 35.30 is the output in a univariate format associated with the PRINT=(IMPULSE=) option for the impulse response function. The keyword STD stands for the standard errors of the elements. The matrix in terms of the lag 0 does not print since it is the identity. In Figure 35.30, the variables y1 and y2 of the first row are impulses, and the variables y1 and y2 of the first column are responses. You can read the table matching the *impulse* → *response* pairs, such as y1 → y1, y1 → y2, y2 → y1, and y2 → y2. For example, in the pair of y1 → y1 at lag 3, the response is 0.8055. This represents the impact on y1 of one-unit change in y1 after 3 periods. As the lag gets higher, you can see the long-run responses of y1 to an impulse in itself.

In Figure 35.4, there is a positive correlation between ε_{1t} and ε_{2t} . Therefore, shock in y1 can be accompanied by a shock in y2 in the same period. For example, in the pair of $y1_innovation \rightarrow y2$, you can see the long-run responses of y2 to an impulse in $y1_innovation$.

Figure 35.35 shows the orthogonalized responses of y_1 and y_2 to a forecast error impulse in y_1 with two standard errors.

Figure 35.35 Plot of Orthogonalized Impulse Response

Forecasting

The optimal (minimum MSE) l -step-ahead forecast of \mathbf{y}_{t+l} is

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^p \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+l-j|t} - \sum_{j=l}^q \Theta_j \boldsymbol{\epsilon}_{t+l-j}, \quad l \leq q$$

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^p \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+l-j|t}, \quad l > q$$

with $\mathbf{y}_{t+l-j|t} = \mathbf{y}_{t+l-j}$ and $\mathbf{x}_{t+l-j|t} = \mathbf{x}_{t+l-j}$ for $l \leq j$. For the forecasts $\mathbf{x}_{t+l-j|t}$, see the section “State-Space Representation” on page 2438.

Covariance Matrices of Prediction Errors without Exogenous (Independent) Variables

Under the stationarity assumption, the optimal (minimum MSE) l -step-ahead forecast of y_{t+l} has an infinite moving-average form, $y_{t+l|t} = \sum_{j=l}^{\infty} \Psi_j \epsilon_{t+l-j}$. The prediction error of the optimal l -step-ahead forecast is $e_{t+l|t} = y_{t+l} - y_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \epsilon_{t+l-j}$, with zero mean and covariance matrix,

$$\Sigma(l) = \text{Cov}(e_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi_j' = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$$

where $\Psi_j^o = \Psi_j P$ with a lower triangular matrix P such that $\Sigma = PP'$. Under the assumption of normality of the ϵ_t , the l -step-ahead prediction error $e_{t+l|t}$ is also normally distributed as multivariate $N(0, \Sigma(l))$. Hence, it follows that the diagonal elements $\sigma_{ii}^2(l)$ of $\Sigma(l)$ can be used, together with the point forecasts $y_{i,t+l|t}$, to construct l -step-ahead prediction intervals of the future values of the component series, $y_{i,t+l}$.

The following statements use the COVPE option to compute the covariance matrices of the prediction errors for a VAR(1) model. The parts of the VARMAX procedure output are shown in Figure 35.36 and Figure 35.37.

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=5
    printform=both
    print=(decompose(5) impulse=(all) covpe(5));
run;
```

Figure 35.36 is the output in a matrix format associated with the COVPE option for the prediction error covariance matrices.

Figure 35.36 Covariances of Prediction Errors (COVPE Option)

Covariance Matrices of Prediction Errors in the Presence of Exogenous (Independent) Variables

Exogenous variables can be both stochastic and nonstochastic (deterministic) variables. Considering the forecasts in the VARMAX(p, q, s) model, there are two cases.

When exogenous (independent) variables are stochastic (future values not specified):

As defined in the section “[State-Space Representation](#)” on page 2438, $\mathbf{y}_{t+l|t}$ has the representation

$$\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} V_j \mathbf{a}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and hence

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} V_j \mathbf{a}_{t+l-j} + \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Therefore, the covariance matrix of the l -step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} V_j \Sigma_a V_j' + \sum_{j=0}^{l-1} \Psi_j \Sigma_{\epsilon} \Psi_j'$$

where Σ_a is the covariance of the white noise series \mathbf{a}_t , and \mathbf{a}_t is the white noise series for the VARMA(p, q) model of exogenous (independent) variables, which is assumed not to be correlated with $\boldsymbol{\epsilon}_t$ or its lags.

When future exogenous (independent) variables are specified:

The optimal forecast $\mathbf{y}_{t+l|t}$ of \mathbf{y}_t conditioned on the past information and also on known future values $\mathbf{x}_{t+1}, \dots, \mathbf{x}_{t+l}$ can be represented as

$$\mathbf{y}_{t+l|t} = \sum_{j=0}^{\infty} \Psi_j^* \mathbf{x}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and the forecast error is

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Thus, the covariance matrix of the l -step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma_{\epsilon} \Psi_j'$$

Decomposition of Prediction Error Covariances

In the relation $\Sigma(l) = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$, the diagonal elements can be interpreted as providing a decomposition of the l -step-ahead prediction error covariance $\sigma_{ii}^2(l)$ for each component series y_{it} into contributions from the components of the standardized innovations $\boldsymbol{\epsilon}_t$.

If you denote the (i, n) th element of Ψ_j^o by $\psi_{j,in}$, the MSE of $y_{i,t+h|t}$ is

$$\text{MSE}(y_{i,t+h|t}) = E(y_{i,t+h} - y_{i,t+h|t})^2 = \sum_{j=0}^{l-1} \sum_{n=1}^k \psi_{j,in}^2$$

Note that $\sum_{j=0}^{l-1} \psi_{j,in}^2$ is interpreted as the contribution of innovations in variable n to the prediction error covariance of the l -step-ahead forecast of variable i .

The proportion, $\omega_{l,in}$, of the l -step-ahead forecast error covariance of variable i accounting for the innovations in variable n is

$$\omega_{l,in} = \sum_{j=0}^{l-1} \psi_{j,in}^2 / \text{MSE}(y_{i,t+h|t})$$

The following statements use the DECOMPOSE option to compute the decomposition of prediction error covariances and their proportions for a VAR(1) model:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint print=(decompose(15))
              printform=univariate;
run;
```

The proportions of decomposition of prediction error covariances of two variables are given in [Figure 35.38](#). The output explains that about 91.356% of the one-step-ahead prediction error covariances of the variable y_{2t} is accounted for by its own innovations and about 8.644% is accounted for by y_{1t} innovations.

Figure 35.38 Decomposition of Prediction Error Covariances (DECOMPOSE Option)

Proportions of Prediction Error Covariances by Variable			
Variable	Lead	y1	y2

	5	0.53549	0.46451

Forecasting of the Centered Series

If the CENTER option is specified, the sample mean vector is added to the forecast.

Forecasting of the Differenced Series

If dependent (endogenous) variables are differenced, the final forecasts and their prediction error covariances are produced by integrating those of the differenced series. However, if the PRIOR option is specified, the forecasts and their prediction error variances of the differenced series are produced.

Let \mathbf{z}_t be the original series with some appended zero values that correspond to the unobserved past observations. Let $\Delta(B)$ be the $k \times k$ matrix polynomial in the backshift operator that corresponds to the differencing specified by the MODEL statement. The off-diagonal elements of Δ_i are zero, and the diagonal elements can be different. Then $\mathbf{y}_t = \Delta(B)\mathbf{z}_t$.

This gives the relationship

$$\mathbf{z}_t = \Delta^{-1}(B)\mathbf{y}_t = \sum_{j=0}^{\infty} \Lambda_j \mathbf{y}_{t-j}$$

where $\Delta^{-1}(B) = \sum_{j=0}^{\infty} \Lambda_j B^j$ and $\Lambda_0 = I_k$.

The l -step-ahead prediction of \mathbf{z}_{t+l} is

$$\mathbf{z}_{t+l|t} = \sum_{j=0}^{l-1} \Lambda_j \mathbf{y}_{t+l-j|t} + \sum_{j=l}^{\infty} \Lambda_j \mathbf{y}_{t+l-j}$$

The l -step-ahead prediction error of \mathbf{z}_{t+l} is

$$\sum_{j=0}^{l-1} \Lambda_j (\mathbf{y}_{t+l-j} - \mathbf{y}_{t+l-j|t}) = \sum_{j=0}^{l-1} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right) \boldsymbol{\epsilon}_{t+l-j}$$

Letting $\Sigma_z(0) = 0$, the covariance matrix of the l -step-ahead prediction error of \mathbf{z}_{t+l} , $\Sigma_z(l)$, is

$$\begin{aligned}\Sigma_z(l) &= \sum_{j=0}^{l-1} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right) \Sigma_\epsilon \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right)' \\ &= \Sigma_z(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right) \Sigma_\epsilon \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right)'\end{aligned}$$

If there are stochastic exogenous (independent) variables, the covariance matrix of the l -step-ahead prediction error of \mathbf{z}_{t+l} , $\Sigma_z(l)$, is

$$\begin{aligned}\Sigma_z(l) &= \Sigma_z(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right) \Sigma_\epsilon \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right)' \\ &\quad + \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j} \right) \Sigma_a \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j} \right)'\end{aligned}$$

Tentative Order Selection

Sample Cross-Covariance and Cross-Correlation Matrices

Given a stationary multivariate time series \mathbf{y}_t , cross-covariance matrices are

$$\Gamma(l) = E[(\mathbf{y}_t - \boldsymbol{\mu})(\mathbf{y}_{t+l} - \boldsymbol{\mu})']$$

where $\boldsymbol{\mu} = E(\mathbf{y}_t)$, and cross-correlation matrices are

$$\rho(l) = D^{-1} \Gamma(l) D^{-1}$$

where D is a diagonal matrix with the standard deviations of the components of \mathbf{y}_t on the diagonal.

The sample cross-covariance matrix at lag l , denoted as $C(l)$, is computed as

$$\hat{\Gamma}(l) = C(l) = \frac{1}{T} \sum_{t=1}^{T-l} \tilde{\mathbf{y}}_t \tilde{\mathbf{y}}_{t+l}'$$

where $\tilde{\mathbf{y}}_t$ is the centered data and T is the number of nonmissing observations. Thus, $\hat{\Gamma}(l)$ has (i, j) th element $\hat{\gamma}_{ij}(l) = c_{ij}(l)$. The sample cross-correlation matrix at lag l is computed as

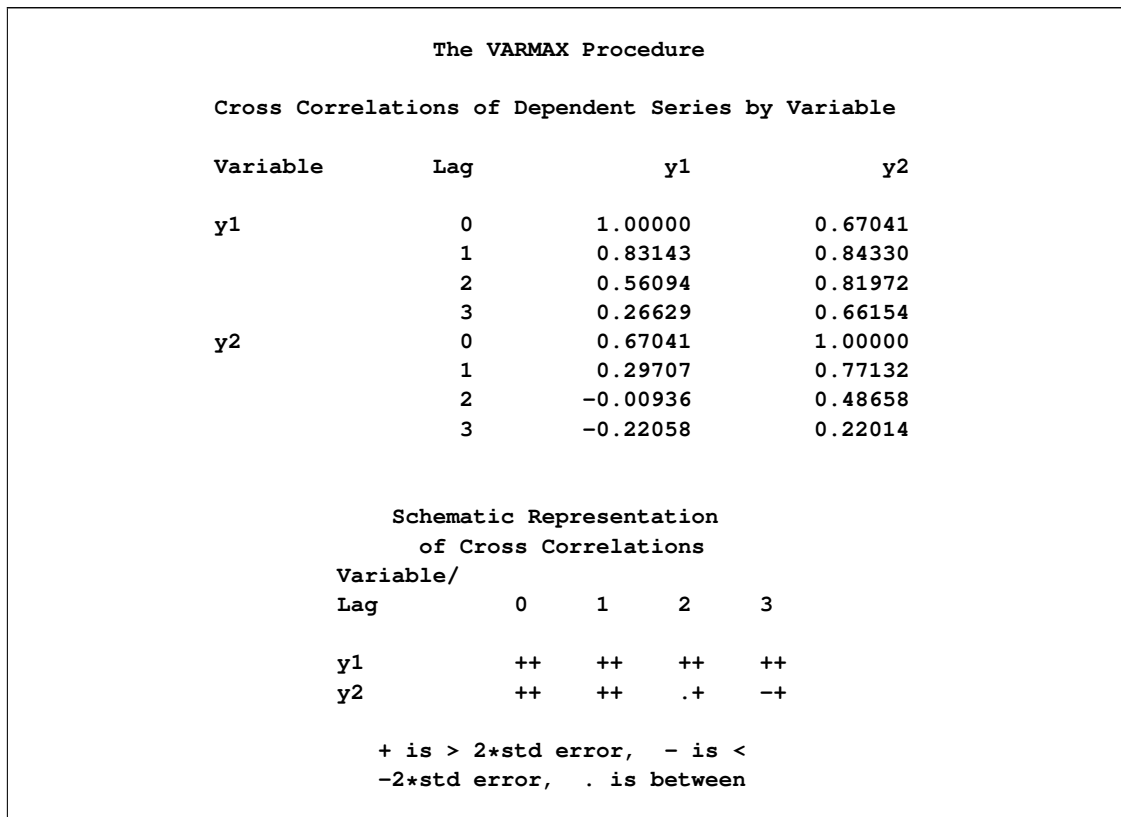

$$\hat{\rho}_{ij}(l) = c_{ij}(l) / [c_{ii}(0)c_{jj}(0)]^{1/2}, \quad i, j = 1, \dots, k$$

The following statements use the CORRY option to compute the sample cross-correlation matrices and their summary indicator plots in terms of +, −, and ·, where + indicates significant positive cross-correlations, − indicates significant negative cross-correlations, and · indicates insignificant cross-correlations.

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3 print=(corry)
           printform=univariate;
run;
```

Figure 35.39 shows the sample cross-correlation matrices of y_{1t} and y_{2t} . As shown, the sample autocorrelation functions for each variable decay quickly, but are significant with respect to two standard errors.

Figure 35.39 Cross-Correlations (CORRY Option)

Partial Autoregressive Matrices

For each $m = 1, 2, \dots, p$ you can define a sequence of matrices Φ_{mm} , which is called the partial autoregression matrices of lag m , as the solution for Φ_{mm} to the Yule-Walker equations of order m ,

$$\Gamma(l) = \sum_{i=1}^m \Gamma(l-i) \Phi'_{im}, \quad l = 1, 2, \dots, m$$

The sequence of the partial autoregression matrices Φ_{mm} of order m has the characteristic property that if the process follows the $AR(p)$, then $\Phi_{pp} = \Phi_p$ and $\Phi_{mm} = 0$ for $m > p$. Hence, the matrices Φ_{mm} have the cutoff property for a $VAR(p)$ model, and so they can be useful in the identification of the order of a pure VAR model.

The following statements use the PARCOEF option to compute the partial autoregression matrices:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
    printform=univariate
    print=(corry parcoef pcorr
      pcancorr roots);
run;
```

Figure 35.40 shows that the model can be obtained by an AR order $m = 1$ since partial autoregression matrices are insignificant after lag 1 with respect to two standard errors. The matrix for lag 1 is the same as the Yule-Walker autoregressive matrix.

Figure 35.40 Partial Autoregression Matrices (PARCOEF Option)

Partial Correlation Matrices

Define the forward autoregression

$$y_t = \sum_{i=1}^{m-1} \Phi_{i,m-1} y_{t-i} + \mathbf{u}_{m,t}$$

and the backward autoregression

$$y_{t-m} = \sum_{i=1}^{m-1} \Phi_{i,m-1}^* y_{t-m+i} + \mathbf{u}_{m,t-m}^*$$

The matrices $P(m)$ defined by Ansley and Newbold (1979) are given by

$$P(m) = \Sigma_{m-1}^{*1/2} \Phi_{mm}' \Sigma_{m-1}^{-1/2}$$

where

$$\Sigma_{m-1} = \text{Cov}(\mathbf{u}_{m,t}) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(-i) \Phi_{i,m-1}'$$

and

$$\Sigma_{m-1}^* = \text{Cov}(\mathbf{u}_{m,t-m}^*) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(m-i) \Phi_{m-i,m-1}^{*'}.$$

$P(m)$ are the partial cross-correlation matrices at lag m between the elements of y_t and y_{t-m} , given $y_{t-1}, \dots, y_{t-m+1}$. The matrices $P(m)$ have the cutoff property for a VAR(p) model, and so they can be useful in the identification of the order of a pure VAR structure.

The following statements use the PCORR option to compute the partial cross-correlation matrices:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
           print=(pcorr)
           printform=univariate;
run;
```

The partial cross-correlation matrices in [Figure 35.41](#) are insignificant after lag 1 with respect to two standard errors. This indicates that an AR order of $m = 1$ can be an appropriate choice.

Figure 35.41 Partial Correlations (PCORR Option)

Partial Canonical Correlation Matrices

The partial canonical correlations at lag m between the vectors \mathbf{y}_t and \mathbf{y}_{t-m} , given $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$, are $1 \geq \rho_1(m) \geq \rho_2(m) \geq \dots \geq \rho_k(m)$. The partial canonical correlations are the canonical correlations between the residual series $\mathbf{u}_{m,t}$ and $\mathbf{u}_{m,t-m}^*$, where $\mathbf{u}_{m,t}$ and $\mathbf{u}_{m,t-m}^*$ are defined in the previous section. Thus, the squared partial canonical correlations $\rho_i^2(m)$ are the eigenvalues of the matrix

$$\{\text{Cov}(\mathbf{u}_{m,t})\}^{-1} \text{E}(\mathbf{u}_{m,t} \mathbf{u}_{m,t-m}^{*'}) \{\text{Cov}(\mathbf{u}_{m,t-m}^*)\}^{-1} \text{E}(\mathbf{u}_{m,t-m}^* \mathbf{u}_{m,t}') = \Phi_{mm}' \Phi_{mm}'$$

It follows that the test statistic to test for $\Phi_m = 0$ in the VAR model of order $m > p$ is approximately

$$(T - m) \text{tr} \{\Phi_{mm}' \Phi_{mm}'\} \approx (T - m) \sum_{i=1}^k \rho_i^2(m)$$

and has an asymptotic chi-square distribution with k^2 degrees of freedom for $m > p$.

The following statements use the PCANCORR option to compute the partial canonical correlations:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3 print=(pcancorr);
run;
```

Figure 35.42 shows that the partial canonical correlations $\rho_i(m)$ between y_t and y_{t-m} are $\{0.918, 0.773\}$, $\{0.092, 0.018\}$, and $\{0.109, 0.011\}$ for lags $m = 1$ to 3. After lag $m = 1$, the partial canonical correlations are insignificant with respect to the 0.05 significance level, indicating that an AR order of $m = 1$ can be an appropriate choice.

Figure 35.42 Partial Canonical Correlations (PCANCORR Option)

The VARMAX Procedure					
Partial Canonical Correlations					
Lag	Correlation1	Correlation2	DF	Chi-Square	Pr > ChiSq
1	0.91783	0.77335	4	142.61	<.0001
2	0.09171	0.01816	4	0.86	0.9307
3	0.10861	0.01078	4	1.16	0.8854

The Minimum Information Criterion (MINIC) Method

The minimum information criterion (MINIC) method can tentatively identify the orders of a VARMA(p, q) process (Spliid 1983; Koreisha and Pukkila 1989; Quinn 1980). The first step of this method is to obtain estimates of the innovations series, ϵ_t , from the VAR(p_ϵ), where p_ϵ is chosen sufficiently large. The choice of the autoregressive order, p_ϵ , is determined by use of a selection criterion. From the selected VAR(p_ϵ) model, you obtain estimates of residual series

$$\tilde{\epsilon}_t = y_t - \sum_{i=1}^{p_\epsilon} \hat{\Phi}_i^{p_\epsilon} y_{t-i} - \hat{\delta}^{p_\epsilon}, \quad t = p_\epsilon + 1, \dots, T$$

In the second step, you select the order (p, q) of the VARMA model for p in $(p_{min} : p_{max})$ and q in $(q_{min} : q_{max})$

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} - \sum_{i=1}^q \Theta_i \tilde{\epsilon}_{t-i} + \epsilon_t$$

which minimizes a selection criterion like SBC or HQ.

The following statements use the MINIC= option to compute a table that contains the information criterion associated with various AR and MA orders:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint minic=(p=3 q=3);
run;
```

Figure 35.43 shows the output associated with the MINIC= option. The criterion takes the smallest value at AR order 1.

Figure 35.43 MINIC= Option

The VARMAX Procedure				
Minimum Information Criterion Based on AICC				
Lag	MA 0	MA 1	MA 2	MA 3
AR 0	3.3574947	3.0331352	2.7080996	2.3049869
AR 1	0.5544431	0.6146887	0.6771732	0.7517968
AR 2	0.6369334	0.6729736	0.7610413	0.8481559
AR 3	0.7235629	0.7551756	0.8053765	0.8654079

VAR and VARX Modeling

The p th-order VAR process is written as

$$y_t - \mu = \sum_{i=1}^p \Phi_i (y_{t-i} - \mu) + \epsilon_t \quad \text{or} \quad \Phi(B)(y_t - \mu) = \epsilon_t$$

with $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$.

Equivalently, it can be written as

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \epsilon_t \quad \text{or} \quad \Phi(B)y_t = \delta + \epsilon_t$$

with $\delta = (I_k - \sum_{i=1}^p \Phi_i)\mu$.

Stationarity

For stationarity, the VAR process must be expressible in the convergent causal infinite MA form as

$$y_t = \mu + \sum_{j=0}^{\infty} \Psi_j \epsilon_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1} = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\sum_{j=0}^{\infty} \|\Psi_j\| < \infty$, where $\|A\|$ denotes a norm for the matrix A such as $\|A\|^2 = \text{tr}\{A' A\}$. The matrix Ψ_j can be recursively obtained from the relation $\Phi(B)\Psi(B) = I$; it is

$$\Psi_j = \Phi_1 \Psi_{j-1} + \Phi_2 \Psi_{j-2} + \cdots + \Phi_p \Psi_{j-p}$$

where $\Psi_0 = I_k$ and $\Psi_j = 0$ for $j < 0$.

The stationarity condition is satisfied if all roots of $|\Phi(z)| = 0$ are outside of the unit circle. The stationarity condition is equivalent to the condition in the corresponding VAR(1) representation, $\mathbf{Y}_t = \Phi \mathbf{Y}_{t-1} + \boldsymbol{\epsilon}_t$, that all eigenvalues of the $k p \times k p$ companion matrix Φ be less than one in absolute value, where $\mathbf{Y}_t = (\mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1})'$, $\boldsymbol{\epsilon}_t = (\boldsymbol{\epsilon}'_t, 0', \dots, 0')'$, and

$$\Phi = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

If the stationarity condition is not satisfied, a nonstationary model (a differenced model or an error correction model) might be more appropriate.

The following statements estimate a VAR(1) model and use the ROOTS option to compute the characteristic polynomial roots:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint print=(roots);
run;
```

Figure 35.44 shows the output associated with the ROOTS option, which indicates that the series is stationary since the modulus of the eigenvalue is less than one.

Figure 35.44 Stationarity (ROOTS Option)

The VARMAX Procedure

2	0.77238	-0.35899	0.8517	-0.4351	-24.9284

Parameter Estimation

Consider the stationary VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_{-p+1}, \dots, \mathbf{y}_0$ are assumed to be available (for convenience of notation). This can be represented by the general form of the multivariate linear model,

$$\mathbf{Y} = \mathbf{X}\mathbf{B} + \mathbf{E} \quad \text{or} \quad \mathbf{y} = (\mathbf{X} \otimes \mathbf{I}_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned}
 Y &= (\mathbf{y}_1, \dots, \mathbf{y}_T)' \\
 B &= (\boldsymbol{\delta}, \Phi_1, \dots, \Phi_p)' \\
 X &= (X_0, \dots, X_{T-1})' \\
 X_t &= (1, \mathbf{y}_t', \dots, \mathbf{y}_{t-p+1}')' \\
 E &= (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)' \\
 \mathbf{y} &= \text{vec}(Y') \\
 \boldsymbol{\beta} &= \text{vec}(B') \\
 \mathbf{e} &= \text{vec}(E')
 \end{aligned}$$

with vec denoting the column stacking operator.

The conditional least squares estimator of $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = ((X'X)^{-1}X' \otimes I_k)\mathbf{y}$$

and the estimate of Σ is

$$\hat{\Sigma} = (T - (kp + 1))^{-1} \sum_{t=1}^T \hat{\boldsymbol{\epsilon}}_t \hat{\boldsymbol{\epsilon}}_t'$$

where $\hat{\boldsymbol{\epsilon}}_t$ is the residual vectors. Consistency and asymptotic normality of the LS estimator are that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

where $X'X/T$ converges in probability to Γ_p and \xrightarrow{d} denotes convergence in distribution.

The (conditional) maximum likelihood estimator in the VAR(p) model is equal to the (conditional) least squares estimator on the assumption of normality of the error vectors.

Asymptotic Distributions of Impulse Response Functions

As before, vec denotes the column stacking operator and vech is the corresponding operator that stacks the elements on and below the diagonal. For any $k \times k$ matrix A , the commutation matrix K_k is defined as $K_k \text{vec}(A) = \text{vec}(A')$; the duplication matrix D_k is defined as $D_k \text{vech}(A) = \text{vec}(A)$; the elimination matrix L_k is defined as $L_k \text{vec}(A) = \text{vech}(A)$.

The asymptotic distribution of the impulse response function (Lütkepohl 1993) is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G_j') \quad j = 1, 2, \dots$$

where $\Sigma_{\boldsymbol{\beta}} = \Gamma_p^{-1} \otimes \Sigma$ and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{J}(\boldsymbol{\Phi}')^{j-1-i} \otimes \Psi_i$$

where $\mathbf{J} = [I_k, 0, \dots, 0]$ is a $k \times kp$ matrix and $\boldsymbol{\Phi}$ is a $kp \times kp$ companion matrix.

The asymptotic distribution of the accumulated impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_l^a - \Psi_l^a) \xrightarrow{d} N(0, F_l \Sigma_{\beta} F_l') \quad l = 1, 2, \dots$$

where $F_l = \sum_{j=1}^l G_j$.

The asymptotic distribution of the orthogonalized impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j^o - \Psi_j^o) \xrightarrow{d} N(0, C_j \Sigma_{\beta} C_j' + \bar{C}_j \Sigma_{\sigma} \bar{C}_j') \quad j = 0, 1, 2, \dots$$

where $C_0 = 0$, $C_j = (\Psi_0^{o'} \otimes I_k) G_j$, $\bar{C}_j = (I_k \otimes \Psi_j) H$,

$$H = \frac{\partial \text{vec}(\Psi_0^o)}{\partial \sigma'} = L_k' \{L_k(I_{k^2} + K_k)(\Psi_0^o \otimes I_k)L_k'\}^{-1}$$

and $\Sigma_{\sigma} = 2D_k^+(\Sigma \otimes \Sigma)D_k^{+'}$ with $D_k^+ = (D_k' D_k)^{-1} D_k'$ and $\sigma = \text{vech}(E_{\epsilon})$.

Granger Causality Test

Let \mathbf{y}_t be arranged and partitioned in subgroups \mathbf{y}_{1t} and \mathbf{y}_{2t} with dimensions k_1 and k_2 , respectively ($k = k_1 + k_2$); that is, $\mathbf{y}_t = (\mathbf{y}_{1t}', \mathbf{y}_{2t}')'$ with the corresponding white noise process $\epsilon_t = (\epsilon_{1t}', \epsilon_{2t}')'$. Consider the VAR(p) model with partitioned coefficients $\Phi_{ij}(B)$ for $i, j = 1, 2$ as follows:

$$\begin{bmatrix} \Phi_{11}(B) & \Phi_{12}(B) \\ \Phi_{21}(B) & \Phi_{22}(B) \end{bmatrix} \begin{bmatrix} \mathbf{y}_{1t} \\ \mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \delta_1 \\ \delta_2 \end{bmatrix} + \begin{bmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{bmatrix}$$

The variables \mathbf{y}_{1t} are said to cause \mathbf{y}_{2t} , but \mathbf{y}_{2t} do not cause \mathbf{y}_{1t} if $\Phi_{12}(B) = 0$. The implication of this model structure is that future values of the process \mathbf{y}_{1t} are influenced only by its own past and not by the past of \mathbf{y}_{2t} , where future values of \mathbf{y}_{2t} are influenced by the past of both \mathbf{y}_{1t} and \mathbf{y}_{2t} . If the future \mathbf{y}_{1t} are not influenced by the past values of \mathbf{y}_{2t} , then it can be better to model \mathbf{y}_{1t} separately from \mathbf{y}_{2t} .

Consider testing $H_0: C\beta = c$, where C is a $s \times (k^2 p + k)$ matrix of rank s and c is an s -dimensional vector where $s = k_1 k_2 p$. Assuming that

$$\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

you get the Wald statistic

$$T(C\hat{\beta} - c)'[C(\hat{\Gamma}_p^{-1} \otimes \hat{\Sigma})C']^{-1}(C\hat{\beta} - c) \xrightarrow{d} \chi^2(s)$$

For the Granger causality test, the matrix C consists of zeros or ones and c is the zero vector. See Lütkepohl (1993) for more details of the Granger causality test.

VARX Modeling

The vector autoregressive model with exogenous variables is called the VARX(p, s) model. The form of the VARX(p, s) model can be written as

$$\mathbf{y}_t = \delta + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$Y = XB + E \text{ or } y = (X \otimes I_k)\beta + e$$

where

$$\begin{aligned} Y &= (y_1, \dots, y_T)' \\ B &= (\delta, \Phi_1, \dots, \Phi_p, \Theta_0^*, \dots, \Theta_s^*)' \\ X &= (X_0, \dots, X_{T-1})' \\ X_t &= (1, y_t', \dots, y_{t-p+1}', x_{t+1}', \dots, x_{t-s+1}')' \\ E &= (\epsilon_1, \dots, \epsilon_T)' \\ y &= \text{vec}(Y') \\ \beta &= \text{vec}(B') \\ e &= \text{vec}(E') \end{aligned}$$

The conditional least squares estimator of β can be obtained by using the same method in a VAR(p) modeling. If the multivariate linear model has different independent variables that correspond to dependent variables, the SUR (seemingly unrelated regression) method is used to improve the regression estimates.

The following example fits the ordinary regression model:

```
proc varmax data=one;
  model y1-y3 = x1-x5;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:

```
proc reg data=one;
  model y1 = x1-x5;
  model y2 = x1-x5;
  model y3 = x1-x5;
run;
```

The following example fits the second-order lagged regression model:

```
proc varmax data=two;
  model y1 y2 = x / xlag=2;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:

```
data three;
  set two;
  xlag1 = lag1(x);
  xlag2 = lag2(x);
run;

proc reg data=three;
  model y1 = x xlag1 xlag2;
  model y2 = x xlag1 xlag2;
run;
```

The following example fits the ordinary regression model with different regressors:

```
proc varmax data=one;
  model y1 = x1-x3, y2 = x2 x3;
run;
```

This is equivalent to the following SYSLIN procedure statements:

```
proc syslin data=one vardef=df sur;
  endogenous y1 y2;
  model y1 = x1-x3;
  model y2 = x2 x3;
run;
```

From the output in [Figure 35.20](#) in the section “Getting Started: VARMAX Procedure” on page 2372, you can see that the parameters, XL0_1_2, XL0_2_1, XL0_3_1, and XL0_3_2 associated with the exogenous variables, are not significant. The following example fits the VARX(1,0) model with different regressors:

```
proc varmax data=grunfeld;
  model y1 = x1, y2 = x2, y3 / p=1 print=(estimates);
run;
```

Figure 35.45 Parameter Estimates for the VARX(1, 0) Model

The VARMAX Procedure				
XLag				
Lag	Variable	x1	x2	
0	y1	1.83231	—	
	y2	—	2.42110	
	y3	—	—	

As you can see in [Figure 35.45](#), the symbol ‘—’ in the elements of matrix corresponds to endogenous variables that do not take the denoted exogenous variables.

Bayesian VAR and VARX Modeling

Consider the VAR(p) model

$$y_t = \delta + \Phi_1 y_{t-1} + \cdots + \Phi_p y_{t-p} + \epsilon_t$$

or

$$y = (X \otimes I_k) \beta + e$$

When the parameter vector β has a prior multivariate normal distribution with known mean β^* and covariance matrix V_β , the prior density is written as

$$f(\beta) = \left(\frac{1}{2\pi}\right)^{k^2 p/2} |V_\beta|^{-1/2} \exp\left[-\frac{1}{2}(\beta - \beta^*)' V_\beta^{-1} (\beta - \beta^*)\right]$$

The likelihood function for the Gaussian process becomes

$$\begin{aligned} \ell(\beta|\mathbf{y}) &= \left(\frac{1}{2\pi}\right)^{kT/2} |I_T \otimes \Sigma|^{-1/2} \times \\ &\quad \exp\left[-\frac{1}{2}(\mathbf{y} - (X \otimes I_k)\beta)' (I_T \otimes \Sigma^{-1})(\mathbf{y} - (X \otimes I_k)\beta)\right] \end{aligned}$$

Therefore, the posterior density is derived as

$$f(\beta|\mathbf{y}) \propto \exp\left[-\frac{1}{2}(\beta - \bar{\beta})' \bar{\Sigma}_\beta^{-1} (\beta - \bar{\beta})\right]$$

where the posterior mean is

$$\bar{\beta} = [V_\beta^{-1} + (X'X \otimes \Sigma^{-1})]^{-1} [V_\beta^{-1} \beta^* + (X' \otimes \Sigma^{-1})\mathbf{y}]$$

and the posterior covariance matrix is

$$\bar{\Sigma}_\beta = [V_\beta^{-1} + (X'X \otimes \Sigma^{-1})]^{-1}$$

In practice, the prior mean β^* and the prior variance V_β need to be specified. If all the parameters are considered to shrink toward zero, the null prior mean should be specified. According to Litterman (1986), the prior variance can be given by

$$v_{ij}(l) = \begin{cases} (\lambda/l)^2 & \text{if } i = j \\ (\lambda\theta\sigma_{ii}/l\sigma_{jj})^2 & \text{if } i \neq j \end{cases}$$

where $v_{ij}(l)$ is the prior variance of the (i, j) th element of Φ_l , λ is the prior standard deviation of the diagonal elements of Φ_l , θ is a constant in the interval $(0, 1)$, and σ_{ii}^2 is the i th diagonal element of Σ . The deterministic terms have diffused prior variance. In practice, you replace the σ_{ii}^2 by the diagonal element of the ML estimator of Σ in the nonconstrained model.

For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + \phi_{1,11}y_{1,t-1} + \phi_{1,12}y_{2,t-1} + \phi_{2,11}y_{1,t-2} + \phi_{2,12}y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + \phi_{1,21}y_{1,t-1} + \phi_{1,22}y_{2,t-1} + \phi_{2,21}y_{1,t-2} + \phi_{2,22}y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

with the prior covariance matrix

$$V_\beta = \text{Diag} \left(\begin{array}{c} \infty, \lambda^2, (\lambda\theta\sigma_1/\sigma_2)^2, (\lambda/2)^2, (\lambda\theta\sigma_1/2\sigma_2)^2, \\ \infty, (\lambda\theta\sigma_2/\sigma_1)^2, \lambda^2, (\lambda\theta\sigma_2/2\sigma_1)^2, (\lambda/2)^2 \end{array} \right)$$

For the Bayesian estimation of integrated systems, the prior mean is set to the first lag of each variable equal to one in its own equation and all other coefficients at zero. For example, for a bivariate BVAR(2) model,

$$\begin{aligned}y_{1t} &= 0 + 1 y_{1,t-1} + 0 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{1t} \\y_{2t} &= 0 + 0 y_{1,t-1} + 1 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{2t}\end{aligned}$$

Forecasting of BVAR Modeling

The mean squared error (MSE) is used to measure forecast accuracy (Litterman 1986). The MSE of the s -step-ahead forecast is

$$MSE_s = \frac{1}{J-s+1} \sum_{j=1}^{J-s+1} (A_{t_j} - F_{t_j}^s)^2$$

where J is the number specified by NREP= option, t_j is the time index of the observation to be forecasted in repetition j , A_{t_j} is the actual value at time t_j , and $F_{t_j}^s$ is the forecast made s periods earlier.

Bayesian VARX Modeling

The Bayesian vector autoregressive model with exogenous variables is called the BVARX(p,s) model. The form of the BVARX(p,s) model can be written as

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$y = (X \otimes I_k) \beta + e$$

The prior means for the AR coefficients are the same as those specified in BVAR(p). The prior means for the exogenous coefficients are set to zero.

Some examples of the Bayesian VARX model are as follows:

```
model y1 y2 = x1 / p=1 xlag=1 prior;

model y1 y2 = x1 / p=(1 3) xlag=1 nocurrentx
      prior=(lambda=0.9 theta=0.1);
```

VARMA and VARMAX Modeling

A zero-mean VARMA(p, q) process is written as

$$\mathbf{y}_t = \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$ and $\Theta(B) = I_k - \sum_{i=1}^q \Theta_i B^i$.

Stationarity and Invertibility

For stationarity and invertibility of the VARMA process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.

Parameter Estimation

Under the assumption of normality of the $\boldsymbol{\epsilon}_t$ with zero mean vector and nonsingular covariance matrix Σ , the conditional (approximate) log-likelihood function of a zero-mean VARMA(p, q) model is considered.

Define $Y = (\mathbf{y}_1, \dots, \mathbf{y}_T)'$ and $E = (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)'$ with $B^i Y = (\mathbf{y}_{1-i}, \dots, \mathbf{y}_{T-i})'$ and $B^i E = (\boldsymbol{\epsilon}_{1-i}, \dots, \boldsymbol{\epsilon}_{T-i})'$; define $\mathbf{y} = \text{vec}(Y')$ and $\mathbf{e} = \text{vec}(E')$. Then

$$\mathbf{y} - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i \mathbf{y} = \mathbf{e} - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i \mathbf{e}$$

where $B^i \mathbf{y} = \text{vec}[(B^i Y)']$ and $B^i \mathbf{e} = \text{vec}[(B^i E)']$.

Then, the conditional (approximate) log-likelihood function can be written as follows (Reinsel 1997):

$$\begin{aligned} \ell &= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \sum_{t=1}^T \boldsymbol{\epsilon}_t' \Sigma^{-1} \boldsymbol{\epsilon}_t \\ &= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \mathbf{w}' \Theta'^{-1} (I_T \otimes \Sigma^{-1}) \Theta^{-1} \mathbf{w} \end{aligned}$$

where $\mathbf{w} = \mathbf{y} - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i \mathbf{y}$, and Θ is such that $\mathbf{e} - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i \mathbf{e} = \Theta \mathbf{e}$.

For the exact log-likelihood function of a VARMA(p, q) model, the Kalman filtering method is used for transforming the VARMA process into the state-space form (Reinsel 1997).

The state-space form of the zero-mean VARMA(p, q) model consists of a state equation

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + G \boldsymbol{\epsilon}_t$$

and an observation equation

$$\mathbf{y}_t = H \mathbf{z}_t$$

where for $v = \max(p, q + 1)$

$$\mathbf{z}_t = (\mathbf{y}'_t, \mathbf{y}'_{t+1|t}, \dots, \mathbf{y}'_{t+v-1|t})'$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ \Psi_1 \\ \vdots \\ \Psi_{v-1} \end{bmatrix}$$

and

$$H = [I_k, 0, \dots, 0]$$

The Kalman filtering approach is used for evaluation of the likelihood function. The updating equation is

$$\hat{\mathbf{z}}_{t|t} = \hat{\mathbf{z}}_{t|t-1} + K_t \boldsymbol{\epsilon}_{t|t-1}$$

where

$$K_t = P_{t|t-1} H' [H P_{t|t-1} H']^{-1}$$

The prediction equation is

$$\hat{\mathbf{z}}_{t|t-1} = F \hat{\mathbf{z}}_{t-1|t-1}, \quad P_{t|t-1} = F P_{t-1|t-1} F' + G \Sigma G'$$

where $P_{t|t} = [I - K_t H] P_{t|t-1}$ for $t = 1, 2, \dots, n$.

The log-likelihood function can be expressed as

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |\Sigma_{t|t-1}| + (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})' \Sigma_{t|t-1}^{-1} (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})]$$

where $\hat{\mathbf{y}}_{t|t-1}$ and $\Sigma_{t|t-1}$ are determined recursively from the Kalman filter procedure. To construct the likelihood function from Kalman filtering, you obtain $\hat{\mathbf{y}}_{t|t-1} = H \hat{\mathbf{z}}_{t|t-1}$, $\hat{\boldsymbol{\epsilon}}_{t|t-1} = \mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1}$, and $\Sigma_{t|t-1} = H P_{t|t-1} H'$.

Define the vector $\boldsymbol{\beta}$ as

$$\boldsymbol{\beta} = (\phi'_1, \dots, \phi'_p, \theta'_1, \dots, \theta'_q, \text{vech}(\Sigma))'$$

where $\phi_i = \text{vec}(\Phi_i)$ and $\theta_i = \text{vec}(\Theta_i)$. All elements of $\boldsymbol{\beta}$ are estimated through the preceding maximum likelihood method. The estimates of $\Phi_i, i = 1, \dots, p$ and $\Theta_i, i = 1, \dots, q$ are output in the ParameterEstimates ODS table. The estimates of the covariance matrix (Σ) are output in the CovarianceParameterEstimates ODS table. If you specify the OUTEST=, OUTCOV, PRINT=(COVB), or PRINT=(CORRB) option, you can see all elements of $\boldsymbol{\beta}$, including the covariance matrix Σ , in the parameter estimates, covariance of parameter estimates, or correlation of parameter estimates. You can also apply the BOUND, INITIAL, RESTRICT, and TEST statements to any elements of $\boldsymbol{\beta}$, including the covariance matrix Σ . For more information, see the syntax of the corresponding statement.

The log-likelihood equations are solved by iterative numerical procedures such as quasi-Newton optimization. The starting values for the AR and MA parameters are obtained from the least squares estimates.

Asymptotic Distribution of the Parameter Estimates

Under the assumptions of stationarity and invertibility for the VARMA model and the assumption that ϵ_t is a white noise process, $\hat{\beta}$ is a consistent estimator for β and $\sqrt{T}(\hat{\beta} - \beta)$ converges in distribution to the multivariate normal $N(0, V^{-1})$ as $T \rightarrow \infty$, where V is the asymptotic information matrix of β .

Asymptotic Distributions of Impulse Response Functions

Defining the vector β

$$\beta = (\phi'_1, \dots, \phi'_p, \theta'_1, \dots, \theta'_q)'$$

the asymptotic distribution of the impulse response function for a VARMA(p, q) model is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\beta} G'_j) \quad j = 1, 2, \dots$$

where Σ_{β} is the covariance matrix of the parameter estimates and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \beta'} = \sum_{i=0}^{j-1} \mathbf{H}'(\mathbf{A}')^{j-1-i} \otimes \mathbf{J} \mathbf{A}^i \mathbf{J}'$$

where $\mathbf{H} = [I_k, 0, \dots, 0, I_k, 0, \dots, 0]'$ is a $k(p+q) \times k$ matrix with the second I_k following after p block matrices; $\mathbf{J} = [I_k, 0, \dots, 0]$ is a $k \times k(p+q)$ matrix; \mathbf{A} is a $k(p+q) \times k(p+q)$ matrix,

$$\mathbf{A} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

where

$$A_{11} = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix} \quad A_{12} = \begin{bmatrix} -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 \end{bmatrix}$$

A_{21} is a $kq \times kp$ zero matrix, and

$$A_{22} = \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

An Example of a VARMA(1,1) Model

Consider a VARMA(1,1) model with mean zero,

$$y_t = \Phi_1 y_{t-1} + \epsilon_t - \Theta_1 \epsilon_{t-1}$$

where ϵ_t is the white noise process with a mean zero vector and the positive-definite covariance matrix Σ .

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
  sig = {1.0  0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  theta = {0.5 -0.2, 0.1 0.3};
  /* to simulate the vector time series */
  call varmasim(y,phi,theta) sigma=sig n=100 seed=34657;
  cn = {'y1' 'y2'};
  create simul3 from y[colname=cn];
  append from y;
run;
```

The following statements fit a VARMA(1,1) model to the simulated data. You specify the order of the autoregressive model by using the P= option and specify the order of moving-average model by using the Q= option. You specify the quasi-Newton optimization in the NLOPTIONS statement as an optimization method.

```
proc varmax data=simul3;
  nloptions tech=qn;
  model y1 y2 / p=1 q=1 noint print=(estimates);
run;
```

Figure 35.46 shows the initial values of parameters. The initial values were estimated by using the least squares method.

The fitted VARMA(1,1) model with estimated standard errors in parentheses is given as

$$\mathbf{y}_t = \begin{pmatrix} 1.01846 & -0.38682 \\ (0.10256) & (0.09644) \\ 0.39182 & 0.55281 \\ (0.10062) & (0.08422) \end{pmatrix} \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t - \begin{pmatrix} 0.32292 & -0.02160 \\ (0.14524) & (0.14203) \\ -0.16501 & 0.58576 \\ (0.15704) & (0.14115) \end{pmatrix} \boldsymbol{\epsilon}_{t-1}$$

and

$$\boldsymbol{\epsilon}_t \sim \text{iid } N(0, \begin{pmatrix} 1.25202 & 0.37950 \\ (0.17697) & (0.13401) \\ 0.37950 & 1.31315 \\ (0.13401) & (0.18610) \end{pmatrix})$$

VARMAX Modeling

A general VARMAX(p, q, s) process is written as

$$\mathbf{y}_t = \boldsymbol{\delta}_t + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\delta}_t + \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$, $\Theta(B) = I_k - \sum_{i=1}^q \Theta_i B^i$. The $\boldsymbol{\delta}_t$ consists of all possible deterministic terms, namely constant, seasonal dummies, linear trend, quadratic trend, and exogenous variables; $\boldsymbol{\delta}_t = \Delta \mathbf{c}_t$, where $\mathbf{c}_t = (D_t' \mathbf{x}_t' \dots \mathbf{x}_{t-s}')'$; $D_t = (1 \ d_{t,1} \dots d_{t,n_s-1} \ t \ t^2)'$; $d_{t,i}, i = 1, \dots, n_s-1$, are seasonal dummies and n_s is based on NSEASON= option; $\Delta = (A \ \Theta_0^* \dots \Theta_s^*)$; A is the parameter matrix corresponding to D_t and Θ_i^* for $\mathbf{x}_{t-i}, i = 0, \dots, s$.

The state-space form of the VARMAX(p, q, s) model consists of a state equation

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + \mathbf{w}_t + G \boldsymbol{\epsilon}_t$$

and an observation equation

$$\mathbf{y}_t = H \mathbf{z}_t$$

where for $v = \max(p, q + 1)$

$$\mathbf{z}_t = (\mathbf{y}_t', \mathbf{y}_{t+1|t}', \dots, \mathbf{y}_{t+v-1|t}', \mathbf{c}_{t+v-1}')'$$

$$\mathbf{w}_t = (0, \mathbf{c}_{t+v-1}')'$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 & 0 \\ 0 & 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & 0 \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 & \Delta \\ 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ \Psi_1 \\ \vdots \\ \Psi_{v-1} \\ 0 \end{bmatrix}$$

and

$$H = [I_k, 0, \dots, 0]$$

The Kalman filtering approach is used to evaluate the likelihood function. The updating equation is

$$\hat{\mathbf{z}}_{t|t} = \hat{\mathbf{z}}_{t|t-1} + K_t \boldsymbol{\epsilon}_{t|t-1}$$

where

$$K_t = P_{t|t-1} H' [H P_{t|t-1} H']^{-1}$$

The prediction equation is

$$\hat{\mathbf{z}}_{t|t-1} = F \hat{\mathbf{z}}_{t-1|t-1} + \mathbf{w}_t, \quad P_{t|t-1} = F P_{t-1|t-1} F' + G \Sigma G'$$

where $P_{t|t} = [I - K_t H] P_{t|t-1}$ for $t = 1, 2, \dots, n$.

The log-likelihood function can be expressed as

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |\Sigma_{t|t-1}| + (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})' \Sigma_{t|t-1}^{-1} (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})]$$

where $\hat{\mathbf{y}}_{t|t-1}$ and $\Sigma_{t|t-1}$ are determined recursively from the Kalman filter procedure. To construct the likelihood function from Kalman filtering, you obtain $\hat{\mathbf{y}}_{t|t-1} = H \hat{\mathbf{z}}_{t|t-1}$, $\hat{\boldsymbol{\epsilon}}_{t|t-1} = \mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1}$, and $\Sigma_{t|t-1} = H P_{t|t-1} H'$. Note that the dimension of the state-space vector of the Kalman filtering method for the VARMAX(p, q, s) model is large, so it takes a lot of time and memory for computing.

Two examples of VARMAX modeling follow:

```
model y1 y2 = x1 / q=1;
nloptions tech=qn;

model y1 y2 = x1 / p=1 q=1 xlag=1 nocurrentx;
nloptions tech=qn;
```

Model Diagnostic Checks

Multivariate Model Diagnostic Checks

- **Information Criterion** After fitting some candidate models to the data, various model selection criteria (normalized by T) can be used to choose the appropriate model. The following list includes the Akaike information criterion (AIC), the corrected Akaike information criterion (AICC), the final prediction error criterion (FPE), the Hannan-Quinn criterion (HQC), and the Schwarz Bayesian criterion (SBC, also referred to as BIC):

$$\begin{aligned} \text{AIC} &= \log(|\tilde{\Sigma}|) + 2r/T \\ \text{AICC} &= \log(|\tilde{\Sigma}|) + 2r/(T - r/k) \\ \text{FPE} &= \left(\frac{T + r/k}{T - r/k}\right)^k |\tilde{\Sigma}| \\ \text{HQC} &= \log(|\tilde{\Sigma}|) + 2r \log(\log(T))/T \\ \text{SBC} &= \log(|\tilde{\Sigma}|) + r \log(T)/T \end{aligned}$$

where r denotes the number of parameters estimated, k is the number of dependent variables, T is the number of observations used to estimate the model, and $\tilde{\Sigma}$ is the maximum likelihood estimate of Σ . When comparing models, choose the model with the smallest criterion values.

An example of the output was displayed in [Figure 35.4](#).

- **Portmanteau Q_s statistic** The Portmanteau Q_s statistic is used to test whether correlation remains on the model residuals. The null hypothesis is that the residuals are uncorrelated. Let $C_\epsilon(l)$ be the residual cross-covariance matrices, $\hat{\rho}_\epsilon(l)$ be the residual cross-correlation matrices as

$$C_\epsilon(l) = T^{-1} \sum_{t=1}^{T-l} \epsilon_t \epsilon_{t+l}'$$

and

$$\hat{\rho}_\epsilon(l) = \hat{V}_\epsilon^{-1/2} C_\epsilon(l) \hat{V}_\epsilon^{-1/2} \quad \text{and} \quad \hat{\rho}_\epsilon(-l) = \hat{\rho}_\epsilon(l)'$$

where $\hat{V}_\epsilon = \text{Diag}(\hat{\sigma}_{11}^2, \dots, \hat{\sigma}_{kk}^2)$ and $\hat{\sigma}_{ii}^2$ are the diagonal elements of $\hat{\Sigma}$. The multivariate portmanteau test defined in Hosking (1980) is

$$Q_s = T^2 \sum_{l=1}^s (T-l)^{-1} \text{tr}\{\hat{\rho}_\epsilon(l) \hat{\rho}_\epsilon(0)^{-1} \hat{\rho}_\epsilon(-l) \hat{\rho}_\epsilon(0)^{-1}\}$$

The statistic Q_s has approximately the chi-square distribution with $k^2(s - p - q)$ degrees of freedom. An example of the output is displayed in [Figure 35.7](#).

Univariate Model Diagnostic Checks

There are various ways to perform diagnostic checks for a univariate model. For details, see the section “Testing for Nonlinear Dependence: Heteroscedasticity Tests” on page 397 in Chapter 8, “The AUTOREG Procedure.” An example of the output is displayed in Figure 35.8 and Figure 35.9.

- Durbin-Watson (DW) statistics: The DW test statistics test for the first order autocorrelation in the residuals.
- Jarque-Bera normality test: This test is helpful in determining whether the model residuals represent a white noise process. This tests the null hypothesis that the residuals have normality.
- F tests for autoregressive conditional heteroscedastic (ARCH) disturbances: F test statistics test for the heteroscedastic disturbances in the residuals. This tests the null hypothesis that the residuals have equal covariances
- F tests for AR disturbance: These test statistics are computed from the residuals of the univariate AR(1), AR(1,2), AR(1,2,3) and AR(1,2,3,4) models to test the null hypothesis that the residuals are uncorrelated.

Cointegration

This section briefly introduces the concepts of cointegration (Johansen 1995a).

Definition 1. (Engle and Granger 1987): *If a series y_t with no deterministic components can be represented by a stationary and invertible ARMA process after differencing d times, the series is integrated of order d , that is, $y_t \sim I(d)$.*

Definition 2. (Engle and Granger 1987): *If all elements of the vector \mathbf{y}_t are $I(d)$ and there exists a cointegrating vector $\boldsymbol{\beta} \neq 0$ such that $\boldsymbol{\beta}'\mathbf{y}_t \sim I(d - b)$ for any $b > 0$, the vector process is said to be cointegrated $CI(d, b)$.*

A simple example of a cointegrated process is the following bivariate system:

$$\begin{aligned} y_{1t} &= \gamma y_{2t} + \epsilon_{1t} \\ y_{2t} &= y_{2,t-1} + \epsilon_{2t} \end{aligned}$$

with ϵ_{1t} and ϵ_{2t} being uncorrelated white noise processes. In the second equation, y_{2t} is a random walk, $\Delta y_{2t} = \epsilon_{2t}$, $\Delta \equiv 1 - B$. Differencing the first equation results in

$$\Delta y_{1t} = \gamma \Delta y_{2t} + \Delta \epsilon_{1t} = \gamma \epsilon_{2t} + \epsilon_{1t} - \epsilon_{1,t-1}$$

Thus, both y_{1t} and y_{2t} are $I(1)$ processes, but the linear combination $y_{1t} - \gamma y_{2t}$ is stationary. Hence $\mathbf{y}_t = (y_{1t}, y_{2t})'$ is cointegrated with a cointegrating vector $\boldsymbol{\beta} = (1, -\gamma)'$.

In general, if the vector process \mathbf{y}_t has k components, then there can be more than one cointegrating vector $\boldsymbol{\beta}'$. It is assumed that there are r linearly independent cointegrating vectors with $r < k$, which make the $k \times r$ matrix $\boldsymbol{\beta}$. The rank of matrix $\boldsymbol{\beta}$ is r , which is called the *cointegration rank* of \mathbf{y}_t .

Common Trends

This section briefly discusses the implication of cointegration for the moving-average representation. Let \mathbf{y}_t be cointegrated $CI(1, 1)$, then $\Delta \mathbf{y}_t$ has the Wold representation:

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

where $\boldsymbol{\epsilon}_t$ is $iid(0, \Sigma)$, $\Psi(B) = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\Psi_0 = I_k$, and $\sum_{j=0}^{\infty} j|\Psi_j| < \infty$.

Assume that $\boldsymbol{\epsilon}_t = 0$ if $t \leq 0$ and \mathbf{y}_0 is a nonrandom initial value. Then the difference equation implies that

$$\mathbf{y}_t = \mathbf{y}_0 + \boldsymbol{\delta}t + \Psi(1) \sum_{i=0}^t \boldsymbol{\epsilon}_i + \Psi^*(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = (1 - B)^{-1}(\Psi(B) - \Psi(1))$ and $\Psi^*(B)$ is absolutely summable.

Assume that the rank of $\Psi(1)$ is $m = k - r$. When the process \mathbf{y}_t is cointegrated, there is a cointegrating $k \times r$ matrix $\boldsymbol{\beta}$ such that $\boldsymbol{\beta}'\mathbf{y}_t$ is stationary.

Premultiplying \mathbf{y}_t by $\boldsymbol{\beta}'$ results in

$$\boldsymbol{\beta}'\mathbf{y}_t = \boldsymbol{\beta}'\mathbf{y}_0 + \boldsymbol{\beta}'\Psi^*(B)\boldsymbol{\epsilon}_t$$

because $\boldsymbol{\beta}'\Psi(1) = 0$ and $\boldsymbol{\beta}'\boldsymbol{\delta} = 0$.

Stock and Watson (1988) showed that the cointegrated process \mathbf{y}_t has a common trends representation derived from the moving-average representation. Since the rank of $\Psi(1)$ is $m = k - r$, there is a $k \times r$ matrix H_1 with rank r such that $\Psi(1)H_1 = 0$. Let H_2 be a $k \times m$ matrix with rank m such that $H_2'H_1 = 0$; then $A = C(1)H_2$ has rank m . The $H = (H_1, H_2)$ has rank k . By construction of H ,

$$\Psi(1)H = [0, A] = AS_m$$

where $S_m = (0_{m \times r}, I_m)$. Since $\boldsymbol{\beta}'\Psi(1) = 0$ and $\boldsymbol{\beta}'\boldsymbol{\delta} = 0$, $\boldsymbol{\delta}$ lies in the column space of $\Psi(1)$ and can be written

$$\boldsymbol{\delta} = C(1)\tilde{\boldsymbol{\delta}}$$

where $\tilde{\boldsymbol{\delta}}$ is a k -dimensional vector. The common trends representation is written as

$$\begin{aligned} \mathbf{y}_t &= \mathbf{y}_0 + \Psi(1)[\tilde{\boldsymbol{\delta}}t + \sum_{i=0}^t \boldsymbol{\epsilon}_i] + \Psi^*(B)\boldsymbol{\epsilon}_t \\ &= \mathbf{y}_0 + \Psi(1)H[H^{-1}\tilde{\boldsymbol{\delta}}t + H^{-1}\sum_{i=0}^t \boldsymbol{\epsilon}_i] + \mathbf{a}_t \\ &= \mathbf{y}_0 + A\boldsymbol{\tau}_t + \mathbf{a}_t \end{aligned}$$

and

$$\boldsymbol{\tau}_t = \boldsymbol{\pi} + \boldsymbol{\tau}_{t-1} + \mathbf{v}_t$$

where $\mathbf{a}_t = \Psi^*(B)\boldsymbol{\epsilon}_t$, $\boldsymbol{\pi} = S_m H^{-1}\tilde{\boldsymbol{\delta}}$, $\boldsymbol{\tau}_t = S_m[H^{-1}\tilde{\boldsymbol{\delta}}t + H^{-1}\sum_{i=0}^t \boldsymbol{\epsilon}_i]$, and $\mathbf{v}_t = S_m H^{-1}\boldsymbol{\epsilon}_t$.

Stock and Watson showed that the common trends representation expresses \mathbf{y}_t as a linear combination of m random walks ($\boldsymbol{\tau}_t$) with drift $\boldsymbol{\pi}$ plus $I(0)$ components (\mathbf{a}_t).

Test for the Common Trends

Stock and Watson (1988) proposed statistics for common trends testing. The null hypothesis is that the k -dimensional time series \mathbf{y}_t has m common stochastic trends, where $m \leq k$ and the alternative is that it has s common trends, where $s < m$. The test procedure of m versus s common stochastic trends is performed based on the first-order serial correlation matrix of \mathbf{y}_t . Let β_\perp be a $k \times m$ matrix orthogonal to the cointegrating matrix such that $\beta_\perp' \beta = 0$ and $\beta_\perp \beta_\perp' = I_m$. Let $\mathbf{z}_t = \beta' \mathbf{y}_t$ and $\mathbf{w}_t = \beta_\perp' \mathbf{y}_t$. Then

$$\mathbf{w}_t = \beta_\perp' \mathbf{y}_0 + \beta_\perp' \delta t + \beta_\perp' \Psi(1) \sum_{i=0}^t \epsilon_i + \beta_\perp' \Psi^*(B) \epsilon_t$$

Combining the expression of \mathbf{z}_t and \mathbf{w}_t ,

$$\begin{bmatrix} \mathbf{z}_t \\ \mathbf{w}_t \end{bmatrix} = \begin{bmatrix} \beta' \mathbf{y}_0 \\ \beta_\perp' \mathbf{y}_0 \end{bmatrix} + \begin{bmatrix} 0 \\ \beta_\perp' \delta \end{bmatrix} t + \begin{bmatrix} 0 \\ \beta_\perp' \Psi(1) \end{bmatrix} \sum_{i=1}^t \epsilon_i + \begin{bmatrix} \beta' \Psi^*(B) \\ \beta_\perp' \Psi^*(B) \end{bmatrix} \epsilon_t$$

The Stock-Watson common trends test is performed based on the component \mathbf{w}_t by testing whether $\beta_\perp' \Psi(1)$ has rank m against rank s .

The following statements perform the Stock-Watson test for common trends:

```
proc iml;
    sig = 100*i(2);
    phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
    call varmasim(y,phi) sigma=sig n=100 initial=0
                seed=45876;

    cn = {'y1' 'y2'};
    create simul2 from y[colname=cn];
    append from y;
quit;

data simul2;
    set simul2;
    date = intnx('year', '01jan1900'd, _n_-1 );
    format date year4. ;
run;

proc varmax data=simul2;
    model y1 y2 / p=2 cointtest=(sw);
run;
```

In Figure 35.51, the first column is the null hypothesis that \mathbf{y}_t has $m \leq k$ common trends; the second column is the alternative hypothesis that \mathbf{y}_t has $s < m$ common trends; the third column contains the eigenvalues used for the test statistics; the fourth column contains the test statistics using $AR(p)$ filtering of the data. The table shows the output of the case $p = 2$.

Figure 35.51 Common Trends Test (COINTTEST=(SW) Option)

The VARMAX Procedure						
Common Trend Test						
H0:	H1:	Eigenvalue	Filter	5% Critical Value	Lag	
Rank=m	Rank=s					
1	0	1.000906	0.09	-14.10	2	
2	0	0.996763	-0.32	-8.80		
	1	0.648908	-35.11	-23.00		

The test statistic for testing for 2 versus 1 common trends is more negative (−35.1) than the critical value (−23.0). Therefore, the test rejects the null hypothesis, which means that the series has a single common trend.

Vector Error Correction Modeling

This section discusses the implication of cointegration for the autoregressive representation. Assume that the cointegrated series can be represented by a vector error correction model according to the Granger representation theorem (Engle and Granger 1987). Consider the vector autoregressive process with Gaussian errors defined by

$$y_t = \sum_{i=1}^p \Phi_i y_{t-i} + \epsilon_t$$

or

$$\Phi(B)y_t = \epsilon_t$$

where the initial values, y_{-p+1}, \dots, y_0 , are fixed and $\epsilon_t \sim N(0, \Sigma)$. Since the AR operator $\Phi(B)$ can be re-expressed as $\Phi(B) = \Phi^*(B)(1 - B) + \Phi(1)B$, where $\Phi^*(B) = I_k - \sum_{i=1}^{p-1} \Phi_i^* B^i$ with $\Phi_i^* = -\sum_{j=i+1}^p \Phi_j$, the vector error correction model is

$$\Phi^*(B)(1 - B)y_t = \alpha\beta'y_{t-1} + \epsilon_t$$

or

$$\Delta y_t = \alpha\beta'y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t$$

where $\alpha\beta' = -\Phi(1) = -I_k + \Phi_1 + \Phi_2 + \dots + \Phi_p$.

One motivation for the VECM(p) form is to consider the relation $\beta'y_t = c$ as defining the underlying economic relations and assume that the agents react to the disequilibrium error $\beta'y_t - c$ through the

adjustment coefficient α to restore equilibrium; that is, they satisfy the economic relations. The cointegrating vector, β is sometimes called the *long-run parameters*.

You can consider a vector error correction model with a deterministic term. The deterministic term D_t can contain a constant, a linear trend, and seasonal dummy variables. Exogenous variables can also be included in the model.

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

where $\Pi = \alpha \beta'$.

The alternative vector error correction representation considers the error correction term at lag $t - p$ and is written as

$$\Delta \mathbf{y}_t = \sum_{i=1}^{p-1} \Phi_i^\# \Delta \mathbf{y}_{t-i} + \Pi^\# \mathbf{y}_{t-p} + A D_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

If the matrix Π has a full-rank ($r = k$), all components of \mathbf{y}_t are $I(0)$. On the other hand, \mathbf{y}_t are stationary in difference if $\text{rank}(\Pi) = 0$. When the rank of the matrix Π is $r < k$, there are $k - r$ linear combinations that are nonstationary and r stationary cointegrating relations. Note that the linearly independent vector $\mathbf{z}_t = \beta' \mathbf{y}_t$ is stationary and this transformation is not unique unless $r = 1$. There does not exist a unique cointegrating matrix β since the coefficient matrix Π can also be decomposed as

$$\Pi = \alpha M M^{-1} \beta' = \alpha^* \beta^{*'}$$

where M is an $r \times r$ nonsingular matrix.

Test for the Cointegration

The cointegration rank test determines the linearly independent columns of Π . Johansen and Juselius proposed the cointegration rank test by using the reduced rank regression (Johansen 1988, 1995b; Johansen and Juselius 1990).

Different Specifications of Deterministic Trends

When you construct the $\text{VECM}(p)$ form from the $\text{VAR}(p)$ model, the deterministic terms in the $\text{VECM}(p)$ form can differ from those in the $\text{VAR}(p)$ model. When there are deterministic cointegrated relationships among variables, deterministic terms in the $\text{VAR}(p)$ model are not present in the $\text{VECM}(p)$ form. On the other hand, if there are stochastic cointegrated relationships in the $\text{VAR}(p)$ model, deterministic terms appear in the $\text{VECM}(p)$ form via the error correction term or as an independent term in the $\text{VECM}(p)$ form. There are five different specifications of deterministic trends in the $\text{VECM}(p)$ form.

- **Case 1:** There is no separate drift in the $\text{VECM}(p)$ form.

$$\Delta \mathbf{y}_t = \alpha \beta' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \epsilon_t$$

- **Case 2:** There is no separate drift in the VECM(p) form, but a constant enters only via the error correction term.

$$\Delta y_t = \alpha(\beta', \beta_0)(y'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t$$

- **Case 3:** There is a separate drift and no separate linear trend in the VECM(p) form.

$$\Delta y_t = \alpha\beta'y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \epsilon_t$$

- **Case 4:** There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only via the error correction term.

$$\Delta y_t = \alpha(\beta', \beta_1)(y'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \epsilon_t$$

- **Case 5:** There is a separate linear trend in the VECM(p) form.

$$\Delta y_t = \alpha\beta'y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \delta_1 t + \epsilon_t$$

First, focus on Cases 1, 3, and 5 to test the null hypothesis that there are at most r cointegrating vectors. Let

$$\begin{aligned} Z_{0t} &= \Delta y_t \\ Z_{1t} &= y_{t-1} \\ Z_{2t} &= [\Delta y'_{t-1}, \dots, \Delta y'_{t-p+1}, D_t]' \\ Z_0 &= [Z_{01}, \dots, Z_{0T}]' \\ Z_1 &= [Z_{11}, \dots, Z_{1T}]' \\ Z_2 &= [Z_{21}, \dots, Z_{2T}]' \end{aligned}$$

where D_t can be empty for Case 1, 1 for Case 3, and $(1, t)$ for Case 5.

In Case 2, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [y'_{t-1}, 1]' \\ Z_{2t} &= [\Delta y'_{t-1}, \dots, \Delta y'_{t-p+1}]' \end{aligned}$$

In Case 4, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [y'_{t-1}, t]' \\ Z_{2t} &= [\Delta y'_{t-1}, \dots, \Delta y'_{t-p+1}, 1]' \end{aligned}$$

Let Ψ be the matrix of parameters consisting of $\Phi_1^*, \dots, \Phi_{p-1}^*$, A , and $\Theta_0^*, \dots, \Theta_s^*$, where parameters A corresponds to regressors D_t . Then the VECM(p) form is rewritten in these variables as

$$Z_{0t} = \alpha\beta'Z_{1t} + \Psi Z_{2t} + \epsilon_t$$

The log-likelihood function is given by

$$\begin{aligned} \ell = & -\frac{kT}{2} \log 2\pi - \frac{T}{2} \log |\Sigma| \\ & - \frac{1}{2} \sum_{t=1}^T (Z_{0t} - \alpha\beta'Z_{1t} - \Psi Z_{2t})' \Sigma^{-1} (Z_{0t} - \alpha\beta'Z_{1t} - \Psi Z_{2t}) \end{aligned}$$

The residuals, R_{0t} and R_{1t} , are obtained by regressing Z_{0t} and Z_{1t} on Z_{2t} , respectively. The regression equation of residuals is

$$R_{0t} = \alpha\beta'R_{1t} + \hat{\epsilon}_t$$

The crossproducts matrices are computed

$$S_{ij} = \frac{1}{T} \sum_{t=1}^T R_{it} R'_{jt}, \quad i, j = 0, 1$$

Then the maximum likelihood estimator for β is obtained from the eigenvectors that correspond to the r largest eigenvalues of the following equation:

$$|\lambda S_{11} - S_{10} S_{00}^{-1} S_{01}| = 0$$

The eigenvalues of the preceding equation are squared canonical correlations between R_{0t} and R_{1t} , and the eigenvectors that correspond to the r largest eigenvalues are the r linear combinations of y_{t-1} , which have the largest squared partial correlations with the stationary process Δy_t after correcting for lags and deterministic terms. Such an analysis calls for a reduced rank regression of Δy_t on y_{t-1} corrected for $(\Delta y_{t-1}, \dots, \Delta y_{t-p+1}, D_t)$, as discussed by Anderson (1951). Johansen (1988) suggests two test statistics to test the null hypothesis that there are at most r cointegrating vectors

$$H_0 : \lambda_i = 0 \text{ for } i = r + 1, \dots, k$$

Trace Test

The trace statistic for testing the null hypothesis that there are at most r cointegrating vectors is as follows:

$$\lambda_{trace} = -T \sum_{i=r+1}^k \log(1 - \lambda_i)$$

The asymptotic distribution of this statistic is given by

$$tr \left\{ \int_0^1 (dW) \tilde{W}' \left(\int_0^1 \tilde{W} \tilde{W}' dr \right)^{-1} \int_0^1 \tilde{W} (dW)' \right\}$$

where $tr(A)$ is the trace of a matrix A , W is the $k - r$ dimensional Brownian motion, and \tilde{W} is the Brownian motion itself, or the demeaned or detrended Brownian motion according to the different specifications of deterministic trends in the vector error correction model.

Maximum Eigenvalue Test

The maximum eigenvalue statistic for testing the null hypothesis that there are at most r cointegrating vectors is as follows:

$$\lambda_{max} = -T \log(1 - \lambda_{r+1})$$

The asymptotic distribution of this statistic is given by

$$\max\left\{\int_0^1 (dW)\tilde{W}'\left(\int_0^1 \tilde{W}\tilde{W}'dr\right)^{-1}\int_0^1 \tilde{W}(dW)'\right\}$$

where $\max(A)$ is the maximum eigenvalue of a matrix A . Osterwald-Lenum (1992) provided detailed tables of the critical values of these statistics.

The following statements use the JOHANSEN option to compute the Johansen cointegration rank trace test of integrated order 1:

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(johansen=(normalize=y1));
run;
```

Figure 35.52 shows the output based on the model specified in the MODEL statement, an intercept term is assumed. In the “Cointegration Rank Test Using Trace” table, the column Drift In ECM means there is no separate drift in the error correction model and the column Drift In Process means the process has a constant drift before differencing. The “Cointegration Rank Test Using Trace” table shows the trace statistics based on Case 3 and the “Cointegration Rank Test Using Trace under Restriction” table shows the trace statistics based on Case 2. The output indicates that the series are cointegrated with rank 1 because the trace statistics are smaller than the critical values in both Case 2 and Case 3.

Figure 35.52 Cointegration Rank Test (COINTTEST=(JOHANSEN=) Option)

The VARMAX Procedure						
Cointegration Rank Test Using Trace						
H0: Rank=r	H1: Rank>r	Eigenvalue	Trace	5% Critical Value	Drift in ECM	Drift in Process
0	0	0.4644	61.7522	15.34	Constant	Linear
1	1	0.0056	0.5552	3.84		
Cointegration Rank Test Using Trace Under Restriction						
H0: Rank=r	H1: Rank>r	Eigenvalue	Trace	5% Critical Value	Drift in ECM	Drift in Process
0	0	0.5209	76.3788	19.99	Constant	Constant
1	1	0.0426	4.2680	9.13		

Figure 35.53 shows which result, either Case 2 (the hypothesis H_0) or Case 3 (the hypothesis H_1), is appropriate depending on the significance level. Since the cointegration rank is chosen to be 1 by the result in Figure 35.52, look at the last row that corresponds to rank=1. Since the p -value is 0.054, the Case 2 cannot be rejected at the significance level 5%, but it can be rejected at the significance level 10%. For modeling of the two Case 2 and Case 3, see Figure 35.56 and Figure 35.57.

1	0.0056	0.0426	1	3.71	0.0540

Figure 35.54 shows the estimates of long-run parameter (Beta) and adjustment coefficients (Alpha) based on Case 3.

Figure 35.54 Cointegration Rank Test Continued

Beta		
Variable	1	2
y1	1.00000	1.00000
y2	-2.04869	-0.02854
Alpha		
Variable	1	2
y1	-0.46421	-0.00502
y2	0.17535	-0.01275

Using the NORMALIZE= option, the first row of the “Beta” table has 1. Considering that the cointegration rank is 1, the long-run relationship of the series is

$$\begin{aligned}\beta' y_t &= \begin{bmatrix} 1 & -2.04869 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \\ &= y_{1t} - 2.04869 y_{2t} \\ y_{1t} &= 2.04869 y_{2t}\end{aligned}$$

Figure 35.55 shows the estimates of long-run parameter (Beta) and adjustment coefficients (Alpha) based on Case 2.

Figure 35.55 Cointegration Rank Test Continued

Beta Under Restriction		
Variable	1	2
y1	1.00000	1.00000
y2	-2.04366	-2.75773
1	6.75919	101.37051
Alpha Under Restriction		
Variable	1	2
y1	-0.48015	0.01091
y2	0.12538	0.03722

Considering that the cointegration rank is 1, the long-run relationship of the series is

$$\begin{aligned}\beta' y_t &= \begin{bmatrix} 1 & -2.04366 & 6.75919 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ 1 \end{bmatrix} \\ &= y_{1t} - 2.04366 y_{2t} + 6.75919 \\ y_{1t} &= 2.04366 y_{2t} - 6.75919\end{aligned}$$

Estimation of Vector Error Correction Model

The preceding log-likelihood function is maximized for

$$\begin{aligned}\hat{\beta} &= S_{11}^{-1/2} [v_1, \dots, v_r] \\ \hat{\alpha} &= S_{01} \hat{\beta} (\hat{\beta}' S_{11} \hat{\beta})^{-1} \\ \hat{\Pi} &= \hat{\alpha} \hat{\beta}' \\ \hat{\Psi}' &= (Z_2' Z_2)^{-1} Z_2' (Z_0 - Z_1 \hat{\Pi}') \\ \hat{\Sigma} &= (Z_0 - Z_2 \hat{\Psi}' - Z_1 \hat{\Pi}')' (Z_0 - Z_2 \hat{\Psi}' - Z_1 \hat{\Pi}') / T\end{aligned}$$

The estimators of the orthogonal complements of α and β are

$$\hat{\beta}_{\perp} = S_{11}[v_{r+1}, \dots, v_k]$$

and

$$\hat{\alpha}_{\perp} = S_{00}^{-1} S_{01}[v_{r+1}, \dots, v_k]$$

The ML estimators have the following asymptotic properties:

$$\sqrt{T} \text{vec}([\hat{\Pi}, \hat{\Psi}] - [\Pi, \Psi]) \xrightarrow{d} N(0, \Sigma_{co})$$

where

$$\Sigma_{co} = \Sigma \otimes \left(\begin{bmatrix} \beta & 0 \\ 0 & I_k \end{bmatrix} \Omega^{-1} \begin{bmatrix} \beta' & 0 \\ 0 & I_k \end{bmatrix} \right)$$

and

$$\Omega = \text{plim} \frac{1}{T} \begin{bmatrix} \beta' Z_1' Z_1 \beta & \beta' Z_1' Z_2 \\ Z_2' Z_1 \beta & Z_2' Z_2 \end{bmatrix}$$

The following statements are examples of fitting the five different cases of the vector error correction models mentioned in the previous section.

For fitting Case 1,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) noint;
```

For fitting Case 2,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend);
```

For fitting Case 3,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
```

For fitting Case 4,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
trend=linear;
```

For fitting Case 5,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) trend=linear;
```

From [Figure 35.53](#) that uses the COINTTEST=(JOHANSEN) option, you can fit the model by using either Case 2 or Case 3 because the test was not significant at the 0.05 level, but was significant at the 0.10 level. Here both models are fitted to show the difference in output display. [Figure 35.56](#) is for Case 2, and [Figure 35.57](#) is for Case 3.

For Case 2,

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
    print=(estimates);
run;
```

Test for the Linear Restriction on the Parameters

Consider the example with the variables m_t log real money, y_t log real income, i_t^d deposit interest rate, and i_t^b bond interest rate. It seems a natural hypothesis that in the long-run relation, money and income have equal coefficients with opposite signs. This can be formulated as the hypothesis that the cointegrated relation contains only m_t and y_t through $m_t - y_t$. For the analysis, you can express these restrictions in the parameterization of β such that $\beta = H\phi$, where H is a known $k \times s$ matrix and ψ is the $s \times r$ ($r \leq s < k$) parameter matrix to be estimated. For this example, H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Restriction $H_0: \beta = H\phi$

When the linear restriction $\beta = H\phi$ is given, it implies that the same restrictions are imposed on all cointegrating vectors. You obtain the maximum likelihood estimator of β by reduced rank regression of Δy_t on $H y_{t-1}$ corrected for $(\Delta y_{t-1}, \dots, \Delta y_{t-p+1}, D_t)$, solving the following equation

$$|\rho H' S_{11} H - H' S_{10} S_{00}^{-1} S_{01} H| = 0$$

for the eigenvalues $1 > \rho_1 > \dots > \rho_s > 0$ and eigenvectors (v_1, \dots, v_s) , S_{ij} given in the preceding section. Then choose $\hat{\phi} = (v_1, \dots, v_r)$ that corresponds to the r largest eigenvalues, and the $\hat{\beta}$ is $H\hat{\phi}$.

The test statistic for $H_0: \beta = H\phi$ is given by

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi_{r(k-s)}^2$$

If the series has no deterministic trend, the constant term should be restricted by $\alpha'_{\perp} \delta_0 = 0$ as in Case 2. Then H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The following statements test that $2\beta_1 + \beta_2 = 0$:

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 h=(1,-2);
run;
```

Figure 35.58 shows the results of testing $H_0: 2\beta_1 + \beta_2 = 0$. The input H matrix is $H = (1 - 2)'$. The adjustment coefficient is reestimated under the restriction, and the test indicates that you cannot reject the null hypothesis.

Hypothesis Test					
Index	Eigenvalue	Restricted Eigenvalue	DF	Chi-Square	Pr > ChiSq
1	0.4644	0.4616	1	0.51	0.4738

Test for the Weak Exogeneity and Restrictions of Alpha

Consider a vector error correction model:

$$\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + A D_t + \epsilon_t$$

Divide the process y_t into $(y'_{1t}, y'_{2t})'$ with dimension k_1 and k_2 and the Σ into

$$\Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

Similarly, the parameters can be decomposed as follows:

$$\alpha = \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} \quad \Phi_i^* = \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \quad A = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix}$$

Then the VECM(p) form can be rewritten by using the decomposed parameters and processes:

$$\begin{bmatrix} \Delta y_{1t} \\ \Delta y_{2t} \end{bmatrix} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} \beta' y_{t-1} + \sum_{i=1}^{p-1} \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \Delta y_{t-i} + \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} D_t + \begin{bmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{bmatrix}$$

The conditional model for \mathbf{y}_{1t} given \mathbf{y}_{2t} is

$$\begin{aligned}\Delta \mathbf{y}_{1t} = & \omega \Delta \mathbf{y}_{2t} + (\alpha_1 - \omega \alpha_2) \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} (\Phi_{1i}^* - \omega \Phi_{2i}^*) \Delta \mathbf{y}_{t-i} \\ & + (A_1 - \omega A_2) D_t + \boldsymbol{\epsilon}_{1t} - \omega \boldsymbol{\epsilon}_{2t}\end{aligned}$$

and the marginal model of \mathbf{y}_{2t} is

$$\Delta \mathbf{y}_{2t} = \alpha_2 \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_{2i}^* \Delta \mathbf{y}_{t-i} + A_2 D_t + \boldsymbol{\epsilon}_{2t}$$

where $\omega = \Sigma_{12} \Sigma_{22}^{-1}$.

The test of weak exogeneity of \mathbf{y}_{2t} for the parameters $(\alpha_1, \boldsymbol{\beta})$ determines whether $\alpha_2 = 0$. Weak exogeneity means that there is no information about $\boldsymbol{\beta}$ in the marginal model or that the variables \mathbf{y}_{2t} do not react to a disequilibrium.

Restriction $H_0: \boldsymbol{\alpha} = J\boldsymbol{\psi}$

Consider the null hypothesis $H_0: \boldsymbol{\alpha} = J\boldsymbol{\psi}$, where J is a $k \times m$ matrix with $r \leq m < k$.

From the previous residual regression equation

$$R_{0t} = \boldsymbol{\alpha} \boldsymbol{\beta}' R_{1t} + \hat{\boldsymbol{\epsilon}}_t = J\boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \hat{\boldsymbol{\epsilon}}_t$$

you can obtain

$$\begin{aligned}\bar{J}' R_{0t} &= \boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \bar{J}' \hat{\boldsymbol{\epsilon}}_t \\ J_{\perp}' R_{0t} &= J_{\perp}' \hat{\boldsymbol{\epsilon}}_t\end{aligned}$$

where $\bar{J} = J(J'J)^{-1}$ and J_{\perp} is orthogonal to J such that $J_{\perp}' J = 0$.

Define

$$\Sigma_{JJ_{\perp}} = \bar{J}' \Sigma J_{\perp} \text{ and } \Sigma_{J_{\perp} J_{\perp}} = J_{\perp}' \Sigma J_{\perp}$$

and let $\omega = \Sigma_{JJ_{\perp}} \Sigma_{J_{\perp} J_{\perp}}^{-1}$. Then $\bar{J}' R_{0t}$ can be written as

$$\bar{J}' R_{0t} = \boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \omega J_{\perp}' R_{0t} + \bar{J}' \hat{\boldsymbol{\epsilon}}_t - \omega J_{\perp}' \hat{\boldsymbol{\epsilon}}_t$$

Using the marginal distribution of $J_{\perp}' R_{0t}$ and the conditional distribution of $\bar{J}' R_{0t}$, the new residuals are computed as

$$\begin{aligned}\tilde{R}_{Jt} &= \bar{J}' R_{0t} - S_{JJ_{\perp}} S_{J_{\perp} J_{\perp}}^{-1} J_{\perp}' R_{0t} \\ \tilde{R}_{1t} &= R_{1t} - S_{1J_{\perp}} S_{J_{\perp} J_{\perp}}^{-1} J_{\perp}' R_{0t}\end{aligned}$$

where

$$S_{JJ_{\perp}} = \bar{J}' S_{00} J_{\perp}, \quad S_{J_{\perp} J_{\perp}} = J'_{\perp} S_{00} J_{\perp}, \quad \text{and} \quad S_{J_{\perp} 1} = J'_{\perp} S_{01}$$

In terms of \tilde{R}_{Jt} and \tilde{R}_{1t} , the MLE of β is computed by using the reduced rank regression. Let

$$S_{ij.J_{\perp}} = \frac{1}{T} \sum_{t=1}^T \tilde{R}_{it} \tilde{R}'_{jt}, \quad \text{for } i, j = 1, J$$

Under the null hypothesis $H_0: \alpha = J\psi$, the MLE $\tilde{\beta}$ is computed by solving the equation

$$|\rho S_{11.J_{\perp}} - S_{1J.J_{\perp}} S_{JJ.J_{\perp}}^{-1} S_{J1.J_{\perp}}| = 0$$

Then $\tilde{\beta} = (v_1, \dots, v_r)$, where the eigenvectors correspond to the r largest eigenvalues and are normalized such that $\tilde{\beta}' S_{11.J_{\perp}} \tilde{\beta} = I_r$; $\tilde{\alpha} = J S_{J1.J_{\perp}} \tilde{\beta}$. The likelihood ratio test for $H_0: \alpha = J\psi$ is

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi^2_{r(k-m)}$$

See Theorem 6.1 in Johansen and Juselius (1990) for more details.

The test of weak exogeneity of y_{2t} is a special case of the test $\alpha = J\psi$, considering $J = (I_{k_1}, 0)'$. Consider the previous example with four variables (m_t, y_t, i_t^b, i_t^d) . If $r = 1$, you formulate the weak exogeneity of (y_t, i_t^b, i_t^d) for m_t as $J = [1, 0, 0, 0]'$ and the weak exogeneity of i_t^d for (m_t, y_t, i_t^b) as $J = [I_3, 0]'$.

The following statements test the weak exogeneity of other variables, assuming $r = 1$:

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 exogeneity;
run;

proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 j=exogeneity;
run;
```

Figure 35.59 shows that each variable is not the weak exogeneity of other variable.

Forecasting of the VECM

Consider the cointegrated moving-average representation of the differenced process of \mathbf{y}_t

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

Assume that $\mathbf{y}_0 = 0$. The linear process \mathbf{y}_t can be written as

$$\mathbf{y}_t = \boldsymbol{\delta}t + \sum_{i=1}^t \sum_{j=0}^{t-i} \Psi_j \boldsymbol{\epsilon}_i$$

Therefore, for any $l > 0$,

$$\mathbf{y}_{t+l} = \boldsymbol{\delta}(t+l) + \sum_{i=1}^t \sum_{j=0}^{t+l-i} \Psi_j \boldsymbol{\epsilon}_i + \sum_{i=1}^l \sum_{j=0}^{l-i} \Psi_j \boldsymbol{\epsilon}_{t+i}$$

The l -step-ahead forecast is derived from the preceding equation:

$$\mathbf{y}_{t+l|t} = (t+l)\boldsymbol{\delta} + \sum_{i=1}^t \sum_{j=0}^{t+l-i} \Psi_j \boldsymbol{\epsilon}_i$$

Note that

$$\lim_{l \rightarrow \infty} \boldsymbol{\beta}' \mathbf{y}_{t+l|t} = 0$$

since $\lim_{l \rightarrow \infty} \sum_{j=0}^{t+l-i} \Psi_j = \Psi(1)$ and $\boldsymbol{\beta}'\Psi(1) = 0$. The long-run forecast of the cointegrated system shows that the cointegrated relationship holds, although there might exist some deviations from the equilibrium status in the short-run. The covariance matrix of the predict error $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t}$ is

$$\Sigma(l) = \sum_{i=1}^l \left[\left(\sum_{j=0}^{l-i} \Psi_j \right) \Sigma \left(\sum_{j=0}^{l-i} \Psi_j' \right) \right]$$

When the linear process is represented as a VECM(p) model, you can obtain

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{j=1}^{p-1} \Phi_j^* \Delta \mathbf{y}_{t-j} + \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

The transition equation is defined as

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + \mathbf{e}_t$$

where $\mathbf{z}_t = (y'_{t-1}, \Delta y'_t, \Delta y'_{t-1}, \dots, \Delta y'_{t-p+2})'$ is a state vector and the transition matrix is

$$F = \begin{bmatrix} I_k & I_k & 0 & \cdots & 0 \\ \Pi & (\Pi + \Phi_1^*) & \Phi_2^* & \cdots & \Phi_{p-1}^* \\ 0 & I_k & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

where 0 is a $k \times k$ zero matrix. The observation equation can be written

$$\mathbf{y}_t = \boldsymbol{\delta}t + H\mathbf{z}_t$$

where $H = [I_k, I_k, 0, \dots, 0]$.

The l -step-ahead forecast is computed as

$$\mathbf{y}_{t+l|t} = \boldsymbol{\delta}(t+l) + HF^l\mathbf{z}_t$$

Cointegration with Exogenous Variables

The error correction model with exogenous variables can be written as follows:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The following statements demonstrate how to fit VECMX(p, s), where $p = 2$ and $s = 1$ from the P=2 and XLAG=1 options:

```
proc varmax data=simul3;
  model y1 y2 = x1 / p=2 xlag=1 ecm=(rank=1);
run;
```

The following statements demonstrate how to BVECMX(2,1):

```
proc varmax data=simul3;
  model y1 y2 = x1 / p=2 xlag=1 ecm=(rank=1)
  prior=(lambda=0.9 theta=0.1);
run;
```

I(2) Model

The VARX(p, s) model can be written in the error correction form:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

Let $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

If α and β have full-rank r , and $\text{rank}(\alpha'_{\perp} \Phi^* \beta_{\perp}) = k - r$, then y_t is an $I(1)$ process.

If the condition $\text{rank}(\alpha'_{\perp} \Phi^* \beta_{\perp}) = k - r$ fails and $\alpha'_{\perp} \Phi^* \beta_{\perp}$ has reduced-rank $\alpha'_{\perp} \Phi^* \beta_{\perp} = \xi \eta'$ where ξ and η are $(k - r) \times s$ matrices with $s \leq k - r$, then α_{\perp} and β_{\perp} are defined as $k \times (k - r)$ matrices of full rank such that $\alpha'_{\perp} \alpha_{\perp} = 0$ and $\beta'_{\perp} \beta_{\perp} = 0$.

If ξ and η have full-rank s , then the process y_t is $I(2)$, which has the implication of $I(2)$ model for the moving-average representation.

$$y_t = B_0 + B_1 t + C_2 \sum_{j=1}^t \sum_{i=1}^j \epsilon_i + C_1 \sum_{i=1}^t \epsilon_i + C_0(B) \epsilon_t$$

The matrices C_1 , C_2 , and $C_0(B)$ are determined by the cointegration properties of the process, and B_0 and B_1 are determined by the initial values. For details, see Johansen (1995b).

The implication of the $I(2)$ model for the autoregressive representation is given by

$$\Delta^2 y_t = \Pi y_{t-1} - \Phi^* \Delta y_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 y_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j^*$ and $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

Test for $I(2)$

The $I(2)$ cointegrated model is given by the following parameter restrictions:

$$H_{r,s}: \Pi = \alpha \beta' \text{ and } \alpha'_{\perp} \Phi^* \beta_{\perp} = \xi \eta'$$

where ξ and η are $(k - r) \times s$ matrices with $0 \leq s \leq k - r$. Let H_r^0 represent the $I(1)$ model where α and β have full-rank r , let $H_{r,s}^0$ represent the $I(2)$ model where ξ and η have full-rank s , and let $H_{r,s}$ represent the $I(2)$ model where ξ and η have rank $\leq s$. The following table shows the relation between the $I(1)$ models and the $I(2)$ models.

Table 35.6 Relation between the $I(1)$ and $I(2)$ Models

			$I(2)$					$I(1)$			
$r \backslash k - r - s$	k		k-1		\cdots		1				
0	H_{00}	\subset	H_{01}	\subset	\cdots	\subset	$H_{0,k-1}$	\subset	H_{0k}	$=$	H_0^0
1			H_{10}	\subset	\cdots	\subset	$H_{1,k-2}$	\subset	$H_{1,k-1}$	$=$	H_1^0
\vdots							\vdots	\vdots	\vdots	\vdots	\vdots
$k - 1$							$H_{k-1,0}$	\subset	$H_{k-1,1}$	$=$	H_{k-1}^0

Johansen (1995b) proposed the two-step procedure to analyze the $I(2)$ model. In the first step, the values of (r, α, β) are estimated using the reduced rank regression analysis, performing the regression analysis $\Delta^2 y_t$,

Δy_{t-1} , and y_{t-1} on $\Delta^2 y_{t-1}, \dots, \Delta^2 y_{t-p+2}$, and D_t . This gives residuals R_{0t} , R_{1t} , and R_{2t} , and residual product moment matrices

$$M_{ij} = \frac{1}{T} \sum_{t=1}^T R_{it} R'_{jt} \text{ for } i, j = 0, 1, 2$$

Perform the reduced rank regression analysis $\Delta^2 y_t$ on y_{t-1} corrected for Δy_{t-1} , $\Delta^2 y_{t-1}, \dots, \Delta^2 y_{t-p+2}$, and D_t , and solve the eigenvalue problem of the equation

$$|\lambda M_{22.1} - M_{20.1} M_{00.1}^{-1} M_{02.1}| = 0$$

where $M_{ij.1} = M_{ij} - M_{i1} M_{11}^{-1} M_{1j}$ for $i, j = 0, 2$.

In the second step, if (r, α, β) are known, the values of (s, ξ, η) are determined using the reduced rank regression analysis, regressing $\hat{\alpha}'_{\perp} \Delta^2 y_t$ on $\hat{\beta}'_{\perp} \Delta y_{t-1}$ corrected for $\Delta^2 y_{t-1}, \dots, \Delta^2 y_{t-p+2}$, D_t , and $\hat{\beta}' \Delta y_{t-1}$.

The reduced rank regression analysis reduces to the solution of an eigenvalue problem for the equation

$$|\rho M_{\beta_{\perp} \beta_{\perp} \cdot \beta} - M_{\beta_{\perp} \alpha_{\perp} \cdot \beta} M_{\alpha_{\perp} \alpha_{\perp} \cdot \beta}^{-1} M_{\alpha_{\perp} \beta_{\perp} \cdot \beta}| = 0$$

where

$$\begin{aligned} M_{\beta_{\perp} \beta_{\perp} \cdot \beta} &= \beta'_{\perp} (M_{11} - M_{11} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{11}) \beta_{\perp} \\ M'_{\beta_{\perp} \alpha_{\perp} \cdot \beta} &= M_{\alpha_{\perp} \beta_{\perp} \cdot \beta} = \bar{\alpha}'_{\perp} (M_{01} - M_{01} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{11}) \beta_{\perp} \\ M_{\alpha_{\perp} \alpha_{\perp} \cdot \beta} &= \bar{\alpha}'_{\perp} (M_{00} - M_{01} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{10}) \bar{\alpha}_{\perp} \end{aligned}$$

where $\bar{\alpha} = \alpha(\alpha' \alpha)^{-1}$.

The solution gives eigenvalues $1 > \rho_1 > \dots > \rho_s > 0$ and eigenvectors (v_1, \dots, v_s) . Then, the ML estimators are

$$\begin{aligned} \hat{\eta} &= (v_1, \dots, v_s) \\ \hat{\xi} &= M_{\alpha_{\perp} \beta_{\perp} \cdot \beta} \hat{\eta} \end{aligned}$$

The likelihood ratio test for the reduced rank model $H_{r,s}$ with rank $\leq s$ in the model $H_{r,k-r} = H_r^0$ is given by

$$Q_{r,s} = -T \sum_{i=s+1}^{k-r} \log(1 - \rho_i), \quad s = 0, \dots, k - r - 1$$

The following statements compute the rank test to test for cointegrated order 2:

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(johansen=(iorder=2));
run;
```

The last two columns in Figure 35.60 explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level because the test statistic of 0.5552 is smaller than the critical value of 3.84. Now, look at the row associated with $r = 1$. Compare the test statistic value, 211.84512, to the critical value, 3.84, for the cointegrated order 2. There is no evidence that the series are integrated order 2 at the 0.05 significance level.

Figure 35.60 Cointegrated I(2) Test (IORDER= Option)

Multivariate GARCH Modeling

Stochastic volatility modeling is important in many areas, particularly in finance. To study the volatility of time series, GARCH models are widely used because they provide a good approach to conditional variance modeling.

BEKK Representation

Engle and Kroner (1995) propose a general multivariate GARCH model and call it a BEKK representation. Let $\mathcal{F}(t-1)$ be the sigma field generated by the past values of ϵ_t , and let H_t be the conditional covariance matrix of the k -dimensional random vector ϵ_t . Let H_t be measurable with respect to $\mathcal{F}(t-1)$; then the multivariate GARCH model can be written as

$$\begin{aligned}\epsilon_t | \mathcal{F}(t-1) &\sim N(0, H_t) \\ H_t &= C + \sum_{i=1}^q A_i' \epsilon_{t-i} \epsilon_{t-i}' A_i + \sum_{i=1}^p G_i' H_{t-i} G_i\end{aligned}$$

where C , A_i and G_i are $k \times k$ parameter matrices.

Consider a bivariate GARCH(1,1) model as follows:

$$\begin{aligned}H_t &= \begin{bmatrix} c_{11} & c_{12} \\ c_{12} & c_{22} \end{bmatrix} + \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}' \begin{bmatrix} \epsilon_{1,t-1}^2 & \epsilon_{1,t-1} \epsilon_{2,t-1} \\ \epsilon_{2,t-1} \epsilon_{1,t-1} & \epsilon_{2,t-1}^2 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \\ &\quad + \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}' H_{t-1} \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}\end{aligned}$$

or, representing the univariate model,

$$\begin{aligned}
 h_{11,t} &= c_{11} + a_{11}^2 \epsilon_{1,t-1}^2 + 2a_{11}a_{21}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}^2 \epsilon_{2,t-1}^2 \\
 &\quad + g_{11}^2 h_{11,t-1} + 2g_{11}g_{21}h_{12,t-1} + g_{21}^2 h_{22,t-1} \\
 h_{12,t} &= c_{12} + a_{11}a_{12}\epsilon_{1,t-1}^2 + (a_{21}a_{12} + a_{11}a_{22})\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}a_{22}\epsilon_{2,t-1}^2 \\
 &\quad + g_{11}g_{12}h_{11,t-1} + (g_{21}g_{12} + g_{11}g_{22})h_{12,t-1} + g_{21}g_{22}h_{22,t-1} \\
 h_{22,t} &= c_{22} + a_{12}^2 \epsilon_{1,t-1}^2 + 2a_{12}a_{22}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{22}^2 \epsilon_{2,t-1}^2 \\
 &\quad + g_{12}^2 h_{11,t-1} + 2g_{12}g_{22}h_{12,t-1} + g_{22}^2 h_{22,t-1}
 \end{aligned}$$

For the BEKK representation of the bivariate GARCH(1,1) model, the SAS statements are:

```

model y1 y2;
garch q=1 p=1 form=bekk;

```

CCC Representation

Bollerslev (1990) proposes a multivariate GARCH model with time-varying conditional variances and covariances but constant conditional correlations.

The conditional covariance matrix H_t consists of

$$H_t = D_t S D_t$$

where D_t is a $k \times k$ stochastic diagonal matrix with element $\sigma_{i,t}$ and S is a $k \times k$ time-invariant correlation matrix with the typical element s_{ij} .

The element of H_t is

$$h_{ij,t} = s_{ij}\sigma_{i,t}\sigma_{j,t} \quad i, j = 1, \dots, k$$

Note that $h_{ii,t} = \sigma_{i,t}^2, i = 1, \dots, k$.

If you specify CORRCONSTANT=EXPECT, the element s_{ij} of the time-invariant correlation matrix S is

$$s_{ij} = \frac{1}{T} \sum_{t=1}^T \frac{\epsilon_{i,t}}{\sqrt{h_{ii,t}}} \frac{\epsilon_{j,t}}{\sqrt{h_{jj,t}}}$$

where T is the sample size.

By default, or when you specify SUBFORM=GARCH, $\sigma_{i,t}^2$ follows a univariate GARCH process,

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^q a_{ii,l} \epsilon_{i,t-l}^2 + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \dots, k$$

As shown in many empirical studies, positive and negative innovations have different impacts on future volatility. There is a long list of variations of univariate GARCH models that consider the asymmetry. Four typical variations follow:

- Exponential GARCH (EGARCH) model (Nelson and Cao 1992)
- Quadratic GARCH (QGARCH) model (Engle and Ng 1993)
- Threshold GARCH (TGARCH) model (Glosten, Jaganathan, and Runkle 1993; Zakoian 1994)
- Power GARCH (PGARCH) model (Ding, Granger, and Engle 1993)

For more information about the asymmetric GARCH models, see Engle and Ng (1993). You can choose the type of GARCH model of interest by specifying the SUBFORM= option.

The EGARCH model was proposed by Nelson (1991). Nelson and Cao (1992) argue that the nonnegativity constraints in the GARCH model are too restrictive. The GARCH model, implicitly or explicitly, imposes the nonnegative constraints on the parameters, whereas these parameters have no restrictions in the EGARCH model. In the EGARCH model, the conditional variance is an asymmetric function of lagged disturbances:

$$\ln(\sigma_{i,t}^2) = c_i + \sum_{l=1}^q a_{ii,l} \left(b_{ii,l} \frac{\epsilon_{i,t-l}}{\sigma_{i,t-l}} + \left| \frac{\epsilon_{i,t-l}}{\sigma_{i,t-l}} \right| - \sqrt{\frac{2}{\pi}} \right) + \sum_{l=1}^p g_{ii,l} \ln(\sigma_{i,t-l}^2) \quad i = 1, \dots, k$$

In the QGARCH model, the lagged errors' centers are shifted from zero to some constant values:

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^q a_{ii,l} (\epsilon_{i,t-l} - b_{ii,l})^2 + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \dots, k$$

In the TGARCH model, each lagged squared error has an extra slope coefficient:

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^q (a_{ii,l} + 1_{\epsilon_{i,t-l} < 0} b_{ii,l}) \epsilon_{i,t-l}^2 + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \dots, k$$

where the indicator function $1_{\epsilon_{i,t} < 0}$ is one if $\epsilon_{i,t} < 0$ and zero otherwise.

The PGARCH model not only considers the asymmetric effect but also provides a way to model the long memory property in the volatility:

$$\sigma_{i,t}^{2\lambda_i} = c_i + \sum_{l=1}^q a_{ii,l} (|\epsilon_{i,t-l}| - b_{ii,l} \epsilon_{i,t-l})^{2\lambda_i} + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^{2\lambda_i} \quad i = 1, \dots, k$$

where $\lambda_i > 0$ and $|b_{ii,l}| \leq 1, l = 1, \dots, q, i = 1, \dots, k$.

Note that the implemented TGARCH model is also well known as GJR-GARCH (Glosten, Jaganathan, and Runkle 1993), which is similar to the threshold GARCH model proposed by Zakoian (1994) but not exactly the same. In Zakoian's model, the conditional standard deviation is a linear function of the past values of the white noise. Zakoian's model can be regarded as a special case of the PGARCH model when $\lambda_i = 1/2$.

DCC Representation

Engle (2002) proposes a parsimonious parametric multivariate GARCH model that has time-varying conditional covariances and correlations.

The conditional covariance matrix H_t consists of

$$H_t = D_t \Gamma_t D_t$$

where D_t is a $k \times k$ stochastic diagonal matrix with the element $\sigma_{i,t}$ and Γ_t is a $k \times k$ time-varying matrix with the typical element $\rho_{ij,t}$.

The element of H_t is

$$h_{ij,t} = \rho_{ij,t} \sigma_{i,t} \sigma_{j,t} \quad i, j = 1, \dots, k$$

Note that $h_{ii,t} = \sigma_{i,t}^2, i = 1, \dots, k$.

As in the CCC GARCH model, you can choose the type of GARCH model of interest by specifying the SUBFORM= option.

In the GARCH model,

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^q a_{ii,l} \epsilon_{i,t-l}^2 + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \dots, k$$

In the EGARCH model, the conditional variance is an asymmetric function of lagged disturbances:

$$\ln(\sigma_{i,t}^2) = c_i + \sum_{l=1}^q a_{ii,l} (b_{ii,l} \frac{\epsilon_{i,t-l}}{\sigma_{i,t-l}} + |\frac{\epsilon_{i,t-l}}{\sigma_{i,t-l}}| - \sqrt{\frac{2}{\pi}}) + \sum_{l=1}^p g_{ii,l} \ln(\sigma_{i,t-l}^2) \quad i = 1, \dots, k$$

In the QGARCH model, the lagged errors' centers are shifted from zero to some constant values:

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^q a_{ii,l} (\epsilon_{i,t-l} - b_{ii,l})^2 + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \dots, k$$

In the TGARCH model, each lagged squared error has an extra slope coefficient:

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^q (a_{ii,l} + 1_{\epsilon_{i,t-l} < 0} b_{ii,l}) \epsilon_{i,t-l}^2 + \sum_{l=1}^p g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \dots, k$$

where the indicator function $1_{\epsilon_{i,t} < 0}$ is one if $\epsilon_{i,t} < 0$ and zero otherwise.

The PGARCH model not only considers the asymmetric effect but also provides another way to model the long memory property in the volatility:

$$\sigma_{i,t}^{2\lambda_i} = c_i + \sum_{l=1}^q a_{ii,l}(|\epsilon_{i,t-l}| - b_{ii,l}\epsilon_{i,t-l})^{2\lambda_i} + \sum_{l=1}^p g_{ii,l}\sigma_{i,t-l}^{2\lambda_i} \quad i = 1, \dots, k$$

where $\lambda_i > 0$ and $|b_{ii,l}| \leq 1, l = 1, \dots, q, i = 1, \dots, k$.

The conditional correlation estimator $\rho_{ij,t}$ is

$$\begin{aligned} \rho_{ij,t} &= \frac{q_{ij,t}}{\sqrt{q_{ii,t}q_{jj,t}}} \quad i, j = 1, \dots, k \\ q_{ij,t} &= (1 - \alpha - \beta)s_{ij} + \alpha \frac{\epsilon_{i,t-1}}{\sigma_{i,t-1}} \frac{\epsilon_{j,t-1}}{\sigma_{j,t-1}} + \beta q_{ij,t-1} \end{aligned}$$

where s_{ij} is the element of S , the unconditional correlation matrix.

If you specify CORRCONSTANT=EXPECT, the element s_{ij} of the unconditional correlation matrix S is

$$s_{ij} = \frac{1}{T} \sum_{t=1}^T \frac{\epsilon_{i,t}}{\sigma_{i,t}} \frac{\epsilon_{j,t}}{\sigma_{j,t}}$$

where T is the sample size.

Estimation of GARCH Model

The log-likelihood function of the multivariate GARCH model is written without a constant term as

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |H_t| + \epsilon_t' H_t^{-1} \epsilon_t]$$

The log-likelihood function is maximized by an iterative numerical method such as quasi-Newton optimization. The starting values for the regression parameters are obtained from the least squares estimates. The covariance of ϵ_t is used as the starting values for the GARCH constant parameters, and the starting value for the other GARCH parameters is either 10^{-6} or 10^{-3} , depending on the GARCH model's representation.

Covariance Stationarity

Define the multivariate GARCH process as

$$\mathbf{h}_t = \sum_{i=1}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\eta_t]$$

where $\mathbf{h}_t = \text{vec}(H_t)$, $\mathbf{c} = \text{vec}(C_0)$, and $\boldsymbol{\eta}_t = \text{vec}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t')$. This representation is equivalent to a GARCH(p, q) model by the following algebra:

$$\begin{aligned} \mathbf{h}_t &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + \sum_{i=2}^{\infty} G(B)^{i-1}[\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\ &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B) \sum_{i=1}^{\infty} G(B)^{i-1}[\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\ &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B)\mathbf{h}_t \end{aligned}$$

Defining $A(B) = \sum_{i=1}^q (A_i \otimes A_i)' B^i$ and $G(B) = \sum_{i=1}^p (G_i \otimes G_i)' B^i$ gives a BEKK representation.

The necessary and sufficient conditions for covariance stationarity of the multivariate GARCH process are that all the eigenvalues of $A(1) + G(1)$ are less than 1 in modulus.

An Example of a VAR(1)–ARCH(1) Model

The following DATA step simulates a bivariate vector time series to provide test data for the multivariate GARCH model:

```
data garch;
  retain seed 16587;
  esq1 = 0; esq2 = 0;
  ly1 = 0; ly2 = 0;
  do i = 1 to 1000;
    ht = 6.25 + 0.5*esq1;
    call rannor(seed, ehat);
    e1 = sqrt(ht)*ehat;
    ht = 1.25 + 0.7*esq2;
    call rannor(seed, ehat);
    e2 = sqrt(ht)*ehat;
    y1 = 2 + 1.2*ly1 - 0.5*ly2 + e1;
    y2 = 4 + 0.6*ly1 + 0.3*ly2 + e2;
    if i>500 then output;
    esq1 = e1*e1; esq2 = e2*e2;
    ly1 = y1; ly2 = y2;
  end;
  keep y1 y2;
run;
```

The following statements fit a VAR(1)–ARCH(1) model to the data. For a VAR-ARCH model, you specify the order of the autoregressive model with the P=1 option in the MODEL statement and the Q=1 option in the GARCH statement. In order to produce the initial and final values of parameters, the TECH=QN option is specified in the NLOPTIONS statement.

```
proc varmax data=garch;
  model y1 y2 / p=1
    print=(roots estimates diagnose);
  garch q=1;
  nloptions tech=qn;
run;
```

Figure 35.61 through Figure 35.65 show the details of this example. Figure 35.61 shows the initial values of parameters.

Output Data Sets

The VARMAX procedure can create the OUT=, OUTEST=, OUTHT=, and OUTSTAT= data sets. In general, if processing fails, the output is not recorded or is set to missing in the relevant output data set, and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the forecast values produced by the OUTPUT statement. The following output variables can be created:

- the BY variables
- the ID variable
- the MODEL statement dependent (endogenous) variables. These variables contain the actual values from the input data set.
- FOR_i , numeric variables that contain the forecasts. The FOR_i variables contain the forecasts for the i th endogenous variable in the MODEL statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option. Multistep forecasts can be computed after that point based on the LEAD= option.
- RES_i , numeric variables that contain the residual for the forecast of the i th endogenous variable in the MODEL statement list. For multistep forecast observations, the actual values are missing and the RES_i variables contain missing values.
- STD_i , numeric variables that contain the standard deviation for the forecast of the i th endogenous variable in the MODEL statement list. The values of the STD_i variables can be used to construct univariate confidence limits for the corresponding forecasts.
- LCI_i , numeric variables that contain the lower confidence limits for the corresponding forecasts of the i th endogenous variable in the MODEL statement list.
- UCI_i , numeric variables that contain the upper confidence limits for the corresponding forecasts of the i th endogenous variable in the MODEL statement list.

The OUT= data set contains the values shown in Table 35.7 and Table 35.8 for a bivariate case.

Table 35.7 OUT= Data Set

Obs	ID variable	y1	FOR1	RES1	STD1	LCI1	UCI1
1	date	y_{11}	f_{11}	r_{11}	σ_{11}	l_{11}	u_{11}

OUTEST= Data Set

The OUTEST= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created:

- BY variables
- NAME, a character variable that contains the name of the endogenous (dependent) variables or the name of the parameters for the covariance of the matrix of the parameter estimates if you specify the OUTCOV option
- TYPE, a character variable that contains the value EST for parameter estimates, the value STD for standard error of parameter estimates, and the value COV for the covariance of the matrix of the parameter estimates if you specify the OUTCOV option
- CONST, a numeric variable that contains the estimates of constant parameters and their standard errors
- SEASON_*i*, a numeric variable that contains the estimates of seasonal dummy parameters and their standard errors, where $i = 1, \dots, (nseason - 1)$, and *nseason* is based on the NSEASON= option
- LTREND, a numeric variable that contains the estimates of linear trend parameters and their standard errors
- QTREND, a numeric variable that contains the estimates of quadratic trend parameters and their standard errors
- XL*l*_*i*, numeric variables that contain the estimates of exogenous parameters and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, r$, where *r* is the number of exogenous variables
- AR*l*_*i*, numeric variables that contain the estimates of autoregressive parameters and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, k$, where *k* is the number of endogenous variables
- MA*l*_*i*, numeric variables that contain the estimates of moving-average parameters and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, k$, where *k* is the number of endogenous variables
- COV_*i*, numeric variables that contain the estimates of the covariance of innovations parameters when the maximum likelihood method is applied, where $i = 1, \dots, k$
- DCCAB, a numeric variable that contains the estimates of α or β in the correlation equation for DCC representation and their standard errors
- CCC_*i*, numeric variables that contain the estimates of the conditional constant correlation parameters for CCC representation, where $i = 2, \dots, k$
- DCCS_*i*, numeric variables that contain the estimates of the unconditional correlation parameters for DCC representation, where $i = 2, \dots, k$
- GCHC_*i*, numeric variables that contain the estimates of the constant parameters of the covariance matrix and their standard errors, where $i = 1, \dots, k$ for BEKK representation, *k* is the number of endogenous variables, and $i = 1$ for CCC and DCC representations

- $ACHl_i$, numeric variables that contain the estimates of the ARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for BEKK, CCC, and DCC representations, where k is the number of endogenous variables
- $EACHl_i$, numeric variables that contain the estimates of the exponential ARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for CCC and DCC representations, where k is the number of endogenous variables
- $PACHl_i$, numeric variables that contain the estimates of the power ARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for CCC and DCC representations, where k is the number of endogenous variables
- $QACHl_i$, numeric variables that contain the estimates of the quadratic ARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for CCC and DCC representations, where k is the number of endogenous variables
- $TACHl_i$, numeric variables that contain the estimates of the threshold ARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for CCC and DCC representations, where k is the number of endogenous variables
- $GCHl_i$, numeric variables that contain the estimates of the GARCH parameters of the covariance matrix and their standard errors, where l is the lag l th coefficient matrix and $i = 1, \dots, k$ for BEKK, CCC, and DCC representations, where k is the number of endogenous variables
- LAMBDA, a numeric variable that contains the estimates of power parameters in the PGARCH model for CCC and DCC representations and their standard errors

The OUTEST= data set contains the values shown in Table 35.9 for a bivariate case.

Table 35.9 OUTEST= Data Set

Obs	NAME	TYPE	CONST	AR1_1	AR1_2	AR2_1	AR2_2

OUTHT= Data Set

The OUTHT= data set contains prediction of the fitted GARCH model produced by the GARCH statement. The following output variables can be created.

- the BY variables
- $H_{i,j}$, numeric variables that contain the prediction of covariance, where $1 \leq i < j \leq k$, where k is the number of dependent variables

The OUTHT= data set contains the values shown in [Table 35.10](#) for a bivariate case.

Table 35.10 OUTHT= Data Set

OUTSTAT= Data Set

The OUTSTAT= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created. The subindex i is $1, \dots, k$, where k is the number of endogenous variables.

- the BY variables
- NAME, a character variable that contains the name of endogenous (dependent) variables
- SIGMA_ i , numeric variables that contain the estimate of the innovation covariance matrix
- AICC, a numeric variable that contains the corrected Akaike's information criterion value
- HQC, a numeric variable that contains the Hannan-Quinn's information criterion value
- AIC, a numeric variable that contains the Akaike's information criterion value
- SBC, a numeric variable that contains the Schwarz Bayesian's information criterion value
- FPEC, a numeric variable that contains the final prediction error criterion value
- FValue, a numeric variable that contains the F statistics
- PValue, a numeric variable that contains p -value for the F statistics

If the JOHANSEN= option is specified, the following items are added:

- Eigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1
- RestrictedEigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1 when the NOINT option is not specified
- Beta_ i , numeric variables that contain long-run effect parameter estimates, β
- Alpha_ i , numeric variables that contain adjustment parameter estimates, α

If the JOHANSEN=(IORDER=2) option is specified, the following items are added:

- EValueI2_1, numeric variables that contain eigenvalues for the cointegration rank test of integrated order 2
- EValueI1, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1
- Eta_1, numeric variables that contain the parameter estimates in integrated order 2, η
- Xi_1, numeric variables that contain the parameter estimates in integrated order 2, ξ

The OUTSTAT= data set contains the values shown [Table 35.11](#) for a bivariate case.

Table 35.11 OUTSTAT= Data Set

Obs	NAME	SIGMA_1	SIGMA_2	AICC	RSquare	FValue	PValue
1	y1	σ_{11}	σ_{12}	<i>aicc</i>	R_1^2	F_1	$prob_1$
2	y2	σ_{21}	σ_{22}	.	R_2^2	F_2	$prob_2$

Obs	EValueI2_1	EValueI2_2	EValueI1	Beta_1	Beta_2

2	α_{21}	α_{22}	η_{21}	η_{22}	ξ_{21}	ξ_{22}

Consider the following example:

```
proc varmax data=simul2 outstat=stat;
  model y1 y2 / p=2 noint
    cointtest=(johansen=(iorder=2))
    ecm=(rank=1 normalize=y1)
    noprint;
run;

proc print data=stat;
run;
```

The output in [Figure 35.69](#) shows the results of the OUTSTAT= data set.

Printed Output

The default printed output produced by the VARMAX procedure is described in the following list:

- descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (STD), their minimums and maximums, the differencing operations used, and the labels of the variables
- a type of model to fit the data and an estimation method
- a table of parameter estimates that shows the following for each parameter: the variable name for the left-hand side of equation, the parameter name, the parameter estimate, the approximate standard error, t value, the approximate probability ($Pr > |t|$), and the variable name for the right-hand side of equations in terms of each parameter
- the innovation covariance matrix
- the information criteria

If PRINT=ESTIMATES is specified, the VARMAX procedure prints the following list with the default printed output:

- the estimates of the constant vector (or seasonal constant matrix), the trend vector, the coefficient matrices of the distributed lags, the AR coefficient matrices, and the MA coefficient matrices
- the ALPHA and BETA parameter estimates for the error correction model
- the schematic representation of parameter estimates

If PRINT=DIAGNOSE is specified, the VARMAX procedure prints the following list with the default printed output:

- the cross-covariance and cross-correlation matrices of the residuals
- the tables of test statistics for the hypothesis that the residuals of the model are white noise:
 - Durbin-Watson (DW) statistics
 - F test for autoregressive conditional heteroscedastic (ARCH) disturbances
 - F test for AR disturbance
 - Jarque-Bera normality test
 - Portmanteau test

ODS Table Names

The VARMAX procedure assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 35.12](#).

Table 35.12 ODS Tables Produced in the VARMAX Procedure

ODS Table Name	Description	Option

ODS Graphics

This section describes the use of ODS for creating statistical graphs with the VARMAX procedure.

When ODS GRAPHICS are in effect, the VARMAX procedure produces a variety of plots for each dependent variable.

The plots available are as follows:

- The procedure displays the following plots for each dependent variable in the MODEL statement with the PLOT= option in the VARMAX statement:
 - impulse response function
 - impulse response of the transfer function
 - time series and predicted series
 - prediction errors
 - distribution of the prediction errors
 - normal quantile of the prediction errors
 - ACF of the prediction errors
 - PACF of the prediction errors
 - IACF of the prediction errors
 - log scaled white noise test of the prediction errors
- The procedure displays forecast plots for each dependent variable in the OUTPUT statement with the PLOT= option in the VARMAX statement.

ODS Graph Names

The VARMAX procedure assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 35.13](#).

Table 35.13 ODS Graphics Produced in the VARMAX Procedure

ODS Table Name	Plot Description	Statement

Computational Issues

Computational Method

The VARMAX procedure uses numerous linear algebra routines and frequently uses the sweep operator (Goodnight 1979) and the Cholesky root (Golub and Van Loan 1983).

In addition, the VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks for the maximum likelihood estimation. The optimization requires intensive computation.

Convergence Problems

For some data sets, the computation algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data.

If you experience convergence problems, the following points might be helpful:

- Data that contain extreme values can affect results in PROC VARMAX. Rescaling the data can improve stability.
- Changing the TECH=, MAXITER=, and MAXFUNC= options in the **NLOPTIONS** statement can improve the stability of the optimization process.
- Specifying a different model that might fit the data more closely and might improve convergence.

Memory

Let T be the length of each series, k be the number of dependent variables, p be the order of autoregressive terms, and q be the order of moving-average terms. The number of parameters to estimate for a VARMA(p, q) model is

$$k + (p + q)k^2 + k * (k + 1)/2$$

As k increases, the number of parameters to estimate increases very quickly. Furthermore the memory requirement for VARMA(p, q) quadratically increases as k and T increase.

For a VARMAX(p, q, s) model and GARCH-type multivariate conditional heteroscedasticity models, the number of parameters to estimate and the memory requirements are considerable.

Computing Time

PROC VARMAX is computationally intensive, and execution times can be long. Extensive CPU time is often required to compute the maximum likelihood estimates.

Examples: VARMAX Procedure

Example 35.1: Analysis of U.S. Economic Variables

Consider the following four-dimensional system of U.S. economic variables. Quarterly data for the years 1954 to 1987 are used (Lütkepohl 1993, Table E.3.).

```

title 'Analysis of U.S. Economic Variables';
data us_money;
    date=intnx( 'qtr', '01jan54'd, _n_-1 );
    format date yyq. ;
    input y1 y2 y3 y4 @@;
    y1=log(y1);
    y2=log(y2);
    label y1='log(real money stock M1)'
          y2='log(GNP in bil. of 1982 dollars)'
          y3='Discount rate on 91-day T-bills'
          y4='Yield on 20-year Treasury bonds';
datalines;
450.9 1406.8 0.010800000 0.026133333
453.0 1401.2 0.0081333333 0.025233333
459.1 1418.0 0.0087000000 0.024900000
... more lines ...

```

The following statements plot the series and proceed with the VARMAX procedure.

```
proc timeseries data=us_money vectorplot=series;
  id date interval=qtr;
  var y1 y2;
run;
```

Output 35.1.1 shows the plot of the variables y1 and y2.

Output 35.1.1 Plot of Data

The following statements plot the variables y3 and y4.

```
proc timeseries data=us_money vectorplot=series;
  id date interval=qtr;
  var y3 y4;
run;
```

Output 35.1.2 shows the plot of the variables y3 and y4.

Output 35.1.2 Plot of Data

```
proc varmax data=us_money;
  id date interval=qtr;
  model y1-y4 / p=2 lagmax=6 dfest
    print=(iarr(3) estimates diagnose)
    cointtest=(johansen=(iorder=2))
    ecm=(rank=1 normalize=y1);
  cointeg rank=1 normalize=y1 exogeneity;
run;
```

This example performs the Dickey-Fuller test for stationarity, the Johansen cointegrated test integrated order 2, and the exogeneity test. The VECM(2) is fit to the data. From the outputs shown in [Output 35.1.5](#), you can see that the series has unit roots and is cointegrated in rank 1 with integrated order 1. The fitted

VECM(2) is given as

$$\Delta \mathbf{y}_t = \begin{pmatrix} 0.0408 \\ 0.0860 \\ 0.0052 \\ -0.0144 \end{pmatrix} + \begin{pmatrix} -0.0140 & 0.0065 & -0.2026 & 0.1306 \\ -0.0281 & 0.0131 & -0.4080 & 0.2630 \\ -0.0022 & 0.0010 & -0.0312 & 0.0201 \\ 0.0051 & -0.0024 & 0.0741 & -0.0477 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.3460 & 0.0913 & -0.3535 & -0.9690 \\ 0.0994 & 0.0379 & 0.2390 & 0.2866 \\ 0.1812 & 0.0786 & 0.0223 & 0.4051 \\ 0.0322 & 0.0496 & -0.0329 & 0.1857 \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The Δ prefixed to a variable name implies differencing.

Output 35.1.3 through Output 35.1.14 show the details. Output 35.1.3 shows the descriptive statistics.

Output 35.1.3 Descriptive Statistics

Analysis of U.S. Economic Variables						
The VARMAX Procedure						
Number of Observations		136

y4	Yield on 20-year Treasury bonds					

Output 35.1.4 shows the output for Dickey-Fuller tests for the nonstationarity of each series. The null hypotheses is to test a unit root. All series have a unit root.

Output 35.1.4 Unit Root Tests

Unit Root Test					
Variable	Type	Rho	Pr < Rho	Tau	Pr < Tau
y1	Zero Mean	0.05	0.6934	1.14	0.9343
	Single Mean	-2.97	0.6572	-0.76	0.8260
	Trend	-5.91	0.7454	-1.34	0.8725
y2	Zero Mean	0.13	0.7124	5.14	0.9999
	Single Mean	-0.43	0.9309	-0.79	0.8176
	Trend	-9.21	0.4787	-2.16	0.5063
y3	Zero Mean	-1.28	0.4255	-0.69	0.4182
	Single Mean	-8.86	0.1700	-2.27	0.1842
	Trend	-18.97	0.0742	-2.86	0.1803
y4	Zero Mean	0.40	0.7803	0.45	0.8100
	Single Mean	-2.79	0.6790	-1.29	0.6328
	Trend	-12.12	0.2923	-2.33	0.4170

The Johansen cointegration rank test shows whether the series is integrated order either 1 or 2 as shown in [Output 35.1.5](#). The last two columns in [Output 35.1.5](#) explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level because the test statistic of 20.6542 is smaller than the critical value of 29.38. Now, look at the row associated with $r = 1$. Compare the test statistic value and critical value pairs such as (219.62395, 29.38), (89.21508, 15.34), and (27.32609, 3.84). There is no evidence that the series are integrated order 2 at the 0.05 significance level.

Output 35.1.5 Cointegration Rank Test

y3	1	0.09	0.7695
y4	1	1.81	0.1786

Example 35.2: Analysis of German Economic Variables

This example considers a three-dimensional VAR(2) model. The model contains the logarithms of a quarterly, seasonally adjusted West German fixed investment, disposable income, and consumption expenditures. The data used are in Lütkepohl (1993, Table E.1).

```

title 'Analysis of German Economic Variables';
data west;
    date = intnx( 'qtr', '01jan60'd, _n_-1 );
    format date yyq. ;
    input y1 y2 y3 @@;
    y1 = log(y1);
    y2 = log(y2);
    y3 = log(y3);
    label y1 = 'logarithm of investment'
           y2 = 'logarithm of income'
           y3 = 'logarithm of consumption';
datalines;
180 451 415 179 465 421 185 485 434 192 493 448
211 509 459 202 520 458 207 521 479 214 540 487

... more lines ...

data use;
    set west;
    where date < '01jan79'd;
    keep date y1 y2 y3;
run;

proc varmax data=use;
    id date interval=qtr;
    model y1-y3 / p=2 dify=(1)
           print=(decompose(6) impulse=(stderr) estimates diagnose)
           printform=both lagmax=3;

```

```

causal group1=(y1) group2=(y2 y3);
output lead=5;
run;

```

First, the differenced data is modeled as a VAR(2) with the following result:

$$\Delta y_t = \begin{pmatrix} -0.01672 \\ 0.01577 \\ 0.01293 \end{pmatrix} + \begin{pmatrix} -0.31963 & 0.14599 & 0.96122 \\ 0.04393 & -0.15273 & 0.28850 \\ -0.00242 & 0.22481 & -0.26397 \end{pmatrix} \Delta y_{t-1} + \begin{pmatrix} -0.16055 & 0.11460 & 0.93439 \\ 0.05003 & 0.01917 & -0.01020 \\ 0.03388 & 0.35491 & -0.02223 \end{pmatrix} \Delta y_{t-2} + \epsilon_t$$

The parameter estimates AR1_1_2, AR1_1_3, AR2_1_2, and AR2_1_3 are insignificant, and the VARX model is fitted in the next step.

The detailed output is shown in [Output 35.2.1](#) through [Output 35.2.8](#).

[Output 35.2.1](#) shows the descriptive statistics.

Output 35.2.1 Descriptive Statistics

The proportions of decomposition of the prediction error covariances of three variables are given in [Output 35.2.7](#). If you see the y3 variable in the first column, then the output explains that about 64.713% of the one-step-ahead prediction error covariances of the variable y_{3t} is accounted for by its own innovations, about 7.995% is accounted for by y_{1t} innovations, and about 27.292% is accounted for by y_{2t} innovations.

Output 35.2.7 Proportions of Prediction Error Covariance Decomposition

Proportions of Prediction Error Covariances by Variable				
Variable	Lead	y1	y2	y3
y1	1	1.00000	0.00000	0.00000
	2	0.95996	0.01751	0.02253

[Output 35.2.9](#) shows that you cannot reject Granger noncausality from (y2, y3) to y1 using the 0.05 significance level.

Output 35.2.9 Granger Causality Tests

Granger-Causality Wald Test			
Test	DF	Chi-Square	Pr > ChiSq
1	4	6.37	0.1734
Test 1: Group 1 Variables: y1			
Group 2 Variables: y2 y3			

The following SAS statements show that the variable y1 is the exogenous variable and fit the VARX(2,1) model to the data.

```
proc varmax data=use;
  id date interval=qtr;
  model y2 y3 = y1 / p=2 difx=(1) difx=(1) xlag=1 lagmax=3
    print=(estimates diagnose);
run;
```

The fitted VARX(2,1) model is written as

$$\begin{pmatrix} \Delta y_{2t} \\ \Delta y_{3t} \end{pmatrix} = \begin{pmatrix} 0.01542 \\ 0.01319 \end{pmatrix} + \begin{pmatrix} 0.02520 \\ 0.05130 \end{pmatrix} \Delta y_{1t} + \begin{pmatrix} 0.03870 \\ 0.00363 \end{pmatrix} \Delta y_{1,t-1} \\
 + \begin{pmatrix} -0.12258 & 0.25811 \\ 0.24367 & -0.31809 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-1} \\ \Delta y_{3,t-1} \end{pmatrix} \\
 + \begin{pmatrix} 0.01651 & 0.03498 \\ 0.34921 & -0.01664 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-2} \\ \Delta y_{3,t-2} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{pmatrix}$$

The detailed output is shown in [Output 35.2.10](#) through [Output 35.2.13](#).

[Output 35.2.10](#) shows the parameter estimates in terms of the constant, the current and the lag one coefficients of the exogenous variable, and the lag two coefficients of the dependent variables.

Output 35.2.10 Parameter Estimates

Example 35.3: Numerous Examples

The following are examples of syntax for model fitting:

```
/* Data 'a' Generated Process */
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  call varmasim(y,phi) sigma = sig n = 100 seed = 46859;
  cn = {'y1' 'y2'};
  create a from y[colname=cn];
  append from y;
run;;

/* when the series has a linear trend */
proc varmax data=a;
  model y1 y2 / p=1 trend=linear;
run;

/* Fit subset of AR order 1 and 3 */
proc varmax data=a;
```

```

    model y1 y2 / p=(1,3);
run;

/* Check if the series is nonstationary */
proc varmax data=a;
    model y1 y2 / p=1 dfestest print=(roots);
run;

/* Fit VAR(1) in differencing */
proc varmax data=a;
    model y1 y2 / p=1 print=(roots) dify=(1);
run;

/* Fit VAR(1) in seasonal differencing */
proc varmax data=a;
    model y1 y2 / p=1 dify=(4) lagmax=5;
run;

/* Fit VAR(1) in both regular and seasonal differencing */
proc varmax data=a;
    model y1 y2 / p=1 dify=(1,4) lagmax=5;
run;

/* Fit VAR(1) in different differencing */
proc varmax data=a;
    model y1 y2 / p=1 dif=(y1(1,4) y2(1)) lagmax=5;
run;

/* Options related to prediction */
proc varmax data=a;
    model y1 y2 / p=1 lagmax=3
        print=(impulse covpe(5) decompose(5));
run;

/* Options related to tentative order selection */
proc varmax data=a;
    model y1 y2 / p=1 lagmax=5 minic
        print=(parcoef pcancorr pcorr);
run;

/* Automatic selection of the AR order */
proc varmax data=a;
    model y1 y2 / minic=(type=aic p=5);
run;

/* Compare results of LS and Yule-Walker Estimators */
proc varmax data=a;
    model y1 y2 / p=1 print=(yw);
run;

/* BVAR(1) of the nonstationary series y1 and y2 */
proc varmax data=a;
    model y1 y2 / p=1
        prior=(lambda=1 theta=0.2 ivar);

```

```

run;

proc varmax data=grunfeld;
    model y1 y2 = x1 / p=1 xlag=2 difx=(1) dify=(1);
run;

```

Example 35.4: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. For information about the graphics available in the VARMAX procedure, see the section “ODS Graphics” on page 2526.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the series of masonry workers. The series and predict plots, the residual plot, and the forecast plot are created in [Output 35.4.1](#) through [Output 35.4.3](#). These are a selection of the plots created by the VARMAX procedure.

```
title "Illustration of ODS Graphics";
proc varmax data=sashelp.workers plot(unpack)=(residual model forecasts);
  id date interval=month;
  model electric masonry / dify=(1,12) noint p=1;
  output lead=12;
run;
```

Overview: X11 Procedure

The X11 procedure, an adaptation of the U.S. Bureau of the Census X-11 Seasonal Adjustment program, seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set containing the adjusted time series and intermediate calculations.

The X11 procedure also provides the X-11-ARIMA method developed by Statistics Canada. This method fits an ARIMA model to the original series, then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

The X11 procedure incorporates sliding spans analysis. This type of analysis provides a diagnostic for determining the suitability of seasonal adjustment for an economic series.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t , $t = 1, \dots, n$, and separated from trend cycle, trading-day, and irregular fluctuations. The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated constantly or in an evolving fashion from year to year. The trend cycle component, C_t , includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading-day component, D_t , is the variation that can be attributed to the composition of the calendar. The irregular component, I_t , is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). A seasonally adjusted time series, $C_t I_t$, consists of only the trend cycle and irregular components.

Getting Started: X11 Procedure

The most common use of the X11 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X11 to produce a seasonally adjusted series, $C_t I_t$, from an original series $O_t = S_t C_t D_t I_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t , while S_t , D_t , and I_t vary around 1.0. In all printed tables and in the output data set, these latter components are expressed as percentages, and thus will vary around 100.0 (in the additive case, they vary around 0.0).

The naming convention used in PROC X11 for the tables follows the original U.S. Bureau of the Census X-11 Seasonal Adjustment program specification (Shiskin, Young, and Musgrave 1967). Also, see the section “Printed Output” on page 2599. This convention is outlined in Figure 36.1.

The tables corresponding to parts A – C are intermediate calculations. The final estimates of the individual components are found in the D tables: table D10 contains the final seasonal factors, table D12 contains the final trend cycle, and table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you only need to look at table D11, the final seasonally adjusted series.

For further details about the X-11-ARIMA tables, see Ladiray and Quenneville (2001).

Basic Seasonal Adjustment

Suppose you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the MONTHLY statement, which associates a SAS date value to each observation. To see the results of the seasonal adjustment, you must request table D11, the final seasonally adjusted series, in a TABLES statement.

```
data sales;
    input sales @@;
    date = intnx( 'month', '01sep1978'd, _n_-1 );
    format date monyy7.;
datalines;
112 118 132 129 121 135 148 148 136 119 104 118

... more lines ...

/*--- X-11 ARIMA ---*/
proc x11 data=sales;
    monthly date=date;
    var sales;
    tables d11;
run;
```

```

Figure 36.3 Plot of Original and Seasonally Adjusted Data

X-11-ARIMA

An inherent problem with the X-11 method is the revision of the seasonal factor estimates as new data become available. The X-11 method uses a set of centered moving averages to estimate the seasonal components. These moving averages apply symmetric weights to all observations except those at the beginning and end of the series, where asymmetric weights have to be applied. These asymmetric weights can cause poor estimates of the seasonal factors, which then can cause large revisions when new data become available.

While large revisions to seasonally adjusted values are not common, they can happen. When they do happen, it undermines the credibility of the X-11 seasonal adjustment method.

A method to address this problem was developed at Statistics Canada (Dagum 1980, 1982a). This method, known as X-11-ARIMA, applies an ARIMA model to the original data (after adjustments, if any) to forecast the series one or more years. This extended series is then seasonally adjusted, allowing symmetric weights to be applied to the end of the original data. This method was tested against a large number of Canadian economic series and was found to greatly reduce the amount of revisions as new data were added.

The X-11-ARIMA method is available in PROC X11 through the use of the ARIMA statement. The ARIMA statement extends the original series either with a user-specified ARIMA model or by an automatic selection process in which the best model from a set of five predefined ARIMA models is used.

The following example illustrates the use of the ARIMA statement. The ARIMA statement does not contain a user-specified model, so the best model is chosen by the automatic selection process. Forecasts from this best model are then used to extend the original series by one year. The following partial listing shows parameter estimates and model diagnostics for the ARIMA model chosen by the automatic selection process.

```
proc x11 data=sales;
  monthly date=date;
  var sales;
  arima;
run;
```

Figure 36.4 X-11-ARIMA Model Selection

Monthly Retail Sales Data (in \$1000)

Parameter	Estimate	Std Error	t Value	Lag
MU	0.0001728	0.0009596	0.18	0
MA1,1	0.3739984	0.0893427	4.19	1
MA1,2	0.0231478	0.0892154	0.26	2
MA2,1	0.5727914	0.0790835	7.24	12

Figure 36.4 continued

Conditional Least Squares Estimation			
Variance Estimate =	0.0014313		
Std Error Estimate =	0.0378326		
AIC	=	-482.2412	*
SBC	=	-470.7404	*
Number of Residuals=	131		
* Does not include log determinant			
Criteria Summary for Model 2: (0,1,2) (0,1,1)s, Log Transform			
Box-Ljung Chi-square: 22.03 with 21 df Prob= 0.40			
(Criteria prob > 0.05)			
Test for over-differencing: sum of MA parameters = 0.57			
(must be < 0.90)			
MAPE - Last Three Years: 2.84 (Must be < 15.00 %)			
- Last Year: 3.04			
- Next to Last Year: 1.96			
- Third from Last Year: 3.51			

Table D11 (final seasonally adjusted series) is now constructed using symmetric weights on observations at the end of the actual data. This should result in better estimates of the seasonal factors and, thus, smaller revisions in Table D11 as more data become available.

Syntax: X11 Procedure

The X11 procedure uses the following statements:

```

PROC X11 options ;
  ARIMA options ;
  BY variables ;
  ID variables ;
  MACURVES option ;
  MONTHLY options ;
  OUTPUT OUT=dataset options ;
  PDWEIGHTS option ;
  QUARTERLY options ;
  SSPAN options ;
  TABLES tablenames ;
  VAR variables ;

```

Either the MONTHLY or QUARTERLY statement must be specified, depending on the type of time series data you have. The PDWEIGHTS and MACURVES statements can be used only with the MONTHLY statement. The TABLES statement controls the printing of tables, while the OUTPUT statement controls the creation of the OUT= data set.

Functional Summary

The statements and options controlling the X11 procedures are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set	PROC X11	DATA=
write the trading-day regression results to an output data set	PROC X11	OUTTDR=
write the stable seasonality test results to an output data set	PROC X11	OUTSTB=
write table values to an output data set	OUTPUT	OUT=
add extrapolated values to the output data set	PROC X11	OUTEX
add year ahead estimates to the output data set	PROC X11	YRAHEADOUT
write the sliding spans analysis results to an output data set	PROC X11	OUTSPAN=
Printing Control Options		
suppress all printed output	PROC X11	NOPRINT
suppress all printed ARIMA output	ARIMA	NOPRINT
print all ARIMA output	ARIMA	PRINTALL
print selected tables and charts	TABLES	
print selected groups of tables	MONTHLY	PRINTOUT=
	QUARTERLY	PRINTOUT=
print selected groups of charts	MONTHLY	CHARTS=
	QUARTERLY	CHARTS=
print preliminary tables associated with ARIMA processing	ARIMA	PRINTFP
specify number of decimals for printed tables	MONTHLY	NDEC=
	QUARTERLY	NDEC=
suppress all printed SSPAN output	SSPAN	NOPRINT
print all SSPAN output	SSPAN	PRINTALL
Date Information Options		
specify a SAS date variable	MONTHLY	DATE=
	QUARTERLY	DATE=
specify the beginning date	MONTHLY	START=
	QUARTERLY	START=
specify the ending date	MONTHLY	END=
	QUARTERLY	END=
specify beginning year for trading-day regression	MONTHLY	TDCOMPUTE=

Description	Statement	Option
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the variables to be seasonally adjusted	VAR	
specify identifying variables	ID	
specify the prior monthly factor	MONTHLY	PMFACTOR=
Controlling the Table Computations		
use additive adjustment	MONTHLY	ADDITIVE
	QUARTERLY	ADDITIVE
specify seasonal factor moving average length	MACURVES	
specify the extreme value limit for trading-day regression	MONTHLY	EXCLUDE=
specify the lower bound for extreme irregulars	MONTHLY	FULLWEIGHT=
	QUARTERLY	FULLWEIGHT=
specify the upper bound for extreme irregulars	MONTHLY	ZEROWEIGHT=
	QUARTERLY	ZEROWEIGHT=
include the length-of-month in trading-day regression	MONTHLY	LENGTH
specify trading-day regression action	MONTHLY	TDREGR=
compute summary measure only	MONTHLY	SUMMARY
	QUARTERLY	SUMMARY
modify extreme irregulars prior to trend cycle estimation	MONTHLY	TRENDADJ
	QUARTERLY	TRENDADJ
specify moving average length in trend cycle estimation	MONTHLY	TRENDMA=
	QUARTERLY	TRENDMA=
specify weights for prior trading-day factors	PDWEIGHTS	

PROC X11 Statement

PROC X11 *options* ;

The following options can appear in the PROC X11 statement:

DATA= *SAS-data-set*

specifies the input SAS data set used. If it is omitted, the most recently created SAS data set is used.

OUTEXTRAP

adds the extra observations used in ARIMA processing to the output data set.

When ARIMA forecasting/backcasting is requested, extra observations are appended to the ends of the series, and the calculations are carried out on this extended series. The appended observations are not normally written to the OUT= data set. However, if OUTEXTRAP is specified, these extra observations are written to the output data set. If a DATE= variable is specified in the MONTHLY/QUARTERLY statement, the date variable is extrapolated to identify forecasts/backcasts. The OUTEXTRAP option can be abbreviated as OUTEX.

NOPRINT

suppresses any printed output. The NOPRINT option overrides any PRINTOUT=, CHARTS=, or TABLES statement and any output associated with the ARIMA statement.

OUTSPAN= SAS-data-set

specifies the output data set to store the sliding spans analysis results. Tables A1, C18, D10, and D11 for each span are written to this data set. See the section “[The OUTSPAN= Data Set](#)” on page 2597 for details.

OUTSTB= SAS-data-set

specifies the output data set to store the stable seasonality test results (table D8). All the information in the analysis of variance table associated with the stable seasonality test is contained in the variables written to this data set. See the section “[OUTSTB= Data Set](#)” on page 2597 for details.

OUTTDR= SAS-data-set

specifies the output data set to store the trading-day regression results (tables B15 and C15). All the information in the analysis of variance table associated with the trading-day regression is contained in the variables written to this data set. This option is valid only when TDREGR=PRINT, TEST, or ADJUST is specified in the MONTHLY statement. See the section “[OUTTDR= Data Set](#)” on page 2598 for details.

YRAHEADOUT

adds one-year-ahead forecast values to the output data set for tables C16, C18, and D10. The original purpose of this option was to avoid recomputation of the seasonal adjustment factors when new data became available. While computing costs were an important factor when the X-11 method was developed, this is no longer the case and this option is obsolete. See the section “[The YRAHEADOUT Option](#)” on page 2593 for details.

ARIMA Statement

ARIMA options ;

The ARIMA statement applies the X-11-ARIMA method to the series specified in the VAR statement. This method uses an ARIMA model estimated from the original data to extend the series one or more years. The ARIMA statement options control the ARIMA model used and the estimation, forecasting, and printing of this model.

There are two ways of obtaining an ARIMA model to extend the series. A model can be given explicitly with the MODEL= and TRANSFORM= options. Alternatively, the best-fitting model from a set of five predefined models is found automatically whenever the MODEL= option is absent. See the section “[Details of Model Selection](#)” on page 2594 for details.

BACKCAST= *n*

specifies the number of years to backcast the series. The default is BACKCAST= 0. See the section “[Effect of Backcast and Forecast Length](#)” on page 2593 for details.

CHICR= value

specifies the criteria for the significance level for the Box-Ljung chi-square test for lack of fit when testing the five predefined models. The default is CHICR= 0.05. The CHICR= option values must be between 0.01 and 0.90. The hypothesis being tested is that of model adequacy. Nonrejection of the hypothesis is evidence for an adequate model. Making the CHICR= value smaller makes it easier to accept the model. See the section “[Criteria Details](#)” on page 2595 for further details on the CHICR= option.

CONVERGE= value

specifies the convergence criterion for the estimation of an ARIMA model. The default value is 0.001. The CONVERGE= value must be positive.

FORECAST= n

specifies the number of years to forecast the series. The default is FORECAST= 1. See the section “[Effect of Backcast and Forecast Length](#)” on page 2593 for details.

MAPECR= value

specifies the criteria for the mean absolute percent error (MAPE) when testing the five predefined models. A small MAPE value is evidence for an adequate model; a large MAPE value results in the model being rejected. The MAPECR= value is the boundary for acceptance/rejection. Thus a larger MAPECR= value would make it easier for a model to pass the criteria. The default is MAPECR= 15. The MAPECR= option values must be between 1 and 100. See the section “[Criteria Details](#)” on page 2595 for further details on the MAPECR= option.

MAXITER= n

specifies the maximum number of iterations in the estimation process. MAXITER must be between 1 and 60; the default value is 15.

METHOD= CLS**METHOD= ULS****METHOD= ML**

specifies the estimation method. ML requests maximum likelihood, ULS requests unconditional least squares, and CLS requests conditional least squares. METHOD=CLS is the default. The maximum likelihood estimates are more expensive to compute than the conditional least squares estimates. In some cases, however, they can be preferable. For further information on the estimation methods, see “[Estimation Details](#)” on page 242 in Chapter 7, “[The ARIMA Procedure](#).”

MODEL= (P=n1 Q=n2 SP=n3 SQ=n4 DIF=n5 SDIF=n6 < NOINT > < CENTER >)

specifies the ARIMA model. The AR and MA orders are given by P=n1 and Q=n2, respectively, while the seasonal AR and MA orders are given by SP=n3 and SQ=n4, respectively. The lag corresponding to seasonality is determined by the MONTHLY or QUARTERLY statement. Similarly, differencing and seasonal differencing are given by DIF=n5 and SDIF=n6, respectively.

For example

```
arima model=( p=2 q=1 sp=1 dif=1 sdif=1 );
```

specifies a (2,1,1)(1,1,0)_s model, where *s*, the seasonality, is either 12 (monthly) or 4 (quarterly). More examples of the MODEL= syntax are given in the section “[Details of Model Selection](#)” on page 2594.

NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

CENTER

centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

For example, to fit an AR(1) model on the centered data without an intercept, use the following ARIMA statement:

```
arima model=( p=1 center noint );
```

NOPRINT

suppresses the normal printout generated by the ARIMA statement. Note that the effect of specifying the NOPRINT option in the ARIMA statement is different from the effect of specifying the NOPRINT in the PROC X11 statement, since the former only affects ARIMA output.

OVDIFCR= value

specifies the criteria for the over-differencing test when testing the five predefined models. When the MA parameters in one of these models sum to a number close to 1.0, this is an indication of over-parameterization and the model is rejected. The OVDIFCR= value is the boundary for this rejection; values greater than this value fail the over-differencing test. A larger OVDIFCR= value would make it easier for a model to pass the criteria. The default is OVDIFCR= 0.90. The OVDIFCR= option values must be between 0.80 and 0.99. See the section “[Criteria Details](#)” on page 2595 for further details on the OVDIFCR= option.

PRINTALL

provides the same output as the default printing for all models fit and, in addition, prints an estimation summary and chi-square statistics for each model fit. See “[Printed Output](#)” on page 2599 for details.

PRINTFP

prints the results for the initial pass of X11 made to exclude trading-day effects. This option has an effect only when the TDREGR= option specifies ADJUST, TEST, or PRINT. In these cases, an initial pass of the standard X11 method is required to get rid of calendar effects before doing any ARIMA estimation. Usually this first pass is not of interest, and by default no tables are printed. However, specifying PRINTFP in the ARIMA statement causes any tables printed in the final pass to also be printed for this initial pass.

TRANSFORM= (LOG) | LOG**TRANSFORM= (constant ** power)**

The ARIMA statement in PROC X11 allows certain transformations on the series before estimation. The specified transformation is applied only to a user-specified model. If TRANSFORM= is specified and the MODEL= option is not specified, the transformation request is ignored and a warning is printed.

The LOG transformation requests that the natural log of the series be used for estimation. The resulting forecast values are transformed back to the original scale.

A general power transformation of the form $X_t \rightarrow (X_t + a)^b$ is obtained by specifying

```
transform= ( a ** b )
```

If the constant a is not specified, it is assumed to be zero. The specified ARIMA model is then estimated using the transformed series. The resulting forecast values are transformed back to the original scale.

BY Statement

BY *variables* ;

A BY statement can be used with PROC X11 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

ID Statement

ID *variables* ;

If you are creating an output data set, use the ID statement to put values of the ID variables, in addition to the table values, into the output data set. The ID statement has no effect when an output data set is not created. If the DATE= variable is specified in the MONTHLY or QUARTERLY statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from ARIMA forecasting or backcasting, or from YRAHEADOUT) are extrapolated, while all other ID variables are missing.

MACURVES Statement

MACURVES *month=option* ... ;

The MACURVES statement specifies the length of the moving-average curves for estimating the seasonal factors for any month. This statement can be used only with monthly time series data.

The *month=option* specifications consist of the month name (or the first three letters of the month name), an equal sign, and one of the following option values:

'3'	specifies a three-term moving average for the month
'3X3'	specifies a three-by-three moving average
'3X5'	specifies a three-by-five moving average
'3X9'	specifies a three-by-nine moving average
STABLE	specifies a stable seasonal factor (average of all values for the month)

For example, the statement

```
macurves jan='3' feb='3x3' march='3x5' april='3x9';
```

uses a three-term moving average to estimate seasonal factors for January, a 3×3 (a three-term moving average of a three-term moving average) for February, a 3×5 (a three-term moving average of a five-term moving average) for March, and a 3×9 (a three-term moving average of a nine-term moving average) for April.

The numeric values used for the weights of the various moving averages and a discussion of the derivation of these weights are given in Shiskin, Young, and Musgrave (1967). A general discussion of moving average weights is given in Dagum (1985).

If the specification for a month is omitted, the X11 procedure uses a three-by-three moving average for the first estimate of each iteration and a three-by-five average for the second estimate.

MONTHLY Statement

MONTHLY *options* ;

The MONTHLY statement must be used when the input data to PROC X11 are a monthly time series. The MONTHLY statement specifies options that determine the computations performed by PROC X11 and what is included in its output. Either the DATE= or START= option must be used.

The following options can appear in the MONTHLY statement.

ADDITIVE

performs additive adjustments. If the ADDITIVE option is omitted, PROC X11 performs multiplicative adjustments.

CHARTS= STANDARD

CHARTS= FULL

CHARTS= NONE

specifies the charts produced by the procedure. The default is CHARTS=STANDARD, which specifies 12 monthly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE.

The TABLES statement can also be used to specify particular monthly charts to be printed. If no CHARTS= option is given, and a TABLES statement is given, the TABLES statement overrides the default value of CHARTS=STANDARD; that is, no charts (or tables) are printed except those specified in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. You would specify the following statements:

```
monthly date=date;
tables g1 g4;
```

DATE= *variable*

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have 12 years of monthly data (144 observations, no missing values) beginning in January 1970 and ending in December 1981, and you wanted to seasonally adjust only six years beginning in January 1974. Specifying

```
monthly date=date start=jan1974 end=dec1979;
```

would seasonally adjust only this subset of the data. If instead you wanted to adjust the last eight years of data, only the START= option is needed:

```
monthly date=date start=jan1974;
```

END= *mmmyyyy*

specifies that only the part of the input series ending with the month and year given be adjusted (for example, END=DEC1970). See the DATE=*variable* option for using the START= and END= options to subset a series for processing.

EXCLUDE= *value*

excludes from the trading-day regression any irregular values that are more than *value* standard deviations from the mean. The EXCLUDE=*value* must be between 0.1 and 9.9, with the default value being 2.5.

FULLWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= *value* (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The FULLWEIGHT=*value* must be between 0.1 and 9.9 but must be less than the ZEROWEIGHT=*value*. The default is FULLWEIGHT=1.5.

LENGTH

includes length-of-month allowance in computing trading-day factors. If this option is omitted, length-of-month allowances are included with the seasonal factors.

NDEC= *n*

specifies the number of decimal places shown in the printed tables in the listing. This option has no effect on the precision of the variable values in the output data set.

PMFACTOR= *variable*

specifies a variable containing the prior monthly factors. Use this option if you have previous knowledge of monthly adjustment factors. The PMFACTOR= option can be used to make the following adjustments:

- adjust the level of all or part of a series with discontinuities
- adjust for the influence of holidays that fall on different dates from year to year, such as the effect of Easter on certain retail sales
- adjust for unreasonable weather influence on series, such as housing starts
- adjust for changing starting dates of fiscal years (for budget series) or model years (for automobiles)
- adjust for temporary dislocating events, such as strikes

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2591 for details and examples using the PMFACTOR= option.

PRINTOUT= STANDARD | LONG | FULL | NONE

specifies the tables to be printed by the procedure. If the PRINTOUT=STANDARD option is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed; however, charts are still printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also be used to specify particular monthly tables to be printed. If no PRINTOUT= option is specified, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are specified, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= *mmmyyyy*

adjusts only the part of the input series starting with the specified month and year. When the DATE= option is not used, the START= option gives the year and month of the first input observation — for example, START=JAN1966. START= must be specified if DATE= is not given. If START= is specified (and no DATE= option is given), and an OUT= data set is requested, a variable named `_DATE_` is added to the data set, giving the date value for each observation. See the DATE= *variable* option for using the START= and END= options to subset a series.

SUMMARY

specifies that the data are already seasonally adjusted and the procedure is to produce summary measures. If the SUMMARY option is omitted, the X11 procedure performs seasonal adjustment of the input data before calculating summary measures.

TDCOMPUTE= *year*

uses the part of the input series beginning with January of the specified year to derive trading-day weights. If this option is omitted, the entire series is used.

TDREGR= NONE | PRINT | ADJUST | TEST

specifies the treatment of trading-day regression. TDREG=NONE omits the computation of the trading-day regression. TDREG=PRINT computes and prints the trading-day regressions but does not adjust the series. TDREG=ADJUST computes and prints the trading-day regression and adjusts the irregular components to obtain preliminary weights. TDREG=TEST adjusts the final series if the trading-day regression estimates explain significant variation on the basis of an F test (or residual trading-day variation if prior weights are used). The default is TDREGR=NONE.

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2591 for details and examples using the TDREGR= option.

If ARIMA processing is requested, any value of TDREGR other than the default TDREGR=NONE will cause PROC X11 to perform an initial pass (see the “[Details: X11 Procedure](#)” on page 2583 section and the PRINTFP option).

The significance level reported in Table C15 should be viewed with caution. The dependent variable in the trading-day regression is the irregular component formed by an averaging operation. This induces a correlation in the dependent variable and hence in the residuals from which the F test is computed. Hence the distribution of the trading-day regression F statistics differs from an exact F ; see Cleveland and Devlin (1980) for details.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates in the first iteration. If the TRENDADJ option is omitted, the trend cycle is computed without modifications for extremes.

TRENDMA= 9 | 13 | 23

specifies the number of terms in the moving average to be used by the procedure in estimating the variable trend cycle component. The value of the TRENDMA= option must be 9, 13, or 23. If the TRENDMA= option is omitted, the procedure selects an appropriate moving average. For information about the number of terms in the moving average, see Shiskin, Young, and Musgrave (1967).

ZEROWEIGHT= value

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The ZEROWEIGHT=value must be between 0.1 and 9.9 but must be greater than the FULLWEIGHT=value. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See [Example 36.3](#) later in this chapter for an illustration of this use.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set tablename=var1 var2 ... ;*

The OUTPUT statement creates an output data set containing specified tables. The data set is named by the OUT= option.

OUT= *SAS-data-set*

If OUT= is omitted, the SAS System names the new data set by using the DATA n convention.

For each table to be included in the output data set, write the X11 table identification keyword, an equal sign, and a list of new variable names:

tablename = var1 var2 ...

The *tablename* keywords that can be used in the OUTPUT statement are listed in the section “[Printed Output](#)” on page 2599. The following is an example of a VAR statement and an OUTPUT statement:

```
var z1 z2 z3;
output out=out_x11 b1=s d11=w x y;
```

The variable s contains the table B1 values for the variable z1, while the table D11 values for variables z1, z2, and z3 are contained in variables w, x, and y, respectively. As this example shows, the list of variables following a *tablename*= keyword can be shorter than the VAR variable list.

In addition to the variables named by *tablename* =var1 var2 ..., the ID variables, and BY variables, the output data set contains a date identifier variable. If the DATE= option is given in the MONTHLY or QUARTERLY statement, the DATE= variable is the date identifier. If no DATE= option is given, a variable named _DATE_ is the date identifier.

PDWEIGHTS Statement

PDWEIGHTS *day=w* ... ;

The PDWEIGHTS statement can be used to specify one to seven daily weights. The statement can only be used with monthly series that are seasonally adjusted using the multiplicative model. These weights are used to compute prior trading-day factors, which are then used to adjust the original series prior to the seasonal adjustment process. Only relative weights are needed; the X11 procedure adjusts the weights so that they sum to 7.0. The weights can also be corrected by the procedure on the basis of estimates of trading-day variation from the input data.

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2591 for details and examples using the PDWEIGHTS statement.

Each *day=w* option specifies a weight (*w*) for the named day. The *day* can be any day, Sunday through Saturday. The *day* keyword can be the full spelling of the day, or the three-letter abbreviation. For example, SATURDAY=1.0 and SAT=1.0 are both valid. The weights *w* must be a numeric value between 0.0 and 10.0.

The following is an example of a PDWEIGHTS statement:

```
pdweights sun=.2 mon=.9 tue=1 wed=1 thu=1 fri=.8 sat=.3;
```

Any number of days can be specified with one PDWEIGHTS statement. The default weight value for any day that is not specified is 0. If you do not use a PDWEIGHTS statement, the program computes daily weights if TDREGR=ADJUST is specified. See Shiskin, Young, and Musgrave (1967) for details.

QUARTERLY Statement

QUARTERLY *options* ;

The QUARTERLY statement must be used when the input data are quarterly time series. This statement includes options that determine the computations performed by the procedure and what is in the printed output. The DATE= option or the START= option must be used.

The following options can appear in the QUARTERLY statement.

ADDITIVE

performs additive adjustments. If this option is omitted, the procedure performs multiplicative adjustments.

CHARTS= STANDARD

CHARTS= FULL

CHARTS= NONE

specifies the charts to be produced by the procedure. The default value is CHARTS=STANDARD, which specifies four quarterly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE. The TABLES statement can also be used to specify particular charts to be printed. The presence of a TABLES statement overrides the default value of CHARTS=STANDARD; that is, if a TABLES statement is specified, and no CHARTS=option is specified, no charts (nor tables) are printed except those given in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. This is accomplished by specifying the following statements:

```
quarterly date=date;
tables g1 g4;
```

DATE= *variable*

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested, and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have a series with 10 years of quarterly data (40 observations, no missing values) beginning in '1970Q1' and ending in '1979Q4', and you want to seasonally adjust only four years beginning in '1974Q1' and ending in '1977Q4'. Specifying

```
quarterly date=variable start='1974q1' end='1977q4';
```

seasonally adjusts only this subset of the data. If instead you wanted to adjust the last six years of data, only the START= option is needed:

```
quarterly date=variable start='1974q1';
```

END= 'yyyyQq'

specifies that only the part of the input series ending with the quarter and year given be adjusted (for example, END='1973Q4'). The specification must be enclosed in quotes and *q* must be 1, 2, 3, or 4. See the DATE= *variable* option for using the START= and END= options to subset a series.

FULLWEIGHT= value

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= value (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is FULLWEIGHT=1.5.

NDEC= n

specifies the number of decimal places shown on the output tables. This option has no effect on the precision of the variables in the output data set.

PRINTOUT= STANDARD**PRINTOUT= LONG****PRINTOUT= FULL****PRINTOUT= NONE**

specifies the tables to print. If PRINTOUT=STANDARD is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also specify particular quarterly tables to be printed. If no PRINTOUT= is given, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are given, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= 'yyyyQq'

adjusts only the part of the input series starting with the quarter and year given. When the DATE= option is not used, the START= option gives the year and quarter of the first input observation (for example, START='1967Q1'). The specification must be enclosed in quotes, and *q* must be 1, 2, 3, or 4. START= must be specified if the DATE= option is not given. If START= is specified (and no DATE= is given), and an OUTPUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for a given observation. See the DATE= option for using the START= and END= options to subset a series.

SUMMARY

specifies that the input is already seasonally adjusted and that the procedure is to produce summary measures. If this option is omitted, the procedure performs seasonal adjustment of the input data before calculating summary measures.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates. If this option is omitted, the trend cycle is computed without modification for extremes.

ZEROWEIGHT= value

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the **ZEROWEIGHT=** option are assigned zero weights. Values that fall between the two limits (**ZEROWEIGHT=** and **FULLWEIGHT=**) are assigned weights linearly graduated between 0 and 1. For example, if **ZEROWEIGHT=2** and **FULLWEIGHT=1**, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is **ZEROWEIGHT=2.5**.

The **ZEROWEIGHT** option can be used in conjunction with the **FULLWEIGHT=** option to adjust outliers from a monthly or quarterly series. See [Example 36.3](#) later in this chapter for an illustration of this use.

SSPAN Statement

SSPAN options ;

The **SSPAN** statement applies sliding spans analysis to determine the suitability of seasonal adjustment for an economic series.

The following options can appear in the **SSPAN** statement:

NDEC= n

specifies the number of decimal places shown on selected sliding span reports. This option has no effect on the precision of the variables values in the **OUTSPAN** output data set.

CUTOFF= value

gives the percentage value for determining an excessive difference within a span for the seasonal factors, the seasonally adjusted series, and month-to-month and year-to-year differences in the seasonally adjusted series. The default value is 3.0. The use of the **CUTOFF=value** in determining the maximum percent difference (MPD) is described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2588. Caution should be used in changing the default **CUTOFF=value**. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when value is changed.

TDCUTOFF= value

gives the percentage value for determining an excessive difference within a span for the trading-day factors. The default value is 2.0. The use of the **TDCUTOFF=value** in determining the maximum percent difference (MPD) is described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2588. Caution should be used in changing the default **TDCUTOFF=value**. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when the value is changed.

NOPRINT

suppresses all sliding span reports. See “[Computational Details for Sliding Spans Analysis](#)” on page 2588 for more details on sliding span reports.

PRINT

prints the summary sliding span reports S 0 through S 6.E.

PRINTALL

prints the summary sliding spans report S 0 through S 6.E, along with detail reports S 7.A through S 7.E.

TABLES Statement

TABLES *tablename* ;

The TABLES statement prints the tables specified in addition to the tables that are printed as a result of the PRINTOUT= option in the MONTHLY or QUARTERLY statement. Table names are listed in [Table 36.4](#) later in this chapter.

To print only selected tables, omit the PRINTOUT= option in the MONTHLY or QUARTERLY statement and list the tables to be printed in the TABLES statement. For example, to print only the final seasonal factors and final seasonally adjusted series, use the statement

```
tables d10 d11;
```

VAR Statement

VAR *variables* ;

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those appearing in a BY or ID statement or the variable named in the DATE= option in the MONTHLY or QUARTERLY statement.

Details: X11 Procedure

Historical Development of X-11

This section briefly describes the historical development of the standard X-11 seasonal adjustment method and the later development of the X-11-ARIMA method. Most of the following discussion is based on a comprehensive article by Bell and Hillmer (1984), which describes the history of X-11 and the justification of using seasonal adjustment methods, such as X-11, given the current availability of time series software. For further discussions about statistical problems associated with the X-11 method, see Ghysels (1990).

Seasonal adjustment methods began to be developed in the 1920s and 1930s, before there were suitable analytic models available and before electronic computing devices were in existence. The lack of any suitable model led to methods that worked the same for any series — that is, methods that were not model-based and

that could be applied to any series. Experience with economic series had shown that a given mathematical form could adequately represent a time series only for a fixed length; as more data were added, the model became inadequate. This suggested an approach that used moving averages. For further analysis of the properties of X-11 moving averages, see Cleveland and Tiao (1976).

The basic method was to break up an economic time series into long-term trend, long-term cyclical movements, seasonal movements, and irregular fluctuations.

Early investigators found that it was not possible to uniquely decompose the trend and cycle components. Thus, these two were grouped together; the resulting component is usually referred to as the “trend cycle component.”

It was also found that estimating seasonal components in the presence of trend produced biased estimates of the seasonal components, but, at the same time, estimating trend in the presence of seasonality was difficult. This eventually led to the iterative approach used in the X-11 method.

Two other problems were encountered by early investigators. First, some economic series appear to have changing or evolving seasonality. Secondly, moving averages were very sensitive to extreme values. The estimation method used in the X-11 method allows for evolving seasonal components. For the second problem, the X-11 method uses repeated adjustment of extreme values.

All of these problems encountered in the early investigation of seasonal adjustment methods suggested the use of moving averages in estimating components. Even with the use of moving averages instead of a model-based method, massive amounts of hand calculations were required. Only a small number of series could be adjusted, and little experimentation could be done to evaluate variations on the method.

With the advent of electronic computing in the 1950s, work on seasonal adjustment methods proceeded rapidly. These methods still used the framework previously described; variants of these basic methods could now be easily tested against a large number of series.

Much of the work was done by Julian Shiskin and others at the U.S. Bureau of the Census beginning in 1954 and culminating after a number of variants into the *X-11 Variant of the Census Method II Seasonal Adjustment Program*, which PROC X11 implements.

References for this work during this period include Shiskin and Eisenpress (1957), Shiskin (1958), and Marris (1961). The authoritative documentation for the X-11 Variant is in Shiskin, Young, and Musgrave (1967). This document is not equivalent to a program specification; however, the FORTRAN code that implements the X-11 Variant is in the public domain. A less detailed description of the X-11 Variant is given in U.S. Bureau of the Census (1969).

Development of the X-11-ARIMA Method

The X-11 method uses symmetric moving averages in estimating the various components. At the end of the series, however, these symmetric weights cannot be applied. Either asymmetric weights have to be used, or some method of extending the series must be found.

While various methods of extending a series have been proposed, the most important method to date has been the X-11-ARIMA method developed at Statistics Canada. This method uses Box-Jenkins ARIMA models to extend the series.

The Time Series Research and Analysis Division of Statistics Canada investigated 174 Canadian economic series and found five ARIMA models out of twelve that fit the majority of series well and reduced revisions for the most recent months. References that give details of various aspects of the X-11-ARIMA methodology

include Dagum (1980, 1982a, c, 1983, 1988), Laniel (1985), Lothian and Morry (1978a), and Huot et al. (1986).

Differences between X11ARIMA/88 and PROC X11

The original implementation of the X-11-ARIMA method was by Statistics Canada in 1980 (Dagum 1980), with later changes and enhancements made in 1988 (Dagum 1988). The calculations performed by PROC X11 differ from those in X11ARIMA/88, which will result in differences in the final component estimates provided by these implementations.

There are three areas where Statistics Canada made changes to the original X-11 seasonal adjustment method in developing X11ARIMA/80 (Monsell 1984). These are (a) selection of extreme values, (b) replacement of extreme values, and (c) generation of seasonal and trend cycle weights.

These changes have not been implemented in the current version of PROC X11. Thus the procedure produces results identical to those from previous versions of PROC X11 in the absence of an ARIMA statement.

Additional differences can result from the ARIMA estimation. X11ARIMA/88 uses conditional least squares (CLS), while CLS, unconditional least squares (ULS) and maximum likelihood (ML) are all available in PROC X11 by using the METHOD= option in the ARIMA statement. Generally, parameters estimates will differ for the different methods.

Implementation of the X-11 Seasonal Adjustment Method

The following steps describe the analysis of a monthly time series using multiplicative seasonal adjustment. Additional steps used by the X-11-ARIMA method are also indicated. Equivalent descriptions apply for an additive model if you replace *divide* with *subtract* where applicable.

In the multiplicative adjustment, the original series O_t is assumed to be of the form

$$O_t = C_t S_t I_t P_t D_t$$

where C_t is the trend cycle component, S_t is the seasonal component, I_t is the irregular component, P_t is the prior monthly factors component, and D_t is the trading-day component.

The trading-day component can be further factored as

$$D_t = D_{r,t} D_{tr,t},$$

where $D_{tr,t}$ are the trading-day factors derived from the prior daily weights, and $D_{r,t}$ are the residual trading-day factors estimated from the trading-day regression. For further information about estimating trading day variation, see Young (1965).

Additional Steps When Using the X-11-ARIMA Method

The X-11-ARIMA method consists of extending a given series by an ARIMA model and applying the usual X-11 seasonal adjustment method to this extended series. Thus in the simplest case in which there are no prior factors or calendar effects in the series, the ARIMA model selection, estimation, and forecasting are performed first, and the resulting extended series goes through the standard X-11 steps described in the next section.

If prior factor or calendar effects are present, they must be eliminated from the series before the ARIMA estimation is done because these effects are not stochastic.

Prior factors, if present, are removed first. Calendar effects represented by prior daily weights are then removed. If there are no further calendar effects, the adjusted series is extended by the ARIMA model, and this extended series goes through the standard X-11 steps without repeating the removal of prior factors and calendar effects from prior daily weights.

If further calendar effects are present, a trading-day regression must be performed. In this case it is necessary to go through an initial pass of the X-11 steps to obtain a final trading-day adjustment. In this initial pass, the series, adjusted for prior factors and prior daily weights, goes through the standard X-11 steps. At the conclusion of these steps, a final series adjusted for prior factors and all calendar effects is available. This adjusted series is then extended by the ARIMA model, and this extended series goes through the standard X-11 steps again, without repeating the removal of prior factors and calendar effects from prior daily weights and trading-day regression.

The Standard X-11 Seasonal Adjustment Method

The standard X-11 seasonal adjustment method consists of the following steps. These steps are applied to the original data or the original data extended by an ARIMA model.

1. In step 1, the data are read, ignoring missing values until the first nonmissing value is found. If prior monthly factors are present, the procedure reads prior monthly P_t factors and divides them into the original series to obtain $O_t/P_t = C_t S_t I_t D_{tr,t} D_{r,t}$.

Seven daily weights can be specified to develop monthly factors to adjust the series for trading-day variation, $D_{tr,t}$; these factors are then divided into the original or prior adjusted series to obtain $C_t S_t I_t D_{r,t}$.

2. In steps 2, 3, and 4, three iterations are performed, each of which provides estimates of the seasonal S_t , trading-day $D_{r,t}$, trend cycle C_t , and irregular components I_t . Each iteration refines estimates of the extreme values in the irregular components. After extreme values are identified and modified, final estimates of the seasonal component, seasonally adjusted series, trend cycle, and irregular components are produced. Step 2 consists of three substeps:

- a) During the first iteration, a centered, 12-term moving average is applied to the original series O_t to provide a preliminary estimate \hat{C}_t of the trend cycle curve C_t . This moving average combines 13 (a 2-term moving average of a 12-term moving average) consecutive monthly values, removing the S_t and I_t . Next, it obtains a preliminary estimate $\widehat{S_t I_t}$ by

$$\widehat{S_t I_t} = \frac{O_t}{\hat{C}_t}$$

- b) A moving average is then applied to the $\widehat{S_t I_t}$ to obtain an estimate \hat{S}_t of the seasonal factors. $\widehat{S_t I_t}$ is then divided by this estimate to obtain an estimate \hat{I}_t of the irregular component. Next, a moving standard deviation is calculated from the irregular component and is used in assigning a weight to each monthly value for measuring its degree of extremeness. These weights are used to modify extreme values in $\widehat{S_t I_t}$. New seasonal factors are estimated by applying a moving average to the modified value of $\widehat{S_t I_t}$. A preliminary seasonally adjusted series is obtained by dividing the original series by these new seasonal factors. A second estimate of the trend cycle is obtained by applying a weighted moving average to this seasonally adjusted series.

- c) The same process is used to obtain second estimates of the seasonally adjusted series and improved estimates of the irregular component. This irregular component is again modified for extreme values and then used to provide estimates of trading-day factors and refined weights for the identification of extreme values.
3. Using the same computations, a second iteration is performed on the original series that has been adjusted by the trading-day factors and irregular weights developed in the first iteration. The second iteration produces final estimates of the trading-day factors and irregular weights.
4. A third and final iteration is performed using the original series that has been adjusted for trading-day factors and irregular weights computed during the second iteration. During the third iteration, PROC X11 develops final estimates of seasonal factors, the seasonally adjusted series, the trend cycle, and the irregular components. The procedure computes summary measures of variation and produces a moving average of the final adjusted series.

Sliding Spans Analysis

The motivation for sliding spans analysis is to answer the question, When is a economic series unsuitable for seasonal adjustment? There have been a number of past attempts to answer this question: stable seasonality F test; moving seasonality F test, Q statistics, and others.

Sliding spans analysis attempts to quantify the stability of the seasonal adjustment process, and hence quantify the suitability of seasonal adjustment for a given series.

It is based on a very simple idea: for a stable series, deleting a small number of observations should not result in greatly different component estimates compared with the original, full series. Conversely, if deleting a small number of observations results in drastically different estimates, the series is unstable. For example, a drastic difference in the seasonal factors (Table D10) might result from a dominating irregular component or sudden changes in the seasonally component. When the seasonal component estimates of a series is unstable in this manner, they have little meaning and the series is likely to be unsuitable for seasonal adjustment.

Sliding spans analysis, developed at the Statistical Research Division of the U.S. Census Bureau (Findley et al. 1990; Findley and Monsell 1986), performs a repeated seasonal adjustment on subsets or spans of the full series. In particular, an initial span of the data, typically eight years in length, is seasonally adjusted, and the Tables C18, the trading-day factors (if trading-day regression performed), D10, the seasonal factors, and D11, the seasonally adjusted series are retained for further processing. Next, one year of data is deleted from the beginning of the initial span and one year of data is added. This new span is seasonally adjusted as before, with the same tables retained. This process continues until the end of the data is reached. The beginning and ending dates of the spans are such that the last observation in the original data is also the last observation in the last span. This is discussed in more detail in the following paragraphs.

The following notation for the components or differences computed in the sliding spans analysis follows Findley et al. (1990). The meaning for the symbol $X_t(k)$ is component X in month (or quarter) t , computed from data in the k th span. These components are now defined.

- Seasonal Factors (Table D10): $S_t(k)$
- Trading-Day Factors (Table C18): $TD_t(k)$
- Seasonally Adjusted Data (Table D11): $SA_t(k)$

- Month-to-Month Changes in the Seasonally Adjusted Data: $MM_t(k)$
- Year-to-Year Changes in the Seasonally Adjusted Data: $YY_t(k)$

The key measure is the maximum percent difference across spans. For example, consider a series that begins in January 1972, ends in December 1984, and has four spans, each of length 8 years (see Figure 1 in Findley et al. (1990), p. 346). Consider $S_t(k)$ the seasonal factor (Table D10) for month t for span k , and let N_t denote the number of spans containing month t ; that is,

$$N_t = \{k : \text{span } k \text{ contains month } t\}$$

In the middle years of the series there is overlap of all four spans, and N_t will be 4. The last year of the series will have only one span, while the beginning can have 1 or 0 spans depending on the original length.

Since we are interested in how much the seasonal factors vary for a given month across the spans, a natural quantity to consider is

$$\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)$$

In the case of the multiplicative model, it is useful to compute a percentage difference; define the maximum percentage difference (MPD) at time t as

$$MPD_t = \frac{\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)}{\min_{k \in N_t} S_t(k)}$$

The seasonal factor for month t is then unreliable if MPD_t is large. While no exact significance level can be computed for this statistic, empirical levels have been established by considering over 500 economic series (Findley et al. 1990; Findley and Monsell 1986). For these series it was found that for four spans, stable series typically had less than 15% of the MPD values exceeding 3.0%, while in marginally stable series, between 15% and 25% of the MPD values exceeded 3.0%. A series in which 25% or more of the MPD values exceeded 3.0% is almost always unstable.

While these empirical values cannot be considered an exact significance level, they provide a useful empirical basis for deciding if a series is suitable for seasonal adjustment. These percentage values are shifted down when fewer than four spans are used.

Computational Details for Sliding Spans Analysis

Length and Number of Spans

The algorithm for determining the length and number of spans for a given series was developed at the U.S. Bureau of the Census, Statistical Research Division. A summary of this algorithm is as follows.

First, an initial length based on the MACURVE *month=option* specification is determined, and then the maximum number of spans possible using this length is determined. If this maximum number exceeds four, set the number of spans to four. If this maximum number is one or zero, there are not enough observations to perform the sliding spans analysis. In this case a note is written to the log and the sliding spans analysis is skipped for this variable.

If the maximum number of spans is two or three, the actual number of spans used is set equal to this maximum. Finally, the length is adjusted so that the spans begin in January (or the first quarter) of the beginning year of the span.

The remainder of this section gives the computation formulas for the maximum percentage difference (MPD) calculations along with the threshold regions.

Seasonal Factors (Table D10)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)}{\min_{k \in N_t} S_t(k)}$$

A series for which less than 15% of the MPD values of D10 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% is unstable. Span reports S 2.A through S 2.C give the various breakdowns for the number of times the MPD exceeded these levels.

Trading Day Factor (Table C18)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} TD_t(k) - \min_{k \in N_t} TD_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{\max_{k \in N_t} TD_t(k) - \min_{k \in N_t} TD_t(k)}{\min_{k \in N_t} TD_t(k)}$$

The U.S. Census Bureau currently gives no recommendation concerning MPD thresholds for the trading-day factors. Span reports S 3.A through S 3.C give the various breakdowns for MPD thresholds. When TDREGR=NONE is specified, no trading-day computations are done, and this table is skipped.

Seasonally Adjusted Data (Table D11)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} SA_t(k) - \min_{k \in N_t} SA_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{\max_{k \in N_t} SA_t(k) - \min_{k \in N_t} SA_t(k)}{\min_{k \in N_t} SA_t(k)}$$

A series for which less than 15% of the MPD values of D11 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% is unstable. Span reports S 4.A through S 4.C give the various breakdowns for the number of times the MPD exceeded these levels.

Month-to-Month Changes in the Seasonally Adjusted Data

Some additional notation is needed for the month-to-month and year-to-year differences. Define $N1_t$ as

$$N1_t = \{k : \text{span } k \text{ contains month } t \text{ and } t - 1\}$$

For the additive model, the month-to-month change for span k is defined as

$$MM_t(k) = SA_t - SA_{t-1}$$

while for the multiplicative model

$$MM_t(k) = \frac{SA_t - SA_{t-1}}{SA_{t-1}}$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined as

$$MPD_t = \max_{k \in N1_t} MM_t(k) - \min_{k \in N1_t} MM_t(k)$$

The current recommendation of the U.S. Census Bureau is that if 35% or more of the MPD values of the month-to-month differences of D11 exceed 3.0%, then the series is usually not stable; 40% exceeding this level clearly marks an unstable series. Span reports S 5.A.1 through S 5.C give the various breakdowns for the number of times the MPD exceeds these levels.

Year-to-Year Changes in the Seasonally Adjusted Data

First define $N12_t$ as

$$N12_t = \{k : \text{span } k \text{ contains month } t \text{ and } t - 12\}$$

(Appropriate changes in notation for a quarterly series are obvious.)

For the additive model, the month-to-month change for span k is defined as

$$YY_t(k) = SA_t - SA_{t-12}$$

while for the multiplicative model

$$YY_t(k) = \frac{SA_t - SA_{t-12}}{SA_{t-12}}$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined as

$$MPD_t = \max_{k \in N12_t} YY_t(k) - \min_{k \in N12_t} YY_t(k)$$

The current recommendation of the U.S. Census Bureau is that if 10% or more of the MPD values of the month-to-month differences of D11 exceed 3.0%, then the series is usually not stable. Span reports S 6.A through S 6.C give the various breakdowns for the number of times the MPD exceeds these levels.

Data Requirements

The input data set must contain either quarterly or monthly time series, and the data must be in chronological order. For the standard X-11 method, there must be at least three years of observations (12 for quarterly time series or 36 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

For the X-11-ARIMA method, there must be at least five years of observations (20 for quarterly time series or 60 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

Missing Values

Missing values at the beginning of a series to be adjusted are skipped. Processing starts with the first nonmissing value and continues until the end of the series or until another missing value is found.

Missing values are not allowed for the DATE= variable. The procedure terminates if missing values are found for this variable.

Missing values found in the PMFACTOR= variable are replaced by 100 for the multiplicative model (default) and by 0 for the additive model.

Missing values can occur in the output data set. If the time series specified in the OUTPUT statement is not computed by the procedure, the values of the corresponding variable are missing. If the time series specified in the OUTPUT statement is a moving average, the values of the corresponding variable are missing for the first n and last n observations, where n depends on the length of the moving average. Additionally, if the time series specified is an irregular component modified for extremes, only the modified values are given, and the remaining values are missing.

Prior Daily Weights and Trading-Day Regression

Suppose that a detailed examination of retail sales at ZXY Company indicates that certain days of the week have higher amounts of sales. In particular, Thursday, Friday, and Saturday have approximately twice the amount of sales as Monday, Tuesday, and Wednesday, and no sales occur on Sunday. This means that months with five Saturdays would have higher amounts of sales than months with only four Saturdays.

This phenomenon is called a calendar effect; it can be handled in PROC X11 by using the PDWEIGHTS (prior daily weights) statement or the TDREGR=option (trading-day regression). The PDWEIGHTS statement and the TDREGR=option can be used separately or together.

If the relative weights are known (as in the preceding) it is appropriate to use the PDWEIGHTS statement. If further residual calendar variation is present, TDREGR=ADJUST should also be used. If you know that a calendar effect is present, but know nothing about the relative weights, use TDREGR=ADJUST without a PDWEIGHTS statement.

In this example, it is assumed that the calendar variation is due to both prior daily weights and residual variation. Thus both a PDWEIGHTS statement and TDREGR=ADJUST are specified.

Note that only the relative weights are needed; in the actual computations, PROC X11 normalizes the weights to sum to 7.0. If a day of the week is not present in the PDWEIGHTS statement, it is given a value of zero. Thus “sun=0” is not needed.

```
proc x11 data=sales;
  monthly date=date tdregr=adjust;
  var sales;
  tables a1 a4 b15 b16 c14 c15 c18 d11;
  pdweights mon=1 tue=1 wed=1 thu=2 fri=2 sat=2;
  output out=x11out a1=a1 a4=a4 b1=b1 c14=c14
              c16=c16 c18=c18 d11=d11;
run;
```

Tables of interest include A1, A4, B15, B16, C14, C15, C18, and D11. Table A4 contains the adjustment factors derived from the prior daily weights; Table C14 contains the extreme irregular values excluded from trading-day regression; Table C15 contains the trading-day-regression results; Table C16 contains the monthly factors derived from the trading-day regression; and Table C18 contains the final trading-day factors derived from the combined daily weights. Finally, Table D11 contains the final seasonally adjusted series.

Adjustment for Prior Factors

Suppose now that a strike at ZXY Company during July and August of 1988 caused sales to decrease an estimated 50%. Since this is a one-time event with a known cause, it is appropriate to prior adjust the data to reflect the effects of the strike. This is done in PROC X11 through the use of PMFACTOR=*varname* (prior monthly factor) in the MONTHLY statement.

In the following example, the PMFACTOR variable is named PMF. Since the estimate of the decrease in sales is 50%, PMF has a value of 50.0 for the observations corresponding to July and August 1988, and a value of 100.0 for the remaining observations.

This prior adjustment on SALES is performed by replacing SALES with the calculated value $(\text{SALES}/\text{PMF}) * 100.0$. A value of 100.0 for PMF leaves SALES unchanged, while a value of 50.0 for PMF doubles SALES. This value is the estimate of what SALES would have been without the strike. The following example shows how this prior adjustment is accomplished.

```
data sales2;
  set sales;
  if '01jul1988'd <= date <= '01aug1988'd then pmf = 50;
  else pmf = 100;
run;

proc x11 data=sales2;
  monthly date=date pmfactor=pmf;
  var sales;
  tables a1 a2 a3 d11;
  output out=x11out a1=a1 a2=a2 a3=a3 d11=d11;
run;
```

Table A2 contains the prior monthly factors (the values of PMF), and Table A3 contains the prior adjusted series.

The YRAHEADOUT Option

For monthly data, the YRAHEADOUT option affects only Tables C16 (regression trading-day adjustment factors), C18 (trading-day factors from combined daily weights), and D10 (seasonal factors). For quarterly data, only Table D10 is affected. Variables for all other tables have missing values for the forecast observations. The forecast values for a table are included only if that table is specified in the OUTPUT statement.

Tables C16 and C18 are calendar effects that are extrapolated by calendar composition. These factors are independent of the data once trading-day weights have been calculated. Table D10 is extrapolated by a linear combination of past values. If N is the total number of nonmissing observations for the analysis variable, this linear combination is given by

$$D10_t = \frac{1}{2}(3 \times D10_{t-12} - D10_{t-24}), \quad t = N + 1, \dots, N + 12$$

If the input data are monthly time series, 12 extra observations are added to the end of the output data set. (If a BY statement is used, 12 extra observations are added to the end of each BY group.) If the input data are a quarterly time series, four extra observations are added to the end of the output data set. (If a BY statement is used, four extra observations are added to each BY group.)

The DATE= variable (or _DATE_) is extrapolated for the extra observations generated by the YRAHEADOUT option, while all other ID variables will have missing values.

If ARIMA processing is requested, and if both the OUTEXTRAP and YRAHEADOUT options are specified in the PROC X11 statement, an additional 12 (or 4) observations are added to the end of output data set for monthly (or quarterly) data after the ARIMA forecasts, using the same linear combination of past values as before.

Effect of Backcast and Forecast Length

Based on a number of empirical studies (Dagum 1982a, b, c; Dagum and Laniel 1987), one year of forecasts minimize revisions when new data become available. Two and three years of forecasts show only small gains.

Backcasting improves seasonal adjustment but introduces permanent revisions at the beginning of the series and also at the end for series of length 8, 9, or 10 years. For series shorter than 7 years, the advantages of backcasting outweigh the disadvantages (Dagum 1988).

Other studies (Pierce 1980; Bobbit and Otto 1990; Buszuwski 1987) suggest “full forecasting”—that is, using enough forecasts to allow symmetric weights for the seasonal moving averages for the most current data. For example, if a 3×9 seasonal moving average was specified for one or more months by using the MACURVES statement, five years of forecasts would be required. This is because the seasonal moving averages are performed on calendar months separately, and the 3×9 is an 11-term centered moving average, requiring five observations before and after the current observation. Thus

```
macurves dec='3x9';
```

would require five additional December values to compute the seasonal moving average.

Details of Model Selection

If an ARIMA statement is present but no MODEL= is given, PROC X11 estimates and forecasts five predefined models and selects the best. This section describes the details of the selection criteria and the selection process.

The five predefined models used by PROC X11 are the same as those used by X11ARIMA/88 from Statistics Canada. These particular models, shown in Table 36.2, were chosen on the basis of testing a large number of economics series (Dagum 1988) and should provide reasonable forecasts for most economic series.

Table 36.2 Five Predefined Models

Model #	Specification	Multiplicative	Additive
1	(0,1,1)(0,1,1)s	log transform	no transform
2	(0,1,2)(0,1,1)s	log transform	no transform
3	(2,1,0)(0,1,1)s	log transform	no transform
4	(0,2,2)(0,1,1)s	log transform	no transform
5	(2,1,2)(0,1,1)s	no transform	no transform

The selection process proceeds as follows. The five models are estimated and one-step-ahead forecasts are produced in the order shown in Table 36.2. As each model is estimated, the following three criteria are checked:

- The mean absolute percent error (MAPE) for the last three years of the series must be less than 15%.
- The significance probability for the Box-Ljung chi-square for up to lag 24 for monthly (8 for quarterly) must greater than 0.05.
- The over-differencing criteria must not exceed 0.9.

The descriptions of these three criteria are given in the section “Criteria Details” on page 2595. The default values for these criteria are those used by X11ARIMA/88 from Statistics Canada; these defaults can be changed by the MAPECR=, CHICR=, and OVDIFCR= options.

A model that fails any one of these three criteria is excluded from further consideration. In addition, if the ARIMA estimation fails for a given model, a warning is issued, and the model is excluded. The final set of all models considered consists of those that pass all three criteria and are estimated successfully. From this set, the model with the smallest MAPE for the last three years is chosen.

If all five models fail, ARIMA processing is skipped for the variable being processed, and the standard X-11 seasonal adjustment is performed. A note is written to the log with this information.

The chosen model is then used to forecast the series one or more years (determined by the FORECAST= option in the ARIMA statement). These forecasts are appended to the original data (or the prior and calendar-adjusted data).

If a BACKCAST= option is specified, the chosen model form is used, but the parameters are reestimated using the reversed series. Using these parameters, the reversed series is forecast for the number of years specified by the BACKCAST= option. These forecasts are then reversed and appended to the beginning of the original series, or the prior and calendar-adjusted series, to produce the backcasts.

Note that the final selection rule (the smallest MAPE using the last three years) emphasizes the quality of the forecasts at the end of the series. This is consistent with the purpose of the X-11-ARIMA methodology, which is to improve the estimates of seasonal factors and thus minimize revisions to recent past data as new data become available.

Criteria Details

Mean Absolute Percent Error (MAPE)

For the MAPE criteria testing, only the last three years of the original series (or prior and calendar adjusted series) is used in computing the MAPE.

Let y_t , $t = 1, \dots, n$, be the last three years of the series, and denote its one-step-ahead forecast by \hat{y}_t , where $n = 36$ for a monthly series and $n = 12$ for a quarterly series.

With this notation, the MAPE criteria are computed as

$$MAPE = \frac{100}{n} \sum_{t=1}^n \frac{|y_t - \hat{y}_t|}{|y_t|}$$

Box-Ljung Chi-Square

The Box-Ljung chi-square is a lack-of-fit test based on the model residuals. This test statistic is computed using the Ljung-Box formula

$$\chi_m^2 = n(n+2) \sum_{k=1}^m \frac{r_k^2}{(n-k)}$$

where n is the number of residuals that can be computed for the time series, and

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^n a_t^2}$$

where the a_t 's are the residual sequence. This formula has been suggested by Ljung and Box (1978) as yielding a better fit to the asymptotic chi-square distribution. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977) and by Ljung and Box (1978).

For monthly series, $m = 24$, while for quarterly series, $m = 8$.

Over-Differencing Test

From Table 36.2 you can see that all models have a single seasonal MA factor and at most two nonseasonal MA factors. Also, all models have seasonal and nonseasonal differencing. Consider model 2 applied to a monthly series y_t with $E(y_t) = \mu$:

$$(1 - B^1)(1 - B^{12})(y_t - \mu) = (1 - \theta_1 B - \theta_2 B^2)(1 - \theta_3 B^{12})a_t$$

If $\theta_3 = 1.0$, then the factors $(1 - \theta_3 B^{12})$ and $(1 - B^{12})$ will cancel, resulting in a lower-order model.

Similarly, if $\theta_1 + \theta_2 = 1.0$,

$$(1 - \theta_1 B - \theta_2 B^2) = (1 - B)(1 - \alpha B)$$

for some $\alpha \neq 0.0$. Again, this results in cancellation and a lower-order model.

Since the parameters are not exact, it is not reasonable to require that

$$\theta_3 < 1.0 \text{ and } \theta_1 + \theta_2 < 1.0$$

Instead, an approximate test is performed by requiring that

$$\theta_3 \leq 0.9 \text{ and } \theta_1 + \theta_2 \leq 0.9$$

The default value of 0.9 can be changed by the OVDIFCR= option. Similar reasoning applies to the other models.

ARIMA Statement Options for the Five Predefined Models

Table 36.3 lists the five predefined models and gives the equivalent MODEL= parameters in a PROC X11 ARIMA statement.

In all models except the fifth, a log transformation is performed before the ARIMA estimation for the multiplicative case; no transformation is performed for the additive case. For the fifth model, no transformation is done for either case.

The multiplicative case is assumed in the following table. The indicated seasonality s in the specification is either 12 (monthly) or 4 (quarterly). The MODEL statement assumes a monthly series.

Table 36.3 ARIMA Statements Options for Predefined Models

Model	ARIMA Statement Options
(0,1,1)(0,1,1) s	MODEL=(Q=1 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(0,1,2)(0,1,1) s	MODEL=(Q=2 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(2,1,0)(0,1,1) s	MODEL=(P=2 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(0,2,2)(0,1,1) s	MODEL=(Q=2 SQ=1 DIF=2 SDIF=1) TRANSFORM=LOG
(2,1,2)(0,1,1) s	MODEL=(P=2 Q=2 SQ=1 DIF=1 SDIF=1)

OUT= Data Set

The OUT= data set specified in the OUTPUT statement contains the BY variables, if any; the ID variables, if any; and the DATE= variable if the DATE= option is given, or _DATE_ if the DATE= option is not specified.

In addition, the variables specified by the option

tablename =var1 var2 ... varn

are placed in the OUT= data set. A list of tables available for monthly and quarterly series is given later, in Table 36.4.

The OUTSPAN= Data Set

The OUTSPAN= option is specified in the PROC statement, and writes the sliding spans results to the specified output data set. The OUTSPAN= data set contains the following variables:

- A1, a numeric variable that is a copy of the original series truncated to the current span. Note that overlapping spans will contain identical values for this variable.
- C18, a numeric variable that contains the trading-day factors for the seasonal adjustment for the current span
- D10, a numeric variable that contains the seasonal factors for the seasonal adjustment for the current span
- D11, a numeric variable that contains the seasonally adjusted series for the current span
- DATE, a numeric variable that contains the date within the current span
- SPAN, a numeric variable that contains the current span. The first span is the earliest span—that is the one with the earliest starting date.
- VARNAME, a character variable containing the name of each variable in the VAR list. A separate sliding spans analysis is performed on each variable in the VAR list.

