Software

The procedures in SAS/QC software were implemented by the Statistical Quality Improvement Research and Development Department. Substantial support was given to the project by other members of the Analytical Solutions Division. The Core Development Division, Display Products Division, Graphics Division, and Host Systems Division also contributed to this product.

Using This Book

Contents

Overview

The *SAS/QC User's Guide* provides complete documentation, including introductory examples, syntax, computational details, and advanced examples for the procedures in SAS/QC 12.1. In general, this book can be used for all current releases of SAS/QC software, and it replaces and updates the information provided by *SAS/QC 9.3 User's Guide*.

Point-and-click interfaces for basic statistical quality improvement methods and design of experiments are also included in SAS/QC software. The SQC Menu System for statistical quality control applications is described in *SAS/QC Software: SQC Menu System, Version 6, First Edition*. The ADX Interface for the design and analysis of experiments is described in *Getting Started with the SAS ADX Interface for Design of Experiments*.

NOTE: For SAS/QC 12.1 you must enter the follow statements before invoking the SQC Menu System to ensure its proper operation:

```
ods graphics off;  
ods html close;  
ods listing;
```

Organization

This book is organized as follows.

Chapter 1, “What’s New in SAS/QC 12.1 and 12.3,” provides information about the changes and enhancements to SAS/QC software in SAS/QC 12.1.

Chapter 2, “Components of SAS/QC Software,” gives an overview of the tools provided by SAS/QC software and their uses.

The majority of SAS/QC procedures produce graphs as an important part of their output. Chapter 3, “SAS/QC Graphics,” describes the different approaches available for producing this graphical output.

Each of the remaining chapters describes one SAS/QC procedure. These chapters appear in alphabetical order by procedure name. The following list summarizes the types of information provided for each procedure:

Overview	provides a general description of what the procedure does.
Getting Started	illustrates simple uses of the procedure using tutorial examples.
Syntax	constitutes the major reference section for the syntax of the procedure. First, the statement syntax is summarized. Next, functional summary tables list the options classified by function. Finally, a dictionary of options, listed in alphabetical order, provides details on each option.
Details	describes features of the procedure, including equations, computational methods, and input and output data sets.
Examples	provides examples that illustrate common and advanced applications of the procedure.
References	lists books and journal articles relevant to the procedure.

Several of the SAS/QC procedures are quite large and support several statements that are described independently within the procedure chapter. For example, the chapter describing the CAPABILITY procedure contains a major section for each plot statement (such as the HISTOGRAM statement) supported by the procedure. Each plot statement section contains its own “Overview,” “Getting Started,” “Syntax,” “Details,” and “Examples” subsections.

Typographical Conventions

SAS/QC User's Guide uses various type styles, as explained in the following list:

roman	is the standard type style used for most text.
UPPERCASE ROMAN	is used for SAS statements, options, and other SAS language elements when they appear in the text. However, you can enter these elements in your own SAS programs in lowercase, uppercase, or a mixture of the two.
UPPERCASE BOLD	is used in the “Syntax” sections’ initial lists of SAS statements and options.
<i>oblique</i>	is used for user-supplied values for options in the syntax definitions. In the text, these values are written in <i>italic</i> .
helvetica	is used for the names of variables and data sets when they appear in the text.
bold	is used to refer to matrices and vectors.

<i>italic</i>	is used for terms that are defined in the text, for emphasis, and for references to publications.
monospace	is used for example code. In most cases, this book uses lowercase type for SAS code.

Conventions for Examples

Most of the output shown in this book is produced with the following SAS System options:

```
options linesize=80 pagesize=200 nonumber nodate;
```

The HTMLBLUE style is used to create the HTML output and graphs that appear in the online documentation. A style template controls stylistic elements such as colors, fonts, and presentation attributes. The style template is specified in the ODS HTML statement as follows:

```
ods html style=htmlblue;
```

See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for more information about styles.

If you run the examples, you might get slightly different output. This is a function of the SAS System options used and the precision used by your computer for floating-point calculations.

The following GOPTIONS statement is used to create traditional graphics output (see Chapter 3, “SAS/QC Graphics”).

```
filename GSASFILE 'file-specification';
goptions gsfname = GSASFILE
        gsfmode = replace
        fileonly
        dev      = png
        htext   = 2.6pct
        htitle  = 3.5pct
        hsize   = 6.4in
        border
        horigin = 0in
        vorigin = 0in ;
```

Accessing the SAS/QC Sample Library

The SAS/QC sample library includes many examples that illustrate the use of SAS/QC software, including the examples used in this documentation. To access these sample programs, select the **Help** pull-down menu and then select **SAS Help and Documentation**. From the **Contents** list, choose **Learning to Use SAS** and **Sample SAS Programs**. Choose **SAS/QC** to bring up a list of sample programs.

Online Documentation

This documentation is available online with the SAS System. If you are using the SAS windowing environment with pull-down menus, you can select **SAS Help and Documentation** from the **Help** menu. Under the **Contents** tab select **SAS Products**, then **SAS/QC**, and select *SAS/QC User's Guide* from the list of available topics.

Alternatively, you can type **help QC** in the command line. Note that you can use the online facility to search the documentation. You can also access the documentation from the SAS Web site. Go to **support.sas.com** and select **Documentation** for more detail.

Chapter 1

What's New in SAS/QC 12.1 and 12.3

Contents

Overview	1
Production Status for the MVP Procedures	1
CAPABILITY Procedure Enhancements	2
PARETO Procedure Enhancements	3
RELIABILITY Procedure Enhancements	3
References	4

Overview

SAS/QC 12.1 includes three new procedures for multivariate process monitoring, as well as enhancements to the CAPABILITY, PARETO, and RELIABILITY procedures.

In previous years, SAS/QC software was updated only with new releases of Base SAS software, but this is no longer the case. This means that SAS/QC software can be released to customers when enhancements are ready, and the goal is to update SAS/QC every 12 to 18 months. To mark this newfound independence, the release numbering scheme for SAS/QC changed starting with SAS/QC 12.1. This new numbering scheme will be maintained when new versions of Base SAS and SAS/QC are shipped at the same time.

SAS/QC 12.3 is a maintenance release. No new features have been added. The information in this book applies to SAS/QC 12.1 and SAS/QC 12.3.

Production Status for the MVP Procedures

The MVPMODEL, MVPMONITOR, and MVPDIAGNOSE procedures, referred to collectively as the *MVP procedures*, are used together for multivariate process monitoring. The MVPMODEL and MVPMONITOR procedures were introduced as experimental procedures in SAS/QC 9.3 and are production for SAS/QC 12.1. The MVPDIAGNOSE procedure is new in SAS/QC 12.1.

The MVPMODEL procedure provides computational and graphical tools for building a principal component model from multivariate process data in which the measured variables are continuous and correlated. It implements principal component analysis (PCA) techniques that evolved in the field of chemometrics for monitoring hundreds or even thousands of correlated process variables; see Kourti and MacGregor (1995, 1996) for an introduction. A principal component model reduces the dimensionality of the data by projecting the process measurements to a low-dimensional subspace

that is defined by a small number of principal components. This subspace is known as the *model hyperplane*.

The principal component model and other output from PROC MVPMODEL serve as input to the MVPMONITOR and MVPDIAGNOSE procedures.

The MVPMONITOR procedure creates control charts for multivariate process data by using the principal component model that is produced by the MVPMODEL procedure. Multivariate control charts detect unusual variation that would not be uncovered by individually monitoring the process variables with univariate control charts, such as Shewhart charts. PROC MVPMONITOR creates two types of multivariate control chart. T^2 charts detect unusual variation within the model hyperplane, whereas squared prediction error (SPE) charts detect unusual variation from the hyperplane.

The MVPDIAGNOSE procedure produces principal component score plots and process variable contribution plots that are used to investigate the causes of unusual variation in a process.

See Chapter 10, “[Introduction to Multivariate Process Monitoring Procedures](#),” for a thorough description of how the MVP procedures work together.

CAPABILITY Procedure Enhancements

The CAPABILITY procedure supports several new options. The CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PPLOT, PROBPLOT, and QQPLOT statements support the following new options for specifying titles and footnotes in graphs that are produced by using ODS Graphics:

- ODSFOOTNOTE= adds a footnote to the graph.
- ODSFOOTNOTE2= adds a secondary footnote to the graph.
- ODSTITLE= specifies the graph title.
- ODSTITLE2= specifies a secondary graph title.

You can use these options to specify your own graph titles and footnotes without modifying ODS graph templates or using the ODS Graphics Editor.

The CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements support the following new options for displaying reference lines at the values of computed statistics:

- STATREF= specifies keywords that identify the statistics.
- CSTATREF= specifies the colors of the reference lines.
- LSTATREF= specifies the line types of the reference lines.
- STATREFLABELS= specifies labels for the reference lines.
- STATREFSUBCHAR= specifies a substitution character for incorporating statistic values into reference line labels.

For example, specifying `STATREF=MEAN` in a `HISTOGRAM` statement produces a histogram that has a vertical reference line at the mean of the data.

The `COMPHISTOGRAM` and `HISTOGRAM` statements support the new `CLIPCURVES` option, which clips fitted distribution curves that extend above the highest histogram bar. This eliminates compression of the histogram bars caused by extremely high fitted curve peaks.

The `OUTPUT` statement supports the following new options:

- `CIPCTLDF=` computes distribution-free confidence limits for percentiles that you request by specifying the `PCTLPTS=` option.
- `CIPCTLNORMAL=` computes confidence limits that assume normality for percentiles that you request by specifying the `PCTLPTS=` option.
- `PCTLGROUP=` controls how variables that you request by specifying the `PCTLPTS=` option are grouped in the `OUTPUT` data set.

In addition, the `CHREF=`, `CVREF=`, `LHREF=`, and `LVREF=` options have been enhanced. These options now accept lists of values so that different reference lines in a single graph can be displayed by using different colors and line types. They are available in the `CDFPLOT`, `COMPHISTOGRAM`, `HISTOGRAM`, `PPLOT`, `PROBPLOT`, and `QQPLOT` statements.

PARETO Procedure Enhancements

The `HBAR` and `VBAR` statements now support the `CHARTTYPE=` option, which enables you to create variations on the traditional Pareto chart, as described by Wilkinson (2006). These statements also support the following new options for specifying titles and footnotes in graphs that are produced by using ODS Graphics:

- `ODSFOOTNOTE=` adds a footnote to the graph.
- `ODSFOOTNOTE2=` adds a secondary footnote to the graph.
- `ODSTITLE=` specifies the graph title.
- `ODSTITLE2=` specifies a secondary graph title.

These options enable you to specify your own graph titles without modifying ODS graph templates or using the ODS Graphics Editor.

RELIABILITY Procedure Enhancements

The `RELIABILITY` procedure now supports the following statements that provide further analysis of regression models that are fit by using a `MODEL` statement:

- The **EFFECTPLOT** statement produces a display of the fitted model and provides options for changing and enhancing the displays.
- The **ESTIMATE** statement provides a mechanism for obtaining custom hypothesis tests.
- The **LSMEANS** statement computes and compares least squares means of fixed effects.
- The **LSMESTIMATE** statement provides a mechanism for obtaining custom hypothesis tests among least squares means.
- The **SLICE** statement provides a general mechanism for performing a partitioned analysis of the least squares means for an interaction.
- The **STORE** statement saves the context and results of the statistical analysis to an item store.
- The **TEST** statement performs F tests for model effects that test Type I, Type II, or Type III hypotheses.

These statements are common to many SAS/STAT[®] procedures and are fully documented in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User's Guide*).

PROC RELIABILITY also provides the following new features:

- confidence bands for mean and intensity functions for recurrent events
- two-sample log-rank-type test for recurrent events
- trend tests for recurrent events parametric models
- Duane plots
- profile likelihood confidence intervals for survival function

Components of SAS/QC Software

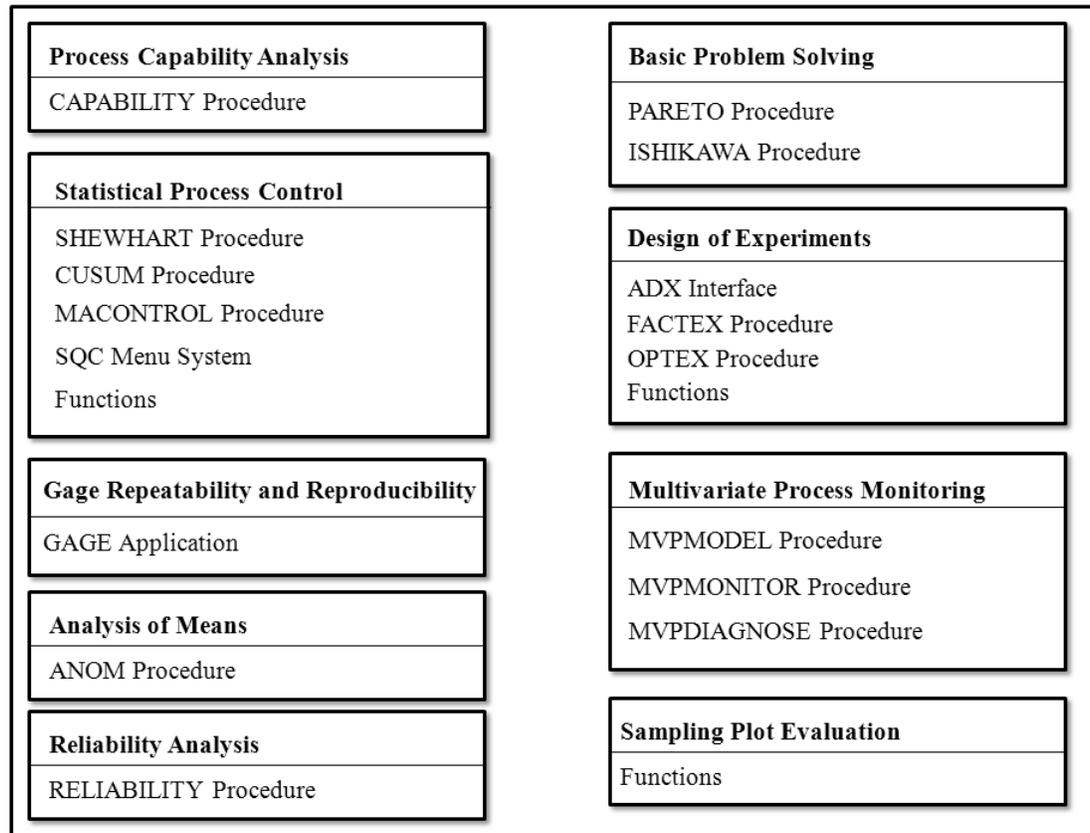

Contents

Overview	5
ADX Interface for Design of Experiments	7
SQC Menu System for Statistical Quality Control	8
Procedures for Design of Experiments	9
Procedures for Control Chart Analysis	10
Procedure for Process Capability Analysis	11
Procedures for Basic Quality Problem Solving	12
Procedure for Reliability Analysis	13
Procedure for Analysis of Means	14
Procedures for Multivariate Process Monitoring	15

Overview

SAS/QC software, a component of the SAS System, provides a comprehensive set of tools for statistical quality improvement. You can use these tools to

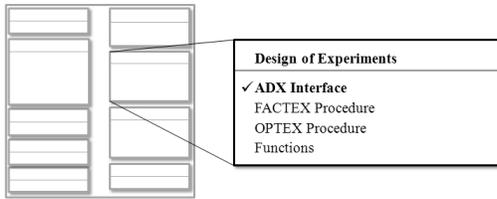

- organize quality improvement efforts
- design industrial experiments for product and process improvement
- apply Taguchi methods for quality engineering
- establish statistical control of a process
- maintain statistical control and reduce variation
- analyze process capability
- develop and evaluate acceptance sampling plans

Figure 2.1 Components of SAS/QC Software

There are two types of tools in SAS/QC software: interfaces and procedures.

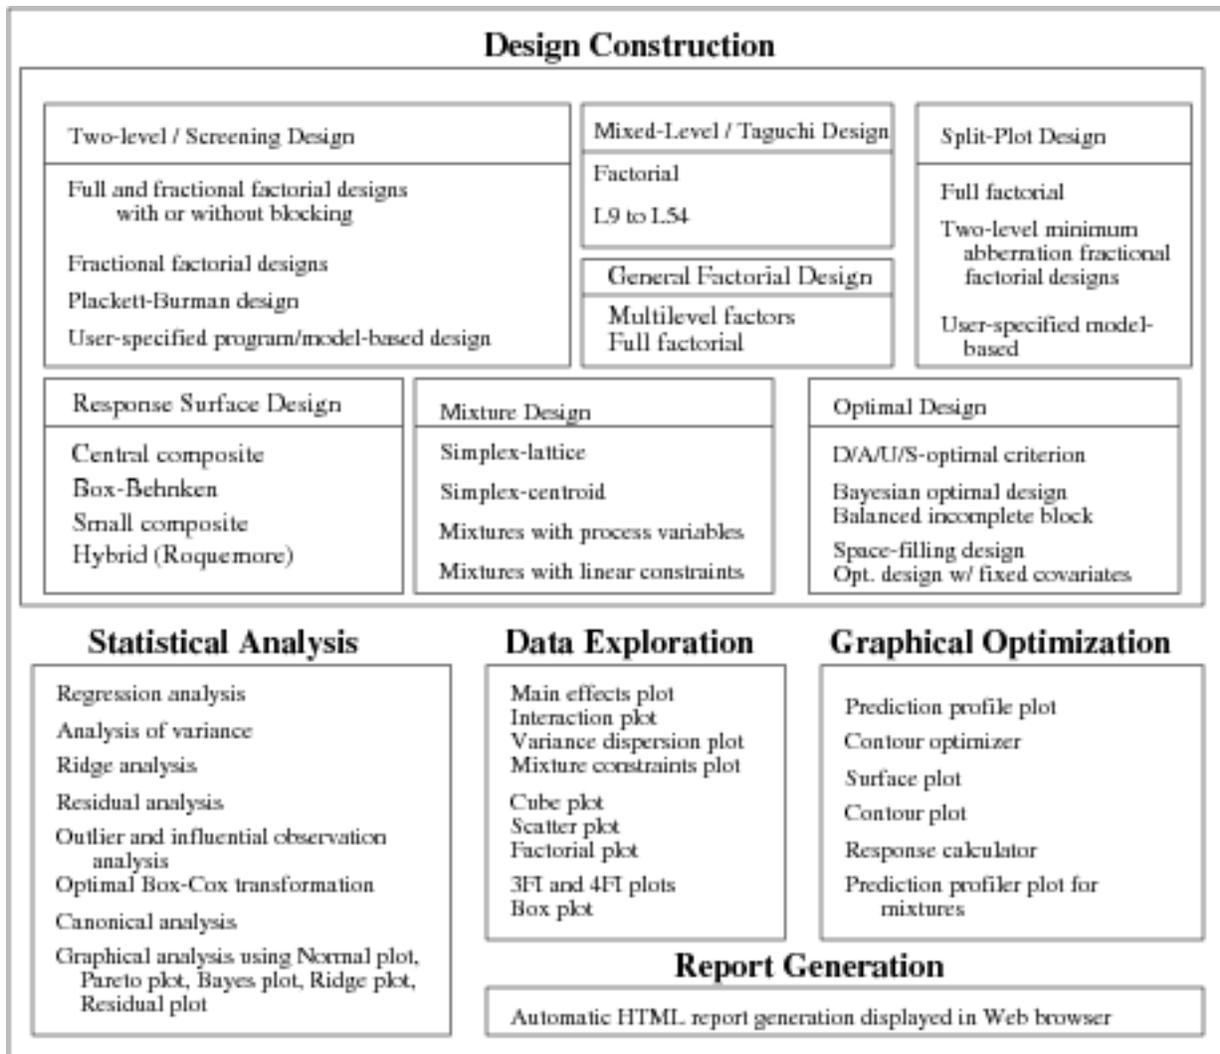

- The interfaces are complete, full-screen-oriented environments for statistical quality-improvement applications. Unlike with the procedures, using the interfaces requires no knowledge of SAS programming. These include the SQC menu system and the ADX interfaces for statistical quality-control applications.
- The procedures in SAS/QC software offer greater flexibility and power than the interface. To use a procedure, you must have a basic knowledge of the SAS language and the syntax of the procedure.

ADX Interface for Design of Experiments

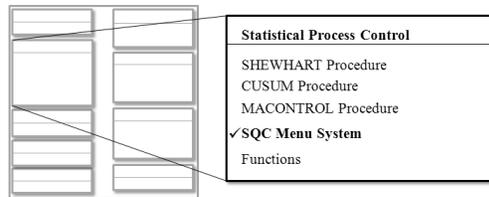

The ADX Interface provides a solution for engineers and researchers who require a point-and-click interface for designing and analyzing experimental designs.

Figure 2.2 General Design and Analysis Facilities

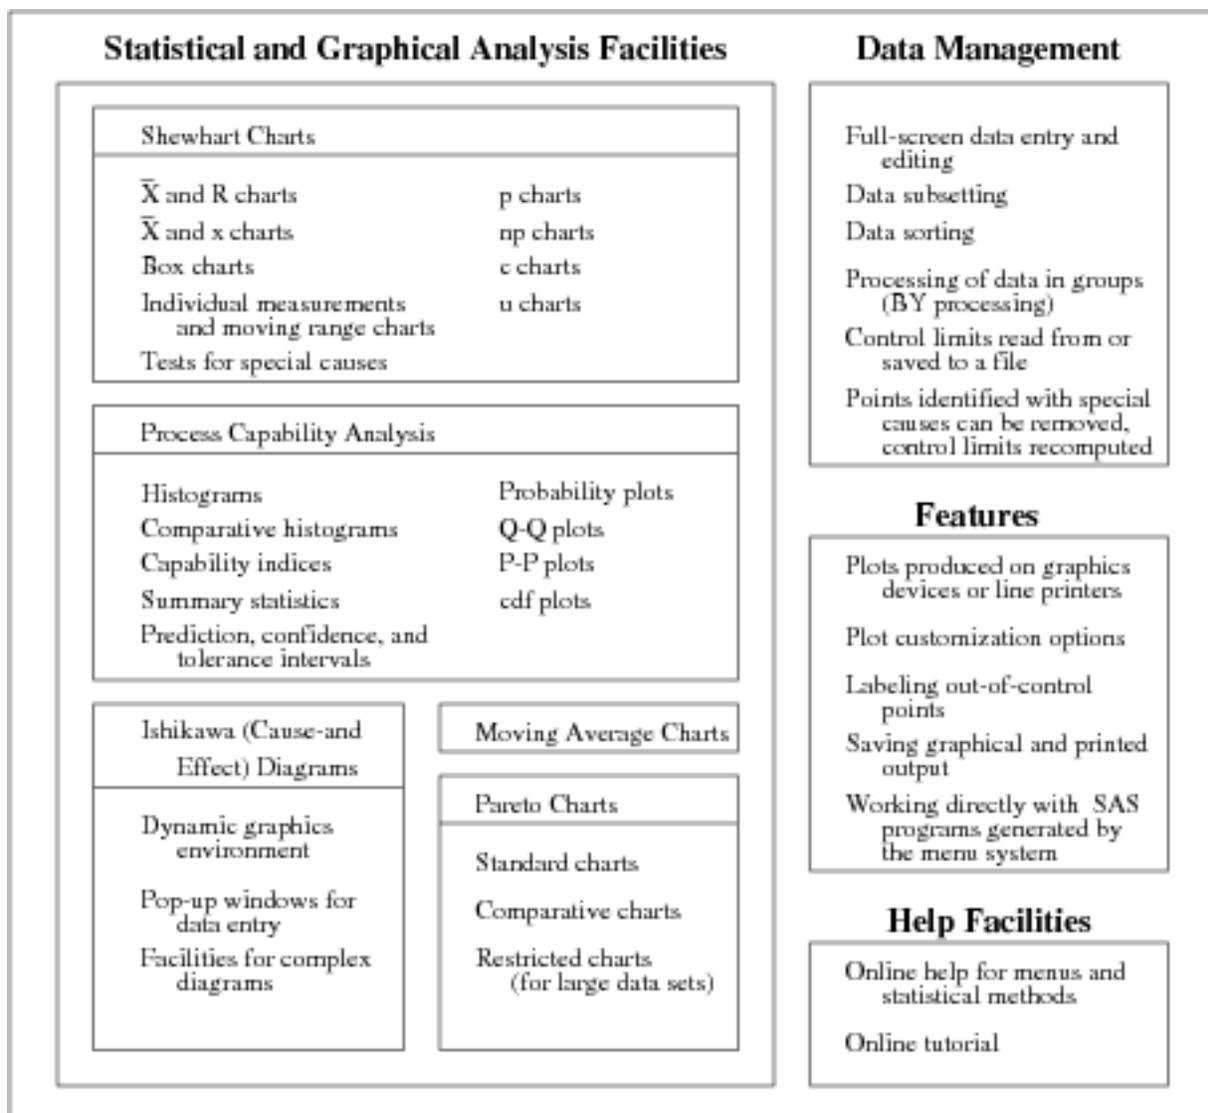

NOTE: For more information about the ADX Interface, see *Getting Started with the SAS ADX Interface for Design of Experiments*

SQC Menu System for Statistical Quality Control

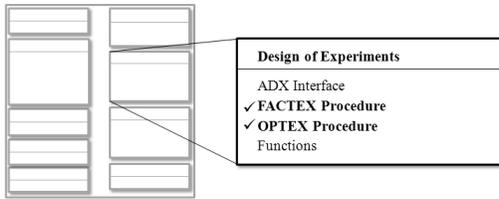

The SQC Menu System provides facilities for standard statistical quality-control applications and is intended for quality analysts and quality-control managers, rather than for statisticians.

Figure 2.3 Overview of the SQC Menu System

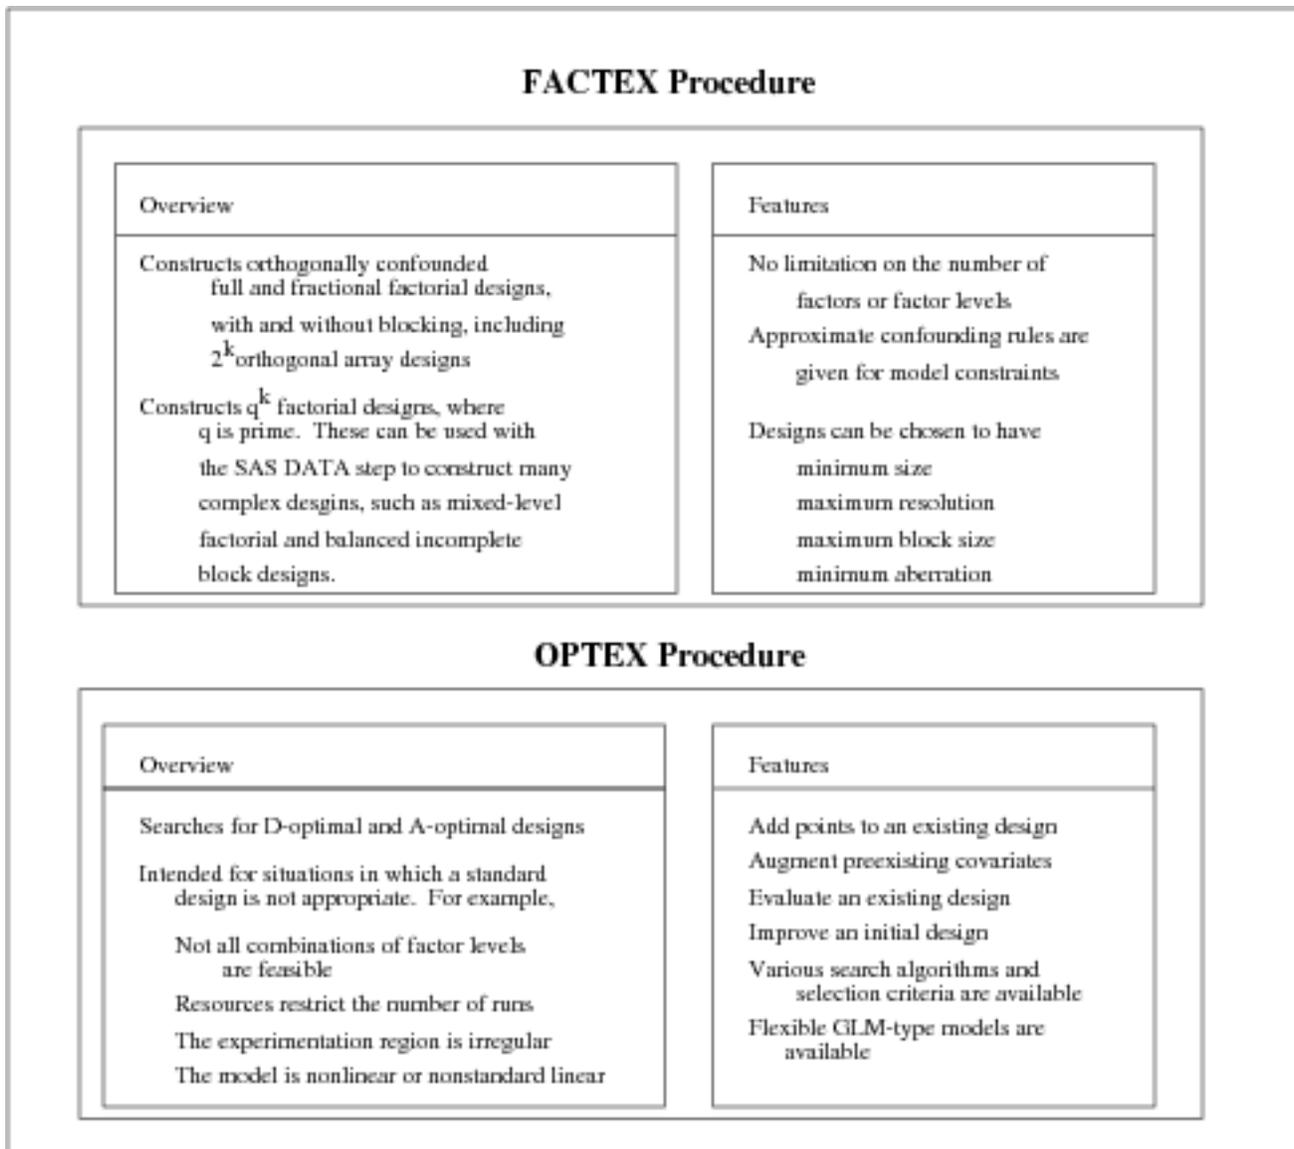

NOTE: The SQC Menu System is documented in *SAS/QC Software: SQC Menu System for Quality Improvement, Version 6, Second Edition*.

Procedures for Design of Experiments

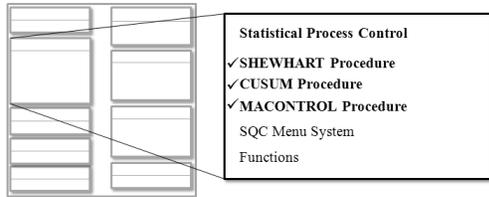

The FACTEX procedure constructs factorial experimental designs, which are useful for studying the effects of various factors on a response. The OPTEX procedure searches for optimal designs in situations in which standard designs are not available.

Figure 2.4 Overview of the Experimental Design Procedures

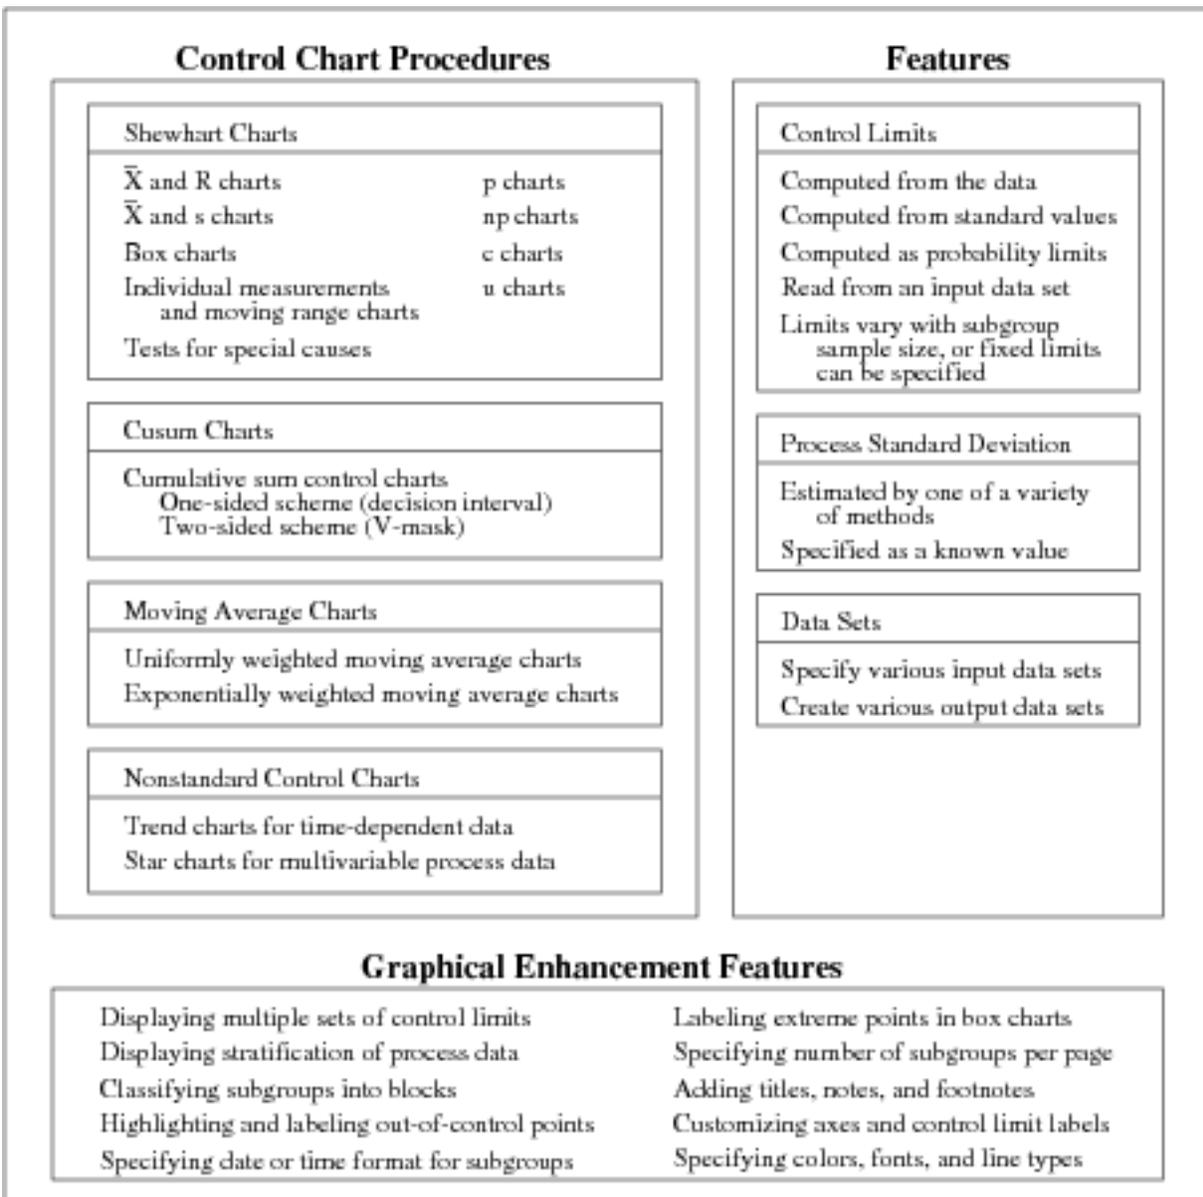

Procedures for Control Chart Analysis

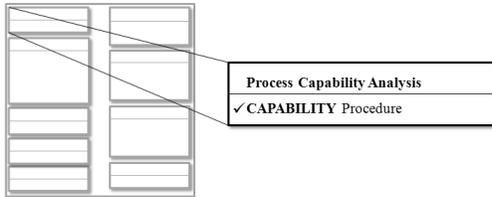

The SHEWHART procedure creates all commonly encountered Shewhart charts for variables and attributes. The CUSUM procedure creates cumulative sum control charts. The MACONTROL procedure creates moving average charts.

Figure 2.5 Overview of Control Chart Analysis Procedures

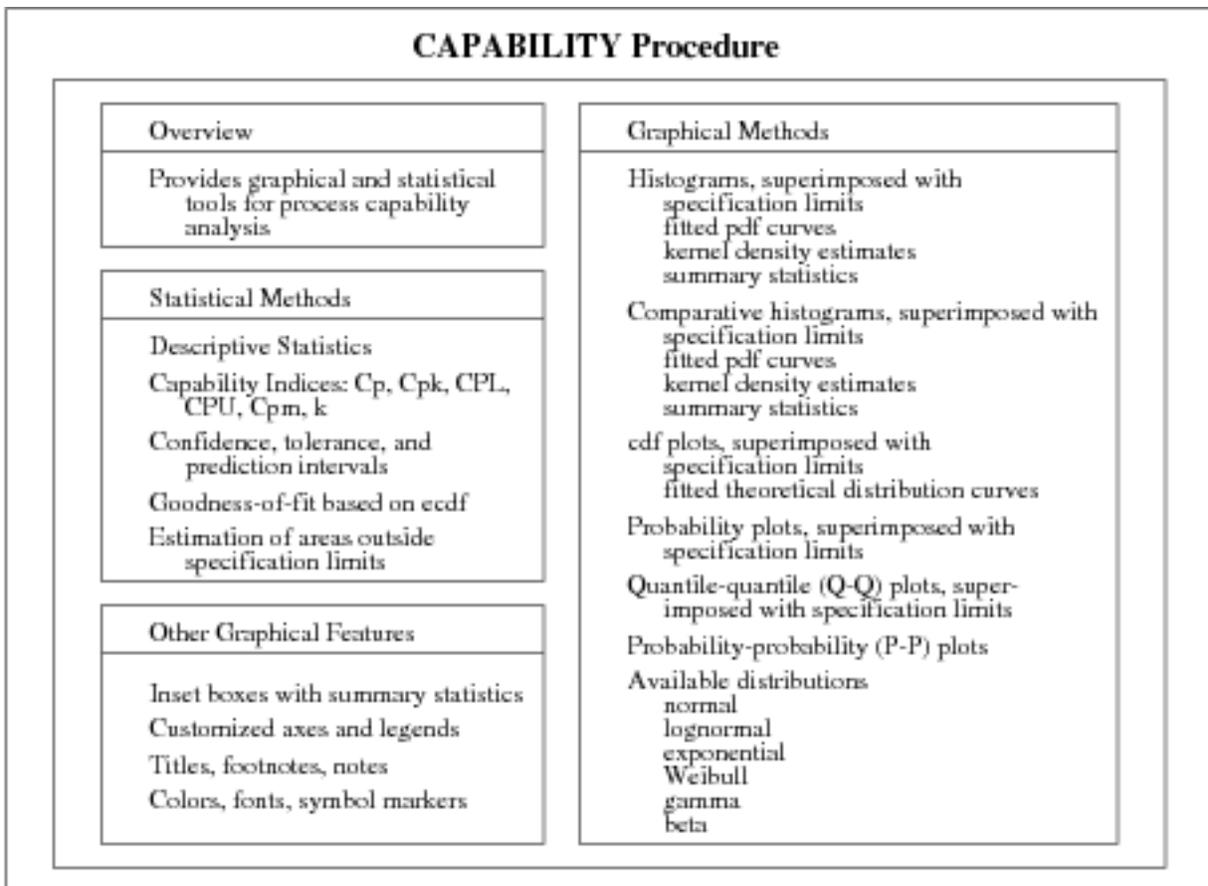

Procedure for Process Capability Analysis

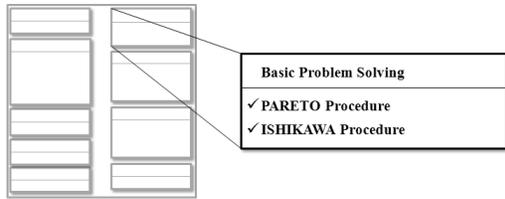

The CAPABILITY procedure compares the distribution of output from an in-control process to the specification limits of the process to determine the consistency with which the specification limits can be met.

Figure 2.6 Overview of Process Capability Analysis Procedure

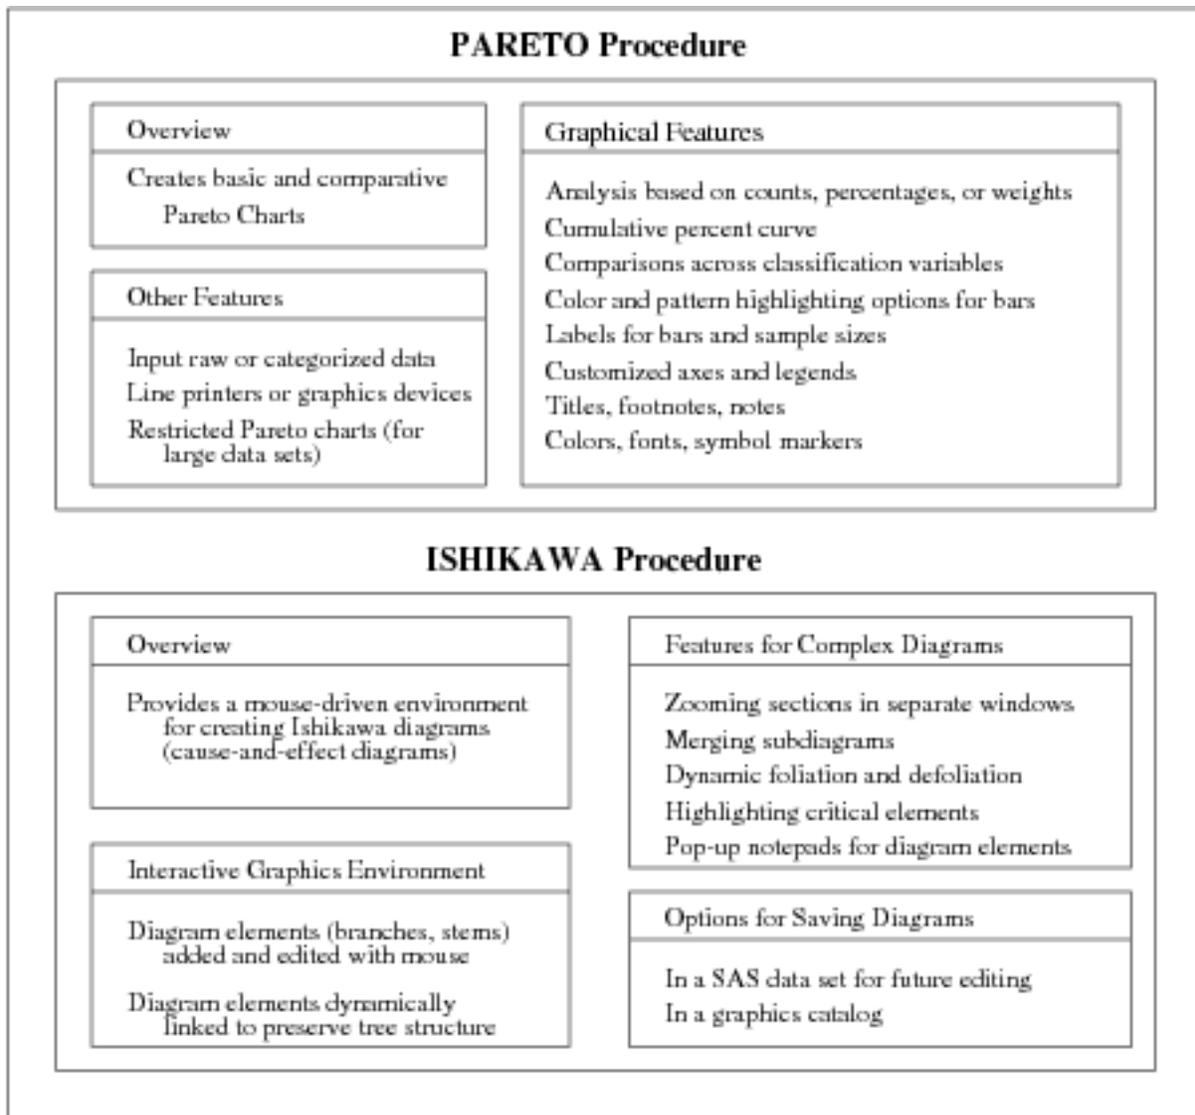

Procedures for Basic Quality Problem Solving

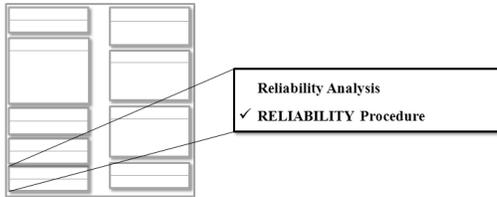

The PARETO procedure creates charts that display the relative frequency of problems in a process or operation. The ISHIKAWA procedure creates a cause-and-effect or fishbone diagram, which displays factors that affect a quality characteristic or problem.

Figure 2.7 Overview of Quality Problem-Solving Procedures

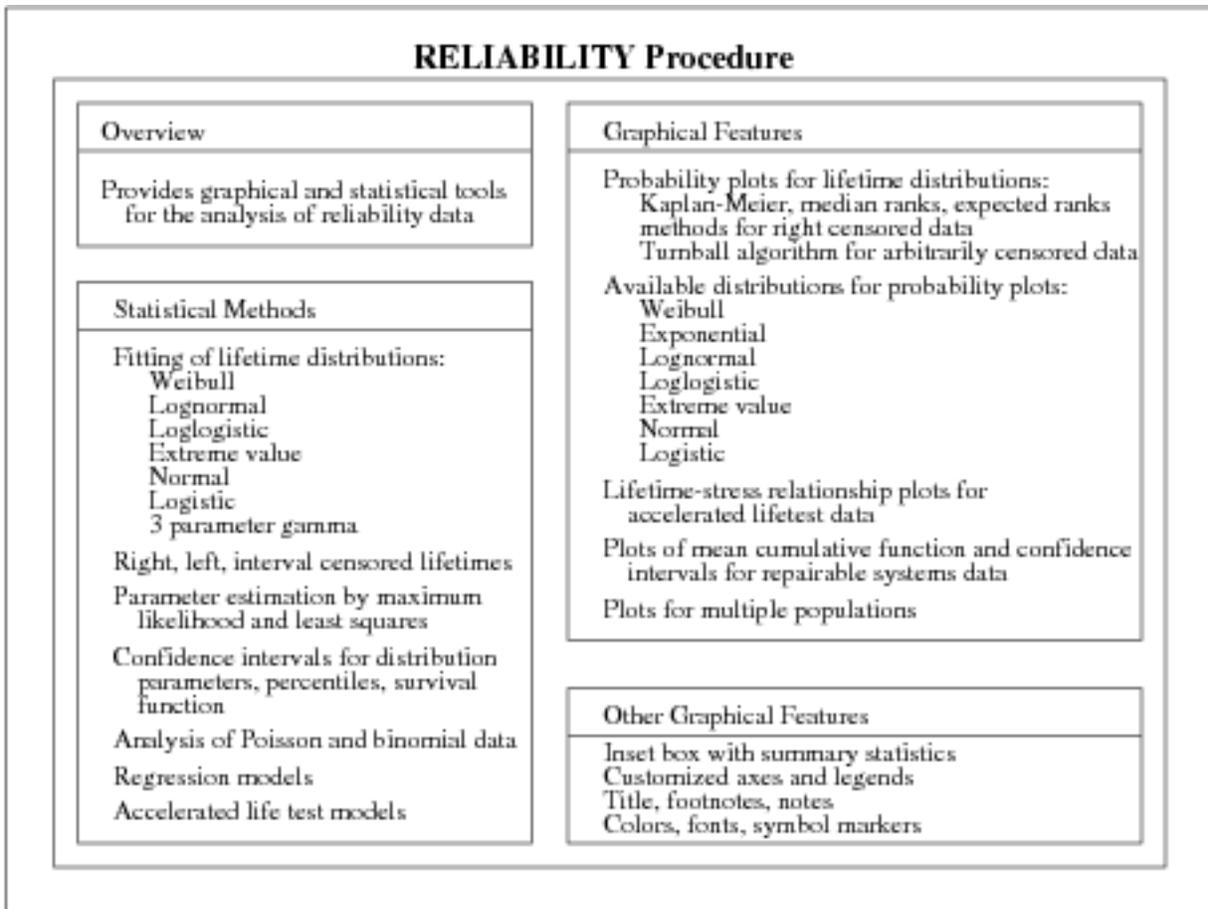

Procedure for Reliability Analysis

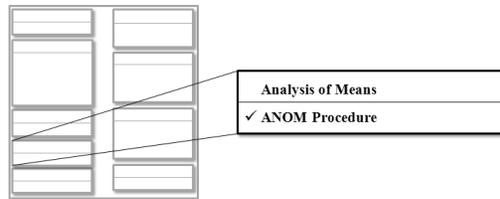

The RELIABILITY procedure provides tools for reliability and survival data analysis and for recurrence data analysis.

Figure 2.8 Overview of Reliability Analysis Procedure

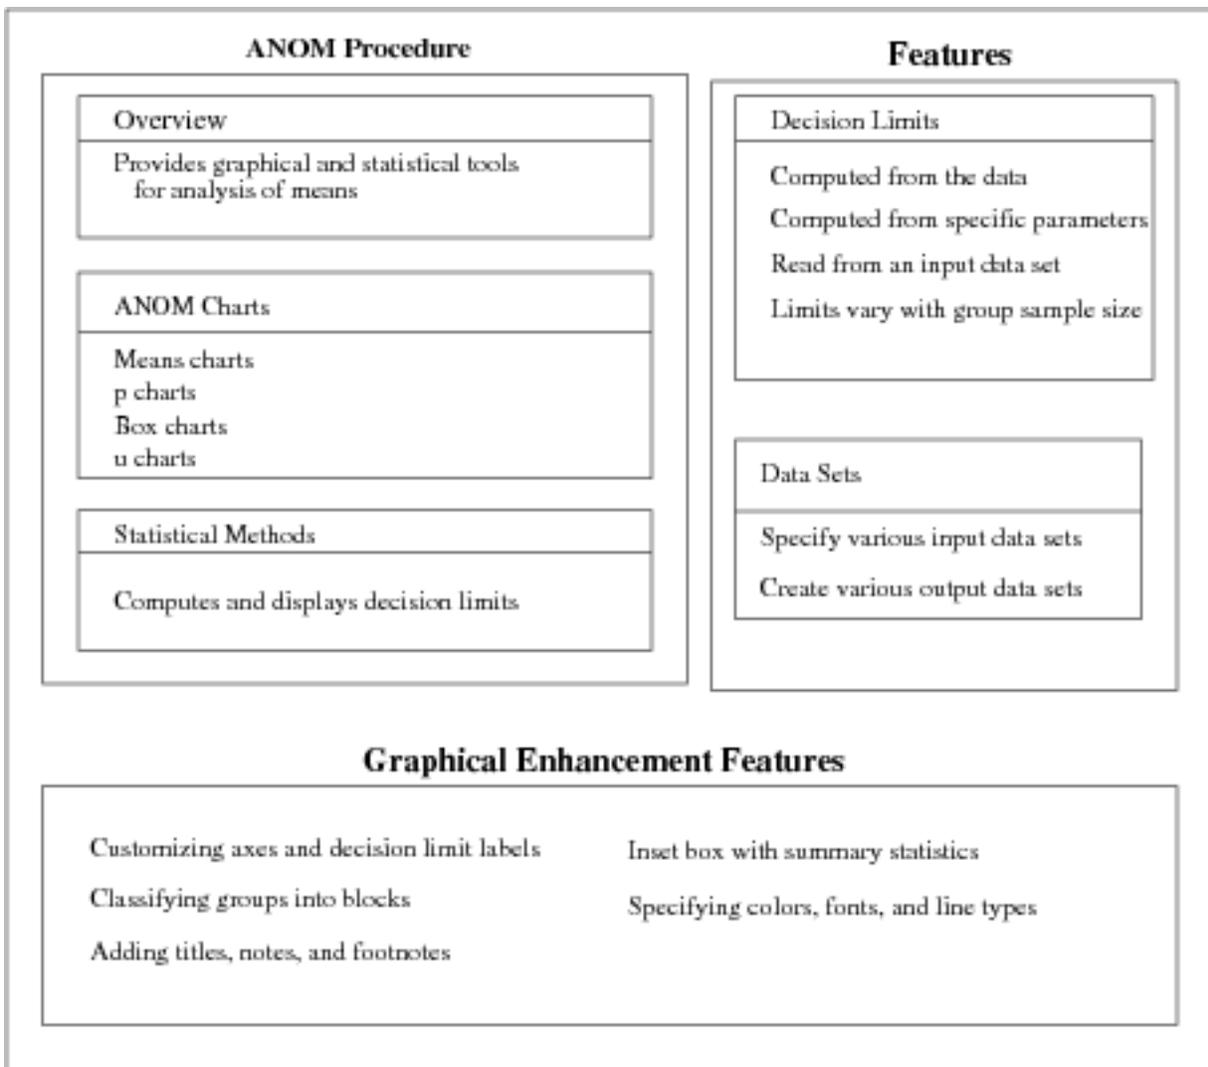

Procedure for Analysis of Means

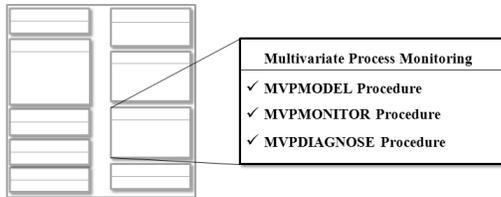

The ANOM procedure provides tools for simultaneously comparing a group of k treatment means with their overall mean at a specified significance level α . The procedure creates ANOM charts for various types of response data, including continuous measurements, proportions, and rates.

Figure 2.9 Overview of Analysis of Means Procedure

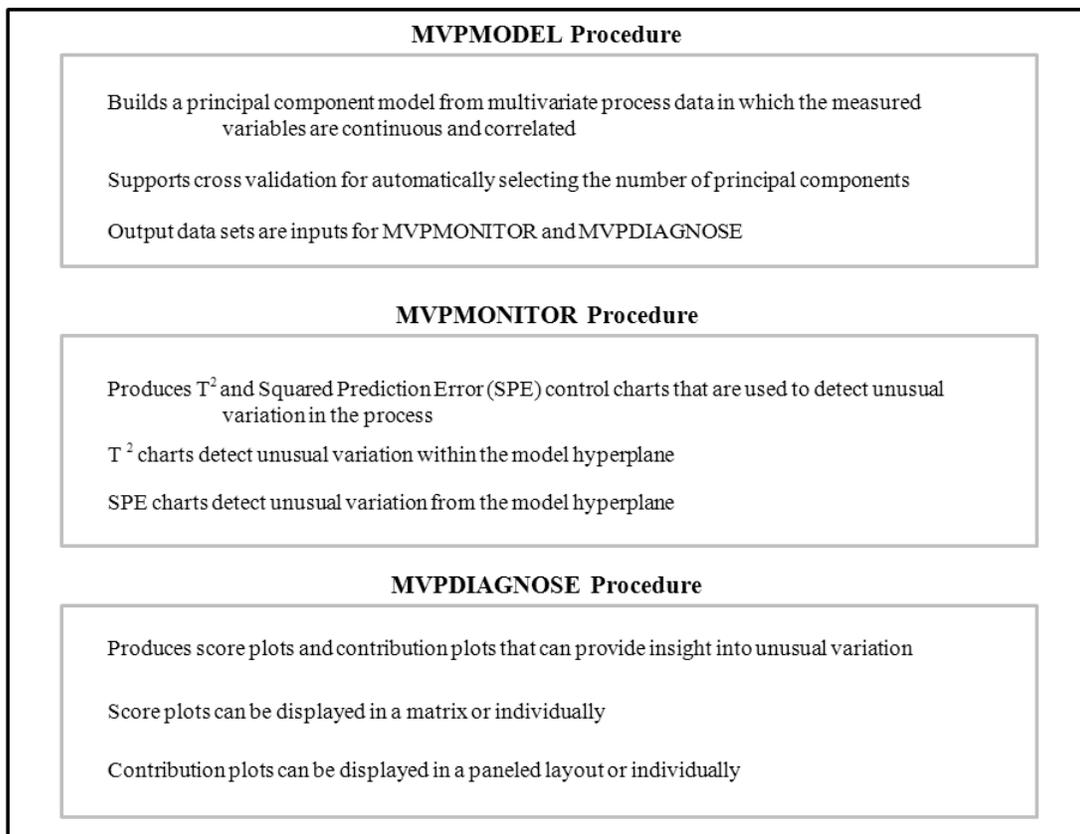

Procedures for Multivariate Process Monitoring

The MVPMODEL procedure builds a principal component model from multivariate process data. The MVPMONITOR procedure creates multivariate control charts that are used to detect unusual variation in the process. The MVPDIAGNOSE procedure produces plots that can be used to investigate unusual variation.

Figure 2.10 Overview of Multivariate Process Monitoring Procedures

Chapter 3

SAS/QC Graphics

Contents

Overview	17
Which Graphics Approach Should You Use?	18
Traditional Graphics	19
ODS Graphics	25
Legacy Line Printer Displays	34

This chapter describes the alternatives available for producing graphical output with the SAS/QC procedures. The statements you use to produce graphical output and the options you specify to control its appearance are described in the chapters of *SAS/QC User's Guide* devoted to the various procedures.

Overview

The following SAS/QC procedures produce graphical output:

- ANOM
- CAPABILITY
- CUSUM
- ISHIKAWA
- MACONTROL
- MVPDIAGNOSE
- MVPMODEL
- MVPMONITOR
- PARETO
- RELIABILITY
- SHEWHART

The ISHIKAWA procedure (Chapter 8, “The ISHIKAWA Procedure,”) provides an interactive environment for creating Ishikawa diagrams. This discussion applies to the other procedures, which generate graphical displays when you specify appropriate statements and options.

SAS/QC procedures can produce two types of graphical output¹:

- traditional graphics
- ODS Statistical Graphics output

Traditional graphics are saved in a graphics catalogs with entry type GRSEG, and their appearance is controlled by global statements such as the GOPTIONS, AXIS, and SYMBOL statements, which are described in *SAS/GRAPH: Reference*. In addition, SAS/QC procedures provide numerous options for controlling the appearance of traditional graphics. You must have a SAS/GRAPH[®] license to produce traditional graphics.

Beginning with SAS 9.2, SAS/QC procedures can use ODS Statistical Graphics to create graphs. ODS Statistical Graphics (or ODS Graphics for short) is an extension to the Output Delivery System (ODS). Graphs are produced in standard image file formats (such as PNG) instead of graphics catalogs, and the details of their appearance and layout are controlled by ODS styles and templates rather than global statements and procedure options. Graphical output produced by SAS/QC procedures using ODS Graphics is consistent in appearance with graphical output produced by statistical procedures using ODS Graphics.

When ODS Graphics is enabled (for example, with the ODS GRAPHICS ON statement) SAS/QC procedures produce ODS Graphics output. Otherwise, they produce traditional graphics by default. **NOTE:** The MVPDIAGNOSE, MVPMODEL, and MVPMONITOR procedures do not support traditional graphics.

Which Graphics Approach Should You Use?

Beginning with SAS 9.2, SAS/QC procedures can produce ODS Graphics output as an alternative to traditional graphics. Also beginning with SAS 9.2, the default appearance of traditional graphics is determined by the ODS style that is in effect for the ODS destination that you are using. You can prevent the ODS style from affecting the appearance of traditional graphics by specifying the NOGSTYLE system option. Therefore, you have three alternatives for producing graphical output with SAS/QC procedures:

- traditional graphics without ODS styles
- traditional graphics using ODS styles
- ODS Graphics

¹Some SAS/QC procedures can also produce legacy line printer charts. See “Legacy Line Printer Displays” on page 34.

The appropriate approach depends on your objective, as follows:

- If you are working with a SAS program written prior to SAS 9.2, and your priority is to preserve the appearance of traditional graphics produced with SAS/QC procedures, you should specify the NOGSTYLE system option.
- If you are writing a new SAS program, consider using traditional graphics with ODS style-dependent defaults to take advantage of their improved appearance while retaining control over every detail of your graphs with procedure options.
- If you are writing a new SAS program, consider using ODS Graphics for the highest-quality graphics output and consistency with output from SAS/STAT procedures and other procedures that are enabled to use ODS Graphics.

The next two sections provide more details and examples of these approaches.

Traditional Graphics

The following SAS/QC procedures support traditional graphics:

- ANOM
- CAPABILITY
- CUSUM
- MACONTROL
- PARETO
- RELIABILITY
- SHEWHART

These procedures support global SAS statements (such as GOPTIONS, AXIS, and SYMBOL statements) used to control the appearance of traditional graphics. Each procedure also supports a rich set of options providing detailed control of features specific to its graphs.

Prior to SAS 9.2 the default appearance of SAS/QC graphs was primitive. To produce attractive graphical output, careful selection of colors, fonts, and other attributes specified with global statements and procedure options was required. Beginning with SAS 9.2, the default appearance of traditional graphs is determined by the ODS style that is in effect.

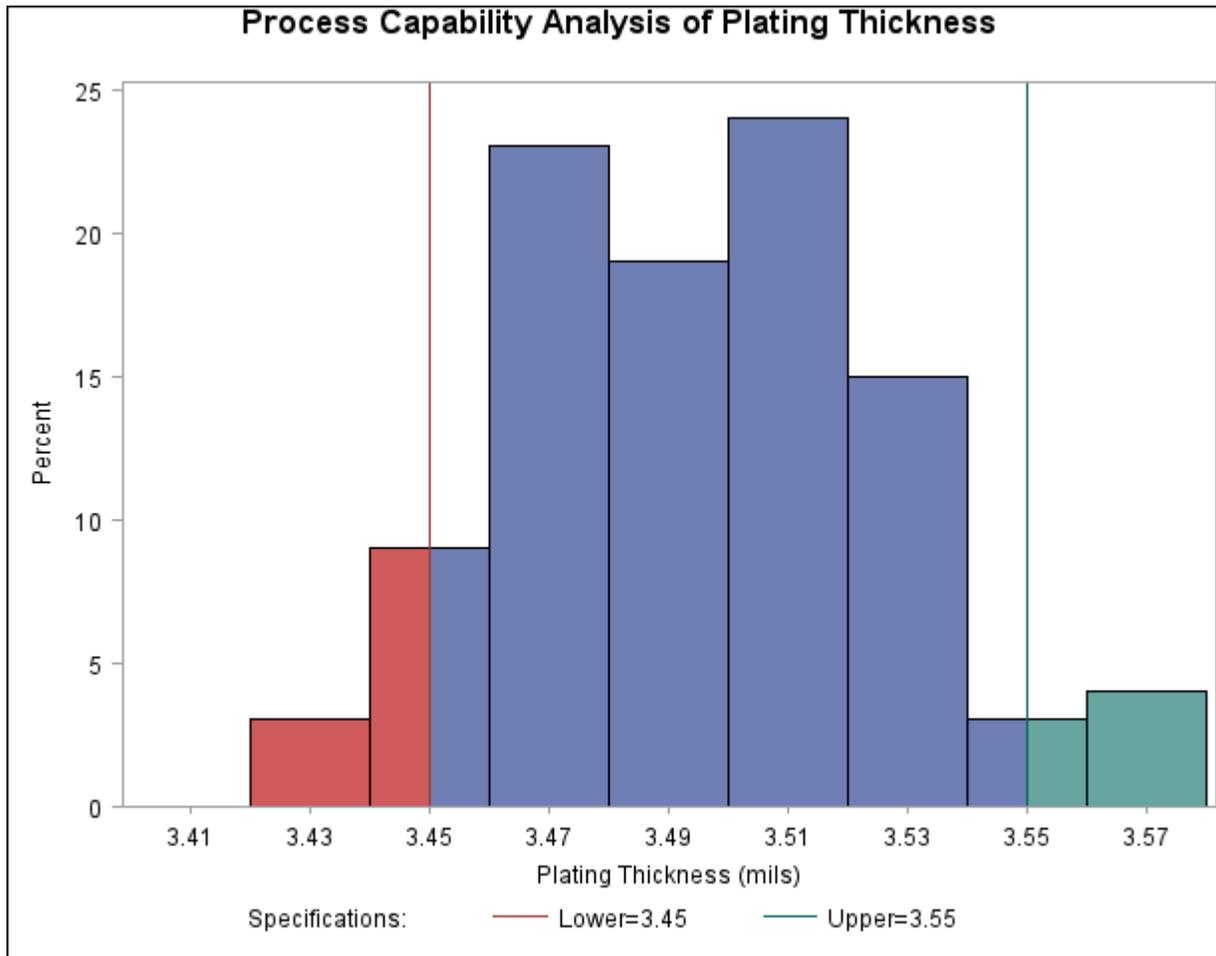

An example taken from the “Getting Started: HISTOGRAM Statement” on page 310 section of Chapter 5, “The CAPABILITY Procedure,” demonstrates the alternatives for producing SAS/QC graphics. The following statements create a data set named Trans containing measurements of the thickness of copper plating on 100 printed circuit boards:

```
data Trans;
  input Thickness @@;
  label Thickness='Plating Thickness (mils)';
  datalines;
3.468 3.428 3.509 3.516 3.461 3.492 3.478 3.556 3.482 3.512
3.490 3.467 3.498 3.519 3.504 3.469 3.497 3.495 3.518 3.523
3.458 3.478 3.443 3.500 3.449 3.525 3.461 3.489 3.514 3.470
3.561 3.506 3.444 3.479 3.524 3.531 3.501 3.495 3.443 3.458
3.481 3.497 3.461 3.513 3.528 3.496 3.533 3.450 3.516 3.476
3.512 3.550 3.441 3.541 3.569 3.531 3.468 3.564 3.522 3.520
3.505 3.523 3.475 3.470 3.457 3.536 3.528 3.477 3.536 3.491
3.510 3.461 3.431 3.502 3.491 3.506 3.439 3.513 3.496 3.539
3.469 3.481 3.515 3.535 3.460 3.575 3.488 3.515 3.484 3.482
3.517 3.483 3.467 3.467 3.502 3.471 3.516 3.474 3.500 3.466
;
```

The following statements produce a histogram of the variable Thickness using traditional graphics whose default appearance is determined by the ODS style.

```
ods graphics off;
title 'Process Capability Analysis of Plating Thickness';
proc capability data=Trans noprint;
  spec lsl=3.45 usl=3.55 cleft cright;
  histogram Thickness;
run;
```

The SPEC statement LSL= and USL= options specify the lower specification limit (LSL) and upper specification limit (USL) for Thickness. The CLEFT and CRIGHT options request that histogram bars (and portions of bars) below the LSL and above the USL be filled with contrasting colors. Figure 3.1 shows the resulting histogram.

Figure 3.1 Traditional Graphics with Default Appearance Determined by ODS Style

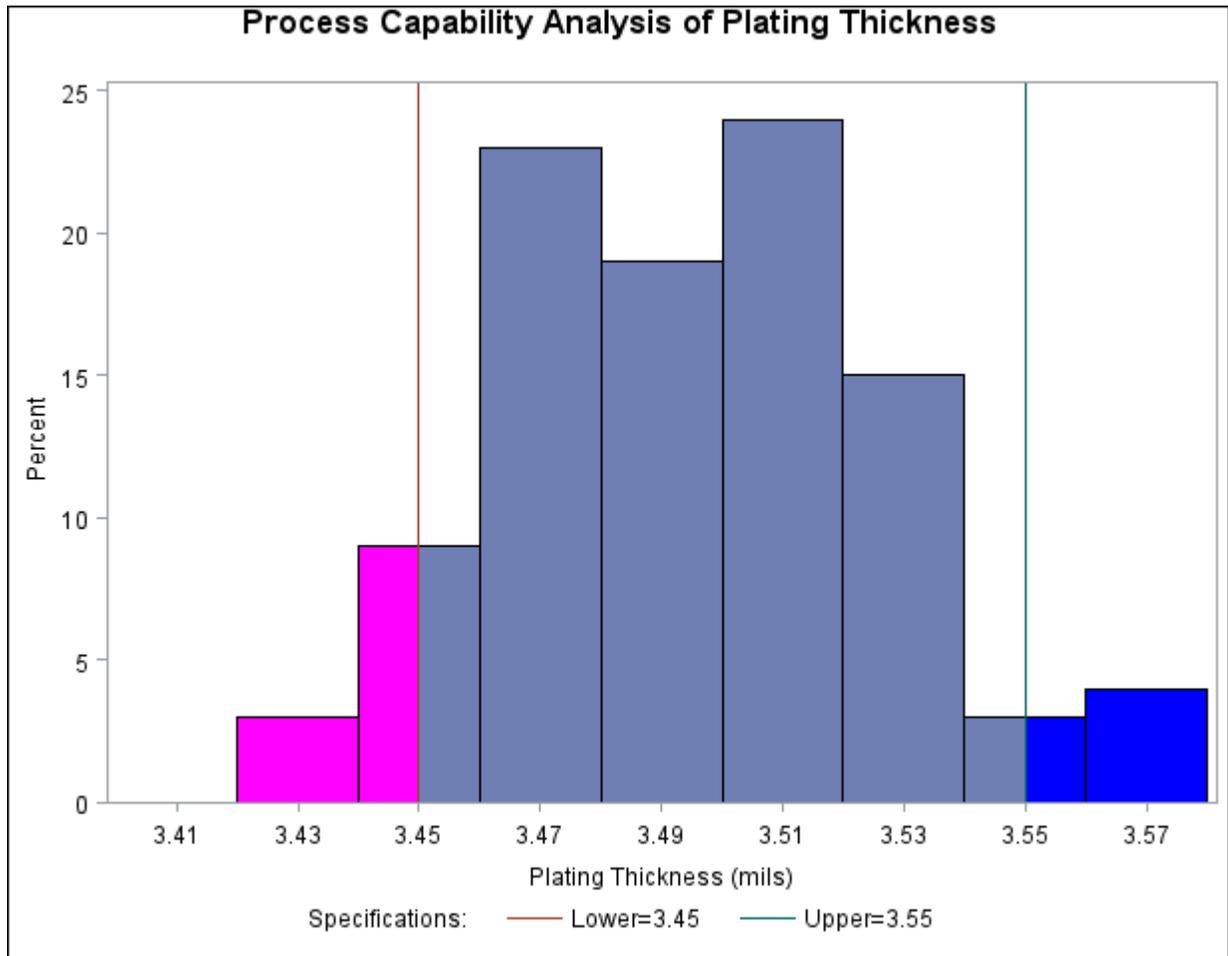

The attributes determining the appearance of the graph elements—including text fonts and heights, line styles and thicknesses, and fill colors—all come from the ODS style associated with the output destination. In this case the HTMLBLUE style is in effect.

Prior to SAS 9.2, in order to fill histogram bars outside the specification limits with contrasting colors, it was necessary to specify CLEFT= and CRIGHT= colors explicitly. SAS/QC procedures now support options such as CLEFT and CRIGHT that enable optional graph features *without* explicitly specifying colors.

In SAS 9.2, you can still specify colors “on top of” the ODS style, as the following statements demonstrate:

```
proc capability data=Trans noprint;
  spec ls1=3.45 us1=3.55 cleft=magenta cright=blue;
  histogram Thickness;
run;
```

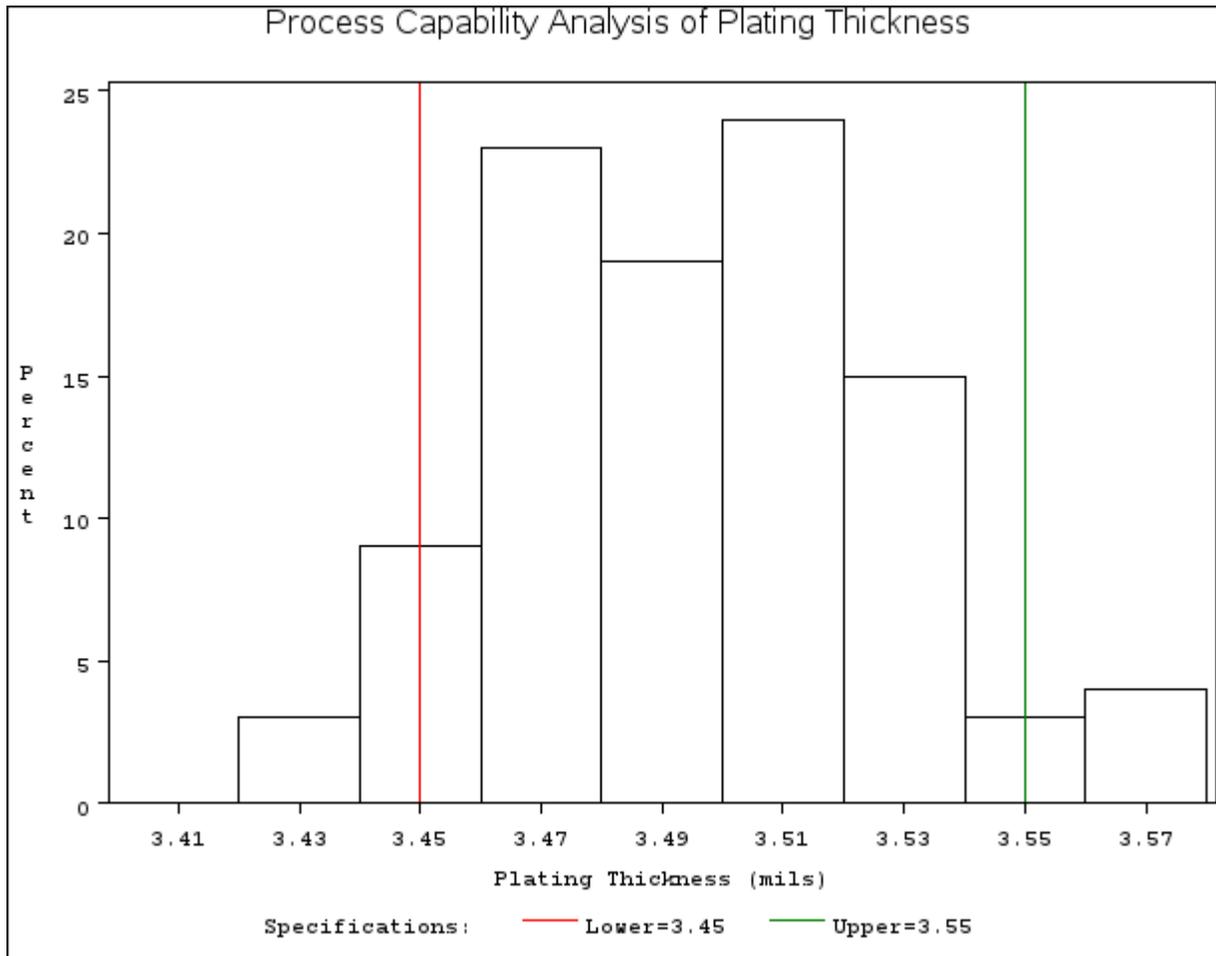

The colors explicitly specified with the CLEFT= and CRIGHT= options replace the CLEFT and CRIGHT colors used in Figure 3.1. The resulting histogram is shown in Figure 3.2.

Figure 3.2 Traditional Graphics Using ODS Style and Appearance Options

Graphical attributes, such as colors or fonts, specified with global graphics statements or procedure options take precedence over default attributes from the ODS style. To avoid using style-based defaults or to revert to the defaults used prior to SAS 9.2, you can specify the NOGSTYLE system option:

```
options nogstyle;
proc capability data=Trans noprint;
  spec lsl=3.45 usl=3.55;
  histogram Thickness;
run;
```

The appearance of the resulting histogram, shown in [Figure 3.3](#), is very similar to that of a histogram produced by the same CAPABILITY procedure statements in SAS 9.1.

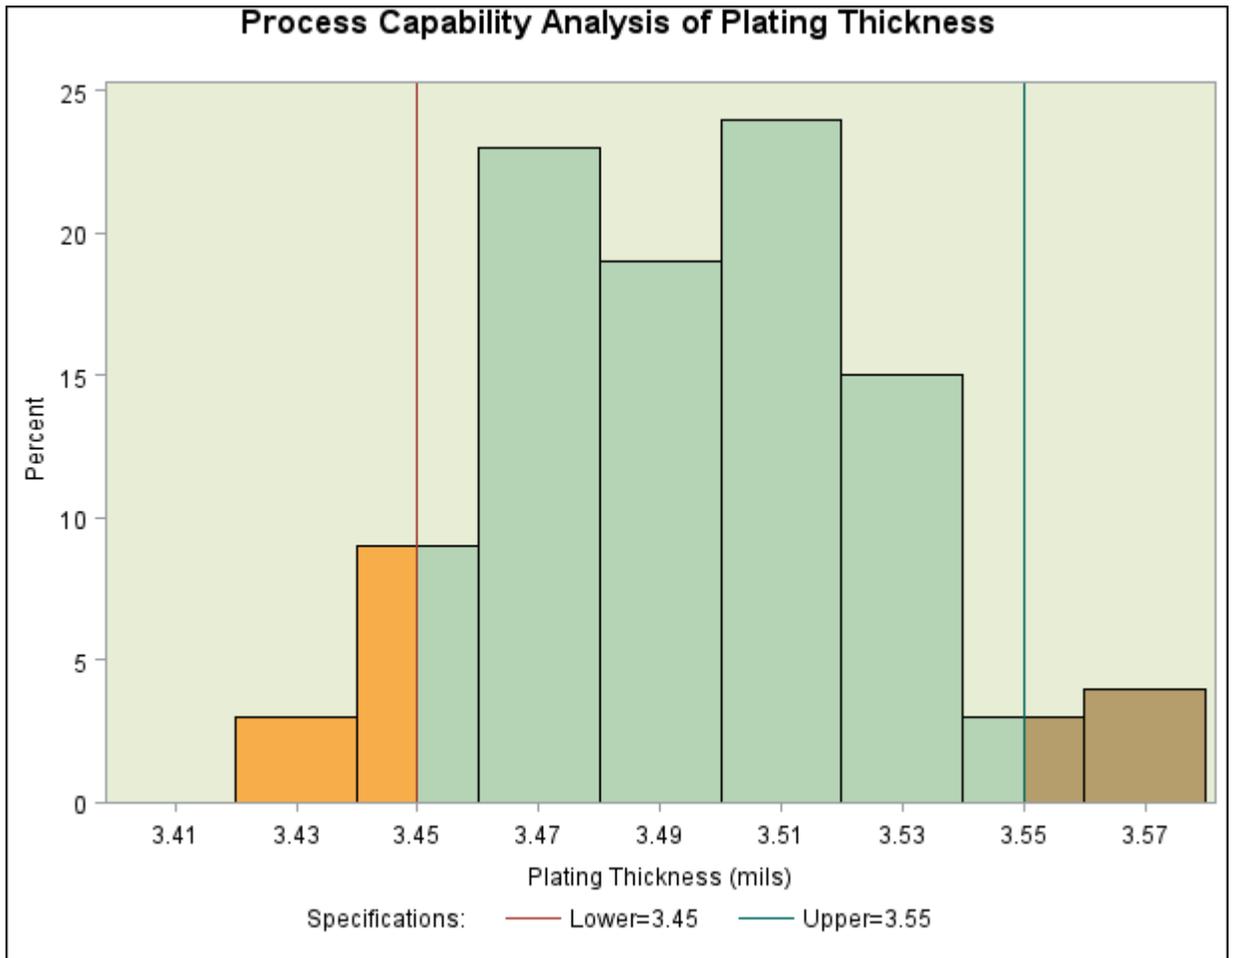

Figure 3.3 Traditional Graphics with NOGSTYLE

When you specify the NOGSTYLE option, traditional graphics output remains unaffected by ODS styles until the default behavior is restored with the GSTYLE option:

```
options gstyle;
proc capability data=Trans noprint;
  spec lsl=3.45 usl=3.55 cleft=CXf7AE4A cright=CXB59E6B;
  histogram Thickness / cframe = ywh
                    cfill = CXB5D3B5;
run;
```

The preceding statements produce the histogram shown in [Figure 3.4](#). Here, the default attributes provided by the HTMLBLUE style are overridden by the CLEFT=, CRIGHT=, CFRAME=, and CFILL= options.

Figure 3.4 Traditional Graphics Using ODS Style and Attribute Options

ODS Graphics

The following SAS/QC procedures support ODS Graphics:

- ANOM
- CAPABILITY
- CUSUM
- MACONTROL
- MVPDIAGNOSE
- MVPMODEL
- MVPMONITOR
- PARETO
- RELIABILITY
- SHEWHART

ODS Graphics provides the highest quality graphical output available from SAS/QC procedures. It is unaffected by global graphics statements, procedure options for controlling traditional graphics, and the GSTYLE system option. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for a thorough discussion of ODS Graphics. **NOTE:** In SAS/QC 12.1 the ANOM, CUSUM, MACONTROL, MVPMONIOR, and SHEWHART procedures do not support the creation of graphs that are editable with the ODS Graphics Editor.

The following statements produce a histogram of the variable Thickness, which is discussed in the previous section. Here, the ODS GRAPHICS statement is specified to request ODS Graphics.

```
ods listing style=htmlblue;
ods graphics on;
proc capability data=Trans noprint;
    spec lsl = 3.45 usl = 3.55 cleft cright;
    histogram Thickness;
run;
```

Figure 3.5 shows the ODS Graphics version of the histogram. Note that fonts, colors, and other attributes are determined by the HTMLBLUE style. Options for specifying these attributes (as used, for example, in the statements that produced Figure 3.4) are not applicable with ODS Graphics and are ignored when you use the ODS GRAPHICS statement.

Figure 3.5 ODS Graphics Using HTMLBLUE Style

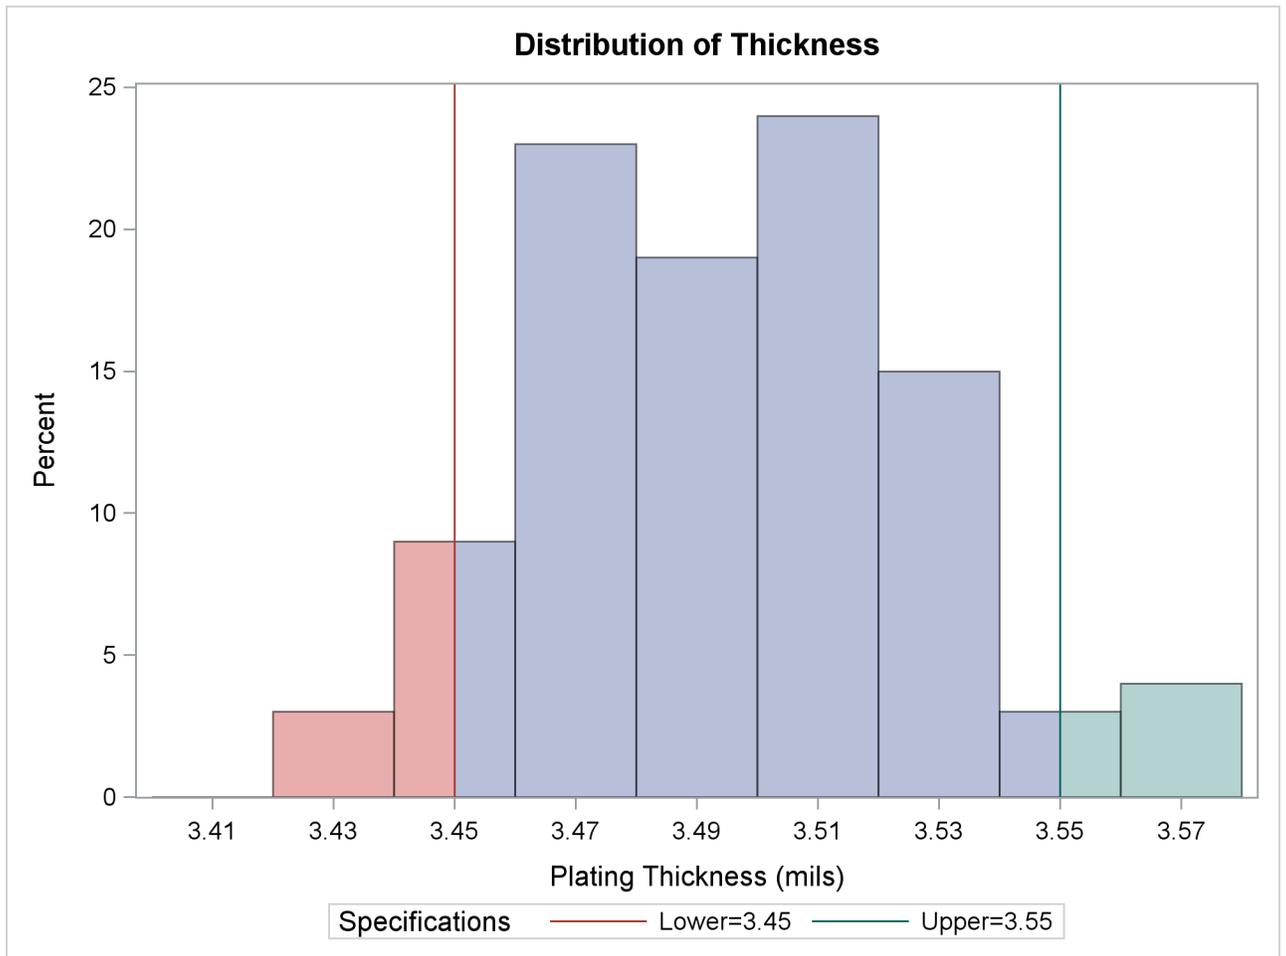

Figure 3.6 through Figure 3.13 show examples of ODS Graphics output produced by SAS/QC procedures. These graphs were all created with the HTMLBLUE style.

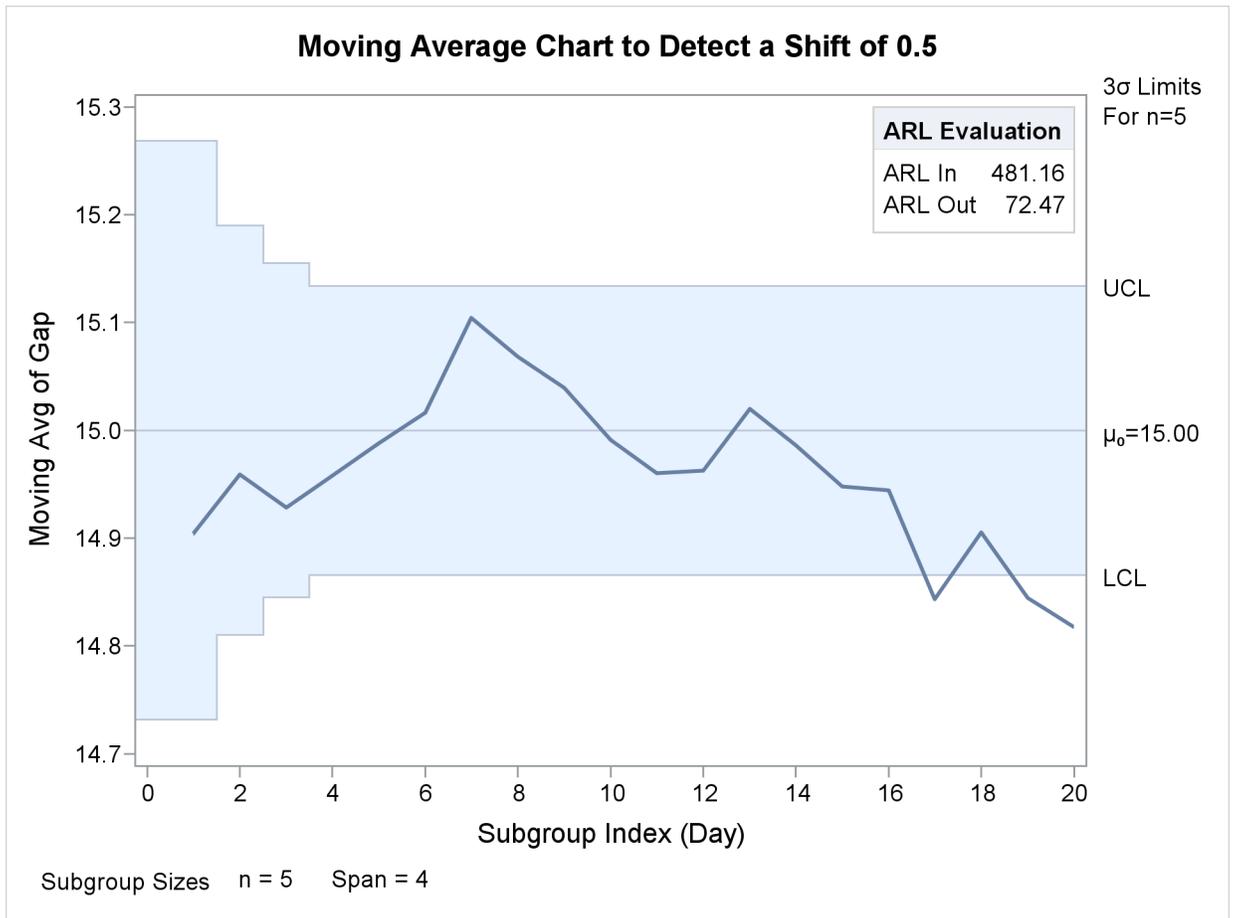

Figure 3.10 Pareto Chart

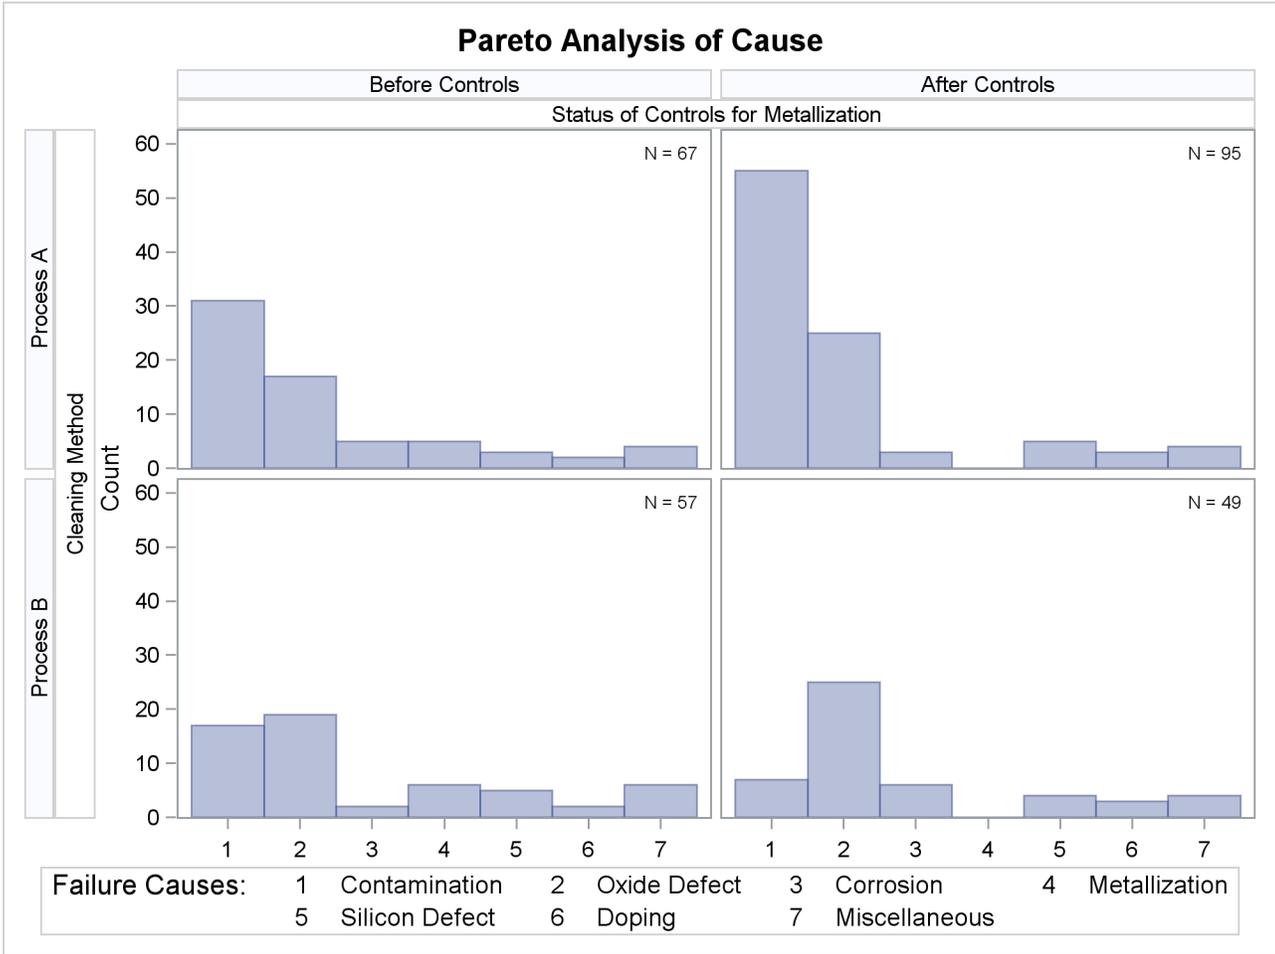

Figure 3.11 Probability Plot (RELIABILITY)

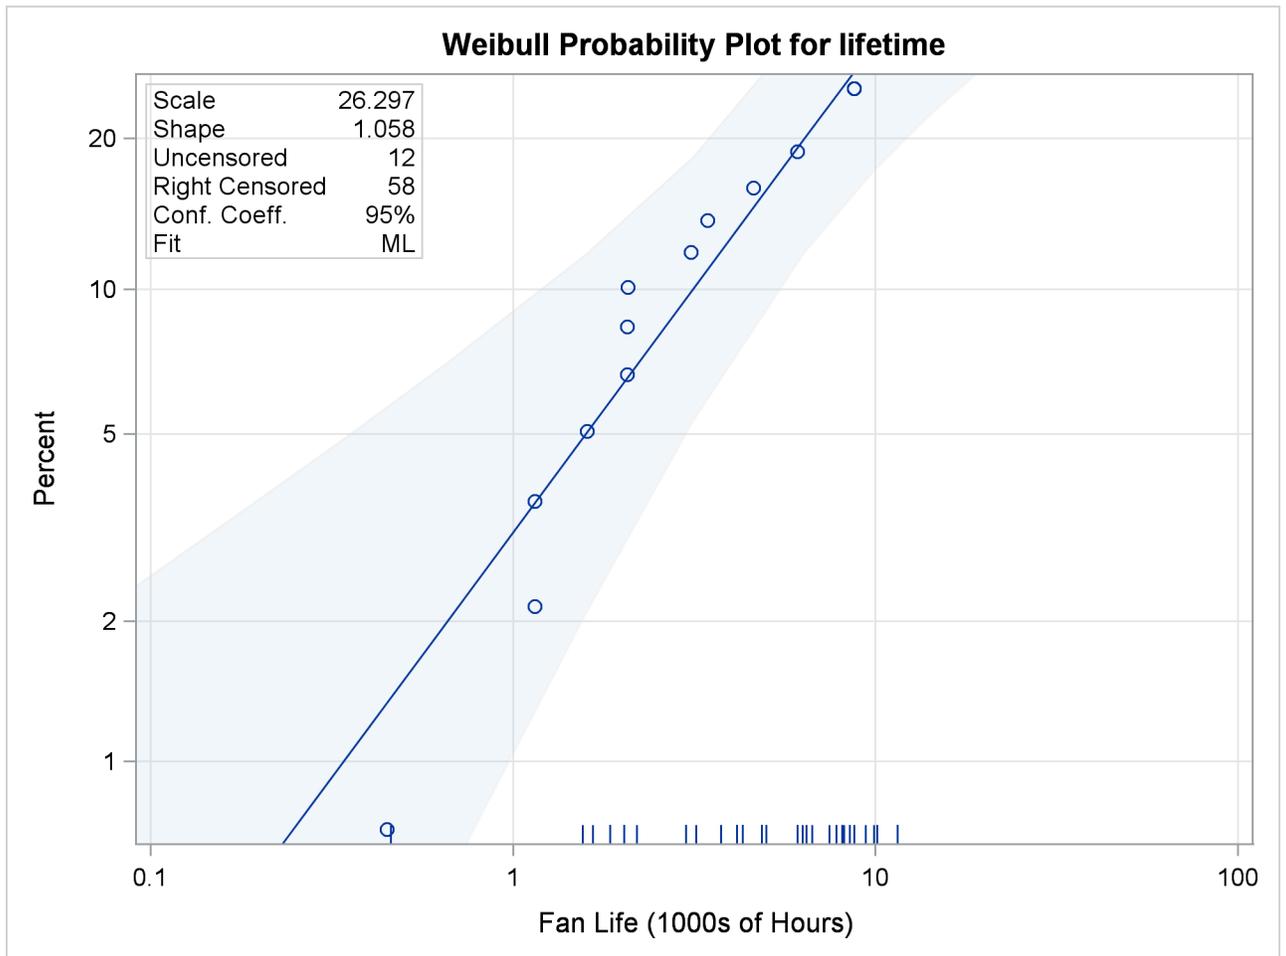

Figure 3.12 Q-Q Plot (CAPABILITY)

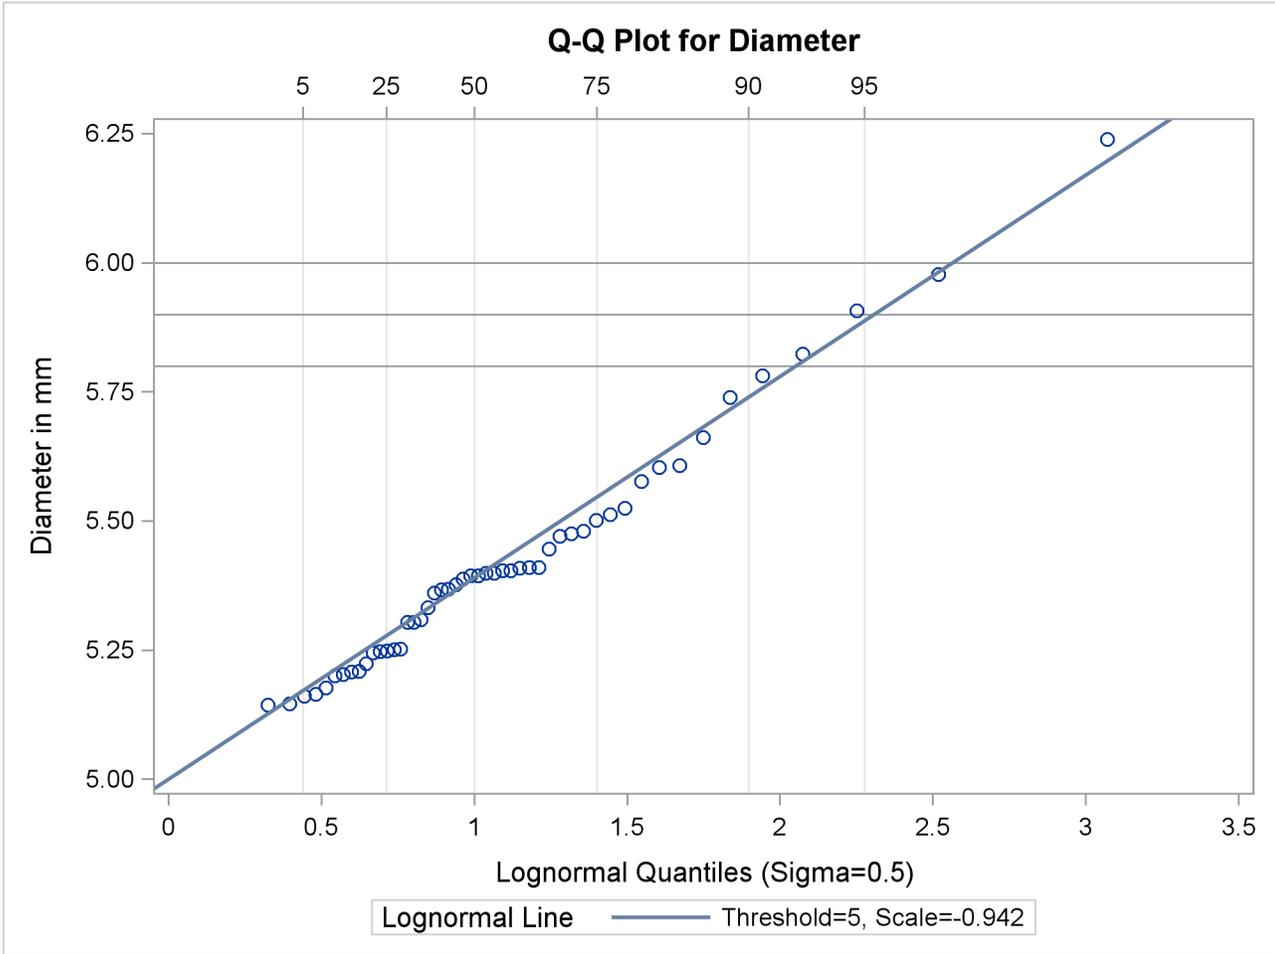

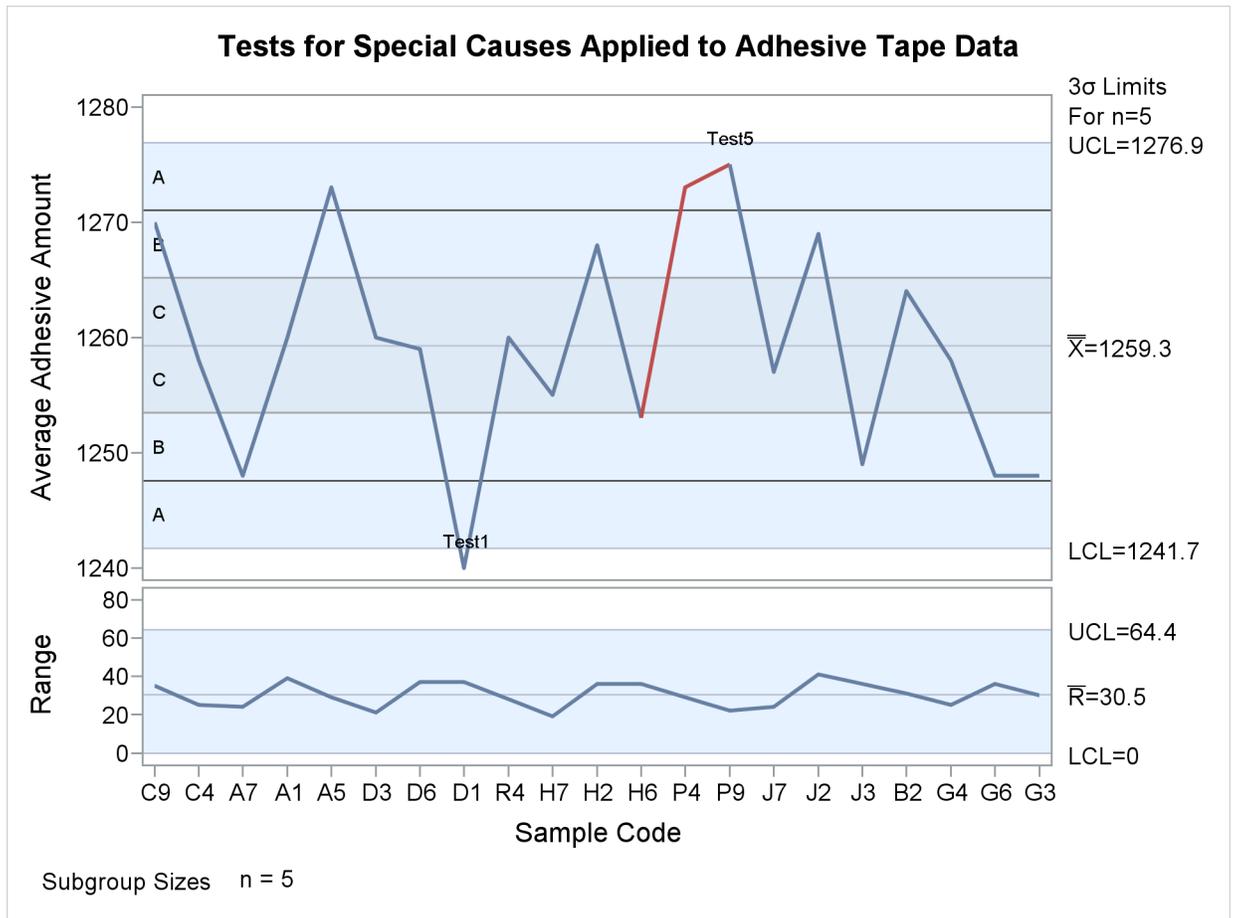

Figure 3.13 \bar{X} and R Chart (SHEWHART)

Legacy Line Printer Displays

The following SAS/QC procedures continue to support legacy line printer charts and plots, drawn with characters, which are produced in the SAS output listing:

- CAPABILITY
- CUSUM
- MACONTROL
- PARETO
- SHEWHART

Beginning with SAS 7, these procedures produce high-resolution graphics by default, and you must specify the LINEPRINTER option in the PROC statement to create line printer charts, as illustrated by the following statements.

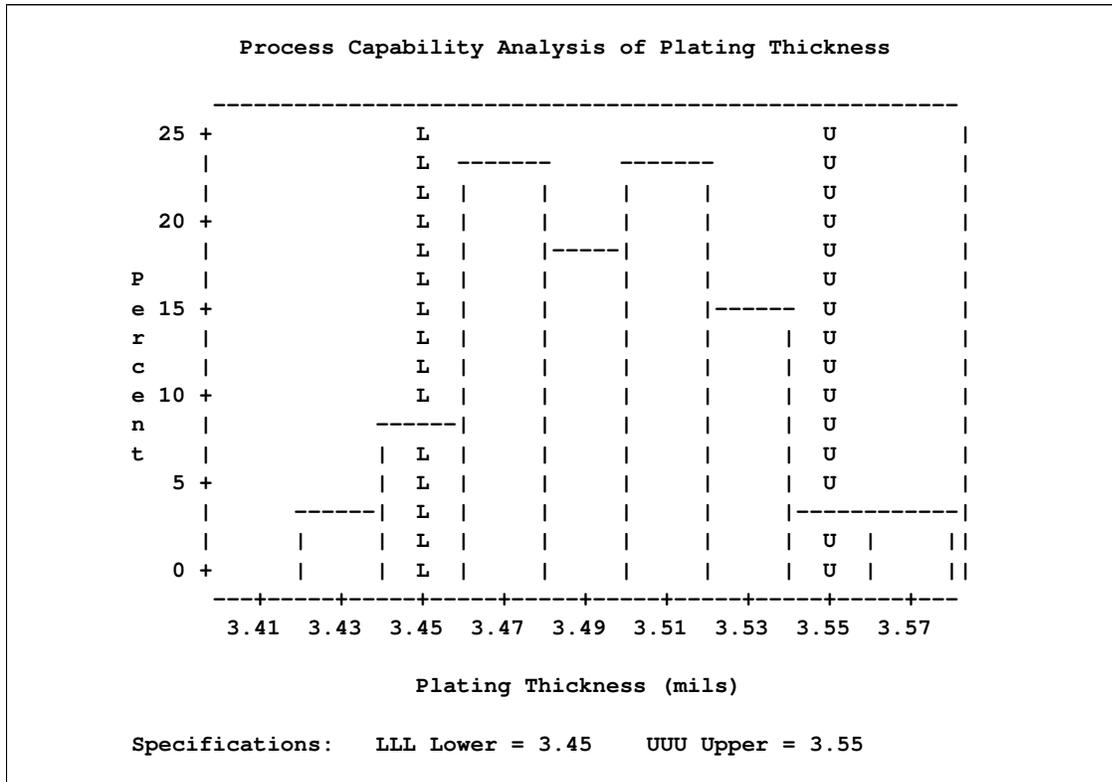

```

title 'Process Capability Analysis of Plating Thickness';
proc capability data=Trans noprint lineprinter;
  spec lsl=3.45 usl=3.55;
  histogram Thickness;
run;

```

The resulting histogram is shown in Figure 3.14.

Figure 3.14 Legacy Line Printer Display

In SAS/QC, some charts and plots are not supported with the LINEPRINTER option. For example, line printer displays are not available with the CAPABILITY procedure's COMPHISTOGRAM statement or the PARETO procedure's HBAR statement.

PROC ANOM and General Statements

Overview: ANOM Procedure

Analysis of means (ANOM) is a graphical and statistical method for simultaneously comparing k treatment means with their overall mean at a specified significance level α . You can use the ANOM procedure to create ANOM charts for various types of response data, including continuous measurements, proportions, and rates.

In addition, you can use the ANOM procedure to do the following:

- create charts from either response values or summarized data
- analyze multiple response variables
- specify decision limits in terms of the significance level (α)
- compute decision limits from the data and automatically adjust decision limits for unequal sample sizes
- save chart statistics and decision limits in output data sets
- tabulate chart statistics and decision limits.

See Chapter 3, “SAS/QC Graphics,” for a detailed discussion of the alternatives available for producing charts with SAS/QC procedures.

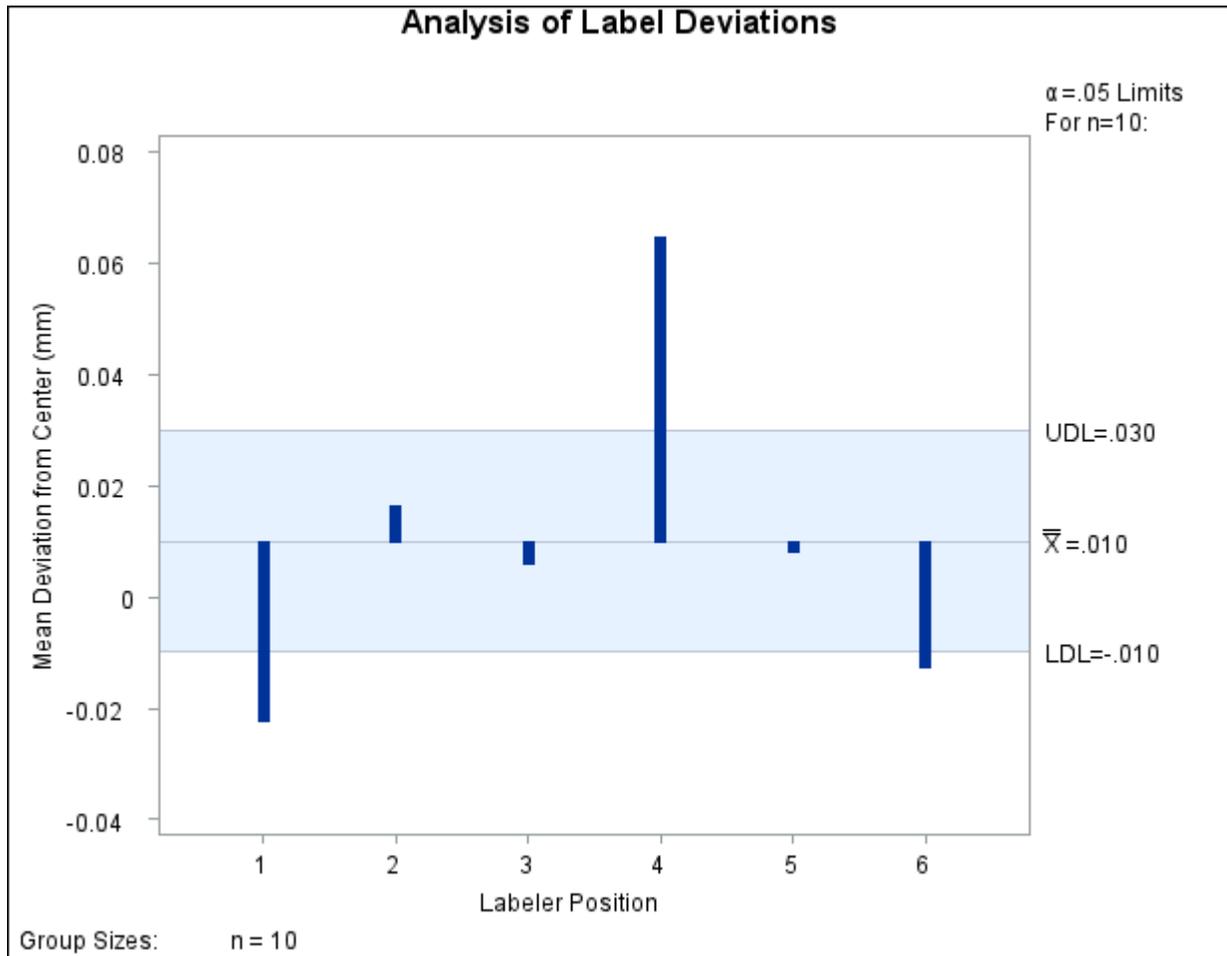

Uses of Analysis of Means

Many statistical quality improvement applications involve a comparison of treatment means to determine which are significantly different from the overall average. For example, a manufacturing engineer might run an experiment to investigate which of six positions on a machine are producing different output, in the sense that the average measurement for each position differs from the overall average. Likewise, a health care system administrator might ask which clinics in the system have a higher or lower rate of admissions than the average for all clinics.

Questions of this type can be answered with *analysis of means*, which is an alternative to one-way analysis of variance (ANOVA) for a fixed effects model. However, unlike ANOVA, which simply determines whether there is a statistically significant difference in the treatment means, ANOM identifies the means that are significantly different from the overall mean. As a statistical technique, ANOM is a method for making multiple comparisons that is sometimes referred to as a “multiple comparison with the weighted mean.” Analysis of means lends itself to quality improvement applications because it has a simple graphical representation that is similar to a Shewhart chart and requires little training to interpret. This representation is also useful for assessing practical significance.

Figure 4.1 illustrates a typical ANOM chart. The central line represents the overall average. The treatment means, plotted as deviations from the overall average are compared with upper and lower decision limits to identify which are significantly different from the overall mean (in this case, the means corresponding to the first, fourth, and sixth positions).

Figure 4.1 Typical ANOM Chart

Although the term “analysis of means” suggests that the method is intended for means of continuous response measurements, the method is also applicable to means of attributes data, including proportions and rates.

Analysis of means was introduced as a tool for statistical quality control by Ellis Ott in 1967, and it became popular during the early 1980s, when it was applied to experimental data in manufacturing. In this setting, measurements are taken at a number of treatment levels (factor levels). During the 1990s, the use of ANOM spread to service industry applications and, in particular, health care quality improvement. In these settings, data (such as utilization rates) are observed for a number of groups (such as hospitals or clinics).

Terminology

In order to accommodate the growing variety of modern applications for analysis of means, the term *group* is used instead of treatment level throughout the documentation for the ANOM procedure. Likewise, the term *group-variable* is used to refer to the variable in the input data set that classifies the observations into treatment levels. In the ANOM procedure, a *group-variable* plays the same role as a CLASS variable in the GLM and ANOVA procedures, and it is syntactically the same as a *subgroup-variable* in the SHEWHART procedure.

The nomenclature for ANOM charts is the same as that for Shewhart charts: \bar{X} charts for means, p charts for proportions, and u charts for rates. Consequently, the syntax for the ANOM procedure is patterned after the syntax for the SHEWHART procedure. However, there are some important differences between ANOM charts and Shewhart charts:

- Analysis of means is formally a test of hypothesis, whereas a Shewhart chart is used to distinguish between special and common causes of variation.
- In an ANOM chart, the horizontal axis corresponds to the *group-variable*, and it identifies the groups, which can be displayed in any order. In a Shewhart chart, the horizontal axis corresponds to the *subgroup-variable*, and it identifies the order in which the subgroup measurements were taken.
- An ANOM chart displays response summary statistics for a set of groups (treatments) at a specific time. A Shewhart chart displays subgroup summary statistics for a specific process where the subgroups are made up of measurements taken over successive points in time.
- In an ANOM chart, the decision limits are determined by a specified significance level (α), which is the probability that under the null hypothesis of no treatment differences, at least one of the response summary statistics will exceed the decision limits. In a Shewhart chart, control limits are typically computed as 3σ limits.

History

Analysis of means compares the absolute deviations of group means from their overall mean, an approach that was initially studied by Laplace in 1827. Halperin et al. derived a version of this method in the form of a multiple significance test in 1955. Ott developed a graphical representation for the test and introduced the term “analysis of means” in 1967. Refer to Ott (1967) and Ott (1975).

P. R. Nelson (1982a) and L. S. Nelson (1983) provided exact critical values for ANOM when the groups have equal sample sizes. P. R. Nelson (1991) developed a method for computing exact critical values for ANOM when the group sample sizes are not equal. Refer to Nelson, Coffin, and Copeland (2003) for more information on the use of ANOM in engineering experimentation.

Using the ANOM Procedure

The PROC ANOM statement invokes the ANOM procedure and it optionally identifies various data sets.

To create an ANOM chart, you specify a chart statement (after the PROC ANOM statement) that specifies the type of ANOM chart you want to create and the variables in the input data set that you want to analyze. For example, the following statements request a basic ANOM chart for treatment means:

```
proc anom data=Values;
    xchart Weight*Treatment;
run;
```

Here, the DATA= option specifies an input data set (Values) that contains the *response* measurement variable (Weight) and the *group-variable* (Treatment). You can use options in the PROC ANOM statement to

- specify input data sets containing variables to be analyzed, decision limits, and annotation information
- specify a graphics catalog for saving graphical output

NOTE: If you are learning to use the ANOM procedure, you should read both this section and the “Getting Started” subsection in the section for the chart statement that corresponds to the chart you want to create.

Syntax: ANOM Procedure

The following are the primary statements that control the ANOM procedure:

```

PROC ANOM < options > ;
BOXCHART (responses) * group-variable <(block-variables)>
           <=symbol-variable> </ options > ;
PCHART (responses) * group-variable
           <(block-variables)>
           <=symbol-variable> </ options > ;
UCHART (responses) * group-variable
           <(block-variables)>
           <=symbol-variable> </ options > ;
XCHART (responses) * group-variable <(block-variables)>
           <=symbol-variable> </ options > ;
INSET keyword-list </ options > ;

```

The PROC ANOM statement invokes the procedure and specifies the input data set. The chart statements create different types of charts. You can specify one or more of each of the chart statements. For details, read the section on the chart statement that corresponds to the type of chart that you want to produce.

BY Statement

BY variables ;

You can specify a BY statement with PROC ANOM to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ANOM procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

In addition, you can optionally specify the following statement:

ID *variables* ;

The ID statement specifies variables used to identify observations. The ID variables must be variables in the DATA= or SUMMARY= input data sets.

The ID variables are used in the following ways:

- If you create an OUTSUMMARY= or OUTTABLE= data set, the ID variables are included. If the input data set is a DATA= data set, only the values of the ID variables from the first observation in each group are passed to the output data set.
- If you specify the TABLEID or TABLEALL options in a chart statement, the table produced is augmented by a column for each of the ID variables. Only the values of the ID variables from the first observation in each group are tabulated.
- If you specify the BOXSTYLE= SCHEMATICID option or the BOXSTYLE= SCHEMATICIDFAR option in the BOXCHART statement, the value of the first variable listed in the ID statement is used to label each extreme observation.

Graphical Enhancement Statements

You can use TITLE, FOOTNOTE, and NOTE statements to enhance graphical and printed output. You can also use AXIS, LEGEND, and SYMBOL statements to enhance traditional graphics. For details, refer to *SAS/GRAPH: Reference* and see the chapter for the chart statement that you are using.

PROC ANOM Statement

The syntax for the PROC ANOM statement is as follows:

PROC ANOM *options* ;

The PROC ANOM statement starts the ANOM procedure and optionally identifies various data sets. The following options can appear in the PROC ANOM statement. The marginal note *Traditional Graphics* identifies options that apply only when producing traditional graphics.

ANNOTATE=SAS-data-set**ANNO=SAS-data-set**

specifies an input data set containing ANNOTATE= variables as described in *SAS/GRAPH: Traditional Graphics Reference*. You can use this data set to add features to ANOM charts produced as traditional graphics. Features provided in this data set are displayed on every chart produced in the current run of the ANOM procedure.

BOX=SAS-data-set

names an input data set that contains group summary statistics, decision limits, and outlier values in “strung out” form, with more than one observation per group. Each observation corresponds to one feature of one group’s box-and-whisker plot. Typically, this data set is created as an OUTBOX= data set in a previous run of the ANOM procedure with a BOX-CHART statement. The BOX= data set is the only kind of summary data set you can use to produce schematic box-and-whisker plots. The BOXCHART statement is the only chart statement you can use with a BOX= input data set.

DATA=SAS-data-set

names an input data set that contains response values (typically, measurements or counts) as observations. Note that the DATA= data set may need sorting. If the values of the *group-variable* are numeric, you must sort the data set so that these values are in increasing order (within BY groups). Use PROC SORT if the data are not already sorted.

The DATA= data set may contain more than one observation for each value of the *group-variable*. This happens, for example, when you produce a chart for means and ranges with the XCHART statement.

You cannot use a DATA= data set together with a SUMMARY= or a TABLE= data set. If you do not specify one of these three input data sets, the ANOM procedure uses the most recently created data set as a DATA= data set. For more information, see the “DATA= Data Set” subsection in the section for the chart statement you are using.

GOUT=graphics-catalog

specifies the graphics catalog for traditional graphics output from the ANOM procedure. This is useful if you want to save the output. *Traditional Graphics*

SUMMARY=SAS-data-set

names an input data set that contains group summary statistics. For example, you can read sample sizes, means, and standard deviations for the groups to create an ANOM chart. Typically, this data set is created as an OUTSUMMARY= data set in a previous run of the ANOM procedure, but it can also be created using a SAS summarization procedure such as PROC MEANS.

Note that the SUMMARY= data sets may need sorting. If the values of the *group-variable* are numeric, you need to sort the data set so that these values are in increasing order (within BY groups). Use PROC SORT if the data are not already sorted. The SUMMARY= data set can contain only one observation for each value for the *group-variable*.

You cannot use a SUMMARY= data set with a DATA= or a TABLE= data set. If you do not specify one of these three input data sets, the ANOM procedure uses the most recently created data set as a DATA= data set. For more information, see the “SUMMARY= Data Set” subsection in the section for the chart statement you are using.

LIMITS=SAS-data-set

names an input data set that contains preestablished decision limits or the parameters from which decision limits can be computed. Each observation in a LIMITS= data set provides decision limit information for a *response*. Typically, this data set is created as an OUTLIMITS= data set in a previous run of the ANOM procedure.

If you omit the LIMITS= option, then decision limits are computed from the data in the DATA= or SUMMARY= input data sets. For details about the variables needed in a LIMITS= data set, see the “LIMITS= Data Set” subsection in the section for the chart statement you are using.

TABLE=SAS-data-set

names an input data set that contains group summary statistics and decision limits. Each observation in a TABLE= data set provides information for a particular group and *response*. Typically, this data set is created as an OUTTABLE= data set in a previous run of the ANOM procedure.

You cannot use a TABLE= data set with a DATA= or a SUMMARY= data set. If you do not specify one of these three input data sets, the ANOM procedure uses the most recently created data set as a DATA= data set. For more information, see the “TABLE= Data Set” subsection in the section for the chart statement that you are using.

BOXCHART Statement: ANOM Procedure

Overview: BOXCHART Statement

The BOXCHART statement creates an ANOM chart for group (treatment level) means of response values superimposed with box-and-whisker plots of the measurements in each group. Throughout this chapter, a chart of this type is referred to as an *ANOM boxchart*. You can use options in the BOXCHART statement to

- compute decision limits from the data based on a specified parameters, such as the significance level (α)
- tabulate group sample sizes, group means, decision limits, and other information
- save decision limits in an output data set
- save group sample sizes and group means in an output data set
- read decision limits and decision limit parameters from a data set
- display distinct sets of decision limits for different sets of groups
- specify one of several methods for calculating quantile statistics (percentiles)
- control the style of the box-and-whisker plots

- add block legends and symbol markers to identify special groups
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have two alternatives for producing ANOM boxcharts with the BOXCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced if SAS/GRAPH[®] is licensed.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: BOXCHART Statement

This section introduces the BOXCHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the BOXCHART statement is presented in the section “Syntax: BOXCHART Statement” on page 57, and advanced examples are given in the section “Examples: BOXCHART Statement” on page 79.

Creating ANOM Boxcharts from Response Values

A manufacturing engineer carries out a study to determine the source of excessive variation in the positioning of labels on shampoo bottles.¹ A labeling machine removes bottles from the line, attaches the labels, and returns the bottles to the line. There are six positions on the machine, and the engineer suspects that one or more of the position heads might be faulty. *See ANMBX1 in the SAS/QC Sample Library*

A sample of 60 bottles, 10 per position, is run through the machine. For each bottle, the deviation of each label is measured in millimeters, and the machine position is recorded. The following statements create a SAS data set named LabelDeviations, which contains the deviation measurements for the 60 bottles:

```
data LabelDeviations;
  input Position @;
  do i = 1 to 5;
    input Deviation @;
    output;
  end;
  drop i;
  datalines;
1 -0.0239 -0.0285 -0.0300 -0.0043 -0.0362
```

¹This example is based on a case study described by Hansen (1990).

```

1  -0.0422  -0.0014  -0.0647   0.0094  -0.0016
2  -0.0201  -0.0273   0.0227  -0.0332   0.0366
2   0.0438   0.0556   0.0098   0.0564   0.0182
3  -0.0073   0.0285  -0.0440  -0.0221  -0.0139
3   0.0486   0.0357   0.0235   0.0134  -0.0020
4   0.0669   0.1073   0.0597   0.0609   0.0755
4   0.0362   0.0561   0.0899   0.0418   0.0530
5   0.0368   0.0036   0.0374   0.0116  -0.0074
5   0.0250  -0.0080   0.0302  -0.0015  -0.0464
6   0.0049  -0.0384  -0.0204  -0.0049  -0.0120
6   0.0071  -0.0308   0.0017  -0.0285  -0.0070
;

```

A partial listing of LabelDeviations is shown in Figure 4.2.

Figure 4.2 Listing of the Data Set LabelDeviations

The Data Set LabelDeviations	
Position	Deviation
1	-0.0239
1	-0.0285
1	-0.0300
1	-0.0043
1	-0.0362
1	-0.0422
1	-0.0014
1	-0.0647
1	0.0094
1	-0.0016

The data set LabelDeviations is said to be in “strung-out” form, since each observation contains the position and the deviation measurement for a single bottle. The first 10 observations contain the measurements for the first position, the second 10 observations contain the measurements for the second position, and so on. Because the variable Position classifies the observations into groups (treatment levels), it is referred to as the *group-variable*. The variable Deviation contains the deviation measurements and is referred to as the *response variable* (or *response* for short).

The following statements create the ANOM boxchart shown in Figure 4.3:

```

ods graphics off;
title 'Analysis of Label Deviations';
proc anom data=LabelDeviations;
  boxchart Deviation*Position / alpha = 0.05;
  label Deviation = 'Mean Deviation from Center (mm)';
  label Position = 'Labeler Position';
run;

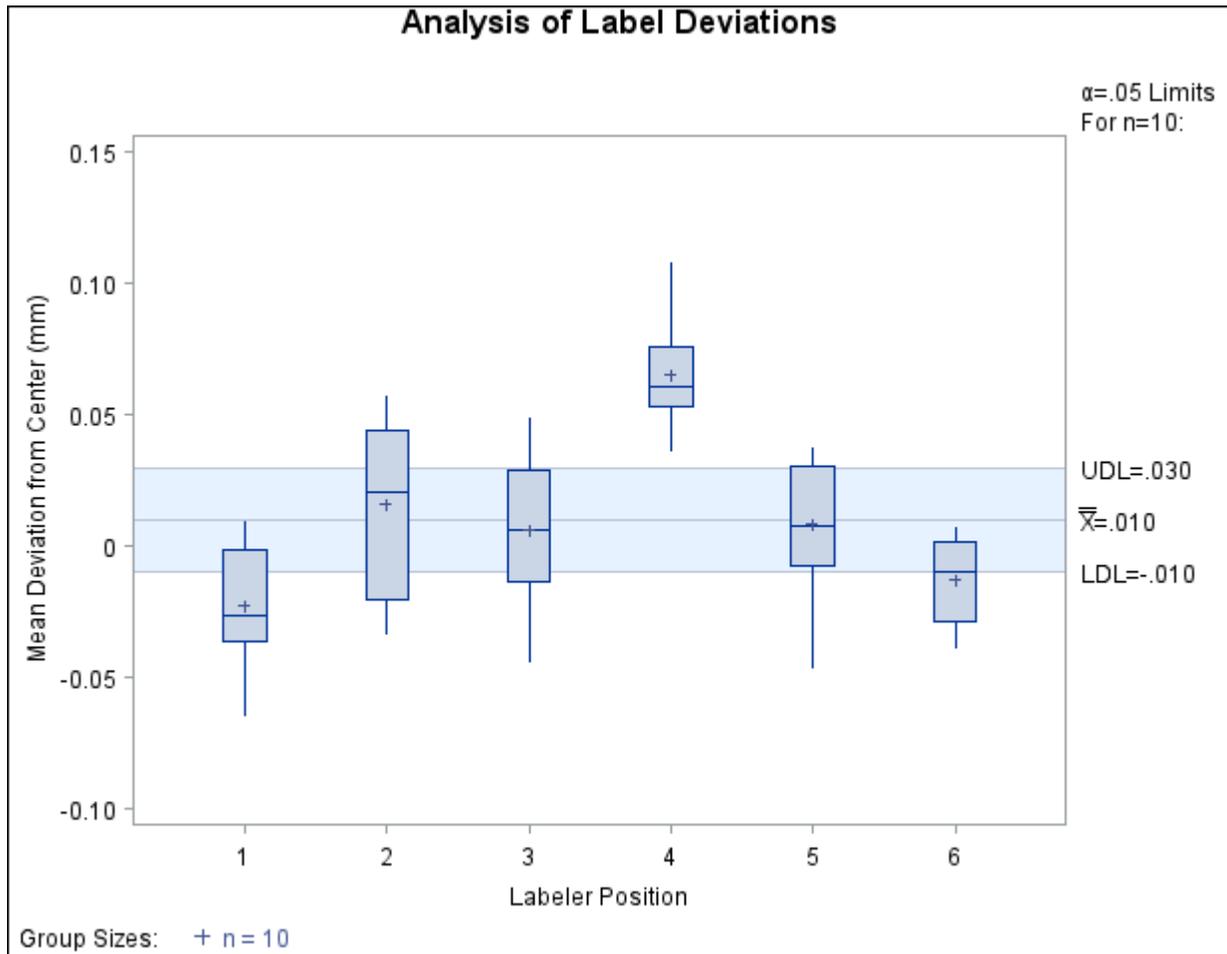

```

This example illustrates the basic form of the BOXCHART statement. After the keyword BOXCHART, you specify the *response* to analyze (in this case, Deviation) followed by an asterisk and the *group-variable* (Position). Options are specified after the slash (/) in the BOXCHART statement. A complete list of options is presented in the section “Syntax: BOXCHART Statement” on page 57.

The input data set is specified with the DATA= option in the PROC ANOM statement when it contains raw measurements for the *response*.

Each point on the ANOM chart represents the average (mean) of the response measurements for a particular sample.

Figure 4.3 ANOM Chart for Means of Labeler Position Data

The average for Position 1 is below the lower decision limit (LDL), and the average for Position 6 is slightly below the lower decision limit. The average for Position 4 exceeds the upper decision limit (UDL). The conclusion is that Positions 1, 4, and 6 are operating differently.

By default, the decision limits shown correspond to a significance level of $\alpha = 0.05$; the formulas for the limits are given in the section “Decision Limits” on page 66. You can also read decision limits from an input data set.

For computational details, see “Constructing ANOM Boxcharts” on page 65. For details on reading raw measurements, see “DATA= Data Set” on page 74.

Creating ANOM Boxcharts from Group Summary Data

See ANMBXGRP in the SAS/QC Sample Library The previous example illustrates how you can create ANOM charts for means using measurement data. However, in many applications, the data are provided as group summary statistics. This example illustrates how you can use the BOXCHART statement with data of this type.

The following data set (Labels) provides the data from the preceding example in summarized form:

```
data Labels;
  input Position DeviationL Deviation1 DeviationX
         DeviationM Deviation3 DeviationH DeviationS;
  DeviationN = 10;
  datalines;
1  -0.0647  -0.0362  -0.02234  -0.02620  -0.0016  0.0094  0.02281
2  -0.0332  -0.0201   0.01625   0.02045   0.0438  0.0564  0.03347
3  -0.0440  -0.0139   0.00604   0.00570   0.0285  0.0486  0.02885
4   0.0362   0.0530   0.06473   0.06030   0.0755  0.1073  0.02150
5  -0.0464  -0.0074   0.00813   0.00760   0.0302  0.0374  0.02593
6  -0.0384  -0.0285  -0.01283  -0.00950   0.0017  0.0071  0.01599
;
```

A listing of Labels is shown in [Figure 4.4](#). There is exactly one observation for each group (note that the groups are still indexed by Position). There are eight summary variables in Labels.

- DeviationL contains the group minimums (low values).
- Deviation1 contains the 25th percentile (first quartile) of each group.
- DeviationX contains the group means.
- DeviationM contains the group medians.
- Deviation3 contains the 75th percentile (third quartile) of each group.
- DeviationH contains the group maximums (high values).
- DeviationS contains the group standard deviations.
- DeviationN contains the group sample sizes (these are all 10 in this case).

Figure 4.4 The Summary Data Set Labels

The Data Set Labels								
	D	D	D	D	D	D	D	D
P	e	e	e	e	e	e	e	e
o	v	v	v	v	v	v	v	v
s	i	i	i	i	i	i	i	i
i	a	a	a	a	a	a	a	a
t	t	t	t	t	t	t	t	t
t	i	i	i	i	i	i	i	i
i	o	o	o	o	o	o	o	o
o	n	n	n	n	n	n	n	n
n	L	1	X	M	3	H	S	N
1	-0.0647	-0.0362	-0.02234	-0.02620	-0.0016	0.0094	0.02281	10
2	-0.0332	-0.0201	0.01625	0.02045	0.0438	0.0564	0.03347	10
3	-0.0440	-0.0139	0.00604	0.00570	0.0285	0.0486	0.02885	10
4	0.0362	0.0530	0.06473	0.06030	0.0755	0.1073	0.02150	10
5	-0.0464	-0.0074	0.00813	0.00760	0.0302	0.0374	0.02593	10
6	-0.0384	-0.0285	-0.01283	-0.00950	0.0017	0.0071	0.01599	10

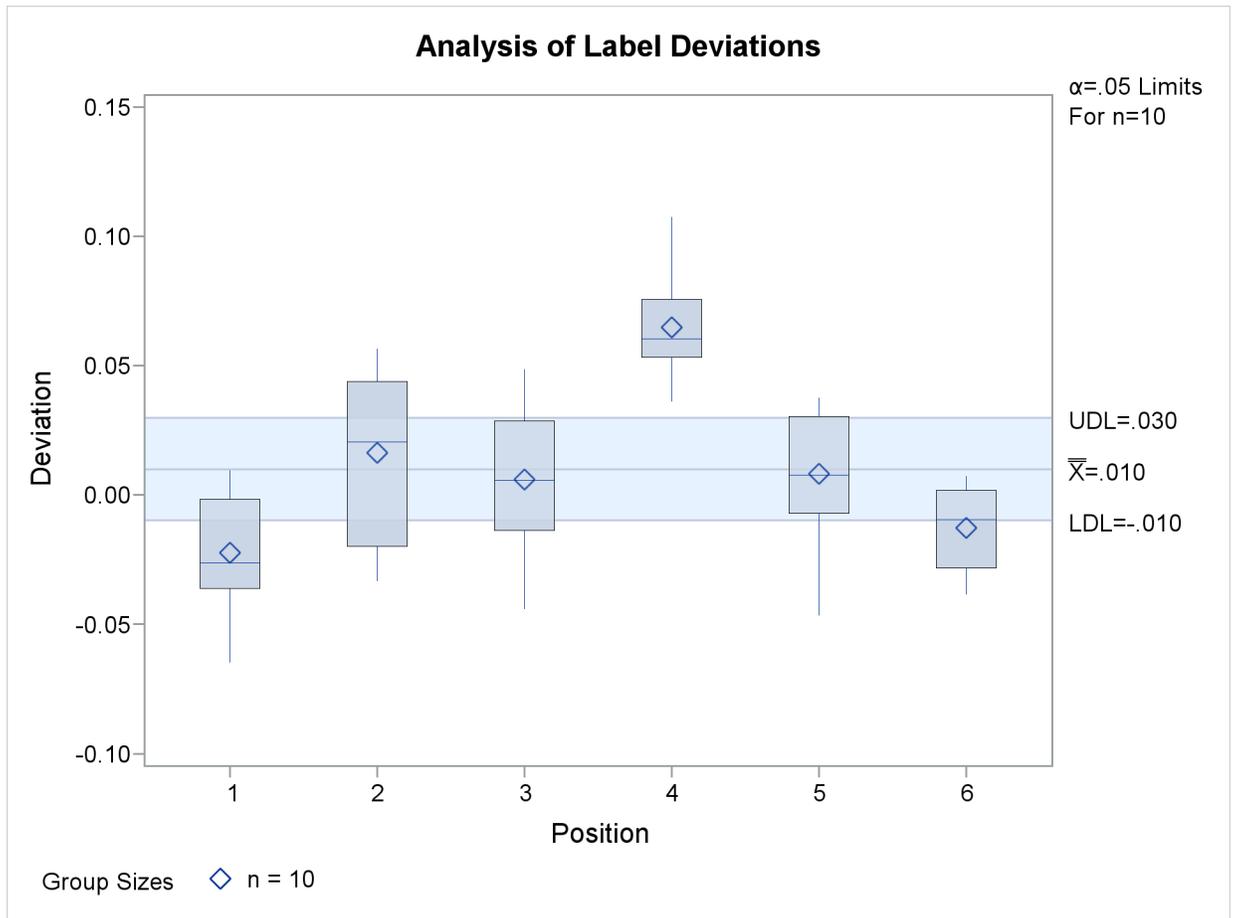

You can read this data set by specifying it as a SUMMARY= data set in the PROC ANOM statement, as follows:

```
ods graphics on;
title 'Analysis of Label Deviations';
proc anom summary=Labels;
  boxchart Deviation*Position / odstitle=title1;
run;
```

The ODS GRAPHICS ON statement specified before the PROC ANOM statement enables ODS Graphics, so the boxchart is created by using ODS Graphics instead of traditional graphics. The resulting ANOM boxchart is shown in Figure 4.5.

Note that Deviation is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the eight summary variables. The suffix characters *L*, *1*, *X*, *M*, *3*, *H*, *S*, and *N* indicate the contents of the variable. For example, the suffix characters *1* and *3* indicate first and third quartiles. Thus, you can specify three group summary variables in a SUMMARY= data set with a single name (Deviation), which is referred to as the *response*. The name Position specified after the asterisk is the name of the *group-variable*.

Figure 4.5 ANOM Chart for Means in Data Set Labels

In general, a SUMMARY= input data set used with the BOXCHART statement must contain the following variables:

- group variable
- group minimum variable
- group first quartile variable
- group mean variable
- group median variable
- group third quartile variable
- group maximum variable
- group standard deviation variable
- group sample size variable

Furthermore, the names of the summary variables must begin with the *response* name specified in the BOXCHART statement and end with the appropriate suffix characters. If the names do not follow this convention, you can use the RENAME option in the PROC ANOM statement to rename the variables for the duration of the ANOM procedure step. If a label is associated with the group mean variable, it is used to label the vertical axis.

In summary, the interpretation of *response* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *response* is the name of the SAS variable containing the response measurements.
- If summary data are read using the SUMMARY= option (as in this example), *response* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “SUMMARY= Data Set” on page 76.

Saving Summary Statistics for Groups

In this example, the BOXCHART statement is used to create a data set containing group summary statistics that can be read later by the ANOM procedure (as in the preceding example). The following statements read measurements from the data set LabelDeviations and create a summary data set named LabelSummary: *See ANMBXSUM in the SAS/QC Sample Library*

```
proc anom data=LabelDeviations;
  boxchart Deviation*Position / outsummary=LabelSummary
  nochart;
run;
```

The OUTSUMMARY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to [Figure 4.3](#).

[Figure 4.6](#) contains a listing of LabelSummary.

Figure 4.6 The Summary Data Set LabelSummary

The Data Set LabelSummary								
	D	D	D	D	D	D	D	D
P	e	e	e	e	e	e	e	e
o	v	v	v	v	v	v	v	v
s	i	i	i	i	i	i	i	i
i	a	a	a	a	a	a	a	a
t	t	t	t	t	t	t	t	t
t	i	i	i	i	i	i	i	i
i	o	o	o	o	o	o	o	o
o	n	n	n	n	n	n	n	n
n	L	1	X	M	3	H	S	N
1	-0.0647	-0.0362	-0.02234	-0.02620	-0.0016	0.0094	0.022807	10
2	-0.0332	-0.0201	0.01625	0.02045	0.0438	0.0564	0.033473	10
3	-0.0440	-0.0139	0.00604	0.00570	0.0285	0.0486	0.028849	10
4	0.0362	0.0530	0.06473	0.06030	0.0755	0.1073	0.021495	10
5	-0.0464	-0.0074	0.00813	0.00760	0.0302	0.0374	0.025928	10
6	-0.0384	-0.0285	-0.01283	-0.00950	0.0017	0.0071	0.015986	10

There are nine variables in the data set LabelSummary.

- Position identifies the group.
- DeviationL contains the group minimums.
- Deviation1 contains the first quartile for each group.
- DeviationX contains the group means.
- DeviationM contains the group medians.
- Deviation3 contains the third quartile for each group.
- DeviationH contains the group maximums.
- DeviationS contains the group standard deviations.
- DeviationN contains the group sizes.

Note that the summary statistic variables are named by adding the suffix characters *L*, *1*, *X*, *M*, *3*, *H*, *S*, and *N* to the *response* Deviation specified in the BOXCHART statement. In other words, the variable naming convention for OUTSUMMARY= data sets is the same as that for SUMMARY= data sets.

For more information, see “OUTSUMMARY= Data Set” on page 70.

Saving Decision Limits

You can save the decision limits for an ANOM chart, together with the parameters used to compute the limits, in a SAS data set. *See ANMBXLIM in the SAS/QC Sample Library*

The following statements read measurements from the data set LabelDeviations (see “Creating ANOM Boxcharts from Response Values” on page 47.) and save the decision limits displayed in Figure 4.3 in a data set named LabelLimits:

```
proc anom data=LabelDeviations;
  boxchart Deviation*Position / outlimits=LabelLimits
  nochart;
run;
```

The OUTLIMITS= option names the data set containing the decision limits, and the NOCHART option suppresses the display of the chart. The data set LabelLimits is listed in Figure 4.7.

Figure 4.7 The Data Set LabelLimits Containing Decision Limit Information

Decision Limits for Labler Position Deviations					
<u>_VAR_</u>	<u>_GROUP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_LDLX_</u>
Deviation	Position	ESTIMATE	10	0.05	-.009875811
<u>_MEAN_</u>	<u>_UDLX_</u>	<u>_MSE_</u>	<u>_DFE_</u>	<u>_LIMITK_</u>	
.009996667	0.029869	.000643787	54	6	

The data set LabelLimits contains one observation with the limits for *response* Deviation. The values of _LDLX_ and _UDLX_ are the lower and upper decision limits for the means, and the value of _MEAN_ is the weighted average of the group means, which is represented by the central line.

The values of _MEAN_, _MSE_, _DFE_, _LIMITK_, _LIMITN_, and _ALPHA_ are the parameters used to compute the decision limits. The value of _MSE_ is the mean square error, and the value of _DFE_ is the associated degrees of freedom. The value of _LIMITK_ is the group size (*k*), the value of _LIMITN_ is the nominal sample size associated with the decision limits, and the value of _ALPHA_ is the value of the significance level (α). The variables _VAR_ and _GROUP_ are bookkeeping variables that save the *response* and *group-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _MSE_ are estimates computed from the data or standard (known) values specified with procedure options. In most applications, the value of _TYPE_ will be ‘ESTIMATE.’

You can create an output data set containing both decision limits and group summary statistics with the OUTTABLE= option, as illustrated by the following statements: *See ANMBXTAB in the SAS/QC Sample Library*

```
proc anom data=LabelDeviations;
  boxchart Deviation*Position / outtable=LabelTab
  nochart;
run;
```

The data set LabelTab is listed in Figure 4.8.

Figure 4.8 The Data Set LabelTab

Summary Statistics and Decision Limits							
<u>_VAR_</u>	<u>Position</u>	<u>_ALPHA_</u>	<u>_LIMITN_</u>	<u>_SUBN_</u>	<u>_LDLX_</u>	<u>_SUBX_</u>	<u>_MEAN_</u>
Deviation	1	0.05	10	10	-.009875811	-0.02234	.009996667

<u>_UDLX_</u>	<u>_EXLIM_</u>	<u>_SUBMIN_</u>	<u>_SUBQ1_</u>	<u>_SUBMED_</u>	<u>_SUBQ3_</u>	<u>_SUBMAX_</u>	
0.029869	LOWER	-0.0647	-0.0362	-0.02620	-0.0016	0.0094	
0.029869		-0.0332	-0.0201	0.02045	0.0438	0.0564	
0.029869		-0.0440	-0.0139	0.00570	0.0285	0.0486	
0.029869	UPPER	0.0362	0.0530	0.06030	0.0755	0.1073	
0.029869		-0.0464	-0.0074	0.00760	0.0302	0.0374	
0.029869	LOWER	-0.0384	-0.0285	-0.00950	0.0017	0.0071	

This data set contains one observation for each group sample. The variable `_SUBMIN_` contains the group minimums, and the variable `_SUBQ1_` contains the first quartile for each group. The variables `_SUBX_` and `_SUBMED_` contain the group means and medians. The variable `_SUBQ3_` contains the third quartiles, `_SUBMAX_` contains the group maximums, and `_SUBN_` contains the group sample sizes. The variables `_LDLX_` and `_UDLX_` contain the lower and upper decision limits, and the variable `_MEAN_` contains the central line. The variables `_VAR_` and `Position` contain the *response* name and values of the *group-variable*, respectively. For more information, see “OUTTABLE= Data Set” on page 71.

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read LabelTab and display an ANOM boxchart (not shown here) identical to the chart in Figure 4.3:

```

title 'Analysis of Label Deviations';
proc anom table=LabelTab;
  xchart Deviation*Position;
  label _SUBX_ = 'Mean Deviation from Center (mm)';
run;

```

Because the ANOM procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized ANOM boxcharts.

For more information, see “TABLE= Data Set” on page 77.

Syntax: BOXCHART Statement

The basic syntax for the BOXCHART statement is as follows:

```
BOXCHART response * group-variable ;
```

The general form of this syntax is as follows:

```
BOXCHART (responses) * group-variable <(block-variables)>  
    <=symbol-variable> <options> ;
```

You can use any number of BOXCHART statements in the ANOM procedure. The components of the BOXCHART statement are described as follows.

responses

identify one or more responses to be analyzed. The specification of *response* depends on the input data set specified in the PROC ANOM statement.

- If response values (raw data) are read from a DATA= data set, *response* must be the name of the variable containing the values. For an example, see “[Creating ANOM Boxcharts from Response Values](#)” on page 47.
- If summary data are read from a SUMMARY= data set, *response* must be the common prefix of the summary variables in the SUMMARY= data set. For an example, see “[Creating ANOM Boxcharts from Group Summary Data](#)” on page 50.
- If summary data and decision limits are read from a TABLE= data set, *response* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Decision Limits](#)” on page 55.

A *response* is required. If you specify more than one response, enclose the list in parentheses. For example, the following statements request distinct ANOM charts for the means of Weight, Length, and Width:

```
proc anom data=Measures;  
    xchart (Weight Length Width)*Day;  
run;
```

group-variable

is the variable that identifies groups in the data. The *group-variable* is required. In the preceding BOXCHART statement, Day is the group variable.

block-variables

are optional variables that group the data into blocks of consecutive groups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker used to plot the means. Distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOLn statements.

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)” lists all options by function.

Summary of Options

The following tables list the BOXCHART statement options by function. Options unique to the ANOM procedure are listed in [Table 4.1](#), and are described in detail in “[Dictionary of ANOM Chart Statement Options](#)” on page 192. Options that are common to both the ANOM and SHEWHART procedures are listed in [Table 4.2](#), and are described in detail in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 4.1 BOXCHART Statement Special Options

Option	Description
Options for Specifying Parameters for Decision Limits	
ALPHA=	specifies the probability of a Type I error
DFE=	specifies the degrees of freedom associated with the root mean square error
LIMITK=	specifies number of groups for decision limits
LIMITN=	specifies either nominal sample size for fixed decision limits or varying limits
MEAN=	specifies the mean
MSE=	specifies the mean square error
NOREADLIMITS	computes decision limits for each <i>response</i> from the data rather than a LIMITS= data set
READINDEXES=	reads multiple sets of decision limits for each <i>response</i> from a LIMITS= data set
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Displaying Decision Limits	
CINFILL=	specifies color for area inside decision limits
CLIMITS=	specifies color of decision limits, central line, and related labels
LDLLABEL=	specifies label for lower decision limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the decision limit
LLIMITS=	specifies line type for decision limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for decision limits and central line
NOCTL	suppresses display of central line
NOLDL	suppresses display of lower decision limit
NOLIMITLABEL	suppresses labels for decision limits and central line
NOLIMITS	suppresses display of decision limits

Table 4.1 *continued*

Option	Description
NOLIMITSFRAME	suppresses default frame around decision limit information when multiple sets of decision limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for decision limits
NOUDL	suppresses display of upper decision limit
UDLLABEL=	specifies label for upper decision limit
WLIMITS=	specifies width for decision limits and central line
XSYMBOL=	specifies label for central line
Output Data Set Option	
OUTSUMMARY=	creates output data set containing group summary statistics

Table 4.2 BOXCHART Statement General Options

Option	Description
Options for Controlling Box Appearance	
BOXCONNECT=	connects group means, medians, maximum values, minimum values, or quartiles in box-and-whisker plots
BOXSTYLE=	specifies style of box-and-whisker plots
BOXWIDTH=	specifies width of box-and-whisker plots
BOXWIDTHSCALE=	specifies that widths of box-and-whisker plots vary proportionately to group sample size
CBOXES=	specifies color for outlines of box-and-whisker plots
CBOXFILL=	specifies fill color for interior of box-and-whisker plots
IDCOLOR=	specifies outlier symbol color in schematic box-and-whisker plots
IDCTEXT=	specifies text color to label outliers or response variable values
IDFONT=	specifies text font to label outliers or response variable values
IDHEIGHT=	specifies text height to label outliers or response variable values
IDSYMBOL=	specifies outlier symbol in schematic box-and-whisker plots
LBOXES=	specifies line types for outlines of box-and-whisker plots
NOTCHES	specifies that box-and-whisker plots are to be notched
PCTLDEF=	specifies percentile definition used for box-and-whisker plots
SERIFS	adds serifs to the whiskers of skeletal box-and-whisker plots
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on ANOM boxchart
CLABEL=	specifies color for labels

Table 4.2 continued

Option	Description
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
COUT=	specifies color for portions of line segments that connect points outside decision limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels
LABELHEIGHT=	specifies height of labels
OUTLABEL=	labels points outside decision limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent group values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of ANOM boxchart
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for ANOM boxchart
WAXIS=	specifies width of axis lines

Table 4.2 *continued*

Option	Description
Plot Layout Options	
ALLN	plots means for all groups
BILEVEL	creates ANOM boxchart using half-screens and half-pages
EXCHART	creates ANOM boxchart for a response only when a group mean exceeds the decision limits
INTERVAL=	natural time interval between consecutive group positions when time, date, or datetime format is associated with a numeric group variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed decision limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for group sample sizes
NPANELPOS=	specifies number of group positions per panel on each chart
REPEAT	repeats last group position on panel as first group position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays ANOM boxchart regardless of whether root mean square error is zero
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= option
CVREF=	specifies color for lines requested by VREF= option
HREF=	specifies position of reference lines perpendicular to horizontal axis on ANOM boxchart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on ANOM boxchart
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on ANOM boxchart
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies position of VREFLABELS= labels

Table 4.2 continued

Option	Description
Grid Options	
CGRID=	specifies color for grid requested with GRID or END-GRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to ANOM boxchart
DESCRIPTION=	specifies description of ANOM boxchart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on chart
NAME=	specifies name of ANOM boxchart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
BOXES=	specifies variables whose values define colors box outlines
BOXFILL=	specifies variables whose values define colors for filling boxes
CFRAMELAB	draws a frame around labeled points
CPHASEBOX	requests boxes enclosing all plotted points for a phase
CPHASEBOXCONNECT	requests lines connecting adjacent enclosing boxes
CPHASEBOXFILL	fills boxes enclosing all plotted points for a phase
CPHASEMEANCONNECT	requests lines connecting phase average value points

Table 4.2 continued

Option	Description
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
BOXTRANSPARENCY=	specifies the box fill transparency for box-and-whisker charts
INFILLTRANSPARENCY=	specifies the decision limit infill transparency
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOBOXFILLLEGEND	suppresses legend for levels of a BOXFILL= variable
NOFILLLEGEND	suppresses legend for levels of a BOXFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEBOXLABELS	draws phase labels as titles along the top of phase boxes
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
URL=	specifies a variable whose values are URLs to be associated with groups
WBOXES=	specifies width of box outlines for box-and-whisker charts
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTBOX=	creates output data set containing group summary statistics, decision limits, and outlier values
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing decision limits
OUTTABLE=	creates output data set containing group summary statistics and decision limits

Table 4.2 continued

Option	Description
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of group means, group sample sizes, and decision limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLEOUTLIM	augments basic table with columns indicating decision limits exceeded
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the <code>OUTSUMMARY=</code> data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels decision limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays

Table 4.2 continued

Option	Description
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive ANOM Charts	
HTML=	specifies a variable whose values create links to be associated with groups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Details: BOXCHART Statement

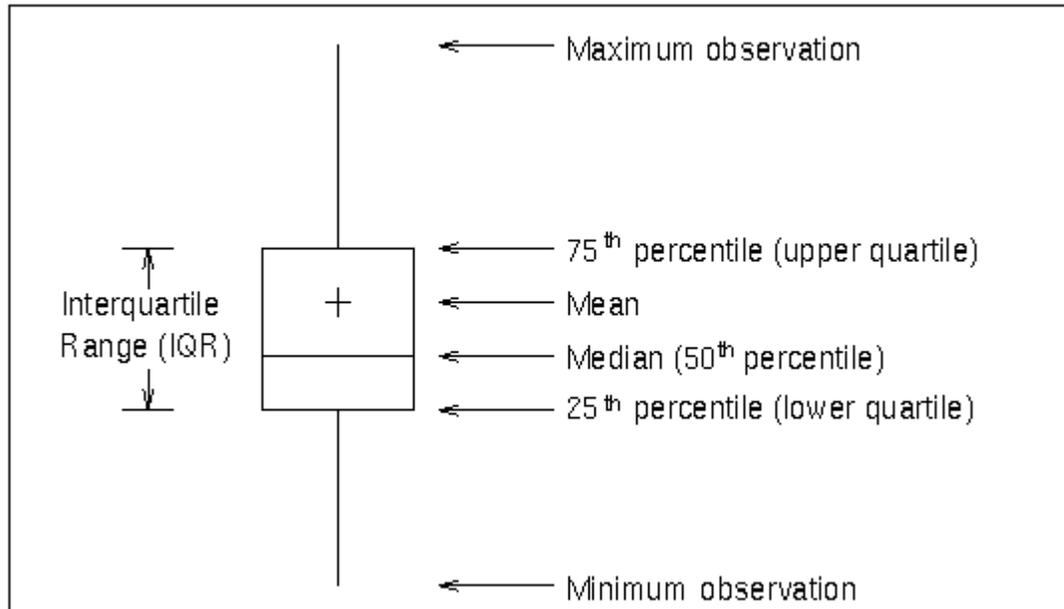

Constructing ANOM Boxcharts

The following notation is used in this section:

X_{ij}	j th response in the i th group
k	number of groups
n_i	sample size of i th group
N	total sample size = $n_1 + \dots + n_k$
μ_i	expected value of a response in the i th group
σ	standard deviation of response
\bar{X}_i	average response in i th group
$\bar{\bar{X}}$	weighted average of k group means
s_i^2	sample variance of the responses in the i th group
$\hat{\sigma}^2$	mean square error (MSE)
ν	degrees of freedom associated with the mean square error
α	significance level
$h(\alpha; k, n, \nu)$	critical value for analysis of means when the sample sizes n_i are equal ($n_i \equiv n$)
$h(\alpha; k, n_1, \dots, n_k, \nu)$	critical value for analysis of means when the sample sizes n_i are not equal

Elements of Box-and-Whisker Plots

A box-and-whisker plot is displayed for the measurements in each group on the ANOM boxchart. Figure 4.9 illustrates the elements of each plot.

Figure 4.9 Box-and-Whisker Plot

The skeletal style of the box-and-whisker plot shown in Figure 4.9 is the default. You can specify alternative styles with the `BOXSTYLE=` option; see the entry for the `BOXSTYLE=` option in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Central Line

By default, the central line on an ANOM chart for means represents the weighted average of the group means, which is computed as

$$\bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \cdots + n_k \bar{X}_k}{n_1 + \cdots + n_k}$$

You can specify a value for $\bar{\bar{X}}$ with the `MEAN=` option in the `BOXCHART` statement or with the variable `_MEAN_` in a `LIMITS=` data set.

Decision Limits

In the analysis of means for continuous data, it is assumed that the responses in the i th group are at least approximately normally distributed with a constant variance:

$$X_{ij} \sim N(\mu_i, \sigma^2), \quad j = 1, \dots, n_i$$

When the group sizes are constant ($n_i \equiv n$), then $\nu = N - k = k(n - 1)$ and the decision limits are computed as follows:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \bar{\bar{X}} - h(\alpha; k, n, \nu) \sqrt{\text{MSE}} \sqrt{\frac{k-1}{N}} \\ \text{upper decision limit (UDL)} &= \bar{\bar{X}} + h(\alpha; k, n, \nu) \sqrt{\text{MSE}} \sqrt{\frac{k-1}{N}} \end{aligned}$$

Here the mean square error (MSE) is computed as follows:

$$\text{MSE} = \widehat{\sigma^2} = \frac{1}{k} \sum_{j=1}^k s_j^2$$

For details concerning the function $h(\alpha; k, n, \nu)$, see Nelson (1981, 1982a, 1993).

When the group sizes n_i are not constant (the unbalanced case), $\nu = N - k$ and the decision limits for the i th group are computed as follows:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \bar{\bar{X}} - h(\alpha; k, n_1, \dots, n_k, \nu) \sqrt{\text{MSE}} \sqrt{\frac{N - n_i}{N n_i}} \\ \text{upper decision limit (UDL)} &= \bar{\bar{X}} + h(\alpha; k, n_1, \dots, n_k, \nu) \sqrt{\text{MSE}} \sqrt{\frac{N - n_i}{N n_i}} \end{aligned}$$

Here the mean square error (MSE) is computed as follows:

$$\text{MSE} = \widehat{\sigma^2} = \frac{(n_1 - 1)s_1^2 + \dots + (n_k - 1)s_k^2}{n_1 + \dots + n_k - k}$$

This requires that ν be positive. A chart is not produced if $\nu > 0$ but MSE is equal to zero (unless you specify the ZEROSTD option). For details concerning the function $h(\alpha; k, n_1, \dots, n_k, \nu)$, see Fritsch and Hsu (1997), Nelson (1982b, 1991), and Soong and Hsu (1997).

You can specify parameters for the limits as follows:

- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set. By default, $\alpha = 0.05$.
- Specify a constant nominal sample size $n_i \equiv n$ for the decision limits in the balanced case with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set. By default, n is the observed sample size in the balanced case.
- Specify k with the LIMITK= option or with the variable `_LIMITK_` in a LIMITS= data set. By default, k is the number of groups.

- Specify $\bar{\bar{X}}$ with the MEAN= option or with the variable `_MEAN_` in a LIMITS= data set. By default, $\bar{\bar{X}}$ is the weighted average of the responses.
- Specify $\widehat{\sigma^2}$ with the MSE= option or with the variable `_MSE_` in a LIMITS= data set. By default, $\widehat{\sigma^2}$ is computed as indicated above.
- Specify ν with the DFE= option or with the variable `_DFE_` in a LIMITS= data set. By default, ν is determined as indicated above.

Output Data Sets

OUTBOX= Data Set

The OUTBOX= data set saves group summary statistics, decision limits, and outlier values. The following variables can be saved:

- the *group-variable*
- the variable `_VAR_`, containing the analysis variable name
- the variable `_TYPE_`, identifying features of box-and-whisker plots
- the variable `_VALUE_`, containing values of box-and-whisker plot features
- the variable `_ID_`, containing labels for outliers
- the variable `_HTML_`, containing links associated with box-and-whisker plot features

`_ID_` is included in the OUTBOX= data set only if one of the keywords SCHEMATICID or SCHEMATICIDFAR is specified with the BOXSTYLE= option. `_HTML_` is present only if the HTML= or HTML2= option is specified.

Each observation in an OUTBOX= data set records the value of a single feature of one group's box-and-whisker plot, such as its mean. The `_TYPE_` variable identifies the feature whose value is recorded in `_VALUE_`. The following table lists valid `_TYPE_` variable values:

Table 4.3 Valid `_TYPE_` Values in an `OUTBOX=` Data Set

<code>_TYPE_</code> Value	Description
N	group size
ALPHA	significance level
LIMITN	nominal sample size associated with decision limits
LDLX	lower decision limit for group mean
UDLX	upper decision limit for group mean
RESPMEAN	overall response variable mean
MIN	group minimum value
Q1	group first quartile
MEDIAN	group median
MEAN	group mean
Q3	group third quartile
MAX	group maximum value
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

Additionally, the following variables, if specified, are included:

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

***OUTLIMITS=* Data Set**

The `OUTLIMITS=` data set saves decision limits and decision limit parameters. The following variables can be saved:

Table 4.4 OUTLIMITS= Data Set

Variable	Description
ALPHA	significance level
DFE	degrees of freedom for mean square error
GROUP	<i>group-variable</i> specified in the BOXCHART statement
INDEX	optional identifier for the decision limits specified with the OUTINDEX= option
LDLX	lower decision limit for group means
LIMITK	number of groups
LIMITN	sample size associated with the decision limits
MEAN	weighted average of group means ($\bar{\bar{X}}$)
MSE	mean square error
TYPE	type (estimate or standard value) of _MEAN_ and _MSE_
UDLX	upper decision limit for group means
VAR	<i>response</i> specified in the BOXCHART statement

Notes:

1. In the unbalanced case, the special missing value V is assigned to the variables _LIMITN_, _LDLX_, and _UDLX_.
2. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *response* specified in the BOXCHART statement. For an example, see “[Saving Decision Limits](#)” on page 55.

OUTSUMMARY= Data Set

The OUTSUMMARY= data set saves group summary statistics. The following variables can be saved:

- the *group-variable*
- a group minimum variable named by *response* suffixed with L
- a group first-quartile variable named by *response* suffixed with 1
- a group mean variable named by *response* suffixed with X
- a group median variable named by *response* suffixed with M
- a group third-quartile variable named by *response* suffixed with 3
- a group maximum variable named by *response* suffixed with H
- a group standard deviation variable named by *response* suffixed with S
- a group sample size variable named by *response* suffixed with N

Given a *response* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Group summary variables are created for each *response* specified in the BOXCHART statement. For example, consider the following statements:

```
proc anom data=Steel;
  xchart (Width Diameter)*Lot / outsummary=Summary;
run;
```

The data set Summary contains variables named Lot, WidthL, Width1, WidthX, WidthM, Width3, WidthH, WidthS, WidthN, DiameterL, Diameter1, DiameterX, DiameterM, Diameter3, DiameterH, DiameterS, and DiameterN. Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTSUMMARY= data set, see “Saving Summary Statistics for Groups” on page 53.

OUTTABLE= Data Set

The OUTTABLE= data set saves group summary statistics, decision limits, and related information. The following variables can be saved:

Variable	Description
<code>_ALPHA_</code>	significance level
<code>_EXLIM_</code>	decision limit exceeded (if any)
<i>group</i>	values of the group variable
<code>_LDLX_</code>	lower decision limit for group mean
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_MEAN_</code>	central line
<code>_SUBMAX_</code>	group maximum
<code>_SUBMED_</code>	group median
<code>_SUBMIN_</code>	group minimum
<code>_SUBN_</code>	group sample size
<code>_SUBQ1_</code>	group first quartile
<code>_SUBQ3_</code>	group third quartile
<code>_SUBX_</code>	group mean
<code>_UDLX_</code>	upper decision limit for group mean
<code>_VAR_</code>	<i>response</i> specified in the BOXCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)

NOTE: The variable `_EXLIM_` is a character variable of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “[Saving Decision Limits](#)” on page 55.

ODS Tables

The following table summarizes the ODS tables that you can request with the `BOXCHART` statement.

Table 4.5 ODS Tables Produced with the `BOXCHART` Statement

Table Name	Description	Options
BOXCHART	ANOM chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the ANOM procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. `BOXCHART` options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the `BOXCHART` statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 4.6](#).

Table 4.6 ODS Graphics Produced by the BOXCHART Statement

ODS Graph Name	Plot Description
BoxChart	ANOM boxchart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

BOX= Data Set

You can read summary statistics, decision limits, and outlier values from a BOX= data set specified in the PROC ANOM statement. This enables you to reuse an OUTBOX= data set created in a previous run of the ANOM procedure to display a box chart.

A BOX= data set must contain the following variables:

- the group variable
- `_VAR_`, containing the analysis variable name
- `_TYPE_`, identifying features of box-and-whisker plots
- `_VALUE_`, containing values of those features

Each observation in a BOX= data set records the value of a single feature of one group’s box-and-whisker plot, such as its mean. The `_TYPE_` variable identifies the feature whose value is recorded in a given observation. The following table lists valid `_TYPE_` variable values:

Table 4.7 Valid `_TYPE_` Values in a BOX= Data Set

<code>_TYPE_</code> Value	Description
N	group size
ALPHA	significance level
LIMITN	nominal sample size associated with decision limits
LDLX	lower decision limit for group mean
UDLX	upper decision limit for group mean
RESPMEAN	overall response variable mean
MIN	group minimum value
Q1	group first quartile
MEDIAN	group median
MEAN	group mean
Q3	group third quartile
MAX	group maximum value
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

The features identified by `_TYPE_` values N, LDLX, UDLX, RESPMEAN, MIN, Q1, MEDIAN, MEAN, Q3, and MAX are required for each group.

Other variables that can be read from a `BOX=` data set include:

- the variable `_ID_`, containing labels for outliers
- the variable `_HTML_`, containing links to be associated with features on box plots
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

When you specify one of the keywords `SCHEMATICID` or `SCHEMATICIDFAR` with the `BOXSTYLE=` option, values of `_ID_` are used as outlier labels. If `_ID_` does not exist in the `BOX=` data set, the values of the first variable listed in the `ID` statement are used.

DATA= Data Set

You can read raw data (response values) from a `DATA=` data set specified in the `PROC ANOM` statement. Each *response* specified in the `BOXCHART` statement must be a SAS variable in the `DATA=` data set. This variable provides measurements that must be grouped into group samples indexed by the *group-variable*. The *group-variable*, which is specified in the `BOXCHART` statement, must also be a SAS variable in the `DATA=` data set. Each observation in a `DATA=` data set must contain a value for each *response* and a value for the *group-variable*. If the *i*th group contains n_i items, there should be n_i consecutive observations for which the value of the *group-variable* is the index of the *i*th group. For example, if each group contains five items and there are 10 groups, the `DATA=` data set should contain 50 observations.

Other variables that can be read from a `DATA=` data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the ANOM procedure reads all of the observations in a `DATA=` data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the `READPHASES=` option.

For an example of a `DATA=` data set, see “[Creating ANOM Boxcharts from Response Values](#)” on page 47.

LIMITS= Data Set

You can read preestablished decision limits (or parameters from which the decision limits can be calculated) from a LIMITS= data set specified in the PROC ANOM statement. For example, the following statements read decision limit information from the data set Conlims:

```
proc anom data=Info limits=Conlims;
  xchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the ANOM procedure. Such data sets always contain the variables required for a LIMITS= data set; see [Table 4.4](#). The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LDLX_`, `_MEAN_`, and `_UDLX_`, which specify the decision limits directly
- the variables `_MEAN_`, `_MSE_`, and `_DFE_`, which are used to calculate the decision limits according to the equations in the section “[Decision Limits](#)” on page 66.

In addition, note the following:

- The variables `_VAR_` and `_GROUP_` are required. These must be character variables whose lengths are no greater than 32.
- `_DFE_` is optional. The default is $\nu = N - k$, and in the case of equal group sizes, $\nu = k(n - 1)$.
- `_MSE_` is optional if `_LDLX_` and `_UDLX_` are specified; otherwise it is required.
- `_LDLX_` and `_UDLX_` must be specified together; otherwise their values are computed.
- `_ALPHA_` is optional but is recommended in order to maintain a complete set of decision limit information. The default value is 0.05.
- `_LIMITK_` is optional. The default value is k , the number of groups. A group must have at least one nonmissing value ($n_i \geq 1$) and there must be at least one group with $n_i \geq 2$. If specified, `_LIMITK_` overrides the value of k .
- `_LIMITN_` is optional. The default value is the common group size (n), in the balanced case $n_i \equiv n$. If specified, `_LIMITN_` overrides the value of n .
- The variable `_TYPE_` is optional, but is recommended to maintain a complete set of decision limit information. The variable `_TYPE_` must be a character variable of length 8. Valid values are ‘ESTIMATE,’ ‘STANDARD,’ ‘STDMEAN,’ and ‘STDRMS.’ The default is ‘ESTIMATE.’
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- BY variables are required if specified with a BY statement.

SUMMARY= Data Set

You can read group summary statistics from a SUMMARY= data set specified in the PROC ANOM statement. This enables you to reuse OUTSUMMARY= data sets that have been created in previous runs of the ANOM procedure or to read output data sets created with SAS summarization procedures, such as PROC MEANS.

A SUMMARY= data set used with the BOXCHART statement must contain the following:

- the *group-variable*
- a group minimum variable for each *response*
- a group first-quartile variable for each *response*
- a group mean variable for each *response*
- a group median variable for each *response*
- a group third-quartile variable for each *response*
- a group maximum variable for each *response*
- a group standard deviation variable for each *response*
- a group sample size variable for each *response*

The names of the group summary statistics variables must be the *response* name concatenated with the following special suffix characters:

Group Summary Statistic	Suffix Character
group minimum	L
group first-quartile	1
group median	M
group mean	X
group third-quartile	3
group maximum	H
group standard deviation	S
group sample size	N

For example, consider the following statements:

```
proc anom summary=Summary;
  xchart (Weight Yieldstrength)*Batch;
run;
```

The data set Summary must include the variables Batch, WeightL, Weight1, WeightX, WeightM, Weight3, WeightH, WeightS, WeightN, YieldstrengthL, Yieldstrength1, YieldstrengthX, YieldstrengthM, Yieldstrength3, YieldstrengthH, YieldstrengthS, and YieldstrengthN. Note that if you specify a *response* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *response* name, suffixed with the appropriate character.

Other variables that can be read from a SUMMARY= data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the ANOM procedure reads all of the observations in a `SUMMARY=` data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the `READPHASES=` option.

For an example of a `SUMMARY=` data set, see “Creating ANOM Boxcharts from Group Summary Data” on page 50.

TABLE= Data Set

You can read summary statistics and decision limits from a `TABLE=` data set specified in the PROC ANOM statement. This enables you to reuse an `OUTTABLE=` data set created in a previous run of the ANOM procedure. Because the ANOM procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized ANOM charts.

The following table lists the variables required in a `TABLE=` data set used with the BOXCHART statement:

Table 4.8 Variables Required in a `TABLE=` Data Set

Variable	Description
<i>group-variable</i>	values of the <i>group-variable</i>
<code>_LDLX_</code>	lower decision limit for mean
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_MEAN_</code>	central line
<code>_SUBMAX_</code>	group maximum
<code>_SUBMED_</code>	group median
<code>_SUBMIN_</code>	group minimum
<code>_SUBN_</code>	group sample size
<code>_SUBQ1_</code>	group first quartile
<code>_SUBQ3_</code>	group third quartile
<code>_SUBX_</code>	group mean
<code>_UDLX_</code>	upper decision limit for mean

Other variables that can be read from a `TABLE=` data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

- `_PHASE_` (if the `READPHASES=` option is specified). This variable must be a character variable whose length is no greater than 48.
- `_VAR_`. This variable is required if more than one *response* is specified or if the data set contains information for more than one *response*. This variable must be a character variable whose length is no greater than 32.

For an example of a `TABLE=` data set, see “Saving Decision Limits” on page 55.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>group-variable</i>
Vertical	<code>DATA=</code>	<i>response</i>
Vertical	<code>SUMMARY=</code>	group mean variable
Vertical	<code>TABLE=</code>	<code>_SUBX_</code>

Missing Values

An observation read from a `DATA=`, `SUMMARY=`, or `TABLE=` data set is not analyzed if the value of the group variable is missing. For a particular response variable, an observation read from a `DATA=` data set is not analyzed if the value of the response variable is missing. Missing values of response variables generally lead to unequal group sample sizes. For a particular response variable, an observation read from a `SUMMARY=` or `TABLE=` data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: BOXCHART Statement

This section provides an advanced example of the BOXCHART statement.

Example 4.1: ANOM Boxcharts with Unequal Group Sizes

Consider the example described in “Creating ANOM Boxcharts from Response Values” on page 47. *See ANMBXEX1 in the SAS/QC Sample Library*. Suppose that four of the 10 measurements were missing for the third and fourth labeler positions. The following statements create a SAS data set named LabelDev2, which contains the resulting deviation measurements:

```

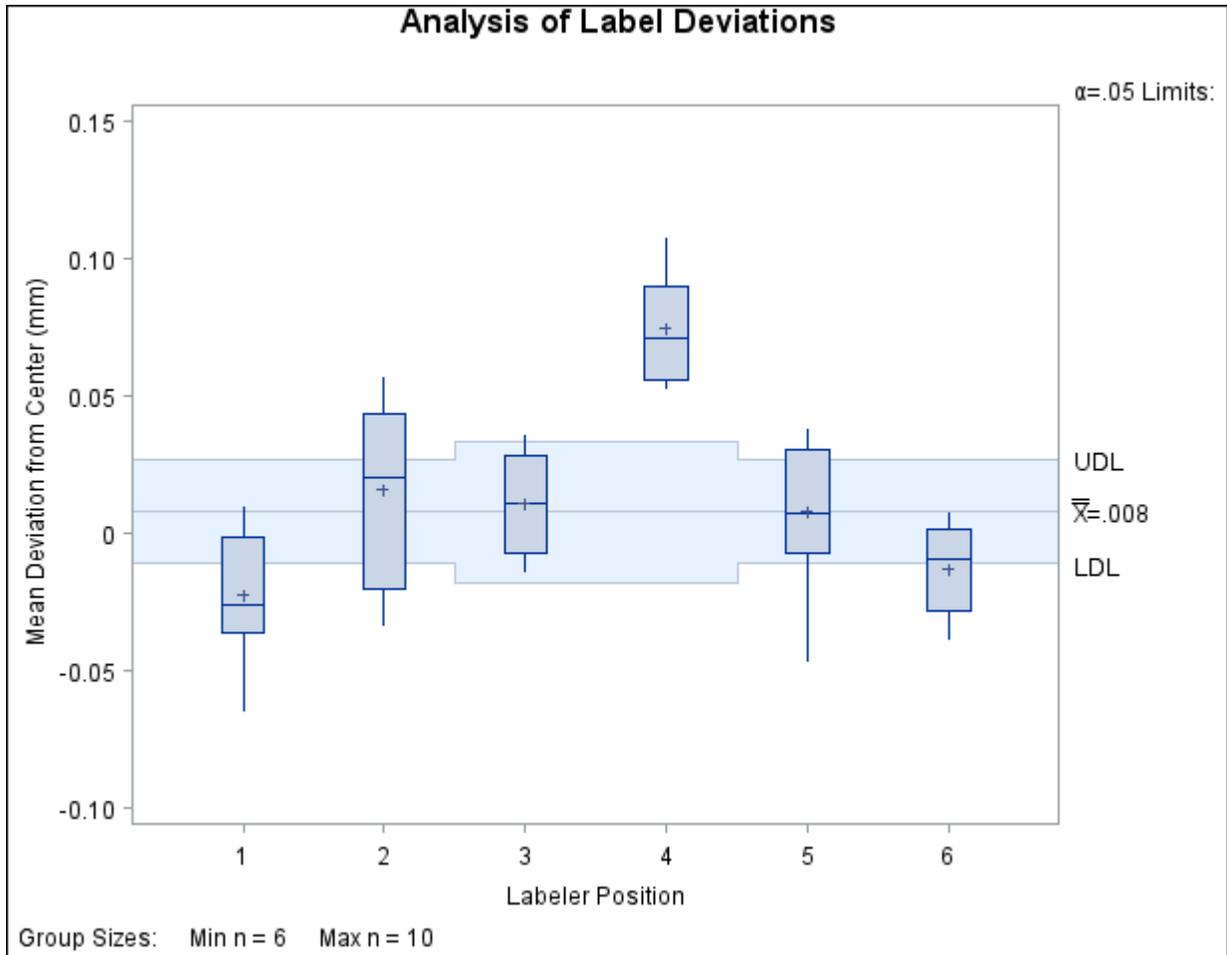

data LabelDev2;
  input Position @;
  do i = 1 to 5;
    input Deviation @;
    output;
  end;
  drop i;
  datalines;
1 -0.0239 -0.0285 -0.0300 -0.0043 -0.0362
1 -0.0422 -0.0014 -0.0647 0.0094 -0.0016
2 -0.0201 -0.0273 0.0227 -0.0332 0.0366
2 0.0438 0.0556 0.0098 0.0564 0.0182
3 -0.0073 0.0285 . . -0.0139
3 . 0.0357 0.0235 . -0.0020
4 0.0669 0.1073 . . 0.0755
4 . 0.0561 0.0899 . 0.0530
5 0.0368 0.0036 0.0374 0.0116 -0.0074
5 0.0250 -0.0080 0.0302 -0.0015 -0.0464
6 0.0049 -0.0384 -0.0204 -0.0049 -0.0120
6 0.0071 -0.0308 0.0017 -0.0285 -0.0070
;

```

The following statements create the ANOM chart shown in [Output 4.1.1](#):

```
ods graphics off;
title 'Analysis of Label Deviations';
proc anom data=LabelDev2;
  boxchart Deviation*Position;
  label Deviation = 'Mean Deviation from Center (mm)';
  label Position = 'Labeler Position';
run;
```

Output 4.1.1 ANOM Chart with Unequal Group Sizes

Note that the decision limits are automatically adjusted for the varying group sizes. The legend reports the minimum and maximum group sizes.

PCHART Statement: ANOM Procedure

Overview: PCHART Statement

The PCHART statement creates ANOM charts for group (treatment level) proportions, also referred to as ANOM p charts.

You can use options in the PCHART statement to

- compute decision limits from the data based on specified parameters, such as the significance level (α)
- tabulate group sample sizes, group proportions, decision limits, and other information
- save decision limits in an output data set
- save group sample sizes and group proportions in an output data set
- read decision limits and decision limit parameters from a data set
- display distinct sets of decision limits for different sets of groups on the same chart
- add block legends and symbol markers to identify special groups
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have two alternatives for producing ANOM p charts with the PCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced if SAS/GRAPH[®] is licensed.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: PCHART Statement

This section introduces the PCHART statement with simple examples that illustrate commonly used options. Complete syntax for the PCHART statement is presented in the section “Syntax: PCHART Statement” on page 90.

Creating ANOM Charts for Proportions from Group Counts

See ANMPI in the SAS/QC Sample Library A health care system administrator uses ANOM to compare cesarean section rates for a set of medical groups. For more background concerning this application, refer to Rodriguez (1996).

The following statements create a SAS data set named Csection, which contains the number of c-sections and the total number of deliveries for each medical group over a one-year period.

```
data Csection;
  length ID $ 2;
  input ID Csections Total @@;
  label ID = 'Medical Group Identification Number';
  datalines;
1A 150 923 1K 45 298 1B 34 170 1D 18 132
3I 20 106 3M 12 105 1E 10 77 1N 19 74
1Q 7 69 3H 11 65 1R 11 49 1H 9 48
3J 7 20 1C 8 43 3B 6 43 1M 4 29
3C 5 28 1O 4 27 1J 6 22 1T 3 22
3E 4 18 1G 4 15 3D 4 13 3G 1 11
1L 2 10 1I 1 8 1P 0 3 1F 0 3
1S 1 3
;
```

A partial listing of CSECTION is shown in Figure 4.10.

Figure 4.10 The Data Set Csection

Cesarean Section Data		
ID	Csections	Total
1A	150	923
1K	45	298
1B	34	170
1D	18	132
3I	20	106
3M	12	105
1E	10	77
1N	19	74
1Q	7	69
3H	11	65

The variable ID identifies the medical groups and is referred to as the *group-variable*. The variable Csections provides the number of c-sections, and is referred to as the *response variable* (or *response* for short). The variable Total provides the total number of deliveries.

The following statements create the *p* chart shown in [Figure 4.11](#):

```
ods graphics off;
title 'Analysis of C-Sections';
proc anom data=Csection;
  pchart Csections*ID / groupn    = Total
                    hoffset    = 2
                    nolegend
                    turnhlabels;
  label Csections = 'Proportion of Cesarean Sections';
run;
```

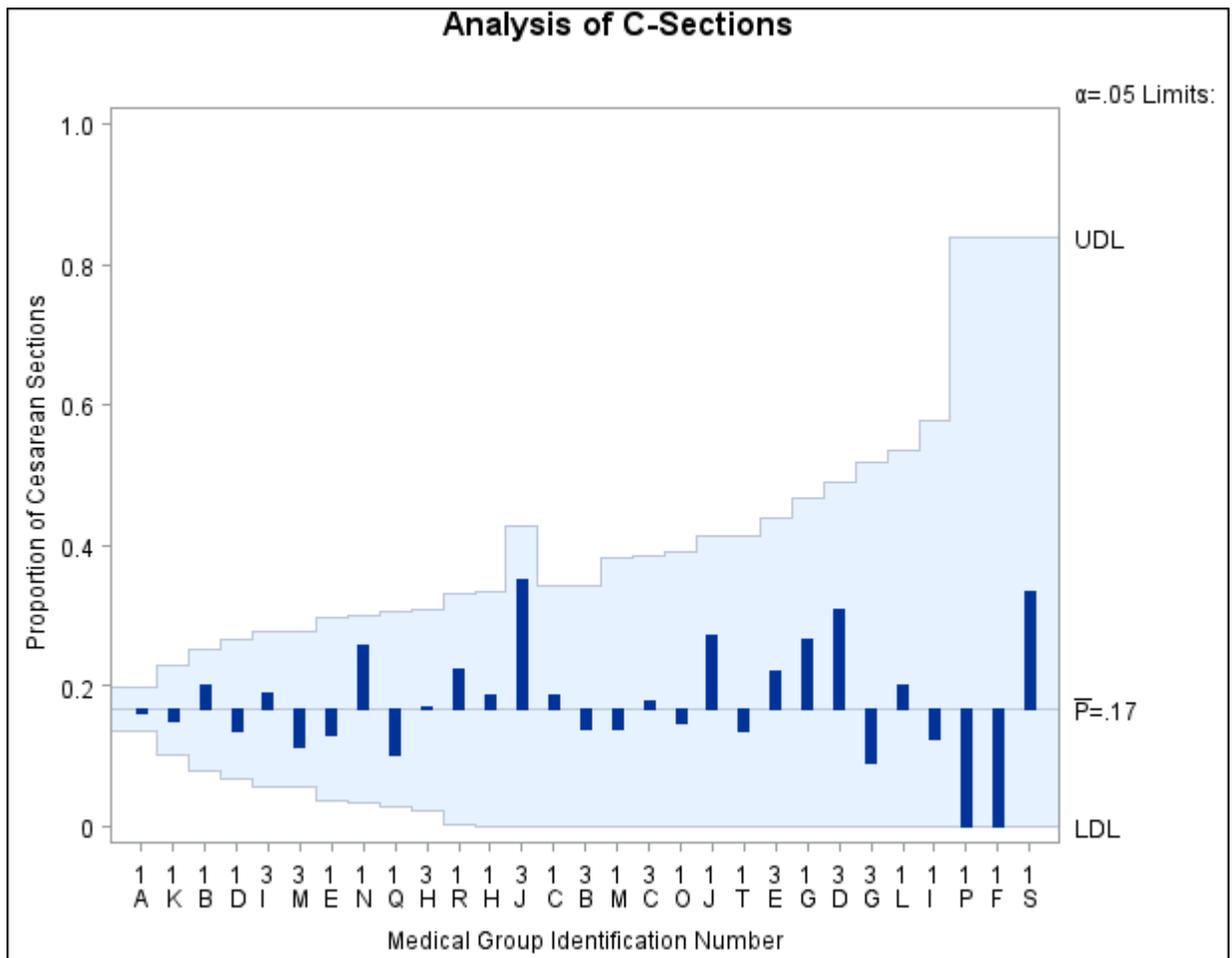

This example illustrates the basic form of the PCHART statement. After the keyword PCHART, you specify the *response* to analyze (in this case, Csections, followed by an asterisk and the *group-variable* ID).

The input data set is specified with the DATA= option in the PROC ANOM statement. The GROUPN= option specifies the sample size in each group and is required with a DATA= input data set. The GROUPN= option specifies one of the following:

- a constant group sample size
- a variable in the input data set whose values provide the group sample sizes (in this case, Total)

The TURNHLABELS option turns the horizontal axis labels since the default labeling skips labels if the characters exceed the space allotted. See [Axis and Axis Label Options](#). To angle the axis labels, see [Example 4.2](#).

Options such as GROUPN= and TURNHLABELS are specified after the slash (/) in the PCHART statement. A complete list of options is presented in the section “[Syntax: PCHART Statement](#)” on page 90.

Figure 4.11 ANOM p Chart for Cesarean Sections

Each point on the p chart represents the proportion of c-sections for a particular group. For instance, the value plotted for group 1A is $150/923 = 0.163$.

Since all the points fall within the decision limits, it can be concluded that the variation in proportions of c-sections across medical groups is strictly due to chance.

By default, the decision limits shown correspond to a significance level of $\alpha = 0.05$. This means that, assuming all groups have the same proportion of c-sections, there is a 0.05 probability that one or more of the decision limits would be exceeded purely by chance. The formulas for the limits are given in “Decision Limits” on page 99. Note that the decision limits vary with the number of deliveries in each group, and the widest limits correspond to the group with the smallest number of deliveries.

For more details on reading group counts, see “DATA= Data Set” on page 104.

Creating ANOM Charts for Proportions from Group Summary Data

The previous example illustrates how you can create ANOM charts for proportions using count data. *See ANMPGRP in the SAS/QC Sample Library* However, in many applications, the group data are provided in summarized form as proportions or percentages. This example illustrates how you can use the PCHART statement with data of this type.

The following data set provides the data from the preceding example in summarized form:

```
data CsectProp;
  length ID $ 2;
  input ID CsectionsP CsectionsN @@;
  datalines;
1A 0.163 923 1K 0.151 298 1B 0.200 170 1D 0.136 132
3I 0.189 106 3M 0.114 105 1E 0.130 77 1N 0.257 74
1Q 0.101 69 3H 0.169 65 1R 0.224 49 1H 0.188 48
3J 0.350 20 1C 0.186 43 3B 0.140 43 1M 0.138 29
3C 0.179 28 1O 0.148 27 1J 0.273 22 1T 0.136 22
3E 0.222 18 1G 0.267 15 3D 0.308 13 3G 0.091 11
1L 0.200 10 1I 0.125 8 1P 0.000 3 1F 0.000 3
1S 0.333 3
;
```

A partial listing of CsectProp is shown in [Figure 4.12](#). The groups are still indexed by ID. The variable CsectionsP contains the proportions of c-sections, and the variable CsectionsN contains the group sample sizes.

Figure 4.12 The Data Set CsectProp

Proportions of Cesarean Sections		
ID	Csections P	Csections N
1A	0.163	923
1K	0.151	298
1B	0.200	170
1D	0.136	132
3I	0.189	106
3M	0.114	105
1E	0.130	77
1N	0.257	74
1Q	0.101	69
3H	0.169	65

You can analyze this data set by specifying it as a SUMMARY= data set in the PROC ANOM statement.

Note that Csections is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the two SAS variables CsectionsP and CsectionsN. The suffix characters *P* and *N* indicate *proportion* and *sample size*, respectively. Thus, you can specify two group variables in a SUMMARY= data set with a single name Csections, which is referred to as the *response*. The name ID specified after the asterisk is the name of the *group-variable*.

A SUMMARY= data set used with the PCHART statement must contain the following variables:

- group variable
- group proportion variable
- group sample size variable

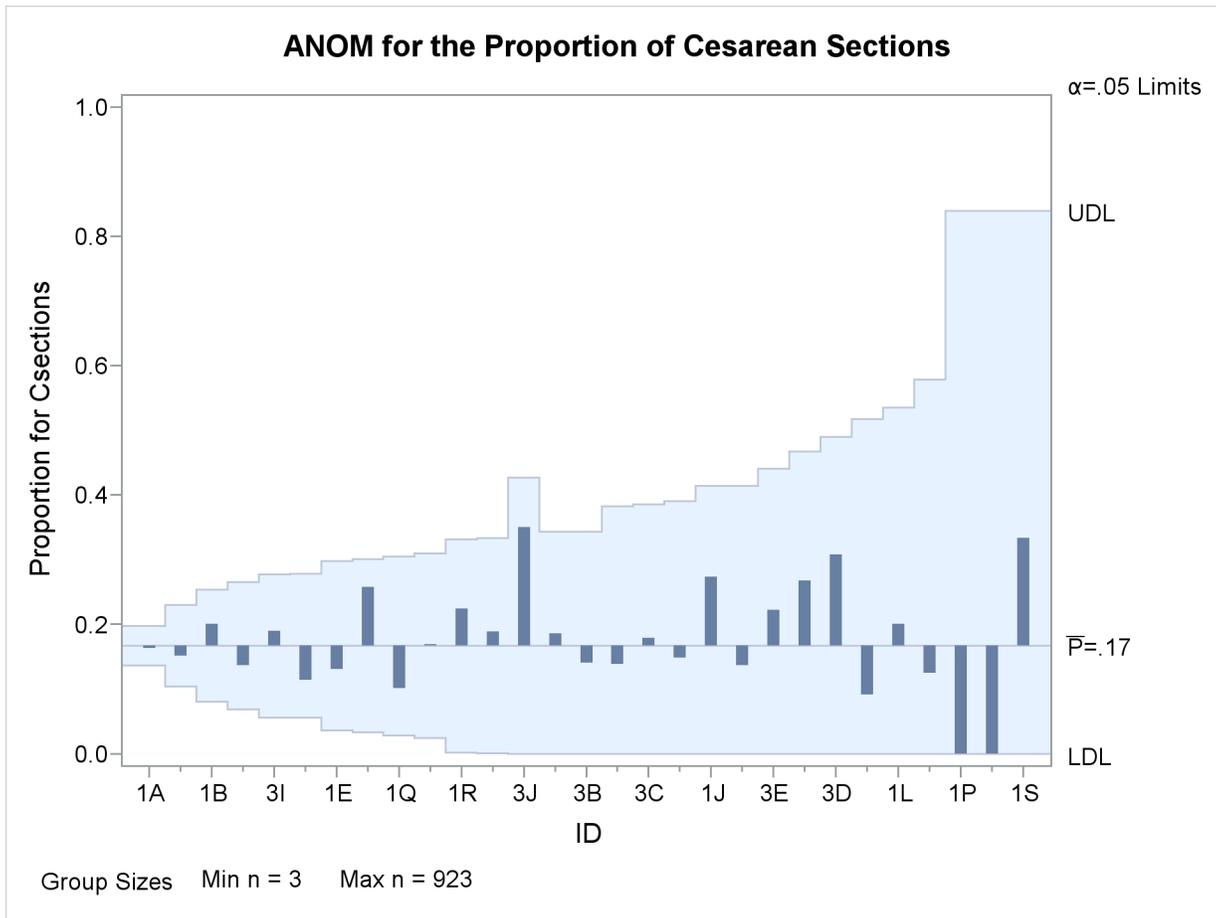

Furthermore, the names of the group proportion and sample size variables must begin with the *response* name specified in the PCHART statement and end with the special suffix characters *P* and *N*, respectively.

For more information, see “SUMMARY= Data Set” on page 105.

The following statements create a *p* Chart for C-Sections using the SUMMARY= data set CsectProp:

```
title 'ANOM for the Proportion of Cesarean Sections';
ods graphics on;
proc anom summary=CsectProp;
  pchart Csections*ID / odstitle = title1;
run;
```

The ODS GRAPHICS ON statement specified before the PROC ANOM statement enables ODS Graphics, so the *p* chart is created using ODS Graphics instead of traditional graphics. The resulting ANOM *p* chart is shown in [Figure 4.13](#).

Figure 4.13 ANOM p Chart from Group Proportions

Saving Group Proportions

In this example, the PCHART statement is used to create a summary data set that can later be read *See ANMPSUM in the SAS/QC Sample Library* by the ANOM procedure (as in the preceding example). The following statements read the data set CSection (see “Creating ANOM Charts for Proportions from Group Counts” on page 82) and create a summary data set named CSummary:

```
proc anom data=Csection;
  pchart Csections*ID / groupn      = Total
                    outsummary = CSummary
                    nochart;
run;
```

The OUTSUMMARY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 4.11. Figure 4.14 contains a partial listing of CSummary.

Figure 4.14 The Data Set CSummary

Group Proportions and Decision Limit Information		
ID	Csections P	Csections N
1A	0.16251	923
1K	0.15101	298
1B	0.20000	170
1D	0.13636	132
3I	0.18868	106
3M	0.11429	105
1E	0.12987	77
1N	0.25676	74
1Q	0.10145	69
3H	0.16923	65

There are three variables in the data set CSummary:

- ID identifies the groups.
- CSectionsP contains the group proportions.
- CSectionsN contains the group sample sizes.

Note that the variables containing the group proportions and group sample sizes are named by adding the suffix characters *P* and *N* to the *response* CSections specified in the PCHART statement. In other words, the variable naming convention for OUTSUMMARY= data sets is the same as that for SUMMARY= data sets. For more information, see “OUTSUMMARY= Data Set” on page 101.

Saving Decision Limits

See ANMPLIM in the SAS/QC Sample Library

You can save the decision limits for an ANOM *p* chart in a SAS data set.

The following statements read the number of c-sections per group from the data set CSection (see “Creating ANOM Charts for Proportions from Group Counts” on page 82) and save the decision limits displayed in Figure 4.11 in a data set named CSectionLim:

```
proc anom data=Csection;
  pchart csections*ID / groupn      = Total
                        outlimits = CsectionLim
                        nochart;
run;
```

The OUTLIMITS= option names the data set containing the decision limits, and the NOCHART option suppresses the display of the chart. The data set CSectionLim is listed in Figure 4.15.

Figure 4.15 The Data Set CSectionLim with Decision Limits

Decision Limits for the Proportion of Cesarean Sections								
<u>_VAR_</u>	<u>_GROUP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_LDLP_</u>	<u>_P_</u>	<u>_UDLP_</u>	<u>_LIMITK_</u>
Csections	ID	ESTIMATE	V	0.05	V	0.16680	V	29

The data set CSectionLim contains one observation with the limits for the *response* CSections. The variables _LDLP_ and _UDLP_ contain the lower and upper decision limits, and the variable _P_ contains the central line. The value of _LIMITN_ is the nominal sample size associated with the decision limits, the value of _LIMITK_ is the number of groups, and the value of _ALPHA_ is the significance level associated with the decision limits. The variables _VAR_ and _GROUP_ are bookkeeping variables that save the *response* and *group-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the value of _P_ is an estimate or a known (standard) value. Typically, the value of _TYPE_ is 'ESTIMATE.'

For more information, see the section “[OUTLIMITS= Data Set](#)” on page 101.

You can create an output data set containing both decision limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements: *See ANMPTAB in the SAS/QC Sample Library*

```
proc anom data=Csection;
  pchart Csections*ID / groupn   = Total
                        outtable = CsectionTab
                        nochart;
run;
```

A partial listing of the data set CSectionTab is shown in [Figure 4.16](#).

Figure 4.16 The Data Set CSectionTab

Proportions and Decision Limits for Cesarean Sections									
<u>_VAR_</u>	ID	<u>_ALPHA_</u>	<u>_LIMITN_</u>	<u>_SUBN_</u>	<u>_LDLP_</u>	<u>_SUBP_</u>	<u>_P_</u>	<u>_UDLP_</u>	<u>_EXLIM</u>
Csections	1A	0.05	923	923	0.13658	0.16251	0.16680	0.19703	
Csections	1K	0.05	298	298	0.10355	0.15101	0.16680	0.23006	
Csections	1B	0.05	170	170	0.08059	0.20000	0.16680	0.25302	
Csections	1D	0.05	132	132	0.06814	0.13636	0.16680	0.26547	
Csections	3I	0.05	106	106	0.05608	0.18868	0.16680	0.27752	
Csections	3M	0.05	105	105	0.05553	0.11429	0.16680	0.27807	
Csections	1E	0.05	77	77	0.03609	0.12987	0.16680	0.29752	
Csections	1N	0.05	74	74	0.03338	0.25676	0.16680	0.30023	
Csections	1Q	0.05	69	69	0.02849	0.10145	0.16680	0.30512	
Csections	3H	0.05	65	65	0.02417	0.16923	0.16680	0.30943	

This data set contains one observation for each group sample. The variables _SUBP_ and _SUBN_ contain the group proportions and group sample sizes. The variables _LDLP_ and _UDLP_ contain the lower and upper decision limits, and the variable _P_ contains the central line. The variables _VAR_ and ID contain the *response* name and values of the *group-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 102.

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read the information in CSectionTab and display an ANOM p chart (not shown here) identical to the chart in Figure 4.11:

```
title 'Analysis of C-Sections';
proc anom table=CSectionTab;
    pchart CSections*id;
label _subp_ = 'Proportion of Cesarean Sections';
run;
```

Because the ANOM procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized ANOM charts. For more information, see “TABLE= Data Set” on page 106.

Syntax: PCHART Statement

The basic syntax for the PCHART statement is as follows:

```
PCHART response * group-variable ;
```

The general form of this syntax is as follows:

```
PCHART responses * group-variable < (block-variables) >
    < =symbol-variable | ='character' > < options > ;
```

You can use any number of PCHART statements in the ANOM procedure. The components of the PCHART statement are described as follows.

response

responses

identify one or more responses to be analyzed. The specification of *response* depends on the input data set specified in the PROC ANOM statement.

- If response counts are read from a DATA= data set, *response* must be the name of the variable containing the counts. For an example, see “Creating ANOM Charts for Proportions from Group Summary Data” on page 85.
- If response proportions are read from a SUMMARY= data set, *response* must be the common prefix of the summary variables in the SUMMARY= data set. For an example, see “Creating ANOM Charts for Proportions from Group Summary Data” on page 85.
- If response proportions and decision limits are read from a TABLE= data set, *response* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “Saving Decision Limits” on page 88.

A *response* is required. If you specify more than one response, enclose the list in parentheses. For example, the following statements request distinct ANOM p charts for the responses Rejects and Reworks:

```
proc anom data=Measures;
  pchart (Rejects Reworks)*Sample / groupn=100;
run;
```

Note that when data are read from a DATA= data set, the GROUPN= option, which specifies group sample sizes, is required.

group-variable

is the variable that identifies groups in the data. The *group-variable* is required. In the preceding PCHART statement, Sample is the group variable.

block-variables

are optional variables that identify sets of consecutive groups on the chart. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker used to plot proportions. Distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOLN statements.

options

control the analysis, enhance the appearance of the chart, save results in data sets, and so on. The section “[Summary of Options](#)” lists all options by function.

Summary of Options

The following tables list the PCHART statement options by function. Options unique to the ANOM procedure are listed in [Table 4.9](#), and are described in detail in “[Dictionary of ANOM Chart Statement Options](#)” on page 192. Options that are common to both the ANOM and SHEWHART procedures are listed in [Table 4.10](#), and are described in detail in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 4.9 PCHART Statement Special Options

Option	Description
Options for Specifying Decision Limits	
ALPHA=	specifies significance level
LIMITK=	specifies number of groups for decision limits
LIMITN=	specifies either nominal sample size for fixed decision limits or varying limits
NOREADLIMITS	computes decision limits for each <i>response</i> from the data rather than a LIMITS= data set
P=	specifies the weighted average of group proportions
READINDEXES=	reads multiple sets of decision limits for each <i>response</i> from a LIMITS= data set
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set

Table 4.9 continued

Option	Description
Options for Displaying Decision Limits	
CINFILL=	specifies color for area inside decision limits
CLIMITS=	specifies color of decision limits, central line, and related labels
LDLLABEL=	specifies label for lower decision limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the decision limit
LLIMITS=	specifies line type for decision limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for decision limits and central line
NOCTL	suppresses display of central line
NOLDL	suppresses display of lower decision limit
NOLIMIT0	suppresses display of lower decision limit if it is 0
NOLIMIT1	suppresses display of upper decision limit if it is 1 (100%)
NOLIMITLABEL	suppresses labels for decision limits and central line
NOLIMITS	suppresses display of decision limits
NOLIMITSFRAME	suppresses default frame around decision limit information when multiple sets of decision limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for decision limits
NOUDL	suppresses display of upper decision limit
PSYMBOL=	specifies label for central line
UDLLABEL=	specifies label for upper decision limit
WLIMITS=	specifies width for decision limits and central line
Input Data Set Option	
GROUPN=	specifies group sample sizes as constant number n or as values of variable in a DATA= data set
Output Data Set Option	
OUTSUMMARY=	creates output data set containing group summary statistics

Table 4.10 PCHART Statement General Options

Option	Description
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on ANOM p chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line

Table 4.10 *continued*

Option	Description
COUT=	specifies color for portions of line segments that connect points outside decision limits
COUTFILL=	specifies color for shading areas between the connected points and decision limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels
LABELHEIGHT=	specifies height of labels
NONEEDLES	suppresses vertical needles connecting points to central line
OUTLABEL=	labels points outside decision limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value for numeric horizontal axis with date, time, or datetime format
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent group values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of ANOM <i>p</i> chart
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis

Table 4.10 continued

Option	Description
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for ANOM p chart
WAXIS=	specifies width of axis lines
YSCALE=	scales vertical axis in percent units (rather than proportions)
Plot Layout Options	
ALLN	plots means for all groups
BILEVEL	creates ANOM p chart using half-screens and half-pages
EXCHART	creates ANOM p chart for a response only when a group mean exceeds the decision limits
INTERVAL=	natural time interval between consecutive group positions when time, date, or datetime format is associated with a numeric group variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed decision limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for group sample sizes
NPANELPOS=	specifies number of group positions per panel on each chart
REPEAT	repeats last group position on panel as first group position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays ANOM p chart regardless of whether root mean square error is zero
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= option
CVREF=	specifies color for lines requested by VREF= option
HREF=	specifies position of reference lines perpendicular to horizontal axis on ANOM p chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on ANOM p chart
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups

Table 4.10 continued

Option	Description
VREF=	specifies position of reference lines perpendicular to vertical axis on ANOM <i>p</i> chart
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to ANOM <i>p</i> chart
DESCRIPTION=	specifies description of ANOM <i>p</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on chart
NAME=	specifies name of ANOM <i>p</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside decision limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color

Table 4.10 *continued*

Option	Description
OUTFILL	shades areas between decision limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the decision limit infill transparency
MARKERS	plots group points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
OUTFILLTRANSPARENCY=	specifies decision limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with groups
Input Data Set Option	
DATAUNIT=	specifies that input values are proportions or percentages rather than counts
Output Data Set Options	
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing decision limits

Table 4.10 *continued*

Option	Description
OUTTABLE=	creates output data set containing group summary statistics and decision limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of group means, group sample sizes, and decision limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLEOUTLIM	augments basic table with columns indicating decision limits exceeded
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels decision limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars

Table 4.10 *continued*

Option	Description
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on ANOM p chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive ANOM Charts	
HTML=	specifies a variable whose values create links to be associated with groups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Details: PCHART Statement

Constructing ANOM Charts for Proportions

The following notation is used in this section:

X_i	response number (count) in the i th group
k	number of groups
n_i	sample size of the i th group
N	total sample size = $n_1 + \dots + n_k$
p_i	proportion in the i th group, where $p_i = X_i/n_i$
\bar{p}	weighted average of proportions across groups: $\bar{p} = \frac{n_1 p_1 + \dots + n_k p_k}{N} = \frac{X_1 + \dots + X_k}{N}$
α	significance level
$h(\alpha; k, n, \infty)$	critical value for ANOM for normal data in the balanced case ($n_i \equiv n$)
$h(\alpha; k, n_1, \dots, n_k, \infty)$	critical value for ANOM for normal data in the unbalanced case

Plotted Points

Each point on an ANOM p chart represents the response proportion ($p_i = X_i/n_i$) for a group.

Central Line

By default, the central line on an ANOM p chart is computed as \bar{p} , the weighted average of the group proportions. You can specify \bar{p} with the P= option or with the variable `_P_` in a LIMITS= data set.

Decision Limits

For the i th group, the response counts are assumed to have the binomial distribution $B(n_i, p_i)$. The ANOM method for proportions tests the null hypothesis that $p_1 = p_2 = \dots = p_k$, that is, that the proportions are the same, against the alternative that at least one of the p_i 's is different from the average of the k proportions.

The decision limits are computed using the normal approximation to the binomial distribution, which is appropriate when the sample sizes for the groups are large; refer to Ramig (1983). A commonly recommended check for this assumption is that $n_i p_i > 5$ and $n_i(1 - p_i) > 5$ for all the groups. The critical values in the ANOM method for normally distributed data are adapted to the binomial case by using infinite degrees of freedom for the variance.

When the sample sizes are constant across groups ($n_i \equiv n$), the decision limits are computed as follows:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \max \left(\bar{p} - h(\alpha; k, n, \infty) \sqrt{\bar{p}(1 - \bar{p})} \sqrt{\frac{k-1}{N}}, 0 \right) \\ \text{upper decision limit (UDL)} &= \min \left(\bar{p} + h(\alpha; k, n, \infty) \sqrt{\bar{p}(1 - \bar{p})} \sqrt{\frac{k-1}{N}}, 1 \right) \end{aligned}$$

For the theoretical derivation of the decision limits, refer to Nelson (1982a).

When the sample sizes (n_i) are different across groups (the unbalanced case), the decision limits are computed as follows:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \max \left(\bar{p} - h(\alpha; k, n_1, \dots, n_k, \infty) \sqrt{\bar{p}(1 - \bar{p})} \sqrt{\frac{N - n_i}{N n_i}}, 0 \right) \\ \text{upper decision limit (UDL)} &= \min \left(\bar{p} + h(\alpha; k, n_1, \dots, n_k, \infty) \sqrt{\bar{p}(1 - \bar{p})} \sqrt{\frac{N - n_i}{N n_i}}, 1 \right) \end{aligned}$$

Note that the decision limits for the i th group depend on n_i . If the sample sizes are constant across groups ($n_i \equiv n$), the decision limits in the unbalanced case reduce to the formulas given for the balanced case since $n_i = n$ and $N = kn$ so

$$\sqrt{\frac{N - n_i}{N n_i}} = \sqrt{\frac{kn - n}{N n}} = \sqrt{\frac{k-1}{N}}$$

For the derivation of the decision limits for unequal sample sizes, refer to Nelson (1991).

Exact critical values $h(\alpha; k, n, \infty)$ were first tabulated by L. S. Nelson (1983). Refer to Nelson (1993) for derivation of critical values.

You can specify parameters for the limits as follows:

- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set. By default, $\alpha = 0.05$.
- Specify a constant nominal sample size $n_i \equiv n$ for the decision limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set. By default, n is the observed sample size in the balanced case.
- Specify \bar{p} with the P= option or with the variable `_P_` in a LIMITS= data set. By default, \bar{p} is the weighted average of the group proportions.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves decision limits and decision limit parameters. The following variables can be saved:

Table 4.11 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	significance level (α)
<code>_GROUP_</code>	<i>group-variable</i> specified in the PCHART statement
<code>_INDEX_</code>	optional identifier for the decision limits specified with the OUTINDEX= option
<code>_LDLP_</code>	lower decision limit for proportions
<code>_LIMITK_</code>	number of groups
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_P_</code>	average proportion of nonconforming items (\bar{p})
<code>_TYPE_</code>	type (standard or estimate) of <code>_P_</code>
<code>_UDLP_</code>	upper decision limit for proportions
<code>_VAR_</code>	<i>response</i> specified in the PCHART statement

Notes:

1. If the decision limits vary with group sample size, the special missing value V is assigned to the variables `_LIMITN_`, `_LDLP_`, and `_UDLP_`.
2. A group must have at least one nonmissing value ($n_i \geq 1$), and there must be at least one group with $n_i \geq 2$.
3. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *response* specified in the PCHART statement. For an example, see “[Saving Decision Limits](#)” on page 88.

OUTSUMMARY= Data Set

The OUTSUMMARY= data set saves group summary statistics. The following variables are saved:

- the *group-variable*
- a group proportion variable named by *response* suffixed with P
- a group sample size variable named by *response* suffixed with N

Given a *response* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Group summary variables are created for each *response* specified in the PCHART statement. For example, consider the following statements:

```

proc anom data=Input;
  pchart (Rework Rejected)*Batch / outsummary=Summary
        groupn =30;
run;

```

The data set Summary contains variables named Batch, ReworkP, ReworkN, RejectedP, and RejectedN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `OUTPHASE=` option is specified)

For an example of an `OUTSUMMARY=` data set, see “[Saving Group Proportions](#)” on page 87.

Note that an `OUTSUMMARY=` data set created with the `PCHART` statement can be reused as a `SUMMARY=` data set.

OUTTABLE= Data Set

The `OUTTABLE=` data set saves group summary statistics, decision limits, and related information. The variables shown in the following table are saved:

Variable	Description
<code>_ALPHA_</code>	significance level (α)
<code>_EXLIM_</code>	decision limit exceeded on p chart
<code>group</code>	values of the group variable
<code>_LDLP_</code>	lower decision limit for proportions
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_SUBP_</code>	group proportion
<code>_SUBN_</code>	group sample size
<code>_UDLP_</code>	upper decision limit for proportions
<code>_VAR_</code>	<i>response</i> specified in the <code>PCHART</code> statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)

NOTE: The variable `_EXLIM_` is a character variable of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “[Saving Decision Limits](#)” on page 88.

ODS Tables

The following table summarizes the ODS tables that you can request with the PCHART statement.

Table 4.12 ODS Tables Produced with the PCHART Statement

Table Name	Description	Options
PCHART	<i>p</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the ANOM procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. PCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the PCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 4.13](#).

Table 4.13 ODS Graphics Produced by the PCHART Statement

ODS Graph Name	Plot Description
PChart	ANOM <i>p</i> chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read count data from a DATA= data set specified in the PROC ANOM statement. Each *response* specified in the PCHART statement must be a SAS variable in the DATA= data set. This variable provides counts for group samples indexed by the values of the *group-variable*. The *group-variable*, which is specified in the PCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a count for each *response* and a value for the *group-variable*. The data set must contain one observation for each group. Note that you can specify the DATAUNIT= option in the PCHART statement to read proportions or percentages instead of counts. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

When you use a DATA= data set with the PCHART statement, the GROUPN= option (which specifies the group sample size) is required.

For an example of a DATA= data set, see “Creating ANOM Charts for Proportions from Group Counts” on page 82.

LIMITS= Data Set

You can read preestablished decision limits (or parameters from which the decision limits can be calculated) from a LIMITS= data set specified in the PROC ANOM statement. For example, the following statements read decision limit information from the data set Conlims:

```
proc anom data=Info limits=Conlims;
  pchart Rejects*Batch / groupn= 100;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the ANOM procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LDLP_`, `_P_`, and `_UDLP_`, which specify the decision limits directly
- the variable `_P_`, without providing `_LDLP_` and `_UDLP_`. The value of `_P_` is used to calculate the decision limits according to the equations in the section “Decision Limits” on page 99.

In addition, note the following:

- The variables `_VAR_` and `_GROUP_` are always required. These must be character variables whose lengths are no greater than 32.
- `_LDLP_` and `_UDLP_` must be specified together; otherwise their values are computed.
- `_ALPHA_` is optional but is recommended in order to maintain a complete set of decision limit information. The default value is 0.05.
- `_LIMITK_` is optional. The default value is k , the number of groups. A group must have at least one nonmissing value ($n_i \geq 1$) and there must be at least one group with $n_i \geq 2$. If specified, `_LIMITK_` overrides the value of k .
- `_LIMITN_` is optional. The default value is the common group size (n), in the balanced case $n_i \equiv n$. If specified, `_LIMITN_` overrides the value of n .
- The variable `_TYPE_` is optional, but is recommended to maintain a complete set of decision limit information. The variable `_TYPE_` must be a character variable of length 8. Valid values are 'ESTIMATE,' 'STANDARD,' 'STDMEAN,' and 'STDRMS.' The default is 'ESTIMATE.'
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- BY variables are required if specified with a BY statement.

SUMMARY= Data Set

You can read group summary statistics from a `SUMMARY=` data set specified in the `PROC ANOM` statement. This enables you to reuse `OUTSUMMARY=` data sets that have been created in previous runs of the `ANOM` procedure or to create your own `SUMMARY=` data set.

A `SUMMARY=` data set used with the `PCHART` statement must contain the following:

- the *group-variable*
- a group proportion variable for each *response*
- a group sample size variable for each *response*

The names of the proportion sample size variables must be the *response* name concatenated with the special suffix characters *P* and *N*, respectively.

For example, consider the following statements:

```
proc anom summary=Summary;
  pchart (Rework Rejected)*Batch / groupn=50;
run;
```

The data set Summary must include the variables Batch, ReworkP, ReworkN, RejectedP, and RejectedN.

Note that if you specify a *response* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *response* name, suffixed with the appropriate character.

Other variables that can be read from a SUMMARY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

For an example of a SUMMARY= data set, see “Creating ANOM Charts for Proportions from Group Summary Data” on page 85.

TABLE= Data Set

You can read summary statistics and decision limits from a TABLE= data set specified in the PROC ANOM statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the ANOM procedure. Because the ANOM procedure simply displays the information read from a TABLE= data set, you can use TABLE= data sets to create specialized ANOM charts.

The following table lists the variables required in a TABLE= data set used with the PCHART statement:

Table 4.14 Variables Required in a TABLE= Data Set

Variable	Description
<i>group-variable</i>	values of the <i>group-variable</i>
<code>_LDLP_</code>	lower decision limit for proportions
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_P_</code>	average proportion of nonconforming items
<code>_SUBN_</code>	group sample size
<code>_SUBP_</code>	group proportion of nonconforming items
<code>_UDLP_</code>	upper decision limit for proportions

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

- `_PHASE_` (if the `READPHASES=` option is specified). This variable must be a character variable whose length is no greater than 48.
- `_VAR_`. This variable is required if more than one *response* is specified or if the data set contains information for more than one *response*. This variable must be a character variable whose length is no greater than 32.

For an example of a `TABLE=` data set, see “[Saving Decision Limits](#)” on page 88.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>group-variable</i>
Vertical	<code>DATA=</code>	<i>response</i>
Vertical	<code>SUMMARY=</code>	group proportion variable
Vertical	<code>TABLE=</code>	<code>_SUBP_</code>

For example, the following sets of statements specify the label *Proportion Nonconforming* for the vertical axis of the *p* chart:

```
proc anom data=Circuits;
  pchart Fail*Batch / groupn=50;
  label Fail = 'Proportion Nonconforming';
run;

proc anom summary=Cirhist;
  pchart Fail*Batch ;
  label Failp = 'Proportion Nonconforming';
run;

proc anom table=Cirtable;
  pchart Fail*batch ;
  label _SUBP_ = 'Proportion Nonconforming';
run;
```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a `DATA=`, `SUMMARY=`, or `TABLE=` data set is not analyzed if the value of the group variable is missing. For a particular response variable, an observation read from a `DATA=` data set is not analyzed if the value of the response variable is missing. Missing values of response variables generally lead to unequal group sample sizes. For a particular response variable, an observation read from a `SUMMARY=` or `TABLE=` data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: PCHART Statement

This section provides advanced examples of the PCHART statement.

Example 4.2: ANOM p Charts with Angled Axis Labels

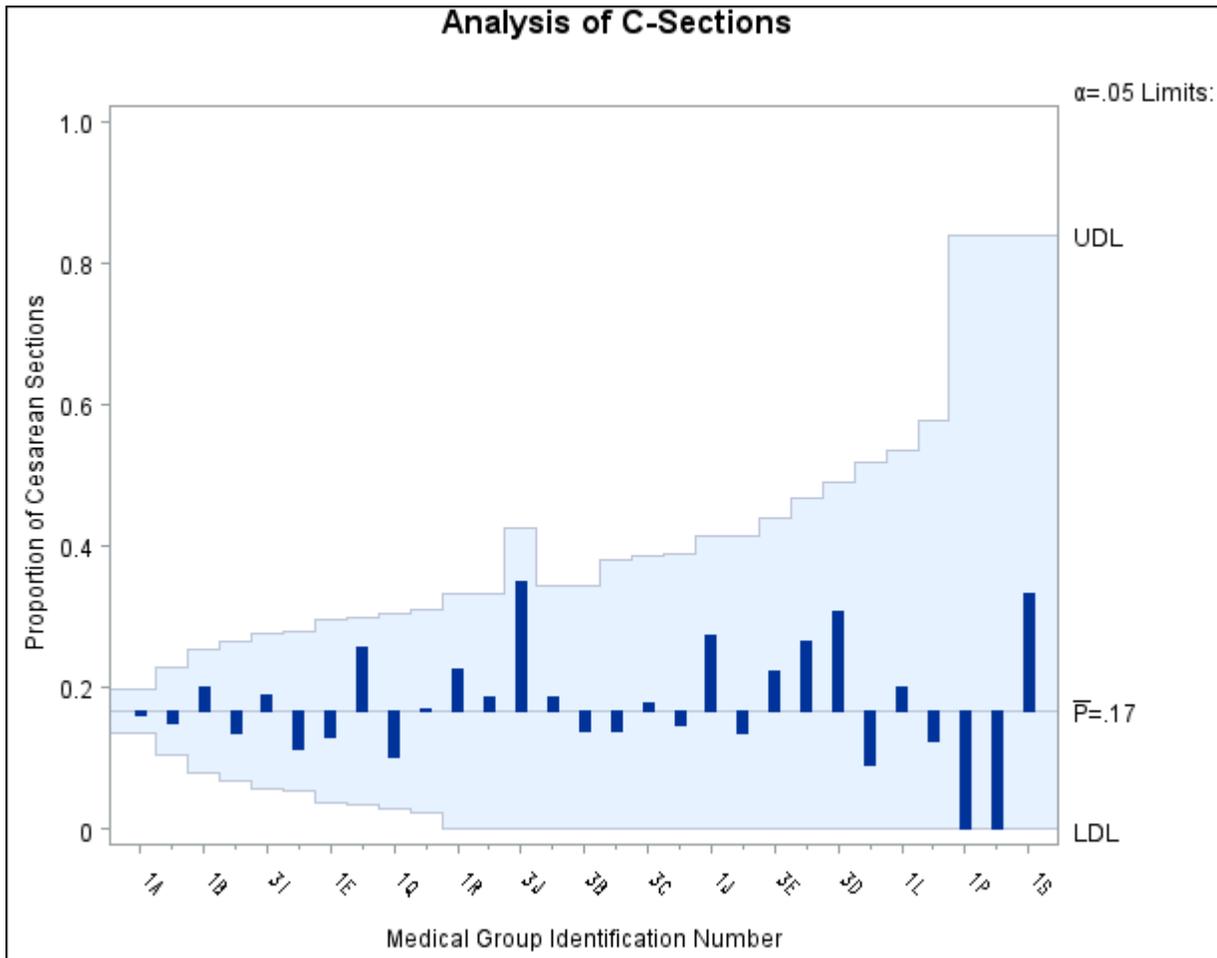

See ANMPEX1 in the SAS/QC Sample Library

Consider the example described in the section “Creating ANOM Charts for Proportions from Group Counts” on page 82. In the example, the option TURNHLABELS was used to vertically display the horizontal axis labels. You can also use an AXIS statement to create an angled display of the horizontal or vertical axis labels. The following statements create the p CHART shown in Output 4.2.1:

```
ods graphics off;
title 'Analysis of C-Sections';
proc anom data=Csection;
  pchart Csections*ID / groupn   = Total
                    nolegend
                    haxis      = axis1;
  axis1 value       = (a=-45 h=2.0pct);
  label Csections = 'Proportion of Cesarean Sections';
run;
```

The angle is specified with the a= option in the AXIS1 statement. Valid angle values are between -90 and 90. The height of the labels is specified with the h= option in the AXIS1 statement. See [Axis and Axis Label Options](#).

Output 4.2.1 ANOM p Chart for C-Sections with Angled Axis Labels

UCHART Statement: ANOM Procedure

Overview: UCHART Statement

The UCHART statement creates ANOM charts for group (treatment level) rates, also referred to as ANOM *u* charts. The rate plotted on a *u* chart is the number or *count* of events occurring in a group divided by a measure of the opportunity for an event to occur.

You can use options in the UCHART statement to

- compute decision limits from the data based on specified parameters, such as the significance level (α)
- tabulate group summary statistics and decision limits
- save decision limits in an output data set
- save group summary statistics in an output data set
- read decision limits and decision limit parameters from a data set
- display distinct sets of decision limits for different sets of groups on the same chart
- add block legends and symbol markers to identify special groups
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have two alternatives for producing ANOM *u* charts with the UCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced if SAS/GRAPH[®] is licensed.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: UCHART Statement

This section introduces the UCHART statement with simple examples that illustrate commonly used options. Complete syntax for the UCHART statement is presented in the section “Syntax: UCHART Statement” on page 115.

Creating ANOM Charts for Rates from Group Counts

A health care system administrator uses ANOM to compare medical/surgical admissions rates for set of clinics. For more background concerning this application, refer to Rodriguez (1996). *See ANMUI in the SAS/QC Sample Library*

The following statements create a SAS data set named MSAdmits, which contains the number of admissions and the number of member-months for each clinic during a one-year period.

```
data MSAdmits;
  length ID $ 2;
  input ID Count MemberMonths @@;
  KMemberYrs = MemberMonths/12000;
  label ID = 'Medical Group Id Number';
  datalines;
1A 1882 697204 1K 600 224715 1B 438 154720
1D 318 82254 3M 183 76450 3I 220 73529
1N 121 60169 3H 105 52886 1Q 124 52595
1E 171 51229 3B 88 34775 1C 100 31959
1H 112 28782 3C 84 27478 1R 69 26494
1T 21 25096 1M 130 24723 1O 61 24526
3D 66 22359 1J 54 19101 3J 30 16089
3G 36 13851 3E 26 10587 1G 28 10351
1I 25 6041 1L 20 5138 1S 7 2723
1F 7 2424 1P 2 2030
;
proc sort data=MSAdmits;
  by ID;
run;
```

A partial listing of MSAdmits is shown in [Figure 4.17](#).

Figure 4.17 The Data Set MSAdmits

Medical/Surgical Admissions			
ID	Count	Member Months	KMember Yrs
1A	1882	697204	58.1003
1B	438	154720	12.8933
1C	100	31959	2.6633
1D	318	82254	6.8545
1E	171	51229	4.2691
1F	7	2424	0.2020
1G	28	10351	0.8626
1H	112	28782	2.3985
1I	25	6041	0.5034
1J	54	19101	1.5918

There is a single observation per clinic. The variable ID identifies the clinics and is referred to as the *group-variable*. The variable Count provides the number of admissions for each clinic, which is referred to as the *response variable* (or *response* for short). The variable MemberMonths, which provides the number of member-months for each clinic, is divided by 1200 to compute the variable KMemberYrs, the number of 1000-member-years, which serves as the measure of opportunity for an admission to occur.

The following example illustrates the basic form of the UCHART statement. After the keyword UCHART, you specify the *response* to analyze (in this case, Count), followed by an asterisk and the *group-variable* (ID).

The following statements create the *u* chart shown in Figure 4.18:

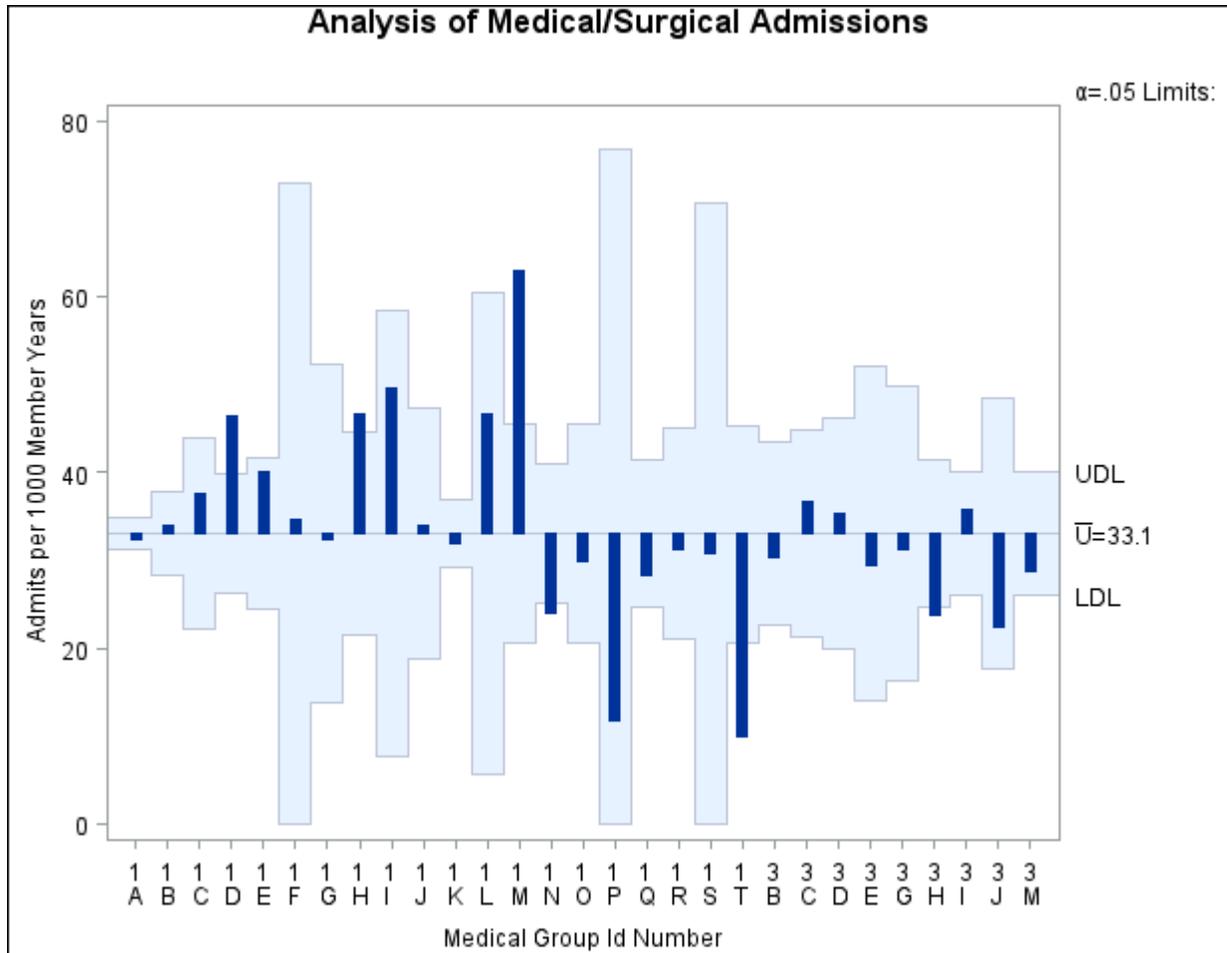

```
ods graphics off;
title 'Analysis of Medical/Surgical Admissions';
proc anom data=MSAdmits;
  uchart Count*ID / groupn = KMemberYrs
          turnhlabels
          nolegend;
  label Count = 'Admits per 1000 Member Years';
run;
```

The TURNHLABELS option is used to vertically display the horizontal axis labels. The GROUPN= option specifies the number of “occurrence opportunity” units in each group and is required if the input data set is a DATA= data set. In this example, 1000 member years represent one unit of opportunity. The number of units per group can be thought of as the group “sample size.” You can use the GROUPN= option to specify one of the following:

- a constant number of units, which applies to all the groups
- an input variable name, which provides the number of units for each group (KMemberYrs in this example)

Options such as GROUPN= are specified after the slash (/) in the UCHART statement. A complete list of options is presented in the section “Syntax: UCHART Statement” on page 115.

Figure 4.18 u Chart Example

The input data set is specified with the DATA= option in the PROC ANOM statement.

Each point on the u chart represents the rate of occurrence, computed as the count divided by the number of opportunity units. The points are displayed in the sort order for the *group-variable* ID. The chart shows that Clinics 1D, 1H, and 1M have significantly higher admissions rates, and Clinics 1N, 1T, and 3H have significantly lower admissions rates.

By default, the decision limits correspond to a significance level of $\alpha = 0.05$. This means that, assuming all clinics have the same rate of admissions, there is a 0.05 probability that one or more of the decision limits would be exceeded purely by chance. The formulas for the limits are given in the section “Decision Limits” on page 124. Note that the decision limits vary with the number of 1000-member-years for each clinic.

For more details on reading count data, see “DATA= Data Set” on page 129.

Saving Decision Limits

See ANMULIM in the SAS/QC Sample Library

You can save the decision limits for an ANOM u chart in a SAS data set.

The following statements read the data set MSAdmits (see “Creating ANOM Charts for Rates from Group Counts” on page 111) and save the decision limits displayed in Figure 4.18 in a data set named MSLimits:

```
proc anom data=MSAdmits;
  uchart Count*ID / groupn      = KMemberYrs
                    outlimits = MSLimits
                    nochart;
run;
```

The GROUPN= option specifies the number of opportunity units for each group. The OUTLIMITS= option names the data set containing the decision limits, and the NOCHART option suppresses the display of the chart. The data set MSLimits is listed in Figure 4.19.

Figure 4.19 Data Set MSLimits Containing Decision Limits

Decision Limits for Medical/Surgical Admissions Rates								
<u>_VAR_</u>	<u>_GROUP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_LDLU_</u>	<u>_U_</u>	<u>_UDLU_</u>	<u>_LIMIT</u>
Count	ID	ESTIMATE	V	0.05	V	33.0789	V	29

The data set MSLimits contains one observation with the limits for *response* Count. The variables _LDLU_ and _UDLU_ contain the lower and upper decision limits, and the variable _U_ contains the central line. The value of _LIMITN_ is the nominal number of units associated with the decision limits (which are varying in this case), the value of _LIMITK_ is the number of groups, and the value of _ALPHA_ is the significance level of the decision limits. The variables _VAR_ and _GROUP_ are bookkeeping variables that save the *response* and *group-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the value of _U_ is an estimate or standard (known) value. Typically, the value of _TYPE_ is ‘ESTIMATE.’ For more information, see “OUTLIMITS= Data Set” on page 126.

Alternatively, you can use the OUTTABLE= option to create an output data set that saves both the decision limits and the group statistics, as illustrated by the following statements:

```
proc anom data=MSAdmits;
  uchart Count*ID / groupn      = KMemberYrs
                    outtable = MSTable
                    nochart;
run;
```

The a partial listing of the data set MSTable is shown in Figure 4.20.

Figure 4.20 Data Set MStable

Rates and Decision Limits for Medical/Surgical Admissions									
<u>_VAR_</u>	<u>ID</u>	<u>_ALPHA_</u>	<u>_LIMITN_</u>	<u>_SUBN_</u>	<u>_LDLU_</u>	<u>_SUBU_</u>	<u>_U_</u>	<u>_UDLU_</u>	<u>_EXLIM_</u>
Count	1A	0.05	58.1003	58.1003	31.2135	32.3922	33.0789	34.9443	
Count	1B	0.05	12.8933	12.8933	28.2837	33.9710	33.0789	37.8741	
Count	1C	0.05	2.6633	2.6633	22.1550	37.5481	33.0789	44.0028	
Count	1D	0.05	6.8545	6.8545	26.3640	46.3929	33.0789	39.7938	UPPER
Count	1E	0.05	4.2691	4.2691	24.4964	40.0554	33.0789	41.6615	
Count	1F	0.05	0.2020	0.2020	0.0000	34.6535	33.0789	73.0631	
Count	1G	0.05	0.8626	0.8626	13.7710	32.4606	33.0789	52.3868	
Count	1H	0.05	2.3985	2.3985	21.5579	46.6959	33.0789	44.5999	UPPER
Count	1I	0.05	0.5034	0.5034	7.7757	49.6607	33.0789	58.3822	
Count	1J	0.05	1.5918	1.5918	18.8992	33.9249	33.0789	47.2587	

This data set contains one observation for each group. The variables `_SUBU_` and `_SUBN_` contain the rate of occurrence and the number of opportunity units for each group. The variables `_LDLU_` and `_UDLU_` contain the lower and upper decision limits, and the variable `_U_` contains the central line. The variables `_VAR_` and `ID` contain the *response* name and values of the *group-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 127.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set by the ANOM procedure. For example, the following statements read `MStable` and display a *u* chart (not shown here) identical to the chart in [Figure 4.18](#): *See ANMUTAB in the SAS/QC Sample Library*

```

title 'Analysis of Medical/Surgical Admissions';
proc anom table=MStable;
  uchart Count*id ;
  label _subu_ = 'Admits per 1000 Member Years';
run;

```

Because the ANOM procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized ANOM charts. For more information, see the section “[TABLE= Data Set](#)” on page 131.

Syntax: UCHART Statement

The basic syntax for the UCHART statement is as follows:

```
UCHART response * group-variable ;
```

The general form of this syntax is as follows:

```
UCHART responses * group-variable <(block-variables)>
  <=symbol-variable | =character'> <options> ;
```

You can use any number of UCHART statements in the ANOM procedure. The components of the UCHART statement are described as follows.

response**responses**

identify one or more responses to be analyzed. The specification of *response* depends on the input data set specified in the PROC ANOM statement.

- If counts are read from a DATA= data set, *response* must be the name of the variable containing the counts. For an example, see “Creating ANOM Charts for Rates from Group Counts” on page 111.
- If rates and numbers of opportunity units are read from a SUMMARY= data set, *response* must be the common prefix of the appropriate variables in the SUMMARY= data set.
- If rates, numbers of opportunity units, and decision limits are read from a TABLE= data set, *response* must be the value of the variable `_VAR_` in the TABLE= data set.

A *response* is required. If you specify more than one response, enclose the list in parentheses. For example, the following statements request distinct ANOM *u* charts for Defects and Flaws:

```
proc anom data=Measures;
    uchart (Defects Flaws)*Sample / groupn=30;
run;
```

Note that when data are read from a DATA= data set with the UCHART statement, the GROUPN= option (which specifies the number of opportunity units per group) is required.

group-variable

is the variable that identifies groups in the data. The *group-variable* is required. In the preceding UCHART statement, `sample` is the group variable.

block-variables

are optional variables that identify sets of consecutive groups on the chart. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker used to plot the rates. Distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements.

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. “Summary of Options” on page 116 lists all options by function.

Summary of Options

The following tables list the UCHART statement options by function. Options unique to the ANOM procedure are listed in Table 4.15, and are described in detail in “Dictionary of ANOM Chart Statement Options” on page 192. Options that are common to both the ANOM and SHEWHART procedures are listed in Table 4.16, and are described in detail in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Table 4.15 UCHART Statement Special Options

Option	Description
Options for Specifying Decision Limits	
ALPHA=	specifies significance level
LIMITK=	specifies number of groups for decision limits
LIMITN=	specifies either nominal sample size for fixed decision limits or varying limits
NOREADLIMITS	computes decision limits for each <i>response</i> from the data rather than a LIMITS= data set
READINDEXES=	reads multiple sets of decision limits for each <i>response</i> from a LIMITS= data set
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
U=	specifies the weighted average of group rates
Options for Displaying Decision Limits	
CINFILL=	specifies color for area inside decision limits
CLIMITS=	specifies color of decision limits, central line, and related labels
LDLLABEL=	specifies label for lower decision limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the decision limit
LLIMITS=	specifies line type for decision limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for decision limits and central line
NOCTL	suppresses display of central line
NOLDL	suppresses display of lower decision limit
NOLIMIT0	suppresses display of lower decision limit if it is 0
NOLIMITLABEL	suppresses labels for decision limits and central line
NOLIMITS	suppresses display of decision limits
NOLIMITSFRAME	suppresses default frame around decision limit information when multiple sets of decision limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for decision limits
NOUDL	suppresses display of upper decision limit
UDLLABEL=	specifies label for upper decision limit
USYMBOL=	specifies label for central line
WLIMITS=	specifies width for decision limits and central line
Input Data Set Option	
GROUPN=	specifies group sample sizes as constant number <i>n</i> or as values of variable in a DATA= data set
Output Data Set Option	
OUTSUMMARY=	creates output data set containing group summary statistics

Table 4.16 UCHART Statement General Options

Option	Description
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on ANOM <i>u</i> chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside decision limits
COUTFILL=	specifies color for shading areas between the connected points and decision limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels
LABELHEIGHT=	specifies height of labels
NONEEDLES	suppresses vertical needles connecting points to central line
OUTLABEL=	labels points outside decision limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value for numeric horizontal axis with date, time, or datetime format
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent group values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default
NOVANGLE	requests vertical axis labels that are strung out vertically

Table 4.16 *continued*

Option	Description
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of ANOM u chart
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for ANOM u chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all groups
BILEVEL	creates ANOM u chart using half-screens and half-pages
EXCHART	creates ANOM u chart for a response only when a group mean exceeds the decision limits
INTERVAL=	natural time interval between consecutive group positions when time, date, or datetime format is associated with a numeric group variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed decision limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for group sample sizes
NPANELPOS=	specifies number of group positions per panel on each chart
REPEAT	repeats last group position on panel as first group position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays ANOM u chart regardless of whether root mean square error is zero
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= option
CVREF=	specifies color for lines requested by VREF= option
HREF=	specifies position of reference lines perpendicular to horizontal axis on ANOM u chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on ANOM u chart
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels

Table 4.16 continued

Option	Description
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on ANOM <i>u</i> chart
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to ANOM <i>u</i> chart
DESCRIPTION=	specifies description of ANOM <i>u</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on chart
NAME=	specifies name of ANOM <i>u</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside decision limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color

Table 4.16 continued

Option	Description
OUTFILL	shades areas between decision limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the decision limit infill transparency
MARKERS	plots group points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
OUTFILLTRANSPARENCY=	specifies decision limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with groups
Output Data Set Options	
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing decision limits
OUTTABLE=	creates output data set containing group summary statistics and decision limits

Table 4.16 continued

Option	Description
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of group means, group sample sizes, and decision limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLEOUTLIM	augments basic table with columns indicating decision limits exceeded
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels decision limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars

Table 4.16 *continued*

Option	Description
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on ANOM <i>u</i> chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive ANOM Charts	
HTML=	specifies a variable whose values create links to be associated with groups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Details: U-Chart Statement

Constructing ANOM Charts for Rates

The following notation is used in this section:

c_i	count (number of occurrences) in the i th group
k	number of groups
n_i	number of occurrence opportunity units in the i th group
N	total sample size = $n_1 + \cdots + n_k$
u_i	occurrence rate in the i th group ($u_i = c_i/n_i$)
\bar{u}	average of occurrence rates taken across groups. The quantity \bar{u} is computed as a weighted average:

$$\bar{u} = \frac{n_1 u_1 + \cdots + n_k u_k}{N} = \frac{c_1 + \cdots + c_k}{N}$$

α	significance level
$h(\alpha; k, n, \infty)$	critical value for ANOM for normal data in the balanced case ($n_i \equiv n$)
$h(\alpha; k, n_1, \dots, n_k, \infty)$	critical value for ANOM for normal data in the unbalanced case

Plotted Points

Each point on a u chart indicates the rate of occurrence (u_i) in a group.

Central Line

In an ANOM chart for rates, the central line represents the weighted average of the group rates, which is denoted by \bar{u} .

Decision Limits

For the i th group, the occurrence counts are assumed to have a Poisson distribution with parameter λ_i . The ANOM method tests the null hypothesis that $\lambda_1 = \cdots = \lambda_k$, that is, that the rates are the same, against the alternative that at least one of the λ_i 's is different from the average of the k rates.

The decision limits are computed using the normal approximation to the Poisson distribution, which is appropriate when the sample sizes for the groups are large; see Ramig (1983). A commonly recommended check for this assumption is that $c_i > 5$ for all the groups. The critical values in the ANOM method for normally distributed data are adapted to the Poisson case by using infinite degrees of freedom for the variance.

When the number of opportunity units is constant ($n_i \equiv n$) across groups, the decision limits are computed as follow:

$$\text{lower decision limit (LDLU)} = \max \left(\bar{u} - h(\alpha; k, n, \infty) \sqrt{\bar{u}} \sqrt{\frac{k-1}{N}}, 0 \right)$$

$$\text{upper decision limit (UDLU)} = \bar{u} + h(\alpha; k, n, \infty) \sqrt{\bar{u}} \sqrt{\frac{k-1}{N}}$$

For the theoretical derivation of the decision limits, refer to Nelson (1982a).

When the number of opportunity units (n_i) is different across groups (the unbalanced case), the decision limits are computed as follows:

$$\text{lower decision limit (LDLU)} = \max \left(\bar{u} - h(\alpha; k, n_1, \dots, n_k, \infty) \sqrt{\bar{u}} \sqrt{\frac{N - n_i}{N n_i}}, 0 \right)$$

$$\text{upper decision limit (UDLU)} = \bar{u} + h(\alpha; k, n_1, \dots, n_k, \infty) \sqrt{\bar{u}} \sqrt{\frac{N - n_i}{N n_i}}$$

Note that the decision limits for the i th group depend on n_i . If the sample sizes are constant across groups ($n_i \equiv n$), the decision limits in the unbalanced case reduce to the formulas given for the balanced case, since $n_i \equiv n$ and $N = kn$, so

$$\sqrt{\frac{N - n_i}{N n_i}} = \sqrt{\frac{kn - n}{N n}} = \sqrt{\frac{k-1}{N}}$$

For the derivation of the decision limits for unequal sample sizes, refer to Nelson (1991).

Exact critical values were first tabulated by Nelson (1982a). Refer to Nelson (1993) for a derivation of the critical values $h(\alpha; k, n, \infty)$ and Nelson (1991) for a derivation of the critical values $h(\alpha; k, n_1, \dots, n_k, \infty)$. Note that the critical values in the unequal sample size case have not been tabulated.

You can specify parameters for the limits as follows:

- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a nominal constant number of opportunity units $n_i \equiv n$ with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify \bar{u} with the U= option or with the variable `_U_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves decision limits and decision limit parameters. The following variables can be saved:

Table 4.17 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	significance level (α)
<code>_GROUP_</code>	<i>group-variable</i> specified in the UCHART statement
<code>_INDEX_</code>	optional identifier for the decision limits specified with the OUTINDEX= option
<code>_LDLU_</code>	lower decision limit for occurrence rates
<code>_LIMITK_</code>	number of groups
<code>_LIMITN_</code>	number of opportunity units associated with the decision limits
<code>_TYPE_</code>	type (estimate or standard value) of <code>_U_</code>
<code>_U_</code>	value of central line of <i>u</i> chart (\bar{u})
<code>_UDLU_</code>	upper decision limit for occurrence rates
<code>_VAR_</code>	<i>response</i> specified in the UCHART statement

Notes:

1. If the decision limits vary with the number of opportunity units, the special missing value *V* is assigned to the variables `_LDLU_`, `_UDLU_`, and `_LIMITN_`.
2. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *response* specified in the UCHART statement. For an example, see “Saving Decision Limits” on page 114.

OUTSUMMARY= Data Set

The OUTSUMMARY= data set saves group summary statistics. The following variables are saved:

- the *group-variable*
- a response rate variable, whose name is *response* suffixed with *U*
- a number of opportunity units variable, whose name is *response* suffixed with *N*

Given a *response* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Group summary variables are created for each *response* specified in the UCHART statement. For example, consider the following statements:

```
proc anom data=Fabric;
    uchart (Flaws Ndefects)*Treatment / outsummary=Summary
        groupn = 30;
run;
```

The data set summary contains the variables Treatment, FlawsU, FlawsN, NdefectsU, and NdefectsN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

OUTTABLE= Data Set

The OUTTABLE= data set saves group summary statistics, decision limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	significance level (α)
<code>_EXLIM_</code>	decision limit exceeded on <i>u</i> chart
<code>group</code>	values of the group variable
<code>_LDLU_</code>	lower decision limit for group rate
<code>_LIMITN_</code>	nominal number of opportunity units associated with the decision limits
<code>_SUBU_</code>	group rate
<code>_SUBN_</code>	number of opportunity units in group
<code>_UDLU_</code>	upper decision limit for group rate
<code>_VAR_</code>	<i>response</i> specified in the UCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

NOTE: The variable `_EXLIM_` is a character variable of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

ODS Tables

The following table summarizes the ODS tables that you can request with the UCHART statement.

Table 4.18 ODS Tables Produced with the UCHART Statement

Table Name	Description	Options
UCHART	ANOM <i>u</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the ANOM procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. UCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the UCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 4.19](#).

Table 4.19 ODS Graphics Produced by the UCHART Statement

ODS Graph Name	Plot Description
UChart	ANOM <i>u</i> chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read response counts for groups from a DATA= data set specified in the PROC ANOM statement. Each *response* specified in the UCHART statement must be a SAS variable in the data set. This variable provides the count (number of occurrences) for groups indexed by the *group-variable*. The *group-variable*, specified in the UCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *response* and a value for the *group-variable*. The data set should contain one observation per group. When you use a DATA= data set with the UCHART statement, the GROUPN= option (which specifies the number of inspection units per group) is required. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

For an example of a DATA= data set, see “Creating ANOM Charts for Rates from Group Counts” on page 111.

LIMITS= Data Set

You can read decision limits (or parameters from which the decision limits can be calculated) from a LIMITS= data set specified in the PROC ANOM statement. For example, the following statements read decision limit information from the data set Conlims:

```
proc anom data=Info limits=Conlims;
  uchart Defects*Treatment / groupn = 30;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the ANOM procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LDLU_`, `_U_`, and `_UDLU_`, which specify the decision limits
- the variable `_U_`, without providing the variables `_LDLU_` and `_UDLU_`, which is used to calculate the decision limits (see “Decision Limits” on page 124)

In addition, note the following:

- The variables `_VAR_` and `_GROUP_` are always required. These must be character variables whose lengths are no greater than 32.
- `_LDLU_` and `_UDLU_` must be specified together; otherwise their values are computed.
- `_ALPHA_` is optional but is recommended in order to maintain a complete set of decision limit information. The default value is 0.05.
- `_LIMITK_` is optional. The default value is k , the number of groups. A group must have at least one nonmissing value ($n_i \geq 1$) and there must be at least one group with $n_i \geq 2$. If specified, `_LIMITK_` overrides the value of k .
- `_LIMITN_` is optional. The default value is the common group size (n), in the balanced case $n_i \equiv n$. If specified, `_LIMITN_` overrides the value of n .
- The variable `_TYPE_` is optional, but is recommended to maintain a complete set of decision limit information. The variable `_TYPE_` must be a character variable of length 8. Valid values are 'ESTIMATE,' 'STANDARD,' 'STDMEAN,' and 'STDRMS.' The default is 'ESTIMATE.'
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- BY variables are required if specified with a BY statement.

SUMMARY= Data Set

You can read group summary statistics from a `SUMMARY=` data set specified in the `PROC ANOM` statement. This enables you to reuse `OUTSUMMARY=` data sets that have been created in previous runs of the ANOM procedure or to read output data sets created with SAS summarization procedures.

A `SUMMARY=` data set used with the `UCHART` statement must contain the following variables:

- *group-variable*
- response rates for each *response*
- number of occurrence units for each *response*

The names of the variables containing the rates and number of occurrence units must be the *response* name concatenated with the special suffix characters *U* and *N*, respectively. For example, consider the following statements:

```
proc anom summary=Summary;
    uchart (Flaws Ndefects)*Treatment;
run;
```

The data set Summary must include the variables Treatment, FlawsU, FlawsN, NdefectsU, and NdefectsN.

Note that if you specify a *response* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *response* name, suffixed with the appropriate character.

Other variables that can be read from a SUMMARY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

TABLE= Data Set

You can read group statistics and decision limits from a TABLE= data set specified in the PROC ANOM statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the ANOM procedure or to create your own TABLE= data set. Because the ANOM procedure simply displays the information read from a TABLE= data set, you can use TABLE= data sets to create specialized ANOM charts.

The following table lists the variables required in a TABLE= data set used with the UCHART statement:

Table 4.20 Variables Required in a TABLE= Data Set

Variable	Description
<i>group-variable</i>	values of the <i>group-variable</i>
<code>_LDLU_</code>	lower decision limit for rate
<code>_LIMITN_</code>	nominal number of opportunity units associated with the decision limits
<code>_SUBN_</code>	number of opportunity units in group
<code>_SUBU_</code>	response rate for group
<code>_U_</code>	weighted average of group rates
<code>_UDLU_</code>	upper decision limit for rate

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified). This variable must be a character variable whose length is no greater than 48.
- `_VAR_`. This variable is required if more than one *response* is specified or if the data set contains information for more than one *response*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Decision Limits” on page 114.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>group-variable</i>
Vertical	DATA=	<i>response</i>
Vertical	SUMMARY=	group defects per unit variable
Vertical	TABLE=	<code>_SUBU_</code>

Missing Values

An observation read from a DATA=, SUMMARY=, or TABLE= data set is not analyzed if the value of the group variable is missing. For a particular response variable, an observation read from a DATA= data set is not analyzed if the value of the response variable is missing. For a particular response variable, an observation read from a SUMMARY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: UCHART Statement

This section provides an advanced example of the UCHART statement.

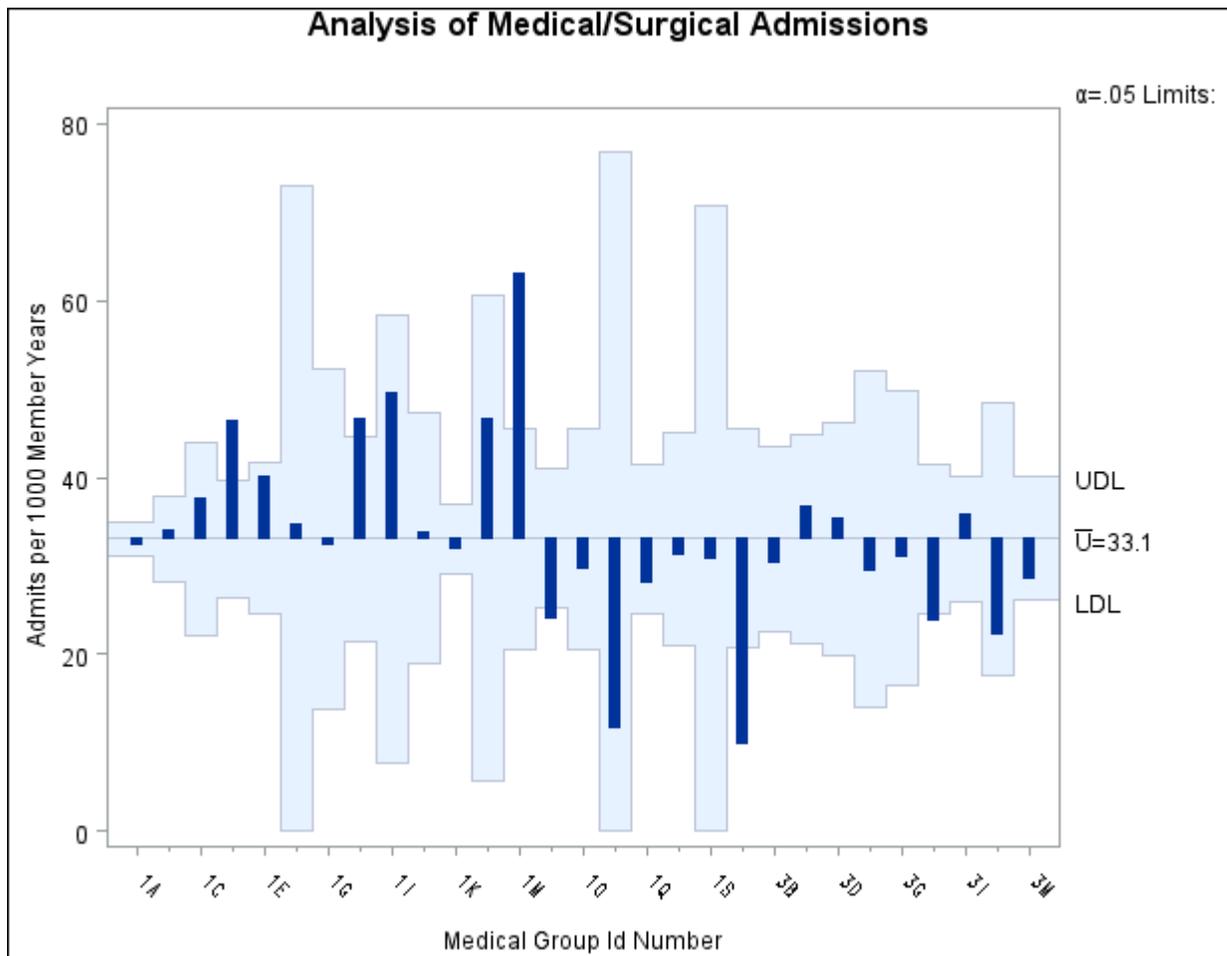

Example 4.3: ANOM u Charts with Angled Axis Labels

See ANMUEX1 in the SAS/QC Sample Library Consider the example described in “Creating ANOM Charts for Rates from Group Counts” on page 111. In the example, the option `TURNHLABELS` was used to vertically display the horizontal axis labels. You can also use an `AXIS` statement to create an angled display of the horizontal or vertical axes labels. The following statements create the u CHART shown in [Output 4.3.1](#):

```
ods graphics off;
title 'Analysis of Medical/Surgical Admissions';
proc anom data=MSAdmits;
  uchart Count*ID / groupn    = KMemberYrs
          nolegend
          haxis    = axis1;
axis1 value = (a=-45 h=2.0pct);
label Count = 'Admits per 1000 Member Years';
run;
```

The angle is specified with the A= option in the AXIS1 statement. Valid angle values are between -90 and 90. The height of the labels is specified with the H= option in the AXIS1 statement. See [Axis and Axis Label Options](#) in Table 4.16 for a list of UCHART statement axis options and *SAS/GRAPH: Reference* for a complete description of the AXIS statement.

Output 4.3.1 ANOM *u* Chart for C-Sections with Angled Axis Labels

XCHART Statement: ANOM Procedure

Overview: XCHART Statement

The XCHART statement creates an ANOM chart for group (treatment level) means of response values. You can use options in the XCHART statement to

- compute decision limits from the data based on specified parameters, such as the significance level (α)
- tabulate group sample sizes, group means, decision limits, and other information
- save decision limits in an output data set
- save group sample sizes and group means in an output data set
- read decision limits and decision limit parameters from a data set
- display distinct sets of decision limits for different sets of groups
- add block legends and symbol markers to identify special groups
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have two alternatives for producing ANOM charts with the XCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced if SAS/GRAPH[®] is licensed.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: XCHART Statement

This section introduces the XCHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the XCHART statement is presented in the section “Syntax: XCHART Statement” on page 143, and advanced examples are given in the section “Examples: XCHART Statement” on page 163.

Creating ANOM Charts for Means from Response Values

A manufacturing engineer carries out a study to determine the source of excessive variation in the positioning of labels on shampoo bottles.² A labeling machine removes bottles from the line, attaches the labels, and returns the bottles to the line. There are six positions on the machine, and the engineer suspects that one or more of the position heads might be faulty.

See ANMX1 in the SAS/QC Sample Library

A sample of 60 bottles, 10 per position, is run through the machine. For each bottle, the deviation of the label is measured in millimeters, and the machine position is recorded. The following statements create a SAS data set named LabelDeviations, which contains the deviation measurements for the 60 bottles:

```
data LabelDeviations;
  input Position @;
  do i = 1 to 5;
    input Deviation @;
    output;
  end;
  drop i;
  datalines;
1 -0.0239 -0.0285 -0.0300 -0.0043 -0.0362
1 -0.0422 -0.0014 -0.0647 0.0094 -0.0016
2 -0.0201 -0.0273 0.0227 -0.0332 0.0366
2 0.0438 0.0556 0.0098 0.0564 0.0182
3 -0.0073 0.0285 -0.0440 -0.0221 -0.0139
3 0.0486 0.0357 0.0235 0.0134 -0.0020
4 0.0669 0.1073 0.0597 0.0609 0.0755
4 0.0362 0.0561 0.0899 0.0418 0.0530
5 0.0368 0.0036 0.0374 0.0116 -0.0074
5 0.0250 -0.0080 0.0302 -0.0015 -0.0464
6 0.0049 -0.0384 -0.0204 -0.0049 -0.0120
6 0.0071 -0.0308 0.0017 -0.0285 -0.0070
;
```

A partial listing of LabelDeviations is shown in Figure 4.21.

²This example is based on a case study described by Hansen (1990).

Figure 4.21 Partial Listing of the Data Set LabelDeviations

The Data Set LabelDeviations	
Position	Deviation
1	-0.0239
1	-0.0285
1	-0.0300
1	-0.0043
1	-0.0362
1	-0.0422
1	-0.0014
1	-0.0647
1	0.0094
1	-0.0016
2	-0.0201
2	-0.0273
2	0.0227
2	-0.0332
2	0.0366
2	0.0438
2	0.0556
2	0.0098
2	0.0564
2	0.0182

The data set LabelDeviations is said to be in “strung-out” form, since each observation contains the position and the deviation measurement for a single bottle. The first 10 observations contain the measurements for the first position, the second 10 observations contain the measurements for the second position, and so on. Because the variable Position classifies the observations into groups (treatment levels), it is referred to as the *group-variable*. The input data set must be sorted by the group variable. The variable Deviation contains the deviation measurements and is referred to as the *response variable* (or *response* for short).

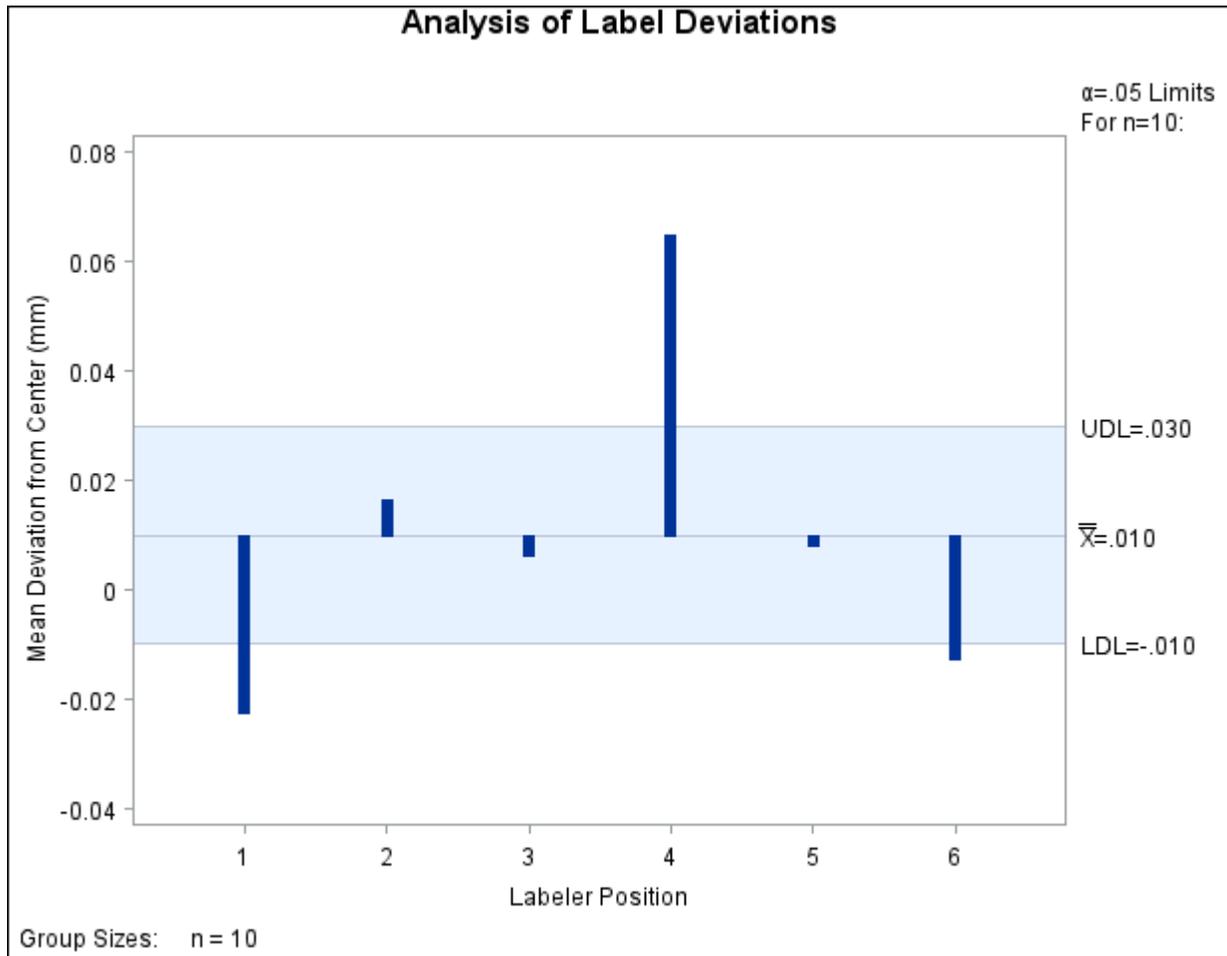

The following statements create the ANOM chart shown in Figure 4.22:

```
ods graphics off;
title 'Analysis of Label Deviations';
proc anom data=LabelDeviations;
  xchart Deviation*Position / alpha = 0.05;
  label Deviation = 'Mean Deviation from Center (mm)';
  label Position = 'Labeler Position';
run;
```

This example illustrates the basic form of the XCHART statement. After the keyword XCHART, you specify the *response* to analyze (in this case, Deviation) followed by an asterisk and the *group-variable* (Position). Options are specified after the slash (/) in the XCHART statement. A complete list of options is presented in the section “Syntax: XCHART Statement” on page 143.

The input data set is specified with the DATA= option in the PROC ANOM statement when it contains raw measurements for the *response*.

Each point on the ANOM chart represents the average (mean) of the response measurements for a particular sample.

Figure 4.22 ANOM Chart for Means of Labeler Position Data

The average for Position 1 is below the lower decision limit (LDL), and the average for Position 6 is slightly below the lower decision limit. The average for Position 4 exceeds the upper decision limit (UDL). The conclusion is that Positions 1, 4, and 6 are operating differently.

By default, the decision limits shown correspond to a significance level of $\alpha = 0.05$; the formulas for the limits are given in the section “Decision Limits” on page 152. You can also read decision limits from an input data set.

For computational details, see “Constructing ANOM Charts for Means” on page 151. For details on reading raw measurements, see “DATA= Data Set” on page 159.

Creating ANOM Charts for Means from Group Summary Data

The previous example illustrates how you can create ANOM charts for means using measurement data. However, in many applications, the data are provided as group summary statistics. This example illustrates how you can use the XCHART statement with data of this type. *See ANMXGRP in the SAS/QC Sample Library*

The following data set (Labels) provides the data from the preceding example in summarized form:

```

data Labels;
  input Position DeviationX DeviationS;
  DeviationN = 10;
  datalines;
1 -0.02234 0.02281
2 0.01624 0.03348
3 0.00601 0.02885
4 0.06473 0.02149
5 0.00812 0.02592
6 -0.01281 0.01597
;

```

A listing of Labels is shown in Figure 4.23. There is exactly one observation for each group (note that the groups are still indexed by Position). The variable DeviationX contains the group means, the variable DeviationS contains the group standard deviations, and the variable DeviationN contains the group sample sizes (these are all 10).

Figure 4.23 The Summary Data Set Labels

The Data Set Labels			
Position	Deviation X	Deviation S	Deviation N
1	-0.02234	0.02281	10
2	0.01624	0.03348	10
3	0.00601	0.02885	10
4	0.06473	0.02149	10
5	0.00812	0.02592	10
6	-0.01281	0.01597	10

You can read this data set by specifying it as a SUMMARY= data set in the PROC ANOM statement, as follows:

```

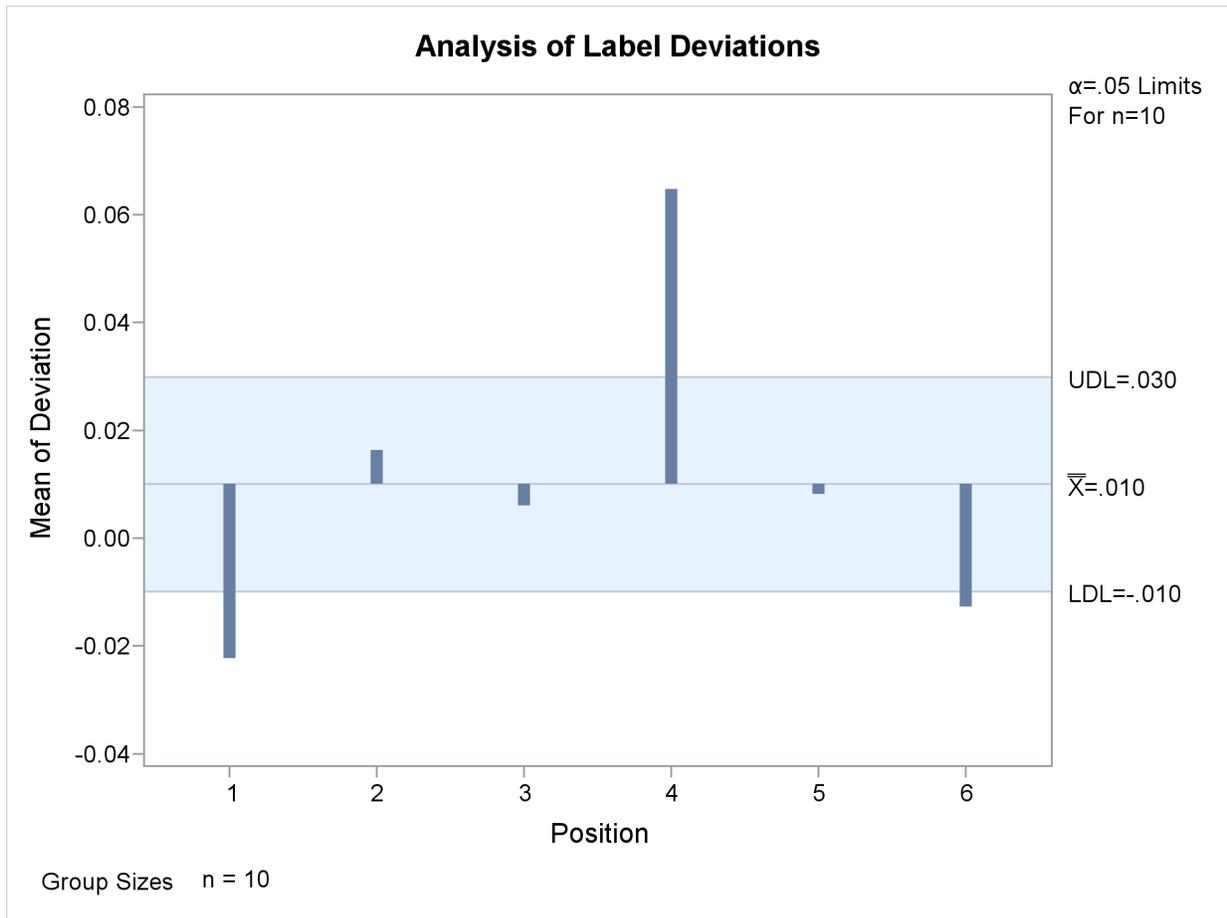

title 'Analysis of Label Deviations';
ods graphics on;
proc anom summary=Labels;
  xchart Deviation*Position / odstitle=title1;
run;

```

The ODS GRAPHICS ON statement specified before the PROC ANOM statement enables ODS Graphics, so the ANOM chart is created using ODS Graphics instead of traditional graphics. The resulting chart is shown in Figure 4.24.

Note that Deviation is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the three SAS variables DeviationX, DeviationS, and DeviationN. The suffix characters X, S, and N indicate *mean*, *standard deviation*, and *sample size*, respectively. Thus, you can specify three group summary variables in a SUMMARY= data set with a single name (Deviation), which is referred to as the *response*. The name Position specified after the asterisk is the name of the *group-variable*.

Figure 4.24 ANOM Chart for Means in Data Set Labels

In general, a SUMMARY= input data set used with the XCHART statement must contain the following variables:

- group variable
- group mean variable
- group standard deviation variable
- group sample size variable

Furthermore, the names of the group mean, standard deviation, and sample size variables must begin with the *response* name specified in the XCHART statement and end with the special suffix characters *X*, *S*, and *N*, respectively. If the names do not follow this convention, you can use the RENAME option in the PROC ANOM statement to rename the variables for the duration of the ANOM procedure step. If a label is associated with the group mean variable, it is used to label the vertical axis.

In summary, the interpretation of *response* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *response* is the name of the SAS variable containing the response measurements.
- If summary data are read using the SUMMARY= option (as in this example), *response* is the common prefix for the names of the variables containing the summary statistics.

For more information, see the section “SUMMARY= Data Set” on page 160.

Saving Summary Statistics for Groups

See ANMXSUM in the SAS/QC Sample Library

In this example, the XCHART statement is used to create a data set containing group summary statistics that can be read later by the ANOM procedure (as in the preceding example). The following statements read measurements from the data set LabelDeviations and create a summary data set named LabelSummary:

```
proc anom data=LabelDeviations;
  xchart Deviation*Position / outsummary=LabelSummary
                                nochart;
run;
```

The OUTSUMMARY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 4.22.

Figure 4.25 contains a listing of LabelSummary.

Figure 4.25 The Summary Data Set LabelSummary

The Data Set LabelSummary			
Position	Deviation X	Deviation S	Deviation N
1	-0.02234	0.022807	10
2	0.01625	0.033473	10
3	0.00604	0.028849	10
4	0.06473	0.021495	10
5	0.00813	0.025928	10
6	-0.01283	0.015986	10

There are four variables in the data set LabelSummary.

- Position identifies the group.
- DeviationX contains the group means.
- DeviationS contains the group standard deviations.
- DeviationN contains the group sizes.

Note that the summary statistic variables are named by adding the suffix characters *X*, *S*, and *N* to the *response* Deviation specified in the XCHART statement. In other words, the variable naming convention for OUTSUMMARY= data sets is the same as that for SUMMARY= data sets.

For more information, see the section “OUTSUMMARY= Data Set” on page 156.

Saving Decision Limits

You can save the decision limits for an ANOM chart, together with the parameters used to compute the limits, in a SAS data set. *See ANMXLIM in the SAS/QC Sample Library*

The following statements read measurements from the data set LabelDeviations (see the section “Creating ANOM Charts for Means from Response Values” on page 135) and save the decision limits displayed in Figure 4.22 in a data set named LabelLimits:

```
proc anom data=LabelDeviations;
    xchart Deviation*Position / outlimits=LabelLimits
        nochart;
run;
```

The OUTLIMITS= option names the data set containing the decision limits, and the NOCHART option suppresses the display of the chart. The data set LabelLimits is listed in Figure 4.26.

Figure 4.26 The Data Set LabelLimits Containing Decision Limit Information

Decision Limits for Labler Position Deviations					
<u>_VAR_</u>	<u>_GROUP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_LDLX_</u>
Deviation	Position	ESTIMATE	10	0.05	-.009875811
<u>_MEAN_</u>	<u>_UDLX_</u>	<u>_MSE_</u>	<u>_DFE_</u>	<u>_LIMITK_</u>	
.009996667	0.029869	.000643787	54	6	

The data set LabelLimits contains one observation with the limits for *response* Deviation. The values of _LDLX_ and _UDLX_ are the lower and upper decision limits for the means, and the value of _MEAN_ is the weighted average of the group means, which is represented by the central line.

The values of _MEAN_, _MSE_, _DFE_, _LIMITN_, _LIMITK_, and _ALPHA_ are the parameters used to compute the decision limits as described in the section “Constructing ANOM Charts for Means” on page 151. The value of _MSE_ is the mean square error, and the value of _DFE_ is the associated degrees of freedom. The value of _LIMITN_ is the nominal sample size (*n*) associated with the decision limits, the value of _LIMITK_ is the number of groups (*k*), and the value of _ALPHA_ is the value of the significance level (α). The variables _VAR_ and _GROUP_ are bookkeeping variables that save the *response* and *group-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _MSE_ are estimates computed from the data or standard (known) values specified with procedure options. In most applications, the value of _TYPE_ will be ‘ESTIMATE.’

You can create an output data set containing both decision limits and group summary statistics with the OUTTABLE= option, as illustrated by the following statements: *See ANMXTAB in the SAS/QC Sample Library*

```
proc anom data=LabelDeviations;
  xchart Deviation*Position / outtable=LabelTab
      nochart;
run;
```

The data set LabelTab is listed in Figure 4.27.

Figure 4.27 The Data Set LabelTab

Summary Statistics and Decision Limits									
	P	—	—	—	—	—	—	—	—
	o	A	L	I	S	L	S	M	U
	s	L	M	S	L	S	M	U	X
	i	P	I	U	D	U	E	D	L
	V	H	T	B	L	B	A	L	I
	A	A	N	N	X	X	N	X	M
	R	—	—	—	—	—	—	—	—
	o	—	—	—	—	—	—	—	—
	n	—	—	—	—	—	—	—	—
Deviation	1	0.05	10	10	-.009875811	-0.02234	.009996667	0.029869	LOWER
Deviation	2	0.05	10	10	-.009875811	0.01625	.009996667	0.029869	
Deviation	3	0.05	10	10	-.009875811	0.00604	.009996667	0.029869	
Deviation	4	0.05	10	10	-.009875811	0.06473	.009996667	0.029869	UPPER
Deviation	5	0.05	10	10	-.009875811	0.00813	.009996667	0.029869	
Deviation	6	0.05	10	10	-.009875811	-0.01283	.009996667	0.029869	LOWER

This data set contains one observation for each group sample. The variables `_SUBX_` and `_SUBN_` contain the group means and sample sizes. The variables `_LDLX_` and `_UDLX_` contain the lower and upper decision limits, and the variable `_MEAN_` contains the central line. The variables `_VAR_` and `Position` contain the *response* name and values of the *group-variable*, respectively. For more information, see the section “`OUTTABLE= Data Set`” on page 157.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set. For example, the following statements read LabelTab and display an ANOM chart (not shown here) identical to the chart in Figure 4.22:

```
title 'Analysis of Label Deviations';
proc anom table=LabelTab;
  xchart Deviation*Position;
  label _SUBX_ = 'Mean Deviation from Center (mm)';
run;
```

Because the ANOM procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized ANOM charts.

For more information, see the section “`TABLE= Data Set`” on page 161.

Syntax: XCHART Statement

The basic syntax for the XCHART statement is as follows:

```
XCHART response * group-variable ;
```

The general form of this syntax is as follows:

```
XCHART responses * group-variable < (block-variables) >  
      <=symbol-variable | ='character'> < options > ;
```

You can use any number of XCHART statements in the ANOM procedure. The components of the XCHART statement are described as follows.

response

responses

identify one or more responses to be analyzed. The specification of *response* depends on the input data set specified in the PROC ANOM statement.

- If response values (raw data) are read from a DATA= data set, *response* must be the name of the variable containing the values. For an example, see the section “[Creating ANOM Charts for Means from Response Values](#)” on page 135.
- If summary data are read from a SUMMARY= data set, *response* must be the common prefix of the summary variables in the SUMMARY= data set. For an example, see the section “[Creating ANOM Charts for Means from Group Summary Data](#)” on page 137.
- If summary data and decision limits are read from a TABLE= data set, *response* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see the section “[Saving Decision Limits](#)” on page 141.

A *response* is required. If you specify more than one response, enclose the list in parentheses. For example, the following statements request distinct ANOM charts for the means of Weight, Length, and Width:

```
proc anom data=Measures;  
  xchart (Weight Length Width)*Day;  
run;
```

group-variable

is the variable that identifies groups in the data. The *group-variable* is required. In the preceding XCHART statement, Day is the group variable.

block-variables

are optional variables that group the data into blocks of consecutive groups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker used to plot the means. Distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with `SYMBOLn` statements.

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function.

Summary of Options

The following tables list the XCHART statement options by function. Options unique to the ANOM procedure are listed in [Table 4.21](#), and are described in detail in “[Dictionary of ANOM Chart Statement Options](#)” on page 192. Options that are common to both the ANOM and SHEWHART procedures are listed in [Table 4.22](#), and are described in detail in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 4.21 XCHART Statement Special Options

Option	Description
Options for Specifying Parameters for Decision Limits	
ALPHA=	specifies the probability of a Type I error
DFE=	specifies the degrees of freedom associated with the root mean square error
LIMITK=	specifies number of groups for decision limits
LIMITN=	specifies either nominal sample size for fixed decision limits or varying limits
MEAN=	specifies the mean
MSE=	specifies the mean square error
NOREADLIMITS	computes decision limits for each <i>response</i> from the data rather than a LIMITS= data set
READINDEXES=	reads multiple sets of decision limits for each <i>response</i> from a LIMITS= data set
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Displaying Decision Limits	
CINFILL=	specifies color for area inside decision limits
CLIMITS=	specifies color of decision limits, central line, and related labels
LDLLABEL=	specifies label for lower decision limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the decision limit
LLIMITS=	specifies line type for decision limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for decision limits and central line
NOCTL	suppresses display of central line

Table 4.21 *continued*

Option	Description
NOLDL	suppresses display of lower decision limit
NOLIMITLABEL	suppresses labels for decision limits and central line
NOLIMITS	suppresses display of decision limits
NOLIMITSFRAME	suppresses default frame around decision limit information when multiple sets of decision limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for decision limits
NOUDL	suppresses display of upper decision limit
UDLLABEL=	specifies label for upper decision limit
WLIMITS=	specifies width for decision limits and central line
XSYMBOL=	specifies label for central line
Output Data Set Option	
OUTSUMMARY=	creates output data set containing group summary statistics

Table 4.22 XCHART Statement General Options

Option	Description
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on ANOM chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside decision limits
COUTFILL=	specifies color for shading areas between the connected points and decision limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels
LABELHEIGHT=	specifies height of labels
NONEEDLES	suppresses vertical needles connecting points to central line
OUTLABEL=	labels points outside decision limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles

Table 4.22 *continued*

Option	Description
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent group values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of ANOM chart
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for ANOM chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all groups
BILEVEL	creates ANOM charts using half-screens and half-pages
EXCHART	creates ANOM chart for a response only when a group mean exceeds the decision limits
INTERVAL=	natural time interval between consecutive group positions when time, date, or datetime format is associated with a numeric group variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed decision limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for group sample sizes
NPANELPOS=	specifies number of group positions per panel on each chart

Table 4.22 continued

Option	Description
REPEAT	repeats last group position on panel as first group position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays ANOM chart regardless of whether root mean square error is zero
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= option
CVREF=	specifies color for lines requested by VREF= option
HREF=	specifies position of reference lines perpendicular to horizontal axis on ANOM chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on ANOM chart
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on ANOM chart
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points

Table 4.22 continued

Option	Description
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to ANOM chart
DESCRIPTION=	specifies description of ANOM chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on chart
NAME=	specifies name of ANOM chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside decision limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between decision limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the decision limit infill transparency
MARKERS	plots group points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
OUTFILLTRANSPARENCY=	specifies decision limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points

Table 4.22 continued

Option	Description
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with groups
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing decision limits
OUTTABLE=	creates output data set containing group summary statistics and decision limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of group means, group sample sizes, and decision limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLEOUTLIM	augments basic table with columns indicating decision limits exceeded
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the <code>OUTHISTORY=</code> data set

Table 4.22 continued

Option	Description
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels decision limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on ANOM chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments

Table 4.22 *continued*

Option	Description
Options for Interactive ANOM Charts	
HTML=	specifies a variable whose values create links to be associated with groups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Details: XCHART Statement

Constructing ANOM Charts for Means

The following notation is used in this section:

X_{ij}	j th response in the i th group
k	number of groups
n_i	sample size of i th group
N	total sample size = $n_1 + \dots + n_k$
μ_i	expected value of a response in the i th group
σ	standard deviation of a response
\bar{X}_i	average response in the i th group
$\bar{\bar{X}}$	weighted average of k group means
s_i^2	sample variance of the responses in the i th group
$\widehat{\sigma^2}$	mean square error (MSE)
ν	degrees of freedom associated with the mean square error
α	significance level
$h(\alpha; k, n, \nu)$	critical value for analysis of means when the sample sizes n_i are equal ($n_i \equiv n$)
$h(\alpha; k, n_1, \dots, n_k, \nu)$	critical value for analysis of means when the sample sizes n_i are not equal

Plotted Points

Each point on an ANOM chart indicates the value of a group mean (\bar{X}_i).

Central Line

By default, the central line on an ANOM chart for means represents the weighted average of the group means, which is computed as

$$\bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \cdots + n_k \bar{X}_k}{n_1 + \cdots + n_k}$$

You can specify a value for $\bar{\bar{X}}$ with the MEAN= option in the XCHART statement or with the variable _MEAN_ in a LIMITS= data set.

Decision Limits

In the analysis of means for continuous data, it is assumed that the responses in the i th group are at least approximately normally distributed with a constant variance:

$$X_{ij} \sim N(\mu_i, \sigma^2), \quad j = 1, \dots, n_i$$

When the group sizes are constant ($n_i \equiv n$), then $\nu = N - k = k(n - 1)$ and the decision limits are computed as follows:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \bar{\bar{X}} - h(\alpha; k, n, \nu) \sqrt{\text{MSE}} \sqrt{\frac{k-1}{N}} \\ \text{upper decision limit (UDL)} &= \bar{\bar{X}} + h(\alpha; k, n, \nu) \sqrt{\text{MSE}} \sqrt{\frac{k-1}{N}} \end{aligned}$$

Here the mean square error (MSE) is computed as follows:

$$\text{MSE} = \hat{\sigma}^2 = \frac{1}{k} \sum_{j=1}^k s_j^2$$

For details concerning the function $h(\alpha; k, n, \nu)$, see Nelson (1982a, 1993).

When the group sizes are not constant (the unbalanced case), $\nu = N - k$ and the decision limits for the i th group are computed as follows:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \bar{\bar{X}} - h(\alpha; k, n_1, \dots, n_k, \nu) \sqrt{\text{MSE}} \sqrt{\frac{N - n_i}{N n_i}} \\ \text{upper decision limit (UDL)} &= \bar{\bar{X}} + h(\alpha; k, n_1, \dots, n_k, \nu) \sqrt{\text{MSE}} \sqrt{\frac{N - n_i}{N n_i}} \end{aligned}$$

Here the mean square error (MSE) is computed as follows:

$$\text{MSE} = \widehat{\sigma^2} = \frac{(n_1 - 1)s_1^2 + \cdots + (n_k - 1)s_k^2}{n_1 + \cdots + n_k - k}$$

This requires that ν be positive. A chart is not produced if $\nu > 0$ but MSE is equal to zero (unless you specify the ZEROSTD option). For details concerning the function $h(\alpha; k, n_1, \dots, n_k, \nu)$, see Nelson (1991).

You can specify parameters for the limits as follows:

- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set. By default, $\alpha = 0.05$.
- Specify a constant nominal sample size $n_i \equiv n$ for the decision limits in the balanced case with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set. By default, n is the observed sample size in the balanced case.
- Specify k with the LIMITK= option or with the variable `_LIMITK_` in a LIMITS= data set. By default, k is the number of groups.
- Specify $\bar{\bar{X}}$ with the MEAN= option or with the variable `_MEAN_` in a LIMITS= data set. By default, $\bar{\bar{X}}$ is the weighted average of the responses.
- Specify $\widehat{\sigma^2}$ with the MSE= option or with the variable `_MSE_` in a LIMITS= data set. By default, $\widehat{\sigma^2}$ is computed as indicated above.
- Specify ν with the DFE= option or with the variable `_DFE_` in a LIMITS= data set. By default, ν is determined as indicated above.

Constructing ANOM Charts for Two-Way Layouts

This section provides the computational details for constructing an ANOM chart for the l th factor in an experiment involving two factors ($l = 1$ or 2). It is assumed that there is no interaction effect. See [Example 4.5](#) for an illustration.

The following notation is used in this section:

X_{ijk}	k th response at the i th level of factor 1 and the j th level of factor 2, where $k = 1, 2, \dots, n_{ij}$
f_l	number of groups (levels) for the l th factor, $l = 1, 2$
n_{ij}	number of replicates in cell (i, j)
N	total sample size = $\sum_{i=1}^{f_1} \sum_{j=1}^{f_2} n_{ij}$
σ^2	variance of a response
$\bar{X}_{ij\cdot}$	average response in cell (i, j)
$\bar{X}_{i\cdot}$	average response for i th level of factor 1 = $\left(\sum_{j=1}^{f_2} n_{ij} \bar{X}_{ij\cdot}\right) / \left(\sum_{j=1}^{f_2} n_{ij}\right)$
$\bar{X}_{\cdot j}$	average response for j th level of factor 2 = $\left(\sum_{i=1}^{f_1} n_{ij} \bar{X}_{ij\cdot}\right) / \left(\sum_{i=1}^{f_1} n_{ij}\right)$
$\bar{\bar{X}}$	$\sum_{i=1}^{f_1} \sum_{j=1}^{f_2} n_{ij} \bar{X}_{ij\cdot} / N$
s_{ij}^2	sample variance of the responses for the i th level of factor 1 and the j th level of factor 2
$\widehat{\sigma^2}$	mean square error (MSE) in the two-way analysis of variance
ν	degrees of freedom associated with the mean square error in the two-way analysis of variance
α	significance level
$h(\alpha; f_l, n, \nu)$	critical value for analysis of means in a one-way layout for f_l groups (treatment levels) when the sample sizes for each level are constant ($\equiv n$) and ν is the degrees of freedom associated with the mean square error; see the section “Constructing ANOM Charts for Means” on page 151.

Plotted Points

The points on the ANOM chart for factor 1 represent $\bar{X}_{i\cdot}$, $i = 1, \dots, f_1$ and the points on the ANOM chart for factor 2 represent $\bar{X}_{\cdot j}$, $j = 1, \dots, f_2$.

Central Line

The central line on the ANOM chart for the l th factor is the overall weighted average $\bar{\bar{X}}$. Some authors use the notation $\bar{X}\dots$ for this average.

Decision Limits

It is assumed that

$$X_{ijk} = \mu + \alpha_i + \beta_j + \epsilon_{ijk}$$

where the quantities ϵ_{ijk} are independent and at least approximately normally distributed with

$$\epsilon_{ijk} \sim N(0, \sigma^2)$$

The correct decision limits for a given factor in a two-way layout are not computed by default when the l th factor is specified as the *group-variable* in the XCHART statement, since the mean square error and degrees of freedom are not adjusted for the two-way structure of the data. Consequently, $\widehat{\sigma^2}$ and ν must be precomputed and provided to the ANOM procedure, as illustrated in Example 4.5.

In the case of a two-way layout with equal group sizes ($n_{ij} \equiv n$), the appropriate decision limits are:

$$\begin{aligned} \text{lower decision limit (LDL)} &= \bar{\bar{X}} - h(\alpha; f_l, n, \nu) \sqrt{\text{MSE}} \sqrt{\frac{f_l - 1}{N}} \\ \text{upper decision limit (UDL)} &= \bar{\bar{X}} + h(\alpha; f_l, n, \nu) \sqrt{\text{MSE}} \sqrt{\frac{f_l - 1}{N}} \end{aligned}$$

where the mean square error (MSE) is computed as in the ANOVA or GLM procedure:

$$\text{MSE} = \widehat{\sigma^2} = \frac{1}{f_1 f_2} \sum_{i=1}^{f_1} \sum_{j=1}^{f_2} s_{ij}^2$$

and the degrees of freedom for error is $\nu = f_1 f_2 (n - 1)$. For details concerning the function $h(\alpha; f_l, n, \nu)$, see Nelson (1982a, 1993).

You can provide the appropriate values of MSE and ν by

- specifying $\widehat{\sigma^2}$ with the MSE= option or with the variable `_MSE_` in a LIMITS= data set
- specifying ν with the DFE= option or with the variable `_DFE_` in a LIMITS= data set

In addition you can:

- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set. By default, $\alpha = 0.05$.
- Specify a constant nominal sample size $n_{ij} \equiv n$ for the decision limits in the balanced case with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify f_l with the LIMITK= option or with the variable `_LIMITK_` in a LIMITS= data set.
- Specify $\bar{\bar{X}}$ with the MEAN= option or with the variable `_MEAN_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves decision limits and decision limit parameters. The following variables can be saved:

Table 4.23 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	significance level (α).
<code>_DFE_</code>	degrees of freedom for mean square error (ν).
<code>_GROUP_</code>	<i>group-variable</i> specified in the XCHART statement
<code>_INDEX_</code>	optional identifier for the decision limits specified with the OUTINDEX= option
<code>_LDLX_</code>	lower decision limit for group means
<code>_LIMITK_</code>	number of groups
<code>_LIMITN_</code>	group sample size associated with the decision limits
<code>_MEAN_</code>	weighted average of group means ($\bar{\bar{X}}$)
<code>_MSE_</code>	mean square error ($\widehat{\sigma^2}$).
<code>_TYPE_</code>	type (estimate or standard value) of <code>_MEAN_</code> and <code>_MSE_</code>
<code>_UDLX_</code>	upper decision limit for group means
<code>_VAR_</code>	<i>response</i> specified in the XCHART statement

Notes:

1. In the unbalanced case, the special missing value V is assigned to the variables `_LIMITN_`, `_LDLX_`, and `_UDLX_` to indicate that the decision limits vary with the group sample size.
2. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *response* specified in the XCHART statement. For an example, see the section “[Saving Decision Limits](#)” on page 141.

OUTSUMMARY= Data Set

The OUTSUMMARY= data set saves group summary statistics. The following variables can be saved:

- the *group-variable*
- a group mean variable named by *response* suffixed with X
- a group sample size variable named by *response* suffixed with N
- a group standard deviation variable named by *response* suffixed with S

Given a *response* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Group summary variables are created for each *response* specified in the XCHART statement. For example, consider the following statements:

```
proc anom data=Steel;
  xchart (Width Diameter)*Lot / outsummary=Summary;
run;
```

The data set Summary contains variables named Lot, WidthX, WidthS, WidthN, DiameterX, DiameterS, and DiameterN. Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTSUMMARY= data set, see the section “Saving Summary Statistics for Groups” on page 140.

OUTTABLE= Data Set

The OUTTABLE= data set saves group summary statistics, decision limits, and related information. The following variables can be saved:

Variable	Description
<code>_ALPHA_</code>	significance level (α)
<code>_EXLIM_</code>	decision limit exceeded (if any)
<code>group</code>	values of the group variable
<code>_LDLX_</code>	lower decision limit for group mean
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_MEAN_</code>	central line
<code>_SUBN_</code>	group sample size
<code>_SUBX_</code>	group mean
<code>_UDLX_</code>	upper decision limit for group mean
<code>_VAR_</code>	<i>response</i> specified in the XCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

NOTE: The variable `_EXLIM_` is a character variable of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see the section “Saving Decision Limits” on page 141.

ODS Tables

The following table summarizes the ODS tables that you can request with the XCHART statement.

Table 4.24 ODS Tables Produced with the XCHART Statement

Table Name	Description	Options
XCHART	ANOM chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT,

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the ANOM procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. XCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the XCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 4.25](#).

Table 4.25 ODS Graphics Produced by the XCHART Statement

ODS Graph Name	Plot Description
XChart	ANOM chart for means

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (response values) from a DATA= data set specified in the PROC ANOM statement. Each *response* specified in the XCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into group samples indexed by the *group-variable*. The *group-variable*, which is specified in the XCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *response* and a value for the *group-variable*. If the *i*th group contains n_i items, there should be n_i consecutive observations for which the value of the *group-variable* is the index of the *i*th group. For example, if each group contains five items and there are 10 groups, the DATA= data set should contain 50 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the ANOM procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option.

For an example of a DATA= data set, see the section “[Creating ANOM Charts for Means from Response Values](#)” on page 135.

LIMITS= Data Set

You can read preestablished decision limits (or parameters from which the decision limits can be calculated) from a LIMITS= data set specified in the PROC ANOM statement. For example, the following statements read decision limit information from the data set `Conlims`:

```
proc anom data=Info limits=Conlims;
  xchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the ANOM procedure. Such data sets always contain the variables required for a LIMITS= data set; see [Table 4.23](#). The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following minimal combinations of variables:

- the variables `_LDLX_`, `_MEAN_`, and `_UDLX_`, which specify the decision limits directly
- the variables `_MEAN_` and `_MSE_`, with `_DFE_` recommended, which are used to calculate the decision limits according to the equations in the section “[Decision Limits](#)” on page 152

In addition, note the following:

- The variables `_VAR_` and `_GROUP_` are always required. These must be character variables whose lengths are no greater than 32.
- `_DFE_` is optional. The default is $\nu = N - k$, and in the case of equal group sizes, $\nu = k(n - 1)$.
- `_MSE_` is optional if `_LDLX_` and `_UDLX_` are specified; otherwise it is required.
- `_LDLX_` and `_UDLX_` must be specified together; otherwise their values are computed.
- `_ALPHA_` is optional but is recommended in order to maintain a complete set of decision limit information. The default value is 0.05.
- `_LIMITK_` is optional. The default value is k , the number of groups. A group must have at least one non-missing value ($n_i \geq 1$) and there must be at least one group with $n_i \geq 2$. If specified, `_LIMITK_` overrides the value of k .
- `_LIMITN_` is optional. The default value is the common group size (n), in the balanced case $n_i \equiv n$. If specified, `_LIMITN_` overrides the value of n .
- The variable `_TYPE_` is optional, but is recommended to maintain a complete set of decision limit information. The variable `_TYPE_` must be a character variable of length 8. Valid values are 'ESTIMATE,' 'STANDARD,' 'STDMEAN,' and 'STDRMS.' The default is 'ESTIMATE.'
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- BY variables are required if specified with a BY statement.

SUMMARY= Data Set

You can read group summary statistics from a `SUMMARY=` data set specified in the `PROC ANOM` statement. This enables you to reuse `OUTSUMMARY=` data sets that have been created in previous runs of the ANOM procedure or to read output data sets created with SAS summarization procedures, such as `PROC MEANS`.

A `SUMMARY=` data set used with the `XCHART` statement must contain the following:

- the *group-variable*
- a group mean variable for each *response*
- a group sample size variable for each *response*
- a group standard deviation variable for each *response*

The names of the group mean, group range, and group sample size variables must be the *response* name concatenated with the suffix characters *X*, *S*, and *N*, respectively.

For example, consider the following statements:

```
proc anom summary=Summary;
  xchart (Weight Yieldstrength)*Batch;
run;
```

The data set Summary must include the variables Batch, WeightX, WeightS, WeightN, YieldstrengthX, YieldstrengthS, and YieldstrengthN. Note that if you specify a *response* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *response* name, suffixed with the appropriate character.

Other variables that can be read from a SUMMARY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the ANOM procedure reads all of the observations in a SUMMARY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option.

For an example of a SUMMARY= data set, see the section “[Creating ANOM Charts for Means from Group Summary Data](#)” on page 137.

TABLE= Data Set

You can read summary statistics and decision limits from a TABLE= data set specified in the PROC ANOM statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the ANOM procedure. Because the ANOM procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized ANOM charts.

The following table lists the variables required in a TABLE= data set used with the XCHART statement:

Table 4.26 Variables Required in a TABLE= Data Set

Variable	Description
<i>group-variable</i>	values of the <i>group-variable</i>
<code>_LDLX_</code>	lower decision limit for mean
<code>_LIMITN_</code>	nominal sample size associated with the decision limits
<code>_MEAN_</code>	central line
<code>_SUBN_</code>	group sample size
<code>_SUBX_</code>	group mean
<code>_UDLX_</code>	upper decision limit for mean

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified). This variable must be a character variable whose length is no greater than 48.
- `_VAR_`. This variable is required if more than one *response* is specified or if the data set contains information for more than one *response*. This variable must be a character variable whose length is no greater than 32.

For an example of a `TABLE=` data set, see the section “[Saving Decision Limits](#)” on page 141.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>group-variable</i>
Vertical	<code>DATA=</code>	<i>response</i>
Vertical	<code>SUMMARY=</code>	group mean variable
Vertical	<code>TABLE=</code>	<code>_SUBX_</code>

Missing Values

An observation read from a `DATA=`, `SUMMARY=`, or `TABLE=` data set is not analyzed if the value of the group variable is missing. For a particular response variable, an observation read from a `DATA=` data set is not analyzed if the value of the response variable is missing. Missing values of response variables generally lead to unequal group sample sizes. For a particular response variable, an observation read from a `SUMMARY=` or `TABLE=` data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: XCHART Statement

This section provides advanced examples of the XCHART statement.

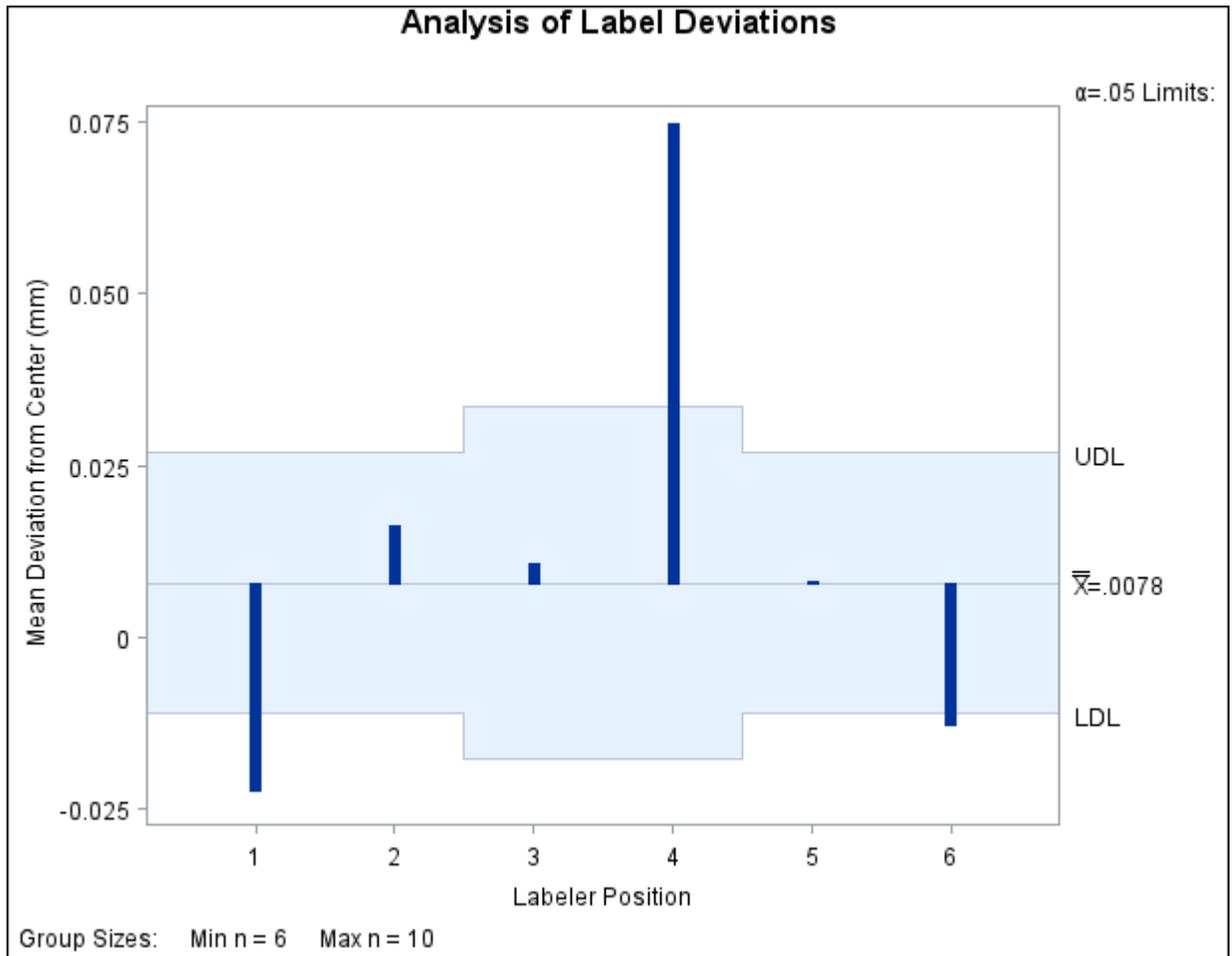

Example 4.4: ANOM Charts with Unequal Group Sizes

Consider the example described in “Creating ANOM Charts for Means from Response Values” on page 135. Suppose that four of the 10 measurements were missing for the third and fourth labeler positions. The following statements create a SAS data set named LabelDev2, which contains the resulting deviation measurements: *See ANMXEX1 in the SAS/QC Sample Library*

```
data LabelDev2;
  input Position @;
  do i = 1 to 5;
    input Deviation @;
    output;
  end;
  drop i;
  datalines;
1 -0.0239 -0.0285 -0.0300 -0.0043 -0.0362
1 -0.0422 -0.0014 -0.0647  0.0094 -0.0016
2 -0.0201 -0.0273  0.0227 -0.0332  0.0366
2  0.0438  0.0556  0.0098  0.0564  0.0182
3 -0.0073  0.0285  .        .        -0.0139
3  .        0.0357  0.0235  .        -0.0020
4  0.0669  0.1073  .        .        0.0755
4  .        0.0561  0.0899  .        0.0530
5  0.0368  0.0036  0.0374  0.0116 -0.0074
5  0.0250 -0.0080  0.0302 -0.0015 -0.0464
6  0.0049 -0.0384 -0.0204 -0.0049 -0.0120
6  0.0071 -0.0308  0.0017 -0.0285 -0.0070
;
```

The following statements create the ANOM chart shown in [Output 4.4.1](#):

```
ods graphics off;
title 'Analysis of Label Deviations';
proc anom data=LabelDev2;
  xchart Deviation*Position;
  label Deviation = 'Mean Deviation from Center (mm)';
  label Position  = 'Labeler Position';
run;
```

Output 4.4.1 ANOM Chart with Unequal Group Sizes

Note that the decision limits are automatically adjusted for the varying group sizes. The legend reports the minimum and maximum group sizes.

Example 4.5: ANOM for a Two-Way Classification

See ANMXEX2 in the SAS/QC Sample Library

A chemical engineer is interested in the effects of two factors, position and depth, on the concentration of a cleaning solution; refer to Ramig (1983) for details concerning the use of ANOM in a two-way classification such as this. The engineer is interested in the following questions:

1. Are there significant group or interaction effects due to position or depth?
2. Assuming a main effect is significant, which levels are significantly different from the overall mean and in which direction?

There are five positions and three depths. The engineer runs a two-way factorial experiment with two replications per cell. The following statements create a data set named Cleaning, which provides the concentration measurements for the $5 \times 3 \times 2 = 30$ observations.

```

data cleaning;
  do position = 1 to 5;
    do depth = 1 to 3;
      do rep = 1 to 2;
        input concentration @@;
        output;
      end;
    end;
  end;
datalines;
15 16 15 14 19 5
15 16 14 14 0 8
19 15 16 16 11 8
18 16 19 15 8 14
15 12 19 15 8 11
;
;

```

In order to test for main effects and an interaction effect, the following statements use the GLM procedure:

```

ods graphics off;
proc glm data=cleaning;
  class position depth;
  model concentration = position depth position*depth;
run;

```

The results are shown in [Output 4.5.1](#):

Output 4.5.1 GLM Results

Analysis of Label Deviations					
The GLM Procedure					
Dependent Variable: concentration					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	14	390.4666667	27.8904762	2.21	0.0694
Error	15	189.0000000	12.6000000		
Corrected Total	29	579.4666667			
	R-Square	Coeff Var	Root MSE	concentration Mean	
	0.673838	26.22893	3.549648	13.53333	

Output 4.5.1 *continued*

Source	DF	Type I SS	Mean Square	F Value	Pr > F
position	4	50.4666667	12.6166667	1.00	0.4374
depth	2	281.6666667	140.8333333	11.18	0.0011
position*depth	8	58.3333333	7.2916667	0.58	0.7802

The results in [Output 4.5.1](#) show no significant interaction effect³ and a significant main effect due to depth. Since no interaction effect is present, you can use analysis of means to evaluate the effect of each factor as if two separate experiments had been run to determine the effect of each factor. In other words, the analysis of means is done twice, once for each factor. However, each analysis must be based on the mean square error ($\widehat{\sigma}^2 = 12.6$) and the degrees of freedom for error ($\nu = 15$) from the two-way analysis of variance. These values must be specified since the ANOM procedure assumes a one-way layout by default for computing the decision limits.

The following statements create the ANOM chart for the effect of position shown in [Output 4.5.2](#):

```

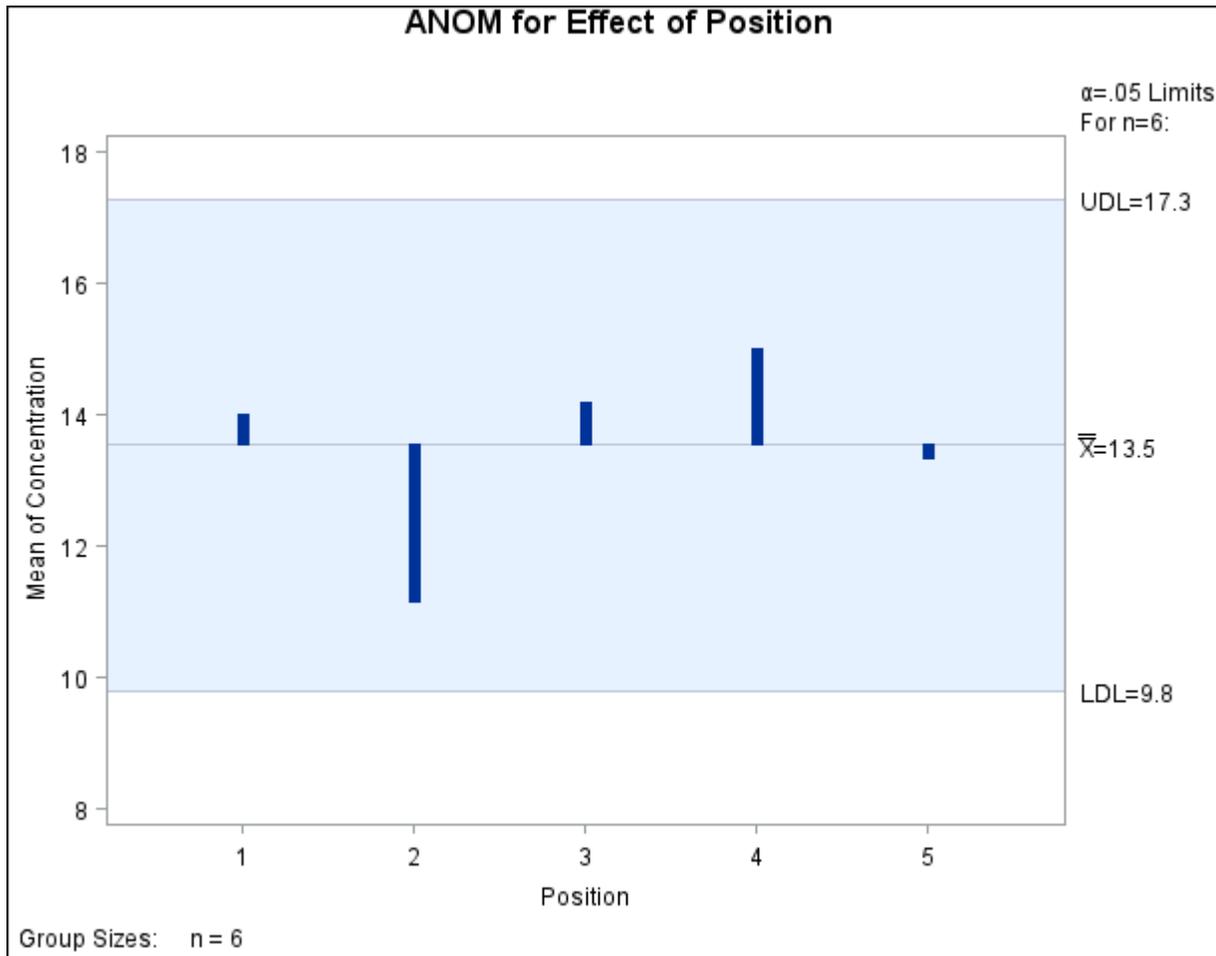

title "ANOM for Effect of Position";
proc anom data=cleaning;
  xchart concentration * position / mse      = 12.6
                                   dfe      = 15
                                   outtable = posmain;
  label position      = 'Position'
       concentration = 'Mean of Concentration';
run;

```

The MSE= and DFE= options are used to specify $\widehat{\sigma}^2$ and ν respectively. See the section “[Constructing ANOM Charts for Two-Way Layouts](#)” on page 153 for how the specified values are used to compute the decision limits. The OUTTABLE= option stores the output data set PosMain, which can be used to create a combined chart for the two factors.

³See [Example 4.7](#) for an example that discusses the use of ANOM for the cell means when an interaction effect is present.

Output 4.5.2 ANOM for Effect of Position

Each point on the ANOM chart represents the average response for a particular level of position. In this case, all of the points are between the upper decision limit (UDL) and the lower decision limit (LDL). This is not surprising considering the fact that the main effect of Position was not significant in the ANOVA.

In order to create the ANOM chart for the effect of depth, the response must be sorted by depth.

```
proc sort data=cleaning out=cleaning2;
  by depth;
run;
```

Note that for the previous chart, the measurements were sorted by Position in the original data set.

The following statements create the chart for depth:

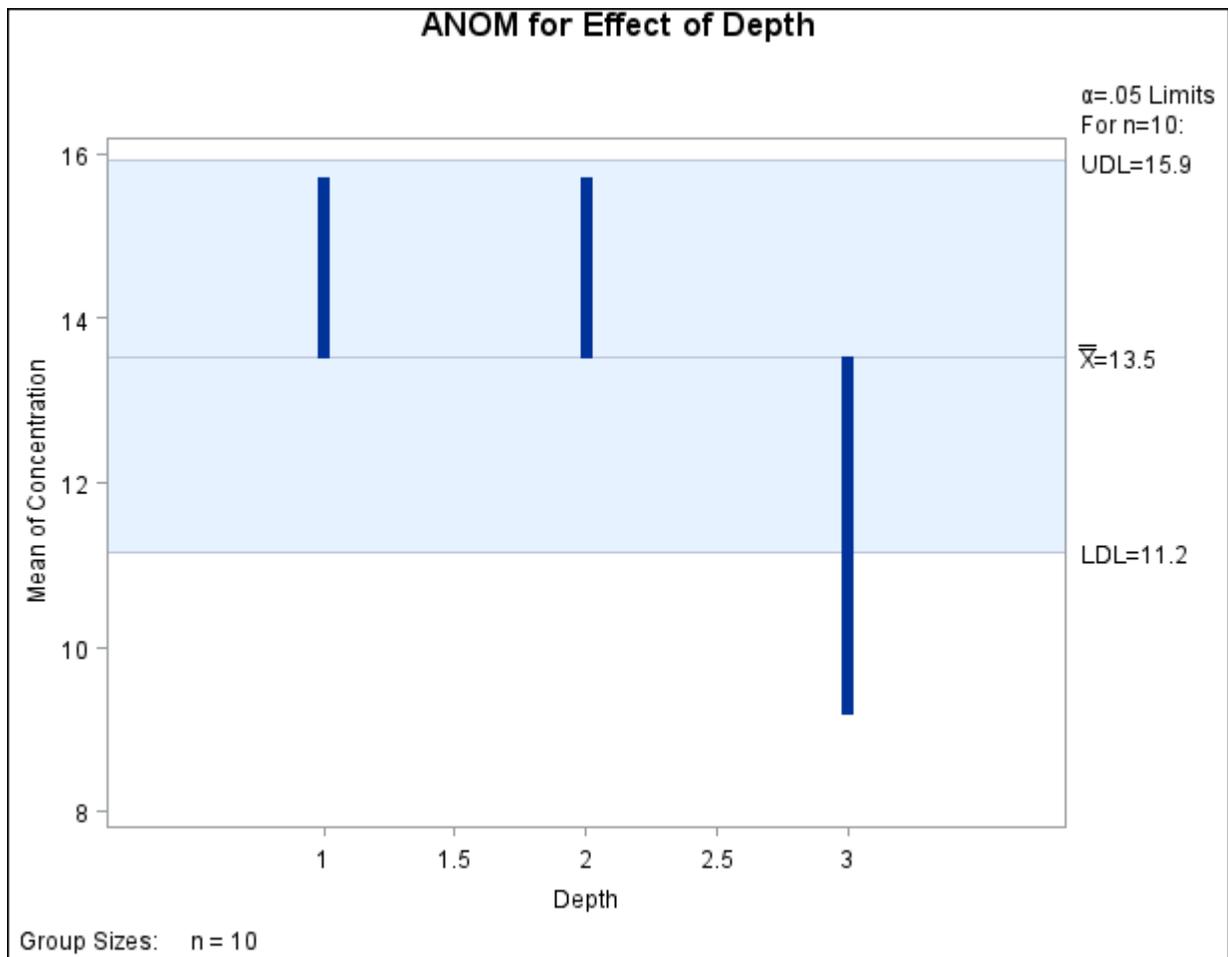

```

title "ANOM for Effect of Depth";
proc anom data=cleaning2;
  xchart concentration * depth / mse      = 12.6
                                dfe      = 15
                                outtable = depmain;
  label depth                    = 'Depth'
        concentration            = 'Mean of Concentration';
run;

```

This produces the chart shown in [Output 4.5.3](#): The OUTTABLE= option stores the output data set depmain, which can be used to create a combined chart for the two factors.

Output 4.5.3 ANOM for Effect of Depth

Since the average concentration for Depth 3 is less than the lower decision limit, you can conclude that the average response for Depth 3 is significantly less than the overall mean.

Example 4.6: ANOM Charts Using LIMITS= Data Set

In Example 4.5, statistics from a two-way ANOVA were passed to the ANOM procedure using options in order to compute the decision limits for the factor effects. This example shows how you can pass the statistics in a LIMITS= data set using the variables `_MSE_` and `_DFE_`. *See ANMXEX4 in the SAS/QC Sample Library*

The GLM output in Output 4.5.1 provides the statistics. The following statements save the results from PROC GLM in the data sets MyFit, MyLimits, and MyOverAll:

```
ods select FitStatistics ModelANOVA OverAllANOVA;
ods output FitStatistics = MyFit
           ModelANOVA   = MyLimits
           OverAllANOVA = MyOverAll;

proc glm data=cleaning;
  class position depth;
  model concentration = position depth position*depth;
run;
```

The results of PROC GLM are identical to the results in Output 4.5.1.

The following statements create a LIMITS= data set to be used to create an ANOM chart for the effect of Position:

```
data ANOMParms;
  keep _var_ _group_ _alpha_ _mean_;
  length _var_ _group_ $ 14;
  set MyFit (rename=(Dependent=_var_ DepMean =_mean_));
  _group_ = 'position';
  _alpha_ = 0.05;
run;

data ANOMParms;
  merge ANOMParms
        MyLimits (where=(source='position')
                  keep = source DF);
  _limitk_ = DF+1;
  drop source DF;
  merge MyOverAll (where=(source='Error')
                  keep = source df ms
                  rename=( df = _dfe_ ms = _mse_));
  drop source;
  merge MyOverAll (where=(source='Corrected Total')
                  keep = source DF);
  _limitn_ = (DF+1)/_limitk_;
  drop source DF;
run;
```

The data set ANOMParms contains a complete set of parameters, as shown in Output 4.6.1. Note these are the same values specified in the options for Example 4.5.

Consider the following data set cleaninginteract:

```

data cleaninginteract;
  do position = 1 to 5;
    do depth = 1 to 3;
      do rep = 1 to 2;
        input concentration @@;
        output;
      end;
    end;
  end;
datalines;
15 16 15 14 19 5
15 16 14 14 0 1
19 15 16 16 11 8
18 16 24 23 8 14
15 12 23 24 8 11
;
;

```

The following statements use PROC GLM to test for an interaction:

```

ods graphics off;
proc glm data=cleaninginteract;
  class position depth;
  model concentration = position depth position*depth;
run;

```

The analysis of variance results in [Output 4.7.1](#) indicate a significant interaction between position and depth.

Output 4.7.1 GLM Results

ANOM for Effect of Position					
The GLM Procedure					
Dependent Variable: concentration					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	14	885.666667	63.261905	6.66	0.0004
Error	15	142.500000	9.500000		
Corrected Total	29	1028.166667			
R-Square	Coeff Var	Root MSE	concentration Mean		
0.861404	21.75676	3.082207	14.16667		

Output 4.7.1 *continued*

Source	DF	Type I SS	Mean Square	F Value	Pr > F
position	4	169.0000000	42.2500000	4.45	0.0144
depth	2	515.4666667	257.7333333	27.13	<.0001
position*depth	8	201.2000000	25.1500000	2.65	0.0496

Since an interaction effect is present, an appropriate way to analyze the data is to create an ANOM chart for the cell means.

In order to create the chart you first need to compute the cell means and a new *group* variable which designates the cells. The following statements use PROC MEANS for this purpose.

```
proc means data=cleaninginteract n mean std;
  class position depth;
  var concentration;
  types position*depth;
  output out=cellmeans mean=concentrationX std=concentrationS;
run;
data cellmeans; set cellmeans;
  rename _FREQ_ = concentrationN;
  pos = put(position, z1.);
  dep = put(depth, z1.);
  cell = cat('P',pos, 'D', dep);
  drop _TYPE_ pos dep;
run;
```

The cell means are stored in the data set cellmeans shown in [Output 4.7.2](#):

Output 4.7.2 Data Set cellmeans

ANOM for Effect of Position					
The MEANS Procedure					
Analysis Variable : concentration					
position	depth	N Obs	N	Mean	Std Dev
1	1	2	2	15.5000000	0.7071068

5	2	2	23.5	0.70711	P5D2	
5	3	2	9.5	2.12132	P5D3	

The data set `cellmeans` has the structure of a `SUMMARY=` input data set for the ANOM procedure. For details concerning a `SUMMARY=` data set, see the section “Creating ANOM Charts for Means from Group Summary Data” on page 137.

The following statements use `cellmeans` to create the ANOM chart for the cell means using `SUMMARY=` option:

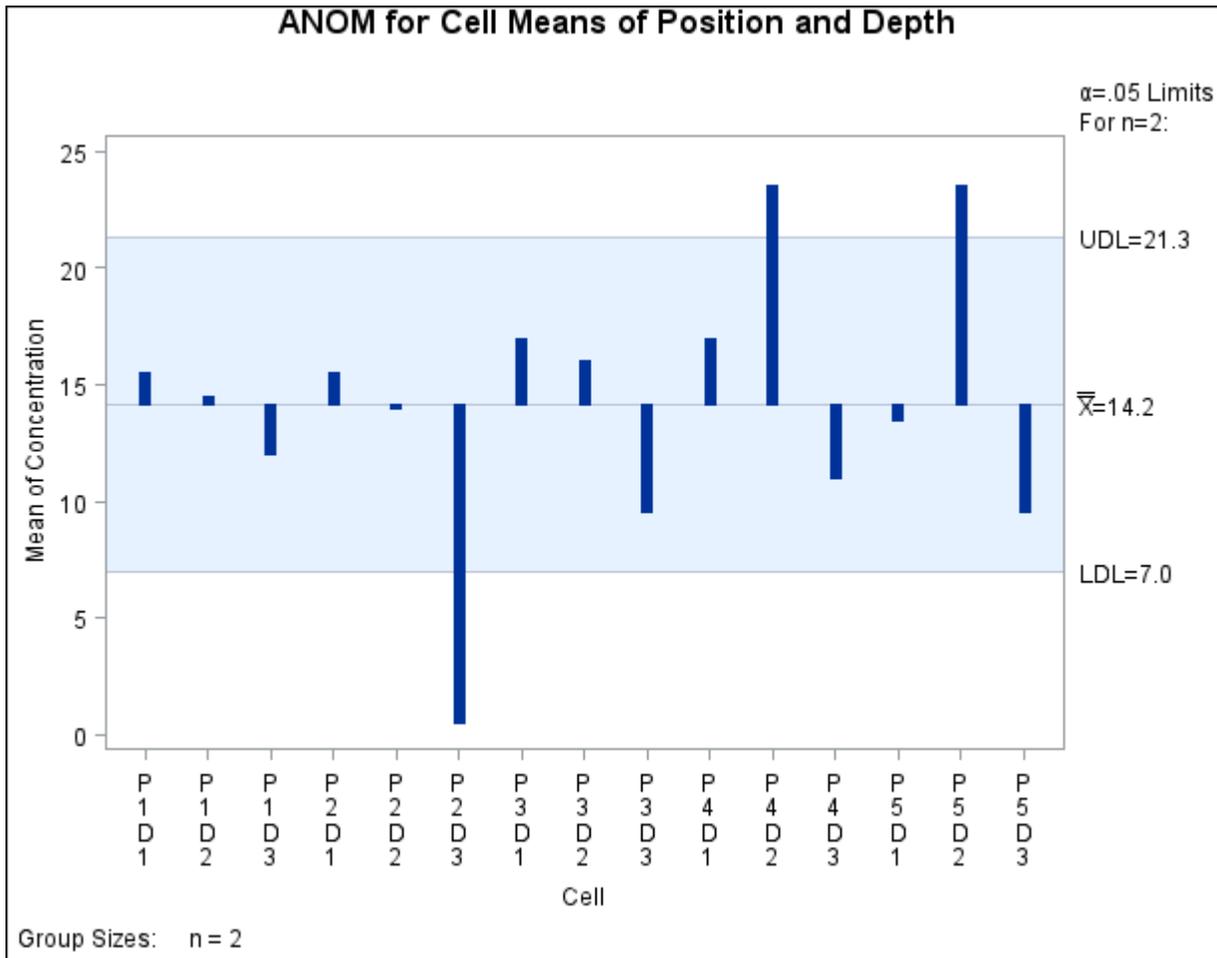

```

title "ANOM for Cell Means of Position and Depth";
proc ANOM summary = cellmeans;
  xchart concentration * cell / turnhlabels;
  label concentrationX = 'Mean of Concentration';
  label cell          = 'Cell';
run;

```

The chart is shown in [Output 4.7.3](#):

Output 4.7.3 ANOM for Cell Means of Position and Depth

The chart shows that the cell means for P2D3, P4D2, and P5D2 are significantly different from the average concentration level.

INSET Statement: ANOM Procedure

Overview: INSET Statement

The INSET statement enables you to enhance an ANOM chart by adding a box or table (referred to as an *inset*) of summary statistics directly to the graph. An inset can display statistics calculated by the ANOM procedure or arbitrary values provided in a SAS data set.

Note that an INSET statement by itself does not produce a display but must be used in conjunction with a chart statement.

You can use options in the INSET statement to

- specify the position of the inset
- specify a header for the inset table
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

Getting Started: INSET Statement

This section introduces the INSET statement with examples that illustrate commonly used options. Complete syntax for the INSET statement is presented in the section “Syntax: INSET Statement” on page 181.

Displaying Summary Statistics on an ANOM Chart

See ANMIN1 in the SAS/QC Sample Library A manufacturing engineer carries out a study to determine the source of excessive variation in the positioning of labels on shampoo bottles.⁴ A labeling machine removes bottles from the line, attaches the labels, and returns the bottles to the line. There are six positions on the machine, and the engineer suspects that one or more of the position heads might be faulty.

A sample of 60 bottles, 10 per position, is run through the machine. For each bottle, the deviation of each label is measured in millimeters, and the machine position is recorded. The following statements create a SAS data set named `LabelDeviations`, which contains the deviation measurements for the 60 bottles:

⁴This example is based on a case study described by Hansen (1990).

```

data LabelDeviations;
  input Position @;
  do i = 1 to 5;
    input Deviation @;
    output;
  end;
  drop i;
  datalines;
1 -0.02386 -0.02853 -0.03001 -0.00428 -0.03623
1 -0.04222 -0.00144 -0.06466 0.00944 -0.00163

;

```

The following statements generate an ANOM chart from the LabelDeviations data. An INSET statement is used to display the mean square error (MSE) and the number of groups outside of the decision limits (NOUT) on the chart:

```

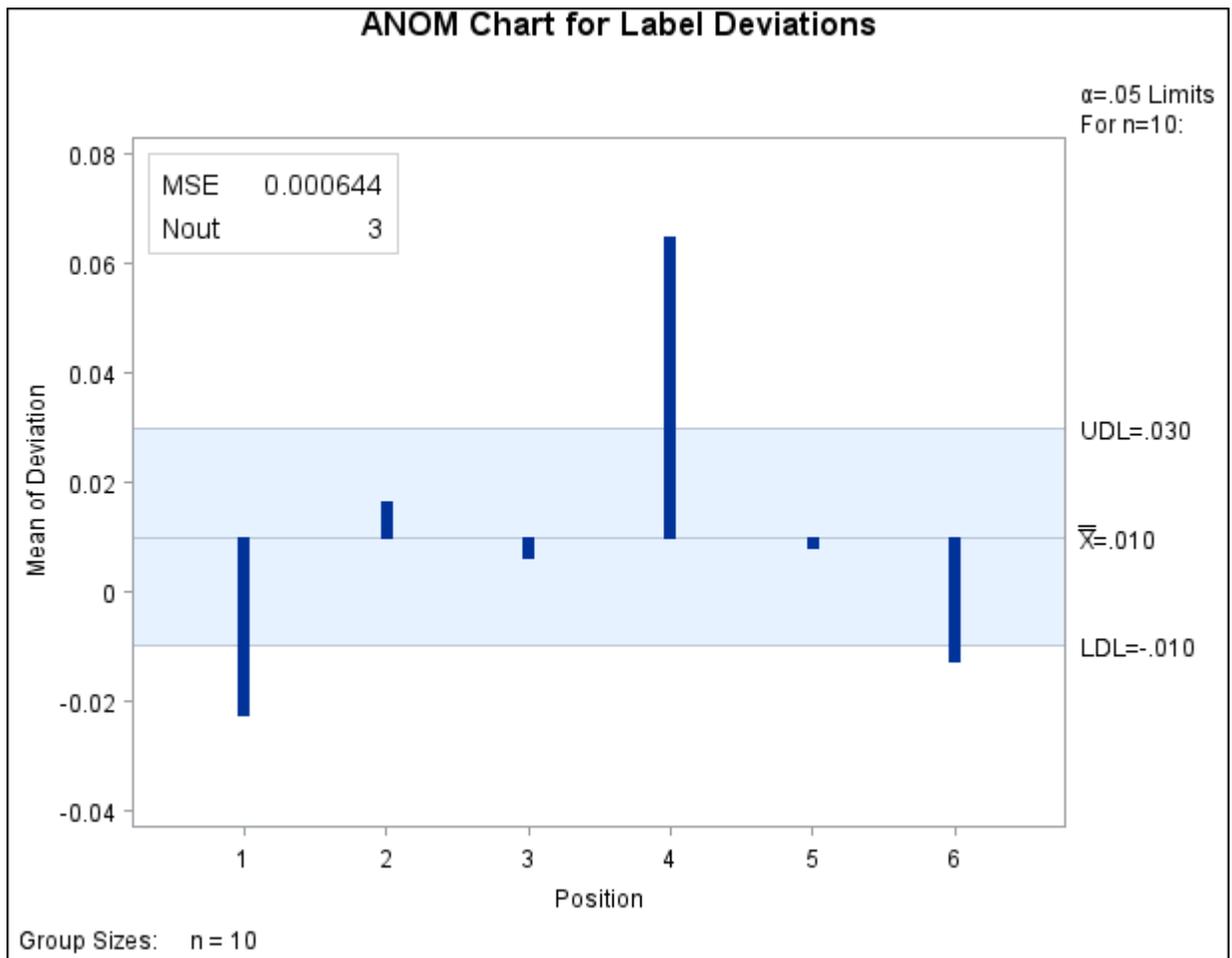

ods graphics off;
title 'ANOM Chart for Label Deviations';
proc anom data=LabelDeviations;
  xchart Deviation*Position;
  inset mse nout /
    height = 3;
run;

```

The resulting ANOM chart is displayed in [Figure 4.28](#). The INSET statement immediately follows the chart statement that creates the graphical display (in this case, the XCHART statement). Specify the keywords for inset statistics (such as ALPHA) immediately after the word INSET. The inset statistics appear in the order in which you specify the keywords. The HEIGHT= option on the INSET statement specifies the text height used to display the statistics in the inset.

A complete list of keywords that you can use with the INSET statement is provided in “[Summary of INSET Keywords](#)” on page 182. Note that the set of keywords available for a particular display may depend on both the chart statement that precedes the INSET statement and the options that you specify in the chart statement.

Figure 4.28 An ANOM Chart with an Inset

The following examples illustrate options commonly used for enhancing the appearance of an inset.

Formatting Values and Customizing Labels

See ANMIN2 in the SAS/QC Sample Library. By default, each inset statistic is identified with an appropriate label, and each numeric value is printed using an appropriate format. However, you may want to provide your own labels and formats. For example, in Figure 4.28 the default format used for the MSE prints an excessive number of decimal places. In the inset produced by the following statements, the unwanted decimal places are eliminated and the default MSE label is replaced by one specified by the user:

```
ods graphics on;
title 'ANOM Chart for Label Deviations';
proc anom data=LabelDeviations;
  xchart Deviation*Position / odstitle=title;
  inset mse='Mean Square Error' (7.5) nout;
run;
```

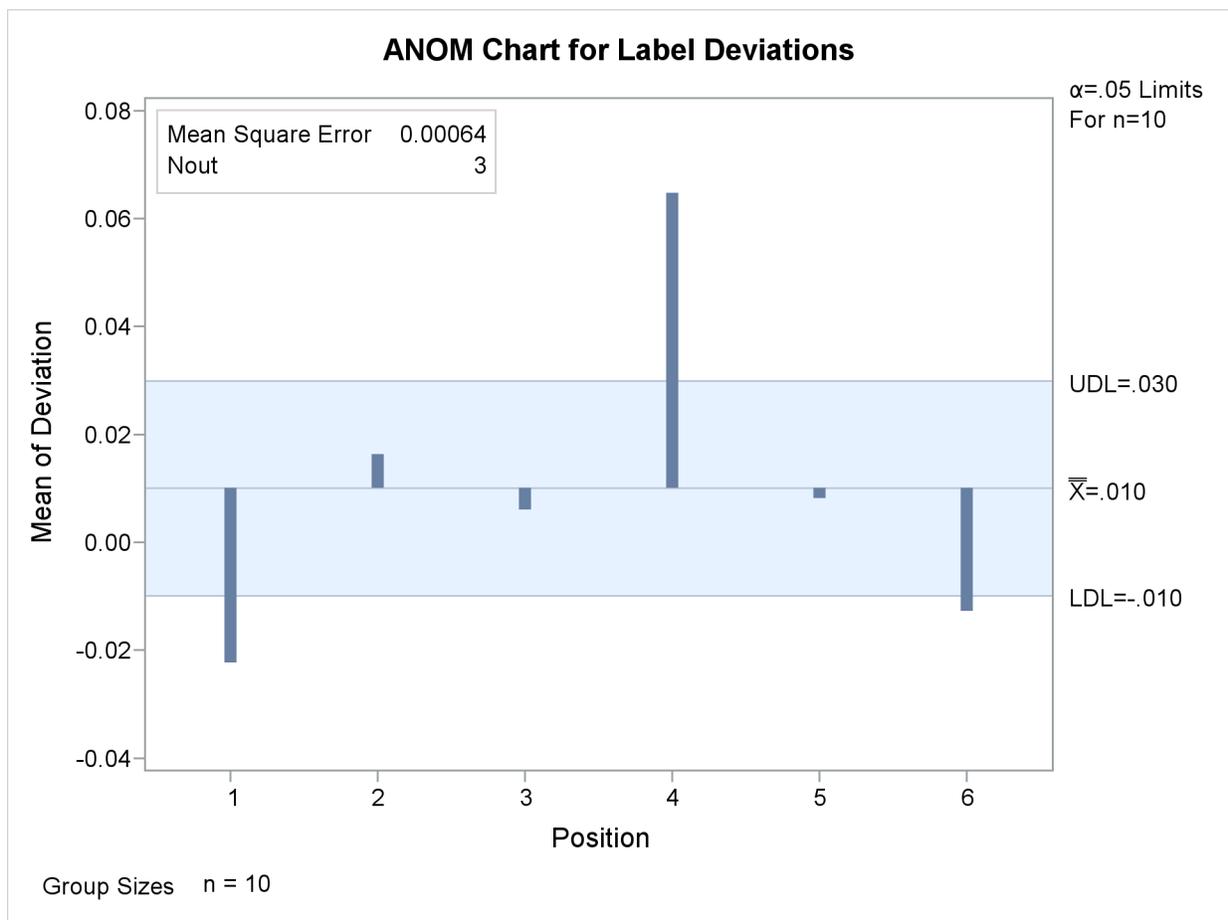

The ODS GRAPHICS ON statement specified before the PROC ANOM statement enables ODS Graphics, so the chart is created using ODS Graphics instead of traditional graphics.

The resulting ANOM chart is displayed in [Figure 4.29](#). You can provide your own label by specifying the keyword for that statistic followed by an equal sign (=) and the label in quotes. The label can have up to 24 characters.

The format 7.5 specified in parentheses after the MSE keyword displays the statistic with a field width of seven and five decimal places. In general, you can specify any numeric SAS format in parentheses after an inset keyword. You can also specify a format to be used for all the statistics in the INSET statement with the FORMAT= option (see [Figure 4.30](#)). For more information about SAS formats, refer to *SAS Formats and Informats: Reference*.

Note that if you specify both a label and a format for a statistic, the label must appear before the format.

Figure 4.29 Formatting Values and Customizing Labels in an Inset

Adding a Header and Positioning the Inset

See ANMIN3 in the SAS/QC Sample Library

In the previous examples, the insets are displayed in the upper left corners of the plots, the default position for insets added to ANOM charts. You can control the inset position with the POSITION= option. In addition, you can display a header at the top of the inset with the HEADER= option. The following statements create a data set to be used with the INSET DATA= keyword and the chart shown in Figure 4.30:

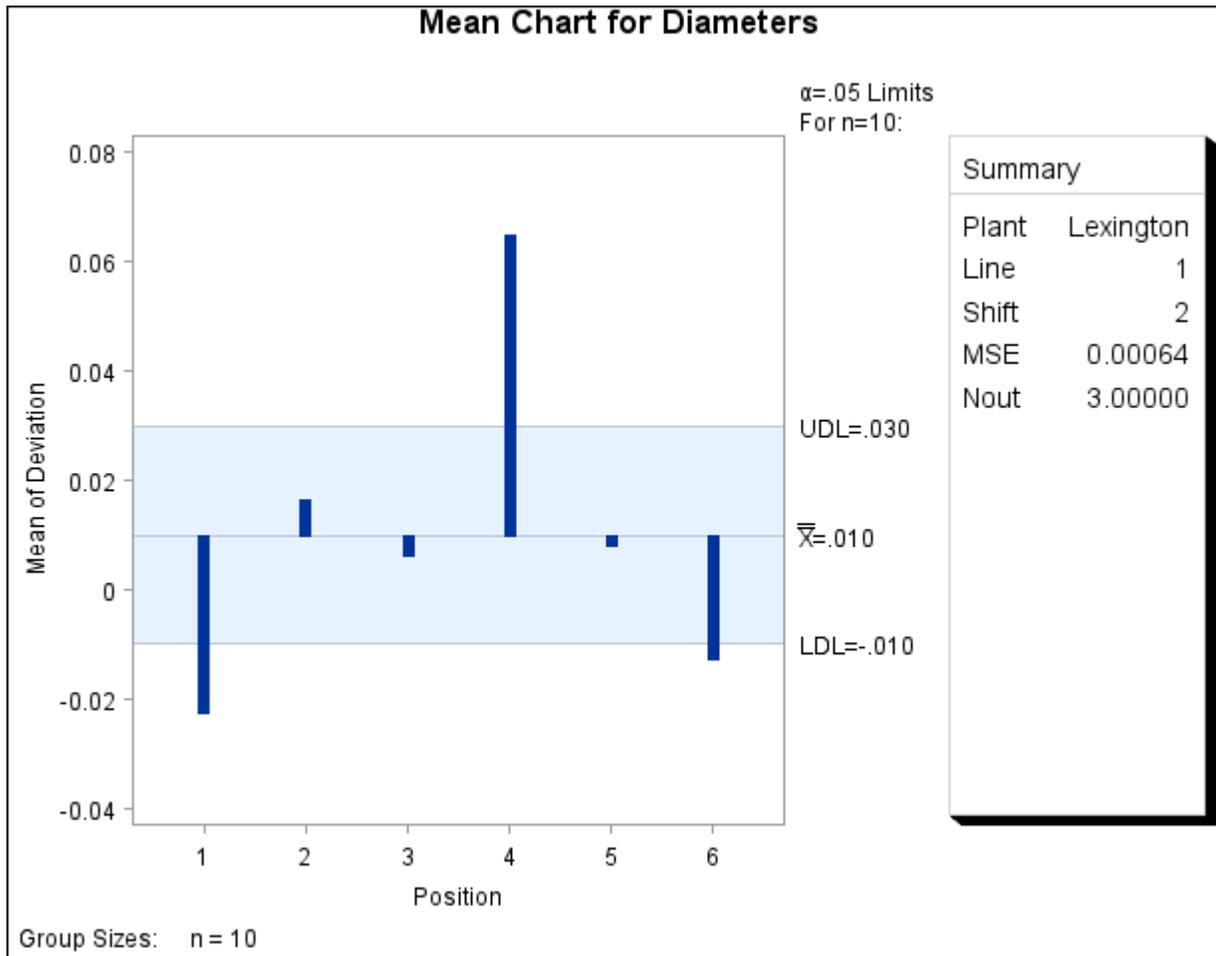

```
data Location;
  length _LABEL_ $ 10 _VALUE_ $ 12;
  input _LABEL_ _VALUE_ &;
  datalines;
Plant      Lexington
Line       1
Shift      2
;

ods graphics off;
title 'Mean Chart for Diameters';
proc anom data=LabelDeviations;
  xchart Deviation*Position;
  inset data=Location mse nout /
    format      = 8.5
    position    = rm
    cshadow     = black
    height      = 3
    header      = 'Summary';
run;
```

The header (in this case, *Summary*) can be up to 40 characters. POSITION=RM is specified to position the inset in the right margin. For more information about positioning, see “[Details: INSET Statement](#)” on page 187. The CSHADOW= option is used to display a drop shadow on this inset. The *options*, such as HEADER=, POSITION=, and CSHADOW=, are specified after the slash (/) in the INSET statement. For more details on INSET statement options, see “[Dictionary of Options](#)” on page 184.

Note that the contents of the data set Location appear before other statistics in the inset. The position of the DATA= keyword in the keyword list determines the position of the data set’s contents in the inset. The FORMAT= option applies format 8.5 to the statistics listed in the INSET statement. Note that the format does not apply to the values from the Location data set. You can associate a format with the _VALUE_ variable in the data set to format those values.

Figure 4.30 Adding a Header and Repositioning the Inset

Syntax: INSET Statement

The syntax for the INSET statement is as follows:

```
INSET keyword-list </ options > ;
```

You can use any number of INSET statements in the ANOM procedure. Each INSET statement produces a separate inset and must follow one of the chart statements. The inset appears on every panel (page) produced by the last chart statement preceding it. The statistics are displayed in the order in which they are specified. The following statements produce an ANOM boxchart with two insets and an ANOM chart for means with one inset.

```
proc anom data=LabelDeviations;  
  boxchart Deviation*Position;  
    inset alpha mse dfe;  
    inset ldl mean udl;  
  xchart Deviation*Position;  
    inset ngroups nmin nmax;  
run;
```

The statistics displayed in an inset are computed for a specific response variable using observations for the current BY group. For example, in the following statements, there are two response variables (Weight and Diameter) and a BY variable (Location). If there are three different locations (levels of Location), then a total of six ANOM charts are produced. The statistics in each inset are computed for a particular variable and location. The labels in the inset are the same for each ANOM chart.

```
proc anom data=Axles;
  by Location;
  xchart (Weight Diameter)*Batch;
  inset alpha mse dfe;
run;
```

The components of the INSET statement are described as follows.

keyword-list

can include any of the *keywords* listed in “[Summary of INSET Keywords](#)” on page 182. By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format. For an example, see “[Formatting Values and Customizing Labels](#)” on page 178.

options

appear after the slash (/) and control the appearance of the inset. For example, the following INSET statement uses two appearance *options* (POSITION= and CTEXT=):

```
inset n nmin nmax / position=ne ctext=yellow;
```

The POSITION= option determines the location of the inset, and the CTEXT= option specifies the color of the text of the inset.

See “[Summary of Options](#)” on page 183 for a list of all available *options*, and “[Dictionary of Options](#)” on page 184 for detailed descriptions. Note the difference between *keywords* and *options*; *keywords* specify the information to be displayed in an inset, whereas *options* control the appearance of the inset.

Summary of INSET Keywords

All keywords available with the ANOM procedure’s INSET statement request a single statistic in an inset, except for the DATA= keyword. The DATA= keyword specifies a SAS data set containing (label, value) pairs to be displayed in an inset. The data set must contain the variables `_LABEL_` and `_VALUE_`. `_LABEL_` is a character variable whose values provide labels for inset entries. `_VALUE_` can be character or numeric, and provides values displayed in the inset. The label and value from each observation in the DATA= data set occupy one line in the inset. [Figure 4.30](#) shows an inset containing entries from a DATA= data set.

Table 4.27 Summary Statistics

Keyword	Description
ALPHA	significance level
DATA=	(label, value) pairs from <i>SAS-data-set</i>
DFE	degrees of freedom
LDL	lower decision limit
MEAN	weighted average of group means
MSE	mean square error
N	nominal group size
NGROUPS	number of groups
NHIGH	number of groups above upper decision limit
NLOW	number of groups below lower decision limit
NMAX	maximum group size
NMIN	minimum group size
NOBS	total number of observations
NOUT	total number of groups outside decision limits
RMSE	root mean square error
UDL	upper decision limit

You can use the keywords in [Table 4.28](#) only when producing ODS Graphics output. The labels for the statistics use Greek letters.

Table 4.28 Keywords Specific to ODS Graphics Output

Keyword	Description
UALPHA	probability of Type 1 error
UMU	weighted average of group means

Summary of Options

The following table lists the INSET statement options. For complete descriptions, see “[Dictionary of Options](#)” on page 184.

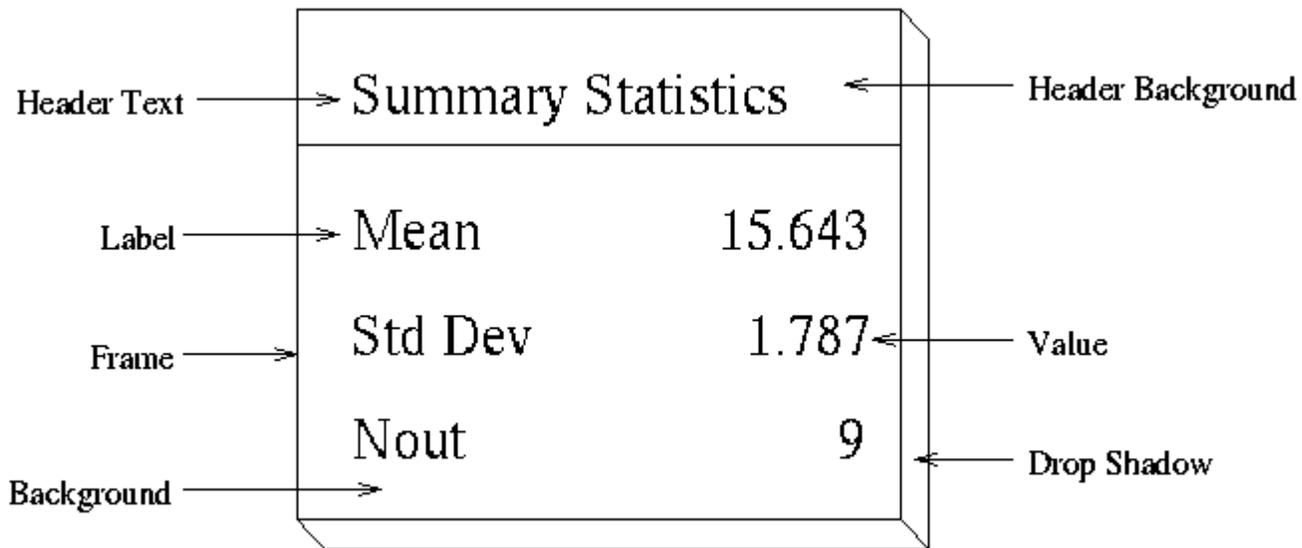

Table 4.29 INSET Options

Option	Description
CFILL= <i>color</i> BLANK	specifies color of inset background
CFILLH= <i>color</i>	specifies color of header background
CFRAME= <i>color</i>	specifies color of frame
CHEADER= <i>color</i>	specifies color of header text
CSHADOW= <i>color</i>	specifies color of drop shadow
CTEXT= <i>color</i>	specifies color of inset text
DATA	specifies data units for POSITION=(<i>x</i> , <i>y</i>) coordinates
FONT= <i>font</i>	specifies font of text
FORMAT= <i>format</i>	specifies format of values in inset
HEADER='string'	specifies header text
HEIGHT= <i>value</i>	specifies height of inset text
HTRANSPARENCY= <i>value</i>	specifies transparency of inset header background
NOFRAME	suppresses frame around inset
TRANSPARENCY= <i>value</i>	specifies transparency of inset background
POSITION= <i>position</i>	specifies position of inset
REFPOINT=BR BL TR TL	specifies reference point of inset positioned with POSITION=(<i>x</i> , <i>y</i>) coordinates

Dictionary of Options

The following entries provide detailed descriptions of options for the INSET statement. The marginal notes *Traditional Graphics* and *ODS Graphics* identify options that apply only to traditional graphics and ODS Graphics output, respectively. Terms used in this section are illustrated in Figure 4.31.

Figure 4.31 The Inset

**CFILL=*color* | BLANK**

specifies the color of the background (including the header background if you do not specify *Traditional Graphics* the CFILLH= option).

If you do not specify the CFILL= option, then by default, the background is empty. This means that items that overlap the inset (such as needles representing group data or decision limits) show through the inset. If you specify any value for the CFILL= option, then overlapping items no longer show through the inset. Specify CFILL=BLANK to leave the background uncolored and also to prevent items from showing through the inset.

CFILLH=*color*

specifies the color of the header background. By default, if you do not specify a CFILLH= *Traditional Graphics* color, the CFILL= color is used.

CFRAME=*color*

specifies the color of the frame. By default, the frame is the same color as the axis of the plot. *Traditional Graphics*

CHEADER=*color*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, *Traditional Graphics* the CTEXT= color is used.

CSHADOW=*color***CS=*color***

specifies the color of the drop shadow. See Figure 4.30 for an example. By default, if you do *Traditional Graphics* not specify the CSHADOW= option, a drop shadow is not displayed.

CTEXT=color

Traditional Graphics **CT=color** specifies the color of the text. By default, the inset text color is the same as the other text on the plot.

DATA

specifies that data coordinates are to be used in positioning the inset with the POSITION= option. The DATA option is available only when you specify POSITION= (x, y), and it must be placed immediately after the coordinates (x, y). For details, see the entry for the POSITION= option or “Positioning the Inset Using Coordinates” on page 189. See Figure 4.33 for an example.

FONT=font

Traditional Graphics specifies the font of the text. By default, the font is SIMPLEX if the inset is located in the interior of the plot, and the font is the same as the other text displayed on the plot if the inset is located in the exterior of the plot.

FONT=SMALL

ODS Graphics changes the fonts used in the inset. By default, the font associated with the GraphLabelText style element is used for the inset header and that associated with the GraphValueText style element is used for text in the body of the inset. When you specify FONT=SMALL, the GraphValueText font is used in the header and the GraphDataText font is used in the inset body.

FORMAT=format

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

HEADER= 'string'

specifies the header text. The *string* cannot exceed 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=value

Traditional Graphics specifies the height of the text in screen percent units.

HEIGHT=SMALL

ODS Graphics reduces the size of the text in the inset. By default, the GraphLabelText style element determines the size of inset header text and the GraphValueText style element determines the size of text in the body of the inset. When you specify HEIGHT=SMALL, the GraphValueText size is used for the inset header and the GraphDataText size is used in the inset body.

HTRANSPARENCY=value

ODS Graphics specifies the inset header background transparency for ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default inset header background transparency is 0.65.

NOFRAME

suppresses the frame drawn around the text.

POSITION=*position***POS=*position***

determines the position of the inset. The *position* can be a compass point keyword, a margin keyword, or a pair of coordinates (x, y). You can specify coordinates in axis percent units or axis data units. For more information, see “[Details: INSET Statement](#)” on page 187. By default, POSITION=NW, which positions the inset in the upper left (northwest) corner of the display.

REFPOINT=BR | BL | TR | TL**RP=BR | BL | TR | TL**

specifies the reference point for an inset that is positioned by a pair of coordinates with the POSITION= option. Use the REFPOINT= option with POSITION= coordinates. The REFPOINT= option specifies which corner of the inset frame you want positioned at coordinates (x, y). The keywords BL, BR, TL, and TR represent bottom left, bottom right, top left, and top right, respectively. See [Figure 4.34](#) for an example. The default is REFPOINT=BL.

If you specify the position of the inset as a compass point or margin keyword, the REFPOINT= option is ignored. For more information, see “[Positioning the Inset Using Coordinates](#)” on page 189.

TRANSPARENCY=*value*

specifies the inset background transparency for ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default inset background transparency is 0.05. *ODS Graphics*

Details: INSET Statement

This section provides details on three different methods of positioning the inset using the POSITION= option. With the POSITION= option, you can specify

- compass points
- keywords for margin positions
- coordinates in data units or percent axis units

Positioning the Inset Using Compass Points

You can specify the eight compass points N, NE, E, SE, S, SW, W, and NW as keywords for the POSITION= option. The following statements create the display in [Figure 4.32](#), which demonstrates all eight compass positions. The default is NW. *See ANMIN4 in the SAS/QC Sample Library*

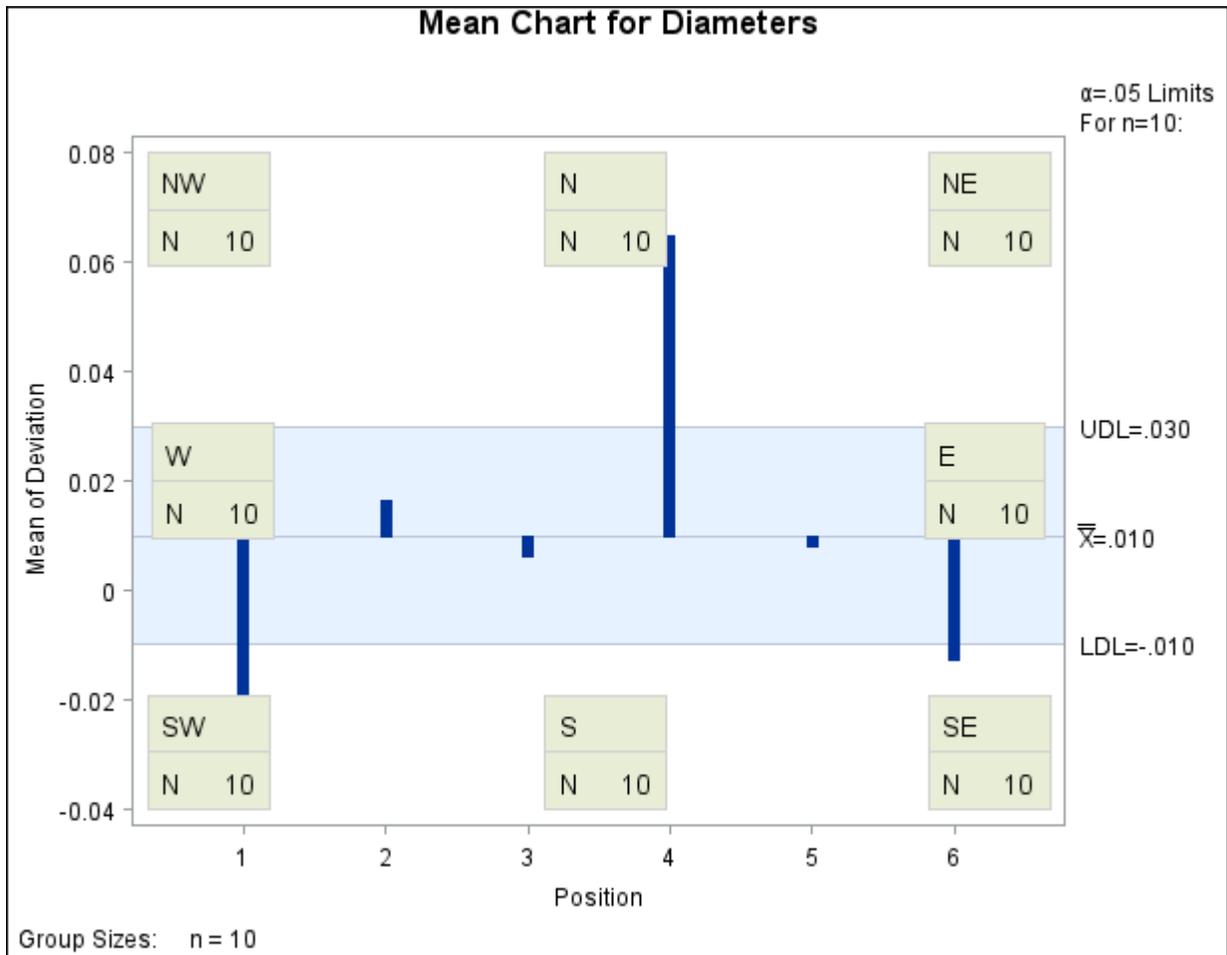

```
ods graphics off;
title 'Mean Chart for Diameters';
proc anom data=LabelDeviations;
  xchart Deviation*Position;
  inset n / height=3 cfill=ywh header='NW' pos=nw;
  inset n / height=3 cfill=ywh header='N ' pos=n ;
```

```

inset n / height=3 cfill=ywh header='NE' pos=ne;
inset n / height=3 cfill=ywh header='E ' pos=e ;
inset n / height=3 cfill=ywh header='SE' pos=se;
inset n / height=3 cfill=ywh header='S ' pos=s ;
inset n / height=3 cfill=ywh header='SW' pos=sw;
inset n / height=3 cfill=ywh header='W ' pos=w ;
run;

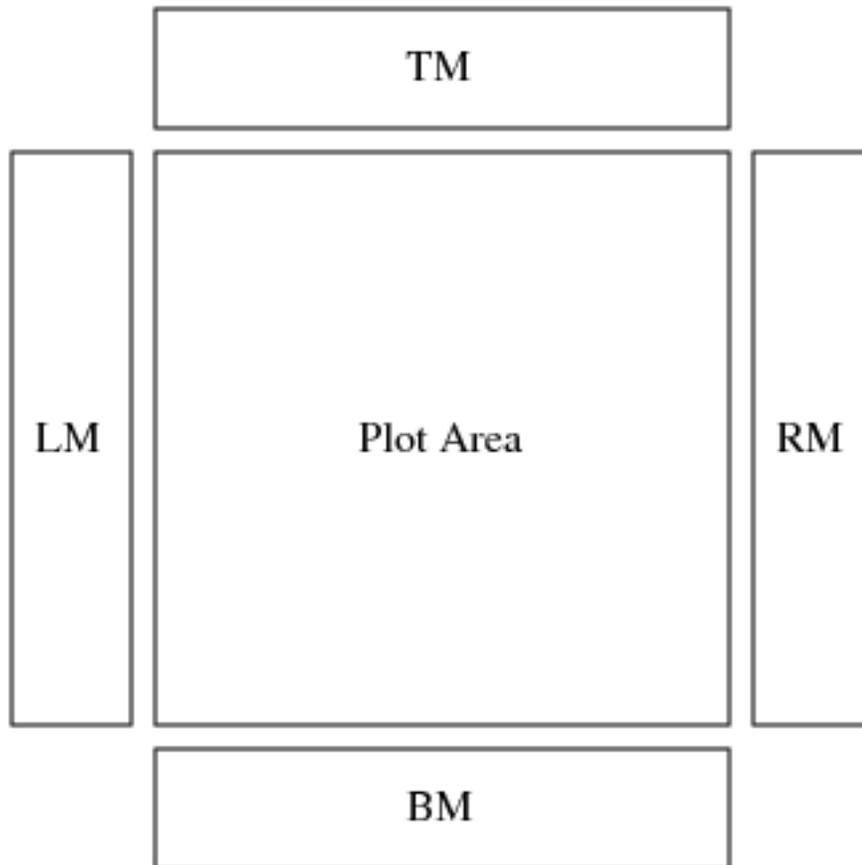

```

Figure 4.32 Insets Positioned Using Compass Points

Positioning the Inset in the Margins

Using the INSET statement you can also position an inset in one of the four margins surrounding the plot area using the margin keywords LM, RM, TM, or BM, as illustrated in Figure 4.7.4.

Output 4.7.4 Positioning Insets in the Margins

For an example of an inset placed in the right margin, see [Figure 4.30](#). Margin positions are recommended if a large number of statistics are listed in the INSET statement. If you attempt to display a lengthy inset in the interior of the plot, it is likely that the inset will collide with the data display.

Positioning the Inset Using Coordinates

You can also specify the position of the inset with coordinates: POSITION= (x, y). The coordinates can be given in axis percent units (the default) or in axis data units.

See ANMIN5 in the SAS/QC Sample Library

Data Unit Coordinates

If you specify the DATA option immediately following the coordinates, the inset is positioned using axis data units. For example, the following statements place the bottom left corner of the inset at 2 on the horizontal axis and 0.04 on the vertical axis:

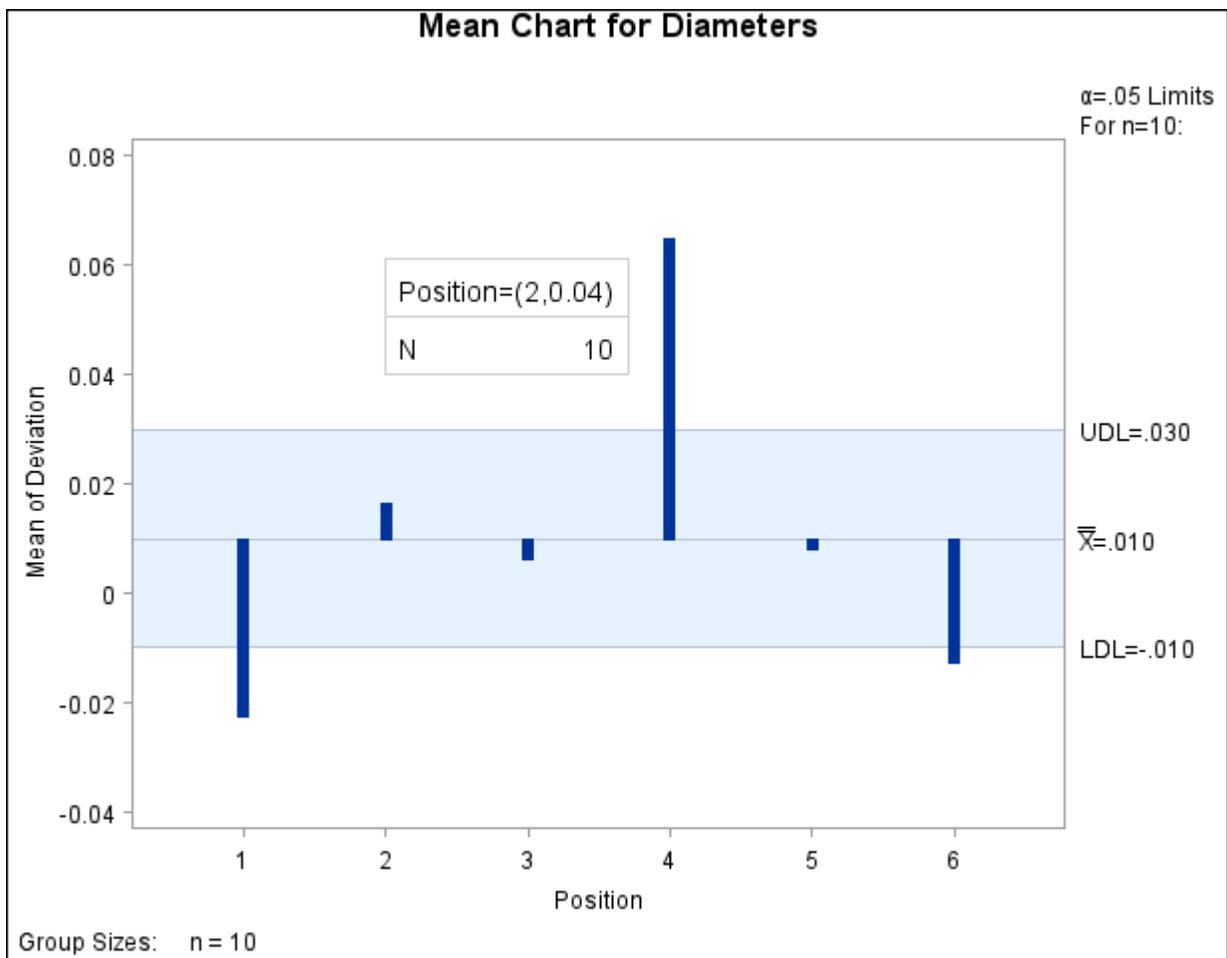

```

title 'Mean Chart for Diameters';
proc anom data=LabelDeviations;
  xchart Deviation*Position;
  inset n /
    header   = 'Position=(2,0.04) '
    height   = 3
    position = (2,0.04) data;
run;

```

The ANOM chart is displayed in Figure 4.33. By default, the specified coordinates determine the position of the bottom left corner of the inset. You can change this reference point with the REFPOINT= option, as in the next example.

Figure 4.33 Inset Positioned Using Data Unit Coordinates

Axis Percent Unit Coordinates

If you do not use the DATA option, the inset is positioned using axis percent units. The coordinates of the bottom left corner of the display are (0, 0), while the upper right corner is (100, 100). For example, the following statements create an ANOM chart with two insets, both positioned using coordinates in axis percent units:

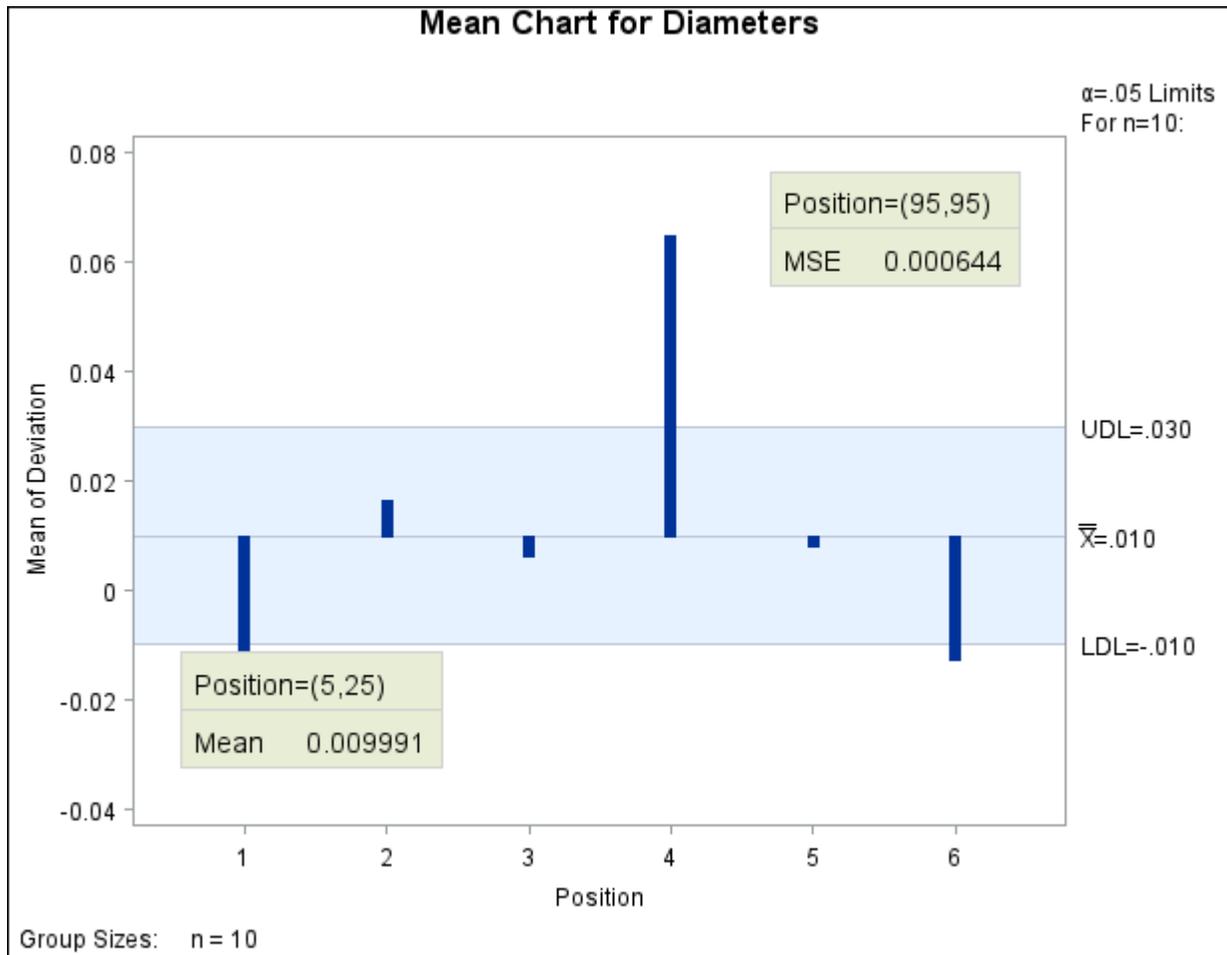

```

title 'Mean Chart for Diameters';
proc anom data=LabelDeviations;
  xchart Deviation*Position;
  inset mean / position = (5,25)
    header = 'Position=(5,25) '
    height = 3
    cfill = ywh
    refpoint = tl;
  inset mse / position = (95,95)
    header = 'Position=(95,95) '
    height = 3
    cfill = ywh
    refpoint = tr;
run;

```

The display is shown in Figure 4.34. Notice that the REFPOINT= option is used to determine which corner of the inset is to be placed at the coordinates specified with the POSITION= option. The first inset has REFPOINT=TL, so the top left corner of the inset is positioned 5% of the way across the horizontal axis and 25% of the way up the vertical axis. The second inset has REFPOINT=TR, so the top right corner of the inset is positioned 95% of the way across the horizontal axis and 95% of the way up the vertical axis. Note also that coordinates in axis percent units must be *between* 0 and 100.

Figure 4.34 Inset Positioned Using Axis Percent Unit Coordinates

Dictionary of ANOM Chart Statement Options

This chapter provides detailed descriptions of options that you can specify in the following chart statements:

- BOXCHART
- PCHART
- UCHART
- XCHART

Options that are common to the ANOM and SHEWHART procedures are listed in the “Summary of Options” section in the chapters for each chart statement. They are described in detail in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018

Options are specified after the slash (/) in a chart statement. For example, to place the label “Mean” on the center line of an ANOM chart, you can use the XSYMBOL= option as follows:

```
proc anom data=Measures;
  xchart Length*Sample / xsymbol='Mean';
run;
```

The options described in this chapter are listed alphabetically. For tables of options organized by function, see the “Summary of Options” sections in the chapters for the various chart statements.

Unless indicated otherwise, the options listed here are available with every chart statement. The marginal note *Traditional Graphics* identifies options that apply only to traditional graphics output.

ALPHA=*value*

specifies the probability of a Type I error.

CINFILL=*color* | **EMPTY** | **NONE**

specifies the color for the area inside the decision limits. By default, this area filled with an appropriate color from the ODS style. You can specify the keyword EMPTY or NONE to leave the area between the decision limits unfilled.

CLIMITS=*color*

Traditional Graphics

specifies the color for the decision limits, the central line, and related labels.

DFE=*n*

specifies the degrees of freedom *n* associated with the root mean square error.

GROUPN=*value*

GROUPN=*variable*

specifies the group sizes as a constant *value* or as the values of a variable in the DATA= data set. The GROUPN= option is available only in the PCHART and UCHART statements. You must specify GROUPN= in a PCHART or UCHART statement when your input data set is a DATA= data set.

If you specify multiple *responses* in a chart statement, the GROUPN= option is used with all of the *responses* listed.

LDLLABEL='label'

specifies a label for the lower decision limit in the ANOM chart. The label can be of length 16 or less. Enclose the label in quotes. The default label is of the form LDL=value if the decision limit has a fixed value; otherwise, the default label is LDL. A related option is UDLLABEL=.

LIMITK=k

specifies the number of groups for computing decision limits.

LIMITN=n

specifies either a nominal sample size for fixed decision limits or varying limits.

LIMLABSUBCHAR='c'

specifies a substitution character *c* for labels provided as quoted strings with the LDLLABEL=, UDLLABEL=, PSYMBOL=, USYMBOL=, and XSYMBOL= options. The substitution character must appear in the label. When the label is displayed on the chart, the character is replaced with the value of the corresponding decision limit or center line, provided that this value is constant across groups. Otherwise, the default label for a varying decision limit or center line is displayed.

LLIMITS=linetype

specifies the line type for decision limits.

Traditional Graphics

MEAN=value

specifies the (known) mean of the response. This value is used for each response specified in the chart statement.

MSE=value

specifies the mean square error.

NDECIMAL=

specifies the number of digits to the right of decimal place in default labels for decision limits and central line

NOCTL

suppresses display of the central line.

NOLDL

suppresses display of the lower decision limit.

NOLIMITLABEL

suppresses labels for the decision limits and central line.

NOLIMIT0

suppresses display of the lower decision limit if it is 0.

NOLIMIT1

suppresses display of the upper decision limit if it is 1 (100%).

NOLIMITS

suppresses display of the decision limits.

NOLIMITSFRAME

suppresses the default frame around decision limit information when multiple sets of decision limits are read from a LIMITS= data set.

NOLIMITSLEGEND

suppresses the decision limits legend.

NONEEDLES

suppresses the needles connecting points to the center line.

NOREADLIMITS

specifies that the decision limits for each *responde* listed in the chart statement are *not* to be read from the LIMITS= data set specified in the PROC ANOM statement. There are two basic methods of displaying decision limits: calculating decision limits from the data and reading decision limits from a LIMITS= data set. If you specify a LIMITS= data set but want the decision limits to be calculated from the data, specify the NOREADLIMITS option.

NOUDL

suppresses display of the upper decision limit.

OUTSUMMARY=SAS-data-set**OUT=SAS-data-set****OUTHISTORY=SAS-data-set**

creates an output data set that contains group summary statistics. You can use an OUTSUMMARY= data set as a SUMMARY= input data set in a subsequent run of the procedure. You cannot request an OUTSUMMARY= data set if the input data set is a TABLE= data set. See “Output Data Sets” in the chapter for the chart statement in which you are interested.

P=

specifies the weighted average of group proportions.

PSYMBOL='label'

specifies the label for the central line on an ANOM *p* chart.

READINDEXES=

reads multiple sets of decision limits for each *response* from a LIMITS= data set.

TYPE=

identifies parameters as estimates or standard values and specifies value of `_TYPE_` in the OUTLIMITS= data set.

U=

specifies the weighted average of group rates.

UDLLABEL=

specifies the label for the upper decision limit.

USYMBOL='label'

specifies the label for the central line on an ANOM *u* chart.

WLIMITS=

specifies the width for the decision limits and central line.

Traditional Graphics

XSYMBOL='label'

specifies the label for the central line on an ANOM chart or ANOM boxchart.

Introduction: CAPABILITY Procedure

A process capability analysis compares the distribution of output from an in-control process to its specification limits to determine the consistency with which the specifications can be met. The CAPABILITY procedure provides the following:

- process capability indices, such as C_p and C_{pk}
- descriptive statistics based on moments, including skewness and kurtosis. Other descriptive information provided includes quantiles or percentiles (such as the median), frequency tables, and details on extreme values.
- histograms and comparative histograms. Optionally, these can be superimposed with specification limits, fitted probability density curves for various distributions, and kernel density estimates.
- cumulative distribution function plots (cdf plots). Optionally, these can be superimposed with specification limits and probability distribution curves for various distributions.
- quantile-quantile plots (Q-Q plots), probability plots, and probability-probability plots (P-P plots). These plots facilitate the comparison of a data distribution with various theoretical distributions. Optionally, Q-Q plots and probability plots can be superimposed with specification limits.
- goodness-of-fit tests for a variety of distributions including the normal. The assumption of normality is critical to the interpretation of capability indices.
- statistical intervals (prediction, tolerance, and confidence intervals) for a normal population
- the ability to produce plots either as traditional graphics, ODS Graphics output, or legacy line printer plots. Traditional graphics can be saved, replayed, and annotated.
- the ability to inset summary statistics and capability indices in graphical output
- the ability to analyze data sets with a frequency variable
- the ability to read specification limits from a data set
- the ability to create output data sets containing summary statistics, capability indices, histogram intervals, parameters of fitted curves, and statistical intervals

You can use the PROC CAPABILITY statement, together with the VAR and SPEC statements, to compute summary statistics and process capability indices. See “Getting Started: CAPABILITY Procedure” on page 206 for introductory examples. In addition, you can use the statements summarized in Table 5.1 to request plots and specialized analyses:

Table 5.1 Statements for Plots and Specialized Analyses

Statement	Result
CDFPLOT	cumulative distribution function plot
COMPHISTOGRAM	comparative histogram
HISTOGRAM	histogram
INSET	inset table on plot
INTERVALS	statistical intervals
OUTPUT	output data set with summary statistics and capability indices
PPPLOT	probability-probability plot
PROBPLOT	probability plot
QQPLOT	quantile-quantile plot

You have three alternatives for producing plots with the CAPABILITY procedure:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

You can use the INSET statement with any of the plot statements to enhance the plot with an inset table of summary statistics. The INSET statement is not applicable when you produce line printer plots.

Learning about the CAPABILITY Procedure

To learn about the CAPABILITY procedure, first select the appropriate statement [Table 5.1](#). Then refer to the corresponding “Getting Started” section for introductory examples:

- “Getting Started: CDFPLOT Statement” on page 266
- “Getting Started: COMPHISTOGRAM Statement” on page 286
- “Getting Started: HISTOGRAM Statement” on page 310
- “Getting Started: INSET Statement” on page 397
- “Getting Started: INTERVALS Statement” on page 428
- “Getting Started: OUTPUT Statement” on page 439
- “Getting Started: PPLOT Statement” on page 456
- “Getting Started: PROBLOT Statement” on page 478
- “Getting Started: QQPLOT Statement” on page 509

To broaden your knowledge of the procedure, read “[PROC CAPABILITY and General Statements](#)” on page 204 which summarizes the syntax for the entire procedure and describes the [PROC CAPABILITY](#) statement, the [VAR](#) statement, the [CLASS](#) statement, and the [SPEC](#) statement. Subsequent chapters describe the statements listed in [Table 5.1](#). In addition to introductory examples, each chapter provides syntax summaries, descriptions of options, computational details, and advanced examples. Although the chapters are self-contained, much of what you learn about one plot statement, including the syntax, is transferable to other plot statements.

PROC CAPABILITY and General Statements

Overview: CAPABILITY Procedure

This chapter describes several statements that are generally used with the CAPABILITY procedure:

- The PROC CAPABILITY statement is required to invoke the CAPABILITY procedure. You can use this statement by itself to compute summary statistics.
- The VAR statement, which is optional, specifies the variables in the input data set that are to be analyzed. These are called the analysis or *process* variables. By default, all of the numeric variables are analyzed.
- The CLASS statement, which is optional, specifies one or two variables that group the data into classification levels. A separate analysis is carried out for each combination of levels, and you can use the CLASS statement with plot statements (such as HISTOGRAM) to create comparative displays.¹
- The SPEC statement, which is optional, provides specification limits for the variables that are to be analyzed. When you use a SPEC statement, the procedure computes process capability indices in addition to summary statistics. Furthermore, the specification limits are displayed in plots created with plot statements that are described in subsequent chapters.

You can use the PROC CAPABILITY statement to request a variety of statistics for summarizing the data distribution of each analysis variable:

- sample moments
- basic measures of location and variability
- confidence intervals for the mean, standard deviation, and variance
- tests for location
- tests for normality
- trimmed and Winsorized means
- robust estimates of scale
- quantiles and related confidence intervals
- extreme observations and extreme values
- frequency counts for observations
- missing values

¹You can use the COMPHISTOGRAM statement to create comparative histograms without applying classification levels to the overall analysis.

You can use the `PROC CAPABILITY` and `SPEC` statements together to request a variety of statistics for process capability analysis:

- percents of measurements within and outside specification limits
- confidence intervals for the probabilities of exceeding the specification limits
- standard capability indices and related confidence intervals
- tests of normality in conjunction with capability indices
- specialized capability indices

In addition, you can use options in the `PROC CAPABILITY` statement to

- specify the input data set to be analyzed
- specify an input data set containing specification limits
- specify a graphics catalog for saving traditional graphics output
- specify rounding units for variable values
- specify the definition used to calculate percentiles
- specify the divisor used to calculate variances and standard deviations
- request legacy line printer plots and define special printing characters used for features
- suppress tables

You can use options in the `SPEC` statement to

- provide lower and upper specification limits and target values
- control the appearance of specification lines on plots
- control the appearance of the areas under a histogram outside the specification limits

Getting Started: CAPABILITY Procedure

This section introduces the PROC CAPABILITY, VAR, and SPEC statements with examples that illustrate the most commonly used options.

Computing Descriptive Statistics

See CAPPROC in the SAS/QC Sample Library

The fluid weights of 100 drink cans are measured in ounces. The filling process is assumed to be in statistical control. The measurements are saved in a SAS data set named Cans.

```
data Cans;
  label Weight = "Fluid Weight (ounces)";
  input Weight @@;
  datalines;
12.07 12.02 12.00 12.01 11.98 11.96 12.04 12.05 12.01 11.97
12.03 12.03 12.00 12.04 11.96 12.02 12.06 12.00 12.02 11.91
12.05 11.98 11.91 12.01 12.06 12.02 12.05 11.90 12.07 11.98
12.02 12.11 12.00 11.99 11.95 11.98 12.05 12.00 12.10 12.04
12.06 12.04 11.99 12.06 11.99 12.07 11.96 11.97 12.00 11.97
12.09 11.99 11.95 11.99 11.99 11.96 11.94 12.03 12.09 12.03
11.99 12.00 12.05 12.04 12.05 12.01 11.97 11.93 12.00 11.97
12.13 12.07 12.00 11.96 11.99 11.97 12.05 11.94 11.99 12.02
11.95 11.99 11.91 12.06 12.03 12.06 12.05 12.04 12.03 11.98
12.05 12.05 12.11 11.96 12.00 11.96 11.96 12.00 12.01 11.98
;
```

You can use the PROC CAPABILITY and VAR statements to compute summary statistics for the weights.

```
title 'Process Capability Analysis of Fluid Weight';
proc capability data=Cans normaltest;
  var Weight;
run;
```

The input data set is specified with the DATA= option. The NORMALTEST option requests tests for normality. The VAR statement specifies the variables to analyze. If you omit the VAR statement, all numeric variables in the input data set are analyzed.

The descriptive statistics² for Weight are shown in Figure 5.1. For instance, the average weight (labeled *Mean*) is 12.0093. The Shapiro-Wilk test statistic labeled *W* is 0.987876, and the probability of a more extreme value of *W* (labeled *Pr < W*) is 0.499. Compared to the usual cutoff value of 0.05, this probability (referred to as a *p*-value) indicates that the weights are normally distributed.

²In SAS 7, the *Moments* table was reorganized. Tables for *Basic Statistical Measures*, *Tests for Location*, and *Tests for Normality* have been added.

Computing Capability Indices

See CAPPROC in the SAS/QC Sample Library This example is a continuation of the previous example and shows how you can provide specification limits with a SPEC statement to request capability indices in addition to descriptive statistics.

```
proc capability data=Cans normaltest freq;
  spec lsl=11.95 target=12 usl=12.05;
  var Weight;
run;
```

The options LSL=, TARGET=, and USL= specify the lower specification limit, target value, and upper specification limit for the weights. These statements produce the output shown in Figure 5.2 in addition to the output shown in Figure 5.1.

Figure 5.2 Capability Indices and Frequency Table

```

```

In Figure 5.2, the table labeled *Specification Limits* lists the specification limits and target value, together with the percents of observations outside and between the limits. The table labeled *Process Capability Indices* lists estimates for the standard process capability indices³ C_p , C_{PL} , C_{PU} , C_{pk} , and C_{pm} , along with 95% confidence limits. The index C_{pm} is not computed unless you specify a TARGET= value. See “Standard Capability Indices” on page 245 for formulas used to compute the indices.

If you specify more than one variable in the VAR statement, you can provide corresponding specification limits and target values by specifying lists of values for the LSL=, USL=, and TARGET=

³In SAS 6.12 and earlier releases, the capability index k was also included in this table; this index is now provided in the table labeled *Specialized Capability Indices*, which you can request with the SPECIALINDICES option.

options. As an alternative to the SPEC statement, you can read specification limits and target values from a data set specified with the SPEC= option in the PROC CAPABILITY statement. This is illustrated in Example 5.1.

The FREQ option in the PROC CAPABILITY statement requests the table labeled *Frequency Counts* in Figure 5.2.

Syntax: CAPABILITY Procedure

The following are the primary statements that control the CAPABILITY procedure:

```

PROC CAPABILITY < options > ;
  VAR variables ;
  CLASS variable-1 < variable-2 > < / options > ;
  SPEC < options > ;
  CDFPLOT < variables > < / options > ;
  COMPHISTOGRAM < variables > / CLASS= (class-variables) < options > ;
  HISTOGRAM < variables > < / options > ;
  PPLOT < variables > < / options > ;
  PROBPLOT < variables > < / options > ;
  QQPLOT < variables > < / options > ;
  INSET keyword-list < / options > ;
  INTERVALS < variables > < / options > ;
  OUTPUT < OUT= SAS-data-set > < keyword1=names . . . keywordk=names > ;

```

The PROC CAPABILITY statement invokes the procedure. The VAR statement specifies the numeric variables to be analyzed, and it is required if the OUTPUT statement is used to save summary statistics and capability indices in an output data set. If you do not use the VAR statement, all numeric variables in the data set are analyzed. The SPEC statement provides specification limits.

The plot statements (CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PPLOT, PROBPLOT, and QQPLOT) create graphical displays, and the INSET statement enhances these displays by adding a table of summary statistics directly on the graph. The INTERVALS statement computes statistical intervals. You can specify one or more of each of the plot statements, the INSET statement, the INTERVALS statement, and the OUTPUT statement. If you use a VAR statement, the variables listed in a plot statement must be a subset of the variables listed in the VAR statement.

BY Statement

```

BY variables ;

```

You can specify a BY statement with PROC CAPABILITY to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the NOTSORTED or DESCENDING option in the BY statement for the CAPABILITY procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ, WEIGHT, and ID Statements

In addition, you can optionally specify one of each of the following statements:

FREQ *variable* ;

WEIGHT *variable* ;

ID *variable* ;

The FREQ statement names a variable that provides frequencies for each observation in the input data set. If n is the value of the FREQ variable for a given observation, then that observation is used n times. If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

The WEIGHT statement names a variable that provides weights for each observation in the input data set. The CAPABILITY procedure uses the values w_i of the WEIGHT variable to modify the computation of a number of summary statistics by assuming that the variance of the i th value X_i of the analysis variable is equal to σ^2/w_i , where σ is an unknown parameter. This assumption is rarely applicable in process capability analysis, and the purpose of the WEIGHT statement is simply to make the CAPABILITY procedure consistent with other data summarization procedures, such as the UNIVARIATE procedure.

The values of the WEIGHT variable do not have to be integers and are typically positive. By default, observations with non-positive or missing values of the WEIGHT variable are handled as follows⁴:

- If the value is zero, the observation is counted in the total number of observations.
- If the value is negative, it is converted to zero, and the observation is counted in the total number of observations.
- If the value is missing, the observation is excluded from the analysis.

To exclude observations that contain negative and zero weights from the analysis, specify the option EXCLNPWGT in the PROC statement. Note that most SAS/STAT[®] procedures, such as PROC GLM, exclude negative and zero weights by default.

When you specify a WEIGHT variable, the procedure uses its values, w_i , to compute weighted versions of the statistics⁵ provided in the *Moments* table. For example, the procedure computes a

⁴In SAS 6.12 and earlier releases, observations were used in the analysis if and only if the WEIGHT variable value was greater than zero.

⁵In SAS 6.12 and earlier releases, weighted skewness and kurtosis were not computed.

weighted mean \bar{X}_w and a weighted variance s_w^2 as $\bar{X}_w = \frac{\sum_i w_i x_i}{\sum_i w_i}$ and $s_w^2 = \frac{1}{d} \sum_i w_i (x_i - \bar{X}_w)^2$ where x_i is the i th variable value. The divisor d is controlled by the VARDEF= option in the PROC CAPABILITY statement.

When you use both the WEIGHT and SPEC statements, capability indices are computed using \bar{X}_w and s_w in place of \bar{X} and s . Again, note that weighted capability indices are seldom needed in practice.

When you specify a WEIGHT statement, the procedure also computes a weighted standard error and a weighted version of Student's t test. This test is the only test of location that is provided when weights are specified.

The WEIGHT statement does not affect the determination of the mode, extreme values, extreme observations, or the number of missing values of the analysis variables. However, the weights w_i are used to compute weighted percentiles⁶.

The WEIGHT variable has no effect on the calculation of extreme values, and it has no effect on graphical displays produced with the plot statements.

Graphical Enhancement Statements

You can use TITLE, FOOTNOTE, and NOTE statements to enhance printed output. If you are creating traditional graphics, you can also use AXIS, LEGEND, PATTERN, and SYMBOL statements to enhance your plots. For details, see SAS/GRAPH documentation and the chapter for the plot statement that you are using.

PROC CAPABILITY Statement

The syntax for the PROC CAPABILITY statement is as follows:

```
PROC CAPABILITY <options> ;
```

The following section lists all *options*. See the section “Dictionary of Options” on page 214 for detailed information.

Summary of Options

Table 5.2 lists all the PROC CAPABILITY *options* by function.

Table 5.2 PROC CAPABILITY Statement Options

Option	Description
Input Data Set Options	
ANNOTATE=	specifies input data set containing annotation information
DATA=	specifies input data set
EXCLNPWGT	specifies that non-positive weights are to be excluded
NOBYSPECS	specifies that specification limits in SPEC= data set are to be applied to all BY groups
SPEC=	specifies input data set with specification limits

⁶In SAS 6.12 and earlier releases, the weights did not affect the computation of percentiles.

Table 5.2 continued

Option	Description
Plotting and Graphics Options	
FORMCHAR(<i>index</i>)=	defines characters used for features on legacy line printer plots
GOUT=	specifies catalog for saving traditional graphics output
LINEPRINTER	requests legacy line printer plots
Computational Options	
PCTLDEF=	specifies definition used to calculate percentiles
ROUND=	specifies units used to round variable values
VARDEF=	specifies divisor used to calculate variances and standard deviations
Data Summary Options	
ALL	requests all tables
FREQ	requests frequency table
MODES	requests table of modes
NEXTROBS=	requests table of n lowest, n highest observations
NEXTRVAL=	requests table of n lowest, n highest values
Output Options	
NOPRINT	suppresses printed output
OUTTABLE=	creates an output data set containing univariate statistics and capability indices in tabular form
Hypothesis Testing Options	
MU0=	specifies mean for null hypothesis in tests for location
LOCCOUNT	requests table of counts used in sign test and signed rank test
NORMALTEST	performs tests for normality
Robust Estimation Options	
ROBUSTSCALE	requests table of robust measures of scale
TRIMMED=(<i>trimmed-options</i>)	requests table of trimmed means
WINSORIZED=(<i>Winsorized-options</i>)	requests table of Winsorized means
TRIMMED-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit
WINSORIZED-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit
Capability Index Options	
CPMA=	(obsolete) specifies a for $C_{pm}(a)$
CHECKINDICES	requests test of normality in conjunction with standard indices
SPECIALINDICES	requests table of specialized indices including Boyles' C_{pm} , C_{jkp} , C_{pmk} , $C_{pm}(a)$, and Wright's C_s
CHECKINDICES-Options	
ALPHA=	specifies cutoff probability for p -values for test for normality used in conjunction with process capability indices

Table 5.2 continued

Option	Description
TEST=	specifies test for normality (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling, Cramér-von Mises, or no test)
Confidence Limit Options	
ALPHA=	specifies level for all confidence limits
CIBASIC	requests confidence limits for the mean, standard deviation, variance
CIINDICES	specifies level and type of confidence limits for capability indices
CIPCTLDF	requests distribution-free confidence limits for percentiles
CIPCTLNORMAL	requests confidence limits for percentiles assuming normality
CIPROBEX	requests confidence limits for the probability of exceeding specifications
CIBASIC-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit
CIINDICES-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit
CIPCTLDF-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit
CIPCTLNORMAL-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit
CIPROBEX-Options	
ALPHA=	specifies confidence level
TYPE=	specifies type of confidence limit

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the PROC CAPABILITY statement. The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply to traditional graphics and line printer plots, respectively.

ALL

requests all of the tables generated by the `FREQ`, `MODES`, `NEXTRVAL=5`, `CIBASIC`, `CIPCTLDF`, and `CIPCTLNORMAL` options. If a `WEIGHT` statement is not used, the `ALL` option also requests the tables generated by the `LOCCOUNT`, `NORMALTEST`, `ROBUSTSCALE`, `TRIMMED=.25`, and `WINSORIZED=.25` options. PROC CAPABILITY uses any values that you specify with the `ALPHA=`, `MUO=`, `NEXTRVAL=`, `CIBASIC`, `CIPCTLDF`, `CIPCTLNORMAL`, `TRIMMED=`, or `WINSORIZED=` options in conjunction with the `ALL` option.

ALPHA=*value*

specifies the default confidence level for all confidence limits computed by the CAPABILITY procedure⁷. The coverage percent for the confidence limits is $(1 - \textit{value})100$. For example, ALPHA=0.10 results in 90% confidence limits. The default *value* is 0.05.

Note that specialized ALPHA= options are available for a number of confidence interval options. For example, you can specify CIBASIC(ALPHA=0.10) to request a table of *Basic Confidence Limits* at the 90% level. The default values of these options default to the value of the general ALPHA= option.

ANNOTATE=*SAS-data-set***ANNO=***SAS-data-set*

specifies an input data set containing annotate variables as described in SAS/GRAPH documentation. You can use this data set to add features to traditional graphics. Use this data set only when creating traditional graphics; it is ignored when the LINEPRINTER option is specified and when ODS Graphics is in effect. Features provided in this data set are added to every plot produced in the current run of the procedure. *Traditional Graphics*

CHECKINDICES< (TEST = SW | KS | AD | CVM | NONE > < ALPHA=*value*>)

specifies the test of normality used in conjunction with process capability indices that are displayed in the *Process Capability Indices* table. If the *p*-value for the test is less than the cutoff probability value specified with the ALPHA= option⁸, a warning is added to the table, as illustrated in [Figure 5.3](#). See “Tests for Normality” on page 236 for details concerning the test.

```
proc capability data=Process;
var p2;
specs lsl=10
      usl=275;
run;
```

⁷In SAS 6.12 and earlier releases, the level for confidence limits for capability indices was specified with the GAMMA= option in the SPEC statement. This option still works but is considered obsolete.

⁸In SAS 6.12 and earlier releases, this value was specified with the ALPHA= option in the SPEC statement. This option still works but is considered obsolete.

Figure 5.3 Warning Message Printed with Capability Indices

Process Capability Analysis of Fluid Weight			
The CAPABILITY Procedure			
Variable: P2			
Process Capability Indices			
Index	Value	95% Confidence Limits	
Cp	0.541072	0.388938	0.692946
CPL	0.642426	0.417087	0.862984
CPU	0.439718	0.257339	0.617184
Cpk	0.439718	0.259310	0.620126

Warning: Normality is rejected for alpha = 0.05 using the Shapiro-Wilk test

ALPHA=value

specifies the cutoff probability for p -values for a test for normality used in conjunction with process capability indices. The *value* must be between zero and 0.5. The default value is 0.05.

TEST = SW | KS | AD | CVM | NONE

specifies the test of normality used in conjunction with process capability indices that are displayed in the *Process Capability Indices* table. The tests available are Shapiro-Wilk (SW), Kolmogorov-Smirnov (KS), Anderson-Darling (AD), and Cramér-von Mises (CVM). The default test is the Shapiro-Wilk test if the sample size is less than or equal to 2000 and the Kolmogorov-Smirnov test if the sample size is greater than 2000.

CIBASIC<(< **TYPE=keyword** > < **ALPHA=value** >)>

requests confidence limits for the mean, standard deviation, and variance based on the assumption that the data are normally distributed. With large sample sizes, this assumption is not required for confidence limits for the mean.

ALPHA=value

specifies the confidence level. The coverage percent for the confidence limits is $(1 - \text{value})100$. For example, ALPHA=0.10 requests 90% confidence limits. The default value is 0.05.

TYPE=keyword

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default value is TWOSIDED.

CIINDICES<(**TYPE=keyword** > < **ALPHA=value** >)>

specifies the type and level of the confidence limits for standard capability indices displayed in the table labeled *Process Capability Indices*.

ALPHA=value

specifies the confidence level. The coverage percent for the confidence limits is $(1 - \text{value})100$. For example, ALPHA=0.10 requests 90% confidence limits. The default value is 0.05.

TYPE=keyword

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default value is TWOSIDED.

CIPCTLDF<(TYPE=keyword >< ALPHA=value >)**CIQUANTDF<(TYPE=keyword >< ALPHA=value >)**

requests confidence limits for quantiles computed using a distribution-free method. In other words, no specific parametric distribution (such as the normal) is assumed for the data. Order statistics are used to compute the confidence limits as described in Section 5.2 of Hahn and Meeker (1991). This option is not available if you specify a WEIGHT statement.

ALPHA=value

specifies the confidence level. The coverage percent for the confidence limits is $(1 - \text{value})100$. For example, ALPHA=0.10 requests 90% confidence limits. The default value is 0.05.

TYPE=keyword

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, SYMMETRIC, or ASYMMETRIC. The default value is SYMMETRIC.

CIPCTLNORMAL<(TYPE=keyword >< ALPHA=value >)**CIQUANTNORMAL<(TYPE=keyword > < ALPHA=value >)**

requests confidence limits for quantiles based on the assumption that the data are normally distributed. The computational method is described in Section 4.4.1 of Hahn and Meeker (1991) and uses the noncentral *t* distribution as given by Odeh and Owen (1980). This option is not available if you specify a WEIGHT statement.

ALPHA=value

specifies the confidence level. The coverage percent for the confidence limits is $(1 - \text{value})100$. For example, ALPHA=0.10 requests 90% confidence limits. The default value is 0.05.

TYPE=keyword

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default value is TWOSIDED.

CIPROBEX<(TYPE=keyword >< ALPHA=value >)

requests confidence limits for $Pr[X \leq \text{LSL}]$ and $Pr[X \geq \text{USL}]$, where *X* is the analysis variable, LSL is the lower specification limit, and USL is the upper specification limit. The computational method, which assumes that *X* is normally distributed, is described in Section 4.5 of Hahn and Meeker (1991) and uses the noncentral *t* distribution as given by Odeh and Owen (1980). This option is not available if you specify a WEIGHT statement.

ALPHA=*value*

specifies the confidence level. The coverage percent for the confidence limits is $(1 - \textit{value})100$. For example, ALPHA=0.10 requests 90% confidence limits. The default value is 0.05.

TYPE=*keyword*

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default value is TWOSIDED.

CPMA=*value*

specifies the *value* of the parameter *a* for the capability index $C_{pm}(a)$. This option has been superseded by the SPECIALINDICES(CPMA=) option.

DATA=*SAS-data-set*

specifies the input data set containing the observations to be analyzed. If the DATA= option is omitted, the procedure uses the most recently created SAS data set.

DEF=*index*

is an alias for the PCTLDEF= option. See the entry for the PCTLDEF= option.

EXCLNPWGT

excludes observations with non-positive weight values (zero or nonnegative) for the analysis. By default, PROC CAPABILITY treats observations with negative weights like those with zero weights and counts them in the total number of observations. This option is applicable only if you specify a WEIGHT statement.

FORMCHAR(*index*)=*'string'*

Line Printer

defines characters used for features on legacy line printer plots, where *index* is a number ranging from 1 to 11, and *string* is a character or hexadecimal string. The *index* identifies which features are controlled with the *string* characters, as discussed in the table that follows. If you specify the FORMCHAR= option omitting the *index*, the *string* controls all 11 features.

By default, the form character list specified with the SAS system option FORMCHAR= is used; otherwise, the default is FORMCHAR=' |---|+|--'. If you print to a PC screen or your device supports the ASCII symbol set (1 or 2), the following is recommended:

```
formchar='B3,C4,DA,C2,BF,C3,C5,B4,C0,C1,D9'X
```

As an example, suppose you want to plot the data values of the empirical cumulative distribution function with asterisks (*). You can change the appropriate character by using the following:

```
formchar(2)='*'
```

Note that the FORMCHAR= option in the PROC CAPABILITY statement enables you to temporarily override the values of the SAS system option with the same name. The values of the SAS system option are not altered by using the FORMCHAR= option in PROC CAPABILITY statement.

The features associated with values of *index* are as follows:

Value of <i>index</i>	Description of Character	Chart Feature
1	vertical bar	frame, ecdf line, HREF= lines
2	horizontal bar	frame, ecdf line, VREF= lines
3	box character (upper left)	frame, ecdf line, histogram bars
4	box character (upper middle)	histogram bars, tick marks (horizontal axis)
5	box character (upper right)	frame, histogram bars
6	box character (middle left)	histogram bars
7	box character (middle middle)	not used
8	box character (middle right)	histogram bars, tick marks (vertical axis)
9	box character (lower left)	frame
10	box character (lower middle)	histogram bars
11	box character (lower right)	frame, ecdf line

FREQ

requests a frequency table in the printed output that contains the variable values, frequencies, percentages, and cumulative percentages. See [Figure 5.2](#) for an example.

GOUT=graphics-catalog

specifies a graphics catalog in which to save traditional graphics output.

Traditional Graphics

LINEPRINTER

requests that legacy line printer plots be produced by the CDFPLOT, HISTOGRAM, PROB- PLOT, PPLOT, and QQPLOT statements. By default, these statements create traditional graphics output.⁹ The **CLASS** and **COMPHISTOGRAM** statements cannot be used when the LINEPRINTER option is specified.

Line Printer

LOCCOUNT

requests a table with the number of observations greater than, not equal to, and less than the value of MUO=. PROC CAPABILITY uses these values to construct the sign test and signed rank test. This option is not available if you specify a WEIGHT statement.

MODES**MODE**

requests a table of all possible modes. By default, when the data contains multiple modes, PROC CAPABILITY displays the lowest mode in the table of basic statistical measures. When all values are unique, PROC CAPABILITY does not produce a table of modes.

⁹In SAS 6.12 and previous releases of SAS/QC software, line printer plots were created by default and the GRAPHICS option was required in the PROC CAPABILITY statement to produce traditional graphics output.

MU0=*value(s)*

LOCATION=*value(s)*

specifies the value of the mean or location parameter (μ_0) in the null hypothesis for the tests summarized in the table labeled *Tests for Location: Mu0=value*. If you specify a single value, PROC CAPABILITY tests the same null hypothesis for all analysis variables. If you specify multiple values, a VAR statement is required, and PROC CAPABILITY tests a different null hypothesis for each analysis variable by matching the VAR variables with the values in the corresponding order. The default value is 0.

NEXTROBS=*n*

specifies the number of extreme observations in the table labeled *Extreme Observations*. The table lists the *n* lowest observations and the *n* highest observations. The default value is 5. The value of *n* must be an integer between 0 and half the number of observations. You can specify NEXTROBS=0 to suppress the table.

NEXTRVAL=*n*

requests the table labeled *Extreme Values* and specifies the number of extreme values in the table. The table lists the *n* lowest unique values and the *n* highest unique values. The value of *n* must be an integer between 0 and half the maximum number of observations. By default, *n* = 0 and no table is displayed.

NOBYSPECS

specifies that specification limits in SPEC= data set be applied to all BY groups. If you use a BY statement and specify a SPEC= data set that does not contain the BY variables, you must specify the NOBYSPECS option.

NOPRINT

suppresses the tables of descriptive statistics and capability indices which are created by the PROC CAPABILITY statement. The NOPRINT option does not suppress the tables created by the INTERVALS or plot statements. You can use the NOPRINT options in these statements to suppress the creation of their tables.

NORMALTEST

NORMAL

requests a table of *Tests for Normality* for each of the analysis variables. The table provides test statistics and *p*-values for the Shapiro-Wilk test (provided the sample size is less than or equal to 2000), the Kolmogorov-Smirnov test, the Anderson-Darling test, and the Cramér-von Mises test. See “[Tests for Normality](#)” on page 236 for details. If specification limits are provided, the NORMALTEST option is assumed.

OUTTABLE=*SAS-data-set*

specifies an output data set that contains univariate statistics and capability indices arranged in tabular form. See “[OUTTABLE= Data Set](#)” on page 231 for details.

PCTLDEF=*index*

DEF=*index*

specifies one of five definitions used to calculate percentiles. The value of *index* can be 1, 2, 3, 4, or 5. See “[Percentile Computations](#)” on page 239 for details. By default, PCTLDEF=5.

ROBUSTSCALE

requests a table of robust measures of scale. These measures include the interquartile range, Gini's mean difference, the median absolute deviation about the median (*MAD*), and two statistics proposed by Rousseeuw and Croux (1993), Q_n , and S_n . This option is not available if you specify a **WEIGHT** statement.

ROUND=value-list

specifies units used to round variable values. The **ROUND=** option reduces the number of unique values for each variable and hence reduces the memory required for temporary storage. *Values* must be greater than 0 for rounding to occur.

If you use only one value, the procedure uses this unit for all variables. If you use a list of values, you must also use a **VAR** statement. The procedure then uses the roundoff values for variables in the order given in the **VAR** statement. For example, the following statements specify a roundoff value of 1 for **Yieldstrength** and a roundoff value of 0.5 for **TENSTREN**.

```
proc capability round=1 0.5;
    var Yieldstrength tenstren;
run;
```

When a variable value is midway between the two nearest rounded points, the value is rounded to the nearest even multiple of the roundoff value. For example, with a roundoff value of 1, the variable values of -2.5 , -2.2 , and -1.5 are rounded to -2 ; the values of -0.5 , 0.2 , and 0.5 are rounded to 0 ; and the values of 0.6 , 1.2 , and 1.4 are rounded to 1 .

SPECIALINDICES

requests a table of specialized process capability indices. These indices include k , Boyles' modified C_{pm} (also denoted as C_{pm+}), C_{jpk} , $C_{pm}(a)$, $C_p(5.15)$, $C_{pk}(5.15)$, C_{pmk} , Wright's C_s , Boyles' S_{jpk} , C_{pp} , C''_{pp} , C_{pg} , C_{pq} , C_p^W , C_{pk}^W , C_{pm}^W , C_{pc} , and Vännmann's $C_p(u, v)$ and $C_p(v)$.

You can provide values for the parameters a for $C_{pm}(a)$, u and v for $C_p(u, v)$ and $C_p(v)$, and for the γ multiplier for C_s by specifying the following options in parentheses after the **SPECIALINDICES** option.

CPMA=value

specifies the *value* of the parameter a for the capability index $C_{pm}(a)$ described in Section 3.7 of Kotz and Johnson (1993). The *value* must be positive. The default *value* is 0.5. The existing **CPMA=** option in the **PROC CAPABILITY** statement is considered obsolete but still works.

CPU=value

specifies the *value* of the parameter u for Vännmann's capability index $C_p(u, v)$. The *value* must be greater than or equal to zero. The default *value* is zero.

CPV=value

specifies the *value* of the parameter v for Vännmann's capability indices $C_p(u, v)$ and $C_p(v)$. The *value* must be greater than or equal to zero. The default *value* is 4.

CSGAMMA=value

specifies the *value* of the γ multiplier suggested by Chen and Kotz (1996) for Wright's capability index C_s . The *value* must be greater than zero. The default *value* is 1.

SPEC=SAS-data-set**SPECS=SAS-data-set**

specifies an input data set containing specification limits for each of the variables in the VAR statement. This option is an alternative to the SPEC statement, which also provides specification limits. See "SPEC= Data Set" on page 229 for details on SPEC= data sets, and Example 5.1 for an example. If you use both the SPEC= option and a SPEC statement, the SPEC= option is ignored.

TRIMMED=values(s) <(TYPE=keyword) <ALPHA=value>

requests a table of trimmed means, where each *value* specifies the number or the proportion of trimmed observations. If the *value* is the number n of trimmed observations, n must be between 0 and half the number of nonmissing observations. If the *value* is a proportion p between 0 and 0.5, the number of observations trimmed is the smallest integer greater than or equal to np , where n is the number of observations. To obtain confidence limits for the mean and the student t -test, you must use the default value of VARDEF= which is DF. The TRIMMED= option is not available if you specify a WEIGHT statement.

ALPHA=value

specifies the confidence level. The coverage percent is $(1 - \text{value})100$. For example, ALPHA=0.10 requests a 90% confidence limit. The default value is 0.05.

TYPE=keyword

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default value is TWOSIDED.

VARDEF=DF | N | WDF | WEIGHT | WGT

specifies the divisor used in calculating variances and standard deviations. The values and associated divisors are shown in the following table. By default, VARDEF=DF.

Value	Divisor	Formula
DF	degrees of freedom	$n - 1$
N	number of observations	n
WEIGHT WGT	sum of weight	$\sum_i w_i$
WDF	sum of weights minus one	$(\sum_i w_i) - 1$

WINSORIZED=values(s) <(TYPE=keyword) <ALPHA=value>**WINSOR=values(s) <(TYPE=keyword) <ALPHA=value>**

requests a table of winsorized means, where each *value* specifies the number or the proportion of winsorized observations. If the *value* is the number n of winsorized observations, n must be between 0 and half the number of nonmissing observations. If the *value* is a proportion p between 0 and 0.5, the number of observations winsorized is the smallest integer greater than or equal to np , where n is the number of observations. To obtain confidence limits for the mean and the student t -test, you must use the default value of VARDEF= which is DF. The WINSORIZED= option is not available if you specify a WEIGHT statement.

ALPHA=*value*

specifies the confidence level. The coverage percent is $(1 - \textit{value})100$. For example, ALPHA=0.10 results in a 90% confidence limit. The default value is 0.05.

TYPE=*keyword*

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default value is TWOSIDED.

CLASS Statement

```
CLASS variable-1 <(v-options)> <variable-2 <(v-options)>>
  </ KEYLEVEL= value1 | (value1 value2)> ;
```

The CLASS statement specifies one or two variables used to group the data into classification levels. Variables in a CLASS statement are referred to as *CLASS variables*. CLASS variables can be numeric or character. Class variables can have floating point values, but they typically have a few discrete values that define levels of the variable. You do not have to sort the data by CLASS variables. PROC CAPABILITY uses the formatted values of the CLASS variables to determine the classification levels.

NOTE: You cannot specify a COMPHISTOGRAM statement together with a CLASS statement.

You can specify the following *v-options* enclosed in parentheses after a CLASS variable:

MISSING

specifies that missing values for the CLASS variable are to be treated as valid classification levels. Special missing values that represent numeric values ('.A' through '.Z' and '._') are each considered as a separate value. If you omit MISSING, PROC CAPABILITY excludes the observations with a missing CLASS variable value from the analysis. Enclose this option in parentheses after the CLASS variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the display order for the CLASS variable values. The default value is INTERNAL. You can specify the following values with the ORDER= option:

DATA orders values according to their order in the input data set. When you use a plot statement, PROC CAPABILITY displays the rows (columns) of the comparative plot from top to bottom (left to right) in the order that the CLASS variable values first appear in the input data set.

FORMATTED orders values by their ascending formatted values. This order might depend on your operating environment. When you use a plot statement, PROC CAPABILITY displays the rows (columns) of the comparative plot from top to bottom (left to right) in increasing order of the formatted CLASS variable values. For example, suppose a numeric CLASS variable DAY (with values 1, 2, and 3) has a user-defined format that assigns Wednesday to the value 1, Thursday to the value 2, and Friday to the value 3. The rows of the comparative plot will appear in alphabetical order (Friday, Thursday, Wednesday) from top to bottom.

If there are two or more distinct internal values with the same formatted value, then PROC CAPABILITY determines the order by the internal

	value that occurs first in the input data set. For numeric variables without an explicit format, the levels are ordered by their internal values.
FREQ	orders values by descending frequency count so that levels with the most observations are listed first. If two or more values have the same frequency count, PROC CAPABILITY uses the formatted values to determine the order. When you use a plot statement, PROC CAPABILITY displays the rows (columns) of the comparative plot from top to bottom (left to right) in order of decreasing frequency count for the CLASS variable values.
INTERNAL	orders values by their unformatted values, which yields the same order as PROC SORT. This order may depend on your operating environment. When you use a plot statement, PROC CAPABILITY displays the rows (columns) of the comparative plot from top to bottom (left to right) in increasing order of the internal (unformatted) values of the CLASS variable. The first CLASS variable is used to label the rows of the comparative plots (top to bottom). The second CLASS variable is used to label the columns of the comparative plots (left to right). For example, suppose a numeric CLASS variable DAY (with values 1, 2, and 3) has a user-defined format that assigns Wednesday to the value 1, Thursday to the value 2, and Friday to the value 3. The rows of the comparative plot will appear in day-of-the-week order (Wednesday, Thursday, Friday) from top to bottom.

You can specify the following options after the slash (/) in the CLASS statement.

KEYLEVEL=*value* | (*value1 value2*)

specifies the *key cells* in comparative plots. For each plot, PROC CAPABILITY first determines the horizontal axis scaling for the key cell, and then extends the axis using the established tick interval to accommodate the data ranges for the remaining cells, if necessary. Thus, the choice of the key cell determines the uniform horizontal axis that PROC CAPABILITY uses for all cells.

If you specify only one CLASS variable and use a plot statement, KEYLEVEL=*value* identifies the key cell as the level for which the CLASS variable is equal to *value*. By default, PROC CAPABILITY sorts the levels in the order determined by the ORDER= option, and the key cell is the first occurrence of a level in this order. The cells display in order from top to bottom or left to right. Consequently, the key cell appears at the top (or left). When you specify a different key cell with the KEYLEVEL= option, this cell appears at the top (or left).

If you specify two CLASS variables, use KEYLEVEL= (*value1 value2*) to identify the key cell as the level for which CLASS variable *n* is equal to *valuen*. By default, PROC CAPABILITY sorts the levels of the first CLASS variable in the order that is determined by its ORDER= option. Then, within each of these levels, it sorts the levels of the second CLASS variable in the order that is determined by its ORDER= option. The default key cell is the first occurrence of a combination of levels for the two variables in this order. The cells display in the order of the first CLASS variable from top to bottom and in the order of the second CLASS variable from left to right. Consequently, the default key cell appears at the upper left corner. When you specify a different key cell with the KEYLEVEL= option, this cell appears at the upper left corner.

The length of the KEYLEVEL= value cannot exceed 16 characters and you must specify a formatted value.

The KEYLEVEL= option has no effect unless you specify a plot statement.

NOKEYMOVE

specifies that the location of the key cell in a comparative plot be unchanged by the CLASS statement KEYLEVEL= option. By default, the key cell is positioned as the first cell in a comparative plot.

The NOKEYMOVE option has no effect unless you specify a plot statement.

SPEC Statement

The syntax for the SPEC statement is as follows:

```
SPEC < options > ;
```

You can use at most one SPEC statement in the CAPABILITY procedure. When you provide specification limits and target values in a SPEC statement, the tabular output produced by the PROC CAPABILITY statement includes process capability indices as well as summary statistics. You can use the SPEC statement in conjunction with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBLOT, and QQPLOT statements to add specification limit and target lines to the plots produced with these statements.

options

control features of the specification limits and target values. The section “Summary of Options”, which follows, lists all options by function. The section “Dictionary of Options” on page 226 describes each option in more detail.

Summary of Options

The following tables list the SPEC statement options by function. For complete descriptions see the section “Dictionary of Options” on page 226.

Table 5.3 SPEC Statement Options

Option	Description
Lower Specification Limit Options	
CLEFT=	color used to fill area left of lower specification limit (histograms only)
CLSL=	color of lower specification limit line
LLSL=	line type of lower specification limit line
LSL=	lower specification limit values
LSLSYMBOL=	character used for lower specification limit line in line printer plots
PLEFT=	pattern type used to fill area left of lower specification limit (histograms only)
WLSL=	width of lower specification limit line
Target Options	
CTARGET=	color of target line
LTARGET=	line type of target line

Table 5.3 continued

Option	Description
TARGET=	target value
TARGETSYMBOL=	character used for target in line printer plots
WTARGET=	width of target line
Upper Specification Limit Options	
CRIGHT=	color used to fill area right of upper specification limit (histograms only)
CUSL=	color of upper specification limit line
LUSL=	line type of upper specification limit line
PRIGHT=	pattern type used to fill area right of upper specification limit (histograms only)
USL=	upper specification limit values
USLSYMBOL=	character used for upper specification limit in line printer plots
WUSL=	width of upper specification limit line

Dictionary of Options

The following entries provide detailed descriptions of options for the SPEC statement. The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that can be used with traditional graphics, ODS Graphics output, and line printer plots, respectively.

CLEFT=*color*

CLEFT

Traditional Graphics
ODS Graphics

determines the color used to fill the area under a histogram to the left of the lower specification limit. You can specify the CLEFT option without an argument to fill this area with an appropriate color from the ODS style. If you are producing ODS Graphics output, an explicit color specification is ignored. This option is applicable only when the SPEC statement is used in conjunction with a HISTOGRAM or COMPHISTOGRAM statement. See [Output 5.2.1](#) for an example. The CLEFT= option also applies to the area under a fitted curve; for an example, see [Output 5.8.1](#).

CLSL=*color*

Traditional Graphics

specifies the color of the lower specification line displayed in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements.

CRIGHT=*color*

CRIGHT

Traditional Graphics
ODS Graphics

determines the color used to fill the area under a histogram to the right of the upper specification limit. You can specify the CRIGHT option without an argument to fill this area with an appropriate color from the ODS style. If you are producing ODS Graphics output, an explicit color specification is ignored. This option is applicable only when the SPEC statement is used in conjunction with a HISTOGRAM or COMPHISTOGRAM statement. See [Output 5.2.1](#) for an example. The CRIGHT= option also applies to the area under a fitted curve; for an example, see [Output 5.8.1](#).

CTARGET=*color*

specifies the color of the target line displayed in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. *Traditional Graphics*

CUSL=*color*

specifies the color of the upper specification line displayed in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. *Traditional Graphics*

LLSL=*linetype*

specifies the line type for the lower specification line displayed in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. *Traditional Graphics*
See [Output 5.2.1](#) for an example. The default is 1, which produces a solid line.

LSL=*value-list*

specifies the lower specification limits for the variables listed in the VAR statement, or for all numeric variables in the input data set if no VAR statement is used. If you specify only one lower limit, it is used for all of the variables; otherwise, the number of limits must match the number of variables. See the section “[Computing Capability Indices](#)” on page 208 for an example.

LSLSYMBOL=*'character'*

specifies the character used to display the lower specification line in line printer plots created with the CDFPLOT, HISTOGRAM, PROBPLOT, and QQPLOT statements. The default character is 'L'. *Line Printer*

LTARGET=*linetype*

specifies the line type for the target line in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. See [Output 5.2.1](#) for an example. The default is 1, which produces a solid line. *Traditional Graphics*

LUSL=*linetype*

specifies the line type for the upper specification line displayed in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. See [Output 5.2.1](#) for an example. The default is 1, which produces a solid line. *Traditional Graphics*

PLEFT=*pattern*

specifies the pattern used to fill the area under a histogram to the left of the lower specification limit. This option is applicable only when the SPEC statement is used in conjunction with a HISTOGRAM or COMPHISTOGRAM statement. For an example, see [Output 5.2.1](#). The PLEFT= option also applies to the area under a fitted curve; for an example, see [Output 5.8.1](#). The default pattern is a solid fill. *Traditional Graphics*

PRIGHT=*pattern*

specifies the pattern used to fill the area under a histogram to the right of the upper specification limit. This option is applicable only when the SPEC statement is used in conjunction with a HISTOGRAM or COMPHISTOGRAM statement. For an example, see [Output 5.2.1](#). The PRIGHT= option also applies to the area under a fitted curve; for an example, see [Output 5.8.1](#). The default pattern is a solid fill. *Traditional Graphics*

TARGET=value-list

specifies target values for the variables listed in the VAR statement, or for all numeric variables in the input data set if no VAR statement is used. If you specify only one target value, it is used for all of the variables; otherwise, the number of values must match the number of variables. See the section “Computing Capability Indices” on page 208 for an example.

TARGETSYMBOL='character'**TARGETSYM='character'**

Line Printer specifies the character used to display the target line in line printer plots created with the CDFPLOT, HISTOGRAM, PROBPLOT, and QQPLOT statements. The default character is 'T'.

USL=value-list

specifies the upper specification limits for the variables listed in the VAR statement, or for all numeric variables in the input data set if no VAR statement is used. If you specify only one upper limit, it is used for all of the variables; otherwise, the number of limits must match the number of variables. See the section “Computing Capability Indices” on page 208 for an example.

USLSYMBOL='character'

Line Printer specifies the character used to display the upper specification line in line printer plots created with the CDFPLOT, HISTOGRAM, PROBPLOT, and QQPLOT statements. The default character is 'U'.

WLSL=n

Traditional Graphics specifies the width in pixels of the lower specification line in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. See [Output 5.2.1](#) for an illustration. The default is 1.

WTARGET=n

Traditional Graphics specifies the width in pixels of the target line in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. See [Output 5.2.1](#) for an illustration. The default is 1.

WUSL=n

Traditional Graphics specifies the width in pixels of the upper specification line in plots created with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PROBPLOT, and QQPLOT statements. See [Output 5.2.1](#) for an illustration. The default is 1.

Details: CAPABILITY Procedure

This section provides details on the following topics:

- input data sets specified with the DATA= option, the SPEC= option, and the ANNOTATE= option
- the output data set specified with the OUTTABLE= option
- descriptive statistics

- the tests for normality requested with the NORMALTEST option
- percentile definitions controlled using the PCTLDEF= option
- robust estimators
- computing the mode
- assumptions and terminology for capability indices
- standard capability indices
- specialized capability indices

Input Data Sets

DATA= Data Set

The DATA= data set contains a set of variables that represent measurements from a process. The CAPABILITY procedure must have a DATA= data set. If you do not specify one with the DATA= option in the PROC CAPABILITY statement, the procedure uses the last data set created.

SPEC= Data Set

The SPEC= option in the PROC CAPABILITY statement identifies a SPEC= data set, which contains specification limits. This option is an alternative to using the SPEC statement. If you use both the SPEC= option and a SPEC statement, the SPEC= option is ignored. The SPEC= option is especially useful when:

- the number of variables is large
- the same specification limits are referred to in more than one analysis
- a BY statement is used
- batch processing is used

The following variables are read from a SPEC= data set:

Variable	Description
<code>_LSL_</code>	lower specification limit
<code>_TARGET_</code>	target value
<code>_USL_</code>	upper specification limit
<code>_VAR_</code>	name of the variable

You may omit either `_LSL_` or `_USL_` but not both. `_TARGET_` is optional. If the SPEC= data set contains both `_LSL_` and `_USL_`, you can assign missing values to `_LSL_` or `_USL_` to indicate one-sided specifications. You can assign missing values to `_TARGET_` when the variable does not use a target value. `_LSL_`, `_USL_`, and `_TARGET_` must be numeric variables. `_VAR_` must be a character variable.

You can include the following optional variables in a SPEC= data set to control the appearance of specification limits on charts:

Variable	Description
CLEFT	color used to fill area left of LSL (histograms only)
CLSL	color of LSL line
CRIGHT	color used to fill area right of USL (histograms only)
CTARGET	color of target line
CUSL	color of USL line
LLSL	line type of LSL line
LSLSYM	character used for LSL line in line printer plots
LTARGET	line type of target line
LUSL	line type of USL line
PLEFT	pattern type used to fill area left of LSL (histograms only)
PRIGHT	pattern type used to fill area right of USL (histograms only)
TARGETSYM	character used for target in line printer plots
USLSYM	character used for USL line in line printer plots
WLSL	width of LSL line
WTARGET	width of target line
WUSL	width of USL line

If you are using the HISTOGRAM statement to create “clickable” histograms in HTML, you can also provide the following variables in a SPEC= data set:

Variable	Description
LOURL	URL associated with area to left of lower specification limit
HIURL	URL associated with area to right of upper specification limit
URL	URL associated with area between specification limits

These are character variables whose values are Uniform Resource Locators (URLs) linked to areas on a histogram. When you view the ODS HTML output with a browser, you can click on an area, and the browser will bring up the page specified by the corresponding URL.

If you use a BY statement, the SPEC= data set must also contain the BY variables. The SPEC= data set must be sorted in the same order as the DATA= data set. Within a BY group, specification limits for each variable plotted are read from the first observation where _VAR_ matches the variable name.

See the section “[Examples: CAPABILITY Procedure](#)” on page 258 for an example of reading specification limits from a SPEC= data set.

ANNOTATE= Data Sets

In the CAPABILITY procedure, you can add features to traditional graphics plots by specifying ANNOTATE= data sets either in the PROC CAPABILITY statement or in individual plot statements. Depending on where you specify an ANNOTATE= data set, however, the information is used for all plots or only for plots produced by a given statement.

Information contained in the ANNOTATE= data set specified in the PROC CAPABILITY statement

is used for all plots produced in a given PROC step; this is a “global” ANNOTATE= data set. By using this global data set, you can keep information common to all plots in one data set.

Information contained in the ANNOTATE= data set specified in a plot statement is used for plots produced by that statement; this is a “local” ANNOTATE= data set. By using this data set, you can add statement-specific features to plots. For example, you can add different features to plots produced by the HISTOGRAM and QQPLOT statements by specifying an ANNOTATE= data set in each plot statement.

In addition, you can specify an ANNOTATE= data set in the PROC CAPABILITY statement and in plot statements. This enables you to add some features to all plots (those given in the data set specified in the PROC statement) and also add statement-specific features to plots (those given in the data set specified in the plot statement).

For complete details on the structure and content of Annotate type data sets, see SAS/GRAPH documentation.

Output Data Set

OUTTABLE= Data Set

The OUTTABLE= data set saves univariate statistics and capability indices. The following variables can be saved:

Table 5.4 OUTTABLE= Data Set

Variable	Description
CP	capability index C_p
CPLCL	lower confidence limit for C_p
CPUCL	upper confidence limit for C_p
CPK	capability index C_{pk}
CPKLCL	lower confidence limit for C_{pk}
CPKUCL	upper confidence limit for C_{pk}
CPL	capability index CPL
CPLLCL	lower confidence limit for CPL
CPLUCL	upper confidence limit for CPL
CPM	capability index C_{pm}
CPMLCL	lower confidence limit for C_{pm}
CPMUCL	upper confidence limit for C_{pm}
CPU	capability index CPU
CPULCL	lower confidence limit for CPU
CPUUCL	upper confidence limit for CPU
CSS	corrected sum of squares
CV	coefficient of variation
GINI	Gini's mean difference
K	capability index K
KURT	kurtosis
LSL	lower specification limit
MAD	median absolute difference about the median
MAX	maximum
MEAN	mean

Table 5.4 (continued)

Variable	Description
MEDIAN	median
MIN	minimum
MODE	mode
MSIGN	sign statistic
NMISS	number of missing observations
NOBS	number of nonmissing observations
P1	1st percentile
P5	5th percentile
P10	10th percentile
P90	90th percentile
P95	95th percentile
P99	99th percentile
PCTGTR	percentage of observations greater than upper specification limit
PCTLSS	percentage of observations less than lower specification limit
PROBM	p-value of sign statistic
PROBN	p-value of test for normality
PROBS	p-value of signed rank test
PROBT	p-value of t statistic
Q1	25th percentile (lower quartile)
Q3	75th percentile (upper quartile)
QN	Q_n (see “Robust Estimates of Scale” on page 243)
QRANGE	interquartile range (upper quartile minus lower quartile)
RANGE	range
SGNRNK	centered sign rank
SKEW	skewness
SN	S_n (see “Robust Estimates of Scale” on page 243)
STD	standard deviation
STDGINI	Gini’s standard deviation
STDMAD	MAD standard deviation
STDMEAN	standard error of the mean
STDQN	Q_n standard deviation
STDQRANGE	interquartile range standard deviation
STDSN	S_n standard deviation
SUMWGT	sum of the weights
SUM	sum
TARGET	target value
USL	upper specification limit
USS	uncorrected sum of squares
VARI	variance
VAR	variable name

NOTE: The variables _CP_, _CPLCL_, _CPUCL_, _CPK_, _CPKLCL_, _CPKUCL_, _CPL_, _CPLLCL_, _CPLUCL_, _CPM_, _CPMLCL_, _CPMUCL_, _CPU_, _CPULCL_, _CPUUCL_, _K_, _LSL_, _PCTGTR_, _PCTLSS_, _TARGET_, and _USL_ are included if you provide specification limits.

The OUTTABLE= data set and the OUT= data set¹⁰ contain essentially the same information. However, the structure of the OUTTABLE= data set may be more appropriate when you are computing summary statistics or capability indices for more than one process variable in the same invocation of the CAPABILITY procedure. Each observation in the OUTTABLE= data set corresponds to a different process variable, and the variables in the data set correspond to summary statistics and indices.

For example, suppose you have ten process variables (P1-P10). The following statements create an OUTTABLE= data set named Table, which contains summary statistics and capability indices for each of these variables: *See CAPTAB1 in the SAS/QC Sample Library*

```
proc capability data=Process outtable=Table noprint;
  var P1-P10;
  specs lsl=5 10 65 35 35 5 25 25 60 15
        usl=175 275 300 450 550 200 275 425 500 525;
run;
```

The following statements create the table shown in Figure 5.4, which contains the mean, standard deviation, lower and upper specification limits, and capability index C_{pk} for each process variable:

```
proc print data=Table label noobs;
  var _VAR_ MEAN STD LSL USL CPK;
  label _VAR_='Process';
run;
```

Figure 5.4 Tabulating Results for Multiple Process Variables

Process Capability Analysis of Fluid Weight					
Process	Mean	Standard Deviation	Lower Specification Limit	Upper Specification Limit	Capability Index CPK
P1	90.76	57.024	5	175	0.49242
P2	167.32	81.628	10	275	0.43972
P3	224.56	96.525	65	300	0.26052
P4	258.08	145.218	35	450	0.44053
P5	283.48	157.033	35	550	0.52745
P6	107.48	52.437	5	200	0.58814
P7	153.20	90.031	25	275	0.45096
P8	217.08	130.031	25	425	0.49239
P9	280.68	140.943	60	500	0.51870
P10	243.24	178.799	15	525	0.42551

Descriptive Statistics

This section provides computational details for the descriptive statistics which are computed with the PROC CAPABILITY statement. These statistics can also be saved in the OUT= data set by specifying the keywords listed in Table 5.52 in the OUTPUT statement.

¹⁰See “OUTPUT Statement: CAPABILITY Procedure” on page 439 for details on the OUT= data set.

Standard algorithms (Fisher 1973) are used to compute the moment statistics. The computational methods used by the CAPABILITY procedure are consistent with those used by other SAS procedures for calculating descriptive statistics. For details on statistics also calculated by Base SAS software, see *Base SAS Procedures Guide*.

The following sections give specific details on several statistics calculated by the CAPABILITY procedure.

Mean

The sample mean is calculated as

$$\frac{\sum_{i=1}^n w_i x_i}{\sum_{i=1}^n w_i}$$

where n is the number of nonmissing values for a variable, x_i is the i th value of the variable, and w_i is the weight associated with the i th value of the variable. If there is no WEIGHT= variable, the formula reduces to $\frac{1}{n} \sum_{i=1}^n x_i$.

Sum

The sum is calculated as $\sum_{i=1}^n w_i x_i$, where n is the number of nonmissing values for a variable, x_i is the i th value of the variable, and w_i is the weight associated with the i th value of the variable. If there is no WEIGHT= variable, the formula reduces to $\sum_{i=1}^n x_i$.

Sum of the Weights

The sum of the weights is calculated as $\sum_{i=1}^n w_i$, where n is the number of nonmissing values for a variable and w_i is the weight associated with the i th value of the variable. If there is no WEIGHT= variable, the sum of the weights is n .

Variance

The variance is calculated as

$$\frac{1}{d} \sum_{i=1}^n w_i (x_i - \bar{X}_w)^2$$

where n is the number of nonmissing values for a variable, x_i is the i th value of the variable, \bar{X}_w is the weighted mean, w_i is the weight associated with the i th value of the variable, and d is the divisor controlled by the VARDEF= option in the PROC CAPABILITY statement. If there is no WEIGHT= variable, the formula reduces to

$$\frac{1}{d} \sum_{i=1}^n (x_i - \bar{X}_w)^2$$

Standard Deviation

The standard deviation is calculated as

$$\sqrt{\frac{1}{d} \sum_{i=1}^n w_i (x_i - \bar{X}_w)^2}$$

where n is the number of nonmissing values for a variable, x_i is the i th value of the variable, \bar{X}_w is the weighted mean, w_i is the weight associated with the i th value of the variable, and d is the divisor controlled by the VARDEF= option in the PROC CAPABILITY statement. If there is no WEIGHT= variable, the formula reduces to

$$\sqrt{\frac{1}{d} \sum_{i=1}^n (x_i - \bar{X}_w)^2}$$

Skewness

The sample skewness is calculated as

$$\frac{n}{(n-1)(n-2)} \sum_{i=1}^n \left(\frac{x_i - \bar{X}}{s} \right)^3$$

where n is the number of nonmissing values for a variable and must be greater than 2, x_i is the i th value of the variable, \bar{X} is the sample average, and s is the sample standard deviation.

The sample skewness can be positive or negative; it measures the asymmetry of the data distribution and estimates the theoretical skewness $\sqrt{\beta_1} = \mu_3 \mu_2^{-\frac{3}{2}}$, where μ_2 and μ_3 are the second and third central moments. Observations that are normally distributed should have a skewness near zero.

Kurtosis

The sample kurtosis is calculated as

$$\frac{n(n+1)}{(n-1)(n-2)(n-3)} \sum_{i=1}^n \left(\frac{x_i - \bar{X}}{s} \right)^4 - \frac{3(n-1)^2}{(n-2)(n-3)}$$

where $n > 3$. The sample kurtosis measures the heaviness of the tails of the data distribution. It estimates the adjusted theoretical kurtosis denoted as $\beta_2 - 3$, where $\beta_2 = \frac{\mu_4}{\mu_2^2}$, and μ_4 is the fourth central moment. Observations that are normally distributed should have a kurtosis near zero.

Coefficient of Variation (CV)

The coefficient of variation is calculated as

$$CV = \frac{100 \times s}{\bar{X}}$$

Signed Rank Statistic

The signed rank statistic S is computed as

$$S = \sum_{i: x_i > \mu_0} r_i^+ - \frac{n(n+1)}{4}$$

where r_i^+ is the rank of $|x_i - \mu_0|$ after discarding values of $x_i = \mu_0$, and n is the number of x_i values not equal to μ_0 . Average ranks are used for tied values.

If $n \leq 20$, the significance of S is computed from the exact distribution of S , where the distribution is a convolution of scaled binomial distributions. When $n > 20$, the significance of S is computed by treating

$$S \sqrt{\frac{n-1}{nV - S^2}}$$

as a Student t variate with $n - 1$ degrees of freedom. V is computed as

$$V = \frac{1}{24}n(n+1)(2n+1) - \frac{1}{48} \sum t_i(t_i+1)(t_i-1)$$

where the sum is over groups tied in absolute value and where t_i is the number of values in the i th group (Iman 1974, Conover 1980). The null hypothesis tested is that the mean (or median) is μ_0 , assuming that the distribution is symmetric. Refer to Lehmann (1998).

Tests for Normality

You can use the NORMALTEST option in the PROC CAPABILITY statement to request several tests of the hypothesis that the analysis variable values are a random sample from a normal distribution. These tests, which are summarized in the table labeled *Tests for Normality*, include the following:

- Shapiro-Wilk test
- Kolmogorov-Smirnov test
- Anderson-Darling test
- Cramér-von Mises test

Tests for normality are particularly important in process capability analysis because the commonly used capability indices are difficult to interpret unless the data are at least approximately normally distributed. Furthermore, the confidence limits for capability indices displayed in the table labeled *Process Capability Indices* require the assumption of normality. Consequently, the tests of normality are always computed when you specify the SPEC statement, and a note is added to the table when the hypothesis of normality is rejected. You can specify the particular test and the significance level with the CHECKINDICES option.

Shapiro-Wilk Test

If the sample size is 2000 or less,¹¹ the procedure computes the Shapiro-Wilk statistic W (also denoted as W_n to emphasize its dependence on the sample size n). The statistic W_n is the ratio of the best estimator of the variance (based on the square of a linear combination of the order statistics) to the usual corrected sum of squares estimator of the variance. When n is greater than three, the coefficients to compute the linear combination of the order statistics are approximated by the method of Royston (1992). The statistic W_n is always greater than zero and less than or equal to one ($0 < W \leq 1$).

Small values of W lead to rejection of the null hypothesis. The method for computing the p -value (the probability of obtaining a W statistic less than or equal to the observed value) depends on n . For $n = 3$, the probability distribution of W is known and is used to determine the p -value. For $n > 4$, a normalizing transformation is computed:

$$Z_n = \begin{cases} (-\log(\gamma - \log(1 - W_n)) - \mu)/\sigma & \text{if } 4 \leq n \leq 11 \\ (\log(1 - W_n) - \mu)/\sigma & \text{if } 12 \leq n \leq 2000 \end{cases}$$

The values of σ , γ , and μ are functions of n obtained from simulation results. Large values of Z_n indicate departure from normality, and since the statistic Z_n has an approximately standard normal distribution, this distribution is used to determine the p -values for $n > 4$.

EDF Tests for Normality

The Kolmogorov-Smirnov, Anderson-Darling and Cramér-von Mises tests for normality are based on the empirical distribution function (EDF) and are often referred to as EDF tests. EDF tests for a variety of non-normal distributions are available in the HISTOGRAM statement; see the section “EDF Goodness-of-Fit Tests” on page 362 for details. For a thorough discussion of these tests, refer to D’Agostino and Stephens (1986).

The empirical distribution function is defined for a set of n independent observations X_1, \dots, X_n with a common distribution function $F(x)$. Under the null hypothesis, $F(x)$ is the normal distribution. Denote the observations ordered from smallest to largest as $X_{(1)}, \dots, X_{(n)}$. The empirical distribution function, $F_n(x)$, is defined as

$$F_n(x) = \begin{cases} 0, & x < X_{(1)} \\ \frac{i}{n}, & X_{(i)} \leq x < X_{(i+1)}, i = 1, \dots, n-1 \\ 1, & X_{(n)} \leq x \end{cases}$$

Note that $F_n(x)$ is a step function that takes a step of height $\frac{1}{n}$ at each observation. This function estimates the distribution function $F(x)$. At any value x , $F_n(x)$ is the proportion of observations less than or equal to x , while $F(x)$ is the probability of an observation less than or equal to x . EDF statistics measure the discrepancy between $F_n(x)$ and $F(x)$.

The EDF tests make use of the probability integral transformation $U = F(X)$. If $F(X)$ is the distribution function of X , the random variable U is uniformly distributed between 0 and 1. Given

¹¹In SAS 6.12 and earlier releases, the CAPABILITY procedure performed a Shapiro-Wilk test for sample sizes of 2000 or smaller, and a Kolmogorov-Smirnov test otherwise. The computed value of W was used to interpolate linearly within the range of simulated critical values given in Shapiro and Wilk (1965). In SAS 7, minor improvements were made to the algorithm for the Shapiro-Wilk test, as described in this section.

n observations $X_{(1)}, \dots, X_{(n)}$, the values $U_{(i)} = F(X_{(i)})$ are computed. These values are used to compute the EDF test statistics, as described in the next three sections. The CAPABILITY procedures compute the associated p -values by interpolating internal tables of probability levels similar to those given by D'Agostino and Stephens (1986).

Kolmogorov-Smirnov Test

The Kolmogorov-Smirnov statistic (D) is defined as

$$D = \sup_x |F_n(x) - F(x)|$$

The Kolmogorov-Smirnov statistic belongs to the supremum class of EDF statistics. This class of statistics is based on the largest vertical difference between $F(x)$ and $F_n(x)$.

The Kolmogorov-Smirnov statistic is computed as the maximum of D^+ and D^- , where D^+ is the largest vertical distance between the EDF and the distribution function when the EDF is greater than the distribution function, and D^- is the largest vertical distance when the EDF is less than the distribution function.

$$\begin{aligned} D^+ &= \max_i \left(\frac{i}{n} - U_{(i)} \right) \\ D^- &= \max_j \left(U_{(j)} - \frac{j-1}{n} \right) \\ D &= \max(D^+, D^-) \end{aligned}$$

PROC CAPABILITY uses a modified Kolmogorov D statistic to test the data against a normal distribution with mean and variance equal to the sample mean and variance.

Anderson-Darling Test

The Anderson-Darling statistic and the Cramér-von Mises statistic belong to the quadratic class of EDF statistics. This class of statistics is based on the squared difference $(F_n(x) - F(x))^2$. Quadratic statistics have the following general form:

$$Q = n \int_{-\infty}^{+\infty} (F_n(x) - F(x))^2 \psi(x) dF(x)$$

The function $\psi(x)$ weights the squared difference $(F_n(x) - F(x))^2$.

The Anderson-Darling statistic (A^2) is defined as

$$A^2 = n \int_{-\infty}^{+\infty} (F_n(x) - F(x))^2 [F(x)(1 - F(x))]^{-1} dF(x)$$

Here the weight function is $\psi(x) = [F(x)(1 - F(x))]^{-1}$.

The Anderson-Darling statistic is computed as

$$A^2 = -n - \frac{1}{n} \sum_{i=1}^n [(2i - 1) \log U_{(i)} + (2n + 1 - 2i) \log (1 - U_{(i)})]$$

Cramér-von Mises Test

The Cramér-von Mises statistic (W^2) is defined as

$$W^2 = n \int_{-\infty}^{+\infty} (F_n(x) - F(x))^2 dF(x)$$

Here the weight function is $\psi(x) = 1$.

The Cramér-von Mises statistic is computed as

$$W^2 = \sum_{i=1}^n \left(U_{(i)} - \frac{2i - 1}{2n} \right)^2 + \frac{1}{12n}$$

Percentile Computations

The CAPABILITY procedure automatically computes the 1st, 5th, 10th, 25th, 50th, 75th, 90th, 95th, and 99th percentiles (quantiles), as well as the minimum and maximum of each analysis variable. To compute percentiles other than these default percentiles, use the PCTLPTS= and PCTLPRE= options in the OUTPUT statement.

You can specify one of five definitions for computing the percentiles with the PCTLDEF= option. Let n be the number of nonmissing values for a variable, and let x_1, x_2, \dots, x_n represent the ordered values of the variable. Let the t th percentile be y , set $p = \frac{t}{100}$, and let

$$\begin{aligned} np &= j + g && \text{when PCTLDEF}=1, 2, 3, \text{ or } 5 \\ (n + 1)p &= j + g && \text{when PCTLDEF}=4 \end{aligned}$$

where j is the integer part of np , and g is the fractional part of np . Then the PCTLDEF= option defines the t th percentile, y , as described in the following table:

PCTLDEF=	Description	Formula
1	weighted average at x_{np}	$y = (1 - g)x_j + gx_{j+1}$ where x_0 is taken to be x_1
2	observation numbered closest to np	$y = x_i$ if $g \neq \frac{1}{2}$ $y = x_j$ if $g = \frac{1}{2}$ and j is even $y = x_{j+1}$ if $g = \frac{1}{2}$ and j is odd where i is the integer part of $np + \frac{1}{2}$
3	empirical distribution function	$y = x_j$ if $g = 0$ $y = x_{j+1}$ if $g > 0$
4	weighted average aimed at $x_{(n+1)p}$	$y = (1 - g)x_j + gx_{j+1}$ where x_{n+1} is taken to be x_n
5	empirical distribution function with averaging	$y = \frac{1}{2}(x_j + x_{j+1})$ if $g = 0$ $y = x_{j+1}$ if $g > 0$

Weighted Percentiles

When you use a WEIGHT statement, the percentiles are computed differently. The 100 p th weighted percentile y is computed from the empirical distribution function with averaging

$$y = \begin{cases} x_1 & \text{if } w_1 > pW \\ \frac{1}{2}(x_i + x_{i+1}) & \text{if } \sum_{j=1}^i w_j = pW \\ x_{i+1} & \text{if } \sum_{j=1}^i w_j < pW < \sum_{j=1}^{i+1} w_j \end{cases}$$

where w_i is the weight associated with x_i , and where $W = \sum_{i=1}^n w_i$ is the sum of the weights.

Note that the PCTLDEF= option is not applicable when a WEIGHT statement is used. However, in this case, if all the weights are identical, the weighted percentiles are the same as the percentiles that would be computed without a WEIGHT statement and with PCTLDEF=5.

Confidence Limits for Percentiles

You can use the CIPCTLNORMAL option to request confidence limits for percentiles which assume the data are normally distributed. These limits are described in Section 4.4.1 of Hahn and Meeker (1991). When $0.0 < p < 0.5$, the two-sided $100(1 - \alpha)\%$ confidence limits for the 100 p -th percentile are

$$\begin{aligned} \text{lower limit} &= \bar{X} - g'(\alpha/2; 1 - p, n)s \\ \text{upper limit} &= \bar{X} - g'(1 - \alpha/2; p, n)s \end{aligned}$$

where n is the sample size. When $0.5 \leq p < 1.0$, the two-sided $100(1 - \alpha)\%$ confidence limits for the 100 p -th percentile are

$$\begin{aligned} \text{lower limit} &= \bar{X} + g'(\alpha/2; 1 - p, n)s \\ \text{upper limit} &= \bar{X} + g'(1 - \alpha/2; p, n)s \end{aligned}$$

One-sided $100(1 - \alpha)\%$ confidence bounds are computed by replacing $\alpha/2$ by α in the appropriate preceding equation. The factor $g'(\gamma, p, n)$ is related to the noncentral t distribution and is described in Owen and Hua (1977) and Odeh and Owen (1980).

You can use the CIPCTLDF option to request confidence limits for percentiles which are distribution free (in particular, it is not necessary to assume that the data are normally distributed). These limits are described in Section 5.2 of Hahn and Meeker (1991). The two-sided $100(1 - \alpha)\%$ confidence limits for the 100 p -th percentile are

$$\begin{aligned} \text{lower limit} &= X_{(l)} \\ \text{upper limit} &= X_{(u)} \end{aligned}$$

where $X_{(j)}$ is the j th order statistic when the data values are arranged in increasing order:

$$X_{(1)} \leq X_{(2)} \leq \dots \leq X_{(n)}$$

The lower rank l and upper rank u are integers that are symmetric (or nearly symmetric) around $[np] + 1$ where $[np]$ is the integer part of np , and where n is the sample size. Furthermore, l and u

are chosen so that $X_{(l)}$ and $X_{(u)}$ are as close to $X_{[n+1]p}$ as possible while satisfying the coverage probability requirement

$$Q(u - 1; n, p) - Q(l - 1; n, p) \geq 1 - \alpha$$

where $Q(k; n, p)$ is the cumulative binomial probability

$$Q(k; n, p) = \sum_{i=0}^k \binom{n}{i} p^i (1 - p)^{n-i}$$

In some cases, the coverage requirement cannot be met, particularly when n is small and p is near 0 or 1. To relax the requirement of symmetry, you can specify CIPCTLDF(TYPE = ASYMMETRIC). This option requests symmetric limits when the coverage requirement can be met, and asymmetric limits otherwise.

If you specify CIPCTLDF(TYPE = LOWER), a one-sided $100(1 - \alpha)\%$ lower confidence bound is computed as X_l , where l is the largest integer that satisfies the inequality

$$1 - Q(l - 1; n, p) \geq 1 - \alpha$$

with $0 < l \leq n$. Likewise, if you specify CIPCTLDF(TYPE = UPPER), a one-sided $100(1 - \alpha)\%$ lower confidence bound is computed as X_l , where l is the largest integer that satisfies the inequality

$$Q(u - 1; n, p) \geq 1 - \alpha$$

where $0 < u \leq n$.

Note that confidence limits for percentiles are not computed when a WEIGHT statement is specified.

Robust Estimators

The CAPABILITY procedure provides several methods for computing robust estimates of location and scale, which are insensitive to outliers in the data.

Winsorized Means

The k -times Winsorized mean is a robust estimator of location which is computed as

$$\bar{x}_{wk} = \frac{1}{n} \left((k + 1)x_{(k+1)} + \sum_{i=k+2}^{n-k-1} x_{(i)} + (k + 1)x_{(n-k)} \right)$$

where n is the number of observations, and $x_{(i)}$ is the i th order statistic when the observations are arranged in increasing order:

$$x_{(1)} \leq x_{(2)} \leq \dots \leq x_{(n)}$$

The Winsorized mean is the mean computed after replacing the k smallest observations with the $(k + 1)$ st smallest observation, and the k largest observations with the $(k + 1)$ st largest observation.

For data from a symmetric distribution, the Winsorized mean is an unbiased estimate of the population mean. However, the Winsorized mean does not have a normal distribution even if the data are normally distributed.

The Winsorized sum of squared deviations is defined as

$$s_{wk}^2 = (k+1)(x_{(k+1)} - \bar{x}_{wk})^2 + \sum_{i=k+2}^{n-k-1} (x_{(i)} - \bar{x}_{wk})^2 + (k+1)(x_{(n-k)} - \bar{x}_{wk})^2$$

A Winsorized t test is given by

$$t_{wk} = \frac{\bar{x}_{wk} - \mu_0}{\text{STDERR}(\bar{x}_{wk})}$$

where the standard error of the Winsorized mean is

$$\text{STDERR}(\bar{x}_{wk}) = \frac{n-1}{n-2k-1} \frac{s_{wk}}{\sqrt{n(n-1)}}$$

When the data are from a symmetric distribution, the distribution of t_{wk} is approximated by a Student's t distribution with $n-2k-1$ degrees of freedom. Refer to Tukey and McLaughlin (1963) and Dixon and Tukey (1968).

A $100(1-\alpha)\%$ Winsorized confidence interval for the mean has upper and lower limits

$$\bar{x}_{wk} \pm t_{1-\alpha/2} \text{STDERR}(\bar{x}_{wk})$$

where $t_{1-\alpha/2}$ is the $(1-\alpha)/2$ 100th percentile of the Student's t distribution with $n-2k-1$ degrees of freedom.

Trimmed Means

The k -times trimmed mean is a robust estimator of location which is computed as

$$\bar{x}_{tk} = \frac{1}{n-2k} \sum_{i=k+1}^{n-k} x_{(i)}$$

where n is the number of observations, and $x_{(i)}$ is the i th order statistic when the observations are arranged in increasing order:

$$x_{(1)} \leq x_{(2)} \leq \dots \leq x_{(n)}$$

The trimmed mean is the mean computed after the k smallest observations and the k largest observations in the sample are deleted.

For data from a symmetric distribution, the trimmed mean is an unbiased estimate of the population mean. However, the trimmed mean does not have a normal distribution even if the data are normally distributed.

A robust estimate of the variance of the trimmed mean t_{tk} can be obtained from the Winsorized sum of squared deviations; refer to Tukey and McLaughlin (1963). the corresponding trimmed t test is given by

$$t_{tk} = \frac{\bar{x}_{tk} - \mu_0}{\text{STDERR}(\bar{x}_{tk})}$$

where the standard error of the trimmed mean is

$$\text{STDERR}(\bar{x}_{tk}) = \frac{s_{wk}}{\sqrt{(n-2k)(n-2k-1)}}$$

and s_{wk} is the square root of the Winsorized sum of squared deviations.

When the data are from a symmetric distribution, the distribution of t_{tk} is approximated by a Student's t distribution with $n - 2k - 1$ degrees of freedom. Refer to Tukey and McLaughlin (1963) and Dixon and Tukey (1968).

A $100(1 - \alpha)\%$ trimmed confidence interval for the mean has upper and lower limits

$$\bar{x}_{tk} \pm t_{1-\alpha/2} \text{STDERR}(\bar{x}_{tk})$$

where $t_{1-\alpha/2}$ is the $(1 - \alpha)/2$ 100th percentile of the Student's t distribution with $n - 2k - 1$ degrees of freedom.

Robust Estimates of Scale

The sample standard deviation, which is the most commonly used estimator of scale, is sensitive to outliers. Robust scale estimators, on the other hand, remain bounded when a single data value is replaced by an arbitrarily large or small value. The CAPABILITY procedure computes several robust measures of scale, including the interquartile range Gini's mean difference G , the median absolute deviation about the median (MAD), Q_n , and S_n . In addition, the procedure computes estimates of the normal standard deviation σ derived from each of these measures.

The interquartile range (IQR) is simply the difference between the upper and lower quartiles. For a normal population, σ can be estimated as $\text{IQR}/1.34898$.

Gini's mean difference is computed as

$$G = \frac{1}{\binom{n}{2}} \sum_{i < j} |x_i - x_j|$$

For a normal population, the expected value of G is $2\sigma/\sqrt{\pi}$. Thus $G\sqrt{\pi}/2$ is a robust estimator of σ when the data are from a normal sample. For the normal distribution, this estimator has high efficiency relative to the usual sample standard deviation, and it is also less sensitive to the presence of outliers.

A very robust scale estimator is the MAD, the median absolute deviation from the median (Hampel 1974), which is computed as

$$\text{MAD} = \text{med}_i(|x_i - \text{med}_j(x_j)|)$$

where the inner median, $\text{med}_j(x_j)$, is the median of the n observations, and the outer median (taken over i) is the median of the n absolute values of the deviations about the inner median. For a normal population, 1.4826MAD is an estimator of σ .

The MAD has low efficiency for normal distributions, and it may not always be appropriate for symmetric distributions. Rousseeuw and Croux (1993) proposed two statistics as alternatives to the MAD. The first is

$$S_n = 1.1926 \text{med}_i(\text{med}_j(|x_i - x_j|))$$

where the outer median (taken over i) is the median of the n medians of $|x_i - x_j|$, $j = 1, 2, \dots, n$. To reduce small-sample bias, $c_{sn}S_n$ is used to estimate σ , where c_{sn} is a correction factor; refer to Croux and Rousseeuw (1992).

The second statistic is

$$Q_n = 2.2219 \{|x_i - x_j|; i < j\}_{(k)}$$

where

$$k = \binom{h}{2}$$

and $h = [n/2] + 1$. In other words, Q_n is 2.2219 times the k th order statistic of the $\binom{n}{2}$ distances between the data points. The bias-corrected statistic $c_{qn}Q_n$ is used to estimate σ , where c_{qn} is a correction factor; refer to Croux and Rousseeuw (1992).

Computing the Mode

The mode is the value that occurs most often in a set of observations. The CAPABILITY procedure counts repetitions of the actual values (or the rounded values, if you specify the ROUND= option). If a tie occurs for the most frequent value, the procedure reports the lowest mode in the table labeled *Basic Statistical Measures*. To list all possible modes, specify the MODES option in the PROC CAPABILITY statement. When no repetitions occur in the data, the procedure does not report the mode. The WEIGHT statement has no effect on the mode.

Assumptions and Terminology for Capability Indices

One of the fundamental assumptions in process capability analysis is that the process must be in statistical control. Without statistical control, the process is not predictable, the concept of a process distribution does not apply, and quantities related to the distribution, such as probabilities, percentiles, and capability indices, cannot be meaningfully estimated. Additionally, all of the standard process capability indices described in the next section require that the process distribution be normal, or at least approximately normal.

In many industries, statistical control is routinely checked with a Shewhart chart (such as an \bar{X} and R chart) before capability indices such as

$$C_{pk} = \min \left(\frac{USL - \mu}{3\sigma}, \frac{LSL - \mu}{3\sigma} \right)$$

are computed. The control chart analysis yields estimates for the process mean μ and standard deviation σ , which are based on subgrouped data and can be used to estimate C_{pk} . In particular, σ can be estimated by

$$s_R = \bar{R}/d_2$$

rather than the ungrouped sample standard deviation

$$s = \frac{1}{n-1} \sqrt{\sum_{i=1}^n n(x_i - \bar{x})^2}$$

You can use the SHEWHART procedure to carry out the control chart analysis and to compute capability indices based on s_R . On the other hand, the CAPABILITY procedure computes indices based on s .

Some industry manuals distinguish these two approaches. For instance, the ASQC/AIAG manual *Fundamental Process Control* uses the notation C_{pk} for the estimate based on s_R , and it uses the notation P_{pk} for the estimate based on s . However, assuming that the process is in control and only common cause variation is present, both s_R and s are estimates of the same parameter σ , and so there is fundamentally no difference in the two approaches².

Once control has been established, attention should focus on the distribution of the process measurements, and at this point there is no practical or statistical advantage to working with subgrouped measurements. In fact, the use of s is closely associated with a wide variety of methods that are highly useful for process capability analysis, including tests for normality, graphical displays such as histograms and probability plots, and confidence intervals for parameters and capability indices.

Standard Capability Indices

This section provides computational details for the standard process capability indices computed by the CAPABILITY procedure: C_p , CPL , CPU , C_{pk} , and C_{pm} .

The Index C_p

The process capability index C_p , sometimes called the “process potential index,” the “process capability ratio,” or the “inherent capability index,” is estimated as

$$\hat{C}_p = \frac{USL - LSL}{6s}$$

where USL is the upper specification limit, LSL is the lower specification limit, and s is the sample standard deviation. If you do not specify both the upper and the lower specification limits in the SPEC statement or the SPEC= data set, then C_p is assigned a missing value.

The interpretation of C_p can depend on the application, on past experience, and on local practice. However, broad guidelines for interpretation have been proposed by several authors. Ekvall and Juran (1974) classify C_p values as

- “not adequate” if $C_p < 1$
- “adequate” if $1 \leq C_p \leq 1.33$, but requiring close control as C_p approaches 1
- “more than adequate” if $C_p > 1.33$

Montgomery (1996) recommends minimum values of C_p as

- 1.33 for existing processes
- 1.50 for new processes or for existing processes when the variable is critical (for example, related to safety or strength)
- 1.67 for new processes when the variable is critical

²Statistically, s is a more efficient estimator of σ than s_R .

Exact $100(1 - \alpha)\%$ lower and upper confidence limits for C_p (denoted by LCL and UCL) are computed using percentiles of the chi-square distribution, as indicated by the following equations:

$$\begin{aligned}\text{lower limit} &= \hat{C}_p \sqrt{\chi_{\alpha/2, n-1}^2 / (n-1)} \\ \text{upper limit} &= \hat{C}_p \sqrt{\chi_{1-\alpha/2, n-1}^2 / (n-1)}\end{aligned}$$

Here, $\chi_{\alpha, \nu}^2$ denotes the lower 100α th percentile of the chi-square distribution with ν degrees of freedom. Refer to Chou, Owen, and Borrego (1990) and Kushler and Hurley (1992).

You can specify α with the ALPHA= option in the PROC CAPABILITY statement or with the CIINDICES(ALPHA=value) in the PROC CAPABILITY statement. The default value is 0.05. You can save these limits in the OUT= data set by specifying the keywords CPLCL and CPUCL in the OUTPUT statement. In addition, you can display these limits on plots produced by the CAPABILITY procedure by specifying the keywords in the INSET statement.

The Index CPL

The process capability index CPL is estimated as

$$\widehat{CPL} = \frac{\bar{X} - LSL}{3s}$$

where \bar{X} is the sample mean, LSL is the lower specification limit, and s is the sample standard deviation. If you do not specify the lower specification limit in the SPEC statement or the SPEC= data set, then CPL is assigned a missing value.

Montgomery (1996) refers to CPL as the “process capability ratio” in the case of one-sided lower specifications and recommends minimum values as follows:

- 1.25 for existing processes
- 1.45 for new processes or for existing processes when the variable is critical
- 1.60 for new processes when the variable is critical

Exact $100(1 - \alpha)\%$ lower and upper confidence limits for CPL are computed using a generalization of the method of Chou, Owen, and Borrego (1990), who point out that the $100(1 - \alpha)$ lower confidence limit for CPL (denoted by CPLLCL) satisfies the equation

$$\Pr\{T_{n-1}(\delta = 3\sqrt{n}) \text{CPLLCL} \leq 3\text{CPL}\sqrt{n}\} = 1 - \alpha$$

where $T_{n-1}(\delta)$ has a non-central t distribution with $n - 1$ degrees of freedom and noncentrality parameter δ . You can specify α with the ALPHA= option in the PROC CAPABILITY statement. The default value is 0.05. The confidence limits can be saved in an output data set by specifying the keywords CPLLCL and CPLUCL in the OUTPUT statement. In addition, you can display these limits on plots produced by the CAPABILITY procedure by specifying these keywords in the INSET statement.

The Index CPU

The process capability index *CPU* is estimated as

$$\widehat{CPU} = \frac{USL - \bar{X}}{3s}$$

where *USL* is the upper specification limit, \bar{X} is the sample mean, and *s* is the sample standard deviation. If you do not specify the upper specification limit in the SPEC statement or the SPEC= data set, then *CPU* is assigned a missing value.

Montgomery (1996) refers to *CPU* as the “process capability ratio” in the case of one-sided upper specifications and recommends minimum values that are the same as those specified previously for *CPL*.

Exact $100(1 - \alpha)\%$ lower and upper confidence limits for *CPU* are computed using a generalization of the method of Chou, Owen, and Borrego (1990), who point out that the $100(1 - \alpha)$ lower confidence limit for *CPU* (denoted by CPULCL) satisfies the equation

$$\Pr\{T_{n-1}(\delta = 3\sqrt{n} \text{ CPULCL} \geq 3\text{CPU}\sqrt{n}\} = 1 - \alpha$$

where $T_{n-1}(\delta)$ has a non-central *t* distribution with $n - 1$ degrees of freedom and noncentrality parameter δ . You can specify α with the ALPHA= option in the PROC CAPABILITY statement. The default value is 0.05. The confidence limits can be saved in an output data set by specifying the keywords CPULCL and CPUUCL in the OUTPUT statement. In addition, you can display these limits on plots produced by the CAPABILITY procedure by specifying these keywords in the INSET statement.

The Index Cpk

The process capability index C_{pk} is defined as

$$C_{pk} = \frac{1}{3\sigma} \min(USL - \mu, \mu - LSL) = \min(CPU, CPL)$$

Note that the indices C_{pk} , C_p , and k are related as $C_{pk} = C_p(1 - k)$. The CAPABILITY procedure estimates C_{pk} as

$$\widehat{C}_{pk} = \frac{1}{3s} \times \min(USL - \bar{X}, \bar{X} - LSL) = \min(CPU, CPL)$$

where *USL* is the upper specification limit, *LSL* is the lower specification limit, \bar{X} is the sample mean, and *s* is the sample standard deviation.

If you specify only the upper limit in the SPEC statement or the SPEC= data set, then C_{pk} is computed as *CPU*, and if you specify only the lower limit in the SPEC statement or the SPEC= data set, then C_{pk} is computed as *CPL*.

Bissell (1990) derived approximate two-sided 95% confidence limits for C_{pk} by assuming that the distribution of \widehat{C}_{pk} is normal. Using Bissell’s approach, $100(1 - \alpha)\%$ lower and upper confidence limits can be computed as

$$\begin{aligned} \text{lower limit} &= \hat{C}_{pk} \left[1 - \Phi^{-1}(1 - \alpha/2) \sqrt{\frac{1}{9n\hat{C}_{pk}^2} + \frac{1}{2(n-1)}} \right] \\ \text{upper limit} &= \hat{C}_{pk} \left[1 + \Phi^{-1}(1 - \alpha/2) \sqrt{\frac{1}{9n\hat{C}_{pk}^2} + \frac{1}{2(n-1)}} \right] \end{aligned}$$

where Φ denotes the cumulative standard normal distribution function. Kushler and Hurley (1992) concluded that Bissell's method gives reasonably accurate results.

You can specify α with the ALPHA= option in the PROC CAPABILITY statement. The default value is 0.05. These limits can be saved in an output data set by specifying the keywords CPKLCL and CPKUCL in the OUTPUT statement. In addition, you can display these limits on plots produced by the CAPABILITY procedure by specifying these same keywords in the INSET statement.

The Index C_{pm}

The process capability index C_{pm} is intended to account for deviation from the target T in addition to variability from the mean. This index is often defined as

$$C_{pm} = \frac{USL - LSL}{6\sqrt{\sigma^2 + (\mu - T)^2}}$$

A closely related version of C_{pm} is the index

$$C_{pm}^* = \frac{\min(USL - T, T - LSL)}{3\sqrt{\sigma^2 + (\mu - T)^2}} = \frac{d - |T - m|}{3\sqrt{\sigma^2 + (\mu - T)^2}}$$

where $d = (USL - LSL)/2$ and $m = (USL + LSL)/2$. If $T = m$, then $C_{pm} = C_{pm}^*$. However, if $T \neq m$, then both indices suffer from problems of interpretation, as pointed out by Kotz and Johnson (1993), and their use should be avoided in this case.

The CAPABILITY procedure computes an estimator of C_{pm} as

$$\hat{C}_{pm} = \frac{\min(USL - T, T - LSL)}{3\sqrt{s^2 + (\bar{X} - T)^2}}$$

where s is the sample standard deviation.

If you specify only a single specification limit SL in the SPEC statement or the SPEC= data set, then C_{pm} is estimated as

$$\hat{C}_{pm} = \frac{|T - SL|}{3\sqrt{s^2 + (\bar{X} - T)^2}}$$

Boyles (1991) proposed a slightly modified point estimate for C_{pm} computed as

$$\tilde{C}_{pm} = \frac{(USL - LSL)/2}{3\sqrt{\left(\frac{n-1}{n}\right)s^2 + (\bar{X} - T)^2}}$$

Boyles also suggested approximate two-sided $100(1 - \alpha)\%$ confidence limits for C_{pm} , which are computed as

$$\begin{aligned} \text{lower limit} &= \tilde{C}_{pm} \sqrt{\chi_{\alpha/2, \nu}^2 / \nu} \\ \text{upper limit} &= \tilde{C}_{pm} \sqrt{\chi_{1-\alpha/2, \nu}^2 / \nu} \end{aligned}$$

Here $\chi_{\alpha, \nu}^2$ denotes the lower 100α th percentile of the chi-square distribution with ν degrees of freedom, where ν equals

$$\frac{n(1 + (\frac{\bar{X}-T}{s})^2)}{1 + 2(\frac{\bar{X}-T}{s})^2}$$

You can specify α with the ALPHA= option in the PROC CAPABILITY statement. The default value is 0.05. These confidence limits can be saved in an output data set by specifying the keywords CPMLCL and CPMUCL in the OUTPUT statement. In addition, you can display these limits on plots produced by the CAPABILITY procedure by specifying these keywords in the INSET statement.

Specialized Capability Indices

This section describes a number of specialized capability indices which you can request with the SPECIALINDICES option in the PROC CAPABILITY statement.

The Index k

The process capability index k (also denoted by K) is computed as

$$k = \frac{2|m - \bar{X}|}{USL - LSL}$$

where $m = \frac{1}{2}(USL + LSL)$ is the midpoint of the specification limits, \bar{X} is the sample mean, USL is the upper specification limit, and LSL is the lower specification limit.

The formula for k used here is given by Kane (1986). Note that k is sometimes computed without taking the absolute value of $m - \bar{X}$ in the numerator. See Wadsworth, Stephens, and Godfrey (1986).

If you do not specify the upper and lower limits in the SPEC statement or the SPEC= data set, then k is assigned a missing value.

Boyles' Index C_{pm}^+

Boyles (1992) proposed the process capability index C_{pm}^+ which is defined as

$$C_{pm}^+ = \frac{1}{3} \left[\frac{E_{X < T} [(X - T)^2]}{(T - LSL)^2} + \frac{E_{X > T} [(X - T)^2]}{(USL - T)^2} \right]^{-1/2}$$

He proposed this index as a modification of C_{pm} for use when $\mu \neq T$. The quantities

$$E_{X < T} [(X - T)^2] = E [(X - T)^2 | X < T] Pr [X < T]$$

and

$$E_{X > T} [(X - T)^2] = E [(X - T)^2 | X > T] Pr [X > T]$$

are referred to as semivariances. Kotz and Johnson (1993) point out that if $T = (LSL + USL)/2$, then $C_{pm}^+ = C_{pm}$.

Kotz and Johnson (1993) suggest that a natural estimator for C_{pm}^+ is

$$\hat{C}_{pm}^+ = \frac{1}{3} \left[\frac{1}{n} \left\{ \frac{\sum_{X_i < T} (X_i - T)^2}{(T - LSL)^2} + \frac{\sum_{X_i > T} (X_i - T)^2}{(USL - T)^2} \right\}^{-1/2} \right]$$

Note that this index is not defined when either of the specification limits is equal to the target T . Refer to Section 3.5 of Kotz and Johnson (1993) for further details.

The Index C_{jkp}

Johnson, Kotz, and Pearn (1994) introduced a so-called “flexible” process capability index which takes into account possible differences in variability above and below the target T . They defined this index as

$$C_{jkp} = \frac{1}{3\sqrt{2}} \min \left(\frac{USL - T}{\sqrt{E_{X > T} [(X - T)^2]}}, \frac{T - LSL}{\sqrt{E_{X < T} [(X - T)^2]}} \right)$$

where $d = (USL - LSL)/2$.

A natural estimator of this index is

$$\hat{C}_{jkp} = \frac{1}{3\sqrt{2}} \min \left(\frac{USL - T}{\sqrt{\sum_{X_i > T} (X_i - T)^2/n}}, \frac{T - LSL}{\sqrt{\sum_{X_i < T} (X_i - T)^2/n}} \right)$$

For further details, refer to Section 4.4 of Kotz and Johnson (1993).

The Indices $C_{pm}(a)$

The class of capability indices $C_{pm}(a)$, indexed by the parameter a ($a > 0$) allows flexibility in choosing between the relative importance of variability and deviation of the mean from the target value T .

The class defined as

$$C_{pm}(a) = (1 - a\zeta^2)C_p$$

where $\zeta = (\mu - T)/\sigma$. The motivation for this definition is that if $|\zeta|$ is small, then

$$C_{pm} \approx (1 - \frac{1}{2}\zeta^2)C_p$$

A natural estimator of $C_{pm}(a)$ is

$$\frac{d}{3s} \widehat{C}_{pm}(a) = \left\{ 1 - a \left(\frac{\bar{X} - T}{s} \right)^2 \right\}$$

where $d = (USL - LSL)/2$. You can specify the value of a with the SPECIALINDICES(CPMA=) option in the PROC CAPABILITY statement. By default, $a = 0.5$.

This index is not recommended for situation in which the target T is not equal to the midpoint of the specification limits.

For additional details, refer to Section 3.7 of Kotz and Johnson (1993).

The Index $C_{p(5.15)}$

Johnson *et al.* (1992) suggest the class of process capability indices defined as

$$C_{p(\theta)} = \frac{USL - LSL}{\theta\sigma}$$

where θ is chosen so that the proportion of conforming items is robust with respect to the shape of the process distribution. In particular, Kotz and Johnson (1993) recommend use of

$$C_{p(5.15)} = \frac{USL - LSL}{5.15\sigma}$$

which is estimated as

$$\widehat{C}_{p(5.15)} = \frac{USL - LSL}{5.15s}$$

For details, refer to Section 4.3.2 of Kotz and Johnson (1993).

The Index $C_{pk(5.15)}$

Similarly, Kotz and Johnson (1993) recommend use of the robust capability index

$$C_{pk(5.15)} = \frac{d - |\mu - (USL + LSL)/2|}{2.575\sigma}$$

where $d = (USL - LSL)/2$. This index is estimated as

$$\widehat{C}_{pk(5.15)} = \frac{d - |\bar{X} - (USL + LSL)/2|}{2.575s}$$

For details, refer to Section 4.3.2 of Kotz and Johnson (1993).

The Index C_{pmk}

Pearn, Kotz, and Johnson (1992) proposed the index C_{pmk}

$$C_{pmk} = \frac{(\text{USL} - \text{LSL})/2 - |\mu - m|}{3\sqrt{\sigma^2 + (\mu - T)^2}}$$

where $m = (\text{LCL} + \text{UCL})/2$. A natural estimator for C_{pmk} is

$$\hat{C}_{pmk} = \frac{(\text{USL} - \text{LSL})/2 - |\bar{X} - m|}{3\sqrt{(\frac{n-1}{n})s^2 + (\bar{X} - T)^2}}$$

where $m = (\text{USL} + \text{LSL})/2$.

For further details, refer to Section 3.6 of Kotz and Johnson (1993).

Wright's Index C_s

Wright (1995) defines the capability index

$$C_s = \frac{\min(\text{USL} - \mu, \mu - \text{LSL})}{3\sqrt{\sigma^2 + (\mu - T)^2 + \mu_3/\sigma}}$$

where $\mu_3 = E(X - \mu)^3$.

A natural estimator of C_s is

$$\hat{C}_s = \frac{(\text{USL} - \text{LSL})/2 - |\bar{X} - m|}{3\sqrt{(\frac{n-1}{n})s^2 + (\bar{X} - T)^2 + |c_4s^2b_3|}}$$

where c_4 is an unbiasing constant for the sample standard deviation, and b_3 is a measure of skewness. Wright (1995) shows that C_s compares favorably with C_{pmk} even when skewness is not present, and he advocates the use of C_s for monitoring near-normal processes when loss of capability typically leads to asymmetry.

Chen and Kotz (1996) proposed a modification to Wright's C_s index which introduces a multiplier, $\gamma > 0$, and is estimated as

$$\hat{C}_s = \frac{(\text{USL} - \text{LSL})/2 - |\bar{X} - m|}{3\sqrt{(\frac{n-1}{n})s^2 + (\bar{X} - T)^2 + \gamma|c_4s^2b_3|}}$$

If you specify a value for γ with the SPECIALINDICES(CSGAMMA=) option, the index C_s is computed with this modification. Otherwise it is computed using Wright's original definition.

The Index S_{jkp}

Boyles (1994) proposed a smooth version of C_{jkp} defined as

$$S_{jkp} = S \left(\frac{\text{USL} - T}{\sqrt{2E_{X>T}[(X - T)^2]}}, \frac{T - \text{LSL}}{\sqrt{2E_{X<T}[(X - T)^2]}} \right)$$

The CAPABILITY procedure estimates S_{jkp} as

$$\widehat{S}_{jkp} = S \left(\frac{USL - T}{\sqrt{2 \sum_{X_i > T} (X_i - T)^2 / n}}, \frac{T - LSL}{\sqrt{2 \sum_{X_i < T} (X_i - T)^2 / n}} \right)$$

where $S(x, y) = \Phi^{-1}[\{\Phi(x) + \Phi(y)\}/2]/3$.

The Index C_{pp}

Chen (1998) devised a process incapability index based on the C_{pm}^* index. The first term measures *inaccuracy* and the second measures *imprecision*. The C_{pp} index is estimated as

$$\widehat{C}_{pp} = \left(\frac{\bar{X} - T}{d^*/3} \right)^2 + \left(\frac{s}{d^*/3} \right)^2$$

where $d^* = \min(USL - T, T - LSL)$.

The Index C''_{pp}

The index C_{pp} does not handle asymmetric tolerances well, as discussed by Kotz and Lovelace (1998). To address that shortcoming, Chen (1998) defined the index C''_{pp} , which is estimated by

$$\widehat{C}''_{pp} = \left(\frac{\widehat{A}}{d^*/3} \right)^2 + \left(\frac{s}{d^*/3} \right)^2$$

where

$$\widehat{A} = \max \left\{ \frac{(\bar{X} - T)d}{T - LSL}, \frac{(T - \bar{X})d}{USL - T} \right\}$$

and $d = (USL - LSL)/2$.

The Index C_{pg}

Marcucci and Beazley (1988) defined the index

$$C_{pg} = \frac{1}{C_{pm}^2}$$

which is estimated as

$$\widehat{C}_{pg} = \frac{1}{\widehat{C}_{pm}^2}$$

The Index C_{pq}

Gupta and Kotz (1997) introduced the index C_{pq} , which is estimated by

$$\hat{C}_{pq} = \hat{C}_p \left[1 - \frac{1}{2} \left(\frac{\bar{X} - T}{s} \right)^2 \right]$$

The Index C_p^W

Bai and Choi (1997) defined the index

$$C_p^W = \frac{C_p}{\sqrt{1 + |1 - 2P_x|}}$$

where $P_x = \Pr(X \leq \mu)$. It is estimated by

$$\hat{C}_p^W = \frac{\hat{C}_p}{\sqrt{1 + |1 - 2\hat{P}_x|}}$$

where \hat{P}_x is the fraction of observations less than or equal to \bar{X} . For more information about C_p^W , see Kotz and Lovelace (1998).

The Index C_{pk}^W

Bai and Choi (1997) also proposed the index

$$C_{pk}^W = \min \left\{ \frac{USL - \mu}{3\sigma\sqrt{2P_x}}, \frac{\mu - LSL}{3\sigma\sqrt{2(1 - P_x)}} \right\}$$

It is estimated by

$$\hat{C}_{pk}^W = \min \left\{ \frac{USL - \bar{X}}{3s\sqrt{2\hat{P}_x}}, \frac{\bar{X} - LSL}{3s\sqrt{2(1 - \hat{P}_x)}} \right\}$$

where \hat{P}_x is the fraction of observations less than or equal to \bar{X} . For more information about C_{pk}^W , see Kotz and Lovelace (1998).

The Index C_{pm}^W

The index C_{pm}^W , also introduced by Bai and Choi (1997), is defined as

$$C_{pm}^W = \frac{C_{pm}}{\sqrt{1 + |1 - 2P_T|}}$$

where $P_T = \Pr(X \leq T)$. It is estimated by

$$\hat{C}_{pm}^W = \frac{\hat{C}_{pm}}{\sqrt{1 + |1 - 2\hat{P}_T|}}$$

where \hat{P}_T is the fraction of observations less than or equal to T . For more information about C_{pm}^W , see Kotz and Lovelace (1998).

The Index C_{pc}

Luceño (1996) proposed the index

$$C_{pc} = \frac{USL - LSL}{6\sqrt{\frac{\pi}{2}}E|X - M|}$$

where $M = (USL + LSL)/2$. It is estimated by

$$\hat{C}_{pc} = \frac{USL - LSL}{6\sqrt{\frac{\pi}{2}}c}$$

where

$$c = \frac{1}{n} \sum_{i=1}^n |X_i - M|$$

Vännmann's Index $C_p(u, v)$

Vännmann (1995) introduced the generalized index $C_p(u, v)$, which reduces to the following capability indices given appropriate choices of u and v :

- $C_p(0, 0) = C_p$
- $C_p(0, 1) = C_{pk}$
- $C_p(1, 0) = C_{pm}$

- $C_p(1, 1) = C_{pmk}$

$C_p(u, v)$ is defined as

$$C_p(u, v) = \frac{d - u|\mu - M|}{3\sqrt{\sigma^2 + v(\mu - T)^2}}$$

and estimated by

$$\hat{C}_p(u, v) = \frac{d - u|\bar{X} - M|}{3\sqrt{(\frac{n-1}{n})s^2 + v(\bar{X} - T)^2}}$$

You can specify u with the SPECIALINDICES(CPU=) option and v with the SPECIALINDICES(CPV=) option. By default, $u = 0$ and $v = 4$.

Vännmann's Index $C_p(v)$

Vännmann (1997) also proposed the index $C_p(v)$, which is equivalent to $C_p(u, v)$ with $u = 1$. It is estimated as

$$\hat{C}_p(v) = \frac{d - |\bar{X} - M|}{3\sqrt{(\frac{n-1}{n})s^2 + v(\bar{X} - T)^2}}$$

You can specify v with the SPECIALINDICES(CPV=) option. By default, $v = 4$.

Missing Values

If a variable for which statistics are calculated has a missing value, that value is ignored in the calculation of statistics, and the missing values are tabulated separately. A missing value for one such variable does not affect the treatment of other variables in the same observation.

If the WEIGHT variable has a missing value, the observation is excluded from the analysis³. If the FREQ variable has a missing value, the observation is excluded from the analysis. If a variable in a BY or ID statement has a missing value, the procedure treats it as it would treat any other value of a BY or ID variable.

ODS Tables

This section describes the ODS tables produced by the CAPABILITY procedure.

Table 5.5 summarizes the ODS tables that you can request with options in the PROC CAPABILITY statement.

³In SAS 6.12 and earlier releases, the observation was included in the analysis, and the missing WEIGHT variable value was taken to be zero.

Table 5.5 ODS Tables Produced with the PROC CAPABILITY Statement

Table Name	Description	Option
BasicIntervals	confidence intervals for mean, standard deviation, variance	CIBASIC
BasicMeasures	measures of location and variability	default
ExtremeObs	extreme observations	default
ExtremeValues	extreme values	NEXTRVAL=
Frequencies	frequencies	FREQ
LocationCounts	counts used for sign test and signed rank test	LOCCOUNTS
MissingValues	missing values	default
Modes	modes	MODES
Moments	sample moments	default
Quantiles	quantiles	default
RobustScale	robust measures of scale	ROBUSTSCALE
TestsForLocation	tests for location	default
TestsForNormality	tests for normality	NORMALTEST
TrimmedMeans	trimmed means	TRIMMED=
WinsorizedMeans	Winsorized means	WINSORIZED=

Table 5.6 summarizes the ODS tables related to capability indices that you can request with options in the PROC CAPABILITY statement when you provide specification limits with a SPEC statement or with a SPEC= data set.

Table 5.6 ODS Tables Related to Specification Limits

Table Name	Description	Option
CIProbExSpecs	confidence limits for probabilities of exceeding specifications	CIPROBEX
Indices	standard capability indices	default
SpecialIndices	specialized capability indices	SPECIALINDICES
Specifications	percents outside specification limits based on empirical	default

Table 5.7 summarizes the ODS tables related to fitted distributions that you can request with options in the HISTOGRAM statement.

Table 5.7 ODS Tables Produced with the HISTOGRAM Statement

Table Name	Description	Option
Bins	histogram bins	MIDPERCENTS suboption with any distribution option, such as NORMAL(MIDPERCENTS)
FitIndices	capability indices computed from fitted distribution	INDICES suboption with any distribution option, such as LOGNORMAL(INDICES)
FitQuantiles	quantiles of fitted distribution	any distribution option such as NORMAL
GoodnessOfFit	goodness-of-fit tests for fitted distribution	any distribution option such as NORMAL
ParameterEstimates	parameter estimates for fitted distribution	any distribution option such as NORMAL
Specifications	percents outside specification limits based on empirical and fitted distributions	any distribution option such as NORMAL

The following table summarizes the ODS tables that you can request with options in the INTERVALS statement.

Table 5.8 ODS Tables Produced with the INTERVALS Statement

Table Name	Description	Option
Intervals1	prediction interval for future observations	METHODS=1
Intervals2	prediction interval for mean	METHODS=2
Intervals3	tolerance interval for proportion of population	METHODS=3
Intervals4	confidence limits for mean	METHODS=4
Intervals5	prediction interval for standard deviation	METHODS=5
Intervals6	confidence limits for standard deviation	METHODS=6

Examples: CAPABILITY Procedure

This section provides a more advanced example of the PROC CAPABILITY statement.

Example 5.1: Reading Specification Limits

See CAPSPEC2 in the SAS/QC Sample Library You can specify specification limits either in the SPEC statement or in a SPEC= data set. In “Computing Capability Indices” on page 208, limits were specified in a SPEC statement. This example illustrates how to create a SPEC= data set to read specification limits with the SPEC= option in the PROC CAPABILITY statement.

Consider the drink can data presented in “Computing Descriptive Statistics” on page 206. Suppose, in addition to the fluid weight of each drink can, the weight of the can itself is stored in a variable named Cweight, and both variables are saved in a data set called Can2. A partial listing of Can2 follows:

```
proc print data=Can2 (obs=5);
run;
```

Output 5.1.1 The Data Set Can2

Process Capability Analysis of Fluid Weight			
Obs	Weight	Cweight	
1	12.07	1.07	
2	12.02	0.86	
3	12.00	1.06	
4	12.01	1.08	
5	11.98	1.02	

The following DATA step creates a data set named Limits containing specification limits for the fluid weight and the can weight. Limits has 4 variables (_VAR_, _LSL_, _USL_, and _TARGET_) and 2 observations. The first observation contains the specification limit information for the variable Weight, and the second contains the specification limit information for the variable Cweight.

```
data Limits;
  length _var_ $8;
  _var_   = 'Weight';
  _lsl_   = 11.95;
  _target_ = 12;
  _usl_   = 12.05;
  output;
  _var_   = 'Cweight';
  _lsl_   = 0.90;
  _target_ = 1;
  _usl_   = 1.10;
  output;
run;
```

The following statements read the specification information from the Limits data set into the CAPABILITY procedure by using the SPEC= option. These statements print summary statistics, capability indices, and specification limit information for Weight and Cweight. Figure 5.1 and Figure 5.2 display the output for Weight. Output 5.1.2 displays the output for Cweight.

```
title 'Process Capability Analysis of Drink Can Data';
proc capability data=Can2 specs=Limits;
  var Cweight;
run;
```

Example 5.2: Enhancing Reference Lines

See CAPSPEC1 in the SAS/QC Sample Library

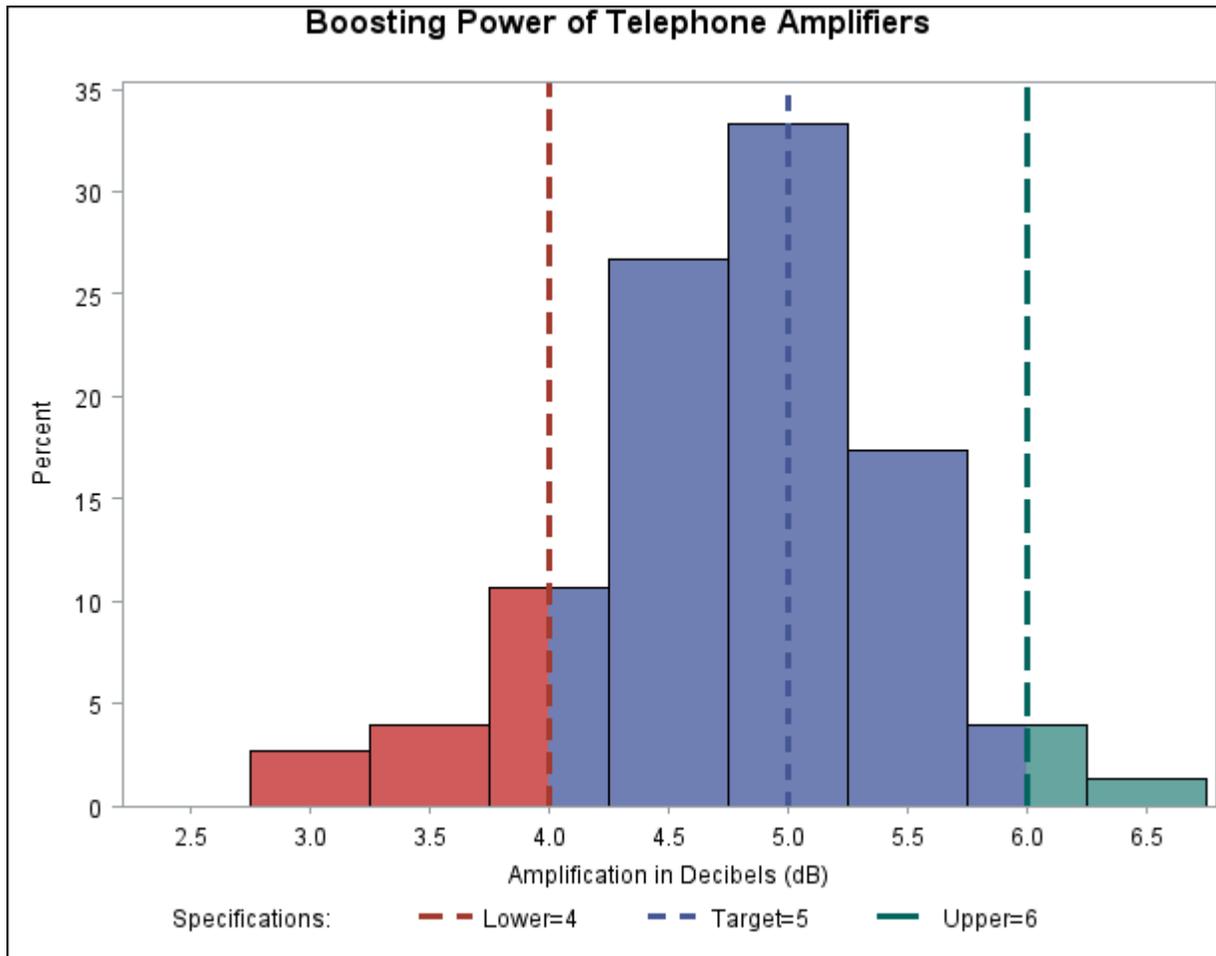

A telecommunications company manufactures amplifiers to be used in telephones. Each amplifier is designed to boost the input signal by 5 decibels (dB). Since it is difficult to make every amplifier's boosting power exactly 5 decibels, the company decides that amplifiers that boost the input signal between 4 and 6 decibels are acceptable. Therefore, the target value is 5 decibels, and the lower and upper specification limits are 4 and 6 decibels, respectively. The following data set contains the boosting powers of a sample of 75 amplifiers:

```
data Amps;
  label Decibels = 'Amplification in Decibels (dB)';
  input Decibels @@;
  datalines;
4.54 4.87 4.66 4.90 4.68 5.22 4.43 5.14 3.07 4.22
5.09 3.41 5.75 5.16 3.96 5.37 5.70 4.11 4.83 4.51
4.57 4.16 5.73 3.64 5.48 4.95 4.57 4.46 4.75 5.38
5.19 4.35 4.98 4.87 3.53 4.46 4.57 4.69 5.27 4.67
5.03 4.50 5.35 4.55 4.05 6.63 5.32 5.24 5.73 5.08
5.07 5.42 5.05 5.70 4.79 4.34 5.06 4.64 4.82 3.24
4.79 4.46 3.84 5.05 5.46 4.64 6.13 4.31 4.81 4.98
4.95 5.57 4.11 4.15 5.95
;
```

The SPEC statement provides several options to control the appearance of reference lines for the specification limits and the target value. The following statements use the data set Amps to create a histogram that demonstrates some of these options:

```
ods graphics off;
legend2 FRAME CFRAME=ligr CBORDER=black POSITION=center;
title 'Boosting Power of Telephone Amplifiers';
proc capability data=Amps;
  spec target = 5      lsl = 4      usl = 6
      ltarget = 2     lls1 = 3     lus1 = 4
      wtarget = 2     wls1 = 2     wus1 = 2
      cleft          cright;
  histogram Decibels / cbarline = black;
run;
```

The resulting histogram is shown in [Output 5.2.1](#). The LTARGET=, LLSL=, and LUSL= options control the line type of the reference lines for the target, lower specification limit, and upper specification limit, respectively. Likewise, the WTARGET=, WLSL=, and WUSL= options control the line widths. The CLEFT= option controls the color used to fill the area to the left of the lower specification limit. Similarly, the CRIGHT= option controls the color used to fill the area to the right of the upper specification limit.

Output 5.2.1 Controlling the Appearance of Specification Limits**Example 5.3: Displaying a Confidence Interval for Cpk**

In this example, the capability index C_{pk} is computed for the amplification data in Amps. To *See CAPSPEC3 in the SAS/QC Sample Library* examine the accuracy of this estimate, the following statements calculate a 90% confidence interval for C_{pk} , then display the interval on a histogram (shown in [Output 5.3.1](#)) with the INSET statement:

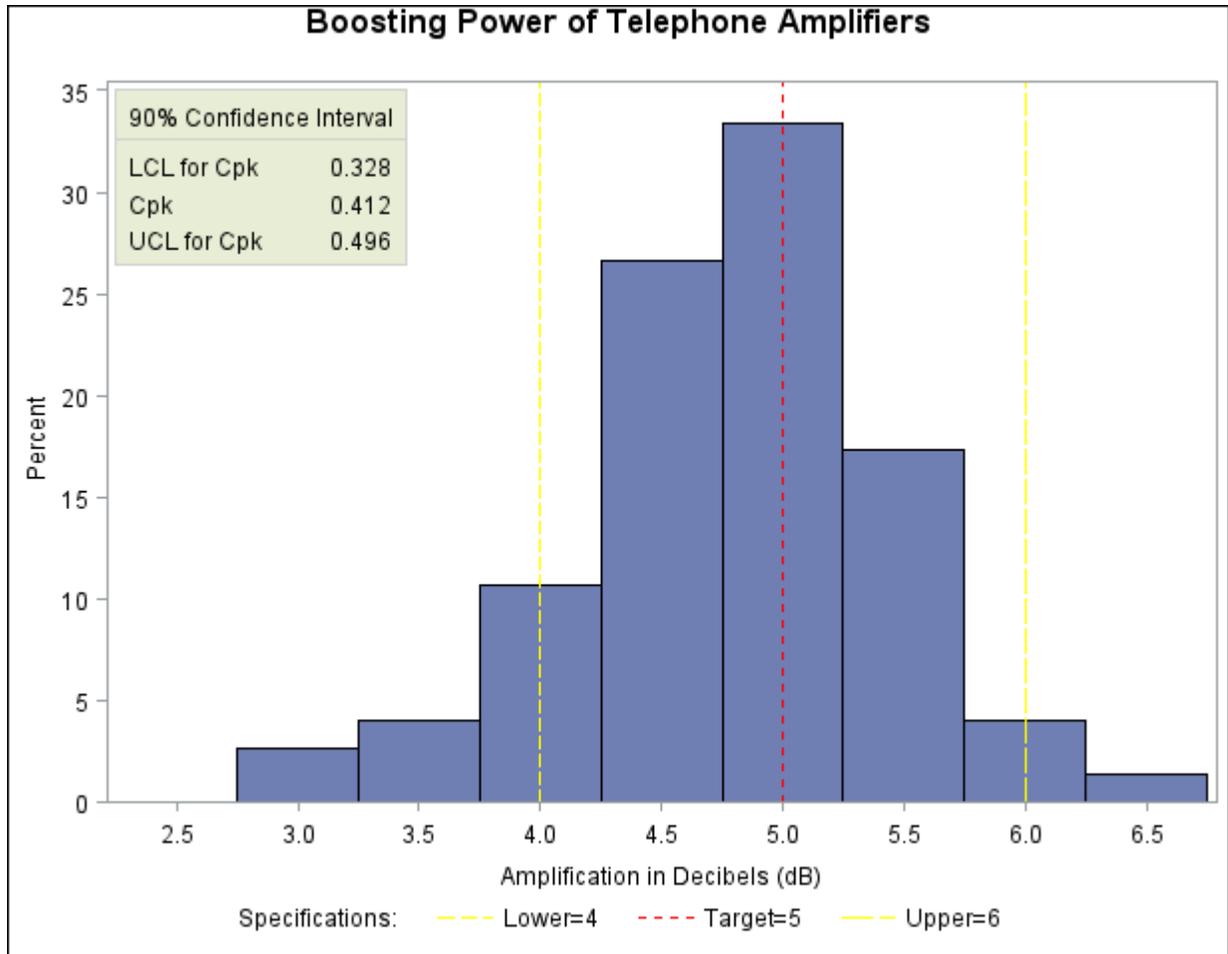

```

title 'Boosting Power of Telephone Amplifiers';
legend2 FRAME CFRAME=ligr CBORDER=black POSITION=center;
proc capability data=Amps noprint alpha=0.10;
  var Decibels;
  spec target = 5    ls1 = 4    us1 = 6
      ltarget = 2    lls1 = 3    lus1 = 4
      ctarget = red  cls1 = yellow  cus1 = yellow;
  histogram Decibels;
  inset cpklcl cpk cpkucl / header = '90% Confidence Interval'
                        cfill = ywh
                        format = 6.3;
run;

```

The ALPHA= option in the PROC CAPABILITY statement controls the level of the confidence interval. In this case, the 90% confidence interval on C_{pk} is wide (from 0.328 to 0.496), indicating that the process may need adjustments in order to improve process variability. Confidence limits for capability indices can be displayed using the INSET statement (as shown in [Output 5.3.1](#)) or saved in an output data set by using the OUTPUT statement. For formulas and details about capability indices, see the section “Specialized Capability Indices” on page 249. For more information about the INSET statement, see “INSET Statement: CAPABILITY Procedure” on page 397.

Output 5.3.1 Confidence Interval on C_{pk}

The following statements can be used to produce a table of process capability indices including the index C_{pk} :

```
ods select indices;
proc capability data=Amps alpha=0.10;
  spec target = 5 lsl = 4 usl = 6
    ltarget = 2 llsl = 3 lusl = 4;
  var Decibels;
run;
```

Output 5.3.2 Process Capability Indices

CDFPLOT Statement: CAPABILITY Procedure

Overview: CDFPLOT Statement

The CDFPLOT statement plots the observed cumulative distribution function (*cdf*) of a variable, defined as

$$\begin{aligned}
 F_N(x) &= \text{percent of nonmissing values } \leq x \\
 &= \frac{\text{number of values } \leq x}{N} \times 100\%
 \end{aligned}$$

where N is the number of nonmissing observations. The *cdf* is an increasing step function that has a vertical jump of $\frac{1}{N}$ at each value of x equal to an observed value. The *cdf* is also referred to as the empirical cumulative distribution function (*ecdf*).

You can use options in the CDFPLOT statement to do the following:

- superimpose specification limits
- superimpose fitted theoretical distributions
- specify graphical enhancements (such as color or text height)

You can also create a comparative *cdf* plot by using the CDFPLOT statement in conjunction with a CLASS statement.

You have three alternatives for producing cdf plots with the CDFPLOT statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: CDFPLOT Statement

Creating a Cumulative Distribution Plot

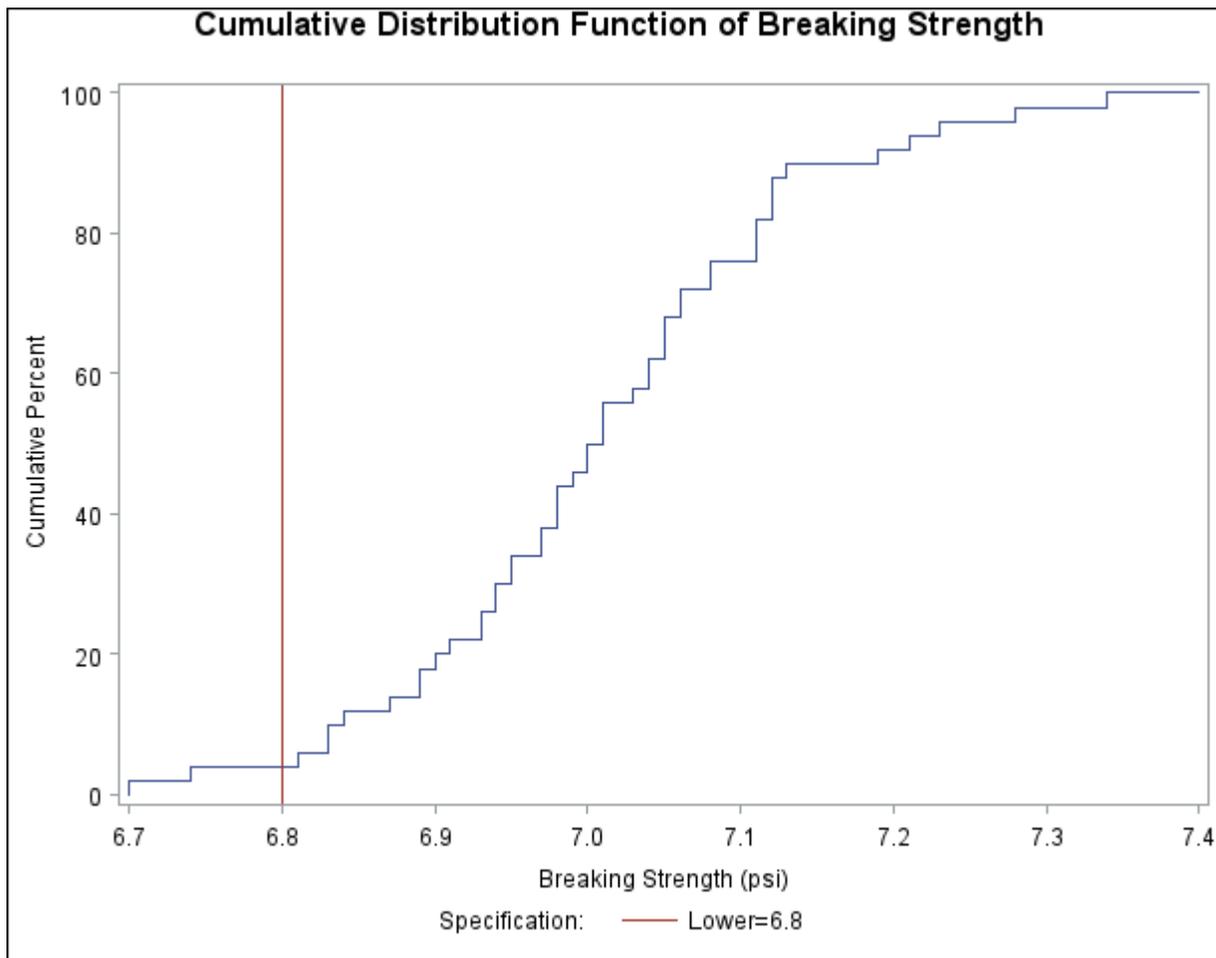

See CAPCDF1 in the SAS/QC Sample Library

This section introduces the CDFPLOT statement with a simple example. A company that produces fiber optic cord is interested in the breaking strength of the cord. The following statements create a data set named Cord, which contains 50 breaking strengths measured in pounds per square inch (psi), and they display the cdf plot in [Figure 5.5](#). The plot shows a symmetric distribution with observations concentrated 6.9 and 7.1. The plot also shows that only a small percentage (< 5%) of the observations are below the lower specification limit of 6.8.

```
data Cord;
  label Strength="Breaking Strength (psi)";
  input Strength @@;
  datalines;
6.94 6.97 7.11 6.95 7.12 6.70 7.13 7.34 6.90 6.83

  spec lsl=6.8;
  cdf Strength;
run;
```

Figure 5.5 Cumulative Distribution Function

Syntax: CDFPLOT Statement

The syntax for the CDFPLOT statement is as follows:

```
CDFPLOT < variables > < / options > ;
```

You can specify the keyword CDF as an alias for CDFPLOT. You can specify any number of CDFPLOT statements after a PROC CAPABILITY statement. The components of the CDFPLOT statement are described as follows:

variables

specify variables for which to create cdf plots. If you specify a VAR statement, the variables must also be listed in the VAR statement. Otherwise, the variables can be any numeric variables in the input data set. If you do not specify variables in a CDFPLOT statement, then a cdf plot is created for each variable listed in the VAR statement, or for each numeric variable in the input data set if you do not use a VAR statement.

For example, suppose a data set named `steel` contains exactly three numeric variables, `length`, `width` and `height`. The following statements create a cdf plot for each of the three variables:

```
proc capability data=steel;
  cdfplot;
run;
```

The following statements create a cdf plot for `length` and a cdf plot for `width`:

```
proc capability data=steel;
  var length width;
  cdfplot;
run;
```

The following statements create a cdf plot for `width`:

```
proc capability data=steel;
  var length width;
  cdfplot width;
run;
```

By default, the horizontal axis of a cdf plot is labeled with the variable name. If you specify a label for a variable, however, the label is used. The default vertical axis label is *Cumulative Percent*, and the axis is scaled in percent of observations.

If you specify a `SPEC` statement or a `SPEC=` data set in addition to the `CDFPLOT` statement, then the specification limits for each variable are displayed as reference lines and are identified in a legend.

options

add features to plots. All options appear after the slash (/) in the `CDFPLOT` statement. In the following example, the `NORMAL` option superimposes a normal cdf on the plot, and the `CTEXT=` option specifies the color of the text.

```
proc capability data=steel;
  cdfplot length / normal ctext=yellow;
run;
```

Summary of Options

The following tables list all options by function. The section “[Dictionary of Options](#)” on page 273 describes each option in detail.

Distribution Options

You can use the options listed in [Table 5.9](#) to superimpose a fitted theoretical distribution function on your cdf plot.

Table 5.9 Options for Specifying a Theoretical Distribution

Option	Description
BETA(<i>beta-options</i>)	plots beta distribution with threshold parameter θ , scale parameter σ , and shape parameters α and β
EXPONENTIAL(<i>exponential-options</i>)	plots exponential distribution with threshold parameter θ and scale parameter σ
GAMMA(<i>gamma-options</i>)	plots gamma distribution with threshold parameter θ , scale parameter σ , and shape parameter α
GUMBEL(<i>Gumbel-options</i>)	plots Gumbel distribution with location parameter μ and scale parameter σ
IGAUSS(<i>iGauss-options</i>)	plots inverse Gaussian distribution with mean μ and shape parameter λ
LOGNORMAL(<i>lognormal-options</i>)	plots lognormal distribution with threshold parameter θ , scale parameter ζ , and shape parameter σ ,
NORMAL(<i>normal-options</i>)	plots normal distribution with mean μ and standard deviation σ
PARETO(<i>Pareto-options</i>)	plots generalized Pareto distribution with threshold parameter θ , scale parameter σ , and shape parameter α
POWER(<i>power-options</i>)	plots power function distribution with threshold parameter θ , scale parameter σ , and shape parameter α
RAYLEIGH(<i>Rayleigh-options</i>)	plots Rayleigh distribution with threshold parameter θ and scale parameter σ
WEIBULL(<i>Weibull-options</i>)	plots Weibull distribution function with threshold parameter θ , scale parameter σ , and shape parameter c

Table 5.10 summarizes options that specify distribution parameters and control the display of the theoretical distribution curve. You can specify these options in parentheses after the distribution option. For example, the following statements use the NORMAL option to superimpose a normal distribution:

```
proc capability;
  cdfplot / normal(mu=10 sigma=0.5 color=red);
run;
```

The COLOR= option specifies the color for the curve, and the *normal-options* MU= and SIGMA= specify the parameters $\mu = 10$ and $\sigma = 0.5$ for the distribution function. If you do not specify these parameters, maximum likelihood estimates are computed.

Table 5.10 Distribution Options

Option	Description
Options Used with All Distributions	
COLOR=	specifies color of theoretical distribution function
L=	specifies line type of theoretical distribution function
SYMBOL=	specifies <i>character</i> used to plot theoretical distribution function on line printer plots
W=	specifies width of theoretical distribution function
Beta-Options	
ALPHA=	specifies first shape parameter α for beta distribution function
BETA=	specifies second shape parameter β for beta distribution function
SIGMA=	specifies scale parameter σ for beta distribution function
THETA=	specifies lower threshold parameter θ for beta distribution function
Exponential-Options	
SIGMA=	specifies scale parameter σ for exponential distribution function
THETA=	specifies threshold parameter θ for exponential distribution function
Gamma-Options	
ALPHA=	specifies shape parameter α for gamma distribution function
ALPHADELTA=	specifies change in successive estimates of α at which the Newton-Raphson approximation of $\hat{\alpha}$ terminates
ALPHAINITIAL=	specifies initial value for α in the Newton-Raphson approximation of $\hat{\alpha}$
MAXITER=	specifies maximum number of iterations in the Newton-Raphson approximation of $\hat{\alpha}$
SIGMA=	specifies scale parameter σ for gamma distribution function
THETA=	specifies threshold parameter θ for gamma distribution function
Gumbel-Options	
MU=	specifies location parameter μ for Gumbel distribution function
SIGMA=	specifies scale parameter σ for Gumbel distribution function
IGauss-Options	
LAMBDA=	specifies shape parameter λ for inverse Gaussian distribution function
MU=	specifies mean μ for inverse Gaussian distribution function
Lognormal-Options	
SIGMA=	specifies shape parameter σ for lognormal distribution function
THETA=	specifies threshold parameter θ for lognormal distribution function
ZETA=	specifies scale parameter ζ for lognormal distribution function
Normal-Options	
MU=	specifies mean μ for normal distribution function
SIGMA=	specifies standard deviation σ for normal distribution function
Pareto-Options	
ALPHA=	specifies shape parameter α for generalized Pareto distribution function
SIGMA=	specifies scale parameter σ for generalized Pareto distribution function

Table 5.10 (continued)

Option	Description
THETA=	specifies threshold parameter θ for generalized Pareto distribution function
Power-Options	
ALPHA=	specifies shape parameter α for power function distribution
SIGMA=	specifies scale parameter σ for power function distribution
THETA=	specifies threshold parameter θ for power function distribution
Rayleigh-Options	
SIGMA=	specifies scale parameter σ for Rayleigh distribution function
THETA=	specifies threshold parameter θ for Rayleigh distribution function
Weibull-Options	
C=	specifies shape parameter c for Weibull distribution function
CDELTA=	specifies change in successive estimates of c at which the Newton-Raphson approximation of \hat{c} terminates
CINITIAL=	specifies initial value for c in the Newton-Raphson approximation of \hat{c}
MAXITER=	specifies maximum number of iterations in the Newton-Raphson approximation of \hat{c}
SIGMA=	specifies scale parameter σ for Weibull distribution function
THETA=	specifies threshold parameter θ for Weibull distribution function

General Options**Table 5.11** General CDFPLOT Statement Options

Option	Description
General Plot Layout Options	
CONTENTS=	specifies table of contents entry for cdf plot grouping
HREF=	specifies reference lines perpendicular to the horizontal axis
HREFLABELS=	specifies labels for HREF= lines
NOCDFLEGEND	suppresses legend for superimposed theoretical cdf
NOECDP	suppresses plot of empirical (observed) distribution function
NOFRAME	suppresses frame around plotting area
NOLEGEND	suppresses legend
NOSPECLEGEND	suppresses specifications legend
VREF=	specifies reference lines perpendicular to the vertical axis
VREFLABELS=	specifies labels for VREF= lines
VSCALE=	specifies scale for vertical axis
Graphics Options	
ANNOTATE=	specifies annotate data set
CAXIS=	specifies color for axis
CFRAME=	specifies color for frame
CHREF=	specifies colors for HREF= lines
CSTATREF=	specifies colors for STATREF= lines
CTEXT=	specifies color for text

Table 5.11 (continued)

Option	Description
CVREF=	specifies colors for VREF= lines
DESCRIPTION=	specifies description for graphics catalog member
FONT=	specifies text font
HAXIS=	specifies AXIS statement for horizontal axis
HEIGHT=	specifies height of text used outside framed areas
HMINOR=	specifies number of horizontal axis minor tick marks
HREFLABPOS=	specifies position for HREF= line labels
INFONT=	specifies software font for text inside framed areas
INHEIGHT=	specifies height of text inside framed areas
LHREF=	specifies line styles for HREF= lines
LSTATREF=	specifies line styles for STATREF= lines
LVREF=	specifies line styles for VREF= lines
NAME=	specifies name for plot in graphics catalog
NOHLABEL	suppresses label for horizontal axis
NOVLABEL	suppresses label for vertical axis
NOVTICK	suppresses tick marks and tick mark labels for vertical axis
STATREF=	specifies reference lines at values of summary statistics
STATREFLABELS=	specifies labels for STATREF= lines
STATREFSUBCHAR=	specifies substitution character for displaying statistic values in STATREFLABELS= labels
TURNVLABELS	turns and vertically strings out characters in labels for vertical axis
VAXIS=	specifies AXIS statement for vertical axis
VAXISLABEL=	specifies label for vertical axis
VMINOR=	specifies number of vertical axis minor tick marks
VREFLABPOS=	specifies position for VREF= line labels
WAXIS=	specifies line thickness for axes and frame
Options for ODS Graphics Output	
ODSFOOTNOTE=	specifies footnote displayed on cdf plot
ODSFOOTNOTE2=	specifies secondary footnote displayed on cdf plot
ODSTITLE=	specifies title displayed on cdf plot
ODSTITLE2=	specifies secondary title displayed on cdf plot
Options for Comparative Plots	
ANNOKEY	applies annotation requested in ANNOTATE= data set to key cell only
CFRAMESIDE=	specifies color for filling row label frames
CFRAMETOP=	specifies color for filling column label frames
CPROP=	specifies color for proportion of frequency bar
CTEXTSIDE=	specifies color for row labels
CTEXTTOP=	specifies color for column labels
INTERTILE=	specifies distance between tiles in comparative plot
NCOLS=	specifies number of columns in comparative plot
NROWS=	specifies number of rows in comparative plot
OVERLAY	overlays plots for different class levels (ODS Graphics only)

Table 5.11 (continued)

Option	Description
Options for Line Printer Charts	
CDFSMBOL=	specifies character for plotted points
HREFCHAR=	specifies line character for HREF= lines
VREFCHAR=	specifies line character for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the options specific to the CDFPLOT statement. The marginal notes *Traditional Graphics* and *Line Printer* identify options that can be used only with traditional graphics and line printer plots, respectively. See “[Dictionary of Common Options: CAPABILITY Procedure](#)” on page 551 for detailed descriptions of options common to all the plot statements.

ALPHA=*value*

specifies the shape parameter α for distribution functions requested with the **BETA**, **GAMMA**, **PARETO**, and **POWER** options. Enclose the ALPHA= option in parentheses after the distribution keyword. If you do not specify a value for α , the procedure calculates a maximum likelihood estimate. For examples, see the entries for the distribution options.

BETA<(beta-options)>

displays a fitted beta distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \begin{cases} 0 & \text{for } x \leq \theta \\ I_{\frac{x-\theta}{\sigma}}(\alpha, \beta) & \text{for } \theta < x < \theta + \sigma \\ 1 & \text{for } x \geq \theta + \sigma \end{cases}$$

where $I_y(\alpha, \beta)$ is the incomplete beta function, and

θ = lower threshold parameter (lower endpoint)

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

β = shape parameter ($\beta > 0$)

The beta distribution is bounded below by the parameter θ and above by the value $\theta + \sigma$. You can specify θ and σ by using the **THETA=** and **SIGMA=** *beta-options*, as illustrated in the following statements, which fit a beta distribution bounded between 50 and 75. The default values for θ and σ are 0 and 1, respectively.

```
proc capability;
  cdfplot / beta(theta=50 sigma=25);
run;
```

The beta distribution has two shape parameters, α and β . If these parameters are known, you can specify their values with the **ALPHA=** and **BETA=** *beta-options*. If you do not specify values for α and β , the procedure calculates maximum likelihood estimates.

The BETA option can appear only once in a CDFPLOT statement. See Table 5.10 for a list of secondary options you can specify with the BETA distribution option.

BETA=value

B=value

specifies the second shape parameter β for beta distribution functions requested by the BETA option. Enclose the BETA= option in parentheses after the BETA keyword. If you do not specify a value for β , the procedure calculates a maximum likelihood estimate. For examples, see the preceding entry for the BETA option.

C=value

specifies the shape parameter c for Weibull distribution functions requested with the WEIBULL option. Enclose the C= option in parentheses after the WEIBULL keyword. If you do not specify a value for c , the procedure calculates a maximum likelihood estimate. You can specify the SHAPE= option as an alias for the C= option.

CDFSMBOL='character'

Line Printer

specifies the character used to plot the points on cdf line printer plots. The default is the plus sign (+). Use the SYMBOL statement to control the plotting symbol in graphical output.

EXPONENTIAL<(exponential-options)>

EXP<(exponential-options)>

displays a fitted exponential distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \begin{cases} 0 & \text{for } x \leq \theta \\ 1 - \exp\left(-\frac{x-\theta}{\sigma}\right) & \text{for } x > \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

The parameter θ must be less than or equal to the minimum data value. You can specify θ with the **THETA= exponential-option**. The default value for θ is 0. You can specify σ with the **SIGMA= exponential-option**. By default, a maximum likelihood estimate is computed for σ . For example, the following statements fit an exponential distribution with $\theta = 10$ and a maximum likelihood estimate for σ :

```
proc capability;
  cdfplot / exponential(theta=10 l=2 color=green);
run;
```

The exponential curve is green and has a line type of 2.

The EXPONENTIAL option can appear only once in a CDFPLOT statement. See Table 5.10 for a list of secondary options you can specify with the EXPONENTIAL option.

GAMMA<(gamma-options)>

displays a fitted gamma distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \begin{cases} 0 & \text{for } x \leq \theta \\ \frac{1}{\Gamma(\alpha)\sigma} \int_{\theta}^x \left(\frac{t-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\frac{t-\theta}{\sigma}\right) dt & \text{for } x > \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

The parameter θ for the gamma distribution must be less than the minimum data value. You can specify θ with the **THETA=** *gamma-option*. The default value for θ is 0. In addition, the gamma distribution has a shape parameter α and a scale parameter σ . You can specify these parameters with the **ALPHA=** and **SIGMA=** *gamma-options*. By default, maximum likelihood estimates are computed for α and σ . For example, the following statements fit a gamma distribution function with $\theta = 4$ and maximum likelihood estimates for α and σ :

```
proc capability;
  cdfplot / gamma(theta=4);
run;
```

Note that the maximum likelihood estimate of α is calculated iteratively using the Newton-Raphson approximation. The *gamma-options* **ALPHADELTA=**, **ALPHAINITIAL=**, and **MAXITER=** control the approximation.

The GAMMA option can appear only once in a CDFPLOT statement. See Table 5.10 for a list of secondary options you can specify with the GAMMA option.

GUMBEL< (*Gumbel-options*) >

displays a fitted Gumbel distribution (also known as Type 1 extreme value distribution) function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \exp\left(-e^{-(x-\mu)/\sigma}\right)$$

where

μ = location parameter

σ = scale parameter ($\sigma > 0$)

You can specify known values for μ and σ with the **MU=** and **SIGMA=** *Gumbel-options*. By default, maximum likelihood estimates are computed for μ and σ .

The GUMBEL option can appear only once in a CDFPLOT statement. See Table 5.10 for a list of secondary options you can specify with the GUMBEL option.

IGAUSS< (*iGauss-options*) >

displays a fitted inverse Gaussian distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \Phi\left\{\sqrt{\frac{\lambda}{x}}\left(\frac{x}{\mu} - 1\right)\right\} + e^{2\lambda/\mu}\Phi\left\{-\sqrt{\frac{\lambda}{x}}\left(\frac{x}{\mu} + 1\right)\right\}$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function, and

μ = mean parameter ($\mu > 0$)

λ = shape parameter ($\lambda > 0$)

You can specify known values for μ and λ with the **MU=** and **LAMBDA=** *iGauss-options*. By default, maximum likelihood estimates are computed for μ and λ .

The IGAUSS option can appear only once in a CDFPLOT statement. See Table 5.10 for a list of secondary options you can specify with the IGAUSS option.

LAMBDA=value

specifies the shape parameter λ for distribution functions requested with the **IGAUSS** option. Enclose the LAMBDA= option in parentheses after the IGAUSS distribution keyword. If you do not specify a value for λ , the procedure calculates a maximum likelihood estimate.