OUTSTB= Data Set

The output data set produced by the OUTSTB= option of the PROC X11 statement contains the information in the analysis of variance on table D8 (Final Unmodified S-I Ratios). This analysis of variance, following table D8 in the printed output, tests for stable seasonality (Shiskin, Young, and Musgrave 1967, Appendix A). These data contain the following variables:

- VARNAME, a character variable containing the name of each variable in the VAR list
- TABLE, a character variable specifying the table from which the analysis of variance is performed. When ARIMA processing is requested, and two passes of X11 are required (when TDREGR=PRINT, TEST, or ADJUST), Table D8 and the stable seasonality test are computed twice: once in the initial pass, then again in the final pass. Both of these computations are put in the OUTSTB data set and are identified by D18.1 and D18.2, respectively.
- SOURCE, a character variable corresponding to the “source” column in the analysis of variance table following Table D8
- SS, a numeric variable containing the sum of squares associated with the corresponding source term
- DF, a numeric variable containing the degrees of freedom associated with the corresponding source term

- MS, a numeric variable containing the mean square associated with the corresponding source term. MS is missing for the source term “Total”
- F, a numeric variable containing the F statistic for the “Between” source term. F is missing for all other source terms.
- PROBF, a numeric variable containing the significance level for the F statistic. PROBF is missing for the source terms “Total” and “Error.”

OUTTDR= Data Set

The trading-day regression results (tables B15 and C15) are written to the OUTTDR= data set, which contains the following variables:

- VARNAME, a character variable containing the name of the VAR variable being processed
- TABLE, a character variable containing the name of the table. It can have only the value B15 (Preliminary Trading-Day Regression) or C15 (Final Trading-Day Regression).
- _TYPE_, a character variable whose value distinguishes the three distinct table format types. These types are (a) the regression, (b) the listing of the standard error associated with length-of-month, and (c) the analysis of variance. The first seven observations in the OUTTDR data set correspond to the regression on days of the week; thus the _TYPE_ variable is given the value “REGRESS” (day-of-week regression coefficient). The next four observations correspond to 31-, 30-, 29-, and 28-day months and are given the value _TYPE_=LOM_STD (length-of-month standard errors). Finally, the last three observations correspond to the analysis of variance table, and _TYPE_=ANOVA.
- PARM, a character variable, further identifying the nature of the observation. PARM is set to blank for the three _TYPE_=ANOVA observations.
- SOURCE, a character variable containing the source in the regression. This variable is missing for all _TYPE_=REGRESS and LOM_STD.
- CWGT, a numeric variable containing the combined trading-day weight (prior weight + weight found from regression). The variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.
- PRWGT, a numeric variable containing the prior weight. The prior weight is 1.0 if PDWEIGHTS are not specified. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.
- COEFF, a numeric variable containing the calculated regression coefficient for the given day. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.
- STDERR, a numeric variable containing the standard errors. For observations with _TYPE_=REGRESS, this is the standard error corresponding to the regression coefficient. For observations with _TYPE_=LOM_STD, this is standard error for the corresponding length-of-month. This variable is missing for all _TYPE_=ANOVA.
- T1, a numeric variable containing the t statistic corresponding to the test that the combined weight is different from the prior weight. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

- T2, a numeric variable containing the t statistic corresponding to the test that the combined weight is different from 1.0. This variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- PROBT1, a numeric variable containing the significance level for t statistic T1. The variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- PROBT2, a numeric variable containing the significance level for t statistic T2. The variable is missing for all `_TYPE_=LOM_STD` and `_TYPE_=ANOVA`.
- SS, a numeric variable containing the sum of squares associated with the corresponding source term. This variable is missing for all `_TYPE_=REGRESS` and `LOM_STD`.
- DF, a numeric variable containing the degrees of freedom associated with the corresponding source term. This variable is missing for all `_TYPE_=REGRESS` and `LOM_STD`.
- MS, a numeric variable containing the mean square associated with the corresponding source term. This variable is missing for the source term 'Total' and for all `_TYPE_=REGRESS` and `LOM_STD`.
- F, a numeric variable containing the F statistic for the 'Regression' source term. The variable is missing for the source terms 'Total' and 'Error', and for all `_TYPE_=REGRESS` and `LOM_STD`.
- PROBF, a numeric variable containing the significance level for the F statistic. This variable is missing for the source term 'Total' and 'Error' and for all `_TYPE_=REGRESS` and `LOM_STD`.

Printed Output

The output from PROC X11, both printed tables and the series written to the OUT= data set, depends on whether the data are monthly or quarterly. For the printed tables, the output depends further on the value of the PRINTOUT= option and the TABLE statement, along with other options specified.

The printed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X11 procedure are as follows:

A	prior adjustments (optional)
B	preliminary estimates of irregular component weights and regression trading-day factors
C	final estimates of irregular component weights and regression trading-day factors
D	final estimates of seasonal, trend cycle, and irregular components
E	analytical tables
F	summary measures
G	charts

Table 36.4 describes the individual tables and charts. Most tables apply both to quarterly and monthly series. Those that apply only to a monthly time series are indicated by an "M" in the notes section, while "P" indicates the table is not a time series, and is only printed, not output to the OUT= data set.

Table 36.4 Table Names and Descriptions

Table	Description	Notes
A1	original series	M
A2	prior monthly adjustment factors	M
A3	original series adjusted for prior monthly factors	M
A4	prior trading-day adjustments	M
A5	prior adjusted or original series	M
A13	ARIMA forecasts	
A14	ARIMA backcasts	
A15	prior adjusted or original series extended by ARIMA backcasts and forecasts	
B1	prior adjusted or original series	
B2	trend cycle	
B3	unmodified seasonal-irregular (S-I) ratios	
B4	replacement values for extreme S-I ratios	
B5	seasonal factors	
B6	seasonally adjusted series	
B7	trend cycle	
B8	unmodified S-I ratios	
B9	replacement values for extreme S-I ratios	
B10	seasonal factors	
B11	seasonally adjusted series	
B13	irregular series	
B14	extreme irregular values excluded from trading-day regression	M
B15	preliminary trading-day regression	M,P
B16	trading-day adjustment factors	M
B17	preliminary weights for irregular components	
B18	trading-day factors derived from combined daily weights	M
B19	original series adjusted for trading-day and prior variation	M
C1	original series modified by preliminary weights and adjusted for trading-day and prior variation	
C2	trend cycle	
C4	modified S-I ratios	
C5	seasonal factors	
C6	seasonally adjusted series	
C7	trend cycle	
C9	modified S-I ratios	
C10	seasonal factors	
C11	seasonally adjusted series	
C13	irregular series	
C14	extreme irregular values excluded from trading-day regression	M
C15	final trading-day regression	M,P
C16	final trading-day adjustment factors derived from regression coefficients	M
C17	final weight for irregular components	

Table 36.4 *continued*

Table	Description	Notes
C18	final trading-day factors derived from combined daily weights	M
C19	original series adjusted for trading-day and prior variation	M
D1	original series modified for final weights and adjusted for trading-day and prior variation	
D2	trend cycle	
D4	modified S-I ratios	
D5	seasonal factors	
D6	seasonally adjusted series	
D7	trend cycle	
D8	final unmodified S-I ratios	
D9	final replacement values for extreme S-I ratios	
D10	final seasonal factors	
D11	final seasonally adjusted series	
D12	final trend cycle	
D13	final irregular series	
E1	original series with outliers replaced	
E2	modified seasonally adjusted series	
E3	modified irregular series	
E4	ratios of annual totals	P
E5	percent changes in original series	
E6	percent changes in final seasonally adjusted series	
F1	MCD moving average	
F2	summary measures	P
G1	chart of final seasonally adjusted series and trend cycle	P
G2	chart of S-I ratios with extremes, S-I ratios without extremes, and final seasonal factors	P
G3	chart of S-I ratios with extremes, S-I ratios without extremes, and final seasonal factors in calendar order	P
G4	chart of final irregular and final modified irregular series	P

The PRINTOUT= Option

The PRINTOUT= option controls printing for groups of tables. See the “[TABLES Statement](#)” on page 2583 for details on specifying individual tables. The following list gives the tables printed for each value of the PRINTOUT= option:

STANDARD (26 tables)	A1–A4, B1, C13–C19, D8–D13, E1–E6, F1, F2
LONG (40 tables)	A1–A5, A13–A15, B1, B2, B7, B10, B13–B15, C1, C7, C10, C13–C19, D1, D7–D11, D13, E1–E6, F1, F2
FULL (62 tables)	A1–A5, A13–A15, B1–B11, B13–B19, C1–C11, C13–C19, D1, D2, D4–D12, E1–E6, F1, F2

The actual number of tables printed depends on the options and statements specified. If a table is not computed, it is not printed. For example, if TDREGR=NONE is specified, none of the tables associated with the trading-day are printed.

The CHARTS= Option

Of the four charts listed in Table 36.4, G1 and G2 are printed by default (CHARTS=STANDARD). Charts G3 and G4 are printed when CHARTS=FULL is specified. See the “TABLES Statement” on page 2583 for details on specifying individual charts.

Stable, Moving, and Combined Seasonality Tests on the Final Unmodified SI Ratios (Table D8)

PROC X11 displays four tests used to identify stable seasonality and moving seasonality and to measure identifiable seasonality. These tests are displayed after Table D8. They are “Stable Seasonality Test,” “Moving Seasonality Test,” “Nonparametric Test for the Presence of Seasonality Assuming Stability,” and “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” The motivation, interpretation, and statistical details of all these tests are now given.

Motivation

The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality). If the increase in the seasonal factors from year to year is too large, then the seasonal factors will introduce distortion into the model. It is important to determine if seasonality is identifiable without distorting the series.

To determine if stable seasonality is present in a series, PROC X11 computes a one-way analysis of variance by using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use because the removal of the trend cycle is equivalent to detrending. PROC X11 prints this test, labeled “Stable Seasonality Test,” immediately after the Table D8.

The X11 seasonal adjustment method tests for moving seasonality. Moving seasonality can be a source of distortion when seasonal factors are used in the model. PROC X11 computes and prints a test for moving seasonality. The test is a two-way analysis of variance that uses months (or quarters) and years. As in the “Stable Seasonality Test,” this analysis of variance is performed on the Final Unmodified SI Ratios (Table D8). PROC X11 prints this test, labeled “Moving Seasonality Test,” after the “Stable Seasonality Test.”

PROC X11 next computes a nonparametric Kruskal-Wallis chi-squared test for stable seasonality, “Nonparametric Test for the Presence of Seasonality Assuming Stability.” The Kruskal-Wallis test is performed on the ranks of the Final Unmodified SI Ratios (Table D8). For further details about the Kruskal-Wallis test, see Lehmann and D’Abrera (2006, pp. 204–210).

The results of the preceding three tests are combined into a joint test to measure identifiable seasonality, “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” This test combines the two F tests previously described, along with the Kruskal-Wallis chi-squared test for stable seasonality, to determine “identifiable” seasonality. This test is printed after “Nonparametric Test for the Presence of Seasonality Assuming Stability.”

Interpretation and Statistical Details

The “Stable Seasonality Test” is a one-way analysis of variance on the “Final Unmodified SI Ratios” with seasons (months or quarters) as the factor.

To determine whether stable seasonality is present in a series, PROC X11 computes a one-way analysis of variance by using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use because the removal of the trend cycle is similar to detrending.

A large F statistic and a small significance level are evidence that a significant amount of variation in the SI-ratios is due to months or quarters, which in turn is evidence of seasonality; the null hypothesis of no month/quarter effect is rejected.

Conversely, a small F statistic and a large significance level (close to 1.0) are evidence that variation due to month or quarter could be due to random error, and the null hypothesis of no month/quarter effect is not rejected. The interpretation and utility of seasonal adjustment are problematic under such conditions.

The F test for moving seasonality is performed by a two-way analysis of variance. The two factors are seasons (months or quarters) and years. The years effect is tested separately; the null hypothesis is no effect due to years after accounting for variation due to months or quarters. For further details about the moving seasonality test, see Lothian (1984a, b, 1978) and Higginson (1975).

The significance level reported in both the moving and stable seasonality tests are only approximate. Table D8, the Final Unmodified SI Ratios, is constructed from an averaging operation that induces a correlation in the residuals from which the F test is computed. Hence the computed F statistic differs from an exact F statistic; see Cleveland and Devlin (1980) for details.

The test for identifiable seasonality is performed by combining the F tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The following description is based on Lothian and Morry (1978b); other details can be found in Dagum (1988, 1983).

Let F_s and F_m denote the F value for the stable and moving seasonality tests, respectively. The combined test is performed as shown in Table 36.5 and as follows:

1. If the null hypothesis of no stable seasonality is not rejected at the 0.10% significance level ($P_S \geq 0.001$), then the series is considered to be nonseasonal. PROC X11 returns the conclusion, "Identifiable Seasonality Not Present."
2. If the null hypothesis in step 1 is rejected, then PROC X11 computes the following quantities:

$$T_1 = \frac{7}{F_s}$$

$$T_2 = \frac{3F_m}{F_s}$$

Let T denote the simple average of T_1 and T_2 :

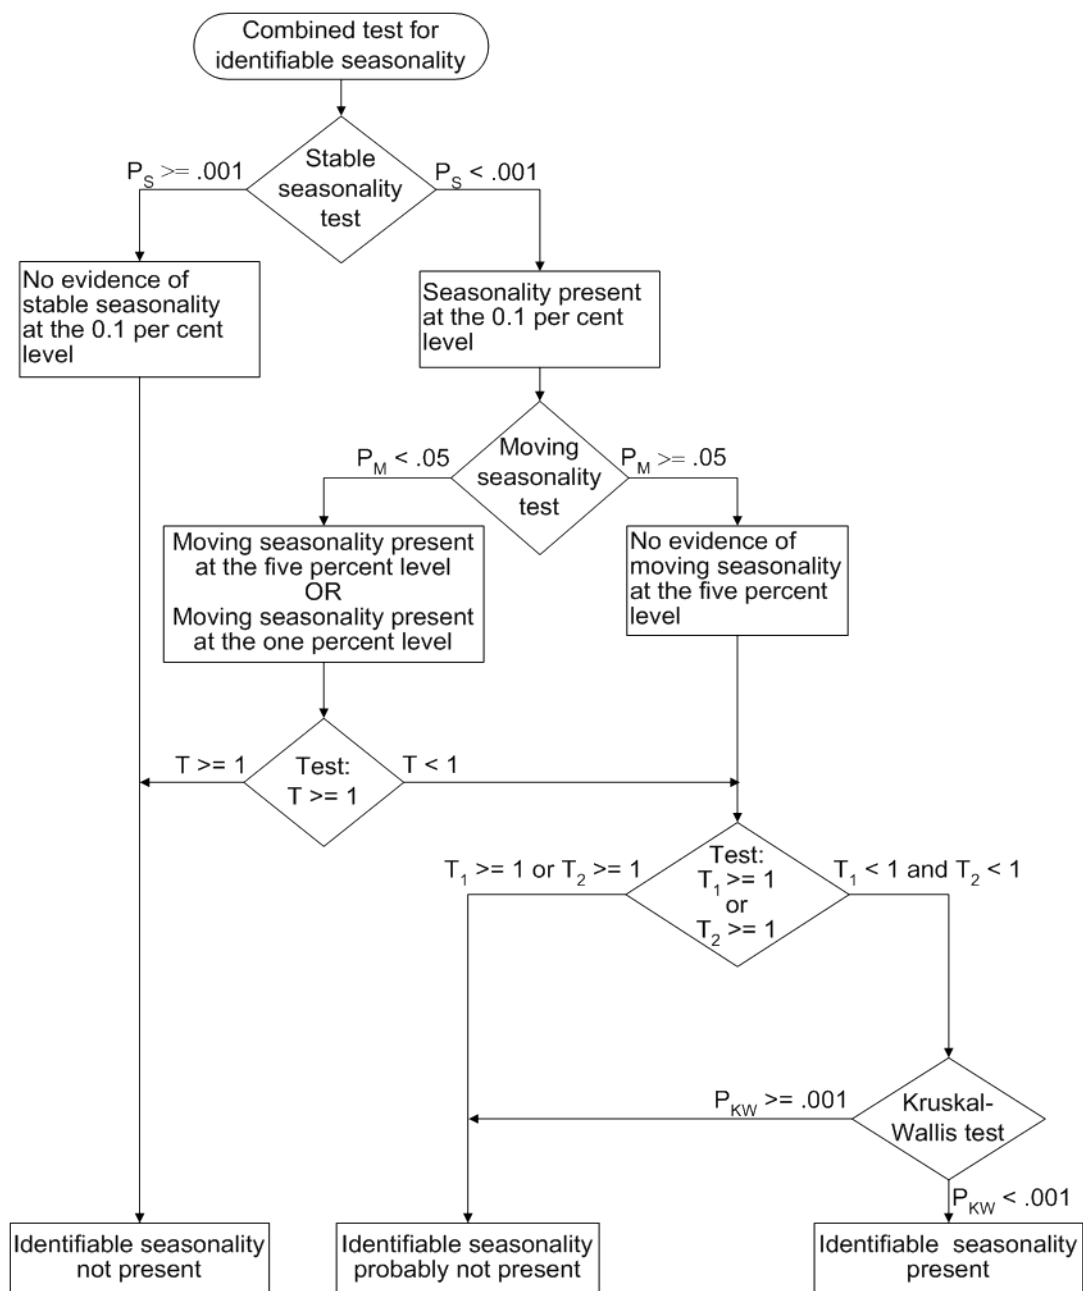

$$T = \frac{(T_1 + T_2)}{2}$$

If the null hypothesis of no moving seasonality is rejected at the 5.0% significance level ($P_M < 0.05$) and if $T \geq 1.0$, the null hypothesis of identifiable seasonality *not* present is not rejected and PROC X11 returns the conclusion, "Identifiable Seasonality Not Present."

3. If the null hypothesis of identifiable seasonality *not* present has not been accepted, but $T_1 \geq 1.0$, $T_2 \geq 1.0$, or the Kruskal-Wallis chi-squared test fails to reject at the 0.10% significance level ($P_{KW} \geq 0.001$), then PROC X11 returns the conclusion "Identifiable Seasonality Probably Not Present."

4. If the null hypotheses of no stable seasonality associated with the F_S and Kruskal-Wallis chi-squared tests are rejected and if none of the combined measures described in steps 2 and 3 fail, then the null hypothesis of identifiable seasonality *not* present is rejected and PROC X11 returns the conclusion “Identifiable Seasonality Present.”

Figure 36.5 Combined Seasonality Test Flowchart

Tables Written to the OUT= Data Set

All tables that are time series can be written to the OUT= data set. However, depending on the specified options and statements, not all tables are computed. When a table is not computed, but is requested in the OUTPUT statement, the resulting variable has all missing values.

For example, if the PMFACTOR= option is not specified, Table A2 is not computed, and requesting this table in the OUTPUT statement results in the corresponding variable having all missing values.

The trading-day regression results, Tables B15 and C15, although not written to the OUT= data set, can be written to an output data set; see the OUTTDR= option for details.

Printed Output Generated by Sliding Spans Analysis

Table S 0.A

Table S 0.A gives the variable name, the length and number of spans, and the beginning and ending dates of each span.

Table S 0.B

Table S 0.B gives the summary of the two F tests performed during the standard X11 seasonal adjustments for stable and moving seasonality on Table D8, the final SI ratios. These tests are described in the section “Printed Output” on page 2599.

Table S 1.A

Table S 1.A gives the range analysis of seasonal factors. This includes the means for each month (or quarter) within a span, the maximum percentage difference across spans for each month, and the average. The minimum and maximum within a span are also indicated.

For example, for a monthly series and an analysis with four spans, the January row would contain a column for each span, with the value representing the average seasonal factor (Table D10) over all January calendar months occurring within the span. Beside each span column is a character column with either a MIN, MAX, or blank value, indicating which calendar month had the minimum and maximum value over that span.

Denote the average over the j th calendar month in span k , $k = 1, \dots, 4$, by $\bar{S}_j(k)$; then the maximum percent difference (MPD) for month j is defined by

$$MPD_j = \frac{\max_{k=1,\dots,4} \bar{S}_j(k) - \min_{k=1,\dots,4} \bar{S}_j(k)}{\min_{k=1,\dots,4} \bar{S}_j(k)}$$

The last numeric column of Table S 1.A is the average value over all spans for each calendar month, with the minimum and maximum row flagged as in the span columns.

Table S 1.B

Table S 1.B gives a summary of range measures for each span. The first column, Range Means, is calculated by computing the maximum and minimum over all months or quarters in a span, then taking the difference. The next column is the range ratio means, which is simply the ratio of the previously described maximum and minimum. The next two columns are the minimum and maximum seasonal factors over the entire span, while the range sf column is the difference of these. Finally, the last column is the ratio of the Max SF and Min SF columns.

Breakdown Tables

Table S 2.A.1 begins the breakdown analysis for the various series considered in the sliding spans analysis. The key concept here is the MPD described above in the section “Table S 1.A” on page 2605 and in the section “Computational Details for Sliding Spans Analysis” on page 2588. For a month or quarter that appears in two or more spans, the maximum percentage difference is computed and tested against a cutoff level. If it exceeds this cutoff, it is counted as an instance of exceeding the level. It is of interest to see if such instances fall disproportionately in certain months and years. Tables S 2.A.1 through S 6.A.3 display this breakdown for all series considered.

Table S 2.A.1

Table S 2.A.1 gives the monthly (quarterly) breakdown for the seasonal factors (table D10). The first column identifies the month or quarter. The next column is the number of times the MPD for D10 exceeded 3.0%, followed by the total count. The last is the average maximum percentage difference for the corresponding month or quarter.

Table S 2.A.2

Table S 2.A.2 gives the same information as Table S 2.A.1, but on a yearly basis.

Table S 2.A.3

The description of Table S 2.A.3 requires the definition of “Sign Change” and “Turning Point.”

First, some motivation. Recall that for a highly stable series, adding or deleting a small number of observations should not affect the estimation of the various components of a seasonal adjustment procedure.

Consider Table D10, the seasonal factors in a sliding spans analysis that uses four spans. For a given observation t , looking across the four spans, we can easily pick out large differences if they occur. More subtle differences can occur when estimates go from above to below (or vice versa) a base level. In the case of multiplicative model, the seasonal factors have a base level of 100.0. So it is useful to enumerate those instances where both a large change occurs (an MPD value exceeding 3.0%) and a change of sign (with respect to the base) occur.

Let B denote the base value (which in general depends on the component being considered and the model type, multiplicative or additive). If, for span 1, $S_t(1)$ is below B (i.e., $S_t(1) - B$ is negative) and for some subsequent span k , $S_t(k)$ is above B (i.e., $S_t(k) - B$ is positive), then a positive “Change in Sign” has occurred at observation t . Similarly, if, for span 1, $S_t(1)$ is above B , and for some subsequent span k , $S_t(k)$ is below B , then a negative “Change in Sign” has occurred. Both cases, positive or negative, constitute a “Change in Sign”; the actual direction is indicated in tables S 7.A through S 7.E, which are described below.

Another behavior of interest occurs when component estimates increase then decrease (or vice versa) across spans for a given observation. Using the preceding example, the seasonal factors at observation t could first increase, then decrease across the four spans.

This behavior, combined with an MPD exceeding the level, is of interest in questions of stability.

Again, consider Table D10, the seasonal factors in a sliding spans analysis that uses four spans. For a given observation t (containing at least three spans), note the level of D10 for the first span. Continue across the spans until a difference of 1.0% or greater occurs (or no more spans are left), noting whether the difference is up or down. If the difference is up, continue until a difference of 1.0% or greater occurs downward (or no more spans are left). If such an up-down combination occurs, the observation is counted as an up-down turning point. A similar description occurs for a down-up turning point. Tables S 7.A through S 7.E, described

below, show the occurrence of turning points, indicating whether up-down or down-up. Note that it requires at least three spans to test for a turning point. Hence Tables S 2.A.3 through S 6.A.3 show a reduced number in the “Turning Point” row for the “Total Tested” column, and in Tables S 7.A through S 7.E, the turning points symbols can occur only where three or more spans overlap.

With these descriptions of sign change and turning point, we now describe Table S 2.A.3. The first column gives the type or category, the second column gives the total number of observations falling into the category, the third column gives the total number tested, and the last column gives the percentage for the number found in the category.

The first category (row) of the table is for flagged observations—that is, those observations where the MPD exceeded the appropriate cutoff level (3.0% is default for the seasonal factors). The second category is for level changes, while the third category is for turning points. The fourth category is for flagged sign changes—that is, for those observations that are sign changes, how many are also flagged. Note the total tested column for this category equals the number found for sign change, reflecting the definition of the fourth category.

The fifth column is for flagged turning points—that is, for those observations that are turning points, how many are also flagged.

The footnote to Table S 2.A.3 gives the U.S. Census Bureau recommendation for thresholds, as described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2588.

Table S 2.B

Table S 2.B gives the histogram of flagged for seasonal factors (Table D10) using the appropriate cutoff value (default 3.0%). This table looks at the spread of the number of times the MPD exceeded the corresponding level. The range is divided up into four intervals: 3.0%–4.0%, 4.0%–5.0%, 5.0%–6.0%, and greater than 6.0%. The first column shows the symbol used in Table S 7.A, the second column gives the range in interval notation, and the last column gives the number found in the corresponding interval. Note that the sum of the last column should agree with the “Number Found” column of the “Flagged MPD” row in Table S 2.A.3.

Table S 2.C

Table S 2.C gives selected percentiles for the MPD for the seasonal factors (Table D10).

Tables S 3.A.1 through S 3.A.3

These tables relate to the trading-day factors (Table C18) and follow the same format as Tables S 2.A.1 through S 2.A.3. The only difference between these tables and Tables S 2.A.1 through S 2.A.3 is the default cutoff value of 2.0% instead of the 3.0% used for the seasonal factors.

Tables S 3.B, S 3.C

These tables, applied to the trading-day factors (Table C18), are the same format as Tables S 2.B through S 2.C. The default cutoff value is different, with corresponding differences in the intervals in S 3.B.

Tables S 4.A.1 through S 4.A.3

These tables relate to the seasonally adjusted series (Table D11) and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 4.B, S 4.C

These tables, applied to the seasonally adjusted series (Table D11), are the same format as tables S 2.B through S 2.C.

Tables S 5.A.1 through S 5.A.3

These table relate to the month-to-month (or quarter-to-quarter) differences in the seasonally adjusted series, and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 5.B, S 5.C

These tables, applied to the month-to-month (or quarter-to-quarter) differences in the seasonally adjusted series, are the same format as tables S 2.B through S 2.C. The same default cutoff value of 3.0% is used.

Tables S 6.A.1 through S 6.A.3

These table relate to the year-to-year differences in the seasonally adjusted series, and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 6.B, S 6.C

These tables, applied to the year-to-year differences in the seasonally adjusted series, are the same format as tables S 2.B through S 2.C. The same default cutoff value of 3.0% is used.

Table S 7.A

Table S 7.A gives the entire listing of the seasonal factors (Table D10) for each span. The first column gives the date for each observation included in the spans. Note that the dates do not cover the entire original data set. Only those observations included in one or more spans are listed.

The next N columns (where N is the number of spans) are the individual spans starting at the earliest span. The span columns are labeled by their beginning and ending dates.

Following the last span is the “Sign Change” column. As explained in the description of Table S 2.A.3, a sign change occurs at a given observation when the seasonal factor estimates go from above to below, or below to above, a base level. For the seasonal factors, 100.0 is the base level for the multiplicative model, 0.0 for the additive model. A blank value indicates no sign change, a “U” indicates a movement “upward” from the base level and a “D” indicates a movement “downward” from the base level.

The next column is the “Turning Point” column. As explained in the description of Table S 2.A.3, a turning point occurs when there is an upward then downward movement, or downward then upward movement, of sufficient magnitude. A blank value indicates no turning point, a “U-D” indicates a movement “upward then downward,” and a “D-U” indicates a movement “downward then upward.”

The next column is the maximum percentage difference (MPD). This quantity, described in the section “Computational Details for Sliding Spans Analysis” on page 2588, is the main computation for sliding spans analysis. A measure of how extreme the MPD value is given in the last column, the “Level of Excess” column. The symbols used and their meaning are described in Table S 2.A.3. If a given observation has exceeded the cutoff, the level of excess column is blank.

Table S 7.B

Table S 7.B gives the entire listing of the trading-day factors (Table C18) for each span. The format of this table is exactly like that of Table S 7.A.

Table S 7.C

Table S 7.C gives the entire listing of the seasonally adjusted data (Table D11) for each span. The format of this table is exactly like that of Table S 7.A except for the “Sign Change” column, which is not printed. The seasonally adjusted data have the same units as the original data; there is no natural base level as in the case of a percentage. Hence the sign change is not appropriate for D11.

Table S 7.D

Table S 7.D gives the entire listing of the month-to-month (or quarter-to-quarter) changes in seasonally adjusted data for each span. The format of this table is exactly like that of Table S 7.A.

Table S 7.E

Table S 7.E gives the entire listing of the year-to-year changes in seasonally adjusted data for each span. The format of this table is exactly like that of Table S 7.A.

Printed Output from the ARIMA Statement

The information printed by default for the ARIMA model includes the parameter estimates, their approximate standard errors, t ratios, and variances, the standard deviation of the error term, and the AIC and SBC statistics for the model. In addition, a criteria summary for the chosen model is given that shows the values for each of the three test criteria and the corresponding critical values.

If the PRINTALL option is specified, a summary of the nonlinear estimation optimization and a table of Box-Ljung statistics is also produced. If the automatic model selection is used, this information is printed for each of the five predefined models. Finally, a model selection summary is printed, showing the final model chosen.

ODS Table Names

PROC X11 assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

NOTE: For monthly and quarterly tables, use the ODS names MonthlyTables and QuarterlyTables; For brevity, only the MonthlyTables are listed here; the QuarterlyTables are simply duplicates. Printing of individual tables can be specified by using the TABLES table_name, which is not listed here. Printing groups of tables is specified in the MONTHLY and QUARTERLY statements by specifying the option PRINTOUT=NONE|STANDARD|LONG|FULL. The default is PRINTOUT=STANDARD.

Table 36.5 ODS Tables Produced in PROC X11

ODS Table Name	Description	Option

Examples: X11 Procedure

Example 36.1: Component Estimation—Monthly Data

This example computes and plots the final estimates of the individual components for a monthly series. In the first plot ([Output 36.1.1](#)), an overlaid plot of the original and seasonally adjusted data is produced. The trend in the data is more evident in the seasonally adjusted data than in the original data. This trend is even more clear in [Output 36.1.3](#), the plot of Table D12, the trend cycle. Note that both the seasonal factors and the irregular factors vary around 100, while the trend cycle and the seasonally adjusted data are in the scale of the original data.

From [Output 36.1.2](#) the seasonal component appears to be slowly increasing, while no apparent pattern exists for the irregular series in [Output 36.1.4](#).

Example 36.3: Outlier Detection and Removal

PROC X11 can be used to detect and replace outliers in the irregular component of a monthly or quarterly series.

The weighting scheme used in measuring the “extremeness” of the irregulars is developed iteratively; thus the statistical properties of the outlier adjustment method are unknown.

In this example, the data are simulated by generating a trend plus a random error. Two periods in the series were made “extreme” by multiplying one generated value by 2.0 and another by 0.10. The additive model is appropriate based on the way the data were generated. Note that the trend in the generated data was modeled automatically by the trend cycle component estimation.

The detection of outliers is accomplished by considering Table D9, the final replacement values for extreme S-I ratios. This table indicates which observations had irregular component values more than FULLWEIGHT= standard deviation units from 0.0 (1.0 for the multiplicative model). The default value of the FULLWEIGHT= option is 1.5; a larger value would result in fewer observations being declared extreme.

In this example, FULLWEIGHT=3.0 is used to isolate the extreme inflated and deflated values generated in the DATA step. The value of ZEROWEIGHT= must be greater than FULLWEIGHT; it is given a value of 3.5.

A plot of the original and modified series, [Output 36.3.2](#), shows that the deviation from the trend line for the modified series is greatly reduced compared with the original series.

```
data a;
  retain seed 99831;
  do kk = 1 to 48;
    x = kk + 100 + rannor( seed );
    date = intnx( 'month', '01jan1970'd, kk-1 );
    if kk = 20 then x = 2 * x;
    else if kk = 30 then x = x / 10;
    output;
  end;
run;
```

Overview: X12 Procedure

The X12 procedure is an adaptation of the U.S. Bureau of the Census X-12-ARIMA Seasonal Adjustment program (U.S. Bureau of the Census 2010). The X-12-ARIMA program was developed by the Time Series Staff of the Statistical Research Division, U.S. Census Bureau. The X-12-ARIMA seasonal adjustment program contains components developed from Statistics Canada's X-11-ARIMA program. The X-12-ARIMA automatic modeling method is based on the work of Gómez and Maravall (1997a, b).

The version of PROC X12 documented here was produced by converting the U.S. Census Bureau's FORTRAN code to the SAS development language and adding typical SAS procedure syntax. This conversion work was performed by SAS and resulted in the X12 procedure. Although several features were added during the conversion, credit for the statistical aspects and general methodology of the X12 procedure belongs to the U.S. Census Bureau.

The X12 procedure seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set that contains the adjusted time series and intermediate calculations.

The X-12-ARIMA program combines the capabilities of the X-11 program (Shiskin, Young, and Musgrave 1967) and the X-11-ARIMA/88 program (Dagum 1988) and also introduces some new features (Findley et al. 1998). One of the main enhancements involves the use of a regARIMA model, a regression model with ARIMA (autoregressive integrated moving average) errors. Thus, the X-12-ARIMA program contains methods developed by both the U.S. Census Bureau and Statistics Canada. In addition, the X-12-ARIMA automatic modeling routine is based on the TRAMO (time series regression with ARIMA noise, missing

values, and outliers) method (Gómez and Maravall 1997a, b). The four major components of the X-12-ARIMA program are regARIMA modeling, model diagnostics, seasonal adjustment that uses enhanced X-11 methodology, and post-adjustment diagnostics. Statistics Canada's X-11 method fits an ARIMA model to the original series, and then uses the model forecasts to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t , $t = 1, \dots, n$, and separated from trend cycle, trading day, and irregular fluctuations. The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated consistently or in an evolving fashion from year to year. The trend cycle component, C_t , includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading day component, D_t , is the variation that can be attributed to the composition of the calendar. The irregular component, I_t , is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). Other economic series are related in an additive fashion ($O_t = S_t + C_t + D_t + I_t$). A seasonally adjusted time series, $C_t I_t$ or $C_t + I_t$, consists of only the trend cycle and irregular components. For more details about seasonal adjustment with the X-11 method, see Ladiray and Quenneville (2001).

Graphics are now available with the X12 procedure. For more information, see the section “[ODS Graphics](#)” on page 2688.

Getting Started: X12 Procedure

The most common use of the X12 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X12 to produce a seasonally adjusted series, $C_t I_t$, from an original series $O_t = S_t C_t D_t I_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t , while S_t , D_t , and I_t vary around 1.0. In all displayed tables, these latter components are expressed as percentages and thus vary around 100.0 (in the additive case, they vary around 0.0). However, in the output data set, the data displayed as percentages in the displayed output are expressed as the decimal equivalent and thus vary around 1.0 in the multiplicative case.

The naming convention used in PROC X12 for the tables follows the convention used in the Census Bureau's X-12-ARIMA program; see *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2009c), *X-12-ARIMA Quick Reference for Windows (PC)* (U.S. Bureau of the Census 2009b), and *X-12-ARIMA Quick Reference for UNIX/Linux* (U.S. Bureau of the Census 2009a). Also see the section “[Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords](#)” on page 2684. The table names are outlined in [Table 37.14](#).

The tables that correspond to parts A through C are intermediate calculations. The final estimates of the individual components are found in the D tables: Table D10 contains the final seasonal factors, Table D12 contains the final trend cycle, and Table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you need to look only at Table D11, the final seasonally adjusted series. Tables in part E contain information about extreme values and changes in the original and seasonally adjusted series. The tables in part F are seasonal adjustment quality measures. Spectral analysis is performed in part G. For further information about the tables produced by the X11 statement, see Ladiray and Quenneville (2001).

Basic Seasonal Adjustment

Suppose that you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point, you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the PROC X12 statement and request seasonal adjustment in the X11 statement as shown in the following statements:

```
data sales;
  set sashelp.air;
  sales = air;
  date = intnx( 'month', '01sep78'd, _n_-1 );
  format date monyy.;
run;

proc x12 data=sales date=date;
  var sales;
  x11;
  ods select d11;
run;
```

The results of the seasonal adjustment are in Table D11 (the final seasonally adjusted series) in the displayed output shown in [Figure 37.1](#).

Figure 37.1 Basic Seasonal Adjustment

The X12 Procedure							
Table D 11: Final Seasonally Adjusted Data For Variable sales							
Year	JAN JUL	FEB AUG	MAR SEP	APR OCT	MAY NOV	JUN DEC	Total

Total: 40323 Mean: 280.02 S.D.: 111.31							
Min: 124.56 Max: 499.2							

You can compare the original series (Table A1) and the final seasonally adjusted series (Table D11) by plotting them together as shown in [Figure 37.2](#). These tables are requested in the OUTPUT statement and are written to the OUT= data set. Note that the default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

```

proc x12 data=sales date=date noprint;
  var sales;
  x11;
  output out=out a1 d11;
run;

proc sgplot data=out;
  series x=date y=sales_A1 / name = "A1" markers
        markerattrs=(color=red symbol='asterisk')
        lineattrs=(color=red);
  series x=date y=sales_D11 / name= "D11" markers
        markerattrs=(symbol='circle')
        lineattrs=(color=blue);
  yaxis label='Original and Seasonally Adjusted Time Series';
run;

```

Figure 37.2 Plot of Original and Seasonally Adjusted Data

Syntax: X12 Procedure

The X12 procedure uses the following statements:

```

PROC X12 options ;
  VAR variables ;
  BY variables ;
  ID variables ;
  EVENT variables < / options > ;
  USERDEFINED variables ;
  TRANSFORM options ;
  ADJUST option ;
  IDENTIFY options ;
  PICKMDL options ;
  AUTOMDL options ;
  OUTLIER options ;
  REGRESSION options ;
  INPUT variables < / options > ;
  ARIMA option ;
  ESTIMATE options ;
  X11 options ;
  FORECAST options ;
  CHECK options ;
  SEATSDECOMP OUT= SAS-data-set < options > ;
  OUTPUT OUT= SAS-data-set < YEARSEAS > tablename1 tablename2 ... ;
  TABLES tablename1 tablename2 ... options ;

```

The statements used by PROC X12 perform basically the same function as the Census Bureau's X-12-ARIMA specs (specifications). *Specs* are used in X-12-ARIMA to control the computations and output. The PROC X12 statement performs some of the same functions as the Series spec in the Census Bureau's X-12-ARIMA software. The ADJUST statement performs some of the same functions as the Transform spec. The ARIMA, AUTOMDL, CHECK, ESTIMATE, FORECAST, IDENTIFY, OUTLIER, PICKMDL, REGRESSION, TRANSFORM, and X11 statements are designed to perform the same functions as the corresponding X-12-ARIMA specs, although full compatibility is not yet available. The Census Bureau documentation *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2009c) provides added insight to the functionality of these statements. The SEATSDECOMP statement is an experimental statement to provide a SEATS (signal extraction in ARIMA time series) seasonal decomposition for the B1 series that uses the same ARIMA model as is used to model the series. For more information about SEATS, see Gómez and Maravall (1997a, b).

Functional Summary

Table 37.1 summarizes the statements and options that control the X12 procedure.

Table 37.1 X12 Syntax Summary

Description	Statement	Option
Data Set Options		
Specifies the auxiliary data set	PROC X12	AUXDATA=
Specifies the input data set	PROC X12	DATA=
Specifies the user-defined event definition data set	PROC X12	INEVENT=
Specifies regression and ARIMA information	PROC X12	MDLINFOIN=
Outputs regression and ARIMA information	PROC X12	MDLINFOOUT=
Writes summary statistics to an output data set	PROC X12	OUTSTAT=
Writes table values to an output data set	OUTPUT	OUT=
Appends forecasts to the OUTPUT OUT= data set	X11 or FORECAST	OUTFORECAST
Prefixes backcasts to the OUTPUT OUT= data set	FORECAST	OUTBACKCAST
Display Control Options		
Suppresses all displayed output	PROC X12	NOPRINT
Specifies the plots to be displayed	PROC X12	PLOTS=
Specifies the type of spectral plot to be displayed	PROC X12	PERIODOGRAM
Specifies the series for spectral analysis	PROC X12	SPECTRUMSERIES=
Displays automatic model information	AUTOMDL	PRINT=
Specifies the number of lags in regARIMA model residuals ACF and PACF tables and plots	CHECK	MAXLAG=
Displays regARIMA model residuals information	CHECK	PRINT=
Displays the iterations history	ESTIMATE	ITPRINT
Displays information about restarted iterations	ESTIMATE	PRINTERR
Specifies the differencing used in the ARIMA model identification ACF and PACF tables and plots	IDENTIFY	DIFF=
Specifies the seasonal differencing used in the ARIMA model identification ACF and PACF tables and plots	IDENTIFY	SDIFF=
Specifies the number of lags in ARIMA model identification ACF and PACF tables and plots	IDENTIFY	MAXLAG=
Displays regression model parameter estimates	IDENTIFY	PRINTREG

Table 37.1 *continued*

Description	Statement	Option
Requests tables that are not displayed by default	TABLES	
Specifies that the summary line not be displayed	TABLES	NOSUM
Date Information Options		
Specifies the date variable	PROC X12	DATE=
Specifies the date of the first observation	PROC X12	START=
Specifies the beginning or ending date or both of the subset	PROC X12	SPAN=
Specifies the interval of the time series	PROC X12	INTERVAL=
Specifies the interval of the time series	PROC X12	SEASONS=
Declaring the Role of Variables		
Specifies BY-group processing	BY	
Specifies identifying variables	ID	
Specifies the variables to be seasonally adjusted	VAR	
Specifies the user-defined variables that are available for regression	USERDEFINED	
Controlling the Table Computations		
Suppresses trimming of leading and trailing missing values (if they exist)	PROC X12	NOTRIMMISS
Transforms or prior-adjusts the series	TRANSFORM	FUNCTION=
Transforms or prior-adjusts the series	TRANSFORM	POWER=
Adjusts the series by using a predefined adjustment variable	ADJUST	PREDEFINED=
Specifies the maximum number of iterations for estimating AR and MA parameters	ESTIMATE	MAXITER
Specifies the convergence tolerance for nonlinear estimation	ESTIMATE	TOL=
Specifies the number of backcasts by which to extend the series for seasonal adjustment	FORECAST	NBACKCAST=
Specifies the number of forecasts by which to extend the series for seasonal adjustment	FORECAST	LEAD=
Specifies that one-step-ahead forecasts be computed	FORECAST	OUT1STEP
Specifying Outlier Detection Options		
Specifies automatic outlier detection	OUTLIER	
Specifies the span for outlier detection	OUTLIER	SPAN=
Specifies the outlier types to be detected	OUTLIER	TYPE=
Specifies the critical values for outlier detection	OUTLIER	CV=
Specifies the critical values for AO outlier	OUTLIER	AOCV=

Table 37.1 *continued*

Description	Statement	Option
detection		
Specifies the critical values for LS outlier detection	OUTLIER	LSCV=
Specifies the critical values for TC outlier detection	OUTLIER	TCCV=
Specifying the Regression Model		
Specifies predefined regression variables	REGRESSION	PREDEFINED=
Specifies user-defined regression variables	REGRESSION	USERVAR=
Specifies user-defined regression variables	INPUT	
Specifies user defined event regression variables	EVENT	
Specifying the ARIMA Model		
Uses the X-12-ARIMA TRAMO-based method to choose a model	AUTOMDL	
Chooses an X-12-ARIMA model from a set that you specify	PICKMDL	
Specifies the ARIMA part of the model	ARIMA	MODEL=
Specifying Automatic Model Detection Options		
Specifies the maximum orders of ARMA polynomials	AUTOMDL	MAXORDER=
Specifies the maximum orders of differencing	AUTOMDL	MAXDIFF=
Specifies the fixed orders of differencing	AUTOMDL	DIFFORDER=
Suppresses fitting of a constant parameter	AUTOMDL	NOINT
Specifies the preference for balanced models	AUTOMDL	BALANCED
Specifies Hannan-Rissanen initial estimation	AUTOMDL	HRINITIAL
Specifies default model acceptance based on Ljung-Box Q	AUTOMDL	ACCEPTDEFAULT
Specifies the acceptance value for Ljung-Box Q	AUTOMDL	LJUNGBOXLIMIT=
Specifies the percentage by which to reduce the outlier critical value	AUTOMDL	REDUCECV=
Specifies the critical value for ARMA coefficients	AUTOMDL	ARMACV=
Model Diagnostics		
Examines the regARIMA model residuals	CHECK	
Specifying Seasonal Adjustment Options		
Specifies seasonal adjustment	X11	
Specifies the mode of seasonal adjustment	X11	MODE=

Table 37.1 *continued*

Description	Statement	Option
decomposition		
Specifies the seasonal filter	X11	SEASONALMA=
Specifies the sigma limits	X11	SIGMALIM=
Specifies the Henderson trend filter	X11	TRENDMA=
Specifies the D11 calculation method	X11	TYPE=
Specifies the adjustment factors to remove from final seasonally adjusted series	X11	FINAL=
Specifies a method for reconciling the seasonally adjusted series to the original series	X11	FORCE=
Specifies that SEATS seasonal decomposition be output to a data set	SEATSDECOMP	OUT=

PROC X12 Statement

PROC X12 *options* ;

The PROC X12 statement provides information about the time series to be processed by PROC X12. Either the DATE= or the START= option must be specified. If both options are specified, then a syntax error results and the X12 procedure is not executed.

The original series is displayed in Table A1. If there are missing values in the original series and a regARIMA model is specified or automatically selected, then Table MV1 is displayed. Table MV1 contains the original series with missing values replaced by the predicted values from the fitted model. If outliers are identified and Table A19 is added in the TABLES statement, then the outlier adjusted series is displayed in Table A19. Table B1 is displayed when the original data are altered (for example, through an ARIMA model estimation, prior adjustment factor, or regression) or the series is extended with forecasts.

Although the X-12-ARIMA method handles missing values, there are some restrictions. In order for PROC X12 to process the series, no month or quarter can contain missing values for all years. For instance, if the third quarter contained only missing values for all years, then processing is skipped for that series. In addition, if more than half the values for a month or a quarter are missing, then a warning message is displayed in the log file, and other errors might occur later in processing. If a series contains many missing values, other methods of missing value replacement should be considered prior to seasonally adjusting the series.

You can specify the following *options* in the PROC X12 statement:

AUXDATA=SAS-data-set

specifies an auxiliary input data set that contains user-defined variables, which are specified in the INPUT statement, the USERVAR= option in the REGRESSION statement, or the USERDEFINED statement. The AUXDATA= data set can also contain the date variable, which is specified in the DATE= option in the PROC X12 statement. If the date variable is present, then the date variable is used to align the observations in the auxiliary data set to the observations in the series that is being processed. The date values must be sorted in ascending order with no gaps or duplications, and the interval

must match the interval of the series. If the date variable is not present or valid, then observations in the auxiliary data set are matched by observation number to the series that is being processed. The auxiliary data set does not support BY-group processing. The variables in the auxiliary data set are applied to all BY groups, where the dates of the BY group correspond to the dates of the auxiliary data set. [Example 37.11](#) shows the use of the AUXDATA= data set.

DATA=SAS-data-set

specifies the input SAS data set to use. If this option is omitted, the most recently created SAS data set is used.

DATE=variable

DATEVAR=variable

specifies a variable that gives the date for each observation. Unless specified in the SPAN= option, the starting and ending dates are obtained from the first and last values of the BY group for the DATE= variable, which must contain SAS date or datetime values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly in ascending order. If the INTERVAL= option or the SEASONS= option is specified, the values of the date variable must be consistent with the specified seasonality or interval. If neither the INTERVAL= option nor the SEASONS= option is specified, then the procedure tries to determine the type of data from the values of the date variable. This variable is automatically added to the OUT= data set if a data set is requested in an OUTPUT statement, and the date values for the variable are extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

INEVENT=SAS-data-set

specifies the input data set that defines any user-defined event variables. This option can be omitted if events are not specified or if only SAS predefined events are specified in an EVENT statement. For more information about the format of this data set, see the section “[INEVENT= Data Set](#)” on page 2694.

INTERVAL=interval

specifies the frequency of the input time series. If the input data consist of quarterly observations, then INTERVAL=QTR should be used. If the input data consist of monthly observations, then INTERVAL=MONTH should be used. If the INTERVAL= option is not specified and SEASONS=4, then INTERVAL=QTR is assumed; likewise, SEASONS=12 implies INTERVAL=MONTH. If both the INTERVAL= option and the SEASONS= option are specified, the values should not be conflicting. If neither the INTERVAL= option nor the SEASONS= option is specified and the START= option is specified, then the data are assumed to be monthly. If a date variable is specified using the DATE= option, it is not necessary to specify the INTERVAL= option or the SEASONS= option; however, if specified, the values of the INTERVAL= option or the SEASONS= option should not be in conflict with the values of the date variable. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more details about intervals.

MDLINFOIN=SAS-data-set

specifies an optional input data set that contains model information that can replace the information contained in the TRANSFORM, REGRESSION, ARIMA, and AUTOMDL statements. The MDLINFOIN= data set can contain BY-group and series names. It is useful for providing specific information about each series to be seasonally adjusted. See the section “[MDLINFOIN= and MDLINFOOUT= Data Sets](#)” on page 2692 for details.

MDLINFOOUT=SAS-data-set

specifies the optional output data set that contains the transformation, regression, and ARIMA information related to each seasonally adjusted series. The data set is sorted by the BY-group variables, if any, and by series names. The MDLINFOOUT= data set can be used as input for the MDLINFOIN= option. See the section “[MDLINFOIN= and MDLINFOOUT= Data Sets](#)” on page 2692 for details.

NOPRINT

suppresses any printed output.

NOTRIMMISS

suppresses the default, by which leading and trailing missing values are trimmed from each variable listed (or implied) in the VAR statement. If you specify the NOTRIMMISS option, PROC X12 treats leading and trailing missing values in the same manner as it treats embedded missing values. For information about the treatment of embedded missing values, see the section “[Missing Values](#)” on page 2675. Missing values are not supported in the regression variables that you specify in the REGRESSION, INPUT, or USERDEFINED statement; therefore, leading and trailing missing values are always trimmed from user-defined regressors even if you specify NOTRIMMISS.

OUTSTAT=SAS-data-set

specifies an optional output data set which contains the summary statistics that related to each seasonally adjusted series. The data set is sorted by the BY-group variables, if any, and by series names. See the section “[OUTSTAT= Data Set](#)” on page 2695 for details.

PERIODOGRAM

specifies that the PERIODOGRAM rather than the spectrum of the series be plotted in the G tables and plots. If PERIODOGRAM is not specified, then the spectrum is plotted in the G tables.

PLOTS<(global-plot-options)> <= plot-request <(options)>>

PLOTS<(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots that are produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Following are some examples of the PLOTS= option:

```
plots=none
plots=all
plots=residual(none)
plots(only)=(series(acf pacf) residual(hist))
```

ODS Graphics must be enabled before you request plots. For example:

```
ods graphics on;

proc x12 data=sales date=date;
  var sales;
  identify diff=(0,1) sdiff=(0,1);
run;
```

Since no specific plot is requested in this program, the default plots associated with the PROC X12 and IDENTIFY statements are produced.

For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*). If you have enabled ODS Graphics but do not specify any specific plot request, then the default plots that are associated with each of the PROC X12 statements used in the program are produced. Line printer plots are suppressed when ODS Graphics is enabled.

If NONE is specified in an option, then no plots are produced for that option. If ALL is specified without NONE in an option, then all plots are produced for that option.

Global Plot Options:

The *global-plot-options* apply to all relevant plots that are generated by the X12 procedure. The following *global-plot-option* is supported:

ONLY

suppresses the default plots. Only the plots specifically requested are produced.

Specific Plot Options:

The following list describes the specific plots and their *options*:

ALL

produces all plots that are appropriate for the particular analysis.

NONE

suppresses all plots.

ADJUSTED(< *sa-plot-options* >)

SA(< *sa-plot-options* >)

produces plots of the seasonally adjusted series that results from the decomposition specified in the X11 statement. The SPECTRUM plot is produced by default.

The following *sa-plot-options* are available:

ALL

produces all seasonally adjusted plots.

NONE

suppresses all seasonally adjusted plots.

SPECTRUM

produces the spectral plot of Table G1. Table G1 is calculated based on the modified seasonally adjusted series (Table E2). The data is first-differenced and transformed as specified in the **TRANSFORM** statement. By default, the type of spectral estimate used to calculate the spectral plot is the spectrum. If the **PERIODOGRAM** option is specified in the PROC X12 statement, then the periodogram of the series is used to calculate the spectral plot.

FORECAST(< forecast-plot-options >)

produces the regARIMA model forecast plots if the **FORECAST** statement is specified. The FORECAST plot is produced by default. The following *forecast-plot-options* are available:

ALL

produces all the forecast plots that are appropriate for the particular analysis.

FORECAST

plots the actual time series and its one-step-ahead forecast over the historical period, and plots the forecast and its confidence bands over the forecast horizon. The **OUT1STEP** option must be specified in the FORECAST statement in order for the X12 procedure to calculate the one-step-ahead forecasts.

FORECASTONLY

plots the forecast and its confidence bands over the forecast horizon only.

MODELFORECASTS

plots the one-step-ahead model forecast and its confidence bands in the historical period; plots the forecast and its confidence bands over the forecast horizon. The **OUT1STEP** option must be specified in the FORECAST statement in order for the X12 procedure to calculate the one-step-ahead forecasts.

MODELS

plots the one-step-ahead model forecast and its confidence bands in the historical period. The **OUT1STEP** option must be specified in the FORECAST statement in order for the X12 procedure to calculate the one-step-ahead forecasts.

NONE

suppresses all the forecast plots.

TRANSFORECAST

plots the transformed time series and its one-step-ahead forecast over the historical period; plots the forecast and its confidence bands over the forecast horizon. The **OUT1STEP** option must be specified in the FORECAST statement in order for the X12 procedure to calculate the one-step-ahead forecasts. The TRANSFORECAST plot is available only if the data have been transformed using the **TRANSFORM** statement.

TRANSFORECASTONLY

plots the forecast of the transformed series and its confidence bands over the forecast horizon only. The TRANSFORECASTONLY plot is available only if the data have been transformed using the [TRANSFORM](#) statement.

TRANSMODELFORECASTS

plots the one-step-ahead model forecast of the transformed series and its confidence bands in the historical period; plots the forecast and its confidence bands over the forecast horizon. The [OUT1STEP](#) option must be specified in the FORECAST statement in order for the X12 procedure to calculate the one-step-ahead forecasts. The TRANSMODELFORECASTS plot is available only if the data have been transformed using the [TRANSFORM](#) statement.

TRANSMODELS

plots the one-step-ahead model forecast of the transformed series and its confidence bands in the historical period. The [OUT1STEP](#) option must be specified in the FORECAST statement in order for the X12 procedure to calculate the one-step-ahead forecasts. The TRANSMODELS plot is available only if the data have been transformed using the [TRANSFORM](#) statement.

IRREGULAR(< ic-plot-options >)**IC(< ic-plot-options >)**

produces plots of the irregular series that results from the decomposition specified in the [X11](#) statement. The SPECTRUM plot is produced by default.

The following *ic-plot-options* are available:

ALL

produces all irregular plots.

NONE

suppresses all irregular plots.

SPECTRUM

produces the spectral plot of Table G2. Table G2 is calculated based on the modified irregular series (Table E3). The data is first-differenced and transformed as specified in the [TRANSFORM](#) statement. By default, the type of spectral estimate used to calculate the spectral plot is the spectrum. If the [PERIODOGRAM](#) option is specified in the PROC X12 statement, then the periodogram of the series is used to calculate the spectral plot.

RESIDUAL(< residual-plot-options >)

produces the regARIMA model residual series plots if the [CHECK](#) statement is specified. The ACF, PACF, HIST, SQACF, and SPECTRUM plots are produced by default. The following *residual-plot-options* are available:

ACF

produces the plot of residual autocorrelations.

ALL

produces all the residual diagnostics plots that are appropriate for the particular analysis.

HIST

produces the histogram of the residuals and also the residual outliers and residual statistics tables that describe the residual histogram.

NONE

suppresses all the residual diagnostics plots.

PACF

produces the plot of residual partial-autocorrelations if PRINT=PACF is specified in the CHECK statement.

SPECTRUM

produces the spectral plot of Table GRs. Table GRs is calculated based on the regARIMA model residual series. By default, the type of spectral estimate used to calculate the spectral plot is the spectrum. If the **PERIODOGRAM** option is specified in the PROC X12 statement, then the periodogram of the series is used to calculate the spectral plot.

SQACF

produces the plot of squared residual autocorrelations.

SERIES(< series-plot-options >)

produces plots that are associated with the identification stage of the modeling. The ACF, PACF, and SPECTRUM plots are produced by default. The following *series-plot-options* are available:

ACF

produces the plot of autocorrelations.

ALL

produces all the plots that are associated with the identification stage.

NONE

suppresses all plots that are associated with the identification stage.

PACF

produces the plot of partial-autocorrelations.

SPECTRUM

produces the spectral plot of Table G0. Table G0 is calculated based on either Table A1, A19, B1 or E1, as specified by the **SPECTRUMSERIES=** option. The original data is first-differenced and transformed as specified in the **TRANSFORM** statement. By default, the type of spectral estimate that is used to calculate the spectral plot is the spectrum. If the **PERIODOGRAM** option is specified in the PROC X12 statement, then the periodogram of the series is used to calculate the spectral plot.

SEASONS=number

specifies the number of observations in a seasonal cycle. If the SEASONS= option is not specified and INTERVAL=QTR, then SEASONS=4 is assumed. If the SEASONS= option is not specified and INTERVAL=MONTH, then SEASONS=12 is assumed. If the SEASONS= option is specified, its value should not conflict with the values of the INTERVAL= option or the values of the date variable. See the preceding descriptions for the START=, DATE=, and INTERVAL= options for more details.

SPAN=(*mmmyy* ,*mmmyy*)

SPAN=('yyQq' ,*'yyQq'*)

specifies the dates of the first and last observations to define a subset for processing. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use **SPAN**=(*mmmyy*). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set or BY group is assumed. Because the dates are input as strings and the quarterly dates begin with a numeric character, the specification for a quarterly date must be enclosed in quotation marks. A four-digit year can be specified; if a two-digit year is specified, the value specified in the **YEARCUTOFF**= SAS system option applies.

SPECTRUMSERIES=*table-name*

specifies the table name of the series that is used in the spectrum of the original series (Table G0). The table names that can be specified are A1, A19, B1, or E1. The default is B1.

START=*mmmyy*

START=*'yyQq'*

STARTDATE=*mmmyy*

STARTDATE=*'yyQq'*

specifies the date of the first observation. Unless the **SPAN**= option is used, the starting and ending dates are the dates of the first and last observations, respectively. Either this option or the **DATE**= option is required. When using this option, use either the **INTERVAL**= option or the **SEASONS**= option to specify monthly or quarterly data. If neither the **INTERVAL**= option nor the **SEASONS**= option is present, monthly data are assumed. Because the dates are input as strings and the quarterly dates begin with a numeric character, the specification for a quarterly date must be enclosed in quotation marks. A four-digit year can be specified; if a two-digit year is specified, the value specified in the **YEARCUTOFF**= SAS system option applies. When using the **START**= option with BY processing, the start date is applied to the first observation in each BY group.

ADJUST Statement

ADJUST *option* ;

The **ADJUST** statement adjusts the series for leap year and length-of-period factors prior to estimating a regARIMA model. The “Prior Adjustment Factors” table is associated with the **ADJUST** statement.

The following *option* can appear in the **ADJUST** statement:

PREDEFINED=**LOM** | **LOQ** | **LPYEAR**

specifies length-of-month adjustment, length-of-quarter adjustment, or leap year adjustment. **PREDEFINED**=**LOM** and **PREDEFINED**=**LOQ** are equivalent because the actual adjustment is determined by the interval of the time series. Also, because leap year adjustment is a limited form of length-of-period adjustment, only one type of predefined adjustment can be specified. The **PREDEFINED**= option should not be used in conjunction with **PREDEFINED**=**TD** or **PREDEFINED**=**TD1COEF** in the **REGRESSION** statement or **MODE**=**ADD** or **MODE**=**PSEUDOADD** in the **X11** statement. **PREDEFINED**=**LPYEAR** cannot be specified unless the series is log transformed.

If the series is to be transformed by using a Box-Cox or logistic transformation, the series is first adjusted according to the **ADJUST** statement, and then it is transformed.

In the case of a length-of-month adjustment for the series with observations Y_t , each observation is first divided by the number of days in that month, m_t , and then multiplied by the average length of month (30.4375), resulting in $(30.4375 \times Y_t)/m_t$. Length-of-quarter adjustments are performed in a similar manner, resulting in $(91.3125 \times Y_t)/q_t$, where q_t is the length in days of quarter t .

Forecasts of the transformed and adjusted data are transformed and adjusted back to the original scale for output.

ARIMA Statement

ARIMA *option* ;

The ARIMA statement specifies the ARIMA part of the regARIMA model. This statement defines a pure ARIMA model if no **REGRESSION** statements, **INPUT** statements, or **EVENT** statements are specified. The ARIMA part of the model can include multiplicative seasonal factors.

The following *option* can appear in the ARIMA statement:

MODEL=((p d q) (P D Q) s)

specifies the ARIMA model. The format follows standard Box-Jenkins notation (Box, Jenkins, and Reinsel 1994). The nonseasonal AR and MA orders are given by p and q , respectively, while the seasonal AR and MA orders are given by P and Q . The number of differences and seasonal differences are given by d and D , respectively. The notation (p d q) and (P D Q) can also be specified as (p , d , q) and (P , D , Q). The maximum lag of any AR or MA parameter is 36. The maximum value of a difference order, d or D , is 144. All values for p , d , q , P , D , and Q should be nonnegative integers. The seasonality parameter, s , should be a positive integer. If s is omitted, it is set equal to the value that is specified in the SEASONS= option in the PROC X12 statement.

For example, the following statements specify an ARIMA (2,1,1)(1,1,0)12 model:

```
proc x12 data=ICMETI seasons=12 start=jan1968;
    arima model=((2,1,1) (1,1,0)) ;
```

AUTOMDL Statement

AUTOMDL *options* ;

The AUTOMDL statement invokes the automatic model selection procedure of the X-12-ARIMA method. This method is based largely on the TRAMO (time series regression with ARIMA noise, missing values, and outliers) method by Gómez and Maravall (1997a, b). If the AUTOMDL statement is used without the OUTLIER statement, then only missing values regressors are included in the regARIMA model. If both the AUTOMDL and the OUTLIER statements are used, then both missing values regressors and regressors for automatically identified outliers are included in the regARIMA model. For more information about missing value regressors, see the section “[Missing Values](#)” on page 2675.

If both the AUTOMDL statement and the ARIMA statement are present, the ARIMA statement is ignored. The ARIMA statement specifies the model, but the AUTOMDL statement allows the X12 procedure to select the model. If the AUTOMDL statement is specified and a data set is specified in the MDLINFOIN= option

in the PROC X12 statement, then the AUTOMDL statement is ignored if the specified data set contains a model specification for the series. If no model for the series is specified in the MDLINFOIN= data set, the AUTOMDL or ARIMA statement is used to determine the model. Thus, it is possible to give a specific model for some series and automatically identify the model for other series by using both the MDLINFOIN= option and the AUTOMDL statement.

When the AUTOMDL statement is specified, the X12 procedure compares a model selected using a TRAMO method to a default model. The TRAMO method is implemented first, and involves two parts: identifying the orders of differencing and identifying the ARIMA model. The table “ARIMA Estimates for Unit Root Identification” provides details about the identification of the orders of differencing, and the table “Results of Unit Root Test for Identifying Orders of Differencing” shows the orders of differencing selected by TRAMO. The table “Models Estimated by Automatic ARIMA Model Selection Procedure” provides details regarding the TRAMO automatic model selection, and the table “Best Five ARIMA Models Chosen by Automatic Modeling” ranks the best five models estimated using the TRAMO method. The “Comparison of Automatically Selected Model and Default Model” table compares the model selected by the TRAMO method to a default model. At this point in the processing, if the default model is selected over the TRAMO model, then PROC X12 displays a note. No note is displayed if the TRAMO model is selected. PROC X12 then performs checks for unit roots, over-differencing, and insignificant ARMA coefficients. If the model is changed due to any of these tests, a note is displayed. The last table, “Final Automatic Model Selection,” shows the results of the automatic model selection.

The following *options* can appear in the AUTOMDL statement:

ACCEPTDEFAULT

specifies that the default model be chosen if its Ljung-Box Q is acceptable.

ARMACV=value

specifies the threshold value for the t statistics that are associated with the highest-order ARMA coefficients. As a check of model parsimony, the parameter estimates and t statistics of the highest-order ARMA coefficients are examined to determine whether the coefficient is insignificant. An ARMA coefficient is considered to be insignificant if the t value that is displayed in the table “Exact ARMA Maximum Likelihood Estimation” is below the value specified in the ARMACV= option and the absolute value of the parameter estimate is reliably close to zero. The absolute value is considered to be *reliably close to zero* if it is below 0.15 for 150 or fewer observations or is below 0.1 for more than 150 observations. If the highest-order ARMA coefficient is found to be insignificant, then the order of the ARMA model is reduced. For example, if AUTOMDL identifies a (3 1 1)(0 0 1) model and the parameter estimate of the seasonal MA lag of order 1 is -0.09 and its t value is -0.55 , then the ARIMA model is reduced to at least (3 1 1)(0 0 0). After the model is reestimated, the check for insignificant coefficients is performed again. If ARMACV=0.54 is specified in the preceding example, then the coefficient is not found to be insignificant and the model is not reduced.

If a constant is allowed in the model and if the t value associated with the constant parameter estimate is below the ARMACV= critical value, then the constant is considered to be insignificant and is removed from the model. Note that if a constant is added to or removed from the model and then the ARIMA model changes, then the t statistic for the constant parameter estimate also changes. Thus, changing the ARMACV= value does not necessarily add or remove a constant term from the model.

The value specified in the ARMACV= option should be greater than zero. The default value is 1.0.

BALANCED

specifies that the automatic modeling procedure prefer balanced models over unbalanced models. A balanced model is one in which the sum of the AR, seasonal AR, differencing, and seasonal differencing orders equals the sum of the MA and seasonal MA orders. Specifying BALANCED gives the same preference as the TRAMO program. If BALANCED is not specified, all models are given equal consideration.

DIFFORDER=(*nonseasonal-order, seasonal-order*)

specifies the fixed orders of differencing to be used in the automatic ARIMA model identification procedure. When the DIFFORDER= option is used, only the AR and MA orders are automatically identified. Acceptable values for the regular (nonseasonal) differencing orders are 0, 1, and 2; acceptable values for the seasonal differencing orders are 0 and 1. If the MAXDIFF= option is also specified, then the DIFFORDER= option is ignored. There are no default values for DIFFORDER. If neither the DIFFORDER= option nor the MAXDIFF= option is specified, then the default is MAXDIFF=(2,1).

HRINITIAL

specifies that Hannan-Rissanen estimation be done before exact maximum likelihood estimation to provide initial values. If the HRINITIAL option is specified, then models for which the Hannan-Rissanen estimation has an unacceptable coefficient are rejected.

LJUNGBOXLIMIT=*value*

specifies acceptance criteria for the confidence coefficient of the Ljung-Box Q statistic. If the Ljung-Box Q for a final model is greater than this value, the model is rejected, the outlier critical value is reduced, and outlier identification is redone with the reduced value. See the REDUCECV option for more information. The value specified in the LJUNGBOXLIMIT= option must be greater than 0 and less than 1. The default value is 0.95.

MAXDIFF=(*nonseasonal-order, seasonal-order*)

specifies the maximum orders of regular and seasonal differencing for the automatic identification of differencing orders. When MAXDIFF is specified, the differencing orders are identified first, and then the AR and MA orders are identified. Acceptable values for the regular differencing orders are 1 and 2. The only acceptable value for the seasonal differencing order is 1. If both the MAXDIFF= option and the DIFFORDER= option are specified, then the DIFFORDER= option is ignored. If neither the DIFFORDER= nor the MAXDIFF= option is specified, the default is MAXDIFF=(2,1).

MAXORDER=(*nonseasonal-order, seasonal-order*)

specifies the maximum orders of nonseasonal and seasonal ARMA polynomials for the automatic ARIMA model identification procedure. The maximum order for the nonseasonal ARMA parameters is 4, and the maximum order for the seasonal ARMA is 2.

NOINT

suppresses the fitting of a constant or intercept parameter in the model.

PRINT=(*value-list*)

specifies the tables to be displayed in the output. You can specify the following values in *value-list*:

NONE	suppresses all automatic modeling output.
ALL	includes all automatic modeling tables in the output if NONE is not specified.

ONLY	specifies that only the listed tables be output.
AUTOCHOICE	displays the tables titled “Comparison of Automatically Selected Model and Default Model” and “Final Automatic Model Selection.” The “Comparison of Automatically Selected Model and Default Model” table compares a default model to the model chosen by the TRAMO-based automatic modeling method. The “Final Automatic Model Selection” table indicates which model has been chosen automatically. These tables are output by default unless NONE or ONLY is specified in the PRINT= option.
AUTOCHOICEMDL	displays the table “Models Estimated by Automatic ARIMA Model Selection Procedure.” This table summarizes the various models that were considered by the TRAMO automatic model selection method and their measures of fit.
BEST5MODEL	displays the table “Best Five ARIMA Models Chosen by Automatic Modeling.” This table ranks the five best models that were considered by the TRAMO automatic modeling method.
UNITROOTTEST	causes the table titled “Results of Unit Root Test for Identifying Orders of Differencing” to be printed. This table displays the orders that were automatically selected by the AUTOMDL statement. Unless the nonseasonal and seasonal differences are specified using the DIFFORDER= option, the AUTOMDL statement automatically identifies the orders of differencing. These tables are output by default unless NONE or ONLY is specified in the PRINT= option.
UNITROOTTESTMDL	displays the table titled “ARIMA Estimates for Unit Root Identification.” This table summarizes the various models that were considered by the TRAMO automatic selection method while identifying the orders of differencing and the statistics associated with those models. The unit root identification method first attempts to obtain the coefficients by using the Hannan-Rissanen method. If Hannan-Rissanen estimation cannot be performed, the algorithm attempts to obtain the coefficients by using conditional likelihood estimation.

The default output tables are the tables specified by the AUTOCHOICE and UNITROOTTEST options.

REDUCECV=value

specifies the percentage by which the outlier critical value be reduced when a final model is found to have an unacceptable confidence coefficient for the Ljung-Box Q statistic. This value should be between 0 and 1. The default value is 0.14286.

BY Statement

BY variables ;

A BY statement can be used with PROC X12 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

CHECK Statement

CHECK *options* ;

The CHECK statement produces statistics for diagnostic checking of residuals from the estimated regARIMA model.

The following tables that are associated with diagnostic checking are displayed in the output: “Autocorrelation of regARIMA Model Residuals,” “Partial Autocorrelation of regARIMA Model Residuals,” “Autocorrelation of Squared regARIMA Model Residuals,” “Outliers of the Unstandardized Residuals,” “Summary Statistics for the Unstandardized Residuals,” “Normality Statistics for regARIMA Model Residuals,” and “Table G Rs: 10*LOG(SPECTRUM) of the regARIMA Model Residuals.” If ODS graphics is enabled, the following plots that are associated with diagnostic checking output are produced: the autocorrelation function (ErrorACF) plot of the residuals, the partial autocorrelation function (ErrorPACF) plot of the residuals, the autocorrelation function (SqErrorACF) plot of the squared residuals, a histogram (ResidualHistogram) of the residuals, and a spectral plot (SpectralPlot) of the residuals. See the [PLOTS=RESIDUAL](#) option in the PROC X12 statement for further information about controlling the display of plots.

The residual histogram displayed by the X12 procedure shows the distribution of the unstandardized, uncentered regARIMA model residuals; the residual histogram displayed by the U.S. Census Bureau’s X-12-ARIMA seasonal adjustment program displays standardized and mean-centered residuals.

The following *options* can appear in the CHECK statement:

MAXLAG=*value*

specifies the number of lags for the residual sample autocorrelation function (ACF) and partial autocorrelation function (PACF). The default is 36 for monthly series and 12 for quarterly series. The minimum value for MAXLAG= is 1.

For the table “Autocorrelation of Squared regARIMA Model Residuals” and the corresponding SqErrorACF plot, the maximum number of lags calculated is 12 for monthly series and 4 for quarterly series. The MAXLAG= option can only reduce the number of lags for this table and plot.

PRINT=ALL | NONE

PRINT=ACF | ACFSQUARED | NORM | PACF

PRINT=RESIDUALOUTLIER | RESIDUALSTATISTICS | SPECRESIDUAL

PRINT=*(options)*

specifies the diagnostic checking tables to be displayed. If the PRINT= option is not specified, the default is equivalent to specifying PRINT=(ACF ACFSQUARED NORM RESIDUALOUTLIER RESIDUALSTATISTICS SPECRESIDUAL). If PRINT=NONE is specified and no other PRINT= option is specified, then none of the tables that are associated with diagnostic checking are displayed. However, PRINT=NONE has no effect if other PRINT= options are specified in the CHECK statement. PRINT=ALL specifies that all tables related to diagnostic checking be displayed.

PRINT=ACF displays the table titled “Autocorrelation of regARIMA Model Residuals.”

PRINT=ACFSQUARED displays the table titled “Autocorrelation of Squared regARIMA Model Residuals.”

PRINT=NORM displays the table titled “Normality Statistics for regARIMA Model Residuals”. Measures of normality included in this table are skewness, Geary’s *a* statistic, and kurtosis.

PRINT=PACF displays the table titled “Partial Autocorrelation of regARIMA Model Residuals.”

PRINT=RESIDUALOUTLIER or PRINT=RESOUTLIER displays the table “Outliers of the Unstandardized Residuals” if the residuals contain outliers.

PRINT=RESIDUALSTATISTICS or PRINT=RESSTAT displays the table titled “Summary Statistics for the Unstandardized Residuals.”

ESTIMATE Statement

ESTIMATE *options* ;

The ESTIMATE statement estimates the regARIMA model. The regARIMA model is specified by the REGRESSION, INPUT, EVENT, and ARIMA statements or by the MDLINFOIN= data set in the PROC X12 statement. Estimation output includes point estimates and standard errors for all estimated AR, MA, and regression parameters; the maximum likelihood estimate of the variance σ^2 ; t statistics for individual regression parameters; χ^2 statistics for assessing the joint significance of the parameters associated with certain regression effects (if included in the model); and likelihood-based model selection statistics (if the exact likelihood function is used). The regression effects for which χ^2 statistics are produced are fixed seasonal effects.

Tables displayed in the output associated with estimation are “Exact ARMA Likelihood Estimation Iteration Tolerances,” “Average Absolute Percentage Error in within-Sample Forecasts,” “ARMA Iteration History,” “AR/MA Roots,” “Exact ARMA Likelihood Estimation Iteration Summary,” “Regression Model Parameter Estimates,” “Chi-Squared Tests for Groups of Regressors,” “Exact ARMA Maximum Likelihood Estimation,” and “Estimation Summary.”

The following *options* can appear in the ESTIMATE statement:

ITPRINT

specifies that the “Iteration History” table be displayed. This table includes detailed output for estimation iterations, including log-likelihood values, parameters, counts of function evaluations, and iterations. It is useful to examine the “Iteration History” table when errors occur within estimation iterations. By default, only successful iterations are displayed, unless the PRINTERR option is specified. An unsuccessful iteration is an iteration that is restarted due to a problem such as a root inside the unit circle. Successful iterations have a status of 0. If restarted iterations are displayed, a note at the end of the table gives definitions for status codes that indicate a restarted iteration. For restarted iterations, the number of function evaluations and the number of iterations is –1, which is displayed as missing. If regression parameters are included in the model, then both IGLS and ARMA iterations are included in the table. The number of function evaluations is a cumulative total.

MAXITER=*value*

specifies the maximum number of iterations used in estimating the AR and MA parameters. For models with regression variables, this limit applies to the total number of ARMA iterations over all iterations of the iterative generalized least squares (IGLS) algorithm. For models without regression variables, this is the maximum number of iterations allowed for the set of ARMA iterations. The default is MAXITER=200.

PRINTERR

causes restarted iterations to be included in the “Iteration History” table if ITPRINT is specified; creates the “Restarted Iterations” table if ITPRINT is not specified. Whether or not PRINTERR is specified, a WARNING message is printed to the log file if any iteration is restarted during estimation.

TOL=value

specifies the convergence tolerance for the nonlinear estimation. Absolute changes in the log-likelihood are compared to the TOL= value to check convergence of the estimation iterations. For models with regression variables, the TOL= value is used to check convergence of the IGLS iterations (where the regression parameters are reestimated for each new set of AR and MA parameters). For models without regression variables, there are no IGLS iterations, and the TOL= value is then used to check convergence of the nonlinear iterations that are used to estimate the AR and MA parameters. The default value is TOL=0.00001. The minimum tolerance value is a positive value based on the machine precision and the length of the series. If a tolerance less than the minimum supported value is specified, an error message is displayed and the series is not processed.

EVENT Statement

EVENT *variables* < / *options* > ;

The EVENT statement specifies events to be included in the regression portion of the regARIMA model. Multiple EVENT statements can be specified. Dummy variable values for EVENT variables are generated by the X12 procedure, however, the EVENT variables are input as user-defined regression effects to the X-12-ARIMA method. Thus, the EVENT variables are treated in the same manner as it treats variables specified in the **USERVAR=** option in the **REGRESSION** statement. If a **MDLINFOIN=** data set is not specified in the PROC X12 statement, then all variables specified in the EVENT statements are applied to all BY groups and all time series that are processed. If a MDLINFOIN= data set is specified, then the EVENT statements apply only if no regression information for the BY group and series is available in the MDLINFOIN= data set. The events specified in the EVENT statements either must be SAS predefined events or must be defined in the data set specified in the **INEVENT=** option in the PROC X12 statement. For a summary of SAS predefined events, see the section “[SAS Predefined Events](#)” on page 2675.

The EVENT statement can also be used to include outlier, level shift, and temporary change regressors that are available as predefined U.S. Census Bureau variables in the X-12-ARIMA program. For example, the following statements specify an additive outlier in January 1970 and a level shift that begins in July 1971:

```
proc x12 data=ICMETI seasons=12 start=jan1968;
  event AO01JAN1970D CBLS01JUL1971D;
```

The following statements specify an additive outlier in the second quarter 1970 and a temporary change that begins in the fourth quarter 1971:

```
proc x12 data=ICMETI seasons=4 start='1970q1';
  event AO01APR1970D TC01OCT1971D;
```

The following *options* can appear in the EVENT statement:

B=(value <F> ...)

specifies initial or fixed values for the EVENT parameters in the order in which they appear in *variables*. Each B= list applies to the variable list that immediately precedes the slash.

For example, the following statements set an initial value of 1 for the event, x:

```
event y ;
event x / b=1 2 ;
```

In this example, the B= option applies only to the second EVENT statement. The value 2 is discarded because there is only one variable in the variable list.

To assign an initial value of 1 to the y regressor and 2 to the x regressor, use the following statements:

```
event y / b=1;
event x / b=2 ;
```

An **F** immediately following the numerical value indicates that this is not an initial value, but a fixed value. See [Example 37.8](#) for an example that uses fixed parameters. In PROC X12, individual parameters can be fixed while other parameters in the same model are estimated.

USERTYPE=(values)

enables a user-defined variable to be processed in the same manner as a U.S. Census predefined variable. You can specify the following *values*: AO, CONSTANT, EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, LS, RP, SCEASTER, SEASONAL, TC, TD, TDSTOCK, THANKS, or USER. For example, the U.S. Census Bureau EASTER(*w*) regression effects are included in the “RegARIMA Holiday Component” table (A7). Specify USERTYPE=EASTER to include an event variable that is processed exactly as the U.S. Census predefined EASTER(*w*) variable, including inclusion in the A7 table. The **NOAPPLY=** option in the **REGRESSION** statement also changes the processing of variables based on the USERTYPE= value. [Table 37.4](#) shows the regression types that are associated with each regression effects table.

Each USERTYPE= list applies to the variable list that immediately precedes the slash. The same rules for assigning B= values to regression variables apply for USERTYPE= options. For example, the following statements specify that the event in the variable MyEaster be processed exactly as the U.S. Census predefined LOM variable:

```
event MyLOM;
event MyEaster / usertype=LOM EASTER;
```

In this example, the USERTYPE= option applies only to the MyEaster variable in the second EVENT statement. The USERTYPE value **EASTER** is discarded because there is only one variable in the variable list.

To assign the USERTYPE value **LOM** to the MyLOM variable and **EASTER** to the MyEaster variable, use the following statements:

```
event MyLOM / usertype=LOM;
event MyEaster / usertype=EASTER;
```

The following `USERTYPE=` options specify that the regression effect be removed from the seasonally adjusted series: `EASTER`, `HOLIDAY`, `LABOR`, `LOM`, `LOMSTOCK`, `LOQ`, `LPYEAR`, `SCEASTER`, `SEASONAL`, `TD`, `TDSTOCK`, `THANKS`, and `USER`. When a regression effect is removed from the seasonally adjusted series, the level (mean) of the seasonally adjusted series can be altered. It is often desirable to use a zero-mean (mean-adjusted) regressor for effects that are to be removed from the seasonally adjusted series. See [Example 37.6](#) for an example showing the effects of specifying a zero-mean regressor.

FORECAST Statement

FORECAST *options* ;

The **FORECAST** statement uses the estimated model to forecast the time series. The output contains point forecasts and forecast statistics for the transformed and original series. Whenever forecasts or backcasts (or both) are generated and seasonal adjustment is performed, the forecasts and backcasts are appended to the original series, and the seasonal adjustment procedures are applied to the forecast or backcast (or both) extended series. If the **FORECAST** statement is not specified, but a **regARIMA** model is specified using either the **ARIMA** or **AUTOMDL** statement, then the series is extended one year ahead by default.

Tables that contain forecasts, standard errors, and confidence limits are displayed in association with the **FORECAST** statement. If the data is transformed, then two tables are displayed: one table for the original data, and one table for the transformed data. Data from these tables can be output to a SAS data set using **ODS**. The auxiliary variable `_SCALE_` is included in forecast data sets that are output using **ODS**. The value of `_SCALE_` is “Original” or “Transformed” to indicate the scale of the data. The auxiliary variable can also be used in **ODS SELECT** and **ODS OUTPUT** statements. For example, you can specify the following statements to output the forecasts on the original scale to a data set `forecasts` and the forecasts on the transformed scale to a data set `Tforecasts`:

```
ods output Original.ForecastCL=forecasts;
ods output Transformed.ForecastCL=Tforecasts;
```

The following *options* can appear in the **FORECAST** statement:

LEAD=*value*

specifies the number of periods ahead to forecast for **regARIMA** extension of the series. The default is the number of periods in a year (4 or 12), and the maximum is 120. Setting **LEAD=0** specifies that the series not be extended by forecasts for seasonal adjustment. The **LEAD=** value also controls the number of forecasts that are displayed in Table D10.A. However, if the series is not extended by forecasts (**LEAD=0**), then the default year of forecasts is displayed in Table D10.A. Forecast values in Table D10.A are calculated using the method shown on page 148 of Ladiray and Quenneville (2001) based on values that are displayed in Table D10. The **regARIMA** forecasts affect the D10.A forecasts only indirectly through the impact of the **regARIMA** forecasts on the seasonal factors that are shown in Table D10. If the **SEATSDECOMP** statement is specified, then *value* is increased to the minimum required for **SEATS** decomposition. See the section “[SEATS Decomposition](#)” on page 2684 for details.

NBACKCAST=*value***BACKCAST=***value***NBACK=***value*

specifies the number of periods to backcast for regARIMA extension of the series. The default is NBACKCAST=0, which specifies that the series not be extended with backcasts. The maximum number of backcasts is 120. When the OUTBACKCAST option is specified, the NBACKCAST= value also controls the number of backcasts that are output to the OUT= data set specified in the OUTPUT statement. If the [SEATSDECOMP](#) statement is specified, then *value* is increased to the minimum required for SEATS decomposition. See the section “[SEATS Decomposition](#)” on page 2684 for details.

OUT1STEP

specifies that the one-step-ahead forecasts be computed and displayed in addition to the multistep forecasts. The default is to compute and display only the multistep forecasts beginning at the forecast horizon.

OUTBACKCAST**OUTBKCAST**

determines whether backcasts are included in certain tables sent to the output data set. If OUTBACKCAST is specified, then backcast values are included in the output data set for tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, and D18. The default is not to include backcasts.

OUTFCST**OUTFORECAST**

determines whether forecasts are included in certain tables sent to the output data set. If OUTFORECAST is specified, then forecast values are included in the output data set for tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, and D18. The default is not to include forecasts. The OUTFORECAST option can be specified in either the [X11](#) statement or the FORECAST statement with identical results.

ID Statement

ID *variables* ;

If you are creating an output data set, use the ID statement to copy values of the ID variables, in addition to the table values, into the output data set. Or, if the VAR statement is omitted, all numeric variables that are not identified as BY variables, ID variables, the DATE= variable, or user-defined regressors are processed as time series. The ID statement has no effect when a VAR statement is specified and an output data set is not created. If the DATE= variable is specified in the PROC X12 statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable `_DATE_` is added.

The date variable (or `_DATE_`) values outside the range of the actual data (from forecasting) are extrapolated, while all other ID variables are missing in the forecast horizon.

IDENTIFY Statement

IDENTIFY *options* ;

The IDENTIFY statement produces plots of the sample autocorrelation function (ACF) and partial autocorrelation function (PACF) for identifying the ARIMA part of a regARIMA model. The sample ACF and PACF are produced for all combinations of the nonseasonal and seasonal differences of the data specified by the DIFF= and SDIFF= options.

The original series is first transformed as specified in the TRANSFORM statement.

If the model includes a regression component (specified using the REGRESSION, INPUT, and EVENT statements or the MDLINFOIN= data set in the PROC X12 statement), both the transformed series and the regressors are differenced at the highest order that is specified in the DIFF= and SDIFF= option. The parameter estimates are calculated using the differenced data. Then the undifferenced regression effects (with the exception of a constant term) are removed from the undifferenced data to produce undifferenced regression residuals. The ACFs and PACFs are calculated for the specified differences of the undifferenced regression residuals.

If the model does not include a regression component, then the ACFs and PACFs are calculated for the specified differences of the transformed data.

Tables displayed in association with identification are “Autocorrelation of Model Residuals” and “Partial Autocorrelation of Model Residuals.” If the model includes a regression component (specified using the REGRESSION, INPUT, and EVENT statements or the MDLINFOIN= data set in the PROC X12 statement), then the “Regression Model Parameter Estimates” table is also displayed if the PRINTREG option is specified.

The following *options* can appear in the IDENTIFY statement:

DIFF=(order, order, order)

specifies orders of nonseasonal differencing to use in model identification. The value 0 specifies no differencing, the value 1 specifies one nonseasonal difference $(1 - B)$, the value 2 specifies two nonseasonal differences $(1 - B)^2$, and so forth. The ACFs and PACFs are produced for all orders of nonseasonal differencing specified, in combination with all orders of seasonal differencing that are specified in the SDIFF= option. The default is DIFF=(0). You can specify up to three values for nonseasonal differences.

MAXLAG=value

specifies the number of lags for the sample autocorrelation function (ACF) and partial autocorrelation function (PACF) of the regression residuals for model identification. The default is 36 for monthly series and 12 for quarterly series. MAXLAG applies to both tables and plots. The minimum value for MAXLAG= is 1.

PRINTREG

causes the “Regression Model Parameter Estimates” table to be printed if the REGRESSION statement is present. By default, this table is not printed.

SDIFF=(order, order, order)

specifies orders of seasonal differencing to use in model identification. The value 0 specifies no seasonal differencing, the value 1 specifies one seasonal difference $(1 - B^s)$, the value 2 specifies two seasonal differences $(1 - B^s)^2$, and so forth. The value for s corresponds to the period specified in the SEASONS= option in the PROC X12 statement. The value of the SEASONS= option is supplied explicitly or is implicitly supplied through the INTERVAL= option or the values of the DATE= variable. The ACFs and PACFs are produced for all orders of seasonal differencing specified, in combination with all orders of nonseasonal differencing specified in the DIFF= option. The default is SDIFF=(0). You can specify up to three values for seasonal differences.

For example, the following statement produces ACFs and PACFs for two levels of differencing: $(1 - B)$ and $(1 - B)(1 - B^s)$:

```
identify diff=(1) sdiff=(0, 1);
```

INPUT Statement

INPUT *variables* < / *options* > ;

The INPUT statement specifies variables in the DATA= or AUXDATA= data set (which are specified in the PROC X12 statement) that are to be used as regressors in the regression portion of the regARIMA model. The variables in the data set should contain the values for each observation that define the regressor. Past values of regression variables should also be included in the DATA= or AUXDATA= data set if the time series listed in the VAR statement is to be extended with regARIMA backcasts. Similarly, future values of regression variables should also be included in the DATA= or AUXDATA= data set if the time series listed in the VAR statement is to be extended with regARIMA forecasts.

You can specify multiple INPUT statements. If you do not specify a MDLINFOIN= data set in the PROC X12 statement, then all variables listed in the INPUT statements are applied to all BY groups and all time series that are processed. If you specify a MDLINFOIN= data set, then the INPUT statements apply only if no regression information for the BY group and series is available in the MDLINFOIN= data set.

The INPUT statement provides the same functionality as the USERVAR= option in the REGRESSION statement. For more information about specifying user-defined regression variables, see the section “User-Defined Regression Variables” on page 2680, Example 37.6, and Example 37.11.

The following *options* can appear in the INPUT statement:

B=(value < F > ...)

specifies initial or fixed values for the regression parameters in the order in which they appear in *variables*. Each B= list applies to the variable list that immediately precedes the slash.

For example, the following statements set an initial value of 1 for the user-defined regressor, x:

```
input y ;
input x / b=1 2 ;
```

In this example, the B= option applies only to the second INPUT statement. The value 2 is discarded because there is only one variable in the variable list.

To assign an initial value of 1 to the y regressor and 2 to the x regressor, use the following statements:

```
input y / b=1;
input x / b=2 ;
```

An **F** immediately following the numerical value indicates that this is not an initial value, but a fixed value. See Example 37.8 for an example that uses fixed parameters. In PROC X12, individual parameters can be fixed while other parameters in the same model are estimated.

USERTYPE=(values)

enables a user-defined variable to be processed in the same manner as a U.S. Census predefined variable. You can specify the following *values*: AO, CONSTANT, EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, LS, RP, SCEASTER, SEASONAL, TC, TD, TDSTOCK, THANKS, or USER. For example, the U.S. Census Bureau EASTER(*w*) regression effects are included in the “RegARIMA Holiday Component” table (A7). Specify USERTYPE=EASTER to include a user-defined variable that is processed exactly as the U.S. Census predefined EASTER(*w*) variable, including inclusion in the A7 table. The NOAPPLY= option in the REGRESSION statement also changes the processing of variables based on the USERTYPE= value. Table 37.4 shows the regression types that are associated with each regression effects table.

Each USERTYPE= list applies to the variable list that immediately precedes the slash. The same rules for assigning B= values to regression variables apply for USERTYPE= options. For example, the following statements specify that the user-defined regressor in the variable MyEaster be processed exactly as the U.S. Census predefined LOM variable:

```
input MyLOM;
input MyEaster / usertype=LOM EASTER;
```

In this example, the USERTYPE= option applies only to the MyEaster variable in the second INPUT statement. The USERTYPE value EASTER is discarded because there is only one variable in the variable list.

To assign the USERTYPE value LOM to the MyLOM variable and EASTER to the MyEaster variable, use the following statements:

```
input MyLOM / usertype=LOM;
input MyEaster / usertype=EASTER;
```

The following USERTYPE= options specify that the regression effect be removed from the seasonally adjusted series: EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, SCEASTER, SEASONAL, TD, TDSTOCK, THANKS, and USER. When a regression effect is removed from the seasonally adjusted series, the level (mean) of the seasonally adjusted series can be altered. It is often desirable to use a zero-mean (mean-adjusted) regressor for effects that are to be removed from the seasonally adjusted series. See Example 37.6 for an example that specifies a zero-mean regressor.

OUTLIER Statement

OUTLIER options ;

The OUTLIER statement specifies that the X12 procedure perform automatic detection of additive point outliers, temporary change outliers, level shifts, or any combination of the three when using the specified model. After outliers are identified, the appropriate regression variables are incorporated into the model as “Automatically Identified Outliers,” and the model is reestimated. This procedure is repeated until no additional outliers are found.

The OUTLIER statement also identifies potential outliers and lists them in the table “Potential Outliers” in the displayed output. Potential outliers are identified by decreasing the critical value by 0.5.

In the output, the default initial critical values used for outlier detection in a given analysis are displayed in the table “Critical Values to Use in Outlier Detection.” Outliers that are detected and incorporated into the model are displayed in the output in the table “Regression Model Parameter Estimates,” where the regression variable is listed as “Automatically Identified.”

The following *options* can appear in the OUTLIER statement:

AOCV=value

specifies a critical value to use for additive point outliers. If AOCV is specified, this value overrides any default critical value for AO outliers. See the [CV= option](#) for more details.

CV=value

specifies an initial critical value to use for detection of all types of outliers. The absolute value of the t statistic associated with an outlier parameter estimate is compared with the critical value to determine the significance of the outlier. If the CV= option is not specified, then the default initial critical value is computed using a formula presented by Ljung (1993), which is based on the number of observations or model span used in the analysis. [Table 37.2](#) gives default critical values for various series lengths. Increasing the critical value decreases the sensitivity of the outlier detection routine and can reduce the number of observations treated as outliers. The automatic model identification process might lower the critical value by a certain percentage if the automatic model identification process fails to identify an acceptable model.

Table 37.2 Default Critical Values for Outlier Identification

Number of Observations	Outlier Critical Value
1	1.96
2	2.24
3	2.44
4	2.62
5	2.74
6	2.84
7	2.92
8	2.99
9	3.04
10	3.09
11	3.13
12	3.16
24	3.42
36	3.55
48	3.63
72	3.73
96	3.80
120	3.85
144	3.89
168	3.92
192	3.95
216	3.97
240	3.99
264	4.01

Table 37.2 *continued*

Number of Observations	Outlier Critical Value
288	4.03
312	4.04
336	4.05
360	4.07

LSCV=*value*

specifies a critical value to use for level shift outliers. If LSCV is specified, this value overrides any default critical value for LS outliers. See the [CV= option](#) for more details.

SPAN=(*mmmyy* ,*mmmyy*)**SPAN=**('yyQq' ,*yyQq*)

specifies the dates of the first and last observations to define a subset for searching for outliers. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use SPAN=(*mmmyy*) or SPAN=(*yyQq*). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set or BY group is assumed. Because the dates are input as strings and the quarterly dates begin with a numeric character, the specification for a quarterly date must be enclosed in quotation marks. A four-digit year can be specified. If a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies.

TCCV=*value*

specifies a critical value to use for temporary change outliers. If TCCV is specified, this value overrides any default critical value for TC outliers. See the [CV= option](#) for more details.

TYPE=NONE**TYPE=**(*outlier types*)

lists the outlier types to be detected by the automatic outlier identification method. TYPE=NONE turns off outlier detection. The valid outlier types are AO, LS, and TC. The default is TYPE=(AO LS).

OUTPUT Statement

OUTPUT OUT= *SAS-data-set* < **YEARSEAS** > *tablename1 tablename2 ...* ;

The OUTPUT statement creates an output data set that contains specified tables. The data set is named by the OUT= option.

OUT=*SAS-data-set*

names the data set to contain the specified tables. If the OUT= option is omitted, the data set is named using the default DATA n convention.

YEARSEAS**YRSEAS**

specifies that two additional variables be added to the OUT= data set. The two additional variables are the variables `_YEAR_` and `_SEASON_`. The variable `_YEAR_` contains the year of the date identifying the observation. The variable `_SEASON_` contains the month for monthly data, or quarter for quarterly

data, of the date that identifies the observation. For monthly data, the value of `_SEASON_` is between 1 and 12. For quarterly data, the value of `_SEASON_` is between 1 and 4. The `_YEAR_` and `_SEASON_` variables are useful when creating seasonal plots.

tablename1 tablename2 ...

For each table to be included in the output data set, you must specify the X12 *tablename* keyword. The keyword corresponds to the title label used by the U.S. Census Bureau X-12-ARIMA software. Currently available tables are A1, A2, A6, A7, A8, A8AO, A8LS, A8TC, A9, A10, A19, B1, C17, C20, D1, D7, D8, D9, D10, D10B, D10D, D11, D11A, D11F, D11R, D12, D13, D16, D16B, D18, E1, E2, E3, E5, E6, E6A, E6R, E7, E8, and MV1. If no table is specified in the OUTPUT statement, Table A1 is output to the OUT= data set by default.

The *tablename* keywords that can be used in the OUTPUT statement are listed in the section “[Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords](#)” on page 2684. The following is an example of a VAR statement and an OUTPUT statement:

```
var sales costs;
output out=out_x12 b1 d11;
```

The default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name. The variable `sales_B1` contains the Table B1 values for the variable `sales`, the variable `costs_B1` contains the Table B1 values for the variable `costs`, the variable `sales_D11` contains the Table D11 values for the variable `sales`, and the variable `costs_D11` contains the Table D11 values for the variable `costs`. If necessary, the variable name is shortened so that the table name can be added. If the `DATE=` variable is specified in the PROC X12 statement, then that variable is included in the output data set; otherwise, a variable named `_DATE_` is written to the OUT= data set as the date identifier.

PICKMDL Statement

PICKMDL *options* ;

The PICKMDL statement uses models specified in the `MDLINFOIN=` data set to choose a regARIMA model. The `MDLINFOIN=` data set can include a variable that identifies different models. All observations with the same value for the model identification variable are considered to be relevant to the same model. A single model can be considered to consist of all the observations for a BY group that consists of the BY variables (if any), the `_NAME_` variable if it exists, and the `MDLVAR=` variable. The default variable name that identifies the model is `_MODEL_`. [Example 37.9](#) demonstrates the use of the PICKMDL statement.

For more information about using the U.S. Census Bureau’s PICKMDL method for model selection, see the section “[PICKMDL Model Selection](#)” on page 2683 .

You can specify the following *options* in the PICKMDL statement:

MDLVAR=*variable*

specifies the variable in the `MDLINFOIN=` data set that identifies the models.

METHOD= BEST | FIRST

specifies the method for choosing the regARIMA model. If you specify METHOD=BEST, the best model is chosen. If you specify METHOD=FIRST, the first acceptable model is chosen.

REGRESSION Statement

REGRESSION *regression-group-options* ;

REGRESSION PREDEFINED= *variables* < / **B=(value < F > ...)** > ;

REGRESSION USERVAR= *variables* < / **B=(value < F > ...)** **USERTYPE=(values)** > ;

The REGRESSION statement includes regression variables in a regARIMA model or specifies regression variables whose effects are to be removed by the IDENTIFY statement to aid in ARIMA model identification. Include the **PREDEFINED=** option to select predefined regression variables. Include the **USERVAR=** option to specify user-defined regression variables.

Table 37.3 shows the X-12-ARIMA tables that contain regression factors. Tables A8AO, A8LS, and A8TC are available only when more than one outlier type is present in the model.

Table 37.3 X-12-ARIMA Regression Effects Tables

Table	Regression Effects
A6	Trading day effects
A7	Holiday effects including Easter, Labor Day, and Thanksgiving-Christmas
A8	Combined effects of outliers, level shifts, ramps, and temporary changes
A8AO	Point outlier effects; available only when more than one outlier type is present in the model
A8LS	Level shift and ramp effects; available only when more than one outlier type is present in the model
A8TC	Temporary change effects; available only when more than one outlier type is present in the model
A9	User-defined regression effects
A10	User-defined seasonal component effects

Missing values in the span of an input series automatically create missing value regressors. See the **NOTRIMMISS** option in the PROC X12 statement and the section “[Missing Values](#)” on page 2675 for further details about missing values.

Combining your model with additional predefined regression variables can result in a singularity problem. To successfully perform the regression if a singularity occurs, you might need to alter either the model or the choices of the regressors.

To seasonally adjust a series that uses a regARIMA model, the factors derived from regression are used as multiplicative or additive factors, depending on the mode of seasonal decomposition. Therefore, regressors that are appropriate to the mode of the seasonal decomposition should be defined, so that meaningful combined adjustment factors can be derived and adjustment diagnostics can be generated. For example, if a regARIMA model is applied to a log-transformed series, then the regression factors are expressed as ratios, which match the form of the seasonal factors that are generated by the multiplicative or log-additive adjustment modes. Conversely, if a regARIMA model is fit to the original series, then the regression factors are measured on the same scale as the original series, which matches the scale of the seasonal factors that are generated by the additive adjustment mode. Note that the default transformation (no transformation) and the

default seasonal adjustment mode (multiplicative) are in conflict. Thus, when you specify the X11 statement and any of the REGRESSION, INPUT, or EVENT statements, you must also either use the **TRANSFORM** statement to specify a transformation or use the **MODE=** option in the X11 statement to specify a different mode to seasonally adjust the data that uses the regARIMA model.

According to Ladiray and Quenneville (2001), “X-12-ARIMA is based on the same principle [as the X-11 method] but proposes, in addition, a complete module, called Reg-ARIMA, that allows for the initial series to be corrected for all sorts of undesirable effects. These effects are estimated using regression models with ARIMA errors (Findley et al. [23]).” The REGRESSION, INPUT, and EVENT statements specify these regression effects. Predefined effects that can be corrected in this manner are listed in the **PREDEFINED=** option. You can create your own definitions to remove other effects by using the **USERVAR=** option and the **EVENT** statement.

You can specify either the **PREDEFINED=** option or the **USERVAR=** option, but not both, in a single REGRESSION statement. You can use multiple REGRESSION statements.

You can specify the following *regression-group-options* in the REGRESSION statement. The *regression-group-options* apply to all regression variables in a regression group. For predefined regression variables, the regression group is predefined. For user-defined regression variables, you can specify the regression group in the **USERTYPE=** option.

AICTEST=(EASTER | TD | TD1COEF | TD1NOLPYEAR | TDNOLPYEAR | TDSTOCK | USER)

specifies that an AIC-based selection be used to determine whether a given set of regression variables are to be included with the specified regARIMA model. For example, if you specify a trading day model selection, then AIC values (with a correction for the length of the series, henceforth referred to as AICC) are derived for models with and without the specified trading day variable. By default, the model with a smaller AICC is used to generate forecasts, identify outliers, and so on. If you specify more than one type of regressor, the AIC tests are performed sequentially in this order: (a) trading day regressors, (b) Easter regressors, (c) user-defined regressors. If there are several variables of the same type (for example, several trading day regressors), then AIC-based selection is applied to them as a group. That is, either all variables of this type or none are included in the final model. If you do not specify this option, no automatic AIC-based selection is performed.

If you use the **AUTOMDL** statement to identify the model and you also specify this option, then this option affects the model selection process in the following manner:

- AIC-based selection tests are performed on the default model.
- A new series is created by removing the regression effects that are identified in the default model from the original series. The automatic model identification process attempts to identify a model that is based on the new series.
- After a model is automatically identified, AIC-based selection tests that use the automatically identified model are performed on the original series.
- The default model, including regressors that are identified by using AIC-based selection, is compared to the automatically identified model, which also might include regressors that are identified by using AIC-based selections. The regressors for the two models can differ.

For more information about the X-12-ARIMA automatic modeling method, see section 7.2 of the *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2009c).

NOAPPLY=(AO | HOLIDAY | LS | TC | TD | USER | USERSEASONAL)

specifies a list of the types of regression effects whose model-estimated values are not to be removed from the original series before performing the seasonal adjustment calculations that are specified by the X11 statement. The NOAPPLY= option applies to the regression component values displayed in the X11 seasonal adjustment method regARIMA component tables as shown in [Table 37.4](#).

Table 37.4 NOAPPLY= Types and Regression Effects

NOAPPLY= Option	Regression Effects Table	Description
AO	A8AO	Point outliers
HOLIDAY	A7	Easter, Labor Day, and Thanksgiving-to-Christmas holiday effects
LS	A8LS	Level changes and ramps
TC	A8TC	Temporary changes
TD	A6	Trading day effects
USER	A9	User-defined regression effects
USERSEASONAL	A10	User-defined seasonal regression effects

You can specify the following regression variable specification options in the REGRESSION statement.

PREDEFINED=CONSTANT | EASTER(value) | LABOR(value) | LOM | LOMSTOCK | LOQ | LPYEAR

PREDEFINED=SCEASTER(value) | SEASONAL | SINCOS(value ...) | TD | TD1COEF

PREDEFINED=TD1NOLPYEAR | TDNOLPYEAR | TDSTOCK(value) | THANK(value)

lists the predefined regression variables to be included in the model. Data values for these variables are calculated by the program, mostly as functions of the calendar. [Table 37.5](#) gives definitions for the available predefined variables. The values LOM and LOQ are equivalent: the actual regression is controlled by the SEASONS= option in the PROC X12 statement. You can specify multiple predefined regression variables. The syntax for using both a length-of-month and a seasonal regression can be in one of the following forms:

```
regression predefined=lom seasonal;

regression predefined=(lom seasonal);

regression predefined=lom predefined=seasonal;
```

The following restrictions apply when you use more than one predefined regression variable:

- You can specify only one of TD, TDNOLPYEAR, TD1COEF, or TD1NOLPYEAR.
- You cannot specify LPYEAR with TD, TD1COEF, LOM, LOMSTOCK, or LOQ.
- You cannot specify LOM or LOQ with TD or TD1COEF.
- If you specify the SINCOS predefined regression variable, then you must also specify the INTERVAL= option or the SEASONS= option in the PROC X12 statement because there are restrictions on this regression variable that are based on the frequency of the data.

The predefined regression variables, EASTER, LABOR, SCEASTER, SINCOS, TDSTOCK, and THANK, require extra parameters. Only one TDSTOCK regressor can be implemented in the regression

model. If you specify multiple TDSTOCK variables, PROC X12 uses the last TDSTOCK variable specified. For EASTER, LABOR, SCEASTER, SINCOS, and THANK, you can specify the variables with different parameters to implement multiple regressors in the model. For example, the following statement specifies two EASTER regressors with widths 7 and 14:

```
regression predefined=easter(7) easter(14);
```

For SINCOS, specifying a parameter includes both the sine and the cosine regressor except for the highest order allowed (2 for quarterly data and 6 for monthly data.) For quarterly data, the following statement is the most common use of the SINCOS variable; it includes three regressors in the model:

```
regression predefined=sincos(1,2);
```

For monthly data, the following statement is the most common use of the SINCOS variable; it includes 11 regressors in the model:

```
regression predefined=sincos(1,2,3,4,5,6);
```

Table 37.5 Predefined Regression Variables in X-12-ARIMA

Regression Effect	Variable Definitions
Trend constant CONSTANT	$(1 - B)^{-d}(1 - B^s)^{-D}I(t \geq 1)$ where $I(t \geq 1) = \begin{cases} 1 & \text{for } t \geq 1 \\ 0 & \text{for } t < 1 \end{cases}$
Easter holiday EASTER(<i>w</i>)	$E(w, t) = \frac{1}{w} \times n_t$ and n_t is the number of the w days before Easter that fall in month (or quarter) t . (Note: This variable is 0 except in February, March, and April (or first and second quarter). It is nonzero in February only for $w > 22$.) Restriction: $1 \leq w \leq 25$.
Labor Day LABOR(<i>w</i>)	$L(w, t) = \frac{1}{w} \times [\text{no. of the } w \text{ days before Labor Day that fall in month } t]$ (Note: This variable is 0 except in August and September.) Restriction: $1 \leq w \leq 25$.

Table 37.5 continued

Regression Effect	Variable Definitions
Length-of-month (monthly flow) LOM	$m_t - \bar{m}$ where m_t = length of month t (in days) and $\bar{m} = 30.4375$ (average length of month)
Stock length-of-month LOMSTOCK	$SLOM_t = \begin{cases} m_t - \bar{m} - \mu(l) & \text{for } t = 1 \\ SLOM_{t-1} + m_t - \bar{m} & \text{otherwise} \end{cases}$ <p>where \bar{m} and m_t are defined in LOM and</p> $\mu(l) = \begin{cases} 0.375 & \text{when first February in series is a leap year} \\ 0.125 & \text{when second February in series is a leap year} \\ -0.125 & \text{when third February in series is a leap year} \\ -0.375 & \text{when fourth February in series is a leap year} \end{cases}$
Length-of-quarter (quarterly flow) LOQ	$q_t - \bar{q}$ where q_t = length of quarter t (in days) and $\bar{q} = 91.3125$ (average length of quarter)
Leap year (monthly and quarterly flow) LPYEAR	$LY_t = \begin{cases} 0.75 & \text{in leap year February (first quarter)} \\ -0.25 & \text{in other Februaries (first quarter)} \\ 0 & \text{otherwise} \end{cases}$
Statistics Canada Easter (monthly or quarterly flow) SCEASTER(w)	<p>If Easter falls before April w, let n_E be the number of the w days on or before Easter that fall in March. Then:</p> $E(w, t) = \begin{cases} n_E/w & \text{in March} \\ -n_E/w & \text{in April} \\ 0 & \text{otherwise} \end{cases}$ <p>If Easter falls on or after April w, then $E(w, t) = 0$. (Note: This variable is 0 except in March and April (or first and second quarter).) Restriction: $1 \leq w \leq 24$.</p>
Fixed seasonal SEASONAL	$M_{1,t} = \begin{cases} 1 & \text{in January} \\ -1 & \text{in December} \\ 0 & \text{otherwise} \end{cases}$ $, \dots, M_{11,t} = \begin{cases} 1 & \text{in November} \\ -1 & \text{in December} \\ 0 & \text{otherwise} \end{cases}$

Table 37.5 continued

Regression Effect	Variable Definitions
Fixed seasonal SINCOS(j) SINCOS(j_1, \dots, j_n)	$\sin(w_j t), \cos(w_j t)$, where $w_j = 2\pi j/s$, $1 \leq j \leq s/2$, and s is the seasonal period (drop $\sin(w_j t) \equiv 0$ for $j = s/2$) Restrictions: $1 \leq j_i \leq s/2$, $1 \leq n \leq s/2$.
Trading day TD, TDNOLPYEAR	$T_{1,t} = (\text{number of Mondays}) - (\text{number of Sundays})$ $\dots, T_{6,t} = (\text{number of Saturdays}) - (\text{number of Sundays})$
One coefficient trading day TD1COEF, TD1NOLPYEAR	$(\text{number of weekdays}) - \frac{5}{2}(\text{number of Saturdays and Sundays})$
Stock trading day TDSTOCK(w)	$D_{1,t} = \begin{cases} 1 & \tilde{w}\text{th day of month } t \text{ is a Monday} \\ -1 & \tilde{w}\text{th day of month } t \text{ is a Sunday} \\ 0 & \text{otherwise} \end{cases}$ $\dots, D_{6,t} = \begin{cases} 1 & \tilde{w}\text{th day of month } t \text{ is a Saturday} \\ -1 & \tilde{w}\text{th day of month } t \text{ is a Sunday} \\ 0 & \text{otherwise} \end{cases}$ <p>where \tilde{w} is the smaller of w and the length of month t. For end-of-month stock series, set w to 31; that is, specify TDSTOCK(31). Restriction: $1 \leq w \leq 31$.</p>
Thanksgiving THANK(w)	$ThC(w, t) = \text{proportion of days from } w \text{ days before Thanksgiving}$ through December 24 that fall in month t (negative values of w indicate days after Thanksgiving). (Note: This variable is 0 except in November and December.) Restriction: $-8 \leq w \leq 17$.

USERVAR=(variables)

specifies variables in the DATA= or AUXDATA= data set (which are specified in the PROC X12 statement) that are to be used as regressors. The variables in the data set should contain the values for each observation that define the regressor. Regression variables should also include future values in the data set for the forecast horizon if the time series is to be extended with regARIMA forecasts. Regression variables should include past values if the time series is to be extended with regARIMA backcasts. Missing values are not permitted within the data span, including backcasts and forecasts, of the user-defined regressors. [Example 37.6](#) shows how to create an input data set that contains both the series to be seasonally adjusted and a user-defined input variable. [Example 37.11](#) shows how to create an auxiliary data set that contains a user-defined input variable. For more information about specifying user-defined regression variables see the section “[User-Defined Regression Variables](#)” on page 2680.

All regression variables in the USERVAR= option apply to all time series to be seasonally adjusted

unless the MDLINFOIN= data set specifies different regression information. You cannot specify the PREDEFINED= option and the USERVAR= option in the same REGRESSION statement; however, you can specify multiple REGRESSION statements.

You can specify the following *options* for individual regression variables. Individual regression variable options are specified in the PREDEFINED= and USERVAR= options after the slash. The B= option can be specified in both the PREDEFINED= and USERVAR= options. Because the regression group is predefined for predefined variables, you can specify the USERTYPE= option only in the USERVAR= option.

B=(value <F> ...)

specifies initial or fixed values for the regression parameters in the order in which they appear in a PREDEFINED= or USERVAR= option. Each B= list applies to the PREDEFINED= or USERVAR= variable list that immediately precedes the slash.

For example, the following statements set an initial value of 1 for the user-defined regressor, x:

```
regression predefined=LOM ;
regression uservar=x / b=1 2 ;
```

In this example, the B= option applies only to the USERVAR= option. The value 2 is discarded because there is only one variable in the USERVAR= list.

To assign an initial value of 1 to the LOM regressor and 2 to the x regressor, use the following statements:

```
regression predefined=LOM / b=1;
regression uservar=x / b=2 ;
```

An F immediately following the numerical value indicates that this is not an initial value, but a fixed value. See [Example 37.8](#) for an example that uses fixed parameters. In PROC X12, individual parameters can be fixed while other parameters in the same model are estimated.

USERTYPE=(values)

enables a variable that you define to be processed in the same manner as a U.S. Census predefined variable. You can specify the following *values*: AO, CONSTANT, EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, LS, RP, SCEASTER, SEASONAL, TC, TD, TDSTOCK, THANKS, or USER. For example, the U.S. Census Bureau EASTER(*w*) regression effects are included the “RegARIMA Holiday Component” table (A7). Specify USERTYPE=EASTER to define a variable that is processed exactly as the U.S. Census predefined EASTER(*w*) variable, including inclusion in the A7 table. Each USERTYPE= list applies to the USERVAR= variable list that immediately precedes the slash. USERTYPE= does not apply to U.S. Census predefined variables.

The same rules for assigning B= values to regression variables apply for USERTYPE= options. For example, the following statements specify that the user-defined regressor in the variable MyEaster be processed exactly as the U.S. Census predefined LOM variable:

```
regression uservar=MyLOM;
regression uservar=MyEaster / usertype=LOM EASTER;
```

In this example, the `USERTYPE=` option applies only to the `MyEaster` variable in the second `REGRES-`
`SION` statement. The `USERTYPE` value `EASTER` is discarded because there is only one variable in
the `USERVAR=` list.

To assign the `USERTYPE` value `LOM` to the `MyLOM` variable and `EASTER` to the `MyEaster` variable,
use the following statements:

```
regression uservar=MyLOM / usertype=LOM;
regression uservar=MyEaster / usertype=EASTER;
```

The following `USERTYPE=` options specify that the regression effect be removed from the seasonally
adjusted series: `EASTER`, `HOLIDAY`, `LABOR`, `LOM`, `LOMSTOCK`, `LOQ`, `LPYEAR`, `SCEASTER`,
`SEASONAL`, `TD`, `TDSTOCK`, `THANKS`, and `USER`. When a regression effect is removed from the
seasonally adjusted series, the level (mean) of the seasonally adjusted series can be altered. It is often
desirable to use a zero-mean (mean-adjusted) regressor for effects that are to be removed from the
seasonally adjusted series. See [Example 37.6](#) for an example that specifies a zero-mean regressor.

SEATSDECOMP Statement

SEATSDECOMP OUT= *SAS-data-set* *< options >* ;

The `SEATSDECOMP` statement creates an output data set (named by the `OUT=` option) that contains the
`SEATS` decomposition series.

The following is an example of a `VAR` statement and a `SEATSDECOMP` statement:

```
var sales costs;
seatsdecomp out=SEATS_DECOMP;
```

The default variable name used in the output data set is the input variable name followed by an underscore
and the corresponding table name. Because the `B1` series is used as the original input series for the
`SEATS` decomposition, the output data set `SEATS_DECOMP` from the example will contain the seasonal
decomposition variables in the following order:

<code>sales_OS</code>	contains the Table B1 values for the variable <code>sales</code> .
<code>sales_SC</code>	contains the <code>SEATS</code> decomposition seasonal component for the variable <code>sales</code> .
<code>sales_TC</code>	contains the <code>SEATS</code> trend component values for the variable <code>sales</code> .
<code>sales_SA</code>	contains the <code>SEATS</code> seasonally adjusted series for the variable <code>sales</code> .
<code>sales_IC</code>	contains the <code>SEATS</code> irregular component for the variable <code>sales</code> .
<code>costs_OS</code>	contains the Table B1 values for the variable <code>costs</code> .
<code>costs_SC</code>	contains the <code>SEATS</code> decomposition seasonal component for the variable <code>costs</code> .
<code>costs_TC</code>	contains the <code>SEATS</code> trend component values for the variable <code>costs</code> .
<code>costs_SA</code>	contains the <code>SEATS</code> seasonally adjusted series for the variable <code>costs</code> .
<code>costs_IC</code>	contains the <code>SEATS</code> irregular component for the variable <code>costs</code> .

If necessary, the variable name is shortened so that the component name can be added. If you specify the `DATE=` variable in the PROC X12 statement, then that variable is included in the output data set; otherwise, a variable named `_DATE_` is written to the `OUT=` data set as the date identifier. For further information about the output data set, see [SEATSDECOMP OUT= Data Set](#).

You can specify the following *options* in the SEATSDECOMP statement:

LEAD=*value*

specifies the number of periods ahead to forecast for a regARIMA extension of the series. The default is twice the number of periods in a year (8 or 24), and the maximum is 120. In the SEATS computations, the number of backcasts and forecasts are the same, and the minimum number is also dependent on the ARIMA model orders. For more information, see the section “[SEATS Decomposition](#)” on page 2684. If you specify a `LEAD=` value that is less than the default, then the number of forecasts specified in the `LEAD=` option are displayed in the `OUT=` data set. If the value of the `LEAD=` option and `NBACKCAST=` options in the FORECAST statement are less than the required number for SEATS decomposition, then the values of the `LEAD=` and `NBACKCAST=` options in the FORECAST statement are increased.

NBACKCAST=*value*

BACKCAST=*value*

NBACK=*value*

specifies the number of periods to backcast for a regARIMA extension of the series. The default is twice the number of periods in a year (8 or 24), and the maximum is 120. In the SEATS computations, the number of backcasts and forecasts are the same, and the minimum number is also dependent on the ARIMA model orders. For more information, see the section “[SEATS Decomposition](#)” on page 2684. If you specify a `NBACKCAST=` value that is less than the default, then the number of backcasts specified in the `NBACKCAST=` option are displayed in the `OUT=` data set. If the value of the `LEAD=` option and `NBACKCAST=` option specified in the FORECAST statement are less than the required number for SEATS decomposition when SEATSDECOMP is specified, then the value of `LEAD=` and `NBACKCAST=` in the FORECAST statement will be increased.

OUT=*SAS-data-set*

names the data set to contain the SEATS decomposition series: original series, seasonal component, trend component, seasonally adjusted series, irregular component. If the `OUT=` option is omitted, the data set is named using the default `DATAn` convention.

YEARSEAS

YRSEAS

specifies that two additional variables be added to the `OUT=` data set: `_YEAR_` and `_SEASON_`. The variable `_YEAR_` contains the year of the date that identifies the observation. The variable `_SEASON_` contains the month for monthly data, or quarter for quarterly data, of the date that identifies the observation. For monthly data, the value of `_SEASON_` is between 1 and 12. For quarterly data, the value of `_SEASON_` is between 1 and 4. The `_YEAR_` and `_SEASON_` variables are useful when you create seasonal plots.

TABLES Statement

TABLES *tablename1 tablename2 ... options ;*

The TABLES statement enables you to alter the display of the PROC X12 tables. You can specify the display of tables that are not displayed by default by PROC X12, and the NOSUM option enables you to suppress the printing of the period summary line in the time series tables.

tablename1 tablename2 ...

are keywords that correspond to the title label used by the U.S. Census Bureau X-12-ARIMA software. For each table to be included in the displayed output, you must specify the X12 *tablename* keyword. Currently available tables are A19, C20, D1, D7, E1, E2, and E3. Although these tables are not displayed by default, their values are sometimes useful in understanding the X-12-ARIMA method. For further description of the available tables, see the section “[Displayed Output, ODS Table Names, and OUTPUT Table Name Keywords](#)” on page 2684.

NOSUM

NOSUMMARY

NOSUMMARYLINE

applies to the tables available for output in the [OUTPUT Statement](#). By default, these tables include a summary line that gives the average, total, or standard deviation for the historical data by period. The NOSUM option suppresses the display of the summary line in the listing. Also, if the tables are output with ODS, the summary line is not an observation in the data set. Thus, the output to the data set is only the time series, both the historical data and the forecast data, if available.

TRANSFORM Statement

TRANSFORM *options ;*

The TRANSFORM statement transforms or adjusts the series prior to estimating a regARIMA model. With this statement, the series can be Box-Cox (power) transformed. The “Prior Adjustment Factors” table is associated with the TRANSFORM statement.

Only one of the following *options* can appear in the TRANSFORM statement:

POWER=*value*

transforms the input series, Y_t , by using a Box-Cox power transformation,

$$Y_t \rightarrow y_t = \begin{cases} \log(Y_t) & \lambda = 0 \\ \lambda^2 + (Y_t^\lambda - 1)/\lambda & \lambda \neq 0 \end{cases}$$

The power λ must be specified (for example, POWER=0.33). The default is no transformation ($\lambda = 1$); that is, POWER=1. The log transformation (POWER=0), square root transformation (POWER=0.5), and the inverse transformation (POWER=-1) are equivalent to the corresponding FUNCTION= option.

Table 37.6 Power Values Related to the Census Bureau Function Argument

FUNCTION=	Transformation	Range for Y_t	Equivalent Power Argument
NONE	Y_t	All values	POWER=1
LOG	$\log(Y_t)$	$Y_t > 0$ for all t	POWER=0
SQRT	$2(\sqrt{Y_t} - 0.875)$	$Y_t \geq 0$ for all t	POWER=0.5
INVERSE	$2 - \frac{1}{Y_t}$	$Y_t \neq 0$ for all t	POWER=-1
LOGISTIC	$\log(\frac{Y_t}{1-Y_t})$	$0 < Y_t < 1$ for all t	No equivalent

FUNCTION=NONE | LOG | SQRT | INVERSE | LOGISTIC | AUTO

specifies the transformation to be applied to the series prior to estimating a regARIMA model. The transformation used by FUNCTION=NONE, LOG, SQRT, INVERSE, or LOGISTIC is related to the POWER= option as shown in Table 37.6. FUNCTION=AUTO uses selection based on Akaike's information criterion (AIC) to decide between a log transformation and no transformation. The default is FUNCTION=NONE.

However, the FUNCTION= and POWER= options are not completely equivalent. In some cases, using the FUNCTION= option causes the program to automatically select other options. For example, FUNCTION=NONE causes the default mode to be MODE=ADD in the X11 statement. Also, the choice of transformation invoked by the FUNCTION=AUTO option can impact the default mode of the X11 statement.

There are restrictions on the value used in the POWER= and FUNCTION= options when preadjustment factors for seasonal adjustment are generated from a regARIMA model. When seasonal adjustment is requested with the X11 statement, any value of the POWER option can be used for the purpose of forecasting the series with a regARIMA model. However, this is not the case when factors generated from the regression coefficients are used to adjust either the original series or the final seasonally adjusted series. In this case, the only accepted transformations are the log transformation, which can be specified as POWER=0 for multiplicative or log-additive seasonal adjustments, and no transformation, which can be specified as POWER=1 for additive seasonal adjustments. If no seasonal adjustment is performed, any POWER transformation can be used. The preceding restrictions also apply when FUNCTION=NONE and FUNCTION=LOG are specified.

USERDEFINED Statement

USERDEFINED *variables* ;

The USERDEFINED statement is used to identify the variables in the input data set or auxiliary data set that are available for user-defined regression. Only numeric variables can be specified. Specifying variables in the USERDEFINED statement does not include the variables as regressors. If a variable is specified in the INPUT statement or USERVAR= option in the REGRESSION statement, it is not necessary to include that variable in the USERDEFINED statement. However, if a variable is specified in the MDLINFOIN= data set in the PROC X12 statement and is not specified in an INPUT statement or in the USERVAR= option in the REGRESSION statement, then the variable should be specified in the USERDEFINED statement in order to make the variable available for regression.

VAR Statement

VAR *variables* ;

The VAR statement specifies the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those that appear in a BY statement, ID statement, INPUT statement, USERDEFINED statement, in the USERVAR= option in the REGRESSION statement, or the variable named in the DATE= option in the PROC X12 statement.

X11 Statement

X11 *options* ;

The X11 statement is an optional statement for invoking seasonal adjustment by an enhanced version of the methodology of the U.S. Census Bureau X-11 and X-11Q programs. You can control the type of seasonal adjustment decomposition calculated with the MODE= option. The output includes the final tables and diagnostics for the X-11 seasonal adjustment method listed in [Table 37.7](#). Tables E1, E2, E3, C20, D1, and D7 are not displayed by default; however, you can display these tables by requesting them in the [TABLES statement](#).

Table 37.7 Tables Related to X11 Seasonal Adjustment

Table Name	Description
B1	Original series, adjusted for prior effects and forecast extended
C17	Final weights for the irregular component
C20	Final extreme value adjustment factors
D1	Modified original data, D iteration
D7	Preliminary trend cycle, D iteration
D8	Final unmodified SI ratios (differences)
D8A	<i>F</i> tests for stable and moving seasonality, D8
D9	Final replacement values for extreme SI ratios (differences), D iteration
D9A	Moving seasonality ratios for each period
SeasonalFilter	Seasonal filter statistics for Table D10
D10	Final seasonal factors
D10B	Seasonal factors, adjusted for user-defined seasonal
D10D	Final seasonal difference
D11	Final seasonally adjusted series
D11A	Final seasonally adjusted series with forced yearly totals
D11R	Rounded final seasonally adjusted series (with forced yearly totals)
TrendFilter	Trend filter statistics for Table D12
D12	Final trend cycle
D13	Final irregular component
D16	Combined seasonal and trading day factors
D16B	Final adjustment differences
D18	Combined calendar adjustment factors
E1	Original data modified for extremes
E2	Modified seasonally adjusted series
E3	Modified irregular series
E4	Ratio of yearly totals of original and seasonally adjusted series
E5	Percent changes (differences) in original series
E6	Percent changes (differences) in seasonally adjusted series
E6A	Percent changes (differences) in seasonally adjusted series with forced yearly totals (D11.A)
E6R	Percent changes (differences) in rounded seasonally adjusted series (D11.R)
E7	Percent changes (differences) in final trend component series
E8	Percent changes (differences) in original series adjusted for calendar factors (A18)
F2A–F2I	X11 diagnostic summary
F3	Monitoring and quality assessment statistics
F4	Day of the week trading day component factors
G	Spectral plots

For more details about the X-11 seasonal adjustment diagnostics, see Shiskin, Young, and Musgrave (1967), Lothian and Morry (1978a), and Ladiray and Quenneville (2001).

The following *options* can appear in the X11 statement:

FINAL=AO | LS | TC | USER | ALL**FINAL=(options)**

lists the types of prior adjustment factors, obtained from the EVENT, REGRESSION, and OUTLIER statements, that are to be removed from the final seasonally adjusted series. Additive outliers are removed by specifying FINAL=AO. Level change and ramp outliers are removed by specifying FINAL=LS. Temporary change outliers are removed by specifying FINAL=TC. User-defined regressors or events (USERTYPE=USER) are removed by specifying FINAL=USER. All the preceding are removed by specifying FINAL=ALL or by specifying all the options in parentheses, FINAL=(AO LS TC USER). If this option is not specified, the final seasonally adjusted series contains these effects.

FORCE=TOTALS | ROUND | BOTH

specifies that the seasonally adjusted series be modified to: (a) force the yearly totals of the seasonally adjusted series and the original series to be the same (FORCE=TOTALS), (b) adjust the seasonally adjusted values for each calendar year so that the sum of the rounded seasonally adjusted series for any year equals the rounded annual total (FORCE=ROUND), or (c) first force the yearly totals, then round the adjusted series (FORCE=BOTH). When FORCE=TOTALS is specified, the differences between the annual totals is distributed over the seasonally adjusted values in a way that approximately preserves the month-to-month (or quarter-to-quarter) movements of the original series. For more details, see Huot (1975) and Cholette (1979). This forcing procedure is not recommended if the seasonal pattern is changing or if trading day adjustment is performed. Forcing the seasonally adjusted totals to be the same as the original series annual totals can degrade the quality of the seasonal adjustment, especially when the seasonal pattern is undergoing change. It is not natural if trading day adjustment is performed because the aggregate trading day effect over a year is variable and moderately different from zero.

MODE=ADD | MULT | LOGADD | PSEUDOADD

determines the mode of the seasonal adjustment decomposition to be performed. The four option choices correspond to additive, multiplicative, log-additive, and pseudo-additive decomposition, respectively. If this option is omitted, the procedure performs multiplicative adjustments. Table 37.8 shows the values of the MODE= option and the corresponding models for the original (O) and the seasonally adjusted (SA) series.

Table 37.8 Modes of Seasonal Adjustment and Their Models

Value of Mode Option	Name	Model for <i>O</i>	Model for <i>SA</i>
MULT	Multiplicative	$O = C \times S \times I$	$SA = C \times I$
ADD	Additive	$O = C + S + I$	$SA = C + I$
PSEUDOADD	Pseudo-additive	$O = C \times [S + I - 1]$	$SA = C \times I$
LOGADD	Log-additive	$Log(O) = C + S + I$	$SA = exp(C + I)$

OUTFORECAST**OUTFCST**

determines whether forecasts are included in certain tables sent to the output data set. If OUTFORECAST is specified, then forecast values are included in the output data set for tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, and D18. The default is not to include forecasts. The OUTFORECAST option can be specified in either the X11 statement or the FORECAST statement with identical results.

SEASONALMA=S3X1 | S3X3 | S3X5 | S3X9 | S3X15 | STABLE | X11DEFAULT | MSR

specifies which seasonal moving average (also called seasonal “filter”) is used to estimate the seasonal factors. These seasonal moving averages are $n \times m$ moving averages, meaning that an n -term simple average is taken of a sequence of consecutive m -term simple averages. X11DEFAULT is the method used by the U.S. Census Bureau’s X-11-ARIMA program. The default for PROC X12 is SEASONALMA=MSR, which is the methodology of Statistic Canada’s X-11-ARIMA/88 program.

Table 37.9 describes the seasonal filter options available for the entire series:

Table 37.9 X-12-ARIMA Seasonal Filter Options and Descriptions

Filter Name	Description of Filter
S3X1	A 3×1 moving average
S3X3	A 3×3 moving average
S3X5	A 3×5 moving average
S3X9	A 3×9 moving average
S3X15	A 3×15 moving average
STABLE	Stable seasonal filter. A single seasonal factor for each calendar month or quarter is generated by calculating the simple average of all the values for each month or quarter (taken after detrending and outlier adjustment).
X11DEFAULT	A 3×3 moving average is used to calculate the initial seasonal factors in each iteration, and a 3×5 moving average to calculate the final seasonal factors
MSR	Filter chosen automatically by using the moving seasonality ratio of X-11-ARIMA/88 (Dagum 1988)

SIGMALIM=(lower limit, upper limit)

SIGMALIM=(lower limit)

SIGMALIM=(, upper limit)

specifies the lower and upper sigma limits in standard deviation units which are used to identify and down-weight extreme irregular values in the internal seasonal adjustment computations. One or both limits can be specified. The lower limit must be greater than 0 and not greater than the upper limit. If the lower sigma limit is not specified, then it defaults to a value of 1.5. The default upper sigma limit is 2.5. The comma must be used if the upper limit is specified.

Table 37.10 shows the effect of the SIGMALIM= option on the weights that are applied to the internal irregular values.

Table 37.10 Weights for Irregular Values

Weight	Sigma Limit
0	If $\frac{ I_t - \mu }{\sigma_{1,I_t}} \geq \text{upper limit}$
Partial weight	If $\text{lower limit} < \frac{ I_t - \mu }{\sigma_{2,I_t}} < \text{upper limit}$
1	If $\frac{ I_t - \mu }{\sigma_{2,I_t}} \leq \text{lower limit}$

In Table 37.10, μ is the theoretical mean of the irregular component, and σ_{1,I_t} and σ_{2,I_t} are the respective estimates of the standard deviation of the irregular component before and after extreme values are removed. The estimates of the standard deviation σ_{1,I_t} and σ_{2,I_t} vary with respect to t , and they are the same if no extreme values are removed. If they are different ($\sigma_{2,I_t} < \sigma_{1,I_t}$), then the first line in Table 37.10 is reevaluated with σ_{2,I_t} . In the special case where the lower limit equals the upper limit, the weight is 1 for $\frac{|I_t - \mu|}{\sigma_{2,I_t}} \leq \text{lower limit}$, and 0 otherwise. For more information about how extreme irregular values are handled in the X11 computations, see Ladiray and Quenneville 2001, pp. 53–68, 122–125.

TRENDMA=value

specifies which Henderson moving average is used to estimate the final trend cycle. Any odd number greater than one and less than or equal to 101 can be specified (for example, TRENDMA=23). If the TRENDMA= option is not specified, the program selects a trend moving average based on statistical characteristics of the data. For monthly series, a 9-, 13-, or 23-term Henderson moving average is selected. For quarterly series, the program chooses either a 5- or a 7-term Henderson moving average.

TYPE=SA | SUMMARY | TREND

specifies the method used to calculate the final seasonally adjusted series (Table D11). The default method is TYPE=SA. This method assumes that the original series has not been seasonally adjusted. For method TYPE=SUMMARY, the trend cycle, irregular, trading day, and holiday factors are calculated, but not removed from the seasonally adjusted series. Thus, for TYPE=SUMMARY, Table D11 is the same as the original series. For TYPE=TREND, trading day, holiday, and prior adjustment factors are removed from the original series to calculate the seasonally adjusted series (Table D11) and also are used in the calculation of the final trend (Table D12).

Details: X12 Procedure

Data Requirements

The input data set must contain either quarterly or monthly time series, and the data must be sorted in chronological order within each BY group. For the standard X-12-ARIMA method, there must be at least three years of observations (12 for quarterly time series or 36 for monthly).

If an ARIMA model is specified in the ARIMA statement, AUTOMDL statement, PICKMDL statement, or the MDLINFOIN= data set, then more than three years of observations might be required in order to fit the ARIMA model and perform the computations associated with the seasonal decomposition and other diagnostics.

The minimum number of observations applies to each series listed in the VAR statement and within each BY group and is determined after any missing values are trimmed from the series.

Missing Values

PROC X12 can process a series with missing values.

Types of Missing Values

Missing values in a series are considered to be one of two types:

- A leading or trailing missing value occurs before the first nonmissing value or after the last nonmissing value, respectively, in the span of a series. The span of a series can be determined either explicitly by the SPAN= option or implicitly by the START= or DATE= option in the PROC X12 statement. By default, leading and trailing missing values are ignored. If you specify the **NOTRIMMISS** option in the PROC X12 statement, PROC X12 processes leading and trailing missing values according to the X-12-ARIMA missing value method.
- An embedded missing value occurs between the first nonmissing value and the last nonmissing value in the span of the series. PROC X12 processes embedded missing values according to the X-12-ARIMA missing value method.

X-12-ARIMA Missing Value Method

When the X-12-ARIMA method encounters a missing value, it inserts an additive outlier for the missing observation into the set of regression variables for the model of the series and then replaces the missing observation with a value large enough to be considered an outlier during model estimation. After the regARIMA model is estimated, the X-12-ARIMA method adjusts the original series by using factors that are generated from these missing value outlier regressors. The adjusted values are estimates of the missing values, and the adjusted series is displayed in Table MV1. The X-12-ARIMA missing value method requires the use of a regARIMA model to replace the missing values. Thus, either an ARIMA or AUTOMDL statement or the MDLINFOIN= option in the PROC X12 statement must be specified if there are embedded missing values in the time series.

SAS Predefined Events

SAS predefined events are summarized in this section. For complete details about SAS predefined events, see the section “EVENTKEY Statement” in Chapter 9, “The HPFEVENTS Procedure” (*SAS High-Performance Forecasting User’s Guide*).

Table 37.11 shows a summary of the SAS predefined event keywords. Table 37.12 lists the holiday date keywords that can be used as SAS predefined events. Table 37.13 lists the seasonal date keywords that can be used as SAS predefined events.

Table 37.11 Definitions for EVENTKEY Predefined Event Keywords

Variable Name or Variable Name Format	Description	Qualifier Options

Table 37.12 Holiday Date Keywords and Definitions

Date Keyword	Definition
BOXING	December 26th
CANADA	July 1st
CANADAOBSERVED	July 1st, or July 2nd if July 1st is a Sunday
CHRISTMAS	December 25th
COLUMBUS	Second Monday in October
EASTER	Easter Sunday
FATHERS	Third Sunday in June
HALLOWEEN	October 31st
LABOR	First Monday in September
MLK	Third Monday in January
MEMORIAL	Last Monday in May
MOTHERS	Second Sunday in May
NEWYEAR	January 1st
THANKSGIVING	Fourth Thursday in November
THANKSGIVINGCANADA	Second Monday in October
USINDEPENDENCE	July 4th
USPRESIDENTS	Third Monday in February (since 1971)
VALENTINES	February 14th
VETERANS	November 11th
VETERANSUSG	Veterans Day date that is observed by U.S. government for Monday–Friday schedule
VETERANSUSPS	Veterans Day date that is observed by U.S. government for Monday–Saturday schedule (U.S. Post Office)
VICTORIA	Monday on or preceding May 24th

Table 37.13 Seasonal Date Keywords and Definitions

Date Keyword	Definition
SECOND_1, ..., SECOND_60	Specified second
MINUTE_1, ..., MINUTE_60	Beginning of the specified minute
HOUR_1, ..., HOUR_24	Beginning of the specified hour
SUNDAY, ..., SATURDAY	All Sundays, and so on, in the time series
WEEK_1, ..., WEEK_53	First day of the n th week of the year (PULSE=WEEK. n shifts this date for $n \neq 1$)
TENDAY_1, TENDAY_4, ..., TENDAY_34	The 1st of the month
TENDAY_2, TENDAY_5, ..., TENDAY_35	The 11th of the month
TENDAY_3, TENDAY_6, ..., TENDAY_36	The 21st of the month
SEMIMONTH_1, SEMIMONTH_3, ..., SEMIMONTH_23	The 1st of the month
SEMIMONTH_2, SEMIMONTH_4, ..., SEMIMONTH_24	The 16th of the month
JANUARY, ..., DECEMBER	The 1st of the specified month
QTR_1, QTR_2, QTR_3, QTR_4	The first date of the quarter indicated after the underscore (PULSE=QTR. n shifts this date for $n \neq 1$)
SEMIYEAR_1, SEMIYEAR_2	The first date of the semiyear (PULSE=SEMIYEAR. n shifts this date for $n \neq 1$)

User-Defined Regression Variables

The X-12-ARIMA method enables you to define regression variables to be included in the regARIMA model. A user-defined regression variable is composed of a value at each time series observation that you provide; the entire variable is implemented as a regressor in the regARIMA model. The regARIMA model is used in the seasonal decomposition process to extend the series prior to X11 decomposition. Because the X-12-ARIMA method does not impute, forecast, nor backcast user-defined regression variables, you must provide a nonmissing value at each observation in the span of the time series to be modeled and also provide a nonmissing value at each observation to be forecast or backcast.

A user-defined regression variable can be included in either the PROC X12 **DATA=** or **AUXDATA=** data set. You can supply the values for the user-defined regression variable by one of the following methods:

- You can include them in an auxiliary data set. The auxiliary data set should have a date variable that corresponds to the date variable in the **DATA=** data set. The name of the auxiliary data set is specified in the **AUXDATA=** option in the PROC X12 statement. The name of the date variable that exists in both the **DATA=** and **AUXDATA=** data sets is specified in the **DATE=** option in the PROC X12 statement. The observations in the auxiliary data set must span the entire series plus any forecast and backcast period.
- You can include them in the **DATA=** data set. Because the number of observations and the date values are exactly the same for both user-defined regressors and time series values, you need to include forecast and backcast values for user-defined regression variables beyond the span of the time series in one of the following ways:
 - You must specify leading missing values in the series to be seasonally adjusted for backcast periods. You must specify trailing missing values in the series to be seasonally adjusted for forecast periods. You must not use the **NOTRIMMISS** option in this case. The span of the series to be seasonally adjusted that is implied by trimming the leading and trailing missing values will be less than the span of the date values in the **DATA=** data set. Using this method, forecast error cannot be computed for the forecast and backcast periods.
 - You can use the **SPAN=** option in the PROC X12 statement to alter the span of the series to be seasonally adjusted to allow for backcast and forecast periods within the span of the date values in the **DATA=** data set. Using this method, forecast error can be computed for the forecast and backcast periods.

These methods of including user-defined regression variables in the regARMIA model are illustrated in [Example 37.6](#) and [Example 37.11](#).

If missing values for the user-defined regression variable are present within the span of the the time series, including backcast and forecast observations, then an error message is displayed and the time series is not processed. If the span of the user-defined regression variable, or the span after leading and trailing missing values are trimmed, is not sufficient to cover the span of the series to be seasonally adjusted, including any backcasts and forecasts, then an error message is also displayed, and the time series is not processed.

Combined Test for the Presence of Identifiable Seasonality

The seasonal component of a time series, S_t , is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality). If the increase in the seasonal factors from year to year is too large, then the seasonal factors introduce distortion into the model. It is important to determine whether seasonality is identifiable without distorting the series.

For seasonality to be identifiable, the series should be identified as seasonal by using the “Test for the Presence of Seasonality Assuming Stability” and “Nonparametric Test for the Presence of Seasonality Assuming Stability.” Also, since the presence of moving seasonality can cause distortion, it is important to evaluate the moving seasonality in conjunction with the stable seasonality to determine whether the seasonality is identifiable. The results of these tests are displayed in “ F tests for Seasonality” (Table D8.A) in the X12 procedure.

The test for identifiable seasonality is performed by combining the F tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The following description is based on Lothian and Morry (1978b). Other details can be found in Dagum (1988, 1983).

Let F_s and F_m denote the F value for the stable and moving seasonality tests, respectively. The combined test is performed as follows (see also Figure 37.3):

1. If the null hypothesis of no stable seasonality is not rejected at the 0.10% significance level ($P_S \geq 0.001$), then the series is considered to be nonseasonal. PROC X12 returns the conclusion, “Identifiable Seasonality Not Present.”
2. If the null hypothesis in step 1 is rejected, then PROC X12 computes the following quantities:

$$T_1 = \frac{7}{F_s}$$

$$T_2 = \frac{3F_m}{F_s}$$

Let T denote the simple average of T_1 and T_2 :

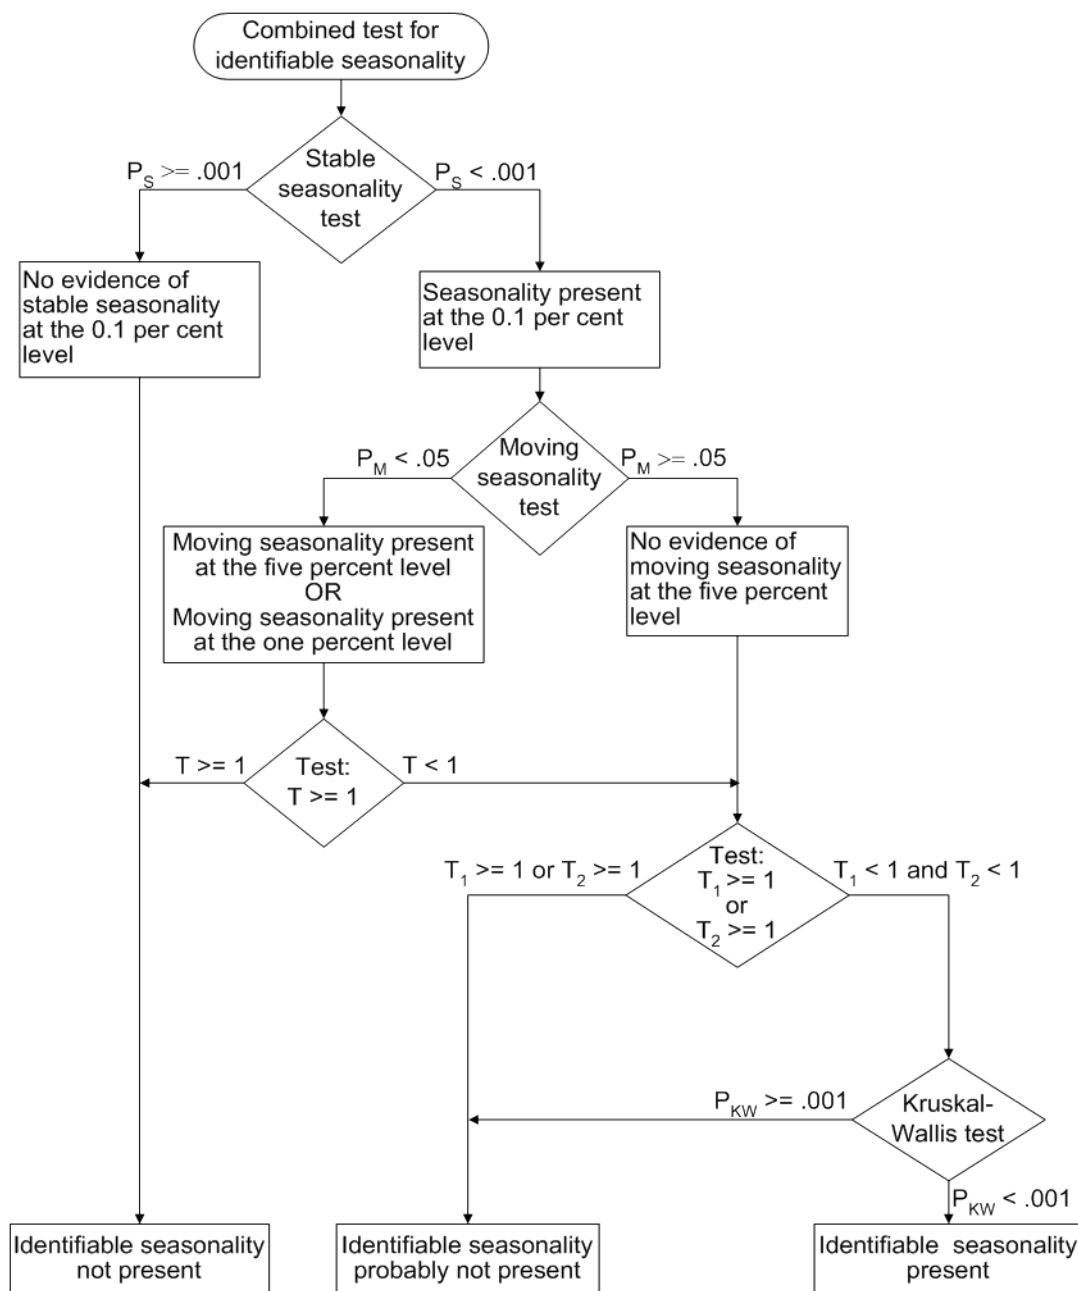

$$T = \frac{(T_1 + T_2)}{2}$$

If the null hypothesis of no moving seasonality is rejected at the 5.0% significance level ($P_M < 0.05$) and if $T \geq 1.0$, the null hypothesis of identifiable seasonality *not* present is not rejected and PROC X12 returns the conclusion, “Identifiable Seasonality Not Present.”

3. If the null hypothesis of identifiable seasonality *not* present has not been accepted, but $T_1 \geq 1.0$, $T_2 \geq 1.0$, or the Kruskal-Wallis chi-squared test fails to reject at the 0.10% significance level ($P_{KW} \geq 0.001$), then PROC X12 returns the conclusion “Identifiable Seasonality Probably Not Present.”
4. If the null hypotheses of no stable seasonality associated with the F_S and Kruskal-Wallis chi-squared tests are rejected and if none of the combined measures described in steps 2 and 3 fail, then the null hypothesis of identifiable seasonality *not* present is rejected and PROC X12 returns the conclusion “Identifiable Seasonality Present.”

Included in the displayed output of Table D8A is the table “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” This table displays the T_1 , T_2 , and T values and the significance levels for the stable seasonality test, the moving seasonality test, and the Kruskal-Wallis test. The last item in the table is the result of the combined test for identifiable seasonality.

Figure 37.3 Combined Seasonality Test Flowchart

Computations

For more details about the computations used in PROC X12, see the *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2009c).

For more details about the X-11 method of decomposition, see *Seasonal Adjustment with the X-11 Method* (Ladiray and Quenneville 2001).

PICKMDL Model Selection

You can request that the X-12-ARIMA method select a model in a manner similar to the method used in X-11-ARIMA (Dagum 1988, 1983) by specifying the **PICKMDL** statement. Information about this model selection (PICKMDL) is based on the description in the *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2009c).

The default settings for the **PICKMDL** automatic model selection method classify a model as acceptable if all of the following conditions are true:

- The absolute average percentage error of the extrapolated values within the last three years of data is less than 15%.
- The p -value is greater than 5% for the fitted model's Ljung-Box Q statistic test of the lack of correlation in the model's residuals.
- There are no signs of overdifferencing. Overdifferencing is indicated if the sum of the nonseasonal MA parameter estimates (for models with at least one nonseasonal difference) is greater than 0.9.

No model is selected when none of the models in the **MDLINFOIN=** data set is acceptable.

The regARIMA model consists of a transformation, a regression component, and an ARIMA model component. For each series, the following conditions hold:

- If no regression is specified in the **MDLINFOIN=** data set model but regressors are specified using the **INPUT**, **EVENT**, or **REGRESSION** statements, then the ARIMA models from the **MDLINFOIN=** data set are tested in conjunction with the regression variables specified by the **INPUT**, **EVENT**, and **REGRESSION** statements.
- If no ARIMA model is specified in the **MDLINFOIN=** data set but an ARIMA model is specified using an **ARIMA** statement or **TRANSFORM** statement, then the regression information from each model specified in the **MDLINFOIN=** data set is used in conjunction with the ARIMA model specified by the **TRANSFORM** and **ARIMA** statements.
- If no model information is specified in the **MDLINFOIN=** data set, then any model information specified by the **TRANSFORM**, **INPUT**, **REGRESSION**, **EVENT**, and **ARIMA** statements is used, and the **PICKMDL** statement is not in effect for that series.

SEATS Decomposition

PROC X12 can decompose the B1 series by using the SEATS decomposition method described in Gómez and Maravall (1997a, b). The SEATS decomposition method is planned for inclusion in the U.S. Census Bureau's X13 program, which is not yet available for release.

The SEATS method requires the series to be extended with the same number of backcast and forecast observations. The number of observations backcast and forecast must meet the following minimum criteria:

- The number of forecast and backcast observations must be at least twice the number of observations in a year, with a minimum of 8.
- The number of forecast and backcast observations must be at least $2 \times (q + Q * s)$, where the ARIMA model used to extend the series is $(pdq)(PDQ)s$ in standard Box-Jenkins notation.
- The number of forecast and backcast observations must be at least $p + d + q + (P + D + Q) * s$, where the ARIMA model used to extend the series is $(pdq)(PDQ)s$ in standard Box-Jenkins notation.

If you specify the SEATSDECOMP statement and the number of forecasts or backcasts (either the default number or the number you specify) is not sufficient for SEATS decomposition, then the number of forecasts or backcasts is increased to the minimum required.

Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords

The options specified in PROC X12 control both the tables produced by the procedure and the tables available for output to the OUT= data set specified in the OUTPUT statement.

The displayed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X12 procedure are as follows:

- A prior adjustments and regARIMA components (optional)
- B preliminary estimates of irregular component weights and trading day regression factors (X-11 method)
- C final estimates of irregular component weights and trading day regression factors
- D final estimates of seasonal, trend cycle, and irregular components
- E analytical tables
- F summary measures
- G charts

Table 37.14 describes the individual tables and charts. “P” indicates that the table is only displayed and is not available for output to the OUT= data set. Data from displayed tables can be extracted into data sets by using the Output Delivery System (ODS). For more information about the SAS Output Delivery System, see the *SAS Output Delivery System: User's Guide*. For more information about the features of the ODS Graphics system, including the many ways that you can control or customize the plots that are produced by SAS procedures, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User's Guide*).

When tables available through the **OUTPUT statement** are output using ODS, the summary line is included in the ODS output by default. The summary line gives the average, standard deviation, or total by each period. The value -1 for YEAR indicates that the summary line is a total; the value -2 for YEAR indicates that the summary line is an average; and the value -3 for YEAR indicates that the line is a standard deviation. The value of YEAR for historical and forecast values is greater than or equal to zero. Thus, a negative value indicates a summary line. You can suppress the summary line altogether by specifying the **NOSUM** option in the **TABLES** statement. However, the **NOSUM** option also suppresses the display of the summary line in the displayed table.

“T” indicates that the table is available using the **OUTPUT** statement, but is not displayed by default; you must request that these tables be displayed by using the **TABLES Statement**. If there is no notation in the “Notes” column, then the table is available directly using the **OUTPUT** statement, without specifying the **TABLES** statement. If a table is not computed, then it is not displayed; if it is requested in the **OUTPUT** statement, then the variable in the **OUT=** data set contains missing values. The actual number of tables displayed depends on the options and statements specified.

Table 37.14 Table Names and Descriptions

Table	Description	Notes
Tables Associated with Model Order Identification		
ModelDescription	Regression model used in ARIMA model identification	P
ACF	Autocorrelation function	P
PACF	Partial autocorrelation function	P
Tables Associated with Automatic Modeling		
UnitRootTestModel	ARIMA estimates for unit root identification	P
UnitRootTest	Results of unit root test for identifying orders of differencing	P
AutoChoiceModel	Models estimated by automatic ARIMA model selection procedure	P
Best5Model	Best five ARIMA models chosen by automatic modeling	P
AutomaticModelChoice	Comparison of automatically selected model and default model	P
FinalModelChoice	Final automatic model choice	P
Diagnostic Tables		
ErrorACF	Autocorrelation of regARIMA model residuals	P
ErrorPACF	Partial autocorrelation of regARIMA model residuals	P
SqErrorACF	Autocorrelation of squared regARIMA model residuals	P
ResidualOutliers	Outliers of the unstandardized residuals	P
ResidualStatistics	Summary statistics for the unstandardized residuals	P
NormalityStatistics	Normality statistics for regARIMA model residuals	P
G	Spectral analysis of regARIMA model residuals	P
Modeling Tables		
MissingExtreme	Extreme or missing values	P

Table 37.14 continued

Table	Description	Notes
ARMAIterationTolerances	Exact ARMA likelihood estimation iteration tolerances	P
IterHistory	ARMA iteration history	P
OutlierDetection	Critical values to use in outlier detection	P
PotentialOutliers	Potential outliers	P
ARMAIterationSummary	Exact ARMA likelihood estimation iteration summary	P
ModelDescription	Model description for regARIMA model estimation	P
RegParameterEstimates	Regression model parameter estimates	P
RegressorGroupChiSq	Chi-squared tests for groups of regressors	P
ARMAParameterEstimates	Exact ARMA maximum likelihood estimation	P
AvgFcstErr	Average absolute percentage error in within-sample or without-sample forecasts or backcasts	P
Roots	Seasonal or nonseasonal AR or MA roots	P
MLESummary	Estimation summary	P
ForecastCL	Forecasts, standard errors, and confidence limits	P
MV1	Original series adjusted for missing value regressors	
Sequenced Tables		
A1	Original series	
A2	Prior-adjustment factors	
A6	RegARIMA trading day component	
A7	RegARIMA holiday component	
A8	RegARIMA combined outlier component	
A8AO	RegARIMA AO outlier component	
A8LS	RegARIMA level change outlier component	
A8TC	RegARIMA temporary change outlier component	
A9	RegARIMA user-defined regression component	
A10	RegARIMA user-defined seasonal component	
A19	RegARIMA outlier adjusted original data	T
B1	Prior-adjusted or original series	
C17	Final weight for irregular components	
C20	Final extreme value adjustment factors	T
D1	Modified original data, D iteration	T
D7	Preliminary trend cycle, D iteration	T
D8	Final unmodified S-I ratios	
D8A	Seasonality tests	P
D9	Final replacement values for extreme S-I ratios	
D9A	Moving seasonality ratio	P
SeasonalFilter	Seasonal filter statistics for table D10	P
D10	Final seasonal factors	
D10B	Seasonal factors, adjusted for user-defined seasonal	
D10D	Final seasonal difference	
D11	Final seasonally adjusted series	
D11A	Final seasonally adjusted series with forced yearly totals	
D11F	Factors applied to get adjusted series with forced yearly totals	

Table 37.14 *continued*

Table	Description	Notes
D11R	Rounded final seasonally adjusted series (with forced yearly totals)	
TrendFilter	Trend filter statistics for table D12	P
D12	Final trend cycle	
D13	Final irregular series	
D16	Combined adjustment factors	
D16B	Final adjustment differences	
D18	Combined calendar adjustment factors	
E1	Original data modified for extremes	
E2	Modified seasonally adjusted series	
E3	Modified irregular series	
E4	Ratios of annual totals	P
E5	Percent changes in original series	
E6	Percent changes in final seasonally adjusted series	
E6A	Percent changes (differences) in seasonally adjusted series with forced yearly totals (D11.A)	
E6R	Percent changes (differences) in rounded seasonally adjusted series (D11.R)	
E7	Differences in final trend cycle	
E8	Percent changes (differences) in original series adjusted for calendar factors (A18)	
F2A-I	Summary measures	P
F3	Quality assessment statistics	P
F4	Day of the week trading day component factors	P
G	Spectral analysis	P

Using Auxiliary Variables to Subset Output Data Sets

The X12 procedure can produce more than one table with the same name. For example, the following **IDENTIFY** statement produces ACF and PACF tables for two levels of differencing:

```
identify diff=(1) sdiff=(0, 1);
```

Auxiliary variables in the output data can be used to subset the data. In this example, the auxiliary variables Diff and SDiff specify the levels of regular and seasonal differencing that are used to compute the ACF. The following statements show how to retrieve the ACF results for the first differenced series:

```
ods select acf;
ods output acf=acf;
proc x12 data=sashelp.air date=date;
    identify diff=(1) sdiff=(0,1);
run;
title "Regular Difference=1 Seasonal Difference=0";
data acfd1D0;
    set acf(where=(Diff=1 and Sdiff=0));
run;
```

In addition to any BY variables, the auxiliary variables in the ACF and PACF data sets are `_NAME_`, `_TYPE_`, Transform, Adjust, Regressors, Diff and SDiff. Auxiliary variables can be related to the group as shown in the Results Viewer (for example, BY variables, `_NAME_`, and `_TYPE_`). However, they can also be variables in the template where printing is suppressed by using `PRINT=OFF`. Auxiliary variables such as Transform, Adjust, and Regressors are not displayed in the ACF and PACF tables because similar information is displayed in the ModelDescription table that immediately precedes the ACF and PACF tables. The variables Diff and SDiff are not displayed because the levels of differencing are included in the title of the ACF and PACF tables.

The BY variables and the `_NAME_` variable are available for all ODS OUTPUT data sets that are produced by the X12 procedure. The `_TYPE_` variable is available for all ODS OUTPUT data sets that are produced during the model identification and model estimation stages. The `_TYPE_` variable enables you to determine whether data in a table, such as the ModelDescription table, originated from the model identification stage or the model estimation stage.

The forecast data sets contain the auxiliary variable `_SCALE_`. The value of `_SCALE_` is “Original” or “Transformed” to indicate the scale of the data. The auxiliary variable `_SCALE_` is the same as the group in the Results Viewer. It is not displayed in the forecast tables because the table titles indicate the scale of the data.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

This section describes the use of ODS for creating graphics with the X12 procedure.

The graphs available through ODS Graphics are ACF plots, PACF plots, a residual histogram, spectral graphs, and forecasting plots. ACF and PACF plots for regARIMA model identification are not available unless the **IDENTIFY** statement is used. ACF plots, PACF plots, the residual histogram, and the residual spectral graph for diagnosis of the regARIMA model residuals are not available unless the **CHECK** statement is used. Forecasting plots are not available unless the **FORECAST** statement is used. A spectral plot of the original series is always available; however, additional spectral plots are provided when the **X11** statement and **CHECK** statement are used. When ODS Graphics is not enabled, the ACF, PACF, and spectral analysis

are displayed as columns of a table. The residual histogram is available only when ODS Graphics is enabled. To obtain a table that contains values related to the residual histogram, use the ODS OUTPUT statement.

ODS Graph Names

PROC X12 assigns a name to each graph it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in [Table 37.15](#).

Table 37.15 ODS Graphs Produced by PROC X12

ODS Graph Name	Plot Description	PROC X12 PLOTS= Option
ACFPlot	Autocorrelation of regression residuals	SERIES(ACF)
ErrorACFPlot	Autocorrelation of regARIMA model residuals	RESIDUAL(ACF)
ErrorPACFPlot	Partial autocorrelation of regARIMA model residuals	RESIDUAL(PACF)
ForecastsOnlyPlot	Forecasts only of the original series	FORECAST(FORECASTONLY)
ForecastsOnlyPlot	Forecasts only of the transformed series	FORECAST(TRANSFORECASTONLY)
ForecastsPlot	Forecasts of the original series	FORECAST(FORECAST)
ForecastsPlot	Forecasts of the transformed series	FORECAST(TRANSFORECAST)
ModelForecastsPlot	Model and forecasts of the original series	FORECAST(MODELFORECASTS)
ModelForecastsPlot	Model and forecasts of the transformed series	FORECAST(TRANSMODELFORECASTS)
ModelPlot	Model of the original series	FORECAST(MODELS)
ModelPlot	Model of the transformed series	FORECAST(TRANSMODELS)
PACFPlot	Partial autocorrelation of regression residuals	SERIES(PACF)
ResidualHistogram	Distribution of regARIMA residuals	RESIDUAL(HIST)
SpectralPlot	Spectral plot of the seasonally adjusted series	ADJUSTED(SPECTRUM)
SpectralPlot	Spectral plot of irregular series	IRREGULAR(SPECTRUM)
SpectralPlot	Spectral plot of the regARIMA model residuals	RESIDUAL(SPECTRUM)

Table 37.15 continued

ODS Graph Name	Plot Description	PROC X12 PLOTS= Option
SpectralPlot	Spectral plot of the original series	SERIES(SPECTRUM)
SqErrorACFPlot	Autocorrelation of squared regARIMA model residuals	RESIDUAL(SQACF)

OUT= Data Set

You can use the OUTPUT statement to output the component series computed in the X-12-ARIMA decomposition.

The OUT= data set specified in the OUTPUT statement contains the BY variables (if any), the ID variables (if any), and the DATE= variable if the DATE= option is specified or the variable `_DATE_` if the DATE= option is not specified. If user-defined regressor variables or EVENT variables are specified, they are included. In addition, the various components specified by the table names in the OUTPUT statement are included in the OUT= data set.

The OUTPUT OUT= data set can contain the following variables:

BY variables	are the BY variables used to subset the series by BY groups. The BY variables included in this data set match the BY variables, if any, used to process the series in the DATA= data set.
ID variables	enable the series observations to be identified using further information. The ID variables included in this data set match the ID variables, if any, specified in the ID statement and input from the DATA= data set.
DATE variable	is the time ID variable used to process the time series. It is either the variable specified in the DATE= option in the PROC X12 statement or the variable <code>_DATE_</code> generated by the START= option in the PROC X12 statement.
<code>_YEAR_</code> variable	contains a value for the year of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.
<code>_SEASON_</code> variable	contains a value for the month or quarter of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.
User-defined variables	are variables specified in the INPUT statement or the USERVAR= option in the REGRESSION statement. The values of these variables are copied from the DATA= data set or from the AUXDATA= data set.
EVENT variables	variables specified in the EVENT statement. The values of these variables are computed based on the event definition and the dates of the time series observations.
Table variables	contains the data from the X-12-ARIMA decomposition tables: A1, A2, A6, A7, A8, A8AO, A8LS, A8TC, A9, A10, A19, B1, C17, C20, D1, D7, D8, D9, D10, D10B, D10D, D11, D11A, D11F, D11R, D12, D13, D16, D16B, D18, E1, E2, E3, E5, E6,

E6A, E6R, E7, E8, and MV1. The variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

SEATSDECOMP OUT= Data Set

You can use the **SEATSDECOMP** statement to output the component series that is computed using the SEATS method of seasonal decomposition.

The OUT= data set specified in the SEATSDECOMP statement contains the BY variables (if any), the ID variables (if any), and either the DATE= variable if the DATE= option is specified or the variable `_DATE_` if the DATE= option is not specified. If user-defined regressor variables or EVENT variables are specified, they are included. In addition, the five components computed by the SEATS decomposition method are included in the OUT= data set for each series.

The SEATSDECOMP OUT= data set can contain the following variables:

BY variables	are the BY variables used to subset the series by BY groups. The BY variables included in this data set match the BY variables (if any) that are used to process the series in the DATA= data set.
ID variables	enable the series observations to be identified using further information. The ID variables included in this data set match the ID variables (if any) that are specified in the ID statement and input from the DATA= data set.
DATE variable	is the time ID variable used to process the time series. It is either the variable specified in the DATE= option in the PROC X12 statement or the variable <code>_DATE_</code> that is generated by the START= option in the PROC X12 statement.
<code>_YEAR_</code> variable	contains a value for the year of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.
<code>_SEASON_</code> variable	contains a value for the month or quarter of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.
User-defined variables	are variables specified in the INPUT statement or the USERVAR= option in the REGRESSION statement. The values of these variables are copied from the DATA= data set or from the AUXDATA= data set.
EVENT variables	are variables that are specified in the EVENT statement. The values of these are computed based on the event definition and the dates of the time series observations.
Component variables	contains the data from the SEATS decomposition tables. The variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.
<code><variable>_OS</code>	contains the original series for SEATS decomposition. This is the B1 series from the X-12-ARIMA method.
<code><variable>_SC</code>	contains the seasonal component series that is calculated by SEATS decomposition.
<code><variable>_TC</code>	contains the trend component series that is calculated by SEATS decomposition.
<code><variable>_SA</code>	contains the seasonally adjusted series that is calculated by SEATS decomposition.

<variable>_IC contains the irregular series that is calculated by SEATS decomposition.

Special Data Sets

The X12 procedure can input the MDLINFOIN= and output the MDLINFOOUT= data sets. The structure of both of these data sets is the same. The difference is that when the MDLINFOIN= data set is read, only information relative to specifying a model is processed, whereas the MDLINFOOUT= data set contains the results of estimating a model. The X12 procedure can also read data sets that contain event definition data. The structure of these data sets is the same as in the SAS[®] High Performance Forecasting system.

MDLINFOIN= and MDLINFOOUT= Data Sets

The MDLINFOIN= and MDLINFOOUT= data sets can contain the following variables:

BY variables	enable the model information to be specified by BY groups. BY variables can be included in this data set that match the BY variables used to process the series. If no BY variables are included, then the models specified by _NAME_ in the MDLINFOIN= data set apply to all BY groups in the DATA= data set.
NAME	should contain the variable name of the time series to which a particular model is to be applied. Omit the _NAME_ variable if you are specifying the same model for all series in a BY group.
MODELTYPE	specifies whether the observation contains regression or ARIMA information. The value of _MODELTYPE_ should be either REG to supply regression information or ARIMA to supply model information. If valid regression information exists in the MDLINFOIN= data set for a BY group and series being processed, then the REGRESSION, INPUT, and EVENT statements are ignored for that BY group and series. Likewise, if valid ARIMA model information exists in the data set, then the AUTOMDL, ARIMA, and TRANSFORM statements are ignored. Valid values for the other variables in the data set depend on the value of the _MODELTYPE_ variable. Although other values of _MODELTYPE_ might be permitted in other SAS procedures, PROC X12 recognizes only REG and ARIMA.
MODELPART	further qualifies the regression information in the observation. For _MODELTYPE_=REG, valid values of _MODELPART_ are INPUT, EVENT, and PREDEFINED. A value of INPUT indicates that this observation refers to the user-defined variable whose name is given in _DSVAR_. Likewise, a value of EVENT indicates that the observation refers to the SAS or user-defined event whose name is given in _DSVAR_. PREDEFINED indicates that the name given in _DSVAR_ is a predefined U.S. Census Bureau variable. If only ARIMA model information is included in the data set (that is, all observations have _MODELTYPE_=ARIMA), then the _MODELPART_ variable can be omitted. For observations where _MODELTYPE_=ARIMA, valid values for _MODELPART_ are FORECAST, “.”, or blank.
COMPONENT	further qualifies the regression or ARIMA information in the observation. For _MODELTYPE_=REG, the only valid value of _COMPONENT_ is SCALE. For _MODELTYPE_=ARIMA, the valid values of _COMPONENT_ are TRANSFORM, CONSTANT, NON-SEASONAL, and SEASONAL. TRANSFORM indicates that the observation contains the information that would be supplied in the TRANSFORM statement. CONSTANT is

specified to control the constant term in the model. NONSEASONAL and SEASONAL refer to the AR, MA, and differencing terms in the ARIMA model.

<code>_PARMTYPE_</code>	further qualifies the regression or ARIMA information in the observation. For <code>_MODELTYPE_=REG</code> , the value of <code>_PARMTYPE_</code> is the same as the value of the <code>USERTYPE=</code> option in the REGRESSION statement. Since the <code>USERTYPE=</code> option applies only to user-defined events and variables, the value of <code>_PARMTYPE_</code> does not alter processing in observations where <code>_MODELPART_=PREDEFINED</code> . However, it is consistent to use a value for <code>_PARMTYPE_</code> that matches the U.S. Census Bureau predefined variable. For the constant term in the model information, <code>_PARMTYPE_</code> should be SCALE. For transformation information, the value of <code>_PARMTYPE_</code> should be NONE, LOG, LOGIT, SQRT, or BOXCOX. For <code>_MODELTYPE_=ARIMA</code> , valid values of <code>_PARMTYPE_</code> are AR, MA, and DIF.
<code>_DSVAR_</code>	specifies the variable name associated with the current observation. For <code>_MODELTYPE_=REG</code> , the value of <code>_DSVAR_</code> is the name of the user-defined variable, the event, or the U.S. Census Bureau predefined variable. For <code>_MODELTYPE_=ARIMA</code> , <code>_DSVAR_</code> should match the name of the series being processed. If the ARIMA model information applies to more than one series, then <code>_DSVAR_</code> can be blank or “:”, equivalently.
<code>_VALUE_</code>	contains a numerical value that is used as a parameter for certain types of information. For example, the <code>PREDEFINED=EASTER(6)</code> option in the REGRESSION statement is implemented in the MDLINFOIN= data set by using <code>_DSVAR_=EASTER</code> and <code>_VALUE_=6</code> . For a BOXCOX transformation, <code>_VALUE_</code> is set equal to the λ parameter value. For <code>_COMPONENT_=SEASONAL</code> , if <code>_VALUE_</code> is nonmissing, then <code>_VALUE_</code> is used as the seasonal period. If <code>_VALUE_</code> is missing for <code>_COMPONENT_=SEASONAL</code> , then the seasonal period is determined by the interval of the series.
<code>_FACTOR_</code>	applies only to the AR and MA portions of the ARIMA model. The value of <code>_FACTOR_</code> identifies the factor of the given AR or MA term. Therefore, the value of <code>_FACTOR_</code> is the same for all observations that are related to the same factor.
<code>_LAG_</code>	identifies the degree for differencing and AR and MA lags. If <code>_COMPONENT_=SEASONAL</code> , then the value in <code>_LAG_</code> is multiplied by the seasonal period indicated by the value of <code>_VALUE_</code> .
<code>_SHIFT_</code>	contains the shift value for transfer functions. This value is not processed by PROC X12, but it might be processed by other procedures in which transfer functions can be specified.
<code>_NOEST_</code>	indicates whether a parameter associated with the observation is to be estimated. For example, the NOINT option is indicated by <code>_COMPONENT_=CONSTANT</code> with <code>_NOEST_=1</code> and <code>_EST_=0</code> . <code>_NOEST_=1</code> indicates that the value in <code>_EST_</code> is a fixed value. <code>_NOEST_</code> pertains to the constant term, to AR and MA parameters, and to regression parameters.
<code>_EST_</code>	contains an initial or fixed value for a parameter associated with the observation that is to be estimated. <code>_NOEST_=1</code> indicates the value in <code>_EST_</code> is a fixed value. <code>_EST_</code> pertains to the constant term, to AR and MA parameters, and to regression parameters.
<code>_STDERR_</code>	contains output information about estimated parameters. The variable <code>_STDERR_</code> is not processed by the MDLINFOIN= data set for PROC X12. In the MDLINFOOUT= data set, <code>_STDERR_</code> contains the standard error that pertains to the estimated parameter in the variable <code>_EST_</code> .

<code>_TVALUE_</code>	contains output information about estimated parameters. The variable <code>_TVALUE_</code> is not processed by the MDLINFOIN= data set for PROC X12. In the MDLINFOOUT= data set, <code>_TVALUE_</code> contains the t value that pertains to the estimated parameter in the variable <code>_EST_</code> .
<code>_PVALUE_</code>	contains output information about estimated parameters. The variable <code>_PVALUE_</code> is not processed by the MDLINFOIN= data set for PROC X12. In the MDLINFOOUT= data set, <code>_PVALUE_</code> contains the p -value that pertains to the estimated parameter in the variable <code>_EST_</code> .

INEVENT= Data Set

The INEVENT= data set can contain the following variables. When a variable is omitted from the data set, that variable is assumed to have the default value for all observations. The default values are specified in the list.

<code>_NAME_</code>	specifies the event variable name. <code>_NAME_</code> is displayed with the case preserved. Since <code>_NAME_</code> is a SAS variable name, the event can be referenced by using any case. The <code>_NAME_</code> variable is required; there is no default.
<code>_CLASS_</code>	specifies the class of event: SIMPLE, COMBINATION, PREDEFINED. The default for <code>_CLASS_</code> is SIMPLE.
<code>_KEYNAME_</code>	contains either a date keyword (SIMPLE EVENT), a predefined event variable name (PREDEFINED EVENT), or an event name (COMBINATION EVENT). All <code>_KEYNAME_</code> values are displayed in upper case. However, if the <code>_KEYNAME_</code> value refers to an event name, then the actual name can be of mixed case. The default for <code>_KEYNAME_</code> is no keyname, designated by “.”.
<code>_STARTDATE_</code>	contains either the date timing value or the first date timing value to use in a do-list. The default for <code>_STARTDATE_</code> is no date, designated by a missing value.
<code>_ENDDATE_</code>	contains the last date timing value to use in a do-list. The default for <code>_ENDDATE_</code> is no date, designated by a missing value.
<code>_DATEINTRVL_</code>	contains the interval for the date do-list. The default for <code>_DATEINTRVL_</code> is no interval, designated by “.”.
<code>_STARTDT_</code>	contains either the datetime timing value or the first datetime timing value to use in a do-list. The default for <code>_STARTDT_</code> is no datetime, designated by a missing value.
<code>_ENDDT_</code>	contains the last datetime timing value to use in a do-list. The default for <code>_ENDDT_</code> is no datetime, designated by a missing value.
<code>_DTINTRVL_</code>	contains the interval for the datetime do-list. The default for <code>_DTINTRVL_</code> is no interval, designated by “.”.
<code>_STARTOBS_</code>	contains either the observation number timing value or the first observation number timing value to use in a do-list. The default for <code>_STARTOBS_</code> is no observation number, designated by a missing value.
<code>_ENDOBS_</code>	contains the last observation number timing value to use in a do-list. The default for <code>_ENDOBS_</code> is no observation number, designated by a missing value.
<code>_OBSINTRVL_</code>	contains the interval length of the observation number do-list. The default for <code>_OBSINTRVL_</code> is no interval, designated by “.”.

<code>_TYPE_</code>	specifies the type of event. The valid values of <code>_TYPE_</code> are POINT, LS, RAMP, TR, TEMPRAMP, TC, LIN, LINEAR, QUAD, CUBIC, INV, INVERSE, LOG, and LOGARITHMIC. The default for <code>_TYPE_</code> is POINT.
<code>_VALUE_</code>	specifies the value for nonzero observation. The default for <code>_VALUE_</code> is 1.0.
<code>_PULSE_</code>	specifies the interval that defines the units for the duration values. The default for <code>_PULSE_</code> is no interval, designated by “.”.
<code>_DUR_BEFORE_</code>	specifies the number of durations before the timing value. The default for <code>_DUR_BEFORE_</code> is 0.
<code>_DUR_AFTER_</code>	specifies the number of durations after the timing value. The default for <code>_DUR_AFTER_</code> is 0.
<code>_SLOPE_BEF_</code>	determines whether the curve is GROWTH or DECAY before the timing value for <code>_TYPE_=RAMP</code> , <code>_TYPE_=TEMPRAMP</code> , and <code>_TYPE_=TC</code> . Valid values are GROWTH and DECAY. The default for <code>_SLOPE_BEF_</code> is GROWTH.
<code>_SLOPE_AFT_</code>	determines whether the curve is GROWTH or DECAY after the timing value for <code>_TYPE_=RAMP</code> , <code>_TYPE_=TEMPRAMP</code> , and <code>_TYPE_=TC</code> . Valid values are GROWTH and DECAY. The default for <code>_SLOPE_AFT_</code> is GROWTH unless <code>_TYPE_=TC</code> ; then the default is DECAY.
<code>_SHIFT_</code>	specifies the number of <code>_PULSE_</code> intervals to shift the timing value. The shift can be positive (forward in time) or negative (backward in time). If <code>_PULSE_</code> is not specified, then the shift is in observations. The default for <code>_SHIFT_</code> is 0.
<code>_TCPARM_</code>	specifies the parameter for EVENT of TYPE=TC. The default for <code>_TCPARM_</code> is 0.5.
<code>_RULE_</code>	specifies the rule to use when combining events or when timing values of an event overlap. The valid values of <code>_RULE_</code> are ADD, MAX, MIN, MINNZ, MINMAG, and MULT. The default for <code>_RULE_</code> is ADD.
<code>_PERIOD_</code>	specifies the frequency interval at which the event should be repeated. If this value is missing, then the event is not periodic. The default for <code>_PERIOD_</code> is no interval, designated by “.”.
<code>_LABEL_</code>	specifies the label or description for the event. If a label is not specified, then the default label value is displayed as “.”. For events that produce dummy variables, either the user-supplied label or the default label is used. For COMPLEX events, the <code>_LABEL_</code> value is merely a description of the group of events.

OUTSTAT= Data Set

The OUTSTAT= data set can contain the following variables:

BY variables	sorts the statistics into BY groups. BY variables are included in this data set that match the BY variables used to process the series.
NAME	specifies the variable name of the time series to which the statistics apply.
STAT	describes the statistic that is stored in VALUE or CVALUE. STAT takes on the following values:

Period	the period of the series, 4 or 12.
Mode	the mode of the seasonal adjustment from the X11 statement. Possible values are ADD, MULT, LOGADD, and PSEUDOADD.
Start	the beginning of the model span expressed as <i>monyyyy</i> for monthly series or <i>yyyyQq</i> for quarterly series.
End	the end of the model span expressed as <i>monyyyy</i> for monthly series or <i>yyyyQq</i> for quarterly series.
NbFcst	the number of forecast observations.
SigmaLimLower	the lower sigma limit in standard deviation units.
SigmaLimUpper	the upper sigma limit in standard deviation units.
pLBQ_24	the Ljung-Box <i>Q</i> statistic of the residuals at lag 24, for monthly series. Note that lag 12 (pLBQ_12) and lag 16 (pLBQ_16) are included in the data set for quarterly series.
D8Fs	the stable seasonality <i>F</i> test value from Table D8.
D8Fm	the moving seasonality <i>F</i> test value from Table D8.
ISRatio	the final irregular-to-seasonal ratio from Table F 2.H.
SMA_ALL	the final seasonal moving average filter for all periods.
RSF	the residual seasonality <i>F</i> test value for Table D11 for the entire series.
RSF3	the residual seasonality <i>F</i> test value for Table D11 for the last three years.
RSFA	the residual seasonality <i>F</i> test value for Table D11.A for the entire series.
RSF3A	the residual seasonality <i>F</i> test value for Table D11.A for the last three years.
RSFR	the residual seasonality <i>F</i> test value for Table D11.R for the entire series.
RSF3R	the residual seasonality <i>F</i> test value for Table D11.R for the last three years.
TMA	the Henderson trend moving average filter selected.
ICRatio	the final irregular-to-trend cycle ratio from Table F 2.H.
E5sd	the standard deviation from Table E5.
E6sd	the standard deviation from Table E6.
E6Asd	the standard deviation from Table E6.A.

MCD	months of cyclical dominance.
Q	the overall level Q from Table F3.
Q2	Q overall level without M2 from Table F3.
FMT	indicates whether the format is numeric or character. FMT="NUM" if the value is numeric and stored in the VALUE variable. FMT="CHAR" if the value is a string and stored in the CVALUE variable.
VALUE	contains the numerical value of the statistic or missing if the statistic is of type character.
CVALUE	contains the character value of the text statistic or blank if the statistic is of type numeric.

Examples: X12 Procedure

Example 37.1: ARIMA Model Identification

This example shows typical PROC X12 statements that are used for ARIMA model identification. This example invokes the X12 procedure and uses the TRANSFORM and IDENTIFY statements. It specifies the time series data, takes the logarithm of the series (TRANSFORM statement), and generates ACFs and PACFs for the specified levels of differencing (IDENTIFY statement). The ACFs and PACFs for DIFF=1 and SDIFF=1 are shown in [Output 37.1.1](#), [Output 37.1.2](#), [Output 37.1.3](#), and [Output 37.1.4](#). The data set is the same as in the section “[Basic Seasonal Adjustment](#)” on page 2628.

The graphical displays are available when ODS Graphics is enabled. For more information about the graphics available in the X12 procedure, see the section “[ODS Graphics](#)” on page 2688.

```
proc x12 data=sales date=date;
  var sales;
  transform power=0;
  identify diff=(0,1) sdiff=(0,1);
run;
```

Output 37.1.1 ACFs (Nonseasonal Order=1 Seasonal Order=1)

Example 37.2: Model Estimation

After studying the output from [Example 37.1](#) and identifying the ARIMA part of the model as, for example, $(0\ 1\ 1)(0\ 1\ 1)_{12}$, you can replace the IDENTIFY statement with the ARIMA and ESTIMATE statements as follows:

```
proc x12 data=sales date=date;
  var sales;
  transform power=0;
  arima model=( 0,1,1 ) (0,1,1 ) ;
  estimate;
run ;
```

The parameter estimates and estimation summary statistics are shown in [Output 37.2.1](#).

Output 37.2.1 Estimation Data

Example 37.3: Seasonal Adjustment

Assuming that the model in [Example 37.2](#) is satisfactory, a seasonal adjustment that uses forecast extension can be performed by adding the X11 statement to the procedure. By default, the data is forecast one year ahead at the end of the series.

```
ods output D8A#1=SalesD8A_1;
ods output D8A#2=SalesD8A_2;
ods output D8A#3=SalesD8A_3;
ods output D8A#4=SalesD8A_4;
proc x12 data=sales date=date;
  var sales;
  transform power=0;
  arima model=( 0,1,1) (0,1,1) );
  estimate;
  x11;
run;

Example 37.4: RegARIMA Automatic Model Selection

This example demonstrates regARIMA modeling and TRAMO-based automatic model selection, which is available with the AUTOMDL statement. ODS SELECT statements are used to limit the displayed output to the model selection and estimation stages. The same data set is used as in the previous examples.

```

run;

```

The automatic model selection output is shown in [Output 37.4.1](#), [Output 37.4.2](#), and [Output 37.4.3](#). The first table, “ARIMA Estimate for Unit Root Identification,” gives details of the method that TRAMO uses to automatically select the orders of differencing. The second table, “Results of Unit Root Test for Identifying Orders of Differencing,” shows that a regular difference order of 1 and a seasonal difference order of 1 has been determined by TRAMO. The third table, “Models Estimated by Automatic ARIMA Model Selection Procedure,” shows all the models examined by the TRAMO-based method. The fourth table, “Best Five ARIMA Models Chosen by Automatic Modeling,” shows the top five models in order of rank and their BIC2 statistic. The fifth table, “Comparison of Automatically Selected Model and Default Model,” compares the model selected by the TRAMO model to the default X-12-ARIMA model. The sixth table, “Final Automatic Model Selection,” shows which model was actually selected.

Table 37.16 and Output 37.4.4 illustrate the regARIMA modeling method. Table 37.16 shows the relationship between the output variables in PROC X12 that results from a regARIMA model. Note that some of these formulas apply only to this example. Output 37.4.4 shows the values of these variables for the first 23 observations in the example.

Table 37.16 regARIMA Output Variables and Descriptions

Table	Title	Type	Formula
A1	Time series data (for the span analyzed)	Data	Input
A2	Prior-adjustment factors leap year (from trading day regression) adjustments	Factor	Calculated from regression
A6	RegARIMA trading day component leap year prior adjustments included from Table A2	Factor	Calculated from regression
B1	Original series (prior adjusted) (adjusted for regARIMA factors)	Data	$B1 = A1/A6 *$ * because only TD specified
C17	Final weights for irregular component	Factor	Calculated using moving standard deviation
C20	Final extreme value adjustment factors	Factor	Calculated using C16 and C17
D1	Modified original data, D iteration	Data	$D1 = B1/C20 **$ $D1 = C19/C20$ ** C19=B1 in this example
D7	Preliminary trend cycle, D iteration	Data	Calculated using Henderson moving average
D8	Final unmodified SI ratios	Factor	$D8 = B1/D7 ***$ $D8 = C19/D7$ *** TD specified in regression
D9	Final replacement values for SI ratios	Factor	If C17 shows extreme values, $D9 = D1/D7$; $D9 = .$ otherwise
D10	Final seasonal factors	Factor	Calculated using moving averages
D11	Final seasonally adjusted data (also adjusted for trading day)	Data	$D11 = B1/D10 ****$ $D11 = C19/D10$ **** $B1 = C19$ for this example
D12	Final trend cycle	Data	Calculated using Henderson moving average
D13	Final irregular component	Factor	$D13 = D11/D12$
D16	Combined adjustment factors (includes seasonal, trading day factors)	Factor	$D16 = A1/D11$
D18	Combined calendar adjustment factors (includes trading day factors)	Factor	$D18 = D16/D10$ $D18 = A6 *****$ ***** regression TD is the only calendar adjustment factor in this example

Example 37.5: Automatic Outlier Detection

This example demonstrates the use of the OUTLIER statement to automatically detect and remove outliers from a time series to be seasonally adjusted. The data set is the same as in the section “Basic Seasonal Adjustment” on page 2628 and the previous examples. Adding the OUTLIER statement to Example 37.3 requests that outliers be detected by using the default critical value as described in the section “OUTLIER Statement” on page 2655. The tables associated with outlier detection for this example are shown in Output 37.5.1. The first table shows the critical values; the second table shows that a single potential outlier was identified; the third table shows the estimates for the ARMA parameters. Since no outliers are included in the regression model, the “Regression Model Parameter Estimates” table is not displayed. Because only a potential outlier was identified, and not an actual outlier, in this case the A1 series and the B1 series are identical.

```
title 'Automatic Outlier Identification';
proc x12 data=sales date=date;
  var sales;
  transform function=log;
  arima model=( 0,1,1)(0,1,1) );
  outlier;
  estimate;
  x11;
  output out=nooutlier a1 b1 d10;
run ;
```

Output 37.5.1 PROC X12 Output When Potential Outliers Are Identified

Automatic Outlier Identification			
The X12 Procedure			
Critical Values to use in Outlier Detection For Variable sales			
Begin	SEP1978		
End	AUG1990		
Observations	144		
Method	Add One		
AO Critical Value	3.889838		
LS Critical Value	3.889838		

NOTE: The following time series values might later be identified as outliers when data are added or revised. They were not identified as outliers in this run either because their test t-statistics were slightly below the critical value or because they were eliminated during the backward deletion step of the identification procedure, when a non-robust t-statistic is used.

Potential Outliers For Variable sales			
Type of Outlier	Date	t Value for AO	t Value for LS
AO	NOV1989	-3.48	-1.51

Output 37.5.1 *continued*

Exact ARMA Maximum Likelihood Estimation For Variable sales					
Parameter	Lag	Estimate	Standard Error	t Value	Pr > t
Nonseasonal MA	1	0.40181	0.07887	5.09	<.0001
Seasonal MA	12	0.55695	0.07626	7.30	<.0001

In the next example, reducing the critical value to 3.3 causes the outlier identification routine to more aggressively identify outliers as shown in [Output 37.5.2](#). The first table shows the critical values. The second table shows that three additive outliers and a level shift have been included in the regression model. The third table shows how the inclusion of outliers in the model affects the ARMA parameters.

```
proc x12 data=sales date=date;
  var sales;
  transform function=log;
  arima model=((0,1,1) (0,1,1));
  outlier cv=3.3;
  estimate;
  x11;

The first 50 observations of the A1, A8, A8AO, A8LS, B1, and D10 series are displayed in [Output 37.5.3](#). You can confirm the following relationships from the data:

$$A8 = A8AO \times A8LS$$

$$B1 = A1/A8$$

The seasonal factors are stored in the variable sales_D10.

50	OCT82	196	1.10156	1.00000	1.10156	177.930	0.89970

From the two previous examples, you can examine how outlier detection affects the seasonally adjusted series. [Output 37.5.4](#) shows a plot of A1 versus B1 in the series where outliers are detected. B1 has been adjusted for the additive outliers and the level shift.

```
proc sgplot data=outlier;
  series x=date y=sales_A1 / name='A1' markers
        markerattrs=(color=red symbol='circle')
        lineattrs=(color=red);
  series x=date y=sales_B1 / name='B1' markers
        markerattrs=(color=black symbol='asterisk')
        lineattrs=(color=black);
  yaxis label='Original and Outlier Adjusted Time Series';
run;
```

Output 37.5.4 Original Series and Outlier Adjusted Series

Output 37.5.5 compares the seasonal factors (table D10) of the series unadjusted for outliers to the series adjusted for outliers. The seasonal factors are based on the B1 series.

```
data both;
  merge nooutlier(rename=(sales_D10=unadj_D10)) outlier;
run;

title 'Results of Outlier Identification on Final Seasonal Factors';
proc sgplot data=both;
  series x=date y=unadj_D10 / name='unadjusted' markers
        markerattrs=(color=red symbol='circle')
        lineattrs=(color=red)
        legendlabel='Unadjusted for Outliers';
  series x=date y=sales_D10 / name='adjusted' markers
        markerattrs=(color=blue symbol='asterisk')
        lineattrs=(color=blue)
        legendlabel='Adjusted for Outliers';
  yaxis label='Final Seasonal Factors';
run;
```

Output 37.5.5 Seasonal Factors Based on Original and Outlier Adjusted Series

Example 37.6: User-Defined Regressors

This example demonstrates the use of the `USERVAR=` option in the `REGRESSION` statement to include user-defined regressors in the `regARIMA` model. The user-defined regressors must be defined as nonmissing values for the span of the series being modeled plus any backcast or forecast values. Suppose you have the data set `SALESdata` with 132 monthly observations beginning in January of 1949.

```
title 'Data Set to be Seasonally Adjusted';
data salesdata;
    set sashelp.air(obs=132);
run;
```

Because the `regARIMA` model forecasts one year ahead, you must define the regressor for 144 observations that start in January of 1949. You can construct a simple length-of-month regressor by using the following `DATA` step:

```
title 'User-defined Regressor for Data to be Seasonally Adjusted';
data regressors(keep=date LengthOfMonth);
    set sashelp.air;
    LengthOfMonth = INTNX('MONTH',date,1) - date;
run;
```

In this example, the two data sets are merged to use them as input to `PROC X12`. You can also use the `AUXDATA=` data set to input user-defined regressors. See [Example 37.11](#) for more information. The `BY` statement is used to align the regressors with the time series by the time ID variable `DATE`.

```
title 'Data Set Containing Series and Regressors';
data datain;
    merge regressors salesdata;
    by date;
run;

proc print data=datain(firstobs=121);
run;
```

The last 24 observations of the input data set are displayed in [Output 37.6.1](#). The regressor variable is defined for one year (12 observations) beyond the span of the time series to be seasonally adjusted.