LEGEND=name | NONE

Traditional Graphics

specifies the name of a LEGEND statement describing the legend for specification limit reference lines and superimposed distribution functions. Specifying LEGEND=NONE, which suppresses all legend information, is equivalent to specifying the NOLEGEND option.

LOGNORMAL<(lognormal-options)>

displays a fitted lognormal distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \begin{cases} 0 & \text{for } x \leq \theta \\ \Phi\left(\frac{\log(x-\theta)-\zeta}{\sigma}\right) & \text{for } x > \theta \end{cases}$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function, and

θ = threshold parameter

ζ = scale parameter

σ = shape parameter ($\sigma > 0$)

The parameter θ for the lognormal distribution must be less than the minimum data value. You can specify θ with the **THETA=** *lognormal-option*. The default value for θ is 0. In addition, the lognormal distribution has a shape parameter σ and a scale parameter ζ . You can specify these parameters with the **SIGMA=** and **ZETA=** *lognormal-options*. By default, maximum likelihood estimates are computed for σ and ζ . For example, the following statements fit a lognormal distribution function with $\theta = 10$ and maximum likelihood estimates for σ and ζ :

```
proc capability;
  cdfplot / lognormal(theta = 10);
run;
```

The LOGNORMAL option can appear only once in a CDFPLOT statement. See Table 5.10 for a list of secondary options you can specify with the LOGNORMAL option.

MU=value

specifies the parameter μ for distribution functions requested with the **GUMBEL**, **IGAUSS**, and **NORMAL** options. Enclose the MU= option in parentheses after the distribution keyword. For the normal and inverse Gaussian distributions, the default value of μ is the sample mean. If you do not specify a value for μ for the Gumbel distribution, the procedure calculates a maximum likelihood estimate.

NOCDFLEGEND

suppresses the legend for the superimposed theoretical cumulative distribution function.

NOECDF

suppresses the observed distribution function (the empirical cumulative distribution function) of the variable, which is drawn by default. This option enables you to create theoretical cdf plots without displaying the data distribution. The NOECDF option can be used only with a theoretical distribution (such as the NORMAL option).

NOLEGEND

suppresses legends for specification limits, theoretical distribution functions, and hidden observations. Specifying the NOLEGEND option is equivalent to specifying LEGEND=NONE.

NORMAL< (*normal-options*) >

displays a fitted normal distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \Phi\left(\frac{x-\mu}{\sigma}\right) \quad \text{for } -\infty < x < \infty$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function, and

μ = mean

σ = standard deviation ($\sigma > 0$)

You can specify known values for μ and σ with the **MU=** and **SIGMA=** *normal-options*, as shown in the following statements:

```
proc capability;
  cdfplot / normal(mu=14 sigma=.05);
run;
```

By default, the sample mean and sample standard deviation are calculated for μ and σ . The NORMAL option can appear only once in a CDFPLOT statement. For an example, see [Output 5.4.1](#). See [Table 5.10](#) for a list of secondary options you can specify with the NORMAL option.

NOSPECLEGEND**NOSPECL**

suppresses the portion of the legend for specification limit reference lines.

PARETO< (*Pareto-options*) >

displays a fitted generalized Pareto distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = 1 - \left(1 - \frac{\alpha(x - \theta)}{\sigma}\right)^{\frac{1}{\alpha}}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter

The parameter θ for the generalized Pareto distribution must be less than the minimum data value. You can specify θ with the **THETA=** *Pareto-option*. The default value for θ is 0. In addition, the generalized Pareto distribution has a shape parameter α and a scale parameter σ . You can specify these parameters with the **ALPHA=** and **SIGMA=** *Pareto-options*. By default, maximum likelihood estimates are computed for α and σ .

The PARETO option can appear only once in a CDFPLOT statement. See [Table 5.10](#) for a list of secondary options you can specify with the PARETO option.

POWER< (*power-options*) >

displays a fitted power function distribution on the cdf plot. The equation of the fitted cdf is

$$F(x) = \begin{cases} 0 & \text{for } x \leq \theta \\ \left(\frac{x-\theta}{\sigma}\right)^\alpha & \text{for } \theta < x < \theta + \sigma \\ 1 & \text{for } x \geq \theta + \sigma \end{cases}$$

where

θ = lower threshold parameter (lower endpoint)

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

The power function distribution is bounded below by the parameter θ and above by the value $\theta + \sigma$. You can specify θ and σ by using the **THETA=** and **SIGMA=** *power-options*. The default values for θ and σ are 0 and 1, respectively.

You can specify a value for the shape parameter, α , with the **ALPHA=** *power-option*. If you do not specify a value for α , the procedure calculates a maximum likelihood estimate.

The power function distribution is a special case of the beta distribution with its second shape parameter, $\beta = 1$.

The POWER option can appear only once in a CDFPLOT statement. See [Table 5.10](#) for a list of secondary options you can specify with the POWER option.

RAYLEIGH< (*Rayleigh-options*) >

displays a fitted Rayleigh distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = 1 - e^{-(x-\theta)^2/(2\sigma^2)}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

The parameter θ for the Rayleigh distribution must be less than the minimum data value. You can specify θ with the **THETA=** *Rayleigh-option*. The default value for θ is 0. You can specify σ with the **SIGMA=** *Rayleigh-option*. By default, a maximum likelihood estimate is computed for σ .

The RAYLEIGH option can appear only once in a CDFPLOT statement. See [Table 5.10](#) for a list of secondary options you can specify with the RAYLEIGH option.

SIGMA=value

specifies the parameter σ for distribution functions requested by the **BETA**, **EXPONENTIAL**, **GAMMA**, **GUMBEL**, **LOGNORMAL**, **NORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, and **WEIBULL** options. Enclose the **SIGMA=** option in parentheses after the distribution keyword. The following table summarizes the use of the **SIGMA=** option:

Distribution Option	SIGMA= Specifies	Default Value	Alias
BETA POWER	scale parameter σ	1	SCALE=
EXPONENTIAL GAMMA WEIBULL	scale parameter σ	maximum likelihood estimate	SCALE=
GUMBEL PARETO RAYLEIGH	scale parameter σ	maximum likelihood estimate	
LOGNORMAL	shape parameter σ	maximum likelihood estimate	SHAPE=
NORMAL	scale parameter σ	standard deviation	

SYMBOL='character'

specifies the *character* used to plot the theoretical distribution function on line printer plots. *Line Printer*
Enclose the **SYMBOL=** option in parentheses after the distribution option. The default character is the first letter of the distribution option keyword.

THETA=value**THRESHOLD=value**

specifies the lower threshold parameter θ for theoretical cumulative distribution functions requested with the **BETA**, **EXPONENTIAL**, **GAMMA**, **LOGNORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, and **WEIBULL** options. Enclose the **THETA=** option in parentheses after the distribution keyword. The default *value* is 0.

VSCALE=PERCENT | PROPORTION

specifies the scale of the vertical axis. The value **PERCENT** scales the data in units of percent of observations per data unit. The value **PROPORTION** scales the data in units of proportion of observations per data unit. The default is **PERCENT**.

WEIBULL<(Weibull-options)>

displays a fitted Weibull distribution function on the cdf plot. The equation of the fitted cdf is

$$F(x) = \begin{cases} 0 & \text{for } x \leq \theta \\ 1 - \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right) & \text{for } x > \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

c = shape parameter ($c > 0$)

The parameter θ must be less than the minimum data value. You can specify θ with the `THETA=` *Weibull-option*. The default value for θ is 0. In addition, the Weibull distribution has a shape parameter c and a scale parameter σ . You can specify these parameters with the `SIGMA=` and `C=` *Weibull-options*. By default, maximum likelihood estimates are computed for c and σ . For example, the following statements fit a Weibull distribution function with $\theta = 15$ and maximum likelihood estimates for σ and c :

```
proc capability;
  cdfplot / weibull(theta=15);
run;
```

Note that the maximum likelihood estimate of c is calculated iteratively using the Newton-Raphson approximation. The *Weibull-options* `CDELTA=`, `CINITIAL=`, and `MAXITER=` control the approximation.

The `WEIBULL` option can appear only once in a `CDFPLOT` statement. See [Table 5.10](#) for a list of secondary options you can specify with the `WEIBULL` option.

ZETA=*value*

specifies a value for the scale parameter ζ for a lognormal distribution function requested with the `LOGNORMAL` option. Enclose the `ZETA=` option in parentheses after the `LOGNORMAL` keyword. If you do not specify a *value* for ζ , a maximum likelihood estimate is computed. You can specify the `SCALE=` option as an alias for the `ZETA=` option.

Details: CDFPLOT Statement

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. `CDFPLOT` options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the CDFPLOT statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 5.12](#).

Table 5.12 ODS Graphics Produced by the CDFPLOT Statement

ODS Graph Name	Plot Description
CDFPlot	cumulative distribution function plot

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Examples: CDFPLOT Statement

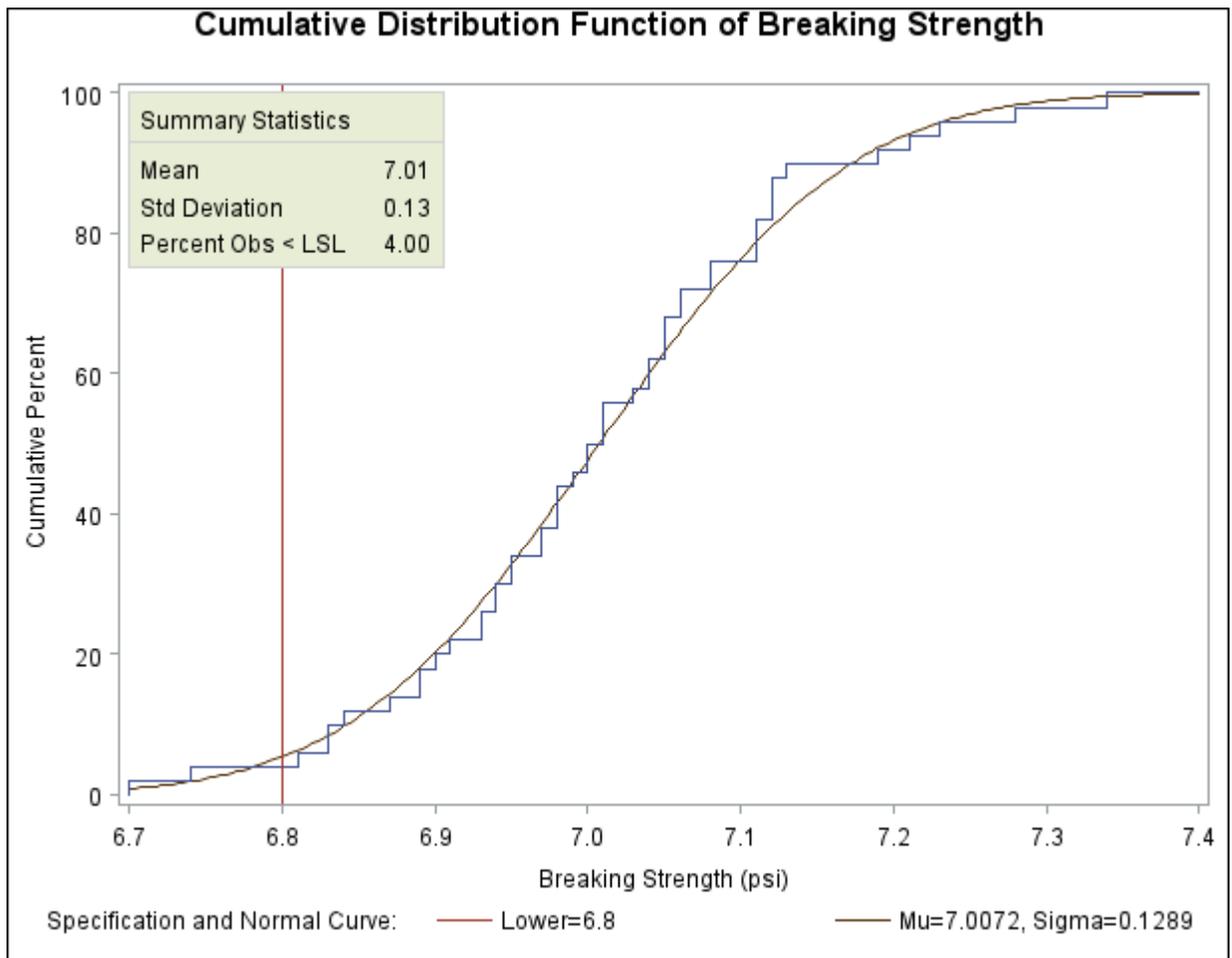

This section illustrates how to display a fitted distribution function, inset tables, and display reference lines on your cdf plot.

Example 5.4: Fitting a Normal Distribution

You can use the CDFPLOT statement to fit any of eleven theoretical distributions (beta, exponential, gamma, Gumbel, inverse Gaussian, lognormal, normal, generalized Pareto, power function, Rayleigh, and Weibull) and superimpose them on the cdf plot. The following statements use the NORMAL option to display a fitted normal distribution function on a cdf plot of breaking strengths. The data set Cord is given in [Figure 5.5](#), and the plot is shown in [Output 5.4.1](#).

See CAPCDF1 in the SAS/QC Sample Library

```
ods graphics off;
title 'Cumulative Distribution Function of Breaking Strength';
proc capability data=Cord noprint;
  spec lsl=6.8;
  cdf Strength / normal;
  inset mean std pctlss / cfill = ywh
    format = 5.2
    header = "Summary Statistics";
run;
```

Output 5.4.1 Superimposed Normal Distribution Function

The NORMAL option requests the fitted curve. The INSET statement requests an inset containing the mean, the standard deviation, and the percent of observations below the lower specification limit. For more information about the INSET statement, see “INSET Statement: CAPABILITY Procedure” on page 397. The SPEC statement requests a lower specification limit at 6.8. For more information about the SPEC statement, see “SPEC Statement” on page 225.

The agreement between the empirical and the normal distribution functions in [Output 5.4.1](#) is evidence that the normal distribution is an appropriate model for the distribution of breaking strengths.

The CAPABILITY procedure provides a variety of other tools for assessing goodness of fit. Goodness-of-fit tests (see “Printed Output” on page 359) provide a quantitative assessment of a proposed distribution. Probability and Q-Q plots, created with the PROBLOT (“PROBLOT Statement: CAPABILITY Procedure” on page 477), QQPLOT (“QQPLOT Statement: CAPABILITY Procedure” on page 508), and PPLOT (“PPLOT Statement: CAPABILITY Procedure” on page 455) statements, provide effective graphical diagnostics.

Example 5.5: Using Reference Lines with CDF Plots

Customer requirements dictate that the breaking strengths in the previous example have upper and lower specification limits of 7.2 and 6.8 psi, respectively. Moreover, less than 5% of the cords can have breaking strengths outside the limits. *See CAPCDF1 in the SAS/QC Sample Library*

The following statements create a cdf plot with reference lines at the 5% and 95% cumulative percent levels:

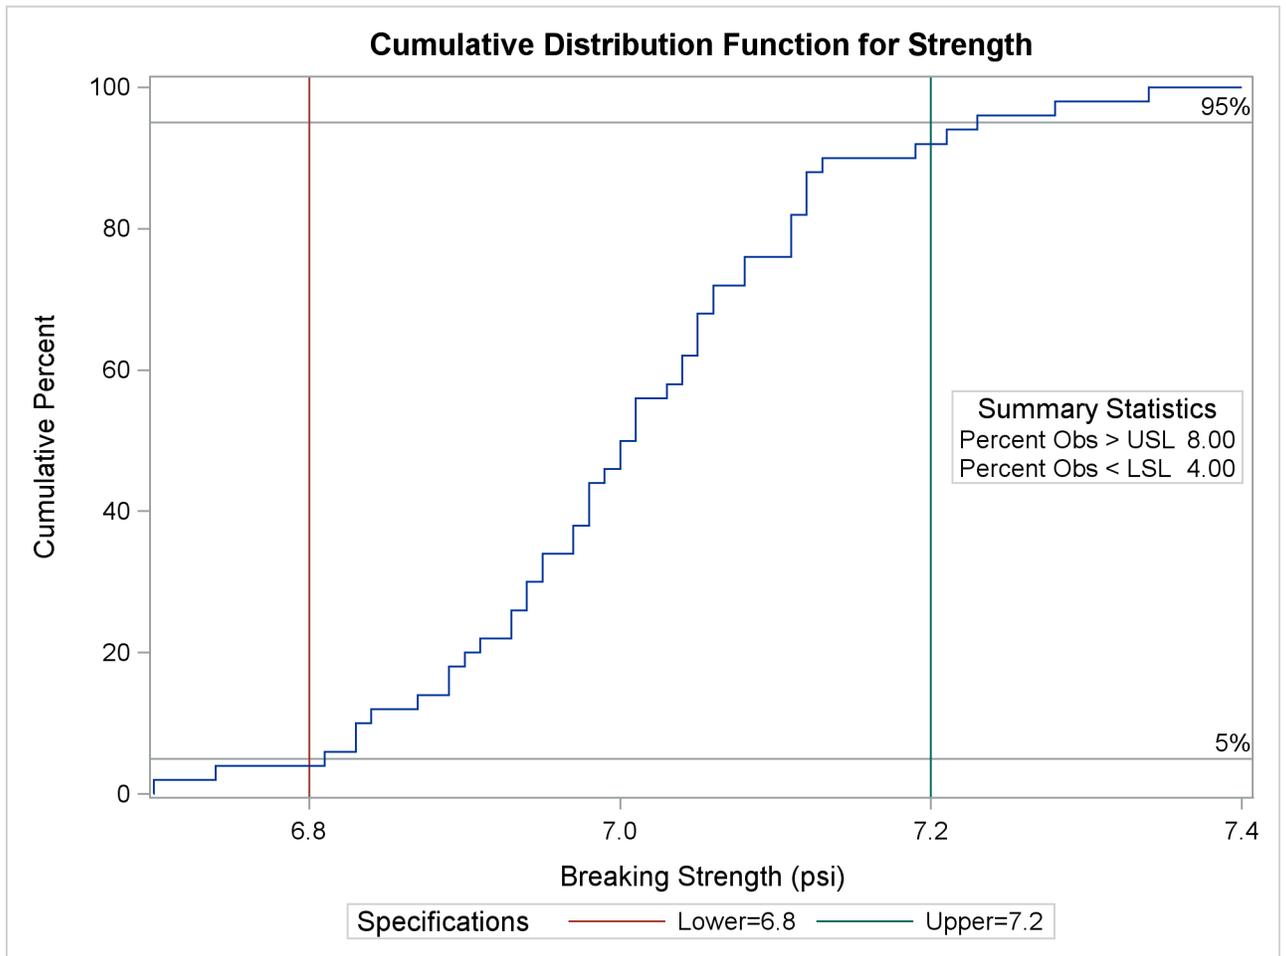

```
ods graphics on;
proc capability data=Cord noprint;
  spec lsl=6.8 usl=7.2;
  cdf Strength / vref          = 5 95
                        vreflabels = '5%' '95%' ;
  inset pctgtr pctlss / format = 5.2
                        pos      = e
                        header = "Summary Statistics";
run;
```

The ODS GRAPHICS ON statement specified before the PROC CAPABILITY statement enables ODS Graphics, so the cdf plot is created by using ODS Graphics instead of traditional graphics.

The INSET statement requests an inset with the percentages of measurements above the upper limit and below the lower limit. For more information about the INSET statement, see [“INSET Statement: CAPABILITY Procedure”](#) on page 397.

In [Output 5.5.1](#), the empirical cdf is below the intersection between the lower specification limit line and the 5% line, so less than 5% of the measurements are below the lower limit. The ecdf, however, is *also* below the intersection between the upper specification limit line and the 95% line, implying that *more* than 5% of the measurements are greater than the upper limit. Thus, the goal of having less than 5% of the measurements above the upper specification limit has not been met.

Output 5.5.1 Reference Lines with a Cumulative Distribution Function Plot

COMPHISTOGRAM Statement: CAPABILITY Procedure

Overview: COMPHISTOGRAM Statement

Comparative histograms are useful for comparing the distribution of a process variable across levels of classification variables. You can use the COMPHISTOGRAM statement to create one-way and two-way comparative histograms. When used with a single classification variable, the COMPHISTOGRAM statement displays an array of component histograms (stacked or side-by-side), one for each level of the classification variable. When used with two classification variables, the COMPHISTOGRAM statement displays a matrix of component histograms, one for each combination of levels of the classification variables.

In quality improvement applications, typical uses of comparative histograms include

- comparing the capability of a process before and after an improvement
- comparing process capabilities of two or more suppliers
- exploring stratification in process data due to different lots, machines, manufacturing methods, and so forth
- studying the evolution of process capability over successive time periods

You can use options in the COMPHISTOGRAM statement to

- specify the midpoints or endpoints for histogram intervals
- specify the number of rows and/or columns of component histograms
- display specification limits on the component histograms
- display density curves for fitted normal distributions
- display kernel density estimates
- request graphical enhancements
- inset summary statistics and process capability indices on the component histograms

You have two alternatives for producing comparative histograms with the COMPHISTOGRAM statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced if SAS/GRAPH[®] is licensed.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

NOTE: You cannot use the COMPHISTOGRAM statement together with the CLASS statement.

Getting Started: COMPHISTOGRAM Statement

This section introduces the COMPHISTOGRAM statement with examples that illustrate commonly used options. Complete syntax for the COMPHISTOGRAM statement is presented in the section “Syntax: COMPHISTOGRAM Statement” on page 289, and advanced examples are given in the section “Examples: COMPHISTOGRAM Statement” on page 305.

Creating a One-Way Comparative Histogram

See CAPCMHI in the SAS/QC Sample Library The effective channel length (in microns) is measured for 1225 field effect transistors. The channel lengths are saved as values of the variable Length in a SAS data set named Channel:

```
data Channel;
  length Lot $ 16;
  input Length @@;
  select;
    when (_n_ <= 425) Lot='Lot 1';
    when (_n_ >= 926) Lot='Lot 3';
    otherwise Lot='Lot 2';
  end;
  datalines;
0.91 1.01 0.95 1.13 1.12 0.86 0.96 1.17 1.36 1.10
0.98 1.27 1.13 0.92 1.15 1.26 1.14 0.88 1.03 1.00
0.98 0.94 1.09 0.92 1.10 0.95 1.05 1.05 1.11 1.15
1.11 0.98 0.78 1.09 0.94 1.05 0.89 1.16 0.88 1.19
1.01 1.08 1.19 0.94 0.92 1.27 0.90 0.88 1.38 1.02

... more lines ...

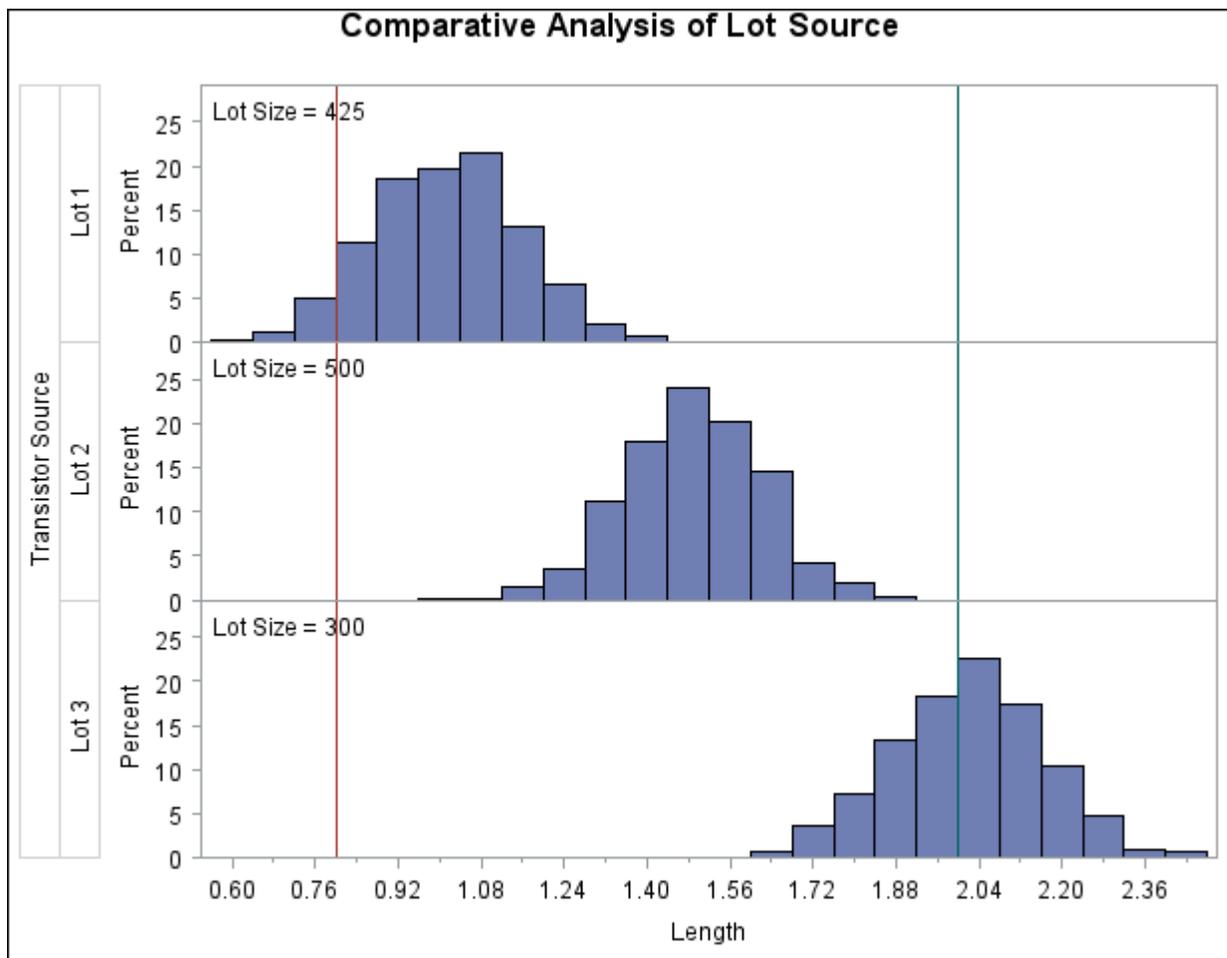

1.80 2.35 2.23 1.96 2.16 2.08 2.06 2.03 2.18 1.83
2.13 2.05 1.90 2.07 2.15 1.96 2.15 1.89 2.15 2.04
1.95 1.93 2.22 1.74 1.91
;
```

The data set Channel is also used in [Example 5.12](#), where a kernel density estimate is superimposed on the histogram of channel lengths. The display in [Output 5.12.1](#) reveals that there are three distinct peaks in the process distribution. To investigate whether these peaks (modes) in the histogram are related to the lot source, you can create a comparative histogram that uses Lot as a classification variable. The following statements create the comparative histogram shown in [Figure 5.6](#):

```
ods graphics off;
title "Comparative Analysis of Lot Source";
proc capability data=Channel noprint;
  specs lsl = 0.8 usl = 2.0;
  comphist Length / class      = Lot
                        nrows  = 3
                        nlegend = 'Lot Size'
                        nlegendpos = nw;
  label Lot = 'Transistor Source';
run;
```

The COMPHISTOGRAM statement requests a comparative histogram for the process variable Length. The CLASS= option requests a component histogram for each level (distinct value) of the classification variable Lot. The option NROWS=3 stacks the histograms three to a page. The NLEGEND= option adds a sample size legend to each component histogram, and the option NLEGENDPPOS=NW positions each legend in the northwest corner. The SPEC statement provides the specification limits displayed as vertical reference lines. See the section “[Dictionary of Options](#)” on page 294 for descriptions of these options, and see the section “[SPEC Statement](#)” on page 225 for details of the SPEC statement.

Figure 5.6 Comparison by Lot Source

Adding Fitted Normal Curves to a Comparative Histogram

See CAPCMHI in the
SAS/QC Sample Library

In Figure 5.6, it appears that each lot produces transistors with channel lengths that are normally distributed. The following statements use the NORMAL option to fit a normal distribution to the data for each lot (the observations corresponding to a specific level of the classification variable are referred to as a *cell*). The normal parameters μ and σ are estimated from the data for each lot, and the curves are superimposed on each component histogram.

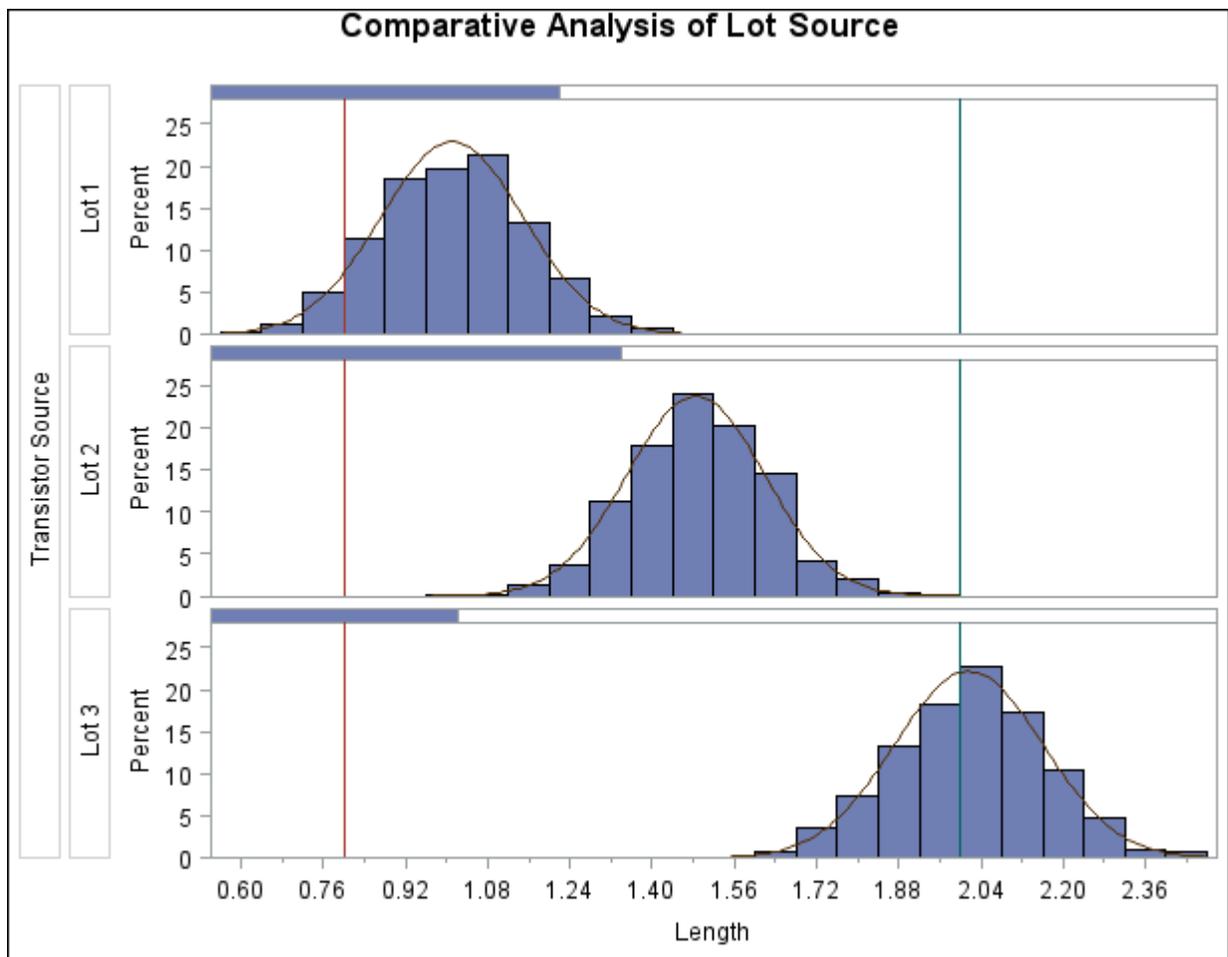

```

title "Comparative Analysis of Lot Source";
proc capability data=Channel noprint;
  specs lsl = 0.8 usl = 2.0;
  comphist Length / class      = Lot
                            nrows      = 3
                            intertile = 1
                            cprop
                            normal;
  label Lot = 'Transistor Source';
run;

```

The comparative histogram is displayed in Figure 5.7.

Figure 5.7 Fitting Normal Curves

Specifying INTERTILE=1 inserts a space of one percent screen unit between the framed areas, which are referred to as *tiles*. The shaded bars, added with the CPROP= option, represent the relative frequency of observations in each cell. See “Dictionary of Options” on page 294 for details concerning these options.

Syntax: COMPHISTOGRAM Statement

The syntax for the COMPHISTOGRAM statement is as follows:

```
COMPHISTOGRAM < variables > / CLASS=(class-variables) < options > ;
```

You can specify the keyword COMPHIST as an alias for COMPHISTOGRAM. You can use any number of COMPHISTOGRAM statements after a PROC CAPABILITY statement.

To create a comparative histogram, you must specify at least one *variable* and either one or two *class-variables* (also referred to as *classification variables*).⁴ The COMPHISTOGRAM statement displays a component histogram of the values of the *variable* for each level of the *class-variables*. The observations in a given level are referred to as a *cell*.

The components of the COMPHISTOGRAM statement are described as follows:

variables

are the process variables for which comparative histograms are to be created. If you specify a VAR statement, the variables must also be listed in the VAR statement. Otherwise, variables can be any numeric variables in the input data set that are not also listed as *class-variables*. If you do not specify variables in a COMPHISTOGRAM statement or a VAR statement, then by default a comparative histogram is created for each numeric variable in the DATA= data set that is not used as a class-variable. If you use a VAR statement and do not specify variables in the COMPHISTOGRAM statement, then by default a comparative histogram is created for each variable listed in the VAR statement.

For example, suppose a data set named `steel` contains two process variables named `length` and `width`, a numeric classification variable named `lot`, and a character classification variable named `day`. The following statements create two comparative histograms, one for `length` and one for `Width`:

```
proc capability data=steel;
  comphist / class = lot;
run;
```

Likewise, the following statements create comparative histograms for `length` and `width`:

```
proc capability data=steel;
  var length width;
  comphist / class = day;
run;
```

⁴In SAS 6.12 and in previous releases of SAS/QC software, the keyword GRAPHICS was required in the PROC CAPABILITY statement since the COMPHISTOGRAM statement creates plots only for graphical output.

The following statements create three comparative histograms (for length, width, and lot):

```
proc capability data=steel;
  comphist / class = day;
run;
```

The following statements create a comparative histogram for Width only:

```
proc capability data=steel;
  var length width;
  comphist width / class=lot;
run;
```

class-variables

are one or two required classification variables. For example, the following statements create a one-way comparative histogram for width by using the classification variable lot:

```
proc capability data=steel;
  comphist width / class=lot;
run;
```

The following statements create a two-way comparative histogram for width classified by lot and day:

```
proc capability data=steel;
  comphist width / class=(lot day);
run;
```

Note that the parentheses surrounding the *class-variables* are needed only if two classification variables are specified. See [Output 5.6.1](#) and [Output 5.7.1](#) for further examples.

options

control the features of the comparative histogram. All options are specified after the slash (/) in the COMPHIST statement. In the following example, the CLASS= option specifies the classification variable, the NORMAL option fits a normal density curve in each cell, and the CTEXT= option specifies the color of the text:

```
proc capability data=steel;
  comphist length / class = lot
                    normal
                    ctext = yellow;
run;
```

Summary of Options

The following tables list the COMPHIST statement options by function. For complete descriptions, see “Dictionary of Options” on page 294.

Distribution Options

Table 5.13 lists the options for requesting that a fitted normal distribution or a kernel density estimate be overlaid on the comparative histogram.

Table 5.13 Density Estimation Options

Option	Description
<code>KERNEL(kernel-options)</code>	fits kernel density estimates
<code>NORMAL(normal-options)</code>	fits normal distribution with mean μ and standard deviation σ

You can specify the secondary options listed in Table 5.14 in parentheses after the `KERNEL` option to control features of kernel density estimates.

Table 5.14 Kernel-Options

Option	Description
<code>C=</code>	specifies standardized bandwidth parameter c for kernel density estimate
<code>COLOR=</code>	specifies color of the kernel density curve
<code>FILL</code>	fills area under kernel density curve
<code>K=</code>	specifies NORMAL, TRIANGULAR, or QUADRATIC kernel
<code>L=</code>	specifies line type used for kernel density curve
<code>LOWER=</code>	specifies lower bound for kernel density curve
<code>UPPER=</code>	specifies upper bound for kernel density curve
<code>W=</code>	specifies line width for kernel density curve

You can specify the secondary options listed in Table 5.15 in parentheses after the `NORMAL` option to control features of fitted normal distributions.

Table 5.15 Normal-Options

Option	Description
<code>COLOR=</code>	specifies color of normal curve
<code>FILL</code>	fills area under normal curve
<code>L=</code>	specifies line type of normal curve
<code>MU=</code>	specifies mean μ for fitted normal curve
<code>SIGMA=</code>	specifies standard deviation σ for fitted normal curve
<code>W=</code>	specifies width of normal curve

For example, the following statements use the NORMAL option to fit a normal curve in each cell of the comparative histogram:

```
proc capability;
  comphistogram / class = machine
                 normal(color=red l=2);
run;
```

The COLOR= *normal-option* draws the curve in red, and the L= *normal-option* specifies a line style of 2 (a dashed line) for the curve. In this example, maximum likelihood estimates are computed for the normal parameters μ and σ for each cell since these parameters are not specified.

General Options

Table 5.16 General COMPHISTOGRAM Statement Options

Option	Description
Classification Options	
CLASS=	specifies classification variables
CLASSKEY=	specifies key cell
MISSING1	requests that missing values of first CLASS= variable be treated as a level of that CLASS= variable
MISSING2	requests that missing values of second CLASS= variable be treated as a level of that CLASS= variable
ORDER1=	specifies display order for values of the first CLASS= variable
ORDER2=	specifies display order for values of the second CLASS= variable
Layout Options	
BARLABEL=	produces labels above histogram bars
BARWIDTH=	specifies width for the bars
CLIPSPEC=	clips histogram bars at specification limits if there are no observations beyond the limits
ENDPOINTS=	labels interval endpoints and specifies how they are determined
HOFFSET=	specifies offset for horizontal axis
INTERTILE=	specifies distance between tiles
MAXNBIN=	specifies maximum number of bins displayed
MAXSIGMAS=	limits number of bins displayed to range of <i>value</i> standard deviations above and below mean of data in key cell
MIDPOINTS=	specifies how midpoints are determined
NCOLS=	specifies number of columns in comparative histogram
NOBARS	suppresses histogram bars
NOFRAME	suppresses frame around plotting area
NOKEYMOVE	suppresses rearrangement of cells that occurs by default with the CLASSKEY= option
NOPLOT	suppresses plot
NROWS=	specifies number of rows in comparative histogram
RTINCLUDE	includes right endpoint in interval
WBARLINE=	specifies line thickness for bar outlines
Axis and Legend Options	
GRID	adds grid corresponding to vertical axis

Table 5.16 (continued)

Option	Description
LGRID=	specifies line style for grid requested with GRID option
NLEGEND	specifies form of the legend displayed inside tiles
NLEGENDPOS=	specifies position of legend displayed inside tiles
NOHLABEL	suppresses label for horizontal axis
NOVLABEL	suppresses label for vertical axis
NOVTICK	suppresses tick marks and tick mark labels for vertical axis
TILELEGLABEL=	specifies label displayed when <code>_CTILE_</code> and <code>_TILELG_</code> variables are provided in the <code>CLASSSPEC=</code> data set
TURNVLABELS	turns and strings out vertically characters in vertical axis labels
VAXIS=	specifies tick mark values for vertical axis
VAXISLABEL=	specifies label for vertical axis
VOFFSET=	specifies length of offset at upper end of vertical axis
VSCALE=	specifies scale for vertical axis
WAXIS=	specifies line thickness for axes and frame
WGRID=	specifies line thickness for grid
Reference Line Options	
FRONTREF	draws reference lines in front of histogram bars
HREF=	specifies reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies vertical position of labels for HREF= lines
LHREF=	specifies line style for HREF= lines
LVREF=	specifies line style for VREF= lines
VREF=	specifies reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies horizontal position of labels for VREF= lines
Text Enhancement Options	
FONT=	specifies software font for text
HEIGHT=	specifies height of text used outside framed areas
INFONT=	specifies software font for text inside framed areas
INHEIGHT=	specifies height of text inside framed areas
Color and Pattern Options	
CAXIS=	specifies color for axis
CBARLINE=	specifies color for outline of the bars
CFILL=	specifies color for filling bars
CFRAME=	specifies color for frame
CFRAMENLEG=	specifies the color for the frame requested by the NLEGEND option
CFRAMESIDE=	specifies color for filling frame for row labels
CFRAMETOP=	specifies color for filling frame for column labels
CGRID=	specifies color for grid lines
CHREF=	specifies color for HREF= lines
CPROP=	specifies color for proportion of frequency bar
CTEXT=	specifies color for text
CTEXTSIDE=	specifies color for row labels

Table 5.16 (continued)

Option	Description
CTEXTTOP=	specifies color for column labels
CVREF=	specifies color for VREF= lines
PFILL=	specifies pattern used to fill bars
Input and Output Data Set Options	
ANNOKEY	applies annotation requested in ANNOTATE= data set to key cell only
ANNOTATE=	annotate data set
CLASSSPEC=	data set with specification limit information for each cell
OUTHISTOGRAM=	information on histogram intervals
Graphics Catalog Options	
DESCRIPTION=	specifies description for graphics catalog member
NAME=	specifies name for plot in graphics catalog

Dictionary of Options

The following entries describe in detail the options specific to the COMPHISTOGRAM statement. The marginal note *Traditional Graphics* identifies options that can be used only with traditional graphics output. See “[Dictionary of Common Options: CAPABILITY Procedure](#)” on page 551 for detailed descriptions of options common to all the plot statements.

BARLABEL=COUNT | PERCENT | PROPORTION

Traditional Graphics

displays labels above the histogram bars. If you specify BARLABEL=COUNT, the label shows the number of observations associated with a given bar. BARLABEL=PERCENT shows the percent of observations represented by that bar. If you specify BARLABEL=PROPORTION, the label displays the proportion of observations associated with the bar.

BARWIDTH=value

Traditional Graphics

specifies the width of the histogram bars in screen percent units.

C=value-list | MISE

specifies the standardized bandwidth parameter c for kernel density estimates requested with the KERNEL option. You can specify up to five *values* to display multiple estimates in each cell. You can also specify the keyword MISE to request the bandwidth parameter that minimizes the estimated mean integrated square error (MISE). For example, consider the following statements (for more information, see “[Kernel Density Estimates](#)” on page 358):

```
proc capability;
  comphist length / class=batch kernel(c = 0.5 1.0 mise);
run;
```

The KERNEL option displays three density estimates. The first two have standardized bandwidths of 0.5 and 1.0, respectively. The third has a bandwidth parameter that minimizes the MISE. You can also use the C= and K= options (K= specifies kernel type) to display multiple estimates. For example, consider the following statements:

```

proc capability;
  comphist length / class = batch
                kernel(c = 0.75 k = normal triangular);
run;

```

Here two estimates are displayed. The first uses a normal kernel and bandwidth parameter of 0.75, and the second uses a triangular kernel and a bandwidth parameter of 0.75. In general, if more kernel types are specified than bandwidth parameters, the last bandwidth parameter in the list will be repeated for the remaining estimates. Likewise, if more bandwidth parameters are specified than kernel types, the last kernel type will be repeated for the remaining estimates. The default is MISE.

CBARLINE=*color*

specifies the color of the outline of the histogram bars. This option overrides the C= option in the SYMBOL1 statement. *Traditional Graphics*

CFILL=*color*

specifies a color used to fill the bars of the histograms (or the areas under a fitted curve if you also specify the FILL option). See the entry for the FILL option for additional details. See [Output 5.6.1](#) and [Example 5.7](#) for examples. Refer to *SAS/GRAPH: Reference* for a list of colors. By default, bars and curve areas are not filled. *Traditional Graphics*

CFRAMENLEG=*color* | **EMPTY**

CFRAMENLEG

specifies that the legend requested with the NLEGEND option (or the variable `_TILELB_` in a CLASSSPEC= data set) is to be framed and that the frame is to be filled with the color indicated. If you specify CFRAMENLEG=EMPTY, a frame is drawn but not filled with a color. *Traditional Graphics*

CGRID=*color*

specifies the color for grid lines requested with the GRID option. By default, grid lines are the same color as the axes. If you use CGRID=, you do not need to specify the GRID option. *Traditional Graphics*

CLASS=*variable*

CLASS=(*variable1 variable2***)**

specifies that a comparative histogram is to be created using the levels of the *variables* (also referred to as *class-variables* or *classification variables*).

If you specify a single *variable*, a one-way comparative histogram is created. The observations in the input data set are sorted by the formatted values (levels) of the variable. A separate histogram is created for the process variable values in each level, and these component histograms are arranged in an array to form the comparative histogram. Uniform horizontal and vertical axes are used to facilitate comparisons. For an example, see [Figure 5.6](#).

If you specify two *classification variables*, a two-way comparative histogram is created. The observations in the input data set are cross-classified according to the values (levels) of these variables. A separate histogram is created for the process variable values in each cell of the cross-classification, and these component histograms are arranged in a matrix to form the comparative histogram. The levels of *variable1* are used to label the rows of the matrix, and

the levels of *variable2* are used to label the columns of the matrix. Uniform horizontal and vertical axes are used to facilitate comparisons. For an example, see [Output 5.7.1](#).

Classification variables can be numeric or character. Formatted values are used to determine the levels. You can specify whether missing values are to be treated as a level with the MISSING1 and MISSING2 options.

If a label is associated with a classification variable, the label is displayed on the comparative histogram. The variable label is displayed parallel to the column (or row) labels. For an example, see [Figure 5.6](#).

CLASSKEY='value'

CLASSKEY=('value1' 'value2')

specifies the *key cell* in a comparative histogram requested with the CLASS= option. The bin size and midpoints are first determined for the key cell, and then the midpoint list is extended to accommodate the data ranges for the remaining cells. Thus, the choice of the key cell determines the uniform horizontal axis used for all cells.

If you specify CLASS=*variable*, you can specify CLASSKEY='value' to identify the key cell as the level for which *variable* is equal to *value*. You must specify a formatted *value*. By default, the levels are sorted in the order determined by the ORDER1= option, and the key cell is the level that occurs first in this order. The cells are displayed in this order from top to bottom (or left to right), and, consequently, the key cell is displayed at the top or at the left. If you specify a different key cell with the CLASSKEY= option, this cell is displayed at the top or at the left unless you also specify the NOKEYMOVE option.

If you specify CLASS=(*variable1 variable2*), you can specify CLASSKEY=('value1' 'value2') to identify the key cell as the level for which *variable1* is equal to *value1* and *variable2* is equal to *value2*. Here, *value1* and *value2* must be formatted values, and they must be enclosed in quotes. For an example of the CLASSKEY= option with a two-way comparative histogram, see [Output 5.7.1](#). By default, the levels of *variable1* are sorted in the order determined by the ORDER1= option, and within each of these levels, the levels of *variable2* are sorted in the order determined by the ORDER2= option. The default key cell is the combination of levels of *variable1* and *variable2* that occurs first in this order. The cells are displayed in order of *variable1* from top to bottom and in order of *variable2* from left to right. Consequently, the default key cell is displayed in the upper left corner. If you specify a different key cell with the CLASSKEY= option, this cell is displayed in the upper left corner unless you also specify the NOKEYMOVE option.

CLASSSPEC=SAS-data-set

CLASSSPECs=SAS-data-set

specifies a data set that provides distinct specification limits for each cell, as well as a color, legend, and label for the corresponding tile. The following table lists the variables that are read from a CLASSSPEC= data set:

Variable Name	Description
BY variables	subsets the data set
Classification variables	specifies the structure of the comparative histogram
VAR	specifies name of process variable (must be character variable of length 8)
LSL	specifies lower specification limit for tile
TARGET	specifies target value for tile
USL	specifies upper specification limit for tile
CTILE	specifies background color for tiles (must be character variable of length 8)
TILELG	specifies text displayed in color tile legend at bottom of comparative histogram (character variable of length not greater than 16)
TILELB	specifies text displayed in corner of each tile (character variable of length not greater than 16)

If you specify a CLASSSPEC= data set, you cannot use the SPEC statement or a SPEC= data set. If you use a BY statement, the CLASSSPEC= data set must contain one observation for each unique combination of process and classification variables within each BY group. See [Example 5.6](#) for an example of a CLASSSPEC= data set.

Also note that

- you can suppress the background color for a tile by assigning the value 'EMPTY' or a blank value to the variable _CTILE_
- you can use the NLEGENDPOS= option to specify the corner of the tile in which the _TILELB_ label is displayed. You can frame the label with the CFRAMENLEG= option.
- you cannot use the variable _TILELG_ unless you specify the variable _CTILE_
- the variable _TILELB_ takes precedence over the NLEGEND option

CLIPSPEC=CLIP | NOFILL

specifies that histogram bars are clipped at the upper and lower specification limit lines when there are no observations outside the specification limits. The bar intersecting the lower specification limit is clipped if there are no observations less than the lower limit; the bar intersecting the upper specification limit is clipped if there are no observations greater than the upper limit. If you specify CLIPSPEC=CLIP, the histogram bar is truncated at the specification limit. If you specify CLIPSPEC=NOFILL, the portion of a filled histogram bar outside the specification limit is left unfilled. Specifying CLIPSPEC=NOFILL when histogram bars are not filled has no effect. *Traditional Graphics*

ENDPOINTS=value-list | KEY | UNIFORM

specifies that histogram interval endpoints, rather than midpoints, are aligned with horizontal axis tick marks, and specifies how the endpoints are determined. The method you specify is used for all process variables analyzed with the COMPHISTOGRAM statement.

If you specify ENDPOINTS=value-list, the values must be listed in increasing order and must be evenly spaced. The difference between consecutive endpoints is used as the width of the

histogram bars. The first value is the lower bound of the first histogram bin and the last value is the upper bound of the last bin. Thus, the number of values in the list is one greater than the number of bins it specifies. If the range of the *values* does not cover the range of the data as well as any specification limits (LSL and USL) that are given, the list is extended in either direction as necessary.

If you specify `ENDPOINTS=KEY`, the procedure first determines the endpoints for the data in the key cell. The initial number of endpoints is based on the number of observations in the key cell by using the method of Terrell and Scott (1985). The endpoint list for the key cell is then extended in either direction as necessary until it spans the data in the remaining cells. If the key cell contains no observations, the method of determining bins reverts to `ENDPOINTS=UNIFORM`.

If you specify `ENDPOINTS=UNIFORM`, the procedure determines the endpoints by using all the observations as if there were no cells. In other words, the number of endpoints is computed from the total sample size by using the method of Terrell and Scott (1985).

FILL

fills areas under a fitted density curve with colors and patterns. Enclose the `FILL` option in parentheses after the keyword `NORMAL` or `KERNEL`. Depending on the area to be filled (outside or between the specification limits), you can specify the color and pattern with options in the `SPEC` statement and the `COMPHISTOGRAM` statement, as summarized in the following table:

Area Under Curve	Statement	Option
between specification limits	COMPHIST	CFILL= <i>color</i>
	COMPHIST	PFILL= <i>pattern</i>
left of lower specification limit	SPEC	CLEFT= <i>color</i>
	SPEC	PLEFT= <i>pattern</i>
right of upper specification limit	SPEC	CRIGHT= <i>color</i>
	SPEC	PRIGHT= <i>pattern</i>

If you do not display specification limits, you can use the `CFILL=` and `PFILL=` options to specify the color and pattern for the entire area under the curve. Solid fills are used by default if patterns are not specified. You can specify the `FILL` option with only one fitted curve. For an example, see [Output 5.6.1](#). Refer to *SAS/GRAPH: Reference* for a list of available patterns and colors. If you do not specify the `FILL` option but you do specify the options in the preceding table, the colors and patterns are applied to the corresponding areas under the histogram.

FRONTREF

Traditional Graphics

draws reference lines requested with the `HREF=` and `VREF=` options in front of the histogram bars. By default, reference lines are drawn behind the histogram bars and can be obscured by them.

GRID

adds a grid to the comparative histogram. Grid lines are horizontal lines positioned at major tick marks on the vertical axis.

HOFFSET=*value*

specifies the offset in percent screen units at both ends of the horizontal axis. Specify HOFFSET=0 to eliminate the default offset. *Traditional Graphics*

INTERTILE=*value*

specifies the distance in horizontal percent screen units between tiles. For an example, see [Figure 5.7](#). By default, the tiles are contiguous.

K=NORMAL | TRIANGULAR | QUADRATIC

specifies the type of kernel (normal, triangular, or quadratic) used to compute kernel density estimates requested with the KERNEL option. Enclose the K= option in parentheses after the keyword KERNEL. You can specify a single type or a list of types. If you specify more estimates than types, the last kernel type in the list is used for the remaining estimates. By default, a normal kernel is used.

KERNEL<(*kernel-options*)>

requests a kernel density estimate for each cell of the comparative histogram. You can specify the *kernel-options* described in the following table:

Option	Description
FILL	specifies that the area under the curve is to be filled
COLOR=	specifies the color of the curve
L=	specifies the line style for the curve
W=	specifies the width of the curve
K=	specifies the type of kernel
C=	specifies the smoothing parameter
LOWER=	specifies the lower bound for the curve
UPPER=	specifies the upper bound for the curve

See [Output 5.6.1](#) for an example. By default, the estimate is based on the AMISE method. For more information, see “Kernel Density Estimates” on page 358.

LOWER=*value*

specifies the lower bound for a kernel density estimate curve. Enclose the LOWER= option in parentheses after the KERNEL option. You can specify a single lower bound or a list of lower bounds. By default, a kernel density estimate curve has no lower bound.

LGRID=*n*

specifies the line type for the grid requested with the GRID option. If you use the LGRID= option, you do not need to specify the GRID option. The default is 1, which produces a solid line. *Traditional Graphics*

MAXNBIN=*n*

specifies the maximum number of bins to be displayed. This option is useful in situations where the scales or ranges of the data distributions differ greatly from cell to cell. By default, the bin size and midpoints are determined for the key cell, and then the midpoint list is extended to accommodate the data ranges for the remaining cells. However, if the cell scales differ considerably, the resulting number of bins may be so great that each cell histogram is scaled into a narrow region. By limiting the number of bins with the MAXNBIN= option, you can narrow the window about the data distribution in the key cell. Note that the MAXNBIN= option provides an alternative to the MAXSIGMAS= option.

MAXSIGMAS=*value*

limits the number of bins to be displayed to a range of *value* standard deviations (of the data in the key cell) above and below the mean of the data in the key cell. This option is useful in situations where the scales or ranges of the data distributions differ greatly from cell to cell. By default, the bin size and midpoints are determined for the key cell, and then the midpoint list is extended to accommodate the data ranges for the remaining cells. If the cell scales differ considerably, however, the resulting number of bins may be so great that each cell histogram is scaled into a narrow region. By limiting the number of bins with the MAXSIGMAS= option, you narrow the window about the data distribution in the key cell. Note that the MAXSIGMAS= option provides an alternative to the MAXNBIN= option.

MIDPOINTS=*value-list* | KEY | UNIFORM

specifies how midpoints are determined for the bins in the comparative histogram. The method you specify is used for all process variables analyzed with the COMPHISTOGRAM statement.

If you specify MIDPOINTS=*value-list*, the *values* must be listed in increasing order and must be evenly spaced. The difference between consecutive midpoints is used as the width of the histogram bars. If the range of the *values* does not cover the range of the data as well as any specification limits (LSL and USL) that are given, the list is extended in either direction as necessary. See [Example 5.6](#) for an illustration.

If you specify MIDPOINTS=KEY, the procedure first determines the midpoints for the data in the key cell. The initial number of midpoints is based on the number of observations in the key cell by using the method of Terrell and Scott (1985). The midpoint list for the key cell is then extended in either direction as necessary until it spans the data in the remaining cells.

If you specify MIDPOINTS=UNIFORM, the procedure determines the midpoints using all the observations as if there were no cells. In other words, the number of midpoints is computed from the total sample size by using the method of Terrell and Scott (1985).

By default, MIDPOINTS=KEY. However, if the key cell contains no observations, the default is MIDPOINTS=UNIFORM.

MISSING1

specifies that missing values of the first CLASS= variable are to be treated as a level of the CLASS= variable. If the first CLASS= variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the process variable is numeric, a missing value is defined as any of the SAS System missing values. If you do not specify MISSING1, observations for which the first CLASS= variable is missing are excluded from the analysis.

MISSING2

specifies that missing values of the second CLASS= variable are to be treated as a level of the CLASS= variable. If the second CLASS= variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the process variable is numeric, a missing value is defined as any of the SAS System missing values. If you do not specify MISSING2, observations for which the second CLASS= variable is missing are excluded from the analysis.

MU=value

specifies the parameter μ for the normal density curves requested with the NORMAL option. Enclose the MU= option in parentheses after the NORMAL option. The default value is the sample mean of the observations in the cell.

NLEGEND<='label'>

specifies the form of a legend that is displayed inside each tile and indicates the sample size *Traditional Graphics* of the cell. The following two forms are available:

- If you specify the NLEGEND option, the form is $N = n$ where n is the cell sample size.
- If you specify the NLEGEND='label' option, the form is $label = n$ where n is the cell sample size. The label can be up to 16 characters and must be enclosed in quotes. For instance, you might specify NLEGEND='Number of Parts' to request a label of the form *Number of Parts = n*.

See [Figure 5.6](#) for an example. You can use the CFRAMENLEG= option to frame the sample size legend. The variable _TILELB_ in a CLASSSPEC= data set overrides the NLEGEND option. By default, no legend is displayed.

NLEGENDPOS=NW | NE

specifies the position of the legend requested with the NLEGEND option or the variable *Traditional Graphics* _TILELB_ in a CLASSSPEC= data set. If NLEGENDPOS=NW, the legend is displayed in the northwest corner of the tile; if NLEGENDPOS=NE, the legend is displayed in the northeast corner of the tile. See [Figure 5.6](#) for an illustration. The default is NE.

NOBARS

suppresses the display of the bars in a comparative histogram.

NOCHART

suppresses the creation of a comparative histogram. This is an alias for NOPLOT.

NOKEYMOVE

suppresses the rearrangement of cells that occurs by default when you use the CLASSKEY= option to specify the key cell. For details, see the entry for the CLASSKEY= option.

NOPLOT

suppresses the creation of a comparative histogram. This option is useful when you are using the COMPHISTOGRAM statement solely to create an output data set.

NORMAL<(normal-options)>

displays a normal density curve for each cell of the comparative histogram. The equation of the normal density curve is

$$p(x) = \frac{h\nu}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right) \quad \text{for } -\infty < x < \infty$$

where

μ = mean

σ = standard deviation ($\sigma > 0$)

h = width of histogram interval
 v = vertical scaling factor
 and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

If you specify values for μ and σ with the MU= and SIGMA= *normal-options*, the same curve is displayed for each cell. By default, a distinct curve is displayed for each cell based on the sample mean and standard deviation for that cell. For example, the following statements display a distinct curve for each level of the variable Supplier:

```
proc capability noprint;
  comphist width / class=supplier normal(color=red l=2);
run;
```

The curves are drawn in red with a line style of 2 (a dashed line). See Figure 5.7 for another illustration. Table 5.15 lists options that can be specified in parentheses after the NORMAL option.

ORDER1=INTERNAL | FORMATTED | DATA | FREQ

specifies the display order for the values of the first CLASS= variable.

The levels of the first CLASS= variable are always constructed using the *formatted* values of the variable, and the formatted values are always used to label the rows (columns) of a comparative histogram. You can use the ORDER1= option to determine the order of the rows (columns) corresponding to these values, as follows:

- **If you specify ORDER1=INTERNAL**, the rows (columns) are displayed from top to bottom (left to right) in increasing order of the internal (unformatted) values of the first CLASS= variable. If there are two or more distinct internal values with the same formatted value, then the order is determined by the internal value that occurs first in the input data set.

For example, suppose that you specify a numeric CLASS= variable called Day (with values 1, 2, and 3). Suppose also that a format (created with the FORMAT procedure) is associated with Day and that the formatted values are as follows: 1 = 'Wednesday', 2 = 'Thursday', and 3 = 'Friday'. If you specify ORDER1=INTERNAL, the rows of the comparative histogram will appear in day-of-the-week order (*Wednesday, Thursday, Friday*) from top to bottom.

- **If you specify ORDER1=FORMATTED**, the rows (columns) are displayed from top to bottom (left to right) in increasing order of the formatted values of the first CLASS= variable. In the preceding illustration, if you specify ORDER1=FORMATTED, the rows will appear in alphabetical order (*Friday, Thursday, Wednesday*) from top to bottom.
- **If you specify ORDER1=DATA**, the rows (columns) are displayed from top to bottom (left to right) in the order in which the values of the first CLASS= variable first appear in the input data set.

- If you specify **ORDER1=FREQ**, the rows (columns) are displayed from top to bottom (left to right) in order of *decreasing* frequency count. If two or more classes have the same frequency count, the order is determined by the formatted values.

By default, ORDER1=INTERNAL.

ORDER2=INTERNAL | FORMATTED | DATA | FREQ

specifies the display order for the values of the second CLASS= variable.

The levels of the second CLASS= variable are always constructed using the *formatted* values of the variable, and the formatted values are always used to label the columns of a two-way comparative histogram. You can use the ORDER2= option to determine the order of the columns.

The layout of a two-way comparative histogram is determined by using the ORDER1= option to obtain the order of the rows from top to bottom (recall that ORDER1=INTERNAL by default). Then the ORDER2= option is applied to the observations corresponding to the first row to obtain the order of the columns from left to right. If any columns remain unordered (that is, the categories are *unbalanced*), the ORDER2= option is applied to the observations in the second row, and so on, until all the columns have been ordered.

The values of the ORDER2= option are interpreted as described for the ORDER1= option. By default, ORDER2=INTERNAL.

OUTHISTOGRAM=SAS-data-set

creates a SAS data set that saves the midpoints or endpoints of the histogram intervals, the observed percent of observations in each interval, and (optionally) the percent of observations in each interval estimated from a fitted normal distribution. By default, interval midpoint values are saved in the variable `_MIDPT_`. If the ENDPOINTS= option is specified, intervals are identified by endpoint values instead. If RTINCLUDE is specified, the `_MAXPT_` variable contains upper endpoint values. Otherwise, lower endpoint values are saved in the `_MINPT_` variable.

PFILL=pattern

specifies a pattern used to fill the bars of the histograms (or the areas under a fitted curve *Traditional Graphics* if you also specify the FILL option). See the entries for the CFILL= and FILL options for additional details. Refer to *SAS/GRAPH: Reference* for a list of pattern values. By default, the bars and curve areas are not filled.

RTINCLUDE

includes the right endpoint of each histogram interval in that interval. The left endpoint is included by default.

SIGMA=value

specifies the parameter σ for normal density curves requested with the NORMAL option. Enclose the SIGMA= option in parentheses after the NORMAL option. The default value is the sample standard deviation of the observations in the cell.

TILELEGLABEL='label'

specifies a label displayed to the left of the legend that is created when you provide `_CTILE_` *Traditional Graphics* and `_TILELG_` variables in a CLASSSPEC= data set. The *label* can be up to 16 characters and must be enclosed in quotes. The default *label* is *Tiles:*.

UPPER=value

specifies the upper bound for a kernel density estimate curve. Enclose the UPPER= option in parentheses after the KERNEL option. You can specify a single upper bound or a list of upper bounds. By default, a kernel density estimate curve has no upper bound.

VOFFSET=value

Traditional Graphics

specifies the offset in percent screen units at the upper end of the vertical axis.

VSCALE=PERCENT | COUNT | PROPORTION

specifies the scale of the vertical axis. The value COUNT scales the data in units of the number of observations per data unit. The value PERCENT scales the data in units of percent of observations per data unit. The value PROPORTION scales the data in units of proportion of observations per data unit. The default is PERCENT.

WBARLINE=n

Traditional Graphics

specifies the width of bar outlines. By default, $n = 1$.

WGRID=n

Traditional Graphics

specifies the width of the grid lines requested with the GRID option. By default, grid lines are the same width as the axes. If you use the WGRID= option, you do not need to specify the GRID option.

Details: COMPHISTOGRAM Statement

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. COMPHISTOGRAM options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the COMPHISTOGRAM statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in Table 5.17.

Table 5.17 ODS Graphics Produced by the COMPHISTOGRAM Statement

ODS Graph Name	Plot Description
Histogram	comparative histogram

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Examples: COMPHISTOGRAM Statement

This section provides advanced examples of comparative histograms.

Example 5.6: Adding Insets with Descriptive Statistics

Three similar machines are used to attach a part to an assembly. One hundred assemblies are sampled from the output of each machine, and a part position is measured in millimeters. The following statements save the measurements in a SAS data set named Machines: *See CAPCMH2 in the SAS/QC Sample Library*

```
data Machines;
  input position @@;
  label position='Position in Millimeters';
  if      (_n_ <= 100) then Machine = 'Machine 1';
  else if (_n_ <= 200) then Machine = 'Machine 2';
  else           Machine = 'Machine 3';
  datalines;
-0.17 -0.19 -0.24 -0.24 -0.12  0.07 -0.61  0.22  1.91 -0.08
-0.59  0.05 -0.38  0.82 -0.14  0.32  0.12 -0.02  0.26  0.19
-0.07  0.13 -0.49  0.07  0.65  0.94 -0.51 -0.61 -0.57 -0.51
  0.01 -0.51  0.07 -0.16 -0.32 -0.42 -0.42 -0.34 -0.34 -0.35
-0.49  0.11 -0.42  0.76  0.02 -0.59 -0.28  1.12 -0.02 -0.60
-0.64  0.13 -0.32 -0.77 -0.02 -0.07 -0.49 -0.53 -0.22  0.61
-0.23  0.02  0.53  0.23 -0.44 -0.05  0.37 -0.42  0.70 -0.35

  ... more lines ...

  0.58  0.46  0.58  0.92  0.70  0.81  0.07  0.33  0.82  0.62
  0.48  0.41  0.78  0.58  0.43  0.07  0.27  0.49  0.79  0.92
  0.79  0.66  0.22  0.71  0.53  0.57  0.90  0.48  1.17  1.03
;
```

Distinct specification limits for the three machines are provided in a data set named speclims.

```
data speclims;
  input Machine $9. _lsl_ _usl_;
  _var_ = 'position';
  datalines;
Machine 1 -0.5 0.5
Machine 2  0.0 1.0
Machine 3  0.0 1.0
;
```

The following statements create a comparative histogram for the measurements in Machines that displays the specification limits in speclims.

```
ods graphics on;
proc capability data=Machines noprint;
  spec cleft cright;
  comphist position / class      = Machine
                    nrows      = 3
                    intertile  = 1
                    midpoints  = -1.2 to 2.2 by 0.1
```

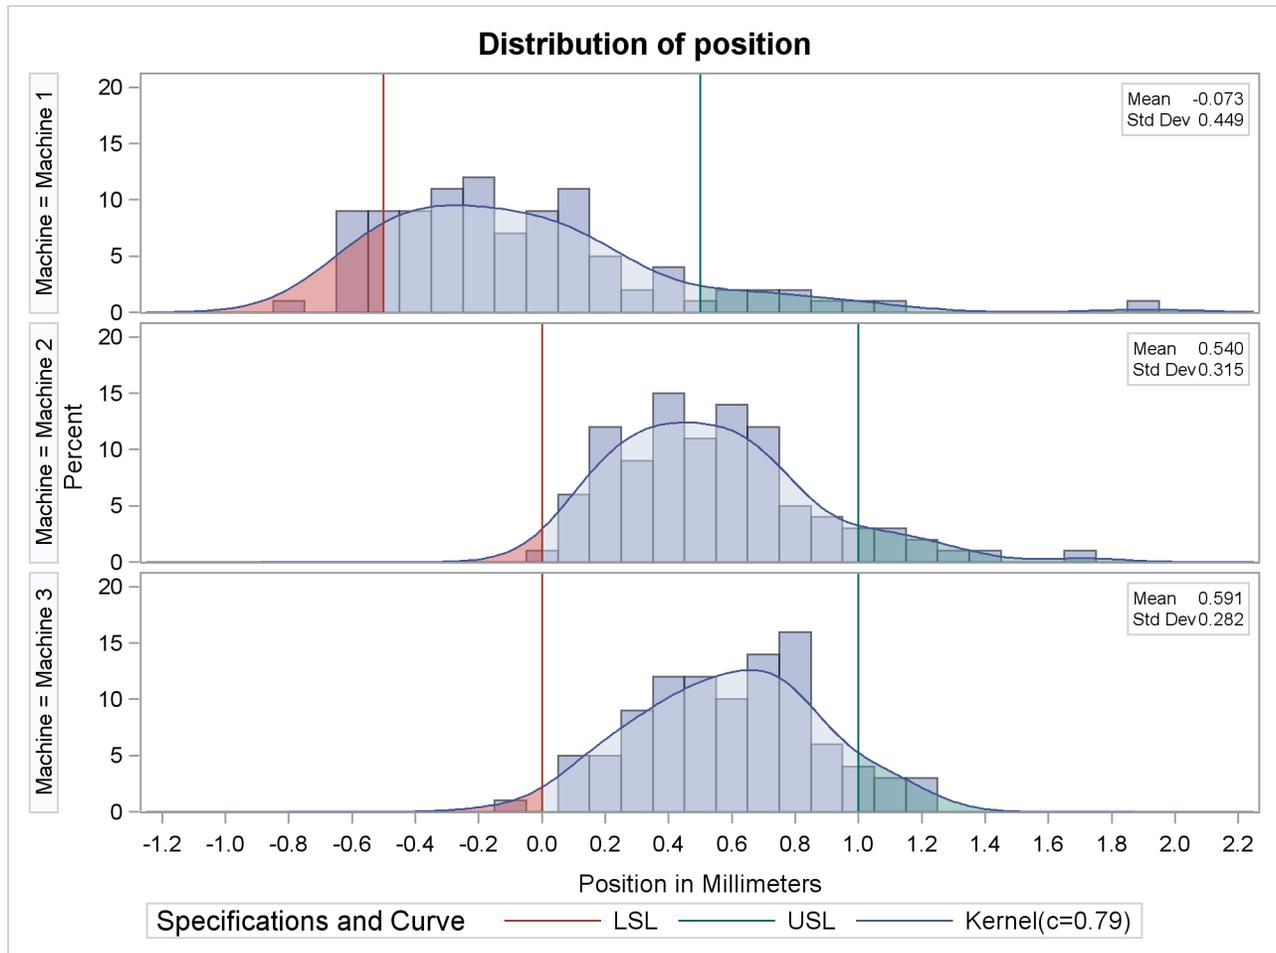

```

kernel(fill)
classspecs = speclims;
inset mean std="Std Dev" / pos = ne format = 6.3;
run;

```

The ODS GRAPHICS ON statement specified before the PROC CAPABILITY statement enables ODS Graphics, so the comparative histogram is created using ODS Graphics instead of traditional graphics. The display is shown in [Output 5.6.1](#).

Output 5.6.1 Comparative Histogram

The INSET statement is used to inset the sample mean and standard deviation for each machine in the corresponding tile. The MIDPOINTS= option specifies the midpoints of the histogram bins. Kernel density estimates are displayed using the KERNEL option. The curve areas outside the specification limits are filled using the CLEFT and CRIGHT options in the SPEC statement, and the area between the limits is filled using the CFILL= option in COMPHISTOGRAM statement.

Example 5.7: Creating a Two-Way Comparative Histogram

Two suppliers (A and B) provide disk drives for a computer manufacturer. The manufacturer measures the disk drive opening width to compare the process capabilities of the suppliers and determine whether there has been an improvement from 1992 to 1993. *See CAPCMH3 in the SAS/QC Sample Library*

The following statements save the measurements in a data set named Disk. There are two classification variables, Supplier and Year, and a format is associated with Year.

```
proc format ;
  value mytime  1 = '1992'
                2 = '1993' ;

data disk;
  input @1 supplier $10. year width;
  label width = 'Opening Width (inches)';
  format year mytime.;
  datalines;
Supplier A    1    1.8932
Supplier A    1    1.8952
.            .    .
.            .    .
Supplier B    1    1.8980
Supplier B    1    1.8986
Supplier A    2    1.8978
Supplier A    2    1.8966
.            .    .
.            .    .
Supplier B    2    1.8967
Supplier B    2    1.8997
;
```

The following statements create the comparative histogram in [Output 5.7.1](#):

```
* Define a format for time periods;
proc format ;
  value mytime
    1 = '1992'
    2 = '1993'
    3 = 'Target for 1994'
  ;
* Simulate the data;
data Disk;
  keep Supplier Year Width;
  length Supplier $ 16;
  label Width = 'Opening Width (inches)';
  format Year mytime. ;
  Year = 1;
  Supplier = 'Supplier A';
  avg      = 1.895 ;
  std      = 0.0027 ;
  do i = 1 to 260;
    Width = avg + std * rannor(15535); output;
```

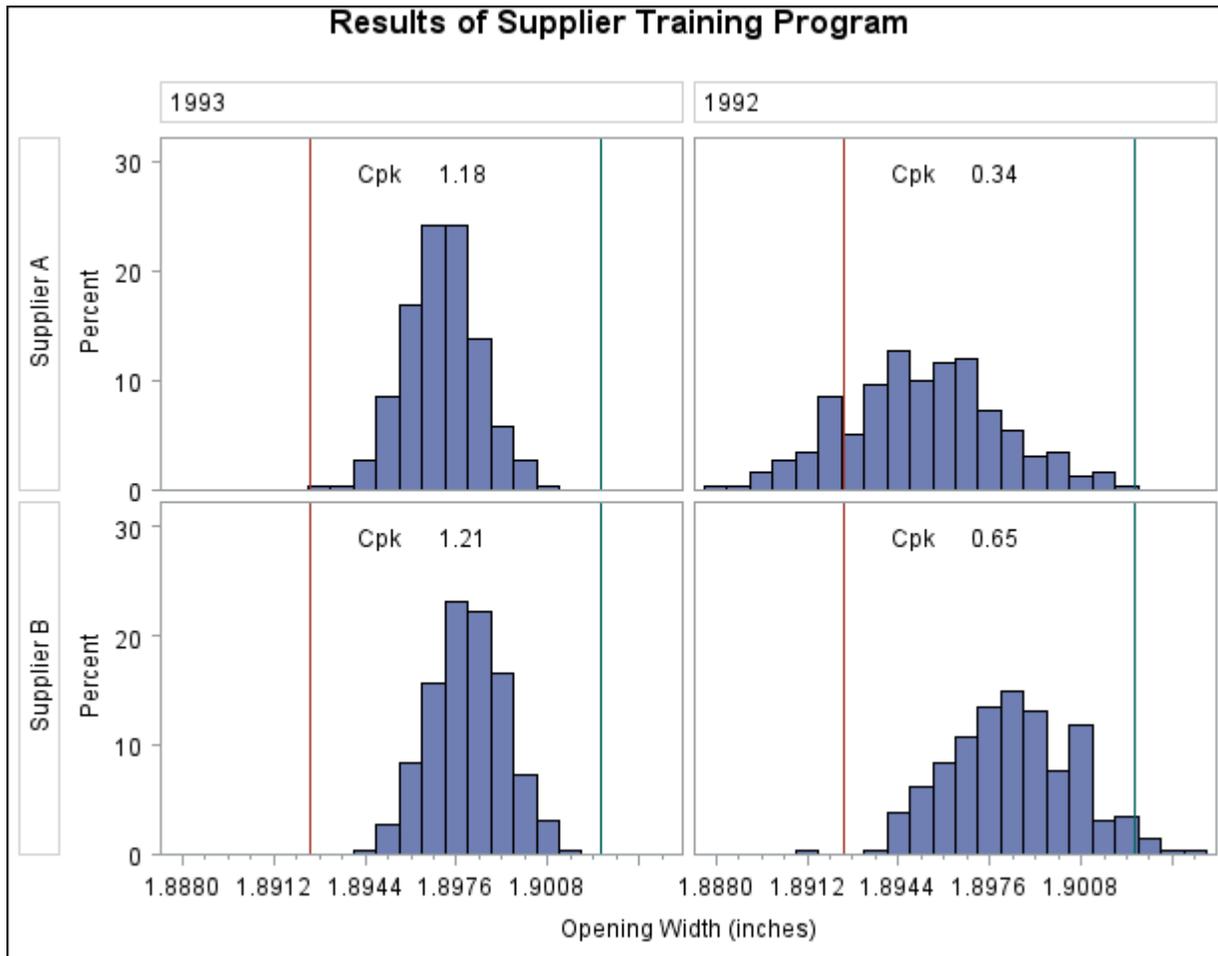

```

end;
Supplier = 'Supplier B';
avg      = 1.8983 ;
std      = 0.0024 ;
do i = 1 to 260;
    Width = avg + std * rannor(15535); output;
end;
Year = 2;
Supplier = 'Supplier A';
avg      = 1.8970 ;
std      = 0.0013 ;
do i = 1 to 260;
    Width = avg + std * rannor(15535); output;
end;
Supplier = 'Supplier B';
avg      = 1.8980 ;
std      = 0.0013 ;
do i = 1 to 260;
    Width = avg + std * rannor(15535); output;
end;
run;

ods graphics off;
title "Results of Supplier Training Program";
proc capability data=Disk noprint;
    specs  lsl = 1.8925
           usl = 1.9027;
    comphist Width / class      = ( Supplier Year )
                               classkey = ('Supplier A' '1993')
                               intertile = 1.0
                               vaxis     = 0 10 20 30
                               ncols     = 2
                               nrows     = 2;
    inset cpk (4.2) / noframe pos = n;
run;

```

Output 5.7.1 Two-Way Comparative Histogram

The CLASSKEY= option specifies the key cell as the observations for which Supplier is equal to 'SUPPLIER A' and Year is equal to 2. This cell determines the binning for the other cells, and (since the NOKEYMOVE option is not specified) the columns are interchanged so that this cell is displayed in the upper left corner. Note that if the CLASSKEY= option were not specified, the default key cell would be the observations for which Supplier is equal to 'SUPPLIER A' and Year is equal to 1. If the CLASSKEY= option were not specified (or if the NOKEYMOVE option were specified), the column labeled 1992 would be displayed to the left of the column labeled 1993. See the entry for the CLASSKEY= option on page 296 for details.

The VAXIS= option specifies the tick mark labels for the vertical axis, while NROWS=2 and NCOLS=2 specify a 2 × 2 arrangement for the tiles. The INSET statement is used to display the capability index C_{pk} for each cell. Output 5.7.1 provides evidence that both suppliers have reduced variability from 1992 to 1993.

HISTOGRAM Statement: CAPABILITY Procedure

Overview: HISTOGRAM Statement

Histograms are typically used in process capability analysis to compare the distribution of measurements from an in-control process with its specification limits. In addition to creating histograms, you can use the HISTOGRAM statement to do the following:

- specify the midpoints or endpoints for histogram intervals
- display specification limits on histograms
- display density curves for fitted theoretical distributions on histograms
- request goodness-of-fit tests for fitted distributions
- display kernel density estimates on histograms
- inset summary statistics and process capability indices on histograms
- save histogram intervals and parameters of fitted distributions in output data sets
- create hanging histograms
- request graphical enhancements
- create comparative histograms by using the HISTOGRAM statement together with a CLASS statement

You have three alternatives for producing histograms with the HISTOGRAM statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: HISTOGRAM Statement

This section introduces the HISTOGRAM statement with examples that illustrate commonly used options. Complete syntax for the HISTOGRAM statement is presented in the section “Syntax: HISTOGRAM Statement” on page 316, and advanced examples are given in the section “Examples: HISTOGRAM Statement” on page 375.

Creating a Histogram with Specification Limits

A semiconductor manufacturer produces printed circuit boards that are sampled to determine whether the thickness of their copper plating lies between a lower specification limit of 3.45 mils and an upper specification limit of 3.55 mils. The plating process is assumed to be in statistical control. The plating thicknesses of 100 boards are saved in a data set named Trans, created by the following statements: *See CAPHSTI in the SAS/QC Sample Library*

```
data Trans;
  input Thick @@;
  label Thick='Plating Thickness (mils)';
  datalines;
3.468 3.428 3.509 3.516 3.461 3.492 3.478 3.556 3.482 3.512
3.490 3.467 3.498 3.519 3.504 3.469 3.497 3.495 3.518 3.523
3.458 3.478 3.443 3.500 3.449 3.525 3.461 3.489 3.514 3.470
3.561 3.506 3.444 3.479 3.524 3.531 3.501 3.495 3.443 3.458
3.481 3.497 3.461 3.513 3.528 3.496 3.533 3.450 3.516 3.476
3.512 3.550 3.441 3.541 3.569 3.531 3.468 3.564 3.522 3.520
3.505 3.523 3.475 3.470 3.457 3.536 3.528 3.477 3.536 3.491
3.510 3.461 3.431 3.502 3.491 3.506 3.439 3.513 3.496 3.539
3.469 3.481 3.515 3.535 3.460 3.575 3.488 3.515 3.484 3.482
3.517 3.483 3.467 3.467 3.502 3.471 3.516 3.474 3.500 3.466
;
```

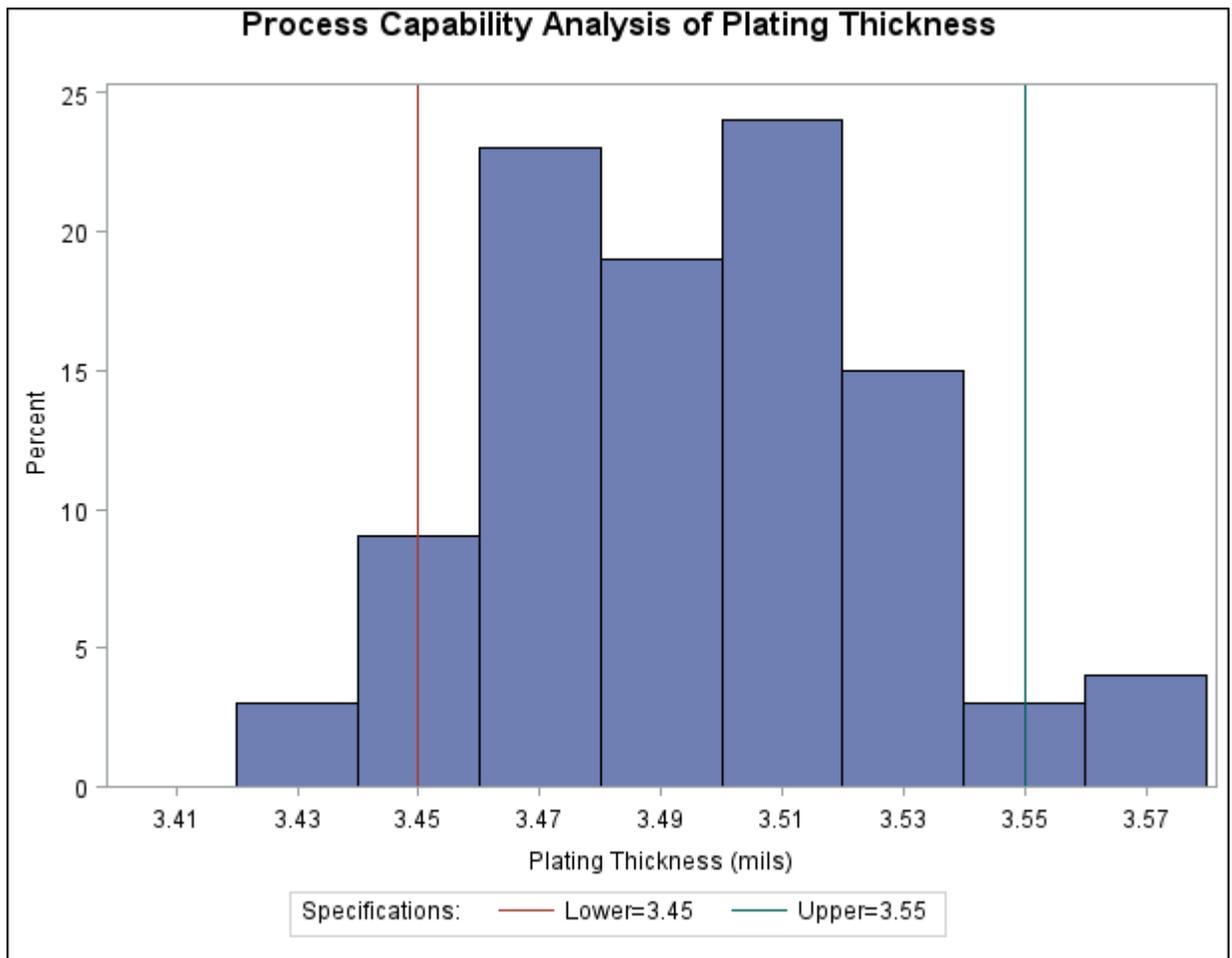

The following statements create the histogram shown in [Figure 5.8](#):

```
ods graphics off;
title 'Process Capability Analysis of Plating Thickness';
legend2 frame;
proc capability data=Trans noprint;
  spec lsl = 3.45 usl = 3.55;
  histogram Thick / legend = legend2;
run;
```

A histogram is created for each variable listed after the keyword HISTOGRAM. The SPEC statement, which is optional, provides the specification limits that are displayed on the histogram. For more information about the SPEC statement, see “[SPEC Statement](#)” on page 225.

The NOPRINT option suppresses printed output with summary statistics for the variable Thick that would be displayed by default. See “[Computing Descriptive Statistics](#)” on page 206 for an example of this output.

Figure 5.8 Histogram Created with Traditional Graphics

Adding a Normal Curve to the Histogram

See CAPHST1 in the SAS/QC Sample Library This example is a continuation of the preceding example.

The following statements fit a normal distribution from the thickness measurements and superimpose the fitted density curve on the histogram:

```
ods graphics on;
proc capability data=Trans;
  spec lsl = 3.45 usl = 3.55;
  histogram / normal;
run;
```

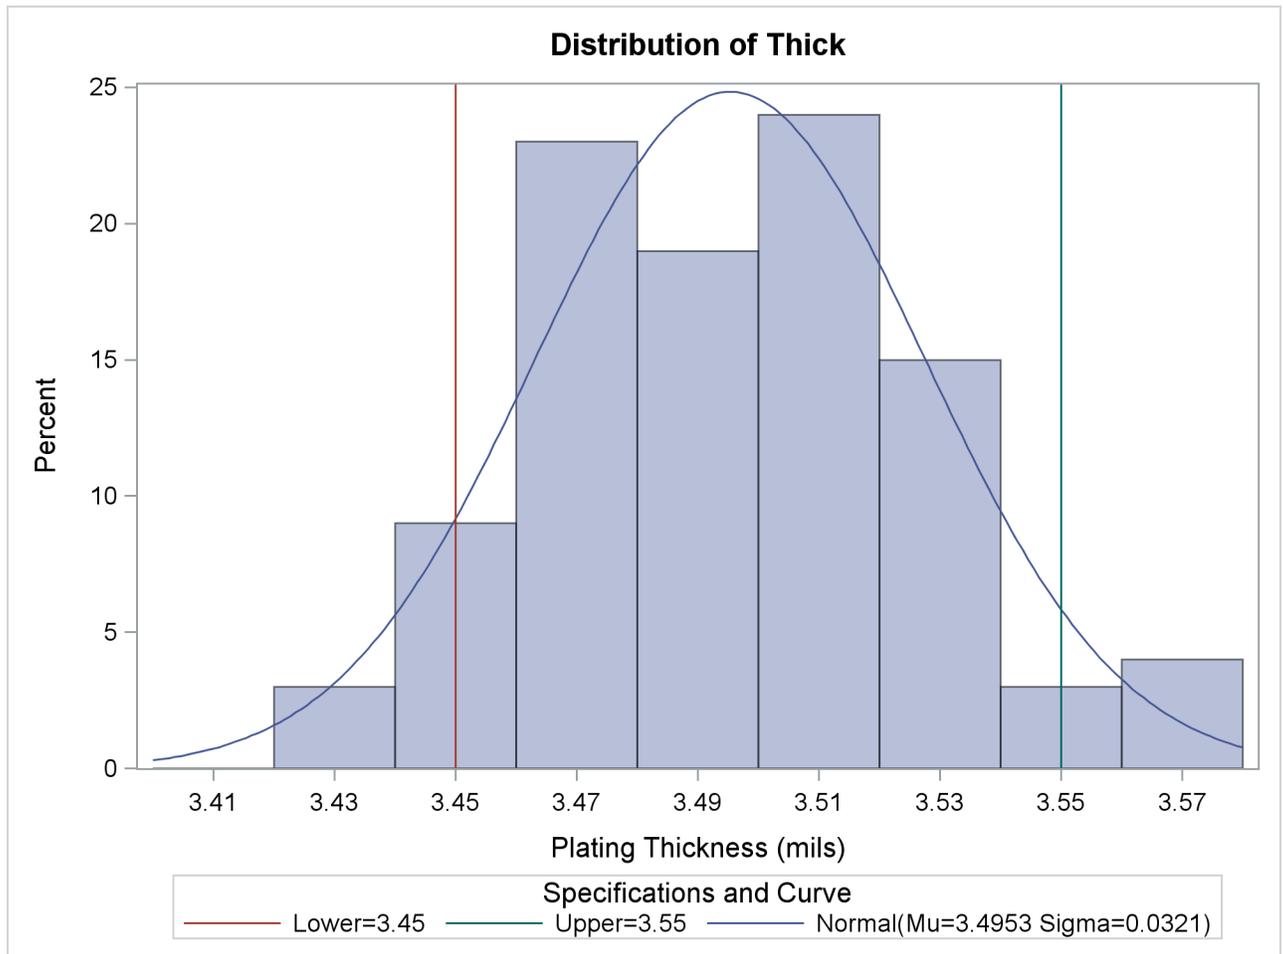

The ODS GRAPHICS ON statement specified before the PROC CAPABILITY statement enables ODS Graphics, so the histogram is created using ODS Graphics instead of traditional graphics.

The NORMAL option summarizes the fitted distribution in the printed output shown in Figure 5.9, and it specifies that the normal curve be displayed on the histogram shown in Figure 5.10.

Figure 5.9 Summary for Fitted Normal Distribution

Process Capability Analysis of Plating Thickness				
The CAPABILITY Procedure				
Fitted Normal Distribution for Thick (Plating Thickness (mils))				
Parameters for Normal Distribution				
Parameter	Symbol	Estimate		
Mean	Mu	3.49533		
Std Dev	Sigma	0.032117		
Goodness-of-Fit Tests for Normal Distribution				
Test	----Statistic----		DF	-----p Value-----
Kolmogorov-Smirnov	D	0.05563823		Pr > D >0.150
Cramer-von Mises	W-Sq	0.04307548		Pr > W-Sq >0.250
Anderson-Darling	A-Sq	0.27840748		Pr > A-Sq >0.250
Chi-Square	Chi-Sq	6.96953022	5	Pr > Chi-Sq 0.223
Percent Outside Specifications for Normal Distribution				
Lower Limit		Upper Limit		
LSL	3.450000	USL	3.550000	
Obs Pct < LSL	8.000000	Obs Pct > USL	5.000000	
Est Pct < LSL	7.906248	Est Pct > USL	4.435722	
Quantiles for Normal Distribution				
Percent	-----Quantile-----			
	Observed	Estimated		
1.0	3.42950	3.42061		
5.0	3.44300	3.44250		
10.0	3.45750	3.45417		
25.0	3.46950	3.47367		
50.0	3.49600	3.49533		
75.0	3.51650	3.51699		
90.0	3.53550	3.53649		
95.0	3.55300	3.54816		
99.0	3.57200	3.57005		

Figure 5.10 Histogram Superimposed with Normal Curve

The printed output includes the following:

- parameters for the normal curve. The normal parameters μ and σ are estimated by the sample mean ($\hat{\mu} = 3.49533$) and the sample standard deviation ($\hat{\sigma} = 0.032117$).
- goodness-of-fit tests based on the empirical distribution function (EDF): the Anderson-Darling, Cramer-von Mises, and Kolmogorov-Smirnov tests. The p -values for these tests are greater than the usual cutoff values of 0.05 and 0.10, indicating that the thicknesses are normally distributed.
- a chi-square goodness-of-fit test. The p -value of 0.223 for this test indicates that the thicknesses are normally distributed. In general EDF tests (when available) are preferable to chi-square tests. See the section “EDF Goodness-of-Fit Tests” on page 362 for details.
- observed and estimated percentages outside the specification limits
- observed and estimated quantiles

For details, including formulas for the goodness-of-fit tests, see “Printed Output” on page 359. Note that the NOPRINT option in the PROC CAPABILITY statement suppresses only the printed output

with summary statistics for the variable Thick. To suppress the printed output in [Figure 5.9](#), specify the NOPRINT option enclosed in parentheses after the NORMAL option as in “[Customizing a Histogram](#)” on page 315.

The NORMAL option is one of many options that you can specify in the HISTOGRAM statement. See the section “[Syntax: HISTOGRAM Statement](#)” on page 316 for a complete list of options or the section “[Dictionary of Options](#)” on page 325 for detailed descriptions of options.

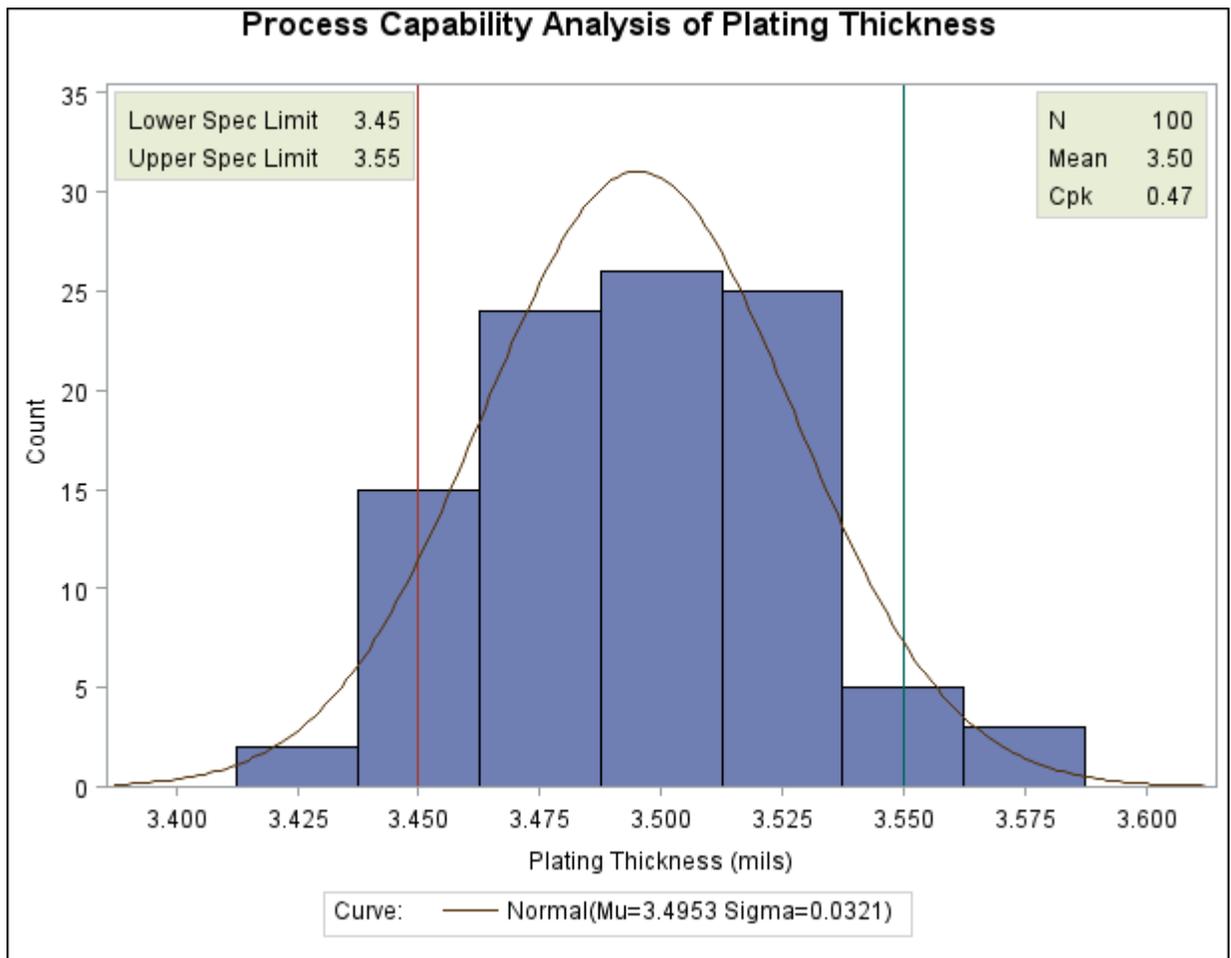

Customizing a Histogram

This example is a continuation of the preceding example. The following statements show how you can use HISTOGRAM statement options and INSET statements to customize a histogram: *See CAPHSTI in the SAS/QC Sample Library*

```
ods graphics off;
title 'Process Capability Analysis of Plating Thickness';
legend2 frame;
proc capability data=Trans noprint;
  spec lsl = 3.45 usl = 3.55;
  histogram Thick / normal
                    midpoints = 3.4 to 3.6 by 0.025
                    vscale    = count
                    legend    = legend2
                    nospeclegend ;
  inset lsl usl      / cfill = ywh;
  inset n mean (5.2) cpk (5.2) / cfill = ywh;
run;
```

The histogram is displayed in [Figure 5.11](#).

Figure 5.11 Customizing the Appearance of the Histogram

The MIDPOINTS= option specifies a list of values to use as bin midpoints. The VSCALE=COUNT option requests a vertical axis scaled in counts rather than percents. The INSET statements inset the specification limits and summary statistics. The NOSPECLEGEND option suppresses the default legend for the specification limits that is shown in Figure 5.8.

For more information about HISTOGRAM statement options, see the section “Dictionary of Options” on page 325. For details on the INSET statement, see “INSET Statement: CAPABILITY Procedure” on page 397.

Syntax: HISTOGRAM Statement

The syntax for the HISTOGRAM statement is as follows:

```
HISTOGRAM < variables > < / options > ;
```

You can specify the keyword HIST as an alias for HISTOGRAM. You can use any number of HISTOGRAM statements after a PROC CAPABILITY statement. The components of the HISTOGRAM statement are described as follows.

variables

are the process variables for which histograms are to be created. If you specify a VAR statement, the variables must also be listed in the VAR statement. Otherwise, the variables can be any numeric variables in the input data set. If you do not specify variables in a VAR statement or in the HISTOGRAM statement, then by default, a histogram is created for each numeric variable in the DATA= data set. If you use a VAR statement and do not specify any variables in the HISTOGRAM statement, then by default, a histogram is created for each variable listed in the VAR statement.

For example, suppose a data set named `steel` contains exactly two numeric variables named `length` and `width`. The following statements create two histograms, one for `length` and one for `width`:

```
proc capability data=steel;
  histogram;
run;
```

The following statements also create histograms for `length` and `width`:

```
proc capability data=steel;
  var length width;
  histogram;
run;
```

The following statements create a histogram for `length` only:

```
proc capability data=steel;
  var length width;
  histogram length;
run;
```

options

add features to the histogram. Specify all options after the slash (/) in the HISTOGRAM statement.

For example, in the following statements, the `NORMAL` option displays a fitted normal curve on the histogram, the `MIDPOINTS=` option specifies midpoints for the histogram, and the `CTEXT=` option specifies the color of the text:

```
proc capability data=steel;
  histogram length / normal
                        midpoints = 5.6 5.8 6.0 6.2 6.4
                        ctext      = yellow;
run;
```

Summary of Options

The following tables list the HISTOGRAM statement options by function. For detailed descriptions, see “Dictionary of Options” on page 325.

Parametric Density Estimation Options

Table 5.18 lists options that display a parametric density estimate on the histogram.

Table 5.18 Parametric Distribution Options

Option	Description
BETA(<i>beta-options</i>)	fits beta distribution with threshold parameter θ , scale parameter σ , and shape parameters α and β
EXPONENTIAL(<i>exponential-options</i>)	fits exponential distribution with threshold parameter θ and scale parameter σ
GAMMA(<i>gamma-options</i>)	fits gamma distribution with threshold parameter θ , scale parameter σ , and shape parameter α
GUMBEL(<i>Gumbel-options</i>)	plots Gumbel distribution with location parameter μ and scale parameter σ
IGAUSS(<i>iGauss-options</i>)	plots inverse Gaussian distribution with mean μ and shape parameter λ
LOGNORMAL(<i>lognormal-options</i>)	fits lognormal distribution with threshold parameter θ , scale parameter ζ , and shape parameter σ
NORMAL(<i>normal-options</i>)	fits normal distribution with mean μ and standard deviation σ
PARETO(<i>Pareto-options</i>)	plots Pareto distribution with threshold parameter θ , scale parameter σ , and shape parameter α
POWER(<i>power-options</i>)	plots power function distribution with threshold parameter θ , scale parameter σ , and shape parameter α
RAYLEIGH(<i>Rayleigh-options</i>)	plots Rayleigh distribution with threshold parameter θ and scale parameter σ
SB(<i>SB-options</i>)	fits Johnson S_B distribution with threshold parameter θ , scale parameter σ , and shape parameters δ and γ
SU(<i>SU-options</i>)	fits Johnson S_U distribution with location parameter θ , scale parameter σ , and shape parameters δ and γ
WEIBULL(<i>Weibull-options</i>)	fits Weibull distribution with threshold parameter θ , scale parameter σ , and shape parameter c

Table 5.19 lists secondary options that specify parameters for fitted parametric distributions and that control the display of fitted curves. Specify these secondary options in parentheses after the distri-

bution keyword. For example, the following statements fit a normal curve by using the **NORMAL** option:

```
proc capability;
  histogram / normal(color=red mu=10 sigma=0.5);
run;
```

The **COLOR=** *normal-option* draws the curve in red, and the **MU=** and **SIGMA=** *normal-options* specify the parameters $\mu = 10$ and $\sigma = 0.5$ for the curve. Note that the sample mean and sample standard deviation are used to estimate μ and σ , respectively, when the **MU=** and **SIGMA=** options are not specified.

You can specify lists of values for distribution parameters to display more than one fitted curve from the same distribution family on a histogram. Option values are matched by list position. You can specify the value *EST* in a list of distribution parameter values to use an estimate of the parameter.

For example, the following code displays two normal curves on a histogram:

```
proc capability;
  histogram / normal(color=(red blue) mu=10 est sigma=0.5 est);
run;
```

The first curve is red, with $\mu = 10$ and $\sigma = 0.5$. The second curve is blue, with μ equal to the sample mean and σ equal to the sample standard deviation.

See the section “[Formulas for Fitted Curves](#)” on page 346 for detailed information about the families of parametric distributions that you can fit with the **HISTOGRAM** statement.

Table 5.19 Distribution Options

Option	Description
Options Used with All Parametric Distributions	
COLOR=	specifies color of fitted density curve
FILL	fills area under fitted density curve
INDICES	calculates capability indices based on fitted distribution
L=	specifies line type of fitted curve
MIDPERCENTS	prints table of midpoints of histogram intervals
NOPRINT	suppresses printed output summarizing fitted curve
PERCENTS=	lists percents for which quantiles calculated from data and quantiles estimated from fitted curve are tabulated
SYMBOL=	specifies character used for fitted density curve in line printer plots
W=	specifies width of fitted density curve
Beta-Options	
ALPHA=	specifies first shape parameter α for fitted beta curve
BETA=	specifies second shape parameter β for fitted beta curve
SIGMA=	specifies scale parameter σ for fitted beta curve
THETA=	specifies lower threshold parameter θ for fitted beta curve
Exponential-Options	
SIGMA=	specifies scale parameter σ for fitted exponential curve
THETA=	specifies threshold parameter θ for fitted exponential curve

Table 5.19 (continued)

Option	Description
Gamma-Options	
ALPHA=	specifies shape parameter α for fitted gamma curve
ALPHADELTA=	specifies change in successive estimates of α at which the Newton-Raphson approximation of $\hat{\alpha}$ terminates
ALPHAINITIAL=	specifies initial value for α in Newton-Raphson approximation of $\hat{\alpha}$
MAXITER=	specifies maximum number of iterations in Newton-Raphson approximation of $\hat{\alpha}$
SIGMA=	specifies scale parameter σ for fitted gamma curve
THETA=	specifies threshold parameter θ for fitted gamma curve
Gumbel-Options	
EDFNSAMPLES=	specifies number of samples for EDF goodness-of-fit simulation
EDFSEED=	specifies seed value for EDF goodness-of-fit simulation
MU=	specifies location parameter μ for fitted Gumbel curve
SIGMA=	specifies scale parameter σ for fitted Gumbel curve
IGauss-Options	
EDFNSAMPLES=	specifies number of samples for EDF goodness-of-fit simulation
EDFSEED=	specifies seed value for EDF goodness-of-fit simulation
LAMBDA=	specifies shape parameter λ for fitted inverse Gaussian curve
MU=	specifies mean μ for fitted inverse Gaussian curve
Lognormal-Options	
SIGMA=	specifies shape parameter σ for fitted lognormal curve
THETA=	specifies threshold parameter θ for fitted lognormal curve
ZETA=	specifies scale parameter ζ for fitted lognormal curve
Normal-Options	
MU=	specifies mean μ for fitted normal curve
SIGMA=	specifies standard deviation σ for fitted normal curve
Pareto-Options	
ALPHA=	specifies shape parameter α for fitted Pareto curve
EDFNSAMPLES=	specifies number of samples for EDF goodness-of-fit simulation
EDFSEED=	specifies seed value for EDF goodness-of-fit simulation
SIGMA=	specifies scale parameter σ for fitted Pareto curve
THETA=	specifies threshold parameter θ for fitted Pareto curve
Power-Options	
ALPHA=	specifies shape parameter α for fitted power function curve
SIGMA=	specifies scale parameter σ for fitted power function curve
THETA=	specifies threshold parameter θ for fitted power function curve
Rayleigh-Options	
EDFNSAMPLES=	specifies number of samples for EDF goodness-of-fit simulation
EDFSEED=	specifies seed value for EDF goodness-of-fit simulation
SIGMA=	specifies scale parameter σ for fitted Rayleigh curve
THETA=	specifies threshold parameter θ for fitted Rayleigh curve
S_B-Options	
DELTA=	specifies first shape parameter δ for fitted S_B curve

Table 5.19 (continued)

Option	Description
FITINTERVAL=	specifies z -value for method of percentiles
FITMETHOD=	specifies method of parameter estimation
FITTOLERANCE=	specifies tolerance for method of percentiles
GAMMA=	specifies second shape parameter γ for fitted S_B curve
SIGMA=	specifies scale parameter σ for fitted S_B curve
THETA=	specifies lower threshold parameter θ for fitted S_B curve
S_U-Options	
DELTA=	specifies first shape parameter δ for fitted S_U curve
FITINTERVAL=	specifies z -value for method of percentiles
FITMETHOD=	specifies method of parameter estimation
FITTOLERANCE=	specifies tolerance for method of percentiles
GAMMA=	specifies second shape parameter γ for fitted S_U curve
SIGMA=	specifies scale parameter σ for fitted S_U curve
THETA=	specifies location parameter θ for fitted S_U curve
Weibull-Options	
C=	specifies shape parameter c for fitted Weibull curve
CDELTA=	specifies change in successive estimates of c at which the Newton-Raphson approximation of \hat{c} terminates
CINITIAL=	specifies initial value for c in Newton-Raphson approximation of \hat{c}
MAXITER=	specifies maximum number of iterations in Newton-Raphson approximation of \hat{c}
SIGMA=	specifies scale parameter σ for fitted Weibull curve
THETA=	specifies threshold parameter θ for fitted Weibull curve

Nonparametric Density Estimation Options**Table 5.20** Kernel Density Estimation Options

Option	Description
KERNEL(<i>kernel-options</i>)	fits kernel density estimates

Specify the options listed in Table 5.21 in parentheses after the keyword **KERNEL** to control features of kernel density estimates requested with the **KERNEL** option.

Table 5.21 Kernel-Options

Option	Description
C=	specifies standardized bandwidth parameter c for fitted kernel density estimate
COLOR=	specifies color of the fitted kernel density curve
FILL	fills area under fitted kernel density curve
K=	specifies type of kernel function
L=	specifies line type used for fitted kernel density curve
LOWER=	specifies lower bound for fitted kernel density curve
SYMBOL=	specifies character used for fitted kernel density curve in line printer plots
UPPER=	specifies upper bound for fitted kernel density curve
W=	specifies line width for fitted kernel density curve

General Options

Table 5.22 summarizes general options for the HISTOGRAM statement, including options for enhancing charts and producing output data sets.

Table 5.22 General HISTOGRAM Statement Options

Option	Description
Options to Create Output Data Sets	
OUTFIT=	requests information about fitted curves
OUTHISTOGRAM=	requests information about histogram intervals
OUTKERNEL=	creates a data set containing kernel density estimates
General Histogram Layout Options	
CLIPCURVES	scales vertical axis without considering fitted curves
CONTENTS=	specifies table of contents entry for histogram grouping
CURVELEGEND=	specifies LEGEND statement for curves
ENDPOINTS=	lists endpoints for histogram intervals
HANGING	constructs hanging histogram
HREF=	specifies reference lines perpendicular to the horizontal axis
HREFLABELS=	specifies labels for HREF= lines
MIDPERCENTS	prints table of histogram intervals
MIDPOINTS=	lists midpoints for histogram intervals
NENDPOINTS=	specifies number of histogram interval endpoints
NMIDPOINTS=	specifies number of histogram interval midpoints
NOBARS	suppresses histogram bars
NOCURVELEGEND	suppresses legend for curves
NOFRAME	suppresses frame around plotting area
NOLEGEND	suppresses legend
NOPLOT	suppresses plot
NOSPECLEGEND	suppresses specifications legend
NOTABCONTENTS	suppresses table of contents entries for tables produced by HISTOGRAM statement

Table 5.22 (continued)

Option	Description
RTINCLUDE	includes right endpoint in interval
SPECLEGEND=	specifies LEGEND statement for specification limits
VREF=	specifies reference lines perpendicular to the vertical axis
VREFLABELS=	specifies labels for VREF= lines
VSCALE=	specifies scale for vertical axis
Options to Enhance Graphical Output	
ANNOTATE=	specifies annotate data set
BARLABEL=	produces labels above histogram bars
BARWIDTH=	specifies width for the bars
BMCFILL=	specifies fill color for box-and-whisker plot in bottom margin
BMCFRAME=	specifies fill color bottom margin plot frame
BMCOLOR=	specifies color for bottom margin plot
BMMARGIN=	specifies height of margin for bottom margin plot
BMPLOT=	requests a plot in bottom margin of histogram
CAXIS=	specifies color for axis
CBARLINE=	specifies color for outlines of histogram bars
CFILL=	specifies color for filling under curve
CFRAME=	specifies color for frame
CGRID=	specifies color for grid lines
CHREF=	specifies colors for HREF= lines
CLIPREF	draws reference lines behind histogram bars
CLIPSPEC=	clips histogram bars at specification limits
CSTATREF=	specifies colors for STATREF= lines
CTEXT=	specifies color for text
CVREF=	specifies colors for VREF= lines
DESCRIPTION=	specifies description for plot in graphics catalog
FONT=	specifies software font for text
FRONTREF	draws reference lines in front of histogram bars
GRID	creates a grid
HAXIS=	specifies AXIS statement for horizontal axis
HEIGHT=	specifies height of text used outside framed areas
HMINOR=	specifies number of horizontal minor tick marks
HOFFSET=	specifies offset for horizontal axis
HREFLABPOS=	specifies vertical position of labels for HREF= lines
INFONT=	specifies software font for text inside framed areas
INHEIGHT=	specifies height of text inside framed areas
INTERBAR=	specifies space between histogram bars
LEGEND=	identifies LEGEND statement
LGRID=	specifies a line type for grid lines
LHREF=	specifies line styles for HREF= lines
LSTATREF=	specifies line styles for STATREF= lines
LVREF=	specifies line styles for VREF= lines
MAXNBIN=	specifies maximum number of bins to display

Table 5.22 (continued)

Option	Description
MAXSIGMAS=	limits the number of bins that display to within a specified number of standard deviations above and below mean of data in key cell
MIDPOINTS=	specifies midpoints for histogram intervals
NAME=	specifies name for plot in graphics catalog
NOHLABEL	suppresses label for horizontal axis
NOVLABEL	suppresses label for vertical axis
NOVTICK	suppresses tick marks and tick mark labels for vertical axis
PFILL=	specifies pattern for filling under curve
STATREF=	specifies reference lines at values of summary statistics
STATREFLABELS=	specifies labels for STATREF= lines
STATREFSUBCHAR=	specifies substitution character for displaying statistic values in STATREFLABELS= labels
TURNVLABELS	turns and vertically strings out characters in labels for vertical axis
VAXIS=	specifies AXIS statement or values for vertical axis
VAXISLABEL=	specifies label for vertical axis
VMINOR=	specifies number of vertical minor tick marks
VOFFSET=	specifies length of offset at upper end of vertical axis
VREFLABPOS=	specifies horizontal position of labels for VREF= lines
WAXIS=	specifies line thickness for axes and frame
WBARLINE=	specifies line thickness for bar outlines
WGRID=	specifies line thickness for grid
Options for ODS Graphics Output	
ODSFOOTNOTE=	specifies footnote displayed on histogram
ODSFOOTNOTE2=	specifies secondary footnote displayed on histogram
ODSTITLE=	specifies title displayed on histogram
ODSTITLE2=	specifies secondary title displayed on histogram
Options for Comparative Plots	
ANNOKEY	applies annotation requested in ANNOTATE= data set to key cell only
CFRAMESIDE=	specifies color for filling frame for row labels
CFRAMETOP=	specifies color for filling frame for column labels
CPROP=	specifies color for proportion of frequency bar
CTEXTSIDE=	specifies color for row labels of comparative histograms
CTEXTTOP=	specifies color for column labels of comparative histograms
INTERTILE=	specifies distance between tiles
NCOLS=	specifies number of columns in comparative histogram
NROWS=	specifies number of rows in comparative histogram
Options to Enhance Line Printer Plots	
HREFCHAR=	specifies line character for HREF= lines
VREFCHAR=	specifies line character for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of options specific to the HISTOGRAM statement. The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics, ODS Graphics output, and line printers plots, respectively. See “[Dictionary of Common Options: CAPABILITY Procedure](#)” on page 551 for detailed descriptions of options common to all the plot statements.

ALPHA=*value-list*

specifies the shape parameter α for fitted curves requested with the **BETA**, **GAMMA**, **PARETO**, and **POWER** options. Enclose the ALPHA= option in parentheses after the distribution keyword. If you do not specify a value for α , the procedure calculates a maximum likelihood estimate. See [Example 5.8](#). You can specify A= as an alias for ALPHA= if you use it as a *beta-option*. You can specify SHAPE= as an alias for ALPHA= if you use it as a *gamma-option*.

BARLABEL=COUNT | PERCENT | PROPORTION

displays labels above the histogram bars. If you specify BARLABEL=COUNT, the label shows the number of observations associated with a given bar. *Traditional Graphics* BARLABEL=PERCENT shows the percent of observations represented by that bar. If you specify BARLABEL=PROPORTION, the label displays the proportion of observations associated with the bar.

BARWIDTH=*value*

specifies the width of the histogram bars in screen percent units. *Traditional Graphics*

BETA<(beta-options)>

displays a fitted beta density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{(x-\theta)^{\alpha-1}(\sigma+\theta-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}}hv & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$ and

θ = lower threshold parameter (lower endpoint parameter)

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

β = shape parameter ($\beta > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The beta distribution is bounded below by the parameter θ and above by the value $\theta + \sigma$. You can specify θ and σ by using the THETA= and SIGMA= *beta-options*. The following statements fit a beta distribution bounded between 50 and 75 by using maximum likelihood estimates for α and β :

```
proc capability;
    histogram length / beta(theta=50 sigma=25);
run;
```

In general, the default values for THETA= and SIGMA= are 0 and 1, respectively. You can specify THETA=EST and SIGMA=EST to request maximum likelihood estimates for θ and σ .

The beta distribution has two shape parameters, α and β . If these parameters are known, you can specify their values with the ALPHA= and BETA= *beta-options*. If you do not specify values, the procedure calculates maximum likelihood estimates for α and β .

The BETA option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the BETA option. See Example 5.8. Also see “Formulas for Fitted Curves” on page 346.

BETA=value-list

B=value-list

specifies the second shape parameter β for beta density curves requested with the BETA option. Enclose the BETA= option in parentheses after the BETA option. If you do not specify a value for β , the procedure calculates a maximum likelihood estimate. See Example 5.8.

BMCFILL=color

Traditional Graphics

specifies the fill color for a box-and-whisker plot in a bottom margin requested with the BMPLOT= option. By default, the box-and-whisker plot is not filled.

BMCFRAME=color

Traditional Graphics

specifies the color for filling the frame of a bottom margin plot requested with the BMPLOT= option. By default, this area is not filled.

BMCOLOR=color

Traditional Graphics

specifies the color of a carpet plot, or the outline color of a box-and-whisker plot, in a bottom margin plot requested with the BMPLOT= option.

BMMARGIN=height

Traditional Graphics

specifies the height in screen percentage units of a bottom margin plot requested with the BMPLOT= option. By default, a bottom margin plot occupies 15 percent of the vertical display space.

BMPLOT=CARPET | DOTPLOT | SKELETAL | SCHEMATIC

Traditional Graphics

produces a carpet plot, dot plot, or box-and-whisker plot along the bottom margin of a histogram. A carpet plot or dot plot shows the distribution of individual observations along the histogram’s horizontal axis. A carpet plot represents each observation with a vertical line. A dot plot marks each observation with a symbol. A box-and-whisker plot gives a summary of the data distribution that a histogram alone does not provide. The left and right edges of the box are located at the first and third quartiles. A central vertical line is drawn at the median and a symbol is plotted inside the box at the mean. If you specify the SKELETAL keyword, a box-and-whisker plot is produced with whiskers extending to the minimum and maximum values. If you specify SCHEMATIC, a *schematic* box-and-whisker plot is produced. In a schematic box-and-whisker plot, the whiskers extend to the smallest value within the *lower*

fence and the largest value within the *upper fence*. Fences are defined in terms of the interquartile range (IQR). The lower fence is 1.5 IQR below the first quartile and the upper fence is 1.5 IQR above the third quartile. Each observation outside the fences is plotted with a symbol.

C=value-list

specifies the shape parameter c for Weibull density curves requested with the WEIBULL option. Enclose the C= option in parentheses after the WEIBULL option. If you do not specify a value for c , the procedure calculates a maximum likelihood estimate. See [Example 5.9](#). You can specify the SHAPE= option as an alias for the C= option.

C=value-list | MISE

specifies the standardized bandwidth parameter c for kernel density estimates requested with the KERNEL option. Enclose the C= option in parentheses after the KERNEL option. You can specify up to five values to request multiple estimates. You can also specify the C=MISE option, which produces the estimate with a bandwidth that minimizes the approximate mean integrated square error (MISE). For example, the following statements compute three density estimates:

```
proc capability;
  histogram length / kernel(c=0.5 1.0 mise);
run;
```

The first two estimates have standardized bandwidths of 0.5 and 1.0, respectively, and the third has a bandwidth that minimizes the approximate MISE.

You can also use the C= option with the K= option, which specifies the kernel function, to compute multiple estimates. If you specify more kernel functions than bandwidths, the last bandwidth in the list is repeated for the remaining estimates. Likewise, if you specify more bandwidths than kernel functions, the last kernel function is repeated for the remaining estimates. For example, the following statements compute three density estimates:

```
proc capability;
  histogram length / kernel(c=1 2 3 k=normal quadratic);
run;
```

The first uses a normal kernel and a bandwidth of 1, the second uses a quadratic kernel and a bandwidth of 2, and the third uses a quadratic kernel and a bandwidth of 3. See [Example 5.12](#).

If you do not specify a value for c , the bandwidth that minimizes the approximate MISE is used for all the estimates.

CBARLINE=color

specifies the color of the outline of histogram bars. This option overrides the C= option in the *Traditional Graphics* SYMBOL1 statement.

CFILL=color

specifies a color used to fill the bars of the histogram (or the area under a fitted curve if you also specify the FILL option). See the entries for the FILL and PFILL= options for additional details. See [Figure 5.11](#) and [Output 5.8.1](#). Refer to *SAS/GRAPH: Reference* for a list of colors. By default, bars are filled with an appropriate color from the ODS style. *Traditional Graphics*

CGRID=color*Traditional Graphics*

specifies the color for grid lines requested with the GRID option. By default, grid lines are the same color as the axes. If you use CGRID=, you do not need to specify the GRID option.

CLIPCURVES

scales the vertical axis without taking fitted curves into consideration. Curves that extend above the tallest histogram bar may be clipped. You can use this option to avoid compression of the histogram bars due to extremely high fitted curve peaks.

CLIPREF*Traditional Graphics*

draws reference lines requested with the HREF= and VREF= options behind the histogram bars. By default, reference lines are drawn in front of the histogram bars.

CLIPSPEC=CLIP | NOFILL*Traditional Graphics*

specifies that histogram bars are clipped at the upper and lower specification limit lines when there are no observations outside the specification limits. The bar intersecting the lower specification limit is clipped if there are no observations less than the lower limit; the bar intersecting the upper specification limit is clipped if there are no observations greater than the upper limit. If you specify CLIPSPEC=CLIP, the histogram bar is truncated at the specification limit. If you specify CLIPSPEC=NOFILL, the portion of a filled histogram bar outside the specification limit is left unfilled. Specifying CLIPSPEC=NOFILL when histogram bars are not filled has no effect.

CURVELEGEND=name | NONE

specifies the name of a LEGEND statement describing the legend for specification limits and fitted curves. Specifying CURVELEGEND=NONE suppresses the legend for fitted curves; this is equivalent to specifying the NOCURVELEGEND option.

DELTA=value-list

specifies the first shape parameter δ for Johnson S_B and Johnson S_U density curves requested with the SB and SU options. Enclose the DELTA= option in parentheses after the SB or SU option. If you do not specify a value for δ , the procedure calculates an estimate.

EDFNSAMPLES=value

specifies the number of simulation samples used to compute p -values for EDF goodness-of-fit statistics for density curves requested with the GUMBEL, IGAUSS, PARETO, and RAYLEIGH options. Enclose the EDFNSAMPLES= option in parentheses after the distribution option. The default value is 500.

EDFSEED=value

specifies an integer value used to start the pseudo-random number generator when creating simulation samples for computing EDF goodness-of-fit statistic p -values for density curves requested with the GUMBEL, IGAUSS, PARETO, and RAYLEIGH options. Enclose the EDFSEED= option in parentheses after the distribution option. By default, the procedure uses a random number seed generated from reading the time of day from the computer's clock.

ENDPOINTS**ENDPOINTS=***value-list*

specifies that histogram interval endpoints, rather than midpoints, are aligned with horizontal axis tick marks. If you specify ENDPOINTS, the number of histogram intervals is based on the number of observations by using the method of Terrell and Scott (1985). If you specify ENDPOINTS=*value-list*, the *values* must be listed in increasing order and must be evenly spaced. All observations in the input data set, as well as any specification limits, must lie between the first and last values specified. The same *value-list* is used for all variables.

EXPONENTIAL<(exponential-options)>**EXP**<(exponential-options)>

displays a fitted exponential density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{hv}{\sigma} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)\right) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The parameter θ must be less than or equal to the minimum data value. You can specify θ with the THETA= *exponential-option*. The default value for θ is zero. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . You can specify σ with the SIGMA= *exponential-option*. By default, a maximum likelihood estimate is computed for σ . For example, the following statements fit an exponential curve with $\theta = 10$ and with a maximum likelihood estimate for σ :

```
proc capability;
  histogram / exponential(theta=10 l=2 color=red);
run;
```

The curve is red and has a line type of 2. The EXPONENTIAL option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the EXPONENTIAL option. See “Formulas for Fitted Curves” on page 346.

FILL

fills areas under a parametric density curve or kernel density estimate with colors and patterns. *Traditional Graphics*
Enclose the FILL option in parentheses after a curve option or the KERNEL option, as in the *ODS Graphics*
following statements:

```
proc capability;
  histogram length / normal(fill) cfill=green pfill=solid;
run;
```

Depending on the area to be filled (outside or between the specification limits), you can specify the color and pattern with options in the SPEC statement and HISTOGRAM statement, as summarized in the following table:

Area Under Curve	Statement	Option
between specification limits	HISTOGRAM	CFILL=
	HISTOGRAM	PFILL=
left of lower specification limit	SPEC	CLEFT=
	SPEC	PLEFT=
right of upper specification limit	SPEC	CRIGHT=
	SPEC	PRIGHT=

If you do not display specification limits, the CFILL= and PFILL= options specify the color and pattern for the entire area under the curve. Solid fills are used by default if patterns are not specified. You can specify the FILL option with only one fitted curve. For an example, see [Output 5.8.1](#). Refer to *SAS/GRAPH: Reference* for a list of available patterns and colors. If you do not specify the FILL option but specify the options in the preceding table, the colors and patterns are applied to the corresponding areas under the histogram.

FRONTREF

Traditional Graphics

draws reference lines requested with the HREF= and VREF= options in front of the histogram bars. When the NOGSTYLE system option is specified, reference lines are drawn behind the histogram bars by default, and can be obscured by them.

GAMMA<(gamma-options)>

displays a fitted gamma density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{hv}{\Gamma(\alpha)\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The parameter θ for the gamma distribution must be less than the minimum data value. You can specify θ with the THETA= *gamma-option*. The default value for θ is 0. If you specify

THETA=EST, a maximum likelihood estimate is computed for θ . In addition, the gamma distribution has a shape parameter α and a scale parameter σ . You can specify these parameters with the ALPHA= and SIGMA= *gamma-options*. By default, maximum likelihood estimates are computed for α and σ . For example, the following statements fit a gamma curve with $\theta = 4$ and with maximum likelihood estimates for α and σ :

```
proc capability;
  histogram length / gamma(theta=4);
run;
```

Note that the maximum likelihood estimate of α is calculated iteratively using the Newton-Raphson approximation. The ALPHADELTA=, ALPHAINITIAL=, and MAXITER= *gamma-options* control the approximation.

The GAMMA option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the GAMMA option. See Example 5.9 and “Formulas for Fitted Curves” on page 346.

GAMMA=*value-list*

specifies the second shape parameter γ for Johnson S_B and Johnson S_U density curves requested with the SB and SU options. Enclose the GAMMA= option in parentheses after the SB or SU option. If you do not specify a value for γ , the procedure calculates an estimate.

GRID

adds a grid to the histogram. Grid lines are horizontal lines positioned at major tick marks on the vertical axis. *Traditional Graphics*
ODS Graphics

GUMBEL< (*Gumbel-options*) >

displays a fitted Gumbel (also known as Type 1 extreme value distribution) density curve on the histogram. The curve equation is

$$p(x) = \frac{hv}{\sigma} e^{-(x-\mu)/\sigma} \exp\left(-e^{-(x-\mu)/\sigma}\right)$$

where

μ = location parameter

σ = scale parameter ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

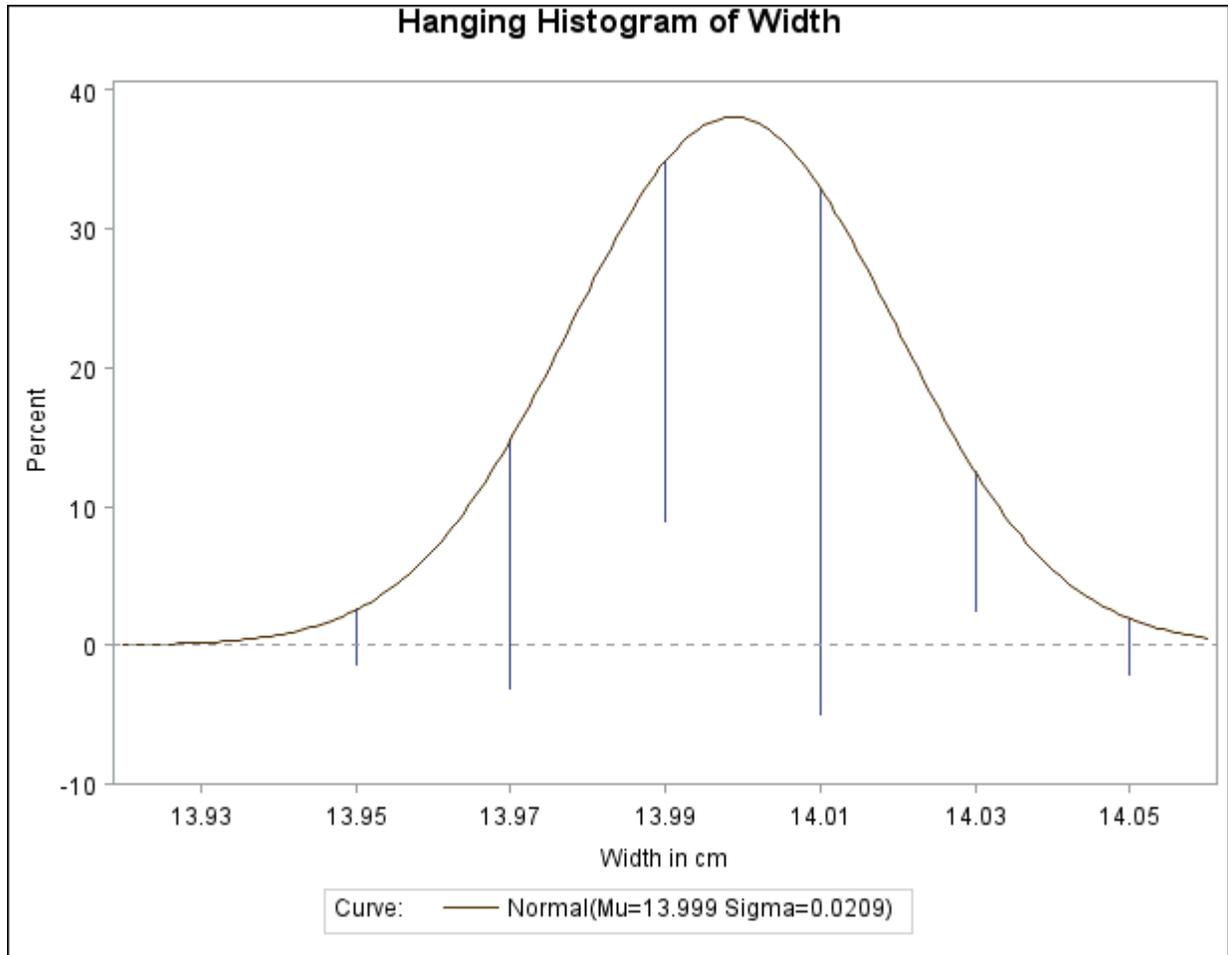

You can specify values for μ and σ with the MU= and SIGMA= *Gumbel-options*. By default, maximum likelihood estimates are computed for μ and σ .

The GUMBEL option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the GUMBEL option. See “Formulas for Fitted Curves” on page 346.

HANGING**HANG**

requests a hanging histogram, as illustrated in Figure 5.12.

Figure 5.12 Hanging Histogram

You can use the **HANGING** option with only one fitted density curve. A hanging histogram aligns the tops of the histogram bars (displayed as lines) with the fitted curve. The lines are positioned at the midpoints of the histogram bins. A hanging histogram is a goodness-of-fit diagnostic in the sense that the closer the lines are to the horizontal axis, the better the fit. Hanging histograms are discussed by Tukey (1977), Wainer (1974), and Velleman and Hoaglin (1981).

HOFFSET=value

Traditional Graphics

specifies the offset in percent screen units at both ends of the horizontal axis. Specify **HOFFSET=0** to eliminate the default offset.

IGAUSS<(iGauss-options)>

displays a fitted inverse Gaussian density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} hv \left(\frac{\lambda}{2\pi x^3} \right)^{1/2} \exp\left(-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right) & \text{for } x > 0 \\ 0 & \text{for } x \leq 0 \end{cases}$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function, and

μ = mean parameter ($\mu > 0$)

λ = shape parameter ($\lambda > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

You can specify values for μ and λ with the **MU=** and **LAMBDA=** *iGauss-options*. By default, the sample mean is used for μ and a maximum likelihood estimate is computed for λ .

The IGAUSS option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the IGAUSS option. See “Formulas for Fitted Curves” on page 346.

INDICES

requests capability indices based on the fitted distribution. Enclose the keyword INDICES in parentheses after the distribution keyword. See “Indices Using Fitted Curves” on page 365 for computational details and see Output 5.11.2.

INTERBAR=*value*

specifies the horizontal space in percent screen units between histogram bars. By default, the *Traditional Graphics* bars are contiguous.

K=NORMAL | QUADRATIC | TRIANGULAR

specifies the kernel function (normal, quadratic, or triangular) used to compute a kernel density estimate. Enclose the K= option in parentheses after the KERNEL option, as in the following statements:

```
proc capability;
  histogram length / kernel(k=quadratic);
run;
```

You can specify kernel functions for up to five estimates. You can also use the K= option together with the C= option, which specifies standardized bandwidths. If you specify more kernel functions than bandwidths, the last bandwidth in the list is repeated for the remaining estimates. Likewise, if you specify more bandwidths than kernel functions, the last kernel function is repeated for the remaining estimates. For example, the following statements compute three estimates with bandwidths of 0.5, 1.0, and 1.5:

```
proc capability;
  histogram length / kernel(c=0.5 1.0 1.5 k=normal quadratic);
run;
```

The first estimate uses a normal kernel, and the last two estimates use a quadratic kernel. By default, a normal kernel is used.

KERNEL< (*kernel-options*) >

superimposes up to five kernel density estimates on the histogram. You can specify the *kernel-options* described in the following table:

Option	Description
C=	specifies the smoothing parameter
COLOR=	specifies the color of the curve
FILL	specifies that the area under the curve is to be filled
K=	specifies the type of kernel function
L=	specifies the line style for the curve
LOWER=	specifies the lower bound for the curve
SYMBOL=	specifies the character used for the kernel density curve in line printer plots
UPPER=	specifies the upper bound for the curve
W=	specifies the width of the curve

You can request multiple kernel density estimates on the same histogram by specifying a list of values for either the C= or K= option. For more information, see the entries for these options. Also see [Output 5.6.1](#) and “Kernel Density Estimates” on page 358. By default, kernel density estimates are computed using the AMISE method.

LAMBDA=*value*

specifies the shape parameter λ for fitted curves requested with the IGAUSS option. Enclose the LAMBDA= option in parentheses after the IGAUSS distribution keyword. If you do not specify a value for λ , the procedure calculates a maximum likelihood estimate.

LEGEND=*name* | NONE

Traditional Graphics

specifies the name of a LEGEND statement describing the legend for specification limit reference lines and fitted curves. Specifying LEGEND=NONE suppresses all legend information and is equivalent to specifying the NOLEGEND option.

LGRID=*n*

Traditional Graphics

specifies the line type for the grid requested with the GRID option. If you use the LGRID= option, you do not need to specify the GRID option. The default is 1, which produces a solid line.

LOGNORMAL< (*lognormal-options*) >

displays a fitted lognormal density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{hv}{\sigma\sqrt{2\pi}(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\zeta)^2}{2\sigma^2}\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

ζ = scale parameter

σ = shape parameter ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

Note that the lognormal distribution is also referred to as the S_L distribution in the Johnson system of distributions.

The parameter θ for the lognormal distribution must be less than the minimum data value. You can specify θ with the THETA= *lognormal-option*. The default value for θ is zero. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . You can specify the parameters σ and ζ with the SIGMA= and ZETA= *lognormal-options*. By default, maximum likelihood estimates are computed for σ and ζ . For example, the following statements fit a lognormal distribution function with a default value of $\theta = 0$ and with maximum likelihood estimates for σ and ζ :

```
proc capability;
  histogram length / lognormal;
run;
```

The LOGNORMAL option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options that you can specify with the LOGNORMAL option. See Example 5.9 and “Formulas for Fitted Curves” on page 346.

LOWER=*value-list*

specifies lower bounds for kernel density estimates requested with the KERNEL option. Enclose the LOWER= option in parentheses after the KERNEL option. You can specify up to five lower bounds for multiple kernel density estimates. If you specify more kernel estimates than lower bounds, the last lower bound is repeated for the remaining estimates.

MAXNBIN=*n*

specifies the maximum number of bins to be displayed in a comparative histogram. This option is useful in situations where the scales or ranges of the data distributions differ greatly from cell to cell. By default, the bin size and midpoints are determined for the key cell, and then the midpoint list is extended to accommodate the data ranges for the remaining cells. However, if the cell scales differ considerably, the resulting number of bins may be so great that each cell histogram is scaled into a narrow region. By limiting the number of bins with the MAXNBIN= option, you can narrow the window about the data distribution in the key cell. Note that the MAXNBIN= option provides an alternative to the MAXSIGMAS= option.

MAXSIGMAS=*value*

limits the number of bins to be displayed to a range of *value* standard deviations (of the data in the key cell) above and below the mean of the data in the key cell. This option is useful in situations where the scales or ranges of the data distributions differ greatly from cell to cell. By default, the bin size and midpoints are determined for the key cell, and then the midpoint list is extended to accommodate the data ranges for the remaining cells. If the cell scales differ considerably, however, the resulting number of bins may be so great that each cell histogram is scaled into a narrow region. By limiting the number of bins with the MAXSIGMAS= option, you narrow the window about the data distribution in the key cell. Note that the MAXSIGMAS= option provides an alternative to the MAXNBIN= option.

MIDPERCENTS

requests a table listing the midpoints and percent of observations in each histogram interval. For example, the following statements create the table in Figure 5.13:

```
proc capability;
  histogram Length / midpercents;
run;
```

Figure 5.13 Table of Midpoints and Observed Percentages

The CAPABILITY Procedure		
Histogram Bins for Length		
Bin Midpoint	Observed Percent	
10.02	12.000	
10.08	32.000	
10.14	28.000	
10.20	18.000	
10.26	6.000	
10.32	4.000	

If you specify the MIDPERCENTS option in parentheses after a density estimate option, a table listing the midpoints, observed percent of observations, and the estimated percent of the population in each interval (estimated from the fitted distribution) is printed.

The following statements create the table shown in Figure 5.14:

```
proc capability;
  histogram Length / gamma(theta=3 midpercents);
run;
```

Figure 5.14 Table of Observed and Expected Percentages

The CAPABILITY Procedure			
Fitted Gamma Distribution for Length (Attachment Point Offset in mm)			
Histogram Bin Percents for Gamma Distribution			
Bin Midpoint	-----Percent-----		
	Observed	Estimated	
10.02	12.000	11.480	
10.08	32.000	26.182	
10.14	28.000	31.354	
10.20	18.000	19.916	
10.26	6.000	6.766	
10.32	4.000	1.238	

MIDPOINTS=*value-list* | **KEY** | **UNIFORM**

specifies how to determine the midpoints for the histogram intervals, where *values-list* determines the width of the histogram bars as the difference between consecutive midpoints. The procedure uses the same values for all variables. See [Output 5.9.1](#).

The range of midpoints, extended at each end by half of the bar width, must cover the range of the data as well as any specification limits. For example, if you specify

```
midpoints=2 to 10 by 0.5
```

then all of the observations and specification limits should fall between 1.75 and 10.25. (Otherwise, a default list of midpoints is used.) You must use evenly spaced midpoints listed in increasing order.

KEY determines the midpoints for the data in the key cell. The initial number of midpoints is based on the number of observations in the key cell that use the method of Terrell and Scott (1985). The procedure extends the midpoint list for the key cell in either direction as necessary until it spans the data in the remaining cells.

UNIFORM determines the midpoints by using all the observations as if there were no cells. In other words, the number of midpoints is based on the total sample size by using the method of Terrell and Scott (1985).

Neither **KEY** nor **UNIFORM** apply unless you use the **CLASS** statement. By default, if you use a **CLASS** statement, **MIDPOINTS=KEY**. However, if the key cell is empty then **MIDPOINTS=UNIFORM**. Otherwise, the procedure computes the midpoints by using the algorithm described in Terrell and Scott (1985). The default midpoints are primarily applicable to continuous data that are approximately normally distributed.

If you produce traditional graphics and use the **MIDPOINTS=** and **HAXIS=** options, you can use the **ORDER=** option in the **AXIS** statement you specified with the **HAXIS=** option. However, for the tick mark labels to coincide with the histogram interval midpoints, the range of the **ORDER=** list must encompass the range of the **MIDPOINTS=** list, as illustrated in the following statements:

```
proc capability;
  histogram length / midpoints=20 to 80 by 10
                    haxis=axis1;
  axis1 length=6 in order=10 20 30 40 50 60 70 80 90;
run;
```

MIDPTAXIS=*name*

is an alias for the **HAXIS=** option described earlier in this section.

Traditional Graphics

MU=*value-list*

specifies the parameter μ for fitted curves requested with the **GUMBEL**, **IGAUSS**, and **NORMAL** options. Enclose the **MU=** option in parentheses after the distribution keyword. For the normal and inverse Gaussian distributions, the default value of μ is the sample mean. If you do not specify a value for μ for the Gumbel distribution, the procedure calculates a maximum likelihood estimate.

NENDPOINTS=*n*

specifies the number of histogram interval endpoints and causes the endpoints, rather than interval midpoints, to be aligned with horizontal axis tick marks.

NMIDPOINTS=*n*

specifies the number of histogram intervals.

NOBARS

suppresses drawing of histogram bars. This option is useful when you want to display fitted curves only.

NOCURVELEGEND**NOCURVEL**

suppresses the portion of the legend for fitted curves. If you use the INSET statement to display information about the fitted curve on the histogram, you can use the NOCURVELEGEND option to prevent the information about the fitted curve from being repeated in a legend at the bottom of the histogram. See [Output 5.15.1](#).

NOLEGEND

suppresses legends for specification limits, fitted curves, distribution lines, and hidden observations. See [Example 5.13](#). Specifying the NOLEGEND option is equivalent to specifying LEGEND=NONE.

NO PLOT

suppresses the creation of a plot. Use the NO PLOT option when you want only to print summary statistics for a fitted density or create either an OUTFIT= or an OUTHISTOGRAM= data set. See [Example 5.11](#).

NO PRINT

suppresses printed output summarizing the fitted curve. Enclose the NO PRINT option in parentheses following the distribution option. See “[Customizing a Histogram](#)” on page 315 for an example.

NORMAL<(normal-options)>

displays a fitted normal density curve on the histogram. The curve equation is

$$p(x) = \frac{hv}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right) \quad \text{for } -\infty < x < \infty$$

where

μ = mean

σ = standard deviation ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

Note that the normal distribution is also referred to as the S_N distribution in the Johnson system of distributions.

You can specify values for μ and σ with the MU= and SIGMA= *normal-options*, as shown in the following statements:

```
proc capability;
  histogram length / normal(mu=14 sigma=0.05);
run;
```

By default, the sample mean and sample standard deviation are used for μ and σ . The NORMAL option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options that you can specify with the NORMAL option. See Figure 5.10 and “Formulas for Fitted Curves” on page 346.

NOSPECLEGEND

NOSPECL

suppresses the portion of the legend for specification limit reference lines. See Figure 5.11.

NOTABCONTENTS

suppresses the table of contents entries for tables produced by the HISTOGRAM statement. See the section “ODS Tables” on page 371 for descriptions of the tables produced by the HISTOGRAM statement.

OUTFIT=SAS-data-set

creates a SAS data set that contains parameter estimates for fitted curves and related goodness-of-fit information. See “Output Data Sets” on page 367.

OUTHISTOGRAM=SAS-data-set

OUTHIST=SAS-data-set

creates a SAS data set that contains information about histogram intervals. Specifically, the data set contains the midpoints of the histogram intervals, the observed percent of observations in each interval, and the estimated percent of observations in each interval (estimated from each of the specified fitted curves). See “Output Data Sets” on page 367.

OUTKERNEL=SAS-data-set

creates a SAS data set containing information about kernel density estimates requested with the KERNEL option. See “OUTKERNEL= Output Data Set” on page 370 for details.

PARETO<(Pareto-options)>

displays a fitted generalized Pareto density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{hv}{\sigma} (1 - \alpha(x - \theta)/\sigma)^{1/\alpha-1} & \text{if } \alpha \neq 0 \\ \frac{hv}{\sigma} \exp(-(x - \theta)/\sigma) & \text{if } \alpha = 0 \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter

h = width of histogram interval

v = vertical scaling factor
and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The parameter θ must be less than the minimum data value. You can specify θ with the **THETA=** *Pareto-option*. The default value for θ is zero. If you specify **THETA=EST**, a maximum likelihood estimate is computed for θ . In addition, the generalized Pareto distribution has a shape parameter α and a scale parameter σ . You can specify these parameters with the **ALPHA=** and **SIGMA=** *Pareto-options*. By default, maximum likelihood estimates are computed for α and σ .

The **PARETO** option can appear only once in a **HISTOGRAM** statement. Table 5.19 lists secondary options you can specify with the **PARETO** option. See “Formulas for Fitted Curves” on page 346.

PCTAXIS=*name|value-list*
is an alias for the **VAXIS=** option.

PERCENTS=*value-list*

PERCENT=*value-list*

specifies a list of percents for which quantiles calculated from the data and quantiles estimated from the fitted curve are tabulated. The percents must be between 0 and 100. Enclose the **PERCENTS=** option in parentheses after the curve option. The default percents are 1, 5, 10, 25, 50, 75, 90, 95, and 99.

For example, the following statements create the table shown in Figure 5.15:

```
proc capability;
  histogram Length / lognormal (percent=1 3 5 95 97 99);
run;
```

Figure 5.15 Estimated and Observed Quantiles for the Lognormal Curve

The CAPABILITY Procedure		
Fitted Lognormal Distribution for Length (Attachment Point Offset in mm)		
Quantiles for Lognormal Distribution		
Percent	-----Quantile-----	
	Observed	Estimated
1.0	10.0180	9.95696
3.0	10.0180	9.98937
5.0	10.0310	10.00658
95.0	10.2780	10.24963
97.0	10.2930	10.26729
99.0	10.3220	10.30071

PFILL=pattern

specifies a pattern used to fill the bars of the histograms (or the areas under a fitted curve *Traditional Graphics* if you also specify the FILL option). See the entries for the CFILL= and FILL options for additional details. Refer to *SAS/GRAPH: Reference* for a list of pattern values. By default, the bars and curve areas are not filled.

POWER<(power-options)>

displays a fitted power function density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} hv \frac{\alpha}{\sigma} \left(\frac{x-\theta}{\sigma} \right)^{\alpha-1} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The parameter θ must be less than or equal to the minimum data value. You can specify θ and σ with the **THETA=** and the **SIGMA=power-options**. The default values for θ and σ are 0 and 1, respectively. You can specify **THETA=EST** and **SIGMA=EST** to request maximum likelihood estimates for θ and σ .

In addition, the generalized Pareto distribution has a shape parameter α . You can specify α with the **ALPHA=power-option**. By default, a maximum likelihood estimate is computed for α .

The POWER option can appear only once in a HISTOGRAM statement. [Table 5.19](#) lists secondary options you can specify with the POWER option. See “[Formulas for Fitted Curves](#)” on page 346.

RAYLEIGH<(Rayleigh-options)>

displays a fitted Rayleigh density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} hv \frac{x-\theta}{\sigma^2} e^{-(x-\theta)^2/(2\sigma^2)} & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The parameter θ must be less than or equal to the minimum data value. You can specify θ with the THETA= *Rayleigh-option*. The default value for θ is zero. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . You can specify σ with the SIGMA= *Rayleigh-option*. By default, a maximum likelihood estimate is computed for σ .

The RAYLEIGH option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the RAYLEIGH option. See “Formulas for Fitted Curves” on page 346.

RTINCLUDE

includes the right endpoint of each histogram interval in that interval. By default, the left endpoint is included in the histogram interval.

SB<(S_B-options)>

displays a fitted Johnson S_B density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{\delta h v}{\sigma \sqrt{2\pi}} \left[\left(\frac{x-\theta}{\sigma} \right) \left(1 - \frac{x-\theta}{\sigma} \right) \right]^{-1} \times \\ \exp \left[-\frac{1}{2} \left(\gamma + \delta \log \left(\frac{x-\theta}{\theta+\sigma-x} \right) \right)^2 \right] & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where

θ = threshold parameter ($-\infty < \theta < \infty$)

σ = scale parameter ($\sigma > 0$)

δ = shape parameter ($\delta > 0$)

γ = shape parameter ($-\infty < \gamma < \infty$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The S_B distribution is bounded below by the parameter θ and above by the value $\theta + \sigma$. The parameter θ must be less than the minimum data value. You can specify θ with the THETA= S_B-option, or you can request that θ be estimated with the THETA = EST S_B-option. The default value for θ is zero. The sum $\theta + \sigma$ must be greater than the maximum data value. The default value for σ is one. You can specify σ with the SIGMA= S_B-option, or you can request that σ be estimated with the SIGMA = EST S_B-option. You can specify δ with the DELTA= S_B-option, and you can specify γ with the GAMMA= S_B-option. Note that the S_B-options are given in parentheses after the SB option.

By default, the method of percentiles is used to estimate the parameters of the S_B distribution. Alternatively, you can request the method of moments or the method of maximum likelihood with the FITMETHOD = MOMENTS or FITMETHOD = MLE options, respectively. Consider the following example:

```

proc capability;
  histogram length / sb;
  histogram length / sb( theta=est sigma=est );
  histogram length / sb( theta=0.5 sigma=8.4
                        delta=0.8 gamma=-0.6 );
run;

```

The first HISTOGRAM statement fits an S_B distribution with default values of $\theta = 0$ and $\sigma = 1$ and with percentile-based estimates for δ and γ . The second HISTOGRAM statement estimates all four parameters with the method of percentiles. The third HISTOGRAM statement displays an S_B curve with specified values for all four parameters.

The SB option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the SB option.

SIGMA=*value-list*

specifies the parameter σ for fitted curves requested with the BETA, EXPONENTIAL, GAMMA, GUMBEL, LOGNORMAL, NORMAL, PARETO, POWER, RAYLEIGH, SB, SU, and WEIBULL options. Enclose the SIGMA= option in parentheses after the distribution keyword. The following table summarizes the use of the SIGMA= option.

Distribution Keyword	SIGMA= Specifies	Default Value	Alias
BETA	scale parameter σ	1	SCALE=
EXPONENTIAL	scale parameter σ	maximum likelihood estimate	SCALE=
GAMMA	scale parameter σ	maximum likelihood estimate	SCALE=
GUMBEL	scale parameter σ	maximum likelihood estimate	
LOGNORMAL	shape parameter σ	maximum likelihood estimate	SHAPE=
NORMAL	scale parameter σ	standard deviation	
PARETO	scale parameter σ	maximum likelihood estimate	
POWER	scale parameter σ	1	SCALE=
RAYLEIGH	scale parameter σ	maximum likelihood estimate	
SB	scale parameter σ	1	SCALE=
SU	scale parameter σ	percentile-based estimate	SCALE=
WEIBULL	scale parameter σ	maximum likelihood estimate	SCALE=

If you specify SIGMA=EST, an estimate is computed for σ . For syntax examples, see the entries for the distribution options.

SPECLEGEND=*name* | **NONE**

specifies the name of a LEGEND statement describing the legend for specification limits and fitted curves. Specifying SPECLEGEND=NONE, which suppresses the portion of the legend for specification limit references lines, is equivalent to specifying the NOSPECLEGEND option.

SU<(*SU*-options)>

displays a fitted Johnson S_U density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{\delta h v}{\sigma \sqrt{2\pi}} \frac{1}{\sqrt{1 + ((x-\theta)/\sigma)^2}} \times \\ \exp \left[-\frac{1}{2} \left(\gamma + \delta \sinh^{-1} \left(\frac{x-\theta}{\sigma} \right) \right)^2 \right] & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = location parameter ($-\infty < \theta < \infty$)

σ = scale parameter ($\sigma > 0$)

δ = shape parameter ($\delta > 0$)

γ = shape parameter ($-\infty < \gamma < \infty$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

You can specify the parameters with the THETA=, SIGMA=, DELTA=, and GAMMA= S_U -options, which are enclosed in parentheses after the SU option. If you do not specify these parameters, they are estimated.

By default, the method of percentiles is used to estimate the parameters of the S_U distribution. Alternatively, you can request the method of moments or the method of maximum likelihood with the FITMETHOD = MOMENTS or FITMETHOD = MLE options, respectively. Consider the following example:

```
proc capability;
  histogram length / su;
  histogram length / su( theta=0.5 sigma=8.4
                        delta=0.8 gamma=-0.6 );
run;
```

The first HISTOGRAM statement estimates all four parameters with the method of percentiles. The second HISTOGRAM statement displays an S_U curve with specified values for all four parameters.

The SU option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options you can specify with the SU option.

SYMBOL='character'

Line Printer

specifies the *character* used for the density curve or kernel density curve in line printer plots. Enclose the SYMBOL= option in parentheses after the distribution option or the KERNEL option. The default character is the first letter of the distribution keyword or '1' for the first kernel density estimate, '2' for the second kernel density estimate, and so on. If you use the SYMBOL= option with the KERNEL option, you can specify a list of up to five characters in parentheses for multiple kernel density estimates. If there are more estimates than characters, the last character specified is used for the remaining estimates.

THETA=*value-list*

THRESHOLD=*value-list*

specifies the lower threshold parameter θ for curves requested with the **BETA**, **EXPONENTIAL**, **GAMMA**, **LOGNORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, **SB**, and **WEIBULL** options, and the location parameter θ for curves requested with the **SU** option. Enclose the **THETA=** option in parentheses after the curve option. See [Example 5.8](#). The default *value* is zero. If you specify **THETA=EST**, an estimate is computed for θ .

UPPER=*value-list*

specifies upper bounds for kernel density estimates requested with the **KERNEL** option. Enclose the **UPPER=** option in parentheses after the **KERNEL** option. You can specify up to five upper bounds for multiple kernel density estimates. If you specify more kernel estimates than upper bounds, the last upper bound is repeated for the remaining estimates.

VOFFSET=*value*

specifies the offset in percent screen units at the upper end of the vertical axis.

Traditional Graphics

VSCALE=**COUNT** | **PERCENT** | **PROPORTION**

specifies the scale of the vertical axis. The value **COUNT** scales the data in units of the number of observations per data unit. The value **PERCENT** scales the data in units of percent of observations per data unit. The value **PROPORTION** scales the data in units of proportion of observations per data unit. See [Figure 5.11](#) for an illustration of **VSCALE=COUNT**. The default is **PERCENT**.

WBARLINE=*n*

specifies the width of bar outlines. By default, $n = 1$.

Traditional Graphics

WEIBULL< (*Weibull-options*) >

displays a fitted Weibull density curve on the histogram. The curve equation is

$$p(x) = \begin{cases} \frac{chv}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

c = shape parameter ($c > 0$)

h = width of histogram interval

v = vertical scaling factor

and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The parameter θ must be less than the minimum data value. You can specify θ with the **THETA=** *Weibull-option*. The default value for θ is zero. If you specify **THETA=EST**, a maximum likelihood estimate is computed for θ . You can specify σ and c with the **SIGMA=** and **C=** *Weibull-options*. By default, maximum likelihood estimates are computed for c and σ . For example, the following statements fit a Weibull distribution with $\theta = 15$ and with maximum likelihood estimates for σ and c :

```
proc capability;
  histogram length / weibull(theta=15);
run;
```

Note that the maximum likelihood estimate of c is calculated iteratively using the Newton-Raphson approximation. The CDELTA=, CINITIAL=, and MAXITER= *Weibull-options* control the approximation.

The WEIBULL option can appear only once in a HISTOGRAM statement. Table 5.19 lists secondary options that you can specify with the WEIBULL option. See Example 5.9 and “Formulas for Fitted Curves” on page 346.

WGRID= n

Traditional Graphics

specifies the width of the grid lines requested with the GRID option. By default, grid lines are the same width as the axes. If you use the WGRID= option, you do not need to specify the GRID option.

ZETA= $value-list$

specifies a value for the scale parameter ζ for lognormal density curves requested with the LOGNORMAL option. Enclose the ZETA= option in parentheses after the LOGNORMAL option. By default, the procedure calculates a maximum likelihood estimate for ζ . You can specify the SCALE= option as an alias for the ZETA= option.

Details: HISTOGRAM Statement

This section provides details on the following topics:

- formulas for fitted distributions
- formulas for kernel density estimates
- printed output
- OUTFIT=, OUTHISTOGRAM=, and OUTKERNEL= data sets
- graphical enhancements to histograms

Formulas for Fitted Curves

The following sections provide information about the families of parametric distributions that you can fit with the HISTOGRAM statement. Properties of these distributions are discussed by Johnson, Kotz, and Balakrishnan (1994) and Johnson, Kotz, and Balakrishnan (1995).

Beta Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{(x-\theta)^{\alpha-1}(\sigma+\theta-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}}hv & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$ and

θ = lower threshold parameter (lower endpoint parameter)

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

β = shape parameter ($\beta > 0$)

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

NOTE: This notation is consistent with that of other distributions that you can fit with the HISTOGRAM statement. However, many texts, including Johnson, Kotz, and Balakrishnan (1995), write the beta density function as

$$p(x) = \begin{cases} \frac{(x-a)^{p-1}(b-x)^{q-1}}{B(p,q)(b-a)^{p+q-1}} & \text{for } a < x < b \\ 0 & \text{for } x \leq a \text{ or } x \geq b \end{cases}$$

The two notations are related as follows:

$$\sigma = b - a$$

$$\theta = a$$

$$\alpha = p$$

$$\beta = q$$

The range of the beta distribution is bounded below by a threshold parameter $\theta = a$ and above by $\theta + \sigma = b$. If you specify a fitted beta curve by using the BETA option, θ must be less than the minimum data value, and $\theta + \sigma$ must be greater than the maximum data value. You can specify θ and σ with the THETA= and SIGMA= *beta-options* in parentheses after the keyword BETA. By default, $\sigma = 1$ and $\theta = 0$. If you specify THETA=EST and SIGMA=EST, maximum likelihood estimates are computed for θ and σ .

In addition, you can specify α and β with the ALPHA= and BETA= *beta-options*, respectively. By default, the procedure calculates maximum likelihood estimates for α and β . For example, to fit a beta density curve to a set of data bounded below by 32 and above by 212 with maximum likelihood estimates for α and β , use the following statement:

```
histogram length / beta(theta=32 sigma=180);
```

The beta distributions are also referred to as Pearson Type I or II distributions. These include the *power-function* distribution ($\beta = 1$), the *arc-sine* distribution ($\alpha = \beta = \frac{1}{2}$), and the *generalized arc-sine* distributions ($\alpha + \beta = 1$, $\beta \neq \frac{1}{2}$).

You can use the DATA step function BETAINV to compute beta quantiles and the DATA step function PROBBETA to compute beta probabilities.

Exponential Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{hv}{\sigma} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)\right) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The threshold parameter θ must be less than or equal to the minimum data value. You can specify θ with the THRESHOLD= *exponential-option*. By default, $\theta = 0$. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . In addition, you can specify σ with the SCALE= *exponential-option*. By default, the procedure calculates a maximum likelihood estimate for σ . Note that some authors define the scale parameter as $\frac{1}{\sigma}$.

The exponential distribution is a special case of both the gamma distribution (with $\alpha = 1$) and the Weibull distribution (with $c = 1$). A related distribution is the *extreme value* distribution. If $Y = \exp(-X)$ has an exponential distribution, then X has an extreme value distribution.

Gamma Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{hv}{\Gamma(\alpha)\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

h = width of histogram interval
 v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The threshold parameter θ must be less than the minimum data value. You can specify θ with the THRESHOLD= *gamma-option*. By default, $\theta = 0$. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . In addition, you can specify σ and α with the SCALE= and ALPHA= *gamma-options*. By default, the procedure calculates maximum likelihood estimates for σ and α .

The gamma distributions are also referred to as Pearson Type III distributions, and they include the chi-square, exponential, and Erlang distributions. The probability density function for the chi-square distribution is

$$p(x) = \begin{cases} \frac{1}{2\Gamma(\frac{\nu}{2})} \left(\frac{x}{2}\right)^{\frac{\nu}{2}-1} \exp(-\frac{x}{2}) & \text{for } x > 0 \\ 0 & \text{for } x \leq 0 \end{cases}$$

Notice that this is a gamma distribution with $\alpha = \frac{\nu}{2}$, $\sigma = 2$, and $\theta = 0$. The exponential distribution is a gamma distribution with $\alpha = 1$, and the Erlang distribution is a gamma distribution with α being a positive integer. A related distribution is the Rayleigh distribution. If $R = \frac{\max(X_1, \dots, X_n)}{\min(X_1, \dots, X_n)}$ where the X_i 's are independent χ_ν^2 variables, then $\log R$ is distributed with a χ_ν distribution having a probability density function of

$$p(x) = \begin{cases} \left[2^{\frac{\nu}{2}-1} \Gamma(\frac{\nu}{2})\right]^{-1} x^{\nu-1} \exp(-\frac{x^2}{2}) & \text{for } x > 0 \\ 0 & \text{for } x \leq 0 \end{cases}$$

If $\nu = 2$, the preceding distribution is referred to as the Rayleigh distribution.

You can use the DATA step function GAMINV to compute gamma quantiles and the DATA step function PROBGAM to compute gamma probabilities.

Gumbel Distribution

The fitted density function is

$$p(x) = \frac{hv}{\sigma} e^{-(x-\mu)/\sigma} \exp\left(-e^{-(x-\mu)/\sigma}\right)$$

where

μ = location parameter
 σ = scale parameter ($\sigma > 0$)
 h = width of histogram interval
 v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

You can specify μ and σ with the MU= and SIGMA= *Gumbel-options*, respectively. By default, the procedure calculates maximum likelihood estimates for these parameters.

NOTE: The Gumbel distribution is also referred to as Type 1 extreme value distribution.

NOTE: The random variable X has Gumbel (Type 1 extreme value) distribution if and only if e^{-X} has Weibull distribution and $\exp((X - \mu)/\sigma)$ has standard exponential distribution.

Inverse Gaussian Distribution

The fitted density function is

$$p(x) = \begin{cases} hv \left(\frac{\lambda}{2\pi x^3} \right)^{1/2} \exp\left(-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right) & \text{for } x > 0 \\ 0 & \text{for } x \leq 0 \end{cases}$$

where

μ = location parameter ($\mu > 0$)

λ = shape parameter ($\lambda > 0$)

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The location parameter μ has to be greater than zero. You can specify μ with the MU= *iGauss-option*. In addition, you can specify shape parameter λ with the LAMBDA= *iGauss-option*. By default, the procedure uses the sample mean for μ and calculates a maximum likelihood estimate for λ .

NOTE: The special case where $\mu = 1$ and $\lambda = \phi$ corresponds to the Wald distribution.

Lognormal Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{hv}{\sigma\sqrt{2\pi}(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\xi)^2}{2\sigma^2}\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

ξ = scale parameter ($-\infty < \xi < \infty$)

σ = shape parameter ($\sigma > 0$)
 h = width of histogram interval
 v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The threshold parameter θ must be less than the minimum data value. You can specify θ with the THRESHOLD= *lognormal-option*. By default, $\theta = 0$. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . You can specify ζ and σ with the SCALE= and SHAPE= *lognormal-options*, respectively. By default, the procedure calculates maximum likelihood estimates for these parameters.

NOTE: The lognormal distribution is also referred to as the S_L distribution in the Johnson system of distributions.

NOTE: This book uses σ to denote the shape parameter of the lognormal distribution, whereas σ is used to denote the scale parameter of the beta, exponential, gamma, Gumbel, inverse Gaussian, normal, generalized Pareto, power function, Rayleigh, and Weibull distributions. The use of σ to denote the lognormal shape parameter is based on the fact that $\frac{1}{\sigma}(\log(X - \theta) - \zeta)$ has a standard normal distribution if X is lognormally distributed.

Normal Distribution

The fitted density function is

$$p(x) = \frac{hv}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right) \quad \text{for } -\infty < x < \infty$$

where

μ = mean
 σ = standard deviation ($\sigma > 0$)
 h = width of histogram interval
 v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

You can specify μ and σ with the MU= and SIGMA= *normal-options*, respectively. By default, the procedure estimates μ with the sample mean and σ with the sample standard deviation.

You can use the DATA step function PROBIT to compute normal quantiles and the DATA step function PROBNORM to compute probabilities.

NOTE: The normal distribution is also referred to as the S_N distribution in the Johnson system of distributions.

Generalized Pareto Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{hv}{\sigma} (1 - \alpha(x - \theta)/\sigma)^{1/\alpha-1} & \text{if } \alpha \neq 0 \\ \frac{hv}{\sigma} \exp(-(x - \theta)/\sigma) & \text{if } \alpha = 0 \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The support of the distribution is $x > \theta$ for $\alpha \leq 0$ and $\theta < x < \sigma/\alpha$ for $\alpha > 0$.

NOTE: Special cases of the generalized Pareto distribution with $\alpha = 0$ and $\alpha = 1$ correspond respectively to the exponential distribution with mean σ and uniform distribution on the interval $(0, \sigma)$.

The threshold parameter θ must be less than the minimum data value. You can specify θ with the **THETA= Pareto-option**. By default, $\theta = 0$. You can also specify α and σ with the **ALPHA=** and **SIGMA= Pareto-options**, respectively. By default, the procedure calculates maximum likelihood estimates for these parameters.

NOTE: Maximum likelihood estimation of the parameters works well if $\alpha < \frac{1}{2}$, but not otherwise. In this case the estimators are asymptotically normal and asymptotically efficient. The asymptotic normal distribution of the maximum likelihood estimates has mean (α, σ) and variance-covariance matrix

$$\frac{1}{n} \begin{pmatrix} (1 - \alpha)^2 & \sigma(1 - \alpha) \\ \sigma(1 - \alpha) & 2\sigma^2(1 - \alpha) \end{pmatrix}.$$

NOTE: If no local minimum found in the space

$$\{\alpha < 0, \sigma > 0\} \cup \{0 < \alpha \leq 1, \sigma/\alpha > \max(X_i)\},$$

there is no maximum likelihood estimator. More details on how to find maximum likelihood estimators and suggested algorithm can be found in Grimshaw(1993).

Power Function Distribution

The fitted density function is

$$p(x) = \begin{cases} hv \frac{\alpha}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where

θ = lower threshold parameter (lower endpoint parameter)

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

NOTE: This notation is consistent with that of other distributions that you can fit with the HISTOGRAM statement. However, many texts, including Johnson, Kotz, and Balakrishnan (1995), write the density function of power function distribution as

$$p(x) = \begin{cases} \frac{p}{b-a} \left(\frac{x-a}{b-a}\right)^{p-1} & \text{for } a < x < b \\ 0 & \text{for } x \leq a \text{ or } x \geq b \end{cases}$$

The two parameterizations are related as follows:

$$\sigma = b - a$$

$$\theta = a$$

$$\alpha = p$$

NOTE: The family of power function distributions is a subclass of beta distribution with density function

$$p(x) = \begin{cases} hv \frac{(x-\theta)^{\alpha-1} (\sigma+\theta-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$ with parameter $\beta = 1$. Therefore, all properties and estimation procedures of beta distribution apply.

The range of the power function distribution is bounded below by a threshold parameter $\theta = a$ and above by $\theta + \sigma = b$. If you specify a fitted power function curve by using the POWER option, θ must be less than the minimum data value and $\theta + \sigma$ must be greater than the maximum data value. You can specify θ and σ with the **THETA=** and **SIGMA=** *power-options* in parentheses after the keyword POWER. By default, $\sigma = 1$ and $\theta = 0$. If you specify THETA=EST and SIGMA=EST, maximum likelihood estimates are computed for θ and σ . However, three-parameter maximum likelihood estimation does not always converge.

In addition, you can specify α with the **ALPHA=** *power-option*. By default, the procedure calculates a maximum likelihood estimate for α . For example, to fit a power function density curve to a set of data bounded below by 32 and above by 212 with maximum likelihood estimate for α , use the following statement:

```
histogram Length / power(theta=32 sigma=180);
```

Rayleigh Distribution

The fitted density function is

$$p(x) = \begin{cases} hv \frac{x-\theta}{\sigma^2} e^{-(x-\theta)^2/(2\sigma^2)} & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where

θ = lower threshold parameter (lower endpoint parameter)

σ = scale parameter ($\sigma > 0$)

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

NOTE: The Rayleigh distribution is a Weibull distribution with density function

$$p(x) = \begin{cases} hv \frac{k}{\lambda} \left(\frac{x-\theta}{\lambda}\right)^{k-1} \exp\left(-\left(\frac{x-\theta}{\lambda}\right)^k\right) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

and with shape parameter $k = 2$ and scale parameter $\lambda = \sqrt{2}\sigma$.

The threshold parameter θ must be less than the minimum data value. You can specify θ with the **THETA=Rayleigh-option**. By default, $\theta = 0$. In addition you can specify σ with the **SIGMA=Rayleigh-option**. By default, the procedure calculates maximum likelihood estimate for σ .

For example, to fit a Rayleigh density curve to a set of data bounded below by 32 with maximum likelihood estimate for σ , use the following statement:

```
histogram Length / rayleigh(theta=32);
```

Johnson S_B Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{\delta hv}{\sigma\sqrt{2\pi}} \left[\left(\frac{x-\theta}{\sigma}\right) \left(1 - \frac{x-\theta}{\sigma}\right) \right]^{-1} \times \\ \exp \left[-\frac{1}{2} \left(\gamma + \delta \log\left(\frac{x-\theta}{\theta+\sigma-x}\right) \right)^2 \right] & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where

θ = threshold parameter ($-\infty < \theta < \infty$)

σ = scale parameter ($\sigma > 0$)
 δ = shape parameter ($\delta > 0$)
 γ = shape parameter ($-\infty < \gamma < \infty$)
 h = width of histogram interval
 v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The S_B distribution is bounded below by the parameter θ and above by the value $\theta + \sigma$. The parameter θ must be less than the minimum data value. You can specify θ with the THETA= S_B -option, or you can request that θ be estimated with the THETA = EST S_B -option. The default value for θ is zero. The sum $\theta + \sigma$ must be greater than the maximum data value. The default value for σ is one. You can specify σ with the SIGMA= S_B -option, or you can request that σ be estimated with the SIGMA = EST S_B -option.

By default, the method of percentiles given by Slifker and Shapiro (1980) is used to estimate the parameters. This method is based on four data percentiles, denoted by x_{-3z} , x_{-z} , x_z , and x_{3z} , which correspond to the four equally spaced percentiles of a standard normal distribution, denoted by $-3z$, $-z$, z , and $3z$, under the transformation

$$z = \gamma + \delta \log \left(\frac{x - \theta}{\theta + \sigma - x} \right)$$

The default value of z is 0.524. The results of the fit are dependent on the choice of z , and you can specify other values with the FITINTERVAL= option (specified in parentheses after the SB option). If you use the method of percentiles, you should select a value of z that corresponds to percentiles which are critical to your application.

The following values are computed from the data percentiles:

$$\begin{aligned} m &= x_{3z} - x_z \\ n &= x_{-z} - x_{-3z} \\ p &= x_z - x_{-z} \end{aligned}$$

It was demonstrated by Slifker and Shapiro (1980) that

$$\begin{aligned} \frac{mn}{p^2} &> 1 \quad \text{for any } S_U \text{ distribution} \\ \frac{mn}{p^2} &< 1 \quad \text{for any } S_B \text{ distribution} \\ \frac{mn}{p^2} &= 1 \quad \text{for any } S_L \text{ (lognormal) distribution} \end{aligned}$$

A tolerance interval around one is used to discriminate among the three families with this ratio criterion. You can specify the tolerance with the FITTOLERANCE= option (specified in parentheses after the SB option). The default tolerance is 0.01. Assuming that the criterion satisfies the inequality

$$\frac{mn}{p^2} < 1 - \text{tolerance}$$

the parameters of the S_B distribution are computed using the explicit formulas derived by Slifker and Shapiro (1980).

If you specify FITMETHOD = MOMENTS (in parentheses after the SB option) the method of moments is used to estimate the parameters. If you specify FITMETHOD = MLE (in parentheses after the SB option) the method of maximum likelihood is used to estimate the parameters. Note that maximum likelihood estimates may not always exist. Refer to Bowman and Shenton (1983) for discussion of methods for fitting Johnson distributions.

Johnson S_U Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{\delta h v}{\sigma \sqrt{2\pi}} \frac{1}{\sqrt{1 + ((x-\theta)/\sigma)^2}} \times \\ \exp \left[-\frac{1}{2} \left(\gamma + \delta \sinh^{-1} \left(\frac{x-\theta}{\sigma} \right) \right)^2 \right] & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = location parameter ($-\infty < \theta < \infty$)

σ = scale parameter ($\sigma > 0$)

δ = shape parameter ($\delta > 0$)

γ = shape parameter ($-\infty < \gamma < \infty$)

h = width of histogram interval

v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

You can specify the parameters with the THETA=, SIGMA=, DELTA=, and GAMMA= S_U -options, which are enclosed in parentheses after the SU option. If you do not specify these parameters, they are estimated.

By default, the method of percentiles given by Slifker and Shapiro (1980) is used to estimate the parameters. This method is based on four data percentiles, denoted by x_{-3z} , x_{-z} , x_z , and x_{3z} , which correspond to the four equally spaced percentiles of a standard normal distribution, denoted by $-3z$, $-z$, z , and $3z$, under the transformation

$$z = \gamma + \delta \sinh^{-1} \left(\frac{x - \theta}{\sigma} \right)$$

The default value of z is 0.524. The results of the fit are dependent on the choice of z , and you can specify other values with the FITINTERVAL= option (specified in parentheses after the SU option). If you use the method of percentiles, you should select a value of z that corresponds to percentiles which are critical to your application.

The following values are computed from the data percentiles:

$$\begin{aligned} m &= x_{3z} - x_z \\ n &= x_{-z} - x_{-3z} \\ p &= x_z - x_{-z} \end{aligned}$$

It was demonstrated by Slifker and Shapiro (1980) that

$$\begin{aligned} \frac{mn}{p^2} &> 1 \quad \text{for any } S_U \text{ distribution} \\ \frac{mn}{p^2} &< 1 \quad \text{for any } S_B \text{ distribution} \\ \frac{mn}{p^2} &= 1 \quad \text{for any } S_L \text{ (lognormal) distribution} \end{aligned}$$

A tolerance interval around one is used to discriminate among the three families with this ratio criterion. You can specify the tolerance with the FITTOLERANCE= option (specified in parentheses after the SU option). The default tolerance is 0.01. Assuming that the criterion satisfies the inequality

$$\frac{mn}{p^2} > 1 + \text{tolerance}$$

the parameters of the S_U distribution are computed using the explicit formulas derived by Slifker and Shapiro (1980).

If you specify FITMETHOD = MOMENTS (in parentheses after the SU option) the method of moments is used to estimate the parameters. If you specify FITMETHOD = MLE (in parentheses after the SU option) the method of maximum likelihood is used to estimate the parameters. Note that maximum likelihood estimates may not always exist. Refer to Bowman and Shenton (1983) for discussion of methods for fitting Johnson distributions.

Weibull Distribution

The fitted density function is

$$p(x) = \begin{cases} \frac{chv}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

- θ = threshold parameter
- σ = scale parameter ($\sigma > 0$)
- c = shape parameter ($c > 0$)
- h = width of histogram interval
- v = vertical scaling factor, and

$$v = \begin{cases} n & \text{the sample size, for VSCALE=COUNT} \\ 100 & \text{for VSCALE=PERCENT} \\ 1 & \text{for VSCALE=PROPORTION} \end{cases}$$

The threshold parameter θ must be less than the minimum data value. You can specify θ with the THRESHOLD= *Weibull-option*. By default, $\theta = 0$. If you specify THETA=EST, a maximum likelihood estimate is computed for θ . You can specify σ and c with the SCALE= and SHAPE= *Weibull-options*, respectively. By default, the procedure calculates maximum likelihood estimates for σ and c .

The exponential distribution is a special case of the Weibull distribution where $c = 1$.

Kernel Density Estimates

You can use the `KERNEL` option to superimpose kernel density estimates on histograms. Smoothing the data distribution with a kernel density estimate can be more effective than using a histogram to examine features that might be obscured by the choice of histogram bins or sampling variation. A kernel density estimate can also be more effective than a parametric curve fit when the process distribution is multimodal. See [Example 5.12](#).

The general form of the kernel density estimator is

$$\hat{f}_\lambda(x) = \frac{1}{n\lambda} \sum_{i=1}^n K_0\left(\frac{x - x_i}{\lambda}\right)$$

where $K_0(\cdot)$ is a kernel function, λ is the bandwidth, n is the sample size, and x_i is the i th observation.

The `KERNEL` option provides three kernel functions (K_0): normal, quadratic, and triangular. You can specify the function with the `K=kernel-option` in parentheses after the `KERNEL` option. Values for the `K=` option are `NORMAL`, `QUADRATIC`, and `TRIANGULAR` (with aliases of `N`, `Q`, and `T`, respectively). By default, a normal kernel is used. The formulas for the kernel functions are

$$\begin{array}{ll} \text{Normal} & K_0(t) = \frac{1}{\sqrt{2\pi}} \exp(-\frac{1}{2}t^2) \quad \text{for } -\infty < t < \infty \\ \text{Quadratic} & K_0(t) = \frac{3}{4}(1 - t^2) \quad \text{for } |t| \leq 1 \\ \text{Triangular} & K_0(t) = 1 - |t| \quad \text{for } |t| \leq 1 \end{array}$$

The value of λ , referred to as the bandwidth parameter, determines the degree of smoothness in the estimated density function. You specify λ indirectly by specifying a standardized bandwidth c with the `C=kernel-option`. If Q is the interquartile range, and n is the sample size, then c is related to λ by the formula

$$\lambda = cQn^{-\frac{1}{5}}$$

For a specific kernel function, the discrepancy between the density estimator $\hat{f}_\lambda(x)$ and the true density $f(x)$ is measured by the mean integrated square error (MISE):

$$\text{MISE}(\lambda) = \int_x \{E(\hat{f}_\lambda(x)) - f(x)\}^2 dx + \int_x \text{var}(\hat{f}_\lambda(x)) dx$$

The MISE is the sum of the integrated squared bias and the variance. An approximate mean integrated square error (AMISE) is

$$\text{AMISE}(\lambda) = \frac{1}{4}\lambda^4 \left(\int_t t^2 K(t) dt \right)^2 \int_x (f''(x))^2 dx + \frac{1}{n\lambda} \int_t K(t)^2 dt$$

A bandwidth that minimizes AMISE can be derived by treating $f(x)$ as the normal density having parameters μ and σ estimated by the sample mean and standard deviation. If you do not specify a bandwidth parameter or if you specify `C=MISE`, the bandwidth that minimizes AMISE is used. The value of AMISE can be used to compare different density estimates. For each estimate, the

bandwidth parameter c , the kernel function type, and the value of AMISE are reported in the SAS log.

The general kernel density estimates assume that the domain of the density to estimate can take on all values on a real line. However, sometimes the domain of a density is an interval bounded on one or both sides. For example, if a variable Y is a measurement of only positive values, then the kernel density curve should be bounded so that it is zero for negative Y values.

The CAPABILITY procedure uses a reflection technique to create the bounded kernel density curve, as described in Silverman (1986, pp 30-31). It adds the reflections of kernel density that are outside the boundary to the bounded kernel estimates. The general form of the bounded kernel density estimator is computed by replacing $K_0\left(\frac{x-x_i}{\lambda}\right)$ in the original equation with

$$\left\{ K_0\left(\frac{x-x_i}{\lambda}\right) + K_0\left(\frac{(x-x_l)+(x_i-x_l)}{\lambda}\right) + K_0\left(\frac{(x_u-x)+(x_u-x_i)}{\lambda}\right) \right\}$$

where x_l is the lower bound and x_u is the upper bound.

Without a lower bound, $x_l = \infty$ and $K_0\left(\frac{(x-x_l)+(x_i-x_l)}{\lambda}\right)$ equals zero. Similarly, without an upper bound, $x_u = \infty$ and $K_0\left(\frac{(x_u-x)+(x_u-x_i)}{\lambda}\right)$ equals zero.

When C=MISE is used with a bounded kernel density, the CAPABILITY procedure uses a bandwidth that minimizes the AMISE for its corresponding unbounded kernel.

Printed Output

If you request a fitted parametric distribution, printed output summarizing the fit is produced in addition to the graphical display. Figure 5.16 shows the printed output for a fitted lognormal distribution requested by the following statements:

```
ods graphics off;
proc capability data=Hang;
  spec target=14 lsl=13.95 usl=14.05;
  hist / lognormal(color=black indices midpercents);
run;
```

The summary is organized into the following parts:

- Parameters
- Chi-Square Goodness-of-Fit Test
- EDF Goodness-of-Fit Tests
- Specifications
- Indices Using the Fitted Curve
- Histogram Intervals
- Quantiles

These parts are described in the sections that follow.

Parameters

This section lists the parameters for the fitted curve as well as the estimated mean and estimated standard deviation. See “Formulas for Fitted Curves” on page 346.

Chi-Square Goodness-of-Fit Test

The chi-square goodness-of-fit statistic for a fitted parametric distribution is computed as follows:

$$\chi^2 = \sum_{i=1}^m \frac{(O_i - E_i)^2}{E_i}$$

where

O_i = observed value in i th histogram interval

E_i = expected value in i th histogram interval

m = number of histogram intervals

p = number of estimated parameters

The degrees of freedom for the chi-square test is equal to $m - p - 1$. You can save the observed and expected interval values in the OUTFIT= data set discussed in “Output Data Sets” on page 367.

Note that empty intervals are not combined, and the range of intervals used to compute χ^2 begins with the first interval containing observations and ends with the final interval containing observations.

EDF Goodness-of-Fit Tests

When you fit a parametric distribution, the HISTOGRAM statement provides a series of goodness-of-fit tests based on the empirical distribution function (EDF). The EDF tests offer advantages over the chi-square goodness-of-fit test, including improved power and invariance with respect to the histogram midpoints. For a thorough discussion, refer to D’Agostino and Stephens (1986).

The empirical distribution function is defined for a set of n independent observations X_1, \dots, X_n with a common distribution function $F(x)$. Denote the observations ordered from smallest to largest as $X_{(1)}, \dots, X_{(n)}$. The empirical distribution function, $F_n(x)$, is defined as

$$\begin{aligned} F_n(x) &= 0, & x < X_{(1)} \\ F_n(x) &= \frac{i}{n}, & X_{(i)} \leq x < X_{(i+1)} \quad i = 1, \dots, n-1 \\ F_n(x) &= 1, & X_{(n)} \leq x \end{aligned}$$

Note that $F_n(x)$ is a step function that takes a step of height $\frac{1}{n}$ at each observation. This function estimates the distribution function $F(x)$. At any value x , $F_n(x)$ is the proportion of observations less than or equal to x , while $F(x)$ is the probability of an observation less than or equal to x . EDF statistics measure the discrepancy between $F_n(x)$ and $F(x)$.

The computational formulas for the EDF statistics make use of the probability integral transformation $U = F(X)$. If $F(X)$ is the distribution function of X , the random variable U is uniformly distributed between 0 and 1.

Given n observations $X_{(1)}, \dots, X_{(n)}$, the values $U_{(i)} = F(X_{(i)})$ are computed by applying the transformation, as shown in the following sections.

The HISTOGRAM statement provides three EDF tests:

- Kolmogorov-Smirnov
- Anderson-Darling
- Cramér-von Mises

These tests are based on various measures of the discrepancy between the empirical distribution function $F_n(x)$ and the proposed parametric cumulative distribution function $F(x)$.

The following sections provide formal definitions of the EDF statistics.

Kolmogorov-Smirnov Statistic The Kolmogorov-Smirnov statistic (D) is defined as

$$D = \sup_x |F_n(x) - F(x)|$$

The Kolmogorov-Smirnov statistic belongs to the supremum class of EDF statistics. This class of statistics is based on the largest vertical difference between $F(x)$ and $F_n(x)$.

The Kolmogorov-Smirnov statistic is computed as the maximum of D^+ and D^- , where D^+ is the largest vertical distance between the EDF and the distribution function when the EDF is greater than the distribution function, and D^- is the largest vertical distance when the EDF is less than the distribution function.

$$\begin{aligned} D^+ &= \max_i \left(\frac{i}{n} - U_{(i)} \right) \\ D^- &= \max_i \left(U_{(i)} - \frac{i-1}{n} \right) \\ D &= \max(D^+, D^-) \end{aligned}$$

Anderson-Darling Statistic The Anderson-Darling statistic and the Cramér-von Mises statistic belong to the quadratic class of EDF statistics. This class of statistics is based on the squared difference $(F_n(x) - F(x))^2$. Quadratic statistics have the following general form:

$$Q = n \int_{-\infty}^{+\infty} (F_n(x) - F(x))^2 \psi(x) dF(x)$$

The function $\psi(x)$ weights the squared difference $(F_n(x) - F(x))^2$.

The Anderson-Darling statistic (A^2) is defined as

$$A^2 = n \int_{-\infty}^{+\infty} (F_n(x) - F(x))^2 [F(x)(1 - F(x))]^{-1} dF(x)$$

Here the weight function is $\psi(x) = [F(x)(1 - F(x))]^{-1}$.

The Anderson-Darling statistic is computed as

$$A^2 = -n - \frac{1}{n} \sum_{i=1}^n [(2i - 1) \log U_{(i)} + (2n + 1 - 2i) \log (1 - U_{(i)})]$$

Cramér-von Mises Statistic The Cramér-von Mises statistic (W^2) is defined as

$$W^2 = n \int_{-\infty}^{+\infty} (F_n(x) - F(x))^2 dF(x)$$

Here the weight function is $\psi(x) = 1$.

The Cramér-von Mises statistic is computed as

$$W^2 = \sum_{i=1}^n \left(U_{(i)} - \frac{2i - 1}{2n} \right)^2 + \frac{1}{12n}$$

Probability Values for EDF Tests Once the EDF test statistics are computed, the associated probability values (p -values) must be calculated.

For the Gumbel, inverse Gaussian, generalized Pareto, and Rayleigh distributions, the procedure computes associated probability values (p -values) by resampling from the estimated distribution. It generates k random samples of size n , where k is specified by the `EDFNSAMPLES=` option and n is the number of observations in the original data. EDF test statistics are computed for each sample, and the p -value is the proportion of samples whose EDF statistic is greater than or equal to the statistic computed for the original data. You can use the `EDFSEED=` option to specify a seed value for generating the sample values.

For the beta, exponential, gamma, lognormal, normal, power function, and Weibull distributions, the CAPABILITY procedure uses internal tables of probability levels similar to those given by D'Agostino and Stephens (1986). If the value is between two probability levels, then linear interpolation is used to estimate the probability value. The probability value depends upon the parameters that are known and the parameters that are estimated for the distribution you are fitting. Table 5.23 summarizes different combinations of estimated parameters for which EDF tests are available.

Table 5.23 Availability of EDF Tests

Distribution	Parameters		Tests Available	
	Threshold	Scale		Shape

	θ unknown	σ unknown	$c > 2$ unknown	all

Specifications

This section is included in the summary only if you provide specification limits, and it tabulates the limits as well as the observed percentages and estimated percentages outside the limits.

The estimated percentages are computed only if fitted distributions are requested and are based on the probability that an observed value exceeds the specification limits, assuming the fitted distribution. The observed percentages are the percents of observations outside the specification limits.

Indices Using Fitted Curves

This section is included in the summary only if you specify the INDICES option in parentheses after a distribution option, as in the statements that produce Figure 5.16. Standard process capability indices, such as C_p and C_{pk} , are not appropriate if the data are not normally distributed. The INDICES option computes generalizations of the standard indices by using the fact that for the normal distribution, 3σ is both the distance from the lower 0.135 percentile to the median (or mean) and the distance from the median (or mean) to the upper 99.865 percentile. These percentiles are estimated from the fitted distribution, and the appropriate percentile-to-median distances are substituted for 3σ in the standard formulas.

Writing T for the target, LSL and USL for the lower and upper specification limits, and P_α for the 100α th percentile, the generalized capability indices are as follows:

$$CPL = \frac{P_{0.5} - LSL}{P_{0.5} - P_{0.00135}}$$

$$CPU = \frac{USL - P_{0.5}}{P_{0.99865} - P_{0.5}}$$

$$C_p = \frac{USL - LSL}{P_{0.99865} - P_{0.00135}}$$

$$C_{pk} = \min \left(\frac{P_{0.5} - LSL}{P_{0.5} - P_{0.00135}}, \frac{USL - P_{0.5}}{P_{0.99865} - P_{0.5}} \right)$$

$$K = 2 \times \frac{|\frac{1}{2}(USL + LSL) - P_{0.5}|}{USL - LSL}$$

$$C_{pm} = \frac{\min \left(\frac{T - LSL}{P_{0.5} - P_{0.00135}}, \frac{USL - T}{P_{0.99865} - P_{0.5}} \right)}{\sqrt{1 + \left(\frac{\mu - T}{\sigma} \right)^2}}$$

If the data are normally distributed, these formulas reduce to the formulas for the standard capability indices, which are given in the section “[Standard Capability Indices](#)” on page 245.

The following guidelines apply to the use of generalized capability indices requested with the INDICES option:

- When you choose the family of parametric distributions for the fitted curve, consider whether an appropriate family can be derived from assumptions about the process.
- Whenever possible, examine the data distribution with a histogram, probability plot, or quantile-quantile plot.
- Apply goodness-of-fit tests to assess how well the parametric distribution models the data.
- Consider whether a generalized index has a meaningful practical interpretation in your application.

At the time of this writing, there is ongoing research concerning the application of generalized capability indices, and it is important to note that other approaches can be used with nonnormal data:

- Transform the data to normality, then compute and report standard capability indices on the transformed scale.
- Report the proportion of nonconforming output estimated from the fitted distribution.
- If it is not possible to adequately model the data distribution with a parametric density, smooth the data distribution with a kernel density estimate and simply report the proportion of nonconforming output.

Refer to Rodriguez and Bynum (1992) for additional discussion.

Histogram Intervals

This section is included in the summary only if you specify the MIDPERCENTS option in parentheses after the distribution option, as in the statements that produce Figure 5.16. This table lists the interval midpoints along with the observed and estimated percentages of the observations that lie in the interval. The estimated percentages are based on the fitted distribution.

In addition, you can specify the MIDPERCENTS option to request a table of interval midpoints with the observed percent of observations that lie in the interval. See the entry for the MIDPERCENTS option on page 336.

Quantiles

This table lists observed and estimated quantiles. You can use the PERCENTS= option to specify the list of quantiles to appear in this list. The list in Figure 5.16 is the default list. See the entry for the PERCENTS= option on page 340.

Output Data Sets

You can create two output data sets with the HISTOGRAM statement: the OUTFIT= data set and the OUTHISTOGRAM= data set. These data sets are described in the following sections.

OUTFIT= Data Set

The OUTFIT= data set contains the parameters of fitted density curves, information about chi-square and EDF goodness-of-fit tests, specification limit information, and capability indices based on the fitted distribution. Since you can specify multiple HISTOGRAM statements with the CAPABILITY procedure, you can create several OUTFIT= data sets. For each variable plotted with the HISTOGRAM statement, the OUTFIT= data set contains one observation for each fitted distribution requested in the HISTOGRAM statement. If you use a BY statement, the OUTFIT= data set contains several observations for each BY group (one observation for each variable and fitted density combination). ID variables are not saved in the OUTFIT= data set.

The OUTFIT= data set contains the variables listed in Table 5.24. By default, an OUTFIT= data set contains _MIDPT1_ and _MIDPTN_ variables, whose values identify histogram intervals by their midpoints. When the ENDPOINTS= or NENDPOINTS option is specified, intervals are identified by endpoint values instead. If the RTINCLUDE option is specified, the variables _MAXPT1_ and _MAXPTN_ contain upper endpoint values. Otherwise, the variables _MINPT1_ and _MINPTN_ contain lower endpoint values.

Table 5.24 Variables in the OUTFIT= Data Set

Variable	Description
ADASQ	Anderson-Darling EDF goodness-of-fit statistic
ADP	<i>p</i> -value for Anderson-Darling EDF goodness-of-fit test
CHISQ	chi-square goodness-of-fit statistic
CP	generalized capability index C_p based on the fitted curve
CPK	generalized capability index C_{pk} based on the fitted curve
CPL	generalized capability index CPL based on the fitted curve
CPM	generalized capability index C_{pm} based on the fitted curve
CPU	generalized capability index CPU based on the fitted curve
CURVE	name of fitted distribution (abbreviated to 8 characters)

Table 5.24 (continued)

Variable	Description
CVMWSQ	Cramer-von Mises EDF goodness-of-fit statistic
CVMP	p -value for Cramer-von Mises EDF goodness-of-fit test
DF	degrees of freedom for chi-square goodness-of-fit test
ESTGTR	estimated percent of population greater than upper specification limit
ESTLSS	estimated percent of population less than lower specification limit
ESTSTD	estimated standard deviation
EXPECT	estimated mean
K	generalized capability index K based on the fitted curve
KSD	Kolmogorov-Smirnov EDF goodness-of-fit statistic
KSP	p -value for Kolmogorov-Smirnov EDF goodness-of-fit test
LOCATN	location parameter for fitted distribution. For the Gumbel, inverse Gaussian, and normal distributions, this is either the value of μ specified with the MU= option or the value estimated by the procedure. For all other distributions, this is either the value specified or estimated according to the THETA= option, or zero.
LSL	lower specification limit
MAXPT1	upper endpoint of first interval used to calculate the value of the chi-square statistic.
MAXPTN	upper endpoint of last interval used to calculate the value of the chi-square statistic.
MIDPT1	midpoint of first interval used to calculate the value of the chi-square statistic. This is the leftmost interval that contains at least one value of the variable.
MIDPTN	midpoint of last interval used to calculate the value of the chi-square statistic. This is the rightmost interval that contains at least one value of the variable.
MINPT1	lower endpoint of first interval used to calculate the value of the chi-square statistic.
MINPTN	lower endpoint of last interval used to calculate the value of the chi-square statistic.
OBSGTR	observed percent of data greater than upper specification limit
OBSLSS	observed percent of data less than the lower specification limit
PCHISQ	p -value for chi-square goodness-of-fit test
SCALE	value of scale parameter for fitted distribution. For the lognormal distribution, this is the value of ζ specified or estimated according to the ZETA= option. For all other distributions, this is the value specified or estimated according to the SIGMA= option.

Table 5.24 (continued)

Variable	Description
<code>_SHAPE1_</code>	value of shape parameter for fitted distribution. For the beta, gamma, generalized Pareto, and power function distributions, this is the value of α , either specified with the <code>ALPHA=</code> option or estimated by the procedure. For the lognormal distribution, this is the value of σ , either specified with the <code>SIGMA=</code> option or estimated by the procedure. For the Weibull distribution, this is the value of c , either specified with the <code>C=</code> option or estimated by the procedure. For the Johnson S_B and S_U distributions, this is the value of δ , either specified with the <code>DELTA=</code> option or estimated by the procedure. For distributions without a shape parameter (Gumbel, normal, exponential, and Rayleigh distributions), <code>_SHAPE1_</code> is set to missing.
<code>_SHAPE2_</code>	value of shape parameter for fitted distribution. For the beta distribution, this is the value of β , either specified with the <code>BETA=</code> option or estimated by the procedure. For the Johnson S_B and S_U distributions, this is the value of γ , either specified with the <code>GAMMA=</code> option or estimated by the procedure. For all other distributions, <code>_SHAPE2_</code> is set to missing.
<code>_TARGET_</code>	target value
<code>_USL_</code>	upper specification limit
<code>_VAR_</code>	variable name
<code>_WIDTH_</code>	width of histogram interval

OUTHISTOGRAM= Data Set

The OUTHISTOGRAM= data set contains information about histogram intervals. Since you can specify multiple HISTOGRAM statements with the CAPABILITY procedure, you can create multiple OUTHISTOGRAM= data sets.

The data set contains a group of observations for each variable plotted with the HISTOGRAM statement. The group contains an observation for each interval of the histogram, beginning with the leftmost interval that contains a value of the variable and ending with the rightmost interval that contains a value of the variable. These intervals will not necessarily coincide with the intervals displayed in the histogram since the histogram may be padded with empty intervals at either end. If you superimpose one or more fitted curves on the histogram, the OUTHISTOGRAM= data set contains multiple groups of observations for each variable (one group for each curve). If you use a BY statement, the OUTHISTOGRAM= data set contains groups of observations for each BY group. ID variables are not saved in the OUTHISTOGRAM= data set.

The OUTHISTOGRAM= data set contains the variables listed in Table 5.25. By default, an OUTHISTOGRAM= data set contains the `_MIDPT_` variable, whose values identify histogram intervals by their midpoints. When the `ENDPOINTS=` or `NENDPOINTS` option is specified, intervals are identified by endpoint values instead. If the `RTINCLUDE` option is specified, the `_MAXPT_` variable contains an interval's upper endpoint value. Otherwise, the `_MINPT_` variable contains the interval's lower endpoint value.

Table 5.25 Variables in the OUTHISTOGRAM= Data Set

Variable	Description
COUNT	number of variable values in histogram interval
CURVE	name of fitted distribution (if requested in HISTOGRAM statement)
EXPPCT	estimated percent of population in histogram interval determined from optional fitted distribution
MAXPT	upper endpoint of histogram interval
MIDPT	midpoint of histogram interval
MINPT	lower endpoint of histogram interval
OBSPCT	percent of variable values in histogram interval
VAR	variable name

OUTKERNEL= Output Data Set

An OUTKERNEL= data set contains information about kernel density estimates requested with the **KERNEL** option. Because you can specify multiple HISTOGRAM statements with the CAPABILITY procedure, you can create multiple OUTKERNEL= data sets.

An OUTKERNEL= data set contains a group of observations for each kernel density estimate requested with the HISTOGRAM statement. These observations span a range of analysis variable values recorded in the _VALUE_ variable. The procedure determines the increment between values, and therefore the number of observations in the group. The variable _DENSITY_ contains the kernel density calculated for the corresponding analysis variable value.

When a density curve is overlaid on a histogram, the curve is scaled so that the area under the curve equals the total area of the histogram bars. The scaled density values are saved in the variable _COUNT_, _PERCENT_, or _PROPORTION_, depending on the histogram's vertical axis scale, determined by the VSCALE= option. Only one of these variables appears in a given OUTKERNEL= data set.

Table 5.26 lists the variables in an OUTKERNEL= data set.

Table 5.26 Variables in the OUTKERNEL= Data Set

Variable	Description
C	standardized bandwidth parameter
COUNT	kernel density scaled for VSCALE=COUNT
DENSITY	kernel density
PERCENT	kernel density scaled for VSCALE=PERCENT (default)
PROPORTION	kernel density scaled for VSCALE=PROPORTION
TYPE	kernel function
VALUE	variable value at which kernel function is calculated
VAR	variable name

ODS Tables

The following table summarizes the ODS tables related to fitted distributions that you can request with the HISTOGRAM statement.

Table 5.27 ODS Tables Produced with the HISTOGRAM Statement

Table Name	Description	Option
Bins	histogram bins	MIDPERCENTS suboption with any distribution option, such as NORMAL(MIDPERCENTS)
FitIndices	capability indices computed from fitted distribution	INDICES suboption with any distribution option, such as LOGNORMAL(INDICES)
FitQuantiles	quantiles of fitted distribution	any distribution option such as NORMAL
GoodnessOfFit	goodness-of-fit tests for fitted distribution	any distribution option such as NORMAL
ParameterEstimates	parameter estimates for fitted distribution	any distribution option such as NORMAL
Specifications	percents outside specification limits based on empirical and fitted distributions	any distribution option such as NORMAL

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. HISTOGRAM options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the HISTOGRAM statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 5.28](#).

Table 5.28 ODS Graphics Produced by the HISTOGRAM Statement

ODS Graph Name	Plot Description
Histogram	histogram

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

SYMBOL and PATTERN Statement Options

In earlier releases of SAS/QC software, graphical features (such as colors and line types) of specification lines, histogram bars, and fitted curves were controlled with options in SYMBOL and PATTERN statements when producing traditional graphics. These options are still supported, although they have been superseded by options in the HISTOGRAM and SPEC statements. The following tables summarize the two sets of options. **NOTE:** These statements have no effect on ODS Graphics output.

Table 5.29 Graphical Enhancement of Histogram Outlines and Specification Lines

Examples: HISTOGRAM Statement

This section provides advanced examples of the HISTOGRAM statement.

Example 5.8: Fitting a Beta Curve

You can use a beta distribution to model the distribution of a quantity that is known to vary between lower and upper bounds. In this example, a manufacturing company uses a robotic arm to attach hinges on metal sheets. The attachment point should be offset 10.1 mm from the left edge of the sheet. The actual offset varies between 10.0 and 10.5 mm due to variation in the arm. Offsets for 50 attachment points are saved in the following data set: *See CAPBTA2 in the SAS/QC Sample Library*

```

title ;
data Measures;
  input Length @@;
  label Length = 'Attachment Point Offset in mm';
  datalines;
10.147 10.070 10.032 10.042 10.102
10.034 10.143 10.278 10.114 10.127
10.122 10.018 10.271 10.293 10.136
10.240 10.205 10.186 10.186 10.080
10.158 10.114 10.018 10.201 10.065
10.061 10.133 10.153 10.201 10.109
10.122 10.139 10.090 10.136 10.066
10.074 10.175 10.052 10.059 10.077
10.211 10.122 10.031 10.322 10.187
10.094 10.067 10.094 10.051 10.174
;

```

The following statements create a histogram with a fitted beta density curve:

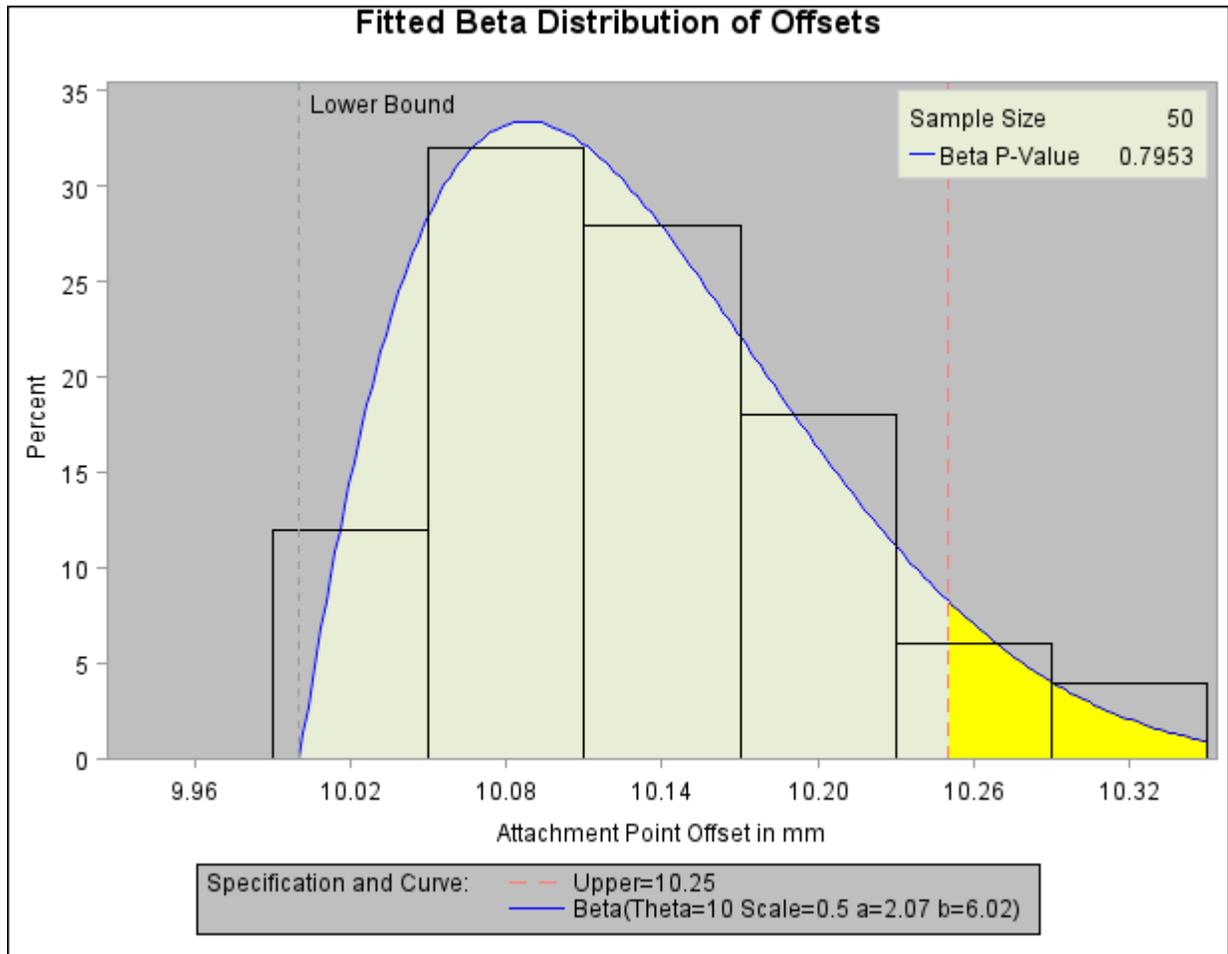

```

ods graphics off;
legend2 frame cframe=ligr cborder=black position=center;
title1 'Fitted Beta Distribution of Offsets';
proc capability data=Measures;
  specs usl=10.25 lusl=20 cusl=salmon cright=yellow pright=solid;
  histogram Length /
    beta(theta=10 scale=0.5 color=blue fill)
    cfill      = ywh
    cframe     = ligr
    href       = 10
    hreflabel  = 'Lower Bound'
    lhref      = 2
    legend     = legend2
    vaxis      = axis1;
  axis1 label=(a=90 r=0);
  inset n = 'Sample Size'
        beta(pchisq = 'P-Value') / pos=ne cfill=ywh;
run;

```

The histogram is shown in [Output 5.8.1](#). The `THETA=` *beta-option* specifies the lower threshold. The `SCALE=` *beta-option* specifies the range between the lower threshold and the upper threshold (in this case, 0.5 mm). Note that in general, the default `THETA=` and `SCALE=` values are zero and one, respectively.

Output 5.8.1 Superimposing a Histogram with a Fitted Beta Curve

The `FILL` *beta-option* specifies that the area under the curve is to be filled with the `CFILL=` color. (If `FILL` were omitted, the `CFILL=` color would be used to fill the histogram bars instead.) The `CRIGHT=` option in the `SPEC` statement specifies the color under the curve to the right of the upper specification limit. If the `CRIGHT=` option were not specified, the entire area under the curve would be filled with the `CFILL=` color. When a lower specification limit is available, you can use the `CLEFT=` option in the `SPEC` statement to specify the color under the curve to the left of this limit.

The `HREF=` option draws a reference line at the lower bound, and the `HREFLABEL=` option adds the label *Lower Bound*. The option `LHREF=2` specifies a dashed line type. The `INSET` statement adds an inset with the sample size and the *p*-value for a chi-square goodness-of-fit test.

In addition to displaying the beta curve, the `BETA` option summarizes the curve fit, as shown in [Output 5.8.2](#). The output tabulates the parameters for the curve, the chi-square goodness-of-fit test whose *p*-value is shown in [Output 5.8.1](#), the observed and estimated percents above the upper

specification limit, and the observed and estimated quantiles. For instance, based on the beta model, the percent of offsets greater than the upper specification limit is 6.6%. For computational details, see the section “Formulas for Fitted Curves” on page 346.

Output 5.8.2 Summary of Fitted Beta Distribution

```

Example 5.9: Fitting Lognormal, Weibull, and Gamma Curves

See CAPCURV in the SAS/QC Sample Library

To find an appropriate model for a process distribution, you should consider curves from several distribution families. As shown in this example, you can use the HISTOGRAM statement to fit more than one type of distribution and display the density curves on the same histogram.

The gap between two plates is measured (in cm) for each of 50 welded assemblies selected at random from the output of a welding process assumed to be in statistical control. The lower and upper specification limits for the gap are 0.3 cm and 0.8 cm, respectively. The measurements are saved in a data set named Plates.

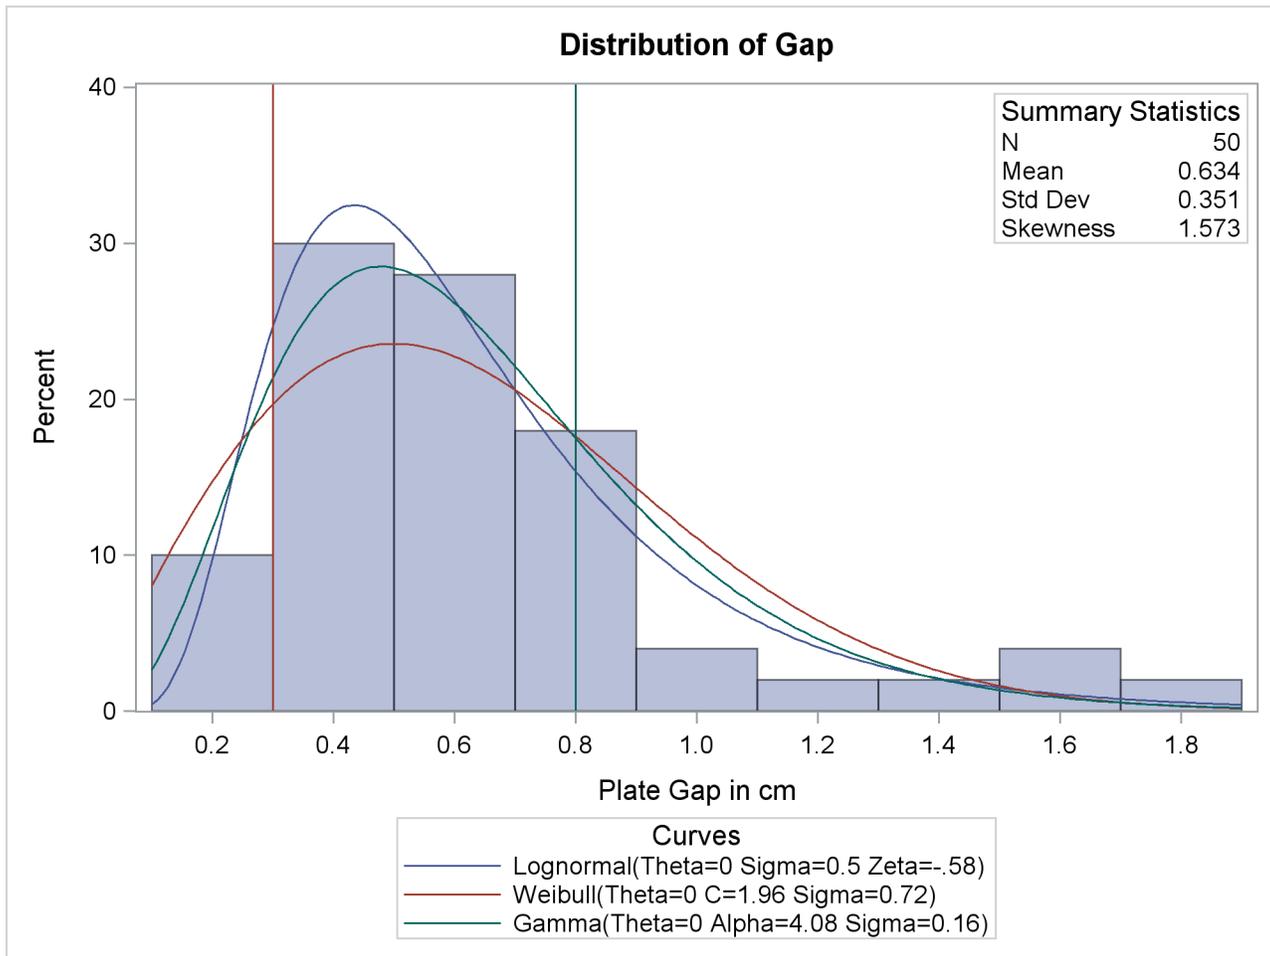

```
data Plates;
  label Gap='Plate Gap in cm';
  input Gap @@;
  datalines;
0.746 0.357 0.376 0.327 0.485 1.741 0.241 0.777 0.768 0.409
0.252 0.512 0.534 1.656 0.742 0.378 0.714 1.121 0.597 0.231
0.541 0.805 0.682 0.418 0.506 0.501 0.247 0.922 0.880 0.344
0.519 1.302 0.275 0.601 0.388 0.450 0.845 0.319 0.486 0.529

;
```

The following statements fit three distributions (lognormal, Weibull, and gamma) and display their density curves on a single histogram:

```
ods graphics on;
proc capability data=Plates;
  var Gap;
  specs lsl = 0.3 usl = 0.8;
  histogram /
    midpoints=0.2 to 1.8 by 0.2
    lognormal
    weibull
    gamma
  nospeclegend;
  inset n mean(5.3) std='Std Dev' (5.3) skewness(5.3)
    / pos = ne header = 'Summary Statistics';
run;
```

The LOGNORMAL, WEIBULL, and GAMMA options superimpose fitted curves on the histogram in Output 5.9.1. Note that a threshold parameter $\theta = 0$ is assumed for each curve. In applications where the threshold is not zero, you can specify θ with the THETA= option.

Output 5.9.1 Superimposing a Histogram with Fitted Curves

The LOGNORMAL, WEIBULL, and GAMMA options also produce the summaries for the fitted distributions shown in [Output 5.9.2](#), [Output 5.9.3](#), and [Output 5.9.4](#).

Output 5.9.2 Summary of Fitted Lognormal Distribution

The CAPABILITY Procedure
Fitted Lognormal Distribution for Gap (Plate Gap in cm)

Parameters for Lognormal Distribution

95.0	1.54700	1.26862	
99.0	1.74100	1.78313	

Output 5.9.2 provides four goodness-of-fit tests for the lognormal distribution: the chi-square test and three tests based on the EDF (Anderson-Darling, Cramer-von Mises, and Kolmogorov-Smirnov). See “Chi-Square Goodness-of-Fit Test” on page 361 and “EDF Goodness-of-Fit Tests” on page 362 for more information. The EDF tests are superior to the chi-square test because they are not dependent on the set of midpoints used for the histogram.

At the $\alpha = 0.10$ significance level, all four tests support the conclusion that the two-parameter lognormal distribution with scale parameter $\hat{\zeta} = -0.58$, and shape parameter $\hat{\sigma} = 0.50$ provides a good model for the distribution of plate gaps.

Output 5.9.3 Summary of Fitted Weibull Distribution

```

```

Output 5.9.3 provides two EDF goodness-of-fit tests for the Weibull distribution: the Anderson-Darling and the Cramer-von Mises tests. (See Table 5.23 for a complete list of the EDF tests available in the HISTOGRAM statement.) The probability values for the chi-square and EDF tests are all less than 0.10, indicating that the data do not support a Weibull model.

Output 5.9.4 Summary of Fitted Gamma Distribution

The CAPABILITY Procedure				
Fitted Gamma Distribution for Gap (Plate Gap in cm)				
Parameters for Gamma Distribution				
Parameter	Symbol	Estimate		
Threshold	Theta	0		
Scale	Sigma	0.155198		
Shape	Alpha	4.082646		
Mean		0.63362		
Std Dev		0.313587		
Goodness-of-Fit Tests for Gamma Distribution				
Test	----Statistic-----		DF	-----p Value-----
Kolmogorov-Smirnov	D	0.0969533		Pr > D >0.250
Cramer-von Mises	W-Sq	0.0739847		Pr > W-Sq >0.250
Anderson-Darling	A-Sq	0.5810661		Pr > A-Sq 0.137

5.0	0.24700	0.21951		
10.0	0.29450	0.27938		
25.0	0.37800	0.40404		
50.0	0.53150	0.58271		
75.0	0.74600	0.80804		
90.0	1.10050	1.05392		
95.0	1.54700	1.22160		
99.0	1.74100	1.57939		

Output 5.9.4 provides four goodness-of-fit tests for the gamma distribution. The probability value for the chi-square test is less than 0.10, indicating that the data do not support a gamma model.

Based on this analysis, the fitted lognormal distribution is the best model for the distribution of plate gaps. You can use this distribution to calculate useful quantities. For instance, you can compute the probability that the gap of a randomly sampled plate exceeds the upper specification limit, as follows:

$$\begin{aligned}\Pr[\text{gap} > \text{USL}] &= \Pr\left[Z > \frac{1}{\sigma}(\log(\text{USL} - \theta) - \zeta)\right] \\ &= 1 - \Phi\left[\frac{1}{\sigma}(\log(\text{USL} - \theta) - \zeta)\right]\end{aligned}$$

where Z has a standard normal distribution, and $\Phi(\cdot)$ is the standard normal cumulative distribution function. Note that $\Phi(\cdot)$ can be computed with the DATA step function PROBNORM. In this example, $\text{USL} = 0.8$ and $\Pr[\text{gap} > 0.8] = 0.2352$. This value is expressed as a percent (*Est Pct > USL*) in [Output 5.9.2](#).

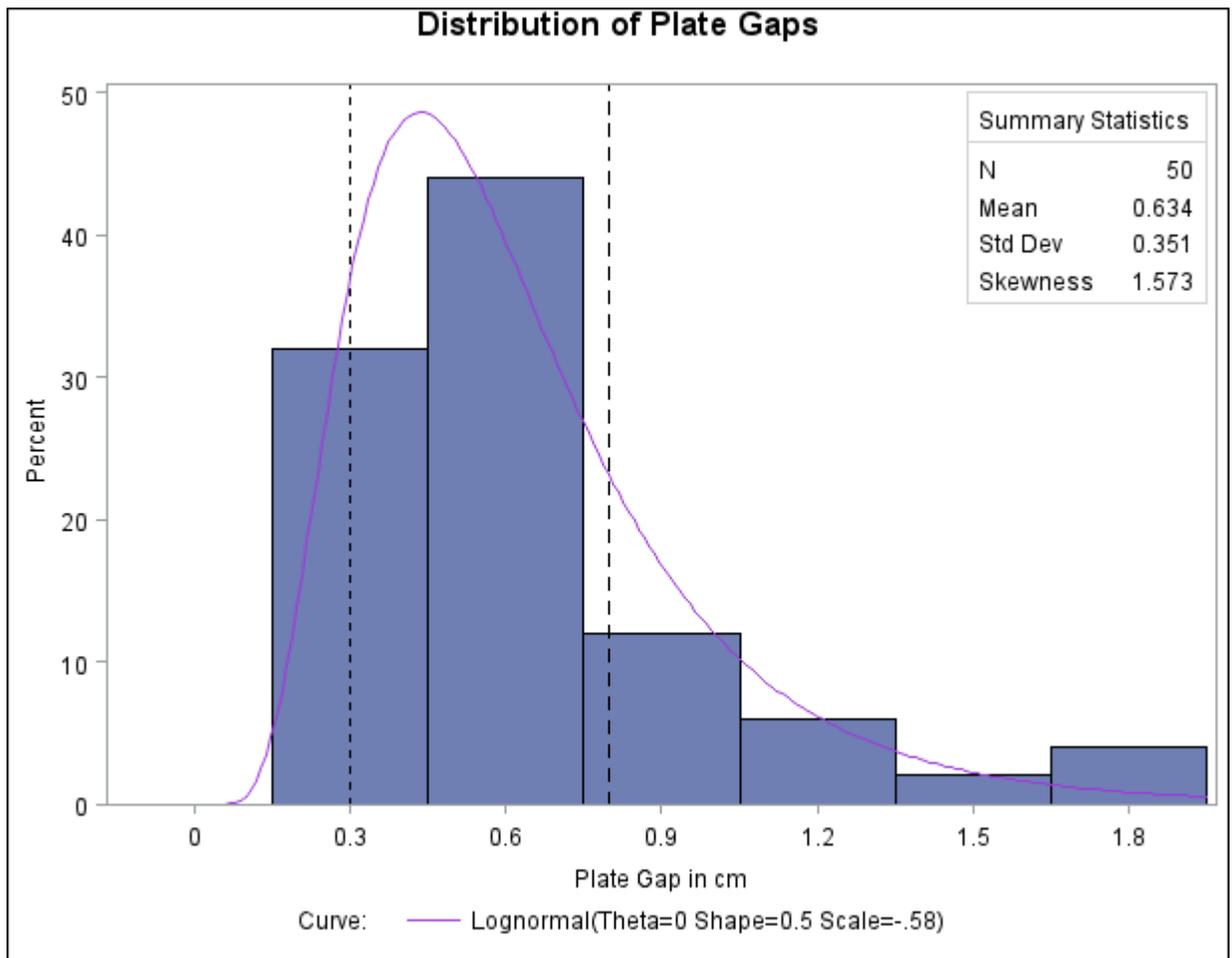

Example 5.10: Comparing Goodness-of-Fit Tests

A weakness of the chi-square goodness-of-fit test is its dependence on the choice of histogram midpoints. An advantage of the EDF tests is that they give the same results regardless of the midpoints, as illustrated in this example. *See CAPGOF in the SAS/QC Sample Library*

In [Example 5.9](#), the option MIDPOINTS=0.2 TO 1.8 BY 0.2 was used to specify the histogram midpoints for Gap. The following statements refit the lognormal distribution by using default midpoints (0.3 to 1.8 by 0.3).

```
ods graphics off;
title1 'Distribution of Plate Gaps';
proc capability data=Plates noprint;
  var Gap;
  specs lsl = 0.3 lls1 = 2 clsl=black
        usl = 0.8 lus1 = 20 cusl=black;
  histogram /
    lognormal
    nospeclegend
    vaxis = axis1;
  inset n mean(5.3) std='Std Dev'(5.3) skewness(5.3)
    / pos = ne header = 'Summary Statistics';
  axis1 label=(a=90 r=0);
run;
```

The histogram is shown in [Output 5.10.1](#).

Output 5.10.1 Lognormal Curve Fit with Default Midpoints

A summary of the lognormal fit is shown in [Output 5.10.2](#). The p -value for the chi-square goodness-of-fit test is 0.082. Since this value is less than 0.10 (a typical cutoff level), the conclusion is that the lognormal distribution is not an appropriate model for the data. This is the *opposite* conclusion drawn from the chi-square test in [Example 5.9](#), which is based on a different set of midpoints and has a p -value of 0.2756 (see [Output 5.9.2](#)). Moreover, the results of the EDF goodness-of-fit tests are the same since these tests do not depend on the midpoints. When available, the EDF tests provide more powerful alternatives to the chi-square test. For a thorough discussion of EDF tests, refer to D'Agostino and Stephens (1986).

Output 5.10.2 Printed Output for the Lognormal Curve

Distribution of Plate Gaps					
The CAPABILITY Procedure					
Fitted Lognormal Distribution for Gap (Plate Gap in cm)					
Parameters for Lognormal Distribution					
Parameter	Symbol	Estimate			
Threshold	Theta	0

Example 5.11: Computing Capability Indices for Nonnormal Distributions

Standard capability indices such as C_{pk} are generally considered meaningful only if the process output has a normal (or reasonably normal) distribution. In practice, however, many processes have nonnormal distributions. This example, which is a continuation of [Example 5.9](#) and [Example 5.10](#), shows how you can use the HISTOGRAM statement to compute generalized capability indices based on fitted nonnormal distributions.

See CAPIND in the SAS/QC Sample Library

The following statements produce printed output that is partially listed in [Output 5.11.1](#) and [Output 5.11.2](#):

```
ods graphics off;
proc capability data=Plates checkindices(alpha=0.05);
  specs lsl=0.3 usl= 0.8;
  histogram Gap / lognormal(indices) noplot;
run;
```

The PROC CAPABILITY statement computes the standard capability indices that are shown in [Output 5.11.1](#).

Output 5.11.1 Standard Capability Indices for Variable Gap

Distribution of Plate Gaps			
The CAPABILITY Procedure			
Variable: Gap (Plate Gap in cm)			
Process Capability Indices			
Index	Value	95% Confidence Limits	
Cp	0.237112	0.190279	0.283853
CPL	0.316422	0.203760	0.426833
CPU	0.157803	0.059572	0.254586
Cpk	0.157803	0.060270	0.255336

Warning: Normality is rejected for alpha = 0.05 using the Shapiro-Wilk test

The **CHECKINDICES** option in the PROC statement requests a goodness-of-fit test for normality in conjunction with the indices and displays the warning that normality is rejected at the significance level $\alpha = 0.05$.

Example 5.9 concluded that the fitted lognormal distribution summarized in **Output 5.9.2** is a good model, so one might consider computing generalized capability indices based on this distribution. These indices are requested with the **INDICES** option and are shown in **Output 5.11.2**. Formulas and recommendations for these indices are given in “**Indices Using Fitted Curves**” on page 365.

Output 5.11.2 Fitted Lognormal Distribution Information

Capability Indices Based on Lognormal Distribution	
Cp	0.210804
CPL	0.595156
CPU	0.124927
Cpk	0.124927

Example 5.12: Computing Kernel Density Estimates

This example illustrates the use of kernel density estimates to visualize a nonnormal data distribution. *See CAPKERN1 in the SAS/QC Sample Library*

The effective channel length (in microns) is measured for 1225 field effect transistors. The channel lengths are saved as values of the variable Length in a SAS data set named Channel:

```
data Channel;
  length Lot $ 16;
  input Length @@;
  select;
    when (_n_ <= 425) Lot='Lot 1';
    when (_n_ >= 926) Lot='Lot 3';
    otherwise Lot='Lot 2';
  end;
  datalines;
0.91 1.01 0.95 1.13 1.12 0.86 0.96 1.17 1.36 1.10
0.98 1.27 1.13 0.92 1.15 1.26 1.14 0.88 1.03 1.00
0.98 0.94 1.09 0.92 1.10 0.95 1.05 1.05 1.11 1.15
1.11 0.98 0.78 1.09 0.94 1.05 0.89 1.16 0.88 1.19
1.01 1.08 1.19 0.94 0.92 1.27 0.90 0.88 1.38 1.02

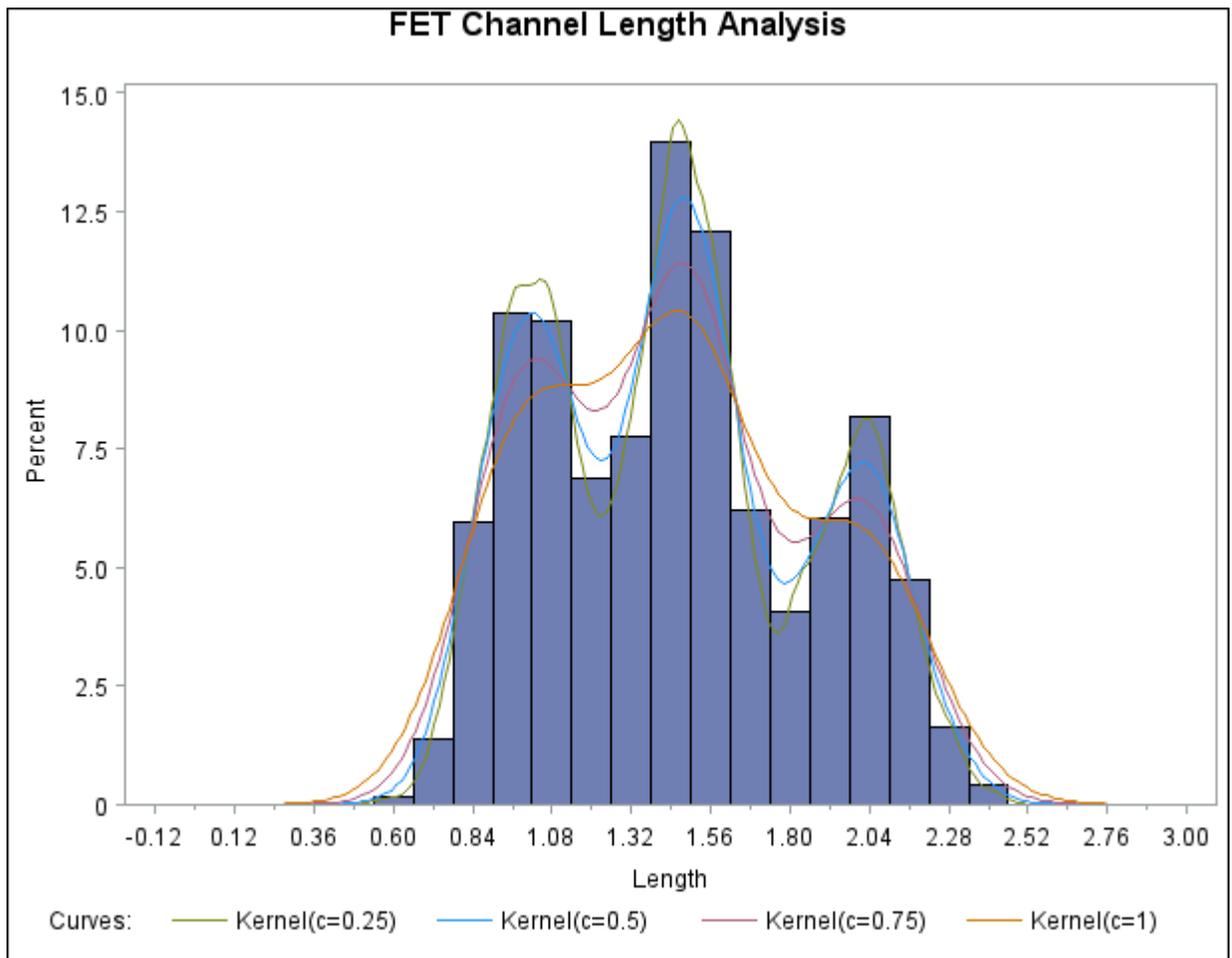

... more lines ...

1.80 2.35 2.23 1.96 2.16 2.08 2.06 2.03 2.18 1.83
2.13 2.05 1.90 2.07 2.15 1.96 2.15 1.89 2.15 2.04
1.95 1.93 2.22 1.74 1.91
;
```

When you use kernel density estimates to explore a data distribution, you should try several choices for the bandwidth parameter c since this determines the smoothness and closeness of the fit. You can specify a list of $C=$ values with the KERNEL option to request multiple density estimates, as shown in the following statements:

```
ods graphics off;
title "FET Channel Length Analysis";
proc capability data=Channel noprint;
  histogram Length / kernel(c = 0.25 0.50 0.75 1.00);
run;
```

The display, shown in [Output 5.12.1](#), demonstrates the effect of c . In general, larger values of c yield smoother density estimates, and smaller values yield estimates that more closely fit the data distribution.

Output 5.12.1 Multiple Kernel Density Estimates

Output 5.12.1 reveals strong trimodality in the data, which are explored further in “Creating a One-Way Comparative Histogram” on page 286.

Example 5.13: Fitting a Three-Parameter Lognormal Curve

See CAPL3A in the SAS/QC Sample Library If you request a lognormal fit with the LOGNORMAL option, a *two-parameter* lognormal distribution is assumed. This means that the shape parameter σ and the scale parameter ζ are unknown (unless specified) and that the threshold θ is known (it is either specified with the THETA= option or assumed to be zero).

If it is necessary to estimate θ in addition to ζ and σ , the distribution is referred to as a *three-parameter* lognormal distribution. The equation for this distribution is the same as the equation given in section “Lognormal Distribution” on page 350 but the method of maximum likelihood must be modified. This example shows how you can request a three-parameter lognormal distribution.

A manufacturing process (assumed to be in statistical control) produces a plastic laminate whose strength must exceed a minimum of 25 psi. Samples are tested, and a lognormal distribution is observed for the strengths. It is important to estimate θ to determine whether the process is capable of meeting the strength requirement. The strengths for 49 samples are saved in the following data set:

```
data Plastic;
  label Strength='Strength in psi';
  input Strength @@;
  datalines;
30.26 31.23 71.96 47.39 33.93 76.15 42.21
81.37 78.48 72.65 61.63 34.90 24.83 68.93
43.27 41.76 57.24 23.80 34.03 33.38 21.87
31.29 32.48 51.54 44.06 42.66 47.98 33.73
25.80 29.95 60.89 55.33 39.44 34.50 73.51
43.41 54.67 99.43 50.76 48.81 31.86 33.88
35.57 60.41 54.92 35.66 59.30 41.96 45.32
;
```

The following statements use the LOGNORMAL option in the HISTOGRAM statement to display the fitted three-parameter lognormal curve shown in [Output 5.13.1](#):

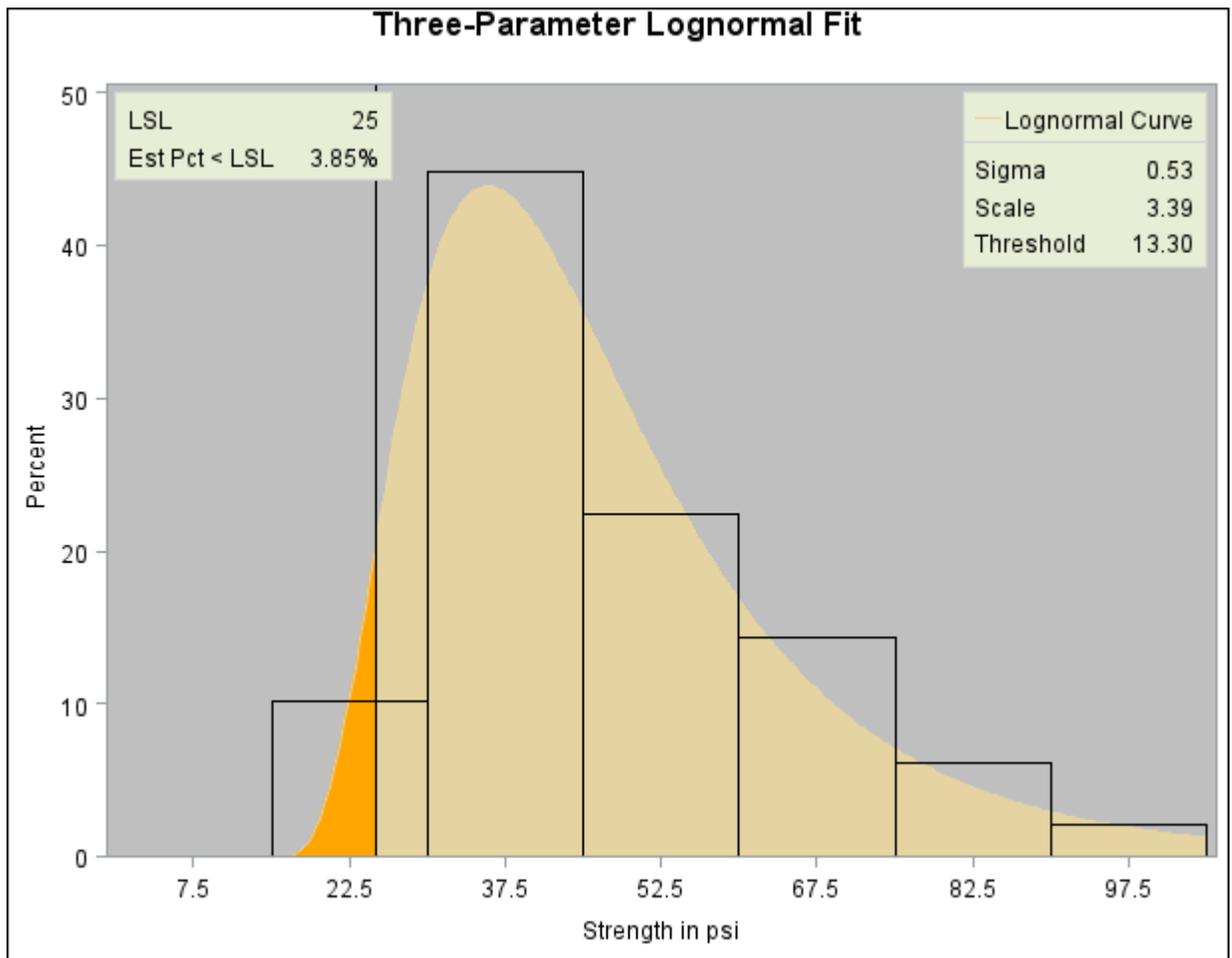

```
ods graphics off;
title 'Three-Parameter Lognormal Fit';
proc capability data=Plastic noprint;
  spec lsl=25 cleft=orange clsl=black;
  histogram Strength / lognormal(fill color = paoy
                                theta = est)
                    cfill = paoy
                    cframe = ligr
                    nolegend;
  inset lsl='LSL' lslpct / cfill = ywh pos=nw;
  inset lognormal      / format=6.2 pos=ne cfill = ywh;
run;
```

Specifying THETA=EST requests a *local* maximum likelihood estimate (LMLE) for θ , as described by Cohen (1951). This estimate is then used to compute maximum likelihood estimates for σ and ζ . The sample program CAPL3A illustrates a similar computational method implemented as a SAS/IML program.

Note that you can specify THETA=EST as a *Weibull-option* to fit a three-parameter Weibull distribution.

See CAPW3A in the SAS/QC Sample Library

Output 5.13.1 Three-Parameter Lognormal Fit

Example 5.14: Annotating a Folded Normal Curve

See *FNORM2* in the *SAS/QC Sample Library*. This example shows how to display a fitted curve that is not supported by the HISTOGRAM statement.

The offset of an attachment point is measured (in mm) for a number of manufactured assemblies, and the measurements are saved in a data set named *Assembly*.

```
data Assembly;
  label Offset = 'Offset (in mm)';
  input Offset @@;
  datalines;
11.11 13.07 11.42  3.92 11.08  5.40 11.22 14.69  6.27  9.76

 ;

The assembly process is in statistical control, and it is decided to fit a *folded normal distribution* to the offset measurements. A variable X has a folded normal distribution if $X = |Y|$, where Y is distributed as $N(\mu, \sigma)$. The fitted density is

$$h(x) = \frac{1}{\sqrt{2\pi}\sigma} \left[\exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) + \exp\left(-\frac{(x+\mu)^2}{2\sigma^2}\right) \right], \quad x \geq 0$$

You can use SAS/IML software to compute preliminary estimates of μ and σ based on a method of moments given by Elandt (1961). These estimates are computed by solving equation (19) of Elandt (1961), which is given by

$$f(\theta) = \frac{\left(\frac{2}{\sqrt{2\pi}}e^{-\theta^2/2} - \theta[1 - 2\Phi(\theta)]\right)^2}{1 + \theta^2} = A$$

where $\Phi(\cdot)$ is the standard normal distribution function, and

$$A = \frac{\bar{x}^2}{\frac{1}{n} \sum_{i=1}^n x_i^2}$$

Then the estimates of σ and μ are given by

$$\hat{\sigma}_0 = \sqrt{\frac{\frac{1}{n} \sum_{i=1}^n x_i^2}{1 + \hat{\theta}^2}}$$

$$\hat{\mu}_0 = \hat{\theta} \cdot \hat{\sigma}_0$$

Begin by using the MEANS procedure to compute the first and second moments and using the DATA step to compute the constant A .

```
proc means data = Assembly noprint;
  var Offset;
  output out=Stat mean=m1 var=var n=n min = min;
run;

* Compute constant A from equation (19) of Elandt (1961) ;
data Stat;
  keep m2 a min;
  set Stat;
  a = (m1*m1);
  m2 = ((n-1)/n)*var + a;
  a = a/m2;
run;
```

Next, use the SAS/IML subroutine NLPDD to solve equation (19) by minimizing $(f(\theta) - A)^2$, and compute $\hat{\mu}_0$ and $\hat{\sigma}_0$.

```

proc iml;
  use Stat;
  read all var {m2} into m2;
  read all var {a} into a;
  read all var {min} into min;

  * f(t) is the function in equation (19) of Elandt (1961) ;
  start f(t) global(a);
    y = .39894*exp(-0.5*t*t);
    y = (2*y-(t*(1-2*probnorm(t))))**2/(1+t*t);
    y = (y-a)**2;
    return(y);
  finish;

  * Minimize (f(t)-A)**2 and estimate mu and sigma ;
  if ( min < 0 ) then do;
    print "Warning: Observations are not all nonnegative.";
    print "      The folded normal is inappropriate.";
    stop;
  end;
  if ( a < 0.637 ) then do;
    print "Warning: the folded normal may be inappropriate";
  end;
  opt = { 0 0 };
  con = { 1e-6 };
  x0 = { 2.0 };
  tc = { . . . . . 1e-12 . . . . . };
  call nlpdd(rc,etheta0,"f",x0,opt,con,tc);
  esig0 = sqrt(m2/(1+etheta0*etheta0));
  emu0 = etheta0*esig0;

  create Prelim var {emu0 esig0 etheta0};
  append;
  close Prelim;
  * Define the log likelihood of the folded normal ;
  start g(p) global(x);
    y = 0.0;
    do i = 1 to nrow(x);
      z = exp( (-0.5/p[2])*(x[i]-p[1])*(x[i]-p[1]) );
      z = z + exp( (-0.5/p[2])*(x[i]+p[1])*(x[i]+p[1]) );
      y = y + log(z);
    end;
    y = y - nrow(x)*log( sqrt( p[2] ) );
    return(y);
  finish;
  * Maximize the log likelihood with subroutine NLPDD ;
  use Assembly;
  read all var {Offset} into x;
  esig0sq = esig0*esig0;
  x0 = emu0||esig0sq;
  opt = { 1 0 };
  con = { . 0.0, . . };
  call nlpdd(rc,xr,"g",x0,opt,con);

```

```

emu      = xr[1];
esig     = sqrt(xr[2]);
etheta   = emu/esig;
create Parmest var{emu esig etheta};
append;

run;

```

The data set Parmest saves the maximum likelihood estimates $\hat{\mu}$ and $\hat{\sigma}$ (as well as $\hat{\mu}/\hat{\sigma}$), as shown in [Output 5.14.2](#).

Output 5.14.2 Final Estimates of μ , σ , and θ

The Data Set PARMEST		
EMU	ESIG	ETHETA
6.66761	6.39650	1.04239

To annotate the curve on a histogram, begin by computing the width and endpoints of the histogram intervals. The following statements save these values in an OUTFIT= data set called OUT. Note that a plot is not produced at this point.

```

ods graphics off;
proc capability data = Assembly noprint;
  histogram Offset / outfit = Out normal(noprint) noplot;
run;

title 'OUTFIT= Data Set Out';
proc print data=Out noobs round;
var _var_ _curve_ _locatn_ _scale_ _chisq_ _df_ _pchisq_
  _midpt1_ _width_ _midptn_ _expect_ _eststd_ _adasq_
  _adp_ _cvmwsq_ _cvmp_ _ksd_ _ksp_;
run;

```

[Output 5.14.3](#) provides a partial listing of the data set Out. The width and endpoints of the histogram bars are saved as values of the variables `_WIDTH_`, `_MIDPT1_`, and `_MIDPTN_`. See “[Output Data Sets](#)” on page 367.

Output 5.14.3 The OUTFIT= Data Set Out

OUTFIT= Data Set Out										
VAR	_CURVE_	_LOCATN_	_SCALE_	_CHISQ_	_DF_	_PCHISQ_	_MIDPT1_	_WIDTH_		
Offset	NORMAL	7.62	5.24	31.17	5	0	1.5	3		
MIDPTN	_EXPECT_	_ESTSTD_	_ADASQ_	_ADP_	_CVMWSQ_	_CVMP_	_KSD_	_KSP_		
22.5	7.62	5.24	1.9	0.01	0.28	0.01	0.09	0.01		

The following statements create an annotate data set named Anno, which contains the coordinates of the fitted curve:

```

data Anno;
  merge Parmest Out;
  length function color $ 8;

  function = 'point';
  color    = 'black';
  size     = 2;
  xsys     = '2';
  ysys     = '2';
  when     = 'a';
  constant = 39.894*_width_;
  left     = _midpt1_ - .5*_width_;
  right    = _midptn_ + .5*_width_;
  inc      = (right-left)/100;
  do x = left to right by inc;
    z1 = (x-emu)/esig;
    z2 = (x+emu)/esig;
    y = (constant/esig)*(exp(-0.5*z1*z1)+exp(-0.5*z2*z2));
    output;
    function = 'draw';
  end;
run;

```

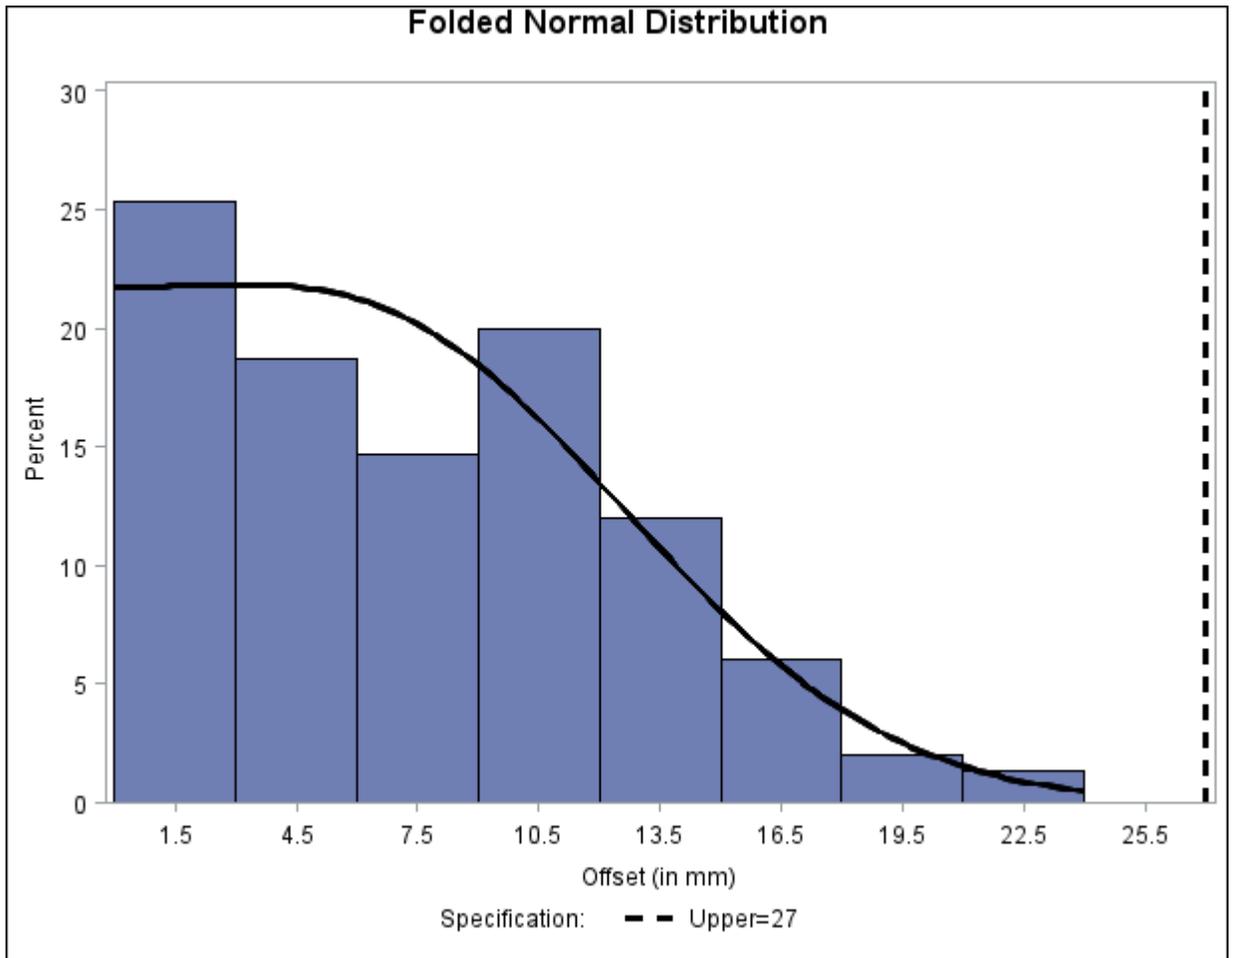

The following statements read the ANNOTATE= data set and display the histogram and fitted curve, as shown in [Output 5.14.4](#):

```

ods graphics off;
title "Folded Normal Distribution";
proc capability data=Assembly noprint;
  spec usl=27 cusl=black lusl=2 wusl=2;
  histogram Offset / annotate = Anno;
run;

```

Output 5.14.4 Histogram with Annotated Folded Normal Curve

INSET Statement: CAPABILITY Procedure

Overview: INSET Statement

Graphical displays such as histograms and probability plots are commonly used for process capability analysis. You can use the INSET statement to enhance these plots by adding a box or table (referred to as an *inset*) of summary statistics directly to the graph. An inset typically displays statistics calculated by the CAPABILITY procedure but can also display values provided in a SAS data set. A typical application of the INSET statement is to augment a histogram with the sample size, mean, standard deviation, and process capability index C_{pk} .

Note that the INSET statement by itself does not produce a display and must be used with the CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PPLOT, PROBPLOT, or QQPLOT statement.⁵

You can use options in the INSET statement to

- specify the position of the inset
- specify a header for the inset table
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

The INSET statement is not applicable when you produce line printer plots by specifying the LINEPRINTER option in the PROC CAPABILITY statement.

Getting Started: INSET Statement

This section introduces the INSET statement with examples that illustrate commonly used options. Complete syntax for the INSET statement is presented in the section “Syntax: INSET Statement” on page 402, and advanced examples are given in the section “Examples: INSET Statement” on page 423.

⁵In SAS 6.12 and in previous releases of SAS/QC software, the keyword GRAPHICS was required in the PROC CAPABILITY statement since the INSET statement only applies to graphical output.

Displaying Summary Statistics on a Histogram

See CAPINS1 in the SAS/QC Sample Library

In a plant producing copper wire, an important quality characteristic is the torsion strength, measured as the twisting force in pounds per inch necessary to break the wire. The following statements create the SAS data set Wire, which contains the torsion strengths (Strength) for 50 different wire samples:

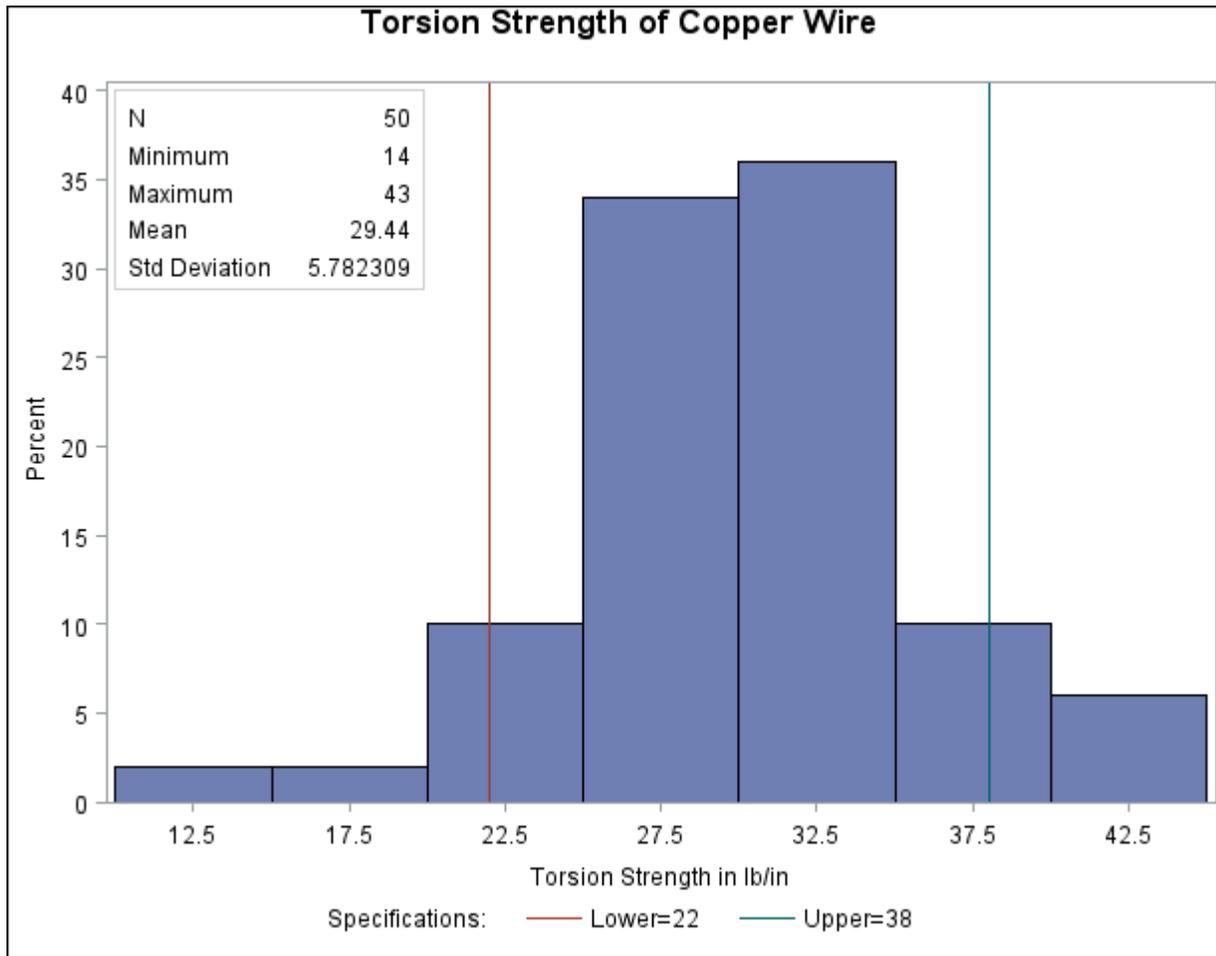

```
data Wire;
  label Strength='Torsion Strength in lb/in';
  input Strength @@;
  datalines;
25 25 36 31 26 36 29 37 37 20
34 27 21 35 30 41 33 21 26 26
19 25 14 32 30 29 31 26 22 24
34 33 28 26 43 30 40 32 32 31
25 26 27 34 33 27 33 29 30 31
;
```

A histogram is used to examine the data distribution. For a more complete report, the sample size, minimum value, maximum value, mean, and standard deviation are displayed on the histogram. The following statements illustrate how to inset these statistics:

```
ods graphics off;
title 'Torsion Strength of Copper Wire';
proc capability data=Wire noprint;
  spec lsl=22 usl=38;
  histogram Strength;
  inset n min max mean std;
run;
```

The resulting histogram is displayed in [Figure 5.17](#). The INSET statement immediately follows the plot statement that creates the graphical display (in this case, the HISTOGRAM statement). Specify the keywords for inset statistics (such as N, MIN, MAX, MEAN, and STD) immediately after the word INSET. The inset statistics appear in the order in which you specify the keywords.

Figure 5.17 A Histogram with an Inset

A complete list of keywords that you can use with the INSET statement is provided in “[Summary of INSET Keywords](#)” on page 405. Note that the set of keywords available for a particular display depends on both the plot statement that precedes the INSET statement and the options that you specify in the plot statement.

The following examples illustrate options commonly used for enhancing the appearance of an inset.

Formatting Values and Customizing Labels

See CAPINS1 in the SAS/QC Sample Library

By default, each inset statistic is identified with an appropriate label, and each numeric value is printed using an appropriate format. However, you may want to provide your own labels and formats. For example, in [Figure 5.17](#) the default format for the standard deviation prints an excessive number of decimal places. The following statements correct this problem, as well as customizing some of the labels displayed in the inset:

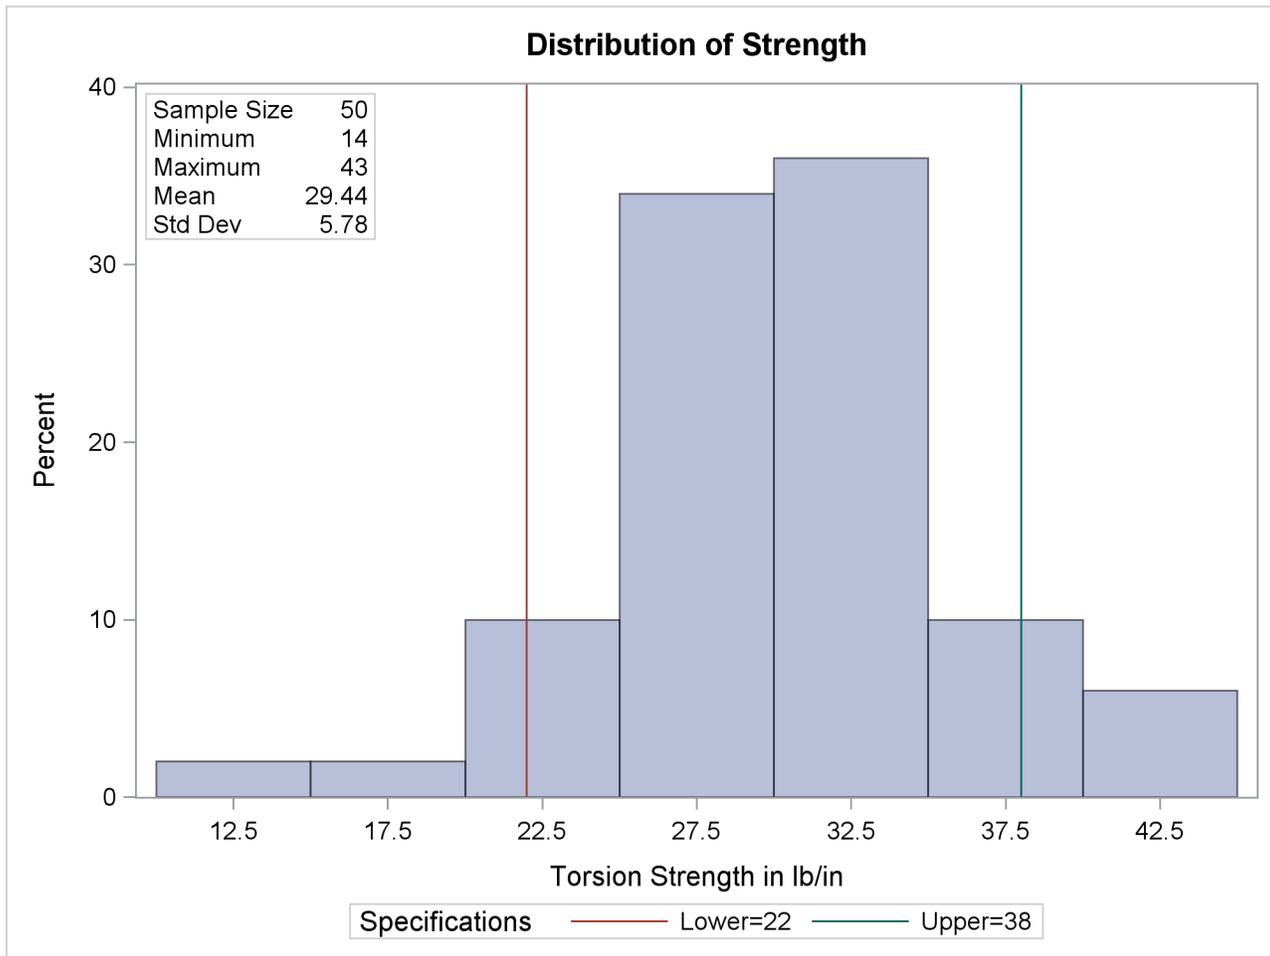

```
ods graphics on;
proc capability data=Wire noprint;
  spec lsl=22 usl=38;
  histogram Strength;
  inset n='Sample Size' min max mean std='Std Dev' (5.2);
run;
```

The ODS GRAPHICS ON statement specified before the PROC CAPABILITY statement enables ODS Graphics, so the histogram is created using ODS Graphics instead of traditional graphics.

The resulting histogram is displayed in [Figure 5.18](#). You can provide your own label by specifying the keyword for that statistic followed by an equal sign (=) and the label in quotes. The label can have up to 24 characters.

The format 5.2 specified in parentheses after the keyword STD displays the standard deviation with a field width of five and two decimal places. In general, you can specify any numeric SAS format in parentheses after an inset keyword. You can also specify a format to be used for all the statistics in the INSET statement with the FORMAT= option (see the next section, “[Adding a Header and Positioning the Inset](#)” on page 401). For more information about SAS formats, refer to *SAS Formats and Informats: Reference*.

Note that if you specify both a label and a format for a statistic, the label must appear before the format, as with the keyword STD in the previous statements.

Figure 5.18 Formatting Values and Customizing Labels in an Inset

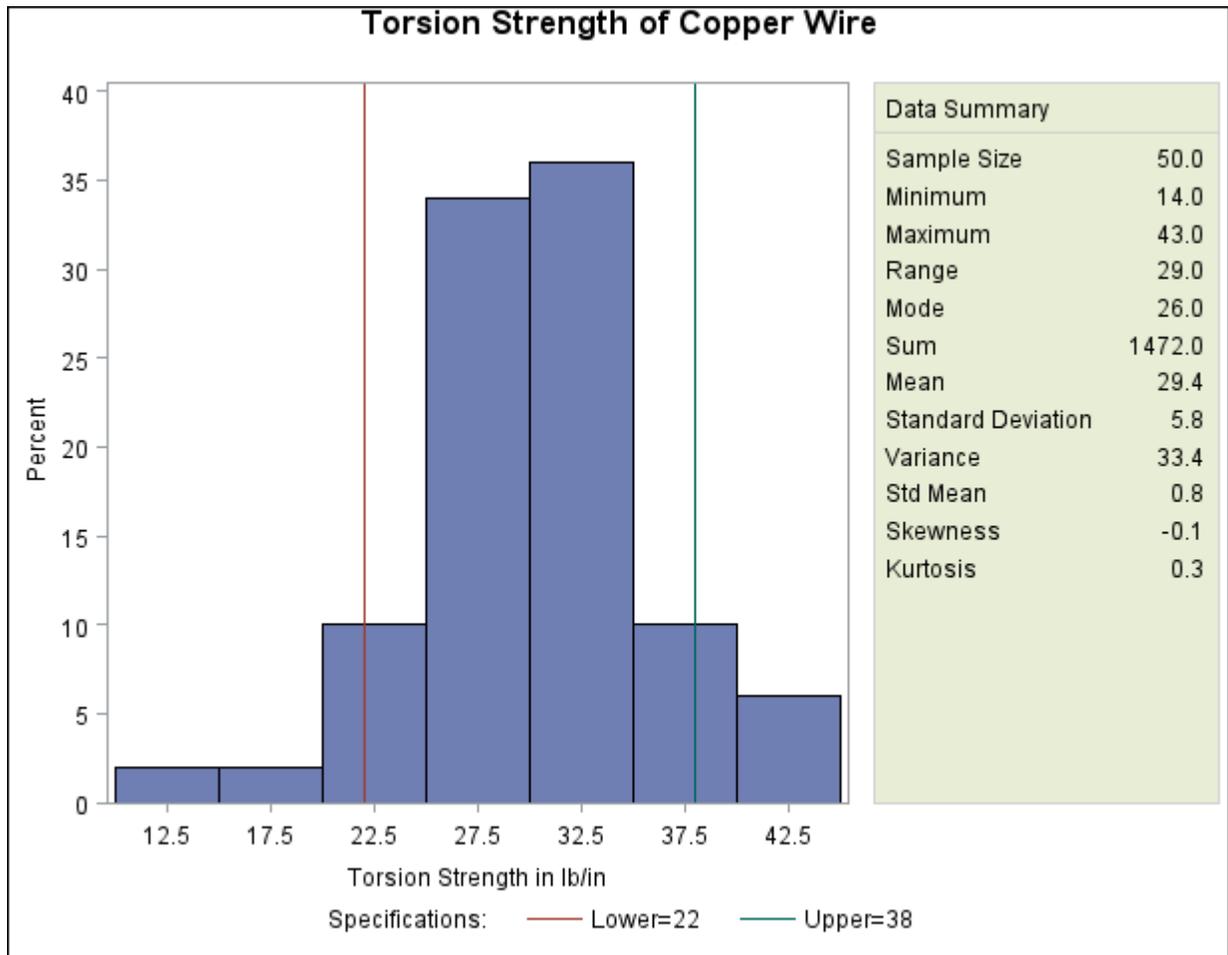

Adding a Header and Positioning the Inset

In the previous examples, the inset is displayed in the upper left corner of the plot, the default position for insets added to histograms. You can control the inset position with the `POSITION=` option. In addition, you can display a header at the top of the inset with the `HEADER=` option. The following statements create the chart shown in Figure 5.19: *See CAPINS1 in the SAS/QC Sample Library*

```
ods graphics off;
title 'Torsion Strength of Copper Wire';
proc capability data=Wire noprint;
  spec lsl=22 usl=38;
  histogram Strength;
  inset n='Sample Size' min max range mode sum mean
        std='Standard Deviation' var stdmean skewness
        kurtosis / format = 6.1
        pos      = rm
        header = 'Data Summary' cfill = ywh;
run;
```

The header (in this case, *Data Summary*) can be up to 40 characters. Note that a long list of inset statistics is requested. Consequently, POSITION=RM is specified to position the inset in the right margin. For more information about positioning, see “Details: INSET Statement” on page 418. Also note that the FORMAT= option is used to format all inset statistics. The options, such as HEADER=, POSITION=, and FORMAT=, are specified after the slash (/) in the INSET statement. For more details on INSET statement options, see “Dictionary of Options” on page 415.

Figure 5.19 Adding a Header and Repositioning the Inset

Syntax: INSET Statement

The syntax for the INSET statement is as follows:

```
INSET keyword-list </ options> ;
```

You can use any number of INSET statements in the CAPABILITY procedure. Each INSET statement produces an inset and must follow one of the plot statements: CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PPLOT, PROBPLOT, or QQPLOT. The inset appears in all displays produced by the plot statement that immediately precedes it. The statistics are displayed in the

order in which they are specified. For example, the following statements produce a cumulative distribution plot with two insets and a histogram with one inset:

```
proc capability data=Wire;
  cdfplot Strength;
    inset mean std min max n;
    inset p1 p5 p10;
  histogram Strength;
    inset var skewness kurtosis;
run;
```

The statistics displayed in an inset are computed for a specific process variable from observations for the current BY group. For example, in the following statements, there are two process variables (Strength and Diameter) and a BY variable (Batch). If there are three different batches (levels of Batch), then a total of six histograms are produced. The statistics in each inset are computed for a particular variable and batch. The labels in the inset are the same for each histogram.

```
proc capability data=Wire2;
  by Batch;
  histogram Strength Diameter / normal;
  inset mean std min max normal(mu sigma);
run;
```

The components of the INSET statement are described as follows.

keyword-list

can include any of the keywords listed in “[Summary of INSET Keywords](#)” on page 405. Some keywords allow *secondary keywords* to be specified in parentheses immediately after the *primary keyword*. Also, some inset statistics are available only if you request plot statements and options for which those statistics are calculated. For example, consider the following statements:

```
proc capability data=Wire;
  histogram Strength / normal;
  inset mean std normal(ad adpval);
run;
```

The keywords MEAN and STD display the sample mean and standard deviation of Strength. The primary keyword NORMAL with the secondary keywords AD and ADPVAL display the Anderson-Darling goodness-of-fit test statistic and *p*-value in the inset as well. The statistics specified with the NORMAL keyword are available only because a normal distribution has been fit to the data by using the NORMAL option in the HISTOGRAM statement. See the section “[Summary of INSET Keywords](#)”, which follows, for a list of available keywords.

Typically, you specify keywords, to display statistics computed by the CAPABILITY procedure. However, you can also specify the keyword DATA= followed by the name of a SAS data set to display customized statistics. This data set must contain two variables:

- a character variable named `_LABEL_` whose values provide labels for inset entries.
- a variable named `_VALUE_`, which can be either character or numeric, and whose values provide values for inset entries.

The label and value from each observation in the DATA= data set occupy one line in the inset. The position of the DATA= keyword in the keyword list determines the position of its lines in the inset.

By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the keyword for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the keyword. Note that if you specify both a label and a format for a statistic, the label must appear before the format. For an example, see “[Formatting Values and Customizing Labels](#)” on page 400.

options

appear after the slash (/) and control the appearance of the inset. For example, the following INSET statement uses two appearance options (POSITION= and CTEXT=):

```
inset mean std min max / position=ne ctext=yellow;
```

The POSITION= option determines the location of the inset, and the CTEXT= option specifies the color of the text of the inset.

See “[Summary of Options](#)” on page 414 for a list of all available options, and “[Dictionary of Options](#)” on page 415 for detailed descriptions. Note the difference between keywords and options; keywords specify the information to be displayed in an inset, whereas options control the appearance of the inset.

Summary of INSET Keywords

Summary Statistics and Process Capability Indices

Table 5.32 Summary Statistics

Keyword	Description
CSS	corrected sum of squares
CV	coefficient of variation
KURTOSIS KURT	kurtosis
MAX	largest value
MEAN	sample mean
MIN	smallest value
MODE	most frequent value
N	sample size
NEXCL	number of observations excluded by MAXNBIN= or MAXSIGMAS= option
NMISS	number of missing values
NOBS	number of observations
RANGE	range
SKEWNESS SKEW	skewness
STD STDDEV	standard deviation
STDMEAN STDERR	standard error of the mean
SUM	sum of the observations
SUMWGT	sum of the weights
USS	uncorrected sum of squares
VAR	variance

Table 5.33 Percentile Statistics

Keyword	Description
P1	1st percentile
P5	5th percentile
P10	10th percentile
Q1 P25	lower quartile (25th percentile)
MEDIAN Q2 P50	median (50th percentile)
Q3 P75	upper quartile (75th percentile)
P90	90th percentile
P95	95th percentile
P99	99th percentile
QRANGE	interquartile range (Q3 - Q1)

Table 5.34 lists keywords for distribution-free confidence limits for percentiles requested with the CIPCTLDF option.

Table 5.34 Keywords for Distribution-Free Confidence Limits for Percentiles

Keyword	Description
P1_LCL_DF	1st percentile lower confidence limit
P1_UCL_DF	1st percentile upper confidence limit
P5_LCL_DF	5th percentile lower confidence limit
P5_UCL_DF	5th percentile upper confidence limit
P10_LCL_DF	10th percentile lower confidence limit
P10_UCL_DF	10th percentile upper confidence limit
Q1_LCL_DF P25_LCL_DF	lower quartile (25th percentile) lower confidence limit
Q1_UCL_DF P25_UCL_DF	lower quartile (25th percentile) upper confidence limit
MEDIAN_LCL_DF Q2_LCL_DF P50_LCL_DF	median (50th percentile) lower confidence limit
MEDIAN_UCL_DF Q2_UCL_DF P50_UCL_DF	median (50th percentile) upper confidence limit
Q3_LCL_DF P75_LCL_DF	upper quartile (75th percentile) lower confidence limit
Q3_UCL_DF	
P75_UCL_DF	upper quartile (75th percentile) upper confidence limit
P90_LCL_DF	90th percentile lower confidence limit
P90_UCL_DF	90th percentile upper confidence limit
P95_LCL_DF	95th percentile lower confidence limit
P95_UCL_DF	95th percentile upper confidence limit
P99_LCL_DF	99th percentile lower confidence limit
P99_UCL_DF	99th percentile upper confidence limit

Table 5.35 lists keywords for percentile confidence limits computed assuming normality requested with the CIPCTLNORMAL option.

Table 5.35 Keywords Percentile Confidence Limits Assuming Normality

Keyword	Description
P1_LCL	1st percentile lower confidence limit
P1_UCL	1st percentile upper confidence limit
P5_LCL	5th percentile lower confidence limit
P5_UCL	5th percentile upper confidence limit
P10_LCL	10th percentile lower confidence limit
P10_UCL	10th percentile upper confidence limit
Q1_LCL P25_LCL	lower quartile (25th percentile) lower confidence limit
Q1_UCL P25_UCL	lower quartile (25th percentile) upper confidence limit
MEDIAN_LCL Q2_LCL P50_LCL	median (50th percentile) lower confidence limit
MEDIAN_UCL Q2_UCL P50_UCL	median (50th percentile) upper confidence limit
Q3_LCL P75_LCL	upper quartile (75th percentile) lower confidence limit
Q3_UCL P75_UCL	upper quartile (75th percentile) upper confidence limit
P90_LCL	90th percentile lower confidence limit
P90_UCL	90th percentile upper confidence limit
P95_LCL	95th percentile lower confidence limit
P95_UCL	95th percentile upper confidence limit
P99_LCL	99th percentile lower confidence limit
P99_UCL	99th percentile upper confidence limit

Table 5.36 Robust Statistics

Keyword	Description
GINI	Gini's mean difference
MAD	median absolute difference about the median
QN	Q_n , alternative to MAD
SN	S_n , alternative to MAD
STD_GINI	Gini's standard deviation
STD_MAD	MAD standard deviation
STD_QN	Q_n standard deviation
STD_QRANGE	interquartile range standard deviation
STD_SN	S_n standard deviation

Table 5.37 Hypothesis Testing

Keyword	Description
MSIGN	sign statistic
NORMALTEST	test statistic for normality
PNORMAL	probability value for the test of normality
SIGNRANK	signed rank statistic
PROBM	probability of greater absolute value for the sign statistic
PROBN	probability value for the test of normality
PROBS	probability value for the signed rank test
PROBT	probability value for the Student's t test
T	statistics for Student's t test

Table 5.38 Input Data Set

Keyword	Description
DATA=	(label, value) pairs from input data set

Table 5.39 Capability Indices and Confidence Limits

Keyword	Description
CP	capability index C_p
CPLCL	lower confidence limit for C_p
CPUCL	upper confidence limit for C_p
CPK	capability index C_{pk}
CPKLCL	lower confidence limit for C_{pk}
CPKUCL	upper confidence limit for C_{pk}
CPL	capability index CPL
CPM	capability index C_{pm}
CPMLCL	lower confidence limit for C_{pm}
CPMUCL	upper confidence interval for C_{pm}
CPU	capability index CPU
K	capability index K

Table 5.40 Specification Limits and Related Information

Keyword	Description
LSL	lower specification limit
USL	upper specification limit
TARGET	target value
PCTGTR	percent of nonmissing observations that exceed the upper specification limit
PCTLSS	percent of nonmissing observations that are less than the lower specification limit
PCTBET	percent of nonmissing observations between the upper and lower specification limits (inclusive)

Statistics Available with Parametric Density Estimates

You can request parametric density estimates with all plot statements in the CAPABILITY procedure (CDFPLOT, COMPHISTOGRAM, HISTOGRAM, PPLOT, PROBPLOT, and QQPLOT). You can display parameters and statistics associated with these estimates in an inset by specifying a distribution keyword followed by secondary keywords in parentheses. For example, the following statements create a histogram for Strength with a fitted exponential density curve:

```
proc capability data=Wire;
  histogram Strength / exp;
  inset exp(sigma theta);
run;
```

The secondary keywords SIGMA and THETA for the EXP distribution keyword request an inset displaying the values of the exponential scale parameter σ and threshold parameter θ . You must request the distribution option in the plot statement to display the corresponding distribution statistics in an inset. Specifying a distribution keyword with no secondary keywords produces an inset displaying the full set of parameters for that distribution. See [Output 5.15.1](#) for an example of an inset with statistics from a fitted normal curve.

The following table describes the available distribution keywords. Note that some keywords are not available with all plot statements.

Table 5.41 Density Estimation Primary Keywords

Keyword	Distribution	Plot Statement Availability
BETA	beta	all but COMPHISTOGRAM
EXPONENTIAL	exponential	all but COMPHISTOGRAM
GAMMA	gamma	all but COMPHISTOGRAM
GUMBEL	Gumbel	all but COMPHISTOGRAM
IGAUSS	inverse Gaussian	CDFPLOT, HISTOGRAM, PPLOT
LOGNORMAL	lognormal	all but COMPHISTOGRAM
NORMAL	normal	all
PARETO	generalized Pareto	all but COMPHISTOGRAM
POWER	power function	all but COMPHISTOGRAM
RAYLEIGH	Rayleigh	all but COMPHISTOGRAM
SB	Johnson S_B	HISTOGRAM
SU	Johnson S_U	HISTOGRAM
WEIBULL	Weibull	all but COMPHISTOGRAM
WEIBULL2	2-parameter Weibull	PROBPLOT, QQPLOT

Table 5.42 lists the secondary keywords available with each distribution keyword listed in Table 5.41. In many cases, aliases can be used (for example, ALPHA in place of SHAPE1).

Table 5.42 Density Estimation Secondary Keywords

Secondary Keyword	Alias	Description
Secondary Keywords Available with the BETA Keyword		
ALPHA	SHAPE1	first shape parameter α
BETA	SHAPE2	second shape parameter β
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	lower threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the EXPONENTIAL Keyword		
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the GAMMA Keyword		
ALPHA	SHAPE	shape parameter α
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the GUMBEL Keyword		
MU		location parameter μ
SIGMA	SCALE	scale parameter σ
MEAN		mean of the fitted distribution

Table 5.42 (continued)

Secondary Keyword	Alias	Description
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the IGAUSS Keyword		
MU		mean parameter μ
LAMBDA		shape parameter λ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the LOGNORMAL Keyword		
SIGMA	SHAPE	shape parameter σ
THETA	THRESHOLD	threshold parameter θ
ZETA	SCALE	scale parameter ζ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the NORMAL Keyword		
MU	MEAN	mean parameter μ
SIGMA	STD	scale parameter σ
Secondary Keywords Available with the PARETO Keyword		
ALPHA		shape parameter α
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the POWER Keyword		
ALPHA		shape parameter α
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the RAYLEIGH Keyword		
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the SB Keyword		
DELTA	SHAPE1	shape parameter δ
GAMMA	SHAPE2	shape parameter γ
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the SU Keyword		
DELTA	SHAPE1	shape parameter δ
GAMMA	SHAPE2	shape parameter γ
SIGMA	SCALE	scale parameter σ

Table 5.42 (continued)

Secondary Keyword	Alias	Description
THETA		location parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the WEIBULL Keyword		
C	SHAPE	shape parameter c
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	threshold parameter θ
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution
Secondary Keywords Available with the WEIBULL2 Keyword		
C	SHAPE	shape parameter c
SIGMA	SCALE	scale parameter σ
THETA	THRESHOLD	known lower threshold θ_0
MEAN		mean of the fitted distribution
STD		standard deviation of the fitted distribution

The secondary keywords listed in Table 5.43 can be used with any distribution keyword but *only* with the HISTOGRAM and COMPHISTOGRAM plot statements.

Table 5.43 Statistics Computed from Any Parametric Density Estimate

Secondary Keyword	Description
CP	capability index C_p
CPK	capability index C_{pk}
CPL	capability index C_{PL}
CPM	capability index C_{pm}
CPU	capability index C_{PU}
ESTPCTLSS	estimated percentage less than the lower specification limit
ESTPCTGTR	estimated percentage greater than the upper specification limit
K	capability index K

The secondary keywords listed in Table 5.44 can be used with any distribution keyword but *only* with the HISTOGRAM plot statement (see Example 5.15).

Table 5.44 Goodness-of-Fit Statistics for Fitted Curves

Secondary Keyword	Description
CHISQ	chi-square statistic
DF	degrees of freedom for the chi-square test
PCHISQ	probability value for the chi-square test
AD	Anderson-Darling EDF test statistic
ADPVAL	Anderson-Darling EDF test p -value
CVM	Cramér-von Mises EDF test statistic
CVMPVAL	Cramér-von Mises EDF test p -value
KSD	Kolmogorov-Smirnov EDF test statistic
KSDPVAL	Kolmogorov-Smirnov EDF test p -value

Table 5.45 lists primary keywords available only with the HISTOGRAM and COMPHISTOGRAM plot statements. These keywords display fill areas on a histogram. If you fit a parametric density on a histogram and request that the area under the curve be filled, these keywords display the percentage of the distribution area that lies below the lower specification limit, between the specification limits, or above the upper specification limit. If you do not fill the area beneath a parametric density estimate, these keywords display the observed proportion of observations (that is, the area in the bars of the histogram).

You should use these options with the FILL, CFILL=, and PFILL= options in the HISTOGRAM and COMPHISTOGRAM statements and with the CLEFT=, CRIGHT=, PLEFT=, and PRIGHT= options in the SPEC statements. See [Output 5.16.1](#) for an example.

Table 5.45 Curve Area Keywords

Keyword	Alias	Description
BETWEENPCT	BETPCT	area between the specification limits
LSLPCT		area below the lower specification limit
USLPCT		area above the upper specification limit

Statistics Available with Nonparametric Kernel Density Estimates

You can request nonparametric kernel density estimates with the HISTOGRAM and COMPHISTOGRAM plot statements. You can display statistics associated with these estimates by specifying a kernel density keyword followed by secondary keywords in parentheses. For example, the following statements create a histogram for Strength with a fitted kernel density estimate:

```
proc capability data=Wire;
  histogram Strength / kernel;
  inset kernel(c amise);
run;
```

The secondary keywords C and AMISE for the KERNEL keyword display the values of the standardized bandwidth c and the approximate mean integrated square error.

Note that you can specify more than one kernel density estimate on a single histogram. If you specify multiple kernel density estimates, you can request inset statistics for all of the estimates with the `KERNEL` keyword, or you can display inset statistics for up to five individual curves with `KERNEL n` keywords, as in the following example:

```
proc capability data=Wire;
  histogram Strength / kernel(c = 1 2 3);
  inset kernel2(c) kernel3(c);
run;
```

Three kernel density estimates are displayed on the histogram, but the inset displays the value of c only for the second and third estimates.

Table 5.46 lists the kernel density keywords. Table 5.47 lists the available secondary keywords.

Table 5.46 Kernel Density Estimate Primary Keywords

Keyword	Description
KERNEL	displays statistics for all kernel estimates
KERNEL n	displays statistics for only the n th kernel density estimate $n = 1, 2, 3, 4, \text{ or } 5$

Table 5.47 Secondary Keywords Available with the `KERNEL` Keyword

Secondary Keyword	Description
TYPE	kernel type: normal, quadratic, or triangular
BANDWIDTH	bandwidth λ for the density estimate
BWIDTH	alias for BANDWIDTH
C	standardized bandwidth c for the density estimate: $c = \frac{\lambda}{Q} n^{\frac{1}{5}}$ where n = sample size, λ = bandwidth, and Q = interquartile range
AMISE	approximate mean integrated square error (MISE) for the kernel density

Summary of Options

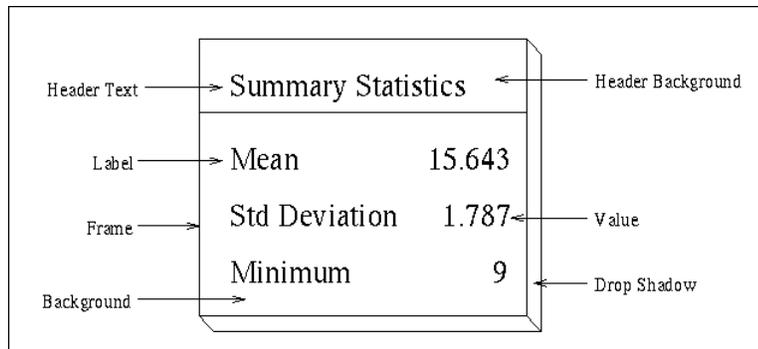

The following table lists the `INSET` statement options. For complete descriptions, see the section “Dictionary of Options”, which follows this section.

Table 5.48 INSET Options

Option	Description
CFILL=	specifies color of inset background
CFILLH=	specifies color of header background
CFRAME=	specifies color of frame
CHEADER=	specifies color of header text
CSHADOW=	specifies color of drop shadow
CTEXT=	specifies color of inset text
DATA	specifies data units for POSITION=(<i>x</i> , <i>y</i>) coordinates
FONT=	specifies font of text
FORMAT=	specifies format of values in inset
GUTTER=	specifies gutter width for inset in top or bottom margin
HEADER=	specifies header text
HEIGHT=	specifies height of inset text
NCOLS=	specifies number of columns for inset in top or bottom margin
NOFRAME	suppresses frame around inset
POSITION=	specifies position of inset
REFPOINT=	specifies reference point of inset positioned with POSITION=(<i>x</i> , <i>y</i>) coordinates

Dictionary of Options

The following entries provide detailed descriptions of options for the INSET statement. The marginal notes *Traditional Graphics* and *ODS Graphics* identify options that apply only to traditional graphics and ODS Graphics output, respectively. Terms used in this section are illustrated in Figure 5.20.

Figure 5.20 The Inset

CFILL=*color* | BLANK*Traditional Graphics*

specifies the color of the background (including the header background if you do not specify the CFILLH= option). See [Output 5.15.1](#) for an example.

If you do not specify the CFILL= option, then by default, the background is empty. This means that items that overlap the inset (such as curves, histogram bars, or specification limits) show through the inset. If you specify any value for the CFILL= option, then overlapping items no longer show through the inset. Specify CFILL=BLANK to leave the background uncolored and also to prevent items from showing through the inset.

CFILLH=*color**Traditional Graphics*

specifies the color of the header background. By default, if you do not specify a CFILLH= color, the CFILL= color is used.

CFRAME=*color**Traditional Graphics*

specifies the color of the frame. By default, the frame is the same color as the axis of the plot.

CHEADER=*color**Traditional Graphics*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, the CTEXT= color is used.

CSHADOW=*color***CS=*color****Traditional Graphics*

specifies the color of the drop shadow. See [Output 5.16.1](#) for an example. By default, if you do not specify the CSHADOW= option, a drop shadow is not displayed.

CTEXT=*color***CT=*color****Traditional Graphics*

specifies the color of the text. By default, the inset text color is the same as the other text on the plot.

DATA

specifies that data coordinates are to be used in positioning the inset with the POSITION= option. The DATA option is available only when you specify POSITION= (x, y), and it must be placed immediately after the coordinates (x, y). For details, see the entry for the POSITION= option or “[Positioning the Inset Using Coordinates](#)” on page 420. See [Figure 5.23](#) for an example.

FONT=*font**Traditional Graphics*

specifies the font of the text. By default, the font is SIMPLEX if the inset is located in the interior of the plot, and the font is the same as the other text displayed on the plot if the inset is located in the exterior of the plot.

FORMAT=*format*

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option. See [Figure 5.19](#) or [Output 5.15.1](#) for an example.

GUTTER=value

specifies the gutter width in percent screen units for an inset located in the top or bottom margin. The gutter is the space between columns of (label, value) pairs in an inset. The default value is four. *ODS Graphics*

HEADER= 'string'

specifies the header text. The *string* cannot exceed 40 characters. If you do not specify the HEADER= option, no header line appears in the inset. If all the keywords listed in the INSET statement are secondary keywords corresponding to a fitted curve on a histogram, a default header is displayed that indicates the distribution and identifies the curve. See [Figure 5.19](#) for an example of a specified header and [Output 5.15.1](#) for an example of the default header for a fitted normal curve.

HEIGHT=value

specifies the height of the text. *Traditional Graphics*

NCOLS=n

specifies the number of columns of (label, value) pairs displayed in an inset located in the top or bottom margin. The default value is three. *ODS Graphics*

NOFRAME

suppresses the frame drawn around the text.

POSITION=position**POS=position**

determines the position of the inset. The *position* can be a compass point keyword, a margin keyword, or a pair of coordinates (x, y). You can specify coordinates in axis percent units or axis data units. For more information, see “[Details: INSET Statement](#)” on page 418. By default, POSITION=NW, which positions the inset in the upper left (northwest) corner of the display.

NOTE: In this release of the CAPABILITY procedure, you cannot specify coordinates with the POSITION= option when producing ODS Graphics output.

REFPOINT=BR | BL | TR | TL**RP=BR | BL | TR | TL**

specifies the reference point for an inset that is positioned by a pair of coordinates with the POSITION= option. Use the REFPOINT= option with POSITION= coordinates. The REFPOINT= option specifies which corner of the inset frame you want positioned at coordinates (x, y). The keywords BL, BR, TL, and TR represent bottom left, bottom right, top left, and top right, respectively. See [Figure 5.24](#) for an example. The default is REFPOINT=BL. *Traditional Graphics*

If you specify the position of the inset as a compass point or margin keyword, the REFPOINT= option is ignored. For more information, see “[Positioning the Inset Using Coordinates](#)” on page 420.

Details: INSET Statement

This section provides details on three different methods of positioning the inset with the POSITION= option. With the POSITION= option, you can specify

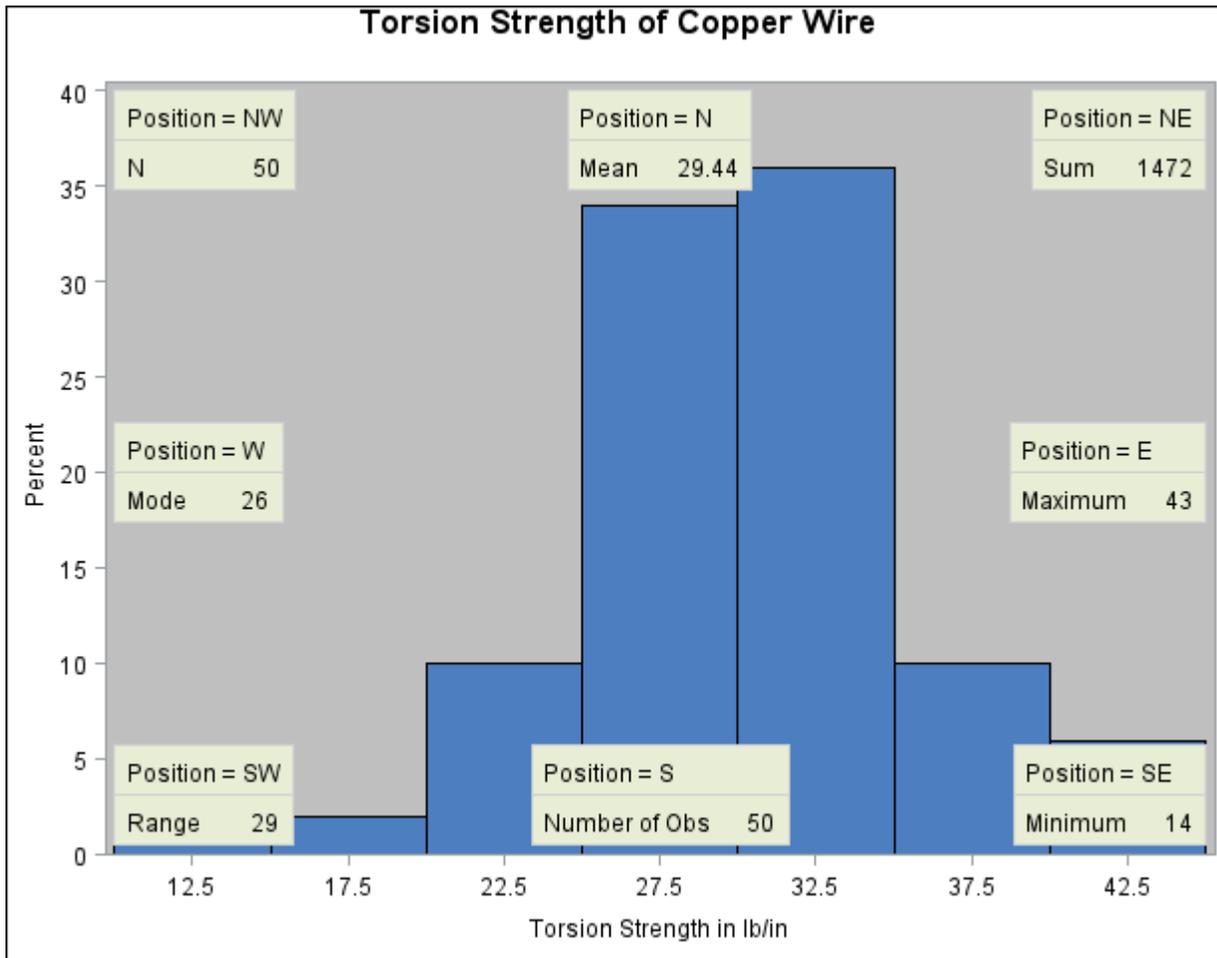

- compass points
- keywords for margin positions
- coordinates in data units or percent axis units

Positioning the Inset Using Compass Points

See CAPINS2 in the SAS/QC Sample Library You can specify the eight compass points N, NE, E, SE, S, SW, W, and NW as keywords for the POSITION= option. The following statements create the display in [Figure 5.21](#), which demonstrates all eight compass positions. The default is NW.

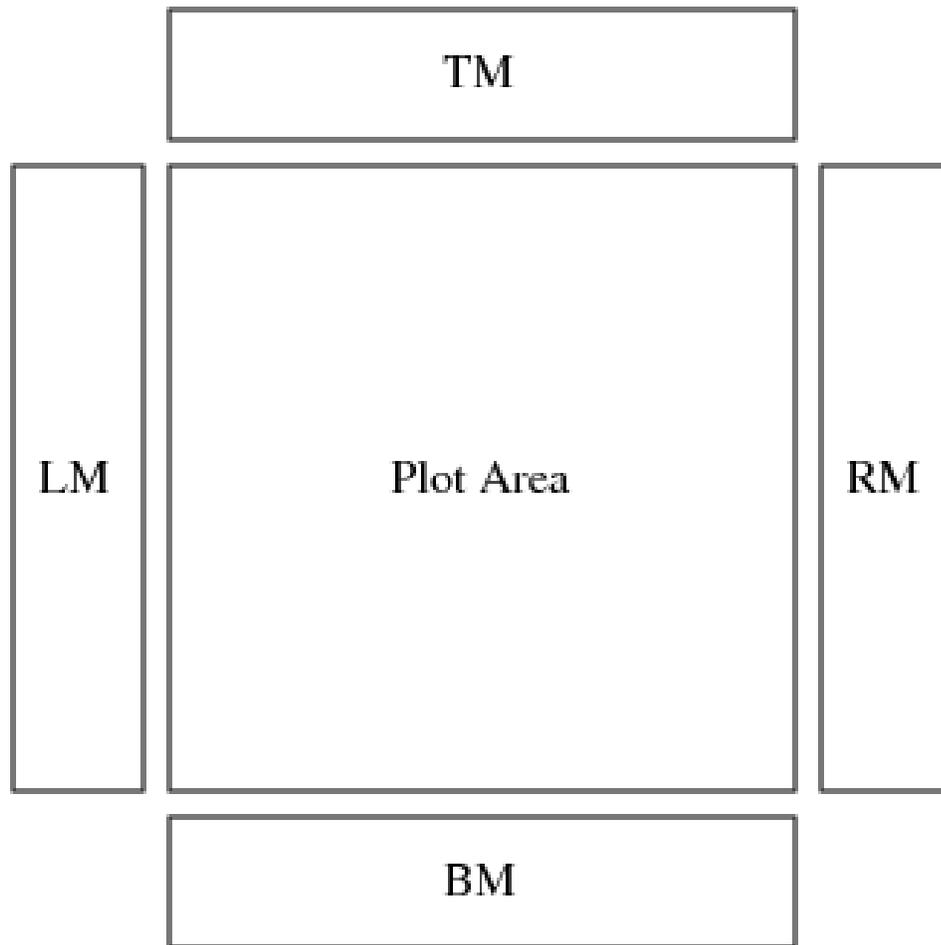

```
ods graphics off;
title 'Torsion Strength of Copper Wire';
proc capability data=Wire;
  histogram Strength / cfill = bigb
                    cframe = ligr;
  inset n          / cfill=ywh header='Position = NW' pos=nw;
  inset mean      / cfill=ywh header='Position = N ' pos=n ;
  inset sum       / cfill=ywh header='Position = NE' pos=ne;
  inset max       / cfill=ywh header='Position = E ' pos=e ;
  inset min       / cfill=ywh header='Position = SE' pos=se;
  inset nobs      / cfill=ywh header='Position = S ' pos=s ;
  inset range     / cfill=ywh header='Position = SW' pos=sw;
  inset mode      / cfill=ywh header='Position = W ' pos=w ;
run;
```

Figure 5.21 Insets Positioned Using Compass Points

Positioning the Inset in the Margins

You can also position the inset in one of the four margins surrounding the plot area using the margin keywords LM, RM, TM, or BM, as illustrated in Figure 5.22.

Figure 5.22 Positioning Insets in the Margins

For an example of an inset placed in the right margin, see [Figure 5.19](#). Margin positions are recommended if a large number of statistics are listed in the INSET statement. If you attempt to display a lengthy inset in the interior of the plot, it is likely that the inset will collide with the data display.

Positioning the Inset Using Coordinates

You can also specify the position of the inset with coordinates: `POSITION= (x, y)`. The coordinates can be given in axis percent units (the default) or in axis data units.

NOTE: In this release of the CAPABILITY procedure, you cannot position insets by using coordinates when producing ODS Graphics output.

Data Unit Coordinates

If you specify the DATA option immediately following the coordinates, the inset is positioned using axis data units. For example, the following statements place the bottom left corner of the inset at 12.5 on the horizontal axis and 10 on the vertical axis: *See CAPINS2 in the SAS/QC Sample Library*

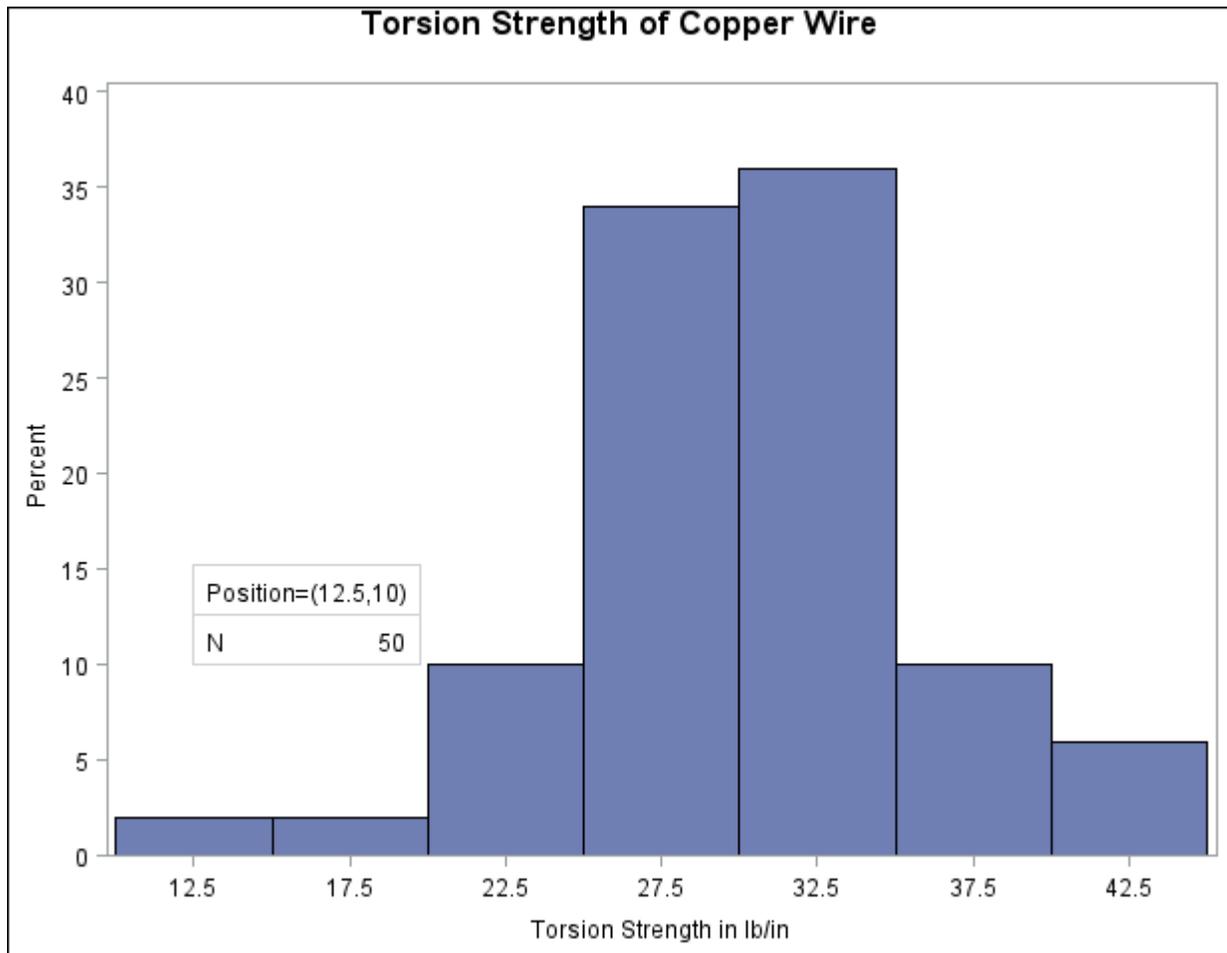

```

title 'Torsion Strength of Copper Wire';
proc capability data=Wire;
  histogram Strength;
  inset n / header = 'Position=(12.5,10)'
           position = (12.5,10) data;
run;

```

The histogram is displayed in [Figure 5.23](#). By default, the specified coordinates determine the position of the bottom left corner of the inset. You can change this reference point with the REFPOINT= option, as in the next example.

Figure 5.23 Inset Positioned Using Data Unit Coordinates

Axis Percent Unit Coordinates

See CAPINS2 in the
SAS/QC Sample Library

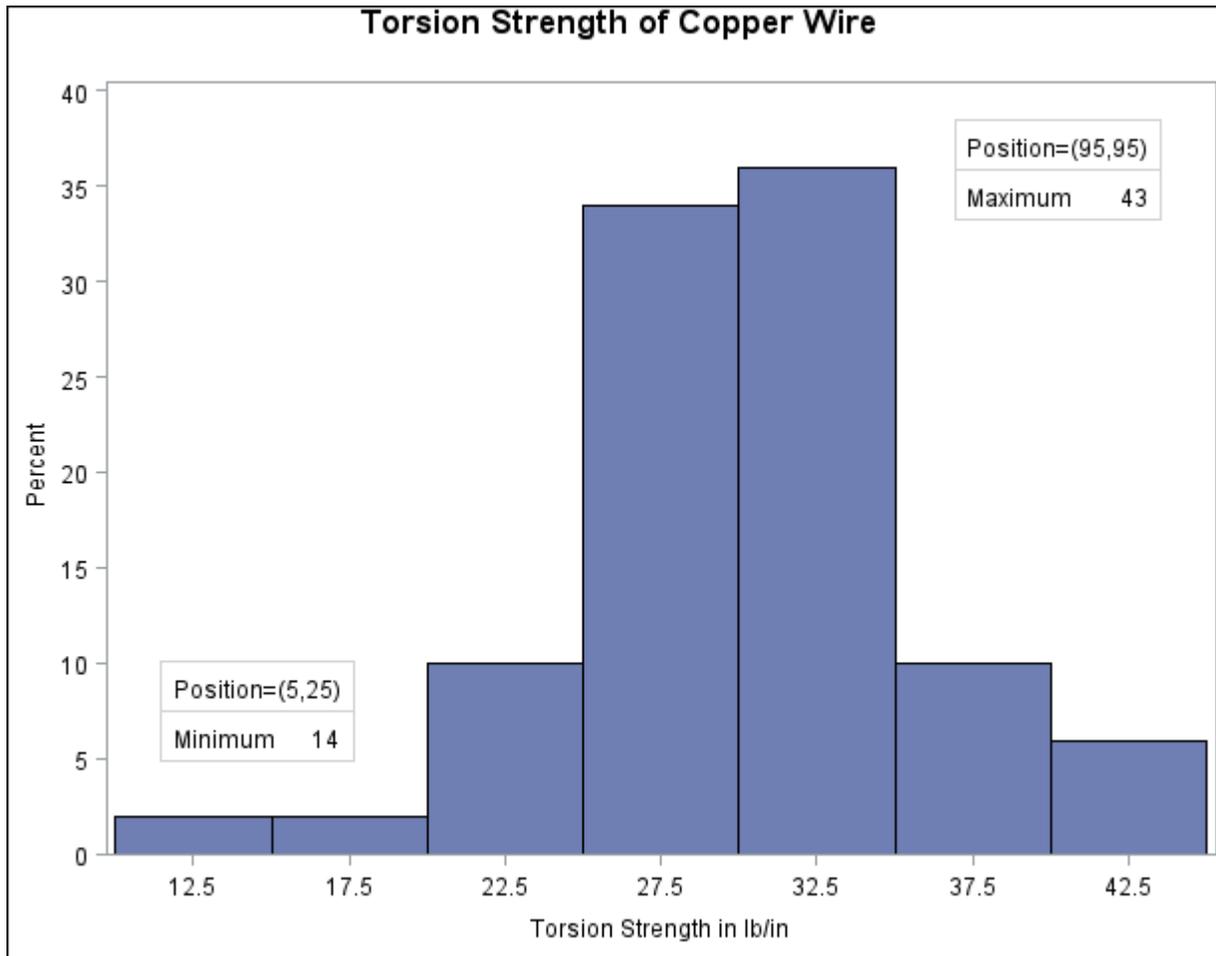

If you do not use the DATA option, the inset is positioned using axis percent units. The coordinates of the bottom left corner of the display are (0, 0), while the upper right corner is (100, 100). For example, the following statements create a histogram with two insets, both positioned using coordinates in axis percent units:

```

title 'Torsion Strength of Copper Wire';
proc capability data=Wire;
  histogram Strength;
  inset min / position = (5,25)
           header   = 'Position=(5,25) '
           refpoint = tl;
  inset max / position = (95,95)
           header   = 'Position=(95,95) '
           refpoint = tr;
run;

```

The display is shown in [Figure 5.24](#). Notice that the REFPOINT= option is used to determine which corner of the inset is to be placed at the coordinates specified with the POSITION= option. The first inset has REFPOINT=TL, so the top left corner of the inset is positioned 5% of the way across the horizontal axis and 25% of the way up the vertical axis. The second inset has REFPOINT=TR, so the top right corner of the inset is positioned 95% of the way across the horizontal axis and 95% of the way up the vertical axis. Note also that coordinates in axis percent units must be *between* 0 and 100.

Figure 5.24 Inset Positioned Using Axis Percent Unit Coordinates

Examples: INSET Statement

This section provides advanced examples that use the INSET statement.

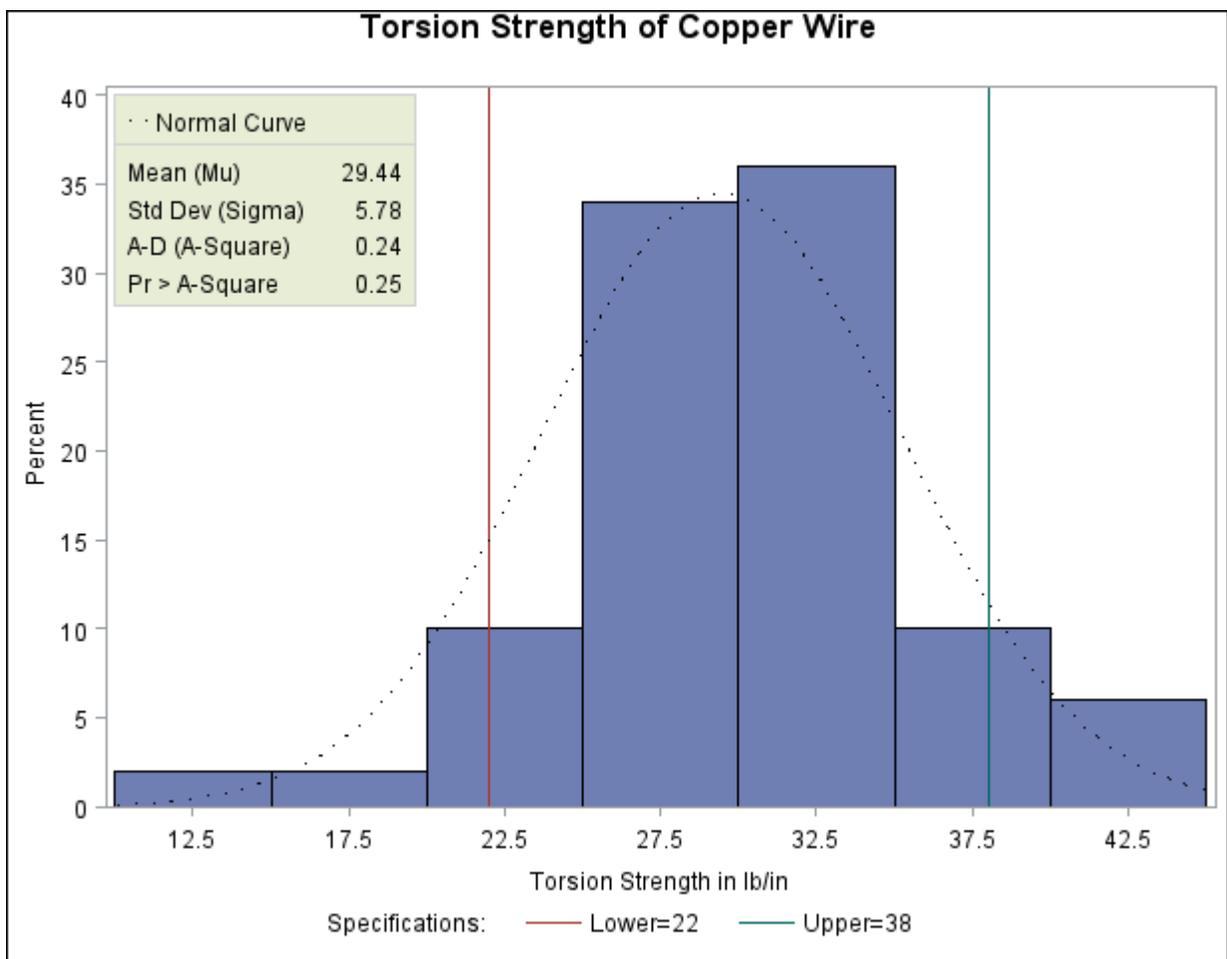

Example 5.15: Inset for Goodness-of-Fit Statistics

This example fits a normal curve to the torsion strength data used in the section “Getting Started: *See CAPINS3 in the SAS/QC Sample Library* INSET Statement” on page 397. The following statements fit a normal curve and request an inset summarizing the fitted curve with the mean, the standard deviation, and the Anderson-Darling goodness-of-fit test:

```
ods graphics off;
title 'Torsion Strength of Copper Wire';
proc capability data=Wire noprint;
  spec lsl=22 usl=38;
  histogram Strength / normal(color=black noprint l=34)
    nocurvelegend;
  inset normal(mu sigma ad adpval) / cfill = ywh
    format = 7.2;
run;
```

The resulting histogram is displayed in [Output 5.15.1](#). The NOCURVELEGEND option in the HISTOGRAM statement suppresses the default legend for curve parameters.

Output 5.15.1 Inset Table with Normal Curve Information

Example 5.16: Inset for Areas Under a Fitted Curve

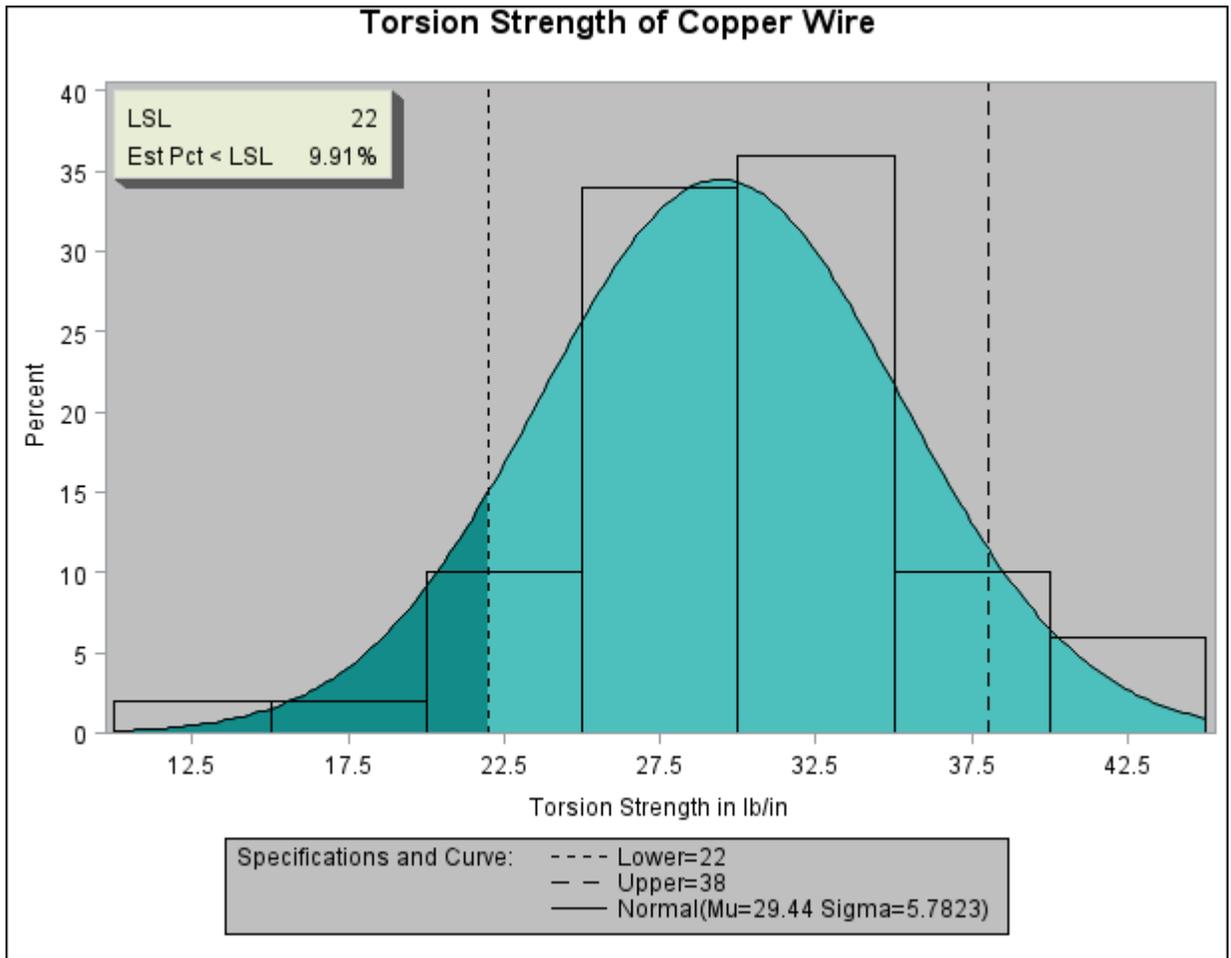

You can use the INSET keywords LSLPCT, USLPCT, and BETWEENPCT to inset legends for areas under histogram bars or fitted curves. The following statements create a histogram with an inset legend for the shaded area under the fitted normal curve to the left of the lower specification limit. *See CAPINS4 in the SAS/QC Sample Library*

```
ods graphics off;
title 'Torsion Strength of Copper Wire';
legend2 FRAME CFRAME=ligr CBORDER=black POSITION=center;
proc capability data=Wire noprint;
  spec lsl=22 lls1=2  csl=black cleft=vibg
      usl=38 lus1=20 cusl=black;
  histogram Strength / cframe = ligr
                      cfill  = bibg
                      legend = legend2
                      normal(color=black noprint fill);
  inset  lsl='LSL' lslpct / cfill=ywh cshadow=dagr;
run;
```

The histogram is displayed in [Output 5.16.1](#). The LSLPCT keyword in the INSET statement requests a legend for the area under the curve to the left of the lower specification limit. The CLEFT= option is used to fill the area under the normal curve to the left of the line, and the CFILL= color is used to fill the remaining area. If the FILL normal-option were not specified, the CLEFT= and CFILL= colors would be applied to the corresponding areas under the histogram, not the normal curve, and the inset box would reflect the area under the histogram bars.

You can use the USLPCT keyword in the INSET statement to request a legend for the area to the right of an upper specification limit, and you can use the BETWEENPCT keyword to request a legend for the area between the lower and upper limits. By default, the legend requested with each of the keywords LSLPCT, USLPCT, and BETWEENPCT displays a rectangle that matches the color of the corresponding area. You can substitute a customized label for each rectangle by specifying the keyword followed by an equal sign (=) and the label in quotes.

Output 5.16.1 Displaying Areas Under the Normal Curve

INTERVALS Statement: CAPABILITY Procedure

Overview: INTERVALS Statement

The INTERVALS statement tabulates various statistical intervals for selected process variables. The types of intervals you can request include

- approximate simultaneous prediction intervals for future observations
- prediction intervals for the mean of future observations
- approximate statistical tolerance intervals that contain at least a specified proportion of the population
- confidence intervals for the population mean
- prediction intervals for the standard deviation of future observations
- confidence intervals for the population standard deviation

These intervals are computed assuming the data are sampled from a normal population. See Hahn and Meeker (1991) for a detailed discussion of these intervals.

You can use options in the INTERVALS statement to

- specify which intervals to compute
- provide probability or confidence levels for intervals
- suppress printing of output tables
- create an output data set containing interval information
- specify interval type (one-sided lower, one-sided upper, or two-sided)

Getting Started: INTERVALS Statement

This section introduces the INTERVALS statement with simple examples that illustrate commonly used options. Complete syntax for the INTERVALS statement is presented in the section “Syntax: INTERVALS Statement” on page 432.

Computing Statistical Intervals

See CAPINT1 in the SAS/QC Sample Library The following statements create the data set Cans, which contains measurements (in ounces) of the fluid weights of 100 drink cans. The filling process is assumed to be in statistical control.

```
data Cans;
  label Weight = "Fluid Weight (ounces)";
  input Weight @@;
  datalines;
12.07 12.02 12.00 12.01 11.98 11.96 12.04 12.05 12.01 11.97
12.03 12.03 12.00 12.04 11.96 12.02 12.06 12.00 12.02 11.91
12.05 11.98 11.91 12.01 12.06 12.02 12.05 11.90 12.07 11.98
12.02 12.11 12.00 11.99 11.95 11.98 12.05 12.00 12.10 12.04
12.06 12.04 11.99 12.06 11.99 12.07 11.96 11.97 12.00 11.97
12.09 11.99 11.95 11.99 11.99 11.96 11.94 12.03 12.09 12.03
11.99 12.00 12.05 12.04 12.05 12.01 11.97 11.93 12.00 11.97
12.13 12.07 12.00 11.96 11.99 11.97 12.05 11.94 11.99 12.02
11.95 11.99 11.91 12.06 12.03 12.06 12.05 12.04 12.03 11.98
12.05 12.05 12.11 11.96 12.00 11.96 11.96 12.00 12.01 11.98
;
```

Note that this data set is introduced in “Computing Descriptive Statistics” on page 206 of “PROC CAPABILITY and General Statements” on page 204. The analysis in that section provides evidence that the weight measurements are normally distributed.

By default, the INTERVALS statement computes and prints the six intervals described in the entry for the METHODS= option. The following statements tabulate these intervals for the variable Weight:

```
title 'Statistical Intervals for Fluid Weight';
proc capability data=Cans noprint;
  intervals Weight;
run;
```

The intervals are displayed in Figure 5.27.

95.00%	0.041	0.055	
90.00%	0.042	0.053	

Computing One-Sided Lower Prediction Limits

You can specify options after the slash (/) in the INTERVALS statement to control the computation and printing of intervals. The following statements produce a table of one-sided lower prediction limits for the mean, which is displayed in [Figure 5.26](#). *See CAPINT1 in the SAS/QC Sample Library*

```

title 'Statistical Intervals for Fluid Weight';
proc capability data=Cans noprint;
  intervals Weight / methods = 1 2
                    type     = lower;
run;

```

The METHODS= option specifies which intervals to compute, and the TYPE= option requests one-sided lower limits. All the options available in the INTERVALS statement are listed in “[Summary of Options](#)” on page 432 and are described in “[Dictionary of Options](#)” on page 433.

90.00%	3	11.97

Syntax: INTERVALS Statement

The syntax for the INTERVALS statement is as follows:

```
INTERVALS < variables > < / options > ;
```

You can specify INTERVAL as an alias for INTERVALS. You can use any number of INTERVALS statements in the CAPABILITY procedure. The components of the INTERVALS statement are described as follows.

variables

gives a list of variables for which to compute intervals. If you specify a VAR statement, the variables must also be listed in the VAR statement. Otherwise, the variables can be any numeric variable in the input data set. If you do not specify a list of variables, then by default the INTERVALS statement computes intervals for all variables in the VAR statement (or all numeric variables in the input data set if you do not use a VAR statement).

options

alter the defaults for computing and printing intervals and for creating output data sets.

Summary of Options

The following tables list the INTERVALS statement options by function. For complete descriptions, see “Dictionary of Options” on page 433.

Table 5.49 INTERVAL Statement Options

Option	Description
ALPHA=	specifies probability or confidence levels associated with the intervals
K=	specifies values of k for prediction intervals
METHODS=	specifies which intervals are computed
NOPRINT	suppresses the output tables
OUTINTERVALS=	specifies an output data set containing interval information
P=	specifies values of p for tolerance intervals
TYPE=	specifies the type of intervals (one-sided lower, one-sided upper, or two-sided)

Dictionary of Options

The following entries provide detailed descriptions of options in the INTERVALS statement.

ALPHA=*value-list*

specifies values of α , the probability or confidence associated with the interval. For example, the following statements tabulate the default intervals at probability or confidence levels of $\alpha = 0.05$, $\alpha = 0.10$, $\alpha = 0.15$, and $\alpha = 0.20$:

```
proc capability data=steel;
  intervals width / alpha = 0.05 0.10 0.15 0.20;
run;
```

Note that some references use $\gamma = 1 - \alpha$ to denote probability or confidence levels. Values for the ALPHA= option must be between 0.00001 to 0.99999. By default, values of 0.01, 0.05, and 0.10 are used.

K=*value-list*

specifies values of k for prediction intervals. Default values of 1, 2, and 3 are used for the prediction interval for k future observations and for the prediction interval for the mean of k future observations. Default values of 2 and 3 are used for the prediction interval for the standard deviation of k future observations. The values must be integers.

METHODS=*indices*

METHOD=*indices*

specifies which intervals are computed. The indices can range from 1 to 6, and they correspond to the intervals described in Table 5.50.

Table 5.50 Intervals Computed for METHOD=*Index*

Index	Statistical Interval
1	approximate simultaneous prediction interval for k future observations
2	prediction interval for the mean of k future observations
3	approximate statistical tolerance interval that contains at least proportion p of the population
4	confidence interval for the population mean
5	prediction interval for the standard deviation of k future observations
6	confidence interval for the population standard deviation

For example, the following statements tabulate confidence limits for the population mean (METHOD=4) and confidence limits for the population standard deviation (METHOD=6):

```
proc capability data=steel;
  intervals width / methods=4 6;
run;
```

Formulas for the intervals are given in “Methods for Computing Statistical Intervals” on page 435. By default, the procedure computes all six intervals.

NOPRINT

suppresses the tables produced by default. This option is useful when you only want to save the interval information in an OUTINTERVALS= data set.

OUTINTERVALS=SAS-data-set**OUTINTERVAL=SAS-data-set****OUTINT=SAS-data-set**

specifies an output SAS data set containing the intervals and related information. For example, the following statements create a data set named ints containing intervals for the variable width:

```
proc capability data=steel;
  intervals width / outintervals=ints;
run;
```

See “OUTINTERVALS= Data Set” on page 438 for details.

P=value-list

specifies values of p for the tolerance intervals. These values must be between 0.00001 to 0.99999. Note that the P= option applies only to the tolerance intervals (METHODS=3). By default, values of 0.90, 0.95, and 0.99 are used.

TYPE=LOWER | UPPER | TWOSIDED

determines whether the intervals computed are one-sided lower, one-sided upper, or two-sided intervals, respectively. See “Computing One-Sided Lower Prediction Limits” on page 431 for an example. The default interval type is TWOSIDED.

Details: INTERVALS Statement

This section provides details on the following topics:

- formulas for statistical intervals
- OUTINTERVALS= data sets

Methods for Computing Statistical Intervals

The formulas for statistical intervals given in this section use the following notation:

Notation	Definition
n	number of nonmissing values for a variable
\bar{X}	mean of variable
s	standard deviation of variable
z_α	100 α th percentile of the standard normal distribution
$t_\alpha(\nu)$	100 α th percentile of the central t distribution with ν degrees of freedom
$t'_\alpha(\delta, \nu)$	100 α th percentile of the noncentral t distribution with noncentrality parameter δ and ν degrees of freedom
$F_\alpha(\nu_1, \nu_2)$	100 α th percentile of the F distribution with ν_1 degrees of freedom in the numerator and ν_2 degrees of freedom in the denominator
$\chi^2_\alpha(\nu)$	100 α th percentile of the χ^2 distribution with ν degrees of freedom.

The values of the variable are assumed to be independent and normally distributed. The intervals are computed using the degrees of freedom as the divisor for the standard deviation s . This divisor corresponds to the default of VARDEF=DF in the PROC CAPABILITY statement. If you specify another value for the VARDEF= option, intervals are not computed.

You select the intervals to be computed with the METHODS= option. The next six sections give computational details for each of the METHODS= options.

METHODS=1

This requests an approximate simultaneous prediction interval for k future observations. Two-sided intervals are computed using the conservative approximations

$$\text{Lower Limit} = \bar{X} - t_{1-\frac{\alpha}{2k}}(n-1)s\sqrt{1 + \frac{1}{n}}$$

$$\text{Upper Limit} = \bar{X} + t_{1-\frac{\alpha}{2k}}(n-1)s\sqrt{1 + \frac{1}{n}}$$

One-sided limits are computed using the conservative approximation

$$\text{Lower Limit} = \bar{X} - t_{1-\frac{\alpha}{k}}(n-1)s\sqrt{1+\frac{1}{n}}$$

$$\text{Upper Limit} = \bar{X} + t_{1-\frac{\alpha}{k}}(n-1)s\sqrt{1+\frac{1}{n}}$$

Hahn (1970c) states that these approximations are satisfactory except for combinations of small n , large k , and large α . Refer also to Hahn (1969, 1970a) and Hahn and Meeker (1991).

METHODS=2

This requests a prediction interval for the mean of k future observations. Two-sided intervals are computed as

$$\text{Lower Limit} = \bar{X} - t_{1-\frac{\alpha}{2}}(n-1)s\sqrt{\frac{1}{k} + \frac{1}{n}}$$

$$\text{Upper Limit} = \bar{X} + t_{1-\frac{\alpha}{2}}(n-1)s\sqrt{\frac{1}{k} + \frac{1}{n}}$$

One-sided limits are computed as

$$\text{Lower Limit} = \bar{X} - t_{1-\alpha}(n-1)s\sqrt{\frac{1}{k} + \frac{1}{n}}$$

$$\text{Upper Limit} = \bar{X} + t_{1-\alpha}(n-1)s\sqrt{\frac{1}{k} + \frac{1}{n}}$$

METHODS=3

This requests an approximate statistical tolerance interval that contains at least proportion p of the population. Two-sided intervals are approximated by

$$\text{Lower Limit} = \bar{X} - g(p; n; 1 - \alpha)s$$

$$\text{Upper Limit} = \bar{X} + g(p; n; 1 - \alpha)s$$

$$\text{where } g(p; n; 1 - \alpha) = z_{\frac{1+p}{2}} \left(1 + \frac{1}{2n}\right) \sqrt{\frac{n-1}{\chi_{\alpha}^2(n-1)}}.$$

Exact one-sided limits are computed as

$$\text{Lower Limit} = \bar{X} - g'(p; n; 1 - \alpha)s$$

$$\text{Upper Limit} = \bar{X} + g'(p; n; 1 - \alpha)s$$

$$\text{where } g'(p; n; 1 - \alpha) = \frac{1}{\sqrt{n}} t'_{1-\alpha}(z_p \sqrt{n}, n-1).$$

In some cases (for example, if $z_p \sqrt{n}$ is large), $g'(p; n; 1 - \alpha)$ is approximated by

$$\frac{1}{a} \left(z_p + \sqrt{z_p^2 - ab} \right)$$

where $a = 1 - \frac{z_{1-\alpha}^2}{2(n-1)}$ and $b = z_p^2 - \frac{z_{1-\alpha}^2}{n}$.

Hahn (1970b) states that this approximation is “poor for very small n , especially for large p and large $1 - \alpha$, and is not advised for $n < 8$.” Refer also to Hahn and Meeker (1991).

METHODS=4

This requests a confidence interval for the population mean. Two-sided intervals are computed as

$$\text{Lower Limit} = \bar{X} - t_{1-\frac{\alpha}{2}}(n-1) \frac{s}{\sqrt{n}}$$

$$\text{Upper Limit} = \bar{X} + t_{1-\frac{\alpha}{2}}(n-1) \frac{s}{\sqrt{n}}$$

One-sided limits are computed as

$$\text{Lower Limit} = \bar{X} - t_{1-\alpha}(n-1) \frac{s}{\sqrt{n}}$$

$$\text{Upper Limit} = \bar{X} + t_{1-\alpha}(n-1) \frac{s}{\sqrt{n}}$$

METHODS=5

This requests a prediction interval for the standard deviation of k future observations. Two-sided intervals are computed as

$$\text{Lower Limit} = s \left(F_{1-\frac{\alpha}{2}}(n-1, k-1) \right)^{-\frac{1}{2}}$$

$$\text{Upper Limit} = s \left(F_{1-\frac{\alpha}{2}}(k-1, n-1) \right)^{\frac{1}{2}}$$

One-sided limits are computed as

$$\text{Lower Limit} = s \left(F_{1-\alpha}(n-1, k-1) \right)^{-\frac{1}{2}}$$

$$\text{Upper Limit} = s \left(F_{1-\alpha}(k-1, n-1) \right)^{\frac{1}{2}}$$

METHODS=6

This requests a confidence interval for the population standard deviation. Two-sided intervals are computed as

$$\text{Lower Limit} = s \sqrt{\frac{n-1}{\chi^2_{1-\frac{\alpha}{2}}(n-1)}}$$

$$\text{Upper Limit} = s \sqrt{\frac{n-1}{\chi^2_{\frac{\alpha}{2}}(n-1)}}$$

One-sided limits are computed as

$$\text{Lower Limit} = s \sqrt{\frac{n-1}{\chi^2_{1-\alpha}(n-1)}}$$

$$\text{Upper Limit} = s \sqrt{\frac{n-1}{\chi^2_{\alpha}(n-1)}}$$

OUTINTERVALS= Data Set

Each INTERVALS statement can create an output data set specified with the OUTINTERVALS= option. The OUTINTERVALS= data set contains statistical intervals and related parameters.

The number of observations in the OUTINTERVALS= data set depends on the number of variables analyzed, the number of tests specified, and the results of the tests. The OUTINTERVALS= data set is constructed as follows:

- The OUTINTERVALS= data set contains a group of observations for each variable analyzed.
- Each group contains one or more observations for each interval you specify with the METHODS= option. The actual number depends upon the number of combinations of the ALPHA=, K=, and P= values.

The following variables are saved in the OUTINTERVALS= data set:

Variable	Description
ALPHA	value of α associated with the intervals
K	value of K= for the prediction intervals
LOWER	lower endpoint of interval
METHOD	interval index (1–6)
P	value of P= for the tolerance intervals
TYPE	type of interval (ONESIDED or TWOSIDED)
UPPER	upper endpoint of interval
VAR	variable name

If you use a BY statement, the BY variables are also saved in the OUTINTERVALS= data set.

ODS Tables

The following table summarizes the ODS tables that you can request with the INTERVALS statement.

Table 5.51 ODS Tables Produced with the INTERVALS Statement

Table Name	Description	Option
Intervals1	prediction interval for future observations	METHODS=1
Intervals2	prediction interval for mean	METHODS=2
Intervals3	tolerance interval for proportion of population	METHODS=3
Intervals4	confidence limits for mean	METHODS=4
Intervals5	prediction interval for standard deviation	METHODS=5
Intervals6	confidence limits for standard deviation	METHODS=6

OUTPUT Statement: CAPABILITY Procedure

Overview: OUTPUT Statement

You can use the OUTPUT statement to save summary statistics in a SAS data set. This information can then be used to create customized reports or to save historical information about a process.

You can use options in the OUTPUT statement to

- specify the statistics to save in the output data set
- specify the name of the output data set
- compute and save percentiles not automatically computed by the CAPABILITY procedure

Getting Started: OUTPUT Statement

This section introduces the OUTPUT statement with simple examples that illustrate commonly used options. Complete syntax for the OUTPUT statement is presented in the section “Syntax: OUTPUT Statement” on page 442, and advanced examples are given in the section “Examples: OUTPUT Statement” on page 450.

Saving Summary Statistics in an Output Data Set

See CAPOUT1 in the SAS/QC Sample Library An automobile manufacturer producing seat belts saves summary information in an output data set with the CAPABILITY procedure. The following statements create the data set Belts, which contains the breaking strengths (Strength) and widths (Width) of a sample of 50 belts:

```
data Belts;
  label Strength = 'Breaking Strength (lb/in)'
        Width    = 'Width in Inches';
  input Strength Width @@;
  datalines;
1243.51 3.036 1221.95 2.995 1131.67 2.983 1129.70 3.019
1198.08 3.106 1273.31 2.947 1250.24 3.018 1225.47 2.980
1126.78 2.965 1174.62 3.033 1250.79 2.941 1216.75 3.037
1285.30 2.893 1214.14 3.035 1270.24 2.957 1249.55 2.958
1166.02 3.067 1278.85 3.037 1280.74 2.984 1201.96 3.002
1101.73 2.961 1165.79 3.075 1186.19 3.058 1124.46 2.929
1213.62 2.984 1213.93 3.029 1289.59 2.956 1208.27 3.029
1247.48 3.027 1284.34 3.073 1209.09 3.004 1146.78 3.061
1224.03 2.915 1200.43 2.974 1183.42 3.033 1195.66 2.995
1258.31 2.958 1136.05 3.022 1177.44 3.090 1246.13 3.022
1183.67 3.045 1206.50 3.024 1195.69 3.005 1223.49 2.971
1147.47 2.944 1171.76 3.005 1207.28 3.065 1131.33 2.984
1215.92 3.003 1202.17 3.058
;
```

The following statements produce two output data sets containing summary statistics:

```
proc capability data=Belts;
  var Strength Width;
  output out=Means mean=smean wmean;
  output out=Strstats mean=smean std=sstd min=smin max=smax;
run;

proc print data=Means;
run;

proc print data=Strstats;
run;
```

Note that if you specify an OUTPUT statement, you must also specify a VAR statement. You can use multiple OUTPUT statements with a single procedure statement. Each OUTPUT statement creates a new data set. The OUT= option specifies the name of the output data set. In this case, two data sets, Means and Strstats, are created. See [Figure 5.27](#) for a listing of Means and [Figure 5.28](#) for a listing of Strstats.

Summary statistics are saved in an output data set by specifying *keyword=names* after the OUT= option. In the preceding statements, the first OUTPUT statement specifies the keyword MEAN followed by the names smean and wmean. The second OUTPUT statement specifies the keywords MEAN, STD, MIN, and MAX, for which the names smean, sstd, smin, and smax are given.

The keyword specifies the statistic to be saved in the output data set, and the names determine the names for the new variables. The first name listed after a keyword contains that statistic for the first variable listed in the VAR statement; the second name contains that statistic for the second variable in the VAR statement, and so on.

Thus, the data set Means contains the mean of Strength in a variable named smean and the mean of Width in a variable named wmean. The data set Strstats contains the mean, standard deviation, minimum value, and maximum value of Strength in the variables smean, sstd, smin, and smax, respectively.

Figure 5.27 Listing of the Output Data Set Means

Statistical Intervals for Fluid Weight			
Obs	smean	wmean

Figure 5.28 Listing of the Output Data Set Strstats

Statistical Intervals for Fluid Weight				
Obs	smean	sstd	smax	smin
1	1205.75	48.3290	1289.59	1101.73

Saving Percentiles in an Output Data Set

The CAPABILITY procedure automatically computes the 1st, 5th, 10th, 25th, 75th, 90th, 95th, and 99th percentiles for each variable. You can save these percentiles in an output data set by specifying the appropriate keywords. For example, the following statements create an output data set named pctlstr containing the 5th and 95th percentiles of the variable Strength: *See CAPOUT1 in the SAS/QC Sample Library*

```
proc capability data=Belts noprint;
  var Strength Width;
  output out=pctlstr p5=p5str p95=p95str;
run;

proc print data=pctlstr;
run;
```

The output data set pctlstr is listed in Figure 5.29.

Figure 5.29 Listing of the Output Data Set pctlstr

Statistical Intervals for Fluid Weight		
Obs	p95str	p5str
1	1284.34	1126.78

You can use the PCTLPTS=, PCTLPRE=, and PCTLNAME= options to save percentiles not automatically computed by the CAPABILITY procedure. For example, the following statements create an output data set named pctls containing the 20th and 40th percentiles of the variables Strength and Width:

```
proc capability data=Belts noprint;
  var Strength Width;
  output out=pctls pctlpts = 20 40
         pctlpre = S W
         pctlname = pct20 pct40;

run;

proc print data=pctls;
run;
```

The PCTLPTS= option specifies the percentiles to compute (in this case, the 20th and 40th percentiles). The PCTLPRE= and PCTLNAME= options build the names for the variables containing the percentiles. The PCTLPRE= option gives prefixes for the new variables, and the PCTLNAME= option gives a suffix to add to the prefix. Note that if you use the PCTLPTS= specification, you must also use the PCTLPRE= specification. For details on these options, see the section “Syntax: OUTPUT Statement” on page 442.

The preceding OUTPUT statement saves the 20th and 40th percentiles of Strength and Width in the variables spct20, wpct20, spct40, and wpct40. The output data set pctls is listed in Figure 5.30.

Figure 5.30 Listing of the Output Data Set pctls

Statistical Intervals for Fluid Weight				
Obs	Spct20	Wpct20	Spct40	Wpct40
1	1165.91	2.9595	1199.26	2.995

Syntax: OUTPUT Statement

The syntax for the OUTPUT statement is as follows:

```
OUTPUT <OUT=SAS-data-set> <keyword1=names ...keywordk=names> <percentile-
options>;
```

You can use any number of OUTPUT statements in the CAPABILITY procedure. Each OUTPUT statement creates a new data set containing the statistics specified in that statement. When you use the OUTPUT statement, you must also use the VAR statement. In addition, the OUTPUT statement must contain at least one of the following:

- a specification of the form *keyword=names*
- the PCTLPTS= and PCTLPRE= options

You can use the OUT= option to specify the name of the output data set:

OUT=SAS-data-set

specifies the name of the output data set. To create a permanent SAS data set, specify a two-level name. See *SAS Statements: Reference* for more information on permanent SAS data sets. For example, the previous statements create an output data set named Summary. If the OUT= option is omitted, then by default the new data set is named using the DATAn convention.

A *keyword=names* specification selects a statistic to be included in the output data set and gives names to the new variables that contain the statistics. Specify a *keyword* for each desired statistic, an equal sign, and the *names* of the variables to contain the statistic.

In the output data set, the first variable listed after a keyword in the OUTPUT statement contains the statistic for the first variable listed in the VAR statement; the second variable contains the statistic for the second variable in the VAR statement, and so on. The list of *names* following the equal sign can be shorter than the list of variables in the VAR statement. In this case, the procedure uses the *names* in the order in which the variables are listed in the VAR statement. Consider the following example:

```
proc capability noprint;
  var length width height;
  output out=summary mean=mlength mwidth;
run;
```

The variables mlength and mwidth contain the means for length and width. The mean for height is computed by the procedure but is not saved in the output data set.

Table 5.52 lists all keywords available in the OUTPUT statement grouped by type. Formulas for selected statistics are given in the section “[Details: CAPABILITY Procedure](#)” on page 228.

Table 5.52 OUTPUT Statement Statistic Keywords

Keyword	Description
Descriptive Statistics	
CSS	sum of squares corrected for the mean
CV	percent coefficient of variation
KURTOSIS KURT	kurtosis
MAX	largest (maximum) value
MEAN	mean
MIN	smallest (minimum) value
MODE	most frequent value (if not unique, the smallest mode)
N	number of observations on which calculations are based
NMISS	number of missing values
NOBS	number of observations
RANGE	range
SKEWNESS SKEW	skewness
STD STDDEV	standard deviation
STDMEAN STDERR	standard error of the mean
SUM	sum
SUMWGT	sum of weights
USS	uncorrected sum of squares

Table 5.52 (continued)

Keyword	Description
VAR	variance
Quantile Statistics	
MEDIAN P50 Q2	median (50th percentile)
P1	1st percentile
P5	5th percentile
P10	10th percentile
P90	90th percentile
P95	95th percentile
P99	99th percentile
Q1 P25	lower quartile (25th percentile)
Q3 P75	upper quartile (75th percentile)
QRANGE	interquartile range (Q3 – Q1)
Robust Statistics	
GINI	Gini's mean difference
MAD	median absolute difference
QN	2nd variation of median absolute difference
SN	1st variation of median absolute difference
STD_GINI	standard deviation for Gini's mean difference
STD_MAD	standard deviation for median absolute difference
STD_QN	standard deviation for the second variation of the median absolute difference
STD_QRANGE	estimate of the standard deviation, based on interquartile range
STD_SN	standard deviation for the first variation of the median absolute difference
Hypothesis Test Statistics	
MSIGN	sign statistic
NORMAL	test statistic for normality. If the sample size is less than or equal to 2000, this is the Shapiro-Wilk W statistic. Otherwise, it is the Kolmogorov D statistic.
PNORMAL PROB N	p -value for normality test
PROBM	probability of a greater absolute value for the sign statistic
PROBS	probability of a greater absolute value for the signed rank statistic
PROBT	two-tailed p -value for Student's t statistic with $n - 1$ degrees of freedom
SIGNRANK	signed rank statistic
T	Student's t statistic to test the null hypothesis that the population mean is equal to μ_0
Specification Limits and Related Statistics	
LSL	lower specification limit
PCTGTR	percent of nonmissing observations greater than the upper specification limit

Table 5.52 (continued)

Keyword	Description
PCTLSS	percent of nonmissing observations less than the lower specification limit
TARGET	target value
USL	upper specification limit
Capability Indices and Related Statistics	
CP	capability index C_p
CPLCL	lower confidence limit for C_p
CPUCL	upper confidence limit for C_p
CPK	capability index C_{pk} (also denoted CPK)
CPKLCL	lower confidence limit for C_{pk}
CPKUCL	upper confidence limit for C_{pk}
CPL	capability index CPL
CPLLCL	lower confidence limit for CPL
CPLUCL	upper confidence limit for CPL
CPM	capability index C_{pm}
CPMLCL	lower confidence limit for C_{pm}
CPMUCL	upper confidence limit for C_{pm}
CPU	capability index CPU
CPULCL	lower confidence limit for CPU
CPUCL	upper confidence limit for CPU
K	capability index k (also denoted K)

The CAPABILITY procedure automatically computes the 1st, 5th, 10th, 25th, 50th, 75th, 90th, 95th, and 99th percentiles for the data. You can save these statistics in an output data set by using *keyword=names* specifications. You can request additional percentiles by using the PCTLPTS= option. The following *percentile-options* are related to these additional percentiles:

CIPCTLDF=(*cipctl-options*)

CIQUANTDF=(*cipctl-options*)

requests distribution-free confidence limits for percentiles that are requested with the PCTLPTS= option. In other words, no specific parametric distribution such as the normal is assumed for the data. PROC CAPABILITY uses order statistics (ranks) to compute the confidence limits as described by Hahn and Meeker (1991). This option does not apply if you use a WEIGHT statement. You can specify the following *cipctl-options*:

ALPHA= α

specifies the level of significance α for $100(1 - \alpha)\%$ confidence intervals. The value α must be between 0 and 1; the default value is 0.05, which results in 95% confidence intervals. The default value is the value of ALPHA= given in the PROC statement.

LOWERPRE=*prefixes*

specifies one or more prefixes that are used to create names for variables that contain the lower confidence limits. To save lower confidence limits for more than one analysis

variable, specify a list of prefixes. The order of the prefixes corresponds to the order of the analysis variables in the VAR statement.

LOWERNAME=*suffixes*

specifies one or more suffixes that are used to create names for variables that contain the lower confidence limits. PROC CAPABILITY creates a variable name by combining the LOWERPRE= value and suffix name. Because the suffixes are associated with the requested percentiles, list the suffixes in the same order as the PCTLPTS= percentiles.

TYPE=*keyword*

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, SYMMETRIC, or ASYMMETRIC. The default value is SYMMETRIC.

UPPERPRE=*prefixes*

specifies one or more prefixes that are used to create names for variables that contain the upper confidence limits. To save upper confidence limits for more than one analysis variable, specify a list of prefixes. The order of the prefixes corresponds to the order of the analysis variables in the VAR statement.

UPPERNAME=*suffixes*

specifies one or more suffixes that are used to create names for variables that contain the upper confidence limits. PROC CAPABILITY creates a variable name by combining the UPPERPRE= value and suffix name. Because the suffixes are associated with the requested percentiles, list the suffixes in the same order as the PCTLPTS= percentiles.

NOTE: See the entries for the PCTLPTS=, PCTLPRE=, and PCTLNAME= options for a detailed description of how variable names are created using prefixes, percentile values, and suffixes.

CIPCTLNORMAL=*(cipctl-options)*

CIQUANTNORMAL=*(cipctl-options)*

requests confidence limits based on the assumption that the data are normally distributed for percentiles that are requested with the PCTLPTS= option. The computational method is described in Section 4.4.1 of Hahn and Meeker (1991) and uses the noncentral t distribution as given by Odeh and Owen (1980). This option does not apply if you use a WEIGHT statement. You can specify the following *cipctl-options*:

ALPHA= α

specifies the level of significance α for $100(1 - \alpha)\%$ confidence intervals. The value α must be between 0 and 1; the default value is 0.05, which results in 95% confidence intervals. The default value is the value of ALPHA= given in the PROC statement.

LOWERPRE=*prefixes*

specifies one or more prefixes that are used to create names for variables that contain the lower confidence limits. To save lower confidence limits for more than one analysis variable, specify a list of prefixes. The order of the prefixes corresponds to the order of the analysis variables in the VAR statement.

LOWERNAME=*suffixes*

specifies one or more suffixes that are used to create names for variables that contain the lower confidence limits. PROC CAPABILITY creates a variable name by combining the LOWERPRE= value and suffix name. Because the suffixes are associated with the requested percentiles, list the suffixes in the same order as the PCTLPTS= percentiles.

TYPE=*keyword*

specifies the type of confidence limit, where *keyword* is LOWER, UPPER, or TWOSIDED. The default is TWOSIDED.

UPPERPRE=*prefixes*

specifies one or more prefixes that are used to create names for variables that contain the upper confidence limits. To save upper confidence limits for more than one analysis variable, specify a list of prefixes. The order of the prefixes corresponds to the order of the analysis variables in the VAR statement.

UPPERNAME=*suffixes*

specifies one or more suffixes that are used to create names for variables that contain the upper confidence limits. PROC CAPABILITY creates a variable name by combining the UPPERPRE= value and suffix name. Because the suffixes are associated with the requested percentiles, list the suffixes in the same order as the PCTLPTS= percentiles.

NOTE: See the entries for the PCTLPTS=, PCTLPRE=, and PCTLNAME= options for a detailed description of how variable names are created using prefixes, percentile values, and suffixes.

PCTLGROUP=BYSTAT | BYVAR

specifies the order in which variables that you request with the PCTLPTS= option are added to the OUT= data set when the VAR statement lists more than one analysis variable. By default (or if you specify PCTLGROUP=BYSTAT), all variables that are associated with a percentile value are created consecutively. If you specify PCTLGROUP=BYVAR, all variables that are associated with an analysis variable are created consecutively.

Consider the following statements:

```
proc univariate data=Score;
  var PreTest PostTest;
  output out=ByStat pctlpts=20 40 pctlpre=Pre_ Post_;
  output out=ByVar pctlgroup=byvar pctlpts=20 40 pctlpre=Pre_ Post_;
run;
```

The order of variables in the data set ByStat is Pre_20, Post_20, Pre_40, Post_40. The order of variables in the data set ByVar is Pre_20, Pre_40, Post_20, Post_40.

PCTLNAME=*suffixes*

provides name suffixes for the new variables created by the PCTLPTS= option. These suffixes are appended to the prefixes you specify with the PCTLPRE= option, replacing the percentile values that are used as suffixes by default. List the suffixes in the same order in which you specify the percentiles. If you specify n suffixes with the PCTLNAME= option and m percentile values with the PCTLPTS= option, where $m > n$, the suffixes are used to name the first n percentiles, and the default names are used for the remaining $m - n$ percentiles. For example, consider the following statements:

```

proc capability;
  var length width height;
  output pctlpts = 20 40
         pctlpre = pl pw ph
         pctlname = twenty;
run;

```

The value “twenty” in the PCTLNAME= option is used for only the first percentile in the PCTLPTS= list. This suffix is appended to the values in the PCTLPRE= option to generate the new variable names pltwenty, pwtwenty, and phtwenty, which contain the 20th percentiles for length, width, and height, respectively. Since a second PCTLNAME= suffix is not specified, variable names for the 40th percentiles for length, width, and height are generated using the prefixes and percentile values. Thus, the output data set contains the variables pltwenty, pl40, pwtwenty, pw40, phtwenty, and ph40.

PCTLNDEC=value

specifies the number of decimal places in percentile values that are incorporated into percentile variable names. The default value is 1. For example, the following statements create two output data sets, each containing one percentile variable. The variable in data set short is named pwid85_1, while the one in data set long is named pwid85_125.

```

proc capability;
  var width;
  output out=short pctlpts=85.125 pctlpre=pwid;
  output out=long pctlpts=85.125 pctlpre=pwid pctlndec=3;
run;

```

PCTLPRE=prefixes

specifies prefixes used to create variable names for percentiles requested with the PCTLPTS= option. The PCTLPRE= and PCTLPTS= options must be used together.

The procedure generates new variable names by using the prefix and the percentile values. If the specified percentile is an integer, the variable name is simply the prefix followed by the value. For noninteger percentiles, an underscore replaces the decimal point in the variable name, and decimal values are truncated to one decimal place. For example, the following statements create the variables pwid20, pwid33_3, pwid66_6, and pwid80 for the 20th, 33.33rd, 66.67th, and 80th percentiles of width, respectively:

```

proc capability noprint;
  var width;
  output pctlpts=20 33.33 66.67 80 pctlpre=pwid;
run;

```

If you request percentiles for more than one variable, you should list prefixes in the same order in which the variables appear in the VAR statement. For example, the following statements compute the 80th and 87.5th percentiles for length and width and save the new variables plength80, plength87_5, pwidth80, and pwidth87_5 in the output data set:

```
proc capability noprint;
  var length width;
  output pctlpts=80 87.5 pctlpre=length pwidth;
run;
```

PCTLPTS=percentiles

specifies *percentiles* that are not automatically computed by the procedure. The CAPABILITY procedure automatically computes the 1st, 5th, 10th, 25th, 50th, 75th, 90th, 95th, and 99th percentiles for the data. These can be saved in an output data set by using keyword=names specifications. The PCTLPTS= option generates additional percentiles and outputs them to a data set; these additional percentiles are not printed.

If you use the PCTLPTS= option, you must also use the PCTLPRE= option to provide a prefix for the new variable names. For example, to create variables that contain the 20th, 40th, 60th, and 80th percentiles of length, use the following statements:

```
proc capability noprint;
  var length;
  output pctlpts=20 40 60 80 pctlpre=plen;
run;
```

This creates the variables plen20, plen40, plen60, and plen80, whose values are the corresponding percentiles of length. In addition to specifying name prefixes with the PCTLPRE= option, you can also use the PCTLNAME= option to create name suffixes for the new variables created by the PCTLPTS= option.

Details: OUTPUT Statement

OUT= Data Set

The CAPABILITY procedure creates an OUT= data set for each OUTPUT statement. The new data set contains an observation for each combination of levels of the variables in the BY statement, or a single observation if you do not specify a BY statement. Thus, the number of observations in the new data set corresponds to the number of groups for which statistics are calculated. The variables in the new data set are as follows:

- variables in the BY statement. The values of these variables match the values in the corresponding BY group in the DATA= data set.
- variables in the ID statement. The values of these variables match those for the first observation in each BY group, or for the first observation in the data set if you do not specify a BY statement.
- variables created by selecting statistics in the OUTPUT statement. The values of the statistics are computed using all the nonmissing data, or statistics are computed for each BY group if you use a BY statement.

- variables created by requesting new percentiles with the PCTLPTS= option. The names of these new variables depend on the values of the PCTLPRE= and PCTLNAME= options.

If the output data set contains a percentile variable or a quartile variable, the percentile definition assigned with the PCTLDEF= option in the PROC CAPABILITY statement is recorded on the output data set label.

The values of variables requested with the statistics keywords CP, CPK, CPL, CPM, CPU, K, PCTGTR, and PCTLSS are missing unless you identify specification limits in a SPEC statement or in a SPEC= data set.

As an alternative to OUT= data sets, you can create an OUTTABLE= data set. The structure of the OUTTABLE= data set may be more appropriate when you are computing summary statistics and capability indices for multiple process variables. See “OUTTABLE= Data Set” on page 231.

Examples: OUTPUT Statement

This section provides additional examples of the OUTPUT statement.

Example 5.17: Computing Nonstandard Capability Indices

See CPCPMK in the SAS/QC Sample Library

In recent years, a number of process capability indices that have been proposed in the research literature are gradually being introduced in applications. As shown in this example, you can compute such indices in the DATA step after using the OUTPUT statement in the CAPABILITY procedure to save various summary statistics.

Hardness measurements (in scaled units) for 50 titanium samples are saved as values of the variable Hardness in the following SAS data set:

```
data Titanium;
  label Hardness = 'Hardness Measurement';
  input Hardness @@;
  datalines;
1.38 1.49 1.43 1.60 1.59
1.34 1.44 1.64 1.83 1.57
1.45 1.74 1.61 1.39 1.63
1.73 1.61 1.35 1.51 1.47
1.46 1.41 1.56 1.40 1.58
1.43 1.53 1.53 1.58 1.62
1.58 1.46 1.26 1.57 1.41
1.53 1.36 1.63 1.36 1.66
1.49 1.55 1.67 1.41 1.39
1.75 1.37 1.36 1.86 1.49
;
```

The target value for hardness is 1.6, and the lower and upper specification limits are 0.8 and 2.4, respectively. The samples are produced by an in-control process, and the measurements are assumed to be normally distributed.

The following statements use the OUTPUT statement to save various descriptive statistics and an estimate of the index C_{pm} in a data set named Indices:

```
proc capability data=Titanium noprint;
  var Hardness;
  specs lsl=0.8 target=1.6 usl=2.4;
  output out=Indices
    n      = n
    mean   = avg
    std    = std
    var    = var
    lsl    = lsl
    target = t
    usl    = usl
    pnormal = pnormal
    cpm    = cpm ;
run;
```

In addition to C_{pm} , you want to report an estimate for the index C_{pmk} , which is defined as follows:

$$C_{pmk} = \frac{d - |\mu - m|}{3\sqrt{\sigma^2 + (\mu - T)^2}}$$

where $d = (\text{USL} - \text{LSL})/2$, $m = (\text{USL} + \text{LSL})/2$, and μ and σ are the mean and standard deviation of the normal distribution. Refer to Section 3.6 of Kotz and Johnson (1993). A natural estimator for C_{pmk} is

$$\hat{C}_{pmk} = \frac{d - |\bar{X} - m|}{3\sqrt{\frac{1}{n} \sum_{i=1}^n (X_i - T)^2}}$$

The following statements compute this estimate:

```
data Indices;
  set Indices;
  d   = 0.5*( USL - LSL );
  m   = 0.5*( USL + LSL );
  num = d - abs( avg - m );
  den  = 3 * sqrt( (n-1)*var/n + (avg-t)*(avg-t) );
  cpmk = num/den;
run;

title "Capability Analysis of Titanium Hardness";
proc print data=Indices noobs;
  var n avg std lsl t usl cpm cpmk pnormal;
run;
```

The results are listed in [Output 5.17.1](#).

Output 5.17.1 Computation of C_{pmk}

Capability Analysis of Titanium Hardness								
n	avg	std	lsl	t	usl	cpm	cpmk	pnormal
50	1.5212	0.13295	0.8	1.6	2.4	1.72545	1.56713	0.25111

Note that the p -value for the Kolmogorov-Smirnov test of normality is 0.25111, indicating that the assumption of normality is justified.

The following statements also compute an estimate of the index C_{pm} by using the SPECIALINDICES option:

```
proc capability data=Titanium specialindices;
  var Hardness;
  specs lsl=0.8 target=1.6 usl=2.4;
run;
```

Output 5.17.2 Computation of C_{pmk} by Using the SPECIALINDICES Option

Capability Analysis of Titanium Hardness

Example 5.18: Approximate Confidence Limits for Cpk

See CPKCON3 in the SAS/QC Sample Library This example illustrates how you can use the OUTPUT statement to compute confidence limits for the capability index C_{pk} .

You can request the approximate confidence limits given by Bissell (1990) with the keywords CPKLCL and CPKUCL in the OUTPUT statement. However, this is not the only method that has been proposed for computing confidence limits for C_{pk} . Zhang, Stenback, and Wardrop (1990), referred to here as ZSW, proposed approximate confidence limits of the form

$$\hat{C}_{pk} \pm k\hat{\sigma}_{pk}$$

where $\hat{\sigma}_{pk}$ is an estimator of the standard deviation of \hat{C}_{pk} . Equation (8) of ZSW provides an approximation to the variance of \hat{C}_{pk} from which one can obtain 100 γ % confidence limits for C_{pk}

as

$$\begin{aligned} \text{LCL} &= \hat{C}_{pk} \left[1 - \Phi^{-1}((1-\gamma)/2) \sqrt{\frac{n-1}{n-3} - \frac{(n-1)\Gamma^2((n-2)/2)}{2\Gamma^2((n-1)/2)}} \right] \\ \text{UCL} &= \hat{C}_{pk} \left[1 + \Phi^{-1}(1-(1-\gamma)/2) \sqrt{\frac{n-1}{n-3} - \frac{(n-1)\Gamma^2((n-2)/2)}{2\Gamma^2((n-1)/2)}} \right] \end{aligned}$$

This assumes that \hat{C}_{pk} is normally distributed. You can also compute approximate confidence limits based on equation (6) of ZSW, which provides an exact expression for the variance of \hat{C}_{pk} .

The following program uses the methods of Bissell (1990) and ZSW to compute approximate confidence limits for C_{pk} for the variable Hardness in the data set Titanium (see [Example 5.17](#)).

```
proc capability data=Titanium noprint;
  var Hardness;
  specs lsl=0.8 usl=2.4;
  output out=Summary
    n = n
    mean = mean
    std = std
    lsl = lsl
    usl = usl
    cpk = cpk
    cpklcl = cpklcl
    cpkucl = cpkucl
    cpl = cpl
    cpu = cpu ;

data Summary;
  set Summary;
  length Method $ 16;

  Method = "Bissell";
  lcl = cpklcl;
  ucl = cpkucl;
  output;

  * Assign confidence level;
  level = 0.95;
  aux = probit( 1 - (1-level)/2 );

  Method = "ZSW Equation 6";
  zsw = log(0.5*n-0.5)
    + ( 2*(lgamma(0.5*n-1)-lgamma(0.5*n-0.5)) );
  zsw = sqrt((n-1)/(n-3)-exp(zsw));
  lcl = cpk*(1-aux*zsw);
  ucl = cpk*(1+aux*zsw);
```

```

output;

Method = "ZSW Equation 8";
ds = 3*(cpu+cpl)/2;
ms = 3*(cpl-cpu)/2;
f1 = (1/3)*sqrt((n-1)/2)*gamma((n-2)/2)*(1/gamma((n-1)/2));
f2 = sqrt(2/n)*(1/gamma(0.5))*exp(-n*0.5*ms*ms);
f3 = ms*(1-(2*probnorm(-sqrt(n)*ms)));
ex = f1*(ds-f2-f3);
sd = ((n-1)/(9*(n-3)))*(ds**2-(2*ds*(f2+f3))+ms**2+(1/n));
sd = sd-(ex*ex);
sd = sqrt(sd);
lcl = cpk-aux*sd;
ucl = cpk+aux*sd;
output;

run;

title "Approximate 95% Confidence Limits for Cpk";
proc print data = Summary noobs;
var Method lcl cpk ucl;
run;

```

The results are shown in Output 5.18.1.

Output 5.18.1 Approximate Confidence Limits for C_{pk}

Approximate 95% Confidence Limits for Cpk			
Method	lcl	cpk	ucl
Bissell	1.43845	1.80818	2.17790
ZSW Equation 6	1.43596	1.80818	2.18040
ZSW Equation 8	1.42419	1.80818	2.19217

Note that there is fairly close agreement in the three methods.

You can display the confidence limits computed using Bissell's approach on plots produced by the CAPABILITY procedure by specifying the keywords CPKLCL and CPKUCL in the INSET statement.

The following statements also compute an estimate of the index C_{pk} along with approximate limits by using the SPECIALINDICES option:

```

proc capability data=Titanium specialindices;
var Hardness;
specs lsl=0.8 usl=2.4;
run;

```

Output 5.18.2 Approximate Confidence Limits for C_{pk} using the SPECIALINDICES option

PPPLOT Statement: CAPABILITY Procedure

Overview: PPPLOT Statement

The PPPLOT statement creates a probability-probability plot (also referred to as a P-P plot or percent plot), which compares the empirical cumulative distribution function (ecdf) of a variable with a specified theoretical cumulative distribution function such as the normal. If the two distributions match, the points on the plot form a linear pattern that passes through the origin and has unit slope. Thus, you can use a P-P plot to determine how well a theoretical distribution models a set of measurements.

You can specify one of the following theoretical distributions with the PPPLOT statement:

- beta
- exponential
- gamma
- Gumbel
- inverse Gaussian

- lognormal
- normal
- generalized Pareto
- power function
- Rayleigh
- Weibull

You can use options in the PPLOT statement to do the following:

- specify or estimate parameters for the theoretical distribution
- request graphical enhancements

You can also create a comparative P-P plot by using the PPLOT statement in conjunction with a CLASS statement.

You have three alternatives for producing P-P plots with the PPLOT statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

NOTE: Probability-probability plots should not be confused with probability plots, which compare a set of ordered measurements with *percentiles* from a specified distribution. You can create probability plots with the PROBLOT statement.

Getting Started: PPLOT Statement

The following example illustrates the basic syntax of the PPLOT statement. For complete details of the PPLOT statement, see the section “Syntax: PPLOT Statement” on page 458.

Creating a Normal Probability-Probability Plot

The distances between two holes cut into 50 steel sheets are measured and saved as values of the variable Distance in the following data set: ⁶ *See CAPPP1 in the SAS/QC Sample Library*

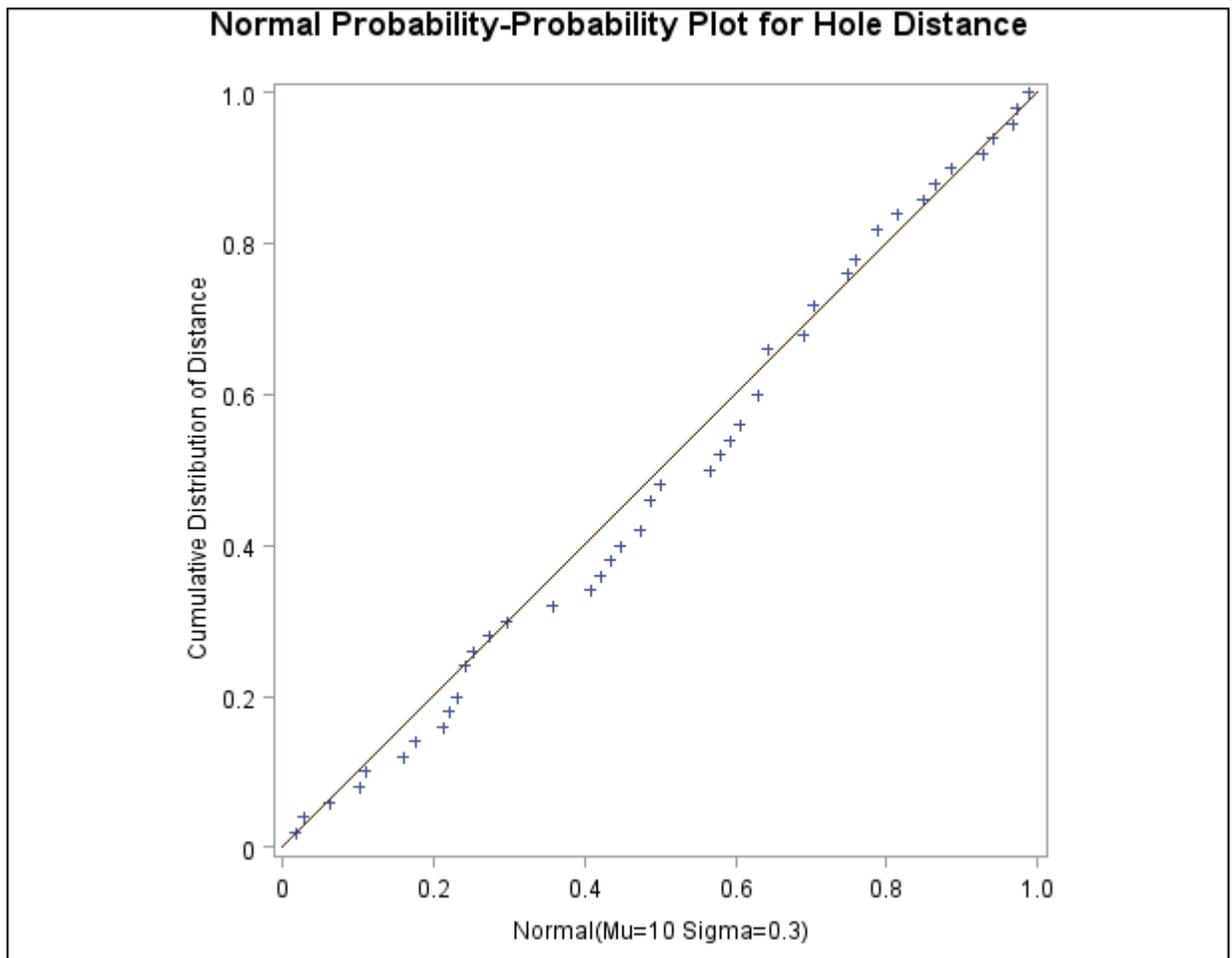

```
data Sheets;
  input Distance @@;
  label Distance='Hole Distance in cm';
  datalines;
  9.80 10.20 10.27  9.70  9.76
 10.11 10.24 10.20 10.24  9.63
  9.99  9.78 10.10 10.21 10.00
  9.96  9.79 10.08  9.79 10.06
 10.10  9.95  9.84 10.11  9.93
 10.56 10.47  9.42 10.44 10.16
 10.11 10.36  9.94  9.77  9.36
  9.89  9.62 10.05  9.72  9.82
  9.99 10.16 10.58 10.70  9.54
 10.31 10.07 10.33  9.98 10.15
  ;
```

The cutting process is in statistical control. As a preliminary step in a capability analysis of the process, it is decided to check whether the distances are normally distributed. The following statements create a P-P plot, shown in [Figure 5.31](#), which is based on the normal distribution with mean $\mu = 10$ and standard deviation $\sigma = 0.3$:

```
ods graphics off;
symbol v=plus;
title 'Normal Probability-Probability Plot for Hole Distance';
proc capability data=Sheets noprint;
  ppplot Distance / normal(mu=10 sigma=0.3)
                square;
run;
```

The NORMAL option in the PPLOT statement requests a P-P plot based on the normal cumulative distribution function, and the MU= and SIGMA= *normal-options* specify μ and σ . Note that a P-P plot is always based on a *completely specified* distribution, in other words, a distribution with specific parameters. In this example, if you did not specify the MU= and SIGMA= *normal-options*, the sample mean and sample standard deviation would be used for μ and σ .

⁶These data are also used to create Q-Q plots in “QQPLOT Statement: CAPABILITY Procedure” on page 508.

Figure 5.31 Normal P-P Plot with Diagonal Reference Line

The linearity of the pattern in Figure 5.31 is evidence that the measurements are normally distributed with mean 10 and standard deviation 0.3. The SQUARE option displays the plot in a square format.

Syntax: PPLOT Statement

The syntax for the PPLOT statement is as follows:

```
PPLOT < variables > < / options > ;
```

You can specify the keyword PP as an alias for PPLOT, and you can use any number of PPLOT statements in the CAPABILITY procedure. The components of the PPLOT statement are described as follows.

variables

are the process variables for which to create P-P plots. If you specify a VAR statement, the variables must also be listed in the VAR statement. Otherwise, the variables can be any numeric variables in the input data set. If you do not specify a list of variables, then by

default, the procedure creates a P-P plot for each variable listed in the VAR statement or for each numeric variable in the input data set if you do not specify a VAR statement. For example, each of the following PPLOT statements produces two P-P plots, one for length and one for width:

```
proc capability data=measures;
  var length width;
  ppplot;
run;

proc capability data=measures;
  ppplot length width;
run;
```

options

specify the theoretical distribution for the plot or add features to the plot. If you specify more than one variable, the options apply equally to each variable. Specify all options after the slash (/) in the PPLOT statement. You can specify only one option naming a distribution, but you can specify any number of other options. The distributions available are the beta, exponential, gamma, Gumbel, inverse Gaussian, lognormal, normal, generalized Pareto, power function, Rayleigh, and Weibull. By default, the procedure produces a P-P plot based on the normal distribution.

In the following example, the NORMAL, MU= and SIGMA= options request a P-P plot based on the normal distribution with mean 10 and standard deviation 0.3. The SQUARE option displays the plot in a square frame, and the CTEXT= option specifies the text color.

```
proc capability data=measures;
  ppplot length width / normal(mu=10 sigma=0.3)
                        square
                        ctext=blue;
run;
```

Summary of Options

The following tables list the PPLOT statement options by function. For complete descriptions, see the section “Dictionary of Options” on page 463.

Distribution Options

Table 5.53 summarizes the options for requesting a specific theoretical distribution.

Table 5.53 Options for Specifying a Theoretical Distribution

Option	Description
BETA(<i>beta-options</i>)	specifies beta P-P plot
EXPONENTIAL(<i>exponential-options</i>)	specifies exponential P-P plot
GAMMA(<i>gamma-options</i>)	specifies gamma P-P plot
GUMBEL(<i>Gumbel-options</i>)	specifies Gumbel P-P plot
IGAUSS(<i>iGauss-options</i>)	specifies inverse Gaussian P-P plot
LOGNORMAL(<i>lognormal-options</i>)	specifies lognormal P-P plot
NORMAL(<i>normal-options</i>)	specifies normal P-P plot
PARETO(<i>Pareto-options</i>)	specifies generalized Pareto P-P plot
POWER(<i>power-options</i>)	specifies power function P-P plot
RAYLEIGH(<i>Rayleigh-options</i>)	specifies Rayleigh P-P plot
WEIBULL(<i>Weibull-options</i>)	specifies Weibull P-P plot

Table 5.54 summarizes options that specify distribution parameters and control the display of the diagonal distribution reference line. Specify these options in parentheses after the distribution option. For example, the following statements use the NORMAL option to request a normal P-P plot:

```
proc capability data=measures;
  ppplot length / normal(mu=10 sigma=0.3 color=red);
run;
```

The MU= and SIGMA= *normal-options* specify μ and σ for the normal distribution, and the COLOR= *normal-option* specifies the color for the line.

Table 5.54 Distribution Options

Option	Description
Distribution Reference Line Options	
COLOR=	specifies color of distribution reference line
L=	specifies line type of distribution reference line
NOLINE	suppresses the distribution reference line
SYMBOL=	specifies plotting character for line printer plots
W=	specifies width of distribution reference line
Beta-Options	
ALPHA=	specifies shape parameter α
BETA=	specifies shape parameter β
SIGMA=	specifies scale parameter σ
THETA=	specifies lower threshold parameter θ
Exponential-Options	
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ
Gamma-Options	
ALPHA=	specifies shape parameter α
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ

Table 5.54 (continued)

Option	Description
Gumbel-Options	
MU=	specifies location parameter μ
SIGMA=	specifies scale parameter σ
IGauss-Options	
LAMBDA=	specifies shape parameter λ
MU=	specifies mean μ
Lognormal-Options	
SIGMA=	specifies shape parameter σ
THETA=	specifies threshold parameter θ
ZETA=	specifies scale parameter ζ
Normal-Options	
MU=	specifies mean μ
SIGMA=	specifies standard deviation σ
Pareto-Options	
ALPHA=	specifies shape parameter α
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ
Power-Options	
ALPHA=	specifies shape parameter α
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ
Rayleigh-Options	
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ
Weibull-Options	
C=	specifies shape parameter c
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ

General Options

Table 5.55 lists options that control the appearance of the plots.

Table 5.55 General PPLOT Statement Options

Option	Description
General Plot Layout Options	
CONTENTS=	specifies table of contents entry for P-P plot grouping
HREF=	specifies reference lines perpendicular to the horizontal axis
HREFLABELS=	specifies line labels for HREF= lines
NOFRAME	suppresses frame around plotting area
SQUARE	displays P-P plot in square format
VREF=	specifies reference lines perpendicular to the vertical axis
VREFLABELS=	specifies line labels for VREF= lines

Table 5.55 (continued)

Option	Description
Graphics Options	
ANNOTATE=	provides an annotate data set
CAXIS=	specifies color for axis
CFRAME=	specifies color for frame
CHREF=	specifies colors for HREF= lines
CTEXT=	specifies color for text
CVREF=	specifies colors for VREF= lines
DESCRIPTION=	specifies description for plot in graphics catalog
FONT=	specifies software font for text
HAXIS=	specifies AXIS statement for horizontal axis
HEIGHT=	specifies height of text used outside framed areas
HMINOR=	specifies number of minor tick marks on horizontal axis
HREFLABPOS=	specifies position for HREF= line labels
INFONT=	specifies software font for text inside framed areas
INHEIGHT=	specifies height of text inside framed areas
LHREF=	specifies line styles for HREF= lines
LVREF=	specifies line styles for VREF= lines
NAME=	specifies name for plot in graphics catalog
NOHLABEL	suppresses label for horizontal axis
NOVLABEL	suppresses label for vertical axis
NOVTICK	suppresses tick marks and tick mark labels for vertical axis
TURNVLABELS	turns and vertically strings out characters in labels for vertical axis
VAXIS=	specifies AXIS statement for vertical axis
VAXISLABEL=	specifies label for vertical axis
VMINOR=	specifies number of minor tick marks on vertical axis
VREFLABPOS=	specifies position for VREF= line labels
WAXIS=	specifies line thickness for axes and frame
Options for ODS Graphics Output	
ODSFOOTNOTE=	specifies footnote displayed on P-P plot
ODSFOOTNOTE2=	specifies secondary footnote displayed on P-P plot
ODSTITLE=	specifies title displayed on P-P plot
ODSTITLE2=	specifies secondary title displayed on P-P plot
Options for Comparative Plots	
ANNOKEY	applies annotation requested in ANNOTATE= data set to key cell only
CFRAMESIDE=	specifies color for filling row label frames
CFRAMETOP=	specifies color for filling column label frames
CPROP=	specifies color for proportion of frequency bar
CTEXTSIDE=	specifies color for row labels
CTEXTTOP=	specifies color for column labels
INTERTILE=	specifies distance between tiles in comparative plot
NCOLS=	specifies number of columns in comparative plot
NROWS=	specifies number of rows in comparative plot

Table 5.55 (continued)

Option	Description
OVERLAY	overlays plots for different class levels (ODS Graphics only)
Options for Line Printer Charts	
HREFCHAR=	specifies line character for HREF= lines
NOOBSLEGEND	suppresses legend for hidden points
PPSYMBOL=	specifies character for plotted points
VREFCHAR=	specifies line character for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the options specific to the PPLOT statement. The marginal note *Line Printer* identifies options that apply only to line printer plots. See “Dictionary of Common Options: CAPABILITY Procedure” on page 551 for detailed descriptions of options common to all the plot statements.

ALPHA=*value*

specifies the shape parameter α ($\alpha > 0$) for P-P plots requested with the BETA, GAMMA, PARETO, and POWER options. For examples, see the entries for the distribution options.

BETA<(beta-options)>

creates a beta P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical beta cdf value

$$B_{\alpha\beta} \left(\frac{x_{(i)} - \theta}{\sigma} \right) = \int_{\theta}^{x_{(i)}} \frac{(t - \theta)^{\alpha - 1} (\theta + \sigma - t)^{\beta - 1}}{B(\alpha, \beta) \sigma^{\alpha + \beta - 1}} dt$$

where $B_{\alpha\beta}(\cdot)$ is the normalized incomplete beta function, $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha + \beta)}$, and

θ = lower threshold parameter

σ = scale parameter ($\sigma > 0$)

α = first shape parameter ($\alpha > 0$)

β = second shape parameter ($\beta > 0$)

You can specify α , β , σ , and θ with the ALPHA=, BETA=, SIGMA=, and THETA= *beta-options*, as illustrated in the following example:

```
proc capability data=measures;
  ppplot width / beta(theta=1 sigma=2 alpha=3 beta=4);
run;
```

If you do not specify values for these parameters, then by default, $\theta = 0$, $\sigma = 1$, and maximum likelihood estimates are calculated for α and β .

IMPORTANT: If the default unit interval (0,1) does not adequately describe the range of your data, then you should specify THETA= θ and SIGMA= σ so that your data fall in the interval ($\theta, \theta + \sigma$).

If the data are beta distributed with parameters α , β , σ , and θ , then the points on the plot for ALPHA= α , BETA= β , SIGMA= σ , and THETA= θ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified beta distribution is a good fit. You can specify the SCALE= option as an alias for the SIGMA= option and the THRESHOLD= option as an alias for the THETA= option.

BETA=value

specifies the shape parameter β ($\beta > 0$) for P-P plots requested with the BETA distribution option. See the preceding entry for the BETA distribution option for an example.

C=value

specifies the shape parameter c ($c > 0$) for P-P plots requested with the WEIBULL option. See the entry for the WEIBULL option for examples.

EXPONENTIAL<(exponential-options)>

EXP<(exponential-options)>

creates an exponential P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical exponential cdf value

$$F(x_{(i)}) = 1 - \exp\left(-\frac{x_{(i)} - \theta}{\sigma}\right)$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

You can specify σ and θ with the SIGMA= and THETA= *exponential-options*, as illustrated in the following example:

```
proc capability data=measures;
  ppplot width / exponential(theta=1 sigma=2);
run;
```

If you do not specify values for these parameters, then by default, $\theta = 0$ and a maximum likelihood estimate is calculated for σ .

IMPORTANT: Your data must be greater than or equal to the lower threshold θ . If the default $\theta = 0$ is not an adequate lower bound for your data, specify θ with the THETA= option.

If the data are exponentially distributed with parameters σ and θ , the points on the plot for SIGMA= σ and THETA= θ tend to fall on or near the diagonal line $y = x$, which is displayed

by default. Agreement between the diagonal line and the point pattern is evidence that the specified exponential distribution is a good fit. You can specify the SCALE= option as an alias for the SIGMA= option and the THRESHOLD= option as an alias for the THETA= option.

GAMMA< (*gamma-options*) >

creates a gamma P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical gamma cdf value

$$G_{\alpha} \left(\frac{x_{(i)} - \theta}{\sigma} \right) = \int_{\theta}^{x_{(i)}} \frac{1}{\sigma \Gamma(\alpha)} \left(\frac{t - \theta}{\sigma} \right)^{\alpha - 1} \exp \left(-\frac{t - \theta}{\sigma} \right) dt$$

where $G_{\alpha}(\cdot)$ is the normalized incomplete gamma function, and

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

You can specify α , σ , and θ with the ALPHA=, SIGMA=, and THETA= *gamma-options*, as illustrated in the following example:

```
proc capability data=measures;
  ppplot width / gamma(alpha=1 sigma=2 theta=3);
run;
```

If you do not specify values for these parameters, then by default, $\theta = 0$ and maximum likelihood estimates are calculated for α and σ .

IMPORTANT: Your data must be greater than or equal to the lower threshold θ . If the default $\theta = 0$ is not an adequate lower bound for your data, specify θ with the THETA= option.

If the data are gamma distributed with parameters α , σ , and θ , the points on the plot for ALPHA= α , SIGMA= σ , and THETA= θ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified gamma distribution is a good fit. You can specify the SHAPE= option as an alias for the ALPHA= option, the SCALE= option as an alias for the SIGMA= option, and the THRESHOLD= option as an alias for the THETA= option.

GUMBEL< (*Gumbel-options*) >

creates a Gumbel P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical Gumbel cdf value

$$F(x_{(i)}) = \exp \left(-e^{-(x_{(i)} - \mu)/\sigma} \right)$$

where

μ = location parameter

σ = scale parameter ($\sigma > 0$)

You can specify μ and σ with the **MU=** and **SIGMA=** *Gumbel-options*. By default, maximum likelihood estimates are computed for μ and σ .

If the data are Gumbel distributed with parameters μ and σ , the points on the plot for **MU=** μ and **SIGMA=** σ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified Gumbel distribution is a good fit.

IGAUSS< (*iGauss-options*) >

creates an inverse Gaussian P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical inverse Gaussian cdf value

$$F(x_{(i)}) = \Phi \left\{ \sqrt{\frac{\lambda}{x_{(i)}}} \left(\frac{x_{(i)}}{\mu} - 1 \right) \right\} + e^{2\lambda/\mu} \Phi \left\{ -\sqrt{\frac{\lambda}{x_{(i)}}} \left(\frac{x_{(i)}}{\mu} + 1 \right) \right\}$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function, and

μ = mean parameter ($\mu > 0$)

λ = shape parameter ($\lambda > 0$)

You can specify known values for μ and λ with the **MU=** and **LAMBDA=** *iGauss-options*. By default, the sample mean is calculated for μ and a maximum likelihood estimate is computed for and λ .

If the data are inverse Gaussian distributed with parameters μ and λ , the points on the plot for **MU=** μ and **LAMBDA=** λ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified inverse Gaussian distribution is a good fit.

LAMBDA=value

specifies the shape parameter λ ($\lambda > 0$) for P-P plots requested with the **IGAUSS** option. Enclose the **LAMBDA=** option in parentheses after the **IGAUSS** distribution keyword. If you do not specify a value for λ , the procedure calculates a maximum likelihood estimate.

LOGNORMAL< (*lognormal-options*) >

LNORM< (*lognormal-options*) >

creates a lognormal P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical lognormal cdf value

$$\Phi\left(\frac{\log(x_{(i)}-\theta)-\zeta}{\sigma}\right)$$

where $\Phi(\cdot)$ is the cumulative standard normal distribution function, and

θ = threshold parameter

ζ = scale parameter

σ = shape parameter ($\sigma > 0$)

You can specify θ , ζ , and σ with the THETA=, ZETA=, and SIGMA= *lognormal-options*, as illustrated in the following example:

```
proc capability data=measures;
  ppplot width / lognormal(theta=1 zeta=2);
run;
```

If you do not specify values for these parameters, then by default, $\theta = 0$ and maximum likelihood estimates are calculated for σ and ζ .

IMPORTANT: Your data must be greater than the lower threshold θ . If the default $\theta = 0$ is not an adequate lower bound for your data, specify θ with the THETA= option.

If the data are lognormally distributed with parameters σ , θ , and ζ , the points on the plot for SIGMA= σ , THETA= θ , and ZETA= ζ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified lognormal distribution is a good fit. You can specify the SHAPE= option as an alias for the SIGMA= option, the SCALE= option as an alias for the ZETA= option, and the THRESHOLD= option as an alias for the THETA= option.

MU=value

specifies the parameter μ for a P-P plot requested with the GUMBEL, IGAUSS, and NORMAL options. For examples, see Figure 5.31, or Figure 5.32 and Figure 5.33. For the normal and inverse Gaussian distributions, the default value of μ is the sample mean. If you do not specify a value for μ for the Gumbel distribution, the procedure calculates a maximum likelihood estimate.

NOLINE

suppresses the diagonal reference line.

NOOBSLEGEND

NOOBSL

suppresses the legend that indicates the number of hidden observations.

Line Printer

NORMAL<(normal-options)>

NORM<(normal-options)>

creates a normal P-P plot. By default, if you do not specify a distribution option, the procedure displays a normal P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical normal cdf value

$$\Phi\left(\frac{x^{(i)}-\mu}{\sigma}\right) = \int_{-\infty}^{x^{(i)}} \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(t-\mu)^2}{2\sigma^2}\right) dt$$

where $\Phi(\cdot)$ is the cumulative standard normal distribution function, and

μ = location parameter or mean

σ = scale parameter or standard deviation ($\sigma > 0$)

You can specify μ and σ with the **MU=** and **SIGMA=** *normal-options*, as illustrated in the following example:

```
proc capability data=measures;
  ppplot width / normal(mu=1 sigma=2);
run;
```

By default, the sample mean and sample standard deviation are used for μ and σ .

If the data are normally distributed with parameters μ and σ , the points on the plot for **MU=** μ and **SIGMA=** σ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified normal distribution is a good fit. For an example, see [Figure 5.31](#).

PARETO< (*Pareto-options*) >

creates a generalized Pareto P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical generalized Pareto cdf value

$$F(x_{(i)}) = 1 - \left(1 - \frac{\alpha(x_{(i)} - \theta)}{\sigma}\right)^{\frac{1}{\alpha}}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter

The parameter θ for the generalized Pareto distribution must be less than the minimum data value. You can specify θ with the **THETA=** *Pareto-option*. The default value for θ is 0. In addition, the generalized Pareto distribution has a shape parameter α and a scale parameter σ . You can specify these parameters with the **ALPHA=** and **SIGMA=** *Pareto-options*. By default, maximum likelihood estimates are computed for α and σ .

If the data are generalized Pareto distributed with parameters θ , σ , and α , the points on the plot for **THETA=** θ , **SIGMA=** σ , and **ALPHA=** α tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified generalized Pareto distribution is a good fit.

POWER< (*power-options*) >

creates a power function P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical power function cdf value

$$F(x_{(i)}) = \left(\frac{x_{(i)} - \theta}{\sigma} \right)^\alpha$$

where

θ = lower threshold parameter (lower endpoint)

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

The power function distribution is bounded below by the parameter θ and above by the value $\theta + \sigma$. You can specify θ and σ by using the **THETA=** and **SIGMA=** *power-options*. The default values for θ and σ are 0 and 1, respectively.

You can specify a value for the shape parameter, α , with the **ALPHA=** *power-option*. If you do not specify a value for α , the procedure calculates a maximum likelihood estimate.

The power function distribution is a special case of the beta distribution with its second shape parameter, $\beta = 1$.

If the data are power function distributed with parameters θ , σ , and α , the points on the plot for **THETA=** θ , **SIGMA=** σ , and **ALPHA=** α tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified power function distribution is a good fit.

PPSYMBOL='*character*'

specifies the character used to plot the points in a line printer plot. The default is the plus sign *Line Printer* (+).

RAYLEIGH< (*Rayleigh-options*) >

creates a Rayleigh P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y -coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x -coordinate is the theoretical Rayleigh cdf value

$$F(x_{(i)}) = 1 - e^{-(x_{(i)} - \theta)^2 / (2\sigma^2)}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

The parameter θ for the Rayleigh distribution must be less than the minimum data value. You can specify θ with the **THETA=** *Rayleigh-option*. The default value for θ is 0. You can

specify σ with the **SIGMA=** *Rayleigh-option*. By default, a maximum likelihood estimate is computed for σ .

If the data are Rayleigh distributed with parameters θ and σ , the points on the plot for **THETA=** θ and **SIGMA=** σ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified Rayleigh distribution is a good fit.

SIGMA=*value*

specifies the parameter σ , where $\sigma > 0$. When used with the **BETA**, **EXPONENTIAL**, **GAMMA**, **GUMBEL**, **NORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, and **WEIBULL** options, the **SIGMA=** option specifies the scale parameter. When used with the **LOGNORMAL** option, the **SIGMA=** option specifies the shape parameter. Enclose the **SIGMA=** option in parentheses after the distribution keyword. For an example of the **SIGMA=** option used with the **NORMAL** option, see Figure 5.31.

SQUARE

displays the P-P plot in a square frame. The default is a rectangular frame. See Figure 5.31 for an example.

SYMBOL='character'

Line Printer

specifies the character used for the diagonal reference line in line printer plots. The default character is the first letter of the distribution option keyword.

THETA=*value*

THRESHOLD=*value*

specifies the lower threshold parameter θ for plots requested with the **BETA**, **EXPONENTIAL**, **GAMMA**, **LOGNORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, and **WEIBULL** options.

WEIBULL< (*Weibull-options*) >

WEIB< (*Weibull-options*) >

creates a Weibull P-P plot. To create the plot, the n nonmissing observations are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

The y-coordinate of the i th point is the empirical cdf value $\frac{i}{n}$. The x-coordinate is the theoretical Weibull cdf value

$$F(x_{(i)}) = 1 - \exp\left(-\left(\frac{x_{(i)} - \theta}{\sigma}\right)^c\right)$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

c = shape parameter ($c > 0$)

You can specify c , σ , and θ with the **C=**, **SIGMA=**, and **THETA=** *Weibull-options*, as illustrated in the following example:

```
proc capability data=measures;
  ppplot width / weibull(theta=1 sigma=2);
run;
```

If you do not specify values for these parameters, then by default $\theta = 0$ and maximum likelihood estimates are calculated for σ and c .

IMPORTANT: Your data must be greater than or equal to the lower threshold θ . If the default $\theta = 0$ is not an adequate lower bound for your data, you should specify θ with the THETA= option.

If the data are Weibull distributed with parameters c , σ , and θ , the points on the plot for C= c , SIGMA= σ , and THETA= θ tend to fall on or near the diagonal line $y = x$, which is displayed by default. Agreement between the diagonal line and the point pattern is evidence that the specified Weibull distribution is a good fit. You can specify the SHAPE= option as an alias for the C= option, the SCALE= option as an alias for the SIGMA= option, and the THRESHOLD= option as an alias for the THETA= option.

ZETA=*value*

specifies a value for the scale parameter ζ for lognormal P-P plots requested with the LOG-NORMAL option.

Details: PPLOT Statement

This section provides details on the following topics:

- construction and interpretation of P-P plots
- comparison of P-P plots with Q-Q plots
- distributions supported by the PPLOT statement
- graphical enhancements of P-P plots

Construction and Interpretation of P-P Plots

A P-P plot compares the empirical cumulative distribution function (ecdf) of a variable with a specified theoretical cumulative distribution function $F(\cdot)$. The ecdf, denoted by $F_n(x)$, is defined as the proportion of nonmissing observations less than or equal to x , so that $F_n(x_{(i)}) = \frac{i}{n}$.

To construct a P-P plot, the n nonmissing values are first sorted in increasing order:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

Then the i th ordered value $x_{(i)}$ is represented on the plot by the point whose x -coordinate is $F(x_{(i)})$ and whose y -coordinate is $\frac{i}{n}$.

Like Q-Q plots and probability plots, P-P plots can be used to determine how well a theoretical distribution models a data distribution. If the theoretical cdf reasonably models the ecdf in all respects, including location and scale, the point pattern on the P-P plot is linear through the origin and has unit slope.

See CAPPP2 in the
SAS/QC Sample Library

Unlike Q-Q and probability plots, P-P plots are not invariant to changes in location and scale. For example, the data in the section “Getting Started: PPLOT Statement” on page 456 are reasonably described by a normal distribution with mean 10 and standard deviation 0.3. It is instructive to display these data on normal P-P plots with a different mean and standard deviation, as created by the following statements:

```
ods graphics on;
proc capability data=Sheets noprint;
  ppplot Distance / normal(mu=9.5 sigma=0.3) square;
  ppplot Distance / normal(mu=10 sigma=0.5) square;
run;
```

The ODS GRAPHICS ON statement specified before the PROC CAPABILITY statement enables ODS Graphics, so the P-P plots are created using ODS Graphics instead of traditional graphics. The resulting plots are shown in Figure 5.32 and Figure 5.33.

Figure 5.32 Normal P-P Plot with Mean Specified Incorrectly

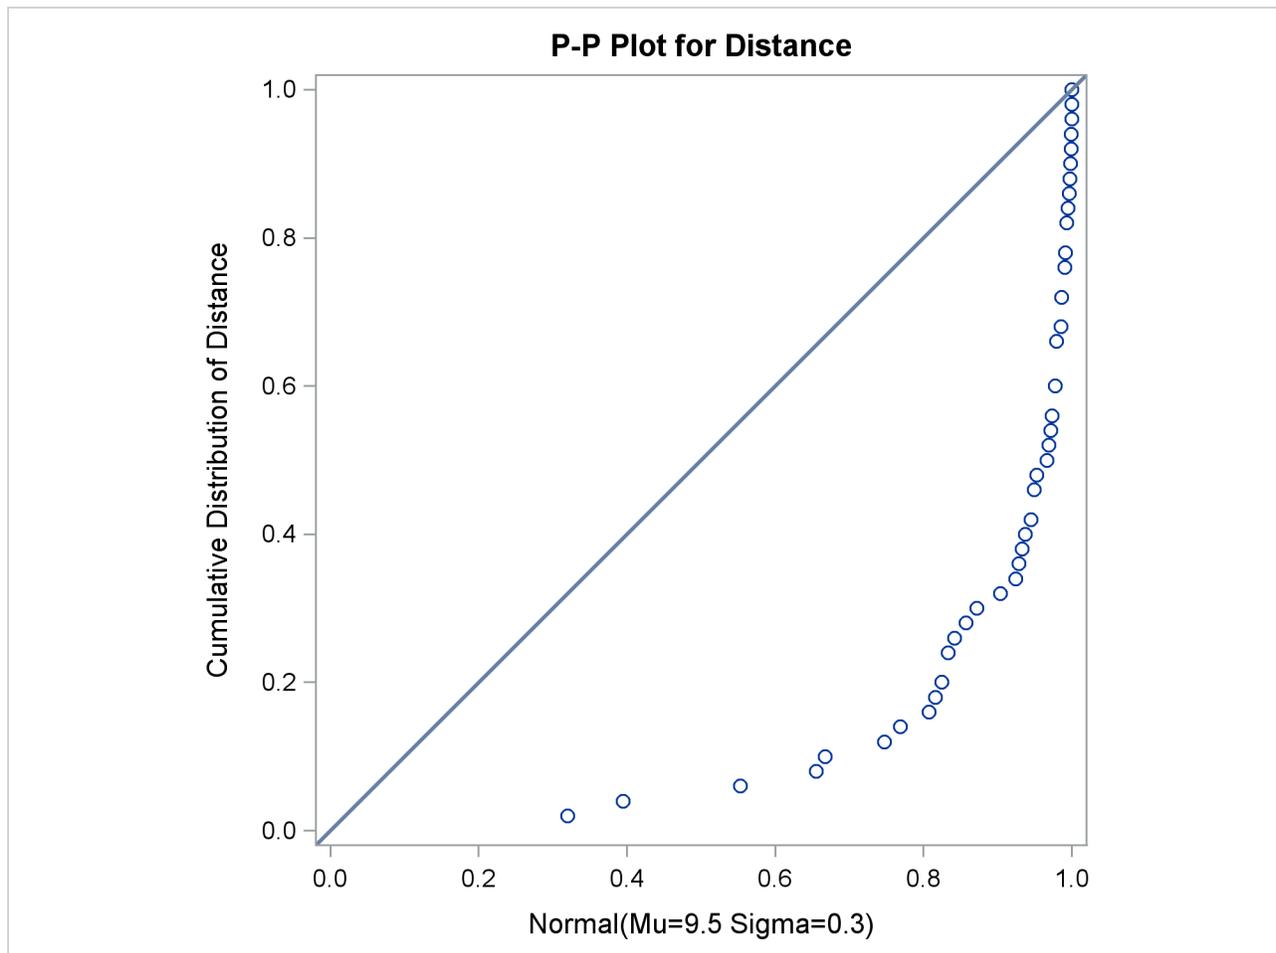

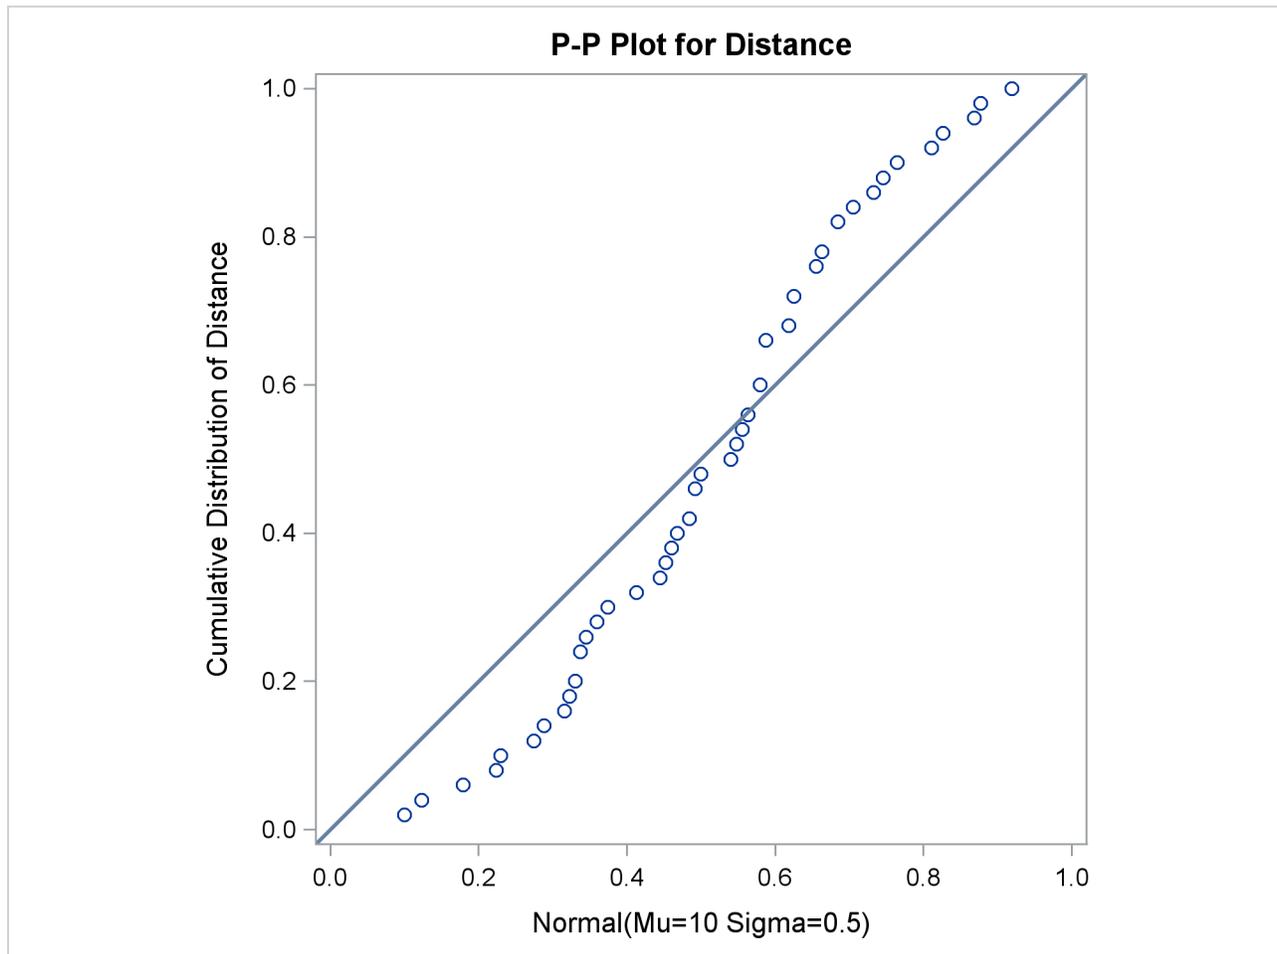

Figure 5.33 Normal P-P Plot with Standard Deviation Specified Incorrectly

Specifying a mean of 9.5 instead of 10 results in the plot shown in Figure 5.32, while specifying a standard deviation of 0.5 instead of 0.3 results in the plot shown in Figure 5.33. Both plots clearly reveal the model misspecification.

Comparison of P-P Plots and Q-Q Plots

A P-P plot compares the empirical cumulative distribution function of a data set with a specified theoretical cumulative distribution function $F(\cdot)$. A Q-Q plot compares the quantiles of a data distribution with the quantiles of a standardized theoretical distribution from a specified family of distributions. There are three important differences in the way P-P plots and Q-Q plots are constructed and interpreted:

- The construction of a Q-Q plot does not require that the location or scale parameters of $F(\cdot)$ be specified. The theoretical quantiles are computed from a standard distribution within the specified family. A linear point pattern indicates that the specified family reasonably describes the data distribution, and the location and scale parameters can be estimated visually as the intercept and slope of the linear pattern. In contrast, the construction of a P-P plot requires the location and scale parameters of $F(\cdot)$ to evaluate the cdf at the ordered data values.

- The linearity of the point pattern on a Q-Q plot is unaffected by changes in location or scale. On a P-P plot, changes in location or scale do not necessarily preserve linearity.
- On a Q-Q plot, the reference line representing a particular theoretical distribution depends on the location and scale parameters of that distribution, having intercept and slope equal to the location and scale parameters. On a P-P plot, the reference line for any distribution is always the diagonal line $y = x$.

Consequently, you should use a Q-Q plot if your objective is to compare the data distribution with a family of distributions that vary only in location and scale, particularly if you want to estimate the location and scale parameters from the plot.

An advantage of P-P plots is that they are discriminating in regions of high probability density, since in these regions the empirical and theoretical cumulative distributions change more rapidly than in regions of low probability density. For example, if you compare a data distribution with a particular normal distribution, differences in the middle of the two distributions are more apparent on a P-P plot than on a Q-Q plot.

For further details on P-P plots, refer to Gnanadesikan (1997) and Wilk and Gnanadesikan (1968).

Summary of Theoretical Distributions

You can use the PPLOT statement to request P-P plots based on the theoretical distributions summarized in the following table:

Table 5.56 Distributions and Parameters

Family	Distribution Function $F(x)$	Range	Parameters		
			Location	Scale	Shape
Beta	$\int_{\theta}^x \frac{(t-\theta)^{\alpha-1}(\theta+\sigma-t)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}} dt$	$\theta < x < \theta + \sigma$	θ	σ	α, β
Exponential	$1 - \exp\left(-\frac{x-\theta}{\sigma}\right)$	$x \geq \theta$	θ	σ	
Gamma	$\int_{\theta}^x \frac{1}{\sigma\Gamma(\alpha)} \left(\frac{t-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\frac{t-\theta}{\sigma}\right) dt$	$x > \theta$	θ	σ	α
Gumbel	$\exp\left(-e^{(x-\mu)/\sigma}\right)$	all x	μ	σ	
Inverse Gaussian	$\Phi\left\{\sqrt{\frac{\lambda}{x}}\left(\frac{x}{\mu}-1\right)\right\} + e^{2\lambda/\mu}\Phi\left\{-\sqrt{\frac{\lambda}{x}}\left(\frac{x}{\mu}+1\right)\right\}$	$x > 0$	μ		λ
Lognormal	$\int_{\theta}^x \frac{1}{\sigma\sqrt{2\pi}(t-\theta)} \exp\left(-\frac{(\log(t-\theta)-\xi)^2}{2\sigma^2}\right) dt$	$x > \theta$	θ	ξ	σ
Normal	$\int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(t-\mu)^2}{2\sigma^2}\right) dt$	all x	μ	σ	
Generalized Pareto	$1 - \left(1 - \frac{\alpha(x-\theta)}{\sigma}\right)^{1/\alpha}$	all x	θ	σ	α

Table 5.56 (continued)

Family	Distribution Function $F(x)$	Range	Parameters		
			Location	Scale	Shape
Power Function	$\left(\frac{x-\theta}{\sigma}\right)^\alpha$	$\theta < x < \theta + \sigma$	θ	σ	α
Rayleigh	$1 - e^{-(x-\theta)^2/(2\sigma^2)}$	$x \geq \theta$	θ	σ	
Weibull	$1 - \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right)$	$x > \theta$	θ	σ	c

You can request these distributions with the **BETA**, **EXPONENTIAL**, **GAMMA**, **GUMBEL**, **IGAUSS**, **NORMAL**, **LOGNORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, and **WEIBULL** options, respectively. If you do not specify a distribution option, a normal P-P plot is created.

To create a P-P plot, you must provide all of the parameters for the theoretical distribution. If you do not specify parameters, then default values or estimates are substituted, as summarized by the following table:

Table 5.57 Defaults for Parameters

Family	Default Values	Estimated Values
Beta	$\theta = 0, \sigma = 1$	maximum likelihood estimates for α and β
Exponential	$\theta = 0$	maximum likelihood estimate for σ
Gamma	$\theta = 0$	maximum likelihood estimates for σ and α
Gumbel	None	maximum likelihood estimates for μ and σ
Inverse Gaussian	None	sample estimate for μ , maximum likelihood estimate for λ
Lognormal	$\theta = 0$	maximum likelihood estimates for σ and ζ
Normal	None	sample estimates for μ and σ
Generalized Pareto	$\theta = 0$	maximum likelihood estimates for σ and α
Power Function	$\theta = 0, \sigma = 1$	maximum likelihood estimate for α
Rayleigh	$\theta = 0$	maximum likelihood estimate for σ
Weibull	$\theta = 0$	maximum likelihood estimates for σ and c

Specification of Symbol Markers

If you produce traditional graphics, you can use options in the **SYMBOL1** statement to specify the appearance of the symbol marker for the points. The **V=** option specifies the symbol, the **C=** option specifies the color, and the **H=** option specifies the height. Refer to *SAS/GRAPH: Reference* for details concerning these options. If you produce a line printer plot, you can use the **PPSYMBOL=** option in the **PPLOT** statement to specify the character used to plot the points.

Specification of the Distribution Reference Line

If you produce traditional graphics, you can control the color, type, and width of the diagonal distribution reference line by specifying the **COLOR=**, **L=**, and **W=** options in parentheses after the

distribution option in the PPLOT statement. Alternatively, you can control these features with the C=, L=, and W= options in the SYMBOL4 statement. Refer to *SAS/GRAPH: Reference* for details concerning these options. If you produce a line printer plot, you can specify the character used for the line with the SYMBOL= option enclosed in parentheses after the distribution option in the PPLOT statement.

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. PPLOT options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the PPLOT statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 5.58](#).

Table 5.58 ODS Graphics Produced by the PPLOT Statement

ODS Graph Name	Plot Description
PPPlot	P-P plot

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

PROBPLOT Statement: CAPABILITY Procedure

Overview: PROBPLOT Statement

The PROBPLOT statement creates a probability plot, which compares ordered values of a variable with percentiles of a specified theoretical distribution such as the normal. If the data distribution matches the theoretical distribution, the points on the plot form a linear pattern. Thus, you can use a probability plot to determine how well a theoretical distribution models a set of measurements.

You can specify one of the following theoretical distributions with the PROBPLOT statement:

- beta
- exponential
- gamma
- Gumbel
- three-parameter lognormal
- normal
- generalized Pareto
- power function
- Rayleigh
- two-parameter Weibull
- three-parameter Weibull

You can use options in the PROBPLOT statement to do the following:

- specify or estimate shape parameters for the theoretical distribution
- display a reference line corresponding to specified or estimated location and scale parameters for the theoretical distribution
- request graphical enhancements

You can also create a comparative probability plot by using the PROBPLOT statement in conjunction with a CLASS statement.

You have three alternatives for producing probability plots the PROBPLOT statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.

- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

NOTE: Probability plots are similar to Q-Q plots, which you can create with the QQPLOT statement (see “QQPLOT Statement: CAPABILITY Procedure” on page 508). Probability plots are preferable for graphical estimation of percentiles, whereas Q-Q plots are preferable for graphical estimation of distribution parameters and capability indices.

Getting Started: PROBPLOT Statement

The following examples illustrate the basic syntax of the PROBPLOT statement. For complete details of the PROBPLOT statement, see the section “Syntax: PROBPLOT Statement” on page 483. Advanced examples are provided on the section “Examples: PROBPLOT Statement” on page 505.

Creating a Normal Probability Plot

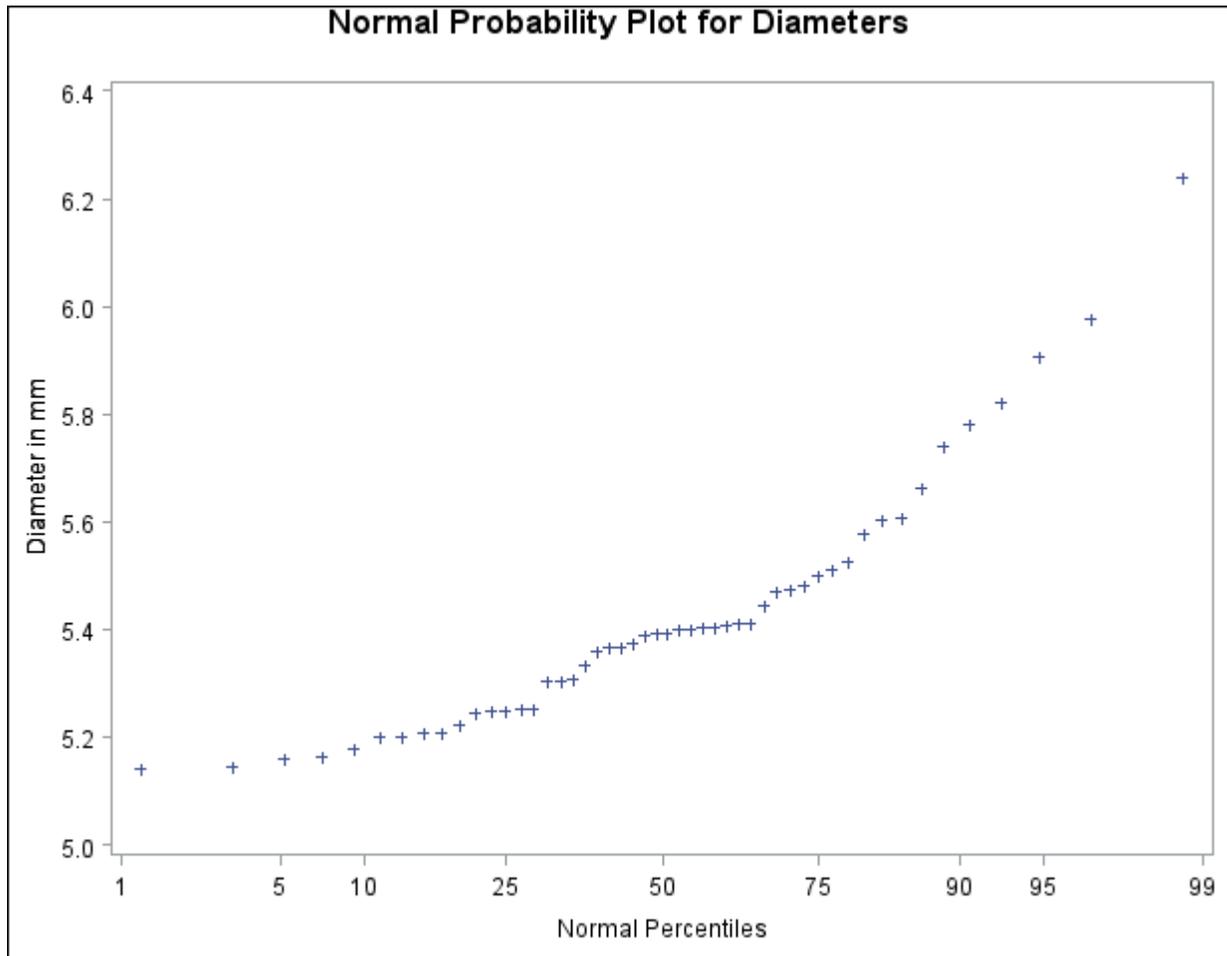

See CAPPROB1 in the SAS/QC Sample Library. The diameters of 50 steel rods are measured and saved as values of the variable Diameter in the following data set:⁷

```
data Rods;
  input Diameter @@;
  label Diameter='Diameter in mm';
  datalines;
  5.501 5.251 5.404 5.366 5.445
  5.576 5.607 5.200 5.977 5.177
  5.332 5.399 5.661 5.512 5.252
  5.404 5.739 5.525 5.160 5.410
  5.823 5.376 5.202 5.470 5.410
  5.394 5.146 5.244 5.309 5.480
  5.388 5.399 5.360 5.368 5.394
  5.248 5.409 5.304 6.239 5.781
  5.247 5.907 5.208 5.143 5.304
  5.603 5.164 5.209 5.475 5.223
  ;
```

The process producing the rods is in statistical control, and as a preliminary step in a capability analysis of the process, you decide to check whether the diameters are normally distributed. The following statements create the normal probability plot shown in Figure 5.34:

```
ods graphics off;
symbol v=plus;
title 'Normal Probability Plot for Diameters';
proc capability data=Rods noprint;
  probplot Diameter;
run;
```

⁷This data set is analyzed using quantile-quantile plots in Example 5.21 and Example 5.22.

Figure 5.34 Normal Probability Plot Created with Traditional Graphics

Note that the PROBLOT statement creates a normal probability plot for Diameter by default.

The nonlinearity of the point pattern indicates a departure from normality. Since the point pattern is curved with slope increasing from left to right, a theoretical distribution that is skewed to the right, such as a lognormal distribution, should provide a better fit than the normal distribution. This possibility is explored in the next example.

Creating Lognormal Probability Plots

When you request a lognormal probability plot, you must specify the shape parameter σ for the lognormal distribution (see Table 5.62 for the equation). The value of σ must be positive, and typical values of σ range from 0.1 to 1.0. Alternatively, you can specify that σ is to be estimated from the data. *See CAPPROB3 in the SAS/QC Sample Library*

The following statements illustrate the first approach by creating a series of three lognormal probability plots for the variable Diameter introduced in the preceding example:

```
ods graphics on;
proc capability data=Rods noprint;
  probplot Diameter / lognormal(sigma=0.2 0.5 0.8)
    href = 95
    square;
run;
```

The ODS GRAPHICS ON statement specifies that the probability plot be produced by using ODS Graphics. The LOGNORMAL option requests plots based on the lognormal family of distributions, and the SIGMA= option requests plots for σ equal to 0.2, 0.5, and 0.8. The SQUARE option displays the probability plot in a square format and the HREF= option requests a reference line at the 95th percentile.

The resulting plots are displayed in Figure 5.35, Figure 5.36, and Figure 5.37, respectively. The value $\sigma = 0.5$ in Figure 5.36 produces the most linear pattern.

Figure 5.35 Probability Plot Based on Lognormal Distribution with $\sigma = 0.2$

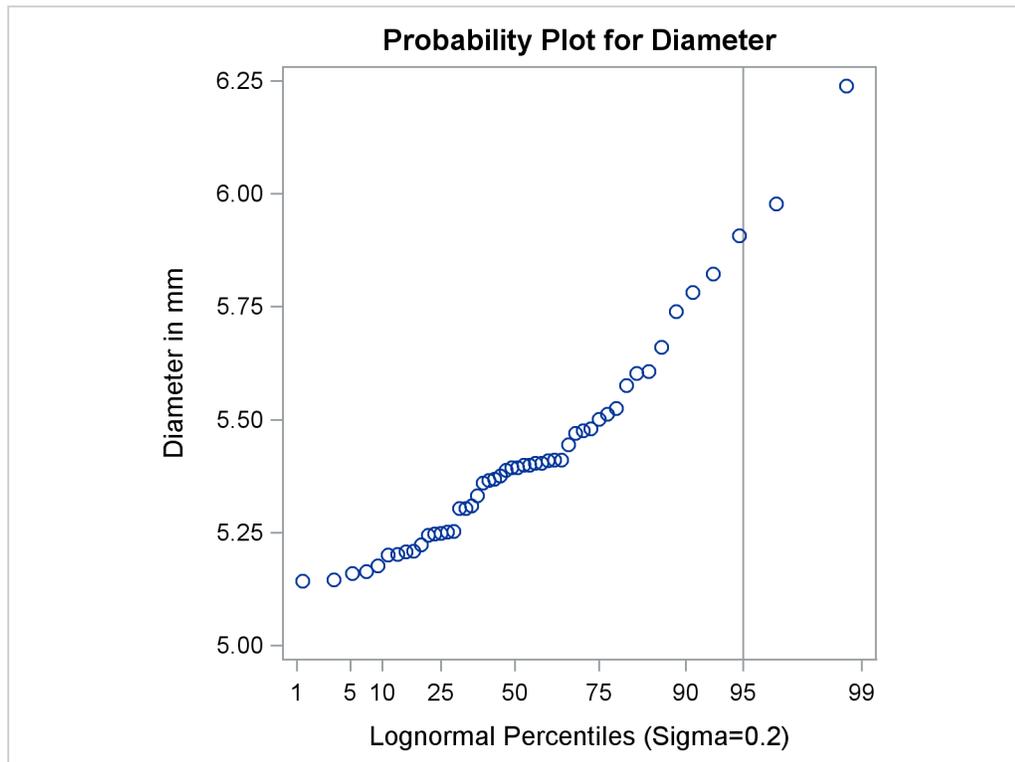

Figure 5.36 Probability Plot Based on Lognormal Distribution with $\sigma = 0.5$

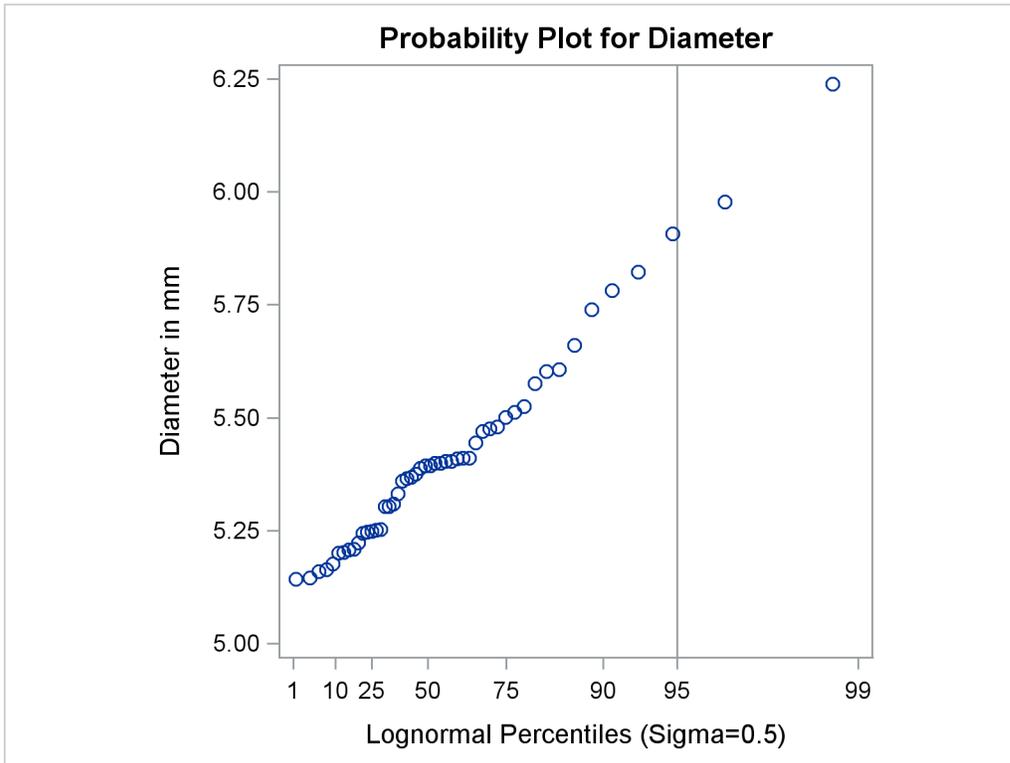

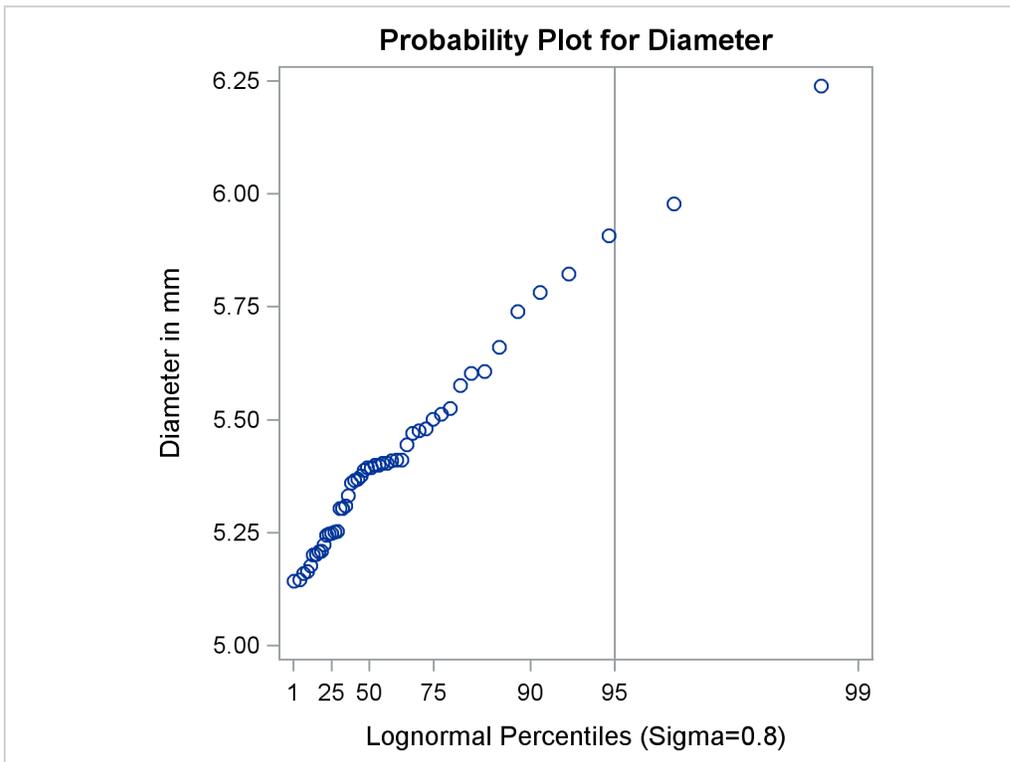

Figure 5.37 Probability Plot Based on Lognormal Distribution with $\sigma = 0.8$

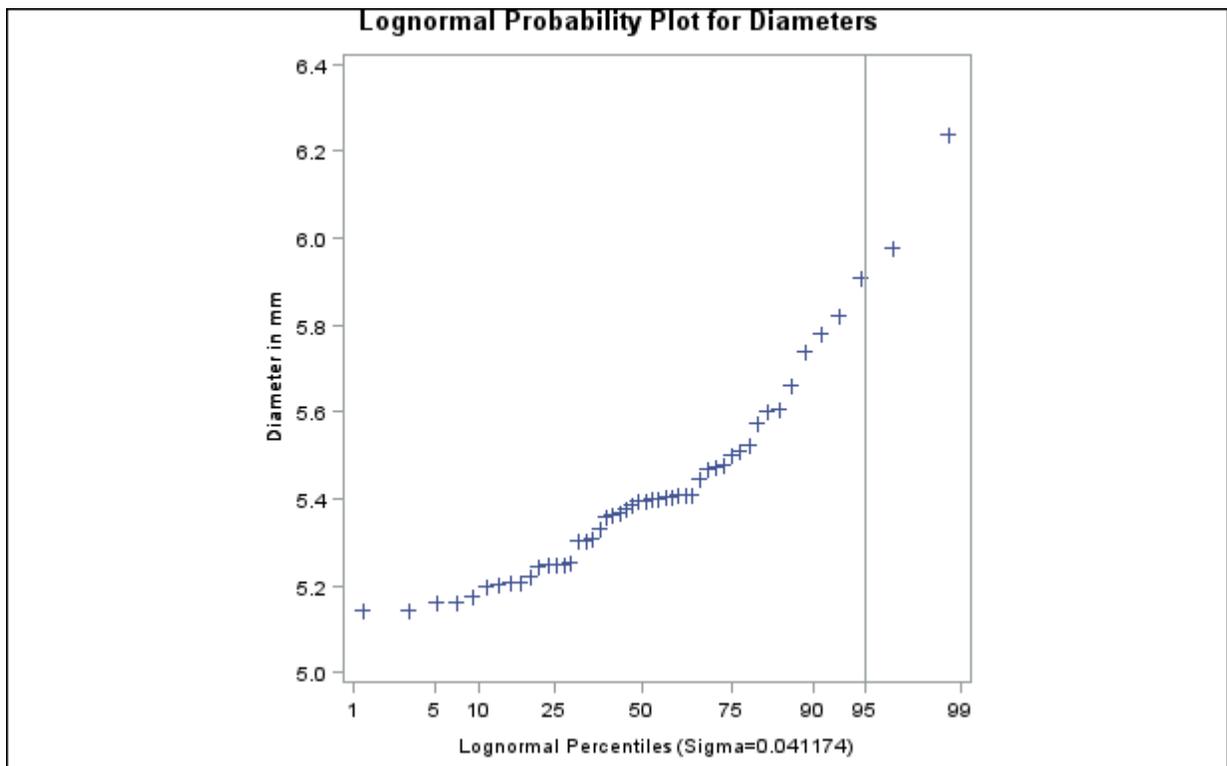

Based on Figure 5.36, the 95th percentile of the diameter distribution is approximately 5.9 mm, since this is the value corresponding to the intersection of the point pattern with the reference line.

The following statements illustrate how you can create a lognormal probability plot for Diameter using a local maximum likelihood estimate for σ .

```
ods graphics off;
symbol v=plus height=3.5pct;
title 'Lognormal Probability Plot for Diameters';
proc capability data=Rods noprint;
  probplot Diameter / lognormal(sigma=est)
    href = 95
    square;
run;
```

The plot is displayed in Figure 5.38. Note that the maximum likelihood estimate of σ (in this case 0.041) does not necessarily produce the most linear point pattern. This example is continued in Example 5.20.

Figure 5.38 Probability Plot Based on Lognormal Distribution with Estimated σ

Syntax: PROBLOT Statement

The syntax for the PROBLOT statement is as follows:

```
PROBLOT < variables > < / options > ;
```

You can specify the keyword **PROB** as an alias for **PROBLOT**, and you can use any number of **PROBLOT** statements in the **CAPABILITY** procedure. The components of the **PROBLOT** statement are described as follows.

variables

are the process variables for which to create probability plots. If you specify a **VAR** statement, the variables must also be listed in the **VAR** statement. Otherwise, the variables can be any numeric variables in the input data set. If you do not specify a list of variables, then by default the procedure creates a probability plot for each variable listed in the **VAR** statement, or for each numeric variable in the **DATA=** data set if you do not specify a **VAR** statement. For example, each of the following **PROBLOT** statements produces two probability plots, one for length and one for width:

```
proc capability data=measures;
  var length width;
  probplot;
run;
```

```
proc capability data=measures;
  probplot length width;
run;
```

options

specify the theoretical distribution for the plot or add features to the plot. If you specify more than one variable, the options apply equally to each variable. Specify all options after the slash (/) in the **PROBLOT** statement. You can specify only one option naming the distribution in each **PROBLOT** statement, but you can specify any number of other options. The distributions available are the beta, exponential, gamma, Gumbel, lognormal, normal, generalized Pareto, power function, Rayleigh, two-parameter Weibull, and three-parameter Weibull. By default, the procedure produces a plot for the normal distribution.

In the following example, the **NORMAL** option requests a normal probability plot for each variable, while the **MU=** and **SIGMA=** *normal-options* request a distribution reference line corresponding to the normal distribution with $\mu = 10$ and $\sigma = 0.3$. The **SQUARE** option displays the plot in a square frame, and the **CTEXT=** option specifies the text color.

```
proc capability data=measures;
  probplot length1 length2 / normal(mu=10 sigma=0.3)
                          square
                          ctext=blue;
run;
```

Summary of Options

The following tables list the PROBPLOT statement options by function. For complete descriptions, see the section “Dictionary of Options” on page 488.

Distribution Options

Table 5.59 summarizes the options for requesting a specific theoretical distribution.

Table 5.59 Options for Specifying a Theoretical Distribution

Option	Description
BETA(<i>beta-options</i>)	specifies beta probability plot for shape parameters α , β specified with mandatory ALPHA= and BETA= <i>beta-options</i>
EXPONENTIAL(<i>exponential-options</i>)	specifies exponential probability plot
GAMMA(<i>gamma-options</i>)	specifies gamma probability plot for shape parameter α specified with mandatory ALPHA= <i>gamma-option</i>
GUMBEL(<i>Gumbel-options</i>)	specifies Gumbel probability plot
LOGNORMAL(<i>lognormal-options</i>)	specifies lognormal probability plot for shape parameter σ specified with mandatory SIGMA= <i>lognormal-option</i>
NORMAL(<i>normal-options</i>)	specifies normal probability plot
PARETO(<i>Pareto-options</i>)	specifies generalized Pareto probability plot for shape parameter α specified with mandatory ALPHA= <i>Pareto-option</i>
POWER(<i>power-options</i>)	specifies power function probability plot for shape parameter α specified with mandatory ALPHA= <i>power-option</i>
RAYLEIGH(<i>Rayleigh-options</i>)	specifies Rayleigh probability plot
WEIBULL(<i>Weibull-options</i>)	specifies three-parameter Weibull probability plot for shape parameter c specified with mandatory C= <i>Weibull-option</i>
WEIBULL2(<i>Weibull2-options</i>)	specifies two-parameter Weibull probability plot

Table 5.60 summarizes options that specify distribution parameters and control the display of a distribution reference line. Specify these options in parentheses after the distribution option. For example, the following statements use the NORMAL option to request a normal probability plot with a distribution reference line:

```
proc capability data=measures;
  probplot length / normal(mu=10 sigma=0.3 color=red);
run;
```

The **MU=** and **SIGMA=** *normal-options* display a distribution reference line that corresponds to the normal distribution with mean $\mu_0 = 10$ and standard deviation $\sigma_0 = 0.3$, and the **COLOR=** *normal-option* specifies the color for the line.

Table 5.60 Distribution Options

Option	Description
Distribution Reference Line Options	
COLOR=	specifies color of distribution reference line
L=	specifies line type of distribution reference line
SYMBOL=	specifies plotting character for line printer plots
W=	specifies width of distribution reference line
Beta-Options	
ALPHA=	specifies mandatory shape parameter α
BETA=	specifies mandatory shape parameter β
SIGMA=	specifies σ_0 for distribution reference line
THETA=	specifies θ_0 for distribution reference line
Exponential-Options	
SIGMA=	specifies σ_0 for distribution reference line
THETA=	specifies θ_0 for distribution reference line
Gamma-Options	
ALPHA=	specifies mandatory shape parameter α
SIGMA=	specifies σ_0 for distribution reference line
THETA=	specifies θ_0 for distribution reference line
Gumbel-Options	
MU=	specifies location parameter μ
SIGMA=	specifies scale parameter σ
Lognormal-Options	
SIGMA=	specifies mandatory shape parameter σ
SLOPE=	specifies slope of distribution reference line
THETA=	specifies θ_0 for distribution reference line
ZETA=	specifies ζ_0 for distribution reference line (slope is $\exp(\zeta_0)$)
Normal-Options	
MU=	specifies μ_0 for distribution reference line
SIGMA=	specifies σ_0 for distribution reference line
Pareto-Options	
ALPHA=	specifies mandatory shape parameter α
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ
Power-Options	
ALPHA=	specifies mandatory shape parameter α
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ

Table 5.60 (continued)

Option	Description
Rayleigh-Options	
SIGMA=	specifies scale parameter σ
THETA=	specifies threshold parameter θ
Weibull-Options	
C=	specifies mandatory shape parameter c
SIGMA=	specifies σ_0 for distribution reference line
THETA=	specifies θ_0 for distribution reference line
Weibull2-Options	
C=	specifies c_0 for distribution reference line (slope is $1/c_0$)
SIGMA=	specifies σ_0 for distribution reference line (intercept is $\log(\sigma_0)$)
SLOPE=	specifies slope of distribution reference line
THETA=	specifies known lower threshold θ_0

General Options

Table 5.61 lists options that control the appearance of the plots.

Table 5.61 General PROBPLOT Statement Options

Option	Description
General Plot Layout Options	
CONTENTS=	specifies table of contents entry for probability plot grouping
GRID	draws grid lines perpendicular to the percentile axis
HREF=	specifies reference lines perpendicular to the horizontal axis
HREFLABELS=	specifies line labels for HREF= lines
LEGEND=	identifies LEGEND statement
NADJ=	adjusts sample size (N) when computing percentiles
NOFRAME	suppresses frame around plotting area
NOLEGEND	suppresses legend
NOLINELEGEND	suppresses distribution reference line information in legend
NOSPECLEGEND	suppresses specifications information in legend
PCTLMINOR	requests minor tick marks for percentile axis
PCTLORDER=	specifies tick mark labels for percentile axis
RANKADJ=	adjusts ranks when computing percentiles
ROTATE	switches horizontal and vertical axes
SQUARE	displays plot in square format
VREF=	specifies reference lines perpendicular to the vertical axis
VREFLABELS=	specifies line labels for VREF= lines
Graphics Options	
ANNOTATE=	specifies annotate data set
CAXIS=	specifies color for axis
CFRAME=	specifies color for frame
CGRID=	specifies color for grid lines

Table 5.61 (continued)

Option	Description
CHREF=	specifies colors for HREF= lines
CTEXT=	specifies color for text
CSTATREF=	specifies colors for STATREF= lines
CVREF=	specifies colors for VREF= lines
DESCRIPTION=	specifies description for plot in graphics catalog
FONT=	specifies software font for text
HAXIS=	specifies AXIS statement for horizontal axis
HEIGHT=	specifies height of text used outside framed areas
HMINOR=	specifies number of horizontal minor tick marks
HREFLABPOS=	specifies position for HREF= line labels
INFONT=	specifies software font for text inside framed areas
INHEIGHT=	specifies height of text inside framed areas
LGRID=	specifies a line type for grid lines
LHREF=	specifies line styles for HREF= lines
LSTATREF=	specifies line styles for STATREF= lines
LVREF=	specifies line styles for VREF= lines
NAME=	specifies name for plot in graphics catalog
NOHLABEL	suppresses label for horizontal axis
NOVLABEL	suppresses label for vertical axis
NOVTICK	suppresses tick marks and tick mark labels for vertical axis
STATREF=	specifies reference lines at values of summary statistics
STATREFLABELS=	specifies labels for STATREF= lines
STATREFSUBCHAR=	specifies substitution character for displaying statistic values in STATREFLABELS= labels
TURNVLABELS	turns and vertically strings out characters in labels for vertical axis
VAXIS=	specifies AXIS statement for vertical axis
VAXISLABEL=	specifies label for vertical axis
VMINOR=	specifies number of vertical minor tick marks
VREFLABPOS=	specifies horizontal position of labels for VREF= lines
WAXIS=	specifies line thickness for axes and frame
WGRID=	specifies line thickness for grid
Options for ODS Graphics Output	
ODSFOOTNOTE=	specifies footnote displayed on probability plot
ODSFOOTNOTE2=	specifies secondary footnote displayed on probability plot
ODSTITLE=	specifies title displayed on probability plot
ODSTITLE2=	specifies secondary title displayed on probability plot
Options for Comparative Plots	
ANNOKEY	applies annotation to key cell only
CFRAMESIDE=	specifies color for filling frame for row labels
CFRAMETOP=	specifies color for filling frame for column labels
CPROP=	specifies color for proportion of frequency bar
CTEXTSIDE=	specifies color for row labels
CTEXTTOP=	specifies color for column labels

Table 5.61 (continued)

Option	Description
INTERTILE=	specifies distance between tiles
NCOLS=	specifies number of columns in comparative probability plot
NROWS=	specifies number of rows in comparative probability plot
OVERLAY	overlays plots for different class levels (ODS Graphics only)
Options to Enhance Line Printer Plots	
GRIDCHAR=	specifies character for GRID lines
HREFCHAR=	specifies character for HREF= lines
NOBSLEGEND	suppresses legend for hidden points
PROBSYMBOL=	specifies character for plotted points
VREFCHAR=	specifies character for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of options specific to the PROBLOT statement. The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics, ODS Graphics output, and line printer plots, respectively. See “[Dictionary of Common Options: CAPABILITY Procedure](#)” on page 551 for detailed descriptions of options common to all the plot statements.

ALPHA=*value-list*|EST

specifies values for a mandatory shape parameter α ($\alpha > 0$) for probability plots requested with the BETA, GAMMA, PARETO, and POWER options. A plot is created for each value specified. For examples, see the entries for the distribution options. If you specify ALPHA=EST, a maximum likelihood estimate is computed for α .

BETA(ALPHA=*value-list*|EST BETA=*value-list*|EST <*beta-options*>)

creates a beta probability plot for each combination of the shape parameters α and β given by the mandatory ALPHA= and BETA= options. If you specify ALPHA=EST and BETA=EST, a plot is created based on maximum likelihood estimates for α and β . In the following examples, the first PROBLOT statement produces one plot, the second statement produces four plots, the third statement produces six plots, and the fourth statement produces one plot:

```
proc capability data=measures;
  probplot width / beta(alpha=2 beta=2);
  probplot width / beta(alpha=2 3 beta=1 2);
  probplot width / beta(alpha=2 to 3 beta=1 to 2 by 0.5);
  probplot width / beta(alpha=est beta=est);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $B_{\alpha\beta}^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $B_{\alpha\beta}^{-1}(\cdot)$ is the inverse normalized incomplete beta function, n is the number of nonmissing observations, and α and β are the shape parameters of the beta distribution. The horizontal axis is scaled in percentile units.

The point pattern on the plot for ALPHA= α and BETA= β tends to be linear with intercept θ and slope σ if the data are beta distributed with the specific density function

$$p(x) = \begin{cases} \frac{(x-\theta)^{\alpha-1}(\theta+\sigma-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$ and

θ = lower threshold parameter

σ = scale parameter ($\sigma > 0$)

α = first shape parameter ($\alpha > 0$)

β = second shape parameter ($\beta > 0$)

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To obtain graphical estimates of α and β , specify lists of values for the ALPHA= and BETA= options, and select the combination of α and β that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *beta-options* THETA= θ_0 and SIGMA= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *beta-options* THETA=EST and SIGMA=EST. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  probplot width / beta(alpha=2 beta=3 theta=4 sigma=5);
run;
```

Agreement between the reference line and the point pattern indicates that the beta distribution with parameters α , β , θ_0 and σ_0 is a good fit. You can specify the SCALE= option as an alias for the SIGMA= option and the THRESHOLD= option as an alias for the THETA= option.

BETA=value-list|EST

specifies values for the shape parameter β ($\beta > 0$) for probability plots requested with the BETA distribution option. A plot is created for each value specified with the BETA= option. If you specify BETA=EST, a maximum likelihood estimate is computed for β . For examples, see the preceding entry for the BETA option.

C=value(-list)|EST

specifies the shape parameter c ($c > 0$) for probability plots requested with the WEIBULL and WEIBULL2 options. You must specify C= as a *Weibull-option* with the WEIBULL option; in this situation it accepts a list of values, or if you specify C=EST, a maximum likelihood estimate is computed for c . You can optionally specify C=value or C=EST as a *Weibull2-option* with the WEIBULL2 option to request a distribution reference line; in this situation, you must also specify SIGMA=value or SIGMA=EST.

For example, the first PROBLOT statement below creates three three-parameter Weibull plots corresponding to the shape parameters $c = 1$, $c = 2$, and $c = 3$. The second PROBLOT statement creates a single three-parameter Weibull plot corresponding to an estimated value of c . The third PROBLOT statement creates a single two-parameter Weibull plot with a distribution reference line corresponding to $c_0 = 2$ and $\sigma_0 = 3$.

```

proc capability data=measures;
  probplot width / weibull(c=1 2 3);
  probplot width / weibull(c=est);
  probplot width / weibull2(c=2 sigma=3);
run;

```

CGRID=*color**Traditional Graphics*specifies the color for the grid lines requested by the **GRID** option.**EXPONENTIAL**<(exponential-options)>**EXP**<(exponential-options)>

creates an exponential probability plot. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $-\log\left(1 - \frac{i-0.375}{n+0.25}\right)$, where n is the number of nonmissing observations. The horizontal axis is scaled in percentile units.

The point pattern on the plot tends to be linear with intercept θ and slope σ if the data are exponentially distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma} \exp\left(-\frac{x-\theta}{\sigma}\right) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where θ is a threshold parameter, and σ is a positive scale parameter.

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *exponential-options* **THETA**= θ_0 and **SIGMA**= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *exponential-options* **THETA**=**EST** and **SIGMA**=**EST**. Specify these options in parentheses, as in the following example:

```

proc capability data=measures;
  probplot width / exponential(theta=4 sigma=5);
run;

```

Agreement between the reference line and the point pattern indicates that the exponential distribution with parameters θ_0 and σ_0 is a good fit. You can specify the **SCALE**= option as an alias for the **SIGMA**= option and the **THRESHOLD**= option as an alias for the **THETA**= option.

GAMMA(**ALPHA**=*value-list*|**EST** <*gamma-options*>)

creates a gamma probability plot for each value of the shape parameter α given by the mandatory **ALPHA**= option. If you specify **ALPHA**=**EST**, a plot is created based on a maximum likelihood estimate for α .

For example, the first **PROBPLOT** statement below creates three plots corresponding to $\alpha = 0.4$, $\alpha = 0.5$, and $\alpha = 0.6$. The second **PROBPLOT** statement creates a single plot.

```
proc capability data=measures;
  probplot width / gamma(alpha=0.4 to 0.6 by 0.2);
  probplot width / gamma(alpha=est);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $G_{\alpha}^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $G_{\alpha}^{-1}(\cdot)$ is the inverse normalized incomplete gamma function, n is the number of nonmissing observations, and α is the shape parameter of the gamma distribution. The horizontal axis is scaled in percentile units.

The point pattern on the plot for $\text{ALPHA}=\alpha$ tends to be linear with intercept θ and slope σ if the data are gamma distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma\Gamma(\alpha)} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\frac{x-\theta}{\sigma}\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To obtain a graphical estimate of α , specify a list of values for the **ALPHA=** option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *gamma-options* **THETA**= θ_0 and **SIGMA**= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *gamma-options* **THETA**=EST and **SIGMA**=EST. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  probplot width / gamma(alpha=2 theta=3 sigma=4);
run;
```

Agreement between the reference line and the point pattern indicates that the gamma distribution with parameters α , θ_0 and σ_0 is a good fit. You can specify the **SCALE=** option as an alias for the **SIGMA=** option and the **THRESHOLD=** option as an alias for the **THETA=** option.

GRID

draws reference lines perpendicular to the percentile axis at major tick marks.

GRIDCHAR='character'

specifies the character used for the lines requested by the **GRID** option for a line printer plot. *Line Printer*
The default is the vertical bar (|).

GUMBEL(*< Gumbel-options >*)

creates a Gumbel probability plot. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $-\log\left(-\log\left(\frac{i-0.375}{n+0.25}\right)\right)$, where n is the number of nonmissing observations. The horizontal axis is scaled in percentile units.

The point pattern on the plot tends to be linear with intercept μ and slope σ if the data are Gumbel distributed with the specific density function

$$p(x) = \frac{e^{-(x-\mu)/\sigma}}{\sigma} \exp\left(-e^{-(x-\mu)/\sigma}\right)$$

where μ is a location parameter and σ is a positive scale parameter.

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to μ_0 and σ_0 with the *Gumbel-options* **MU**= μ_0 and **SIGMA**= σ_0 . Alternatively, you can add a line corresponding to estimated values of μ_0 and σ_0 with the *Gumbel-options* **MU**=EST and **SIGMA**=EST. Specify these options in parentheses following the GUMBEL option.

Agreement between the reference line and the point pattern indicates that the Gumbel distribution with parameters μ_0 and σ_0 is a good fit.

LEGEND=*name* | **NONE***Traditional Graphics*

specifies the name of a LEGEND statement describing the legend for specification limit reference lines and fitted curves. Specifying LEGEND=NONE is equivalent to specifying the **NOLEGEND** option.

LGRID=*linetype**Traditional Graphics*

specifies the line type for the grid lines requested by the **GRID** option.

LOGNORMAL(**SIGMA**=*value-list*|**EST** *< lognormal-options >*)**LNORM**(**SIGMA**=*value-list*|**EST** *< lognormal-options >*)

creates a lognormal probability plot for each value of the shape parameter σ given by the mandatory **SIGMA**= option or its alias, the **SHAPE**= option. If you specify **SIGMA**=EST, a plot is created based on a maximum likelihood estimate for σ .

For example, the first PROBPLOT statement below produces two plots, and the second PROBPLOT statement produces a single plot:

```
proc capability data=measures;
  probplot width / lognormal(sigma=1.5 2.5 l=2);
  probplot width / lognormal(sigma=est);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\exp\left(\sigma \Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)\right)$, where $\Phi^{-1}(\cdot)$ is the inverse standard cumulative normal distribution, n is the number of nonmissing observations, and σ is the shape parameter of the lognormal distribution. The horizontal axis is scaled in percentile units.

The point pattern on the plot for $\text{SIGMA}=\sigma$ tends to be linear with intercept θ and slope $\exp(\zeta)$ if the data are lognormally distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma\sqrt{2\pi}(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\zeta)^2}{2\sigma^2}\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

ζ = scale parameter

σ = shape parameter ($\sigma > 0$)

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To obtain a graphical estimate of σ , specify a list of values for the **SIGMA=** option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and ζ_0 with the *lognormal-options* **THETA**= θ_0 and **ZETA**= ζ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and ζ_0 with the *lognormal-options* **THETA**=EST and **ZETA**=EST.

Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  probplot width / lognormal(sigma=2 theta=3 zeta=0);
run;
```

Agreement between the reference line and the point pattern indicates that the lognormal distribution with parameters σ , θ_0 , and ζ_0 is a good fit. See [Example 5.20](#) for an example.

You can specify the **THRESHOLD=** option as an alias for the **THETA=** option and the **SCALE=** option as an alias for the **ZETA=** option.

MU=value|EST

specifies the mean μ_0 for a probability plot requested with the **GUMBEL** and **NORMAL** options. If you specify **MU=EST**, μ_0 is equal to the sample mean for the normal distribution. For the Gumbel distribution, a maximum likelihood estimate is calculated. See [Example 5.19](#).

NADJ=value

specifies the adjustment value added to the sample size in the calculation of theoretical percentiles. The default is $\frac{1}{4}$, as recommended by Blom (1958). Also refer to Chambers et al. (1983) for additional information.

NOLEGEND

suppresses legends for specification limits, fitted curves, distribution lines, and hidden observations.

NOLINELEGEND

NOLINEL

suppresses the legend for the optional distribution reference line.

NOOBSLEGEND**NOOBSL**

Line Printer suppresses the legend that indicates the number of hidden observations.

NORMAL< (*normal-options*) >**NORM**< (*normal-options*) >

creates a normal probability plot. This is the default if you do not specify a distribution option. To create the plot, the observations are ordered from smallest to largest, and the *i*th ordered observation is plotted against the quantile $\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $\Phi^{-1}(\cdot)$ is the inverse cumulative standard normal distribution, and *n* is the number of nonmissing observations. The horizontal axis is scaled in percentile units.

The point pattern on the plot tends to be linear with intercept μ and slope σ if the data are normally distributed with the specific

$$p(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) \quad \text{for all } x$$

where μ is the mean and σ is the standard deviation ($\sigma > 0$).

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to μ_0 and σ_0 with the *normal-options* MU= μ_0 and SIGMA= σ_0 . Alternatively, you can add a line corresponding to estimated values of μ_0 and σ_0 with the *normal-options* THETA=EST and SIGMA=EST; the estimates of μ_0 and σ_0 are the sample mean and sample standard deviation.

Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  probplot length / normal(mu=10 sigma=0.3);
  probplot length / normal(mu=est sigma=est);
run;
```

Agreement between the reference line and the point pattern indicates that the normal distribution with parameters μ_0 and σ_0 is a good fit.

NOSPECLEGEND**NOSPECL**

suppresses the legend for specification limit reference lines.

PARETO< (*Pareto-options*) >

creates a generalized Pareto probability plot for each value of the shape parameter α given by the mandatory ALPHA= option. If you specify ALPHA=EST, a plot is created based on a maximum likelihood estimate for α .

To create the plot, the observations are ordered from smallest to largest, and the *i*th ordered observation is plotted against the quantile $(1 - (1 - \frac{i-0.375}{n+0.25})^\alpha)/\alpha$ ($\alpha \neq 0$) or $-\log(1 - \frac{i-0.375}{n+0.25})$ ($\alpha = 0$), where *n* is the number of nonmissing observations and α is the shape parameter of the generalized Pareto distribution. The horizontal axis is scaled in percentile units.

The point pattern on the plot for $\text{ALPHA}=\alpha$ tends to be linear with intercept θ and slope σ if the data are generalized Pareto distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma}(1 - \alpha(x - \theta)/\sigma)^{1/\alpha-1} & \text{if } \alpha \neq 0 \\ \frac{1}{\sigma} \exp(-(x - \theta)/\sigma) & \text{if } \alpha = 0 \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To obtain a graphical estimate of α , specify a list of values for the $\text{ALPHA}=\text{option}$, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *Pareto-options* $\text{THETA}=\theta_0$ and $\text{SIGMA}=\sigma_0$. Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *Pareto-options* $\text{THETA}=\text{EST}$ and $\text{SIGMA}=\text{EST}$. Specify these options in parentheses following the PARETO option.

Agreement between the reference line and the point pattern indicates that the generalized Pareto distribution with parameters α , θ_0 , and σ_0 is a good fit.

PCTLMINOR

requests minor tick marks for the percentile axis. See [Output 5.20.1](#) for an example.

Traditional Graphics

PCTLORDER=*value-list*

specifies the tick mark values labeled on the theoretical percentile axis. Since the values are percentiles, the labels must be between 0 and 100, exclusive. The values must be listed in increasing order and must cover the plotted percentile range. Otherwise, a default list is used. For example, consider the following:

```
proc capability data=measures;
  probplot length / pctlorder=1 10 25 50 75 90 99;
run;
```

Note that the $\text{ORDER}=\text{option}$ in the AXIS statement is not supported by the PROBPLOT statement.

POWER(<power-options>)

creates a power function probability plot for each value of the shape parameter α given by the mandatory $\text{ALPHA}=\text{option}$. If you specify $\text{ALPHA}=\text{EST}$, a plot is created based on a maximum likelihood estimate for α .

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $B_{\alpha(1)}^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $B_{\alpha(1)}^{-1}(\cdot)$ is the inverse normalized incomplete beta function, n is the number of nonmissing observations, α is one shape parameter of the beta distribution, and the second shape parameter, $\beta = 1$. The horizontal axis is scaled in percentile units.

The point pattern on the plot for ALPHA= α tends to be linear with intercept θ and slope σ if the data are power function distributed with the specific density function

$$p(x) = \begin{cases} \frac{\alpha}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where

θ = threshold parameter
 σ = scale parameter ($\sigma > 0$)
 α = shape parameter ($\alpha > 0$)

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To obtain a graphical estimate of α , specify a list of values for the ALPHA= option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *power-options* THETA= θ_0 and SIGMA= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *power-options* THETA=EST and SIGMA=EST. Specify these options in parentheses following the POWER option.

Agreement between the reference line and the point pattern indicates that the power function distribution with parameters α , θ_0 , and σ_0 is a good fit.

PROBSYMBOL='character'

Line Printer

specifies the character used to mark the points in a line printer plot. The default is the plus sign (+).

RANKADJ=value

specifies the adjustment value added to the ranks in the calculation of theoretical percentiles. The default is $-\frac{3}{8}$, as recommended by Blom (1958). Also refer to Chambers et al. (1983) for additional information.

RAYLEIGH(< Rayleigh-options >)

creates a Rayleigh probability plot. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\sqrt{-2 \log \left(1 - \frac{i-0.375}{n+0.25}\right)}$, where n is the number of nonmissing observations. The horizontal axis is scaled in percentile units.

The point pattern on the plot tends to be linear with intercept θ and slope σ if the data are Rayleigh distributed with the specific density function

$$p(x) = \begin{cases} \frac{x-\theta}{\sigma^2} \exp(-(x-\theta)^2/(2\sigma^2)) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where θ is a threshold parameter, and σ is a positive scale parameter.

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *Rayleigh-options* **THETA**= θ_0 and **SIGMA**= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *Rayleigh-options* **THETA**=EST and **SIGMA**=EST. Specify these options in parentheses after the **RAYLEIGH** option.

Agreement between the reference line and the point pattern indicates that the Rayleigh distribution with parameters θ_0 and σ_0 is a good fit.

ROTATE

switches the horizontal and vertical axes so that the theoretical percentiles are plotted vertically while the data are plotted horizontally. Regardless of whether the plot has been rotated, horizontal axis options (such as **HAXIS**=) still refer to the horizontal axis, and vertical axis options (such as **VAXIS**=) still refer to the vertical axis. All other options that depend on axis placement adjust to the rotated axes.

SIGMA=value-list|EST

specifies the value of the parameter σ , where $\sigma > 0$. Alternatively, you can specify **SIGMA**=EST to request a maximum likelihood estimate for σ_0 . The interpretation and use of the **SIGMA**= option depend on the distribution option with which it is specified, as indicated by the following table.

Distribution Option	Use of the SIGMA = Option
BETA EXPONENTIAL GAMMA PARETO POWER RAYLEIGH WEIBULL	THETA = θ_0 and SIGMA = σ_0 request a distribution reference line corresponding to θ_0 and σ_0 .
GUMBEL	MU = μ_0 and SIGMA = σ_0 request a distribution reference line corresponding to μ_0 and σ_0 .
LOGNORMAL	SIGMA = $\sigma_1 \dots \sigma_n$ requests n probability plots with shape parameters $\sigma_1 \dots \sigma_n$. The SIGMA = option must be specified.
NORMAL	MU = μ_0 and SIGMA = σ_0 request a distribution reference line corresponding to μ_0 and σ_0 . SIGMA =EST requests a line with σ_0 equal to the sample standard deviation.
WEIBULL2	SIGMA = σ_0 and C = c_0 request a distribution reference line corresponding to σ_0 and c_0 .

In the following example, the first **PROBLOT** statement requests a normal plot with a distribution reference line corresponding to $\mu_0 = 5$ and $\sigma_0 = 2$, and the second **PROBLOT** statement requests a lognormal plot with shape parameter $\sigma = 3$:

```
proc capability data=measures;
  probplot length / normal(mu=5 sigma=2);
  probplot width / lognormal(sigma=3);
run;
```

SLOPE=*value*|EST

specifies the slope for a distribution reference line requested with the **LOGNORMAL** and **WEIBULL2** options. The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “**QQPLOT Statement: CAPABILITY Procedure**” on page 508.

When you use the **SLOPE=** option with the **LOGNORMAL** option, you must also specify a threshold parameter value θ_0 with the **THETA= *lognormal-option*** to request the line. The **SLOPE=** option is an alternative to the **ZETA= *lognormal-option*** for specifying ζ_0 , since the slope is equal to $\exp(\zeta_0)$.

When you use the **SLOPE=** option with the **WEIBULL2** option, you must also specify a scale parameter value σ_0 with the **SIGMA= *Weibull2-option*** to request the line. The **SLOPE=** option is an alternative to the **C= *Weibull2-option*** for specifying c_0 , since the slope is equal to $1/c_0$. See “**Location and Scale Parameters**” on page 502.

For example, the first and second **PROBPLOT** statements below produce the same set of probability plots as the third and fourth **PROBPLOT** statements:

```
proc capability data=measures;
  probplot width / lognormal(sigma=2 theta=0 zeta=0);
  probplot width / weibull2(sigma=2 theta=0 c=0.25);
  probplot width / lognormal(sigma=2 theta=0 slope=1);
  probplot width / weibull2(sigma=2 theta=0 slope=4);
run;
```

SQUARE

Traditional Graphics
ODS Graphics

displays the probability plot in a square frame. For an example, see **Output 5.20.1**. The default is a rectangular frame.

SYMBOL='character'

Line Printer

specifies the character used to display the distribution reference line in a line printer plot. The default character is the first letter of the distribution option keyword.

THETA=*value*|EST**THRESHOLD=*value***

specifies the lower threshold parameter θ for probability plots requested with the **BETA**, **EXPONENTIAL**, **GAMMA**, **LOGNORMAL**, **PARETO**, **POWER**, **RAYLEIGH**, **WEIBULL**, and **WEIBULL2** options. When used with the **WEIBULL2** option, the **THETA=** option specifies the known lower threshold θ_0 , for which the default is 0. When used with the other distribution options, the **THETA=** option specifies θ_0 for a distribution reference line; alternatively in this situation, you can specify **THETA=EST** to request a maximum likelihood estimate for θ_0 . To request the line, you must also specify a scale parameter. See **Output 5.20.1** for an example of the **THETA=** option with a lognormal probability plot.

WEIBULL(C=*value-list*|EST < *Weibull-options* >)**WEIB(C=*value-list* < *Weibull-options* >)**

creates a three-parameter Weibull probability plot for each value of the shape parameter c given by the mandatory **C=** option or its alias, the **SHAPE=** option. If you specify **C=EST**, a plot is created based on a maximum likelihood estimate for c . In the following example, the

first PROBLOT statement creates four plots, and the second PROBLOT statement creates a single plot:

```
proc capability data=measures;
  probplot width / weibull(c=1.8 to 2.4 by 0.2 w=2);
  probplot width / weibull(c=est);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\left(-\log\left(1 - \frac{i-0.375}{n+0.25}\right)\right)^{\frac{1}{c}}$, where n is the number of nonmissing observations, and c is the Weibull distribution shape parameter. The horizontal axis is scaled in percentile units.

The point pattern on the plot for $C=c$ tends to be linear with intercept θ and slope σ if the data are Weibull distributed with the specific density function

$$p(x) = \begin{cases} \frac{c}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

c = shape parameter ($c > 0$)

The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

To obtain a graphical estimate of c , specify a list of values for the **C=** option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *Weibull-options* **THETA**= θ_0 and **SIGMA**= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *Weibull-options* **THETA**=**EST** and **SIGMA**=**EST**. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  probplot width / weibull(c=2 theta=3 sigma=4);
run;
```

Agreement between the reference line and the point pattern indicates that the Weibull distribution with parameters c , θ_0 , and σ_0 is a good fit. You can specify the **SCALE=** option as an alias for the **SIGMA=** option and the **THRESHOLD=** option as an alias for the **THETA=** option.

WEIBULL2<(Weibull2-options)>

W2<(Weibull2-options)>

creates a two-parameter Weibull probability plot. You should use the **WEIBULL2** option when your data have a *known* lower threshold θ_0 . You can specify the threshold value θ_0 with the **THETA=** Weibull2-option or its alias, the **THRESHOLD=** Weibull2-option. The default is $\theta_0 = 0$.

To create the plot, the observations are ordered from smallest to largest, and the log of the shifted i th ordered observation $x_{(i)}$, denoted by $\log(x_{(i)} - \theta_0)$, is plotted against the quantile $\log\left(-\log\left(1 - \frac{i-0.375}{n+0.25}\right)\right)$, where n is the number of nonmissing observations. The horizontal axis is scaled in percentile units. Note that the **C=** shape parameter option is not mandatory with the **WEIBULL2** option.

The point pattern on the plot for **THETA**= θ_0 tends to be linear with intercept $\log(\sigma)$ and slope $\frac{1}{c}$ if the data are Weibull distributed with the specific density function

$$p(x) = \begin{cases} \frac{c}{\sigma} \left(\frac{x-\theta_0}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta_0}{\sigma}\right)^c\right) & \text{for } x > \theta_0 \\ 0 & \text{for } x \leq \theta_0 \end{cases}$$

where

θ_0 = known lower threshold

σ = scale parameter ($\sigma > 0$)

c = shape parameter ($c > 0$)

An advantage of the two-parameter Weibull plot over the three-parameter Weibull plot is that the parameters c and σ can be estimated from the slope and intercept of the point pattern. A disadvantage is that the two-parameter Weibull distribution applies only in situations where the threshold parameter is known.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to σ_0 and c_0 with the *Weibull2-options* **SIGMA**= σ_0 and **C**= c_0 . Alternatively, you can add a distribution reference line corresponding to estimated values of σ_0 and c_0 with the *Weibull2-options* **SIGMA**=**EST** and **C**=**EST**. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  probplot width / weibull2(theta=3 sigma=4 c=2);
run;
```

Agreement between the distribution reference line and the point pattern indicates that the Weibull distribution with parameters c_0 , θ_0 and σ_0 is a good fit. You can specify the **SCALE**= option as an alias for the **SIGMA**= option and the **SHAPE**= option as an alias for the **C**= option.

WGRID= n

Traditional Graphics

specifies the width of the grid lines requested with the **GRID** option. If you use the **WGRID**= option, you do not need to specify the **GRID** option.

ZETA=*value*|**EST**

specifies a value for the scale parameter ζ for lognormal probability plots requested with the **LOGNORMAL** option. Specify **THETA**= θ_0 and **ZETA**= ζ_0 to request a distribution reference line with intercept θ_0 and slope $\exp(\zeta_0)$. See [Output 5.20.1](#) for an example.

Details: PROBLOT Statement

This section provides details on the following topics:

- distributions supported by the PROBLOT statement
- SYMBOL statement options

Summary of Theoretical Distributions

You can use the PROBLOT statement to request probability plots based on the theoretical distributions summarized in Table 5.62.

Table 5.62 Distributions and Parameters

Distribution	Density Function $p(x)$	Range	Parameters		
			Location	Scale	Shape
Beta	$\frac{(x-\theta)^{\alpha-1}(\theta+\sigma-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}}$	$\theta < x < \theta + \sigma$	θ	σ	α, β
Exponential	$\frac{1}{\sigma} \exp\left(-\frac{x-\theta}{\sigma}\right)$	$x \geq \theta$	θ	σ	
Gamma	$\frac{1}{\sigma\Gamma(\alpha)} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\frac{x-\theta}{\sigma}\right)$	$x > \theta$	θ	σ	α
Gumbel	$\frac{e^{-(x-\mu)/\sigma}}{\sigma} \exp\left(-e^{-(x-\mu)/\sigma}\right)$	all x	μ	σ	
Lognormal (3-parameter)	$\frac{1}{\sigma\sqrt{2\pi}(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\zeta)^2}{2\sigma^2}\right)$	$x > \theta$	θ	ζ	σ
Normal	$\frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$	all x	μ	σ	
Generalized Pareto	$\alpha \neq 0 \quad \frac{1}{\sigma}(1-\alpha(x-\theta)/\sigma)^{1/\alpha-1}$ $\alpha = 0 \quad \frac{1}{\sigma} \exp(-(x-\theta)/\sigma)$	$x > \theta$	θ	σ	α
Power Function	$\frac{\alpha}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1}$	$x > \theta$	θ	σ	α
Rayleigh	$\frac{x-\theta}{\sigma^2} \exp(-(x-\theta)^2/(2\sigma^2))$	$x \geq \theta$	θ	σ	
Weibull (3-parameter)	$\frac{c}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right)$	$x > \theta$	θ	σ	c
Weibull (2-parameter)	$\frac{c}{\sigma} \left(\frac{x-\theta_0}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta_0}{\sigma}\right)^c\right)$	$x > \theta_0$ (known)	θ_0	σ	c

You can request these distributions with the **BETA**, **EXPONENTIAL**, **GAMMA**, **LOGNORMAL**, **NORMAL**, **WEIBULL**, and **WEIBULL2** options, respectively. If you do not specify a distribution option, a normal probability plot is created.

Shape Parameters

Some of the distribution options in the **PROBPLOT** statement require you to specify one or two shape parameters in parentheses after the distribution keyword. These are summarized in [Table 5.63](#).

Table 5.63 Shape Parameter Options for the **PROBPLOT** Statement

Distribution Keyword	Mandatory Shape Parameter Option	Range
BETA	ALPHA= α , BETA= β	$\alpha > 0, \beta > 0$
EXPONENTIAL	None	
GAMMA	ALPHA= α	$\alpha > 0$
GUMBEL	None	
LOGNORMAL	SIGMA= σ	$\sigma > 0$
NORMAL	None	
PARETO	ALPHA= α	$\alpha > 0$
POWER	ALPHA= α	$\alpha > 0$
RAYLEIGH	None	
WEIBULL	C= c	$c > 0$
WEIBULL2	None	

You can visually estimate the value of a shape parameter by specifying a list of values for the shape parameter option. The **PROBPLOT** statement produces a separate plot for each value. You can then use the value of the shape parameter producing the most nearly linear point pattern. Alternatively, you can request that the plot be created using an estimated shape parameter. For an example, see “[Creating Lognormal Probability Plots](#)” on page 479.

Location and Scale Parameters

If you specify the location and scale parameters for a distribution (or if you request estimates for these parameters), a diagonal distribution reference line is displayed on the plot. (An exception is the two-parameter Weibull distribution, for which a line is displayed when you specify or estimate the scale and shape parameters.) Agreement between this line and the point pattern indicates that the distribution with these parameters is a good fit. For illustrations, see [Example 5.19](#) and [Example 5.20](#).

The following table shows how the specified parameters determine the intercept⁸ and slope of the line:

⁸The intercept and slope are based on the quantile scale for the horizontal axis, which is displayed on a Q-Q plot; see “[QQPLOT Statement: CAPABILITY Procedure](#)” on page 508.

Table 5.64 Intercept and Slope of Distribution Reference Line

Distribution	Parameters			Linear Pattern	
	Location	Scale	Shape	Intercept	Slope
Beta	θ	σ	α, β	θ	σ
Exponential	θ	σ		θ	σ
Gamma	θ	σ	α	θ	σ
Gumbel	μ	σ		μ	σ
Lognormal	θ	ζ	σ	θ	$\exp(\zeta)$
Normal	μ	σ		μ	σ
Generalized Pareto	θ	σ	α	θ	σ
Power Function	θ	σ	α	θ	σ
Rayleigh	θ	σ		θ	σ
Weibull (3-parameter)	θ	σ	c	θ	σ
Weibull (2-parameter)	θ_0 (known)	σ	c	$\log(\sigma)$	$\frac{1}{c}$

For the LOGNORMAL and WEIBULL2 options, you can specify the slope directly with the SLOPE= option. That is, for the LOGNORMAL option, specifying THETA= θ_0 and SLOPE= $\exp(\zeta_0)$ displays the same line as specifying THETA= θ_0 and ZETA= ζ_0 . For the WEIBULL2 option, specifying SIGMA= σ_0 and SLOPE= $\frac{1}{c_0}$ displays the same line as specifying SIGMA= σ_0 and C= c_0 .

SYMBOL Statement Options

In earlier releases of SAS/QC software, graphical features of lower and upper specification lines and diagonal distribution reference lines were controlled with options in the SYMBOL2, SYMBOL3, and SYMBOL4 statements, respectively. These options are still supported, although they have been superseded by options in the PROBLOT and SPEC statements. Table 5.65 summarizes the two sets of options. **NOTE:** These statements have no effect on ODS Graphics output.

Table 5.65 SYMBOL Statement Options

Feature	Statement and Options	Alternative Statement and Options
Symbol markers	SYMBOL1 Statement	
character	VALUE= <i>special-symbol</i>	
color	COLOR= <i>color</i>	
font	FONT= <i>font</i>	
height	HEIGHT= <i>value</i>	
Lower specification line	SPEC Statement	SYMBOL2 Statement
position	LSL= <i>value</i>	
color	CLSL= <i>color</i>	COLOR= <i>color</i>
line type	LLSL= <i>linetype</i>	LINE= <i>linetype</i>
width	WLSL= <i>value</i>	WIDTH= <i>value</i>
Upper specification line	SPEC Statement	SYMBOL3 Statement
position	USL= <i>value</i>	
color	CUSL= <i>color</i>	COLOR= <i>color</i>
line type	LUSL= <i>linetype</i>	LINE= <i>linetype</i>
width	WUSL= <i>value</i>	WIDTH= <i>value</i>
Target reference line	SPEC Statement	
position	TARGET= <i>value</i>	
color	CTARGET= <i>color</i>	
line type	LTARGET= <i>linetype</i>	
width	WTARGET= <i>value</i>	
Distribution reference line	PROBPLOT Statement	SYMBOL4 Statement
color	COLOR= <i>color</i>	COLOR= <i>color</i>
line type	LINE= <i>linetype</i>	LINE= <i>linetype</i>
width	WIDTH= <i>value</i>	WIDTH= <i>value</i>

For an illustration of these options, see [Example 5.19](#).

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. PROBPLOT options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the PROBPLOT statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 5.66](#).

Table 5.66 ODS Graphics Produced by the PROBLOT Statement

ODS Graph Name	Plot Description
ProbPlot	probability plot

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Examples: PROBLOT Statement

This section provides advanced examples of the PROBLOT statement.

Example 5.19: Displaying a Normal Reference Line

Measurements of the distance between two holes cut into 50 steel sheets are saved as values of the variable Distance in the following data set: *See CAPPROB4 in the SAS/QC Sample Library*

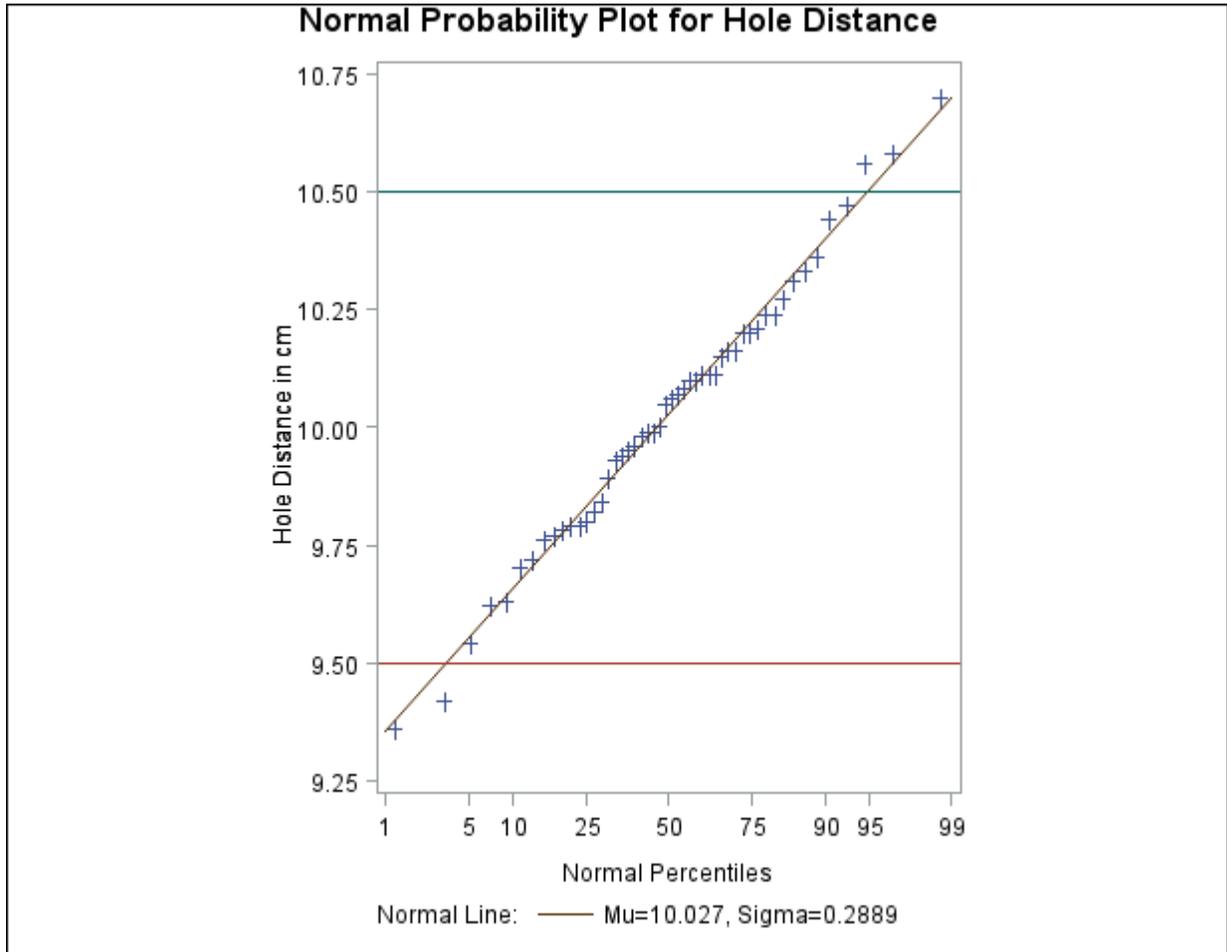

```
data Sheets;
  input Distance @@;
  label Distance='Hole Distance in cm';
  datalines;
  9.80 10.20 10.27  9.70  9.76
 10.11 10.24 10.20 10.24  9.63
  9.99  9.78 10.10 10.21 10.00
  9.96  9.79 10.08  9.79 10.06
 10.10  9.95  9.84 10.11  9.93
 10.56 10.47  9.42 10.44 10.16
 10.11 10.36  9.94  9.77  9.36
  9.89  9.62 10.05  9.72  9.82
  9.99 10.16 10.58 10.70  9.54
 10.31 10.07 10.33  9.98 10.15
  ;
```

The cutting process is in control, and you decide to check whether the process distribution is normal. The following statements create a normal probability plot for Distance with lower and upper specification lines at 9.5 cm and 10.5 cm:

```
ods graphics off;
symbol v=plus height=3.5pct;
title 'Normal Probability Plot for Hole Distance';
proc capability data=Sheets noprint;
  spec lsl=9.5 usl=10.5;
  probplot Distance / normal(mu=est sigma=est)
                    square
                    nospeclegend;
run;
```

The plot is shown in [Output 5.19.1](#). The MU= and SIGMA= *normal-options* request the diagonal reference line that corresponds to the normal distribution with estimated parameters $\hat{\mu} = 10.027$ and $\hat{\sigma} = 0.2889$. The LSL= and USL= SPEC statement options request the lower and upper specification lines. The SYMBOL statement specifies the symbol marker for the plotted points.

Output 5.19.1 Normal Reference Line

Example 5.20: Displaying a Lognormal Reference Line

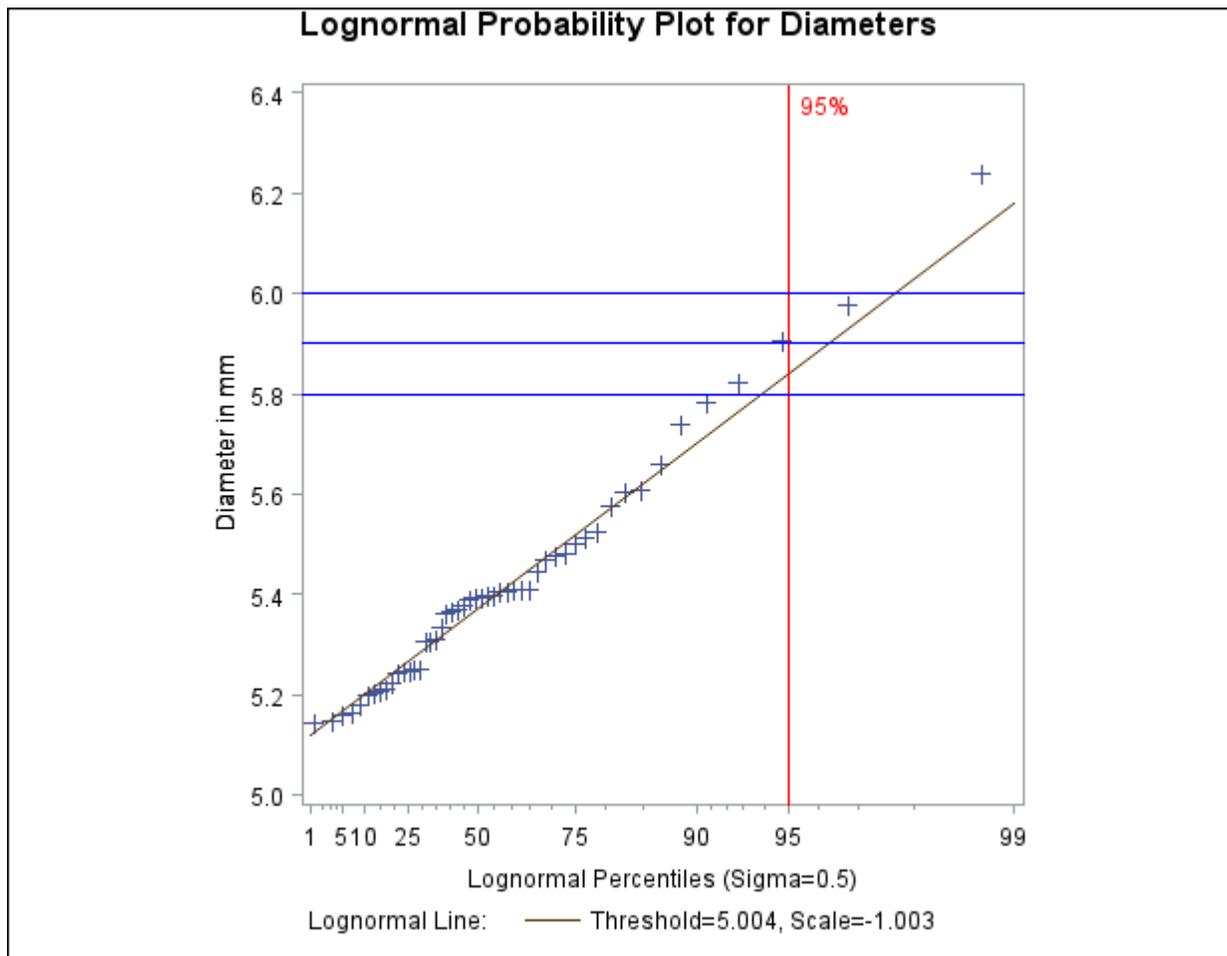

See CAPPROB3 in the SAS/QC Sample Library This example is a continuation of “Creating Lognormal Probability Plots” on page 479. Figure 5.36 shows that a lognormal distribution with shape parameter $\sigma = 0.5$ is a good fit for the distribution of Diameter in the data set Rods.

The lognormal distribution involves two other parameters: a threshold parameter θ and a scale parameter ζ . See [Table 5.62](#) for the equation of the lognormal density function. The following statements illustrate how you can request a diagonal distribution reference line whose slope and intercept are determined by estimates of θ and ζ .

```
ods graphics off;
symbol v=plus height=3.5pct;
title 'Lognormal Probability Plot for Diameters';
proc capability data=Rods noprint;
  probplot Diameter / lognormal(sigma=0.5 theta=est zeta=est)
    square
    pctlminor
    href      = 95
    hreflabel = '95%'
    vref      = 5.8 to 6.0 by 0.1
    chref     = red
    cvref     = blue;
run;
```

The plot is shown in Output 5.20.1.

Output 5.20.1 Lognormal Reference Line

The close agreement between the diagonal reference line and the point pattern indicates that the specific lognormal distribution with $\hat{\sigma} = 0.5$, $\hat{\theta} = 5.004$, and $\hat{\zeta} = -1.003$ is a good fit for the diameter measurements.

Specifying HREF=95 adds a reference line indicating the 95th percentile of the lognormal distribution. The HREFLABEL= option specifies a label for this line. The PCTLMINOR option displays minor tick marks on the percentile axis. The VREF= option adds reference lines indicating diameter values of 5.8, 5.9, and 6.0, and the CHREF= and CVREF= options specify colors for the horizontal and vertical reference lines.

Based on the intersection of the diagonal reference line with the HREF= line, the estimated 95th percentile of the diameter distribution is 5.85 mm.

Note that you could also construct a similar plot in which all three parameters are estimated by substituting SIGMA=EST for SIGMA=0.5 in the preceding statements.

QQPLOT Statement: CAPABILITY Procedure

Overview: QQPLOT Statement

The QQPLOT statement creates a quantile-quantile plot (Q-Q plot), which compares ordered values of a variable with quantiles of a specified theoretical distribution such as the normal. If the data distribution matches the theoretical distribution, the points on the plot form a linear pattern. Thus, you can use a Q-Q plot to determine how well a theoretical distribution models a set of measurements.

You can specify one of the following theoretical distributions with the QQPLOT statement:

- beta
- exponential
- gamma
- Gumbel
- three-parameter lognormal
- normal
- generalized Pareto
- power function
- Rayleigh
- two-parameter Weibull
- three-parameter Weibull

You can use options in the QQPLOT statement to do the following:

- specify or estimate parameters for the theoretical distribution
- display a reference line corresponding to specific location and scale parameters for the theoretical distribution
- request graphical enhancements

You can also create a comparative Q-Q plot by using the QQPLOT statement in conjunction with a CLASS statement.

You have three alternatives for producing Q-Q plots with the QQPLOT statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

NOTE: Q-Q plots are similar to probability plots, which you can create with the PROBPLOT statement (see “PROBPLOT Statement: CAPABILITY Procedure” on page 477). Q-Q plots are preferable for graphical estimation of distribution parameters and capability indices, whereas probability plots are preferable for graphical estimation of percentiles.

Getting Started: QQPLOT Statement

The following examples illustrate the basic syntax of the QQPLOT statement. For complete details of the QQPLOT statement, see the section “Syntax: QQPLOT Statement” on page 512. Advanced examples are provided on the section “Examples: QQPLOT Statement” on page 539.

Creating a Normal Quantile-Quantile Plot

Measurements of the distance between two holes cut into 50 steel sheets are saved as values of the variable Distance in the following data set: *See CAPQQ1 in the SAS/QC Sample Library*

```
data Sheets;
  input Distance @@;
  label Distance='Hole Distance in cm';
  datalines;
  9.80 10.20 10.27  9.70  9.76
 10.11 10.24 10.20 10.24  9.63
  9.99  9.78 10.10 10.21 10.00
  9.96  9.79 10.08  9.79 10.06
```

```

10.10  9.95  9.84 10.11  9.93
10.56 10.47  9.42 10.44 10.16
10.11 10.36  9.94  9.77  9.36
 9.89  9.62 10.05  9.72  9.82
 9.99 10.16 10.58 10.70  9.54
10.31 10.07 10.33  9.98 10.15

```

```
;
```

The cutting process is in control, and you decide to check whether the process distribution is normal. The following statements create a Q-Q plot for Distance, shown in [Figure 5.39](#), with lower and upper specification lines at 9.5 cm and 10.5 cm:⁹

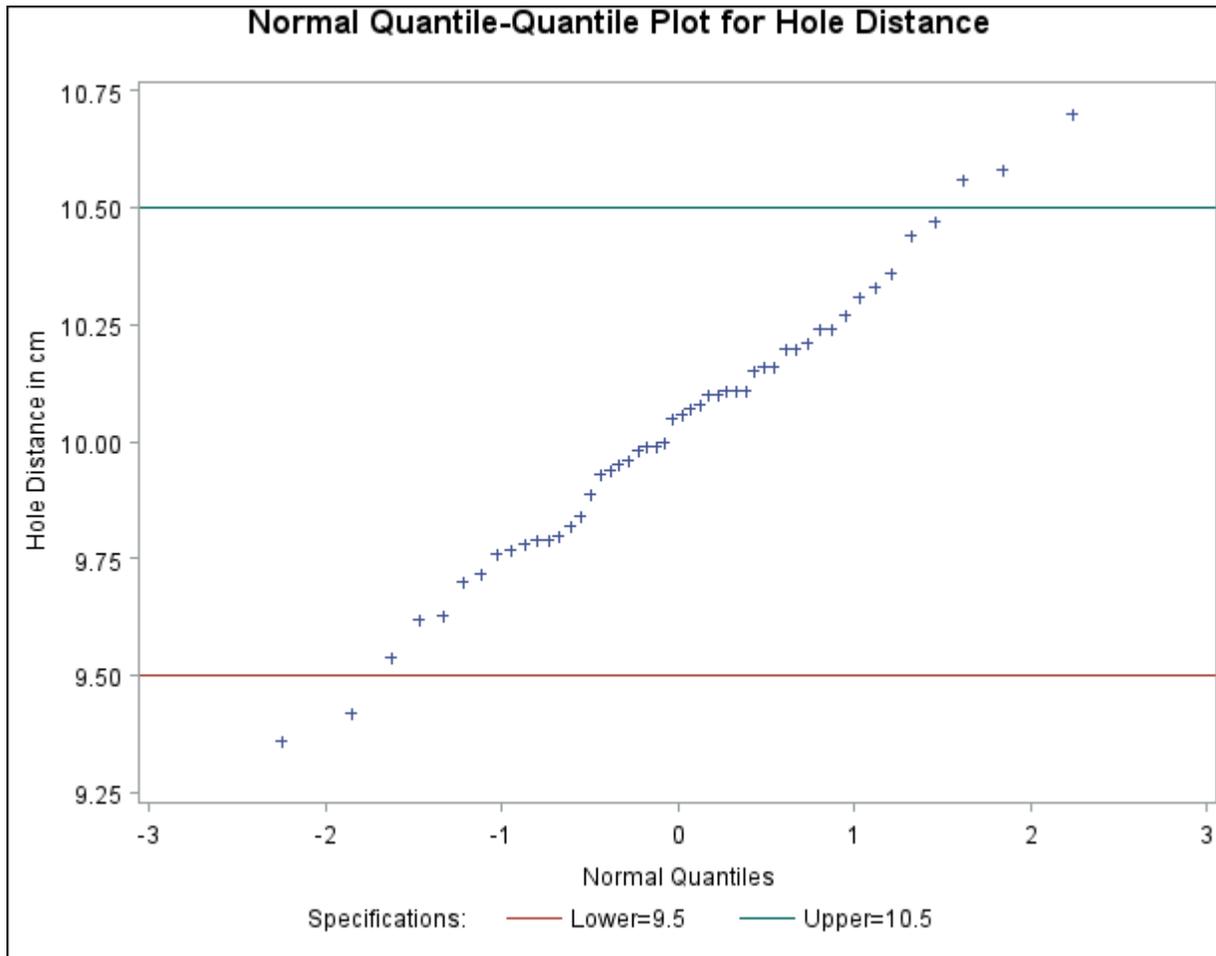

```

ods graphics off;
symbol v=plus;
title 'Normal Quantile-Quantile Plot for Hole Distance';
proc capability data=Sheets noprint;
  spec lsl=9.5 usl=10.5;
  qqplot Distance;
run;

```

The plot compares the ordered values of Distance with quantiles of the normal distribution. The linearity of the point pattern indicates that the measurements are normally distributed. Note that a normal Q-Q plot is created by default. The specification lines are requested with the `LSL=` and `USL=` options in the SPEC statement.

⁹For a P-P plot using these data, see [Figure 5.31](#). For a probability plot using these data, see [Example 5.20](#).

Figure 5.39 Normal Quantile-Quantile Plot Created with Traditional Graphics

Adding a Distribution Reference Line

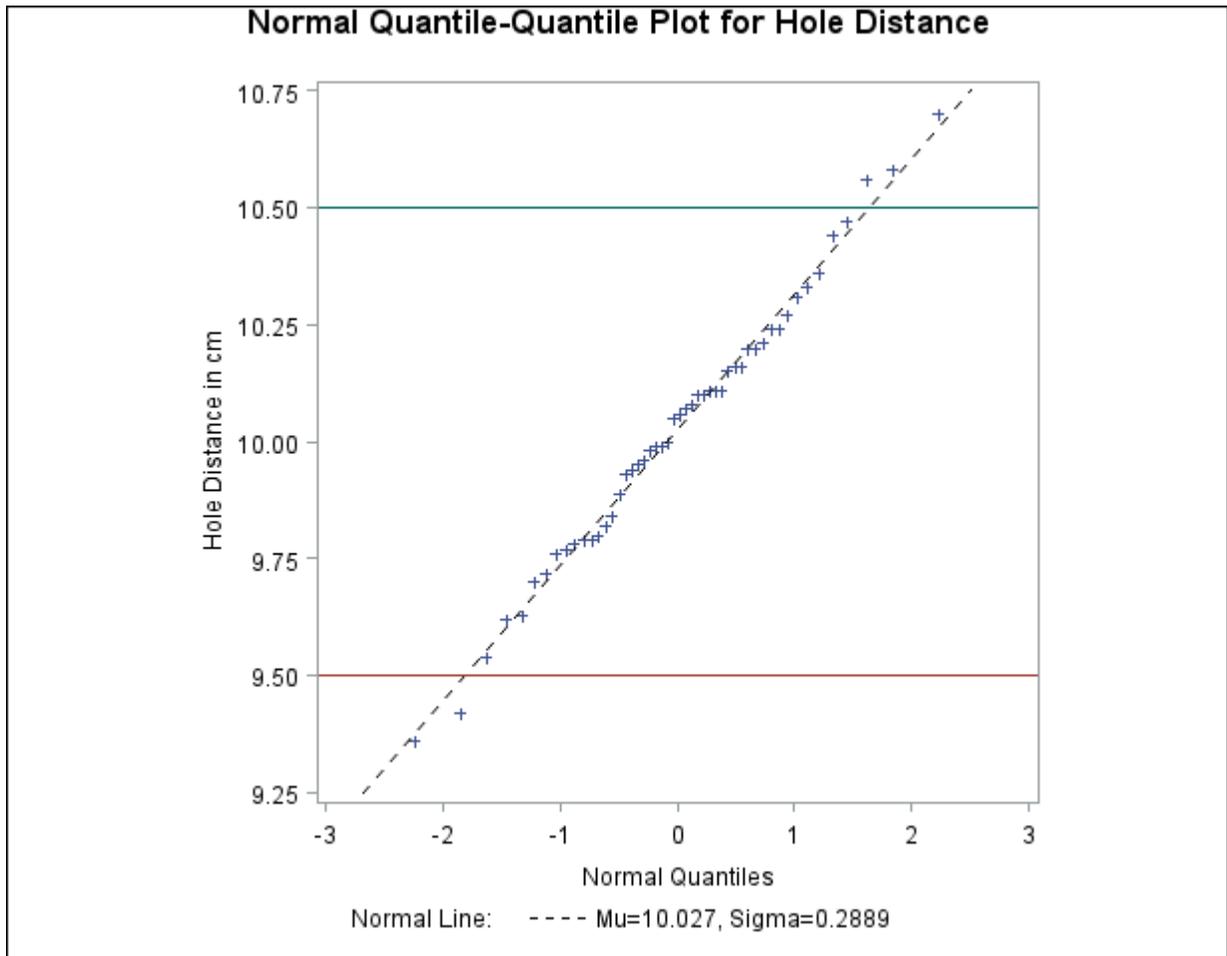

In a normal Q-Q plot, the normal distribution with mean μ_0 and standard deviation σ_0 is represented by a reference line with intercept μ_0 and slope σ_0 . The following statements reproduce the Q-Q plot in Figure 5.39, adding the line for which μ_0 and σ_0 are estimated by the sample mean and standard deviation: *See CAPQQ1 in the SAS/QC Sample Library*

```

symbol v=plus;
title 'Normal Quantile-Quantile Plot for Hole Distance';
proc capability data=Sheets noprint;
  spec lsl=9.5 usl=10.5;
  qqplot Distance / normal(mu=est sigma=est color=black l=2)
    square
    nospeclegend;
run;

```

The plot is displayed in Figure 5.40.

Figure 5.40 Adding a Distribution Reference Line to a Q-Q Plot

Specifying `MU=EST` and `SIGMA=EST` with the `NORMAL` option requests the reference line (alternatively, you can specify numeric values for μ_0 and σ_0 with the `MU=` and `SIGMA=` options). The `COLOR=` and `L=` options specify the color of the line and the line type. The `SQUARE` option displays the plot in a square format, and the `NOSPECLEGEND` option suppresses the legend for the specification lines.

Syntax: QQPLOT Statement

The syntax for the `QQPLOT` statement is as follows:

```
QQPLOT < variables > < / options > ;
```

You can specify the keyword `QQ` as an alias for `QQPLOT`, and you can use any number of `QQPLOT` statements in the `CAPABILITY` procedure. The components of the `QQPLOT` statement are described as follows.

variables

are the process variables for which to create Q-Q plots. If you specify a VAR statement, the variables must also be listed in the VAR statement. Otherwise, the variables can be any numeric variables in the input data set. If you do not specify a list of variables, then by default the procedure creates a Q-Q plot for each variable listed in the VAR statement, or for each numeric variable in the DATA= data set if you do not specify a VAR statement. For example, each of the following QQPLOT statements produces two Q-Q plots, one for length and one for width:

```
proc capability data=measures;
  var length width;
  qqplot;
run;
```

```
proc capability data=measures;
  qqplot length width;
run;
```

options

specify the theoretical distribution for the plot or add features to the plot. If you specify more than one variable, the options apply equally to each variable. Specify all options after the slash (/) in the QQPLOT statement. You can specify only one option naming the distribution in each QQPLOT statement, but you can specify any number of other options. The distributions available are the beta, exponential, gamma, Gumbel, lognormal, normal, generalized Pareto, power function, Rayleigh, two-parameter Weibull, and three-parameter Weibull. By default, the procedure produces a plot for the normal distribution.

In the following example, the **NORMAL** option requests a normal Q-Q plot for each variable. The **MU=** and **SIGMA=** *normal-options* request a distribution reference line with intercept 10 and slope 0.3 for each plot, corresponding to a normal distribution with mean $\mu = 10$ and standard deviation $\sigma = 0.3$. The **SQUARE** option displays the plot in a square frame, and the **CTEXT=** option specifies the text color.

```
proc capability data=measures;
  qqplot length1 length2 / normal(mu=10 sigma=0.3)
                        square
                        ctext=blue;
run;
```

Summary of Options

The following tables list the QQPLOT statement options by function. For complete descriptions, see “Dictionary of Options” on page 518.

Distribution Options

Table 5.67 summarizes the options for requesting a specific theoretical distribution.

Table 5.67 Options for Specifying a Theoretical Distribution

Option	Description
BETA(<i>beta-options</i>)	specifies beta Q-Q plot for shape parameters α , β specified with mandatory ALPHA= and BETA= <i>beta-options</i>
EXPONENTIAL(<i>exponential-options</i>)	specifies exponential Q-Q plot
GAMMA(<i>gamma-options</i>)	specifies gamma Q-Q plot for shape parameter α specified with mandatory ALPHA= <i>gamma-option</i>
GUMBEL(<i>Gumbel-options</i>)	specifies Gumbel Q-Q plot
LOGNORMAL(<i>lognormal-options</i>)	specifies lognormal Q-Q plot for shape parameter σ specified with mandatory SIGMA= <i>lognormal-option</i>
NORMAL(<i>normal-options</i>)	specifies normal Q-Q plot
PARETO(<i>Pareto-options</i>)	specifies generalized Pareto Q-Q plot for shape parameter α specified with mandatory ALPHA= <i>Pareto-option</i>
POWER(<i>power-options</i>)	specifies power function Q-Q plot for shape parameter α specified with mandatory ALPHA= <i>power-option</i>
RAYLEIGH(<i>Rayleigh-options</i>)	specifies Rayleigh Q-Q plot
WEIBULL(<i>Weibull-options</i>)	specifies three-parameter Weibull Q-Q plot for shape parameter c specified with mandatory C= <i>Weibull-option</i>
WEIBULL2(<i>Weibull2-options</i>)	specifies two-parameter Weibull Q-Q plot

Table 5.68 summarizes options that specify parameter values for theoretical distributions and that control the display of a distribution reference line. Specify these options in parentheses after the distribution option. For example, the following statements use the NORMAL option to request a normal Q-Q plot with a specific distribution reference line. The MU= and SIGMA= *normal-options* display a distribution reference line with intercept 10 and slope 0.3. The COLOR= *normal-option* draws the line in red.

```
proc capability data=measures;
  qqplot length / normal(mu=10 sigma=0.3 color=red);
run;
```

Table 5.68 Distribution Options

Option	Description
Distribution Reference Line Options	
COLOR=	specifies color of distribution reference line
L=	specifies line type of distribution reference line
SYMBOL=	specifies plotting character for line printer plots
W=	specifies width of distribution reference line

Table 5.68 (continued)

Option	Description
Beta-Options	
ALPHA=	specifies mandatory shape parameter α
BETA=	specifies mandatory shape parameter β
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Exponential-Options	
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Gamma-Options	
ALPHA=	specifies mandatory shape parameter α
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Gumbel-Options	
MU=	specifies reference line intercept μ
SIGMA=	specifies reference line slope σ
Lognormal-Options	
SIGMA=	specifies mandatory shape parameter σ
SLOPE=	specifies reference line slope
THETA=	specifies reference line intercept θ
ZETA=	specifies reference line slope $\exp(\zeta_0)$
Normal-Options	
CPKREF	specifies vertical reference lines at intersection of specification limits with distribution reference line
CPKSCALE	rescales horizontal axis in C_{pk} units
MU=	specifies reference line intercept μ
SIGMA=	specifies reference line slope σ
Pareto-Options	
ALPHA=	specifies mandatory shape parameter α
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Power-Options	
ALPHA=	specifies mandatory shape parameter α
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Rayleigh-Options	
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Weibull-Options	
C=	specifies mandatory shape parameter c
SIGMA=	specifies reference line slope σ
THETA=	specifies reference line intercept θ
Weibull2-Options	
C=	specifies c_0 for reference line (slope is $\frac{1}{c_0}$)
SIGMA=	specifies σ_0 for reference line (intercept is $\log(\sigma_0)$)

Table 5.68 (continued)

Option	Description
SLOPE=	specifies reference line slope
THETA=	specifies known lower threshold θ_0

General Options

Table 5.69 lists options that control the appearance of the plots.

Table 5.69 General QQPLOT Statement Options

Option	Description
General Plot Layout Options	
CONTENTS=	specifies table of contents entry for Q-Q plot grouping
HREF=	specifies reference lines perpendicular to the horizontal axis
HREFLABELS=	specifies labels for HREF= lines
LEGEND=	specifies LEGEND statement
NADJ=	adjusts sample size (N) when computing quantiles
NOFRAME	suppresses frame around plotting area
NOLEGEND	suppresses legend
NOLINELEGEND	suppresses distribution reference line information in legend
NOSPECLEGEND	suppresses specifications information in legend
PCTLAXIS	adds a nonlinear percentile axis
PCTLMINOR	adds minor tick marks to percentile axis
PCTLSCALE	replaces theoretical quantiles with percentiles
RANKADJ=	adjusts ranks when computing quantiles
ROTATE	switches horizontal and vertical axes
SQUARE	displays Q-Q plot in square format
VREF=	specifies reference lines perpendicular to the vertical axis
VREFLABELS=	specifies labels for VREF= lines
Graphics Options	
ANNOTATE=	specifies annotate data set
CAXIS=	specifies color for axis
CFRAME=	specifies color for frame
CGRID=	specifies color for grid lines
CHREF=	specifies colors for HREF= lines
CSTATREF=	specifies colors for STATREF= lines
CTEXT=	specifies color for text
CVREF=	specifies colors for VREF= lines
DESCRIPTION=	specifies description for plot in graphics catalog
FONT=	specifies software font for text
GRID	draws grid lines perpendicular to the quantile axis
HEIGHT=	specifies height of text used outside framed areas
HMINOR=	specifies number of horizontal minor tick marks
HREFLABPOS=	specifies vertical position of labels for HREF= lines
INFONT=	specifies software font for text inside framed areas

Table 5.69 (continued)

Option	Description
INHEIGHT=	specifies height of text inside framed areas
LGRID=	specifies a line type for grid lines
LHREF=	specifies line styles for HREF= lines
LSTATREF=	specifies line styles for STATREF= lines
LVREF=	specifies line styles for VREF= lines
NAME=	specifies name for plot in graphics catalog
NOHLABEL	suppresses label for horizontal axis
NOVLABEL	suppresses label for vertical axis
NOVTICK	suppresses tick marks and tick mark labels for vertical axis
STATREF=	specifies reference lines at values of summary statistics
STATREFLABELS=	specifies labels for STATREF= lines
STATREFSUBCHAR=	specifies substitution character for displaying statistic values in STATREFLABELS= labels
VAXIS=	specifies AXIS statement for vertical axis
VAXISLABEL=	specifies label for vertical axis
VMINOR=	specifies number of vertical minor tick marks
VREFLABPOS=	specifies horizontal position of labels for VREF= lines
WAXIS=	specifies line thickness for axes and frame
WGRID=	specifies thickness for grid lines
Options for ODS Graphics Output	
ODSFOOTNOTE=	specifies footnote displayed on Q-Q plot
ODSFOOTNOTE2=	specifies secondary footnote displayed on Q-Q plot
ODSTITLE=	specifies title displayed on Q-Q plot
ODSTITLE2=	specifies secondary title displayed on Q-Q plot
Options for Comparative Plots	
ANNOKEY	applies annotation requested in ANNOTATE= data set to key cell only
CFRAMESIDE=	specifies color for filling frame for row labels
CFRAMETOP=	specifies color for filling frame for column labels
CPROP=	specifies color for proportion of frequency bar
CTEXTSIDE=	specifies color for row labels
CTEXTTOP=	specifies color for column labels
INTERTILE=	specifies distance between tiles
NCOLS=	specifies number of columns in comparative Q-Q plot
NROWS=	specifies number of rows in comparative Q-Q plot
OVERLAY	overlays plots for different class levels (ODS Graphics only)
Options to Enhance Line Printer Plots	
HREFCHAR=	specifies line character for HREF= lines
NOOBSLEGEND	suppresses legend for hidden points
QQSYMBOL=	specifies character for plotted points
VREFCHAR=	specifies character for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of options specific to the QQPLOT statement. The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics, ODS Graphics output, and line printers plots, respectively. See “[Dictionary of Common Options: CAPABILITY Procedure](#)” on page 551 for detailed descriptions of options common to all the plot statements.

ALPHA=*value-list*|EST

specifies values for a mandatory shape parameter α ($\alpha > 0$) for Q-Q plots requested with the **BETA**, **GAMMA**, **PARETO**, and **POWER** options. A plot is created for each value specified. For examples, see the entries for the distribution options. If you specify ALPHA=EST, a maximum likelihood estimate is computed for α .

BETA(ALPHA=*value-list*|EST BETA=*value-list*|EST <*beta-options*>)

creates a beta Q-Q plot for each combination of the shape parameters α and β given by the mandatory **ALPHA=** and **BETA=** options. If you specify ALPHA=EST and BETA=EST, a plot is created based on maximum likelihood estimates for α and β . In the following example, the first QQPLOT statement produces one plot, the second statement produces four plots, the third statement produces six plots, and the fourth statement produces one plot:

```
proc capability data=measures;
  qqplot width / beta(alpha=2 beta=2);
  qqplot width / beta(alpha=2 3 beta=1 2);
  qqplot width / beta(alpha=2 to 3 beta=1 to 2 by 0.5);
  qqplot width / beta(alpha=est beta=est);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $B_{\alpha\beta}^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $B_{\alpha\beta}^{-1}(\cdot)$ is the inverse normalized incomplete beta function, n is the number of nonmissing observations, and α and β are the shape parameters of the beta distribution.

The point pattern on the plot for ALPHA= α and BETA= β tends to be linear with intercept θ and slope σ if the data are beta distributed with the specific density function

$$p(x) = \begin{cases} \frac{(x-\theta)^{\alpha-1}(\theta+\sigma-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$, and

θ = lower threshold parameter

σ = scale parameter ($\sigma > 0$)

α = first shape parameter ($\alpha > 0$)

β = second shape parameter ($\beta > 0$)

To obtain graphical estimates of α and β , specify lists of values for the **ALPHA=** and **BETA=** options, and select the combination of α and β that most nearly linearizes the point pattern. To assess the point pattern, you can add a diagonal distribution reference line with intercept θ_0 and slope σ_0 with the *beta-options* THETA= θ_0 and SIGMA= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and slope σ_0 with the *beta-options* THETA=EST and SIGMA=EST. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  qqplot width / beta(alpha=2 beta=3 theta=4 sigma=5);
run;
```

Agreement between the reference line and the point pattern indicates that the beta distribution with parameters α , β , θ_0 , and σ_0 is a good fit. You can specify the **SCALE=** option as an alias for the **SIGMA=** option and the **THRESHOLD=** option as an alias for the **THETA=** option.

BETA=*value-list*|**EST**

specifies values for the shape parameter β ($\beta > 0$) for Q-Q plots requested with the **BETA** distribution option. A plot is created for each value specified with the **BETA=** option. If you specify **BETA=EST**, a maximum likelihood estimate is computed for β . For examples, see the preceding entry for the **BETA** distribution option.

C=*value(-list)*|**EST**

specifies the shape parameter c ($c > 0$) for Q-Q plots requested with the **WEIBULL** and **WEIBULL2** options. You must specify **C=** as a *Weibull-option* with the **WEIBULL** option; in this situation it accepts a list of values, or if you specify **C=EST**, a maximum likelihood estimate is computed for c . You can optionally specify **C=value** or **C=EST** as a *Weibull2-option* with the **WEIBULL2** option to request a distribution reference line; in this situation, you must also specify **SIGMA=value** or **SIGMA=EST**. For an example, see [Output 5.23.1](#).

CGRID=*color*

specifies the color for the grid lines associated with the quantile axis, requested by the **GRID** *Traditional Graphics* option.

CPKREF

draws reference lines extending from the intersections of the specification limits with the distribution reference line to the quantile axis in plots requested with the **NORMAL** option. *Traditional Graphics* Specify **CPKREF** in parentheses after the **NORMAL** option. You can use the **CPKREF** option with the **CPKSCALE** option for graphical estimation of the capability indices *CPU*, *CPL*, and C_{pk} , as illustrated in [Output 5.24.1](#).

CPKSCALE

rescales the quantile axis in C_{pk} units for plots requested with the **NORMAL** option. Specify **CPKSCALE** in parentheses after the **NORMAL** option. You can use the **CPKSCALE** option with the **CPKREF** option for graphical estimation of the capability indices *CPU*, *CPL*, and C_{pk} , as illustrated in [Output 5.24.1](#).

EXPONENTIAL<(*exponential-options*)>

EXP<(*exponential-options*)>

creates an exponential Q-Q plot. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $-\log\left(1 - \frac{i-0.375}{n+0.25}\right)$, where n is the number of nonmissing observations.

The pattern on the plot tends to be linear with intercept θ and slope σ if the data are exponentially distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma} \exp\left(-\frac{x-\theta}{\sigma}\right) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where θ is the threshold parameter, and σ is the scale parameter ($\sigma > 0$).

To assess the point pattern, you can add a diagonal distribution reference line with intercept θ_0 and slope σ_0 with the *exponential-options* THETA= θ_0 and SIGMA= σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and slope σ_0 with the *exponential-options* THETA=EST and SIGMA=EST. Specify these options in parentheses, as in the following example: as in the following example:

```
proc capability data=measures;
  qqplot width / exponential(theta=4 sigma=5);
run;
```

Agreement between the reference line and the point pattern indicates that the exponential distribution with parameters θ_0 and σ_0 is a good fit. You can specify the SCALE= option as an alias for the SIGMA= option and the THRESHOLD= option as an alias for the THETA= option.

GAMMA(ALPHA=*value-list***|EST** <*gamma-options*>)

creates a gamma Q-Q plot for each value of the shape parameter α given by the mandatory ALPHA= option or its alias, the SHAPE= option. The following example produces three probability plots:

```
proc capability data=measures;
  qqplot width / gamma(alpha=0.4 to 0.6 by 0.1);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $G_{\alpha}^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $G_{\alpha}^{-1}(\cdot)$ is the inverse normalized incomplete gamma function, n is the number of nonmissing observations, and α is the shape parameter of the gamma distribution.

The pattern on the plot for ALPHA= α tends to be linear with intercept θ and slope σ if the data are gamma distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma\Gamma(\alpha)} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\frac{x-\theta}{\sigma}\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter
 σ = scale parameter ($\sigma > 0$)
 α = shape parameter ($\alpha > 0$)

To obtain a graphical estimate of α , specify a list of values for the ALPHA= option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line with intercept θ_0 and slope σ_0 with the *gamma-options* THETA= θ_0 and SIGMA= σ_0 . Alternatively,

you can add a line corresponding to estimated values of θ_0 and σ_0 with the *gamma-options* THETA=EST and SIGMA=EST. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  qqplot width / gamma(alpha=2 theta=3 sigma=4);
run;
```

Agreement between the reference line and the point pattern indicates that the gamma distribution with parameters α , θ_0 , and σ_0 is a good fit. You can specify the **SCALE=** option as an alias for the **SIGMA=** option and the **THRESHOLD=** option as an alias for the **THETA=** option.

GUMBEL(< *Gumbel-options* >)

creates a Gumbel Q-Q plot. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $-\log\left(-\log\left(\frac{i-0.375}{n+0.25}\right)\right)$, where n is the number of nonmissing observations.

The point pattern on the plot tends to be linear with intercept μ and slope σ if the data are Gumbel distributed with the specific density function

$$p(x) = \frac{e^{-(x-\mu)/\sigma}}{\sigma} \exp\left(-e^{-(x-\mu)/\sigma}\right)$$

where μ is a location parameter and σ is a positive scale parameter.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to μ_0 and σ_0 with the *Gumbel-options* **MU**= μ_0 and **SIGMA**= σ_0 . Alternatively, you can add a line corresponding to estimated values of μ_0 and σ_0 with the *Gumbel-options* **MU**=EST and **SIGMA**=EST. Specify these options in parentheses following the **GUMBEL** option.

Agreement between the reference line and the point pattern indicates that the Gumbel distribution with parameters μ_0 and σ_0 is a good fit.

GRID

draws reference lines perpendicular to the quantile axis at major tick marks.

LEGEND=*name* | **NONE**

specifies the name of a **LEGEND** statement describing the legend for specification limit reference lines and fitted curves. Specifying **LEGEND**=**NONE** is equivalent to specifying the **NOLEGEND** option.

LGRID=*linetype*

specifies the line type for the grid lines associated with the quantile axis, requested by the *Traditional Graphics* **GRID** option.

LOGNORMAL(**SIGMA**=*value-list*|**EST** < *lognormal-options* >)

LNORM(**SIGMA**=*value-list*|**EST** < *lognormal-options* >)

creates a lognormal Q-Q plot for each value of the shape parameter σ given by the mandatory **SIGMA=** option or its alias, the **SHAPE=** option. For example,

```
proc capability data=measures;
  qqplot width/ lognormal(shape=1.5 2.5);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\exp\left(\sigma\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)\right)$, where $\Phi^{-1}(\cdot)$ is the inverse cumulative standard normal distribution, n is the number of nonmissing observations, and σ is the shape parameter of the lognormal distribution.

The pattern on the plot for $\text{SIGMA}=\sigma$ tends to be linear with intercept θ and slope $\exp(\zeta)$ if the data are lognormally distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma\sqrt{2\pi}(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\zeta)^2}{2\sigma^2}\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where

θ = threshold parameter

ζ = scale parameter

σ = shape parameter ($\sigma > 0$)

To obtain a graphical estimate of σ , specify a list of values for the $\text{SIGMA}=\text{option}$, and select the value that most nearly linearizes the point pattern. For an illustration, see [Example 5.22](#).

To assess the point pattern, you can add a diagonal distribution reference line corresponding to the threshold parameter θ_0 and the scale parameter ζ_0 with the *lognormal-options* $\text{THETA}=\theta_0$ and $\text{ZETA}=\zeta_0$. Alternatively, you can add a line corresponding to estimated values of θ_0 and ζ_0 with the *lognormal-options* $\text{THETA}=\text{EST}$ and $\text{ZETA}=\text{EST}$. This line has intercept θ_0 and slope $\exp(\zeta_0)$. Agreement between the line and the point pattern indicates that the lognormal distribution with parameters σ , θ_0 , and ζ_0 is a good fit. See [Output 5.22.4](#) for an example. You can specify the $\text{THRESHOLD}=\text{option}$ as an alias for the $\text{THETA}=\text{option}$ and the $\text{SCALE}=\text{option}$ as an alias for the $\text{ZETA}=\text{option}$.

You can also display the reference line by specifying $\text{THETA}=\theta_0$, and you can specify the slope with the $\text{SLOPE}=\text{option}$. For example, the following two QQPLOT statements produce charts with identical reference lines:

```
proc capability data=measures;
  qqplot width / lognormal(sigma=2 theta=3 zeta=1);
  qqplot width / lognormal(sigma=2 theta=3 slope=2.718);
run;
```

MU=value|EST

specifies a value for the mean μ for a Q-Q plot requested with the [GUMBEL](#) and [NORMAL](#) options. For the normal distribution, you can specify $\text{MU}=\text{EST}$ to request a distribution reference line with intercept equal to the sample mean, as illustrated in [Figure 5.40](#). If you specify $\text{MU}=\text{EST}$ for the Gumbel distribution, a maximum likelihood estimate is calculated.

NADJ=value

specifies the adjustment value added to the sample size in the calculation of theoretical quantiles. The default is $\frac{1}{4}$, as described by Blom (1958). Also refer to Chambers et al. (1983) for additional information.

NOLEGEND**LEGEND=NONE**

suppresses legends for specification limits, fitted curves, distribution lines, and hidden observations. For an example, see [Output 5.24.1](#).

NOLINELEGEND**NOLINEL**

suppresses the legend for the optional distribution reference line.

NOOBSLEGEND**NOOBSL**

suppresses the legend that indicates the number of hidden observations.

Line Printer

NORMAL<(normal-options)>**NORM<(normal-options)>**

creates a normal Q-Q plot. This is the default if you do not specify a distribution option. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $\Phi^{-1}(\cdot)$ is the inverse cumulative standard normal distribution, and n is the number of nonmissing observations.

The pattern on the plot tends to be linear with intercept μ and slope σ if the data are normally distributed with the specific density function

$$p(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) \quad \text{for all } x$$

where μ is the mean, and σ is the standard deviation ($\sigma > 0$).

To assess the point pattern, you can add a diagonal distribution reference line with intercept μ_0 and slope σ_0 with the *normal-options* MU= μ_0 and SIGMA= σ_0 . Alternatively, you can add a line corresponding to estimated values of μ_0 and σ_0 with the *normal-options* THETA=EST and SIGMA=EST; the estimates of μ_0 and σ_0 are the sample mean and sample standard deviation. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  qqplot length / normal(mu=10 sigma=0.3);
run;
```

For an example, see “[Adding a Distribution Reference Line](#)” on page 511. Agreement between the reference line and the point pattern indicates that the normal distribution with parameters μ_0 and σ_0 is a good fit. You can specify MU=EST and SIGMA=EST to request a distribution reference line with the sample mean and sample standard deviation as the intercept and slope.

Other *normal-options* include **CPKREF** and **CPKSCALE**. The **CPKREF** option draws reference lines extending from the intersections of specification limits with the distribution reference line to the theoretical quantile axis. The **CPKSCALE** option rescales the theoretical quantile axis in C_{pk} units. You can use the **CPKREF** option with the **CPKSCALE** option for graphical estimation of the capability indices CPU , CPL , and C_{pk} , as illustrated in [Output 5.24.1](#).

NOSPECLEGEND

NOSPECL

suppresses the legend for specification limit reference lines. For an example, see [Figure 5.40](#).

PARETO(< Pareto-options >)

creates a generalized Pareto Q-Q plot for each value of the shape parameter α given by the mandatory **ALPHA=** option. If you specify **ALPHA=EST**, a plot is created based on a maximum likelihood estimate for α .

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $(1 - (1 - \frac{i-0.375}{n+0.25})^\alpha)/\alpha$ ($\alpha \neq 0$) or $-\log(1 - \frac{i-0.375}{n+0.25})$ ($\alpha = 0$), where n is the number of nonmissing observations and α is the shape parameter of the generalized Pareto distribution.

The point pattern on the plot for **ALPHA=** α tends to be linear with intercept θ and slope σ if the data are generalized Pareto distributed with the specific density function

$$p(x) = \begin{cases} \frac{1}{\sigma} (1 - \alpha(x - \theta)/\sigma)^{1/\alpha - 1} & \text{if } \alpha \neq 0 \\ \frac{1}{\sigma} \exp(-(x - \theta)/\sigma) & \text{if } \alpha = 0 \end{cases}$$

where

θ = threshold parameter

σ = scale parameter ($\sigma > 0$)

α = shape parameter ($\alpha > 0$)

To obtain a graphical estimate of α , specify a list of values for the **ALPHA=** option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *Pareto-options* **THETA=** θ_0 and **SIGMA=** σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *Pareto-options* **THETA=EST** and **SIGMA=EST**. Specify these options in parentheses following the **PARETO** option.

Agreement between the reference line and the point pattern indicates that the generalized Pareto distribution with parameters α , θ_0 , and σ_0 is a good fit.

PCTLAXIS(axis-options)

adds a nonlinear percentile axis along the frame of the Q-Q plot opposite the theoretical quantile axis. The added axis is identical to the axis for probability plots produced with the **PROBPLOT** statement. When using the **PCTLAXIS** option, you must specify **HREF=** values in quantile units, and you cannot use the **NOFRAME** option. You can specify the following *axis-options*:

CGRID=*color*

specifies the color used for grid lines.

GRID

draws grid lines perpendicular to the percentile axis at major tick marks.

GRIDCHAR=*'character'*

specifies the character used to draw grid lines associated with the percentile axis on line printer plots.