Output 37.6.1 PROC X12 Input Data Set with User-Defined Regressor

Data Set Containing Series and Regressors				
Obs	DATE	Length OfMonth	AIR	
121	JAN59	31	360	
122	FEB59	28	342	
123	MAR59	31	406	
124	APR59	30	396	
125	MAY59	31	420	
126	JUN59	30	472	
127	JUL59	31	548	
128	AUG59	31	559	
129	SEP59	30	463	
130	OCT59	31	407	
131	NOV59	30	362	
132	DEC59	31	405	
133	JAN60	31	.	
134	FEB60	29	.	
135	MAR60	31	.	
136	APR60	30	.	
137	MAY60	31	.	
138	JUN60	30	.	
139	JUL60	31	.	
140	AUG60	31	.	
141	SEP60	30	.	
142	OCT60	31	.	
143	NOV60	30	.	
144	DEC60	31	.	

The DATAIN data set is now ready to be used as input to PROC X12. The DATE= variable and the user-defined regressors are automatically excluded from the variables to be seasonally adjusted.

```

title 'regARIMA Model with User-defined Regressor';
proc x12 data=datain date=DATE interval=MONTH plots=none;
  transform function=log;
  regression uservar=LengthOfMonth / usertype=lom;
  automdl;
  x11;
  output out=out a1 d11;
run;

```

The parameter estimates for the regARIMA model are shown in [Output 37.6.2](#)

Output 37.6.2 PROC X12 Output for User-Defined Regression Parameter

regARIMA Model with User-defined Regressor						
The X12 Procedure						
Regression Model Parameter Estimates For Variable AIR						
Type	Parameter	NoEst	Estimate	Standard Error	t Value	Pr > t
User Defined	LengthOfMonth	Est	0.04683	0.01834	2.55	0.0119
Exact ARMA Maximum Likelihood Estimation For Variable AIR						
Parameter	Lag		Estimate	Standard Error	t Value	Pr > t
Nonseasonal MA	1		0.33678	0.08506	3.96	0.0001
Seasonal MA	12		0.54078	0.07726	7.00	<.0001

Another way to include user-defined regressors in the regARIMA model is to specify the **SPAN=** option in the PROC X12 statement. The following user-defined regressor is similar to the one defined previously. However, this length-of-month regressor is mean adjusted. Using a zero-mean regressor prevents the regressor from altering the level of the series. In this instance, the series to be seasonally adjusted, AIR, and the regression variable, LengthOfMonth, have nonmissing observations at all time periods in the data set DATAIN.

```

title 'User-defined Regressor for Data to be Seasonally Adjusted, Mean Adjusted';
data datain(keep=date AIR LengthOfMonth);
  set sashelp.air;
  LengthOfMonth = INTNX('MONTH',date,1) - date - 30.4375;
run;

```

Because the default forecast period is one year ahead, the span of the series must be limited to one year before the end of the regression variable definition to forecast using the regression variable LengthOfMonth,

```

title 'regARIMA Model with Zero-Mean User-defined Regressor';
proc x12 data=datain date=DATE interval=MONTH span=(,DEC1959) plots=none;
  transform function=log;
  regression uservar=LengthOfMonth / usertype=lom;
  automdl;
  x11;
  output out=outzm a1 d11;
run;

```

The parameter estimates for the regARIMA model that are estimated using a zero-mean regressor are shown in [Output 37.6.3](#)

Output 37.6.3 PROC X12 Output for Zero-Mean User-Defined Regression Parameter

regARIMA Model with Zero-Mean User-defined Regressor						
The X12 Procedure						
Regression Model Parameter Estimates						
For Variable AIR						
Type	Parameter	NoEst	Estimate	Standard Error	t Value	Pr > t
User Defined	LengthOfMonth	Est	0.04683	0.01834	2.55	0.0119
Exact ARMA Maximum Likelihood Estimation						
For Variable AIR						
Parameter	Lag		Estimate	Standard Error	t Value	Pr > t
Nonseasonal MA	1		0.33678	0.08506	3.96	0.0001
Seasonal MA	12		0.54078	0.07726	7.00	<.0001

Specifying USERTYPE=LOM causes the regression effect to be removed from the seasonally adjusted series. The effect of the mean of the regression variable on the seasonally adjusted series can be seen by examining the plots of the original series and the seasonally adjusted series.

```

title 'regARIMA Model with Non-Zero-Mean User-Defined Regressor';
proc sgplot data=out;
  series x=date y=air_A1 / name = "A1" markers
        markerattrs=(color=red symbol='asterisk')
        lineattrs=(color=red);
  series x=date y=air_D11 / name= "D11" markers
        markerattrs=(symbol='circle')
        lineattrs=(color=blue);
  yaxis label='Original and Seasonally Adjusted Time Series';
run;

title 'regARIMA Model with Zero-Mean User-Defined Regressor';
proc sgplot data=outzm;
  series x=date y=air_A1 / name = "A1" markers
        markerattrs=(color=red symbol='asterisk')
        lineattrs=(color=red);
  series x=date y=air_D11 / name= "D11" markers
        markerattrs=(symbol='circle')
        lineattrs=(color=blue);
  yaxis label='Original and Seasonally Adjusted Time Series';
run;

```

The graph of the original and seasonally adjusted series in [Output 37.6.4](#) shows that the level of the seasonally adjusted series has been altered due to the user-defined regressor. The graph of the original and seasonally adjusted series in [Output 37.6.5](#) shows that the level of the seasonally adjusted series is the same as the original series since the user-defined regressor has zero-mean.

Output 37.6.4 Plot of Original and Seasonally Adjusted Data

Output 37.6.5 Plot of Original and Seasonally Adjusted Data (Zero-Mean Regressor)

When actual values are available for the forecast periods, information about forecast error is available in the output. [Output 37.6.6](#) shows the table “Forecasts and Standard Errors of the Transformed Data on the Original Scale” for a series with missing values in the forecast period. [Output 37.6.7](#) shows the table “Forecasts and Standard Errors of the Transformed Data on the Original Scale” for a series with actual values in the forecast period. Thus, it is more desirable to use SPAN= option to limit the span of a series if the actual values are available for the forecast period.

Output 37.6.6 PROC X12 Forecasts for Series Extended with Missing Values

Suppose that after examining the output from the preceding example, you decide that an Easter regressor should be added to the model. The following statements create a data set with the model identified above and adds a U.S. Census Bureau Predefined Easter(25) regressor. The new model data set to be used as input in the MDLINFOIN= option is displayed in the data set shown in [Output 37.7.3](#).

```
data pluseaster;
  _NAME_ = 'y';
  _MODELTYPE_ = 'REG';
  _MODELPART_ = 'PREDEFINED';
  _COMPONENT_ = 'SCALE';
  _PARMTYPE_ = 'EASTER';
  _DSVAR_ = 'EASTER';
  _VALUE_ = 25;
run;

data mdlpluseaster;
  set mdl;
run;

proc append base=mdlpluseaster data=pluseaster force;
run;

proc print data=mdlpluseaster;
run;
```

Example 37.8: Setting Regression Parameters

This example illustrates the use of fixed regression parameters in PROC X12. Suppose that you have the same data set as in the section “[Basic Seasonal Adjustment](#)” on page 2628. You can specify the following statements to use TRAMO to automatically identify a model that includes a U.S. Census Bureau Easter(25) regressor:

```
title 'Estimate Easter(25) Parameter';
proc x12 data=sales date=date MdlInfoOut=mdlout1;
  var sales;
  regression predefined=easter(25);
  automdl;
run ;
```

The displayed results are shown in [Output 37.8.1](#).

Output 37.8.1 Automatic Model ID with Easter(25) Regression

Estimate Easter(25) Parameter						
The X12 Procedure						
Regression Model Parameter Estimates

To fix the Easter(25) parameter while adding a regressor that is weighted according to the number of Saturdays in a month, either use the REGRESSION and EVENT statements or create a MDLINFOIN= data set. The following statements show the method for using the REGRESSION statement to fix the EASTER parameter and the EVENT statement to add the SATURDAY regressor. The output is shown in [Output 37.8.3](#).

```

title 'Use SAS Statements to Alter Model';
proc x12 data=sales date=date MdlInfoOut=mdlout2grm;
  var sales;
  regression predefined=easter(25) / b=-5.029298 F;
  event Saturday;
  automdl;
run ;

```

Output 37.8.3 Automatic Model ID with Fixed Easter(25) and Saturday Regression

Use SAS Statements to Alter Model						
The X12 Procedure						
Regression Model Parameter Estimates For Variable sales

The MDLINFOOUT= data set provides a method for comparing the results of the model identification. The data set mdlout3grm that results from using the MODEL= option in the ARIMA statement can be compared to the data set mdlout2DS that results from using the MDLINFOIN= data set with initial values for the AR

and MA parameters. The mdlout2DS data set is shown in [Output 37.8.7](#), and the results of the comparison are shown in [Output 37.8.8](#). The slight difference in the estimated parameters can be attributed to the difference in the initial values for the AR and MA parameters.

Example 37.9: Creating an MDLINFO= Data Set for Use with the PICKMDL Statement

This example illustrates how you can create a data set for use in the [PICKMDL](#) statement that contains five commonly used ARIMA models:

- ARIMA (0 1 1)(0 1 1)s
- ARIMA (0 1 2)(0 1 1)s
- ARIMA (2 1 0)(0 1 1)s
- ARIMA (0 2 2)(0 1 1)s
- ARIMA (2 1 2)(0 1 1)s

The following macro code creates a MDLINFOIN= data set for a general ARIMA model:

```

%macro makemodel(name,p,d,q,sp,sd,sq,model);
  data "&name" (keep= _MODELTYPE_ _MODELPART_ _COMPONENT_
                     _DSVAR_ _PARMTYPE_ _FACTOR_ _LAG_
                     _LABEL_ );
    length _MODELTYPE_ _MODELPART_ _COMPONENT_ _DSVAR_
           _PARMTYPE_ $32;

```

```

length _FACTOR_ _LAG_ 8;
length _LABEL_ $32;

_MODELTYPE_="ARIMA";
_MODELPART_="FORECAST";
_DSVAR_=".";

_LABEL_="(||"&p"||" ||"&d"||" ||"&q"||") (||
        "&sp"||" ||"&sd"||" ||"&sq"||")s";

/* nonseasonal AR factors */
_COMPONENT_="NONSEASONAL";
_PARMTYPE_="AR";
_FACTOR_=1;
do _LAG_=1 to &p;
    output;
end;

/* seasonal AR factors */
_COMPONENT_="SEASONAL";
_PARMTYPE_="AR";
_FACTOR_=2;
do _LAG_=1 to &sp;
    output;
end;

/* nonseasonal MA factors */
_COMPONENT_="NONSEASONAL";
_PARMTYPE_="MA";
_FACTOR_=1;
do _LAG_=1 to &q;
    output;
end;

/* seasonal MA factors */
_COMPONENT_="SEASONAL";
_PARMTYPE_="MA";
_FACTOR_=2;
do _LAG_=1 to &sq;
    output;
end;

/* nonseasonal DIF */
_COMPONENT_="NONSEASONAL";
_PARMTYPE_="DIF";
_FACTOR_=1;
_LAG_=1;
do i_=1 to &d;
    output;
end;

/* seasonal DIF */
_COMPONENT_="SEASONAL";
_PARMTYPE_="DIF";

```

```

    _FACTOR_=2;
    _LAG_=1;
    do i_=1 to &sd;
        output;
    end;

run;
data sasuser.&name;
    length _MODEL_ $32;
    set "&name";
    _MODEL_ = "&model";
run;

%mend makemodel;

```

The following SAS statements use the macro to generate a data set with some commonly used models for use in the [PICKMDL](#) statement:

```

%makemodel(x12mdl1,0,1,1,0,1,1,Model1);
%makemodel(x12mdl2,0,1,2,0,1,1,Model2);

The following statements reverse the order of the models in the input data set. The default METHOD=FIRST option is used to select the model. The chosen model is shown in the mdlchosen data set in [Output 37.9.3](#). With METHOD=FIRST, a different model is chosen because the order is changed.

```

data Models;
  length _NAME_ $32;
  set sasuser.x12mdl5 sasuser.x12mdl4 sasuser.x12mdl3
      sasuser.x12mdl2 sasuser.x12mdl1 ;
  _NAME_ = 'sales';
run;

```

```

proc x12 data=sales date=date mdlinfoin=Models mdlinfoout=mdlchosen;
  var sales;
  transform function=log;
  pickmdl method=first;
run;

The following example shows the use of **PICKMDL** statement option **METHOD=BEST** to select the model. The chosen model is shown in the mdlchosen data set in [Output 37.9.4](#). With **METHOD=BEST**, a different model is chosen than either of the previous models chosen. Because the order in which the models occur in

the MDLINFOIN= data set affects model selection when METHOD=FIRST is specified, it is a common practice to list models from the simplest model to the most complex in the MDLINFOIN= data set that is used in conjunction with the PICKMDL statement.

```
proc x12 data=sales date=date mdlinfoin=Models mdlinfoout=mdlchosen;
  var sales;
  transform function=log;
  pickmdl method=best;
run;

title 'Chosen Model';
proc print data=mdlchosen;
run ;
```

Example 37.10: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. Using the same data set as in the section “[Basic Seasonal Adjustment](#)” on page 2628 and the previous examples, a spectral plot of the original series is displayed in [Output 37.10.1](#).

The graphical displays are available when ODS Graphics is enabled. For specific information about the graphics available in the X12 procedure, see the section “[ODS Graphics](#)” on page 2688.

```
proc x12 data=sales date=date;
    var sales;
run;
```

Output 37.10.1 Spectral Plot for Original Data

Example 37.11: AUXDATA= Data Set

This example demonstrates the use of the AUXDATA= data set to input user-defined regressors for use in the regARIMA model. User-defined regressors are often economic indicators, but in this example a user-defined regressor is generated in the following statements:

```
data auxreg(keep=date lengthofmonth);
  set sales;
  lengthofmonth = (INTNX('MONTH',date,1) - date) - (365/12);
  format date monyy.;
run;
```

When you use the AUXDATA= data set, it is not necessary to merge the user-defined regressor data set with the DATA= data set. The following statements input the regressor lengthofmonth in the data set auxreg. The regressor lengthofmonth is specified in the REGRESSION statement, and the data set auxreg is specified in the AUXDATA= option in the PROC X12 statement.

```
title 'Align lengthofmonth Regressor from Auxreg to First Three Years';
ods select regParameterEstimates;
proc x12 data=sales(obs=36) date=date auxdata=auxreg;
  var sales;
  regression uservar=lengthofmonth;
  arima model=((0 1 1) (0 1 1));
  estimate;
run;

title 'Align lengthofmonth Regressor from Auxreg to Second Three Years';
ods select regParameterEstimates;
proc x12 data=sales(firstobs=37 obs=72) date=date auxdata=auxreg;
  var sales;
  regression uservar=lengthofmonth;
  arima model=((0 1 1) (0 1 1));
  estimate;
run;
```

Output 37.11.1 and Output 37.11.2 display the parameter estimates for the two series.

Output 37.11.1 Using Regressors in the AUXDATA= Data for the First Three Years of Series

Align lengthofmonth Regressor from Auxreg to First Three Years						
The X12 Procedure						
Regression Model Parameter Estimates						
For Variable sales						
Type	Parameter	NoEst	Estimate	Standard Error	t Value	Pr > t
User Defined	lengthofmonth	Est	2.98046	5.36251	0.56	0.5840

Output 37.11.2 Using Regressors in the AUXDATA= Data for the Second Three Years of Series

Align lengthofmonth Regressor from Auxreg to Second Three Years						
The X12 Procedure						
Regression Model Parameter Estimates						
For Variable sales						
Type	Parameter	NoEst	Estimate	Standard Error	t Value	Pr > t
User Defined	lengthofmonth	Est	-0.51215	8.43145	-0.06	0.9521

The X12 procedure uses the date variable in the sales data set and the auxreg data set to align the user-defined regressors.

In the following example, the DATA= data set salesby contains BY groups. The X12 procedure aligns the regressor in the auxreg data set to each BY group in the salesby data set according to the variable date that is specified by the DATE= option in the PROC X12 statement. The variable date must be present in the auxreg data set to align the values.

```
data salesby;
  set sales(obs=72);
  if ( _n_ < 37 ) then by=1;
  else by=2;
run;
ods select regParameterEstimates;
title 'Align lengthofmonth Regressor from Auxreg to BY Groups';
proc x12 data=salesby date=date auxdata=auxreg;
  var sales;
  by by;
  regression uservar=lengthofmonth;
  arima model=((0 1 1) (0 1 1));
  estimate;
run;
```

The results in [Output 37.11.3](#) match the previous results in [Output 37.11.1](#) and [Output 37.11.2](#).

Output 37.11.3 Using Regressors in the AUXDATA= Data with BY Groups

Align lengthofmonth Regressor from Auxreg to BY Groups						
----- by=1 -----						
The X12 Procedure						
Regression Model Parameter Estimates						
For Variable sales						
Type	Parameter	NoEst	Estimate	Standard Error	t Value	Pr > t
User Defined	lengthofmonth	Est	2.98046	5.36251	0.56	0.5840

Output 37.11.3 continued

Align lengthofmonth Regressor from Auxreg to BY Groups						
----- by=2 -----						
The X12 Procedure						
Regression Model Parameter Estimates						
For Variable sales						
Type	Parameter	NoEst	Estimate	Standard Error	t Value	Pr > t
User Defined	lengthofmonth	Est	-0.51215	8.43145	-0.06	0.9521

Overview: SASECRSP Interface Engine

Introduction

The SASECRSP interface engine in SAS/ETS software enables SAS users to access and process time series, events, portfolios, and group data that reside in Center for Research in Security Prices databases (CRSPAccess data). It also provides a seamless interface between CRSP and SAS data processing. Currently, the SASECRSP engine supports access of CRSP US Stock Databases and CRSP Indices Databases.

Opening a Database

The SASECRSP interface engine uses the LIBNAME statement to enable you to specify which CRSPAccess database you want to access and how you want to select time series or events from that database.

To specify the database, you supply the combination of a physical path to indicate the location of the CRSPAccess data files and a set identifier (SETID) to identify the selected database from those available at the physical path. Specify one SETID from [Table 38.1](#). Notice that the CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars that provide the time ID variables and enable the libref to be assigned successfully. If your database SETID is 250, use the SASEXCCM interface to access your data. For more information about the SASEXCCM interface engine, see Chapter 40, “[The SASEXCCM Interface Engine](#).” Because CRSP no longer supports the CPZ data format, the SASECRSP engine no longer supports the SETID 200 (CRSP/Compustat Merged, CCM) data access.

Table 38.1 CRSPAccess Databases SETIDs

SETID	Data Set
10	CRSP Stock, daily data
20	CRSP Stock, monthly data
400	CRSP Indices data, monthly index groups
420	CRSP Indices data, monthly index series
440	CRSP Indices data, daily index groups
460	CRSP Indices data, daily index series

Usually you do not want to open the entire CRSPAccess database, so for efficiency and ease of use, the SASECRSP engine supports a variety of options for performing data selection on your CRSPAccess database by using the LIBNAME statement. These options enable you to open and retrieve data for only the portion of the database that you want. The availability of some of these options depends on the type of database that you open.

CRSP US Stock Databases

When accessing the CRSP US Stock Databases, you can select which securities to access by specifying their PERMNOs with the PERMNO= option. A PERMNO is CRSP’s unique permanent issue identification number and the primary key for its stock databases. Alternatively, a number of secondary keys can be used to select stock data. For example, you can use the PERMCO= option to read selected securities based

on CRSP's unique permanent company identification number, PERMCO. A full list of possible keys for accessing CRSP Stock data is shown in [Table 38.2](#).

Table 38.2 Keys for Accessing CRSP Stock Data

Key	Access By
PERMNO	CRSP's unique permanent issue identification number. This is the primary key for CRSP Stock Databases.
PERMCO	CRSP's unique permanent company identification number
CUSIP	CUSIP number
HCUSIP	Historical CUSIP
SICCD	Standard industrial classification (SIC) code
TICKER	Ticker symbol (for active companies only)

CRSP/Compustat Merged Databases—No Longer Supported by the SASECRSP Engine

Use the SASEXCCM interface engine instead of the SASECRSP interface engine to access your Xpressfeed CCM data. The SASEXCCM interface engine provides data item handling access methods by using CRSPAccess version 3.23. For a detailed description of this new SAS/ETS interface engine, see Chapter 40, “[The SASEXCCM Interface Engine](#).”

Because CRSPAccess version 3.23 does not support CPZ data (legacy Compustat data format for SETID 200), the SASECRSP engine issues the following error messages when you specify the SETID=200 option and/or the CRSPLINKPATH= option:

```
ERROR: Use the SASEXCCM engine instead of the SASECRSP engine for CCM access.
The CPZ data format needed for SETID=200 and the CRSPLINKPATH= options
was last shipped in July 2011 and is no longer supported by CRSP.
Use of the SASECRSP engine for this purpose is not allowed:
Depreciated calendar configurations can result in fatal errors,
corrupted memory, tracebacks, exceptions, or incorrect results
for all libref assignments that follow the deassignment
of a CCM/CRSPLINKPATH libref.
ERROR: Engine is unable to open crspdb CPZ200606
with SETID 200. Check that your CRSP database contains the
crsp_ca_ref_2.bin file.
```

CRSP Indices Databases

When accessing the CRSP Indices Databases, you can select which indices to access by specifying their INDNOs. INDNO is the primary key for the CRSP Indices Databases. You can specify which INDNO to use by specifying the INDNO= option. No secondary key access is supported for CRSP Indices. A full list of possible keys for accessing CRSP Indices data is shown in [Table 38.3](#).

Table 38.3 Keys for Accessing CRSP Indices Data

Key	Access By
INDNO	CRSP's unique permanent index identifier number. This is the primary key for CRSP Indices Databases. It enables you to specify which index series or groups you want to select.

Regardless of which database you access, you can always use the INSET= and RANGE= options for subsetting and selection. The RANGE= option subsets the data by date. The INSET= option enables you to specify which issues or companies to select from the CRSP Indices data by using an input SAS data set.

Using Your Opened Database

After the libref is assigned, the database is opened. You can retrieve data for any member that you want in the opened database. For a complete description of available data sets and their fields, see the section “[Data Elements Reference: SASECRSP Interface Engine](#)” on page 2768. You can also use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. Because CRSP and SAS use three different date representations, you can use the CRSP date formats, informats, and functions that the SASECRSP engine provides for your data processing needs. For more information about dates in the SASECRSP engine, see the section “[Understanding CRSP Date Formats, Informats, and Functions](#)” on page 2765 and [Example 38.6](#) later in this chapter.

The SASECRSP engine supports Linux X64 (64-bit), Solaris Sun Ultra Sparc, Solaris on Intel x86, and Windows.

Getting Started: SASECRSP Interface Engine

Structure of a SAS Data Set That Contains Time Series Data

SAS requires time series data to be in a specific form that is recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain points in time. The time at which observations are recorded can be included in the data set as a time ID variable. Because CRSP sets the date at the end of a time period instead of at the beginning, the SASECRSP interface engine follows this convention. For example, the time ID variable for any particular month in a monthly time series is set to the last trading day of that month.

The SASECRSP engine provides several different time ID variables, depending on the data member that is opened. For most members, a time ID variable named CALDT is provided. CALDT provides a day-based calendar date and is in a CRSP date format. The dates are stored as an offset in an array of trading days or a trading-day calendar. Five different CRSP trading-day calendars are available; which calendar is used depends on the frequency of the data member. For example, the CRSP date for a daily time series refers to a daily trading-day calendar.

The five trading-day calendar frequencies are annual, quarterly, monthly, weekly, and daily. For convenience, the format and informat for the frequency field are set so that the CRSP date is automatically converted to an integer date representation when viewed or printed. For data programming, the SASECRSP engine provides 23 different user functions for date conversions between CRSP, SAS, and integer dates.

Reading CRSP Data Files

The SASECRSP engine supports reading time series, events, portfolios, and group data from CRSPAccess databases. The SETID that you specify determines the database that is read. See [Table 38.1](#) for a list of possible databases. The CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars that provide the time ID variables and enable the libref to be successfully assigned.

Using the SAS DATA Step

You can store the selected series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. After the data are stored in a SAS data set, you can use them as you would use data in any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure, and you can report information about the contents of your data set by using the CONTENTS procedure.

You can also create a view of the CRSPAccess database by using the SQL procedure in conjunction with a SASECRSP libref.

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment. To do so, select the SASECRSP engine libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking the desired output data set libref in the LIBNAME window of the SAS windowing environment. Type **Viewtable** on the SAS command line to view any of your SASECRSP engine tables, views, or librefs both for input and output data sets.

Before you use the **Viewtable** command, it is recommended that you store your output data sets in a physical folder or library that is separate from the folder or library used for your input databases. (The default location for output data sets is the SAS Work library.)

Using CRSP Date Formats, Informats, and Functions

Historically, CRSP has used two different methods to represent dates, and SAS has used a third. The SASECRSP engine provides 23 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. For more information, see the section “[Understanding CRSP Date Formats, Informats, and Functions](#)” on page 2765.

Syntax: SASECRSP Interface Engine

The SASECRSP engine uses standard engine syntax. The options that the SASECRSP engine uses are summarized in [Table 38.4](#).

Table 38.4 Summary of SASECRSP Engine Options

Option	Description
SETID=	specifies which CRSP database subset to open. This option is required. See Table 38.1 for complete list of supported SETIDs.
PERMNO=	specifies a CRSP PERMNO to be selected for access
PERMCO=	specifies a CRSP PERMCO to be selected for access
CUSIP=	specifies a current CUSIP to be selected for access
HCUSIP=	specifies a historic CUSIP to be selected for access
TICKER=	specifies a ticker to be selected for access (for active companies only)
SICCD=	specifies a SIC code to be selected for access
INDNO=	specifies a CRSP INDNO to be selected for access
RANGE=	specifies the range of data to keep in format 'YYYYMMDD-YYYYMMDD'
INSET=	uses a SAS data set named Setname as input for issues

The LIBNAME *libref* SASECRSP Statement

LIBNAME *libref* SASECRSP '*physical name*' options ;

The physical name that the LIBNAME statement requires should point to the directory of CRSPAccess data files where the CRSP database that you want to open is located. Note that the physical name **must** end in a slash for UNIX environments and a backslash for Windows environments.

The CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars. The CRSP environment variable CRSPDB_SASCAL is necessary for the SASECRSP libref to be assigned successfully. This environment variable should be defined automatically either by the CRSP software installation or, in later versions, by the CRSP data installation. Because occasionally the variable is not set properly, always check to ensure that the CRSPDB_SASCAL environment variable is set to the location where your most recent CRSP data reside. Remember to include the final slash or backslash as required.

After the libref is assigned, you can access any of the available data sets or members within the opened database. For a complete description of available data sets and their fields, see the section “[Data Elements Reference: SASECRSP Interface Engine](#)” on page 2768.

You can specify the following options.

SETID=*crsp_setidnumber*

specifies the CRSP database that you want to read from. SETID= is a required option. Choose one SETID from the six possible values in [Table 38.1](#). The SETID limits the frequency selection of time series that are included in the SAS data set.

For example, to access monthly CRSP US Stock data, you would use the following statements:

```
LIBNAME myLib sasecrsp 'physical-name'
      SETID=20;
```

PERMNO=*crsp_permnumber*

enables you to select data from your CRSP database by the PERMNO (or other keys) that you specify. A PERMNO is CRSP's unique permanent issue identification number. There is no limit to the number of *crsp_permnumber* options that you can use. By default, the SASECRSP engine reads all keys for the CRSPAccess database that you specified in your SASECRSP libref.

From a performance standpoint, the PERMNO= option enables efficient random access and reads *only* the data for the PERMNOs specified.

For example, the following LIBNAME statement reads data only for Microsoft Corporation (PERMNO=10107) and International Business Machines Corporation (PERMNO=12490) by using the primary PERMNO key and thus is very efficient:

```
LIBNAME myLib sasecrsp 'physical-name'
      SETID=20
      PERMNO=10107
      PERMNO=12490;
```

The PERMCO=, CUSIP=, HCUSIP=, SICCD=, TICKER=, and INDNO= options behave similarly, and you can use them in conjunction with or in place of the PERMNO= option. For example, you could use the following statement to access monthly data for Microsoft and IBM:

```
LIBNAME myLib sasecrsp 'physical-name'
      SETID=20
      TICKER='MSFT'
      CUSIP=59491810;
```

Details about the use of the other key selection options (PERMCO, CUSIP, HCUSIP, TICKER, SICCD, and INDNO) follow.

PERMNOs that you specify by using this option can select the companies or issues to keep for CRSP US Stock data, but PERMNO is not a supported option for CRSP Indices data. Use the INDNO= option with the CRSP Indices data and use the PERMNO= option with the CRSP US Stock data. Details on the use of key selection options for each type of database follows.

STK Databases

PERMNO is the primary key for CRSP Stock data. Every valid PERMNO that you specify with the PERMNO= option keeps exactly one issue.

IND Databases

INDNO is the primary key for accessing CRSP Indices data. PERMNO is not available as a key for the IND (CRSP Indices) Databases; use INDNO for efficient access of the IND Databases.

PERMCO=*crsp_permcompany*

is similar to the PERMNO= option in that it enables you to use the CRSP's unique permanent company identification key (PERMCO) to select the companies or issues to keep. There is no limit to the number of *crsp_permcompany* options that you can use.

STK Databases

PERMCO is a secondary key for accessing CRSP US Stock data. One PERMCO can map to multiple PERMNOs. Access by a PERMCO key is equivalent to access by all mapped PERMNOs.

IND Databases

Use INDNO for accessing CRSP Indices data. PERMCO is not available as a key for accessing CRSP Indices data; use INDNO instead.

CUSIP=*crsp_cusip*

is similar to the PERMNO= option in that it enables you to use the CUSIP key to select the companies or issues to keep. There is no limit to the number of *crsp_cusip* options that you can use.

STK Databases

CUSIP is a secondary key for accessing CRSP US Stock data. One CUSIP maps to one PERMNO.

IND Databases

Use INDNO for accessing CRSP Indices data. CUSIP is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

HCUSIP=*crsp_hcusip*

is similar to the PERMNO= option in that it enables you to use the historical CUSIP key, HCUSIP, to select the companies or issues to keep. There is no limit to the number of *crsp_hcusip* options that you can use.

STK Databases

HCUSIP is a secondary key for accessing CRSP US Stock Databases. One HCUSIP maps to one PERMNO.

IND Databases

Use INDNO for accessing CRSP Indices Databases. HCUSIP is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

TICKER=*crsp_ticker*

is similar to the PERMNO= option in that it enables you to use the TICKER key to select the companies or issues to keep. There is no limit to the number of *crsp_ticker* options that you can use.

STK Databases

TICKER is a secondary key for accessing CRSP US Stock Databases. One TICKER maps to one PERMNO. **NOTE:** Some PERMNOs are inaccessible by the TICKER key.

IND Databases

Use INDNO for accessing CRSP Indices Databases. TICKER is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

SICCD=crsp_siccd

is similar to the PERMNO= option in that it enables you to use the Standard Industrial Classification (SIC) code (SICCD) to select the companies or issues to keep. There is no limit to the number of *crsp_siccd* options that you can use.

STK Databases

SICCD is a secondary key for accessing CRSP US Stock Databases. One SICCD can map to multiple PERMNOs. All PERMNOs that have been classified once under the specified SICCD are mapped and the data for them are retrieved. Access by the SICCD key is equivalent to access by all PERMNOs that have ever been classified under the specified SICCD key.

IND Databases

Use INDNO for accessing CRSP Indices Databases. SICCD is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

INDNO=crsp_indno

is similar to the PERMNO= option in that it enables you to use CRSP's permanent index number INDNO to select the companies or issues to keep. There is no limit to the number of *crsp_indno* options that you can use.

STK Databases

INDNO is not available as a key for accessing CRSP US Stock Databases, but it can be used in the combined CRSP US Stock and Indices Databases.

IND Databases

INDNO is the primary key for accessing CRSP Indices Databases. Every INDNO that you specify keeps exactly one index series or group.

For example, you can use the following statement to access the CRSP NYSE Value-Weighted and Equal-Weighted daily market indices:

```
LIBNAME myLib3 sasecrsp 'physical-name'
      SETID=460
      INDNO=1000000 /* Value-Weighted */
      INDNO=1000001; /* Equal-Weighted */
```

RANGE='crsp_begdt-crsp_enddt'

limits the time range of data that are read from your CRSPAccess database. Specify this option in your LIBNAME *libref* SASECRSP statement, where *crsp_begdt* is the beginning date of the range in YYYYMMDD format and *crsp_enddt* is the ending date of the range in YYYYMMDD format.

For example, to access monthly stock data for Microsoft Corporation and for International Business Machines Corporation for the first quarter of 1999, you can use the following statement:

```
LIBNAME myLib sasecrsp 'physical-name'
      SETID=20
      PERMNO=10107
      PERMNO=12490
      RANGE='19990101-19990331';
```

The specified beginning and ending dates are interpreted as calendar dates.

You can use the RANGE= option for all members of CRSP US Stock and Indices Databases. CRSP data members are associated with only one date, and all CRSP data members have a date resolution to the day. For example, monthly time series, although they are monthly, resolve to the last trading day of the month.

INSET= '*setname*[,*keyfieldname*,*keyfieldtype*,*date1field*,*date2field*]

specifies a SAS data set named *setname* as input for issues. The SASECRSP engine assumes that a default PERMNO field that contains selected CRSP PERMNOs is present in the data set. If optional parameters are used, they must all be specified. The only acceptable shorthand for dropping the parameters is to drop those at the very end, assuming they are all being omitted. Dropped parameters use their defaults.

You can specify the following parameters:

keyfieldname	labels the field that contains the keys to be selected. If unspecified, the default is PERMNO.
keyfieldtype	specifies the CRSPAccess key type of the provided keys. Possible key types are: PERMNO, PERMCO, CUSIP, HCUSIP, TICKER, SICCD, or INDNO. If unspecified, the default is "PERMNO".
date1field	specifies the beginning date of the specific date range restriction being applied to this key. If either <i>date1field</i> or <i>date2field</i> is omitted, then by default there is no date range restriction.
date2field	specifies the ending date of the specific date range restriction being applied to this key. If either <i>date1field</i> or <i>date2field</i> is omitted, then by default there is no date range restriction.

Individual date range restrictions that you specify by using the INSET= option can be used in combination with the RANGE= option in the LIBNAME statement. In such a case, only data from the intersection of the individual date restriction and the global RANGE= option date restriction are read.

Details: SASECRSP Interface Engine

Using the INSET= Option

The following examples illustrate the use of the INSET= option.

Basic INSET= Option Use: Providing a List of PERMNOs

This example uses the INSET= option to extract monthly data for a portfolio of three companies. No date range restriction is used.

```
data testin1;
  permno = 10107; output;
  permno = 12490; output;
```

```

    permno = 14322; output;
run;

LIBNAME mstk sasecrsp 'physical-name'
      SETID=20
      INSET='testin1';

proc print data=msk.stkhead (keep=permno permco begdt enddt hcomnam htick);
run;

```

General Use of the INSET= Option to Specify Lists of Keys

This example illustrates the use of the INSET= option to select a few index series from the CRSP Indices data, and securities from the CRSP US Stock data. The libref **ind2** is used for accessing the CRSP Indices data by using the two specified INDNO keys. The libref **sec3** is used to access the CRSP US Stock data by using the three specified TICKER keys. Note the use of shorthand in specifying the INSET= option. The *date1field* and the *date2field*, and datatype arguments are all omitted, so the default of no range restriction applies (though the range restriction set by the RANGE= option in the LIBNAME statement still applies). For more information, including sample output, see [Example 38.4](#)

```

data indices;
    indno=1000000; output; /* NYSE Value-Weighted Market Index */
    indno=1000001; output; /* NYSE Equal-Weighted Market Index */
run;

libname ind2 sasecrsp "%sysget(CRSP_MSTK)" setid=420
    inset='indices,INDNO,INDNO' range='19990101-19990401';

title2 'Total Returns for NYSE Value- and Equal-Weighted Market Indices';
proc print data=ind2.tret label;
run;

data securities;
    ticker='BAC'; output; /* Bank of America */
    ticker='DUK'; output; /* Duke Energy */
    ticker='GSK'; output; /* GlaxoSmithKline */
run;

libname sec3 sasecrsp "%sysget(CRSP_MSTK)" setid=20
    inset='securities,TICKER,TICKER'
    range='19970820-19970920';

title2 'PERMNOs and General Header Info of Selected TICKERs';
proc print data=sec3.stkhead (keep=permno htick htsymbol) label;
run;

title3 'Average Price for Bank of America, Duke and GlaxoSmithKline';
proc print data=sec3.prc label; run;

```

Key-Specific Date Range Restriction with the INSET= Option

Suppose you not only want to select keys with your INSET= option, but you also want to specify a date range restriction for each key individually. The following statements show how to do this. Again, shorthand enables you to omit the *date1field* and *date2field* arguments. The dates that are provided default to a calendar interpretation. For more information, including the sample output, see [Example 38.5](#).

```

title2 'INSET=testin2 uses date ranges along with PERMNOs: ';
title3 '10107, 12490, 14322, 25788';
title4 'Begin dates and end dates for each permno are used in the INSET';

data testin2;
    permno = 10107; date1 = 19980731; date2 = 19981231; output;
    permno = 12490; date1 = 19970101; date2 = 19971231; output;
    permno = 14322; date1 = 19950731; date2 = 19960131; output;
    permno = 25778; date1 = 19950101; date2 = 19950331; output;
run;

libname mstk2 sasecrsp "%sysget(CRSP_MSTK)" setid=20
                    inset='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
    set mstk2.prc;
run;

proc print data=b;
run;

```

The SAS Output Data Set

You can use the SAS DATA step to write the selected CRSP data to a SAS data set. This enables you to easily analyze the data by using SAS. When you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set by using the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the date of each observation, the series name of each series read from the CRSPAccess database, event variables, and the label or description of each series/event or array.

You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use PROC SQL with the SASECRSP engine libref to create a custom view of your data.

In general, CRSP missing values are represented as ‘.’ in the SAS data set. When accessing the CRSP US STOCK data, the SASECRSP engine uses the mapping shown in [Table 38.5](#) for converting CRSP missing values into SAS missing codes.

Table 38.5 Mapping of CRSP Stock Missing Values to SAS Missing Codes

CRSP Stock	SAS	Condition
–99	.	No valid price
–88	.A	Out of range
–77	.B	Off-exchange
–66	.C	No valid previous price
–55	.D	No delisting information
–44	.E	No valid comparison for an excess return

Understanding CRSP Date Formats, Informats, and Functions

CRSP has historically used two different methods to represent dates, whereas SAS has used a third. The three formats are SAS dates, CRSP dates, and integer dates. The SASECRSP engine provides 23 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. A SASECRSP engine libref must be assigned prior to your use of the CRSP date formats, informats, and functions. See [Example 38.6](#), “Converting Dates Using the CRSP Date Functions.”

SAS dates are stored internally as the number of days since January 1, 1960. The SAS method is an industry standard that provides a great deal of flexibility, including a wide variety of informats, formats, and functions.

CRSP dates are designed to ease time series storage and access. Internally, the dates are stored as an offset in an array of trading days or a trading-day calendar. There are five different CRSP trading-day calendars: Annual, Quarterly, Monthly, Weekly, and Daily. In this sense, there are five different types of CRSP dates, one for each frequency of calendar that it references. The CRSP method provides fewer missing values and makes trading period calculations very easy. However, many valid calendar dates are not available in the CRSP trading calendars, and you must be careful when you use other dates.

Integer dates are a way to represent dates that are platform-independent and maintain the correct sort order. However, the distance between dates is not maintained.

The best way to illustrate the various date formats is to use some sample data. [Table 38.6](#) shows date representations for CRSP daily and monthly data.

Table 38.6 Date Representations for Daily and Monthly Data

Date	SAS Date	CRSP Date (Daily)	CRSP Date (Monthly)	Integer Date
July 31, 1962	942	21	440	19620731
August 31, 1962	973	44	441	19620831
Dec. 30, 1998	14,243	9190	NA*	19981230
Dec. 31, 1998	14,244	9191	877	19981231

* Not available if an exact match is requested.

Having an understanding of the internal differences in representing SAS dates, CRSP dates, and CRSP integer dates helps you use the SASECRSP engine formats, informats, and functions effectively. Always keep in mind the frequency of the CRSP calendar that you are accessing when you specify a CRSP date.

The CRSP Date Formats

CRSP dates use two types of formats, and five frequencies are available for each type. The two types are exact dates (CRSPDT*) and range dates (CRSPDR*), where the ‘*’ can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The ten types are CRSPDTA, CRSPDTQ, CRSPDTM, CRSPDTW, CRSPDTD, CRSPDRA, CRSPDRQ, CRSPDRM, CRSPDRW, and CRSPDRD.

Table 38.7 shows some samples that use the monthly and daily calendar as examples. The Annual (CRSPDTA and CRSPDRA), Quarterly (CRSPDTQ and CRSPDRQ), and Weekly (CRSPDTW and CRSPDRW) formats work analogously.

Table 38.7 Sample CRSPDT Formats for Daily and Monthly Data

Date	CRSP Date Daily, Monthly	CRSPDTD Daily Date	CRSPDRD Daily Range	CRSPDTM Monthly Date	CRSPDRM Monthly Range
July 31,1962	21, 440	19620731	19620731 +	19620731	19620630, 19620731
August 31,1962	44, 441	19620831	19620831 +	19620831	19620801, 19620831
Dec. 30,1998	9190, NA *	19981230	19981230 +	NA*	NA*
Dec. 31,1998	9191, 877	19981231	19981231 +	19981231	19981201, 19981231

+ Daily ranges look similar to monthly ranges if they are Mondays or immediately follow a trading holiday.

* When you are working with exact matches, no CRSP monthly date exists for December 30, 1998.

The @CRSP Date Informat

CRSP dates use three types of informat, and five frequencies are available for each type. The three types are exact (@CRSPDT*), range (@CRSPDR*), and backward (@CRSPDB*) dates, where the ‘*’ can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The 15 formats are @CRSPDTA, @CRSPDTQ, @CRSPDTM, @CRSPDTW, @CRSPDTD, @CRSPDRA, @CRSPDRQ, @CRSPDRM, @CRSPDRW, @CRSPDRD, @CRSPDBA, @CRSPDBQ, @CRSPDBM, @CRSPDBW, and @CRSPDBD.

The five CRSPDT* informats find exact matches only. The five CRSPDR* informats look for an exact match, and if an exact match is not found, they go forward, matching the CRSPDR* formats. The five CRSPDB* informats look for an exact match, and if an exact match is not found, they go backward.

Table 38.8 shows a sample that uses only the CRSP monthly calendar as an example. The daily, weekly, quarterly, and annual frequencies work analogously.

Table 38.8 Sample @CRSP Date Informats Using Monthly Data

Input Date (Integer Date)	CRSP Date CRSPDTM	CRSP Date CRSPDRM	CRSP Date CRSPDBM	CRSPDTM Monthly Date	CRSPDRM Monthly Range
19620731	440	440	440	19620731	19620630 to 19620731
19620815	.(missing)	441	440	See below+	See below*
19620831	441	441	441	19620831	19620801 to 19620831

+ Missing values are preserved. If 441, then 19620831. If 440, then 19620731.

* Missing values are preserved. If 441, then 19620801 to 19620831. If 440, then 19620630 to 19620731.

The CRSP Date Functions

Table 38.9 shows the 22 date functions that the SASECRSP engine provides. The engine uses these functions internally, but they are also available to end users. There are seven groups of functions. The first four groups have five functions each, one for each CRSP calendar frequency. The next two functions are for converting between SAS and integer date formats.

Table 38.9 CRSP Date Functions

Function Group	Function Name	Argument One	Argument Two	Return Value
CRSP dates to integer dates for December 31, 1998				
Annual	crspdcia	74	None	19981231
Quarterly	crspdcicq	293	None	19981231
Monthly	crspdcim	877	None	19981231
Weekly	crspdciw	1905	None	19981231
Daily	crspdcid	9191	None	19981231
CRSP dates to SAS dates for December 31, 1998				
Annual	crspdcsa	74	None	14,244
Quarterly	crspdcscq	293	None	14,244
Monthly	crspdcsm	877	None	14,244

Data Elements Reference: SASECRSP Interface Engine

Data sets are made available based on the type of CRSP database that you open. [Table 38.10](#) and [Table 38.11](#) show summary views of the two types of CRSP databases (Stock and Indices) and the data sets that they make available. Tables that contain details about the data sets, including their specific fields, immediately follow the summary tables. You can also see the available data sets for an opened database via the SAS Explorer by opening a SASECRSP engine libref that you previously assigned.

Table 38.10 Summary of All Available Data Sets by CRSP Database Type

CRSP Database	Data Set Name	Reference Table Title	Reference Table

Example 38.2: Using the LIBNAME Statement to Access All Keys

To set up the libref to access all keys, no key options such as PERMNO=, TICKER=, or GVKEY= are specified in the LIBNAME statement and no INSET= option is used. Any of these options cause the SASECRSP engine to limit access to specified keys or specified insets. When no such options are specified, the SASECRSP engine correctly defaults to selecting all keys in the database. Other LIBNAME statement options, such as the RANGE= option, can still be used normally to limit the time span of the data—in other words, to define the date range of observations.

This example does not use key-specifying options. This forces the engine to default to all PERMNOs in the monthly STK database. The range that is specified in the LIBNAME statement behaves normally, and data are limited to the first two months of 1995.

```
title2 'Define a range inside the data range ';
title3 'My range is ( 19950101-19950228 )';

libname _all_ clear;
libname testit2 sasecrsp "%sysget(CRSP_MSTK) "
    setid=20
    range='19950101-19950228';
data a;
    set testit2.ask(obs=30);
run;

proc print data=a;
run;
```

The result is shown in [Output 38.2.1](#).

Output 38.2.1 All PERMNOs of ASK Monthly Time Series Data with RANGE= Option

Define a range inside the data range
 My range is (19950101-19950228)

Obs	PERMNO	CALDT	ASK

Example 38.3: Accessing One PERMNO without the RANGE= Option

The SASECRSP engine defaults to providing access to the entire range of available data when you do not restrict the range (that is, when you do not use the RANGE= option).

This example shows access of the entire range of available data for one particular PERMNO extracted from the monthly data set.

```
title2 'Select only PERMNO = 81871';
title3 'Valid trading dates (19890131--19981231)';
title4 'No range option, leave wide open';

libname _all_ clear;
libname testit3 sasecrsp "%sysget(CRSP_MSTK) "
    setid=20
    permno=81871;

data c;
    set testit3.ask;
run;

proc print data=c;
run;
```

The result is shown in [Output 38.3.1](#).

Output 38.3.1 PERMNO=81871 of ASK Monthly Time Series Data without RANGE= Option

Select only PERMNO = 81871
 Valid trading dates (19890131--19981231)
 No range option, leave wide open

40	81871	19981030	26.00000

Example 38.4: Specifying Keys by Using the INSET= Option

The INSET= option enables you to select any companies or issues for which you want data. This example selects two CRSP Index Series from the CRSP Indices data, and four securities from the CRSP US Stock data for data extraction. Note that because each CRSP database might be in a different location and must be opened separately, a total of two different librefs are used, one for each database.

```
data indices;
    indno=1000000; output; /* NYSE Value-Weighted Market Index */
    indno=1000001; output; /* NYSE Equal-Weighted Market Index */
run;

libname _all_ clear;
libname ind2 sasocrsp "%sysget(CRSP_MSTK) "
    setid=420
    inset='indices,INDNO,INDNO'
    range='19990101-19990401';

title2 'Total Returns for NYSE Value- and Equal-Weighted Market Indices';
proc print data=ind2.tret label;
run;
```

Output 38.4.1 shows the result of selecting two CRSP Index Series from the CRSP Indices data.

Output 38.4.1 IND Data Extracted Using INSET= Option

Total Returns for NYSE Value- and Equal-Weighted Market Indices				
Obs	INDNO	Calendar Trading Date	Total Returns	
1	1000000	19990129	0.012419	
2	1000000	19990226	-0.024179	
3	1000000	19990331	0.028591	
4	1000001	19990129	-0.007700	
5	1000001	19990226	-0.041183	
6	1000001	19990331	0.015101	

The following statements select three securities from the CRSP US Stock data by using TICKER keys in the INSET= option for data extraction:

```
data securities;
    ticker='BAC'; output; /* Bank of America */
    ticker='DUK'; output; /* Duke Energy */
    ticker='GSK'; output; /* GlaxoSmithKline */
run;

libname sec3 sasocrsp "%sysget(CRSP_MSTK) "
    setid=20
    inset='securities,TICKER,TICKER'
```

```

range='19970820-19970920';

title2 'PERMNOs and General Header Info of Selected TICKERs';
proc print data=sec3.stkhead(keep=permno htick htsymbol) label;
run;
title3 'Average Price for Bank of America, Duke and GlaxoSmithKline';
proc print data=sec3.prc label;
run;

```

Output 38.4.2 shows the STK header data for the TICKER keys that are specified by using the INSET= option.

Output 38.4.2 STK Header Data Extracted Using INSET= Option

PERMNOs and General Header Info of Selected TICKERs				
Obs	PERMNO	Ticker Symbol Header	Trading Symbol Header	
1	59408	BAC	BAC	
2	27959	DUK	DUK	
3	75064	GSK	GSK	

Output 38.4.3 shows the STK price data for the TICKER keys that are specified by using the INSET= option.

Output 38.4.3 STK Price Data Extracted Using INSET= Option

PERMNOs and General Header Info of Selected TICKERs				
Average Price for Bank of America, Duke and GlaxoSmithKline				
Obs	PERMNO	Calendar Trading Date	Price or Bid/Ask Average	
1	59408	19970829	59.75000	
2	27959	19970829	48.43750	
3	75064	19970829	39.93750	

Example 38.5: Specifying Ranges for Individual Keys with the INSET= Option

Insets enable you to define options that are specific to each individual key. This example uses an inset to select four PERMNOs and specifies a different date restriction for each PERMNO.

```

title2 'INSET=testin2 uses date ranges along with PERMNOs: ';
title3 '10107, 12490, 14322, 25788';
title4 'Begin dates and end dates for each permno are used in the INSET';

data testin2;
    permno = 10107; date1 = 19980731; date2 = 19981231; output;
    permno = 12490; date1 = 19970101; date2 = 19971231; output;
    permno = 14322; date1 = 19950731; date2 = 19960131; output;
    permno = 25778; date1 = 19950101; date2 = 19950331; output;
run;

libname _all_ clear;
libname mstk2 sasexrsp "%sysget(CRSP_MSTK)"
    setid=20
    inset='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
    set mstk2.prc;
run;

proc print data=b;
run;

```

[Output 38.5.1](#) shows CRSP US Stock price time series data selected by PERMNO in the INSET= option, where each PERMNO has its own time span specified in the INSET= option.

Output 38.5.1 PRC Monthly Time Series Using the INSET= Option

INSET=testin2 uses date ranges along with PERMNOs:
 10107, 12490, 14322, 25788
 Begin dates and end dates for each permno are used in the INSET

Obs	PERMNO	CALDT	PRC
1	10107	19980731	109.93750

Overview: SASEFRED Interface Engine

The SASEFRED interface engine enables SAS users to retrieve economic data from the FRED website, which is hosted by the Economic Research Division of the Federal Reserve Bank of St. Louis. FRED stands for Federal Reserve Economic Data. The FRED databases contain more than 61,000 economic data time series from 48 national and international sources, both public and private. These time series are updated at annual, quarterly, monthly, weekly, and daily intervals. The economic time series on the FRED website contain observation or measurement periods that are associated with data values.

The SASEFRED interface engine uses the LIBNAME statement to enable you to specify how to subset your FRED data and how to aggregate the selected time series at the same update frequency. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEFRED interface engine supports 64-bit Windows. Note that the SASEFRED engine uses the FRED API, but it is not endorsed or certified by the Federal Reserve Bank of St. Louis, and that by using the SASEFRED interface, you are agreeing to comply with the FRED terms of use, which are described on the web page at the following URL: http://api.stlouisfed.org/terms_of_use.html.

Getting Started: SASEFRED Interface Engine

You can query the Federal Reserve Economic Data (FRED) databases to retrieve the observations or data values for a list of economic time series by specifying the series ID of each time series that you want to read into SAS and by specifying your unique FRED API key. To obtain your own unique API key, visit the FRED website at the following URL:

http://api.stlouisfed.org/api_key.html

The FRED API key is a 32-character alphanumeric lowercase string, such as 'abcdefghijklmnopqrstuvwxyz123456', and is represented by 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX' in the APIKEY= option in the following example. In addition, the example URLs in this section and in the section “Details: SASEFRED Interface Engine” on page 2802 use the same FRED API key as the argument *your_fred_apikey*.

After you have your assigned FRED API key and you have agreed to the terms of use, before downloading any copyright-protected data series, be aware that you are solely responsible for obtaining copyright permissions for any copyright-protected time series that you download (other than for personal use). To obtain a list of the copyright-protected data series, visit the web page at the following URL:

http://api.stlouisfed.org/fred/series/search?search_text=copyright&api_key=your_fred_apikey

Now that you are informed about the terms of use of the FRED data, you can use your FRED API key to access the FRED data, as shown in the following example.

The following statements enable you to access the exports of goods and services time series data from January 1, 1960, to January 1, 2012, on an annual basis. The observations are sorted by the time ID variable DATE.

```

options validvarname=any;
title 'Retrieve Data for the Exports of Goods and Services';
libname _all_ clear;

libname fred sasefred "%sysget(FRED) "
    OUTXML=exportgs
    XMLMAP="%sysget(FRED) exportgs.map"
    APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    IDLIST='bopxgsa';

data export_gsa;
    set fred.exportgs ;
run;

proc contents data=export_gsa; run;
proc print data=export_gsa(obs=15); run;

```

Figure 39.1 Getting Started with Exports of Goods and Services: export_gsa(obs=15)

Retrieve Data for the Exports of Goods and Services					
Obs	realtime_ start	realtime_ end	date	BOPXGSA	
1	2013-09-26	2013-09-26	1960-01-01	25.940

4	2013-09-26	2013-09-26	1963-01-01	29.620	
5	2013-09-26	2013-09-26	1964-01-01	33.341	
6	2013-09-26	2013-09-26	1965-01-01	35.285	
7	2013-09-26	2013-09-26	1966-01-01	38.926	
8	2013-09-26	2013-09-26	1967-01-01	41.333	
9	2013-09-26	2013-09-26	1968-01-01	45.543	
10	2013-09-26	2013-09-26	1969-01-01	49.220	
11	2013-09-26	2013-09-26	1970-01-01	56.640	
12	2013-09-26	2013-09-26	1971-01-01	59.677	
13	2013-09-26	2013-09-26	1972-01-01	67.222	
14	2013-09-26	2013-09-26	1973-01-01	91.242	
15	2013-09-26	2013-09-26	1974-01-01	120.897	

The XML data that the FRED website returns are placed in a file named by the OUTXML= option, in this case, EXPORTGS.xml. Note that the XML file extension is excluded from the filename given in the OUTXML= option. This XML data file resides in the location given inside the string enclosed in double quotation marks in the SASEFRED LIBNAME statement. So, in the preceding example, if the FRED environment variable is set to:

```
C:\freddata\
```

then the downloaded XML file is located at

```
C:\freddata\EXPORTGS.xml
```

An equivalent LIBNAME statement that does not use any environment variables could be as follows:

```
Libname fred sasefred "C:\freddata\"
  OUTXML=exportgs
  XMLMAP="C:\freddata\exportgs.map"
  APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  IDLIST='bopxgsa';
```

You could also use either a SAS macro variable or a system environment variable to store the value of your FRED API key so that the key does not appear explicitly in your SAS code. The XML map that is created is assigned the full pathname specified by the XMLMAP= option. The IDLIST= option specifies the list of time series that you want to retrieve. This option accepts a string, enclosed in single quotation marks, that denotes a list of one or more time series that you select (keep) in the resulting SAS data set. The result, Export_gsa, is named in the DATA step and is shown in [Figure 39.1](#). It is more efficient to use the DATA step to store your FRED data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC GPLOT statement, but you can also refer to the SASEFRED libref directly, as in the following statement:

```
proc print data=fred.exportgs; run;
```

This statement uses the member name, exportgs, in the PROC PRINT statement; this usage corresponds to specifying the OUTXML=EXPORTGS option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASEFRED libref, the FRED interface reads the entire XML file again into SAS. It is best to refer to the SAS data set repeatedly rather than invoking the interface engine repeatedly. For another example that uses more SASEFRED LIBNAME statement options, see the section “Reading Price Data by Using Indices” on page 2805.

Details: SASEFRED Interface Engine

The SASEFRED interface engine enables SAS users to access both Archival Federal Reserve Economic Data (ALFRED) and FRED data that are provided by the FRED website. Normal use is called the *FRED mode*, for which the real-time period is the current day (today). In FRED mode, you are using the current facts: the information about the past that is available today. Economic data sources, releases, series, and observations can change their names or their observation data values over time. The real-time period marks when facts were true or when information was known until it changed. Economic data sources, releases, series, and observations are all assigned a real-time period. For most URL requests, the default real-time period is today. This can be thought of as FRED mode—what information about the past is available today. ALFRED users can change the real-time period to retrieve information that was known as of a point in history. ALFRED uses vintage dates, which are release dates for a series, excluding the release dates when the data values did not change.

Available Sources That Provide FRED Time Series Data

To obtain a list of the available sources of economic data, enter the following URL in your web browser. [Table 39.1](#) shows some of the sources available.

http://api.stlouisfed.org/fred/sources?api_key=your_fred_apikey

Table 39.1 Some Available Sources of Economic Data

Source ID	Name	URL
1	Board of Governors of the Federal Reserve System	http://www.federalreserve.gov/
3	Federal Reserve Bank of Philadelphia	http://www.philadelphiafed.org/
4	Federal Reserve Bank of St. Louis	http://www.stlouisfed.org/
6	Federal Financial Institutions Examination Council	http://www.ffeec.gov/
11	Dow Jones & Company	http://www.dowjones.com
13	Institute for Supply Management	http://www.ism.ws/
15	The White House: Council of Economic Advisers	http://www.whitehouse.gov/cea/
16	The White House: Office of Management and Budget	http://www.whitehouse.gov/omb/
17	U.S. Congress: Congressional Budget Office	http://www.cbo.gov/
18	U.S. Department of Commerce: Bureau of Economic Analysis	http://www.bea.gov/
19	U.S. Department of Commerce: Census Bureau	http://www.census.gov/
21	U.S. Department of Housing and Urban Development	http://www.hud.gov/

FRED API Key

The API key that is used in these examples, ‘abcdefghijklmnopqrstuvwxyz123456’, is for demonstration purposes only. To successfully download data from the FRED website, use your own FRED API key, which is a 32-character alphanumeric lowercase string. You can request your own API key by visiting the website at the following URL:

http://api.stlouisfed.org/api_key.html

Available Releases for Each Source That Provides FRED Time Series Data

Each of the FRED sources might have several releases. To get a list of the releases for a specific source, enter the following URL in your web browser and specify the ID that corresponds to that source. For example, the response to this request retrieves a list of all releases for Dow Jones & Company (source_ID=11).

http://api.stlouisfed.org/fred/source/releases?source_id=11&api_key=your_fred_apikey

Table 39.2 shows the list of releases for Dow Jones & Company.

Table 39.2 Releases for Dow Jones & Company

Release ID	Name	URL
72	Daily Treasury Inflation-Indexed Securities	—
102	Wall Street Journal	http://online.wsj.com/public/us
197	Dow Jones Averages	http://www.djaverages.com

Available Time Series for Each Release ID

Each release of economic sources contains several time series. To get the list of time series for a specific release, enter the following URL in your web browser and specify the ID that corresponds to that release. For example, the following URL retrieves a list of all time series for the Dow Jones Averages release (release_ID=197):

http://api.stlouisfed.org/fred/release/series?release_id=197&api_key=your_fred_apikey

Table 39.3 shows all the time series that are included in the Dow Jones Averages release.

Table 39.3 Time Series for the Release of Dow Jones Averages

Series ID	Title	Start	End	Frequency
DJCA	Dow Jones Composite Average	1934-01-02	2012-11-23	Daily
DJIA	Dow Jones Industrial Average	1896-05-26	2012-11-23	Daily
DJTA	Dow Jones Transportation Average	1896-10-26	2012-11-23	Daily
DJUA	Dow Jones Utility Average	1929-01-02	2012-11-23	Daily

Available Native Frequency for Each Series ID

To find the native frequency of an economic time series, enter the following URL in your web browser. The output includes the “Frequency” field, which shows the native frequency of that time series.

http://api.stlouisfed.org/fred/series?series_id=DJCA&api_key=your_fred_apikey

The response to the preceding request follows. As the response shows, the native frequency of the Dow Jones Composite Average (DJCA) time series is Daily (frequency=Daily).

```
<series id="DJCA" realtime_start="2012-11-26" realtime_end="2012-11-26" title="Dow Jones Composite Average" observation_start="1934-01-02" observation_end="2012-11-23" frequency="Daily, Close" frequency_short="D" units="Index" units_short="Index" seasonal_adjustment="Not Seasonally Adjusted" seasonal_adjustment_short="NSA" last_updated="2012-11-26 09:05:12-06" popularity="48">
```

Vintage Dates for Each Series ID

Vintage dates are the release dates for a time series, excluding those releases in which the data did not change. To obtain a list of vintage dates for a particular series, you can enter the following URL in your web browser and specify the series ID of the series that you are interested in. For example, the following URL retrieves a list of all vintage dates for the MICH series, showing the median expected price change (the next 12 months from the Survey of Consumers):

http://api.stlouisfed.org/fred/series/vintagedates?series_id=MICH&api_key=your_fred_apikey

The resulting list of observations is too long to show here—172 vintage dates, ranging from 1999-02-26 to 2013-05-31. You can get only the vintage dates that you want by specifying the VINTAGE= option.

SAS Output Data Set

You can use the SAS DATA step to write the selected FRED data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the date of each observation and the series name of each series that is read from the FRED data source.

The SASEFRED interface engine maintains the sort order, so the time series are sorted in the resulting SAS data set by the order specified in the SORT= option, by date (time ID), and by variable (time series item name).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEFRED libref to create a custom view of your data.

SAS OUTXML File

The SAS XML (XML format) data that are returned from the FRED website are placed in a file named by the OUTXML= option. The SAS XML data file is placed in the location that is specified by the *physical-name* in your LIBNAME *libref* SASEXFSD statement, which is described in the section “The LIBNAME *libref* SASEFRED Statement” on page 2809.

SAS XML Map File

The XML map that (by default) is automatically created is assigned the full pathname given by the XMLMAP= option in your LIBNAME *libref* SASEFRED statement. The map file is either reused (not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE (the default). The SASEFRED engine invokes the XMLV2 engine to create the map and to read the data into SAS.

Reading Price Data by Using Indices

The following statements enable you to access the S&P 500 Stock Price Index (IDLIST=SP500) and the Wilshire 5000 Price Index (IDLIST=WILL5000PR) on a monthly basis:

```
options validvarname=any;
title 'FRED Data: SP500 Stock Index and Wilshire 5000 Price Index';
LIBNAME myLib sasefred "%sysget(FRED) "
    OUTXML=gstart
    AUTOMAP=replace
    MAPREF=MyMap
    XMLMAP="%sysget(FRED)gstart.map"
    APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
```

```

IDLIST='sp500,will5000pr'
START='2011-01-01'
END='2012-01-01'
FREQ='m'
FORMAT=xml
;

data stock_price;
    set myLib.gstart ;
run;

proc contents data=stock_price; run;
proc print data=stock_price; run;

```

Figure 39.2 FRED Data: stock_price

FRED Data: SP500 Stock Index and Wilshire 5000 Price Index					
Obs	date	realtime_ start	realtime_ end	SP500	WILL5000PR
1	2011-01-01	2013-09-26	2013-09-26	1282.62	13368.14
2	2011-02-01	2013-09-26	2013-09-26	1321.12	13772.27
3	2011-03-01	2013-09-26	2013-09-26	1304.49	13610.85
4	2011-04-01	2013-09-26	2013-09-26	1331.51	13920.50
5	2011-05-01	2013-09-26	2013-09-26	1338.31	13967.83
6	2011-06-01	2013-09-26	2013-09-26	1287.29	13441.17
7	2011-07-01	2013-09-26	2013-09-26	1325.18	13848.15
8	2011-08-01	2013-09-26	2013-09-26	1185.31	12296.04
9	2011-09-01	2013-09-26	2013-09-26	1173.88	12144.13
10	2011-10-01	2013-09-26	2013-09-26	1207.22	12459.48
11	2011-11-01	2013-09-26	2013-09-26	1226.41	12684.75
12	2011-12-01	2013-09-26	2013-09-26	1243.32	12850.31
13	2012-01-01	2013-09-26	2013-09-26	1300.58	13465.23

The SASEFRED interface engine supports the XML format. The XML data that the FRED website returns are placed in a file named by the OUTXML= option. The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option. In the preceding example, the SASEFRED engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename:

```
FILENAME MyMap "U:\fred\test\gstart.map";
```

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file; it is described in the section “[SAS OUTXML File](#)” on page 2805. The XML data file is placed in the folder designated by ‘physical-name’, which is described in the section “[The LIBNAME libref SASEFRED Statement](#)” on page 2809. You can refer to your data by using the myLib libref in your SASEFRED LIBNAME statement. The myLib libref is shown inside the DATA step in the SET statement. The SET statement reads observations from the input data set myLib.gstart and stores them in a SAS data set named stock_price, as shown in [Figure 39.2](#). You can also use the SAS DATA step to perform further processing and to store the resulting time series in a SAS data set; this process is described in the section “[SAS Output Data Set](#)” on page 2805.

To specify the list of time series that you want to retrieve, use the IDLIST= option. This option accepts a string enclosed in single quotation marks that denotes a list of time series that you select for the resulting SAS data set. The series IDs are separated by commas, so valid time series IDs cannot contain embedded commas or quotes. The stock_price data set contains two time series variables, sp500 and will5000pr, as specified in the IDLIST= option, and the observation range is controlled by the START= and END= options. The stock_price data set contains observations that range from January 1, 2011, to January 1, 2012, as specified by the START= and END= options. The frequency of the data is monthly, as indicated by the ‘m’ in the FREQ= option.

NOTE: The ‘%20’ is a special character for URL encoding of blanks. If the time series ID that you name in the IDLIST= option contains a blank, you must use the ‘%20’ wherever the blank appears in the time series name. If the time series ID contains an underscore, then you must use an underscore in the time series name. The underscore and the blank are not equivalent in the FRED databases, so make sure that you use the ‘%20’ (URL encoded space) to designate blank characters.

Syntax: SASEFRED Interface Engine

The SASEFRED interface engine uses standard engine syntax to read the observations or data values for one or more economic time series. [Table 39.4](#) summarizes the options that the SASEFRED engine uses. In addition, there is one required option: API_KEY=‘fred_api_key’.

Table 39.4 Summary of LIBNAME *libref* SASEFRED Options

Option	Description
IDLIST=	Specifies a list of time series IDs for accessing FRED data. To select more than one time series, list the unique time series IDs, separated by commas.
START=	Specifies the start date for the observation period (YYYY-MM-DD formatted string, optional; the default is 9999-12-31 (latest available))
END=	Specifies the end date for the observation period (YYYY-MM-DD formatted string, optional; the default is 1776-07-04 (earliest available))
FREQ=	Specifies the reporting frequency of the selected data (lower frequency to aggregate values to): 'm' for monthly, 'd' for daily. The FRED frequency aggregation feature converts higher-frequency data series to lower-frequency time series (such as converting a monthly time series to an annual time series). See Table 39.5 for the complete list of frequencies.
AGG=	Specifies the aggregation method used for frequency aggregation. The valid aggregation arguments are 'avg', 'sum', and 'eop'; the default is 'avg'.
LIMIT=	Specifies the maximum number of observations (rows) to return (integer between 1 and 100,000, optional; the default is 100,000)
OFFSET=	Specifies the number of rows (observations) to skip in the returned data set. Specifying OFFSET=0 is the same as omitting the OFFSET= option. If you specify both the OFFSET= and LIMIT= options, the number of rows specified in the OFFSET= option is skipped before the count begins of the number of rows, specified in the LIMIT= option, that are returned (nonnegative integer, optional; the default is 0).
SORT=	Specifies the order of the results in ascending or descending observation_date order. The valid sort arguments are 'asc' and 'desc'; the default is 'asc'.
UNITS=	Specifies a data value transformation. The valid units arguments are 'lin', 'chg', 'ch1', 'pch', 'pc1', 'pca', 'cch', 'cca', and 'log'; the default is 'lin'. See Table 39.6 for more information about units.
VINTAGE=	Specifies one or more dates in history. Vintage dates are used to download data as they existed on that specific date in history (YYYY-MM-DD formatted string, optional; by default no vintage dates are set). You can request one or many vintage dates at a time; dates are in YYYY-MM-DD format and are separated by commas (no blanks allowed). For multiple vintage dates, specify OUTPUT=2 for all observations or OUTPUT=3 for only new or revised observations.
OUTPUT=	Specifies an output type. The valid output arguments are '1' for Observations by Real-Time Period; '2' for Observations by Vintage Date, All Observations; '3' for Observations by Vintage Date, New and Revised Observations Only; and '4' for Observations, Initial Release Only (integer, optional; the default is '1').
FORMAT=	Specifies a file extension that indicates the type of file to retrieve. Only XML is supported for the SASEFRED interface engine in SAS/ETS 13.1 (SAS 9.4).

The LIBNAME libref SASEFRED Statement

LIBNAME libref SASEFRED *'physical-name'* options ;

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of FRED data files in which the downloaded FRED XML data are stored. The required *'physical name'* argument specifies the location of the folder where your FRED XML data reside. It should end with a backslash if you are in a Windows environment and a forward slash if you are in a UNIX environment.

You can specify the following *options* in the LIBNAME libref SASEFRED statement.

APIKEY=*'fred_apikey'*

specifies the FRED access key that enables you to access the data provided by the FRED website. The FRED access key is a 32-character alphanumeric lowercase string, and it is required. You can request your *fred_apikey* by visiting the website at the following URL:

http://api.stlouisfed.org/api_key.html

OUTXML=*fred_xmlfile*

specifies the name of the file where the XML data that are returned from the FRED website are stored.

AUTOMAP=*fred_automap*

specifies whether to overwrite the existing XMLmap file (AUTOMAP=REPLACE) or not to overwrite the existing XMLmap file (AUTOMAP=REUSE). You can set *fred_automap* to REUSE so that a pre-existing XMLmap file named by the XMLMAP= option is used. You can set *fred_automap* to REPLACE so that the most current XMLmap generated by the SASEFRED engine and named by the XMLMAP= option is used.

XMLMAP=*fred_xmlmapfile*

specifies the fully qualified name of the location where the XMLmap file is automatically stored.

MAPREF=*fred_xmlmapref*

specifies the fileref used for the map assignment. For an example of the SASEFRED engine that uses the MAPREF= and the XMLMAP= options in the FILENAME statement to assign a filename, as in the following, see the section “[Reading Price Data by Using Indices](#)” on page 2805:

```
FILENAME MyMap "U:\fred\test\gstart.map";
```

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file. It is placed in the folder designated by *'physical-name'*, and you can reference it by using the myLib libref in your SASEFRED LIBNAME statement. This is shown in the section “[Getting Started: SASEFRED Interface Engine](#)” on page 2800, inside the DATA step in the SET statement. The SET statement reads observations from the input data set myLib.gstart and stores them in a SAS data set named Company_pvol.

IDLIST=*'fred_idlist'*

specifies the list of time series to be included in the output SAS data set. This list is comma delimited and must be enclosed in single quotation marks.

START=*'fred_startdate'*

specifies the start date for the time series in the format YYYY-MM-DD. START= is optional, and the default is 1776-07-04 (earliest available).

END=*'fred_enddate'*

specifies the end date for the time series in the format YYYY-MM-DD. END= is optional, and the default is 9999-12-31 (latest available).

FREQ=*'fred_frequency'*

specifies a lower frequency to aggregate values to. The FRED frequency aggregation feature converts higher-frequency time series to lower-frequency time series (such as converting a daily time series to a monthly time series). In FRED, the highest frequency is daily, and the lowest frequency is annual. The *fred_frequency* argument is optional, and there is no default value for no frequency aggregation. The valid frequency arguments are presented in Table 39.5.

NOTE: An error is returned if you specify a frequency that is higher than the native frequency of the series. For example, if a series has the native frequency 'Annually', it is not possible to aggregate the series to the higher 'Monthly' frequency by using the frequency parameter value 'm'. To find the native frequency of an economic time series, enter the following URL in your web browser. The output includes the 'Frequency' field, which shows native frequency of that time series.

http://api.stlouisfed.org/fred/series?series_id=DJCA&api_key=your_fred_apikey

NOTE: When a single time series is specified in the IDLIST= option and the FREQ= option is not specified or is an empty string, then the native frequency of that time series is used as the reporting frequency. When multiple time series are specified in the IDLIST= option, then the 'Annual' frequency is used as the reporting frequency unless the reporting frequency is specified in the FREQ= option. If any time series in the IDLIST= option list have a lower native frequency than the requested frequency, then those time series are dropped from the list and excluded from the output.

AGG=*'fred_aggregation'*

specifies the aggregation method used for frequency aggregation. It is optional. The valid aggregation arguments are 'avg' for averaging, 'sum' for summation, and 'eop' for end of period. The default is AGG='avg'. The AGG= option has no effect if the frequency option (FREQ=) is not set.

LIMIT=*fred_limit*

specifies the maximum number of rows (time series observations) to return, which is an integer between 1 and 100,000. LIMIT= is optional, and the default is LIMIT=100000.

OFFSET=*fred_offset*

specifies the number of rows (time series observations) to skip before reading the time series observations from the FRED database. It is an optional nonnegative integer, and the default is OFFSET=0.

SORT=*'fred_sort'*

specifies the ascending or descending order of time series observations. The valid order arguments are 'asc' (for ascending) and 'desc' (for descending). SORT= is optional, and the default is SORT='asc'.

UNITS=*'fred_units'*

specifies the data value transformation. The valid units arguments are 'lin', 'chg', 'ch1', 'pch', 'pc1', 'pca', 'cch', 'cca', and 'log'. It is an optional string, and the default is UNITS='lin' (for no transformation). The details of the arguments and the corresponding formulas are presented in Table 39.6.

VINTAGE=*'fred_vintage_date1,fred_vintage_date2,...,fred_vintage_dateN'*

specifies one or more vintage dates in history. The *fred_vintage_dates* are represented in YYYY-MM-DD format and are used to download the data for a time series as it existed on that specific date in history. The dates in the list are separated by commas (no blanks are allowed). When requesting multiple vintage dates, specify OUTPUT=2 to retrieve all observations or OUTPUT=3 to retrieve only new or revised observations. The default setting is no vintage dates.

Archival Federal Reserve Economic Data (ALFRED) enable you to retrieve vintage versions of economic data that were available on specific dates in history. To retrieve vintage versions of various time series, enter the following URL in your web browser:

<http://alfred.stlouisfed.org/>

To see a list of available vintage dates for each series, refer to the FRED documentation at the web page with the following URL:

http://api.stlouisfed.org/docs/fred/series_vintagedates.html

OUTPUT= 1 | 2 | 3 | 4

specifies the type of the file to be received from the FRED website. It is an optional integer value. You can specify the following *fred_output_types*:

- 1 specifies the type, Observations by Real-Time Period.
- 2 specifies the type, Observations by Vintage Date, All Observations.
- 3 specifies the type, Observations by Vintage Date, New and Revised Observations Only.
- 4 specifies the type, Observations, Initial Release Only.

NOTE: If OUTPUT=3 or OUTPUT=4, then you must specify UNITS='lin'.

FORMAT=*fred_xmlformat*

specifies the format of the file to be received from the FRED website. Although FRED can report data in many formats, the SASEFRED engine for 9.4 supports the XML format (default).

Table 39.5 FRED Frequency Codes

Frequency Code	Description
d	Displays data on a daily basis
w	Displays data on a weekly basis
bw	Displays data on a biweekly basis
m	Displays data on a monthly basis
q	Displays data on a quarterly basis
sa	Displays data on a semiannual basis
a	Displays data on an annual basis
wef	Displays data on a weekly (ending Friday) basis
weth	Displays data on a weekly (ending Thursday) basis
wew	Displays data on a weekly (ending Wednesday) basis
wetu	Displays data on a weekly (ending Tuesday) basis
wem	Displays data on a weekly (ending Monday) basis
wesu	Displays data on a weekly (ending Sunday) basis
wesa	Displays data on a weekly (ending Saturday) basis
bwew	Displays data on a biweekly (ending Wednesday) basis
bwem	Displays data on a biweekly (ending Monday) basis

Table 39.6 FRED Transformation UNITS Codes

Units Code	Description	Formula
chg	Change	$x_t - x_{t-1}$
chl	Change from year ago	$x_t - x_{t-N}$
pch	Percent change	$(\frac{x_t}{x_{t-1}} - 1) \times 100$
pcl	Percent change from year ago	$(\frac{x_t}{x_{t-N}} - 1) \times 100$
pca	Compounded annual rate of change	$(\frac{x_t}{x_{t-1}})^N - 1) \times 100$
cch	Continuously compounded rate of change	$(\ln(x_t) - \ln(x_{t-1})) \times 100$
cca	Continuously compounded annual rate of change	$((\ln(x_t) - \ln(x_{t-1})))100) \times N$
log	Natural log	$\ln(x_t)$

x_t is the value of series x at time period t . N is the number of observations per year that differs by frequency: Daily ($N = 260$), Annual ($N = 1$), Monthly ($N = 12$), Quarterly ($N = 4$), Biweekly ($N = 26$), and Weekly ($N = 52$).

Examples: SASEFRED Interface Engine

Example 39.1: Retrieving Data for Multiple Time Series

This example shows how to use multiple time series IDs to retrieve the average balance of payment basis data for the exports (BOPXGS) and imports (BOPMGS) of goods and services for the last 15 years, starting 1997-01-01 and ending 2011-01-01, with an annual frequency.

```

5	2001-01-01	2013-09-26	2013-09-26	251.931	-342.516
6	2002-01-01	2013-09-26	2013-09-26	245.219	-349.762
7	2003-01-01	2013-09-26	2013-09-26	255.984	-378.620
8	2004-01-01	2013-09-26	2013-09-26	290.931	-442.156
9	2005-01-01	2013-09-26	2013-09-26	322.065	-499.043
10	2006-01-01	2013-09-26	2013-09-26	365.198	-553.298
11	2007-01-01	2013-09-26	2013-09-26	413.215	-587.981
12	2008-01-01	2013-09-26	2013-09-26	460.083	-635.659
13	2009-01-01	2013-09-26	2013-09-26	394.547	-490.461
14	2010-01-01	2013-09-26	2013-09-26	461.117	-585.962
15	2011-01-01	2013-09-26	2013-09-26	528.206	-667.416

Example 39.2: Retrieving Data by Using the Vintage Date

This example shows how to use the vintage date to retrieve data for exports of goods and services as they existed on that specific date in history. OUTPUT=3 retrieves the new and revised observations only, by the vintage date (VINTAGE=2012-06-14). If OUTPUT=3, then you must specify UNITS='lin'. In this example, the UNITS= option is not specified, so it assumes its default value, which is 'lin'. Specifying a different argument for the UNITS= option (such as 'chg') is invalid for OUTPUT= 3, so 'chg' is replaced by the default value ('lin').

Example 39.3: Selecting Time Series When Native Frequency Is Less Than Requested Frequency

This example shows how to retrieve data for multiple time series that have different default frequencies. The time series are Domestic Financial Commercial Paper Outstanding (DFINCP), Domestic Nonfinancial Commercial Paper Outstanding (DNFINCP), Foreign Financial Commercial Paper Outstanding (FFINCP), Foreign Nonfinancial Commercial Paper Outstanding (FNFINCP), and Total Credit Market Assets Held by Domestic Financial Sectors (ABSITCMAHDFS). The native frequency of the first four time series is 'Weekly', and the native frequency of the last time series (ABSITCMAHDFS) is 'Quarterly'. Note that the requested frequency as it is specified by the FREQ= option is 'Weekly' (FREQ=w). The native frequency of the last time series (ABSITCMAHDFS) is lower than the requested frequency. Therefore, this time series is excluded from the list, and only the observations that correspond to the first four time series are presented. If you want to retrieve the observations for all five time series, then the value of the FREQ= option needs to be less than or equal to all the native frequencies (here, weekly and quarterly). In this case, the valid frequency parameters would be 'q', 'sa', and 'a'. See [Example 39.4](#).

```

title 'Selecting Time Series When Native Frequency Is Less Than Requested Frequency';
libname _all_ clear;

Example 39.4: Selecting Time Series When Native Frequency Is Greater Than Requested Frequency

This example shows how to retrieve data for multiple time series that have different default frequencies. The time series are Domestic Financial Commercial Paper Outstanding (DFINCP), Domestic Nonfinancial Commercial Paper Outstanding (DNFINCP), Foreign Financial Commercial Paper Outstanding (FFINCP), Foreign Nonfinancial Commercial Paper Outstanding (FNFINCP), and Total Credit Market Assets Held by Domestic Financial Sectors (ABSITCMAHDFS). The native frequency of the first four time series is 'Weekly', and the native frequency of the last time series (ABSITCMAHDFS) is 'Quarterly'. The requested frequency as it is specified by the `FREQ=` option is 'Quarterly' (`FREQ=q`). The native frequency of all five time series is either greater than or equal to the requested frequency. Hence, the output includes the data for all time series.

```

title 'Selecting Time Series When Native Frequency Is Greater Than Requested Frequency';
libname _all_ clear;

libname fred sasefred "%sysget(FRED) "
    OUTXML=fredex04
    AUTOMAP=replace

Example 39.5: Specifying One Series ID with Multiple Vintage Dates for the OUTPUT=2 Option

This example demonstrates how to request the CBI time series, which show the change in private industries for three different vintage dates: 1947-08-17, 1966-08-11, and 1994-08-26. Using the early range of START='1942-01-01' and END='1947-04-01', you can get an idea of how the changes show up for each vintage date. If you specify OUTPUT=2, each time series is named by concatenating the series ID to the vintage date with an underscore.

```

Example 39.6: Specifying Two Series IDs with Multiple Vintage Dates and Descending Sort Order

This example demonstrates how to request the ADJRES and ADJRESN time series, which show the St. Louis adjusted reserves, the first of which is seasonally adjusted and the second of which is not seasonally adjusted. The request is made for three different vintage dates, but only 2006-08-31 and 2013-06-13 yield data when you use the range of START='2004-01-01' and END='2012-12-01'. If you specify OUTPUT=2, each time series is named by concatenating the series ID to the vintage date with an underscore. For brevity, [Output 39.6.1](#) shows only the first 10 and last 10 observations. The sort order is descending; that is why the dates start with the most recent observation and continue in biweekly (ending Wednesday) periods to the least recent.

```

title 'Specifying Two Series IDs with Multiple Vintage Dates and Descending Sort Order';
libname _all_ clear;

libname fred sasefred "%sysget(FRED) "
  OUTXML=fredex06

Overview: SASEXCCM Interface Engine

The SASEXCCM interface engine enables SAS users to access the CRSP/Compustat Merged (CCM) Database, which is created from data delivered via Compustat's Xpressfeed product, the CRSP US Stock (STK) Database, and the CRSP US Stock and Indices (IND) Database. The SASEXCCM engine provides a seamless interface for CRSP, Compustat, and SAS data processing.

The SASEXCCM engine uses the LIBNAME statement to specify which database to open and what parts of the database to access.

To specify the database, you supply the combination of a physical path to indicate the location of the data files (CCM, STK, or IND data) and a set identifier (SETID) to identify the database that you want to access from those available at the physical path. The SASEXCCM engine supports data-item-handling access methods for the SETIDs in [Table 40.1](#).

The SASECRSP engine no longer supports COMPUSTAT access. Instead, use the SASEXCCM engine, SETID 250, to read your CRSP/Compustat Merged data.

Table 40.1 CRSP Database SETIDs

SETID	Data Set
10	CRSP Stock, daily data
20	CRSP Stock, monthly data
250	CRSP/Compustat Merged data
400	CRSP Indices data, monthly index groups
420	CRSP Indices data, monthly index series
440	CRSP Indices data, daily index groups
460	CRSP Indices data, daily index series

Getting Started: SASEXCCM Interface Engine

To specify what parts of the database to access, you supply two things: the appropriate keys for companies or securities that you want to access, and the list of data items that you want to retrieve.

When accessing CCM data, you select the companies that you want to access by specifying the GVKEY for each company. A GVKEY is Compustat's unique identifier and primary key. CRSP uses KYGVKEY to refer to GVKEY in the CCM database. Use the GVKEY= option to specify which GVKEY to include. If no GVKEYs are specified, data for all companies are retrieved. You can use the KEEP= KYGVKEY CONM option to obtain a list of all companies (including their name and GVKEY) in the CCM database, as shown in [Example 40.5](#).

For example, the following statements access the CCM database to retrieve annual sales data for IBM (GVKEY=6066) and Microsoft (GVKEY=12141):

```
LIBNAME myLib sasexccm 'physical-name'
SETID=250
GVKEY=6066    /* IBM */
GVKEY=12141   /* MSFT */
```

```

ITEMLIST='SALE';
data yrlysale;
  set myLib.annitem;
run;

```

When accessing CRSP US Stock (STK) data, you select the securities you want to access by specifying their PERMNOs. A PERMNO is CRSP's unique permanent issue identification number and the primary key for its stock databases. You specify a PERMNO by using the PERMNO= option. If no PERMNOs are specified, data for all securities in the database are retrieved. You can use this feature to obtain a list of all PERMNOs in the STK database.

For example, the following statements access the STK database to retrieve monthly shares data for IBM (PERMNO=12490) and Microsoft (PERMNO=10107):

```

LIBNAME myLib sasexccm 'physical-name'
SETID=20
PERMNO=12490 /* IBM */
PERMNO=10107 /* MSFT */
ITEMLIST="MSHROUT.*;MSHRFLG.*";
data mshares_all;
  set myLib.mshares;
run;

```

When accessing CRSP US Stock and Indices (IND) data, you select the security and indices data from the CRSP Daily or Monthly Stock and Indices database by specifying their INDNOs. An INDNO is the primary key for CRSP Indices Databases. You specify an INDNO by using the INDNO= option. If no INDNOs are specified, data for all securities in the database are retrieved. You can use this feature to obtain a list of all INDNOs in the IND database.

For example, the following statements access the IND database to retrieve monthly Consumer Price Index data (INDNO=1000709):

```

LIBNAME myLib sasexccm 'physical-name'
SETID=420
INDNO=1000709 /* Consumer Price Index */
ITEMLIST=
  "MREBAL.*;MRBBEGDT.*;MRBENDDT.*;MRUSDCNT.*;MMINID.*;MMAXID.*;MMINSTAT.*";

data mindts_all;
  set myLib.mindhdr;
  set myLib.mrebal;
run;

```

To specify the list of data items that you want to retrieve, use the ITEMLIST= option. This option accepts a string that denotes a list of requested data items and the reporting format (for example, data format, population source, consolidation level, and so on) in standard CRSP notation by using CRSP's unique mnemonic text name *itm_name* and the mnemonic tag *keyset*. For more information about CRSP notation, see the ITEMLIST= option in the section [“The LIBNAME libref SASXCCM Statement”](#) on page 2826.

After the LIBNAME is assigned, the database is opened. The selected data are organized into groups such as ANNITEM for annual time series data or LINK for event-based CRSP/Compustat link data. You can also use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set.

The SASEXCCM engine supports Linux X64 (LAX), Solaris X64 (SAX), Solaris SPARC (S64), and Windows.

Syntax: SASEXCCM Interface Engine

The SASEXCCM interface engine uses standard engine syntax. Options that the SASEXCCM engine uses are summarized in Table 40.2. The SETID= and ITEMLIST= options are required.

Table 40.2 Summary of LIBNAME *libref*

Option	Description
SETID=	Specifies which CRSP database at the physical path to open. See Table 40.1 for the complete list of supported SETIDs.
GVKEY=	Specifies a Compustat GVKEY for accessing CCM data. To select more than one GVKEY, use this option multiple times. See Example 40.1 and Example 40.2.
GVIIDKEY=	Specifies a composite GVKEY.IID for accessing security related items by both GVKEY and IID
PERMNO=	Specifies a CRSP PERMNO for accessing STK data. To select more than one PERMNO, use this option multiple times.
INDNO=	Specifies a CRSP INDNO for accessing IND data. To select more than one INDNO, use this option multiple times.
ITEMLIST=	Specifies the selected data items to be accessed. This option accepts a string in standard CRSP notation.

The LIBNAME *libref* SASEXCCM Statement

LIBNAME *libref* **SASEXCCM** '*physical-name*' **SETID=***crsp_setidnumber* *options* ;

The LIBNAME statement assigns a SAS library reference (*libref*) to the physical path of the directory of CRSP data files where the CRSP database that you want to open is located. The required *physical-name* argument must end in a slash for UNIX environments and a backslash for Windows environments. The required *SETID=crsp_setidnumber* argument specifies the CRSP database that you want to read from. Choose one SETID from these values: 10, 20, 250, 400, 420, 440, and 460. For example, the following statement accesses the CCM database and retrieves the annual sales data for IBM (GVKEY=6066):

```
LIBNAME myLib SASEXCCM 'physical-name' SETID=250
GVKEY=6066 /* IBM */
ITEMLIST='SALE';
```

You can specify the following *options*:

GVKEY=crsp_gvkey

selects the companies or issues whose data you want to retrieve. Specify the GVKEY (Compustat's permanent SPC identifier) for the *crsp_gvkey*. There is no limit to the number of GVKEY= options that you can specify. If no GVKEY= options are specified, all GVKEYs in the database are selected.

For example, the following statement accesses the CCM database to retrieve annual sales data for IBM (GVKEY=6066) and Microsoft (GVKEY=12141):

```
LIBNAME myLib sasexccm 'physical-name'
SETID=250
GVKEY=6066 /* IBM */
GVKEY=12141 /* MSFT */
ITEMLIST='SALE';
```

GVIIDKEY="crsp_gviidkey"

selects the companies and issues whose data you want to retrieve. Specify both the GVKEY and the IID (Compustat's permanent issue identifier) by concatenating the two with a '.' and enclosing them in double quotation marks. There is no limit to the number of GVIIDKEY= options that you can specify. The following members use GVIIDKEY access: IDX CST_HIS, MTHSEC, SECHIST, SECURITY, SEC_MDIVFN, SEC_MSPTFN, SEC_MTHSPT, SEC_SPIND, SEC_TS_ITM, and SPIDX_CST.

For example, the following statements access the CCM database to retrieve the security member that gives security header information for Microsoft issue ID=01, IBM issue ID=01, and some other companies' issues shown in the GVIIDKEY= options:

```
LIBNAME crsp sasexccm 'physical-name'
SETID=250
GVIIDKEY="12141.01" /* MSFT issue id 01 */
GVIIDKEY="6066.01" /* IBM issue id 01 */
GVIIDKEY="6008.01" /* INTC issue id 01 */
GVIIDKEY="12142.01" /* ORCL issue id 01 */
GVIIDKEY="62634.01" /* YHOO issue id 01 */
GVIIDKEY="5047.01" /* GE issue id 01 */
GVIIDKEY="7866.01" /* NYT issue id 01 */
GVIIDKEY="7866.02" /* NYTAB issue id 02 */
ITEMLIST="DLDTEI;DLRSNI;DSCI;EPF;EXCHG;IID;IID_SEQ_NUM;ISIN;SBEGDT;SENDDT;SCUSIP;
!SEDOL;SSECSTAT;TIC;TPCI";
data headersecurity;
set crsp.security;
run;
```

PERMNO=crsp_permno

selects the companies or issues whose data you want to retrieve. Specify a CRSP company issue's PERMNO for the *crsp_permno*. There is no limit to the number of PERMNO= options that you can specify. If no PERMNO= options are specified, all PERMNOs in the database are selected.

For example, the following statements access the STK database to retrieve monthly shares data for IBM (PERMNO=12490) and Microsoft (PERMNO=10107):

```
LIBNAME myLib sasexccm 'physical-name'
SETID=20
PERMNO=12490 /* IBM */
PERMNO=10107 /* MSFT */
ITEMLIST="MSHROUT.*;MSHRFLG.*";
data mshares_all;
set myLib.mshares;
run;
```

INDNO=crsp_indno

selects the time series or the group data from the index whose data you want to retrieve. Specify a CRSP Index's INDNO for the *crsp_indno*. There is no limit to the number of INDNO= options that you can specify. If no INDNO= options are specified, all INDNOs in the database are selected.

For example, the following statements access the IND database to retrieve monthly consumer price index data (INDNO=1000709):

```
LIBNAME myLib sasexccm 'physical-name'
SETID=420
INDNO=1000709 /* Consumer Price Index */
ITEMLIST=
  "MREBAL.*;MRBBEGDT.*;MRBENDDT.*;MRUSDCNT.*;MMINID.*;MMAXID.*;MMINSTAT.*";

data mindts_all;
set myLib.mindhdr;
set myLib.mrebal;
run;
```

ITEMLIST="crsp_itemlist"

specifies the items and groups of interest for selection based on keysets, which define the reporting format that you want. Specify a string in CRSP standard notation for *crsp_itemlist*. For an overview of items, groups, and reporting formats, see the section “[Data Reference: Introduction](#)” on page 2831. Reference sections that are based on CRSP documentation follow the overview. For more information, see the *CRSPAccess User Guide for the CRSP/Compustat Merged Database*, the *CRSP US Stock and Indices Database*, and the *CRSP US Treasury Database*.

The CRSP standard notation has the form

```
[global_section:]list_section
```

The *list_section* consists of a semicolon-delimited string of list elements in the form

```
list_element[;list_element]
```

Each *list_element* can be an item or group name. You can also specify a particular keyset for the item or group by appending a period and its keyset number. For example, “sale.2” selects the sales item for keyset 2, which contains the industrial format, consolidated information, and standardized summary data from the latest annual filing.

The optional *global_section* holds flags that modify all elements in the list section. The following flags are recognized:

- f adds applicable and populated footnote items for every item selected. For example, “f:sale;at;ceq” selects sales, total assets, and common equity items with default keysets and available footnotes for the selected items.
- d adds applicable and populated data code items for every item selected. For example, “d:sale;at;ceq” selects sales, total assets, and common equity items with default keysets and available data codes for the selected items.
- k.list applies the list of keysets to all items in the list that do not have a specified keyset. The list can be either * to select all available keysets or #-#, #... to select keysets by their number. For example, “k.1:sale;at;ceq” selects the default keyset, keyset 1, for all items.

The following LIBNAME statement shows how to access the CCM database to retrieve the annual sales data and quarterly total assets data for IBM (GVKEY=6066) and Microsoft (GVKEY=12141):

```
LIBNAME myLib sasexccm 'physical-name'
      SETID=250
      GVKEY=6066    /* IBM */
      GVKEY=12141   /* MSFT */
      ITEMLIST='f:sale;actq';
```

After the libref is assigned, you can access any of the available groups (members) within the opened database:

- STK daily See the section “[Daily STK Data Groups](#)” on page 2836 for more information about groups in the Daily Stock Database, SETID 10.
- STK mthly See the section “[Monthly STK Data Groups](#)” on page 2837 for more information about groups in the Monthly Stock Database, SETID 20.
- CCM See the section “[CCM Data Groups](#)” on page 2834 for more information about groups in the CRSP/Compustat Merged Databases, SETID 250.
- IND mthly grp See the section “[Monthly IND Group Data Group Names](#)” on page 2838 for more information about groups in the Monthly Indices Group Data Database, SETID 400.
- IND mthly ts See the section “[Monthly IND Time Series Data Group Names](#)” on page 2839 for more information about groups in the Monthly Indices Time Series Database, SETID 420.
- IND daily grp See the section “[Daily IND Group Data Group Names](#)” on page 2838 for more information about groups in the Daily Indices Group Data Database, SETID 440.
- IND daily ts See the section “[Daily IND Time Series Data Group Names](#)” on page 2840 for more information about groups in the Daily Indices Time Series Database, SETID 460.

Details: SASEXCCM Interface Engine

SAS Output Data Set

You can use the SAS DATA step to write the selected CRSP or Compustat data to a SAS data set. This enables you to easily analyze the data by using SAS software. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the DATE of each observation, the series name of each series read from the CRSPAccess database, event variables, and the label or description of each series, event, or array.

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEXCCM *libref* to create a custom view of your data.

Missing Values

In general, CRSP missing values are represented as ‘.’ in the SAS data set. When accessing the CCM database, the SASEXCCM engine interprets missing values according to the conditions and codes defined by Compustat and represents them as SAS missing codes, as shown in Table 40.3.

Table 40.3 Mapping of Compustat and SAS Missing Codes

Missing Value	Missing Code	Condition
0.0001	.	No data for data item
0.0002	.S	Data are available only on a semi-annual basis
0.0003	.A	Data are available only on an annual basis
0.0004	.C	Combined into other item
0.0007	.N	Data are not meaningful
0.0008	.I	Reported as insignificant

Missing value codes conform with Compustat’s Strategic Insight and binary conventions for missing values. For more information about how CRSP handles Compustat missing codes, see the section “Notes on Missing Values” in the second chapter of the *CRSP/Compustat Merged Database Guide*.

Data Reference: Introduction

Data reference details are presented for items, keysets, and groups available from four CRSPAccess databases in this order: CCM database, STK databases, and IND databases. In addition to summary tables, sample SAS statements show how to generate a customized list of item names available from each group for a particular database.

CCM Data Items

The CRSP/Compustat Merged (CCM) database is organized by company and security according to Compustat's Permanent SPC Identifier (GVKEY) and Compustat's Permanent Issue Identifier (IID). An identifying relationship exists between IID and GVKEY. The two identifiers must be accessed as a pair to properly identify a Compustat security. One GVKEY can have multiple IIDs. The SASEXCCM interface engine provides the GVIIDKEY= option to provide access to Compustat securities through the composite key designated by "GVKEY.IID".

CCM data are broken down into items, and items can be further qualified by a set of secondary keys. CRSP calls these known collections of keys and values a *keyset*, and it assigns a numeric code and mnemonic tag to each unique collection. Each keyset represents different output series. Items are also organized into groups for selection and presentation. A group can include other groups, or a group can include items. Items can belong to more than one group. Sometimes groups are also called members.

For example, the Compustat data item SALE has secondary keys for industry format, data format, population source, and consolidation level. A different value of company sales can be available for any combination of these keys, such as a combination that represents the originally reported sales or the final restated sales from a later filing. The SALE data item is a part of the ANNITEM (Annual Time Series Items, including footnotes and data codes) group.

The CCM database contains data items provided by Compustat in addition to structures and supplementary data items provided by CRSP. All data items include a mnemonic and a field name. This section provides a summary of Compustat data items whose mnemonic differs in the CCM database, and a summary of the supplementary data items provided by CRSP. For more information about the Compustat data items, refer to your Compustat data documentation or see www.compustatresources.com/support/index.html. For more information about the supplementary CRSP data items, see your CCM Database Guide.

Table 40.4 Items with Different CRSP and Compustat Names

Compustat Mnemonic	CRSP itm_name	Description	Definition
BETA	XPFBETA	Data item	Xpressfeed beta
DVPSXM	XDVPXSM	Data item	Index monthly dividend
PRC	XPFPRC	Data item	Participation rights certificates
PRCCM	XPRCCM	Data item	Index price close monthly
PRCHM	XPRCHM	Data item	Index price high monthly
PRCLM	XPRCLM	Data item	Index price low monthly
PRC_DC	XPFPRC_DC	Data code	Participation rights certificates data code
PRC_FN	XPFPRC_FN	Footnote	Participation rights certificates footnote
RET	XPFRET	Data item	Total real estate property
RET_DC	XPFRET_DC	Data code	Total real estate property data code
RET_FN	XPFRET_FN	Footnote	Total real estate property footnote
YEAR	YEARQ	Data item	Year quarterly

Supplemental CRSP data items are organized into groups. For a list of the supplemental data groups, see the section “[CCM Data Groups](#)” on page 2834.

CCM Keysets

Compustat items can be qualified by a set of secondary keys. This collection of secondary keys and values creates a keyset that assigns a numeric code and mnemonic tag to each unique collection. Each keyset represents different output series. For example, one keyset might represent originally reported sales, and another might represent the final restated sales from a later filing. Full details about keysets can be found in the *CRSP/Compustat Merged Database Guide*. For your convenience, [Table 40.5](#) summarizes the keysets.

Table 40.5 Summary of CCM Keysets

Keyset	Tag	Keyset Description
0		Indices
1	STD	Industrial format, consolidated information, standardized presentation
2	SUMM	Industrial format, standardized summary data (StdSumData) from the latest annual filing
3	PRES	Industrial format, StdSumData collected prior to company amendment
4	FS	Financial services format, consolidated information, standardized presentation
5	PFO	Industrial format, pro forma reporting, standardized presentation
6	PFAS	Pre-FASB reporting
7	SFAS	Industrial format, pre-FASB reporting, standardized presentation
8	PRE	Industrial format, StdSumData collected from the latest annual filing
10	PDIV	Industrial format, pre-divestiture reporting, standardized presentation
11	DOM	Domestic
12	SUPF	Industrial format, pre-FASB reporting, StdSumData from the latest annual filing
14	STD1	Industrial format, consolidated information, standardized presentation, rank 1
15	FSFO	Financial services format, pro forma reporting, standardized presentation
16	FS1	Financial services format, consolidated information, standardized presentation, rank 1
17	FS2	Financial services format, consolidated information, standardized presentation, rank 2
18	SUFS	Industrial format, pro forma reporting, StdSumData from the latest annual filing
19	PDI1	Industrial format, pre-divestiture reporting, standardized presentation, rank 1
20	PFA1	Industrial format, pre-FASB reporting, standardized presentation, rank 1
21	SUPD	Industrial format, pre-divestiture reporting, StdSumData from the latest annual filing
22	FS3	Financial services format, consolidated information, standardized presentation, rank 3
23	PDI2	Industrial format, consolidated information, standardized presentation, rank 2
24	CONS	Consolidated information
25	STD2	Industrial format, consolidated information, standardized presentation, rank 2
26	STD3	Industrial format, consolidated information, standardized presentation, rank 3
27	STD4	Industrial format, consolidated information, standardized presentation, rank 4
28	STD5	Industrial format, consolidated information, standardized presentation, rank 5
29	PFA2	Industrial format, pre-FASB reporting, standardized presentation, rank 2
30	PFA3	Industrial format, pre-FASB reporting, standardized presentation, rank 3
31	CUSD	Calendar-based reporting in US dollars
32	FUSD	Fiscal-based reporting in US dollars
33	CCAD	Calendar-based reporting in Canadian dollars
34	FCAD	Fiscal-based reporting in Canadian dollars
35	PFA4	Industrial format, pre-FASB reporting, standardized presentation, rank 4
36	PFO2	Industrial format, pro forma reporting, standardized presentation, rank 2
37	PFO1	Industrial format, pro forma reporting, standardized presentation, rank 1
38	PRE1	Industrial format, standardized data collected before company amendment, rank 1
39	FFO1	Financial services format, pro forma reporting, standardized presentation, rank 1
40	FS4	Financial services format, consolidated information, standardized presentation, rank 4
41	GICS	Industry code type Global Industry Classification Standard
43	FORD	Pro forma reporting
44	BSTD	Bank format, consolidated information, standardized presentation
45	BSUMM	Bank format, consolidated information, StdSumData from the latest annual filing
46	BPFO	Bank format, pro forma reporting, standard presentation
47	BASTD	Bank format, consolidated information, average standardized presentation
48	BASUMM	Bank format, average standardized summary presentation from the latest annual filing
49	BAPFO	Bank format, pro forma reporting, average standardized presentation

CCM Data Groups

CCM items are organized into groups for ease of selection and presentation. Each group is given a group name. These names are unique and do not overlap with item names. A group can be made up of either items or other groups. Items can belong to more than one group. [Table 40.6](#) provides a summary of some groups. See your *CCM Database Guide* for more information about CCM data groups.

Table 40.6 Selected Xpressfeed Primary and CRSP Supplemental Groups

Item Name	Description
MASTER	CCM company ID and range data
COMPANY	CCM company header information
IDX_INDEX	CCM idx_index header information
SPIND	Standard & Poor's (S&P) index header (pre-GICS)
COMPHIST	CCM company header history
CSTHIST	CST header history
LINK	Link history
LINKUSED	CCM company CRSP link used data
LINKRNG	CCM company CRSP link range data
ADJFACT	CCM company adjustment factor history
HGIC	CCM company GICS code history
OFFTITL	CCM company officer title data
CCM_FILEDATE	CCM company filing date data
CCM_IPCD	CCM industry presentation code data
SECURITY	CCM security header information
SECHIST	CCM security header history
SEC_MTHSPT	CCM security monthly split events
SEC_MSPT_FN	CCM security monthly split event footnotes
SEC_MDIV_FN	CCM security monthly dividend event footnotes
SEC_SPIND	CCM security S&P information events
IDXCST_HIS	CCM security historical index constituents
SPIDX_CST	CCM security S&P index constituent events
CCM_SEG_CUR	CCM operating segment currency rate data
CCM_SEG_SRC	CCM operating segment source data
CCM_SEG_PROD	CCM operating segment product data
CCM_SEG_CUST	CCM operating segment customer data
CCM_SEG_DTL	CCM operating segment detail data
CCM_SEG_ITM	CCM operating segment item data
CCM_SEG_NAICS	CCM operating segment NAICS data
CCM_SEG_GEO	CCM operating segment geographic data

Daily STK Data Items

You can generate a customized list of item names available in the daily stock database (SETID=10) by running the following sample statements for each group name in [Table 40.8](#):

```
libname dstock sasexccm
  "\\bb04smb01\thirdparty\lnx\crspdata\DI201006\"
  setid=10 permno=12490
  itemlist="group_name.*";

proc contents data=dstock.group_name; run;
```

The following statements generate an item list of all the item names available in the group named STKHDR_ID:

```
libname crsp sasexccm
  "\\bb04smb01\thirdparty\lnx\crspdata\DI201006\"
  setid=10 permno=12490
  itemlist="STKHDR_ID.*";

proc contents data=crsp.stkhdr_id; run;
```

The item names in group STKHDR_ID are listed in [Table 40.7](#).

Table 40.7 US Daily Stock Items in Group STKHDR_ID

Item Name	Description
BEGDT	Begdt
COMPNO	COMPNO
CUSIP	CUSIP
ENDDT	Enddt
HCOMNAM	Latest company name
HDLSTCD	DEL
HEXCD	EX
HPRIMEXCH	Ex1
HSECSTAT	Sst
SHRCD	SH
HSICCD	SIC
HSNAICS	Naics
HSUBEXCH	Ex2
HTICK	Htick
HTRDSTAT	Tst
HTSYMBOL	Symbol
ISSUNO	Issuno
KYPERMNO	PERMNO
PERMCO	PERMCO
PERMNO	PERMNO

Daily STK Data Groups

Daily stock groups are shown in [Table 40.8](#).

Table 40.8 US Daily Stock Group Names

Group Name	Description
STKHDR_ID	Stock header (summary)
STKHDR_ALL	All stock headers
STKHDR_RNG	Stock header plus ranges
LSTKHDR_RNG	Stock header plus calendar index ranges
NAMES_SHORT	Name history (short list)
NAMES	Name history
NAMES_ALL	All names
DISTS	Distribution events
ADJDISTS	Daily adjusted distribution events
SHARES	Shares outstanding observations
RSHARES	Raw shares outstanding observations
ADJSHARES	Daily adjusted shares outstanding observations
DELIST	Delisting history
ADJDELIST	Adjusted delisting events
NASDIN	NASDAQ information history
DLY_DATA	Daily price summary time series
DLY_ADJDATA	Daily adjusted price summary time series
DSTK_TS	Daily time series
DLY_WGT	Daily price, shares, and returns
DLY_ADJ_WGT	Daily adjusted price, shares, and returns
DLY_LVL	Daily index level
DLY_RET	Daily returns
PORTF	Portfolio data
GROUP	Group membership data
DLY_TS_NAT	Daily time series (native only)
DSTK_VOLUME	Volume
DSTK_CAP	Capitalization

Monthly STK Data Items

You can generate a customized list of item names available in the monthly stock database by running the following sample statements for each group name in [Table 40.9](#):

```
libname crsp sasexccm
  "\\tappan\crsp1\data201008_little\MIZ201006\"
  setid=20 permno=12490
  itemlist="group_name.*";

proc contents data=crsp.group_name; run;
```

Monthly STK Data Groups

Monthly stock groups are shown in [Table 40.9](#).

Table 40.9 US Monthly Stock Group Names

Group Name	Description
MSTKHDR_ID	Stock header (summary)
MSTKHDR_RNG	Stock header plus ranges
LMSTKHDR_RNG	Stock header plus calendar index ranges
MNAMES_SHORT	Name history (short list)
MNAMES	Name history
MNAMES_ALL	All MNAMES (monthly name histories)
MDISTS	Distribution events
MADJDISTS	Monthly adjusted distribution events
MSHARES	Shares outstanding observations
RMSHARES	Raw shares outstanding observations
MADJSHARES	Monthly adjusted shares outstanding observations
MDELIST	Delisting history
MADJDELIST	Adjusted delisting events
MNASDIN	NASDAQ information history
MTH_DATA	Monthly price summary time series
MTH_ADJDATA	Monthly adjusted price summary time series
MTH_TS	Monthly time series
MTH_WGT	Monthly price, shares, and returns
MTH_ADJ_WGT	Monthly adjusted price, shares, and returns
MTH_LVL	Monthly index level
MTH_RET	Monthly returns
MPORTF	Portfolio data
MGROUP	Group membership data
MTH_TS_NAT	Monthly time series (native only)
MSTK_VOLUME	Volume
MSTK_CAP	Capitalization

IND Group Data Item Names

You can generate a customized list of available indices group data item names by running the following sample statements for each daily or monthly group name from [Table 40.10](#) or [Table 40.11](#) and substituting the corresponding SETID, data path, and actual daily (or monthly) group name for the **group_name**:

```
libname crsp sasexccm
    "\\bb04smb01\thirdparty\lnx\crspdata\DI201006\"
    setid=440
    indno=1000040
    itemlist="group_name.*";

proc contents data=crsp.group_name; run;
```

Monthly IND Group Data Group Names

The monthly group indices data consist of the groups listed in [Table 40.10](#).

Table 40.10 US IND Monthly Group Data Group Names

Group Name	Description
MINDHDRG	Monthly index group header
MINDSUMMG	Monthly index group summary
MLISTG	Monthly index group list history
MREBALG	Monthly index group rebalancing history
MREBALG_ALL	Monthly index group rebalancing
MTHGIND_LVL	Monthly index group levels
MTHGIND_RET	Monthly index group returns
MTHGIND_TS	Monthly index group series
MTHGIND_VAL	Monthly index group values

Daily IND Group Data Group Names

The daily group indices data consist of the groups listed in [Table 40.11](#).

Table 40.11 US IND Daily Group Data Group Names

Group Name	Description
INDHDRG	Index group header
INDSUMMG	Index group summary
LISTG	Index group list history
REBALG	Index group rebalancing history
REBALG_ALL	Index group rebalancing
DLYGIND_LVL	Index group levels
DLYGIND_RET	Index group returns
DLYGIND_TS	Index group series
DLYGIND_VAL	Index group values

IND Time Series Data Item Names

You can generate a customized list of available item names by running the following sample statements for each daily or monthly time series group name from [Table 40.12](#) or [Table 40.13](#) and substituting the corresponding SETID, data path, and actual daily (or monthly) time series group name for the **group_name**:

```
libname daycrsp sasexccm
    "\\bb04smb01\thirdparty\lnx\crspdata\DI2201006\"
    setid=460
    indno=1000040
    itemlist="group_name.*";

proc contents data=daycrsp.group_name; run;
```

Monthly IND Time Series Data Group Names

The monthly indices data consist of the groups listed in [Table 40.12](#).

Table 40.12 US IND Monthly Series Data Group Names

Group Name	Description
MINDHDR	Monthly index header
MINDSUMM	Monthly index summary
MLIST	Monthly index list history
MREBAL	Monthly index rebalancing history
MREBAL_ALL	Monthly index rebalancing
MTHIND_LVL	Monthly index levels
MTHIND_RET	Monthly index returns
MTHIND_TS	Monthly index series
MTHIND_VAL	Monthly index values

Daily IND Time Series Data Group Names

The daily indices data consist of the groups listed in [Table 40.13](#).

Table 40.13 US IND Daily Time Series Data Group Names

Group Name	Description
INDHDR	Index header
INDSUMM	Index summary
LIST	Index list history
REBAL	Index rebalancing history
REBAL_ALL	Index rebalancing
DLYIND_LVL	Index levels
DLYIND_RET	Index returns
DLYIND_TS	Index series
DLYIND_VAL	Index values

Examples: SASEXCCM Interface Engine

Example 40.1: Retrieving SALE Data for One GVKEY

This simple example shows how to retrieve SALE data for one particular GVKEY=6066 (IBM). Because the ITEMLIST= option does not specify a keyset, the default (standard) keyset, KEYSET_TAG=STD, is selected. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

```

title 'Retrieve SALE data for IBM';
libname _all_ clear;

libname crsp sasexccm "%sysget(CRSP_CCM) "
    setid=250
    gvkey=6066
    itemlist="sale";

data recentsales;
    set crsp.annitem;
    where datadate >= '1jan2000'd;

proc print data=recentsales;
run;

```

Output 40.1.1 SALE Data for GVKEY=6066

Retrieve SALE data for IBM					
Obs	KYGVKEY	KEYSET_ TAG	DATADATE	SALE	
1	6066	STD	20001229	88396.0000	
2	6066	STD	20011231	85866.0000	
3	6066	STD	20021231	81186.0000	
4	6066	STD	20031231	89131.0000	
5	6066	STD	20041231	96293.0000	
6	6066	STD	20051230	91134.0000	
7	6066	STD	20061229	91424.0000	
8	6066	STD	20071231	98786.0000	
9	6066	STD	20081231	103630.0000	
10	6066	STD	20091231	95758.0000	
11	6066	STD	20101231	99871.0000	

Example 40.2: Retrieving SALE Data for Multiple Companies

This example shows how to retrieve several data items for several GVKEYs. Note how the item `offtitl` is not an annual item and is stored in its own member. The default (standard) keyset is used for all items. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

```

title 'Retrieve Sales, Revenue, Liabilities, and Officer data for IBM and MSFT';
libname _all_ clear;

libname crsp sasexccm "%sysget(CRSP_CCM) "
    setid=250
    gvkey=6066
    gvkey=12141
    itemlist="sale;revt;lct;offtitl";

data recentannitems;
    set crsp.annitem;
    where datadate >= '1jan2000'd;

proc print data=recentannitems;
proc print data=crsp.offtitl;
run;

```

Output 40.2.1 Data Items for IBM and Microsoft

Example 40.3: Retrieving Data from Different Keysets

This example shows how to retrieve several data items from different keysets. You request data about research and development (R&D) expenses (XRD) and net income (NI) over all available keysets by using the `itm_name.*` syntax in the `ITEMLIST=` option. Note that data are not available for all items in all keysets. For brevity, a subset of the data that contains the most recent figures is specified by the `WHERE` statement.

```

title 'Retrieve R&D Expenses and Net Income for IBM';
libname _all_ clear;

libname crsp sasexccm "%sysget(CRSP_CCM) "
    setid=250
    gvkey=6066
    itemlist="xrd.*;ni.*";

data recent;
    set crsp.annitem;
    where datadate >= '1jan2001'd;

proc print data=recent;
run;
```

Output 40.3.1 R&D Expenses and Net Income for GVKEY=6066

Retrieve R&D Expenses and Net Income for IBM					
Obs	KYGVKEY	KEYSET_ TAG	DATADATE	XRD	NI

Example 40.4: Retrieving Items by Using Global Options

This example shows how to retrieve data on total assets (ATQ) and after tax gain or loss (GLAQ) by using the global option for turning on footnote items, which uses the following syntax:

```
ITEMLIST="f:itm_name1;itm_name2;...itm_nameN"
```

The default (standard) keyset is used for all items. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

```
title 'Retrieve data for IBM with Footnotes';
libname _all_ clear;

libname crsp sasexccm "%sysget(CRSP_CCM) "
    setid=250
    gvkey=6066
    itemlist="f:atq;glAQ";

data recent;
    set crsp.qtritem;
    where datadate >= '1jan2004'd;

proc print data=recent;
run;
```

Output 40.4.1 Data Items with Footnotes

Example 40.5: Retrieving All GVKEYs and Company Names

This example shows how to retrieve the GVKEY and name for every company in the CCM database.

```
title 'Retrieve All GVKEYs and Company Names';
libname _all_ clear;

libname crsp sasexccm "%sysget(CRSP_CCM) "
      setid=250
      itemlist="company";

proc contents data=crsp.company;
proc print data=crsp.company(keep=kygvkey conm obs=20);
run;
```

For brevity, only the first 20 observations are shown, and only KYGVKEY and CONM are kept in [Output 40.5.1](#).

Output 40.5.1 First 20 GVKEYS and Company Names

Example 40.9: Retrieving Information for Availability of Group INDNOs

This example shows how to retrieve header information about group data and how to obtain a list of all the available INDNO keys in the IND database. The INDNO= option is intentionally omitted so that a default list is generated of all INDNOs in the database that are available for SETID 440.

```

title 'Retrieve Header Information for a Complete INDNO list';
libname _all_ clear;

libname crsp sasexccm
      "\\bb04smb01\thirdparty\lnx\crspdata\DIZ201006\"
      setid=440
      itemlist="INDNOG.*; INDCOG.*; INDNAMEG.*; GROUPNAMEG.*";

data dgindts_all;
  set crsp.indhdr;
run;

proc print data=dgindts_all(keep=kyindno indnameg); run;

```

Output 40.9.1 Daily Group Indices Header by INDNO

Retrieve Header Information for a Complete INDNO list

Chapter 41

The SASEFAME Interface Engine

Contents

Overview: SASEFAME Interface Engine	2862
Getting Started: SASEFAME Interface Engine	2862
Structure of a SAS Data Set That Contains Time Series Data	2862
Reading and Converting Fame Database Time Series	2862
Using the SAS DATA Step	2863
Using SAS Procedures	2863
Using the SAS Windowing Environment	2863
Remote Fame Data Access	2863
Creating Views of Time Series by Using SASEFAME LIBNAME Options	2864
Syntax: SASEFAME Interface Engine	2865
LIBNAME <i>libref</i> SASEFAME Statement	2865
Details: SASEFAME Interface Engine	2870
SAS Output Data Set	2870
Mapping Fame Frequencies to SAS Time Intervals	2870
Performing the Crosslist Selection Function	2872
Examples: SASEFAME Interface Engine	2875
Example 41.1: Converting an Entire Fame Database	2875
Example 41.2: Reading Time Series from the Fame Database	2878
Example 41.3: Writing Time Series to the SAS Data Set	2879
Example 41.4: Limiting the Time Range of Data	2883
Example 41.5: Creating a View Using the SQL Procedure and the SASEFAME Engine	2887
Example 41.6: Reading Other Fame Data Objects with the FAMEOUT= Option	2892
Example 41.7: Remote Fame Access by Using Fame CHLI	2895

Overview: SASEFAME Interface Engine

The SASEFAME interface engine provides a seamless interface between Fame and SAS data to enable SAS users to access and process time series, case series, and formulas that reside in a Fame database.

Fame is an integrated, front-to-back market data and historical database solution for storing and managing real-time and high-volume time series data that are used by leading institutions in the financial, energy, and public sectors, as well as by third-party content aggregators, software vendors, and individual investors. Fame provides real-time market data feeds and end-of-day data, a web-based desktop solution, application hosting, data delivery components, and tools for performing analytic modeling.

The SASEFAME engine uses the LIBNAME statement to enable you to specify the time series that you want to read from the Fame database and how you want to convert the selected time series to the same time scale. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEFAME interface engine supports Windows, Solaris, AIX, and Linux Opteron hosts.

Getting Started: SASEFAME Interface Engine

Structure of a SAS Data Set That Contains Time Series Data

The SAS System represents time series data in a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASEFAME engine provides a time ID variable named DATE. The DATE variable can be represented by any of the time intervals shown in the section “[Mapping Fame Frequencies to SAS Time Intervals](#)” on page 2870.

Reading and Converting Fame Database Time Series

The SASEFAME engine supports reading and converting time series that reside in Fame databases. The SASEFAME engine uses Fame’s Work database to temporarily store the converted time series. All series that are specified by the Fame wildcard are written to the Fame Work database. For conversion of very large databases, you might want to define the FAME_TEMP environment variable to point to a location where there is ample space for the Fame Work database.

The SASEFAME engine provides seamless access to Fame databases via Fame's C host language interface (CHLI). Fame expressions that contain formulas and Fame functions can be input to the engine via the INSET= option.

The SASEFAME engine finishes the CHLI whenever a fatal error occurs. To restart the engine after a fatal error, terminate the current SAS session and open a new SAS session.

Using the SAS DATA Step

You can store the converted series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. After your data are stored in a SAS data set, you can use this data set as you would any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure and report information about the contents of your data set by using the CONTENTS procedure, as in [Example 41.1](#). You can create a view of the FAME database by using the SQL procedure's USING clause to reference the SASEFAME engine in your libref. See [Example 41.5](#).

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment. To do so, select the SASEFAME engine libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking the desired output data set libref in the LIBNAME window of the SAS windowing environment. Type **Viewtable** on the SAS command line to view any of your SASEFAME engine tables, views, or librefs both for input and output data sets.

Before you use the **Viewtable** command, it is recommended that you store your output data sets in a physical folder or library that is separate from the folder or library used for your input databases. (The default location for output data sets is the SAS Work library.)

Remote Fame Data Access

The remote access feature of the SASEFAME engine uses the Fame CHLI to communicate with your remote Fame server. It is available to licensed CHLI customers who have Fame CHLI on both their remote and client machines.

As shown in [Example 41.7](#), you simply provide the frdb_m port number and node name of your Fame master server in your *libref*. For more information, see the section "Starting the Master Server" in the *Guide to Fame Database Servers*.

Creating Views of Time Series by Using SASEFAME LIBNAME Options

You can perform selection based on names of your time series simply by using Fame wildcard specifications in the SASEFAME engine WILDCARD= option.

You can limit the time span of time series data by specifying a beginning and ending date range in the SASEFAME engine RANGE= option.

It is also easy to use the SAS input data set INSET= option to create a specific view of your Fame data. You can create multiple views by using multiple LIBNAME statements with customized options that are tailored to the unique views that you want to create.

You can list the INSET variables that you want to keep in your SAS data set by using the KEEP= clause. When you use INSET variables in conjunction with the input data set that you specify in the INSET= option, the SASEFAME engine can show any or all of your expression groups in the same view or in multiple views. The INSET= option defines the valid set of expression groups that you can reference in the KEEP= clause, as shown in [Example 41.16](#).

The INSET variables define the BY variables that enable you to view cross sections (slices) of your data. When you use INSET variables in conjunction with the WHERE clause and the CROSSLIST= option, the SASEFAME engine can show any or all of your BY groups in the same view or in multiple views. When you use the INSET= option along with a WHERE clause that specifies the BY variables that you want to use in your view, you must also use the CROSSLIST= option, as shown in [Example 41.10](#). You can use the CROSSLIST= option without using the INSET= option, as shown in [Example 41.8](#) and [Example 41.9](#).

Syntax: SASEFAME Interface Engine

The SASEFAME engine uses standard engine syntax. Table 41.1 summarizes the options used by the SASEFAME engine.

Table 41.1 Summary of LIBNAME *libref* SASEFAME Statement Options

Option	Description
CONVERT=	Specifies the Fame frequency and the Fame technique
WILDCARD=	Specifies a Fame wildcard to match data object series names within the Fame database
RANGE=	Specifies the range of data to keep in format 'ddmmmyyy'd – 'ddmmmyyy'd
INSET=	Uses a SAS data set named <i>setname</i> and KEEP= <i>fame_expression_group</i> as selection input variables or WHERE= <i>fame_bygroup</i> as selection input for BY variables
CROSSLIST=	Specifies a Fame crosslist <i>fame_namelist</i> to perform selection based on the crossproduct of two Fame namelists
FAMEOUT=	Specifies the Fame data object class/type that you want output to the SAS data set
DBVERSION=	Echoes the present version number of the Fame Work database in the SAS log
TUNEFAME=	Tunes the Fame database engine's use of memory to reduce I/O in favor of a bigger virtual memory for caching database objects
TUNECHLI=	Tunes the CHLI database engine's use of memory to reduce I/O in favor of a bigger virtual memory for caching database objects

LIBNAME *libref* SASEFAME Statement

LIBNAME *libref* **SASEFAME** '*physical name*' *options* ;

Because '*physical name*' specifies the location of the folder where your Fame database resides, it should end in a backslash if you are in a Windows environment or a forward slash if you are in a UNIX environment.

If you are accessing a remote Fame database by using the Fame CHLI, you can use the following syntax for '*physical name*':

```
'#port_number @hostname physical_path_name'
```

You can specify the following *options*.

CONVERT=(**FREQ=***fame_frequency* **TECH=***fame_technique*)

CONV=(**FREQ=***fame_frequency* **TECH=***fame_technique*)

specifies the Fame frequency and the Fame technique, just as you would in the Fame CONVERT

function. There are four possible values for *fame_technique*: *Constant* (default), *Cubic*, *Discrete*, and *Linear*. Table 41.4 shows the Fame frequencies that are supported by the SASEFAME engine.

For a more complete discussion of Fame frequencies and SAS time intervals, see the section “[Mapping Fame Frequencies to SAS Time Intervals](#)” on page 2870. For all possible *fame_frequency* values, see the section “Understanding Frequencies” in the *User’s Guide to Fame*. For example:

```
LIBNAME libref sasefame 'physical-name'
      CONVERT=(TECH=CONSTANT FREQ=TWICEMONTHLY);
```

WILDCARD=*"fame_wildcard"*

WILD=*"fame_wildcard"*

limits the time series read from the Fame database. By default, the SASEFAME engine reads all time series in the Fame database that you name in your SASEFAME libref. The *fame_wildcard* is a quoted string that contains the Fame wildcard you want to use. The wildcard is used for matching against the data object names of series that you want to select from the Fame database that resides in the library you are assigning.

For more information about using wildcards, see the section “Specifying Wildcards” in the *User’s Guide to Fame*.

For example, to read all time series in the TEST library that is being accessed by the SASEFAME engine, you would specify the following statement:

```
LIBNAME test sasefame 'physical name of test database'
      WILDCARD="?";
```

To read series that have names such as A_DATA, B_DATA, and C_DATA, you could specify the following statement:

```
LIBNAME test sasefame 'physical name of test database'
      WILDCARD="^_DATA";
```

When you use the WILDCARD= option, you limit the number of series that are read and converted to the desired frequency. This option can help you save resources when processing large databases or when processing a large number of observations, such as daily or hourly frequencies. Because the SASEFAME engine uses the Fame Work database to store the converted time series, using wildcards is recommended to prevent your workspace from getting too large. When the FAMEOUT= option is also specified, the wildcard is applied to the type of data object series that you specify in the FAMEOUT= option.

RANGE=*'fame_begdt'd-'fame_enddt'd'*

DATERANGE=*'fame_begdt'd-'fame_enddt'd'*

DATE=*'fame_begdt'd-'fame_enddt'd'*

DATECASE=*'fame_begdt'd-'fame_enddt'd'*

limits the time range of data that are read from your Fame database. The string *fame_begdt* is the beginning date in ddmmmyyyy format, and the string *fame_enddt* is the ending date of the range in ddmmmyyyy format; both strings must be enclosed in single quotation marks and followed by the letter d.

For example, to read a series with a date range that spans the first quarter of 1999, you could use the following statement:

```
LIBNAME test sasefame 'physical name of test database'
      RANGE='01jan1999'd - '31mar1999'd;
```

INSET=(setname KEEP=fame_expression_group)

INSET=(setname KEEPLIST=fame_expression_group)

specifies the name of a SAS data set (*setname*) and selects series that are generated by the expressions defined in *fame_expression_group*. You can define *fame_expression_group* by using Fame functions and Fame expressions. It is important to specify the length of the longest expression, or expressions might be truncated because the default length is the first defined variable in the DATA step. The INSET (input data set) must output each expression statement as a character string ending with a semicolon, enclosed in single quotation marks, and followed by another semicolon and an output statement. **NOTE:** The EXPRESS variable is assigned the character string expression, and is shown in [Table 41.2](#). The following statements create an input data set, INSETA, and print it:

```
data inseta; /* Use this for training database */
  length express $52;
  express='{ibm.high,ibm.low,ibm.close}'; output;
  express='crosstlist({gm,f,c},{volume})'; output;
  express='cvx.close'; output;
  express='mave(ibm.close,30)'; output;
  express='cvx.close+ibm.close'; output;
  express='ibm.close'; output;
  express='close * shares/sum(close * shares)'; output;
  express='sum(pep.volume)'; output;
  express='mave(pep.close,20)'; output;
run;

proc print
  data=inseta;
run;
```

Next you can name the input data set that you want to use in the INSET= option, followed by the KEEP= variable that specifies the expression group you want to keep. Only series variables that are defined in the selected expression group are output to the output data set. You can define up to eight different expression groups in an INSET= option.

```
libname lib5 sasefame "C:\PROGRA~1\FAME10\util"
  wildcard="?"
  convert=(frequency=business technique=constant)
  range='23jul1997'd - '25jul1997'd
  inset=( inseta KEEP=express)
;

data trout;
  set lib5.trainten;
run;

title1 'TRAINING DB, Pricing Timeseries for Expressions in INSET=';
title2 'OUT=TROUT from the PRINT Procedure';
```

```
proc print data=trout;
run;
```

Table 41.2 shows the eight expressions that are defined in INSETA.

Table 41.2 SAS Input Data Set, INSETA, Defined for Use in the INSET= Option

Observation	EXPRESS
1	cvx.close;
2	ibm.high,ibm.low,ibm.close;
3	mave(ibm.close,30);
4	crosslist(gm,f,c,volume);
5	cvx.close+ibm.close;
6	ibm.close;
7	sum(pep.volume);
8	mave(pep.close,20);

Table 41.3 shows the output data set, TROUT. The output data set names each derived variable ‘SASTEMPn’ by appending the number, n, to match the observation number of the input data set’s expression for that variable. For example, SASTEMP1 names the series derived by ‘cvx.close’ in observation 1, and SASTEMP3 names the series derived by the expression ‘mave(ibm.close,30);’ in observation 3. Because SASTEMP2 is a simple name list of three series, the original series names are used.

Table 41.3 TRAINING DB, Pricing Timeseries for Expressions in INSETA for OUT=TROUT from the PRINT Procedure

DATE	C.VOLUME	VOLUME	GM.VOLUME	IBM.CLOSE	IBM.HIGH
23JUL1997	33791.88	45864.05	37392	52.5625	53.5000
24JUL1997	41828.85	29651.34	27771	53.9063	54.2188
25JUL1997	46979.83	36716.77	24969	53.5000	54.2188
IBM.LOW	SASTEMP1	SASTEMP3	SASTEMP5	SASTEMP6	SASTEMP8
51.5938	38.4063	.	90.9688	52.5625	.
52.2500	38.4375	.	92.3438	53.9063	.
52.8125	39.0000	.	92.5000	53.5000	.

Note that SASTEMP3 and SASTEMP8 have no observations in the date range July 23, 1997, to July 25, 1997, so the missing value symbol ‘.’ appears for those observations.

INSET=(*setname* WHERE=*fame_bygroup*)

specifies a SAS data set (*setname*) as input for a BY group such as a ticker, and uses the *fame_bygroup* to select time series that are named using the following convention. Selected variable names are glued together by the BY-group name (such as a ticker symbol) concatenated with the glue character (such as DOT) to the series name that is specified in the CROSSLIST= option or in the *fame_bygroup*.

For more information, see the section “[Performing the Crosslist Selection Function](#)” on page 2872.

CROSSLIST=(< *fame_namelist1*, > *fame_namelist2*)**CROSS=(< *fame_namelist1*, > *fame_namelist2*)**

performs a crossproduct of the members of the first namelist with the members of the second namelist, using a glue symbol “.” to join the two. If one of the time series that are listed in *fame_namelist2* does not exist, the SASEFAME engine stops processing the remainder of the namelist. For more information, see the section “[Performing the Crosslist Selection Function](#)” on page 2872.

FAMEOUT=*fame_data_object_class_type*

specifies the class and type of the Fame data series objects to include in your SAS output data set. The possible values for *fame_data_object_class_type* are FORMULA, TIME, BOOLEAN, CASE, DATE, and STRING. Case series can be numeric, boolean, string, and date, or they can be generated using formulas that resolve to series. The SASEFAME engine resolves all formulas that belong to the type of series data object that you specify in the FAMEOUT= option. If the FAMEOUT= option is not specified, numeric time series are output to the SAS data set. FAMEOUT=CASE defaults to case series of numeric type. If you want another type of case series in your output, then you must specify it. Scalar data objects are not supported.

DBVERSION=ON | OFF

specifies whether to display the version number of the Fame Work database. DBVERSION=ON specifies that the SAS log show the version number (3 or 4) of the Fame Work database. By default, DBVERSION=OFF.

TUNEFAME=NODES *fameengine_size_virtual_memory_MB*

specifies the number of megabytes to use for the cache size for the Fame API (CHLI). The *fameengine_size_virtual_memory_MB* can range from a minimum of 0.1 MB (100 KB) to a maximum of 17,592,186,000,000 MB. For more information, see [Example 41.17](#).

TUNECHLI=NODES *famechliengine_size_virtual_memory_MB*

specifies the number of megabytes to use for the cache size for the Fame API (CHLI). The *famechliengine_size_virtual_memory_MB* can range from a minimum of 0.1 MB (100 KB) to a maximum of 17,592,186,000,000 MB. For more information, see [Example 41.17](#).

Details: SASEFAME Interface Engine

SAS Output Data Set

You can use the SAS DATA step to write the selected time series from your Fame database to a SAS data set. This enables you to easily analyze the data by using the SAS System. You can specify the name of the output data set in the DATA statement. This causes the engine supervisor to create a SAS data set by using the specified name in either the SAS Work library or, if specified, the Sasuser library. For more information about naming your SAS data set, see the section “SAS Data Sets: Data Set Names” in the *SAS Language Reference: Concepts*.

The contents of the SAS data set that contains time series include the date of each observation, the name of each series read from the Fame database as specified by the WILDCARD= option, and the label or Fame description of each series. Missing values are represented as ‘.’ in the SAS data set. You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEFAME libref in the LIBNAME window that you have previously used in your LIBNAME statement. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can use PROC SQL and the SASEFAME engine to create a view of your SAS data set. You can view your SAS output observations by double-clicking the desired output data set libref in the LIBNAME window of the SAS windowing environment.

The DATE variable in the SAS data set contains the date of the observation. For Fame weekly intervals that end on a Friday, Fame reports the date on the Friday that ends the week, whereas the SAS System reports the date on the Saturday that begins the week.

A more detailed discussion of how to map Fame frequencies to SAS time intervals follows. For other types of data, such as Boolean case series, numeric case series, date case series, string case series, and extracting source for formulas, see [Example 41.11](#), [Example 41.12](#), [Example 41.13](#), [Example 41.14](#), and [Example 41.15](#), respectively.

Mapping Fame Frequencies to SAS Time Intervals

[Table 41.4](#) summarizes the mapping of Fame frequencies to SAS time intervals. Fame frequencies often have a sample unit in parentheses after the keyword frequency. This sample unit is an end-of-interval unit. SAS dates are represented by beginning-of-interval notation.

For more information about SAS time intervals, see Chapter 4, “[Date Intervals, Formats, and Functions](#).”

For more information about Fame frequencies, see the section “[Understanding Frequencies](#)” in the *User’s Guide to Fame*.

Performing the Crosslist Selection Function

There are two methods of performing the crosslist selection function. The first method uses two Fame namelists, and the second method uses one namelist and one BY group specified in the WHERE= clause of the INSET= option.

For example, suppose that your Fame database has a string case series named TICKER, so that when the Fame NL function is used on TICKER, it returns the following namelist:

```
Ticker = {AOL, C, CVX, F, GM, HPQ, IBM, INDUA, INTC, SPX, SUNW, XOM}
```

Also suppose your time series are named in *fame_namelist2* as

```
{adjust, close, high, low, open, volume, uclose, uhigh, ulow, uopen, uvolume}
```

When you specify the following statements, the 132 variables shown in [Table 41.5](#) are selected by the CROSSLIST= option:

```
LIBNAME test sasefame 'physical name of test database'
RANGE='01jan1999'd - '31mar1999'd
CROSSLIST=(nl(ticker),
           {adjust, close, high, low, open, volume,
            uclose, uhigh, ulow, uopen, uvolume})
;
```

Table 41.5 SAS Variables Selected by CROSSLIST= Option

AOL.ADJUST	C.ADJUST	CVX.ADJUST	F.ADJUST
AOL.CLOSE	C.CLOSE	CVX.CLOSE	F.CLOSE
AOL.HIGH	C.HIGH	CVX.HIGH	F.HIGH
AOL.LOW	C.LOW	CVX.LOW	F.LOW
AOL.OPEN	C.OPEN	CVX.OPEN	F.OPEN
AOL.UCLOSE	C.UCLOSE	CVX.UCLOSE	F.UCLOSE
AOL.UHIGH	C.UHIGH	CVX.UHIGH	F.UHIGH
AOL.ULOW	C.ULOW	CVX.ULOW	F.ULOW
AOL.UOPEN	C.UOPEN	CVX.UOPEN	F.UOPEN
AOL.UVOLUME	C.UVOLUME	CVX.UVOLUME	F.UVOLUME
AOL.VOLUME	C.VOLUME	CVX.VOLUME	F.VOLUME
GM.ADJUST	HPQ.ADJUST	IBM.ADJUST	INDUA.ADJUST
GM.CLOSE	HPQ.CLOSE	IBM.CLOSE	INDUA.CLOSE
GM.HIGH	HPQ.HIGH	IBM.HIGH	INDUA.HIGH
GM.LOW	HPQ.LOW	IBM.LOW	INDUA.LOW
GM.OPEN	HPQ.OPEN	IBM.OPEN	INDUA.OPEN
GM.UCLOSE	HPQ.UCLOSE	IBM.UCLOSE	INDUA.UCLOSE
GM.UHIGH	HPQ.UHIGH	IBM.UHIGH	INDUA.UHIGH
GM.ULOW	HPQ.ULOW	IBM.ULOW	INDUA.ULOW
GM.UOPEN	HPQ.UOPEN	IBM.UOPEN	INDUA.UOPEN
GM.UVOLUME	HPQ.UVOLUME	IBM.UVOLUME	INDUA.UVOLUME
GM.VOLUME	HPQ.VOLUME	IBM.VOLUME	INDUA.VOLUME
INTC.ADJUST	SPX.ADJUST	SUNW.ADJUST	XOM.ADJUST
INTC.CLOSE	SPX.CLOSE	SUNW.CLOSE	XOM.CLOSE
INTC.HIGH	SPX.HIGH	SUNW.HIGH	XOM.HIGH
INTC.LOW	SPX.LOW	SUNW.LOW	XOM.LOW
INTC.OPEN	SPX.OPEN	SUNW.OPEN	XOM.OPEN
INTC.UCLOSE	SPX.UCLOSE	SUNW.UCLOSE	XOM.UCLOSE
INTC.UHIGH	SPX.UHIGH	SUNW.UHIGH	XOM.UHIGH
INTC.ULOW	SPX.ULOW	SUNW.ULOW	XOM.ULOW
INTC.UOPEN	SPX.UOPEN	SUNW.UOPEN	XOM.UOPEN
INTC.UVOLUME	SPX.UVOLUME	SUNW.UVOLUME	XOM.UVOLUME
INTC.VOLUME	SPX.VOLUME	SUNW.VOLUME	XOM.VOLUME

Instead of using two namelists, you can use the WHERE= clause in an INSET= option to perform the crossproduct of the BY variables specified in your input data set via the WHERE= clause and the members named in your namelist. The following statements define a SAS input data set named INSETA to use as input for the CROSSLIST= option instead of using the Fame namelist:

```
DATA INSETA;
  LENGTH tick $5;
  /* AOL, C, CVX, F, GM, HPQ, IBM, INDUA, INTC, SPX, SUNW, XOM */
  tick='AOL'; output;
  tick='C'; output;
  tick='CVX'; output;
  tick='F'; output;
```

```

tick='GM'; output;
tick='HPQ'; output;
tick='IBM'; output;
tick='INDUA'; output;
tick='INTC'; output;
tick='SPX'; output;
tick='SUNW'; output;
tick='XOM'; output;
RUN;

LIBNAME test sasefame 'physical name of test database'
      RANGE='01jan1999'd - '31mar1999'd
      INSET=(inseta, where=tick)
      CROSSLIST=(
        {adjust, close, high, low, open, volume,
         uclose, uhigh, ulow, uopen, uvolume})
      ;

```

Using a SAS INSET statement with a WHERE clause and using a Fame namelist in the CROSSLIST= statement are equivalent ways of performing the same selection function. In the preceding example, the Fame ticker namelist corresponds to the SAS input data set's BY variable named TICK.

Note that the *fame_bygroup* that you specify in the WHERE= clause must match the BY-variable name used in your input data set in order for the CROSSLIST= option to perform the desired selection. If one of the time series listed in *fame_namelist2* does not exist, the SASEFAME engine stops processing the remainder of the namelist. For complete results, make sure that your *fame_namelist2* is accurate and does not name unknown variables. The same holds true for *fame_namelist1* and the BY-variable values named in the input data set and used in the WHERE= clause.

Examples: SASEFAME Interface Engine

In this section, the examples were run on Windows, so the physical names used in the LIBNAME *libref* SASEFAME statement reflect the syntax necessary for that platform. In general, Windows environments use backslashes in their pathname, and the UNIX environments use forward slashes.

Example 41.1: Converting an Entire Fame Database

To enable conversion of all time series, no wildcard is specified, so the default “?” wildcard is used. Always consider both the number of time series and the number of observations generated by the conversion process. The converted series reside in the Fame Work database during the SAS DATA step. You can further limit your resulting SAS data set by using KEEP, DROP, or WHERE statements inside your DATA step.

The following statements convert a Fame database and print out its contents:

```
options pagesize=60 linesize=80 validvarname=any ;
%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put (&FAMETEMP);

libname famedir sasefame "%sysget(FAME_DATA)"
        convert=(freq=annual technique=constant);

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* Read in oecd1.db data from the Organization */
    /* For Economic Cooperation and Development */
    where date between '01jan88'd and '31dec93'd;
run;

proc print data=mydir.a;
run;
```

In the preceding example, the Fame database is called OECD1.DB, and it resides in the famedir directory. The DATA statement names the SAS output data set ‘a’ that will reside in mydir. All time series in the Fame OECD1.DB database will be converted to an annual frequency and reside in the mydir.a SAS data set. Because the time series variable names contain the special glue symbol ‘.’, the SAS option statement specifies VALIDVARNAME=ANY. For more information about this option, see the *SAS System Options: Reference*. The Fame environment variable is the location of the Fame installation. In the Windows environment, the log would look like this:

```

1          options validvarname=any;

2          %let FAME=%sysget(FAME);
3          %put(&FAME);
(C:\PROGRA~1\FAME)
4          %let FAMETEMP=%sysget(FAME_TEMP);
5          %put(&FAMETEMP);
(\\ge\U11\saskff\fametemp\
6
7          libname famedir sasefame "&FAME\util"
8          convert=(freq=annual technique=constant);
NOTE: Libref FAMEDIR was successfully assigned as follows:
      Engine:          FAMECHLI
      Physical Name: C:\PROGRA~1\FAME\util
9
10         libname mydir '\\dntsrc\usrtmp\saskff';
NOTE: Libref MYDIR was successfully assigned as follows:
      Engine:          V9
      Physical Name: \\dntsrc\usrtmp\saskff
11
12         data mydir.a; /* add data set to mydir */
13         set famedir.oecd1;
AUS.DIRDES -- SERIES (NUMERIC by ANNUAL)
AUS.DIRDES copied to work data base as AUS.DIRDES.
```

For more about the glue DOT character, see the section “Gluing Names Together” in the *User’s Guide to Fame*. In the preceding log, the variable name AUS.DIRDES uses the glue DOT between AUS and DIRDES.

The PROC PRINT statement produces the results shown in [Output 41.1.1](#), which displays all observations in the mydir.a SAS data set.

Output 41.1.1 Listing of OUT=MYDIR.A of the OECD1 Fame Data

Example 41.2: Reading Time Series from the Fame Database

This example uses the Fame wildcard option to limit the number of series converted. The following statements show how to read only series whose names begin with WSPCA:

```
options validvarname=any;

%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put (&FAMETEMP);

libname lib1 sasefame "%sysget(FAME_DATA)"
      wildcard="wspca?"
      convert=(technique=constant freq=twicemonthly );

libname lib2 "%sysget(FAME_TEMP)";

data lib2.twild(label='Annual Series from the FAMEECON.db');
  set lib1.subecon;
  where date between '01jan93'd and '31dec93'd;
  /* keep only */
  keep date wspca;
run;

proc contents data=lib2.twild;
run;

proc print data=lib2.twild;
run;
```

Output 41.2.1 and Output 41.2.2 show the results of using WILDCARD="WSPCA?".

Output 41.2.1 Contents of OUT=LIB2.TWILD of the SUBECON Fame Data

The CONTENTS Procedure					
Alphabetic List of Variables and Attributes					
#	Variable	Type	Len	Format	Informat Label
1	DATE	Num	8	DATE9.	9. Date of Observation
2	WSPCA	Num	8		STANDARD & POOR'S WEEKLY BOND YIELD: COMPOSITE, A

The WILDCARD="WSPCA?" option limits reading to only those series whose names begin with WSPCA. The KEEP statement further restricts the SAS data set to include only the series named WSPCA and the DATE variable. The time interval that is used for the conversion is TWICEMONTHLY.

Output 41.2.2 Listing of OUT=LIB2.TWILD of the SUBECON Fame Data

Obs	DATE	WSPCA
1	01JAN1993	8.59400
2	16JAN1993	8.50562
3	01FEB1993	8.47000
4	16FEB1993	8.31000
5	01MAR1993	8.27000
6	16MAR1993	8.29250
7	01APR1993	8.32400
8	16APR1993	8.56333
9	01MAY1993	8.37867
10	16MAY1993	8.26312
11	01JUN1993	8.21333
12	16JUN1993	8.14400
13	01JUL1993	8.09067
14	16JUL1993	8.09937
15	01AUG1993	7.98533
16	16AUG1993	7.91600

Example 41.3: Writing Time Series to the SAS Data Set

The following statements use the DROP statement to exclude certain time series from the SAS data set. (You can also use the KEEP statement to include certain series in the SAS data set.)

```
options validvarname=any;

%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put (&FAMETEMP);

libname famedir sasefame "%sysget(FAME_DATA)"
        convert=(freq=annual technique=constant);

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    drop 'ita.dirdes'n--'jpn.herd'n 'tur.dirdes'n--'usa.herd'n;
    where date between '01jan88'd and '31dec93'd;
run;

title1 "OECD1: TECH=Constant, FREQ=Annual";
title2 "Drop Using N-literals";

proc print data=mydir.a;
run;
```

Output 41.3.1 shows the results.

Note that the SAS option `VALIDVARNAME=ANY` was used at the beginning of this example because special characters are present in the time series names. SAS variables that contain certain special characters are called *n-literals* and are referenced in SAS code, as shown in this example.

You can rename your SAS variables by using the `RENAME` statement. The following statements show how to use *n-literals* when selecting variables that you want to keep and how to rename some of your kept variables:

```
options validvarname=any;

%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put (&FAMETEMP);

libname famedir sasefame "%sysget(FAME_DATA)"
        convert=(freq=annual technique=constant);

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* keep and rename */
    keep date 'ita.dirdes'n--'jpn.herd'n 'tur.dirdes'n--'usa.herd'n;
    rename 'ita.dirdes'n='italy.dirdes'n
           'jpn.dirdes'n='japan.dirdes'n
           'tur.dirdes'n='turkey.dirdes'n
           'usa.dirdes'n='united.states.of.america.dirdes'n ;

run;

title1 "OECD1: TECH=Constant, FREQ=Annual";
title2 "keep statement using n-literals";
title3 "rename statement using n-literals";

proc print data=mydir.a;
run;
```

Output 41.3.2 shows the results.

Output 41.3.2 Listing of OUT=MYDIR.A of the OECD1 Fame Data

OECD1: TECH=Constant, FREQ=Annual					
keep statement using n-literals					
rename statement using n-literals

Example 41.4: Limiting the Time Range of Data

You can also limit the time range of the data in the SAS data set by using the RANGE= option in the LIBNAME statement or the WHERE statement in the DATA step to process the time ID variable DATE only when it falls in the range you are interested in.

All data for 1988, 1989, and 1990 are included in the SAS data set that is generated by using the RANGE='01JAN1988'D - '31DEC1990'D option or the WHERE DATE BETWEEN '01JAN88'D AND '31DEC90'D statement. The difference is that the RANGE= option uses less space in the Fame Work database. If you have a very large database and you want to use less space in your Fame Work database while you are processing the OECD1 database, you should use the RANGE= option as shown in the following statements:

```
options validvarname=any;

%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put (&FAMETEMP);

libname famedir SASEFAME "%sysget(FAME_DATA)"
        convert=(freq=annual technique=constant)
        range='01jan1988'd - '31dec1990'd;

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* range on the libref restricts the dates *
    * read from famedir's oecd1 database      */
run;

title1 "OECD1: TECH=Constant, FREQ=Annual";
proc print data=mydir.a;
run;
```

Output 41.4.1 shows the results.

Output 41.4.1 Listing of OUT=MYDIR.A of the OECD1 Fame Data Using RANGE= Option

Example 41.6: Reading Other Fame Data Objects with the FAMEOUT= Option

This example shows how you can designate the data objects that are output to your SAS data set by using the FAMEOUT= option. In this example, the FAMEOUT=FORMULA option selects the formulas and their source definitions to be output. The RANGE= option is ignored because no time series are selected when FAMEOUT=FORMULA is specified.

```

options validvarname=any ls=90;

%let FAME=%sysget(FAME);
%put (&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put (&FAMETEMP);

libname lib6 sasefame "%sysget(FAME_DATA) "
    fameout=formula
    convert=(frequency=business technique=constant)
    range='02jan1995'd - '25jul1997'd
    wildcard="?YIELD?" ;

data crout;
    set lib6.training;
    keep 'S.GM.YIELD.A'n -- 'S.XON.YIELD.A'n ;
run;

title1 'Formulas from the TRAINING DB, FAMEOUT=FORMULA Option';
title2 'Using WILDCARD="?YIELD?"';
proc contents
    data=crout;
run;

```

Output 41.6.1 shows the results.

Output 41.6.1 Contents of OUT=CROUT from the FAMEOUT=FORMULA Option of the Fame TRAINING Data

Formulas from the TRAINING DB, FAMEOUT=FORMULA Option Using WILDCARD="?YIELD?"			
The CONTENTS Procedure			
Alphabetic List of Variables and Attributes			
#	Variable	Type	Len
1	S.GM.YIELD.A	Char	82
2	S.GM_PP.YIELD.A	Char	82
3	S.HWP.YIELD.A	Char	82
4	S.IBM.YIELD.A	Char	82
5	S.INDUT.YIELD.A	Char	82
6	S.SPAL.YIELD.A	Char	82
7	S.SPALN.YIELD.A	Char	82
8	S.SUNW.YIELD.A	Char	82
9	S.XOM.YIELD.A	Char	82
10	S.XON.YIELD.A	Char	82

The FAMEOUT=FORMULA option restricts the SAS data set to include only formulas. The WILDCARD="?YIELD?" option further limits the selection of formulas to those whose names contain "YIELD".

```

options validvarname=any linesize=79;

title1 'Formulas from the TRAINING DB, FAMEOUT=FORMULA Option';
title2 'Using WILDCARD="?YIELD?"';
proc print
    data=crouit noobs;
run;

```

Output 41.6.2 shows the results.

Output 41.6.2 Listing of OUT=CROUT from the FAMEOUT=FORMULA Option of the Fame TRAINING Data

```

Additional examples of the FAMEOUT= option are shown in [Example 41.11](#), [Example 41.12](#), [Example 41.13](#), [Example 41.14](#), and [Example 41.15](#).

Example 41.7: Remote Fame Access by Using Fame CHLI

When you run Fame in a client/server environment and also have Fame CHLI capability to enable access to the server, you can access Fame remote data. Access the remote data by specifying the port number of the TCP/IP service that is defined for the frdb_m and the node name of the Fame master server in the physical path. In this example, the Fame server node name is STONES, and the port number is 5555, as was designated in the Fame master command. For more information about starting your Fame master server, see the section “Starting the Master Server” in the *Guide to Fame Database Servers*.

```
options ls=78;
title1 "DRIECON Database, Using FAME with Remote Access Via CHLI";
options validvarname=any;
libname test1 sasefame '#5555@stones $FAME/util';

data a;
    set test1.driecon;
    keep YP ZA ZB;
    where date between '01jan98'd and '31dec03'd;
run;

proc means data=a n;
run;
```

Output 41.7.1 shows the results.

Output 41.7.1 Summary Statistics for the Remote FAME Data

DRIECON Database, Using FAME with Remote Access Via CHLI		
The MEANS Procedure		
Variable	Label	N
YP	PERSONAL INCOME	5
ZA	CORPORATE PROFITS AFTER TAX EXCLUDING IVA	4
ZB	CORPORATE PROFITS BEFORE TAX EXCLUDING IVA	4

Example 41.8: Selecting Time Series by Using the CROSSLIST= Option and KEEP Statement

This example shows how to use two Fame namelists to perform selection. Note that *fame_namelist1* could be easily generated using the Fame WILDLIST function. For more about the WILDLIST function, see the section “The WILDLIST Function” in the *Fame Command Reference, Volume 2, Functions*. In the following statements, four tickers are selected in *fame_namelist1*, but when you use the KEEP statement, the resulting

data set contains only the desired IBM ticker:

```
libname lib8 sasefame "%sysget(FAME_DATA)"
      convert=(frequency=business technique=constant)
      crosslist=(
        { IBM, SPALN, SUNW, XOM },
        { adjust, close, high, low, open, volume,
          uclose, uhigh, ulow, uopen, uvolume }
      );

data trout;
  /* eleven companies, keep only the IBM ticker this time */
  set lib8.training;
  where date between '01mar02'd and '20mar02'd;
  keep IBM: ;
run;

title1 'TRAINING DB, Pricing Timeseries for IBM Ticker in CROSSLIST=';
proc contents
  data=trout;
run;

proc print
  data=trout;
run;
```

Output 41.8.1 and Output 41.8.2 show the results.

Output 41.8.1 Contents of the IBM Time Series in the Fame TRAINING Data

Example 41.10: Selecting Time Series by Using the CROSSLIST= Option and WHERE=TICK

Instead of having a Fame namelist with the ticker symbols for companies whose data you are interested in, you can designate an input SAS data set (INSETA) that specifies the tickers to select. Specify your selection by using the WHERE clause in the INSET= option as follows:

```
data inseta;
  length tick $5;
  /* need $5 so SPALN is not truncated */

  tick='AOL';    output;
  tick='C';      output;
  tick='CPQ';    output;
  tick='CVX';    output;
  tick='F';      output;
  tick='GM';     output;
  tick='HWP';    output;
  tick='IBM';    output;
  tick='SPALN';  output;
  tick='SUNW';   output;
  tick='XOM';    output;
run;

libname lib10 sasefame "%sysget(FAME_DATA)";
convert=(frequency=business technique=constant)
range='07jul1997'd - '25jul1997'd
inset=( inseta where=tick )
croslist=
  ( {adjust, close, high, low, open, volume,
    uclose, uhigh, ulow, uopen, uvolume} );

data trout;
```

```

/* eleven companies with unique TICKs specified in INSETA */
set lib10.training;
keep IBM: ;
run;

title1 'TRAINING DB, Pricing Timeseries for Eleven Tickers in CROSSLIST=';
title2 'Using INSET with WHERE=TICK.';
proc print data=trout;
run;

proc contents data=trout;
run;

```

Output 41.10.1 and Output 41.10.2 show the results.

If you want all series of every type, you can merge the resulting data sets. For more information about merging SAS data sets, see *SAS Language Reference: Concepts*.

Example 41.16: Reading Time Series by Defining Fame Expression Groups in the INSET= Option with the KEEP= Clause

To keep all the numeric time series that are listed in the expressions given in the input data set, INSETA, use the INSET=(*setname* KEEPLIST=*fame_expression_group*) and WILDCARD="?" options. The following statements show how to select time series that are specified in a KEEP expression group and are written to the SAS output data set:

```

data inseta; /* Use this for d8690 training database */
  length express $52;
  express='cvx.close;'; output;
  express='{ibm.high,ibm.low,ibm.close}'; output;

```

```

express='mave(ibm.close,30);'; output;
express='crosslist({gm,f,c},{volume});'; output;
express='cvx.close+ibm.close;'; output;
express='ibm.close;'; output;
express='sum(pep.volume);'; output;
express='mave(pep.close,20);'; output;
run;

title1 'TRAINING DB, Pricing Timeseries for Expressions in INSET=';
proc print
  data=inseta;
run;

```

Output 41.16.1 shows the expressions that are stored as observations in the input data set, INSETA.

Output 41.16.1 Listing of INSETA Defining Fame Expression Group

TRAINING DB, Pricing Timeseries for Expressions in INSET=	
Obs	express
1	cvx.close;
2	{ibm.high,ibm.low,ibm.close};

Example 41.17: Optimizing Cache Sizes with the TUNEFAME= and TUNECHLI= Options

This example shows how to use the TUNEFAME= option, the TUNECHLI= option, and a RANGE= option to select pricing time series in the TRAJTEN database. The selected time series are written to the SAS output data set. The Fame database engine's virtual memory is given in megabytes (MB), so this example sets the cache size to 100 MB. The Fame CHLI engine's virtual memory is also given in megabytes (MB), so this example sets the CHLI cache size to 100 MB. These two settings correspond to the default settings. Both the Fame 4GL engine and the Fame CHLI engine can use a cache size that ranges from 0.1 MB to 17,592,186,000 MB.

```

Overview: SASEHAVR Interface Engine

The SASEHAVR interface engine is a seamless interface between Haver Analytics and SAS data processing that enables SAS users to read economic and financial time series data that reside in a Haver Analytics DLX (Data Link Express) database. The Haver Analytics DLX economic and financial database offerings include U.S. economic indicators, specialized databases, and financial indicators; data about industry, industrial countries, emerging markets, and international organizations; forecasts and as-reported data; and data about U.S. regional services. For more information, see the section “[Data Elements Reference: Haver Analytics DLX Database Profile](#)” on page 2928.

The SASEHAVR engine uses the LIBNAME statement to enable you to specify how to subset your Haver data and how to aggregate the selected time series at the same frequency. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEHAVR engine supports both 32-bit and 64-bit Windows hosts. Haver Analytics supplies two versions of the DLX application programming interface (API), one for 32-bit applications (dlxapi32.dll) and one for 64-bit applications (dlxapi64.dll). Choose the appropriate application, either 32-bit or 64-bit, for your platform. You can follow the instructions for setting up your installation of the Haver API in the section “[Setting Up the Haver Analytics DLX Application Programming Interface](#)” on page 2916.

Getting Started: SASEHAVR Interface Engine

Setting Up the Haver Analytics DLX Application Programming Interface

If this is your first time using the SASEHAVR interface engine on your Windows machine, then it is necessary to follow these setup instructions. If you have already used the SASEHAVR interface, then just check the file version number of your already installed dlxapi32.dll (or dlxapi64.dll). For 32-bit installations, the file version is 1.1.9.0, and for 64-bit installations, the file version is 2.0.0.1. The Haver API version number appears in the SAS log the first time you assign a SASEHAVR libref. In Windows Explorer, you can see a file’s properties, including its version number, by hovering the mouse pointer over the file icon. Alternatively, you can right-click on the file icon to bring up the properties and click the **Details** tab to see the version number.

To set up the Haver Analytics API on your machine, visit the SAS Technical Support download site at the following URL:

<http://ftp.sas.com/techsup/download/base/>

First, create a folder on your system drive (usually designated as C:), and name the folder HAVER. Create an environment variable named HAVER as follows:

```
HAVER=C:\HAVER\
```

If your SAS system is 32-bit, then download the files dlxapi32.h, dlxapi32.dll, and dlxapi32.lib to your HAVER folder. If your SAS system is 64-bit, then download the files dlxapi64.h, dlxapi64.dll, and dlxapi64.lib

to your HAVER folder. Second, prepend the location of your HAVER folder to the system environment variable (%PATH%) as follows, so that the SASEHAVR engine can find your downloaded Haver API files:

```
PATH=C:\HAVER\;%PATH%
```

Reboot your system to complete the Haver API setup.

Structure of a SAS Data Set That Contains Time Series Data

SAS represents time series data in a two-dimensional array called a SAS data set whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as time ID variables. The SASEHAVR engine provides a time ID variable called DATE. The DATE variable can be represented in any of the time intervals shown in the section “[Mapping Haver Frequencies to SAS Time Intervals](#)” on page 2924.

Reading and Converting Haver DLX Time Series

The SASEHAVR engine supports reading and converting all selected time series that reside in Haver DLX databases. The SASEHAVR engine enables you to limit the range of data by specifying the START= and END= options in the LIBNAME statement. Start dates and end dates are recommended to help save resources when you are processing large databases or a large number of observations.

The SASEHAVR engine enables you to convert or aggregate all selected time series to a desired frequency. By default, the SASEHAVR engine selects the time series variables that match the frequency of the first selected variable. To select variables of one specific frequency, use the FREQ= option. If no selection criteria are specified, the first selected variable is the first physical DLX record read from the Haver database. To force aggregation of all selected variables to the frequency specified by the FREQ= option, use the FORCE=FREQ option. The AGGMODE= option enables you to specify a strict or relaxed aggregation method; by default, AGGMODE=RELAXED. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. If a conversion to a more frequent frequency is attempted, all missing values are returned by the Haver DLX API. For more information, see the section “[Aggregating to Quarterly Frequency Using the FORCE=FREQ Option](#)” on page 2927. The FORCE= option is ignored if the FREQ= option is not specified.

Using the SAS DATA Step

If desired, you can store your selected time series in a SAS data set by using the SAS DATA step. You can further subset your data by using the WHERE, KEEP, or DROP statement in your DATA step.

For more efficient subsetting of time series by Haver variables, Haver groups, Haver sources, Haver short sources, Haver long sources, or Haver geographic codes, you can use the corresponding KEEP=, GROUP=, SOURCE=, SHORTSOURCE=, LONGSOURCE=, GEOGCODE1=, or GEOGCODE2= option in the LIBNAME *libref* SASEHAVR statement. To see the available Haver selection key values, including geographic codes, short sources, and long sources for your database, specify the OUTSELECT=ON option.

From the OUTSELECT= option output, you can use convenient wildcard symbols to create the selection list for your next LIBNAME *libref* SASEHAVR statement.

There are three wildcard symbols: ‘*’, ‘?’ and ‘#’. The ‘*’ wildcard corresponds to any character string and includes any string pattern that corresponds to that position in the matching variable name. The ‘?’ stands for any single alphanumeric character. Lastly, the ‘#’ wildcard corresponds to a single numeric character.

You can also deselect time series by Haver variables, by Haver groups, by Haver sources, by Haver short sources, by Haver long sources, or by Haver geographic codes, by using the corresponding DROP=, DROP-GROUP=, DROPSOURCE=, DROPSHORT=, DROPLONG=, DROPGEOG1=, or DROPGEOG2= option. These options also support wildcards.

After your selected data is stored in a SAS data set, you can use it as you would any other SAS data set.

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEHAVR *libref* in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking on the desired output data set *libref* in the LIBNAME window of the SAS windowing environment. You can type **Viewtable** on the SAS command line to view your SASEHAVR tables, views, or librefs.

Before you use **Viewtable**, it is recommended that you store your output data sets in a physical folder or library that is separate from the folder or library used for your input databases. (The default location for output data sets is the SAS Work library.) If you do not follow this guideline, you will receive the following error message for each input database that does not have the selected options in the SASEHAVR *libref* that you double-clicked:

```
ERROR: No variable selected with current options.
```

Syntax: SASEHAVR Interface Engine

The SASEHAVR engine uses standard engine syntax. [Table 42.1](#) summarizes the options used in the LIBNAME *libref* SASEHAVR statement.

Table 42.1 Summary of LIBNAME *libref* SASEHAVR Statement Options

Option	Description
FREQUENCY=	Specifies the Haver frequency
START=	Specifies a Haver start date to limit the selection of time series to those that begin with the specified date
END=	Specifies a Haver end date to limit the selection of time series to those that end with the specified date
KEEP=	Specifies a list of comma-delimited Haver variables to keep in the output SAS data set

Table 42.1 *continued*

Option	Description
DROP=	Specifies a list of comma-delimited Haver variables to drop from the output SAS data set
GROUP=	Specifies a list of comma-delimited Haver groups to keep in the output SAS data set
DROPGROUP=	Specifies a list of comma-delimited Haver groups to drop from the output SAS data set
SOURCE=	Specifies a list of comma-delimited Haver sources to keep in the output SAS data set
DROPSOURCE=	Specifies a list of comma-delimited Haver sources to drop from the output SAS data set
SHORT=	Specifies a list of comma-delimited Haver short sources to keep in the output SAS data set
DROPSHORT=	Specifies a list of comma-delimited Haver short sources to drop from the output SAS data set
LONG=	Specifies a list of comma-delimited Haver long sources to keep in the output SAS data set
DROPLONG=	Specifies a list of comma-delimited Haver long sources to drop from the output SAS data set
GEOG1=	Specifies a list of comma-delimited Haver geography1 codes to keep in the output SAS data set
DROPGEOG1=	Specifies a list of comma-delimited Haver geography1 codes to drop from the output SAS data set
GEOG2=	Specifies a list of comma-delimited Haver geography2 codes to keep in the output SAS data set
DROPGEOG2=	Specifies a list of comma-delimited Haver geography2 codes to drop from the output SAS data set
OUTSELECT=	Specifies what values the output data is to contain
FORCE=FREQ	Specifies that all selected time series variables be aggregated to the frequency specified in the FREQ= option
AGGMODE=	Specifies the aggregation method used for aggregating time series (STRICT or RELAXED)

LIBNAME libref SASEHAVR Statement

LIBNAME libref sasehavr *'physical name'* options ;

The *'physical name'* specifies the location of the folder where your Haver DLX database resides.

You can use the following options in the LIBNAME libref SASEHAVR statement:

FREQ=*haver_frequency*

FREQUENCY=*haver_frequency*

INTERVAL=*haver_frequency*

specifies the Haver frequency. All Haver frequencies are supported by the SASEHAVR engine. Accepted frequency values are annual, year, yearly, quarter, quarterly, qtr, monthly, month, mon, week.1, week.2, week.3, week.4, week.5, week.6, week.7, weekly, week, daily, and day.

START=*start_date*

STARTDATE=*start_date*

STDATE=*start_date*

BEGIN=*start_date*

specifies the start date for the time series in the form YYYYMMDD.

END=*end_date*

ENDDATE=*end_date*

ENDATE=*end_date*

specifies the end date for the time series in the form YYYYMMDD.

KEEP="haver_variable_list"

specifies the list of Haver variables to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROP="haver_variable_list"

specifies the list of Haver variables to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

GROUP="haver_group_list"

KEEPGROUP="haver_group_list"

specifies the list of Haver groups to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROPGROUP="haver_group_list"

specifies the list of Haver groups to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

SOURCE="haver_source_list"

KEEPSOURCE="haver_source_list"

specifies the list of Haver sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROPSOURCE="haver_source_list"

specifies the list of Haver sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

SHORT="haver_shortsource_list"

KEEPSHORT="haver_shortsource_list"

SHORTSOURCE="haver_shortsource_list"

specifies the list of Haver short sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes "".

DROPSHORT=*“haver_shortsource_list”*

DROPSHORTSOURCE=*“haver_shortsource_list”*

specifies the list of Haver short sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

LONG=*“haver_longsource_list”*

KEEPLONG=*“haver_longsource_list”*

LONGSOURCE=*“haver_longsource_list”*

specifies the list of Haver long sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

DROPLONG=*“haver_longsource_list”*

DROPLONGSOURCE=*“haver_longsource_list”*

specifies the list of Haver long sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

GEOG1=*“haver_geographycode1_list”*

KEEPGEOG1=*“haver_geographycode1_list”*

GEOGCODE1=*“haver_geographycode1_list”*

specifies the list of Haver geography1 codes to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

DROPGEOG1=*“haver_geographycode1_list”*

DROPGEOGCODE1=*“haver_geographycode1_list”*

specifies the list of Haver geography1 codes to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

GEOG2=*“haver_geographycode2_list”*

KEEPGEOG2=*“haver_geographycode2_list”*

GEOGCODE2=*“haver_geographycode2_list”*

specifies the list of Haver geography2 codes to be included in the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

DROPGEOG2=*“haver_geographycode2_list”*

DROPGEOGCODE2=*“haver_geographycode2_list”*

specifies the list of Haver geography2 codes to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by quotes “”.

OUTSELECT=ON | OFF

specifies what the output data set shows. OUTSELECT=ON specifies that the output data set show values of selection keys (such as geography codes, groups, sources, short sources, and long sources) for each selected variable name (time series) in the database. OUTSELECT=OFF specifies that the output data set show the observations in the range for all selected time series. The default is OUTSELECT=OFF.

AGGMODE=STRICT | RELAXED

specifies whether the SASEHAVR engine uses a strict or relaxed aggregation method when converting time series from a higher to lower frequency.

A strict aggregation method returns a missing value whenever there is a missing observation in a time period. For instance, if a monthly time series has a missing value for the month of February, 2005, then attempting to aggregate to a quarterly frequency results in a missing value for the first quarter of 2005. The SAS log reports the status of this option.

When a relaxed aggregation method is used, some observations can be missing, but the relaxed method returns an aggregated value calculated from the nonmissing data points according to the series aggregation type (average, sum, or end of period). Average type only needs one valid (nonmissing) data point to calculate the average. Sum type needs all the data points to be available in order to sum the values. End of period type calculates the end of period value if there is at least one valid (nonmissing) data point in the aggregated span. It returns the last available valid data point in the aggregated span. The default is AGGMODE=RELAXED.

FORCE=FREQ

specifies that the selected variables be aggregated to the frequency in the FREQ= option. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. See the section [“Aggregating to Quarterly Frequency Using the FORCE=FREQ Option”](#) on page 2927 for sample output and suggested error recovery from attempting a conversion that yields missing values when a higher frequency conversion is specified. This option is ignored if the FREQ= option is not set. For a more complete discussion of Haver frequencies and SAS time intervals, see the section [“Mapping Haver Frequencies to SAS Time Intervals”](#) on page 2924.

Following is an example of the LIBNAME *libref* SASEHAVR statement:

```
LIBNAME libref sasehavr 'physical-name'
      FREQ=MONTHLY;
```

By default, the SASEHAVR engine reads all time series in the Haver database that you reference by *libref*. The *start_date* is specified in the form YYYYMMDD. The start date is used to delimit the data to a specified start date.

For example, to read the time series in the TEST library starting on July 4, 1996, specify the following statement:

```
LIBNAME test sasehavr 'physical-name'
      STARTDATE=19960704;
```

When you use the START= option, you limit the range of observations that are read from the time series and that are converted to the desired frequency. Start dates can help save resources when processing large databases or when processing a large number of observations. It is also possible to select specific variables to be included or excluded from the SAS data set by using the KEEP= or the DROP= option, respectively.

```
LIBNAME test sasehavr 'physical-name'
      KEEP="ABC*, XYZ??";
```

```
LIBNAME test sasehavr 'physical-name'
      DROP="*SC*, #T#";
```

When the KEEP= or the DROP= option is used, the resulting SAS data set keeps or drops the variables that you select in that option. Three wildcards are available: '*', '?', and '#'. The '*' wildcard corresponds to any character string and includes any string pattern that corresponds to that position in the matching variable name. The '?' means that any single alphanumeric character is valid. The '#' wildcard corresponds to a single numeric character. You can also select time series in your data by using the GROUP=, SOURCE=, SHORT=, LONG=, GEOG1=, or the GEOG2= option to select on group name, source name, short source name, long source name, geography1 code, or the geography2 code, respectively. Alternatively, you can deselect time series by using the DROPGROUP=, DROPSOURCE=, DROPSHORT=, DROPLONG=, DROPGEOG1=, or the DROPGEOG2= option, respectively.

Following are examples that perform variable selection (or deselection) based on groups or sources:

```
LIBNAME test sasehavr 'physical-name'
      GROUP="CBA, *ZYX";
```

```
LIBNAME test sasehavr 'physical-name'
      DROPGROUP="TKN*, XCZ?";
```

```
LIBNAME test sasehavr 'physical-name'
      SOURCE="FRB";
```

```
LIBNAME test sasehavr 'physical-name'
      DROPSOURCE="NYSE";
```

SASEHAVR selects only the variables that are of the specified frequency in the FREQ= option. If this option is not specified, SASEHAVR selects the variables that match the frequency of the first selected variable. If no other selection criteria are specified, by default the first selected variable is the first physical DLX record read from the Haver database. You can specify the FORCE=FREQ option to force the aggregation of all variables selected to be of the frequency specified in the FREQ= option. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. See the section [“Aggregating to Quarterly Frequency Using the FORCE=FREQ Option”](#) on page 2927 for suggested recovery from using a frequency that does not aggregate the data appropriately. The FORCE= option is ignored if the FREQ= option is not specified. The AGGMODE= STRICT option is used when a strict aggregation method is desired. The default value for AGGMODE is RELAXED, the same method that was used in prior releases of SASEHAVR.

Details: SASEHAVR Interface Engine

SAS Output Data Set

You can use the SAS DATA step to write the Haver converted series to a SAS data set so that you can easily analyze the data using the SAS System. You can specify the name of the output data set in the DATA statement. This causes the engine supervisor to create a SAS data set with the specified name in either the SAS Work library, or if specified, the Sasuser library.

When `OUTSELECT=OFF` (the default), the contents of the SAS data set include the date of each observation, the name of each series read from the Haver database, and the label or Haver description of each series. Missing values are represented as ‘.’ in the SAS data set. You can use the `PRINT` procedure and the `CONTENTS` procedure to print your output data set and its contents. You can use the `SQL` procedure along with the SASEHAVR engine to create a view of your SAS data set.

The `DATE` variable in the SAS data set contains the date of the observation. The SASEHAVR engine automatically maps the Haver intervals to the appropriate corresponding SAS intervals.

When `OUTSELECT=ON`, the `OUT=` data set does not contain the observations of all time series. Instead, each observation contains the name of the time series, the source of the time series, the geography1 code, the geography2 code, the short source, and the long source for that time series. In addition, the contents of the `OUT=` data set shows every selected time series name and label. See [Output 42.11.1](#) and [Output 42.11.2](#) for more details about the `OUTSELECT=ON` option.

A more detailed discussion of how to map Haver frequencies to SAS time intervals follows.

Mapping Haver Frequencies to SAS Time Intervals

Table 42.2 summarizes the mapping of Haver frequencies to SAS time intervals. For more information, see Chapter 4, “Date Intervals, Formats, and Functions.”

Table 42.2 Mapping Haver Frequencies to SAS Time Intervals

Haver Frequency	SAS Time Interval	FREQ=
ANNUAL	YEAR	YEARLY
QUARTERLY	QTR	QTRLY
MONTHLY	MONTH	MON
WEEKLY (SUNDAY)	WEEK.1	WEEK.1
WEEKLY (MONDAY)	WEEK.2	WEEK.2
WEEKLY (TUESDAY)	WEEK.3	WEEK.3
WEEKLY (WEDNESDAY)	WEEK.4	WEEK.4
WEEKLY (THURSDAY)	WEEK.5	WEEK.5
WEEKLY (FRIDAY)	WEEK.6	WEEK.6
WEEKLY (SATURDAY)	WEEK.7	WEEK.7
WEEKLY WEEK.1-WEEK.7	WEEKLY	WEEKLY
DAILY	WEEKDAY17W	DAY

Error Recovery for the SASEHAVR Interface Engine

Common errors are easy to avoid by noting the valid dates that are specified in the warning messages in your SAS log. Often you can get rid of errors by removing the date restriction (`START=` and `END=` options), by removing the `FORCE=FREQ` option, or by deleting the `FREQ=` option so that the frequency defaults to the original frequency rather than attempting a conversion.

Following are some common error scenarios and how to handle them.

Using the Optimum Range for Best Output Results

Suppose you see the following warnings in your SAS log:

```
libname kgs2 sasehavr "%sysget(HAVER_DATA)"
      start= 19550101 end=19600105
      keep="FCSEED, FCSEEI, FCSEEM, BGSX, BGSM, FXDUSBC"
      group="I01, F56, M02, R30"
      source="JPM,CEN,OMB" ;

NOTE: Libref KGS2 was successfully assigned as follows:
      Engine:          SASEHAVR
      Physical Name: C:\haver

data kgse9;
      set kgs2.haver;
NOTE: Defaulting to MONTHLY frequency.
WARNING: Start date (19550101) is not a valid date.
      Engine is ignoring your start date and using
      default. Setting the default Haver start date to 7001.
WARNING: End date (19600105) is not a valid date.
      Engine is ignoring your end date and using
      default. Setting the default Haver end date to 10103.

run;

NOTE: There were 375 observations read from the data set KGS2.HAVER.
NOTE: The data set WORK.KGSE9 has 375 observations and 4 variables.
```

The important diagnostic to note here is the warning message that tells you that the data starts in January of 1970 (Haver date 7001), and ends in March, 2001 (Haver date 10103). Since the specified range falls outside the range of data, no observations are in range. So, the engine uses the default range stated in the warning messages. Change the START= and END= options to overlap the results in data that span from JAN1970 to MAR2001. To view the entire range of selected data, remove the START= and END= options from the LIBNAME statement:

```
libname kgs sasehavr "%sysget(HAVER_DATA)"
      keep="FCSEED, FCSEEI, FCSEEM, BGSX, BGSM, FXDUSBC"
      group="I01, F56, M02, R30"
      source="JPM,CEN,OMB" ;

NOTE: Libref KGS was successfully assigned as follows:
      Engine:          SASEHAVR
      Physical Name: C:\haver

data kgse5;
      set kgs.haver;
NOTE: Defaulting to MONTHLY frequency.

run;

NOTE: There were 375 observations read from the data set KGS.HAVER.
NOTE: The data set WORK.KGSE5 has 375 observations and 4 variables.
```

Using a Valid Range of Data with START= and END= Options

In this example, an error about an invalid range is issued:

```
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Weekly
  start=20060301 end=20060531;
NOTE: Libref LIB1 was successfully assigned as follows:
      Engine:          SASEHAVR
      Physical Name: C:\haver
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
      Engine:          V9
      Physical Name: \\dntsrc\usrtmp\saskff
data lib2.wweek;
  set lib1.intwkly;
ERROR: No observations found inside RANGE.
      The valid range for HAVER dates is (610104-1050318).
ERROR: No observations found in specified range.
      keep date m11: ;
run;

WARNING: The variable date in the DROP, KEEP, or RENAME list
has never been referenced.
WARNING: The variable m11: in the DROP, KEEP, or RENAME list
has never been referenced.
NOTE: The SAS System stopped processing this step because of errors.
WARNING: The data set LIB2.WWEEK may be incomplete.
      When this step was stopped there were 0
      observations and 0 variables.
WARNING: Data set LIB2.WWEEK was not replaced because this step was stopped.
```

The important diagnostic message is the first error statement which tells you that the range of Haver dates is not valid for the specified frequency. A valid range is one that overlaps the dates (610104–1050318). Removing the range altogether causes the engine to output the entire range of data.

```
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Weekly;

NOTE: Libref LIB1 was successfully assigned as follows:
      Engine:          SASEHAVR
      Physical Name: C:\haver

libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
      Engine:          V9
      Physical Name: \\dntsrc\usrtmp\saskff

data lib2.wweek;
  set lib1.intwkly;
  keep date m11: ;
run;

NOTE: There were 2307 observations read from the data set LIB1.INTWKLY.
NOTE: The data set LIB2.WWEEK has 2307 observations and 35 variables.
```

Since the START= and END= options give day-based dates, it is important to use dates that correspond to the FREQ= option when giving a range of dates, especially with weekly frequencies such as WEEK.1–WEEK.7.

Since `FREQ=WEEK.4` selects weeks that begin on Wednesday, the start and end dates need to be specified as Wednesday dates.

```
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Week.4
    start=20050302 end=20050309;
NOTE: Libref LIB1 was successfully assigned as follows:
    Engine:          SASEHAVR
    Physical Name:   \\tappan\crsp1\haver
title2 'Weekly dataset with freq=week.4 range is small';
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
    Engine:          V9
    Physical Name:   \\dntsrc\usrtmp\saskff

data lib2.wweek;
    set lib1.intwkly;
    keep date m11: ;
run;

NOTE: There were 2 observations read from the data set LIB1.INTWKLY.
NOTE: The data set LIB2.WWEEK has 2 observations and 25 variables.
```

Giving bad dates (for example, Tuesday dates) for a Wednesday `FREQ=WEEK.4` results in the following error:

```
ERROR: Fatal error in GetDate routine.
    Remove the range statement or change the START= date to
    be consistent with the freq=option.
ERROR: No observations found in specified range.
```

Aggregating to Quarterly Frequency Using the `FORCE=FREQ` Option

In the next example, six time series are selected by the `KEEP=` option. Their frequencies are annual, monthly, and quarterly, so when the `FREQ=WEEKLY` and `FORCE=FREQ` options are used, a diagnostic appears in the log stating that the engine is forcing the frequency to `QUARTERLY` for better date alignment of observations. The first selected variable is `BALO`, which is a quarterly time series and causes the default choice of `FREQ` to be quarterly.

```
title1 '***HAVKWC.SAS: KEEP= option tests with wildcards***';

%setup( ets );

/*-----*/
/* Wildcard: * */
/*-----*/

title2 "keep=B*, G*, I*";
title3 "6 valid variables are: BALO BGSX BGSX BPBCA G IUM";
libname lib1 sasehavr 'C:\haver\' keep="B*, G*, I*"
    freq=weekly force=freq;
NOTE: Libref LIB1 was successfully assigned as follows:
    Engine:          SASEHAVR
    Physical Name:   C:\haver\
```

```
data wc;
  set lib1.haver;
WARNING: Earliest Start Date in DLX Database matches QUARTERLY frequency
        better than the specified WEEKLY frequency.
        Engine is forcing the frequency to QUARTERLY for better date
        alignment of observations.

run;

NOTE: There were 221 observations read from the data set LIB1.HAVER.
NOTE: The data set WORK.WC has 221 observations and 7 variables.
```

Note that the time series IUM is an annual frequency. The attempt to convert to a quarterly frequency produces all missing values in the output range because aggregation produces only missing values when forced to go from a lower frequency to a higher frequency.

Data Elements Reference: Haver Analytics DLX Database Profile

The Haver DLX economic and financial database offerings include U.S. economic indicators, specialized databases, financial indicators, industry, industrial countries, emerging markets, international organizations, forecasts and as-reported data, and U.S. regional service. [Table 42.3](#) is a list of available databases and the corresponding description of each.

Table 42.3 Available Data Offerings

Database Name	Offering Type	Description
USECON	U.S. economic indicators	U.S. economic, financial data
USNA	U.S. economic indicators	Complete U.S. NIPA accounts from the Bureau of Economic Analysis (BEA)
SURVEYS	U.S. economic indicators	Business and consumer expectations, surveys
SURVEYW	U.S. economic indicators	Business and consumer expectations, weekly surveys
CPIDATA	U.S. economic indicators	Consumer price indexes (CPI), monthly in CPI detailed report
PPI	U.S. economic indicators	Producer price indexes (PPI), by the Bureau of Labor Statistics (BLS)
PPIR	U.S. economic indicators	Producer price indexes by BLS
LABOR	U.S. economic indicators	Employment and earnings by BLS
EMPL	U.S. economic indicators	Household employment survey, monthly by BLS
CEW	U.S. economic indicators	Covered employment and wages, monthly, quarterly
IP	U.S. economic indicators	Industrial production and capacity utilization by Federal Reserve Board (FRB)

Table 42.3 *continued*

Database Name	Offering Type	Description
FFUNDS	U.S. economic indicators	Flow of funds data by FRB
CAPSTOCK	U.S. economic indicators	Capital stock by the Bureau of Economic Analysis (BEA)
USINT	U.S. economic indicators	U.S. international trade (TIC) data by country and product
CBDB	Specialized databases	Conference Board database, monthly by The Conference Board (TCB)
BCI	Specialized databases	U.S. business cycle indicators, by TCB
UMSCA	Specialized databases	Consumer Sentiment Survey from the University of Michigan
FIBERUS	Specialized databases	U.S. FIBER business cycle indicators from the Foundation of International Business and Economic Research (FIBER)
FIBER	Specialized databases	FIBER business cycle indicators from FIBER
DAILY	Financial indicators	U.S. daily statistics data
INTDAILY	Financial indicators	Country daily statistics
WEEKLY	Financial indicators	U.S. weekly statistics
INTWKLY	Financial indicators	Country weekly statistics
SPD	Financial indicators	Standard and Poor's industry groups, daily
SPW	Financial indicators	Standard and Poor's industry groups, weekly
SPM	Financial indicators	Standard and Poor's industry groups, monthly
SPAH	Financial indicators	Standard and Poor's Analysts' Handbook, yearly
MSCID	Financial indicators	Morgan Stanley Capital International, daily
MSCIW	Financial indicators	Morgan Stanley Capital International, weekly
MSCIM	Financial indicators	Morgan Stanley Capital International, monthly
EMBI	Financial indicators	Emerging Markets Bond Index from J.P. Morgan
BONDINDX	Financial indicators	U.S. bond indexes, from Barclays Capital, Citigroup, Merrill Lynch, and Standard and Poors

Table 42.3 *continued*

Database Name	Offering Type	Description
BONDS	Financial indicators	Citigroup bond performance indexes by Citigroup Global Markets, formerly Salomon Smith Barney
ICI	Financial indicators	Mutual fund activity from the Investment Company Institute
QFR	Financial indicators	Quarterly financial report by FRB
MBAMTG	Financial indicators	Mortgage delinquency rates by the Mortgage Bankers Association
MBAMOS	Financial indicators	Mortgage origination surveys, from two Mortgage Banker Association surveys
MARKIT	Financial indicators	Markit's indexes used to price credit default swaps
DLINQ	Financial indicators	Consumer delinquency rates by American Bankers Association, monthly
FDIC	Financial indicators	FDIC banking statistics TIC data from the Quarterly Banking Profile
GOVFIN	Financial indicators	U.S. government financial statistics by U.S. Treasury
INDUSTRY	Industry	U.S. industry statistics, from Department of Agriculture, trade associations
WARDS	Industry	Automotive statistics, from Ward's Automotive Group
USDA	Industry	World agriculture statistics, from U.S. Department of Agriculture (USDA)
REALTOR	Industry	Home sales from National Association of Realtors
CREALTOR	Industry	Home sales from National Association of Realtors
PREALTOR	Industry	Pending home sales from National Association of Realtors
EEI	Industry	U.S. electric output from the Edison Electric Institute, weekly
ASM	Industry	Annual Survey of Manufactures from the U.S. Census Bureau
RAILSHAR	Industry	Railcar loadings from Association of American Railroads and Atlantic Systems
CHEMWEEK	Industry	Weekly chemical prices from Access Intelligence
BALTIC	Industry	Baltic freight indexes, from the Baltic Exchange in London
OGJ	Industry	U.S. and international energy statistics, from Penwell Publishing's Oil & Gas Journal
OGJANN	Industry	U.S. and international energy statistics, from Penwell Publishing's Oil & Gas Journal, annual
OILWKLY	Industry	Weekly oil statistics, from Penwell Publishing's Oil & Gas Journal
OMI	Industry	Oil market intelligence, from Energy Intelligence

Table 42.3 *continued*

Database Name	Offering Type	Description
NGW	Industry	Natural Gas Week, from Energy Intelligence
WGI	Industry	World Gas Intelligence, from Energy Intelligence
G10+	Industrial countries	International Macroeconomic Data by Haver Analytics
PMI	Industrial countries	Purchasing Managers Indexes by Markit Economics
INTSRVYS	Industrial countries	Country surveys
JAPAN	Industrial countries	Japan from Nomura Research Institute
JAPANW	Industrial countries	Japan from Nomura Research Institute, weekly
CANSIM	Industrial countries	Canada from Statistics Canada and the Bank of Canada
CANSIMR	Industrial countries	Canada from Statistics Canada and the Bank of Canada
UK	Industrial countries	United Kingdom, from the Office of National Statistics and the Bank of England
UKSRVYS	Industrial countries	United Kingdom surveys, by NTC Economics, Ltd.
GERMANY	Industrial countries	Germany, from the Deutsche Bundesbank and Statistics Bundesamt
FRANCE	Industrial countries	France, Statistics from INSEE (France's National Statistical Office), the Bank of France, and the Ministry of France
ITALY	Industrial countries	Italy, from Istituto Nazionale di Statistica and Banca d'Italia
SPAIN	Industrial countries	Spain, from the Instituto Nacional de Estadística and the Banco de España
IRELAND	Industrial countries	Ireland, from the Central Statistics Office and Central Bank
NORDIC	Industrial countries	Norway, Sweden, Denmark, Finland
ALPMED	Industrial countries	Austria, Switzerland, Greece, Portugal

FDICR	U.S. regional	FDIC banking statistics

Examples: SASEHAVR Interface Engine

Before running the following sample code, set your HAVER_DATA environment variable to point to the SAS/ETS SASMISC folder that contains sample Haver databases. The provided sample data files are HAVERD.DAT, HAVERD.IDX, HAVERW.IDX, and HAVERW.DAT. In the following example, the Haver database is called haverw and it resides in the directory lib1. The DATA statement names the SAS output data set hwouty, which will reside in the Work library.

Example 42.1: Examining the Contents of a Haver Database

To see which time series are in your Haver database, use the CONTENTS procedure with the SASEHAVR LIBNAME statement to read the contents.

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=yearly start=19920101
      end=20041231
      force=freq;

data hwouty;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, HAVERW.DAT';
title2 'PROC CONTENTS for Time Series converted to yearly frequency';
proc contents data=hwouty;
run;
```

All time series in the Haver haverw database are listed alphabetically in [Output 42.1.1](#).

Output 42.1.1 Examining the Contents of Haver Analytics Database, haverw.dat

Haver Analytics Database, HAVERW.DAT				
PROC CONTENTS for Time Series converted to yearly frequency				
The CONTENTS Procedure				
Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Format Label
1	DATE	Num	8	YEAR4. Date of Observation
2	FA	Num	8	Total Assets: All Commercial Banks (SA, Bil.\$)
3	FCM1M	Num	8	1-Month Treasury Bill Market Bid Yield at Constant Maturity (%)
4	FM1	Num	8	Money Stock: M1 (SA, Bil.\$)
5	FTA1MA	Num	8	Treasury 4-Week Bill: Total Amount Accepted (Bil\$)
6	FTB3	Num	8	3-Month Treasury Bills, Auction (% p.a.)
7	LICN	Num	8	Unemployment Insurance: Initial Claims, State Programs (NSA, Thous)

You could also use the following SAS statements to create a SAS data set named `hwouty` and to print its contents.

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=yearly
      start=19920101
      end=20041231
      force=freq;

data hwouty;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=yearly, infile=haverw.dat';
title2 'Define a range inside the data range for OUT= dataset,';
title3 'Using the START=19920101 END=20041231 LIBNAME options.';

proc print data=hwouty;
run;
```

The preceding LIBNAME LIB1 statement specifies that all time series in the `haverw` database be converted to a yearly frequency but to select only the range of data from January 1, 1992, to December 31, 2004. The resulting SAS data set `hwouty` is shown in [Output 42.1.2](#).

Output 42.1.2 Defining a Range inside the Data Range for Yearly Time Series

Haver Analytics Database, Frequency=yearly, infile=haverw.dat Define a range inside the data range for OUT= dataset, Using the START=19920101 END=20041231 LIBNAME options.							
Obs	DATE	FA	FCM1M	FM1	FTA1MA	FTB3	LICN
1	1992	3466.3	.	965.31	.	3.45415	407.340

Example 42.2: Viewing Quarterly Time Series from a Haver Database

The following statements specify a quarterly frequency conversion of all time series for the period spanning April 1, 2001, to December 31, 2004:

```

libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=quarterly
      start=20010401
      end=20041231
      force=freq;

data hwoutq;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=quarterly, infile=haverw.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20010401 END=20041231 LIBNAME options.';

proc print data=hwoutq;
run;

```

The resulting SAS data set hwoutq is shown in [Output 42.2.1](#).

Output 42.2.1 Defining a Range inside the Data Range for Quarterly Time Series

Haver Analytics Database, Frequency=quarterly, infile=haverw.dat Define a range inside the data range for OUT= dataset Using the START=20010401 END=20041231 LIBNAME options.

Example 42.3: Viewing Monthly Time Series from a Haver Database

The following statements convert weekly time series to a monthly frequency:

```

libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=monthly
      start=20040401
      end=20041231

```

```

force=freq;

data hwoutm;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=monthly, infile=haverw.dat';
title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20040401 END=20041231 LIBNAME options.';

proc print data=hwoutm;
run;

```

The result from using the range of April 1, 2004, to December 31, 2004, is shown in [Output 42.3.1](#).

Output 42.3.1 Defining a Range inside the Data Range for Monthly Time Series

Haver Analytics Database, Frequency=monthly, infile=haverw.dat Define a range inside the data range for OUT= dataset Using the START=20040401 END=20041231 LIBNAME options.

Example 42.4: Viewing Weekly Time Series from a Haver Database

The following statements show weekly data that span from September 1, 2004, to December 31, 2004:

```

libname lib1 sasehavr "%sysget(HAVER_DATA)"
  freq=weekly
  start=20040901
  end=20041231;

data hwoutw;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=weekly, infile=haverw.dat';
title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20040901 END=20041231 LIBNAME options.';

proc print data=hwoutw;
run;

```

Output 42.4.1 shows the output.

Output 42.4.1 Defining a Range inside the Data Range for Weekly Time Series

Haver Analytics Database, Frequency=weekly, infile=haverw.dat Define a range inside the data range for OUT= dataset Using the START=20040901 END=20041231 LIBNAME options.

Example 42.5: Viewing Daily Time Series from a Haver Database

Consider viewing the Haver Analytics daily database named haverd. The contents of this database can be seen by submitting the following DATA step:

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=daily
      start=20041201
      end=20041231;

data hwoutd;
  set lib1.haverd;
run;

title1 'Haver Analytics Database, HAVERD.DAT';
title2 'PROC CONTENTS for Time Series converted to daily frequency';
proc contents data=hwoutd;
run;
```

Output 42.5.1 shows the output of PROC CONTENTS with the time ID variable DATE followed by the time series variables FCM10, FCM1M, FFED, FFP1D, FXAUS, and TCC with their corresponding attributes such as type, length, format, and label.