LABEL=*'string'*

specifies the label for the percentile axis.

LGRID=*linetype*

specifies the line type used for grid lines associated with the percentile axis.

WGRID=*value*

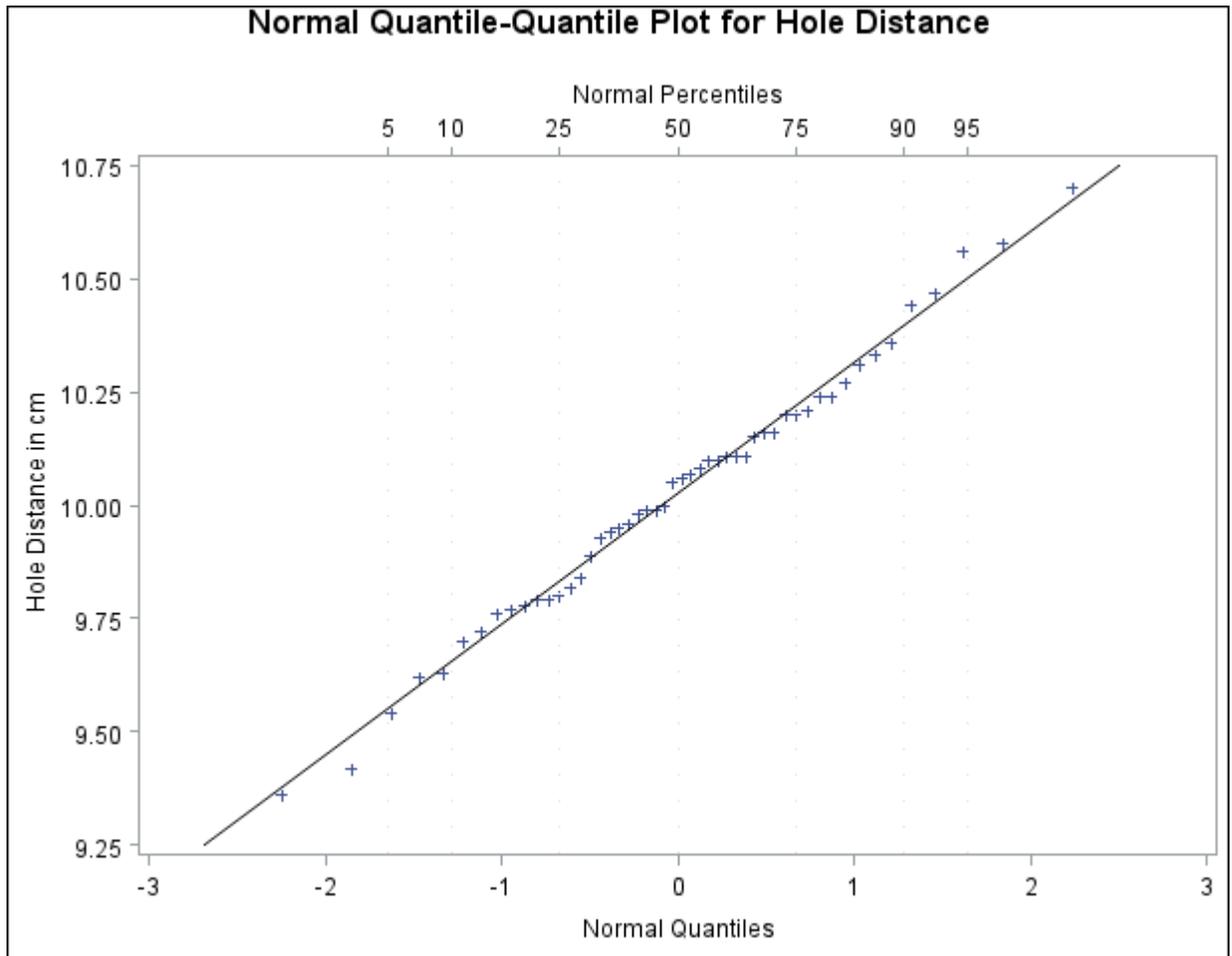

specifies the thickness for grid lines associated with the percentile axis.

For example, the following statements display the plot in [Figure 5.41](#):

*See CAPQQ1 in the
SAS/QC Sample Library*

```
ods graphics off;
symbol v=plus;
title 'Normal Quantile-Quantile Plot for Hole Distance';
proc capability data=Sheets noprint;
  qqplot Distance / normal(mu=est sigma=est color=black)
                nolegend
                pctlaxis(grid lgrid=35 label='Normal Percentiles');
run;
```

Figure 5.41 Normal Q-Q Plot with Percentile Axis

**PCTLMINOR**

Traditional Graphics

requests minor tick marks for the percentile axis displayed when you use the [PCTLAXIS](#) option. See the entry for the [PCTLAXIS](#) option for an example.

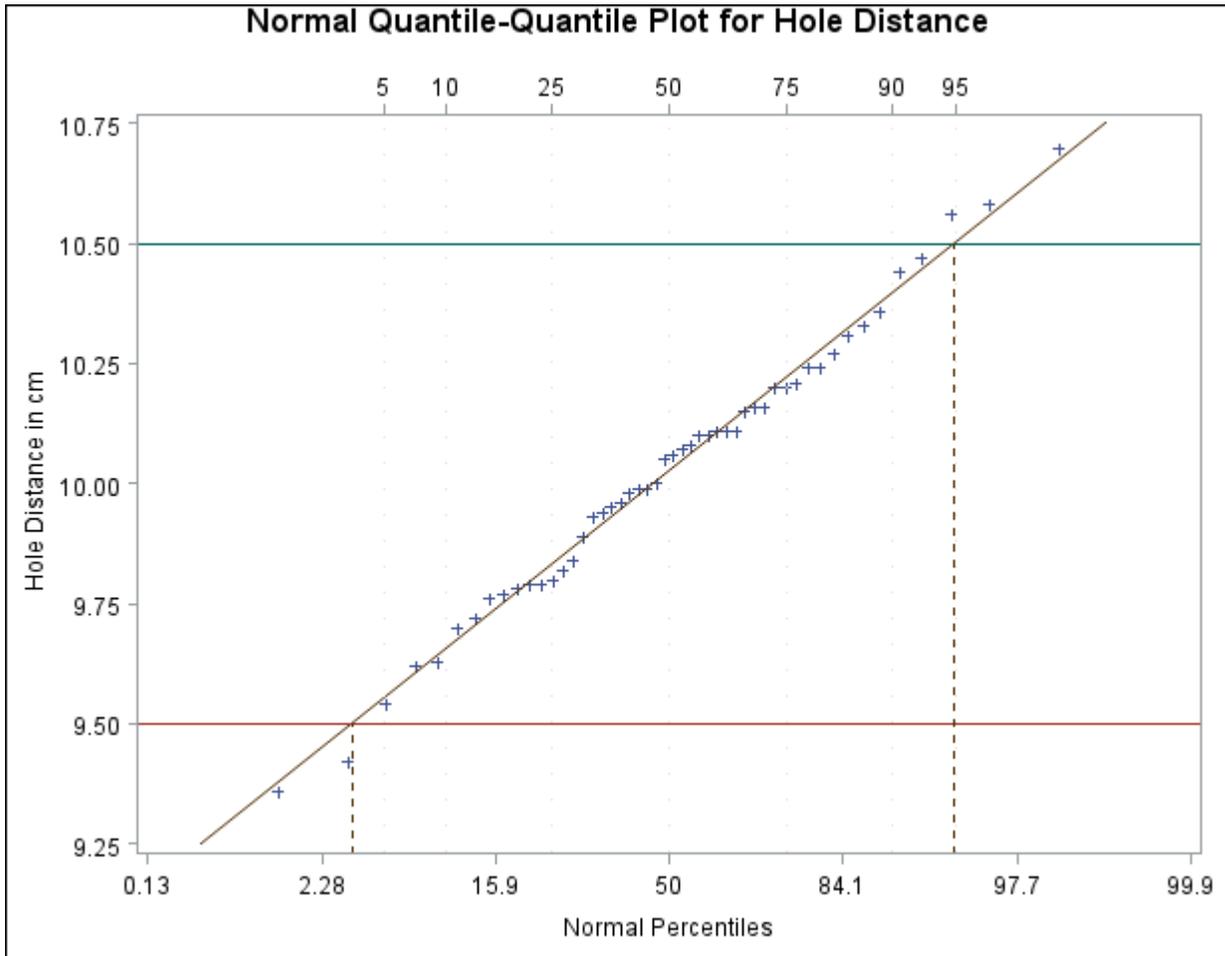

PCTLSCALE

See CAPQQ1 in the SAS/QC Sample Library

requests scale labels for the theoretical quantile axis in percentile units, resulting in a nonlinear axis scale. Tick marks are drawn uniformly across the axis based on the quantile scale. In all other respects, the plot remains the same, and you must specify [HREF=](#) values in quantile units. For a true nonlinear axis, use the [PCTLAXIS](#) option or use the [PROBPLOT](#) statement. For example, the following statements display the plot in [Figure 5.42](#):

```
symbol v=plus;
title 'Normal Quantile-Quantile Plot for Hole Distance';
proc capability data=Sheets noprint;
  spec lsl=9.5 usl=10.5;
  qqplot Distance / normal(mu=est sigma=est cpkref)
    pctlaxis(grid lgrid=35)
    nolegend pctlscale;
run;
```

Figure 5.42 Normal Q-Q Plot for Reading Percentiles of Specification Limits

**POWER(<power-options>)**

creates a power function Q-Q plot for each value of the shape parameter α given by the mandatory ALPHA= option. If you specify ALPHA=EST, a plot is created based on a maximum likelihood estimate for α .

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $B_{\alpha(1)}^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $B_{\alpha(1)}^{-1}(\cdot)$ is the inverse normalized incomplete beta function, n is the number of nonmissing observations, α is one shape parameter of the beta distribution, and the second shape parameter, $\beta = 1$.

The point pattern on the plot for ALPHA= α tends to be linear with intercept θ and slope σ if the data are power function distributed with the specific density function

$$p(x) = \begin{cases} \frac{\alpha}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} & \text{for } \theta < x < \theta + \sigma \\ 0 & \text{for } x \leq \theta \text{ or } x \geq \theta + \sigma \end{cases}$$

where

θ = threshold parameter
 σ = scale parameter ($\sigma > 0$)
 α = shape parameter ($\alpha > 0$)

To obtain a graphical estimate of α , specify a list of values for the **ALPHA=** option, and select the value that most nearly linearizes the point pattern.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *power-options* **THETA=** θ_0 and **SIGMA=** σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *power-options* **THETA=EST** and **SIGMA=EST**. Specify these options in parentheses following the **POWER** option.

Agreement between the reference line and the point pattern indicates that the power function distribution with parameters α , θ_0 , and σ_0 is a good fit.

QQSYMBOL='character'

Line Printer

specifies the character used to plot the Q-Q points in line printer plots. The default is the plus sign (+).

RANKADJ=value

specifies the adjustment value added to the ranks in the calculation of theoretical quantiles. The default is $-\frac{3}{8}$, as described by Blom (1958). Also refer to Chambers et al. (1983) for additional information.

RAYLEIGH(< *Rayleigh-options* >)

creates a Rayleigh Q-Q plot. To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\sqrt{-2 \log \left(1 - \frac{i-0.375}{n+0.25} \right)}$, where n is the number of nonmissing observations.

The point pattern on the plot tends to be linear with intercept θ and slope σ if the data are Rayleigh distributed with the specific density function

$$p(x) = \begin{cases} \frac{x-\theta}{\sigma^2} \exp(-(x-\theta)^2/(2\sigma^2)) & \text{for } x \geq \theta \\ 0 & \text{for } x < \theta \end{cases}$$

where θ is a threshold parameter, and σ is a positive scale parameter.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to θ_0 and σ_0 with the *Rayleigh-options* **THETA=** θ_0 and **SIGMA=** σ_0 . Alternatively, you can add a line corresponding to estimated values of θ_0 and σ_0 with the *Rayleigh-options* **THETA=EST** and **SIGMA=EST**. Specify these options in parentheses after the **RAYLEIGH** option.

Agreement between the reference line and the point pattern indicates that the Rayleigh distribution with parameters θ_0 and σ_0 is a good fit.

ROTATE

switches the horizontal and vertical axes so that the theoretical percentiles are plotted vertically while the data are plotted horizontally. Regardless of whether the plot has been rotated, horizontal axis options (such as **HAXIS=**) refer to the horizontal axis, and vertical axis options (such as **VAXIS=**) refer to the vertical axis. All other options that depend on axis placement adjust to the rotated axes.

SIGMA=value-list|EST

specifies the value of the distribution parameter σ , where $\sigma > 0$. Alternatively, you can specify SIGMA=EST to request a maximum likelihood estimate for σ_0 . The use of the SIGMA= option depends on the distribution option specified, as indicated by the following table:

Distribution Option	Use of the SIGMA= Option
BETA EXPONENTIAL GAMMA PARETO POWER RAYLEIGH WEIBULL	THETA= θ_0 and SIGMA= σ_0 request a distribution reference line with intercept θ_0 and slope σ_0 .
GUMBEL	MU= μ_0 and SIGMA= σ_0 request a distribution reference line corresponding to μ_0 and σ_0 .
LOGNORMAL	SIGMA= $\sigma_1 \dots \sigma_n$ requests n Q-Q plots with shape parameters $\sigma_1 \dots \sigma_n$. The SIGMA= option is mandatory.
NORMAL	MU= μ_0 and SIGMA= σ_0 request a distribution reference line with intercept μ_0 and slope σ_0 . SIGMA=EST requests a slope equal to the sample standard deviation.
WEIBULL2	SIGMA= σ_0 and C= c_0 request a distribution reference line with intercept $\log(\sigma_0)$ and slope $\frac{1}{c_0}$.

For an example using SIGMA=EST, see [Output 5.24.1](#). For an example of lognormal plots using the SIGMA= option, see [Example 5.22](#).

SLOPE=value|EST

specifies the slope for a distribution reference line requested with the LOGNORMAL and WEIBULL2 options.

When you use the SLOPE= option with the LOGNORMAL option, you must also specify a threshold parameter value θ_0 with the THETA= option. Specifying the SLOPE= option is an alternative to specifying ZETA= ζ_0 , which requests a slope of $\exp(\zeta_0)$. See [Output 5.22.4](#) for an example.

When you use the SLOPE= option with the WEIBULL2 option, you must also specify a scale parameter value σ_0 with the SIGMA= option. Specifying the SLOPE= option is an alternative to specifying C= c_0 , which requests a slope of $\frac{1}{c_0}$.

For example, the first and second QQPLOT statements that follow produce plots identical to those produced by the third and fourth QQPLOT statements:

```
proc capability data=measures;
  qqplot width / lognormal(sigma=2 theta=0 zeta=0);
  qqplot width / weibull2(sigma=2 theta=0 c=0.25);
  qqplot width / lognormal(sigma=2 theta=0 slope=1);
  qqplot width / weibull2(sigma=2 theta=0 slope=4);
run;
```

For more information, see “Graphical Estimation” on page 535.

SQUARE

Traditional Graphics

displays the Q-Q plot in a square frame. Compare Figure 5.39 with Figure 5.40. The default

ODS Graphics

is a rectangular frame.

SYMBOL=*character*'

Line Printer

specifies the character used for a distribution reference line in a line printer plot. The default character is the first letter of the distribution option keyword.

THETA=*value*|EST

THRESHOLD=*value*|EST

specifies the lower threshold parameter θ for Q-Q plots requested with the BETA, EXPONENTIAL, GAMMA, LOGNORMAL, PARETO, POWER, RAYLEIGH, WEIBULL, and WEIBULL2 options.

When used with the WEIBULL2 option, the THETA= option specifies the known lower threshold θ_0 , for which the default is 0. See Output 5.23.2 for an example.

When used with the other distribution options, the THETA= option specifies θ_0 for a distribution reference line; alternatively in this situation, you can specify THETA=EST to request a maximum likelihood estimate for θ_0 . To request the line, you must also specify a scale parameter. See Output 5.22.4 for an example of the THETA= option with a lognormal Q-Q plot.

WEIBULL(C=*value-list*|EST < *Weibull-options* >)

WEIB(C=*value-list* < *Weibull-options* >)

creates a three-parameter Weibull Q-Q plot for each value of the shape parameter c given by the mandatory C= option or its alias, the SHAPE= option. For example,

```
proc capability data=measures;
  qqplot width / weibull(c=1.8 to 2.4 by 0.2);
run;
```

To create the plot, the observations are ordered from smallest to largest, and the i th ordered observation is plotted against the quantile $\left(-\log\left(1 - \frac{i-0.375}{n+0.25}\right)\right)^{\frac{1}{c}}$, where n is the number of nonmissing observations, and c is the Weibull distribution shape parameter.

The pattern on the plot for $C=c$ tends to be linear with intercept θ and slope σ if the data are Weibull distributed with the specific density function

$$p(x) = \begin{cases} \frac{c}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

where θ is the threshold parameter, σ is the scale parameter ($\sigma > 0$), and c is the shape parameter ($c > 0$).

To obtain a graphical estimate of c , specify a list of values for the C= option, and select the value that most nearly linearizes the point pattern. For an illustration, see Example 5.23. To assess the point pattern, you can add a diagonal distribution reference line with intercept θ_0 and slope σ_0 with the *Weibull-options* THETA= θ_0 and SIGMA= σ_0 . Alternatively,

you can add a line corresponding to estimated values of θ_0 and σ_0 with the *Weibull-options* THETA=EST and SIGMA=EST. Specify these options in parentheses, as in the following example:

```
proc capability data=measures;
  qqplot width / weibull(c=2 theta=3 sigma=4);
run;
```

Agreement between the reference line and the point pattern indicates that the Weibull distribution with parameters c , θ_0 , and σ_0 is a good fit. You can specify the SCALE= option as an alias for the SIGMA= option and the THRESHOLD= option as an alias for the THETA= option.

WEIBULL2<(Weibull2-options)>

W2<(Weibull2-options)>

creates a two-parameter Weibull Q-Q plot. You should use the WEIBULL2 option when your data have a *known* lower threshold θ_0 . You can specify the threshold value θ_0 with the THETA= option or its alias, the THRESHOLD= option. If you are uncertain of the lower threshold value, you can estimate θ_0 graphically by specifying a list of values for the THETA= option. Select the value that most linearizes the point pattern. The default is $\theta_0 = 0$.

To create the plot, the observations are ordered from smallest to largest, and the log of the shifted i th ordered observation $x_{(i)}$, $\log(x_{(i)} - \theta_0)$, is plotted against the quantile $\log\left(-\log\left(1 - \frac{i-0.375}{n+0.25}\right)\right)$, where n is the number of nonmissing observations. Unlike the three-parameter Weibull quantile, the preceding expression is free of distribution parameters. This is why the C= shape parameter option is not mandatory with the WEIBULL2 option.

The pattern on the plot for THETA= θ_0 tends to be linear with intercept $\log(\sigma)$ and slope $\frac{1}{c}$ if the data are Weibull distributed with the specific density function

$$p(x) = \begin{cases} \frac{c}{\sigma} \left(\frac{x-\theta_0}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta_0}{\sigma}\right)^c\right) & \text{for } x > \theta_0 \\ 0 & \text{for } x \leq \theta_0 \end{cases}$$

where θ_0 is a known lower threshold parameter, σ is a scale parameter ($\sigma > 0$), and c is a shape parameter ($c > 0$).

The advantage of a two-parameter Weibull plot over a three-parameter Weibull plot is that you can visually estimate the shape parameter c and the scale parameter σ from the slope and intercept of the point pattern; see [Example 5.23](#) for an illustration of this method. The disadvantage is that the two-parameter Weibull distribution applies only in situations where the threshold parameter is known. See “[Graphical Estimation](#)” on page 535 for more information.

To assess the point pattern, you can add a diagonal distribution reference line corresponding to the scale parameter σ_0 and shape parameter c_0 with the *Weibull2-options* SIGMA= σ_0 and C= c_0 . Alternatively, you can add a distribution reference line corresponding to estimated values of σ_0 and c_0 with the *Weibull2-options* SIGMA=EST and C=EST. This line has intercept $\log(\sigma_0)$ and slope $\frac{1}{c_0}$. Agreement between the line and the point pattern indicates that the Weibull distribution with parameters c_0 , θ_0 , and σ_0 is a good fit. You can specify the SCALE= option as an alias for the SIGMA= option and the SHAPE= option as an alias for the C= option.

You can also display the reference line by specifying $\text{SIGMA}=\sigma_0$, and you can specify the slope with the **SLOPE=** option. For example, the following QQPLOT statements produce identical plots:

```
proc capability data=measures;
  qqplot width / weibull2(theta=3 sigma=4 c=2);
  qqplot width / weibull2(theta=3 sigma=4 slope=0.5);
run;
```

WGRID=*n*

Traditional Graphics

specifies the width of the grid lines associated with the quantile axis, requested with the **GRID** option. If you use the **WGRID=** option, you do not need to specify the **GRID** option.

ZETA=*value*|EST

specifies a value for the scale parameter ζ for lognormal Q-Q plots requested with the **LOG-NORMAL** option. Specify $\text{THETA}=\theta_0$ and $\text{ZETA}=\zeta_0$ to request a distribution reference line with intercept θ_0 and slope $\exp(\zeta_0)$.

Details: QQPLOT Statement

This section provides details on the following topics:

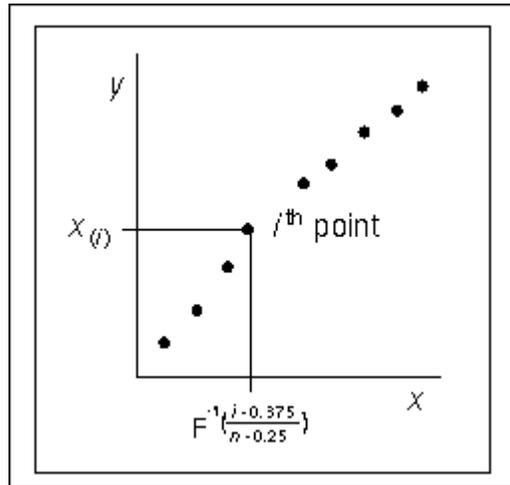

- construction of Q-Q plots
- interpretation of Q-Q plots
- distributions supported by the QQPLOT statement
- graphical estimation of shape parameters, location and scale parameters, theoretical percentiles, and capability indices
- SYMBOL statement options

Construction of Quantile-Quantile and Probability Plots

Figure 5.43 illustrates how a Q-Q plot is constructed. First, the n nonmissing values of the variable are ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

Then the i th ordered value $x_{(i)}$ is represented on the plot by a point whose y -coordinate is $x_{(i)}$ and whose x -coordinate is $F^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $F(\cdot)$ is the theoretical distribution with zero location parameter and unit scale parameter.

Figure 5.43 Construction of a Q-Q Plot

You can modify the adjustment constants -0.375 and 0.25 with the `RANKADJ=` and `NADJ=` options. This default combination is recommended by Blom (1958). For additional information, refer to Chambers et al. (1983). Since $x_{(i)}$ is a quantile of the empirical cumulative distribution function (ecdf), a Q-Q plot compares quantiles of the ecdf with quantiles of a theoretical distribution. Probability plots (see “`PROBPLOT Statement: CAPABILITY Procedure`” on page 477) are constructed the same way, except that the x -axis is scaled nonlinearly in percentiles.

Interpretation of Quantile-Quantile and Probability Plots

The following properties of Q-Q plots and probability plots make them useful diagnostics of how well a specified theoretical distribution fits a set of measurements:

- If the quantiles of the theoretical and data distributions agree, the plotted points fall on or near the line $y = x$.
- If the theoretical and data distributions differ only in their location or scale, the points on the plot fall on or near the line $y = ax + b$. The slope a and intercept b are visual estimates of the scale and location parameters of the theoretical distribution.

Q-Q plots are more convenient than probability plots for graphical estimation of the location and scale parameters since the x -axis of a Q-Q plot is scaled linearly. On the other hand, probability plots are more convenient for estimating percentiles or probabilities.

There are many reasons why the point pattern in a Q-Q plot may not be linear. Chambers et al. (1983) and Fowlkes (1987) discuss the interpretations of commonly encountered departures from linearity, and these are summarized in the following table.

Table 5.70 Quantile-Quantile Plot Diagnostics

Description of Point Pattern	Possible Interpretation
All but a few points fall on a line	Outliers in the data
Left end of pattern is below the line; right end of pattern is above the line	Long tails at both ends of the data distribution
Left end of pattern is above the line; right end of pattern is below the line	Short tails at both ends of the data distribution
Curved pattern with slope increasing from left to right	Data distribution is skewed to the right
Curved pattern with slope decreasing from left to right	Data distribution is skewed to the left
Staircase pattern (plateaus and gaps)	Data have been rounded or are discrete

In some applications, a nonlinear pattern may be more revealing than a linear pattern. However, Chambers et al. (1983) note that departures from linearity can also be due to chance variation.

Summary of Theoretical Distributions

You can use the QQPLOT statement to request Q-Q plots based on the theoretical distributions summarized in Table 5.71.

Table 5.71 QQPLOT Statement Distribution Options

Distribution	Density Function $p(x)$	Range	Parameters		
			Location	Scale	Shape
Beta	$\frac{(x-\theta)^{\alpha-1}(\theta+\sigma-x)^{\beta-1}}{B(\alpha,\beta)\sigma^{\alpha+\beta-1}}$	$\theta < x < \theta + \sigma$	θ	σ	α, β
Exponential	$\frac{1}{\sigma} \exp\left(-\frac{x-\theta}{\sigma}\right)$	$x \geq \theta$	θ	σ	
Gamma	$\frac{1}{\sigma\Gamma(\alpha)} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1} \exp\left(-\frac{x-\theta}{\sigma}\right)$	$x > \theta$	θ	σ	α
Gumbel	$\frac{e^{-(x-\mu)/\sigma}}{\sigma} \exp\left(-e^{-(x-\mu)/\sigma}\right)$	all x	μ	σ	
Lognormal (3-parameter)	$\frac{1}{\sigma\sqrt{2\pi}(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\zeta)^2}{2\sigma^2}\right)$	$x > \theta$	θ	ζ	σ
Normal	$\frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$	all x	μ	σ	
Generalized Pareto	$\alpha \neq 0 \quad \frac{1}{\sigma} (1 - \alpha(x - \theta)/\sigma)^{1/\alpha-1}$ $\alpha = 0 \quad \frac{1}{\sigma} \exp(-(x - \theta)/\sigma)$	$x > \theta$	θ	σ	α

Table 5.71 (continued)

Distribution	Density Function $p(x)$	Range	Parameters		
			Location	Scale	Shape
Power Function	$\frac{\alpha}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{\alpha-1}$	$x > \theta$	θ	σ	α
Rayleigh	$\frac{x-\theta}{\sigma^2} \exp(-(x-\theta)^2/(2\sigma^2))$	$x \geq \theta$	θ	σ	
Weibull (3-parameter)	$\frac{c}{\sigma} \left(\frac{x-\theta}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta}{\sigma}\right)^c\right)$	$x > \theta$	θ	σ	c
Weibull (2-parameter)	$\frac{c}{\sigma} \left(\frac{x-\theta_0}{\sigma}\right)^{c-1} \exp\left(-\left(\frac{x-\theta_0}{\sigma}\right)^c\right)$	$x > \theta_0$ (known)	θ_0	σ	c

You can request these distributions with the **BETA**, **EXPONENTIAL**, **GAMMA**, **LOGNORMAL**, **NORMAL**, **WEIBULL**, and **WEIBULL2** options, respectively. If you do not specify a distribution option, a normal Q-Q plot is created.

Graphical Estimation

You can use Q-Q plots to estimate shape, location, and scale parameters and to estimate percentiles. If you are working with a normal Q-Q plot, you can also estimate certain capability indices.

Shape Parameters

Some distribution options in the QQPLOT statement require that you specify one or two shape parameters in parentheses after the distribution keyword. These are summarized in [Table 5.72](#).

You can visually estimate a shape parameter by specifying a list of values for the shape parameter option. A separate plot is displayed for each value, and you can then select the value that linearizes the point pattern. Alternatively, you can request that the plot be created using an estimated shape parameter. See the entries for the distribution options in the section “[Dictionary of Options](#)” on page 518. for details on specification of shape parameters. [Example 5.22](#) and [Example 5.23](#) illustrate shape parameter estimation with lognormal and Weibull Q-Q plots.

Note that for Q-Q plots requested with the **WEIBULL2** option, you can estimate the shape parameter c from a linear pattern using the fact that the slope of the pattern is $\frac{1}{c}$. For an illustration, see [Example 5.23](#).

Table 5.72 Shape Parameter Options for the QQPLOT Statement

Distribution Keyword	Mandatory Shape Parameter Option	Range
BETA	ALPHA= α , BETA= β	$\alpha > 0, \beta > 0$
EXPONENTIAL	None	
GAMMA	ALPHA= α	$\alpha > 0$
GUMBEL	None	
LOGNORMAL	SIGMA= σ	$\sigma > 0$
NORMAL	None	
PARETO	ALPHA= α	$\alpha > 0$
POWER	ALPHA= α	$\alpha > 0$
RAYLEIGH	None	
WEIBULL	C= c	$a > 0$
WEIBULL2	None	

Location and Scale Parameters

When the point pattern on a Q-Q plot is linear, its intercept and slope provide estimates of the location and scale parameters. (An exception to this rule is the two-parameter Weibull distribution, for which the intercept and slope are related to the scale and shape parameters.) Table 5.73 shows how the intercept and slope are related to the parameters for each distribution supported by the QQPLOT statement.

Table 5.73 Intercept and Slope of Linear Q-Q Plots

Distribution	Parameters			Linear Pattern	
	Location	Scale	Shape	Intercept	Slope
Beta	θ	σ	α, β	θ	σ
Exponential	θ	σ		θ	σ
Gamma	θ	σ	α	θ	σ
Gumbel	μ	σ		μ	σ
Lognormal	θ	ζ	σ	θ	$\exp(\zeta)$
Normal	μ	σ		μ	σ
Generalized Pareto	θ	σ	α	θ	σ
Power Function	θ	σ	α	θ	σ
Rayleigh	θ	σ		θ	σ
Weibull (3-parameter)	θ	σ	c	θ	σ
Weibull (2-parameter)	θ_0 (known)	σ	c	$\log(\sigma)$	$\frac{1}{c}$

You can enhance a Q-Q plot with a diagonal *distribution reference line* by specifying the parameters that determine the slope and intercept of the line; alternatively, you can request estimates for these parameters. This line is an aid to checking the linearity of the point pattern, and it facilitates parameter estimation. For instance, specifying MU=3 and SIGMA=2 with the NORMAL option requests a line with intercept 3 and slope 2. Specifying SIGMA=1 and C=2 with the WEIBULL2 option requests a line with intercept $\log(1) = 0$ and slope $\frac{1}{2}$.

With the **LOGNORMAL** and **WEIBULL2** options, you can specify the slope directly with the **SLOPE=** option. That is, for the **LOGNORMAL** option, specifying **THETA**= θ_0 and **SLOPE**= $\exp(\zeta_0)$ gives the same reference line as specifying **THETA**= θ_0 and **ZETA**= ζ_0 . For the **WEIBULL2** option, specifying **SIGMA**= σ_0 and **SLOPE**= $\frac{1}{c_0}$ gives the same reference line as specifying **SIGMA**= σ_0 and **C**= c_0 .

For an example of parameter estimation using a normal Q-Q plot, see “[Adding a Distribution Reference Line](#)” on page 511. [Example 5.22](#) illustrates parameter estimation using a lognormal plot, and [Example 5.23](#) illustrates estimation using two-parameter and three-parameter Weibull plots.

Theoretical Percentiles

There are two ways to estimate percentiles from a Q-Q plot:

- Specify the **PCTLAXIS** option, which adds a percentile axis opposite the theoretical quantile axis. The scale for the percentile axis ranges between 0 and 100 with tick marks at percentile values such as 1, 5, 10, 25, 50, 75, 90, 95, and 99. See [Figure 5.41](#) for an example.
- Specify the **PCTLSCALE** option, which relabels the horizontal axis tick marks with their percentile equivalents but does not alter their spacing. For example, on a normal Q-Q plot, the tick mark labeled “0” is relabeled as “50” since the 50th percentile corresponds to the zero quantile. See [Figure 5.42](#) for an example.

You can also estimate percentiles using probability plots created with the **PROBPLOT** statement. See [Output 5.20.1](#) for an example.

Capability Indices

When the point pattern on a normal Q-Q plot is linear, you can estimate the capability indices *CPU*, *CPL*, and *C_{pk}* from the plot, as explained by Rodriguez (1992). This method exploits the fact that the horizontal axis of a Q-Q plot indicates the distance in standard deviation units (multiple of σ) between a measurement or specification limit and the process average.

In particular, one-third the standardized distance between an upper specification limit and the mean is the one-sided capability index *CPU*.

$$CPU = \frac{USL - \mu}{3\sigma}$$

Likewise, one-third the standardized distance between a lower specification limit and the mean is the one-sided capability index *CPL*.

$$CPL = \frac{\mu - LSL}{3\sigma}$$

Consequently, if you *rescale* the quantile axis of a normal Q-Q plot by a factor of three, you can read *CPU* and *CPL* from the horizontal coordinates of the points at which the upper and lower specification lines intersect the point pattern. Since *C_{pk}* is defined as the minimum of *CPU* and *CPL*, this method also provides a graphical estimate of *C_{pk}*. For an illustration, see [Example 5.24](#).

SYMBOL Statement Options

In earlier releases of SAS/QC software, graphical features of lower and upper specification lines and diagonal distribution reference lines were controlled with options in the SYMBOL2, SYMBOL3, and SYMBOL4 statements, respectively. These options are still supported, although they have been superseded by options in the QQPLOT and SPEC statements. Table 5.74 summarizes the two sets of options. **NOTE:** These statements have no effect on ODS Graphics output.

Table 5.74 SYMBOL Statement Options

Feature	Statement and Options	Alternative Statement and Options
Symbol markers	SYMBOL1 Statement	
character	VALUE= <i>special-symbol</i>

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. QQPLOT options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the QQPLOT statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 5.75](#).

Table 5.75 ODS Graphics Produced by the QQPLOT Statement

ODS Graph Name	Plot Description
QQPlot	Q-Q plot

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Examples: QQPLOT Statement

This section provides advanced examples of the QQPLOT statement.

Example 5.21: Interpreting a Normal Q-Q Plot of Nonnormal Data

The following statements produce the normal Q-Q plot in [Output 5.21.1](#):

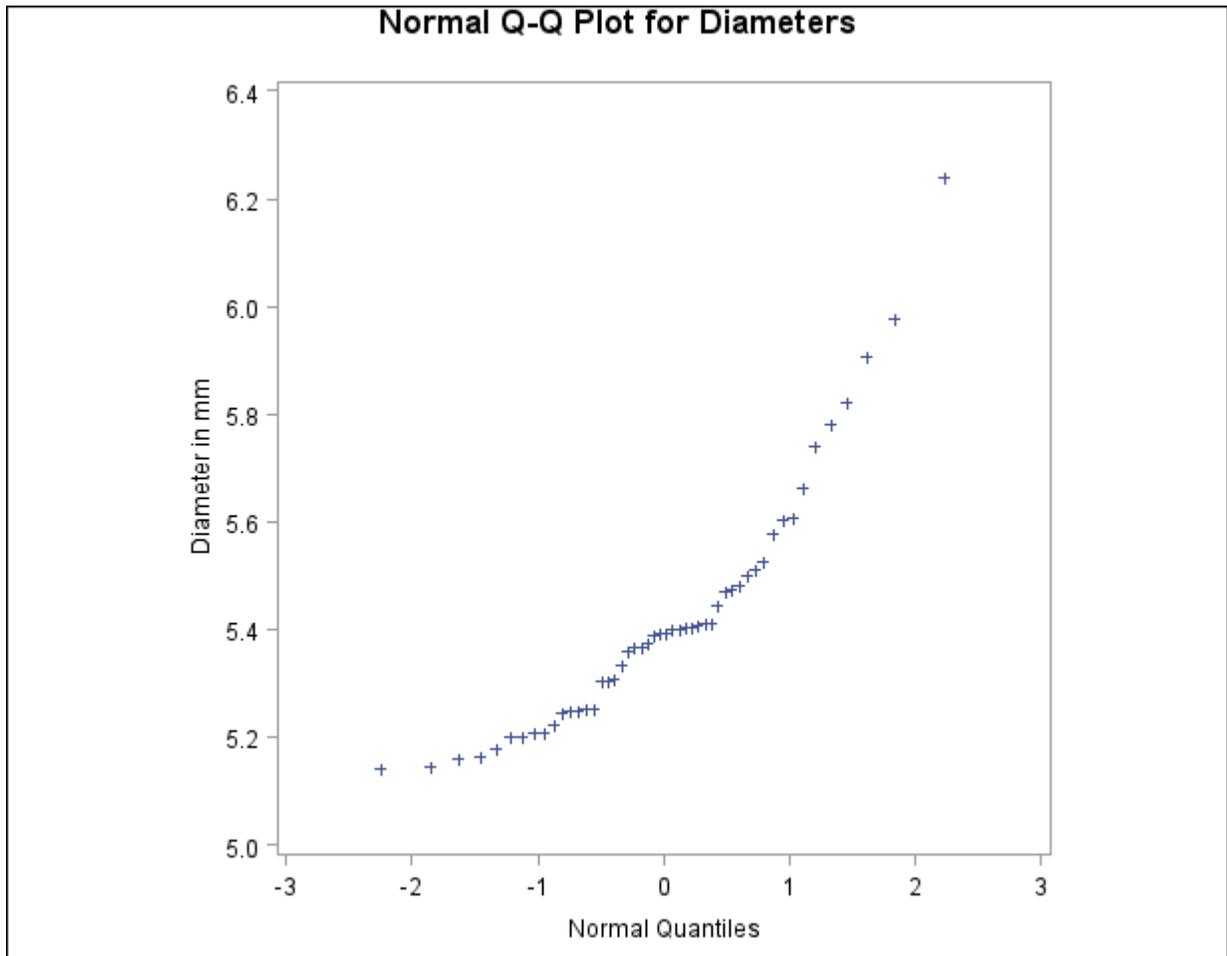

See CAPQQ2 in the SAS/QC Sample Library

```

data Measures;
  input Diameter @@;

proc capability data=Measures noprint;
  qqplot Diameter / normal square;
run;

```

Output 5.21.1 Normal Quantile-Quantile Plot of Nonnormal Data

The nonlinearity of the points in [Output 5.21.1](#) indicates a departure from normality. Since the point pattern is curved with slope increasing from left to right, a theoretical distribution that is skewed to the right, such as a lognormal distribution, should provide a better fit than the normal distribution. The mild curvature suggests that you should examine the data with a series of lognormal Q-Q plots for small values of the shape parameter, as illustrated in the next example.

Example 5.22: Estimating Parameters from Lognormal Plots

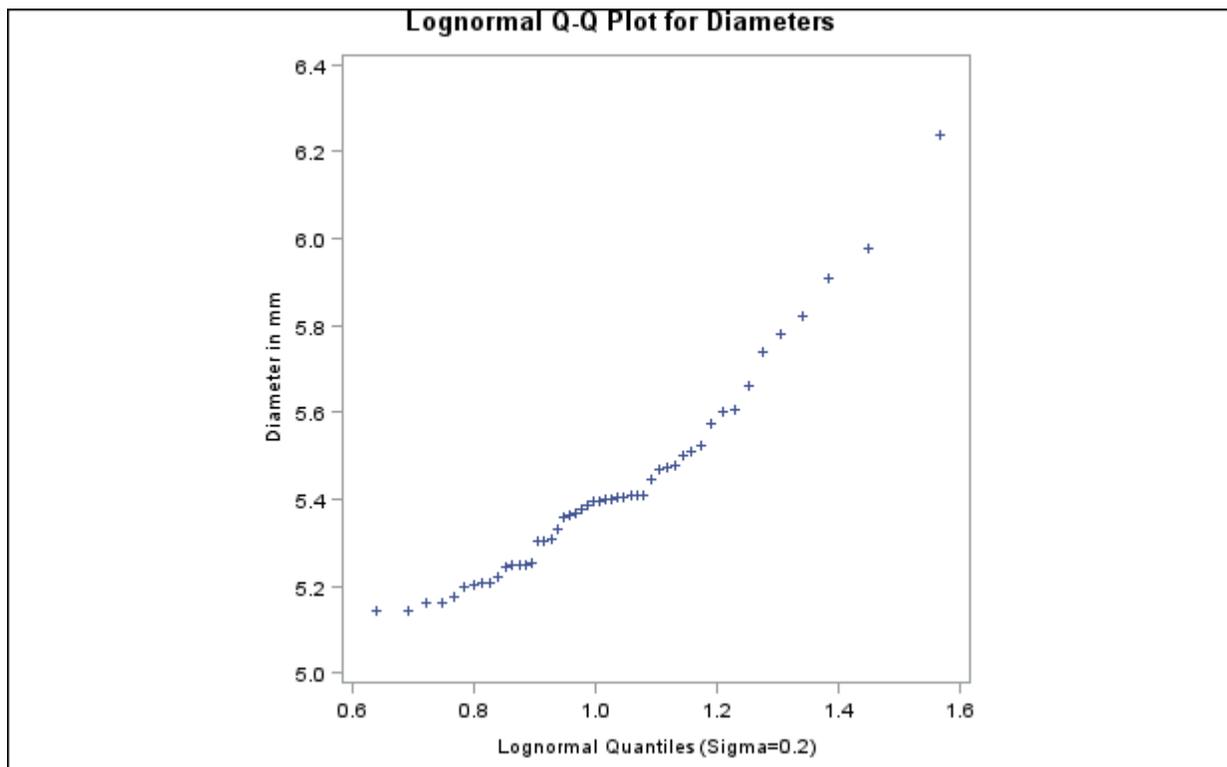

This example, which is a continuation of [Example 5.21](#), demonstrates techniques for estimating the shape parameter, location and scale parameters, and theoretical percentiles for a lognormal distribution.

Three-Parameter Lognormal Plots

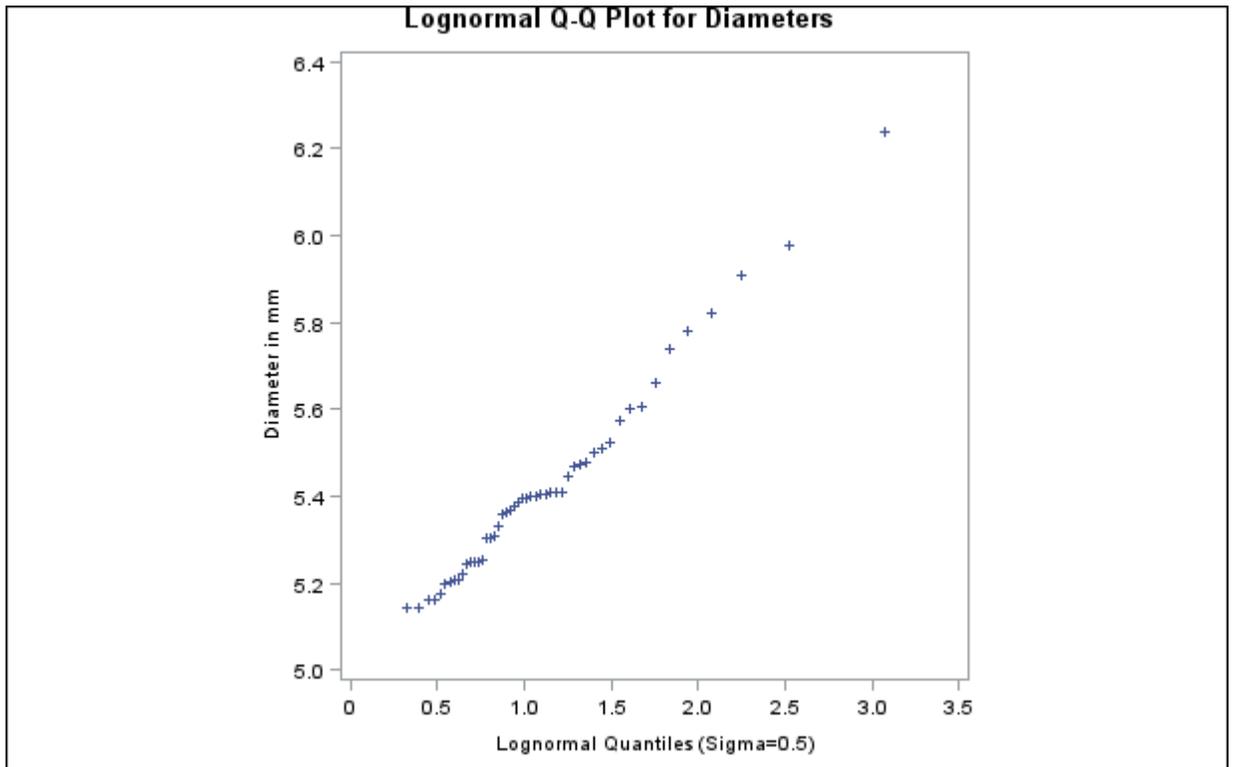

The three-parameter lognormal distribution depends on a threshold parameter θ , a scale parameter ζ , and a shape parameter σ . You can estimate σ from a series of lognormal Q-Q plots with different values of σ . The estimate is the value of σ that linearizes the point pattern. You can then estimate the threshold and scale parameters from the intercept and slope of the point pattern. The following statements create the series of plots in [Output 5.22.1](#) through [Output 5.22.3](#) for σ values of 0.2, 0.5, and 0.8: *See CAPQQ2 in the SAS/QC Sample Library*

```
ods graphics off;
symbol v=plus;
title 'Lognormal Q-Q Plot for Diameters';
proc capability data=Measures noprint;
  qqplot Diameter / lognormal(sigma=0.2 0.5 0.8)
    square;
run;
```

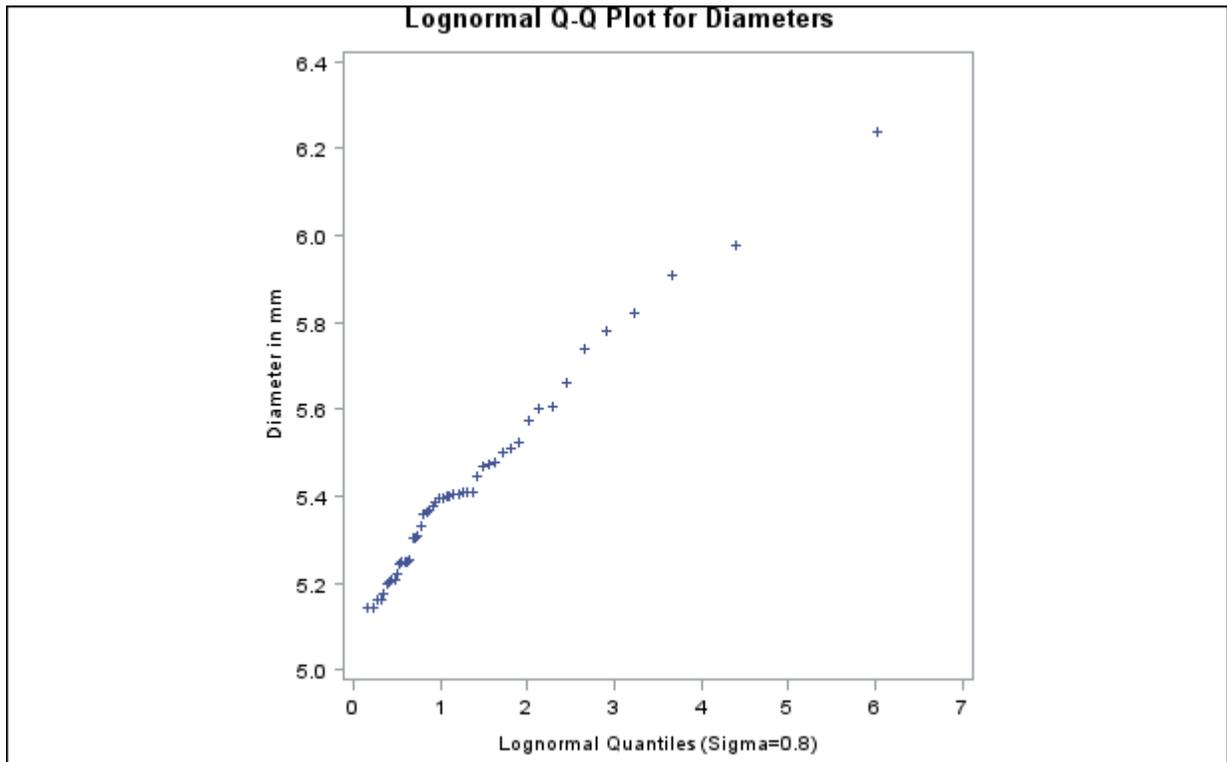

Output 5.22.1 Lognormal Quantile-Quantile Plot ($\sigma = 0.2$)

Output 5.22.2 Lognormal Quantile-Quantile Plot ($\sigma = 0.5$)

Output 5.22.3 Lognormal Quantile-Quantile Plot ($\sigma = 0.8$)

NOTE: You must specify a value for the shape parameter σ for a lognormal Q-Q plot with the **SIGMA=** option or its alias, the **SHAPE=** option.

The plot in [Output 5.22.2](#) displays the most linear point pattern, indicating that the lognormal distribution with $\sigma = 0.5$ provides a reasonable fit for the data distribution.

Data with this particular lognormal distribution have the density function

$$p(x) = \begin{cases} \frac{\sqrt{2}}{\sqrt{\pi}(x-\theta)} \exp(-2(\log(x-\theta) - \zeta)^2) & \text{for } x > \theta \\ 0 & \text{for } x \leq \theta \end{cases}$$

The points in the plot fall on or near the line with intercept θ and slope $\exp(\zeta)$. Based on [Output 5.22.2](#), $\theta \approx 5$ and $\exp(\zeta) \approx \frac{1.2}{3} = 0.4$, giving $\zeta \approx \log(0.4) \approx -0.92$.

Estimating Percentiles

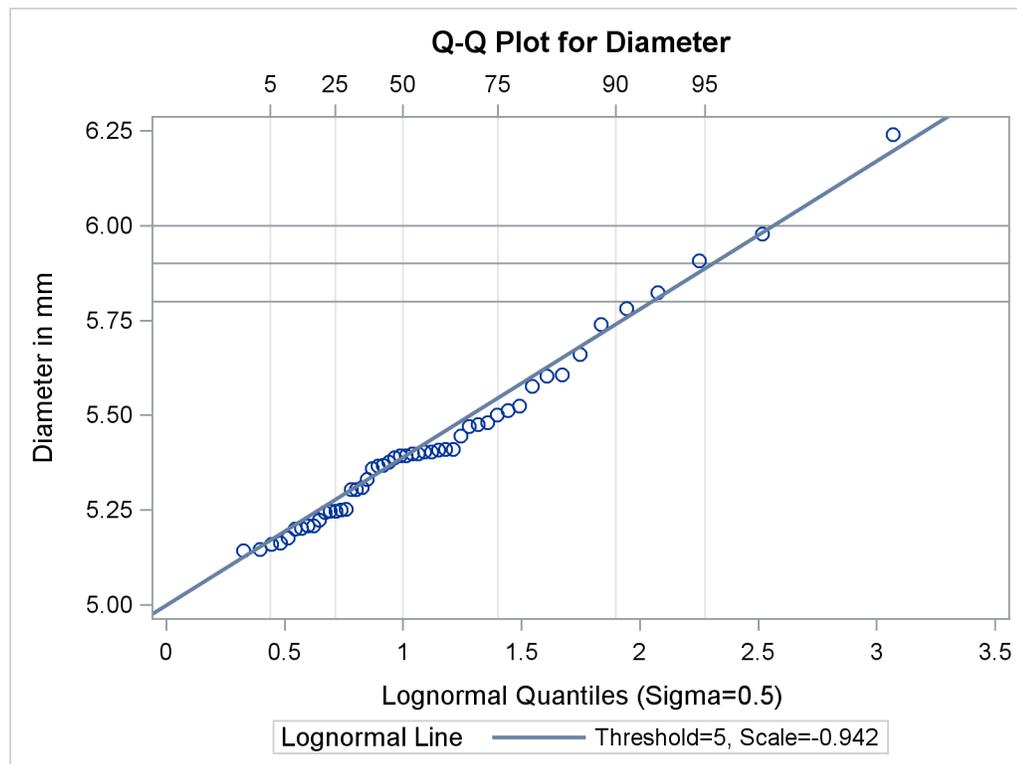

You can use a Q-Q plot to estimate percentiles such as the 95th percentile of the lognormal distribution.¹⁰ *See CAPQQ2 in the SAS/QC Sample Library*

The point pattern in [Output 5.22.2](#) has a slope of approximately 0.39 and an intercept of 5. The following statements reproduce this plot, adding a lognormal reference line with this slope and intercept.

```
ods graphics on;
title 'Lognormal Q-Q Plot for Diameters';
proc capability data=Measures noprint;
  qqplot Diameter / lognormal(sigma=0.5 theta=5 slope=0.39)
    pctlaxis(grid)
    vref = 5.8 5.9 6.0;
run;
```

The ODS GRAPHICS ON statement specified before the PROC CAPABILITY statement enables ODS Graphics, so the Q-Q plot is created using ODS Graphics instead of traditional graphics. The result is shown in [Output 5.22.4](#).

¹⁰You can also use a probability plot for this purpose. See [Output 5.20.1](#).

Output 5.22.4 Lognormal Q-Q Plot Identifying Percentiles

The **PCTLAXIS** option labels the major percentiles, and the **GRID** option draws percentile axis reference lines. The 95th percentile is 5.9, since the intersection of the distribution reference line and the 95th reference line occurs at this value on the vertical axis.

Alternatively, you can compute this percentile from the estimated lognormal parameters. The 100α th percentile of the lognormal distribution is

$$P_{\alpha} = \exp(\sigma \Phi^{-1}(\alpha) + \zeta) + \theta$$

where $\Phi^{-1}(\cdot)$ is the inverse cumulative standard normal distribution. Consequently,

$$P_{0.95} \approx \exp\left(\frac{1}{2}\Phi^{-1}(0.95) + \log(0.39)\right) + 5 \approx \exp\left(\frac{1}{2} \times 1.645 - 0.94\right) + 5 \approx 5.89$$

Two-Parameter Lognormal Plots

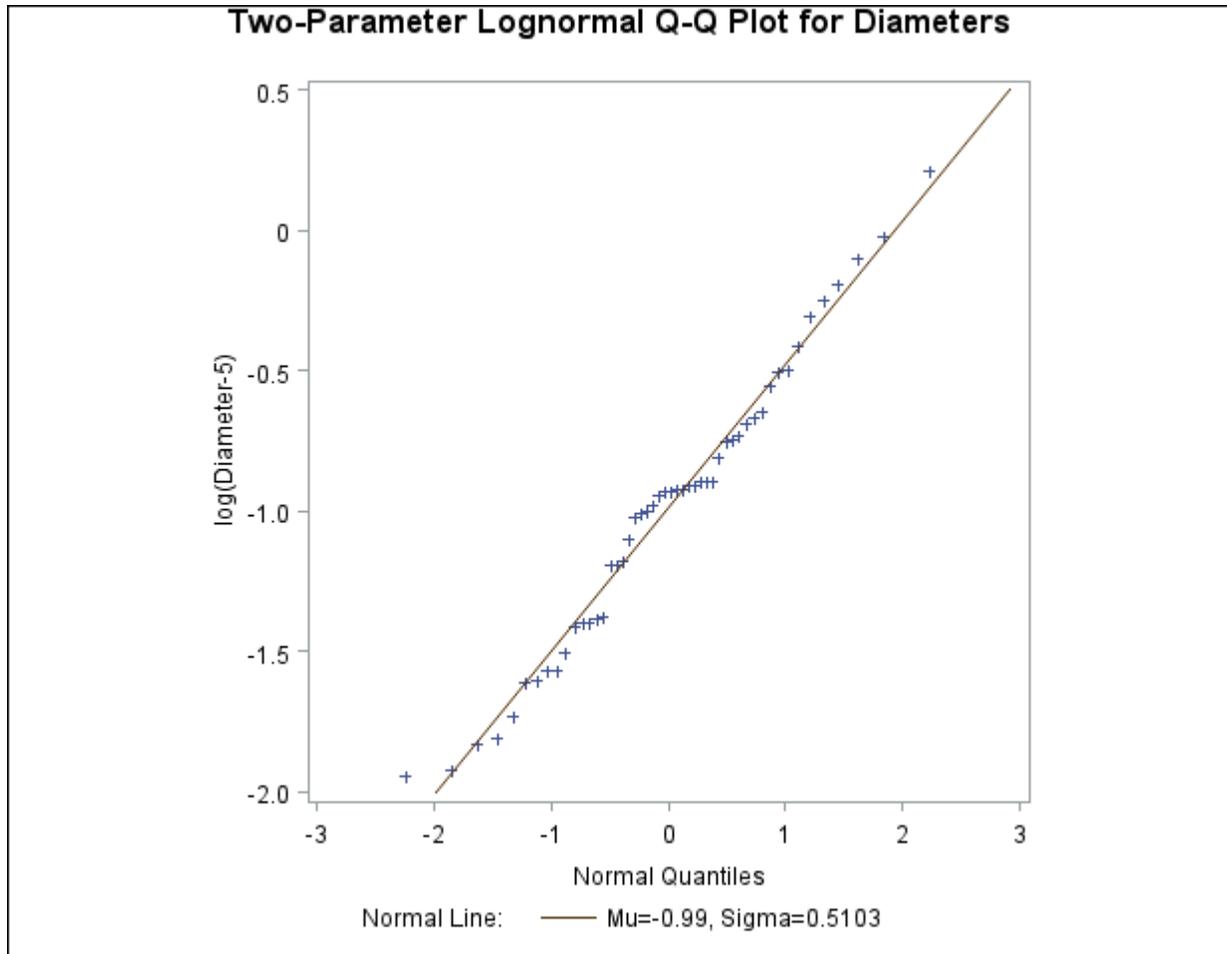

If a known threshold parameter is available, you can construct a two-parameter lognormal Q-Q plot by subtracting the threshold from the data and requesting a normal Q-Q plot. The following statements create this plot for Diameter, assuming a known threshold of five:

```
data Measures;
  set Measures;
  Logdiam=log(Diameter-5);
  label Logdiam='log(Diameter-5)';
run;
```

See CAPQQ2 in the SAS/QC Sample Library

```
ods graphics off;
symbol v=plus;
title 'Two-Parameter Lognormal Q-Q Plot for Diameters';
proc capability data=Measures noprint;
  qqplot Logdiam / normal(mu=est sigma=est)
    square;
run;
```

Output 5.22.5 Two-Parameter Lognormal Q-Q Plot for Diameters

Because the point pattern in [Output 5.22.5](#) is linear, you can estimate the lognormal parameters ζ and σ as the normal plot estimates of μ and σ , which are -0.99 and 0.51 . These values correspond to the previous estimates of -0.92 for ζ and 0.5 for σ .

Example 5.23: Comparing Weibull Q-Q Plots

This example compares the use of three-parameter and two-parameter Weibull Q-Q plots for the failure times in months for 48 integrated circuits. The times are assumed to follow a Weibull distribution.

```

data Failures;
  input Time @@;
  label Time='Time in Months';
  datalines;
29.42 32.14 30.58 27.50 26.08 29.06 25.10 31.34
29.14 33.96 30.64 27.32 29.86 26.28 29.68 33.76
29.32 30.82 27.26 27.92 30.92 24.64 32.90 35.46
30.28 28.36 25.86 31.36 25.26 36.32 28.58 28.88
26.72 27.42 29.02 27.54 31.60 33.46 26.78 27.82
29.18 27.94 27.66 26.42 31.00 26.64 31.44 32.52
;

```

Three-Parameter Weibull Plots

See CAPQQ3 in the
SAS/QC Sample Library

If no assumption is made about the parameters of this distribution, you can use the **WEIBULL** option to request a three-parameter Weibull plot. As in the previous example, you can visually estimate the shape parameter c by requesting plots for different values of c and choosing the value of c that linearizes the point pattern. Alternatively, you can request a maximum likelihood estimate for c , as illustrated in the following statements produce Weibull plots for $c = 1, 2$ and 3 :

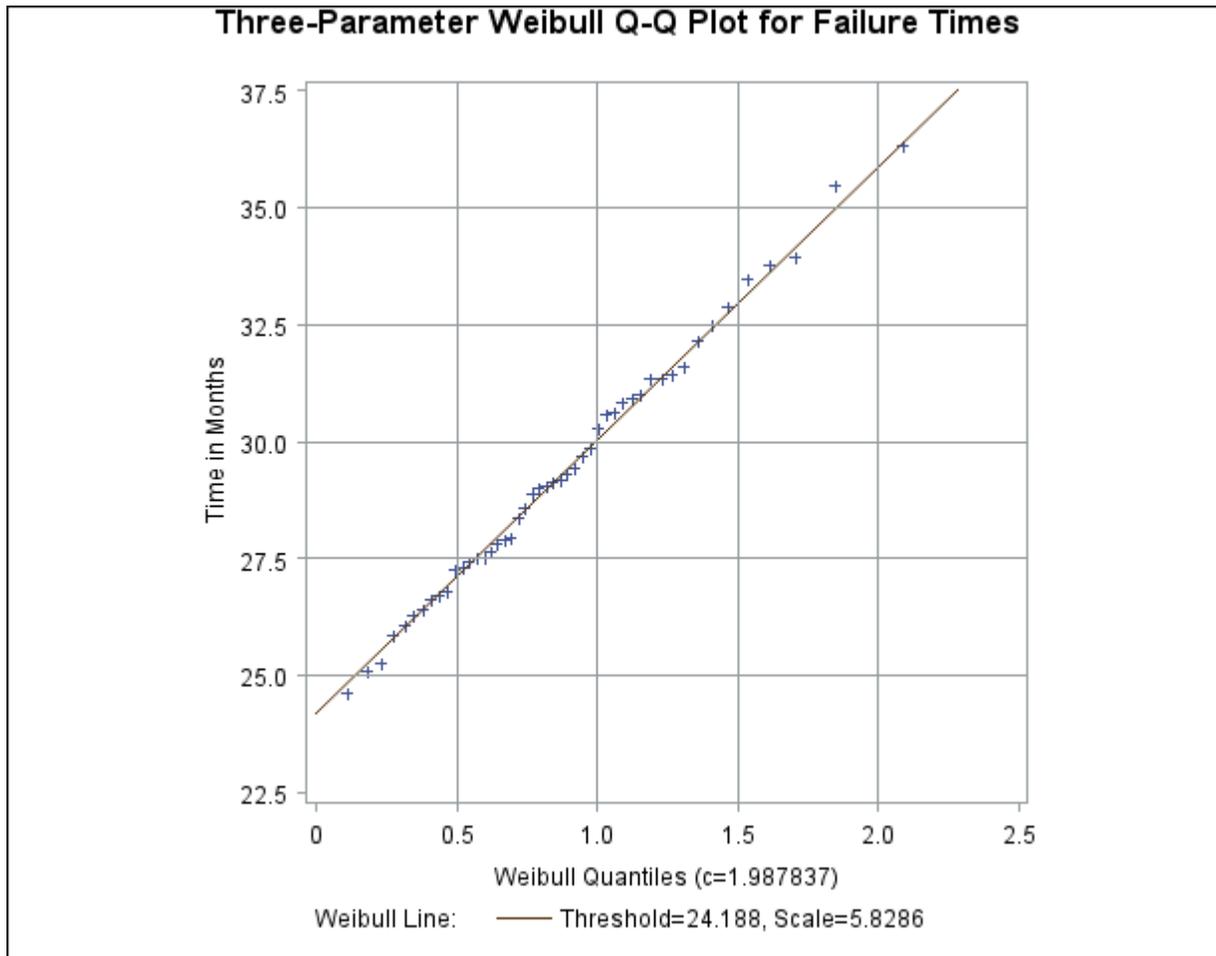

```

ods graphics off;
symbol v=plus;
title 'Three-Parameter Weibull Q-Q Plot for Failure Times';
proc capability data=Failures noprint;
  qqplot Time / weibull(c=est theta=est sigma=est)
    square
    href=0.5 1 1.5 2
    vref=25 27.5 30 32.5 35;
run;

```

NOTE: When using the **WEIBULL** option, you must either specify a list of values for the Weibull shape parameter c with the **C=** option, or you must specify **C=EST**.

Output 5.23.1 displays the plot for the estimated value $c = 1.99$. The reference line corresponds to the estimated values for the threshold and scale parameters of $(\hat{\theta}_0=24.19$ and $\hat{\sigma}_0=5.83$, respectively.

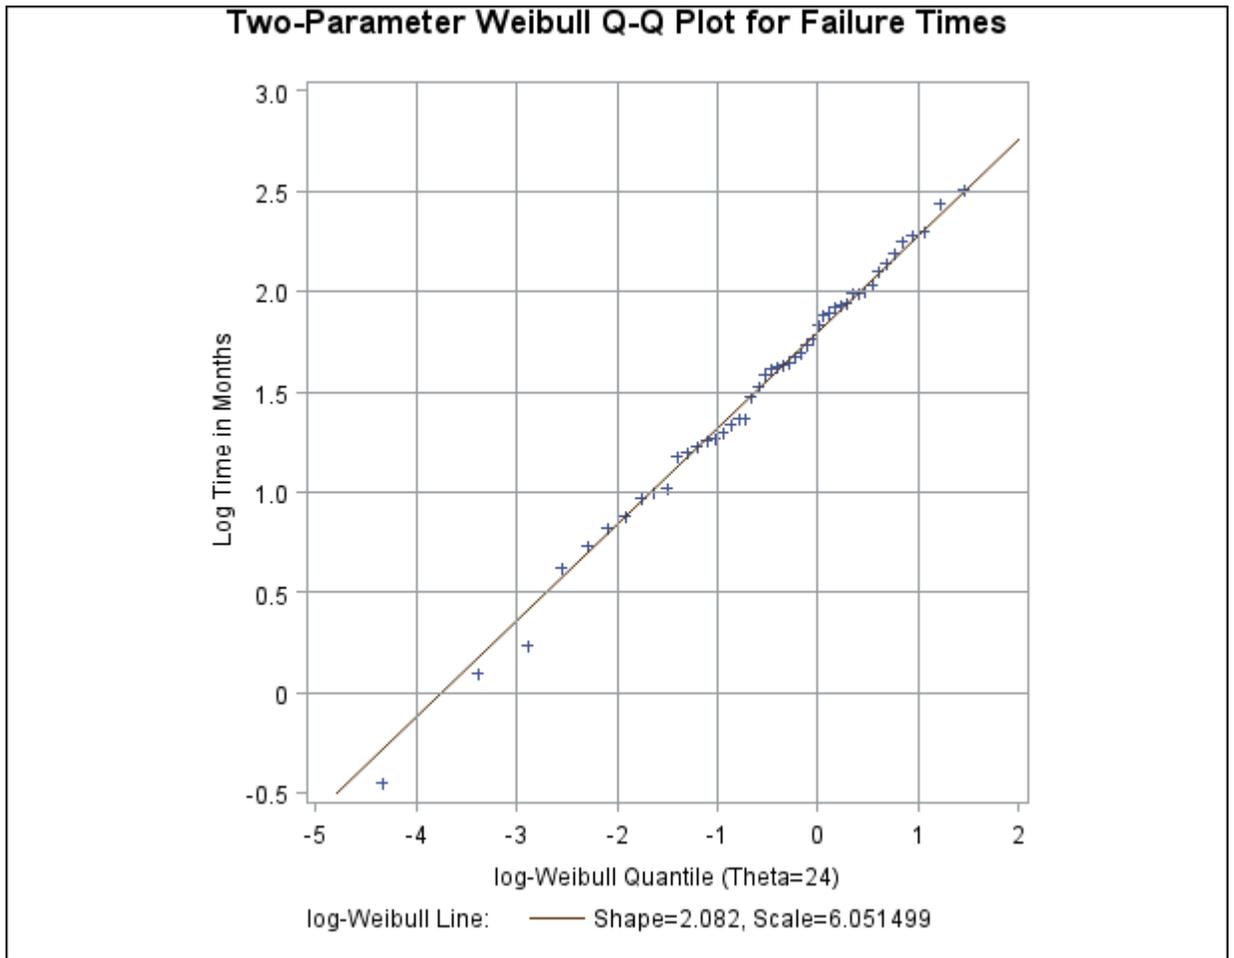

Output 5.23.1 Three-Parameter Weibull Q-Q Plot for $c = 2$ **Two-Parameter Weibull Plots**

Now, suppose it is known that the circuit lifetime is at least 24 months. The following statements use the threshold value $\theta_0 = 24$ to produce the two-parameter Weibull Q-Q plot shown in [Output 5.23.2](#): *See CAPQQ3 in the SAS/QC Sample Library*

```
symbol v=plus;
title 'Two-Parameter Weibull Q-Q Plot for Failure Times';
proc capability data=Failures noprint;
  qqplot Time / weibull2(theta=24 c=est sigma=est) square
    href= -4 to 1
    vref= 0 to 2.5 by 0.5;
run;
```

The reference line is based on maximum likelihood estimates $\hat{c}=2.08$ and $\hat{\sigma}=6.05$. These estimates agree with those of the previous example.

Output 5.23.2 Two-Parameter Weibull Q-Q Plot for $\theta_0 = 24$

Example 5.24: Estimating Cpk from a Normal Q-Q Plot

This example illustrates how you can use a normal Q-Q plot to estimate the capability index C_{pk} . See *CAPQOI* in the *SAS/QC Sample Library*. The data used here are the distance measurements provided in the section “Creating a Normal Quantile-Quantile Plot” on page 509.

The linearity of the point pattern in Figure 5.40 indicates that the measurements are normally distributed (recall that normality should be checked when process capability indices are reported). Furthermore, Figure 5.40 shows that the upper specification limit is about 1.7 standard deviation units above the mean, and the lower specification limit is about 1.8 standard deviation units below the mean. Since CPU is defined as

$$CPU = \frac{USL - \mu}{3\sigma}$$

and CPL is defined as

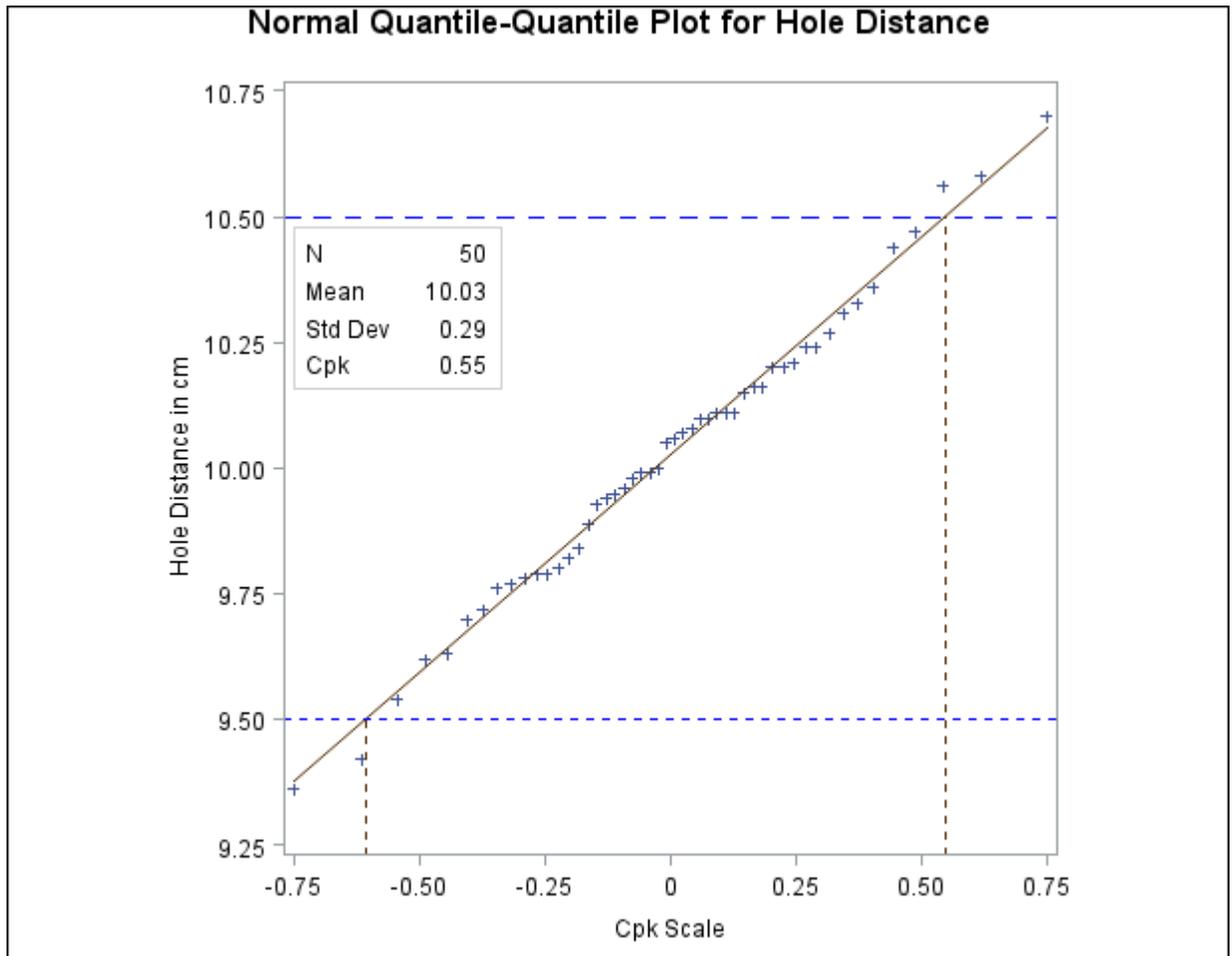

$$CPL = \frac{\mu - LSL}{3\sigma}$$

it follows that an estimate of CPU is $1.7/3 = 0.57$, and an estimate of CPL is $1.8/3 = 0.6$. Thus, except for a factor of three, you can estimate CPU and CPL from the points of intersection between the specification lines and the point pattern.

The following statements facilitate this type of estimation by creating a Q-Q plot, displayed in Output 5.24.1, in which the horizontal axis is rescaled by a factor of three:

```
ods graphics off;
symbol v=plus;
title "Normal Quantile-Quantile Plot for Hole Distance";
proc capability data=Sheets noprint;
  spec lsl=9.5  llsl=2  clsl=blue
       usl=10.5 lusl=20 cusl=blue;
  qqplot Distance / normal(mu=est sigma=est cpkscale cpkref)
           nolegend
           square;
  inset n mean (5.2) std="Std Dev" (4.2) cpk (4.2) /
       pos=(-0.75,10.48) data refpoint=t1;
run;
```

The **CPKSCALE** option rescales the horizontal axis, and the **CPKREF** option adds reference lines indicating the intersections of the distribution reference line and the specification limits.

Output 5.24.1 Normal Q-Q Plot With C_{pk} Scaling

Using this display, you can estimate C_{PU} and C_{PL} directly from the horizontal axis as 0.55 and 0.60, respectively (the negative sign for -0.60 is ignored). The minimum of these values (0.55) is an estimate of C_{pk} . Note that this estimate agrees with the numerically obtained estimate for C_{pk} that is displayed on the plot with the INSET statement.

See Rodriguez (1992) for further discussion concerning the use of Q-Q plots in process capability analysis.

Dictionary of Common Options: CAPABILITY Procedure

This chapter provides detailed descriptions of options that you can specify in the following chart statements:

- CDFPLOT
- COMPHISTOGRAM
- HISTOGRAM
- PPLOT
- PROBPLOT
- QQPLOT

The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics, ODS Graphics output, and line printer charts, respectively. As noted, some options are applicable only to comparative plots produced by the COMPHISTOGRAM statement or by another plot statement in conjunction with a CLASS statement.

ALPHADELTA=*value*

specifies the change in successive estimates of $\hat{\alpha}$ at which iteration terminates in the Newton-Raphson approximation of the maximum likelihood estimate of α for gamma distributions requested with the GAMMA option. Enclose the ALPHADELTA= option in parentheses after the GAMMA keyword. Iteration continues until the change in α is less than the value specified or the number of iterations exceeds the value of the MAXITER= option. The default value is 0.00001.

ALPHAINITIAL=*value*

specifies the initial value for $\hat{\alpha}$ in the Newton-Raphson approximation of the maximum likelihood estimate of α for gamma distributions requested with the GAMMA option. Enclose the ALPHAINITIAL= option in parentheses after the GAMMA keyword. The default value is Thom's approximation of the estimate of α . See Johnson, Kotz, and Balakrishnan (1995).

ANNOKEY

applies the annotation requested with the ANNOTATE= option only to the key cell of a comparative plot. By default, the procedure applies annotation to all of the cells. You can use the KEYLEVEL= option in the CLASS statement or the CLASSKEY= option in the COMPHISTOGRAM statement to specify the key cell. *Traditional Graphics*

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set that contains annotate variables, as described in *SAS/GRAPH: Reference*, for annotating traditional graphics. The ANNOTATE= data set you specify in the plot statement is used for all plots created by the statement. You can also specify an ANNOTATE= data set in the PROC CAPABILITY statement to enhance all plots created by the procedure (see “ANNOTATE= Data Sets” on page 230). *Traditional Graphics*

CAXIS=*color***CAXES=***color***CA=***color**Traditional Graphics*

specifies the color for the axes and tick marks. This option overrides any **COLOR=** specifications in an **AXIS** statement.

CDELTA=*value*

specifies the change in successive estimates of c at which iterations terminate in the Newton-Raphson approximation of the maximum likelihood estimate of c for Weibull distributions requested by the **WEIBULL** option. Enclose the **CDELTA=** option in parentheses after the **WEIBULL** keyword. Iteration continues until the change in c between consecutive steps is less than the *value* specified or until the number of iterations exceeds the value of the **MAXITER=** option. The default value is 0.00001.

CFRAME=*color**Traditional Graphics*

specifies the color for the area that is enclosed by the axes and frame.

CFRAMESIDE=*color**Traditional Graphics*

specifies the color to fill the frame area for the row labels that display along the left side of a comparative plot. This color also fills the frame area for the label of the corresponding **CLASS** variable, if you associate a label with the variable.

CFRAMETOP=*color**Traditional Graphics*

specifies the color to fill the frame area for the column labels that display across the top of a comparative plot. This color also fills the frame area for the label of the corresponding **CLASS** variable, if you associate a label with the variable.

CHREF=*color* | (*color-list*)**CH=***color* | (*color-list*)*Traditional Graphics*

specifies the colors for horizontal axis reference lines requested by the **HREF=** option. If you specify a single color, it is used for all **HREF=** lines. Otherwise, if there are fewer colors specified than reference lines requested, the remaining lines are displayed with the default reference line color. You can also specify the value *_default* in the color list to request the default color.

CINITIAL=*value*

specifies the initial value for \hat{c} in the Newton-Raphson approximation of the maximum likelihood estimate of c for Weibull distributions requested with the **WEIBULL** or **WEIBULL2** option. The default value is 1.8. See Johnson, Kotz, and Balakrishnan (1995).

COLOR=*color***COLOR=***color-list**Traditional Graphics*

specifies the color of the curve or reference line associated with a distribution or kernel density estimate. Enclose the **COLOR=** option in parentheses after a distribution option or the **KERNEL** option. In a **HISTOGRAM** statement, you can specify a list of colors in parentheses for multiple density curves.

CONTENTS='string'

specifies the table of contents grouping entry for output produced by the plot statement. You can specify CONTENTS='' to suppress the grouping entry.

CPROP=color | EMPTY**CPROP**

specifies the color for a horizontal bar whose length (relative to the width of the tile) indicates the proportion of the total frequency that is represented by the corresponding cell in a comparative plot. By default, no proportion bars are displayed. You can specify the keyword EMPTY to display empty bars. *Traditional Graphics*

For traditional graphics with the GSTYLE system option in effect, you can specify CPROP with no argument to produce proportion bars using an appropriate color from the ODS style. The CPROP option is not available with ODS Graphics.

CSTATREF=color | (color-list)

specifies the colors for reference lines requested by the STATREF= option. If you specify a single color, it is used for all STATREF= lines. Otherwise, if there are fewer colors specified than reference lines requested, the remaining lines are displayed with the default reference line color. You can also specify the value *_default* in the color list to request the default color. *Traditional Graphics*

CTEXT=color**CT=color**

specifies the color for tick mark values and axis labels. *Traditional Graphics*

CTEXTSIDE=color

specifies the color for the row labels that display along the left side of a comparative plot. If you do not specify the CTEXTSIDE= option, the color specified with the CTEXT= option is used. You can specify the CFRAMESIDE= option to change the background color for the row labels. *Traditional Graphics*

CTEXTTOP=color

specifies the color for the column labels that display along the left side of a comparative plot. If you do not specify the CTEXTTOP= option, the color specified with the CTEXT= option is used. You can use the CFRAMETOP= option to change the background color for the column labels. *Traditional Graphics*

CVREF=color | (color-list)**CV=color | (color-list)**

specifies the colors for lines requested with the VREF= option. If you specify a single color, it is used for all VREF= lines. Otherwise, if there are fewer colors specified than reference lines requested, the remaining lines are displayed with the default reference line color. You can also specify the value *_default* in the color list to request the default color. *Traditional Graphics*

DESCRIPTION='string'**DES='string'**

specifies a description, up to 256 characters long, for the GRSEG catalog entry for a traditional graphics chart. The default value is the analysis variable name. *Traditional Graphics*

FITINTERVAL=*value*

specifies the value of z for the method of percentiles when this method is used to fit a Johnson S_B or Johnson S_U distribution. The FITINTERVAL= option is specified in parentheses after the SB or SU option. The default of z is 0.524.

FITMETHOD=PERCENTILE | MLE | MOMENTS

specifies the method used to estimate the parameters of a Johnson S_B or Johnson S_U distribution. The FITMETHOD= option is specified in parentheses after the SB or SU option. By default, the method of percentiles is used.

FITTOLERANCE=*value*

specifies the tolerance value for the ratio criterion when the method of percentiles is used to fit a Johnson S_B or Johnson S_U distribution. The FITTOLERANCE= option is specified in parentheses after the SB or SU option. The default value is 0.01.

FONT=*font**Traditional Graphics*

specifies a font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= option takes precedence over the FTEXT= font specified in the GOPTIONS statement. For a list of software fonts, see *SAS/GRAPH: Reference*.

HAXIS=*value*

specifies the name of an AXIS statement describing the horizontal axis.

HEIGHT=*value**Traditional Graphics*

specifies the height, in percentage screen units, of text for axis labels, tick mark labels, and legends. This option takes precedence over the HTEXT= option in the GOPTIONS statement.

HMINOR=*n***HM=***n**Traditional Graphics*

specifies the number of minor tick marks between each major tick mark on the horizontal axis. Minor tick marks are not labeled. By default, HMINOR=0.

HREF=*values*

draws reference lines that are perpendicular to the horizontal axis at the values that you specify. Also see the CHREF= and LHREF= options.

HREFCHAR='*character*'*Line Printer*

specifies the character used to form the lines requested by the HREF= option for a line printer chart. The default is the vertical bar (|).

HREFLABELS='*label1*' ... '*labeln*'**HREFLABEL=**'*label1*' ... '*labeln*'**HREFLAB=**'*label1*' ... '*labeln*'

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can have up to 16 characters.

HREFLABPOS=*n**Traditional Graphics**ODS Graphics*

specifies the vertical position of HREFLABELS= labels, as described in the following table.

***n* Position**

- 1 along top of plot
 - 2 staggered from top to bottom of plot
 - 3 along bottom of plot
 - 4 staggered from bottom to top of plot
-

By default, HREFLABPOS=1. **NOTE:** HREFLABPOS=2 and HREFLABPOS=4 are not supported for ODS Graphics output.

INFONT=font

specifies a font to use for text inside the framed areas of the plot. The INFONT= option takes precedence over the FTEXT= option in the GOPTIONS statement. For a list of software fonts, see *SAS/GRAPH: Reference*. *Traditional Graphics*

INHEIGHT=value

specifies the height, in percentage screen units, of text used inside the framed areas of the plot. If you do not specify the INHEIGHT= option, the height specified with the HEIGHT= option is used. *Traditional Graphics*

INTERTILE=value

specifies the distance in horizontal percentage screen units between the framed areas, called *tiles*, of a comparative plot. By default, INTERTILE=0.75 percentage screen units. You can specify INTERTILE=0 to create contiguous tiles. *Traditional Graphics*

L=linetype**L=linetype-list**

specifies the line type of the curve or reference line associated with a distribution or kernel density estimate. Enclose the L= option in parentheses after the distribution option or the KERNEL option. In a HISTOGRAM statement, you can specify a list of line types in parentheses for multiple density curves. *Traditional Graphics*

LHREF=linetype | linetype-list**LH=linetype | linetype-list**

specifies the line types for the reference lines that you request with the HREF= option. If you specify a single line type, it is used for all HREF= lines. Otherwise, if there are fewer line types specified than reference lines requested, the remaining lines are displayed with the default reference line type. You can also specify line type 0 to request the default color. *Traditional Graphics*

LSTATREF=linetype | linetype-list

specifies the line types for the reference lines that you request with the STATREF= option. If you specify a single line type, it is used for all STATREF= lines. Otherwise, if there are fewer line types specified than reference lines requested, the remaining lines are displayed with the default reference line type. You can also specify line type 0 to request the default color. *Traditional Graphics*

LVREF=linetype | linetype-list**LV=linetype | linetype-list**

specifies the line types for lines requested with the VREF= option. If you specify a single line type, it is used for all VREF= lines. Otherwise, if there are fewer line types specified than reference lines requested, the remaining lines are displayed with the default reference line type. You can also specify line type 0 to request the default color. *Traditional Graphics*

MAXITER=*n*

specifies the maximum number of iterations in the Newton-Raphson approximation of the maximum likelihood estimate of α for gamma distributions requested with the GAMMA option and c for Weibull distributions requested with the WEIBULL and WEIBULL2 options. Enclose the MAXITER= option in parentheses after the GAMMA, WEIBULL, or WEIBULL2 keywords. The default value of n is 20.

NAME='string'

Traditional Graphics specifies the name of the GRSEG catalog entry for a traditional graphics plot, and the name of the graphics output file if one is created. The name can be up to 256 characters long, but the GRSEG name is truncated to eight characters. The default value is 'CAPABILI'.

NCOLS=*n***NCOL=*n***

Traditional Graphics specifies the number of columns per panel in a comparative plot. By default, NCOLS=1 if you specify only one CLASS variable, and NCOLS=2 if you specify two CLASS variables. If you specify two CLASS variables, you can use the NCOLS= option with the NROWS= option.

ODS Graphics

NOFRAME

Traditional Graphics suppresses the frame around the subplot area.

NOHLABEL

Traditional Graphics suppresses the label for the horizontal axis. You can use this option to reduce clutter.

ODS Graphics

NOVLABEL

Traditional Graphics suppresses the label for the vertical axis. You can use this option to reduce clutter.

ODS Graphics

NOVTICK

Traditional Graphics suppresses the tick marks and tick mark labels for the vertical axis. This option also suppresses the label for the vertical axis.

ODS Graphics

NROWS=*n***NROW=*n***

Traditional Graphics specifies the number of rows per panel in a comparative plot. By default, NROWS=2. If you specify two CLASS variables, you can use the NCOLS= option with the NROWS= option.

ODS Graphics

ODSFOOTNOTE=FOOTNOTE | FOOTNOTE1 | 'string'

ODS Graphics adds a footnote to ODS Graphics output. If you specify the FOOTNOTE (or FOOTNOTE1) keyword, the value of SAS FOOTNOTE statement is used as the graph footnote. If you specify a quoted string, that is used as the footnote. The quoted string can contain either of the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	analysis variable name
\l	analysis variable label (or name if the analysis variable has no label)

ODSFOOTNOTE2=FOOTNOTE2 | *'string'*

adds a secondary footnote to ODS Graphics output. If you specify the FOOTNOTE2 keyword, the value of SAS FOOTNOTE2 statement is used as the secondary graph footnote. If you specify a quoted string, that is used as the secondary footnote. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis: *ODS Graphics*

\n analysis variable name
 \l analysis variable label (or name if the analysis variable has no label)

ODSTITLE=TITLE | **TITLE1** | **NONE** | **DEFAULT** | **LABELFMT** | *'string'*

specifies a title for ODS Graphics output. *ODS Graphics*

TITLE (or **TITLE1**) uses the value of SAS TITLE statement as the graph title.

NONE suppresses all titles from the graph.

DEFAULT uses the default ODS Graphics title (a descriptive title consisting of the plot type and the analysis variable name.)

LABELFMT uses the default ODS Graphics title with the variable label instead of the variable name.

If you specify a quoted string, that is used as the graph title. The quoted string can contain the following escaped characters, which are replaced with the appropriate values from the analysis:

\n analysis variable name
 \l analysis variable label (or name if the analysis variable has no label)

ODSTITLE2=TITLE2 | *'string'*

specifies a secondary title for ODS Graphics output. If you specify the TITLE2 keyword, the value of SAS TITLE2 statement is used as the secondary graph title. If you specify a quoted string, that is used as the secondary title. The quoted string can contain the following escaped characters, which are replaced with the appropriate values from the analysis: *ODS Graphics*

\n analysis variable name
 \l analysis variable label (or name if the analysis variable has no label)

OVERLAY

specifies that plots associated with different levels of a CLASS variable be overlaid onto a single plot, rather than displayed as separate cells in a comparative plot. If you specify the OVERLAY option with one CLASS variable, the output associated with each level of the CLASS variable is overlaid on a single plot. If you specify the OVERLAY option with two CLASS variables, a comparative plot based on the first CLASS variable's levels is produced. Each cell in this comparative plot contains overlaid output associated with the levels of the second CLASS variable. *ODS Graphics*

The OVERLAY option applies only to ODS Graphics output. It is not available in the COMPHISTOGRAM and HISTOGRAM statements.

SCALE=*value*

is an alias for the SIGMA= option for distributions requested by the BETA, EXPONENTIAL, GAMMA, SB, SU, WEIBULL, and WEIBULL2 options and for the ZETA= option for distributions requested by the LOGNORMAL option.

SHAPE=*value*

is an alias for the ALPHA= option for distributions requested by the GAMMA option, for the SIGMA= option for distributions requested by the LOGNORMAL option, and for the C= option for distributions requested by the WEIBULL and WEIBULL2 options.

STATREF=*keyword-list*

Traditional Graphics
ODS Graphics

draws reference lines at the values of the statistics requested in the *keyword-list*. These reference lines are perpendicular to the horizontal axis in a histogram or cdf plot, and perpendicular to the vertical axis in a probability or Q-Q plot (unless the ROTATE option is specified). The STATREF= option does not apply to the PPLOT statement.

Valid keywords are listed in the following table.

Keyword	Statistic
MAX	largest value
MEAN	sample mean
MEDIAN Q2	median (50th percentile)
MIN	smallest value
MODE	most frequent value
P <i>pctl</i>	<i>pctl</i> th percentile
Q1	lower quartile (25th percentile)
Q3	upper quartile (75th percentile)
<i>factor</i> STD	<i>factor</i> standard deviations from the mean

Note that the *factor* specified

with the STD keyword can be positive (which puts a reference line above the mean) or negative (below the mean).

Also see the CSTATREF=, LSTATREF=, STATREFLABELS=, and STATREFSUBCHAR= options.

STATREFLABELS=*'label1' ... 'labeln'***STATREFLABEL=***'label1' ... 'labeln'***STATREFLAB=***'label1' ... 'labeln'*

specifies labels for the lines requested by the STATREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can have up to 16 characters.

STATREFSUBCHAR=*'keyword-list'*

Traditional Graphics
ODS Graphics

specifies a substitution character (such as #) for labels specified with the STATREFLABELS= option. When the labels are displayed on a graph, the first occurrence of the specified character in each label is replaced with the value of the corresponding STATREF= statistic.

TURNVLABELS**TURNVLABEL**

Traditional Graphics

turns the characters in the vertical axis labels so that they display vertically.

VAXIS=*name*

VAXIS=*value-list*

specifies the name of an AXIS statement describing the vertical axis. In a COMPHISTOGRAM or HISTOGRAM statement, you can alternatively specify a *value-list* for the vertical axis.

VAXISLABEL='*label*'

specifies a label for the vertical axis. Labels can have up to 40 characters.

Traditional Graphics

VMINOR=*n*

VM=*n*

specifies the number of minor tick marks between each major tick mark on the vertical axis. *Traditional Graphics*
Minor tick marks are not labeled. The default is zero.

VREF=*value-list*

draws reference lines perpendicular to the vertical axis at the values specified. Also see the [CVREF=](#) and [LVREF=](#) options.

VREFCHAR='*character*'

specifies the character used to form the lines requested by the [VREF=](#) option for a line printer *Line Printer*
chart. The default is the hyphen (-).

VREFLABELS='*label1*'...'*labeln*'

VREFLABEL='*label1*'...'*labeln*'

VREFLAB='*label1*'...'*labeln*'

specifies labels for the lines requested by the [VREF=](#) option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can have up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of [VREFLABELS=](#) labels. If you specify [VREFLABPOS=1](#), *Traditional Graphics*
the labels are positioned at the left of the plot. If you specify [VREFLABPOS=2](#), the labels *ODS Graphics*
are positioned at the right of the plot. By default, [VREFLABPOS=1](#) for traditional graphics
and 2 for ODS Graphics.

W=*value*

W=*value-list*

specifies the width in pixels of the curve or reference line associated with a distribution or *Traditional Graphics*
kernel density estimate. Enclose the [W=](#) option in parentheses after the distribution option
or the [KERNEL](#) option. In a HISTOGRAM statement, you can specify a list of widths in
parentheses for multiple density curves.

WAXIS=*n*

specifies the line thickness, in pixels, for the axes and frame.

Traditional Graphics

Introduction: CUSUM Procedure

The CUSUM procedure creates cumulative sum control charts, also known as *cusum charts*, which display cumulative sums of the deviations of measurements or subgroup means from a target value. Cusum charts are used to decide whether a process is in statistical control by detecting a shift in the process mean.

You can use the CUSUM procedure to

- apply a *one-sided cusum scheme*, also referred to as a *decision interval scheme*, which detects a shift in one direction from the target mean. You can specify the scheme with the decision interval h and the reference value k .
- apply a *two-sided cusum scheme* with a V-mask, which detects a shift in either direction from the target mean. You can specify the scheme with geometric parameters (h and k) for the V-mask or with error probabilities (α and β).
- implement cusum schemes graphically or computationally
- specify the shift to be detected as a multiple of standard error or in data units
- estimate the process standard deviation σ using a variety of methods
- compute average run lengths (ARLs)
- read raw data (actual measurements) or summarized data (subgroup means and standard deviations)
- analyze multiple process variables. If used with a BY statement, PROC CUSUM produces charts separately for groups of observations.
- save cusums and cusum scheme parameters in output data sets
- tabulate the information displayed on the chart
- read cusum scheme parameters from an input data set
- read numeric- or character-valued subgroup variables
- display subgroups with date and time formats
- enhance cusum charts with special legends and symbol markers that indicate the levels of stratification variables

- superimpose plotted points with stars (polygons) whose vertices indicate the values of multivariate data related to the process
- display a trend chart below the cusum chart that plots a systematic or fitted trend in the data
- produce charts as traditional graphics, ODS Graphics output, or legacy line printer charts. Line printer charts can use special formatting characters that improve the appearance of the chart. Traditional graphics can be annotated, saved, and replayed.

Learning about the CUSUM Procedure

If you are using the CUSUM procedure for the first time, begin by reading “PROC CUSUM Statement” on page 567 to learn about input data sets. Then turn to “Getting Started: XCHART Statement” on page 574 in “XCHART Statement: CUSUM Procedure” on page 573. This chapter also provides syntax information and advanced examples.

If you are not familiar with cusum charts, read “Formulas for Cumulative Sums” on page 605 “Defining the Decision Interval for a One-Sided Cusum Scheme” on page 607 and “Defining the V-Mask for a Two-Sided Cusum Scheme” on page 608 in the section “Details: XCHART Statement” on page 604. [References](#) lists articles and textbooks that provide more detailed information on cusum charts. The expository articles by Lucas (1976) and Goel (1982) and the textbooks by Montgomery (1996) and Ryan (1989) are recommended introductory reading.

PROC CUSUM Statement

Overview: PROC CUSUM Statement

The PROC CUSUM statement starts the CUSUM procedure and it identifies input data sets.

After the PROC CUSUM statement, you provide an XCHART statement that specifies the cusum chart you want to create and the variables in the input data set that you want to analyze. For example, the following statements request a one-sided (decision interval) cusum chart:

```
proc cusum data=values;
  xchart weight*lot / scheme = onesided
                    mu0    = 8.100
                    sigma0 = 0.050
                    delta  = 1
                    h      = 2.2
                    k      = 0.5;
run;
```

In this example, the DATA= option specifies an input data set (*values*) that contains the *process* measurement variable *weight* and the *subgroup-variable* *lot*.¹

¹In SAS 6.12 and previous releases of SAS/QC software, the keyword GRAPHICS was required in the PROC CUSUM statement to specify that the chart be created using traditional graphics. In SAS 7 and more recent releases, you can specify the LINEPRINTER option to request line printer plots.

You can use options in the PROC CUSUM statement to do the following:

- specify input data sets containing variables to be analyzed, parameters for cusum schemes, or annotation information
- specify a graphics catalog for saving traditional graphics output
- specify that line printer charts are to be produced
- define characters used for features on line printer charts

In addition to the XCHART statement, you can provide BY statements, ID statements, TITLE statements, and FOOTNOTE statements. If you are producing traditional graphics, you can also provide graphics enhancement statements, such as SYMBOL n statements, which are described in *SAS/GRAPH: Reference*.

See Chapter 3, “SAS/QC Graphics,” for a detailed discussion of the alternatives available for producing charts with SAS/QC procedures.

NOTE: If you are using the CUSUM procedure for the first time, you should read both this chapter and the section “Getting Started: XCHART Statement” on page 574 in “XCHART Statement: CUSUM Procedure” on page 573.

Syntax: PROC CUSUM Statement

The syntax for the PROC CUSUM statement is as follows:

```
PROC CUSUM < options > ;
```

The PROC CUSUM statement starts the CUSUM procedure, and it optionally identifies various data sets. You can specify the following options in the PROC CUSUM statement. The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply only when producing traditional graphics and line printer charts, respectively.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

Traditional Graphics

specifies an input data set that contains appropriate annotate variables, as described in *SAS/GRAPH: Reference*. The ANNOTATE= option enables you to add features to the cusum chart (for example, labels that explain out-of-control points). The ANNOTATE= data set is used only when the chart is created as traditional graphics; it is ignored when the LINEPRINTER option is specified or ODS Graphics is enabled. The data set specified with the ANNOTATE= option in the PROC CUSUM statement is a “global” annotate data set in the sense that the information in this data set is displayed on every chart produced in the current run of the CUSUM procedure.

ANNOTATE2=SAS-data-set

ANNO2=SAS-data-set

Traditional Graphics

specifies an input data set that contains appropriate annotate variables that add features to the trend chart (secondary chart) produced with the TRENDVAR= option in the XCHART statement.

DATA=SAS-data-set

names an input data set that contains raw data (measurements) as observations. If the values of the *subgroup-variable* are numeric, you need to sort the data set so that these values are in increasing order (within BY groups). The DATA= data set can contain more than one observation for each value of the *subgroup-variable*.

You cannot use a DATA= data set with a HISTORY= data set. If you do not specify a DATA= or HISTORY= data set, PROC CUSUM uses the most recently created data set as a DATA= data set. For more information, see “DATA= Data Set” on page 620

FORMCHAR(index)='string'

defines characters used for features on line printer charts, where *index* is a list of numbers ranging from 1 to 17 and *string* is a character or hexadecimal string. The *index* identifies which features are controlled with the *string* characters, as described in the following table. If you specify the FORMCHAR= option and omit the *index*, the *string* controls all 17 features. *Line Printer*

Value of <i>index</i>	Description of Character	Chart Feature
1	vertical bar	frame
2	horizontal bar	frame, central line
3	box character (upper left)	frame
4	box character (upper middle)	serifs, tick (horizontal axis)
5	box character (upper right)	frame
6	box character (middle left)	not used
7	box character (middle middle)	serifs
8	box character (middle right)	tick (vertical axis)
9	box character (lower left)	frame
10	box character (lower middle)	serifs
11	box character (lower right)	frame
12	vertical bar	control limits
13	horizontal bar	control limits
14	box character (upper right)	control limits
15	box character (lower left)	control limits
16	box character (lower right)	control limits
17	box character (upper left)	control limits

Not all printers can produce the characters in the preceding list. By default, the form character list specified by the SAS system option FORMCHAR= is used; otherwise, the default is FORMCHAR='|—|+|—|====='. If you print to a PC screen or if your device supports the ASCII symbol set (1 or 2), the following is recommended:

```
formchar= 'B3, C4, DA, C2, BF, C3, C5, B4, C0, C1, D9, BA, CD, BB, C8, BC, D9' X
```

Note that you can use the FORMCHAR= option to temporarily override the values of the SAS system FORMCHAR= option. The values of the SAS system FORMCHAR= option are not altered by the FORMCHAR= option in the PROC CUSUM statement.

- GOUT=***graphics-catalog*
Traditional Graphics specifies the graphics catalog for traditional graphics output from PROC CUSUM. This is useful if you want to save the output. The GOUT= option is used only when the chart is created using traditional graphics; it is ignored when the LINEPRINTER option is specified or ODS Graphics is enabled.
- HISTORY=***SAS-data-set*
HIST=*SAS-data-set*
 names an input data set that contains subgroup summary statistics (means, standard deviations, and sample sizes). Typically, this data set is created as an OUTHISTORY= data set in a previous run of PROC CUSUM or PROC SHEWHART, but it can also be created with a SAS summarization procedure such as PROC MEANS.
- If the values of the *subgroup-variable* are numeric, you need to sort the data set so that these values are in increasing order (within BY groups). A HISTORY= data set can contain only one observation for each value for the *subgroup-variable*.
- You cannot use a HISTORY= data set together with a DATA= data set. If you do not specify a HISTORY= or DATA= data set, PROC CUSUM uses the most recently created data set as a DATA= data set. For more information on HISTORY= data sets, see “[HISTORY= Data Set](#)” on page 622.
- LIMITS=***SAS-data-set*
 names an input data set that contains a set of decision interval or V-mask parameters. Each observation in a LIMITS= data set contains the parameters for a *process*.
- If you are using SAS 6.09 or an earlier release of SAS/QC software, you must specify the options READLIMITS or READINDEX= in the XCHART statement to read the parameters from the LIMITS= data set. In SAS 6.10 and later releases, these options are not needed.
- For details about the variables needed in a LIMITS= data set, see “[LIMITS= Data Set](#)” on page 621. If you do not provide a LIMITS= data set, you must specify the parameters with options in the XCHART statement.
- LINEPRINTER**
Line Printer requests that line printer charts be produced. By default, the procedure creates traditional graphics.

BY Statement

BY variables ;

You can specify a BY statement with PROC CUSUM to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

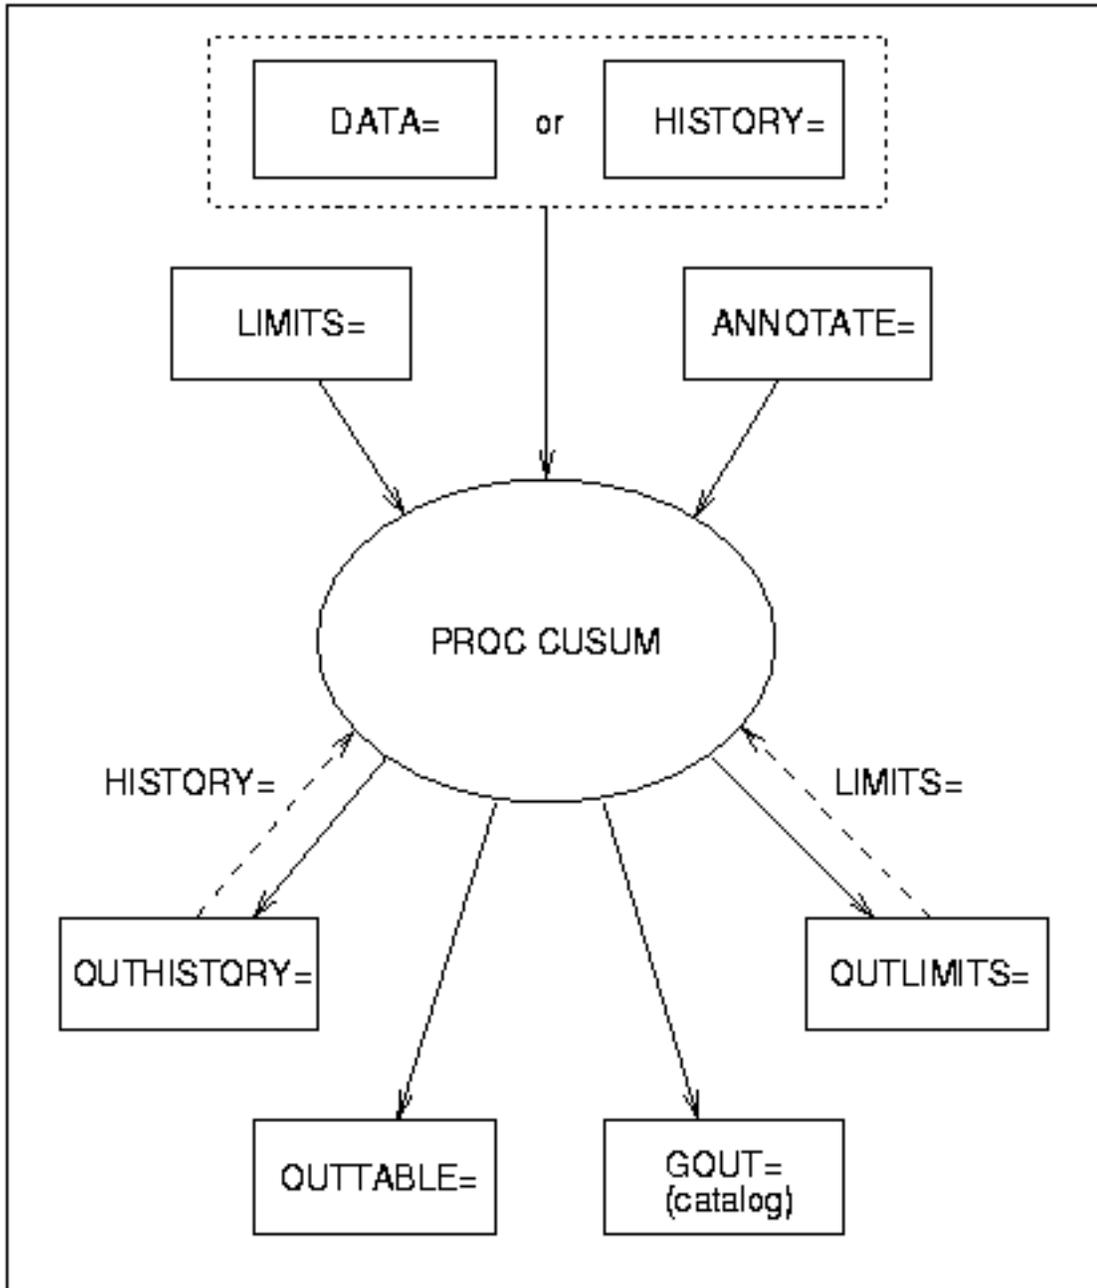

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the CUSUM procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

Input and Output Data Sets: CUSUM Procedure

Figure 6.1 summarizes the data sets used with the CUSUM procedure.

Figure 6.1 Input and Output Data Sets in the CUSUM Procedure

XCHART Statement: CUSUM Procedure

Overview: XCHART Statement

The XCHART statement creates cumulative sum control charts from subgroup means or individual measurements. You can create these charts for one-sided cusum (decision interval) schemes or for two-sided (V-mask) schemes. A one-sided scheme is designed to detect either a positive or a negative shift from the target mean, and a two-sided scheme is designed to detect positive and negative shifts from the target mean.

You can use options in the XCHART statement to

- specify parameters for a decision interval or V-mask
- specify the shift δ to be detected
- specify the target mean μ_0
- specify a known (standard) value σ_0 for the process standard deviation or estimate the standard deviation from the data using various methods
- tabulate the information displayed on the chart
- save the information displayed on the chart in an output data set
- read parameters for the cusum scheme from a data set
- display a secondary chart that plots a time trend that has been removed from the data
- add block legends and special symbol markers to reveal stratification in process data
- superimpose stars at each point to represent related multivariate factors
- display vertical and horizontal reference lines
- modify the axis values and labels
- modify the chart layout and appearance

You have three alternatives for producing cumulative sum control charts with the XCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: XCHART Statement

This section introduces the XCHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the XCHART statement is presented in the section “Syntax: XCHART Statement” on page 589, and advanced examples are given in the section “Examples: XCHART Statement” on page 623.

Creating a V-Mask Cusum Chart from Raw Data

See *CUSTWOS1* in the *SAS/QC Sample Library*

A machine fills eight-ounce cans of two-cycle engine oil additive. The filling process is believed to be in statistical control, and the process is set so that the average weight of a filled can is $\mu_0 = 8.100$ ounces. Previous analysis shows that the standard deviation of fill weights is $\sigma_0 = 0.050$ ounces. A two-sided cusum chart is used to detect shifts of at least one standard deviation in either the positive or negative direction from the target mean of 8.100 ounces.

Subgroup samples of four cans are selected every hour for twelve hours. The cans are weighed, and their weights are saved in a SAS data set named Oil.

```
data Oil;
  label Hour = 'Hour';
  input Hour @;
  do i=1 to 4;
    input Weight @;
    output;
  end;
  drop i;
  datalines;
1  8.024  8.135  8.151  8.065
2  7.971  8.165  8.077  8.157
3  8.125  8.031  8.198  8.050
4  8.123  8.107  8.154  8.095
5  8.068  8.093  8.116  8.128
6  8.177  8.011  8.102  8.030
7  8.129  8.060  8.125  8.144
8  8.072  8.010  8.097  8.153
9  8.066  8.067  8.055  8.059
10 8.089  8.064  8.170  8.086
11 8.058  8.098  8.114  8.156
12 8.147  8.116  8.116  8.018
;
```

The data set Oil is partially listed in [Figure 6.2](#).

Figure 6.2 Partial Listing of the Data Set Oil

Hour	Weight
1	8.024
1	8.135
1	8.151
1	8.065
2	7.971
2	8.165
2	8.077
2	8.157
3	8.125
3	8.031
3	8.198
3	8.050
4	8.123
4	8.107

Each observation contains one value of Weight along with its associated value of Hour, and the values of Hour are in increasing order. The CUSUM procedure assumes that DATA= input data sets are sorted in this “strung-out” form.

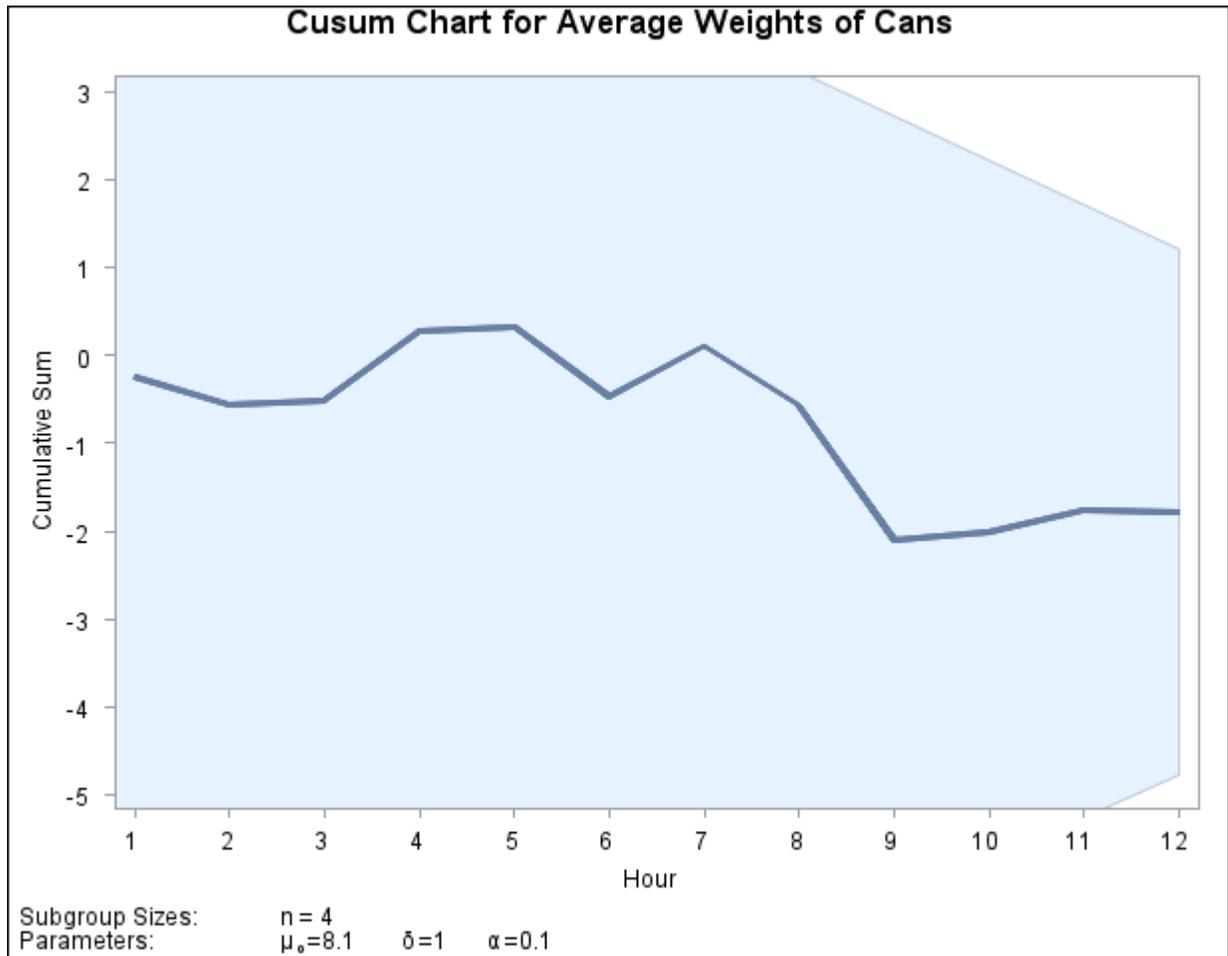

The following statements request a two-sided cusum chart with a V-mask for the average weights:

```
ods graphics off;
title 'Cusum Chart for Average Weights of Cans';
proc cusum data=Oil;
  xchart Weight*Hour /
    mu0    = 8.100          /* Target mean for process */
    sigma0 = 0.050        /* Known standard deviation */
    delta  = 1             /* Shift to be detected    */
    alpha  = 0.10         /* Type I error probability */
    vaxis  = -5 to 3 ;
  label Weight = 'Cumulative Sum';
run;
```

The CUSUM procedure is invoked with the PROC CUSUM statement. The DATA= option in the PROC CUSUM statement specifies that the SAS data set Oil is to be read. The variables to be analyzed are specified in the XCHART statement. The process measurement variable (Weight) is specified before the asterisk (this variable is referred to more generally as a *process*). The time variable (Hour) is specified after the asterisk (this variable is referred to more generally as a *subgroup-variable* because it determines how the measurements are classified into rational subgroups).

The option ALPHA=0.10 specifies the probability of a Type 1 error for the cusum scheme (the probability of detecting a shift when none occurs).

The cusum chart is shown in Figure 6.3.

Figure 6.3 Two-Sided Cusum Chart with V-Mask

The cusum S_1 plotted at Hour=1 is simply the standardized deviation of the first subgroup mean from the target mean.

$$S_1 = \frac{8.09375 - 8.100}{0.050/\sqrt{4}} = -0.250$$

The cusum S_2 plotted at Hour=2 is S_1 plus the standardized deviation of the second subgroup mean from the target mean.

$$S_2 = S_1 + \frac{8.0925 - 8.100}{0.050/\sqrt{4}} = -0.550$$

In general, the cusum plotted at Hour= t is S_{t-1} plus the standardized deviation of the t th subgroup mean from the target mean.

$$S_t = S_{t-1} + \frac{\bar{X}_t - \mu_0}{\sigma_0/\sqrt{n}}$$

For further details, see “Two-Sided Cusum Schemes” on page 606.

You can interpret the chart by comparing the points with the V-mask whose right edge is centered at the most recent point (Hour=12). Since none of the points cross the arms of the V-mask, there is

no evidence that a shift has occurred, and the fluctuations in the cusums can be attributed to chance variation. In general, crossing the lower arm is evidence of an increase in the process mean, whereas crossing the upper arm is evidence of a decrease in the mean.

Creating a V-Mask Cusum Chart from Subgroup Summary Data

The previous example illustrates how you can create a cusum chart using raw process measurements read from a DATA= data set. In many applications, however, the data are provided in *summarized form* as subgroup means. This example illustrates the use of the XCHART statement when the input data set is a HISTORY= data set. *See CUSTWOS1 in the SAS/QC Sample Library*

The following data set provides the subgroup means, standard deviations, and sample sizes corresponding to the variable Weight in the data set Oil (see the section “Creating a V-Mask Cusum Chart from Raw Data” on page 574):

```
data Oilstat;
  label Hour = 'Hour';
  input Hour WeightX WeightS WeightN;
  datalines;
1  8.0938  0.0596  4
2  8.0925  0.0902  4
3  8.1010  0.0763  4
4  8.1198  0.0256  4
5  8.1013  0.0265  4
6  8.0800  0.0756  4
7  8.1145  0.0372  4
8  8.0830  0.0593  4
9  8.0618  0.0057  4
10 8.1023  0.0465  4
11 8.1065  0.0405  4
12 8.0993  0.0561  4
;
```

The data set Oilstat is listed in [Figure 6.4](#).

Figure 6.4 Listing of the Data Set Oilstat

Obs	Hour	Weight X	Weight S	Weight N
1	1	8.0938	0.0596	4
2	2	8.0925	0.0902	4
3	3	8.1010	0.0763	4
4	4	8.1198	0.0256	4
5	5	8.1013	0.0265	4
6	6	8.0800	0.0756	4
7	7	8.1145	0.0372	4
8	8	8.0830	0.0593	4
9	9	8.0618	0.0057	4
10	10	8.1023	0.0465	4
11	11	8.1065	0.0405	4
12	12	8.0993	0.0561	4

Since the data set contains a subgroup variable, a mean variable, a standard deviation variable, and a sample size variable, it can be read as a HISTORY= data set. Note that the names WeightX, WeightS, and WeightN satisfy the naming conventions for summary variables since they begin with a common prefix (Weight) and end with the suffix letters X, S, and N.

The following statements create the cusum chart:

```

title 'Cusum Chart for Average Weights of Cans';
proc cusum history=Oilstat;
  xchart Weight*Hour /
    mu0      = 8.100          /* target mean          */
    sigma0   = 0.050         /* known standard deviation */
    delta    = 1             /* shift to be detected  */
    alpha    = 0.10         /* Type 1 error probability */
    vaxis    = -5 to 3 ;
  label WeightX = 'Cumulative Sum';
run;

```

Note that the *process* Weight specified in the XCHART statement is the prefix of the summary variable names in Oilstat. Also note that the vertical axis label is specified by associating a variable label with the subgroup mean variable (WeightX). The chart (not shown here) is identical to the one in Figure 6.2.

In general, a HISTORY= input data set used with the XRCHART statement must contain the following four variables:

- subgroup variable
- subgroup mean variable
- subgroup range variable
- subgroup sample size variable

Furthermore, the names of subgroup mean, standard deviation, and sample size variables must begin with the prefix *process* specified in the XRCHART statement and end with the special suffix characters X, S, and N, respectively.

Note that the interpretation of *process* depends on the input data set specified in the PROC CUSUM statement.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names containing the summary statistics.

For more information, see “DATA= Data Set” on page 620 and “HISTORY= Data Set” on page 622.

Saving Summary Statistics

In this example, the CUSUM procedure is used to save summary statistics and cusums in an output data set. The summary statistics can subsequently be analyzed by the CUSUM procedure (as in the preceding example). The following statements read the raw measurements from the data set Oil (see “Creating a V-Mask Cusum Chart from Raw Data” on page 574) and create a summary data set named Oilhist: *See CUSTWOS1 in the SAS/QC Sample Library*

```

title 'Cusum Chart for Average Weights of Cans';
proc cusum data=Oil;
  xchart Weight*Hour /
  nochart
  outhistory = Oilhist
  mu0       = 8.100      /* Target mean for process */
  sigma0    = 0.050     /* Known standard deviation */
  delta     = 1         /* Shift to be detected    */
  alpha     = 0.10      /* Type I error probability */
  vaxis     = -5 to 3 ;
  label Weight = 'Cumulative Sum';
run;

```

The OUTHISTORY= option names the SAS data set containing the summary information, and the NOCHART option suppresses the display of the charts (since the purpose here is simply to create an output data set). Figure 6.5 lists the data set Oilhist.

Figure 6.5 Listing of the Data Set Oilhist

Cusum Chart for Average Weights of Cans					
Obs	Hour	Weight X	Weight S	Weight C	Weight N
1	1	8.0938	0.0596	-.2500	4
2	2	8.0925	0.0902	-.5500	4
3	3	8.1010	0.0763	-.5100	4
4	4	8.1198	0.0256	0.2800	4
5	5	8.1013	0.0265	0.3300	4
6	6	8.0800	0.0756	-.4700	4
7	7	8.1145	0.0372	0.1100	4
8	8	8.0830	0.0593	-.5700	4
9	9	8.0618	0.0057	-2.100	4
10	10	8.1023	0.0465	-2.010	4
11	11	8.1065	0.0405	-1.750	4
12	12	8.0993	0.0561	-1.780	4

There are five variables in the data set.

- Hour contains the subgroup index
- WeightX contains the subgroup means
- WeightS contains the subgroup standard deviations

- WeightC contains the cumulative sums
- WeightN contains the subgroup sample sizes

Note that the variables in the OUTHISTORY= data set are named by adding the suffix characters *X*, *S*, *N*, and *C* to the *process* Weight specified in the XCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 618.

Creating a One-Sided Cusum Chart with a Decision Interval

See CUSONES1 in the SAS/QC Sample Library

An alternative to the V-mask cusum chart is the one-sided cusum chart with a decision interval, which is sometimes referred to as the “computational form of the cusum chart.” This example illustrates how you can create a one-sided cusum chart for individual measurements.

A can of oil is selected every hour for fifteen hours. The cans are weighed, and their weights are saved in a SAS data set named Cans:²

```
data Cans;
  length comment $16;
  label Hour = 'Hour';
  input Hour Weight comment $16. ;
  datalines;
1  8.024
2  7.971
3  8.125
4  8.123
5  8.068
6  8.177 Pump Adjusted
7  8.229 Pump Adjusted
8  8.072
9  8.066
10 8.089
11 8.058
12 8.147
13 8.141
14 8.047
15 8.125
;
```

²This data set is used by later examples in this chapter.

Suppose the problem is to detect a *positive* shift in the process mean of one standard deviation ($\delta = 1$) from the target of 8.100 ounces. Furthermore, suppose that

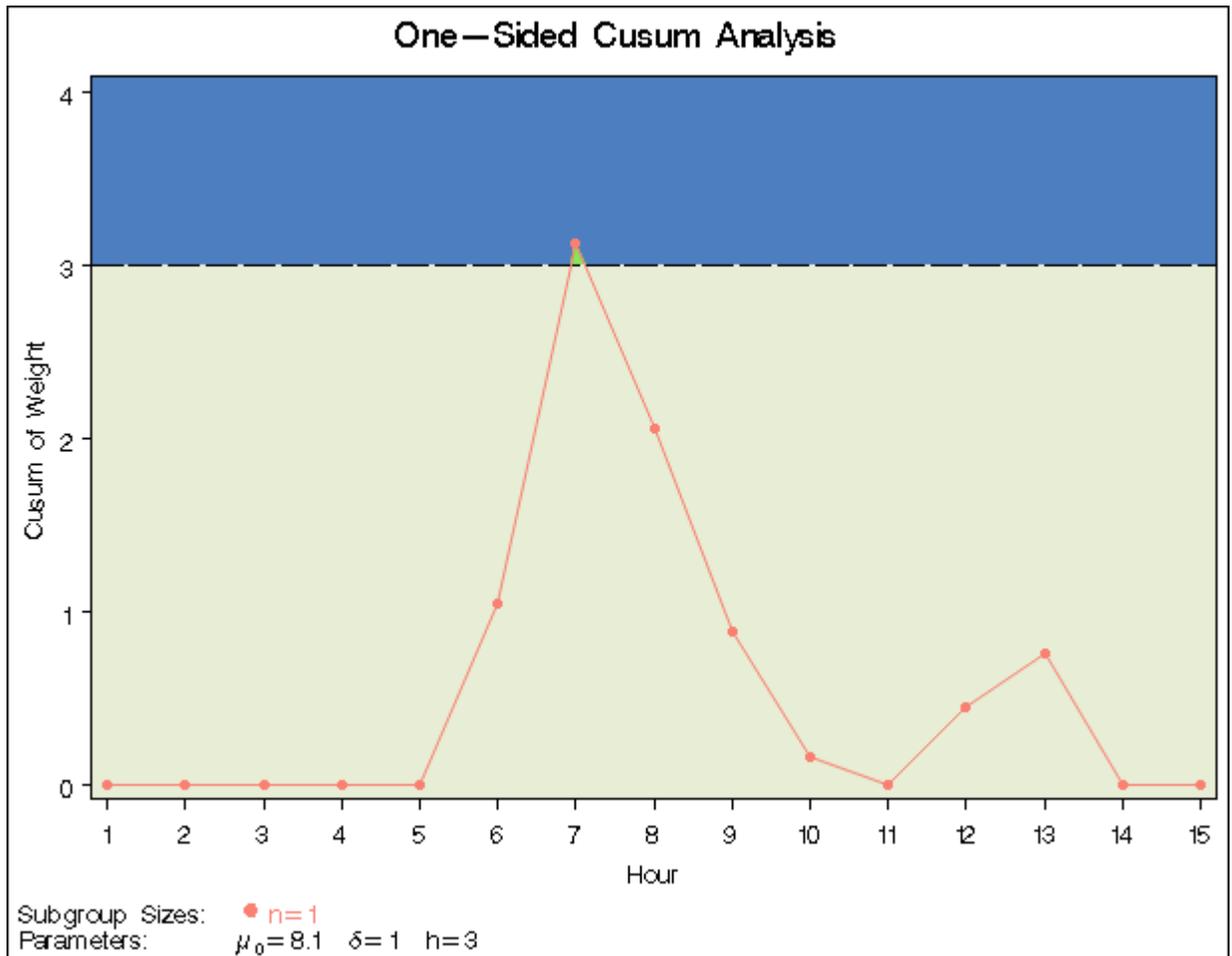

- a known value $\sigma_0 = 0.050$ is available for the process standard deviation
- an in-control average run length (ARL) of approximately 100 is required
- an ARL of approximately five is appropriate for detecting the shift

Table 6.4 indicates that these ARLs can be achieved with the decision interval $h = 3$ and the reference value $k = 0.5$. The following statements use these parameters to create the chart and tabulate the cusum scheme:

```
options nogstyle;
goptions ftext=swiss;
symbol v=dot color=salmon h=1.8 pct;
title "One-Sided Cusum Analysis";
proc cusum data=Cans;
  xchart Weight*Hour /
    mu0      = 8.100      /* target mean for process */
    sigma0   = 0.050     /* known standard deviation */
    delta    = 1         /* shift to be detected */
    h        = 3         /* cusum parameter h */
    k        = 0.5       /* cusum parameter k */
    scheme   = onesided  /* one-sided decision interval */
    tableall /* table */
    cinfile  = ywh
    cframe   = bigb
    cout     = salmon
    cconnect = salmon
    climits  = black
    coutfill = bilg;
  label Weight = 'Cusum of Weight';
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement, GOPTIONS, and XCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The chart is shown in Figure 6.6.

Figure 6.6 One-Sided Cusum Chart with Decision Interval

The cusum plotted at Hour= t is

$$S_t = \max(0, S_{t-1} + (z_t - k))$$

where $S_0 = 0$, and z_t is the standardized deviation of the t th measurement from the target.

$$z_t = \frac{x_t - \mu_0}{\sigma_0}$$

The cusum S_t is referred to as an *upper cumulative sum*. A shift is signaled at the seventh hour since S_7 exceeds h . For further details, see “One-Sided Cusum Schemes” on page 605.

The option TABLEALL requests the tables shown in Figure 6.7, Figure 6.8, and Figure 6.9. The table in Figure 6.7 summarizes the cusum scheme, and it confirms that an in-control ARL of 117.6 and an ARL of 6.4 at $\delta = 1$ are achieved with the specified h and k .

Figure 6.7 Summary Table

Cusum Parameters	
Process Variable	Weight (Cusum of Weight)
Subgroup Variable	Hour (Hour)
Scheme	One-Sided
Target Mean (Mu0)	8.1
Sigma0	0.05
Delta	1
Nominal Sample Size	1
h	3
k	0.5
Average Run Length (Delta)	6.40390895
Average Run Length (0)	117.595692

The table in Figure 6.8 tabulates the information displayed in Figure 6.6.

Figure 6.8 Tabulation of One-Sided Chart

One-Sided Cusum Analysis					
The CUSUM Procedure					
Cumulative Sum Chart Summary for Weight					
Hour	Subgroup Sample Size	Individual Value	Cusum	Decision Interval	Decision Interval Exceeded
1	1	8.0240000	0.0000000	3.0000	
2	1	7.9710000	0.0000000	3.0000	
3	1	8.1250000	0.0000000	3.0000	
4	1	8.1230000	0.0000000	3.0000	
5	1	8.0680000	0.0000000	3.0000	
6	1	8.1770000	1.0400000	3.0000	
7	1	8.2290000	3.1200000	3.0000	Upper
8	1	8.0720000	2.0600000	3.0000	
9	1	8.0660000	0.8800000	3.0000	
10	1	8.0890000	0.1600000	3.0000	
11	1	8.0580000	0.0000000	3.0000	
12	1	8.1470000	0.4400000	3.0000	
13	1	8.1410000	0.7600000	3.0000	
14	1	8.0470000	0.0000000	3.0000	
15	1	8.1250000	0.0000000	3.0000	

The table in Figure 6.9 presents the computational form of the cusum scheme described by Lucas (1976).

Figure 6.9 Computational Form of Cusum Scheme

One-Sided Cusum Analysis				
The CUSUM Procedure				
Computational Cumulative Sum for Weight				
Hour	Subgroup Sample Size	Individual Value	Upper Cusum	Number of Consecutive Upper Sums > 0
1	1	8.0240000	0.0000000	0
2	1	7.9710000	0.0000000	0
3	1	8.1250000	0.0000000	0
4	1	8.1230000	0.0000000	0
5	1	8.0680000	0.0000000	0
6	1	8.1770000	1.0400000	1
7	1	8.2290000	3.1200000	2
8	1	8.0720000	2.0600000	3
9	1	8.0660000	0.8800000	4
10	1	8.0890000	0.1600000	5
11	1	8.0580000	0.0000000	0
12	1	8.1470000	0.4400000	1
13	1	8.1410000	0.7600000	2
14	1	8.0470000	0.0000000	0
15	1	8.1250000	0.0000000	0

Following the method of Lucas (1976), the process average at the out-of-control point (Hour=7) can be estimated as

$$\begin{aligned}
 & \mu_0 + \sigma_0(N_7k + S_7)/(N_7\sqrt{n}) \\
 & = 8.10 + 0.05(2(0.5) + 3.12)/2 \\
 & = 8.203 \text{ ounces}
 \end{aligned}$$

where $S_7 = 3.12$ is the upper sum at Hour=7, and $N_7 = 2$ is the number of successive positive upper sums at Hour=7.

Saving Cusum Scheme Parameters

See CUSONES1 in the SAS/QC Sample Library This example is a continuation of the previous example that illustrates how to save cusum scheme parameters in a data set specified with the OUTLIMITS= option. This enables you to apply the parameters to future data or to subsequently modify the parameters with a DATA step program.

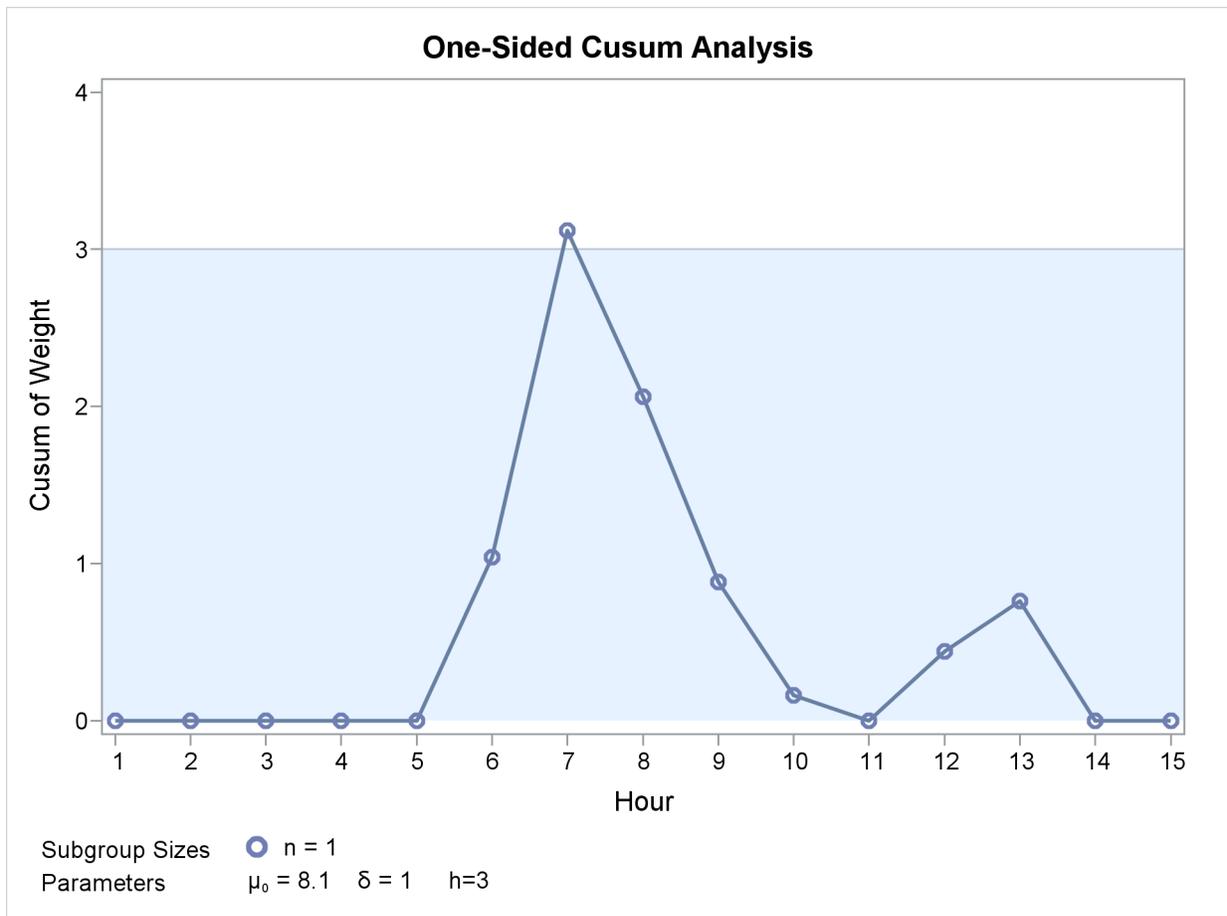

```

ods graphics on;
title 'One-Sided Cusum Analysis';
proc cusum data=Cans;
  xchart Weight*Hour /
    mu0      = 8.100      /* target mean for process */
    sigma0   = 0.050     /* known standard deviation */
    delta    = 1         /* shift to be detected */
    h        = 3         /* cusum parameter h */
    k        = 0.5       /* cusum parameter k */
    scheme   = onesided  /* one-sided decision interval */
    outlimits = cusparm
    odstitle = title
    markers;
  label Weight = 'Cusum of Weight';
run;

```

The chart, shown in Figure 6.10, is similar to the one in Figure 6.6 but is created by using ODS Graphics because the ODS GRAPHICS ON statement is specified before the PROC CUSUM statement.

Figure 6.10 One-Sided Cusum Scheme with Decision Interval

The OUTLIMITS= data set is listed in Figure 6.11.

Figure 6.11 Listing of the OUTLIMITS= Data Set cusparam

One-Sided Cusum Analysis													
	S	L	S		S		A						
	U	I	C	D	T	A	R						
	B	T	M	H	E	M	D	R	L				
	V	G	Y	I	E	M	L	E	D	L	O		
O	A	R	P	T	M	U	T	A	E	I	U		
b	R	P	E	N	H	K	E	0	A	N	V		
s													
1	Weight	Hour	STANDARD	1	3	0.5	ONESIDED	8.1	1	8.09747	0.05	117.596	6.40391

The data set contains one observation with the parameters for *process* Weight. The variables `_TYPE_`, `_H_`, `_K_`, `_MU0_`, `_DELTA_`, and `_STDDEV_` save the parameters specified with the options `SCHEME=`, `H=`, `K=`, `MU0=`, `DELTA=`, and `SIGMA0=`, respectively. The variable `_MEAN_` saves an estimate of the process mean, and the variable `_LIMITN_` saves the nominal sample size. The variables `_ARLIN_` and `_ARLOUT_` save the average run lengths for $\delta = 0$ and for $\delta = 1$.

The variables `_VAR_` and `_SUBGRP_` save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping variable that indicates whether the value of `_STDDEV_` is an estimate or a standard value.

For more information, see “OUTLIMITS= Data Set” on page 617.

Reading Cusum Scheme Parameters

See CUSONES1 in the SAS/QC Sample Library This example shows how the cusum parameters saved in the previous example can be applied to new measurements saved in a data set named Cans2:

```
data Cans2;
  length pump $ 8;
  label Hour = 'Hour';
  input Hour Weight pump $ 8. ;
  datalines;
16 8.1765 Pump 3
17 8.0949 Pump 3
18 8.1393 Pump 3
19 8.1491 Pump 3
20 8.0473 Pump 1
21 8.1602 Pump 1
22 8.0633 Pump 1
23 8.0921 Pump 1
24 8.1573 Pump 1
25 8.1304 Pump 1
26 8.0979 Pump 1
27 8.2407 Pump 1
28 8.0730 Pump 1
```

```

29  8.0986  Pump 2
30  8.0785  Pump 2
31  8.2308  Pump 2
32  8.0986  Pump 2
33  8.0782  Pump 2
34  8.1435  Pump 2
35  8.0666  Pump 2
;

```

The following statements create a one-sided cusum chart for the measurements in Cans2 using the parameters in cusparm:

```

title "One-Sided Cusum Analysis for New Data";
proc cusum data=Cans2 limits=cusparm;
  xchart Weight*Hour( pump ) / odstitle=title markers;
  label Weight = 'Cusum of Weight';
run;
ods graphics off;

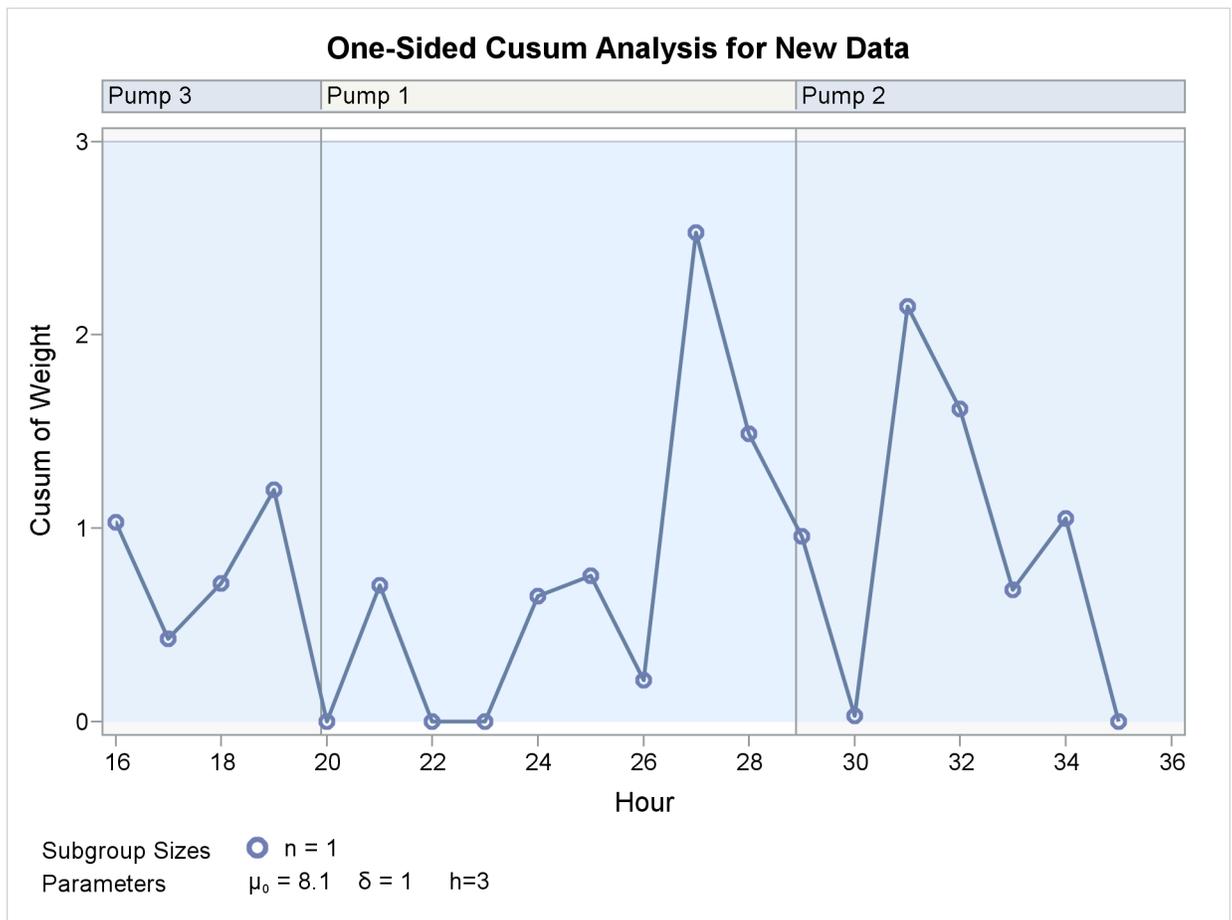

```

ODS Graphics remains enabled until it is disabled with the ODS GRAPHICS OFF statement, so this cusum chart is also created using ODS Graphics.

The LIMITS= option in the PROC CUSUM statement specifies the data set containing preestablished cusum parameters.³ The chart, shown in [Figure 6.12](#), indicates that the process is in control. Levels of the variable pump (referred to as a *block-variable*) do not enter into the analysis but are displayed in a block legend across the top of the chart. See [Block Variable Legend Options](#).

³In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option or the READINDEX= option to read cusum parameters from a LIMITS= data set.

Figure 6.12 Cusum Chart with Decision Interval for New Data

In general, the parameters for a specified *process* and *subgroup-variable* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* (in this case, Weight)
- the value of `_SUBGRP_` matches the *subgroup-variable* name (in this case, Hour)

If you are maintaining more than one set of cusum parameters for a particular *process*, you will find it convenient to include a special identifier variable named `_INDEX_` in the LIMITS= data set. This must be a character variable of length 16. Then, if you specify `READINDEX='value'` in the XCHART statement, the parameters for a specified *process* and *subgroup-variable* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup-variable* name
- the value of `_INDEX_` matches *value*

In this example, the LIMITS= data set was created in a previous run of the CUSUM procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 621 for details concerning the variables that you must provide.

Syntax: XCHART Statement

The basic syntax for a *one-sided (decision interval) scheme* using the XCHART statement is as follows:

```
XCHART process * subgroup-variable / SCHEME=ONESIDED MU0=target DELTA=shift
H=h < options > ;
```

The general form of this syntax is as follows:

```
XCHART processes * subgroup-variable < (block-variables) >
< =symbol-variable ='character' > / SCHEME=ONESIDED MU0=target
DELTA=shift H=h < options > ;
```

Note that the options SCHEME=ONESIDED, MU0=, DELTA=, and H= are required unless their values are read from a LIMITS= data set.

The basic syntax for a *two-sided (V-mask) scheme* is as follows:

```
XCHART process * subgroup-variable / MU0=target DELTA=shift ALPHA=alpha H=h
< options > ;
```

The general form of this syntax is as follows:

```
XCHART processes * subgroup-variable < (block-variables) >
< =symbol-variable | = 'character' > / MU0=target DELTA=shift ALPHA=alpha H=h
< options > ;
```

Note that the options MU0=, DELTA=, and either ALPHA= or H= are required unless their values are read from a LIMITS= data set.

You can use any number of XCHART statements in the CUSUM procedure. The components of the XCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC CUSUM statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “Creating a V-Mask Cusum Chart from Raw Data” on page 574.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “Creating a V-Mask Cusum Chart from Subgroup Summary Data” on page 577.

A *process* is required. If more than one *process* is specified, enclose the list in parentheses. The parameters specified in the XCHART statement are applied to all of the *processes*.⁴

⁴For this reason, it may be preferable to read distinct cusum parameters for each *process* from a LIMITS= data set.

subgroup-variable

is the variable that classifies the data into subgroups. The *subgroup-variable* is required. In the examples “Creating a V-Mask Cusum Chart from Raw Data” on page 574 and “Creating a V-Mask Cusum Chart from Subgroup Summary Data” on page 577, Hour is the subgroup variable.

block-variables

are optionally specified variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See Figure 6.12 for an example.

symbol-variable

is an optionally specified variable whose levels (unique values) determine the plotting character or symbol marker used to plot the cusums.

- If you produce a line printer chart, an ‘A’ marks points corresponding to the first level of the *symbol-variable*, a ‘B’ marks points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOLn statements.

character

specifies a plotting character for line printer charts. See Figure 6.10 for an example.

options

specify optional cusum parameters, enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “Summary of Options”, which follows, lists all options by function.

Summary of Options

The following tables list the XCHART statement options by function. Options unique to the CUSUM procedure are listed in Table 6.1, and are described in detail in the section “Dictionary of Special Options” on page 598. Options that are common to both the CUSUM and SHEWHART procedures are listed in Table 6.2. They are described in detail in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Table 6.1 XCHART Statement Special Options

Option	Description
Options for Specifying a One-Sided (Decision Interval) Cusum Scheme	
DELTA=	specifies shift to be detected as a multiple of standard error
H=	specifies decision interval h ($h > 0$) as a multiple of standard error
HEADSTART=	specifies headstart value S_0 as a multiple of standard error
K=	specifies reference value k ($k > 0$)
LIMITN=	specifies fixed nominal sample size for cusum scheme
LIMITN=	specifies that cusums are to be computed for all subgroups regardless of sample size

Table 6.1 continued

Option	Description
MU0=	specifies target μ_0 for mean
NOREADLIMITS	specifies that cusum parameters are not to be read from LIMITS= data set (SAS 6.10 and later releases)
READINDEX=	reads cusum scheme parameters from a LIMITS= data set
READLIMITS	specifies that cusum parameters are to be read from LIMITS= data set (SAS 6.09 and earlier releases)
SCHEME=ONESIDED	specifies a one-sided scheme
SHIFT=	specifies shift to be detected in data units
SIGMA0=	specifies standard (known) value σ_0 for process standard deviation
Options for Specifying a Two-Sided (V-Mask) Cusum Scheme	
ALPHA=	specifies probability of Type 1 error
BETA=	specifies probability of Type 2 error
H=	specifies vertical distance between V-mask origin and upper (or lower) arm
K=	specifies slope of lower arm of V-mask
LIMITN=	specifies fixed nominal sample size for cusum scheme
LIMITN=	specifies that cusums are to be computed for all subgroups regardless of sample size
NOREADLIMITS	specifies that cusum parameters are not to be read from LIMITS= data set (SAS 6.10 and later releases)
READINDEX=	reads cusum scheme parameters from a LIMITS= data set
READLIMITS	specifies that cusum parameters are to be read from LIMITS= data set (SAS 6.09 and earlier releases)
READSIGMAS	reads <code>_SIGMAS_</code> instead of <code>_ALPHA_</code> from LIMITS= data set when both variables are available
SIGMAS=	specifies probability of Type 1 error as probability that standard normally distributed variable exceeds <i>value</i> in absolute value
Options for Estimating Process Standard Deviation	
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies whether <code>_STDDEV_</code> in OUTLIMITS= data set is an estimate or standard, and specifies value of <code>_TYPE_</code> in OUTLIMITS= data set

Table 6.1 continued

Option	Description
Options for Displaying Decision Interval or V-Mask	
CINFILL=	specifies color for area under decision interval line or inside V-mask
CLIMITS=	specifies color of decision interval line
CMASK=	specifies color of V-mask outline
LLIMITS=	specifies line type for decision interval
LMASK=	specifies line type for V-mask arms
NOMASK	suppresses display of V-mask
ORIGIN=	specifies value of <i>subgroup-variable</i> locating origin of V-mask
WLIMITS=	specifies line width for decision interval
WMASK=	specifies line width for V-mask
Tabulation Options	
TABLEALL	specifies the options TABLECHART, TABLECOMP, TABLEID, TABLEOUT, and TABLESUMMARY
TABLECHART	tabulates the information displayed in the cusum chart
TABLECOMP	tabulates the computational form of the cusum scheme as described by Lucas (1976) and Lucas and Crosier (1982)
TABLEID	augments TABLECHART and TABLECOMP tables with columns for ID variables
TABLEOUT	augments TABLECHART table with a column indicating if the decision interval or V-mask was exceeded
TABLESUMMARY	tabulates the parameters for the cusum scheme and the average run lengths corresponding to shifts of zero and δ

Table 6.2 XCHART Statement General Options

Option	Description
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on cusum chart
ALLLABEL2=	labels every point on trend chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels
LABELHEIGHT=	specifies height of labels
NOCONNECT	suppresses line segments that connect points on chart
NOTRENDCONNECT	suppresses line segments that connect points on trend chart

Table 6.2 continued

Option	Description
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of cusum chart
VAXIS2=	specifies major tick mark values for vertical axis of trend chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages

Table 6.2 *continued*

Option	Description
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
TRENDVAR=	specifies list of trend variables
YPCT1=	specifies length of vertical axis on cusum chart as a percentage of sum of lengths of vertical axes for cusum and trend charts
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on cusum chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on cusum chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on cusum chart

Table 6.2 continued

Option	Description
VREF2=	specifies position of reference lines perpendicular to vertical axis on trend chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to cusum chart
ANNOTATE2=	specifies annotate data set that adds features to trend chart
DESCRIPTION=	specifies description of cusum chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of cusum chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
WTREND=	specifies width of line segments connecting points on trend chart
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors

Table 6.2 continued

Option	Description
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits

Table 6.2 continued

Option	Description
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices

Table 6.2 continued

Option	Description
STARLEGNLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPCS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on cusum chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
VREFCHAR=	specifies line character for VREF= and VREF2= lines

Dictionary of Special Options

The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply only to traditional graphics and line printer charts, respectively.

ALPHA=*value*

specifies the probability α of incorrectly deciding that a shift has occurred when the process mean is equal to the target mean. This is known as the probability of a Type 1 error. The *value* must be between zero and one, and it is typically set at 0.05 or 0.10. If you specify the ALPHA= option, the error probability approach is used to determine the V-mask. For details, see “Defining the V-Mask for a Two-Sided Cusum Scheme” on page 608.

The ALPHA= option is applicable only with two-sided cusum schemes. As an alternative to the ALPHA= *value*, you can specify the percentile $z_{1-\alpha/2}$ from a standard normal distribution with the SIGMAS= option. As a second alternative, you can specify the geometric parameter h for the V-mask (in standard error units) with the H= option.

In addition to the ALPHA= option, you can optionally specify the probability of a Type 2 error with the BETA= option.

BETA=value

specifies the probability β of failing to discover that the specified shift has occurred. This is known as the probability of a Type 2 error. The *value* must be between zero and one. The BETA= option is used in conjunction with either the ALPHA= option or the SIGMAS= option.

The interpretation of β is based on the analogy between cusum charts and sequential probability ratio tests, and it is inexact since the cusum chart does not provide an acceptance region. Refer to Johnson (1961) and van Dobben de Bruyn (1968) for further details.

CINFILL=color

specifies the color for the area under the decision interval or inside the V-mask arms. See also *Traditional Graphics* the COUTFILL= option.

CLIMITS=color

specifies the color for the decision interval line. *Traditional Graphics*

CMASK=color

specifies the color for the V-mask arms. *Traditional Graphics*

DATAUNITS

computes cumulative sums without standardizing the subgroup means or individual measurements. As a result, the vertical axis of the cusum chart is scaled in the same units as the data.

The DATAUNITS option requires constant subgroup sample sizes. If your data do not have constant subgroup sample sizes, you need to specify a constant nominal sample size n for the V-mask or decision interval with the LIMITN= option or with the variable `_LIMITN_` in the LIMITS= data set.

DELTA=value

specifies the absolute value of the smallest shift to be detected as a multiple δ of the process standard deviation σ or the standard error $\sigma_{\bar{X}}$, depending on whether δ is viewed as a shift in the population mean or a shift in the sampling distribution of the subgroup mean \bar{X} , respectively.

If you specify SCHEME=ONESIDED (see the SCHEME= option later in this list) and the *value* is positive, a shift above the process mean is to be detected, whereas if the *value* is negative, a shift below the process mean is to be detected.

As an alternative to specifying the DELTA= option, you can specify the shift in the same units as the data with the SHIFT= option.

H=value

specifies the decision interval h for a one-sided cusum scheme. This type of scheme is completely specified by the parameters h and k (see the K= option later in this list). You can also specify the H= option as an alternative to the ALPHA= or SIGMAS= options for a two-sided cusum scheme with a V-mask. In this case, the H= option specifies the vertical distance h between the origin for the V-mask and the upper or lower arm of the V-mask. In either case, the H=*value* must be positive and must be expressed as a multiple of standard error.

You can use a table of average run lengths to choose h (this is typically between zero and 10). See [Table 6.4](#) and [Table 6.5](#)

HEADSTART=value**HSTART=value**

specifies a headstart value S_0 for a one-sided cusum scheme. The value must be expressed as a multiple of standard error. See the section “[Headstart Values](#)” on page 606, and refer to Lucas and Crosier (1982), Ryan (1989), and Montgomery (1996).

K=value

specifies the reference value k for a one-sided (decision interval) cusum scheme. This type of scheme is completely specified by the parameters k and h (see the H= option earlier in this list). You can also specify the K= and H= options as geometric parameters for a two-sided cusum scheme with a V-mask. In this case, the K= option specifies the slope of the lower arm of the V-mask, and the K= and H= options together are alternatives to the error probability options ALPHA=, SIGMAS=, and BETA=. In either case, the K= value must be positive and must be expressed as a multiple of standard error.

You can use a table of average run lengths to choose k and h (k is typically between zero and two). See [Table 6.4](#) and [Table 6.5](#).

For a one-sided scheme, the default K= value is $\delta/2$, which is referred to as the *central reference value*. For a two-sided scheme where the V-mask is specified geometrically with the H= option, the default K= value is $\delta/2$. If, however, the V-mask is specified by an error probability with the ALPHA= option, then the K= option should not be specified.

CAUTION: The interpretation of the K= value depends on the *subgroup-variable* and the interval between subgroups that is specified with the INTERVAL= option. For a two-sided scheme, the value is the increase in the lower V-mask arm per unit change on the subgroup axis, so the value depends on how the *subgroup-variable* is scaled.

- If integer values are assigned to the *subgroup-variable*, then a unit change is defined as one.
- If the *subgroup-variable* has character values, then a unit change is defined as the increment between adjacent values of the *subgroup-variable*.
- If the *subgroup-variable* is numeric and is formatted with a SAS date or time format, then a unit change is defined as the default value for the INTERVAL= option. For example, if a DATE7. format is associated with the *subgroup-variable*, then a unit change is defined as one day.

You can use the INTERVAL= option to modify the definition of a unit change. For example, if a DATE7. format is associated with the *subgroup-variable* but subgroups are collected hourly, then INTERVAL=HOUR defines a unit change as one hour rather than one day.

LIMITN=n**LIMITN=VARYING**

specifies either a fixed or varying nominal sample size for the control limits. If you specify LIMITN= n , cusums are calculated and displayed only for those subgroups with a sample size equal to n , although you can specify the ALLN option to force all cusums to be plotted. If you specify LIMITN=VARYING, cusums are calculated and displayed for all subgroups, regardless of sample size.

LLIMITS=*linetype*

specifies the line type for the decision interval.

Traditional Graphics

LMASK=*linetype*

specifies the line type for the V-mask arms.

Traditional Graphics

MU0=*value*

specifies the target mean μ_0 for the process. The target mean must be scaled in the same units as the data.

NOARL

suppresses calculation of average run lengths. By default, this calculation is performed if you specify the TABLESUMMARY option or an OUTLIMITS= data set.

NOMASK

suppresses the display of the V-mask on charts for two-sided schemes. This option does not affect computations of cusums or V-mask parameters.

NOREADLIMITS

specifies that the cusum scheme parameters for each *process* listed in the chart statement are *not* to be read from the LIMITS= data set specified in the PROC CUSUM statement. The NOREADLIMITS option is available only in SAS 6.10 and later releases. See the READLIMITS option later in this list.

ORIGIN=*value*

specifies the origin of the V-mask, which is defined as the horizontal coordinate of the right edge of the V-mask. If a date, time, or datetime format is associated with the *subgroup-variable*, you must specify the *value* as a date, time, or datetime constant, respectively. If the subgroup variable is character, you must specify the *value* as a quoted string. The default *value* is the last (most recent) value of the *subgroup-variable*.

Note that estimates for the process mean and standard deviation are calculated only from subgroups up to and including the origin subgroup.

READINDEX=*'value'*

reads cusum scheme parameters from a LIMITS= data set (specified in the PROC CUSUM statement) for each *process* listed in the chart statement. The *i*th set of control limits for a particular *process* is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup-variable*
- the value of `_INDEX_` matches *value*

The *value* can be up to 16 characters and must be enclosed in quotes.

READLIMITS

specifies that cusum scheme parameters are to be read from a LIMITS= data set specified in the PROC CUSUM statement. The parameters for a particular *process* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*

- the value of `_SUBGRP_` matches the *subgroup variable*

The use of the READLIMITS option depends on which release of SAS/QC software you are using.

- **In SAS 6.10 and later releases, the READLIMITS option is not necessary.** To read cusum scheme parameters as described previously, you simply specify a LIMITS= data set. However, even though the READLIMITS option is redundant, it continues to function as in earlier releases.
- **In SAS 6.09 and earlier releases, you must specify the READLIMITS option to read cusum scheme parameters as described previously.** If you specify a LIMITS= data set without specifying the READLIMITS option (or the READINDEX= option), the cusum scheme parameters are computed from the data.

READSIGMAS

specifies that the variable `_SIGMAS_` (instead of `_ALPHA_`) is to be read from a LIMITS= data set that contains both variables. The variables `_SIGMAS_` and `_ALPHA_` provide the same parameters as the SIGMAS= and ALPHA= options. By default, `_ALPHA_` is read from the LIMITS= data set.

SCHEME=ONESIDED

SCHEME=TWOSIDED

indicates whether the cusum scheme is a one-sided (decision interval) scheme or a two-sided scheme with a V-mask. By default, SCHEME=TWOSIDED.

SHIFT=value

specifies the shift to be detected in the same units as the data. The *value* is interpreted as the shift in the mean of the sampling distribution of the subgroup mean. The SHIFT= option is an alternative to the DELTA= option. To specify the SHIFT= option, one of the following must be true:

- The subgroup sample sizes are constant.
- A constant nominal sample size n is provided for the cusum scheme with the LIMITN= option or the `_LIMITN_` variable in a LIMITS= data set.

The relationship between the SHIFT= *value* (denoted by Δ) and the DELTA= value (denoted by δ) is $\delta = \Delta / (\sigma / \sqrt{n})$, where σ is the process standard deviation.

SIGMA0=value

specifies a known standard deviation σ_0 for the process standard deviation σ . The *value* must be positive. By default, PROC CUSUM estimates σ from the data using the formulas given in “Methods for Estimating the Standard Deviation” on page 614. You can use the variable `_STDDEV_` in a LIMITS= data set as an alternative to the SIGMA0= option.

SIGMAS=value

specifies the probability α of false detection for a two-sided cusum scheme with a V-mask as the probability that the absolute value of a standard normally distributed variable is greater than the *value*. For example, SIGMAS=3 corresponds to the probability $\alpha = 0.0027$. The *value*

must be positive. The SIGMAS= option is an alternative to the ALPHA= and H= options, and only one of these three options can be specified.

The SIGMAS= option is useful for defining cusum charts that correspond to Shewhart charts whose control limits are defined with the same *value* as the multiple of σ . Refer to Johnson and Leone (1962, 1974).

SMETHOD=NOWEIGHT | MVLUE | RMSDF

specifies a method for estimating the process standard deviation from subgroup observations, σ , as summarized by the following table.

Keyword	Method for Estimating Standard Deviation
NOWEIGHT	estimates σ as an unweighted average of unbiased subgroup estimates of σ
MVLUE	calculates a minimum variance linear unbiased estimate for σ
RMSDF	calculates a root-mean square estimate for σ

For formulas, see “[Methods for Estimating the Standard Deviation](#)” on page 614.

TABLEALL

requests all the tables specified by the options TABLECHART, TABLECOMP, TABLEID, TABLEOUT, and TABLESUMMARY.

TABLECHART <(EXCEPTIONS)>

creates a table of the subgroup variable, the subgroup sample sizes, the subgroup means, the cumulative sums, and the decision interval or V-mask limits. A table is produced for each *process* specified in the XCHART statement. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the decision interval or V-mask values are exceeded.

TABLECOMP

tabulates the computational form of the cusum scheme as described by Lucas (1976) and Lucas and Crosier (1982). Upper or lower cumulative sums (or both) are tabulated for each *process* given in the XCHART statement. See “[Formulas for Cumulative Sums](#)” on page 605 for more information.

TABLEID

augments the tables specified by the TABLECHART and TABLECOMP options with a column for each of the ID variables.

TABLEOUT

augments the table specified by the TABLECHART option with a column indicating whether the decision interval or V-mask values are exceeded.

TABLESUMMARY

produces a table that summarizes the cusum scheme. The table lists the parameters of the scheme and the average run lengths corresponding to shifts of zero and δ . The average run lengths are computed using the method of Goel and Wu (1971). A table is produced for each *process*. You can save the summary in a data set by specifying the OUTLIMITS= option. See “OUTLIMITS= Data Set” on page 617 for details.

TYPE=ESTIMATE**TYPE=STANDARD**

specifies the value of `_TYPE_` in an OUTLIMITS= data set. The variable `_TYPE_` indicates whether the variable `_STDDEV_` in the OUTLIMITS= data set represents an estimate or a standard (known) value. The default is ‘STANDARD’ if the SIGMA0= option is specified; otherwise, the default is ‘ESTIMATE’.

WLIMITS=*linetype**Traditional Graphics*

specifies the width (in pixels) of the decision interval line.

WMASK=*linetype**Traditional Graphics*

specifies the width (in pixels) of the V-mask arms.

Details: XCHART Statement

Basic Notation for Cusum Charts

The following notation is used in this chapter:

- μ denotes the mean of the population, also referred to as the *process mean* or the *process level*.
- μ_0 denotes the target mean (goal) for the population. Goel and Wu (1971) refer to μ_0 as the “acceptable quality level” and use the symbol μ_a instead. The symbol \bar{X}_0 is used for μ_0 in *Glossary and Tables for Statistical Quality Control*. You can provide μ_0 with the MU0= option or with the variable `_MU0_` in a LIMITS= data set.
- σ denotes the population standard deviation. You can provide σ with the variable `_STDDEV_` in a LIMITS= data set (where `_TYPE_`=‘STANDARD’).
- σ_0 denotes a known standard deviation. You can provide σ_0 with the SIGMA0= option or the variable `_STDDEV_` in a LIMITS= data set.
- $\hat{\sigma}$ denotes an estimate of σ . You can provide $\hat{\sigma}$ with the SIGMA0= option or the variable `_STDDEV_` in a LIMITS= data set. To identify this value as an estimate, specify TYPE=ESTIMATE or assign the value ‘ESTIMATE’ to the variable `_TYPE_` in a LIMITS= data set.
- n denotes the nominal sample size for the cusum scheme. You can provide n with the LIMITN= option or the variable `_LIMITN_` in a LIMITS= data set.

- δ denotes the shift in μ to be detected, expressed as a multiple of the standard deviation. You can provide δ with the DELTA= option or the variable `_DELTA_` in a LIMITS= data set.
- Δ denotes the shift in μ to be detected, expressed in data units. If the sample size n is constant across subgroups, then $\Delta = \delta\sigma_{\bar{X}} = (\delta\sigma)/\sqrt{n}$. Some authors use the symbol D instead of Δ ; for example, refer to Johnson and Leone (1962, 1974) and Wadsworth, Stephens, and Godfrey (1986). You can provide Δ with the SHIFT= option. Although it may be more natural to specify the shift in data units, it is preferable to specify the shift as δ , since this generalizes to data with unequal subgroup sample sizes.

Formulas for Cumulative Sums

One-Sided Cusum Schemes

Positive Shifts If the shift δ to be detected is positive, the cusum computed for the t th subgroup is

$$S_t = \max(0, S_{t-1} + (z_t - k))$$

for $t=1, 2, \dots, n$, where $S_0=0$, z_t is defined as for two-sided schemes, and the parameter k , termed the *reference value*, is positive. The cusum S_t is referred to as an *upper cumulative sum*. Since S_t can be written as

$$\max\left(0, S_{t-1} + \frac{\bar{X}_i - (\mu_0 + k\sigma_{\bar{X}_i})}{\sigma_{\bar{X}_i}}\right)$$

the sequence S_t cumulates deviations in the subgroup means greater than k standard errors from μ_0 . If S_t exceeds a positive value h (referred to as the *decision interval*), a shift or out-of-control condition is signaled. This formulation follows that of Lucas (1976), Lucas and Crosier (1982), and Montgomery (1996).

Negative Shifts If the shift δ to be detected is negative, the cusum computed for the t th subgroup is

$$S_t = \max(0, S_{t-1} - (z_t + k))$$

for $t=1, 2, \dots, n$, where $S_0=0$, z_t is defined as for two-sided cusum schemes, and the parameter k , termed the *reference value*, is positive. The cusum S_t is referred to as a *lower cumulative sum*. Since S_t can be written as

$$\max\left(0, S_{t-1} - \frac{\bar{X}_i - (\mu_0 - k\sigma_{\bar{X}_i})}{\sigma_{\bar{X}_i}}\right)$$

the sequence S_t cumulates the absolute value of deviations in the subgroup means less than k standard errors from μ_0 . If S_t exceeds a positive value h (referred to as the *decision interval*), a shift or out-of-control condition is signaled.

This formulation follows that of Lucas (1976), Lucas and Crosier (1982), and Montgomery (1996). Note that S_t is always positive and h is always positive, regardless of whether δ is positive or negative. For schemes designed to detect a negative shift, some authors, including van Dobben de Bruyn (1968) and Wadsworth, Stephens, and Godfrey (1986), define a reflected version of S_t for which a shift is signaled when S_t is less than a negative limit.

Headstart Values Lucas and Crosier (1982) describe the properties of a fast initial response (FIR) feature for cusum schemes in which the initial cusum S_0 is set to a “headstart” value. Average run length calculations given by Lucas and Crosier (1982) show that the FIR feature has little effect when the process is in control and that it leads to a faster response to an initial out-of-control condition than a standard cusum scheme. You can provide headstart value S_0 with the HEADSTART= option or the variable _HSTART_ in a LIMITS= data set.

Constant Sample Sizes When the subgroup sample sizes are constant ($= n$), it may be preferable to compute cusums that are scaled in the same units as the data. Refer to Montgomery (1996) and Wadsworth, Stephens, and Godfrey (1986). To request this, specify the DATAUNITS option. Cusums are then computed as

$$S_t = \max(0, S_{t-1} + (\bar{X}_t - (\mu_0 + k\sigma/\sqrt{n})))$$

for $\delta > 0$ and the equation

$$S_t = \max(0, S_{t-1} - (\bar{X}_t - (\mu_0 - k\sigma/\sqrt{n})))$$

for $\delta < 0$. In either case, a shift is signaled if S_t exceeds $h' = h\sigma/\sqrt{n}$. Wadsworth, Stephens, and Godfrey (1986) use the symbol H for h' .

If the subgroup sample sizes are not constant, you can specify a constant nominal sample size n with the LIMITN= option or the variable _LIMITN_ in a LIMITS= data set. In this case, only those subgroups with sample size n are analyzed unless you also specify the option ALLN. You can further specify the option NMARKERS to request special symbol markers for points corresponding to sample sizes not equal to n .

Two-Sided Cusum Schemes

If the cusum scheme is two-sided, the cumulative sum S_t plotted for the t th subgroup is

$$S_t = S_{t-1} + z_t$$

for $t=1, 2, \dots, n$. Here $S_0=0$, and the term z_t is calculated as

$$z_t = (\bar{X}_t - \mu_0)/(\sigma/\sqrt{n_t})$$

where \bar{X}_t is the t th subgroup average, and n_t is the t th subgroup sample size. If the subgroup samples consist of individual measurements x_t , the term z_t simplifies to

$$z_t = (x_t - \mu_0)/\sigma$$

Since the first equation can be rewritten as

$$S_t = \sum_{i=1}^t z_i = \sum_{i=1}^t (\bar{X}_i - \mu_0) / \sigma_{\bar{X}_i}$$

the sequence S_t cumulates standardized deviations of the subgroup averages from the target mean μ_0 .

In many applications, the subgroup sample sizes n_i are constant ($n_i = n$), and the equation for S_t can be simplified.

$$S_t = (1/\sigma_{\bar{X}}) \sum_{i=1}^t (\bar{X}_i - \mu_0) = (\sqrt{n}/\sigma) \sum_{i=1}^t (\bar{X}_i - \mu_0)$$

In some applications, it may be preferable to compute S_t as

$$S_t = \sum_{i=1}^t (\bar{X}_i - \mu_0)$$

which is scaled in the same units as the data. Refer to Montgomery (1996), Wadsworth, Stephens, and Godfrey (1986), and American Society for Quality Control (1983). If the subgroup sample sizes are constant ($= n$) and if you specify the DATAUNITS option in the XCHART statement, the CUSUM procedure computes cusums using the final equation above. In this case, the procedure rescales the V-mask parameters h and k to $h' = h\sigma/\sqrt{n}$ and $k' = k\sigma/\sqrt{n}$, respectively. Wadsworth, Stephens, and Godfrey (1986) use the symbols F for k' and H for h' .

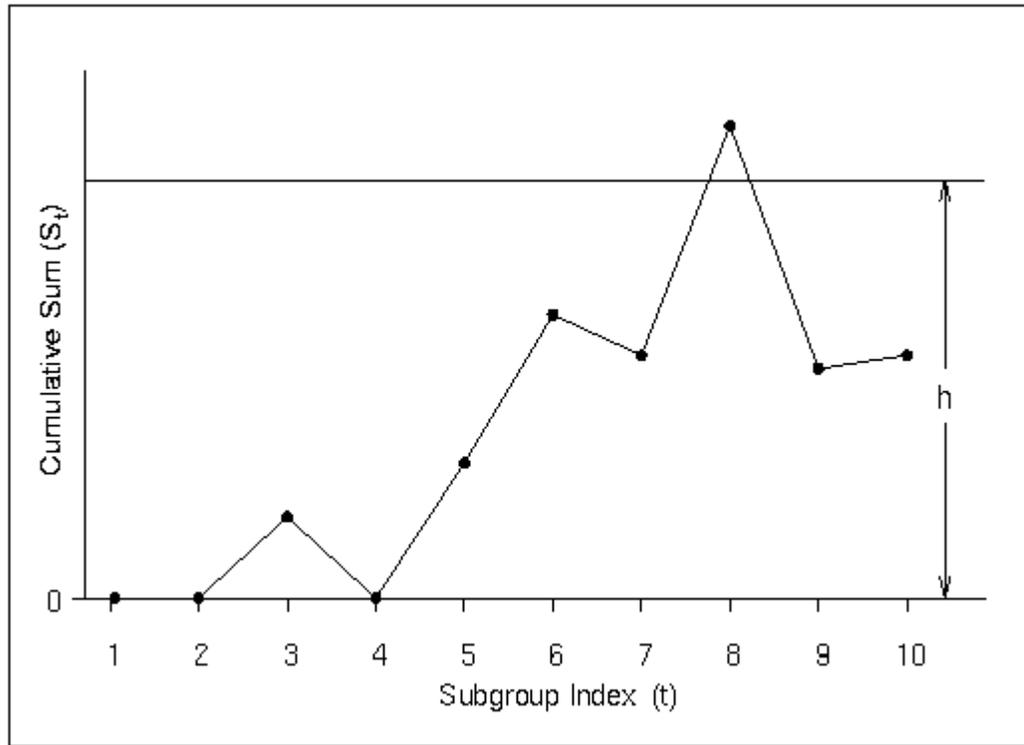

If the subgroup sample sizes are not constant, you can specify a constant nominal sample size n with the LIMITN= option or with the variable _LIMITN_ in a LIMITS= data set. In this case, only those subgroups with sample size n are analyzed unless you also specify the option ALLN. You can further specify the option NMARKERS to request special symbol markers for points corresponding to sample sizes not equal to n .

If the process is in control and the mean μ is at or near the target μ_0 , the points will not exhibit a trend since positive and negative displacements from μ_0 tend to cancel each other. If μ shifts in the positive direction, the points exhibit an upward trend, and if μ shifts in the negative direction, the points exhibit a downward trend.

Defining the Decision Interval for a One-Sided Cusum Scheme

The height of the decision interval is h , expressed as a multiple of the standard error of the subgroup mean. You can specify h with the H= option in the XCHART statement or with the variable _H_ in a LIMITS= data set. The decision interval is displayed as a horizontal line on the cusum chart, as illustrated in Figure 6.13.

Figure 6.13 Decision Interval

Interpreting One-Sided Cusum Charts

A shift or out-of-control condition is signaled at time t if the cusum S_t plotted at time t exceeds the decision interval line.

Defining the V-Mask for a Two-Sided Cusum Scheme

The dimensions of the V-mask can be specified using two distinct sets of two parameters.

- θ , defined as half of the angle formed by the V-mask arms, and d , the distance between the origin and the vertex, as shown in Figure 6.14. This parameterization is used by many authors, including Johnson and Leone (1962, 1974) and Montgomery (1996).
- h , the vertical distance between the origin and the upper (or lower) V-mask arm, and k , the rise (drop) in the lower (upper) arm corresponding to an interval of one subgroup unit on the horizontal axis. You can specify the definition of an interval with the INTERVAL= option. This parameterization is used by Lucas (1976) and Wadsworth, Stephens, and Godfrey (1986). Lucas (1976) uses the symbols h^* for h and k^* for k , and Wadsworth, Stephens, and Godfrey (1986) use the symbol f in place of k .

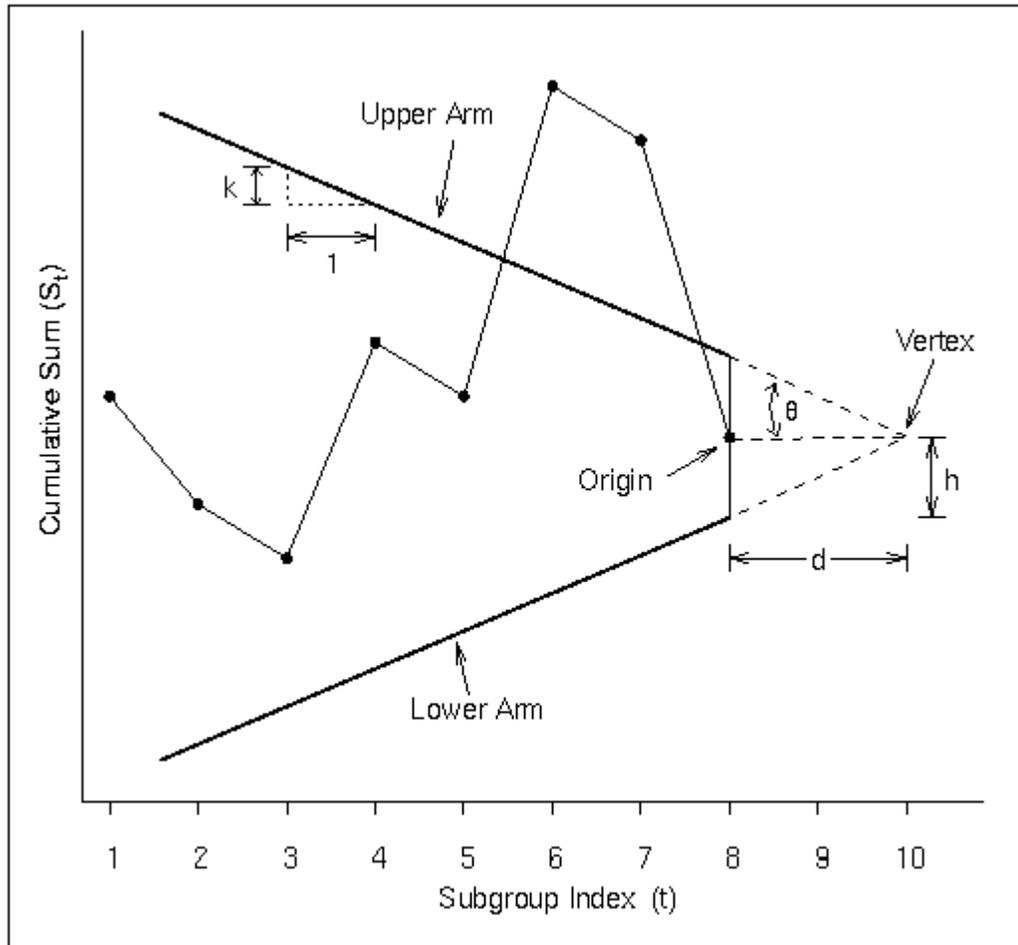

The two parameterizations are related by the equations

$$\theta = \arctan(k/a)$$

$$d = h/k$$

where the aspect ratio a is the number of units on the vertical axis corresponding to one unit on the horizontal axis. The CUSUM procedure uses the h and k parameterization because it eliminates the need for working with aspect ratios. Furthermore, h and k are also useful for average run length computations and for parameterizing one-sided cusum schemes.

Figure 6.14 V-Mask Parameters

You can specify the V-mask in two ways:

- geometrically, by providing h and k (or simply h) with the H= and K= options or with the variables `_H_` and `_K_` in a LIMITS= data set
- in terms of error probabilities, by providing α and β (or simply α) with the ALPHA= and BETA= options or with the variables `_ALPHA_` and `_BETA_` in a LIMITS= data set. The SIGMAS= option is an alternative to the ALPHA= option, and the variable `_SIGMAS_` is an alternative to the variable `_ALPHA_` (if the READSIGMAS option is specified).

If you provide α and β , h and k are computed using the formulas

$$h = |\delta|^{-1} \log((1 - \beta)/(\alpha/2))$$

$$k = |\delta|/2$$

If you provide α but not β , h and k are computed using the formulas

$$h = -|\delta|^{-1} \log(\alpha/2)$$

$$k = |\delta|/2$$

In the preceding equations, the error probability α is divided by two because two-sided deviations from the target mean are detected. Refer to Johnson and Leone (1962, 1974).

Interpreting Two-Sided Cusum Charts

The origin of the V-mask is located at the most recently plotted point, as illustrated in Figure 6.14. As additional data are collected and the cumulative sum sequence is updated, the origin is relocated at the newest point. A shift or out-of-control condition is signaled at time t if one or more of the points plotted up to time t cross an arm of the V-mask. An upward shift is signaled by points crossing the lower arm, and a downward shift is signaled by points crossing the upper arm. The time at which the shift occurred corresponds to the time at which a distinct change is observed in the slope of the plotted points.

Designing a Cusum Scheme

There are three main methods for designing a cusum scheme: the *average run length (ARL) approach*, the *error probability approach*, and the *economic design approach*.

Average Run Length (ARL) Approach

With the ARL approach, the parameters h and k are chosen to yield desired average run lengths when the process is operating at the target mean and when a shift of magnitude δ has occurred. The average run length is the expected number of samples taken before an out-of-control condition is signaled. Ideally, the ARL should be long when $\mu = \mu_0$ and short when μ shifts away from μ_0 .

The ARL method typically involves the use of a table or nomogram. Refer to Kemp (1961), van Dobben de Bruyn (1968), Goel and Wu (1971), Duncan (1974), Lucas (1976), Montgomery (1996), and Wadsworth, Stephens, and Godfrey (1986).

For one-sided charts, average run lengths are tabulated as a function of h , k , and δ in Table 6.4. No headstart is assumed in this table. For two-sided charts, average run lengths are tabulated as a function of h , k , and δ in Table 6.5, which is formatted similarly to Table 2 given by Lucas (1976).

The ARLs in Table 6.4 and Table 6.5 were calculated with the DATA step function CUSUMARL (see the section “CUSUMARL Function” on page 2266). This function uses the method of Goel and Wu (1971). You can use this function to generate more detailed, interpolated versions of the tables or to compute ARLs with headstart values.

It can be shown that the two-sided (V-mask) cusum scheme parameterized by h and k is equivalent to two simultaneously operating one-sided cusum schemes, one that computes an upper cusum and one that computes a lower cusum. Both one-sided schemes use the same parameters h and k .

You can specify h , k , and δ with the options H=, K=, and DELTA= or with the variables _H_, _K_, and _DELTA_ in a LIMITS= data set. The reference value k is optional, and its default value is $k = |\delta|/2$, referred to as the *central reference value*.

Error Probability Approach

This approach is available only for two-sided cusum schemes. Values of α (the probability of incorrectly signaling the occurrence of a shift) and β (the probability of failing to detect a shift) are specified, and h and k are computed from α and β as described in “Defining the V-Mask for a Two-Sided Cusum Scheme” on page 608. The error probability approach interprets the cusum as a sequence of reversed sequential probability ratio tests. Refer to Johnson (1961), Johnson and Leone (1962, 1974), van Dobben de Bruyn (1968), Montgomery (1996), and Wadsworth, Stephens, and Godfrey (1986).

Although the error probability method is intuitively appealing, the actual error probabilities achieved may not be close to those specified since the V-mask does not provide for an acceptance region. This has been pointed out by various authors, including Johnson (1961) and van Dobben de Bruyn (1968). If you follow this approach, it is recommended that you examine the average run lengths for the cusum scheme (these are tabulated by the TABLESUMMARY option and are saved in OUTLIMITS= data sets).

You can specify α and β with the ALPHA= and BETA= options or with the variables _ALPHA_ and _BETA_ in a LIMITS= data set. It is not necessary to specify β , and the interpretation of β is somewhat questionable. The SIGMAS= option is an alternative to the ALPHA= option, and the variable _SIGMAS_ is an alternative to the variable _ALPHA_ (if you specify the READSIGMAS option).

Economic Design

The parameters n , h , and k are chosen so that the long-run average cost of the cusum scheme is minimized. Refer to Chiu (1974), Montgomery (1980), Svoboda (1991), and Ho and Case (1994) for reviews of the literature on economic design. This approach typically requires numerical optimization techniques, which are available in SAS/IML software and in the NLP procedure in SAS/OR software.

You can pass the optimal parameters to the CUSUM procedure as values of the variables _LIMITN_, _H_, and _K_ in a LIMITS= data set.

Table 6.4 Average Run Lengths for One-Sided V-Mask Cusum Charts as a Function of h , k , and δ .

Parameters		δ (shift in mean)

Cusum Charts Compared with Shewhart Charts

Although cusum charts and Shewhart charts are both used to detect shifts in the process mean, there are important differences in the two methods.

- Each point on a Shewhart chart is based on information for a single subgroup sample or measurement. Each point on a cusum chart is based on information from all samples (measurements) up to and including the current sample (measurement).
- On a Shewhart chart, upper and lower control limits are used to decide whether a point signals an out-of-control condition. On a cusum chart, the limits take the form of a decision interval or a V-mask.
- On a Shewhart chart, the control limits are commonly computed as 3σ limits. On a cusum chart, the limits are determined from average run length specifications, specified error probabilities, or an economic design.

A cusum chart offers several advantages over a Shewhart chart.

- A cusum chart is more efficient for detecting small shifts in the process mean, in particular, shifts of 0.5 to 2 standard deviations from the target mean (refer to Montgomery 1996). Lucas (1976) noted that “a V-mask designed to detect a 1σ shift will detect it about four times as fast as a competing Shewhart chart.”
- Shifts in the process mean are visually easy to detect on a cusum chart since they produce a change in the slope of the plotted points. The point at which the slope changes is the point at which the shift has occurred.

These advantages are not as pronounced if the Shewhart chart is augmented by the tests for special causes described by Nelson (1984, 1985). Also see “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146. Moreover,

- cusum schemes are more complicated to design.
- a cusum chart can be slower to detect large shifts in the process mean.
- it can be difficult to interpret point patterns on a cusum chart since the cusums are correlated.

Methods for Estimating the Standard Deviation

It is recommended practice to provide a stable estimate or standard value for σ with either the `SIGMA0=` option or the variable `_STDDEV_` in a `LIMITS=` data set. However, if such a value is not available, you can compute an estimate $\hat{\sigma}$ from the data, as described in this section.

This section provides formulas for various methods used to estimate the standard deviation σ . One method is applicable with individual measurements, and three are applicable with subgrouped data. The methods can be requested with the `SMETHOD=` option.

Method for Individual Measurements

When the cumulative sums are calculated from individual observations

$$x_1, x_2, \dots, x_N$$

rather than subgroup samples of two or more observations, the CUSUM procedure estimates σ as $\sqrt{\hat{\sigma}^2}$, where

$$\hat{\sigma}^2 = \frac{1}{2(N-1)} \sum_{i=1}^{N-1} (x_{i+1} - x_i)^2$$

where N is the number of observations. Wetherill (1977) states that the estimate of the variance is biased if the measurements are autocorrelated.

Note that you can compute alternative estimates (for instance, robust estimates or estimates based on variance components models) by analyzing the data with SAS modeling procedures or your own DATA step program. Such estimates can be passed to the CUSUM procedure as values of the variable `_STDDEV_` in a `LIMITS=` data set.

NOWEIGHT Method for Subgroup Samples

This method is the default for cusum charts for subgrouped data. The estimate is

$$\hat{\sigma} = \frac{(s_1/c_4(n_1)) + \dots + (s_N/c_4(n_N))}{N}$$

where n_i is the sample size of the i th subgroup, N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the observations x_{i1}, \dots, x_{in_i} in the i th subgroup.

$$s_i = \sqrt{(1/(n_i - 1)) \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2) \sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

where $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, then the expected value of s_i is

$$E(s_i) = c_4(n_i)\sigma$$

Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the *ASTM Manual on Presentation of Data and Control Chart Analysis*.

MVLUE Method for Subgroup Samples

If you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed, as introduced by Burr (1969, 1976). This estimate is a weighted average of unbiased estimates of σ of the form

$$s_i/c_4(n_i)$$

where

- s_i is the standard deviation of the i th subgroup.
- $c_4(n_i)$ is the unbiasing factor defined previously.
- n_i is the i th subgroup sample size, $i = 1, 2, \dots, N$.
- N is the number of subgroups for which $n_i \geq 2$.

The estimate is

$$\hat{\sigma} = \frac{h_1 s_1 / c_4(n_1) + \dots + h_N s_N / c_4(n_N)}{h_1 + \dots + h_N}$$

where $h_i = c_4^2(n_i) / (1 - c_4^2(n_i))$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$.

The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes and is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate (NOWEIGHT).

RMSDF Method for Subgroup Samples

If you specify SMETHOD=RMSDF, a weighted root-mean-square estimate is computed:

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \dots + (n_N - 1)s_N^2}}{c_4(n) \sqrt{n_1 + \dots + n_N - N}}$$

where

- n_i is the sample size of the i th subgroup.
- N is the number of subgroups for which $n_i \geq 2$.
- s_i is the sample standard deviation of the i th subgroup.
- $c_4(n_i)$ is the unbiasing factor defined previously.
- n is equal to $(n_1 + \dots + n_N) - (N - 1)$.

The weights in the root-mean-square expression are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, as noted by Burr (1969), “the constancy of σ is the very thing under test,” and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Output Data Sets

OUTLIMITS= Data Set

When you save the parameters for the cusum scheme in an OUTLIMITS= data set, the following variables are included:

Table 6.6 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of Type 1 error
ARLIN	average run length for zero shift
ARLOUT	average run length for shift of δ
BETA	probability (β) of Type 2 error
DELTA	shift (δ) to be detected
H	decision interval h for one-sided scheme; distance h between origin and upper arm V-mask for two-sided scheme
HSTART	headstart value
INDEX	optional identifier for cusum parameters (if the OUTINDEX= option is specified)
K	reference value k for one-sided scheme; slope of lower V-mask arm for two-sided scheme
LIMITN	nominal sample size for cusum scheme
MEAN	estimated process mean ($\bar{\bar{X}}$)
MU0	target mean μ_0
ORIGIN	origin of V-mask
SCHEME	type of scheme ('ONESIDED' or 'TWO SIDED')
SIGMAS	$z_{1-\alpha/2}$
STDDEV	estimated or known standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	<i>subgroup-variable</i> specified in XCHART statement
TYPE	type ('ESTIMATE' or 'STANDARD') of _STDDEV_
VAR	<i>process</i> specified in XCHART statement

Notes:

1. If the subgroup sample sizes vary, the special missing value V is assigned to the variable _LIMITN_.
2. If a V-mask is specified with SIGMAS= k , _ALPHA_ is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.
3. If a V-mask is specified with ALPHA= α , _SIGMAS_ is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.
4. BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the XCHART statement. For an example, see “Saving Cusum Scheme Parameters” on page 584.

OUTHISTORY= Data Set

When you save subgroup summary statistics in an OUTHISTORY= data set, the following variables are included:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup sample size variable named by *process* suffixed with *N*
- a subgroup standard deviation variable named by *process* suffixed with *S*
- a cusum variable named by *process* suffixed with *C*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Variables containing subgroup summary statistics are created for each *process* specified in the XCHART statement. For example, consider the following statements:

```
proc cusum data=Steel limits=Stparm;
  xchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary would contain nine variables named Lot, WidthX, WidthS, WidthN, WidthC, DiameterX, DiameterS, DiameterN, and DiameterC.

Additionally, if specified, the following variables are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example creating an OUTHISTORY= data set, see “Saving Summary Statistics” on page 579.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup means, subgroup sample sizes, cusums, and cusum limits. The following variables are included:

Variable	Description
<code>_CUSUM_</code>	cumulative sum
<code>_EXLIM_</code>	decision interval or V-mask arm exceeded
<code>_H_</code>	decision interval
<code>_MASKL_</code>	lower arm of V-mask
<code>_MASKU_</code>	upper arm of V-mask
<i>subgroup</i>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBX_</code>	subgroup mean
<code>_SUBS_</code>	subgroup standard deviation
<code>_VAR_</code>	<i>process</i> specified in XCHART statement

In addition, the following variables are saved if specified:

- BY variables
- *block-variables*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)
- `_TREND_` (if the TRENDVAR= option is specified)
- *symbol-variable*

Note that the variables `_VAR_` and `_EXLIM_` are character variables of length eight. The variable `_PHASE_` is a character variable of length 16.

ODS Tables

The following table summarizes the ODS tables that you can request with the XCHART statement.

Table 6.7 ODS Tables Produced with the XCHART Statement

Table Name	Description	Options
CompCusum	computational form of the cusum scheme	TABLEALL, TABLECOMP
Parameters	cusum parameters and computed average run lengths	TABLEALL, TABLESUMMARY
XCHART	cusum chart summary statistics	TABLEALL, TABLECHART, TABLEOUT

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s*

Guide). **NOTE:** In SAS/QC 12.1 the CUSUM procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. XCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the XCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 6.8](#).

Table 6.8 ODS Graphics Produced by the XCHART Statement

ODS Graph Name	Plot Description
XChart	cusum chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (measurements) from a DATA= data set specified in the PROC CUSUM statement. Each *process* specified in the XCHART statement must be a SAS variable in the DATA= data set. The values of this variable are typically measurements of a quality characteristic taken on items in subgroup samples indexed by the values of the subgroup variable. The *subgroup-variable* specified in the XCHART statement must also be a SAS variable in the DATA= data set. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

Each observation in a DATA= data set should contain a raw measurement for each *process* and a value for the subgroup variable. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the subgroup variable is the index of the *i*th subgroup. For example, if each of 30 subgroup samples contains five items, the DATA= data set should contain 150 observations.

By default, the CUSUM procedure reads all of the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the `READPHASES=` option in the XCHART statement.

For an example of a DATA= data set, see “Creating a V-Mask Cusum Chart from Raw Data” on page 574.

LIMITS= Data Set

You can read cusum scheme parameters from a LIMITS= data set specified in the PROC CUSUM statement.⁵ As an alternative to specifying the parameters with options, a LIMITS= data set provides the following advantages: it facilitates reusing a permanently saved set of parameters, reading a distinct set of parameters for each *process* specified in the XCHART statement, and keeping track of multiple sets of parameters for the same *process* over time.

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the CUSUM procedure. Such data sets always contain the variables required for a LIMITS= data set; consequently, this is the easiest way to construct a LIMITS= data set.

A LIMITS= data set can also be created directly using a DATA step. The variables required for the data set depend on the type of cusum scheme and how the scheme is specified. The following restrictions apply:

- The variables `_VAR_`, `_SUBGRP_`, `_DELTA_`, and `_MU0_` are required.
- For a one-sided cusum scheme, `_H_` is required.
- For a two-sided cusum scheme, one of the following three variables is required: `_ALPHA_`, `_H_`, or `_SIGMAS_`.
- If you plan to use the `READINDEX=` option, the variable `_INDEX_` is required; otherwise, it is optional.
- For a one-sided scheme, the variable `_SCHEME_` is required; otherwise, it is optional.
- If you want to provide a value for the process standard deviation σ , the variable `_STDDEV_` is required; otherwise, it is optional.

Variable names in a LIMITS= data set are predefined; the procedure reads only variables with these predefined names. With the exception of BY variables, all names start and end with an underscore. In addition, note the following:

- The variables `_VAR_`, `_SUBGRP_`, `_TYPE_`, and `_SCHEME_` must be character variables of length eight. The variable `_INDEX_` must be a character variable of length 16.
- The variable `_TYPE_` is a bookkeeping variable that uses the values ‘ESTIMATE’ and ‘STANDARD’ to record whether the value of `_STDDEV_` represents an estimate or standard (known) value.

⁵If you are using SAS 6.09 or an earlier release, you must also specify the `READLIMITS` or `READINDEX=` option in the XCHART statement.

- BY variables are required if specified with a BY statement.

For an example of reading control limit information from a LIMITS= data set, see “[Reading Cusum Scheme Parameters](#)” on page 586.

HISTORY= Data Set

Instead of reading raw data from a DATA= data set, you can read subgroup summary statistics from a HISTORY= data set specified in the PROC CUSUM statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the CUSUM, MACONTROL, or SHEWHART procedures or to read output data sets created with SAS summarization procedures such as PROC MEANS. A HISTORY= data set must contain the following variables:

- *subgroup-variable*
- subgroup mean variable for each *process*
- subgroup standard deviation variable for each *process*
- subgroup sample size variable for each *process*

The names of the subgroup mean, subgroup standard deviation, and subgroup sample size variables must be the *process* concatenated with the special suffix characters *X*, *S*, and *N* respectively.

For example, consider the following statements:

```
proc cusum history=Steel limits=Steelparm;
  xchart (Weight Yieldstrength)*Batch;
run;
```

The data set Steel must contain the variables Batch, WeightX, WeightS, WeightN, YieldstrengthX, YieldstrengthS, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the CUSUM procedure reads all of the observations in a HISTORY= data set. However, if the HISTORY= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as phases) by specifying the READPHASES= option.

For an example of reading summary information from a HISTORY= data set, see “[Creating a V-Mask Cusum Chart from Subgroup Summary Data](#)” on page 577.

Missing Values

An observation read from a DATA= or HISTORY= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: XCHART Statement

This section provides advanced examples of the XCHART statement.

Example 6.1: Cusum and Standard Deviation Charts

When you are working with subgrouped data, it can be helpful to accompany a cusum chart for means with a Shewhart s chart for monitoring the variability of the process. This example creates this combination for the variable Weight in the data set Oil (see “Creating a V-Mask Cusum Chart from Raw Data” on page 574). *See CUSXS in the SAS/QC Sample Library*

The first step is to create a one-sided cusum chart for means that detects a shift of one standard error ($\delta = -1$) below the target mean.

```
proc cusum data=Oil;
  xchart Weight*Hour /
  nochart
  mu0=8.100          /* target mean for process */
  sigma0=0.050       /* known standard deviation */
  delta=-1           /* shift to be detected */
  h=3                /* cusum parameter h */
  k=0.5              /* cusum parameter k */
  scheme=onesided
  outtable = Tabcusum
    ( drop = _var_ _subn_ _subx_ _exlim_
      rename = ( _cusum_ = _subx_ _h_ = _uclx_ ) )
  ;
run;
```

The results are saved in an OUTTABLE= data set named Tabcusum. The cusum variable (`_CUSUM_`) and the decision interval variable (`_H_`) are renamed to `_SUBX_` and `_LCLX_` so that they can later be read by the SHEWHART procedure.

The next step is to construct a Shewhart \bar{X} and s chart for Weight and save the results in a data set named Tabxscht.

```
proc shewhart data=Oil;
  xschart Weight*Hour /
  nochart
  outtable = Tabxscht
    ( drop = _subx_ _uclx_ );
run;
```

Note that the variables `_SUBX_` and `_UCLX_` are dropped from `Tabxscht`.

The third step is to merge the data sets `Tabcusum` and `Tabxscht`.

```
data taball;
  merge Tabxscht Tabcusum; by Hour;
  _mean_ = _uclx_ * 0.5;
  _lclx_ = 0.0;
run;
```

The variable `_LCLX_` is assigned the role of the lower limit for the cusums, and the variable `_MEAN_` is assigned a dummy value. Now, `TABALL`, which is listed in [Output 6.1.1](#), has the structure required for a `TABLE=` data set used with the `XSCHART` statement in the `SHEWHART` procedure (see “`TABLE=` Data Set” on page 1988).

Output 6.1.1 Listing of the Data Set `TABALL`

		S	L			S				E				
		I	I			T	E			X				
		G	M	S	L	M	D	X	L	S	U	L	s	u

1	Weight	1	3	4	4	0	1.5	0.05	0	0.059640	0.049943	0.11317	0.00	3
2	Weight	2	3	4	4	0	1.5	0.05	0	0.090220	0.049943	0.11317	0.00	3
3	Weight	3	3	4	4	0	1.5	0.05	0	0.076346	0.049943	0.11317	0.00	3
4	Weight	4	3	4	4	0	1.5	0.05	0	0.025552	0.049943	0.11317	0.00	3
5	Weight	5	3	4	4	0	1.5	0.05	0	0.026500	0.049943	0.11317	0.00	3
6	Weight	6	3	4	4	0	1.5	0.05	0	0.075617	0.049943	0.11317	0.30	3
7	Weight	7	3	4	4	0	1.5	0.05	0	0.037242	0.049943	0.11317	0.00	3
8	Weight	8	3	4	4	0	1.5	0.05	0	0.059290	0.049943	0.11317	0.18	3
9	Weight	9	3	4	4	0	1.5	0.05	0	0.005737	0.049943	0.11317	1.21	3
10	Weight	10	3	4	4	0	1.5	0.05	0	0.046522	0.049943	0.11317	0.62	3
11	Weight	11	3	4	4	0	1.5	0.05	0	0.040542	0.049943	0.11317	0.00	3
12	Weight	12	3	4	4	0	1.5	0.05	0	0.056103	0.049943	0.11317	0.00	3

The final step is to use the `SHEWHART` procedure to read `TABALL` as a `TABLE=` data set and to display the cusum and `s` charts.

```
ods graphics off;
symbol v=dot color=salmon h=1.8 pct;
title 'Cusum Chart for Mean and s chart';
proc shewhart table=taball;
  xschart Weight * Hour /
    nolimitslegend
    ucllabel = 'h=3.0'
    noctl
    split = '/'
    nolegend ;
  label _subx_ = 'Lower Cusum/Std Dev';
run;
```

The central line for the primary (cusum) chart is suppressed with the NOCTL option, and the default 3σ Limits legend is suppressed with the NOLIMITLEGEND option. The charts are shown in Output 6.1.2.

Output 6.1.2 Combined Cusum Chart and s Chart

The process variability is stable, and there is no signal of a downward shift in the process mean.

Example 6.2: Upper and Lower One-Sided Cusum Charts

This example illustrates how to combine upper and lower one-sided cusum charts for means in the same display. As in the preceding example, OUTTABLE= data sets are created with the CUSUM procedure, and the display is created with the SHEWHART procedure. *See CUSUPLO in the SAS/QC Sample Library*

The following statements analyze the variable Weight in the data set Oil (see “Creating a V-Mask Cusum Chart from Raw Data” on page 574). The first step is to compute and save upper and lower one-sided cusums for shifts of one standard error in the positive and negative directions.

```

proc cusum data=Oil;
  xchart Weight*Hour /
    nochart
    mu0=8.100      /* target mean for process */
    sigma0=0.050  /* known standard deviation */
    delta=1        /* shift to be detected   */
    h=3            /* cusum parameter h           */
    k=0.5          /* cusum parameter k           */
    scheme=onesided
    outtable = tabupper
      ( drop   = _subx_ _subs_ _exlim_
        rename = ( _cusum_ = _subx_ _h_ = _uclx_ ) )
  ;
  xchart Weight*Hour /
    nochart
    mu0=8.100      /* target mean for process */
    sigma0=0.050  /* known standard deviation */
    delta=-1       /* shift to be detected   */
    h=3            /* cusum parameter h           */
    k=0.5          /* cusum parameter k           */
    scheme=onesided
    outtable = tablower
      ( drop   = _var_ _subn_ _subx_ _subs_ _exlim_
        rename = ( _cusum_ = _subs_ _h_ = _ucls_ ) )
  ;
run;

```

Next, the OUTTABLE= data sets are merged.

```

data Tabboth;
  merge tabupper tablower; by Hour;
  _mean_ = _uclx_ * 0.5;
  _s_    = _ucls_ * 0.5;
  _lclx_ = 0.0;
  _lcls_ = 0.0;
run;

```

The variables `_LCLX_` and `_UCLX_` are assigned lower limits of zero for the cusums, and the variables `_MEAN_` and `_S_` are assigned dummy values. Now, `Tabboth` has the structure required for a `TABLE=` data set used with the `XSCHART` statement in the `SHEWHART` procedure (see “[TABLE= Data Set](#)” on page 1988).

The final step is to read `Tabboth` as a `TABLE=` data set with the `SHEWHART` procedure.

```

title 'Upper and Lower Cusums';
proc shewhart table=Tabboth;
  xschart Weight * Hour /
    nolimitslegend
    ucllabel = 'h=3.0'
    ucllabel2 = 'h=3.0'
    ypct1    = 50
    vref     = 1 2
    vref2    = 1 2
    noct1

```

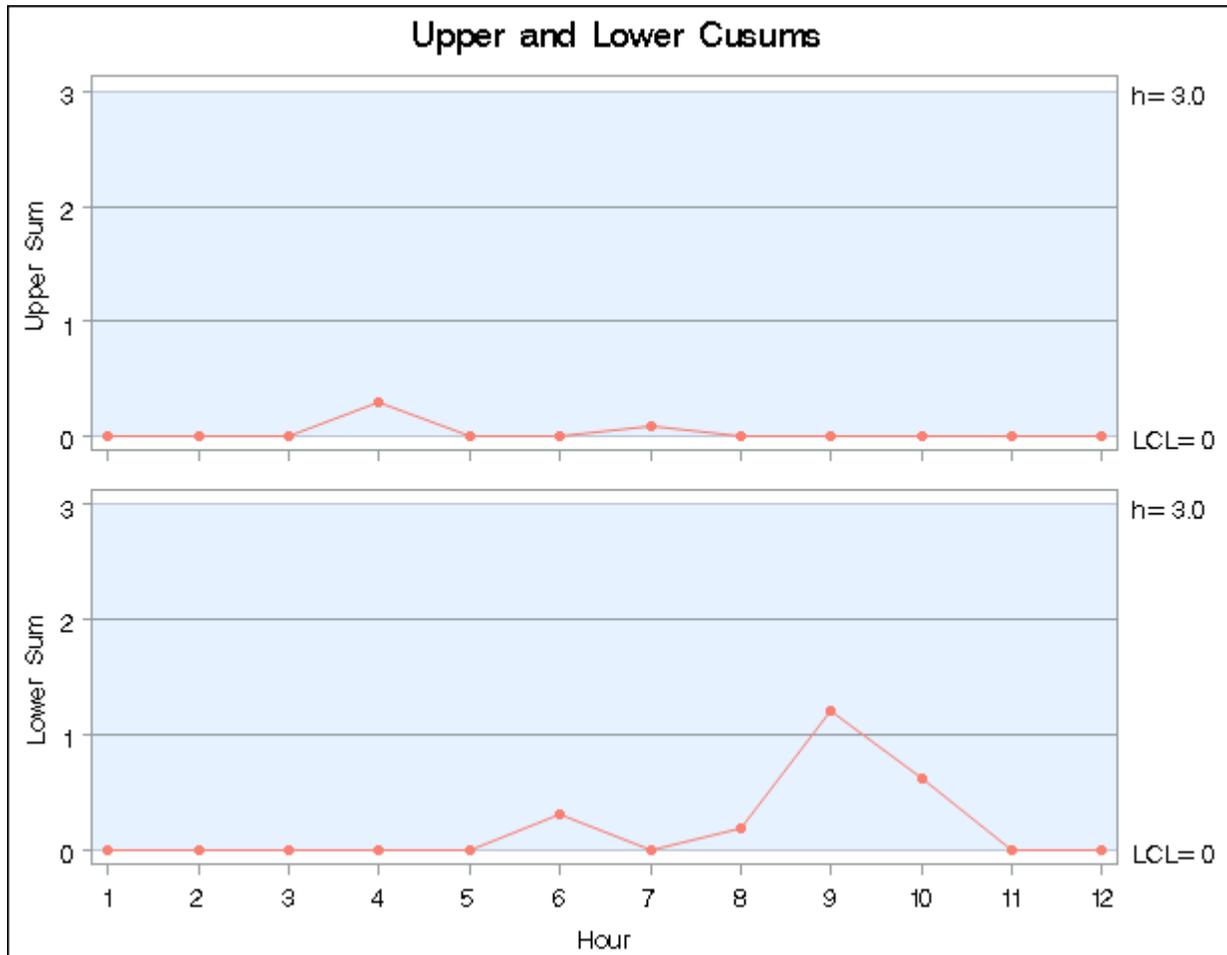

```

noct12
split = '/'
nolegend ;
label _subx_ = 'Upper Sum/Lower Sum';
run;

```

The combined display is shown in [Output 6.2.1](#). There is no evidence of a shift in either direction.

Output 6.2.1 Upper and Lower One-Sided Cusum Charts

Example 6.3: Combined Shewhart–Cusum Scheme

Lucas and Crosier (1982) introduced a combined Shewhart-cusum scheme that is illustrated in this example. Also refer to Ryan (1989). The data set used here is Cans, which is created in “[Creating a One-Sided Cusum Chart with a Decision Interval](#)” on page 580. *See CUSCOMB in the SAS/QC Sample Library*

The first step is to compute and save one-sided cusums to detect a positive shift from the mean.

```

proc cusum data=Cans;
  xchart Weight*Hour /
  nochart
  mu0 = 8.100 /* target mean for process */

```

```

sigma0 = 0.050      /* known standard deviation */
delta  = 1          /* shift to be detected      */
h      = 3          /* cusum parameter h          */
k      = 0.5        /* cusum parameter k          */
scheme = onesided
outtable = Tabcus
      ( drop   = _var_ _subn_ _exlim_
        rename = ( _cusum_ = _subr_ _h_ = _uclr_ ) )
;
run;

```

Note that a headstart value is not used here but can be specified with the HSTART= option. Several variables in the OUTTABLE= data set are dropped or renamed so that they can later be read by the SHEWHART procedure.

The next step is to construct a Shewhart chart (not shown) for individual measurements.

```

proc shewhart data=Cans;
  irchart Weight*Hour /
    nochart
    mu0      = 8.100
    sigma0   = 0.050
    outtable = Tabx
      ( drop   = _subr_ _lclr_ _r_ _uclr_ );
  id comment;
run;

```

By default, 3σ limits are computed, but the multiple of σ can be modified with the SIGMAS= option. As before, the results are saved in an OUTTABLE= data set.

Next, the two OUTTABLE= data sets are merged.

```

data Combine;
  merge Tabx Tabcus; by Hour;
  _lclr_ = 0.0;
  _r_    = 0.5 * _uclr_;
run;

```

The data set Combine has the structure required for a TABLE= data set used with the IRCHART statement in the SHEWHART procedure (see the section “TABLE= Data Set” on page 1560).

Finally, the combined scheme is displayed with the SHEWHART procedure.

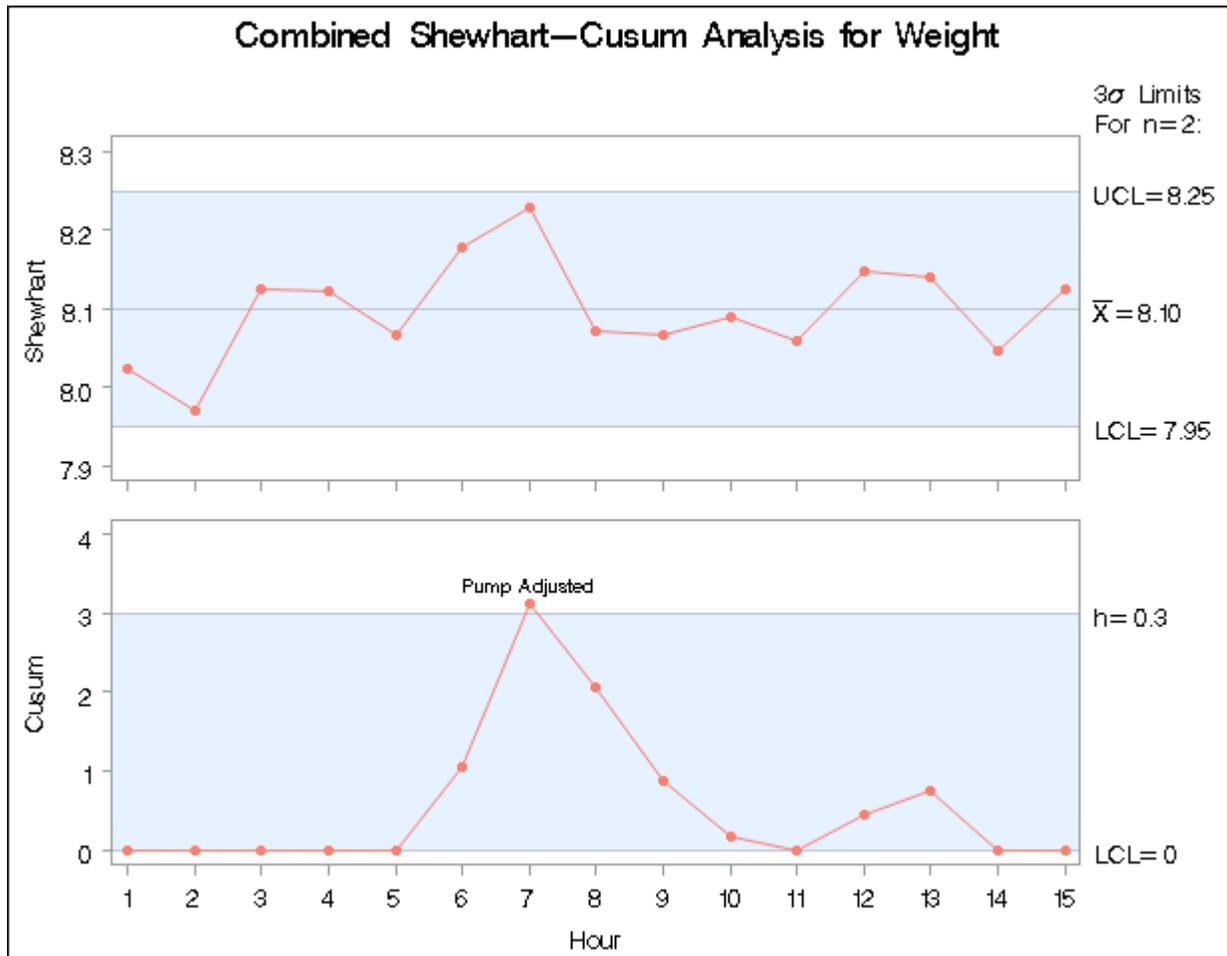

```

title "Combined Shewhart-Cusum Analysis for Weight";
proc shewhart table=Combine;
  irchart Weight*Hour /
    ypct1      = 50
    noctl2
    ucllabel2  = 'h=0.3'
    outlabel   = ( comment )
    outlabel2  = ( comment )
    split      = '/';
  label _subi_ = 'Shewhart/Cusum';
run;

```

The chart is shown in [Output 6.3.1](#).

Output 6.3.1 Combined Shewhart–Cusum Scheme

Note that a shift is detected by the cusum scheme but not by the Shewhart chart. The point exceeding the decision interval is labeled with the variable comment created in the data set Cans.

Lucas and Crosier (1982) tabulates average run lengths for combined Shewhart-cusum schemes. The scheme used here has an ARL of 111.1 for $\delta = 0$ and an ARL of 6.322 for $\delta = 1$.

INSET Statement: CUSUM Procedure

Overview: INSET Statement

The INSET statement enables you to enhance a cusum chart by adding a box or table (referred to as an *inset*) of summary statistics directly to the graph. A possible application of an inset is to present cusum parameters on the chart rather than displaying them in a legend. An inset can also display arbitrary values provided in a SAS data set.

Note that the INSET statement by itself does not produce a display but must be used in conjunction with an XCHART statement. Insets are not available with line printer charts, so the INSET statement is not applicable when the LINEPRINTER option is specified in the PROC CUSUM statement.

You can use options in the INSET statement to do the following:

- specify the position of the inset
- specify a header for the inset table
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

Getting Started: INSET Statement

This section introduces the INSET statement with a basic example showing how it is used. See the section “INSET and INSET2 Statements: SHEWHART Procedure” on page 2000 in Chapter 17, “The SHEWHART Procedure,” for a complete description of the INSET statement.

This example is based on the same scenario as the first example in the “Getting Started” subsection of “XCHART Statement: CUSUM Procedure” on page 573. A machine fills cans with oil additive and a two-sided cusum chart is used to detect shifts from the target mean of 8.100 ounces. The following statements create the data set Oil and request a two-sided cusum chart with an inset:

```
data Oil;
  label Hour = 'Hour';
  input Hour @;
  do i=1 to 4;
    input Weight @;
    output;
  end;
  drop i;
  datalines;
1  8.024  8.135  8.151  8.065
2  7.971  8.165  8.077  8.157
3  8.125  8.031  8.198  8.050
4  8.123  8.107  8.154  8.095
5  8.068  8.093  8.116  8.128
6  8.177  8.011  8.102  8.030
7  8.129  8.060  8.125  8.144
8  8.072  8.010  8.097  8.153
9  8.066  8.067  8.055  8.059
10 8.089  8.064  8.170  8.086
11 8.058  8.098  8.114  8.156
12 8.147  8.116  8.116  8.018
;
```

```

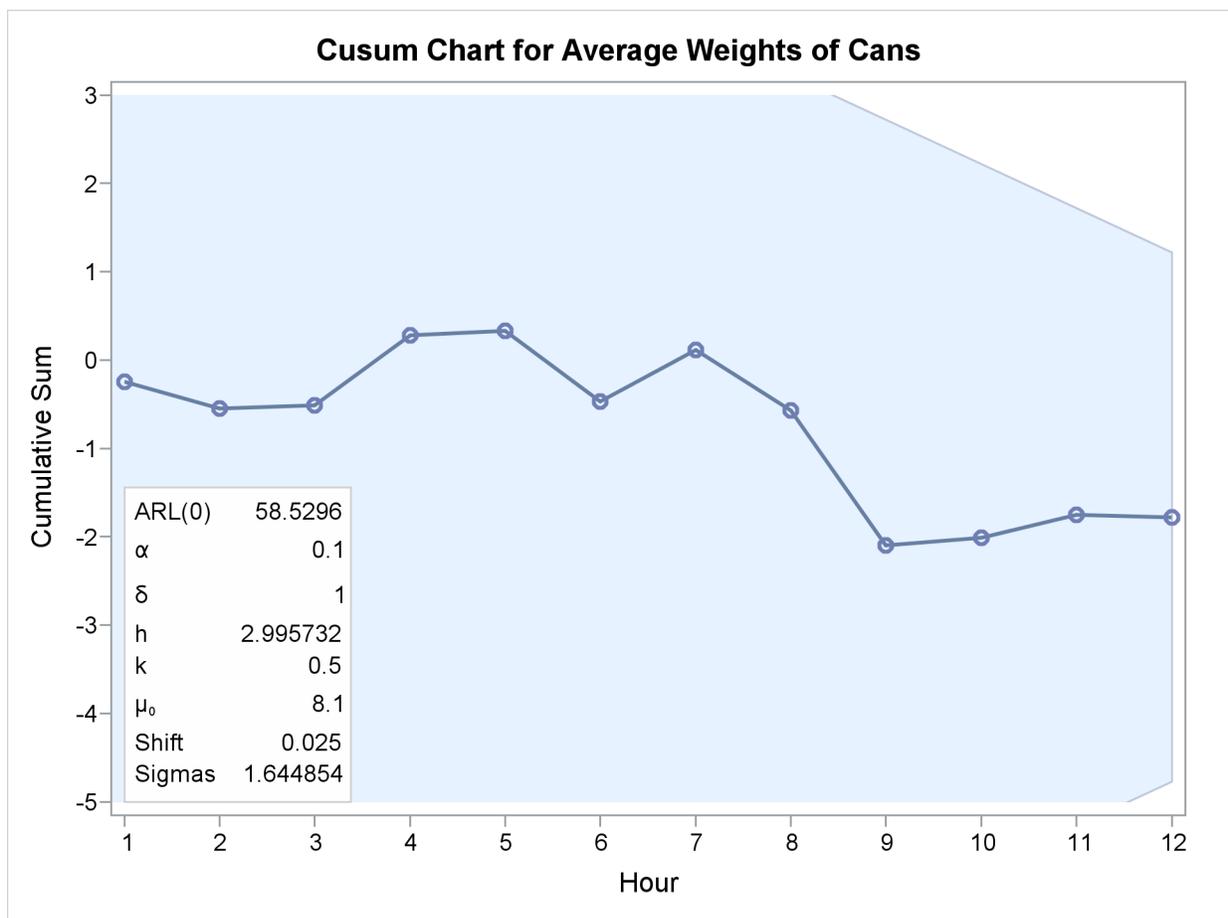

title 'Cusum Chart for Average Weights of Cans';
ods graphics on;
proc cusum data=Oil;
  xchart Weight*Hour /
    mu0      = 8.100          /* Target mean for process */
    sigma0   = 0.050         /* Known standard deviation */
    delta    = 1              /* Shift to be detected     */
    alpha    = 0.10          /* Type I error probability */
    vaxis    = -5 to 3
    odstitle = title
    markers
    nolegend;
  label Weight = 'Cumulative Sum';
  inset arl0 ualpha udelta h k umu0 shift sigmas / pos = sw;
run;

```

The ODS GRAPHICS ON statement specified before the PROC CUSUM statement enables ODS Graphics, so the cusum chart is created using ODS Graphics instead of traditional graphics.

The resulting cusum chart is shown in [Figure 6.3.2](#).

Output 6.3.2 Two-Sided Cusum Chart with an Inset

Syntax: INSET Statement

The syntax for the INSET statement is as follows:

```
INSET keyword-list </ options > ;
```

You can use any number of INSET statements in the CUSUM procedure. Each INSET statement produces a separate inset and must follow an XCHART statement. The inset appears on every panel (page) produced by the last XCHART statement preceding it.

Keywords specify the statistics to be displayed in an inset; options control the inset's location and appearance. A complete description of the INSET statement syntax is given in the section “Syntax: INSET and INSET2 Statements” on page 2006 of Chapter 17, “The SHEWHART Procedure.” The INSET statement options are identical in the CUSUM and SHEWHART procedures, but the available keywords are different. The options are listed in Table 17.87. The keywords available with the CUSUM procedure are listed in Table 6.9 to Table 6.12.

Table 6.9 Summary Statistics

Keyword	Description
ARL0	average run length for zero shift
ARLDELTA	average run length for shift of δ
DATA=	arbitrary values from <i>SAS-data-set</i>
N	nominal subgroup size
NMIN	minimum subgroup size
NMAX	maximum subgroup size

Table 6.10 Parameters for One-Sided (Decision Interval) Cusum Scheme

Keyword	Description
DELTA	shift to be detected as multiple of standard error
H	decision interval h as a multiple of standard error
HEADSTART	headstart value S_0 as a multiple of standard error
K	reference value k
MU0	target mean μ_0
SHIFT	shift to be detected in data units
STDDEV	estimated or specified process standard deviation

Table 6.11 Parameters for Two-Sided (V-Mask) Cusum Scheme

Keyword	Description
ALPHA	probability of Type 1 error
BETA	probability of Type 2 error
H	vertical distance between V-mask origin and upper (or lower) arm
K	slope of lower arm of V-mask
SIGMAS	probability of Type 1 error as probability that standard normally distributed variable exceeds a specified value in absolute value

You can use the keywords in Table 6.12 only when producing ODS Graphics output. The labels for the statistics use Greek letters.

Table 6.12 Keywords Specific to ODS Graphics Output

Keyword	Description
UALPHA	probability of Type 1 error
UARLDELTA	average run length for shift of δ
UBETA	probability of Type 2 error
UDELTA	shift to be detected as multiple of standard error
UMU0	target mean μ_0
USIGMA	estimated or specified process standard deviation

Introduction to the FACTEX Procedure

Overview

The FACTEX procedure constructs orthogonal factorial experimental designs. These designs can be either full or fractional factorial designs, and they can be with or without blocks. You can also construct designs for experiments with multiple stages, such as split-plot (Huang, Chen, and Voelkel 1998) and split-lot designs (Butler 2004). After you have constructed a design by using

the FACTEX procedure and run the experiment, you can analyze the results with a variety of SAS procedures including the GLM and REG procedures.

Factorial experiments are useful for studying the effects of various factors on a response. Texts that discuss experimental design include Box, Hunter, and Hunter (1978), Cochran and Cox (1957), Montgomery (1991), and Wu and Hamada (2000). For details about the general mathematical theory of orthogonal factorial designs, refer to Bose (1947).

NOTE: For two-level designs, instead of using PROC FACTEX directly, a more appropriate tool might be the ADX Interface for Design of Experiments. The ADX Interface is designed primarily for engineers and researchers who require a point-and-click solution for the entire experimental process, from building the designs through determining significant effects to optimization and reporting. ADX gives you most of the two-level designs provided by the FACTEX procedure in a system that integrates construction and analysis of designs, without the need for programming. In addition to two-level designs for standard models (with and without blocking), ADX makes it easy to use PROC FACTEX to construct designs for estimating particular effects of interest. Moreover, ADX also uses the OPTEX procedure to construct two-level designs of nonstandard sizes. For more information, see *Getting Started with the SAS ADX Interface for Design of Experiments*.

Features

There is no inherent limit to the number of factors and the size of the design that you can construct with the FACTEX procedure. Instead of looking up designs in an internal table, the FACTEX procedure uses a general algorithm to search for the construction rules for a specified design.

You can use the FACTEX procedure to generate designs such as the following:

- factorial designs, such as 2^3 designs, with and without blocking
- fractional factorial designs, such as 2_{IV}^{4-1} , with and without blocking
- split-plot and fractional split-plot designs
- three-level designs, with and without blocking
- mixed-level factorial designs, such as 4×3 designs, with and without blocking
- randomized complete block design
- factorial designs with outer arrays
- hyper-Graeco-Latin square designs

You can also create more complex designs, such as incomplete block designs, by using the FACTEX procedure in conjunction with the DATA step.

You can save the design constructed by the FACTEX procedure in a SAS data set. After you have run your experiment, you can add the values of the response variable and use the GLM procedure to perform analysis of variance and study significance of effects.

The FACTEX procedure is an interactive procedure. After specifying an initial design, you can submit additional statements without reinvoking the procedure. After you have constructed a design, you can do the following:

- print the design points
- examine the alias structure for the design
- modify the design by changing its size, changing the use of blocking, or specifying the effects of interest in the model again
- output the design to a data set
- examine the confounding rules that generate the design
- randomize the design
- replicate the design
- recode the design from standard values (such as ± 1) to values appropriate for your situation
- find another design

Learning about the FACTEX Procedure

To learn the basic syntax of the FACTEX procedure, read the section “Getting Started” on page 638, which contains some simple introductory examples. The summary tables in the section “Summary of Functions” on page 645 provide an overview of the syntax. The section “Summary of Designs” on page 647 shows simple ways to construct full factorial designs and fractional factorial designs. The section “Advanced Examples” on page 663 illustrates construction of complex designs.

Getting Started

The following introductory examples illustrate the capabilities of the FACTEX procedure. See the section “Advanced Examples” on page 663 for illustrations of complex features.

Example of a Two-Level Full Factorial Design

See FACTEXG1 in the SAS/QC Sample Library

This example introduces the basic syntax used with the FACTEX procedure.

An experimenter is interested in studying the effects of three factors—cutting speed (Speed), feed rate (FeedRate), and tool angle (Angle)—on the surface finish of a metallic part and decides to run a complete factorial experiment with two levels for each factor as follows:

Factor	Low Level	High Level
Cutting speed	300	500
Feed rate	20	30
Tool angle	6	8

This is a 2^3 factorial design—in other words, a complete factorial experiment with three factors, each at two levels. Hence there are eight runs in the experiment. Since complete factorial designs have full resolution, all of the main effects and interaction terms can be estimated. For a definition of the design resolution, see the section “Resolution” on page 706.

You can use the following statements to create the required design:

```
proc factex;
  factors Speed FeedRate Angle;
  examine design;
run;
```

These statements invoke the FACTEX procedure, list factor names, and display the generated design points. By default, the FACTEX procedure assumes that the size of the design is a full factorial and that each factor has only two levels.

After you submit the preceding statements, you see the following messages in the SAS log:

```
NOTE: No design size specified.
      Default is a full replicate in 8 runs.
NOTE: Design has 8 runs, full resolution.
```

The output is shown in [Figure 7.1](#). The two factor levels are represented by the coded values -1 and $+1$.

Figure 7.1 2^3 Factorial Design

The FACTEX Procedure				
Design Points				
Experiment Number	Speed	Feed Rate	Angle	
1	-1	-1	-1	
2	-1	-1	1	
3	-1	1	-1	
4	-1	1	1	
5	1	-1	-1	
6	1	-1	1	
7	1	1	-1	
8	1	1	1	

If you prefer to work with the actual (decoded) values of the factors, you can specify these values in an OUTPUT OUT= statement, as follows:

```
proc factex;
  factors Speed FeedRate Angle;
  output out=SavedDesign
    Speed    nvals=(300 500)
    FeedRate nvals=(20 30)
    Angle    nvals=(6 8);
run;
proc print;
run;
```

The OUTPUT statement in PROC FACTEX recodes the factor levels and saves the constructed design in the SavedDesign data set. Since the levels in this example are of numeric type, you use the NVALS= option to list the factor levels. Optionally, you can use the CVALS= option for levels of character type (see the section “[Example of a Full Factorial Design in Two Blocks](#)” on

page 640). The design is saved in a user-specified output data set (SavedDesign). This is verified by the following message in the SAS log:

**NOTE: The data set WORK.SAVEDDESIGN has 8 observations
and 3 variables.**

Figure 7.2 shows a listing of the data set SavedDesign.

Figure 7.2 2^3 Factorial Design after Decoding

Obs	Speed	Feed Rate	Angle
1	300	20	6
2	300	20	8
3	300	30	6
4	300	30	8
5	500	20	6
6	500	20	8
7	500	30	6
8	500	30	8

Although small complete factorial designs are not difficult to create manually, you can easily extend this example to construct a design with many factors.

Example of a Full Factorial Design in Two Blocks

See FACTEXG2 in the SAS/QC Sample Library The previous example illustrates a complete factorial experiment that involves eight runs and three factors: cutting speed (Speed), feed rate (FeedRate), and tool angle (Angle).

Now, suppose two machines (A and B) are used to complete the experiment, with four runs being performed on each machine. As there is the possibility that the machine affects the part finish, you should consider machine as a block factor and account for the block effect in assigning the runs to machines.

The following statements construct a blocked design:

```
proc factex;
  factors Speed FeedRate Angle;
  blocks nblocks=2;
  model resolution=max;
  examine design;
run;
```

The FACTORS statement in PROC FACTEX specifies three factors of a 2^3 factorial. The BLOCKS statement specifies that the number of blocks is 2. The RESOLUTION=MAX option in the MODEL statement specifies a design with the highest resolution—that is, the best design in a general sense. Optionally, if you know the resolution of the design, you can replace RESOLUTION=MAX with RESOLUTION= r , where r is the resolution number. For information about resolution, see the section “Resolution” on page 706.

By default, the FACTEX procedure assumes that the size of the design is a full factorial and that each factor is at two levels.

After you submit the preceding statements, you see the following messages in the SAS log:

```
NOTE: No design size specified.
      Default is a full replicate in 8 runs.
NOTE: Design has 8 runs in 2 blocks of size 4,
      resolution = 6.
```

The output is shown in Figure 7.3. Note that, by default, the name for the block variable is BLOCK and its levels are 1 and 2. Also, note that the default factor levels for a two-level design are -1 and 1.

Figure 7.3 2^3 Factorial Design in Two Blocks before Decoding

The FACTEX Procedure				
Design Points				
Experiment Number	Speed	Feed Rate	Angle	Block
1	-1	-1	-1	1
2	-1	-1	1	2
3	-1	1	-1	2
4	-1	1	1	1
5	1	-1	-1	2
6	1	-1	1	1
7	1	1	-1	1
8	1	1	1	2

You can rename the block variable and use actual levels for the block variable appropriate for your situation as follows:

```
proc factex;
  factors Speed FeedRate Angle;
  blocks nblocks=2;
  model resolution=max;
  output out=BlockDesign
    Speed    nvals=(300 500)
    FeedRate nvals=(20 30)
    Angle    nvals=(6 8)
    blockname=Machine cvals=('A' 'B');
run;

proc print;
run;
```

Figure 7.4 shows the listing of the design saved in the data set BlockDesign.

Figure 7.4 2^3 Factorial Design in Two Blocks after Decoding

Obs	Machine	Speed	Feed Rate	Angle
1	A	300	20	6
2	A	300	30	8
3	A	500	20	8
4	A	500	30	6
5	B	300	20	8
6	B	300	30	6
7	B	500	20	6
8	B	500	30	8

Example of a Half-Fraction Factorial Design

See *FACTEX3* in the *SAS/QC Sample Library* Often you do not have the resources for a full factorial design. In this case, a fractional factorial design is a reasonable alternative, provided that the effects of interest can be estimated.

Box, Hunter, and Hunter (1978) describe a fractional factorial design for studying a chemical reaction to determine what percentage of the chemicals responded in a reactor. The researchers identified the following five treatment factors that were thought to influence the percentage of reactant:

- the feed rate of the chemicals (FeedRate), ranging from 10 to 15 liters per minute
- the percentage of the catalyst (Catalyst), ranging from 1% to 2%
- the agitation rate of the reactor (AgitRate), ranging from 100 to 120 revolutions per minute
- the temperature (Temperature), ranging from 140 to 180 degrees Celsius
- the concentration (Concentration), ranging from 3% to 6%

The complete 2^5 factorial design requires 32 runs, but the experimenter can afford only 16 runs.

Suppose that all main effects and two-factor interactions are to be estimated. An appropriate design for this situation is a design of resolution 5 (denoted as 2^{5-1}_V), in which no main effect or two-factor interaction is aliased with any other main effect or two-factor interaction but in which two-factor interactions are aliased with three-factor interactions. This design loses the ability to estimate interactions between three or more factors, but this is usually not a serious loss. For more information about resolution, see the section “[Resolution](#)” on page 706.

You can use the following statements to construct a 16-run factorial design that has five factors and resolution 5:

```
proc factex;
  factors FeedRate Catalyst AgitRate Temperature Concentration;
  size design=16;
  model resolution=5;
  output out=Reaction FeedRate      nvals=(10 15)
                    Catalyst        nvals=(1 2)
                    AgitRate       nvals=(100 120)
```

```

Temperature  nvals=(140 180)
Concentration nvals=(3 6);

run;
proc print;
run;

```

The design saved in the Reaction data set is listed in [Figure 7.5](#).

Figure 7.5 Half-Fraction of a 2^5 Design for Reactors

Obs	Feed Rate	Catalyst	Agit Rate	Temperature	Concentration
1	10	1	100	140	6
2	10	1	100	180	3
3	10	1	120	140	3
4	10	1	120	180	6
5	10	2	100	140	3
6	10	2	100	180	6
7	10	2	120	140	6
8	10	2	120	180	3
9	15	1	100	140	3
10	15	1	100	180	6
11	15	1	120	140	6
12	15	1	120	180	3
13	15	2	100	140	6
14	15	2	100	180	3
15	15	2	120	140	3
16	15	2	120	180	6

The use of a half-fraction causes some interaction terms to be confounded with each other. You can use the EXAMINE statement with the ALIASING option to determine which interaction terms are aliased, as follows:

```

proc factex;
  factors FeedRate Catalyst AgitRate Temperature Concentration;
  size design=16;
  model resolution=5;
  examine aliasing;
run;

```

The alias structure summarizes the estimability of all main effects and two- and three-factor interactions. [Figure 7.6](#) indicates that each of the three-factor interactions is confounded with a two-factor interaction. Thus, if a particular three-factor interaction is believed to be significant, the aliased two-factor interaction cannot be estimated with this half-fraction design.

Figure 7.6 Alias Structure of Reactor Design

```

                                The FACTEX Procedure

Aliasing Structure

FeedRate
Catalyst
AgitRate
Temperature
Concentration
FeedRate*Catalyst = AgitRate*Temperature*Concentration
FeedRate*AgitRate = Catalyst*Temperature*Concentration
FeedRate*Temperature = Catalyst*AgitRate*Concentration
FeedRate*Concentration = Catalyst*AgitRate*Temperature
Catalyst*AgitRate = FeedRate*Temperature*Concentration
Catalyst*Temperature = FeedRate*AgitRate*Concentration
Catalyst*Concentration = FeedRate*AgitRate*Temperature
AgitRate*Temperature = FeedRate*Catalyst*Concentration
AgitRate*Concentration = FeedRate*Catalyst*Temperature
Temperature*Concentration = FeedRate*Catalyst*AgitRate

```

When you submit the preceding statements, the following message is displayed in the SAS log:

```
NOTE: Design has 16 runs, resolution = 5.
```

This message confirms that the design exists. If you specify a factorial design that does *not* exist, an error message is displayed in the SAS log. For instance, suppose that you replaced the MODEL statement in the preceding example with the following statement:

```
model resolution=6;
```

Since the maximum resolution of a 2^{5-1} design is 5, the following message appears in the SAS log:

```
ERROR: No such design exists.
```

In general, it is good practice to check the SAS log to see if a design exists.

Using the FACTEX Procedure Interactively

By using the FACTEX procedure interactively, you can quickly explore many design possibilities. The following steps provide one strategy for interactive use:

- 1 Invoke the procedure by using the PROC FACTEX statement, and use a FACTORS statement to identify factors in the design.
- 2 For a design that involves blocking, use the BLOCKS and MODEL statements. You might want to use the optimization features for the BLOCKS statement.
- 3 For a fractional replicate of a design, use the SIZE and MODEL statements to specify the characteristics of the design. If the design involves blocking, use a BLOCKS statement as well. If you are unsure of the size of the design or of the number of blocks, use the optimization features for either the BLOCKS or SIZE statement.

- 4 Enter a RUN statement and check the SAS log to see if the design exists. If a design exists, go on to the next step; otherwise, modify the characteristics given in the SIZE, BLOCKS, and MODEL statements.
- 5 Examine the alias structure of the design. If it is not appropriate for your situation, go back to step 2 and search for another design.
- 6 After you have repeated steps 2, 3, and 4 and found an acceptable design, use the OUTPUT statement to save the design. You can optionally recode factor values, recode and rename the block factor, and create new factors by using output-value settings.

Details of the FACTEX Procedure

Syntax

You can specify the following statements with the FACTEX procedure. Items within the brackets <> are optional.

```

PROC FACTEX < options > ;
  FACTORS factor-names < / option > ;
  SIZE size-specification ;
  MODEL model-specification < / < MINABS < (d) > > < MAXCLEAR < (d) > > > ;
  BLOCKS block-specification ;
  UNITEFFECT uniteffect / < WHOLE=() > < SUB=() > ;
  EXAMINE < options > ;
  OUTPUT OUT=SAS-data-set < options > ;
    
```

To generate a design and save it in a data set, you use at least the PROC FACTEX, FACTORS, and OUTPUT statements. The FACTORS statement should immediately follow the PROC FACTEX statement. You use the MODEL and SIZE statements for designs that are less than a full replicate (for example, fractional factorial designs). You can use the BLOCKS statement for designs that involve blocking. The EXAMINE statement can be used as needed.

Summary of Functions

Table 7.1 to Table 7.4 classify the statements and options in PROC FACTEX by function.

Table 7.1 Summary of Options for Specifying the Design

Function	Statement	Option
Factor Specification		
Factor names	FACTORS	$factor_1 \dots factor_f$
Number of levels	FACTORS	$factor_1 \dots factor_f / NLEV=q$
Design Size Specification (one of the following)		
Number of runs	SIZE	DESIGN= n

Table 7.1 continued

Function	Statement	Option
Fraction of one full replicate	SIZE	FRACTION= h
Number of <i>run indexing factors</i>	SIZE	NRUNFACS= m
Minimum number of runs	SIZE	DESIGN=MINIMUM or FRACTION=MAXIMUM or NRUNFACS=MINIMUM
Block Specification		
(one of the following)		
Number of blocks	BLOCKS	NBLOCKS= b
Block size	BLOCKS	SIZE= k
Number of <i>block pseudo-factors</i>	BLOCKS	NBLKFACS= s
Minimum block size	BLOCKS	NBLOCKS=MAXIMUM or SIZE=MINIMUM or NBLKFACS=MAXIMUM
Model Specification		
(one of the following)		
Estimated effects	MODEL	ESTIMATE=(<i>effects</i>)
Estimated effects and nonnegligible effects	MODEL	ESTIMATE=(<i>effects</i>) NONNEG=(<i>nonnegligible-effects</i>)
Design resolution number	MODEL	RESOLUTION= r
Design with highest resolution	MODEL	RESOLUTION=MAXIMUM
Minimum aberration design (up to d th-order interactions)	MODEL	EST=(...) <NONNEG=(...)> or RES=... / MINABS<(d)>

Table 7.2 Summary of Options for Searching the Design

Function	Statement	Option
Search for the Design		
Allow maximum time of t seconds	PROC FACTEX	SECONDS= t or TIME= t
Limit the design searches	PROC FACTEX	NOCHECK

Table 7.3 Summary of Options for Replicating and Randomizing the Design

Function	Statement	Option
Replication		
Replicate entire design c times	OUTPUT OUT= <i>SAS-data-set</i>	DESIGNREP= c
Replicate design for each point in the data set	OUTPUT OUT= <i>SAS-data-set</i>	DESIGNREP= <i>SAS-data-set</i>
Replicate each point in design p times	OUTPUT OUT= <i>SAS-data-set</i>	POINTREP= p
Replicate data set for each point in the design	OUTPUT OUT= <i>SAS-data-set</i>	POINTREP= <i>SAS-data-set</i>
Randomization		
Randomize the design	OUTPUT OUT= <i>SAS-data-set</i>	RANDOMIZE

Table 7.3 continued

Function	Statement	Option
Randomize the design but not the assignment of factor levels	OUTPUT OUT= <i>SAS-data-set</i>	RANDOMIZE NOVALRAN
Specify seed number	OUTPUT OUT= <i>SAS-data-set</i>	RANDOMIZE (<i>u</i>)

Table 7.4 Summary of Options for Examining and Saving the Design

Block variable name	OUTPUT OUT= <i>SAS-data-set</i>	BLOCKNAME= <i>block-name</i>
Decoded block levels (numeric type)	OUTPUT OUT= <i>SAS-data-set</i>	BLOCKNAME= <i>block-name</i> NVALS=(<i>level1</i> ... <i>levelb</i>)
Decoded block levels (character type)	OUTPUT OUT= <i>SAS-data-set</i>	BLOCKNAME= <i>block-name</i> CVALS=('level1' ... 'levelb')

Summary of Designs

Table 7.5 summarizes basic design types that you can construct with the FACTEX procedure by providing example code for each type.

Table 7.5 Basic Designs Constructed by the FACTEX Procedure

Design Type	Example Statements
A full factorial design in three factors, each at two levels coded as -1 and +1.	<pre>proc factex; factors Pressure Temperature Time; examine design; run;</pre>

Table 7.5 continued

Design Type	Example Statements
A full factorial design in three factors, each at three levels coded as -1, 0, and +1.	<pre>proc factex; factors Pressure Temperature Time / nlev= 3; examine design; run;</pre>
A full factorial design in three factors, each at two levels. The entire design is replicated twice, and the design with recoded factor levels is saved in a SAS data set.	<pre>proc factex; factors Pressure Temperature Time; output out= SavedDesign designrep= 2 Pressure cvals=('low' 'high') Temperature nvals=(200 300) Time nvals=(10 20); run;</pre>
A full factorial design in three factors, each at two levels coded as -1 and +1. Each run in the design is replicated three times, and the replicated design is randomized and saved in a SAS data set.	<pre>proc factex; factors Pressure Temperature Time; output out= SavedDesign pointrep= 3 randomize; run;</pre>
A full factorial design in three control factors, each at two levels coded as -1 and +1. A noise factor design (<i>outer array</i>) read from a SAS data set is replicated for each run in the control factor design (<i>inner array</i>), and the product design is saved in a SAS data set.	<pre>proc factex; factors+ Pressure Temperature Time; output out += SavedDesign pointrep+= OutArray; run;</pre>
A full factorial blocked design in three factors, each at two levels coded as -1 and +1. The design is arranged in two blocks and saved in a SAS data set. By default, the block variable is named BLOCK and the two block levels are numbered 1 and 2.	<pre>proc factex; factors Pressure Temperature Time; blocks nblocks= 2; output out= SavedDesign; run;</pre>

Table 7.5 *continued*

Design Type	Example Statements
<p>A full factorial blocked design in three factors, each at two levels coded as -1 and $+1$. Each block contains four runs; the block variable is renamed and the block levels of character type are recoded. The design is saved in a SAS data set.</p>	<pre>proc factex; factors Pressure Temperature Time; blocks size= 4; output out= SavedDesign blockname= Machine cvals=('A' 'B'); run;</pre>
<p>A fractional factorial design of resolution 4 in four factors, each at two levels coded as -1 and $+1$. The size of the design is eight runs.</p>	<pre>proc factex; factors Pressure Temperature Time Catalyst; size design= 8; model resolution= 4; examine design; run;</pre>
<p>A one-half fraction of a factorial design in four factors, each at two levels coded as -1 and $+1$. The design is of maximum resolution. The design points, the alias structure, and the confounding rules are listed.</p>	<pre>proc factex; factors Pressure Temperature Time Catalyst; size fraction= 2; model resolution=maximum; examine design aliasing confounding; run;</pre>
<p>A one-quarter fraction of a factorial design in six factors, each at two levels coded as -1 and $+1$. Main effects are estimated, and some two-factor interactions are considered nonnegligible. The design is saved in a SAS data set.</p>	<pre>proc factex; factors x1-x6; size fraction= 4; model estimate=(x1 x2 x3 x4 x5 x6) nonneg =(x1*x5 x1*x6 x5*x6); output out = SavedDesign; run;</pre>

Statement Descriptions

This section provides detailed syntax information for the FACTEX procedure statements, beginning with the PROC FACTEX statement. The remaining statements are presented in alphabetical order.

PROC FACTEX Statement

PROC FACTEX < options > ;

You use the PROC FACTEX statement to invoke the FACTEX procedure. The following *options* are available:

NAMELEN

specifies the length of effect names in tables and output data sets to be n characters long, where n is a value between 20 and 200 characters. The default length is 20 characters.

NOCHECK

suppresses a technique for limiting the amount of search required to find a design. The technique dramatically reduces the search time by pruning branches of the search tree that are unlikely to contain the specified design, but in rare cases it can keep the FACTEX procedure from finding a design that does in fact exist. The NOCHECK option turns off this technique at the potential cost of an increase in run time. Note, however, that the run time is always bounded by the TIME= option or its default value. For more information about the NOCHECK option, see the section “Speeding Up the Search” on page 719.

TIME= t

SECONDS= t

specifies the maximum number of seconds to spend on the search. The default is 60 seconds.

BLOCKS Statement

BLOCKS *block-specification* ;

You use the BLOCKS statement to specify the blocks or split-plot units in the design. By default, the FACTEX procedure constructs designs that do not contain blocks. If you use the BLOCKS statement, you also need to use the MODEL statement or SIZE statement. In particular, if you use the BLOCKS statement and your design is a fractional factorial design, you must use the MODEL statement.

The two simplest explicit *block-specifications* that you can use are as follows:

- NBLOCKS= b , which specifies the number of blocks (b) in the design
- SIZE= k , which specifies the number of runs (k) in each block

Use only one of these two options. In all, there are seven mutually exclusive *block-specifications* that you can use, as described by the following list.

NBLKFACS=*s*

specifies the number of block pseudo-factors for the design. The design contains a different block for each possible combination of the levels of the block pseudo-factors. Values of *s* are the integers 1, 2, and so on. See the section “[Block Size Restrictions](#)” on page 652 for details.

If each factor in the design has *q* levels, then NBLKFACS=*s* specifies a design with q^s blocks. The size of each block depends on the number of runs in the design, as specified in the SIZE statement. If the design has *n* runs, then each block has n/q^s runs.

The following statement illustrates how to request a two-level factorial design arranged in eight (2^3) blocks:

```
blocks nblkfacs=3;
```

For more information about pseudo-factors, see the section “[Types of Factors](#)” on page 704.

NBLOCKS=*b*

specifies the number of blocks in the design. The values of *b* must be a power of *q*, the number of levels of each factor in the design. See the section “[Block Size Restrictions](#)” on page 652 for details. The size of each block depends on the number of runs in the design, as specified in the SIZE statement. If the design has *n* runs, then each block has n/b runs. See the section “[Example of a Full Factorial Design in Two Blocks](#)” on page 640 for an illustration of this option.

The following statement illustrates how to specify a design arranged in four blocks:

```
blocks nblocks=4;
```

SIZE=*k*

specifies the number of runs per block in the design. The value *k* must be a power of *q*, the number of levels for each factor in the design. The number of blocks depends on the number of runs in the design, as specified in the SIZE statement. If the design has *n* runs, then it has n/k blocks.

CAUTION: Do not confuse the SIZE= option in the BLOCKS statement with the SIZE statement, which you use to specify the overall size of the design. See the section “[SIZE Statement](#)” on page 662 for details of the SIZE statement.

The following statement illustrates how to specify blocks of size two:

```
blocks size=2;
```

NBLKFACS=MAXIMUM**NBLOCKS=MAXIMUM****SIZE=MINIMUM**

constructs a blocked design with the minimum number of runs per block, given all the other characteristics of the design. In other words, the block size is optimized. You cannot specify this option if you specify any of the design size optimization options in the SIZE statement (see [DESIGN=MINIMUM](#)).

UNITS=(units-specifications)

specifies unit factors that index the runs of the experiment. Each *unit-specification* has the form

unitfactor = number-of-levels

where the number of levels for each unit factor must be a power of the number of levels specified in the FACTORS statement (2 by default). You can give multiple *unit-specifications* in the UNITS= option; the product of their numbers of levels must be less than the size of the experiment, as specified in the SIZE statement.

Unit factors are not involved in the model structure of the design. Instead, you use a UNITS=() blocks specification in conjunction with one or more UNITEFFECT statements to constrain how the factor levels can change across the runs of the experiment.

The following statement illustrates how to specify two unit factors:

```
blocks units=(Unit1=4 Unit2=8);
```

See the section “Split-Plot Designs” on page 714 for details about how to use the UNITS= option and the UNITEFFECT statement to construct split-plot designs.

Equivalent BLOCK Specifications

The three explicit *block-specifications* are related to each other, as demonstrated by the following example.

Suppose you want to construct a design for 11 two-level factors in 128 runs in blocks of size 8. Since $128/2^4 = 128/16 = 8$, three equivalent block specifications are as follows:

```
blocks nblkfacs=4;
blocks nblocks=16;
blocks size=8;
```

Block Size Restrictions

The number of blocks and the number of runs in each block must be less than the total number of runs in the design. Hence, there are some restrictions on the block size.

- If you use SIZE= k or NBLOCKS= b , the numbers you specify for k and b must be less than or equal to the size of the design, as specified in the SIZE statement. Or, if you do not use a SIZE statement, k and b must be less than or equal to the number of runs for a full replication of all possible combinations of the factors.

For example, for a 2^3 design you cannot specify a design arranged in 8 blocks (NBLOCKS=8). Likewise, you cannot construct a design with block size greater than 8 (SIZE=8).

- If you use NBLKFACS= s , the value of s can be no greater than the number of run-indexing factors, which give the number of runs needed to index the design. For details, see “Types of Factors” on page 704 and “Theory of Orthogonal Designs” on page 715.

UNITEFFECT Statement

UNITEFFECT *uniteffect* / < **WHOLE**=(*wholeuniteffects*) > < **SUB**=(*subuniteffects*) > ;

You use the UNITEFFECT statement to specify constraints on how the factor levels can change across the runs of the experiment. Such constraints are known as randomization restrictions. UNITEFFECT statements are used in conjunction with a UNITS specification in the BLOCKS statement, where unit factors are defined that index the runs of the experiment.

The *uniteffect* is an interaction between *unitfactors* defined in the BLOCKS UNITS=() specification:

unitfactor * ... * *unitfactor*

It defines a partition of the runs on which to apply whole-unit and subunit effects of the factors named in the FACTORS statement.

The *wholeuniteffects* specified by the WHOLE=() option typically define a necessary feature of how the experiment must be designed, and are thus known as “design constraints.” In contrast, the SUB=() option indicates which unit mean contrasts will be used to compute the *subuniteffects* and which random error terms will be used to test them, and are thus known as “model constraints.” For both *wholeuniteffects* and *subuniteffects*, the effects listed must be enclosed within parentheses, as in the MODEL statement. See the section “[Specifying Effects in the MODEL Statement](#)” on page 705 for details.

If you have specified units in the BLOCK statement as

```
blocks units=(WholePlot=4);
```

then the following statement illustrates how to specify unit effects corresponding to these units:

```
uniteffect WholePlot / whole=(x1-x3) sub=(x4-x6);
```

See the section “[Split-Plot Designs](#)” on page 714 for details about how to use the UNITS= option and the UNITEFFECT statement to construct split-plot designs.

EXAMINE Statement

EXAMINE < *options* > ;

You use the EXAMINE statement to specify the characteristics of the design that are to be listed in the output.

The *options* are remembered by the procedure; once specified, they remain in effect until you submit a new EXAMINE statement with different options or until you turn off all EXAMINE options by submitting just

```
examine;
```

The following *options* are available.

ABERRATION

AB

displays the aberration vector for the design, summarizing the confounded interactions. See the section “[Minimum Aberration](#)” on page 712 for more information.

ALIASING <(<*d*> <UNITS <= ONE | ALL>>)>**A** <(<*d*> <UNITS <= ONE | ALL>>)>

lists the alias structure of the design, which identifies effects that are confounded with one another and are thus, indistinguishable.

You can specify *d* in parentheses immediately after the ALIASING option for a listing of the alias structure with effects up to and including order *d*. For example, the following statement requests aliases for up to fourth-order effects (for example, A*B*C*D):

```
examine aliasing(4);
```

Each line of the alias structure is listed in the form

```
effect = effect = ... = effect
```

for as many effects as are aliased with one another.

The default value for *d* is determined automatically from the model as follows:

- If you specify the model with a resolution number *r* in the MODEL statement, then *d* is the integer part of $(r + 1)/2$.
- If you specify the model with a list of effects in the MODEL statement, then *d* is the larger of the following, where main effects have order 1, two-factor interactions have order 2, and so on:
 - one plus the largest order of an effect to be estimated
 - the largest order of an effect considered to be nonnegligible

If your design involves unit effects, then you can also specify UNITS in parentheses immediately after the ALIASING option to display for each treatment effect alias string the top unit effect with which it is aliased. Using the UNITS option can give you information about which error stratum can be used to estimate the background error variance for each estimable treatment effect. If unit effects are nested, as they typically are in complex split-plot designs, then treatment effects can be aliased with more than one unit effect. In this case, specify (UNITS=ALL) to see all unit effects with which each treatment effect is aliased.

For details about aliasing, see the section “[Alias Structure](#)” on page 712.

CONFOUNDING**C**

lists the confounding rules used to construct the design. For the definition of confounding rules, see the sections “[Confounding Rules](#)” on page 711 and “[Suitable Confounding Rules](#)” on page 717.

DESIGN**D**

lists the points in the design in standard order with the factor levels coded. For a description of the randomization and coding rules, see the section “[OUTPUT Statement](#)” on page 658.

SUMMARY <(< *d* >)>**S** <(< *d* >)>

displays the modeling summary for the design, summarizing how many interactions of each order are estimable and how many are clearly estimable (that is, unaliased with any other interactions of interest).

You can specify *d* in parentheses immediately after the SUMMARY option to display the modeling summary accounting for effects up to and including order *d*. The default value for *d* is determined automatically from the model as it is for the ALIASING option.

FACTORS Statement

FACTORS *factor-names* </ *option* > ;

You use the FACTORS statement to start the construction of a new design by naming the factors in the design. The FACTORS statement clears all previous specifications for the design (number of runs, block size, and so on). Use it when you want to start a new design.

NOTE: The FACTORS statement should be the first statement following the PROC FACTEX statement.

In the FACTORS statement,

factor-names

lists names for the factors in the design. These names must be valid SAS variable names. See the section “Types of Factors” on page 704 for details.

The following *option* is available:

NLEV=*q*

specifies the number of levels for each factor in the design. The value of *q* must be an integer greater than or equal to 2. The default value for *q* is 2. In order to construct a design that involves either fractionation or blocking, *q* must be either a prime number or an integer power of a prime number. For the reason behind this restriction, see the section “Structure of General Factorial Designs” on page 716.

MODEL Statement

MODEL *model-specification* < / < **MINABS** <(*d*)> > < **MAXCLEAR** <(*d*)> > > ;

You use the MODEL statement to provide the model for the construction of the factorial design. The model can be specified either directly by specifying the effects to be estimated with the ESTIMATE= option or indirectly by specifying the resolution of the design with the RESOLUTION= option.

NOTE: If you create a fractional factorial design or if you create a design that involves blocking, the MODEL statement is required.

The two *model-specifications* are described as follows:

ESTIMATE=(effects) < option >

identifies the *effects* that you want to estimate with the design. To specify *effects*, simply list the names of main effects, and join terms in interactions with asterisks. The *effects* listed must be enclosed within parentheses. See the section “[Specifying Effects in the MODEL Statement](#)” on page 705 for details. You can use EST or E for the keyword ESTIMATE.

After the ESTIMATE= *option*, you can specify the following *option*:

NONNEGLECTIBLE=(nonnegligible-effects)

identifies nonnegligible effects. These are the effects whose magnitudes are unknown, but you do not necessarily want to estimate them with the design. If you do not want certain effects to be aliased with ESTIMATE= effects, then list them in the NONNEGLECTIBLE= effects. The *nonnegligible-effects* listed must be enclosed within parentheses.

You can use NONNEG or N for the keyword NONNEGLECTIBLE.

For example, suppose that you want to construct a fraction of a 2^4 design in order to estimate the main effects of the four factors. To specify the model, simply list the main effects with the ESTIMATE= option, since these are the effects of interest. Furthermore, if you consider the two-factor interactions to be significant but are not interested in estimating them, then list these interactions with the NONNEGLECTIBLE= option.

See [Example 7.8](#) for an example that uses the ESTIMATE= option. See “[Theory of Orthogonal Designs](#)” on page 715 for details about how the FACTEX procedure interprets the model and derives an appropriate confounding scheme.

RESOLUTION=*r***RESOLUTION=MAXIMUM**

specifies the resolution of the design. The resolution number *r* must be a positive integer greater than or equal to 3. The interpretation of *r* is as follows:

- If *r* is odd, then the effects of interest are taken to be those of order $(r - 1)/2$ or less.
- If *r* is even, then the effects of interest are taken to be those of order $(r - 2)/2$ or less, and the nonnegligible effects are taken to be those of order $r/2$ or less.

If you specify RESOLUTION=MAXIMUM, the FACTEX procedure searches for a design with the highest resolution that satisfies the SIZE statement requirements.

You can use RES or R for the keyword RESOLUTION and MAX for MAXIMUM.

For more information about design resolution, see the section “[Resolution](#)” on page 706. For an example of *model specification* that uses the RESOLUTION=*r* option, see the section “[Example of a Half-Fraction Factorial Design](#)” on page 642. For an example of the RESOLUTION=MAX option, see the section “[Example of a Full Factorial Design in Two Blocks](#)” on page 640.

The following options for the MODEL statement are available:

MAXCLEAR < (*d*) >

requests a search for a design that maximizes the number of clear interactions. Clear interactions are those which are not aliased with any other effects that are either required to

be estimable or assumed to be nonnegligible. Specifying (d) immediately after the MAX-CLEAR option requests a search for a maximum-clarity design that involves interactions up to order d . The default value for d is determined automatically from the model, as it is for the ALIASING option in the EXAMINE statement, as follows:

- If you specify the model with a resolution number r in the MODEL statement, then d is the integer part of $(r + 1)/2$.
- If you specify the model with a list of effects in the MODEL statement, then d is the larger of the following, where main effects have order 1, two-factor interactions have order 2, and so on:
 - one plus the largest order of an effect to be estimated
 - the largest order of an effect considered to be nonnegligible

For details about MaxClear designs, see the section “MaxClear Designs” on page 713.

MINABS <(d)>

requests a search for a design that has minimum aberration. Specifying (d) immediately after the MINABS option requests a search for a minimum aberration design that involves interactions up to order d . The default value for d is determined automatically from the model as follows:

- If you specify the model with a resolution number r in the MODEL statement, then $d = r + 2$.
- If you specify the model with a list of effects in the MODEL statement, then d is the larger of the following, where main effects have order 1, two-factor interactions have order 2, and so on:
 - three plus twice the largest order of an effect to be estimated
 - one plus twice the largest order of an effect considered to be nonnegligible

See the section “Minimum Aberration” on page 712 for more information. For an example of the MINABS option, see Example 7.11.

Examples of the MODEL Statement

Suppose you specify a design with the following FACTORS statement, where the number of factors f can be replaced with a number:

```
factors x1-xf;
```

Then Table 7.6 lists equivalent ways to specify common models.

Table 7.6 Equivalent of Model Specifications

RES= option	EST= and NONNEG= options
model res=3	model est=(x1-x+f);
model res=4	model est=(x1-x+ f) nonneg=(x1 x2 x3 +...+ x+f+@2);
model res=5	model est=(x1 x2 x3 +...+ x+ f+@2);

The resolution specification is more concise than the effects specification and is also more efficient in an algorithmic sense. To decrease the time required to find a design, particularly for designs with a large number of factors, you should specify your model that uses the RESOLUTION= option rather than listing the effects. For more on interpreting the resolution number, see the section “Resolution” on page 706.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set* < *options* > ;

You use the OUTPUT statement to save a design in an output data set. Optionally, you can use the OUTPUT statement to modify the design by specifying values to be output for factors, creating new factors, randomizing the design, and replicating the design. You specify the output data set as follows:

OUT=*SAS-data-set*

gives the name of the output data set in which the design is saved. Note that OUT= is required.

options

You can use the *options* to

- recode the values for design factors
- recode the values for the block variable
- replicate the entire design
- replicate each point of the design
- randomize the design
- create derived factors based on the original factors

The following list describes the preceding *options*:

Recode Design Factors

By default, the output data set contains a variable for each factor in the design coded with standard values, as follows:

- For factors with 2 levels ($q = 2$), the values are -1 and $+1$.
- For factors with 3 levels ($q = 3$), the values are -1 , 0 , and $+1$.
- For factors with q levels ($q > 3$), the values are $0, 1, 2, \dots, q - 1$.

You can recode the levels of the factor from the standard levels to levels appropriate for your situation.

For example, suppose that you want to recode a three-level factorial design from the standard levels $-1, 0$, and $+1$ to the actual levels. Suppose the factors are pressure (Pressure) with character levels, agitation rate (Rate) with numeric levels, and temperature (Temperature) with numeric levels. You can use the following statement to recode the factor levels and save the design in a SAS data set named RECODE:

```

output out=recode Pressure    cvals=('low' 'medium' 'high')
                    Rate      nvals=(20  40  60)
                    Temperature cvals=(100 150 200);

```

The general form of *options* to recode factors is as follows:

factor-name **NVALS=** (*level1 level2 ... levelq*)

or

factor-name **CVALS=**(*'level1' 'level2' ... 'levelq'*)

where

factor-name gives the name of the design factor.

NVALS= lists new numeric levels for design factors.

CVALS= lists new character levels for design factors. Each string can be up to 40 characters long.

When recoding a factor, the **NVALS=** and **CVALS=** options map the first value listed to the lowest value for the factor, the second value listed to the next lowest value, and so on. If you rename and recode a factor, the type and length of the new variable are determined by whether you use the **CVALS=** option (character variable with length equal to the longest string) or the **NVALS=** option (numeric variable). For more information about recoding a factor, see “[Factor Variable Characteristics in the Output Data Set](#)” on page 706.

Recode Block Factor

If the design uses blocking, the output data set automatically contains a block variable named **BLOCK**, and for a design with *b* blocks, the default values of the block variable are 1, 2, ..., *b*. You can rename the block variable and optionally recode the block levels from the default levels to levels appropriate for your situation.

For example, for a design arranged in four blocks, suppose that the block variable is the day of the week (**Day**) and that the four block levels of character type are *Mon*, *Tue*, *Wed*, and *Thu*. You can use the following statement to rename the block variable, recode the block levels, and save the design in a SAS data set named **RECODE**:

```

output out=recode blockname=Day cvals=('Mon' 'Tue' 'Wed' 'Thu');

```

The general form of *options* to change the block variable name or change the block levels is as follows:

BLOCKNAME= *block-name* < **NVALS=** (*level1 level2 ... levelb*) >

or

BLOCKNAME= *block-name* < **CVALS=** ('level1' 'level2' ... 'levelb') >

where

block-name gives a new name for the block factor.

NVALS= lists new numeric levels for the block factor. For details, see the section “[Recode Design Factors](#)” on page 658.

CVALS= lists new character levels for the block factor. For details, see the section “[Recode Design Factors](#)” on page 658.

Note that you can simply rename the block variable by using only the **BLOCKNAME=** option, without using the **NVALS=** and **CVALS=** options.

Replicate Entire Design

DESIGNREP=*c*

DESIGNREP=*SAS-data-set*

replicates the entire design. Specify **DESIGNREP=*c*** to replicate the design *c* times, where *c* is an integer. Alternatively, you can specify a SAS data set with the **DESIGNREP=** option. In this case, the design is replicated once for each point in the **DESIGNREP=** data set, and the **OUT=** data set contains the variables in the **DESIGNREP=** data set in addition to the design variables.

In mathematical notation, the **OUT=** data set is the direct product of the **DESIGNREP=** data set and the design. If the design is *a* and the **DESIGNREP=** data set is *b*, then the **OUT=** data set is $b \otimes a$, where \otimes denotes the direct product.

For details, see the section “[Replication](#)” on page 709. For illustrations of the difference between the **DESIGNREP=** and **POINTREP=** options, see [Example 7.6](#) and [Example 7.7](#).

Replicate Design Point

POINTREP=*p*

POINTREP=*SAS-data-set*

replicates each point of the design. Specify **POINTREP=*p*** to replicate each design point *p* times, where *p* is an integer. Alternatively, you can specify a SAS data set with the **POINTREP=** option. In this case, the **POINTREP=** data set is replicated once for each point in the design and the **OUT=** data set contains the variables in the **POINTREP=** data set in addition to the design variables.

In mathematical notation, the **OUT=** data set is the direct product of the design and the **POINTREP=** data set. If the design is *a* and the **POINTREP=** data set is *b*, then the **OUT=** data set is $a \otimes b$, where \otimes denotes the direct product.

For details, see the section “[Replication](#)” on page 709. For illustrations of the difference between the **DESIGNREP=** and **POINTREP=** options, see [Example 7.6](#) and [Example 7.7](#).

Randomize Design**RANDOMIZE** <(u)> <NOVALRAN>

randomizes the design. See the section “[Randomization](#)” on page 707 for details. The following *options* are available:

(u)

specifies an integer used to start the pseudo-random number generator for randomizing the design. The value of u must be enclosed in parentheses immediately after the keyword RANDOMIZE. If you do not specify a seed, or if you specify a value less than or equal to zero, by default the seed is generated from reading the time of day from the computer’s clock.

NOVALRAN

prevents the randomization of theoretical factor levels to actual levels. The randomization of run order is still performed.

Create Derived Factors

You can create *derived factors* based on the joint values of a set of the design factors. Each distinct combination of levels of the design factors corresponds to a single level for the derived factor. Thus, when you create a derived factor from k design factors, each with q levels, the derived factor has q^k levels. Derived factors are useful when you create mixed-level designs; see [Example 7.8](#) for an example. See the section “[Structure of General Factorial Designs](#)” on page 716 for information about how the levels of design factors are mapped into levels of the derived factor. The general form of the *option* for creating derived factors is

[*design-factors*]= *derived-factor* < NVALS= (*list-of-numbers*)>

or

[*design-factors*]= *derived-factor* < CVALS= ('*string1*' '*string2*' ... '*stringn*')>

where

design-factors gives names of factors currently in the design. These factors are combined to create the new derived factor.

derived-factor gives a name to the new derived factor. This name must not be used in the design.

NVALS= lists new numeric levels for the derived factor.

CVALS= lists new character levels for the derived factor. See the section “[Recode Design Factors](#)” on page 658 for details.

If you create a derived factor and do not use the NVALS= or CVALS= option to assign levels to the derived factor, the FACTEX procedure assigns the values $0, 1, \dots, q^k - 1$, where the derived factor is created from k design factors, each with q levels. In general, the CVALS= or NVALS= list for a derived factor must contain q^k values.

The following statement gives an example of creating a derived factor and then renaming the levels of the factor:

```
output out=new [A1 A2]=A cvals=('A' 'B' 'C' 'D');
```

This statement converts two 2-level factors (A1 and A2) into one 4-level factor (A), which has the levels A, B, C, and D.

SIZE Statement

SIZE *size-specification* ;

You use the SIZE statement to specify the size of the design, which is the number of runs in the design. The SIZE statement is required for designs of less than a full replicate (for example, fractional factorial designs). By default, the design consists of one full replication of all possible combinations of the factors.

The two simplest explicit *size-specifications* that you can use are

- DESIGN=*n*, which specifies the number of runs (*n*) in the design
- FRACTION=*h*, which specifies $1/h$ of one full replicate

Use only one of these two options. In all, there are six mutually exclusive *size-specifications* that you can use, as described by the following list:

DESIGN=*n*

specifies the actual number of runs in the design. The number of runs must be a power of the number of levels *q* for the factors in the design. (See the NLEV= option.) If the last FACTORS statement does not contain the NLEV= option, then $q = 2$ by default, and as a result, *n* must be a power of 2. For an example, see [Example 7.1](#).

FRACTION=*h*

specifies the fraction of one full replication of all possible combinations of the factors. For instance, FRACTION=2 specifies a half-fraction, FRACTION=4 specifies a quarter-fraction, and so on. In general, FRACTION=*h* specifies a design with $1/h$ of the runs in a full replicate. If the design has *f* factors, each with *q* levels, then the size of the design is q^f/h . If you use FRACTION=*h*, *h* must be a power of *q*. See [Example 7.4](#).

NRUNFACS=*m*

specifies the number of run-indexing factors in the design. The design contains one run for each possible combination of the levels of the run-indexing factors. Run-indexing factors are the first *m* factors for a design in q^m runs. All possible combinations of the levels of the run-indexing factors occur in the design. As a result, if each factor has *q* levels, the number of runs in the design is q^m . For details about run-indexing factors, see “Types of Factors” on page 704 and “Structure of General Factorial Designs” on page 716.

DESIGN=MINIMUM

FRACTION=MAXIMUM

NRUNFACS=MINIMUM

constructs a design with the minimum number of runs (no larger than one full replicate) given all of the other characteristics of the design. In other words, the design size is optimized. You cannot specify this option if you specify any of the block size optimization features in the BLOCKS statement (see [NBLKFACS=MAXIMUM](#)).

Equivalence of Specifications

The three explicit *size-specifications* are related to each other, as demonstrated by the following example. Suppose you want to construct a design for 11 two-level factors in 128 runs. Since $128 = 2^{11}/16 = 2^7$, three equivalent size specifications for this design are

```
size design=128;
size fraction=16;
size nrunfacs=7;
```

Advanced Examples

Example 7.1: Completely Randomized Design

An experimenter wants to study the effect of cutting speed (Speed) on the surface finish of a component. He considers testing the components at five levels of cutting speed (100, 125, 150, 175, and 200) and decides to test five components at each level. *See FACTEX8 in the SAS/QC Sample Library*

The design used is a single-factor completely randomized design with five levels and 25 runs. The following statements generate the required design:

```
proc factex;
  factors Speed / nlev=5;
  size design=25;
  output out=SurfaceExperiment randomize(713)
    Speed nvals=(100 125 150 175 200);
run;
proc print data=SurfaceExperiment;
run;
```

The RANDOMIZE option in the OUTPUT statement randomizes the run order; the random seed, 713 here, is optional. The design saved in the data set SurfaceExperiment is displayed in [Output 7.1.1](#).

Output 7.1.1 A Completely Randomized Design

Obs	Speed
1	200
2	175
3	200
4	125
5	100
6	150
7	175
8	125
9	100
10	100
11	100
12	200
13	125
14	125
15	150
16	175
17	175
18	150
19	175
20	150
21	200
22	125
23	200
24	150
25	100

If you are working through this example on your computer, you might find a different run order in your output. This is due to the difference in the seed value of the random number generator. You can specify a seed value with the RANDOMIZE option. For syntax, see “Randomize Design” on page 661.

Example 7.2: Resolution 4 Augmented Design

See FACTEX17 in the SAS/QC Sample Library Box, Hunter, and Hunter (1978) describe an injection molding experiment that involves eight 2-level factors: mold temperature (Temp), moisture content (Moisture), holding pressure (HoldPress), cavity thickness (Thick), booster pressure (BoostPress), cycle time (Time), screw speed (Speed), and gate size (Gate).

The design used has 16 runs and is of resolution 4; it is often denoted as 2_{IV}^{8-4} . You can generate this design, shown in [Output 7.2.1](#), with the following statements:

```
proc factex;
  factors Temp           Moisture HoldPress Thick
           BoostPress Time      Speed   Gate;
  size design=16;
  model resolution=4;
  examine design aliasing;
run;
```

The FACTORS statement lists factor names. The option DESIGN=16 of the SIZE statement specifies the design size. The RESOLUTION=4 specifies the resolution of the design. The EXAMINE statement lists points and aliasing.

Output 7.2.1 A 2_{IV}^{8-4} Design

The FACTEX Procedure									
Design Points									
Experiment Number	Temp	Moisture	Hold Press	Thick	Boost Press	Time	Speed	Gate	
1	-1	-1	-1	-1	-1	-1	-1	-1	-1
2	-1	-1	-1	1	1	1	1	1	-1
3	-1	-1	1	-1	1	1	-1	-1	1
4	-1	-1	1	1	-1	-1	1	1	1
5	-1	1	-1	-1	1	-1	1	1	1
6	-1	1	-1	1	-1	1	-1	-1	1
7	-1	1	1	-1	-1	1	1	1	-1
8	-1	1	1	1	1	-1	-1	-1	-1
9	1	-1	-1	-1	-1	1	1	1	1
10	1	-1	-1	1	1	-1	-1	-1	1
11	1	-1	1	-1	1	-1	1	-1	-1
12	1	-1	1	1	-1	1	-1	-1	-1
13	1	1	-1	-1	1	1	-1	-1	-1
14	1	1	-1	1	-1	-1	1	-1	-1
15	1	1	1	-1	-1	-1	-1	-1	1
16	1	1	1	1	1	1	1	1	1

The alias structure is shown in Output 7.2.2.

Output 7.2.2 Alias Structure for a 2_{IV}^{8-4} Design

Aliasing Structure	
Temp	
Moisture	
HoldPress	
Thick	
BoostPress	
Time	
Speed	
Gate	
Temp*Moisture	= HoldPress*Gate = Thick*Speed = BoostPress*Time
Temp*HoldPress	= Moisture*Gate = Thick*Time = BoostPress*Speed
Temp*Thick	= Moisture*Speed = HoldPress*Time = BoostPress*Gate
Temp*BoostPress	= Moisture*Time = HoldPress*Speed = Thick*Gate
Temp*Time	= Moisture*BoostPress = HoldPress*Thick = Speed*Gate
Temp*Speed	= Moisture*Thick = HoldPress*BoostPress = Time*Gate
Temp*Gate	= Moisture*HoldPress = Thick*BoostPress = Time*Speed

Subsequent analysis of the data collected for the design suggests that HoldPress and BoostPress have statistically significant effects. There also seems to be significant effect associated with the sum of the aliased two-factor interactions Temp*BoostPress, Moisture*Time, HoldPress*Speed, and Thick*Gate. This chain of confounded interactions is identified in [Output 7.2.2](#).

A few runs can be added to the design to distinguish between the effects due to these four interactions. You simply need a design in which these four effects are estimable, regardless of all other main effects and interactions. For example, the following statements generate a suitable set of runs:

```
proc factex nocheck;
  factors Temp           Moisture HoldPress Thick
          BoostPress Time      Speed      Gate;
  model estimate=(Temp*BoostPress
                  Moisture*Time
                  HoldPress*Speed
                  Thick*Gate);
  size design=min;
  examine design aliasing(2);
run;
```

The DESIGN=MIN option directs FACTEX to search for the smallest design that allows all four interactions to be estimated. Eight runs are required: see [Output 7.2.3](#).

Output 7.2.3 Additional Runs to Resolve Ambiguities

The FACTEX Procedure									
Design Points									
Experiment Number	Temp	Moisture	Hold Press	Thick	Boost Press	Time	Speed	Gate	
1	-1	-1	-1	-1	-1	-1	-1	-1	1
2	-1	-1	1	1	1	1	1	1	-1
3	-1	1	-1	1	1	1	1	1	-1
4	-1	1	1	-1	-1	-1	-1	-1	1
5	1	-1	-1	1	1	1	1	1	1
6	1	-1	1	-1	-1	-1	-1	-1	-1
7	1	1	-1	-1	-1	-1	-1	-1	-1
8	1	1	1	1	1	1	1	1	1

[Output 7.2.4](#) shows the alias structure of the additional eight runs. Note that the alias chain of interest

Temp*BoostPress=Moisture*Time=HoldPress*Speed=Thick*Gate

from the original design is broken: in this new set of runs, these four interactions are aliased with main effects and with other two-factor interactions, but they are unaliased with each other. Therefore, when these four runs are added to the original 16 runs, the main effects of the eight factors plus the four two-factor interactions that were originally aliased with each other can all be estimated with the 20 runs.

Output 7.2.4 Alias Structure of the Additional Experiment

```

Aliasing Structure

0 = Thick*BoostPress = Thick*Time = Thick*Speed = BoostPress*Time =
BoostPress*Speed
  = Time*Speed
Temp = Thick*Gate = BoostPress*Gate = Time*Gate = Speed*Gate
Moisture = HoldPress*Gate
HoldPress = Moisture*Gate
Thick = BoostPress = Time = Speed = Temp*Gate
Gate = Temp*Thick = Temp*BoostPress = Temp*Time = Temp*Speed =
Moisture*HoldPress
Temp*Moisture = HoldPress*Thick = HoldPress*BoostPress = HoldPress*Time =
HoldPress*Speed
Temp*HoldPress = Moisture*Thick = Moisture*BoostPress = Moisture*Time =
Moisture*Speed

```

Example 7.3: Factorial Design with Center Points

Factorial designs that involve two levels are the most popular experimental designs. For two-level designs, it is assumed that the response is close to linear over the range of the factor levels. To check for curvature and to obtain an independent estimate of error, you can replicate points at the center of a two-level design. Adding center points to the design does not affect the estimates of factorial effects. *See FACTEX9 in the SAS/QC Sample Library*

To construct a design with center points, you first create a data set with factorial points by using the FACTEX procedure and then augment it with center points by using a simple DATA step. The following example illustrates this technique.

A researcher is studying the effect of three 2-level factors—current (Current), voltage (Voltage), and time (Time)—by conducting an experiment using a complete factorial design. The researcher is interested in studying the overall curvature over the range of factor levels by adding four center points.

You can construct this design in two stages. First, create the basic 2^3 design with the following statements:

```

proc factex;
  factors Current Voltage Time;
  output out=Factorial
    Current nvals=(12 28)
    Voltage nvals=(100 200)
    Time nvals=(50 60);
run;

```

Next, create the center points and append to the basic design as follows:

```

data Center(drop=i);
  do i = 1 to 4;
    Current = 20;
    Voltage = 150;
    Time    = 55;
    output;
  end;
data CPDesign;
  set Factorial Center;
run;
proc print data=CPDesign;
run;

```

The design saved in the data set CPDesign is displayed in [Output 7.3.1](#). Observations 1 to 8 are the factorial points, and observations 9 to 12 are the center points.

Output 7.3.1 A 2^3 Design with Four Center Points

Obs	Current	Voltage	Time
1	12	100	50
2	12	100	60
3	12	200	50
4	12	200	60
5	28	100	50
6	28	100	60
7	28	200	50
8	28	200	60
9	20	150	55
10	20	150	55
11	20	150	55
12	20	150	55

Example 7.4: Fold-Over Design

See FACTEX10 in the SAS/QC Sample Library *Folding over* a fractional factorial design is a method for breaking the links between aliased effects in a design. Folding over a design means adding a new fraction identical to the original fraction except that the signs of all the factors are reversed. The new fraction is called a *fold-over* design. Combining a fold-over design with the original fraction converts a design of odd resolution r into a design of resolution $r + 1$.¹ For example, folding over a resolution 3 design yields a resolution 4 design. You can use the FACTEX procedure to construct the original design fraction and a DATA step to generate the fold-over design.

Consider a $\frac{1}{8}$ fraction of a 2^6 factorial design with factors A, B, C, D, E, and F. The following statements construct a 2_{III}^{6-3} design:

¹This is not true if the original design has even resolution.

```

proc factex;
  factors A B C D E F;
  size fraction=8;
  model resolution=3;
  examine aliasing;
  output out=Original;
run;

title 'Original Design';
proc print data=Original;
run;

```

The option FRACTION=8 of the SIZE statement specifies a $\frac{1}{8}$ fraction of a complete factorial—that is, 8 ($=\frac{1}{8}2^6$). The design, which is saved in the data set Original, is displayed in [Output 7.4.1](#).

Output 7.4.1 A 2_{III}^{6-3} Design

Original Design						
Obs	A	B	C	D	E	F
1	-1	-1	-1	-1	1	1
2	-1	-1	1	1	-1	-1
3	-1	1	-1	1	-1	1
4	-1	1	1	-1	1	-1
5	1	-1	-1	1	1	-1
6	1	-1	1	-1	-1	1
7	1	1	-1	-1	-1	-1
8	1	1	1	1	1	1

Since the design is of resolution 3, the alias structure in [Output 7.4.2](#) indicates that all the main effects are confounded with the two-factor interactions.

Output 7.4.2 Alias Structure for a 2_{III}^{6-3} Design

The FACTEX Procedure	
Aliasing Structure	
A	= C*F = D*E
B	= C*E = D*F
C	= A*F = B*E
D	= A*E = B*F
E	= A*D = B*C
F	= A*C = B*D
A*B	= C*D = E*F

To separate the main effects and the two-factor interactions, augment the original design with a $\frac{1}{8}$ fraction in which the signs of all the factors are reversed. The combined design (original design and fold-over design) of resolution 4 breaks the alias links between the main effects and the two-factor

interactions. The fold-over design can be created by using the following DATA step:

```
data FoldOver;
  set Original;
  A=-A; B=-B; C=-C;
  D=-D; E=-E; F=-F;
run;
title 'Fold-Over Design';
proc print data=FoldOver;
run;
```

Here, the DATA step creates the fold-over fraction by reversing the signs of the values of the factors in the original fraction. The fold-over design is displayed in [Output 7.4.3](#).

Output 7.4.3 A 2_{III}^{6-3} Design with Signs Reversed

Fold-Over Design							
Obs	A	B	C	D	E	F	
1	1	1	1	1	-1	-1	
2	1	1	-1	-1	1	1	
3	1	-1	1	-1	1	-1	
4	1	-1	-1	1	-1	1	
5	-1	1	1	-1	-1	1	
6	-1	1	-1	1	1	-1	
7	-1	-1	1	1	1	1	
8	-1	-1	-1	-1	-1	-1	

Example 7.5: Randomized Complete Block Design

See FACTEX11 in the SAS/QC Sample Library

In a randomized complete block design (RCBD), each level of a “treatment” appears once in each block, and each block contains all the treatments. The order of treatments is randomized separately for each block. You can create RCBDs with the FACTEX procedure.

Suppose you want to construct an RCBD with six treatments in four blocks. To test each treatment once in each block, you need 24 experimental units. The following statements construct the randomized complete block design shown in [Output 7.5.1](#):

```
proc factex;
  factors Block / nlev=4;
  output out=Blocks Block nvals=(1 2 3 4) randomize(12345);
run;
  factors Treatment / nlev=6;
  output out=RCBD
    designrep=Blocks
    randomize(54321)
    Treatment cvals=('A' 'B' 'C' 'D' 'E' 'F');
run;
quit;
proc print data=RCBD;
run;
```

Note that the order of the runs within each block is randomized and that the blocks (1, 2, 3, and 4) are in a random order.

Output 7.5.1 A Randomized Complete Block Design

Obs	Block	Treatment
1	3	F
2	3	D
3	3	C
4	3	A
5	3	B
6	3	E
7	2	C
8	2	D
9	2	F
10	2	B
11	2	E
12	2	A
13	1	C
14	1	F
15	1	B
16	1	E
17	1	A
18	1	D
19	4	A
20	4	D
21	4	C
22	4	F
23	4	E
24	4	B

Example 7.6: Two-Level Design with Design Replication and Point Replication

You can replicate a design to obtain an independent estimate of experimental error or to estimate effects more precisely. There are two ways you can replicate a design with the FACTEX procedure: you can replicate the entire design with the DESIGNREP= option, or you can replicate each point in the design with the POINTREP= option. The following example illustrates the difference. *See FACTEX12 in the SAS/QC Sample Library*

A process engineer is conducting an experiment to study the shrinkage of an injection-molded plastic component. The engineer chooses to determine the effect of the following four factors, each at two levels: holding pressure (Pressure), molding temperature (Temperature), cooling time (Time), and injection velocity (Velocity).

The design used is a half-fraction of a 2^4 factorial design, denoted as 2_{IV}^{4-1} . The following statements construct the design:

```
proc factex;
  factors Pressure Temperature Time Velocity;
  size fraction=2;
  model res=max;
  output out=Unreplicated;
```

```
run;
proc print data=Unreplicated;
run;
```

The design, saved in the data set Unreplicated), is shown in [Output 7.6.1](#).

Output 7.6.1 Unreplicated Design

Obs	Pressure	Temperature	Time	Velocity
1	-1	-1	-1	-1
2	-1	-1	1	1
3	-1	1	-1	1
4	-1	1	1	-1
5	1	-1	-1	1
6	1	-1	1	-1
7	1	1	-1	-1
8	1	1	1	1

To obtain a more precise estimate of the experimental error, the engineer decides to replicate the entire design three times. The following statements generate a 2_{IV}^{4-1} design with three replicates in 24 runs:

```
proc factex;
  factors Pressure Temperature Time Velocity;
  size fraction=2;
  model res=max;
  output out=Replicated designrep=3;
run;
proc print data=Replicated;
run;
```

The design, saved in the data set Replicated, is displayed in [Output 7.6.2](#).

Output 7.6.2 Design Replication

Obs	Pressure	Temperature	Time	Velocity
1	-1	-1	-1	-1
2	-1	-1	1	1
3	-1	1	-1	1
4	-1	1	1	-1
5	1	-1	-1	1
6	1	-1	1	-1
7	1	1	-1	-1
8	1	1	1	1
9	-1	-1	-1	-1
10	-1	-1	1	1
11	-1	1	-1	1
12	-1	1	1	-1
13	1	-1	-1	1
14	1	-1	1	-1
15	1	1	-1	-1
16	1	1	1	1
17	-1	-1	-1	-1
18	-1	-1	1	1
19	-1	1	-1	1
20	-1	1	1	-1
21	1	-1	-1	1
22	1	-1	1	-1
23	1	1	-1	-1
24	1	1	1	1

The first replicate comprises observations 1 to 8, the second replicate comprises observations 9 to 16, and the third replicate comprises observations 17 to 24.

Now, instead of replicating the entire design, suppose the engineer decides to replicate each run in the design three times. The following statements construct a 2_{IV}^{4-1} design in 24 runs with point replication:

```
proc factex;
  factors Pressure Temperature Time Velocity;
  size fraction=2;
  model res=max;
  output out=PointReplicated pointrep=3;
run;
proc print data=PointReplicated;
run;
```

The design, saved in the data set PointReplicated, is displayed in [Output 7.6.3](#). The first design point is replicated three times (observations 1–3), the second design point is replicated three times (observations 4–6), and so on.

Output 7.6.3 Point Replication

Obs	Pressure	Temperature	Time	Velocity
1	-1	-1	-1	-1
2	-1	-1	-1	-1
3	-1	-1	-1	-1
4	-1	-1	1	1
5	-1	-1	1	1
6	-1	-1	1	1
7	-1	1	-1	1
8	-1	1	-1	1
9	-1	1	-1	1
10	-1	1	1	-1
11	-1	1	1	-1
12	-1	1	1	-1
13	1	-1	-1	1
14	1	-1	-1	1
15	1	-1	-1	1
16	1	-1	1	-1
17	1	-1	1	-1
18	1	-1	1	-1
19	1	1	-1	-1
20	1	1	-1	-1
21	1	1	-1	-1
22	1	1	1	1
23	1	1	1	1
24	1	1	1	1

Note the difference in the arrangement of the designs created by using design replication (Output 7.6.2) and point replication (Output 7.6.3). In design replication, the original design is replicated a specified number of times; but in point replication, each run in the original design is replicated a specified number of times. See the section “Replication” on page 709 for more information on design replication.

Example 7.7: Mixed-Level Design Using Design Replication and Point Replication

See FACTEX13 in the SAS/QC Sample Library

Orthogonal factorial designs are most commonly used at the initial stages of experimentation. At these stages, it is best to experiment with as few levels of each factor as possible in order to minimize the number of runs required. Thus, these designs usually involve only two levels of each factor. Occasionally some factors naturally have more than two levels of interest—different types of seed, for instance.

You can create designs for factors with different numbers of levels simply by taking the crossproduct of component designs in which the factors all have the same numbers of levels—that is, replicating every run of one design for each run of the other. (See Example 7.14.) All estimable effects in each of the component designs, in addition to all generalized interactions between estimable effects in different component designs, are estimable in the crossproduct; refer to Section 3 of Chakravarti (1956).

This example illustrates how you can construct a mixed-level design by using the OUTPUT statement with the POINTREP= option or the DESIGNREP= option to take the crossproduct between two designs.

Suppose you want to construct a mixed-level factorial design for two 2-level factors (A and B) and one 3-level factor (C) with 12 runs. The following SAS statements produce a complete 3×2^2 factorial design by using design replication:

```
proc factex;
  factors A B;
  output out=ab;
run;
  factors C / nlev=3;
  output out=DesignReplicated designrep=ab;
run;
proc print data=DesignReplicated;
run;
```

Output 7.7.1 lists the mixed-level design saved in the data set DesignReplicated.

Output 7.7.1 3×2^2 Mixed-Level Design Using Design Replication

Obs	A	B	C
1	-1	-1	-1
2	-1	-1	0
3	-1	-1	1
4	-1	1	-1
5	-1	1	0
6	-1	1	1
7	1	-1	-1
8	1	-1	0
9	1	-1	1
10	1	1	-1
11	1	1	0
12	1	1	1

You can also create a mixed-level design for the preceding factors by using the point replication feature of the FACTEX procedure. The following SAS statements produce a complete $2^2 \times 3$ factorial design by using point replication:

```
proc factex;
  factors A B;
  output out=ab;
run;
  factors C / nlev=3;
  output out=PointReplicated pointrep=ab;
run;
proc print data=PointReplicated;
run;
```

Output 7.7.2 lists the mixed-level design saved in the data set PointReplicated.

Output 7.7.2 $2^2 \times 3$ Mixed-Level Design Using Point Replication

Obs	C	A	B
1	-1	-1	-1
2	-1	-1	1
3	-1	1	-1
4	-1	1	1
5	0	-1	-1
6	0	-1	1
7	0	1	-1
8	0	1	1
9	1	-1	-1
10	1	-1	1
11	1	1	-1
12	1	1	1

Note the difference between the designs in [Output 7.7.1](#) and [Output 7.7.2](#). In design replication, the mixed-level design is given by $AB \otimes C$, while for point replication the mixed-level design is given by $C \otimes AB$, where \otimes denotes the direct product. In design replication, you can view the DESIGNREP= data set as nested *outside* the design, while in point replication, you can view the POINTREP= data set as nested *inside* the design.

Example 7.8: Mixed-Level Design Using Pseudo-Factors

See *FACTEX6A* in the *SAS/QC Sample Library*

If the numbers of levels for the factors of the mixed-level design are all powers of the same prime power q , you can construct the design by using *pseudo-factors*, where the levels of k q -level pseudo-factors are associated with the levels of a single *derived factor* with q^k levels. Refer to Section 5 of Chakravarti (1956) and see the section “Types of Factors” on page 704 for details.

For example, the following statements create a design for one 4-level factor (A) and three 2-level factors (B, C, and D) in 16 runs (a half replicate):

```
proc factex;
  factors A1 A2 B C D;
  model estimate      =(B C D  A1|A2
                        nonnegligible=(B|C|D@2 A1|A2|B A1|A2|C A1|A2|D);
  size design=16;
  output out=DesignA [A1 A2]=A cvals = ('A' 'B' 'C' 'D');
run;
proc print;
  var A B C D;
run;
```

The levels of two 2-level pseudo-factors (A1 and A2) are used to represent the four levels of A. Hence the three degrees of freedom associated with A are given by the main effects of A1 and A2 and their interaction $A1*A2$, and you can thus refer to (A1|A2) as the main effect of A.

The MODEL statement specifies that the main effects of all factors are to be estimable, and that all of the two-factor interactions between B, C, and D, in addition to the interactions between each of these and (A1|A2), are to be nonnegligible. As a result, the mixed-level design has resolution 4. The

design is saved in the data set DesignA, combining the levels of the two pseudo-factors, A1 and A2, to obtain the levels of the 4-level factor A. The data set DesignA is listed in [Output 7.8.1](#).

Output 7.8.1 4×2^3 Design of Resolution 4 in 16 Runs

Obs	A	B	C	D
1	A	-1	-1	1
2	A	-1	1	-1
3	A	1	-1	-1
4	A	1	1	1
5	C	-1	-1	-1
6	C	-1	1	1
7	C	1	-1	1
8	C	1	1	-1
9	B	-1	-1	-1
10	B	-1	1	1
11	B	1	-1	1
12	B	1	1	-1
13	D	-1	-1	1
14	D	-1	1	-1
15	D	1	-1	-1
16	D	1	1	1

Example 7.9: Mixed-Level Design by Collapsing Factors

You can construct a mixed-level design by *collapsing* factors—that is, by replacing a factor with n levels by a factor with m levels, where $m < n$. Orthogonality is retained in the sense that estimates of different effects are uncorrelated, although not all estimates have equal variance; refer to Section 6 of Chakravarti (1956). This method has been used by Addelman (1962) to derive main effects plans for factors with mixed numbers of levels and by Margolin (1967) to construct plans that consider two-factor interactions. *See FACTEX6C in the SAS/QC Sample Library*

You can use the value specification in the OUTPUT statement as a convenient tool for collapsing factors. For example, the following statements create a 27-run design for two 2-level factors (x1 and x2) and two 3-level factors (x3 and x4) such that all main effects and two-factor interactions are uncorrelated:

```
proc factex;
  factors x1-x4 / nlev = 3;
  size design=27;
  model r=4;
  output out=MixedLevel x1 nvals=(-1 1 -1)
          x2 nvals=(-1 1 -1);
run;
proc print data=MixedLevel;
run;
```

The mixed-level design is a three-quarter fraction with resolution 5; refer to Margolin (1967). The design is displayed in [Output 7.9.1](#).

Output 7.9.1 $2^2 \times 3^2$ Design of Resolution V in 27 Runs

Obs	x1	x2	x3	x4
1	-1	-1	-1	-1
2	-1	-1	0	1

24	-1	1	1	0
25	-1	-1	-1	1
26	-1	-1	0	0
27	-1	-1	1	-1

Example 7.10: Hyper-Graeco-Latin Square Design

See FACTEX7A in the SAS/QC Sample Library. A $q \times q$ Latin square is an arrangement of q symbols, each repeated q times, in a square of side q such that each symbol appears exactly once in each row and in each column. Such arrangements are useful as designs for *row-and-column* experiments, where it is necessary to balance the effects of two q -level factors simultaneously.

A Graeco-Latin square is actually a pair of Latin squares; when superimposed, each symbol in one square occurs exactly once with each symbol in the other square. The following is an example of a 5×5 Graeco-Latin square, where Latin letters are used for the symbols of one square and Greek letters are used for the symbols of the other:

$A\alpha$	$B\beta$	$C\gamma$	$D\delta$	$E\epsilon$
$B\gamma$	$C\delta$	$D\epsilon$	$E\alpha$	$A\beta$
$C\epsilon$	$D\alpha$	$E\beta$	$A\gamma$	$B\delta$
$D\beta$	$E\gamma$	$A\delta$	$B\epsilon$	$C\alpha$
$E\delta$	$A\epsilon$	$B\alpha$	$C\beta$	$D\gamma$

Whenever q is a power of a prime number, you can construct up to $q - 1$ squares, each with q symbols that are balanced over all the other factors. The result is called a *hyper-Graeco-Latin square* or a complete set of *mutually orthogonal Latin squares*. Such arrangements can be useful as designs (refer to Williams 1949), or they can be used to construct other designs.

When q is a prime power, hyper-Graeco-Latin squares are straightforward to construct with the FACTEX procedure. This is because a complete set of $q - 1$ mutually orthogonal $q \times q$ Latin squares is equivalent to a resolution 3 design for $q + 1$ q -level factors in q^2 runs, where two of the factors index rows and columns and each of the remaining factors indexes the treatments of one of the squares.

For example, the following statements generate a complete set of three mutually orthogonal 4×4 Latin squares, with rows indexed by the factor Row, columns indexed by the factor Column, and the treatment factors in the respective squares indexed by t1, t2, and t3. The first step is to construct a resolution 3 design for five 4-level factors in 16 runs.

```
proc factex;
  factors Row Column t1-t3 / nlev=4;
  size design=16;
  model resolution=3;
  output out=OrthArray t1 cvals=('A' 'B' 'C' 'D')
                    t2 cvals=('A' 'B' 'C' 'D')
                    t3 cvals=('A' 'B' 'C' 'D');
run;

data _null_;
  array t{3} $ t1-t3;
  array s{4} $ s1-s4; /* Buffer for holding each row      */
  file print;        /* Direct printing to output screen */
  do square=1 to 3;
    put "Square " square ":";
    n = 1;
    do r=1 to 4;
      do c=1 to 4;
        set OrthArray point=n; n=n+1;
        s{c}=t{square};
      end;
      put "      " s1-s4;
    end;
  end;
  put;
end;
stop;
run;
```

In most cases, the form that appears in the output data set OrthArray is most useful. The form that usually appears in textbooks is displayed in [Output 7.10.1](#), which can be produced by using a simple DATA step (not shown here).

Output 7.10.1 Hyper-Graeco-Latin Square

```

Square 1 :
  A D B C
  D A C B
  B C A D
  C B D A

Square 2 :
  A D B C
  C B D A
  D A C B
  B C A D

Square 3 :
  A D B C
  B C A D
  C B D A
  D A C B

```

Example 7.11: Resolution 4 Design with Minimum Aberration

See FACTEX14 in the SAS/QC Sample Library If a design has resolution 4, then you can simultaneously estimate all main effects and *some* two-factor interactions. However, not all resolution 4 designs are equivalent; you might be able to estimate more two-factor interactions with some than with others. Among all resolution 4 designs, a design with the maximum number of estimable two-factor interactions is said to have *minimum aberration*.

For example, if you use the FACTEX procedure to generate a resolution 4 2-level design in 32 runs for seven factors, you can estimate all main effects and 15 of the 21 two-factor interactions with the design that is created by default. The following statements create this design and display its alias structure in [Output 7.11.1](#):

```

proc factex;
  factors A B C D E F G;
  model resolution=4;
  size design=32;
  examine aliasing;
run;

```

Output 7.11.1 Alias Structure for Default 2_{IV}^{7-2} Design

```

C*D = E*G
C*E = D*G
C*F
C*G = D*E
D*F
E*F

```

In contrast, the resolution 4 design given in Table 12.15 of Box, Hunter, and Hunter (1978) is a minimum aberration design that permits estimation of 18 two-factor interactions, three more than can be estimated with the default design. The FACTEX procedure constructs the minimum aberration design if you specify the MINABS option in the MODEL statement, as in the following statements:

```

proc factex;
  factors A B C D E F G;
  model resolution=4 / minabs;
  size design=32;
  examine aliasing;
run;

```

The alias structure for the resulting design is shown in [Output 7.11.2](#).

Output 7.11.2 Alias Structure for Minimum Aberration 2_{IV}^{7-2} Design

F*G

```

All of the designs listed in Table 12.15 of Box, Hunter, and Hunter (1978) have minimum aberration. For most of these cases, the default design constructed by the FACTEX procedure has minimum aberration—that is, the MINABS option is not required. This is important because the MINABS option forces the FACTEX procedure to check many more designs, and the search can therefore take longer to run. You can limit the search time with the TIME= option in the PROC FACTEX statement. In five of the cases (2_{III}^{10-6} , 2_{IV}^{7-2} , 2_{IV}^{8-3} , 2_{IV}^{9-4} , and 2_{V}^{10-3}), the MINABS option is required to construct a design with minimum aberration, and in two cases (2_{III}^{9-5} , 2_{IV}^{9-3}), the NOCHECK option is also required. If the FACTEX procedure is given sufficient time to run, specifying both the MINABS and the NOCHECK options always results in a minimum aberration design. However, with the default search time of 60 seconds, there are three cases (2_{IV}^{10-5} , 2_{IV}^{10-4} , and 2_{IV}^{11-5}) for which the FACTEX procedure is unable to find the minimum aberration design, even with both the MINABS and NOCHECK options specified.

Example 7.12: Replicated Blocked Design with Partial Confounding

In an unreplicated blocked design, the interaction effect that is confounded with the block effect cannot be estimated. You can replicate the experiment so that a different interaction effect is confounded in each replicate. This enables you to obtain information about an interaction effect from the replicates in which it is not confounded. *See FACTEX15 in the SAS/QC Sample Library*

For example, consider a 2^3 design with factors A, B, and C arranged in two blocks. Suppose you decide to run four replicates of the design. By constructing the design sequentially, you can choose the effects to be estimated in each replicate depending on the interaction confounded with the block effect in the other replicates.

In the first replicate, you specify only that the main effects are to be estimable. The following statements generate an eight-run two-level design arranged in two blocks:

```
proc factex;
  factors A B C;
  blocks nblocks=2;
  model est=(A B C);
  examine confounding aliasing;
  output out=Rep1 blockname=block nvals=(1 2);
run;
```

The alias structure and the confounding scheme are listed in [Output 7.12.1](#). The highest-order interaction $A*B*C$ is confounded with the block effect. The design, with recoded block levels, is saved in a data set named REP1.

Output 7.12.1 Confounding Rule and Alias Structure for Replicate 1

The FACTEX Procedure	
Aliasing Structure	
A	
B	
C	
A*B	
A*C	
B*C	

If you were to analyze this replicate by itself, you could not determine whether an effect is due to $A*B*C$ or the block effect. You can construct a second replicate that confounds a different interaction effect with the block effect. Since the FACTEX procedure is interactive, simply submit the following statements to generate the second replicate:

```
model est=(A B C A*B*C);
output out=Rep2
  blockname=block nvals=(3 4);
run;
```

The alias structure and the confounding scheme for the second replicate are listed in [Output 7.12.2](#).

The interaction $A*B*C$ is free of any aliases, but now the two-factor interaction $B*C$ is confounded with the block effect.

Output 7.12.2 Confounding Rule and Alias Structure for Replicate 2

```

                                The FACTEX Procedure

Aliasing Structure

      A
      B
      C
      A*B
      A*C
[B] = B*C
      A*B*C
```

To estimate the interaction $B*C$ with the third replicate, submit the following statements (immediately after the preceding statements):

```

model est=(A B C A*B*C B*C);
output out=Rep3 blockname=block nvals=(5 6);
run;
```

The alias structure and confounding rules are shown in [Output 7.12.3](#). The interaction $B*C$ is free of aliases, but the interaction $A*C$ is confounded with the block effect.

Output 7.12.3 Confounding Rule and Alias Structure for Replicate 3

```

                                The FACTEX Procedure

Aliasing Structure

      A
      B
      C
      A*B
[B] = A*C
      B*C
      A*B*C
```

Finally, to estimate the interaction effect $A*C$ with the fourth replicate, submit the following statements:

```

model est=(A B C A*B*C B*C A*C);
output out=Rep4 blockname=block nvals=(7 8);
run;
```

The alias structure and confounding rules are displayed in [Output 7.12.4](#).

Output 7.12.4 Confounding Rule and Alias Structure for Replicate 4

```

                                The FACTEX Procedure

Aliasing Structure

      A
      B
      C
[B] = A*B
      A*C
      B*C
      A*B*C

```

When combined, these four replicates give full information on the main effects and three-quarter information on each of the interactions. The following statements combine the four replicates:

```

data Combine;
  set Rep1 Rep2 Rep3 Rep4;
run;
proc print data=Combine;
run;

```

The final design is saved in the data set Combine. A partial listing of this data set is shown in [Output 7.12.5](#).

Output 7.12.5 Combined Design

Example 7.13: Incomplete Block Design

See *FACTEX7B* in the *SAS/QC Sample Library*

Several important series of balanced incomplete block designs can be derived from orthogonal factorial designs. One is the series of balanced lattices of Yates (1936); refer to page 396 of Cochran and Cox (1957). In a balanced lattice, the number of treatments v must be the square of a power of a prime number: $v = q^2$, $q = p^k$, where p is a prime number. These designs are based on a complete set of $q - 1$ mutually orthogonal $q \times q$ Latin squares, which is equivalent to a resolution 3 design for $q + 1$ q -level factors in q^2 runs.

The balanced lattice designs include $q + 1$ replicates of the treatments. They are constructed by associating each treatment with a run in the factorial design, each replicate with one of the factors, and each block with one of the q values of that factor. For example, the treatments in Block 3 within Replicate 2 are those treatments that are associated with runs for which factor 2 is set at value 3.

The following statements use this method to construct a balanced lattice design for 16 treatments in five replicates of four blocks each. The construction procedure is based on a resolution 3 design for five 4-level factors in 16 runs.

```

proc factex;
  factors x1-x5 / nlev=4;
  size design=16;
  model r=3;
  output out=a;
run;

```

In the following DATA step, the incomplete block design is built by using the design saved in the data set a by the FACTEX procedure:

```

data b;
  keep Rep Block Plot t;
  array x{5} x1-x5;
  do Rep = 1 to 5;
    do Block = 1 to 4;
      Plot = 0;
      do n = 1 to 16;
        set a point=n;
        if (x{rep}=Block-1) then do;
          t = n;
          Plot = Plot + 1;
          output;
        end;
      end;
    end;
  end;
  stop;
run;

```

For each block within each replicate, the program loops through the run numbers in the factorial design and chooses those that have the Repth factor equal to Block-1. These run numbers are the treatments that go into the particular block.

The design is printed by using a DATA step. Each block of each replicate is built into the variables S1, S2, S3, and S4, and each block is printed with a PUT statement.

```

data _null_;
  array s{4} s1-s4;
  file print;
  n = 1;
  do r = 1 to 5;
    put "Replication " r 1.0 ":";
    do b = 1 to 4;
      do p = 1 to 4;
        set b point=n;
        s{Plot} = t;
        n = n+1;
      end;
      put "    Block " b 1.0 ":" (s1-s4) (3.0);
    end;
  end;
  stop;
run;

```

The ARRAY statement creates a buffer for holding each block, and the FILE statement directs the printing to output screen. The design is displayed in [Output 7.13.1](#).

You can use the PLAN procedure to randomize the block design, as shown by the following statements:

```
proc plan seed=54321;
  factors Rep=5 Block=4 Plot=4 / noprint;
  output data=b out=c;
run;
proc sort;
  by Rep Block Plot;
run;
```

The variable Plot indexes the plots within each block. Refer to the *SAS/STAT User's Guide* for a general discussion of randomizing block designs.

Finally, substitute `set c` for `set b` in the preceding DATA step. Running this DATA step creates the randomized design displayed in [Output 7.13.2](#).

Output 7.13.1 A Balanced Lattice

```
Replication 1:

```

Example 7.14: Design with Inner Array and Outer Array

Byrne and Taguchi (1986) report the use of a fractional factorial design to investigate fitting an elastomeric connector to a nylon tube as tightly as possible. Their experiment applies the design philosophy of Genichi Taguchi, which distinguishes between control factors and noise factors. *Control factors* are typically those that the engineer is able to set under real conditions, while *noise factors* vary uncontrollably in practice (though within a predictable range).

See *FACTEX4* in the *SAS/QC Sample Library*

The experimental layout consists of two designs, one for the control factors and one for the noise factors. The design for the control factors is called the *inner array*, and the design for noise factors is called the *outer array*. The outer array is replicated for each of the runs in the inner array, and a performance measure (“signal-to-noise ratio”) is computed over the replicate. The performance measure thus reflects variation due to changes in the noise factors. You can construct such a crossproduct design with the replication options in the OUTPUT statement of the FACTEX procedure, as shown in this example.

Researchers identified the following four control factors that were thought to influence the amount of force required to pull the connector off the tube:

- interference (Interference), defined as the difference between the outer width of the tubing and the inner width of the connector
- connector wall thickness (ConnectorWall)
- depth of insertion (InsertDepth) of the tubing into the connector
- amount of adhesive (Glue) in the connector pre-dip

Researchers also identified the following three noise factors related to the assembly:

- amount of time (Time) allowed for assembly
- temperature (Temperature))
- relative humidity (Humidity)

Three levels were selected for each of the control factors, and two levels were selected for each of the noise factors.

The following statements construct the 72-run design used by Byrne and Taguchi (1986). First, an eight-run outer array for the three noise factors is created and saved in the data set OUTERARY.

```
proc factex;
  factors Time Temperature Humidity;
  output out=OuterArray Time      nvals=( 24 120)
                    Temperature nvals=( 72 150)
                    Humidity     nvals=(0.25 0.75);
run;
```

Next, a nine-run inner array (design of resolution 3) is chosen for the control factors. The POINTREP option in the OUTPUT statement replicates the eight-run outer array in the data set OUTERARY for each of the nine runs in the inner array and saves the final design containing 72 runs in the data set Design.

```
proc factex;
  factors Interference ConnectorWall InsertDepth Glue /
    nlev=3;
  size design=9;
  model resolution=3;
  output out=Design pointrep=OuterArray
    Interference cvals=('Low' 'Medium' 'High' )
    ConnectorWall cvals=('Thin' 'Medium' 'Thick' )
    InsertDepth  cvals=('Shallow' 'Deep' 'Medium')
    Glue         cvals=('Low' 'High' 'Medium');
run;
```

The final design is listed in [Output 7.14.1](#). Main effects of each factor can be estimated free of each other but are confounded with two-factor interactions.

Output 7.14.1 Design for Control Factor and Noise Factors

70	High	Thick	Medium	Low	120	72	0.75
71	High	Thick	Medium	Low	120	150	0.25
72	High	Thick	Medium	Low	120	150	0.75

Note that the levels of InsertDepth and Glue are listed in the OUTPUT statement in a nonstandard order so that the design produced by the FACTEX procedure matches the design of Byrne and Taguchi (1986). The order of assignment of levels does not affect the properties of the resulting design. Furthermore, the design can be randomized with the RANDOMIZE option in the OUTPUT statement.

Byrne and Taguchi (1986) indicate that a smaller outer array with only four runs would have been sufficient. You can generate this design (not shown here) by modifying the statements in this example; specifically, add the following SIZE and MODEL statements:

```
size design=4;
model resolution=3;
```

In their analysis of the data from the experiment based on the smaller design, Byrne and Taguchi (1986) note several interesting interactions between control and noise factors. However, since the inner array is of resolution 3, it is impossible to say whether interesting interactions exist between the control factors. In other words, you cannot determine whether an effect is due to an interaction or to the main effect with which it is confounded.

One alternative is to begin with a design of resolution 4. Two-factor interactions remain confounded with one another, but they are free of main effects. Moreover, further experimentation can be carried out to distinguish between confounded interactions that seem important. To determine the optimal size of this design, submit the following statements interactively:

```

proc factex;
  factors Interference ConnectorWall InsertDepth Glue /
    nlev=3;
  model resolution=4;
  size design=minimum;
run;

```

This causes the following message to appear in the SAS log:

```
NOTE: Design has 27 runs, resolution = 4.
```

In other words, the smallest resolution 4 design for four 3-level factors has 27 runs, which together with the eight-run outer array requires 216 runs. Even the smaller four-run outer array requires 108 runs. Both of these designs are substantially larger than the design originally reported, but the larger designs protect against the effects of unsuspected interactions.

A second alternative is to begin with only two levels of the control factors. Further experimentation can then be directed toward exploring the effects of factors determined to be important in this initial stage of experimentation. Note that NLEV=2 is the default in the FACTORS statement. Submit the following additional statements:

```

  factors Interference ConnectorWall InsertDepth Glue;
  model resolution=4;
  size design=minimum;
run;

```

This causes the following message to appear in the SAS log:

```
NOTE: Design has 8 runs, resolution = 4.
```

Thus, as few as eight runs can be used for the inner array. This design is amenable to blocking, whereas the proposed nine-run design is not. Blocking is an important consideration whenever experimental conditions can vary over the course of conducting the experiment.

Now, submit the following statements:

```

  size design=8;
  blocks size=minimum;
run;

```

This causes the following message to appear in the SAS log:

```
NOTE: Design has 8 runs in 4 blocks of size 2,
      resolution = 4.
```

Thus the experiment can be run in blocks as small as two runs.

Example 7.15: Fractional Factorial Split-Plot Designs

See *FACTEX18* in the *SAS/QC Sample Library*

In split-plot designs, not all factor levels can change from plot to plot. In the simplest split-plot structure, runs are grouped into whole plots; certain factors are applied to all plots in the whole plot, while others are applied to individual plots within a whole plot. The two types of factors are termed *whole-plot factors* and *subplot factors*, respectively. Split-plot designs are very common in chemical and process industries, where factors of interest are often applied at different stages of the production process and the final measurements of interest are made on the finished product. In this case, the different stages of production might give rise to multiple whole-plot effects.

Suppose you are designing an experiment to measure six factors that affect characteristics of metal wires sheathed with a certain material. Three of the factors (W1, W2, W3) apply to how the wires themselves are made, and the other three (S1, S2, S3) apply to the sheathing material. You propose to first prepare eight different batches of wire, making two wires from each batch, and then to prepare the sheathing material for each wire individually. This describes a standard split-plot experiment with batches of wires forming whole plots and sheathed wires forming subplots. The following code constructs a resolution 4 design for this experiment, specifying the Wire unit effect in the BLOCKS statement, and then in the UNITEFFECT statement specifying that W1, W2, and W3 should be constant within Wire and that S1, S2, and S3 should change within Wire. The resulting design is printed, sorted by Wire.

```
proc factex;
  factors W1 W2 W3
          S1 S2 S3;
  size design=16;
  blocks units=(Wire=8);
  model r=4;
  uniteffect Wire / whole=(W1 W2 W3)
              sub  =(S1 S2 S3);
  examine aliasing(units);
  output out=WireExperiment1;
run;

proc sort data=WireExperiment1;
  by Wire W1-W3 S1-S3;
run;

proc print data=WireExperiment1;
run;
```

Output 7.15.1 shows the aliasing structure for the design, which indicates that the main effects of the wire factors are indeed estimated on the Wire whole plots and the main effects of the sheath factors are estimated on the subplots. Interestingly, some of the sheath factor interactions are also confounded with whole plots.

Output 7.15.1 A Split-Plot Design

```

                                The FACTEX Procedure

Aliasing Structure
Units

Wire          W1
Wire          W2
Wire          W3
Wire          W1*W2 = S1*S2
Wire          W1*W3 = S1*S3
Wire          W2*W3 = S2*S3

Residual      S1
Residual      S2
Residual      S3
Residual      W1*S1 = W2*S2 = W3*S3
Residual      W1*S2 = W2*S1
Residual      W1*S3 = W3*S1
Residual      W2*S3 = W3*S2
    
```

The final design is listed in [Output 7.15.2](#). Notice that the factors W1, W2, and W3 are constant within Wire, while S1, S2, and S3 change within Wire.

Output 7.15.2 A Split-Plot Design

Obs	_1_	_2_	_3_	_4_	W1	W2	W3	S1	S2	S3	Wire
1	-1	-1	-1	1	-1	1	1	-1	1	1	1
2	-1	-1	-1	-1	-1	1	1	1	-1	-1	1
3	-1	-1	1	-1	1	-1	-1	-1	1	1	2
4	-1	-1	1	1	1	-1	-1	1	-1	-1	2
5	-1	1	-1	-1	1	-1	1	-1	1	-1	3
6	-1	1	-1	1	1	-1	1	1	-1	1	3
7	-1	1	1	1	-1	1	-1	-1	1	-1	4
8	-1	1	1	-1	-1	1	-1	1	-1	1	4
9	1	-1	-1	-1	1	1	-1	-1	-1	1	5
10	1	-1	-1	1	1	1	-1	1	1	-1	5
11	1	-1	1	1	-1	-1	1	-1	-1	1	6
12	1	-1	1	-1	-1	-1	1	1	1	-1	6
13	1	1	-1	1	-1	-1	-1	-1	-1	-1	7
14	1	1	-1	-1	-1	-1	-1	1	1	1	7
15	1	1	1	-1	1	1	1	-1	-1	-1	8
16	1	1	1	1	1	1	1	1	1	1	8

To see why the Wire factors are constant within wire and the sheath factors change, examine the confounding rules for the design. The following statements produce the table of confounding rules listed in [Output 7.15.3](#):

```

proc factex;
  factors W1 W2 W3
          S1 S2 S3;
  size design=16;
  blocks units=(Wire=8);
  model r=4;
  uniteffect Wire / whole=(W1 W2 W3)
              sub  =(S1 S2 S3);
  examine confounding;
run;

```

Output 7.15.3 Split-Plot Confounding Rules

The FACTEX Procedure	
Factor Confounding Rules	
W1	= [1]*[2]*[3]
W2	= [2]*[3]
W3	= [1]*[3]
S1	= [1]*[2]*[3]*[4]
S2	= [2]*[3]*[4]
S3	= [1]*[3]*[4]

The terms [i] on the right-hand side of these rules denote plot-indexing pseudo-factors, as discussed in the section “[Split-Plot Designs](#)” on page 714. Note that the wire factors W1, W2, and W3 are confounded only with interactions between the first three pseudo-factors, the ones identified with the eight levels of the Wire unitfactor. This guarantees that these factors are constant within levels of Wire. By contrast, the confounding rules for the sheath factors S1, S2, and S3 each involve the fourth pseudo-factor, so they must change within levels of Wire.

There are only eight different combinations of the sheath factors, but the previous design requires you to produce batches of sheath material 16 times, once for each of the two wires to be made from each wire batch. If instead you propose to make just four batches of sheath material and apply part of each batch to parts of different batches of wires, the design becomes a row-column design instead of a split-plot design. Furthermore, suppose that the number of batches rather than the size of each batch is the main cost, so that you can prepare eight batches of wire and four batches of sheathing material in sufficient quantity to make 64 different sheathed wires. Since there can be only four different combinations of the three sheathing factors, each sheathing factor interaction is aliased with a main effect, and thus the design necessarily has resolution 3. All other interactions are estimable free of main effects. The following FACTEX statements create the design and display the two unit effects with their respective wholeunit factor levels:

```

proc factex;
  factors W1 W2 W3
          S1 S2 S3;
  size design=64;
  blocks units=(Wire=8 Sheath=4);
  model r=3;
  uniteffect Wire / whole=(W1 W2 W3);

```

```

uniteffect Sheath / whole=(S1 S2 S3);
examine aliasing(units);
output out=WireExperiment2;
proc freq data=WireExperiment2;
  table Wire *W1*W2*W3 / list nocum nopct;
  table Sheath*S1*S2*S3 / list nocum nopct;
run;

```

Output 7.15.4 A Split-Lot Design: Wire Units

The FREQ Procedure				
Wire	W1	W2	W3	Frequency
1	-1	1	1	8
2	1	-1	-1	8
3	1	-1	1	8
4	-1	1	-1	8
5	1	1	-1	8
6	-1	-1	1	8
7	-1	-1	-1	8
8	1	1	1	8

Output 7.15.5 A Split-Lot Design: Sheath Units

The FREQ Procedure				
Sheath	S1	S2	S3	Frequency
1	1	-1	-1	16
2	-1	1	-1	16
3	-1	-1	1	16
4	1	1	1	16

The results, listed in [Output 7.15.4](#) and [Output 7.15.5](#), indicate that W1, W2, and W3 are constant within Wire and S1, S2, and S3 are constant within Sheath.

Example 7.16: A Design for a Three-Step Process

Ramirez and Weisz (2009) discuss an experiment on a multistep milling process with 16 processing factors, with a single factor applied at the first stage, seven more factors at the second stage, and eight more at the final stage. The experiment involves eight first-stage runs, eight second-stage runs within each of those, and again, two to four third-stage runs within each of those, for a total of 128 to 256 total experimental units. This example explores several different ways to design this experiment, depending on what kinds of effects are most important.

See FACTEX19 in the SAS/QC Sample Library

The following statements request a design of maximum resolution for this split-plot structure. The factors are listed in macro variables, for ease in specifying them in UNITEFFECT statements. The BLOCK statement defines the unit factors for the first two processing stages, with eight runs of

each. The two UNITEFFECT statements then use these unit factors to specify which unit effects correspond to which factors. Finally, the EXAMINE statement requests that the aliasing structure and the overall modeling summary be displayed to see how many effects of different orders are estimable and clear. The UNITS suboption of the ALIASING option includes the unit effect confounding for each alias string in the alias structure.

```
%let F1 = Z;
%let F2 = A B C D E F G;
%let F3 = P Q R S T U V W;
proc factex;
  factors &F1 &F2 &F3;
  model r=max;
  size design=128;
  blocks units=(Step1=8 Step2=8);
  uniteffect Step1 / whole=(&F1) sub=(&F2 &F3);
  uniteffect Step1*Step2 / whole=(&F2) sub=( &F3);
  examine aliasing(units) summary;
quit;
```

Output 7.16.2 Modeling Summary for Default 128-Run Three-Step Design

Modeling Summary		
	----Effects----	
	Main	2FI
Total	16	120
Estimable	16	30
Clear	16	15

The resulting design has resolution 4, which means that main effects are clear of two-factor interactions but interactions are aliased with each other. [Output 7.16.1](#) shows which interactions are aliased and also shows which units are used to estimate them. Note that several interactions between Step2 and Step3 factors are estimated with Step2 units.

As [Output 7.16.2](#) shows, only 30/120=25% of the two-factor interactions (2FI) are estimable and only 15/120=13% of them are clear. If simply protecting the main-effects estimates against potential two-factor interactions is sufficient, then this design suffices. However, if you want to estimate as many of the two-factor interactions as possible, then you should look for a MaxClear design. The following statements use the MAXCLEAR option in the MODEL statement to request a MaxClear design, and they also use the ORDER=RANDOM(RESTART) option in the PROC FACTEX

statement to improve the chances that the best design is found. For more details about MaxClear designs, see the section “MaxClear Designs” on page 713.

```
%let F1 = Z;
%let F2 = A B C D E F G;
%let F3 = P Q R S T U V W;
proc factex order=random(restart seed=1);
  factors &F1 &F2 &F3;
  model r=max / maxclear;
  size design=128;
  blocks units=(Step1=8 Step2=8);
  uniteffect Step1 / whole=(&F1) sub=(&F2 &F3);
  uniteffect Step1*Step2 / whole=(&F2) sub=( &F3);
  examine summary;
quit;
```

Output 7.16.3 Modeling Summary for MaxClear 128-Run Three-Step Design

The FACTEX Procedure		
Modeling Summary		
	----Effects----	
	Main	2FI
Total	16	120
Estimable	16	87
Clear	16	69

The modeling summary results for the MaxClear design are shown in [Output 7.16.3](#). Now $87/120=73\%$ of the 2FI are estimable and $69/120=58\%$ of them clear. This is a great improvement over the default design, but if complete estimability of all two-factor interactions is required, more than 128 runs are necessary. The following statements construct a design in 256 runs, effectively doubling the number of third-stage runs from two to four:

```
%let F1 = Z;
%let F2 = A B C D E F G;
%let F3 = P Q R S T U V W;
proc factex;
  factors &F1 &F2 &F3;
  model r=max;
  size design=256;
  blocks units=(Step1=8 Step2=8);
  uniteffect Step1 / whole=(&F1) sub=(&F2 &F3);
  uniteffect Step1*Step2 / whole=(&F2) sub=( &F3);
  examine aliasing(units);
quit;
```

The aliasing structure (not shown) shows that the resulting design has resolution 5, which means that all main effects and two factor interactions are estimable free of each other. Even though the required 256 runs means this is a relatively large experiment, it is still only a tiny fraction of the 65,536 runs required for a complete factorial design.

Example 7.17: A Strip-Split-Split-Plot Design

Suppose you are designing an experiment for a three-step process running on different machines. One way to model this is with a row×column strip-split-split-plot structure, with one type of unit, Machine, crossed with a process that has a split-split-plot structure. The following statements create a resolution 4 design in 11 factors for this situation, with one Machine factor MSetting and three, three, and five whole plot, split-plot, and split-split-plot process factors, respectively. The statements also specify that the design's aliasing structure and modeling summary be displayed, with the unit effect confounding for each alias string included in the alias structure. *See FACTEX20 in the SAS/QC Sample Library*

```
%let FR = X11-X13;
%let FC = X21-X23;
%let FX = X31-X35;
proc factex;
  factors MSetting &FR &FC &FX;
  model r=4;
  blocks units=(Machine=2 Step1=8 Step2=4 Step3=2);
  uniteffect Machine          / whole=(MSetting);
  uniteffect Step1            / whole=(&FR) sub=(&FC &FX);
  uniteffect Step1*Step2      / whole=(&FC) sub=(    &FX);
  uniteffect Step1*Step2*Step3 / whole=(&FX);
  size design=128;
  examine aliasing(units) summary;
run;
```

The UNITEFFECT statements define a triply nested split-plot structure for the process on each machine, including the Step1*Step2*Step3 split-split units for the process, in order to ensure that process effects are crossed with Machine.

As [Output 7.17.1](#) shows, 36/66=55% of the 2FI are estimable and 21/66=32% of them are clear. The aliasing structure (not shown) indicates that the main effect of MSetting is the only thing that is estimated with the Machine units; all interactions between MSetting and the process factors are estimated with the experimental units, labeled “Residual” in the alias structure.

Output 7.17.1 A Strip-Split-Split-Plot Design

The FACTEX Procedure		
Modeling Summary		
	----Effects----	
	Main	2FI
Total	12	66
Estimable	12	36
Clear	12	21

If simply protecting the main-effects estimates against potential two-factor interactions is the reason for requiring a resolution 4 design, then the design of [Output 7.17.1](#) suffices. However, if you want to estimate as many of the two-factor interactions as possible, then you should use the MAX-CLEAR option in the MODEL statement to construct a MaxClear design, as shown in the following statements:

```

%let FR = X11-X13;
%let FC = X21-X23;
%let FX = X31-X35;
proc factex order=random(restart seed=230501);
  factors MSetting &FR &FC &FX;
  model r=4 / maxclear;
  blocks units=(Machine=2 Step1=8 Step2=4 Step3=2);
  uniteffect Machine          / whole=(MSetting);
  uniteffect Step1            / whole=(&FR) sub=(&FC &FX);
  uniteffect Step1*Step2      / whole=(&FC) sub=(    &FX);
  uniteffect Step1*Step2*Step3 / whole=(&FX);
  size design=128;
  examine summary;
run;

```

As [Output 7.17.2](#) shows, now $55/66=83\%$ of the 2FI are estimable and $45/66=68\%$ of them are clear—more than twice as many clear interactions as before.

Output 7.17.2 A Strip-Split-Split-Plot Design

The FACTEX Procedure		
Modeling Summary		
	----Effects----	
	Main	2FI
Total	12	66
Estimable	12	55
Clear	12	45

For details about MaxClear designs, see the section “[MaxClear Designs](#)” on page 713.

Example 7.18: Design and Analysis of a Complete Factorial Experiment

See FACTEX16 in the SAS/QC Sample Library Yin and Jillie (1987) describe an experiment on a nitride etch process for a single-wafer plasma etcher. The experiment has four factors: cathode power (Power), gas flow (Flow), reactor chamber pressure (Pressure), and electrode gap (Gap). A single replicate of a 2^4 design is run, and the etch rate (Rate) is measured. You can use the following statements to construct a 16-run design in the four factors:

```

proc factex;
  factors Power Flow Pressure Gap;
  output out=EtcherDesign
    Power    nvals=(0.80 1.20)
    Flow     nvals=(4.50 550)
    Pressure nvals=(125 200)
    Gap      nvals=(275 325);
run;

```

The design with the actual (decoded) factor levels is saved in the data set `EtcherDesign`. The experiment that uses the 16-run design is performed, and the etch rate is measured. The following DATA step updates the data set `EtcherDesign` with the values of `Rate`:

```
data EtcherDesign;
  set EtcherDesign;
  input Rate @@;
  datalines;
  550  669  604  650  633  642  601  635
  1037 749  1052 868  1075 860  1063 729
  ;
  title 'Nitride Etch Process Experiment';
  proc print;
  run;
```

The data set `DESGNDAT` is listed in [Output 7.18.1](#).

Output 7.18.1 A 2^4 Design with Responses

Nitride Etch Process Experiment						
Obs	Power	Flow	Pressure	Gap	Rate	
1	0.8	4.5	125	275	550	
2	0.8	4.5	125	325	669	
3	0.8	4.5	200	275	604	
4	0.8	4.5	200	325	650	
5	0.8	550.0	125	275	633	
6	0.8	550.0	125	325	642	
7	0.8	550.0	200	275	601	
8	0.8	550.0	200	325	635	
9	1.2	4.5	125	275	1037	
10	1.2	4.5	125	325	749	
11	1.2	4.5	200	275	1052	
12	1.2	4.5	200	325	868	
13	1.2	550.0	125	275	1075	
14	1.2	550.0	125	325	860	
15	1.2	550.0	200	275	1063	
16	1.2	550.0	200	325	729	

To perform an analysis of variance on the responses, you can use the GLM procedure, as follows:

```
proc glm data=EtcherDesign;
  class Power Flow Pressure Gap;
  model rate=Power|Flow|Pressure|Gap@2 / ss1;
  run;
```

The factors are listed in both the CLASS and MODEL statements, and the response as a function of the factors is modeled by using the MODEL statement. The MODEL statement requests Type I sum of squares (SS1) and lists all effects that contain two or fewer factors. It is assumed that three-factor and higher interactions are not significant.

Part of the output from the GLM procedure is shown in [Output 7.18.2](#). The main effect of the factors Power and Gap and the interaction between Power and Gap are significant (their p -values are less than 0.01).

Output 7.18.2 Analysis of Variance for the Nitride Etch Process Experiment

Nitride Etch Process Experiment					
The GLM Procedure					
Dependent Variable: Rate					
Source	DF	Type I SS	Mean Square	F Value	Pr > F

Pressure*Gap	1	248.0625	248.0625	0.12	0.7414

Computational Details

Types of Factors

The *factors* of a design are variables that an experimenter can set at several values. In general, experiments are performed to study the effects of different levels of the factors on the response of interest. For example, consider an experiment to maximize the percentage of raw material that responds to a chemical reaction. The factors might include the reaction temperature and the feed rate of the chemicals, while the response is the yield rate. Factors of different types are used in different ways in constructing a design. This section defines the different types of factors.

Block factors are unavoidable factors that are known to affect the response, but in a relatively uninteresting way. For example, in the chemical experiment, the technician operating the equipment might have a noticeable effect on the yield of the process. The operator effect might be unavoidable, but it is usually not very interesting. On the other hand, factors whose effects are directly of interest are called *design factors*. One goal in designing an experiment is to avoid getting the effects of the design factors mixed up, or *confounded*, with the effects of any block factors.

When constructing a design by orthogonal confounding, all factors formally have the same number of levels q , where q is a prime number or a power of a prime number. Usually, q is two, and the factor levels are chosen to represent high and low values.

However, this does not mean, for example, that a design for 2-level factors is restricted to no more than two blocks. Instead, the values of several 2-level factors can be used to index the values of a

single factor with more than two levels. As an example, the values of three 2-level factors (P_1 , P_2 , and P_3) can be used to index the values of an 8-level factor (F), as follows:

P_1	P_2	P_3	F
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	4
1	0	1	5
1	1	0	6
1	1	1	7

The factors P_i are used only to derive the levels of the factor F ; thus, they are called *pseudo-factors*, and F is called a *derived factor*. In general, k q -level pseudo-factors give rise to a single q^k -level derived factor. Block factors can be derived factors, and their associated formal factors (the P_i factors) are called *block pseudo-factors*.

The method for constructing an orthogonally confounded design for q -level factors in q^m runs distinguishes between the first m factors and the remaining factors. Each of the q^m different combinations of the first m factors occurs once in the design in an order similar to the preceding table. For this reason, the first m factors are called the *run-indexing factors*.

Table 7.7 summarizes the different types of factors discussed in this section.

Table 7.7 Types of Factors

Block factor	Unavoidable factor whose effect is not of direct interest
Block pseudo-factor	Pseudo-factor used to derive levels of a block factor
Derived factor	Factor whose levels are derived from pseudo-factors
Design factor	Factor whose effect is of direct interest
Pseudo-factor	Formal factor combined to derive the levels of a real factor
Run-indexing factors	The first m design factors, whose q^m combinations index the runs in the design

Specifying Effects in the MODEL Statement

The FACTEX procedure accepts models that contain terms for main effects and interactions. *Main effects* are specified by writing variable names by themselves:

A B C

Interactions are specified by joining variable names with asterisks:

A*B B*C A*B*C

In addition, the *bar operator* ($()$) simplifies specification for interactions. The *@ operator*, used in combination with the bar operator, further simplifies specification of interactions. For example, two ways of writing the complete set of effects for a model with up to three-factor interactions are

```
model estimate=(A B C A*B A*C B*C A*B*C);
```

and

```
model estimate=(A|B|C);
```

When the bar (|) is used, the right- and left-hand sides become effects, and their cross becomes an interaction effect. Multiple bars are permitted. The expressions are expanded from left to right, using rules given by Searle (1971). For example, A|B|C is evaluated as follows:

$$\begin{aligned}
 A | B | C &\rightarrow \{ A | B \} | C \\
 &\rightarrow \{ A B A*B \} | C \\
 &\rightarrow A B A*B C A*C B*C A*B*C
 \end{aligned}$$

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying the number, preceded by an @ sign, at the end of the bar effect. For example, the specification A|B|C@2 results in only those effects that contain two or fewer factors. In this case, the effects A, B, A*B, C, A*C, and B*C are generated.

Factor Variable Characteristics in the Output Data Set

When you use the OUTPUT statement to save a design in a data set and you rename and recode a factor, the type and length of the new variable are determined by whether you use the NVALS= or CVALS= option. A factor variable whose values are coded with the NVALS= specification is of numeric type. A factor variable whose values are coded with the CVALS= option is of character type, and the length of the variable is set to the length of the longest character string; shorter strings are padded with trailing blanks.

For example, in the specifications

```
cvals=('String 1' 'A longer string')
cvals=('String 1' 'String 2')
```

the first value in the first CVALS= specification is padded with seven trailing blanks. One consequence is that it no longer matches the 'String 1' of the second specification. To match two such values (for example, when merging two designs), use the TRIM function in the DATA step (see *SAS Language Reference: Dictionary* for details).

Statistical Details

Resolution

The resolution of a design indicates which effects can be estimated free of other effects. The resolution of a design is generally defined as the smallest *order*² of the interactions that are confounded with zero. Since having an effect of order $n + m$ confounded with zero is equivalent to having an effect of order n confounded with an effect of order m , the resolution can be interpreted as follows:

²The order of an effect is the number of factors involved in it. For example, main effects have order one, two-factor interactions have order two, and so on.

- If r is odd, then effects of order $e = (r - 1)/2$ or less can be estimated free of each other. However, at least some of the effects of order e are confounded with interactions of order $e + 1$. A design of odd resolution is appropriate when effects of interest are those of order e or less, while those of order $e + 1$ or higher are all negligible.
- If r is even, then effects of order $e = (r - 2)/2$ or less can be estimated free of each other and are also free of interactions of order $e + 1$. A design of even resolution is appropriate when effects of order e or less are of interest, effects of order $e + 1$ are not negligible, and effects of order $e + 2$ or higher are negligible. If the design uses blocking, interactions of order $e + 1$ or higher might be confounded with blocks.

In particular, for resolution 5 designs, all main effects and two-factor interactions can be estimated free of each other. For resolution 4 designs, all main effects can be estimated free of each other and free of two-factor interactions, but some two-factor interactions are confounded with each other and/or with blocks. For resolution 3 designs, all main effects can be estimated free of each other, but some of them are confounded with two-factor interactions.

In general, higher resolutions require larger designs. Resolution 3 designs are popular because they handle relatively many factors in a minimal number of runs. However, they offer no protection against interactions. If resources are available, you should use a resolution 5 design so that all main effects and two-factor interactions are independently estimable. If a resolution 5 design is too large, you should use a design of resolution 4, which ensures estimability of main effects free of any two-factor interactions. In this case, if data from the initial design reveal significant effects associated with confounded two-factor interactions, further experiments can be run to distinguish between effects that are confounded with each other in the design. See [Example 7.2](#) for an example.

Many references on fractional factorial designs use Roman numerals to denote resolution of a design—III, IV, V, and so on. A common notation for an orthogonally confounded design of resolution r for k q -level factors in q^{k-p} runs is

$$q_r^{k-p}$$

For example, 2_{V}^{5-1} denotes a design for five 2-level factors in 16 runs that permits estimation of all main effects and two-factor interactions. This chapter uses Arabic numerals for resolution since these correspond directly to what you specify with the RESOLUTION= option in the MODEL statement.

Randomization

In many experiments, proper randomization is crucial to the validity of the conclusions. Randomization neutralizes the effects of systematic biases that might be involved in implementing the design and provides a basis for the assumptions underlying the analysis. Refer to Kempthorne (1975) for a discussion.

The way in which randomization is handled depends on whether the design involves blocking:

- For designs without block factors, proper randomization consists of randomly permuting the overall order of the runs and randomly assigning the actual levels of each factor to the theoretical levels it has for the purpose of constructing the design.

- For designs with block factors, proper randomization calls for first performing separate random permutations for the runs within each block, and then randomly permuting the order in which the blocks are run.

For example, suppose you generate a full factorial design for three 2-level factors A, B, and C in eight runs. The following steps are involved in randomizing this design:

1. Randomly permute the order of the runs:

$$\text{Runs: } \{1, 2, 3, 4, 5, 6, 7, 8\} \rightarrow \{3, 8, 1, 2, 4, 7, 6, 5\}$$

2. Randomly assign the actual levels to the theoretical levels for each factor:

$$\text{Factor A levels: } \{0, 1\} \rightarrow \{1, -1\}$$

$$\text{Factor B levels: } \{0, 1\} \rightarrow \{1, -1\}$$

$$\text{Factor C levels: } \{0, 1\} \rightarrow \{-1, 1\}$$

Thus, the effect of the randomization is to transform the original design, as follows:

Run	A	B	C		Run	A	B	C
1	0	0	0		3	1	-1	-1
2	0	0	1		8	-1	-1	1
3	0	1	0		1	1	1	-1
4	0	1	1	→	2	1	1	1
5	1	0	0		4	1	-1	1
6	1	0	1		7	-1	-1	-1
7	1	1	0		6	-1	1	1
8	1	1	1		5	-1	1	-1

If the original design is in two blocks, then the first step is replaced with the following two steps:

1. Randomly permute the order of the runs within each block:

$$\text{Block 1 runs: } \{1, 2, 3, 4\} \rightarrow \{4, 1, 2, 3\}$$

$$\text{Block 2 runs: } \{5, 6, 7, 8\} \rightarrow \{8, 7, 6, 5\}$$

2. Randomly permute the order of the blocks:

$$\text{Block levels: } \{1, 2\} \rightarrow \{2, 1\}$$

The resulting transformation is shown in the following:

Run	Block	A	B	C		Run	Block	A	B	C
1	1	0	0	0		8	2	-1	-1	1
2	1	0	1	1		7	2	-1	1	-1
3	1	1	0	1		6	2	1	-1	-1
4	1	1	1	0	→	5	2	1	1	1
5	2	0	0	1		4	1	-1	-1	-1
6	2	0	1	0		1	1	1	1	-1
7	2	1	0	0		2	1	1	-1	1
8	2	1	1	1		3	1	-1	1	1

If you use the `RANDOMIZE` option in the `OUTPUT` statement, the output data set contains a randomized design. In some cases, it is appropriate to randomize the run order but not the assignment of theoretical factor levels to actual levels. In these cases, specify both the `NOVALRAN` and `RANDOMIZE` options in the `OUTPUT` statement.

Replication

In quality improvement applications, it is often important to analyze both the mean response of a process and the variability around the mean. To study variability with an experimental design, you must take several measurements of the response for each different combination of the factors of interest; that is, you must *replicate* the design runs.

Replicating a Fixed Number of Times

A simple method of replication is to take a given number of measurements for each combination of factor levels in the basic design. You can replicate runs in the design by specifying numbers for the `POINTREP=` and `DESIGNREP=` options in the `OUTPUT` statement. For example, the following code constructs a full 2^2 design and uses both of these options to replicate the design three times:

```
proc factex;
  factors A B;
  output out=one pointrep =3;
run;
  output out=two designrep=3;
run;
```

The output data sets `ONE` and `TWO` have the same 12 runs, but they are in different orders. In the data set `ONE`, the `POINTREP=` option causes all three replications of each run to occur together, as shown in [Figure 7.7](#).

Figure 7.7 Four-Run Design Replicated Using the POINTREP= Option

<i>OBS</i>	<i>A</i>	<i>B</i>	
1	-1	-1	}
2	-1	-1	
3	-1	-1	
	<i>three replicates of run 1</i>		
4	-1	1	}
5	-1	1	
6	-1	1	
	<i>three replicates of run 2</i>		
7	1	-1	}
8	1	-1	
9	1	-1	
	<i>three replicates of run 3</i>		
10	1	1	}
11	1	1	
12	1	1	
	<i>three replicates of run 4</i>		

On the other hand, in the data set TWO, the DESIGNREP= option causes all four runs of the design to occur together three times, as shown in [Figure 7.8](#).

Figure 7.8 Four-Run Design Replicated Using the DESIGNREP= Option

	<i>OBS</i>	<i>A</i>	<i>B</i>
<i>Replicate 1</i>	1	-1	-1
	2	-1	1
	3	1	-1
	4	1	1
<i>Replicate 2</i>	5	-1	-1
	6	-1	1
	7	1	-1
	8	1	1
<i>Replicate 3</i>	9	-1	-1
	10	-1	1
	11	1	-1
	12	1	1

Replicating with an Outer Array

Another method of design replication considers the range of environmental conditions over which the process should maintain consistency. This method distinguishes between control factors and noise factors. *Control factors* are factors that are under the control of the designer or the process engineer. *Noise factors* cause the performance of a product to vary when the nominal values of the control variables are fixed (noise factors are controllable for the purposes of experimenting with the process). Typical noise factors are variations in the manufacturing environment or the customer's environment due to temperature or humidity. The object of experimentation is to find the best settings for the control factors for a variety of settings for the noise factors. In other words, the goal is to develop a process that runs well in a variety of environments. Refer to Dehnad (1989) and Phadke (1989) for further discussion.

To achieve this goal, a collection of environmental conditions (settings for the noise factors) is determined. This collection is called the *outer array*. Each run in the control factor design (*inner array*) is replicated within each of these environments. The mean and variance of the process over the outer array are computed for each run in the inner array. Either the outer array or the inner array might consist of all possible different settings for the associated factors, or they might be fractions of all possible settings.

You can replicate designs in this way by using data set names for the POINTREP= and DESIGN-REP= options in the OUTPUT statement. If you construct a design for your control factors and you want to run a noise factor design for each run in the control factor design, specify the data set that holds the noise factor design (that is, the *outer array*) with the POINTREP= option in the OUTPUT statement. See [Example 7.14](#) for an example.

Confounding Rules

Confounding rules give the values of factors in terms of the values of the run-indexing factors for a design. (See “[Types of Factors](#)” on page 704 for a discussion of run-indexing factors.) The FACTEX procedure uses these rules to construct designs. The confounding rules also determine the alias structure of the design. To display the confounding rules for a design, use the CONFOUNDING option in the EXAMINE statement.

For 2-level factors, the rules are displayed in a multiplicative notation that uses the default values of -1 and $+1$ for the factors. For example, the confounding rule

$$X8 = X1 * X2 * X3 * X4 * X5 * X6 * X7$$

means that the level of factor X8 is derived as the product of the levels of factors X1 through X7 for each run in the design. X8 always has a value of -1 or $+1$ since these are the values of X1 through X7. For factors with $q > 2$ levels, confounding rules are printed in an additive notation, and the arithmetic is performed in the Galois field of size q . For example, in a design for 3-level factors, the confounding rule

$$F = B + (2 * C) + D + (2 * E)$$

means that the level of factor F is computed by adding the levels of B and D and two times the levels of C and E, all modulo 3. Note that if q is not a prime number, Galois field arithmetic is not equivalent to arithmetic modulo q .

Blocks are introduced into designs by using block pseudo-factors. The confounding rule for the i th block pseudo-factor has $[B_i]$ on the left-hand side.

For details about how confounding rules are constructed, see “Suitable Confounding Rules” on page 717.

Alias Structure

The alias structure of a design identifies which effects are confounded (or aliased) with each other in the design. Note the difference between alias structure and confounding rules: the confounding rules are used to construct the design, and the alias structure is a result of using a given set of confounding rules. To display the alias structure for a design, use the ALIAS option in the EXAMINE statement.

Examining the alias structure is important because aliased effects cannot be estimated separately from one another. When several effects are listed as equal, the effects are all jointly aliased with one another and form an *alias chain* or *alias string*. For example,

Temperature*Moisture=HoldPress*Gage=Thickness*Screw=BoostPress*Time

is an alias chain that shows the relationship between four 2-factor interactions. If you want separate estimates of Temperature*Moisture and Thickness*Screw, for example, a design with this alias chain would not be acceptable. Designs of even resolution $2k$ contain one or more such chains of confounded k -factor interactions.

By default, the FACTEX procedure displays alias chains with effects up to a certain order d , where main effects are order 1, two-factor interactions are order 2, and so on. The value of d can be specified in the ALIASING option, or you can use the default calculated by the procedure. Alias chains that are confounded with blocks are displayed with $[B]$ on the left-hand side.

Minimum Aberration

As discussed in the section “Speeding Up the Search” on page 719, the FACTEX procedure uses a tree search algorithm to find the confounding rules of a design that matches the size and resolution you specify. There might be more than one solution set of confounding rules, and usually the FACTEX procedure chooses the first one it finds. However, there can still be important differences between designs with the same resolution; to deal with these differences, Fries and Hunter (1980) introduced the concept of *aberration* in confounded fractional factorial designs. This section defines aberration and discusses how to request minimum aberration designs with the FACTEX procedure.

Recall that a design has resolution r if r is the smallest order of the interactions that are confounded with zero. The idea behind minimum aberration is that a resolution r design that confounds as few r th-order interactions as possible is preferable. Technically, the aberration of a design is the vector $\mathbf{k} = \{k_1, k_2, \dots\}$, where k_i is the number of i th-order interactions that are confounded with zero. A design with aberration \mathbf{k} has *minimum aberration* if $\mathbf{k} \leq \mathbf{k}'$ for any other design with aberration \mathbf{k}' , in the sense that $k_i < k'_i$ for the first i for which $k_i \neq k'_i$.

For example, consider the resolution 4 design for seven 2-level factors in 32 runs (2_{IV}^{7-2}) discussed in Example 7.11.

By specifying 5 for the order d for the ALIASING option, you can see how many fourth- and fifth-order interactions are confounded with zero. The default design constructed by the FACTEX procedure confounds two fourth-order interactions and no fifth-order interactions with zero.

$$0 = A*B*F*G = C*D*E*G$$

Thus, part of the aberration for this design is

$$\{k_3, k_4, k_5, \dots\} = \{0, 2, 0, \dots\}$$

On the other hand, the design constructed by using the MINABS option confounds only one fourth-order interaction and two fifth-order interactions with zero.

$$0 = C*D*E*F = A*B*C*F*G = A*B*D*E*G$$

Thus, part of the aberration for this design is

$$\{k'_3, k'_4, k'_5, \dots\} = \{0, 1, 2, \dots\}$$

Since the two aberrations first differ for k_4 and k'_4 and since $k'_4 < k_4$, the aberration for the second design is less than the aberration for the first design.

The definition of aberration requires evaluating the number of i th-order interactions that are confounded with zero for all $i \leq k$, where k is the number of factors. Since there are q^k generalized interactions between k q -level factors, this evaluation can be prohibitive if there are many factors. Moreover, it is unnecessary if, as is usually the case, you are interested only in small-order interactions. Therefore, when you specify the MINABS option, by default, the FACTEX procedure evaluates the aberration only up to order d , where d is the same as the default maximum order for listing the aliasing (see the specifications for the EXAMINE statement in the section “[EXAMINE Statement](#)” on page 653). You can set d to any level by specifying (d) immediately after the MINABS option.

The discussion so far has dealt only with fractional unblocked designs, but one more point to consider is the definition of aberration for block designs. Define a vector $\mathbf{b} = b_1, b_2, \dots$ similar to the aberration vector \mathbf{k} , except that b_i is the number of i th-order interactions that are confounded with blocks. A block design with \mathbf{k} and \mathbf{b} has minimum aberration if

- \mathbf{k} is minimum
- among all designs with minimum \mathbf{k} , \mathbf{b} is minimum

MaxClear Designs

As discussed in the section “[Alias Structure](#)” on page 712, the alias structure for a factorial design can tell you important information about which effects are confounded and hence cannot be estimated separately from one another. In some cases, you cannot avoid the fact that some potentially active effects are aliased; for example, in resolution 4 designs, some two-factor interactions are aliased with each other and hence cannot be jointly estimated. In this case, you might want a design that has as many two-factor interactions as possible unaliased with any other interaction—that is, as many *clear* two-factor interactions as possible. This is known as the *MaxClear* design, and you can use the MAXCLEAR option in the MODEL statement to request it.

To explore how well a given design performs on the MaxClear criterion, you can use the **ALIASING** option in the EXAMINE statement to examine the alias structure. Clear interactions are those that are displayed by themselves, with no other interactions in their alias chain. Alternatively, the **SUMMARY** option in the EXAMINE statement displays a summary count of how many interactions there are in total up to a certain order d , how many of those are unaliased with interactions of lower order and are thus in a sense estimable, and how many are unaliased with any interactions of order d or lower and are thus clear.

Obviously, whether an interaction is clear depends on what other effects are considered to be potentially of interest. For a given design, the default order d for considering interaction clarity is the same as the default order d of interactions included in the alias structure. As with the alias structure, you can specify an alternative value of d in the **MAXCLEAR** option in the MODEL statement or in the **SUMMARY** option in the EXAMINE statement.

Split-Plot Designs

As discussed in the section “Structure of General Factorial Designs” on page 716, for a design with q -level factors in q^m runs, the FACTEX procedure usually treats the first m factors of the design as the run-indexing factors, and computes the levels of all other factors as linear combinations of these over the Galois field of order q . However, when you restrict the design’s randomization by using the **BLOCKS UNITS=()** option and **UNITEFFECT** statements to specify unitfactors and uniteffects, PROC FACTEX instead computes the levels of all factors (including the first m) in terms of underlying plot-indexing pseudo-factors that are distinct from those named in the **FACTORS** statement. These plot-indexing pseudo-factors are denoted $[i]$, for $i=1, \dots, m$, and they are associated with unitfactors as follows: If the **BLOCK UNIT=()** specification has the form

```
block units=(Stage1= $n_1$  Stage2= $n_2$  ...);
```

where $n_1 = q^{k_1}$, $n_2 = q^{k_2}$, \dots , then the first unitfactor, **Stage1**, is identified with all possible interactions between the first k_1 plot-indexing pseudo-factors, the second with the next k_2 pseudo-factors, and so on. If you save a split-plot design to a data set by using the **OUTPUT** statement, then the plot-indexing pseudo-factors are also included in the data set with names $_1_$, $_2_$, \dots , up to the base- q logarithm of the number of runs.

The whole-plot and subplot constraints specified by the **UNITEFFECT** statement define the relation between the plot-indexing pseudo-factors that correspond to the specified *uniteffect* and the factor effects specified in the **WHOLE=()** and **SUB=()** options. In particular, with a **BLOCK UNIT=()** specification of the previous form, a **UNITEFFECT** statement of the form

```
uniteffect Stage1 / whole=(Stage-1-effects);
```

means that the *Stage-1-effects* should be aliased only with interactions between the first k_1 plot-indexing pseudo-factors, while

```
uniteffect Stage1*Stage2 / sub=(Stage-2-effects);
```

means that the *Stage-2-effects* should not be aliased with interactions between the first $k_1 + k_2$ plot-indexing pseudo-factors.

Output

By default, the FACTEX procedure does not display any output. For each design that it constructs, the procedure displays a message in the SAS log that provides the following:

- the number of runs in the design
- the number of blocks and the block size, if appropriate
- the maximum resolution of the design

The DESIGN option in the EXAMINE statement displays the coded runs in the design that uses standard values, as described in the section “**OUTPUT Statement**” on page 658. The CONFOUNDING option in this EXAMINE statement displays the confounding rules used to construct the design. The ALIAS option in this statement displays the aliasing structure for the design.

The FACTEX procedure also creates output data sets with the OUTPUT statement. Since the procedure is interactive, you can use many OUTPUT statements in a given run of the FACTEX procedure to produce many output data sets if you separate them with RUN statements.

ODS Tables

The following table summarizes the ODS tables that you can request with the PROC FACTEX statement.

Table 7.8 ODS Tables Produced in PROC FACTEX

ODS Table Name	Description	Statement	Option
DesignPoints	Design points	EXAMINE	DESIGN
FactorRules	Treatment factor confounding rules	EXAMINE	CONFOUNDING
BlockRules	Block factor confounding rules	EXAMINE	CONFOUNDING
Aliasing	Alias structure	EXAMINE	ALIASING

Theory of Orthogonal Designs

Overview

This chapter provides the mathematical and statistical background for designs that are constructed by the FACTEX procedure; it also outlines the search algorithm that is used to find suitable construction rules. The material in this chapter is general and theoretical; you do not need to read this chapter to use the procedure for constructing most common experimental designs. On the other hand, you might want to read this chapter for the following reasons:

- to understand the general structure of designs that can be constructed with the FACTEX procedure
- to construct designs for factors with more than two levels, especially if interactions are involved
- to improve the search used by the procedure when constructing complicated designs involving many factors

Structure of General Factorial Designs

The FACTEX procedure constructs a fractional design for q -level factors by using the *Galois field* (or *finite field*) of size q . This is a system with q elements and two operations $+$ and \times , which satisfy the usual mathematical axioms for addition and multiplication. When q is a prime number, finite field arithmetic is equivalent to regular integer arithmetic modulo q . When $q = 2$, addition of the two elements of the finite field is equivalent to multiplication of the integers $+1$ and -1 . Since designs for factors with levels $+1$ and -1 are the factorial designs most commonly covered in textbooks, the arithmetic for fractional factorial designs is usually shown in multiplicative form. However, throughout this section a more general notation is used.

A design for q -level factors in q^m runs constructed by the FACTEX procedure has the following general form. The first m factors are taken to index the runs in the design, with one run for each different combination of the levels of these factors, where the levels run from 0 to $q - 1$. These factors are called *run-indexing factors*. For a particular run, the value F of any other factor in the design is derived from the levels P_1, P_2, \dots, P_m of the run-indexing factors by means of *confounding rules*. These rules are of the general form

$$F = r_1 P_1 + r_2 P_2 + \dots + r_m P_m$$

where all the arithmetic is performed in the finite field of size q . The linear combination on the right-hand side of the preceding equation is called a *generalized interaction* between the run-indexing factors. A generalized interaction is part of the statistical interaction between the factors with nonzero coefficients in the linear combination. The factor F is said to be *confounded* or *aliased* with this generalized interaction; two terms are confounded when the levels they take in the design yield identical partitions of the runs, so that their effects cannot be distinguished. The confounding rules characterize the design, and the problem of constructing the design reduces to finding suitable confounding rules.

Suitable Confounding Rules

Design Factors

This section explains how the criteria for a design can be reduced to prescribing that certain generalized interactions are *not* to be “confounded with zero.”

Suitable confounding rules depend on the effects you want to estimate with the design. For example, if you want to estimate the main effects of both A and B , the following rule is inappropriate:

$$A = B$$

With this rule, the levels of A and B are the same in every run of the design, and the main effects of the two factors cannot be estimated independently of one another. Thus, the first criterion for a suitable confounding rule is that no two effects you want to estimate should be confounded with each other.

Furthermore, an effect you want to estimate should not be confounded with an effect that is nonnegligible. For example, if the interaction between C and D is nonnegligible and you want to estimate the main effect of A , the following confounding rule is inappropriate:

$$A = C + D$$

(Recall that this section uses a general linear form for confounding rules instead of the usual multiplicative form. For factors with levels $+1$ and -1 , the preceding rule is equivalent to $A = C * D$.)

Another kind of confounding involves *confounding with zero*. If a factor or a generalized interaction F has the same value in every run of the design, then F is *confounded with zero*. Such confounding is denoted as

$$0 = F$$

Interactions are estimable with the design if and only if they are not confounded with zero. Consequently, another criterion for a suitable confounding rule is that no effect that you want to estimate can be confounded with zero. The confounding rule for two main effects

$$A = B$$

can be written as a generalized interaction confounded with zero:

$$0 = -A + B$$

The right-hand side of the preceding equation is part of the interaction between A and B . Thus, for any two effects to be unconfounded, it is equivalent to prescribe that no part of their generalized interaction be confounded with zero.

It is not enough to make sure that only the confounding rules themselves satisfy these restrictions. The consequences of the confounding rules must also satisfy the restrictions. For example, suppose you want to make sure that main effects are not confounded with two-factor interactions, and suppose that the confounding rule for factor E is

$$E = A + B + C + D$$

Then the following rule cannot be used for factor F :

$$F = A + B + C$$

Even though the rule for F does not confound F with a two-factor interaction, this rule forces a generalized interaction between E and F to be aliased with the main effect of D , since

$$E - F = (A + B + C + D) - (A + B + C) = D$$

Block Factors

If your design involves blocks, additional confounding criteria need to be considered. Blocks are introduced into designs by means of *block pseudo-factors*. (See “Types of Factors” on page 704 for details.) A design for q -level factors in q^s blocks contains s block pseudo-factors. Denoting the levels of these factors for any given run by B_1, B_2, \dots, B_s , the index of the block in which the run occurs is given by

$$B_1 + qB_2 + q^2B_3 + \dots + q^{s-1}B_s$$

For each block to occur in the design, every possible combination of block pseudo-factors must occur. This can happen only if all main effects and interactions between the block factors are estimable, which leads to yet another criterion for the confounding rules. Moreover, the effects you want to estimate cannot be confounded with blocks. In general:

- no generalized block pseudo-factors can be confounded with zero
- no generalized interactions between block pseudo-factors and effects you want to estimate can be confounded with zero

General Criteria

The criteria for an orthogonally confounded q^k design reduce to requiring that no generalized interactions in a certain set \mathcal{M} can be confounded with zero. (See the section “Structure of General Factorial Designs” on page 716 for a definition of *generalized interaction*.) This section presents the general definition of \mathcal{M} . First, define three sets, as follows:

\mathcal{E}	the set of effects that you want to estimate
\mathcal{N}	the set of effects that you do not want to estimate but that have unknown nonzero magnitudes (referred to as <i>nonnegligible</i> effects)
\mathcal{B}	the set of all generalized interactions between block pseudo-factors

Furthermore, for any two sets of effects \mathcal{A} and \mathcal{B} , denote by $\mathcal{A} \times \mathcal{B}$ the set of all generalized interactions between the effects in \mathcal{A} and the effects in \mathcal{B} .

Then the general rules for creating the set of effects \mathcal{M} that are not to be confounded with zero are as follows:

- Put \mathcal{E} in \mathcal{M} . This ensures that all effects in \mathcal{E} are estimable.
- Put $\mathcal{E} \times \mathcal{E}$ in \mathcal{M} . This ensures that all pairs of effects in \mathcal{E} are unconfounded with each other.
- Put $\mathcal{E} \times \mathcal{N}$ in \mathcal{M} . This ensures that effects in \mathcal{E} are unconfounded with effects in \mathcal{N} .
- Put \mathcal{B} in \mathcal{M} . This ensures that all q^s blocks occur in the design.
- Put $\mathcal{E} \times \mathcal{B}$ in \mathcal{M} . This ensures that effects in \mathcal{E} are unconfounded with blocks.

Searching for Confounding Rules

The goal in constructing a design, then, is to find confounding rules that do not confound with zero any of the effects in the set \mathcal{M} defined previously. This section describes the sequential search performed by the FACTEX procedure to accomplish this goal.

First, construct the set C_1 of candidates for the first confounding rule, taking into account the set \mathcal{M} of effects not to be confounded with zero. If C_1 is empty, then no design is possible; otherwise, choose one of the candidates $r_1 \in C_1$ for the first confounding rule and construct the set C_2 of candidates for the second confounding rule, taking both \mathcal{M} and r_1 into account. If C_2 is empty, choose another candidate from C_1 ; otherwise, choose one of the candidates rules $r_2 \in C_2$ and go on to the third rule. The search continues either until it succeeds in finding a rule for every non-run-indexing factor or until the search fails because the set C_1 is exhausted.

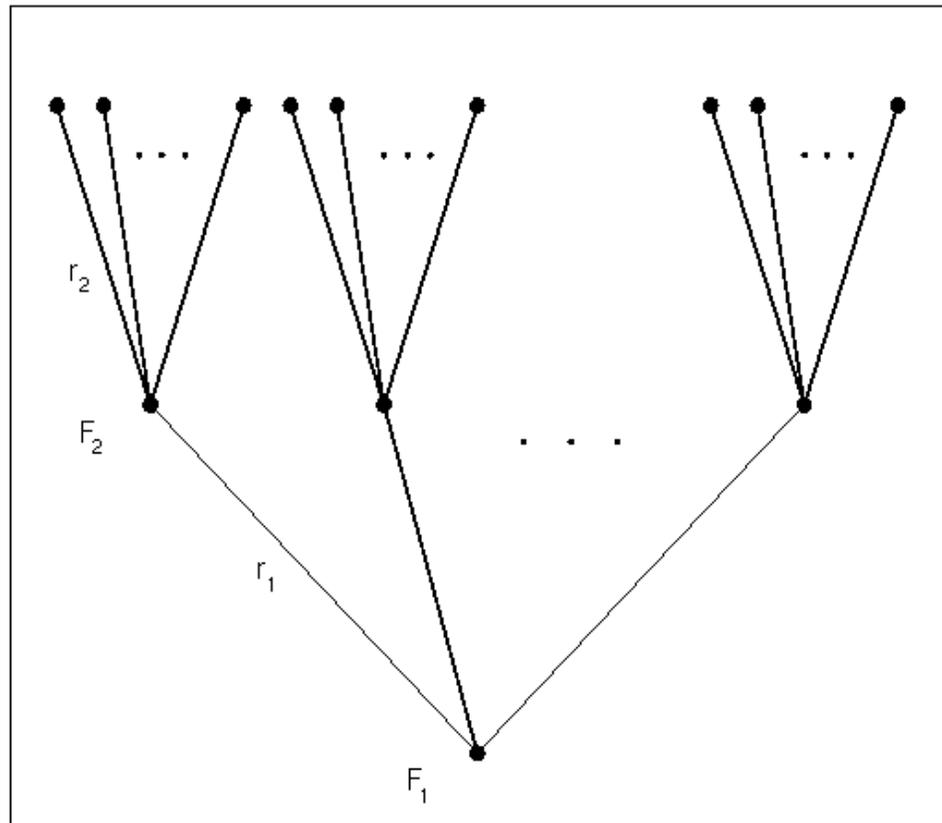

The algorithm used by the FACTEX procedure to select confounding rules is essentially a depth-first tree search. Imagine a tree structure in which the branches connected to the root node correspond to the candidates C_1 . Traversing one of these branches corresponds to choosing the corresponding rule r_1 from C_1 . The branches attached to the node at the next level correspond to the candidates for the second rule given r_1 . In general, each node at level i of the tree corresponds to a set of feasible choices for rules r_1, \dots, r_i , and the rest of the tree above this node corresponds to the set of all possible feasible choices for the rest of the rules.

Speeding Up the Search

For designs with many factors or blocks, the tree of candidate confounding rules can be very large and the search can take a very long time. In these cases, the FACTEX procedure spends a lot of time exploring sets of rules that are essentially the same and that all result in failure. A technique for pruning the search tree (see Figure 7.9) is as follows. Suppose that for some selection r_i for rule i , all the branches for the next rule eventually result in failure. Then any other selection r'_i is immediately declared a failure if the resulting number of candidates is the same as for the failed rule r_i . The search goes on to the next selection for rule i .

This method of pruning is not perfect; it might prune a branch of the search tree that would have resulted in a success. In mathematical terms, candidate sets C_i are not necessarily isomorphic because they have the same size. You can use the NOCHECK option in the PROC FACTEX statement to turn off the pruning. With the NOCHECK option, the FACTEX procedure searches the entire tree of feasible confounding rules, and if given enough time will find a design if one exists. The default argument for the TIME= option in the PROC FACTEX statement limits the search time to one minute.

Figure 7.9 Search Tree

On the other hand, the NOCHECK option is rarely needed to produce a design with a given resolution. For example, consider all possible blocked and unblocked two-level designs with minimum resolution for 20 or fewer factors and 128 or fewer runs. Of the nearly 400 different designs, the NOCHECK option is required to find a design in only nine cases. In one case (seven factors in 128 runs and blocks of size 2), NOCHECK is actually unable to find a design in the default time of 60 seconds, whereas the default search has no trouble finding a design.

General Recommendations

Choosing appropriate confounding rules can be difficult, especially if the set \mathcal{M} is complicated. Even if a design is found that satisfies the model specification, it is a good idea to examine the alias structure to make sure that you understand the alias structure generated by the confounding rules. To do so, use the ALIAS option in the EXAMINE statement.

For more details about the general mathematical theory of orthogonal factorial designs, refer to Bose (1947).

Introduction to the ISHIKAWA Environment

Overview

The Ishikawa diagram,¹ also known as a cause-and-effect diagram or fishbone diagram, is one of the seven basic tools for quality improvement in Japanese industry. It is used to display the factors that affect a particular quality characteristic or problem. For example, the following Ishikawa diagram shows factors affecting the quality of air travel service:

Figure 8.1 Ishikawa Diagram

In this example, the factors are organized into three categories of service (Pre-flight, In-flight, and Post-flight), which are represented as branches. The factors affecting each of these areas are represented as stems.

An Ishikawa diagram is typically the result of a brainstorming session to improve a product, process, or service. The main goal is represented by a main arrow or trunk, and primary factors are represented as sub-arrows or branches. Secondary factors are then added as stems, tertiary factors as leaves, and so on.

Creating the diagram stimulates discussion and often leads to an increased understanding of a complex problem. Japanese QC Circle members often post Ishikawa diagrams in a display area where they will be accessible to managers and other groups; refer to Rodriguez (1991). In the United States, Ishikawa diagrams are often included in presentations by plant personnel to management or customers.

¹ The Ishikawa diagram is named after its developer, Kaoru Ishikawa (1915-1989), a leader in Japanese quality control; refer to Karabatsos (1989), Kume (1985) and Sarazen (1990).

Traditionally, Ishikawa diagrams have been prepared by hand on paper or chalk boards. This limits the amount of detail that can be added and makes it awkward to update the diagram as an understanding of the process evolves. Manual preparation also restricts the collection and display of data on the diagram, as advocated by Ishikawa (1982).

The ISHIKAWA procedure was designed to overcome these limitations by providing a highly interactive graphics environment (referred to in this section as the *ISHIKAWA environment*) for creating and modifying Ishikawa diagrams.

In the ISHIKAWA environment you can

- add and delete arrows with a mouse. You can also swap, copy, and so forth.
- highlight special problems or critical paths with line styles and color
- display additional data for each of the arrows in a popup notepad
- display portions of the diagram in separate windows for increasing or isolating detail. You can also divide sections of the diagram into separate Ishikawa diagrams.
- merge multiple Ishikawa diagrams into a single, master diagram
- display any number of arrows and up to ten levels of detail
- foliate and defoliate diagrams dynamically
- save diagrams for future editing
- save diagrams in graphics catalogs or export them to host clipboards or graphics files
- customize graphical features such as fonts, arrow types, and box styles
- obtain online help at any time

If you are using the ISHIKAWA procedure for the first time, the tutorial at the end of this chapter demonstrates some of the basic operations used in the ISHIKAWA procedure. A summary of these operations (and others) can be found in the section “[Summary of Operations](#)” on page 736.

For a detailed discussion of each of the operations, see “[Details of the ISHIKAWA Environment](#)” on page 735. This chapter includes many tools not presented in the tutorial.

Terminology

This section introduces basic operations used in the ISHIKAWA environment and defines terms used to describe the ISHIKAWA procedure. Some details depend on your *host*, which is the specific system of computing hardware and software you use. For example, all hosts present the ISHIKAWA environment in a system of *windows* on the host’s *display*, but the appearance of your windows may differ from the figures in this book. You can find more information in the SAS companion for your host and in your host system documentation.

Using a Mouse

On most hosts you can use a *mouse* to point to objects on the display. A mouse is a physical device that controls the location of a *cursor*, which is a small, movable symbol on the display. Due to the precision required, you must use a mouse to perform tasks in the ISHIKAWA environment.

Text is placed relative to the *text* cursor and not the *mouse* cursor (↖). The mouse cursor is always visible, while the text cursor is displayed only when text can be entered (for example, when an arrow is being added).

The mouse also has *buttons* that work like keys on the keyboard. On most hosts, you *select* an object by pointing to it with the mouse and clicking the left button on the mouse. To *click*, press the button down and release it quickly without moving the mouse. To *double click*, click *twice* quickly without moving the mouse. To *drag*, move the mouse while holding down the left mouse button.

Popup menus appear to *pop up* on the display when you press a button—usually the right mouse button. Popup menus are convenient to use, since they always appear at the cursor location. Selecting an item from the popup menu, however, is host specific.

For details about using the mouse on your system, consult the SAS companion for your host.

Using Context-Sensitive Operations

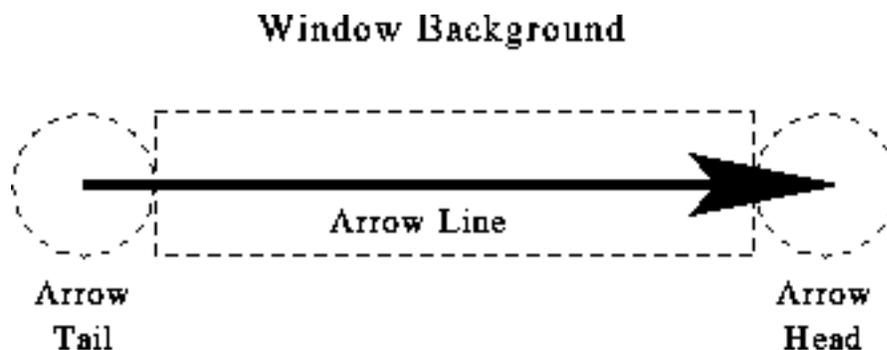

Basic operations such as add, edit, delete, and move are invoked by activating the mouse near various *hotspots* along the arrows rather than selecting tools from a tools palette. The hotspots are the following context-sensitive areas in the Ishikawa diagram:

- arrow heads, tails, lines, and labels
- window background

Given such evident features, and a rigidly defined structure, the hotspots are not highlighted.

The hotspot areas are illustrated in the following figure:

Figure 8.2 Context-Sensitive Locations (Hotspots)

The dotted, circular region at the right end of the arrow is the arrow head hotspot. Arrows attach to other arrows at the head of the arrow. The dotted, circular region at the left end of the arrow is the arrow tail hotspot. The region that encompasses the arrow line is also hot. Every arrow in the diagram has these hotspots.

The window background is any area inside the window and outside the dotted lines. You use the window background to cancel pending operations (such as adds and moves) and to control global or environment-specific operations (such as decreasing detail and tagging arrows).

When you activate the mouse, the ISHIKAWA environment uses the mouse event (click, double click, drag, or popup) and the hotspot type (head, tail, line, label, or background) to infer the intended operation. The ISHIKAWA environment responds differently depending upon which hotspot you select and how you select it. This is often referred to as *context-sensitive* behavior.

Context sensitivity allows the ISHIKAWA environment to operate without modes. In a modeless environment like the ISHIKAWA environment, context-sensitive operations reduce the amount of mouse travel (the time and distance spent moving the cursor from the drawing area to the tools palette and back). For example, you do not go to a tools palette to change from *add mode* to *delete mode*. This allows you to focus on the diagram rather than on the diagramming tool.

In the ISHIKAWA environment, the primary operations such as add, edit, delete, and move are all operations associated with a specific hotspot and the mouse button. Secondary operations such as zoom, copy, highlight, and so forth operate from *context-sensitive* popup menus (typically activated using the right mouse button.) Other, less frequently used operations are available from the command bar.

The relationship between these context-sensitive areas, the mouse actions, and the basic ISHIKAWA tools is introduced in the tutorial that follows. A comprehensive discussion of each operation is given in “[Details of the ISHIKAWA Environment](#)” on page 735. In addition, the tables in the section “[Summary of Operations](#)” on page 736 provide a good overview of how to function inside the ISHIKAWA environment.

Using the Command Bar

In addition to the editing tools, the ISHIKAWA environment provides a number of file management, printing, and help facilities. These facilities are located on the *pull-down* menu associated with the window. The appearance and location of the command bar are host specific. On most hosts, you choose these operations by *pulling down* a menu from a *menu bar* using the mouse button. For more details about using the command bar on your system, consult the SAS companion for your host.

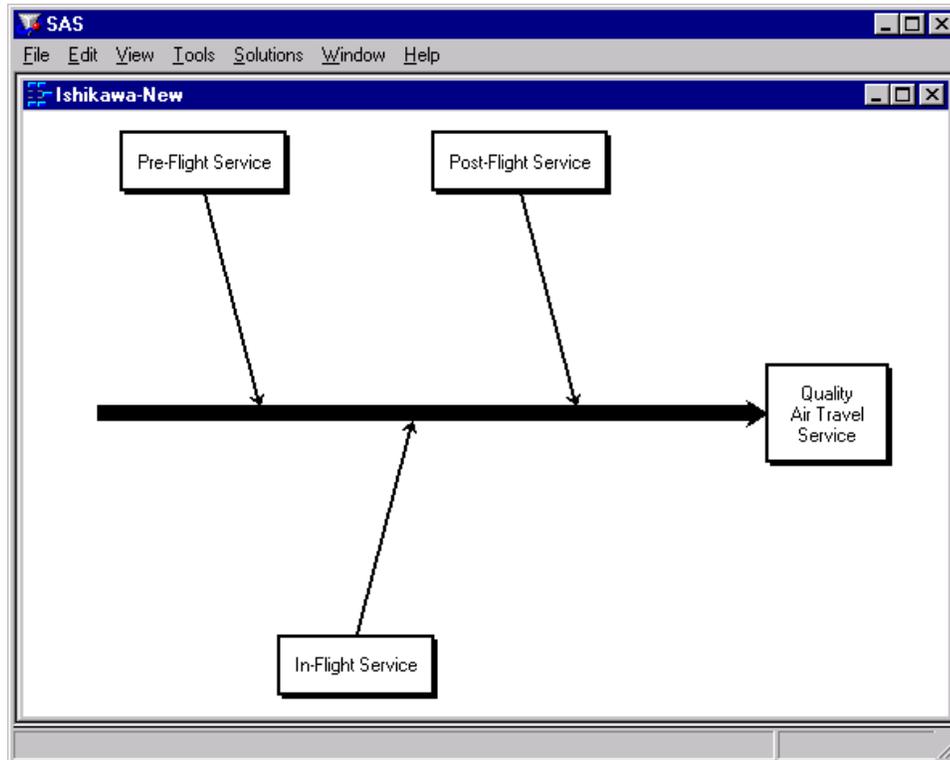

Tutorial

The following example is used throughout the ISHIKAWA chapters. Later examples illustrate how to add to and modify this diagram. If you are not familiar with the ISHIKAWA procedure, you may want to complete this tutorial before proceeding to “[Details of the ISHIKAWA Environment](#)” on page 735. In this tutorial you will learn to create and save a simple Ishikawa diagram.

See ISHPLANE in the SAS/QC Sample Library

A task force is studying ways to improve the quality of passenger service for a major airline. After a preliminary discussion, the team concludes that three major areas should be considered: pre-flight service, in-flight service, and post-flight service. This result is to be displayed with the following preliminary Ishikawa diagram:

Figure 8.3 Preliminary Ishikawa Diagram

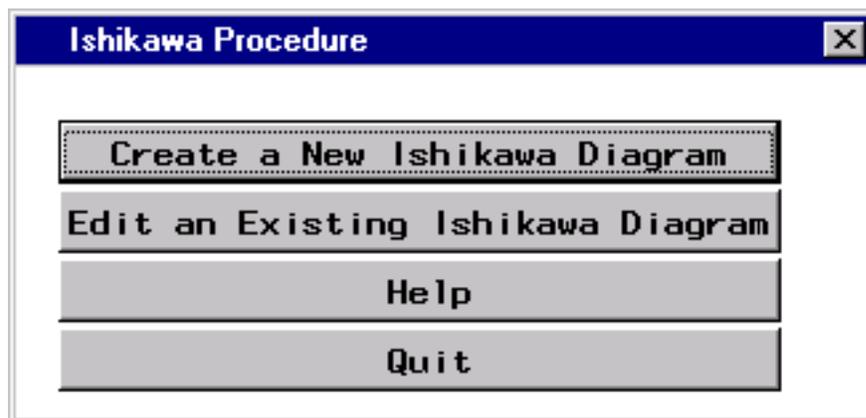

1. To begin using the ISHIKAWA environment, submit the following SAS statements:

```
proc ishikawa;
run;
```

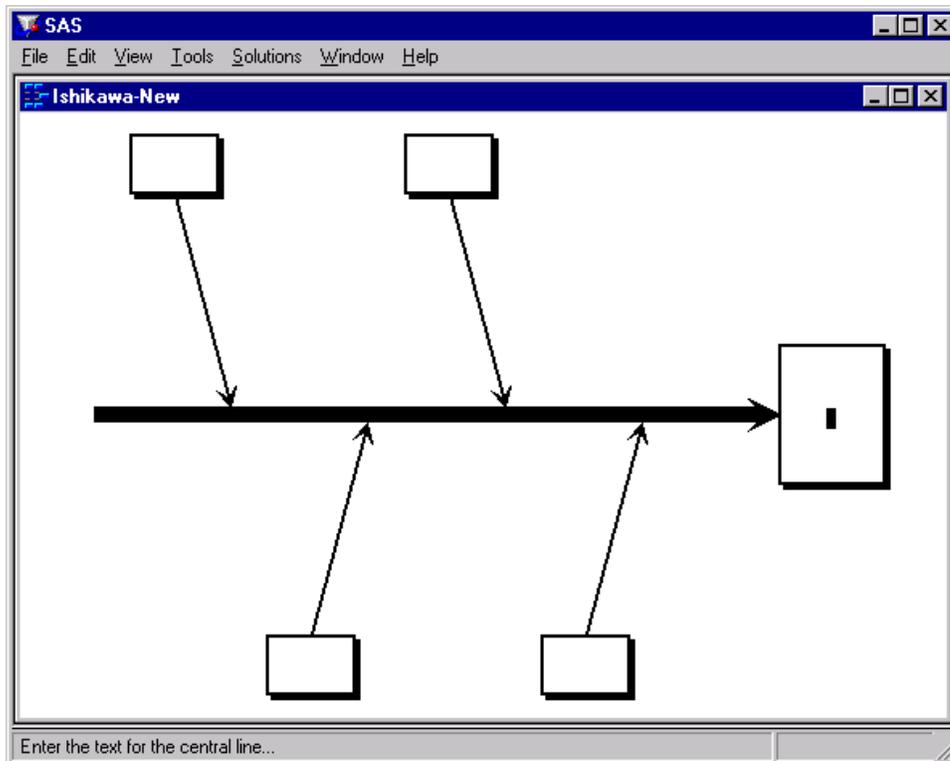

An initial menu appears on your display, as follows:

Figure 8.4 Initial Menu

2. Select **Create a New Ishikawa Diagram** to open a window containing a template for a new Ishikawa diagram.

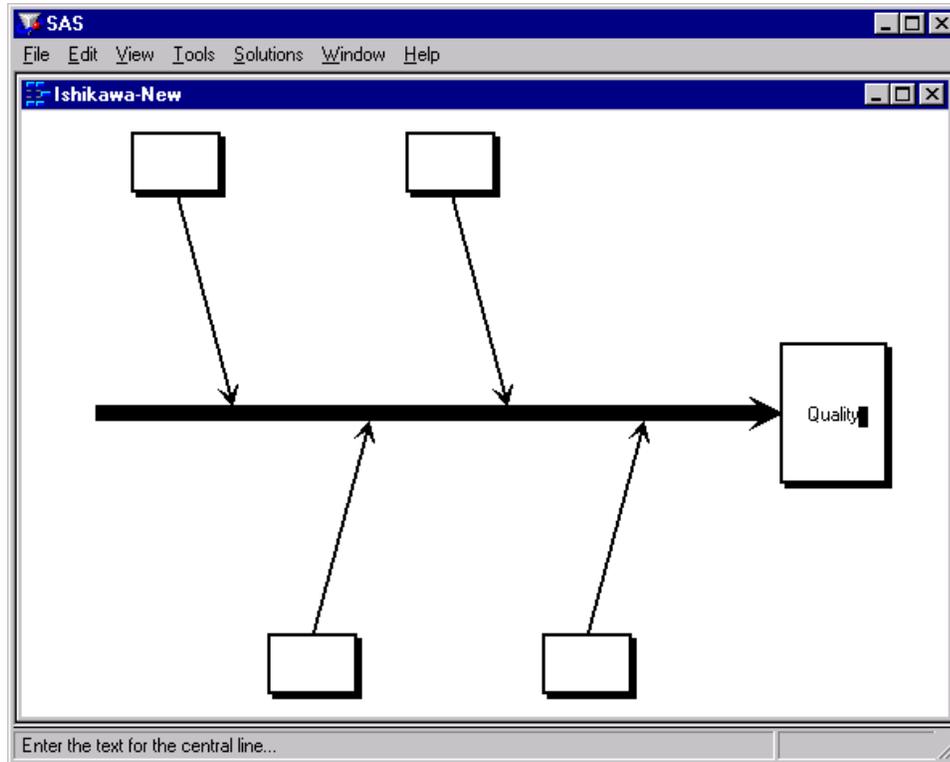

Figure 8.5 Starting a New Ishikawa Diagram

The ISHIKAWA environment guides you through the first steps of the diagramming process by prompting you to enter the text for the central line and then the upper left branch. During each step, a message indicating the action required is displayed in the message area for this window. Once you have completed these preliminary steps, you can proceed in any order you want.

- Initially, the text cursor is positioned inside the box for the trunk. A message is displayed directing you to enter the first line of text for the trunk. Type the word *Quality*.²

Figure 8.6 Labeling the Trunk

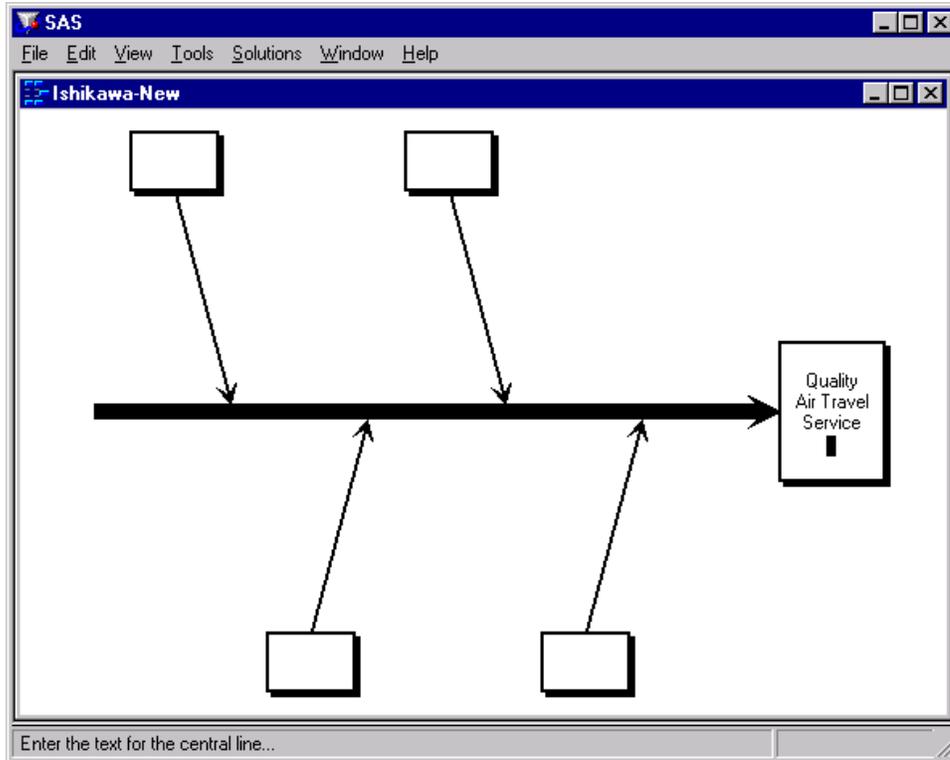

Note that the text is placed relative to the text cursor. You can correct mistakes by using any of the keyboard editing keys or cursor navigation keys (for instance, BACK SPACE and ←).

²You can skip this step, in future diagrams, by pressing RETURN before entering any text.

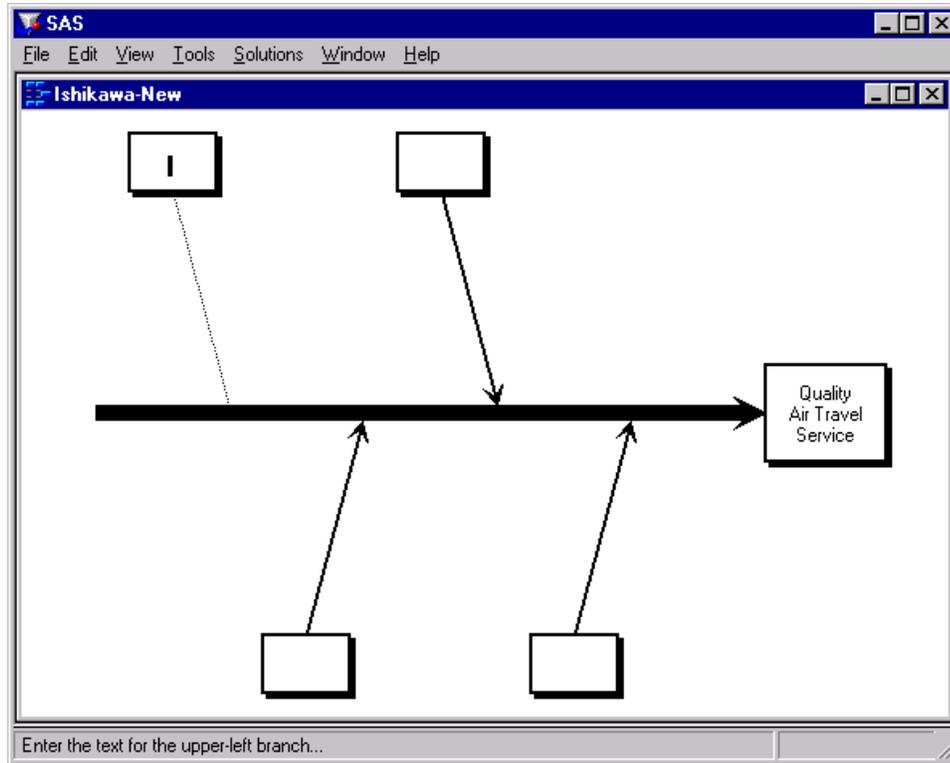

- Advance to the next line by pressing RETURN. Now complete the label by entering *Air Travel* and *Service* on separate lines.

Figure 8.7 Labeling the Trunk (*continued*)

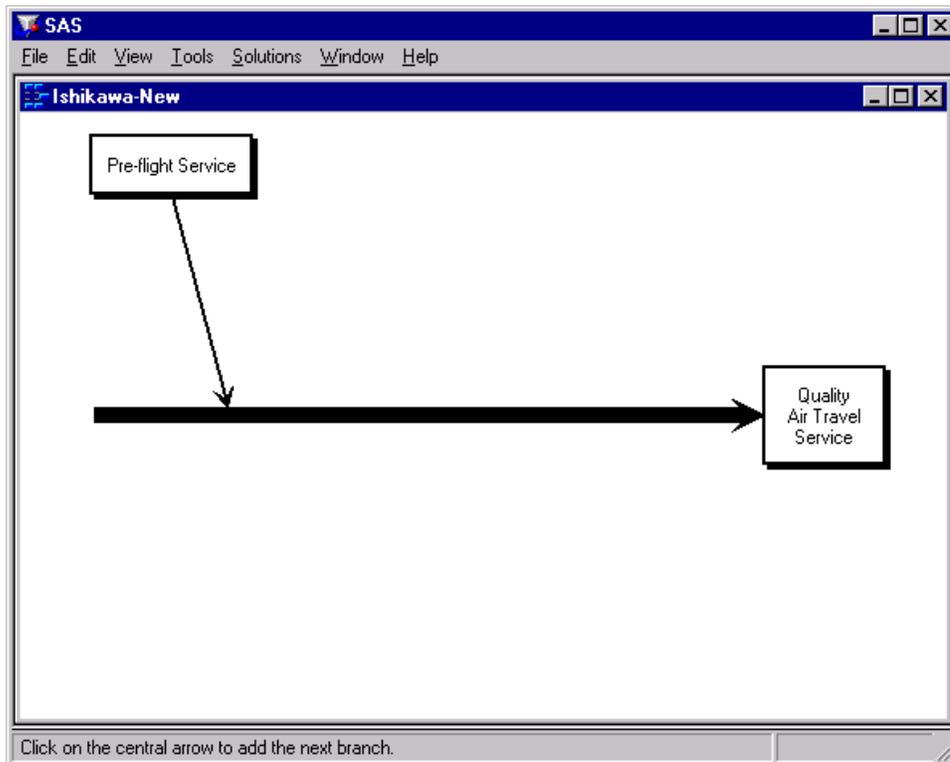

5. To terminate text entry, press RETURN a second time. The ISHIKAWA environment automatically moves the cursor to the upper left branch. If you made a mistake labeling the trunk, continue with the example. You cannot return to the trunk until you have finished the branch.

Figure 8.8 Labeling the First Branch

6. Enter the label *Pre-Flight Service*. Press RETURN twice to terminate text entry for this branch.³ Your window should now look like this:

Figure 8.9 Completed Branch Label

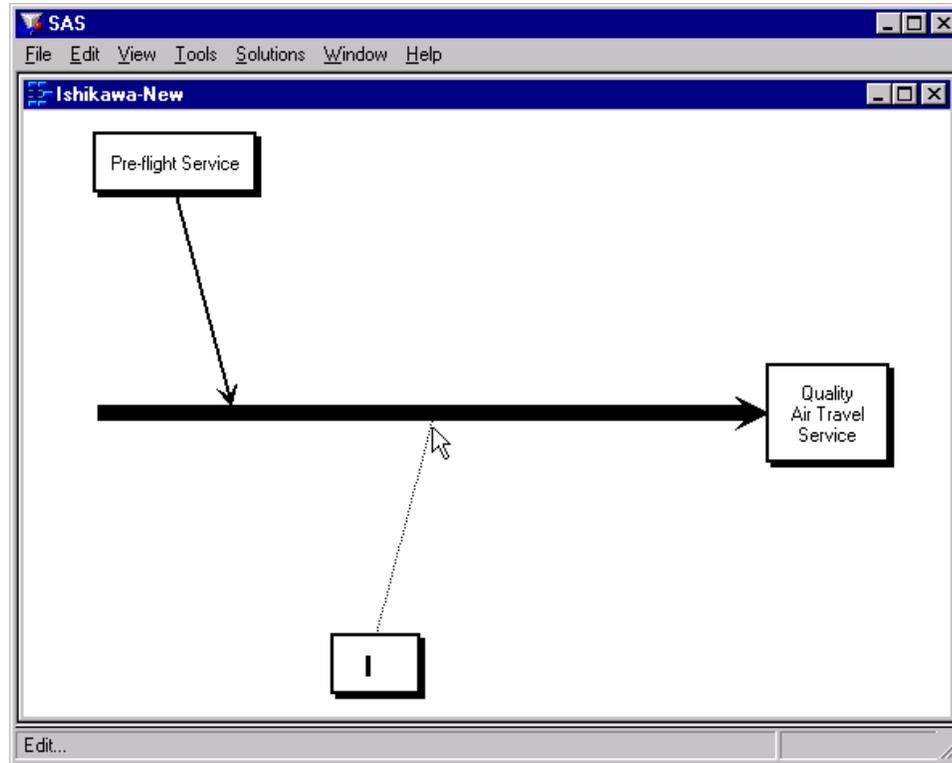

Note that when you finish entering text for the upper left branch, the other branches are deleted. These were temporarily displayed as visual cues, and now it is up to you to decide where to add the remaining branches.

³You can skip this step, in future diagrams, by pressing RETURN before entering any text.

7. To add the branch labeled *In-Flight Service* to the lower half of the diagram, position the cursor slightly below the point where you want the branch to attach to the trunk and click the mouse button. The branch appears with the text cursor centered inside the box. Enter the first line of text.

Figure 8.10 Adding a New Branch

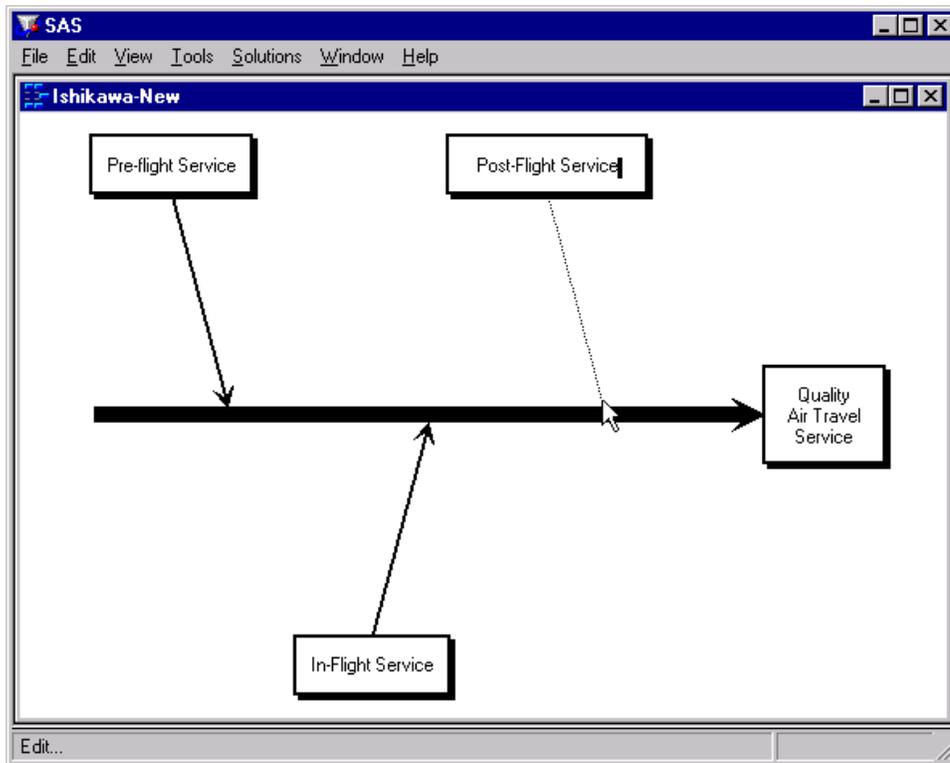

If your branch is not positioned where you want it, move the cursor to the appropriate position along the trunk and click. Each time you click, the branch is moved to the new location.

If, on the other hand, the branch is not drawn at all, the cursor was probably too far away from the trunk to be recognized. Move the cursor closer to the trunk and try again.

Enter the label *In-Flight Service* and press RETURN twice to terminate text entry.

8. Next add the branch *Post-Flight Service* to the upper half of the diagram. Position the cursor so that it is just above the point where you want the branch to attach to the trunk and click.

Figure 8.11 Adding the Last Branch

9. Press RETURN twice to terminate text entry.

Congratulations. You have just completed your first Ishikawa diagram using the ISHIKAWA procedure. In the process you learned to add branches to a diagram using context-sensitive mouse clicks. Future examples will illustrate other context sensitive areas, tools, and popup menus.

The examples that follow will, for the most part, expand on this diagram. To save the diagram, select **File ► Save as ► Data Set** from the command bar. Use SASUSER for the library name and AIRLINE for the data set name. Then select **Save**.

To leave the ISHIKAWA environment and return to the SAS Display Manager, select **File ► Close** from the command bar.

Details of the ISHIKAWA Environment

This chapter presents detailed information about and examples of all the operations available in the ISHIKAWA environment. Some of the examples build upon the diagram created in the [tutorial](#).

Summary of Operations

To invoke the following context-sensitive operations, apply the specified action (mouse event) to the appropriate hotspot, using the left mouse button:

Table 8.1 Primary Operations

Operation	Mouse Event	Hotspot	Section
Add	Click	Near the intended attachment point	“Adding Arrows”
Edit	Click	Arrow tail	“Labeling Arrows”
Move	Click (<i>to pick</i>)	Arrow head	“Moving Arrows”
	Click (<i>to drop</i>)	Near the intended attachment point	
Delete	Double click	Arrow head	“Deleting Arrows”
Resize	Drag	Arrow tail	“Resizing Arrows”
Notepad	Double click	Arrow tail	“Notepads”

To invoke the following operations, make the specified selection from the appropriate context-sensitive popup menu using the right mouse button:

Table 8.2 Secondary Operations

Operation	Menu	Selection	Section
Swap	Head or tail	Swap	“Swapping Arrows”
Balance	Head or tail	Balance	“Balancing Arrows”

Operations

This section provides details concerning the operations available in the ISHIKAWA environment. The order in which the topics appear is the order in which the operations are typically encountered. Some of the examples in this section build upon the diagram created in the tutorial.

Adding Arrows

You add an arrow by pointing with the mouse to the intended attachment point along an existing arrow and clicking the mouse. You control the direction of the new arrow by offsetting the mouse cursor a small distance away from the parent arrow on the side where the new arrow is to appear.

For example, to add upper branches, you offset the cursor slightly above the trunk. To add lower branches, you offset the cursor slightly below the trunk. Likewise, you offset the cursor to the right of the branch to add a right-hand stem and slightly left for a left-hand stem.

If a new arrow is not drawn as you intended (either positionally or directionally), you can easily move or delete it. To delete a new arrow before you have entered any text, click in the background. To move a new arrow before you have entered any text, move the cursor to a new attachment point and click.

Once an arrow is drawn, you are immediately prompted for its label (note the hint, *Edit...*, displayed on the message line and the appearance of the text cursor at the end of the arrow). See “Labeling Arrows” on page 743, for details on the text editing features of the ISHIKAWA environment.

A diagram can contain up to ten levels of detail, but the number of arrows is limited only by the resolution and size of your graphics display.

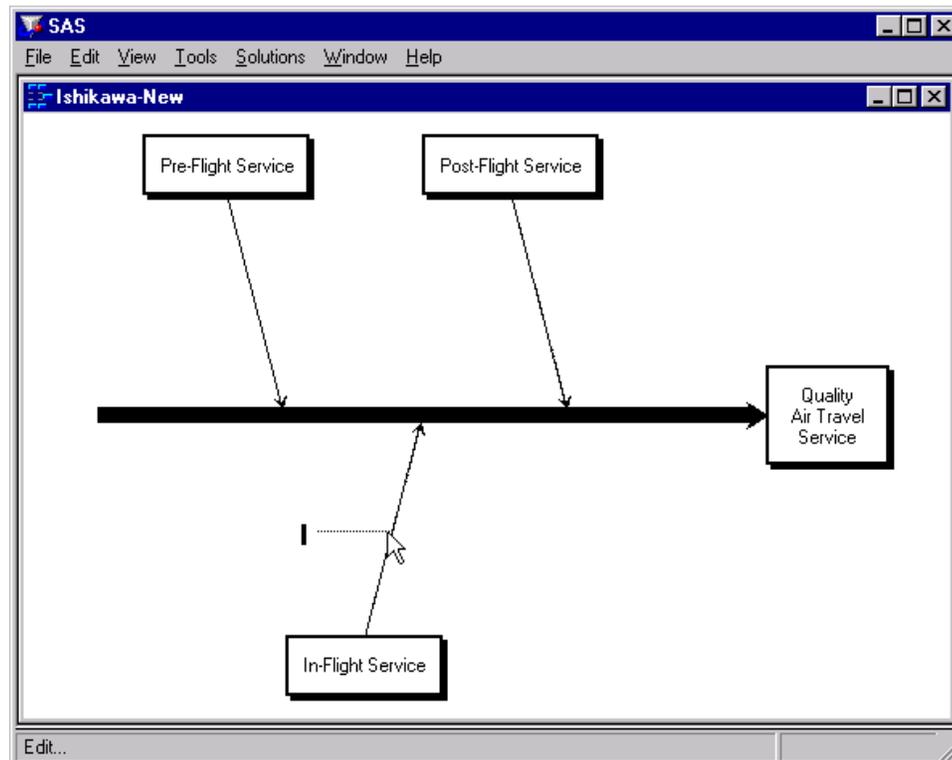

Example

Continuing with the tutorial example from “Tutorial” on page 727, suppose that you have obtained detailed information for each of the three major service areas, which you want to display by adding stems to the branches of the diagram you previously created. If you closed the ISHIKAWA environment after saving the data set, SASUSER.AIRLINE, you can easily restore the diagram by submitting:

```
proc ishikawa data=sasuser.airline;
run;
```

To add a stem to the left side of the branch labeled *In-Flight Service*, position the cursor so that it is just to the left of the point where you want the stem to attach. Click the mouse. The new arrow (pending text) appears as follows:

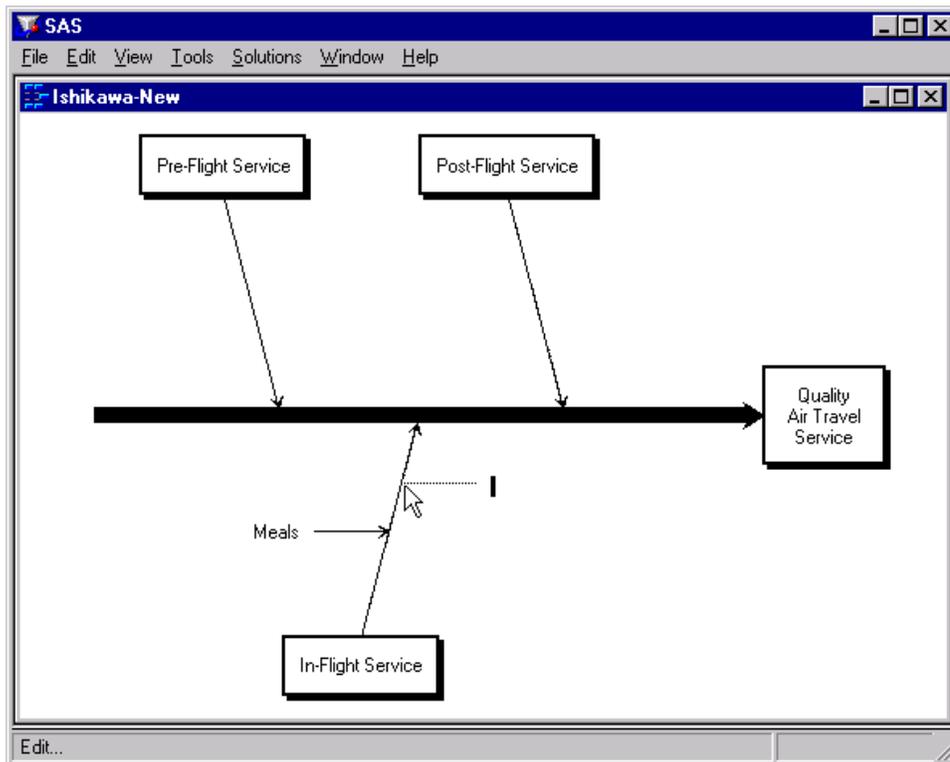

Figure 8.12 Adding the Left Stem

Type the label *Meals* and press RETURN twice.

To add a stem to the right side of the same branch, position the cursor so that it is just to the right of the attachment point. When you click the mouse, your window will appear as follows:

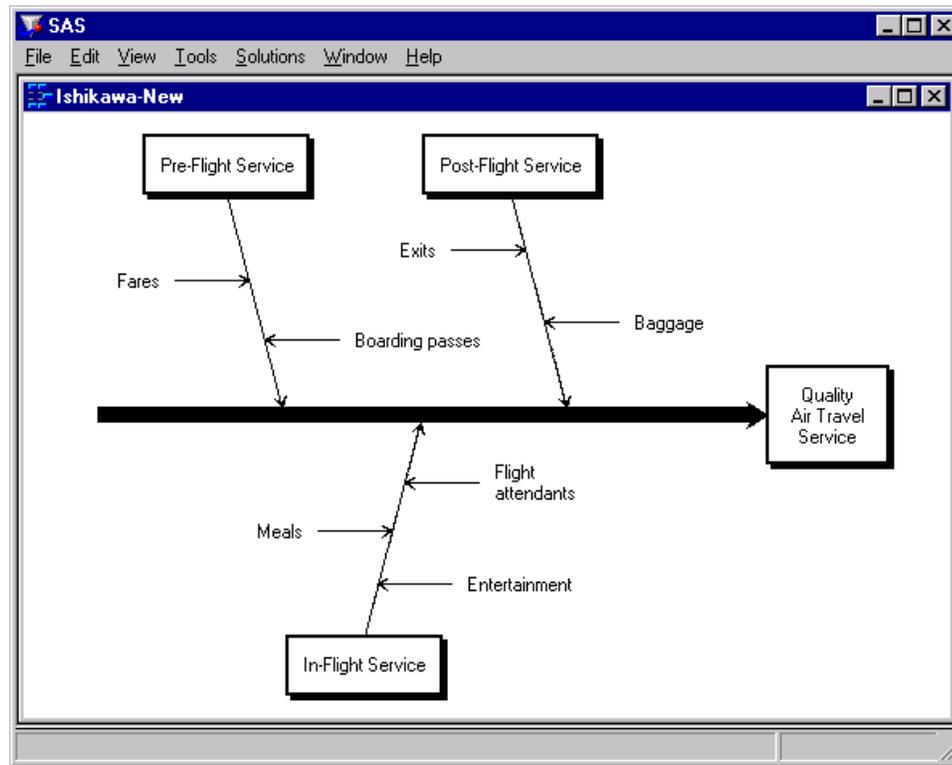

Figure 8.13 Adding the Right Stem

Type the label *Flight attendants* on two lines and press RETURN to terminate text entry.

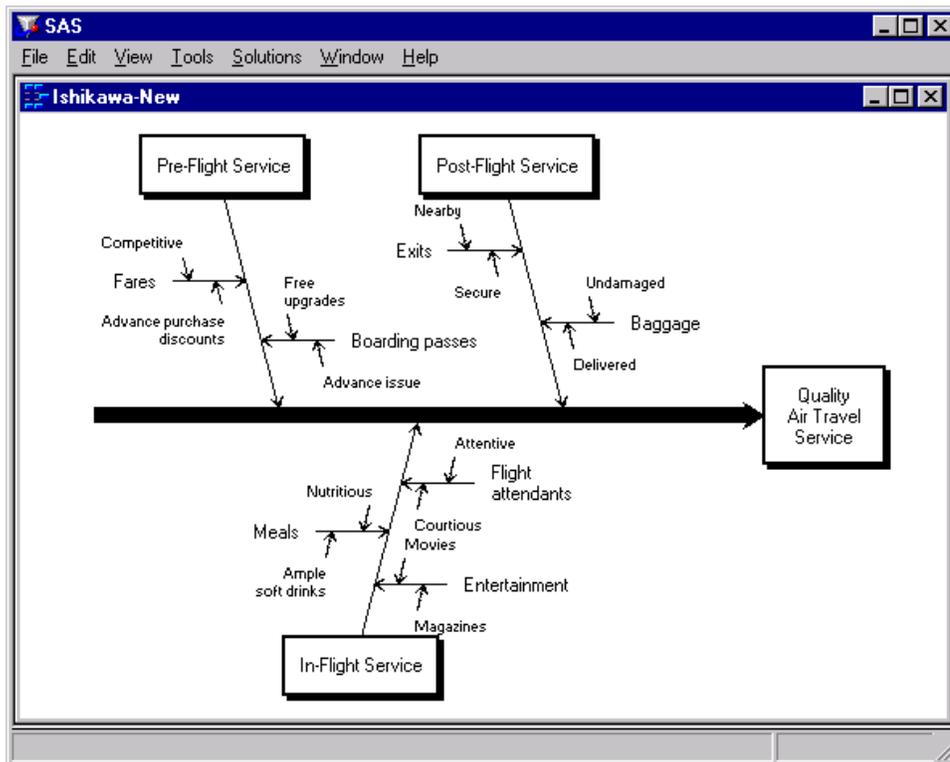

Complete the diagram by adding the remaining stems shown in the following window:

Figure 8.14 Stem-Level Diagram

Experiment further by adding several of the leaves shown in the following window. Don't be concerned if some of the labels collide with each other. Later, you will learn how to move and resize arrows.

Figure 8.15 Leaf-Level Diagram

Labeling Arrows

To edit the label of an existing arrow, click on one of the following areas:

- the label
- the arrow tail (if the arrow does not have a label)
- inside the box for trunk and branch labels

Use your keyboard to enter the text.

On hosts that support direct graphical text entry,⁴ the following functions are supported:

- edit keys such as BACK SPACE, DELETE CHAR, DELETE LINE, and RETURN
- cursor navigation keys such as ↑, ↓, → and ←
- the INSERT key to toggle between insert and overstrike modes
- buffers to copy, cut, or paste text into and from external sources

Text entry is terminated whenever you press RETURN on an empty line or exceed the maximum line limit for a label. Text entry is also terminated whenever you click the mouse. This shifts focus away from the editing operation and to the new location.

Labels are restricted to 40 characters per line. The trunk label can have up to five lines, and labels for other levels are limited to two lines.

You can split a line of text into two lines by pressing the RETURN key anywhere inside the line. Likewise, flow a line with the previous line of text by pressing the BACK SPACE key at the beginning of the line.

You can copy the contents of the paste buffer into a label using the PASTE command. This can be helpful when the information for your diagram is available from another source (a flat file, for example). Use the paste buffer to copy the information from that source to your Ishikawa diagram.

Some hosts designate the right mouse button for pasting, some use control keys (like ctrl-p), while others use a designated function key. For more details about using paste buffers with the SAS System, consult the SAS companion for your host.

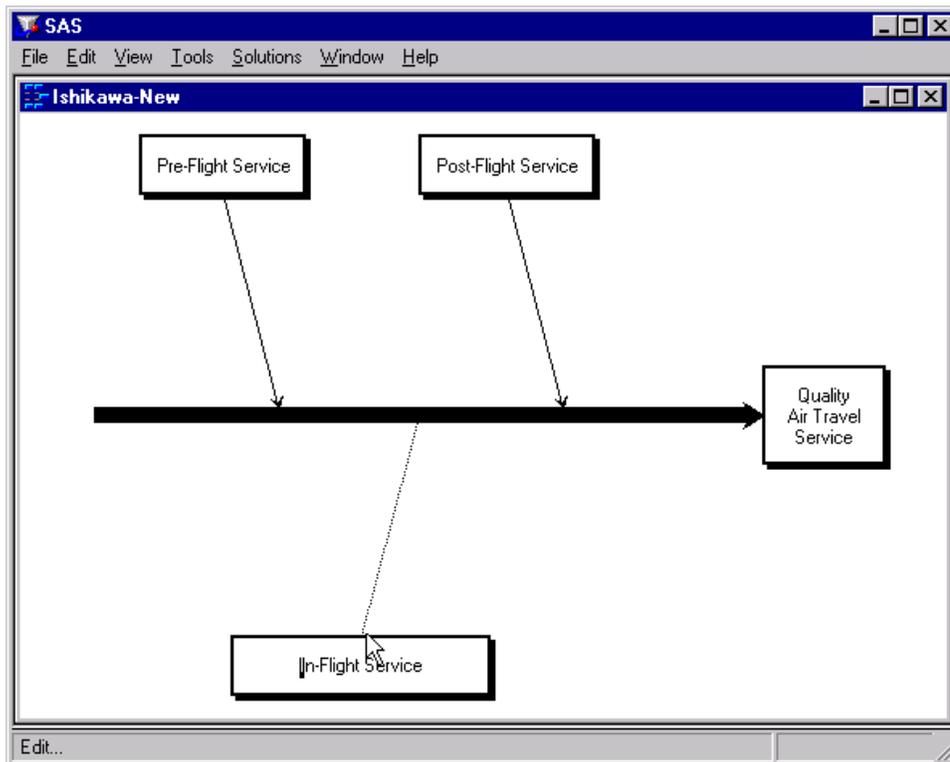

To paste text into a label, you must first select the label. For existing arrows, select the arrow, position the cursor where you want the text to appear, and then issue the PASTE command. For new arrows pending text entry, simply issue the PASTE command. Any text in the paste buffer that causes the label to exceed its limits is truncated.

When your mouse has a paste key defined, instead of adding an arrow and pasting the text in two operations, use the *right* mouse button to add the arrow. This action adds a new arrow, automatically copies the label from the paste buffer, and terminates text entry, in a single operation.

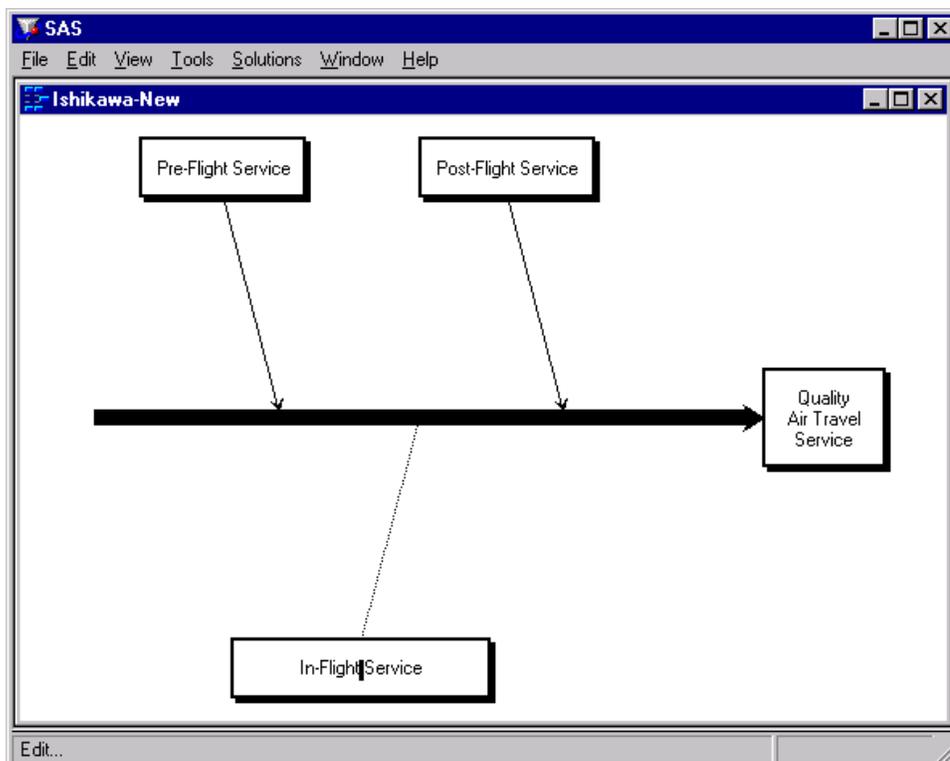

Example

In the following diagram, the branch labeled *In-Flight Service* has been selected by clicking on the arrow tail. The arrow is highlighted with a narrow dotted line, and the text cursor is positioned over the first character in the label.

⁴Devices such as the IBM3179 do not support the direct graphical text entry mechanism described in these examples. Instead, a text entry window pops up whenever you select an arrow for editing. You must edit the text for the arrow from the dialog box and close the text entry window before the diagram is updated.

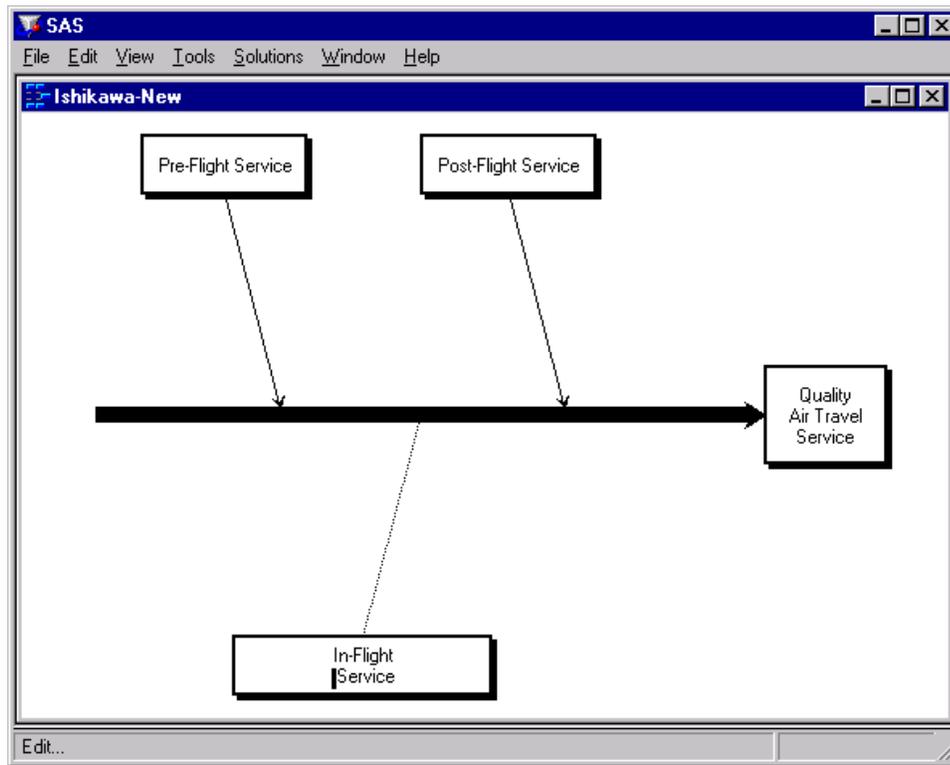

Figure 8.16 Selecting an Arrow for Editing

To change the label so that the word *Service* appears on a separate line, use the → or ← key to move the cursor to the space before the word *Service*, as shown in the following:

Figure 8.17 Using Cursor Keys

Now press RETURN to split the text into two lines.

Figure 8.18 Splitting Text

Remember to delete the space preceding *Service* before pressing RETURN to terminate text entry.

Moving Arrows

You move an arrow by picking up the arrow and dropping it at a new location:

- To *pick up* an arrow, position the cursor over the arrow head and click the mouse. The arrow you selected will be highlighted with a narrow dotted line. If the arrow is not highlighted, move the cursor closer to the arrow head and repeat the click.
- To *drop* an arrow, move the cursor slightly to one side of the new attachment point and click (just as though you are adding a new arrow).

When you move an arrow, all its descendants move with it.

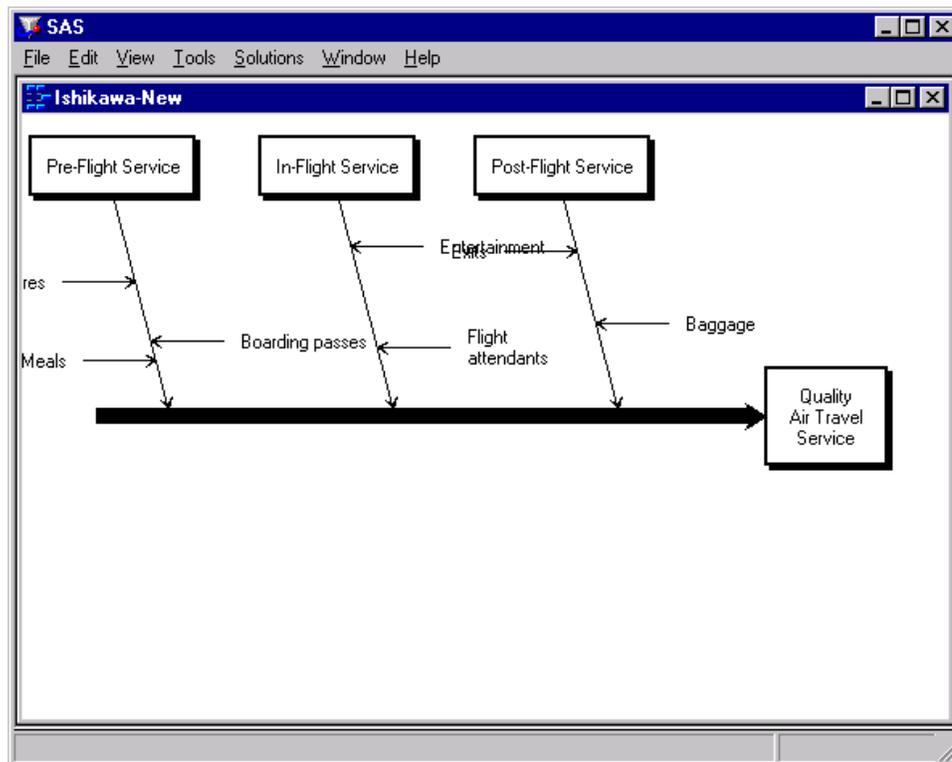

To cancel a move after picking up an arrow, click in the background area of the ISHIKAWA window.

Do not try to drop the arrow back into place by clicking on the arrow head a second time. A double click on (or near) the arrow head deletes the arrow. To move an arrow a short distance, move the cursor away from the arrow head before clicking to drop the arrow. On some systems the cursor will change shape when you have moved outside the context-sensitive area.

Example

As your diagrams develop, you will want to reposition arrows, either because of errors or for aesthetic reasons. The following is an example of an Ishikawa diagram that needs to be modified:

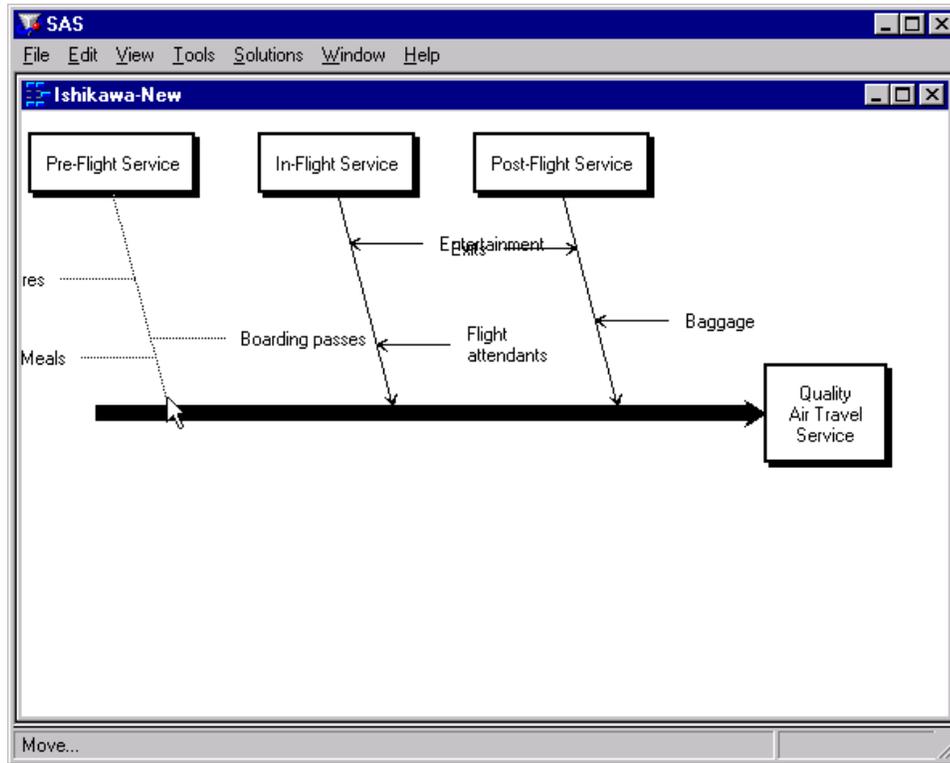

Figure 8.19 An Inelegantly Arranged Ishikawa Diagram

The diagram lacks balance, and some of the branches are too close, resulting in collisions and clipping.

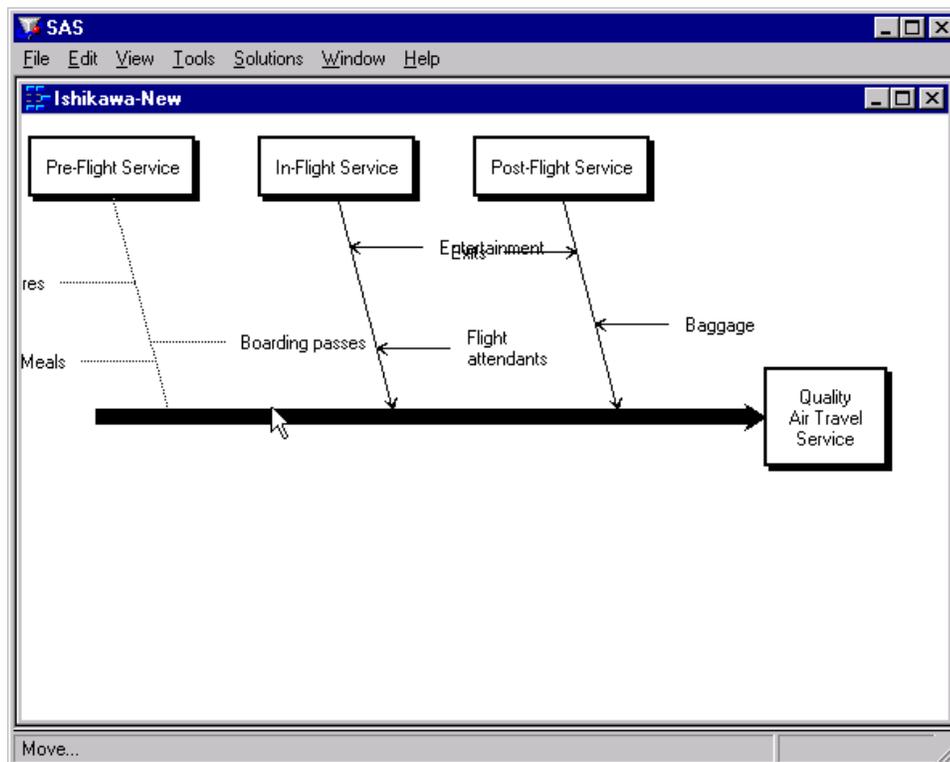

One way to improve the diagram is to move the branch for *Pre-Flight Service* toward the center of the trunk. First select the arrow head for this branch.

Figure 8.20 Selecting an Arrow to Move

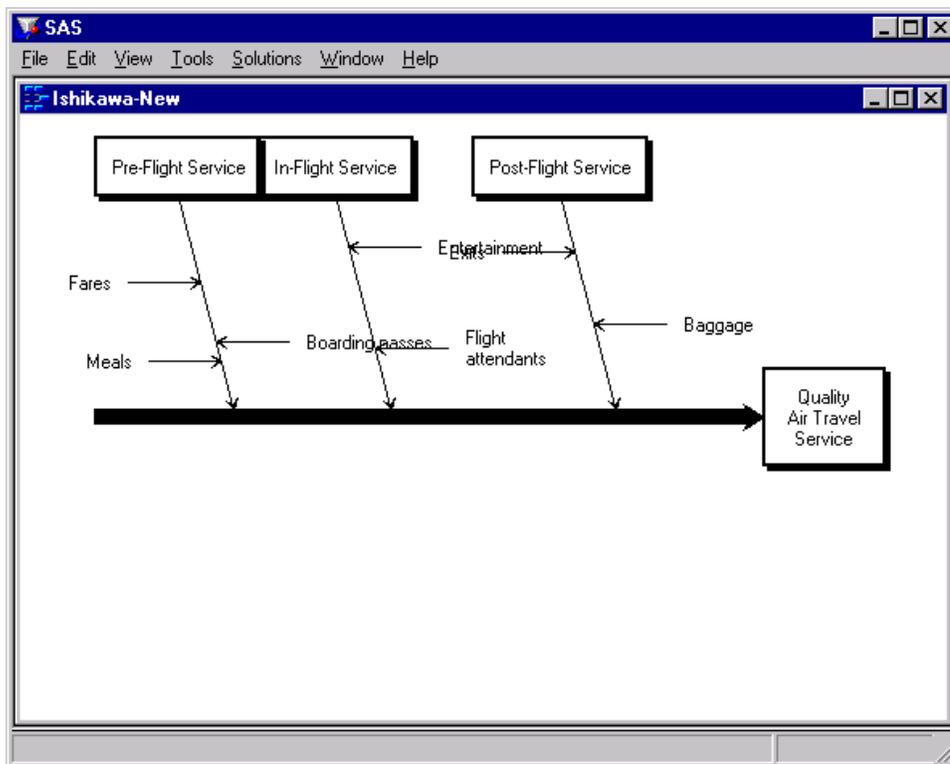

Then move the cursor to a point just slightly above the trunk near the desired new attachment point.

Figure 8.21 Locating the New Attachment Point

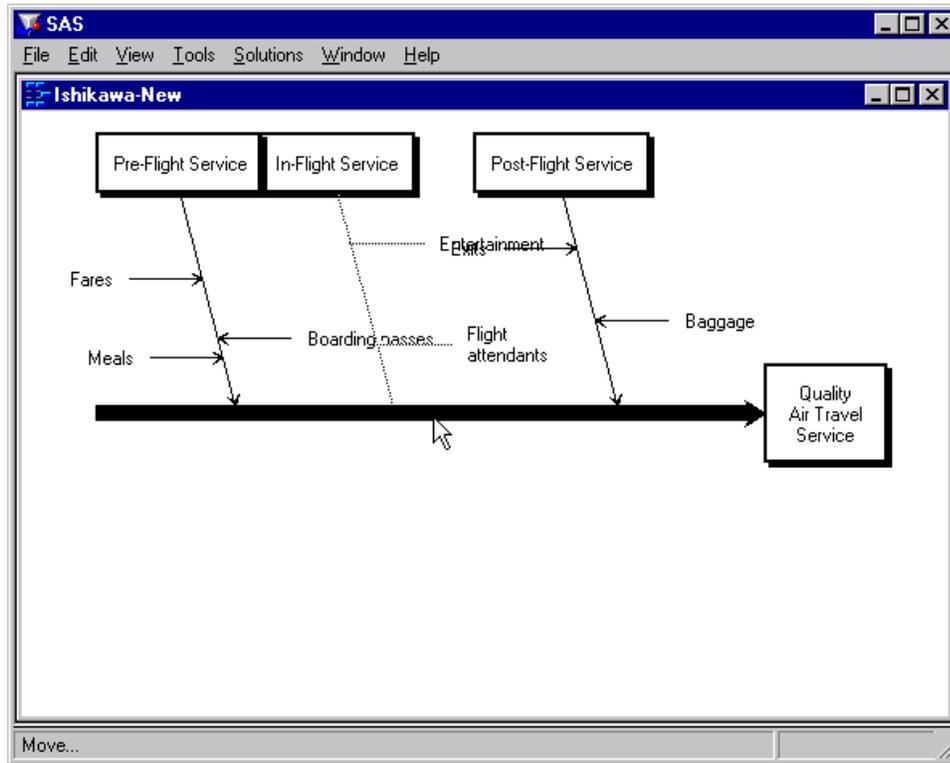

Drop the arrow in place by clicking the mouse.

Figure 8.22 Dropping an Arrow into Position

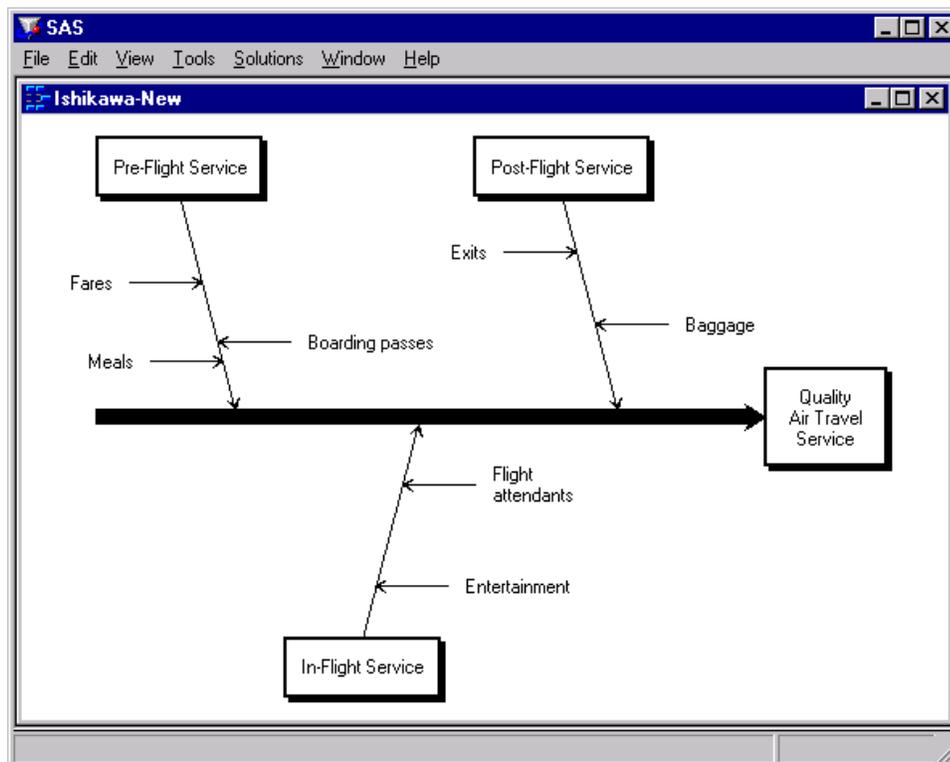

Next, you should reflect the middle branch to the lower half of the diagram to balance the diagram and eliminate the remaining collisions. Once you have selected the branch, position the cursor slightly below the trunk near the desired new attachment point.

Figure 8.23 Selecting an Arrow for Reflecting

Click the mouse to complete the reflection.

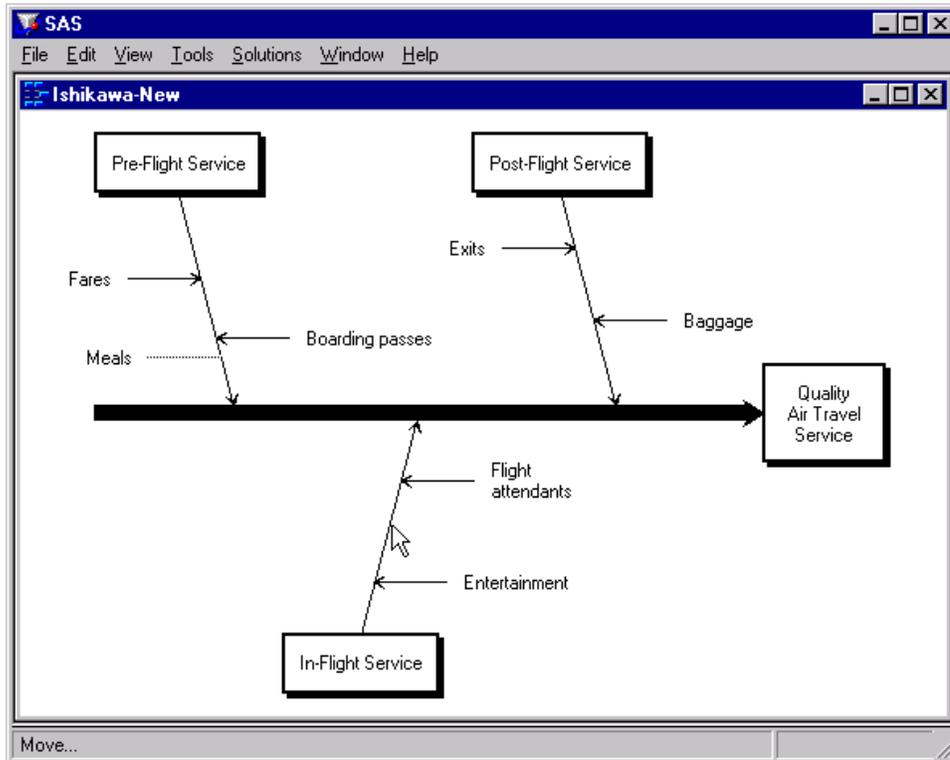

Figure 8.24 Reflecting an Arrow

Note that the stems are reflected with the branch and that their positions (relative to the trunk) are preserved.

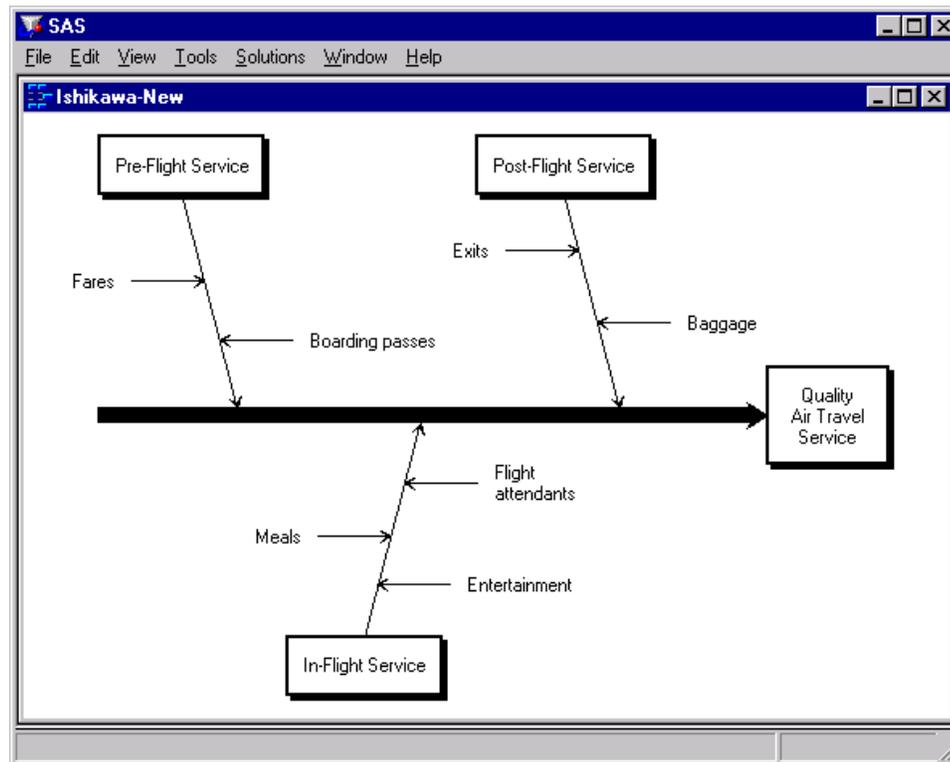

Finally, the stem labeled *Meals* is incorrectly attached to the branch labeled *Pre-Flight Service* and should be moved to the branch labeled *In-Flight Service*. Once you have selected the stem, move the cursor slightly left of the new attachment point.

Figure 8.25 Locating the New Attachment Point

To complete the move, click the mouse.

Figure 8.26 Moving a Stem

Apply the same principles when moving an arrow to a new level (for example, to elevate a stem to a branch) or a new diagram (when you have multiple ISHIKAWA windows open).

Deleting Arrows

You can delete an arrow (with all its descendants) by moving the cursor over the arrow head (attachment point) and double clicking. If you accidentally move the cursor while double clicking, it is possible that the arrow will be moved instead of being deleted. In that case, double click on the arrow head again.

You can undo a deletion by moving the cursor to a background area of the window and using the right mouse button to select **Undelete** from the background popup menu. Repeat the operation when you want to undo several deletions.

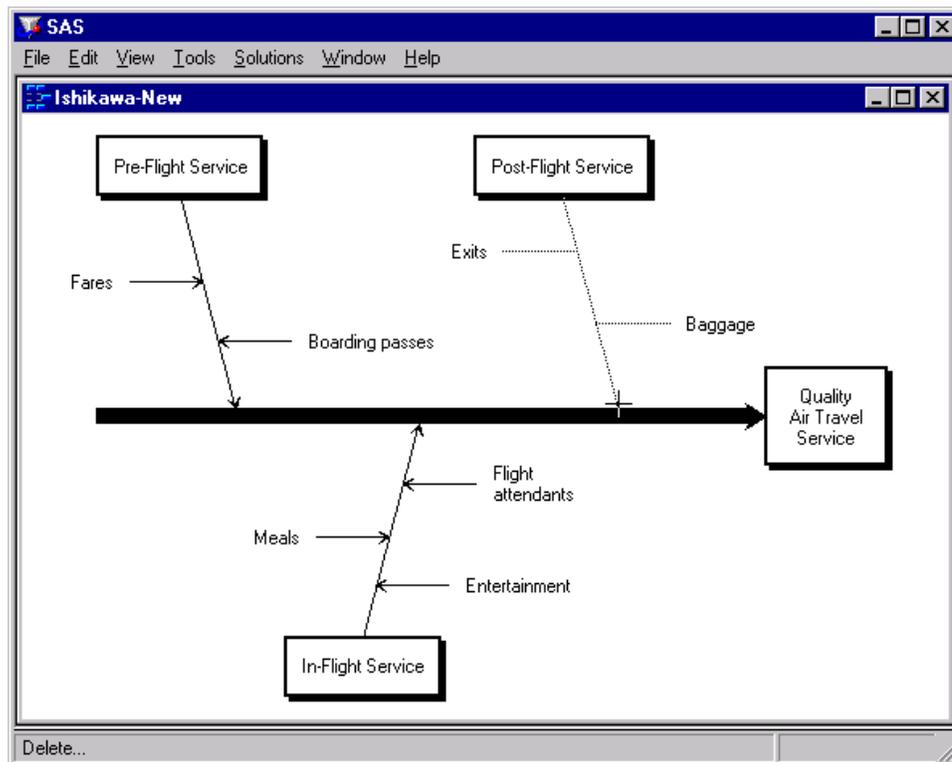

Once an arrow has been selected for deletion, you can cancel the pending operation by moving the cursor to a background area of the diagram and clicking the mouse.

The ISHIKAWA environment does not allow you to delete the trunk. To clear the window, select **Edit ► Clear...** from the command bar. Then start a new diagram by selecting **File ► New...** or **File ► Open...**

Example

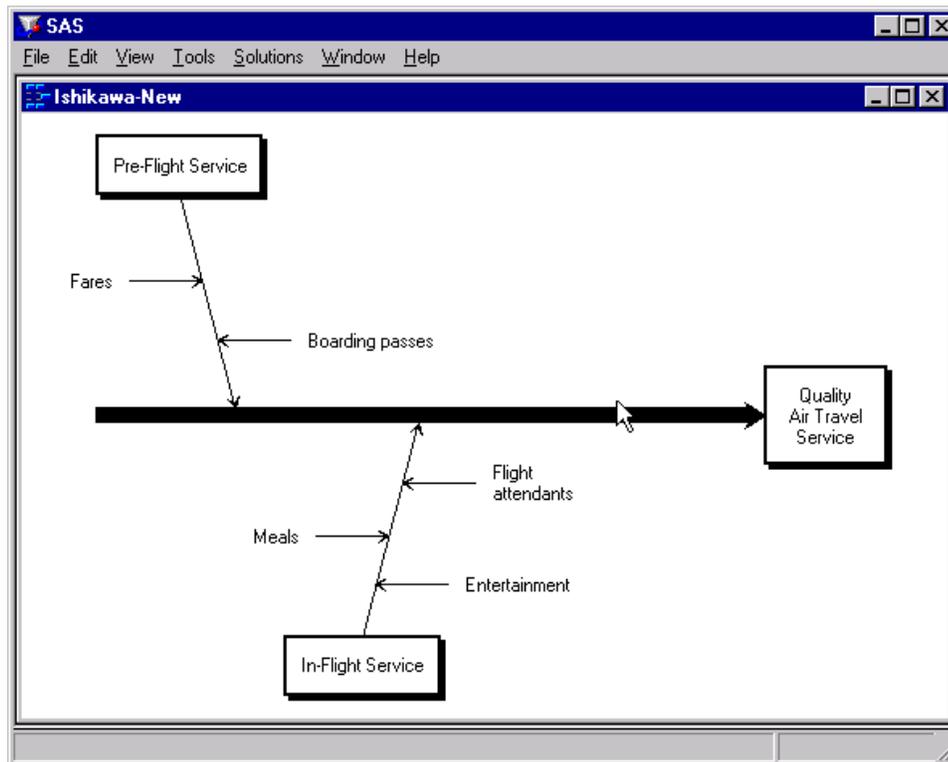

In the following diagram, the branch labeled *Post-Flight Service* has been selected for deletion (note that the branch is highlighted):

Figure 8.27 Selecting a Branch for Deletion

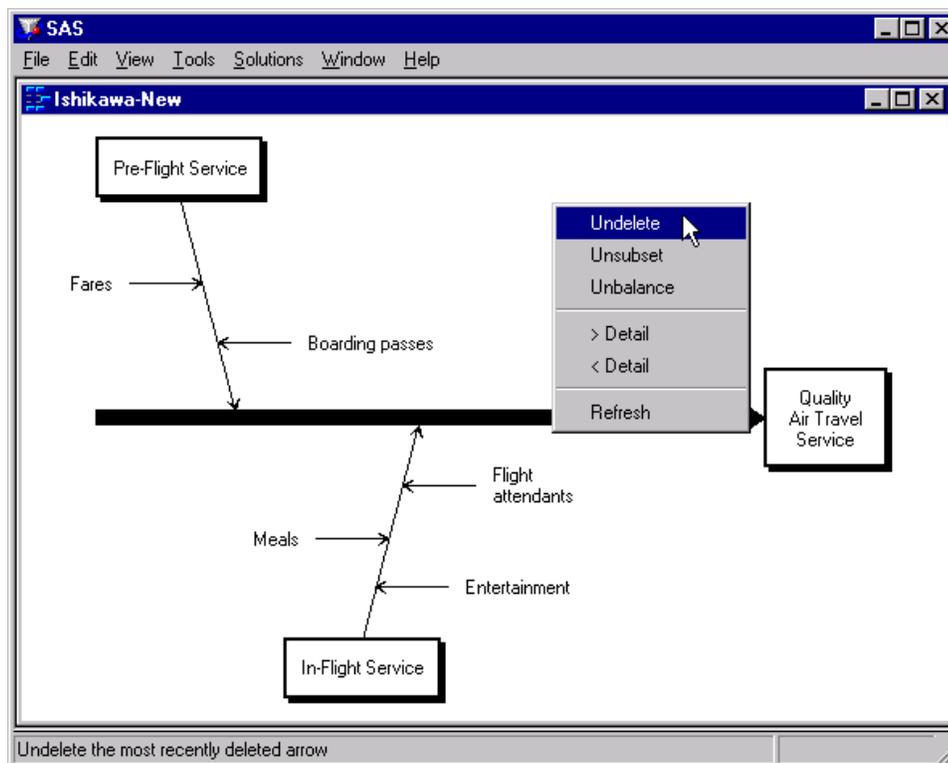

Without moving the cursor, click on the arrow head a second time to delete the branch.

Figure 8.28 Deleting a Branch

To undelete the previous deletion, move the cursor to a background area of the window and use the right mouse button to select **Undelete** from the background popup menu.

Figure 8.29 Undeleting a Branch

Resizing Arrows

You can resize an arrow by holding the mouse button down over the tail end of the arrow and dragging the mouse.⁵ As you move the mouse, the arrow is represented by a rubberband line, and a plus sign (+) is drawn to indicate the original position of the arrow tail. The new length is determined by the position of the cursor when you release the mouse.

To cancel a resize operation once you have depressed the mouse button, release the button outside the ISHIKAWA window.

All non-horizontal arrows are constrained to have the same angle. You control the angle by resizing a branch. That is to say, when you resize a leaf, its angle does not change.

Use **View ► Ishikawa Settings ► Resize Method ►** to control the scope of the resizing operation.

- **Local** resizes only the arrow being dragged.
- **Global** resizes all the arrows at that level to lengths that are proportional to the arrow being dragged. This is the default.
- **Uniform** resizes all arrows at that level to the length of the arrow being dragged.

When you resize an arrow, you also update the default size for all new arrows at that level.

By default, global and uniform resizing applies to all the arrows at the level of the arrow being resized. To restrict resizing to a specific subset of arrows, you can subset them as follows:

- Move the cursor over the arrow head of an arrow to subset that arrow and all its descendants.
- Move the cursor over the arrow tail of an arrow to subset only that arrow (and not its descendants).
- Use the right mouse button to activate the popup menu.
- Select **Subset**.

On some hosts, shift-clicking on the arrow head or tail also subsets an arrow.

Subsetted arrows are indicated by underlined labels. Subsetting is a toggle operation, so to *unsubset* an arrow, repeat the preceding steps.

To unsubset all the arrows in the diagram, do the following:

- Move the cursor to a background area of the window.
- Use the right mouse button to activate the background popup menu.
- Select **Unsubset**.

Be sure to remove all subsets after you have finished modifying the diagram, since remaining subsets can alter the focus of other operations.

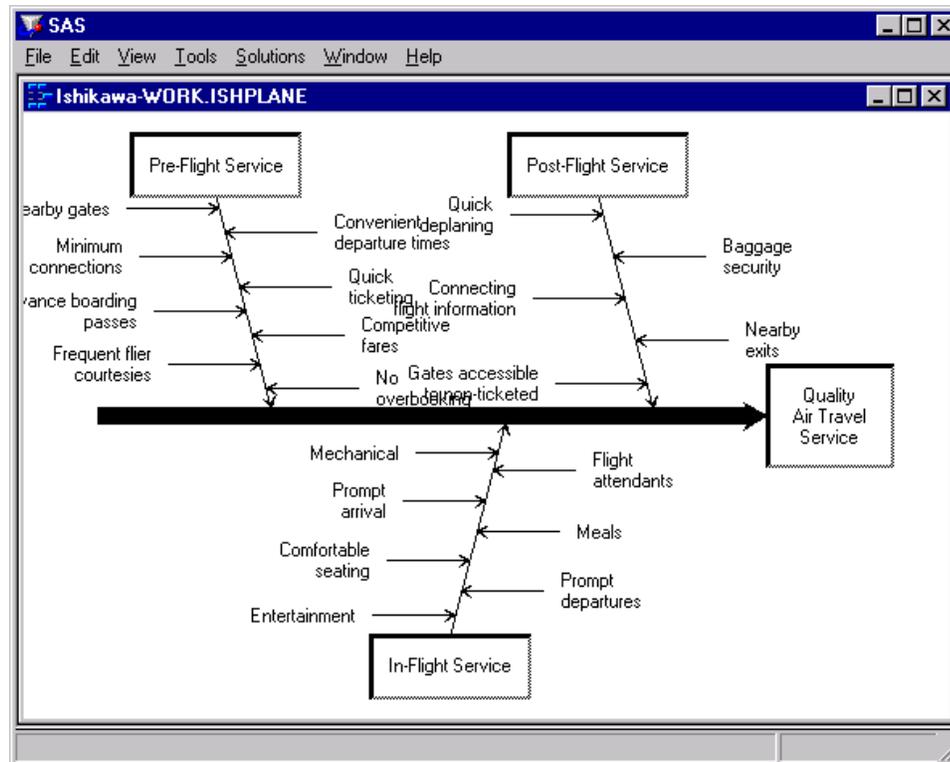

See “[Modifying Arrow Colors and Line Styles](#)” on page 783, for more examples of how subsets are used.

⁵Some devices (such as the IBM3179) require you to define a drag key. For more details about dragging on your system, consult the SAS companion for your host.

Example

Arrows that are too long can cause clipping and collisions, as illustrated in the following diagram:

Figure 8.30 Before Resizing the Diagram

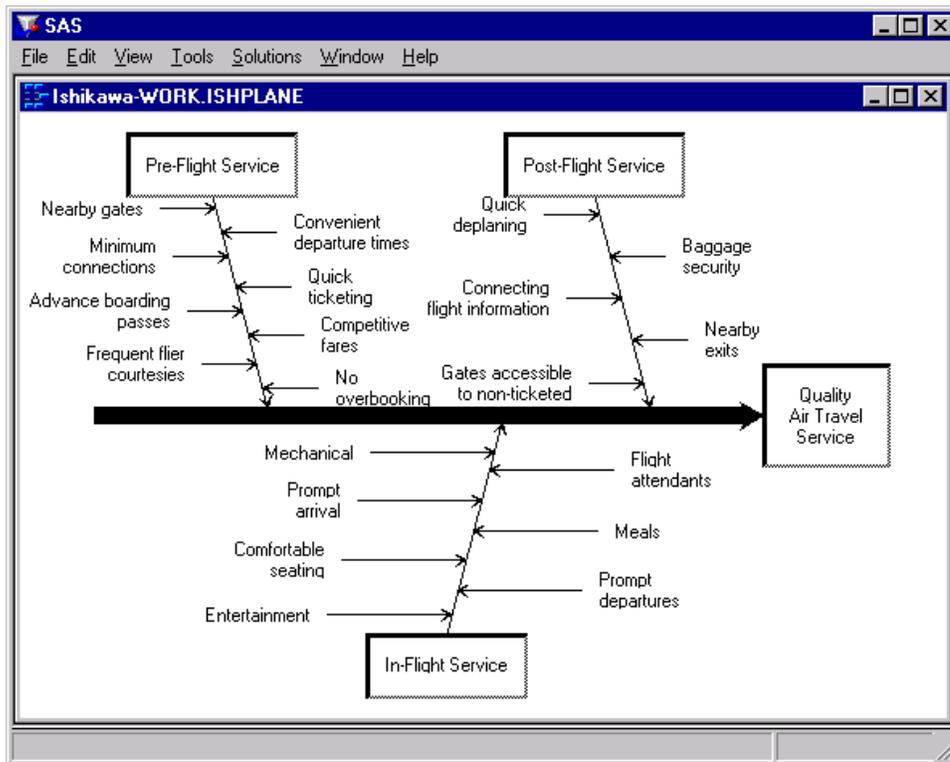

To resize the stems in the upper half of the diagram, proceed as follows:

- Subset the branch for *Pre-Flight Service* by moving the cursor over its arrow head and selecting **Subset**.
- Do the same to *Post-Flight Service*.
- Shorten one of the subsetted stems by dragging its tail to the desired length.
- Remove all subsets by selecting **Unsubset**.

The results are as follows:

Figure 8.31 After Resizing the Diagram

Swapping Arrows

Use the swap operation to interchange two arrows in a single operation instead of using two move operations. Swapping has all the flexibility of the move operation; you can swap arrows that have different parents, different levels, or arrows from different diagrams.

Like moving, the results depend upon whether you select the arrow from the arrow head or the arrow tail. When you select the arrow head, the arrow and all its descendants are moved. When you select the arrow tail, only the labels of the selected arrows are interchanged.

Swapping is a two step operation.

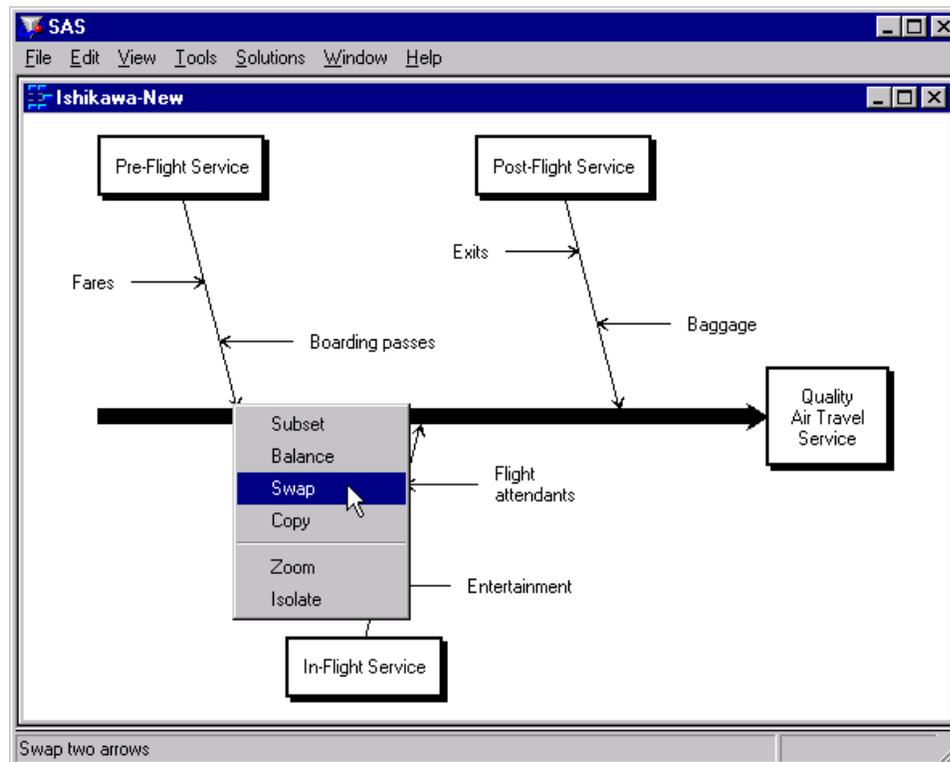

- Move the cursor over the arrow head (tail) of one of the arrows to be swapped and select **Swap** from the context-sensitive popup menu.
- Complete the swap by using the mouse to select the comparable end (head or tail) of the second arrow.

To cancel a swap after you have selected the first arrow, click in a background area of the diagram.

Example

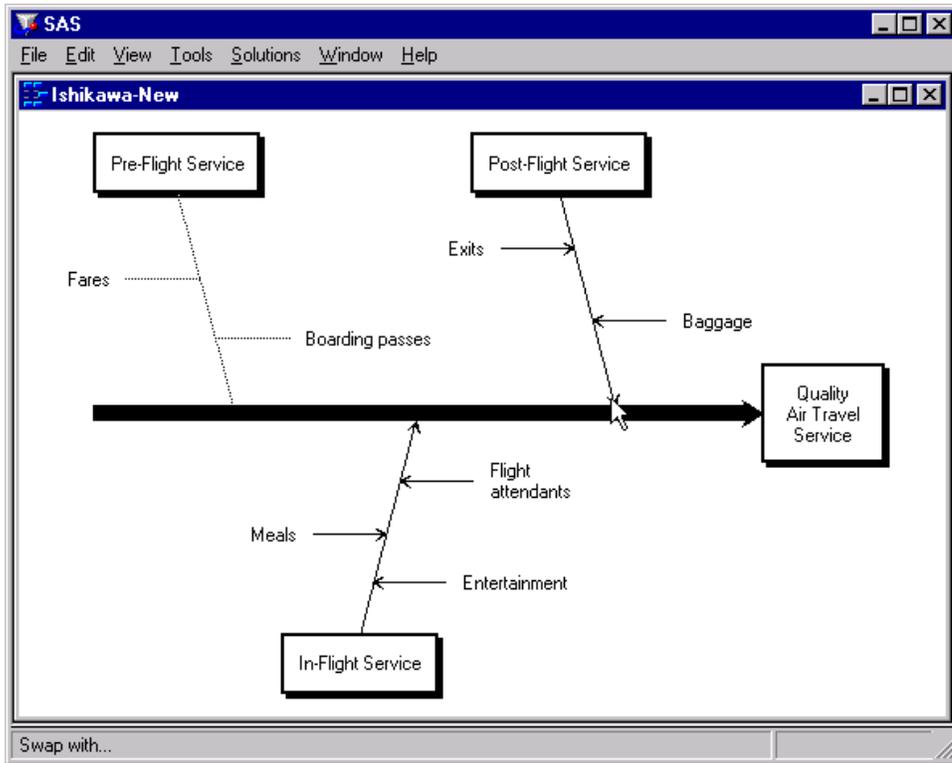

To swap the branch labeled *Pre-Flight Service* (and all its descendants) with the branch labeled *Post-Flight Service* in the following diagram, move your cursor over the arrow head of the *Pre-Flight Service* branch and activate the popup menu using the right mouse button. Select **Swap** to begin the operation.

Figure 8.32 Swapping Two Arrows

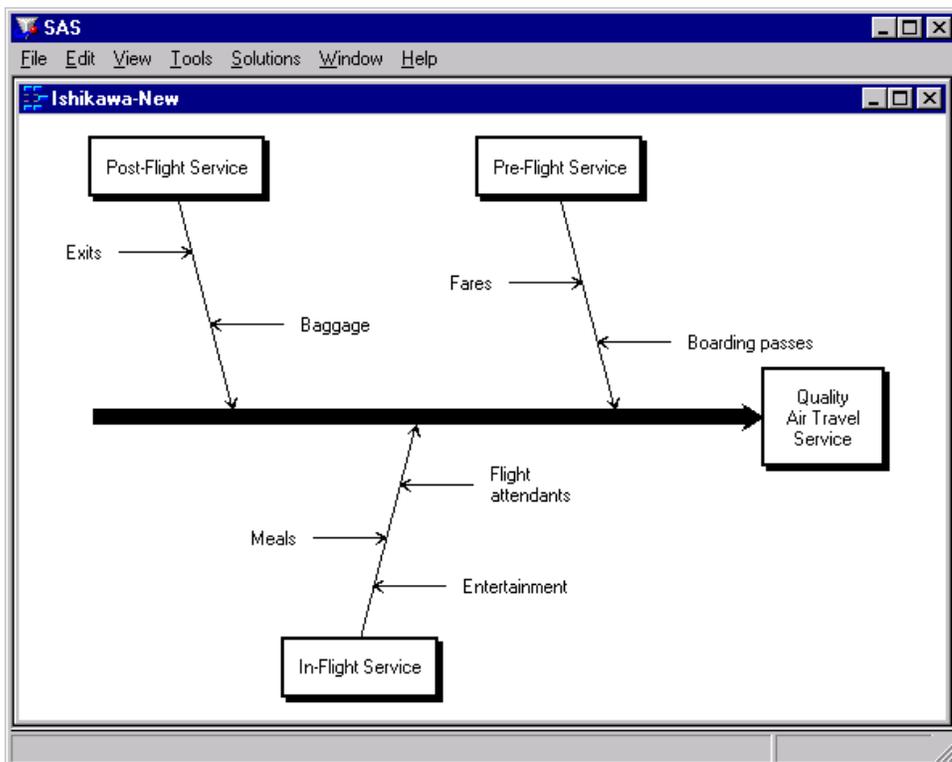

To complete the swap, select the arrow head of the *Post-Flight Service* branch.

Figure 8.33 Swapping Two Arrows (continued)

The completed diagram illustrates how the swap operation simplifies interchanging two arrows.

Figure 8.34 Completing a Swap

An alternative to swapping the arrows is to move them. However, moving arrows in this situation requires more steps and tends to be more cumbersome than swapping.

Balancing Arrows

An Ishikawa diagram is said to be *balanced* if the sub-arrows attached to each arrow are equally spaced.

To balance the immediate descendants of an arrow *and all its descendants*, proceed as follows:

- Move the cursor over the arrow head.
- Activate the popup menu using the right mouse button.
- Select **Balance**.

To balance only the immediate descendants of an arrow, select **Balance** from the popup menu for the arrow tail.

You can restore the arrows to their original positions by doing the following:

- Activate the background popup menu using the right mouse button.
- Select **Unbalance**.

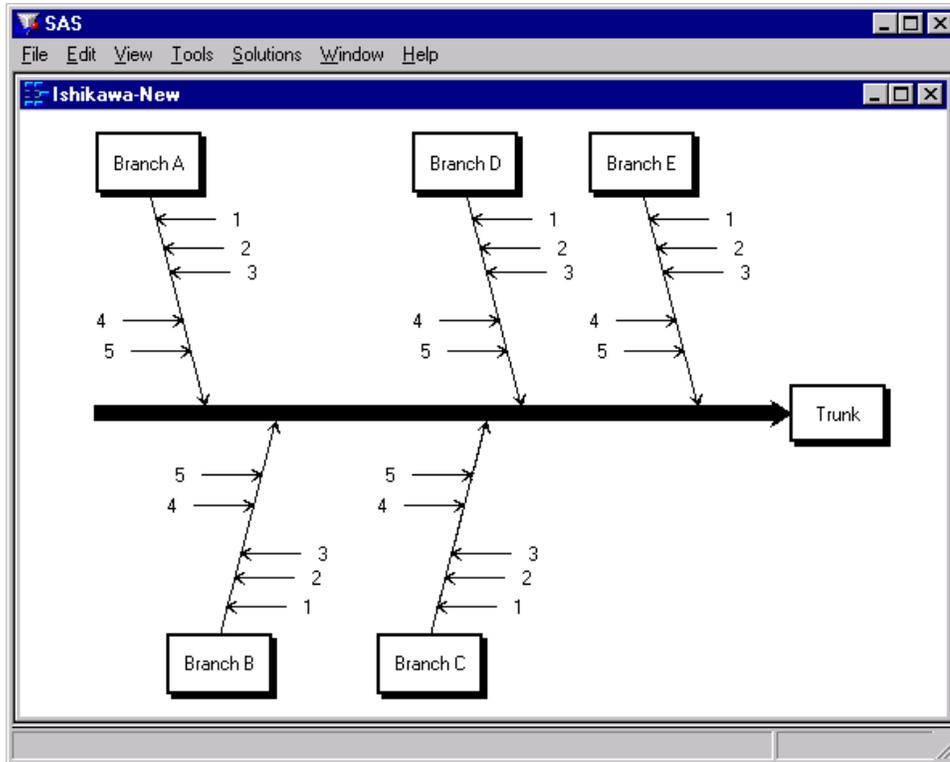

The ISHIKAWA environment provides three alternative methods for balancing arrows. Select one of the following choices from the **View ► Ishikawa Setting ► Balance Method ►** menu:

- **Preserve order/sides** maintains the order and directions of the sub-arrows but repositions them so they are evenly spaced.
- **Preserve order/alternate sides** maintains the ordering of the arrows but repositions adjacent arrows so that they appear on opposite sides. This is the default.
- **Preserve sides** maintains the side on which the sub-arrows are attached then spaces each side of the arrow independently.

Example

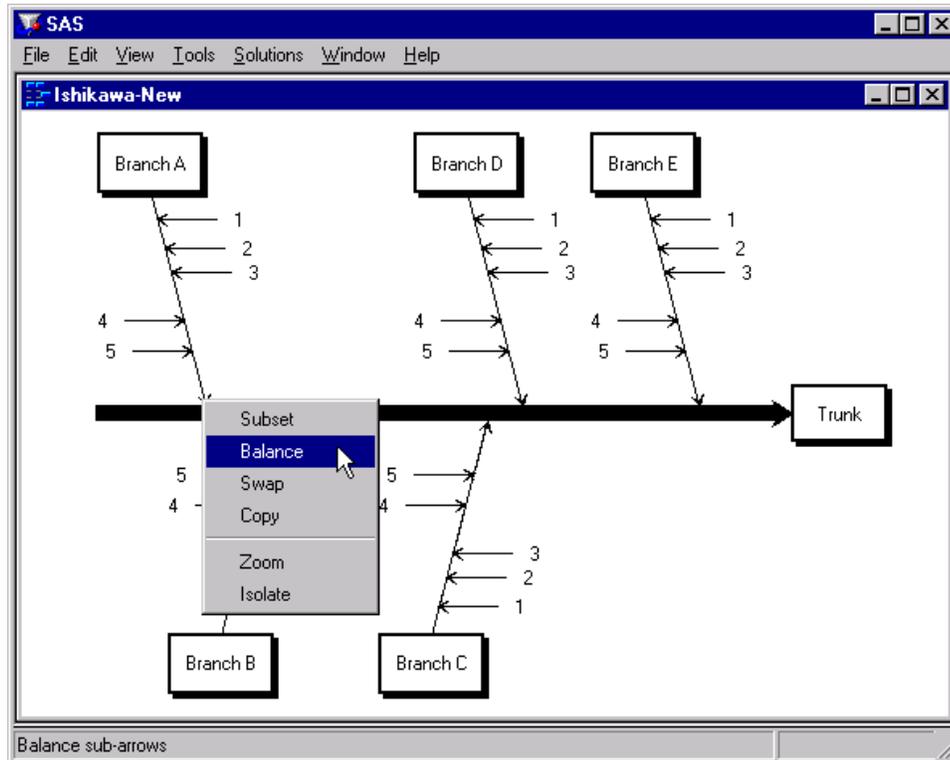

Consider the following unbalanced diagram:

Figure 8.35 An Unbalanced Ishikawa Diagram

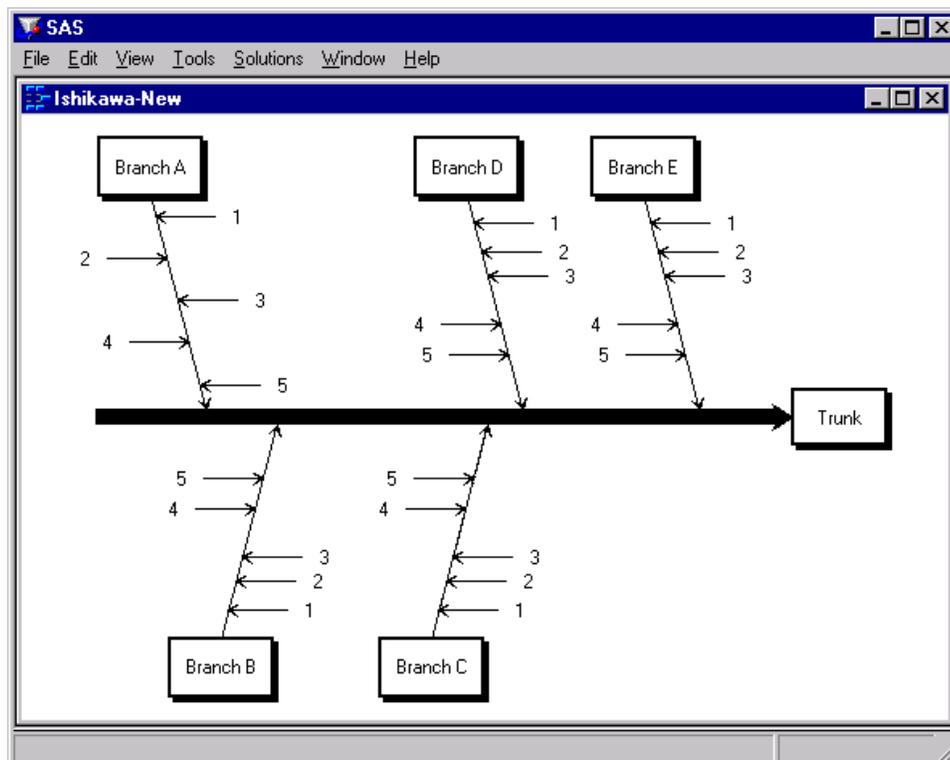

To balance only the stems of the branch labeled *Branch A*, move the cursor over the arrow head and press the right mouse button.

Figure 8.36 Balancing a Branch

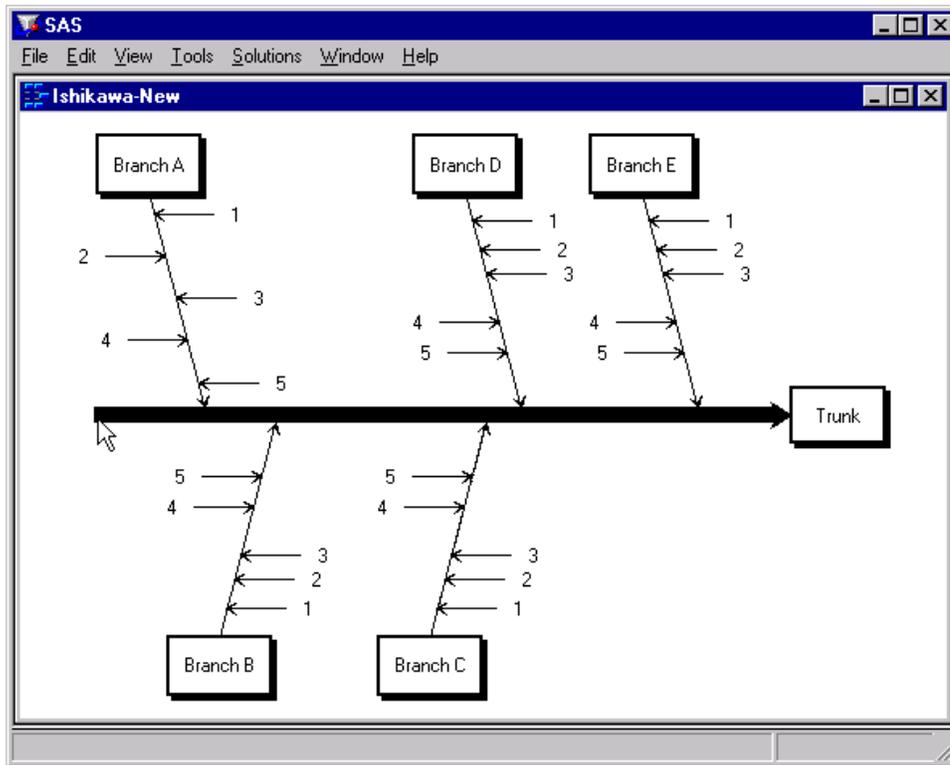

Select **Balance** from the arrow head popup menu.

Figure 8.37 A Balanced Branch

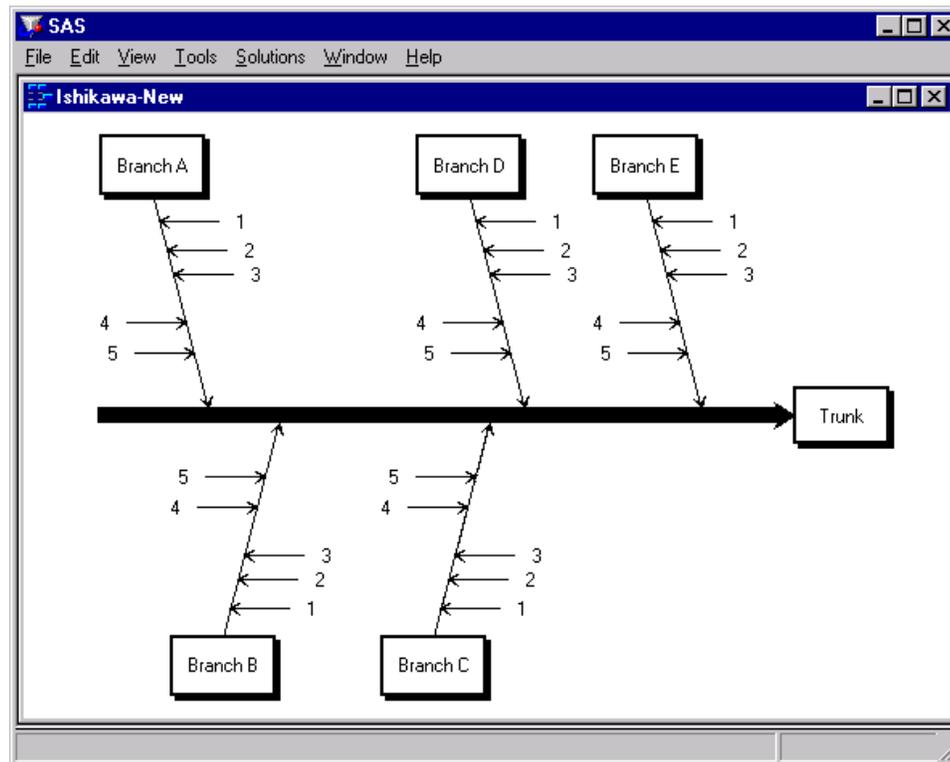

Note that since the stems are without leaves, selecting either the head or the tail has the same result. To balance only the five major branches in the preceding diagram without affecting their stems, move the cursor to the tail end of the trunk and select **Balance** from the popup menu.

Figure 8.38 Balancing Only the Branches

To balance the entire diagram (from head to tail, so to speak), move the cursor to the head of the trunk and select **Balance** from the popup menu.

Figure 8.39 Balancing the Entire Diagram

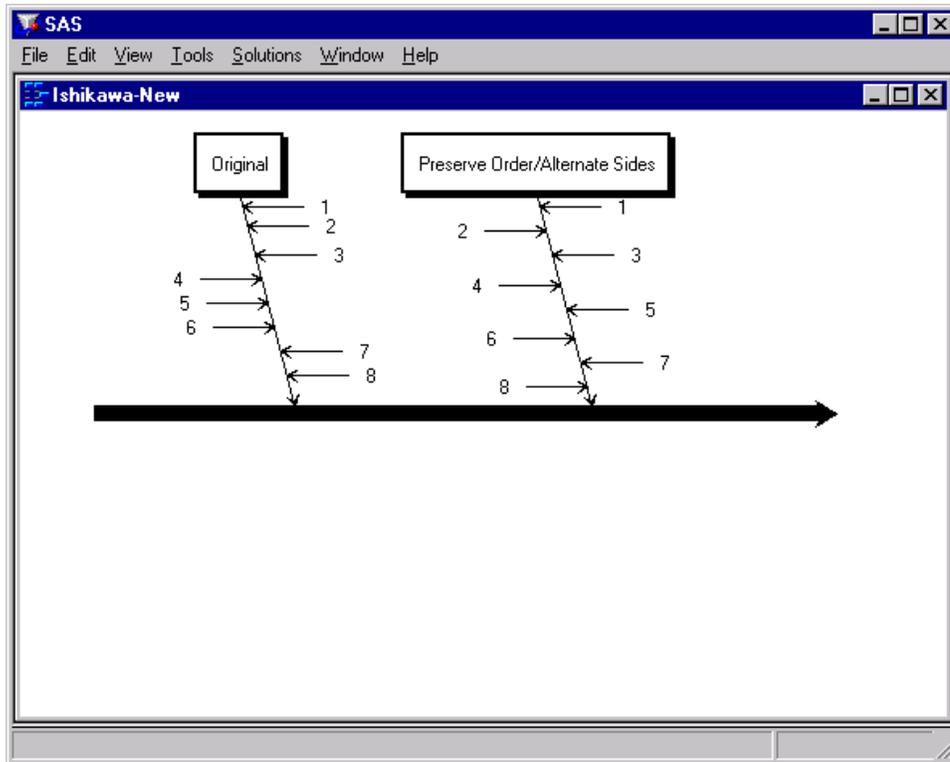

Note that the balancing method used here not only changes the spacing of the stems but reflects them as needed to achieve a balanced appearance. You can control this by specifying a balancing method, as illustrated by the next example.

Example

The following diagram displays an unbalanced branch and a copy of that branch after it was balanced using the **Preserve order/alternate sides** balancing method:

Figure 8.40 Preserving Order But Alternating Sides

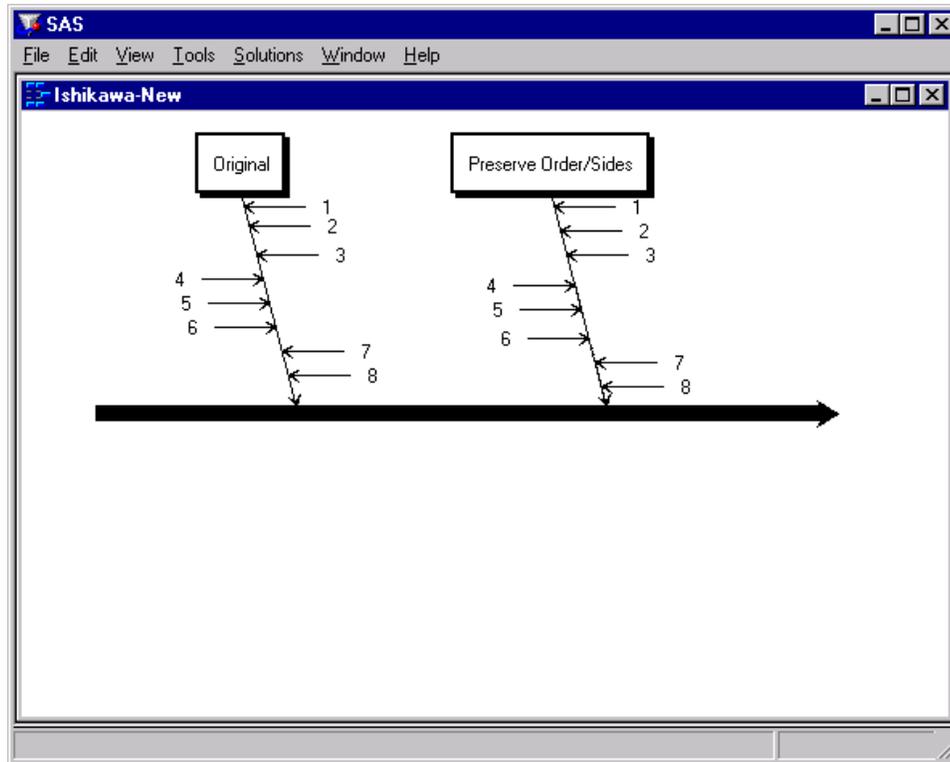

Note that the stems remain in order (1-8) from tail to head, but they now alternate evenly across both sides of the branch. This is the default method used for balancing arrows.

Example

The following diagram displays an unbalanced branch and a copy of that branch after it was balanced using the **Preserve order/sides** method:

Figure 8.41 Preserving Order and Sides

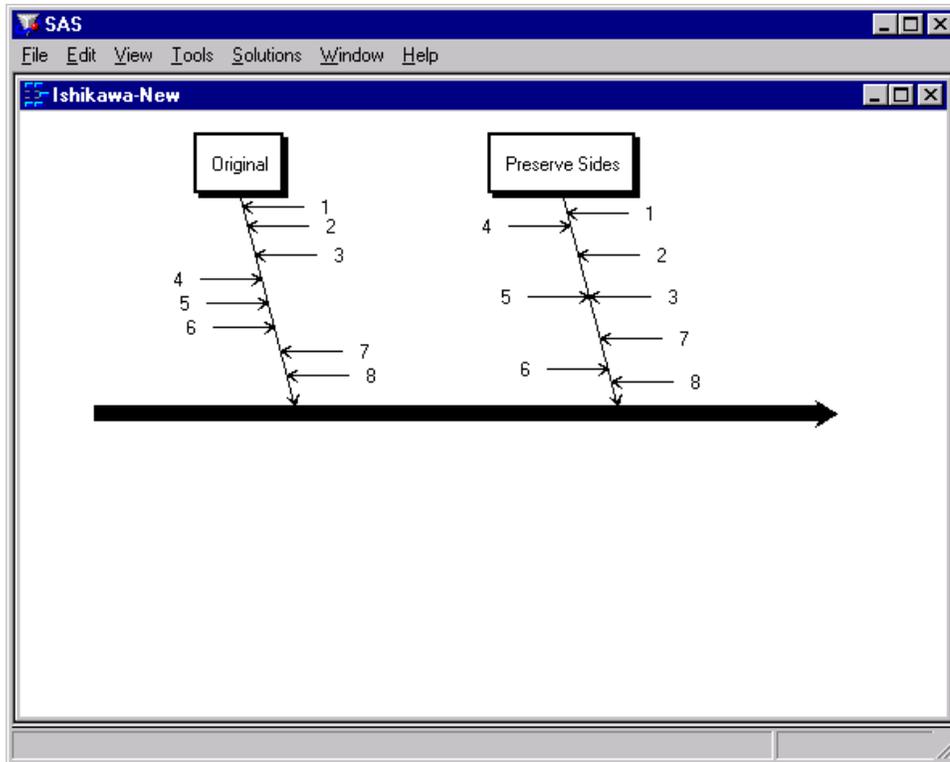

Note that stems 4-6 remain on the left, stems 1-3 and 7-8 remain on the right, and the order from tail to head is still 1-8. However, the stems are now spaced uniformly.

Example

The following diagram displays an unbalanced branch and a copy of that branch after it was balanced using the **Preserve sides** balancing method:

Figure 8.42 Preserving Sides

Note that the stems on the left (4-6) are spaced uniformly, and the stems on the right (1-3 and 7-8) are spaced uniformly. The two sides are spaced independently of each other.

Notepads

Ishikawa (1982) and Kume (1985) advocate the display of quantitative information with the arrows in an Ishikawa diagram.

In the ISHIKAWA environment, you can use *Notepad* windows to record or display information associated with each arrow. To open the Notepad window, move the cursor over the arrow tail and double click.

Figure 8.43 Ishikawa Notepad

Notes are limited to four lines of text with no more than 40 characters per line.

When you save your Ishikawa diagram, your notes are saved with the SAS data set.

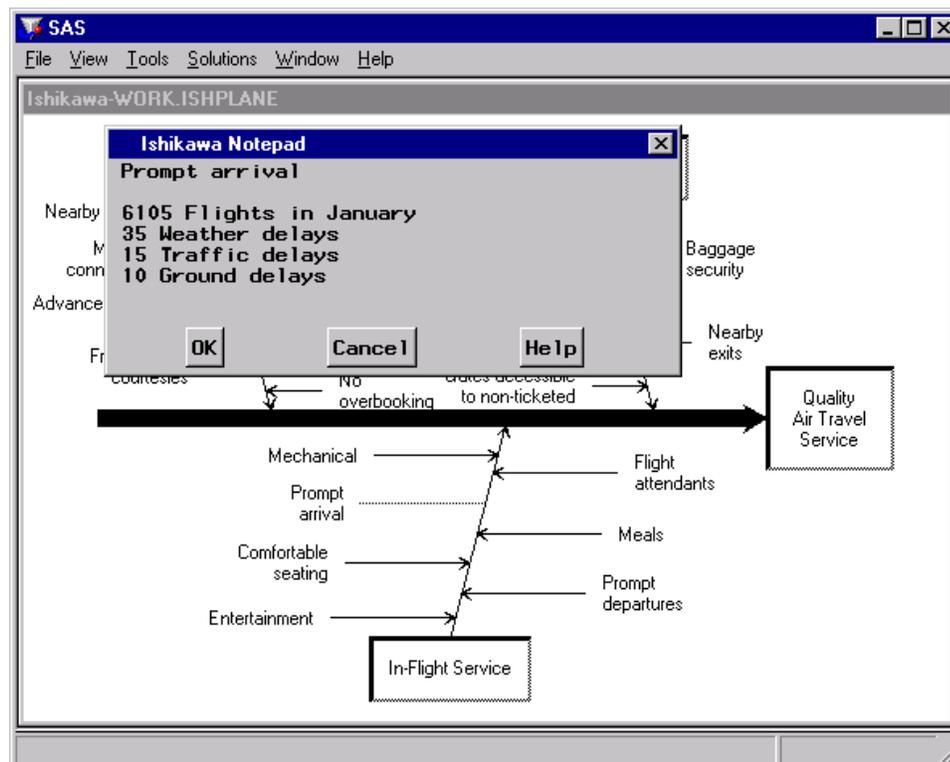

Later, when you retrieve your diagram, all the notes are restored.

You must close the *Notepad* window before you continue working in the ISHIKAWA environment.

Example

In the following figure, double clicking on the *Prompt arrival* stem reveals details about prompt arrival times:

Figure 8.44 Using Notepads to Organize Details

Managing Complexity

A major advantage of the ISHIKAWA environment is that you can quickly organize a highly complex diagram. However, not everyone may be interested in seeing all the details—at least initially.

To increase the level of detail by one level, do the following:

- Move the cursor to a background area of the window, and use the right mouse button to activate the background popup menu.
- Select **> Detail**. On some hosts, you can press the **>** key instead of using the popup menu (as long as you are not editing text).

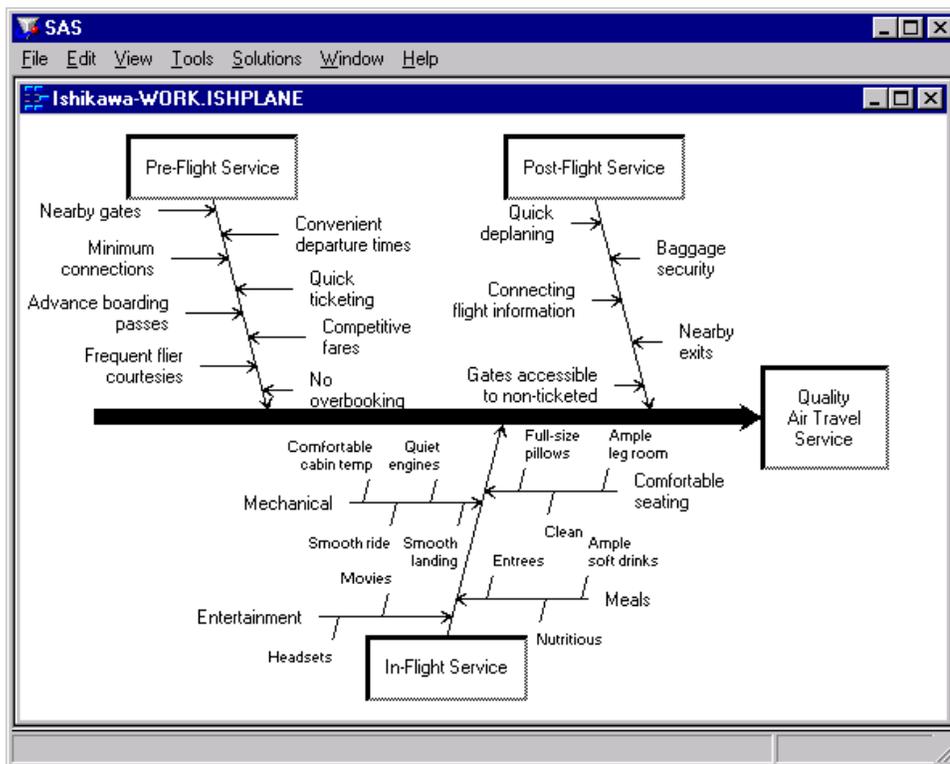

Each time you select **> Detail** from the background popup menu, the detail increases by one level.

To reverse the process and decrease the level of detail, select **< Detail** from the popup menu, or press the **<** key.

Example

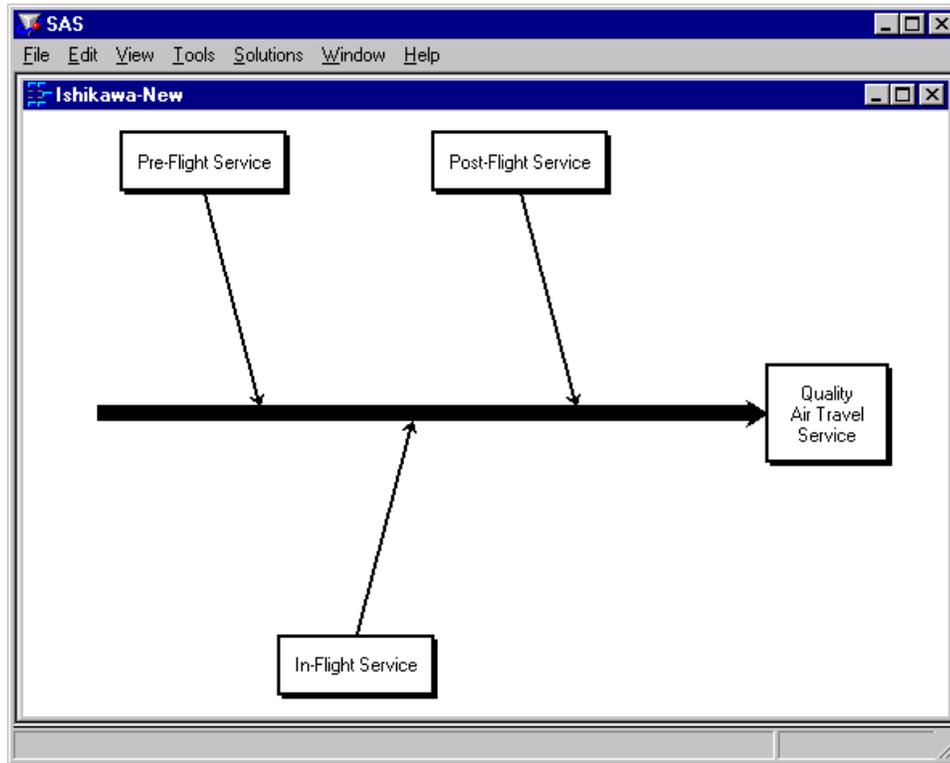

You are making an online presentation about factors that influence the quality of air travel service. The following diagram presents too many details to be a good starting point for your audience:

Figure 8.45 Highly Detailed Ishikawa Diagram

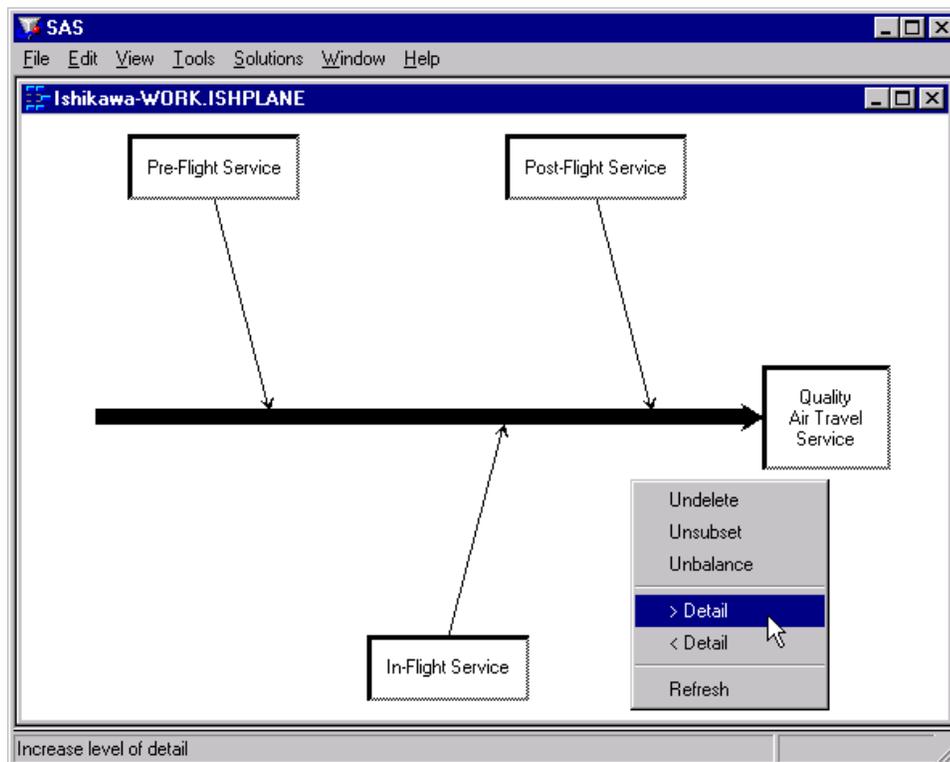

A better way to begin is by displaying only the trunk and branches.

Figure 8.46 Branch-Level Diagram

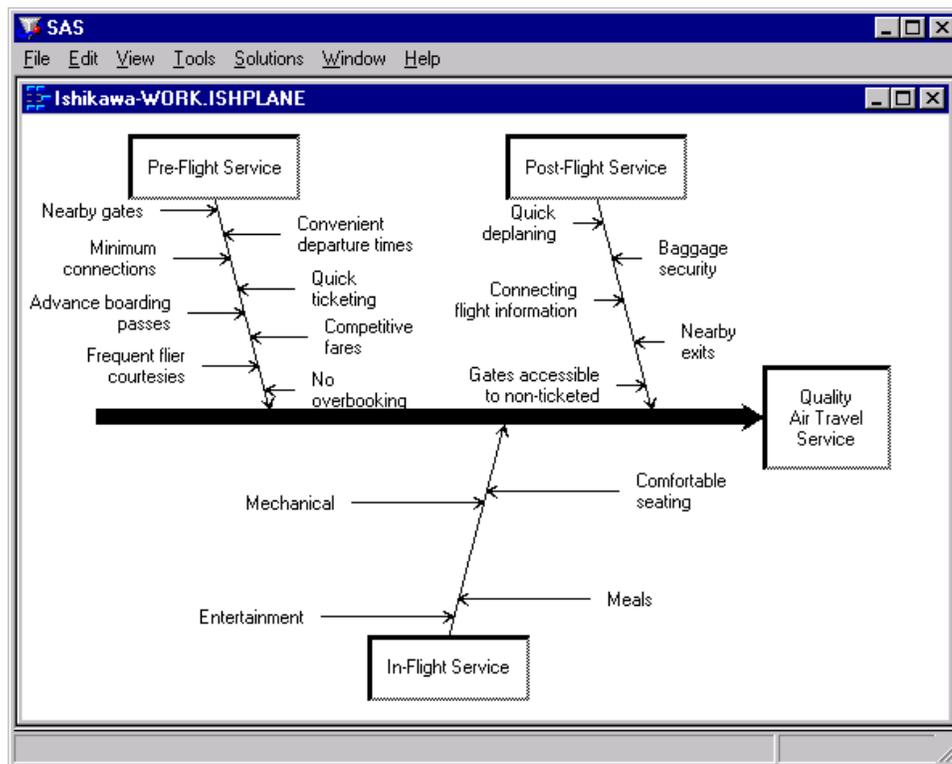

Then, at the next stage of your presentation, dynamically foliate the branches with stems, as follows:

Figure 8.47 Increasing the Level of Detail

The amount of detail is increased by one level.

Figure 8.48 Increasing the Level of Detail

Zooming Arrows

A second method for managing a highly detailed Ishikawa diagram is to work with a subsection of the diagram in a separate window. The window and the sub-arrows inside it can be resized independently of the parent window. In all other respects, the information in the two diagrams is linked dynamically. Changes in one window (for instance, moving, adding, and editing arrows) are reflected in the other window.

To zoom an arrow, proceed as follows:

- Move the cursor over the arrow head.
- Activate the popup menu using the right mouse button.
- Select **Zoom**.

To return or *unzoom*, select **File ► Close**.

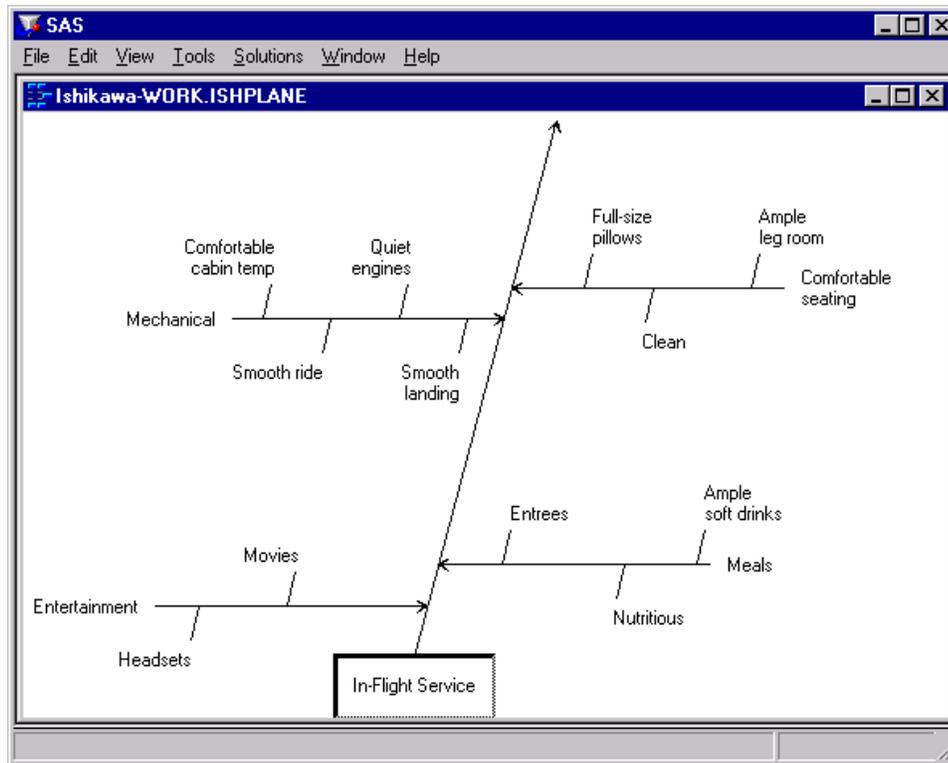

You can have up to four windows open at one time.

To reduce the amount of window management, you can specify that zoomed diagrams are to be displayed in the current window rather than in new windows by setting **Zoom Window** to *Current* in the **View ► Ishikawa Settings ► Other...** dialog.

Example

The following figure shows a branch labeled *In-Flight Service* after it has been zoomed into a new window:

Figure 8.49 Zooming a Branch

**Isolating Arrows**

A third method for managing a highly complex Ishikawa diagram is to view the entire diagram as a collection of smaller diagrams. Any arrow (along with its sub-arrows) can be isolated into a separate diagram in a new window. This diagram can then be easily saved in a separate file.

To isolate a branch as a separate diagram, do the following:

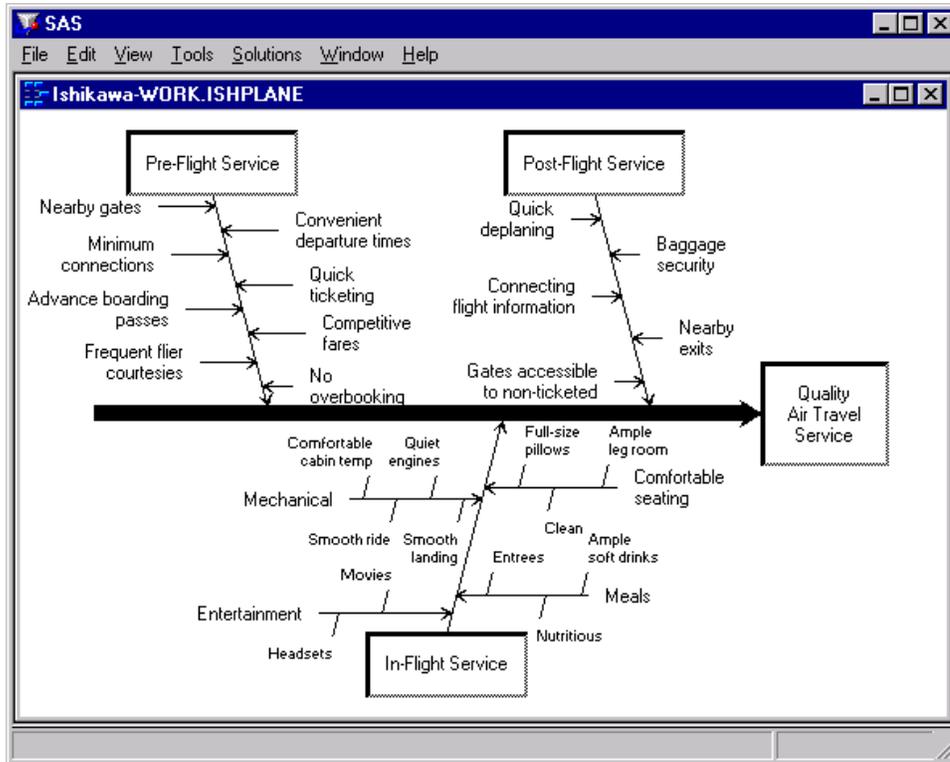

- Move the cursor over the head of the arrow.
- Activate the popup menu using the right mouse button.
- Select **Isolate**.

You can have up to four ISHIKAWA windows open at one time.

Example

Consider the following diagram:

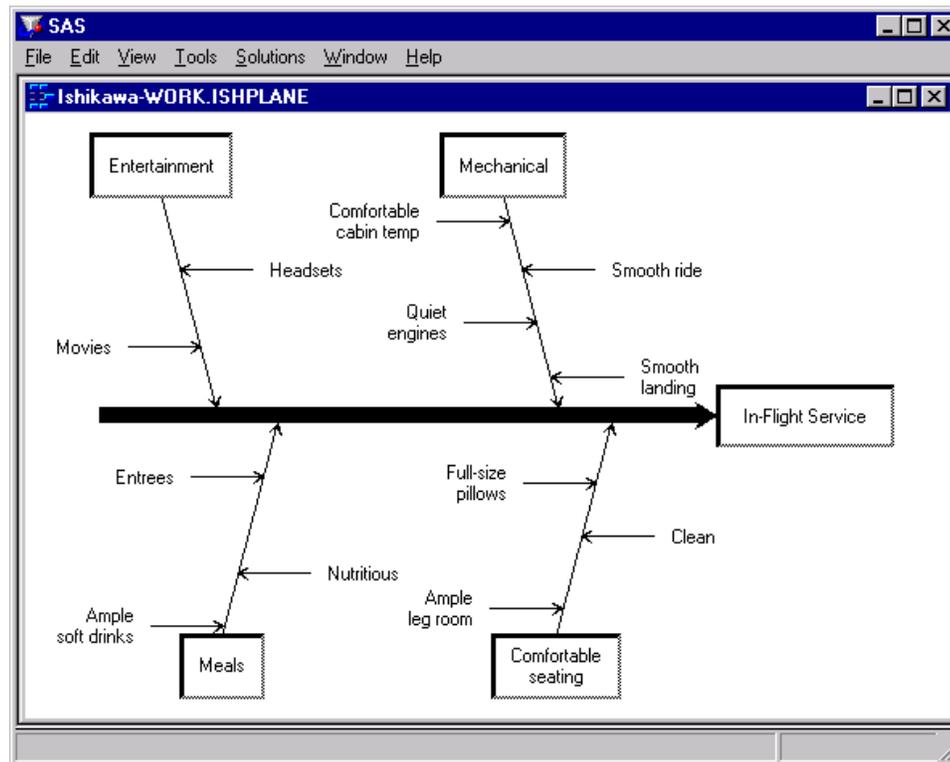

Figure 8.50 A Highly Detailed Diagram

To isolate the branch labeled *In-Flight Service* as a separate Ishikawa diagram, move your cursor over the head of the arrow. Use the right mouse button to activate the popup menu and select **Isolate**.

The following figure shows the main diagram in one window and the branch labeled *In-Flight Service* after it has been isolated to another window:

Figure 8.51 Promoting a Branch into a New Diagram

To return to the original diagram, select **File ► Close**.

Merging Diagrams

You can combine multiple Ishikawa diagrams into a *master* diagram by using the merge operation. To merge a stored diagram into the current diagram, proceed as follows:

- Select **File ► Merge**.
- Specify the name of a SAS data set that contains a saved Ishikawa diagram.

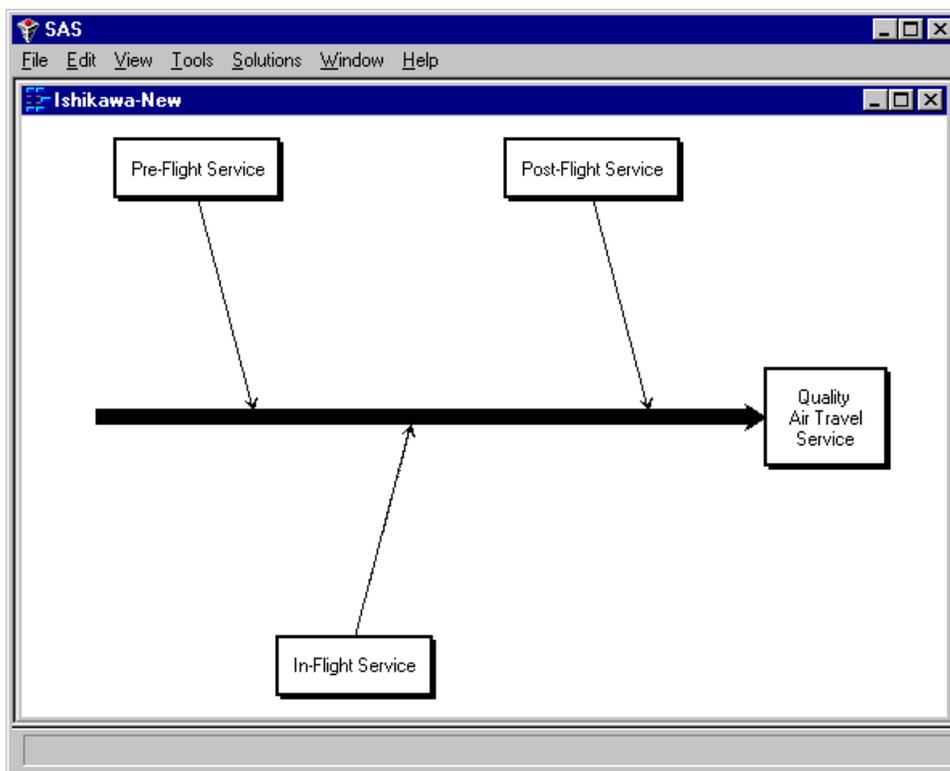

Another way to combine diagrams is to open separate ISHIKAWA windows for each sub-diagram then copy them into the master diagram. To copy all or part of an Ishikawa diagram from one window to another, do the following:

- Move the cursor over the head of the arrow.
- Activate the popup menu using the right mouse button.
- Select **Copy**.
- Position the cursor slightly to one side of the new attachment point and click (just as though you are adding a new arrow).

Example

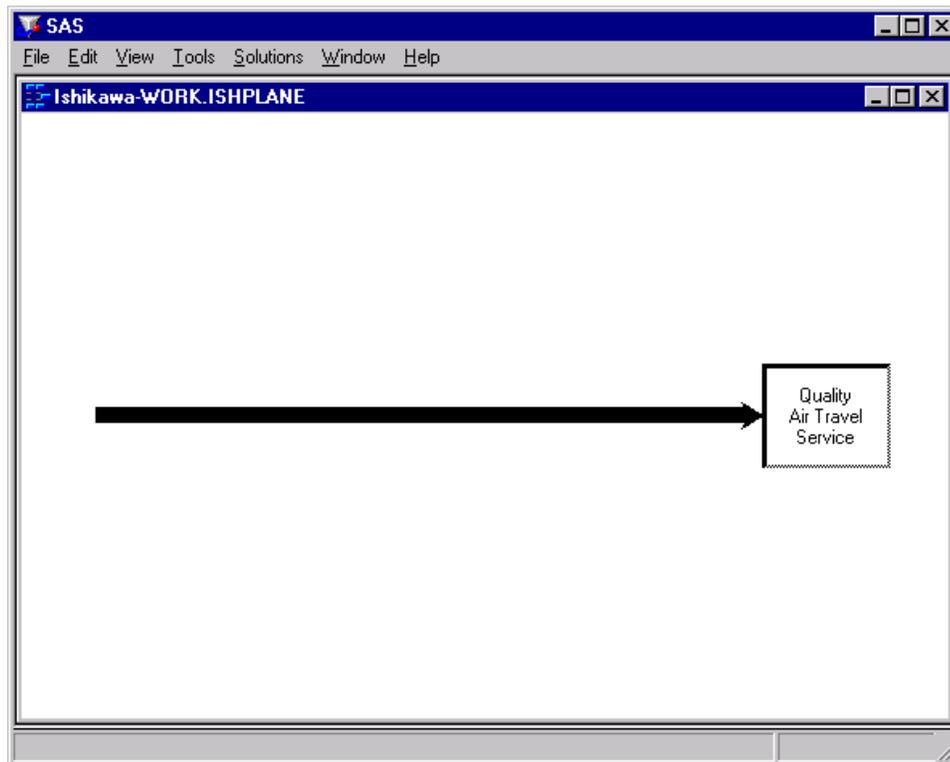

Suppose you want to create the following diagram by combining information from diagrams already created by each of the major service areas (Pre-Flight, In-Flight, and Post-Flight) and stored in different SAS data sets:

Figure 8.52 A Completed Master Diagram

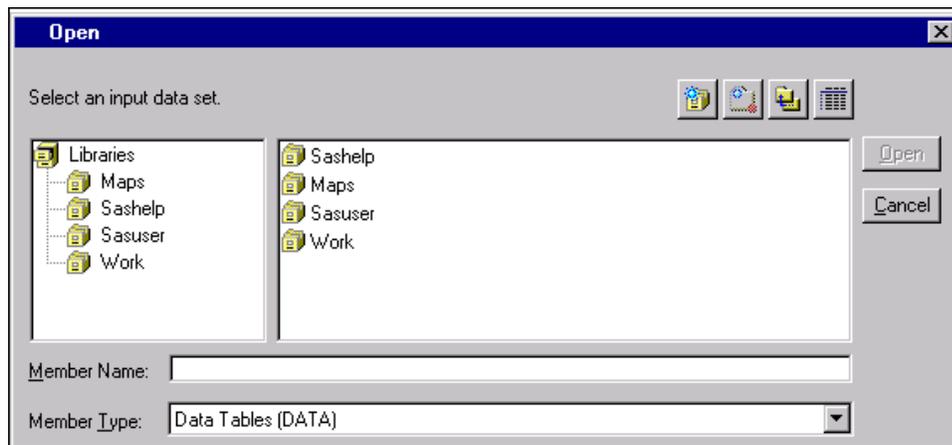

First, use the ISHIKAWA environment to create the trunk for the new master diagram.

Figure 8.53 Starting a Master Diagram

Select **File ► Merge** from the command bar to open the File Requestor dialog.

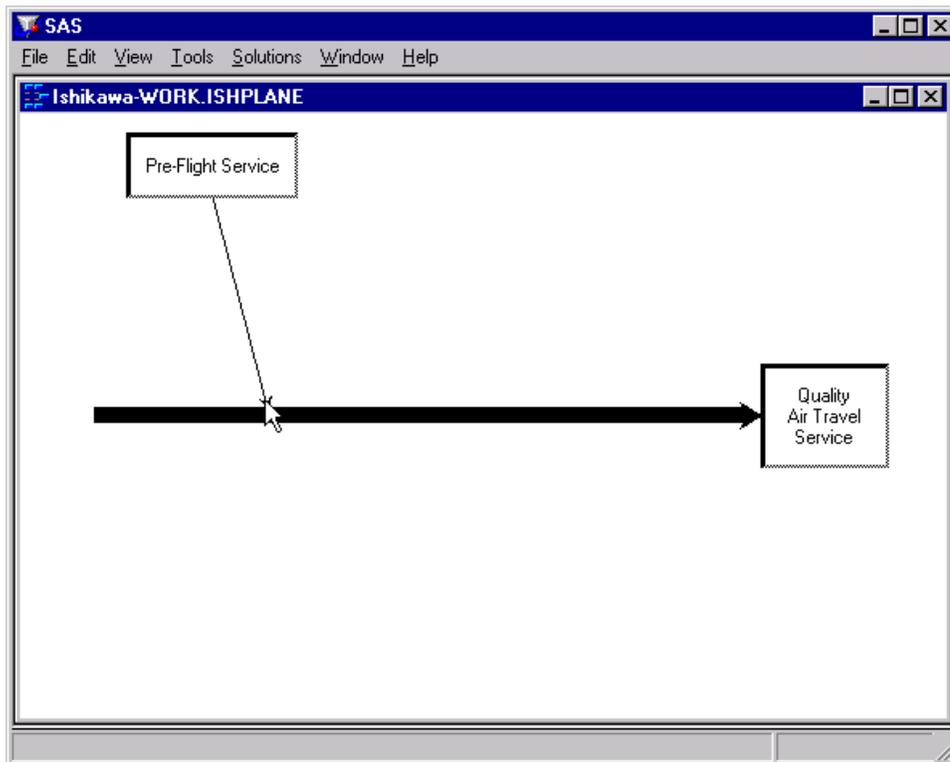

Figure 8.54 Member Selector

Specify the name of the data set for *Pre-flight services* and press **Open**.

Now click on a point along the trunk where this sub-diagram is to attach.

Figure 8.55 Constructing a Master Diagram

To complete the diagram, repeat the process for the remaining branches.

Creating Graphics Output Using SAS/GRAPH Software

One way to create a hard copy of your Ishikawa diagram is to send it to a graphics device using SAS/GRAPH software. To do this, you should submit a GOPTIONS statement to direct the graphics output to the appropriate location and control the output format *before you invoke the ISHIKAWA environment*. For example, the following GOPTIONS statement directs the output to a PostScript device:

```
goptions target=ps1 noprompt;
```

If you do not specify a target device before invoking the ISHIKAWA environment, you will be prompted for one before the graph is generated.

In the ISHIKAWA environment, when you are ready to route your output to a hard copy device, select **File ► Save as ► Graph**. This opens a dialog that enables you to customize various aspects of your graph.

Figure 8.56 Hard Copy Requestor

To save the diagram to the default graphics catalog in the WORK library (WORK.GSEG), simply press **OK** and close the dialog. The default member name is ISHIKAWA.

To save the diagram to a different graphics catalog, select **Save...** and then use the Member selector window to specify a library, a SAS catalog, and a member name.

When sending a diagram directly to an output device, you can ignore the member name entirely.

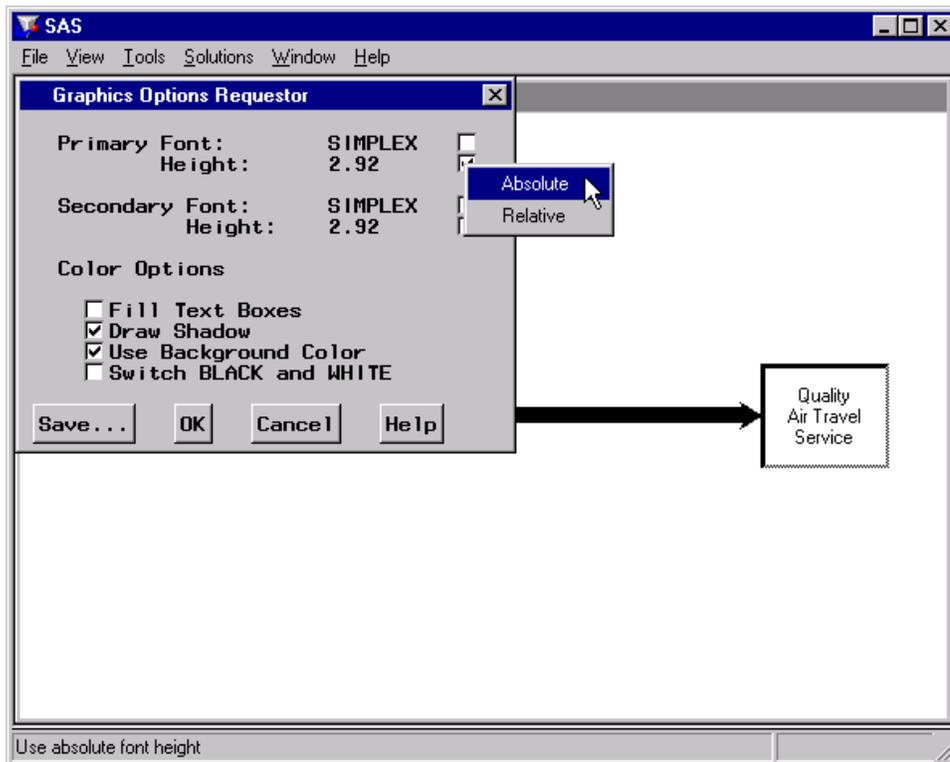

To save to your own graphics catalog, select **Save...** and then use the Save a member selection window to specify a catalog and data set name. Simply select **OK** when you want to save your diagram to the default graphics catalog (WORK.GSEG). When sending a diagram directly to an output device, you can use **OK**.

You must specify two SAS/GRAPH fonts for drawing the labels in the hard copy of the diagram. The hardware fonts used in the ISHIKAWA environment cannot be used for your hard copy. The *primary* font and size are used for the first three levels of text. The *secondary* font and size are used for the remaining levels of text.

To change fonts, enter a valid SAS/GRAPH font name in the font field or click on the button to the right of the font field to display a font requestor dialog. The default font is SIMPLEX.

You can specify the height of the text directly in the height field (in screen percent units), or you can click on the button to the right of the field to request an *absolute* height or a *relative* height.

Figure 8.57 Font Height Selector

Select **Absolute** when you want the font height in the output to be the same height as the font height used in the ISHIKAWA environment even if the output window and the ISHIKAWA window differ in size. Select **Relative** to maintain the same font height to window size proportion in both the ISHIKAWA window and the output window. The numeric value entered in the height field after either choice is a screen percent unit. The default text height is *absolute*.

Use the **Fill Text Boxes** and **Draw Shadow** check boxes to suppress the box fills and box shadows from the output. They cannot be used to *add* these features to the hard copy if they were not present in the ISHIKAWA window.

Use the **Use background color** check box to indicate whether the background color from the ISHIKAWA environment is used in the output. This option is useful when you are sending your diagram to a *color* device and you want the background in your hard copy to match that of your ISHIKAWA environment.

Use the **Switch Black and White** check box to interchange black and white when the diagram is sent to the output device. This option is useful when you send your diagram from a white-on-black display to a black-on-white hard copy device.

Click on **OK** to generate the hard copy output or click on **Cancel** to quit.

Creating Bitmap Graphics Output

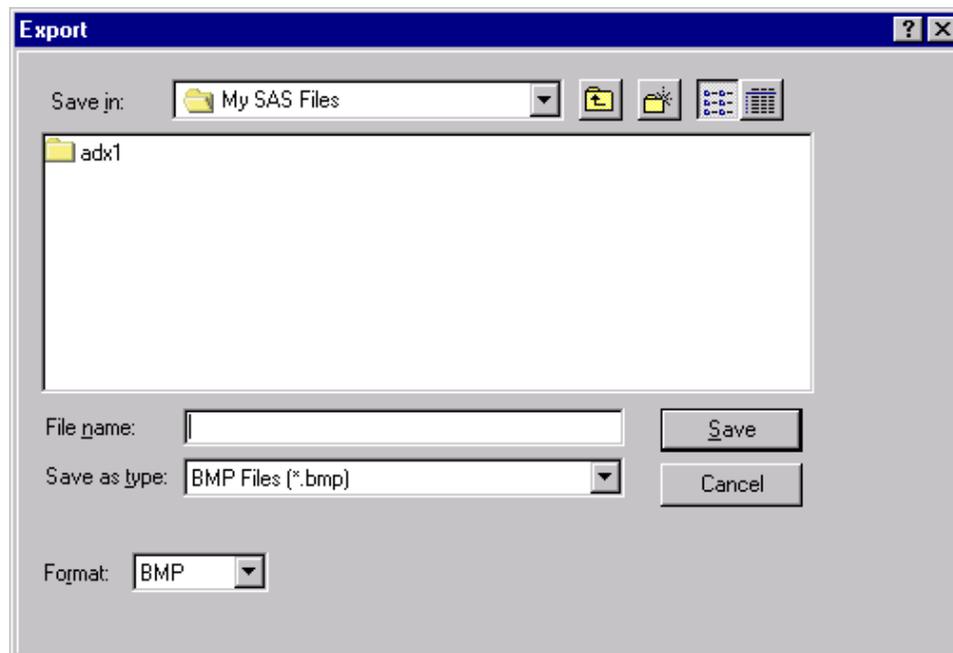

A second way to create a hard copy of your Ishikawa diagram is to export it as a bitmap to one of the following:

- the host graphical clipboard
- an external bitmap file
- a SAS/GRAPH Image catalog entry

To copy the Ishikawa diagram as a bitmap to the host clipboard, select **Edit ► Copy**. The results are host specific. For more details about copying to the host clipboard on your system, consult the SAS companion for your host.

To export the Ishikawa diagram to a bitmap file using SAS/GRAPH software, select **File ► Export as Bitmap ► File...**

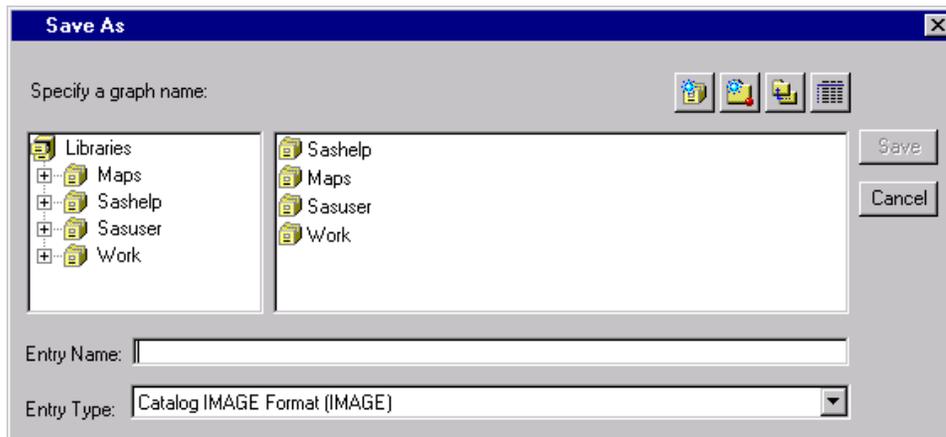

Figure 8.58 Export File Requestor

The appearance of this dialog will be host specific. For more details about the format of this dialog on your system, consult the SAS companion for your host.

To save the Ishikawa diagram as an IMAGE entry in a SAS catalog, select **File ► Save as ► Image**.

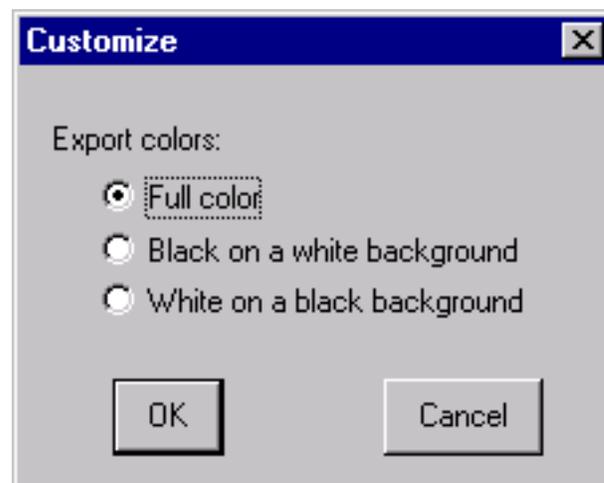

Figure 8.59 Entry Selector

You must specify a SAS catalog in which to save the IMAGE entry as well as a name for the object.

When exporting your diagram to a bitmap or saving to a SAS/GRAPH IMAGE entry, you can have the colors mapped so that color diagrams are saved in black on white or white on black. You do not have to make those changes to the diagram yourself. Use **File ► Export as Bitmap ► Customize...** to display the following dialog:

Figure 8.60 Customize Export Dialog

Select **Black on white** to convert the output to a black diagram on a white background. This is useful when the diagram is being exported to a document.

Select **White on black** to convert the output to a white diagram on a black background. This is useful when the diagram is being exported for display on a black and white terminal.

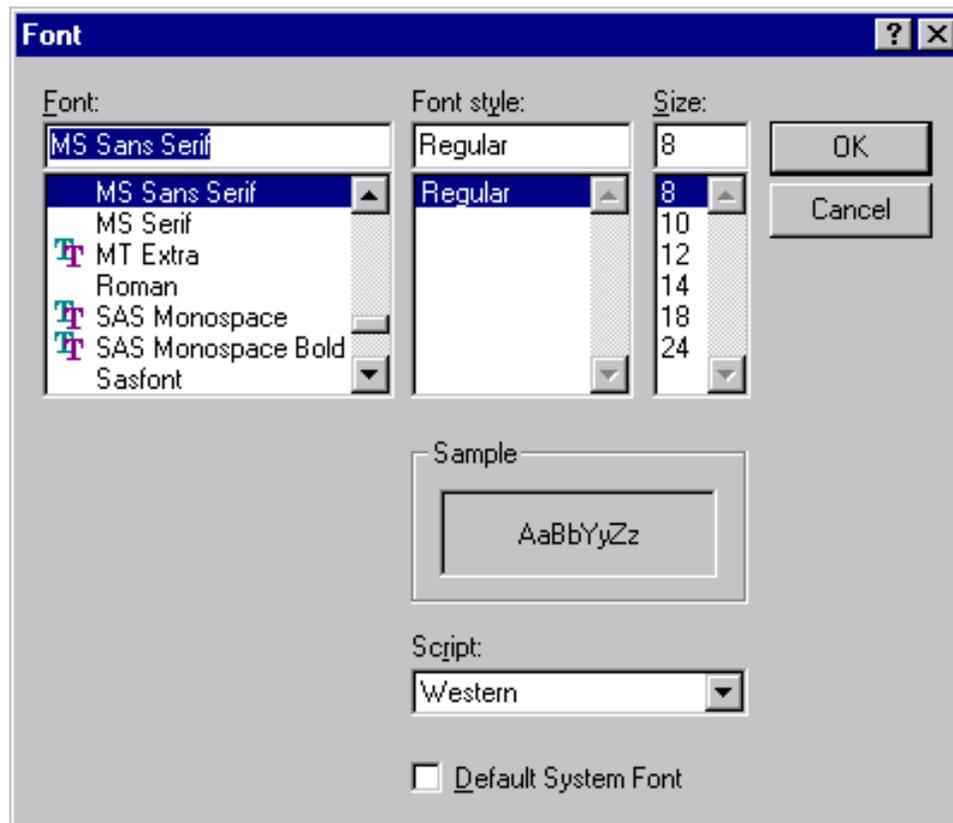

Modifying Fonts

By default, the ISHIKAWA environment uses the same hardware font as the SAS windowing environment. However, you have the option of specifying two different font styles/sizes.

The *primary* font is used for labeling arrows in the first three levels of the diagram. The *secondary* font is used for labeling arrows in the remaining levels. You will typically use a smaller font in the detailed (secondary) areas of the diagram.

To change a font, select **View ► Ishikawa Settings ► Primary Fonts...** or **View ► Ishikawa Settings ► Secondary Fonts...** to display the Font Requestor window, as follows:

Figure 8.61 Font Requestor

The layout of the Font requestor window is host specific. Typically, it will contain a list of available fonts and sizes displayed in a scrollable region. Refer to your host documentation for specific information regarding the format of this dialog.

To change fonts, select a font from the list.

You must close the Font Requestor window before you can proceed. Select **OK** to apply the font or **Cancel** to cancel the dialog.

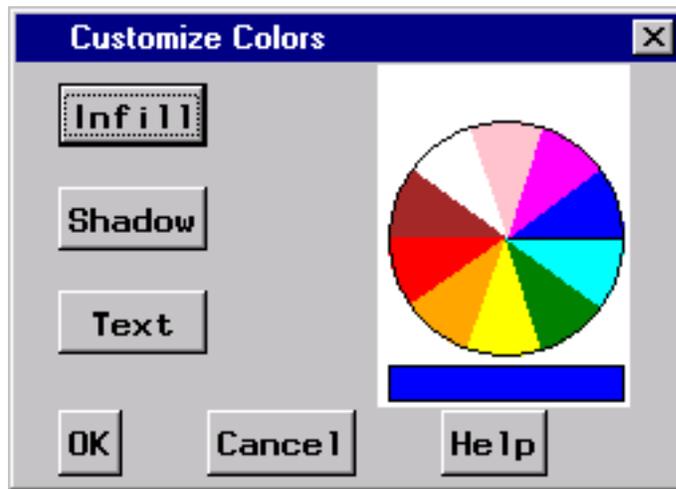

To customize your session so that these fonts are permanently associated with the ISHIKAWA environment, select **View ► Save Attributes** from the command bar.

Modifying Box Colors

By default, the box fill (background) color is empty and the shadow (outline) color is the same as the arrow color.

To modify the colors associated with trunk and branch boxes, select **View ► Ishikawa Settings ► Colors...** A dialog, similar to the following, is displayed:

Figure 8.62 Colors Dialog

To change the fill color of all the boxes⁶ in the Ishikawa diagram, do the following:

- Select a color from the color palette.
- Select **Infill**.

Once modified, the fill color is unaffected by changes in the arrow color. To return the box to an empty fill, proceed as follows:

- Select the current infill color from the color palette (if it is not already the current color).
- Select **Infill**.

To change the shadow color of the boxes, select **Shadow** and follow the same procedure.

Select **OK** to close the dialog or **Cancel** to cancel the changes.

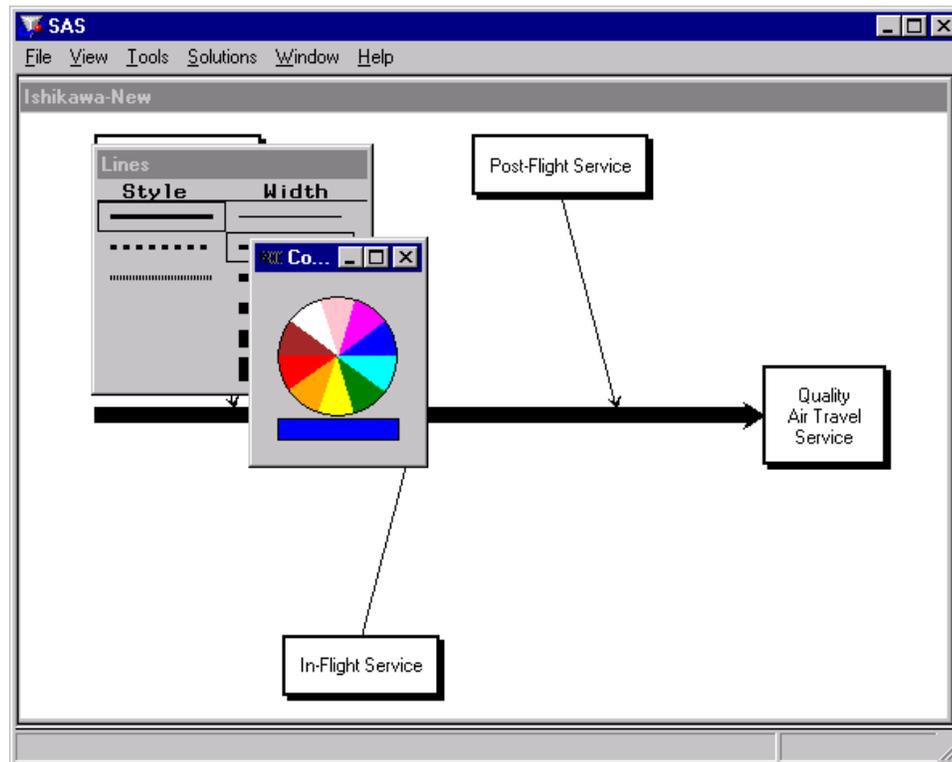

Modifying Arrow Colors and Line Styles

The ISHIKAWA environment provides a line style palette and a color palette that you can use to customize the arrows in your Ishikawa diagram. Select **View ► Palettes** to activate both palettes.⁷

⁶ You cannot directly modify the colors of individual boxes from this dialog.

⁷ If you are working on a black-and-white terminal, you should not use the color palette.

Figure 8.63 Line Style and Color Palettes

To specify the arrows to which color and line selections apply, subset them with the subset function. To toggle an arrow in or out of the list of subsetted arrows, do the following:

- Use the right mouse button to display the arrow head or the arrow tail popup menu. To subset an arrow and all its descendants, use the arrow head popup menu. Use the arrow tail popup menu to subset an arrow without any descendants.
- Select **Subset**.

The labels of all subsetted arrows are underlined.

On some hosts, shift-clicking on the arrow head or tail will also subset the arrow. You can subset any combination of arrows in the diagram.

You can change the color of all the subsetted arrows by selecting the desired color in the color palette with the mouse. Likewise, use the line palette to control the style and width of the arrows.

To unsubset all the arrows in the diagram, do the following:

- Move the cursor to a *background* area of the ISHIKAWA window.
- Use the right mouse button to activate the background popup menu.
- Select **Unsubset** from the popup menu.

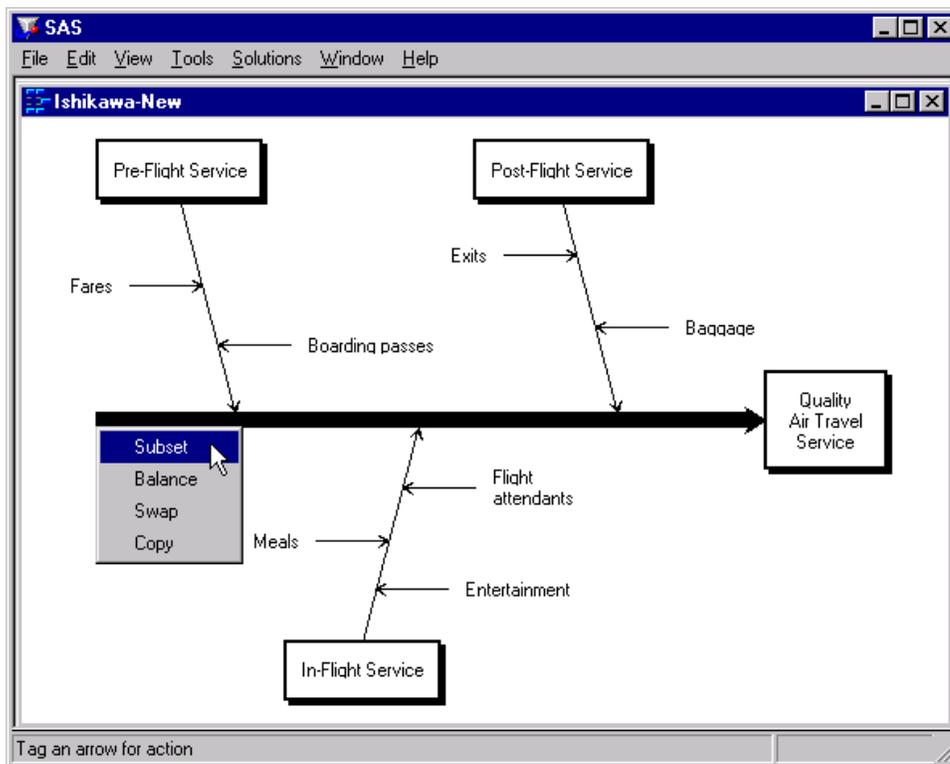

To unsubset a specific arrow in the diagram, select **Subset** from the context-sensitive popup menu for the arrow head or tail.

Be sure to remove all subsets once you have finished modifying the diagram, since subsets affect the focus of many other operations.

Example

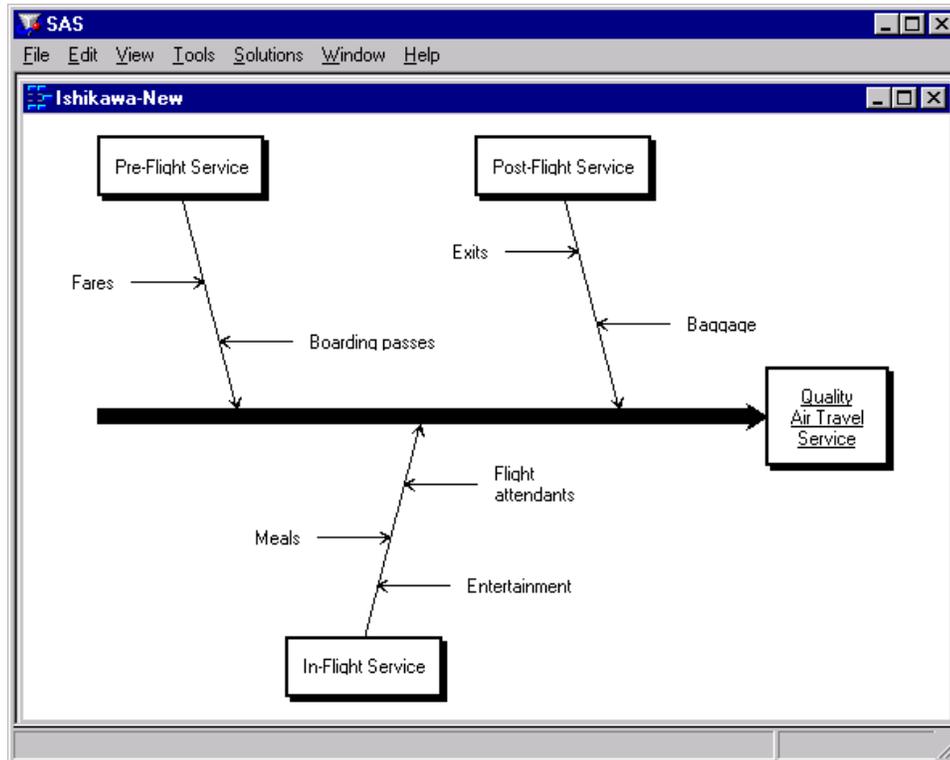

Continuing with the diagram from the previous section, subset the trunk using the arrow tail popup menu.

Figure 8.64 Subsetting Only the Trunk

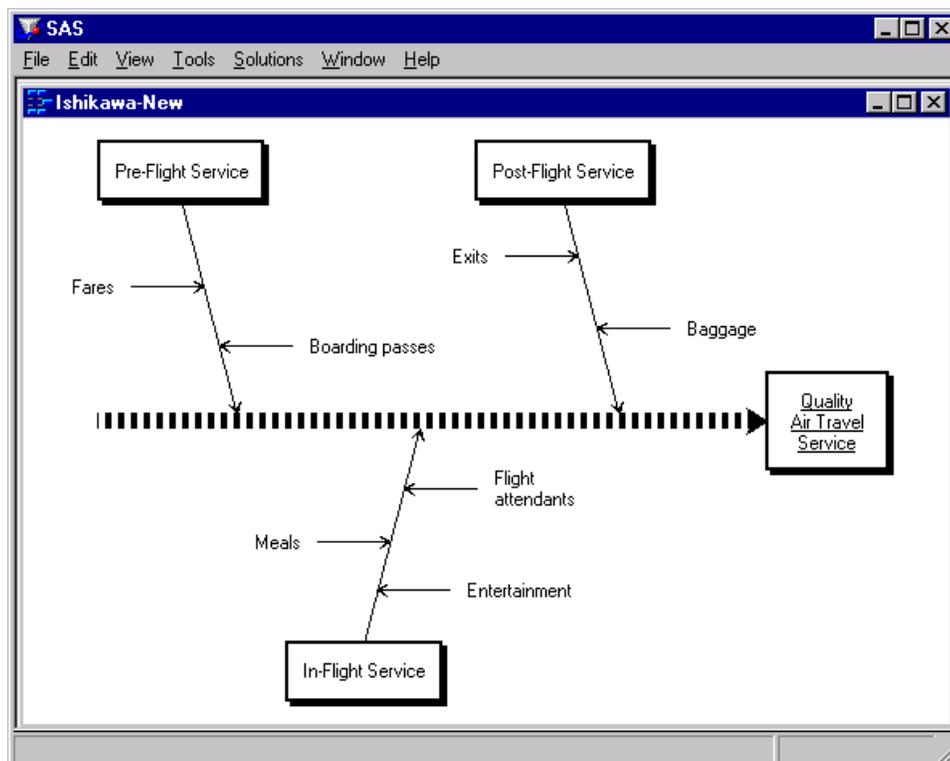

Note that only the trunk is subsetted (as indicated by the underlined label).

Figure 8.65 Subsetting Only the Trunk (continued)

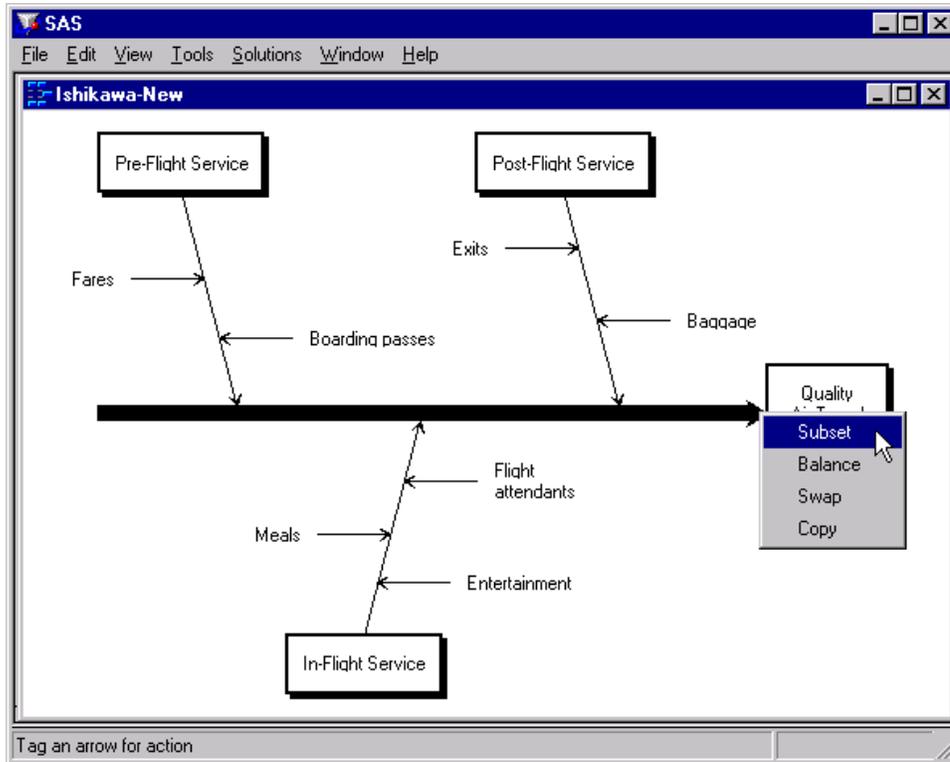

When you select a line style from the line palette, only the line style of the subsetting arrow is changed.

Figure 8.66 Modified Diagram

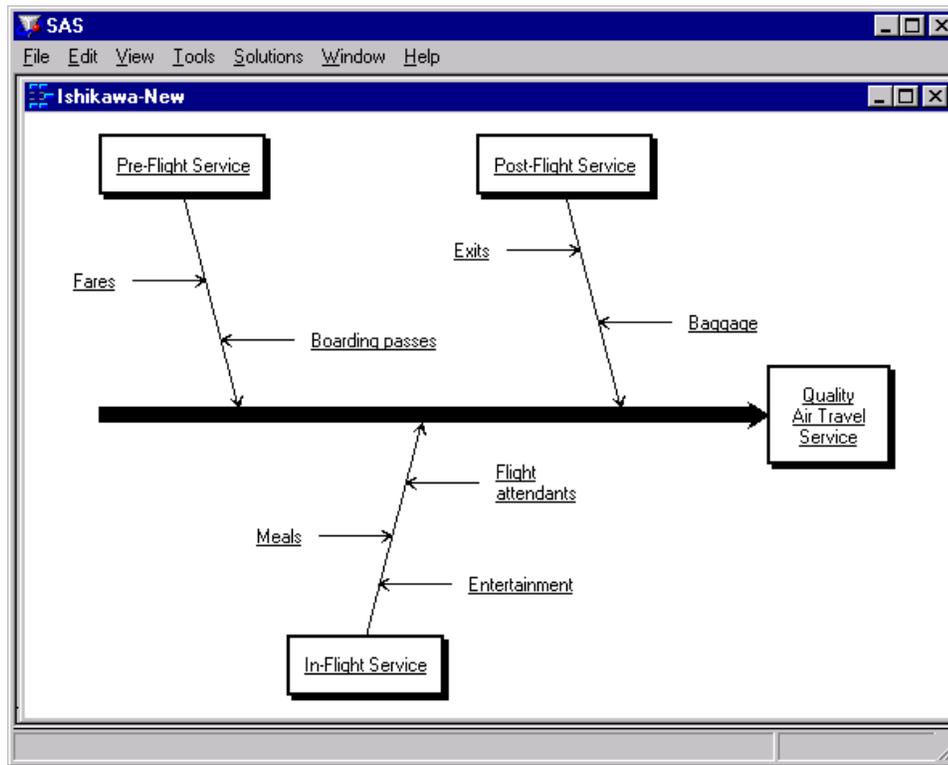

Alternately, if you subset the trunk using the arrow head popup menu, all of the arrows in the diagram are subsetted.

Figure 8.67 Subsetting the Entire Diagram

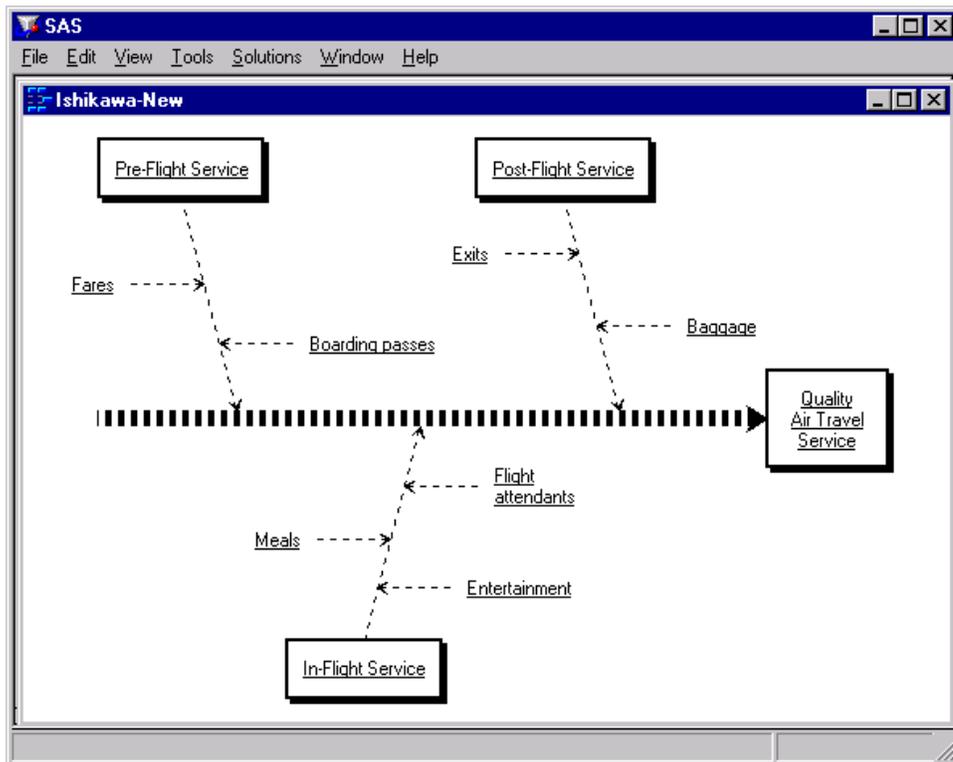

Note that all of the labels in the diagram are now underlined.

Figure 8.68 Subsetting the Entire Diagram (*continued*)

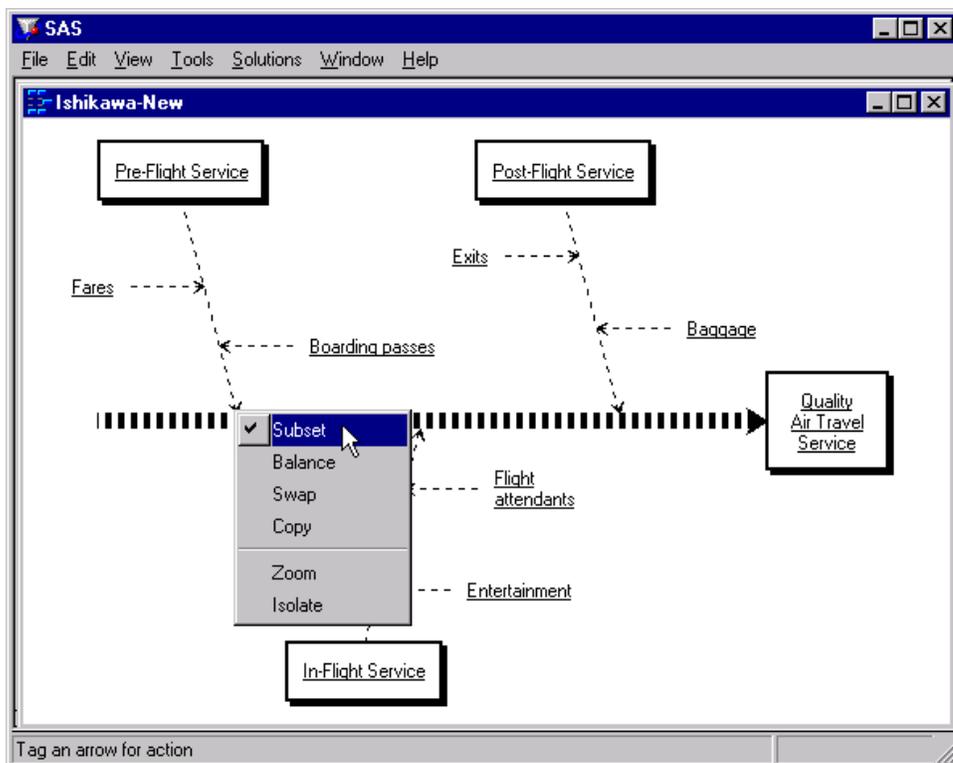

Now, when you select a new line style from the line palette, all the arrows are drawn with this line style.

Figure 8.69 Modified Diagram

To remove the subset from the *Pre-Flight Service* branch and all its descendants, select **Subset** from the arrow head popup menu.

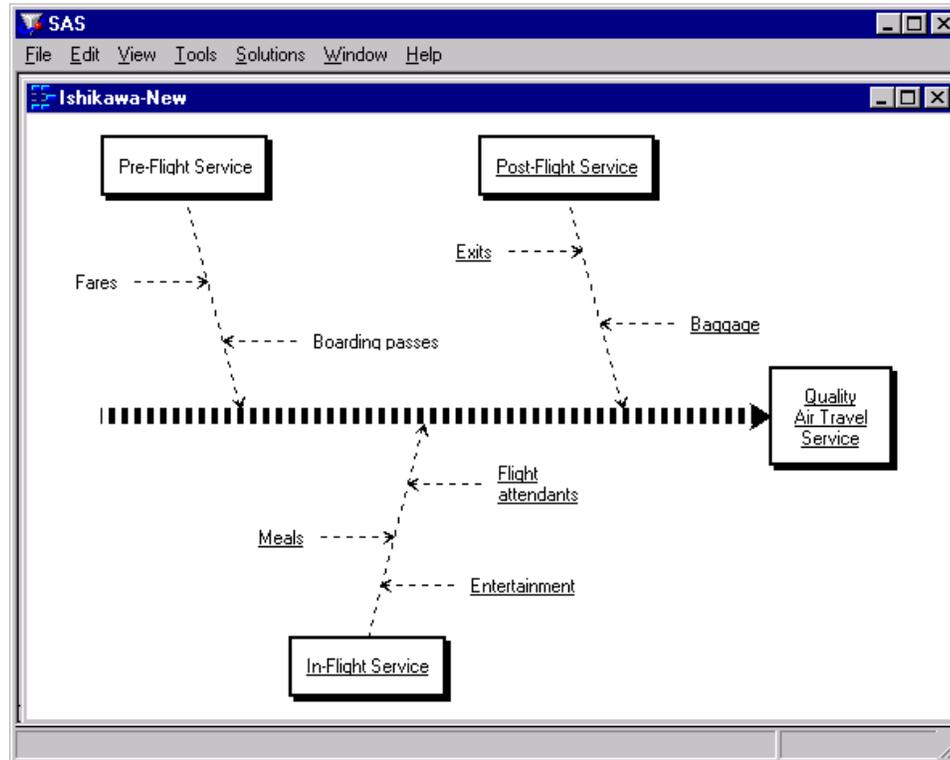

Figure 8.70 Selectively Removing Tags

Tag an arrow for action

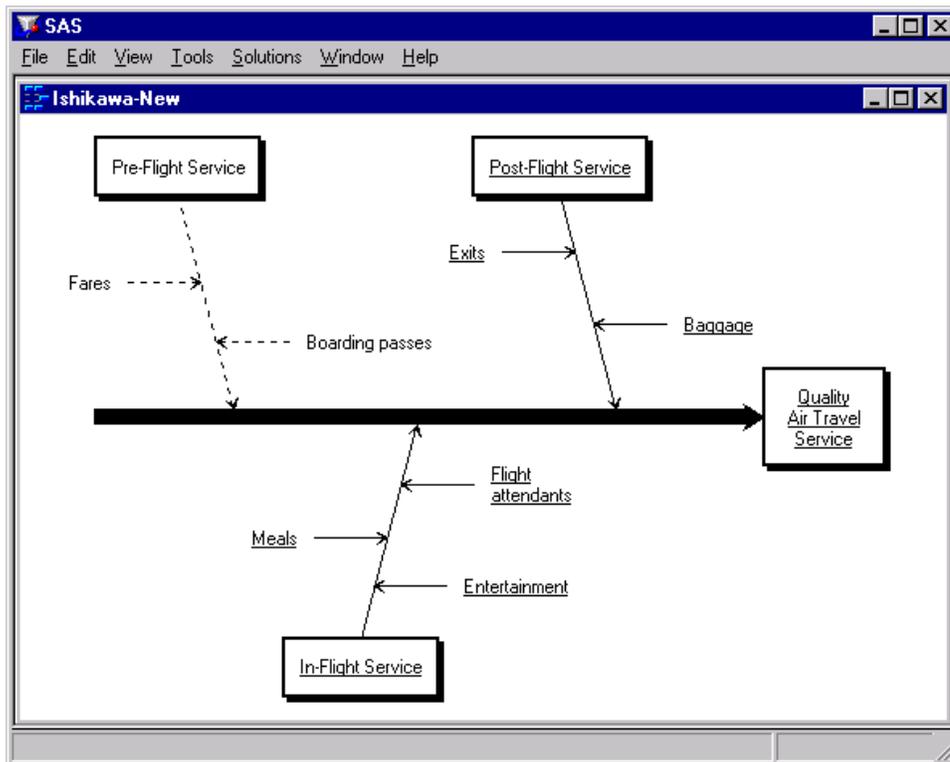

This removes the underlines from the labels in these arrows.

Figure 8.71 Selectively Removing Subsets (*continued*)

You can now use the line palette to change the line style for all the arrows in the diagram with the exception of the *Pre-Flight Service* branch and its descendants:

Figure 8.72 Modified Diagram

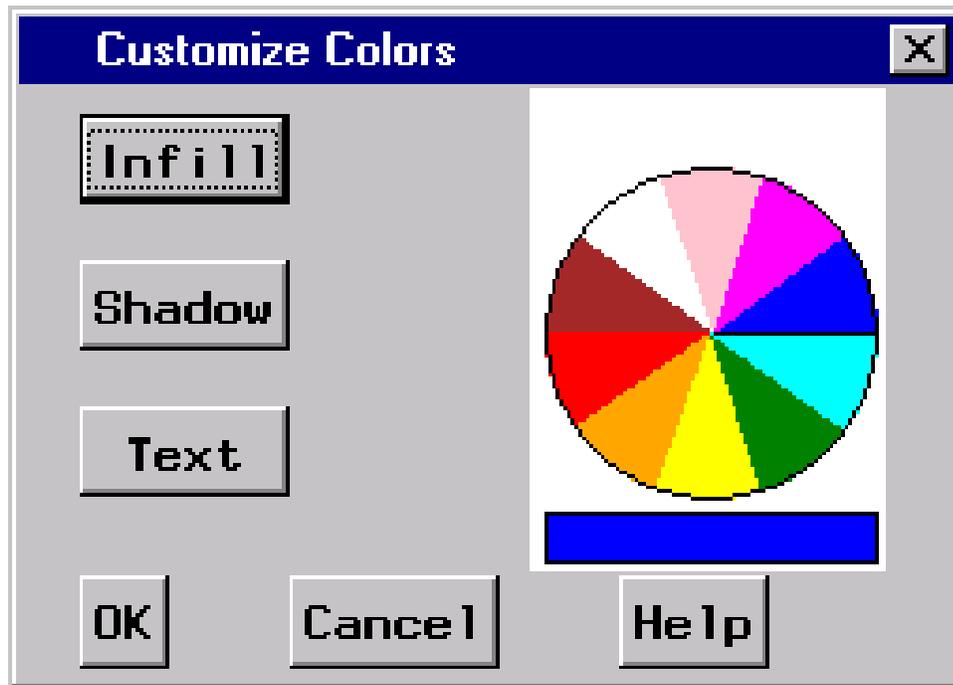

The same principles apply when making color changes—simply use the color palette instead of the line style palette.

Modifying Text Colors

By default, labels have the same color as the arrow. To modify the text color independently of the arrow color, select **View ► Ishikawa Settings ► Colors...** The Customize Color window, similar to the following, will open:

Figure 8.73 Colors Dialog

To change the text color of all the arrows⁸ in the Ishikawa diagram, do the following:

- Select a color from the color palette.
- Select **Text**.

Once modified, the text color is unaffected by changes to the arrow color. To relink the text color to the arrow color, do the following:

- Select the current text color from the color palette (if it is not already the current color).
- Select **Text**.

Select **OK** to close the dialog window. To cancel the changes, select **Cancel**.

Modifying Arrow Heads

To modify the characteristics of the arrow heads in your diagram, select **View ► Ishikawa Settings ► Arrows...** This opens the following dialog:

⁸ You cannot directly modify the text color for individual arrows from this dialog.

Figure 8.74 Arrows Dialog

The dialog controls the characteristics of all arrow heads. Arrow heads cannot be modified individually.

Arrow heads can be tapered, flush, or empty. Use the sliders labeled **Length** and **Width** to control the length and width of the arrow heads. Move the sliders to the right to increase the length/width of the arrow head and to the left to decrease the length/width.

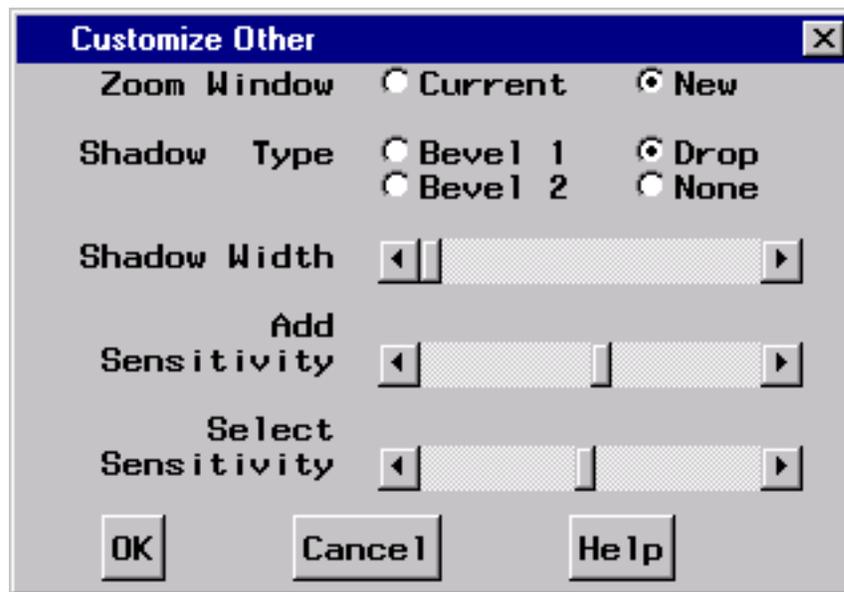

Removing arrow heads increases the readability of a highly detailed diagram. Use the **Display** slider to control the level at which arrow heads are displayed. Move the slider to the extreme left to remove all the arrow heads and to the extreme right to display all the arrow heads. Use the intermediate settings to select a threshold level of detail, above which arrow heads are not displayed. By default, arrow heads are displayed for all levels.

Select **OK** to close the window. To cancel the changes, select **Cancel**.

Modifying Environmental Attributes

You can modify other features of the ISHIKAWA environment such as zooming, mouse sensitivity, and shadow attributes by selecting **View ► Ishikawa Settings ► Other...** to open the following dialog:

Figure 8.75 Others Dialog

Zoom Window controls whether the zoom operation opens a new window or draws in the current window. Select **Current** to reduce the amount of window management required.

The **Shadow Type** button controls the type of shadow that is drawn around the trunk and branch boxes.

- **Bevel 1** draws a beveled edge box with a lower-right light source.
- **Bevel 2** draws a beveled edge box with an upper-left light source.
- **Drop** draws a box with a drop shadow. This is the default.
- **None** suppresses the shadow.

The **Shadow Width** slider controls the shadow width if the boxes have shadows or the outline width when boxes are displayed without shadows. Move the slider to the right to increase the shadow width and to the left to decrease the width.

The **Add Sensitivity** slider controls how closely you must position the cursor to an existing arrow before a mouse click results in an add arrow operation. Move the slider to the right to increase the size of the context-sensitive area and to the left to reduce the size of the context-sensitive area.

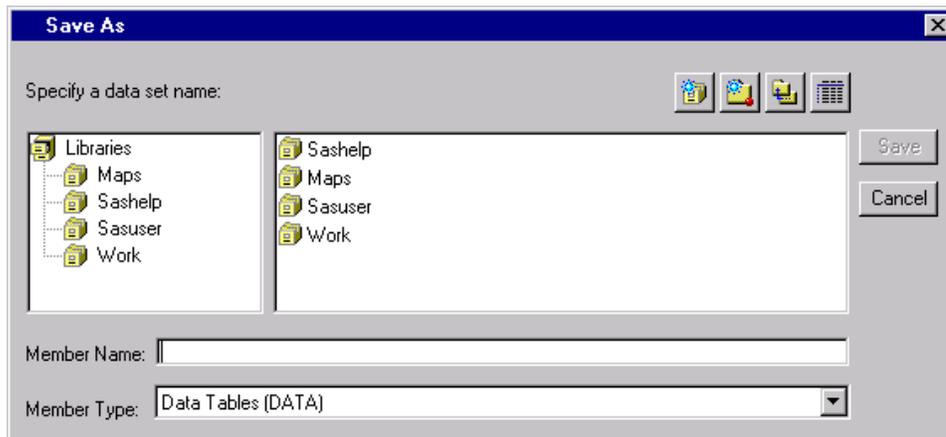

The **Select Sensitivity** slider controls how closely you must position the cursor to an existing arrow before a mouse click results in an edit, delete, move, or popup arrow operation. Operate this slider in the same manner as the **Add Sensitivity** slider.

Saving an Ishikawa Diagram for Future Editing

You must save your Ishikawa diagram as a SAS data set if you intend to edit it in the future with the ISHIKAWA environment. The ISHIKAWA environment does not reconstruct Ishikawa diagrams by reading graphics entries (GRSEG) from SAS catalogs.

Select **File ► Save As ► Data Set** to activate the Data Set Requestor window.

Figure 8.76 Output File Requestor

A list of SAS *librefs* is displayed in the Libraries tree in the left region of the dialog. Begin by selecting a libref from the list. A libref refers to a permanent SAS data library located on your host system. For example, the default SASUSER libref (on most hosts) points to a directory called SASUSER, located under the working directory of your current SAS session. Any data sets saved with the libref **SASUSER** will be saved in that directory.

To direct your SAS data sets to a different directory, select the *Create new library* tool icon to open the New Library dialog. Use this dialog to specify the directory and assign a libref to that directory.

To select the libref **SASUSER**, move your cursor over that entry in the list and click. The region to the right of the Libraries tree is used to display any existing SAS data sets in that library.

To save your diagram in an existing SAS data set, use the mouse to click on an entry in the list. The *member name* field will be updated to reflect your choice. If you want to save your diagram in a new SAS data set, move your cursor to the *member name* field and type the new name (in this example, SERVICE).

Select **Save** to save the diagram and return to the ISHIKAWA environment or select **Cancel** to cancel the save.

Reading an Existing Ishikawa Diagram

To enter the ISHIKAWA environment and resume editing an existing diagram, you must have previously saved the diagram as a SAS data set. The ISHIKAWA environment *does not* allow you to modify graphs stored in SAS/GRAPH catalogs.

You can specify the name of this data set when you establish the ISHIKAWA environment with the following statements:

```
proc ishikawa data=libref.dataset;
run;
```

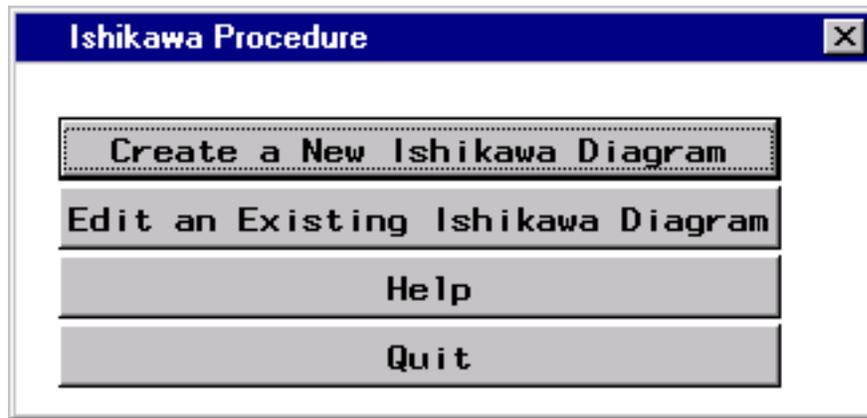

Alternatively, the ISHIKAWA environment will prompt you for a data set after you invoke the environment with the following statements:

```
proc ishikawa;  
run;
```

When you specify a data set in the PROC statement, the ISHIKAWA environment is initialized and your diagram is displayed up to the branch level. The message area will indicate if any additional detail is hidden. You can edit your diagram even if some of the diagram is hidden. To add or remove detail one level at a time, select **> Detail** or **< Detail** from the background popup menu.

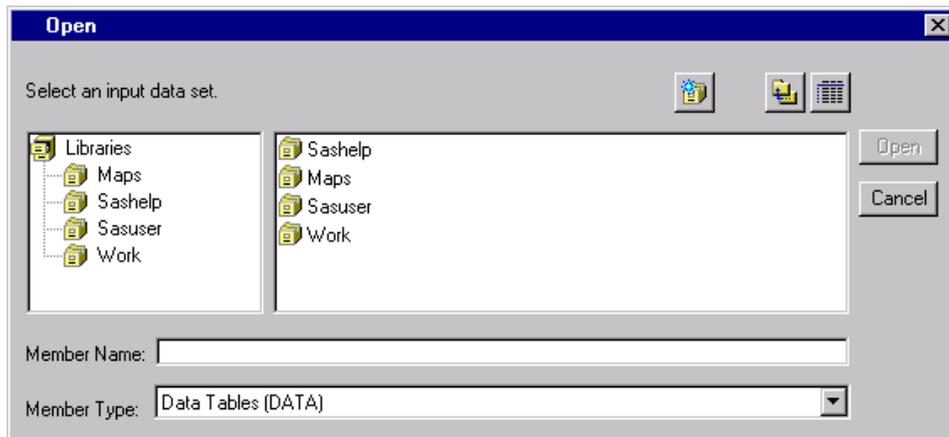

When you do not specify a data set in the PROC statement, you will see the following menu:

Figure 8.77 Initial Menu

Since you are editing an existing diagram rather than starting a new diagram, select **Edit an Existing Diagram** to activate the Member Selector window.

Figure 8.78 Input Member Selector

Use the Member Selector window to specify an input SAS data set. For information on how to specify the SAS data set name, follow the steps outlined in “[Saving an Ishikawa Diagram for Future Editing](#)” on page 794.

To establish the ISHIKAWA environment and display the diagram you have selected, select **Open**. The diagram is displayed up to the branch level.

To quit or start a new diagram, return to the main menu by selecting **Cancel**.

Displaying Multiple Ishikawa Diagrams

The ISHIKAWA environment enables you to view multiple Ishikawa diagrams simultaneously for side-by-side comparisons of different diagrams. You can also use this feature to transfer information between diagrams, since the move and copy operations function across windows. You can have up to four ISHIKAWA windows open at one time.

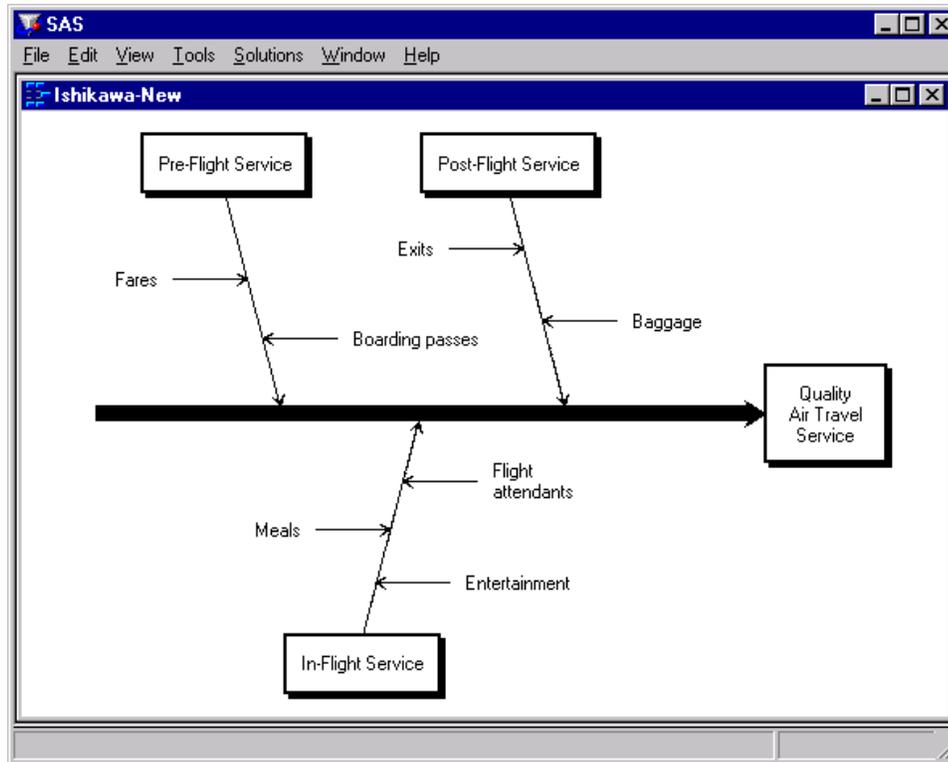

To open a window for another Ishikawa diagram, select **File ► Open**. This will display the Member Selector window, which you can use to specify the name of the input SAS data set for the other Ishikawa diagram.

You can also start new diagrams while displaying other Ishikawa diagrams. To open a window for a new Ishikawa diagram, select **File ► New**. This opens an ISHIKAWA window with a template for a new diagram.

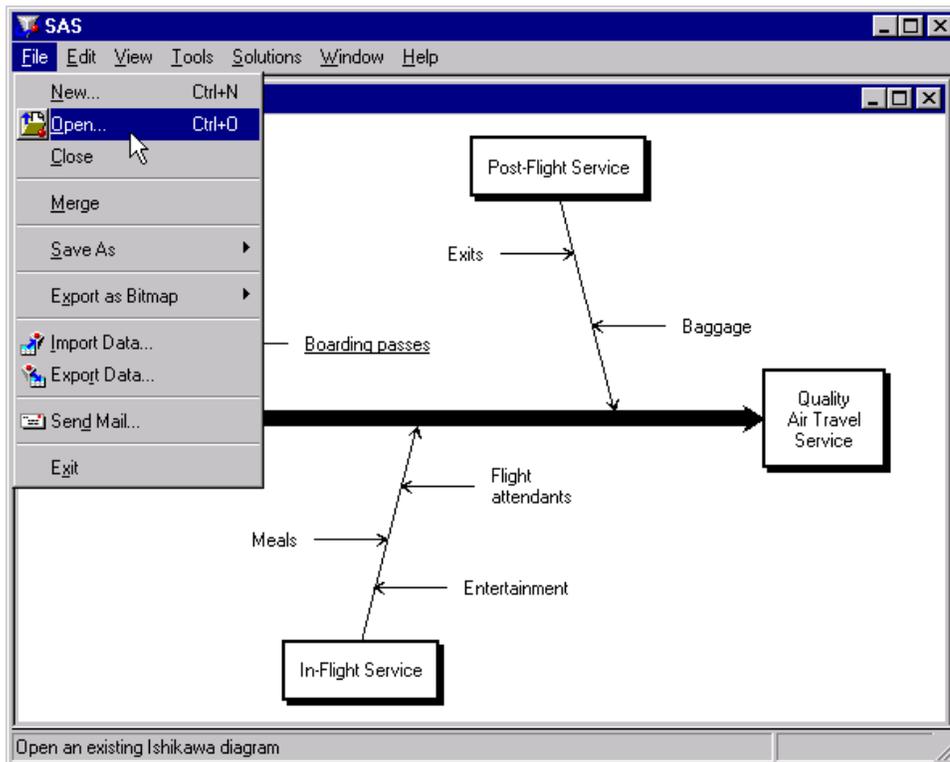

Example

The following figure shows an Ishikawa diagram for *Quality Air Travel Service* after an initial brainstorming session:

Figure 8.79 Single Ishikawa Diagram

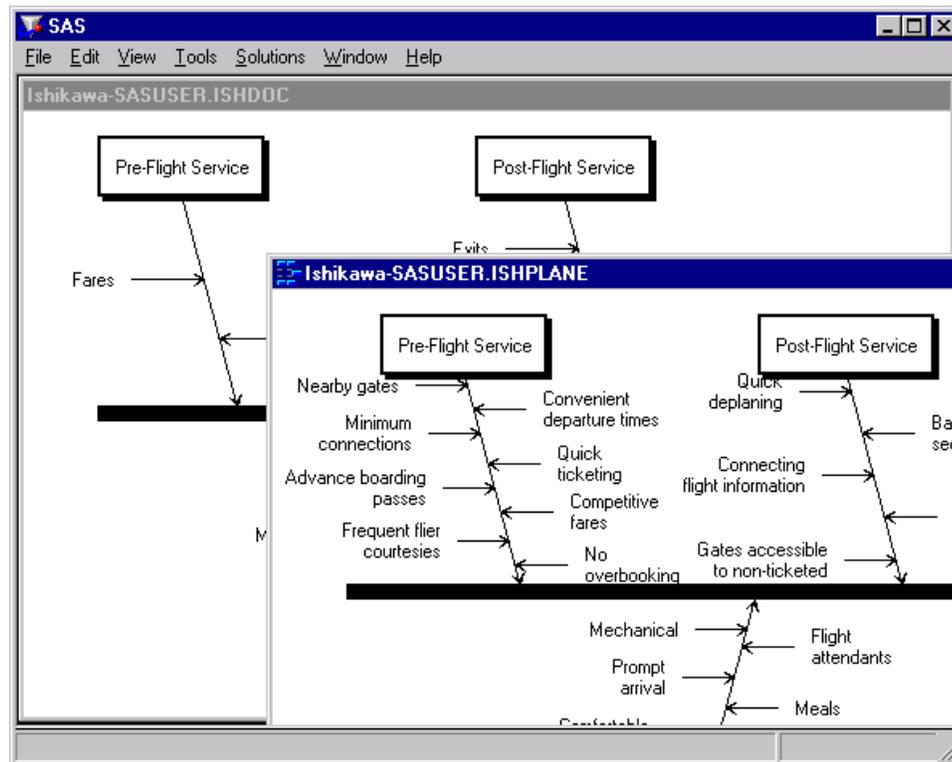

The current diagram and another Ishikawa diagram can be viewed simultaneously by selecting **File** ► **Open** from the command bar.

Figure 8.80 Opening a Second Diagram

In this situation, displaying both diagrams concurrently emphasizes the improved understanding of the process. It also enables you to transfer information from one diagram to another.

Figure 8.81 Viewing Multiple Ishikawa Diagrams

Input and Output Data Sets

The following is a complete list of the variables in output SAS data sets created by the ISHIKAWA environment:

Variable	Type	Len	Description
<u>LEVEL</u>	Num	8	Level of detail
<u>TEXT1</u>	Char	40	First line of label
<u>TEXT2</u>	Char	40	Second line of label
<u>TEXT3</u>	Char	40	Third line of label
<u>TEXT4</u>	Char	40	Fourth line of label
<u>TEXT5</u>	Char	40	Fifth line of label
<u>NOTE1</u>	Char	40	First line of note
<u>NOTE2</u>	Char	40	Second line of note
<u>NOTE3</u>	Char	40	Third line of note
<u>NOTE4</u>	Char	40	Fourth line of note
<u>RELPOS</u>	Num	8	Relative arrow position
<u>SIDE</u>	Char	1	Side arrow attaches to parent
<u>ANGLE</u>	Num	8	Angle (non-horizontal arrows)
<u>LWIDTH</u>	Num	8	Line width
<u>LSTYLE</u>	Num	8	Line style
<u>LCOLOR</u>	Char	8	Line color

<u>TCOLOR</u>	Char	8	Text color
<u>ICOLOR</u>	Char	8	Box infill color
<u>SCOLOR</u>	Char	8	Shadow color
<u>STYPE</u>	Char	1	Shadow type
<u>SWIDTH</u>	Num	8	Shadow width
<u>RELLNG</u>	Num	8	Relative length of an arrow
<u>HLEVEL</u>	Num	8	Arrow head threshold
<u>HSTYLE</u>	Num	8	Arrow head style
<u>HLNGTH</u>	Num	8	Arrow head length
<u>HWIDTH</u>	Num	8	Arrow head width
<u>HTEXT</u>	Num	8	Font height
<u>FTEXT</u>	Char	8	Font

Only the variables LEVEL and TEXT1 are required in the input data set for the ISHIKAWA procedure. Each observation in the input data set corresponds to a particular arrow in the diagram. The order of the observations is critical because it defines the relationships of the arrows.

- The trunk is always the first observation.
- The remaining observations are ordered so that leaves are nested within stems, stems are nested within branches, and branches are nested within the trunk.
- The variable LEVEL is numeric and indicates the level within the diagram. The trunk has a level of 0, branches have a level of 1, stems have a level of 2, and so on.
- The first line of text in a label is stored as TEXT1, the second as TEXT2, and so on.

Example

The following is a partial listing of the SAS data set used to create the Ishikawa diagram shown in Figure 8.15:

```
data ishplane;
  length _text1_ _text2_ _text3_ $ 40 _side_ $ 1;
  input  _level_ _text1_ & _text2_ & _text3_ & _relpos_ _side_;
  datalines;
0 Quality                Air Travel                Service  -1.00  .
1 Pre-Flight Service     .                        .        0.26  T
2 Competitive           fares                    .        0.68  R
2 Convenient            departure times         .        0.18  R
2 Quick                 ticketing               .        0.43  R
2 Frequent flier        courtesies              .        0.81  L
1 In-Flight Service     .                        .        0.61  B
2 Prompt                departures              .        0.21  R
2 Comfortable           seating                 .        0.35  L
;
```

Note the structure of this data set:

- The trunk (always the first observation) has a LEVEL value of zero.
- All subsequent observations for which LEVEL is equal to one are branches that emerge from the trunk.

- Observations 4 and 5 are both leaves that emerge from the preceding stem (observation 3).
- Likewise, leaves 7 and 8 emerge from the preceding stem (observation 6).

You can use this data set as a way of extracting text and notepad information from the diagram.

Syntax

There are only three options that can be specified in the PROC ISHIKAWA statement, since the ISHIKAWA procedure is primarily a user-driven procedure.

DATA=SAS-data-set

identifies the name of a SAS data set that specifies an existing Ishikawa diagram. By default, the procedure will prompt you to edit an existing Ishikawa diagram or start a new one. When you specify the DATA= option, the procedure bypasses this initial menu. For example, the following statements simplify editing an existing Ishikawa diagram saved in a SAS data set:

```
proc ishikawa data=work.airline;  
run;
```

NEW

starts a new Ishikawa diagram. By default, the procedure will prompt you to edit an existing Ishikawa diagram or start a new one. When you specify the NEW option, the procedure bypasses this initial menu and starts with a new diagram. Do not specify any other options when using the NEW option. For example, the following statements simplify starting a new Ishikawa diagram:

```
proc ishikawa new;  
run;
```

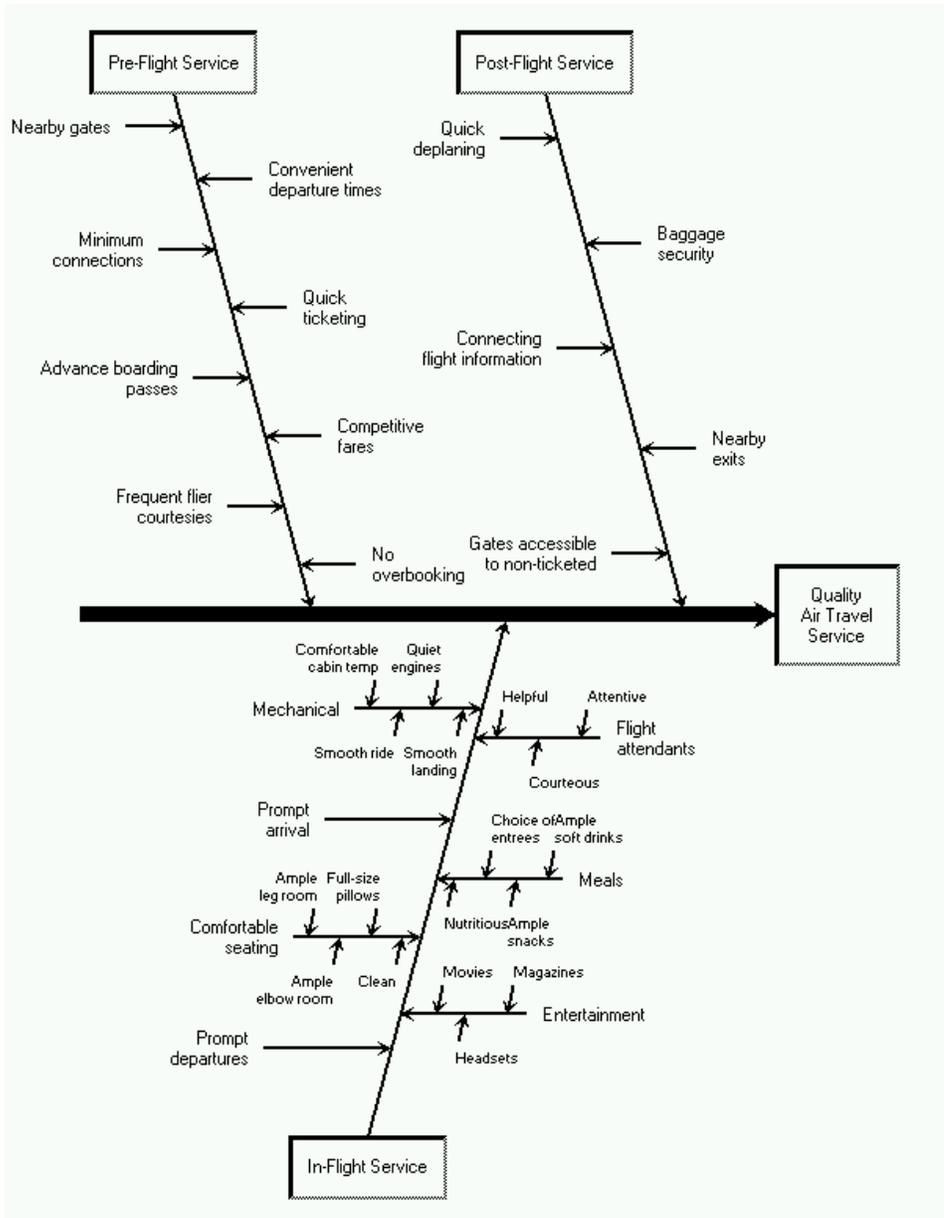

NOFS

allows you to create hard copies of Ishikawa diagrams saved as SAS data sets without invoking the interactive features of the procedure. You must specify the DATA= option when you use the NOFS option. For example, the following statements create a hard copy of the Ishikawa diagram saved in the SAS data set *work.airline*:

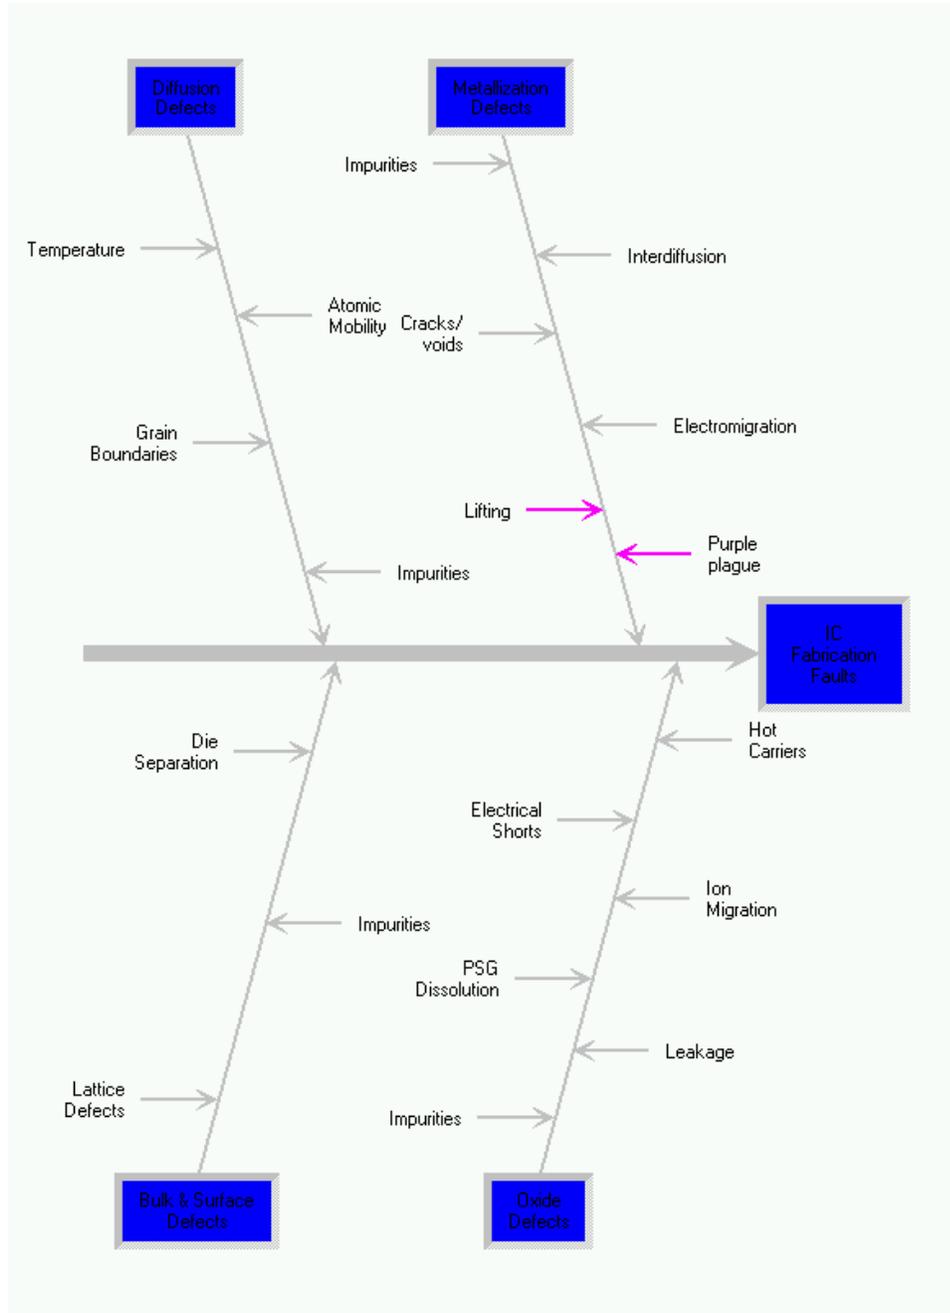

```
goptions dev=ps1 noprompt;  
proc ishikawa data=work.airline nofs;  
run;
```

Introduction: MACONTROL Procedure

The MACONTROL procedure creates moving average control charts, which are tools for deciding whether a process is in a state of statistical control and for detecting shifts in a process average. The procedure creates the following two types of charts:

- *uniformly weighted moving average charts* (commonly referred to as *moving average charts*). Each point on a moving average chart represents the average of the w most recent subgroup means, including the present subgroup mean. The next moving average is computed by dropping the oldest of the previous w subgroup means and including the newest subgroup mean. The constant w , often referred to as the *span* of the moving average, is a parameter of the moving average chart. There is an inverse relationship between w and the magnitude of the shift to be detected; larger values of w are used to guard against smaller shifts.

- *exponentially weighted moving average (EWMA) charts*, also referred to as *geometric moving average (GMA) charts*. Each point on an EWMA chart represents the weighted average of all the previous subgroup means, including the mean of the present subgroup sample. The weights decrease exponentially going backward in time.

The weight r ($0 < r \leq 1$) assigned to the present subgroup sample mean is a parameter of the EWMA chart. Small values of r are used to guard against small shifts. If $r = 1$, the EWMA chart reduces to a Shewhart \bar{X} chart.

In the MACONTROL procedure, the EWMACHART statement produces EWMA charts, and the MACHART statement produces uniformly weighted moving average charts.

In contrast to the Shewhart chart where each point is based on information from a single subgroup sample, each point on a moving average chart combines information from the current sample and past samples. Consequently, the moving average chart is more sensitive to small shifts in the process average. On the other hand, it is more difficult to interpret patterns of points on a moving average chart, since consecutive moving averages can be highly correlated, as pointed out by Nelson (1983).

You can use the MACONTROL procedure to

- read raw data (actual measurements) or summarized data (subgroup means and standard deviations) to create charts
- specify control limits as probability limits or in terms of a multiple of the standard error of the moving average
- adjust the control limits to compensate for unequal subgroup sample sizes
- accept numeric- or character-valued subgroup variables
- display subgroups with date and time formats
- estimate the process standard deviation σ using a variety of methods or specify a standard (known) value for σ
- analyze multiple process variables in the same chart statement
- provide multiple chart statements. If used with a BY statement, the procedure generates charts separately for BY groups of observations.
- tabulate the information displayed in the control chart
- save moving averages, control limits, and control limit parameters in output data sets
- superimpose plotted points with stars (polygons) whose vertices indicate the values of multivariate data related to the process
- display a trend chart below the moving average chart that plots a systematic or fitted trend in the data
- produce charts as traditional graphics, ODS Graphics output, or legacy line printer charts. Line printer charts can use special formatting characters that improve the appearance of the chart. Traditional graphics can be annotated, saved, and replayed.

Learning about the MACONTROL Procedure

If you are using the MACONTROL procedure for the first time, begin by reading “PROC MACONTROL Statement” on page 810 to learn about input data sets. Then read the section “Getting Started: EWMACHART Statement” on page 817 in “EWMACHART Statement: MACONTROL Procedure” on page 816 or the section “Getting Started: MACHART Statement” on page 870 in “MACHART Statement: MACONTROL Procedure” on page 869. These chapters also provide syntax information, computational details, and advanced examples.

PROC MACONTROL Statement

Overview: PROC MACONTROL Statement

The PROC MACONTROL statement starts the MACONTROL procedure and it identifies input data sets.

After the PROC MACONTROL statement, you provide either an EWMACHART or an MACHART statement that specifies the type of moving average chart you want to create and the variables in the input data set that you want to analyze. For example, the following statements request a uniformly weighted moving average chart:

```
proc macontrol data=values;
  machart weight*lot / mu0    = 8.10
                      sigma0 = 0.05
                      span    = 5;
run;
```

In this example, the DATA= option specifies an input data set named values that contains the *process* measurement variable weight and the *subgroup-variable* lot.¹

You can use options in the PROC MACONTROL statement to do the following:

- specify input data sets containing variables to be analyzed, parameters for calculating moving averages, or annotation information
- specify a graphics catalog for saving traditional graphics
- specify that charts be produced as traditional graphics or line printer charts
- define characters used for features on line printer charts

In addition to the chart statement, you can provide BY statements, ID statements, TITLE statements, and FOOTNOTE statements. If you are producing traditional graphics, you can also provide graph-

¹In SAS 6.12 and previous releases of SAS/QC software, the keyword GRAPHICS was required in the PROC MACONTROL statement to specify that the chart be created as traditional graphics. In SAS 7 and later releases, you can specify the LINEPRINTER option to request line printer charts.

ics enhancement statements, such as SYMBOL n statements, which are described in *SAS/GRAPH: Reference*.

See Chapter 3, “SAS/QC Graphics,” for a detailed discussion of the alternatives available for producing charts with SAS/QC procedures.

NOTE: If you are using the MACONTROL procedure for the first time, you should also read the sections “Getting Started: EWMACHART Statement” on page 817 and “Getting Started: MACHART Statement” on page 870.

Syntax: PROC MACONTROL Statement

The syntax for the PROC MACONTROL statement is as follows:

PROC MACONTROL < options > ;

The PROC MACONTROL statement starts the MACONTROL procedure, and it optionally identifies various data sets and requests line printer charts. You can specify the following options in the PROC MACONTROL statement. The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply to traditional graphics and line printer charts, respectively.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

specifies an input data set that contains appropriate annotate variables, as described in *SAS/GRAPH: Reference*. The ANNOTATE= option enables you to add features to the moving average chart (for example, labels that explain out-of-control points). The ANNOTATE= data set is used only when the chart is created as traditional graphics; it is ignored when the LINEPRINTER option is specified and when ODS Graphics is in effect.

The data set specified with the ANNOTATE= option in the PROC MACONTROL statement is a “global” annotate data set in the sense that the information in this data set is displayed on every chart produced in the current run of the MACONTROL procedure.

ANNOTATE2=SAS-data-set

ANNO2=SAS-data-set

specifies an input data set that contains appropriate annotate variables that add features to the trend chart (secondary chart) produced with the TRENDVAR= option in the EWMACHART or MACHART statement.

DATA=SAS-data-set

names an input data set that contains raw data (measurements) as observations. If the values of the *subgroup-variable* are numeric, you need to sort the data set so that these values are in increasing order (within BY groups). The DATA= data set can contain more than one observation for each value of the *subgroup-variable*.

You cannot specify a DATA= data set with a HISTORY= or TABLE= data set. If you do not specify an input data set, PROC MACONTROL uses the most recently created data set as a DATA= data set. For more information, see “DATA= Data Set” in the appropriate chart statement chapter.

FORMCHAR(index)='string'

defines characters used for features on line printer charts, where *index* is a list of numbers ranging from 1 to 17 and *string* is a character or hexadecimal string. The *index* identifies which features are controlled with the *string* characters, as described in the following table. If you specify the FORMCHAR= option and omit the *index*, the *string* controls all 17 features.

Value of index	Description of Character	Chart Feature
1	vertical bar	frame
2	horizontal bar	frame, central line
3	box character (upper left)	frame
4	box character (upper middle)	serifs, tick (horizontal axis)
5	box character (upper right)	frame
6	box character (middle left)	not used
7	box character (middle middle)	serifs
8	box character (middle right)	tick (vertical axis)
9	box character (lower left)	frame
10	box character (lower middle)	serifs
11	box character (lower right)	frame
12	vertical bar	control limits
13	horizontal bar	control limits
14	box character (upper right)	control limits
15	box character (lower left)	control limits
16	box character (lower right)	control limits
17	box character (upper left)	control limits

Not all printers can produce the characters in the preceding list. By default, the form character list specified by the SAS system FORMCHAR= option is used; otherwise, the default is FORMCHAR='|---|+|---|====='. If you print to a PC screen or if your device supports the ASCII symbol set (1 or 2), the following is recommended:

```
formchar=' B3 , C4 , DA , C2 , BF , C3 , C5 , B4 , C0 , C1 , D9 , BA , CD , BB , C8 , BC , D9 ' X
```

Note that you can use the FORMCHAR= option to temporarily override the values of the SAS system FORMCHAR= option. The values of the SAS system FORMCHAR= option are not altered by the FORMCHAR= option in the PROC MACONTROL statement.

GOUT=graphics-catalog

specifies the graphics catalog for traditional graphics output from PROC MACONTROL. This is useful if you want to save the output. The GOUT= option is used only when the chart is created using traditional graphics; it is ignored when the LINEPRINTER option is specified and when ODS Graphics is in effect.

HISTORY=SAS-data-set**HIST=SAS-data-set**

names an input data set that contains subgroup summary statistics (means, standard deviations, and sample sizes). Typically, this data set is created as an OUTHISTORY= data set in a previous run of PROC MACONTROL or PROC SHEWHART, but it can also be created with a SAS summarization procedure such as PROC MEANS.

If the values of the *subgroup-variable* are numeric, you need to sort the data set so that these values are in increasing order (within BY groups). A HISTORY= data set can contain only one observation for each value for the *subgroup-variable*.

You cannot use a HISTORY= data set with a DATA= or TABLE= data set. If you do not specify an input data set, PROC MACONTROL uses the most recently created data set as a DATA= data set. For more information on HISTORY= data sets, see “HISTORY= Data Set” in the appropriate chart statement chapter.

LIMITS=SAS-data-set

names an input data set that contains the control limit parameters for the moving average chart. Each observation in a LIMITS= data set contains the parameters for a *process*.

If you are using SAS 6.09 or an earlier release of SAS/QC software, you must specify the options READLIMITS or READINDEX= in the chart statement to read the parameters from the LIMITS= data set. In SAS 6.10 and later releases, these options are not needed.

For details about the variables needed in a LIMITS= data set, see “LIMITS= Data Set” in the appropriate chart statement chapter.

If you do not provide a LIMITS= data set, you must specify the parameters with options in the chart statement.

LINEPRINTER

requests that line printer charts be produced. By default, the procedure creates traditional graphics.

TABLE=SAS-data-set

names an input data set that contains subgroup summary statistics and control limits. Each observation in a TABLE= data set provides information for a particular subgroup and *process*. Typically, this data set is created as an OUTTABLE= data set in a previous run of PROC MACONTROL.

You cannot use a TABLE= data set with a DATA= or HISTORY= data set. If you do not specify an input data set, PROC MACONTROL uses the most recently created data set as a DATA= data set. For more information, see the “TABLE= Data Set” section in the appropriate chart statement chapter.

BY Statement

BY variables ;

You can specify a BY statement with PROC MACONTROL to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

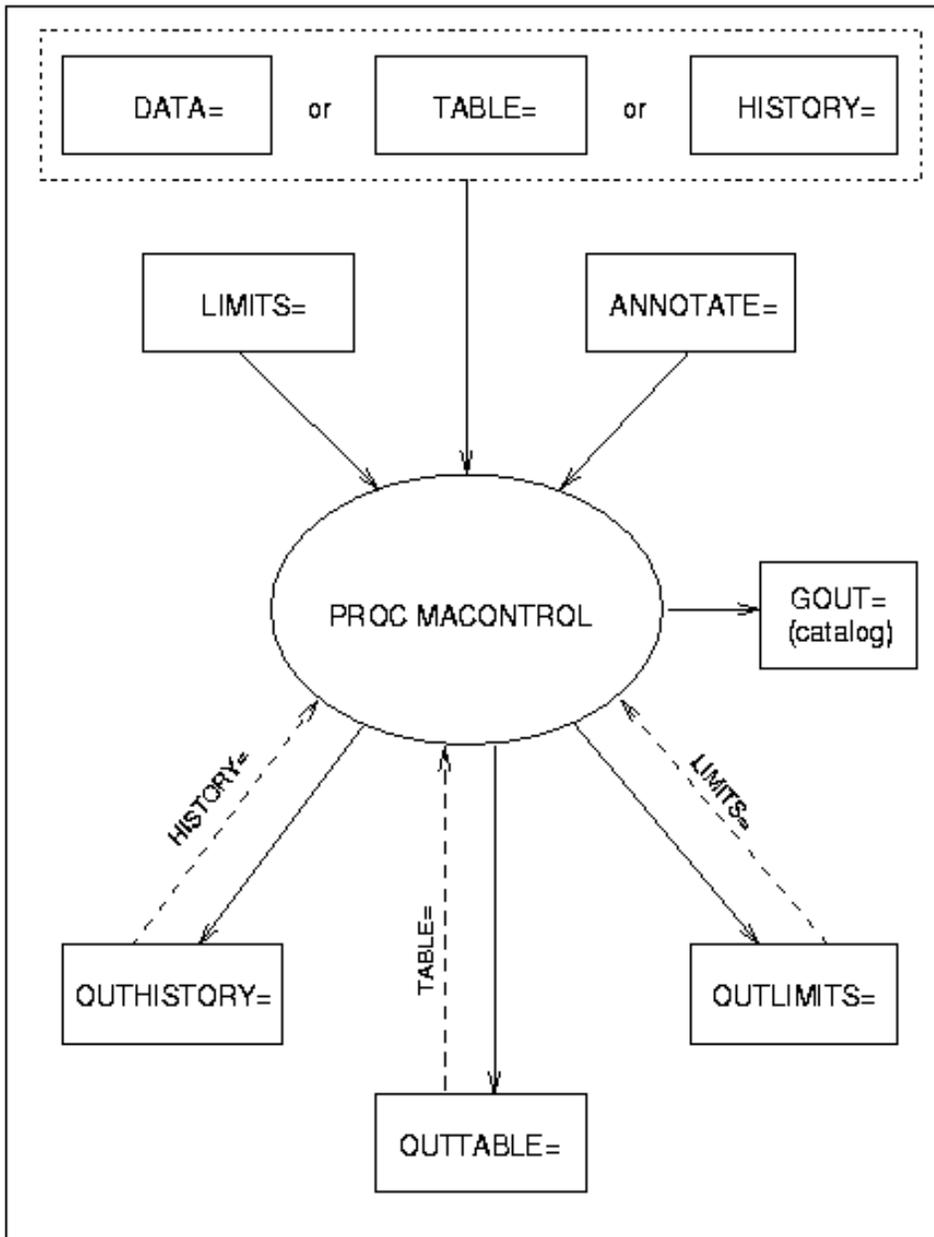

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MACONTROL procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

Input and Output Data Sets: MACONTROL Procedure

Figure 9.1 summarizes the data sets used with the MACONTROL procedure.

Figure 9.1 Input and Output Data Sets in the MACONTROL Procedure

EWMACHART Statement: MACONTROL Procedure

Overview: EWMACHART Statement

The EWMACHART statement creates an exponentially weighted moving average (EWMA) control chart, which is used to determine whether a process is in a state of statistical control and to detect shifts in the process average.

You can use options in the EWMACHART statement to

- specify the weight assigned to the most recent subgroup mean in the computation of the EWMA
- compute control limits from the data based on a multiple of the standard error of the plotted EWMA or as probability limits
- tabulate the EWMA, subgroup sample sizes, subgroup means, subgroup standard deviations, control limits, and other information
- save control limit parameters in an output data set
- save the EWMA, subgroup sample sizes, subgroup means, and subgroup standard deviations in an output data set
- read control limit parameters from an input data set
- specify one of several methods for estimating the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits
- display a secondary chart that plots a time trend removed from the data
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing EWMA charts with the EWMACHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.

- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: EWMACHART Statement

This section introduces the EWMACHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the EWMACHART statement is presented in the section “Syntax: EWMACHART Statement” on page 828, and advanced examples are given in the section “Examples: EWMACHART Statement” on page 855.

Creating EWMA Charts from Raw Data

In the manufacture of a metal clip, the gap between the ends of the clip is a critical dimension. To monitor the process for a change in the average gap, subgroup samples of five clips are selected daily. The data are analyzed with an EWMA chart. The gaps recorded during the first twenty days are saved in a SAS data set named Clips1. *See MACEW1 in the SAS/QC Sample Library*

```
data Clips1;
  input Day @ ;
  do i=1 to 5;
    input Gap @ ;
    output;
  end;
  drop i;
  datalines;
1 14.76 14.82 14.88 14.83 15.23
2 14.95 14.91 15.09 14.99 15.13
3 14.50 15.05 15.09 14.72 14.97
4 14.91 14.87 15.46 15.01 14.99
5 14.73 15.36 14.87 14.91 15.25
6 15.09 15.19 15.07 15.30 14.98
7 15.34 15.39 14.82 15.32 15.23
8 14.80 14.94 15.15 14.69 14.93
9 14.67 15.08 14.88 15.14 14.78
10 15.27 14.61 15.00 14.84 14.94
11 15.34 14.84 15.32 14.81 15.17
12 14.84 15.00 15.13 14.68 14.91
13 15.40 15.03 15.05 15.03 15.18
14 14.50 14.77 15.22 14.70 14.80
15 14.81 15.01 14.65 15.13 15.12
16 14.82 15.01 14.82 14.83 15.00
17 14.89 14.90 14.60 14.40 14.88
18 14.90 15.29 15.14 15.20 14.70
19 14.77 14.60 14.45 14.78 14.91
20 14.80 14.58 14.69 15.02 14.85
;
```

A partial listing of Clips1 is shown in Figure 9.2.

Figure 9.2 Partial Listing of the Data Set Clips1

The Data Set Clips1	
Day	Gap
1	14.76
1	14.82
1	14.88
1	14.83
1	15.23
2	14.95
2	14.91
2	15.09
2	14.99
2	15.13
3	14.50
3	15.05
3	15.09
3	14.72
3	14.97

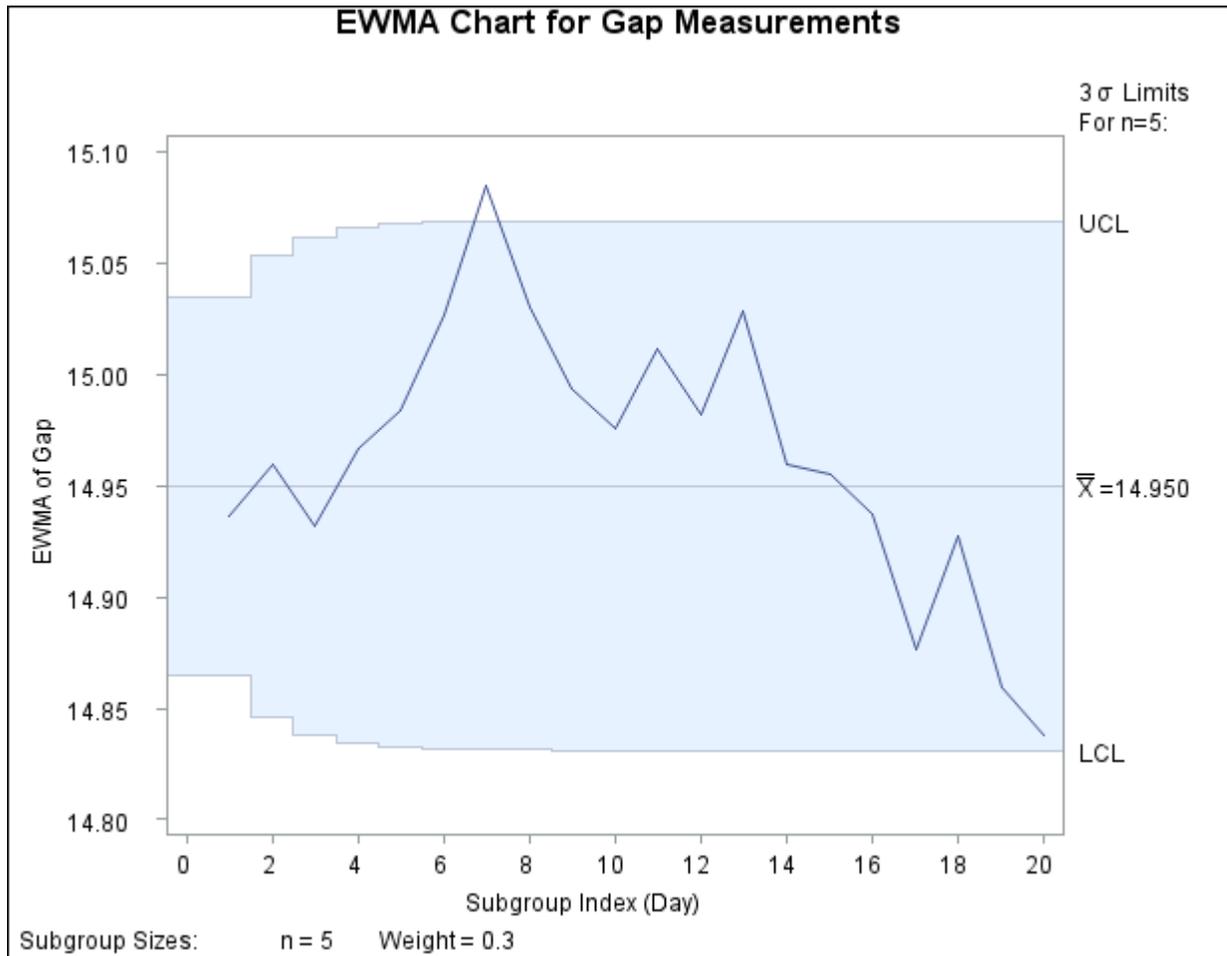

The data set Clips1 is said to be in “strung-out” form, since each observation contains the day and gap measurement of a single clip. The first five observations contain the gap measurements for the first day, the second five observations contain the gap measurements for the second day, and so on. Because the variable Day classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable Gap contains the gap measurements and is referred to as the *process variable* (or *process* for short).

The within-subgroup variability of the gap measurements is known to be stable. You can use an EWMA chart to determine whether the mean level is in control. The following statements create the EWMA chart shown in Figure 9.3:

```
ods graphics off;
symbol h = 0.8;
title 'EWMA Chart for Gap Measurements';
proc macontrol data=Clips1;
    ewmachart Gap*Day /weight=0.3;
run;
```

This example illustrates the basic form of the EWMACHART statement. After the keyword EWMACHART, you specify the *process* to analyze (in this case, Gap) followed by an asterisk and the *subgroup-variable* (Day). The WEIGHT= option specifies the weight parameter used to compute the EWMA. Options such as WEIGHT= are specified after the slash (/) in the EWMACHART statement. A complete list of options is presented in the section “[Syntax: EWMACHART Statement](#)” on page 828. You must provide the weight parameter to create an EWMA chart. As an alternative to specifying the WEIGHT= option, you can read the weight parameter from an input data set; see “[Reading Preestablished Control Limit Parameters](#)” on page 826.

The input data set is specified with the DATA= option in the PROC MACONTROL statement.

Figure 9.3 Exponentially Weighted Moving Average Chart

Each point on the chart represents the EWMA for a particular day. The EWMA E_1 plotted at Day=1 is the weighted average of the overall mean and the subgroup mean for Day=1. The EWMA E_2 plotted at Day=2 is the weighted average of the EWMA E_1 and the subgroup mean for Day=2.

$$E_1 = 0.3(14.904) + 0.7(14.952) = 14.9376\text{mm}$$

$$E_2 = 0.3(15.014) + 0.7(14.9376) = 14.9605\text{mm}$$

For succeeding days, the EWMA is the weighted average of the previous EWMA and the present subgroup mean. In the example, a weight parameter of 0.3 is used (since WEIGHT=0.3 is specified in the EWMACHART statement).

Note that the EWMA for the 7th day lies above the upper control limit, signaling an out-of-control process.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in [Table 9.3](#).

For computational details, see “[Constructing EWMA Charts](#)” on page 841. For more details on reading from a DATA= data set, see “[DATA= Data Set](#)” on page 849.

Creating EWMA Charts from Subgroup Summary Data

See MACEWI in the SAS/QC Sample Library

The previous example illustrates how you can create EWMA charts using raw data (process measurements). However, in many applications the data are provided as subgroup summary statistics. This example illustrates how you can use the EWMACHART statement with data of this type.

The following data set (Clisum) provides the data from the preceding example in summarized form:

```
data Clisum;
  input Day GapX GapS;
  GapN=5;
  datalines;
1  14.904  0.18716
2  15.014  0.09317
3  14.866  0.25006
4  15.048  0.23732
5  15.024  0.26792
6  15.126  0.12260
7  15.220  0.23098
8  14.902  0.17254
9  14.910  0.19824
10 14.932  0.24035
11 15.096  0.25618
12 14.912  0.16903
13 15.138  0.15928
14 14.798  0.26329
15 14.944  0.20876
16 14.896  0.09965
17 14.734  0.22512
18 15.046  0.24141
19 14.702  0.17880
20 14.788  0.16634
;
```

A partial listing of Clisum is shown in [Figure 9.4](#). There is exactly one observation for each subgroup (note that the subgroups are still indexed by Day). The variable GapX contains the subgroup means, the variable GapS contains the subgroup standard deviations, and the variable GapN contains the subgroup sample sizes (these are all five).

Figure 9.4 The Summary Data Set Clipsum

The Data Set Clipsum				
Day	GapX	GapS	GapN	
1	14.904	0.18716	5	
2	15.014	0.09317	5	
3	14.866	0.25006	5	
4	15.048	0.23732	5	
5	15.024	0.26792	5	

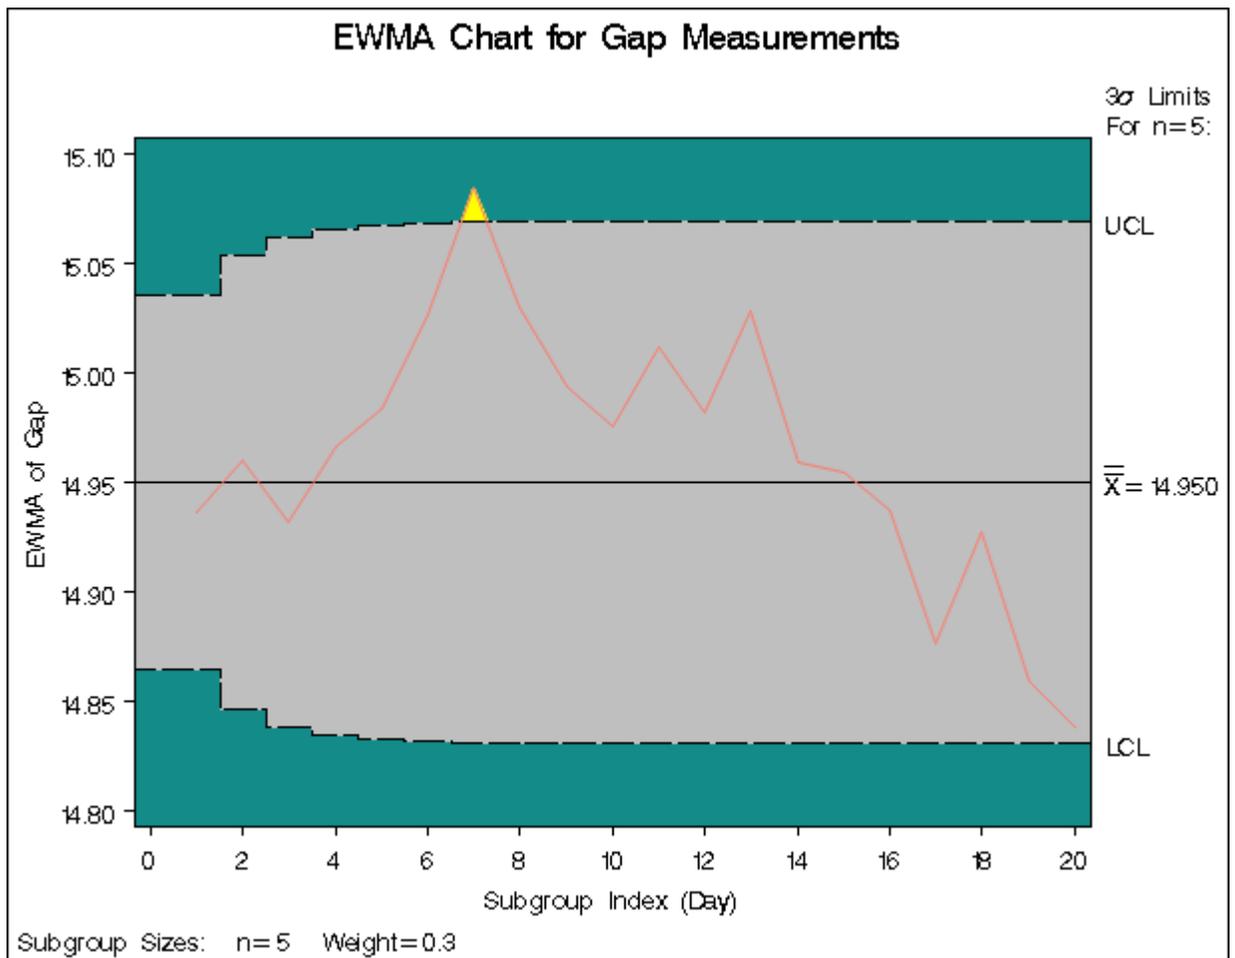

You can read this data set by specifying it as a HISTORY= data set in the PROC MACONTROL statement, as follows:

```
options nogstyle;
goptions ftext=swiss;
symbol color=salmon h=0.8;
title 'EWMA Chart for Gap Measurements';
proc macontrol history=Clipsum;
  ewmachart Gap*Day / weight=0.3
              cframe = vibg
              cinfill = ligr
              coutfill = yellow
              cconnect = salmon;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the GOPTIONS and SYMBOL statements and EWMACHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting EWMA chart is shown in [Figure 9.5](#).

Note that Gap is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the three SAS variables GapX, GapS, and GapN. The suffix characters X, S, and N indicate *mean*, *standard deviation*, and *sample size*, respectively. Thus, you can specify three subgroup summary variables in a HISTORY= data set with a single name (Gap), which is referred to as the *process*. The variables GapX, GapS, and GapN are all required. The name Day specified after the asterisk is the name of the *subgroup-variable*.

Figure 9.5 EWMA Chart from Summary Data

In general, a HISTORY= input data set used with the EWMACHART statement must contain the following variables:

- subgroup variable
- subgroup mean variable
- subgroup standard deviation variable
- subgroup sample size variable

Furthermore, the names of subgroup mean, standard deviation, and sample size variables must begin with the *process* name specified in the EWMACHART statement and end with the special suffix characters *X*, *S*, and *N*, respectively. If the names do not follow this convention, you can use the RENAME option in the PROC MACONTROL statement to rename the variables for the duration of the MACONTROL procedure step (see “Creating Charts for Means and Ranges from Summary Data” on page 1907 for an example of the RENAME option).

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 851.

Saving Summary Statistics

In this example, the EWMACHART statement is used to create a summary data set that can be read later by the MACONTROL procedure (as in the preceding example). The following statements read measurements from the data set Clips1 and create a summary data set named Cliphist: *See MACEW1 in the SAS/QC Sample Library*

```

title 'Summary Data Set for Gap Measurements';
proc macontrol data=Clips1;
  ewmachart Gap*Day / weight      = 0.3
                    outhistory = Cliphist
                    nochart;
run;

```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 9.3.

Figure 9.6 contains a partial listing of Cliphist.

Figure 9.6 The Summary Data Set Cliphist

Summary Data Set for Gap Measurements				
Day	GapX	GapS	GapE	GapN
1	14.904	0.18716	14.9362	5
2	15.014	0.09317	14.9595	5
3	14.866	0.25006	14.9315	5
4	15.048	0.23732	14.9664	5
5	15.024	0.26792	14.9837	5

There are five variables in the data set Cliphist.

- Day contains the subgroup index.
- GapX contains the subgroup means.
- GapS contains the subgroup standard deviations.
- GapE contains the subgroup exponentially weighted moving averages.
- GapN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters *X*, *S*, *E*, and *N* to the *process* Gap specified in the EWMA CHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 847.

Saving Control Limit Parameters

See MACEWI in the SAS/QC Sample Library

You can save the control limit parameters for an EWMA chart in a SAS data set; this enables you to use these parameters with future data (see “Reading Preestablished Control Limit Parameters” on page 826) or modify the parameters with a DATA step program.

The following statements read measurements from the data set Clips1 (see “Creating EWMA Charts from Raw Data” on page 817) and save the control limit parameters in a data set named Cliplim:

```
title 'Control Limit Parameters';
proc macontrol data=Clips1;
  ewmachart Gap*Day / weight      = 0.3
                    outlimits = Cliplim
                    nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limit parameters, and the NOCHART option suppresses the display of the chart. The data set Cliplim is listed in Figure 9.7.

Figure 9.7 The Data Set Cliplim Containing Control Limit Information

Control Limit Parameters								
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	_MEAN_	_STDDEV_	_WEIGHT_
Gap	Day	ESTIMATE	5	.002699796	3	14.95	0.21108	0.3

Note that the data set Cliplim does not contain the actual control limits but rather the parameters required to compute the limits.

The data set contains one observation with the parameters for *process* Gap. The variable `_WEIGHT_` contains the weight parameter used to compute the EWMA's. The value of `_MEAN_` is an estimate of the process mean, and the value of `_STDDEV_` is an estimate of the process standard deviation σ . The value of `_LIMITN_` is the nominal sample size associated with the control limits, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping variable that indicates that the values of `_MEAN_` and `_STDDEV_` are estimates rather than standard values. For more information, see “OUTLIMITS= Data Set” on page 846.

You can create an output data set containing the control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```

title 'Summary Statistics and Control Limits';
proc macontrol data=Clips1;
  ewmachart Gap*Day / weight    = 0.3
                    outtable = Cliptab
                    nochart;
run;

```

The data set `Cliptab` is listed in Figure 9.8.

Figure 9.8 The `OUTTABLE=` Data Set `Cliptab`

Summary Statistics and Control Limits													
	S	L	W							S			
	I	I	E							T	E		
	G	M	I	S	S	S	L	E	M	U	D	X

Gap 2	3	5	0.3	5	15.014	0.09317	14.8463	14.9595	14.95	15.0537	0.21108		
Gap 3	3	5	0.3	5	14.866	0.25006	14.8383	14.9315	14.95	15.0617	0.21108		
Gap 4	3	5	0.3	5	15.048	0.23732	14.8345	14.9664	14.95	15.0655	0.21108		
Gap 5	3	5	0.3	5	15.024	0.26792	14.8327	14.9837	14.95	15.0673	0.21108		
Gap 6	3	5	0.3	5	15.126	0.12260	14.8319	15.0264	14.95	15.0681	0.21108		
Gap 7	3	5	0.3	5	15.220	0.23098	14.8314	15.0845	14.95	15.0686	0.21108	UPPER	
Gap 8	3	5	0.3	5	14.902	0.17254	14.8312	15.0297	14.95	15.0688	0.21108		
Gap 9	3	5	0.3	5	14.910	0.19824	14.8311	14.9938	14.95	15.0689	0.21108		
Gap 10	3	5	0.3	5	14.932	0.24035	14.8311	14.9753	14.95	15.0689	0.21108		
Gap 11	3	5	0.3	5	15.096	0.25618	14.8311	15.0115	14.95	15.0689	0.21108		
Gap 12	3	5	0.3	5	14.912	0.16903	14.8310	14.9816	14.95	15.0690	0.21108		
Gap 13	3	5	0.3	5	15.138	0.15928	14.8310	15.0285	14.95	15.0690	0.21108		
Gap 14	3	5	0.3	5	14.798	0.26329	14.8310	14.9594	14.95	15.0690	0.21108		
Gap 15	3	5	0.3	5	14.944	0.20876	14.8310	14.9548	14.95	15.0690	0.21108		
Gap 16	3	5	0.3	5	14.896	0.09965	14.8310	14.9371	14.95	15.0690	0.21108		
Gap 17	3	5	0.3	5	14.734	0.22512	14.8310	14.8762	14.95	15.0690	0.21108		
Gap 18	3	5	0.3	5	15.046	0.24141	14.8310	14.9271	14.95	15.0690	0.21108		
Gap 19	3	5	0.3	5	14.702	0.17880	14.8310	14.8596	14.95	15.0690	0.21108		
Gap 20	3	5	0.3	5	14.788	0.16634	14.8310	14.8381	14.95	15.0690	0.21108		

This data set contains one observation for each subgroup sample. The variable `_EWMA_` contains the EWMA. The variables `_SUBX_`, `_SUBS_`, and `_SUBN_` contain the subgroup means, subgroup standard deviations, and subgroup sample sizes, respectively. The variables `_LCLE_` and `_UCLE_` contain the lower and upper control limits, and the variable `_MEAN_` contains the central line. The variables `_VAR_` and `Day` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “`OUTTABLE=` Data Set” on page 848.

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Cliptab and display a EWMA chart (not shown here) identical to Figure 9.3:

```
title 'EWMA Chart for Gap Measurements';
proc macontrol table=Cliptab;
  ewmachart Gap*Day ;
run;
```

For more information, see “TABLE= Data Set” on page 852.

Reading Prestablished Control Limit Parameters

See MACEW1 in the SAS/QC Sample Library

In the previous example, the OUTLIMITS= data set saved the control limit parameters in the data set Cliplim. This example shows how to apply these parameters to new data provided in the following data set:

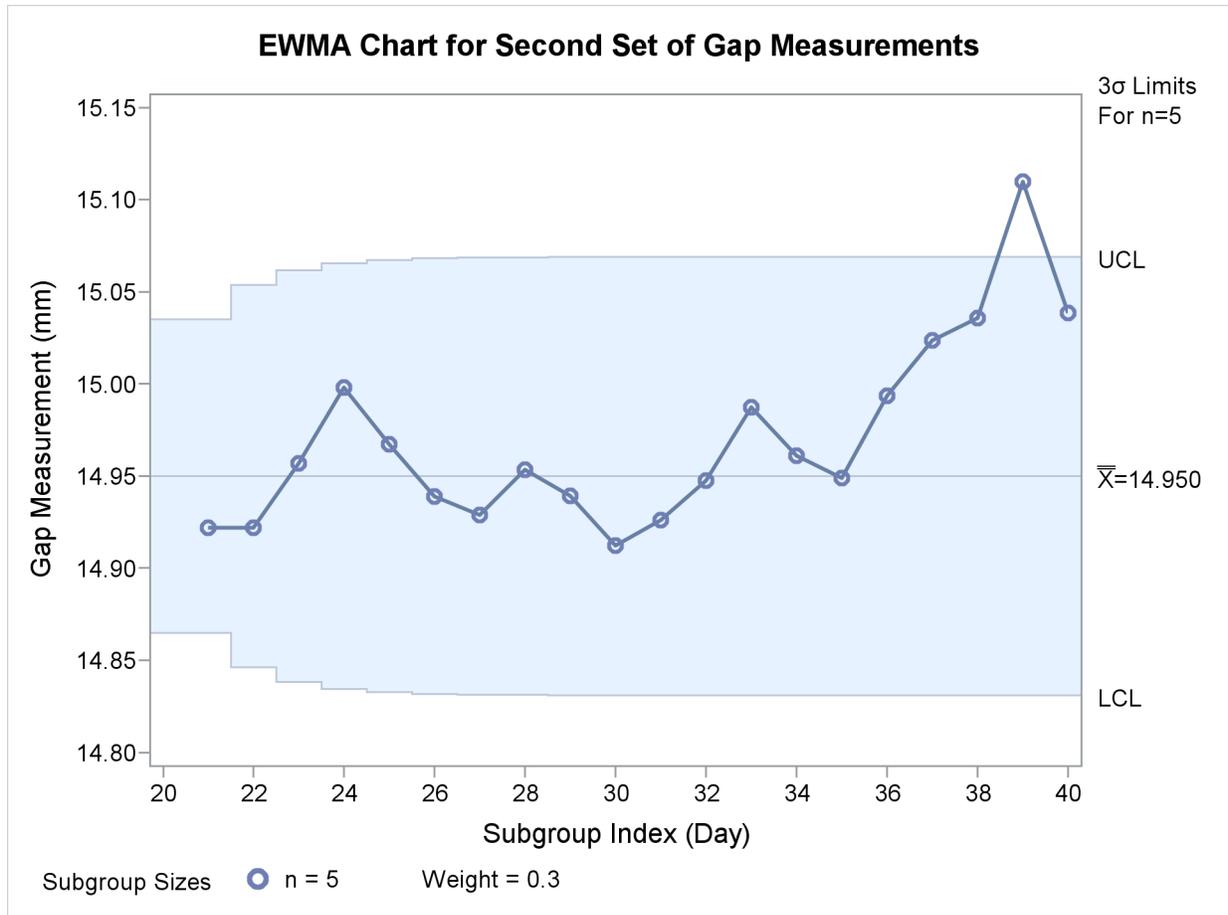

```
data Clips1a;
  label Gap='Gap Measurement (mm)';
  input Day @;
  do i=1 to 5;
    input Gap @;
    output;
  end;
  drop i;
  datalines;
21 14.86 15.01 14.67 14.67 15.07
22 14.93 14.53 15.07 15.10 14.98
23 15.27 14.90 15.12 15.10 14.80
24 15.02 15.21 14.93 15.11 15.20
25 14.90 14.81 15.26 14.57 14.94
26 14.78 15.29 15.13 14.62 14.54
27 14.78 15.15 14.61 14.92 15.07
28 14.92 15.31 14.82 14.74 15.26
29 15.11 15.04 14.61 15.09 14.68
30 15.00 15.04 14.36 15.20 14.65
31 14.99 14.76 15.18 15.04 14.82
32 14.90 14.78 15.19 15.06 15.06
33 14.95 15.10 14.86 15.27 15.22
34 15.03 14.71 14.75 14.99 15.02
35 15.38 14.94 14.68 14.77 14.83
36 14.95 15.43 14.87 14.90 15.34
37 15.18 14.94 15.32 14.74 15.29
38 14.91 15.15 15.06 14.78 15.42
39 15.34 15.34 15.41 15.36 14.96
40 15.12 14.75 15.05 14.70 14.74
;
```

The following statements create an EWMA chart for the data in Clips1a using the control limit parameters in Cliplim:

```
ods graphics on;
title 'EWMA Chart for Second Set of Gap Measurements';
proc macontrol data=Clips1a limits=Cliplim;
  ewmachart Gap*Day / odstitle=title markers;
run;
```

The ODS GRAPHICS ON statement specified before the PROC MACONTROL statement enables ODS Graphics, so the EWMA chart is created using ODS Graphics instead of traditional graphics. The chart is shown in Figure 9.9.

Figure 9.9 EWMA Chart Using Preestablished Control Limit Parameters

The LIMITS= option in the PROC MACONTROL statement specifies the data set containing the control limit parameters. By default,² this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Gap
- the value of `_SUBGRP_` matches the *subgroup-variable* name Day

Note that the EWMA plotted for the 39th day lies above the upper control limit, signalling an out-of-control process.

In this example, the LIMITS= data set was created in a previous run of the MACONTROL procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on

²In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

page 850 for details concerning the variables that you must provide, and see [Example 9.1](#) for an illustration.

Syntax: EWMACHART Statement

The basic syntax for the EWMACHART statement is as follows:

```
EWMACHART process * subgroup-variable / WEIGHT=value < options > ;
```

The general form of this syntax is as follows:

```
EWMACHART processes * subgroup-variable < (block-variables) >  
    < =symbol-variable | ='character' > / WEIGHT=value < options > ;
```

Note that the WEIGHT= option is required unless its *value* is read from a LIMITS= data set. You can use any number of EWMACHART statements in the MACONTROL procedure. The components of the EWMACHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC MACONTROL statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see [“Creating EWMA Charts from Raw Data”](#) on page 817.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see [“Creating EWMA Charts from Subgroup Summary Data”](#) on page 820.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see [“Saving Control Limit Parameters”](#) on page 824.

A *process* is required. If more than one *process* is specified, enclose the list in parentheses. For example, the following statements request distinct EWMA charts (each using a weight parameter of 0.3) for Weight, Length, and Width:

```
proc macontrol data=Measures;  
    ewmachart (Weight Length Width)*Day / weight=0.3;  
run;
```

subgroup-variable

is the variable that classifies the data into subgroups. The *subgroup-variable* is required. In the preceding EWMACHART statement, Day is the subgroup variable. For details, see [“Subgroup Variables”](#) on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or plotting character used to plot the EWMA.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create an EWMA chart using an asterisk (*) to plot the points:

```
proc macontrol data=Values lineprinter;
    ewmachart Length*Hour='*' / weight=0.3;
run;
```

options

specify chart parameters, enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)” on page 829, which follows, lists all options by function.

Summary of Options

The following tables list the EWMACHART statement options by function. Options unique to the MACONTROL procedure are listed in [Table 9.1](#), and are described in detail in the section “[Dictionary of Special Options](#)” on page 837. Options that are common to both the MACONTROL and SHEWHART procedures are listed in [Table 9.2](#). They are described in detail in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 9.1 EWMACHART Statement Special Options

Option	Description
Options for Specifying Exponentially Weighted Moving Average Charts	
ALPHA=	requests probability limits for control charts
ASYMPTOTIC	requests constant control limits based on asymptotic expressions
LIMITN=	specifies either a fixed nominal sample size (n) for control limits or allows the control limits to vary with subgroup sample size

Table 9.1 *continued*

Option	Description
MU0=	specifies a standard (known) value μ_0 for the process mean
NOREADLIMITS	specifies that control limit parameters are not to be read from a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from the LIMITS= data set when both variables are available
READINDEX=	reads control limit parameters from the first observation in the LIMITS= data set where the variable <code>_INDEX_</code> equals <i>value</i>
READLIMITS	reads control limit parameters from a LIMITS= data set (SAS 6.09 and earlier releases)
RESET	requests that the value of the EWMA be reset after each out-of-control point
SIGMA0=	specifies standard (known) value σ_0 for process standard deviation
SIGMAS=	specifies width of control limits in terms of multiple of standard error of plotted EWMA
WEIGHT=	specifies weight assigned to the most recent subgroup mean in the computation of the EWMA
Options for Plotting Subgroup Means	
CMEANSYMBOL=	specifies color for MEANSYMBOL= symbol
MEANCHAR=	specifies <i>character</i> to plot subgroup means on line printer charts
MEANSYMBOL=	specifies symbol to plot subgroup means in traditional graphics

Table 9.2 EWMA CHART Statement General Options

Option	Description
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits

Table 9.2 continued

Option	Description
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
XSymbOL=	specifies label for central line
Process Mean and Standard Deviation Options	
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on EWMA chart
ALLLABEL2=	labels every point on trend chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
NOTRENDCONNECT	suppresses line segments that connect points on trend chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area

Table 9.2 *continued*

Option	Description
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of EWMA chart
VAXIS2=	specifies major tick mark values for vertical axis of trend chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart

Table 9.2 continued

Option	Description
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
TRENDVAR=	specifies list of trend variables
YPCT1=	specifies length of vertical axis on EWMA chart as a percentage of sum of lengths of vertical axes for EWMA and trend charts
ZEROSTD	displays EWMA chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on EWMA chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on EWMA chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on EWMA chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on trend chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines

Table 9.2 continued

Option	Description
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to EWMA chart
ANNOTATE2=	specifies annotate data set that adds features to trend chart
DESCRIPTION=	specifies description of EWMA chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of EWMA chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
WTREND=	specifies width of line segments connecting points on trend chart
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits

Table 9.2 continued

Option	Description
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics

Table 9.2 continued

Option	Description
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the <code>OUTHISTORY=</code> data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for <code>STARCIRCLES=</code> circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for <code>STARCIRCLES=</code> circles

Table 9.2 continued

Option	Description
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on EWMA chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
VREFCHAR=	specifies line character for VREF= and VREF2= lines

Dictionary of Special Options

The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply only to traditional graphics and line printers charts, respectively.

ALPHA=value

requests *probability limits*. If you specify ALPHA= α , the control limits are computed so that the probability is α that a single EWMA exceeds its control limits. The value of α can range between 0 and 1. This assumes that the process is in statistical control and that the data follow a normal distribution. For the equations used to compute probability limits, see “Control Limits” on page 842.

Note the following:

- As an alternative to specifying ALPHA= α , you can read α from the variable `_ALPHA_` in a LIMITS= data set by specifying the READALPHA option.
- As an alternative to specifying ALPHA= α (or reading `_ALPHA_` from a LIMITS= data set), you can request “ $k\sigma$ control limits” by specifying SIGMAS= k (or reading `_SIGMAS_` from a LIMITS= data set).

If you specify neither the ALPHA= option nor the SIGMAS= option, the procedure computes 3σ control limits by default.

ASYMPTOTIC

requests constant upper and lower control limits based on the following asymptotic expressions:

$$\text{LCL} = \bar{\bar{X}} - k\hat{\sigma} \sqrt{r/n(2-r)}$$

$$\text{UCL} = \bar{\bar{X}} + k\hat{\sigma} \sqrt{r/n(2-r)}$$

Here r is the weight parameter ($0 < r \leq 1$), and n is the nominal sample size associated with the control limits. Substitute $\Phi^{-1}(1 - \alpha/2)$ for k if you specify probability limits with the ALPHA= option. When you do not specify the ASYMPTOTIC option, the control limits are computed using the exact formulas in Table 9.3. Use the ASYMPTOTIC option only if all the subgroup sample sizes are the same or if you specify LIMITN= n . See Example 9.2.

CMEANSYMBOL=*color*

Traditional Graphics

specifies the *color* for the symbol requested with the MEANSYMBOL= option.

LIMITN= n

LIMITN=VARYING

specifies either a fixed or varying nominal sample size for the control limits.

If you specify LIMITN= n , EWMA's are calculated and displayed only for those subgroups with a sample size equal to n , unless you also specify the ALLN option, which causes all the EWMA's to be calculated and displayed. By default (or if you specify LIMITN=VARYING), EWMA's are calculated and displayed for all subgroups, regardless of sample size.

MEANCHAR=*'character'*

Line Printer

specifies a *character* used to plot the subgroup mean for each subgroup. By default, subgroup means are not plotted.

MEANSYMBOL=*keyword*

Traditional Graphics

specifies a symbol used to plot the subgroup mean for each subgroup. By default, subgroup means are not plotted.

MU0=*value*

specifies a known (standard) value μ_0 for the process mean μ . By default, μ is estimated from the data. See Example 9.1.

NOTE: As an alternative to specifying MU0= μ_0 , you can read a predetermined value for μ_0 from the variable `_MEAN_` in a LIMITS= data set.

NOREADLIMITS

specifies that control limit parameters for each *process* listed in the EWMACHART statement are *not* to be read from the LIMITS= data set specified in the PROC MACONTROL statement. The NOREADLIMITS option is available only in SAS 6.10 and later releases.

The following example illustrates the NOREADLIMITS option:

```
proc macontrol data=Pistons limits=Diamlim;
  ewmachart Diameter*Hour;
  ewmachart Diameter*Hour / noreadlimits weight=0.3;
run;
```

The first EWMACHART statement reads the control limits from the first observation in the data set Diamlim for which the variable `_VAR_` is equal to 'Diameter' and the variable `_SUBGRP_` is equal to 'Hour'. The second EWMACHART statement computes estimates of the process mean and standard deviation for the control limits from the measurements in the data set Pistons. Note that the second EWMACHART statement is equivalent to the following statements, which would be more commonly used:

```
proc macontrol data=Pistons;
  ewmachart Diameter*Hour / weight=0.3;
run;
```

For more information about reading control limit parameters from a LIMITS= data set, see the READLIMITS option later in this list.

READALPHA

specifies that the variable `_ALPHA_`, rather than the variable `_SIGMAS_`, is to be read from a LIMITS= data set when both variables are available in the data set. Thus the limits displayed are probability limits. If you do not specify the READALPHA option, then `_SIGMAS_` is read by default.

READINDEX='value'

reads control limit parameters from a LIMITS= data set (specified in the PROC MACONTROL statement) for each *process* listed in the EWMACHART statement.

The control limit parameters for a particular *process* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup-variable*
- the value of `_INDEX_` matches *value*

The *value* can be up to 48 characters and must be enclosed in quotes.

READLIMITS

specifies that control limit parameters are to be read from a LIMITS= data set specified in the PROC MACONTROL statement. The parameters for a particular *process* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup variable*

The use of the READLIMITS option depends on which release of SAS/QC software you are using.

- **In SAS 6.10 and later releases, the READLIMITS option is not necessary.** To read control limits parameters as described previously, you simply specify a LIMITS= data set. However, even though the READLIMITS option is redundant, it continues to function as in earlier releases.
- **In SAS 6.09 and earlier releases, you must specify the READLIMITS option to read control limits parameters as described previously.** If you specify a LIMITS= data set without specifying the READLIMITS option (or the READINDEX= option), the control limits are computed from the data and the value of the weight parameter is specified with the WEIGHT= option.

RESET

requests that the value of the EWMA be reset after each out-of-control point. Specifically, when a point exceeds the control limits, the EWMA for the next subgroup is computed as the weighted average of the subgroup mean and the overall mean. By default, the EWMA's are not reset.

SIGMA0=*value*

specifies a known (standard) value σ_0 for the process standard deviation σ . The *value* must be positive. By default, the MACONTROL procedure estimates σ from the data using the formulas given in “[Methods for Estimating the Standard Deviation](#)” on page 853.

NOTE: As an alternative to specifying $\text{SIGMA0}=\sigma_0$, you can read a predetermined value for σ_0 from the variable `_STDDEV_` in a LIMITS= data set.

SIGMAS=*value*

specifies the width of the control limits in terms of the multiple k of the standard error of the plotted EWMA's on the chart. The value of k must be positive. By default, $k = 3$ and the control limits are 3σ limits.

WEIGHT=*value*

specifies the weight r assigned to the most recent subgroup mean in the computation of the EWMA ($0 < r \leq 1$). The WEIGHT= option is required unless you read control limit parameters from a LIMITS= data set or a TABLE= data set. See the section “[Choosing the Value of the Weight Parameter](#)” on page 843 for details.

Details: EWMACHART Statement

Constructing EWMA Charts

The following notation is used in this section:

E_i	exponentially weighted moving average for the i th subgroup
r	EWMA weight parameter ($0 < r \leq 1$)
μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
x_{ij}	j th measurement in i th subgroup, with $j = 1, 2, 3, \dots, n_i$
n_i	sample size of i th subgroup
\bar{X}_i	mean of measurements in i th subgroup. If $n_i = 1$, then the subgroup mean reduces to the single observation in the subgroup
$\bar{\bar{X}}$	weighted average of subgroup means
$\Phi^{-1}(\cdot)$	inverse standard normal function

Plotted Points

Each point on the chart indicates the value of the exponentially weighted moving average (EWMA) for that subgroup. The EWMA for the i th subgroup (E_i) is defined recursively as

$$E_i = r\bar{X}_i + (1 - r)E_{i-1}, \quad i > 0$$

where r is a weight parameter ($0 < r \leq 1$). Some authors (for example, Hunter 1986 and Crowder 1987a,b) use the symbol λ instead of r for the weight. You can specify the weight with the WEIGHT= option in the EWMACHART statement or with the variable _WEIGHT_ in a LIMITS= data set. If you specify a known value (μ_0) for μ , $E_0 = \mu_0$; otherwise, $E_0 = \bar{\bar{X}}$.

The preceding equation can be rewritten as

$$E_i = E_{i-1} + r(\bar{X}_i - E_{i-1})$$

which expresses the current EWMA as the previous EWMA plus the weighted error in the prediction of the current mean based on the previous EWMA.

The EWMA for the i th subgroup can also be written as

$$E_i = r \sum_{j=0}^{i-1} (1 - r)^j \bar{X}_{i-j} + (1 - r)^i E_0$$

which expresses the EWMA as a weighted average of past subgroup means, where the weights decline exponentially, and the heaviest weight is assigned to the most recent subgroup mean.

Central Line

By default, the central line on an EWMA chart indicates an estimate for μ , which is computed as

$$\hat{\mu} = \bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \dots + n_N \bar{X}_N}{n_1 + \dots + n_N}$$

If you specify a known value (μ_0) for μ , the central line indicates the value of μ_0 .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of E_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that E_i exceeds the limits

The following table presents the formulas for the limits:

Table 9.3 Limits for an EWMA Chart

Control Limits
LCL = lower limit = $\bar{\bar{X}} - k\hat{\sigma}r\sqrt{\sum_{j=0}^{i-1}(1-r)^{2j}/n_{i-j}}$
UCL = upper limit = $\bar{\bar{X}} + k\hat{\sigma}r\sqrt{\sum_{j=0}^{i-1}(1-r)^{2j}/n_{i-j}}$
Probability Limits
LCL = lower limit = $\bar{\bar{X}} - \Phi^{-1}(1 - \alpha/2)\hat{\sigma}r\sqrt{\sum_{j=0}^{i-1}(1-r)^{2j}/n_{i-j}}$
UCL = upper limit = $\bar{\bar{X}} + \Phi^{-1}(1 - \alpha/2)\hat{\sigma}r\sqrt{\sum_{j=0}^{i-1}(1-r)^{2j}/n_{i-j}}$

These formulas assume that the data are normally distributed. If standard values μ_0 and σ_0 are available for μ and σ , respectively, replace $\bar{\bar{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 9.3. Note that the limits vary with both n_i and i .

If the subgroup sample sizes are constant ($n_i = n$), the formulas for the control limits simplify to

$$\text{LCL} = \bar{\bar{X}} - k\hat{\sigma}\sqrt{r(1 - (1-r)^{2i})/n(2-r)}$$

$$\text{UCL} = \bar{\bar{X}} + k\hat{\sigma}\sqrt{r(1 - (1-r)^{2i})/n(2-r)}$$

Consequently, when the subgroup sample sizes are constant, the width of the control limits increases monotonically with i . For probability limits, replace k with $\Phi^{-1}(1 - \alpha/2)$ in the previous equations. Refer to Roberts (1959) and Montgomery (1996).

As i becomes large, the upper and lower control limits approach constant values:

$$\text{LCL} = \bar{\bar{X}} - k\hat{\sigma}\sqrt{r/n(2-r)}$$

$$\text{UCL} = \bar{\bar{X}} + k\hat{\sigma}\sqrt{r/n(2-r)}$$

Some authors base the control limits for EWMA charts on the asymptotic expressions in the two previous equations. For asymptotic probability limits, replace k with $\Phi^{-1}(1 - \alpha/2)$ in these equations. You can display asymptotic limits by specifying the ASYMPTOTIC option.

Uniformly weighted moving average charts and exponentially weighted moving average charts have similar properties, and their asymptotic control limits are identical provided that

$$r = 2/(w + 1)$$

where w is the weight factor for uniformly weighted moving average charts. Refer to Wadsworth, Stephens, and Godfrey (1986) and the American Society for Quality Control (1983).

You can specify parameters for the EWMA limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify r with the WEIGHT= option or with the variable `_WEIGHT_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

Choosing the Value of the Weight Parameter

Various approaches have been proposed for choosing the value of r .

- Hunter (1986) states that the choice “can be left to the judgment of the quality control analyst” and points out that the smaller the value of r , “the greater the influence of the historical data.”
- Hunter (1986) also discusses a least squares procedure for estimating r from the data, **assuming an exponentially weighted moving average model for the data**. In this context, the fitted EWMA model provides a forecast of the process that is the basis for dynamic process control. You can use the ARIMA procedure in SAS/ETS[®] software to compute the least squares estimate of r . (Refer to *SAS/ETS User’s Guide* for information about PROC ARIMA.) Also see “Autocorrelation in Process Data” on page 2171.
- A number of authors have studied the design of EWMA control schemes based on average run length (ARL) computations. The ARL is the expected number of points plotted before a shift is detected. Ideally, the ARL should be short when a shift occurs, and it should be long when there is no shift (the process is in control.) The effect of r on the ARL was described by Roberts (1959), who used simulation methods. The ARL function was approximated and tabulated by Robinson and Ho (1978), and a more general method for studying run-length distributions of EWMA charts was given by Crowder (1987a, b). Unlike Hunter (1986), these authors assume the data are independent and identically distributed; typically the normal distribution is assumed for the data, although the methods extend to nonnormal distributions. A more detailed discussion of the ARL approach follows.

Average run lengths for two-sided EWMA charts are shown in Table 9.4, which is patterned after Table 1 of Crowder (1987a, b). The ARLs were computed using the EWMAARL DATA step function (see “EWMAARL Function” on page 2270 for details on the EWMAARL function). Note that Crowder (1987a, b). uses the notation L in place of k and the notation λ in place of r .

You can use Table 9.4 to find a combination of k and r that yields a desired ARL for an in-control process ($\delta = 0$) and for a specified shift of δ . Note that δ is assumed to be standardized; in other words, if a shift of Δ is to be detected in the process mean μ , and if σ is the process standard deviation, you should select the table entry with

$$\delta = \Delta / (\sigma / \sqrt{n})$$

where n is the subgroup sample size. Thus, δ can be regarded as the shift in the sampling distribution of the subgroup mean.

For example, suppose you want to construct an EWMA scheme with an in-control ARL of 90 and an ARL of 9 for detecting a shift of $\delta = 1$. Table 9.4 shows that the combination $r = 0.5$ and $k = 2.5$ yields an in-control ARL of 91.17 and an ARL of 8.27 for $\delta = 1$.

Crowder (1987a, b) cautions that setting the in-control ARL at a desired level does not guarantee that the probability of an early false signal is acceptable. For further details concerning the distribution of the ARL, refer to Crowder (1987a, b).

In addition to using Table 9.4 or the EWMAARL DATA step function to choose a EWMA scheme with desired average run length properties, you can use them to evaluate an existing EWMA scheme. For example, the “Getting Started” section of this chapter contains EWMA schemes with $r = 0.3$ and $k = 3$. The following statements use the EWMAARL function to compute the in-control ARL and the ARLs for shifts of $\delta = 0.25$ and $\delta = 0.5$:

```
data arlewma;
  arlin = ewmaarl( 0, 0.3, 3.0);
  arl1  = ewmaarl(.25, 0.3, 3.0);
  arl2  = ewmaarl(.50, 0.3, 3.0);
run;
```

The in-control ARL is 465.553, the ARL for $\delta = .25$ is 178.741, and the ARL for $\delta = .5$ is 53.1603. See Example 9.5 for an illustration of how to use the EWMAARL function to compute average run lengths for various EWMA schemes and shifts.

Table 9.4 Average Run Lengths for Two-Sided EWMA Charts

		r (weight parameter)

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves the control limit parameters. The following variables can be saved:

Variable	Description
ALPHA	probability (α) of exceeding limits
INDEX	optional identifier for the control limits specified with the OUTINDEX= option
LIMITN	sample size associated with the control limits
MEAN	process mean (\bar{X} or μ_0)
SIGMAS	multiple (k) of standard error of E_i
STDDEV	process standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	subgroup-variable specified in the EWMACHART statement
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
VAR	process specified in the EWMACHART statement
WEIGHT	weight (r) assigned to most recent subgroup mean in computation of EWMA

The OUTLIMITS= data set does not contain the control limits; instead, it contains control limit parameters that can be used to recompute the control limits.

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variable _LIMITN_.
2. If the limits are defined in terms of a multiple k of the standard error of E_i , the value of _ALPHA_ is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.

3. If the limits are probability limits, the value of `_SIGMAS_` is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.
4. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the EWMACHART statement.

You can use OUTLIMITS= data sets

- to keep a permanent record of the control limit parameters
- to write reports. You may prefer to use OUTTABLE= data sets for this purpose.
- as LIMITS= data sets in subsequent runs of PROC MACONTROL

For an example of an OUTLIMITS= data set, see the section “Saving Control Limit Parameters” on page 824.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables can be saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup standard deviation variable named by *process* suffixed with *S*
- a subgroup EWMA variable named by *process* suffixed with *E*
- a subgroup sample size variable named by *process* suffixed with *N*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the EWMACHART statement. For example, consider the following statements:

```
proc macontrol data=Clips;
  ewmachart (Gap YieldStrength)*Day /
    weight    = 0.2
    outhistory = Cliphist;
run;
```

The data set Cliphist would contain nine variables named Day, GapX, GapS, GapE, GapN, YieldStrengthX, YieldStrengthS, YieldStrengthE, and YieldStrengthN.

Additionally, the following variables, if specified, are included:

- BY variables

- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `OUTPHASE=` option is specified)

For an example of an `OUTHISTORY=` data set, see the section “Saving Summary Statistics” on page 823.

OUTTABLE= Data Set

The `OUTTABLE=` data set saves subgroup summary statistics, control limits, and related information. The following variables can be saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on EWMA chart
<code>_EWMA_</code>	exponentially weighted moving average
<code>_LCLE_</code>	lower control limit for EWMA
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<i>subgroup</i>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_SUBX_</code>	subgroup mean
<code>_UCLE_</code>	upper control limit for EWMA
<code>_VAR_</code>	<i>process</i> specified in the <code>EWMACHART</code> statement
<code>_WEIGHT_</code>	weight (r) assigned to most recent subgroup mean in computation of EWMA

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)
- *symbol-variable*

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the `ALPHA=` or `SIGMAS=` options, respectively, or with the corresponding variables in a `LIMITS=` data set).
2. The variables `_VAR_` and `_EXLIM_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. All other variables are numeric.

For an example of an `OUTTABLE=` data set, see “Saving Control Limit Parameters” on page 824.

ODS Tables

The following table summarizes the ODS tables that you can request with the EWMACHART statement.

Table 9.5 ODS Tables Produced with the EWMACHART Statement

Table Name	Description	Options
EWMACHART	exponentially weighted moving average chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT
Parameters	exponentially weighted moving average parameters	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the MACONTROL procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. EWMACHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the EWMACHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in Table 9.6.

Table 9.6 ODS Graphics Produced by the EWMACHART Statement

ODS Graph Name	Plot Description
EWMACHart	EWMA chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC MACONTROL statement. Each *process* specified in the EWMACHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into

subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the EWMA`CHART` statement, must also be a SAS variable in the `DATA=` data set. Each observation in a `DATA=` data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the `DATA=` data set should contain 150 observations.

Other variables that can be read from a `DATA=` data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the MACONTROL procedure reads all the observations in a `DATA=` data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the `READPHASES=` option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a `DATA=` data set, see “[Creating EWMA Charts from Raw Data](#)” on page 817.

LIMITS= Data Set

You can read preestablished control limit parameters from a `LIMITS=` data set specified in the PROC MACONTROL statement. The `LIMITS=` data set used by the MACONTROL procedure does not contain the actual control limits, but rather it contains the parameters required to compute the limits. For example, the following statements read parameters from the data set `Parms`:³

```
proc macontrol data=Parts limits=Parms;
    ewmachart Gap*Day;
run;
```

The `LIMITS=` data set can be an `OUTLIMITS=` data set that was created in a previous run of the MACONTROL procedure. Such data sets always contain the variables required for a `LIMITS=` data set; see the section “[OUTLIMITS= Data Set](#)” on page 846. The `LIMITS=` data set can also be created directly using a `DATA` step.

When you create a `LIMITS=` data set, you must provide the variable `_WEIGHT_`, which specifies the weight parameter used to compute the EWMA. In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables of length 8.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option. This must be a character variable whose length is no greater than 48.

³In SAS 6.09 and earlier releases, it is necessary to specify the `READLIMITS` option.

- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8. Valid values are ‘ESTIMATE’, ‘STANDARD’, ‘STDMEAN’, and ‘STDSIGMA’.
- BY variables are required if specified with a BY statement.

Some advantages of working with a LIMITS= data set are that

- it facilitates reusing a permanently saved set of parameters
- a distinct set of parameters can be read for each *process* specified in the EWMACHART statement
- it facilitates keeping track of multiple sets of parameters that accumulate for the same *process* as the process evolves over time

For an example, see the section “[Reading Preestablished Control Limit Parameters](#)” on page 826.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC MA-CONTROL statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the MACONTROL, SHEWHART, or CUSUM procedures or to read output data sets created with SAS summarization procedures such as PROC MEANS.

A HISTORY= data set used with the EWMACHART statement must contain the following:

- the *subgroup-variable*
- a subgroup mean variable for each *process*
- a subgroup sample size variable for each *process*
- a subgroup standard deviation variable for each *process*

The names of the subgroup mean, subgroup standard deviation, and subgroup sample size variables must be the *process* name concatenated with the suffix characters *X*, *S*, and *N*, respectively.

For example, consider the following statements:

```
proc macontrol history=Cliphist;
    ewmachart (Gap Diameter)*Day / weight=0.2;
run;
```

The data set Cliphist must include the variables Day, GapX, GapS, GapN, DiameterX, DiameterS, and DiameterN.

Although a subgroup EWMA variable (named by the *process* name suffixed with *E*) is saved in an OUTHISTORY= data set, it is not required in a HISTORY= data set, because the subgroup mean variable is sufficient to compute the EWMA.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the MACONTROL procedure reads all the observations in a HISTORY= data set. However, if the HISTORY= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating EWMA Charts from Subgroup Summary Data](#)” on page 820.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC MACONTROL statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the MACONTROL procedure.

The following table lists the variables required in a TABLE= data set used with the EWMACHART statement:

Variable	Description
<code>_EWMA_</code>	exponentially weighted moving average
<code>_LCLE_</code>	lower control limit for EWMA
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_SUBX_</code>	subgroup mean
<code>_UCLE_</code>	upper control limit for EWMA
<code>_WEIGHT_</code>	weight (<i>r</i>) assigned to most recent subgroup mean in computation of EWMA

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*

- BY variables
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified). This variable must be a character variable whose length is no greater than 48.
- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable of length 8.

For an example of a `TABLE=` data set, see “Saving Control Limit Parameters” on page 824.

Methods for Estimating the Standard Deviation

When control limits are computed from the input data, four methods are available for estimating the process standard deviation σ . Three methods (referred to as the default, MVLUE, and RMSDF) are available with subgrouped data. A fourth method is used if the data are individual measurements (see “Default Method for Individual Measurements” on page 854).

Default Method for Subgroup Samples

This method is the default for EWMA charts using subgrouped data. The default estimate of σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \dots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the i th subgroup

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2) \sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, then the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method for Subgroup Samples

If you specify `SMETHOD=MVLUE`, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1/c_4(n_1) + \dots + h_N s_N/c_4(n_N)}{h_1 + \dots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

RMSDF Method for Subgroup Samples

If you specify SMETHOD=RMSDF, a weighted root-mean-square estimate is computed for σ as follows:

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \cdots + (n_N - 1)s_N^2}}{c_4(n)\sqrt{n_1 + \cdots + n_N - N}}$$

The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, in process control applications it is generally not assumed that σ is constant, and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Default Method for Individual Measurements

When each subgroup sample contains a single observation ($n_i \equiv 1$), the process standard deviation σ is estimated as

$$\hat{\sigma} = \sqrt{\frac{1}{2(N-1)} \sum_{i=1}^{N-1} (x_{i+1} - x_i)^2}$$

where N is the number of observations, and x_1, x_2, \dots, x_N are the individual measurements. This formula is given by Wetherill (1977), who states that the estimate of the variance is biased if the measurements are autocorrelated.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup mean variable
Vertical	TABLE=	<u>EWMA</u>

For example, the following sets of statements specify the label *EWMA of Clip Gaps* for the vertical axis and the label *Day* for the horizontal axis of the EWMA chart:

```

proc macontrol data=Clips1;
  ewmachart Gap*Day / weight=0.3;
  label Gap = 'EWMA of Clip Gaps';
  label Day = 'Day';
run;

proc macontrol history=Cliphist;
  ewmachart Gap*Day / weight=0.3;
  label Gapx = 'EWMA of Clip Gaps';
  label Day = 'Day';
run;

proc macontrol table=Cliptab;
  ewmachart Gap*Day;
  label _EWMA_ = 'EWMA of Clip Gaps';
  label Day = 'Day';
run;

```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: EWMACHART Statement

This section provides advanced examples of the EWMACHART statement.

Example 9.1: Specifying Standard Values for the Process Mean and Process Standard Deviation

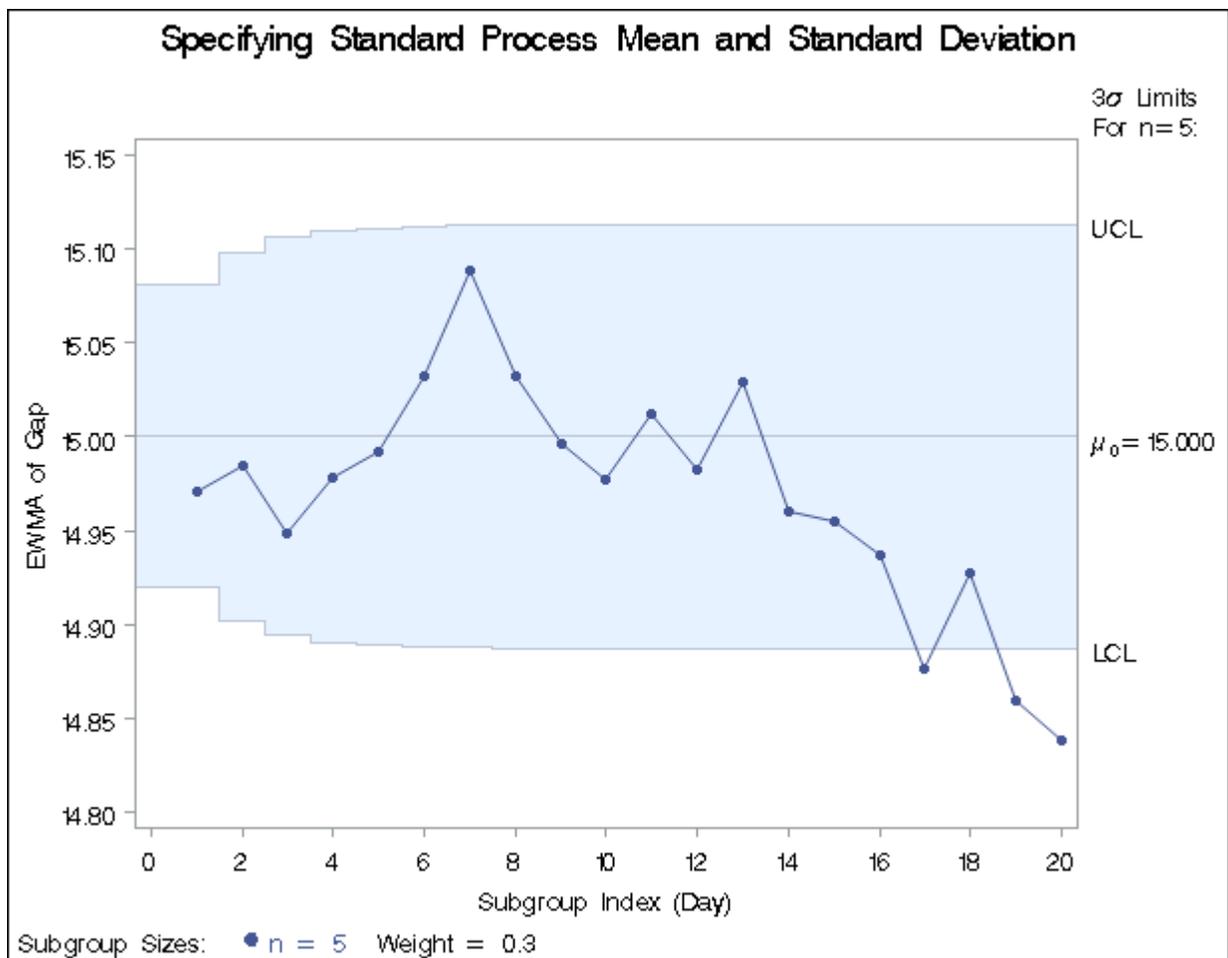

By default, the EWMACHART statement estimates the process mean (μ) and standard deviation (σ) from the data. This is illustrated in the “Getting Started” section of this chapter. However, there are applications in which standard values (μ_0 and σ_0) are available based, for instance, on previous experience or extensive sampling. You can specify these values with the MU0= and SIGMA0= options. *See MACEW2 in the SAS/QC Sample Library*

For example, suppose it is known that the metal clip manufacturing process (introduced in “Creating EWMA Charts from Raw Data” on page 817) has a mean of 15 and standard deviation of 0.2. The following statements specify these standard values:

```
ods graphics off;
title 'Specifying Standard Process Mean and Standard Deviation';
symbol v=dot h=0.8;
proc macontrol data=Clips1;
  ewmachart Gap*Day /
    mu0      = 15
    sigma0   = 0.2
    weight   = 0.3
    xsymbol  = mu0;
run;
```

The XSYMBOL= option specifies the label for the central line. The resulting chart is shown in Output 9.1.1.

Output 9.1.1 Specifying Standard Values with MU0= and SIGMA0=

The central line and control limits are determined using μ_0 and σ_0 (see the equations in Table 9.3). Output 9.1.1 indicates that the process is out-of-control, since the moving averages for Day=17, Day=19, and Day=20 lie below the lower control limit.

You can also specify μ_0 and σ_0 with the variables `_MEAN_` and `_STDDEV_` in a LIMITS= data set, as illustrated by the following statements:

```

data Cliplim;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Gap';
  _subgrp_ = 'Day';
  _type_  = 'STANDARD';
  _limitn_ = 5;
  _mean_  = 15;
  _stddev_ = 0.2;
  _weight_ = 0.3;

proc macontrol data=Clips1 limits=Cliplim;
  ewmachart Gap*Day / xsymbol=mu0;
run;

```

The variable `_WEIGHT_` is required, and its value provides the weight parameter used to compute the EWMA's. The variables `_VAR_` and `_SUBGRP_` are also required, and their values must match the *process* and *subgroup-variable*, respectively, specified in the `EWMACHART` statement. The bookkeeping variable `_TYPE_` is not required, but it is recommended to indicate that the variables `_MEAN_` and `_STDDEV_` provide standard values rather than estimated values.

The resulting chart (not shown here) is identical to the one shown in [Output 9.1.1](#).

Example 9.2: Displaying Limits Based on Asymptotic Values

The upper (lower) control limits in [Output 9.1.1](#) are monotonically increasing (decreasing). As the number of subgroups increases, the control limits approach the following asymptotic values: *See MACEW3 in the SAS/QC Sample Library*

$$LCL = \bar{\bar{X}} - k\hat{\sigma}\sqrt{r/n(2-r)}$$

$$UCL = \bar{\bar{X}} + k\hat{\sigma}\sqrt{r/n(2-r)}$$

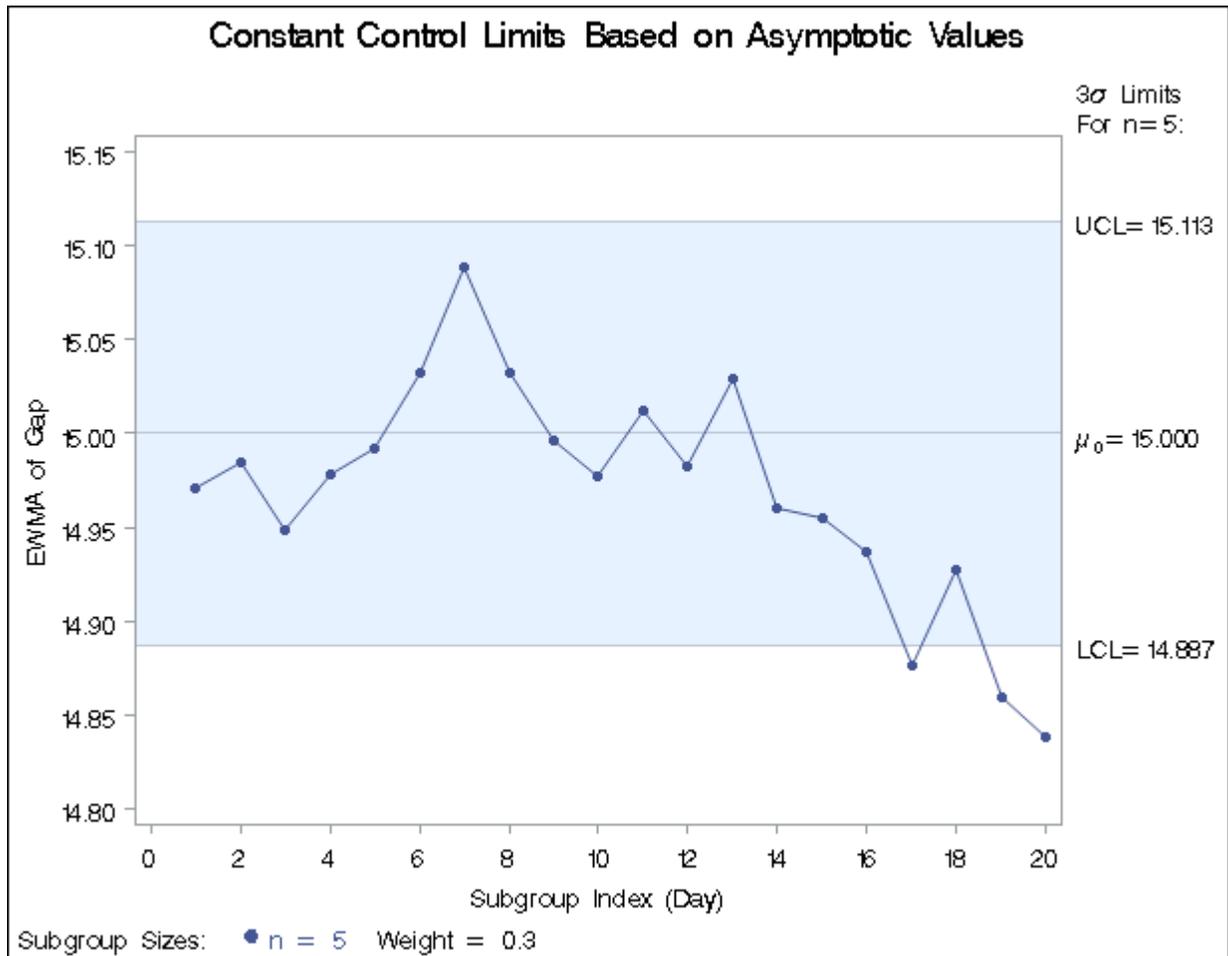

These constant limits are displayed if you specify the `ASYMPTOTIC` option, as illustrated by the following statements:

```

ods graphics off;
title 'Constant Control Limits Based on Asymptotic Values';
proc macontrol data=Clips1;
  ewmachart Gap*Day /
    mu0      = 15
    sigma0   = 0.2
    weight   = 0.3
    asymptotic
    xsymbol  = mu0;
run;

```

The chart is shown in [Output 9.2.1](#).

Output 9.2.1 Asymptotic Control Limits

Note that the same three points that were outside the exact limits (displayed in [Output 9.1.1](#)) fall outside the asymptotic limits. The exact limits quickly approach the asymptotic values, so only the first few subgroups have appreciably different limits.

Example 9.3: Working with Unequal Subgroup Sample Sizes

See MACEW4 in the SAS/QC Sample Library This example contains measurements from the metal clip manufacturing process (introduced in “[Creating EWMA Charts from Raw Data](#)” on page 817). The following statements create a SAS data set named Clips4, which contains additional clip gap measurements taken on a daily basis:

```

data Clips4;
  input Day @;
  length Dayc $2.;
  informat Day ddmmyy8.;
  format Day date5.;
  Dayc=put(Day,date5.);
  Dayc=substr(Dayc,1,2);
  do i=1 to 5;
    input Gap @;
    output;
  end;
  drop i;
  label Dayc='April';
  datalines;
1/4/86 14.93 14.65 14.87 15.11 15.18
2/4/86 15.06 14.95 14.91 15.14 15.41
3/4/86 14.90 14.90 14.96 15.26 15.18
4/4/86 15.25 14.57 15.33 15.38 14.89
7/4/86 14.68 14.63 14.72 15.32 14.86
8/4/86 14.48 14.88 14.98 14.74 15.48
9/4/86 14.99 15.16 15.02 15.53 14.66
10/4/86 14.88 15.44 15.04 15.10 14.89
11/4/86 15.14 15.33 14.75 15.23 14.64
14/4/86 15.46 15.30 14.92 14.58 14.68
15/4/86 15.23 14.63 . . .
16/4/86 15.13 15.25 . . .
17/4/86 15.06 15.25 15.28 15.30 15.34
18/4/86 15.22 14.77 15.12 14.82 15.29
21/4/86 14.95 14.96 14.65 14.87 14.77
22/4/86 15.01 15.11 15.11 14.79 14.88
23/4/86 14.97 15.50 14.93 15.13 15.25
24/4/86 15.23 15.21 15.31 15.07 14.97
25/4/86 15.08 14.75 14.93 15.34 14.98
28/4/86 15.07 14.86 15.42 15.47 15.24
29/4/86 15.27 15.20 14.85 15.62 14.67
30/4/86 14.97 14.73 15.09 14.98 14.46
;

```

Note that only two gap measurements were recorded on April 15 and April 16.

A partial listing of Clips4 is shown in [Output 9.3.1](#). This data set contains three variables: Day is a numeric variable that contains the date (month, day, and year) that the measurement is taken, Dayc is a character variable that contains the day the measurement is taken, and Gap is a numeric variable that contains the measurement.

Output 9.3.1 The Data Set Clips4

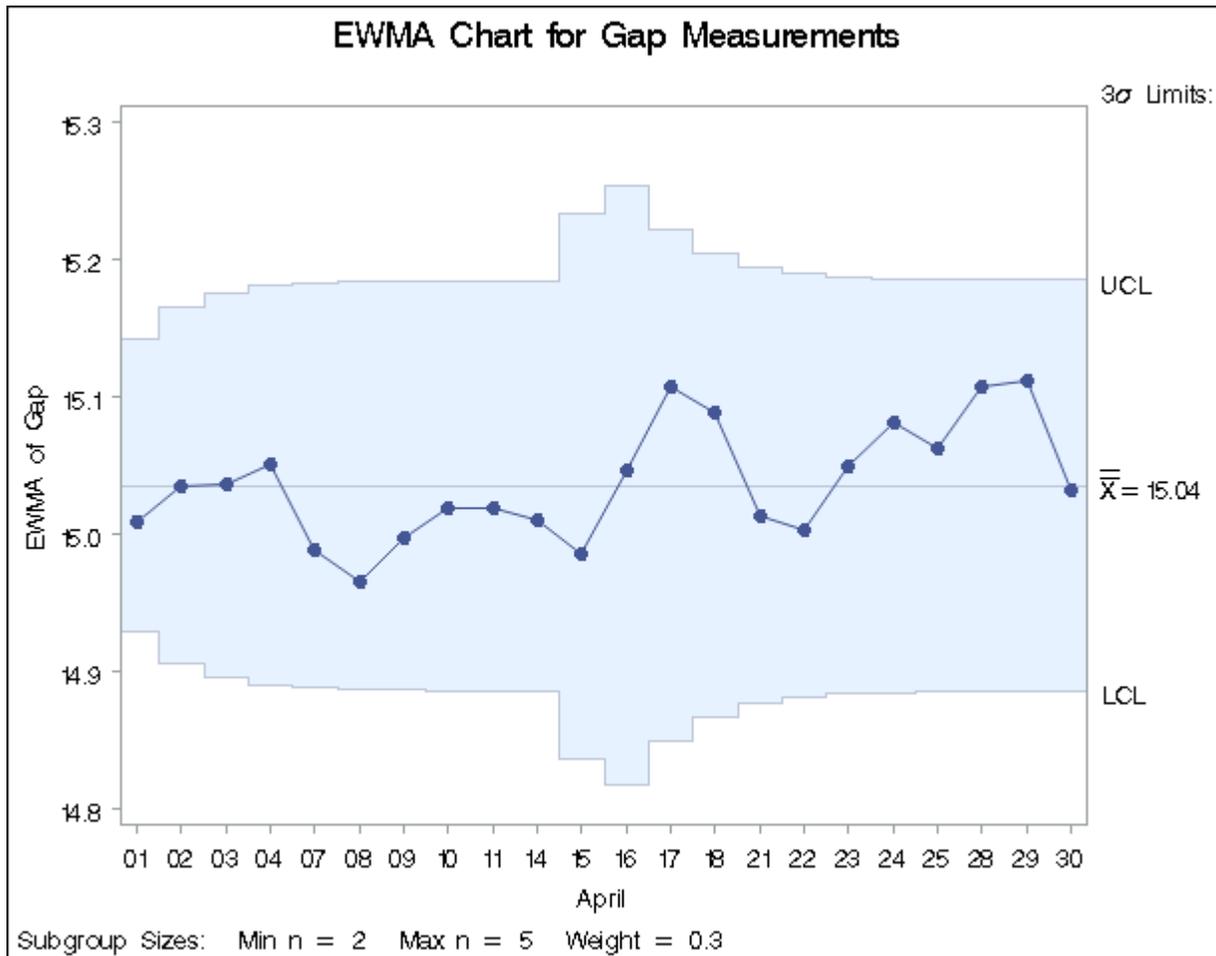

The Data Set Clips4		
Day	Dayc	Gap
01APR	01	14.93
01APR	01	14.65
01APR	01	14.87
01APR	01	15.11
01APR	01	15.18
02APR	02	15.06
02APR	02	14.95
02APR	02	14.91
02APR	02	15.14
02APR	02	15.41
03APR	03	14.90
03APR	03	14.90
03APR	03	14.96
03APR	03	15.26
03APR	03	15.18

The following statements request an EWMA chart, shown in [Output 9.3.2](#), for these gap measurements:

```
ods graphics off;
symbol v=dot h=1.5;
title 'EWMA Chart for Gap Measurements';
proc macontrol data=Clips4;
  ewmachart Gap*Dayc / weight = 0.3;
run;
```

The character variable Dayc (rather than the numeric variable Day) is specified as the *subgroup-variable* in the preceding EWMACHART statement. If Day were the *subgroup-variable*, each day during April would appear on the horizontal axis, including the weekend days of April 5 and April 6 for which no measurements were taken. To avoid this problem, the *subgroup-variable* Dayc is created from Day using the PUT and SUBSTR function. Since Dayc is a character *subgroup-variable*, a discrete axis is used for the horizontal axis, and as a result, April 5 and April 6 do not appear on the horizontal axis in [Output 9.3.2](#). A LABEL statement is used to specify the label *April* for the horizontal axis, indicating the month that these measurements were taken.

Output 9.3.2 EWMA Chart with Varying Sample Sizes

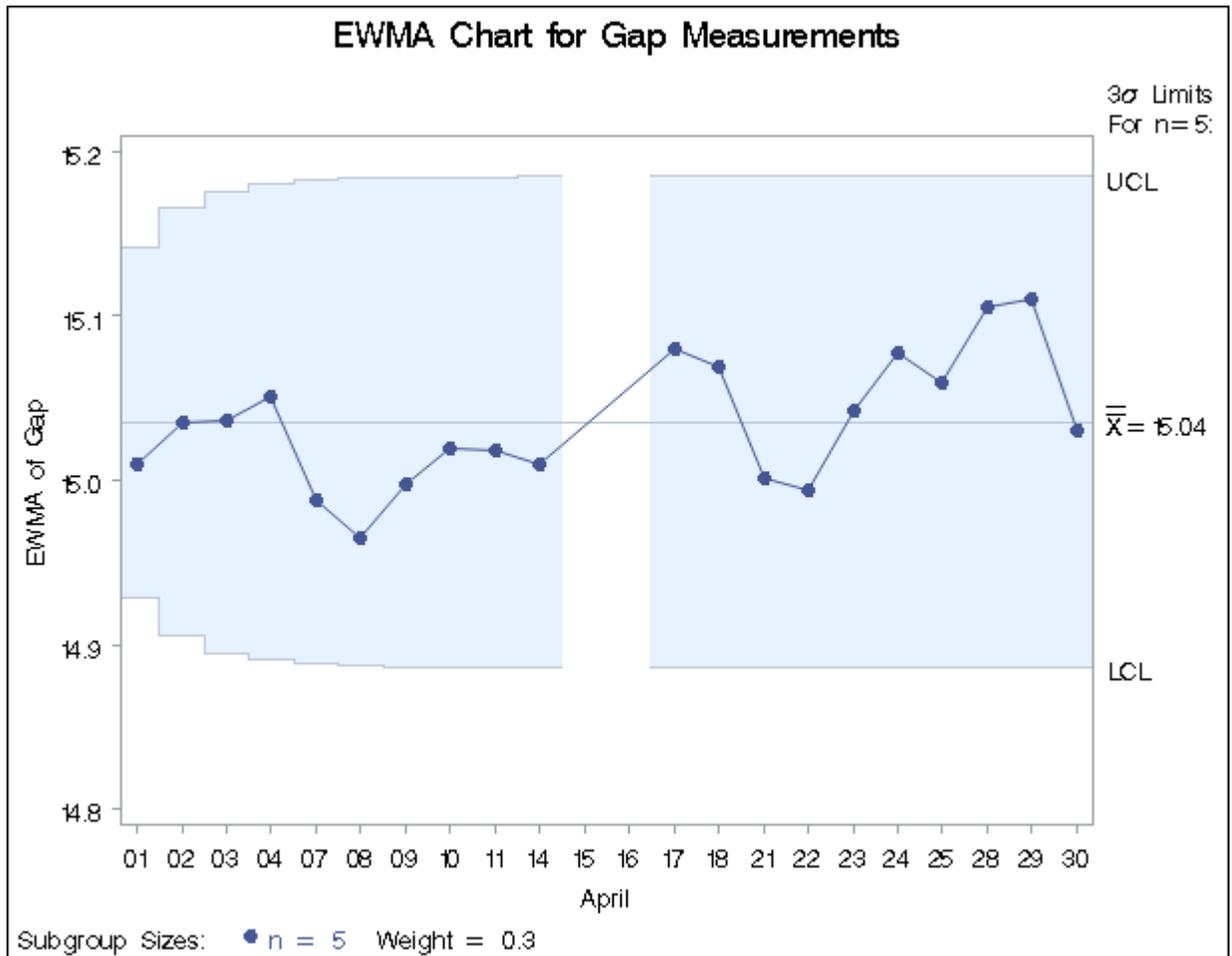

Note that the control limits vary with the subgroup sample size. The sample size legend in the lower left corner displays the minimum and maximum subgroup sample sizes.

The EWMA_{CHART} statement provides various options for working with unequal subgroup sample sizes. For example, you can use the `LIMITN=` option to specify a fixed (nominal) sample size for computing control limits, as illustrated by the following statements:

```
title 'EWMA Chart for Gap Measurements';
proc macontrol data=Clips4;
  ewmachart Gap*Dayc / weight = 0.3
                limitn = 5;
run;
```

The resulting chart is shown in [Output 9.3.3](#).

Output 9.3.3 Control Limits Based on Fixed Sample Size

Note that the only points displayed are those corresponding to subgroups whose sample size matches the nominal sample size of five. Therefore, points are not displayed for April 15 and April 16. To plot points for all subgroups (regardless of subgroup sample size), you can specify the ALLN option, as follows:

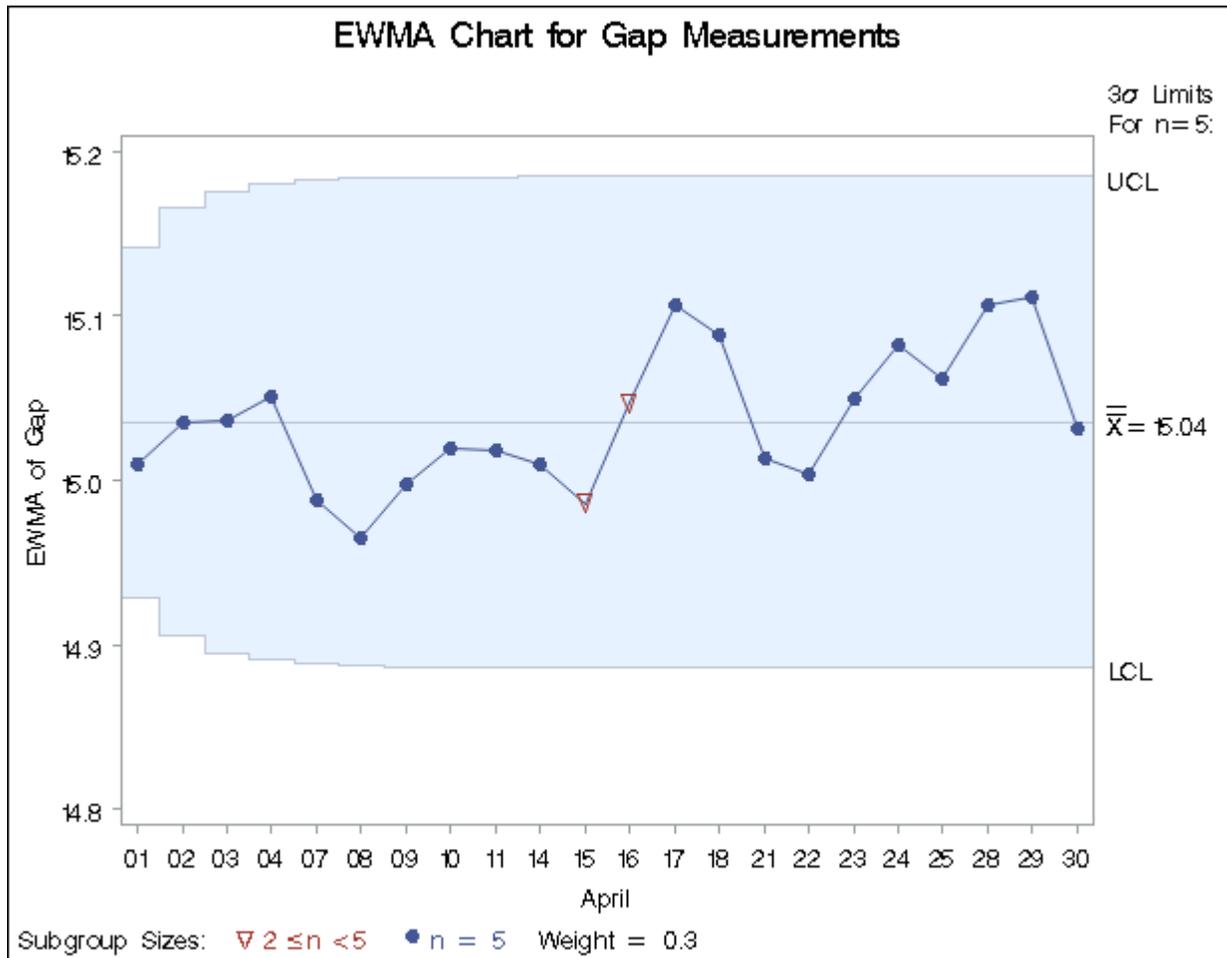

```

title 'EWMA Chart for Gap Measurements';
proc macontrol data=Clips4;
  ewmachart Gap*Dayc/ weight = 0.3
              limitn = 5
              alln
              nmarkers;
run;

```

The chart is shown in Output 9.3.4. The NMARKERS option requests special symbols to identify points for which the subgroup sample size differs from the nominal sample size.

Output 9.3.4 Displaying All Subgroups Regardless of Sample Size

You can use the SMETHOD= option to determine how the process standard deviation σ is to be estimated when the subgroup sample sizes vary. The default method computes $\hat{\sigma}$ as an unweighted average of subgroup estimates of σ . Specifying SMETHOD=MVLUE requests a minimum variance linear unbiased estimate (MVLUE), which assigns greater weight to estimates of σ from subgroups with larger sample sizes. Specifying SMETHOD=RMSDF requests a weighted root-mean-square estimate. If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the MVLUE. For more information, see “Methods for Estimating the Standard Deviation” on page 853.

The following statements apply all three methods:

```
proc macontrol data=Clips4;
  ewmachart Gap*Dayc / outlimits = Cliplim1
                    outindex = 'Default'
                    weight = 0.3
                    nochart;
  ewmachart Gap*Dayc / smethod = mvlue
                    outlimits = Cliplim2
                    outindex = 'MVLUE'
                    weight = 0.3
                    nochart;
  ewmachart Gap*Dayc / smethod = rmsdf
                    outlimits = Cliplim3
                    outindex = 'RMSDF'
                    weight = 0.3
                    nochart;

run;

data Climits;
  set Cliplim1 Cliplim2 Cliplim3;
run;
```

The data set Climits is listed in [Output 9.3.5](#).

Output 9.3.5 Listing of the Data Set Climits

Estimating the Process Standard Deviation								
	S	U	B	V	A	R		
	I	N	G	R	P	X		
	—	—	—	—	—	—		
	L	I	M	I	T	N		
	A	L	P	H	A	S		
	S	G	M	A	A	S		
	—	—	—	—	—	—		
	S	I	M	I	T	N		
	—	—	—	—	—	—		
Gap	Dayc	Default	ESTIMATE	V	.002699796	3	15.0354	0.26503
Gap	Dayc	MVLUE	ESTIMATE	V	.002699796	3	15.0354	0.26096
Gap	Dayc	RMSDF	ESTIMATE	V	.002699796	3	15.0354	0.25959

Note that the estimate of the process standard deviation (stored in the variable `_STDDEV_`) is slightly different depending on the estimation method. The variable `_LIMITN_` is assigned the special missing value `V` in the `OUTLIMITS=` data set, indicating that the subgroup sample sizes vary.

Example 9.4: Displaying Individual Measurements on an EWMA Chart

In the manufacture of automotive tires, the diameter of the steel belts inside the tire is measured. *See MACEW5 in the SAS/QC Sample Library*
The following data set contains these measurements for 30 tires:

```
data tires;
  input sample diameter @@;
  datalines;
  1 24.05    2 23.99    3 23.95
  4 23.93    5 23.97    6 24.02
  7 24.06    8 24.10    9 23.98
 10 24.03   11 23.91   12 24.06
 13 24.06   14 23.96   15 23.98
 16 24.06   17 24.01   18 24.00
 19 23.93   20 23.92   21 24.09
 22 24.11   23 24.05   24 23.98
 25 23.98   26 24.06   27 24.02
 28 24.06   29 23.97   30 23.96
  ;
```

The following statements use the IRCHART statement in the SHEWHART procedure (see “IR-CHART Statement: SHEWHART Procedure” on page 1529) to create a data set containing the control limits for individual measurements and moving range charts for Diameter:

```
proc shewhart data=tires;
  irchart Diameter*Sample / nochart outlimits=Tlimits;
run;
```

A listing of the data set Tlimits is shown in [Output 9.4.1](#).

Output 9.4.1 Listing of the Data Set Tlimits

Control Limits for Diameter Measurements						
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	
diameter	sample	ESTIMATE	2	.002699796	3	
LCLI	_MEAN_	_UCLI_	_LCLR_	_R_	_UCLR_	_STDDE
23.8571	24.0083	24.1596	0	0.056897	0.18585	0.0504

The upper and lower control limits for the diameter measurements are 24.1596 and 23.8571, respectively.

In this example, reference lines will be used to display the control limits for the individual measurements on the EWMA chart. The following DATA step reads these control limits from Tlimits and creates a data set named vrefdata, which contains the reference line information:

```
data vrefdata;
  set Tlimits;
  length _reflab_ $16.;
  keep _ref_ _reflab_;
  _ref_ = _lcli_; _reflab_ = 'LCL for X'; output;
  _ref_ = _ucli_; _reflab_ = 'UCL for X'; output;
run;
```

A listing of the data set vrefdata is shown in [Output 9.4.2](#).

Output 9.4.2 Listing of the Data Set vrefdata

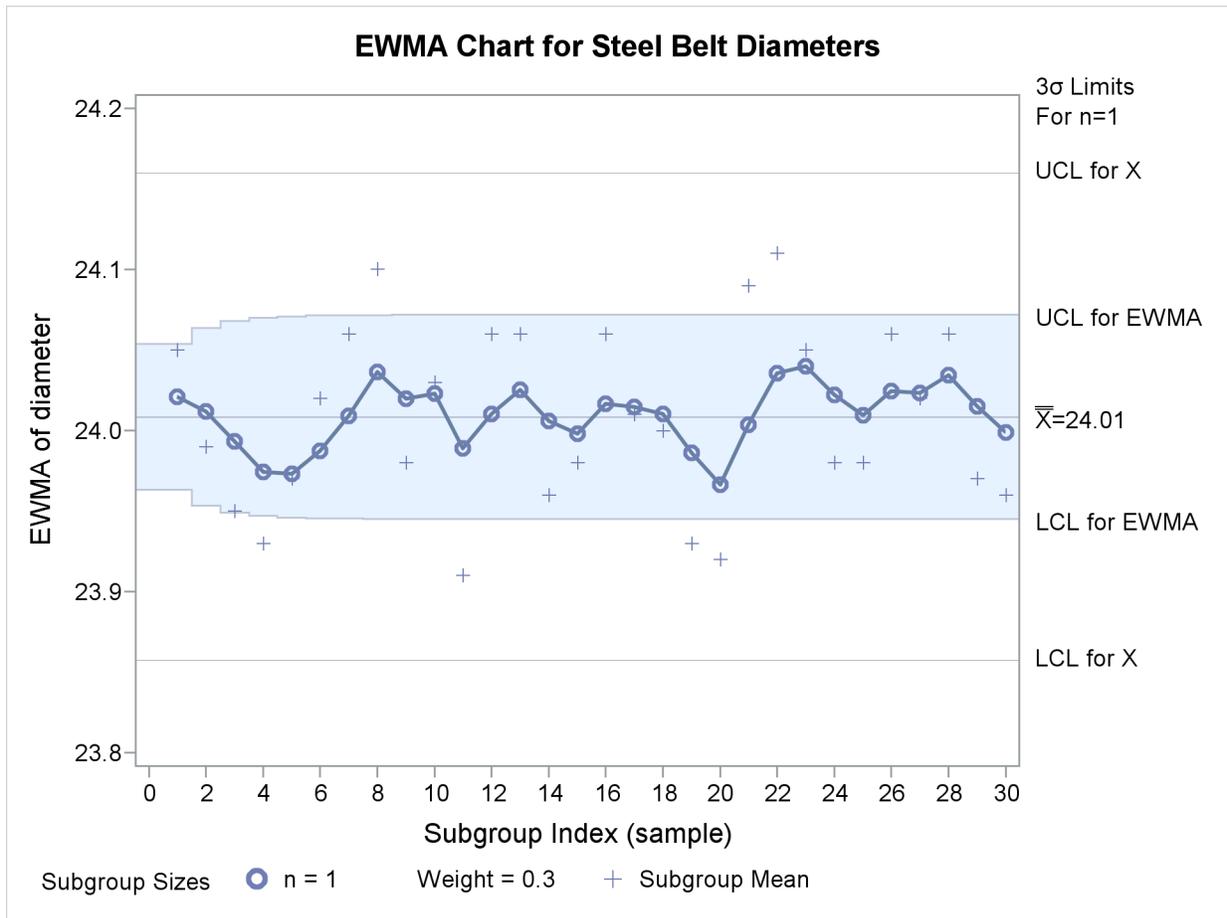

Reference Line Information	
reflab	_ref_
LCL for X	23.8571
UCL for X	24.1596

The following statements request an EWMA chart for these measurements:

```
ods graphics on;
title 'EWMA Chart for Steel Belt Diameters';
proc macontrol data=Tires;
  ewmachart Diameter*Sample / weight      = 0.3
                                meansymbol = square
                                lc1label   = 'LCL for EWMA'
                                uc1label   = 'UCL for EWMA'
                                vref       = vrefdata
                                odstitle   = title
                                vreflabpos = 3
                                markers;
run;
```

The MEANSYMBOL= option displays the individual measurements on the EWMA chart. By default, these values are not displayed. For traditional graphics, the MEANSYMBOL= option specifies the symbol used to plot the individual measurements. For ODS Graphics, specifying a MEANSYMBOL= value causes the subgroup means to be plotted, but the symbol used is determined by the ODS style in effect. The VREF= option reads the reference line information from vrefdata. The resulting chart is shown in [Output 9.4.3](#).

[Output 9.4.3](#) indicates that the process is in control. None of the diameter measurements (indicated by squares) exceed their control limits, and none of the EWMAs exceed their limits.

Output 9.4.3 Displaying Individual Measurements on EWMA Chart**Example 9.5: Computing Average Run Lengths**

The EWMAARL DATA step function computes the average run length for an exponentially weighted moving average (EWMA) scheme (refer to Crowder 1987a,b for details). You can use this function to design a scheme by first calculating average run lengths for a range of values for the weight and then choosing the weight that yields a desired average run length. *See MACEW6 in the SAS/QC Sample Library*

The following statements compute the average run lengths for shifts between 0.5 and 2 and weights between 0.25 and 1. The data set ARLs is displayed in [Output 9.5.1](#).

```
data arls;
  do shift=.5 to 2 by .5;
    do Weight=.25 to 1 by .25;
      arl=ewmaarl(shift,Weight,3.0);
      output;
    end;
  end;
run;
```

Output 9.5.1 Listing of the Data Set ARLs

Average Run Lengths for Various Shifts and Weights		
----- shift=0.5 -----		
Weight	arl	
0.25	48.453	
0.50	75.354	
0.75	110.950	
1.00	155.224	
----- shift=1 -----		
Weight	arl	
0.25	11.1543	
0.50	15.7378	
0.75	25.6391	
1.00	43.8947	
----- shift=1.5 -----		
Weight	arl	
0.25	5.4697	
0.50	6.1111	
0.75	8.7201	
1.00	14.9677	
----- shift=2 -----		
Weight	arl	
0.25	3.61677	
0.50	3.46850	
0.75	4.15346	
1.00	6.30296	

Note that when the weight is 1.0, the EWMAARL function returns the average run length for a Shewhart chart for means. For more details, see “[EWMAARL Function](#)” on page 2270.

In addition to using the EWMAARL function to design a EWMA scheme with desired average run length properties, you can use it to evaluate an existing scheme. For example, suppose you have an EWMA chart with 3σ control limits using a weight parameter of 0.3. The following DATA step computes the average run lengths for various shifts using this scheme:

```
data ARLinfo;
  do shift=0 to 2 by .25;
    arl = ewmaarl(shift,0.3,3.0);
    output;
  end;
run;
```

The data set ARLInfo is displayed in [Output 9.5.2](#).

Output 9.5.2 Listing of the Data Set ARLInfo

MACHART Statement: MACONTROL Procedure

Overview: MACHART Statement

The MACHART statement creates a uniformly weighted moving average control chart (commonly referred to as a moving average control chart), which is used to decide whether a process is in a state of statistical control and to detect shifts in the process average.

You can use options in the MACHART statement to

- specify the span of the moving averages (the number of terms in the moving average)
- compute control limits from the data based on a multiple of the standard error of the plotted moving averages or as probability limits
- tabulate the moving averages, subgroup sample sizes, subgroup means, subgroup standard deviations, control limits, and other information
- save control limit parameters in an output data set
- save the moving averages, subgroup sample sizes, subgroup means, and subgroup standard deviations in an output data set
- read control limit parameters from an input data set
- specify one of several methods for estimating the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits

- display a secondary chart that plots a time trend that has been removed from the data
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing moving average control charts with the MACHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: MACHART Statement

This section introduces the MACHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the MACHART statement is presented in the section “Syntax: MACHART Statement” on page 882, and advanced examples are given in the section “Examples: MACHART Statement” on page 910.

Creating Moving Average Charts from Raw Data

See MACMA1 in the SAS/QC Sample Library

In the manufacture of a metal clip, the gap between the ends of the clip is a critical dimension. To monitor the process for a change in the average gap, subgroup samples of five clips are selected daily. The data are analyzed with a uniformly weighted moving average chart. The gaps recorded during the first twenty days are saved in a SAS data set named Clips1.

```

data Clips1;
  input Day @ ;
  do i=1 to 5;
    input Gap @ ;
    output;
  end;
  drop i;
  datalines;
1 14.76 14.82 14.88 14.83 15.23
2 14.95 14.91 15.09 14.99 15.13
3 14.50 15.05 15.09 14.72 14.97
4 14.91 14.87 15.46 15.01 14.99
5 14.73 15.36 14.87 14.91 15.25
6 15.09 15.19 15.07 15.30 14.98
7 15.34 15.39 14.82 15.32 15.23
8 14.80 14.94 15.15 14.69 14.93
9 14.67 15.08 14.88 15.14 14.78
10 15.27 14.61 15.00 14.84 14.94
11 15.34 14.84 15.32 14.81 15.17
12 14.84 15.00 15.13 14.68 14.91
13 15.40 15.03 15.05 15.03 15.18
14 14.50 14.77 15.22 14.70 14.80
15 14.81 15.01 14.65 15.13 15.12
16 14.82 15.01 14.82 14.83 15.00
17 14.89 14.90 14.60 14.40 14.88
18 14.90 15.29 15.14 15.20 14.70
19 14.77 14.60 14.45 14.78 14.91
20 14.80 14.58 14.69 15.02 14.85
;

```

The following statements produce the listing of the data set Clips1 shown in [Figure 9.10](#):

```

title 'The Data Set CLIPS1';
proc print data=Clips1(obs=15) noobs;
run;

```

Figure 9.10 Partial Listing of the Data Set Clips1

The Data Set CLIPS1	
Day	Gap
1	14.76
1	14.82
1	14.88
1	14.83
1	15.23
2	14.95
2	14.91
2	15.09
2	14.99
2	15.13
3	14.50
3	15.05
3	15.09
3	14.72
3	14.97

The data set Clips1 is said to be in “strung-out” form, since each observation contains the day and gap measurement of a single clip. The first five observations contain the gap measurements for the first day, the second five observations contain the gap measurements for the second day, and so on. Because the variable Day classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable Gap contains the gap measurements and is referred to as the *process variable* (or *process* for short).

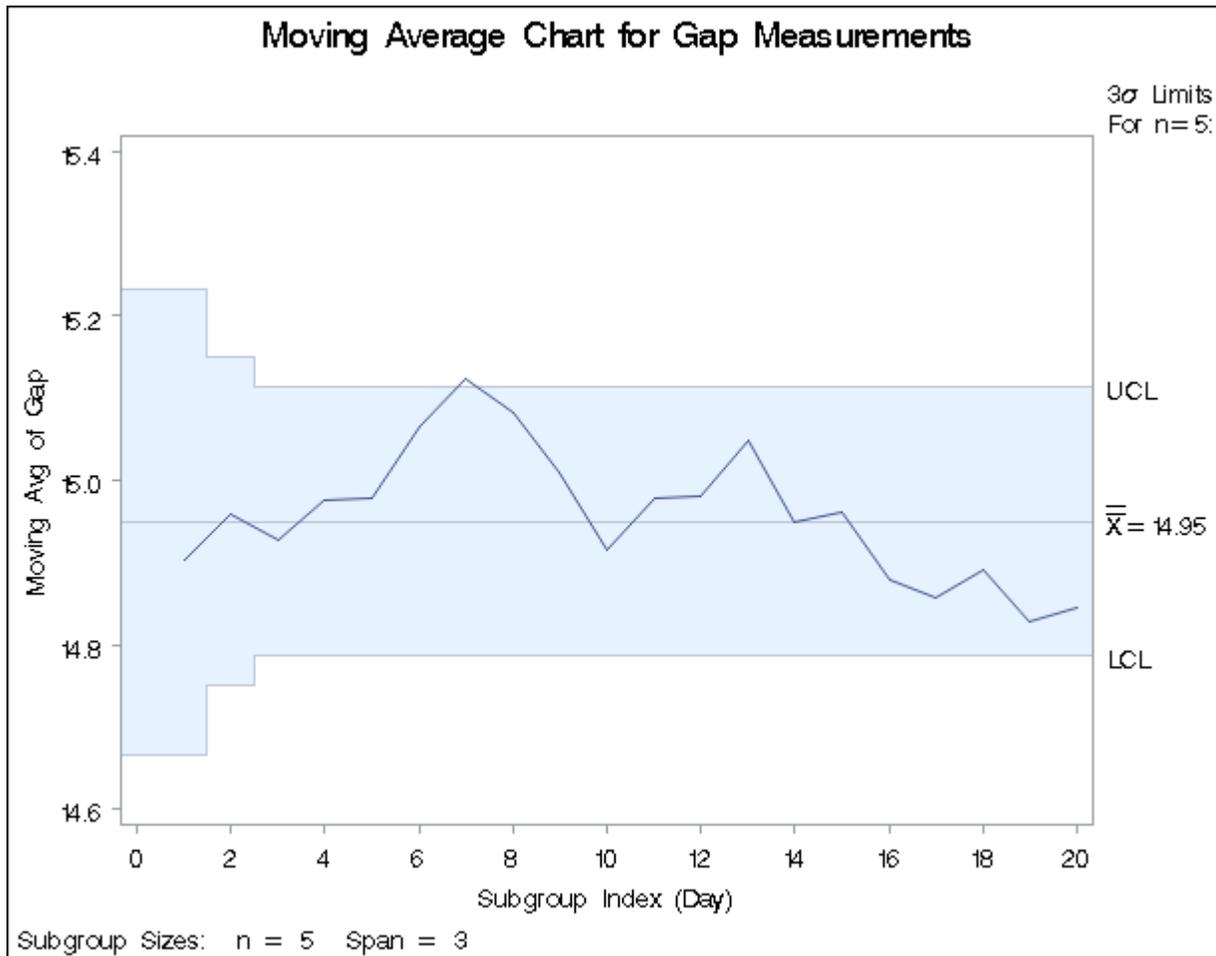

The within-subgroup variability of the gap measurements is known to be stable. You can use a uniformly weighted moving average chart to determine whether the mean level is in control. The following statements create the chart shown in [Figure 9.11](#):

```
ods graphics off;
symbol h = .8;
title 'Moving Average Chart for Gap Measurements';
proc macontrol data=Clips1;
    machart Gap*Day / span=3;
run;
```

This example illustrates the basic form of the MACHART statement. After the keyword MACHART, you specify the *process* to analyze (in this case, Gap) followed by an asterisk and the *subgroup-variable* (Day). The SPAN= option specifies the number of terms to include in the moving average. Options such as SPAN= are specified after the slash (/) in the MACHART statement. A complete list of options is presented in the section “[Syntax: MACHART Statement](#)” on page 882. You must provide the span of the moving average. As an alternative to specifying the SPAN= option, you can read the span from an input data set; see “[Reading Preestablished Control Limit Parameters](#)” on page 880.

The input data set is specified with the DATA= option in the PROC MACONTROL statement.

Figure 9.11 Uniformly Weighted Moving Average Chart for Gap Data

Each point on the chart represents the uniformly weighted moving average for a particular day. The moving average A_1 plotted at Day=1 is simply the subgroup mean for Day=1. The moving average A_2 plotted at Day=2 is the average of the subgroup means for Day=1 and Day=2. The moving average A_3 plotted at Day=3 is the average of the subgroup means for Day=1, Day=2, and Day=3.

$$A_1 = \frac{14.76 + 14.82 + 14.88 + 14.83 + 15.23}{5} = 14.904 \text{ mm}$$

$$A_2 = \frac{14.904 + 15.014}{2} = 14.959 \text{ mm}$$

$$A_3 = \frac{14.904 + 15.014 + 14.866}{3} = 14.928 \text{ mm}$$

For succeeding days, the moving average is similarly calculated as the average of the present and the two previous subgroup means (since a span of three is specified with the SPAN= option).

Note that the moving average for the seventh day lies above the upper control limit, signaling an out-of-control process.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in Table 9.9.

For computational details, see “Constructing Uniformly Weighted Moving Average Charts” on page 895. For more details on reading from a DATA= data set, see “DATA= Data Set” on page 904.

Creating Moving Average Charts from Subgroup Summary Data

See MACMA1 in the SAS/QC Sample Library

The previous example illustrates how you can create moving average charts using raw data (process measurements). However, in many applications the data are provided as subgroup summary statistics. This example illustrates how you can use the MACHART statement with data of this type. The following data set (Clipsum) provides the data from the preceding example in summarized form:

```
data Clipsum;
  input Day GapX GapS;
  Gapn=5;
  datalines;
1  14.904  0.18716
2  15.014  0.09317
3  14.866  0.25006
4  15.048  0.23732
5  15.024  0.26792
6  15.126  0.12260
7  15.220  0.23098
8  14.902  0.17254
9  14.910  0.19824
10 14.932  0.24035
11 15.096  0.25618
12 14.912  0.16903
13 15.138  0.15928
14 14.798  0.26329
15 14.944  0.20876
16 14.896  0.09965
17 14.734  0.22512
18 15.046  0.24141
19 14.702  0.17880
20 14.788  0.16634
;
```

A partial listing of Clipsum is shown in Figure 9.12. There is exactly one observation for each subgroup (note that the subgroups are still indexed by Day). The variable GapX contains the subgroup means, the variable GapS contains the subgroup standard deviations, and the variable GapN contains the subgroup sample sizes (these are all five).

Figure 9.12 The Summary Data Set Clipsum

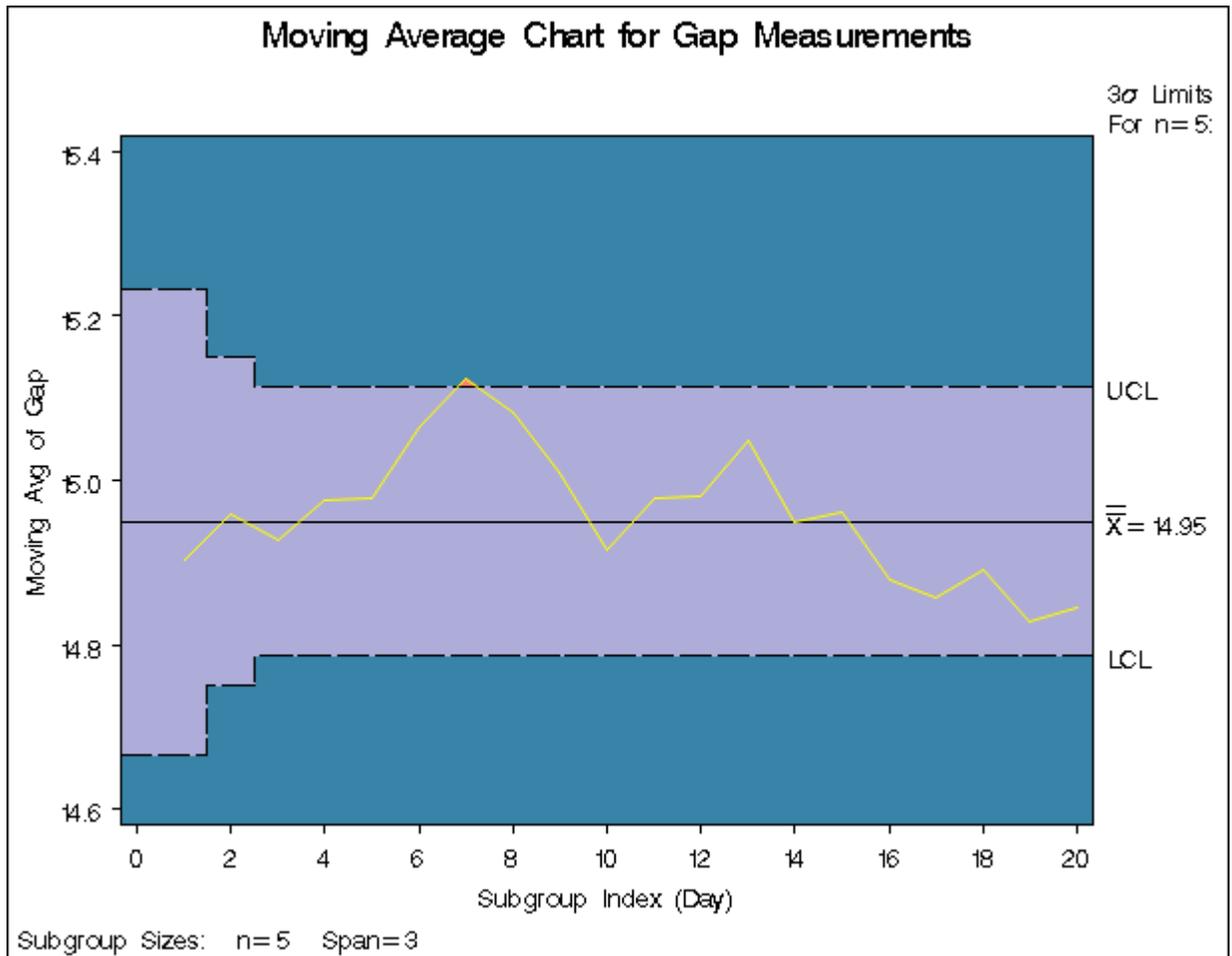

The Data Set Clipsum				
Day	GapX	GapS	Gapn	
1	14.904	0.18716	5	
2	15.014	0.09317	5	
3	14.866	0.25006	5	
4	15.048	0.23732	5	
5	15.024	0.26792	5	

You can read this data set by specifying it as a HISTORY= data set in the PROC MACONTROL statement, as follows:

```
options nogstyle;
symbol color=salmon h=0.8;
title 'Moving Average Chart for Gap Measurements';
proc macontrol history=Clipsum;
  machart Gap*Day / span      = 3
                  cframe     = steel
                  cinfill    = vpab
                  cconnect   = yellow
                  coutfill   = salmon;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement and MACHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting moving average chart is shown in Figure 9.13.

Figure 9.13 Uniformly Weighted Moving Average Chart from Summary Data

Note that Gap is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the three SAS variables GapX, GapS, and GapN. The suffix characters X, S, and N indicate *mean*, *standard deviation*, and *sample size*, respectively. Thus, you can specify three subgroup summary variables in a HISTORY= data set with a single name (Gap), which is referred to as the *process*. The variables GapX, GapS, and GapN are all required. The name Day specified after the asterisk is the name of the *subgroup-variable*.

In general, a HISTORY= input data set used with the MACHART statement must contain the following variables:

- subgroup variable
- subgroup mean variable
- subgroup standard deviation variable
- subgroup sample size variable

Furthermore, the names of subgroup mean, standard deviation, and sample size variables must begin with the *process* name specified in the MACHART statement and end with the special suffix

characters *X*, *S*, and *N*, respectively. If the names do not follow this convention, you can use the RENAME option in the PROC MACONTROL statement to rename the variables for the duration of the MACONTROL procedure step (see “” on page 1909 for an example).

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 906.

Saving Summary Statistics

In this example, the MACHART statement is used to create a summary data set that can be read later by the MACONTROL procedure (as in the preceding example). The following statements read measurements from the data set Clips1 and create a summary data set named Cliphist: *See MACMA1 in the SAS/QC Sample Library*

```

title 'Summary Data Set for Gap Measurements';
proc macontrol data=Clips1;
  machart Gap*Day / span      = 3
                    outhistory = Cliphist
                    nochart;
run;

```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 9.11.

Figure 9.14 contains a partial listing of Cliphist.

Figure 9.14 The Summary Data Set Cliphist

Summary Data Set for Gap Measurements				
Day	GapX	GapS	GapA	GapN
1	14.904	0.18716	14.9040	5
2	15.014	0.09317	14.9590	5
3	14.866	0.25006	14.9280	5
4	15.048	0.23732	14.9760	5
5	15.024	0.26792	14.9793	5

There are five variables in the data set Cliphist.

- Day contains the subgroup index.
- GapX contains the subgroup means.
- GapS contains the subgroup standard deviations.

- GapA contains the subgroup moving averages.
- GapN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters *X*, *S*, *A*, and *N* to the *process* Gap specified in the MACHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 902.

Saving Control Limit Parameters

See MACMA1 in the SAS/QC Sample Library

You can save the control limit parameters used for a moving average chart in a SAS data set; this enables you to use these parameters with future data (see “Reading Preestablished Control Limit Parameters” on page 880) or modify the parameters with a DATA step program.

The following statements read measurements from the data set Clips1 (see “Creating Moving Average Charts from Raw Data” on page 870) and save the control limit parameters in a data set named Cliplim:

```

title 'Control Limit Parameters';
proc macontrol data=Clips1;
  machart Gap*Day / span      = 3
                  outlimits = Cliplim
                  nochart;
run;

```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Cliplim is listed in Figure 9.15.

Figure 9.15 The Data Set Cliplim Containing Control Limit Information

Control Limit Parameters								
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	_MEAN_	_STDDEV_	_SPAN_
Gap	Day	ESTIMATE	5	.002699796	3	14.95	0.21108	3

Note that the data set Cliplim does not contain the actual control limits, but rather the parameters required to compute the limits.

The data set contains one observation with the parameters for *process* Gap. The variable `_SPAN_` contains the number of terms used to calculate the moving average. The value of `_MEAN_` is an estimate of the process mean, and the value of `_STDDEV_` is an estimate of the process standard deviation σ . The value of `_LIMITN_` is the nominal sample size associated with the control limits, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping variable that indicates that the values of `_MEAN_` and `_STDDEV_` are estimates rather than standard values. For more information, see “OUTLIMITS= Data Set” on page 900.

You can create an output data set containing the control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```

title 'Summary Statistics and Control Limits';
proc macontrol data=Clips1;
  machart Gap*Day / span      = 3
                    outtable = Cliptab
                    nochart;
run;

```

The data set `Cliptab` is listed in [Figure 9.16](#).

This data set contains one observation for each subgroup sample. The variable `_UWMA_` contains the uniformly weighted moving average. The variables `_SUBX_`, `_SUBS_`, and `_SUBN_` contain the subgroup means, subgroup standard deviations, and subgroup sample sizes, respectively. The variables `_LCLA_` and `_UCLA_` contain the lower and upper control limits, and the variable `_MEAN_` contains the central line. The variables `_VAR_` and `Day` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 902.

Figure 9.16 The `OUTTABLE=` Data Set `Cliptab`

Summary Statistics and Control Limits												
	S		L								S	
	I	I									T	E

Gap 1	3	5	3	5	14.904	0.18716	14.6668	14.9040	14.95	15.2332	0.21108	
Gap 2	3	5	3	5	15.014	0.09317	14.7498	14.9590	14.95	15.1502	0.21108	
Gap 3	3	5	3	5	14.866	0.25006	14.7865	14.9280	14.95	15.1135	0.21108	
Gap 4	3	5	3	5	15.048	0.23732	14.7865	14.9760	14.95	15.1135	0.21108	
Gap 5	3	5	3	5	15.024	0.26792	14.7865	14.9793	14.95	15.1135	0.21108	
Gap 6	3	5	3	5	15.126	0.12260	14.7865	15.0660	14.95	15.1135	0.21108	
Gap 7	3	5	3	5	15.220	0.23098	14.7865	15.1233	14.95	15.1135	0.21108	UPPER
Gap 8	3	5	3	5	14.902	0.17254	14.7865	15.0827	14.95	15.1135	0.21108	
Gap 9	3	5	3	5	14.910	0.19824	14.7865	15.0107	14.95	15.1135	0.21108	
Gap 10	3	5	3	5	14.932	0.24035	14.7865	14.9147	14.95	15.1135	0.21108	
Gap 11	3	5	3	5	15.096	0.25618	14.7865	14.9793	14.95	15.1135	0.21108	
Gap 12	3	5	3	5	14.912	0.16903	14.7865	14.9800	14.95	15.1135	0.21108	
Gap 13	3	5	3	5	15.138	0.15928	14.7865	15.0487	14.95	15.1135	0.21108	
Gap 14	3	5	3	5	14.798	0.26329	14.7865	14.9493	14.95	15.1135	0.21108	
Gap 15	3	5	3	5	14.944	0.20876	14.7865	14.9600	14.95	15.1135	0.21108	
Gap 16	3	5	3	5	14.896	0.09965	14.7865	14.8793	14.95	15.1135	0.21108	
Gap 17	3	5	3	5	14.734	0.22512	14.7865	14.8580	14.95	15.1135	0.21108	
Gap 18	3	5	3	5	15.046	0.24141	14.7865	14.8920	14.95	15.1135	0.21108	
Gap 19	3	5	3	5	14.702	0.17880	14.7865	14.8273	14.95	15.1135	0.21108	
Gap 20	3	5	3	5	14.788	0.16634	14.7865	14.8453	14.95	15.1135	0.21108	

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Cliptab and display a moving average chart (not shown here) identical to Figure 9.11:

```
title 'Moving Average Chart for Gap Measurements';
proc macontrol table=Cliptab;
  machart Gap*Day;
run;
```

For more information, see “TABLE= Data Set” on page 907.

Reading Prestablished Control Limit Parameters

See MACMAI in the SAS/QC Sample Library

In the previous example, the OUTLIMITS= data set saved the control limit parameters in the data set Cliplim. This example shows how to apply these parameters to new data provided in the following data set:

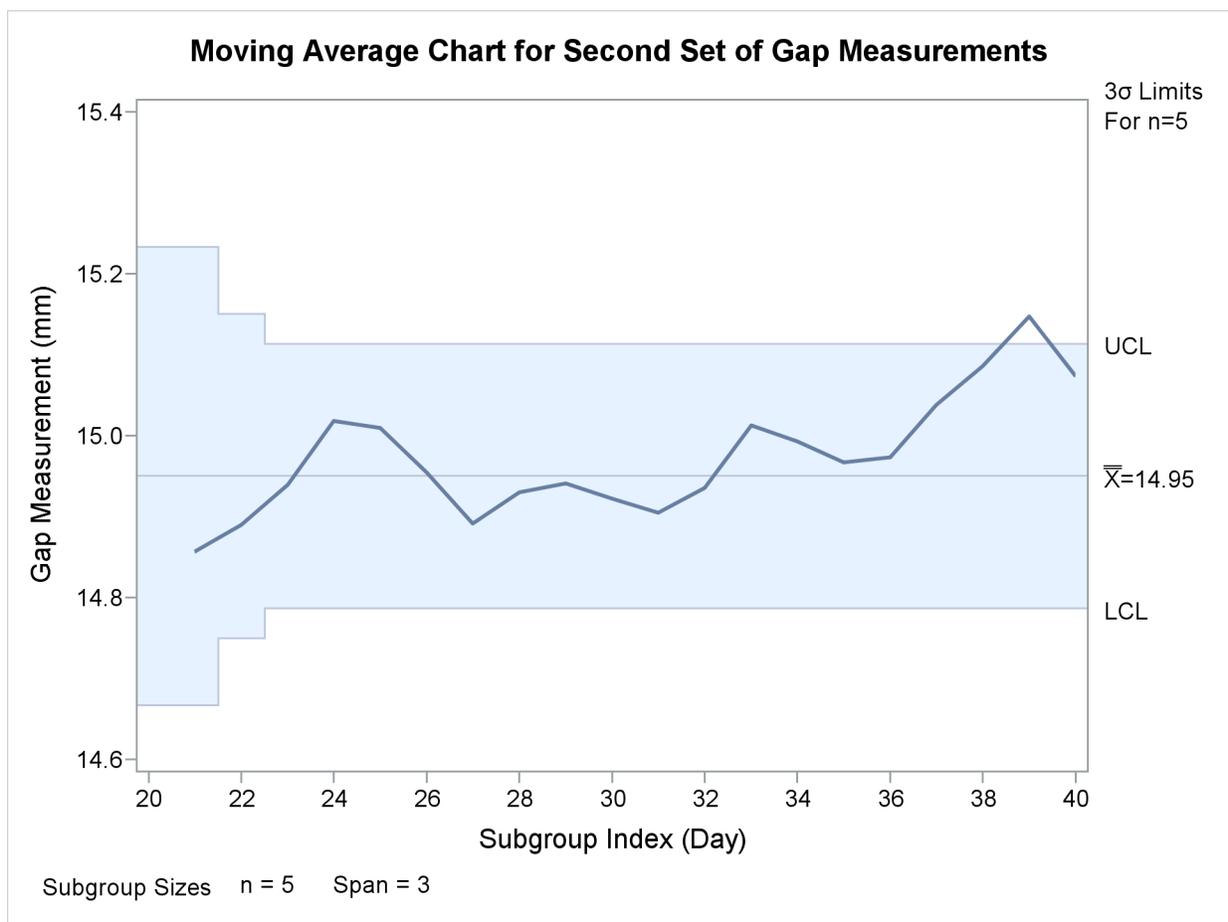

```
data Clips1a;
  label Gap='Gap Measurement (mm)';
  input Day @;
  do i=1 to 5;
    input Gap @;
    output;
  end;
  drop i;
  datalines;
21 14.86 15.01 14.67 14.67 15.07
22 14.93 14.53 15.07 15.10 14.98
23 15.27 14.90 15.12 15.10 14.80
24 15.02 15.21 14.93 15.11 15.20
25 14.90 14.81 15.26 14.57 14.94
26 14.78 15.29 15.13 14.62 14.54
27 14.78 15.15 14.61 14.92 15.07
28 14.92 15.31 14.82 14.74 15.26
29 15.11 15.04 14.61 15.09 14.68
30 15.00 15.04 14.36 15.20 14.65
31 14.99 14.76 15.18 15.04 14.82
32 14.90 14.78 15.19 15.06 15.06
33 14.95 15.10 14.86 15.27 15.22
34 15.03 14.71 14.75 14.99 15.02
35 15.38 14.94 14.68 14.77 14.83
36 14.95 15.43 14.87 14.90 15.34
37 15.18 14.94 15.32 14.74 15.29
38 14.91 15.15 15.06 14.78 15.42
39 15.34 15.34 15.41 15.36 14.96
40 15.12 14.75 15.05 14.70 14.74
;
```

The following statements create a moving average chart for the data in Clips1a using the control limit parameters in Cliplim:

```
ods graphics on;
title 'Moving Average Chart for Second Set of Gap Measurements';
proc macontrol data=Clips1a limits=Cliplim;
  machart Gap*Day / odstitle=title;
run;
```

The ODS GRAPHICS ON statement specified before the PROC MACONTROL statement enables ODS Graphics, so the moving average chart is created using ODS Graphics instead of traditional graphics. The chart is shown in Figure 9.17.

Figure 9.17 Using Control Limit Parameters from a LIMITS= Data Set

The LIMITS= option in the PROC MACONTROL statement specifies the data set containing the control limits parameters. By default,⁴ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Gap
- the value of `_SUBGRP_` matches the *subgroup-variable* name Day

⁴In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Note that the moving average plotted for the 39th day lies above the upper control limit, signalling an out-of-control process.

In this example, the LIMITS= data set was created in a previous run of the MACONTROL procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 905 for details concerning the variables that you must provide, and see Example 9.6 for an illustration.

Syntax: MACHART Statement

The basic syntax for the MACHART statement is as follows:

```
MACHART process * subgroup-variable / SPAN=value < options > ;
```

The general form of this syntax is as follows:

```
MACHART processes * subgroup-variable < (block-variables) >  
      <=symbol-variable | 'character'> / SPAN=value < options > ;
```

Note that the SPAN= option is required unless its *value* is read from a LIMITS= data set. You can use any number of MACHART statements in the MACONTROL procedure. The components of the MACHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC MACONTROL statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “Creating Moving Average Charts from Raw Data” on page 870.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “Creating Moving Average Charts from Subgroup Summary Data” on page 874.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “Saving Control Limit Parameters” on page 878.

A *process* is required. If more than one *process* is specified, enclose the list in parentheses. For example, the following statements request distinct moving average charts (each with a span of 3) for Weight, Length, and Width:

```
proc macontrol data=Measures;  
      machart (Weight Length Width)*Day / span=3;  
run;
```

subgroup-variable

is the variable that classifies the data into subgroups. The *subgroup-variable* is required. In the preceding MACHART statement, Day is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or plotting character used to plot the moving averages.

- If you produce a line printer chart, an ‘A’ is displayed for points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL*n* statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create a moving average chart using an asterisk (*) to plot the points:

```
proc macontrol data=Values lineprinter;
  machart Weight*Hour='*' / span=3;
run;
```

options

specify chart parameters, enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)” on page 883, which follows, lists all options by function.

Summary of Options

The following tables list the MACHART statement options by function. Options unique to the MA-CONTROL procedure are listed in [Table 9.7](#), and are described in detail in the section “[Dictionary of Special Options](#)” on page 892. Options that are common to both the MA-CONTROL and SHEWHART procedures are listed in [Table 9.8](#). They are described in detail in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 9.7 MACHART Statement Special Options

Option	Description
Options for Specifying Uniformly Weighted Moving Average Charts	
ALPHA=	requests probability limits for control charts
ASYMPTOTIC	requests constant control limits
LIMITN=	specifies either a fixed nominal sample size (n) for control limits or allows the control limits to vary with subgroup sample size
MU0=	specifies a standard (known) value μ_0 for the process mean
NOREADLIMITS	specifies that control limit parameters are not to be read from LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from LIMITS= data set when both variables are available
READINDEX=	reads control limit parameters from the first observation in the LIMITS= data set where the variable <code>_INDEX_</code> equals <i>value</i>
READLIMITS	reads control limit parameters from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMA0=	specifies standard (known) value σ_0 for process standard deviation
SIGMAS=	specifies width of control limits in terms of multiple k of standard error of plotted moving averages
SPAN=	specifies the number of terms in the moving average
Options for Plotting Subgroup Means	
CMEANSYMBOL=	specifies color for MEANSYMBOL= symbol
MEANCHAR=	specifies <i>character</i> to plot subgroup means on line printer charts
MEANSYMBOL=	specifies symbol to plot subgroup means in traditional graphics

Table 9.8 MACHART Statement General Options

Option	Description
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITLABEL	suppresses labels for control limits and central line

Table 9.8 continued

Option	Description
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
XSMBOL=	specifies label for central line
Process Mean and Standard Deviation Options	
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on moving average chart
ALLLABEL2=	labels every point on trend chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
NOTRENDCONNECT	suppresses line segments that connect points on trend chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles

Table 9.8 continued

Option	Description
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of moving average chart
VAXIS2=	specifies major tick mark values for vertical axis of trend chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur

Table 9.8 continued

Option	Description
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
TRENDVAR=	specifies list of trend variables
YPCT1=	specifies length of vertical axis on moving average chart as a percentage of sum of lengths of vertical axes for moving average and trend charts
ZEROSTD	displays moving average chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on moving average chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on moving average chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on moving average chart

Table 9.8 continued

Option	Description
VREF2=	specifies position of reference lines perpendicular to vertical axis on trend chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to moving average chart
ANNOTATE2=	specifies annotate data set that adds features to trend chart
DESCRIPTION=	specifies description of moving average chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of moving average chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
WTREND=	specifies width of line segments connecting points on trend chart
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points

Table 9.8 *continued*

Option	Description
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart

Table 9.8 continued

Option	Description
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the <code>OUTHISTORY=</code> data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set

Table 9.8 continued

Option	Description
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on moving average chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
VREFCHAR=	specifies line character for VREF= and VREF2= lines

Dictionary of Special Options

The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply only to traditional graphics and line printer charts, respectively.

ALPHA=value

requests *probability limits*. If you specify ALPHA= α , the control limits are computed so that the probability is α that a single moving average exceeds its control limits. The value of α can range between 0 and 1. This assumes that the process is in statistical control and that the data follow a normal distribution. For the equations used to compute probability limits, see “Control Limits” on page 896.

Note the following:

- As an alternative to specifying ALPHA= α , you can read α from the variable `_ALPHA_` in a LIMITS= data set by specifying the READALPHA option.
- As an alternative to specifying ALPHA= α (or reading `_ALPHA_` from a LIMITS= data set), you can request “ $k\sigma$ control limits” by specifying SIGMAS= k (or reading `_SIGMAS_` from a LIMITS= data set).

If you specify neither the ALPHA= option nor the SIGMAS= option, the procedure computes 3σ control limits by default.

ASYMPTOTIC

requests constant upper and lower control limits for all subgroups having the following values:

$$\begin{aligned} \text{LCL} &= \bar{\bar{X}} - \frac{k\hat{\sigma}}{\sqrt{nw}} \\ \text{UCL} &= \bar{\bar{X}} + \frac{k\hat{\sigma}}{\sqrt{nw}} \end{aligned}$$

Here w is the span of the moving average, and n is the nominal sample size associated with the control limits. Substitute $\Phi^{-1}(1 - \alpha/2)$ for k if you specify probability limits with the ALPHA= option. When you do not specify the ASYMPTOTIC option, the control limits are computed using the exact formulas in Table 9.9. Use the ASYMPTOTIC option only if all the subgroup sample sizes are the same or if you specify LIMITN= n .

CMEANSYMBOL=color

Traditional Graphics

specifies the *color* for the symbol requested with the MEANSYMBOL= option.

LIMITN=n

LIMITN=VARYING

specifies either a fixed or varying nominal sample size for the control limits.

If you specify LIMITN= n , moving averages are calculated and displayed only for those subgroups with a sample size equal to n , unless you also specify the ALLN option, which causes all the moving averages to be calculated and displayed. By default (or if you specify LIMITN=VARYING), moving averages are calculated and displayed for all subgroups, regardless of sample size.

MEANCHAR='character'

specifies a *character* used to plot the subgroup mean for each subgroup. By default, subgroup *Line Printer* means are not plotted.

MEANSYMBOL=keyword

specifies a symbol used to plot the subgroup mean for each subgroup. By default, subgroup *Traditional Graphics* means are not plotted.

MU0=value

specifies a known (standard) value μ_0 for the process mean μ . By default, μ is estimated from the data.

NOTE: As an alternative to specifying $MU0=\mu_0$, you can read a predetermined value for μ_0 from the variable `_MEAN_` in a `LIMITS=` data set.

See [Example 9.6](#).

NOREADLIMITS

specifies that control limit parameters for each *process* listed in the MACHART statement are *not* to be read from the `LIMITS=` data set specified in the PROC MACONTROL statement. The NOREADLIMITS option is available only in SAS 6.10 and later releases.

The following example illustrates the NOREADLIMITS option:

```
proc macontrol data=Pistons limits=Diamlim;
  machart Diameter*Hour;
  machart Diameter*Hour / noreadlimits span=3;
run;
```

The first MACHART statement reads the control limits from the first observation in the data set `Diamlim` for which the variable `_VAR_` is equal to 'Diameter' and the variable `_SUBGRP_` is equal to 'Hour'. The second MACHART statement computes estimates of the process mean and standard deviation for the control limits from the measurements in the data set `Pistons`. Note that the second MACHART statement is equivalent to the following statements, which would be more commonly used:

```
proc macontrol data=Pistons;
  machart Diameter*Hour / span=3;
run;
```

For more information about reading control limit parameters from a `LIMITS=` data set, see the `READLIMITS` option later in this list.

READALPHA

specifies that the variable `_ALPHA_`, rather than the variable `_SIGMAS_`, is to be read from a `LIMITS=` data set when both variables are available in the data set. Thus the limits displayed are probability limits. If you do not specify the `READALPHA` option, then `_SIGMAS_` is read by default.

READINDEX= 'value'

reads control limit parameters from a LIMITS= data set (specified in the PROC MACONTROL statement) for each *process* listed in the MACHART statement. The control limit parameters for a particular *process* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup-variable*
- the value of `_INDEX_` matches *value*

The *value* can be up to 48 characters and must be enclosed in quotes.

READLIMITS

specifies that control limit parameters are to be read from a LIMITS= data set specified in the PROC MACONTROL statement. The parameters for a particular *process* are read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup variable*

The use of the READLIMITS option depends on which release of SAS/QC software you are using.

- **In SAS 6.10 and later releases, the READLIMITS option is not necessary.** To read control limits parameters as described previously, you simply specify a LIMITS= data set. However, even though the READLIMITS option is redundant, it continues to function as in earlier releases.
- **In SAS 6.09 and earlier releases, you must specify the READLIMITS option to read control limits parameters as described previously.** If you specify a LIMITS= data set without specifying the READLIMITS option (or the READINDEX= option), the control limits are computed from the data and the span of the moving averages is specified with the SPAN= option.

SIGMA0=value

specifies a known (standard) value σ_0 for the process standard deviation σ . The *value* must be positive. By default, the MACONTROL procedure estimates σ from the data using the formulas given in “[Methods for Estimating the Standard Deviation](#)” on page 907.

NOTE: As an alternative to specifying $\text{SIGMA0}=\sigma_0$, you can read a predetermined value for σ_0 from the variable `_STDDEV_` in a LIMITS= data set.

SIGMAS=value

specifies the width of the control limits in terms of the multiple k of the standard error of the plotted moving averages on the chart. The value of k must be positive. By default, $k = 3$ and the control limits are 3σ limits.

SPAN=value

specifies the number of terms used to calculate the moving average (*value* is an integer greater than 1). The SPAN= option is required unless you read control limit parameters from a LIMITS= data set or a TABLE= data set. See “Plotted Points” on page 895 and “Choosing the Span of the Moving Average” on page 897 for details.

Details: MACHART Statement

Constructing Uniformly Weighted Moving Average Charts

The following notation is used in this section:

A_i	uniformly weighted moving average for the i th subgroup
w	span parameter (number of terms in moving average)
μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
x_{ij}	j th measurement in i th subgroup, with $j=1, 2, 3, \dots, n_i$
n_i	sample size of i th subgroup
\bar{X}_i	mean of measurements in i th subgroup. If $n_i = 1$, then the subgroup mean reduces to the single observation in the subgroup.
$\bar{\bar{X}}$	weighted average of subgroup means
$\Phi^{-1}(\cdot)$	inverse standard normal function

Plotted Points

Each point on the chart indicates the value of the uniformly weighted moving average for that subgroup. The moving average for the i th subgroup (A_i) is defined as

$$A_i = (\bar{X}_1 + \dots + \bar{X}_i)/i \quad \text{if } i < w$$

$$A_i = (\bar{X}_i + \dots + \bar{X}_{i-w+1})/w \quad \text{if } i \geq w$$

where w is the span, or number of terms, of the moving average. You can specify the span with the SPAN= option in the MACHART statement or with the value of `_SPAN_` in a LIMITS= data set.

Central Line

By default, the central line on a moving average chart indicates an estimate for μ , which is computed as

$$\hat{\mu} = \bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \dots + n_N \bar{X}_N}{n_1 + \dots + n_N}$$

If you specify a known value (μ_0) for μ , the central line indicates the value of μ_0 .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of A_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that A_i exceeds the limits

The following table presents the formulas for the limits:

Table 9.9 Limits for Moving Average Chart

Control Limits
$\text{LCL} = \bar{\bar{X}} - k(\hat{\sigma} / \min(i, w)) \sqrt{(1/n_i) + (1/n_{i-1}) + \dots + (1/n_{1+\max(i-w,0)})}$
$\text{UCL} = \bar{\bar{X}} + k(\hat{\sigma} / \min(i, w)) \sqrt{(1/n_i) + (1/n_{i-1}) + \dots + (1/n_{1+\max(i-w,0)})}$
Probability Limits
$\text{LCL} = \bar{\bar{X}} - \Phi^{-1}(1 - \alpha/2)(\hat{\sigma} / \min(i, w)) \sqrt{(1/n_i) + (1/n_{i-1}) + \dots + (1/n_{1+\max(i-w,0)})}$
$\text{UCL} = \bar{\bar{X}} + \Phi^{-1}(1 - \alpha/2)(\hat{\sigma} / \min(i, w)) \sqrt{(1/n_i) + (1/n_{i-1}) + \dots + (1/n_{1+\max(i-w,0)})}$

These formulas assume that the data are normally distributed. If standard values μ_0 and σ_0 are available for μ and σ , respectively, replace $\bar{\bar{X}}$ with μ_0 and replace $\hat{\sigma}$ with σ_0 in Table 9.9. Note that the limits vary with both n_i and i .

If the subgroup sample sizes are constant ($n_i = n$), the formulas for the control limits simplify to

$$\begin{aligned} \text{LCL} &= \bar{\bar{X}} - \frac{k\hat{\sigma}}{\sqrt{n \min(i, w)}} \\ \text{UCL} &= \bar{\bar{X}} + \frac{k\hat{\sigma}}{\sqrt{n \min(i, w)}} \end{aligned}$$

Refer to Montgomery (1996) for more details. When the subgroup sample sizes are constant, the width of the control limits for the first w moving averages decreases monotonically because each of the first w moving averages includes one more term than the preceding moving average.

If you specify the ASYMPTOTIC option, constant control limits with the following values are displayed:

$$\begin{aligned} \text{LCL} &= \bar{\bar{X}} - \frac{k\hat{\sigma}}{\sqrt{nw}} \\ \text{UCL} &= \bar{\bar{X}} + \frac{k\hat{\sigma}}{\sqrt{nw}} \end{aligned}$$

For asymptotic probability limits, replace k with $\Phi^{-1}(1 - \alpha/2)$ in these equations. You can display asymptotic limits by specifying the ASYMPTOTIC option.

You can specify parameters for the moving average limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify w with the SPAN= option or with the variable `_SPAN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

Choosing the Span of the Moving Average

There are few published guidelines for choosing the span w . In some applications, practical experience may dictate the choice of w . A more systematic approach is to choose w by considering its effect on the average run length (the expected number of points plotted before a shift is detected). This effect was studied by Roberts (1959), who used simulation methods.

You can use Table 9.10 and Table 9.11 to find a combination of k and w that yields a desired ARL for an in-control process ($\delta = 0$) and for a specified shift of δ .

3.5	5.00	1.49	1.74	1.91	2.06	2.21	2.48	2.71

For example, suppose you want to construct a two-sided moving average chart with an in-control ARL of 100 and an ARL of 9 for detecting a shift of $\delta = 1$. [Table 9.11](#) shows that the combination $w = 3$ and $k = 2.5$ yields an in-control ARL of 101.24 and an ARL of 8.61 for $\delta = 1$.

Note that you can also use [Table 9.10](#) and [Table 9.11](#) to evaluate an existing moving average chart (see [Example 9.7](#)).

The following SAS program computes the average run length for a two-sided moving average chart for various shifts in the mean. This program can be adapted to compute averages run lengths for various combinations of k and w .

```

data sim;
  drop span delta time j y x;
  span=4;
  do shift=0, .25, .5, .75, 1, 1.5, 2, 2.5, 3, 4, 5;
    do j=1 to 50000;
      do time=1 to 15000;
        if time<=100 then
          delta=0;
        else
          delta=shift;
          y=delta+rannor(234);
          if time<span then
            x=.;
          else
            x=(y+lag1(y)+lag2(y)+lag3(y))/span;
            if time>=101 and abs(x)>3/sqrt(span)
              then leave;
          end;
          arl=time-100;
          output;
        end;
      end;
    end;
  end;

proc means;
  class shift;
run;

```

In the preceding program, the size of the span w (SPAN) is 4 and the shifts in the mean are introduced to the variable (Y) $y \sim N(0, 1)$ after the first 100 observations. The first DO loop specifies shifts of various magnitude, the second DO loop performs 50000 simulations for each shift, and the third DO loop counts the run length (TIME), that is, the number of samples observed before the control chart signals. A large upper bound (15000) for TIME is specified so that the run length is uncensored.

The program can be generalized for various span sizes by assigning a different value for the variable SPAN and changing the expression for X appropriately. Optionally, you can compute the ARL for a one-sided chart by changing the limits, that is, $x > 3/\text{sqrt}(\text{span})$. This was the technique used to construct Table 9.10 and Table 9.11.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves the control limit parameters. The following variables can be saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTLIMITS= option
<code>_LIMITN_</code>	sample size associated with the control limits
<code>_MEAN_</code>	process mean (\bar{X} or μ_0)
<code>_SIGMAS_</code>	multiple (k) of standard error of A_i
<code>_SPAN_</code>	number of terms in the moving average
<code>_STDDEV_</code>	process standard deviation ($\hat{\sigma}$ or σ_0)
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the MACHART statement
<code>_TYPE_</code>	type (estimate or standard value) of <code>_MEAN_</code> and <code>_STDDEV_</code>
<code>_VAR_</code>	<i>process</i> specified in the MACHART statement

The OUTLIMITS= data set does not contain the control limits; instead, it contains control limit parameters that can be used to recompute the control limits.

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variable `_LIMITN_`.
2. If the limits are defined in terms of a multiple k of the standard error of A_i , the value of `_ALPHA_` is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.
3. If the limits are probability limits, the value of `_SIGMAS_` is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.
4. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the MACHART statement.

You can use OUTLIMITS= data sets

- to keep a permanent record of the control limit parameters
- to write reports. You may prefer to use OUTTABLE= data sets for this purpose.
- as LIMITS= data sets in subsequent runs of PROC MACONTROL

For an example of an OUTLIMITS= data set, see “Saving Control Limit Parameters” on page 878.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables can be saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup standard deviation variable named by *process* suffixed with *S*
- a subgroup moving average variable named by *process* suffixed with *A*
- a subgroup sample size variable named by *process* suffixed with *N*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the MACHART statement. For example, consider the following statements:

```
proc macontrol data=Clips;
    machart (Gap Yieldstrength)*Day / span      =3
                                outhistory=Cliphist;
run;
```

The data set Cliphist would contain nine variables named Day, GapX, GapS, GapA, GapN, YieldstrengthX, YieldstrengthS, YieldstrengthA, and YieldstrengthN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “Saving Summary Statistics” on page 877.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables can be saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on moving average chart
<code>_LCLA_</code>	lower control limit for moving average
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>_SPAN_</code>	number of terms in the moving average
<code>subgroup</code>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_SUBX_</code>	subgroup mean
<code>_UCLA_</code>	upper control limit for moving average
<code>_UWMA_</code>	uniformly weighted moving average
<code>_VAR_</code>	<i>process</i> specified in MACHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)
- *symbol-variable*

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively; or with the corresponding variables in a LIMITS= data set).
2. The variables `_VAR_` and `_EXLIM_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. All other variables are numeric.

For an example of an OUTTABLE= data set, see “Saving Control Limit Parameters” on page 878.

ODS Tables

The following table summarizes the ODS tables that you can request with the MACHART statement.

Table 9.12 ODS Tables Produced with the MACHART Statement

Table Name	Description	Options
MACHART	uniformly weighted moving average chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT
Parameters	uniformly weighted moving average parameters	TABLE, TABLEALL, TABLEC, TABLEID, TABLEOUT

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the MACONTROL procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. MACHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018

When ODS Graphics is in effect, the MACHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 9.13](#).

Table 9.13 ODS Graphics Produced by the MACHART Statement

ODS Graph Name	Plot Description
MACHart	moving average chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC MACONTROL statement. Each *process* specified in the MACHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the MACHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the MACONTROL procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Moving Average Charts from Raw Data](#)” on page 870.

LIMITS= Data Set

You can read preestablished control limits parameters from a LIMITS= data set specified in the PROC MACONTROL statement. The LIMITS= data set used by the MACONTROL procedure does not contain the actual control limits, but rather it contains the parameters required to compute the limits. For example, the following statements read control limit parameters from the data set PARMS:⁵

```
proc macontrol data=Parts limits=Parms;
  machart Gap*Day;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the MACONTROL procedure. Such data sets always contain the variables required for a LIMITS= data set; see the section “[OUTLIMITS= Data Set](#)” on page 900. The LIMITS= data set can also be created directly using a DATA step.

When you create a LIMITS= data set, you must provide the variable `_SPAN_`, which specifies the number of terms to use in the moving average. In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables of length 8.
- The variable `_INDEX_` is required if you specify the READINDEX= option. This must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8. Valid values are ‘ESTIMATE’, ‘STANDARD’, ‘STDMEAN’, and ‘STDSIGMA’.
- BY variables are required if specified with a BY statement.

Some advantages of working with a LIMITS= data set are that

- it facilitates reusing a permanently saved set of parameters
- a distinct set of parameters can be read for each *process* specified in the MACHART statement
- it facilitates keeping track of multiple sets of parameters that accumulate for the same *process* as the process evolves over time

For an example, see “[Reading Preestablished Control Limit Parameters](#)” on page 880.

⁵In SAS 6.09 and earlier releases, it is necessary to specify the READLIMITS option.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC MACONTROL statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the MACONTROL, SHEWHART, or CUSUM procedures or to read output data sets created with SAS summarization procedures such as PROC MEANS.

A HISTORY= data set used with the MACHART statement must contain the following:

- the *subgroup-variable*
- a subgroup mean variable for each *process*
- a subgroup sample size variable for each *process*
- a subgroup standard deviation variable for each *process*

The names of the subgroup mean, subgroup standard deviation, and subgroup sample size variables must be the *process* name concatenated with the suffix characters *X*, *S*, and *N*, respectively.

For example, consider the following statements:

```
proc macontrol history=Cliphist;
  machart (Gap Diameter)*Day / span=3;
run;
```

The data set Cliphist must include the variables Day, GapX, GapS, GapN, DiameterX, DiameterS, and DiameterN.

Although a moving average variable (named by the *process* name suffixed with *A*) is saved in an OUTHISTORY= data set, it is not required in a HISTORY= data set, because the subgroup mean variable is sufficient to compute the moving averages.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the MACONTROL procedure reads all the observations in a HISTORY= data set. However, if the HISTORY= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating Moving Average Charts from Subgroup Summary Data](#)” on page 874.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC MACONTROL statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the MACONTROL procedure.

The following table lists the variables required in a TABLE= data set used with the MACHART statement:

Variable	Description
LCLE	lower control limit for Moving Average
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
SPAN	number of terms in the moving average
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBN	subgroup sample size
SUBS	subgroup standard deviation
SUBX	subgroup mean
UCLA	upper control limit for moving average
UWMA	uniformly weighted moving average

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable of length 8.

For an example of a TABLE= data set, see “Saving Control Limit Parameters” on page 878.

Methods for Estimating the Standard Deviation

When control limits are computed from the input data, four methods are available for estimating the process standard deviation σ . Three methods (referred to as the default, MVLUE, and RMSDF) are available with subgrouped data. A fourth method is used if the data are individual measurements (see “Default Method for Individual Measurements” on page 909).

Default Method for Subgroup Samples

This method is the default for moving average charts using subgrouped data. The default estimate of σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \dots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the i th subgroup

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2) \sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, then the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method for Subgroup Samples

If you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1 / c_4(n_1) + \dots + h_N s_N / c_4(n_N)}{h_1 + \dots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

RMSDF Method for Subgroup Samples

If you specify SMETHOD=RMSDF, a weighted root-mean-square estimate is computed for σ as follows:

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \dots + (n_N - 1)s_N^2}}{c_4(n) \sqrt{n_1 + \dots + n_N - N}}$$

The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, in process control applications it is generally not assumed that σ is constant, and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Default Method for Individual Measurements

When each subgroup sample contains a single observation ($n_i \equiv 1$), the process standard deviation σ is estimated as

$$\hat{\sigma} = \sqrt{\frac{1}{2(N-1)} \sum_{i=1}^{N-1} (x_{i+1} - x_i)^2}$$

where N is the number of observations, and x_1, x_2, \dots, x_N are the individual measurements. This formula is given by Wetherill (1977), who states that the estimate of the variance is biased if the measurements are autocorrelated.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup mean variable
Vertical	TABLE=	<code>_UWMA_</code>

For example, the following sets of statements specify the label *Moving Average of Clip Gaps* for the vertical axis and the label *Day* for the horizontal axis of the moving average chart:

```
proc macontrol data=Clips1;
  machart Gap*Day / span=4;
  label Gap = 'Moving Average of Clip Gaps';
  label Day = 'Day';
run;

proc macontrol history=cliphist;
  machart Gap*Day / span=4;
  label GapX = 'Moving Average of Clip Gaps';
  label Day = 'Day';
run;

proc macontrol table=cliptab;
  machart Gap*Day;
  label _uwma_ = 'Moving Average of Clip Gaps';
  label Day = 'Day';
run;
```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: MACHART Statement

This section provides advanced examples of the MACHART statement.

Example 9.6: Specifying Standard Values for the Process Mean and Process Standard Deviation

See MACMA2 in the SAS/QC Sample Library

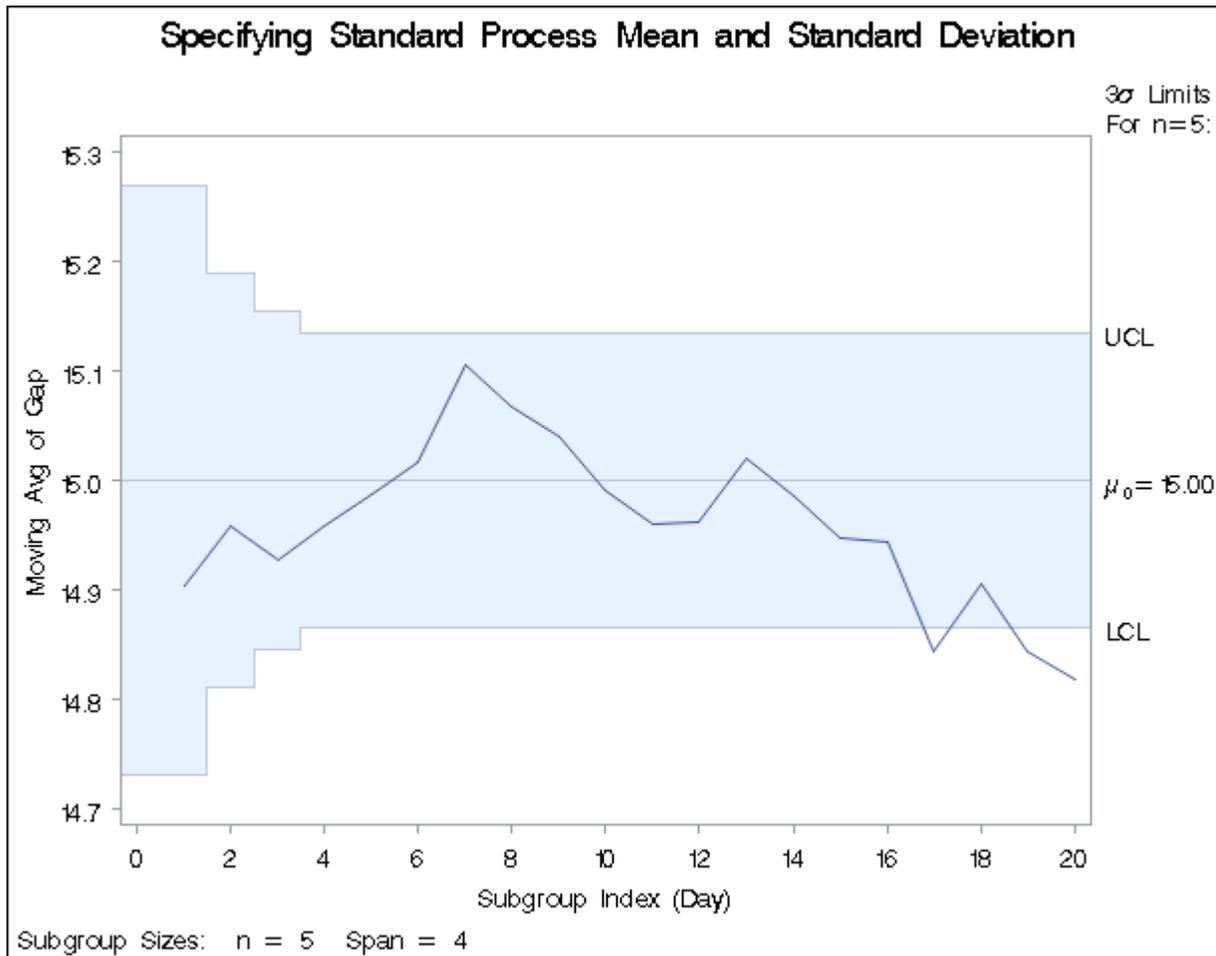

By default, the MACHART statement estimates the process mean (μ) and standard deviation (σ) from the data. This is illustrated in the “Getting Started” section of this chapter. However, there are applications in which standard values (μ_0 and σ_0) are available based, for instance, on previous experience or extensive sampling. You can specify these values with the MU0= and SIGMA0= options.

For example, suppose it is known that the metal clip manufacturing process (introduced in “Creating Moving Average Charts from Raw Data” on page 870) has a mean of 15 and standard deviation of 0.2. The following statements specify these standard values:

```
ods graphics off;
symbol h = .8;
title 'Specifying Standard Process Mean and Standard Deviation';
proc macontrol data=Clips1;
  machart Gap*Day /
    mu0      = 15
    sigma0   = 0.2
    span     = 4
    xsymbol  = mu0;
run;
```

The XSYMBOL= option specifies the label for the central line. The resulting chart is shown in Output 9.6.1.

Output 9.6.1 Specifying Standard Values with MU0= and SIGMA0=

The central line and control limits are determined using μ_0 and σ_0 (see the equations in Table 9.9). Output 9.6.1 indicates that the process is out-of-control since the moving averages for Day=17, Day=19, and Day=20 lie below the lower control limit.

You can also specify μ_0 and σ_0 with the variables `_MEAN_` and `_STDDEV_` in a LIMITS= data set, as illustrated by the following statements:

```
data cliplim;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Gap';
  _subgrp_ = 'Day';
  _type_  = 'STANDARD';
  _limitn_ = 5;
  _mean_  = 15;
  _stddev_ = 0.2;
  _span_  = 4;
run;

proc macontrol data=Clips1 limits=Cliplim;
  machart Gap*Day / xsymbol=mu0;
run;
```

The variable `_SPAN_` is required, and its value provides the number of terms in the moving average. The variables `_VAR_` and `_SUBGRP_` are also required, and their values must match the *process* and *subgroup-variable*, respectively, specified in the MACHART statement. The bookkeeping variable `_TYPE_` is not required, but it is recommended to indicate that the variables `_MEAN_` and `_STDDEV_` provide standard values rather than estimated values.

The resulting chart (not shown here) is identical to the one shown in [Output 9.6.1](#).

Example 9.7: Annotating Average Run Lengths on the Chart

See *MACMA3 in the SAS/QC Sample Library*

You can use [Table 9.10](#) and [Table 9.11](#) to find a moving average chart scheme with the desired average run length properties. Specifically, you can find a combination of k and w that yields a desired ARL for an in-control process ($\delta = 0$) and for a specified shift of δ .

You can also use these tables to evaluate an existing moving average chart scheme. For example, the moving average chart shown in [Output 9.6.1](#) has a two-sided scheme with $w = 4$ and $k = 3$. Suppose you want to detect a shift of $\delta = .5$. From [Table 9.11](#), the average run length with $w = 4$, $k = 3$, and $\delta = .5$ is 72.47. The in-control average run length ($\delta = 0$) for this scheme is 481.16.

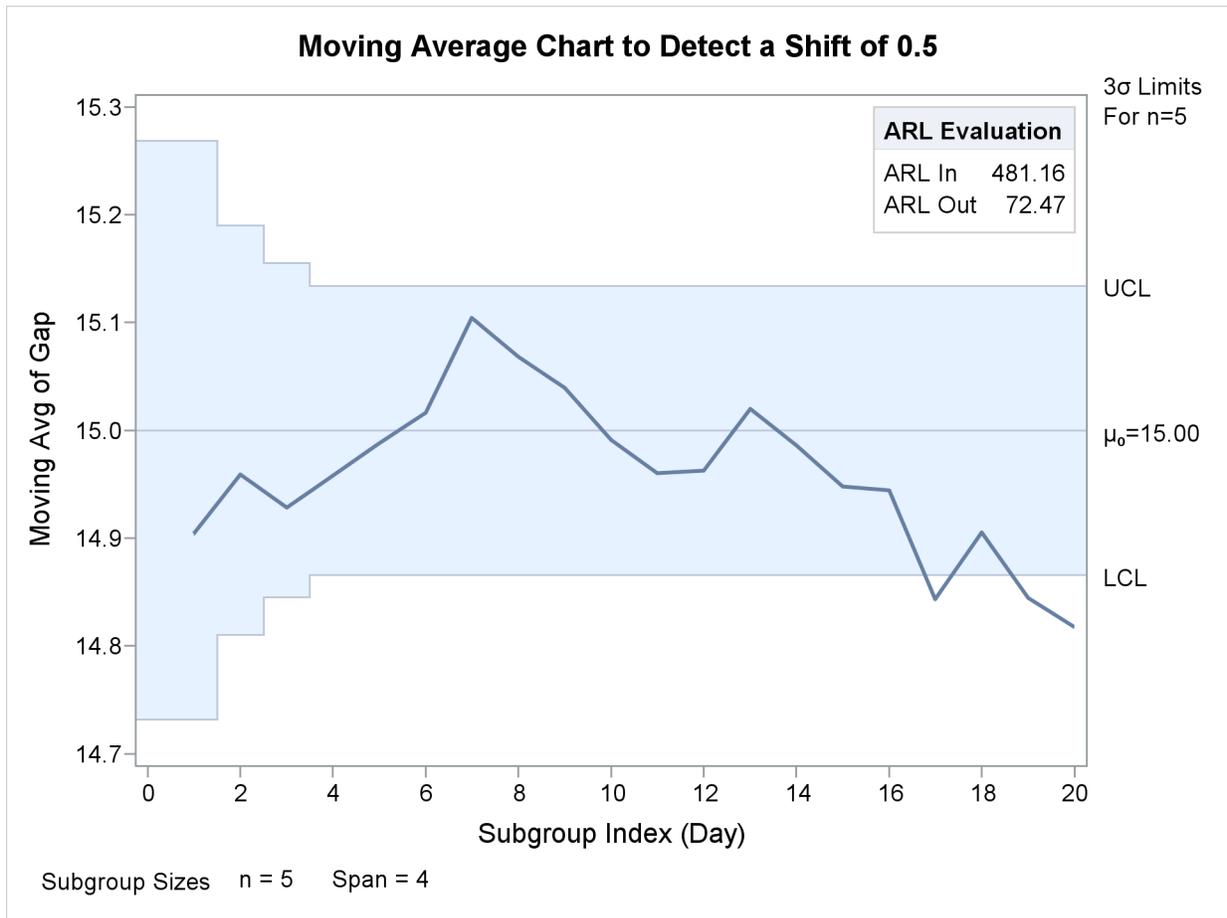

The following statements create an inset data set that can be read to display these ARL values on the moving average chart:

```
data ARLinset;
  length _label_ $ 8;
  _label_ = 'ARL In';
  _value_ = 481.16;
  output;
  _label_ = 'ARL Out';
  _value_ = 72.47;
  output;
run;
```

The following statements create the moving average chart shown in [Output 9.7.1](#).

```
title 'Moving Average Chart to Detect a Shift of 0.5';
ods graphics on;
proc macontrol data=Clips1;
  machart Gap*Day / mu0      = 15
                  sigma0    = 0.2
                  span      = 4
                  xsymbol    = mu0
                  odstitle   = title;
  inset data = ARLinset / header = 'ARL Evaluation'
                  pos        = ne;
run;
```

The average run lengths in this example (481.16 and 72.27) are simply copied from [Table 9.11](#). You can generalize the preceding program so that it computes the average run lengths by incorporating the [simulation program](#) from the section “Choosing the Span of the Moving Average” on page 897.

Output 9.7.1 Displaying Average Run Lengths on Chart

For more information on annotating charts with insets, refer to “INSET Statement: MACONTROL Procedure” on page 913.

INSET Statement: MACONTROL Procedure

Overview: INSET Statement

The INSET statement enables you to enhance a moving average control chart by adding a box or table (referred to as an *inset*) of summary statistics directly to the graph. A possible application of an inset is to present moving average parameters on the chart rather than displaying them in a legend. An inset can also display arbitrary values provided in a SAS data set.

Note that the INSET statement by itself does not produce a display but must be used in conjunction with an MACHART or EWMACHART statement. Insets are not available with line printer charts, so the INSET statement is not applicable when the LINEPRINTER option is specified in the PROC MACONTROL statement.

You can use options in the INSET statement to

- specify the position of the inset
- specify a header for the inset table
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

Getting Started: INSET Statement

This section introduces the INSET statement with a basic example showing how it is used. See “INSET and INSET2 Statements: SHEWHART Procedure” on page 2000 for a complete description of the INSET statement.

This example is based on the same scenario as the first example in the “Getting Started” section of “EWMACHART Statement: MACONTROL Procedure” on page 816. An EWMA chart is used to analyze data from the manufacture of metal clips. The following statements create a data set containing measurements to be analyzed and the EWMA chart shown in Figure 9.18.

```

data Clips1;
  input Day @ ;
  do i=1 to 5;
    input Gap @ ;
    output;
  end;
  drop i;
  datalines;
1 14.76 14.82 14.88 14.83 15.23
2 14.95 14.91 15.09 14.99 15.13
3 14.50 15.05 15.09 14.72 14.97
4 14.91 14.87 15.46 15.01 14.99
5 14.73 15.36 14.87 14.91 15.25
6 15.09 15.19 15.07 15.30 14.98
7 15.34 15.39 14.82 15.32 15.23
8 14.80 14.94 15.15 14.69 14.93
9 14.67 15.08 14.88 15.14 14.78
10 15.27 14.61 15.00 14.84 14.94
11 15.34 14.84 15.32 14.81 15.17
12 14.84 15.00 15.13 14.68 14.91
13 15.40 15.03 15.05 15.03 15.18

15 14.81 15.01 14.65 15.13 15.12
16 14.82 15.01 14.82 14.83 15.00
17 14.89 14.90 14.60 14.40 14.88
18 14.90 15.29 15.14 15.20 14.70
19 14.77 14.60 14.45 14.78 14.91
20 14.80 14.58 14.69 15.02 14.85
;

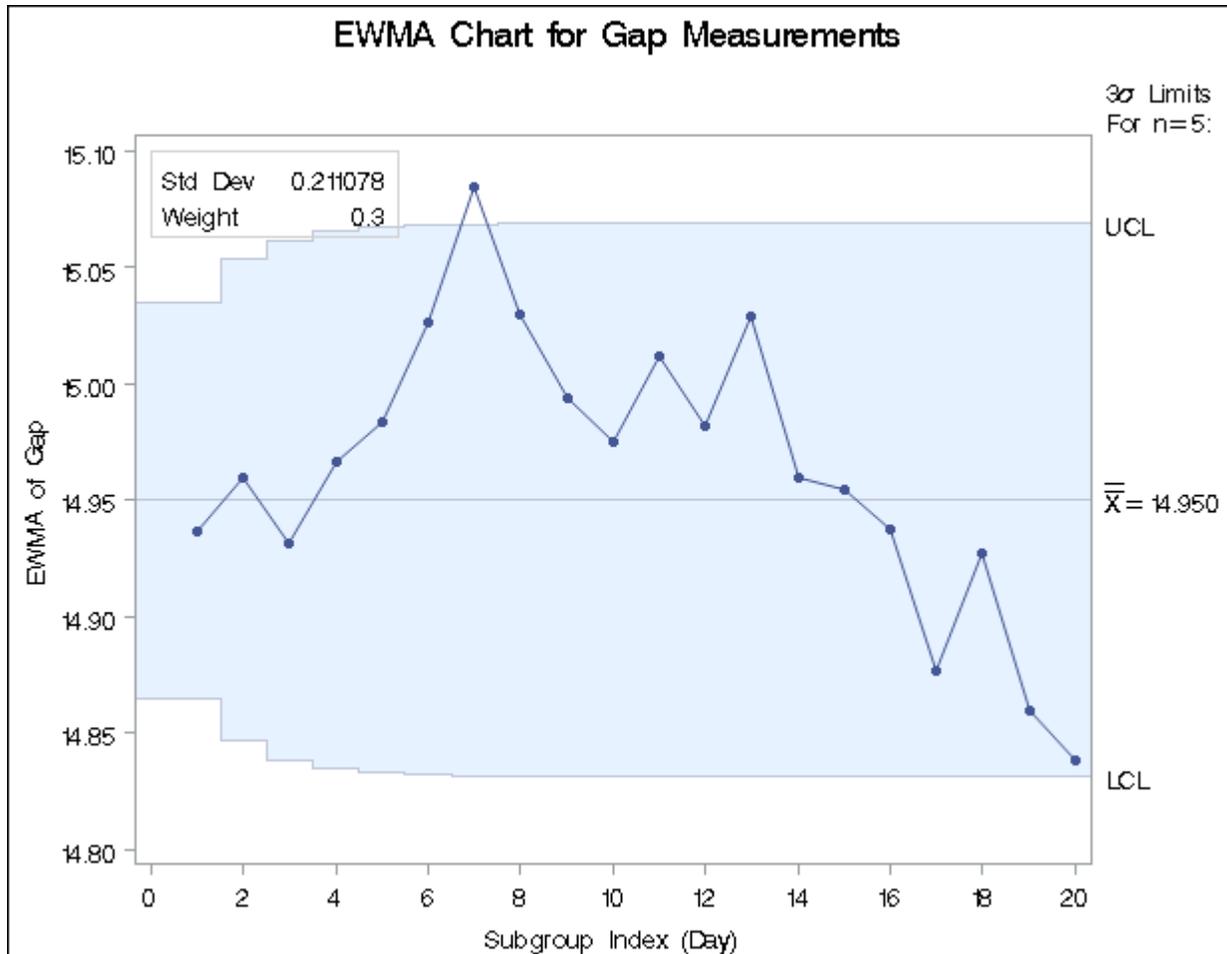

```

```

title 'EWMA Chart for Gap Measurements';
symbol v=dot;
proc macontrol data=Clips1;
  ewmachart Gap*Day / weight = 0.3
                nolegend;
  inset stddev weight;
run;

```

Figure 9.18 Exponentially Weighted Moving Average Chart with an Inset

Syntax: INSET Statement

The syntax for the INSET statement is as follows:

```
INSET keyword-list </ options> ;
```

You can use any number of INSET statements in the MACONTROL procedure. Each INSET statement produces a separate inset and must follow an [EWMACHART](#) or [MACHART](#) statement. The inset appears on every panel (page) produced by the last chart statement preceding it.

Keywords specify the statistics to be displayed in an inset; options control the inset's location and appearance. A complete description of the INSET statement syntax is given in the section “Syntax: INSET and INSET2 Statements” on page 2006 of Chapter 17, “The SHEWHART Procedure.” The INSET statement options are identical in the MACONTROL and SHEWHART procedures, but the available keywords are different. The options are listed in Table 17.87. The keywords available with the MACONTROL procedure are listed in Table 9.14 to Table 9.17.

Table 9.14 Summary Statistics

Keyword	Description
MEAN	estimated or specified process mean
N	nominal subgroup size
NMIN	minimum subgroup size
NMAX	maximum subgroup size
NOUT	number of subgroups outside control limits
NLOW	number of subgroups below lower control limit
NHIGH	number of subgroups above upper control limit
STDDEV	estimated or specified process standard deviation
DATA=	arbitrary values from <i>SAS-data-set</i>

Table 9.15 Parameter for Uniformly Weighted Moving Average Charts

Keyword	Description
SPAN	number of terms used to calculate moving average

Table 9.16 Parameter for Exponentially Weighted Moving Average Charts

Keyword	Description
WEIGHT	weight assigned to most recent subgroup mean in computation of the EWMA

You can use the keywords in Table 9.17 only when producing ODS Graphics output. The labels for the statistics use Greek letters.

Table 9.17 Keywords Specific to ODS Graphics Output

Keyword	Description
UMU	estimated or specified process mean
USIGMA	estimated or specified process standard deviation

Overview: MVP Procedures

This chapter provides an overview of the SAS/QC procedures that perform multivariate process monitoring. They are the `MVPMODEL`, `MVPMONITOR`, and `MVPDIAGNOSE` procedures, referred to collectively as the *MVP procedures*. The MVP procedures are used to monitor multivariate process variation over time in order to determine whether a process is stable, to detect changes in a stable process, and to investigate causes of unusual variation.

The `MVPMODEL` procedure builds a principal component model from multivariate process data. It uses principal component analysis (PCA) techniques that evolved in the field of chemometrics for monitoring hundreds or even thousands of correlated process variables; see Kourti and MacGregor (1995, 1996) for an introduction. A principal component model reduces the dimensionality of the data by projecting the process measurements to a low-dimensional subspace that is defined by a small number of principal components. This subspace is known as the *model hyperplane*. PROC `MVPMODEL` computes T^2 and squared prediction error (SPE) statistics based on these principal components. See Chapter 12, “[The `MVPMODEL` Procedure](#),” for details.

The principal component model and the computed statistics that PROC `MVPMODEL` produces serve as input to the `MVPMONITOR` and `MVPDIAGNOSE` procedures.

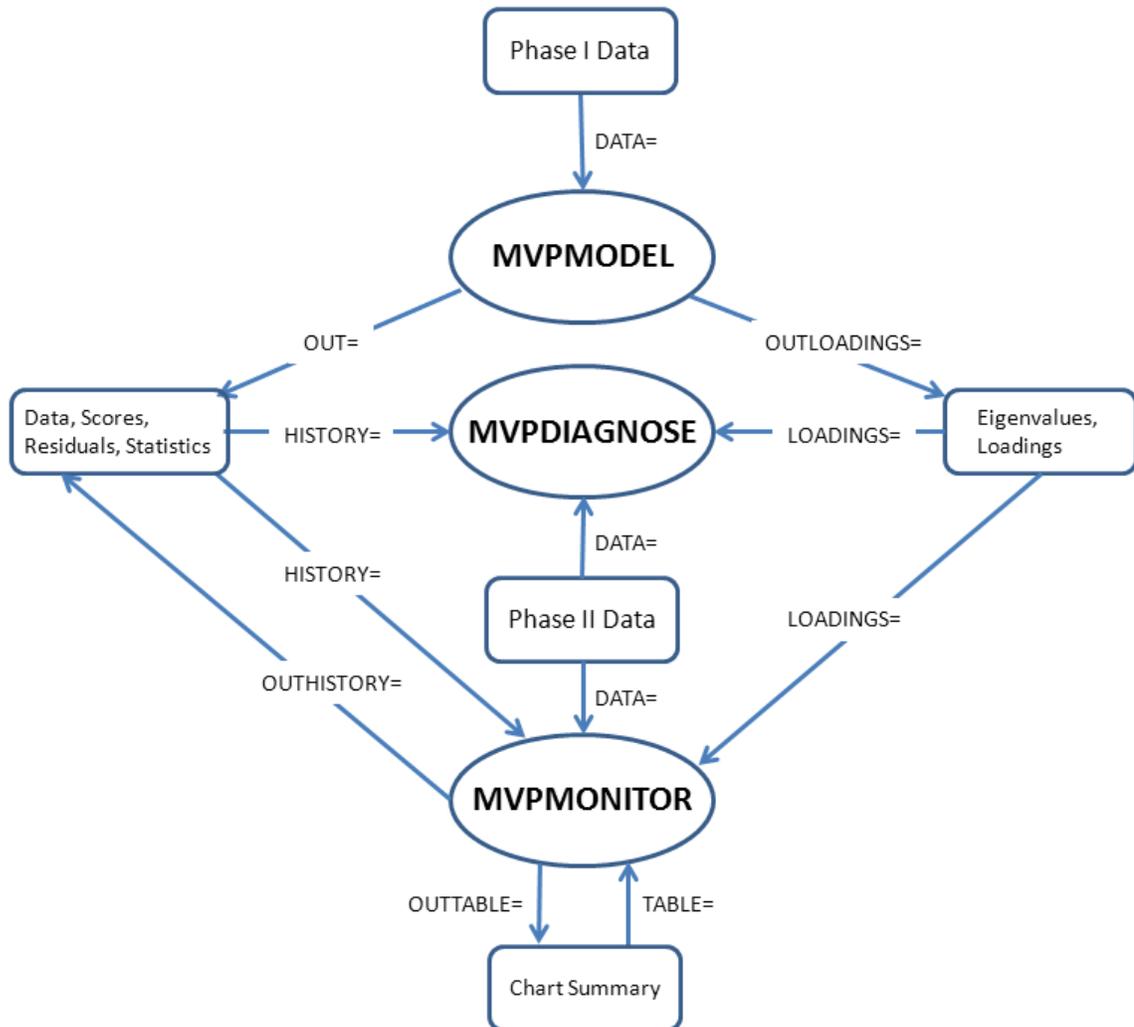

The `MVPMONITOR` procedure creates multivariate control charts of the T^2 and SPE statistics. These control charts are used to monitor and categorize variation in the process. Multivariate control charts can detect unusual variation that is not uncovered by individually monitoring the variables with univariate control charts, such as Shewhart charts. See Chapter 13, “[The `MVPMONITOR` Procedure](#),” for details.

The `MVPDIAGNOSE` procedure produces score plots and contribution plots that can be used to investigate the unusual variation. A score plot is a scatter plot of scores that are associated with a pair of principal components for the multivariate process data. A contribution plot shows the

contributions of the process variables to the T^2 or SPE statistic for a single observation. Both types of plots can be useful in understanding the unusual variation in the process. See Chapter 11, “The MVPDIAGNOSE Procedure,” for details.

Figure 10.1 shows the MVP procedures and their various inputs and outputs.

Figure 10.1 The MVP Procedures

The MVP procedures are represented by ovals. Input and output data sets are represented by rounded rectangles and labeled with brief descriptions of their contents. The arrows between procedures and data sets are labeled with the names of the procedure options that are used to specify the data sets.

The distinction between the Phase I and Phase II data shown in Figure 10.1 is discussed in the next section.

MVP Analysis Phases

The two primary scenarios for using the MVP procedures are referred to as Phase I and Phase II analysis. In Phase I analysis you build a principal component model of a process and determine whether the process is stable. In Phase II analysis you apply the model to new data to monitor the process over time.

Phase I Analysis: Building a Model of a Process

The first step in using the MVP procedures is to build a principal component model by running PROC MVPMODEL on an initial sample of process data, which is labeled “Phase I Data” in Figure 10.1. PROC MVPMODEL produces tabular and graphical output to enable you to determine an appropriate number of principal components for the model. You can also use cross validation to have the procedure automatically select the number of principal components.

After you determine the number of components, you use PROC MVPMODEL to save the eigenvalues, principal component loadings, and other information that describes the model to an `OUTLOADINGS=` data set. At the same time, you can save the Phase I data and the corresponding principal component scores, residuals, and T^2 and SPE statistics to an `OUT=` data set.

Next, you use the MVPMONITOR procedure to determine whether the process is stable. PROC MVPMONITOR reads the `OUT=` data set that is produced by PROC MVPMODEL as a `HISTORY=` data set and creates control charts for the T^2 and SPE statistics that are computed from the Phase I data. A point that falls outside a chart’s control limits indicates unusual variation.

The purpose of using a control chart to signal unusual variation is to distinguish *special cause* variation from *common cause* variation. Special causes, also referred to as *assignable causes*, are local, sporadic, or transient causes of variation, whereas common causes are inherent in a process. You should investigate out-of-control points to determine whether they signal assignable causes of variation.

Contribution plots show how the original process variables contribute to variation displayed by the T^2 and SPE charts. PROC MVPMONITOR can produce contribution plots automatically for out-of-control points. You can also use the MVPDIAGNOSE procedure to produce contribution plots of observations from the `HISTORY=` data set.

Based on your Phase I analysis, you can proceed to monitor the process by using the existing principal component model or collect more Phase I data and build a new model. The goal is to have a model of a stable process before you move on to Phase II analysis.

Phase II Analysis: Process Monitoring

In Phase II analysis you apply the principal component model that you built in Phase I to new process measurements, labeled “Phase II Data” in Figure 10.1. The MVPMONITOR and MVPDIAGNOSE procedures read Phase II data from a data set that is specified with the `DATA=` option. You must also specify the `OUTLOADINGS=` data set that was produced by PROC MVPMODEL as

a `LOADINGS=` data set. The loadings are used to compute principal component scores, residuals, and statistics for the Phase II data.

PROC MVPMONITOR can save the Phase II data and the corresponding computed values in an `OUTHISTORY=` data set. An `OUTHISTORY=` data set has the same structure as an `OUT=` data set that is produced by PROC MVPMODEL, and it can be read by the MVPMONITOR and MVPDIAGNOSE procedures as a `HISTORY=` data set, as shown in Figure 10.1.

You use PROC MVPMONITOR to produce control charts of Phase II data in order to monitor the process for continued stability. Unusual variation might indicate that the process is no longer stable. T^2 charts detect unusual variation within the model hyperplane, whereas SPE charts detect unusual variation outside the model hyperplane. Unexpected SPE chart variation might indicate that the process variation has changed such that the principal component model no longer adequately represents it. You can save a summary of a control chart by using the `OUTTABLE=` option in an `SPECHART` or `TSQUARECHART` statement in PROC MVPMONITOR. This enables you to “replay” a chart by specifying a `TABLE=` input data set. You can also read a `TABLE=` data set that was created outside PROC MVPMONITOR to display a chart with customized control limits.

In addition to producing contribution plots of Phase II data, the MVPDIAGNOSE procedure also produces score plots. Score plots can provide insight into the nature of the variation that is represented by the components. You can compare score plots of Phase II data that are produced by PROC MVPDIAGNOSE to score plots of Phase I data that are produced by PROC MVPMODEL.

Overview: MVPDIAGNOSE Procedure

The MVPDIAGNOSE procedure is used in conjunction with the MVPMODEL and MVPMONITOR procedures to monitor multivariate process variation over time, to determine whether the process is stable, and to detect and diagnose changes in a stable process. Collectively these three procedures are referred to as the *MVP procedures*. See Chapter 10, “Introduction to Multivariate Process Monitoring Procedures,” for a description of how the MVP procedures work together, and Chapter 12, “The MVPMODEL Procedure,” and Chapter 13, “The MVPMONITOR Procedure,” for details about the other MVP procedures.

The MVPDIAGNOSE procedure produces the following graphs that can provide insight into the variation in a process:

- score plots for pairs of principal components

- score plot matrices containing pairwise plots for multiple pairs of principal components
- contribution plots for individual observations
- paneled contribution plots for multiple observations

Each point in a score plot corresponds to a single observation from the input data set. A contribution plot displays the process variable contributions to a squared prediction error (SPE) or T^2 statistic from a single observation in the input data set. Therefore, each observation in the input data is independent in how PROC MVPDIAGNOSE handles it. This enables you to preprocess the input data flexibly by using the DATA step, WHERE expressions, and other SAS language elements to select the data to plot.

NOTE: ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement before invoking the procedure) in order for the MVPDIAGNOSE procedure to produce graphical output.

Getting Started: MVPDIAGNOSE Procedure

This example illustrates the basic features of the MVPDIAGNOSE procedure by using airline flight delay data available from the U.S. Bureau of Transportation Statistics at <http://www.transtats.bts.gov>. Suppose you want to compare process variable contributions for an out-of-control T^2 statistic with contributions for adjacent observations. This kind of comparison can help you understand the underlying causes of unusual variation in the process.

The following statements create a SAS data set named MWflightDelays that provides the delays for flights that originated in the midwestern United States. The data set contains variables for nine airlines: AA (American Airlines), CO (Continental Airlines), DL (Delta Airlines), F9 (Frontier Airlines), FL (AirTran Airways), NW (Northwest Airlines), UA (United Airlines), US (US Airways), and WN (Southwest Airlines).