Output 42.5.1 Examining the Contents of a Daily Haver Analytics Database, haverd.dat

Haver Analytics Database, HAVERD.DAT				
PROC CONTENTS for Time Series converted to daily frequency				
The CONTENTS Procedure				
Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Format Label
1	DATE	Num	8	DATE9. Date of Observation
2	FCM10	Num	8	10-Year Treasury Note Yield at Constant Maturity (Avg, % p.a.)
3	FCM1M	Num	8	1-Month Treasury Bill Market Bid Yield at Constant Maturity (%)
4	FFED	Num	8	Federal Funds [Effective] Rate (% p.a.)
5	FFP1D	Num	8	1-Day AA Financial Commercial Paper (% per annum)
6	FXAUS	Num	8	Foreign Exchange Rate: Australia (US\$/Australian\$)
7	TCC	Num	8	Treasury: Closing Operating Cash Balance (Today, Mil.\$)

Example 42.6: Limiting the Range of Time Series from a Haver Database

The following statements limit the range of data to the month of December:

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=daily
      start=20041201
      end=20041231;

data hwoutd;
  set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20041201 END=20041231 LIBNAME options.';

proc print data=hwoutd;
run;
```

Note that [Output 42.6.1](#) for daily conversion shows the frequency as the SAS time interval for WEEKDAY.

Output 42.6.1 Defining a Range inside the Data Range for Daily Time Series

Haver Analytics Database, Frequency=daily, infile=haverd.dat
 Define a range inside the data range for OUT= dataset
 Using the START=20041201 END=20041231 LIBNAME options.

21	29DEC2004	4.33	1.76	2.23	2.23	0.7709	34754
22	30DEC2004	4.27	1.68	2.24	2.18	0.7785	20045
23	31DEC2004	4.24	1.89	1.97	2.18	0.7805	24690

Example 42.7: Using the WHERE Statement to Subset Time Series from a Haver Database

Using a WHERE statement in the DATA step can be useful for further subsetting.

```
libname lib1 sasehavr "%sysget(HAVER_DATA)"
      freq=daily start=20041101 end=20041231;

data hwoutd;
  set lib1.haverd;
  where date between '01nov2004'd and '01dec2004'd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20041101 END=20041231 LIBNAME options.';
title4 'Subset further: where date between 01nov2004 and 31dec2004.';
proc print data=hwoutd;
run;
```

Output 42.7.1 shows that the time slice of November 1, 2004, to December 31, 2004, is narrowed further by the DATE test in the WHERE statement to stop at December 1, 2004.

Output 42.7.1 Defining a Range Using the WHERE Statement, START=20041101, and END=20041231

```
Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041231 LIBNAME options.
Subset further: where date between 01nov2004 and 31dec2004.
```

Example 42.8: Using the KEEP Option to Subset Time Series from a Haver Database

To select specific time series, you can use the KEEP= or DROP= option as follows:

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=daily
      start=20041101
      end=20041231
      keep="FCM*";

data hwoutd;
  set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20041101 END=20041231 LIBNAME options.';
title4 '  Subset further: Using keep="FCM*" LIBNAME option ';
proc print data=hwoutd;
run;
```

Output 42.8.1 shows two series that are selected by using KEEP="FCM*" in the LIBNAME statement.

Output 42.8.1 Using the KEEP Option and Defining a Range Using START=20041101 and END=20041231

```
Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041231 LIBNAME options.
Subset further: Using keep="FCM*" LIBNAME option
```

You can use the DROP option to drop specific variables from a Haver database. To specify this option, use DROP= instead of KEEP=.

Example 42.9: Using the SOURCE Option to Subset Time Series from a Haver Database

You can use the SOURCE= or DROPSOURCE= option to select specific variables that belong to a certain source, similar to the way you use the KEEP= or DROP= option.

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=daily
      start=20041101
      end=20041223
      source="FRB";

data hwoutd;
  set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20041101 END=20041223 LIBNAME options.';
title4 '  Subset further: Using source="FRB" LIBNAME option';
proc print data=hwoutd;
run;
```

Output 42.9.1 shows two series that are selected by using SOURCE="FRB" in the LIBNAME statement.

Output 42.9.1 Using the SOURCE Option and Defining a Range Using START=20041101 and END=20041223

Haver Analytics Database, Frequency=daily, infile=haverd.dat
 Define a range inside the data range for OUT= dataset
 Using the START=20041101 END=20041223 LIBNAME options.
 Subset further: Using source="FRB" LIBNAME option

Example 42.10: Using the GROUP Option to Subset Time Series from a Haver Database

You can use the GROUP= or DROPGROUP= option to select specific variables that belong to a certain group, similar to the way you use the KEEP= or DROP= option.

Output 42.10.1, Output 42.10.2, and Output 42.10.3 show three different cross sections of the same database, haverw, by specifying three unique GROUP= options: GROUP="F*" in LIBNAME LIB1, GROUP="M*" in LIBNAME LIB2, and GROUP="E*" in LIBNAME LIB3.

The following statements specify GROUP="F*" in the LIBNAME LIB1 statement:

```
libname lib1 sasehavr "%sysget(HAVER_DATA) "
      freq=week.6
      force=freq
      start=20040102
      end=20041001
      group="F*";

data hwoutwA;
  set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=week.6, infile=haverw.dat';
title2 '  Define a range inside the data range for OUT= dataset';
title3 '  Using the START=20040102 END=20041001 LIBNAME options.';
title4 '  Subset further: Using group="F*" LIBNAME option';
proc print data=hwoutwA;
run;
```

Output 42.10.1 shows the output.

Output 42.10.1 Using the GROUP=F* Option and Defining a Range

```
Haver Analytics Database, Frequency=week.6, infile=haverw.dat
Define a range inside the data range for OUT= dataset
Using the START=20040102 END=20041001 LIBNAME options.
Subset further: Using group="F*" LIBNAME option
```

Example 42.11: Using the OUTSELECT=ON Option to View the Key Selection Variables in a Haver Database

Suppose you want to select your time series based on geography codes or source codes. To construct your wildcard for selection, first run with the OUTSELECT=ON option to see the possible values for each selection key.

```
Libname lib1 sasehavr "%sysget(HAVER_DATA) "
      outselect=on ;

data validD1;
  set lib1.haverd;
run;

title1 'OUTSELECT=ON, Print the OUT= Data Set';
title2 'Shows the Values for Key Selection Variables: ';
title3 'Name, Source, Geog1, Geog2, Shortsrc, Longsrc';
title4 'OUTSELECT=ON, the CONTENTS Procedure with Variable Names and Labels';
proc print data=validD1;
run;

proc contents data=validD1;
run;
```

Output 42.11.1 shows the output values for each key selection variable.

Output 42.11.1 OUTSELECT=ON Option Shows the Values for Key Selection Variables

OUTSELECT=ON, Print the OUT= Data Set						
Shows the Values for Key Selection Variables:						
Name, Source, Geog1, Geog2, Shortsrc, Longsrc

2	SOURCE	Char	6	DLXRECORD.Source
12	TCC	Char	8	Treasury: Closing Operating Cash Balance (Today, Mil.\$)

Example 42.12: Selecting Variables Based on Short Source Key Code

Using the information from [Example 42.11](#), you can now select time series by using selection keys such as the SHORT=, GEOG1=, or GEOG2= options. Since the short source values are nontrivial in database haverd, it is best in this case to use the SHORT= option. For more information about using geography codes as selection keys, see [Output 42.13.1](#) for the GEOG1= option and [Output 42.13.2](#) for the GEOG2= option.

```
Libname lib1 sasehavr "%sysget(HAVER_DATA) "
      short="GOLDMAN, FRB, CRB";
data valide2;
  set lib1.haverd;
  where date between '18jan2005'd and '29mar2005'd;
run;

title1 'SHORT= option list: GOLDMAN, FRB, CRB';
title2 'Should contain these time series: ';
title3 'FCM10, FCM1M, FFED, FFP1D';
title4 'SHORT= option, Print the OUT= Valide2 Data Set';
proc print data=valide2;
run;

title4 'SHORT= option, Print the Contents of OUT= Valide2 Data Set';
proc contents data=valide2;
run;
```

[Output 42.12.1](#) shows the output for the SHORT= option.

Output 42.12.1 SHORT= Option Shows the Selected Variables

```

SHORT= option list: GOLDMAN, FRB, CRB
Should contain these time series:
FCM10, FCM1M, FFED, FFP1D
SHORT= option, Print the OUT= ValidE2 Data Set

Example 42.13: Selecting Variables Based on Geography Key Codes

Since the haverd database did not have interesting geography codes, the following statements access the INTWKLY database by using its more complete geography key codes to select the desired time series from the specified geography codes:

```

Libname lib1 sasehavr "%sysget(HAVER_DATA_NEW) "
outselect=on
keep="R273RF3,X924USBE,R023DF,R273G1,F023A,F158FBS,F023ACR,X156VEB,F023ACE";

data valid1(keep=NAME SOURCE GEOG1 GEOG2 SHORTSRC LONGSRC);
set lib1.intwkly;
run;

title1 'OUTSELECT=ON, Print the OUT= Data Set';
title2 'Shows the Values for Key Selection Variables:.';
title3 'Name, Source, Geog1, Geog2, Shortsrc, Longsrc';
title4 'OUTSELECT=ON, the CONTENTS Procedure with Variable Names and Labels';
proc print data=valid1;
run;

Libname lib2 sasehavr "%sysget(HAVER_DATA_NEW) "
geog1="156";

data valid2(
keep=date R273RF3 X924USBE R023DF R273G1 F023A F158FBS F023ACR X156VEB F023ACE);
set lib2.intwkly;
run;

title1 'Only one GEOG1 Code, 156, contains time series X156VEB';
title2 'Select Geography Code 1 Option:.';

```

```

title3 'GEOG1= option';
title4 'Only Time Series X156VEB has Geog1 = 156';

proc contents
    data=valid2;
run;

Libname lib3 sasehavr "%sysget(HAVER_DATA_NEW) "
    geog2="299";

data valid3(
    keep=date R273RF3 X924USBE R023DF R273G1 F023A F158FBS F023ACR X156VEB F023ACE);
    set lib3.intwkly;
run;

title1 'Only one GEOG2 Code, 299, contains time series X156VEB';
title2 'Select Geography Code 2 Option: ';
title3 'GEOG2= option';
title4 'Only Time Series X156VEB has Geog2 = 299';

proc contents
    data=valid3;
run;

title1 'Compare GEOG1 Code 156';
title2 'Over nonmissing values range';
title3 'With GEOG2 Code 299';
title4 'Over nonmissing values range';

proc compare listall briefsummary criterion=1.0e-5
    base=valid2(
        where=( date between '09jan1998'd and '28dec2007'd ))
    compare=valid3(
        where=( date between '09jan1998'd and '28dec2007'd ));
run;

```

Overview: SASEXFSD Interface Engine

The SASEXFSD interface engine enables SAS users to access both FactSet data and FactSet sourced data that are provided by the FactSet OnDemand service (formerly known as FASTFetch). This service provides access to many FactSet Data Sources and to many other databases. This chapter focuses on accessing the FactSet Fundamentals database, but many databases and data types are available that use the SASEXFSD interface engine. For a more comprehensive list of available data, enter the following URL in your web browser:

<http://www.factset.com/data/data>

For detailed descriptions of other databases that you can access, refer to the FactSet workstation Online Assistant.

The SASEXFSD engine uses the LIBNAME statement to specify which factlet (provided by FactSet) to use to open a database and what parts of the database to access. Factlets are functions that encapsulate business logic and data collection procedures. The technology is capable of cross referencing and dealing with time series for a large amount of data.

To specify the factlet, name one of the supported factlets that are listed in [Table 43.1](#). [Table 43.5](#) shows where to find a summary of each factlet's options.

Table 43.1 Supported FactSet OnDemand Factlets

Supported Factlet	Example
ExtractEconData	Example 43.1 , Example 43.2
ExtractEconData (cont.)	Example 43.3 , Example 43.4 , Example 43.5
ExtractFormulaHistory	Example 43.6 , Example 43.7 , Example 43.8
ExtractDataSnapshot	Example 43.9 , Example 43.10
ExtractBenchmarkDetail	Example 43.11 , Example 43.12
ExtractOFDBItem	Example 43.13
ExtractOFDBUniverse	Example 43.14
ExtractScreenUniverse	Example 43.15

The Prefix column in [Table 43.2](#) contains the parameters that you are most likely to refer to when requesting data, but each factlet has its own set of optional parameters and default settings. Often the items that you select use a prefix (see the Prefix column) to designate the database where the item resides. Because the availability of data libraries and their contents are constantly changing, [Table 43.2](#) is included for instructional purposes only.

Table 43.2 Sample Databases Available through FactSet

Prefix	Database
ff	FactSet Fundamentals
fe	FactSet Estimates
fg	FactSet Global
p	FactSet Prices—Security Price Data

Table 43.2 shows only a subset of the available FactSet databases. For a more comprehensive list that also includes third-party databases available through FactSet, refer to the FactSet Online Assistant, page ID 2014.

To specify the data library, specify both a physical path to indicate the location of the data files (XML data returned from FactSet OnDemand) and the LIBNAME statement options to specify which factlet to use to request data items and the desired key IDs (identifiers, such as tickers or country codes) for your selection. The orientation of the data that are returned is ETI, entity-time-item, and is kept with sorted keys (entities or BY groups); each observation is indexed by time interval, and each time series data item is organized in columns by item name (time series variable name). The SASEXFSD engine supports the parameters that are required for each supported factlet.

Use the SASEXFSD engine to access all available data library items. To get started, look at the FactSet Fundamentals data items in Table 43.3.

For a complete list of data items for every category, refer to the FactSet Online Assistant, page ID 16331. FactSet workstation user name and serial number credentials are necessary to launch the FactSet Online Assistant from the FactSet workstation. A FactSet representative can provide these credentials.

Because the availability of data libraries and their contents are constantly changing, Table 43.3 is included for instructional purposes only. At the time of this writing, the available data list and items for the FactSet Fundamentals database are as shown in Table 43.3.

Table 43.3 FactSet Fundamentals Database Sets

Formulas by Category	Data Items (SAS Variable Names) in Category
Identifiers	FF_CUSIP, FF_DISCL_ID, FF_ISIN, FF_SEDOL, FF_TICKER, FF_WS_ID
Balance sheet	FF_ASSETS, FF_BDEBT, FF_GW, FF_INVEN_FG, FF_PPE_DEP, FF_PPE_GROSS, FF_PAY_ACCT
Income statement	FF_COGS, FF_DEP_EXP, FF_DIL_ADJ, FF_EBIT, FF_EQ_AFF_INC, FF_EXP_OPER, FF_GROSS_INC
Cash flow	FF_DEBT_CF, FF_DIV_CF, FF_FIN_CF, FF_CAPEX, FF_INVEST_CF, FF_INVEST_PURCH_CF, FF_SALE_ASSAETS_BUS_CF
Ratios	FF_ASSETS_EQ, FF_DEBT_EQ, FF_LIFE_INS, FF_LOAN_ASSETS, FF_NET_CAP_REQUIRE, FF_RD_SALES
Market data	FF_ACQ_DATE, FF_DIV_RATE, FF_ENTITY_TYPE, FF_PRICE_CLOSE, FF_PRICE_HIGH_52WK
Corporate data and classifications	FF_GEN_IND, FF_IND_GRP, FF_MAJOR_SUBIND, FF_SIC_CODE, FF_EMP_NUM
Financial records	FF_ACTG_STANDARD, FF_COVERAGE, FF_CURN_DOC, FF_DEPS_BK, FF_FREQ_CODE, FF_US_GAAP_AVAIL

For a comprehensive list of FactSet Fundamentals data items, refer to the FactSet Online Assistant, page ID 15099. If the page is not found, enter “FactSet Fundamentals” in the search box near the top of the page.

Getting Started: SASEXFSD Interface Engine

To specify the parts of the database that you want to access, you supply two things: the list of IDs for the companies or securities that you want to access, and the list of data items that you want to retrieve.

When accessing company or security data, use the `ExtractFormulaHistory` factlet. Use the `IDS=` option to specify the list of IDs that identify the companies that you want to access by specifying the entity ID (such as the ticker symbol) for each company.

For example, the following statements access the FactSet Fundamentals database for monthly sales data (`ff_sales`) and the Prices database for pricing data (`p_price`) for IBM (`ID='ibm'`) and for FactSet Research Systems (`ID='fds'`). To include both IDs in the same request, specify `IDS='ibm,fds'`; to include both data items in the same request, specify `ITEMS='p_price,ff_sales'`, as follows:

```
LIBNAME myLib sasexfsd "%sysget(FACTSET)"
  FACTLET=ExtractFormulaHistory
  FORMAT=sml
  OUTXML=gstart1
  AUTOMAP=replace
  MAPREF=MyMap
  XMLMAP="%sysget(FACTSET)gstart1.map"
  IDS='ibm,fds'
  ITEMS='p_price,ff_sales'
  DATES='20110130:20110631:m'
  ORIENTATION=eti
  user='XXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXX';
;

data company_pvol;
  set myLib.gstart1;
run;

proc contents data=company_pvol; run;
proc print data=company_pvol; run;
```

Figure 43.1 Getting Started with ExtractFormulaHistory: Company_pvol

Obs	FQL_ ENTITY	date	p_price	ff_sales
1	ibm	01-31-2011	162.000	99870.00
2	ibm	02-28-2011	161.880	99870.00
3	ibm	03-31-2011	163.070	99870.00
4	ibm	04-30-2011	170.580	99870.00
5	ibm	05-31-2011	168.930	99870.00
6	ibm	06-30-2011	171.550	99870.00
7	fds	01-31-2011	100.800	641.06
8	fds	02-28-2011	104.880	641.06
9	fds	03-31-2011	104.730	641.06
10	fds	04-30-2011	109.410	641.06
11	fds	05-31-2011	110.860	641.06
12	fds	06-30-2011	102.320	641.06

The SASEXFSD engine supports only the SAS XML (SML) format and the ETI orientation. The XML data that are returned from the FactSet OnDemand service are placed in a file specified by the OUTXML= option. The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option. In the preceding example, the SASEXFSD engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename:

```
FILENAME MyMap "U:\factset\test\gstart1.map";
```

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file; this is described in the section “[SAS OUTXML File](#)” on page 2987. This data file is placed in the folder designated by ‘physical-name’, which is described in the section “[The LIBNAME libref SASEXFSD Statement](#)” on page 2972. You can refer to your data by using the myLib libref in your SASEXFSD LIBNAME statement. In the preceding program, this statement appears inside the DATA step in the SET statement, which names the input data set myLib.gstart1 and causes the reading of the GSTART1.xml file to be input and stored in the SAS data set Company_pvol.

The Company_pvol data set contains two time series variables (data items), p_price and ff_sales, as specified in the ITEMS= option, and the observation range is controlled by the DATES= option. The prefixes, ff_ and p_, are the database designators for the FactSet Fundamentals and Prices databases, respectively, as shown in [Table 43.2](#). The Company_pvol data set contains observations that range from January 30, 2011, to June 31, 2011, as specified in the DATES= option. The frequency of the data is monthly, as specified by the ‘m’ at the end of the DATES= option. [Figure 43.1](#) shows the results.

To specify the list of data items that you want to retrieve, use the ITEMS= option. This option accepts a string, enclosed in single quotation marks, that denotes a list of data items that you are selecting for the resulting SAS data set. The data item names are separated by commas, so valid item names cannot contain embedded commas or quotation marks. The prefix in each data item name designates the data source as defined in the Prefix column of [Table 43.2](#).

After the libref is assigned by the LIBNAME statement, the database is opened. The selected data are organized into group entities (BY groups) that are sorted by date. In [Figure 43.1](#), the tickers are the BY groups, and within each ticker, the observations are sorted by the time ID variable DATE.

You can also use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set.

The SASEXFSD engine is supported on 64-bit Windows platforms.

Syntax: SASEXFSD Interface Engine

The SASEXFSD interface engine uses standard engine syntax. [Table 43.4](#) summarizes the options that the SASEXFSD engine supports. In addition, there are two required options: USERNAME='fact_username' and PASS='fact_password'.

Table 43.4 Summary of LIBNAME *libref* SASEXFSD Options

Option	Description
FACTLET=	Specifies which factlet you want to use. See Table 43.5 for the complete list.
IDS=	Specifies a list of FactSet keys or entity identifiers for accessing FactSet OnDemand data. To select more than one ID, list the unique entity identifiers separated by commas. FactSet IDs are often identifiers such as CUSIPs, tickers, SEDOLs, Quick Code, or CINS (CUSIP International Numbering System).
ITEMS=	Specifies a list of FactSet data items for accessing FactSet data sources. To select more than one item, list the data item names, separated by commas.
ITEM=	Specifies one FactSet data item name (time series name)
DATES=	Specifies a list with the start date, end date, and frequency, separated by colons (:)
DATE=	Specifies one date in YYYYMMDD format (default is 0B, for today's date)
CURRENCY=	Specifies a currency in which the data are returned, using a three-character ISO code, such as USD for US dollars or EUR for euros
FORMAT=	Specifies a FactSet format. Only SAS XML format (SML format) is supported.
ORIENTATION=	Specifies the layout of the selected data items for access. Only the ETI (entity-time-item) orientation is supported.
ISON=	Specifies whether the company (security), such as SP500 or MSCI_WORLD, is on the specified database or index. For a list of additional ISON= option examples, refer to the FactSet Online Assistant, page ID 2014.
ISONPARAMS=	Specifies the parameters used by the ISON code
START=	Specifies the start date for the selected data range (in YYYYMMDD format)
END=	Specifies the end date for the selected data range (in YYYYMMDD format)
FREQ=	Specifies the reporting frequency of the selected data, such as M for monthly and D for daily. See Table 43.20 for the complete list of frequencies.
PERIOD=	Specifies the time interval between the data points (observations) in a time series. The valid period parameters are ANN, QTR, SEMI, MON, YTD, YTD_SEMI, LTM, LTM_SEMI, and SEMI-ANN. The default is ANN.
CAL=	Specifies the calendar that replicates the PSETCAL function
DBSOURCE=	Specifies a standardized database source name, such as EWIN_ECON, GI_ECON, OECD_MEI, FDS_ECON, FDS_COM, or the default, a null string, which uses the standardized economic data (EWIN_ECON_RGDPR_Y).
DIST=	Specifies the distribution technique for spreading over periods when a data series of a lower frequency is distributed to a higher frequency; for example, distributing an annual series to a quarterly series (such as STEP, EVEN, or NONE)
CONV=	Specifies the conversion technique for aggregating periods, when a data series of a higher frequency is converted to a lower frequency; for example, converting a quarterly series to an annual series (such as SUM, AVERAGE, or AVERAGENP)
NFB=	Specifies the “no-feel-back” option in FQL codes. If you do not use the NFB= option, the returned data series contains NAs where the data are not available (default is NFB=1).
FUNCTION=	Adds the FQL function property to change data value; for example, FUNCTION=ZSCORE
OFDB=	Specifies the OFDB filename
UNIVERSE=	Specifies the one account or benchmark. Use this instead of the IDS= option.
UNIVERSEGROUP=	Default value is EQUITY; for DEBT securities, use UNIVERSEGROUP=DEBT
SCREEN=	Specifies the screen file to show the CUSIPs for
NAME=	Specifies Y (yes) to see the names of each security along with the CUSIP. The default is N (no).
FQLFLAG=	Sets dates to use FQL instead of screening; FQLFLAG=N (default) or Y
FILE=	Specifies an offsite file

The LIBNAME libref SASEXFSD Statement

LIBNAME libref **SASEXFSD** '*physical-name*' **FACTLET**=fact_factletname options ;

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of FactSet data files where the downloaded FactSet XML data are stored. Because the required '*physical name*' argument specifies the location of the folder where your FactSet XML data reside, it should end in a backslash if you are in a Windows environment and a forward slash if you are in a UNIX environment.

FACTLET=fact_factletname specifies the FactSet factlet that you want to use to download your data. Choose one factlet from these possible values: ExtractEconData, ExtractFormulaHistory, ExtractDataSnapshot, ExtractBenchmarkDetail, ExtractOFDBItem, ExtractOFDBUniverse, and ExtractScreenUniverse. (See [Table 43.1](#).)

For example, the following statements access the FactSet database for daily dividend yield data for IBM:

```
LIBNAME myLib SASEXFSD 'physical-name' FACTLET==ExtractFormulaHistory
  IDS='ibm'
  ITEMS='FG_DIV_YLD'
  FREQ=d
  USER='username'
  PASS='password';
```

After the libref is assigned, you can access the data items for the IDs (keys) from the requested factlet.

You can specify the following *options* in the LIBNAME libref SASEXFSD statement.

FACTLET=fact_factletname

Each factlet type has its own set of parameters (shown in [Table 43.5](#) in the Factlet Options Table column), allowing flexibility and easy access to FactSet data. For more details about each factlet, refer first to the Factlet Description Section listed in [Table 43.5](#). If you need more information, refer to the Online Assistant, page ID 16948. If the factlet is not listed on that page, then enter the factlet name in the search window of the Online Assistant to retrieve additional information about using the factlet.

Table 43.5 Summary of Factlet Options

Factlet Name	Factlet Description Section	Factlet Options Table
ExtractEconData	"The ExtractEconData Factlet" on page 2975	Table 43.10
ExtractFormulaHistory	"The ExtractFormulaHistory Factlet" on page 2979	Table 43.12
ExtractDataSnapshot	"The ExtractDataSnapshot Factlet" on page 2980	Table 43.13
ExtractBenchmarkDetail	"The ExtractBenchmarkDetail Factlet" on page 2981	Table 43.15
ExtractOFDBItem	"The ExtractOFDBItem Factlet" on page 2983	Table 43.16
ExtractOFDBUniverse	"The ExtractOFDBUniverse Factlet" on page 2984	Table 43.17
ExtractScreenUniverse	"The ExtractScreenUniverse Factlet" on page 2984	Table 43.18

IDS=*fact_ids*

specifies a list of FactSet IDs (entity identifiers or keys) for accessing FactSet OnDemand data. To select more than one ID, list the unique entity identifiers, separated by commas (as shown in the following statements). Examples of FactSet IDs include CUSIPs, tickers, SEDOLs, Quick Code, and CINS (CUSIP International Numbering System). For more information, see [Example 43.6](#) and [Example 43.7](#).

```
LIBNAME myLib sasexfsf 'physical-name'
  ids='IBM,MSFT'
  ITEMS='p_price,p_volume,ca_sales';
```

ITEMS=*'fact_itemlist'*

specifies the items and groups of interest for selection based on IDs (keys). Use FactSet's Formula Lookup for a complete list of data items, which is described in the FactSet Online Assistant.

Because the availability of data libraries and their contents are constantly changing, the following tables are included for instructional purposes only. Many other databases are available that are not shown in [Table 43.6](#) to [Table 43.9](#).

Table 43.6 Some FactSet Data Items

Data Source	Table Reference	Online Assistant Page ID

Benchmark Constituent Valuation	FG_CONST_VALUATION
Benchmark Constituent Weights	FG_CONST_WEIGHT
Benchmark Constituents	FG_CONSTITUENTS

For more information, see the FactSet Online Assistant, page ID 1931. To see each data source's list of available data items, use the search feature of the FactSet Online Assistant. You can open any page in the FactSet Online Assistant by entering the appropriate page ID number in the page ID window, which is located below the search window.

DATES=*'fact_startdate:fact_enddate:fact_freqcode'*

specifies the start date, end date, and frequency, separated by colons (:). For more information, see the section “[Specifying Date Ranges and Frequency Codes](#)” on page 2987. An alternative to using the DATES= option is to use the START=, END=, and FREQ= options.

PERIOD=*fact_period*

specifies the periodic frequencies of the actual data points (observations) in a time series. The valid period parameters are ANN, QTR, SEMI, MON, YTD, YTD_SEMI, LTM, LTM_SEMI, and SEMI-ANN. The default is ANN.

OUTXML=*fact_xmlfile*

specifies the filename of the data file where the XML data that are returned from the FactSet OnDemand service are stored. You can use the OUTXML= option to name your XML data file, which is placed in the folder designated by 'physical-name', as shown in the section “[The LIBNAME libref SASEXFSD Statement](#)” on page 2972.

AUTOMAP=*fact_automap*

specifies whether to overwrite the existing XML map file (AUTOMAP=REPLACE) or whether not to overwrite the existing XML map file (AUTOMAP=REUSE). You can set *fact_automap* to REUSE so that a pre-existing XML map named by the XMLMAP= option is used. You can set *fact_automap* to REPLACE so that the most current XML map generated by the SASEXFSD engine and named by the XMLMAP= option is used.

XMLMAP=*fact_xmlmapfile*

specifies the fully qualified name of the file where the XML map is automatically stored.

MAPREF=*fact_xmlmapref*

specifies the fileref to be used for the map assignment.

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file. This file is placed in the folder designated by 'physical-name', and you can reference it by using the myLib libref in your SASEXFSD LIBNAME statement. This is shown in the section "[Getting Started: SASEXFSD Interface Engine](#)" on page 2968. The following filename statement is generated by the SASEXFSD interface engine by using the fileref, MyMap, from the MAPREF=MyMap option and from the fully designated filename in the XMLMAP= option:

```
FILENAME MyMap "U:\factset\test\gstart1.map";
```

FORMAT=*fact_xmlformat*

specifies the SAS XML (SML) format, which is the only format that the SASEXFSD engine supports.

ORIENTATION=*fact_xmlorient*

specifies the ETI orientation, which is the only orientation that the SASEXFSD engine supports. The ETI orientation means that the data are returned and stored in entity-time-item logical layout.

USERNAME=*'fact_username'*

specifies the FactSet user name that enables you to access the data provided by the FactSet OnDemand service.

PASS=*'fact_password'*

specifies the password that is paired with the user name to enable you to access the data provided by the FactSet OnDemand service. **NOTE:** These FactSet OnDemand user name and password credentials are different from your FactSet workstation login credentials. A FactSet representative can provide these credentials.

The ExtractEconData Factlet

The ExtractEconData factlet provides access to a broad array of macroeconomic content, interest rates and yields, country indices, and various exchange rate measures from both the FactSet Economics and the Standardized Economic databases. The ExtractEconData factlet uses the options listed in [Table 43.10](#) to extract Economic data items for a list of country IDs or for no country IDs over time.

The DBSOURCE= option specifies a standardized database source name, such as EWIN_ECON, GI_ECON, OECD_MEI, FDS_ECON, FDS_COM, or the default, a null string, which uses the Standardized Economic

data (EWIN_ECON_RGDPY_Y). Use the IDS= option to specify one or more country IDs based on the database source. See [Table 43.11](#) for the complete list of country IDs that work with the standardized codes for the FactSet Economics database.

Use the ITEM= option to specify an FQL item based on the database source. You can also use the ITEM= option with the downloading syntax for Economic Request Codes described in the FactSet Online Assistant, page ID 11794, and shown in [Example 43.2](#). [Example 43.2](#) uses the shorthand FQL syntax in the ITEM= option to retrieve the same time series data items.

The SASEXFSD engine supports retrieval of the following FQL entities: ECON_EXPR_DATA, SPEC_ID_DATA, FDS_ECON_DATA, EIU_ECON_DATA, CNS_ECON_DATA, EURO_STAT_DATA, IBJ_NIKKO_DATA, IMF_IFS_DATA, NTCS_ECON_DATA, OECD_OTLK_DATA, OECD_MEI_DATA, ONS_ECON_DATA, TCB_BCI_DATA, TCB_CCI_DATA, CEIC_ECON_DATA, and CEIC_CHINA_DATA.

A FactSet representative can provide you with permissions to access the databases that contain the time series data that you are interested in. See [Example 43.3](#) for an example of using ECON_EXPR_DATA. For more information about using ECON_EXPR_DATA and SPEC_ID_DATA, see the section “Downloading Economic Function Codes to Excel” in the FactSet Online Assistant, page ID 12308. You can replace options such as START=, END=, FREQ=, CONV=, DIST=, NFB=, and FUNCTION= by using the corresponding placement of each option’s value in the FQL downloading syntax. In this example, ITEM="FDS_ECON_DATA('FRBIPSB50001', -121,-1,m,step,average)" gives the database source name (FDS_ECON), time series name (FRBIPSB50001), start and end dates, monthly frequency, distribution (step), and conversion (average); no-feel-back defaults to 1.

See the ExtractEconData appendix, linked in the FactSet Online Assistant, page ID 16948, for the complete list of the data series codes available with the standardized FactSet Economics database. The data are available at monthly, quarterly, and annual frequencies, as denoted by the _M, _Q, and _Y suffixes in the code.

Use the FREQ= option to specify the frequency of the data, and use the DATES= option to specify a date range for selecting time series data. For more information, see the section “Frequency” in the FactSet Online Assistant, page ID 11794.

You can use the CONV= option to specify CONV=SUM, AVERAGE, AVERAGENP, or none (the default is none).

You can use the DIST= option to specify DIST=STEP (step distribution), EVEN, or none (the default).

You can use the NFB= option to specify your no-feel-back setting (0, 1, or 2) to indicate full feel-back, no feel-back (the default), or feel-back until most recent data point, respectively (do not fill in data past the last available data point).

You can use the FUNCTION= option to apply an economic function to the data values of the time series (such as FUNCTION=ZSCORE). For a list of economic functions, see the FactSet Online Assistant, page ID 12308.

The ORIENTATION= option supports only ETI, which is the default.

Table 43.10 ExtractEconData Factlet Options

Option	Description
IDS=	Specifies a string array with a list of the country identifiers from the Standardized Economic database
ITEMS=	Specifies the economic series mnemonic (for example, US GDP database source [mnemonic] is FDS_ECON[BEANIPAA191RL1@US])
DATES=	Specifies a date string such as 'YYYYMMDD:YYYYMMDD:F' or relative dates '-1b:-4b:m'
START=	Specifies the numeric start date in YYYYMMDD format
END=	Specifies the numeric end date in YYYYMMDD format
FREQ=	Specifies the valid FQL frequencies, such as M, D, W, Q, and Y. Note: For economic request codes, a frequency argument is necessary to retrieve the data.
DBSOURCE=	Specifies a standardized database source name, such as EWIN_ECON, GI_ECON, OECD_MEI, FDS_ECON, FDS_COM, or the default, a null string, which uses the Standardized Economic data (EWIN_ECON_RGDPY_Y)
DIST=	Specifies the distribution technique for spreading over periods when a data series of a lower frequency is distributed to a higher frequency; for example, you can use it to distribute an annual series to a quarterly series (such as STEP, EVEN, or NONE).
CONV=	Specifies the conversion technique for aggregating periods, when a data series of a higher frequency is converted to a lower frequency; for example, you can use it to convert a quarterly series to an annual series (for example, SUM, AVERAGE, or AVERAGENP, which excludes NAs).
NFB=	Specifies the optional “no-feel-back” argument in FQL codes. If you do not specify the NFB= option, the returned data series contains NAs where the data are not available (default is NFB=1). If you want the data to “feel back” over NAs to find the last actual data point and carry these data forward, specify either NFB=0 or NFB=2.
FUNCTION=	Adds FQL function property to change data value; for example, FUNCTION=ZSCORE
ORIENTATION=	Specifies an optional orientation (default is ETI, entity-time-item)

Table 43.11 Country Identifiers

Latvia	CC_LV	Vietnam	CC_VN

The ExtractFormulaHistory Factlet

The ExtractFormulaHistory factlet is used for extracting one or more items for one security, for an index, or for a list of securities over time. ExtractFormulaHistory uses the FactSet Query Language (FQL). The ExtractFormulaHistory factlet uses the options listed in [Table 43.12](#), such as the IDS= option, which specifies the IDs for one or more securities, or the ISON= and ISONPARAMS= options, which specify an FQL formula that extracts the universe along with any ISON parameters necessary for the ISON code. You can use the START=, END=, and FREQ= options or the DATES= option to specify a date range for selecting time series data. You can select data items by using the ITEMS= option, but only the name/value pairs syntax (not the standard FQL syntax) is supported. The ITEMS= option designates multiple shortcut items or item/statistic combinations. You can use any instance of the Formula Library for the ITEMS= option.

The PERIOD= option is used for FactSet Fundamentals database codes to specify the estimate period of the data that you want to select. The CAL= option enables you to set your calendar in the same way that the PSETCAL function in FQL works. You can specify the CAL= option to be LOCAL, FIVEDAY, FIVEDAYEOM, SEVENDAY, or an exchange code. The list of exchange codes is available in the FactSet Online Assistant, page ID 16610. The ORIENTATION= option is supported only for ETI (entity-time-item), so that your SAS output data set is organized by key entities such as CUSIP or ticker, by date so that observations are kept in time series order, and by item. ETI is the default setting for orientation.

Table 43.12 ExtractFormulaHistory Factlet Options

Option	Description
IDS=	Specifies one or more securities; for example, IDS=IBM,MSFT,FDS
ISON=	Specifies the FQL value that extracts the universe; for example, ISON_SP500 is entered as ISON=SP500, and ISON_MSCI_WORLD(0,1) is written as ISON=MSCI_WORLD.
ISONPARAMS=	Specifies the ISON codes that use parameters; for example, ISON_MSCI_WORLD(0,1) is written as ISONPARAMS=0,1.
DATES=	Specifies a date string such as YYYYMMDD:YYYYMMDD:F or relative dates -1b:-4b:m
START=	Specifies a valid FQL date; START=0 is the default
END=	Specifies a valid FQL date; END=0 is the default
FREQ=	Specifies a valid FQL frequencies; for example, M, D, Y. See Table 43.20 .
ITEMS=	Specifies one or more FQL items (only the name/value pair syntax is supported; for example, ff_sales, p_price)
PERIOD=	Specifies valid time intervals between the data points (observations) in a time series; for example, ANN, QTR, and SEMI-ANN; PERIOD=ANN is the default.
ORIENTATION=	Specifies an optional orientation (default is currently ETI)
CAL=	Specifies the calendar setting that replicates the PSETCAL function; for example, LOCAL, FIVEDAY, FIVEDAYEOM, and SEVENDAY, for exchange code CAL=AAM (for a list of exchange codes, see the FactSet Online Assistant, page ID 16610)

The ExtractDataSnapshot Factlet

The ExtractDataSnapshot factlet is used for efficiently extracting multiple items as of a single date, for a universe of both equity and fixed income securities. It uses the FactSet Screening Language to extract data for a large universe of securities as of a single date. The ExtractDataSnapshot factlet uses the options listed in [Table 43.13](#), such as the IDS= option, which specifies the IDS for one or more securities, or you can specify fixed securities by using the UNIVERSEGROUP= option. If you want to access only current constituents, use the ISON= option to specify your ISON codes instead of using the IDS= option. If your ISON code uses parameters, then use the ISONPARAMS= option to specify the parameters for the code that you use in your ISON= option. Use DATE=YYYYMMDD to specify the day that your snapshot is for, or use the START=, END=, and FREQ= options for the FQL scalar data item date that you are interested in. Use the ITEMS= option to specify one or more screening items. The SASEXFSD engine does not support the standard screening syntax, so use the name/value pair syntax instead. For example, instead of using ITEMS='FF_SALES(QTR,20110401)', use ITEMS='FF_SALES' PERIOD=QTR REL_DATE=20110401 in your LIBNAME *libref* SASEXFSD statement. Specify the UNIVERSEGROUP= option to choose between the EQUITY group and the DEBT group. The CAL= option enables you to set your calendar in the same way that the PSETCAL function in FQL works. You can specify the CAL= option to be LOCAL, FIVEDAY, FIVEDAYEOM, SEVENDAY, or an exchange code. The list of exchange codes is available in the FactSet Online Assistant, page ID 16610. The ORIENTATION= option is supported only for ETI (entity-time-item), which is also the default.

Table 43.13 ExtractDataSnapshot Factlet Options

Option	Description
IDS=	Specifies one or more securities; for example, IDS='IBM,MSFT'. Fixed securities are used in conjunction with UNIVERSEGROUP=DEBT (for example, IDS=88579EAE).
ISON=	Specifies a screening code that extracts the universe; for example, ISON_SP500 is entered as ISON=SP500, and ISON_MSCI_WORLD(0,1) is entered as ISON=MSCI_WORLD.
ISONPARAMS=	Specifies ISON codes that use parameters; for example, ISON_MSCI_WORLD(0,1) is written as ISONPARAMS=0,1.
DATE=	Specifies one date in the format YYYYMMDD (default is 0B, for today's date)
START=	Specifies a valid start date; START=0 is the default.
END=	Specifies a valid end date; END=0 is the default.
FREQ=	Specifies a valid frequency; for example, M, D, Y. See Table 43.20 .
ITEMS=	Specifies one or more screening items (only the name/value pair syntax is supported)
PERIOD=	Specifies a valid time interval between the data points (observations) in a time series; for example, ANN, QTR, SEMI-ANN; PERIOD=ANN is the default.
UNIVERSEGROUP=	Specifies the universe group. The default value is EQUITY; for DEBT securities, specify UNIVERSEGROUP=DEBT.
ORIENTATION=	Specifies an optional orientation (default is ETI)
CAL=	Specifies a calendar setting that replicates the PSETCAL function; for example, LOCAL, FIVEDAY, FIVEDAYEOM, and SEVENDAY, for exchange code CAL=AAM (for a list of exchange codes, refer to the FactSet Online Assistant, page ID 16610)

The ExtractBenchmarkDetail Factlet

The ExtractBenchmarkDetail factlet is used for retrieving a more comprehensive overview of the index constituent data for a benchmark, without requiring the additional codes and calculations that are needed with the ExtractFormulaHistory factlet. ExtractBenchmarkDetail uses default output in which the identifiers are sorted in descending order by weight in the index, and each row shows the index ID, company ID, date, ticker, and weight. Any additional items are displayed at the end of each row.

The ExtractBenchmarkDetail factlet uses the options that are listed in [Table 43.15](#), such as the IDS= option, which specifies the IDs for one or more benchmarks (indexes). Use DATES='YYYYMMDD:YYYYMMDD:freq' to specify the range of dates in start:end:freq format.

You can designate dates in absolute or relative form, as shown in [Table 43.14](#). Absolute dates specify a day in 'MM/DD/YYYY' format (such as 7/11/1999), a month end in 'MM/YYYY' format (such as 6/1999), a fiscal quarter end in 'YY/FQ' or 'YYY/FQ' format (such as 1999/1F, 2000/3F, or 2001/2F), a calendar quarter end in 'YY/CQ' or 'YYYY/CQ' format (such as 1999/1C, 00/3C, or 2001/1C), or a fiscal year end in 'YY' or 'YYYY' format (such as 2000, 01, or 1999).

Table 43.14 ExtractBenchmarkDetail Factlet Relative Date Arguments

Relative Date Argument	Description
D	0D is the most recent trading day; -1D is one trading day prior.
AW	0AW is the most recent trading day; -1AW is the one actual week (7 days) prior to the most recent trading day.
W	0W is the last day of the most recent trading week (usually Friday); -1W is the last trading day of the prior week.
AM	0AM is the most recent trading day; -1AM is the same day, one actual month prior.
M	0M is the last trading day of the most recent month; -1M is the last trading day of the prior month.
AQ	0AQ is the most recent trading day; -1AQ is the same day 3 months prior.
Q	0Q is the last trading day of the company's most recent fiscal quarter; -1Q is the last day of the prior fiscal quarter.
CQ	0CQ is the last trading day of the most recent calendar quarter (March, June, September, or December); -1CQ is the last trading day of the prior calendar quarter.
AY	0AY is the most recent trading day; -1AY is one actual year (365 days) prior.
Y	0Y is the last trading day of the company's most recent fiscal year; -1Y is the last trading day of the prior fiscal year.
CY	0CY is the last trading day of the most recent calendar year (the last trading day in December); -1CY is the last trading day of the prior calendar year.

Use the ITEMS= option to specify one or more screening items, such as p_price or ca_sales. The CUTOFF= option specifies the number of holdings to show. The default is to show all instances. The optional MATCHDATE= option is used to limit the output to not repeat the dates that “feel back” to a holiday. The default behavior (no MATCHDATE= option) repeats the dates that “feel back” to a holiday. The MATCHDATE= option is always used with a frequency argument set to B, which indicates business days. Use MATCHDATE=ON for better response time and to limit the large amount of data being returned. The UNIVERSEGROUP= option is necessary only when you specify UNIVERSEGROUP=DEBT. By default, UNIVERSEGROUP=EQUITY.

Table 43.15 ExtractBenchmarkDetail Factlet Options

Option	Description
IDS=	Specifies one or more benchmarks; for example, IDS=SP50, R.3000
DATES=	Specifies one or more dates entered in start:end:freq format, '20101215:20100115:d'
ITEMS=	Specifies one or more screening items (such as ITEMS='p_price, ca_sales'). FQL items are named with a preceding underscore.
CUTOFF=	Specifies an optional number of holdings to show; default (no cutoff) displays all instances.
MATCHDATE=	Specifies an optional argument that turns off the default behavior, in which dates are repeated when “feeling back” to a holiday. It is always used with a frequency argument set to B (indicating business days).
UNIVERSEGROUP=	Specifies the universe group. The default value is EQUITY. For fixed income indices, specify UNIVERSEGROUP=DEBT.

The ExtractOFDBItem Factlet

The ExtractOFDBItem factlet provides access to a list of securities and multiple data items for a range of dates uploaded into a single Open FactSet Database (OFDB). An OFDB is a high-performance multidimensional database system that securely stores proprietary numeric and textual data in FactSet. The ExtractOFDBItem factlet uses the options listed in [Table 43.16](#), such as the OFDB= option, which specifies the OFDB file. Use either the IDS= option, which specifies the IDs for one or more securities, or the ISON= and ISONPARAMS= options, which specify an FQL formula (ISON code) that extracts the universe along with any ISON parameters necessary for the ISON code. Use the ITEMS= option to specify one or more items in the OFDB file. Use the DATES= option to specify a date range in YYYYMMDD:YYYYMMDD:freq format, or use FQL dates when FQLFLAG=Y (yes). By default, FQLFLAG=N (no). The DATESONLY= option specifies whether only the dates in the OFDB file are reported. By default, DATESONLY=N. The ORIENTATION= option supports only ETI, which is the default.

Table 43.16 ExtractOFDBItem Factlet Options

Option	Description
OFDB=	Specifies the OFDB file
IDS=	Specifies one or more securities; for example, IDS=IBM, GM
ISON=	Specifies the FQL value that extracts the universe; for example, ISON_SP500 is entered as ISON=SP500, and ISON_MSCI_WORLD(0,1) is written as ISON=MSCI_WORLD.
ISONPARAMS=	Specifies the parameters for the ISON codes that use parameters; for example, ISON_MSCI_WORLD(0,1) is written as ISONPARAMS=0,1.
ITEMS=	Specifies one or more data items from the OFDB file
DATES=	Specifies dates in the format YYYYMMDD:YYYYMMDD:F or relative dates in relative format, such as -1b:-4b:m
DATE=	Specifies one date in the format YYYYMMDD (default is 0B, for today's date)
DATESONLY=	Specifies that dates are reported from the OFDB file only when the option is set to Y (default is N)
FQLFLAG=	Sets dates to use FQL instead of screening; FQLFLAG=N (default) or Y
ORIENTATION=	Specifies an optional orientation (default is currently ETI)

The ExtractOFDBUniverse Factlet

The ExtractOFDBUniverse factlet uses the options that are listed in [Table 43.17](#) to extract a list of CUSIPs that belong to a single OFDB file or ISON code. Use the OFDB= option to specify a OFDB file, and use the DATE= option to specify the date for showing the list of CUSIPs.

Table 43.17 ExtractOFDBUniverse Factlet Options

Option	Description
OFDB=	Specifies the OFDB file
DATE=	Specifies one date in YYYYMMDD format only; DATE="" specifies the most recent date.

The ExtractScreenUniverse Factlet

The ExtractScreenUniverse factlet is used for extracting a list of CUSIPs stored in a single FactSet screen. On the FactSet workstation, a user can screen for equity and fixed income securities based on specified criteria and store a list of companies by using FactSet Universal Screening for equity or debt securities. The ExtractScreenUniverse factlet uses the options that are listed in [Table 43.18](#) to extract a list of CUSIPs that belong to a single user-defined screen. Use the SCREEN= option to specify a screen file, and use the NAME= option to specify whether or not to make the names of the corresponding securities visible. Specify NAME=Y (yes) to view the security names for each CUSIP in the screen. NAME=N (no) is the default, for which security names are not shown with the CUSIP list. Because screen filenames can contain blanks and special characters, enclose the screen filename with single quotation marks:

```
options validvarname=any;
```

```

LIBNAME myFast sasexfsd "%sysget (FACTSET) "
  debug=on
  factlet=ExtractScreenUniverse
  screen='factset:1 Week EPS Estimate Revisions - FactSet Consensus'
  name=y
  format=sml
  outXml=sasscrn4
  automap=replace
  mapref=MyMap
  xmlmap="%sysget (FACTSET) sasscrn4.map"
  period=QTR
  user='XXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXX'
;

```

Table 43.18 ExtractScreenUniverse Factlet Options

Option	Description
SCREEN=	Specifies a screen file
NAME=	Specifies whether security names are to be visible. NAME=Y indicates yes to show names; default is N, indicating that no names are shown.

Details: SASEXFSD Interface Engine

FactSet Data and FactSet Sourced Data

The SASEXFSD interface engine enables SAS users to access both FactSet data and FactSet sourced data that are provided by the FactSet OnDemand service. FactSet OnDemand offerings can provide access to many databases. Because the list of available data is constantly changing, [Table 43.19](#) is included for instructional purposes only. Many other data offerings are available that are not shown in [Table 43.19](#).

Table 43.19 Sample FactSet Data Types

Pricing and IPO Data
Estimates
Broker Research
Commodity Benchmarks
Equity Benchmarks
Fixed Income Benchmarks
Mutual Fund/Account Return Data
Economic Data
Financial News and Events/Corporate Information
Quantitative Data
Options Data
Investment Banking Data
Fixed Income Data
Deal Data
Other Databases

SAS Output Data Set

You can use the SAS DATA step to write the selected FactSet data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA step, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the BY groups, the date of each observation, and the series name of each series that is read from the FactSet data source.

The SASEXFSD interface engine sorts the IDs into keys or BY groups, so that the time series are sorted in the resulting SAS data set by key (entity identifier such as a ticker), by date (time ID), and by variable (time series item name).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEXFSD libref to create a custom view of your data.

SAS OUTXML File

The SAS XML (SML format) data that are returned from the FactSet OnDemand service are placed in a file named by the OUTXML= option. The SAS XML data file is placed in the location that is specified by the *physical-name* in your LIBNAME *libref* SASEXFSD statement.

SAS XML Map File

The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option in your LIBNAME *libref* SASEXFSD statement. The XML map file is either reused (not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE. The SASEXFSD interface engine invokes the XMLV2 engine to create the map and to read the data into SAS.

Specifying Date Ranges and Frequency Codes

When you specify a range of dates for selecting your time series observations, you can specify the range in either absolute or relative dates. The absolute start and end dates are given in YYYYMMDD format and separated by a colon (:). The frequency is given along with the date range and can be any one of the codes shown in [Table 43.20](#). The code frequency indicates the frequency with which you want to display data. Relative dates are relative to the most recently updated period (0). A minus sign (as in -1) represents the period prior to the most recently updated period. The zero date is determined by the natural frequency of the time series data, so a 0 for monthly data represents the most recent month end. Annual data use -1 to represent the fiscal year prior to the most recently updated fiscal year.

Table 43.20 FactSet Frequency Codes

Freq. Code	Description
AD	Displays data on an actual daily basis (that is, all days, not just trading days)
D	Displays data on a daily basis
AW	Displays data weekly, based on the day of the week of the start date
W	Displays data weekly, based on the last day of the completed trading week (usually Friday)
WTD	For a range item (such as price change), displays the week-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data weekly, based on the last day of the completed trading week (usually Friday).
AM	Displays data monthly, based on the start date (for example, if the start date is June 16, data are displayed for June 16, May 16, April 16, and so on)
M	Displays data monthly, based on the last trading day of the month
MTD	For a range item (such as price change), displays the month-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data monthly, based on the last trading day of the month.
QTD	For a range item (such as price change), displays the calendar quarter-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data quarterly, based on the last trading day of the quarter.
CQTD	For a range item (such as price change), displays the calendar quarter-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data quarterly, based on the last trading day of the calendar quarter.
FQTD	For a range item (such as price change), displays the fiscal quarter-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data quarterly, based on the last trading day of the fiscal quarter.
AQ	Displays data in three-month periods, based on the start date (for example, if the start date is April 7, data are displayed for April 7, January 7, October 7, July 7, and so on)
Q	Displays data quarterly, based on the last trading day of the company's fiscal quarter
CQ	Displays data quarterly, based on the last trading day of the calendar quarter (March, June, September, or December)
FSA	Displays data semiannually, based on the last trading day of the fiscal semiannual period
CSA	Displays data semiannually, based on the last trading day of the calendar semiannual period
ASA	Displays data in six-month periods, based on the start date (for example, if the start date is June, data are displayed for June, January, June (prior), January (prior), and so on)
YTD	For a range item (such as price change), displays the calendar year-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data annually, based on the last trading day of the year.
CYTD	For a range item (such as price change), displays the calendar year-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data annually, based on the last trading day of the calendar year.
FYTD	For a range item (such as price change), displays the fiscal year-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data annually, based on the last trading day of the fiscal year.
AY	Displays data annually, based on the start date (for example, if the start date is October 31, 1995, data are displayed for October 31, 1995, October 31, 1994, October 31, 1993, and so on)
Y	Displays data annually, based on the last trading day of the company's fiscal year
CY	Displays data annually, based on the last trading day of the calendar year

Specifying Currency Codes

Currency is represented by three-character ISO (International Organization for Standardization) codes, such as USD for US dollars or EUR for euros. For a complete list of currency codes, see [Table 43.21](#) and [Table 43.22](#).

Table 43.21 ISO Currency Codes

Currency	ISO Code	Currency	ISO Code

12	CC_GR	12-31-2011	290.04	

Example 43.2: Retrieving Economic Items by Using the FQL Syntax for Function Z Score

This example shows how to use the ExtractEconData factlet to retrieve the Z score for the GRLM0347861 monthly time series for Greece over the last three years by using the FQL economic download syntax. It is not necessary to use the IDS= option, because all necessary information is contained in the ITEMS= option. The PRINT procedure uses the LABEL option to allow the time series name to be in the column heading in the output. Without the LABEL option, the column heading would be 'ECON_EXPR_DATA'.

```
option validvarname=any;

title 'Retrieve the Z Score Using ECON_EXPR_DATA for the US CFTNCLOI%ALLNQ100CMEF Series';

Example 43.3: Using ECON_EXPR_DATA with the FQL Syntax for Function Returns

This example shows how to use the ExtractEconData factlet to retrieve the Returns for the GDPEURNS quarterly time series for Greece over the last 10 years by using the FQL economic download syntax. It is not necessary to use the IDS= option, because the FQL downloading syntax allows '@GR' to be appended to the series name in the ITEMS= option. The PRINT procedure uses the LABEL option to allow the time series name to be in the column heading in the output. Without the LABEL option, the column heading would be 'ECON_EXPR_DATA'.

```
option validvarname=any;

title 'Retrieve Returns Using ECON_EXPR_DATA for the GDPEURNS@GR Series';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
  factlet=ExtractEconData
  items="ECON_EXPR_DATA('RETURNS(EURO_STAT[GDPEURNS@GR],-1A0,4)',0,0/0/-10,q)"
  format=sml
  outXml=fsdecon20
  automap=replace
  mapref=MyMap
  xmlmap="%sysget(FACTSET)fsdecon20.map"
  orientation=eti
  user='XXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXX';

data EUROFunc; set xfsd.fsdecon20; run;
proc print data=EUROFunc label; run;
```

Example 43.4: Using SPEC_ID_DATA with the FQL Economic Download Syntax

This example shows how to use the ExtractEconData factlet and SPEC_ID_DATA to retrieve the WTI-FDS:FG_PRICE daily time series for the last 30 days by using the FQL economic download syntax. For more information about real-time data and specifying identifiers for commodity spot prices, see the FactSet Online Assistant, page ID 16992.

```
option validvarname=any;

title 'Retrieve WTI-FDS:FG_PRICE Using SPEC_ID_DATA for the Last 30 Days';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET) "
    factlet=ExtractEconData
    item="SPEC_ID_DATA('WTI-FDS:FG_PRICE',0,-30,d) "
    format=sml
    outXml=fsdecon14
    automap=replace
    mapref=MyMap
    xmlmap="%sysget(FACTSET) fsdecon14.map"
    orientation=eti
    user='XXXXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXXXX';

data WTIPrice; set xfsd.fsdecon14; run;
proc print data=WTIPrice; run;

Example 43.5: Using Multiple Database Sources with the FQL Syntax

This example shows how to use the ExtractEconData factlet and two database sources, FDS_ECON_DATA and EURO_STAT_DATA, to retrieve two time series for the last 11 months by using the FQL economic download syntax. The database source name is prepended to the time series name to retain the integrity of the name of the database source (dbsource). Only the same frequency and same range of observations for multiple series can be requested concurrently.

```
option validvarname=any;

title 'Retrieve Monthly Data from Two Database Sources: FDS_ECON_DATA and EURO_STAT';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
  factlet=ExtractEconData

12	fds	06-30-2011	102.320	641.06	

Example 43.8: Retrieving Book Value Data for One Company by Using Relative Dates

This example shows how to use the ExtractFormulaHistory factlet to retrieve book value data for one company (in this case Exxon Mobil, or XOM) by using relative dates. The book value represents the proportional common equity divided by outstanding shares at the end of the company's fiscal year. The relative date specifies the date as n periods ago based on the frequency (specified or implied); for example, DATES=0:-8:y returns data for the nine years prior to the most recently updated year.

```

title 'Retrieve Book Value Data for Exxon Mobil (XOM) for the Last 9 Years';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
  factlet=ExtractFormulaHistory
  ids='xom'
  items='ff_bps'
  dates='0:-8:y'
  format=sml
  outXml=fsdex03
  automap=replace
  mapref=MyMap
  xmlmap="%sysget(FACTSET) fsdex03.map"
  orientation=eti
  user='XXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXX';

data bookRelative; set xfsd.fsdex03; run;
proc print data=bookRelative; run;

```

Output 43.8.1 Book Value Data for Exxon Mobil for the Last 9 Years

Retrieve Book Value Data for Exxon Mobil (XOM) for the Last 9 Years

9	xom	12-31-2012	36.8421	

Example 43.9: Retrieving Multiple Screen Items for Multiple Companies

This example shows how to use the ExtractDataSnapshot factlet to extract multiple screen items (price and sales) as of a single date for multiple companies (in this case IBM and Microsoft) for the quarterly estimate period (PERIOD=QTR).

```

title 'Retrieve Multiple Screen Items for Multiple Companies';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
  factlet=ExtractDataSnapshot
  ids='ibm,msft'
  items='p_price,ff_sales'
  dates='20110401'
  period=QTR
  format=sml
  outXml=fsdex05
  automap=replace
  mapref=MyMap
  xmlmap="%sysget(FACTSET) fsdex05.map"
  orientation=eti
  user='XXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXX';

data snapshot; set xfsd.fsdex05; run;
proc print data=snapshot; run;

```

Output 43.9.1 Multiple Screen Items for Multiple Companies

Retrieve Multiple Screen Items for Multiple Companies				
Obs	FOL_ ENTITY	date	p_price	ff_sales
1	ibm	04-01-2011	164.270	24607
2	msft	04-01-2011	25.480	16428

Example 43.10: Retrieving Data by Using the ISON= and ISONPARAMS= Options

This example shows how to use the ExtractDataSnapshot factlet to retrieve price-to-earnings (PE) data for the quarterly estimate period by using the ISON= and ISONPARAMS= options. For brevity, only a subset of the output (the first 10 CUSIPs) is displayed.

```

title 'Retrieve Price-to-Earnings Data by Using ISON/ISONPARAMS';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
    factlet=ExtractDataSnapshot
    ison='sp500'
    isonparams='0,1'
    items='ff_pe'
    dates='20110401'
    period=QTR
    format=sml
    outXml=fsdex10
    automap=replace
    mapref=MyMap
    xmlmap="%sysget(FACTSET) fsdex10.map"
    orientation=eti
    user='XXXXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXXXX';

data snapIson; set xfsd.fsdex10; run;
proc print data=snapIson(firstobs=1 obs=10); run;

```

Output 43.10.1 Retrieving Price-to-Earnings Data by Using the ISON= and ISONPARAMS= Options

Retrieve Price-to-Earnings Data by Using ISON/ISONPARAMS				
Obs	FQL_ Entity	date	ff_pe

8	31190010	04-01-2011	33.0765	
9	20911510	04-01-2011	13.5979	
10	53983010	04-01-2011	10.0212	

Example 43.11: Retrieving Benchmark Data by Using the CUTOFF= option

This example shows how to use the ExtractBenchmarkDetail factlet to retrieve the holdings for the Standard & Poor's (S&P) 500 (ID='sp50') and display the P_PRICE data that correspond to each holding. For brevity, only a subset of the output (the first 10 holdings) is displayed.

```

title 'Retrieve Benchmark Data for Top Ten Holdings, CUTOFF=10';
libname _all_ clear;

libname fsd sasexfsd "%sysget(FACTSET) "
    factlet=ExtractBenchmarkDetail
    ids='sp50'
    items='p_price,proper_name'
    dates='20130320'
    cutoff=10
    format=sml
    outXml=fsdex12
    automap=replace
    mapref=MyMap
    xmlmap="%sysget(FACTSET) fsdex12.map"
    orientation=eti
    user='XXXXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXXXX';

data bench;
    set fsd.fsdex12;
run;
proc print
    data=bench;
run;

```

The CUTOFF= option limits the output to the number of holdings that are specified. This example uses CUTOFF=10 to print the top 10 holdings. If you omit the CUTOFF= option, all 500 holdings are reported.

Output 43.11.1 Retrieving Benchmark Data for Top 10 Holdings in the S&P 500 Index

```

Retrieve Benchmark Data for Top Ten Holdings, CUTOFF=10

Obs      FQL_      SECURITY_      Weight      p_price

8      Microsoft Corp.
9      Procter & Gamble Co.
10     Pfizer Inc.

```

Example 43.12: Retrieving Benchmark Data by Using the MATCHDATE= Option

This example shows how to use the ExtractBenchmarkDetail factlet to retrieve data from the Prices database for the Russell 1000 constituents (R.1000).

```

title 'Retrieve Benchmark Data for R.1000 with MATCHDATE=ON';
libname _all_ clear;

libname fsd sasexfsd "%sysget(FACTSET)"
    factlet=ExtractBenchmarkDetail
    ids='r.1000'
    items='p_price'
    dates='20120118:20120113:b'
    matchDate=on
    format=sml
    outXml=fsdex13
    automap=replace
    mapref=MyMap
    xmlmap="%sysget(FACTSET) fsdex13.map"
    orientation=eti
    user='XXXXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXXXX';

data benchmatch;
    set fsd.fsdex13;
run;
proc print
    data=benchmatch(firstobs=1 obs=50);
run;

```

If the frequency argument were not set to B (indicating business days) and the MATCHDATE= option were not turned on, the output would contain repetitive dates because of feel-back, resulting in unnecessarily lengthy output.

Output 43.12.1 Retrieving Benchmark Data for the Russell 1000 Index by Using the MATCHDATE=ON Option

Time Series Forecasting System

Chapter 44

Overview of the Time Series Forecasting System

Contents

Introduction	3015
Using the Time Series Forecasting System	3016
SAS Software Products Needed	3017

Introduction

The Time Series Forecasting system forecasts future values of time series variables by extrapolating trends and patterns in the past values of the series or by extrapolating the effect of other variables on the series. The system provides convenient point-and-click windows to control the time series analysis and forecasting tools of SAS/ETS software.

You can use the system in a fully automatic mode, or you can use the system's diagnostic features and time series modeling tools interactively to develop forecasting models customized to best predict your time series. The system provides both graphical and statistical features to help you choose the best forecasting method for each series.

The following is a brief summary of the features of the Time Series Forecasting system. You can use the system in the following ways:

- use a wide variety of forecasting methods, including several kinds of exponential smoothing models, Winters method, and ARIMA (Box-Jenkins) models. You can also produce forecasts by combining the forecasts from several models.
- use predictor variables in forecasting models. Forecasting models can include time trend curves, regressors, intervention effects (dummy variables), adjustments you specify, and dynamic regression (transfer function) models.
- view plots of the data, predicted versus actual values, prediction errors, and forecasts with confidence limits, as well as autocorrelations and results of white noise and stationarity tests. Any of these plots can be zoomed and can represent raw or transformed series.
- use hold-out samples to select the best forecasting method
- compare goodness-of-fit measures for any two forecasting models side by side or list all models sorted by a particular fit statistic

- view the predictions and errors for each model in a spreadsheet or compare the fit of any two models in a spreadsheet
- examine the fitted parameters of each forecasting model and their statistical significance
- control the automatic model selection process: the set of forecasting models considered, the goodness-of-fit measure used to select the best model, and the time period used to fit and evaluate models
- customize the system by adding forecasting models for the automatic model selection process and for point-and-click manual selection
- save your work in a project catalog
- print an audit trail of the forecasting process
- show source statements for PROC ARIMA code
- save and print system output including spreadsheets and graphs

Using the Time Series Forecasting System

Chapters starting from Chapter 45, “[Getting Started with Time Series Forecasting](#),” through Chapter 49, “[Using Predictor Variables](#),” contain a series of example sessions that show the major features of the system. Chapters from Chapter 50, “[Command Reference](#),” through Chapter 52, “[Forecasting Process Details](#),” serve as reference and provide more details about how the system operates. The reference chapters contain a complete list of system features.

To get started using the Time Series Forecasting system, it is a good idea to work through a few of the example sessions. Start with Chapter 45, “[Getting Started with Time Series Forecasting](#),” and use the system to reproduce the steps shown in the examples. Continue with the other chapters when you feel comfortable using the system.

The example sessions make use of time series data sets contained in the SASHELP library: `air`, `citimon`, `citiqtr`, `citiyr`, `citiwk`, `citiday`, `gnp`, `retail`, `usecon`, and `workers`. You can use these data sets to work through the example sessions or to experiment further with the system.

Once you are familiar with how the system operates, start working with your own data to build your own forecasting models. When you have questions, consult the reference chapters mentioned above for more information about particular features.

The Time Series Forecasting system forecasts *time series*, that is, variables that consist of ordered observations taken at regular intervals over time. Since the Time Series Forecasting system is a part of the SAS software system, time series values must be stored as variables in a SAS data set or data view, with the observations representing the time periods. The data can also be stored in an external spreadsheet or data base if you license SAS/ACCESS software.

The Time Series Forecasting System chapters refer to *series* and *variables*. Since time series are stored as variables in SAS data sets or data views, these terms are used interchangeably. However, the term *series* is preferred when attention is focused on the sequence of data values, and the term *variable* is preferred when attention is focused on the data set.

SAS Software Products Needed

The Time Series Forecasting system is part of SAS/ETS software. To use it, you must have a license for SAS/ETS. To use the graphical display features of the system, you must also license SAS/GRAPH software.

This chapter outlines the forecasting process and introduces the major windows of the system through three example sessions.

The first example, beginning with the section “The Time Series Forecasting Window,” shows how to use the system for fully automated forecasting of a set of time series. This example also introduces the system’s features for viewing data and forecasts through tables and interactive graphs. It also shows how to save and restore forecasting work in SAS catalogs.

The second example, beginning with the section “Develop Models Window,” introduces the features for developing the best forecasting models for individual time series. The chapter concludes with an example showing how to create dating variables for your data in the form expected by the system.

After working through the examples in this chapter, you should be able to do the following:

- select a data set of time series to work with and specify its periodicity and time ID variable
- use the automatic forecasting model selection feature to create forecasting models for the variables in a data set
- produce and save forecasts of variables in a data set
- examine your data and forecasts as tables of values and through interactive graphs
- save and restore your forecasting models by using project files in a SAS catalog and edit project information
- use some of the model development features to fit and select forecasting models for individual time series variables

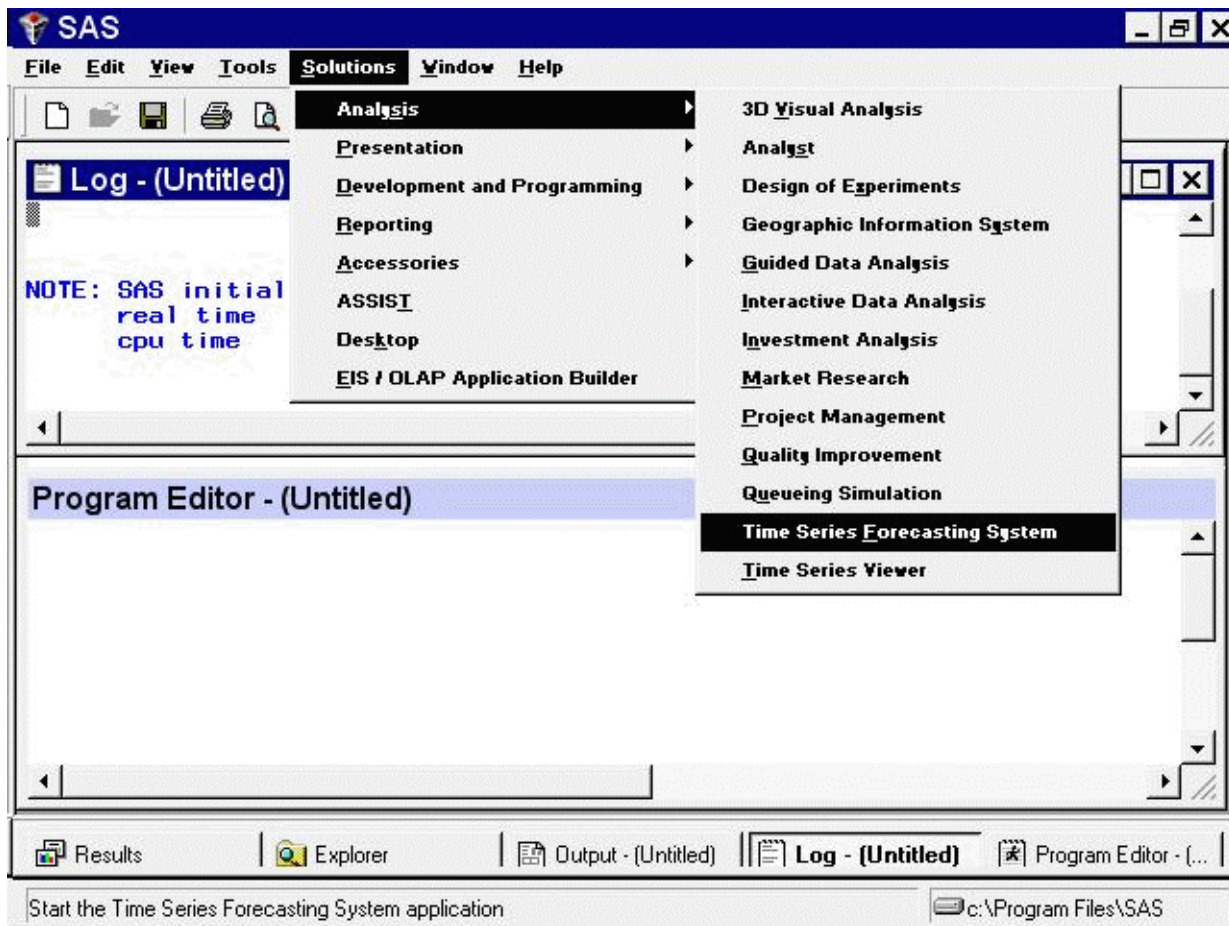

This chapter introduces these topics and helps you get started using the system. Later chapters present these topics in greater detail and document more advanced features and options.

The Time Series Forecasting Window

There are several ways to get to the Time Series Forecasting System. If you prefer to use commands, invoke the system by entering `forecast` on the command line. You can optionally specify additional information on the command line; see Chapter 50, “[Command Reference](#),” for details.

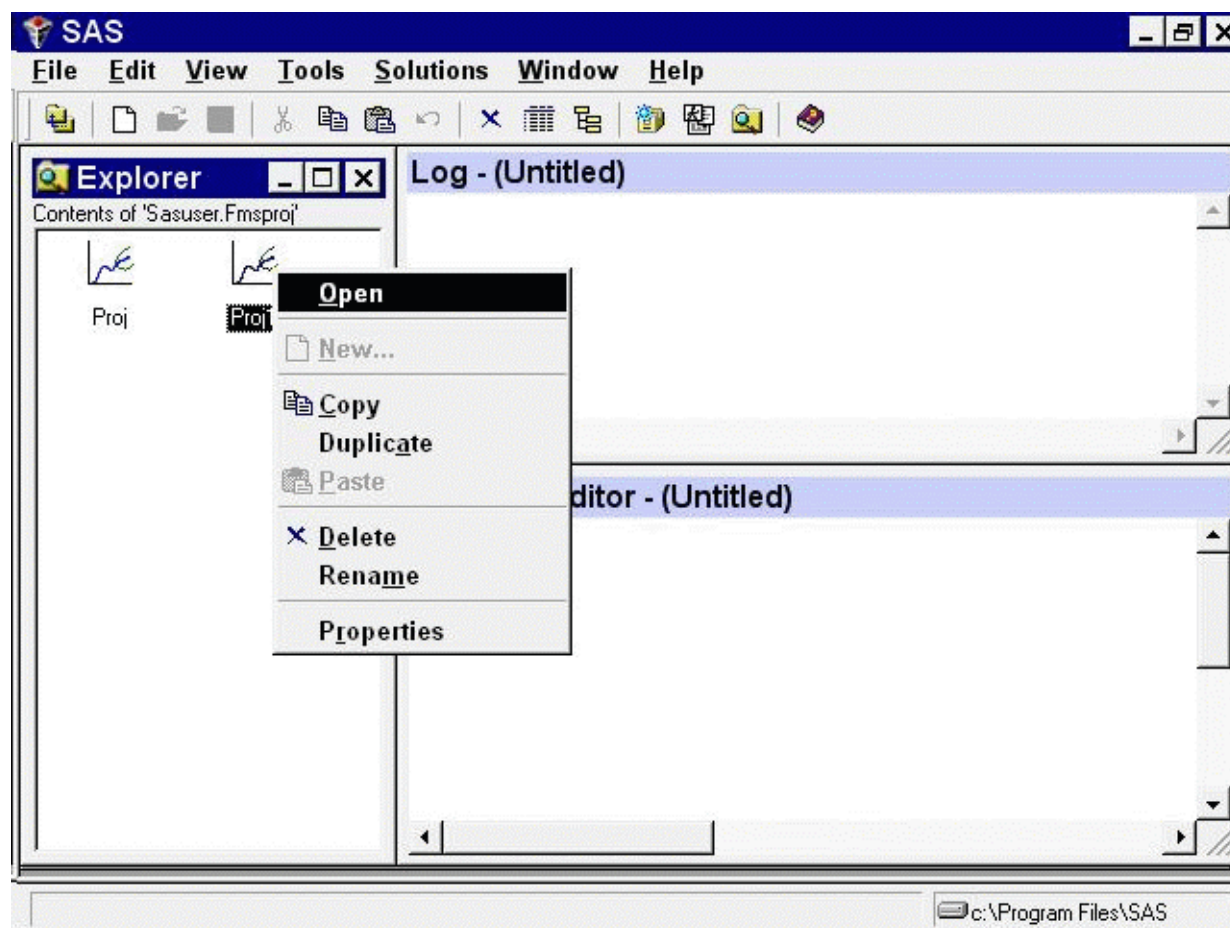

If you are using the SAS windowing environment with pull-down menus, select the Solutions menu from the menu bar, select the Analysis item, and then select `Time Series Forecasting System`, as shown in [Figure 45.1](#).

Figure 45.1 Time Series Forecasting System Menu Selection

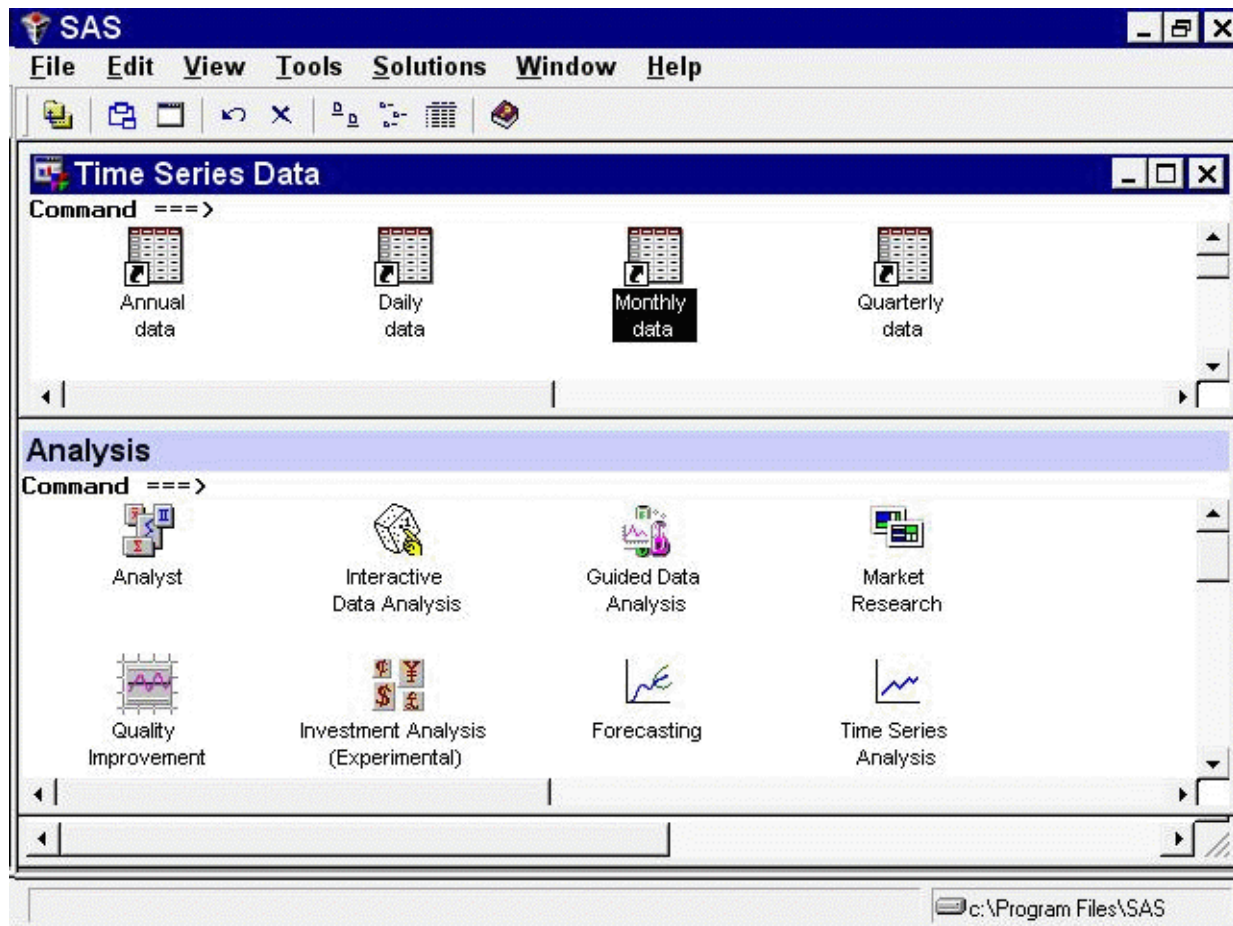

You can invoke the Forecasting System from the SAS Explorer window by opening an existing forecasting project. By default these projects are stored in the FMSPROJ catalog in the SASUSER library. Select SASUSER in the Explorer to display its contents. Then select FMSPROJ. This catalog is created the first time you use the Forecasting System. If you have saved projects, they appear in the Explorer with the forecasting graph icon, as shown in Figure 45.2. Double-click one of the projects, or select it with the right mouse button and then select Open from the pop-up menu, as shown in the figure. This opens the Forecasting System and opens the selected project.

Figure 45.2 Opening a Project from the Explorer

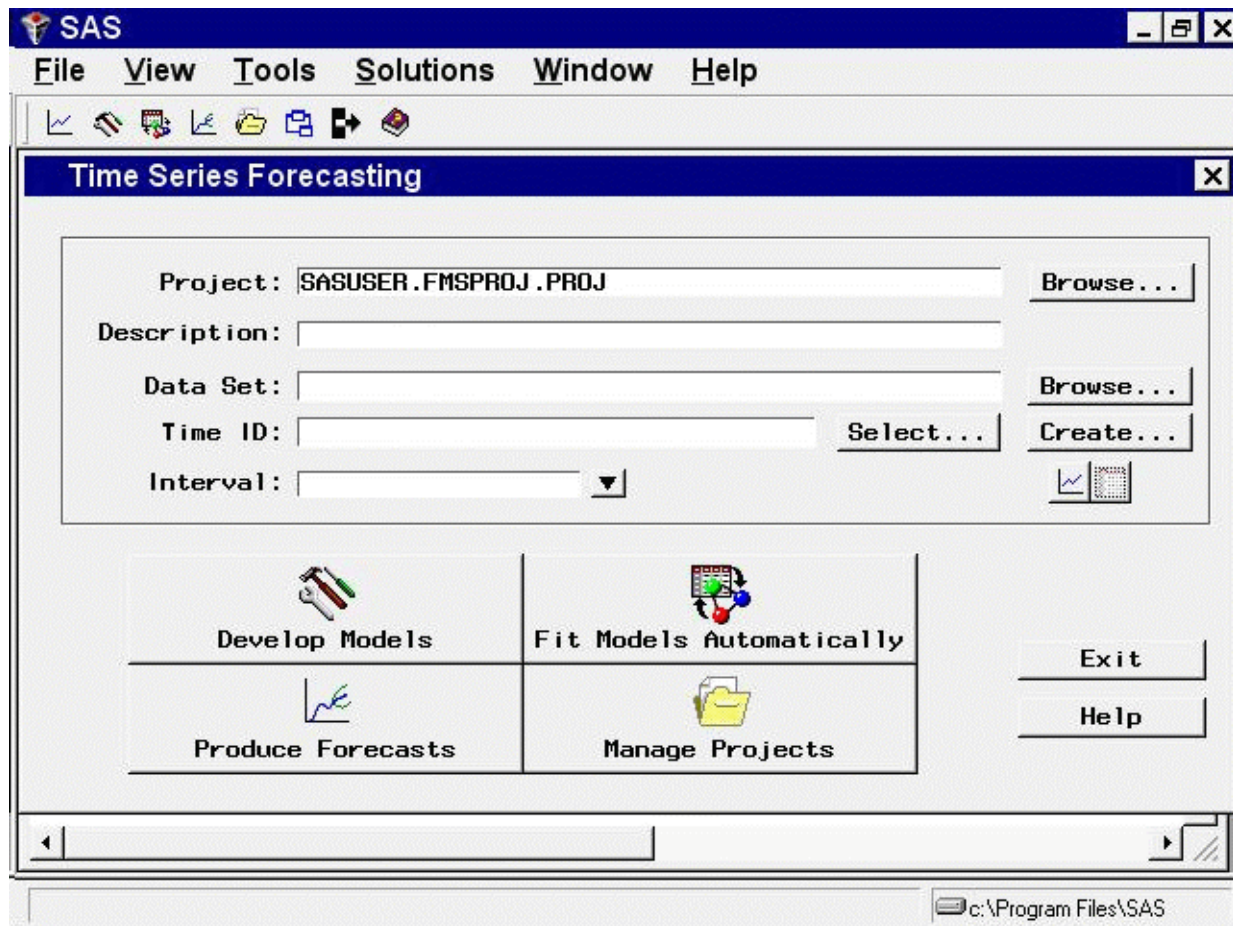

To invoke the Forecasting System in the SAS desktop environment, select the **Solutions** menu from the menu bar, select **Desktop**, and then open the **Analysis** folder. You can run the Time Series Forecasting System or the Time Series Viewer directly, or you can drag and drop. Figure 45.3 illustrates dragging a data set (known as a table in the Desktop environment) and dropping it on the Forecasting icon. In this example, the tables reside in a user-defined folder called *Time Series Data*.

Figure 45.3 Drag and Drop on the SAS Desktop

If you are using SAS/ASSIST software, select the Planning button and then select `Forecasting` from the pop-up menu.

Any of these methods takes you to the Time Series Forecasting window, as shown in [Figure 45.4](#).

Figure 45.4 Time Series Forecasting Window

At the top of the window is a data selection area for specifying a project file and the input data set containing historical data (the known past values) for the time series variables that you want to forecast. This area also contains buttons for opening viewers to explore your input data either graphically, one series at a time, or as a table, one data set at a time.

The Project and Description fields are used to specify a project file for saving and restoring forecasting models created by the system. Using project files is discussed later, and these fields are ignored for now.

The lower part of the window contains six buttons:

Develop Models

opens the Develop Models window, which you use to develop and fit forecasting models interactively for individual time series.

Fit Models Automatically

opens the Automatic Model Fitting window, which you use to search automatically for the best forecasting model for multiple series in the input data set.

Produce Forecasts

opens the Produce Forecasts window, which you use to compute forecasts for all the variables in the input data set for which forecasting models have been fit.

Manage Projects

opens the Manage Forecasting Project window, which lists the time series for which you have fit forecasting models. You can drill down on a series to see the models that have been fit. You can delete series or models from the project, re-evaluate or refit models, and explore models and forecasts graphically or in tabular form.

Exit

exits the Forecasting System.

Help

displays information about the Forecasting System.

Outline of the Forecasting Process

The examples shown in the following sections illustrate the basic process you use with the Forecasting System.

Specify the Input Data Set

Suppose you have a number of *time series*, variables recorded over time, for which you want to forecast future values. The past values of these time series are stored as variables in a SAS data set or data view. The observations of this data set correspond to regular time periods, such as days, weeks, or months. The first step in the forecasting process is to tell the system to use this data set by setting the Data Set field.

If your time series are not in a SAS data set, you must provide a way for the SAS System to access the data. You can use SAS features to read your data into a SAS data set; refer to *SAS Language Reference*. You can use a SAS/ACCESS product to establish a view of data in a database management system; refer to SAS/ACCESS documentation. You can use PROC SQL to create a SAS data view. You can use PROC DATASOURCE to read data from files supplied by supported data vendors; refer to Chapter 12, “[The DATASOURCE Procedure](#),” for more details.

Provide a Valid Time ID Variable

To use the Forecasting System, your data set must be dated: the data set must contain a *time ID variable* that gives the date of each observation. The time ID variable must represent the observation dates with *SAS date values* or with *SAS datetime values* (for hourly data or other frequencies less than a day), or you can use a simple time index.

When SAS date values are used, the ID variable contains dates within the time periods corresponding to the observations. For example, for monthly data, the values for the time ID variable can be the date of the first day of the month corresponding to each observation, or the time ID variable can contain the date of the last day in the month. (Any date within the period serves as the time ID for the observation.)

If your data set already contains a valid time ID variable with SAS date or datetime values, the next step is to specify this time ID variable in the Time ID field. If the time ID variable is named DATE, the system fills in the Time ID field automatically.

If your data set does not contain a time ID, you must add a valid time ID variable before beginning the forecasting process. The Forecasting System provides features that make this easy to do. See Chapter 46, “Creating Time ID Variables,” for details.

Select and Fit a Forecasting Model for Each Series

If you are using the automated model selection feature, the system performs this step for you and chooses a forecasting model for each series automatically. All you need to do is select the Fit Models Automatically button and then select the variables to fit models for.

If you want more control over forecasting model selection, you can select the Develop Models button, select the series you want to forecast, and use the Develop Models window to specify a forecasting model. As part of this process, you can use the Time Series Viewer and Model Viewer graphical tools. Once you have selected a model for the first series, you can select a different series to work with and repeat the model development process until you have created forecasting models for all the series you want to forecast.

The system provides many features to help you choose the best forecasting model for each series. The features of the Develop Models window and graphical viewer tools are introduced in later sections.

Produce the Forecasts

Once a forecasting model has been fit for each series, select the Produce Forecasts button and use the Produce Forecasts window to compute forecast values and store them in a SAS data set.

Save Your Work

If you want only a single forecast, your task is now complete. But you might want to produce updated forecasts later, as more data becomes available. In this case, you want to save the forecasting models you have created, so that you do not need to repeat the model selection and fitting process.

To save your work, fill in the Project field with the name of a SAS catalog member in which the system will store the model information when you exit the system. Later, you will select the same catalog member name when you first enter the Forecasting System, and the model information will be reloaded.

Note that any number of people can work with the same project file. If you are working on a forecasting project as part of a team, you should take care to avoid conflicting updates to the project file by different team members.

Summary

This is the basic outline of how the Forecasting System works. The system offers many other features and options that you might need to use (for example, the time range of the data used to fit models and how far into the future to forecast). These options will become apparent as you work with the Forecasting System.

As an introductory example, the following sections use the Automatic Model Fitting and Produce Forecasts windows to perform automated forecasting of the series in an example data set.

The Input Data Set

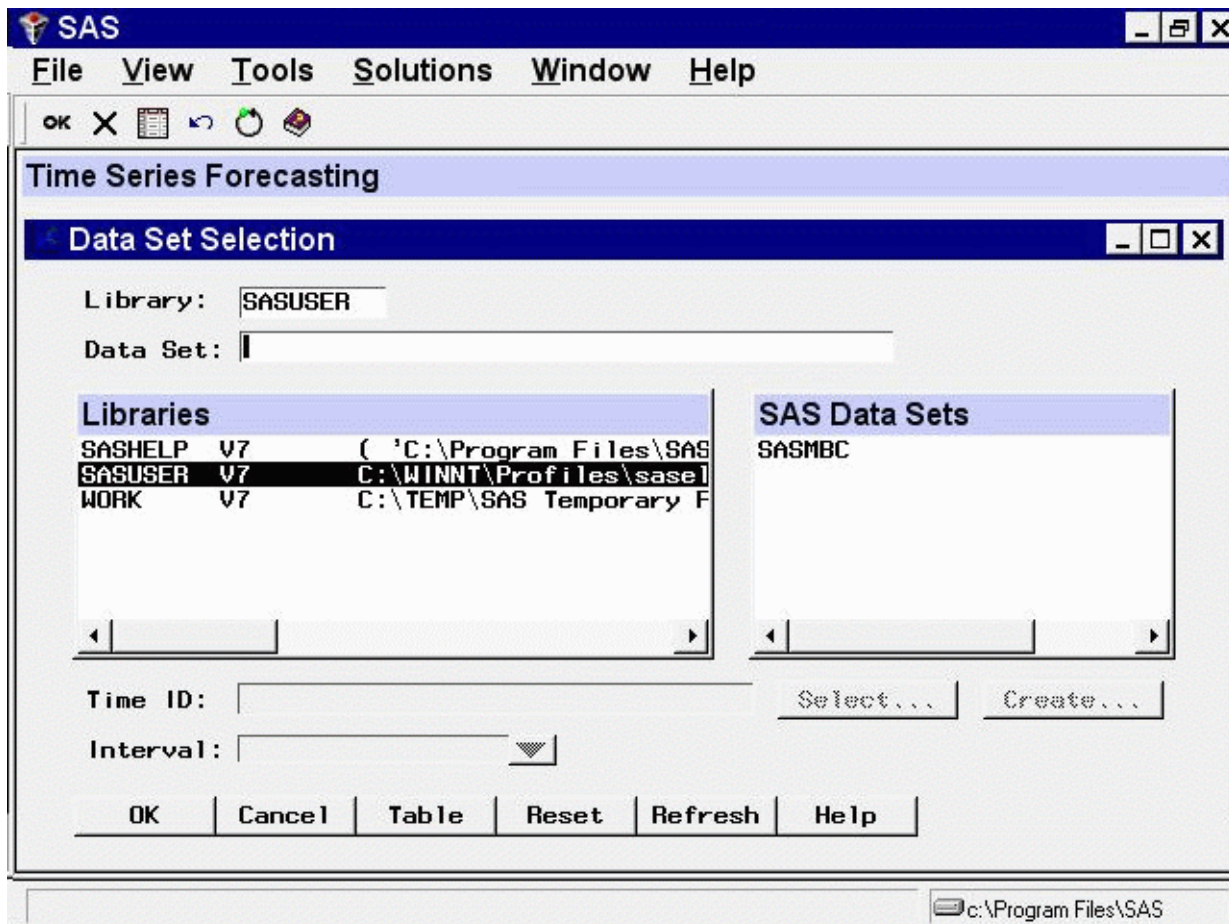

As the first step, you must specify the input data set.

The Data Set field in the Time Series Forecasting window gives the name of the input data set containing the time series to forecast. Initially, this field is blank. You can specify the input data set by typing the data set name in this field. Alternatively, you can select the Browse button at the right of the Data Set field to select the data set from a list, as shown in the following section.

The Data Set Selection Window

Select the Browse button to the right of the Data Set field. This opens the Data Set Selection window, as shown in Figure 45.5.

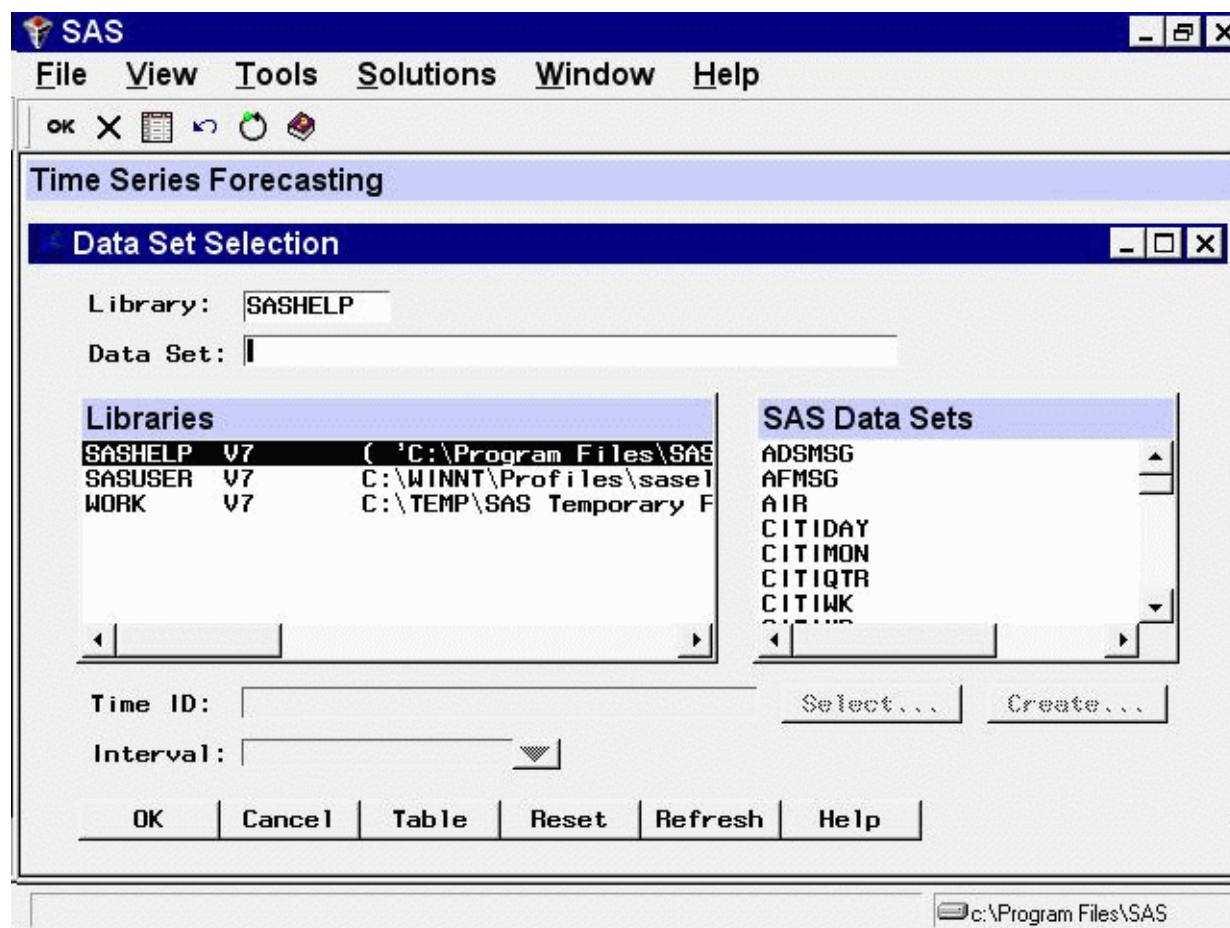

Figure 45.5 Data Set Selection Window

The `Libraries` list shows the SAS librefs that are currently allocated in your SAS session. Initially, the `SASUSER` library is selected, and the `SAS Data Sets` list shows the data sets available in your `SASUSER` library.

In the **Libraries** list, select the row that starts with SASHELP. The Data Set Selection window now lists the data sets in the SASHELP library, as shown in Figure 45.6.

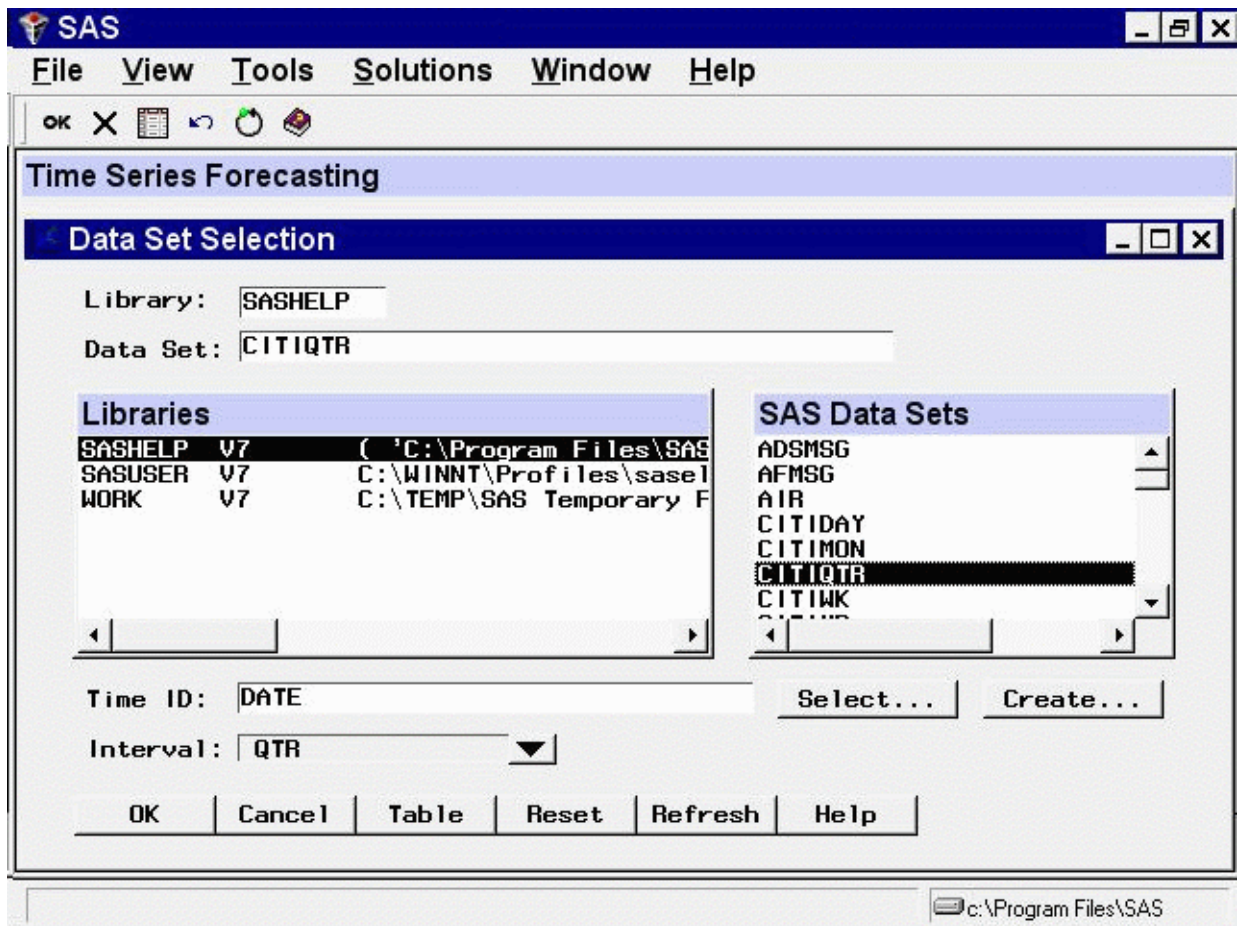

Figure 45.6 SASHELP Library

Use the vertical scroll bar on the SAS Data Sets list to scroll down the list until the data set CITIQTR appears. Then select the CITIQTR row. This selects the data set SASHELP.CITIQTR as the input data set.

Figure 45.7 shows the Data Set Selection window after selection of CITIQTR from the SAS Data Sets list.

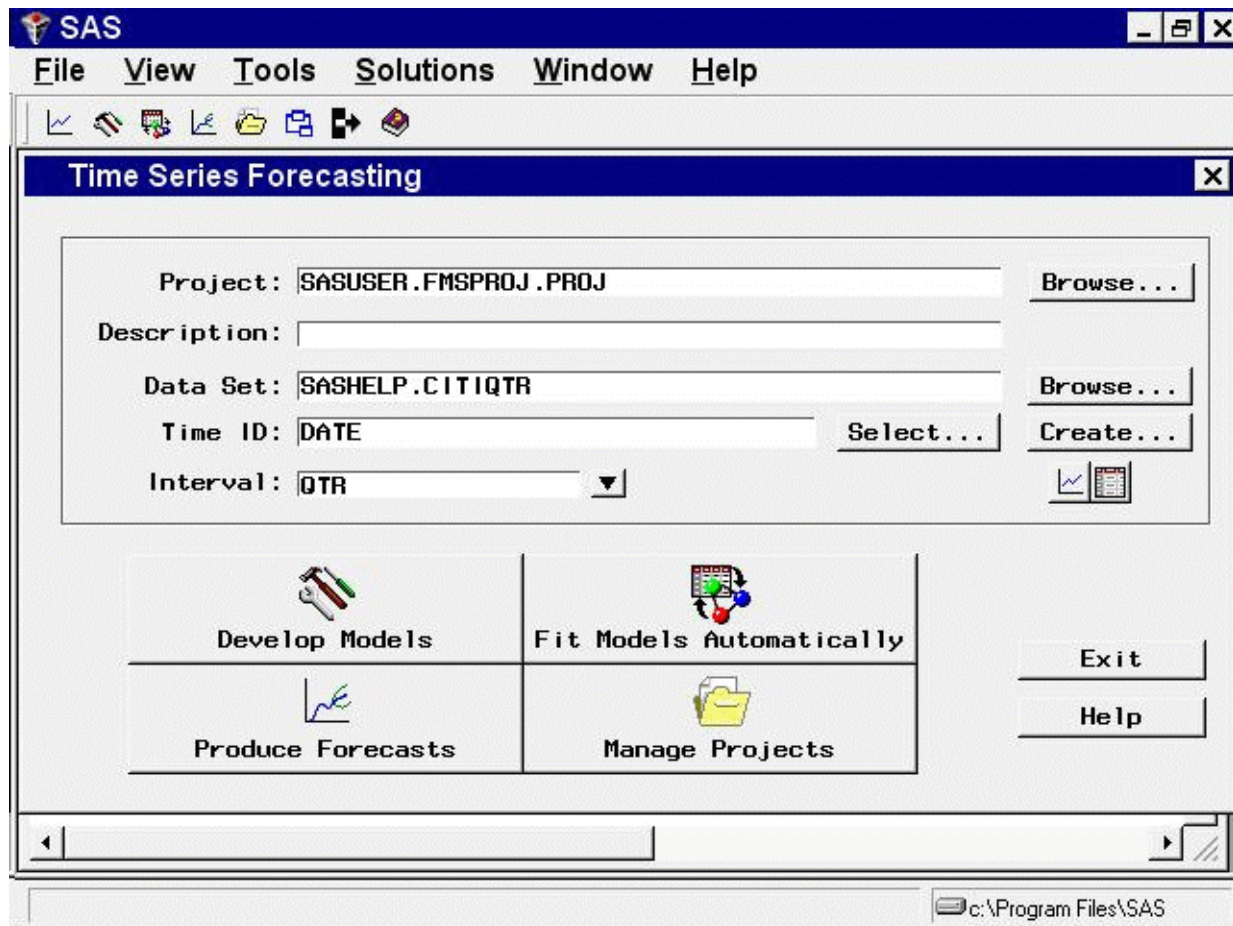

Figure 45.7 CITIQTR Data Set Selected

Note that the Time ID field is now set to DATE and the Interval field is set to QTR. These fields are explained in the following section.

Now select the OK button to complete selection of the CITIQTR data set. This closes the Data Set Selection window and returns to the Time Series Forecasting window, as shown in Figure 45.8.

Figure 45.8 Time Series Forecasting Window

Time Series Data Sets, ID Variables, and Time Intervals

Before you continue with the example, it is worthwhile to consider how the system determined the values for the Time ID and Interval fields in the Data Set Selection window.

The Forecasting System requires that the input data set contain time series observations, with one observation for each time period. The observations must be sorted in increasing time order, and there must be no gaps in the sequence of observations. The time period of each observation must be identified by an ID variable, which is shown in the Time ID field.

If the data set contains a variable named DATE, TIME, or DATETIME, the system assumes that this variable is the SAS date or datetime valued ID variable, and the Time ID field is filled in automatically. The time ID variable for the SASHELP.CITIQTR data set is named DATE, and therefore the system set the Time ID field to DATE.

If the time ID variable for a data set is not named DATE, TIME, or DATETIME, you must specify the time ID variable name. You can specify the time ID variable either by typing the ID variable name in the Time ID field or by clicking the Select button.

If your data set does not contain a time ID variable with SAS date values, you can add a time ID variable using one of the windows described in Chapter 46, “[Creating Time ID Variables](#).”

Once the time ID variable is known, the Forecasting System examines the ID values to determine the time interval between observations. The data set SASHELP.CITIQTR contains quarterly observations. Therefore, the system determined that the data have a quarterly interval, and set the Interval field to QTR.

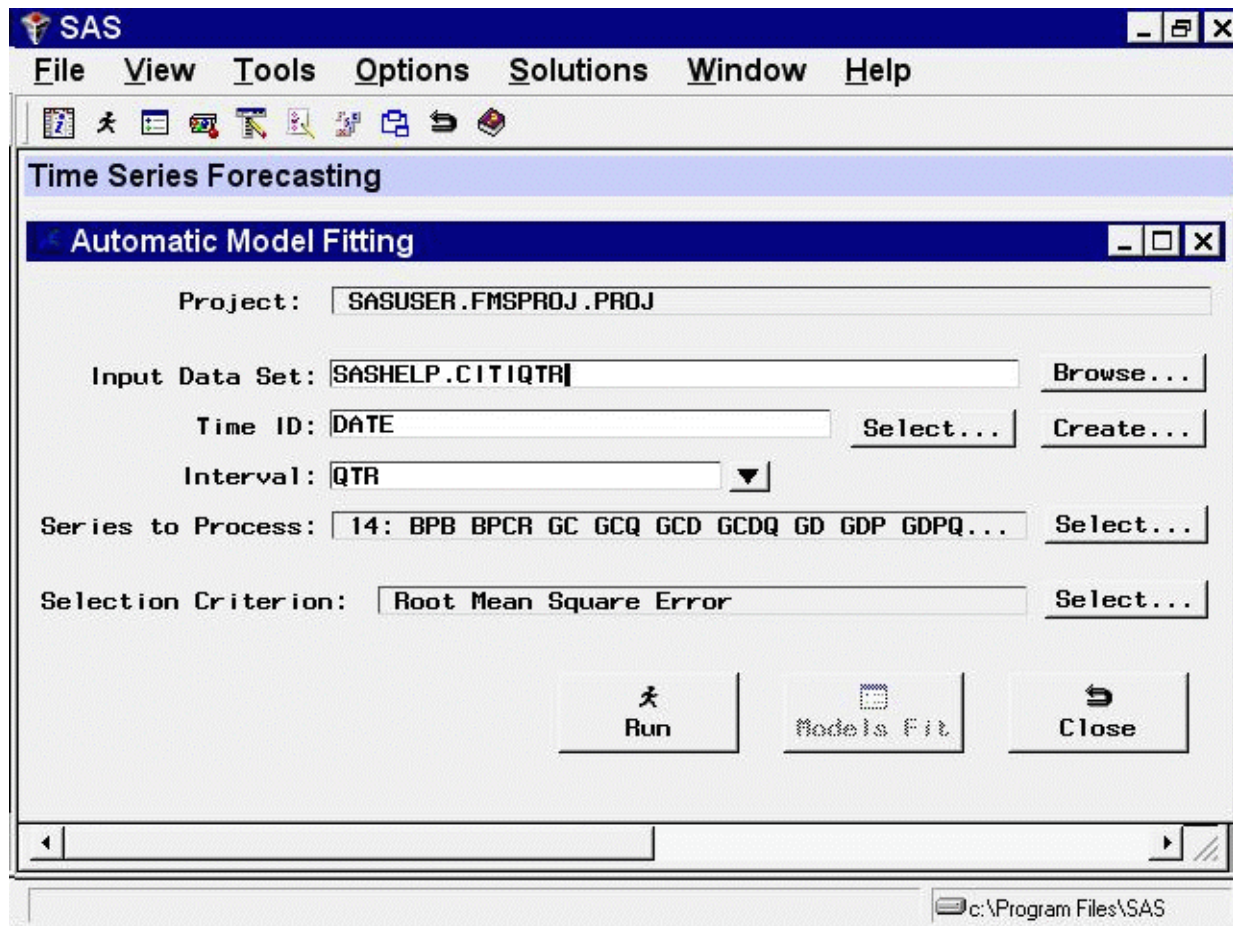

If the system cannot determine the data frequency from the values of the time ID variable, you must specify the time interval between observations. You can specify the time interval by using the `Interval` combo box. In addition to the interval names provided in the pop-up list, you can type in more complex interval names to specify an interval that is a multiple of other intervals or that has date values in the middle of the interval (such as monthly data with time ID values falling on the 10th day of the month).

See Chapter 3, “[Working with Time Series Data](#),” and Chapter 4, “[Date Intervals, Formats, and Functions](#),” for more information about time intervals, SAS date values, and ID variables for time series data sets.

Automatic Model Fitting Window

Before you can produce forecasts, you must fit forecasting models to the time series. Select the Fit Models Automatically button. This opens the Automatic Model Fitting window, as shown in [Figure 45.9](#).

Figure 45.9 Automatic Model Fitting Window

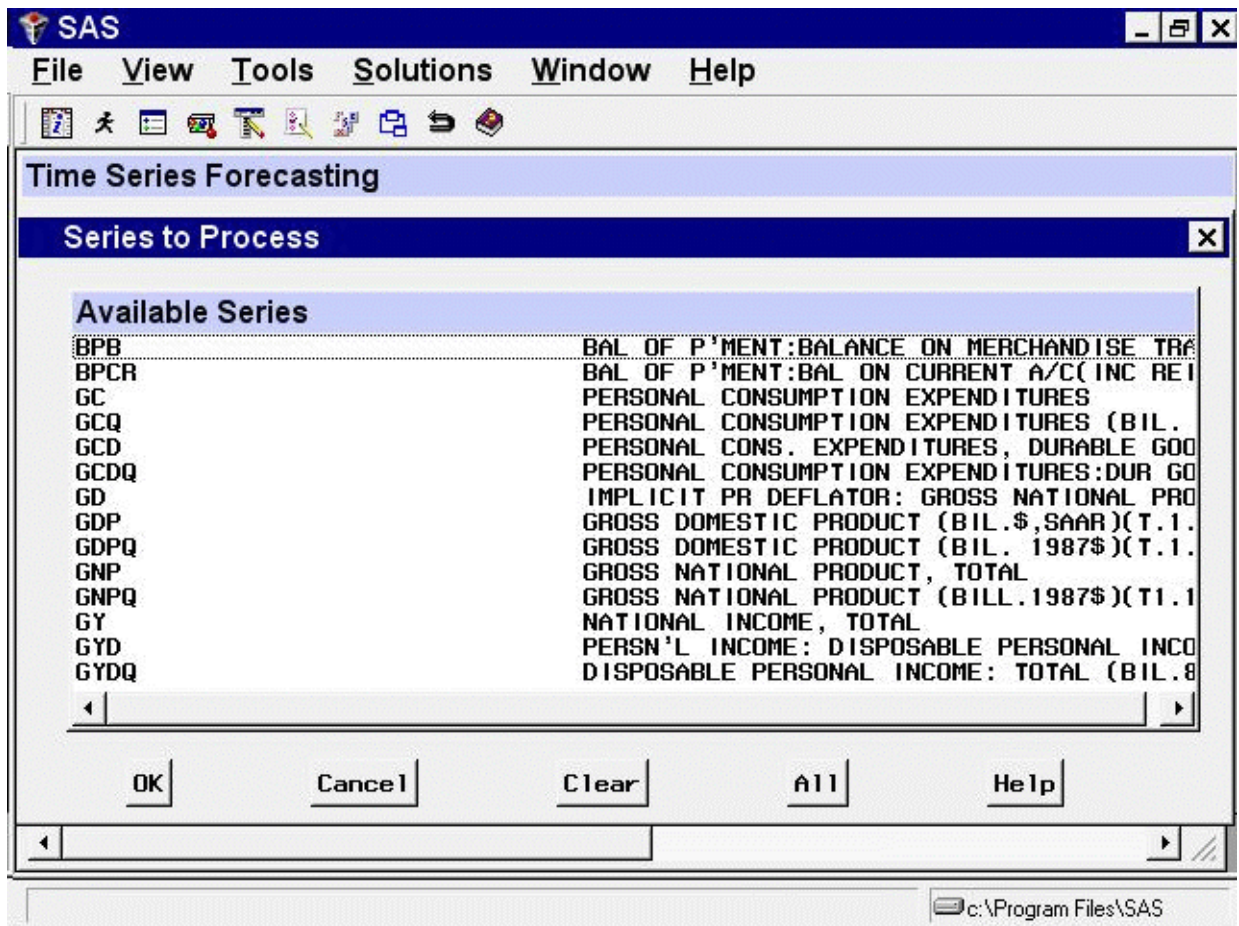

The first part of the Automatic Model Fitting window confirms the project filename and the input data set name.

The Series to Process field shows the number and lists the names of the variables in the input data set to which the Automatic Model Fitting process will be applied. By default, all numeric variables (except the time ID variable) are processed. However, you can specify that models be generated for only a select subset of these variables.

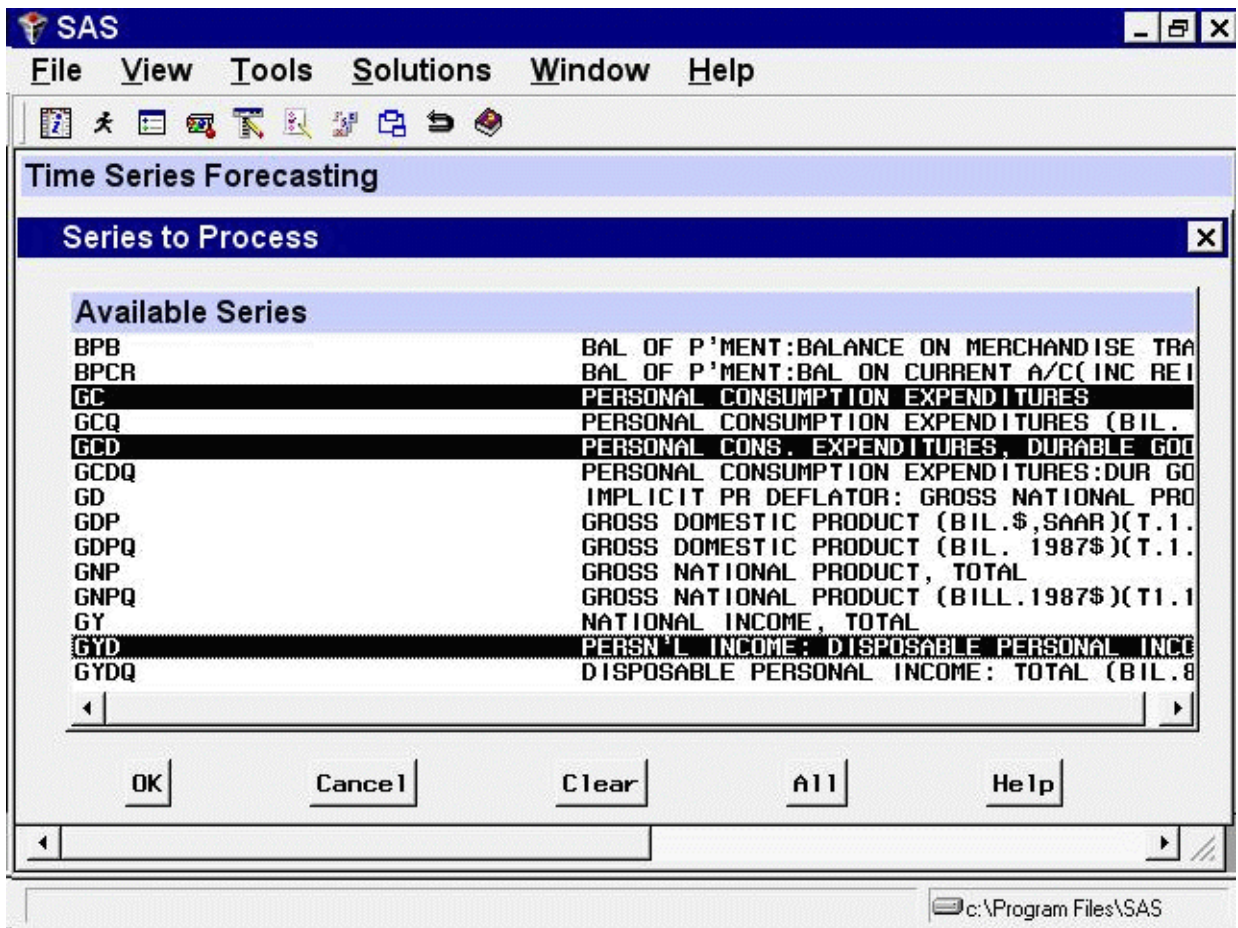

Click the Select button to the right of the Series to Process field. This opens the Series to Process window, as shown in [Figure 45.10](#).

Figure 45.10 Series to Process Window

Use the mouse and the CTRL key to select the personal consumption expenditures series (GC), the personal consumption expenditures for durable goods series (GCD), and the disposable personal income series (GYD), as shown in Figure 45.11. (Remember to hold down the CTRL key as you make the selections; otherwise, selecting a second series will deselect the first.)

Figure 45.11 Selecting Series for Automatic Model Fitting

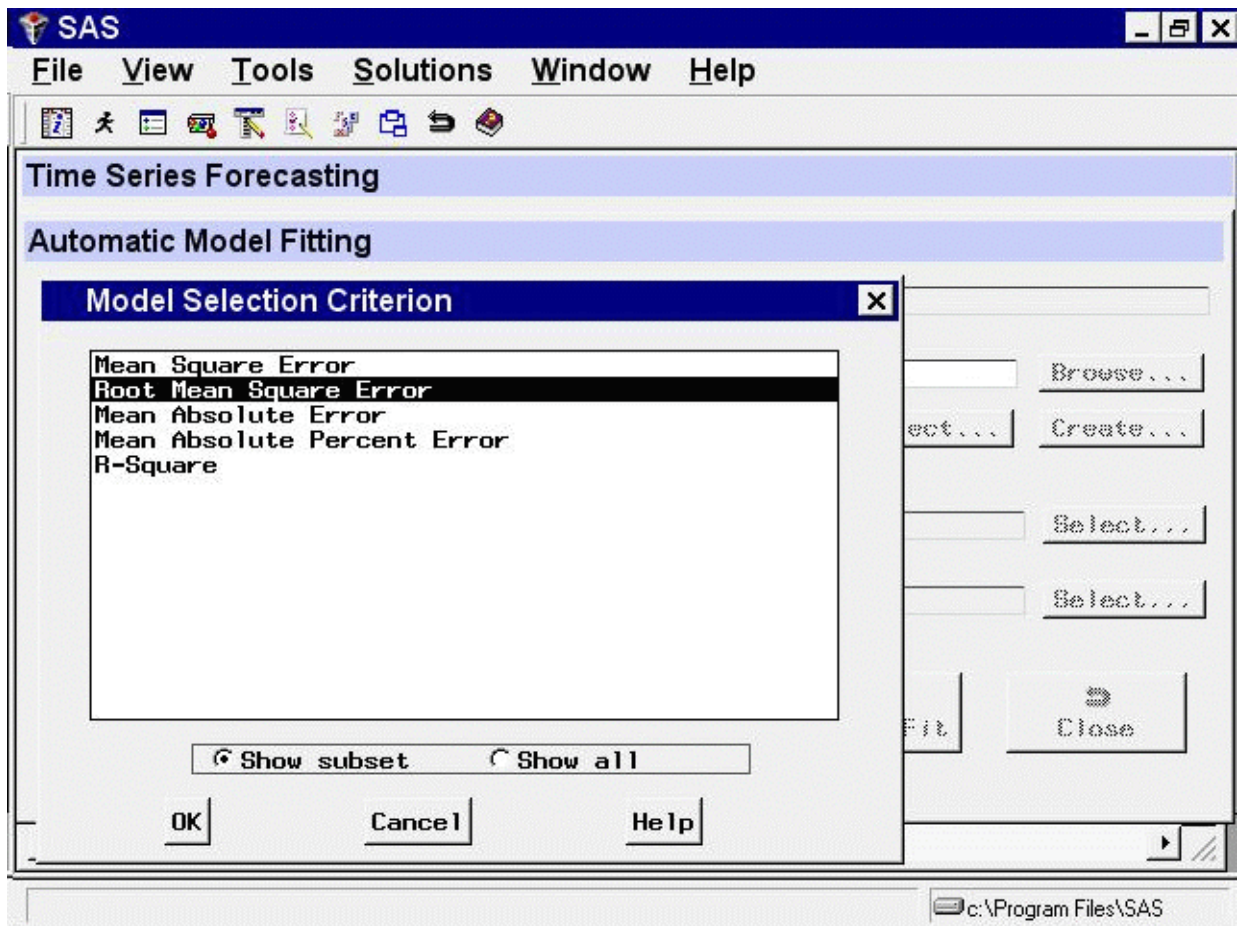

Now select the OK button. This returns you to the Automatic Model Fitting window. The Series to Process field now shows the selected variables.

The Selection Criterion field shows the goodness-of-fit measure that the Forecasting System will use to select the best fitting model for each series. By default, the selection criterion is the root mean squared error. To illustrate how you can control the selection criterion, this example uses the mean absolute percent error to select the best fitting models.

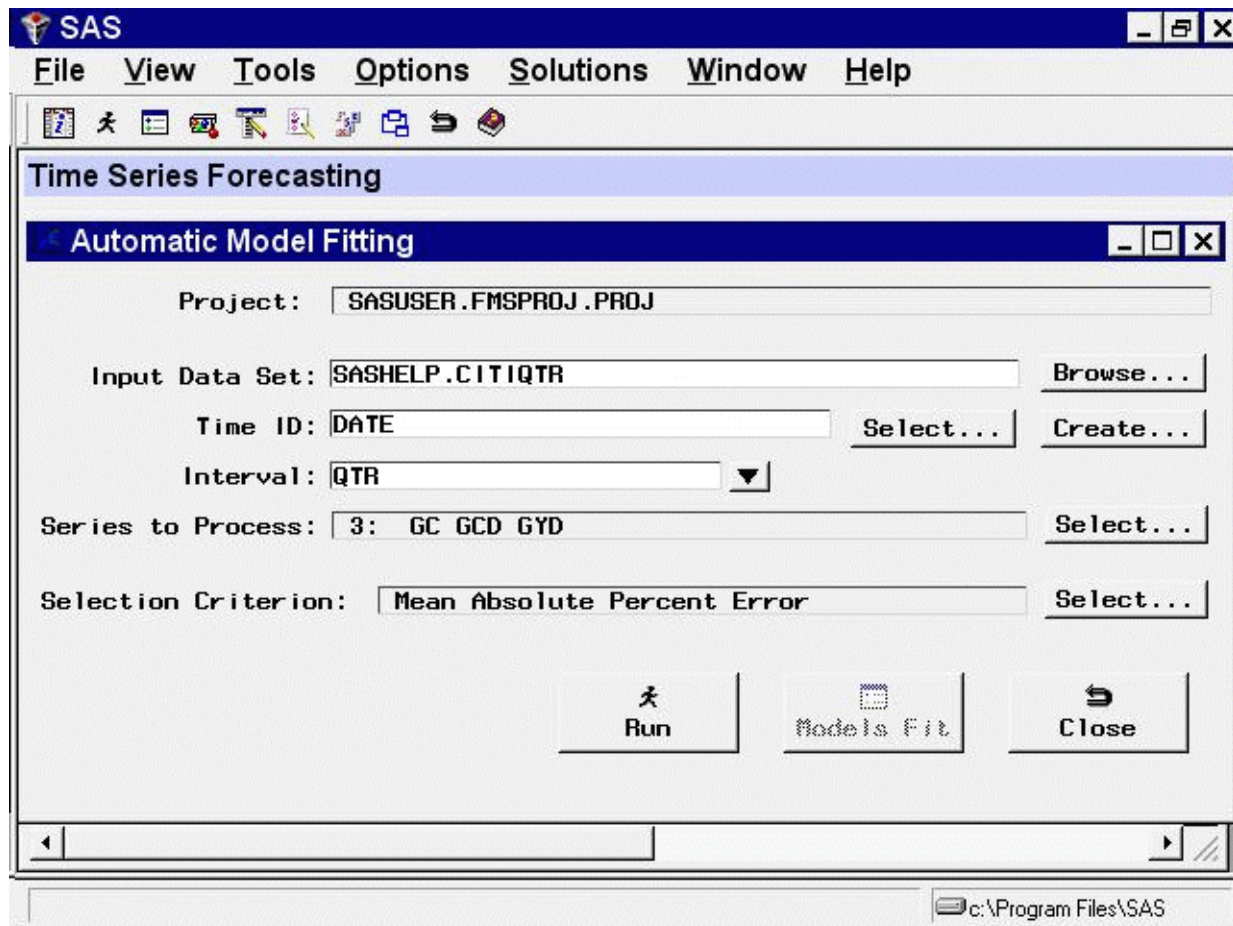

Click the Select button to the right of the Selection Criterion field. This opens a list of statistics of fit, as shown in [Figure 45.12](#).

Figure 45.12 Choosing the Model Selection Criterion

Select *Mean Absolute Percent Error* and then select the OK button. The Automatic Model Fitting window now appears as shown in [Figure 45.13](#).

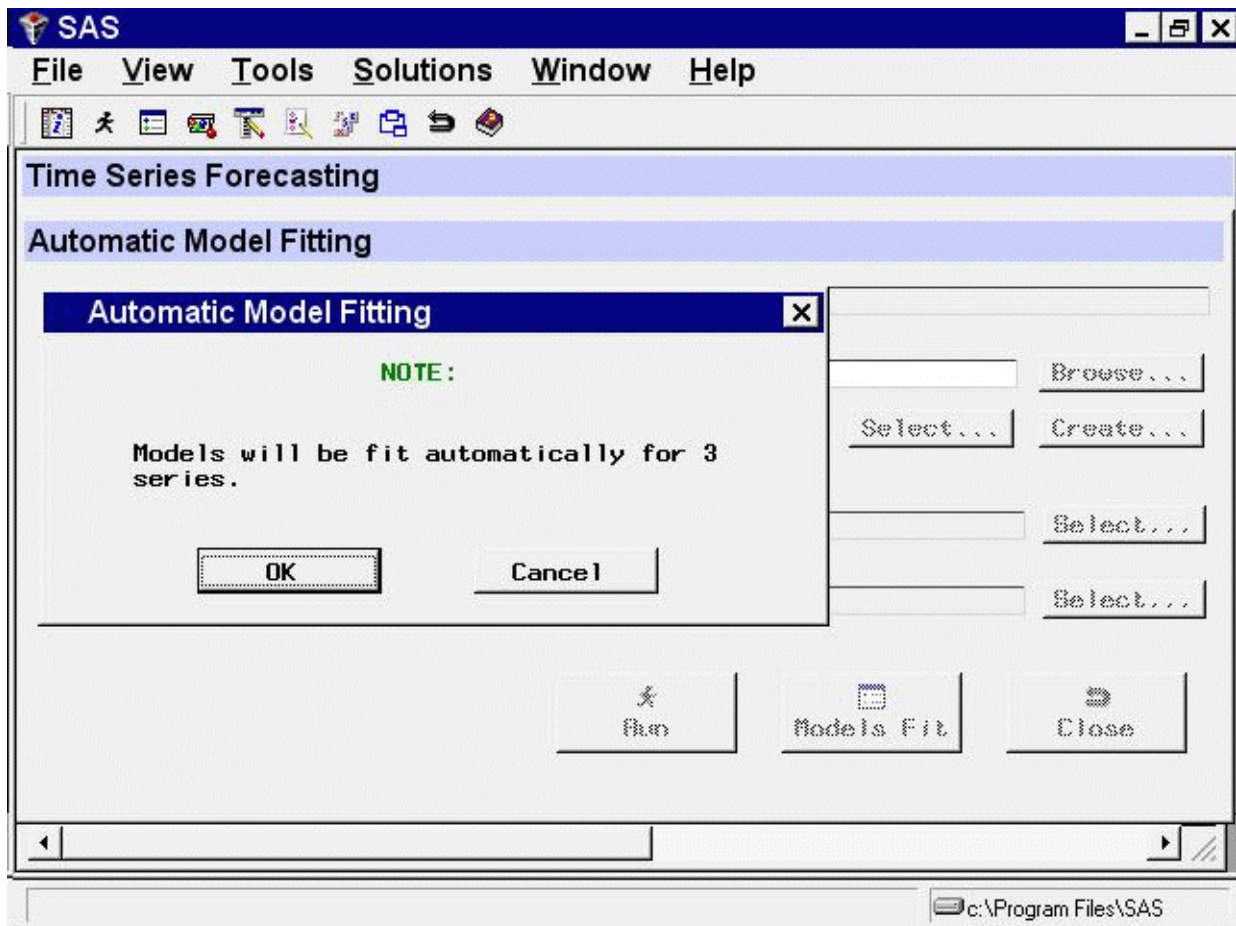

Figure 45.13 Automatic Model Fitting Window

Now that all the options are set appropriately, select the Run button.

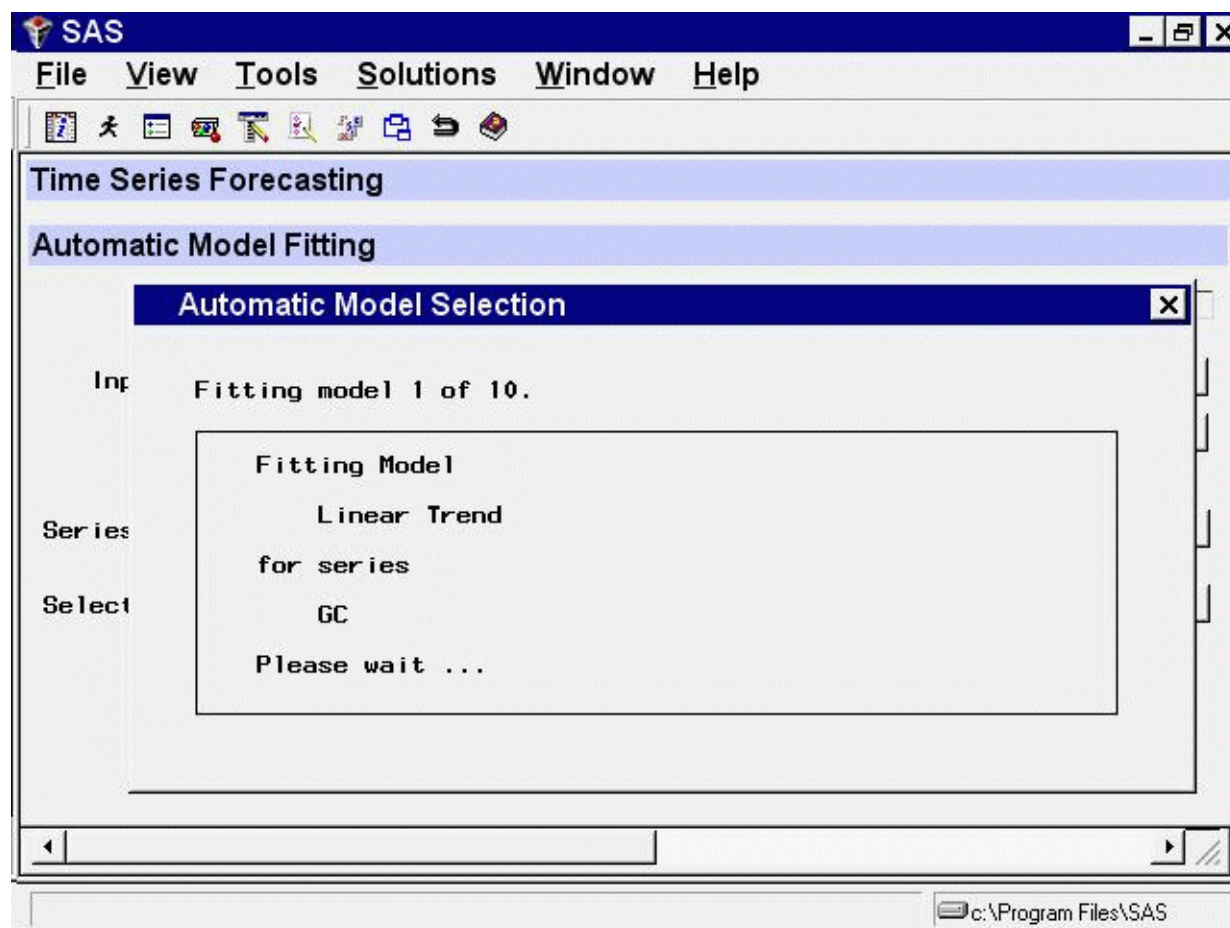

The Forecasting System now displays a notice, shown in [Figure 45.14](#), confirming that models will be fit for three series using the automatic forecasting model search feature. This prompt is displayed because it is possible to fit models for a large number of series at once, which might take a lot of time. So the system gives you a chance to cancel if you accidentally ask to fit models for more series than you intended. Select the OK button.

Figure 45.14 Automatic Model Fitting Note

The system now fits several forecasting models to each of the three series you selected. While the models are being fit, the Forecasting System displays notices indicating what it is doing so that you can observe its progress, as shown in [Figure 45.15](#).

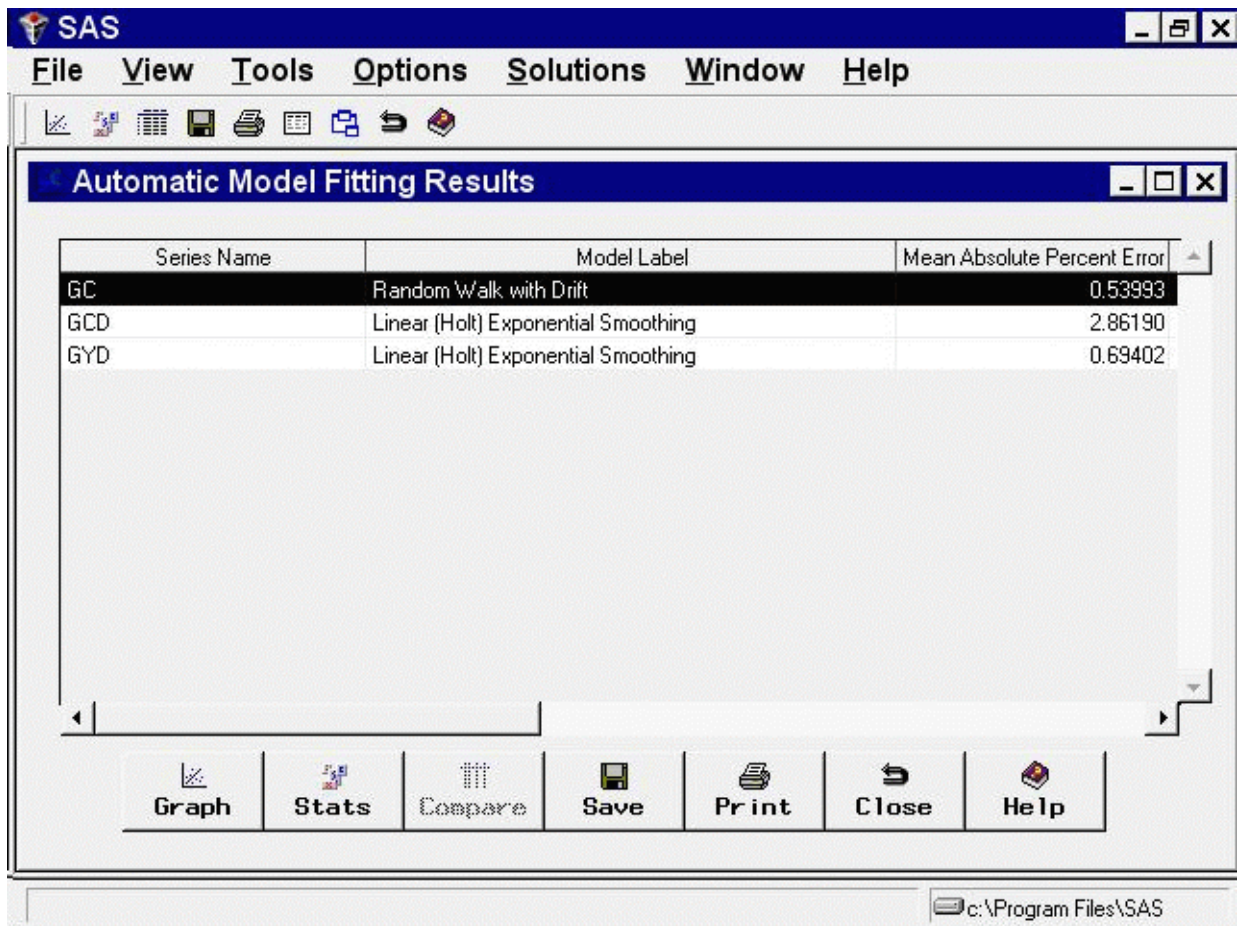

Figure 45.15 “Working” Notice

For each series, the system saves the model that produces the smallest mean absolute percent error. You can have the system save all the models fit by selecting *Automatic Fit* from the Options menu.

After the Automatic Model Fitting process has completed, the results are displayed in the Automatic Model Fitting Results window, as shown in [Figure 45.16](#).

Figure 45.16 Automatic Model Fitting Results

This resizable window shows the list of series names and descriptive labels for the forecasting models chosen for them, as well as the values of the model selection criterion and other statistics of fit. Select the Close button.

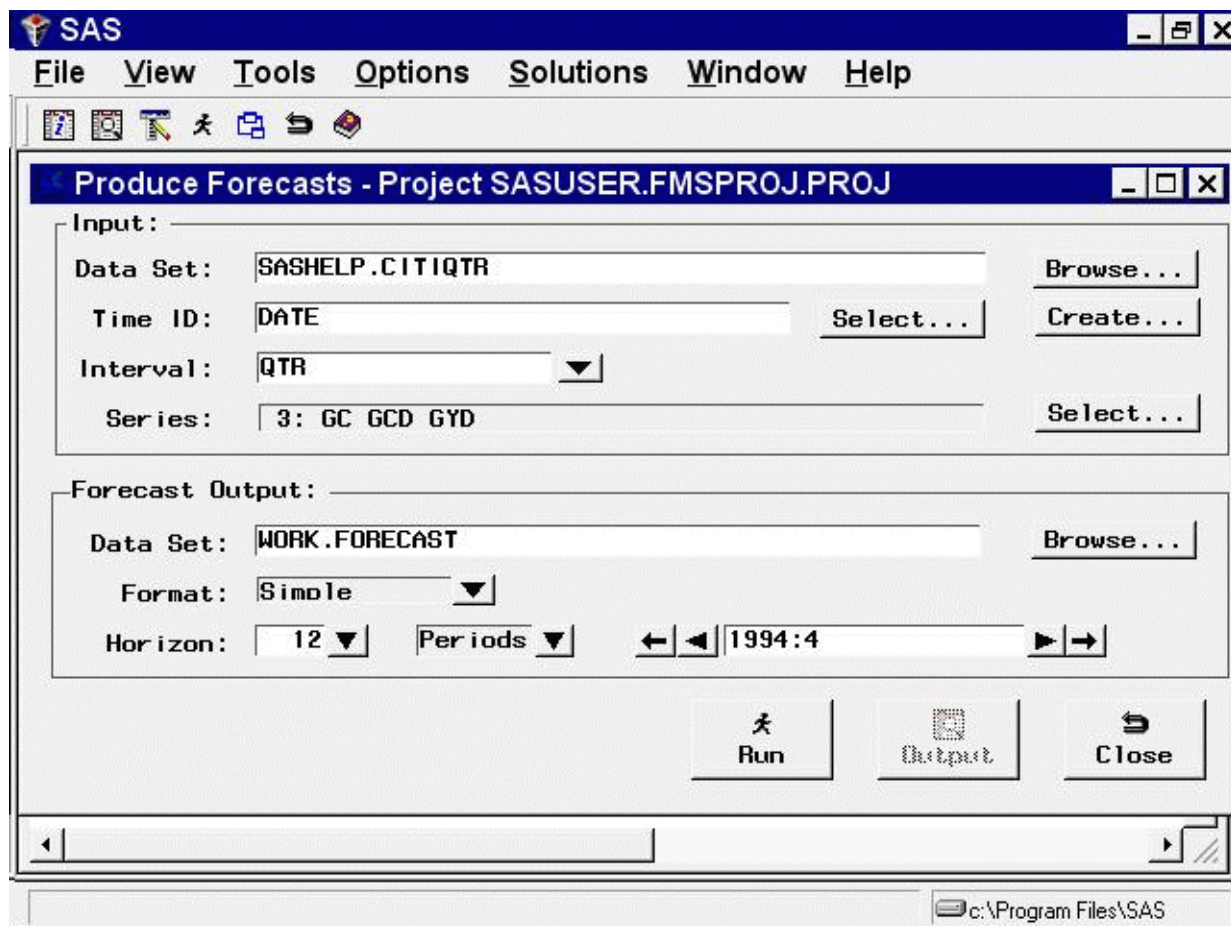

This returns you to the Automatic Model Fitting window. You can now fit models for other series in this data set or change to a different data set and fit models for series in the new data set.

Select the Close button to return to the Time Series Forecasting window.

Produce Forecasts Window

Now that you have forecasting models for these three series, you are ready to produce forecasts. Select the Produce Forecasts button. This opens the Produce Forecasts window, as shown in Figure 45.17.

Figure 45.17 Produce Forecasts Window

The Produce Forecasts window shows the input data set information and indicates the variables in the input data set for which forecasting models exist. Forecasts will be produced for these series. If you want to produce forecasts for only some of these series, use the Select button at the right of the Series field to select the series to forecast. The Data Set field in the Forecast Output box contains the name of the SAS data set in which the system will store the forecasts. The default output data set is WORK.FORECAST.

You can set the forecast horizon by using the controls on the line labeled Horizon. The default horizon is 12 periods. You can change it by specifying the number of periods, number of years, or the date of the last forecast period. Position the cursor in the date field and change the forecast ending date to 1 January 1996 by typing `jan1996` and pressing the ENTER key.

The window now appears as shown in Figure 45.18.

Figure 45.18 Produce Forecasts Window

SAS

File View Tools Options Solutions Window Help

Produce Forecasts - Project SASUSER.FMSPROJ.PROJ

Input:

Data Set: SASHELP.CITIQTR Browse...

Time ID: DATE Select... Create...

Interval: QTR

Series: 3: GC GCD GYD Select...

Forecast Output:

Data Set: WORK.FORECAST Browse...

Format: Simple

Horizon: 17 Periods 1996:1

Run Output Close

c:\Program Files\SAS

Now select the Run button to produce the forecasts. The system indicates that the forecasts have been stored in the output data set. Select OK to dismiss the notice.

The Forecast Data Set

The Forecasting System can save the forecasts to a SAS data set in three different formats. Depending on your needs, you might find one of these output formats more convenient. The output data set format is controlled by the `Format` combo box. You can select the following output formats. The simple format is the default.

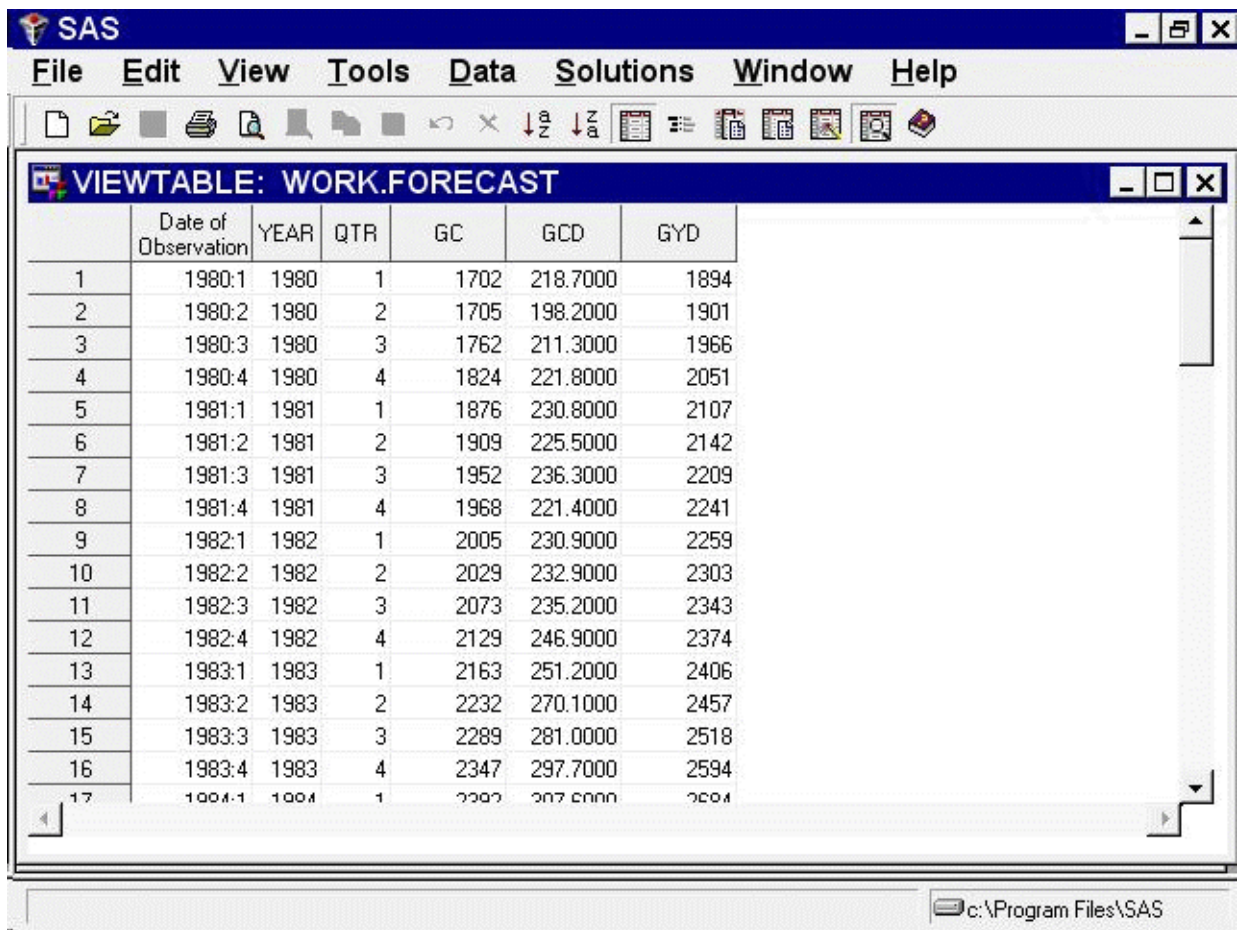

Simple	The data set contains time ID variables and the forecast variables, and it contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.
Interleaved	The data set contains time ID variables, the variable <code>TYPE</code> , and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the <code>TYPE</code> variable.

Concatenated The data set contains the variable **SERIES**, time ID variables, and the variables **ACTUAL**, **PREDICT**, **ERROR**, **UPPER**, **LOWER**, and **STD**. There is one observation per time period per forecast series. The variable **SERIES** contains the name of the forecast series, and the data set is sorted by **SERIES** and **DATE**.

Simple Format Forecast Data Set

To see the simple format forecast data set that the system created, select the **Output** button. This opens a **VIEWTABLE** window to display the data set, as shown in [Figure 45.19](#).

Figure 45.19 Forecast Data Set—Simple Format

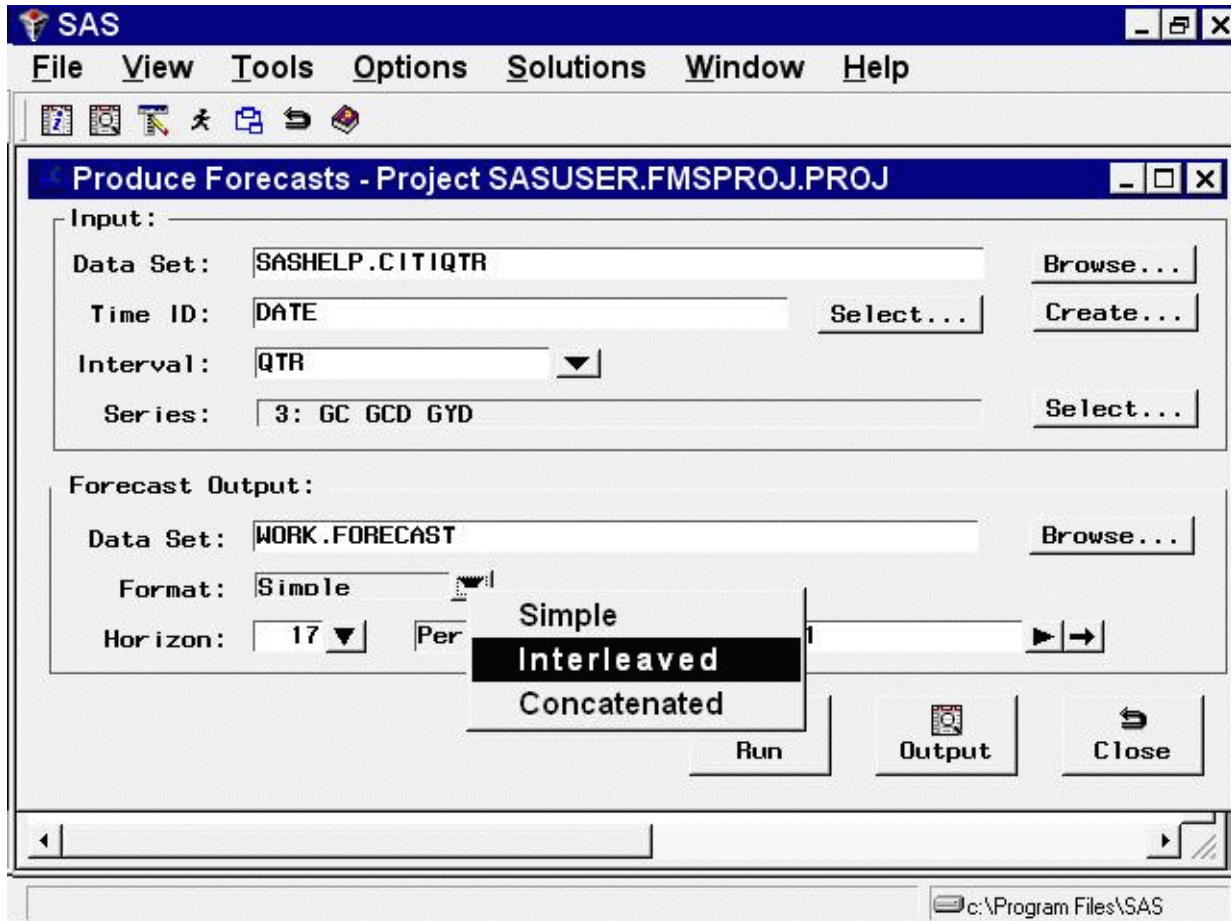

[Figure 45.19](#) shows the default simple format. This form of the forecast data set contains time ID variables and the variables that you forecast. The forecast variables contain actual values or predicted values, depending on whether the date of the observation is within the range of data supplied in the input data set.

Select **File** and **Close** to close the Viewtable window.

Interleaved Format Forecast Data Set

From the Produce Forecasts window, use the list to select the *Interleaved* format, as shown in Figure 45.20.

Figure 45.20 Forecast Data Set Options

Now select the Run button again. The system presents a warning notice reminding you that the data set WORK.FORECAST already exists and asking if you want to replace it. Select *Replace*.

The forecasts are stored in the data set WORK.FORECAST again, this time in the *Interleaved* format. Dismiss the notice that the forecast was stored.

Now select the Output button again. This opens a Viewtable window to display the data set, as shown in Figure 45.21.

Figure 45.21 Forecast Data Set—Interleaved Format

	Date of Observation	YEAR	QTR	Type of Observation	GC	GCD	GYD
1	1980:1	1980	1	ACTUAL	1702	218.7000	1894
2	1980:1	1980	1	ERROR	.	8.3333	0.2423

17	1980:3	1980	3	STD	17.5000	12.5457	25.9165

NOTE: Table has been opened in browse mode.

c:\Program Files\SAS

In the interleaved format, there are several output observations for each input observation, identified by the TYPE variable. The values of the forecast variables for observations with different TYPE values are as follows.

ACTUAL	actual values copied from the input data set
ERROR	the difference between the actual and predicted values
LOWER	the lower confidence limits
PREDICT	the predicted values from the forecasting model These are within-sample, one-step-ahead predictions for observations within the historical period, or multistep predictions for observations within the forecast period
STD	the estimated standard deviations of the prediction errors
UPPER	the upper confidence limits

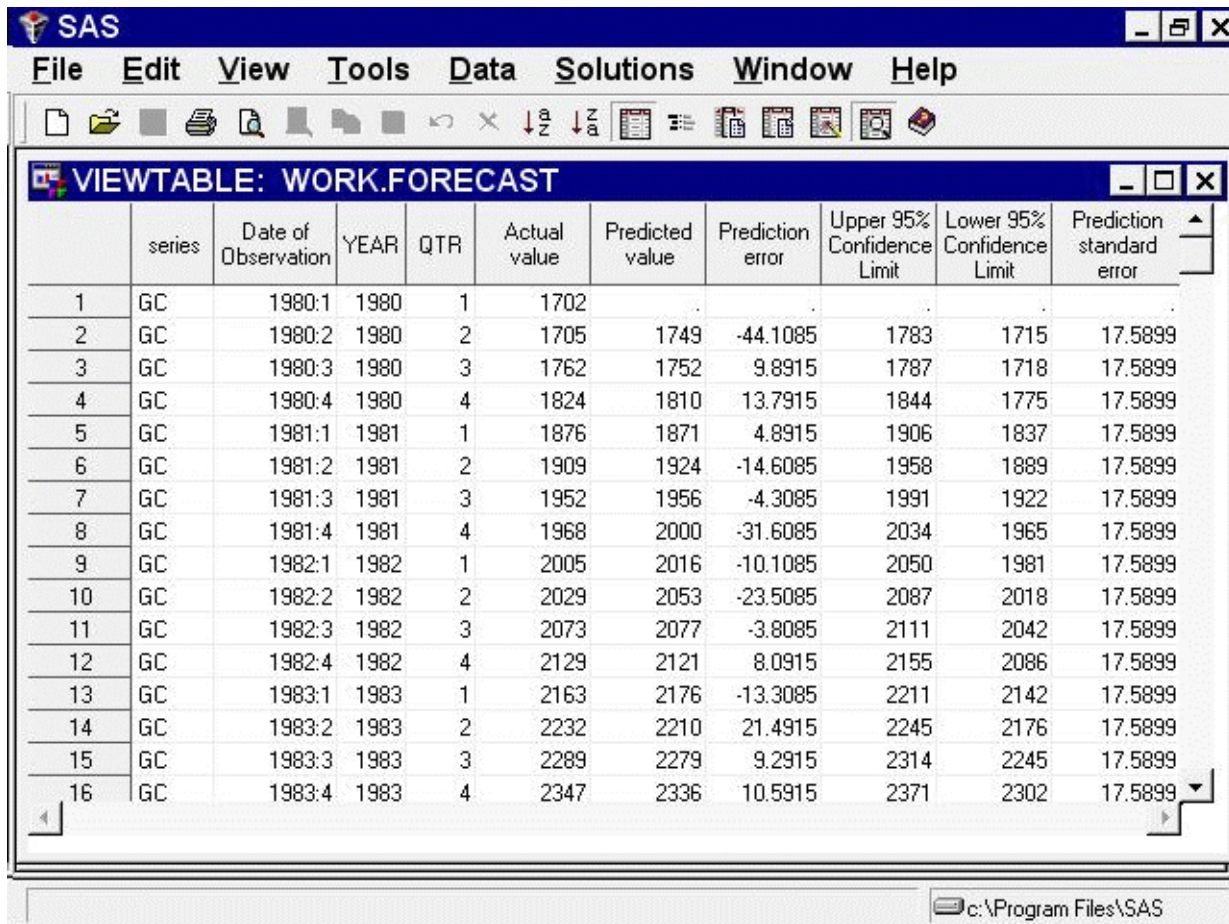

Select **File** and **Close** to close the VIEWTABLE window.

Concatenated Format Forecast Data Set

Use the list to select the *Concatenated* format. Create the forecast data set again, and then select the *Output* button.

The Viewtable window showing the concatenated format of the forecast data set appears, as shown in Figure 45.22.

Figure 45.22 Forecast Data Set—Concatenated Format

	series	Date of Observation	YEAR	QTR	Actual value	Predicted value	Prediction error	Upper 95% Confidence Limit	Lower 95% Confidence Limit	Prediction standard error
1	GC	1980:1	1980	1	1702					
2	GC	1980:2	1980	2	1705	1749	-44.1085	1783	1715	17.5899
3	GC	1980:3	1980	3	1762	1752	9.8915	1787	1718	17.5899
4	GC	1980:4	1980	4	1824	1810	13.7915	1844	1775	17.5899
5	GC	1981:1	1981	1	1876	1871	4.8915	1906	1837	17.5899
6	GC	1981:2	1981	2	1909	1924	-14.6085	1958	1889	17.5899
7	GC	1981:3	1981	3	1952	1956	-4.3085	1991	1922	17.5899
8	GC	1981:4	1981	4	1968	2000	-31.6085	2034	1965	17.5899
9	GC	1982:1	1982	1	2005	2016	-10.1085	2050	1981	17.5899
10	GC	1982:2	1982	2	2029	2053	-23.5085	2087	2018	17.5899
11	GC	1982:3	1982	3	2073	2077	-3.8085	2111	2042	17.5899
12	GC	1982:4	1982	4	2129	2121	8.0915	2155	2086	17.5899
13	GC	1983:1	1983	1	2163	2176	-13.3085	2211	2142	17.5899
14	GC	1983:2	1983	2	2232	2210	21.4915	2245	2176	17.5899
15	GC	1983:3	1983	3	2289	2279	9.2915	2314	2245	17.5899
16	GC	1983:4	1983	4	2347	2336	10.5915	2371	2302	17.5899

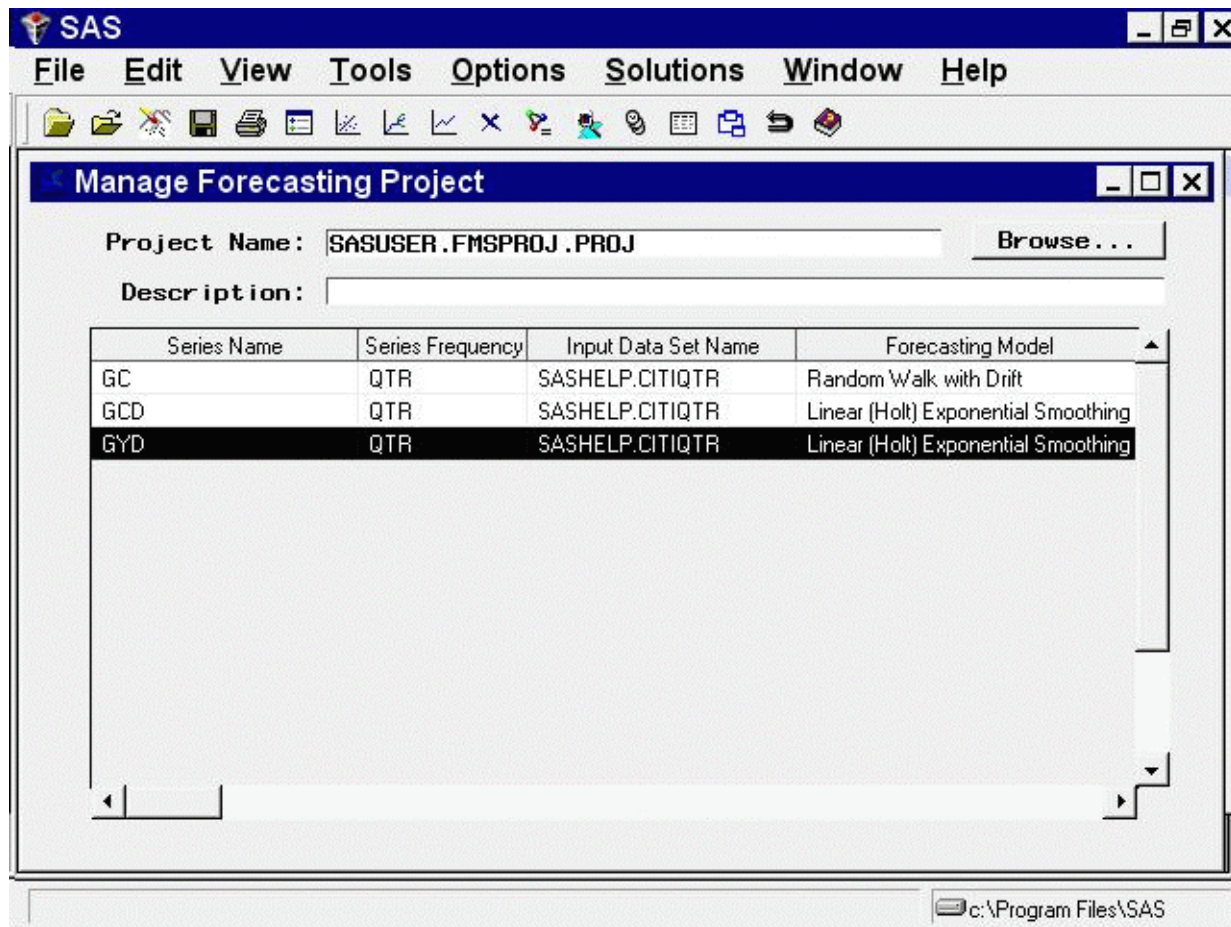

This completes the example of how to use the Produce Forecasts window. Select *File* and *Close* to close the Viewtable window. Select the *Close* button to return to the Time Series Forecasting window.

Forecasting Projects

The system collects all the forecasting models you create, together with the options you set, into a package called a *forecasting project*. You can save this information in a SAS catalog entry and restore your work in later forecasting sessions. You can store any number of forecasting projects under different catalog entry names.

To see how this works, select the Manage Projects button. This opens the Manage Forecasting Project window, as shown in Figure 45.23.

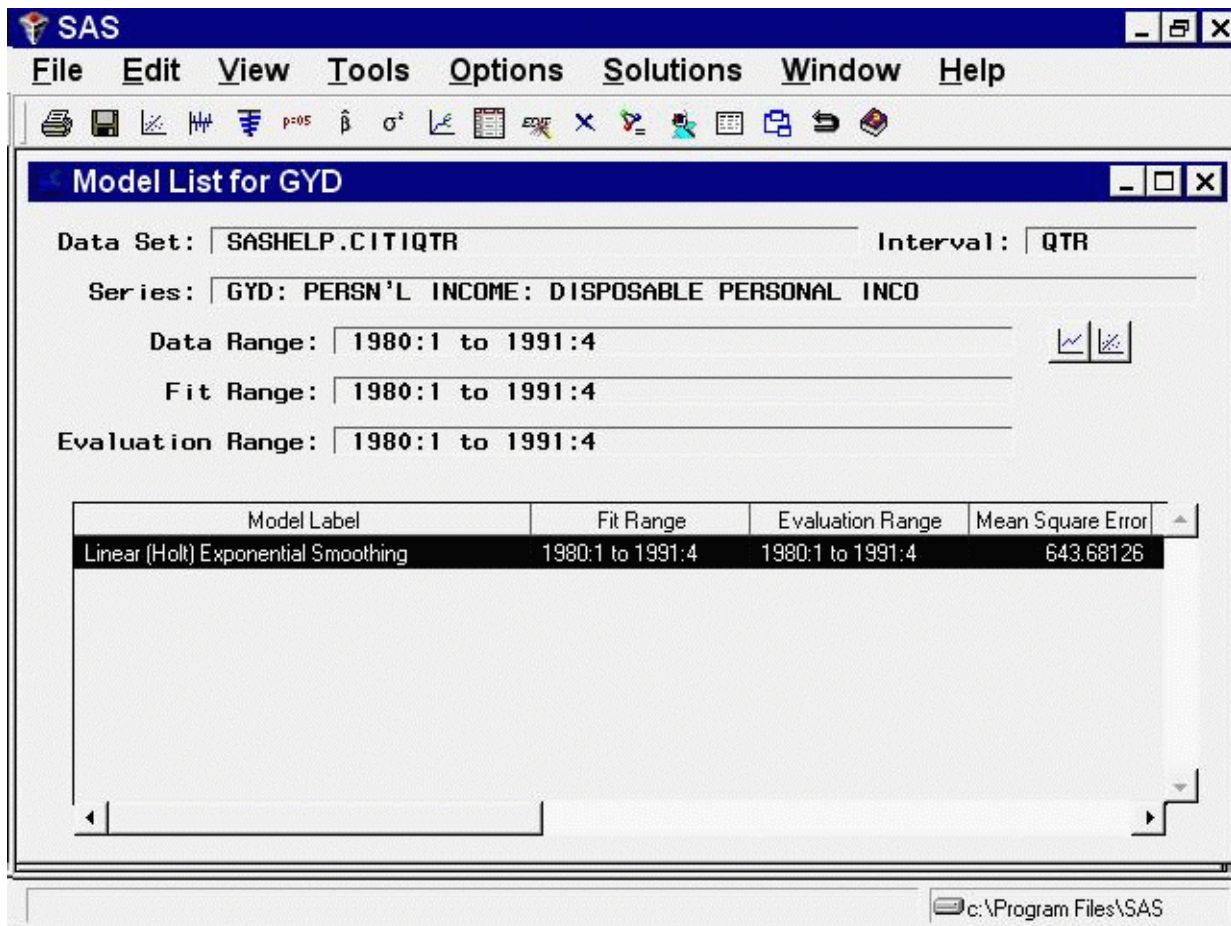

Figure 45.23 Manage Forecasting Project Window

The table in this window lists the series for which forecasting models have been fit, and it shows for each series the forecasting model used to produce the forecasts. This window provides several features that allow you to manage the information in your forecasting project.

You can select a row of the table to drill down to the list of models fit to the series. Select the GYD row of the table, either by double-clicking with the mouse or by clicking once to highlight the table row and then selecting **List Models** from the toolbar or from the Tools menu. This opens the Model List window for this series, as shown in Figure 45.24.

Figure 45.24 Model List Window

Because the Automatic Model Fitting process kept only the best fitting model, only one model appears in the model list. You can fit and retain any number of models for each series, and all the models fit and kept will appear in the series' model list.

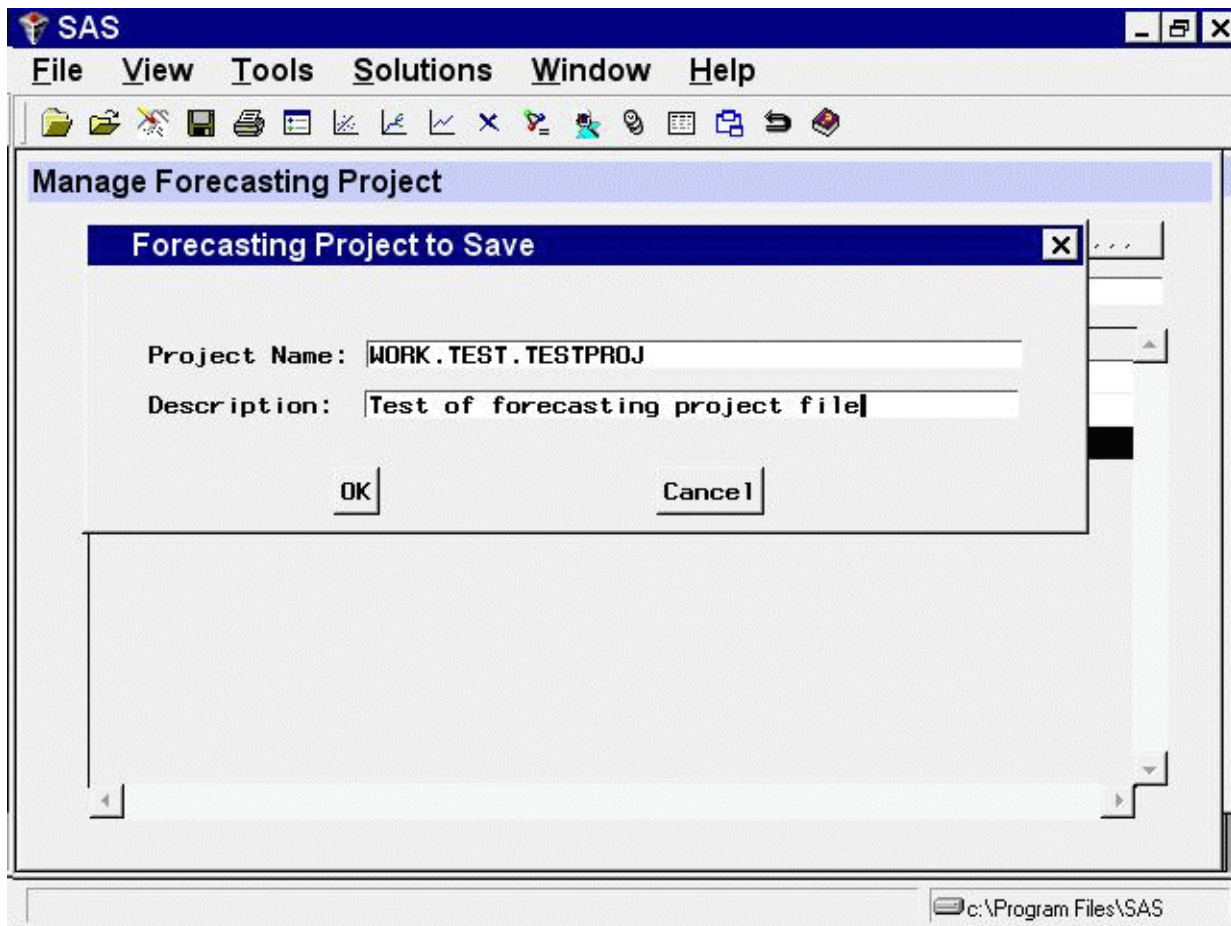

Select **Close** from the toolbar or from the **File** menu to return to the Manage Forecasting Project window.

Saving and Restoring Project Information

To illustrate how you can save your work between sessions, in this section you will exit and then re-enter the Forecasting System.

From the Manage Forecasting Project window, select **File** and **Save as**. This opens the Forecasting Project to Save window. In the Project Name field, type the name `WORK.TEST.TESTPROJ`. In the Description field, type "Test of forecasting project file." The window should now appear as shown in Figure 45.25.

Figure 45.25 Project to Save Name and Description

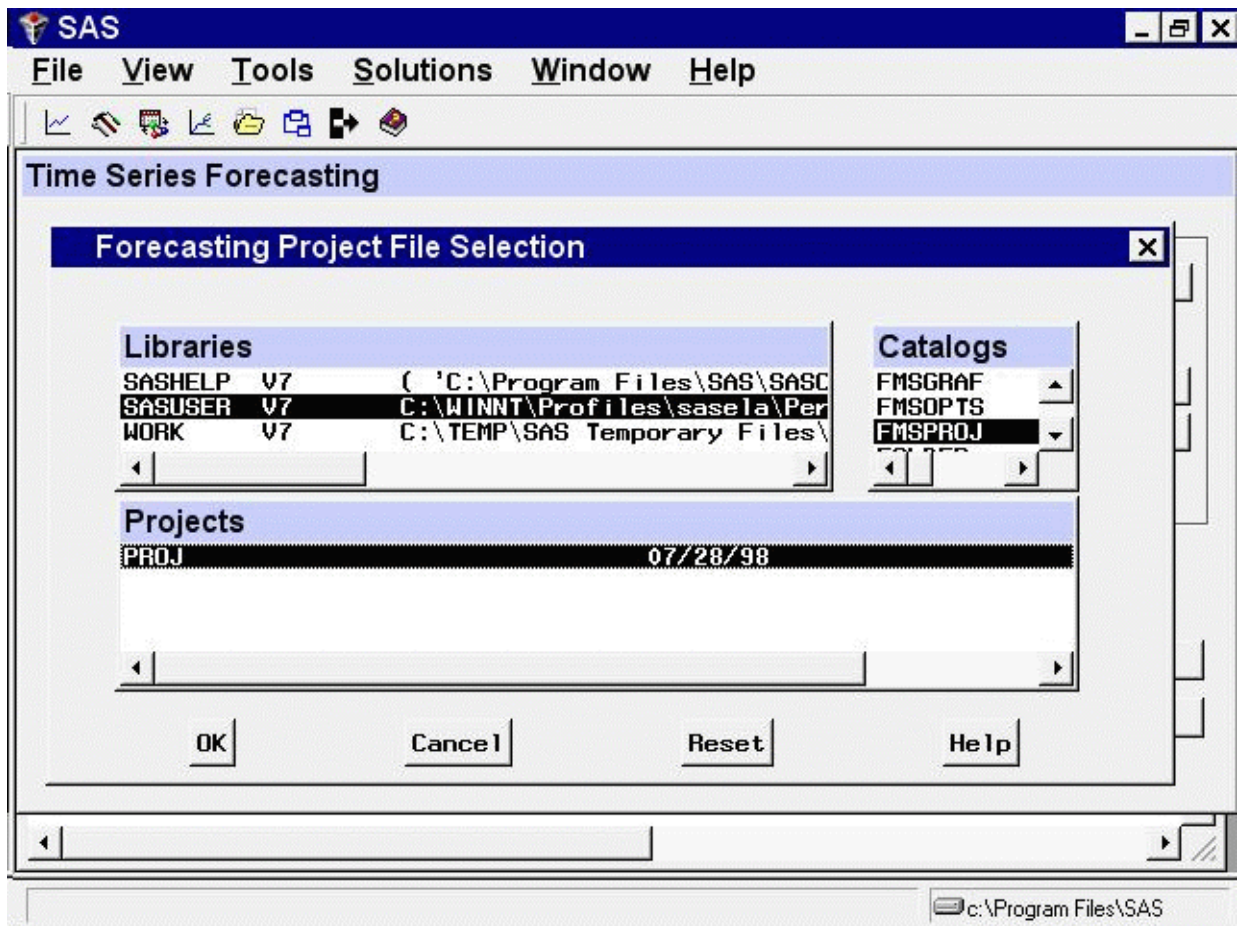

Select the OK button. This returns you to the Project Management window and displays a message indicating that the project was saved.

Select **C**lose from the toolbar or from the File menu to return to the Time Series Forecasting window. Now select the **E**xit button. The system asks if you are sure you want to exit the system; select **Y**es. The forecasting application now terminates.

Open the forecasting application again. A new project name is displayed by default.

Now restore the forecasting project you saved previously. Select the **B**rowse button to the right of the Project field. This opens the Forecasting Project File Selection window, as shown in [Figure 45.26](#).

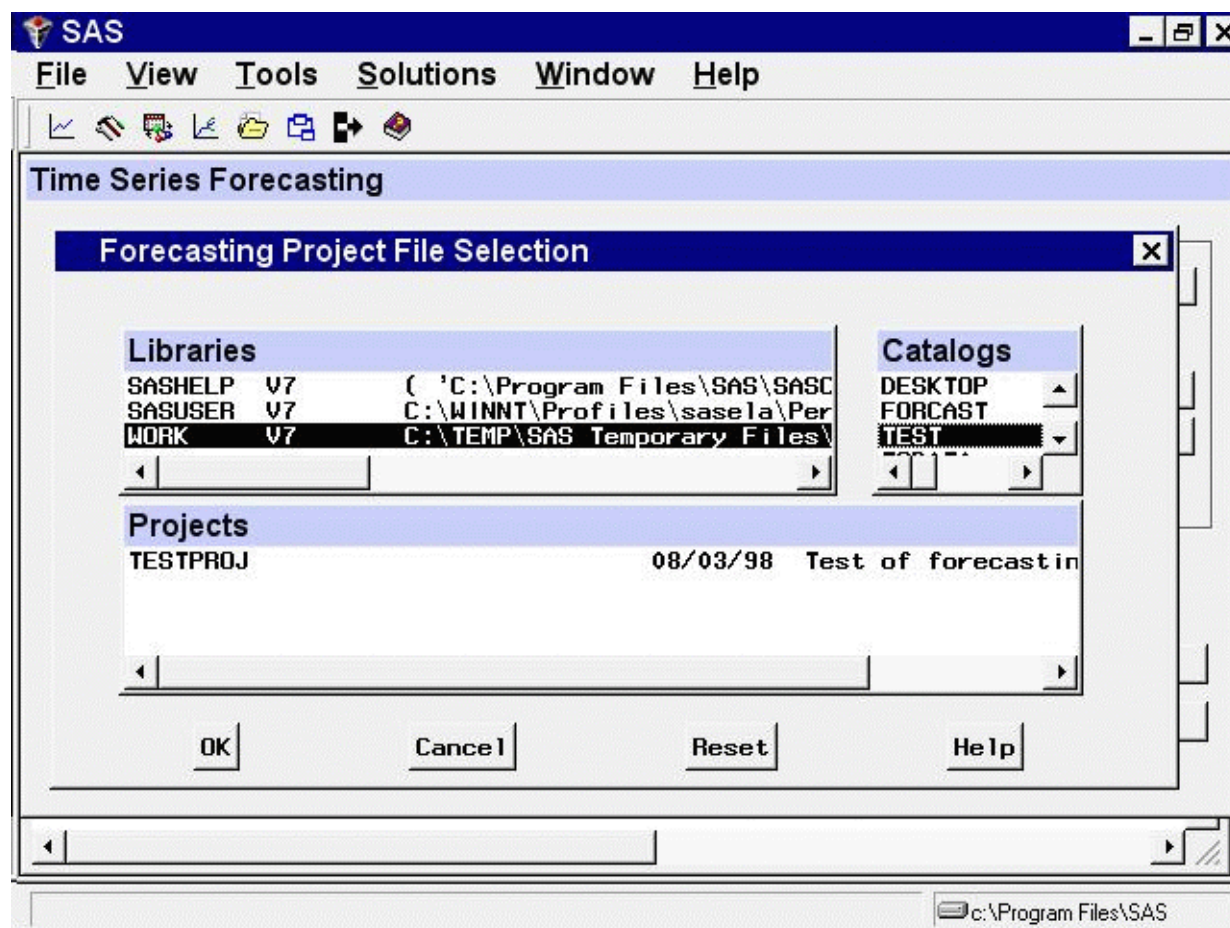

Figure 45.26 Forecasting Project File Selection Window

Select the WORK library from the Libraries list. The Catalogs list now shows all the SAS catalogs in the WORK library.

Select the TEST catalog. The Projects list now shows the list of forecasting projects in the catalog TEST. So far, you have created only one project file, TESTPROJ; so TESTPROJ is the only entry in the Projects list, as shown in Figure 45.27.

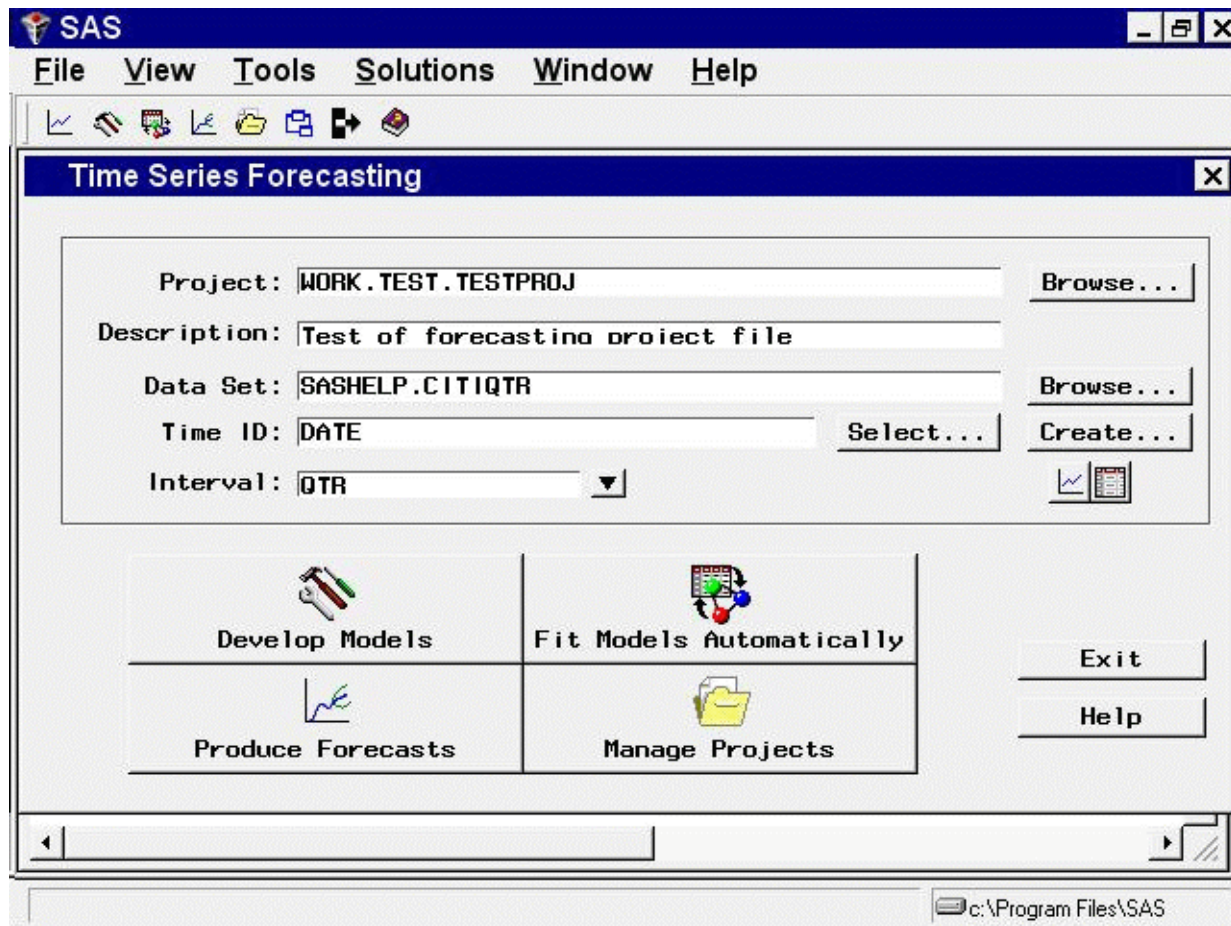

Figure 45.27 Forecasting Projects List

Select TESTPROJ from the Projects list and then select the OK button. This returns you to the Time Series Forecasting window.

The system loads the project information you saved in TESTPROJ and displays a message indicating this. The Project field is now set to WORK.TEST.TESTPROJ, and the description is the description you previously gave to TESTPROJ, as shown in Figure 45.28.

Figure 45.28 Time Series Forecasting Window after Loading Project

If you now select the Manage Projects button, you will see the list of series and forecasting models you created in the previous forecasting session.

Sharing Projects

If you plan to work with others on a forecasting project, you might need to consider how project information can be shared. The series, models, and results of your project are stored in a forecasting project (FMSPROJ) catalog entry in the location you specify, as illustrated in the previous section. You need only read access to the catalog to work with it, but you must have write access to save the project. Multiple users cannot open a project for update at the same time, but they can do so at different times if they all have write access to the catalog where it is stored.

Project options settings such as the *model selection criterion* and *number of models to keep* are stored in an SLIST catalog entry in the SASUSER or TSFSUSER library. Write access to this catalog is required. If you have only read access to the SASUSER library, you can use the -RSASUSER option when starting SAS. You will be prompted for a location for the TSFSUSER library, if it is not already assigned. If you want to use TSFSUSER routinely, assign it before you start the Time Series Forecasting System. Select New from the SAS Explorer file menu. In the New Library window, type TSFSUSER for the name. Click the Browse

button and select the directory or folder you want to use. Turn on the *enable at startup* option so this library will be assigned automatically in subsequent sessions.

The SASUSER library is typically used for private settings saved by individual users. This is the default location for project options. If a work group shares a single options catalog (SASUSER or TSFSUSER points to the same location for all users), then only one user can use the system at a time.

Develop Models Window

In the first forecasting example, you used the Automatic Model Fitting window to fit and select the forecasting model for each series automatically. In addition to this automatic forecasting process, you can also work with time series one at a time to fit forecasting models and apply your own judgment to choose the best forecasting model for each series.

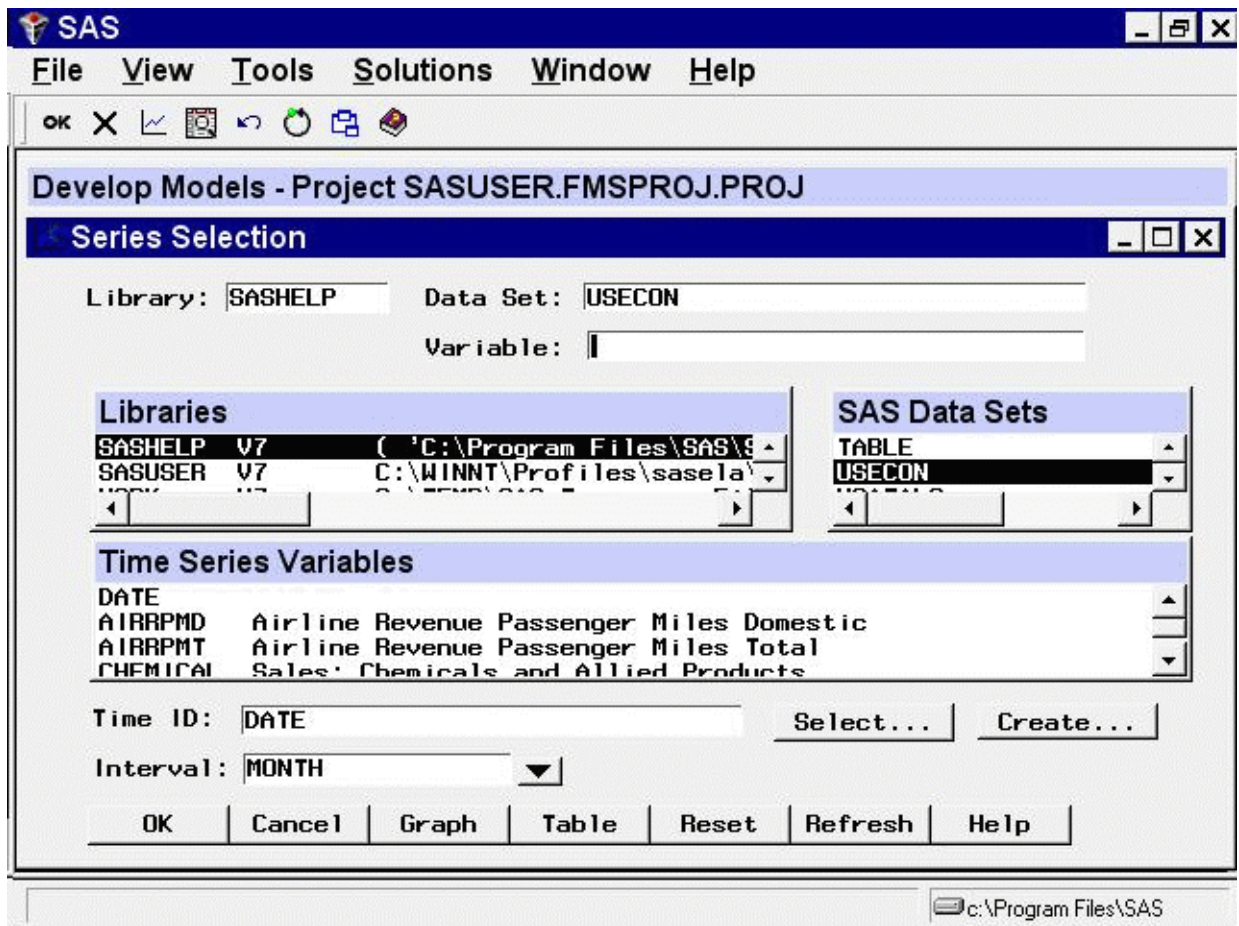

Using the Automatic Model Fitting feature, the system acts like a “black box.” This section goes inside the black box to look at the kinds of forecasting methods that the system provides and introduces some of the tools the system offers to help you find the best forecasting model.

Introduction

From the Time Series Forecasting window, select the Browse button to the right of the Data Set field to open the Data Set Selection window. Select the USECON data set from the SASHELP library. This data set contains monthly data on the U.S. economy.

Select OK to close the selection window. Now select the Develop Models button. This opens the Series Selection window, as shown in [Figure 45.29](#). You can enlarge this window for easier viewing of lists of data sets and series.

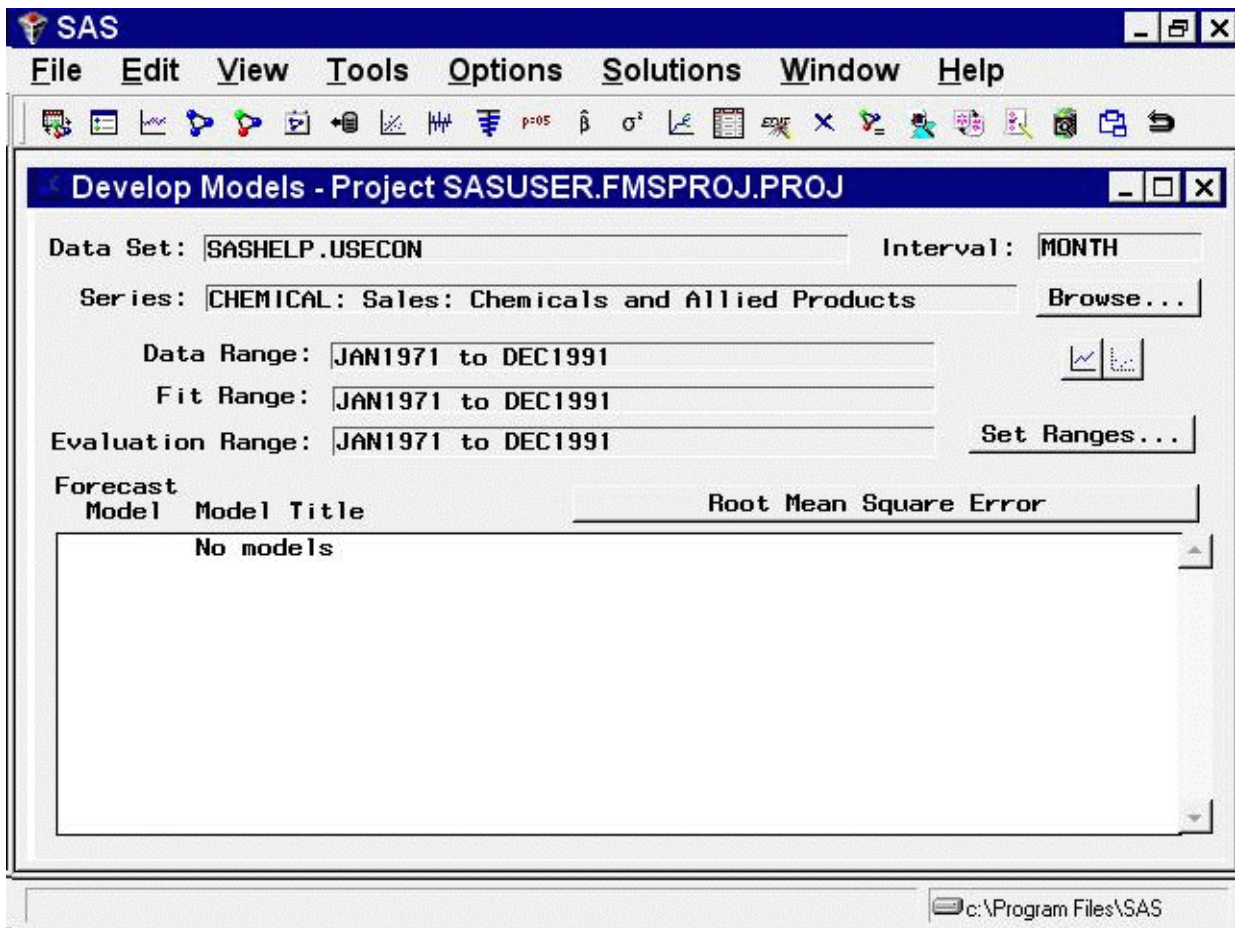

Figure 45.29 Series Selection Window

Select the series CHEMICAL: Sales of Chemicals and Allied Products, and then select the OK button.

This opens the Develop Models window, as shown in Figure 45.30.

Figure 45.30 Develop Models Window

The Data Set, Interval, and Series fields in the upper part of the Develop Models window indicate the series with which you are currently working. You can change the settings of these fields by selecting the Browse button.

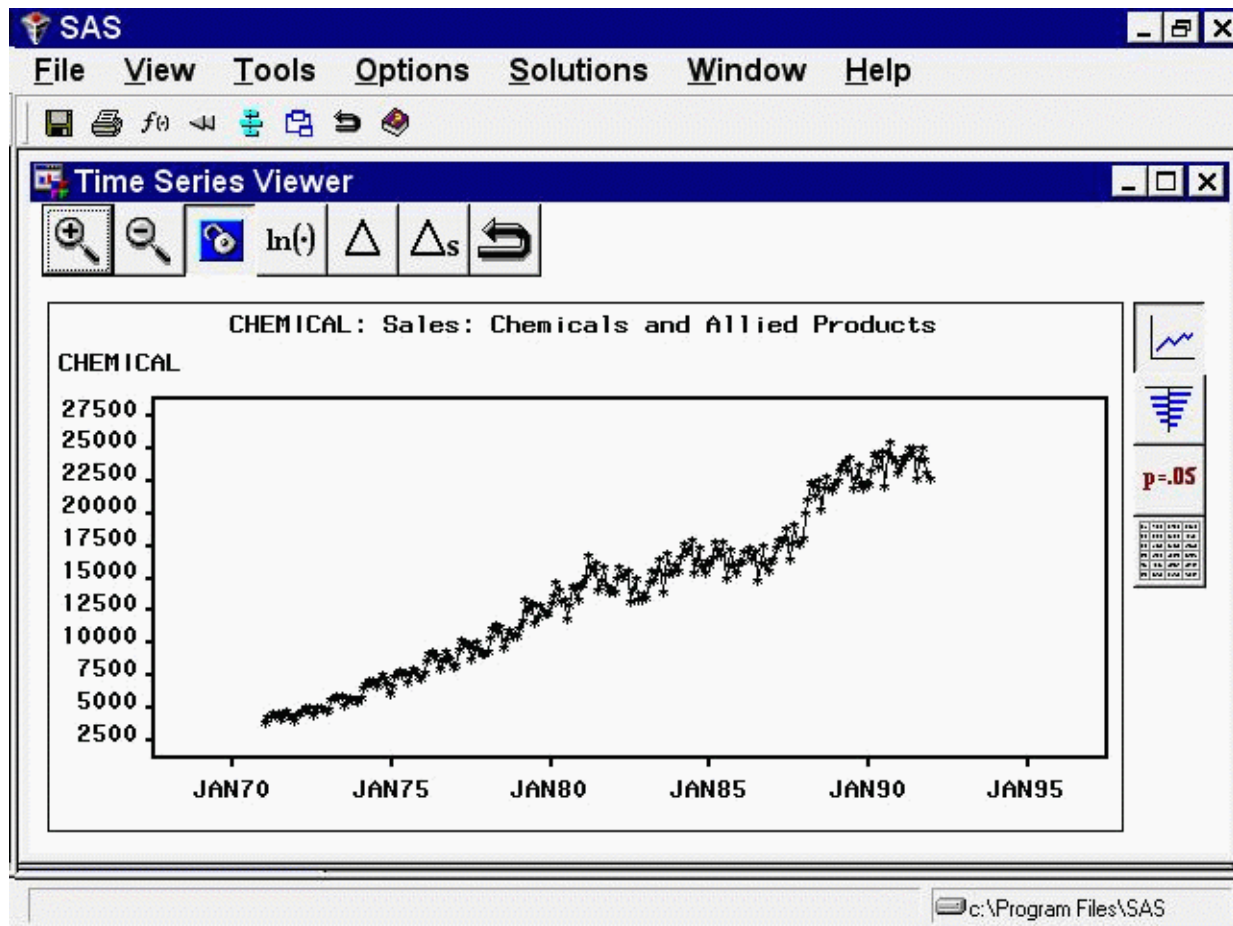

The Data Range, Fit Range, and Evaluation Range fields show the time period over which data are available for the current series, and what parts of that time period are used to fit forecasting models to the series and to evaluate how well the models fit the data. You can change the settings of these fields by selecting the Set Ranges button.

The bottom part of the Develop Models window consists of a table of forecasting models fit to the series. Initially, the list is empty, as indicated by the message “No models.” You can fit any number of forecasting models to each series and designate which one you want to use to produce forecasts.

Graphical tools are available for exploring time series and fitted models. The two icons below the Browse button access the Time Series Viewer and the Model Viewer.

Select the left icon. This opens the Time Series Viewer window, as shown in [Figure 45.31](#).

Figure 45.31 Chemical and Allied Product Series

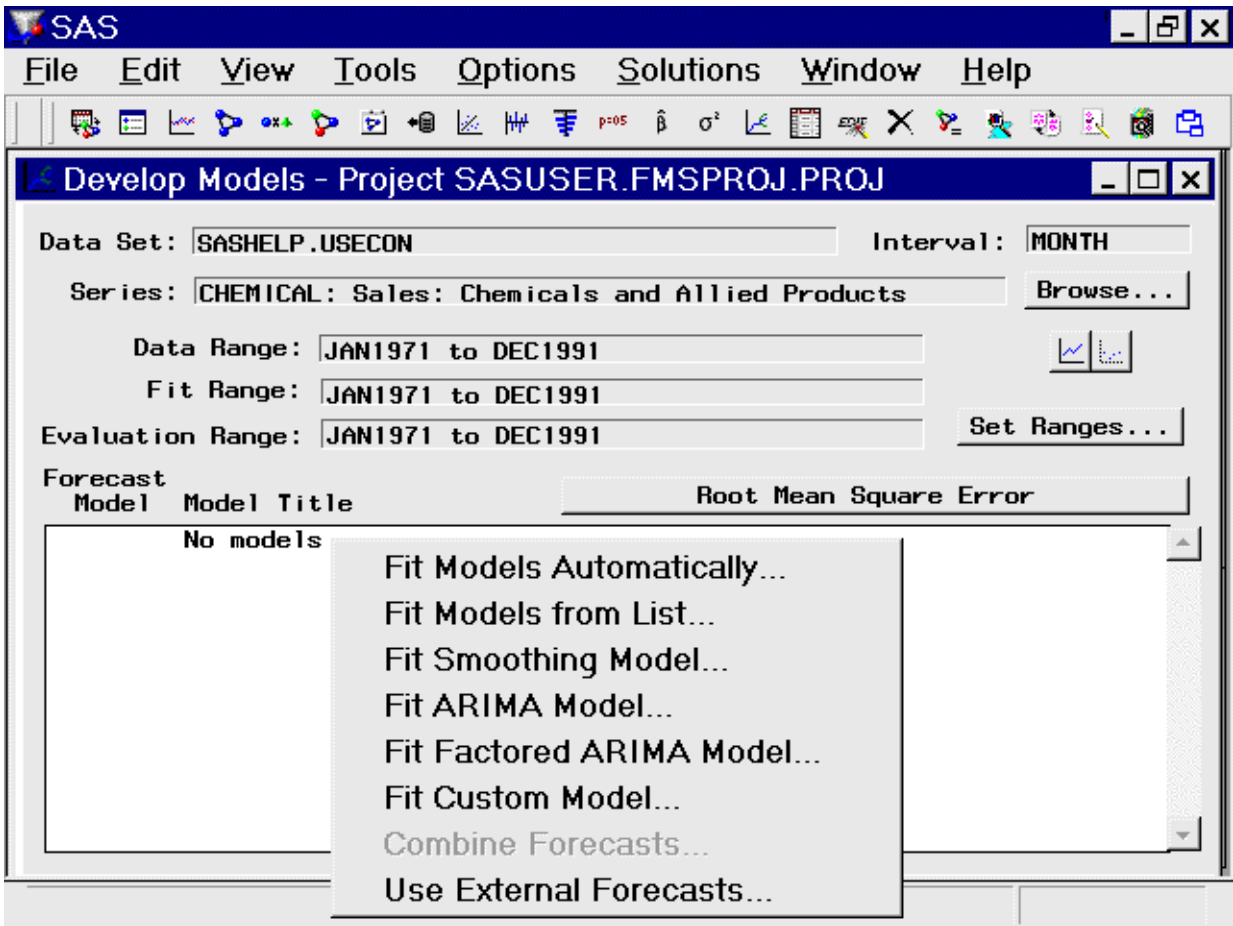

The Time Series Viewer displays a plot of the CHEMICAL series. The Time Series Viewer offers many useful features, which are explored in later sections.

The Time Series Viewer appears in a separate resizable window. You can switch back and forth between the Time Series Viewer window and other windows. For now, return to the Develop Models window. You can close the Time Series Viewer window or leave it open. (To close the Time Series Viewer window, select **Close** from the toolbar or from the File menu.)

Fitting Models

To open a menu of model fitting choices, select **Edit** from the menu bar and then select **Fit Model**, or select **Fit Models** from **List** in the toolbar, or simply select a blank line in the table as shown in Figure 45.32.

Figure 45.32 Menu of Model Fitting Choices

The Forecasting System provides several ways to specify forecasting models. The eight choices given by the menu shown in Figure 45.32 are as follows:

- Fit Models Automatically
 - performs for the current series the same automatic model selection process that the Automatic Model Fitting window applies to a set of series.
- Fit Models from List
 - presents a list of commonly used forecasting models for convenient point-and-click selection.

Fit Smoothing Model

displays the Smoothing Model Specification window, which enables you to specify several kinds of exponential smoothing and Winters method forecasting models.

Fit ARIMA Model

displays the ARIMA Model Specification window, which enables you to specify many kinds of autoregressive integrated moving average (ARIMA) models, including seasonal ARIMA models and ARIMA models with regressors, transfer functions, and other predictors.

Fit Factored ARIMA Model

displays the Factored ARIMA Model Specification window, which enables you to specify more general ARIMA models, including subset models and models with unusual and/or multiple seasonal cycles. It also supports regressors, transfer functions, and other predictors.

Fit Custom Model

displays the Custom Model Specification window, which enables you to construct a forecasting model by specifying separate options for transforming the data, modeling the trend, modeling seasonality, modeling autocorrelation of the errors, and modeling the effect of regressors and other independent predictors.

Combine Forecasts

displays the Forecast Combination Model Specification window, which enables you to specify models that produce forecasts by combining, or averaging, the forecasts from other models. (This option is not available unless you have fit at least two models.)

Use External Forecasts

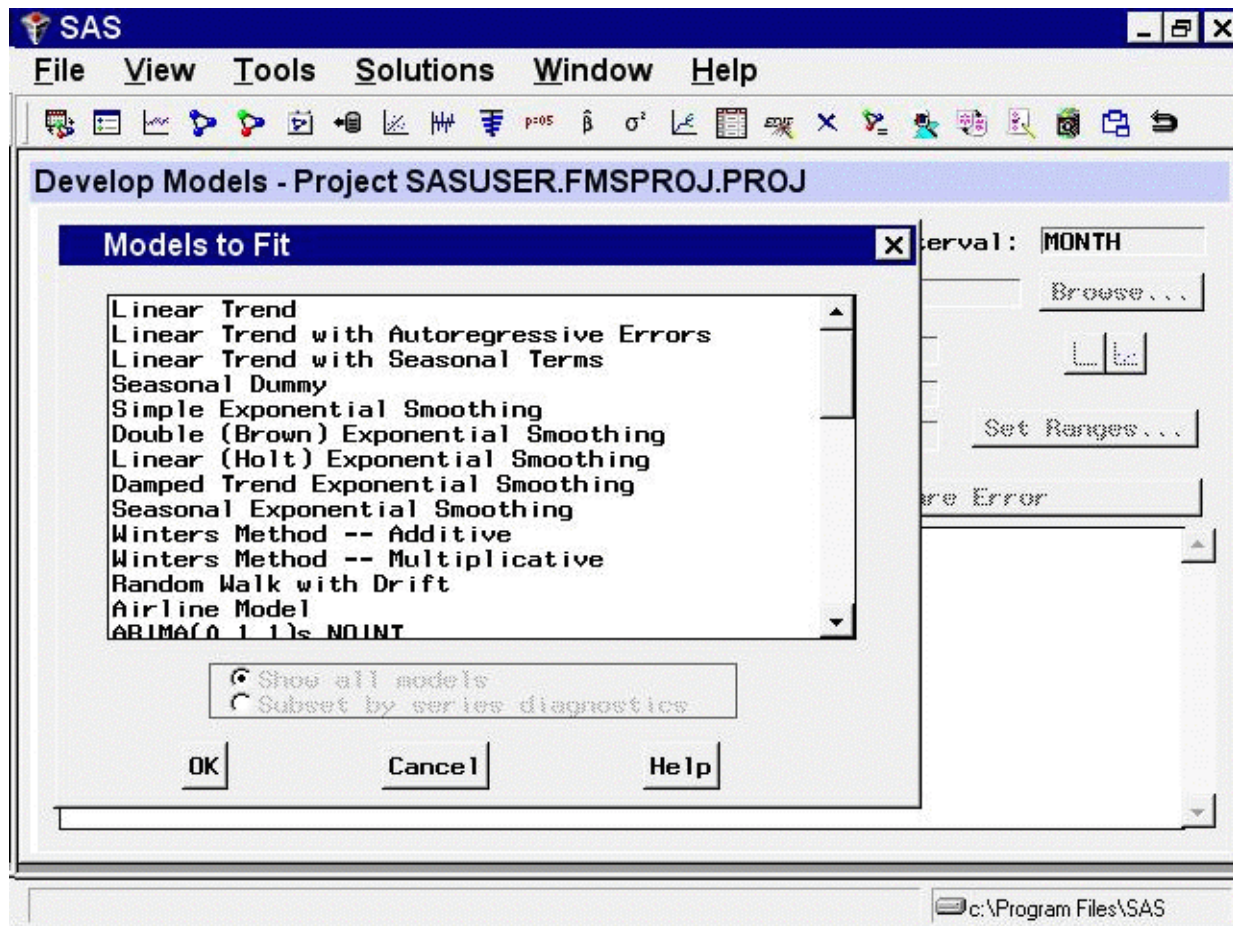

displays the External Forecast Model Specification window, which enables you to use judgmental or externally produced forecasts that have been saved in a separate series in the data set.

All of the forecasting models used by the system are ultimately specified through one of the four windows: Smoothing Method Specification, ARIMA Model Specification, Factored ARIMA Model Specification, or Custom Model Specification. You can specify the same models with either the ARIMA Model Specification window or the Custom Model Specification window, but the Custom Model Specification window can provide a more natural way to specify models for those who are less familiar with the Box-Jenkins style of time series model specification.

The Automatic Model feature, the Models to Fit window, and the Forecast Combination Model Specification window all deal with lists of forecasting models previously defined through the Smoothing Model, ARIMA Model, or Custom Model specification windows. These windows are discussed in detail in later sections.

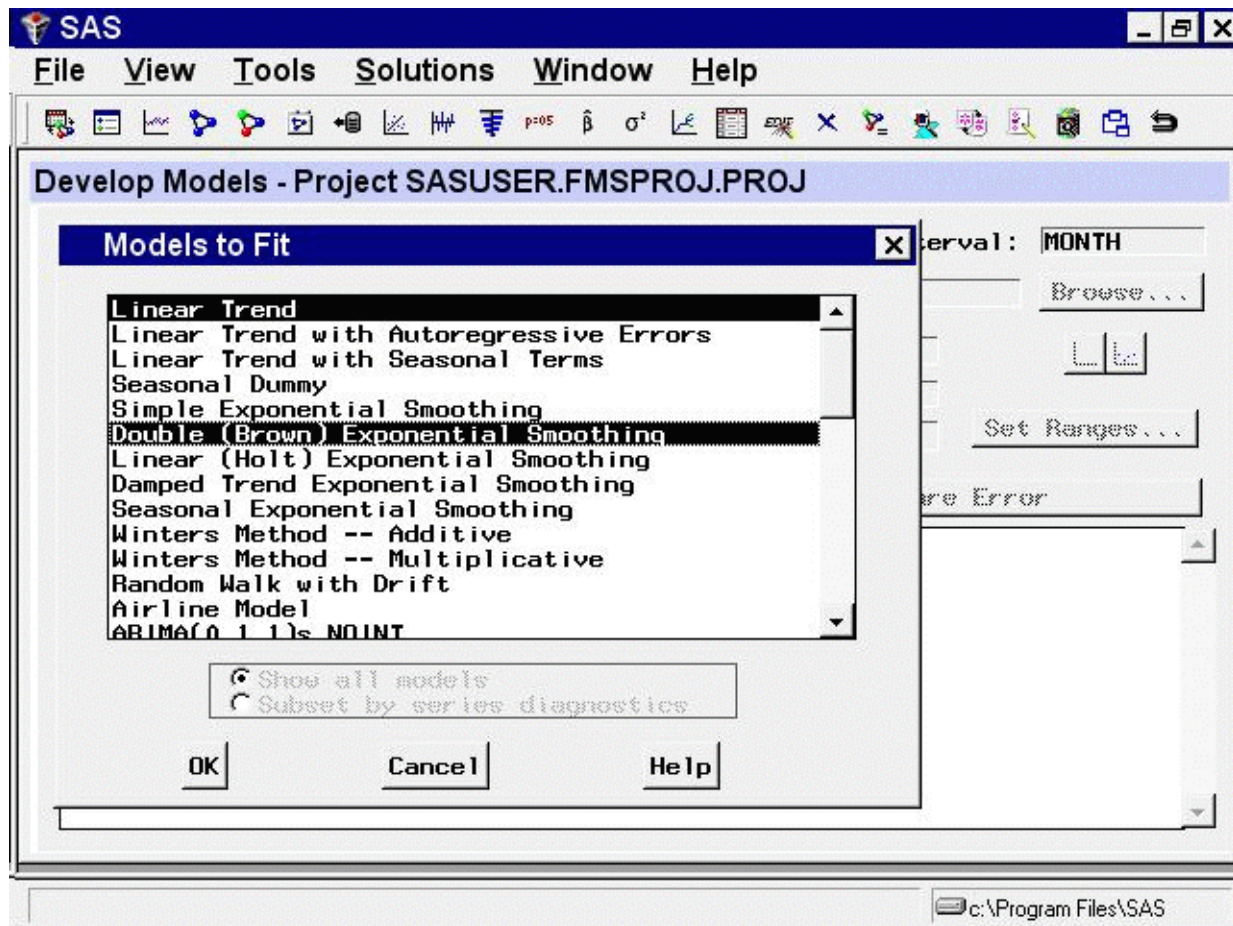

To get started using the Develop Models window, select the Fit Models from List item from the menu shown in [Figure 45.32](#). This opens the Models to Fit window, as shown in [Figure 45.33](#).

Figure 45.33 Models to Fit Window

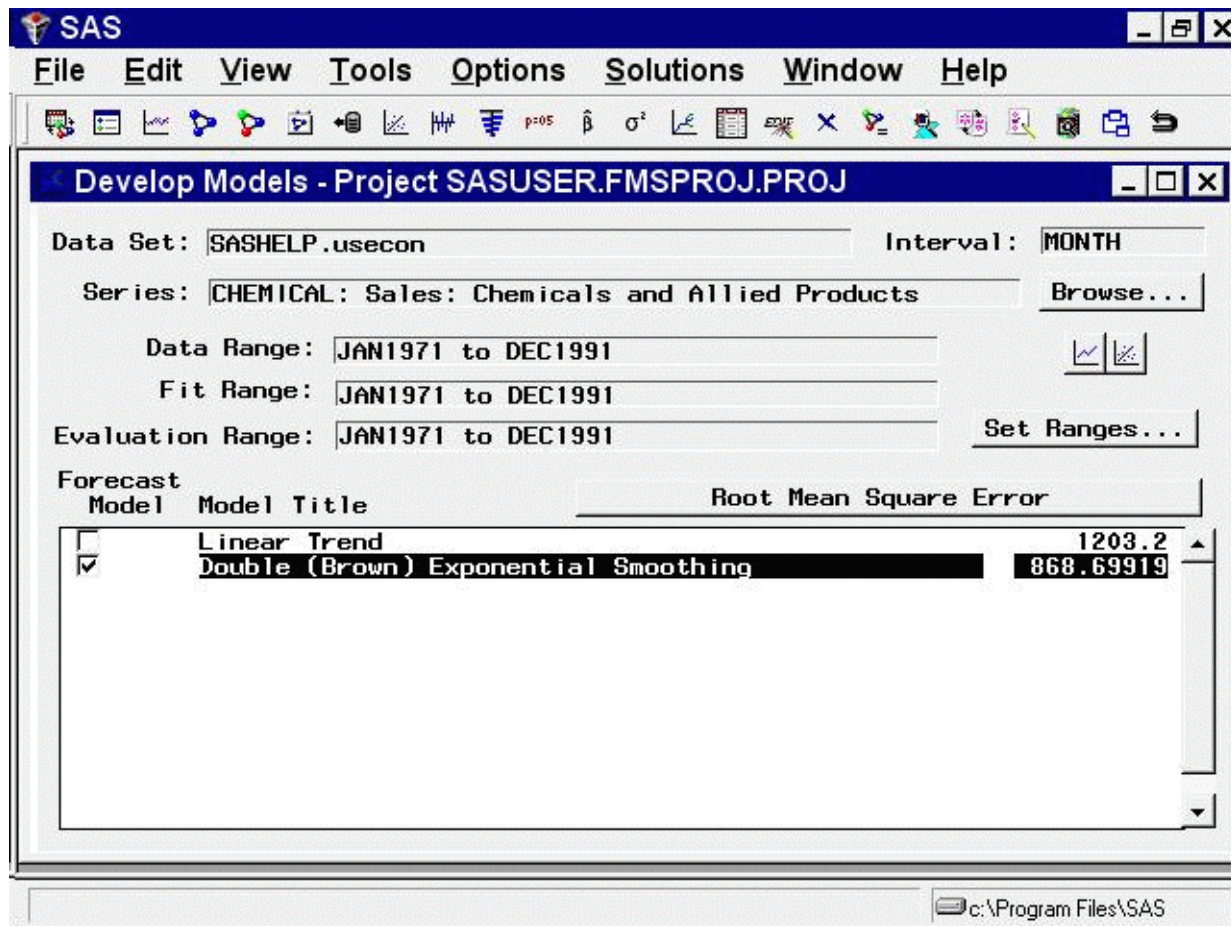

You can select several models to fit at once by holding down the CTRL key as you make the selections. Select **Linear Trend** and **Double (Brown) Exponential Smoothing**, as shown in Figure 45.34, and then select the **OK** button.

Figure 45.34 Selecting Models to Fit

The system fits the two models you selected. After the models are fit, the labels of the two models and their goodness-of-fit statistic are added to the model table, as shown in Figure 45.35.

Figure 45.35 Fitted Models List

Model List and Statistics of Fit

In the model list, the *Model Title* column shows the descriptive labels for the two fitted models, in this case Linear Trend and Double Exponential Smoothing.

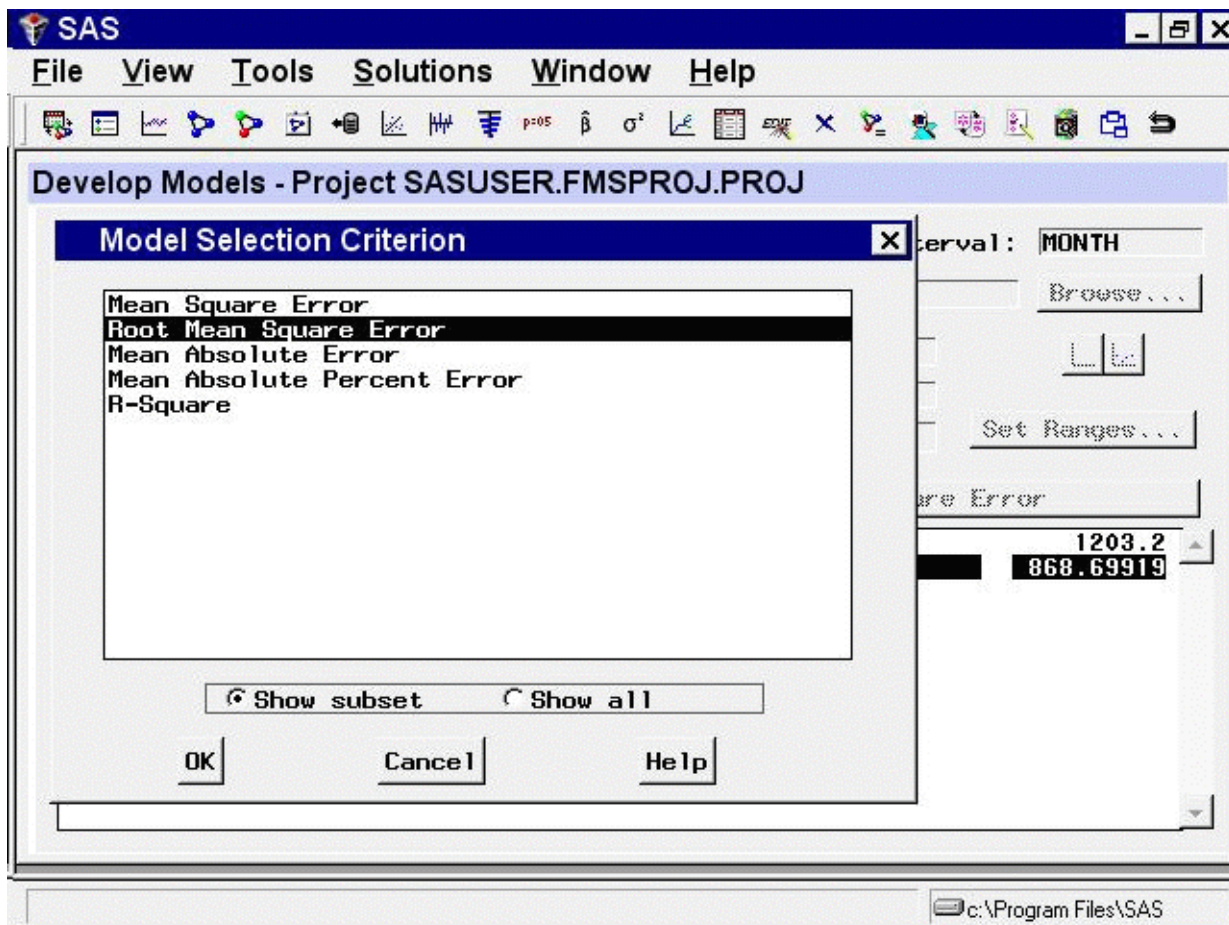

The column labeled *Root Mean Square Error* (or labeled *Mean Absolute Percent Error* if you continued from the example in the previous section) shows the goodness-of-fit criterion used to decide which model fits better. By default, the criterion used is the root mean square error, but you can choose a different measure of fit. The linear trend model has a root mean square error of 1203, while the double exponential smoothing model fits better, with a RMSE of only 869.

The left column labeled *Forecast Model* consists of check boxes that indicate which one of the models in the list has been selected as the model to use to produce the forecasts for the series. When new models are fit and added to the model list, the system sets the Forecast Model flags to designate the one model with the best fit—as measured by the selected goodness-of-fit statistic—as the forecast model. (In the case of ties, the first model with the best fit is selected.)

Because the Double Exponential Smoothing model has the smaller RMSE of the two models in the list, its Forecast Model check box is set. If you would rather produce forecasts by using the Linear Trend model, choose it by selecting the corresponding check box in the Forecast Model column.

To use a different goodness-of-fit criterion, select the button with the current criterion name on it (Root Mean Square Error or Mean Absolute Percent Error). This opens the Model Selection Criterion window, as shown in Figure 45.36.

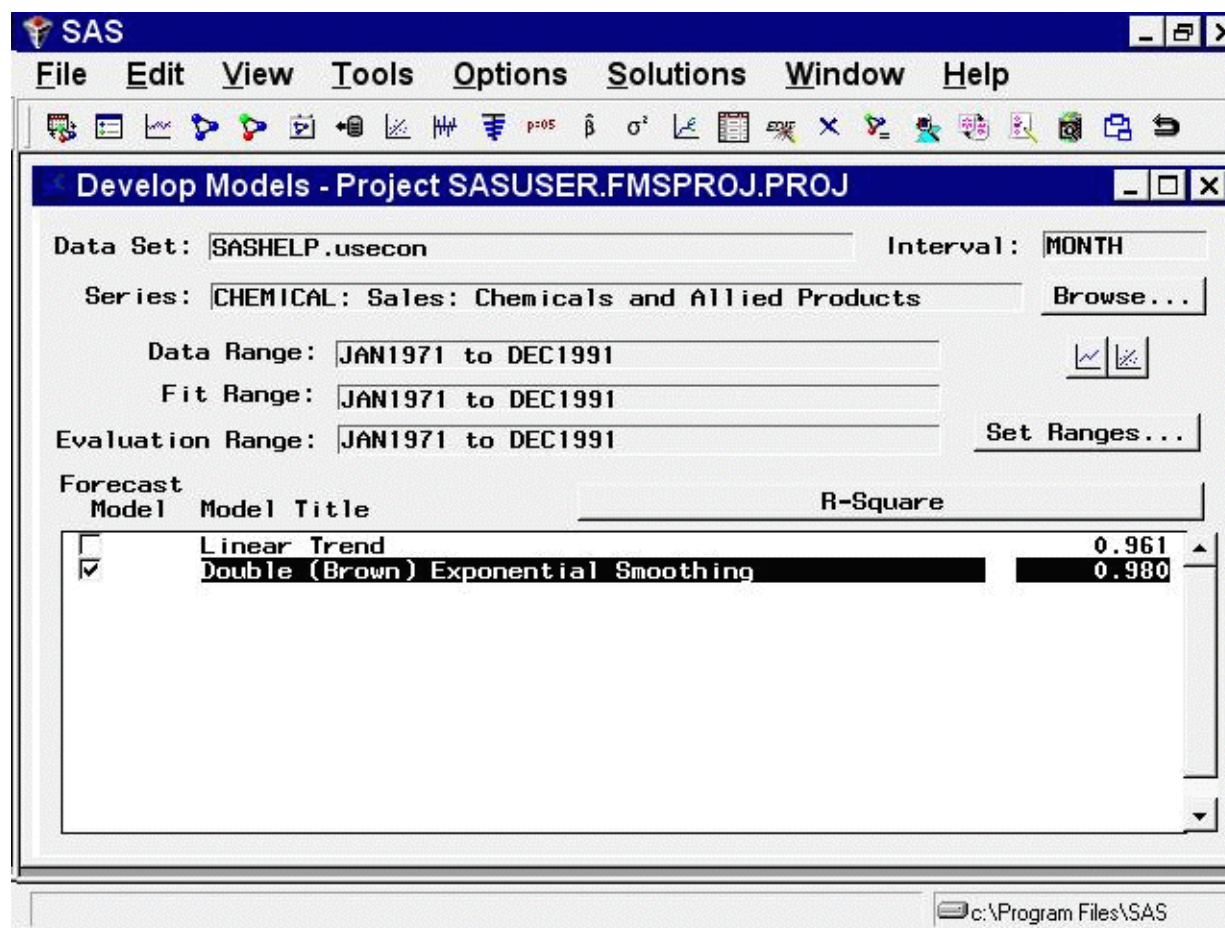

Figure 45.36 Model Selection Criterion Window

The system provides many measures of fit that you can use as the model selection criterion. To avoid confusion, only the most popular of the available fit statistics are shown in this window by default. To display the complete list, you can select the *Show all* option. You can control the subset of statistics listed in this window through the Statistics of Fit item in the Options menu on the Develop Models window.

Initially, Root Mean Square Error is selected. Select R-Square and then select the OK button. This changes the fit statistic displayed in the model list, as shown in Figure 45.37.

Figure 45.37 Model List with R-Square Statistics

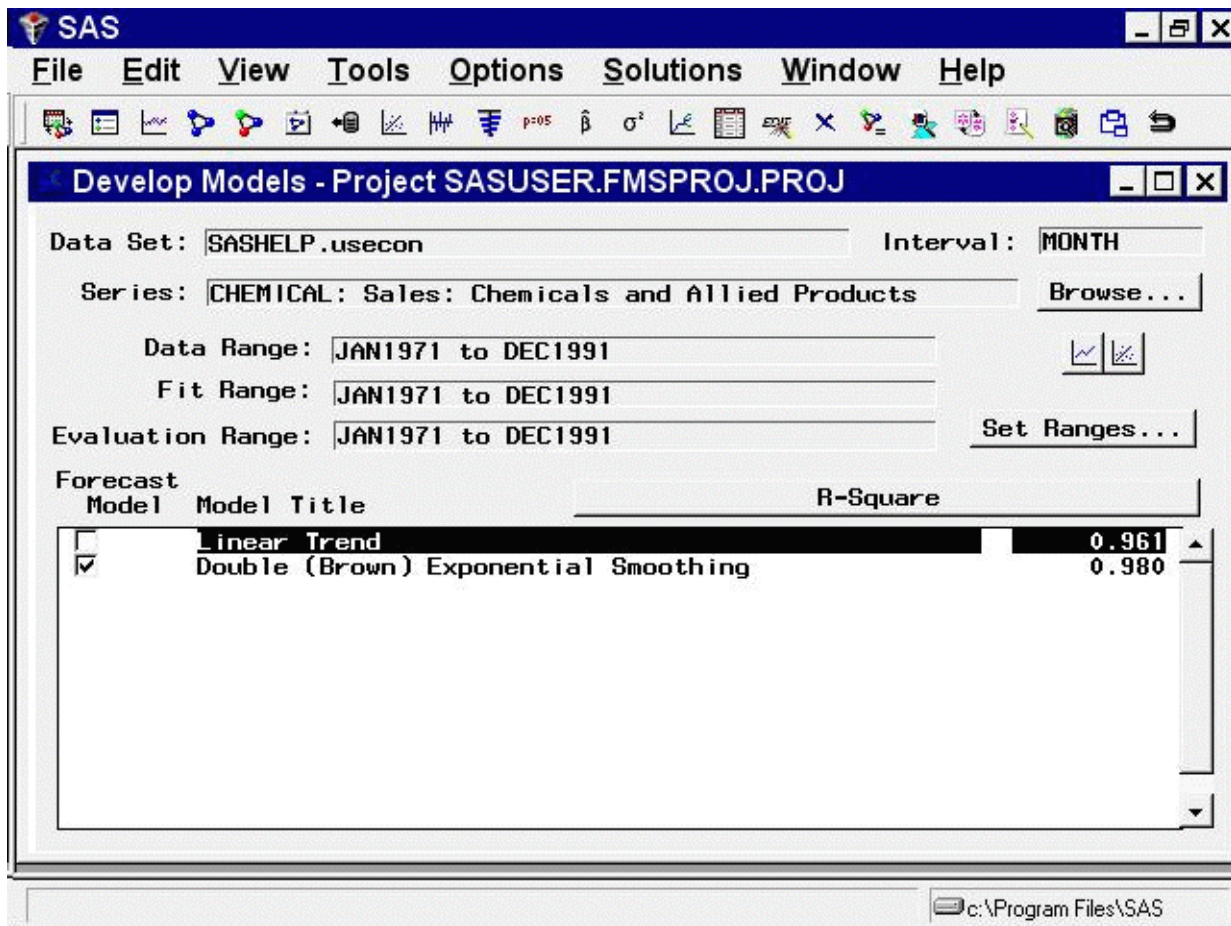

Now that you have fit some models to the series, you can use the Model Viewer button to take a closer look at the predictions of these models.

Model Viewer

In the Develop Models window, select the row in the table containing the Linear Trend model so that this model is highlighted. The model list should now appear as shown in Figure 45.38.

Figure 45.38 Selecting a Model to View

Note that the Linear Trend model is now highlighted, but the Forecast Model column still shows the Double Exponential Smoothing model as the model chosen to produce the final forecasts for the series. Selecting a model in the list means that this is the model that menu items such as *View Model*, *Delete*, *Edit*, and *Refit* will act upon. Choosing a model by selecting its check box in the Forecast Model column means that this model will be used by the Produce Forecasts process to generate forecasts.

Now open the Model Viewer by selecting the right-hand icon under the Browse button, or by selecting *Model Predictions* in the toolbar or from the View menu. The Model Viewer displays the Linear Trend model, as shown in Figure 45.39.

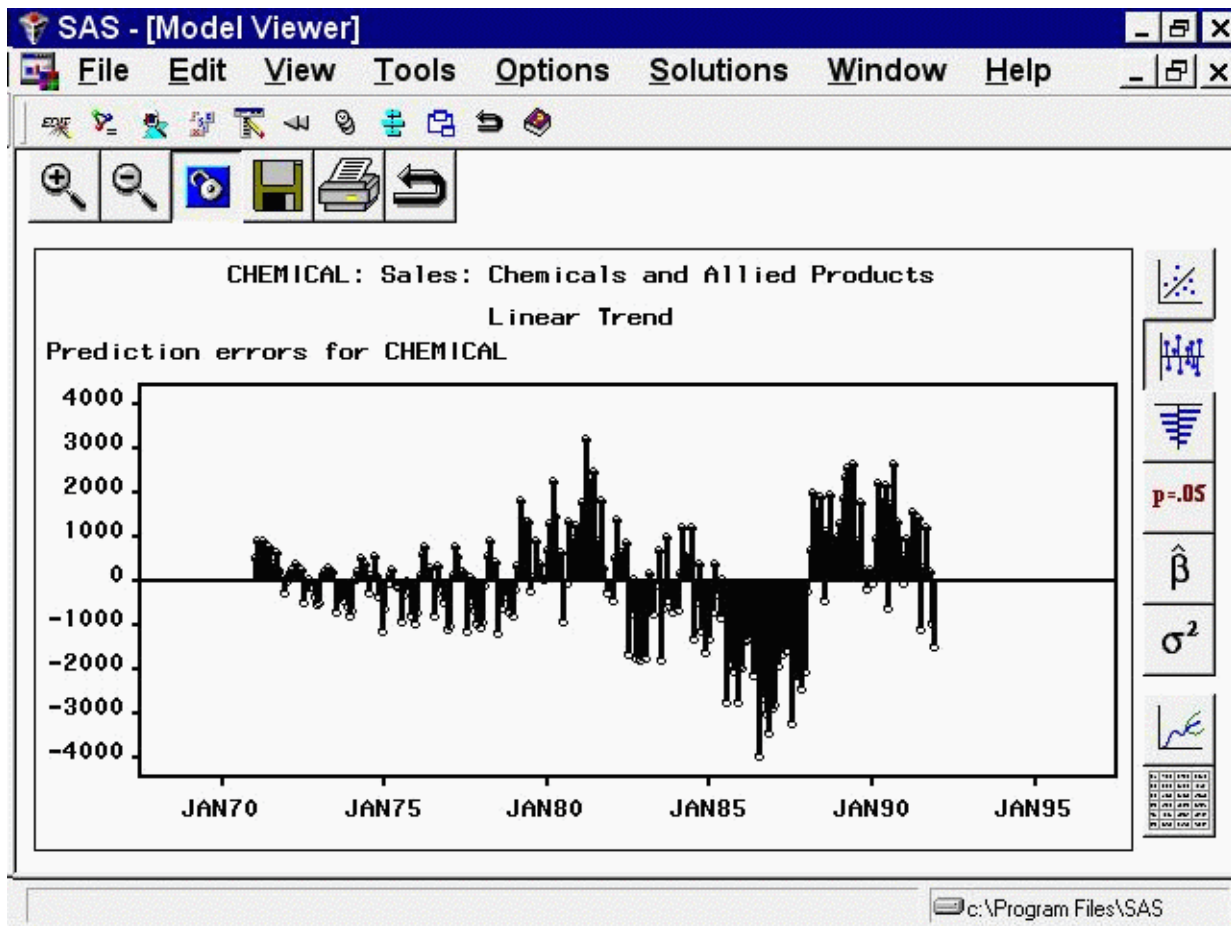

Figure 45.39 Model Viewer: Actual and Predicted Values Plot

This graph shows the linear trend line representing the model predicted values together with a plot of the actual data values, which fluctuate about the trend line.

Prediction Error Plots

Select the second icon from the top in the vertical toolbar in the Model Viewer window. This switches the Viewer to display a plot of the model prediction errors (actual data values minus the predicted values), as shown in Figure 45.40.

Figure 45.40 Model Viewer: Prediction Errors Plot

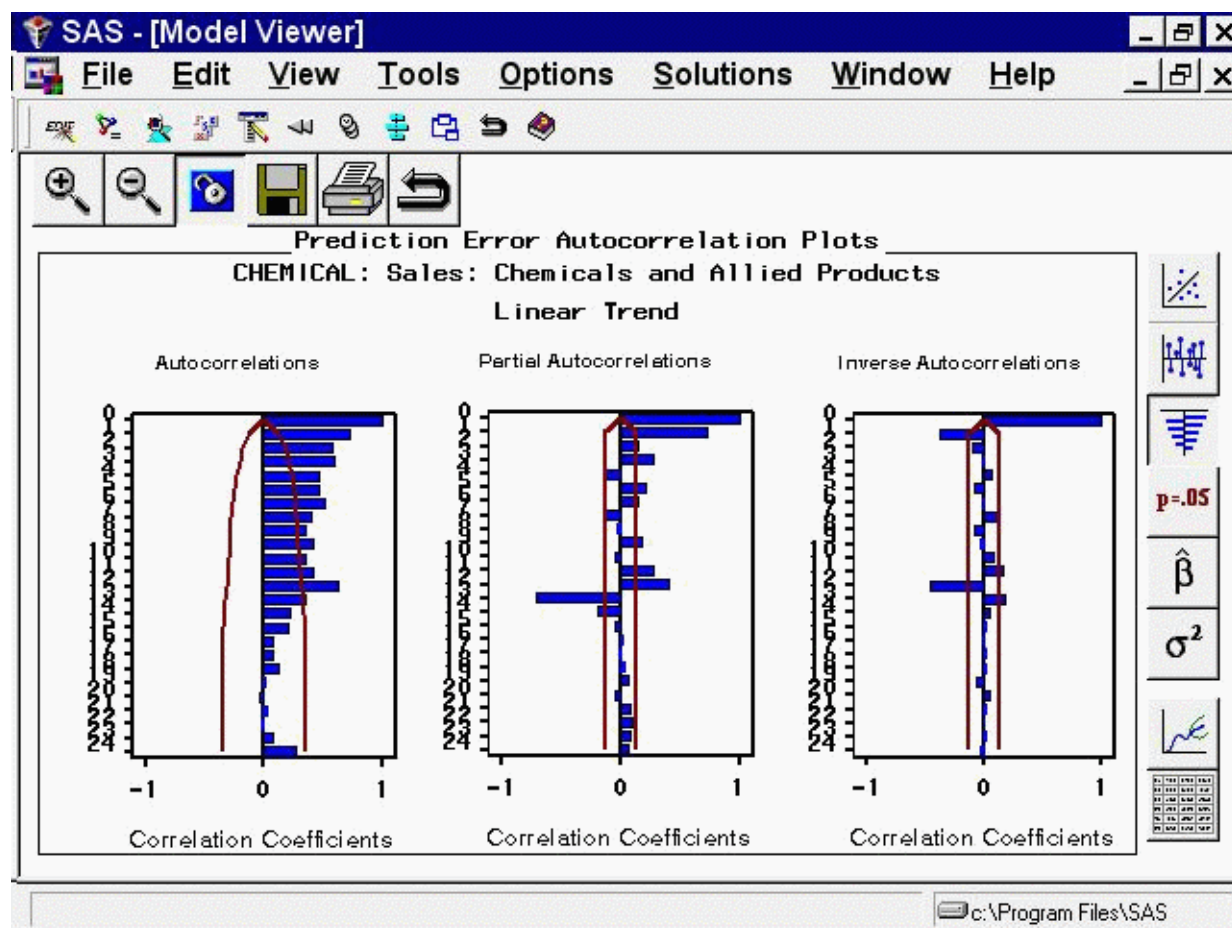

If the model being viewed includes a transformation, prediction errors are defined as the difference between the transformed series actual values and model predictions. You can choose to graph instead the difference between the untransformed series values and untransformed model predictions, which are called *model residuals*. You can also graph normalized prediction errors or normalized model residuals. Use the Residual Plot Options submenu under the Options menu.

Autocorrelation Plots

Select the third icon from the top in the vertical toolbar. This switches the Viewer to display a plot of autocorrelations of the model prediction errors at different lags, as shown in Figure 45.41. Autocorrelations, partial autocorrelations, and inverse autocorrelations are displayed, with lines overlaid at plus and minus two standard errors. You can switch the graphs so that the bars represent significance probabilities by selecting the Correlation Probabilities item on the toolbar or from the View menu. For more information about the meaning and use of autocorrelation plots, see Chapter 7, “The ARIMA Procedure.”

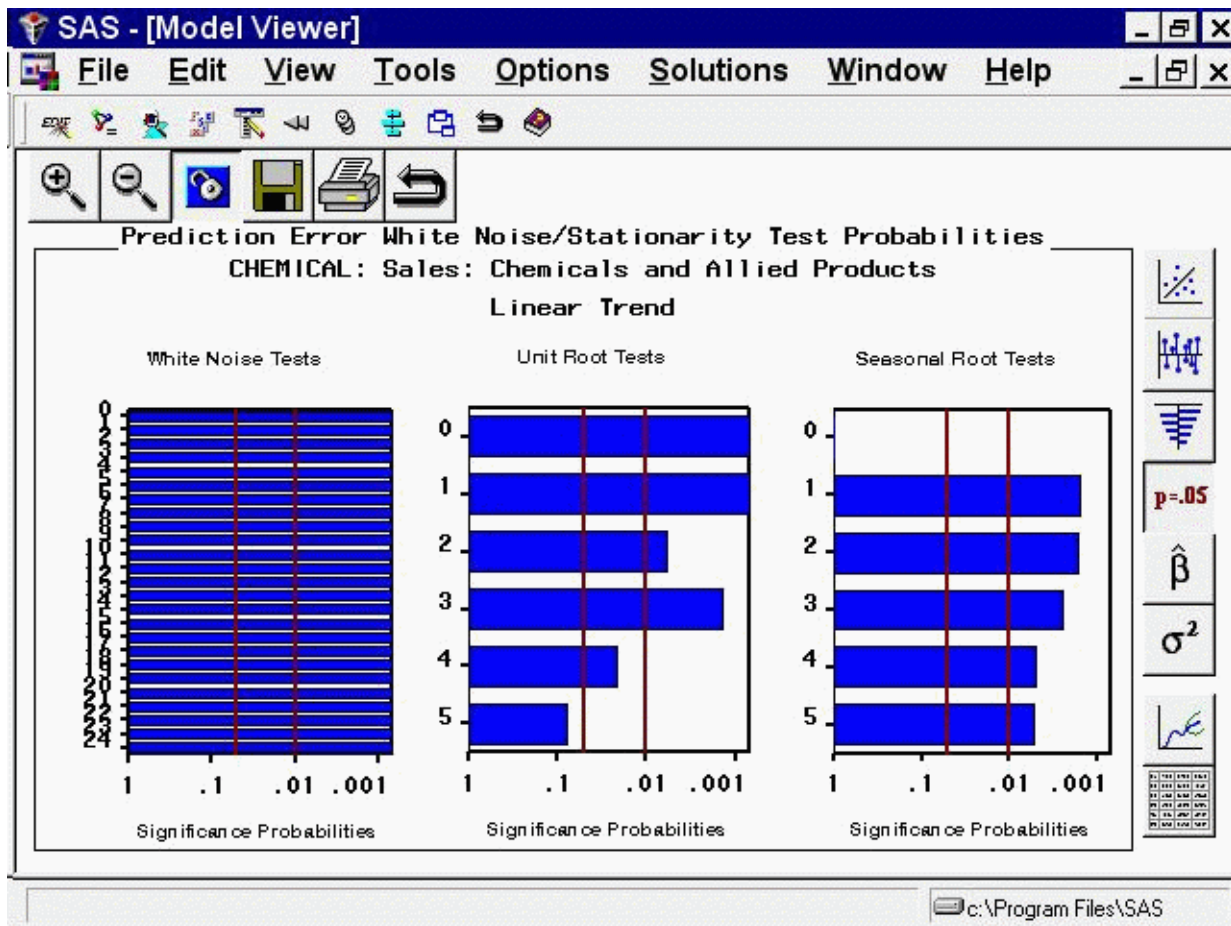

Figure 45.41 Model Viewer: Autocorrelations Plot

White Noise and Stationarity Plots

Select the fourth icon from the top in the vertical toolbar. This switches the Viewer to display a plot of white noise and stationarity tests on the model prediction errors, as shown in Figure 45.42.

Figure 45.42 Model Viewer: White Noise and Stationarity Plot

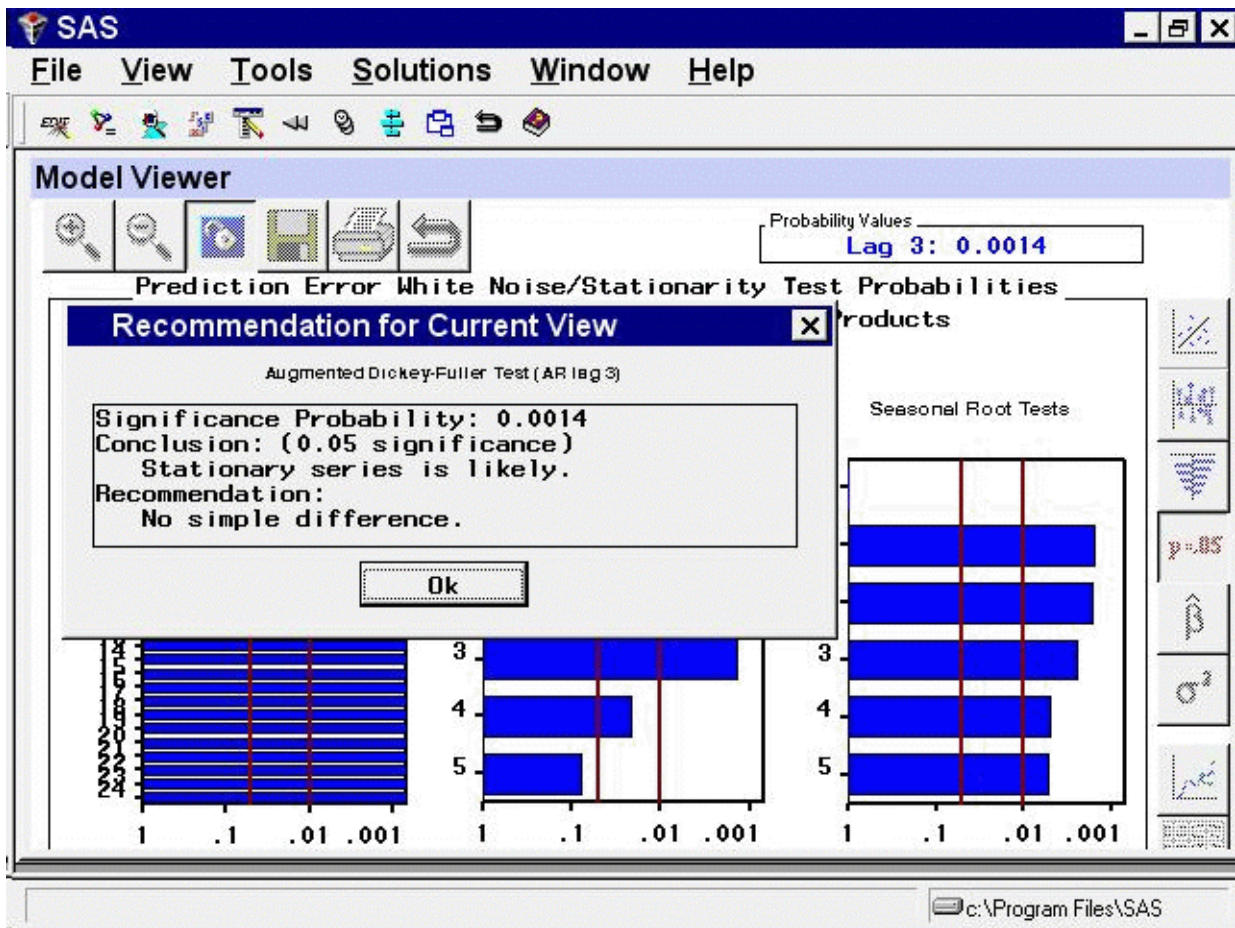

The white noise test bar chart shows significance probabilities of the Ljung-Box chi square statistic. Each bar shows the probability computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the prediction errors represent white noise. In this example, they are all significant beyond the 0.001 probability level, so that you reject the null hypothesis. In other words, the high level of significance at all lags makes it clear that the linear trend model is inadequate for this series.

The second bar chart shows significance probabilities of the augmented Dickey-Fuller test for unit roots. For example, the bar at lag three indicates a probability of 0.0014, so that you reject the null hypothesis that the series is nonstationary. The third bar chart is similar to the second except that it represents the seasonal lags. Since this series has a yearly seasonal cycle, the bars represent yearly intervals.

You can select any of the bars to display an interpretation. Select the fourth bar of the middle chart. This displays the *Recommendation for Current View*, as shown in Figure 45.43. This window gives an interpretation of the test represented by the bar that was selected; it is significant, therefore a stationary series is likely. It also gives a recommendation: You do not need to perform a simple difference to make the series stationary.

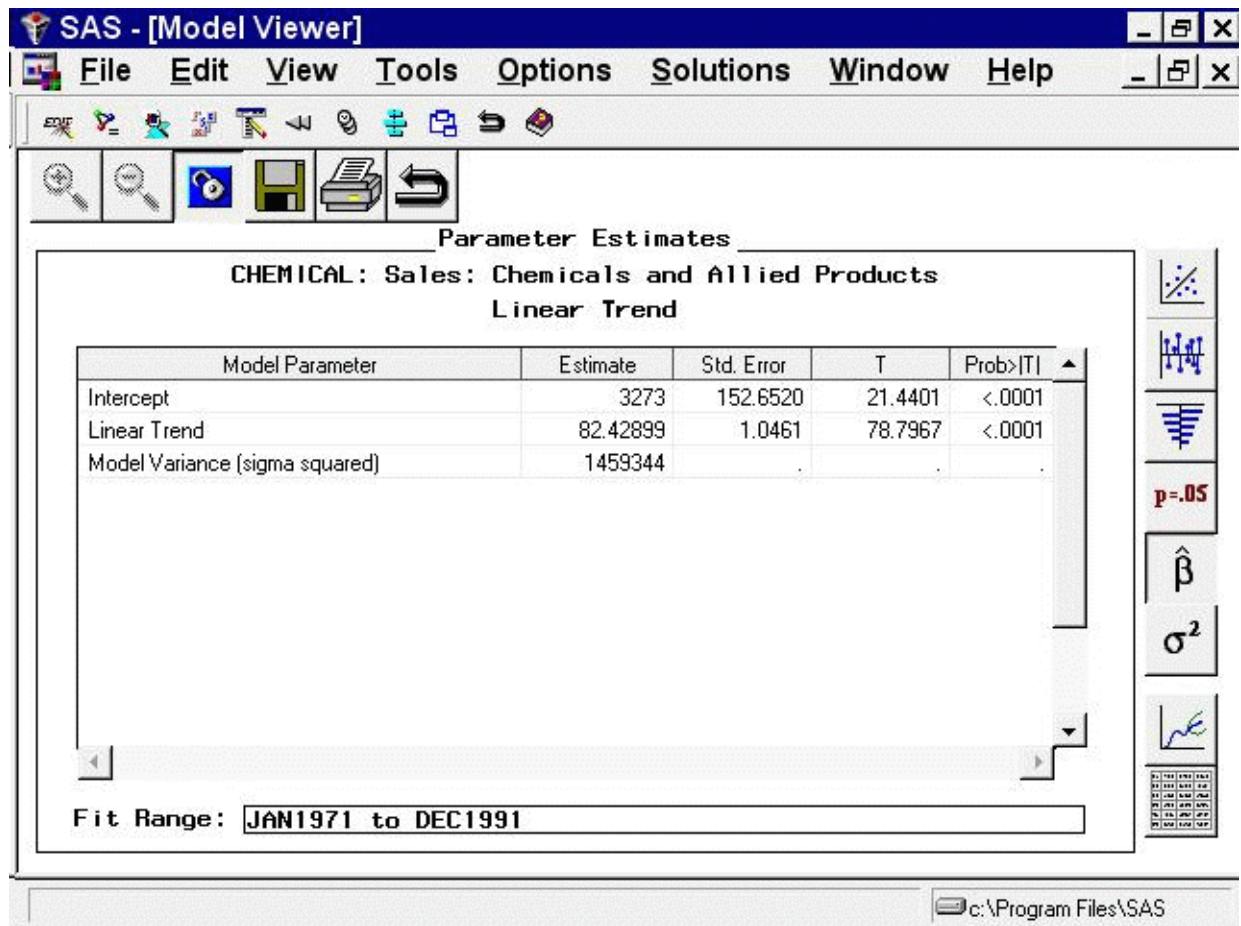

Figure 45.43 Model Viewer: Recommendation for Current View

Parameter Estimates Table

Select the fifth icon from the top in the vertical toolbar to the right of the graph. This switches the Viewer to display a table of parameter estimates for the fitted model, as shown in Figure 45.44.

Figure 45.44 Model Viewer: Parameter Estimates Table

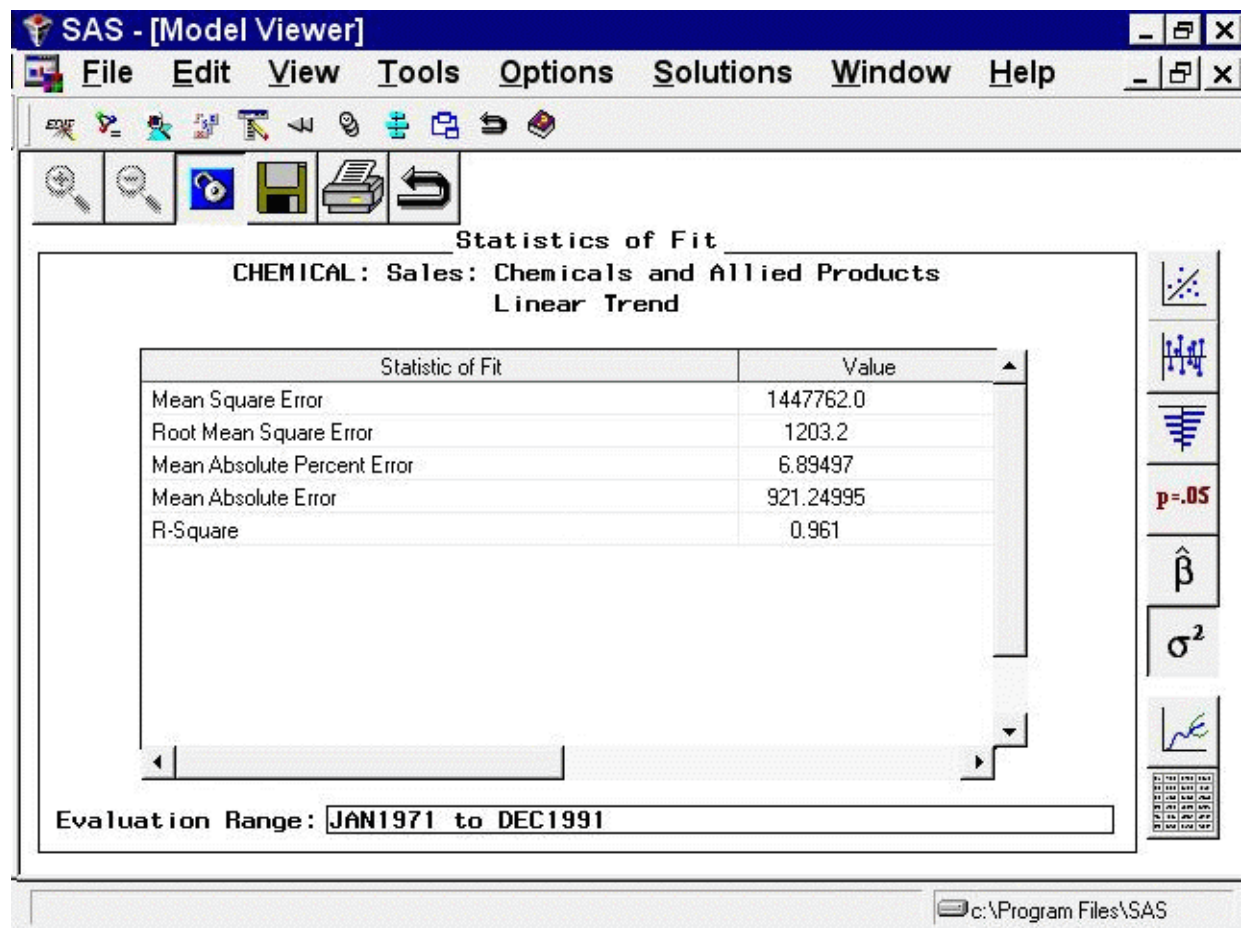

For the linear trend model, the parameters are the intercept and slope coefficients. The table shows the values of the fitted coefficients together with standard errors and t tests for the statistical significance of the estimates. The model residual variance is also shown.

Statistics of Fit Table

Select the sixth icon from the top in the vertical toolbar to the right of the table. This switches the Viewer to display a table of statistics of fit computed from the model prediction errors, as shown in Figure 45.45. The list of statistics displayed is controlled by selecting *Statistics of Fit* from the Options menu.

Figure 45.45 Model Viewer: Statistics of Fit Table

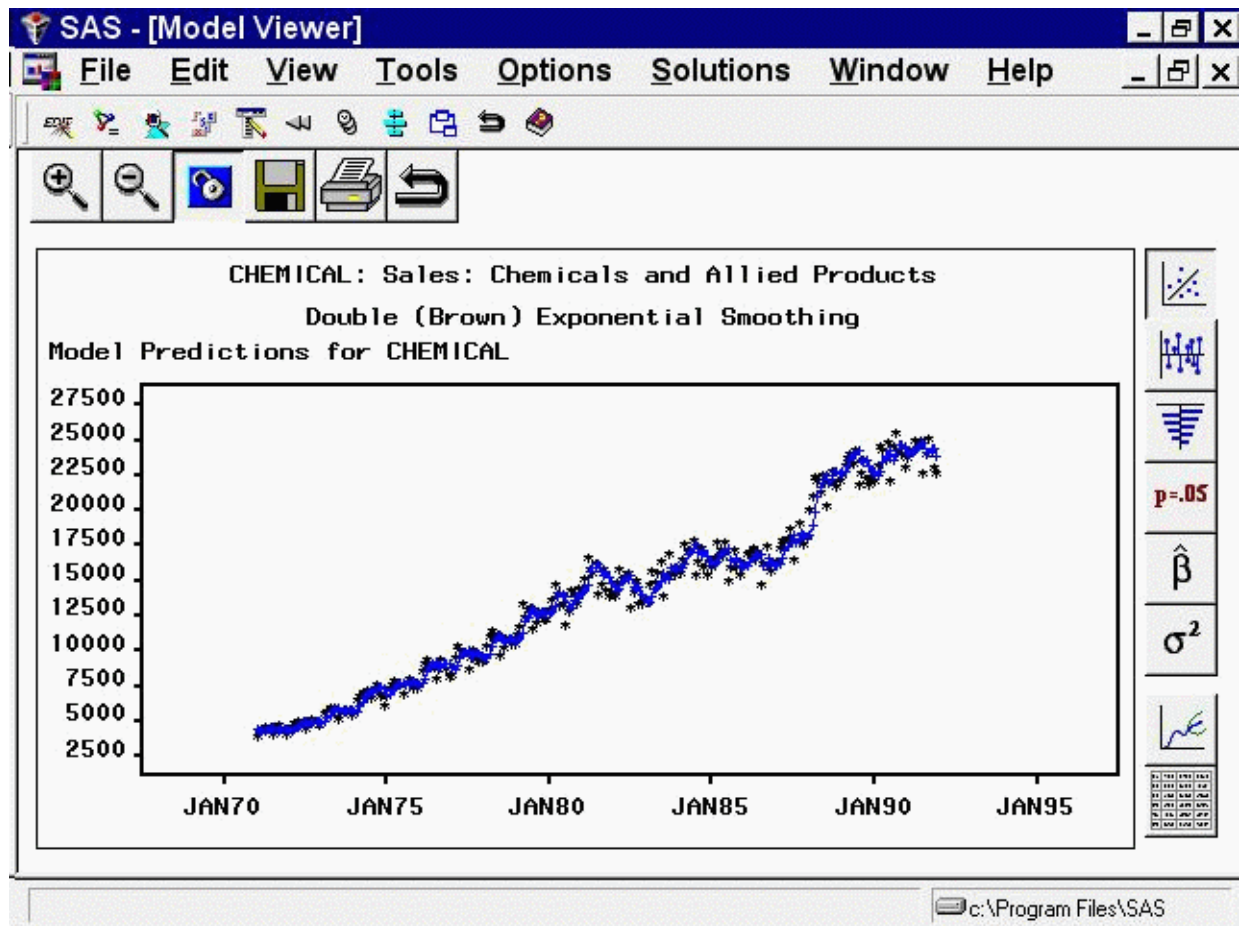

Changing to a Different Model

Select the first icon in the vertical toolbar to the right of the table to return the display to the predicted and actual values plots (Figure 45.39).

Now return to the Develop Models window, but do not close the Model Viewer window. You can use the Next Viewer icon in the toolbar or your system's window manager controls to switch windows. You can resize the windows to make them both visible.

Select the Double Exponential Smoothing model so that this line of the model list is highlighted. The Model Viewer window is now updated to display a plot of the predicted values for the Double Exponential Smoothing model, as shown in Figure 45.46. The Model Viewer is automatically updated to display the currently selected model, unless you specify `Unlink` (the third icon in the window's horizontal toolbar).

Figure 45.46 Model Viewer Plot for Exponential Smoothing Model

Forecasts and Confidence Limits Plots

Select the seventh icon from the top in the vertical toolbar to the right of the graph. This switches the Viewer to display a plot of forecast values and confidence limits, together with actual values and one-step-ahead within-sample predictions, as shown in Figure 45.47.

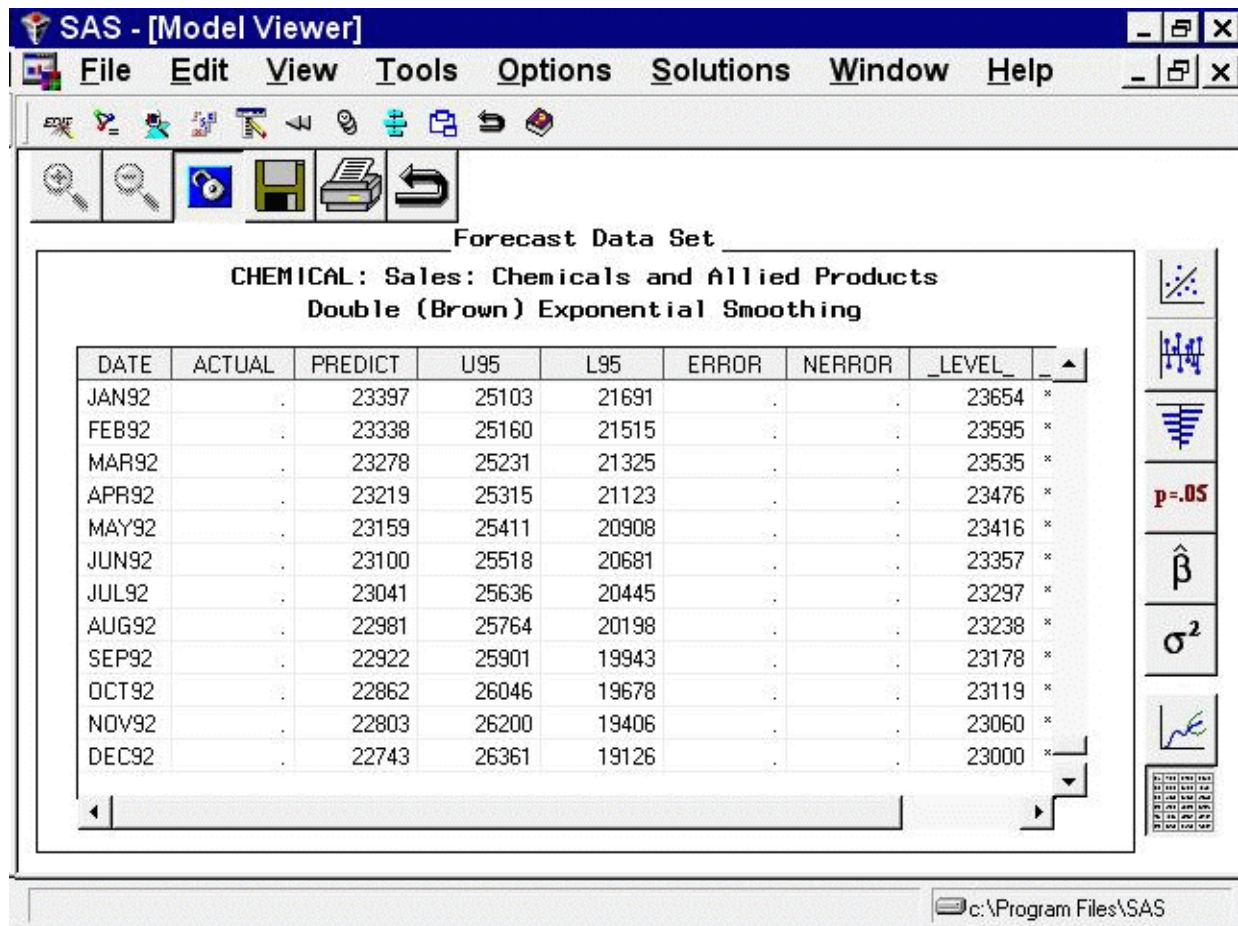

Figure 45.47 Model Viewer: Forecasts and Confidence Limits

Data Table

Select the last icon at the bottom of the vertical toolbar to the right of the graph. This switches the Viewer to display the forecast data set as a table, as shown in Figure 45.48.

Figure 45.48 Model Viewer: Forecast Data Table

To view the full data set, use the vertical and horizontal scroll bars on the data table or enlarge the window.

Closing the Model Viewer

Other features of the Model Viewer and Develop Models window are discussed later in this book. For now, close the Model Viewer window and return to the Time Series Forecasting window.

To close the Model Viewer window, select **Close** from the window's horizontal toolbar or from the File menu.

Chapter 46

Creating Time ID Variables

Contents

Creating a Time ID Value from a Starting Date and Frequency	3075
Using Observation Numbers as the Time ID	3079
Creating a Time ID from Other Dating Variables	3083

The Forecasting System requires that the input data set contain a time ID variable. If the data you want to forecast are not in this form, you can use features of the Forecasting System to help you add time ID variables to your data set. This chapter shows examples of how to use these features.

Creating a Time ID Value from a Starting Date and Frequency

As a first example of adding a time ID variable, use the SAS data set created by the following statements. (Or use your own data set if you prefer.)

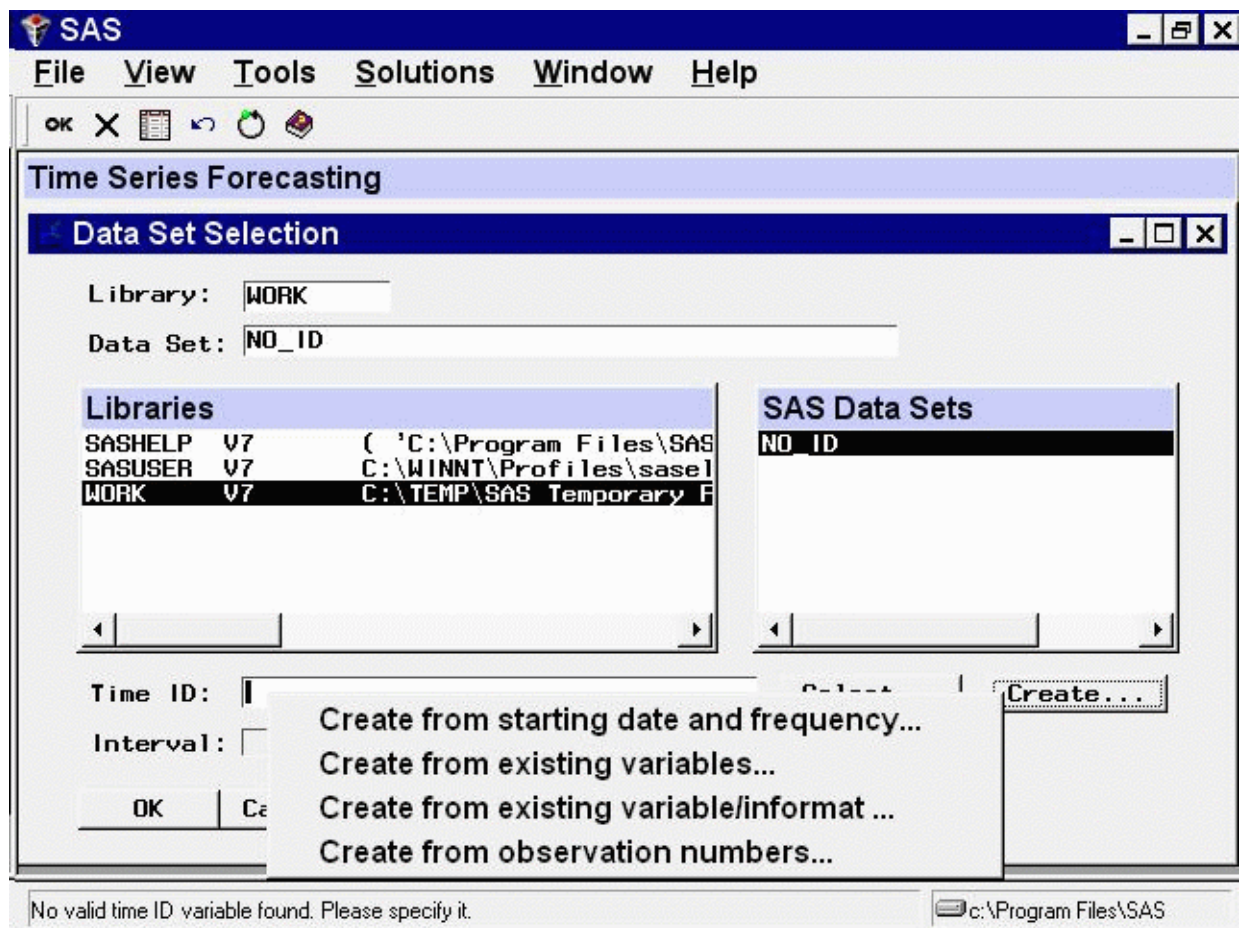

```
data no_id;
  input y @@;
datalines;
  10 15 20 25 30 35 40 45
  50 55 60 65 70 75 80 85
run;
```

Submit these SAS statements to create the data set NO_ID. This data set contains the single variable Y. Assume that Y is a quarterly series and starts in the first quarter of 1991.

In the Time Series Forecasting window, use the Browse button to the right of the Data set field to bring up the Data Set Selection window. Select the WORK library, and then select the NO_ID data set.

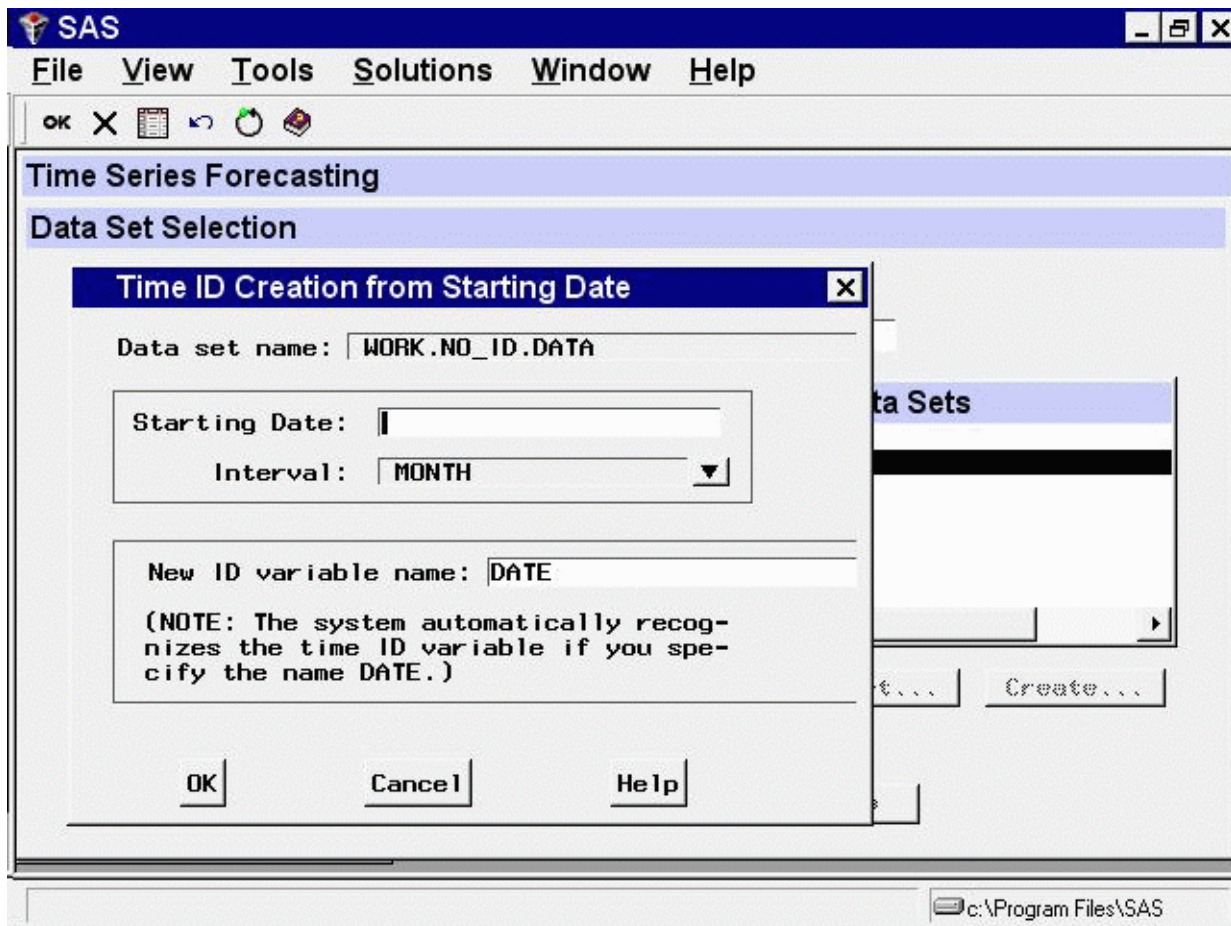

You must create a time ID variable for the data set. Click the Create button to the right of the Time ID field. This opens a menu of choices for creating the Time ID variable, as shown in [Figure 46.1](#).

Figure 46.1 Time ID Creation Popup Menu

Select the first choice, Create from starting date and frequency. This opens the Time ID Creation from Starting Date window shown in Figure 46.2.

Figure 46.2 Time ID Creation from Starting Date Window

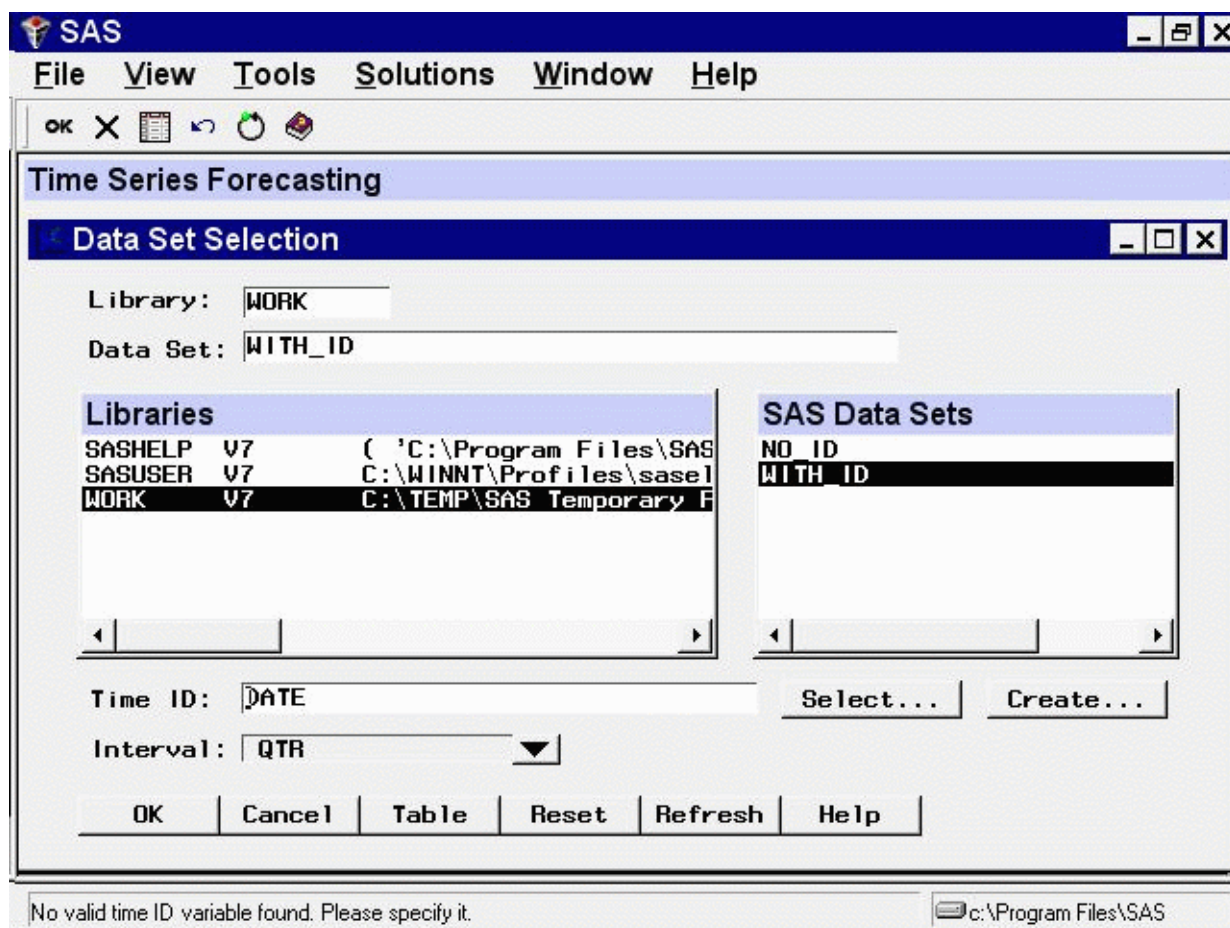

Enter the starting date, 1991:1, in the *Starting Date* field.

Select the *Interval* list arrow and select QTR. The Interval value QTR means that the time interval between successive observations is a quarter of a year; that is, the data frequency is quarterly.

Now select the OK button. The system prompts you for the name of the new data set. If you want to create a new copy of the input data set with the DATE variable added, enter a name for the new data set. If you want to replace the NO_ID data set with the new copy containing DATE, just select the OK button without changing the name.

For this example, change the *New name* field to WITH_ID and select the OK button. The data set WITH_ID is created containing the series Y from NO_ID and the added ID variable DATE. The system returns to the Data Set Selection window, which now appears as shown in [Figure 46.3](#).

Figure 46.3 Data Set Selection Window after Creating Time ID

Select the **Table** button to see the new data set **WITH_ID**. This opens a **VIEWTABLE** window for the data set **WITH_ID**, as shown in [Figure 46.4](#). Select **File** and **Close** to close the **VIEWTABLE** window.

Figure 46.4 Viewtable Display of Data Set with Time ID Added

	DATE	y
1	1991:1	10
2	1991:2	15
3	1991:3	20
4	1991:4	25
5	1992:1	30
6	1992:2	35
7	1992:3	40
8	1992:4	45
9	1993:1	50
10	1993:2	55
11	1993:3	60
12	1993:4	65
13	1994:1	70
14	1994:2	75
15	1994:3	80
16	1994:4	85

NOTE: Table has been opened in browse mode.

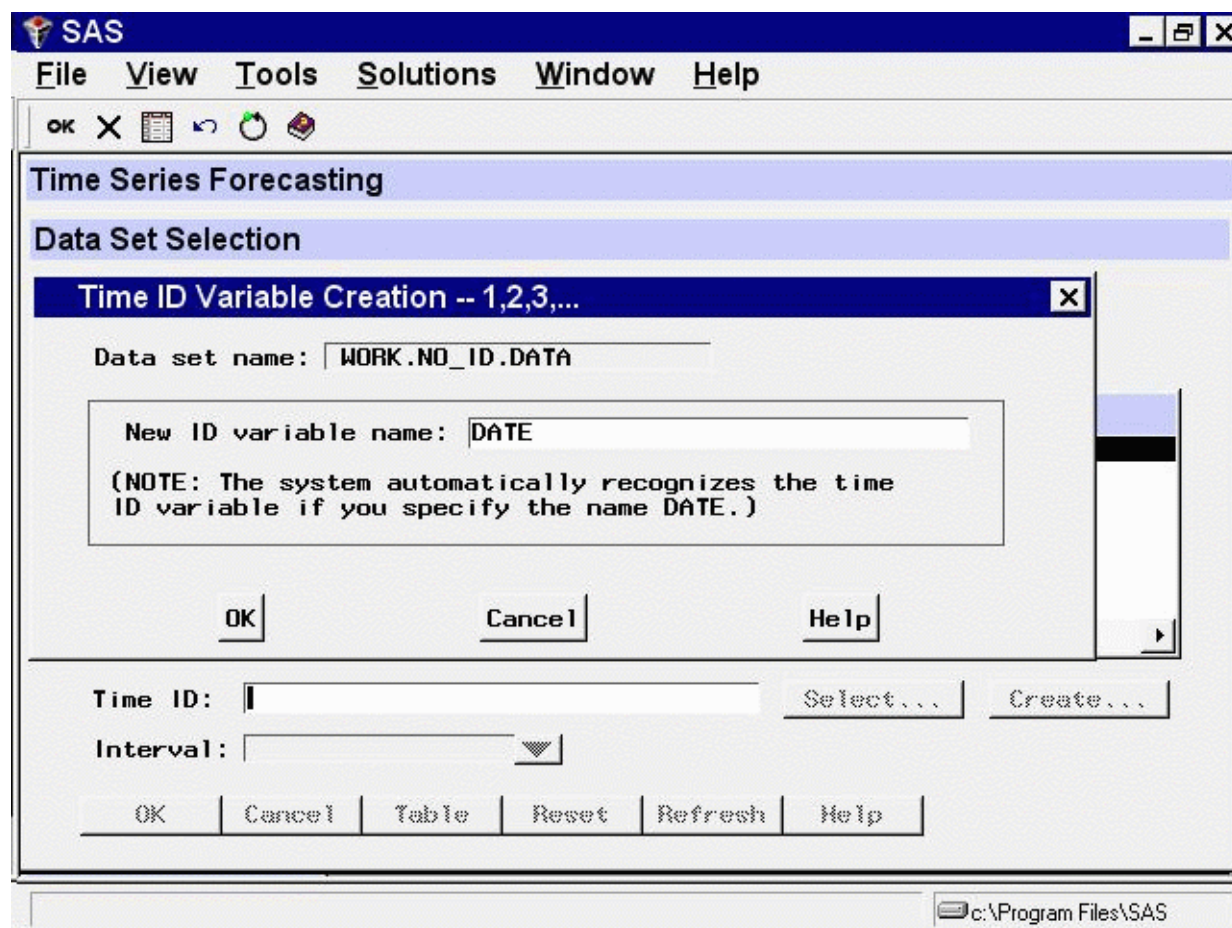

c:\Program Files\SAS

Using Observation Numbers as the Time ID

Normally, the time ID variable contains date values. If you do not want to have dates associated with your forecasts, you can also use observation numbers as time ID variables. However, you still must have an ID variable. This can be illustrated by adding an observation index time ID variable to the data set NO_ID.

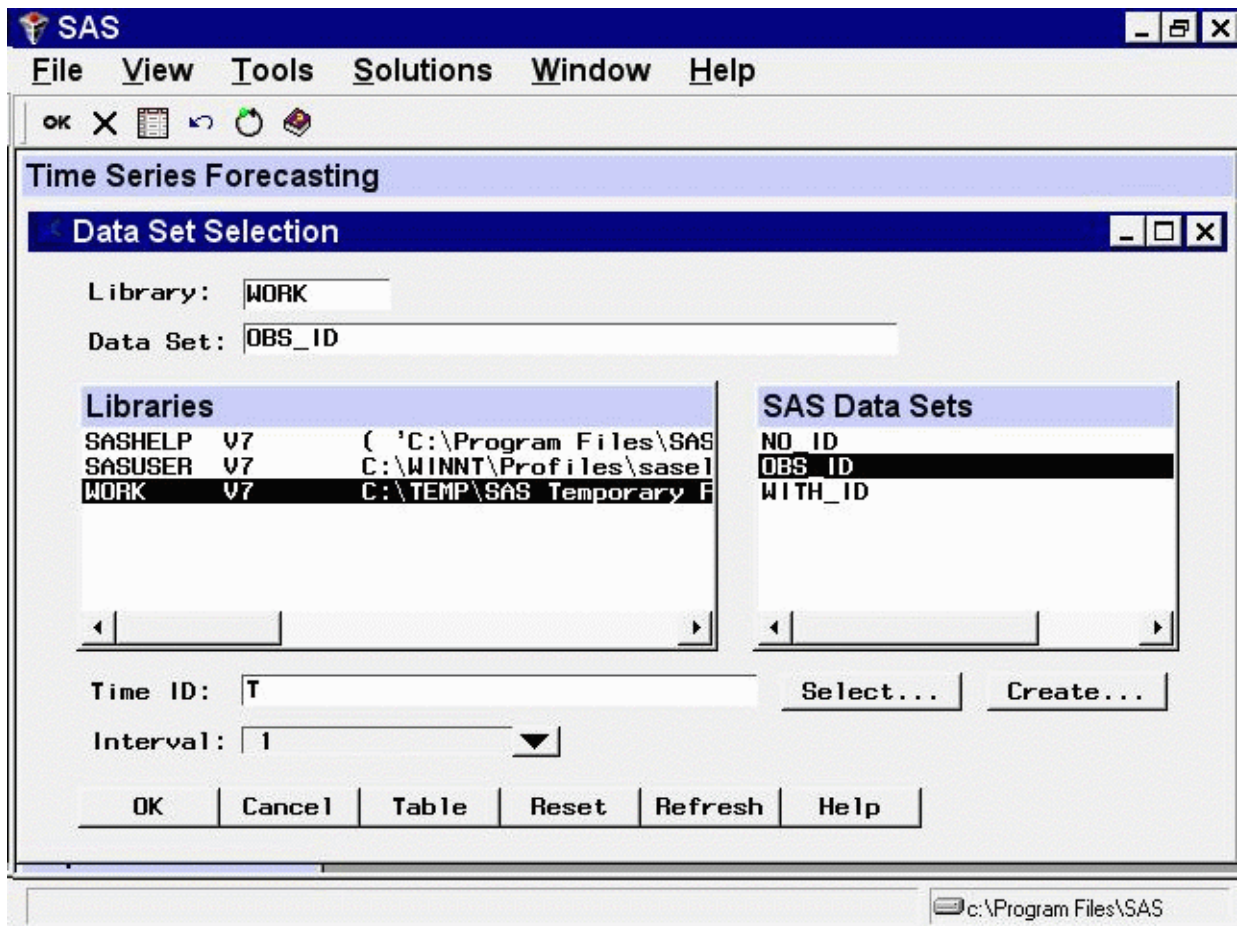

In the Data Set Selection window, select the data set NO_ID again. Select the Create button to the right of the Time ID field. Select the fourth choice, Create from observation numbers. This opens the Time ID Variable Creation window shown in [Figure 46.5](#).

Figure 46.5 Create Time ID Variable Window

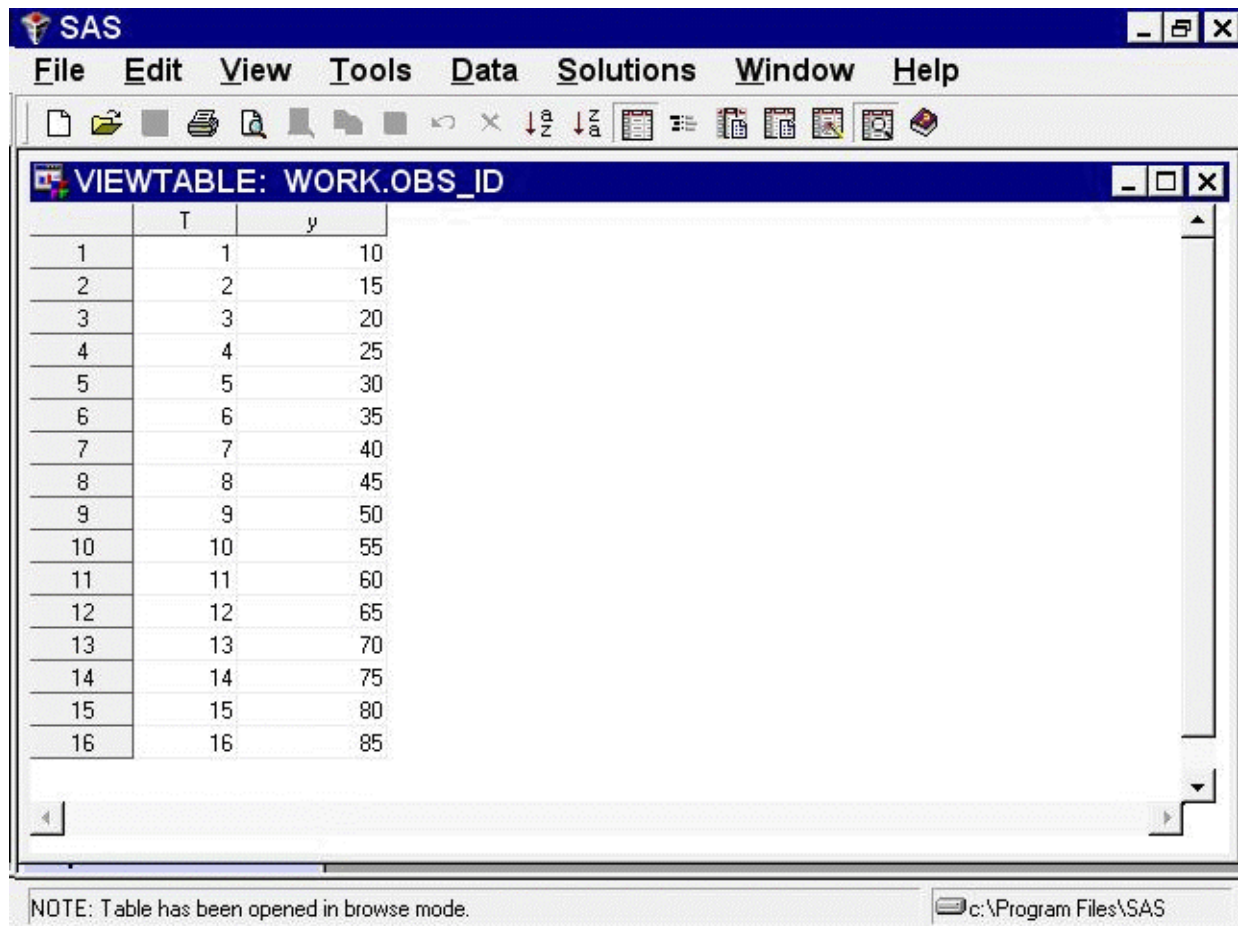

Select the OK button. This opens the New Data Set Name window. Enter “OBS_ID” in the New data set name field. Enter “T” in the New ID variable name field.

Now select the OK button. The new data set OBS_ID is created, and the system returns to the Data Set Selection window, which now appears as shown in [Figure 46.6](#).

Figure 46.6 Data Set Selection Window after Creating Time ID

The `Interval` field for `OBS_ID` has the value '1'. This means that the values of the time ID variable `T` increment by one between successive observations.

Select the `Table` button to look at the `OBS_ID` data set, as shown in [Figure 46.7](#).

Figure 46.7 VIEWTABLE of Data Set with Observation Index ID

The screenshot shows the SAS VIEWTABLE window for the dataset WORK.OBS_ID. The window displays a table with two columns: T (Time Index) and y (Value). The table contains 16 rows of data, with T values ranging from 1 to 16 and y values ranging from 10 to 85. The window title is 'VIEWTABLE: WORK.OBS_ID'. The SAS menu bar and toolbar are visible at the top.

	T	y
1	1	10
2	2	15
3	3	20
4	4	25
5	5	30
6	6	35
7	7	40
8	8	45
9	9	50
10	10	55
11	11	60
12	12	65
13	13	70
14	14	75
15	15	80
16	16	85

NOTE: Table has been opened in browse mode.

c:\Program Files\SAS

Select **File** and **Close** to close the VIEWTABLE window. Select the **OK** button from the Data Set Selection window to return to the Time Series Forecasting window.

Creating a Time ID from Other Dating Variables

Your data set might contain ID variables that date the observations in a different way than the SAS date valued ID variable expected by the forecasting system. For example, for monthly data, the data set might contain the ID variables YEAR and MONTH, which together date the observations.

In these cases, you can use the Forecasting System's Create Time ID features to compute a time ID variable with SAS date values from the existing dating variables. As an example of this, use the SAS data set read in by the following SAS statements:

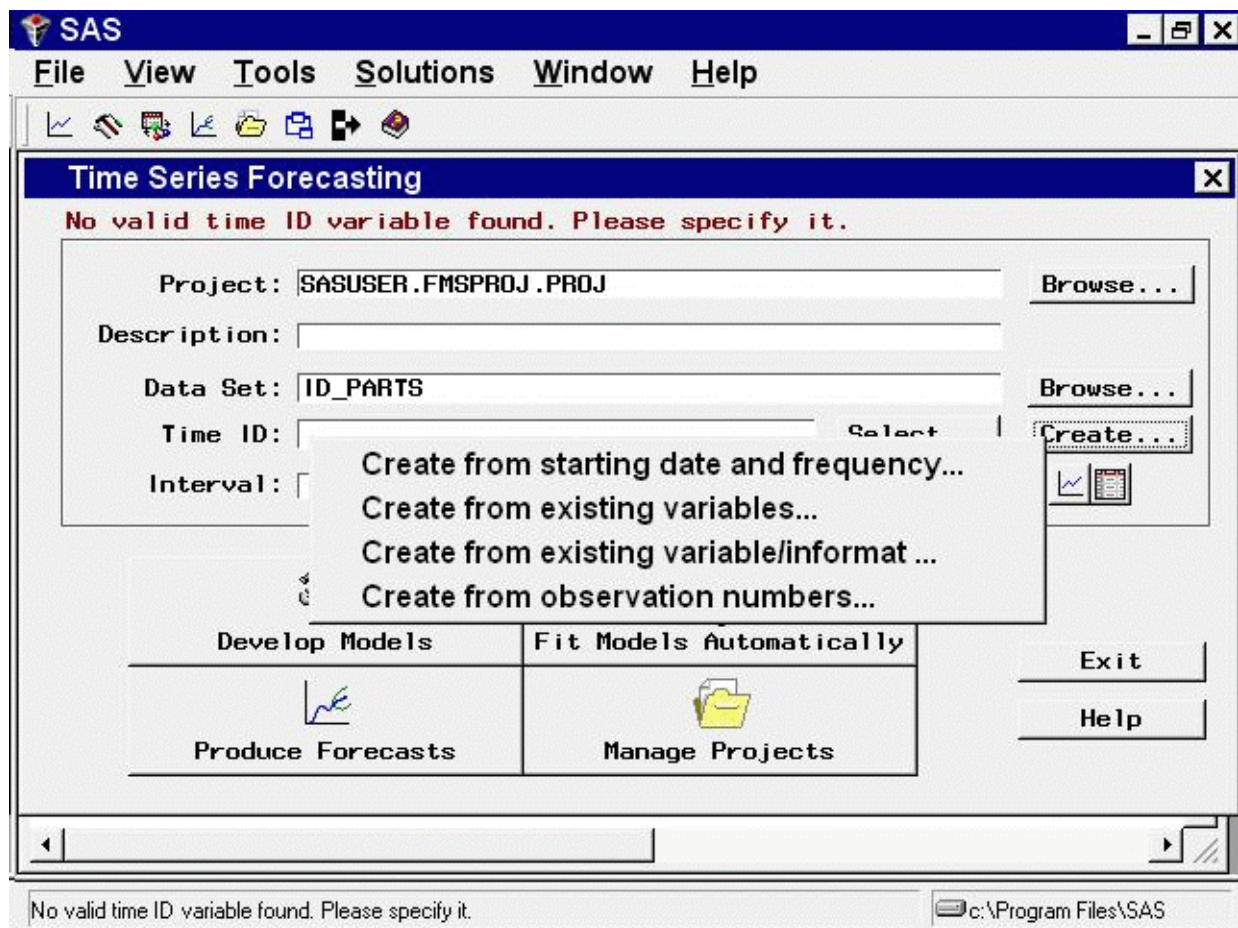

```
data id_parts;
    input yr qtr y;
datalines;
91 1 10
91 2 15
91 3 20
91 4 25
92 1 30
92 2 35
92 3 40
92 4 45
93 1 50
93 2 55
93 3 60
93 4 65
94 1 70
94 2 75
94 3 80
94 4 85
run;
```

Submit these SAS statements to create the data set ID_PARTS. This data set contains the three variables YR, QTR, and Y. YR and QTR are ID variables that together date the observations, but each variable provides only part of the date information. Because the forecasting system requires a single dating variable containing SAS date values, you need to combine YR and QTR to create a single variable DATE.

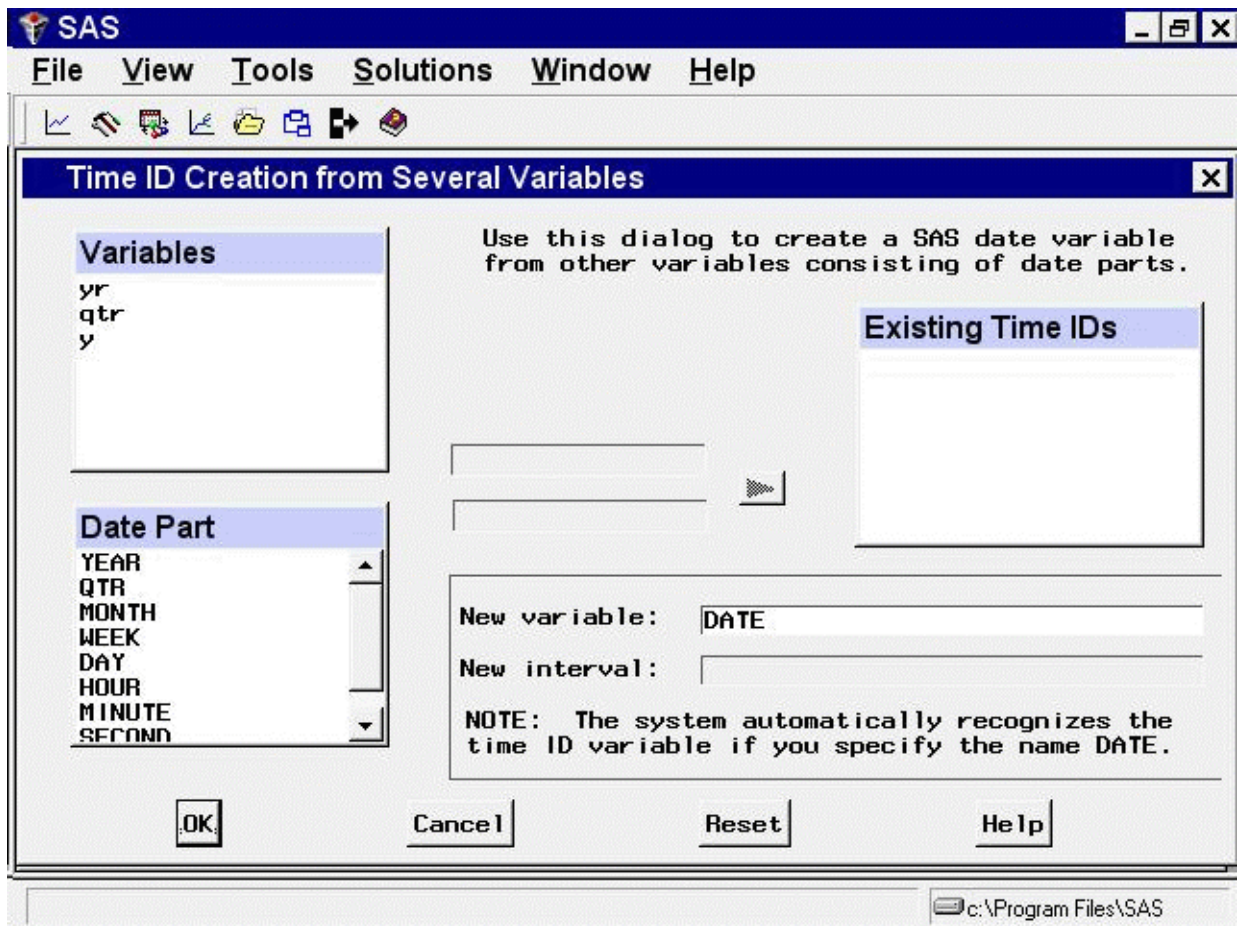

Type "ID_PARTS" in the *Data Set* field and press the ENTER key. (You could also use the Browse button to open the Data Set Selection window, as in the previous example, and complete this example from there.)

Select the Create button at the right of the *Time ID* field. This opens the menu of Create Time ID choices, as shown in [Figure 46.8](#).

Figure 46.8 Adding a Time ID Variable

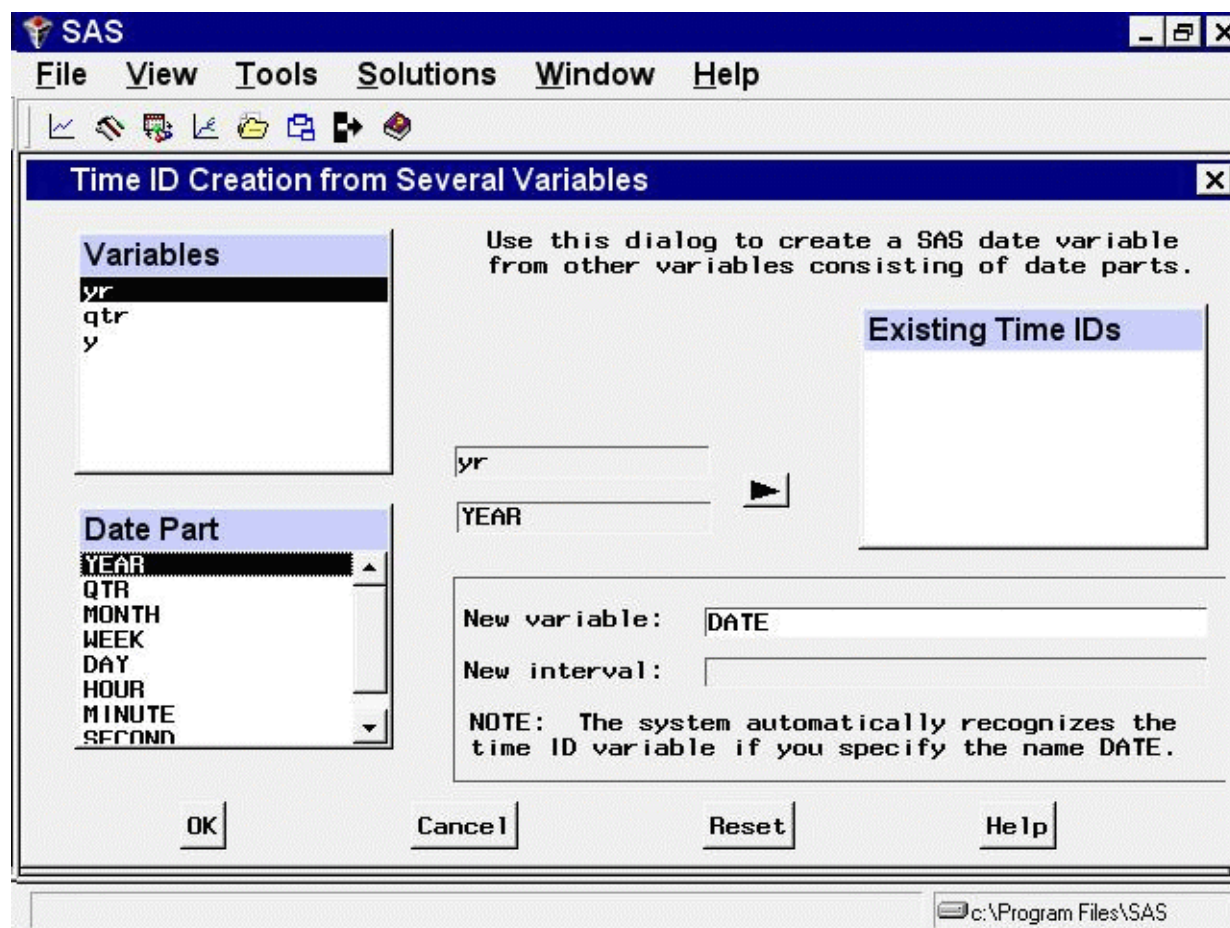

Select the second choice, `Create from existing variables`. This opens the window shown in Figure 46.9.

Figure 46.9 Creating a Time ID Variable from Date Parts

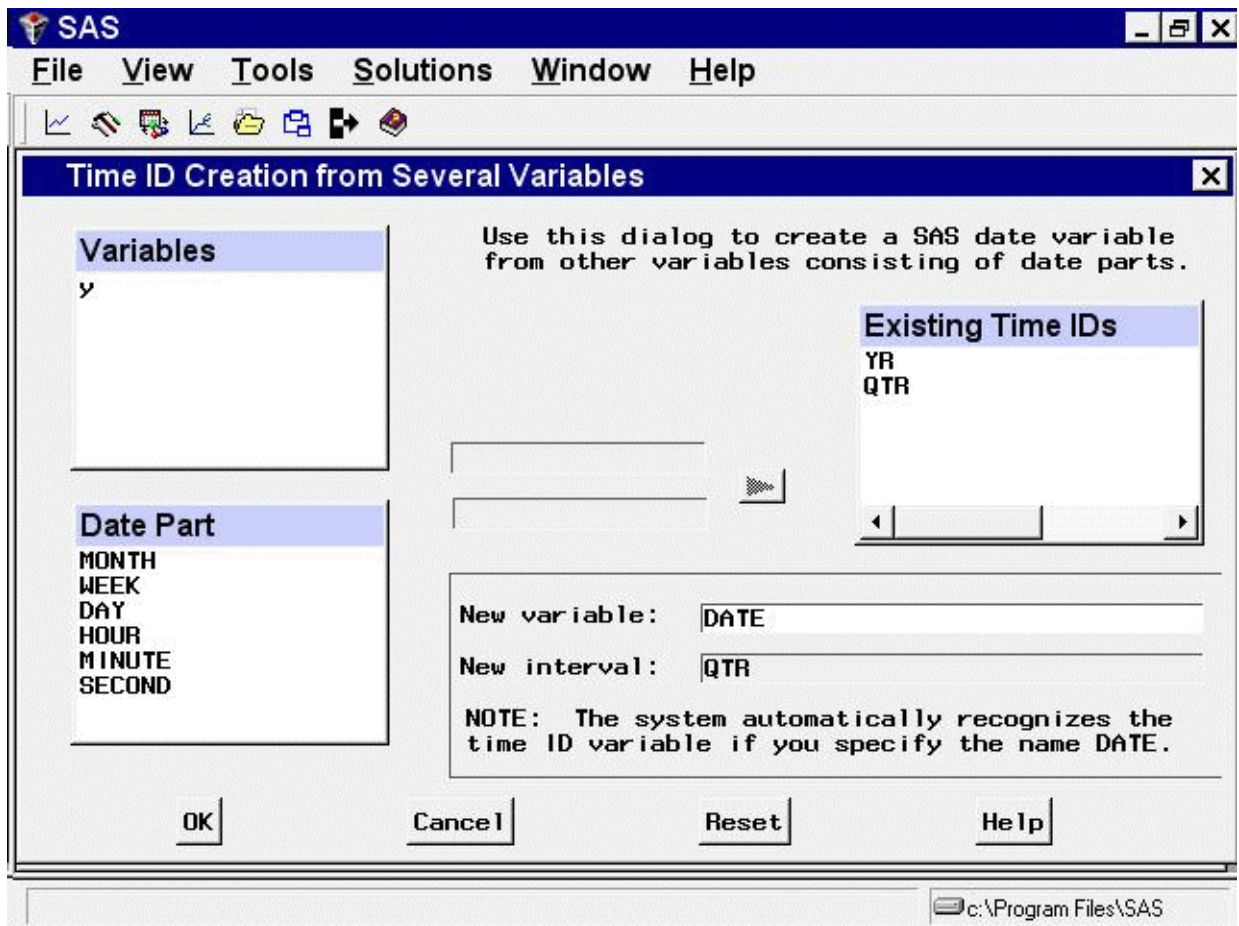

In the `Variables` list, select `YR`. In the `Date Part` list, select `YEAR` as shown in [Figure 46.10](#).

Figure 46.10 Specifying the ID Variable for Years

Now click the right-pointing arrow button. The variable YR and the part code YEAR are added to the Existing Time IDs list.

Next select QTR from the Variables list, select QTR from the Date Part list, and click the arrow button. This adds the variable QTR and the part code QTR to the Existing Time IDs list, as shown in Figure 46.11.

Figure 46.11 Creating a Time ID Variable from Date Parts

Now select the **OK** button. This opens the **New Data Set Name** window. Change the **New data set name** field to **NEWDATE**, and then select the **OK** button.

The data set **NEWDATE** is created, and the system returns to the **Time Series Forecasting** window with **NEWDATE** as the selected Data Set. The **Time ID** field is set to **DATE**, and the **Interval** field is set to **QTR**.

Incorporating Forecasts from Other Sources	3121

This chapter explores the tools available through the Develop Models window for investigating the properties of time series and for specifying and fitting models. The first section shows you how to diagnose time series properties in order to determine the class of models appropriate for forecasting series with such properties. Later sections show you how to specify and fit different kinds of forecasting models.

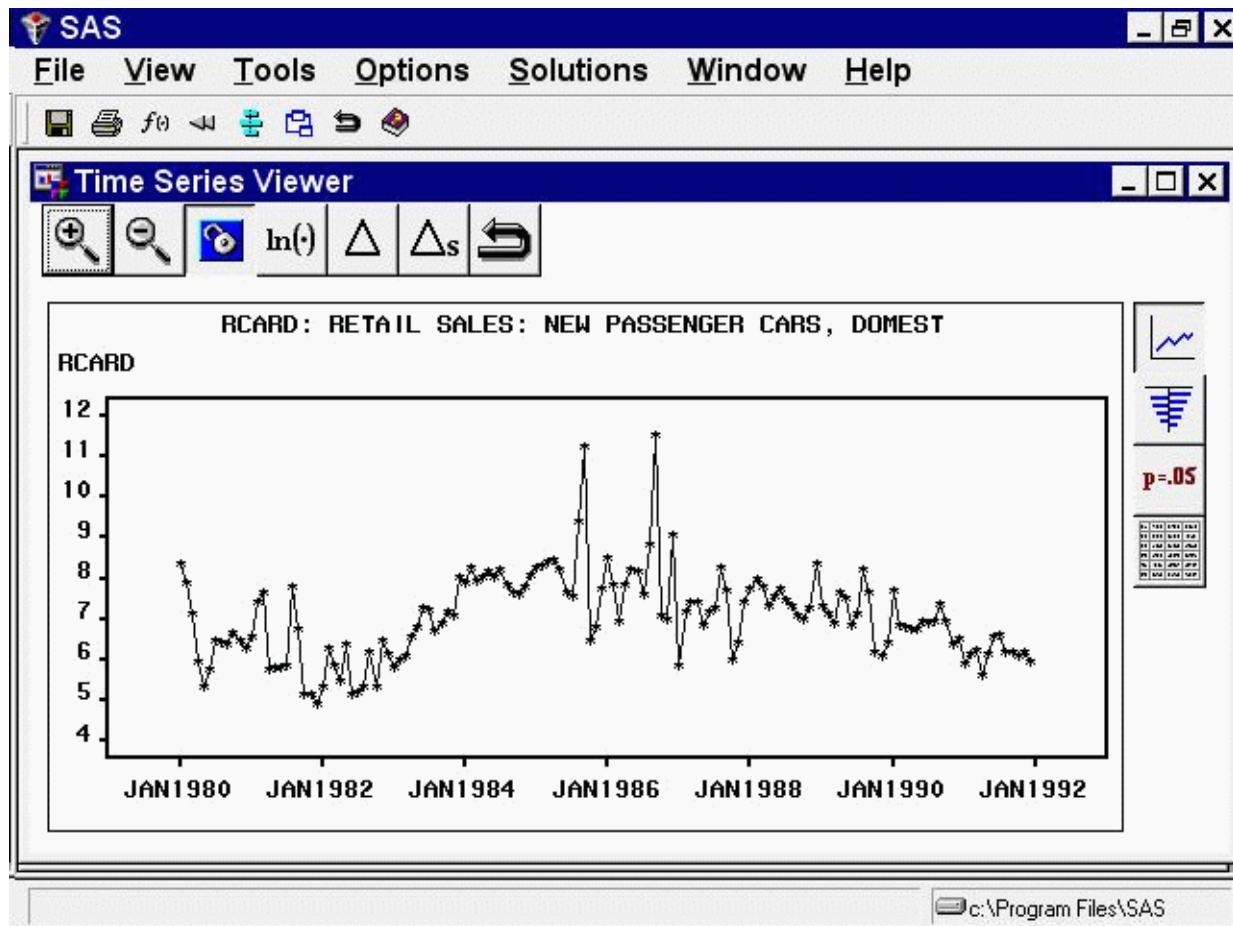

Series Diagnostics

The series diagnostics tool helps you determine the kinds of forecasting models that are appropriate for the data series so that you can limit the search for the best forecasting model. The series diagnostics address these three questions: Is a log transformation needed to stabilize the variance? Is a time trend present in the data? Is there a seasonal pattern to the data?

The automatic model fitting process, which you used in the previous chapter through the Automatic Model Fitting window, performs series diagnostics and selects trial models from a list according to the results. You can also look at the diagnostic information and make your own decisions as to the kinds of models appropriate for the series. The following example illustrates the series diagnostics features.

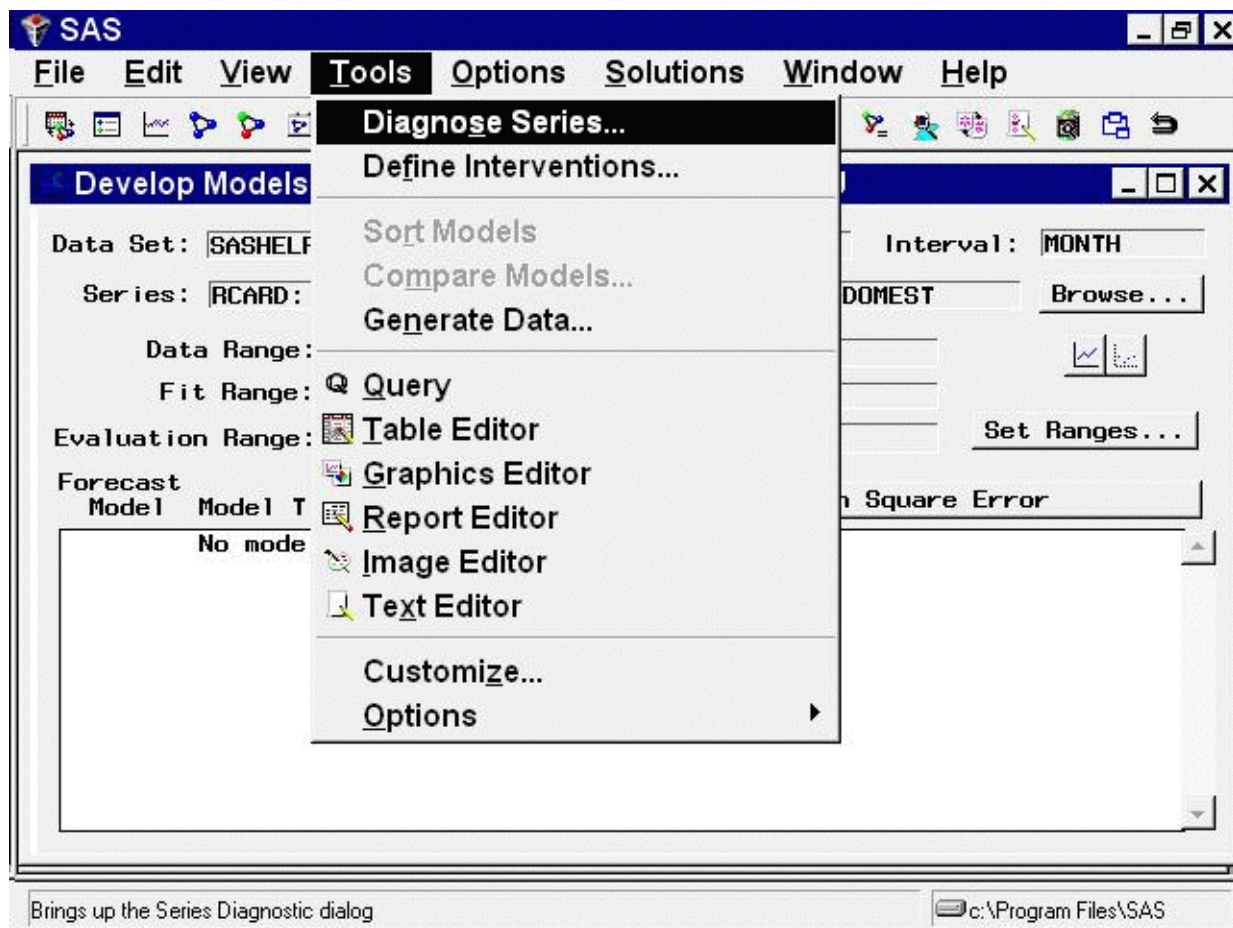

Select “Develop Models” from the Time Series Forecasting window. Select the library SASHELP, the data set CITIMON, and the series RCARD. This series represents domestic retail sales of passenger cars. To look at this series, select “View Series” from the Develop Models window. This opens the Time Series Viewer window, as shown in [Figure 47.1](#).

Figure 47.1 Automobile Sales Series

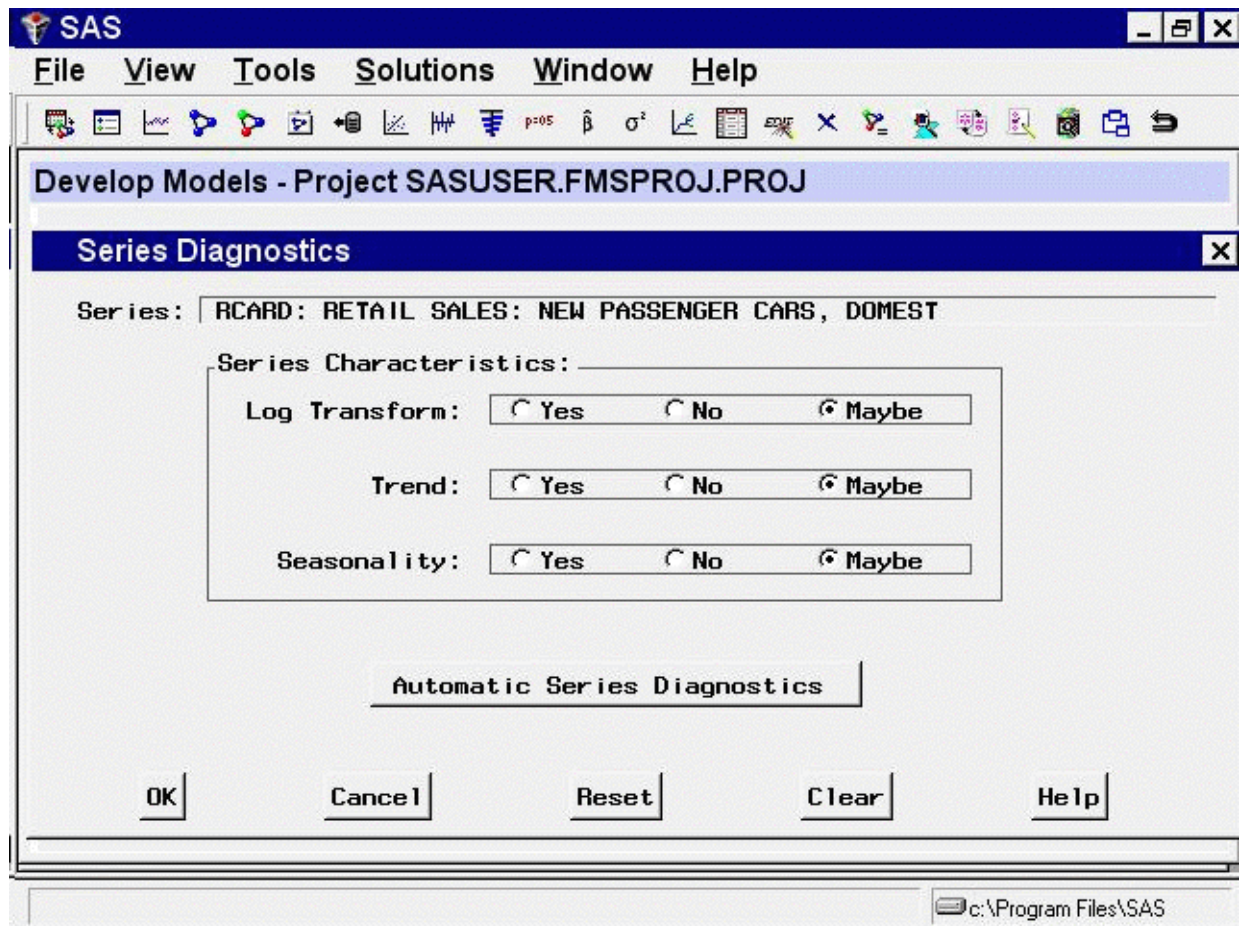

Select "Diagnose Series" from the Tools menu. You can do this from the Develop Models window or from the Time Series Viewer window. [Figure 47.2](#) shows this from the Develop Models window.

Figure 47.2 Selecting Series Diagnostics

This opens the Series Diagnostics window, as shown in [Figure 47.3](#).

Figure 47.3 Series Diagnostics Window

Each of the three series characteristics—need for log transformation, presence of a trend, and seasonality—has a set of options for *Yes*, *No*, and *Maybe*. *Yes* indicates that the series has the characteristic and that forecasting models fit to the series should be able to model and predict this behavior. *No* indicates that you do not need to consider forecasting models designed to predict series with this characteristic. *Maybe* indicates that models with and without the characteristic should be considered. Initially, all these values are set to *Maybe*.

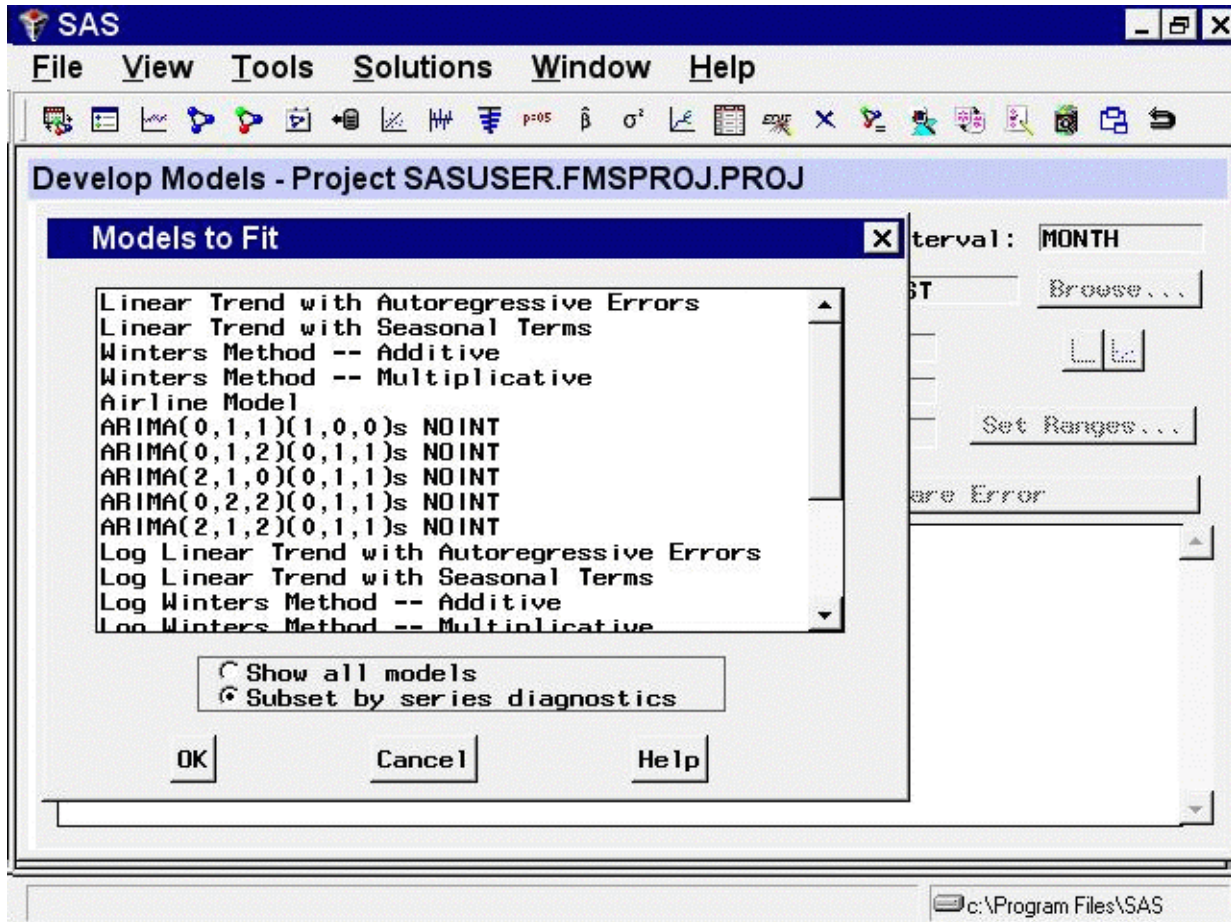

To have the system diagnose the series characteristics, select the Automatic Series Diagnostics button. This runs the diagnostic routines described in Chapter 52, “[Forecasting Process Details](#),” and sets the options according to the results. In this example, *Trend* and *Seasonality* are changed from *Maybe* to *Yes*, while *Log Transform* remains set to *Maybe*.

These diagnostic criteria affect the models displayed when you use the Models to Fit window or the Automatic Model Selection model-fitting options described in the following section. You can set the criteria manually, according to your judgment, by selecting any of the options, whether you have used the Automatic Series Diagnostics button or not. For this exercise, leave them as set by the automatic diagnostics. Select the OK button to close the Series Diagnostics window.

Models to Fit Window

As you saw in the previous chapter, you can select models from a list. Invoke the Models to Fit window by clicking the middle of the table and selecting “Fit Models from List” from the menu. This can also be selected from the tool bar or the Fit Model submenu of the Edit menu. The Models to Fit window comes up, as shown in Figure 47.4.

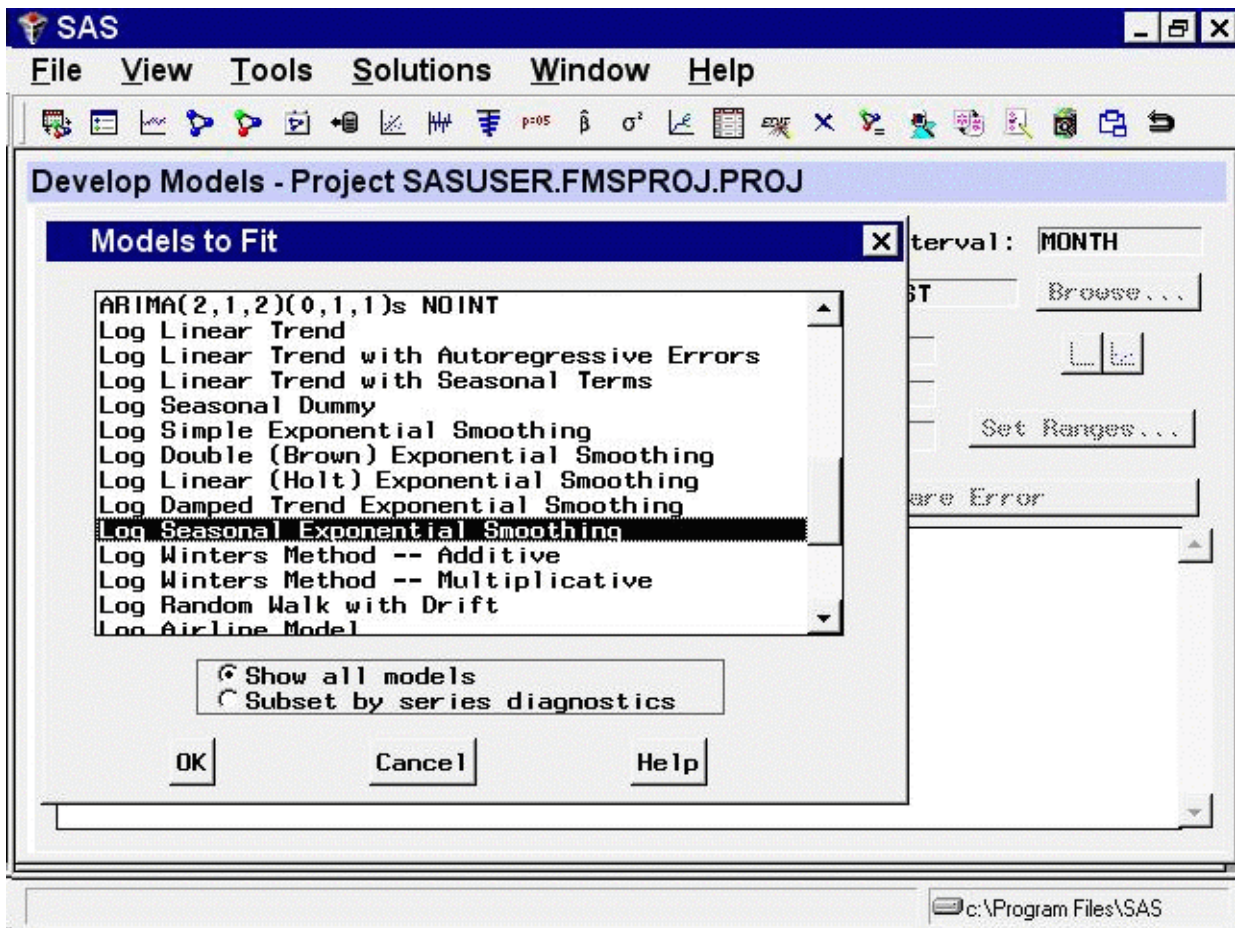

Figure 47.4 Models to Fit Window

Since you have performed series diagnostics, the models shown are the subset that fits the diagnostic criteria.

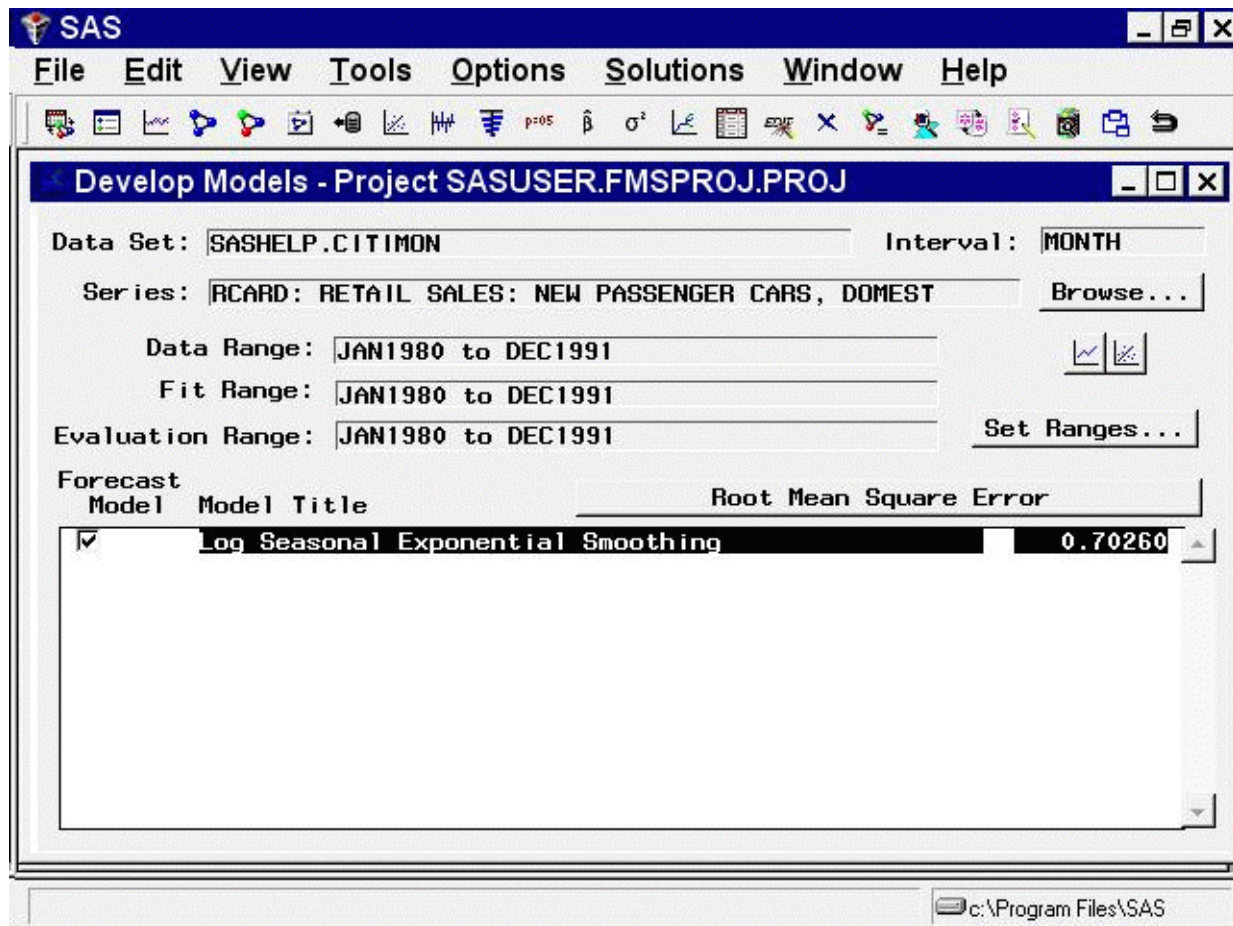

Suppose you want to consider models other than those in this subset because you are undecided about including a trend in the model. Select the Show all models option. Now the entire model selection list is shown. Scroll through the list until you find Log Seasonal Exponential Smoothing, as shown in Figure 47.5.

Figure 47.5 Selecting a Model from List

This is a nontrended model, which seems a good candidate. Select this model, and then select the OK button. The model is fit to the series and then appears in the table with the value of the selected fit criterion, as shown in Figure 47.6.

Figure 47.6 Develop Models Window Showing Model Fit

You can edit the model list that appears in the Models to Fit window by selecting “Options” and “Model Selection List” from the menu bar or by selecting the Edit Model List toolbar icon. You can then delete models you are not interested in from the default list and add models using any of the model specification methods described in this chapter. When you save your project, the edited model selection list is saved in the project file. In this way, you can use the Select from List item and the Automatic Model Selection item to select models from a customized search set.

Automatic Model Selection

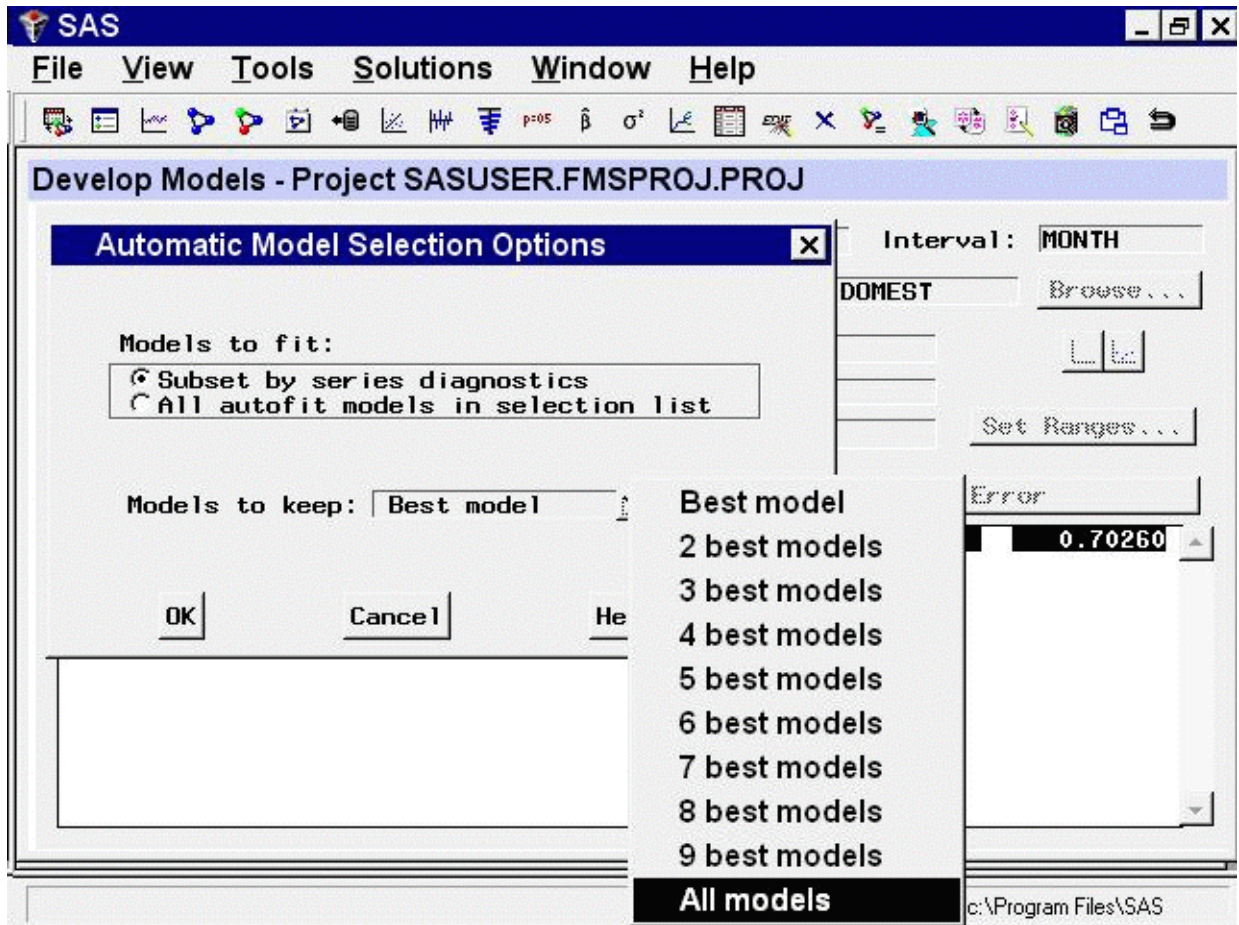

Automatic model selection is equivalent to choosing Select from List, as you did in the preceding section, fitting all the models in the subset list and then deleting all except the best fitting of the models. If series diagnostics have not yet been done, they are performed automatically to determine the model subset to fit. If you set the series diagnostics for log, trend, or seasonal criteria manually using the radio buttons, these choices are honored by the automatic fitting process.

Using automatic selection, the system does not pause to warn you of model fitting errors, such as failure of the estimates to converge (you can track these using the audit trail feature).

By default, only the best fitting model is kept. However, you can control the number of automatically fit models retained in the Develop Models list, and the following example shows how to do this.

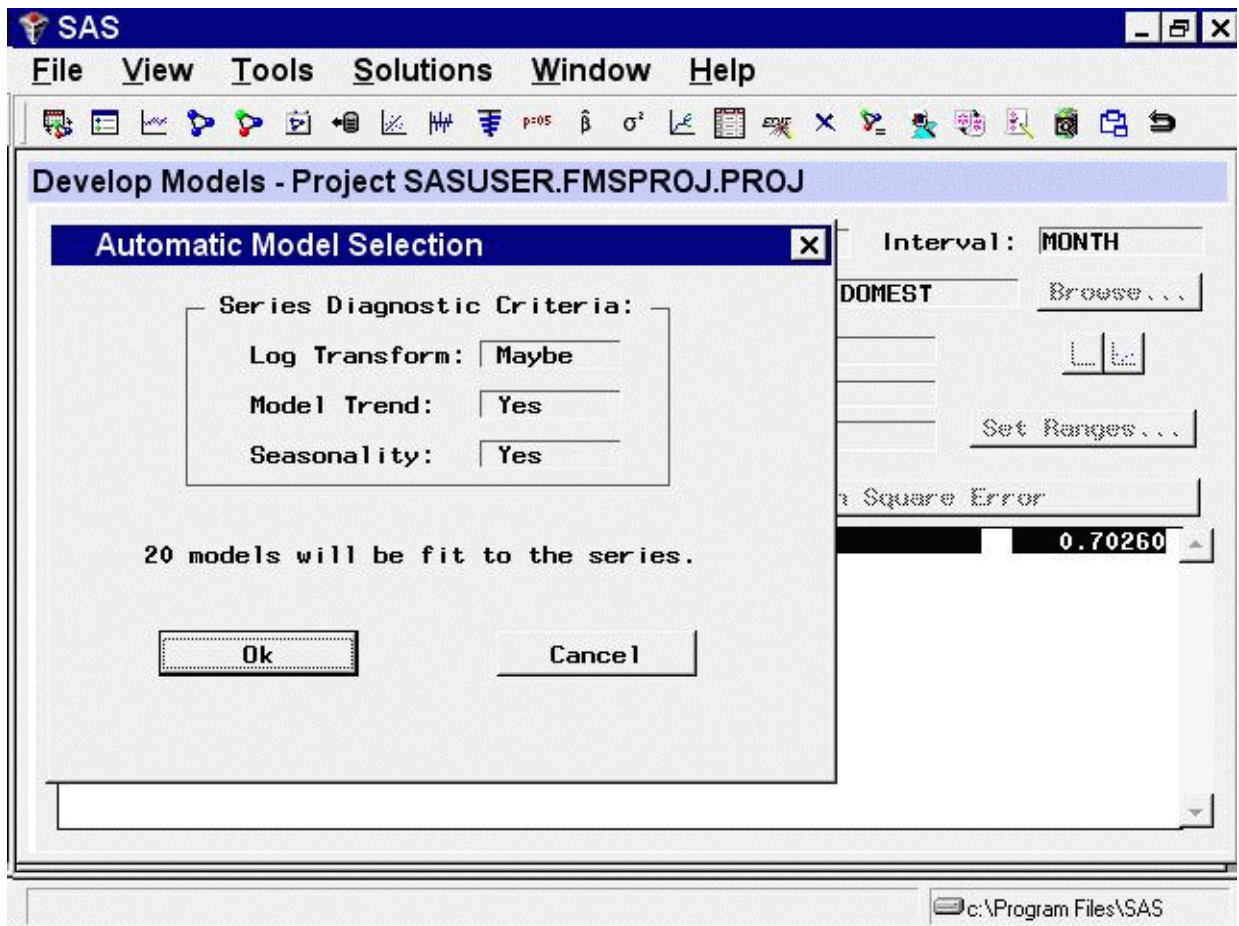

From the menu bar, choose “Options” and “Automatic Fit.” This opens the Automatic Model Selection Options window. Click the Models to Keep list arrow, and select “All models”, as shown in Figure 47.7. Now select OK.

Figure 47.7 Selecting Number of Automatic Fit Models to Keep

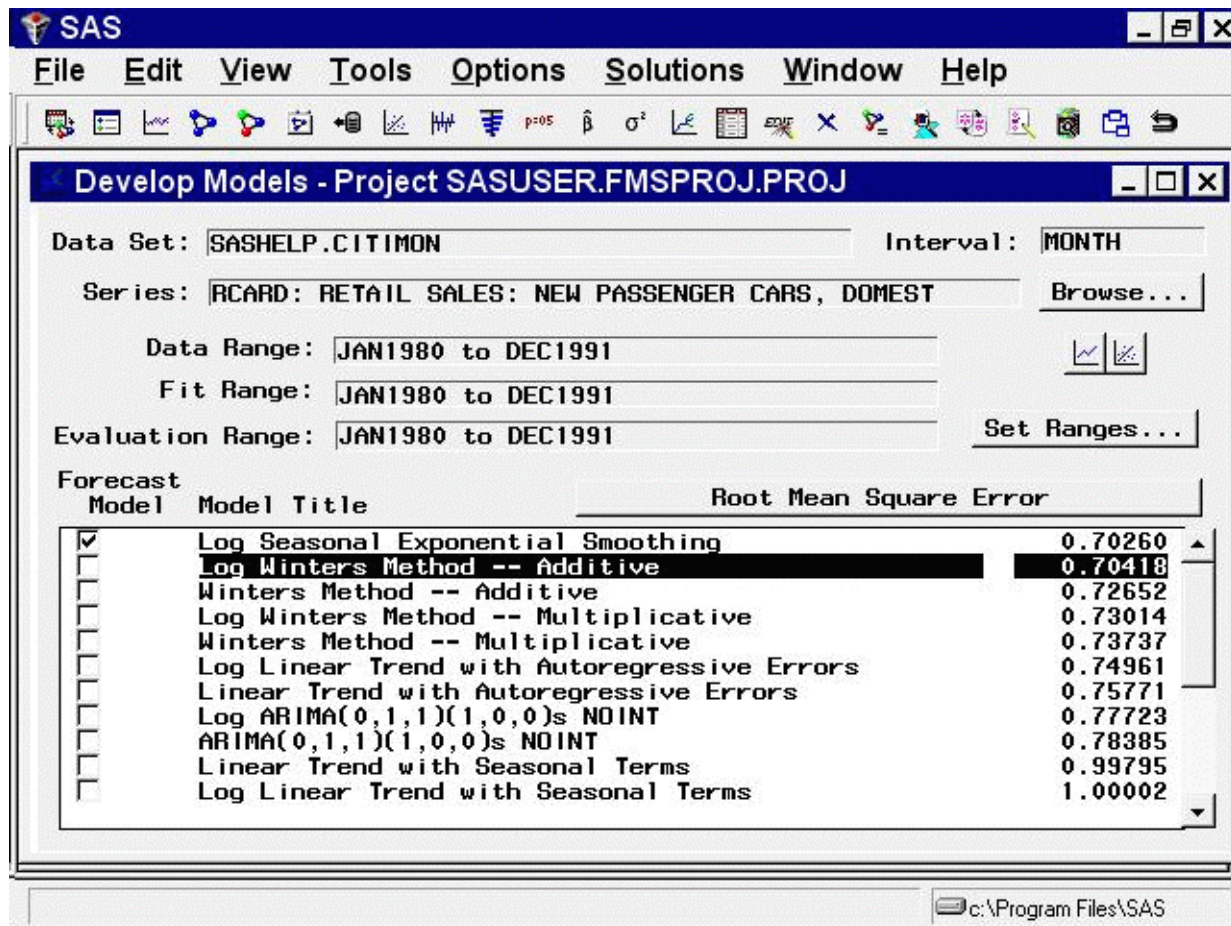

Next, select “Fit Models Automatically” by clicking the middle of the table or using the toolbar or Edit menu. The Automatic Model Selection window appears, showing the diagnostic criteria in effect and the number of models to be fit, as shown in Figure 47.8.

Figure 47.8 Automatic Model Selection Window

Select the OK button. After the models have been fit, all of them appear in the table, in addition to the model which you fit earlier, as shown in [Figure 47.9](#).

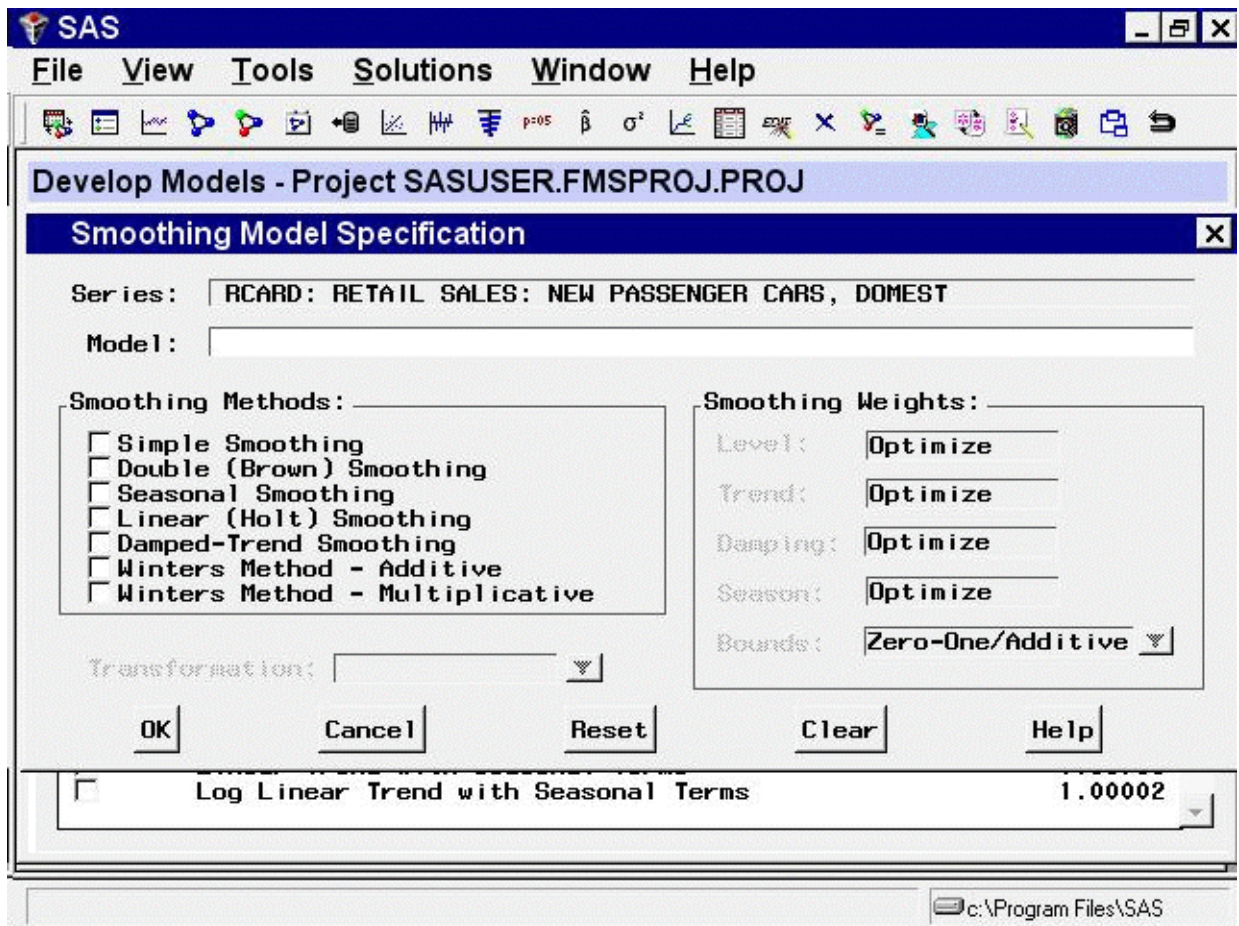

Figure 47.9 Automatically Fit Models

Smoothing Model Specification Window

To fit exponential smoothing and Winters models not already provided in the Models to Fit window, select “Fit Smoothing Model” from the pop-up menu or toolbar or select “Smoothing Model” from the Fit Model submenu of the Edit menu. This opens the Smoothing Model Specification window, as shown in Figure 47.10.

Figure 47.10 Smoothing Model Specification Window

The Smoothing Model Specification window consists of several parts. At the top is the series name and a field for the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

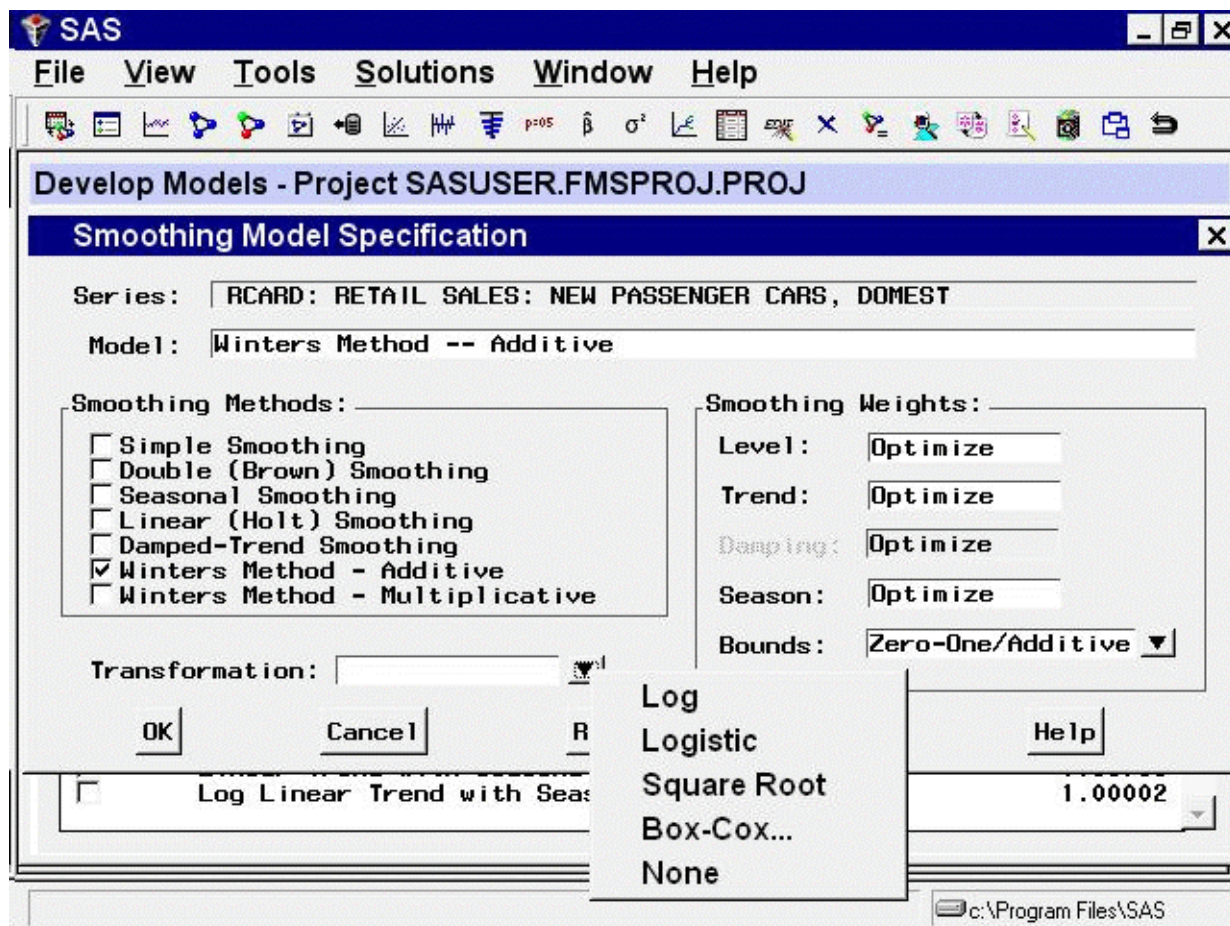

The Smoothing Methods box lists the different methods available. Below the Smoothing Methods box is the Transformation field, which is used to apply the smoothing method to transformed series values.

The Smoothing Weights box specifies how the smoothing weights are determined. By default, the smoothing weights are automatically set to optimize the fit of the model to the data. See Chapter 52, “[Forecasting Process Details](#),” for more information about how the smoothing weights are fit.

Under smoothing methods, select “Winters Method – Additive.” Notice the smoothing weights box to the right. The third item, Damping, is grayed out, while the other items, Level, Trend, and Season, show the word *Optimize*. This tells you that these three smoothing weights are applicable to the smoothing method that you selected and that the system is currently set to optimize these weights for you.

Next, specify a transformation using the Transformation list. A menu of transformation choices pops up, as shown in [Figure 47.11](#).

Figure 47.11 Transformation Options

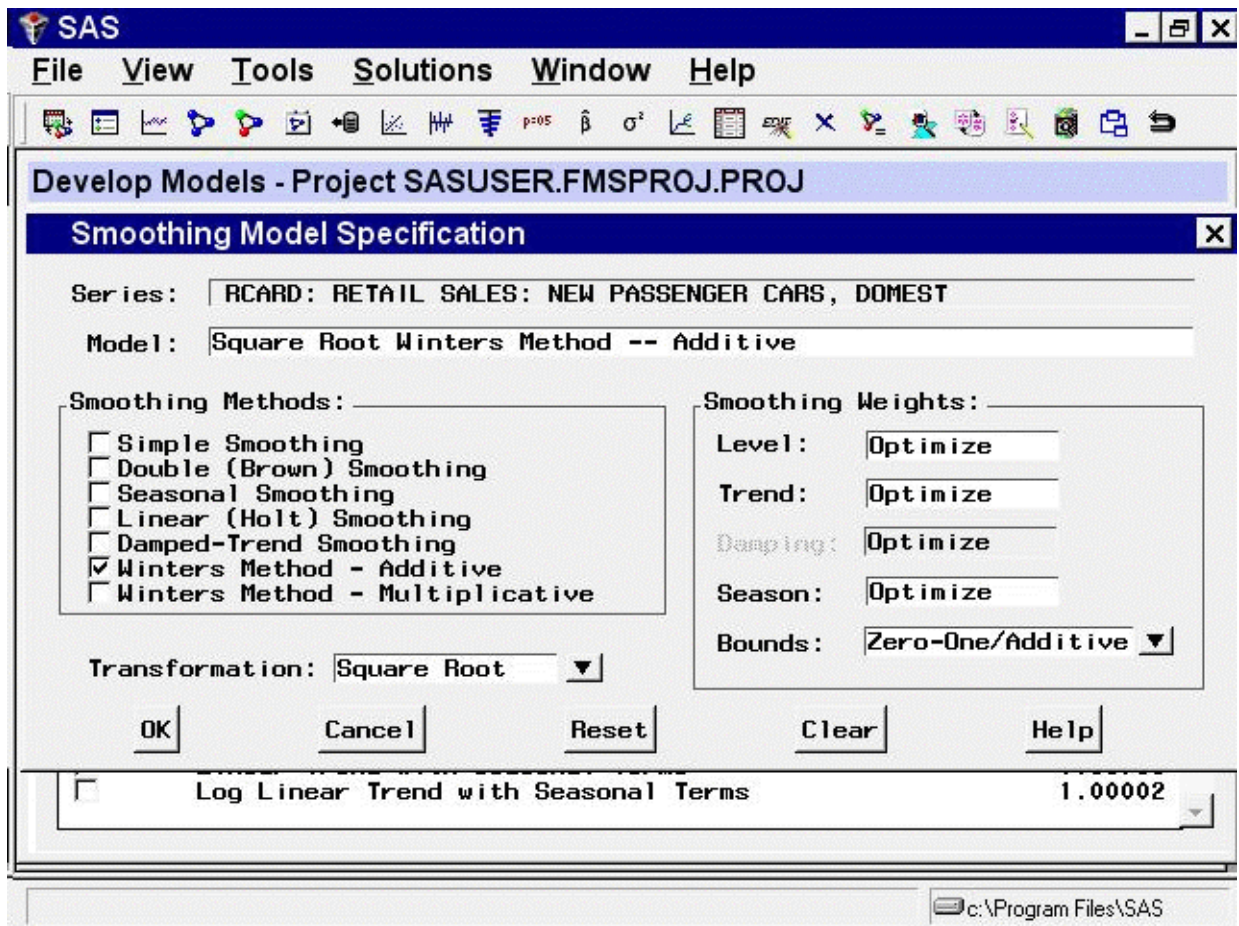

You can specify a logarithmic, logistic, square root, or Box-Cox transformation. For this example, select “Square Root” from the list. The Transformation field is now set to Square Root.

This means that the system will first take the square roots of the series values, apply the additive version of the Winters method to the square root series, and then produce the predictions for the original series by squaring the Winters method predictions (and multiplying by a variance factor if the Mean Prediction option is set in the Forecast Options window). See Chapter 52, “Forecasting Process Details,” for more information about predictions from transformed models.

The Smoothing Model Specification window should now appear as shown in Figure 47.12. Select the OK button to fit the model. The model is added to the table of fitted models in the Develop Models window.

Figure 47.12 Winter's Method Applied to Square Root Series

ARIMA Model Specification Window

To fit ARIMA or Box-Jenkins models not already provided in the Models to Fit window, select the ARIMA model item from the pop-up menu, toolbar, or Edit menu. This opens the ARIMA Model Specification window, as shown in Figure 47.13.

Figure 47.13 ARIMA Model Specification Window

c:\Program Files\SAS

This ARIMA Model Specification window is structured according to the Box and Jenkins approach to time series modeling. You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you may find one more convenient than the other.

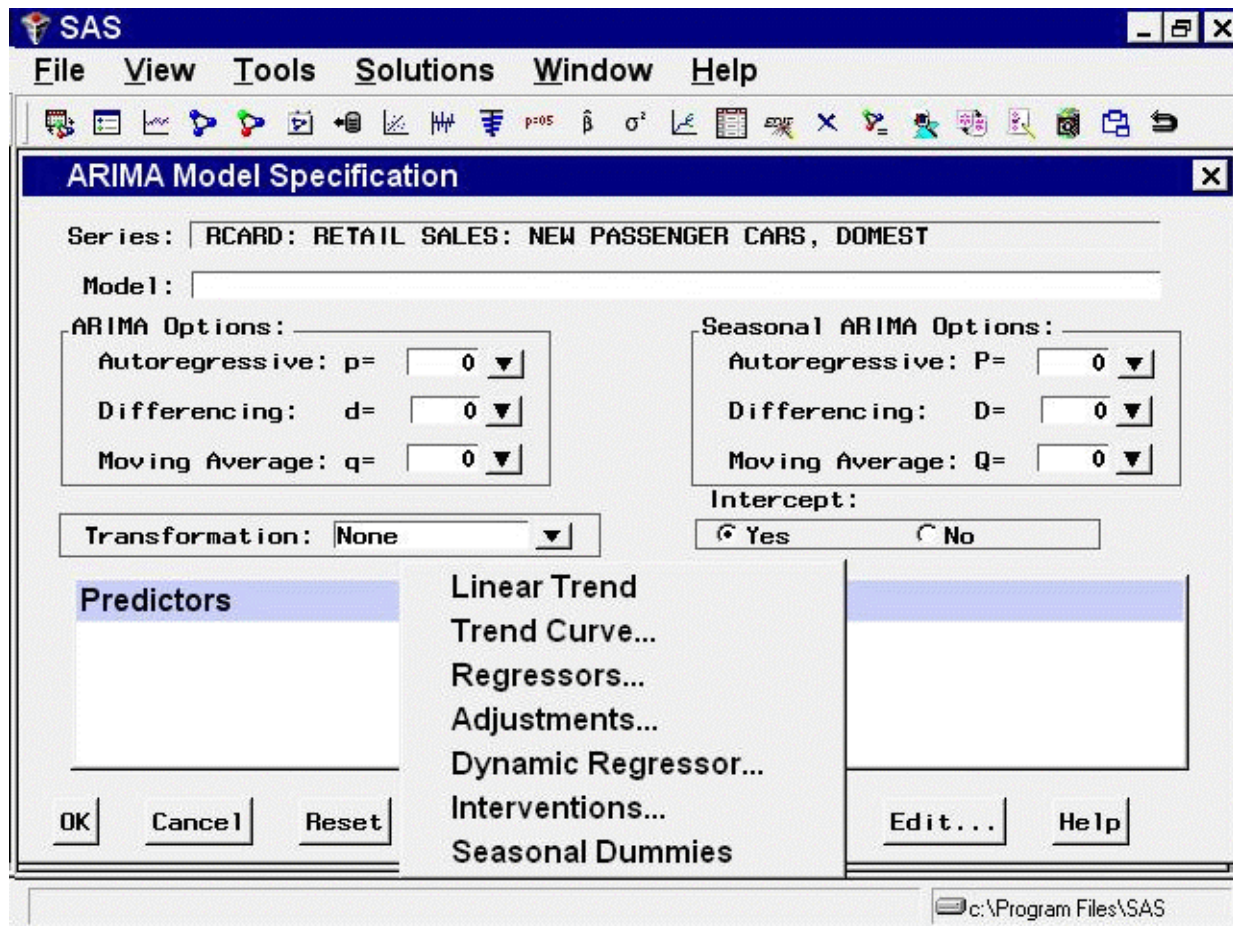

At the top of the ARIMA Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

Using the ARIMA Model Specification window, you can specify autoregressive (p), differencing (d), and moving average (q) orders for both simple and seasonal factors. You can specify transformations with the Transformation list. You can also specify whether an intercept is included in the ARIMA model.

In addition to specifying seasonal and nonseasonal ARIMA processes, you can also specify predictor variables and other terms as inputs to the model. ARIMA models with inputs are sometimes called ARIMAX models or Box-Tiao models. Another term for this kind of model is *dynamic regression*.

In the lower part of the ARIMA Model Specification window is the list of *predictors* to the model (initially empty). You can specify predictors by using the Add button. This opens a menu of different kinds of independent effects, as shown in Figure 47.14.

Figure 47.14 Add Predictors Menu

The kinds of predictor effects allowed include time trends, regressors, adjustments, dynamic regression (transfer functions), intervention effects, and seasonal dummy variables. How to use different kinds of predictors is explained in Chapter 49, “Using Predictor Variables.”

As an example, in the **ARIMA Options** box, set the order of differencing d to 1 and the moving average order q to 2. You can either type in these values or click the arrows and select the values from pop-up lists.

These selections specify an $ARIMA(0,1,2)$ or $IMA(1,2)$ model. (See Chapter 7, “The ARIMA Procedure,” for more information about the notation used for ARIMA models.) Notice that the model label at the top is now $IMA(1,2) NOINT$, meaning that the data are differenced once and a second-order moving-average term is included with no intercept.

In the **Seasonal ARIMA Options** box, set the seasonal moving-average order Q to 1. This adds a first-order moving-average term at the seasonal (12 month) lag. Finally, select “Log” in the Transformation combo box.

The model label is now $Log\ ARIMA(0,1,2)(0,0,1)_s NOINT$, and the window appears as shown in Figure 47.15.

Figure 47.15 Log ARIMA(0,1,2)(0,0,1)s Specified

c:\Program Files\SAS

Select the OK button to fit the model. The model is fit and added to the Develop Models table.

Factored ARIMA Model Specification Window

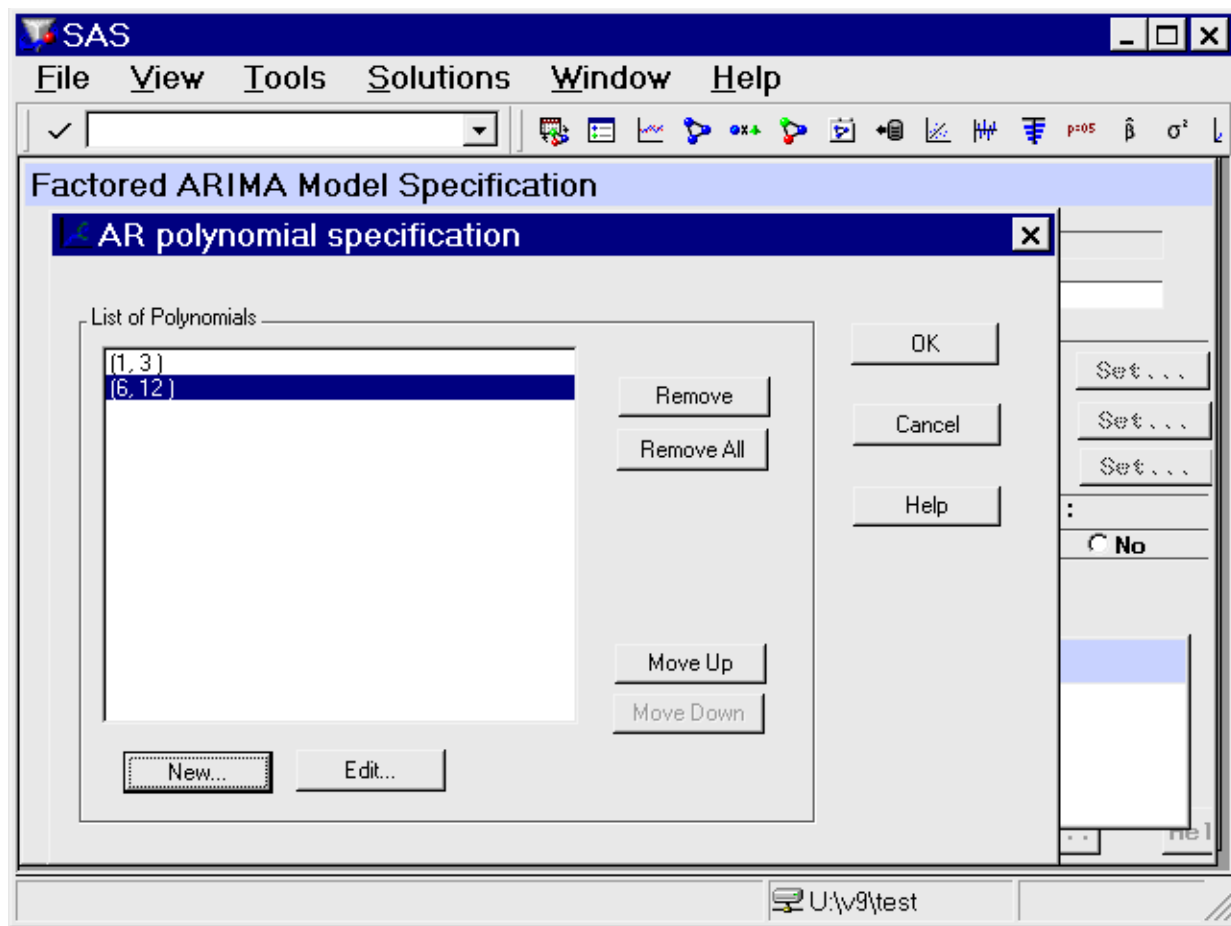

To fit a factored ARIMA model, select the Factored ARIMA model item from the pop-up menu, toolbar, or Edit menu. This brings up the Factored ARIMA Model Specification window, shown in [Figure 47.16](#).

Figure 47.16 Factored ARIMA Model Specification Window

The Factored ARIMA Model Specification window is similar to the ARIMA Model Specification window and has the same features, but it uses a more general specification of the autoregressive (p), differencing (d), and moving-average (q) terms. To specify these terms, select the corresponding Set button, as shown in [Figure 47.16](#). For example, to specify autoregressive terms, select the first Set button. This opens the AR Polynomial Specification Window, shown in [Figure 47.17](#).

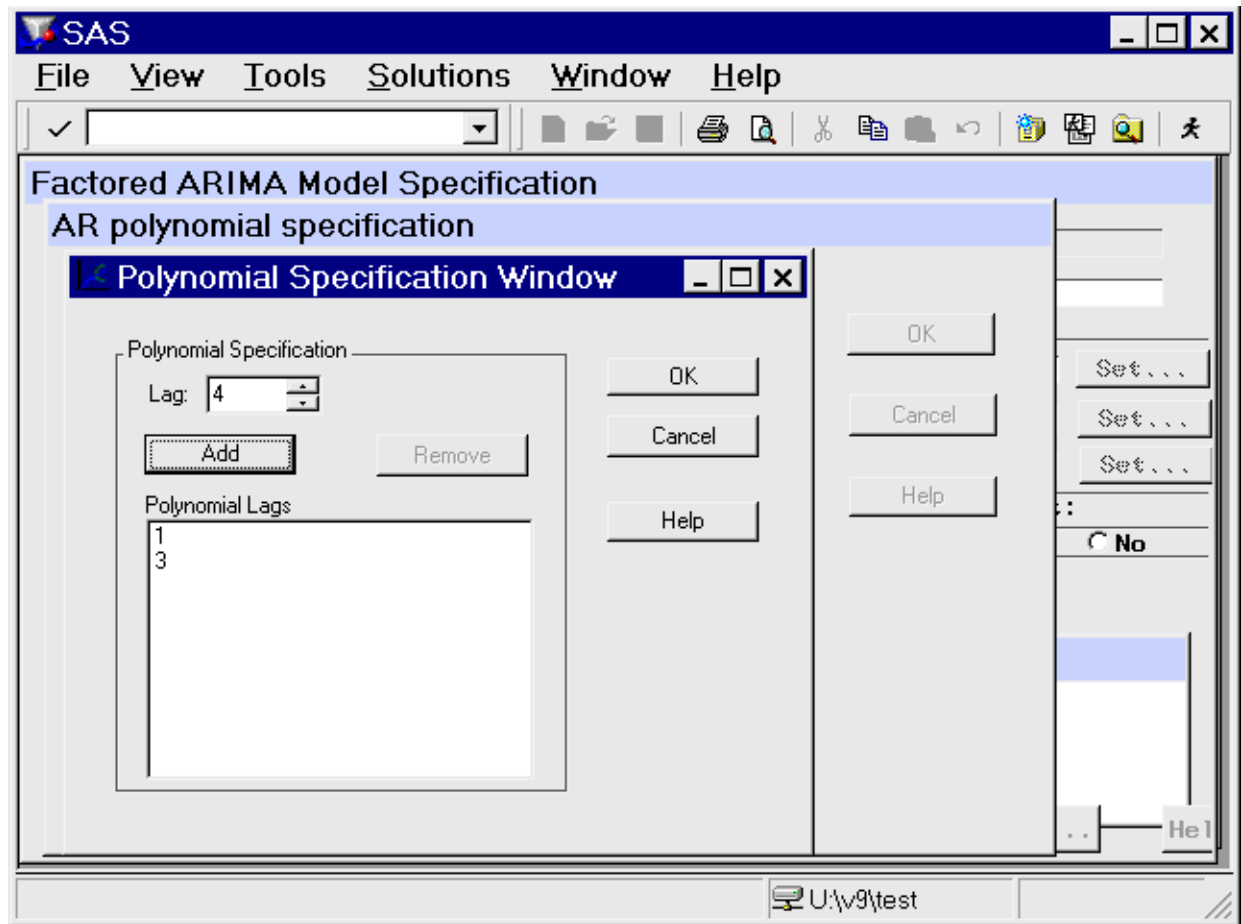

Figure 47.17 AR Polynomial Specification Window

To add AR polynomial terms, select the New button. This opens the Polynomial Specification Window, shown in Figure 47.18. Specify the first lag you want to include by using the Lag spin box, then select the Add button. Repeat this process, adding each lag you want to include in the current list. All lags must be specified. For example, if you add only lag 3, the model contains only lag 3, not 1 through 3.

As an example, add lags 1 and 3, then select the OK button. The AR Polynomial Specification Window now shows (1,3) in the list of polynomials. Now select “New” again. Add lags 6 and 12 and select “OK”. Now the AR Polynomial Specification Window shows (1,3) and (6,12) as shown in Figure 47.17. Select “OK” to close this window. The Factored ARIMA Model Specification Window now shows the factored model $p = (1, 3) (6, 12)$. Use the same technique to specify the q terms, or moving-average part of the model. There is no limit to the number of lags or the number of factors you can include in the model.

Figure 47.18 Polynomial Specification Window

To specify differencing lags, select the middle Set button to open the Differencing Specification window. Specify lags using the spin box and add them to the list with the Add button. When you select “OK” to close the window, the differencing lags appear after $d=$ in the Factored ARIMA Specification Window, within a single pair of parentheses.

You can use the Factored ARIMA Model Specification Window to specify any model that you can specify with the ARIMA Model and Custom Model windows, but the notation is more similar to that of the ARIMA procedure (see Chapter 7, “[The ARIMA Procedure](#)”). Consider as an example the classic Airline model fit to the International Airline Travel series, `SASHELP.AIR`. This is a factored model with one moving-average term at lag one and one moving-average term at the seasonal lag, with first-order differencing at the simple and seasonal lags. Using the ARIMA Model Specification Window, you specify the value 1 for the q and d terms and also for the Q and D terms, which represent the seasonal lags. For monthly data, the seasonal lags represent lag 12, since a yearly seasonal cycle is assumed.

By contrast, the Factored ARIMA Model Specification Window makes no assumptions about seasonal cycles. The Airline model is written as `IMA d=(1,12) q=(1)(12) NOINT`. To specify the differencing terms, add the values 1 and 12 in the Differencing Specification Window and select OK. Then select “New” in the MA Polynomial Specification Window, add the value 1, and select OK. To add the factored term, select “New” again, add the value 12, and select OK. Remember to select “No” in the Intercept radio box, since it is not selected by default. Select OK to close the Factored ARIMA Model Specification Window and fit the model.

You can show that the results are the same as they are when you specify the model by using the ARIMA Model Specification Window and when you select Airline Model from the default model list. If you are familiar with the ARIMA Procedure (Chapter 7, “[The ARIMA Procedure](#)”), you might want to turn on the `Show Source Statements` option before fitting the model, then examine the procedure source statements in the log window after fitting the model.

The strength of the Factored ARIMA Specification approach lies in its ability to construct unusual ARIMA models, such as:

Subset models

These are models of order n , where fewer than n lags are specified. For example, an AR order 3 model might include lags 1 and 3 but not lag 2.

Unusual seasonal cycles

For example, a monthly series might cycle two or four times per year instead of just once.

Multiple cycles

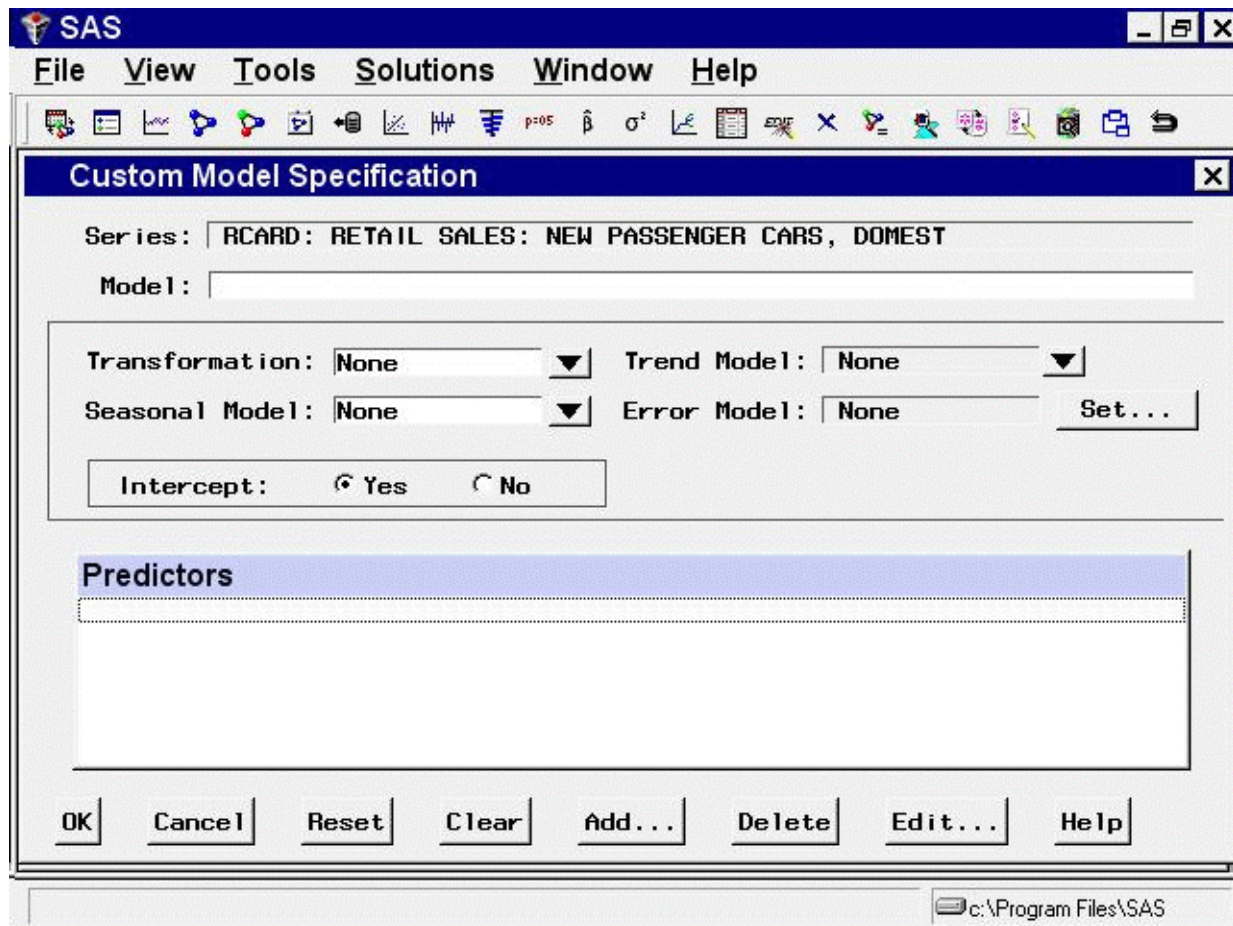

For example, a daily sales series might peak on a certain day each week and also once a year at the Christmas season. Given sufficient data, you can fit a three-factor model, such as `IMA d=(1) q=(1)(7)(365)`.

Models with high order lags take longer to fit and often fail to converge. To save time, select the Conditional Least Squares or Unconditional Least Squares estimation method (see [Figure 47.16](#)). Once you have narrowed down the list of candidate models, change to the Maximum Likelihood estimation method.

Custom Model Specification Window

To fit a custom time series model not already provided in the Models to Fit window, select the Custom Model item from the pop-up menu, toolbar, or Edit menu. This opens the Custom Model Specification window, as shown in [Figure 47.19](#).

Figure 47.19 Custom Model Specification Window

You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you might find one more convenient than the other.

At the top of the Custom Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Custom Model Specification window consists of four fields: *Transformation*, *Trend Model*, *Seasonal Model*, and *Error Model*. These fields allow you to specify the model in four parts. Each part specifies how a different aspect of the pattern of the time series is modeled and predicted.

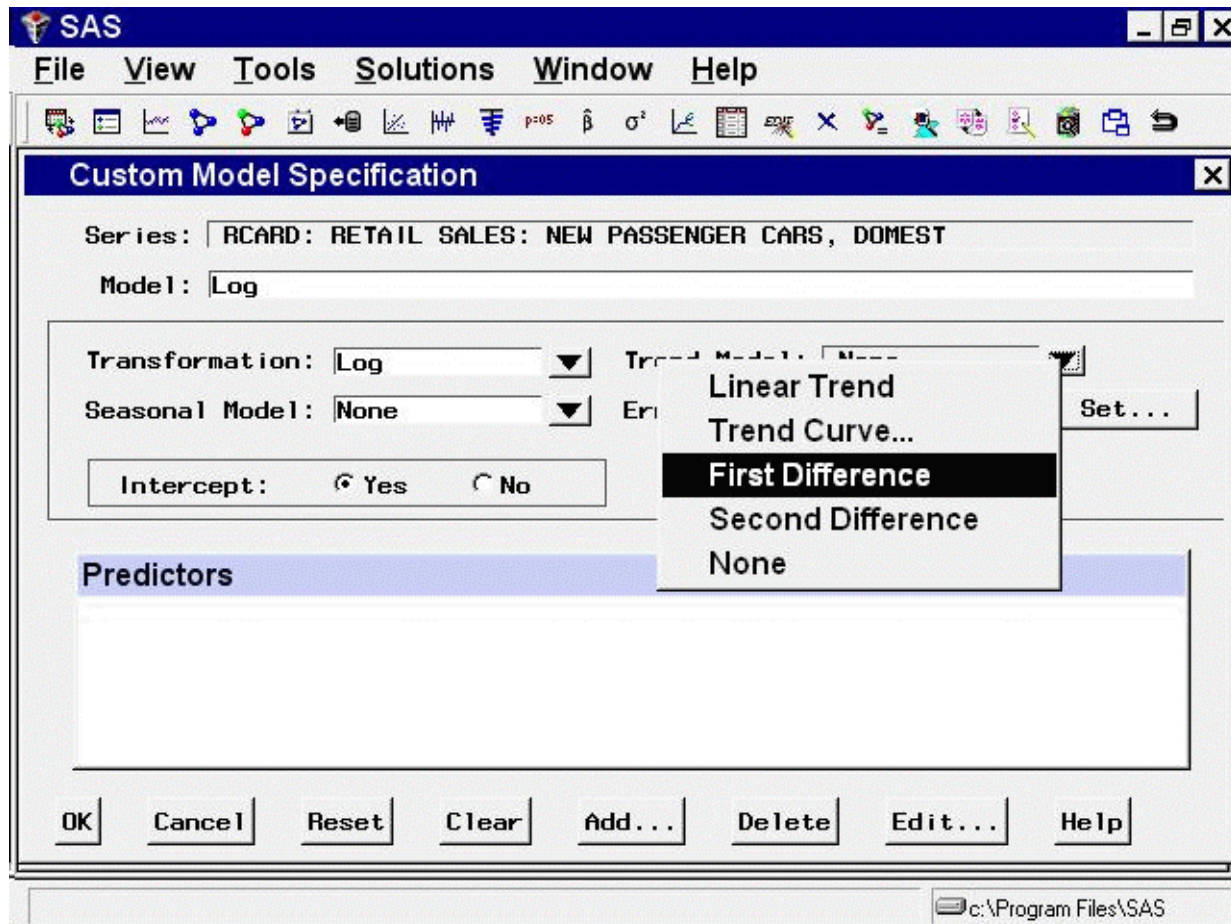

The *Predictors* list at the bottom of the Custom Model Specification window allows you to include different kinds of predictor variables in the forecasting model. The *Predictors* feature for the Custom Model Specification window is like the *Predictors* feature for the ARIMA Model Specification window, except that time trend predictors are provided through the *Trend Model* field and seasonal dummy variable predictors are provided through the *Seasonal Model* field.

To illustrate how to use the Custom Model Specification window, the following example specifies the same model you fit by using the ARIMA Model Specification window.

First, specify the data transformation to use. Select “Log” using the Transformation combo box.

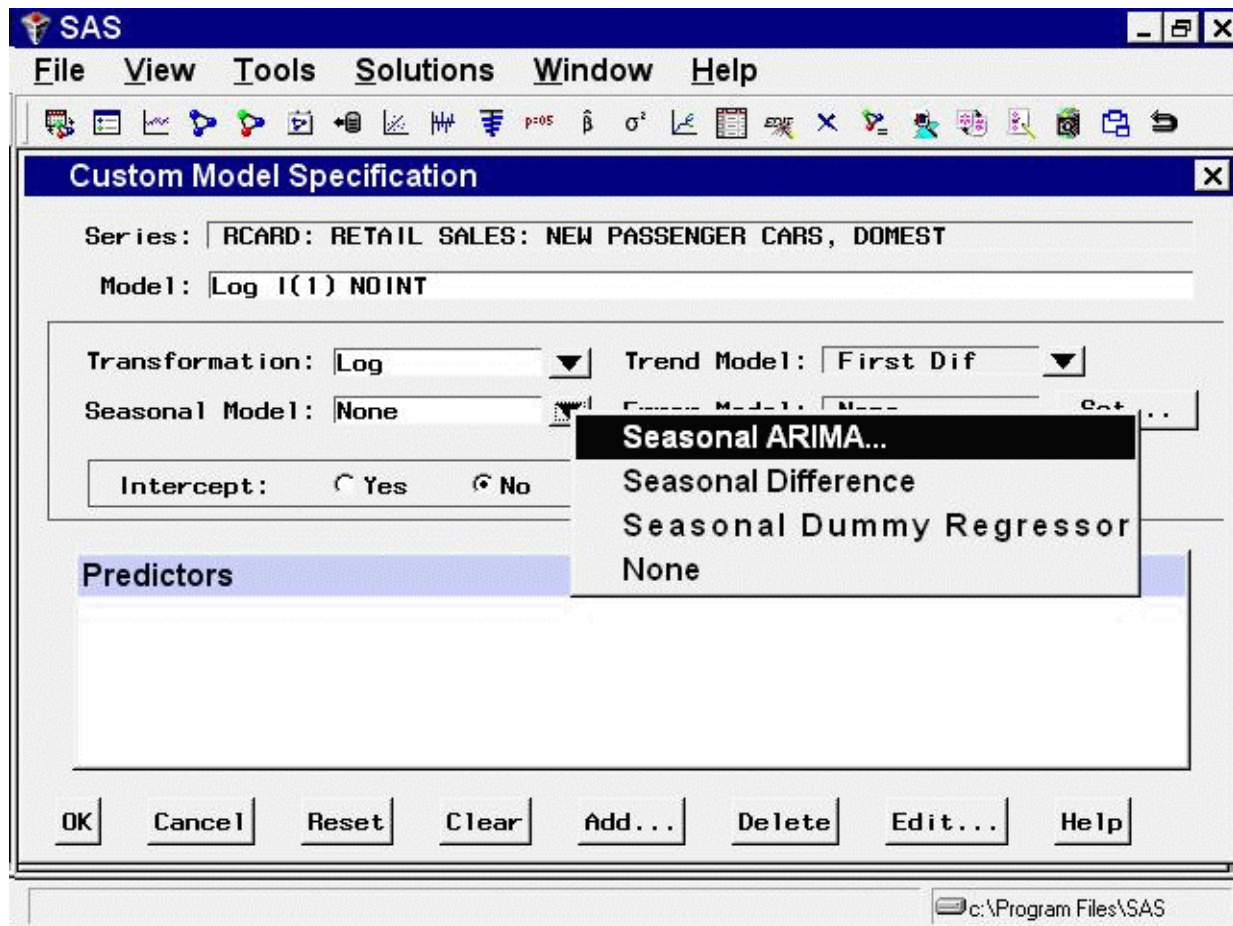

Second, specify how to model the trend in the series. Select **First Difference** in the Trend Model combo box, as shown in [Figure 47.20](#).

Figure 47.20 Trend Model Options

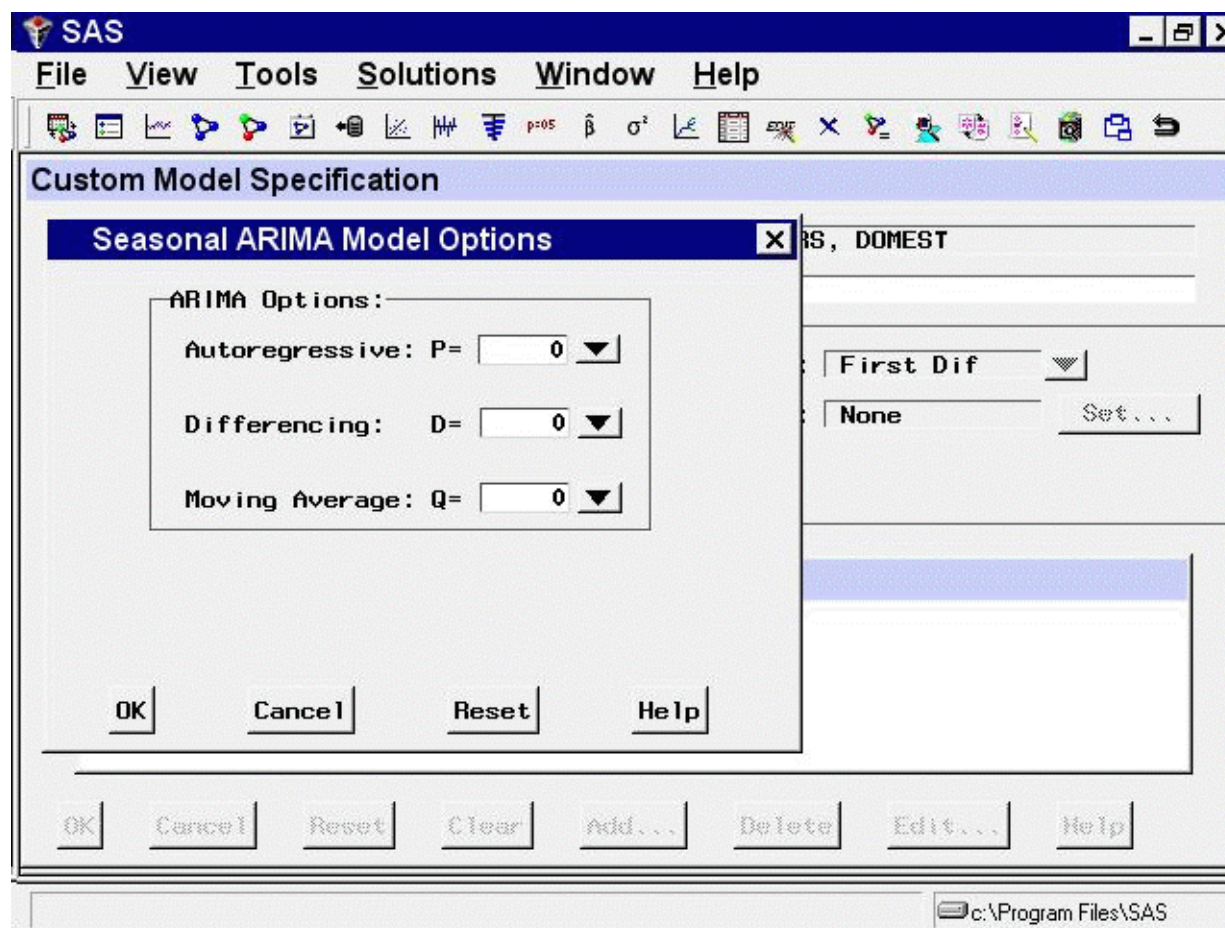

Next, specify how to model the seasonal pattern in the series. Select “Seasonal ARIMA” in the Seasonal Model combo box, as shown in [Figure 47.21](#).

Figure 47.21 Seasonal Model Options

This opens the Seasonal ARIMA Model Options window, as shown in [Figure 47.22](#).

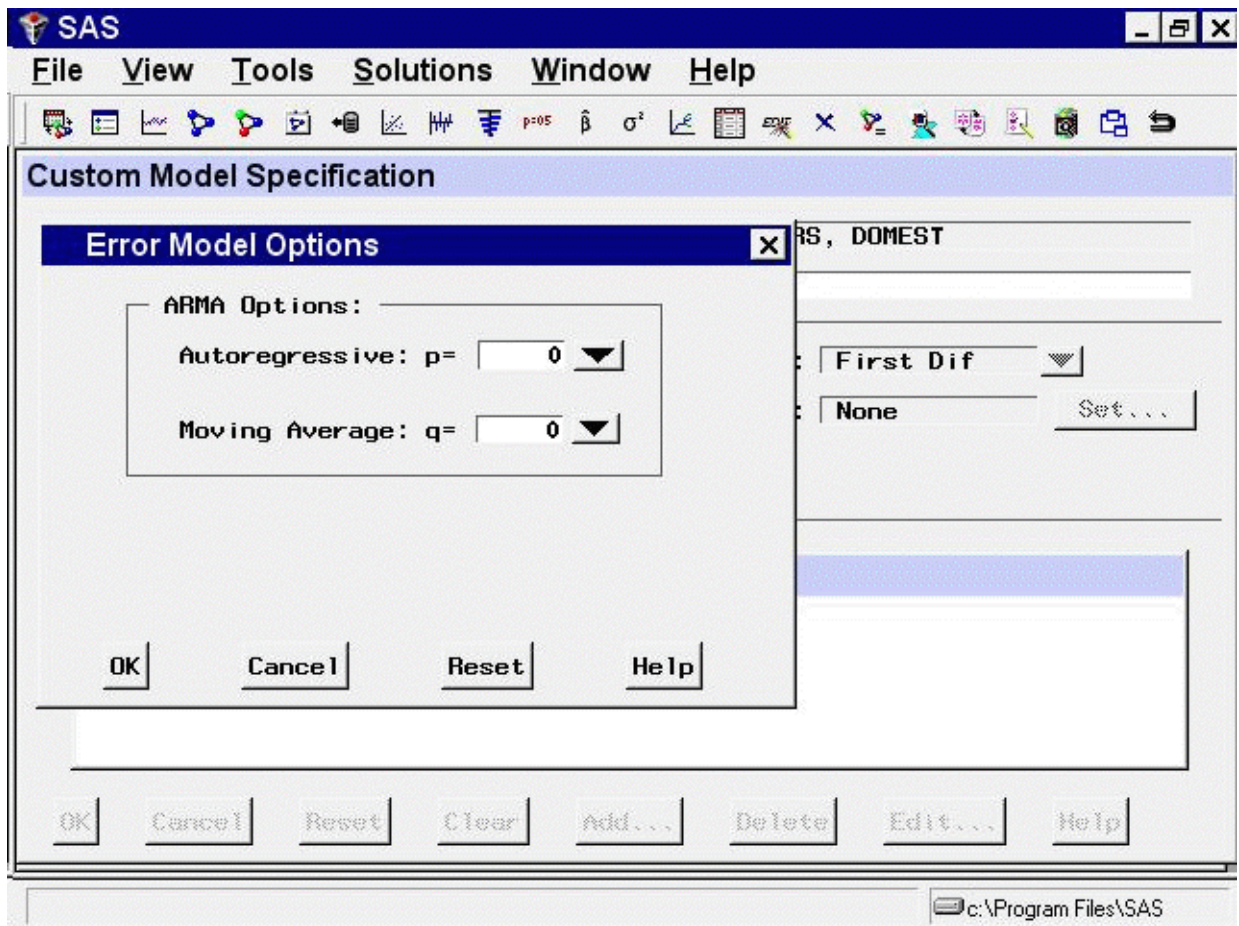

Figure 47.22 Seasonal ARIMA Model Options

Specify a first-order seasonal moving-average term by typing 1 or by selecting “1” from the Moving Average: Q= combo box pop-up menu, and then select the OK button.

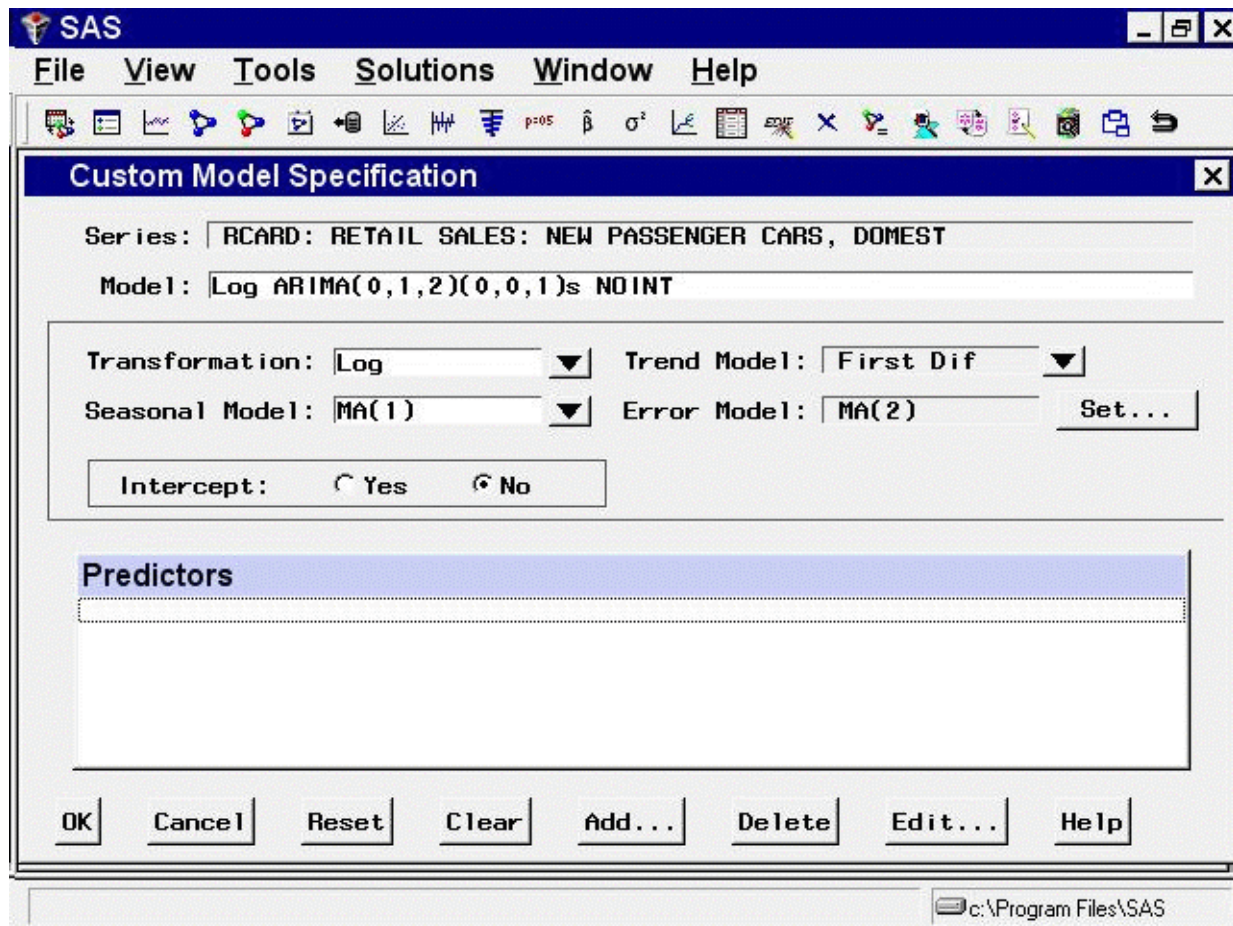

Finally, specify how to model the autocorrelation pattern in the model prediction errors. Select the Set button to the right of the Error Model field. This opens the Error Model Options window, as shown in Figure 47.23. This window allows you to specify an ARMA error process. Set the Moving Average order q to 2, and then select the OK button.

Figure 47.23 Error Model Options

The Custom Model Specification window should now appear as shown in [Figure 47.24](#). The model label at the top of the Custom Model Specification window should now read `Log ARIMA(0,1,2)(0,0,1)s NOINT`, just as it did when you used the ARIMA Model Specification window.

Figure 47.24 Log ARIMA(0,1,2)(0,0,1)s Specified

Now that you have seen how the Custom Model Specification window works, select “Cancel” to exit the window without fitting the model. This should return you to the Develop Models window.

Editing the Model Selection List

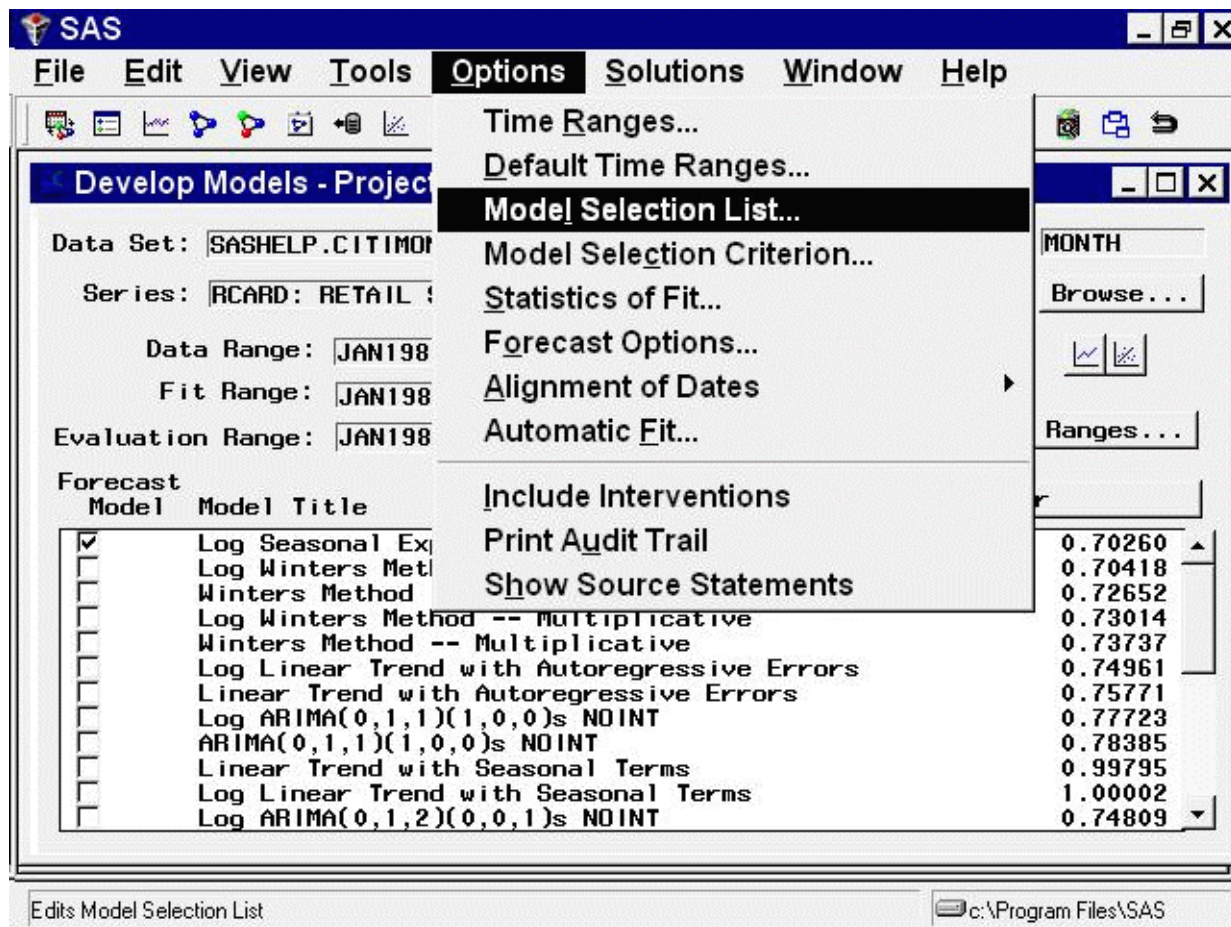

Now that you know how to specify new models that are not included in the system default model selection list, you can edit the model selection list to add models that you expect to use in the future or to delete models that you do not expect to use. When you save the forecasting project to a SAS catalog, the edited model selection list is saved with the project file, and the list is restored when you load the project.

There are two reasons why you would add a model to the model selection list. First, by adding the model to the list, you can fit the model to different time series by selecting it through the **Fit Models from List** action. You do not need to specify the model again every time you use it.

Second, once the model is added to the model selection list, it is available to the automatic model selection process. The model is then considered automatically whenever you use the automatic model selection feature for any series.

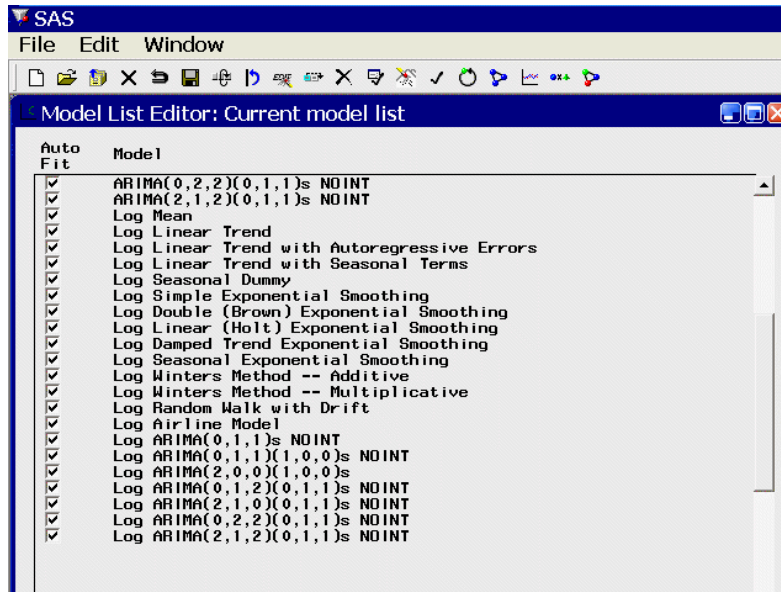

To edit the model selection list, select “Model Selection List” from the Options menu as shown in Figure 47.25, or select the Edit Model List toolbar icon.

Figure 47.25 Model Selection List Option

This selection brings up the Model Selection List editor window, as shown in Figure 47.26. This window consists of the model selection list and an “Auto Fit” column, which controls for each model whether the model is included in the list of models used by the automatic model selection process.

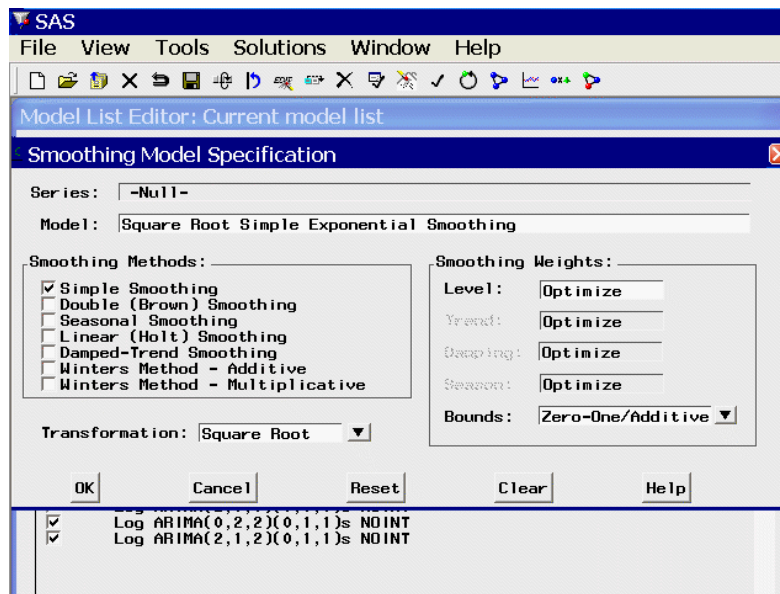

Figure 47.26 Model Selection List Window

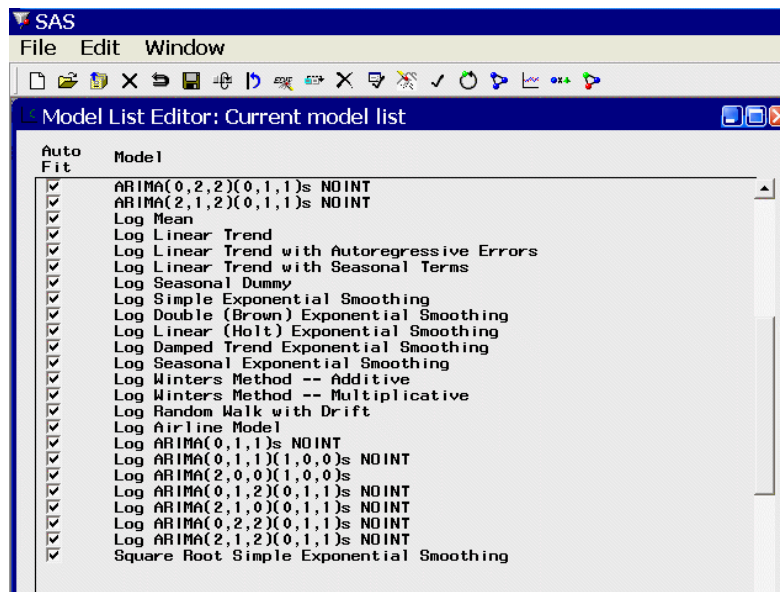

To add a model to the list, select “Add Model” from the Edit menu and then select “Smoothing Model,” “ARIMA Model,” “Factored ARIMA Model,” or “Custom Model” from the submenu. Alternatively, click the corresponding icon on the toolbar.

As an example, select “Smoothing Model.” This brings up the Smoothing Model Specification window. Note that the series name is “-Null-.” This means that you are not specifying a model to be fit to a particular series, but are specifying a model to be added to the selection list for later reference.

Specify a smoothing model. For example, select “Simple Smoothing” and then select the Square Root transformation. The window appears as shown in Figure 47.27.

Figure 47.27 Adding a Model Specification

Select the OK button to add the model to the end of the model selection list and return you to the Model Selection List window, as shown in Figure 47.28. You can now select the Fit Models from List model-fitting option to use the edited selection list.

Figure 47.28 Model Added to Selection List

If you want to delete one or more models from the list, select the model labels to highlight them in the list. Click a second time to clear a selected model. Then select “Delete” from the Edit pull-down menu, or the corresponding toolbar icon. As an example, delete the Square Root Simple Exponential Smoothing model that you just added.

The Model Selection List editor window gives you a lot of flexibility for managing multiple model lists, as

explained in the section “[Model Selection List Editor Window](#)” on page 3242. For example, you can create your own model lists from scratch or modify or combine previously saved model lists and those provided with the software, and you can save them and designate one as the default for future projects.

Now select “Close” from the File menu (or the Close icon) to close the Model Selection List editor window.

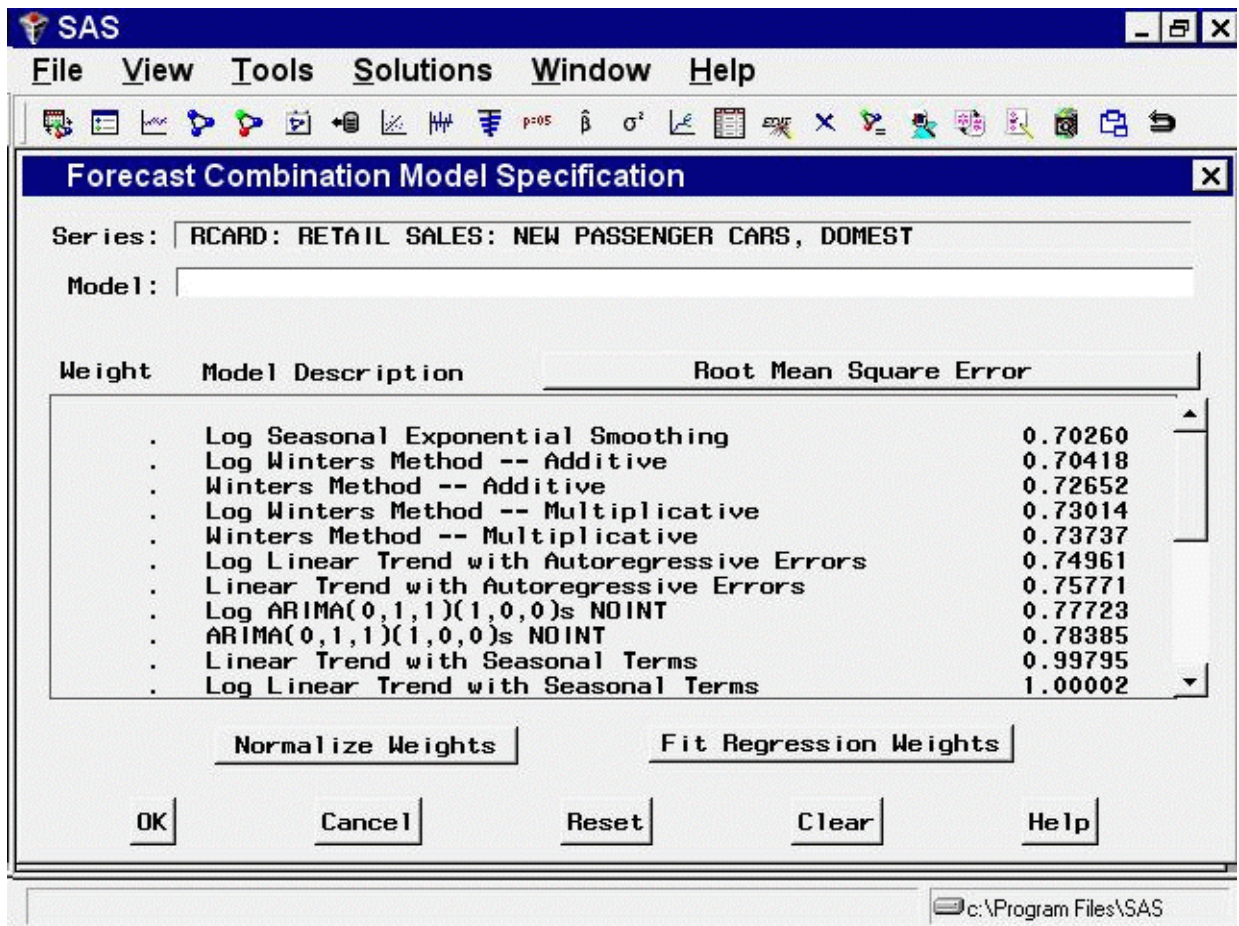

Forecast Combination Model Specification Window

Once you have fit several forecasting models to a series, you face the question of which model to use to produce the final forecasts. One possible answer is to combine or average the forecasts from several models. Combining the predictions from several different forecasting methods is a popular approach to forecasting.

The way that you produce forecast combinations with the Time Series Forecasting System is to use the Forecast Combination Model Specification window to specify a new forecasting model that performs the averaging of forecasts from the models you want to combine. This new model is added to the list of fitted models just like other models. You can then use the Model Viewer window features and Model Fit Comparison window features to examine the fit of the combined model.

To specify a forecast combination model, select “Combine Forecasts” from the pop-up menu or toolbar, or select “Edit” and “Fit Model” from the menu bar. This brings up the Forecast Combination Model Specification window, as shown in [Figure 47.29](#).

Figure 47.29 Forecast Combination Window

At the top of the Forecast Combination window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Forecast Combination window consists of the list of models that you have fit to the series. This table shows the label and goodness-of-fit measure for each model and the combining weight assigned to the model.

The **Weight** column controls how much weight is given to each model in the combined forecasts. A missing weight means that the model is not used. Initially, all the models have missing weight values.

You can enter the weight values you want to use in the **Weight** column. Alternatively, you can select models from the **Model Description** column, and weight values for the models you select are set automatically. To remove a model from the combination, select it again. This resets its weight value to missing.

At the bottom of the Forecast Combination window are two buttons: **Normalize Weights** and **Fit Regression Weights**. The **Normalize Weights** button adjusts the nonmissing weight values so that they sum to one. The **Fit Regression Weights** button uses linear regression to compute the weight values that produce the combination of model predictions with the best fit to the series.

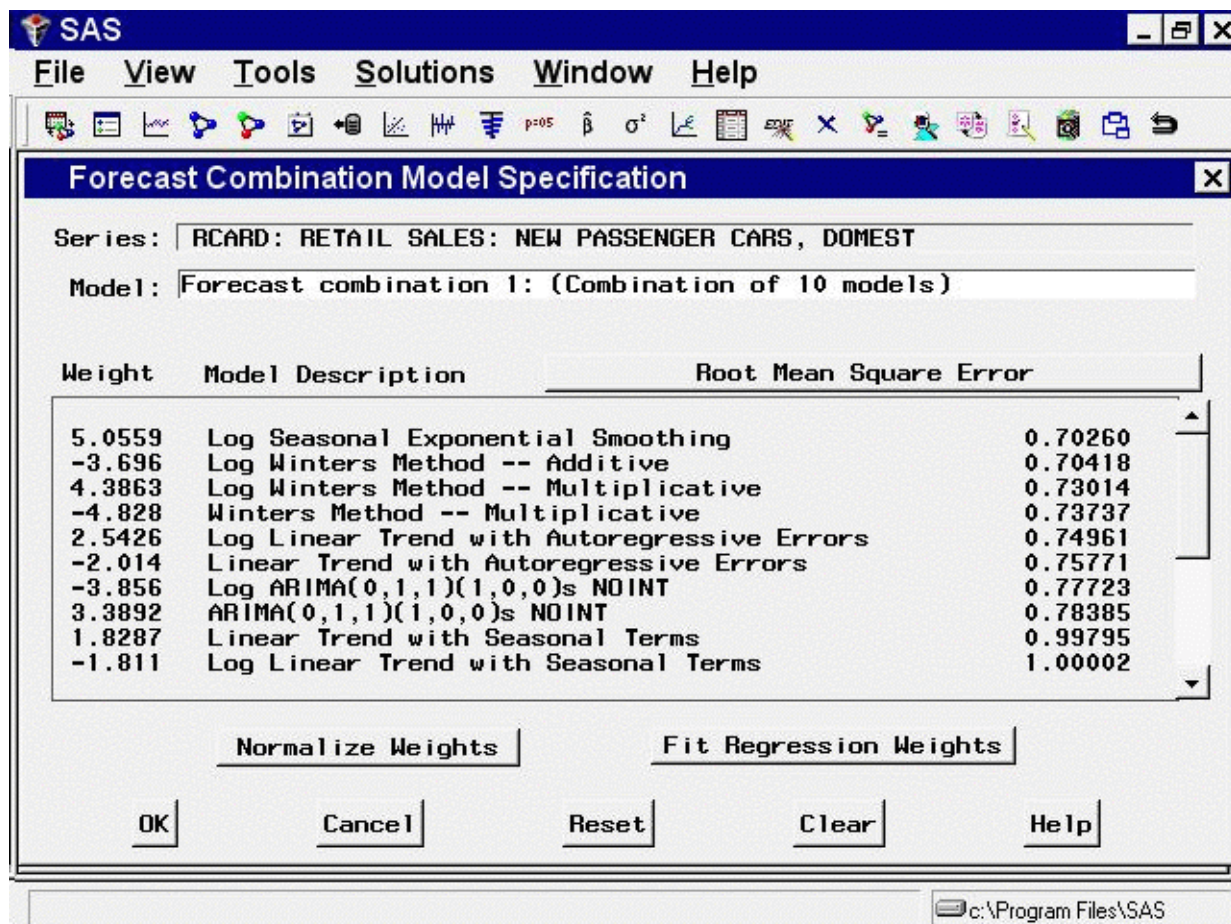

If no models are selected, the Fit Regression Weights button fits weights for all the models in the list. You can compute regression weights for only some of the models by first selecting the models you want to combine and then selecting Fit Regression Weights. In this case, only the nonmissing Weight values are replaced with regression weights.

As an example of how to combine forecasting models, select all the models in the list. After you have finished selecting the models, all the models in the list should now have equal weight values, which implies a simple average of the forecasts.

Now select the Fit Regression Weights button. The system performs a linear regression of the series on the predictions from the models with nonmissing weight values and replaces the weight values with the estimated regression coefficients. These are the combining weights that produce the smallest mean square prediction error within the sample.

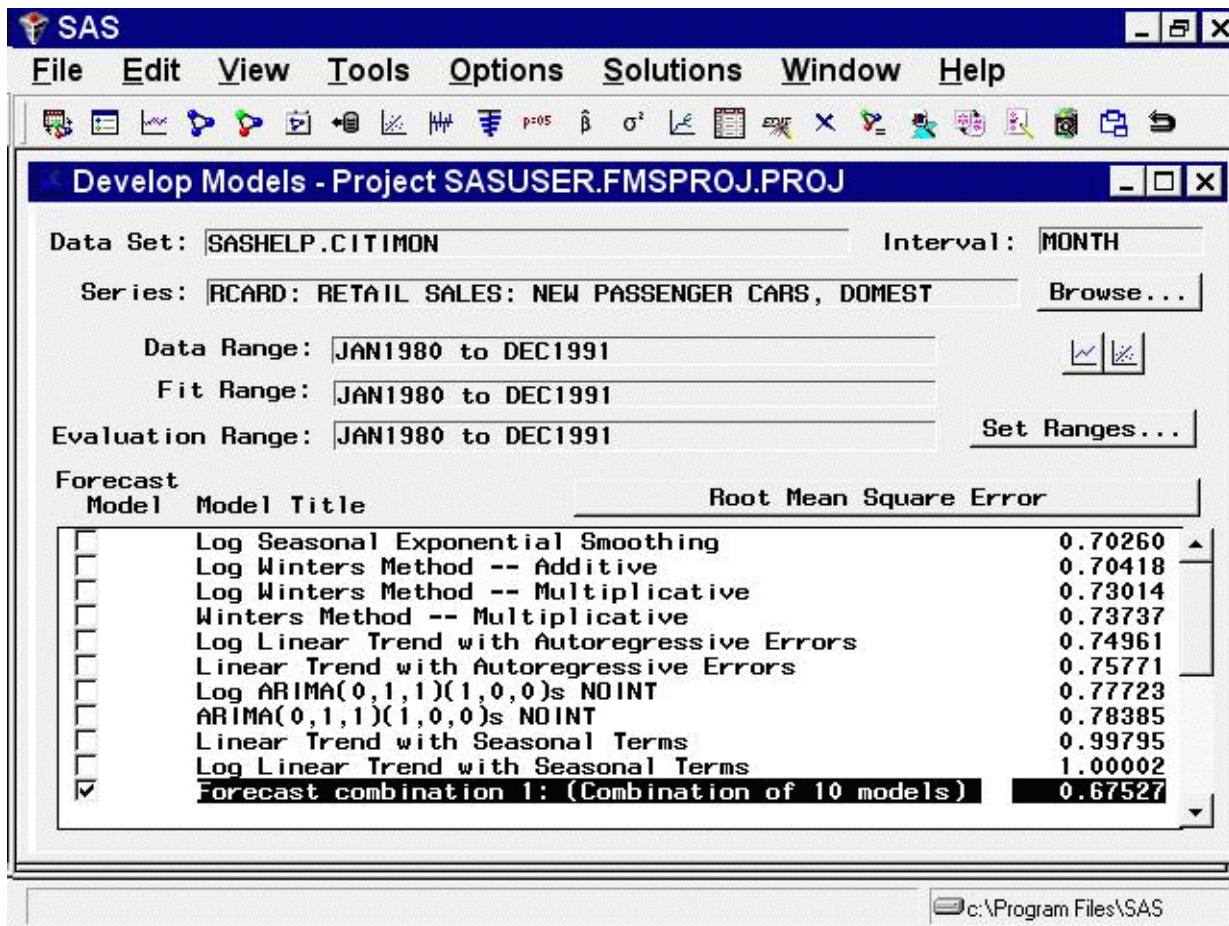

The Forecast Combination window should now appear as shown in Figure 47.30. (Note that some of the regression weight values are negative.)

Figure 47.30 Combining Models

Select the OK button to fit the combined model. Now the Develop Models window shows this model to be the best fitting according to the root mean square error, as shown in Figure 47.31.

Figure 47.31 Develop Models Window Showing All Models Fit

Notice that the combined model has a smaller root mean square error than any one of the models included in the combination. The confidence limits for forecast combinations are produced by taking a weighted average of the mean square prediction errors for the component forecasts, ignoring the covariance between the prediction errors.

Incorporating Forecasts from Other Sources

You might have forecasts from other sources that you want to include in the forecasting process. Examples of other forecasts you might want to use are “best guess” forecasts based on personal judgments, forecasts produced by government agencies or commercial forecasting services, planning scenarios, and reference or “base line” projections. Because such forecasts are produced externally to the Time Series Forecasting System, they are referred to as external forecasts.

You can include external forecasts in combination models to produce compromise forecasts that split the difference between the external forecast and forecasting models that you fit. You can use external forecasts to compare them to the forecasts from models that are fit by the system.

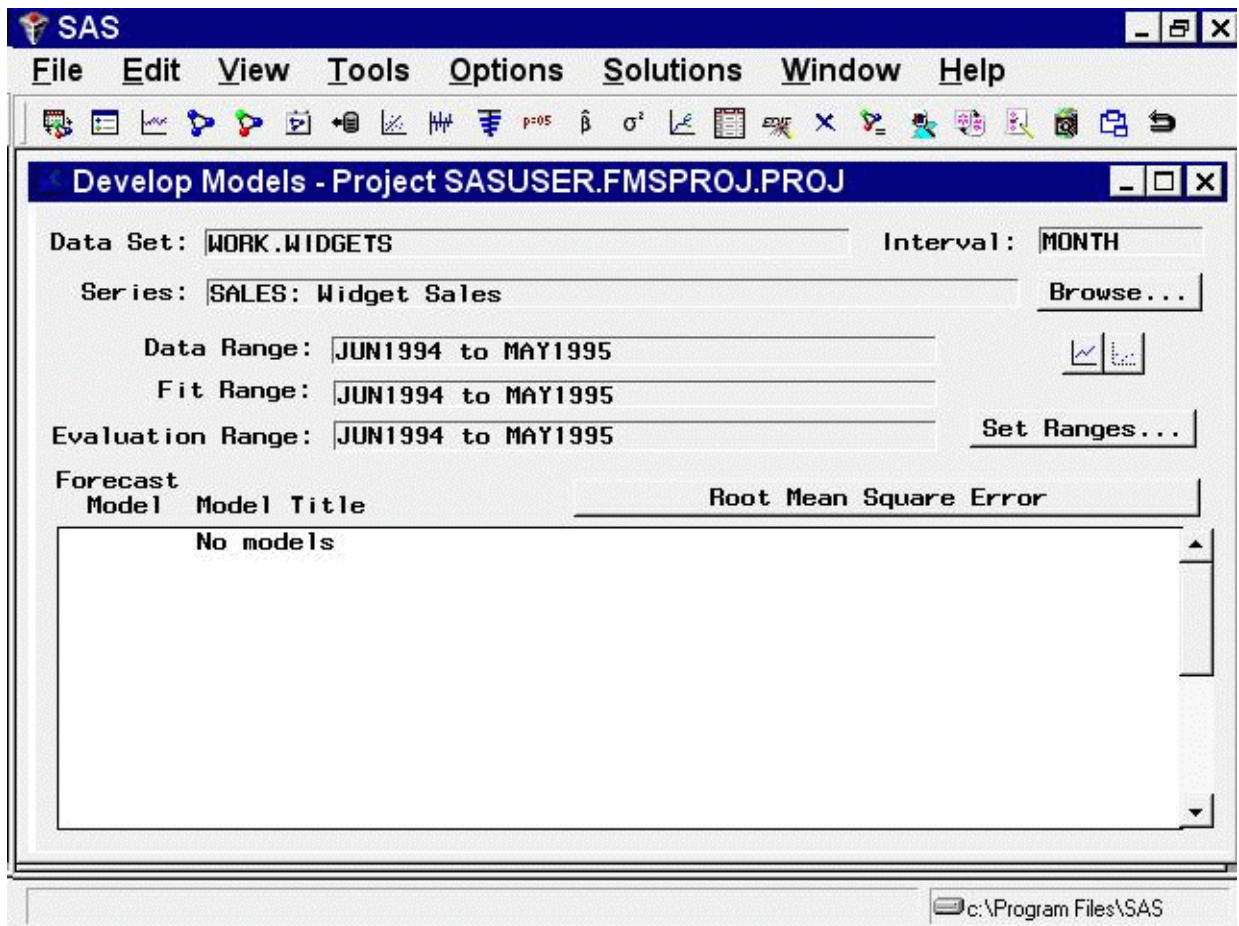

To include external forecasts in the Time Series Forecasting process, you must first supply the external forecast as a variable in the input data set. You then specify a special kind of forecasting “model” whose predictions are identical to the external forecast recorded in the data set.

As an example, suppose you have 12 months of sales data and five months of sales forecasts based on a consensus opinion of the sales staff. The following statements create a SAS data set containing made-up numbers for this situation.

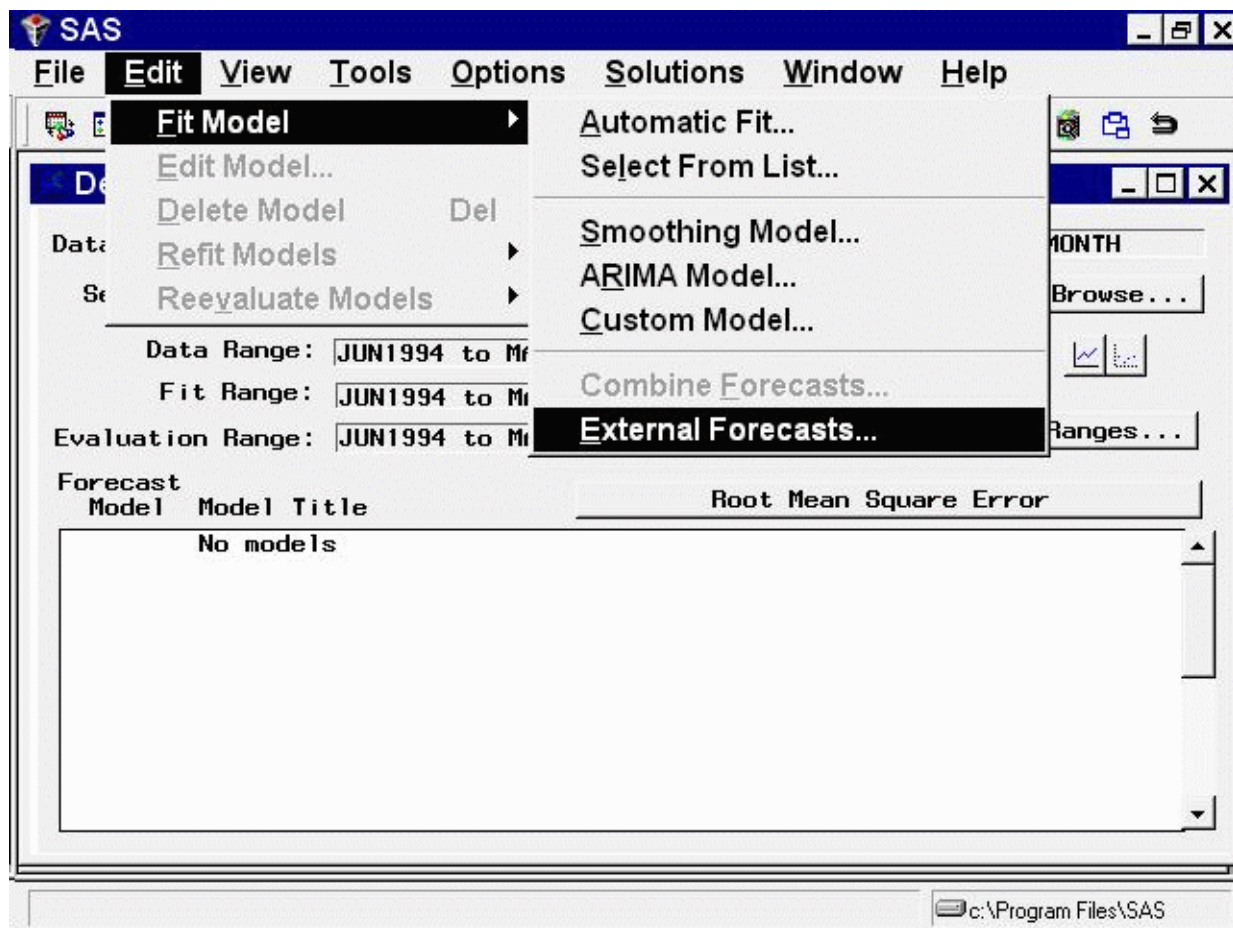

```
data widgets;
  input date monyy5. sales staff;
  format date monyy5.;
  label sales = "Widget Sales"
        staff = "Sales Staff Consensus Forecast";
  datalines;
jun94 142.1 .
jul94 139.6 .
aug94 145.0 .
sep94 150.2 .
oct94 151.1 .
nov94 154.3 .
dec94 158.7 .
jan95 155.9 .
feb95 159.2 .
mar95 160.8 .
apr95 162.0 .
may95 163.3 .
jun95 . 166.
jul95 . 168.
aug95 . 170.
sep95 . 171.
oct95 . 177.
run;
```

Submit the preceding statements in the SAS Program Editor window. From the Time Series Forecasting window, select “Develop Models.” In the Series Selection window, select the data set WORK.WIDGETS and the variable SALES. The Develop Models window should now appear as shown in [Figure 47.32](#).

Figure 47.32 Develop Models Window

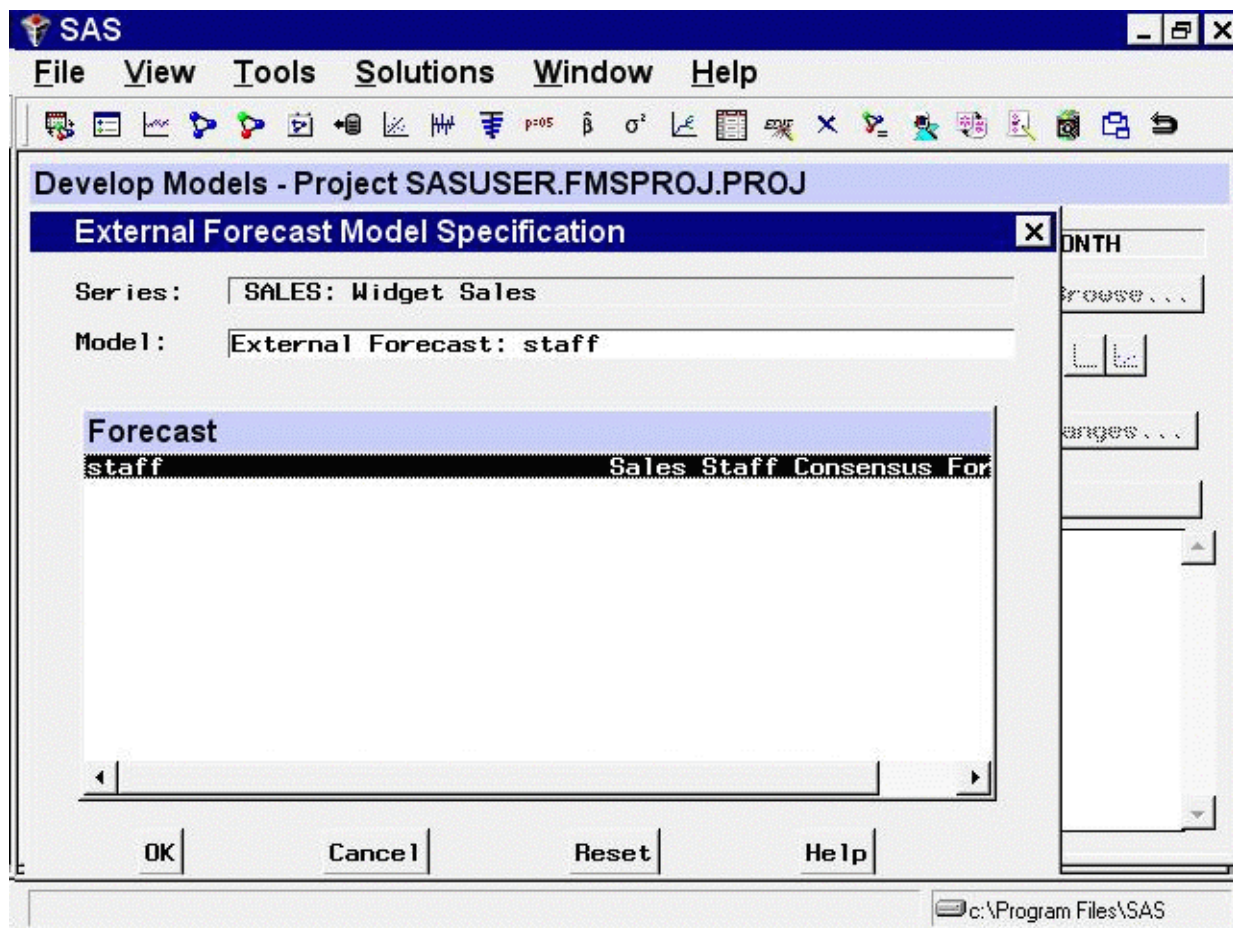

Now select “Edit,” “Fit Model,” and “External Forecasts” from the menu bar of the Develop Models window, as shown in Figure 47.33, or the Use External Forecasts toolbar icon.

Figure 47.33 Adding a Model for an External Forecast Series

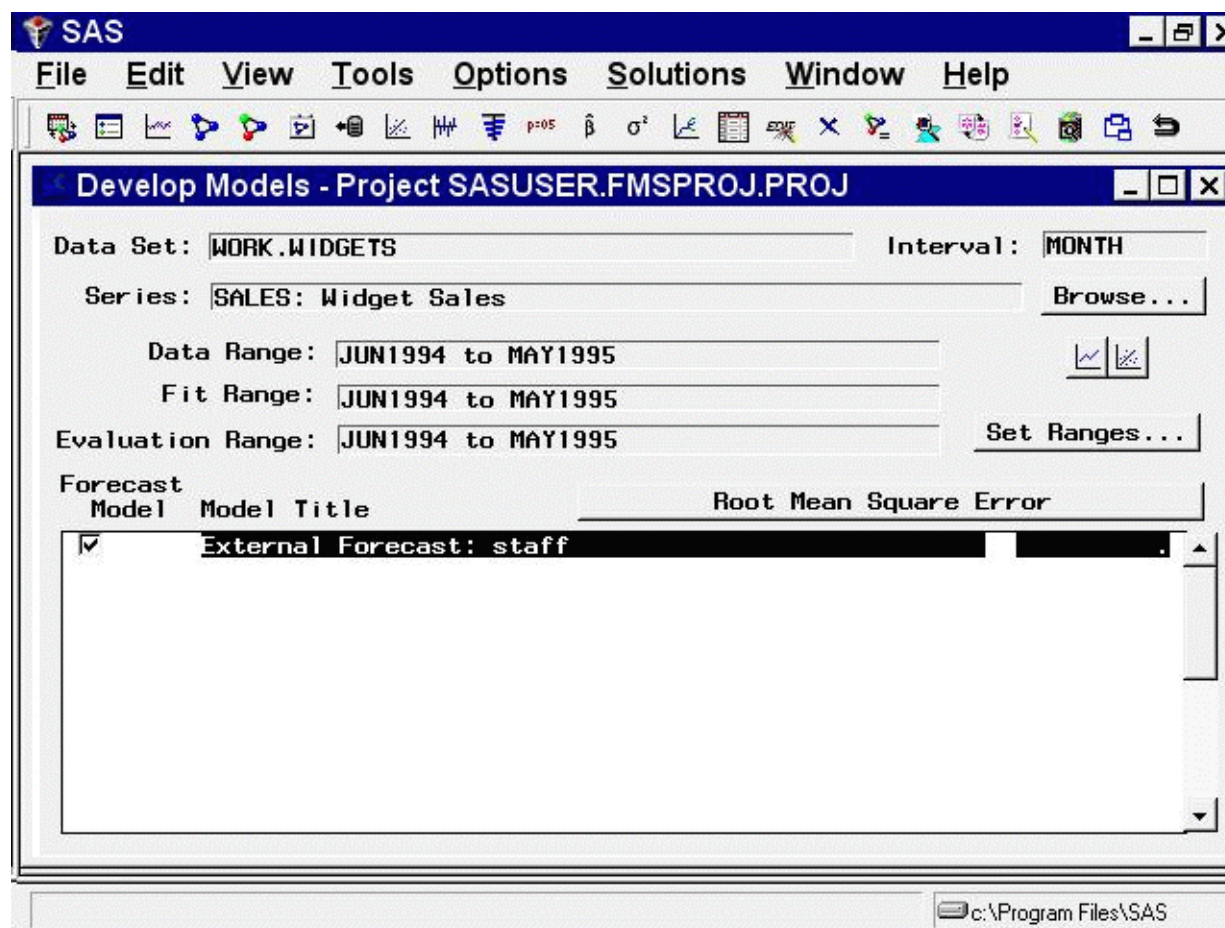

This selection opens the External Forecast Model Specification window. Select the STAFF variable as shown in Figure 47.34.

Figure 47.34 External Forecast Series Selected

Select the OK button. The external forecast model is now “fit” and added to the Develop Models list, as shown in [Figure 47.35](#).

Figure 47.35 Model for External Forecast

You can now use this model for comparison with the predictions from other forecasting models that you fit, or you can include it in a forecast combination model.

Note that no fitting is actually performed for an external forecast model. The predictions of the external forecast model are simply the values of the external forecast series read from the input data set. The goodness-of-fit statistics for such models will depend on the values that the external forecast series contains for observations within the period of fit. In this case, no STAFF values are given for past periods, and therefore the fit statistics for the model are missing.

Comparing Models	3141
Controlling the Period of Evaluation and Fit	3142
Refitting and Reevaluating Models	3143
Using Hold-out Samples	3143

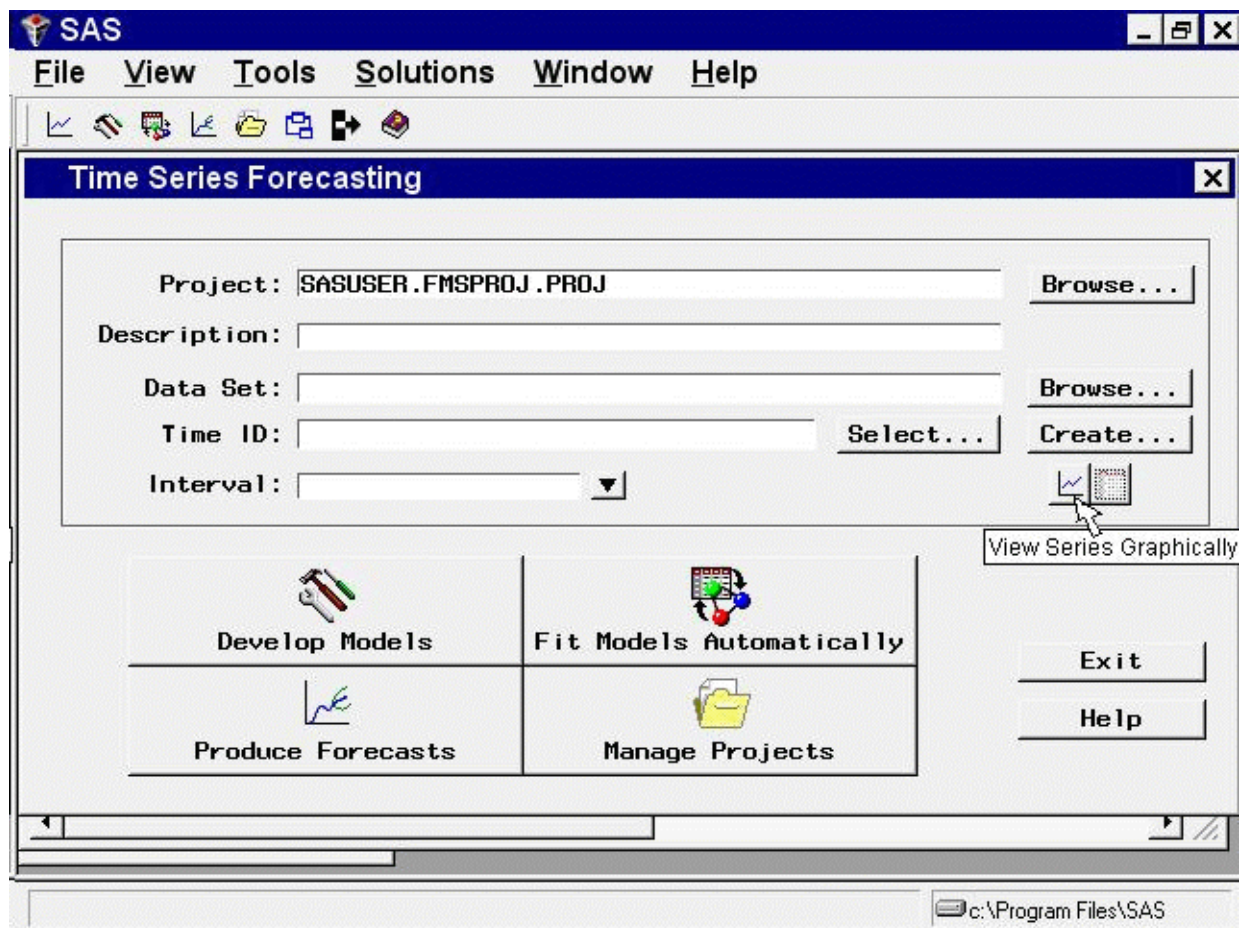

The Time Series Forecasting System provides a variety of tools for identifying potential forecasting models and for choosing the best fitting model. It allows you to decide how much control you want to have over the process, from a hands-on approach to one that is completely automated. This chapter begins with an exploration of the tools available through the Series Viewer and Model Viewer. It presents an example of identifying models graphically and exercising your knowledge of model properties. The remainder of the chapter shows you how to compare models by using a variety of statistics and by controlling the fit and evaluation time ranges. It concludes by showing you how to refit existing models and how to compare models using hold-out samples.

Time Series Viewer Features

The Time Series Viewer is a graphical tool for viewing and analyzing time series. It can be used separately from the Time Series Forecasting System by using the `TSVIEW` command or by selecting Time Series Viewer from the Analysis pull-down menu under Solutions.

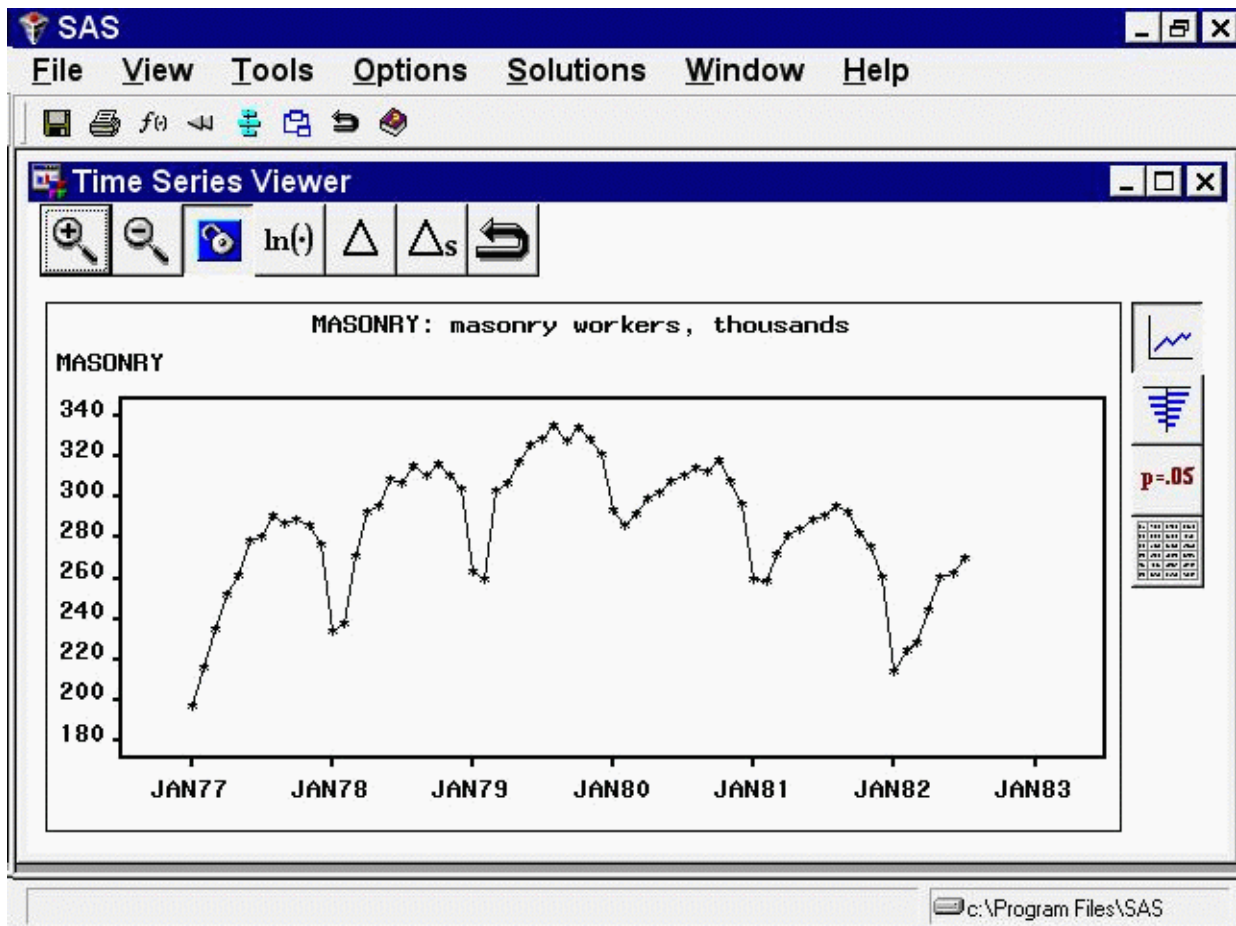

In this chapter you will use the Time Series Viewer to examine plots of your series before fitting models. Begin this example by invoking the Forecasting system and selecting the View Series Graphically button, as shown in Figure 48.1, or the View Series toolbar icon.

Figure 48.1 Invoking the Time Series Viewer

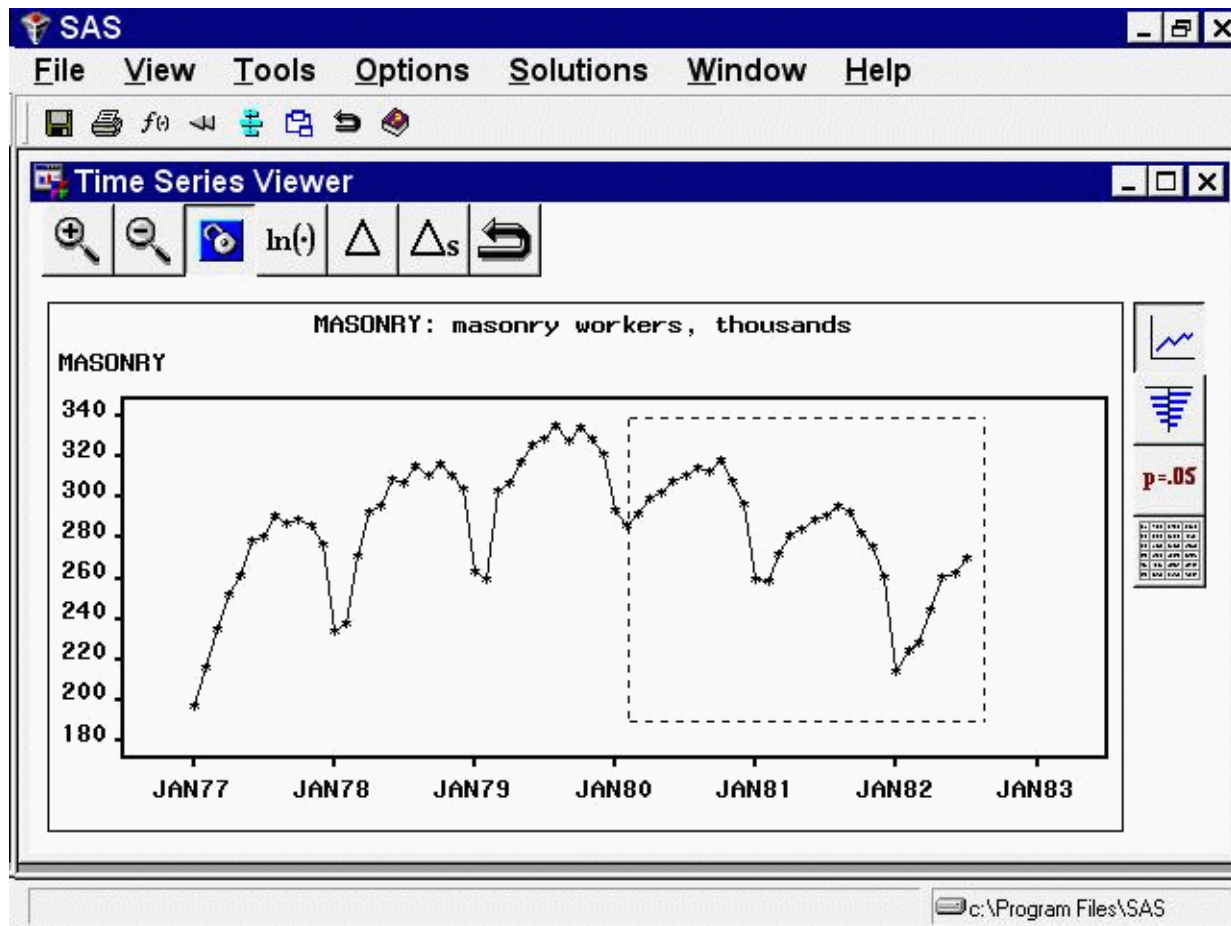

From the Series Selection window, select SASHELP as the library, WORKERS as the data set, and MASONRY as the time series, and then click the *Graph* button. The Time Series Viewer displays a plot of the series, as shown in Figure 48.2.

Figure 48.2 Series Plot

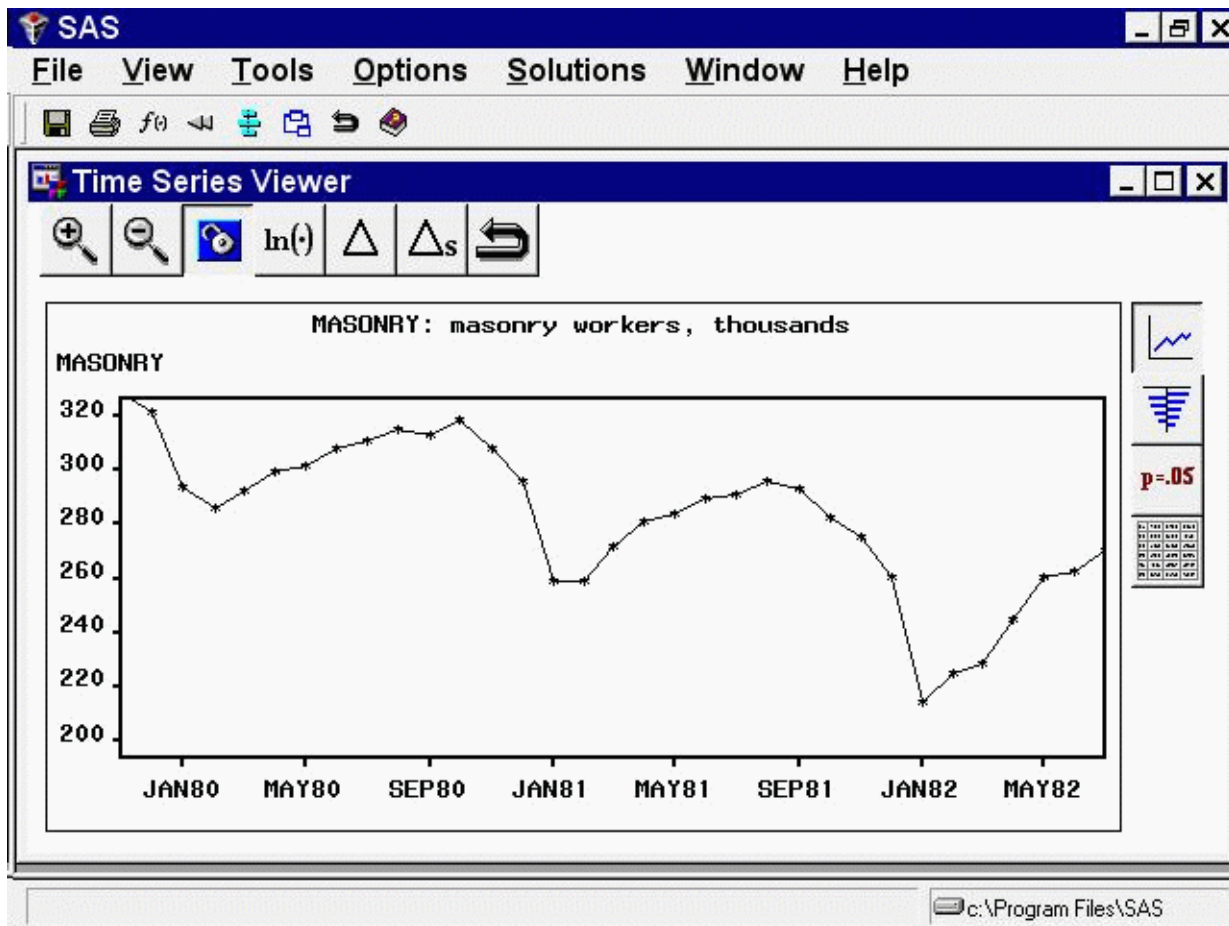

Select the Zoom In icon, the first one on the window's horizontal toolbar. Notice that the mouse cursor changes shape and that "Note: Click on a corner of the region, then drag to the other corner" appears on the message line. Outline an area, as shown in Figure 48.3, by clicking the mouse at the upper-left corner, holding the button down, dragging to the lower-right corner, and releasing the button.

Figure 48.3 Selecting an Area for Zoom

The zoomed plot should appear as shown in [Figure 48.4](#).

Figure 48.4 Zoomed Plot

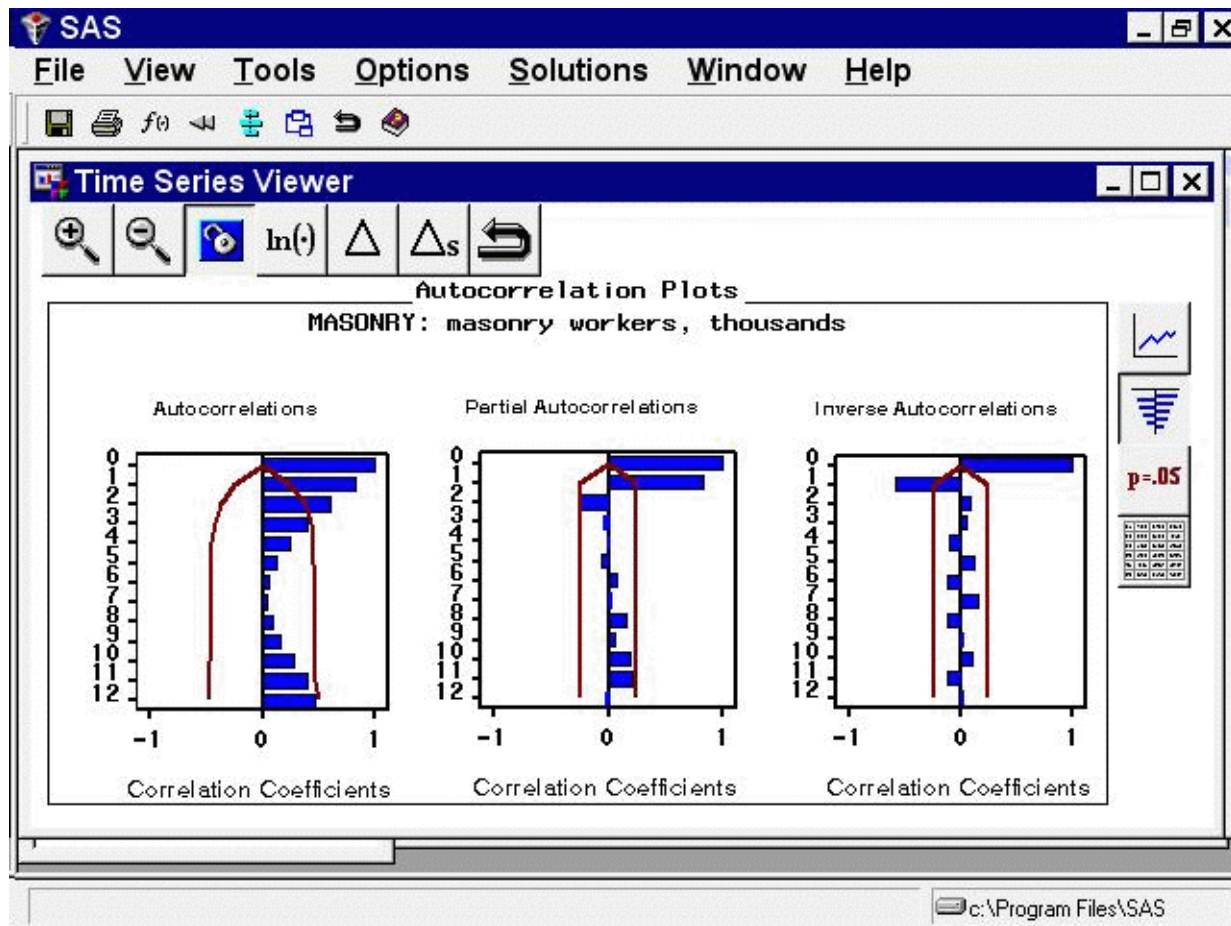

You can repeat the process to zoom in still further. To return to the previous view, select the Zoom Out icon, the second icon on the window's horizontal toolbar.

The third icon on the horizontal toolbar is used to link or unlink the viewer window. By default, the viewer is linked, meaning that it is automatically updated to reflect selection of a different time series. To see this, return to the Series Selection window by clicking on it or using the Window menu or Next Viewer toolbar icon. Select the Electric series in the Time Series Variables list box. Notice that the Time Series Viewer window is updated to show a plot of the ELECTRIC series. Select the Link/Unlink icon if you prefer to unlink the viewer so that it is not automatically updated in this way. Successive selections toggle between the linked and unlinked state. A note on the message line informs you of the state of the Time Series Viewer window.

When a Time Series Viewer window is linked, selecting View Series again makes the linked Viewer window active. When no Time Series Viewer window is linked, selecting View Series opens an additional Time Series Viewer window. You can bring up as many Time Series Viewer windows as you want.

Having seen the plot in Figure 48.2, you might suspect that the series is nonstationary and seasonal. You can gain further insight into this by examining the sample autocorrelation function (ACF), partial autocorrelation function (PACF), and inverse autocorrelation function (IACF) plots. To switch the display to the autocorrelation plots, select the second icon from the top on the vertical toolbar at the right side of the Time Series Viewer. The plot appears as shown in Figure 48.5.

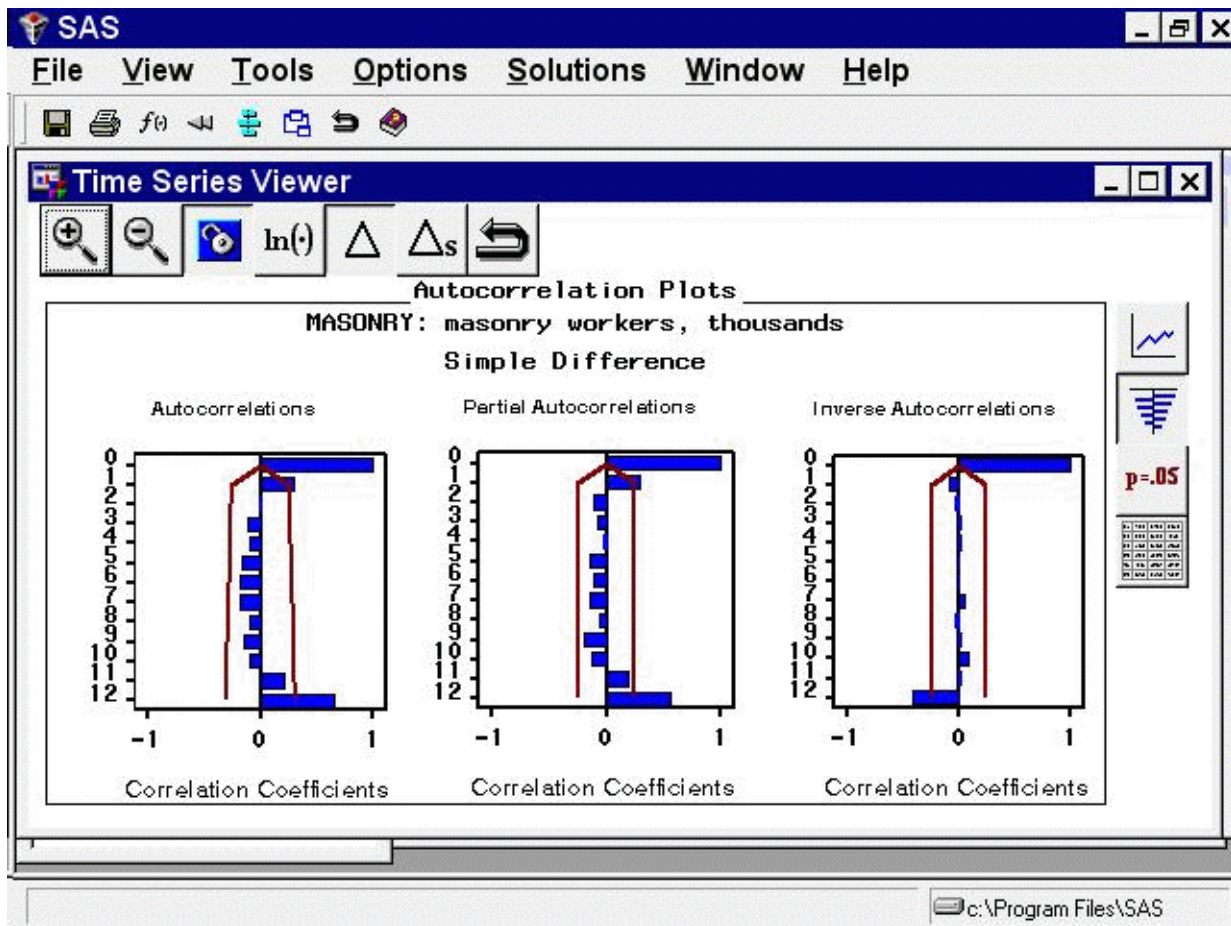

Figure 48.5 Sample Autocorrelation Plots

Each bar represents the value of the correlation coefficient at the given lag. The overlaid lines represent confidence limits computed at plus and minus two standard errors. You can switch the graphs to show significance probabilities by selecting **Correlation Probabilities** under the **Options** pull-down menu, or by selecting the **Toggle ACF Probabilities** toolbar icon.

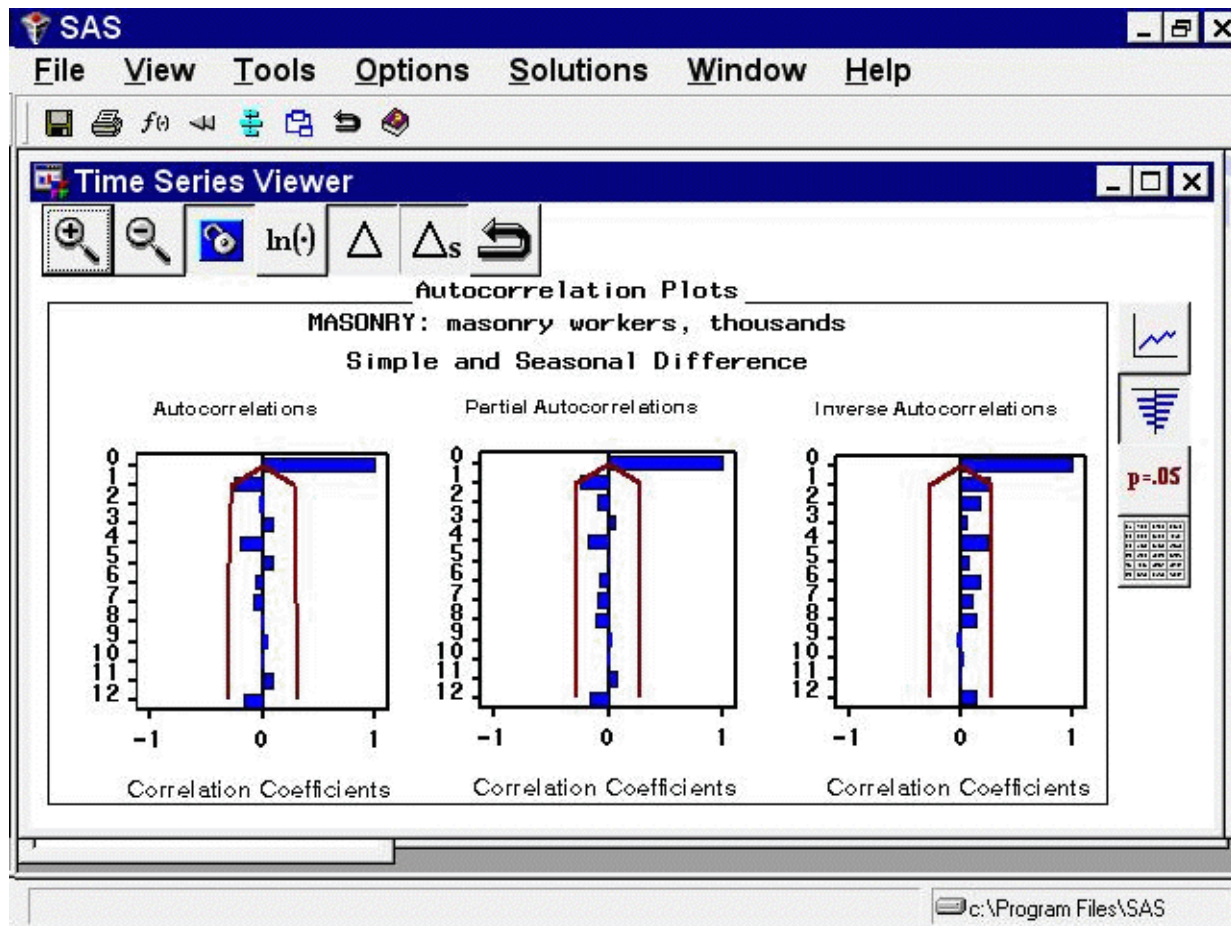

The slow decline of the ACF suggests that first differencing might be warranted. To see the effect of first differencing, select the simple difference icon, the fifth icon from the left on the window's horizontal toolbar. The plot now appears as shown in [Figure 48.6](#).

Figure 48.6 ACF Plots with First Difference Applied

Since the ACF still displays slow decline at seasonal lags, seasonal differencing is appropriate (in addition to the first differencing already applied). Select the *Seasonal Difference* icon, the sixth icon from the left on the horizontal toolbar. The plot now appears as shown in Figure 48.7.

Figure 48.7 ACF Plot with Simple and Seasonal Differencing

Model Viewer Prediction Error Analysis

Leave the Time Series Viewer open for the remainder of this exercise. Drag it out of the way or push it to the background so that you can return to the Time Series Forecasting window. Select **Develop Models**, then click an empty part of the table to bring up the pop-up menu, and select **Fit ARIMA Model**. Define the $ARIMA(0,1,0)(0,1,0)_s$ model by selecting 1 for Differencing under ARIMA Options, 1 for Differencing under Seasonal ARIMA Options, and No for Intercept, as shown in Figure 48.8.

c:\Program Files\SAS

When you select the **OK** button, the model is fit and you are returned to the Develop Models window. Click on an empty part of the table and choose **Fit Models from List** from the pop-up menu. Select **Airline Model** from the window. (Airline Model is a common name for the ARIMA(0,1,1)(0,1,1)s model, which is often used for seasonal data with a linear trend.) Select the **OK** button. Once the model has been fit, the table shows the two models and their root mean square errors. Notice that the Airline Model provides only a slight improvement over the differencing model, ARIMA(0,1,0)(0,1,0)s. Select the first row to highlight the differencing model, as shown in [Figure 48.9](#).

Figure 48.9 Selecting a Model

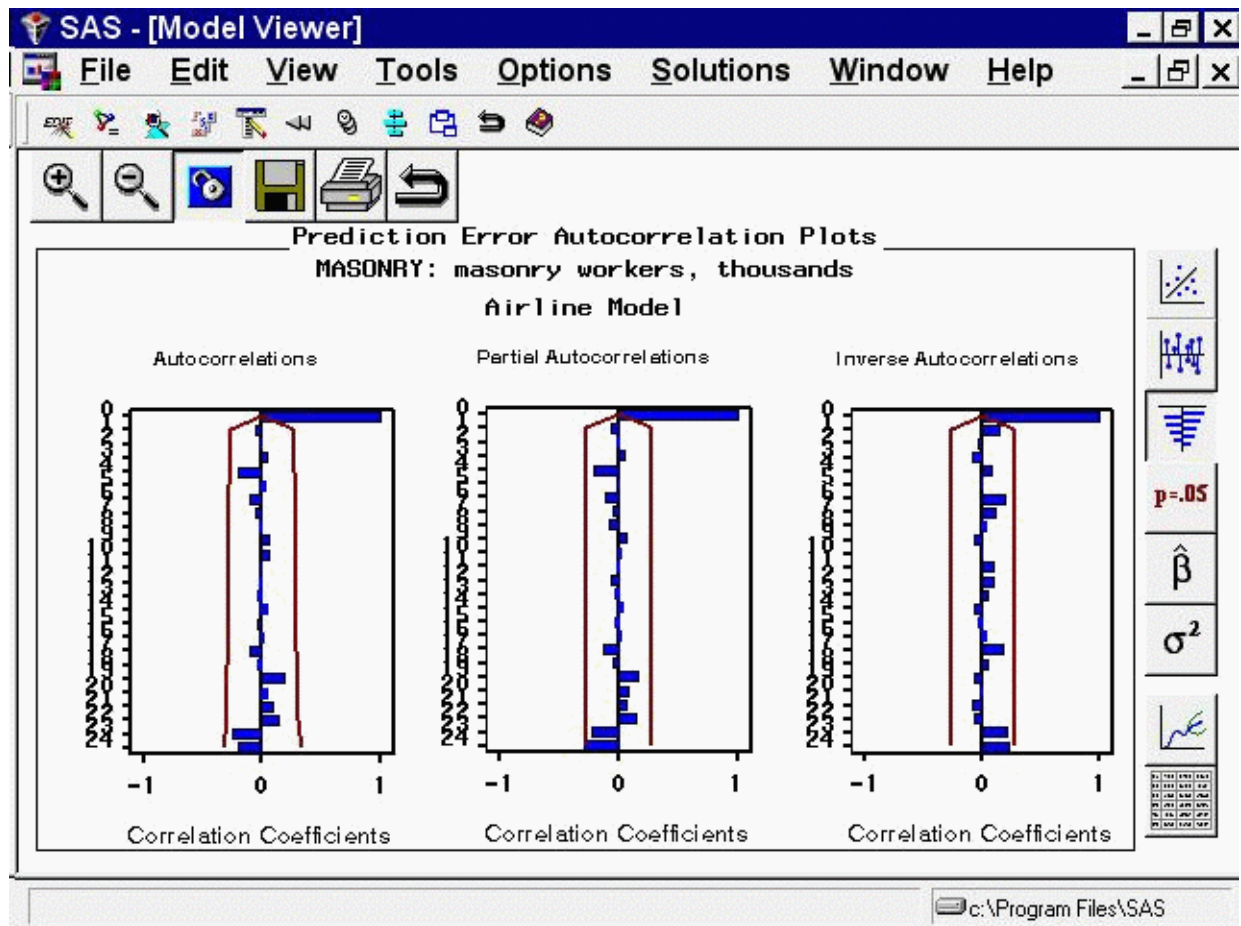

Now select the **View Selected Model Graphically** button, below the **Browse** button at the right side of the **Develop Models** window. The **Model Viewer** window appears, showing the actual data and model predictions for the MASONRY series. (Note that predicted values are missing for the first 13 observations due to simple and seasonal differencing.)

To examine the ACF plot for the model prediction errors, select the third icon from the top on the vertical toolbar. For this model, the prediction error ACF is the same as the ACF of the original data with first differencing and seasonal differencing applied. This differencing is apparent if you bring the Time Series Viewer back into view for comparison.

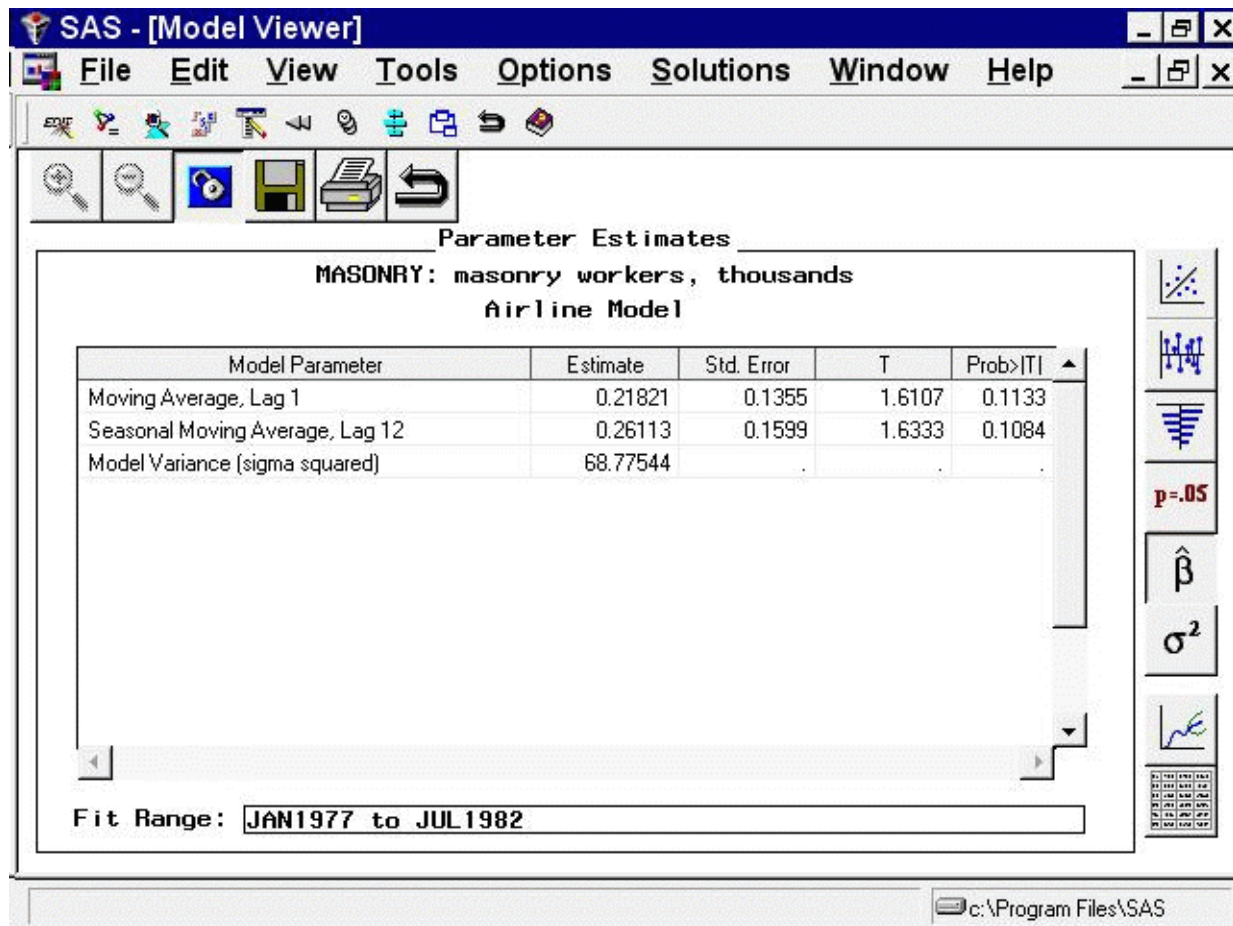

Return to the **Develop Models** Window by clicking on it or using the window pull-down menu or the **Next Viewer** toolbar icon. Select the second row of the table in the **Develop Models** window to highlight the **Airline Model**. The **Model Viewer** is automatically updated to show the prediction error ACF of the newly selected model, as shown in Figure 48.10.

Figure 48.10 Prediction Error ACF Plot for the Airline Model

Another helpful tool available within the Model Viewer is the parameter estimates table. Select the fifth icon from the top of the vertical toolbar. The table gives the parameter estimates for the two moving-average terms in the Airline Model, as well as the model residual variance, as shown in Figure 48.11.

Figure 48.11 Parameter Estimates for the Airline Model

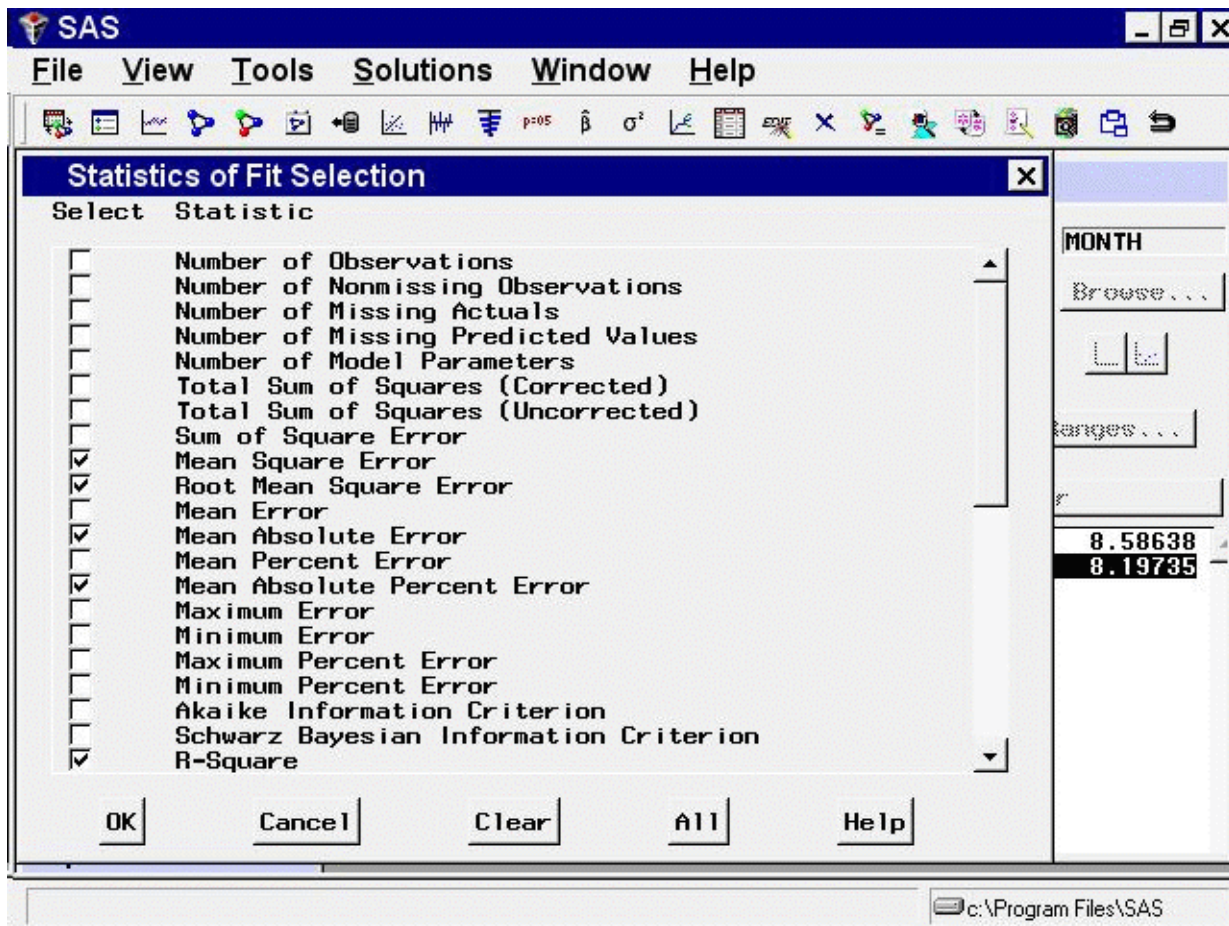

You can adjust the column widths in the table by dragging the vertical borders of the column titles with the mouse. Notice that neither of the parameter estimates is significantly different from zero at the 0.05 level of significance, since $\text{Prob}>|t|$ is greater than 0.05. This suggests that the Airline Model should be discarded in favor of the more parsimonious differencing model, which has no parameters to estimate.

The Model Selection Criterion

Return to the Develop Models window (Figure 48.9) and notice the Root Mean Square Error button at the right side of the table banner. This is the model selection criterion—the statistic used by the system to select the best fitting model. So far in this example you have fit two models and have left the default criterion, root mean square error (RMSE), in effect. Because the Airline Model has the smaller value of this criterion and because smaller values of the RMSE indicate better fit, the system has chosen this model as the forecasting model, indicated by the check box in the Forecast Model column.

The statistics available as model selection criteria are a subset of the statistics available for informational purposes. To access the entire set, select **Options** from the menu bar, and then select **Statistics of Fit**. The Statistics of Fit Selection window appears, as shown in Figure 48.12.

Figure 48.12 Statistics of Fit

By default, five of the more well known statistics are selected. You can select and deselect statistics by clicking the check boxes in the left column. For this exercise, select **All**, and notice that all the check boxes become checked. Select the **OK** button to close the window. Now if you choose **Statistics of Fit** in the **Model Viewer** window, all of the statistics will be shown for the selected model.

To change the model selection criterion, click the **Root Mean Square Error** button or select **Options** from the menu bar and then select **Model Selection Criterion**. Notice that most of the statistics of fit are shown, but those which are not relevant to model selection, such as number of observations, are not shown. Select **Schwarz Bayesian Information Criterion** and click **OK**. Since this statistic puts a high penalty on models with larger numbers of parameters, the **ARIMA(0,1,0)(0,1,0)s** model comes out with the better fit.

Notice that changing the selection criterion does not automatically select the model that is best according to that criterion. You can always choose the model you want to use for forecasts by selecting its check box in the **Forecast Model** column.

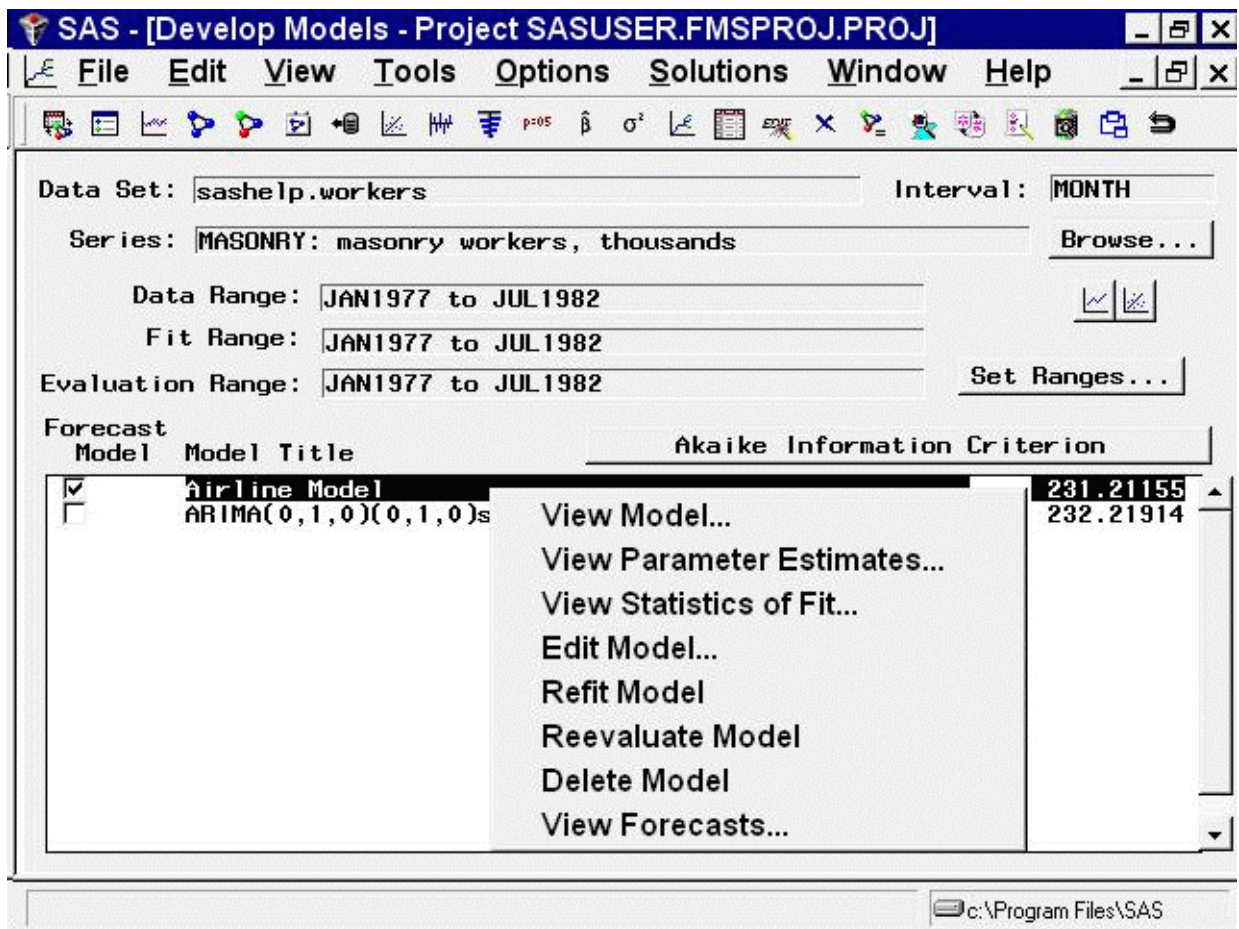

Now bring up the **Model Selection Criterion** window again and select **Akaike Information Criterion**. This statistic puts a lesser penalty on number of parameters, and the **Airline Model** comes out as the better fitting model.

Sorting and Selecting Models

Select **Sort Models** on the **Tools** menu or from the toolbar. This sorts the current list of fitted models by the current selection criterion. Although some selection criteria assign larger values to better fitting models (for example, R-square) while others assign smaller values to better fitting models, **Sort Models** always orders models with the best fitting model—in this case, the Airline Model—at the top of the list.

When you select a model in the table, its name and criterion value become highlighted, and actions that apply to that model become available. If your system supports a right mouse button, you can click it to invoke a pop-up menu, as shown in Figure 48.13.

Figure 48.13 Right Mouse Button Pop-up Menu

Whether or not you have a right mouse button, the same choices are available under **Edit** and **View** from the menu bar. If the model viewer has been invoked, it is automatically updated to show the selected model, unless you have unlinked the viewer by using the **Link/Unlink** toolbar button.

Select the highlighted model in the table again. Notice that it is no longer highlighted. When no models are highlighted, the right mouse button pop-up menu changes, and items on the menu bar that apply to a selected model become unavailable. For example, you can choose **Edit** from the menu bar, but you can't choose the **Edit Model** or **Delete Model** selections unless you have highlighted a model in the table.

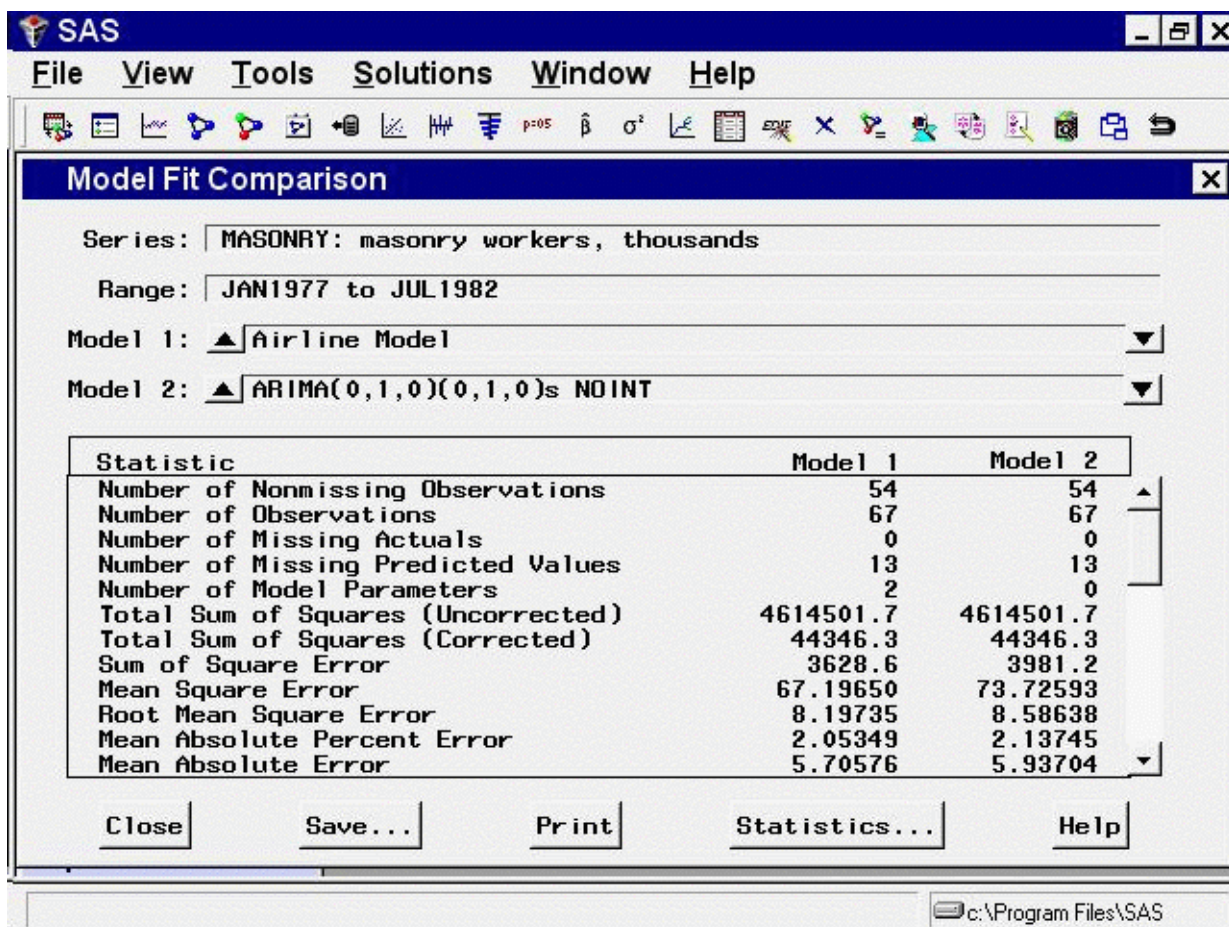

When you select the check box in the **Forecast Model** column of the table, the model in that row becomes

the forecasting model. This is the model that will be used the next time forecasts are generated by choosing `View Forecasts` or by using the `Produce Forecasts` window. Note that this forecasting model flag is automatically set when you use `Fit Automatic Model` or when you fit an individual model that fits better, using the current selection criterion, than the current forecasting model.

Comparing Models

Select `Tools` and `Compare Models` from the menu bar. This displays the `Model Fit Comparison` table, as shown in Figure 48.14.

Figure 48.14 Model Comparison Window

The two models you have fit are shown as `Model 1` and `Model 2`. When there are more than two models, you can bring any two of them into the table by selecting the up and down arrows. In this way, it is easy to do pairwise comparisons on any number of models, looking at as many statistics of fit as you like. Since you previously chose to display all statistics of fit, all of them are shown in the comparison table. Use the vertical scroll bar to move through the list.

After you have examined the model comparison table, select the `Close` button to return to the `Develop Models` window.

Controlling the Period of Evaluation and Fit

Notice the three time ranges shown on the Develop Models window (Figure 48.9). The data range shows the beginning and ending dates of the MASONRY time series. The period of fit shows the beginning and ending dates of data used to fit the models. The period of evaluation shows the beginning and ending dates of data used to compute statistics of fit. By default, the fit and evaluate ranges are the same as the data range. To change these ranges, select the **Set Ranges** button, or select **Options** and **Time Ranges** from the menu bar. This brings up the **Time Ranges Specification** window, as shown in Figure 48.15.

Figure 48.15 Time Ranges Specification Window

SAS File View Tools Solutions Window Help

Develop Models - Project SASUSER.FMSPROJ.PROJ

Time Ranges Specification

Data Set:

Interval:

Series:

Time Ranges:

	From	To
Data Range:	<input type="text" value="JAN1977"/>	<input type="text" value="JUL1982"/>
Period of Fit:	<input type="text" value="JAN1977"/>	<input type="text" value="JUL1982"/>
Period of Evaluation:	<input type="text" value="JAN1977"/>	<input type="text" value="JUL1982"/>
Forecast Horizon:	<input type="text" value="12"/> <input type="text" value="Periods"/>	<input type="text" value="JUL1983"/>
Hold-out Sample:	<input type="text" value="0"/> <input type="text" value="Periods"/>	

OK Cancel Reset Clear Help

c:\Program Files\SAS

For this example, suppose the early data in the series is unreliable, and you want to use the range June 1978 to the latest available for both model fitting and model evaluation. You can either type JUN1978 in the **From** column for **Period of Fit** and **Period of Evaluation**, or you can advance these dates by clicking the right pointing arrows. The outer arrow advances the date by a large amount (in this case, by a year), and the inner arrow advances it by a single period (in this case, by a month). Once you have changed the **Period of Fit** and the **Period of Evaluation** to JUN1978 in the **From** column, select the **OK** button to return to the **Develop Models** window. Notice that these time ranges are updated at the top of the window, but the models already fit have not been affected. Your changes to the time ranges affect *subsequently fit* models.

Refitting and Reevaluating Models

If you fit the ARIMA(0,1,0)(0,1,0)s and Airline models again in the same way as before, they will be added to the model list, with the same names but with different values of the model selection criterion. Parameter estimates will be different, due to the new fit range, and statistics of fit will be different, due to the new evaluation range.

For this exercise, instead of specifying the models again, refit the existing models by selecting **Edit** from the menu bar and then selecting **Refit Models** and **All Models**. After the models have been refit, you should see the same two models listed in the table but with slightly different values for the selection criterion. The ARIMA (0,1,0)(0,1,0)s and Airline models have now been fit to the MASONRY series by using data from June 1978 to July 1982, since this is the period of fit you specified. The statistics of fit have been computed for the period of evaluation, which was the same as the period of fit. If you had specified a period of evaluation different from the period of fit, the statistics would have been computed accordingly.

In practice, another common reason for refitting models is the availability of new data. For example, when data for a new month become available for a monthly series, you might add them to the input data set, then invoke the forecasting system, open the project containing models fit previously, and refit the models prior to generating new forecasts. Unless you specify the period of fit and period of evaluation in the **Time Ranges Specification** window, they default to the full data range of the series found in the input data set at the time of refitting.

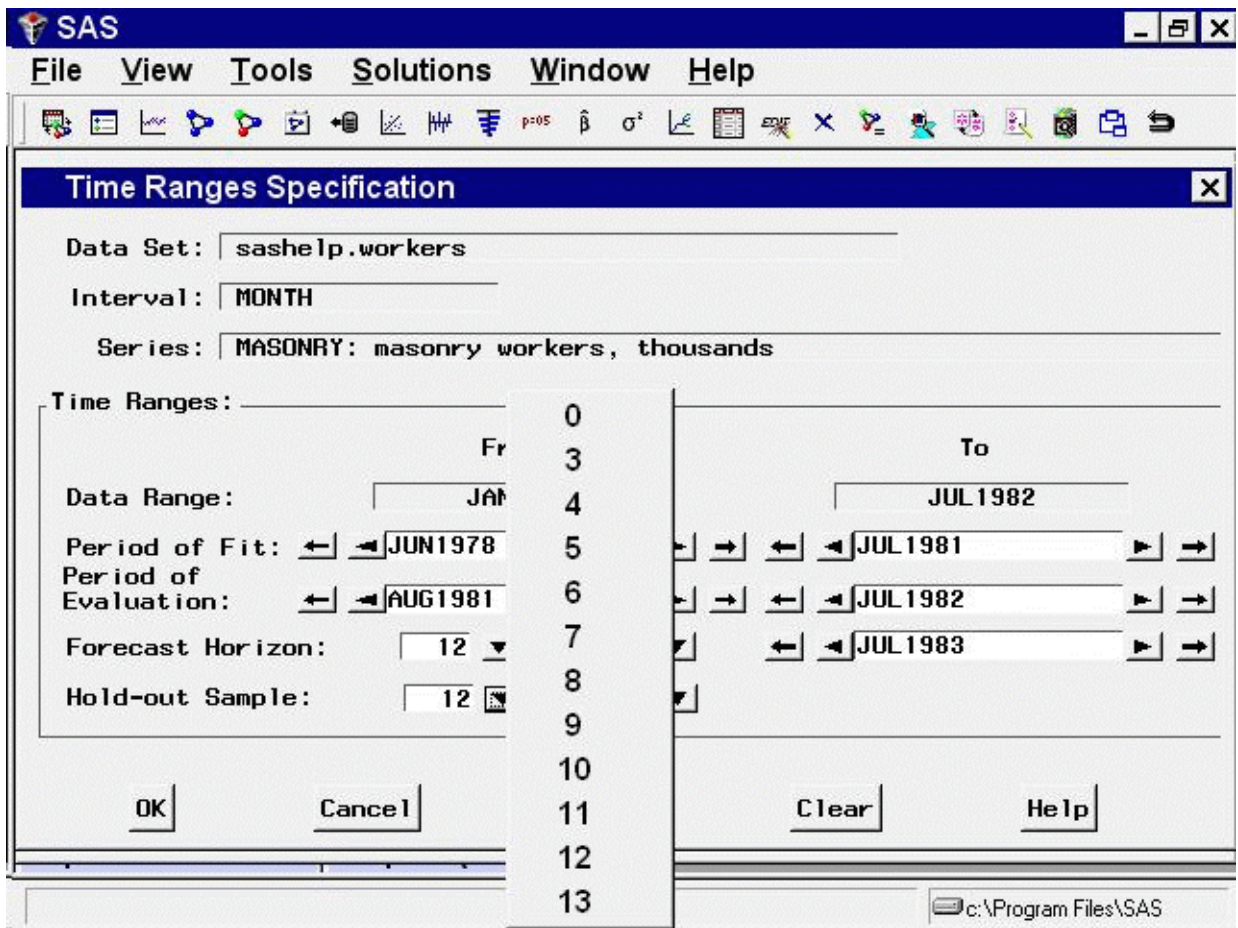

If you prefer to apply previously fit models to revised data without refitting, use **Reevaluate Models** instead of **Refit Models**. This recomputes the statistics of fit by using the current evaluation range, but does not re-estimate the model parameters.

Using Hold-out Samples

One important application of model fitting where the period of fit is different from the period of evaluation is the use of hold-out samples. With this technique of model evaluation, the period of fit ends at a time point before the end of the data series, and the remainder of the data are held out as a nonoverlapping period of evaluation. With respect to the period of fit, the hold-out sample is a period in the future, used to compare the forecasting accuracy of models fit to past data.

For this exercise, use a hold-out sample of 12 months. Bring up the **Time Ranges Specification** window again by selecting the **Set Ranges** button. Set **Hold-out Sample** to 12 using the combo box, as shown in [Figure 48.16](#). You can also type in a value. To specify a hold-out sample period in different units, you can use the **Periods** combo box. In this case, it allows you to select years as the unit, instead of periods.

Figure 48.16 Specifying the Hold-out Sample Size

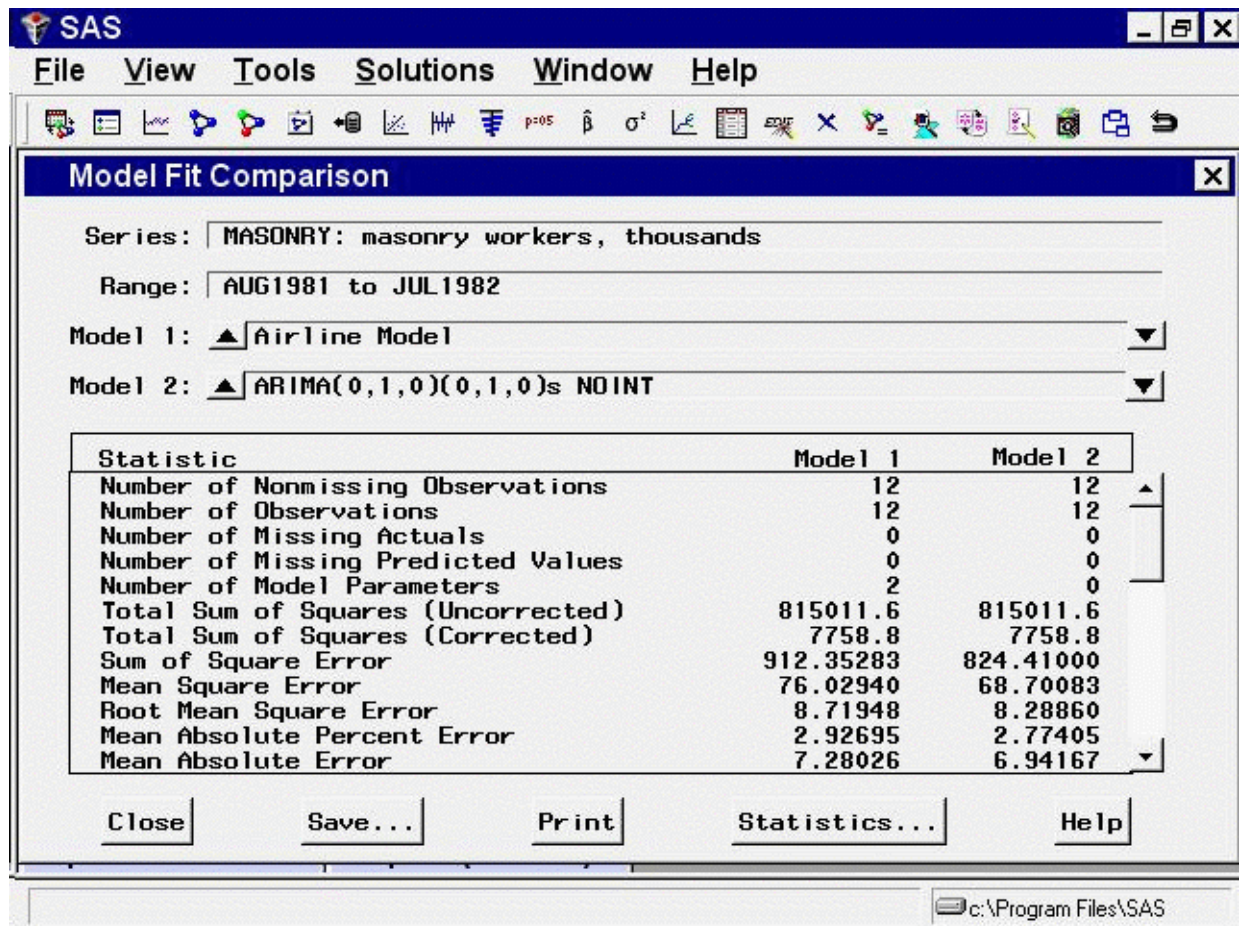

Notice that setting the hold-out sample to 12 automatically sets the fit range to JUN1978–JUL1981 and the evaluation range to AUG1981–JUL1982. If you had set the period of fit and period of evaluation to these ranges, the hold-out sample would have been automatically set to 12 periods.

Select the **OK** button to return to the **Develop Models** window. Now refit the models again. Select **Tools** and **Compare Models** to compare the models now that they have been fit to the period June 1978 through July 1981 and evaluated for the hold-out sample period August 1981 through July 1982. Note that the fit statistics for the hold-out sample are based on one-step-ahead forecasts. (See *Statistics of Fit* in Chapter 52, “Forecasting Process Details.”)

As shown in Figure 48.17, the ARIMA (0,1,0)(0,1,0)_s model now seems to provide a better fit to the data than does the Airline model. It should be noted that the results can be quite different if you choose a different size hold-out sample.

Seasonal Dummies	3174
References	3178

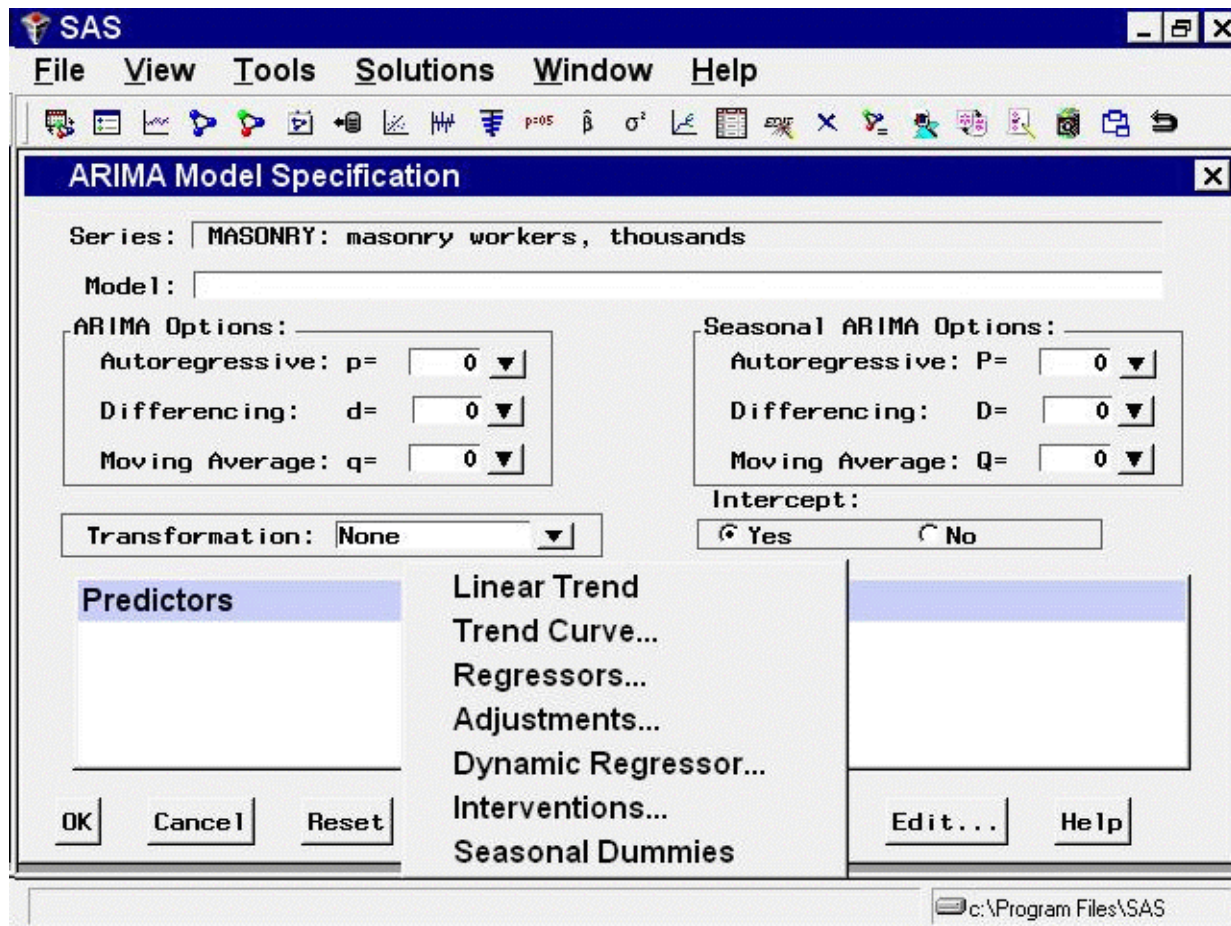

Forecasting models predict the future values of a series by using two sources of information: the past values of the series and the values of other time series variables. Other variables used to predict a series are called *predictor variables*.

Predictor variables that are used to predict the dependent series can be variables in the input data set, such as regressors and adjustment variables, or they can be special variables computed by the system as functions of time, such as trend curves, intervention variables, and seasonal dummies.

You can specify seven different types of predictors in forecasting models by using the ARIMA Model or Custom Model Specification windows. You cannot specify predictor variables with the Smoothing Model Specification window.

Figure 49.1 shows the menu of options for adding predictors to an ARIMA model that is opened by clicking the Add button. The Add menu for the Custom Model Specification menu is similar.

Figure 49.1 Add Predictors Menu

These types of predictors are as follows.

Linear Trend	adds a variable that indexes time as a predictor series. A straight line time trend is fit to the series by regression when you specify a linear trend.
Trend Curve	provides a menu of various functions of time that you can add to the model to fit nonlinear time trends. The Linear Trend option is a special case of the Trend Curve option for which the trend curve is a straight line.
Regressors	allows you to predict the series by regressing it on other variables in the data set.
Adjustments	allows you to specify other variables in the data set that supply adjustments to the forecast.
Dynamic Regressor	allows you to select a predictor variable from the input data set and specify a complex model for the way that the predictor variable affects the dependent series.
Interventions	allows you to model the effect of special events that “intervene” to change the pattern of the dependent series. Examples of intervention effects are strikes, tax increases, and special sales promotions.
Seasonal Dummies	adds seasonal indicator or “dummy” variables as regressors to model seasonal effects.

You can add any number of predictors to a forecasting model, and you can combine predictor variables with other model options.

The following sections explain these seven kinds of predictors in greater detail and provide examples of their use. The examples illustrate these different kinds of predictors by using series in the SASHELP.USECON data set.

Select the `Develop Models` button from the main window. Select the data set SASHELP.USECON and select the `View Series Graphically` button from the Develop Models window. The plot of the example series PETROL appears as shown in Figure 49.2.

Figure 49.2 Sales of Petroleum and Coal

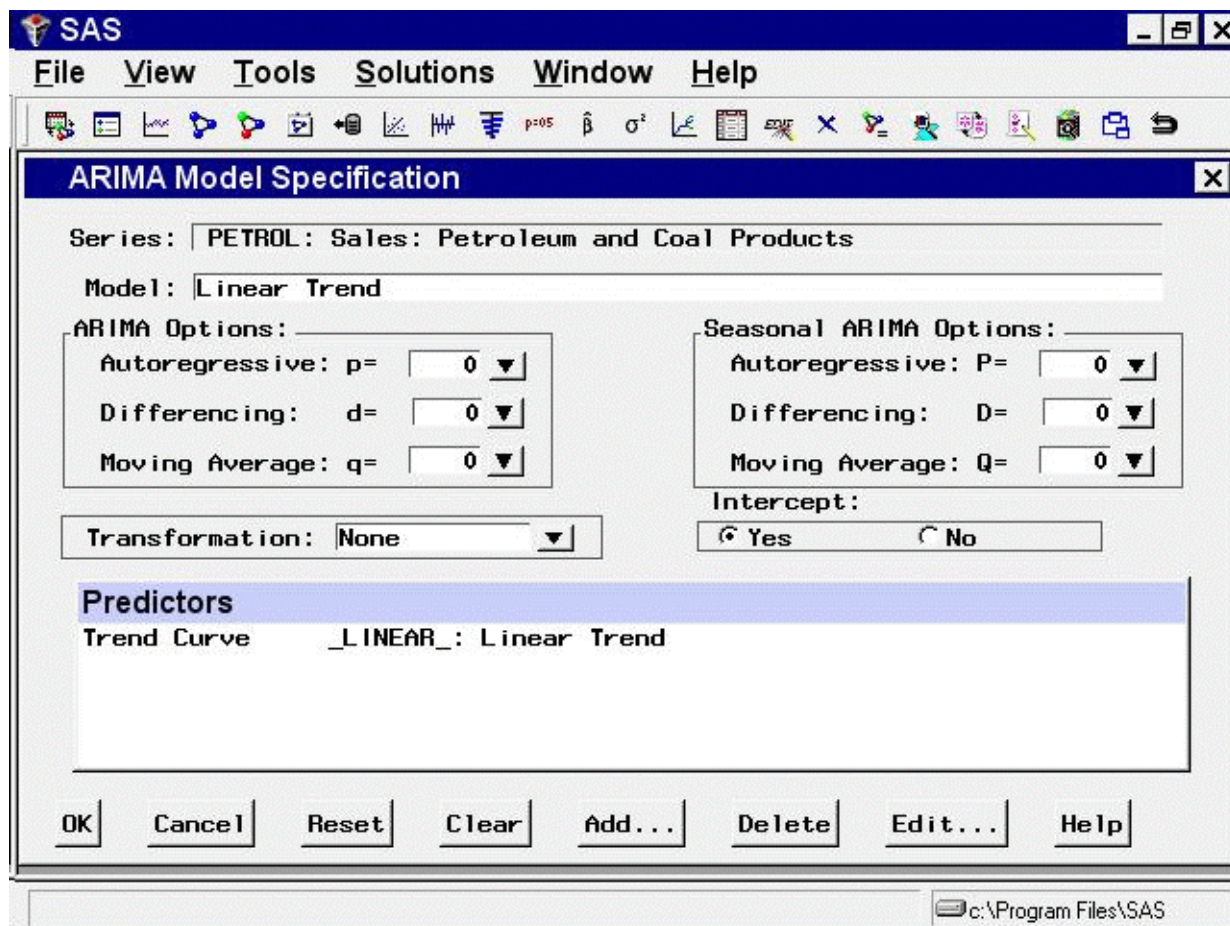

Linear Trend

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select `Add` and then select `Linear Trend` from the menu (shown in Figure 49.1).

A linear trend is added to the Predictors list, as shown in Figure 49.3.

Figure 49.3 Linear Trend Predictor Specified

The description for the linear trend item shown in the Predictors list has the following meaning. The first part of the description, Trend Curve, describes the type of predictor. The second part, `_LINEAR_`, gives the variable name of the predictor series. In this case, the variable is a time index that the system computes. This variable is included in the output forecast data set. The final part, Linear Trend, describes the predictor.

Notice that the model you have specified consists only of the time index regressor `_LINEAR_` and an intercept. Although this window is normally used to specify ARIMA models, in this case no ARIMA model options are specified, and the model is a simple regression on time.

Select the **OK** button. The Linear Trend model is fit and added to the model list in the Develop Models window.

Now open the Model Viewer by using the **View Model Graphically** icon or the **Model Predictions** item under the **View** pull-down menu or toolbar. This displays a plot of the model predictions and actual series values, as shown in Figure 49.4. The predicted values lie along the least squares trend line.

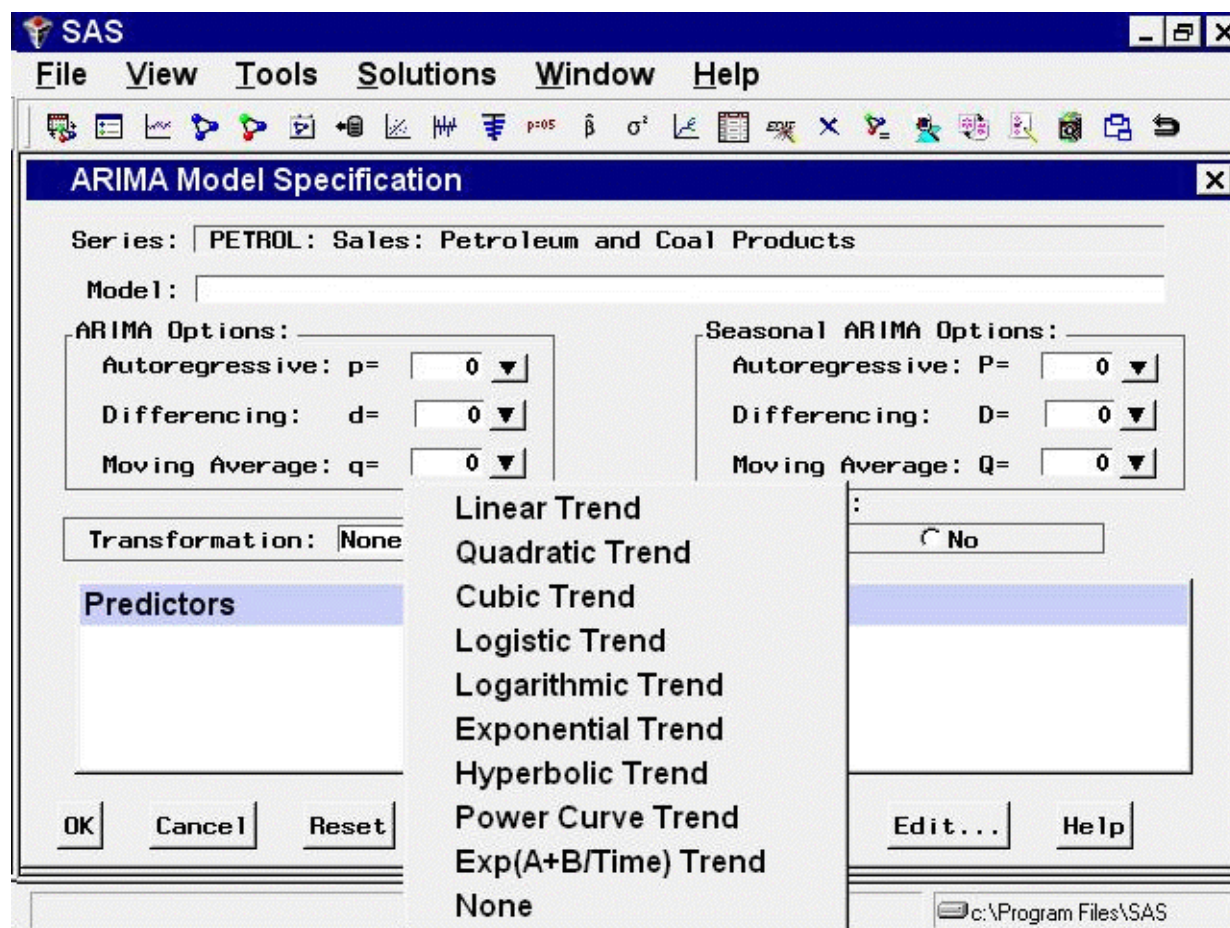

Figure 49.4 Linear Trend Model

Time Trend Curves

From the Develop Models window, select **Fit ARIMA Model**. From the ARIMA Model Specification window, select **Add** and then select **Trend Curve** from the menu (shown in Figure 49.1). A menu of different kinds of trend curves is displayed, as shown in Figure 49.5.

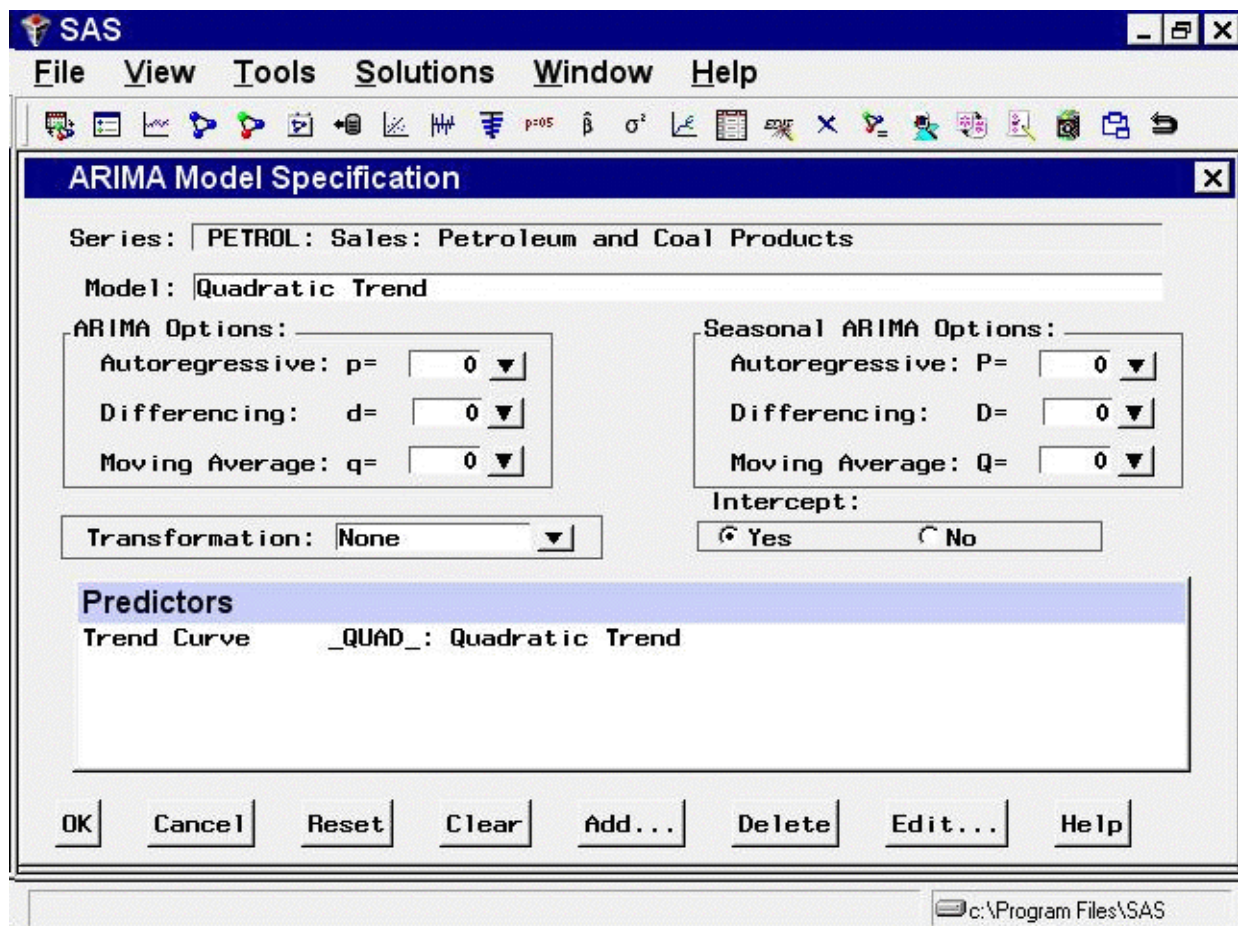

Figure 49.5 Time Trend Curves Menu

These trend curves work in a similar way as the Linear Trend option (which is a special case of a trend curve and one of the choices on the menu), but with the Trend Curve menu you have a choice of various nonlinear time trends.

Select `Quadratic Trend`. This adds a quadratic time trend to the Predictors list, as shown in [Figure 49.6](#).

Figure 49.6 Quadratic Trend Specified

Now select the **OK** button. The quadratic trend model is fit and added to the list of models in the Develop Models window. The Model Viewer displays a plot of the quadratic trend model, as shown in [Figure 49.7](#).

Figure 49.7 Quadratic Trend Model

This curve does not fit the PETROL series very well, but the View Model plot illustrates how time trend models work. You might want to experiment with different trend models to see what the different trend curves look like.

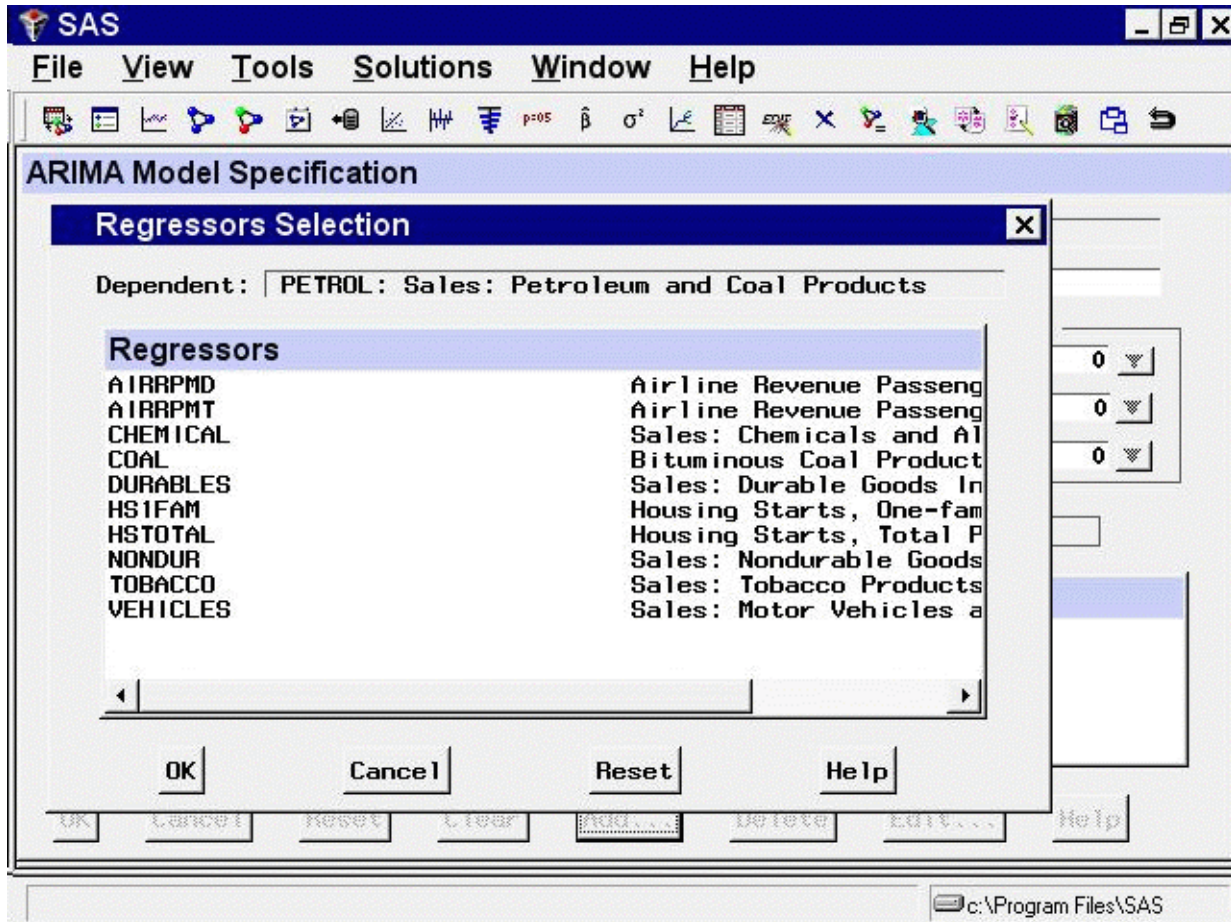

Some of the trend curves require transforming the dependent series. When you specify one of these curves, a notice is displayed reminding you that a transformation is needed, and the Transformation field is automatically filled in. Therefore, you cannot control the Transformation specification when some kinds of trend curves are specified.

See the section “Time Trend Curves” on page 3151 in Chapter 52, “Forecasting Process Details,” for more information about the different trend curves.

Regressors

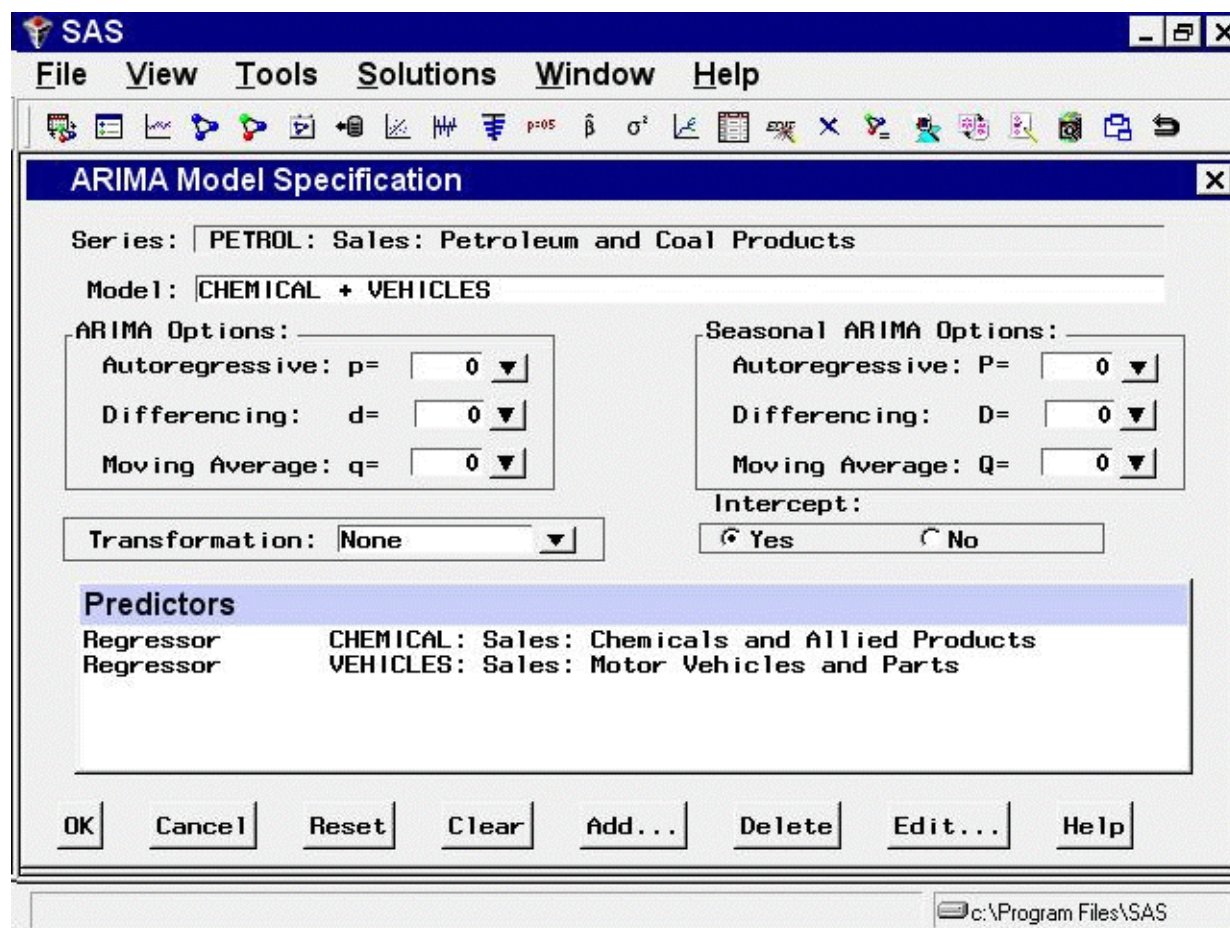

From the Develop Models window, select **Fit ARIMA Model**. From the ARIMA Model Specification window, select **Add** and then select **Regressors** from the menu (shown in [Figure 49.1](#)). This displays the **Regressors Selection** window, as shown in [Figure 49.8](#). This window allows you to select any number of other series in the input data set as regressors to predict the dependent series.

Figure 49.8 Regressors Selection Window

For this example, select **CHEMICAL**, **Sales: Chemicals and Allied Products**, and **VEHICLES**, **Sales: Motor Vehicles and Parts**. (Note: You do not need to use the CTRL key when selecting more than one regressor.) Then select the **OK** button. The two variables you selected are added to the Predictors list as regressor type predictors, as shown in [Figure 49.9](#).

Figure 49.9 Regressors Selected

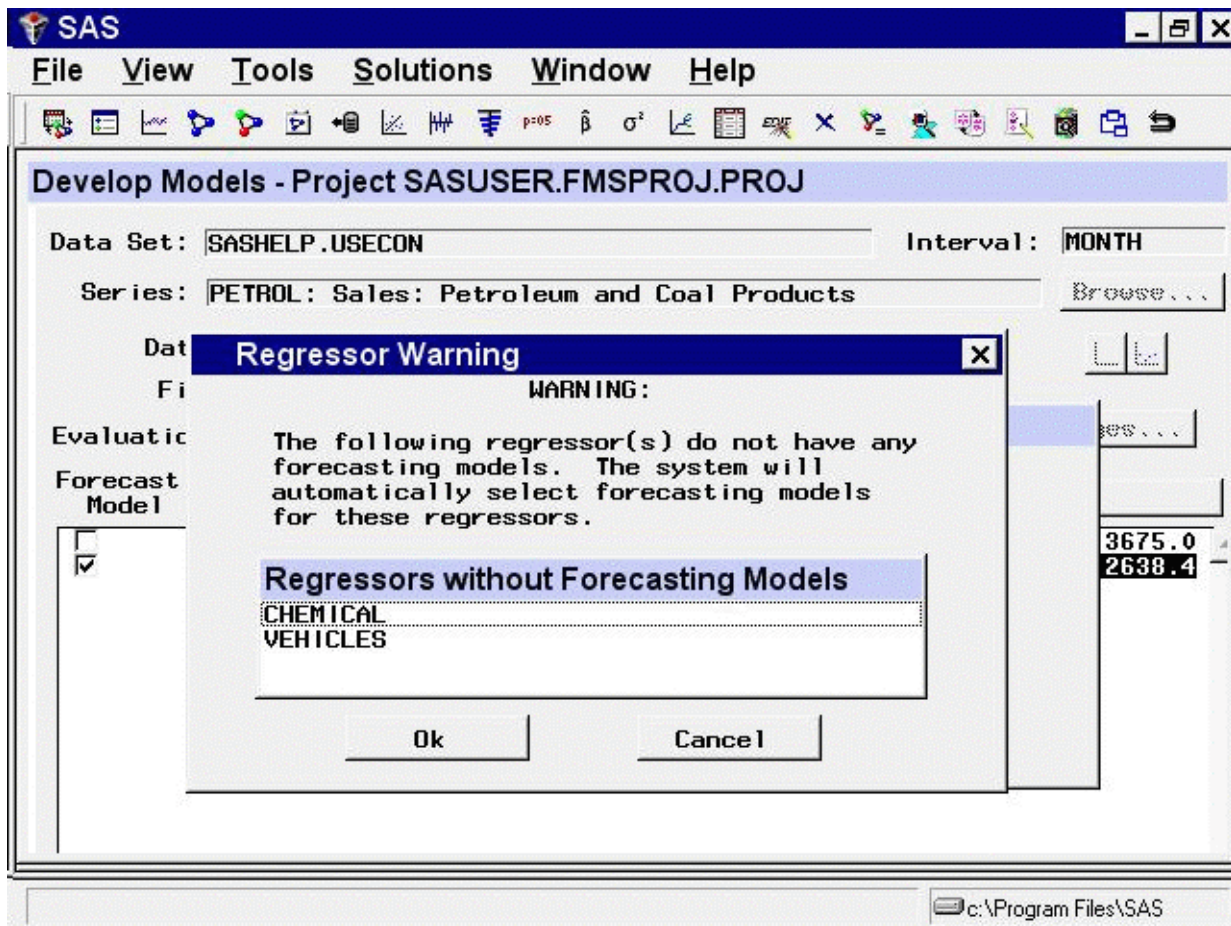

You must have forecasts of the future values of the regressor variables in order to use them as predictors. To do this, you can specify a forecasting model for each regressor, have the system automatically select forecasting models for the regressors, or supply predicted future values for the regressors in the input data set.

Even if you have supplied future values for a regressor variable, the system requires a forecasting model for the regressor. Future values that you supply in the input data set take precedence over predicted values from the regressor's forecasting model when the system computes the forecasts for the dependent series.

Select the **OK** button. The system starts to fit the regression model but then stops and displays a warning that the regressors that you selected do not have forecasting models, as shown in [Figure 49.10](#).

Figure 49.10 Regressors Needing Models Warning

If you want the system to create forecasting models automatically for the regressor variables by using the automatic model selection process, select the **OK** button. If not, you can select the **Cancel** button to abort fitting the regression model.

For this example, select the **OK** button. The system now performs the automatic model selection process for **CHEMICAL** and **VEHICLES**. The selected forecasting models for **CHEMICAL** and **VEHICLES** are added to the model lists for those series. If you switch the current time series in the **Develop Models** window to **CHEMICAL** or **VEHICLES**, you will see the model that the system selected for that series.

Once forecasting models have been fit for all regressors, the system proceeds to fit the regression model for **PETROL**. The fitted regression model is added to the model list displayed in the **Develop Models** window.

Adjustments

An *adjustment* predictor is a variable in the input data set that is used to adjust the forecast values produced by the forecasting model. Unlike a regressor, an adjustment variable does not have a regression coefficient. No model fitting is performed for adjustments. Nonmissing values of the adjustment series are simply added to the model prediction for the corresponding period. Missing adjustment values are ignored. If you supply

adjustment values for observations within the period of fit, the adjustment values are subtracted from the actual values, and the model is fit to these adjusted values.

To add adjustments, select `Add` and then select `Adjustments` from the pop-up menu (shown in [Figure 49.1](#)). This displays the `Adjustments Selection` window. The `Adjustments Selection` window functions the same as the `Regressor Selection` window (which is shown in [Figure 49.8](#)). You can select any number of adjustment variables as predictors.

Unlike regressors, adjustments do not require forecasting models for the adjustment variables. If a variable that is used as an adjustment does have a forecasting model fit to it, the adjustment variable's forecasting model is ignored when the variable is used as an adjustment.

You can use forecast adjustments to account for expected future events that have no precedent in the past and so cannot be modeled by regression. For example, suppose you are trying to forecast the sales of a product, and you know that a special promotional campaign for the product is planned during part of the period you want to forecast. If such sales promotion programs have been frequent in the past, then you can record the past and expected future level of promotional efforts in a variable in the data set and use that variable as a regressor in the forecasting model.

However, if this is the first sales promotion of its kind for this product, you have no way to estimate the effect of the promotion from past data. In this case, the best you can do is to make an educated guess at the effect the promotion will have and add that guess to what your forecasting model would predict in the absence of the special sales campaign.

Adjustments are also useful for making judgmental alterations to forecasts. For example, suppose you have produced forecast sales data for the next 12 months. Your supervisor believes that the forecasts are too optimistic near the end and asks you to prepare a forecast graph in which the numbers that you have forecast are reduced by 1000 in the last three months. You can accomplish this task by editing the input data set so that it contains observations for the actual data range of sales plus 12 additional observations for the forecast period, and a new variable called, for example, `ADJUSTMENT`. The variable `ADJUSTMENT` contains the value 1000 for the last three observations and is missing for all other observations. You fit the same model previously selected for forecasting by using the `ARIMA Model Specification` or `Custom Model Specification` window, but with an adjustment added that uses the variable `ADJUSTMENT`. Now when you graph the forecasts by using the `Model Viewer`, the last three periods of the forecast are reduced by 1000. The confidence limits are unchanged, which helps draw attention to the fact that the adjustments to the forecast deviate from what would be expected statistically.

Dynamic Regressor

Selecting `Dynamic Regressor` from the `Add Predictors` menu (shown in [Figure 49.1](#)) allows you to specify a complex time series model of the way that a predictor variable influences the series that you are forecasting.

When you specify a predictor variable as a simple regressor, only the current period value of the predictor effects the forecast for the period. By specifying the predictor with the `Dynamic Regression` option, you can use past values of the predictor series, and you can model effects that take place gradually.

Dynamic regression models are an advanced feature that you are unlikely to find useful unless you have studied the theory of statistical time series analysis. You might want to skip this section if you are not trained in time series modeling.

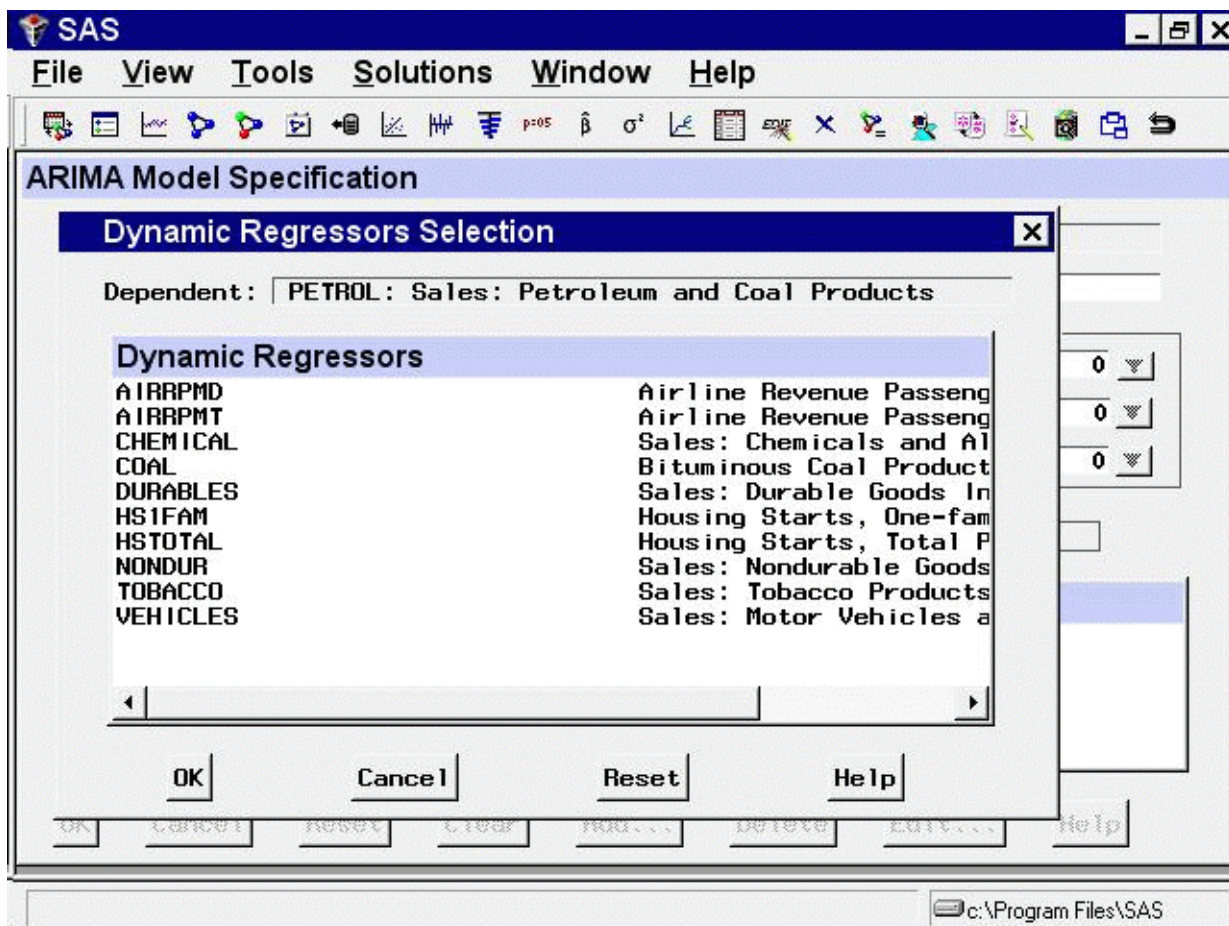

The term *dynamic regression* was introduced by Pankratz (1991) and refers to what Box and Jenkins (1976) named *transfer function models*. In dynamic regression, you have a time series model, similar to an ARIMA model, that predicts how changes in the predictor series affect the dependent series over time.

The dynamic regression model relates the predictor variable to the expected value of the dependent series in the same way that an ARIMA model relates the fluctuations of the dependent series about its conditional mean to the random error term (which is also called the innovation series). For more information about dynamic regression or transfer function see Pankratz (1991); Box and Jenkins (1976). See also Chapter 7, “The ARIMA Procedure.”

From the Develop Models window, select **Fit ARIMA Model**. From the ARIMA Model Specification window, select **Add** and then select **Linear Trend** from the menu (shown in Figure 49.1).

Now select **Add** and select **Dynamic Regressor**. This displays the Dynamic Regressors Selection window, as shown in Figure 49.11.

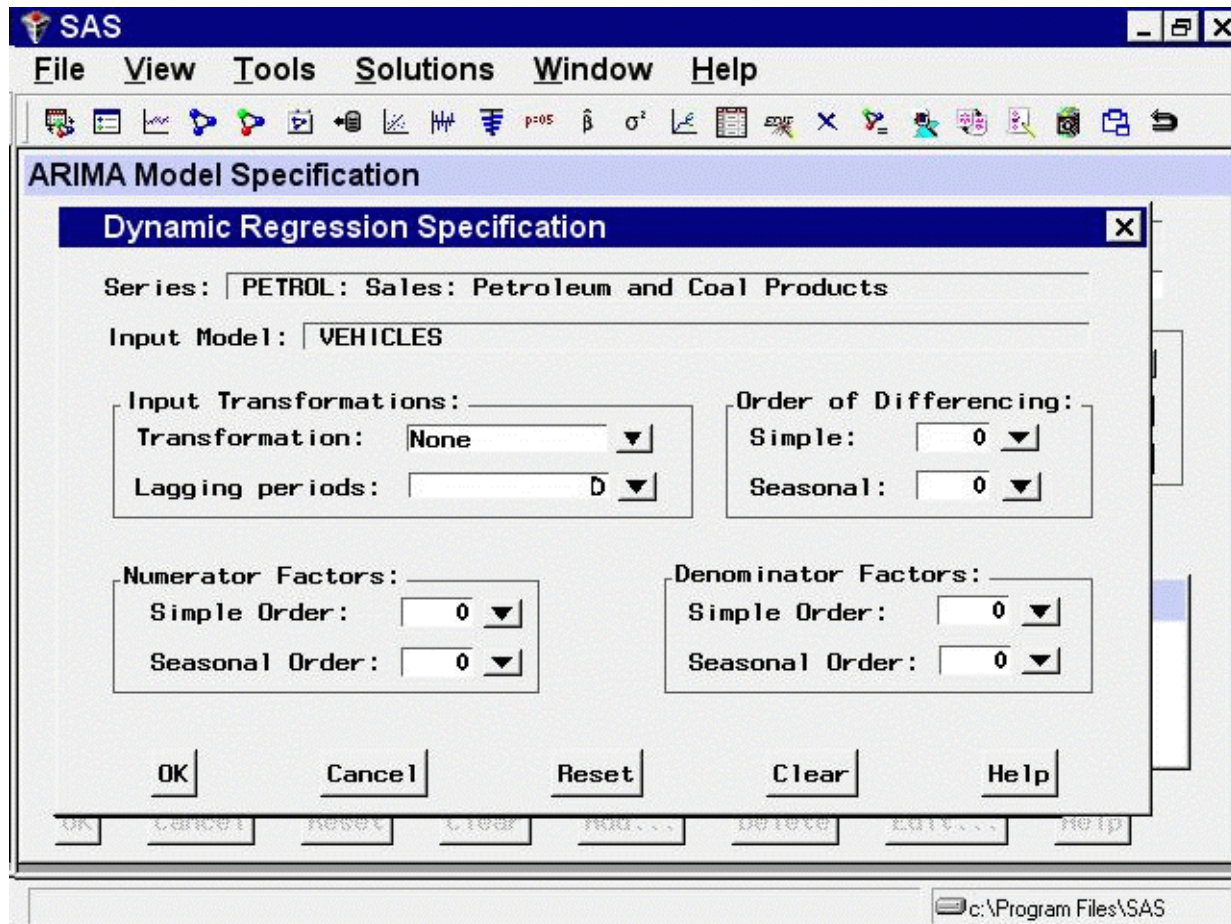

Figure 49.11 Dynamic Regressors Selection Window

You can select only one predictor series when specifying a dynamic regression model. For this example, select `VEHICLES`, Sales: Motor Vehicles and Parts. Then select the `OK` button.

This displays the `Dynamic Regression Specification` window, as shown in [Figure 49.12](#).

Figure 49.12 Dynamic Regression Specification Window

This window consists of four parts. The `Input Transformations` fields enable you to transform or lag the predictor variable. For example, you might use the lagged logarithm of the variable as the predictor series.

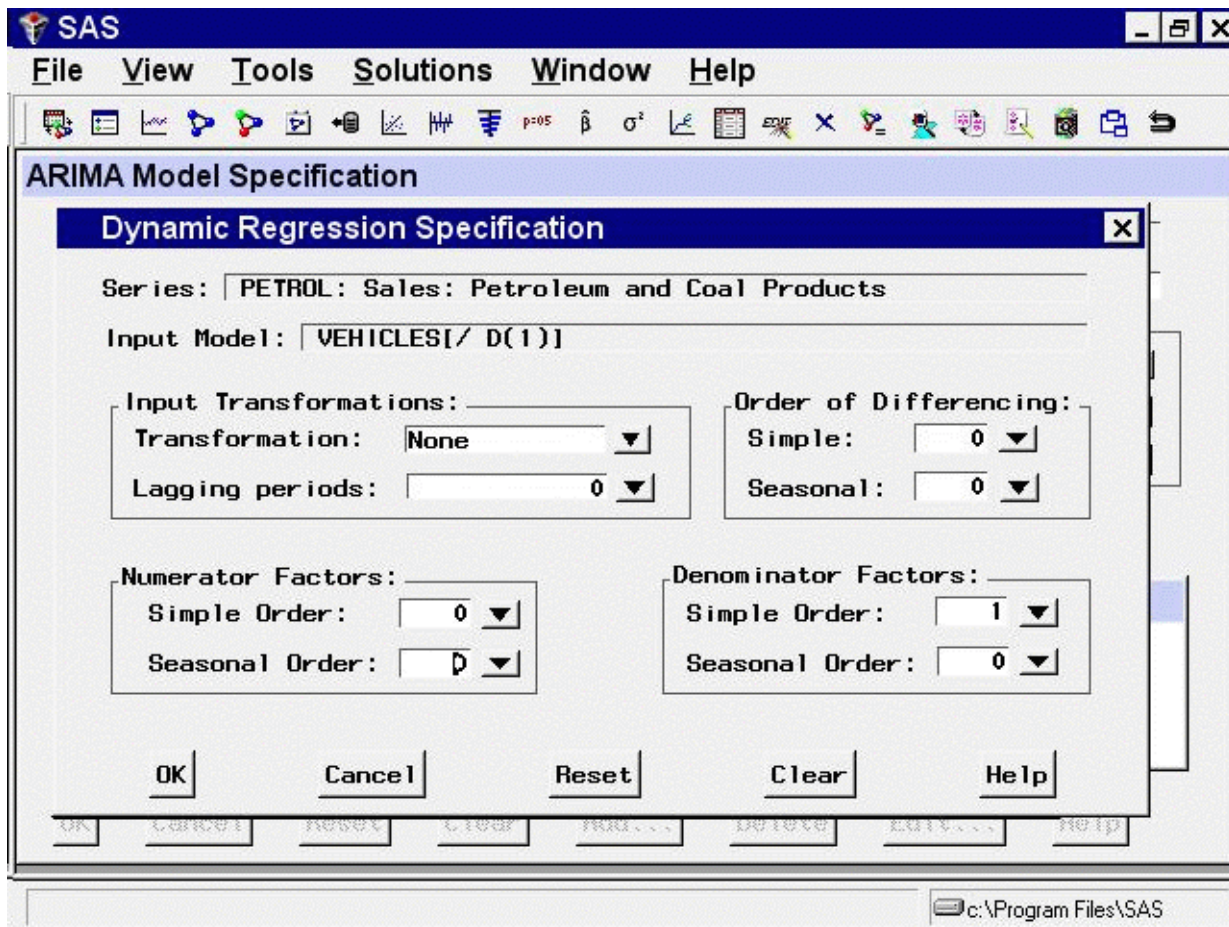

The `Order of Differencing` fields enable you to specify simple and seasonal differencing of the predictor series. For example, you might use changes in the predictor variable instead of the variable itself as the predictor series.

The `Numerator Factors` and `Denominator Factors` fields enable you to specify the orders of simple and seasonal numerator and denominator factors of the transfer function.

Simple regression is a special case of dynamic regression in which the dynamic regression model consists of only a single regression coefficient for the current value of the predictor series. If you select the `OK` button without specifying any options in the `Dynamic Regression Specification` window, a simple regressor will be added to the model.

For this example, use the `Simple` Order combo box for `Denominator Factors` and set its value to 1. The window now appears as shown in [Figure 49.13](#).

Figure 49.13 Distributed Lag Regression Specified

This model is equivalent to regression on an exponentially weighted infinite distributed lag of `VEHICLES` (in the same way an `MA(1)` model is equivalent to single exponential smoothing).

Select the `OK` button to add the dynamic regressor to the model predictors list.

In the ARIMA Model Specification window, the Predictors list should now contain two items, a linear trend and a dynamic regressor for `VEHICLES`, as shown in [Figure 49.14](#).

c:\Program Files\SAS

This model is a multiple regression of PETROL on a time trend variable and an infinite distributed lag of VEHICLES. Select the **OK** button to fit the model.

As with simple regressors, if VEHICLES does not already have a forecasting model, an automatic model selection process is performed to find a forecasting model for VEHICLES before the dynamic regression model for PETROL is fit.

Interventions

An *intervention* is a special indicator variable, computed automatically by the system, that identifies time periods affected by unusual events that influence or intervene in the normal path of the time series you are forecasting. When you add an intervention predictor, the indicator variable of the intervention is used as a regressor, and the impact of the intervention event is estimated by regression analysis.

To add an intervention to the Predictors list, you must use the Intervention Specification window to specify the time or times that the intervening event took place and to specify the type of intervention. You can add interventions either through the `Interventions` item of the `Add` action or by selecting `Tools` from the menu bar and then selecting `Define Interventions`.

Intervention specifications are associated with the series. You can specify any number of interventions for each series, and once you define interventions you can select them for inclusion in forecasting models. If you select the `Include Interventions` option in the `Options` menu, any interventions that you have previously specified for a series are automatically added as predictors to forecasting models for the series.

From the Develop Models window, invoke the series viewer by selecting the `View Series Graphically` icon or `Series` under the `View` menu. This displays the Time Series Viewer, as was shown in [Figure 49.2](#).

Note that the trend in the PETROL series shows several clear changes in direction. The upward trend in the first part of the series reverses in 1981. There is a sharp drop in the series towards the end of 1985, after which the trend is again upwardly sloped. Finally, in 1991 the series takes a sharp upward excursion but quickly returns to the trend line.

You might have no idea what events caused these changes in the trend of the series, but you can use these patterns to illustrate the use of intervention predictors. To do this, you fit a linear trend model to the series, but modify that trend line by adding intervention effects to model the changes in trend you observe in the series plot.

The Intervention Specification Window

From the Develop Models window, select `Fit ARIMA` model. From the ARIMA Model Specification window, select `Add` and then select `Linear Trend` from the menu (shown in [Figure 49.1](#)).

Select `Add` again and then select `Interventions`. If you have any interventions already defined for the series, this selection displays the `Interventions for Series` window. However, since you have not previously defined any interventions, this list is empty. Therefore, the system assumes that you want to add an intervention and displays the `Intervention Specification` window instead, as shown in [Figure 49.15](#).

c:\Program Files\SAS

The top of the Intervention Specification window shows the current series and the label for the new intervention (initially blank). At the right side of the window is a scrollable table showing the values of the series. This table helps you locate the dates of the events you want to model.

At the left of the window is an area titled *Intervention Specification* that contains the options for defining the intervention predictor. The *Date* field specifies the time that the intervention occurs. You can type a date value in the *Date* field, or you can set the *Date* value by selecting a row from the table of series values at the right side of the window.

The area titled *Type of Intervention* controls the kind of indicator variable constructed to model the intervention effect. You can specify the following kinds of interventions:

- Point** is used to indicate an event that occurs in a single time period. An example of a point event is a strike that shuts down production for part of a time period. The value of the intervention's indicator variable is zero except for the date specified.
- Step** is used to indicate a continuing event that changes the level of the series. An example of a step event is a change in the law, such as a tax rate increase. The value of the intervention's indicator variable is zero before the date specified and 1 thereafter.

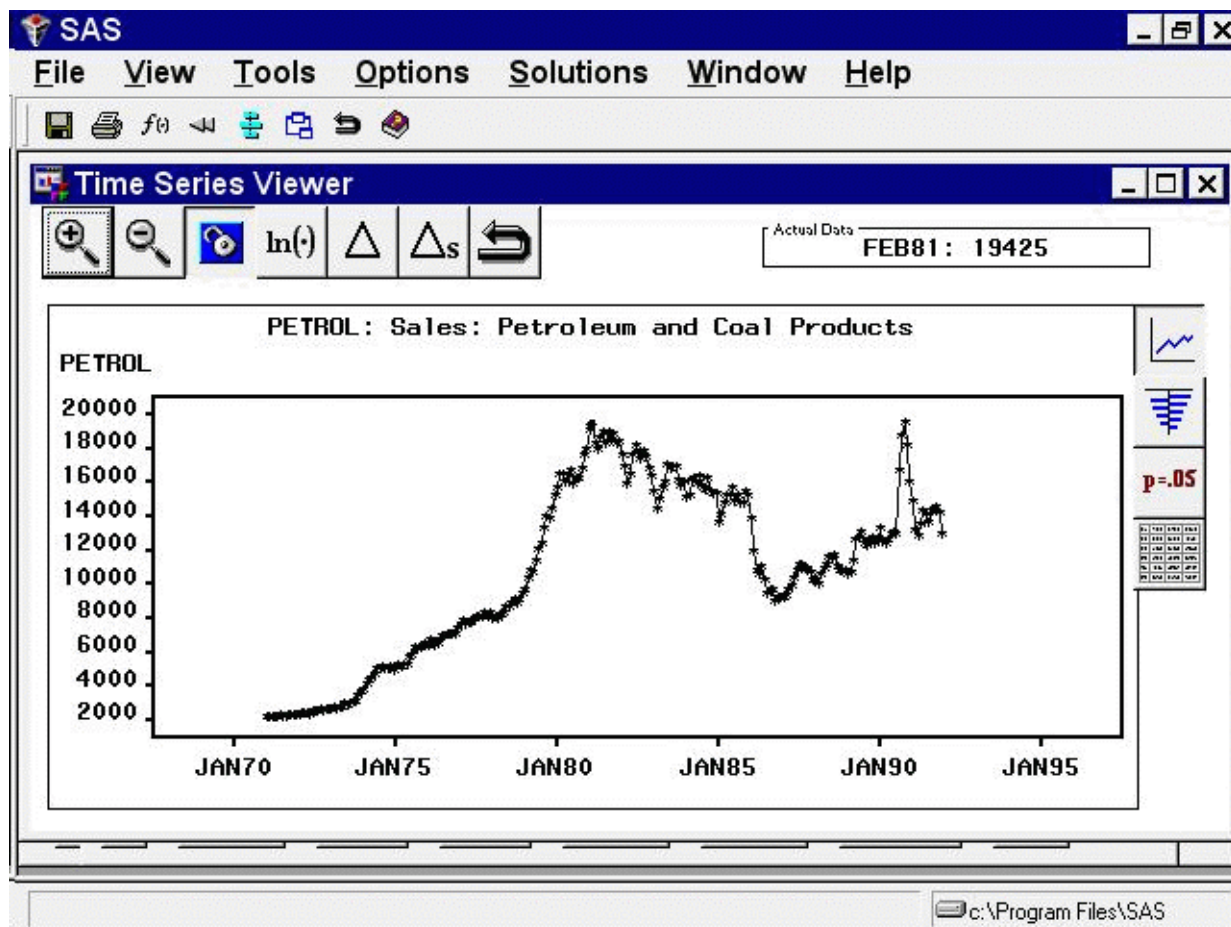

Ramp is used to indicate a continuing event that changes the trend of the series. The value of the intervention's indicator variable is zero before the date specified, and it increases linearly with time thereafter.

The areas titled **Effect Time Window** and **Effect Decay Pattern** specify how to model the effect that the intervention has on the dependent series. These options are not used for simple interventions, they will be discussed later in this chapter.

Specifying a Trend Change Intervention

In the Time Series Viewer window position the mouse over the highest point in 1981 and select the point. This displays the data value, 19425, and date, February 1981, of that point in the upper-right corner of the Time Series Viewer, as shown in Figure 49.16.

Figure 49.16 Identifying the Turning Point

Now that you know the date that the trend reversal occurred, enter that date in the **Date** field of the Intervention Specification window. Select **Ramp** as the type of intervention. The window should now appear as shown in Figure 49.17.

Figure 49.17 Ramp Intervention Specified

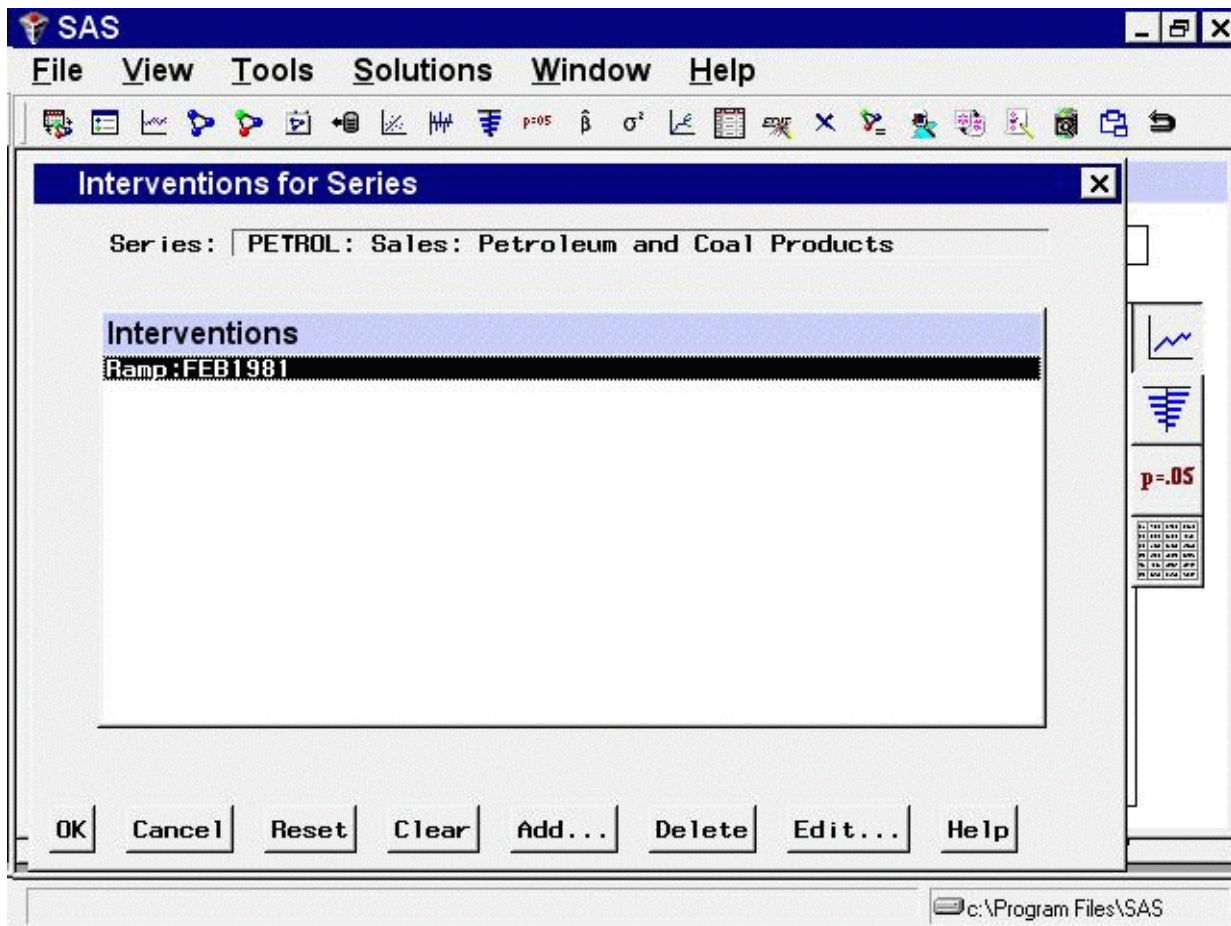

The screenshot shows the SAS 'Intervention Specification' dialog box. The 'Series' is 'PETROL: Sales: Petroleum and Coal Products' and the 'Label' is 'Ramp:FEB1981'. Under 'Intervention Specification', the 'Date' is 'FEB1981', the 'Type of Intervention' is 'Ramp' (selected with a radio button), the 'Effect Time Window' is 'Number of lags: 0', and the 'Effect Decay Pattern' is 'None' (selected with a radio button). To the right is a table of the PETROL series data from February 1981 to December 1981.

DATE	PETROL
FEB81	19425
MAR81	18351
APR81	18024
MAY81	18629
JUN81	19015
JUL81	18306
AUG81	18988
SEP81	18577
OCT81	18853
NOV81	18366
DEC81	18470

At the bottom of the dialog are buttons for 'OK', 'Cancel', 'Reset', 'Clear', and 'Help'. The taskbar at the bottom shows the path 'c:\Program Files\SAS'.

Select the **OK** button. This adds the intervention to the list of interventions for the PETROL series, and returns you to the Interventions for Series window, as shown in Figure 49.18.

Figure 49.18 Interventions for Series Window

This window allows you to select interventions for inclusion in the forecasting model. Since you need to define other interventions, select the **Add** button. This returns you to the Intervention Specification window (shown in Figure 49.15).

Specifying a Level Change Intervention

Now add an intervention to account for the drop in the series in late 1985. You can locate the date of this event by selecting points in the Time Series Viewer plot or by scrolling through the data values table in the Interventions Specification window. Use the latter method so that you can see how this works.

Scrolling through the table, you see that the drop was from 15262 in December 1985, to 13937 in January 1986, to 12002 in February, to 10834 in March. Since the drop took place over several periods, you could use another ramp type intervention. However, this example represents the drop as a sudden event by using a step intervention and uses February 1986 as the approximate time of the drop.

Select the table row for February 1986 to set the **Date** field. Select **Step** as the intervention type. The window should now appear as shown in Figure 49.19.

Figure 49.19 Step Intervention Specified

The dialog box is titled "Intervention Specification". It contains the following fields and options:

- Series:** PETROL: Sales: Petroleum and Coal Products
- Label:** Step:FEB1986
- Intervention Specification:**
 - Date:** FEB1986
 - Type of Intervention:** ☐ Point ☒ Step ☐ Ramp
 - Effect Time Window:**
 - Number of lags:** 0
 - Effect Decay Pattern:** ☒ None ☐ Exp ☐ Wave
- Data Table:**

DATE	PETROL
SEP85	14825
OCT85	14776
NOV85	15449
DEC85	15262
JAN86	13937
FEB86	12002
MAR86	10834
APR86	10568
MAY86	11049
JUN86	10246
JUL86	9412.0000
- Buttons:** OK, Cancel, Reset, Clear, Help

Select the **OK** button to add this intervention to the list for the series.

Since the trend reverses again after the drop, add a ramp intervention for the same date as the step intervention. Select **Add** from the Interventions for Series window. Enter FEB86 in the **Date** field, select **Ramp**, and then select the **OK** button.

Modeling Complex Intervention Effects

You have now defined three interventions to model the changes in trend and level. The excursion near the end of the series remains to be dealt with.

Select **Add** from the Interventions for Series window. Scroll through the data values and select the date on which the excursion began, August 1990. Leave the intervention type as **Point**.

The pattern of the series from August 1990 through January 1991 is more complex than a simple shift in level or trend. For this pattern, you need a complex intervention model for an event that causes a sharp rise followed by a rapid return to the previous trend line. To specify this model, use the **Effect Time Window** and **Effect Decay Rate** options.

The **Effect Time Window** option controls the number of lags of the intervention's indicator variable used to model the effect of the intervention on the dependent series. For a simple intervention, the number of lags is zero, which means that the effect of the intervention is modeled by fitting a single regression coefficient to the intervention's indicator variable.

When you set the number of lags greater than zero, regression coefficients are fit to lags of the indicator variable. This allows you to model interventions whose effects take place gradually, or to model rebound effects. For example, severe weather might reduce production during one period but cause an increase in production in the following period as producers struggle to catch up. You could model this by using a point intervention with an effect time window of 1 lag. This would fit two coefficients for the intervention, one for the immediate effect and one for the delayed effect.

The **Effect Decay Pattern** option controls how the effect of the intervention dissipates over time. **None** specifies that there is no gradual decay: for point interventions, the effect ends immediately; for step and ramp interventions, the effect continues indefinitely. **Exp** specifies that the effect declines at an exponential rate. **Wave** specifies that the effect declines like an exponentially damped sine wave (or as the sum of two exponentials, depending on the fit to the data).

If you are familiar with time series analysis, these options might be clearer if you note that together the **Effect Time Window** and **Effect Decay Pattern** options define the numerator and denominator orders of a transfer function or dynamic regression model for the indicator variable of the intervention. See the section “[Dynamic Regressor](#)” on page 3158 for more information.

For this example, select 2 lags as the value of the **Event Time Window** option, and select **Exp** as the **Effect Decay Pattern** option. The window should now appear as shown in [Figure 49.20](#).

Select the **OK** button to fit this model. After the model is fit, bring up the Model Viewer. You will see a plot of the model predictions, as shown in Figure 49.23.

Figure 49.23 Linear Trend with Interventions Model

You can use the Zoom In feature to take a closer look at how the complex intervention effect fits the excursion in the series starting in August 1990.

Limitations of Intervention Predictors

Note that the model you have just fit is intended only to illustrate the specification of interventions. It is not intended as an example of good forecasting practice.

The use of continuing (step and ramp type) interventions as predictors has some limitations that you should consider. If you model a change in trend with a simple ramp intervention, then the trend in the data before the date of the intervention has no influence on the forecasts. Likewise, when you use a step intervention, the average level of the series before the intervention has no influence on the forecasts.

Only the final trend and level at the end of the series are extrapolated into the forecast period. If a linear trend is the only pattern of interest, then instead of specifying step or ramp interventions, it would be simpler to adjust the period of fit so that the model ignores the data before the final trend or level change.

Step and ramp interventions are valuable when there are other patterns in the data—such as seasonality, autocorrelated errors, and error variance—that are stable across the changes in level or trend. Step and ramp interventions enable you to fit seasonal and error autocorrelation patterns to the whole series while fitting the trend only to the latter part of the series.

Point interventions are a useful tool for dealing with outliers in the data. A point intervention will fit the series value at the specified date exactly, and it has the effect of removing that point from the analysis. When you specify an effect time window, a point intervention will exactly fit as many additional points as the number of lags specified.

Seasonal Dummies

A *Seasonal Dummies* predictor is a special feature that adds to the model seasonal indicator or “dummy” variables to serve as regressors for seasonal effects.

From the Develop Models window, select **Fit ARIMA Model**. From the ARIMA Model Specification window, select **Add** and then select **Seasonal Dummies** from the menu (shown in [Figure 49.1](#)).

A Seasonal Dummies input is added to the Predictors list, as shown in [Figure 49.24](#).

c:\Program Files\SAS

Select the **OK** button. A model consisting of an intercept and 11 seasonal dummy variables is fit and added to the model list in the Develop Models window. This is effectively a mean model with a separate mean for each month.

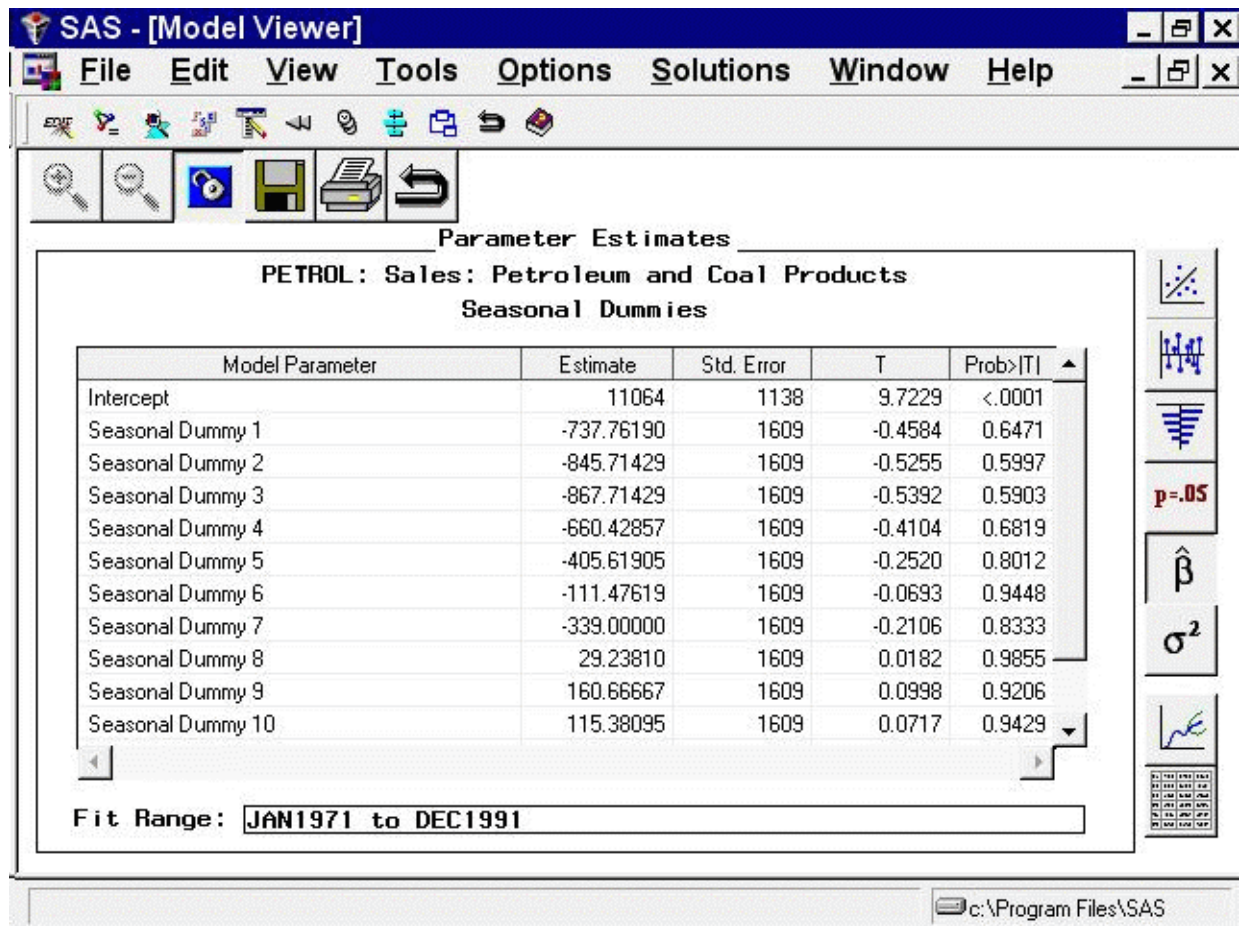

Now return to the Model Viewer, which displays a plot of the model predictions and actual series values, as shown in Figure 49.25. This is obviously a poor model for this series, but it serves to illustrate how seasonal dummy variables work.

Figure 49.25 Seasonal Dummies Model

Now select the parameter estimates icon, the fifth from the top on the vertical toolbar. This displays the Parameter Estimates table, as shown in Figure 49.26.

Figure 49.26 Parameter Estimates for Seasonal Dummies Model

Since the data for this example are monthly, the Seasonal Dummies option added 11 seasonal dummy variables. These include a dummy regressor variable that is 1.0 for January and 0 for other months, a regressor that is 1.0 only for February, and so forth through November.

Because the model includes an intercept, no dummy variable is added for December. The December effect is measured by the intercept, while the effect of other seasons is measured by the difference between the intercept and the estimated regression coefficient for the season's dummy variable.

The same principle applies for other data frequencies: the "Seasonal Dummy 1" parameter always refers to the first period in the seasonal cycle; and, when an intercept is present in the model, there is no seasonal dummy parameter for the last period in the seasonal cycle.

TSVIEW Command and Macro	3179
Syntax	3179
Examples	3180
FORECAST Command and Macro	3180
Syntax	3181
Examples	3184

TSVIEW Command and Macro

The TSVIEW command invokes the Time Series Viewer. This is a component of the Time Series Forecasting System that can also be used as a standalone graphical viewer for any time series data set or view. See the section “Time Series Viewer Window” in Chapter 51, “[Window Reference](#),” for more information.

The TSVIEW command must be specified from the command line or an SCL program. If you need to submit from the program editor, use the %TSVIEW macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the TSVIEW command or %TSVIEW macro is issued without arguments, the Series Selection window appears to enable you to select an input data set and series. This is equivalent to selecting “Time Series Viewer” from the Analysis submenu of the Solutions menu. By specifying the DATA= and VAR= arguments, you can bring up the Time Series Viewer window directly. The ID= and INTERVAL= arguments are useful when the system cannot determine them automatically from the data.

Syntax

The TSVIEW command has the following form:

TSVIEW *[options]* ;

The %TSVIEW macro has the following form:

%TSVIEW [(*option*, . . . , *option*)] ;

The following options can be specified for the command and the macro.

DATA=*data set name*

specifies the name of the SAS data set containing the input data.

VAR=*time series variable name*

specifies the series variable name. It must be a numeric variable contained in the data set.

ID=*time id variable name*

specifies the time ID variable name for the data set. If the ID= option is not specified, the system attempts to locate the variables named DATE, DATETIME, and TIME in the data set specified by the DATA= option.

INTERVAL=*interval name*

specifies the time ID interval between observations in the data set.

Examples

TSVIEW Command

```
tsview data=sashelp.air var=air
tsview data=dept.prod var=units id=period interval=qtr
```

%TSVIEW Macro

```
%tsview( data=sashelp.air, var=air);
%tsview( data=dept.prod, var=units, id=period, interval=qtr);
```

FORECAST Command and Macro

The FORECAST command invokes the Time Series Forecasting System. The command must be specified from the command line or an SCL program. If you need to submit from the program editor, use the %FORECAST macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the FORECAST command or %FORECAST macro is issued without arguments, the Time Series Forecasting window appears. This is equivalent to selecting “Time Series Forecasting System” from the Analysis submenu of the Solutions menu.

Using the arguments, it is possible to do the following:

- Bring up the system with information already filled into some of the fields
- Bring up the system starting at a different window than the default Time Series Forecasting window

- Run the system in unattended mode so that a task such as creating a forecast data set is accomplished without any user interaction. By submitting such commands repeatedly from a SAS/AF or SAS/EIS application, it is possible to do “batch” processing for many data sets or by-group processing for many subsets of a data set. You can create a project in unattended mode and later open it for inspection interactively. You can also create a project interactively in order to set options, fit a model, or edit the list of models, and then use this project later in unattended mode.

The `Forecast Command Builder`, a point-and-click SAS/AF application, makes it easy to specify, run, save, and rerun forecasting jobs by using the `FORECAST` command. To use it, enter the following on the command line (not the program editor):

```
%FCB
```

or

```
AF C=SASHELP.FORECAST.FORCCMD.FRAME.
```

Syntax

The `FORECAST` command has the following form:

```
FORECAST [options] ;
```

The `%FORECAST` macro has the following form:

```
%FORECAST [(option, ..., option) ] ;
```

The following options can be specified for the command and the macro.

PROJECT=*project name*

specifies the name of the SAS catalog entry in which forecasting models and other results are stored and from which previously stored results are loaded into the forecasting system.

DATA=*data set name*

specifies the name of the SAS data set containing the input data.

VAR=*time series variable name*

specifies the series variable name. It must be a numeric variable contained in the data set.

ID=*time id variable name*

specifies the time ID variable name for the data set. If the `ID=` option is not specified, the system attempts to locate the variables named `DATE`, `DATETIME`, and `TIME` in the data set specified by the `DATA=` option. However, it is recommended that you specify the time ID variable whenever you are using the `ENTRY=` argument.

INTERVAL=*interval name*

specifies the time ID interval between observations in the data set. Commonly used intervals are `year`, `semyear`, `qtr`, `month`, `semimonth`, `week`, `weekday`, `day`, `hour`, `minute`, and `second`. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for information about more complex interval specifications. If the `INTERVAL=` option is not specified, the system attempts to determine the interval based on the time ID variable. However, it is recommended that you specify the interval whenever you are using the `ENTRY=` argument.

STAT=statistic

specifies the name of the goodness-of-fit statistic to be used as the model selection criterion. The default is RMSE. Valid names are

sse	sum of square error
mse	mean square error
rmse	root mean square error
mae	mean absolute error
mape	mean absolute percent error
aic	Akaike information criterion
sbc	Schwarz Bayesian information criterion
rsquare	R-square
ajdrsqr	adjusted R-square
rwrsqr	random walk R-square
arsqr	Amemiya's adjusted R-square
apc	Amemiya's prediction criterion

CLIMIT=integer

specifies the level of the confidence limits to be computed for the forecast. This integer represents a percentage; for example, 925 indicates 92.5% confidence limits. The default is 95—that is, 95% confidence limits.

HORIZON=integer

specifies the number of periods into the future for which forecasts are computed. The default is 12 periods. The maximum is 9999.

ENTRY=name

The name of an entry point into the system. Valid names are

main	starts the system at the Time Series Forecasting window (default).
devmod	starts the system at the Develop Models window.
viewmod	starts the system at the Model Viewer window. Specify a project that contains a forecasting model by using the PROJECT= option. If a project containing a model is not specified, the message “No forecasting model to view” appears.
viewer	starts the system at the Time Series Viewer window.
autofit	runs the system in unattended mode, fitting a forecasting model automatically and saving it in a project. If PROJECT= is not specified, the default project name SASUSER.FMSPROJ.PROJ is used.
forecast	runs the system in unattended mode to generate a forecast data set. The name of this data set is specified by the OUT= parameter. If OUT= is not specified, a window appears to prompt for the name and label of the output data set. If PROJECT= is not specified, the default project name SASUSER.FMSPROJ.PROJ is used. If the project does not exist or does not contain a forecasting model for the specified

series, automatic model fitting is performed and the forecast is computed by using the automatically selected model. If the project exists and contains a forecasting model for the specified series, the forecast is computed by using this model. If the series covers a different time range than it did when the project was created, use the REFIT or REEVAL keyword to reset the time ranges.

OUT=argument

specifies one or two-level name of a SAS data set in which forecasts are saved. Use in conjunction with ENTRY=FORECAST. If omitted, the system prompts for the name of the forecast data set.

KEEP=argument

specifies the number of models to keep in the project when automatic model fitting is performed. This corresponds to *Models to Keep* in the Automatic Model Selection Options window. A value greater than 9 indicates that all models are kept. The default is 1.

DIAG=YES|NO

specifies which models to search with regard to series diagnostics. DIAG= YES causes the automatic model selection process to search only over those models that are consistent with the series diagnostics. DIAG= NO causes the automatic model selection process to search over all models in the selection list, without regard for the series diagnostics. This corresponds to *Models to Fit* in the Automatic Model Selection Options window. The default is YES.

REFIT=keyword

(for macro usage) refits a previously saved forecasting model by using the current fit range; that is, it reestimates the model parameters. Refitting also causes the model to be reevaluated (statistics of fit recomputed), and it causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). This keyword has no effect if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REFIT keyword if you have added new data to the input series and you want to refit the forecasting model and update the forecast by using the new time ranges. Be sure to use the same project, data set, and series names that you used previously.

REEVAL=keyword

(for macro usage) reevaluates a previously saved forecasting model by using the current evaluation range; that is, it recomputes the statistics of fit. Reevaluating also causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). It does not refit the model parameters. This keyword has no effect if you also specify REFIT, or if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REEVAL keyword if you have added new data to the input series and want to update your forecast by using a previously fit forecasting model and the same project, data set, and series names that you used previously.

Examples

FORECAST Command

The following command opens the Time Series Forecasting window with the data set name and series name filled in. The time ID variable is also filled in since the data set contains the variable DATE. The interval is filled in because the system recognizes that the observations are monthly.

```
forecast data=sashelp.air var=air
```

The following command opens the Time Series Forecasting window with the project, data set name, series, time ID, and interval fields filled in, assuming that the project SAMPROJ was previously saved either interactively or by using unattended mode as depicted below. Previously fit models appear when the Develop Models or Manage Projects window is opened.

```
forecast project=samproj
```

The following command runs the system in unattended mode, fitting a model automatically, storing it in the project SAMPROJ in the default catalog SASUSER.FMSPROJ, and placing the forecasts in the data set WORK.SAMPOUT.

```
forecast data=sashelp.workers var=electric id=date interval=month  
project=samproj entry=forecast out=sampout
```

The following command assumes that a new month's data have been added to the data set from the previous example and that an updated forecast is needed that uses the previously fit model. Time ranges are automatically updated to include the new data since the REEVAL keyword is included. Substitute REFIT for REEVAL if you want the system to reestimate the model parameters.

```
forecast data=sashelp.workers var=electric id=date interval=month  
project=samproj entry=forecast out=sampout reeval
```

The following command opens the model viewer with the project created in the previous example and with 99 percent confidence limits in the forecast graph.

```
forecast data=sashelp.workers var=electric id=date interval=month  
project=samproj entry=viewmod climit=99
```

The final example illustrates using unattended mode with an existing project that has been defined interactively. In this example, the goal is to add a model to the model selection list, to specify that all models in that list be fit, and that all models which are fit successfully be retained.

First open the Time Series Forecasting window and specify a new project name, WORKPROJ. Then select *Develop Models*, choosing SASHELP.WORKERS as the data set and MASONRY as the series. Now select "Model Selection List" from the Options menu. In the Model Selection List window, click *Actions*, then *Add*, and then *ARIMA Model*. Define the model `ARIMA(0,1,0)(0,1,0)s NOINT` by setting the differencing

value to 1 under both `ARIMA Options` and `Seasonal ARIMA Options`. Select `OK` to save the model and `OK` to close the `Model Selection List` window. Now select “Automatic Fit” from the `Options` menu. In the `Automatic Model Selection Options` window, select “All autofit models in selection list” in the `Models to fit` radio box, select “All models” from the `Models to keep` combo box, and then click `OK` to close the window. Select “Save Project” from the `File` menu, and then close the `Develop Models` window and the `Time Series Forecasting` window. You now have a project with a new model added to the selection list, options set for automatic model fitting, and one series selected but no models fit.

Now enter the command:

```
forecast data=sashelp.workers var=electric id=date interval=month
project=workproj entry=forecast out=workforc
```

The system runs in unattended mode to update the project and create the forecast data set `WORKFORC`. Check the messages in the `Log` window to find out if the run was successful and which model was selected for forecasting. To see the forecast data set, issue the command `viewtable WORKFORC`. To see the contents of the project, open the `Time Series Forecasting` window, open the project `WORKPROJ`, and select “Manage Projects.” You will see that the variable `ELECTRIC` was added to the project and has a forecasting model. Select this row in the table and then select `List Models` from the `Tools` menu. You will see that all of the models in the selection list which fit successfully are there, including the new model you added to the selection list.

%FORECAST Macro

This example demonstrates the use of the `%FORECAST` macro to start the `Time Series Forecasting System` from a SAS program submitted from the `Editor` window. The `SQL` procedure is used to create a view of a subset of a products data set. Then the `%FORECAST` macro is used to produce forecasts.

```
proc sql;
  create view selprod as
  select * from products
  where type eq 'A'
  order by date;
run;

%forecast(data=selprod, var=amount, id=date, interval=day,
  entry=forecast, out=typea, project=proda, refit= );
```

Overview

This chapter provides a reference to the various windows of the Time Series Forecasting System. The windows are presented in alphabetical order by name. Each section describes the purpose of the window, how to open it, its controls, fields, and menus. For windows that have their own menus, there is a description of each menu item under the heading “Menu Bar.” These windows also have a toolbar with icons that duplicate the more commonly used menu items. Each icon has a *screen tip*: a brief description that appears when you hover the mouse cursor over the icon. If you don’t see the screen tips, open the SAS Preferences window, under the Options submenu of the Tools menu. Select the View tab and make sure the “Screen tips” check box is checked.

Adjustments Selection Window

Use the Adjustments Selection window to select input variables for use as adjustments to the forecasts and add them to the Predictors list. Invoke this window from the pop-up menu that appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window. For more information, see the “Adjustments” section in Chapter 49, “Using Predictor Variables.”

Controls and Fields

Dependent

is the name and variable label of the current series.

Adjustments

is a table that lists the names and labels in the input data set available for selection as adjustments. The variables you select are highlighted. Selecting a highlighted row again deselects that variable.

OK

closes the Adjustments Selection window and adds the selected variables as adjustments in the model.

Cancel

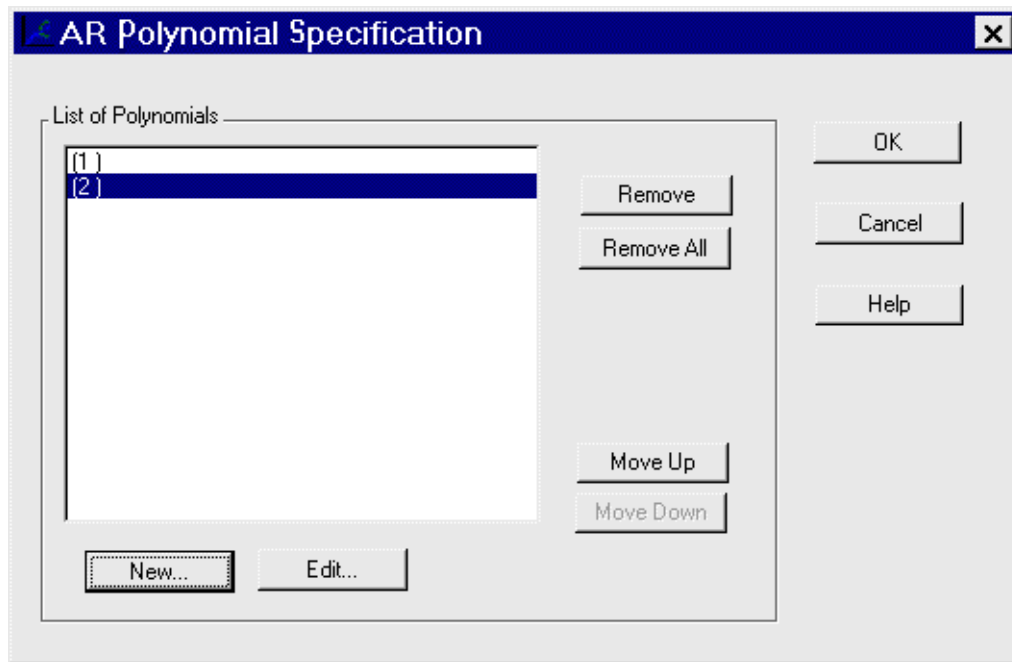

closes the window without adding any adjustments.

Reset

resets all selections to their initial values upon entry to the window.

AR/MA Polynomial Specification Window

Use these windows to specify the autoregressive and moving-average terms in a factored ARIMA model. Access the AR Polynomial Specification window from the Set button next to the Autoregressive term in the Factored ARIMA Model Specification window. Access the MA Polynomial Specification window from the Set button next to the Moving Average term.

Controls and Fields

List of Polynomials

Lists the polynomials that have been specified. Each polynomial is represented by a comma-delimited list of lag values enclosed in parentheses.

New

Opens the Polynomial Specification window to add a new polynomial to the model.

Edit

Opens the Polynomial Specification window to edit a polynomial that has been selected. If no polynomial is selected, this button is unavailable.

Remove

Removes a selected polynomial from the list. If none are selected, this button is unavailable.

Remove All

Clears the list of polynomials.

Move Up

Moves a selected polynomial up one position in the list. If no polynomial is selected, or the first one is selected, this button is unavailable.

Move Down

Moves a selected polynomial down one position in the list. If no polynomial is selected, or the last one is selected, this button is unavailable.

OK

Closes the window and returns the specified list of polynomials to the Factored ARIMA Model Specification window.

Cancel

Closes the window and discards any changes made to the list of polynomials.

ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit in the menu bar, or from the pop-up menu when you click an empty area of the model table.

ARIMA Model Specification

Predictors

OK Cancel Reset Clear Add... Delete Edit... Help

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

ARIMA Options

specify the orders of the ARIMA model. You can either type in a value or click the arrow to select from a list.

Autoregressive

defines the order of the autoregressive part of the model.

Differencing

defines the order of simple differencing—for example, first difference or second difference.

Moving Average

defines the order of the moving-average part of the model.

Seasonal ARIMA Options

specify the orders of the seasonal part of the ARIMA model. You can either type in a value or click the arrow to select from a list.

Autoregressive

defines the order of the seasonal autoregressive part of the model.

Differencing

defines the order of seasonal differencing—for example, first difference or second difference at the seasonal lags.

Moving Average

defines the order of the seasonal moving-average part of the model.

Transformation

defines the series transformation for the model. When a transformation is specified, the ARIMA model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the ARIMA model predictions. The available transformations are: *Log*, *Logistic*, *Square Root*, *Box-Cox*, and *None*.

Intercept

specify whether a mean or intercept parameter is included in the ARIMA model. By default, the Intercept option is set to *No* when the model includes differencing and *Yes* when there is no differencing.

Predictors

lists the predictor effects included as inputs in the model.

OK

closes the ARIMA Model Specification window and fits the model.

Cancel

closes the ARIMA Model Specification window without fitting the model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the ARIMA Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Add

opens a menu of types of predictors to add to the Predictors list.

Delete

deletes the selected (highlighted) entry from the Predictors list.

Edit

edits the selected (highlighted) entry in the Predictors list.

Mouse Button Actions

You can select or deselect entries in the Predictors list by clicking them. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you right-click an entry in the Predictors list, the system displays the following menu of actions that encompass the features of the Add, Delete, and Edit buttons.

Add Linear Trend

adds a Linear Trend item to the Predictors list.

Add Trend Curve

opens a menu of different time trend curves and adds the curve you select to the Predictors list. Certain trend curve specifications also set the Transformation field.

Add Regressors

opens the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

Add Adjustments

opens the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

Add Dynamic Regressor

opens the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

Add Interventions

opens the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

Add Seasonal Dummies

adds a Seasonal Dummies predictor item to the Predictors list.

Edit Predictor

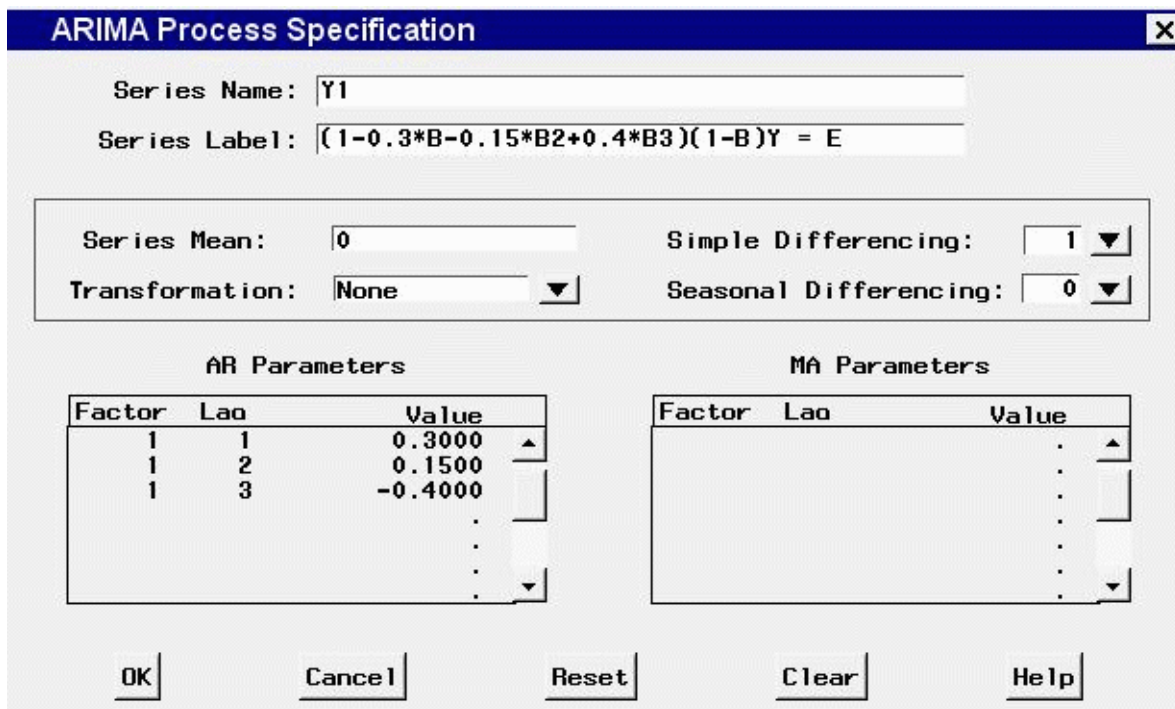

edits the selected (highlighted) entry in the Predictors list.

Delete Predictors

deletes the selected (highlighted) entry from the Predictors list.

ARIMA Process Specification Window

Use the ARIMA Process Specification window to define ARIMA processes for simulation. Invoke this window from the Add Series button in the Time Series Simulation window.

ARIMA Process Specification

Series Name:

Series Label:

Series Mean: Simple Differencing: ▼

Transformation: ▼ Seasonal Differencing: ▼

Factor	Lag	Value
1	1	0.3000
1	2	0.1500
1	3	-0.4000
.	.	.
.	.	.
.	.	.

Factor	Lag	Value
.	.	.
.	.	.
.	.	.
.	.	.
.	.	.

OK Cancel Reset Clear Help

Controls and Fields

Series Name

is the variable name for the series to be simulated.

Series Label

is the variable label for the series to be simulated.

Series Mean

is the mean of the simulated series.

Transformation

defines the series transformation.

Simple Differencing

is the order of simple differencing for the series.

Seasonal Differencing

is the order of seasonal differencing for the series.

AR Parameters

is a table of autoregressive terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the AR part of the process you want to simulate. For a non-factored AR model, make the Factor values the same for all terms. For a factored AR model, use different Factor values to group the terms into the factors.

MA Parameters

is a table of moving-average terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the MA part of the process you want to simulate. For a non-factored MA model, make the Factor values the same for all terms. For a factored MA model, use different Factor values to group the terms into the factors.

OK

closes the ARIMA Process Specification window and adds the specified process to the Series to Generate list in the Time Series Simulation window.

Cancel

closes the window without adding to the Series to Generate list. Any options you specified are lost.

Reset

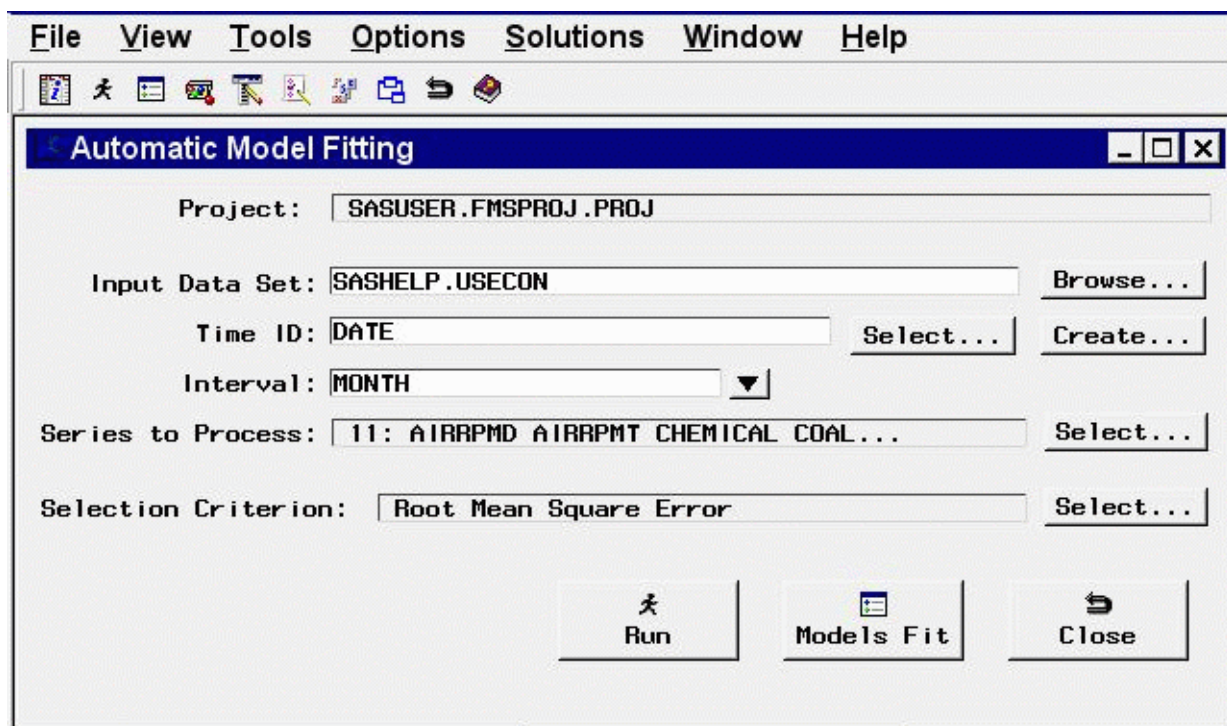

resets all the fields to their initial values upon entry to the window.

Clear

resets all the fields to their default values.

Automatic Model Fitting Window

Use the Automatic Model Fitting window to perform automatic model selection on all series or selected series in an input data set. Invoke this window by using the Fit Models Automatically button on the Time Series Forecasting window. Note that you can also perform automatic model fitting, one series at a time, from the Develop Models window.

Controls and Fields

Project

the name of the SAS catalog entry in which the results of the model search process are stored.

Input Data Set

is the name of the current input data set. You can type in a one-level or two-level data set name here.

Browse button

opens the Data Set Selection window for selecting an input data set.

Time ID

is the name of the ID variable for the input data set. You can type in the variable name here or use the Select or Create button.

time ID Select button

opens the Time ID Variable Specification window.

time ID Create button

opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the current input data set. You can type in an interval name or select one by using the combo box pop-up menu.

Series to Process

indicates the number and names of time series variables for which forecasting model selection will be applied.

Series to Process Select button

opens the Series to Process window to let you select the series for which you want to fit models.

Selection Criterion

shows the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

Selection Criterion Select button

opens the Model Selection Criterion window to enable you to select the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

Run button

begins the automatic model fitting process.

Models Fit button

opens the Automatic Model Fitting Results window to display the models fit during the current invocation of the Automatic Model Fitting window. The results appear automatically when model fitting is complete, but this button enables you to redisplay the results window.

Close button

Closes the Automatic Model Fitting window.

Menu Bar

File**Import Data**

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the Automatic Model Fitting window.

View**Input Data Set**

opens a Viewtable window to browse the current input data set.

Models Fit

opens Automatic Model Fitting Results window to show the forecasting models fit during the current invocation of the Automatic Model Fitting window. This is the same as the Models Fit button.

Tools**Fit Models**

performs the automatic model selection process for the selected series. This is the same as the Run button.

Options**Default Time Ranges**

opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series.

Model Selection List

opens the Model Selection List editor window. Use this action to control the forecasting models considered by the automatic model selection process and displayed in the Models to Fit window.

Model Selection Criterion

opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This action is the same as the Selection Criterion Select button.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion menu.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Forecast Data Set

see Produce Forecasts window.

Alignment of Dates**Beginning**

aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle

aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End

aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Tool Bar Type**Image Only**

displays the toolbar items as icons without text.

Label Only

displays the toolbar items as text without icon images.

Both

displays the toolbar items with both text and icon images.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

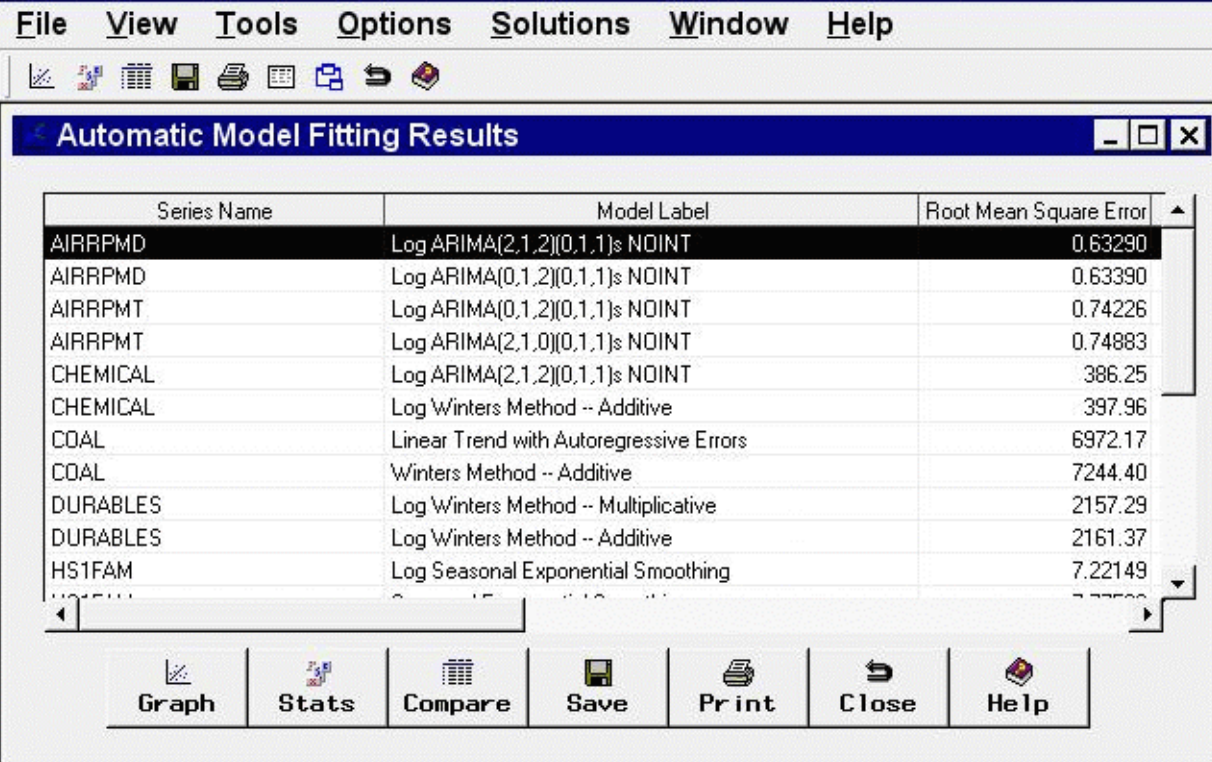

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Automatic Model Fitting Results Window

This resizable window displays the models fit by the most recent invocation of the Automatic Model Fitting window. It appears automatically after Automatic Model Fitting runs, and can be opened repeatedly from that window by using the Models Fit button or by selecting Models Fit from the View menu. Once you exit the Automatic Model Fitting window, the Automatic Model Fitting Results window cannot be opened again until you fit additional models by using Automatic Model Fitting.

Series Name	Model Label	Root Mean Square Error
AIRRPMD	Log ARIMA(2,1,2)(0,1,1)s NOINT	0.63290
AIRRPMD	Log ARIMA(0,1,2)(0,1,1)s NOINT	0.63390
AIRRPMT	Log ARIMA(0,1,2)(0,1,1)s NOINT	0.74226
AIRRPMT	Log ARIMA(2,1,0)(0,1,1)s NOINT	0.74883
CHEMICAL	Log ARIMA(2,1,2)(0,1,1)s NOINT	386.25
CHEMICAL	Log Winters Method -- Additive	397.96
COAL	Linear Trend with Autoregressive Errors	6972.17
COAL	Winters Method -- Additive	7244.40
DURABLES	Log Winters Method -- Multiplicative	2157.29
DURABLES	Log Winters Method -- Additive	2161.37
HS1FAM	Log Seasonal Exponential Smoothing	7.22149

Table Contents The results table displays the series name in the first column and the model label in the second column. If you have chosen to retain more than one model by using the Automatic Model Selection Options window, more than one row appears in the table for each series; that is, there is a row for each model fit. If you have already fit models to the same series before invoking the Automatic Model Fitting window, those models do not appear here, since the Automatic Model Fitting Results window is intended to show the results of the current operation of Automatic Model Fitting. To see all models that have been fit, use the Manage Projects window.

The third column of the table shows the values of the current model selection criterion statistic. Additional columns show the values of other fit statistics. The set of statistics shown are selectable by using the Statistics of Fit Selection window.

The table can be sorted by any column other than Series Name by clicking on the column heading.

Controls and Fields

Graph

opens the Model Viewer window on the model currently selected in the table.

Stats

opens the Statistics of Fit Selection window. This controls the set of goodness-of-fit statistics displayed in the table and in other parts of the Time Series Forecasting System.

Compare

opens the Model Fit Comparison window for the series currently selected in the table. This button is unavailable if the currently selected row in the table represents a series for which fewer than two models have been fit.

Save

opens an output data set dialog, enabling you to specify a SAS data set to which the contents of the table is saved. Note that this operation saves what you see in the table. If you want to save the models themselves for use in a future session, use the Manage Projects window.

Print

prints the contents of the table.

Close

closes the window and returns to the Automatic Model Fitting window.

Menu Bar

File

Save

opens an output data set dialog, enabling you to specify a SAS data set to which the contents of the table is saved. This is the same as the Save button.

Print

prints the contents of the table. This is the same as the Print button.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the window and returns to the Automatic Model Fitting window.

View

Model Predictions

opens the Model Viewer to display a predicted and actual plot for the currently highlighted model.

Prediction Errors

opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations

opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests

opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit

opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph

opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table

opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Tools

Compare Models

opens the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This item is unavailable until you select a series in the table for which the automatic model fitting run selected two or more models.

Options

Statistics of Fit

opens the Statistics of Fit Selection window. This is the same as the Stats button.

Column Labels

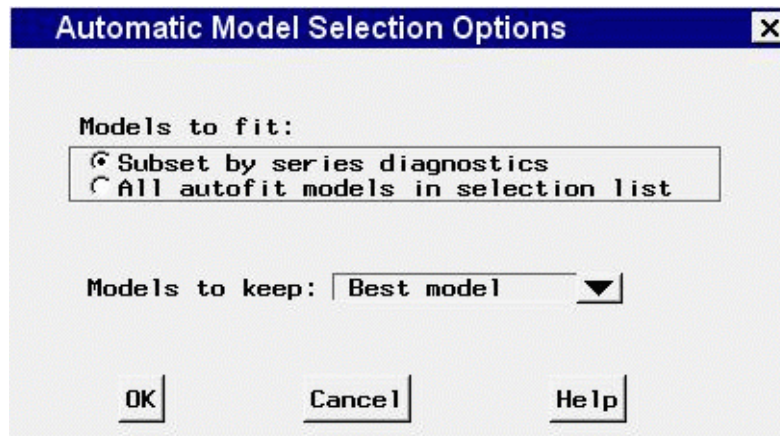

selects long or short column labels for the table. Long column labels are used by default.

ID Columns

freezes or unfreezes the series and model columns. By default they are frozen so that they remain visible when you scroll the table horizontally to view other columns.

Automatic Model Selection Options Window

Use the Automatic Model Selection Options window to control the automatic selection process. This window is available from the Automatic Fit item of the Options menu in the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.

Controls and Fields

Models to fit

Subset by series diagnostics

when selected, causes the automatic model selection process to search only over those models consistent with the series diagnostics.

All models in selection list

when selected, causes the automatic model selection process to search over all models in the search list, without regard for the series diagnostics.

Models to keep

specifies how many of the models tried by the automatic model selection process are retained and added to the model list for the series. You can specify the best fitting model only, the best n models, where n can be 1 through 9, or all models tried.

OK

closes the window and saves the automatic model selection options you specified.

Cancel

closes the window without changing the automatic model selection options.

Custom Model Specification Window

Use the Custom Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models window, where it is invoked from the Fit Model item under the Edit menu, or from the pop-up menu when you click an empty area of the model table.

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Transformation

defines the series transformation for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the resulting forecasts. The following transformations are available:

Log

specifies a logarithmic transformation.

Logistic

specifies a logistic transformation.

Square Root

specifies a square root transformation.

Box-Cox

specifies a Box-Cox transform and opens a window to specify the Box-Cox λ parameter.

None

specifies no series transformation.

Trend Model

controls the model options to model and forecast the series trend. Select from the following:

Linear Trend

adds a Linear Trend item to the Predictors list.

Trend Curve

brings of a menu of different time trend curves and adds the curve you select to the Predictors list.

First Difference

specifies differencing the series.

Second Difference

specifies second-order differencing of the series.

None

specifies no model for the series trend.

Seasonal Model

controls the model options to model and forecast the series seasonality. Select from the following:

Seasonal ARIMA

opens the Seasonal ARIMA Model Options window to enable you to specify an ARIMA model for the seasonal pattern in the series.

Seasonal Difference

specifies differencing the series at the seasonal lag.

Seasonal Dummy Regressors

adds a Seasonal Dummies predictor item to the Predictors list.

None

specifies no seasonal model.

Error Model

displays the current settings of the autoregressive and moving-average terms, if any, for modeling the prediction error autocorrelation pattern in the series.

Set button

opens the Error Model Options window to enable you to set the autoregressive and moving-average terms for modeling the prediction error autocorrelation pattern in the series.

Intercept

specifies whether a mean or intercept parameter is included in the model. By default, the Intercept option is set to No when the model includes differencing and set to Yes when there is no differencing.

Predictors

is a list of the predictor effects included as inputs in the model.

OK

closes the Custom Model Specification window and fits the model.

Cancel

closes the Custom Model Specification window without fitting the model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the Custom Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Add

opens a menu of types of predictors to add to the Predictors list. Select from the following:

Linear Trend

adds a Linear Trend item to the Predictors list.

Trend Curve

opens a menu of different time trend curves and adds the curve you select to the Predictors list.

Regressors

opens the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

Adjustments

opens the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

Dynamic Regressor

opens the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

Interventions

opens the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

Seasonal Dummies

adds a Seasonal Dummies predictor item to the Predictors list. This is unavailable if the series interval is not one which has a seasonal cycle.

Delete

deletes the selected (highlighted) entry from the Predictors list.

Edit

edits the selected (highlighted) entry in the Predictors list.

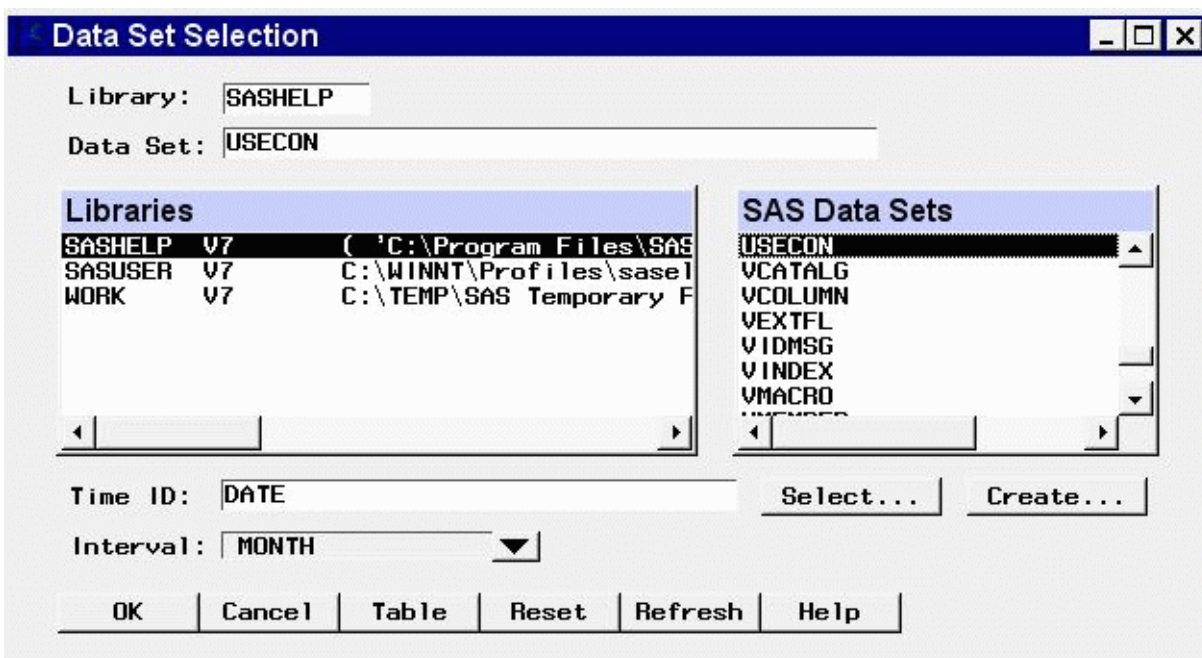

Mouse Button Actions

You can select or deselect entries in the Predictors list by clicking them. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you right-click an entry in the Predictors list and press the right mouse button, the system displays a menu of actions that encompass the features of the Add, Delete, and Edit buttons.

Data Set Selection Window

Use this resizable window to select a data set to process by specifying a library and a SAS data set or view. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set.

Access this window by using the Browse button to the right of the Data Set field in the Time Series Forecasting, Automatic Model Fitting, and Produce Forecasts windows. It functions in the same way as the Series Selection window, except that it does not allow you to select or view a time series variable.

Controls and Fields

Library

is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname. See also Libraries under Selection Lists.

Data Set

is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted.

Time ID

is the name of the ID variable for the selected input data set. To specify the ID variable, you can type the ID variable name in this field or select the control arrows to the right of the field.

Time ID Select button

opens the Time ID Variable Specification window.

Time ID Create button

opens a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically identified by the system, you can type in the interval name or select it from a list by clicking the combo box arrow. For more information about intervals, see Chapter 4, “[Date Intervals, Formats, and Functions](#),” in this book.

OK

closes the Data Set Selection window and makes the selected data set the current input data set.

Cancel

closes the window without applying any selections made.

Table

opens a Viewtable window for browsing the selected data set.

Reset

resets the fields to their initial values upon entry to the window.

Refresh

updates all fields and lists in the window. If you assign a new libname without exiting the Data Set Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname.

Selection Lists

Libraries

displays a list of currently assigned libnames. You can select a libname by clicking it with the left mouse button, which is equivalent to typing its name in the Library field.

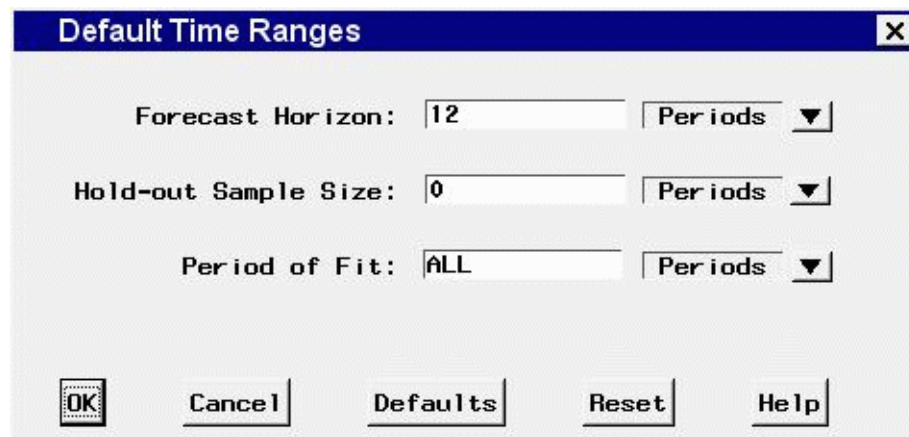

If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File menu, then select “Library” and “OK.” This opens the New Library window. You also assign a libname by submitting a libname statement from the Editor window. Select the Refresh button to make the new libname available in the libraries list.

SAS Data Sets

displays a list of the SAS data sets (data files or data views) contained in the selected library. You can select one of these by clicking with the left mouse button, which is equivalent to typing its name in the Data set field. You can double-click a data set name to select it and exit the window.

Default Time Ranges Window

Use the Default Time Ranges window to control how the period of fit and evaluation and the forecasting horizon are determined for each series when you do not explicitly set these ranges for a particular series. Invoke this window from the Options menu of the Develop Models, Automatic Model Fitting, Produce Forecasts, and Manage Forecasting Project windows. The settings you make in this window affect subsequently selected series; they do not alter the time ranges of series you have already selected.

Controls and Fields

Forecast Horizon

specifies the forecast horizon as either a number of periods or years from the last nonmissing data value or as a fixed date. You can type a number or date value in this field. Date value must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.)

Forecast Horizon Units

indicates whether the value in the forecast horizon field represents periods or years or a date. Click the arrow and select one from the pop-up list.

Hold-out Sample Size

specifies that a number of observations, number of years, or percent of the data at the end of the data range be used for the period of evaluation with the remainder of data used as the period of fit.

Hold-out Sample Size Units

indicates whether the hold-out sample size represents periods or years or percent of data range.

Period of Fit

specifies how much of the data range for a series is to be used as the period of fit for models fit to the series. ALL indicates that all the available data is used. You can specify a number of periods, number of years, or a fixed date, depending on the value of the units field to the right. When you specify a date, the start of the period of fit is the specified date or the first nonmissing series value, whichever is more recent. Date value must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) When you specify the number of

periods or years, the start of the period of fit is computed as the date that number of periods or years from the end of the data.

Period of Fit Units

indicates whether the period-of-fit value represents periods or years or a date.

OK

closes the window and stores the specified changes.

Cancel

closes the window without saving changes. Any options you specified are lost.

Defaults

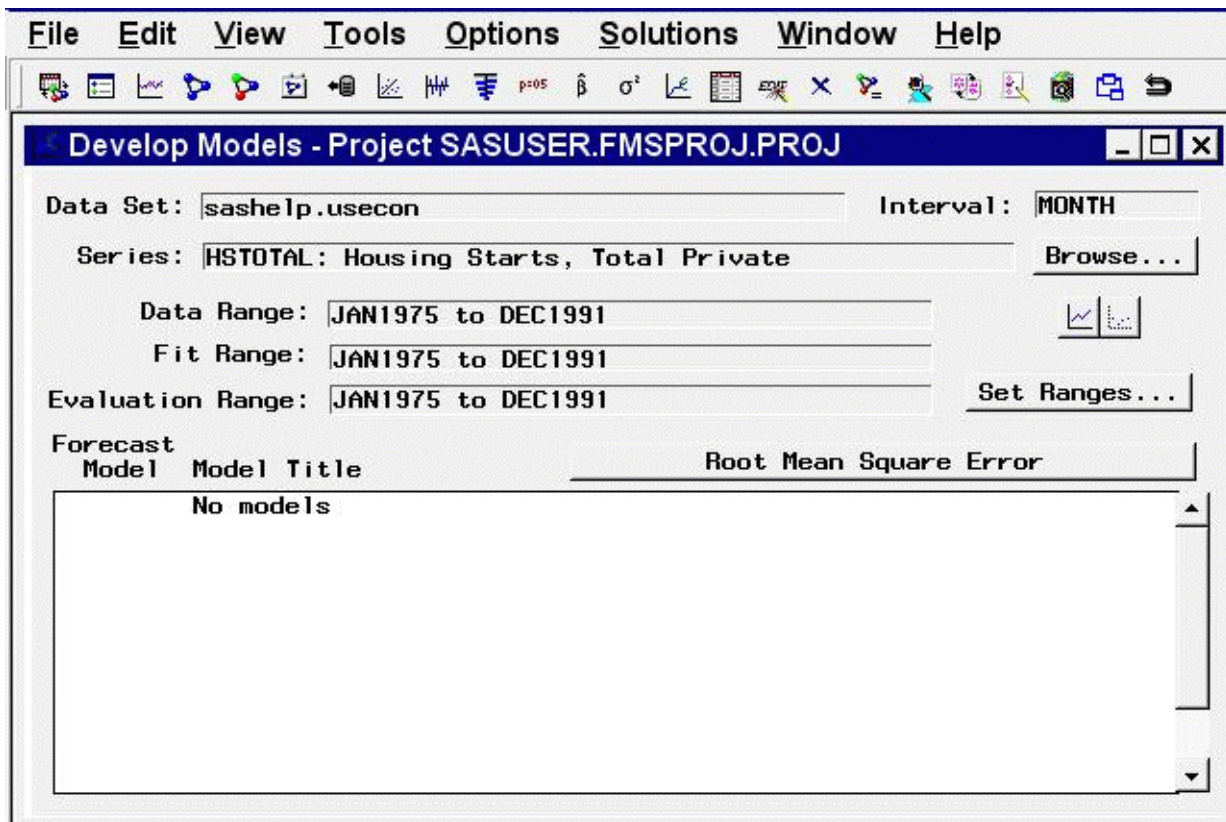

resets all options to their default values.

Reset

resets the options to their initial values upon entry to the window.

Develop Models Window

This resizable window provides access to all of the Forecasting System's interactive model fitting and graphical tools. Use it to fit forecasting models to an individual time series and choose the best model to use to produce the final forecasts of the series. Invoke this window by using the Develop Models button on the Time Series Forecasting window.

Controls and Fields

Data Set

is the name of the current input data set.

Interval

is the time interval (data frequency) for the input data set.

Series

is the variable name and label of the current time series.

Browse button

opens the Series Selection window to enable you to change the current input data set or series.

Data Range

is the date of the first and last nonmissing data values available for the current series in the input data set.

Fit Range

is the current period of fit setting. This is the range of data that will be used to fit models to the series.

Evaluation Range

is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series.

Set Ranges button

opens the Time Ranges Specification window to enable you to change the fit range or evaluation range. Note: A new fit range is applied when new models are fit or when existing models are refit. A new evaluation range is applied when new models are fit or when existing models are refit or reevaluated. Changing the ranges does not automatically refit or reevaluate any models in the table: Use the Refit Models or Reevaluate Models items under the Edit menu.

View Series Graphically icon

opens the Time Series Viewer window to display plots of the current series.

View Selected Model Graphically icon

opens the Model Viewer to display graphs and tables for the currently highlighted model.

Forecast Model

is the column of the model table that contains check boxes to select which model is used to produce the final forecasts for the current series.

Model Title

is the column of the model table that contains the descriptive labels of the forecasting models fit to the current series.

Root Mean Square Error (or other statistic name) button

is the button above the right side of the table. It displays the name of the current model selection criterion: a statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button opens the Model Selection Criterion window to let you to select a different statistic. When you select a statistic, the model table the Develop Models window is updated to show current values of that statistic.

Menu Bar

File

New Project

opens a dialog that lets you create a new project, assign it a name and description, and make it the active project.

Open Project

opens a dialog that lets you select and load a previously saved project.

Save Project

saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

Save Project as

saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

Clear Project

clears the system, deleting all the models for all series.

Save Forecast

writes forecasts from the currently highlighted model to an output data set.

Save Forecast As

prompts for an output data set name and saves the forecasts from the currently highlighted model.

Output Forecast Data Set

opens a dialog for specifying the default data set used when you select “Save Forecast.”

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which enables you to access your operating system print setup.

Close

closes the Develop Models window and returns to the main window.

Edit

Fit Model

Automatic Fit

invokes the automatic model selection process.

Select From List

opens the Models to Fit window.

Smoothing Model

opens the Smoothing Model Specification window.

ARIMA Model

opens the ARIMA Model Specification window.

Custom Model

opens the Custom Model Specification window.

Combine Forecasts

opens the Forecast Combination Model Specification window.

External Forecasts

opens the External Forecast Model Specification window.

Edit Model

enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

Delete Model

deletes the currently highlighted model from the model table.

Refit Models

All Models

refits all models in the table by using data within the current fit range.

Selected Model

refits the currently highlighted model by using data within the current fit range.

Reevaluate Models

All Models

recomputes statistics of fit for all models in the table by using data within the current evaluation range.

Selected Model

recomputes statistics of fit for the currently highlighted model by using data within the current evaluation range.

View

Project

opens the Manage Forecasting Project window.

Data Set

opens a Viewtable window to display the current input data set.

Series

opens the Time Series Viewer window to display plots of the current series. This is the same as the View Series Graphically icon.

Model Predictions

opens the Model Viewer to display a predicted versus actual plot for the currently highlighted model. This is the same as the View Selected Model Graphically icon.

Prediction Errors

opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations

opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests

opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit

opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph

opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table

opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Tools**Diagnose Series**

opens the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

Define Interventions

opens the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

Sort Models

sorts the models in the table by the values of the currently displayed fit statistic.

Compare Models

opens the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This is unavailable if there are fewer than two models in the table.

Generate Data

opens the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

Options**Time Ranges**

opens the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon. This action is the same as the Set Ranges button.

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made by using this window do not affect series you are already working with; they take effect when you select a new series.

Model Selection List

opens the Model Selection List editor window. Use this action to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Model Selection Criterion

opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This action is the same as clicking the button above the table which displays the name of the current model selection criterion.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Alignment of Dates**Beginning**

aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle

aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End

aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Models to Fit window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

Controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions for the Model Table

When the cursor is over the description of a model in the table, the left mouse button selects (highlights) or deselects that model. On some computer systems, you can double-click to open the Model Viewer window for the selected model.

When the cursor is over an empty part of the model table, the left mouse button opens a menu of model fitting choices. These choices are the same as those in the Fit Model submenu of the Edit menu.

Right Mouse Button Actions for the Model Table

When a model in the table is selected, the right mouse opens a menu of actions that apply to the highlighted model. The actions available in this menu are as follows.

View Model

opens the Model Viewer for the selected model. This action is the same as the View Model Graphically icon.

View Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model. This is the same as the Parameter Estimates item in the View menu.

View Statistics of Fit

opens the Model Viewer to display a table of goodness-of-fit statistics for the currently highlighted model. This is the same as the Statistics of Fit item in the View menu.

Edit Model

enables you to modify the specification of the currently highlighted model in the table and fit the modified model. This is the same as the Edit Model item in the Edit menu.

Refit Model

refits the highlighted model by using data within the current fit range. This is the same as the Selected Model item under the Refit Models submenu of the Edit menu.

Reevaluate Model

reevaluates the highlighted model by using data within the evaluation fit range. This is the same as the Selected Model item under the Reevaluate Models submenu of the Edit menu.

Delete Model

deletes the currently highlighted model from the model table. This is the same as the Delete Model item under the Edit menu.

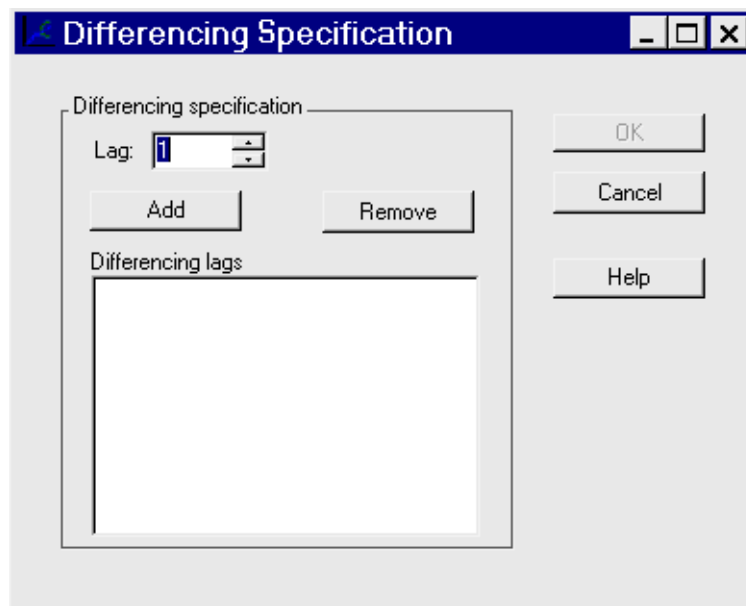

View Forecasts

opens the Model Viewer to display the forecasts for the currently highlighted model. This is the same as the Forecast Graph item under the View menu.

When the model list is empty or when no model is selected, the right mouse button opens the same menu of model fitting actions as the left mouse button.

Differencing Specification Window

Use the Differencing Specification window to specify the list of differencing lags $d = (\text{lag}, \dots, \text{lag})$ in a factored ARIMA model. To specify a first difference, add the value 1 ($d = (1)$). To specify a second difference (difference twice at lag 1), add the value 1 again ($d = (1, 1)$). For first differencing at lags 1 and 12, use the values 1 and 12 ($d = (1, 12)$).

Controls and Fields

Lag

specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows. Duplicates are allowed.

Add

adds the value in the `Lag` spin box to the list of differencing lags.

Remove

deletes a selected lag from the list of differencing lags.

OK

closes the window and returns the specified list to the Factored ARIMA Model Specification window.

Cancel

closes the window and discards any lags added to the list.

Dynamic Regression Specification Window

Use the Dynamic Regression Specification window to specify a dynamic regression or transfer function model for the effect of the predictor variable. It is invoked from the Dynamic Regressors Selection window.

Dynamic Regression Specification

Series:

Input Model:

Input Transformations:

Transformation:

Lagging periods:

Order of Differencing:

Simple:

Seasonal:

Numerator Factors:

Simple Order:

Seasonal Order:

Denominator Factors:

Simple Order:

Seasonal Order:

Controls and Fields

Series

is the name and variable label of the current series.

Input Model

is a descriptive label for the dynamic regression model. You can type a label in this field or allow the

system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify. When no options are specified, the label is the name and variable label of the predictor variable.

Input Transformation

displays the transformation specified for the predictor variable. When a transformation is specified, the transfer function model is fit to the transformed input variable.

Lagging periods

is the pure delay in the effect of the predictor, l .

Simple Order of Differencing

is the order of differencing, d . Set this field to 1 to use the changes in the predictor variable.

Seasonal Order of Differencing

is the order of seasonal differencing, D . Set this field to 1 to difference the predictor variable at the seasonal lags—for example, to use the year-over-year or week-over-week changes in the predictor variable.

Simple Order Numerator Factors

is the order of the numerator factor of the transfer function, p .

Seasonal Order Numerator Factors

is the order of the seasonal numerator factor of the transfer function, P .

Simple Order Denominator Factors

is the order of the denominator factor of the transfer function, q .

Seasonal Order Denominator Factors

is the order of the seasonal denominator factor of the transfer function, Q .

OK

closes the window and adds the dynamic regression model specified to the model predictors list.

Cancel

closes the window without adding the dynamic regression model. Any options you specified are lost.

Reset

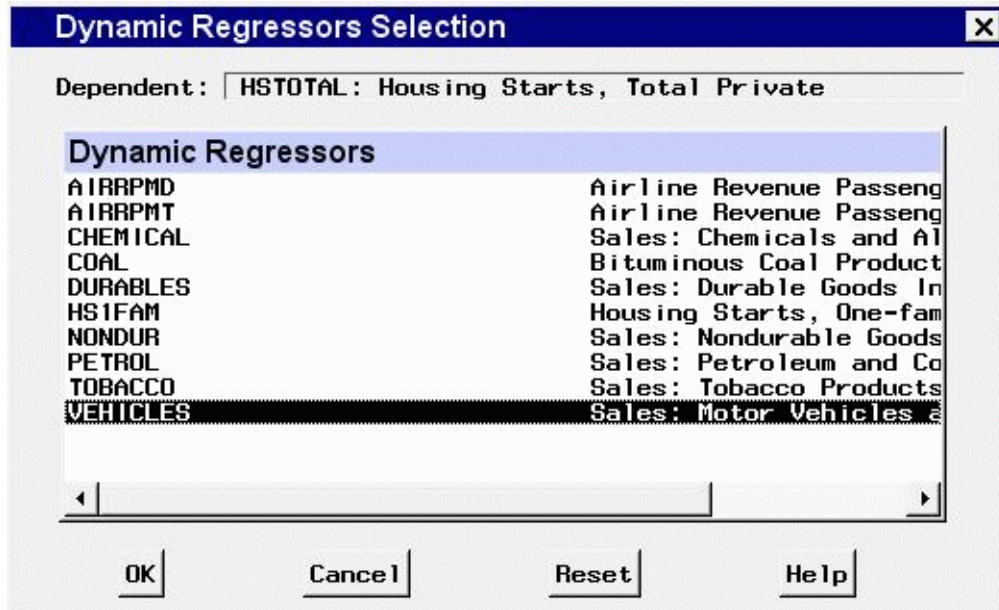

resets all options to their initial values upon entry to the window. This might be useful when editing a predictor specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Dynamic Regressors Selection Window

Use the Dynamic Regressors Selection window to select an input variable as a dynamic regressor. Access this window from the pop-up menu which appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window.

Controls and Fields

Dependent

is the name and variable label of the current series.

Dynamic Regressors

is a table listing the variables in the input data set. Select one variable in this list as the predictor series.

OK

opens the Dynamic Regression Specification window for you to specify the form of the dynamic regression for the selected predictor series, and then closes the Dynamic Regressors Selection window and adds the specified dynamic regression to the model predictors list.

Cancel

closes the window without adding the dynamic regression model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the window.

Error Model Options Window

Use the Error Model Options window to specify the autoregressive and moving-average orders for the residual autocorrelation part of a model defined by using the Custom Model Specification window. Access it by using the Set button of that window.

Controls and Fields

ARIMA Options

Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a pop-up list.

Autoregressive

defines the order of the autoregressive part of the model.

Moving Average

defines the order of the moving-average term.

OK

closes the Error Model Options window and returns to the Custom Model Specification window.

Cancel

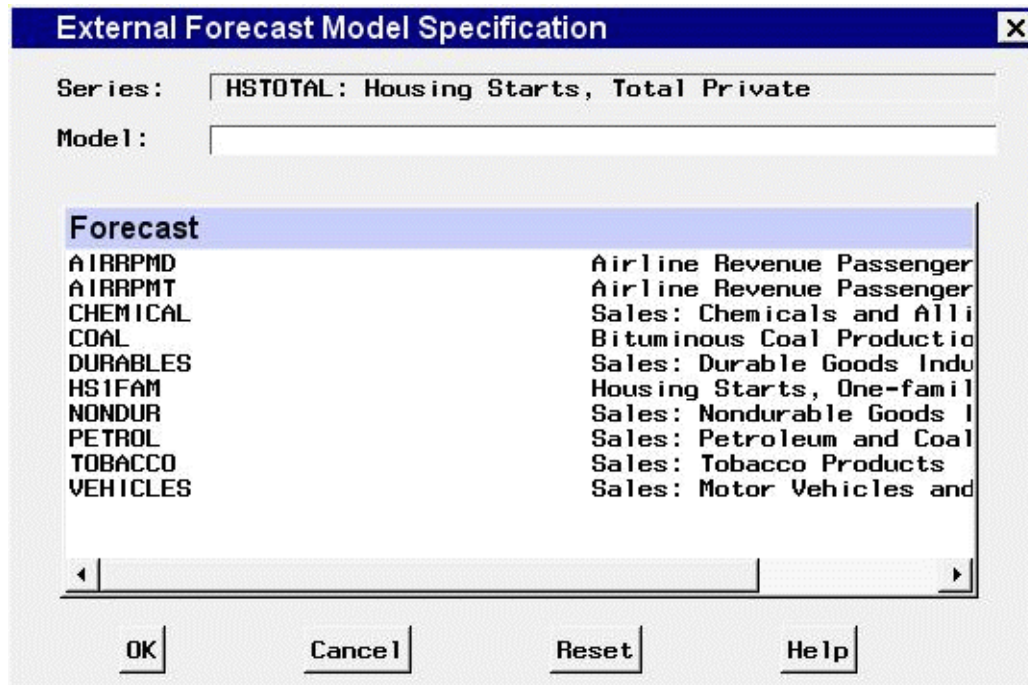

closes the Error Model Options window and returns to the Custom Model Specification window, discarding any changes made.

Reset

resets all options to their initial values upon entry to the window.

External Forecast Model Specification Window

Use the External Forecast Model Specification window to add to the current project forecasts produced externally to the Time Series Forecasting System. To add an external forecast, select a variable from the selection list and choose the OK button. The name of the selected variable will be added to the list of models fit, and the values of this variable will be used as the forecast. For more information, see “Incorporating Forecasts from Other Sources” in the “Specifying Forecasting Models” chapter.

Controls and Fields

OK

closes the window and adds the external forecast to the project.

Cancel

closes the window without adding an external forecast to the project.

Reset

deselects any selection made in the selection list.

Factored ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify an ARIMA model by using the notation:

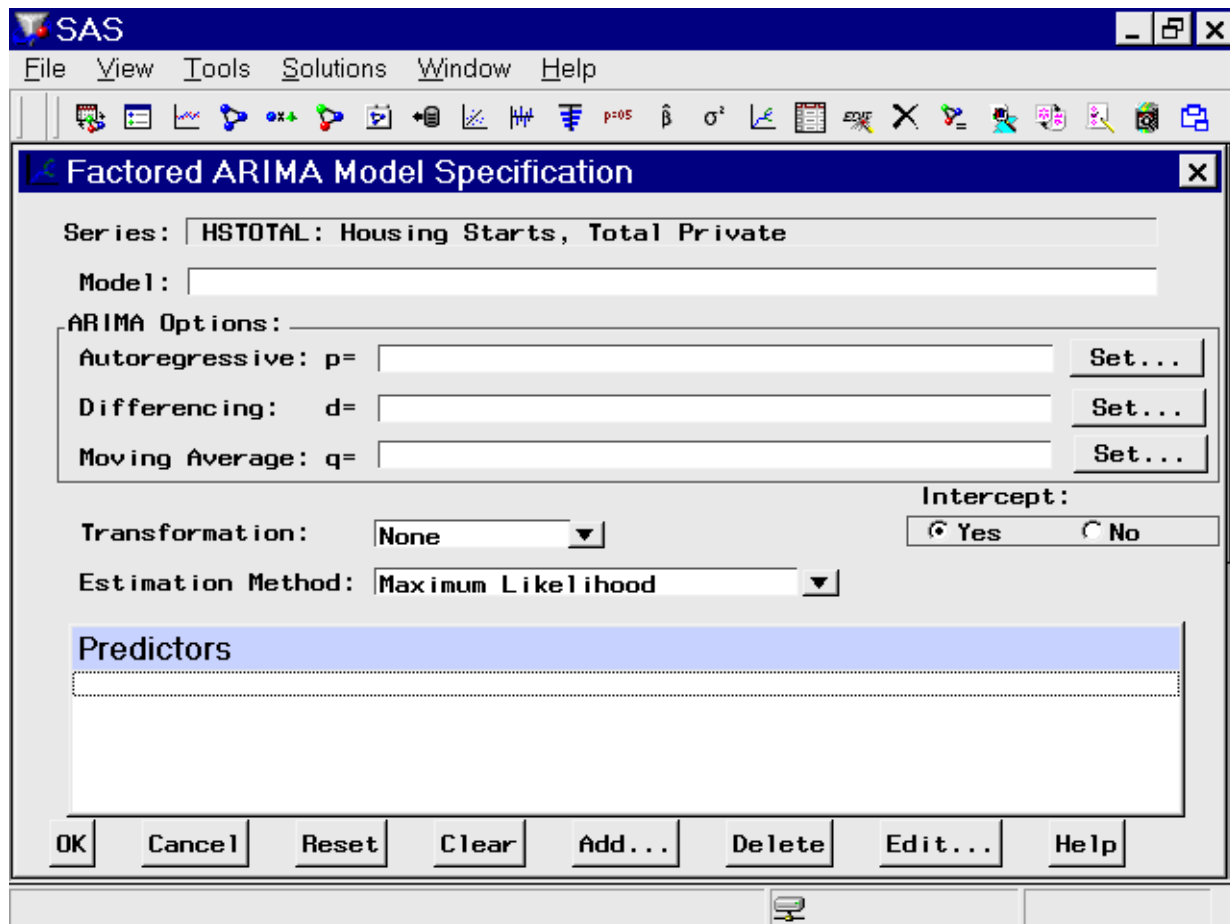

$p = (\text{lag}, \dots, \text{lag}) \dots (\text{lag}, \dots, \text{lag})$

$d = (\text{lag}, \dots, \text{lag})$

$q = (\text{lag}, \dots, \text{lag}) \dots (\text{lag}, \dots, \text{lag})$

where p , d , and q represent autoregressive, differencing, and moving-average terms, respectively.

Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit in the menu bar, or from the pop-up menu when you click an empty area of the model table.

The Factored ARIMA Model Specification window is identical to the ARIMA Model Specification window, except that the p , d , and q terms are specified in a more general and less limited way. Only those controls and fields that differ from the ARIMA Model Specification window are described here.

Controls and Fields

Model

is a descriptive label for the model. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the p , d , and q terms that you specify. For example, if you specify $p=(1,2,3)$, $d=(1)$, $q=(12)$ and no intercept, the model label is `ARIMA p=(1,2,3) d=(1) q=(12) NOINT`. For monthly data, this is equivalent to the model `ARIMA(3,1,0)(0,0,1)s NOINT` as specified in the ARIMA Model Specification window or the Custom Model Specification window.

ARIMA Options

Specifies the ARIMA model in terms of the autoregressive lags (p), differencing lags (d), and moving-average lags (q).

Autoregressive

defines the autoregressive part of the model. Select the Set button to open the AR Polynomial Specification window, where you can add any set of autoregressive lags grouped into any number of factors.

Differencing

specifies differencing to be applied to the input data. Select the Set button to open the Differencing Specification window, where you can specify any set of differencing lags.

Moving Average

defines the moving-average part of the model. Select the Set button to open the MA Polynomial Specification window, where you can add any set of moving-average lags grouped into any number of factors.

Estimation Method

specifies the method used to estimate the model parameters. The Conditional Least Squares and Unconditional Least Squares methods generally require fewer computing resources and are more likely to succeed in fitting complex models. The Maximum Likelihood method requires more resources but provides a better fit in some cases. See also Estimation Details in Chapter 7, “[The ARIMA Procedure](#).”

Forecast Combination Model Specification Window

Use the Forecast Combination Model Specification window to produce forecasts by averaging the forecasts of two or more forecasting models. The specified combination of models is added to the model list for the series. Access this window from the Develop Models window whenever two or more models have been fit to the current series. It is invoked by selecting Combine Forecasts from the Fit Model submenu of the Edit menu, or from the pop-up menu which appears when you click an empty part of the model table.

Forecast Combination Model Specification

Series:

Model:

Weight	Model Description	Root Mean Square Error
.	Linear Trend	37.01371
.	Linear Trend with Autoregressive Errors	14.13055

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Weight

is a column of the forecasting model table that contains the weight values for each model. The forecasts for the combined model are computed as a weighted average of the predictions from the models in the table that use these weights. Models with missing weight values are not included in the forecast combination. You can type weight values in these fields or you can use other features of the window to set the weights.

Model Description

is a column of the forecasting model table that contains the descriptive labels of the forecasting models fit to the current series that are available for combination.

Root Mean Square Error (or other statistic name) button

is the button above the right side of the table. It displays the name of the current model selection criterion: a statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button opens the Model Selection Criterion window to enable you to select a different statistic.

Normalize Weights button

replaces each nonmissing value in the Weights column with the current value divided by the sum of the weights. The resulting weights are proportional to original weights and sum to 1.

Fit Regression Weights button

computes weight values for the models in the table by regressing the series on the predictions from the models. The values in the Weights column are replaced by the estimated coefficients produced by this linear regression. If some weight values are nonmissing and some are missing, only models with nonmissing weight values are included in the regression. If all weights are missing, all models are used.

OK

closes the Forecast Combination Model Specification window and fits the model.

Cancel

closes the Forecast Combination Model Specification window without fitting the model. Any options you specified are lost.

Reset

resets all options to their initial values upon entry to the Forecast Combination Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

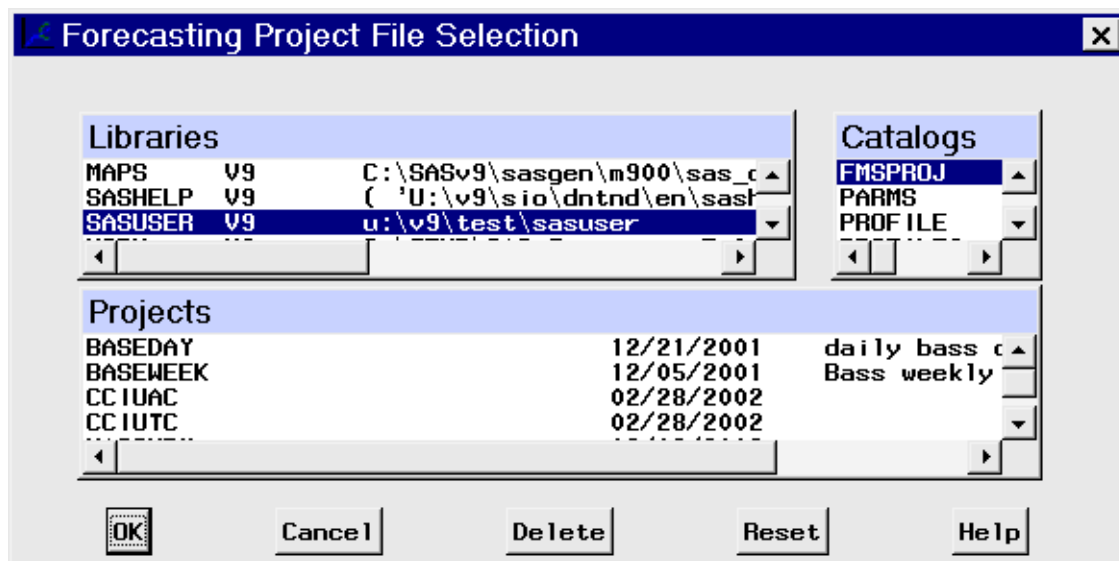

Mouse Button Actions

You can select or deselect models for inclusion in the combination model by positioning the mouse cursor over the model description and pressing the left mouse button. When you select a model in this way, the weights are automatically updated.

The newly selected model is given a weight equal to the average weight of the previously selected models, and all the nonmissing weights are normalized to sum to 1. When you use the mouse to remove a model from the combination, the weight of the deselected model is set to missing and the remaining nonmissing weights are normalized to sum to 1.

Forecasting Project File Selection Window

Use the Forecasting Project File Selection window to locate and load a previously stored forecasting project. Access it from the project Browse button of the Manage Forecasting Project window or the Time Series Forecasting window or from the Open Project item under the File menu of the Develop Models window.

Selection Lists

Libraries

is a list of currently assigned libraries. When you select a library from this list, the catalogs in that library are shown in the catalog selection list.

Catalogs

is a list of catalogs contained in the currently selected library. When you select a catalog from this list, any forecasting project entries stored in that catalog are shown in the projects selection list.

Projects

is a list of forecasting project entries contained in the currently selected catalog.

Controls and Fields

OK

closes the window and opens the selected project.

Cancel

closes the window without selecting a project.

Delete

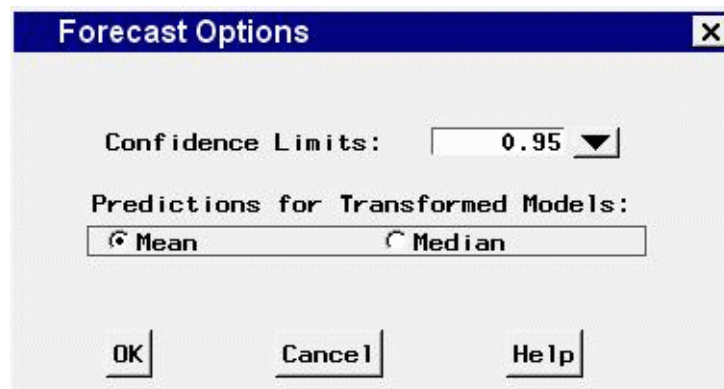

deletes the selected project file.

Reset

restores selections to those which were set before the window was opened.

Forecast Options Window

Use the Forecast Options window to set options to control how forecasts and confidence limits are computed. It is available from the Forecast Options item in the Options menu of the Develop Models window, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

Controls and Fields

Confidence Limits

specifies the size of the confidence limits for the forecast values. For example, a value of 0.95 specifies 95% confidence intervals. You can type in a number or select from the pop-up list.

Predictions for transformed models

controls how forecast values are computed for models that employ a series transformation. See the section [Predictions for Transformed Models](#) in Chapter 52, “Forecasting Process Details,” for more information. The values are as follows.

Mean

specifies that forecast values be predictions of the conditional mean of the series.

Median

specifies that forecast values be predictions of the conditional median of the series.

OK

closes the window and saves the option settings you specified.

Cancel

closes the window without changing the forecast options. Any options you specified are lost.

Intervention Specification Window

Use the Intervention Specification window to specify intervention effects to model the impact on the series of unusual events. Access it from the Intervention for Series window. For more information, see the section “Interventions” on page 3162.

DATE	HSTOTAL
JAN75	56.1000
FEB75	54.7000
MAR75	80.2000
APR75	97.9000
MAY75	116.1000
JUN75	110.3000
JUL75	119.3000
AUG75	117.3000
SEP75	111.9000
OCT75	123.6000
NOV75	96.9000

Controls and Fields

Series

is the name and variable label of the current series.

Label

is a descriptive label for the intervention effect that you specify. You can type a label in this field or allow the system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify.

Date

is the date that the intervention occurs. You can type a date value in this field, or you can set the date by selecting a row of the data table on the right side of the window.

Type of Intervention**Point**

specifies that the intervention variable is zero except for the specified date.

Step

specifies that the intervention variable is zero before the specified date and a constant 1.0 after the date.

Ramp

specifies that the intervention variable is an increasing linear function of time after the date of the intervention and zero before the intervention date.

Number of lags

specifies the numerator order for the transfer function model for the intervention effect. Select a value from the pop-up list.

Effect Decay Pattern

specifies the denominator order for the transfer function model for the intervention effect. The value “Exp” specifies a single lag denominator factor; the value “Wave” specifies a two-lag denominator factor.

OK

closes the window and adds the intervention effect specified to the series interventions list.

Cancel

closes the window without adding the intervention. Any options you specified are lost.

Reset

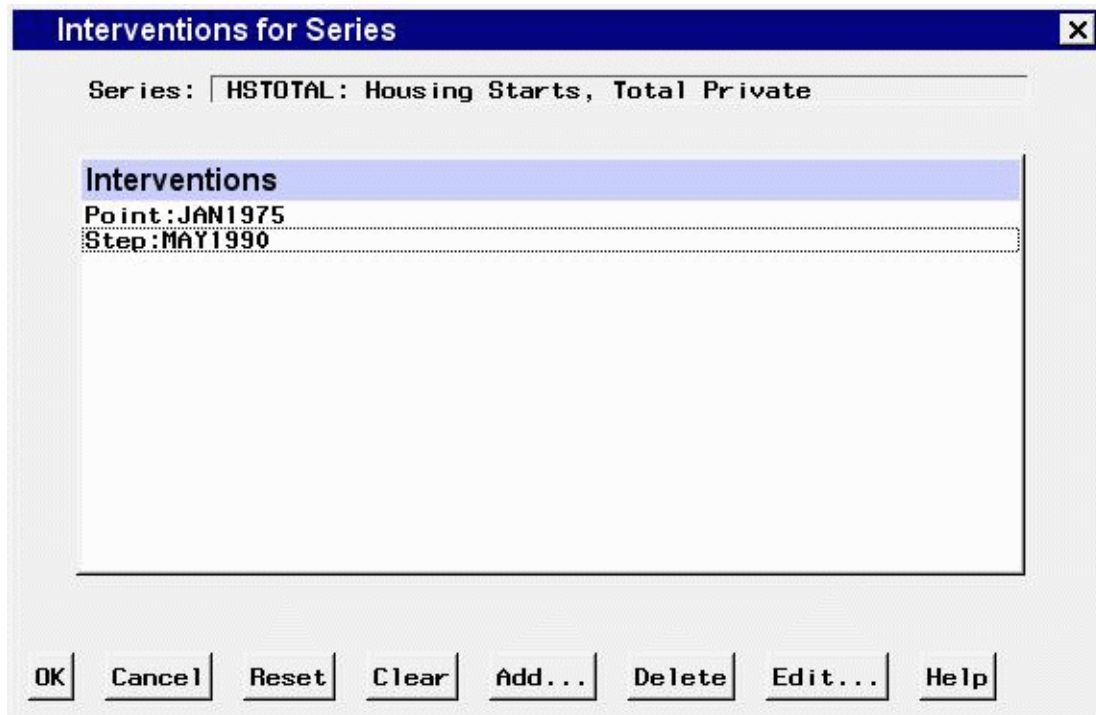

resets all options to their initial values upon entry to the window. This might be useful when editing an intervention specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Interventions for Series Window

Use the Interventions for Series window to create and edit a list of intervention effects to model the impact on the series of unusual events and to select intervention effects as predictors for forecasting models. Access it from the Add button pop-up menu of the ARIMA Model Specification or Custom Model Specification window, or by selecting Define Interventions from the Tools in the Develop Models window. For more information, see the section “[Interventions](#)” on page 3162.

Controls and Fields

Series

is the name and variable label of the current series.

OK

closes the window. If you access this window from the ARIMA Model Specification window or the Custom Model Specification window, any interventions that are selected (highlighted) in the list are added to the model. If you access this window from the Tools menu, all interventions in the list are saved for the current series.

Cancel

closes the window without returning a selection or changing the interventions list. Any options you specified are lost.

Reset

resets the list as it was on entry to the window.

Clear

deletes all interventions from the list.

Add

opens the Intervention Specification window to specify a new intervention effect and add it to the list.

Delete

deletes the currently selected (highlighted) entries from the list.

Edit

opens the Intervention Specification window to edit the currently selected (highlighted) intervention.

Mouse Button Actions

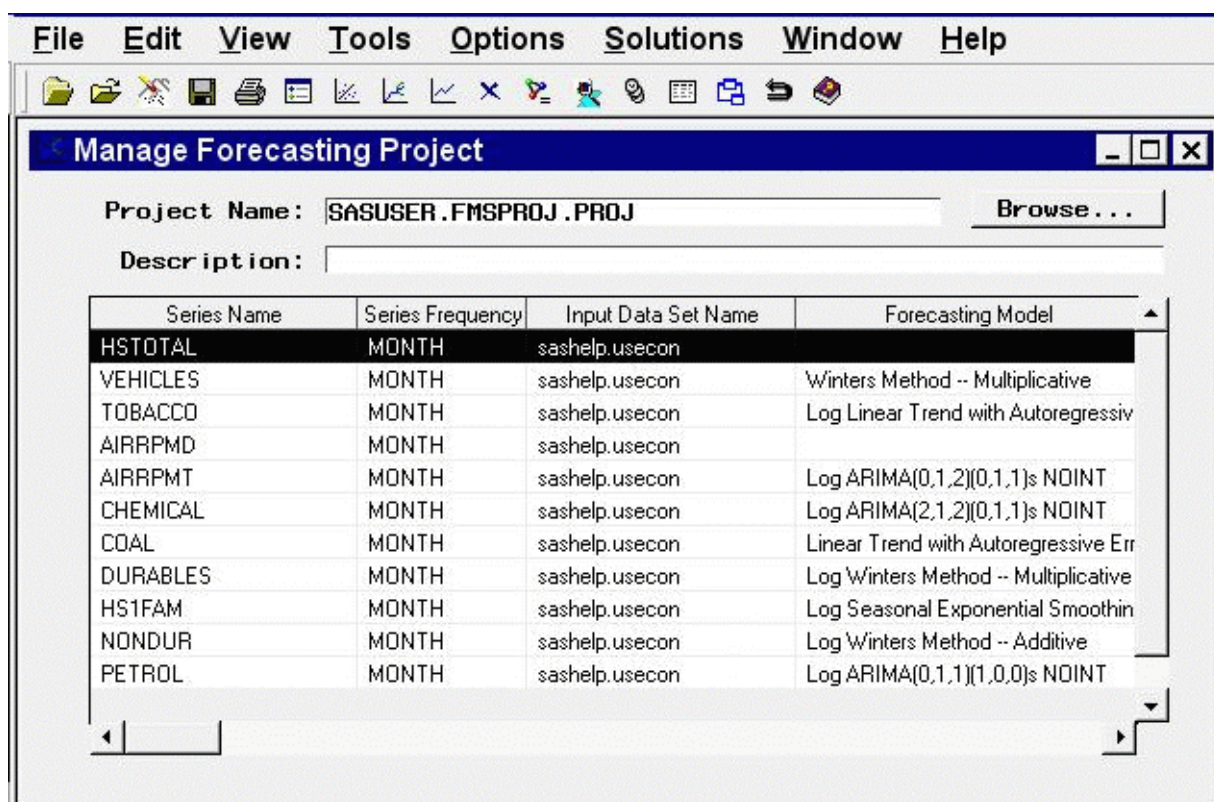

To select or deselect interventions, position the mouse cursor over the intervention's label in the Interventions list and press the left mouse button.

When you position the mouse cursor in the Interventions list and press the right mouse button, a menu containing the actions Add, Delete, and Edit appears. These actions are the same as the Add, Delete, and Edit buttons.

Double-clicking on an intervention in the list invokes an Edit action for that intervention specification.

Manage Forecasting Project Window

Use this resizable window to work with collections of series, models, and options called *projects*. The window contains a project name, a description field, and a table of information about all the series for which you have fit forecasting models. Access it by using the Manage Projects button on the Time Series Forecasting window.

Controls and Fields

Project Name

is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project

by typing a SAS catalog entry name in this field or by selecting the Browse button to the right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one-level name, it is assumed to be the name of a project in the “fmsproj” catalog in the “sasuser” library. For example, typing `samproj` is equivalent to typing `sasuser.fmsproj.samproj`.

project Browse button

opens the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored project files.

Description

is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field if you save the project.

Series List Table

The table of series for which forecasting models have been fit contains the following columns.

Series Name

is the name of the time series variable represented in the given row of the table.

Series Frequency

is the time interval (data frequency) for the time series.

Input Data Set Name

is the input data set that provided the data for the series.

Forecasting Model

is the descriptive label for the forecasting model selected for the series.

Statistic Name

is the statistic of fit for the forecasting model selected for the series.

Number of Models

is the total number of forecasting models fit to the series. If there is more than one model for a series, use the Model List window to see a list of models.

Series Label

is the variable label for the series.

Time ID Variable Name

is the time ID variable for the input data set for the series.

Series Data Range

is the time range of the nonmissing values of the series.

Model Fit Range

is the period of fit used for the series.

Model Evaluation Range

is the evaluation period used for the series.

Forecast Range

is the forecast period set for the series.

Menu Bar

File

New

opens a dialog which lets you create a new project, assign it a name and description, and make it the active project.

Open

opens a dialog that lets you select and load a previously saved project.

Close

closes the Manage Forecasting Project window and returns to the main window.

Save

saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

Save As

saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

Save to Data Set

saves the current project file information in a SAS data set. The contents of the data set are the same as the information displayed in the series list table.

Delete

deletes the current project file.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print

prints the current project file information.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Edit

Delete Series

deletes all models for the selected (highlighted) row of the table and removes the series from the project.

Clear

resets the system, deleting all series and models from the project.

Reset

restores the Manage Forecasting Project window to its initial state.

View**Data Set**

opens a Viewtable window to display the input data set for the selected (highlighted) series.

Series

opens the Time Series Viewer window to display plots of the selected (highlighted) series.

Model

opens the Model Viewer window to show the current forecasting model for the selected series.

Forecast

opens the Model Viewer to display plots of the forecasts produced by the forecasting model for the selected (highlighted) series.

Tools**Diagnose Series**

opens the Series Diagnostics window to perform the automatic series diagnostic process to determine the kinds of forecasting models appropriate for the selected (highlighted) series.

List Models

opens the Model List window for the selected (highlighted) series, which displays a list of all the models that you fit for the series. This action is the same as double-clicking the mouse on the table row.

Generate Data

opens the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

Refit Models**All Series**

refits all the models for all the series in the project by using data within the current fit range.

Selected Series

refits all the models for the currently highlighted series by using data within the current fit range.

Reevaluate Models

All Series

reevaluates all the models for all the series in the project by using data within the current evaluation fit range.

Selected Series

reevaluates all the models for the currently highlighted series by using data within the current evaluation range.

Options

Time Ranges

opens the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon.

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made by using this window do not affect series you are already working with; they take effect when you select a new series.

Model Selection List

opens the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Statistics of Fit

opens the Statistics of Fit Selection window, which controls which of the available statistics will be displayed.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Column Labels

enables you to set long or short column labels. Long labels are used by default.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Model Selection List editor window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option

SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions

If you select a series in the table by positioning the cursor over the table row and clicking with the left mouse button once, that row of the table is highlighted. Menu bar actions such as Delete Series will apply to the highlighted row of the table.

If you select a series in the table by positioning the cursor over the table row and double-clicking with the left mouse button, the system opens the Model List window for that series, which displays a list of all the models that you fit for the series. This is the same as the List Models action under Tools in the menu bar.

Right Mouse Button Actions

Clicking the right mouse button invokes a pop-up menu of actions applicable to the highlighted series. The actions in this menu are as follows.

Delete Series

deletes the highlighted series and its models from the project. This is the same as Delete Series in the Edit menu.

Refit All Models

refits all models attached to the highlighted series by using data within the current fit range. This is the same as the Selected Series item under Refit Models in the Tools menu.

Reevaluate All Models

reevaluates all models attached to the highlighted series by using data within the current evaluation range. This is the same as the Selected Series item under Reevaluate Models in the Tools menu.

List Models

invokes the Model List window. This is the same as List Models under the Tools menu.

View Series

opens the Time Series Viewer window to display plots of the highlighted series. This is the same as the Series item under the View menu.

View Forecasting Model

invokes the Model Viewer window to display the forecasting model for the highlighted series. This is the same as the Model item under the View menu.

View Forecast

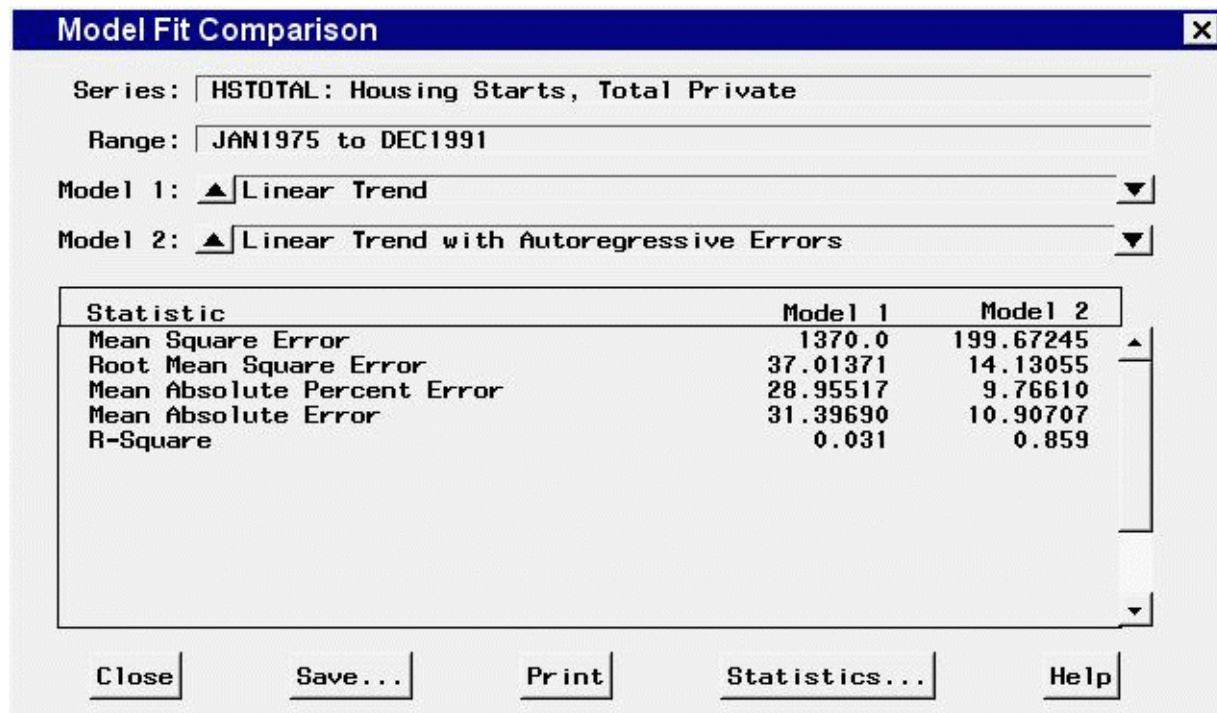

opens the Model Viewer window to display the forecasts for the highlighted series. This is the same as the Forecast item under the View menu.

Refresh

updates information shown in the Manage Forecasting Project window.

Model Fit Comparison Window

Use the Model Fit Comparison window to compare goodness-of-fit statistics for any two models fit to the current series. Access it from the Tools menu of the Develop Models window and the Automatic Model Fitting Results window whenever two or more models have been fit to the series.

Controls and Fields

Series

identifies the current time series variable.

Range

displays the starting and ending dates of the series data range.

Model 1

shows the model currently identified as Model 1.

Model 1 upward arrow button

enables you to change the model identified as Model 1 if it is not already the first model in the list of models associated with the series. Select this button to cycle upward through the list of models.

Model 1 downward arrow button

enables you to change the model identified as Model 1 if it is not already the last model in the list of models. Select this button to cycle downward through the list of models.

Model 2

shows the model currently identified as Model 2.

Model 2 upward arrow button

enables you to change the model identified as Model 2 if it is not already the first model in the list of models associated with the series. Select this button to cycle upward through the list of models.

Model 2 downward arrow button

enables you to change the model identified as Model 2 if it is not already the last model in the list of models. Select this button to cycle downward through the list of models.

Close

closes the Model Fit Comparison window.

Save

opens a dialog for specifying the name and label of a SAS data set to which the statistics will be saved. The data set will contain all available statistics and their values for Model 1 and Model 2, as well as a flag variable that is set to 1 for those statistics that were displayed.

Print

prints the contents of the table to the SAS Output window. If you find that the contents do not appear immediately in the Output window, you need to set scrolling options. Select “Preferences” under the Options submenu of the Tools menu. In the Preferences window, select the Advanced tab, then set output scroll lines to a number greater than zero.

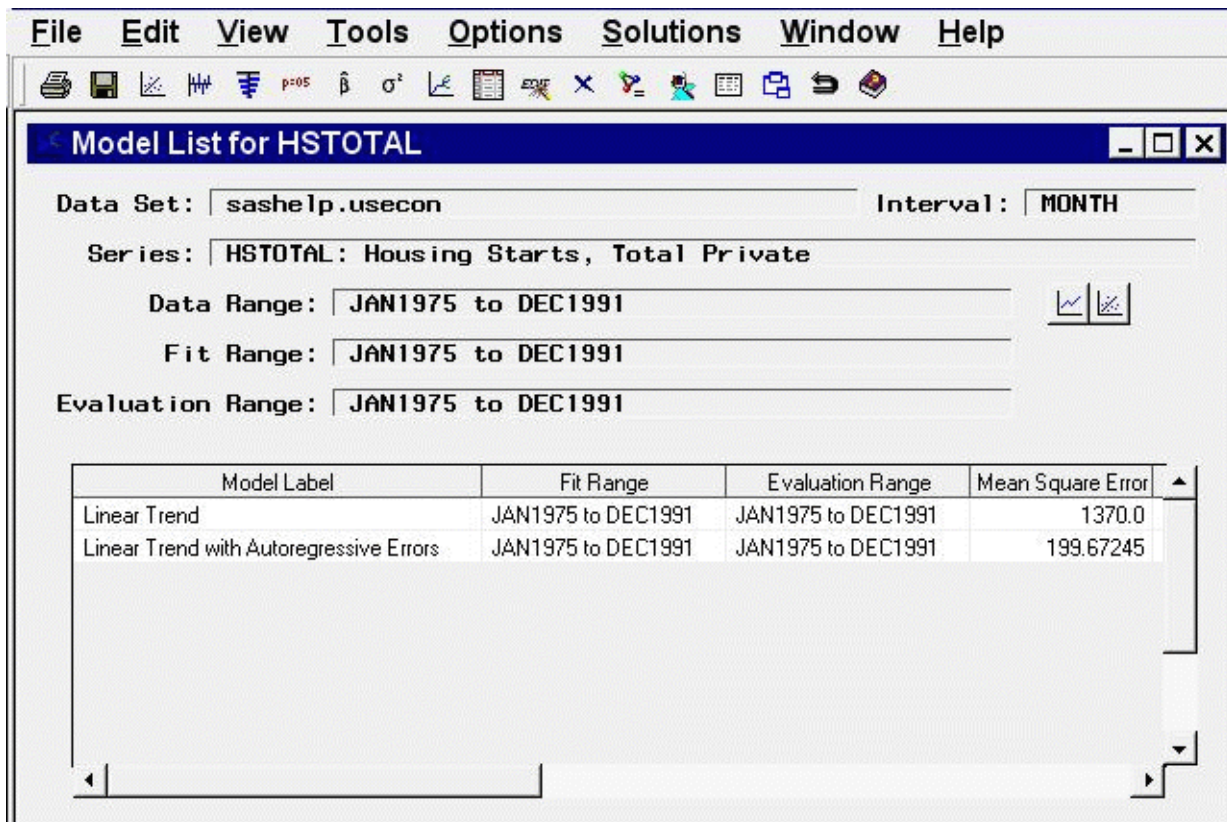

If you want to route the contents to a printer, go to the Output window and select “Print” from the File menu.

Statistics

opens the Statistics of Fit Selection window for controlling which statistics are displayed.

Model List Window

This resizable window shows all of the models that have been fit to a particular series in a project. Access it from the Manage Forecasting Project window by selecting a series in the series list table and choosing “List Models” from the Tools menu or by double-clicking the series.

Controls and Fields

Data Set

is the name of the current input data set.

Interval

is the time interval (data frequency) for the input data set.

Series

is the variable name and label of the current time series.

Data Range

is the date of the first and last nonmissing data values available for the current series in the input data set.

Fit Range

is the current period of fit setting. This is the range of data that will be used to fit models to the series. It might be different from the fit ranges shown in the table, which were in effect when the models were fit.

Evaluation Range

is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series. It might be different from the evaluation ranges shown in the table, which were in effect when the models were fit.

View Series Graphically icon

opens the Time Series Viewer window to display plots of the current series.

View Model Graphically icon

opens the Model Viewer to display graphs and tables for the currently highlighted model.

Model List Table

The table of models fit to the series contains columns that show the model label, the fit range and evaluation range used to fit the models, and all of the currently selected fit statistics. You can change the selection of fit statistics by using the Statistics of Fit Selection window.

Click on column headings to sort the table by a particular column. If a model is highlighted, clicking with the right mouse button invokes a pop-up menu that provides actions applicable to the highlighted model. It includes the following items.

View Model

opens the Model Viewer on the selected model. This is the same as “Model Predictions” under the View menu.

View Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model. This is the same as “Parameter Estimates” under the View menu.

View Statistics of Fit

opens the Model Viewer to display the statistics of fit table for the currently highlighted model. This is the same as “Statistics of Fit” under the View menu.

Edit Model

opens the appropriate model specification window for changing the attributes of the highlighted model and fitting the modified model.

Refit Model

refits the highlighted model using the current fit range.

Reevaluate Model

reevaluates the highlighted model using the current evaluation range.

Delete Model

deletes the highlighted model from the project.

View Forecasts

opens the Model Viewer to show the forecasts for the highlighted model. This is the same as “Forecast Graph” under the View menu.

Menu Bar

File

Save

opens a dialog which lets you save the contents of the table to a specified SAS data set.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print

sends the contents of the table to a printer as defined through Print Setup.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the window and returns to the Manage Forecasting Projects window.

Edit**Edit Model**

enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

Refit Model

refits the currently highlighted model using data within the current fit range.

Reevaluate Model

recomputes statistics of fit for the currently highlighted model using data within the current evaluation range.

Delete Model

deletes the currently highlighted model from the model table.

Reset

restores the contents of the Model List window to the state initially displayed.

View**Series**

opens the Time Series Viewer window to display plots of the current series. This is the same as the View Series Graphically icon.

Model Predictions

opens the Model Viewer to display a predicted and actual plot for the currently highlighted model. This is the same as the View Model Graphically icon.

Prediction Errors

opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations

opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests

opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit

opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph

opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table

opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Options**Statistics of Fit**

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

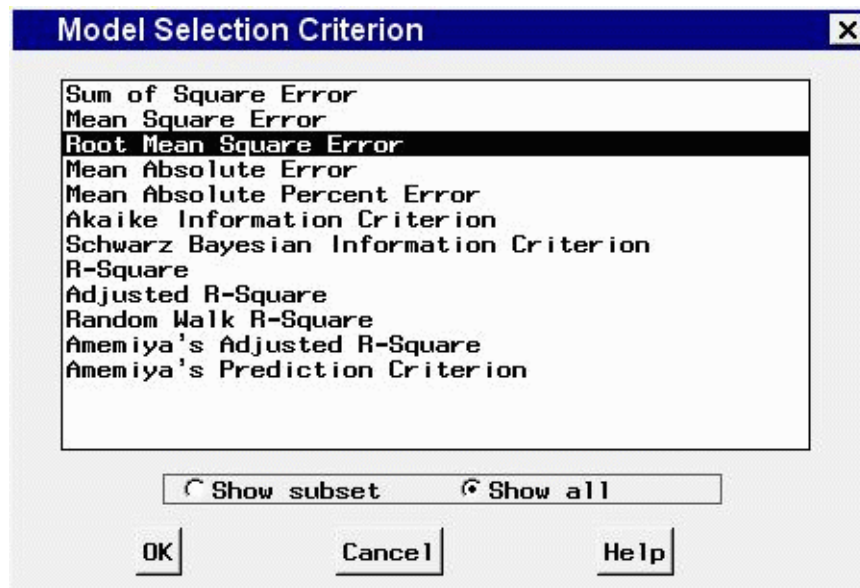

Column Labels

enables you to set long or short column labels. Long labels are used by default.

Model Selection Criterion Window

Use the Model Selection Criterion window to select the model selection criterion statistic used by the automatic selection process to determine the best fitting forecasting model. Model selection criterion statistics are a subset of those shown in the Statistics of Fit Selection window, since some statistics of fit, such as number of observations, are not useful for model selection.

This window is available from the Model Selection Criterion item of the Options menu of the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.

Controls and Fields

Show subset

when selected, lists only those model selection criterion statistics that are selected in the Statistics of Fit Selection window.

Show all

when selected, lists all available model selection criterion statistics.

OK

closes the window and sets the model selection criterion to the statistic you specified.

Cancel

closes the window without changing the model selection criterion.

Model Selection List Editor Window

Use the Model Selection List Editor window to edit the model selection list, including adding your own custom models, and to specify which models in the list are to be used in the automatic fitting process. Access it from the Options menu in the Develop Models, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

The window initially displays the current model list for your project. You can modify this set of models in several ways:

- Open one or more alternate model lists to replace or append to the current model list. These can be either model lists included with the software or model lists previously saved by you or other users.

- Turn the autofit option on or off for individual models. Those that are not flagged for autofit will be available by using the Models to Fit window but not by using automatic model fitting.
- Delete models from the list that are not needed for your project.
- Reorder the models in the list.
- Edit models in the list.
- Create a new empty list.
- Add new models to the list.

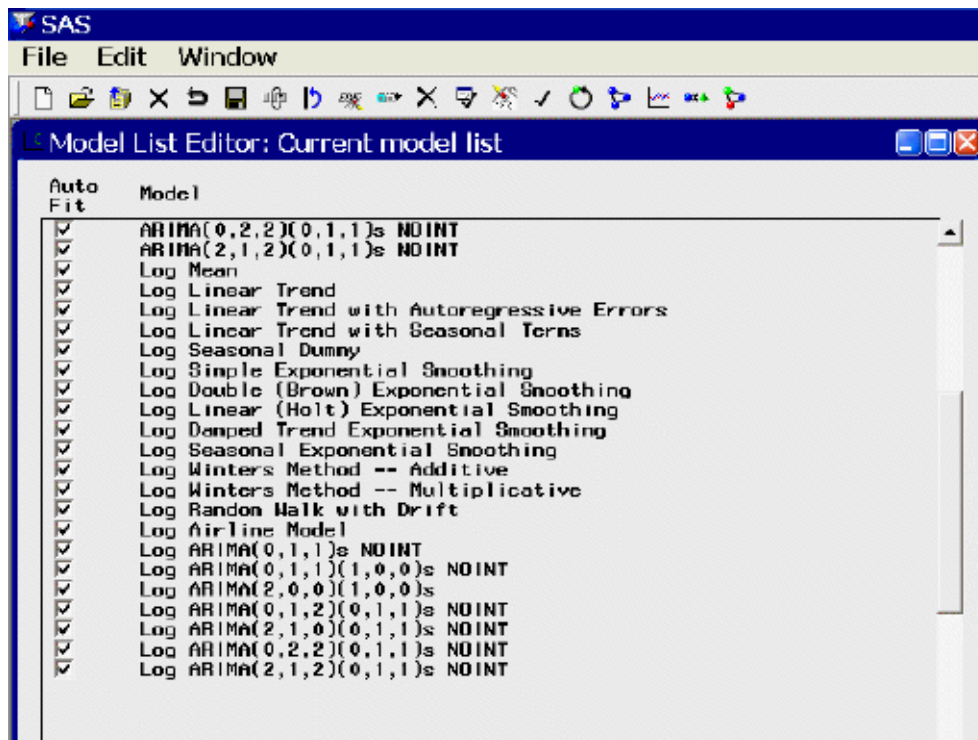

Having modified the current model list, you can save it for future use in several ways:

- Save it in a catalog so it can be opened later in the Model Selection List Editor.
- Save it as the user default to be used automatically when new projects are created.
- Select *close* to close the Model Selection List Editor and attach the modified model selection list to the current project.
- Select *cancel* to close the Model Selection List Editor without changing the current project's model selection list.

Since model selection lists are not bound to specific data sources, care must be taken when including data-specific features such as interventions and regressors. When you add an ARIMA, Factored ARIMA, or Custom model to the list, you can add regressors by selecting from the variables in the current data set. If there is no current data set, you will be prompted to specify a data set so you can select regressors from the series it contains.

If you use a model list that has models with a particular regressor name on a data set that does not contain a series of that name, model fitting will fail. However, you can make global changes to the regressor names in the model list by using *Set regressor names*. For example, you might use the list of dynamic regression models found in the sashelp.forecast catalog. It uses the regressor name "price." If your regressor series is named "x," you can specify "price" as the current regressor name and "x" as the "change to" name. The change will be applied to all models in the list that contain the specified regressor name.

Interventions cannot be defined for models defined from the Model Selection List Editor. However, you can define interventions by using the Intervention Specification Window and apply them to your models by turning on the Include Interventions option.

Auto Fit

The auto fit column of check boxes enables you to eliminate some of the models from being used in the automatic fitting process without having to delete them from the list. By default, all models are checked, meaning that they are all used for automatic fitting.

Model

This column displays the descriptions of all models in the model selection list. You can select one or more models by clicking them. Selected models are highlighted and become the object of the actions Edit, Move, and Delete.

Menu Bar

File

New

creates a new empty model selection list.

Open

opens a dialog for selecting one or more existing model selection lists to open. If you select multiple lists, they are all opened at once as a concatenated list. This helps you build large specialized model lists quickly by mixing and matching various existing lists such as the various ARIMA model lists included in SASHELP.FORCAST. By default, the lists you open replace the current model list. Select the "append" radio button if you want to append them to the current model list.

Open System Default

opens the default model list supplied with the product.

Cancel

exits the window without applying any changes to the current project's model selection list.

Close

closes the window and applies any changes made to the project's model selection list.

Save

opens a dialog for saving the edited model selection list in a catalog of your choice.

Save as User Default

saves your edited model list as a default list for new projects. The location of this saved list is shown on the message line. When you create new projects, the system searches for this model list and uses it if it is found. If it is not found, the system uses the original default model list supplied with the product.

Edit

Reset

restores the list to its initial state when the window was invoked.

Add Model

enables you to add new models to the selection list. You can use the Smoothing Model Specification window, the ARIMA Model Specification window, the Factored ARIMA Model Specification window, or the Custom Model Specification window.

Edit Selected

opens the appropriate model specification window for changing the attributes of the highlighted model and adding the modified model to the selection list. The original model is not deleted.

Move Selected

enables you to reorder the models in the list. Select one or more models, then select Move Selected from the menu or toolbar. A note appears on the message line: "Select the row after which the selected models are to be moved." Then select any unhighlighted row in the table. The selected models will be moved after this row.

Delete

deletes any highlighted models from the list. This item is not available if no models are selected.

Set Regressor Names

opens a dialog for changing all occurrences of a given regressor name in the models of the current model selection list to a name that you specify.

Select All

selects all models in the list.

Clear Selections

deselects all models in the list.

Select All for Autofit

checks the autofit check boxes of all models in the list.

Clear Autofit Selections

deselects the autofit check boxes of all models in the list.

Mouse Button Actions

Clicking any model description in the table selects (highlights) that model. Clicking the same model again deselects it. Multiple selections are allowed.

Clicking the auto fit check box in any row toggles the associated model's eligibility for use in automatic model fitting.

Right-clicking the right mouse button opens a pop-up menu.

Model Viewer Window

This resizable window provides plots and tables of actual values, model predictions, forecasts, and related statistics. The various plots and tables available are referred to as *views*. The section “View Selection Icons” on page 3247 explains how to change the view.

You can access Model Viewer in a number of ways, including the View Model Graphically icon of the Develop Models and Model List windows, the Graph button of the Automatic Model Fitting Results window, and the Model item under the View menu in the Manage Forecasting Project window. In addition, you can go directly to a selected view in the Model Viewer window by selecting Model Predictions, Prediction Errors, Statistics of Fit, Prediction Error Autocorrelations, Prediction Error Tests, Parameter Estimates, Forecast Graph, or Forecast Table from the View menu or corresponding toolbar icon or pop-up menu item in the Develop Models, Model List, or Automatic Model Fitting Results windows.

The state of the Model Viewer window is controlled by the current model and the currently selected view. You can resize this window, and you can use other windows without closing the Model Viewer window. By default, the Model Viewer window is automatically updated to display the new model when you switch to working with another model (that is, when you highlight a different model). You can unlink the Model Viewer window from the current model selection by selecting the Link/Unlink icon from the window's horizontal toolbar. See “Link/Unlink” in the section “[Toolbar Icons](#)” on page 3247.

For more information, see the section “[Model Viewer](#)” on page 3062.

Toolbar Icons

The Model Viewer window contains a horizontal row of icons called the Toolbar. Corresponding menu items appear under various menus. The function of each icon is explained in the following list.

Zoom in

In the Model Predictions, Prediction Errors, and Forecast Graph views, the Zoom In action changes the mouse cursor into cross hairs that you can use with the left mouse button to define a region of the graph to zoom in on. In the Prediction Error Autocorrelations and Prediction Error Tests views, Zoom In reduces the number of lags displayed.

Zoom out

reverses the previous Zoom In action.

Link/Unlink viewer

disconnects or connects the Model Viewer window to the model table (Develop Models window, Model List window, or Automatic Model Fitting Results window). When the viewer is linked, selecting another model in the model table causes the model viewer to be updated to show the selected model. When the Viewer is unlinked, selecting another model does not affect the viewer. This feature is useful for comparing two or more models graphically. You can display a model of interest in the Model Viewer, unlink it, then select another model and open another Model Viewer window for that model. Position the viewer windows side by side for convenient comparisons of models, or use the Next Viewer icon or F12 function key to switch between them.

Save

saves the contents of the Model Viewer window. By default, an HTML page is created. This enables you to display graphs and tables by using the Results Viewer or publish them on the Web or your intranet. See also “Save Graph As” and “Save Data As” under “Menu Bar” below.

Print

prints the contents of the viewer window.

Close

closes the Model Viewer window and returns to the window from which it was invoked.

View Selection Icons

At the right hand side of the Model Viewer window is a vertical toolbar to select the view—that is, the kind of plot or table that the viewer displays. Corresponding menu items appear under View in the menu bar. The function of each icon is explained in the following list.

Model Predictions

displays a plot of actual series values and model predictions over time. Click individual points in the graph to get a display of the type (actual or predicted), ID value, and data value in the upper right corner of the window.

Prediction Errors

displays a plot of model prediction errors (residuals) over time. Click individual points in the graph to get a display of the prediction error value in the upper right corner of the window.

Prediction Error Autocorrelations

displays horizontal bar charts of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the model prediction errors. Overlaid line plots represent confidence limits computed at plus and minus two standard errors. Click any of the bars to display its value.

Prediction Error Tests

displays horizontal bar charts that represent results of white noise and stationarity tests on the model prediction errors. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click any of the bars to display an interpretation.

The second bar chart shows tests of stationarity of the model prediction errors, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click on any of the bars to display an interpretation.

Parameter Estimates

displays a table showing model parameter estimates along with standard errors and t tests for the null hypothesis that the parameter is zero.

Statistics of Fit

displays a table of statistics of fit for the selected model. The set of statistics shown can be changed by using the Statistics of Fit item under Options in the menu bar.

Forecast Graph

displays a plot of actual and predicted values for the series data range, followed by a horizontal reference line and forecasted values with confidence limits. Click individual points in the graph to get a display of the type, date/time, and value of the data point in the upper right corner of the window.

Forecast Table

displays a data table with columns containing the date/time, actual, predicted, error (residual), lower confidence limit, and upper confidence limit values, together with any predictor series.

Menu Bar

File**Save Graph**

saves the plot displayed in viewer window as a SAS/GRAPH grseg catalog entry. When the current view is a table, this menu item is not available. See also “Save” in the section “[Toolbar Icons](#)” on page 3247. If a graphics catalog entry name has not already been specified, this action functions like “Save Graph As.”

Save Graph As

saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the graph embedded as a gif image.

Save Data

saves the data displayed in the viewer window in a SAS data set, where applicable.

Save Data As

saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the data displayed as a table.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Graph

prints the contents of the viewer window if the current view is a graph. This is the same as the Print toolbar icon. If the current view is a table, this menu item is not available.

Print Data

prints the data displayed in the viewer window, where applicable.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Print Preview

opens a preview window to show how your plots will appear when printed.

Close

closes the Model Viewer window and returns to the window from which it was invoked.

Edit**Edit Model**

enables you to modify the specification of the current model and to fit the modified model, which is then displayed in the viewer.

Refit Model

refits the current model by using data within the current fit range. This action also causes the ranges to be reset if the data range has changed.

Reevaluate Model

reevaluates the current model by using data within the current evaluation range. This action also causes the ranges to be reset if the data range has changed.

View

See [“View Selection Icons”](#) on page 3247. It describes each of the items available under “View,” except “Zoom Way Out.”

Zoom Way Out

zooms the plot out as far as it will go, undoing all prior zoom in operations.

Tools**Link Viewer**

See “Link/Unlink” in the section “[Toolbar Icons](#)” on page 3247.

Options**Time Ranges**

opens the Time Ranges Specification window to enable you to change the period of fit, period of evaluation, or forecast horizon to be applied to subsequently fit models.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the statistics of fit table and available for selection in the Model Selection Criterion menu.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Residual Plot Options

Provides a choice of four methods of computing prediction errors for models which include a data transformation.

Prediction Errors

computes the difference between the transformed series actual values and model predictions.

Normalized Prediction Errors

computes prediction errors in normalized form.

Model Residuals

computes the difference between the untransformed series values and the untransformed model predictions.

Normalized Model Residuals

computes model residuals in normalized form.

Number of Lags

opens a window to enable you to specify the number of lags shown in the Prediction Error Autocorrelations and Prediction Error Tests views. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

Correlation Probabilities

controls whether the bar charts in the Prediction Error Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Mouse Button Actions

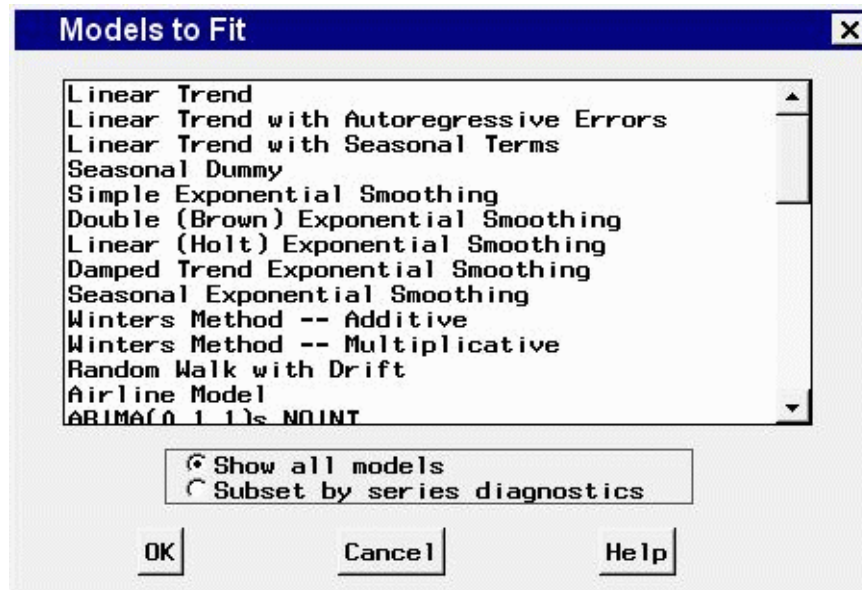

You can examine the data values of individual points in the Model Predictions, Model Prediction Errors, and Forecast Graph views of the Model Viewer by clicking the point. The date/time and data values as well as the type (actual, predicted, and so forth) are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

Similarly, you can display values in the Prediction Error Autocorrelations view by clicking any of the bars. Clicking bars in the Prediction Error Tests view displays a Recommendation for Current View window which explains the test represented by the bar.

When you select the Zoom In action in the Predicted Values, Model Prediction Errors, and Forecasted Values views, you can use the mouse to define a region of the graph to zoom. Position the mouse cursor at one corner of the region, press the left mouse button, and move the mouse cursor to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

Models to Fit Window

Use the Models to Fit window to fit models by choosing them from the current model selection list. Access it by using “Fit Models from List” under the Fit Model submenu of the Edit menu in the Develop Models window, or the pop-up menu that appears when you click an empty area of the model table in the Develop Models window. If you want to alter the list of models that appears here, use the Model Selection List editor window.

To select a model to be fit, use the left mouse button. To select more than one model to fit, drag with the mouse, or select the first model, then press the shift key while selecting the last model. For noncontiguous selections, press the control key while selecting with the mouse. To begin fitting the models, double-click the last selection or select the OK button.

If series diagnostics have been performed, the radio box is available. If the Subset by series diagnostics radio button is selected, only those models in the selection list that fit the diagnostic criteria will be shown for selection. If you want to choose models that do not fit the diagnostic criteria, select the Show all models button.

Controls and Fields

Show all models

when selected, lists all available models, regardless of the setting of the series diagnostics options.

Subset by series diagnostics

when selected, lists only the available models that are consistent with the series diagnostics options.

OK

closes the Models to Fit window and fits the selected models.

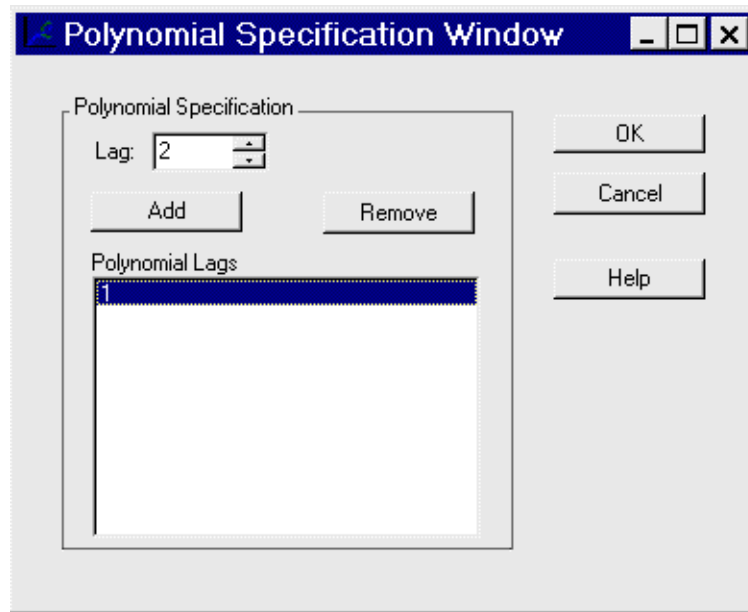

Cancel

closes the window without fitting any models. Any selections you made are lost.

Polynomial Specification Window

Use the Polynomial Specification window to add a polynomial to an ARIMA model. The set of lags defined here become a polynomial factor, denoted by a list of lags in parentheses, when you select “OK.” If you accessed this window from the AR Polynomial Specification window, then it is added to the autoregressive

part of the model. If you accessed it from the MA Polynomial Specification window, it is added to the moving-average part of the model.

Controls and Fields

Lag

specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows.

Add

adds the value in the Lag spin box to the list of polynomial lags. Duplicate values are not allowed.

Remove

deletes a selected lag from the list of polynomial lags.

Polynomial Lags

is a list of unique integers that represent lags to be added to the model.

OK

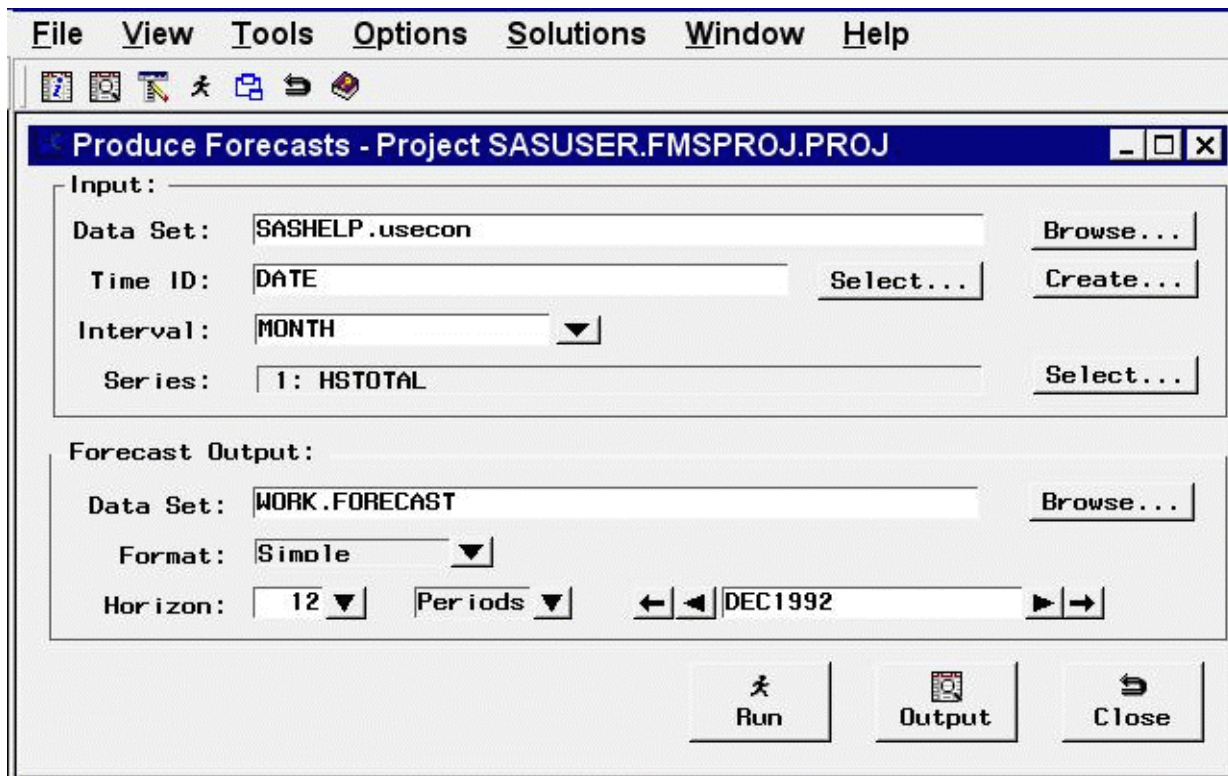

closes the window and returns the specified polynomial to the AR or MA polynomial specification window.

Cancel

closes the window and discards any polynomial lags added to the list.

Produce Forecasts Window

Use the Produce Forecasts window to produce forecasts for the series in the current input data set for which you have fit forecasting models. Access it by using the Produce Forecasts button of the Time Series Forecasting window.

Controls and Fields

Input Data Set

is the name of the current input data set. To specify the input data set, you can type a one-level or two-level SAS data set name in this field or select the Browse button to the right of the field.

Input data set Browse button

opens the Data Set Selection window to enable you to select the input data set.

Time ID

is the name of the time ID variable for the input data set. To specify this variable, you can type the ID variable name in this field or use the Select button.

Time ID Select button

opens the Time ID Variable Specification window.

Create button

opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in by the system, you can type in an interval name here, or select one from the pop-up list.

Series

indicates the number and names of time series variables for which forecasts will be produced.

Series Select button

opens the Series to Process window to let you select the series for which you want to produce forecasts.

Forecast Output Data Set

is the name of the output data set that will contain the forecasts. Type the name of the output data set in this field or click the Browse button.

Forecast Output Browse button

opens a dialog to let you locate an existing data set to which to save the forecasts.

Format

enables you to select one of three formats for the forecast data set:

Simple

specifies the simple format for the output data set. The data set contains the time ID variable and the forecast variables and contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.

Interleaved

specifies the interleaved format for the output data set. The data set contains the time ID variable, the variable TYPE, and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the TYPE variable.

Concatenated

specifies the concatenated format for the output data set. The data set contains the variable SERIES, the time ID variable, and the variables ACTUAL, PREDICT, ERROR, LOWER, and UPPER. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

Horizon

is the number of periods or years to forecast beyond the end of the input data range. To specify the forecast horizon, you can type a value in this field or select one from the pop-up list.

Horizon periods

selects the units to apply to the horizon. By default, the horizon value represents number of periods. For example, if the interval is month, the horizon represents the number of months to forecast. Depending on the interval, you can also select weeks or years, so that the horizon is measured in those units.

Horizon date

is the ending date of the forecast horizon. You can type in a date that uses a form recognized by a SAS date informat, or you can increment or decrement the date shown by using the left and right arrows. The outer arrows change the date by a larger amount than the inner arrows. The date field and the horizon field reset each other, so you can use either one to specify the forecasting horizon.

Run button

produces forecasts for the selected series and stores the forecasts in the specified output SAS data set.

Output button

opens a Viewtable window to display the output data set. This button becomes available once the forecasts have been written to the data set.

Close button

closes the Produce Forecasts window and returns to the Time Series Forecasting window.

Menu Bar

File

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Close

closes the Produce Forecasts window and returns to the Time Series Forecasting window.

View

Input Data Set

opens a Viewtable window to browse the current input data set.

Output Data Set

opens a Viewtable window to browse the output data set. This is the same as the Output button.

Tools

Produce Forecasts

produces forecasts for the selected series and stores the forecasts in the specified output SAS data set. This is the same as the Run button.

Options

Default Time Ranges

opens the Default Time Ranges window to enable you to control how the system sets the time ranges when new series are selected.

Model Selection List

opens the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Model Selection Criterion

opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model.

Statistics of Fit

opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion window.

Forecast Options

opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Forecast Data Set

enables you to select one of three formats for the forecast data set. See **Format**, which is described previously in this section.

Alignment of Dates**Beginning**

aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle

aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End

aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Set Toolbar Type**Image Only**

displays the toolbar items as icons without text.

Label Only

displays the toolbar items as text without icon images.

Both

displays the toolbar items as both text and icon images.

Include Interventions

controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

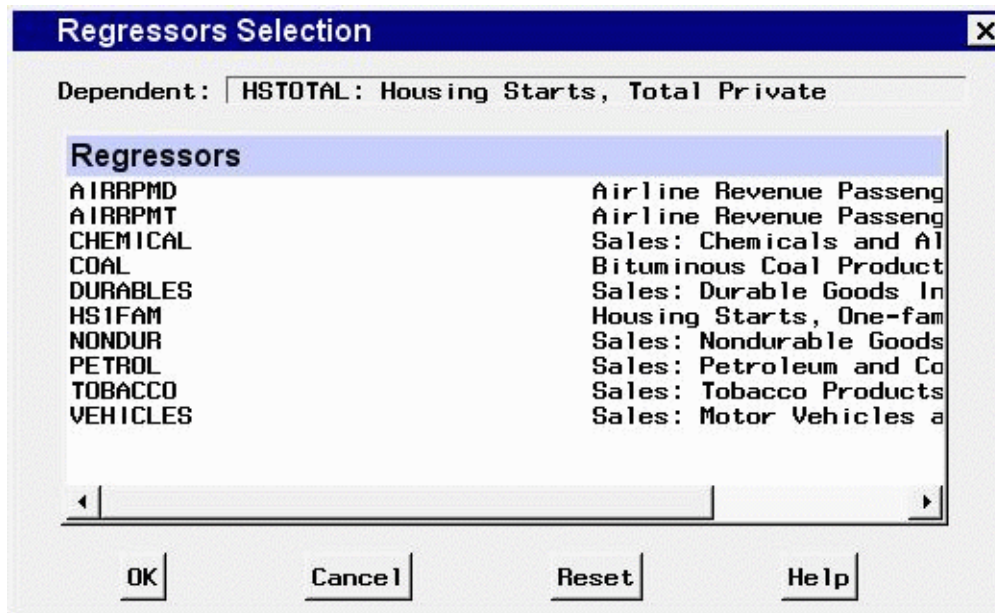

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Regressors Selection Window

Use the Regressors Selection window to select one or more time series variables in the input data set to include as regressors in the forecasting model to predict the dependent series. Access it from the pop-up menu that appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window.

Controls and Fields

Dependent

is the name and variable label of the current series.

Regressors

is a table listing the names and labels of the variables in the input data set available for selection as regressors. The variables that you select are highlighted. Selecting a highlighted row again deselects that variable.

OK

closes the Regressors Selection window and adds the selected variables as regressors in the model.

Cancel

closes the window without adding any regressors. Any selections you made are lost.

Reset

resets all options to their initial values upon entry to the window.

Save Data As

Use Save Data As from the Time Series Viewer Window or the Model Viewer Window to save data displayed in a table to a SAS data set or external file.

Use Save Forecast As from the Develop Models Window to save forecasts and related data including the series name, model, and interval. It supports append mode, enabling you to accumulate the forecasts of multiple series in a single data set.

Save Data as

SAS Library Output

Library: Browse...

Data Set:

Label: ↻

External File Output

☒ Save External File Results Preferences... Customize...

Title 1: ↻

Title 2: ↻

Title 3: ↻

OK Cancel

To save your data in a SAS data set, provide a library name or assign one by using the Browse button, then provide a data set name or accept the default. Enter a descriptive label for the data set in the Label field. Click OK to save the data set. If you specify an existing data set, it will be overwritten, except in the case of Save Forecast As.

External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating HTML tables for Web reporting. You can build a set of Web pages quickly and use the ODS Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, then select the Results tab in the Preferences dialog.

If you have previously saved data of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro that contains ODS statements. The default macro simply runs the PRINT procedure. A custom macro can be used to add PRINT procedure and/or ODS statements to customize the type and organization of output files produced.

Save Graph As

Use Save Graph As from the Time Series Viewer Window or the Model Viewer Window to save any of the graphs in a catalog or external file.

Save Forecast Graph as

SAS Library Output

Catalog:

Graphics Entry:

Label:

External File Output

☒ Save External File

Title 1:

To save your graph as a grseg catalog entry, enter a two level name for the catalog or select Browse to open an Open dialog. Use it to select an existing library or assign a new one and then select a catalog to contain the graph. Click the Open button to open the catalog and close the dialog. Then enter a graphics entry name (eight characters or less) and a label or accept the defaults and click the OK button to save the graph.

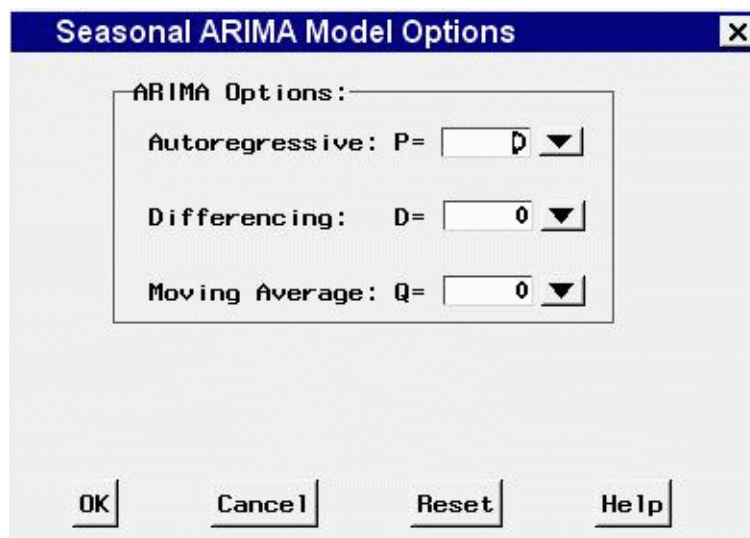

External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating gif images and HTML for Web reporting. You can build a set of Web pages that contain graphs and use the Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, then select the Results tab in the Preferences dialog.

If you have previously saved graphs of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro that contains ODS statements. The default macro simply runs the GREPLAY procedure. Users familiar with ODS might want to add statements to the macro to customize the type and organization of output files produced.

Seasonal ARIMA Model Options Window

Use the Seasonal ARIMA Model Options window to specify the autoregressive, differencing, and moving-average orders for the seasonal part of a model defined by using the Custom Model Specification window. Access it by selecting “Seasonal ARIMA...” from the Seasonal Model combo box of that window.

Controls and Fields

ARIMA Options

Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a pop-up list.

Autoregressive

defines the order of the seasonal autoregressive part of the model.

Differencing

defines the order of seasonal differencing.

Moving Average

defines the order of the seasonal moving-average term.

OK

closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window.

Cancel

closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window, discarding any changes made.

Reset

resets all options to their initial values upon entry to the window.

Series Diagnostics Window

Use the Series Diagnostics window to set options to limit the kinds of forecasting models considered for the series according to series characteristics. Access it by selecting “Diagnose Series” from the Tools menu in the Develop Models, Manage Project, and Time Series Viewer window menu bars. You can let the system diagnose the series characteristics automatically or you can specify series characteristics according to your judgment by using the radio buttons.

Series Diagnostics

Series:

Series Characteristics:

Log Transform: ☐ Yes ☐ No ☒ Maybe

Trend: ☐ Yes ☐ No ☒ Maybe

Seasonality: ☐ Yes ☐ No ☒ Maybe

For each of the options Log Transform, Trend, and Seasonality, the value “Yes” means that only models appropriate for series with that characteristic should be considered. The value “No” means that only models appropriate for series without that characteristic should be considered. The value “Maybe” means that models should be considered without regard for that characteristic.

Controls and Fields

Series

is the name and variable label of the current series.

Series Characteristics

Log Transform

specifies whether forecasting models with or without a logarithmic series transformation are appropriate for the series.

Trend

specifies whether forecasting models with or without a trend component are appropriate for the series.

Seasonality

specifies whether forecasting models with or without a seasonal component are appropriate for the series.

Automatic Series Diagnostics

performs the automatic series diagnostic process. The options Log Transform, Trend, and Seasonality are set according to the results of statistical tests.

OK

closes the Series Diagnostics window.

Cancel

closes the Series Diagnostics window without changing the series diagnostics options. Any options you specified are lost.

Reset

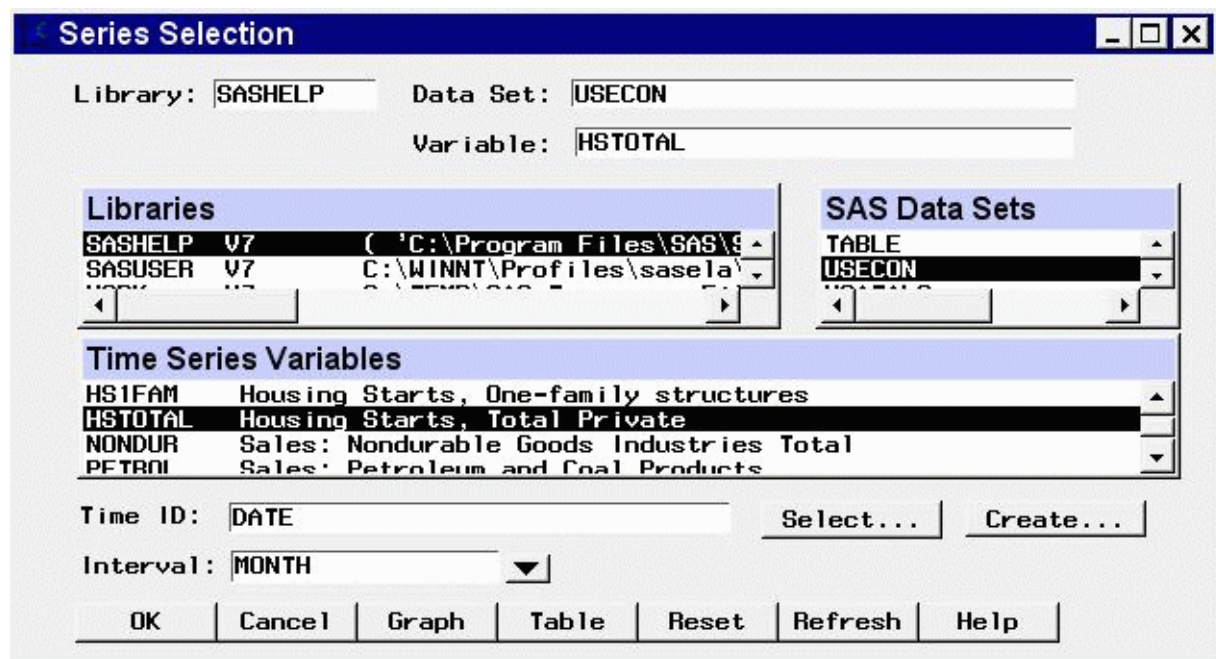

resets all options to their initial values upon entry to the Series Diagnostics window.

Clear

resets all options to their default values.

Series Selection Window

Use this resizable window to select a time series variable by specifying a library, a SAS data set or view, and a variable. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set or view plots of the series from this window.

This window appears automatically when you select the View Series Graphically or Develop Models buttons in the Time Series Forecasting window and no series has been selected, and when you open the Time Series Viewer as a standalone tool. It is also invoked by using the Browse button in the Develop Models window.

The system requires that series names be unique for each frequency (interval) within the forecasting project. If you select a series from the current input data set that already exists in the project with the same interval but a different input data set name, the system warns you and gives you the option to cancel the selection, to refit all models associated with the series by using the data from the current input data set, to delete the models for the series, or to inherit the existing models.

Controls and Fields

Library

is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field and press Return. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname.

Data Set

is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted, and the Time Series Variables list will be populated with the numeric variables in the data set.

Variable

is the name of a numeric variable contained in the selected data set. You can type the variable name in this field or you can select the variable with the mouse from the Time Series Variables list.

Time ID

is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or click the Select button.

Select button

opens the Time ID Variable Specification window to let you select an existing variable in the data set as the Time ID.

Create button

opens a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically filled in by the system, you can type in an interval name or select one from the pop-up list. For more information about intervals, see Chapter 4, “[Date Intervals, Formats, and Functions](#),” in this book.

OK

This button is present when you have selected “Develop Models” from the Time Series Forecasting window. It closes the Series Selection window and makes the selected series the current series.

Close

If you have selected the View Series Graphically icon from the Time Series Forecasting window, this button returns you to that window. If you have selected a series, it remains selected as the current series. If you are using the Time Series Viewer as a standalone application, this button closes the application.

Cancel

This button is present when you have selected “Develop Models” from the Time Series Forecasting window. It closes the Series Selection window without applying any selections made.

Reset

resets the fields to their initial values at entry to the window.

Table

opens a Viewtable window for browsing the selected data set. This can assist you in locating the variable containing data you are looking for.

Graph

opens the Time Series Viewer window to display the selected time series variable. You can switch to a different series in the Series Selection window without closing the Time Series Viewer window. Position the windows so they are both visible, or use the Next Viewer toolbar icon or F12 function key to switch between windows.

Refresh

updates all fields and lists on the window. If you assign a new libname without exiting the Series Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname. Also use the Refresh action to update the variables list if the input data set is changed.

Selection Lists

Libraries

displays a list of currently assigned libnames. You can select a libname by clicking it, which is equivalent to typing its name in the Library field. If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File menu, then select “Library” and “OK.” This opens the New Library dialog window. You also assign a libname by submitting a libname statement from the Editor window. Select the Refresh button to make the new libname available in the libraries list.

SAS Data Sets

displays a list of the SAS data sets (data files or data views) located under the selected libname. You can select one of these by clicking it, which is equivalent to typing its name in the Data Set field.

Time Series Variables

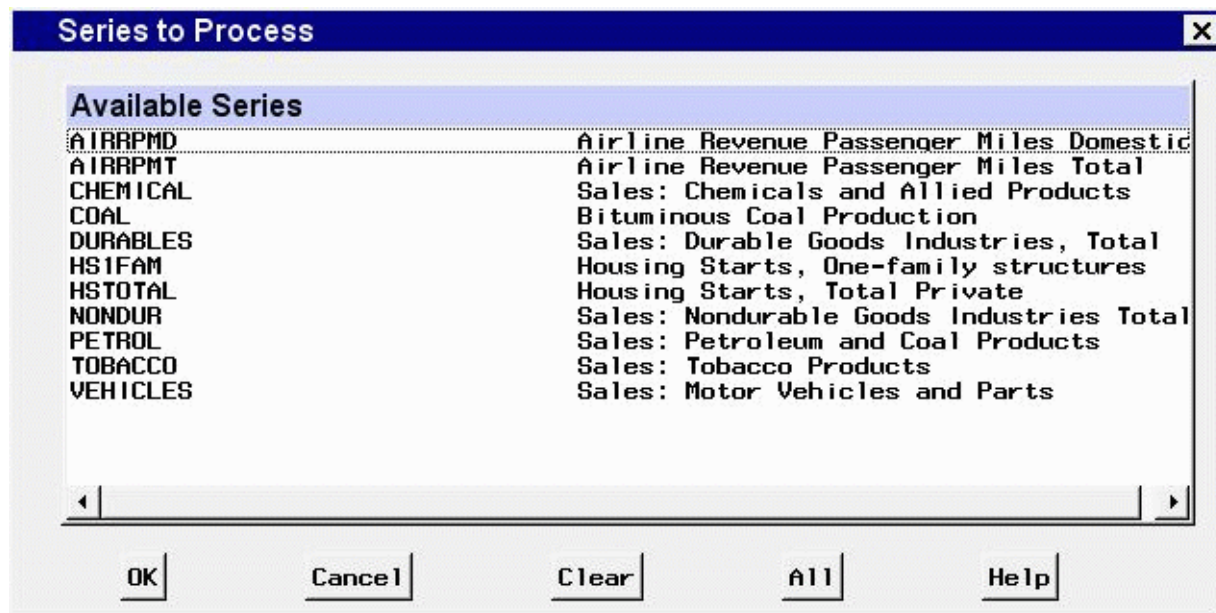

displays a list of numeric variables contained within the selected data set. You can select one of these by clicking it, which is equivalent to typing its name in the Variable field. You can double-click a series to select it and exit the window.

Series to Process Window

Use the Series to Process window to select series for model fitting or forecasting. Access it by using the Select button in the Automatic Model Fitting and Produce Forecasts windows. Hold down the shift key or drag with the left mouse button for multiple selections. Use the control key for noncontiguous multiple selections. Once you make selections and select OK, the number of selected series and their names are listed in the Series to Process field of the calling window (with ellipses if not all the names will fit).

When invoked from Automatic Model Fitting, the Series to Process window shows all the numeric variables in the input data set except the time ID variable. These are the series which are currently available for model fitting.

When invoked from Produce Forecasts, the Series to Process window shows all the series in the input data set for which models have been fit. These are the series which are currently available for forecasting.

Controls and Fields

OK

closes the window and applies the series selection(s) which have been made. At least one series must be selected.

Cancel

closes the window, ignoring series selections which have been made, if any.

Clear

deselects all series in the selection list.

All

selects all series in the selection list.

Series Viewer Transformations Window

Use the Series Viewer Transformations window to view plots of transformations of the current series in the Time Series Viewer window. It provides a larger set of transformations than those available from the viewer window's toolbar. It is invoked by using "Other Transformations" under the Tools menu of the Time Series Viewer window. The options that you specify in this window are applied to the series displayed in the Time Series Viewer window when you select "OK" or "Apply."

Use the Apply button if you want to make repeated transformations to a series without having to close and reopen the Series Viewer Transformations window each time.

Series Viewer Transformations

Series:

Transformation:

Simple Differencing:

Seasonal Differencing:

☐ Percent Change

Classical Decomposition:

☒ Additive Decomposition

☐ Multiplicative Decomposition

Component:

OK Cancel Apply Reset Clear Help

Controls and Fields

Series

is the variable name for the current time series.

Transformation

is the transformation applied to the time series displayed in the Time Series Viewer window. Select Log, Logistic, Square Root, Box-Cox, or none from the pop-up list.

Simple Differencing

is the order of differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 5 from the pop-up list.

Seasonal Differencing

is the order of seasonal differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 3 from the pop-up list.

Percent Change

is a check box that if selected displays the series in terms of percent change from the previous period.

Additive Decomposition

is a check box that produces a display of a selected series component derived by using additive decomposition.

Multiplicative Decomposition

is a check box that produces a display of a selected series component derived using multiplicative decomposition.

Component

selects a series component to display when either additive or multiplicative decomposition is turned on. You can display the seasonally adjusted component, the trend-cycle component, the seasonal component, or the irregular component—that is, the residual that remains after removal of the other components. The heading in the viewer window shows which component is currently displayed.

OK

applies the transformation options you selected to the series displayed in the Time Series Viewer window and closes the Series Viewer Transformations window.

Cancel

closes the Series Viewer Transformations window without changing the series displayed by the Time Series Viewer window.

Apply

applies the transformation options you selected to the series displayed in the Time Series Viewer window without closing the Series Viewer Transformations window.

Reset

resets the transformation options to their initial values upon entry to the Series Viewer Transformations window.

Clear

resets the transformation options to their default values (no transformations).

Smoothing Model Specification Window

Use the Smoothing Model Specification window to specify and fit exponential smoothing and Winters method models. Access it from the Develop Models window by using the Fit Model submenu of the Edit menu or from the pop-up menu when you click an empty area of the model table.

Smoothing Model Specification

Series:

Model:

Smoothing Methods:

- ☐ Simple Smoothing
- ☐ Double (Brown) Smoothing
- ☐ Seasonal Smoothing
- ☐ Linear (Holt) Smoothing
- ☐ Damped-Trend Smoothing
- ☐ Winters Method - Additive
- ☒ Winters Method - Multiplicative

Transformation: ▼

Smoothing Weights:

Level:

Bounds: ▼

OK Cancel Reset Clear Help

Controls and Fields

Series

is the name and variable label of the current series.

Model

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Smoothing Methods

Simple Smoothing

specifies simple (single) exponential smoothing.

Double (Brown) Smoothing

specifies double exponential smoothing by using Brown's one parameter model (single exponential smoothing applied twice).

Seasonal Smoothing

specifies seasonal exponential smoothing. (This is like Winters method with the trend term omitted.)

Linear (Holt) Smoothing

specifies exponential smoothing of both the series level and trend (Holt's two parameter model).

Damped-Trend Smoothing

specifies exponential smoothing of both the series level and trend with a trend damping weight.

Winters Method - Additive

specifies Winters method with additive seasonal factors.

Winters Method - Multiplicative

specifies Winters method with multiplicative seasonal factors.

Smoothing Weights

displays the values used for the smoothing weights. By default, the Smoothing Weights fields are set to “optimize,” which means that the system will compute the weight values that best fit the data. You can also type smoothing weight values in these fields.

Level

is the smoothing weight used for the level of the series.

Trend

is the smoothing weight used for the trend of the series.

Damping

is the smoothing weight used by the damped-trend method to damp the forecasted trend towards zero as the forecast horizon increases.

Season

is the smoothing weight used for the seasonal factors in Winters method and seasonal exponential smoothing.

Transformation

displays the series transformation specified for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the model predictions. Select *Log*, *Logistic*, *Square Root*, *Box-Cox*, or *None* from the pop-up list.

Bounds

displays the constraints imposed on the fitted smoothing weights. Select one of the following from the pop-up list:

Zero-One/Additive

sets the smoothing weight optimization region to the intersection of the region bounded by the intervals from zero (0.001) to one (0.999) and the additive invertible region. This is the default.

Zero-One Boundaries

sets the smoothing weight optimization region to the region bounded by the intervals from zero (0.001) to one (0.999).

Additive Invertible

sets the smoothing weight optimization region to the additive invertible region.

Unrestricted

sets the smoothing weight optimization region to be unbounded.

Custom

opens the **Smoothing Weights** window to enable you to customize the constraints for smoothing weights optimization.

OK

closes the Smoothing Model Specification window and fits the model you specified.

Cancel

closes the Smoothing Model Specification window without fitting the model. Any options you specified are lost.

Reset

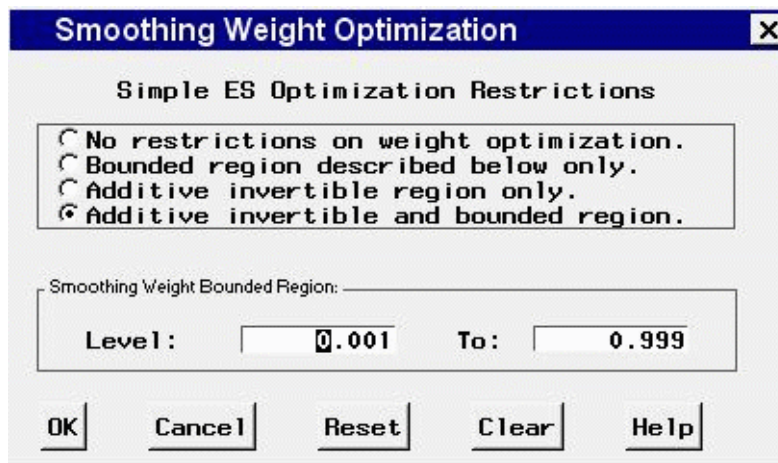

resets all options to their initial values upon entry to the window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear

resets all options to their default values.

Smoothing Weight Optimization Window

Use the Smoothing Weight Optimization window to specify constraints for the automatic fitting of smoothing weights for exponential smoothing and Winters method models. Access it from the Smoothing Models Specification window when you select “Custom” in the “Bounds” combo box.

Controls and Fields

No restrictions

when selected, specifies unrestricted smoothing weights.

Bounded region

when selected, restricts the fitted smoothing weights to be within the bounds that you specify with the “Smoothing Weight Bounded Region” options.

Additive invertible region

when selected, restricts the fitted smoothing weights to be within the additive invertible region of the parameter space of the ARIMA model equivalent to the smoothing model. (See the section “[Smoothing Models](#)” on page 3298 for details.)

Additive invertible and bounded region

when selected, restricts the fitted smoothing weights to be both within the additive invertible region and within bounds that you specify.

Smoothing Weight Bounded Region

is a group of numeric entry fields that enable you to specify lower and upper limits on the fitted value of each smoothing weight. The fields that appear in this part of the window depend on the kind of smoothing model that you specified.

OK

closes the window and sets the options that you specified.

Cancel

closes the window without changing any options. Any values you specified are lost.

Reset

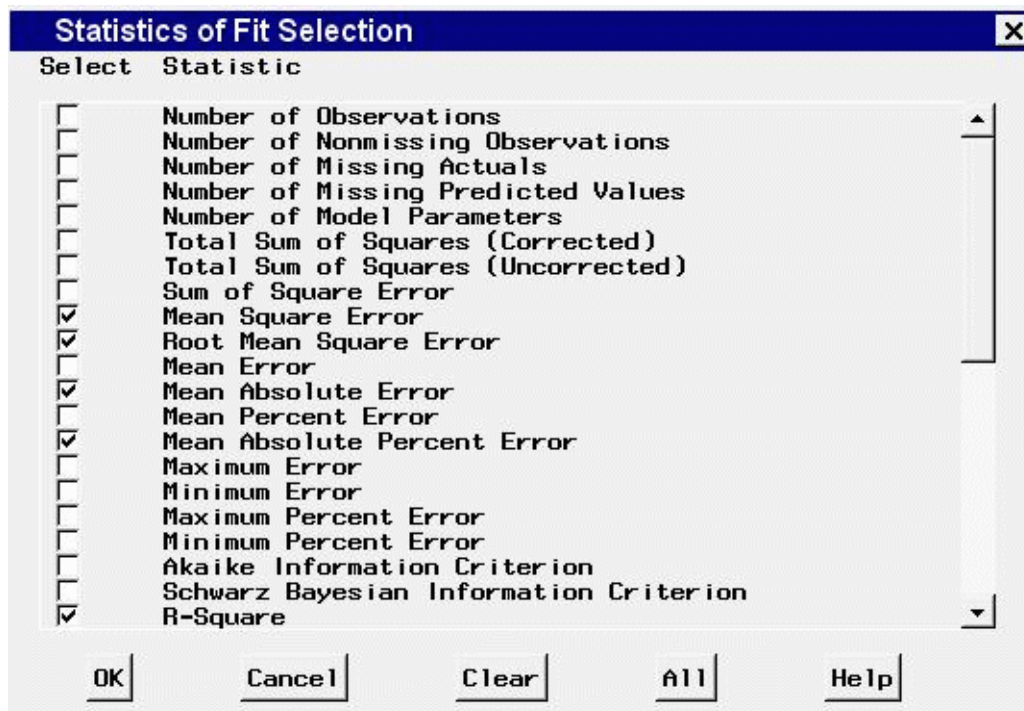

resets all options to their initial values upon entry to the window.

Clear

resets all options to their default values.

Statistics of Fit Selection Window

Use the Statistics of Fit Selection window to specify which of the available goodness-of-fit statistics are reported for models you fit and are available for selection as the model selection criterion used by the automatic selection process. This window is available under the Options menu in the Develop Models, Automatic Model Fitting, Produce Forecasts, and Model List windows, and from the Statistics button of the Model Fit Comparison window and Automatic Model Fitting results windows.

Controls and Fields

Select Statistics Table

list the available statistics. Select a row of the table to select or deselect the statistic shown in that row.

OK

closes the window and applies the selections made.

Cancel

closes the window without applying any selections.

Clear

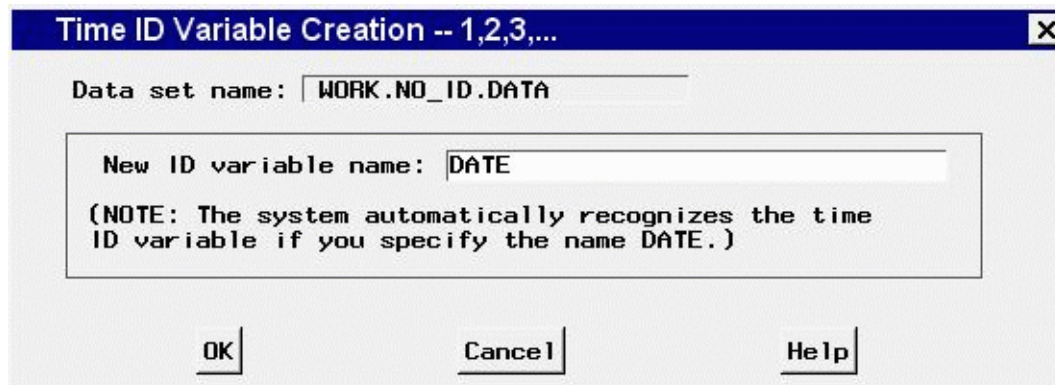

deselects all statistics.

All

selects all statistics.

Time ID Creation – 1,2,3 Window

Use the Time ID Creation – 1,2,3 window to add a time ID variable to an input data set with observation numbers as the ID values. The interval for the series will be 1. Use this approach if the data frequency does not match any of the system's date or date-time intervals, or if other methods of assigning a time ID do not work. To access this window, select "Create from observation numbers" from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 4, "Date Intervals, Formats, and Functions," in this book.

Controls and Fields

Data set name

is the name of the input data set.

New ID variable name

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK

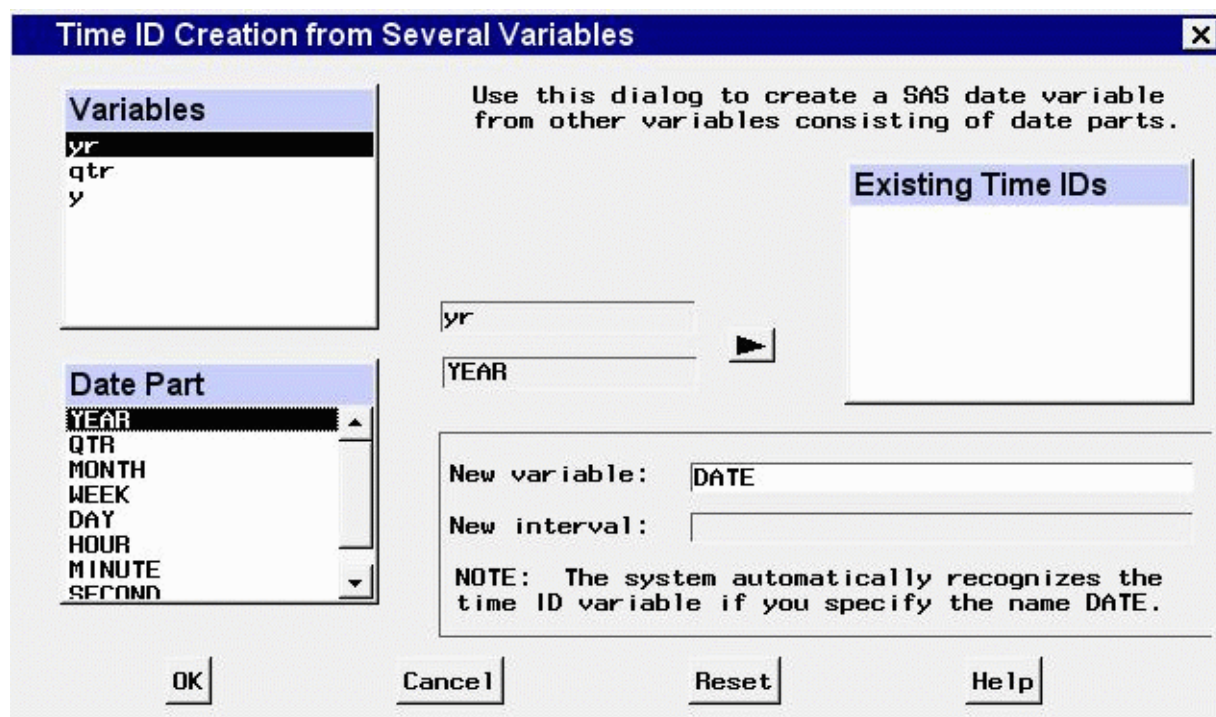

closes the window and proceeds to the next step in the time ID creation process.

Cancel

closes the window without creating a Time ID variable. Any options you specified are lost.

Time ID Creation from Several Variables Window

Use the Time ID Creation from Several Variables window to add a SAS date valued time ID variable to an input data set when the input data set already contains several dating variables, such as day, month, and year. To access this window, select “Create from existing variables” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 46, “Creating Time ID Variables.”

Controls and Fields

Variables

is a list of variables in the input data set. Select existing ID variables from this list.

Date Part

is a list of date parts that you can specify for the selected ID variable. For each ID variable that you select from the Variables list, select the Date Part value that describes what the values of the ID variable represent.

arrow button

moves the selected existing ID variable and date part specification to the “Existing Time IDs” list. Once you have done this, you can select another ID variable from the Variables list.

New variable

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

New interval

is the time interval between observations in the input data set implied by the date part ID variables you have selected.

OK

closes the window and proceeds to the next step in the time ID creation process.

Cancel

closes the window without creating a time ID. Any options you specified are lost.

Reset

resets the options to their initial values upon entry to the window.

Time ID Creation from Starting Date Window

Use the Time ID Creation from Starting Date window to add a SAS date valued time ID variable to an input data set. This is a convenient way to add a time ID of any interval as long as you know the starting date of the series. To access this window, select “Create from starting date and frequency” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 46, “[Creating Time ID Variables](#).”

Time ID Creation from Starting Date

Data set name:

Starting Date:

Interval:

New ID variable name:

(NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.)

Controls and Fields

Data set name

is the name of the input data set.

Starting Date

is the starting date for the time series in the data set. Enter a date value in this field, using a form recognizable by a SAS date informat, for example, 1998:1, feb1997, or 03mar1998.

Interval

is the time interval between observations in the data set. Select an interval from the pop-up list.

New ID variable name

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK

closes the window and proceeds to the next step in the time ID creation process.

Cancel

closes the window without changing the input data set. Any options you specified are lost.

Time ID Creation Using Informat Window

Use the Time ID Creation using Informat window to add a SAS date valued time ID variable to an input data set. Use this window if your data set contains a date variable that is stored as a character string. Using the appropriate SAS date informat, the date string is read in and used to create a date or date-time variable. To access this window, select “Create from existing variable/informat” from the Create pop-up list in any window where you can select a Time ID variable.

Time Id Creation using Informat [X]

Existing Variable and Informat:

Variable Name: **Select...**

Informat: ▼

First obs:

Date Value:

New ID variable name:

NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.

OK **Cancel** **Reset** **Help**

Controls and Fields

Variable Name

is the name of an existing ID variable in the input data set. Click the Select button to select a variable.

Select button

opens a list of variables in the input data set for you to select from.

Informat

is a SAS date or datetime informat for reading date or datetime value from the values of the specified existing ID variable. You can type in an informat or select one from the pop-up list.

First Obs

is the value of the variable you selected from the first observation in the data set, displayed here for convenience.

Date Value

is the SAS date or datetime value read from the first observation value that uses the informat that you specified.

New ID variable name

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK

closes the window and proceeds to the next step in the time ID creation process.

Cancel

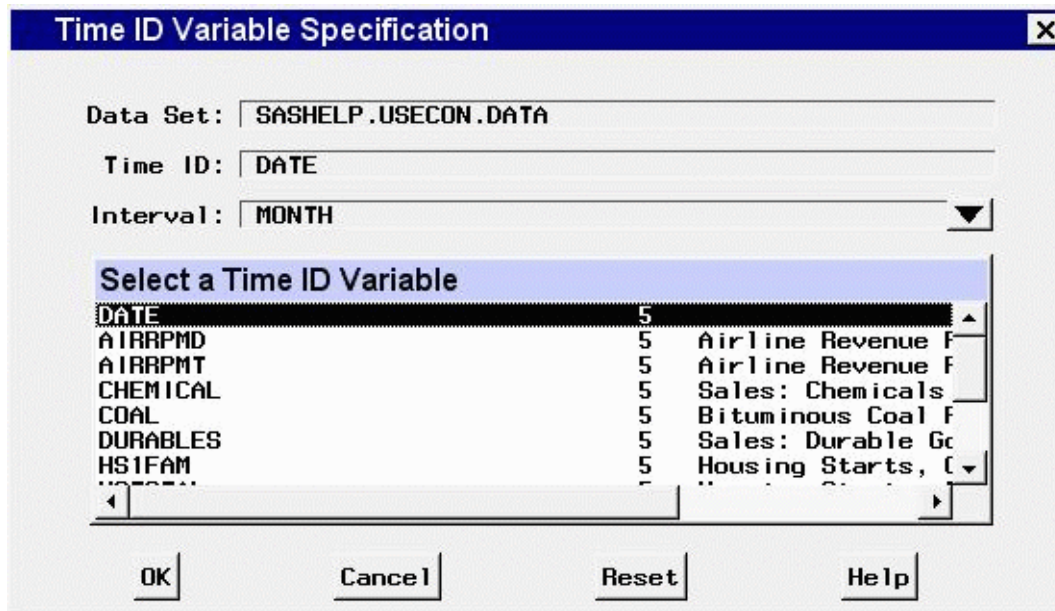

closes the window without changing the input data set. Any options you specified are lost.

Reset

resets the options to their initial values upon entry to the window.

Time ID Variable Specification Window

Use the Time ID Variable Specification window to specify a variable in the input data set that contains the SAS date or datetime value of each observation. You do not need to use this window if your time ID variable is named `date`, `time`, or `datetime`, since these are picked up automatically. Invoke the window from the Select button to the right of the Time ID field in the Data Set Selection, Automatic Model Fitting, Produce Forecasts, Series Selection, and Time Series Forecasting windows.

Controls and Fields

Data Set

is the name of the current input data set.

Time ID

is the name of the currently selected Time ID variable, if any.

Interval

is the time interval between observations (data frequency) in the input data set.

Select a Time ID Variable

is a selection list of variables in the input set. Select one variable to assign it as the Time ID variable.

OK

closes the window and retains the selection made, if it is a valid time ID.

Cancel

closes the window and ignores any selection made.

Reset

restores the time ID variable to the one assigned when the window was initially opened, if any.

Time Ranges Specification Window

Use the Time Ranges Specification window to control the period of fit and evaluation and the forecasting horizon. Invoke this window from the Options menu in the Develop Models, Manage Forecasting Project, and Model Viewer windows or the Set Ranges button in the Develop Models window.

Time Ranges Specification

Data Set:

Interval:

Series:

Time Ranges:

	From	To
Data Range:	<input type="text" value="JAN1975"/>	<input type="text" value="DEC1991"/>
Period of Fit:	<input type="text" value="JAN1975"/>	<input type="text" value="DEC1991"/>
Period of Evaluation:	<input type="text" value="JAN1975"/>	<input type="text" value="DEC1991"/>
Forecast Horizon:	<input type="text" value="12"/> <input type="text" value="Periods"/>	<input type="text" value="DEC1992"/>
Hold-out Sample:	<input type="text" value="0"/> <input type="text" value="Periods"/>	

OK Cancel Reset Clear Help

Controls and Fields

Data Set

is the name of the current input data set.

Interval

is the time interval (data frequency) for the input data set.

Series

is the variable name and label of the current time series.

Data Range

gives the date of the first and last nonmissing data values available for the current series in the input data set.

Period of Fit

gives the starting and ending dates of the period of fit. This is the time range used for estimating model parameters. By default, it is the same as the data range. You can type dates in these fields, or you can use the arrow buttons to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

Period of Evaluation

gives the starting and ending dates of the period of evaluation. This is the time range used for evaluating models in terms of statistics of fit. By default, it is the same as the data range. You can type dates in these fields, or you can use the control arrows to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

Forecast Horizon

is the forecasting horizon expressed as a number of forecast periods or number of years (or number of weeks for daily data). You can type a number or select one from the pop-up list. The ending date for the forecast period is automatically updated when you change the number of forecasts periods.

Forecast Horizon - Units

indicates whether the Forecast Horizon value represents periods or years (or weeks for daily data).

Forecast Horizon Date Value

is the date of the last forecast observation. You can type a date in this field, or you can use the arrow buttons to the left and right of the date field to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See *SAS Language Reference: Concepts* for information about SAS date informats.) The Forecast Horizon is automatically updated when you change the ending date for the forecast period.

Hold-out Sample

specifies that a number of observations or years (or weeks) of data at the end of the data range are used for the period of evaluation with the remainder of data used as the period of fit. You can type a number in this field or select one from the pop-up list. When the hold-out sample value is changed, the Period of Fit and Period of Evaluation ranges are changed to reflect the hold-out sample specification.

Hold-out Sample - Units

indicates whether the hold-out sample field represents periods or years (or weeks for daily data).

OK

closes the window and stores the specified changes.

Cancel

closes the window without saving changes. Any options you specified are lost.

Reset

resets the options to their initial values upon entry to the window.

Clear

resets all options to their default values.

Time Series Forecasting Window

The Time Series Forecasting window is the main application window that appears when you invoke the Time Series Forecasting System. It enables you to specify a project file and an input data set and provides access to the other windows described in this chapter.

Time Series Forecasting

Project:

Description:

Data Set:

Time ID:

Interval:

Controls and Fields

Project

is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project by typing a SAS catalog entry name in this field or by selecting the Browse button to right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one-level name, the catalog name is assumed to be `fmsproj` and the library is assumed to be `sasuser`. For example, `samproj` is equivalent to `sasuser.fmsproj.samproj`.

Project Browse button

opens the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored projects.

Description

is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field.

Data Set

is the name of the current input data set. To specify the input data set, you can type the data set name in this field or use the Browse button to the right of the field.

Data set Browse button

opens the Data Set Selection window to enable you to select the input data set.

Time ID

is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or use the Select button. If the time ID variable is named `date`, `time`, or `datetime`, it is automatically picked up by the system.

Select button

opens the Time ID Variable Specification window.

Create button

opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in, you can type an interval name or select one from the pop-up list. For more information about intervals, see the section “[Time Series Data Sets, ID Variables, and Time Intervals](#)” on page 3030.

View Series Graphically icon

opens the Time Series Viewer window to display plots of series in the current input data set.

View Data as a Table

opens a Viewtable window for browsing the selected input data set.

Develop Models

opens the Develop Models window to enable you to fit forecasting models to individual time series and choose the best models to use to produce the final forecasts of each series.

Fit Models Automatically

opens the Automatic Model Fitting window for applying the automatic model selection process to all series or to selected series in an input data set.

Produce Forecast

opens the Produce Forecasts window for producing forecasts for the series in the current input data set for which you have fit forecasting models.

Manage Projects

opens the Manage Forecasting Project window for viewing or editing information stored in projects.

Exit

closes the Time Series Forecasting system.

Help

accesses the help system.

Time Series Simulation Window

Use the Time Series Simulation window to create a data set of simulated series generated by ARIMA processes. Access this window from the Tools menu in the Develop Models and Manage Forecasting Project windows.

Time Series Simulation

Output Data Set:

Interval: N Observations:

ID Name: Starting Date:

Seed: Ending Date:

Series to Generate

Controls and Fields

Output Data Set

is the name of the data set to be created. Type in a one-level or two-level SAS data set name.

Interval

is the time interval between observations (data frequency) in the simulated data set. Type in an interval name or select one from the pop-up list.

Seed

is the seed for the random number generator used to produce the simulated time series.

N Observations

is the number of time periods to simulate.

Starting Date

is the starting date for the simulated observations. Type in a date in a form recognizable by a SAS data informat, for example, 1998:1, feb1997, or 03mar1998.

Ending Date

is the ending date for the simulated observations. Type in a date in a form recognizable by a SAS data informat.

Series to Generate

is the list of variable names and ARIMA processes to simulate.

Add Series

opens the ARIMA Process Specification window to enable you to add entries to the Series to Generate list.

Delete Series

deletes selected (highlighted) entries from the Series to Generate list.

OK

closes the Time Series Simulation window and performs the specified simulations and creates the specified data set.

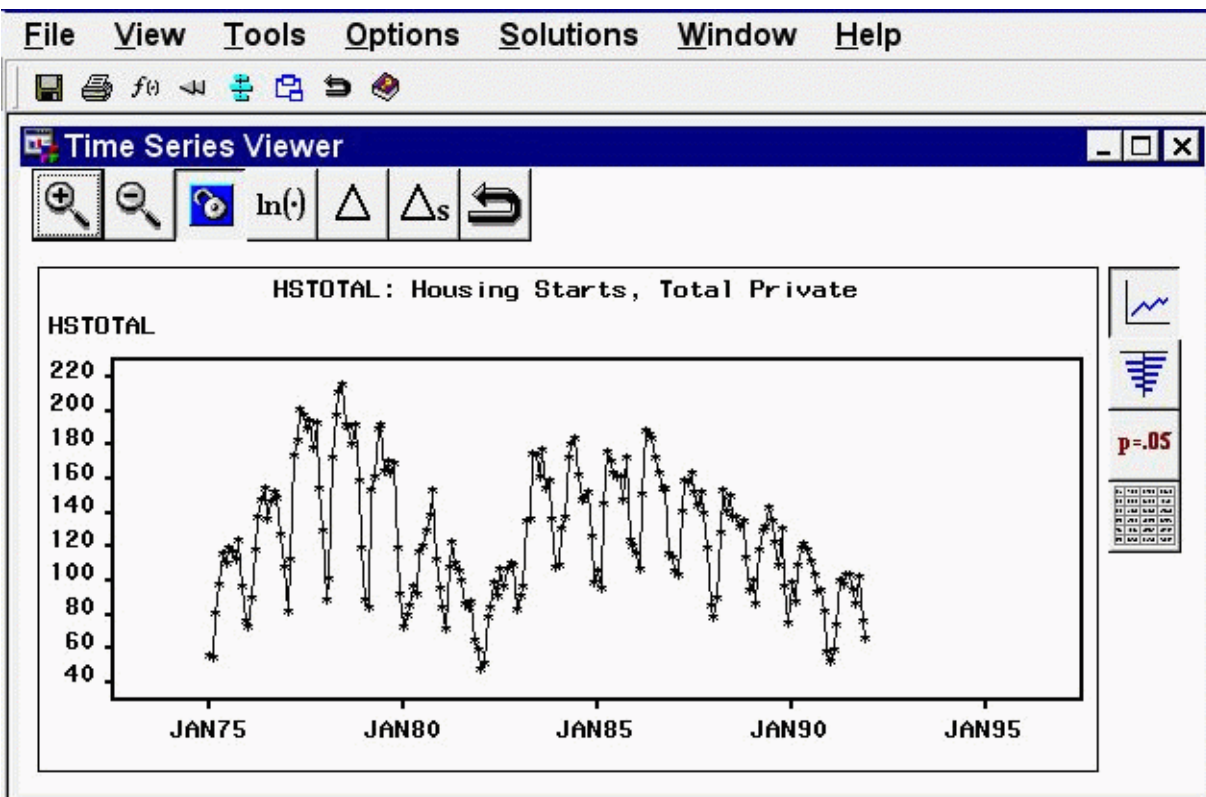

Cancel

closes the window without creating a simulated data set. Any options you specified are lost.

Time Series Viewer Window

Use the Time Series Viewer window to explore time series data using plots, transformations, statistical tests, and tables. It is available as a standalone application and as part of the Time Series Forecasting System. To use it as a standalone application, select it from the Analysis submenu of the Solutions menu, or use the `tsview` command (see Chapter 50, “[Command Reference](#),” in this book). To use it within the Time Series Forecasting System, select the View Series Graphically icon in the Time Series Forecasting, Develop Models, or Model List window, or select “Series” from the View menu of the Develop Models, Manage Project, or Model List window.

The various plots and tables available are referred to as *views*. The section “[View Selection Icons](#)” on page 3247 explains how to change the view.

The state of the Time Series Viewer window is controlled by the current series, the current series transformation specification, and the currently selected view. You can resize this window, and you can use other windows without closing the Time Series Viewer window. You can explore a number of series conveniently

by keeping the Series Selection window open. Each time you make a selection, the viewer window is updated to show the selected series. Keep both windows visible, or switch between them by using the Next Viewer toolbar icon or the F12 function key.

You can open multiple Time Series Viewer windows. This enables you to “freeze” a plot so you can come back to it later, or compare two plots side by side on your screen. To do this, unlink the viewer by using the Link/Unlink icon on the window’s toolbar or the corresponding item in the Tools menu. While the viewer window remains unlinked, it is not updated when other selections are made in the Series Selection window. Instead, when you select a series and click the Graph button, a new Time Series Viewer window is invoked. You can continue this process to open as many viewer windows as you want. The Next Viewer icon and corresponding F12 function key are useful for navigating between windows when they are not simultaneously visible on your screen.

A wide range of series transformations is available. Basic transformations are available from the window’s horizontal toolbar, and others are available by selecting “Other Transformations” from the Tools menu.

Horizontal Tool Bar

The Time Series Viewer window contains a horizontal toolbar with the following icons:

Zoom in

changes the mouse cursor into cross hairs that you can use with the left mouse button to drag out a region of the time series plot to zoom in on. In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom In reduces the number of lags displayed.

Zoom out

reverses the previous Zoom In action and expands the time range of the plot to show more of the series. In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom Out increases the number of lags displayed.

Link/Unlink viewer

disconnects or connects the Time Series Viewer window to the window in which the series was selected. When the Viewer is linked, it always shows the current series. If you select another series, linked Viewers are updated. Unlinking a Viewer freezes its current state, and changing the current series has no effect on the Viewer’s display. The View Series action creates a new Series Viewer window if there is no linked Viewer. By using the unlink feature, you can open several Time Series Viewer windows and display several different series simultaneously.

Log Transform

applies a log transform to the current view. This can be combined with other transformations; the current transformations are shown in the title.

Difference

applies a simple difference to the current view. This can be combined with other transformations; the current transformations are shown in the title.

Seasonal Difference

applies a seasonal difference to the current view. For example, if the data are monthly, the seasonal cycle is one year. Each value has subtracted from it the value from one year previous. This can be combined with other transformations; the current transformations are shown in the title.

Close

closes the Time Series Viewer window and returns to the window from which it was invoked.

Vertical Toolbar View Selection Icons

At the right-hand side of the Time Series Viewer window is a vertical toolbar used to select the kind of plot or table that the Viewer displays.

Series

displays a plot of series values over time.

Autocorrelations

displays plots of the sample autocorrelations, partial autocorrelation, and inverse autocorrelation functions for the series, with lines overlaid at plus and minus two standard errors.

White Noise and Stationarity Tests

displays horizontal bar charts that represent results of white noise and stationarity tests. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click any of the bars to display an interpretation.

The second bar chart shows tests of stationarity, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click any of the bars to display an interpretation.

Data Table

displays a data table containing the values in the input data set.

Menu Bar

File

Save Graph

saves the current plot as a SAS/GRAPH grseg catalog entry in a default or most recently specified catalog. This item is unavailable in the Data Table view.

Save Graph as

saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the graph embedded as a gif image. This item is unavailable in the Data Table view.

Save Data

saves the data displayed in the viewer window to an output SAS data set. This item is unavailable in the Series view.

Save Data as

saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the data displayed as a table.

Import Data

is available if you license SAS/Access software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data

is available if you license SAS/Access software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Graph

prints the plot displayed in the viewer window. This item is unavailable in the Data Table view.

Print Data

prints the data displayed in the viewer window. This item is unavailable in the Series view.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Print Preview

opens a preview window to show how your plots will look when printed.

Close

closes the Time Series Viewer window and returns to the window from which it was invoked.

View**Series**

displays a plot of series values over time. This is the same as the Series icon in the vertical toolbar.

Autocorrelations

displays plots of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the series. This is the same as the Autocorrelations icon in the vertical toolbar.

White Noise and Stationarity Tests

displays horizontal bar charts representing results of white noise and stationarity tests. This is the same as the White Noise and Stationarity Tests icon in the vertical toolbar.

Data Table

displays a data table containing the values in the input data set. This is the same as the Data Table icon in the vertical toolbar.

Zoom In

zooms the display. This is the same as the Zoom In icon in the window's horizontal toolbar.

Zoom Out

undoes the last zoom in action. This is the same as the Zoom Out icon in the window's horizontal toolbar.

Zoom Way Out

reverses all previous Zoom In actions and expands the time range of the plot to show all of the series, or shows the maximum number of lags in the Autocorrelations View or the White Noise and Stationarity Tests view.

Tools**Log Transform**

applies a log transformation. This is the same as the Log Transform icon in the window's horizontal toolbar.

Difference

applies simple differencing. This is the same as the Difference icon in the window's horizontal toolbar.

Seasonal Difference

applies seasonal differencing. This is the same as the Seasonal Difference icon in the window's horizontal toolbar.

Other Transformations

opens the Series Viewer Transformations window to enable you to apply a wide range of transformations.

Diagnose Series

opens the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

Define Interventions

opens the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

Link Viewer

connects or disconnects the Time Series Viewer window to the window from which series are selected. This is the same as the Link item in the window's horizontal toolbar.

Options**Number of Lags**

opens a window to let you specify the number of lags shown in the Autocorrelations view and the White Noise and Stationarity Tests view. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

Correlation Probabilities

controls whether the bar charts in the Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

Mouse Button Actions

You can examine the data value and date of individual points in the Series view by clicking them. The date and value are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

You can examine the values of the bars and confidence limits at different lags in the Autocorrelations view by clicking individual bars in the vertical bar charts.

You can display an interpretation of the tests in the White Noise and Stationarity Tests view by clicking the bars.

When you select the Zoom In action, you can use the mouse to define a region of the graph to take a closer look at. Position the mouse cursor at one corner of the region, press the left mouse button, and move the mouse cursor to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

This chapter provides computational details on several aspects of the Time Series Forecasting System.

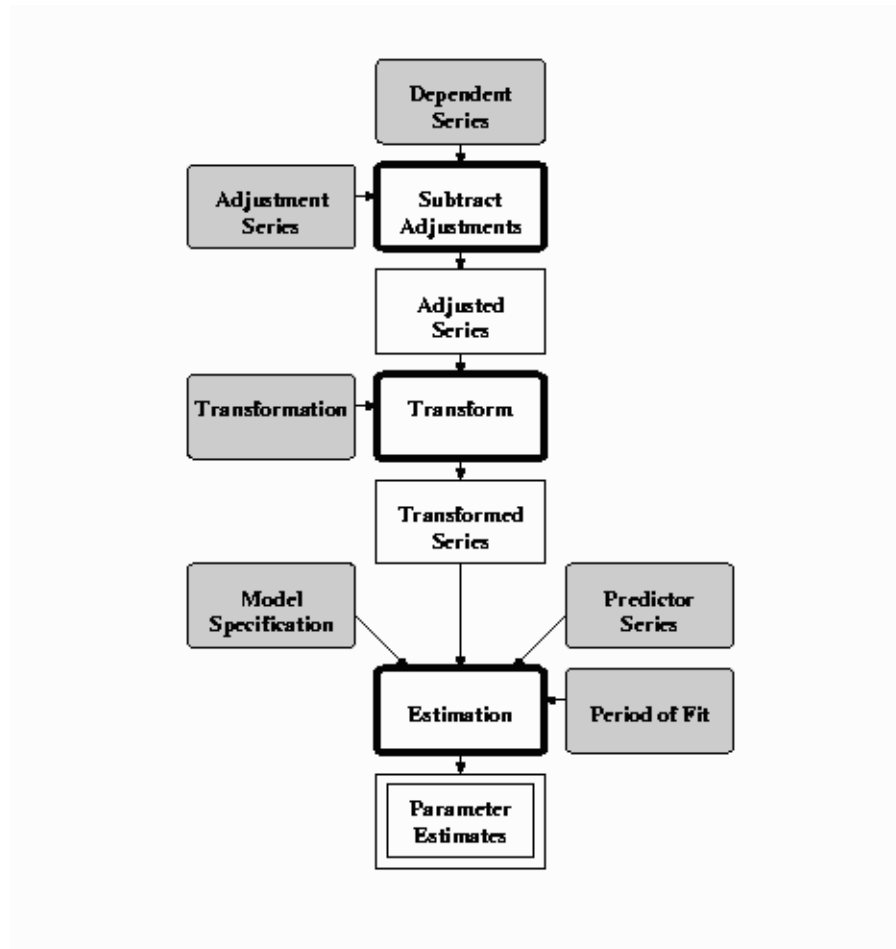

Forecasting Process Summary

This section summarizes the forecasting process.

Parameter Estimation

The parameter estimation process for ARIMA and smoothing models is described graphically in [Figure 52.1](#).

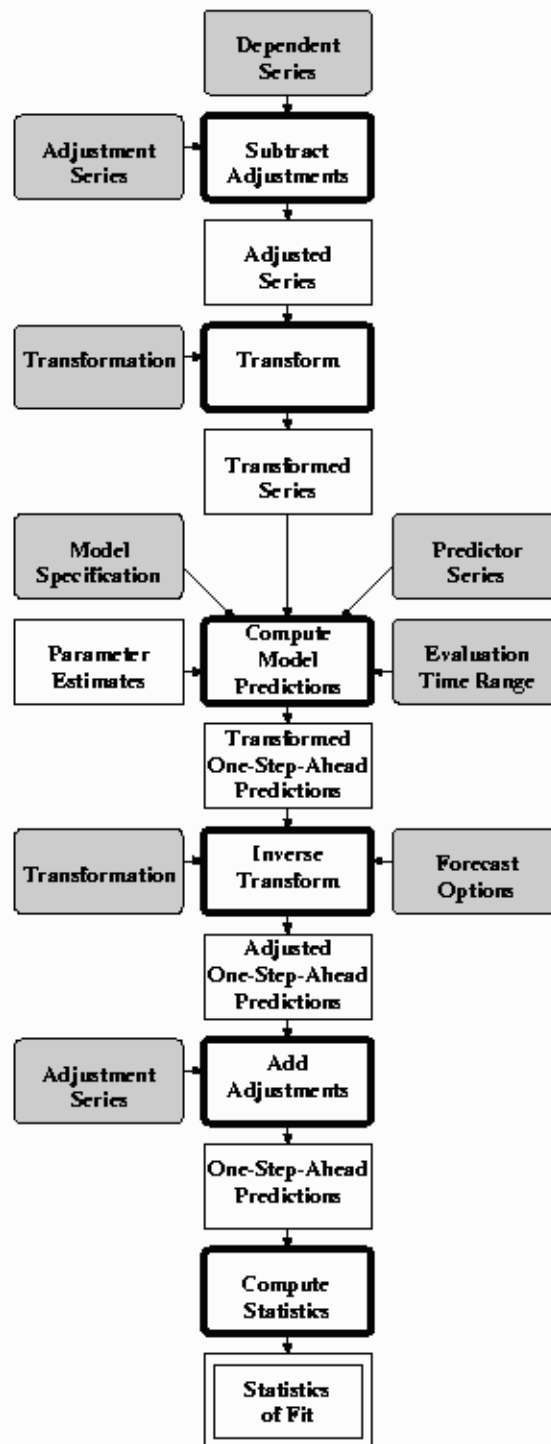

Figure 52.1 Model Fitting Flow Diagram

The specification of smoothing and ARIMA models is described in Chapter 47, “[Specifying Forecasting Models](#).” Computational details for these kinds of models are provided in the following sections “[Smoothing Models](#)” on page 3298 and “[ARIMA Models](#)” on page 3309. The results of the parameter estimation process are displayed in the Parameter Estimates table of the Model Viewer windows along with the estimate of the model variance and the final smoothing state.

Model Evaluation

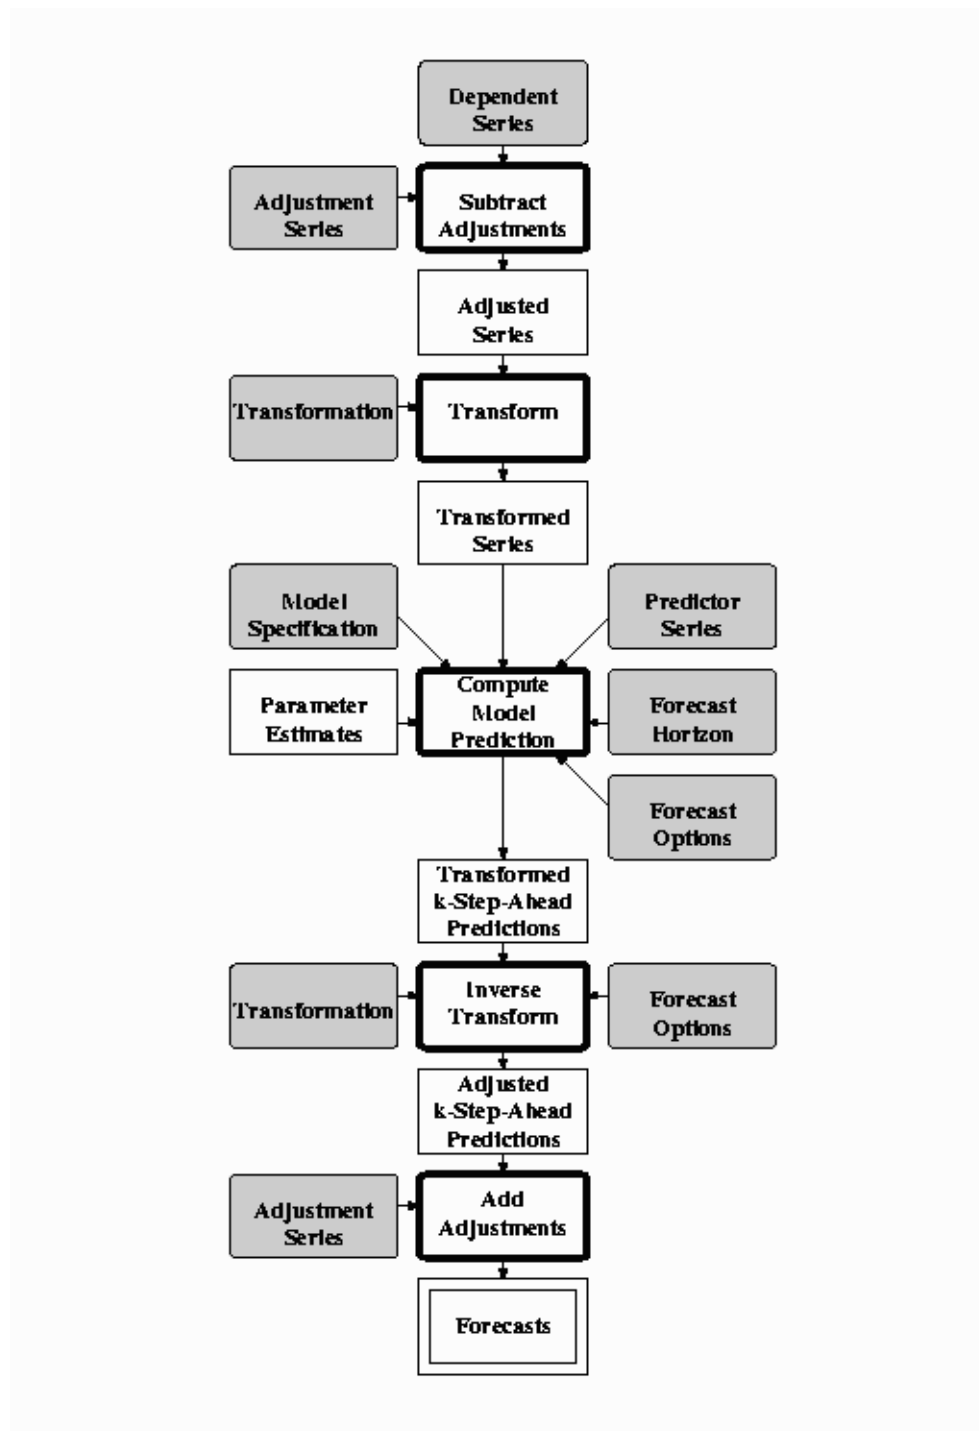

The model evaluation process is described graphically in [Figure 52.2](#).

Figure 52.2 Model Evaluation Flow Diagram

Model evaluation is based on the one-step-ahead prediction errors for observations within the period of evaluation. The one-step-ahead predictions are generated from the model specification and parameter estimates. The predictions are inverse transformed (median or mean) and adjustments are removed. The prediction errors (the difference of the dependent series and the predictions) are used to compute the statistics of fit, which are described in the section “[Series Diagnostic Tests](#)” on page 3316. The results generated by the evaluation process are displayed in the Statistics of Fit table of the Model Viewer window.

Forecasting

The forecasting generation process is described graphically in [Figure 52.3](#).

Figure 52.3 Forecasting Flow Diagram

The forecasting process is similar to the model evaluation process described in the preceding section, except that k -step-ahead predictions are made from the end of the data through the specified forecast horizon, and prediction standard errors and confidence limits are calculated. The forecasts and confidence limits are displayed in the Forecast plot or table of the Model Viewer window.

Forecast Combination Models

This section discusses the computation of predicted values and confidence limits for forecast combination models. See Chapter 47, “[Specifying Forecasting Models](#),” for information about how to specify forecast combination models and their combining weights.

Given the response time series $\{y_t : 1 \leq t \leq n\}$ with previously generated forecasts for the m component models, a combined forecast is created from the component forecasts as follows:

$$\begin{aligned} \text{Predictions:} \quad & \hat{y}_t = \sum_{i=1}^m w_i \hat{y}_{i,t} \\ \text{Prediction Errors:} \quad & \hat{e}_t = y_t - \hat{y}_t \end{aligned}$$

where $\hat{y}_{i,t}$ are the forecasts of the component models and w_i are the combining weights.

The estimate of the root mean square prediction error and forecast confidence limits for the combined forecast are computed by assuming independence of the prediction errors of the component forecasts, as follows:

$$\begin{aligned} \text{Standard Errors:} \quad & \hat{\sigma}_t = \sqrt{\sum_{i=1}^m w_i^2 \hat{\sigma}_{i,t}^2} \\ \text{Confidence Limits:} \quad & \pm \hat{\sigma}_t Z_{\alpha/2} \end{aligned}$$

where $\hat{\sigma}_{i,t}$ are the estimated root mean square prediction errors for the component models, α is the confidence limit width, $1 - \alpha$ is the confidence level, and $Z_{\alpha/2}$ is the $\frac{\alpha}{2}$ quantile of the standard normal distribution.

Since, in practice, there might be positive correlation between the prediction errors of the component forecasts, these confidence limits may be too narrow.

External or User-Supplied Forecasts

This section discusses the computation of predicted values and confidence limits for external forecast models.

Given a response time series y_t and external forecast series \hat{y}_t , the prediction errors are computed as $\hat{e}_t = y_t - \hat{y}_t$ for those t for which both y_t and \hat{y}_t are nonmissing. The mean squared error (MSE) is computed from the prediction errors.

The variance of the k -step-ahead prediction errors is set to k times the MSE. From these variances, the standard errors and confidence limits are computed in the usual way. If the supplied predictions contain so many missing values within the time range of the response series that the MSE estimate cannot be computed, the confidence limits, standard errors, and statistics of fit are set to missing.

Adjustments

Adjustment predictors are subtracted from the response time series prior to model parameter estimation, evaluation, and forecasting. After the predictions of the adjusted response time series are obtained from the forecasting model, the adjustments are added back to produce the forecasts.

If y_t is the response time series and $X_{i,t}$, $1 \leq i \leq m$ are m adjustment predictor series, then the adjusted response series w_t is

$$w_t = y_t - \sum_{i=1}^m X_{i,t}$$

Parameter estimation for the model is performed by using the adjusted response time series w_t . The forecasts \hat{w}_t of w_t are adjusted to obtain the forecasts \hat{y}_t of y_t .

$$\hat{y}_t = \hat{w}_t + \sum_{i=1}^m X_{i,t}$$

Missing values in an adjustment series are ignored in these computations.

Series Transformations

For pure ARIMA models, transforming the response time series can aid in obtaining stationary noise series. For general ARIMA models with inputs, transforming the response time series or one or more of the input time series can provide a better model fit. Similarly, the fit of smoothing models can improve when the response series is transformed.

There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation,

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation,

$$w_t = \ln(cy_t/(1 - cy_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square Root is the square root transformation,

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation,

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

Parameter estimation is performed by using the transformed series. The transformed model predictions and confidence limits are then obtained from the transformed time series and these parameter estimates.

The transformed model predictions \hat{w}_t are used to obtain either the minimum mean absolute error (MMAE) or minimum mean squared error (MMSE) predictions \hat{y}_t , depending on the setting of the forecast options. The model is then evaluated based on the residuals of the original time series and these predictions. The transformed model confidence limits are inverse-transformed to obtain the forecast confidence limits.

Predictions for Transformed Models

Since the transformations described in the previous section are monotonic, applying the inverse-transformation to the transformed model predictions results in the *median* of the conditional probability density function at each point in time. This is the minimum mean absolute error (MMAE) prediction.

If $w_t = F(y_t)$ is the transform with inverse-transform $y_t = F^{-1}(w_t)$, then

$$\text{median}(\hat{y}_t) = F^{-1}(E[w_t]) = F^{-1}(\hat{w}_t)$$

The minimum mean squared error (MMSE) predictions are the *mean* of the conditional probability density function at each point in time. Assuming that the prediction errors are normally distributed with variance σ_t^2 , the MMSE predictions for each of the transformations are as follows:

Log is the conditional expectation of inverse-logarithmic transformation,

$$\hat{y}_t = E[e^{w_t}] = \exp(\hat{w}_t + \sigma_t^2/2)$$

Logistic is the conditional expectation of inverse-logistic transformation,

$$\hat{y}_t = E\left[\frac{1}{c(1 + \exp(-w_t))}\right]$$

where the scaling factor $c = (1 - e^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$.

Square Root is the conditional expectation of the inverse-square root transformation,

$$\hat{y}_t = E[w_t^2] = \hat{w}_t^2 + \sigma_t^2$$

Box Cox is the conditional expectation of the inverse Box-Cox transformation,

$$\hat{y}_t = \begin{cases} E[(\lambda w_t + 1)^{1/\lambda}], & \lambda \neq 0 \\ E[e^{w_t}] = \exp(\hat{w}_t + \frac{1}{2}\sigma_t^2), & \lambda = 0 \end{cases}$$

The expectations of the inverse logistic and Box-Cox ($\lambda \neq 0$) transformations do not generally have explicit solutions and are computed by using numerical integration.

Smoothing Models

This section details the computations performed for the exponential smoothing and Winters method forecasting models.

Smoothing Model Calculations

The descriptions and properties of various smoothing methods can be found in Gardner (1985); Chatfield (1978); Bowerman and O'Connell (1979). The following section summarizes the smoothing model computations.

Given a time series $\{Y_t : 1 \leq t \leq n\}$, the underlying model assumed by the smoothing models has the following (additive seasonal) form:

$$Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t$$

where

μ_t	represents the time-varying mean term.
β_t	represents the time-varying slope.
$s_p(t)$	represents the time-varying seasonal contribution for one of the p seasons.
ϵ_t	are disturbances.

For smoothing models without trend terms, $\beta_t = 0$; and for smoothing models without seasonal terms, $s_p(t) = 0$. Each smoothing model is described in the following sections.

At each time t , the smoothing models estimate the time-varying components described above with the *smoothing state*. After initialization, the smoothing state is updated for each observation using the *smoothing equations*. The smoothing state at the last nonmissing observation is used for predictions.

Smoothing State and Smoothing Equations

Depending on the smoothing model, the *smoothing state* at time t consists of the following:

- L_t is a smoothed level that estimates μ_t .
- T_t is a smoothed trend that estimates β_t .
- S_{t-j} , $j = 0, \dots, p - 1$, are seasonal factors that estimate $s_p(t)$.

The smoothing process starts with an initial estimate of the smoothing state, which is subsequently updated for each observation by using the *smoothing equations*.

The smoothing equations determine how the smoothing state changes as time progresses. Knowledge of the smoothing state at time $t - 1$ and that of the time series value at time t uniquely determine the smoothing state at time t . The *smoothing weights* determine the contribution of the previous smoothing state to the current smoothing state. The smoothing equations for each smoothing model are listed in the following sections.

Smoothing State Initialization

Given a time series $\{Y_t : 1 \leq t \leq n\}$, the smoothing process first computes the smoothing state for time $t = 1$. However, this computation requires an initial estimate of the smoothing state at time $t = 0$, even though no data exists at or before time $t = 0$.

An appropriate choice for the initial smoothing state is made by backcasting from time $t = n$ to $t = 1$ to obtain a prediction at $t = 0$. The initialization for the backcast is obtained by regression with constant and linear terms and seasonal dummies (additive or multiplicative) as appropriate for the smoothing model. For models with linear or seasonal terms, the estimates obtained by the regression are used for initial smoothed trend and seasonal factors; however, the initial smoothed level for backcasting is always set to the last observation, Y_n .

The smoothing state at time $t = 0$ obtained from the backcast is used to initialize the smoothing process from time $t = 1$ to $t = n$ (Chatfield and Yar 1988).

For models with seasonal terms, the smoothing state is normalized so that the seasonal factors S_{t-j} for $j = 0, \dots, p - 1$ sum to zero for models that assume additive seasonality and average to one for models (such as Winters method) that assume multiplicative seasonality.

Missing Values

When a missing value is encountered at time t , the smoothed values are updated using the *error-correction form* of the smoothing equations with the one-step-ahead prediction error, e_t , set to zero. The missing value is estimated using the one-step-ahead prediction at time $t - 1$, that is $\hat{Y}_{t-1}(1)$ (Aldrin and Damsleth 1989). The error-correction forms of each of the smoothing models are listed in the following sections.

Predictions and Prediction Errors

Predictions are made based on the last known smoothing state. Predictions made at time t for k steps ahead are denoted $\hat{Y}_t(k)$ and the associated prediction errors are denoted $e_t(k) = Y_{t+k} - \hat{Y}_t(k)$. The *prediction equation* for each smoothing model is listed in the following sections.

The *one-step-ahead predictions* refer to predictions made at time $t - 1$ for one time unit into the future—that is, $\hat{Y}_{t-1}(1)$. The *one-step-ahead prediction errors* are more simply denoted $e_t = e_{t-1}(1) = Y_t - \hat{Y}_{t-1}(1)$. The one-step-ahead prediction errors are also the model residuals, and the sum of squares of the one-step-ahead prediction errors is the objective function used in smoothing weight optimization.

The *variance of the prediction errors* are used to calculate the confidence limits (Sweet 1985; McKenzie 1986; Yar and Chatfield 1990; Chatfield and Yar 1991). The equations for the variance of the prediction errors for each smoothing model are listed in the following sections.

Note: $\text{var}(\epsilon_t)$ is estimated by the mean square of the one-step-ahead prediction errors.

Smoothing Weights

Depending on the smoothing model, the smoothing weights consist of the following:

α	is a level smoothing weight.
γ	is a trend smoothing weight.
δ	is a seasonal smoothing weight.
ϕ	is a trend damping weight.

Larger smoothing weights (less damping) permit the more recent data to have a greater influence on the predictions. Smaller smoothing weights (more damping) give less weight to recent data.

Specifying the Smoothing Weights

Typically the smoothing weights are chosen to be from zero to one. (This is intuitive because the weights associated with the past smoothing state and the value of current observation would normally sum to one.) However, each smoothing model (except Winters Method—Multiplicative Version) has an ARIMA equivalent. Weights chosen to be within the ARIMA additive-invertible region will guarantee stable predictions (Archibald 1990; Gardner 1985). The ARIMA equivalent and the additive-invertible region for each smoothing model are listed in the following sections.

Optimizing the Smoothing Weights

Smoothing weights are determined so as to minimize the sum of squared, one-step-ahead prediction errors. The optimization is initialized by choosing from a predetermined grid the initial smoothing weights that result in the smallest sum of squared, one-step-ahead prediction errors. The optimization process is highly dependent on this initialization. It is possible that the optimization process will fail due to the inability to obtain stable initial values for the smoothing weights (Greene 1993; Judge et al. 1980), and it is possible for the optimization to result in a local minima.

The optimization process can result in weights to be chosen outside both the zero-to-one range and the ARIMA additive-invertible region. By restricting weight optimization to additive-invertible region, you can obtain a local minimum with stable predictions. Likewise, weight optimization can be restricted to the zero-to-one range or other ranges. It is also possible to fix certain weights to a specific value and optimize the remaining weights.

Standard Errors

The standard errors associated with the smoothing weights are calculated from the Hessian matrix of the sum of squared, one-step-ahead prediction errors with respect to the smoothing weights used in the optimization process.

Weights Near Zero or One

Sometimes the optimization process results in weights near zero or one.

For simple or double (Brown) exponential smoothing, a level weight near zero implies that simple differencing of the time series might be appropriate.

For linear (Holt) exponential smoothing, a level weight near zero implies that the smoothed trend is constant and that an ARIMA model with deterministic trend might be a more appropriate model.

For damped-trend linear exponential smoothing, a damping weight near one implies that linear (Holt) exponential smoothing might be a more appropriate model.

For Winters method and seasonal exponential smoothing, a seasonal weight near one implies that a nonseasonal model might be more appropriate and a seasonal weight near zero implies that deterministic seasonal factors might be present.

Equations for the Smoothing Models

Simple Exponential Smoothing

The model equation for simple exponential smoothing is

$$Y_t = \mu_t + \epsilon_t$$

The smoothing equation is

$$L_t = \alpha Y_t + (1 - \alpha)L_{t-1}$$

The error-correction form of the smoothing equation is

$$L_t = L_{t-1} + \alpha e_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t$$

The ARIMA model equivalency to simple exponential smoothing is the ARIMA(0,1,1) model

$$(1 - B)Y_t = (1 - \theta B)\epsilon_t$$

$$\theta = 1 - \alpha$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \alpha \epsilon_{t-j}$$

For simple exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \alpha^2 \right] = \text{var}(\epsilon_t)(1 + (k-1)\alpha^2)$$

Double (Brown) Exponential Smoothing

The model equation for double exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha Y_t + (1 - \alpha) L_{t-1} \\ T_t &= \alpha (L_t - L_{t-1}) + (1 - \alpha) T_{t-1} \end{aligned}$$

This method can be equivalently described in terms of two successive applications of simple exponential smoothing:

$$\begin{aligned} S_t^{[1]} &= \alpha Y_t + (1 - \alpha) S_{t-1}^{[1]} \\ S_t^{[2]} &= \alpha S_t^{[1]} + (1 - \alpha) S_{t-1}^{[2]} \end{aligned}$$

where $S_t^{[1]}$ are the smoothed values of Y_t , and $S_t^{[2]}$ are the smoothed values of $S_t^{[1]}$. The prediction equation then takes the form:

$$\hat{Y}_t(k) = (2 + \alpha k / (1 - \alpha)) S_t^{[1]} - (1 + \alpha k / (1 - \alpha)) S_t^{[2]}$$

The error-correction forms of the smoothing equations are

$$\begin{aligned} L_t &= L_{t-1} + T_{t-1} + \alpha e_t \\ T_t &= T_{t-1} + \alpha^2 e_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + ((k - 1) + 1/\alpha) T_t$$

The ARIMA model equivalency to double exponential smoothing is the ARIMA(0,2,2) model,

$$\begin{aligned} (1 - B)^2 Y_t &= (1 - \theta B)^2 \epsilon_t \\ \theta &= 1 - \alpha \end{aligned}$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (2\alpha + (j - 1)\alpha^2) \epsilon_{t-j}$$

For double exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (2\alpha + (j - 1)\alpha^2)^2 \right]$$

Linear (Holt) Exponential Smoothing

The model equation for linear exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha Y_t + (1 - \alpha)(L_{t-1} + T_{t-1}) \\ T_t &= \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1} \end{aligned}$$

The error-correction form of the smoothing equations is

$$\begin{aligned} L_t &= L_{t-1} + T_{t-1} + \alpha e_t \\ T_t &= T_{t-1} + \alpha \gamma e_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + kT_t$$

The ARIMA model equivalency to linear exponential smoothing is the ARIMA(0,2,2) model,

$$\begin{aligned} (1 - B)^2 Y_t &= (1 - \theta_1 B - \theta_2 B^2) \epsilon_t \\ \theta_1 &= 2 - \alpha - \alpha \gamma \\ \theta_2 &= \alpha - 1 \end{aligned}$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + j\alpha\gamma) \epsilon_{t-j}$$

For linear exponential smoothing, the additive-invertible region is

$$\begin{aligned} \{0 < \alpha < 2\} \\ \{0 < \gamma < 4/\alpha - 2\} \end{aligned}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (\alpha + j\alpha\gamma)^2 \right]$$

Damped-Trend Linear Exponential Smoothing

The model equation for damped-trend linear exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha Y_t + (1 - \alpha)(L_{t-1} + \phi T_{t-1}) \\ T_t &= \gamma(L_t - L_{t-1}) + (1 - \gamma)\phi T_{t-1} \end{aligned}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + \phi T_{t-1} + \alpha e_t \quad T_t = \phi T_{t-1} + \alpha \gamma e_t$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + \sum_{i=1}^k \phi^i T_t$$

The ARIMA model equivalency to damped-trend linear exponential smoothing is the ARIMA(1,1,2) model,

$$\begin{aligned} (1 - \phi B)(1 - B)Y_t &= (1 - \theta_1 B - \theta_2 B^2)\epsilon_t \\ \theta_1 &= 1 + \phi - \alpha - \alpha \gamma \phi \\ \theta_2 &= (\alpha - 1)\phi \end{aligned}$$

The moving-average form of the equation (assuming $|\phi| < 1$) is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + \alpha \gamma \phi (\phi^j - 1)/(\phi - 1)) \epsilon_{t-j}$$

For damped-trend linear exponential smoothing, the additive-invertible region is

$$\begin{aligned} \{0 < \alpha < 2\} \\ \{0 < \phi \gamma < 4/\alpha - 2\} \end{aligned}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (\alpha + \alpha \gamma \phi (\phi^j - 1)/(\phi - 1))^2 \right]$$

Seasonal Exponential Smoothing

The model equation for seasonal exponential smoothing is

$$Y_t = \mu_t + s_p(t) + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha(Y_t - S_{t-p}) + (1 - \alpha)L_{t-1} \\ S_t &= \delta(Y_t - L_t) + (1 - \delta)S_{t-p} \end{aligned}$$

The error-correction form of the smoothing equations is

$$\begin{aligned} L_t &= L_{t-1} + \alpha e_t \\ S_t &= S_{t-p} + \delta(1 - \alpha)e_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + S_{t-p+k}$$

The ARIMA model equivalency to seasonal exponential smoothing is the $\text{ARIMA}(0,1,p+1)(0,1,0)_p$ model,

$$\begin{aligned} (1 - B)(1 - B^p)Y_t &= (1 - \theta_1 B - \theta_2 B^p - \theta_3 B^{p+1})\epsilon_t \\ \theta_1 &= 1 - \alpha \\ \theta_2 &= 1 - \delta(1 - \alpha) \\ \theta_3 &= (1 - \alpha)(\delta - 1) \end{aligned}$$

The moving-average form of the equation is

$$\begin{aligned} Y_t &= \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j} \\ \psi_j &= \begin{cases} \alpha & \text{for } j \bmod p \neq 0 \\ \alpha + \delta(1 - \alpha) & \text{for } j \bmod p = 0 \end{cases} \end{aligned}$$

For seasonal exponential smoothing, the additive-invertible region is

$$\{\max(-p\alpha, 0) < \delta(1 - \alpha) < (2 - \alpha)\}$$

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \psi_j^2 \right]$$

Multiplicative Seasonal Smoothing

In order to use the multiplicative version of seasonal smoothing, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of seasonal smoothing is

$$Y_t = \mu_t s_p(t) + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha(Y_t/S_{t-p}) + (1 - \alpha)L_{t-1} \\ S_t &= \delta(Y_t/L_t) + (1 - \delta)S_{t-p} \end{aligned}$$

The error-correction form of the smoothing equations is

$$\begin{aligned} L_t &= L_{t-1} + \alpha e_t / S_{t-p} \\ S_t &= S_{t-p} + \delta(1 - \alpha)e_t / L_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t S_{t-p+k}$$

The multiplicative version of seasonal smoothing does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of seasonal described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[\sum_{i=0}^{\infty} \sum_{j=0}^{p-1} (\psi_{j+ip} S_{t+k} / S_{t+k-j})^2 \right]$$

where ψ_j are as described for the additive version of seasonal method, and $\psi_j = 0$ for $j \geq k$.

Winters Method—Additive Version

The model equation for the additive version of Winters method is

$$Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t$$

The smoothing equations are

$$\begin{aligned} L_t &= \alpha(Y_t - S_{t-p}) + (1 - \alpha)(L_{t-1} + T_{t-1}) \\ T_t &= \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1} \\ S_t &= \delta(Y_t - L_t) + (1 - \delta)S_{t-p} \end{aligned}$$

The error-correction form of the smoothing equations is

$$\begin{aligned} L_t &= L_{t-1} + T_{t-1} + \alpha e_t \\ T_t &= T_{t-1} + \alpha \gamma e_t \\ S_t &= S_{t-p} + \delta(1 - \alpha)e_t \end{aligned}$$

(Note: For missing values, $e_t = 0$.)

The k -step prediction equation is

$$\hat{Y}_t(k) = L_t + kT_t + S_{t-p+k}$$

The ARIMA model equivalency to the additive version of Winters method is the ARIMA(0,1,p+1)(0,1,0)_p model,

$$(1 - B)(1 - B^p)Y_t = \left[1 - \sum_{i=1}^{p+1} \theta_i B^i \right] \epsilon_t$$

$$\theta_j = \begin{cases} 1 - \alpha - \alpha\gamma & j = 1 \\ -\alpha\gamma & 2 \leq j \leq p-1 \\ 1 - \alpha\gamma - \delta(1 - \alpha) & j = p \\ (1 - \alpha)(\delta - 1) & j = p+1 \end{cases}$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j}$$

$$\psi_j = \begin{cases} \alpha + j\alpha\gamma & \text{for } j \bmod p \neq 0 \\ \alpha + j\alpha\gamma + \delta(1 - \alpha), & \text{for } j \bmod p = 0 \end{cases}$$

For the additive version of Winters method (Archibald 1990), the additive-invertible region is

$$\begin{aligned} &\{\max(-p\alpha, 0) < \delta(1 - \alpha) < (2 - \alpha)\} \\ &\{0 < \alpha\gamma < 2 - \alpha - \delta(1 - \alpha)(1 - \cos(\vartheta))\} \end{aligned}$$

where ϑ is the smallest nonnegative solution to the equations listed in Archibald (1990).

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \psi_j^2 \right]$$

Winters Method—Multiplicative Version

In order to use the multiplicative version of Winters method, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of Winters method is

$$Y_t = (\mu_t + \beta_t t)s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t/S_{t-p}) + (1 - \alpha)(L_{t-1} + T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1}$$

$$S_t = \delta(Y_t/L_t) + (1 - \delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t/S_{t-p}$$

$$T_t = T_{t-1} + \alpha \gamma e_t/S_{t-p}$$

$$S_t = S_{t-p} + \delta(1 - \alpha)e_t/L_t$$

NOTE: For missing values, $e_t = 0$.

The k -step prediction equation is

$$\hat{Y}_t(k) = (L_t + kT_t)S_{t-p+k}$$

The multiplicative version of Winters method does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of Winters method described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

$$\text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[\sum_{i=0}^{\infty} \sum_{j=0}^{p-1} (\psi_{j+ip} S_{t+k}/S_{t+k-j})^2 \right]$$

where ψ_j are as described for the additive version of Winters method and $\psi_j = 0$ for $j \geq k$.

ARIMA Models

Autoregressive integrated moving-average (ARIMA) models predict values of a dependent time series with a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series (predictor time series).

The Time Series Forecasting System uses the ARIMA procedure of SAS/ETS software to fit and forecast ARIMA models. The maximum likelihood method is used for parameter estimation. Refer to Chapter 7, “[The ARIMA Procedure](#),” for details of ARIMA model estimation and forecasting.

This section summarizes the notation used for ARIMA models.

Notation for ARIMA Models

A dependent time series that is modeled as a linear combination of its own past values and past values of an error series is known as a (pure) ARIMA model.

Nonseasonal ARIMA Model Notation

The order of an ARIMA model is usually denoted by the notation $\text{ARIMA}(p,d,q)$, where

p	is the order of the autoregressive part.
d	is the order of the differencing (rarely should $d > 2$ be needed).
q	is the order of the moving-average process.

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA model is written as

$$(1 - B)^d Y_t = \mu + \frac{\theta(B)}{\phi(B)} a_t$$

where

t	indexes time.
μ	is the mean term.
B	is the backshift operator; that is, $BX_t = X_{t-1}$.
$\phi(B)$	is the autoregressive operator, represented as a polynomial in the back shift operator: $\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$.
$\theta(B)$	is the moving-average operator, represented as a polynomial in the back shift operator: $\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$.
a_t	is the independent disturbance, also called the random error.

For example, the mathematical form of the $\text{ARIMA}(1,1,2)$ model is

$$(1 - B)Y_t = \mu + \frac{(1 - \theta_1 B - \theta_2 B^2)}{(1 - \phi_1 B)} a_t$$

Seasonal ARIMA Model Notation

Seasonal ARIMA models are expressed in factored form by the notation $\text{ARIMA}(p,d,q)(P,D,Q)_s$, where

P	is the order of the seasonal autoregressive part.
D	is the order of the seasonal differencing (rarely should $D > 1$ be needed).
Q	is the order of the seasonal moving-average process.
s	is the length of the seasonal cycle.

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA seasonal model is written as

$$(1 - B)^d (1 - B^s)^D Y_t = \mu + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)} a_t$$

where

$\phi_s(B^s)$	is the seasonal autoregressive operator, represented as a polynomial in the back shift operator: $\phi_s(B^s) = 1 - \phi_{s,1}B^s - \dots - \phi_{s,P}B^{sP}$
$\theta_s(B^s)$	is the seasonal moving-average operator, represented as a polynomial in the back shift operator: $\theta_s(B^s) = 1 - \theta_{s,1}B^s - \dots - \theta_{s,Q}B^{sQ}$

For example, the mathematical form of the ARIMA(1,0,1)(1,1,2)₁₂ model is

$$(1 - B^{12})Y_t = \mu + \frac{(1 - \theta_1 B)(1 - \theta_{s,1}B^{12} - \theta_{s,2}B^{24})}{(1 - \phi_1 B)(1 - \phi_{s,1}B^{12})}a_t$$

Abbreviated Notation for ARIMA Models

If the differencing order, autoregressive order, or moving-average order is zero, the notation is further abbreviated as

$I(d)(D)_s$	integrated model or ARIMA(0,d,0)(0,D,0)
$AR(p)(P)_s$	autoregressive model or ARIMA(p,0,0)(P,0,0)
$IAR(p,d)(P,D)_s$	integrated autoregressive model or ARIMA(p,d,0)(P,D,0) _s
$MA(q)(Q)_s$	moving average model or ARIMA(0,0,q)(0,0,Q) _s
$IMA(d,q)(D,Q)_s$	integrated moving average model or ARIMA(0,d,q)(0,D,Q) _s
$ARMA(p,q)(P,Q)_s$	autoregressive moving-average model or ARIMA(p,0,q)(P,0,Q) _s .

Notation for Transfer Functions

A transfer function can be used to filter a predictor time series to form a dynamic regression model.

Let Y_t be the dependent series, let X_t be the predictor series, and let $\Psi(B)$ be a linear filter or transfer function for the effect of X_t on Y_t . The ARIMA model is then

$$(1 - B)^d(1 - B^s)^D Y_t = \mu + \Psi(B)(1 - B)^d(1 - B^s)^D X_t + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)}a_t$$

This model is called a *dynamic regression* of Y_t on X_t .

Nonseasonal Transfer Function Notation

Given the i th predictor time series $\{X_{i,t} : 1 \leq t \leq n\}$, the transfer function is written as

$$\text{Dif}(d_i)\text{Lag}(k_i)\text{N}(q_i)/\text{D}(p_i)$$

where

d_i	is the simple order of the differencing for the i th predictor time series, $(1 - B)^{d_i} X_{i,t}$ (rarely should $d_i > 2$ be needed).
k_i	is the pure time delay (lag) for the effect of the i th predictor time series, $X_{i,t} B^{k_i} = X_{i,t-k_i}$.
p_i	is the simple order of the denominator for the i th predictor time series.
q_i	is the simple order of the numerator for the i th predictor time series.

The mathematical notation used to describe a transfer function is

$$\Psi_i(B) = \frac{\omega_i(B)}{\delta_i(B)} (1 - B)^{d_i} B^{k_i}$$

where

B	is the backshift operator; that is, $BX_t = X_{t-1}$.
$\delta_i(B)$	is the denominator polynomial of the transfer function for the i th predictor time series: $\delta_i(B) = 1 - \delta_{i,1}B - \dots - \delta_{i,p_i}B^{p_i}$.
$\omega_i(B)$	is the numerator polynomial of the transfer function for the i th predictor time series: $\omega_i(B) = 1 - \omega_{i,1}B - \dots - \omega_{i,q_i}B^{q_i}$.

The numerator factors for a transfer function for a predictor series are like the MA part of the ARMA model for the noise series. The denominator factors for a transfer function for a predictor series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

For example, the transfer function for the i th predictor time series with

$k_i = 3$	time lag is 3
$d_i = 1$	simple order of differencing is one
$p_i = 1$	simple order of the denominator is one
$q_i = 2$	simple order of the numerator is two

would be written as [Dif(1)Lag(3)N(2)/D(1)]. The mathematical notation for the transfer function in this example is

$$\Psi_i(B) = \frac{(1 - \omega_{i,1}B - \omega_{i,2}B^2)}{(1 - \delta_{i,1}B)} (1 - B) B^3$$

Seasonal Transfer Function Notation

The general transfer function notation for the i th predictor time series $X_{i,t}$ with seasonal factors is [Dif(d_i)(D_i)_s Lag(k_i) N(q_i)(Q_i)_s/D(p_i)(P_i)_s] where

D_i	is the seasonal order of the differencing for the i th predictor time series (rarely should $D_i > 1$ be needed).
P_i	is the seasonal order of the denominator for the i th predictor time series (rarely should $P_i > 2$ be needed).

Q_i	is the seasonal order of the numerator for the i th predictor time series, (rarely should $Q_i > 2$ be needed).
s	is the length of the seasonal cycle.

The mathematical notation used to describe a seasonal transfer function is

$$\Psi_i(B) = \frac{\omega_i(B)\omega_{s,i}(B^s)}{\delta_i(B)\delta_{s,i}(B^s)}(1-B)^{d_i}(1-B^s)^{D_i}B^{k_i}$$

where

$\delta_{s,i}(B^s)$	is the denominator seasonal polynomial of the transfer function for the i th predictor time series: $\delta_{s,i}(B) = 1 - \delta_{s,i,1}B - \dots - \delta_{s,i,P_i}B^{sP_i}$
$\omega_{s,i}(B^s)$	is the numerator seasonal polynomial of the transfer function for the i th predictor time series: $\omega_{s,i}(B) = 1 - \omega_{s,i,1}B - \dots - \omega_{s,i,Q_i}B^{sQ_i}$

For example, the transfer function for the i th predictor time series $X_{i,t}$ whose seasonal cycle $s = 12$ with

$d_i = 2$	simple order of differencing is two
$D_i = 1$	seasonal order of differencing is one
$q_i = 2$	simple order of the numerator is two
$Q_i = 1$	seasonal order of the numerator is one

would be written as $[\text{Dif}(2)(1)_s \text{N}(2)(1)_s]$. The mathematical notation for the transfer function in this example is

$$\Psi_i(B) = (1 - \omega_{i,1}B - \omega_{i,2}B^2)(1 - \omega_{s,i,1}B^{12})(1-B)^2(1-B^{12})$$

Note: In this case, $[\text{Dif}(2)(1)_s \text{N}(2)(1)_s] = [\text{Dif}(2)(1)_s \text{Lag}(0)\text{N}(2)(1)_s/\text{D}(0)(0)_s]$.

Predictor Series

This section discusses time trend curves, seasonal dummies, interventions, and adjustments.

Time Trend Curves

When you specify a time trend curve as a predictor in a forecasting model, the system computes a predictor series that is a deterministic function of time. This variable is then included in the model as a regressor, and the trend curve is fit to the dependent series by linear regression, in addition to other predictor series.

Some kinds of nonlinear trend curves are fit by transforming the dependent series. For example, the exponential trend curve is actually a linear time trend fit to the logarithm of the series. For these trend curve

specifications, the series transformation option is set automatically, and you cannot independently control both the time trend curve and transformation option.

The computed time trend variable is included in the output data set in a variable named in accordance with the trend curve type. Let t represent the observation count from the start of the period of fit for the model, and let X_t represent the value of the time trend variable at observation t within the period of fit. The names and definitions of these variables are as follows. (Note: These deterministic variables are reserved variable names.)

Linear trend	variable name <code>_LINEAR_</code> , with $X_t = t - c$
Quadratic trend	variable name <code>_QUAD_</code> , with $X_t = (t - c)^2$. Note that a quadratic trend implies a linear trend as a special case and results in two regressors: <code>_QUAD_</code> and <code>_LINEAR_</code> .
Cubic trend	variable name <code>_CUBE_</code> , with $X_t = (t - c)^3$. Note that a cubic trend implies a quadratic trend as a special case and results in three regressors: <code>_CUBE_</code> , <code>_QUAD_</code> , and <code>_LINEAR_</code> .
Logistic trend	variable name <code>_LOGIT_</code> , with $X_t = t$. The model is a linear time trend applied to the logistic transform of the dependent series. Thus, specifying a logistic trend is equivalent to specifying the logistic series transformation and a linear time trend. A logistic trend predictor can be used only in conjunction with the logistic transformation, which is set automatically when you specify logistic trend.
Logarithmic trend	variable name <code>_LOG_</code> , with $X_t = \ln(t)$
Exponential trend	variable name <code>_EXP_</code> , with $X_t = t$. The model is a linear time trend applied to the logarithms of the dependent series. Thus, specifying an exponential trend is equivalent to specifying the log series transformation and a linear time trend. An exponential trend predictor can be used only in conjunction with the log transformation, which is set automatically when you specify exponential trend.
Hyperbolic trend	variable name <code>_HYP_</code> , with $X_t = 1/t$
Power curve trend	variable name <code>_POW_</code> , with $X_t = \ln(t)$. The model is a logarithmic time trend applied to the logarithms of the dependent series. Thus, specifying a power curve is equivalent to specifying the log series transformation and a logarithmic time trend. A power curve predictor can be used only in conjunction with the log transformation, which is set automatically when you specify a power curve trend.
EXP(A+B/TIME) trend	variable name <code>_ERT_</code> , with $X_t = 1/t$. The model is a hyperbolic time trend applied to the logarithms of the dependent series. Thus, specifying this trend curve is equivalent to specifying the log series transformation and a hyperbolic time trend. This trend curve can be used only in conjunction with the log transformation, which is set automatically when you specify this trend.

Intervention Effects

Interventions are used for modeling events that occur at specific times. That is, they are known changes that affect the dependent series or outliers.

The i th intervention series is included in the output data set with variable name `_INTVi _`, which is a reserved variable name.

Point Interventions

The point intervention is a one-time event. The i th intervention series $X_{i,t}$ has a point intervention at time t_{int} when the series is nonzero only at time t_{int} —that is,

$$X_{i,t} = \begin{cases} 1, & t = t_{int} \\ 0, & \text{otherwise} \end{cases}$$

Step Interventions

Step interventions are continuing, and the input time series flags periods after the intervention. For a step intervention, before time t_{int} , the i th intervention series $X_{i,t}$ is zero and then steps to a constant level thereafter—that is,

$$X_{i,t} = \begin{cases} 1, & t \geq t_{int} \\ 0, & \text{otherwise} \end{cases}$$

Ramp Interventions

A ramp intervention is a continuing intervention that increases linearly after the intervention time. For a ramp intervention, before time t_{int} , the i th intervention series $X_{i,t}$ is zero and increases linearly thereafter—that is, proportional to time.

$$X_{i,t} = \begin{cases} t - t_{int}, & t \geq t_{int} \\ 0, & \text{otherwise} \end{cases}$$

Intervention Effect

Given the i th intervention series $X_{i,t}$, you can define how the intervention takes effect by filters (transfer functions) of the form

$$\Psi_i(B) = \frac{1 - \omega_{i,1}B - \dots - \omega_{i,q_i}B^{q_i}}{1 - \delta_{i,1}B - \dots - \delta_{i,p_i}B^{p_i}}$$

where B is the backshift operator $By_t = y_{t-1}$.

The denominator of the transfer function determines the decay pattern of the intervention effect, whereas the numerator terms determine the size of the intervention effect time window.

For example, the following intervention effects are associated with the respective transfer functions.

Immediately	$\Psi_i(B) = 1$
Gradually	$\Psi_i(B) = 1/(1 - \delta_{i,1}B)$
1 lag window	$\Psi_i(B) = 1 - \omega_{i,1}B$
3 lag window	$\Psi_i(B) = 1 - \omega_{i,1}B - \omega_{i,2}B^2 - \omega_{i,3}B^3$

Intervention Notation

The notation used to describe intervention effects has the form $type : t_{int} (q_i)/(p_i)$, where $type$ is point, step, or ramp; t_{int} is the time of the intervention (for example, OCT87); q_i is the transfer function numerator order; and p_i is the transfer function denominator order. If $q_i = 0$, the part “(q_i)” is omitted; if $p_i = 0$, the part “/(p_i)” is omitted.

In the Intervention Specification window, the `Number of Lags` option specifies the transfer function numerator order q_i , and the `Effect Decay Pattern` option specifies the transfer function denominator order p_i . In the `Effect Decay Pattern` options, values and resulting p_i are: `None`, $p_i = 0$; `Exp`, $p_i = 1$; `Wave`, $p_i = 2$.

For example, a step intervention with date 08MAR90 and effect pattern `Exp` is denoted “Step:08MAR90/(1)” and has a transfer function filter $\Psi_i(B) = 1/(1 - \delta_1 B)$. A ramp intervention immediately applied on 08MAR90 is denoted “Ramp:08MAR90” and has a transfer function filter $\Psi_i(B) = 1$.

Seasonal Dummy Inputs

For a seasonal cycle of length s , the seasonal dummy regressors include

$$\{X_{i,t} : 1 \leq i \leq (s-1), 1 \leq t \leq n\}$$

for models that include an intercept term and

$$\{X_{i,t} : 1 \leq i \leq s, 1 \leq t \leq n\}$$

for models that exclude an intercept term. Each element of a seasonal dummy regressor is either zero or one, based on the following rule:

$$X_{i,t} = \begin{cases} 1, & \text{when } i = t \pmod{s} \\ 0, & \text{otherwise} \end{cases}$$

Note that if the model includes an intercept term, the number of seasonal dummy regressors is one less than s to ensure that the linear system is full rank.

The seasonal dummy variables are included in the output data set with variable names prefixed with “SDUMMY i ” and sequentially numbered. They are reserved variable names.

Series Diagnostic Tests

This section describes the diagnostic tests that are used to determine the kinds of forecasting models appropriate for a series.

The series diagnostics are a set of heuristics that provide recommendations on whether or not the forecasting model should contain a log transform, trend terms, and seasonal terms. These recommendations are used by the automatic model selection process to restrict the model search to a subset of the model selection list. (You can disable this behavior by using the Automatic Model Selection Options window.)

The tests that are used by the series diagnostics do not always produce the correct classification of the series. They are intended to accelerate the process of searching for a good forecasting model for the series, but you should not rely on them if finding the very best model is important to you.

If you have information about the appropriate kinds of forecasting models (perhaps from studying the plots and autocorrelations shown in the Series Viewer window), you can set the series diagnostic flags in the Series Diagnostics window. Select the YES, NO, or MAYBE values for the `Log Transform`, `Trend`, and `Seasonality` options in the Series Diagnostics window as you think appropriate.

The series diagnostics tests are intended as a heuristic tool only, and no statistical validity is claimed for them. These tests might be modified and enhanced in future releases of the Time Series Forecasting System. The testing strategy is as follows:

1. **Log transform test.** The log test fits a high-order autoregressive model to the series and to the log of the series and compares goodness-of-fit measures for the prediction errors of the two models. If this test finds that log transforming the series is suitable, the `Log Transform` option is set to YES, and the subsequent diagnostic tests are performed on the log transformed series.
2. **Trend test.** The resultant series is tested for presence of a trend by using an augmented Dickey-Fuller test and a random walk with drift test. If either test finds that the series appears to have a trend, the `Trend` option is set to YES, and the subsequent diagnostic tests are performed on the differenced series.
3. **Seasonality test.** The resultant series is tested for seasonality. A seasonal dummy model with AR(1) errors is fit and the joint significance of the seasonal dummy estimates is tested. If the seasonal dummies are significant, the AIC statistic for this model is compared to the AIC for an AR(1) model without seasonal dummies. If the AIC for the seasonal model is lower than that of the nonseasonal model, the `Seasonal` option is set to YES.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well different models fit the data. The statistics of fit for the various forecasting models can be viewed or stored in a data set by using the Model Viewer window.

Statistics of fit are computed by using the actual and forecasted values for observations in the period of evaluation. One-step forecasted values are used whenever possible, including the case when a hold-out sample contains no missing values. If a one-step forecast for an observation cannot be computed due to missing values for previous series observations, a multi-step forecast is computed, using the minimum number of steps as the previous nonmissing values in the data range permit.

The various statistics of fit reported are as follows. In these formulas, n is the number of nonmissing observations and k is the number of fitted parameters in the model.

Number of Nonmissing Observations.

The number of nonmissing observations used to fit the model.

Number of Observations.

The total number of observations used to fit the model, including both missing and nonmissing observations.

Number of Missing Actuals.

The number of missing actual values.

Number of Missing Predicted Values.

The number of missing predicted values.

Number of Model Parameters.

The number of parameters fit to the data. For combined forecast, this is the number of forecast components.

Total Sum of Squares (Uncorrected).

The total sum of squares for the series, SST, uncorrected for the mean: $\sum_{t=1}^n y_t^2$.

Total Sum of Squares (Corrected).

The total sum of squares for the series, SST, corrected for the mean: $\sum_{t=1}^n (y_t - \bar{y})^2$, where \bar{y} is the series mean.

Sum of Square Errors.

The sum of the squared prediction errors, SSE. $SSE = \sum_{t=1}^n (y_t - \hat{y}_t)^2$, where \hat{y} is the one-step predicted value.

Mean Squared Error.

The mean squared prediction error, MSE, calculated from the one-step-ahead forecasts. $MSE = \frac{1}{n} SSE$. This formula enables you to evaluate small hold-out samples.

Root Mean Squared Error.

The root mean square error (RMSE), \sqrt{MSE} .

Mean Absolute Percent Error.

The mean absolute percent prediction error (MAPE), $\frac{100}{n} \sum_{t=1}^n |(y_t - \hat{y}_t)/y_t|$.
The summation ignores observations where $y_t = 0$.

Mean Absolute Error.

The mean absolute prediction error, $\frac{1}{n} \sum_{t=1}^n |y_t - \hat{y}_t|$.

R-Square.

The R^2 statistic, $R^2 = 1 - SSE/SST$. If the model fits the series badly, the model error sum of squares, SSE, can be larger than SST and the R^2 statistic will be negative.

Adjusted R-Square.

The adjusted R^2 statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$.

Amemiya's Adjusted R-Square.

Amemiya's adjusted R^2 , $1 - (\frac{n+k}{n-k})(1 - R^2)$.

Random Walk R-Square.

The random walk R^2 statistic (Harvey's R^2 statistic by using the random walk model for comparison), $1 - (\frac{n-1}{n})SSE/RWSSE$, where $RWSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$.

Akaike's Information Criterion.

Akaike's information criterion (AIC), $n \ln(MSE) + 2k$.

Schwarz Bayesian Information Criterion.

Schwarz Bayesian information criterion (SBC or BIC),
 $n \ln(MSE) + k \ln(n)$.

Amemiya's Prediction Criterion.

Amemiya's prediction criterion, $\frac{1}{n} SST(\frac{n+k}{n-k})(1 - R^2) = (\frac{n+k}{n-k})\frac{1}{n} SSE$.

Maximum Error.

The largest prediction error.

Minimum Error.

The smallest prediction error.

Maximum Percent Error.

The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

Minimum Percent Error.

The smallest percent prediction error, $100 \min((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

Mean Error.

The mean prediction error, $\frac{1}{n} \sum_{t=1}^n (y_t - \hat{y}_t)$.

Mean Percent Error.

The mean percent prediction error, $\frac{100}{n} \sum_{t=1}^n \frac{(y_t - \hat{y}_t)}{y_t}$. The summation ignores observations where $y_t = 0$.

Using Help	3327
Software Requirements	3327

About Investment Analysis

The Investment Analysis system is an interactive environment for the time-value of money of a variety of investments:

- loans
- savings
- depreciations
- bonds
- generic cashflows

Various analyses are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and breakeven analysis.

These analyses can help answer a number of questions you may have about your investments:

- Which option is more profitable or less costly?
- Is it better to buy or rent?
- Are the extra fees for refinancing at a lower interest rate justified?
- What is the balance of this account after saving this amount periodically for so many years?
- How much is legally tax-deductible?
- Is this a reasonable price?

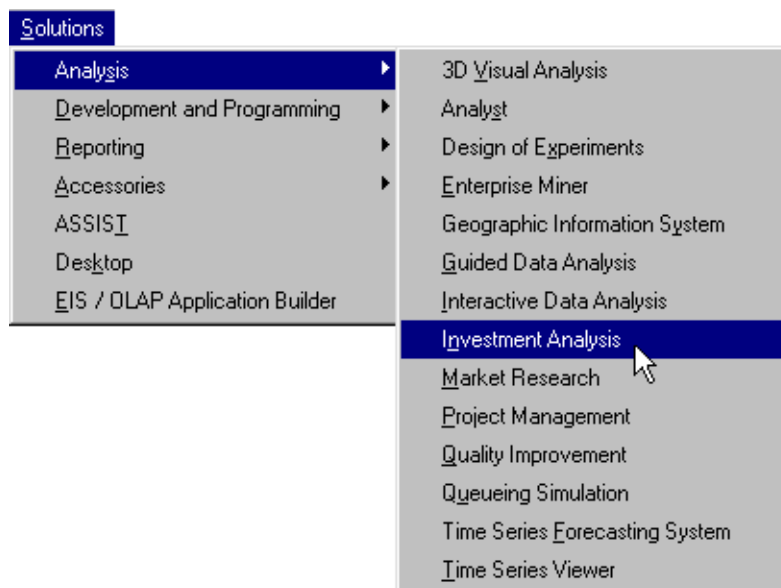

Investment Analysis can be beneficial to users in many industries for a variety of decisions:

- manufacturing: cost justification of automation or any capital investment, replacement analysis of major equipment, or economic comparison of alternative designs
- government: setting funds for services
- finance: investment analysis and portfolio management for fixed-income securities

Starting Investment Analysis

There are two ways to invoke Investment Analysis from the main SAS window. One way is to select **Solutions** → **Analysis** → **Investment Analysis** from the main SAS menu, as displayed in Figure 53.1.

Figure 53.1 Initializing Investment Analysis with the Menu Bar

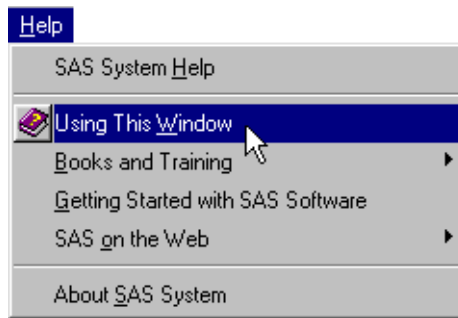

The other way is to type **INVEST** into the toolbar's command prompt, as displayed in Figure 53.2.

Figure 53.2 Initializing Investment Analysis with the Toolbar

Getting Help

You can get help in Investment Analysis in three ways. One way is to use the Help Menu, as displayed in Figure 53.3. This is the right-most menu item on the menu bar.

Figure 53.3 The Help Menu

Help buttons, as in [Figure 53.4](#), provide another way to access help. Most dialog boxes provide help buttons in their lower-right corners.

Figure 53.4 A Help Button

Also, the toolbar has a button (see [Figure 53.5](#)) that invokes the help system. This is the right-most icon on the toolbar.

Figure 53.5 The Help Icon

Each of these methods invokes a browser that gives specific help for the active window.

Using Help

The chapters pertaining to Investment Analysis in this document typically have a section that introduces you to a menu and summarizes the options available through the menu. Such chapters then have sections titled Task and Dialog Box Guides. The Task section provides a description of how to perform many useful tasks. The Dialog Box Guide lists all dialog boxes pertinent to those tasks and gives a brief description of each element of each dialog box.

Software Requirements

Investment Analysis uses the following SAS software:

- Base SAS
- SAS/ETS
- SAS/GRAPH (optional, to view bond pricing and breakeven graphs)

Chapter 54

Portfolios

Contents

The File Menu	3329
Tasks	3330
Creating a New Portfolio	3330
Saving a Portfolio	3330
Opening an Existing Portfolio	3331
Saving a Portfolio to a Different Name	3332
Selecting Investments within a Portfolio	3332
Dialog and Utility Guide	3333
Investment Analysis	3333
Menu Bar Options	3334
Right-Clicking within the Portfolio Area	3335

The File Menu

Investment Analysis stores portfolios as catalog entries. Portfolios contain a collection of investments, providing a structure to collect investments with a common purpose or goal (like a retirement or building fund portfolio). It may be advantageous also to collect investments into a common portfolio if they are competing investments you want to perform a comparative analysis upon. Within this structure you can perform computations and analyses on a collection of investments in a portfolio, just as you would perform them on a single investment.

Investment Analysis provides many tools to aid in your manipulation of portfolios through the **File** menu, shown in Figure 54.1.

Figure 54.1 File Menu

The **File** menu offers the following items:

New Portfolio creates an empty portfolio with a new name.

Open Portfolio opens the standard SAS Open dialog box where you select a portfolio to open.

Save Portfolio saves the current portfolio to its current name.

Save Portfolio As opens the standard SAS Save As dialog box where you supply a new portfolio name for the current portfolio.

Close closes Investment Analysis.

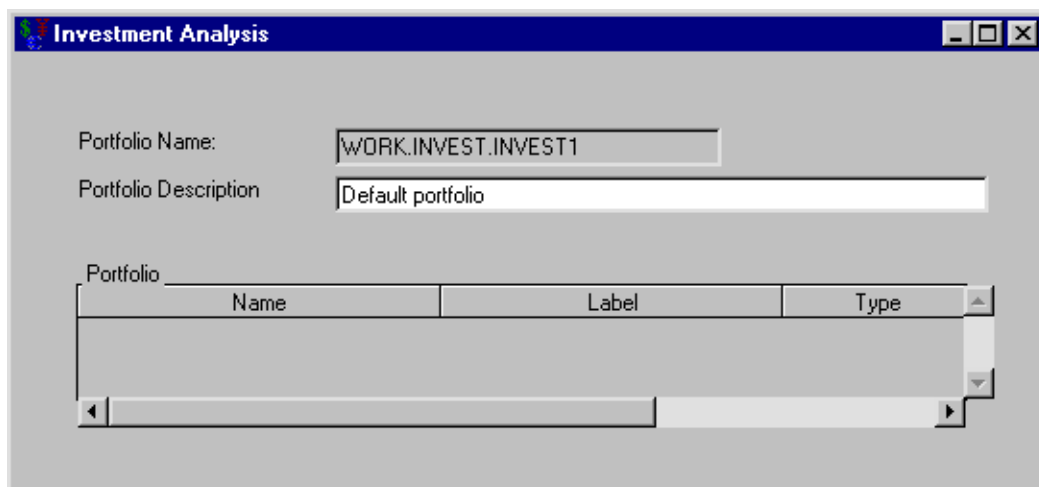

Exit closes SAS (Windows only).

Tasks

Creating a New Portfolio

From the Investment Analysis dialog box, select **File** → **New Portfolio**.

Figure 54.2 Creating a New Portfolio

The **Portfolio Name** is WORK.INVEST.INVEST1 as displayed in Figure 54.2, unless you have saved a portfolio to that name in the past. In that case, some other unused portfolio name is given to the new portfolio.

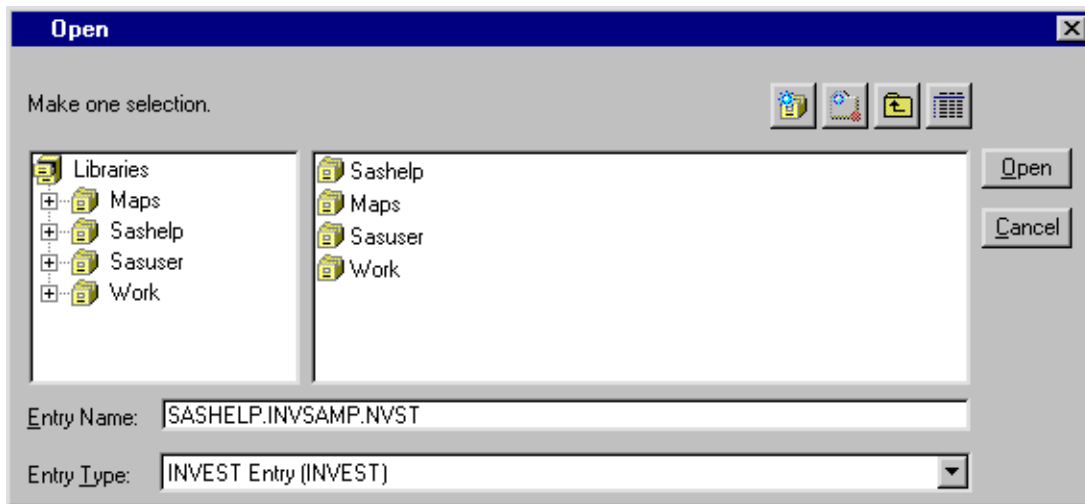

Saving a Portfolio

From the Investment Analysis dialog box, select **File** → **Save Portfolio**. The portfolio is saved to a catalog-entry with the name in the **Portfolio Name** box.

Opening an Existing Portfolio

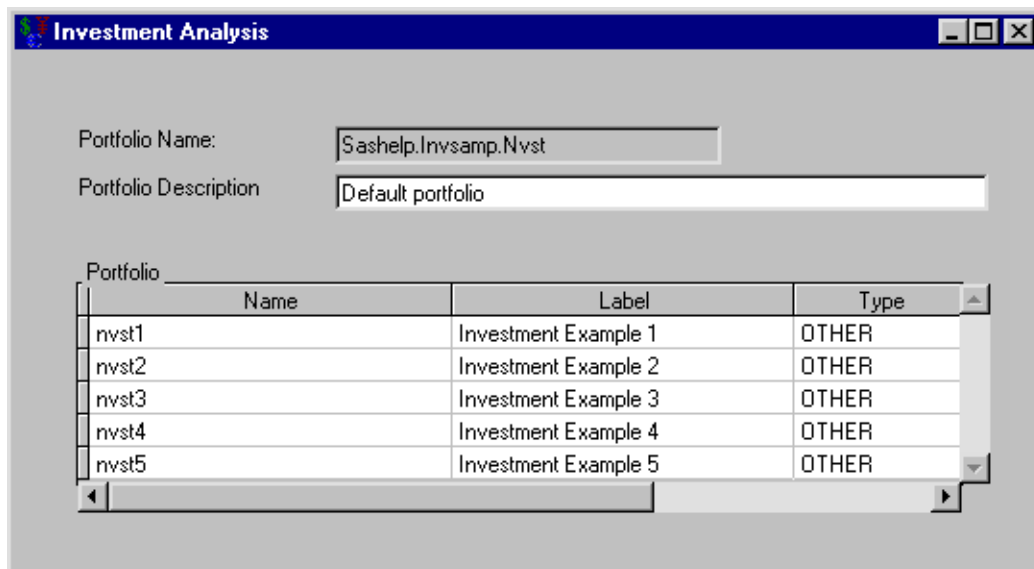

From the Investment Analysis dialog box, select **File** → **Open Portfolio**. This opens the standard SAS Open dialog box. You enter the name of a SAS portfolio to open in the **Entry Name** box. For example, enter SASHELP.INVSAMP.NVST as displayed in Figure 54.3.

Figure 54.3 Opening an Existing Portfolio

Click **Open** to load the portfolio. The portfolio should look like Figure 54.4.

Figure 54.4 The Opened Portfolio

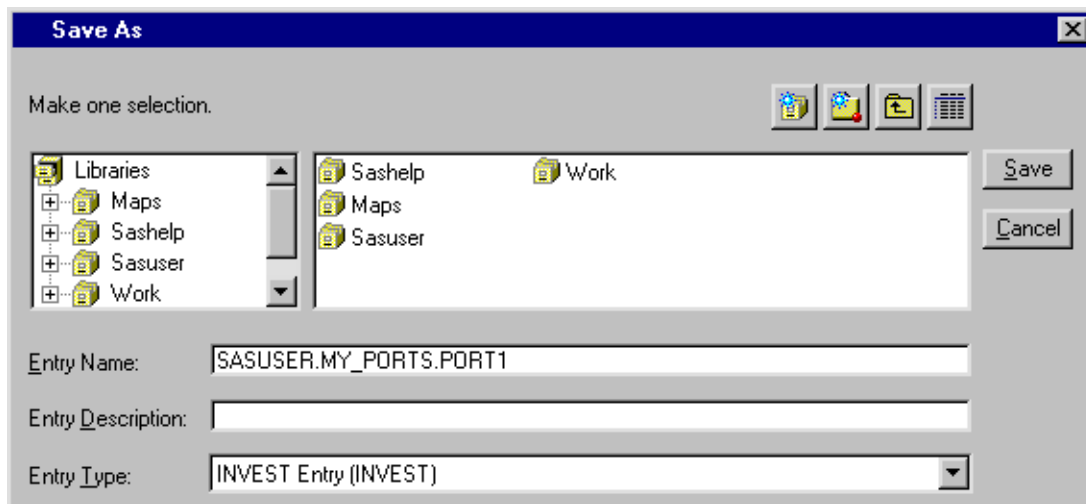

Saving a Portfolio to a Different Name

From the Investment Analysis dialog box, select **File** → **Save Portfolio As**.

This opens the standard SAS Save As dialog box. You can enter the name of a SAS portfolio into the **Entry Name** box. For example, enter SASUSER.MY_PORTS.PORT1, as in [Figure 54.5](#).

Figure 54.5 Saving a Portfolio to a Different Name

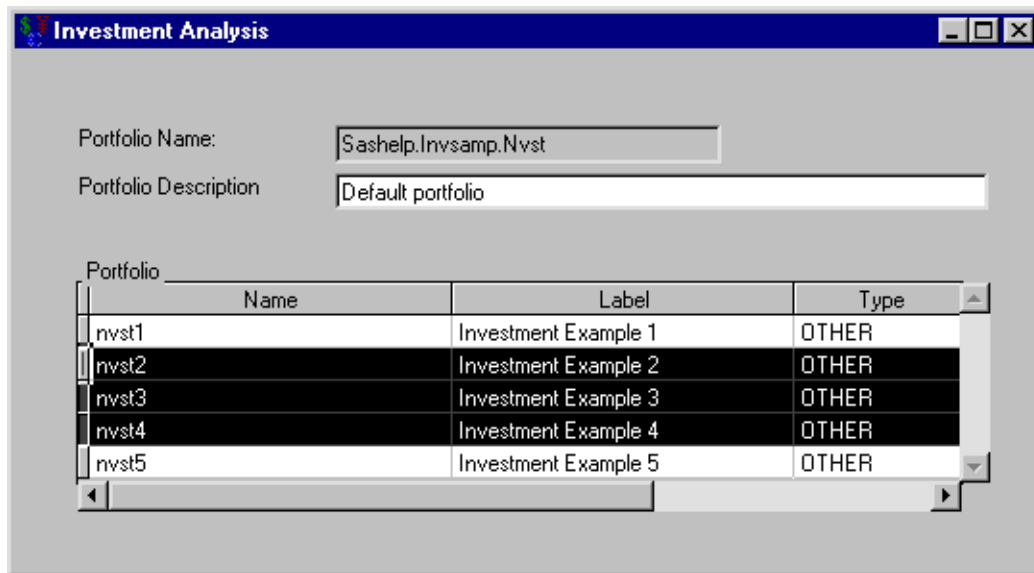

Click **Save** to save the portfolio.

Selecting Investments within a Portfolio

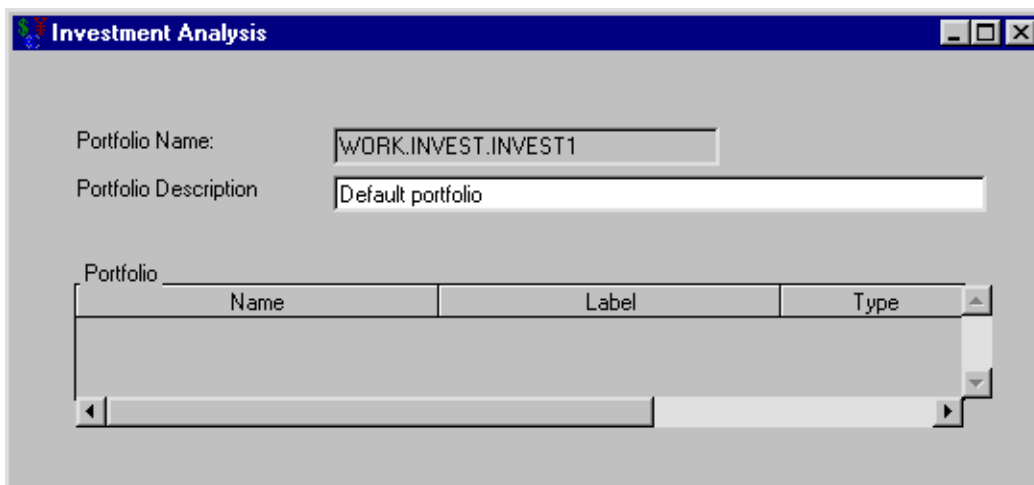

To select a single investment in an opened portfolio, click the investment in the Portfolio area within the Investment Analysis dialog box.

To select a list of adjacent investments, do the following: click the first investment, hold down SHIFT, and click the final investment. After the list of investments is selected, you can release the SHIFT key. The selected investments will appear highlighted as in [Figure 54.6](#).

Figure 54.6 Selecting Investments within a Portfolio

Dialog and Utility Guide

Investment Analysis

Figure 54.7 Investment Analysis Dialog Box

Investment Portfolio Name holds the name of the portfolio. The name is of the form `library.catalog_entry.portfolio`. The default portfolio name is `work.invest.invest1`, as in [Figure 54.7](#).

Portfolio Description provides a more descriptive explanation of the portfolio's contents. You can edit this description any time this dialog box is active.

The **Portfolio** area contains the list of investments comprising the particular portfolio. Each investment in the **Portfolio** area displays the following attributes:

Name is the name of the investment. It must be a valid SAS name. It is used to distinguish investments when performing analyses and computations.

Label is a place where you can provide a more descriptive explanation of the investment.

Type is the type of investment, which is fixed when you create the investment. It is one of the following: LOAN, SAVINGS, DEPRECIATION, BOND, or OTHER.

Additional tools to aid in the management of your portfolio are available by selecting from the [menu bar](#) or by [right-clicking](#) within the **Portfolio** area.

Menu Bar Options

Figure 54.8 The Menu Bar

The menu bar (shown in [Figure 54.8](#)) provides many tools to aid in the management of portfolios and the investments that comprise them. The following menu items provide functionality particular to Investment Analysis:

File opens and saves portfolios.

Investment creates new investments within the portfolio.

Compute performs constant dollar, after tax, and currency conversion computations on generic cashflows.

Analyze analyzes investments to aid in decision-making.

Tools sets default values of inflation and income tax rates.

Right-Clicking within the Portfolio Area

Figure 54.9 Right-Clicking

After selecting an investment, right-clicking in the **Portfolio** area pops up a menu (see [Figure 54.9](#)) that offers the following options:

Edit opens the selected investment within the portfolio.

Duplicate creates a duplicate of the selected investment within the portfolio.

Delete removes the selected investment from the portfolio.

If you wish to perform one of these actions on a collection of investments, you must select a collection of investments (as described in the section “[Selecting Investments within a Portfolio](#)” on page 3332) before right-clicking.

The Investment Menu

Because there are many types of investments, a tool that manages and analyzes collections of investments must be robust and flexible. Providing specifications for four specific investment types and one generic type, Investment Analysis can model almost any real-world investment.

Figure 55.1 Investment Menu

The **Investment** menu, shown in Figure 55.1, offers the following items:

New → **Loan** opens the **Loan** dialog box. Loans are useful for acquiring capital to pursue various interests. Available terms include rate adjustments for variable rate loans, initialization costs, prepayments, and balloon payments.

New → **Savings** opens the **Savings** dialog box. Savings are necessary when planning for the future, whether for business or personal purposes. Account summary calculations available per deposit include starting balance, deposits, interest earned, and ending balance.

New → **Depreciation** opens the **Depreciation** dialog box. Depreciations are relevant in tax calculation. The available depreciation methods are Straight Line, Sum-of-years Digits, Depreciation Table, and Declining Balance. Depreciation Tables are necessary when depreciation calculations must conform to set yearly percentages. Declining Balance with conversion to Straight Line is also provided.

New → **Bond** opens the **Bond** dialog box. Bonds have widely varying terms depending on the issuer. Because bond issuers frequently auction their bonds, the ability to price a bond between the issue date and maturity date is desirable. Fixed-coupon bonds may be analyzed for the following: price versus yield-to-maturity, duration, and convexity. These are available at different times in the bond's life.

New → **Generic Cashflow** opens the **Generic Cashflow** dialog box. Generic cashflows are the most flexible investments. Only a sequence of date-amount pairs is necessary for specification. You can enter date-amount pairs and load values from SAS data sets to specify any type of investment. You can generate uniform, arithmetic, and geometric cashflows with ease. SAS's forecasting ability is available to forecast future cashflows as well. The new graphical display aids in visualization of the cashflow and enables the user to change the frequency of the cashflow view to aggregate and disaggregate the view.

Edit opens the specification dialog box for an investment selected within the portfolio.

Duplicate creates a duplicate of an investment selected within the portfolio.

Delete removes an investment selected from the portfolio.

If you want to edit, duplicate, or delete a collection of investments, you must select a collection of investments as described in the section "[Selecting Investments within a Portfolio](#)" on page 3332 before performing the menu-option.

Tasks

Loan Tasks

Suppose you want to buy a home that costs \$100,000. You can make a down payment of \$20,000. Hence, you need a loan of \$80,000. You are able to acquire a 30-year loan at 7% interest starting January 1, 2000. Let's use Investment Analysis to specify and analyze this loan.

In the Investment Analysis dialog box, select **Investment** → **New** → **Loan** from the menu bar to open the Loan dialog box.

Specifying Loan Terms to Create an Amortization Schedule

You must specify the loan before generating the amortization table. To specify the loan, follow these steps:

1. Enter MORTGAGE for the **Name**.
2. Enter 80000 for the **Loan Amount**.
3. Enter 7 for the **Initial Rate**.
4. Enter 360 for the **Number of Payments**.
5. Enter 01JAN2000 for the **Start Date**.

After you have specified the loan, click **Create Amortization Schedule** to generate the amortization schedule displayed in [Figure 55.2](#).

Figure 55.2 Creating an Amortization Schedule

The 'Loan' dialog box is shown with the following fields and buttons:

- Name: MORTGAGE
- Loan Specification section:
 - Loan Amount: 80000
 - Initial Rate: 7.00
 - Periodic Payment: (empty)
 - Start Date: 01JAN2000
 - Number of Payments: 360
 - Payment Interval: MONTH
 - Compounding Interval: MONTH
- Buttons on the right: Initialization..., Prepayments..., Balloon Payments..., Rate Adjustments..., Rounding Off...
- Create Amortization Schedule button
- Amortization Schedule table:

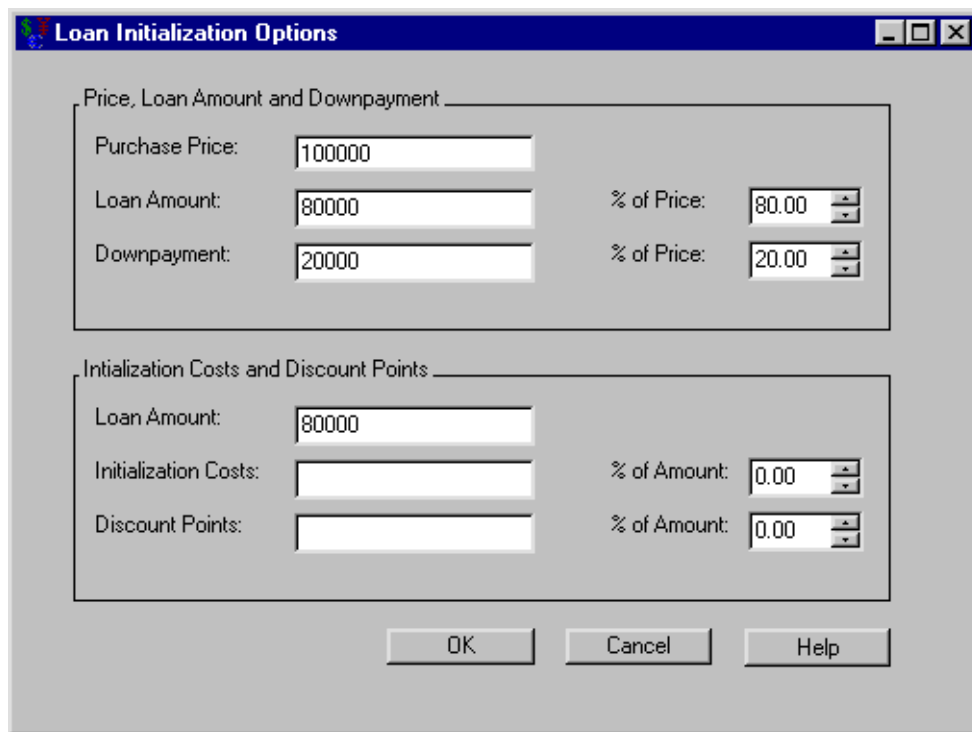

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Rep
JAN2000	80000.00	0.00	0.00	0.00
FEB2000	80000.00	532.24	466.67	65.57
MAR2000	79934.43	532.24	466.28	65.96
APR2000	79868.47	532.24	465.90	66.34

Buttons at the bottom: Save Data As..., OK, Cancel, Help

Storing Other Loan Terms

Let’s include information concerning the purchase price and downpayment. These terms are not necessary to specify the loan, but it may be advantageous to store such information with the loan.

Consider the loan described in the section “[Loan Tasks](#)” on page 3339. In the Loan dialog box ([Figure 55.2](#)) click **Initialization** to open the Loan Initialization Options dialog box, where you can specify the down payment, initialization costs, and discount points. To specify the down payment, enter 100000 for the **Purchase Price**, as shown in [Figure 55.3](#).

Figure 55.3 Including the Purchase Price

Loan Initialization Options

Price, Loan Amount and Downpayment

Purchase Price: 100000

Loan Amount: 80000 % of Price: 80.00

Downpayment: 20000 % of Price: 20.00

Initialization Costs and Discount Points

Loan Amount: 80000

Initialization Costs: % of Amount: 0.00

Discount Points: % of Amount: 0.00

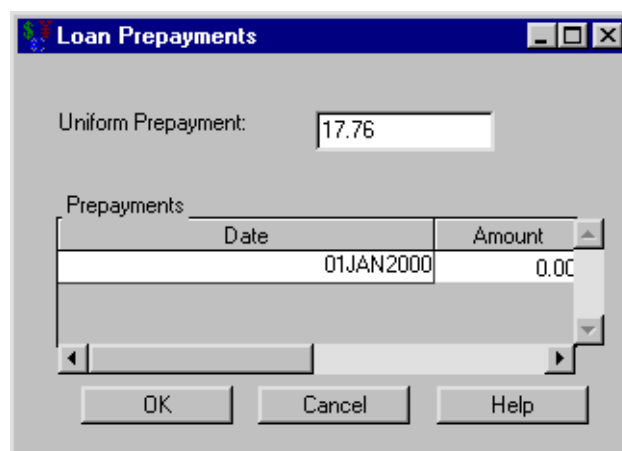

OK Cancel Help

Click **OK** to return to the Loan dialog box.

Adding Prepayments

Now let's observe the effect of prepayments on the loan. Consider the loan described in the section “[Loan Tasks](#)” on page 3339. You must pay a minimum of \$532.24 each month to keep up with payments. However, let's say you dislike entering this amount in your checkbook. You would rather pay \$550.00 to keep the arithmetic simpler. This would constitute a uniform prepayment of \$17.76 each month.

In the Loan dialog box, click **Prepayments**, which opens the Loan Prepayments dialog box shown in [Figure 55.4](#).

Figure 55.4 Specifying the Loan Prepayments

Loan Prepayments

Uniform Prepayment: 17.76

Prepayments

Date	Amount
01JAN2000	0.00

OK Cancel Help

You can specify an arbitrary sequence of prepayments in the **Prepayments** area. If you want a uniform prepayment, clear the **Prepayments** area and enter the uniform payment amount in the **Uniform Prepayment** text box. That amount will be added to each payment until the loan is paid off.

To specify this uniform prepayment, follow these steps:

1. Enter 17.76 for the **Uniform Prepayment**.
2. Click **OK** to return to the Loan dialog box.
3. Click **Create Amortization Schedule**, and the amortization schedule is updated, as displayed in Figure 55.5.

Figure 55.5 The Amortization Schedule with Loan Prepayments

Loan

Name:

Loan Specification

Loan Amount: Initial Rate:

Periodic Payment: Start Date:

Number of Payments:

Payment Interval:

Compounding Interval:

Amortization Schedule

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Rep
JAN2000	80000.00	0.00	0.00	0.00
FEB2000	80000.00	550.00	466.67	83.33
MAR2000	79916.67	550.00	466.18	83.82
APR2000	79832.85	550.00	465.69	84.31

The last payment is on January 2030 without prepayments and February 2027 with prepayment; you would pay the loan off almost three years earlier with the \$17.76 prepayments.

To continue this example you must remove the prepayments from the loan specification, following these steps:

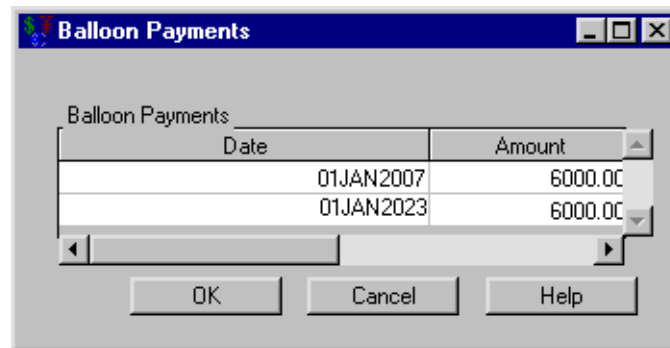

1. Reopen the Loan Prepayments dialog box from the Loan dialog box by clicking **Prepayments**.
2. Enter 0 for **Uniform Prepayment**.
3. Click **OK** to return to the Loan dialog box.

Adding Balloon Payments

Consider the loan described in the section “[Loan Tasks](#)” on page 3339. Suppose you cannot afford the payments of \$532.24 each month. To lessen your monthly payment, you could pay balloon payments of \$6,000 at the end of 2007 and 2023. You wonder how this would affect your monthly payment. (Note that Investment Analysis does not allow both balloon payments and rate adjustments to be specified for a loan.)

In the Loan dialog box, click **Balloon Payments**, which opens the Balloon Payments dialog box shown in [Figure 55.6](#).

Figure 55.6 Defining Loan Balloon Payments

You can specify an arbitrary sequence of balloon payments by adding date-amount pairs to the **Balloon Payments** area.

To specify these balloon payments, follow these steps:

1. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **New**.
2. Set the pair's **Date** to 01JAN2007.
3. Set **Amount** to 6000.
4. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **New**.
5. Set the new pair's **Date** to 01JAN2023.
6. Set its **Amount** to 6000.

Click **OK** to return to the Loan dialog box. Click **Create Amortization Schedule**, and the amortization schedule is updated. Your monthly payment is now \$500.30, a difference of approximately \$32 each month.

To continue this example you must remove the balloon payments from the loan specification, following these steps:

1. Reopen the Balloon Payments dialog box.
2. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **Clear**.
3. Click **OK** to return to the Loan dialog box.

Figure 55.8 The Amortization Schedule with Rate Adjustments

The screenshot shows a 'Loan' dialog box with the following fields and buttons:

- Name:** untitled_loan
- Loan Specification:**
 - Loan Amount:** 80000
 - Initial Rate:** 6.00
 - Periodic Payment:** (empty)
 - Start Date:** 01JAN2000
 - Number of Payments:** 360
 - Payment Interval:** MONTH
 - Compounding Interval:** MONTH
- Buttons:** Initialization..., Prepayments..., Balloon Payments..., Rate Adjustments..., Rounding Off...
- Create Amortization Schedule** (button)
- Amortization Schedule Table:**

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Repay
AUG2029	3722.76	636.84	27.92	608.92
SEP2029	3113.84	636.84	23.35	613.49
OCT2029	2500.35	636.84	18.75	618.09
NOV2029	1882.26	636.84	14.12	622.72
DEC2029	1259.54	636.84	9.45	627.39
JAN2030	632.15	636.89	4.74	632.15
- Bottom Buttons:** Save Data As..., OK, Cancel, Help

Click **OK** to return to the Investment Analysis dialog box.

Specifying Savings Terms to Create an Account Summary

Suppose you put \$500 each month into an account that earns 6% interest for 20 years. What is the balance of the account after those 20 years?

In the Investment Analysis dialog box, select **Investment** → **New** → **Savings** from the menu bar to open the Savings dialog box.

To specify the savings, follow these steps:

1. Enter RETIREMENT for the **Name**.
2. Enter 500 for the **Periodic Deposit**.
3. Enter 240 for the **Number of Deposits**.
4. Enter 6 for the **Initial Rate**.

You must specify the savings before generating the account summary. After you have specified the savings, click **Create Account Summary** to compute the ending date and balance and to generate the account summary displayed in Figure 55.9.

Figure 55.9 Creating an Account Summary

The 'Savings' dialog box contains the following fields and controls:

- Name:** RETIREMENT
- Savings Specification:**
 - Periodic Deposit: 500
 - Start Date: 01JAN2000
 - Number of Deposits: 240
 - Deposit Interval: MONTH
 - Initial Rate: 6.00
 - Compounding Interval: MONTH
- Ending Date:** 01JAN2020
- Balance:** 232175.54982
- Create Account Summary** button
- Account Summary Table:**

Date	StartingBalance	Deposits	InterestEarned	EndingBalance
01JAN2000	0.00	500.00	0.00	500.00
01FEB2000	500.00	500.00	2.50	1002.50
01MAR2000	1002.50	500.00	5.01	1507.51
- Buttons: Save Data As..., OK, Cancel, Help

Click **OK** to return to the Investment Analysis dialog box.

Depreciation Tasks

Commercial assets are considered to lose value as time passes. For tax purposes, you want to quantify this loss. This investment structure helps calculate appropriate values.

Suppose you spend \$50,000 for a commercial fishing boat that is considered to have a ten-year useful life. How would you depreciate it?

In the Investment Analysis dialog box, select **Investment** → **New** → **Depreciation** from the menu bar to open the Depreciation dialog box.

Specifying Depreciation Terms to Create a Depreciation Table

To specify the depreciation, follow these steps:

1. Enter FISHING_BOAT for the **Name**.
2. Enter 50000 for the **Cost**.
3. Enter 2000 for the **Year of Purchase**.

4. Enter 10 for the **Useful Life**.
5. Enter 0 for the **Salvage Value**.

You must specify the depreciation before generating the depreciation schedule. After you have specified the depreciation, click **Create Depreciation Schedule** to generate a depreciation schedule like the one displayed in Figure 55.10.

Figure 55.10 Creating a Depreciation Schedule

The screenshot shows a 'Depreciation' dialog box with the following fields and options:

- Name:** FISHING_BOAT
- Depreciable Asset Specification:**
 - Cost:** 50000
 - Year of Purchase:** 2000
 - Useful Life:** 10
 - Salvage Value:** 0
- Depreciation Method:**
 - ☐ Straight Line (SL)
 - ☐ Sum-of-years-digits
 - ☐ Depreciation Table....
 - ☒ Declining Balance (DB)
- DB Factor:** ☒ 2 ☐ 1.5 ☐ 1
- Conversion to SL:** ☒ Yes ☐ No
- Create Depreciation Schedule** button

Below the dialog box is a table titled 'Depreciation Schedule' showing the following data:

Year	StartBookValue	Depreciation	EndBookValue
2000	50000.00	10000.00	40000.00
2001	40000.00	8000.00	32000.00
2002	32000.00	6400.00	25600.00
2003	25600.00	5120.00	20480.00
2004	20480.00	4096.00	16384.00

At the bottom of the dialog box are buttons for 'Save Data As...', 'OK', 'Cancel', and 'Help'.

The default depreciation method is Declining Balance (with Conversion to Straight Line). Try the following methods to see how they each affect the schedule:

- Straight Line
- Sum-of-years Digits
- Declining Balance (without conversion to Straight Line)

It might be useful to compare the value of the boat at 5 years for each method.

A description of these methods is available in the section “[Depreciation Methods](#)” on page 3409.

Using the Depreciation Table

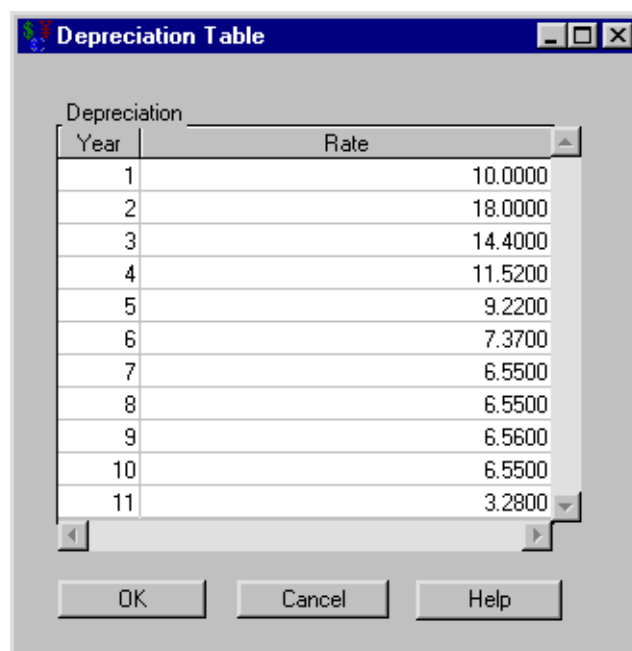

Sometimes you want to force the depreciation rates to be certain percentages each year. This option is particularly useful for calculating modified accelerated cost recovery system (MACRS) depreciations. The United States' Tax Reform Act of 1986 set depreciation rates for an asset based on an assumed lifetime for that asset. Since these lists of rates are important to many people, Investment Analysis provides SAS data sets for situations with yearly rates (using the “half-year convention”). Find them at `SASHELP.MACRS*` where * refers to the class of the property. For example, use `SASHELP.MACRS15` for a fifteen-year property. (When using the MACRS with the Tax Reform Act tables, you must set the **Salvage Value** to zero.)

Suppose you want to compute the depreciation schedule for the commercial fishing boat described in the section “[Depreciation Tasks](#)” on page 3346. The boat is a ten-year property according to the Tax Reform Act of 1986.

To employ the MACRS depreciation from the Depreciation dialog box, follow these steps:

1. Select the **Depreciation Table** option within the **Depreciation Method** area and click **OK**. This opens the Depreciation Table dialog box.
2. Right-click within the **Depreciation** area (which pops up a menu) and select **Load**.
3. Enter `SASHELP.MACRS10` for the **Dataset Name**. The dialog box should look like [Figure 55.11](#).

Figure 55.11 MACRS Percentages for a Ten-Year Property

The screenshot shows a window titled "Depreciation Table". Inside, there is a table with two columns: "Year" and "Rate". The table contains 11 rows of data. Below the table are three buttons: "OK", "Cancel", and "Help".

Year	Rate
1	10.0000
2	18.0000
3	14.4000
4	11.5200
5	9.2200
6	7.3700
7	6.5500
8	6.5500
9	6.5600
10	6.5500
11	3.2800

Click **OK** to return to the Depreciation dialog box. Click **Create Depreciation Schedule** and the depreciation schedule fills (see [Figure 55.12](#)).

Note there are eleven entries in this depreciation schedule. This is because of the half-year convention that enables you to deduct one half of a year the first year which leaves a half year to deduct after the useful life is over.

Figure 55.12 Depreciation Table with MACRS10

Conversion to SL: ☒ Yes ☐ No

Depreciation Schedule

Year	StartBookValue	Depreciation	EndBookValue
2000	50000.00	5000.00	45000.00
2001	45000.00	9000.00	36000.00
2002	36000.00	7200.00	28800.00
2003	28800.00	5760.00	23040.00
2004	23040.00	4608.00	18432.00

Click **OK** to return to the Investment Analysis dialog box.

Bond Tasks

Suppose someone offers to sell you a 20-year utility bond that was issued six years ago. It has a \$1,000 face value and pays semi-year coupons at 2%. You can purchase it for \$780. Would you be satisfied with this bond if you expect an 8% minimum attractive rate of return (MARR)?

In the Investment Analysis dialog box, select **Investment** → **New** → **Bond** from the menu bar to open the Bond dialog box.

Specifying Bond Terms

To specify the bond, follow these steps:

1. Enter **UTILITY_BOND** for the **Name**.
2. Enter 1000 for the **Face Value**.
3. Enter 2 for the **Coupon Rate**. The **Coupon Payment** updates to 20.
4. Select **SEMIYEAR** for **Coupon Interval**.

5. Enter 28 for the **Number of Coupons**. Because 14 years remain before the bond matures, the bond still has 28 semiyear coupons to pay. The **Maturity Date** updates.

Computing the Price from Yield

Enter 8 for **Yield** within the **Valuation** area. You see the bond's value would be \$666.72 as in Figure 55.13.

Figure 55.13 Bond Value

The screenshot shows a Windows-style dialog box titled "Bond". It contains two main sections: "Bond Specification" and "Valuation".

Bond Specification:

- Name: UTILITY_BOND
- Face Value: 1000
- Coupon Interval: SEMIYEAR (dropdown menu)
- Coupon Payment: 20
- Number of Coupons: 28
- Coupon Rate: 2.00
- Maturity Date: 01JAN2014

Valuation:

- Value: 666.73873564
- Yield: 8.00

Buttons: "Analyze...", "OK", "Cancel", "Help".

Computing the Yield from Price

Now enter 780 for **Value** within the **Valuation** area. You see the yield is only 6.5%, as in Figure 55.14. This is not acceptable if you desire an 8% MARR.

Figure 55.14 Bond Yield

The screenshot shows a 'Bond' dialog box with the following fields and values:

- Name:** UTILITY_BOND
- Bond Specification:**
 - Face Value: 1000
 - Coupon Interval: SEMIYEAR (dropdown)
 - Coupon Payment: 20
 - Number of Coupons: 28
 - Coupon Rate: 2.00
 - Maturity Date: 01JAN2014
- Valuation:**
 - Value: 780
 - Yield: 6.51
- Buttons:** Analyze..., OK, Cancel, Help

Performing Bond Analysis

To perform bond-pricing analysis, follow these steps:

1. Click **Analyze** to open the Bond Analysis dialog box.
2. Enter 8.0 as the **Yield to Maturity**.
3. Enter 4.0 as the **+/-**.
4. Enter 0.5 as the **Increment by**.
5. Enter 780 as the **Reference Price**.
6. Click **Create Bond Valuation Summary**.

The **Bond Valuation Summary** area fills and shows you the different values for various yields as in [Figure 55.15](#).

Graphics... Save Data As... Return Help

Creating a Price versus Yield-to-Maturity Graph

Click **Graphics** to open the Bond Price dialog box. This contains the price versus yield-to-maturity graph shown in Figure 55.16.

Figure 55.16 Bond Price Graph

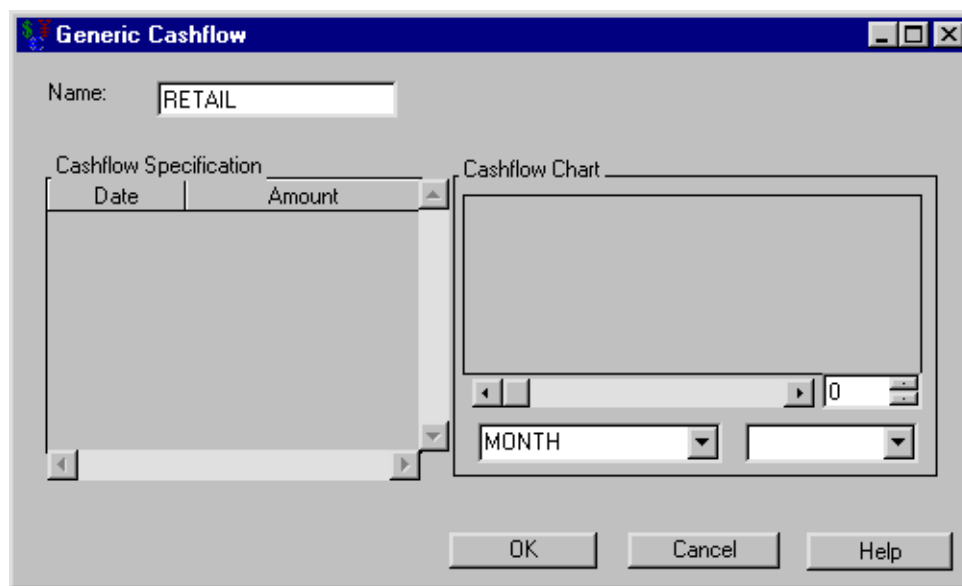

Click **Return** to return to the Bond Analysis dialog box. In the Bond Analysis dialog box, click **OK** to return to the Bond dialog box. In the Bond dialog box, click **OK** to return to the Investment Analysis dialog box.

Generic Cashflow Tasks

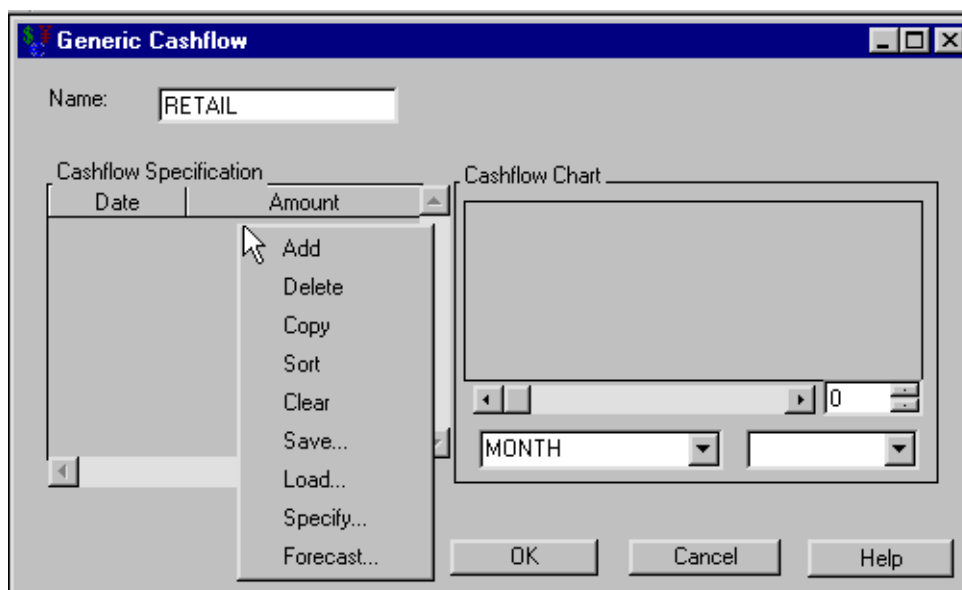

To specify a generic cashflow, you merely define any sequence of date-amount pairs. The flexibility of generic cashflows enables the user to represent economic alternatives or investments that do not fit into loan, savings, depreciation, or bond specifications.

In the Investment Analysis dialog box, select **Investment** → **New** → **Generic Cashflow** from the menu bar to open the **Generic Cashflow** dialog box. Enter RETAIL for the **Name** as in Figure 55.17.

Figure 55.17 Introducing the Generic Cashflow

Right-Clicking within the Cashflow Specification Area

Right-clicking within Generic Cashflow's **Cashflow Specification** area reveals the pop-up menu displayed in Figure 55.18. The menu provides many useful tools to assist you in creating these date-amount pairs.

Figure 55.18 Right-Clicking within the Cashflow Specification Area

The following sections describe how to use most of these right-click options. The **Specify** and **Forecast** menu items are described in the sections “[Including a Generated Cashflow](#)” on page 3356 and “[Including a Forecasted Cashflow](#)” on page 3358.

Adding a New Date-Amount Pair

To add a new date-amount pair manually, follow these steps:

1. Right-click in the **Cashflow Specification** area as shown in Figure 55.18, and release on **Add**.
2. Enter 01JAN01 for the date.
3. Enter 100 for the amount.

Copying a Date-Amount Pair

To copy a selected date-amount pair, follow these steps:

1. Select the pair you just created.
2. Right-click in the **Cashflow Specification** area as shown in Figure 55.18, but this time release on **Copy**.

Sorting All of the Date-Amount Pairs

Change the second date to 01JAN00. Now the dates are unsorted. Right-click in the **Cashflow Specification** area as shown in Figure 55.18, and release on **Sort**.

Deleting a Date-Amount Pair

To delete a selected date-amount pair, follow these steps:

1. Select a date-amount pair.
2. Right-click in the **Cashflow Specification** area as shown in Figure 55.18, and release on **Delete**.

Clearing All of the Date-Amount Pairs

To clear all date-amount pairs, right-click in the **Cashflow Specification** area as shown in Figure 55.18, and release on **Clear**.

Loading Date-Amount Pairs from a Data Set

To load date-amount pairs from a SAS data set into the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area, and release on **Load**. This opens the Load Dataset dialog box.
2. Enter SASHELP.RETAIL for **Dataset Name**.
3. Click **OK** to return to the Generic Cashflow dialog box.

If there is a **Date** variable in the SAS data set, Investment Analysis loads it into the list. If there is no date-time-formatted variable, it loads the first available date or date-time-formatted variable. Investment Analysis then searches the SAS data set for an **Amount** variable to use. If none exists, it takes the first numeric variable that is not used by the **Date** variable.

Saving Date-Amount Pairs to a Data Set

To save date-amount pairs from the **Cashflow Specification** area to a SAS data set, follow these steps:

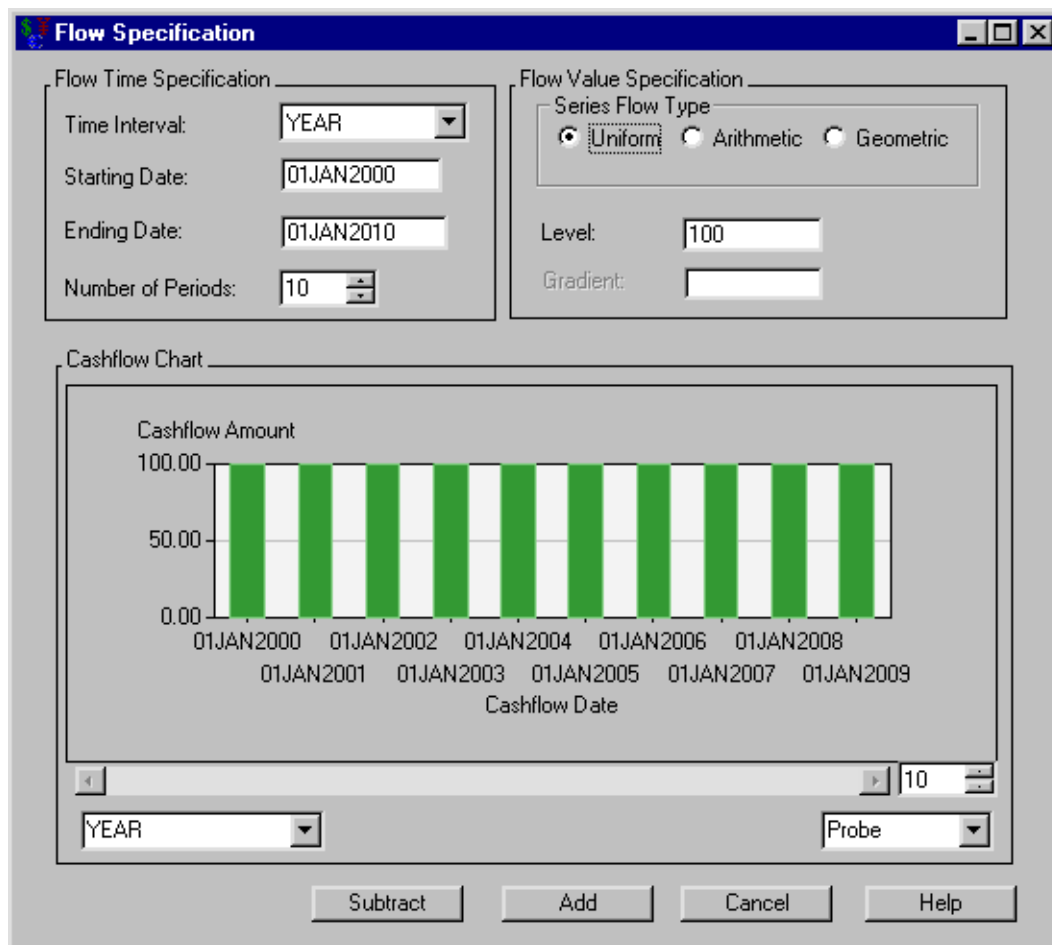

1. Right-click in the **Cashflow Specification** area and release on **Save**. This opens the Save Dataset dialog box.
2. Enter the name of the SAS data set for **Dataset Name**.
3. Click **OK** to return to the Generic Cashflow dialog box.

Including a Generated Cashflow

To generate date-amount pairs for the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Specify**. This opens the Flow Specification dialog box.
2. Select YEAR for the **Time Interval**.
3. Enter today's date for the **Starting Date**.
4. Enter 10 for the **Number of Periods**. The **Ending Date** updates.
5. Enter 100 for the level. You can visualize the specification in the Cashflow Chart area (see [Figure 55.19](#)).
6. Click **Add** to add the specified cashflow to the list in the Generic Cashflow dialog box. Clicking **Add** also returns you to the Generic Cashflow dialog box.

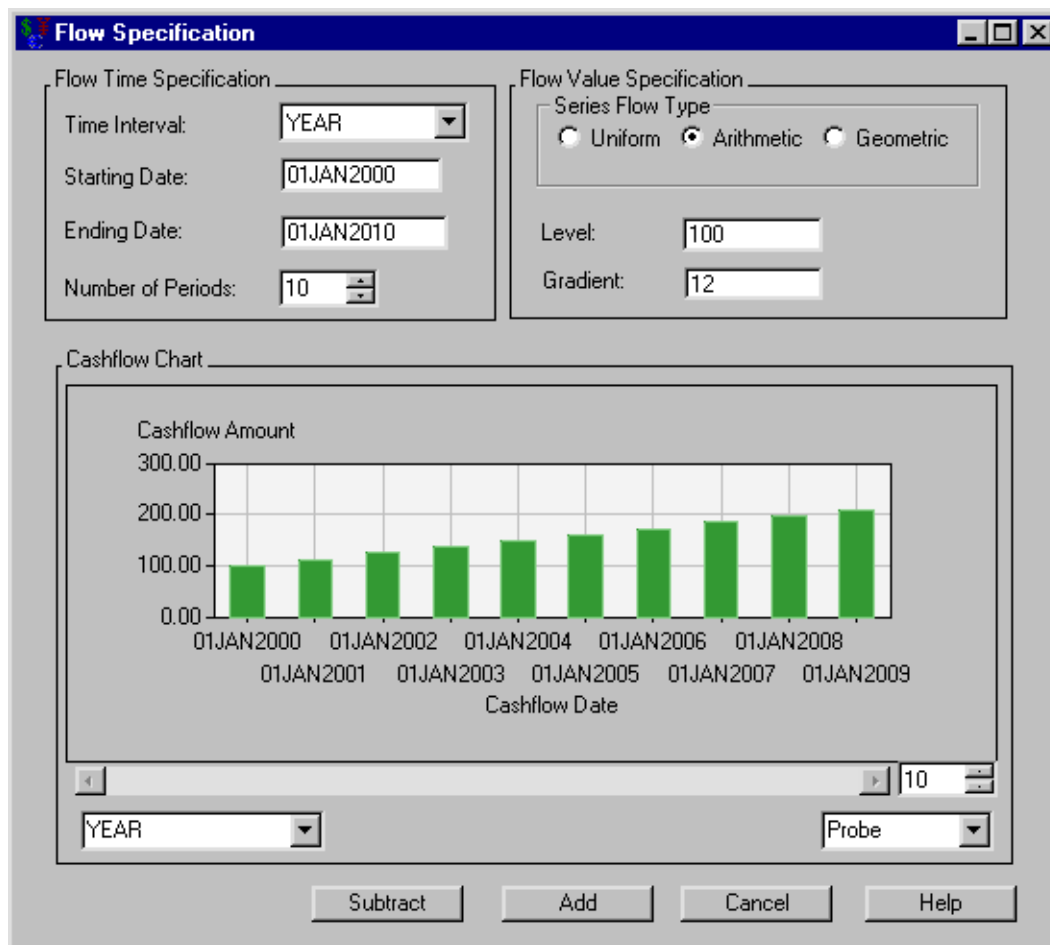

Figure 55.19 Uniform Cashflow Specification

Clicking **Subtract** subtracts the current cashflow from the Generic Cashflow dialog box, and it returns you to the Generic Cashflow dialog box.

You can generate arithmetic and geometric specifications by clicking them within the **Series Flow Type** area. However, you must enter a value for the **Gradient**. In both cases the **Level** value is the value of the list at the **Starting Date**. With an arithmetic flow type, entries increment by the value **Gradient** for each **Time Interval**. With a geometric flow type, entries increase by the factor **Gradient** for each **Time Interval**. Figure 55.20 displays an arithmetic cashflow with a **Level** of 100 and a **Gradient** of 12.

Figure 55.20 Arithmetic Cashflow Specification

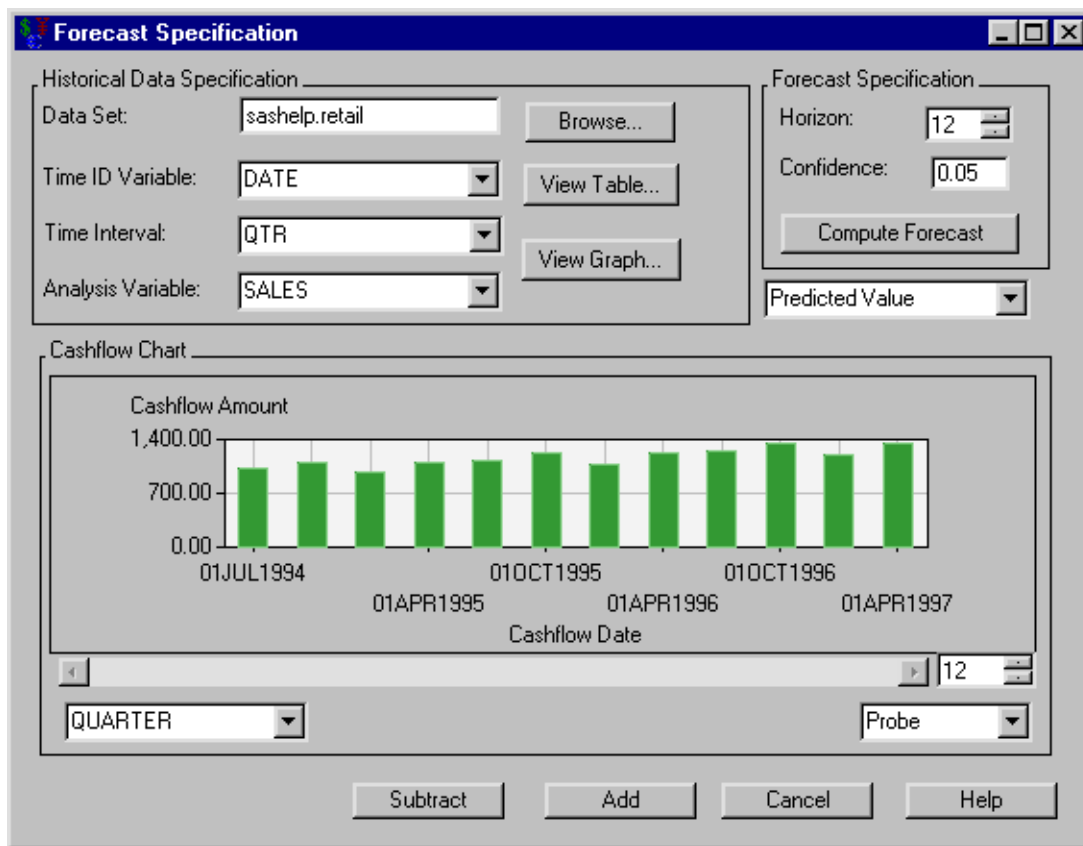

Including a Forecasted Cashflow

To generate date-amount pairs for the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Forecast** to open the **Forecast Specification** dialog box.
2. Enter `sashelp.retail` as the **Data Set**.
3. Select **SALES** for the **Analysis Variable**.
4. Click **Compute Forecast** to generate the forecast. You can visualize the forecast in the Cashflow Chart area (see Figure 55.21).
5. Click **Add** to add the forecast to the list in the Generic Cashflow dialog box. Clicking **Add** also returns you to the Generic Cashflow dialog box.

Figure 55.21 Cashflow Forecast

Clicking **Subtract** subtracts the current forecast from the Generic Cashflow dialog box, and it returns you to the Generic Cashflow dialog box.

To review the values from the SAS data set you forecast, click **View Table** or **View Graph**.

You can adjust the following values for the SAS data set you forecast: **Time ID Variable**, **Time Interval**, and **Analysis Variable**.

You can adjust the following values for the forecast: the **Horizon**, the **Confidence**, and choice of predicted value, lower confidence limit, and upper confidence limit.

Using the Cashflow Chart

Three dialog boxes contain the Cashflow Chart to aid in your visualization of cashflows: Generic Cashflow, Flow Specification, and Forecast Specification. Within this chart, you possess the following tools:

You can click on a bar in the plot and view its **Cashflow Date** and **Cashflow Amount**.

You can change the aggregation period of the view with the box in the lower-left corner of the Cashflow Chart. You can take the quarterly sales figures from the previous example, select **YEAR** as the value for this box, and view the annual sales figures. You can change the number in the box to the right of the horizontal scroll bar to alter the number of entries you want to view. The number in that box must be no greater than the number of entries in the cashflow list. Lessening this number has the effect of zooming in upon a portion of the cashflow. When the number is less than the number of entries in the cashflow list, you can use the scroll bar at the bottom of the chart to scroll through the chart.

Dialog Box Guide

Loan

Selecting **Investment** → **New** → **Loan** from the Investment Analysis dialog box's menu bar opens the Loan dialog box displayed in Figure 55.22.

Figure 55.22 Loan Dialog Box

The following items are displayed:

Name holds the name you assign to the loan. You can set the name here or within the **Portfolio** area of the **Investment Analysis** dialog box. This must be a valid SAS name.

The **Loan Specification** area gives access to the values that define the loan.

Loan Amount holds the borrowed amount.

Periodic Payment holds the value of the periodic payments.

Number of Payments holds the number of payments in loan terms.

Payment Interval holds the frequency of the Periodic Payment.

Compounding Interval holds the compounding frequency.

Initial Rate holds the interest rate (a nominal percentage between 0 and 120) you pay on the loan.

Start Date holds the SAS date when the loan is initialized. The first payment is due one **Payment Interval** after this time.

Initialization opens the [Loan Initialization Options](#) dialog box where you can define initialization costs and down-payments relevant to the loan.

Prepayments opens the [Loan Prepayments](#) dialog box where you can specify the SAS dates and amounts of any prepayments.

Balloon Payments opens the [Balloon Payments](#) dialog box where you can specify the SAS dates and amounts of any balloon payments.

Rate Adjustments opens the [Rate Adjustment Terms](#) dialog box where you can specify terms for a variable-rate loan.

Rounding Off opens the [Rounding Off](#) dialog box where you can select the number of decimal places for calculations.

Create Amortization Schedule becomes available when you adequately define the loan within the **Loan Specification** area. Clicking it generates the amortization schedule.

Amortization Schedule fills when you click **Create Amortization Schedule**. The schedule contains a row for the loan's start-date and each payment-date with information about the following:

Date is a SAS date, either the loan's start-date or a payment-date.

Beginning Principal Amount is the balance at that date.

Periodic Payment Amount is the expected payment at that date.

Interest Payment is zero for the loan's start-date; otherwise it holds the interest since the previous date.

Principal Repayment is the amount of the payment that went toward the principal.

Ending Principal is the balance at the end of the payment interval.

Print becomes available when you generate the amortization schedule. Clicking it sends the contents of the amortization schedule to the SAS session print device.

Save Data As becomes available when you generate the amortization schedule. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the amortization table (or portions thereof) as a SAS Dataset.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new loan specification, clicking **OK** appends the current loan specification to the portfolio. If this is an existing loan specification, clicking **OK** returns the altered loan specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new loan specification, clicking **Cancel** discards the current loan specification. If this is an existing loan specification, clicking **Cancel** discards the current changes.

Loan Initialization Options

Clicking **Initialization** in the Loan dialog box opens the Loan Initialization Options dialog box displayed in Figure 55.23.

Figure 55.23 Loan Initialization Options Dialog Box

Loan Initialization Options

Price, Loan Amount and Downpayment

Purchase Price:

Loan Amount: % of Price:

Downpayment: % of Price:

Initialization Costs and Discount Points

Loan Amount:

Initialization Costs: % of Amount:

Discount Points: % of Amount:

OK Cancel Help

The following items are displayed:

The **Price, Loan Amount and Downpayment** area contains the following information:

Purchase Price holds the actual price of the asset. This value equals the loan amount plus the downpayment.

Loan Amount holds the loan amount.

% of Price (to the right of **Loan Amount**) updates when you enter the **Purchase Price** and either the **Loan Amount** or **Downpayment**. This holds the percentage of the **Purchase Price** that comprises the **Loan Amount**. Setting the percentage manually causes the **Loan Amount** and **Downpayment** to update.

Downpayment holds any downpayment paid for the asset.

% of Price (to the right of **Downpayment**) updates when you enter the **Purchase Price** and either the **Loan Amount** or **Downpayment**. This holds the percentage of the **Purchase Price** that comprises the **Downpayment**. Setting the percentage manually causes the **Loan Amount** and **Downpayment** to update.

Initialization Costs and Discount Points area

Loan Amount holds a copy of the **Loan Amount** above.

Initialization Costs holds the value of any initialization costs.

% of Amount (to the right of **Initialization Costs**) updates when you enter the **Purchase Price** and either the **Initialization Costs** or **Discount Points**. This holds the percentage of the **Loan Amount** that comprises the **Initialization Costs**. Setting the percentage manually causes the **Initialization Costs** to update.

Discount Points holds the value of any discount points.

% of Amount (to the right of **Discount Points**) updates when you enter the **Purchase Price** and either the **Initialization Costs** or **Discount Points**. This holds the percentage of the **Loan Amount** that comprises the **Discount Points**. Setting the percentage manually causes the **Discount Points** to update.

OK returns you to the [Loan](#) dialog box, saving the information that is entered.

Cancel returns you to the [Loan](#) dialog box, discarding any changes made since you opened the dialog box.

Loan Prepayments

Clicking **Prepayments** in the Loan dialog box opens the Loan Prepayments dialog box displayed in [Figure 55.24](#).

Figure 55.24 Loan Prepayments Dialog Box

Prepayments	
Date	Amount
01JAN2000	0.00

The following items are displayed:

Uniform Prepayment holds the value of a regular prepayment concurrent to the usual periodic payment.

Prepayments holds a list of date-amount pairs to accommodate any prepayments. [Right-clicking](#) within the **Prepayments** area reveals many helpful tools for managing date-amount pairs.

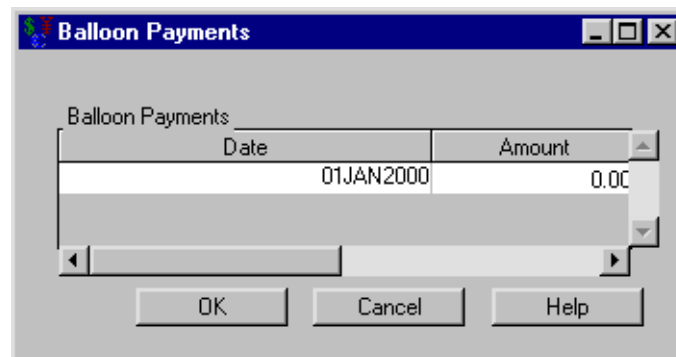

OK returns you to the [Loan](#) dialog box, storing the information entered on the prepayments.

Cancel returns you to the [Loan](#) dialog box, discarding any prepayments entered since you opened the dialog box.

Balloon Payments

Clicking **Balloon Payments** in the Loan dialog box opens the Balloon Payments dialog box displayed in Figure 55.25.

Figure 55.25 Balloon Payments Dialog Box

The following items are displayed:

Balloon Payments holds a list of date-amount pairs to accommodate any balloon payments. [Right-clicking](#) within the **Balloon Payments** area reveals many helpful tools for managing date-amount pairs.

OK returns you to the [Loan](#) dialog box, storing the information entered on the balloon payments.

Cancel returns you to the [Loan](#) dialog box, discarding any balloon payments entered since you opened the dialog box.

Rate Adjustment Terms

Clicking **Rate Adjustments** in the Loan dialog box opens the Rate Adjustment Terms dialog box displayed in Figure 55.26.

Figure 55.26 Rate Adjustment Terms Dialog Box

Rate Adjustment Terms

Rate Adjustment Terms:

Life Cap:

Periodic Cap:

Adjustment Frequency: months

Rate Adjustment Assumption

☒ Worst Case

☐ Best Case

☐ Fixed Case

☐ Estimated Case

Estimated Rates

Date	Rate
------	------

OK Cancel Help

The following items are displayed:

The **Rate Adjustment Terms** area

Life Cap holds the maximum deviation from the **Initial Rate** allowed over the life of the loan.

Periodic Cap holds the maximum adjustment allowed per adjustment.

Adjustment Frequency holds how often (in months) the lender can adjust the interest rate.

The **Rate Adjustment Assumption** determines the scenario the adjustments will take.

Worst Case uses information from the **Rate Adjustment Terms** area to forecast a worst-case scenario.

Best Case uses information from the **Rate Adjustment Terms** area to forecast a best-case scenario.

Fixed Case specifies a fixed-rate loan.

Estimated Case uses information from the **Rate Adjustment Terms** and **Estimated Rate** area to forecast a best-case scenario.

Estimated Rates holds a list of date-rate pairs, where each date is a SAS date and the rate is a nominal percentage between 0 and 120. The **Estimated Case** assumption uses these rates for its calculations. [Right-clicking](#) within the **Estimated Rates** area reveals many helpful tools for managing date-rate pairs.

OK returns you to the [Loan](#) dialog box, taking rate adjustment information into account.

Cancel returns you to the [Loan](#) dialog box, discarding any rate adjustment information provided since opening the dialog box.

Rounding Off

Clicking **Rounding Off** in the Loan dialog box opens the Rounding Off dialog box displayed in [Figure 55.27](#).

Figure 55.27 Rounding Off Dialog Box

The following items are displayed:

Decimal Places fixes the number of decimal places your results will display.

OK returns you to the [Loan](#) dialog box. Numeric values will then be represented with the number of decimals specified in **Decimal Places**.

Cancel returns you to the [Loan](#) dialog box. Numeric values will be represented with the number of decimals specified prior to opening this dialog box.

Savings

Selecting **Investment** → **New** → **Savings** from the Investment Analysis dialog box's menu bar opens the Savings dialog box displayed in [Figure 55.28](#).

Figure 55.28 Savings Dialog Box

The Savings Dialog Box contains the following elements:

- Name:** A text field containing "untitled_saving".
- Savings Specification:** A group box containing:
 - Periodic Deposit:** An empty text field.
 - Start Date:** A date field containing "01JAN2000".
 - Number of Deposits:** An empty text field.
 - Deposit Interval:** A dropdown menu set to "MONTH".
 - Initial Rate:** An empty text field.
 - Compounding Interval:** A dropdown menu set to "MONTH".
- Ending Date:** An empty text field.
- Balance:** An empty text field.
- Create Account Summary:** A button that becomes enabled after specifying the savings details.
- Account Summary:** A list box with a scrollbar, currently empty.
- Buttons:** "Save Data As...", "OK", "Cancel", and "Help" at the bottom.

The following items are displayed:

Name holds the name you assign to the savings. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

The **Savings Specification** area

Periodic Deposit holds the value of your regular deposits.

Number of Deposits holds the number of deposits into the account.

Initial Rate holds the interest rate (a nominal percentage between 0 and 120) the savings account earns.

Start Date holds the SAS date when deposits begin.

Deposit Interval holds the frequency of your **Periodic Deposit**.

Compounding Interval holds how often the interest compounds.

Create Account Summary becomes available when you adequately define the savings within the **Savings Specification** area. Clicking it generates the account summary.

Account Summary fills when you click **Create Account Summary**. The schedule contains a row for each deposit-date with information about the following:

Date is the SAS date of a deposit.

Starting Balance is the balance at that date.

Deposits is the deposit at that date.

Interest Earned is the interest earned since the previous date.

Ending Balance is the balance after the payment.

Print becomes available when you generate an account summary. Clicking it sends the contents of the account summary to the SAS session print device.

Save Data As becomes available when you generate an account summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the account summary (or portions thereof) as a SAS Dataset.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new savings, clicking **OK** appends the current savings specification to the portfolio. If this is an existing savings specification, clicking **OK** returns the altered savings to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new savings, clicking **Cancel** discards the current savings specification. If this is an existing savings, clicking **Cancel** discards the current changes.

Depreciation

Selecting **Investment** → **New** → **Depreciation** from the Investment Analysis dialog box's menu bar opens the Depreciation dialog box displayed in [Figure 55.29](#).

Figure 55.29 Depreciation Dialog Box

The screenshot shows the 'Depreciation' dialog box with the following details:

- Name:** untitled_depreciation
- Depreciable Asset Specification:**
 - Cost: [empty field]
 - Year of Purchase: 2000
 - Useful Life: [empty field]
 - Salvage Value: 0
- Depreciation Method:**
 - ☐ Straight Line (SL)
 - ☐ Sum-of-years-digits
 - ☐ Depreciation Table....
 - ☒ Declining Balance (DB)
- DB Factor:** ☒ 2 ☐ 1.5 ☐ 1
- Conversion to SL:** ☒ Yes ☐ No
- Create Depreciation Schedule** (button)
- Depreciation Schedule** (empty list box)
- Buttons:** Save Data As..., OK, Cancel, Help

The following items are displayed:

Name holds the name you assign to the depreciation. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

Depreciable Asset Specification

Cost holds the asset's original cost.

Year of Purchase holds the asset's year of purchase.

Useful Life holds the asset's useful life (in years).

Salvage Value holds the asset's value at the end of its **Useful Life**.

The **Depreciation Method** area holds the depreciation methods available:

- Straight Line
- Sum-of-years Digits
- [Depreciation Table](#)
- Declining Balance
 - DB Factor: choice of 2, 1.5, or 1
 - Conversion to SL: choice of Yes or No

Create Depreciation Schedule becomes available when you adequately define the depreciation within the **Depreciation Asset Specification** area. Clicking the **Create Depreciation Schedule** button then fills the **Depreciation Schedule** area.

Depreciation Schedule fills when you click **Create Depreciation Schedule**. The schedule contains a row for each year. Each row holds:

Year is a year.

Start Book Value is the starting book value for that year.

Depreciation is the depreciation value for that year.

End Book Value is the ending book value for that year.

Print becomes available when you generate the depreciation schedule. Clicking it sends the contents of the depreciation schedule to the SAS session print device.

Save Data As becomes available when you generate the depreciation schedule. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the depreciation table (or portions thereof) as a SAS Dataset.

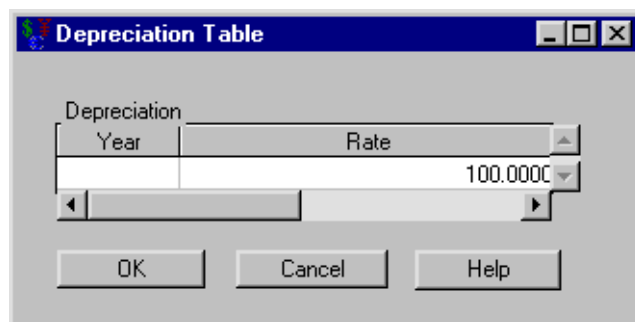

OK returns you to the [Investment Analysis](#) dialog box. If this is a new depreciation specification, clicking **OK** appends the current depreciation specification to the portfolio. If this is an existing depreciation specification, clicking **OK** returns the altered depreciation specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new depreciation specification, clicking **Cancel** discards the current depreciation specification. If this is an existing depreciation specification, clicking **Cancel** discards the current changes.

Depreciation Table

Clicking **Depreciation Table** from **Depreciation Method** area of the Depreciation dialog box opens the Depreciation Table dialog box displayed in Figure 55.30.

Figure 55.30 Depreciation Table Dialog Box

The following items are displayed:

The **Depreciation** area holds a list of year-rate pairs where the rate is an annual depreciation rate (a percentage between 0% and 100%). **Right-clicking** within the **Depreciation** area reveals many helpful tools for managing year-rate pairs.

OK returns you to the **Depreciation** dialog box with the current list of depreciation rates from the **Depreciation** area.

Cancel returns you to the **Depreciation** dialog box, discarding any editions to the **Depreciation** area since you opened the dialog box.

Bond

Selecting **Investment** → **New** → **Bond** from the Investment Analysis dialog box's menu bar opens the Bond dialog box displayed in Figure 55.31.

Figure 55.31 Bond

The screenshot shows a 'Bond' dialog box with the following fields and controls:

- Name:** A text field containing 'untitled_bond'.
- Bond Specification:** A group box containing:
 - Face Value:** A text field.
 - Coupon Payment:** A text field.
 - Coupon Rate:** A text field.
 - Coupon Interval:** A dropdown menu set to 'SEMIYEAR'.
 - Number of Coupons:** A text field.
 - Maturity Date:** A text field.
- Valuation:** A group box containing:
 - Value:** A text field.
 - Yield:** A text field.
- Analyze...:** A button located to the right of the 'Valuation' group box.
- OK, Cancel, Help:** Three buttons at the bottom of the dialog.

The following items are displayed:

Name holds the name you assign to the bond. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

Bond Specification

Face Value holds the bond's value at maturity.

Coupon Payment holds the amount of money you receive periodically as the bond matures.

Coupon Rate holds the rate (a nominal percentage between 0% and 120%) of the **Face Value** that defines the **Coupon Payment**.

Coupon Interval holds how often the bond pays its coupons.

Number of Coupons holds the number of coupons before maturity.

Maturity Date holds the SAS date when you can redeem the bond for its **Face Value**.

The **Valuation** area becomes available when you adequately define the bond within the **Bond Specification** area. Entering either the **Value** or the **Yield** causes the calculation of the other. If you respecify the bond after performing a calculation here, you must reenter the **Value** or **Yield** value to update the calculation.

Value holds the bond's value if expecting the specified **Yield**.

Yield holds the bond's yield if the bond is valued at the amount of **Value**.

You must specify the bond before analyzing it. After you have specified the bond, clicking **Analyze** opens the [Bond Analysis](#) dialog box where you can compare various values and yields.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new bond specification, clicking **OK** appends the current bond specification to the portfolio. If this is an existing bond specification, clicking **OK** returns the altered bond specification to the portfolio.

Cancel returns you to the **Investment Analysis** dialog box. If this is a new bond specification, clicking **Cancel** discards the current bond specification. If this is an existing bond specification, clicking **Cancel** discards the current changes.

Bond Analysis

Clicking **Analyze** from the Bond dialog box opens the Bond Analysis dialog box displayed in Figure 55.32.

Figure 55.32 Bond Analysis

The following items are displayed:

Analysis Specifications

Yield-to-maturity holds the percentage yield upon which to center the analysis.

+/- holds the maximum deviation percentage to consider from the **Yield-to-maturity**.

Increment by holds the percentage increment by which the analysis is calculated.

Reference Price holds the reference price.

Analysis Dates holds a list of SAS dates for which you perform the bond analysis.

You must specify the analysis before valuing the bond for the various yields. After you adequately specify the analysis, click **Create Bond Valuation Summary** to generate the bond valuation summary.

Bond Valuation Summary fills when you click **Create Bond Valuation Summary**. The schedule contains a row for each rate with information concerning the following:

Date is the SAS date when the **Value** gives the particular **Yield**.

Yield is the percent yield that corresponds to the **Value** at the given **Date**.

Value is the value of the bond at **Date** for the given **Yield**.

Percent Change is the percent change if the **Reference Price** is specified.

Duration is the duration.

Convexity is the convexity.

Graphics opens the [Bond Price](#) graph that represents the price versus yield-to-maturity.

Print becomes available when you generate the **Bond Valuation Summary**. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you fill the **Bond Valuation Summary** area. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the valuation summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Bond](#) dialog box.

Bond Price

Clicking **Graphics** from the Bond dialog box opens the Bond Price dialog box displayed in [Figure 55.33](#).

Figure 55.33 Bond Price Graph

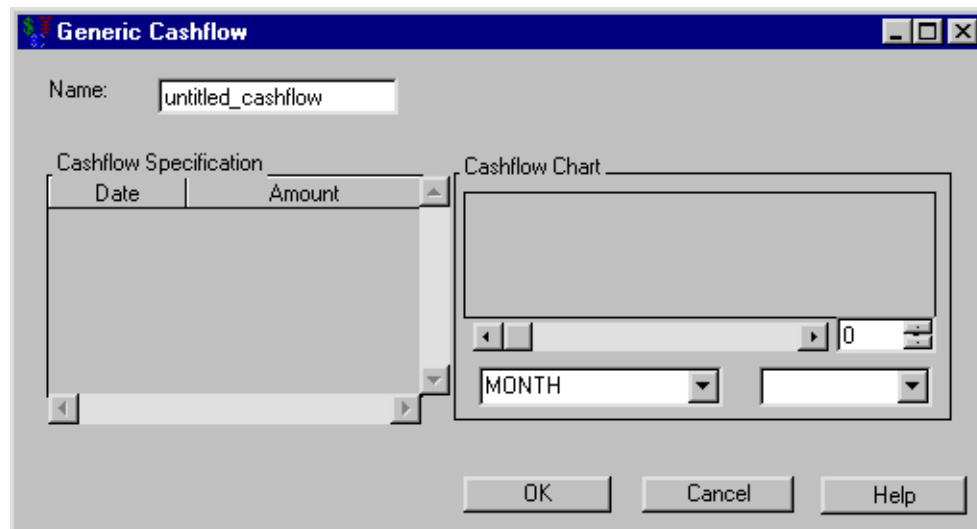

It possesses the following item:

Return takes you back to the [Bond Analysis](#) dialog box.

Generic Cashflow

Selecting **Investment** → **New** → **Generic Cashflow** from the Investment Analysis dialog box's menu bar opens the Generic Cashflow dialog box displayed in Figure 55.34.

Figure 55.34 Generic Cashflow

The following items are displayed:

Name holds the name you assign to the generic cashflow. You can set the name here or within the **Portfolio** area of the [Investment Analysis](#) dialog box. This must be a valid SAS name.

Cashflow Specification holds date-amount pairs that correspond to deposits and withdrawals (or benefits and costs) for the cashflow. Each date is a SAS date. [Right-clicking](#) within the **Cashflow Specification** area reveals many helpful tools for managing date-amount pairs.

The **Cashflow Chart** fills with a graph representing the cashflow when the **Cashflow Specification** area is nonempty. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency for drilling purposes.

OK returns you to the [Investment Analysis](#) dialog box. If this is a new generic cashflow specification, clicking **OK** appends the current cashflow specification to the portfolio. If this is an existing cashflow specification, clicking **OK** returns the altered cashflow specification to the portfolio.

Cancel returns you to the [Investment Analysis](#) dialog box. If this is a new cashflow specification, clicking **Cancel** discards the current cashflow specification. If this is an existing cashflow specification, clicking **Cancel** discards the current changes.

Right-Clicking within Generic Cashflow's Cashflow Specification Area

Right-click within the **Cashflow Specification** area of the Generic Cashflow dialog box pops up the menu displayed in Figure 55.35.

Figure 55.35 Right-Clicking

Add creates a blank pair.

Delete removes the currently highlighted pair.

Copy duplicates the currently selected pair.

Sort arranges the entered pairs in chronological order.

Clear empties the area of all pairs.

Save opens the [Save Dataset](#) dialog box where you can save the entered pairs as a SAS Dataset for later use.

Load opens the [Load Dataset](#) dialog box where you select a SAS Dataset to populate the area.

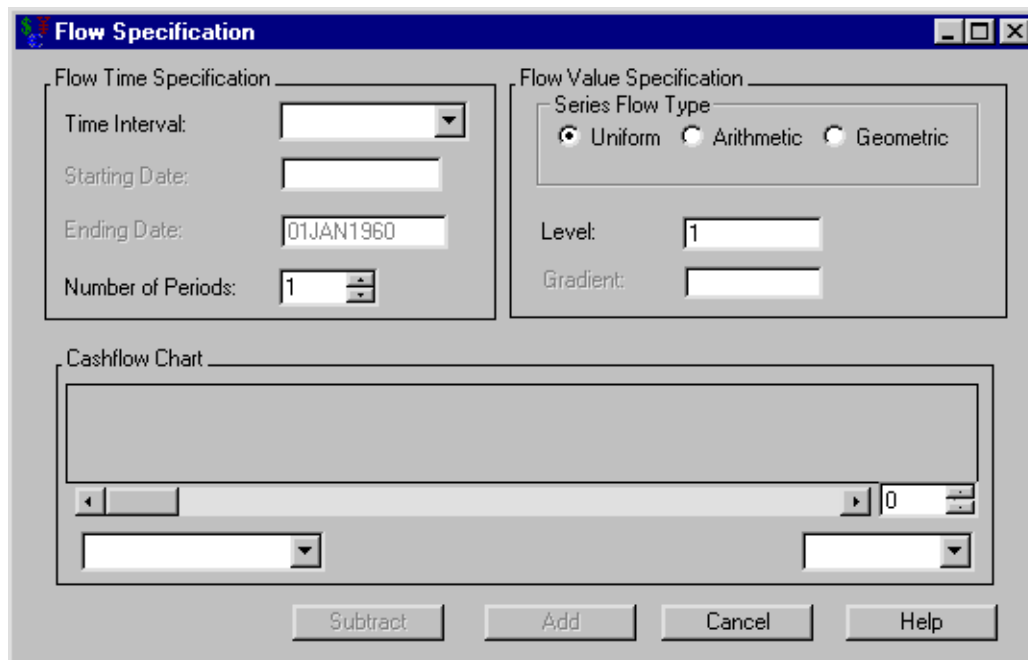

Specify opens the [Flow Specification](#) dialog box where you can generate date-rate pairs to include in your cashflow.

Forecast opens the [Forecast Specification](#) dialog box where you can generate the forecast of a SAS data set to include in your cashflow.

If you want to perform one of these actions on a collection of pairs, you must select a collection of pairs before right-clicking. To select an adjacent list of pairs, do the following: click the first pair, hold down the SHIFT key, and click the final pair. After the list of pairs is selected, you can release the SHIFT key.

Flow Specification

Figure 55.36 Flow Specification

The dialog box is titled "Flow Specification". It is divided into two main sections: "Flow Time Specification" and "Flow Value Specification".

Flow Time Specification:

- Time Interval:** A dropdown menu.
- Starting Date:** A text input field.
- Ending Date:** A text input field containing "01JAN1960".
- Number of Periods:** A spinner box set to "1".

Flow Value Specification:

- Series Flow Type:** A group box containing three radio buttons: "Uniform" (selected), "Arithmetic", and "Geometric".
- Level:** A text input field containing "1".
- Gradient:** A text input field.

Cashflow Chart:

A large rectangular area for a chart, with a horizontal axis at the bottom. The axis has a dropdown menu on the left and a text input field on the right containing "0". Below the chart area are two more dropdown menus.

Buttons: "Subtract", "Add", "Cancel", and "Help" are located at the bottom of the dialog.

The following items are displayed:

Flow Time Specification

Time Interval holds the uniform frequency of the entries.

You can set the **Starting Date** when you set the **Time Interval**. It holds the SAS date the entries will start.

You can set the **Ending Date** when you set the **Time Interval**. It holds the SAS date the entries will end.

Number of Periods holds the number of entries.

Flow Value Specification

Series Flow Type describes the movement the entries can assume:

- **Uniform** assumes all entries are equal.
- **Arithmetic** assumes the entries begin at **Level** and increase by the value of **Gradient** per entry.
- **Geometric** assumes the entries begin at **Level** and increase by a factor of **Gradient** per entry.

Level holds the starting amount for all flow types.

You can set the **Gradient** when you select either **Arithmetic** or **Geometric** series flow type. It holds the arithmetic and geometric gradients, respectively, for the **Arithmetic** and **Geometric** flow types.

When the cashflow entries are adequately defined, the **Cashflow Chart** fills with a graph displaying the dates and values of the entries. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency.

Subtract becomes available when the collection of entries is adequately specified. Clicking **Subtract** then returns you to the [Generic Cashflow](#) dialog box and subtracts the entries from the current cashflow.

Add becomes available when the collection of entries is adequately specified. Clicking **Add** then returns you to the [Generic Cashflow](#) dialog box and adds the entries to the current cashflow.

Cancel returns you to [Generic Cashflow](#) dialog box without changing the cashflow.

Forecast Specification

Figure 55.37 Forecast Specification

The screenshot shows the 'Forecast Specification' dialog box. It has a title bar with the text 'Forecast Specification'. The dialog is organized into several sections. The 'Historical Data Specification' section on the left contains four input fields: 'Data Set' with the value 'SASHELP.BUY', 'Time ID Variable' with a dropdown showing 'DATE', 'Time Interval' with a dropdown showing 'YEAR', and 'Analysis Variable' with a dropdown showing 'AMOUNT'. To the right of these fields are three buttons: 'Browse...', 'View Table...', and 'View Graph...'. The 'Forecast Specification' section on the right contains two input fields: 'Horizon' with the value '12' and 'Confidence' with the value '0.05'. Below these is a 'Compute Forecast' button and a 'Predicted Value' dropdown menu. At the bottom of the dialog is a 'Cashflow Chart' section, which includes a large rectangular area for the chart, a horizontal scroll bar, and a frequency dropdown menu currently set to 'MONTH'. A 'Probe' button is located to the right of the frequency dropdown. At the very bottom of the dialog are four buttons: 'Subtract', 'Add', 'Cancel', and 'Help'.

The following items are displayed:

Historical Data Specification

Data Set holds the name of the SAS data set to forecast.

Browse opens the standard SAS **Open** dialog box to help select a SAS data set to forecast.

Time ID Variable holds the time ID variable to forecast over.

Time Interval fixes the time interval for the **Time ID Variable**.

Analysis Variable holds the data variable upon which to forecast.

View Table opens a table that displays the contents of the specified SAS data set.

View Graph opens the Time Series Viewer that graphically displays the contents of the specified SAS data set.

Forecast Specification

Horizon holds the number of periods into the future you want to forecast.

Confidence holds the confidence limit for applicable forecasts.

Compute Forecast fills the **Cashflow Chart** with the forecast.

The box below **Forecast Specification** holds the type of forecast you want to generate:

- Predicted Value
- Lower Confidence Limit
- Upper Confidence Limit

The **Cashflow Chart** fills when you click **Compute Forecast**. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency.

Subtract becomes available when the collection of entries is adequately specified. Clicking **Subtract** then returns you to the [Generic Cashflow](#) dialog box subtracting the forecast from the current cashflow.

Add becomes available when the collection of entries is adequately specified. Clicking **Add** then returns you to the [Generic Cashflow](#) adding the forecast to the current cashflow.

Cancel returns to [Generic Cashflow](#) dialog box without changing the cashflow.

Computations

Contents

The Compute Menu	3379
Tasks	3380
Taxing a Cashflow	3380
Converting Currency	3382
Deflating Cashflows	3384
Dialog Box Guide	3386
After Tax Cashflow Calculation	3386
Currency Conversion	3387
Constant Dollar Calculation	3388

The Compute Menu

Figure 56.1 shows the **Compute** menu.

Figure 56.1 The Compute Menu

The **Compute** menu offers the following options that apply to generic cashflows.

After Tax Cashflow opens the **After Tax Cashflow Calculation** dialog box. Computing an after tax cashflow is useful when taxes affect investment alternatives differently. Comparing after tax cashflows provides a more accurate determination of the cashflows' profitabilities. You can set default values for income tax rates by selecting **Tools** → **Define Rate** → **Income Tax Rate** from the Investment Analysis dialog box. This opens the **Income Tax Specification** dialog box where you can enter the tax rates.

Currency Conversion opens the **Currency Conversion** dialog box. Currency conversion is necessary when investments are in different currencies. For data concerning currency conversion rates, see <http://dsbb.imf.org/>, the International Monetary Fund's Dissemination Standards Bulletin Board.

Constant Dollars opens the **Constant Dollar Calculation** dialog box. A constant dollar (inflation adjusted monetary value) calculation takes cashflow and inflation information and discounts the cashflow to a level where the buying power of the monetary unit is constant over time. Groups quantify inflation (in the

form of price indices and inflation rates) for countries and industries by averaging the growth of prices for various products and sectors of the economy. For data concerning price indices, see the United States Department of Labor at <http://www.dol.gov/> and the International Monetary Fund's Dissemination Standards Bulletin Board at <http://dsbb.imf.org/>. You can set default values for inflation rates by clicking **Tools** → **Define Rate** → **Inflation** from the Investment Analysis dialog box. This opens the **Inflation Specification** dialog box where you can enter the inflation rates.

Tasks

The next few sections show how to perform computations for the following situation. Suppose you buy a \$10,000 certificate of deposit that pays 12% interest a year for five years. Your earnings are taxed at a rate of 30% federally and 7% locally. Also, you want to transfer all the money to an account in England. British pounds convert to American dollars at an exchange rate of \$1.00 to £0.60. The inflation rate in England is 3%. The instructions in this example assume familiarity with the following:

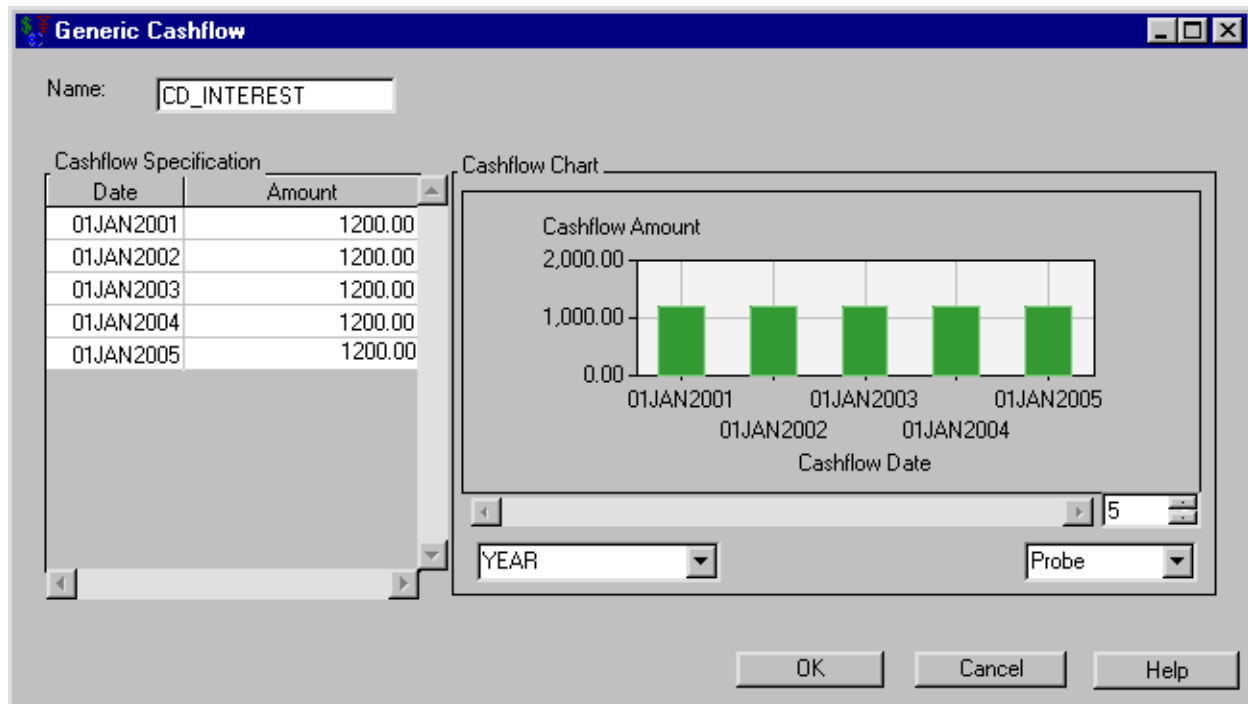

- The right-clicking options of the **Cashflow Specification** area in the Generic Cashflow dialog box (described in the section “[Right-Clicking within Generic Cashflow's Cashflow Specification Area](#)” on page 3375.)
- The **Save Data As** button located in many dialog boxes (described in the section “[Saving Output to SAS Data Sets](#)” on page 3405.)

Taxing a Cashflow

Consider the example described in the section “[The Compute Menu](#)” on page 3379. To create the earnings, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to create a generic cashflow.
2. Enter CD_INTEREST for the **Name**.
3. Enter 1200 for each of the five years starting one year from today as displayed in [Figure 56.2](#).
4. Click **OK** to return to the Investment Analysis dialog box.

Figure 56.2 Computing the Interest on the CD

To compute the tax on the earnings, follow these steps:

1. Select CD_INTEREST from the **Portfolio** area.
2. Select **Compute** → **After Tax Cashflow** from the pull-down menu.
3. Enter 30 for **Federal Tax**.
4. Enter 7 for **Local Tax**. Note that **Combined Tax** updates.
5. Click **Create After Tax Cashflow**. The **After Tax Cashflow** area fills, as displayed in Figure 56.3.

Figure 56.3 Computing the Interest After Taxes

After Tax Cashflow Calculation

Name:

Federal Tax:

Local Tax:

Combined Tax:

After Tax Cashflow

Date	Amount
01JAN2001	781.20
01JAN2002	781.20
01JAN2003	781.20
01JAN2004	781.20
01JAN2005	781.20

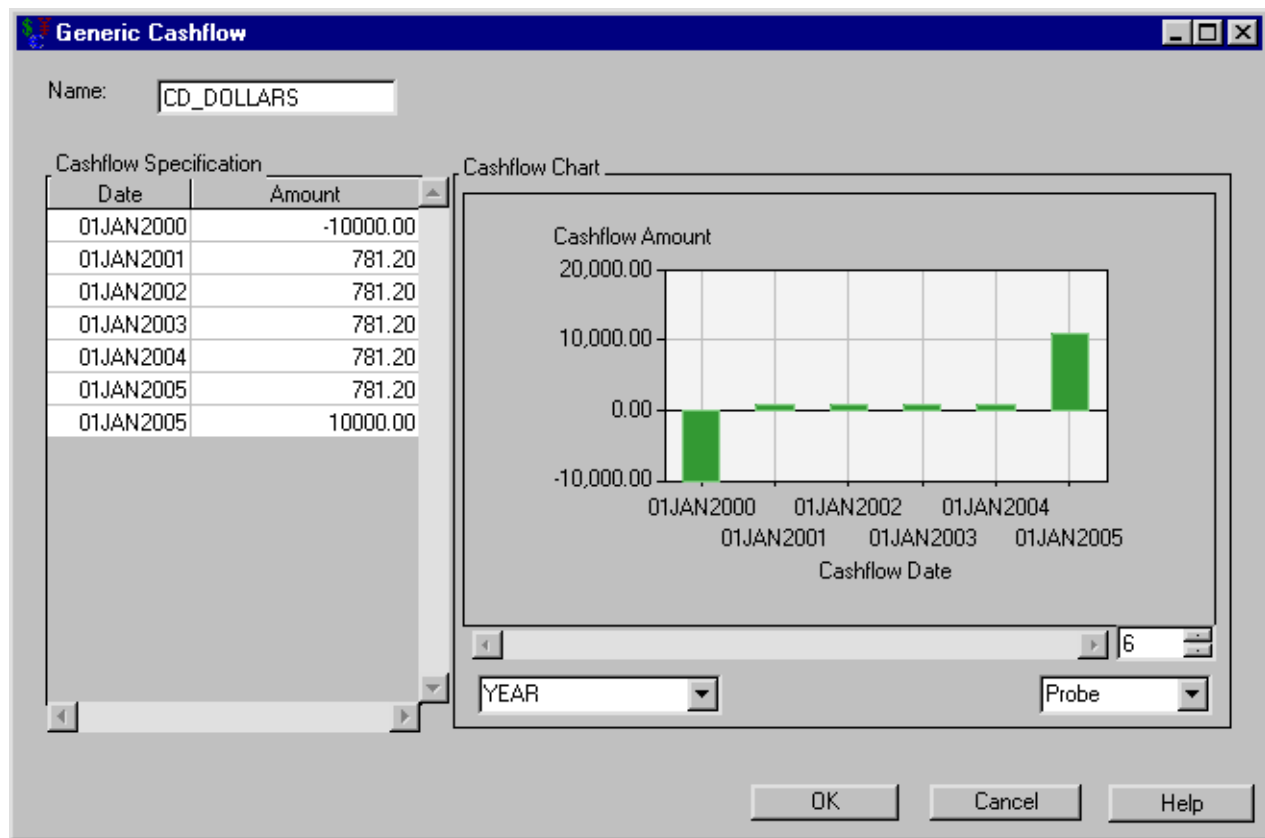

Save the taxed earnings to a SAS data set named WORK.CD_AFTERTAX. Click **Return** to return to the Investment Analysis dialog box.

Converting Currency

Consider the example described in the section “[The Compute Menu](#)” on page 3379. To create the cashflow to convert, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to open a new generic cashflow.
2. Enter CD_DOLLARS for the **Name**.
3. Load WORK.CD_AFTERTAX into its **Cashflow Specification**.
4. Add –10,000 for today and +10,000 for five years from today to the cashflow as displayed in [Figure 56.4](#).
5. Sort the transactions by date to aid your reading.
6. Click **OK** to return to the Investment Analysis dialog box.

Figure 56.4 The CD in Dollars

To convert from British pounds to American dollars, follow these steps:

1. Select CD_DOLLARS from the portfolio.
2. Select **Compute** → **Currency Conversion** from the pull-down menu. This opens the Currency Conversion dialog box.
3. Select USD for the **From Currency**.
4. Select GBP for the **To Currency**.
5. Enter 0.60 for the **Exchange Rate**.
6. Click **Apply Currency Conversion** to fill the **Currency Conversion** area as displayed in Figure 56.5.

Figure 56.5 Converting the CD to Pounds

Currency Conversion

Name:

From Currency:

To Currency:

Exchange Rate:

Date	CD_DOLLARS	GBP
01JAN2000	-10000.00	-6000.00
01JAN2001	781.20	468.72
01JAN2002	781.20	468.72
01JAN2003	781.20	468.72
01JAN2004	781.20	468.72
01JAN2005	781.20	468.72
01JAN2005	10000.00	6000.00

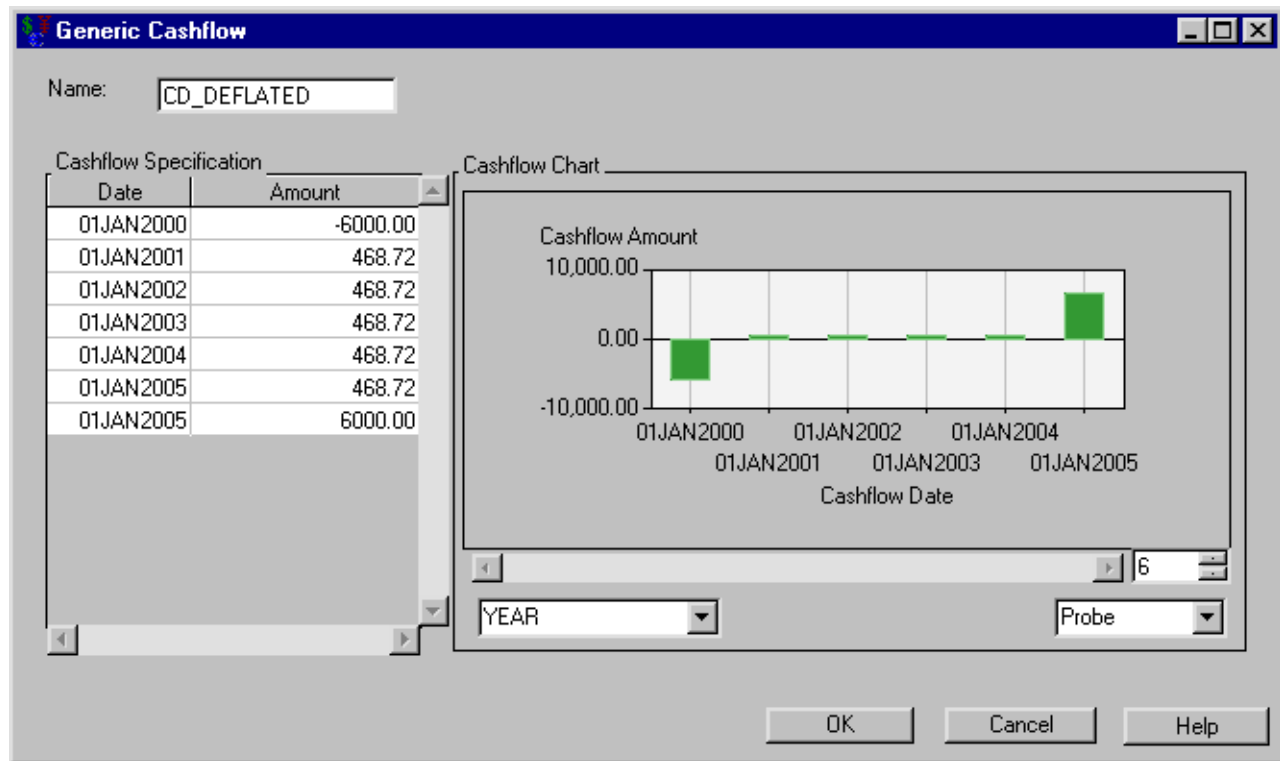

Save the converted values to a SAS data set named WORK.CD_POUNDS. Click **Return** to return to the Investment Analysis dialog box.

Deflating Cashflows

Consider the example described in the section “[The Compute Menu](#)” on page 3379. To create the cashflow to deflate, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to open a new generic cashflow.
2. Enter CD_DEFLATED for **Name**.
3. Load WORK.CD_POUNDS into its **Cashflow Specification** (see [Figure 56.6](#)).
4. Click **OK** to return to the Investment Analysis dialog box.

Figure 56.6 The CD before Deflation

To deflate the values, follow these steps:

1. Select CD_DEFLATED from the portfolio.
2. Select **Compute** → **Constant Dollars** from the menu. This opens the Constant Dollar Calculation dialog box.
3. Clear the **Variable Inflation List** area.
4. Enter 3 for the **Constant Inflation Rate**.
5. Click **Create Constant Dollar Equivalent** to generate a constant dollar equivalent summary (see Figure 56.7).

Figure 56.7 CD Values after Deflation

Constant Dollar Calculation

Name:

Constant Inflation Rate:

Variable Inflation List

Date	Rate

Dates

Date
01JAN2000

Constant Dollar Equivalent Summary

Date	JAN2000
01JAN2000	-6000.00
01JAN2001	455.07
01JAN2002	441.81
01JAN2003	428.95
01JAN2004	416.45
01JAN2005	404.32
01JAN2005	5175.65

You can save the deflated cashflow to a SAS data set for use in an internal rate of return analysis or breakeven analysis.

Click **Return** to return to the Investment Analysis dialog box.

Dialog Box Guide

After Tax Cashflow Calculation

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an after tax calculation, select **Compute** → **After Tax** from the Investment Analysis dialog box's menu bar. This opens the After Tax Cashflow Calculation dialog box displayed in [Figure 56.8](#).

Figure 56.8 After Tax Cashflow Calculation Dialog Box

The following items are displayed:

Name holds the name of the investment for which you are computing the after-tax cashflow.

Federal Tax holds the federal tax rate (a percentage between 0% and 100%).

Local Tax holds the local tax rate (a percentage between 0% and 100%).

Combined Tax holds the effective tax rate from federal and local income taxes.

Create After Tax Cashflow becomes available when **Combined Tax** is not empty. Clicking **Create After Tax Cashflow** then fills the **After Tax Cashflow** area.

After Tax Cashflow fills when you click **Create After Tax Cashflow**. It holds a list of date-amount pairs where the amount is the amount retained after taxes for that date.

Print becomes available when you fill the after-tax cashflow. Clicking it sends the contents of the after tax cashflow to the SAS session print device.

Save Data As becomes available when you fill the after tax cashflow. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the resulting cashflow (or portions thereof) as a SAS Dataset.

Return returns you to the [Investment Analysis](#) dialog box.

Currency Conversion

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a currency conversion, select **Compute** → **Currency Conversion** from the Investment Analysis dialog box's menu bar. This opens the Currency Conversion dialog box displayed in [Figure 56.9](#).

Figure 56.9 Currency Conversion Dialog Box

The screenshot shows a Windows-style dialog box titled "Currency Conversion". It has a blue title bar with standard window controls. The main area contains several input fields and buttons. The "Name" field is labeled "Name:" and contains the text "untitled_cashflo". Below it are two dropdown menus: "From Currency:" set to "USD" and "To Currency:" set to "GBP". An "Exchange Rate:" field is empty. To the right of these fields is a button labeled "Apply Currency Conversion". Below the exchange rate field is a large rectangular area labeled "Currency Conversion" which appears to be a table or list with a scrollbar. At the bottom of the dialog are three buttons: "Save Data As...", "Return", and "Help".

The following items are displayed:

Name holds the name of the investment to which you are applying the currency conversion.

From Currency holds the name of the currency the cashflow currently represents.

To Currency holds the name of the currency to which you wish to convert.

Exchange Rate holds the rate of exchange between the **From Currency** and the **To Currency**.

Apply Currency Conversion becomes available when you fill **Exchange Rate**. Clicking **Apply Currency Conversion** fills the **Currency Conversion** area.

Currency Conversion fills when you click **Apply Currency Conversion**. The schedule contains a row for each cashflow item with the following information:

- **Date** is a SAS date within the cashflow.
- The **From Currency** value is the amount in the original currency at that date.
- The **To Currency** value is the amount in the new currency at that date.

Print becomes available when you fill the **Currency Conversion** area. Clicking it sends the contents of the conversion table to the SAS session print device.

Save Data As becomes available when you fill the **Currency Conversion** area. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the conversion table (or portions thereof) as a SAS Dataset.

Return returns you to the [Investment Analysis](#) dialog box.

Constant Dollar Calculation

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a constant dollar calculation, select **Compute** → **Constant Dollars** from the Investment Analysis dialog box's menu bar. This opens the Constant Dollar Calculation dialog box displayed in [Figure 56.10](#).

Figure 56.10 Constant Dollar Calculation Dialog Box

Constant Dollar Calculation

Name:

Constant Inflation Rate:

Variable Inflation List

Date	Rate
01JAN2000	0.0000

Dates

Date
01JAN2000

Constant Dollar Equivalent Summary

The following items are displayed:

Name holds the name of the investment for which you are computing the constant dollars value.

Constant Inflation Rate holds the constant inflation rate (a percentage between 0% and 120%). This value is used if the **Variable Inflation List** area is empty.

Variable Inflation List holds date-rate pairs that describe how inflation varies over time. Each date is a SAS date, and the rate is a percentage between 0% and 120%. Each date refers to when that inflation rate begins. Right-clicking within the **Variable Inflation** area reveals many helpful tools for managing date-rate pairs. If you assume a fixed inflation rate, just insert that rate in **Constant Rate**.

Dates holds the SAS date(s) at which you wish to compute the constant dollar equivalent. Right-clicking within the **Dates** area reveals many helpful tools for managing date lists.

Create Constant Dollar Equivalent becomes available when you enter inflation rate information. Clicking it fills the constant dollar equivalent summary with the computed constant dollar values.

Constant Dollar Equivalent Summary fills with a summary when you click **Create Constant Dollar Equivalent**. The first column lists the dates of the generic cashflow. The second column contains the constant dollar equivalent of the original generic cashflow item of that date.

Print becomes available when you fill the constant dollar equivalent summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you fill the constant dollar equivalent summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return returns you to the [Investment Analysis](#) dialog box.

Time Value Analysis	3399
Uniform Periodic Equivalent	3400
Internal Rate of Return	3401
Benefit-Cost Ratio Analysis	3402
Breakeven Analysis	3403
Breakeven Graph	3404

The Analyze Menu

Figure 57.1 shows the **Analyze** menu.

Figure 57.1 Analyze Menu

The **Analyze** menu offers the following options for use on applicable investments.

Time Value opens the **Time Value Analysis** dialog box. Time value analysis involves moving money through time across a defined minimum attractive rate of return (MARR) so that you can compare value at a consistent date. The MARR can be constant or variable over time.

Periodic Equivalent opens the **Uniform Periodic Equivalent** dialog box. Uniform periodic equivalent analysis determines the payment needed to convert a cashflow to uniform amounts over time, given a periodicity, a number of periods, and a MARR. This option helps when making comparisons where one alternative is uniform (such as renting) and another is not (such as buying).

Internal Rate of Return opens the **Internal Rate of Return** dialog box. The internal rate of return of a cashflow is the interest rate that makes the time value equal to 0. This calculation assumes uniform periodicity of the cashflow. It is particularly applicable where the choice of MARR would be difficult.

Benefit-Cost Ratio opens the **Benefit-Cost Ratio Analysis** dialog box. The benefit-cost ratio divides the time value of the benefits by the time value of the costs. For example, governments often use this analysis when deciding whether to commit to a public works project.

Breakeven Analysis opens the **Breakeven Analysis** dialog box. Breakeven analysis computes time values at various MARRs to compare, which can be advantageous when it is difficult to determine a MARR. This analysis can help you determine how the cashflow's profitability varies with your choice of MARR. A graph displaying the relationships between time value and MARR is also available.

Tasks

Performing Time Value Analysis

Suppose a rock quarry needs equipment to use the next five years. It has two alternatives:

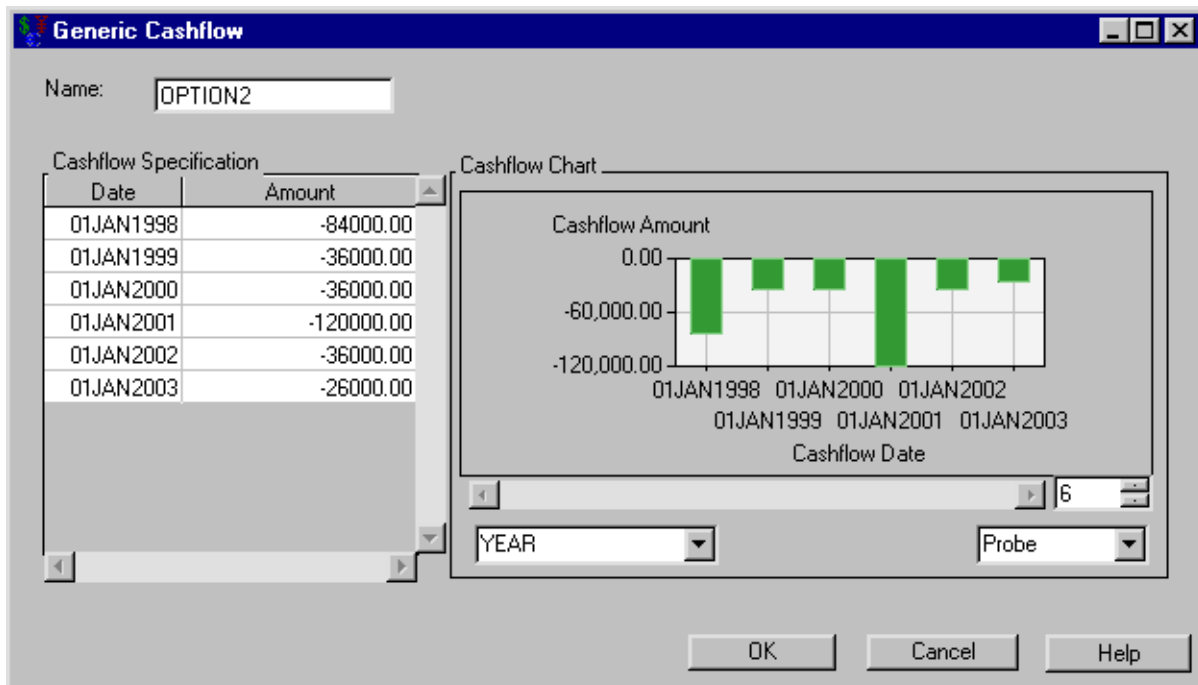

- a box loader and conveyer system that has a one-time cost of \$264,000
- a two-shovel loader, which costs \$84,000 but has a yearly operating cost of \$36,000. This loader has a service life of three years, which necessitates the purchase of a new loader for the final two years of the rock quarry project. Assume the second loader also costs \$84,000 and its salvage value after its two-year service is \$10,000. A SAS data set that describes this is available at `SASHELP.ROCKPIT`

You expect a 13% MARR. Which is the better alternative?

To create the cashflows, follow these steps:

1. Create a cashflow with the single amount –264,000. Date the amount 01JAN1998 to be consistent with the SAS data set you load.
2. Load SASHELP.ROCKPIT into a second cashflow, as displayed in [Figure 57.2](#).

Figure 57.2 The contents of SASHELP.ROCKPIT

To compute the time values of these investments, follow these steps:

1. Select both cashflows.
2. Select **Analyze** → **Time Value**. This opens the Time Value Analysis dialog box.
3. Enter the date 01JAN1998 into the **Dates** area.
4. Enter 13 for the **Constant MARR**.
5. Click **Create Time Value Summary**.

Figure 57.3 Performing the Time Value Analysis

Time Value Analysis

Analysis Specifications

Dates: 01JAN1998

Constant MARR: 13.00

MARR List

Time Value Summary

Date	OPTION1	OPTION2
01JAN1998	-264000.00	-263408.94

Buttons: Create Time Value Summary, Save Data As..., Return, Help

As shown in Figure 57.3, option 1 has a time value of $-\$264,000.00$ naturally on 01JAN1998. However, option 2 has a time value of $-\$263,408.94$, which is slightly less expensive.

Computing an Internal Rate of Return

You are choosing between five investments. A portfolio containing these investments is available at SASHELP.INVSAMP.NVST. Which investments are acceptable if you expect a MARR of 9%?

Open the portfolio SASHELP.INVSAMP.NVST and compare the investments. Note that Internal Rate of Return computations assume regular periodicity of the cashflow. To compute the internal rates of return, follow these steps:

1. Select all five investments.
2. Select **Analyze** → **Internal Rate of Return**.

Figure 57.4 Computing an Internal Rate of Return

Name	IRR	interval
nvst1	7.9308	YEAR
nvst2	9.0009	YEAR
nvst3	7.9308	YEAR
nvst4	13.5526	YEAR
nvst5	11.8410	YEAR

The results displayed in [Figure 57.4](#) indicate that the internal rates of return for investments 2, 4, and 5 are greater than 9%. Hence, each of these is acceptable.

Performing a Benefit-Cost Ratio Analysis

Suppose a municipality has excess funds to invest. It is choosing between the same investments described in the previous example. Government agencies often compute benefit-cost ratios to decide which investment to pursue. Which is best in this case?

Open the portfolio SASHELP.INVSAMP.NVST and compare the investments.

To compute the benefit-cost ratios, follow these steps:

1. Select all five investments.
2. Select **Analyze** → **Benefit-Cost Ratio**.
3. Enter 01JAN1996 for the **Date**.
4. Enter 9 for **Constant MARR**.
5. Click **Create Benefit-Cost Ratio Summary** to fill the **Benefit-Cost Ratio Summary** area.

The results displayed in [Figure 57.5](#) indicate that investments 2, 4, and 5 have ratios greater than 1. Therefore, each is profitable with a MARR of 9%.

Figure 57.5 Performing a Benefit-Cost Ratio Analysis

Buttons: Create Benefit-Cost Ratio Summary, Save Data As..., Return, Help

Computing a Uniform Periodic Equivalent

Suppose you need a warehouse for ten years. You have two options:

- pay rent for ten years at \$23,000 per year
- build a two-stage facility that you will maintain and which you intend to sell at the end of those ten years

Data sets describing these scenarios are available in the portfolio SASHELP.INVSAMP.BUYRENT. Which option is more financially sound if you desire a 12% MARR?

Open the portfolio SASHELP.INVSAMP.BUYRENT and compare the options.

To perform the periodic equivalent, follow these steps:

1. Load the portfolio SASHELP.INVSAMP.BUYRENT.
2. Select both cashflows.
3. Select **Analyze** → **Periodic Equivalent**.
This opens the Uniform Periodic Equivalent dialog box.
4. Enter 01JAN1996 for the **Start Date**.
5. Enter 10 for the **Number of Periods**.
6. Select YEAR for the **Interval**.

7. Enter 12 for the **Constant MARR**.
8. Click **Create Time Value Summary**.

Figure 57.6 Computing a Uniform Periodic Equivalent

Uniform Periodic Equivalent

Analysis Specifications

Start Date: 01JAN1996 Interval: YEAR

Number of Periods: 10 Constant MARR: 12.00

Create Periodic Equivalent Summary

Periodic Equivalent Summary

Name	Amount
buy	-21868.44
rent	-20535.71

Save Data As... Return Help

Figure 57.6 indicates that renting costs about \$1,300 less each year. Hence, renting is more financially sound. Notice the periodic equivalent for renting is not \$23,000. This is because the \$23,000 per year does not account for the MARR.

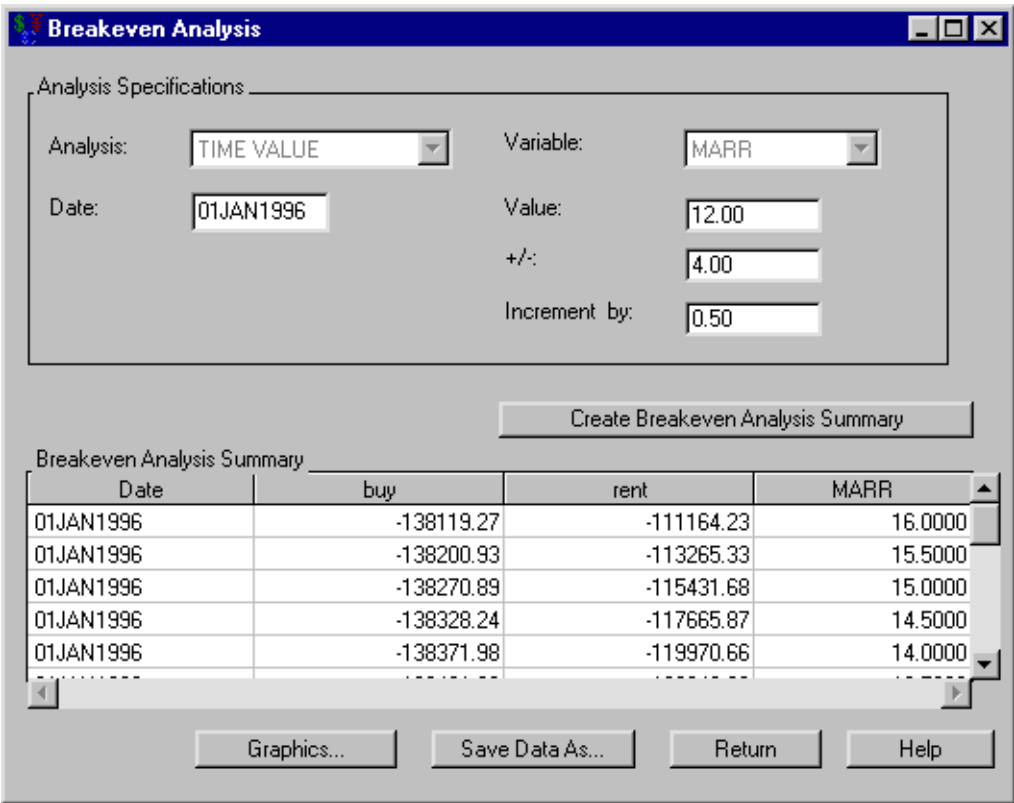

Performing a Breakeven Analysis

In the previous example you computed the uniform periodic equivalent for a rent-buy scenario. Now let's perform a breakeven analysis to see how the MARR affects the time values.

To perform the breakeven analysis, follow these steps:

1. Select both options.
2. Select **Analyze** → **Breakeven Analysis**.
3. Enter 01JAN1996 for the **Date**.
4. Enter 12.0 for **Value**.
5. Enter 4.0 for **(+/-)**.
6. Enter 0.5 for **Increment by**.
7. Click **Create Breakeven Analysis Summary** to fill the **Breakeven Analysis Summary** area as displayed in Figure 57.7.

Figure 57.7 Performing a Breakeven Analysis

Click **Graphics** to view a plot displaying the relationship between time value and MARR.

Figure 57.8 Viewing a Breakeven Graph

As shown in Figure 57.8, renting is better if you want a MARR of 12%. However, if your MARR should drop to 10.5%, buying would be better.

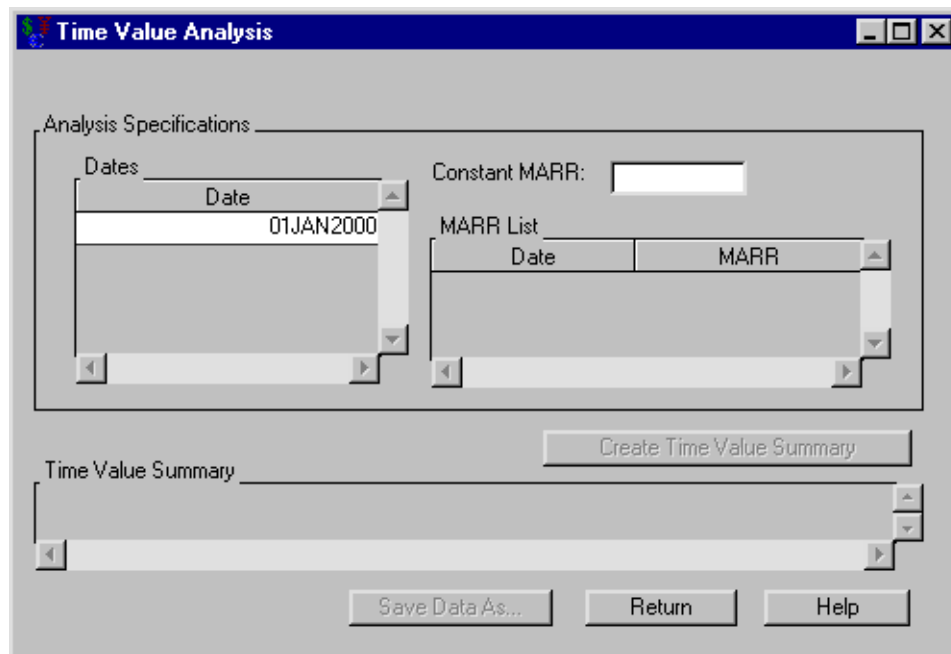

With a single investment, knowing where the graph has a time value of 0 tells the MARR when a venture switches from being profitable to being a loss. With multiple investments, knowing where the graphs for the various investments cross each other tells at what MARR a particular investment becomes more profitable than another.

Dialog Box Guide

Time Value Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an time value analysis, select **Analyze** → **Time Value** from the Investment Analysis dialog box's menu bar. This opens the Time Value Analysis dialog box displayed in Figure 57.9.

Figure 57.9 Time Value Analysis Dialog Box

The following items are displayed:

Analysis Specifications

Dates holds the list of dates as of which to perform the time value analysis. [Right-clicking](#) within the **Dates** area reveals many helpful tools for managing date lists.

Constant MARR holds the desired MARR for the time value analysis. This value is used if the **MARR List** area is empty.

MARR List holds date-rate pairs that express your desired MARR as it changes over time. Each date refers to when that expected MARR begins. [Right-clicking](#) within the **MARR List** area reveals many helpful tools for managing date-rate pairs.

Create Time Value Summary becomes available when you adequately specify the analysis within the **Analysis Specifications** area. Clicking **Create Time Value Summary** then fills the **Time Value Summary** area.

Time Value Summary fills when you click **Create Time Value Summary**. The table contains a row for each date in the **Dates** area. The remainder of each row holds the time values at that date, one value for each investment selected.

Print becomes available when you fill the time value summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you fill the time value summary. Clicking it opens the **Save Output Dataset** dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the **Investment Analysis** dialog box.

Uniform Periodic Equivalent

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a uniform periodic equivalent, select **Analyze** → **Periodic Equivalent** from the Investment Analysis dialog box's menu bar. This opens the Uniform Periodic Equivalent dialog box displayed in [Figure 57.10](#).

Figure 57.10 Uniform Periodic Equivalent Dialog Box

The following items are displayed:

Analysis Specifications

Start Date holds the date the uniform periodic equivalents begin.

Number of Periods holds the number of uniform periodic equivalents.

Interval holds how often the uniform periodic equivalents occur.

Constant MARR holds the Minimum Attractive Rate of Return.

Create Periodic Equivalent Summary becomes available when you adequately fill the **Analysis Specification** area. Clicking **Create Periodic Equivalent Summary** then fills the periodic equivalent summary.

Periodic Equivalent Summary fills with two columns when you click **Create Periodic Equivalent Summary**. The first column lists the investments selected. The second column lists the computed periodic equivalent amount.

Print becomes available when you fill the periodic equivalent summary. Clicking it sends the contents of the summary to the SAS session print device.

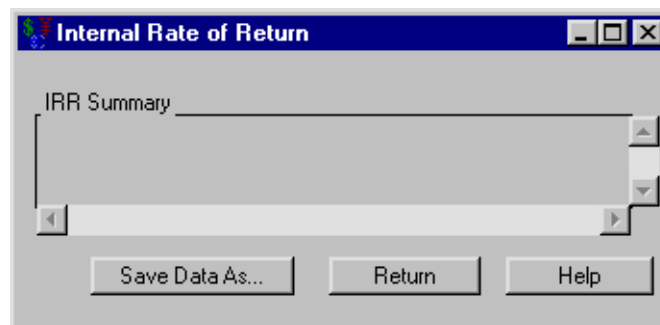

Save Data As becomes available when you generate the periodic equivalent summary. Clicking it opens the **Save Output Dataset** dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the **Investment Analysis** dialog box.

Internal Rate of Return

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an internal rate of return calculation, select **Analyze** → **Internal Rate of Return** from the Investment Analysis dialog box's menu bar. This opens the Internal Rate of Return dialog box displayed in [Figure 57.11](#).

Figure 57.11 Internal Rate of Return Dialog Box

The following items are displayed:

IRR Summary contains a row for each deposit. Each row holds:

Name holds the name of the investment.

IRR holds the internal rate of return for that investment.

interval holds the interest rate interval for that **IRR**.

Print becomes available when you fill the IRR summary. Clicking it sends the contents of the summary to the SAS session print device.

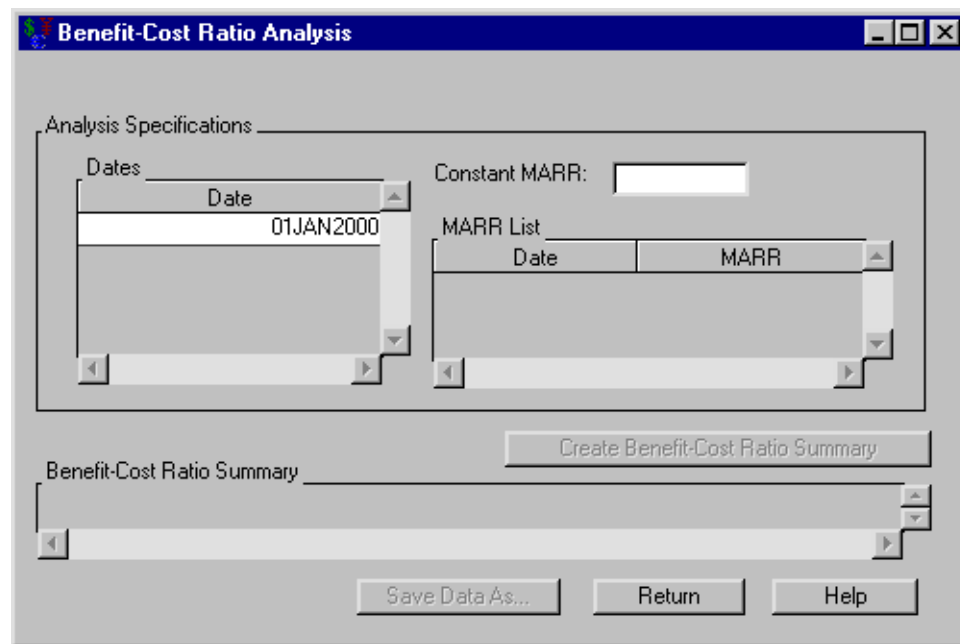

Save Data As opens the **Save Output Dataset** dialog box where you can save the IRR summary (or portions thereof) as a SAS data set.

Return takes you back to the **Investment Analysis** dialog box.

Benefit-Cost Ratio Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to compute a benefit-cost ratio, select **Analyze** → **Benefit-Cost Ratio** from the Investment Analysis dialog box's menu bar. This opens the Benefit-Cost Ratio Analysis dialog box displayed in Figure 57.12.

Figure 57.12 Benefit-Cost Ratio Analysis Dialog Box

The following items are displayed:

Analysis Specifications

Dates holds the dates as of which to compute the Benefit-Cost ratios.

Constant MARR holds the desired MARR. This value is used if the **MARR List** area is empty.

MARR List holds date-rate pairs that express your desired MARR as it changes over time. Each date refers to when that expected MARR begins. [Right-clicking](#) within the **MARR List** area reveals many helpful tools for managing date-rate pairs.

Create Benefit-Cost Ratio Summary becomes available when you adequately specify the analysis. Clicking **Create Benefit-Cost Ratio Summary** fills the benefit-cost ratio summary.

Benefit-Cost Ratio Summary fills when you click **Exchange the Rates**. The area contains a row for each date in the **Dates** area. The remainder of each row holds the benefit-cost ratios at that date, one value for each investment selected.

Print becomes available when you fill the benefit-cost ratio summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you generate the benefit-cost ratio summary. Clicking it opens the [Save Output Dataset](#) dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the [Investment Analysis](#) dialog box.

Breakeven Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a breakeven analysis, select **Analyze** → **Breakeven Analysis** from the Investment Analysis dialog box's menu bar. This opens the Breakeven Analysis dialog box displayed in [Figure 57.13](#).

Figure 57.13 Breakeven Analysis Dialog Box

The following items are displayed:

Analysis Specification

Analysis holds the analysis type. Only Time Value is currently available.

Date holds the date for which you perform this analysis.

Variable holds the variable upon which the breakeven analysis will vary. Only MARR is currently available.

Value holds the desired rate upon which to center the analysis.

+/- holds the maximum deviation from the **Value** to consider.

Increment by holds the increment by which the analysis is calculated.

Create Breakeven Analysis Summary becomes available when you adequately specify the analysis. Clicking **Create Breakeven Analysis Summary** then fills the **Breakeven Analysis Summary** area.

Breakeven Analysis Summary fills when you click **Create Breakeven Analysis Summary**. The schedule contains a row for each MARR and date.

Graphics becomes available when you fill the **Breakeven Analysis Summary** area. Clicking it opens the **Breakeven Graph** graph representing the time value versus MARR.

Print becomes available when you fill the breakeven analysis summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As becomes available when you generate the breakeven analysis summary. Clicking it opens the **Save Output Dataset** dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the **Investment Analysis** dialog box.

Breakeven Graph

Suppose you perform a breakeven analysis in the Breakeven Analysis dialog box. Once you create the breakeven analysis summary, you can click the **Graphics** button to open the Breakeven Graph dialog box displayed in Figure 57.14.

Figure 57.14 Breakeven Graph Dialog Box

The following item is displayed:

Return takes you back to the **Breakeven Analysis** dialog box.

Investments and Data Sets

Investment Analysis provides tools to assist you in moving data between SAS data sets and lists you can use within Investment Analysis.

Saving Output to SAS Data Sets

Many investment specifications have a button that reads **Save Data As**. Clicking that button opens the Save Output Dataset dialog box (see [Figure 58.1](#)). This dialog box enables you to save all or part of the area generated by the specification.

Figure 58.1 Saving to a Dataset

The following items are displayed:

Dataset Name holds the SAS data set name to which you want to save.

Browse opens the standard SAS **Open** dialog box, which enables you to select an existing SAS data set to overwrite.

Dataset Label holds the SAS data set's label.

Dataset Variables organizes variables. The variables listed in the **Selected** area will be included in the SAS data set.

- You can select variables one at a time, by clicking the single right-arrow after each selection to move it to the **Selected** area.
- If the desired SAS data set has many variables you want to save, it may be simpler to follow these steps:
 1. Click the double right-arrow to select all available variables.
 2. Remove any unwanted variable by selecting it from the **Selected** area and clicking the single left-arrow.
- The double left-arrow removes all selected variables from the proposed SAS data set.
- The up and down arrows below the **Available** and **Selected** boxes enable you to scroll up and down the list of variables in their respective boxes.

Save Dataset attempts to save the SAS data set. If the SAS data set name exists, you are asked if you want to replace the existing SAS data set, append to the existing SAS data set, or cancel the current save attempt. You then return to this dialog box ready to create another SAS data set to save.

Return takes you back to the specification dialog box.

Loading a SAS Data Set into a List

Right-click in the area that you want to load the list and release on **Load**. This opens the Load Dataset dialog box (see Figure 58.2).

Figure 58.2 Load Dataset Dialog Box

The following items are displayed:

Dataset Name holds the name of the SAS data set that you want to load.

Browse opens the standard SAS **Open** dialog box, which aids in finding a SAS data set to load. If there is a **Date** variable in the SAS data set, Investment Analysis loads it into the list. If there is no **Date** variable, it loads the first available time-formatted variable. If an amount or rate variable is needed, Investment Analysis searches the SAS data set for a **Amount** or **Rate** variable to use. Otherwise it takes the first numeric variable that is not used by the **Date** variable.

Dataset Label holds a SAS data set label.

OK attempts to load the SAS data set specified in **Dataset Name**. If the specified SAS data set exists, clicking **OK** returns you to the calling dialog box with the selected SAS data set filling the list. If the specified SAS data set does not exist and you click **OK**, you receive an error message and no SAS data set is loaded.

Cancel returns you to the calling dialog box without loading a SAS data set.

Saving Data from a List to a SAS Data Set

Right-click in the area you want to hold the list, and release on **Save**. This opens the Save Dataset dialog box.

Figure 58.3 Save Dataset Dialog Box

The following items are displayed:

Dataset Name holds the SAS data set name to which you want to save.

Browse opens the standard SAS **Save As** dialog box, which enables you to find an existing SAS data set to overwrite.

Dataset Label holds a user-defined description to be saved as the label of the SAS data set.

OK saves the current data to the SAS data set specified in **Dataset Name**. If the specified SAS data set does not already exist, clicking **OK** saves the SAS data set and returns you to the calling dialog box. If the specified SAS data set does already exist, clicking **OK** warns you and enables you to replace the old SAS data set with the new SAS data set or cancel the save attempt.

Cancel aborts the save process. Clicking **Cancel** returns you to the calling dialog box without attempting to save.

Right Mouse Button Options

A pop-up menu often appears when you right-click within table editors. The menus offer tools to aid in the management of the table's entries. Most table editors provide the following options.

Figure 58.4 Right-Clicking Options

Add creates a blank row.

Delete removes any currently selected row.

Copy duplicates the currently selected row.

Sort arranges the rows in chronological order according to the date variable.

Clear empties the table of all rows.

Save opens the [Save Dataset](#) dialog box where you can save the all rows to a SAS Dataset for later use.

Load opens the [Load Dataset](#) dialog box where you select a SAS Dataset to fill the rows.

If you want to perform one of these actions on a collection of rows, you must select a collection of rows before right-clicking. To select an adjacent list of rows, do the following: click the first pair, hold down SHIFT, and click the final pair. After the list of rows is selected, you may release the SHIFT key.

Depreciation Methods

Suppose an asset's price is \$20,000 and it has a salvage value of \$5,000 in five years. The following sections describe various methods to quantify the depreciation.

Straight Line (SL)

This method assumes a constant depreciation value per year.

Assuming that the price of a depreciating asset is P and its salvage value after N years is S , the annual depreciation is:

$$\frac{P - S}{N}$$

For our example, the annual depreciation would be

$$\frac{\$20,000 - \$5,000}{5} = \$3,000$$

Sum-of-Years Digits

An asset often loses more of its value early in its lifetime. A method that exhibits this dynamic is desirable.

Assume an asset depreciates from price P to salvage value S in N years. First compute the sum-of-years as $T = 1 + 2 + \cdots + N$. The depreciation for the years after the asset's purchase is:

Table 58.1 Sum-of-Years General Example

Year Number	Annual Depreciation
first	$\frac{N}{T}(P - S)$
second	$\frac{N-1}{T}(P - S)$
third	$\frac{N-2}{T}(P - S)$
\vdots	\vdots
final	$\frac{1}{T}(P - S)$

For the i th year of the asset's use, the annual depreciation is:

$$\frac{N + 1 - i}{T}(P - S)$$

For our example, $N = 5$ and the sum of years is $T = 1 + 2 + 3 + 4 + 5 = 15$. The depreciation during the first year is

$$(\$20,000 - \$5,000)\frac{5}{15} = \$5,000$$

Table 58.2 describes how Declining Balance would depreciate the asset.

Table 58.2 Sum-of-Years Example

Year	Depreciation	Year-End Value
1	$(\$20,000 - \$5,000)\frac{5}{15} = \$5,000$	\$15,000.00
2	$(\$20,000 - \$5,000)\frac{4}{15} = \$4,000$	\$11,000.00
3	$(\$20,000 - \$5,000)\frac{3}{15} = \$3,000$	\$8,000.00
4	$(\$20,000 - \$5,000)\frac{2}{15} = \$2,000$	\$6,000.00
5	$(\$20,000 - \$5,000)\frac{1}{15} = \$1,000$	\$5,000.00

As expected, the value after N years is S .

$$\begin{aligned}
 S &= P - (5 \text{ years' depreciation}) \\
 &= P - \left(\frac{5}{15}(P - S) + \frac{4}{15}(P - S) + \frac{3}{15}(P - S) + \frac{2}{15}(P - S) + \frac{1}{15}(P - S) \right) \\
 &= P - (P - S)
 \end{aligned}$$

Declining Balance (DB)

Recall that the straight line method assumes a constant depreciation value. Conversely, the declining balance method assumes a constant depreciation rate per year. And like the sum-of-years method, more depreciation tends to occur earlier in the asset's life.

Assume the price of a depreciating asset is P and its salvage value after N years is S . You could assume the asset depreciates by a factor of $\frac{1}{N}$ (or a rate of $\frac{100}{N}\%$). This method is known as single declining balance. The annual depreciation is:

$$\frac{1}{N}(\text{previous year's value})$$

So for our example, the depreciation during the first year is $\frac{\$20,000}{5} = \$4,000$. Table 58.3 describes how declining balance would depreciate the asset.

Table 58.3 Declining Balance Example

Year	Depreciation	Year-End Value
1	$\frac{\$20,000.00}{5} = \$4,000.00$	\$16,000.00
2	$\frac{\$16,000.00}{5} = \$3,200.00$	\$12,800.00
3	$\frac{\$12,800.00}{5} = \$2,560.00$	\$10,240.00
4	$\frac{\$10,240.00}{5} = \$2,048.00$	\$8,192.00
5	$\frac{\$12,800.00}{5} = \$1,638.40$	\$6,553.60

DB Factor

You could also accelerate the depreciation by increasing the factor (and hence the rate) at which depreciation occurs. Other commonly accepted depreciation rates are $\frac{200}{N}\%$ (called double declining balance as the depreciation factor becomes $\frac{2}{N}$) and $\frac{150}{N}\%$. Investment Analysis enables you to choose between these three types for declining balance: 2 (with $\frac{200}{N}\%$ depreciation), 1.5 (with $\frac{150}{N}\%$), and 1 (with $\frac{100}{N}\%$).

Declining Balance and the Salvage Value

The declining balance method assumes that depreciation is faster earlier in an asset's life; this is what you wanted. But notice the final value is greater than the salvage value. Even if the salvage value were greater than \$6,553.60, the final year-end value would not change. The salvage value never enters the calculation, so there is no way for the salvage value to force the depreciation to assume its value. Newnan and Lavelle (1998) describe two ways to adapt the declining balance method to assume the salvage value at the final time. One way is as follows:

Suppose you call the depreciated value after i years $V(i)$. This sets $V(0) = P$ and $V(N) = S$.

- If $V(N) > S$ according to the usual calculation for $V(N)$, redefine $V(N)$ to equal S .
- If $V(i) < S$ according to the usual calculation for $V(i)$ for some i (and hence for all subsequent $V(i)$ values), you can redefine all such $V(i)$ to equal S .

This alteration to declining balance forces the depreciated value of the asset after N years to be S and keeps $V(i)$ no less than S .

Conversion to SL

The second (and preferred) way to force declining balance to assume the salvage value is by conversion to straight line. If $V(N) > S$, the first way redefines $V(N)$ to equal S ; you can think of this as converting to the straight line method for the last time step.

If the $V(N)$ value supplied by DB is appreciably larger than S , then the depreciation in the final year would be unrealistically large. An alternate way is to compute the DB and SL step at each timestep and take whichever step gives a larger depreciation (unless DB drops below the salvage value).

After SL assumes a larger depreciation, it continues to be larger over the life of the asset. SL forces the value at the final time to equal the salvage value. As an algorithm, this looks like the following statements:

```
V(0) = P;
for i=1 to N
  if DB step > SL step from (i,V(i))
    take a DB step to make V(i);
  else
    break;
  for j = i to N
    take a SL step to make V(j);
```

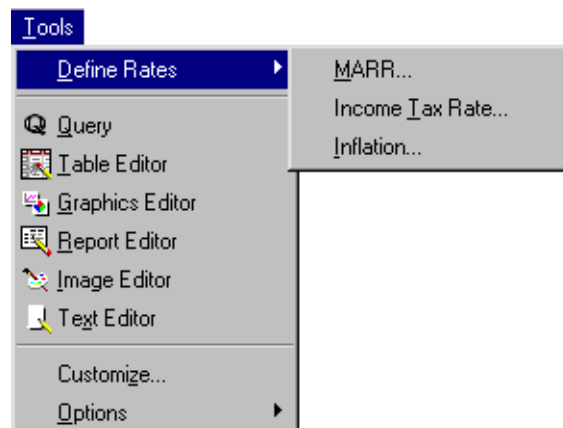

The MACRS, which is discussed in the section that describes the [Depreciation Table](#) window, is actually a variation on the declining balance method with conversion to the straight line method.

Rate Information

The Tools Menu

Figure 58.5 shows the **Tools** menu.

Figure 58.5 The Tools Menu

The **Tools** → **Define Rates** menu offers the following options.

MARR opens the [Minimum Attractive Rate of Return \(MARR\)](#) dialog box.

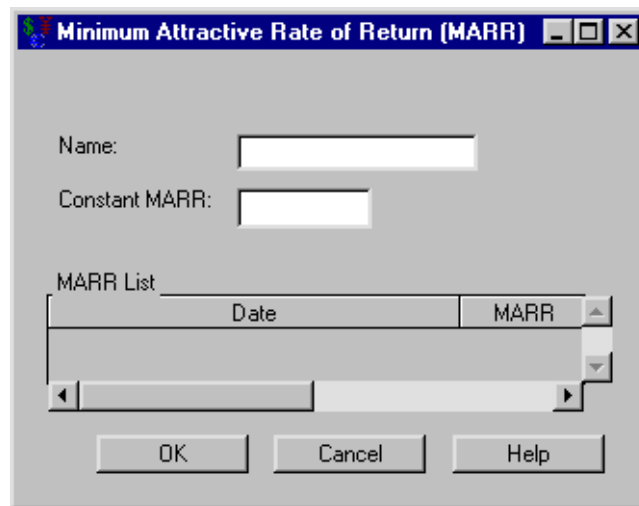

Income Tax Rate opens the [Income Tax Specification](#) dialog box.

Inflation opens the [Inflation Specification](#) dialog box.

Minimum Attractive Rate of Return (MARR)

Selecting **Tools** → **Define Rates** → **MARR** from the Investment Analysis dialog box menu bar opens the MARR dialog box that is displayed in [Figure 58.6](#).

Figure 58.6 MARR Dialog Box

MARR List	
Date	MARR

Name holds the name that you assign to the MARR specification. This must be a valid SAS name.

Constant MARR holds the numeric value that you choose to be the constant MARR. This value is used if the **MARR List** table editor is empty.

MARR List holds date-MARR pairs where the date refers to when the particular MARR value begins. Each date is a SAS date.

OK returns you to the [Investment Analysis](#) dialog box. Clicking it causes the preceding MARR specification to be assumed when you do not specify MARR rates in a dialog box that needs MARR rates.

Cancel returns you to the [Investment Analysis](#) dialog box, discarding any work that was done in the MARR dialog box.

Income Tax Specification

Selecting **Tools** → **Define Rates** → **Income Tax Rate** from the Investment Analysis dialog box menu bar opens the Income Tax Specification dialog box displayed in [Figure 58.7](#).

Figure 58.7 Income Tax Specification Dialog Box

The dialog box titled "Income Tax Specification" contains the following elements:

- Name:** A text input field.
- Federal Tax:** A numeric input field.
- Local Tax:** A numeric input field.
- Taxrate List:** A table with three columns: "Date", "Federal", and "Local". The table is currently empty.
- Buttons:** "OK", "Cancel", and "Help" at the bottom right.

Name holds the name you assign to the Income Tax specification. This must be a valid SAS name.

Federal Tax holds the numeric value that you want to be the constant Federal Tax.

Local Tax holds the numeric value that you want to be the constant Local Tax.

Taxrate List holds date-Income Tax triples where the date refers to when the particular Income Tax value begins. Each date is a SAS date, and the value is a percentage between 0% and 100%.

OK returns you to the [Investment Analysis](#) dialog box. Clicking it causes the preceding income tax specification to be the default income tax rates when using the [After Tax Cashflow Calculation](#) dialog box.

Cancel returns you to the [Investment Analysis](#) dialog box, discarding any changes that were made since this dialog box was opened.

Inflation Specification

Selecting **Tools** → **Define Rates** → **Inflation** from the Investment Analysis dialog box menu bar opens the Inflation Specification dialog box displayed in [Figure 58.8](#).

Figure 58.8 Inflation Specification Dialog Box

Inflation Rate List	
Date	Rate

Name holds the name that you assign to the Inflation specification. This must be a valid SAS name.

Constant Rate holds the numeric value that you want to be the constant inflation rate. This value is used if the **Inflation Rate List** table editor is empty.

Inflation Rate List holds date-rate pairs where the date refers to when the particular inflation rate begins. Each date is a SAS date and the rate is a percentage between 0% and 120%.

OK returns you to the [Investment Analysis](#) dialog box. Clicking it causes the preceding inflation specification to be assumed when you use the [Constant Dollar Calculation](#) dialog box and do not specify inflation rates.

Cancel returns you to the [Investment Analysis](#) dialog box, discarding any changes that were made since this dialog box was opened.