```
data MWflightDelays;
    format flightDate MMDDYY8.;
    label flightDate='Date';
    input flightDate :MMDDYY8. AA CO DL F9 FL NW UA US WN;
    datalines;
02/01/07 14.9  7.1  7.9  8.5 14.8  4.5  5.1 13.4  5.1
02/02/07 14.3  9.6 14.1  6.2 12.8  6.0  3.9 15.3 11.4
02/03/07 23.0  6.1  1.7  0.9 11.9 15.2  9.5 18.4  7.6

    ... more lines ...

02/15/07 46.6 36.3 23.9 20.8 30.4 24.3 30.3 59.9 25.6
02/16/07 31.2 20.8 15.2 20.1  9.1 12.9 22.9 36.4 16.4
;
```

The observations for a given date are the average delays in minutes for flights that depart from the Midwest. For example, on February 2, 2007, F9 (Frontier Airlines) flights departed an average of 6.2 minutes late.

The first step in multivariate process monitoring of the data is to build a principal component model of the process variation. The following statements use `PROC MVPMODEL` to create a model with three principal components. (See Chapter 12, “The MVPMODEL Procedure,” for details.)

```
proc mvpmodel data=MWflightDelays ncomp=3 noprint
    out=mvpair outloadings=mvpairloadings;
    var AA CO DL F9 FL NW UA US WN;
run;
```

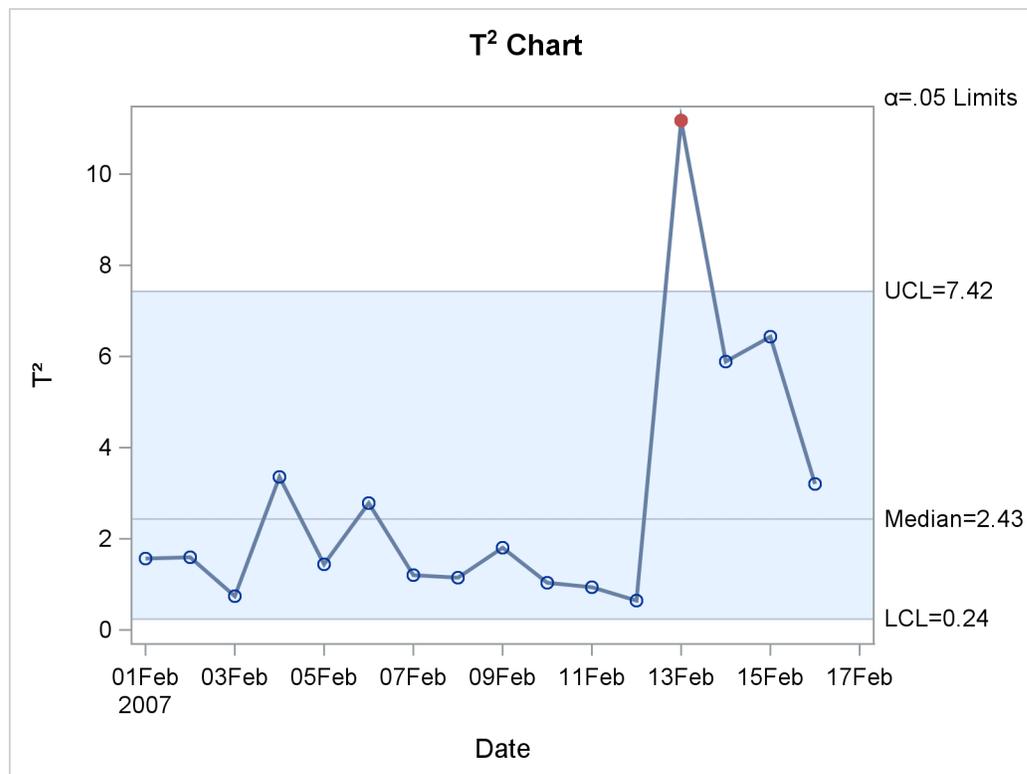

The `mvpair` data set contains the process data and associated principal component scores. The `mvpairloadings` data set contains the principal component loadings for the process variables and other data that describe the model.

The following statements create a T^2 control chart by using the principal components. (See Chapter 13, “The MVPMONITOR Procedure,” for details.)

```
ods graphics on;
proc mvpmonitor history=mvpair loadings=mvpairloadings;
    time flightDate;
    tsquarechart / contributions;
run;
```

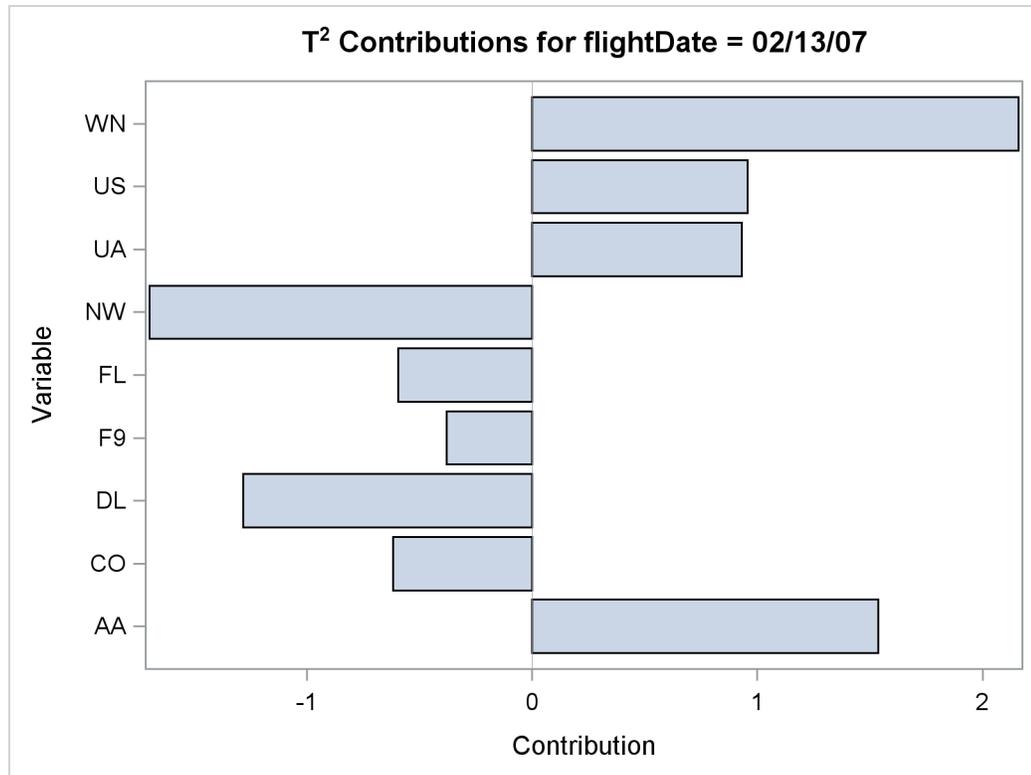

The `CONTRIBUTIONS` option produces contribution plots for any out-of-control points in the T^2 chart. Figure 11.1 shows the T^2 chart.

Figure 11.1 Multivariate Control Chart for T^2 Statistics

The T^2 chart shows an out-of-control point on February 13, 2007. Figure 11.2 shows the contribution plot for this date that was produced by the CONTRIBUTIONS option.

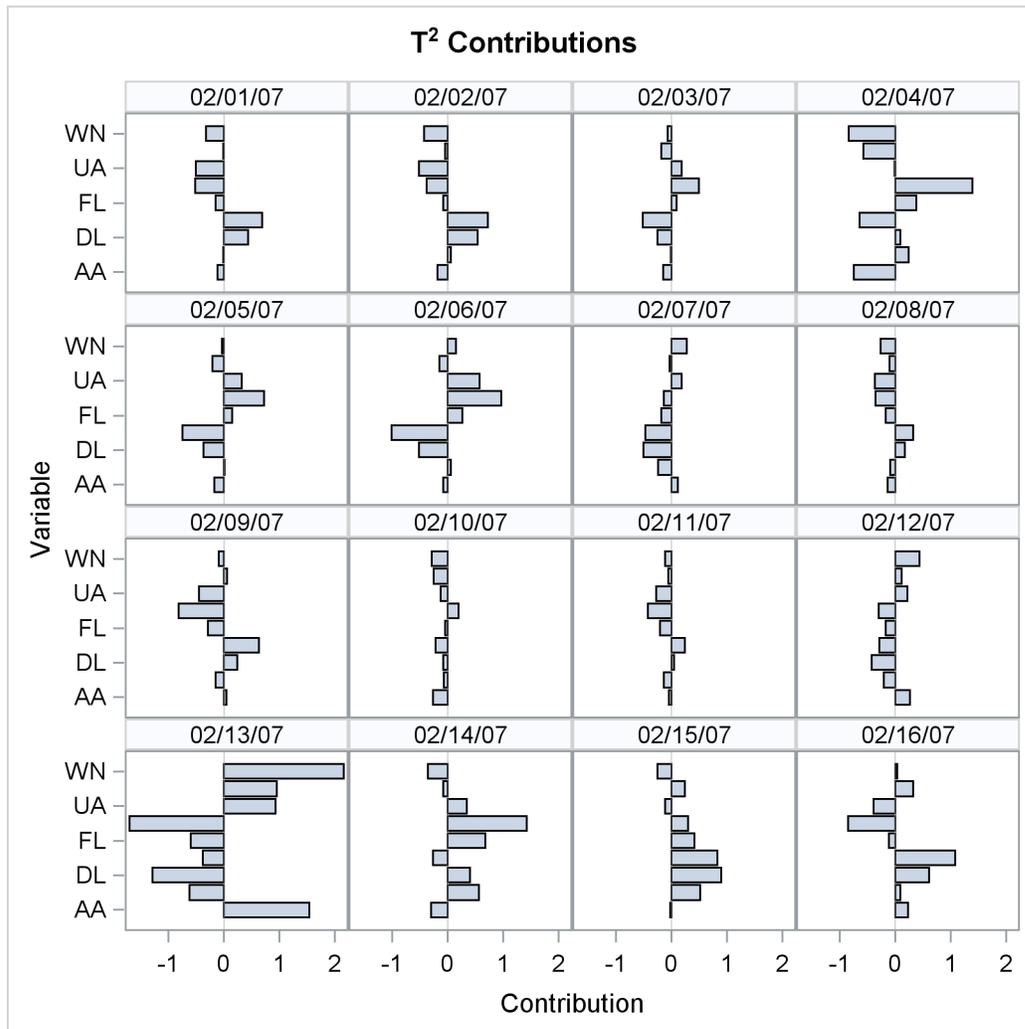

Figure 11.2 Contribution Plot for Out-of-Control Point

The contribution plot shows that the delays for airlines AA, DL, NW, and WN are the major contributors to the out-of-control point. You can use PROC MVPDIAGNOSE to compare the contributions for this point to those for adjacent points. The following statements produce paneled contribution plots of all the observations in mvpair:

```
proc mvpdiagnose history=mvpair loadings=mvpairloadings;
  time flightDate;
  contributionpanel /type=tsquare;
run;
```

Figure 11.3 shows the paneled contribution plots.

Figure 11.3 T^2 Contributions for Flight Delays

The contribution plot for February 13 is in the lower-left corner of the plot. Notice that the magnitudes of all the process variable contributions are quite large for this date compared to those for the other dates. All the process variables contributed strongly to the out-of-control T^2 statistic. This implies that something unusual occurred on February 13 that affected the flight delays for all the airlines.

In fact, on this day a strong winter storm battered the Midwest. This is an example of variation due to a *special cause*. Special causes, also referred to as *assignable causes*, are local, sporadic, or transient problems in a process. They are distinguished from *common causes* of variation, which are inherent in a system. Control charts are used to monitor the process for the occurrence of special causes and to measure and potentially to reduce the effects of common causes.

Syntax: MVPDIAGNOSE Procedure

```

PROC MVPDIAGNOSE < options > ;
  BY variables ;
  CONTRIBUTIONPANEL < / options > ;
  CONTRIBUTIONPLOT < / options > ;
  ID variables ;
  SCOREMATRIX < / options > ;
  SCOREPLOT < / options > ;
  TIME variable ;

```

The following sections describe the PROC MVPDIAGNOSE statement and then describe the other statements in alphabetical order.

PROC MVPDIAGNOSE Statement

```

PROC MVPDIAGNOSE < options > ;

```

The PROC MVPDIAGNOSE statement invokes the MVPDIAGNOSE procedure and specifies input data sets. You can specify the following *options*:

DATA=SAS-data-set

specifies an input SAS data set that contains process measurement data for a Phase II analysis. If you specify a DATA= data set, you must also specify a **LOADINGS=** data set. You cannot specify both the **HISTORY=** option and the DATA= option. See the section “**DATA= Data Set**” on page 937 for details about DATA= data sets.

HISTORY=SAS-data-set

specifies an input SAS data set that contains process variable data that are augmented with principal component scores, multivariate summary statistics, and other calculated values. Usually you create a HISTORY= data set by using the **OUT=** option in the PROC MVPMODEL statement or the **OUTHISTORY=** option in the PROC MVPMONITOR statement. You cannot specify both the DATA= option and the HISTORY= option. See the section “**HISTORY= Data Set**” on page 938 for details about HISTORY= data sets.

LOADINGS=SAS-data-set

specifies an input SAS data set that contains eigenvalues, principal component loadings, and process variable means and standard deviations that are used to compute principal component scores and multivariate summary statistics for a Phase II analysis. Usually you create a LOADINGS= data set by using the **OUTLOADINGS=** option in the PROC MVPMODEL statement. See the section “**LOADINGS= Data Set**” on page 938 for details about LOADINGS= data sets.

MISSING=AVG | NONE

specifies how observations that have missing process variable values in the DATA= data set are to be handled. The option MISSING=AVG specifies that missing values for a given variable be replaced by the average of the nonmissing values for that variable. The default is

MISSING=NONE, which excludes from the analysis any observation that has missing values for any of the process variables.

PREFIX=*name*

specifies the prefix that is used to identify variables that contain principal component scores in the **HISTORY=** data set. For example, if you specify **PREFIX=ABC**, PROC MVPDIAGNOSE attempts to read the score variables ABC1, ABC2, ABC3, and so on. The default prefix is Prin, which is also the default score variable prefix for data sets created by using the **OUT=** option in the PROC MVPMODEL statement. If you are using an **OUT=** data set from PROC MVPMODEL in the **HISTORY=** data set, the **PREFIX=** values must match. That is, the **PREFIX=** value that is specified in the PROC MVPDIAGNOSE statement must match the **PREFIX=** value in the data set that is specified in the **OUT=** option in the PROC MVPMODEL statement.

NOTE: The number of characters in the prefix plus the number of digits that are required to enumerate the principal components must not exceed the current name length defined by the **VALIDVARNAME=** system option.

RPREFIX=*name*

specifies the prefix that is used to identify variables that contain residuals in the **HISTORY=** data set. A residual variable name is formed by appending a process variable name to the prefix. The default prefix is R_, which is also the default residual variable prefix for data sets created by using the **OUT=** option in the PROC MVPMODEL statement. If you are using a data set produced with the **OUT=** option in the PROC MVPMODEL statement as a **HISTORY=** data set, the **RPREFIX=** value must match the **RPREFIX=** value specified when the **OUT=** data set was created by PROC MVPMODEL.

If the combined length of the residual prefix and a process variable name exceeds the maximum name length defined by the **VALIDVARNAME=** system option, characters are removed from the middle of the process variable name before it is appended to the residual prefix. For example, if you specify **RPREFIX=Residual_** (nine characters), the maximum variable name length is 32, and there is a process variable named PrimaryThermometerReading (25 characters), then two characters are dropped from the middle of the process variable name. The resulting residual variable name is Residual_PrimaryThermometerReading.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC MVPDIAGNOSE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the `NOTSORTED` or `DESCENDING` option in the `BY` statement for the MVPDIAGNOSE procedure. The `NOTSORTED` option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the `BY` variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the `BY` variables by using the `DATASETS` procedure (in Base SAS software).

For more information about `BY`-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the `DATASETS` procedure, see the discussion in the *Base SAS Procedures Guide*.

CONTRIBUTIONPANEL Statement

CONTRIBUTIONPANEL < /options > ;

The `CONTRIBUTIONPANEL` statement displays a paneled layout of the contribution plots for each observation in the input data set, up to a maximum specified by the `MAXNPLOTS=` option. Individual contribution plots are displayed in panels from left to right and top to bottom, and they are identified by `TIME` variable values or observation numbers. You can use the `CONTRIBUTIONPLOT` statement to display each contribution plot as a separate graph.

Table 11.1 summarizes the *options* available in the `CONTRIBUTIONPANEL` statement.

Table 11.1 CONTRIBUTIONPANEL Statement Options

Option	Description
<code>MAXNPLOTS=</code>	Specifies the maximum number of contribution plots displayed
<code>MAXNVAR=</code>	Specifies the maximum number of process variable contributions displayed in each plot
<code>NCOLS=</code>	Specifies the number of columns in the panel layout
<code>NROWS=</code>	Specifies the number of rows in the panel layout
<code>ODSFOOTNOTE=</code>	Adds a footnote to the paneled contribution plots
<code>ODSFOOTNOTE2=</code>	Adds a secondary footnote to the paneled contribution plots
<code>ODSTITLE=</code>	Specifies a title for the paneled contribution plots
<code>ODSTITLE2=</code>	Specifies a secondary title for the paneled contribution plots
<code>TYPE=</code>	Specifies the type of contribution plots produced

You can specify the following *options* in the `CONTRIBUTIONPANEL` statement. The section “Common Plot Statement Options” on page 935 describes additional options that are available in all plot statements.

MAXNPLOTS=*n*

specifies the maximum number of contribution plots to be produced by the `CONTRIBUTIONPANEL` statement. The number of plots that are produced is the minimum of *n* and the number of observations in the input data set. When *n* is less than the

number of observations, contribution plots are produced for the first n observations. The default is 50.

MAXNVAR= n

specifies the maximum number of process variable contributions to be displayed in the paneled layout. The magnitudes for each contribution are summed over the observations to be plotted, and the n contributions with the greatest total magnitudes are displayed. Therefore each plot displays contributions for the same process variables. By default, all contributions are displayed.

NCOLS= c

specifies the number of columns in the panel layout. See the section “[Paneled Contribution Plot Layouts](#)” on page 937 for a description of how the default numbers of columns and rows are calculated.

NROWS= r

specifies the number of rows in the panel layout. See the section “[Paneled Contribution Plot Layouts](#)” on page 937 for a description of how the default numbers of columns and rows are calculated.

TYPE=SPE | TSQUARE

specifies the type of contribution plots displayed. If you specify TYPE=SPE, the contribution plots are based on the SPE statistics; if you specify TYPE=TSQUARE, the contribution plots are based on the T^2 statistics. You must specify a **LOADINGS=** data set to create T^2 contribution plots. By default, TYPE=TSQUARE if a **LOADINGS=** data set is provided and TYPE=SPE otherwise.

CONTRIBUTIONPLOT Statement

CONTRIBUTIONPLOT < / *options* > ;

The CONTRIBUTIONPLOT statement produces a contribution plot for each observation in the input data set, up to a maximum that is specified by the **MAXNPLOTS=** option. Each contribution plot is displayed as a separate graph. You can use the **CONTRIBUTIONPANEL** statement to display multiple contribution plots in a paneled layout.

Table 11.2 summarizes the *options* available in the CONTRIBUTIONPLOT statement.

Table 11.2 CONTRIBUTIONPLOT Statement Options

Option	Description
MAXNPLOTS=	Specifies the maximum number of contribution plots displayed
MAXNVAR=	Specifies the maximum number of process variable contributions displayed in each plot
ODSFOOTNOTE=	Adds a footnote to the contribution plots
ODSFOOTNOTE2=	Adds a secondary footnote to the contribution plots
ODSTITLE=	Specifies a title for the contribution plots
ODSTITLE2=	Specifies a secondary title for the contribution plots
TYPE=	Specifies the type of contribution plots produced

You can specify the following *options* in the CONTRIBUTIONPLOT statement. The section “[Common Plot Statement Options](#)” on page 935 describes additional options that are available in all plot statements.

MAXNPLOTS=*n*

specifies the maximum number of contribution plots to be produced by the CONTRIBUTIONPLOT statement. The number of plots that are produced is the minimum of *n* and the number of observations in the input data set. When *n* is less than the number of observations, contribution plots are produced for the first *n* observations. The default is 50.

MAXNVAR=*n*

specifies that only the *n* contributions that have the greatest magnitudes be displayed in each plot. The contributions are ranked independently for each plot, so different process variable contributions might be displayed in different plots. By default, all contributions are displayed.

TYPE=SPE | TSQUARE

specifies the type of contribution plot to be created. The option TYPE=TSQUARE specifies that the contribution plots be based on the T^2 statistics. The option TYPE=SPE specifies that the contribution plots be based on the SPE statistics. By default, TYPE=TSQUARE if a **LOADINGS=** data set is provided and TYPE=SPE otherwise. You can use more than one CONTRIBUTIONPLOT statement. You must specify a **LOADINGS=** data set to create T^2 contribution plots.

ID Statement

ID *variables* ;

The first ID *variable* that is specified provides the labels for points in score plots. The values of all the ID variables are displayed in tooltips associated with points in a score plot when you create HTML output and specify the IMAGEMAP option in the ODS GRAPHICS statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for details.

SCOREMATRIX Statement

SCOREMATRIX < / *options* > ;

The SCOREMATRIX statement produces a matrix of score plots, each of which is a scatter plot of scores for a pair of principal components. You can use the **SCOREPLOT** statement to display a single score plot in a graph by itself.

Table 11.3 summarizes the *options* available in the SCOREMATRIX statement.

Table 11.3 SCOREMATRIX Statement Options

Option	Description
ALPHA=	Specifies the α value for prediction ellipses
ELLIPSE	Requests prediction ellipses to be overlaid on score plots

Table 11.3 (continued)

Option	Description
GROUP=	Specifies a variable for grouping points in score plots
LABELS=	Specifies whether points in the score plots are labeled
NCOMP=	Specifies the number of principal components whose scores are plotted
ODSFOOTNOTE=	Adds a footnote to the score matrix
ODSFOOTNOTE2=	Adds a secondary footnote to the score matrix
ODSTITLE=	Specifies a title for the score matrix
ODSTITLE2=	Specifies a secondary title for the score matrix

You can specify the following *options* in the SCOREMATRIX statement. The section “Common Plot Statement Options” on page 935 describes additional options that are available in all plot statements.

ALPHA= α

specifies the α value for prediction ellipses that are overlaid on the score plots. The probability that a new observation falls outside the ellipse is α . The default is 0.05. If you specify the ALPHA= option, you do not need to specify the ELLIPSE option.

ELLIPSE

requests that prediction ellipses be overlaid on the score plots. The probability that a new observation falls outside the ellipse is specified by the ALPHA= option.

GROUP=*variable*

specifies a *variable* in the input data set that is used to group the points in the score plots. Points that have different GROUP= values are plotted using different markers or colors (or both) to distinguish the groups.

LABELS=ON | OFF

specifies whether points in the score plots are labeled. Points are labeled with the values of the first variable listed in the ID statement, or the observation number if no ID statement is specified. The default is LABELS=OFF.

NCOMP=*n*

specifies the number of principal components whose scores are plotted in the matrix. The principal components that are plotted are always 1 through *n*. By default, the matrix contains score plots for all principal components.

SCOREPLOT Statement

SCOREPLOT < / *options* > ;

The SCOREPLOT statement produces a single score plot, which is a scatter plot of the scores that are associated with a pair of principal components. You can use the SCOREMATRIX statement to display a matrix of score plots for more than two principal components.

Table 11.4 summarizes the *options* available in the SCOREPLOT statement.

Table 11.4 SCOREPLOT Statement Options

Option	Description
ALPHA=	Specifies the α value for the prediction ellipse
ELLIPSE	Requests a prediction ellipse to be overlaid on the score plot
GROUP=	Specifies a variable for grouping points in the score plot
LABELS=	Specifies which points in the score plot are to be labeled
ODSFOOTNOTE=	Adds a footnote to the score matrix
ODSFOOTNOTE2=	Adds a secondary footnote to the score matrix
ODSTITLE=	Specifies a title for the score matrix
ODSTITLE2=	Specifies a secondary title for the score matrix
XCOMP=	Specifies the principal component whose scores are plotted on the horizontal axis
YCOMP=	Specifies the number of principal components whose scores are plotted on the vertical axis

You can specify the following *options* in the SCOREPLOT statement. The section “[Common Plot Statement Options](#)” on page 935 describes additional options that are available in all plot statements.

ALPHA= α

specifies the α value for a prediction ellipse that is overlaid on the score plot. The probability that a new observation falls outside the ellipse is α . The default is 0.05. If you specify the ALPHA= option, you do not need to specify the [ELLIPSE](#) option.

ELLIPSE

requests that a prediction ellipse be overlaid on the principal component score plot. The probability that a new observation falls outside the ellipse is specified by the [ALPHA=](#) option.

GROUP=*variable*

specifies a *variable* in the input data set that is used to group the points in the score plot. Points that have different GROUP= values are plotted with different markers or colors (or both) to distinguish the groups.

LABELS=ON | OFF | OUTSIDE

specifies which points in the score plot to label. Points are labeled with the values of the first variable listed in the ID statement, or the observation number if no ID statement is specified. By default, LABELS=ON and all points are labeled. You can specify LABELS=OFF to suppress all point labels.

If you overlay a prediction ellipse on the score plot by specifying the [ELLIPSE](#) or [ALPHA=](#) option, you can specify LABELS=OUTSIDE to label only the points outside the prediction ellipse.

XCOMP= x

specifies an integer x that identifies the principal component whose scores are plotted on the horizontal axis of the score plot. The default is 1. You cannot specify the same principal component number in both the XCOMP= and YCOMP= options.

YCOMP=*y*

specifies an integer *y* that identifies the principal component whose scores are plotted on the vertical axis of the score plot. The default is $\text{mod}(x, j) + 1$, where *x* is the value that is specified by the **XCOMP=** option and *j* is the number of principal components in the model. You cannot specify the same principal component number in both the **XCOMP=** and **YCOMP=** options.

TIME Statement

TIME *variable* ;

The **TIME** *variable* is a numeric variable that provides the chronological order or time values for measurements in the input data set. The *variable* name and value are incorporated into contribution plot titles to identify the observations represented. If you do not specify a **TIME** variable, the observation number from the input data set is used instead.

Common Plot Statement Options

You can specify the following *options* after a slash (/) in the **CONTRIBUTIONPANEL**, **CONTRIBUTIONPLOT**, **SCOREMATRIX**, and **SCOREPLOT** statements.

ODSFOOTNOTE=FOOTNOTE | FOOTNOTE1 | *'string'*

adds a footnote to the plot. If you specify the **FOOTNOTE** (or **FOOTNOTE1**) keyword, the value of the SAS **FOOTNOTE** statement is used as the plot footnote. If you specify a quoted string, that string is used as the footnote. The quoted string can contain the following escaped characters, which are replaced by the values indicated:

<code>\n</code>	is replaced by the TIME variable name.
<code>\l</code>	is replaced by the TIME variable label (or name if the analysis TIME has no label).

ODSFOOTNOTE2=FOOTNOTE2 | *'string'*

adds a secondary footnote to the plot. If you specify the **FOOTNOTE2** keyword, the value of the SAS **FOOTNOTE2** statement is used as the secondary plot footnote. If you specify a quoted string, that string is used as the secondary footnote. The quoted string can contain the following escaped characters, which are replaced by the values indicated:

<code>\n</code>	is replaced by the TIME variable name.
<code>\l</code>	is replaced by the TIME variable label (or name if the TIME variable has no label).

ODSTITLE=TITLE | TITLE1 | NONE | DEFAULT | *'string'*

specifies a title for the plot. You can specify the following values:

TITLE (or TITLE1) uses the value of the SAS TITLE statement as the plot title.
 NONE suppresses all titles from the plot.
 DEFAULT uses the default title.

If you specify a quoted string, that string is used as the graph title. The quoted string can contain the following escaped characters, which are replaced by the values indicated:

\n is replaced by the **TIME** variable name.
 \l is replaced by the **TIME** variable label (or name if the analysis variable has no label).

ODSTITLE2=TITLE2 | '*string*'

specifies a secondary title for the plot. If you specify the TITLE2 keyword, the value of the SAS TITLE2 statement is used as the secondary plot title. If you specify a quoted string, that string is used as the secondary title. The quoted string can contain the following escaped characters, which are replaced by the values indicated:

\n is replaced by the **TIME** variable name.
 \l is replaced by the **TIME** variable label (or name if the analysis variable has no label).

Details: MVPDIAGNOSE Procedure

Contribution Plots

One way to diagnose the behavior of out-of-control points in multivariate control charts is to use contribution plots (Miller, Swanson, and Heckler 1998). These plots tell you which variables contribute to the distance between the points in an SPE or T^2 chart and the sample mean of the data.

A contribution plot is a bar chart of the contributions of the process variables to the statistic. For the i th SPE statistic, the contribution of the k th variable is the k th entry of the vector \mathbf{e}_i , which is computed as

$$\mathbf{e}_i = \mathbf{x}_i (\mathbf{I} - \mathbf{P}_j \mathbf{P}'_j)$$

where \mathbf{e}_i is the vector of errors from the principal component model for observation i and \mathbf{x}_i is the i th observation. The contributions to the i th T^2 statistic are computed in the same way as the entries of the vector

$$\mathbf{T}_i^2 = \mathbf{x}_i \mathbf{P}_j \mathbf{L}^{-1} \mathbf{P}'_j$$

where \mathbf{P}_j is the matrix of the first j eigenvectors and \mathbf{L} is the diagonal matrix of the first j eigenvalues.

Paneled Contribution Plot Layouts

The `CONTRIBUTIONPANEL` statement produces paneled contribution plots. You can use the options `NCOLS=c` and `NROWS=r` to specify the number of columns and rows in the layout, respectively.

By default, c and r are determined by p , the number of contribution plots to be displayed. If $p \leq 16$, then $c = \lceil \sqrt{p} \rceil$ and $r = \lceil p/c \rceil$. Otherwise, one of the following three layouts is used to minimize the number of empty panels in the last page of the graph:

- $c = 4, r = 4$
- $c = 4, r = 3$
- $c = 3, r = 3$

If you specify only `NCOLS=c`, then $r = \lceil p/c \rceil$. If you specify only `NROWS=r`, then $c = \lceil p/r \rceil$.

Although $c \leq 4$ and $r \leq 4$ by default, you can specify values greater than 4 in the `NCOLS=` and `NROWS=` options.

Input Data Sets

The `MVPDIAGNOSE` procedure accepts a primary input data set that has one of the following two types:

- a `DATA=` data set that contains new process data to be analyzed by using an existing principal component model (Phase II analysis)
- a `HISTORY=` data set that contains process data and the accompanying scores, residuals, and statistics that are produced by using a principal component model. The process data can be the original data that were used to create the model (Phase I analysis) or subsequent data that were analyzed by using a previously created model (Phase II analysis)

These options are mutually exclusive. If you do not specify an option that identifies a primary input data set, `PROC MVPDIAGNOSE` uses the most recently created SAS data set as a `DATA=` data set.

When you specify a `DATA=` data set, you must also specify a `LOADINGS=` data set that contains principal component loadings and other information that describes the principal component model. When you specify a `HISTORY=` data set, you must also specify a `LOADINGS=` data set if you use a `CONTRIBUTIONPANEL` or `CONTRIBUTIONPLOT` statement and specify the `TYPE=TSQUARE` option.

DATA= Data Set

A `DATA=` data set provides the process measurement data for a Phase II analysis. In addition to containing the process variables, a `DATA=` data set can contain the following:

- BY variables
- ID variables
- a TIME variable

When you specify a DATA= data set, you must also specify a LOADINGS= data set that contains the loadings for the principal component model that describes the variation of the process. These loadings are used to score the new data from the DATA= data set. The process variables in the LOADINGS= data set must have the same names as those in the DATA= data set.

HISTORY= Data Set

A HISTORY= data set provides the input data set for a Phase I or Phase II analysis. In addition to containing the original process variables, a HISTORY= data set contains principal component scores, residuals, SPE and T^2 statistics, and a count of the observations that are used to construct the principal component model. These variables are summarized in Table 11.5.

Table 11.5 Variables in the HISTORY= Data Set

Variable	Description
Prin1–Prinj	Principal component scores
R_var1–R_varp	Residuals
NOBS	Number of observations used in the analysis
SPE	Squared prediction error (SPE) statistic
TSQUARE	T^2 statistic computed from principal component scores

The score variables names must consist of a common prefix followed by the numbers 1, 2, . . . , j , where j is the number of principal components. By default, the common prefix is Prin. You can use the PREFIX= option to specify another prefix for score variables.

If the number of principal components is less than the total number of process variables, the HISTORY= data set should also contain residual variables. A residual variable name consists of a common prefix followed by the corresponding process variable name. The default residual variable prefix is R_. For example, if the process variables are A, B, and C, the default residual variable names are R_A, R_B, and R_C. You can use the RPREFIX= option to specify a different residual variable prefix.

NOTE: Usually you create a HISTORY= data set by specifying the OUT= option in the PROC MVPMODEL statement or the OUTHISTORY= option in the PROC MVPMONITOR statement. If the PREFIX= or RPREFIX= option is used when such an output data set is created, you must specify the same prefixes to identify the score and residual variables when you read it as a HISTORY= data set.

LOADINGS= Data Set

A LOADINGS= data set contains the following information about the principal component model:

- eigenvalues of the correlation or covariance matrix used to construct the model

- principal component loadings
- process variable means used to center the variable values
- process variable standard deviations used to scale the variable values

You can produce a `LOADINGS=` data set by using the `OUTLOADINGS=` option in the `PROC MVPMODEL` statement. Table 11.6 lists the variables that are required in a `LOADINGS=` data set.

Table 11.6 Variables in the `LOADINGS=` Data Set

Variable	Description
<code>_VALUE_</code>	The value contained in <i>process variables</i> for a given observation
<code>_NOBS_</code>	Number of observations used to build the principal component model
<code>_PC_</code>	The principal component number; 0 for the observation that contains eigenvalues
<i>process variables</i>	Values associated with the process variables

Valid values for the `_VALUE_` variable are as follows:

EIGEN	eigenvalues from the principal component analysis
LOADING	principal component loadings
MEAN	process variable means
STD	process variable standard deviations

The `LOADINGS=` data set contains one EIGEN observation and j LOADING observations, where j is the number of principal components in the model. The presence of a MEAN observation indicates that the process variables were centered when the principal component model was built, and the presence of a STD observation indicates that the process variables were scaled when the principal component model was built. The means and standard deviations are used to center and scale new data in a Phase II analysis.

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The `MVPDIAGNOSE` procedure assigns a name to each graph that it creates. You can use these names to refer to the graphs when you use ODS Graphics. The ODS graph names are listed in Table 11.7.

Table 11.7 ODS Graphics Produced by PROC MVPDIAGNOSE

ODS Graph Name	Plot Description	Statement
ContributionPanel	Paneled contribution plots	CONTRIBUTIONPANEL
ContributionPlot	Contribution plots	CONTRIBUTIONPLOT
ScoreMatrix	Matrix of pairwise score plots	SCOREMATRIX
ScorePlot	Score plot	SCOREPLOT

Examples: MVPDIAGNOSE Procedure

Example 11.1: Phase II Analysis with MVPDIAGNOSE

The example in “Getting Started: MVPDIAGNOSE Procedure” on page 924 illustrates how you build a principal component model and apply the MVPMONITOR and MVPDIAGNOSE procedures to perform a Phase I analysis. In Phase I analysis you analyze the data that were used to build the principal component model. This example is a continuation of that example and illustrates how you can use PROC MVPDIAGNOSE to analyze process data that were not used to build the model. This is called a Phase II analysis. A Phase II analysis is usually performed on data that are collected after the data that are used to build the model.

In the original example the principal component model was built using flight delay data from February 1–16, 2007. The following statements create a data set named MWflightDelays2 that contains average delays for flights that originated in the midwestern United States on February 17–28, 2007:

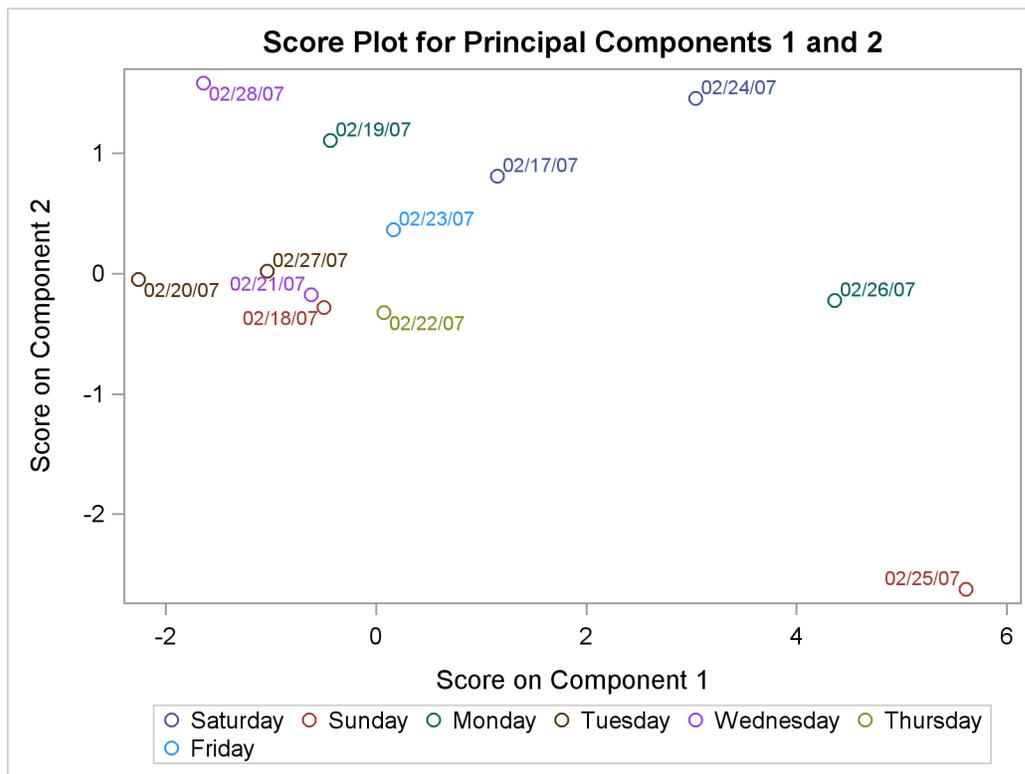

```
data MWflightDelays2;
  label flightDate='Date';
  format flightDate MMDDYY8.;
  input flightDate :MMDDYY8. AA CO DL F9 FL NW UA US WN;
  dayofweek = put(flightDate,downname.);
  datalines;
02/17/07 25.6 7.8 15.5 13.4 16.1 16.2 23.0 24.2 8.2
02/18/07 5.4 16.0 9.9 1.1 11.5 17.0 15.6 15.5 5.1
02/19/07 13.2 16.3 10.0 10.6 5.4 10.3 9.5 16.8 9.3
02/20/07 4.2 6.9 1.4 0.1 7.2 6.6 7.4 10.4 2.9
02/21/07 5.4 -0.1 7.4 8.7 16.3 24.3 9.4 6.0 10.2
02/22/07 19.6 30.2 6.8 2.7 8.9 16.4 14.3 12.6 8.2
02/23/07 14.9 18.9 9.9 9.1 12.0 16.5 17.4 12.8 6.0
02/24/07 21.4 5.5 11.1 46.1 10.6 55.3 22.9 8.8 3.4
02/25/07 42.6 7.7 14.6 14.4 32.0 50.7 46.1 49.4 39.1
02/26/07 43.2 25.1 18.1 18.2 28.8 31.1 38.6 29.6 18.6
02/27/07 11.3 17.1 5.3 4.1 4.8 13.9 9.8 9.7 7.1
02/28/07 8.1 3.7 2.7 17.1 -0.8 5.5 11.0 14.3 3.1
;
```

The dayofweek variable contains the day of the week for each date in the input data set. The following statements apply the model that is saved in the mvpairloadings data set to the flightDelays2 data and produce a score plot for the first two principal components:

```
proc mvpdiagnose data=MWflightDelays2 loadings=mvpairloadings;
  id flightDate;
  scoreplot / labels=on group=dayofweek;
  label dayofweek='';
run;
```

The **ID** statement labels the points in the score plot with `flightDate` variable values. The **GROUP=** option displays the observations grouped by day of the week. The **LABEL** statement suppresses the **GROUP=** legend label. Figure 11.1.1 shows the score plot.

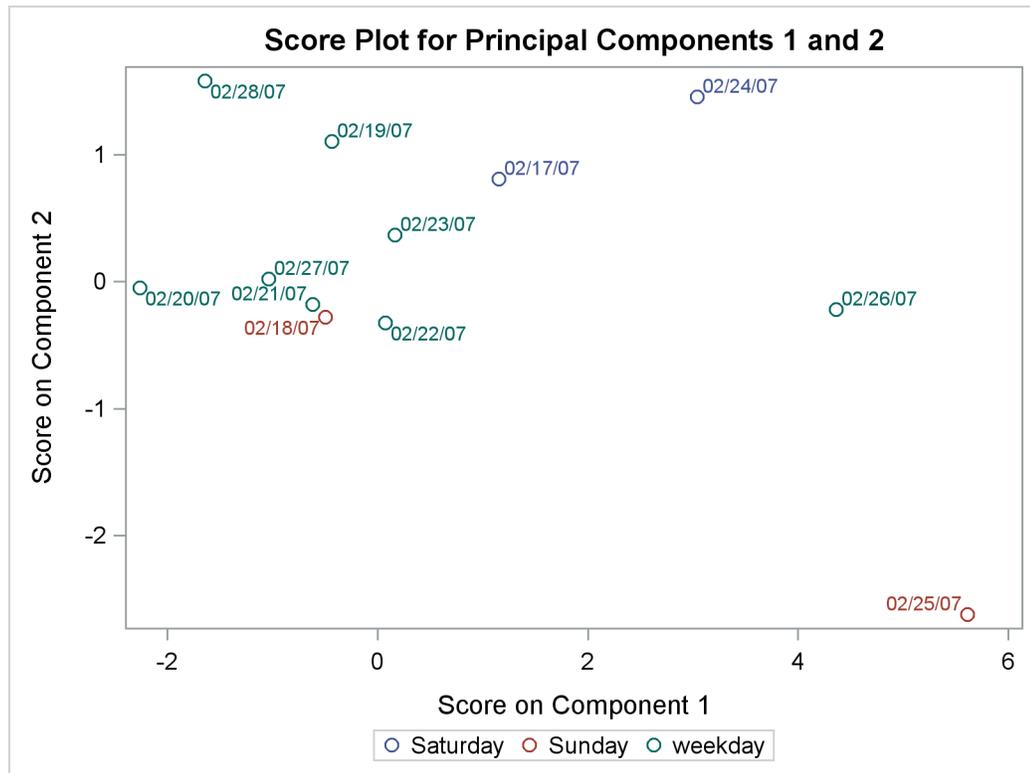

Output 11.1.1 Score Plot with Observations Grouped by Day of the Week

The Saturday and Sunday observations seem to be divided by scores for principal component 1. The following statements modify the `dayofweek` values to merge the observations for the other days into a “weekday” group:

```
data MWflightDelays2;
  set MWflightDelays2;
  weekday = put(flightDate, weekday.);
  if not ( weekday in (1 7) ) then dayofweek='weekday';
run;
```

Figure 11.1.2 shows the score plot that is produced by running PROC MVPDIAGNOSE with this new grouping. Merging the weekday observations into a single group emphasizes the Saturday and Sunday scores.

Output 11.1.2 Score Plot with Alternate Grouping

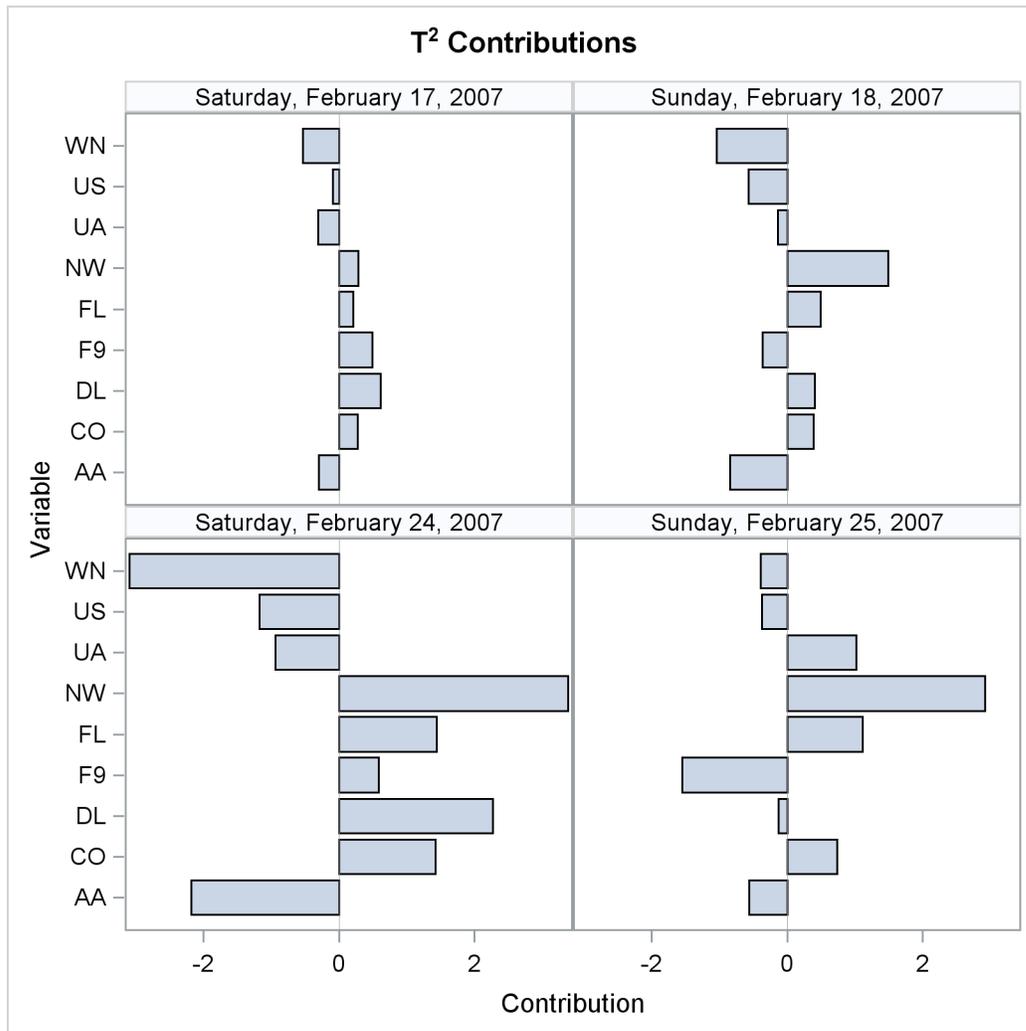

Because the score plot shows that something interesting might be happening on the weekends, you might want to examine contribution plots for those days. The following statements produce paneled T^2 and SPE contribution plots for the weekend observations:

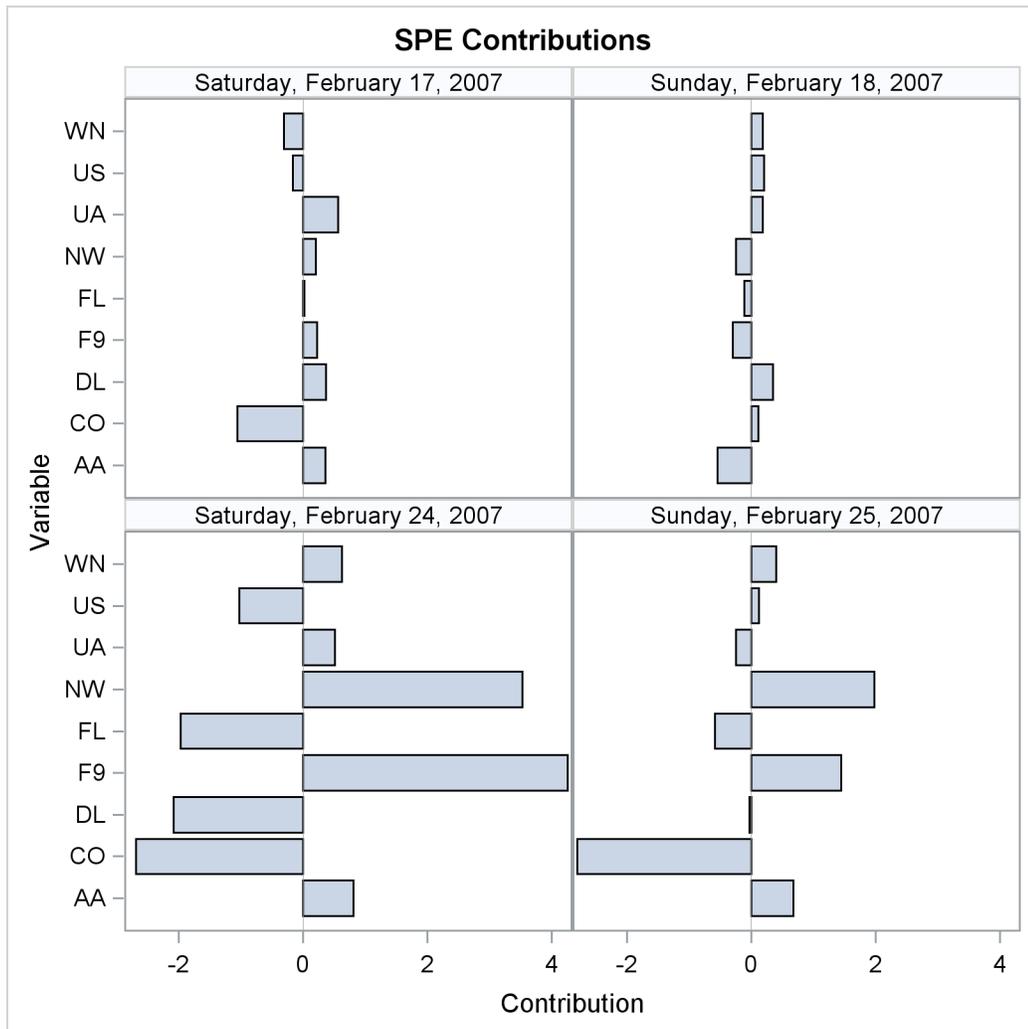

```
proc mvpdiagnose data=MWflightDelays2 loadings=mvpairloadings;
  where dayofweek ne 'weekday';
  time flightDate;
  contributionpanel;
  contributionpanel / type=spe;
  format flightDate weekdate.;
run;
```

Because the **CONTRIBUTIONPANEL** statement produces contribution plots for a series of observations starting with the first observation in the input data set, it is convenient to use a **WHERE** statement to select observations of interest.

Figure 11.1.3 and Figure 11.1.4 show the paneled contribution plots.

Output 11.1.3 T^2 Contribution Plots for Weekends

Output 11.1.4 SPE Contribution Plots for Weekends

Overview: MVPMODEL Procedure

The MVPMODEL procedure is used in conjunction with the MVPMONITOR and MVPDIAGNOSE procedures to monitor multivariate process variation over time, to determine whether the process is stable, and to detect and diagnose changes in a stable process. Collectively these three procedures are referred to as the *MVP procedures*. See Chapter 10, “Introduction to Multivariate Process Monitoring Procedures,” for a description of how the MVP procedures work together, and Chapter 13, “The MVPMONITOR Procedure,” and Chapter 11, “The MVPDIAGNOSE Procedure,” for details about the other MVP procedures.

The MVPMODEL procedure provides computational and graphical tools for building a principal component model from multivariate process data in which the measured variables are continuous and correlated. This model then serves as input to the other MVP procedures, described in Chapter 11, “The MVPDIAGNOSE Procedure,” and Chapter 13, “The MVPMONITOR Procedure.” The MVPMONITOR procedure creates various multivariate control charts, including T^2 charts and SPE (squared prediction error) charts, which are used to detect and diagnose changes in the process. Multivariate control charts can detect unusual variation that would not be detected by individually monitoring the variables with univariate control charts, such as Shewhart charts.

The MVPMODEL procedure implements principal component analysis (PCA) techniques that evolved in the field of chemometrics for monitoring hundreds or even thousands of correlated process variables; see Kourti and MacGregor (1995, 1996) for an introduction. These techniques differ from the classical multivariate T^2 chart in which Hotelling’s T^2 statistic is computed as a distance from the multivariate mean scaled by the covariance matrix of the variables; see Alt (1985). Instead, principal component methods compute T^2 based on a small number of principal components that model most of the variation in the data.

One advantage of PCA methods over the classical T^2 chart is that they avoid computational issues that arise when the process measurement variables are collinear and their covariance matrix is nearly singular. A second advantage is that they offer diagnostic tools for interpreting unusual values of T^2 . A third advantage is that by projecting the data to a low-dimensional subspace, a principal component model more adequately describes the variation in a multivariate process, which is often driven by a small number of underlying factors that are not directly observable.

Using the MVP Procedures

There are two primary scenarios for using the MVP procedures:

1. To determine whether a process is stable, you can construct T^2 and SPE charts from an existing set of process measurements (this is referred to as a Phase I analysis). First, build a principal component model with the MVPMODEL procedure, saving the measurements and the computed observationwise statistics (including T^2 and SPE) in an **OUT=** data set. Then specify this data set as a **HISTORY=** input data set for the MVPMONITOR procedure to create T^2 and SPE charts. Contribution plots indicate which of the original variables are involved in unusual variation displayed by the T^2 and SPE charts. Follow-up action might be needed to adjust the process and eliminate unusual variation signaled by the charts.
2. To detect changes in a stable process, you can construct T^2 and SPE charts from newly acquired data by using the principal component model developed from previous data (this is referred to as a Phase II analysis). You can save information about the model in the **OUTLOADINGS=** data set created by the MVPMODEL procedure. Specify this data set as a **LOADINGS=** input data set and specify the new data as a **DATA=** input data set to create T^2 and SPE charts with the MVPMONITOR procedure.

Functionality of the MVPMODEL Procedure

The MVPMODEL procedure performs principal component analysis (PCA) on multivariate process measurement data that consist of p continuous variables that are assumed to be correlated. The input data set for PROC MVPMODEL provides the values of the p variables that are to be analyzed.

The MVPMODEL procedure computes the following quantities:

- the loadings from the principal component analysis
- the eigenvalues from the principal component analysis, which are the variances of the principal component variables
- the scores from the principal component analysis
- the T^2 statistic for each observation
- the SPE (squared prediction error) statistic for each observation, also known as SSE, Q, or DModX

By default, principal components are computed from the correlation matrix of the variables. Optionally, they can be computed from their covariance matrix instead. The number of principal components in the model (denoted by j , where $j \leq p$) can be specified or determined by one of several cross validation methods.

By default, PROC MVPMODEL outputs the correlation matrix of the input variables and the eigenvalues of the correlation matrix. When ODS Graphics is enabled, the output can also include the following plots:

- a scree plot and a variance-explained plot of the principal components (these plots are created by default)
- when using cross validation, plots of W and root mean PRESS (predicted residual sum of squares) for each principal component
- pairwise score plots of principal component scores
- pairwise loading plots of principal component loadings

PROC MVPMODEL saves information about the principal component model in the following two output data sets, which can subsequently serve as inputs to the MVPMONITOR and MVPDIAGNOSE procedures:

- an output data set which contains all the variables and observations in the input data set together with observationwise statistics, such as scores, residuals, T^2 , and SPE
- an output data set that contains the j loadings for each process variable and the eigenvalues associated with each of the principal components

Getting Started: MVPMODEL Procedure

This example illustrates the basic features of the MVPMODEL procedure by using airline flight delay data available from the U.S. Bureau of Transportation Statistics at <http://www.transtats.bts.gov>. The example applies multivariate process monitoring to flight delays.

Suppose you want to use a principal component model to create T^2 and SPE charts to monitor the variation in flight delays. These charts are appropriate because the data are multivariate and correlated.

The following statements create a SAS data set named MWflightDelays to contain the average flight delays for flights that originate in the midwestern United States by airline. The data set contains variables for nine airlines: AA (American Airlines), CO (Continental Airlines), DL (Delta Airlines), F9 (Frontier Airlines), FL (AirTran Airways), NW (Northwest Airlines), UA (United Airlines), US (US Airways), and WN (Southwest Airlines).

```
data MWflightDelays;
    format flightDate MMDDYY8.;
    label flightDate='Date';
    input flightDate :MMDDYY8. AA CO DL F9 FL NW UA US WN;
    datalines;
02/01/07 14.9 7.1 7.9 8.5 14.8 4.5 5.1 13.4 5.1
02/02/07 14.3 9.6 14.1 6.2 12.8 6.0 3.9 15.3 11.4
02/03/07 23.0 6.1 1.7 0.9 11.9 15.2 9.5 18.4 7.6
02/04/07 6.5 6.3 3.9 -0.2 8.4 18.8 6.2 8.8 8.0
02/05/07 12.0 14.1 3.3 -1.3 10.0 13.1 22.8 16.5 11.5
02/06/07 31.9 8.6 4.9 2.0 11.9 21.9 29.0 15.5 15.2

    ... more lines ...

02/16/07 31.2 20.8 15.2 20.1 9.1 12.9 22.9 36.4 16.4
;
```

The observations for a given date are the average flight delays in minutes of flights that depart from the Midwest. For example, on February 2, 2007, F9 (Frontier Airlines) flights departed an average of 6.2 minutes late.

Preliminary Analysis

The following statements use the MVPMODEL procedure to conduct a preliminary principal component analysis:

```
ods graphics on;
proc mvpmode data=MWflightDelays;
    var AA CO DL F9 FL NW UA US WN;
run;
```

The `DATA=` option specifies the input data set, which contains the process measurement variables. The `VAR` statement specifies the process measurement variables to be analyzed. The `ODS GRAPHICS ON` statement enables ODS Graphics, which is used to produce plots for interpreting the model.

The procedure first outputs a summary of the model and the data, as shown in [Figure 12.1](#).

Figure 12.1 Summary of Model and Data Information

The MVPMODEL Procedure	
Data Set	WORK.MWFLIGHTDELAYS
Number of Variables	9
Missing Value Handling	Exclude
Number of Observations Read	16
Number of Observations Used	16
Number of Principal Components	9

This output includes the number of principal components in the model and the number of variables. In this case the procedure produces a model with nine principal components by default, because there are nine process variables.

Next, the procedure outputs the correlation matrix shown in [Figure 12.2](#).

Figure 12.2 Correlation Matrix

Correlation Matrix							
	AA	CO	DL	F9	FL	NW	UA
AA	1.0000	0.5640	0.5206	0.4874	0.5403	0.4860	0.6466
CO	0.5640	1.0000	0.7855	0.6580	0.8519	0.6421	0.7672
DL	0.5206	0.7855	1.0000	0.8231	0.7598	0.4782	0.4951
F9	0.4874	0.6580	0.8231	1.0000	0.5119	0.2279	0.3509
FL	0.5403	0.8519	0.7598	0.5119	1.0000	0.6807	0.6975
NW	0.4860	0.6421	0.4782	0.2279	0.6807	1.0000	0.6715
UA	0.6466	0.7672	0.4951	0.3509	0.6975	0.6715	1.0000
US	0.7856	0.8415	0.7463	0.6832	0.8207	0.5598	0.7540
WN	0.5506	0.6526	0.4525	0.3914	0.7186	0.3970	0.7736

Correlation Matrix		
	US	WN
	0.7856	0.5506
	0.8415	0.6526
	0.7463	0.4525
	0.6832	0.3914
	0.8207	0.7186
	0.5598	0.3970
	0.7540	0.7736
	1.0000	0.8152
	0.8152	1.0000

There are strong correlations (greater than 0.8) between variable pairs F9 and DL, CO and FL, and US and WN. This is not surprising, because these pairs of airlines have closely located hubs or focus cities.

The procedure also outputs the eigenvalue and variance information shown in [Figure 12.3](#).

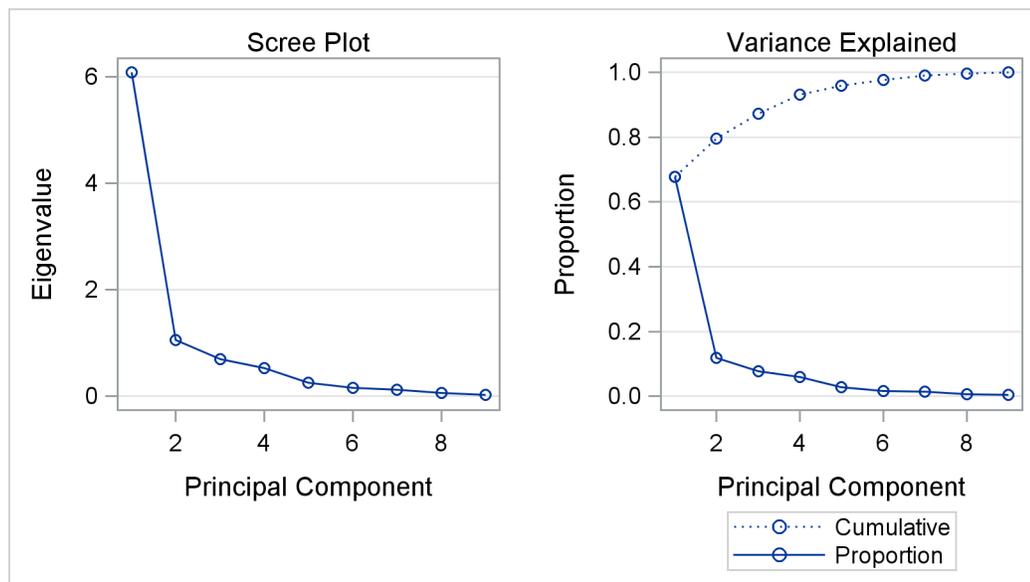

Figure 12.3 Eigenvalue and Variance Information

Eigenvalues of the Correlation Matrix				
	Eigenvalue	Difference	Proportion	Cumulative
1	6.09006397	5.02872938	0.6767	0.6767
2	1.06133459	0.36642409	0.1179	0.7946
3	0.69491050	0.16102099	0.0772	0.8718
4	0.53388951	0.28357563	0.0593	0.9311
5	0.25031387	0.09537517	0.0278	0.9589
6	0.15493870	0.03339131	0.0172	0.9762
7	0.12154739	0.06166364	0.0135	0.9897
8	0.05988375	0.02676604	0.0067	0.9963
9	0.03311771		0.0037	1.0000

The eigenvalues are the variances of the principal components, and the proportions reflect the relative amount of variance explained by each component. The eigenvalues and the proportions are ordered from largest to smallest. Recall that principal components are orthogonal linear combinations of the variables that maximize variance in orthogonal directions.

More than 85% of the variance is explained by the first three principal components, as shown in the cumulative variance column. This suggests that a model with three principal components is adequate; this is confirmed by the plots in Figure 12.4.

Figure 12.4 shows a paneled display, with a scree plot in the left panel and a variance-explained plot in the right panel.

Figure 12.4 Scree Plot and Variance-Explained Plot

The scree plot shows the eigenvalues for each principal component. Traditionally, the scree plot has been recommended as an aid in selecting the number of principal components for the model by examining the “knee” in the plot (Mardia, Kent, and Bibby 1979). The variance-explained plot shows both the proportion of variance and the cumulative variance explained by the principal components.

Building a Principal Component Model

To build a model that has only three principal components, you can use the `NCOMP=` option as shown in the following statements:

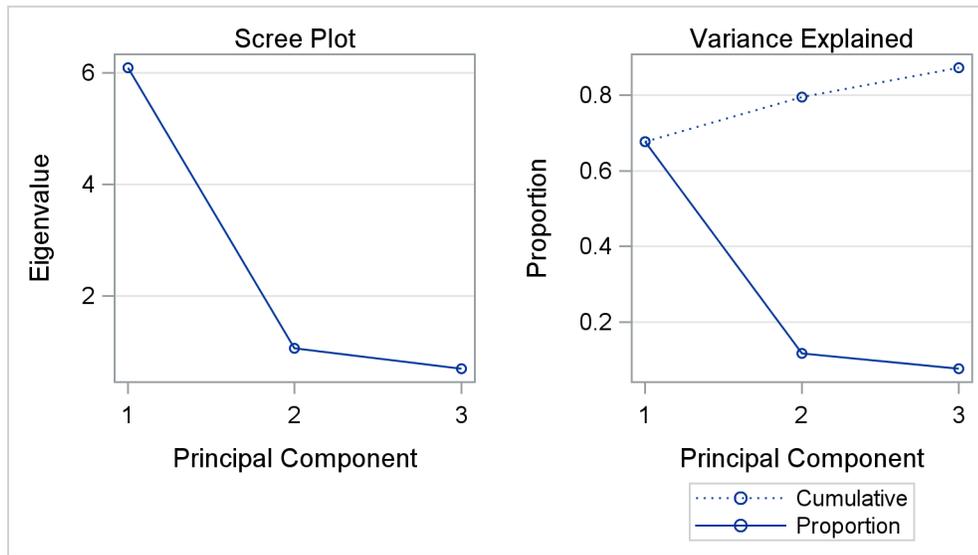

```
proc mvpmode1 data=MWflightDelays ncomp=3 plots=(all score(labels=on))
      out=outDelays;
  var AA CO DL F9 FL NW UA US WN;
run;
```

The `PLOTS=ALL` option requests all possible plots, which include pairwise plots of the principal component scores and loadings in addition to the default scree plot and variance-explained plot. The `OUT=` option produces an output data set called `outDelays` that contains principal component scores, T^2 statistics, SPE statistics, residuals, and more, as described in the section “[Output Data Sets](#)” on page 971. Note that ODS Graphics is still enabled, so you do not need to specify the `ODS GRAPHICS ON` statement here.

The correlation matrix is the same as in [Figure 12.2](#). The eigenvalue information, scree plot, and variance-explained plot are similar to those in [Figure 12.3](#) and [Figure 12.4](#). However, the use of the `NCOMP=3` option results in outputs that show information only for the three components in the model, as seen in [Figure 12.5](#) and [Figure 12.6](#).

Figure 12.5 Eigenvalue and Variance Information

The MVPMODEL Procedure				
Eigenvalues of the Correlation Matrix				
	Eigenvalue	Difference	Proportion	Cumulative
1	6.09006397	5.02872938	0.6767	0.6767
2	1.06133459	0.36642409	0.1179	0.7946
3	0.69491050		0.0772	0.8718

Figure 12.6 Scree Plot and Variance-Explained Plot

Also, the model summary, shown in Figure 12.7, is different because there are now only three principal components in the model.

Figure 12.7 Summary of Model and Data Information

The MVPMODEL Procedure	
Data Set	WORK.MWFLIGHTDELAYS
Number of Variables	9
Missing Value Handling	Exclude
Number of Observations Read	16
Number of Observations Used	16
Number of Principal Components	3

The outDelays output data set that is partially listed in Figure 12.8 contains T^2 and SPE statistics based on the model that has three principal components, in addition to the original variables and other observationwise statistics.

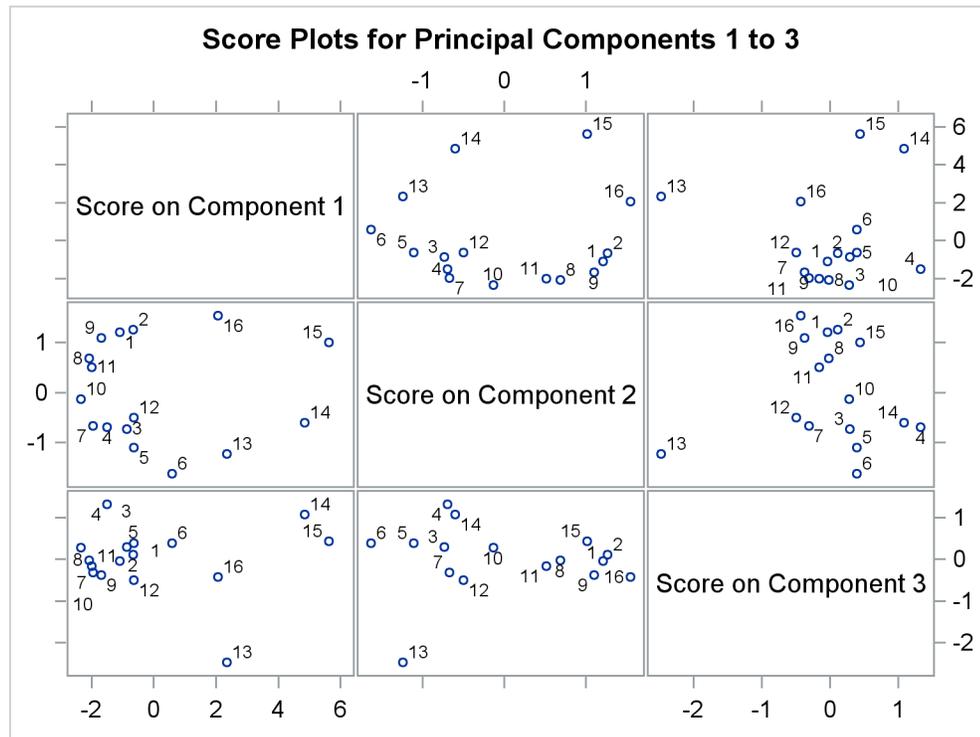

Figure 12.8 Partial Listing of Output Data Set outDelays

The variables Prin1, Prin2, and Prin3 contain the principal component scores. Variables R_AA through R_WN are the residuals for the process variables. The contents of an OUT= data set are described in detail in the section “Output Data Sets” on page 971. See the section “Principal Component Analysis” on page 966 for computational details of the results saved in the output data set.

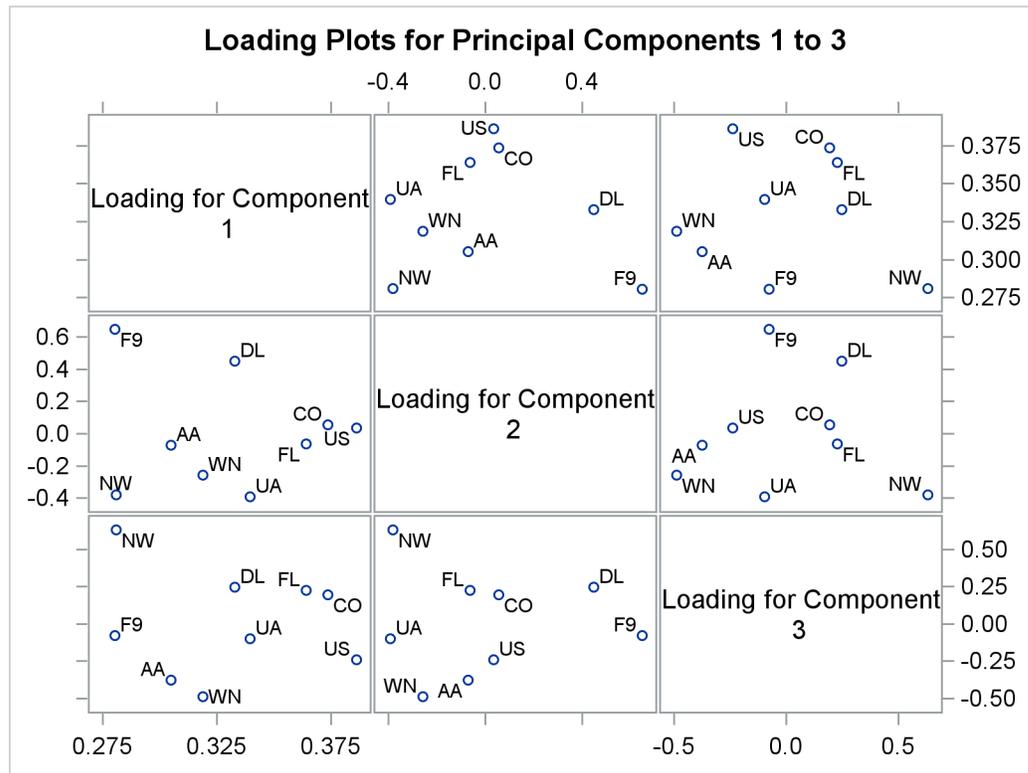

You can use an OUT= data set as an input to the MVPMONITOR and MVPDIAGNOSE procedures. The MVPMONITOR procedure produces control charts for the T^2 and SPE statistics. Control charts that are created from the outDelays data set are shown in Example 12.2 and in the MVPMONITOR procedure chapter.

The PLOTS=ALL option produces score plots for pairs of principal components in the model. By default, the score plots are displayed in a matrix. You can specify the PLOTS(SCORES(UNPACK)) option to display the score plots as separate graphs. The score plot matrix is shown in Figure 12.9.

Figure 12.9 Score Plots for Principal Components 1–3

A score plot is a scatter plot of the scores for two principal components. The labels indicate the observation numbers of the points. By examining clusters and outliers in these plots, you can better understand the relationships among the observations and the variation in the process. For example, points 13 through 16 are extreme points in the direction of the first principal component. The directions of the principal components are not uniquely determined, so you need the loadings and external information to interpret them. These points represent flight delays between February 13, 2007, and February 16, 2007, when there was a major winter storm in the Midwest.

Figure 12.10 displays the loading plots that are produced. Loading plots are also displayed in a matrix by default, and they can be unpacked into separate graphs with the `PLOT(LOADINGS(UNPACK))` option.

Figure 12.10 Loading Plot for Principal Components 1–3

A loading plot is a scatter plot of the variable loadings for a pair of principal components, and it helps you understand the relationships among the variables. Loadings are the variable coefficients in the eigenvectors (linear combinations of variables) that define the principal component. The loadings explain how variables contribute to the linear combination. Here, the loadings for the first principal component are all positive and all similar in value, which suggests that the first principal component describes the average delay. The second principal component appears to be a contrast between the delays of F9, DL, CO, and US and those of the remaining airlines. See the section “Principal Component Analysis” on page 966 for more information about interpreting principal component loadings and scores.

Syntax: MVPMODEL Procedure

The following statements are available in PROC MVPMODEL:

```
PROC MVPMODEL < options > ;
  BY variables ;
  ID variables ;
  VAR variables ;
```

The following sections describe the PROC MVPMODEL statement and then describe the other statements in alphabetical order.

PROC MVPMODEL Statement

```
PROC MVPMODEL < options > ;
```

The PROC MVPMODEL statement invokes the MVPMODEL procedure and optionally identifies input and output data sets, specifies details of the analyses performed, and controls displayed output. Table 12.1 summarizes the *options*.

Table 12.1 Summary of PROC MVPMODEL Statement Options

<i>option</i>	Description
COV	Computes the principal components from the covariance matrix
CV=	Performs cross validation to select the number of principal components
DATA=	Specifies the input data set
MISSING=	Specifies how observations with missing values are handled
NCOMP=	Specifies the number of principal components to extract
NOCENTER	Suppresses centering of process variables before fitting the model
NOCVSTDIZE	Suppresses re-centering and rescaling of process variables before each model is fit in the cross validation
NOPRINT	Suppresses the display of all output
NOSCALE	Suppresses scaling of process variables before fitting the model
OUT=	Specifies the output data set
OUTLOADINGS=	Specifies the output data set for loadings (eigenvectors)
PLOTS=	Requests and specifies details of plots
PREFIX=	Specifies the prefix for naming principal component score variables in the OUT= data set
RPREFIX=	Specifies the prefix for naming residual variables in the OUT= data set
STDSCORES	Standardizes the principal component scores

You can specify the following *options*.

COV

computes the principal components from the covariance matrix. By default, the correlation matrix is analyzed. The COV option causes variables with large variances to be more strongly associated with components that have large eigenvalues, and it causes variables with small variances to be more strongly associated with components that have small eigenvalues. You should not specify the COV option unless the units in which the variables are measured are comparable or the variables are standardized in some way.

NOTE: Specifying the COV option has the same effect as specifying the [NOSCALE](#) option.

CV=ONE

CV=BLOCK <(cv-block-options)>

CV=SPLIT <(cv-split-options)>

CV=RANDOM <(cv-random-options)>

specifies that cross validation be performed to determine the number of principal components and specifies the method to be used. If you do not specify the CV= option, no cross validation is performed.

In cross validation, the input data are repeatedly divided into a *training set*, which is used to compute a model, and a *test set*, which is used to test the model fit. The cross validation that is performed here is along both observations and variables, as described in Eastment and Krzanowski (1982), which is a more detailed version of the “alternative scheme” of Wold (1978). The observations and variables are separately divided into groups. Each test set is the intersection of one observation group and one variable group, so the number of test sets that are used is the product of the number of observation groups and the number of variable groups. See the section “[Cross Validation \(Experimental\)](#)” on page 968 for more information.

NOTE: The CV= option is experimental in this release.

CV=ONE requests *one-at-a-time* cross validation, in which each observation group contains one observation and each variable group contains one variable. This approach is very computationally intensive because it computes $n \times p$ separate principal component models for each potential number of principal components, where n is the number of observations in the input data set and p is the number of process variables.

CV=BLOCK requests *blocked* cross validation, in which observation groups consist of blocks of *nobs* consecutive observations and variable groups consist of blocks of *nvar* consecutive variables. You can specify the following *cv-block-options* in parentheses after the CV=BLOCK option:

NOBS=*nobs*

specifies that observation groups consist of blocks of *nobs* consecutive observations from the input data. For example, if you specify NOBS=8, the first group contains observations 1 through 8, the second group contains observations 9 through 16, and so on. The default is 7.

NVAR=*nvar*

specifies that variable groups consist of blocks of *nvar* consecutive variables from the input data. For example, if you specify NVAR=3, the first group contains variables 1 through 3, the second group contains variables 4 through 6, and so on. The default is 7.

CV=SPLIT requests *split-sample* cross validation, in which observation groups are formed by selecting every *nobsth* observation and variable groups are formed by selecting every *nvarth* variable. You can specify the following *cv-split-options* in parentheses after the CV=SPLIT option:

NOBS=*nobs*

specifies that observation groups be created by selecting every *nobsth* observation from the input data. For example, if you specify NOBS=8, the first group contains observations {1, 9, 17, ...}, the second group contains observations {2, 10, 18, ...}, and so on. The default is 7.

NVAR=*nvar*

specifies that variable groups be created by selecting every *nvarth* variable from the input data. For example, if you specify NVAR=5, the first group contains variables {1, 6, 11, ...}, the second group contains variables {2, 7, 12, ...}, and so on. The default is 7.

CV=RANDOM requests that observations and variables be assigned to groups randomly. You can specify the following *cv-random-options* in parentheses after the CV=RANDOM option:

NITEROBS=*nogrp*

specifies the number of observation groups. The default is 10.

NITERVAR=*nvgrp*

specifies the number of variable groups. The default is 10.

NTESTOBS=*nobs*

specifies the number of observations in each observation group. The default is one-tenth the total number of observations.

NTESTVAR=*nvar*

specifies the number of variables in each variable group. The default is one-tenth the total number of variables.

SEED=*n*

specifies an integer used to start the pseudorandom number generator for selecting the random test set. If you do not specify a seed or if you specify a value less than or equal to zero, the seed is generated by default from reading the time of day from the computer's clock.

NOTE: You cannot specify the CV= option together with the NCOMP= option.

DATA=SAS-data-set

specifies the input SAS data set to be analyzed. If the DATA= option is omitted, the procedure uses the most recently created SAS data set.

MISSING=AVG | NONE

specifies how observations with missing values are to be handled in computing the fit. MISSING=AVG specifies that the fit be computed by replacing missing values of a process variable with the average of its nonmissing values. The default is MISSING=NONE, which excludes observations with missing values for any process variables from the analysis.

NCOMP=*n* | ALL

specifies the number of principal components to extract. The default is $\min\{15, p, N\}$, where p is the number of process variables and N is the number of observations (runs). You can specify NCOMP=ALL to override the limit of 15 principal components. You cannot specify the NCOMP= option together with the CV= option. If the number of nonzero eigenvalues of the correlation matrix is less than the number of components specified, p , then the p will be reset to the number of nonzero eigenvalues.

NOCENTER

suppresses centering of the process variables before fitting. This is useful if the variables are already centered and scaled. See the section “Centering and Scaling” on page 970 for more information.

NOCVSTDIZE

suppresses re-centering and rescaling of the process variables before each model is fit in the cross validation. See the section “Centering and Scaling” on page 970 for more information.

NOPRINT

suppresses the display of all results, both tabular and graphical. This is useful when you want to produce only output data sets.

NOSCALE

suppresses scaling of the process variables before fitting. This is useful if the variables are already centered and scaled.

NOTE: Specifying the NOSCALE option has the same effect as specifying the COV option.

OUT=SAS-data-set

creates an output data set that contains all the original data from the input data set, principal component scores, and multivariate summary statistics. See the section “Output Data Sets” on page 971 for details.

OUTLOADINGS=SAS-data-set

creates an output data set that contains the loadings for the principal components and the eigenvalues of the correlation (or covariance) matrix. See the section “Output Data Sets” on page 971 for details.

PLOTS < (*global-plot-options*) > <= *plot-request* < (*options*) >>

PLOTS < (*global-plot-options*) > <= (*plot-request* < (*options*) > < ... *plot-request* < (*options*) >> >
controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. For example:

```
plots=none
plots=score
plots=loadings
```

ODS Graphics must be enabled before you request plots. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

You can specify the following *global-plot-options*:

FLIP

interchanges the X-axis and Y-axis dimensions for all score and loading plots.

NCOMP=*n*

specifies that pairwise score and loading plots be produced for the first *n* principal components. The default is 5 or the total number of components $j (\geq 2)$, whichever is smaller. If $n > j$, then the default is $NCOMP=j$. Be aware that the number of score or loading plots produced ($\frac{n \times (n-1)}{2}$) grows quadratically as *n* increases.

ONLY

suppresses the default plots. Only plots specifically requested are displayed. The default plots are the CV plot, when you specify the **CV=** option, and the scree and variation-explained plots otherwise.

You can specify the following *plot-requests*:

ALL

produces all appropriate plots.

CVPLOT

produces a plot that displays the results of the cross validation and R-square analysis. This plot requires that the **CV=** option be specified and in that case is displayed by default.

LOADINGS <(loading-options)>

produces a matrix of pairwise scatter plots of the principal component loadings. Use $NCOMP=n$ to specify the number of principal components for which plots are produced, and use the **FLIP** option to interchange the default X-axis and Y-axis dimensions.

You can specify the following *loading-options*:

FLIP

flips or interchanges the X-axis and Y-axis dimensions of the loading plots. Specify **PLOTS=LOADING(FLIP)** to flip the X-axis and Y-axis dimensions.

NCOMP=*n*

specifies that pairwise loading plots be produced for the first *n* principal components. The default is the value specified by the **NCOMP=** *global-plot-option*. If $n > j$, then the default is $NCOMP=j$. Be aware that the number of loading plots produced ($\frac{n \times (n-1)}{2}$) grows quadratically as *n* increases.

UNPACKPANEL**UNPACK**

suppresses paneling of loading plots. By default, all the loading plots appear in a single output panel. Specify UNPACKPANEL to display each loading plot in a separate panel.

NONE

suppresses the display of all plots.

SCORES < (*score-options*) >

produces pairwise scatter plots of the principal component scores. You can use the **NCOMP=** option to control the number of plots that are displayed.

You can specify the following *score-options*:

ALPHA=*value*

specifies the probability used to compute a prediction ellipse that is overlaid on the score plot. The default is 0.05. If you specify the ALPHA= option, you do not need to specify the **ELLIPSE** option.

ELLIPSE

requests that a prediction ellipse be overlaid on the principal component score plots. The probability that a new observation falls outside the prediction ellipse is specified by the **ALPHA=** option.

FLIP

flips or interchanges the X-axis and Y-axis dimensions of the score plots. Specify **PLOTS=SCORES(FLIP)** to flip the X-axis and Y-axis dimensions.

GROUP=*variable*

specifies a variable in the input data set used to group the points on the score plots. Points with different GROUP= variable values are plotted using different markers and colors to distinguish the groups.

LABELS=ON | OFF | OUTSIDE

specifies which points in the score plots to label. Specify **LABELS=ON** to label all points and **LABELS=OFF** to label none of the points. Points are labeled with the values of the first variable listed in the **ID** statement, or the observation number if no ID statement is specified.

If you specify the **ELLIPSE** and **UNPACKPANEL** options, you can specify **LABELS=OUTSIDE** to label only the points outside the confidence ellipse.

The default is ON if you specify UNPACKPANEL and OFF otherwise.

NCOMP=*n*

specifies that pairwise score plots be produced for the first *n* principal components. The default is the value specified by the **NCOMP=** *global-plot-option*. If $n > j$, then the default is **NCOMP=j**. Be aware that the number of loading plots produced ($\frac{n \times (n-1)}{2}$) grows quadratically as *n* increases.

UNPACKPANEL

suppresses paneling of score plots. By default, all the score plots appear in a single output panel. Specify UNPACKPANEL to display each score plot in a separate panel.

SCREE < UNPACK >**EIGEN****EIGENVALUE**

produces a scree plot of eigenvalues and a variance-explained plot. By default, both plots are produced in a panel. Specify PLOTS= SCREE(UNPACKPANEL) to display each plot in a separate panel. This plot is produced by default unless you specify the CV= option.

PREFIX=*name*

specifies a prefix for naming the principal component scores in the OUT= data set. By default, the names are Prin1, Prin2, . . . , Prin*j*. If you specify PREFIX=ABC, the components are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits in *j* should not exceed the current name length defined by the VALIDVARNAME= system option.

RPREFIX=*name*

specifies a prefix for naming the residual variables in the OUT= data set. The default is R_. Residual variable names are formed by appending process variable names to the prefix.

If the length of the resulting residual variable exceeds the maximum name length defined by the VALIDVARNAME= system option, characters are removed from the middle of the process variable name before it is appended to the residual prefix. For example, if you specify RPREFIX=*Residual_*, the maximum variable name length is 32, and there is a process variable named PrimaryThermometerReading, then the corresponding residual variable name is Residual_PrimaryThermometerReading.

STDSCORES

standardizes the principal component scores in the OUT= data set to unit variance. If you omit the STDSCORES option, the variances of the scores are equal to the corresponding eigenvalues. STDSCORES has no effect on the eigenvalues themselves.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC MVPMODEL to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the `NOTSORTED` or `DESCENDING` option in the `BY` statement for the `MVPMODEL` procedure. The `NOTSORTED` option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the `BY` variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the `BY` variables by using the `DATASETS` procedure (in Base SAS software).

For more information about `BY`-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the `DATASETS` procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variables* ;

The first variable that is specified in the `ID` statement is used to label observations in score plots for principal components. If you do not specify an `ID` statement, then score plot points are labeled with their observation numbers.

The values of all `ID` variables are displayed in tooltips when you create HTML output and specify the `IMAGEMAP` option in the `ODS GRAPHICS` statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for details.

VAR Statement

VAR *variables* ;

The `VAR` statement specifies the process variables and their order in the results. By default, if you omit the `VAR` statement, the `MVPMODEL` procedure analyzes all numeric variables that are not listed in the `BY` or `ID` statement.

Details: MVPMODEL Procedure

Classical T^2 Charts

Classical T^2 charts are defined as follows. Assume that there are n observations for p variables, denoted by $\mathbf{X}_1, \dots, \mathbf{X}_n$, where \mathbf{X}_i is a p -dimensional vector. The T^2 statistic for observation i is

$$T_i^2 = (\mathbf{X}_i - \bar{\mathbf{X}}_n)' \mathbf{S}^{-1} (\mathbf{X}_i - \bar{\mathbf{X}}_n)$$

where

$$\bar{X}_j = \frac{1}{n} \sum_{i=1}^n X_{ij}, \quad \mathbf{X}_i = \begin{bmatrix} X_{i1} \\ X_{i2} \\ \vdots \\ X_{ip} \end{bmatrix}, \quad \bar{\mathbf{X}}_n = \begin{bmatrix} \bar{X}_1 \\ \bar{X}_2 \\ \vdots \\ \bar{X}_p \end{bmatrix}$$

and

$$\mathbf{S} = \frac{1}{n-1} \sum_{i=1}^n (\mathbf{X}_i - \bar{\mathbf{X}}_n) (\mathbf{X}_i - \bar{\mathbf{X}}_n)'$$

For purposes of deriving control limits for the T^2 chart, it is assumed that \mathbf{X}_i has a p -dimensional multivariate normal distribution with mean vector $\boldsymbol{\mu} = (\mu_1, \mu_2, \dots, \mu_p)'$ and covariance matrix $\boldsymbol{\Sigma}$ for $i = 1, 2, \dots, n$. The classical formulation of the T^2 chart does not involve a principal component model for the data, and it bases the computation of T^2 on the sample covariance matrix \mathbf{S} . See Alt (1985) for theoretical details and the section “[Multivariate Control Charts](#)” on page 2206 for an example.

A classical T^2 chart is equivalent to a T^2 chart based on a full principal component model (with p components), as discussed in the section “[Relationship of Principal Components to Multivariate Control Charts](#)” on page 967. See [Example 12.2](#) for more information.

Principal Component Analysis

Principal component analysis was originated by Pearson (1901) and later developed by Hotelling (1933). The application of principal components is discussed by Rao (1964), Cooley and Lohnes (1971), Gnanadesikan (1977), and Jackson (1991). Excellent statistical treatments of principal components are found in Kshirsagar (1972), Morrison (1976), and Mardia, Kent, and Bibby (1979).

Principal component modeling focuses on the number of components used. The analysis begins with an eigenvalue decomposition of the sample covariance matrix, \mathbf{S} ,

$$\mathbf{S} = \frac{1}{n-1} \sum_{i=1}^n (\mathbf{X}_i - \bar{\mathbf{X}}_n) (\mathbf{X}_i - \bar{\mathbf{X}}_n)'$$

as

$$\begin{aligned} \mathbf{S} &= \mathbf{P}\mathbf{L}\mathbf{P}' \\ \mathbf{P}'\mathbf{S}\mathbf{P} &= \mathbf{L} \end{aligned}$$

where \mathbf{L} is a diagonal matrix and \mathbf{P} is an orthogonal matrix (Jackson 1991; Mardia, Kent, and Bibby 1979). The columns of \mathbf{P} are the eigenvectors, and the diagonal elements of \mathbf{L} are the eigenvalues. The eigenvectors are customarily scaled so that they have unit length.

A principal component, t_i , is a linear combination of the original variables. The coefficients are the eigenvectors of the covariance matrix. The principal component scores for the i th observation are computed as

$$t_i = \mathbf{P}'(\mathbf{x}_i - \bar{\mathbf{x}})$$

The principal components are sorted by descending order of the eigenvalues, which are equal to the variances of the components.

The eigenvectors are the principal component loadings. The eigenvectors are orthogonal, so the principal components represent jointly perpendicular directions through the space of the original variables. The scores on the first j principal components have the highest possible generalized variance of any set of j unit-length linear combinations of the original variables.

The first j principal components provide a least squares solution to the model

$$\mathbf{X} = \mathbf{TP}' + \mathbf{E}$$

where \mathbf{X} is an $n \times p$ matrix of the centered observed variables, \mathbf{T} is the $n \times j$ matrix of scores on the first j principal components, \mathbf{P}' is the $j \times p$ matrix of eigenvectors, and \mathbf{E} is an $n \times p$ matrix of residuals. The first j principal components are the vectors (rows of \mathbf{P}') that minimize $\text{trace}(\mathbf{E}'\mathbf{E})$, the sum of all the squared elements in \mathbf{E} .

The first j principal components are the best linear predictors of the process variables among all possible sets of j variables, although any nonsingular linear transformation of the first j principal components provides equally good prediction. The same result is obtained by minimizing the determinant or the Euclidean norm of $\mathbf{E}'\mathbf{E}$ rather than the trace.

Relationship of Principal Components to Multivariate Control Charts

Multivariate control charts typically plot the T^2 statistic, which is a summary of multivariate variation. The classical T^2 statistic is defined in “Classical T^2 Charts” on page 965. When there is high correlation among the process variables, the correlation matrix is nearly singular. The subspace in which the process varies can be adequately explained by fewer variables than the original p variables. Thus, the principal component approach to multivariate control charts is to project the original p variables into a lower-dimensional subspace by using a model based on j principal components, where $j < p$.

The key to the relationship between principal components and multivariate control charts is the decomposition of the sample covariance matrix, \mathbf{S} , into the form $\mathbf{S} = \mathbf{PLP}'$, where \mathbf{L} is a diagonal matrix (Jackson 1991; Mardia, Kent, and Bibby 1979). This is also the eigenvalue decomposition of \mathbf{S} , where the columns of \mathbf{P} are the eigenvectors and the diagonal elements of \mathbf{L} are the eigenvalues.

Equivalence of T^2 Statistics

The T^2 statistic that is produced by the full principal component model is equivalent to the classical T^2 statistic. This is seen in the matrix representation of the T^2 statistic computed from a principal component model that uses all p components,

$$T_i^2 = (\mathbf{t}_i - \bar{\mathbf{t}}_n)' \mathbf{L}_n^{-1} (\mathbf{t}_i - \bar{\mathbf{t}}_n)$$

Because $\bar{\mathbf{t}}_n$ is the zero matrix by construction, then

$$T_i^2 = \mathbf{t}_i' \mathbf{L}_n^{-1} \mathbf{t}_i$$

Because $\mathbf{t}_i = \mathbf{P}'(\mathbf{x}_i - \bar{\mathbf{x}})$, then

$$\begin{aligned} T_i^2 &= \mathbf{t}_i' \mathbf{L}_n^{-1} \mathbf{t}_i \\ &= (\mathbf{P}'(\mathbf{x}_i - \bar{\mathbf{x}}))' \mathbf{L}_n^{-1} (\mathbf{P}'(\mathbf{x}_i - \bar{\mathbf{x}})) \\ &= (\mathbf{x}_i - \bar{\mathbf{x}})' \mathbf{P} \mathbf{L}_n^{-1} \mathbf{P}' (\mathbf{x}_i - \bar{\mathbf{x}}) \\ &= (\mathbf{x}_i - \bar{\mathbf{x}})' \mathbf{S}^{-1} (\mathbf{x}_i - \bar{\mathbf{x}}) \end{aligned}$$

which is the classical form. Consequently the classical T^2 statistic can be expressed as a sum of squares,

$$T_i^2 = \frac{t_{i1}^2}{l_1^2} + \dots + \frac{t_{ip}^2}{l_p^2}$$

where l_k^2 is the variance of the k th principal component.

Computing the T^2 and SPE Statistics

Creating a T^2 chart that is based on a principal component model begins with choosing the number (j) of principal components. Effectively, this involves selecting a subspace in $j < p$ dimensions and then creating a T^2 statistic based on that j -component model.

The T^2 statistic is meant to monitor variation in the model space. However, if variation appears in the $p - j$ subspace orthogonal to model space, then the model assumptions and physical process should be reexamined. Variation outside the model space can be detected with an SPE chart.

In a model with j principal components, the T^2 statistic is calculated as

$$T_i^2 = \frac{t_{i1}^2}{l_1^2} + \dots + \frac{t_{ij}^2}{l_j^2}$$

where t_{ik} is the principal component score for the k th principal component of the i th observation and l_k is the standard deviation of t_{ik} .

The information in the remaining $p - j$ principal components is monitored with charts for the SPE statistic, which is calculated as

$$\begin{aligned} \text{SPE}_i &= \sum_{k=j+1}^p e_{ik}^2 \\ &= \sum_{k=j+1}^p (x_{ik} - \hat{x}_{ik})^2 \end{aligned}$$

Cross Validation (Experimental)

NOTE: The CV= option is experimental in this release.

You can use cross validation to choose the number of principal components in the model to avoid overfitting.

One method of choosing the number of principal components is to fit the model to only part of the available data (the *training set*) and to measure how well models with different numbers of extracted components fit the other part of the data (the *test set*). This is called *test set validation*. However, it is rare that you have enough make both parts large enough for pure test set validation to be useful.

Alternatively, you can make several different divisions of the observed data into a training set and a test set. This is called *cross validation*. The MVPMODEL procedure supports four types of cross validation. In *one-at-a-time* cross validation, the first observation is held out as a single-element test set, with all other observations as the training set; next, the second observation is held out, then the third, and so on. Another method is to hold out successive blocks of observations as test sets—for example, observations 1 through 7, then observations 8 through 14, and so on; this is known as *blocked* validation. A similar method is *split-sample* cross validation, in which successive groups of widely separated observations are held out as the test set—for example, observations {1, 11, 21, ...}, then observations {2, 12, 22, ...}, and so on. Finally, test sets can be selected from the observed data randomly; this is known as *random-sample* cross validation.

Which cross validation method you should use depends on your data. The most common method is one-at-a-time validation (**CV=ONE**), but it is not appropriate when the observed data are serially correlated. In that case either blocked (**CV=BLOCK**) or split-sample (**CV=SPLIT**) validation might be more appropriate; you can select the number of test sets in blocked or split-sample validation by specifying options in parentheses after the CV= option. The numbers in parentheses are the number of test sets over the rows and columns. For more information, see the section “An Alternative Scheme” in Wold (1978), as well as Eastment and Krzanowski (1982), both of which describe the cross validation approach used here in more detail.

CV=ONE is the most computationally intensive of the cross validation methods, because it requires you to recompute the principal component model for every input observation. Using random subset selection with **CV=RANDOM** might lead different researchers to produce different principal component models from the same data (unless the same seed is used).

Whichever validation method you use, the number of principal components that are chosen is usually the one that optimizes some criterion or selection rule. Choices of a criterion include the ratio described by Wold (1978), the W statistic described by Eastment and Krzanowski (1982), and the predicted residual sum of squares (PRESS). The W statistic is used by the MVPMODEL procedure.

The method of choosing the number of principal components in the MVPMODEL procedure is described in Eastment and Krzanowski (1982). This method is a heuristic based on the ratio of the mean PRESS (MPRESS) to the degrees of freedom for the principal component model. First, the MPRESS is computed for models with 0 to $maxcomp$ principal components. The maximum number of components is $\min(15, nvar, nobs) - 1$ and can be further reduced to the number of nonzero eigenvalues in the covariance matrix. Second, for each of the i possible number of components, the W_i statistic is computed as

$$W_i = \frac{MPRESS(i - 1) - MPRESS(i)}{D_i} \div \frac{MPRESS(i)}{D_R}$$

where $MPRESS = \frac{1}{np} PRESS$, D_i is the number of degrees of freedom used to fit the model with i principal components, and D_R is the remaining number of degrees of freedom.

Extracting too many components can lead to an overfit model, one that matches the training data too well, sacrificing predictive ability. Thus, if you specify the number of principal components in the model, you should not use cross validation to select the appropriate number of components for the final model, or you should consider the analysis to be preliminary and examine the results to determine the appropriate number of components for a subsequent analysis.

Centering and Scaling

By default, the variables are centered and scaled to have mean 0 and standard deviation 1. Without centering, both the mean variable value and the variation around that mean are involved in selecting principal component loadings. Scaling serves to place all process variables on an equal footing relative to their variation in the data. For example, if Time and Temp are two of the process variables, then scaling says that a change of std (Time) in Time is roughly equivalent to a change of std (Temp) in Temp.

The formulas that are used to compute the variation in the different centering and scaling cases are defined in the section “Definitional Formulas” in Chapter A, “Special SAS Data Sets” (*SAS/STAT User’s Guide*). The definitional formula that is used when either the NOSCALE or COV option is specified is the COV formula. The definitional formula that is used when the NOCENTER option is specified is the UCORR formula. The definitional formula that is used when both the NOCENTER and NOSCALE options are specified is the UCOV formula. The default definitional formula, when no centering or scaling options are specified, is the CORR formula.

Missing Values

By default, observations that have missing process variables are simply excluded from the analysis. If you specify `MISSING=AVG` in the `PROC MVPMODEL` statement, then all observations in the input data set contribute to both the analysis and the `OUT=` data set. With `MISSING=AVG`, the fit is computed by replacing missing values of a process variable with the average of its nonmissing values.

Input Data Set

The input data set provides the set of process variables that are analyzed. You can specify the input data set by using the `DATA=` option in the `PROC MVPMODEL` statement. If you do not specify the `DATA=` option, the procedure uses the last data set created as its input data set.

The MVPMODEL procedure treats each observation in the `DATA=` data set as an individual multivariate observation. The observations do not need to be identified or sorted by time because the sequence of the data is not used to build the principal component model. If you provide a time variable in the input data set, it is preserved in the `OUT=` data set and can be used subsequently by the MVPMONITOR procedure to create control charts.

In basic applications of the MVPMODEL procedure, the observations in the `DATA=` data set represent measurements from a single process. You can build different principal component models for two or more processes by grouping their measurements in the `DATA=` data and processing them as BY groups.

In some applications, it is desirable to combine the data from two or more processes and build a common principal component model. This might be the case with processes that are peers in

the sense that they are believed to share the same pattern of common cause variation. When you provide the MVPMONITOR procedure with a common model for a set of peer processes, it uses the model to construct identical control limits for each process. This enables you to decide whether a particular process exhibits unusual variation relative to the behavior of its peers.

Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the input data set plus new variables that contain the principal component scores, residuals, and other computed values listed in Table 12.2.

The names of the score variables are formed by concatenating the value given by the PREFIX= option (or the default Prin, if PREFIX= is not specified) and the numbers 1, 2, ..., j , where j is the number of principal components in the model.

The names of the residual variables are formed by concatenating the value given by the RPREFIX= option (or the default R_, if RPREFIX= is not specified) and the names of the process variables used in the analysis. Residual variables are created only when the number of principal components in the model is less than the number of process measurement variables in the input data set.

Table 12.2 Computed Variables in the OUT= Data Set

Variable	Description
Prin1–Prin j	Principal component scores
R_var1–R_var p	Residuals
NOBS	Number of observations used in the analysis
SPE	Squared prediction error (SPE)
TSQUARE	T^2 statistic computed from principal component scores

OUTLOADINGS= Data Set

The OUTLOADINGS= data set contains the eigenvalues of the correlation (or covariance) matrix, the loadings computed for the process variables, and other information about the principal component model. The variables that are saved in the OUTLOADINGS= data set are listed in Table 12.3.

Table 12.3 Variables in the OUTLOADINGS= Data Set

Variable	Description
VALUE	Character variable identifying the type of values in an observation
PC	Principal component number
NOBS	Number of observations used in the analysis
<i>process variables</i>	Eigenvalues, means, standard deviations, and loadings for <i>process variables</i>

Valid values for the `_VALUE_` variable are as follows:

EIGEN	eigenvalues from the principal component analysis
LOADING	principal component loadings
MEAN	process variable means
STD	process variable standard deviations

For an observation where `_VALUE_` is equal to `LOADING`, the `_PC_` variable identifies the principal component whose loadings are recorded in that observation.

The process variable means and standard deviations are used by the other MVP procedures to center and scale new data in a Phase II analysis. If you specify the `NOCENTER` option, the `OUTLOADINGS=` data set does not contain a `MEAN` observation. If you specify the `NOSCALE` option, the `OUTLOADINGS=` data set does not contain a `STD` observation.

ODS Table Names

PROC MVPMODEL assigns a name to each table that it creates. You can use these names to refer to the tables when you use the Output Delivery System (ODS) to select tables and create output data sets. The ODS table names are listed in Table 12.4.

Table 12.4 ODS Tables Produced with the PROC MVPMODEL Statement

ODS Table Name	Description	Option
Corr	Correlation matrix	Default
Cov	Covariance matrix	<code>COV</code> or <code>NOSCALE</code>
CVResults	Results of cross validation	<code>CV=</code>
Eigenvalues	Eigenvalues of the correlation or covariance matrix	Default
ModelInfo	Model information	Default
ResidualSummary	Residual summary from cross validation	<code>CV=</code>

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The MVPMODEL procedure assigns a name to each graph that it creates using ODS Graphics. You can use these names to refer to the graphs when you use ODS. The ODS graph names are listed in Table 12.5.

Table 12.5 ODS Graphics Produced by PROC MVPMODEL

ODS Graph Name	Plot Description	Statement
CVPlot	Cross validation and R^2 analysis	CV=
LoadingMatrix	Scatter plot matrix of variable loadings	PLOTS=LOADINGS
LoadingPlot	Scatter plot of variable loadings	PLOTS=LOADINGS(UNPACK)
ScoreMatrix	Scatter plot of scores	PLOTS=SCORE
ScorePlot	Scatter plot of scores	PLOTS=SCORE(UNPACK)
ScreePlot	Scree and variance-explained plots	Default
VariancePlot	Variance-explained plot	PLOTS=SCREE(UNPACK)

Examples: MVPMODEL Procedure

Example 12.1: Using Cross Validation to Select the Number of Principal Components

This example uses cross validation to select the number of principal components in a model. It uses the chromatography data from McReynolds (1970), which is also used in Wold (1978) and Eastment and Krzanowski (1982). The following statements create the chromatography data set:

```

data mcreynolds;
  input x1 - x10;
  datalines;
653  590  627  652  699  690  818  841  654  1006
654  591  628  654  701  691  818  842  655  1006
665  592  624  653  710  690  828  843  659  1014
662  595  629  658  710  692  827  843  660  1012
663  595  630  659  712  693  829  843  663  1013
664  596  629  659  712  692  830  843  663  1015
667  604  635  669  720  700  833  846  668  1016
684  612  642  682  739  702  850  851  682  1035
685  612  642  684  741  703  853  852  685  1039

... more lines ...

1247  1447  1386  1683  1616  1370  1327  1220  1508  1275
1300  1509  1424  1695  1675  1403  1362  1229  1571  1305
1343  1581  1480  1762  1699  1463  1375  1212  1618  1285
;

```

The observations are liquid phases, and the variables are compounds. The (i, j) value is the retention index for liquid phase i in compound j . The retention index values in the original article had the value of squalane subtracted from them. In this data set, the values have been corrected by adding the retention indices for squalane to all observations.

The following statements use the MVPMODEL procedure to select the number of principal components by using one-at-a-time cross validation:

```
proc mvpmodel data=mcreynolds plots=(scree cvplot) noscale cv=one;
run;
```

The `CV=` option specifies which method of cross validation to use to produce model diagnostics; in this case one-at-a-time cross validation is used. The `PLOTS=` option produces only the combination scree plot and variance-explained plot in addition to the cross validation plots.

Output 12.1.1 shows the model and data set information.

Output 12.1.1 Summary of Model and Data Set Information

The MVPMODEL Procedure		
Data Set		WORK.MCREYNOLDS
Number of Variables		10
Missing Value Handling		Exclude
Number of Observations Read		226
Number of Observations Used		225
Maximum Number of Principal Components		9
Validation Method		Leave-one-out Cross Validation

Output 12.1.1 shows that one observation, liquid phase 69 (Triton X-400), was omitted because of a missing value. Also, notice that the maximum number of principal components is $\min(15, nvar, nobs) - 1 = 9$, which is less than the number of variables; this is described in detail in Eastment and Krzanowski (1982).

The root mean PRESS values and the W statistic are shown in Output 12.1.2.

Output 12.1.2 Residual Summary

Cross Validation for the Number of Components		
Number of Components	Root Mean PRESS	W
0	974.3136	.
1	30.77631	9586.179
2	26.85973	2.707278
3	26.49878	0.211824
4	22.94873	2.261922
5	21.50501	0.810642
6	20.91568	0.279385
7	20.53967	0.14514
8	20.25766	0.082967
9	20.03932	0.04342

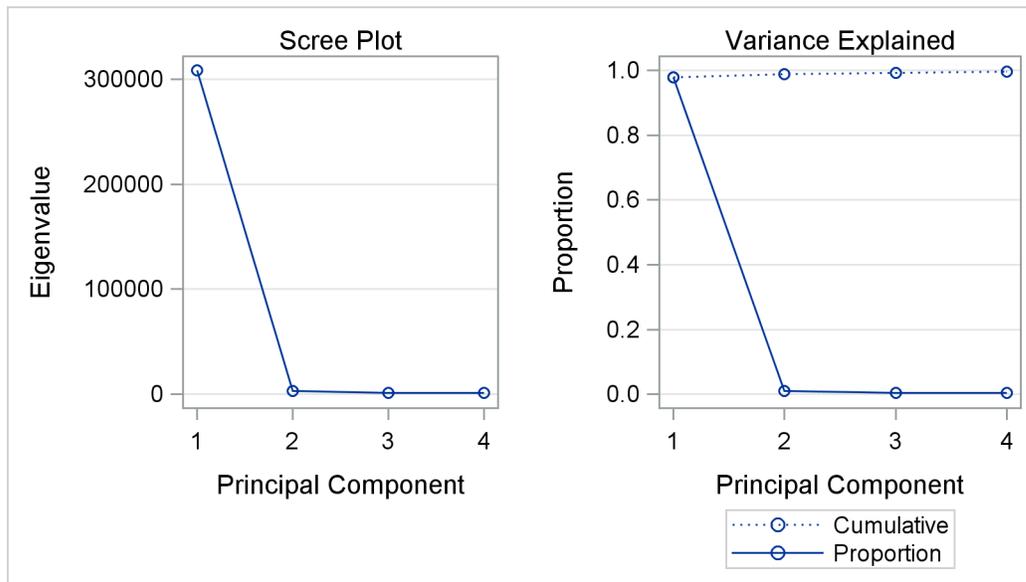

In this case the index of the last W statistics greater than one is $W[4]$, suggesting a model with four components as shown in [Output 12.1.3](#).

Output 12.1.3 Cross Validation Results

Number of Components Suggested by W Statistic	4
---	---

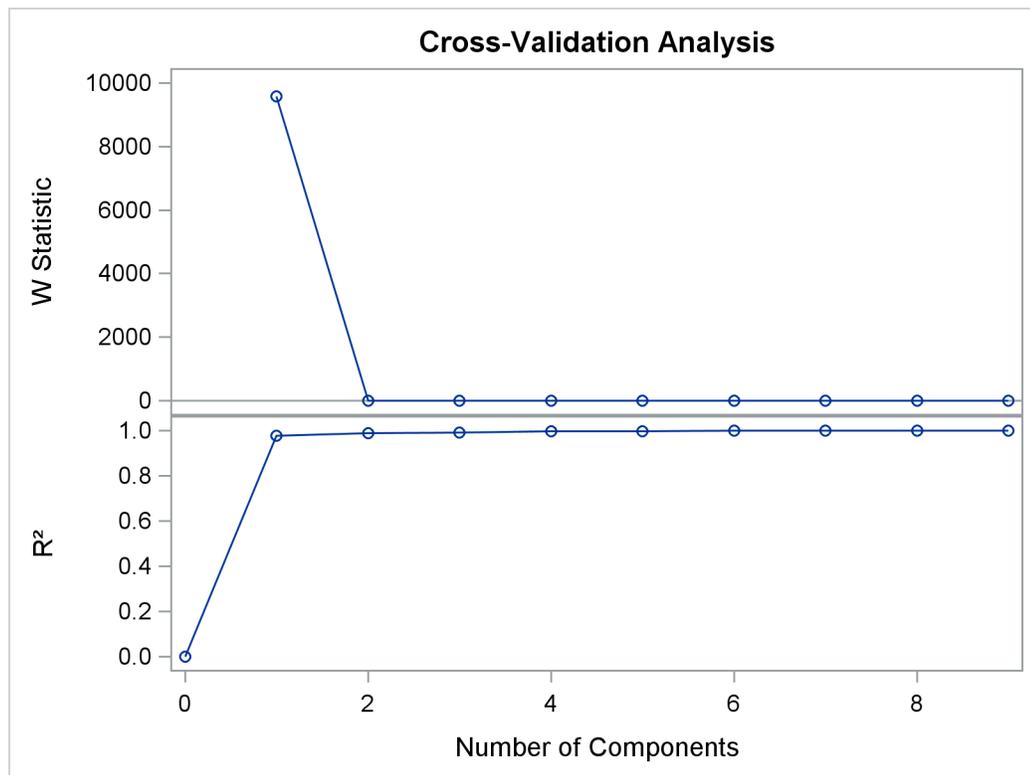

You can also use scree and variance-explained plots to select the number of principal components, as shown in [Output 12.1.4](#).

Output 12.1.4 Scree and Variance-Explained Plots

The plots in [Output 12.1.4](#) indicate that one or two principal components explain almost all the variation.

The W statistic and R^2 plots are shown in [Output 12.1.5](#).

Output 12.1.5 Cross Validation Analysis

The cross validation plot is produced only when you specify both the `CV=` option and `PLOTS=ALL` or `PLOTS=CVPLOT`.

It is interesting that the cross validation methods of Wold (1978) and Eastment and Krzanowski (1982) choose five and four components, respectively, for this model, whereas a visual examination of the knee in the scree plot might suggest using only one or two components.

Example 12.2: Computing the Classical T^2 Statistic

NOTE: The `CV=` option is experimental in this release.

This example uses the MVPMODEL procedure to produce a classical T^2 statistic and then compares it to the T^2 statistic produced by the principal component model with the `NCOMP=ALL` option. The two statistics are discussed in the section “[Details: MVPMODEL Procedure](#)” on page 965, and this example demonstrates that when the data set is centered and scaled correctly, the statistics are equal. The classical T^2 statistic is computed using the common quadratic form, which is implemented in SAS/IML. This example highlights the standardization that occurs by default in the MVPMODEL procedure. The example uses more of the airline delay data set that is first described in the section “[Getting Started: MVPMODEL Procedure](#)” on page 950. This data set covers the New England region of the continental United States. As before, the variables are airlines and the observations are mean daily delays during February 2007. The following statements create a SAS data set that contains these airline flight delays:

```

data flightDelaysNE;
  input AA CO DL F9 FL NW UA US WN;
  datalines;
15.7  7.1  8.6  6.3 14.6  6.2  7.0 11.0  6.4
16.0 19.4 10.7  6.4 19.0  6.1  8.3 14.4 14.2
14.5  1.5  5.4 13.3 13.6  9.7 16.6  7.5  9.9
12.4 14.3  5.8  0.7 11.8 20.1 11.2  8.6  8.1
19.8 27.6  7.3 16.1 13.3 14.8 39.9 16.4  9.7
20.5 12.2  0.2 -4.8  3.7 14.2 41.7  4.9  9.2
  8.3  4.1  3.4  4.2 -2.3  6.3 24.9  8.7  4.4
  4.7 14.1  1.8 18.1 -1.9 10.2  5.4  5.8  3.7
16.7 15.0  3.5 11.8  0.8  7.3 11.1  7.2  5.1

  ... more lines ...

21.2 10.2  5.6  1.1 18.7  9.2 35.0 49.7 35.9
22.5 30.0 26.1 14.2 41.5 46.2 43.6 75.5 34.1
62.7 60.4 39.5 27.6 44.9 27.9 51.5 64.7 38.2
31.3 41.4 23.1 40.2 19.3 19.7 28.3 40.4 17.3

```

The following statements use the MVPMODEL procedure to create classical T^2 statistics:

```

proc mvpmode data=flightDelaysNE ncomp=all plots=none out=mvout;
  var AA CO DL F9 FL NW UA US WN;
run;

```

Specifying `NCOMP=ALL` sets the number of principal components to be used in the model equal to the number of process variables. Therefore, as discussed in the section “[Details: MVPMODEL Procedure](#)” on page 965, the mvout data set contains the classical T^2 statistic for each observation, $T_i^2 = (\mathbf{x}_i - \bar{\mathbf{x}})' \mathbf{S}^{-1} (\mathbf{x}_i - \bar{\mathbf{x}})$.

The following SAS/IML statements generate the Hotelling T^2 statistic for the data set by using the traditional quadratic form. However, the data must first be standardized as done by the MVPMODEL procedure.

NOTE: If you do not want PROC MVPMODEL to center or scale the data, specify the `NOCENTER` or `NOSCALE` option, respectively.

```

proc iml;
  use flightDelaysNE;
  read all into x;
  n = nrow(x);
  p = ncol(x);
  xc = x-x[1,:]; /* Create a centered data set*/
  ss = xc[##,]; /* Compute sum of squares */
  std=sqrt(ss/(n-1)); /* Compute standard deviations */
  std_x = xc/std; /* Create a standardized data set*/
  S= cov(std_x); /* Compute covariance of standardized data*/
  tsq = J(n,1,.);
  do i = 1 to n;
  /* Compute the classical T2 statistic using quadratic form */
    tsq[i] = std_x[i,]*inv(S)*std_x[i,]`;
  end;
  varnames = "tsq";

```

```

create classicTsq from tsq [colname = varnames];
append from tsq;
quit;

```

To compare the output from the MIVMODEL procedure with the output from SAS/IML, a new data set, `mvpTsq`, which contains the T^2 statistics computed by using the quadratic form in SAS/IML, is created:

```

data mvpTsq;
  set mvpOut(rename=(TSQUARE=tsq));
  keep tsq;
run;

```

Finally, you can verify that the two statistics are equivalent within machine precision by using the COMPARE procedure:

```

proc compare base=classicTsq compare=mvpTsq
  method=relative briefsummary;
run;

```

Output 12.2.1 Comparison of T^2 Statistics

```

The COMPARE Procedure
Comparison of WORK.CLASSICTSQ with WORK.MVPTSQ
(Method=RELATIVE, Criterion=0.00001)

NOTE: All values compared are within the equality criterion used. However, 16
of the values compared are not exactly equal.

```

Overview: MVPMONITOR Procedure

The MVPMONITOR procedure is used in conjunction with the MVPMODEL and MVPDIAGNOSE procedures to monitor multivariate process variation over time, to determine whether the process is stable, and to detect and diagnose changes in a stable process. Collectively, these three procedures are referred to as the *MVP procedures*. See Chapter 10, “Introduction to Multivariate Process Monitoring Procedures,” for a description of how the MVP procedures work together, and Chapter 12, “The MVPMODEL Procedure,” and Chapter 11, “The MVPDIAGNOSE Procedure,” for detailed descriptions of the other MVP procedures.

The MVPMONITOR procedure produces control charts for multivariate process data. It reads data sets that contain statistics and principal component model information such as those created by the MVPMODEL procedure. The MVPMONITOR procedure creates two types of multivariate control chart: T^2 charts and squared prediction error (SPE) charts. It can also produce contribution plots for out-of-control points in the control charts.

Multivariate control charts detect unusual variation that would not be uncovered by individually monitoring the process variables with univariate control charts, such as Shewhart charts. A major impetus in the development of multivariate control charts is the inadequacy of individual univariate control charts in handling correlated measurement variables. A multivariate control chart can detect changes in the linear relationships of the variables in addition to their marginal means and variances.

The multivariate control charts that the MVPMONITOR procedure produces are based on principal component models that reduce the dimensionality of the data by projecting the process measurements to a low-dimensional subspace that is defined by a small number of principal components. This subspace is also known as the *model hyperplane*. T^2 charts are used to monitor variation within the model hyperplane, whereas SPE charts show variation from the model hyperplane.

The principal component approach offers several advantages over the construction of the classical T^2 chart:

- It avoids computational issues that arise when the process variables are collinear and their covariance matrix is nearly singular.
- It offers diagnostic tools for interpreting unusual values of T^2 .
- By projecting the data to a low-dimensional subspace, it more adequately describes the variation in a multivariate process, which is often driven by a small number of underlying factors that are not directly observable.

Getting Started: MVPMONITOR Procedure

This example illustrates the basic features of the MVPMONITOR procedure by using airline flight delay data available from the U.S. Bureau of Transportation Statistics at <http://www.transtats.bts.gov>. The example applies multivariate process monitoring to flight delays, and it is a continuation of the example in the section “Getting Started: MVPMODEL Procedure” on page 950.

Suppose you want to use a principal component model to create T^2 and SPE charts to monitor the variation in flight delays. These charts are appropriate because the data are multivariate and correlated.

The following statements create a SAS data set named `MWflightDelays`, which provides daily average delays by airline for flights that originated in the midwestern United States. The data set contains variables for nine airlines: AA (American Airlines), CO (Continental Airlines), DL (Delta Airlines), F9 (Frontier Airlines), FL (AirTran Airways), NW (Northwest Airlines), UA (United Airlines), US (US Airways), and WN (Southwest Airlines).

```

data MWflightDelays;
  format flightDate MMDDYY8.;
  label flightDate='Date';
  input flightDate :MMDDYY8. AA CO DL F9 FL NW UA US WN;
  datalines;
02/01/07 14.9  7.1  7.9  8.5 14.8  4.5  5.1 13.4  5.1

```

The observations for a given date are the average flight delays in minutes for flights that departed from the midwestern United States. For example, on February 2, 2007, F9 (Frontier Airlines) flights departed 6.2 minutes late on average.

Creating a Multivariate Control Chart in a Phase I Situation

In a Phase I analysis you first perform a principal component analysis (PCA) of the data. Then you can use control charts to determine whether the data that you use to build the principal component model indicate a stable multivariate process. The MVPMONITOR procedure creates multivariate control charts from T^2 and SPE statistics computed from a principal component model that the MVPMODEL procedure produced. This example uses the model built in the section “Building a Principal Component Model” on page 953 in Chapter 12, “The MVPMODEL Procedure.”

The following statements fit the model:

```

proc mvpmode data=MWflightDelays ncomp=3 noprint
  out=mvpair outloadings=mvpairloadings;
  var AA CO DL F9 FL NW UA US WN;
run;

```

The **NCOMP=** option requests a principal component model that contains three principal components. The **OUT=** option creates a data set that contains the original data, the scores, and the T^2 and SPE statistics. The **OUTLOADINGS=** data set contains the variances and loadings for the principal components.

The following statements produce the multivariate control charts:

```

ods graphics on;
proc mvpmonitor history=mvpair loadings=mvpairloadings;
  time flightDate;
  tsquarechart / contributions;
  spechart / contributions;
run;

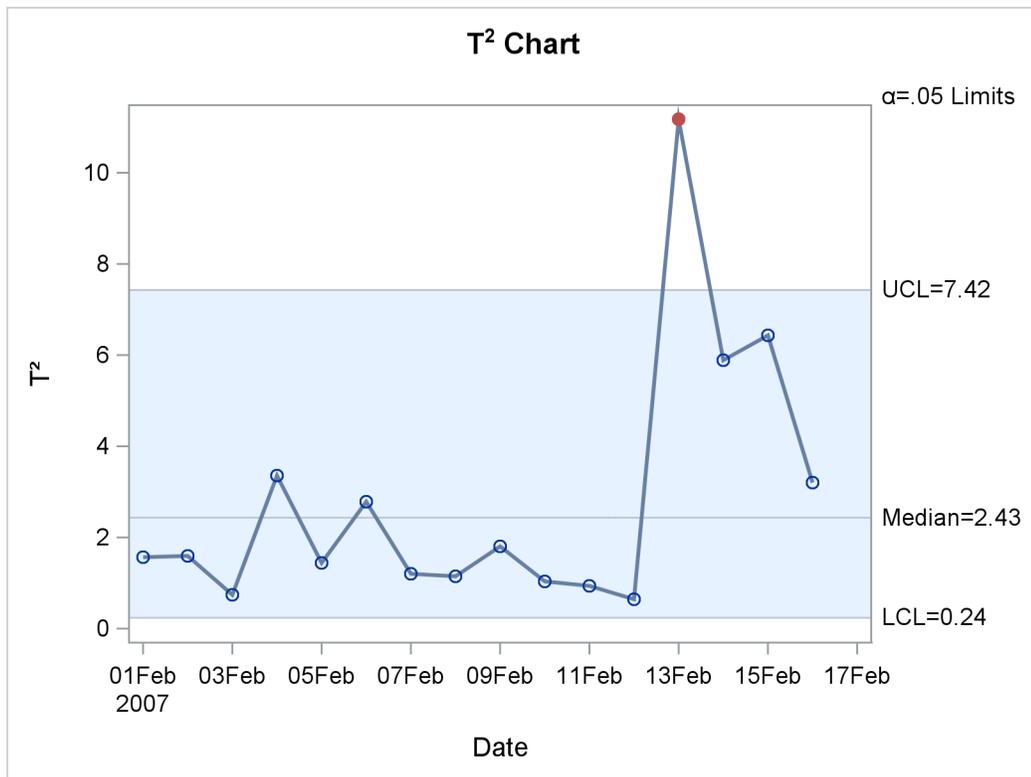

```

The **HISTORY=** option specifies the input data set. The **LOADINGS=** option specifies the data set that contains the principal component model information. The **TSQUARECHART** statement requests a T^2 chart, and the **SPECHART** statement requests an SPE chart. The **CONTRIBUTIONS** options that are specified in the **TSQUARECHART** and **SPECHART** statements request contribu-

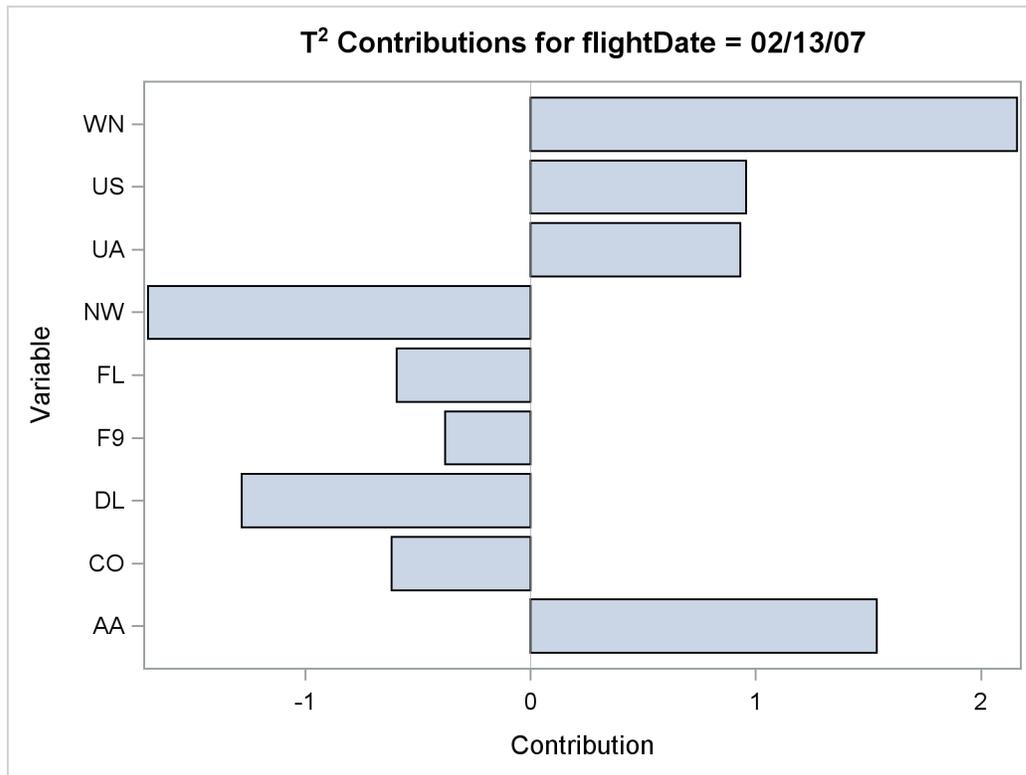

tion plots for all out-of-control points in the charts. The `TIME` statement specifies that the variable `flightDate` provide the chronological ordering of the observations.

Figure 13.1 shows the T^2 chart.

Figure 13.1 Multivariate Control Chart for T^2 Statistics

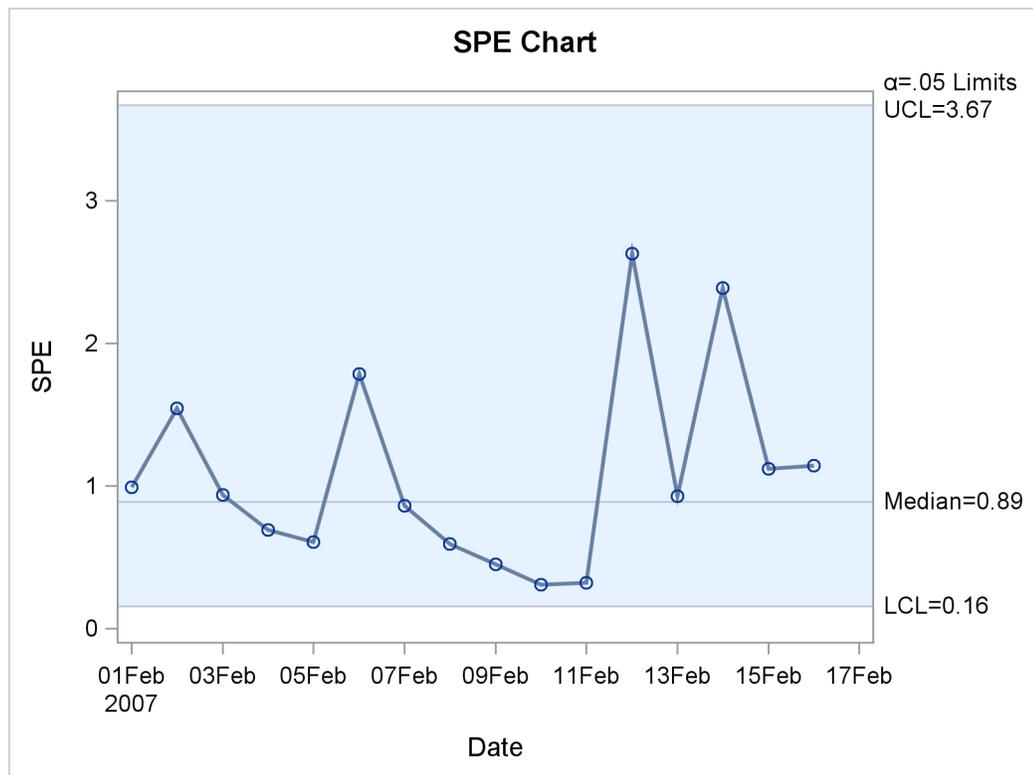

The T^2 chart shows an out-of-control point on February 13, 2007. On this day, a strong winter storm battered the midwestern United States. To see which variables contributed to this statistic, you can use the contribution plot shown in Figure 13.2.

Figure 13.2 Contribution Plot

The contribution plot shows that the variables WN, AA, NW, and DL are the major contributors to the out-of-control point.

Figure 13.3 shows the SPE chart.

Figure 13.3 Multivariate Control Chart for SPE Statistics

There are no out-of-control points in the SPE chart. This indicates that the unusual point displayed in the T^2 chart represents a departure from the variation described by the principal component model that lies within the model hyperplane.

Syntax: MVPMONITOR Procedure

```
PROC MVPMONITOR < options > ;
  BY variables ;
  ID variable ;
  SERIES variable ;
  SPECHART < / options > ;
  TIME variable ;
  TSQUARECHART < / options > ;
```

The following sections describe the PROC MVPMONITOR statement and then describe the other statements in alphabetical order.

PROC MVPMONITOR Statement

PROC MVPMONITOR < options > ;

The PROC MVPMONITOR statement invokes the MVPMONITOR procedure and specifies input and output data sets. You can specify the following *options*:

DATA=SAS-data-set

specifies an input SAS data set that contains process measurement data for a Phase II analysis. If you specify a DATA= data set, you must also specify a **LOADINGS=** data set. You cannot specify the **HISTORY=** or **TABLE=** option together with the DATA= option. See the section “**DATA= Data Set**” on page 997 for details about DATA= data sets.

HISTORY=SAS-data-set

specifies an input SAS data set that contains process variable data augmented with principal component scores, multivariate summary statistics, and other calculated values. This data set is used for a Phase I analysis. Usually, a HISTORY= data set is created as an **OUT=** data set from the MVPMODEL procedure. You cannot specify the **DATA=** or **TABLE=** option with the HISTORY= option. See the section “**HISTORY= Data Set**” on page 997 for details about HISTORY= data sets.

LOADINGS=SAS-data-set

specifies an input SAS data set that contains eigenvalues, principal component loadings, and process variable means and standard deviations that are used to compute principal component scores and multivariate summary statistics for a Phase II analysis. Usually, the LOADINGS= data set is produced by the MVPMODEL procedure as an **OUTLOADINGS=** data set. See the section “**LOADINGS= Data Set**” on page 998 for details about LOADINGS= data sets.

MISSING=AVG | NONE

specifies how to handle observations that have missing process variable values in the **DATA=** data set. The option **MISSING=AVG** specifies that missing values for a given variable be replaced by the average of the nonmissing values for that variable. The default is **MISSING=NONE**, for which observations that have missing values for any of the process variables are excluded from the analysis.

OUTHISTORY=SAS-data-set

OUT=SAS-data-set

creates an output data set that contains all the original data from the input data set, principal component scores, and multivariate summary statistics. See the section “**OUTHISTORY= Data Set**” on page 1000 for details. You can produce an OUTHISTORY= data set only when you specify a **DATA=** input data set.

PREFIX=name

specifies the prefix to use to identify variables that contain principal component scores in the **HISTORY=** data set. For example, if you specify **PREFIX=ABC**, PROC MVPMONITOR attempts to read the score variables ABC1, ABC2, ABC3, and so on. The default **PREFIX=** value is Prin, which is the default score variable prefix that PROC MVPMODEL uses when it creates an **OUT=** data set. If you use an **OUT=** data set from MVPMODEL as a **HISTORY=** data set, the **PREFIX=** value must match the **PROC MVPMODEL PREFIX=** value that is specified when the **OUT=** data set is created.

NOTE: The number of characters in the prefix plus the number of digits that are required to enumerate the principal components must not exceed the current name length defined by the VALIDVARNAME= system option.

RPREFIX=*name*

specifies the prefix to use to identify variables that contain residuals in the HISTORY= data set. Residual variable names are formed by appending process variable names to the prefix. The default RPREFIX= value is R_, which is the default residual variable prefix that PROC MVPMODEL uses when it creates an OUT= data set. If you use an OUT= data set from PROC MVPMODEL as a HISTORY= data set, the RPREFIX= value must match the PROC MVPMODEL RPREFIX= value that is specified when the OUT= data set is created.

If the combined length of the residual prefix and a process variable name exceeds the maximum name length defined by the VALIDVARNAME= system option, characters are removed from the middle of the process variable name before it is appended to the residual prefix. For example, if you specify RPREFIX=*Residual_* (nine characters), the maximum variable name length is 32, and there is a process variable named PrimaryThermometerReading (25 characters), then two characters are dropped from the middle of the process variable name. The resulting residual variable name is Residual_PrimaryThermometerReading.

TABLE=*SAS-data-set*

specifies an input SAS data set that contains summary information from an SPE or T^2 chart. You can produce a TABLE= data set by specifying the OUTTABLE= option in an SPECHART or TSQUARECHART statement. You can use a TABLE= input data set to display a previously computed control chart. You cannot specify the DATA= or HISTORY= option together with the TABLE= option. See the section “TABLE= Data Set” on page 999 for details.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC MVPMONITOR to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MVPMONITOR procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variables* ;

The values of the *ID variables* are displayed in tooltips associated with points on a control chart when you create HTML output and specify the IMAGEMAP option in the ODS GRAPHICS statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for details.

SERIES Statement

SERIES *variable* ;

The *SERIES variable* uniquely identifies a series of observations in the input data set to be plotted in a control chart. You must specify a **SERIES** statement when you specify an **SPECHART** or **TSQUARECHART** statement and when the input data set contains more than one observation that has the same **TIME** variable value. See [Example 13.1](#) for an illustration of how to use the **SERIES** statement.

SPECHART Statement

SPECHART < / *options* > ;

The **SPECHART** statement produces a control chart of the squared prediction error (SPE) statistics based on a principal component model that the **MVPMODEL** procedure computes. In a Phase I analysis, the SPE statistics are computed by **PROC MVPMODEL** and read from the **HISTORY=** data set. In a Phase II analysis, the SPE statistics are computed by the **MVPMONITOR** procedure from information about the principal component model that is specified in the **LOADINGS=** data set.

[Table 13.1](#) summarizes the *options* available in the **SPECHART** statement. For detailed descriptions, see the section “[Common Chart Statement Options](#)” on page 991.

Table 13.1 SPECHART Statement Options

Option	Description
ALPHA=	Specifies the probability used to compute SPE chart limits
CONTRIBUTIONS	Creates contribution plots for points outside control limits
EXCHART	Specifies that an SPE chart be displayed only if there are points lying outside control limits
INTERVAL=	Specifies the time interval between consecutive positions on an SPE chart
NOCHART	Suppresses creation of an SPE chart

Table 13.1 (continued)

Option	Description
NOHLABEL	Suppresses the horizontal axis label of an SPE chart
NOVLABEL	Suppresses the vertical axis label of an SPE chart
NPANELPOS=	Specifies the number of horizontal axis plotting positions per panel
ODSFOOTNOTE=	Adds a footnote to an SPE chart
ODSFOOTNOTE2=	Adds a secondary footnote to an SPE chart
ODSTITLE=	Specifies a title for an SPE chart
ODSTITLE2=	Specifies a secondary title for an SPE chart
OUTTABLE=	Creates a SAS data set that contains a summary of an SPE chart
OVERLAY	Specifies that separate sequences of observations be plotted in a single SPE chart
SERIESVALUE=	Specifies SERIES variable values selecting sequences to be plotted
TOTPANELS=	Specifies the number of panels used to display an SPE chart

TIME Statement

TIME *variable* ;

The **TIME** *variable* is a numeric variable that provides the chronological order or time values for measurements in a **DATA=**, **HISTORY=**, or **TABLE=** input data set. The values of the **TIME** *variable* are displayed on the horizontal axis of control charts. If no **TIME** statement is specified, the observation numbers from the input data set are displayed on the horizontal axis.

When there are multiple observations per time point in the data that are used to create the principal component model, the control limits for the SPE chart are computed differently; see the section “Computing SPE Control Limits” on page 995.

TSQUARECHART Statement

TSQUARECHART < / *options* > ;

The **TSQUARECHART** statement produces a T^2 chart based on a principal component model that the **MVPMODEL** procedure computes. In a Phase I analysis, the T^2 statistics are computed by **PROC MVPMODEL** and read from the **HISTORY=** data set. In a Phase II analysis, the T^2 statistics are computed by the **MVPMONITOR** procedure from information about the principal component model specified in the **LOADINGS=** data set.

Table 13.2 summarizes the *options* available in the **TSQUARECHART** statement. For detailed descriptions, see the section “Common Chart Statement Options” on page 991.

Table 13.2 TSQUARECHART Statement Options

Option	Description
ALPHA=	Specifies the probability used to compute T^2 chart limits
CONTRIBUTIONS	Creates contribution plots for points outside the control limits

Table 13.2 (continued)

Option	Description
EXCHART	Specifies that a T^2 chart be displayed only if there are points lying outside the control limits
INTERVAL=	Specifies the time interval between consecutive positions on a T^2 chart
NOCHART	Suppresses creation of a T^2 chart
NOHLABEL	Suppresses the horizontal axis label of a T^2 chart
NOVLABEL	Suppresses the vertical axis label of a T^2 chart
NPANELPOS=	Specifies the number of horizontal axis plotting positions per panel
ODSFOOTNOTE=	Adds a footnote to a T^2 chart
ODSFOOTNOTE2=	Adds a secondary footnote to a T^2 chart
ODSTITLE=	Specifies a title for a T^2 chart
ODSTITLE2=	Specifies a secondary title for a T^2 chart
OUTTABLE=	Creates a SAS data set that contains a summary of a T^2 chart
OVERLAY	Specifies that separate sequences of observations be plotted on a single T^2 chart
SERIESVALUE=	Specifies SERIES variable values selecting sequences to be plotted
TOTPANELS=	Specifies the number of panels used to display a T^2 chart

Common Chart Statement Options

You can specify the following *options* after a slash (/) in an **SPECHART** or **TSQUARECHART** statement.

ALPHA=value

specifies the probability used to compute control limits for an SPE or T^2 chart. If you specify **ALPHA**= α , the control limits are computed so that the probability is α that the statistic exceeds its control limits. The *value* of α can range from 0 to 1. By default, α is 0.05.

CONTRIBUTIONS <(contribution-options)>

creates a contribution plot for each point that falls outside the control limits of the chart. You can specify the following *contribution-options* in parentheses:

MAXNPLOTS=n

specifies the maximum number, n , of contribution plots to produce. When n is less than the number of points outside the control limits, contribution plots are produced for the first n out-of-control points.

MAXNVARs=n

specifies that only the n contributions with the greatest magnitudes be displayed in the contribution plots. For each out-of-control point, the n variables that contribute the most to that value of the statistic are displayed. By default, all variable contributions are displayed.

EXCHART

specifies that a control chart be displayed only when one or more points lie outside the control limits.

INTERVAL=DAY | DTDAY | HOUR | MINUTE | MONTH | QTR | SECOND

specifies the natural time interval between consecutive **TIME** variable positions when a time, date, or datetime format is associated with the **TIME** variable. By default, the **INTERVAL=** option uses the number of positions per panel that you specify with the **NPANELPOS=** option. The default time interval keywords for various time formats are shown in [Table 13.3](#).

Table 13.3 Default Time Intervals

Time Format	Default Interval
DATE	DAY
DATETIME	DTDAY
DDMMYY	DAY
HHMM	HOUR
HOUR	HOUR
MMDDYY	DAY
MMSS	MINUTE
MONYY	MONTH
TIME	SECOND
TOD	SECOND
WEEKDATE	DAY
WORDDATE	DAY
YYMMDD	DAY
YYQ	QTR

You can use the **INTERVAL=** option to modify the effect of the **NPANELPOS=** option, which specifies the number of positions per panel. The **INTERVAL=** option enables you to match the scale of the horizontal axis to the scale of the **TIME** variable without having to associate a different format with the **TIME** variable.

For example, suppose your formatted time values span 100 days and a datetime format is associated with the **TIME** variable. Since the default interval for the datetime format is **dtday** and because **NPANELPOS=50** by default, the chart is displayed with two panels.

Now suppose your data span 100 hours and a datetime format is associated with the **TIME** variable. The chart for these data is created in a single panel, but the data occupy only a small fraction of the chart because the scale of the data (hours) does not match that of the horizontal axis (days). If you specify **INTERVAL=HOUR**, the horizontal axis is scaled for 50 hours, matching the scale of the data, and the chart is displayed with two panels.

NOCHART

suppresses display of the control chart. You can use the **NOCHART** option with the **CONTRIBUTIONS** option to produce contribution plots for out-of-control points without displaying the control chart. You can use the **NOCHART** option with the **OUTTABLE=** option to save a summary of the control chart to an output data set without displaying the chart.

NOHLABEL

suppresses the horizontal axis label in the control chart.

NOVLABEL

suppresses the vertical axis label in the control chart.

NPANELPOS=*n***NPANEL=*n***

specifies the number of horizontal axis plotting positions per panel in the chart. You typically specify the NPANELPOS= option to display more points in a panel than the default number, which is 50.

You can specify a positive or negative value for *n*. The absolute value of *n* must be at least 5. If *n* is positive, the number of positions is adjusted so that it is approximately equal to *n* and so that all panels display approximately the same number of positions. If *n* is negative, then no balancing is done, and each panel (except possibly the last) displays approximately $|n|$ positions.

ODSFOOTNOTE=FOOTNOTE | FOOTNOTE1 | 'string'

adds a footnote to the chart. If you specify the FOOTNOTE (or FOOTNOTE1) keyword, the value of the SAS FOOTNOTE statement is used as the chart footnote. If you specify a quoted string, that string is used as the footnote. The quoted string can contain the following escaped characters, which are replaced with the values indicated:

\n	is replaced by the TIME variable name.
\l	is replaced by the TIME variable label (or name if the analysis TIME has no label).

ODSFOOTNOTE2=FOOTNOTE2 | 'string'

adds a secondary footnote to the chart. If you specify the FOOTNOTE2 keyword, the value of the SAS FOOTNOTE2 statement is used as the secondary chart footnote. If you specify a quoted string, that string is used as the secondary footnote. The quoted string can contain the following escaped characters, which are replaced with the values indicated:

\n	is replaced by the TIME variable name.
\l	is replaced by the TIME variable label (or name if the TIME variable has no label).

ODSTITLE=TITLE | TITLE1 | NONE | DEFAULT | 'string'

specifies a title for the chart. You can specify the following values:

TITLE (or TITLE1)	uses the value of the SAS TITLE statement as the chart title.
NONE	suppresses all titles from the chart.
DEFAULT	uses the default title.

If you specify a quoted string, that string is used as the graph title. The quoted string can contain the following escaped characters, which are replaced with the values indicated:

\n is replaced by the TIME variable name.
 \l is replaced by the TIME variable label (or name if the analysis variable has no label).

ODSTITLE2=TITLE2 | 'string'

specifies a secondary title for the chart. If you specify the TITLE2 keyword, the value of the SAS TITLE2 statement is used as the secondary chart title. If you specify a quoted string, that string is used as the secondary title. The quoted string can contain the following escaped characters, which are replaced with the values indicated:

\n is replaced by the TIME variable name.
 \l is replaced by the TIME variable label (or name if the analysis variable has no label).

OUTTABLE=SAS-data-set

creates an output SAS data set that contains the information plotted in the control chart, including the statistic values and control limits. See the section “[OUTTABLE= Data Set](#)” on page 1000 for a description of the OUTTABLE= data set.

OVERLAY

specifies that the separate sequences of observations defined by the [SERIES](#) variable and selected by the [SERIESVALUE=](#) option be plotted in a single control chart. By default, each sequence is plotted in a separate chart. The OVERLAY option is applicable only when a [TIME](#) variable is specified and the input data set contains multiple observations that have the same time value.

SERIESVALUE=value-list

specifies a list of values of the [SERIES](#) variable that define one or more sequences of observations to be plotted. If the [SERIES](#) variable is a character variable, the *value-list* must be a list of quoted strings. By default, a series is plotted for each unique value of the [SERIES](#) variable. The [SERIESVALUE=](#) option is applicable only when a [TIME](#) variable is specified and the input data set contains multiple observations that have the same time value.

TOTPANELS=n

specifies the number of panels to use to display the chart. By default, the number of panels is determined by the value that you specify in the [NPANELPOS=](#) option. If you specify both the [TOTPANELS=](#) and [NPANELPOS=](#) options, the [TOTPANELS=](#) value takes precedence.

Details: MVPMONITOR Procedure

Computing T^2 Control Limits

The control limits for the T^2 chart are the same for all the T^2 statistics in the chart. The control limits are computed using the method of Tracy, Young, and Mason (1992), in which the distribution

of the T^2 statistic is shown to follow a scaled beta distribution:

$$T_i^2 \sim \frac{(n-1)^2}{n} B\left(\frac{j}{2}, \frac{n-j-1}{2}\right) \quad j \geq 2, n \geq j+1$$

where i is the observation, j is the number of principal components in the model, and n is the number of observations used to build the principal component model.

The upper control limit is computed as the $(1 - \frac{\alpha}{2})$ quantile of this distribution, and the lower control limit is computed by the $\frac{\alpha}{2}$ quantile. You can use the ALPHA= option in the TSQUARECHART statement to specify α .

See the section “Computing the T^2 and SPE Statistics” on page 968 for details of computing the T^2 statistic based on a principal component model.

Computing SPE Control Limits

The SPE chart plots the sum of squares of the residuals from the principal component model. If either $j = p$ or the data matrix has rank less than p , then the SPE statistic is not defined and an SPE chart is not produced. The SPE statistic for observation i is denoted as

$$Q_i = \sum_{k=1}^p e_{ik}^2$$

where p is the number of variables and e_{ik} is the i th observation for the k th variable in the error matrix, E , in the principal component model

$$\mathbf{X} = \mathbf{TP}' + \mathbf{E}$$

The distribution of Q_i has been approximated in the literature under different conditions. Two methods of computing control limits for Q_i are implemented by the MVPMONITOR procedure. One method is used when the data that are used to build the principal component model consist of a single measurement per time point. The other method is used when there are multiple measurements per time point (Jensen and Solomon 1972; Nomikos and MacGregor 1995).

One Observation per Time Point

When there is a single observation at each time point, the data matrix \mathbf{X} is $n \times p$, with exactly one observation at each time point in the input data set. The derivation of the control limits uses the central limit theorem approach of Jensen and Solomon (1972). They begin by defining $\theta_i = \sum_{k=j+1}^p \lambda_k^i$, $i = 1, 2, 3$, where λ_k is the k th eigenvalue from the principal component model.

Then the quantity

$$z = \frac{\theta_1 \left[\left(\frac{Q}{\theta_1} \right)^{h_0} - 1 - \frac{\theta_2 h_0 (h_0 - 1)}{\theta_1^2} \right]}{\sqrt{2\theta_2 h_0^2}}$$

is distributed $N(0, 1)$ as $n \rightarrow \infty$, where h_0 is defined as $1 - \frac{2\theta_1\theta_3}{3\theta_2^2}$. The upper control limit for all Q_i is then computed by

$$Q_{i,1-\frac{\alpha}{2}} = \theta_1 \left[1 + \frac{z_{(1-\alpha/2)} \sqrt{2\theta_2 h_0^2}}{\theta_1} + \frac{\theta_2 h_0 (h_0 - 1)}{\theta_1^2} \right]^{\frac{1}{h_0}}$$

where $z_{(1-\alpha/2)}$ is the $(1 - \frac{\alpha}{2})$ percentile of the standard normal distribution. The lower control limit is obtained similarly by using $\frac{\alpha}{2}$. You can specify α by using the **ALPHA=** option in the **SPECHART** statement.

Multiple Observations per Time Point

When there are multiple observations at a time value in an input data set, a different approximation of the SPE distribution is used to compute control limits. The approximate distribution at time i is the scaled chi-square distribution,

$$\frac{s_i^2}{2\bar{x}_i} \chi_{\frac{2\bar{x}_i^2}{s_i^2}}$$

where \bar{x}_i and s_i^2 are the mean and variance, respectively, of the SPE statistics at time i . The upper control limit for all observations at time point i is computed as the $(1 - \frac{\alpha}{2})$ percentile of the scaled chi-square distribution:

$$SPE_{i,1-\frac{\alpha}{2}} = \frac{s_i^2}{2\bar{x}_i} \chi_{\frac{2\bar{x}_i^2}{s_i^2}, 1-\frac{\alpha}{2}}$$

Similarly the lower control limit is computed from the $\frac{\alpha}{2}$ percentile. You can specify α by using the **ALPHA=** option in the **SPECHART** statement.

For more information about the distribution approximations, see Nomikos and MacGregor (1995) and Jackson and Mudholkar (1979).

Contribution Plots

One way to diagnose the behavior of out-of-control points in multivariate charts is to use contribution plots (Miller, Swanson, and Heckler 1998). These plots tell you which variables contribute to the distance between the points in an SPE or T^2 chart and the sample mean of the data.

A contribution plot is a bar chart of the contributions of the process variables to the statistic. For the i th SPE statistic, the contribution of the k th variable is the k th entry of the vector \mathbf{e}_i , which is computed as

$$\mathbf{e}_i = \mathbf{x}_i (\mathbf{I} - \mathbf{P}_j \mathbf{P}'_j)$$

where \mathbf{e}_i is the vector of errors from the principal component model for observation i and \mathbf{x}_i is the i th observation. The contributions to the i th T^2 statistic are computed in the same way as the entries of the vector

$$\mathbf{T}_i^2 = \mathbf{x}_i \mathbf{P}_j \mathbf{L}^{-1} \mathbf{P}'_j$$

where P_j is the matrix of the first j eigenvectors and L is the diagonal matrix of the first j eigenvalues.

Input Data Sets

The MVPMONITOR procedure accepts a single primary input data set of one of three types.

- A **DATA=** data set contains new process data to be analyzed by using an existing PCA model (Phase II analysis).
- A **HISTORY=** data set contains process data and the accompanying scores, residuals, and statistics produced by applying a PCA model. The process data can be the original data that was used to create the model (Phase I analysis) or subsequent data that was analyzed by using a previously created model (Phase II analysis).
- A **TABLE=** data set contains a summary of an SPE or T^2 control chart, consisting of the statistics, control limits, and other information.

These options are mutually exclusive. If you do not specify an option identifying a primary input data set, PROC MVPMONITOR uses the most recently created SAS data set as a **DATA=** data set.

When you specify a **DATA=** data set, you must also specify a **LOADINGS=** data set that contains loadings and other information describing the PCA model. When you specify a **HISTORY=** data set, you must also specify a **LOADINGS=** data set if you specify the **CONTRIBUTIONS** option in a **TSQUARECHART** statement.

DATA= Data Set

A **DATA=** data set provides the process measurement data for a Phase II analysis. In addition to the process variables, a **DATA=** data set can include the following:

- **BY** variables
- **ID** variables
- a **SERIES** variable
- a **TIME** variable

When you specify a **DATA=** data set, you must also specify a **LOADINGS=** data set that contains the loadings for the principal component model that describes the variation of the process. These loadings are used to score the new data from the **DATA=** data set. The process variables in the **LOADINGS=** data set must have the same names as those in the **DATA=** data set.

HISTORY= Data Set

A **HISTORY=** data set provides the input data set for a Phase I or Phase II analysis. In addition to the original process variables, it contains principal component scores, residuals, SPE and T^2 statistics, and a count of the observations that are used to construct the principal component model, as summarized in Table 13.4.

Table 13.4 Variables in the HISTORY= Data Set

Variable	Description
Prin1–Prin <i>j</i>	Principal component scores
R_ <i>var</i> 1–R_ <i>varp</i>	Residuals
NOBS	Number of observations used to build the principal component model
SPE	Squared prediction error (SPE)
TSQUARE	T^2 statistic computed from principal component scores

A HISTORY= data set must include variables that contain principal component scores. The score variables names must consist of a common prefix followed by the numbers 1, 2, . . . , *j*, where *j* is the number of principal components. By default, the common prefix is Prin. You can use the PREFIX= option to specify another prefix for score variables.

If the number of principal components is less than the total number of process variables, the HISTORY= data set should also contain residual variables. A residual variable name consists of a common prefix followed by the corresponding process variable name. The default residual variable prefix is R_. For example, if the process variables are A, B, and C, the default residual variable names are R_A, R_B, and R_C. You can use the RPREFIX= option to specify a different residual variable prefix.

NOTE: Usually you create a HISTORY= data set by specifying the PROC MVPMODEL OUT= option or the PROC MVPMONITOR OUTHISTORY= option. If the PREFIX= or RPREFIX= option is used when such an output data set is created, you must specify the same prefixes to identify the score and residual variables when you read it as a HISTORY= data set.

LOADINGS= Data Set

The LOADINGS= data set contains the following information about the principal component model:

- eigenvalues of the correlation or covariance matrix used to construct the model
- principal component loadings
- process variable means used to center the variable values
- process variable standard deviations used to scale the variable values

You can produce a LOADINGS= data set by using the PROC MVPMODEL OUTLOADINGS= option. Table 13.5 lists the variables that are required in a LOADINGS= data set.

Table 13.5 Variables in the LOADINGS= Data Set

Variable	Description
VALUE	The value contained in <i>process variables</i> for a given observation
NOBS	Number of observations used to build the principal component model

Table 13.5 (continued)

Variable	Description
<code>_PC_</code>	Principal component number; 0 for the observation that contains eigenvalues
<i>process variables</i>	Values associated with the process variables

Valid values for the `_VALUE_` variable are as follows:

EIGEN	eigenvalues from the principal component analysis
LOADING	principal component loadings
MEAN	process variable means
STD	process variable standard deviations

The `LOADINGS=` data set contains one EIGEN observation and j LOADING observations, where j is the number of principal components in the model. The presence of a MEAN observation indicates that the process variables were centered when the principal component model was constructed, and the presence of a STD observation indicates that the process variables were scaled when the principal component model was constructed. The means and standard deviations are used to center and scale new data in a Phase II analysis.

TABLE= Data Set

A `TABLE=` data set contains a summary of an SPE or T^2 control chart. Usually, you create a `TABLE=` data set by specifying the `OUTTABLE=` option in an `SPECHART` or `TSQUARECHART` statement. A `TABLE=` data set contains the variables listed in Table 13.6.

Table 13.6 Variables in an `OUTTABLE=` Data Set

Variable	Description
<code>_ALPHA_</code>	Probability (α) of exceeding control limits
<code>_EXLIM_</code>	Flag to indicate control limit was exceeded
<code>_LCL_</code>	Lower control limit
<code>_MEDIAN_</code>	Center line
<code>_SPE_</code>	Squared prediction error (SPE) statistic (<code>SPECHART</code> statement only)
<i>time</i>	Optional <code>TIME</code> variable
<code>_TSQUARE_</code>	T^2 statistic (<code>TSQUARECHART</code> statement only)
<code>_UCL_</code>	Upper control limit

A `TABLE=` data set must contain either an `_SPE_` or `_TSQUARE_` variable but not both. When you use a `TABLE=` input data set, you can specify only chart statements that correspond to the statistic in the data set.

You can use a `TABLE=` data set to display a previously created control chart or to specify custom control limits by computing your own `_LCL_` and `_UCL_` values.

Output Data Sets

OUTHISTORY= Data Set

The OUTHISTORY= data set contains all the variables in the input data set plus new variables that contain the principal component scores, residuals, and other computed values listed in Table 13.7.

Table 13.7 Computed Variables in the OUT= Data Set

Variable	Description
Prin1–Prin j	Principal component scores
R_var1–R_var p	Residuals
NOBS	Number of observations used in the analysis
SPE	Squared prediction error (SPE)
TSQUARE	T^2 statistic computed from principal component scores

The names of the score variables are formed by concatenating the value given by the PREFIX= option (or the default Prin, if PREFIX= is not specified) and the numbers 1, 2, . . . , j , where j is the number of principal components in the model.

The names of the residual variables are formed by concatenating the value given by the RPREFIX= option (or the default R_, if RPREFIX= is not specified) and the names of the process variables used in the analysis. Residual variables are created only when the number of principal components in the model is less than the number of process measurement variables in the input data set.

OUTTABLE= Data Set

You can save multivariate control chart statistics, control limits, and related information by specifying the OUTTABLE= option in an SPECHART or TSQUARECHART statement. An OUTTABLE= data set contains the variables listed in Table 13.8.

Table 13.8 Variables in an OUTTABLE= Data Set

Variable	Description
ALPHA	Probability (α) of exceeding control limits
EXLIM	Flag to indicate control limit was exceeded
LCL	Lower control limit
MEDIAN	Center line
SPE	Squared prediction error (SPE) statistic (SPECHART statement only)
<i>time</i>	TIME variable, if specified
TSQUARE	T^2 statistic (TSQUARECHART statement only)
UCL	Upper control limit

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The MVPMONITOR procedure assigns a name to each graph that it creates using ODS Graphics. You can use these names to refer to the graphs when you use ODS. The graph names are listed in Table 13.9.

Table 13.9 ODS Graphics Produced by PROC MVPMONITOR

ODS Graph Name	Plot Description	Statement or Option
ContributionPlot	Contribution plot	CONTRIBUTIONS option
SPEChart	Squared prediction error chart	SPECHART statement
TSquareChart	T^2 chart	TSQUARECHART statement

Examples: MVPMONITOR Procedure

The following examples use an airline flight delay data set similar to the one described in the section “Getting Started: MVPMONITOR Procedure” on page 982. The following statements create a data set named flightDelays, which contains average flight delays for each region of the continental United States:

```
data flightDelays;
  label flightDate='Date';
  format flightDate MMDDYY8.;
  input flightDate :MMDDYY8. region $ AA CO DL F9 FL NW UA US WN;
  datalines;
02/01/07 MW 14.9 7.1 7.9 8.5 14.8 4.5 5.1 13.4 5.1
02/01/07 NE 15.7 7.1 8.6 6.3 14.6 6.2 7.0 11.0 6.4
02/01/07 NW 17.8 2.6 6.1 28.8 11.6 6.1 11.6 27.3 3.7
02/01/07 SC 19.9 8.3 13.9 4.9 25.8 15.3 9.0 15.1 12.8
02/01/07 SE 16.1 1.9 8.7 8.7 15.1 18.3 4.0 10.4 6.5
02/01/07 SW 19.3 7.8 4.8 11.5 34.7 7.4 7.3 12.0 5.6
02/02/07 MW 14.3 9.6 14.1 6.2 12.8 6.0 3.9 15.3 11.4

... more lines ...

02/16/07 SC 19.3 21.9 24.5 24.6 5.1 8.5 24.9 42.9 23.2

;
```

Example 13.1: Combining Data from Peer Processes

In some situations you might want to build a common principal component model by combining data from multiple peer processes that have similar patterns of stable variation. This enables you to borrow strength from the data. A common set of control limits is then computed for each peer process.

This example uses observations from all regions in the continental United States at each time value to construct a common principal component model. It then applies the model to flight data for one region.

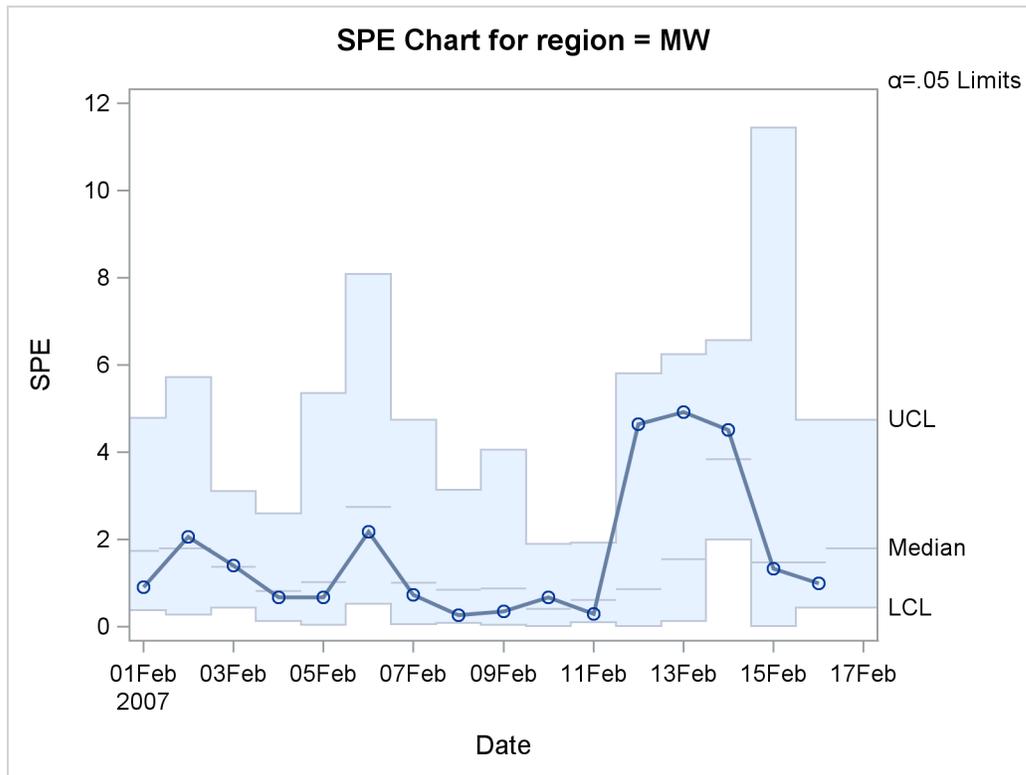

The following statements create a principal component model that contains three principal components from the `flightDelays` data set and apply the model to data for the Midwest region:

```
proc mvpmode1 data=flightDelays ncomp=3 noprint
    out=mvpair outloadings=mvpairloadings;
    var AA CO DL F9 FL NW UA US WN;
run;
proc mvpmonitor history=mvpair loadings=mvpairloadings;
    time flightDate;
    series region;
    spechart / seriesvalue='MW';
    tsquarechart / seriesvalue='MW';
run;
```

The `flightDelays` data set contains observations from all continental United States regions, with multiple observations (one for each region) at each time point as defined by the `flightDate` variable. The `OUTLOADINGS=` data set that is produced by PROC MVPMODEL contains the model information. The `SERIES` statement specifies `region` as the variable that identifies sequences of related observations. The `SERIESVALUE=` option selects the Midwest region statistics to be plotted.

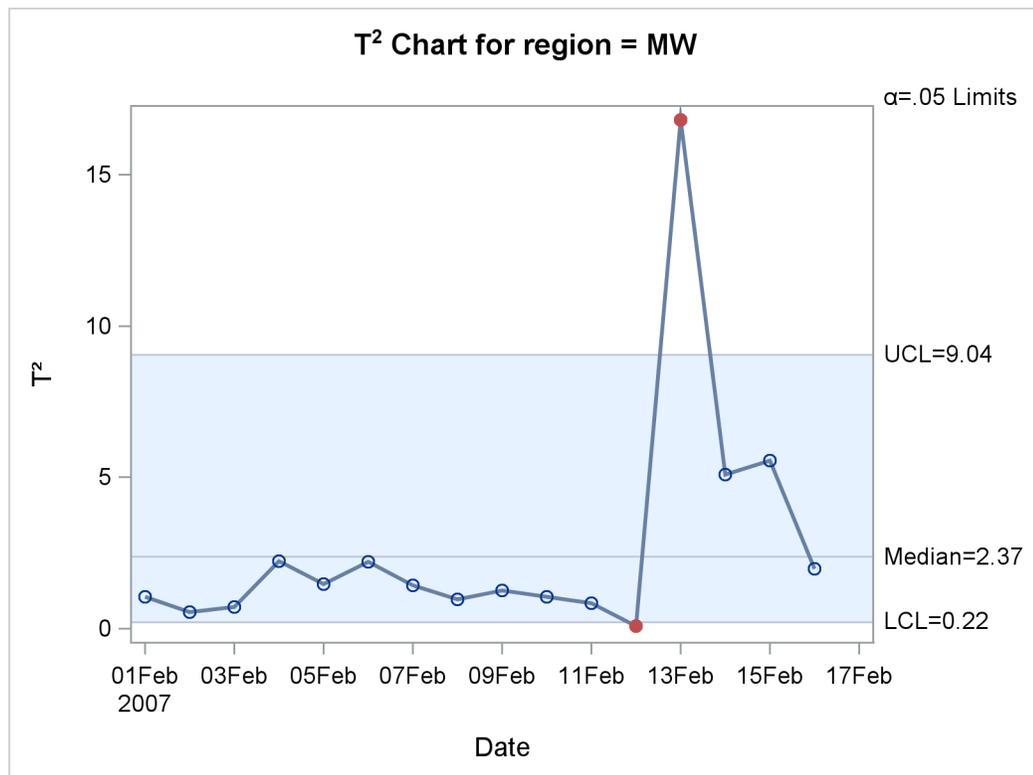

The resulting SPE chart is shown in [Output 13.1.1](#).

Output 13.1.1 Multivariate Control Chart for SPE Statistics

The control limits for the SPE chart are computed differently from a case with a single observation per time value, such as the chart shown in [Figure 13.3](#). The control limits are based on different reference distributions for the SPE statistics in addition to different approximations to the reference distribution. See the section “[Computing SPE Control Limits](#)” on page 995 for more information.

The T^2 chart is shown in [Output 13.1.2](#).

Output 13.1.2 Multivariate Control Chart for T^2 Statistics

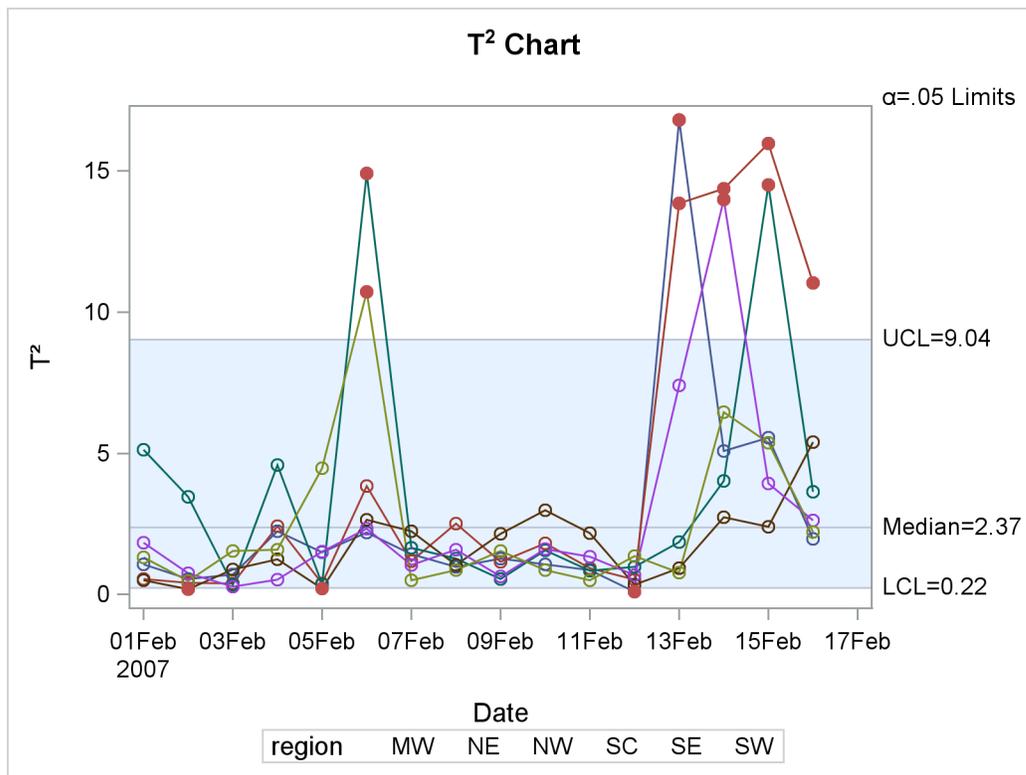

Compare the T^2 chart in [Output 13.1.2](#) to the one in [Figure 13.1](#). Both charts display T^2 statistics for the same flight delays from the Midwest region, but the charts are different because in this example the principal component model was constructed with data from all regions of the continental United States.

You can produce control charts for all the peer processes (regions in this example) by omitting the `SERIESVALUE=` option. The following statements illustrate this approach:

```
proc mvpmonitor history=mvpair;
  time flightDate;
  series region;
  spechart;
  tsquarechart / overlay;
run;
```

By default, a separate control chart is created for each distinct value of the `SERIES` variable. The separate SPE charts for each region are not shown. The `OVERLAY` option in the `TSQUARECHART` statement specifies that the sequences for each region be plotted on a single T^2 chart, which is shown in [Output 13.1.3](#).

Output 13.1.3 Overlaid T^2 Charts by Region

Example 13.2: Creating Multivariate Control Charts for Phase II

This example is a continuation of the example in “Getting Started: MVPMONITOR Procedure” on page 982. The following statements create a data set named `flightDelays2`, which provides flight delays for the date range February 17–28, 2007, for the northeastern United States:

```
data flightDelays2;
  label flightDate='Date';
  format flightDate MMDDYY8.;
  input flightDate :MMDDYY8. AA CO DL F9 FL NW UA US WN;
  datalines;
02/17/07 25.6 7.8 15.5 13.4 16.1 16.2 23.0 24.2 8.2
02/18/07 5.4 16.0 9.9 1.1 11.5 17.0 15.6 15.5 5.1
02/19/07 13.2 16.3 10.0 10.6 5.4 10.3 9.5 16.8 9.3
... more lines ...
02/27/07 11.3 17.1 5.3 4.1 4.8 13.9 9.8 9.7 7.1
02/28/07 8.1 3.7 2.7 17.1 -0.8 5.5 11.0 14.3 3.1
;
```

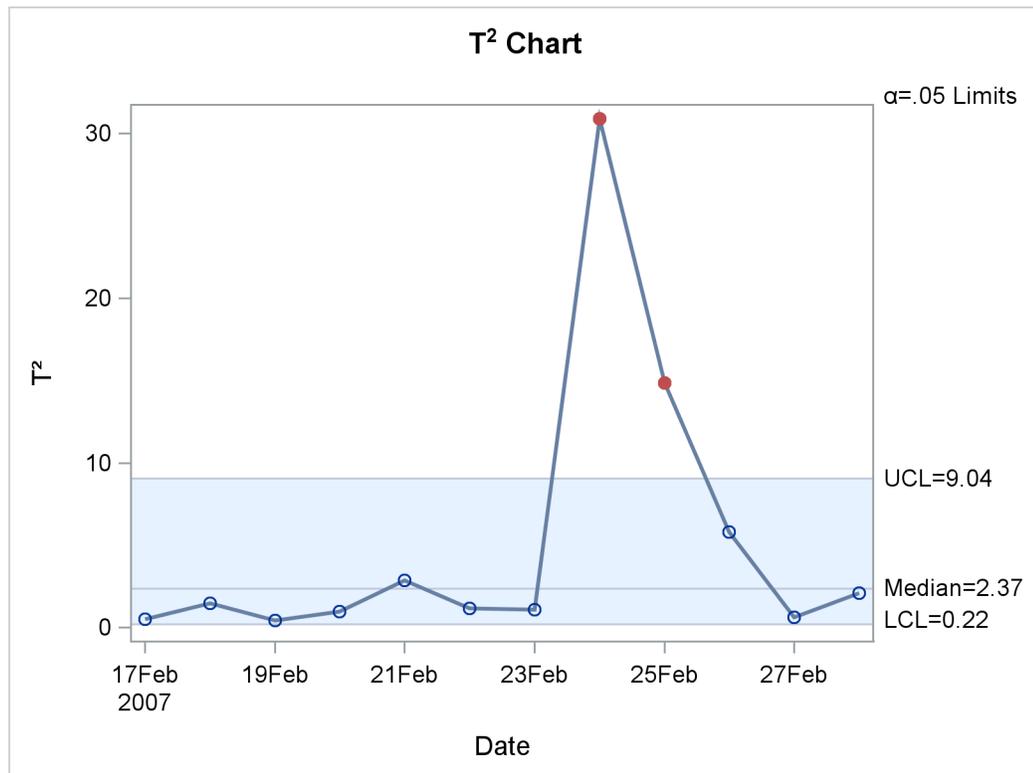

To use PROC MVPMONITOR in a Phase II analysis, you need a principal component model based on a process data from a stable process. The model that is produced by the MVPMODEL procedure in “Example 13.1: Combining Data from Peer Processes” on page 1002 is used here. The model was generated from data for the continental United States during February 1–16, 2007. The model

information is contained in the principal component loadings, which come from the mvpairloadings data set. The following statements apply the model to the new data in flightDelays2:

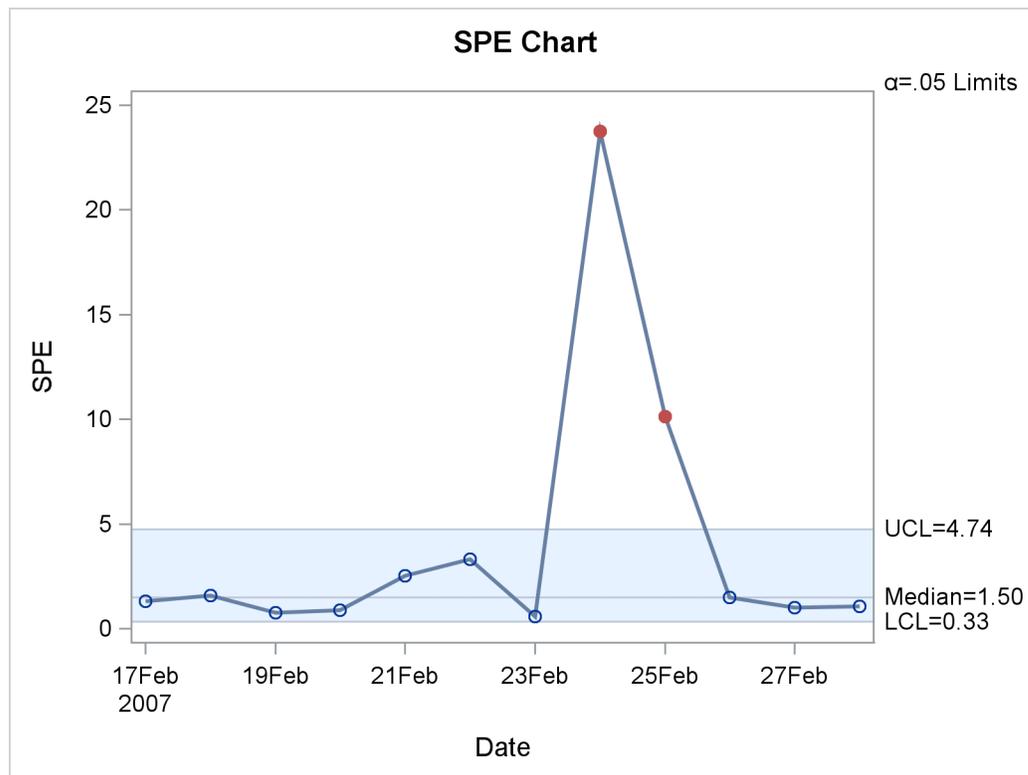

```
proc mvpmonitor data=flightDelays2 loadings=mvpairloadings;
  time flightDate;
  id flightDate;
  tsquarechart;
  spechart;
run;
```

The T^2 chart is shown in Output 13.2.1.

Output 13.2.1 Multivariate Control Chart for T^2 Statistics

The SPE chart is shown in Output 13.2.2.

Output 13.2.2 Multivariate Control Chart for SPE Statistics

The SPE chart has out-of-control points on February 22, 24, and 25. This indicates that the variation is not along the model hyperplane, which suggests that the model is not appropriate for these new data.

Both the SPE chart and the T^2 chart have an out-of-control point on February 25. This point has very unusual variation. On that date, a major winter storm with high winds and blizzard conditions battered the Midwest while snow, sleet, and freezing rain hit the Northeast. These conditions contributed to delays that are not seen in the data set that the model was built with.

Example 13.3: Comparison of Univariate and Multivariate Control Charts

This example shows the effect of a change in correlation of the process variables on the SPE chart. The following statements create a data set called `mvpStable`, which consists of 30 samples from a trivariate normal distribution with strong positive correlation between all three variables:

```

proc iml;
  Mean = {0,0,0};
  Cor = {1.0 0.8 0.8,
         0.8 1.0 0.8,
         0.8 0.8 1.0};
  StdDevs = {2 2 2};
  D = diag(StdDevs);
  Cov = D*Cor*D; /* covariance matrix */
  NumSamples = 30;
  call randseed(123321); /* set seed for the RandNormal module */
  X = RandNormal(NumSamples, Mean, Cov);
  varnames = { x1 x2 x3};
  create.mvpStable from X [colname = varnames];
  append from X;
  quit;
run;
data.mvpStable;
  set.mvpStable;
  hour=_n_;
run;

```

The next statements create a data set called `mvpOOC`, which has five observations in which the correlations are negative:

```

proc iml;
  Mean = {0,0,0};
  Cor = { 1.0 -0.8 0.8,
         -0.8 1.0 -0.8,
         0.8 -0.8 1.0};
  StdDevs = {2 2 2};
  D = diag(StdDevs);
  Cov = D*Cor*D; /* covariance matrix */
  NumSamples = 5;
  call randseed(123321); /* set seed for the RandNormal module */
  X = RandNormal(NumSamples, Mean, Cov);
  varnames = { x1 x2 x3};
  create.mvpOOC from X [colname = varnames];
  append from X;
  quit;
run;
data.mvpOOC;
  set.mvpStable.mvpOOC;
  hour=_n_;
run;

```

The following statements produce a principal component model for the data in `mvpStable`:

```

proc.mvpmodel data=mvpStable ncomp=1 plots=none out=scores
              outloadings=loadings;
  var x1 x2 x3;
run;

```

The model hyperplane that is defined by specifying `NCOMP= 1` is a line. The loadings in the principal component model, which are used to project the data to the model hyperplane, are defined by the correlation structure present in the `DATA=` data set.

The model explains about 90% of the variance in the data, as shown in [Output 13.3.1](#).

Output 13.3.1 Eigenvalue and Variance Information

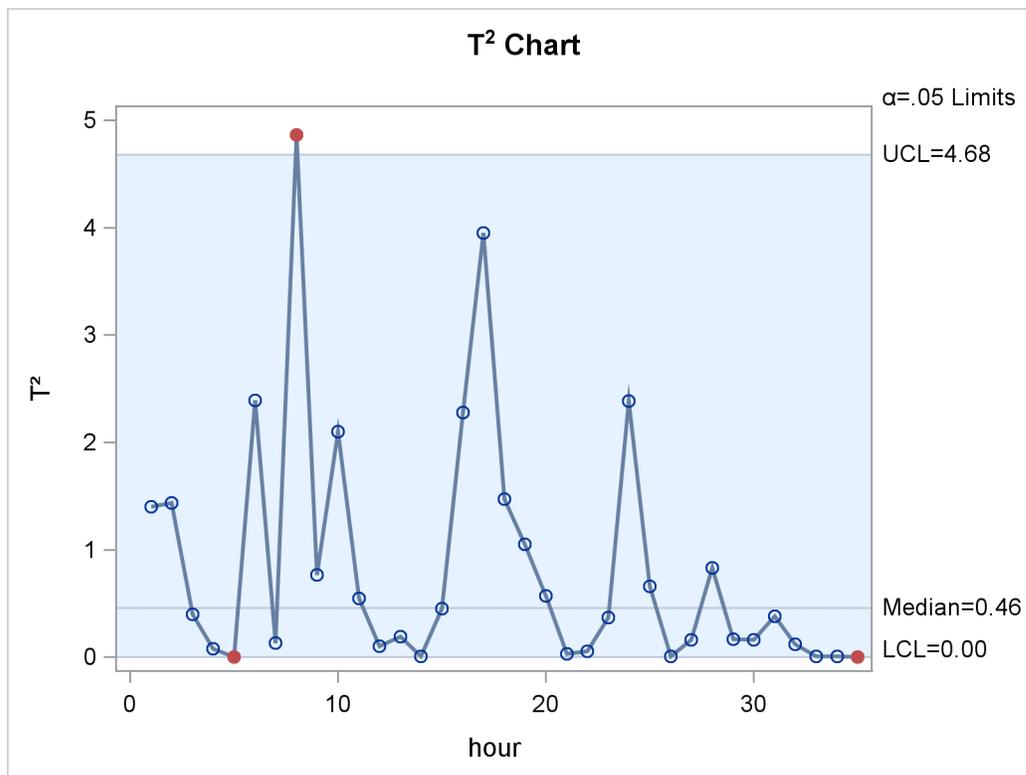

The MVPMODEL Procedure			
Eigenvalues of the Correlation Matrix			
	Eigenvalue	Difference	Proportion
1	2.67725690		0.8924
			Cumulative
			0.8924

The loadings from the model are then applied to the data in `mvpOOC`, which includes observations that have a different correlation structure, which vary in direction orthogonal to the model line. The following statements apply the loadings to these new data to produce T^2 and SPE charts:

```
proc mvpmonitor data=mvpOOC loadings=loadings;
  time hour;
  tsquarechart;
  spechart;
run;
```

The MVPMONITOR procedure generates a T^2 chart, shown in [Output 13.3.2](#).

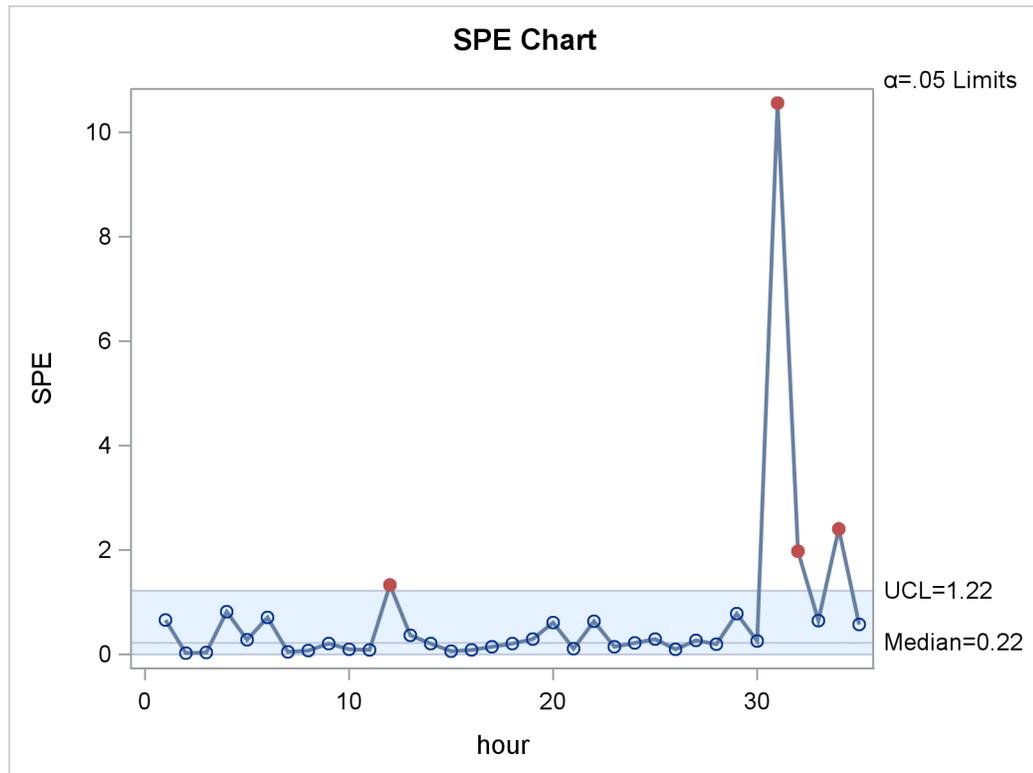

Output 13.3.2 T^2 Chart

The projection of the last five points to the model line results in small amounts of variation, and thus small T^2 statistics, for two reasons: the last five points are orthogonal to the model line, and they share the same mean. However, the orthogonality means that they are out-of-control points in the SPE chart.

The MVPMONITOR procedure also produces an SPE chart, shown in [Output 13.3.3](#).

Output 13.3.3 SPE Chart

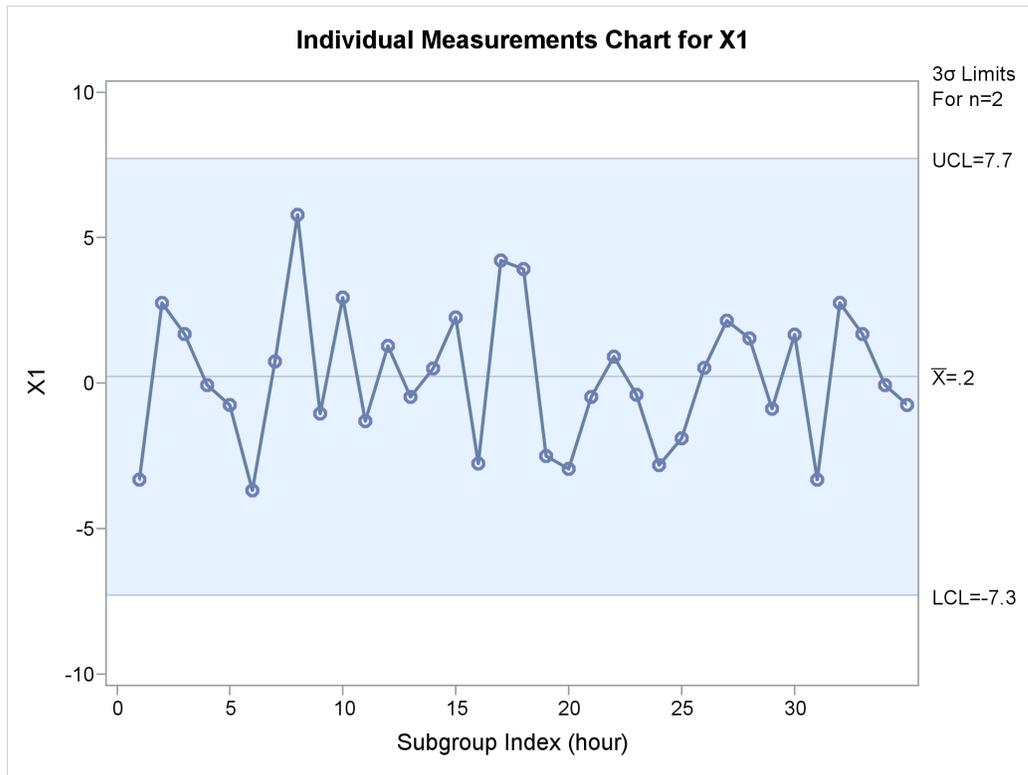

Because the last five points come from a correlation structure that is not seen in the data from which the model was built, these points can lie far from the model line, resulting in large values in the SPE statistics.

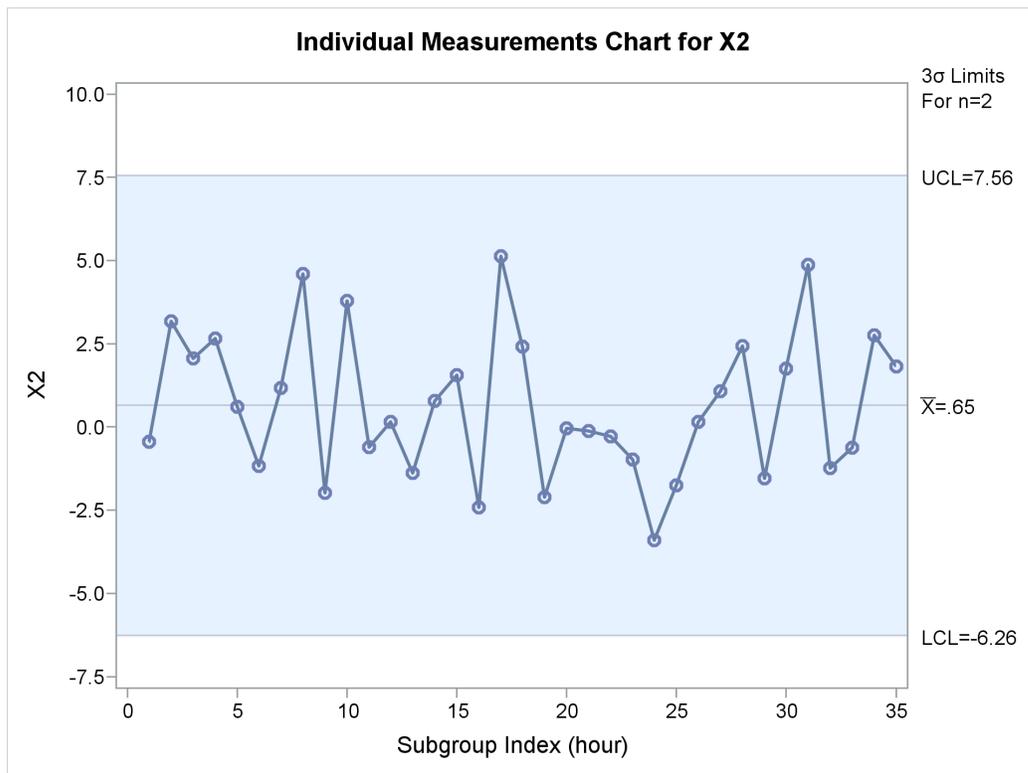

Because the marginal distributions are the same in both the original 30 points and the additional five points, the univariate control charts in [Output 13.3.4](#), [Output 13.3.5](#), and [Output 13.3.6](#) fail to signal the multivariate change at hour 31. The following statements produce univariate control charts for each of the variables by using the SHEWHART procedure:

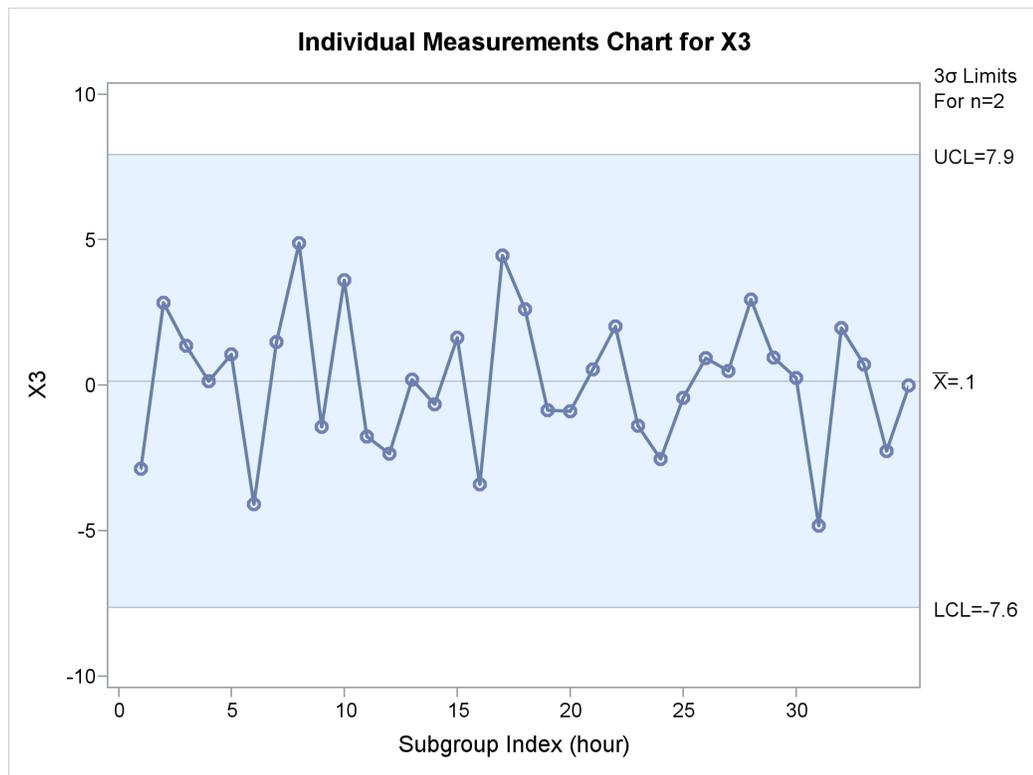

```
proc shewhart data=mvpOOC;
  irchart (x1 x2 x3) * hour / markers nochart2;
run;
```

Output 13.3.4 Univariate Chart for x_1

Output 13.3.5 Univariate Chart for x_2

Output 13.3.6 Univariate Chart for x_3 

Example 13.4: Creating a Classical T^2 Chart

The following statements use PROC MVPMODEL to create a model from which classical T^2 charts can be produced:

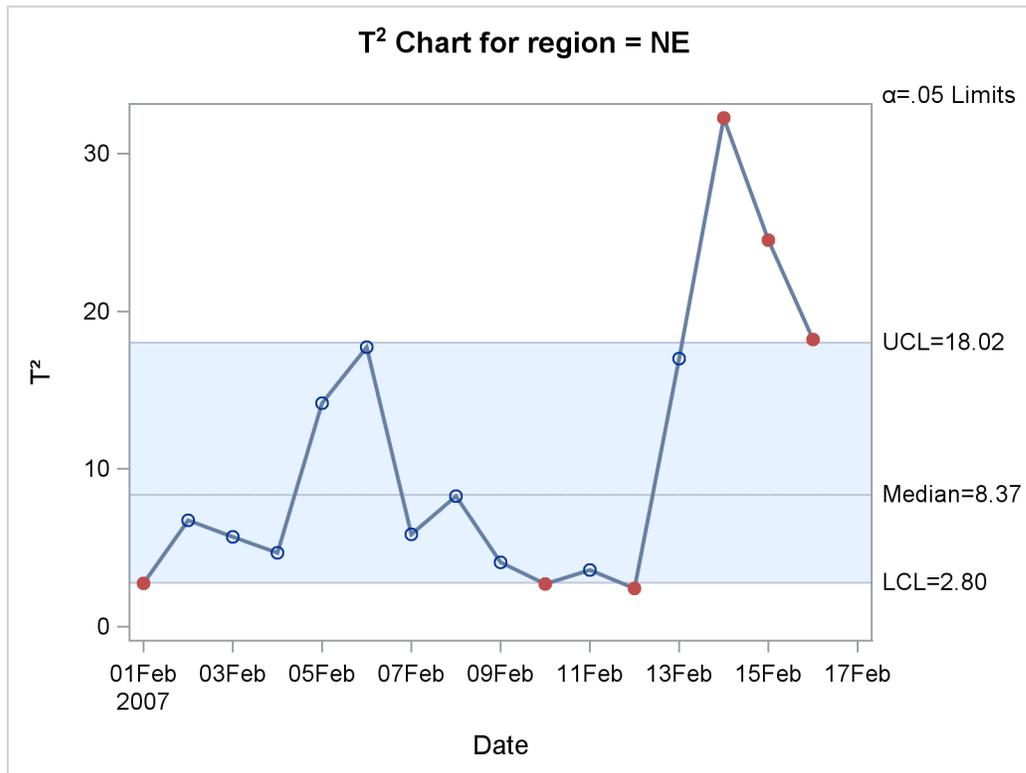

```
proc mvpmodel data=flightDelays ncomp=all noprint out=mvpout;
  var AA CO DL F9 FL NW UA US WN;
run;
```

The `NCOMP=ALL` option specifies that the number of principal components equal the number of process variables, so the `mvpout` data set contains the classical T^2 statistic for each observation. The `mvpout` data set contains six observations per time point—one for each region.

The following statements create the classical T^2 chart:

```
proc mvpmonitor history=mvpout;
  time flightDate;
  series region;
  tsquarechart / seriesvalue='NE';
run;
```

The `SERIES` statement specifies `region` as the variable that identifies sequences of T^2 statistics, and the `SERIESVALUE=` option selects the region to be plotted, the Northeast. The classical T^2 chart is shown in Output 13.4.1.

Output 13.4.1 Classical T^2 Chart

In this case, the classical T^2 chart finds out-of-control observations above the upper control limit during February 14–16 and below the lower control limit on February 1, 10, and 12.

Output 13.4.2 shows a partial listing of the mvput data set. It contains T^2 statistics based on the model that has nine principal components, in addition to the original variables and other observationwise statistics.

Output 13.4.2 Partial Listing of Output Data Set mvput

Introduction to the OPTEX Procedure

Overview

The OPTEX procedure searches for optimal experimental designs. You specify a set of candidate design points and a linear model, and the procedure chooses points so that the terms in the model can be estimated as efficiently as possible.

Most experimental situations call for standard designs, such as fractional factorials, orthogonal arrays, central composite designs, or Box-Behnken designs. Standard designs have assured degrees of precision and orthogonality that are important for the exploratory nature of experimentation. In some situations, however, standard designs are not available, such as when

- not all combinations of the factor levels are feasible
- the region of experimentation is irregularly shaped
- resource limitations restrict the number of experiments that can be performed
- there is a nonstandard linear or a nonlinear model

The OPTEX procedure can generate an efficient experimental design for any of these situations.

NOTE: Instead of using PROC OPTEX directly, a more appropriate tool for you might be the ADX Interface. The ADX Interface is designed primarily for engineers and researchers who require a point-and-click solution for the entire experimental process, from building the designs through determining significant effects to optimization and reporting. In addition to offering the standard designs, ADX makes it easy to use PROC OPTEX to find optimal designs for nonstandard factorial, response surface, and mixture experiments, with and without blocking. For more information about the ADX Interface, see *Getting Started with the SAS ADX Interface for Design of Experiments*.

Features

This section summarizes key features of the OPTEX procedure.

The OPTEX procedure offers various criteria for searching a design; these criteria are summarized in [Table 14.1](#) and [Table 14.2](#). In the formulas for these criteria, X denotes the design matrix, \mathcal{C} the set of candidate points, and \mathcal{D} the set of design points. The default criterion is D-optimality. You can also use the OPTEX procedure to generate G- and I-efficient designs.

The OPTEX procedure also offers a variety of search algorithms, ranging from a simple sequential search (Dijkstra 1971) to the computer-intensive Fedorov algorithm (Fedorov 1972, Cook and Nachtsheim 1980). You can customize many aspects of the search, such as the initialization method and the number of iterations.

You can use the full general linear modeling facilities of the GLM procedure to specify a model for your design, allowing for general polynomial effects as well as classification or ANOVA effects. Optionally, you can specify

- design points to be optimally augmented
- fixed covariates (for example, blocks) for the design
- prior precisions for Bayesian optimal design

The OPTEX procedure is an interactive procedure. After specifying an initial design, you can submit additional statements without reinvoking the OPTEX procedure. Once you have found a design, you can

- examine the design
- output the design to a data set
- change the model and find another design
- change the characteristics of the search and find another design

Table 14.1 Information-Based Optimality Criteria

Criterion	Goal	Formula
D-optimality	Maximize determinant of the information matrix	$\max X'X $
A-optimality	Minimize sum of the variances of estimated coefficients	$\min \text{trace}(X'X)^{-1}$

Table 14.2 Distance-Based Optimality Criteria

Criterion	Goal	Formula
U-optimality	Minimize distance from design to candidates	$\min \sum_{\mathbf{x} \in \mathcal{C}} d(\mathbf{x}, \mathcal{D})$
S-optimality	Maximize distance between design points	$\min \sum_{\mathbf{y} \in \mathcal{D}} d(\mathbf{y}, \mathcal{D} - \mathbf{y})$

Learning about the OPTEX Procedure

To learn the basic syntax of the OPTEX procedure, read the introductory example in the next section, which covers a typical application of optimal designs. Other applications are illustrated in “Optimal Design Scenarios” on page 1025. The summary tables in the section “Summary of Functions” on page 1030 provides an overview of the syntax. The section “Advanced Examples” on page 1046 illustrates construction of complex designs.

Getting Started

The examples in this section illustrate basic features of the OPTEX procedure. In addition, the examples show how a variety of SAS software tools can be used to construct candidate sets. If you are working through these examples on your own computer, note that the randomness in the OPTEX procedure’s search algorithm will cause your results to be slightly different from those shown.

See the section “Advanced Examples” on page 1046 for illustrations of complex features.

Constructing a Nonstandard Design

See OPTEXG1 in the SAS/QC Sample Library This example shows how you can use the OPTEX procedure to construct a design for a complicated experiment for which no standard design is available.

A chemical company is designing a new reaction process. The engineers have isolated the following five factors that might affect the total yield:

Variable	Description	Range
RTemp	Temperature of the reaction chamber	150-350 degrees
Press	Pressure of the reaction chamber	10-30 psi
Time	Amount of time for the reaction	3-5 minutes
Solvent	Amount of solvent used	20-25 %
Source	Source of raw materials	1, 2, 3, 4, 5

While there are only two solvent levels of interest, the reaction control factors (RTemp, Press, and Time) might be curvilinearly related to the total yield, and thus, require three levels in the experiment. The Source factor is categorical with five levels. Additionally, some combinations of the factors are known to be problematic; simultaneously setting all three reaction control factors to their lowest feasible levels will result in worthless sludge, while setting them all to their highest levels can damage the reactor. Standard experimental designs do not apply to this situation.

Creating the Candidate Set

You can use the OPTEX procedure to generate a design for this experiment. The first step in generating an optimal design is to prepare a data set containing the candidate runs (that is, the feasible factor level combinations). In many cases, this step involves the most work. You can use a variety of SAS data manipulation tools to set up the candidate data set. In this example, the candidate runs are all possible combinations of the factor levels except those with all three control factors at their low levels and at their high levels, respectively. The PLAN procedure (refer to the *SAS/STAT User's Guide*) provides an easy way to create a full factorial data set, which can then be subsetted by using the DATA step, as shown in the following statements:

```
proc plan ordered;
  factors RTemp=3 Press=3 Time=3 Solvent=2 Source=5 / noprint;
  output out=Candidate
    RTemp  nvals=(150 to 350 by 100)
    Press  nvals=( 10 to 30 by 10)
    Time   nvals=( 3 to 5 )
    Solvent nvals=( 20 to 25 by 5)
    Source nvals=( 1 to 5 );
data Candidate; set Candidate;
  if (^((RTemp = 150) & (Press = 10) & (Time = 3)));
  if (^((RTemp = 350) & (Press = 30) & (Time = 5)));
run;
proc print data=Candidate(obs=10);
run;
```

A partial listing of the candidate data set Candidate is shown in [Figure 14.1](#).

Figure 14.1 Candidate Set of Runs for Chemical Reaction Design

Obs	RTemp	Press	Time	Solvent	Source
1	150	10	4	20	1
2	150	10	4	20	2
3	150	10	4	20	3
4	150	10	4	20	4
5	150	10	4	20	5
6	150	10	4	25	1
7	150	10	4	25	2
8	150	10	4	25	3
9	150	10	4	25	4
10	150	10	4	25	5

Generating the Design

The next step is to invoke the OPTEX procedure, specifying the candidate data set as the input data set. You must also provide a model for the experiment by using the MODEL statement, which uses the linear modeling syntax of the GLM procedure (refer to the *SAS/STAT User's Guide*). Since Source is a classification (qualitative) factor, you need to specify it in a CLASS statement. To detect possible crossproduct effects in the other factors, as well as the quadratic effects of the three reaction control factors, you can use a modified response surface model, as shown in the following statements:

```

proc optex data=Candidate seed=12345;
  class Source;
  model Source Solvent|RTemp|Press|Time@2
         RTemp*RTemp Press*Press Time*Time;
run;

```

Note that the MODEL statement does not involve a response variable (unlike the MODEL statement in the GLM procedure). The default number of runs for a design is assumed by the OPTEX procedure to be 10 plus the number of parameters (a total of $10 + 18 = 28$ in this case). Thus, the procedure searches for 28 runs among the candidates in Candidate that enable D-optimal estimation of the effects in the model. (See the section “Optimality Criteria” on page 1077 for a precise definition of D-optimality.) Randomness is built into the search algorithm to overcome the problem of local optima. As such by default, the OPTEX procedure takes 10 random “tries” to find the best design. The output, shown in Figure 14.2, lists efficiency factors for the 10 designs found. These designs are all very close in terms of their D-efficiency.

Figure 14.2 Efficiencies for Chemical Reaction Design

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	57.0082	32.8139	78.3162	0.8319
2	56.7660	27.3874	75.8168	0.8563
3	56.2145	28.7217	74.9937	0.8594
4	55.8960	28.7509	74.4196	0.8559
5	55.7341	29.9372	74.4554	0.8544
6	55.6224	31.4902	73.6200	0.8626
7	55.5762	28.3016	75.8959	0.8652
8	55.5080	30.3889	78.4385	0.8552
9	55.3366	28.5103	74.7014	0.8614
10	55.2176	26.8133	76.2307	0.8660

The final step is to save the best design in a data set. You can do this interactively by submitting the OUTPUT statement immediately after the preceding statements. Then use the PRINT procedure to list the design. The design is listed in Figure 14.3.

```

output out=Reactor;
proc print data=Reactor;
run;

```

Figure 14.3 Optimal Design for Chemical Reaction Process Experiment

Obs	Solvent	RTemp	Press	Time	Source
1	20	150	20	4	5
2	20	250	10	5	5
3	20	350	30	3	5
4	25	150	30	5	5
5	25	250	10	3	5
6	25	350	20	5	5
7	20	150	10	5	4
8	20	150	30	3	4
9	20	350	10	3	4
10	20	350	20	5	4
11	25	250	30	4	4
12	20	250	10	3	3
13	20	350	30	4	3
14	25	150	30	3	3
15	25	350	10	5	3
16	25	350	20	3	3
17	20	150	30	5	2
18	20	250	30	3	2
19	20	350	10	5	2
20	25	150	10	4	2
21	25	250	20	5	2
22	25	350	30	4	2
23	20	150	20	3	1
24	20	250	20	4	1
25	20	250	30	5	1
26	25	150	10	5	1
27	25	350	10	4	1
28	25	350	30	3	1

Customizing the Number of Runs

The OPTEX procedure provides options with which you can customize many aspects of the design optimization process. Suppose the budget for this experiment can only accommodate 25 runs. You can use the N= option in the GENERATE statement to request a design with this number of runs.

```
proc optex data=Candidate seed=12345;
  class source;
  model source Solvent|RTemp|Press|Time@2
           RTemp*RTemp Press*Press Time*Time;
  generate n=25;
run;
```

Including Specific Runs

If there are factor combinations that you want to include in the final design, you can use the OPTEX procedure to *augment* those combinations optimally. For example, suppose you want to force four specific factor combinations to be in the design. If these combinations are saved in a data set, you can force them into the design by specifying the data set with the AUGMENT= option in the GENERATE statement. This technique is demonstrated in the following statements:

```

data Preset;
  input Solvent RTemp Press Time Source;
  datalines;
20 350 10 5 4
20 150 10 4 3
25 150 30 3 3
25 250 10 5 3
;
proc optex data=Candidate seed=12345;
  class Source;
  model Source Solvent|RTemp|Press|Time@2
        RTemp*RTemp Press*Press Time*Time;
  generate n=25 augment=preset;
  output out=Reactor2;
run;

```

The final design is listed in Figure 14.4.

```

proc print data=Reactor2;
run;

```

Figure 14.4 Augmented Design for Chemical Reaction Process Experiment

Obs	Solvent	RTemp	Press	Time	Source
1	20	150	30	3	5
2	20	350	20	5	5
3	25	150	10	4	5
4	25	250	30	4	5
5	20	350	10	5	4
6	20	350	30	3	4
7	25	150	30	5	4
8	25	250	10	3	4
9	25	350	20	5	4
10	20	150	10	4	3
11	20	150	30	5	3
12	20	350	20	3	3
13	25	150	30	3	3
14	25	250	10	5	3
15	20	150	10	5	2
16	20	250	30	5	2
17	20	350	10	4	2
18	25	150	20	3	2
19	25	350	10	5	2
20	20	250	10	3	1
21	20	250	20	4	1
22	20	350	30	4	1
23	25	150	10	5	1
24	25	350	10	3	1
25	25	350	30	3	1

Note that the points in the AUGMENT= data set appear as observations 7, 11, 15, and 16.

Using an Alternative Search Technique

You can also specify a variety of optimization methods with the GENERATE statement. The default method is relatively fast; while other methods might find better designs, they take longer to run and the improvement is usually only marginal. The method that generally finds the best designs is the Fedorov procedure described by Fedorov (1972). The following statements show how to request this method:

```
proc optex data=Candidate seed=12345;
  class Source;
  model Source Solvent|RTemp|Press|Time@2
         RTemp*RTemp Press*Press Time*Time;
  generate n=25 method=fedorov;
  output out=Reactor2;
run;
```

The efficiencies for the resulting designs are shown in [Figure 14.5](#).

Figure 14.5 Efficiency Factors for the Fedorov Search

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	56.9072	27.6680	75.2161	0.9023
2	56.8715	27.4939	72.8202	0.9058
3	56.6148	27.7799	75.1840	0.9031
4	56.3021	31.4247	76.0654	0.9044
5	56.0569	25.4498	70.2491	0.9290
6	55.9501	26.8714	75.6991	0.9144
7	55.8461	29.0473	74.1291	0.9138
8	55.8355	26.9242	76.8595	0.9062
9	55.7253	27.4625	74.3391	0.9189
10	55.6071	26.3825	74.1827	0.9107

In this case, the Fedorov procedure takes several times longer than the default method, and D-efficiency shows no improvement. On the other hand, the longer search method often does improve the design and might take only a few seconds on a reasonably fast computer.

Optimal Design Scenarios

The following examples briefly describe some additional common situations that call for optimal designs. These examples show how you can

- use a variety of SAS software tools to generate an appropriate set of candidate runs
- use the OPTEX procedure to search the candidate set for an optimal design

The emphasis here is on the programming techniques; output is omitted.

Constructing a Saturated Second-Order Design

Suppose you want a design for seven 2-level factors that is as small as possible but still permits estimation of all main effects and two-factor interactions—that is, a *saturated* design. Among standard orthogonal arrays, the smallest appropriate 2^k design has 64 runs, far more than the 29 parameters you want to estimate. To generate a D-efficient nonorthogonal design, first use the FACTEX procedure to create the full set of $2^7 = 128$ candidate runs. Then invoke the OPTeX procedure with a full second-order model, asking for a saturated design.

```
proc factex;
  factors x1-x7;
  output out=Candidate1;
run;
proc optex data=Candidate1 seed=12345;
  model x1|x2|x3|x4|x5|x6|x7@2;
  generate n=saturated;
  output out=Design1a;
run;
```

The default search procedure quickly finds a design with a D-efficiency of 82.3%. If search time is not an issue, you can try a more powerful search technique. For example, you can specify 500 tries with the Fedorov method.

```
proc optex data=Candidate1 seed=12345;
  model x1|x2|x3|x4|x5|x6|x7@2;
  generate n=saturated
         method=fedorov
         iter=500;
  output out=Design1b;
run;
```

This takes much longer to run, and the resulting design is only slightly more D-efficient.

Augmenting a Resolution 4 Design

In a situation similar to the previous example, suppose you have performed an experiment for seven two-level factors with a 16-run, fractional factorial design of resolution 4. You can estimate all main effects with this design, but some two-factor interactions will be confounded with each other. You now want to add enough runs to estimate all two-factor interactions as well. You can use the FACTEX procedure to create the original design as well as the candidate set.

```
proc factex;
  factors x1-x7;
  output out=Candidate2;
run;
proc optex data=Candidate2;
  model resolution=4;
  size design=min;
  output out=Augment2;
run;
```

Now specify Augment2 (the data set containing the design to be augmented) with the AUGMENT= option in the GENERATE statement.

```

proc optex data=Candidate2 seed=12345;
  model x1|x2|x3|x4|x5|x6|x7@2;
  generate n=30 augment=Augment2;
  output out=Design2;
run;

```

Handling Many Variables

When you have many factors, the set of all possible factor level combinations might be too large to work with as a candidate set. Suppose you want a main-effects design for 15 three-level factors. The complete set of $3^{15} = 14,348,907$ candidates is too large to use with the OPTEX procedure; in fact, it will probably be too large to store in your computer. One solution is to find a subset of the full factorial set to use as candidates. For example, an alternative candidate set is the 81-run orthogonal design of resolution 3, which can easily be constructed by the FACTEX procedure.

```

proc factex;
  factors x1-x15 / nlev=3;
  model resolution=3;
  size design=81;
  output out=Candidate3;
run;
proc optex data=can3 seed=12345;
  class x1-x15;
  model x1-x15;
  generate n=saturated;
  output out=Design3;
run;

```

Constructing an Incomplete Block Design

An incomplete block design is a design for v (qualitative) treatments in b blocks of size k , where $k < v$ so that not all treatments can occur in each block. To construct an incomplete block design with the OPTEX procedure, simply create a candidate data set containing a treatment variable with t values and then use the BLOCKS statement. For example, the following statements construct a design for seven treatments in seven blocks of size three:

```

data Candidate4;
  do Treatment = 1 to 7;
    output;
  end;
proc optex data=Candidate4 seed=12345;
  class Treatment;
  model Treatment;
  blocks structure=(7)3;
run;

```

The resulting design is *equireplicated* in the sense that each treatment occurs the same number of times and *balanced* in the sense that each pair of treatments occur together in the same number of blocks. Balanced designs, when they exist, are known to be optimal, and the OPTEX procedure usually succeeds at finding them for small to moderately sized problems.

Constructing a Mixture-Process Design

Suppose you want to design an experiment with three *mixture factors* X1, X2, and X3 (continuous factors that represent proportions of the components of a mixture) and one *process factor* A (a classification factor with five levels). Furthermore, suppose that X1 can account for no more than 50% of the mixture. The following statements create a data set containing the vertices and generalized edge centroids of the region defined by the mixture factor constraints and then use the FACTEX procedure (see “[Introduction](#)” on page 636) to create a candidate set that includes the process factor.

```

data XVert;
  input x1 x2 x3 @@;
datalines;
0.50 0.000 0.500
0.50 0.500 0.000
0.00 1.000 0.000
0.00 0.000 1.000
0.00 0.500 0.500
0.50 0.250 0.250
0.25 0.000 0.750
0.25 0.750 0.000
0.25 0.375 0.375
;
proc factex;
  factors a / nlev=5;
  output out=Candidate5 pointrep=XVert;
run;

```

Analyzing mixture designs with linear models can be problematic because of the constraint that the mixture factors sum to one; however, to generate an optimal design, you can simply drop one of the mixture factors. The following statements use the preceding candidate set to find an optimal design for fitting the main effect of A and a second-order model in the mixture factors:

```

proc optex data=Candidate5 seed=12345;
  class a;
  model a x1|x2 x1*x1 x2*x2;
run;

```

See [Example 14.10](#) for a more detailed example of a mixture experiment.

Details of the OPTEX Procedure

Syntax

You can specify the following statements with the OPTEX procedure. Items within the brackets <> are optional.

```
PROC OPTEX < options > ;  
  CLASS class-variables ;  
  MODEL effects < / options > ;  
  BLOCKS block-specification < options > ;  
  EXAMINE < options > ;  
  GENERATE < options > ;  
  ID variables ;  
  OUTPUT OUT= SAS-data-set < options > ;
```

To generate a design, you have to use the PROC OPTEX and MODEL statements. You can use the other statements as needed. As the OPTEX procedure is interactive, you can use all statements (except the PROC OPTEX statement) after the first RUN statement.

Statement Ordering for Covariate Designs

You use the CLASS and MODEL statements to define a linear model for the runs in the candidate data set. You can also use these statements to define a general covariate model. In this case, list the CLASS and MODEL statements that define the model for the candidate points directly after the PROC OPTEX statement. Then list the CLASS and MODEL statements that define the covariate model after the BLOCKS DESIGN= specification. Thus, in this case, the ordering for these statements should be

1. PROC OPTEX statement
2. CLASS and MODEL statements for the candidate points
3. BLOCKS DESIGN= statement
4. CLASS and MODEL statements for the covariates

Note also that a CLASS statement naming classification variables must precede the MODEL statement that uses those variables.

Summary of Functions

Table 14.3, Table 14.4, and Table 14.5 classify the OPTEX statements and options by function.

Table 14.3 Summary of Options for Specifying the Design

Function	Statement	Option
Design Characteristics		
Number of design points	GENERATE	N= <i>number</i>
Saturated design	GENERATE	N=SATURATED
Augmented design	GENERATE	AUGMENT= <i>SAS-data-set</i>
Bayesian optimal design	MODEL	/ PRIOR= p_1, p_2, \dots
Optimality Criteria		
Minimize trace of $(X'X)^{-1}$	GENERATE	CRITERION=A
Maximize $ X'X $	GENERATE	CRITERION=D
Minimize mean minimum distance to design	GENERATE	CRITERION=U
Maximize mean distance between nearest design points	GENERATE	CRITERION=S
Model Specification		
Specify independent effects	MODEL	<i>effects</i>
Exclude intercept term	MODEL	<i>effects</i> NOINT
Specify CLASS variables	CLASS	<i>variables</i>
Specify CLASS variable parameterization	CLASS	/ PARAM= <i>parameterization</i>
Display CLASS variable parameterization	PROC OPTEX	CLASSPARAM
Static coding	PROC OPTEX	CODING=STATIC
Orthogonal coding	PROC OPTEX	CODING=ORTH
Orthogonal coding with respect to candidates only	PROC OPTEX	CODING=ORTHCAN
Suppress coding of effects	PROC OPTEX	NOCODE
Block Specification		
Specify general covariance matrix for runs	BLOCKS	COVAR= <i>SAS-data-set</i> < <i>options</i> > VAR= <i>variables</i>
Specify general covariate model	BLOCKS	DESIGN= <i>SAS-data-set</i> < <i>options</i> >
Specify b blocks of size k	BLOCKS	STRUCTURE=(b) k < <i>options</i> >
<i>Options for block specifications</i>		
Repeat the search n times		ITER= n
Retain best m searches		KEEP= m
Select initial design at random		INIT=RANDOM
Select initial design in order		INIT=CHAIN

Function	Statement	Option
Initial Design Characteristics		
Random and sequential methods	GENERATE	INITDESIGN=PARTIAL < (<i>m</i>) >
Random initial design	GENERATE	INITDESIGN=RANDOM
Sequential initial design	GENERATE	INITDESIGN=SEQUENTIAL
Specify initial design	GENERATE	INITDESIGN=SAS- <i>data-set</i>

Table 14.4 Summary of Options for Searching for the Design

Function	Statement	Option
Design Search Specification		
Retain best <i>n</i> searches	GENERATE	KEEP= <i>n</i>
Search <i>n</i> times	GENERATE	ITER= <i>n</i>
Specify candidate points	PROC OPTEX	DATA=SAS- <i>data-set</i>
Specify random seed	PROC OPTEX	SEED= <i>number</i>
Specify effective zero	PROC OPTEX	EPSILON= ϵ
Design Search Methods

Specific optimal design	EXAMINE	NUMBER= <i>design-number</i>
Variance matrix $(X'X)^{-1}$	EXAMINE	VARIANCE
Suppress all output	PROC OPTEX	NOPRINT

Statement Descriptions

This section provides detailed syntax information for the OPTEX procedure statements, beginning with the PROC OPTEX statement. The remaining statements are presented in alphabetical order.

PROC OPTEX Statement

PROC OPTEX < options > ;

You use the PROC OPTEX statement to invoke the procedure. The following *options* can be used:

CLASSPARAM

specifies that a table should be displayed summarizing the parameterization of classification variables in the model for the design.

CODING=NONE

CODING=STATIC

CODING=ORTH

CODING=ORTHCAN

specifies which type of coding to use for modeling effects in the design. Coding equalizes all model effects as far as the optimization is concerned. The default is CODING=STATIC, which specifies that the values of all effects are to be coded to have maximum and minimum values of +1 and -1, respectively. The options CODING=ORTH and CODING=ORTHCAN specify orthogonal coding with respect to the points in the candidate data set. The option CODING=NONE suppresses coding of effects; it is equivalent to the NOCODE option. For more details on coding, see the section “[Design Coding](#)” on page 1075.

Note that while CODING=STATIC is the default, CODING=ORTH will usually give more meaningful efficiency values, especially if all possible combinations of factor levels occur in the candidate data set.

DATA=SAS-data-set

specifies the input SAS data set that contains the candidate points for the design. By default, the OPTEX procedure uses the most recently created SAS data set. For details, see the section “[DATA= Data Set](#)” on page 1070.

EPSILON= ϵ

specifies the smallest value ϵ that is considered to be nonzero for determining when the search is no longer yielding an improved design and when the information matrix for the design is singular. By default, $\epsilon = 0.00001$.

NAMELEN= n

specifies the length of effect names in tables and output data sets to be n characters long, where n is a value between 20 and 200 characters. The default length is 20 characters.

NOCODE

suppresses the coding of effects in the model for the design. This option is equivalent to CODING=NONE.

NOPRINT

suppresses all output. This is useful when you only want the final design to be saved in a data set.

SEED=s

specifies an integer used to start the pseudo-random number generator for initialization (see the section “[Search Methods](#)” on page 1081). If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

STATUS=status-level

specifies that the status of the search be checked at the given level, where *status-level* is an integer between 1 and 4, inclusive. If you specify a *status-level*, then a table of the status at each check point is displayed. You can use this table to track the progress of long searches. The allowable *status-levels* are listed in the following table:

Status-level	Checks status after each:
1	design search; the number of searches specified by the NITER= option
2	search loop
3	internal search loop
4	extra internal search loop for METHOD=M_FEDOROV

Each search method loops to produce successively better designs; these are the search loops for STATUS=2. STATUS=3 and STATUS=4 refer to deeper loops within the search methods. You will only need to specify STATUS=3 or STATUS=4 very rarely, since evaluating and displaying the status at either of these levels will usually make the search much slower.

BLOCKS Statement

BLOCKS *block-specification* < options > ;

You use the BLOCKS statement to find a D-optimal design in the presence of fixed covariates (for example, blocks) or covariance. The technique is an extension of the optimal blocking technique of Cook and Nachtsheim (1989); see the section “[Optimal Blocking](#)” on page 1083.

For the purposes of optimal blocking, the model for the original candidate points is referred to as the *treatment model*; the candidate points for the part of the design matrix corresponding to the treatment model form the *treatment set*. If the GENERATE statement is not specified, then the full candidate set is used as the treatment set; otherwise, an optimal design for the treatment model ignoring the blocks is first generated, and the result is used as the treatment set for optimal blocking.

The following are three mutually exclusive *block-specifications* that you can provide:

COVAR=SAS-data-set VAR=(variables)

specifies a data set to use in providing a general covariance matrix for the runs. The argument to VAR= names the variables in this data set that contain the columns of the covariance matrix for the runs. For an example, see [Example 14.9](#).

DESIGN=SAS-data-set

specifies a data set to use in providing a general covariate model. In addition to this data set, you must specify a covariate model with the CLASS and MODEL statements. Covariate models are specified in the same way as the treatment model; CLASS and MODEL statements that come after a BLOCKS statement involving the DESIGN= specification are interpreted as applying to the covariate model. For an example, see [Example 14.8](#).

STRUCTURE=(b) k

specifies a block design with b blocks of size k . For an example, see [Example 14.7](#).

The following *options* can also be used:

INIT=RANDOM

specifies the initialization method for constructing the starting design. The option INIT=RANDOM specifies that the starting design is to be constructed by selecting candidates at random without replacement. The option INIT=CHAIN selects candidate points in the order in which they occur in the original data set.

ITER= n

specifies the number of times to repeat the search from different initial designs. Because local optima are common in difficult search problems, it is often a good idea to make several tries for the optimal design with a random or partially random method of initialization (see the preceding INIT= option). By default, $n = 10$. Specify both INIT=CHAIN and ITER=0 to evaluate the initial design itself.

KEEP= m

specifies that only the best m designs are to be retained. The value m must be less than or equal to the value n of the ITER= option. By default $m = n$, so that all iterations are kept. This option is useful when you want to make many searches to overcome the problem of local optima but you are only interested in the results of the best m designs.

NOEXCHANGE

suppresses the part of the optimal blocking algorithm that exchanges treatment design points for candidate treatment points. When this option is specified, only interchanges between design points are performed. Use this option when you do not want to change which treatment points are included in the design and you only want to find their optimal ordering.

CLASS Statement

```
CLASS variable <(v-options)> <variable <(v-options)> ...> </v-options>> ;
```

You use the CLASS statement to identify classification (qualitative) variables, which are factors that separate the observations into groups. For example, a completely randomized design has a single *class-variable* that identifies the groups of observations. A randomized complete block design has two *class-variables*; one identifies the blocks and one identifies the treatments.

You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *v-options* for the CLASS statement by placing them after a slash (/). Global *v-options* are applied to all the variables specified in the CLASS statement. However, individual CLASS variable *v-options* override the global *v-options*.

Class-variables can be either numeric or character. The OPTEX procedure uses the formatted values of *class-variables* in forming model effects. Any variable in the model that is not listed in the CLASS statement is assumed to be continuous (quantitative). Continuous variables must be numeric.

NOTE: If you specify a data set containing fixed covariate effects with a DESIGN= data set in the BLOCKS statement, then a CLASS or MODEL statement that follows the BLOCKS statement refers to the model for the fixed covariates. A CLASS or MODEL statement that defines the model for the candidate points (treatment model) should be specified *before* the BLOCKS statement.

DESCENDING

DESC

reverses the sorting order of the classification variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option may be useful when you use the CONTRAST statement. When ORDER=FORMATTED (the default) for numeric variables for which you have supplied no explicit format (that is, for which there is no corresponding FORMAT statement in the current PROC OPTEX run or in the DATA step that created the data set), the levels are ordered by their internal (numeric) value. Note that this represents a change from previous releases for how class levels are ordered. Before SAS 8, numeric class levels with no explicit format were ordered by their BEST12. formatted values, and in order to revert to the previous ordering you can specify this format explicitly for the affected classification variables. The change was implemented because the former default behavior for ORDER=FORMATTED often resulted in levels not being ordered numerically. The following table shows how PROC OPTEX interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

For more information on sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PARAM=keyword

specifies the parameterization method for the classification variable(s). Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=ORTHEFFECT. Note that this represents a change from previous releases for how classification variables are parameterized. Before SAS 9, the default was PARAM=EFFECT, and in order to revert to the previous parameterization you can specify PARAM=EFFECT explicitly for the affected classification variables. The change was implemented because an orthogonal parameterization leads to D- and A-efficiency values that more realistically reflect the true efficiency of the design. If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used.

EFFECT	specifies effect coding
POLYNOMIAL POLY	specifies polynomial coding
REFERENCE REF	specifies reference cell coding
ORDINAL ORD	specifies ordinal, or “thermometer” coding
ORTHEFFECT	specifies orthogonal effect coding
ORTHPOLY	specifies orthogonal polynomial coding
ORTHREF	specifies orthogonal reference cell coding
ORTHORDINAL	specifies orthogonal ordinal coding

All of these parameterizations are full rank. The orthogonal versions perform a scaled, intercept-augmented Gram-Schmidt orthogonalization on the columns of the corresponding nonorthogonal parameterizations. For the EFFECT and REFERENCE parameterizations, the REF= option in the CLASS statement determines the reference level.

Consider a model with one CLASS variable A with four levels, 1, 2, 5, and 7. Details of the possible choices for the PARAM= option follow.

EFFECT Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of -1 . For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Effect Coding			
A	Design Matrix		
1	1	0	0
2	0	1	0
5	0	0	1
7	-1	-1	-1

Parameter estimates of CLASS main effects that uses the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all 4 levels.

POLYNOMIAL | POLY Three columns are created. The first represents the linear term (x), the second represents the quadratic term (x^2), and the third represents the cubic term (x^3), where x is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, . . . according to their sorting order. The design matrix columns for A are as follows.

Polynomial Coding			
A	Design Matrix		
1	1	1	1
2	2	4	8
5	5	25	125
7	7	49	343

REFERENCE | REF Three columns are created to indicate group membership of the non-reference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Reference Coding			
A	Design Matrix		
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

Parameter estimates of CLASS main effects that uses the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

ORDINAL | ORD Three columns are created to indicate group membership in successive collections of levels after the first. For instance, the design matrix columns for A are as follows.

Ordinal Coding			
A	Design Matrix		
1	0	0	0
2	1	0	0
5	1	1	0
7	1	1	1

Parameter estimates of CLASS main effects that uses the ordinal coding scheme estimate the difference in the average effect of each successive collection of levels compared to the effect of the first level.

ORTHEFFECT The columns are obtained by applying the Gram-Schmidt orthogonalization to the mean-centered columns for PARAM=EFFECT, and then scaling so that the sum of squares for each column equals the number of levels. The design matrix columns for A are as follows.

Orthogonal Effects Coding			
A	Design Matrix		
1	1.414	-0.816	-0.577
2	0	1.633	-0.577
5	0	0	1.732
7	-1.414	-0.816	-0.577

ORTHPOLY The columns are obtained by applying the Gram-Schmidt orthogonalization to the mean-centered columns for PARAM=POLY, and then scaling so that the sum of squares for each column equals the number of levels. The design matrix columns for A are as follows.

Orthogonal Polynomial Coding			
A	Design Matrix		
1	-1.153	0.907	-0.921
2	-0.734	-0.540	1.473
5	0.524	-1.370	-0.921
7	1.363	1.004	0.368

ORTHREF The columns are obtained by applying the Gram-Schmidt orthogonalization to the mean-centered columns for PARAM=REFERENCE, and then scaling so that the sum of squares for each column equals the number of levels. The design matrix columns for A are as follows.

Orthogonal Reference Coding			
A	Design Matrix		
1	1.732	0	0
2	-0.577	1.633	0
5	-0.577	-0.816	1.414
7	-0.577	-0.816	-1.414

ORTHORDINAL The columns are obtained by applying the Gram-Schmidt orthogonalization to the mean-centered columns for PARAM=REFERENCE, and then scaling so that the sum of squares for each column equals the number of levels. The design matrix columns for A are as follows.

Orthogonal Ordinal Coding			
A	Design Matrix		
1	-1.732	0	0
2	0.577	-1.633	0
5	0.577	0.816	-1.414
7	0.577	0.816	1.414

REF= *'level' | keyword*

specifies the reference level for PARAM=EFFECT or PARAM=REFERENCE. For an individual (but not a global) variable REF= *option*, you can specify the *level* of the variable to use as the reference level. For a global or individual variable REF= *option*, you can use one of the following *keywords*. The default is REF=LAST.

FIRST	designates the first ordered level as reference
LAST	designates the last ordered level as reference

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to SAS 9.

EXAMINE Statement

EXAMINE < *options* > ;

You use the EXAMINE statement to display the characteristics of a selected design. By default, the EXAMINE statement lists certain measures of design efficiency for the best design. (See the section “[Output](#)” on page 1085.) The following *options* can be used to modify the output:

DESIGN

lists the actual points in the selected design. Designs are ordered by the value of the efficiency criterion that is being optimized. Thus, a *design-number* of 1 corresponds to the best design found, a *design-number* of 2 corresponds to the second best design, and so on. By default, the first design (*design-number* = 1) is examined. You can select a different design to be examined by using the NUMBER= option.

INFORMATION**INFO**

I

lists the information matrix $X'X$ for the selected design.

NUMBER= *design-number*

selects a design to examine by specifying its *design-number*.

VARIANCE**VAR**

V

lists the variance matrix $(X'X)^{-1}$ for the parameter estimates for the selected design.

For details on design efficiencies see the section “[Design Efficiency Measures](#)” on page 1074.

If you use the OPTEX procedure interactively, you must enter the options for every EXAMINE statement. For example, the following statements list default information and the design points for the best design but only default information for the second-best design:

```

examine number=1 design;
examine number=2;

```

The following statements list default information and design points for both the best and second-best designs:

```

examine number=1 design;
examine number=2 design;

```

GENERATE Statement

GENERATE < options > ;

You use the GENERATE statement to customize the search for a design. By default, the OPTEX procedure searches for a design as follows:

- using the exchange algorithm (METHOD=EXCHANGE)
- using D-optimality as the optimality criterion (CRITERION=D)
- using a completely random initial design to start the search (INITDESIGN=RANDOM)
- selecting candidate points only from the DATA= data set (modified by using AUGMENT= or INITDESIGN= data sets)
- performing 10 iterations in the search (ITER=10)
- finding a design with $10 + p$ points, where p is the number of parameters in the model (modified by using the N= or INITDESIGN= option)

The following *options* can be used to modify these defaults:

AUGMENT=SAS-data-set

specifies a data set that contains a design to be augmented—in other words, a set of points that must be contained in the design generated. When creating designs, the OPTEX procedure adds points from the DATA= data set (or the last data set created, if DATA= is not specified) to points from the AUGMENT= data set. The number of points in the design to be augmented must be less than the number of points specified with the N= option. For details, see the section “AUGMENT= Data Set” on page 1071.

CRITERION=crit

specifies the optimality criterion used in the search. You can specify any one of the following:

CRITERION=D

specifies D-optimality; the optimal design maximizes the determinant $|X'X|$ of the information matrix for the design. This is the default criterion.

CRITERION=A

specifies A-optimality; the optimal design minimizes the sum of the variances of the estimated parameters for the model, which is the same as minimizing the trace of $(X'X)^{-1}$.

CRITERION=U

specifies U-optimality; the optimal design minimizes the sum of the minimum distances from each candidate point to the design. That is, if \mathcal{C} is the set of candidate points, \mathcal{D} is the set of design points, and $d(\mathbf{x}, \mathcal{D})$ is the minimum distance from \mathbf{x} to any point in \mathcal{D} , then a U-optimal design minimizes

$$\sum_{\mathbf{x} \in \mathcal{C}} d(\mathbf{x}, \mathcal{D})$$

This measures how well the design “covers” the candidate set; thus, a U-optimal design is also called a *uniform coverage design*.

CRITERION=S

specifies S-optimality; the optimal design maximizes the harmonic mean of the minimum distance from each design point to any other design point. Mathematically, an S-optimal design maximizes

$$\frac{N_{\mathcal{D}}}{\sum_{\mathbf{y} \in \mathcal{D}} 1/d(\mathbf{y}, \mathcal{D} - \mathbf{y})}$$

where \mathcal{D} is the set of design points, and $N_{\mathcal{D}}$ is the number of points in \mathcal{D} . This measures how spread out the design points are; thus, an S-optimal design is also called a *maximum spread design*.

For more information on the different criteria, see the section “[Optimality Criteria](#)” on page 1077.

INITDESIGN=*initialization-method*

specifies a method of obtaining an initial design for the search procedure. Valid values of *initialization-method* are as follows:

SEQUENTIAL

specifies an initial design chosen by a sequential search. The design given by INITDESIGN=SEQUENTIAL is the same as the design given by METHOD=SEQUENTIAL. You can use the INITDESIGN=SEQUENTIAL option with other values of the METHOD= option to specify a sequential design as the initial design for various search methods. For details, see “[Search Methods](#)” on page 1081.

RANDOM

specifies a completely random initial design. The initial design generated consists of a random selection of observations from the DATA= data set.

PARTIAL<(m)>

specifies an initial design by using a mixture of RANDOM and SEQUENTIAL methods. A small number n_r of points for the initial design are chosen at random from the candidates, and the rest of the design points are chosen by a sequential search. (For a definition of the sequential search, see the section “[Search Methods](#)” on page 1081.)

You can specify the optional integer m to modify the selection of n_r . By default, or if $m = 0$, n_r is randomly chosen between 0 and one less than half the number of parameters in the linear model. If $m > 0$, then n_r is randomly chosen between 0 and m for each try. If $m < 0$, then $n_r = |m|$ for each try. The maximum value for $|m|$ is the number of points in the design. Refer to Galil and Kiefer (1980) for notes on choosing n_r .

SAS-data-set

specifies a data set that holds the initial design. Use this *initialization-method* when you have a specific design that you want to improve or when you want to evaluate an existing design. For details, see “[INITDESIGN= Data Set](#)” on page 1071.

The default initialization method depends on the search procedure as shown in [Table 14.6](#).

Table 14.6 Default Initialization Methods

Search Procedure (METHOD= option)	Default Initialization Method (INITDESIGN= option)
DETMAX	PARTIAL
EXCHANGE	RANDOM
FEDOROV	RANDOM
M_FEDOROV	PARTIAL
SEQUENTIAL	none

If you specify `INITDESIGN=SAS-data-set` and `METHOD=SEQUENTIAL`, no search is performed; the `INITDESIGN=` data set is taken as the final design. By specifying these options, you can use the procedure to evaluate an existing design.

ITER=*n*

specifies the number *n* of searches to make. Because local optima are common in difficult search problems, it is often a good idea to make several tries for the optimal design with a random or partially random method of initialization (see the preceding `INITDESIGN=` option). By default, $n = 10$.

The *n* designs found are sorted by their respective efficiencies according to the current optimality criterion (see the `CRITERION=` option on page 1040.) The most efficient design is assigned a *design-number* of 1, the second most efficient design is assigned a *design-number* of 2, and so on. You can then use the *design-number* in the `EXAMINE` and `OUTPUT` statements to display the characteristics of a design or to save a design in a data set.

KEEP=*m*

specifies that only the best *m* designs are to be retained. The value *m* must be less than or equal to the value *n* of the `ITER=` option. By default $m = n$, so that all iterations are kept. This option is useful when you want to make many searches to overcome the problem of local optima but are interested only in the results of the best *m* designs.

METHOD=DETMAX < (*level*) >**METHOD=EXCHANGE** < (*k*) >**METHOD=FEDOROV****METHOD=M_FEDOROV****METHOD=SEQUENTIAL**

specifies the procedure used to search for the optimal design. The default is METHOD=EXCHANGE.

With METHOD=DETMAX, the optional *level* gives the maximum excursion level for the search, where *level* is an integer greater than or equal to 1. Enclose the value of *level* in parentheses immediately following the word DETMAX. The default value for *level* is 4. In general, larger values of *level* result in longer search times.

When METHOD=EXCHANGE, the optional *k* specifies the *k*-exchange search method of Johnson and Nachtsheim (1983), which generalizes the modified Fedorov search algorithm of Cook and Nachtsheim (1980). Enclose the value of *k* in parentheses immediately following the word EXCHANGE.

From fastest to slowest, the methods are

SEQUENTIAL → EXCHANGE → DETMAX → M_FEDOROV → FEDOROV

In general, slower methods result in more efficient designs. While the default method EXCHANGE always works relatively quickly, you might want to specify a more reliable method, such as M_FEDOROV, with fast computers or small to moderately sized problems.

See the section “[Search Methods](#)” on page 1081 for details on the algorithms.

N=*n***N=SATURATED**

specifies the number of points in the final design. The default design size is $10 + p$, where p is the number of parameters in the model. If you use the INITDESIGN= option, the default number is the number of points in the initial design. Specify N=*n* to search for a design with *n* points. Specify N=SATURATED to search for a design with the same number of points as there are parameters in the model. A saturated design has no degrees of freedom to estimate error and should be used with caution.

ID Statement

ID *variables* ;

You use the ID statement to name the *variables* in the DATA= data set that are not involved in the model but are to be transferred from the input data set to the output data set.

Variables listed in the ID statement must be contained in the DATA= data set. They can also be contained in other input data sets. If an ID variable is also contained in an AUGMENT= or INITDESIGN= data set and an observation from that data set is used in the final design, the values of the ID variables for that observation are transferred to the OUT= data set. For details, see the section “[Input Data Sets](#)” on page 1069.

MODEL Statement

MODEL *effects* *</ options >* ;

You use the MODEL statement to specify the independent effects used to model data that are to be collected with the design that is being constructed. The *effects* can be

- simple continuous regressor effects
- polynomial continuous effects
- main effects of classification variables
- interactions of classification variables
- continuous-by-class effects

The variables used to form *effects* in the MODEL statement must be present in all input data sets. For details on input data sets, see the section “[Input Data Sets](#)” on page 1069. For details on the specification of different types of effects and on how the design matrix is defined with respect to the effects, see the section “[Specifying Effects in MODEL Statements](#)” on page 1072.

If you specify a data set containing fixed covariate effects with a DESIGN= data set in the BLOCKS statement, then a CLASS or MODEL statement that *follows* the BLOCKS statement refers to the model for the fixed covariates. A CLASS or MODEL statement that defines the model for the candidate points (treatment model) should occur *before* the BLOCKS statement.

The following options can be used in the MODEL statement:

NOINT

excludes the intercept parameter from the model. By default, the OPTEx procedure includes the intercept parameter in the model.

PRIOR=num-list

specifies prior precision values corresponding to groups of effects in the model. Groups of effects in the MODEL statement with the same prior precision must be separated by commas. Then use the PRIOR= option, listing as many prior precision values as there are groups of effects. See [Example 14.6](#) for an example.

When you specify prior precision values, the information matrix for estimating the linear parameters is $X'X + P$, where X is the design matrix and P is a diagonal matrix with the prior precision values that you specify on the diagonal. Thus, in terms of a prior distribution, the inverses of the prior precision values can be interpreted as prior variances for the linear parameters corresponding to each effect. As an alternative interpretation, note that with orthogonal coding the value of the prior for an effect says roughly how many prior “observations’ worth” of information you have for that effect. See the section “[Design Coding](#)” on page 1075 for details on orthogonal coding.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set* < *options* > ;

You use the OUTPUT statement to save a design in an output data set. By default, the saved design is the best design found. You specify the data set name as follows:

OUT=*SAS-data-set*

gives a name for the output data set. The OUT= data set is required in the OUTPUT statement.

The following *options* can be used:

BLOCKNAME=*variable-name*

specifies the name to be given to the blocking variable in the output data set. The default name is BLOCK. You can use this *option* in conjunction with a STRUCTURE= option in the BLOCKS statement. See [Example 14.7](#) for an example.

NUMBER=*design-number*

selects a design to output by specifying its *design-number*. Designs are ordered by the value of the efficiency criterion that is being optimized. Thus, a *design-number* of 1 corresponds to the best design found, a *design-number* of 2 corresponds to the second best design, and so on. The default *design-number* is 1. To modify the number of designs created, see the ITER= option.

Alternatively, you can specify one of the following:

NUMBER=DBEST

selects the design that has the highest D-efficiency value.

NUMBER=ABEST

selects the design that has the highest A-efficiency value.

NUMBER=GBEST

selects the design that has the highest G-efficiency value.

NUMBER=VBEST

selects the design that has the minimum average standard error for prediction.

These options can be used to find designs that are efficient for more than one criterion. For example, you can use the default CRITERION=D option in the GENERATE statement with the NUMBER=GBEST option in the OUTPUT statement to find the D-optimal design that has maximal G-efficiency. In fact, this is the best way to use the OPTEX procedure to find G-efficient designs; see the section “G- and I-optimality” on page 1079 for more details.

Advanced Examples

Example 14.1: Nonstandard Linear Model

See OPTeX3 in the SAS/QC Sample Library The following example is based on an example in Mitchell (1974a). An animal scientist wants to compare wildlife densities in four different habitats over a year. However, due to the cost of experimentation, only 12 observations can be made. The following model is postulated for the density $y_j(t)$ in habitat j during month t :

$$y_j(t) = \mu_j + \beta t + \sum_{i=1}^4 a_i \cos(i\pi t/4) + \sum_{i=1}^3 b_i \sin(i\pi t/4)$$

This model includes the habitat as a classification variable, the effect of time with an overall linear drift term βt , and cyclic behavior in the form of a Fourier series. There is no intercept term in the model.

The OPTeX procedure is used since there are no standard designs that cover this situation. The candidate set is the full factorial arrangement of four habitats by 12 months, which can be generated with a DATA step, as follows:

```
data a;
  drop theta pi;
  array c{4} c1-c4;
  array s{3} s1-s3;
  pi = arcos(-1);
  do Habitat=1 to 4;
    do Month=1 to 12;
      theta = pi * Month / 4;
      do i=1 to 4; c{i} = cos(i*theta); end;
      do i=1 to 3; s{i} = sin(i*theta); end;
      output;
    end;
  end;
run;
```

Data set a contains the 48 candidate points and includes the four cosine variables (c1, c2, c3, and c4) and three sine variables (s1, s2, and s3). The following statements produce [Output 14.1.1](#):

```
proc optex seed=193030034 data=a;
  class  Habitat;
  model  Habitat Month c1-c4 s1-s3 / noint;
  generate n=12;
run;
```

Output 14.1.1 Sampling Wildlife Habitats over Time

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	31.6103	19.7379	57.7350	1.3229
2	31.6103	19.7379	57.7350	1.3229
3	31.6103	19.7379	57.7350	1.3229
4	31.6103	19.3793	57.7350	1.3229
5	31.6103	19.2916	57.7350	1.3229
6	31.6103	19.0335	57.7350	1.3229
7	30.1304	14.8837	44.7214	1.4907
8	30.1304	14.2433	44.7214	1.5092
9	30.1304	13.1687	44.7214	1.5456
10	28.1616	9.8842	40.8248	1.7559

The best determinant (D-efficiency) was found in 6 out of the 10 tries. Thus, you can be confident that this is the best achievable determinant. Only the A-efficiency distinguishes among the designs listed in [Output 14.1.1](#). The best design has an A-efficiency of 19.74%, whereas another design has the same D-efficiency but a slightly smaller A-efficiency of 19.03%, or about 96% relative A-efficiency. To explore the differences, you can save the designs in data sets and print them. Since the OPTEX procedure is interactive, you need to submit only the following statements (immediately after the preceding statements) to produce [Output 14.1.2](#) and [Output 14.1.3](#):

```

output out=d1 number=1;
run;
output out=d6 number=6;
run;

proc sort data=d1;
  by Month Habitat;
run;
proc print data=d1;
  var Month Habitat;
run;

proc sort data=d6;
  by Month Habitat;
run;
proc print data=d6;
  var Month Habitat;
run;

```

Output 14.1.2 The Best Design

Obs	Month	Habitat
1	1	3
2	2	2
3	3	4
4	4	1
5	5	4
6	6	1
7	7	2
8	8	3
9	9	4
10	10	1
11	11	2
12	12	3

Output 14.1.3 Design with Lower A-Efficiency

Obs	Month	Habitat
1	1	4
2	2	2
3	3	3
4	4	1
5	5	1
6	6	4
7	7	4
8	8	1
9	9	2
10	10	1
11	11	4
12	12	3

Note the structure of the best design in [Output 14.1.2](#). One habitat is sampled in each month, each habitat is sampled three times, and the habitats are sampled in consecutive complete blocks. Even though the design in [Output 14.1.3](#) is as D-efficient as the best, it has almost none of this structure; one habitat is sampled each month, but habitats are not sampled an equal number of times. This demonstrates the importance of choosing a final design on the basis of more than one criterion.

You can try searching for the A-optimal design directly. This takes more time but (with only 48 candidate points) is not too large a problem. The following statements produce [Output 14.1.4](#):

```
proc optex seed=193030034 data=a;
  class  Habitat;
  model  Habitat Month c1-c4 s1-s3 / noint;
  generate n=12 criterion=A;
run;
```

Output 14.1.4 Searching Directly for an A-Efficient Design

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	31.6103	19.7379	57.7350	1.3229
2	30.1304	17.8273	52.2233	1.3894
3	30.1304	17.7943	52.2233	1.3944
4	30.1304	17.6471	52.2233	1.4093
5	28.1616	15.7055	44.7214	1.4860
6	28.1616	14.5289	44.7214	1.5343
7	28.1616	13.8603	39.2232	1.5811
8	25.0891	11.6152	37.7964	1.8143
9	25.0891	10.7563	37.7964	1.8143
10	25.0891	10.5437	33.3333	1.8930

The best design found is no more A-efficient than the one found previously.

Example 14.2: Comparing Fedorov Algorithm to Sequential Algorithm

An automotive engineer wants to fit a quadratic model to fuel consumption data in order to find the values of the control variables that minimize fuel consumption (refer to Vance 1986). The three control variables AFR (air fuel ratio), EGR (exhaust gas recirculation), and SA (spark advance) and their possible settings are shown in the following table: *See OPTEX4 in the SAS/QC Sample Library*

Variable	Values								
AFR	15	16	17	18					
EGR	0.020	0.177	0.377	0.566	0.921	1.117			
SA	10	16	22	28	34	40	46	52	

Rather than run all 192 ($4 \times 6 \times 8$) combinations of these factors, the engineer would like to see whether the total number of runs can be reduced to 50 in an optimal fashion.

Since the factors have different numbers of levels, you can use the PLAN procedure (refer to the *SAS/STAT User's Guide*) to generate the full factorial set to serve as a candidate data set for the OPTEX procedure.

```
proc plan;
  factors AFR=4 ordered EGR=6 ordered SA=8 ordered
    / noprint;
  output out=a
    AFR nvals=(15, 16, 17, 18)
    EGR nvals=(0.020, 0.177, 0.377, 0.566, 0.921, 1.117)
    SA nvals=(10, 16, 22, 28, 34, 40, 46, 52);
run;
```

The Fedorov algorithm (Fedorov 1972) is generally the most successful optimal design search algorithm, although it also typically can take relatively much longer to run than other algorithms. This algorithm is not the default search method for the OPTeX procedure. However, you can specify that it be used with the METHOD=FEDOROV option in the GENERATE statement. For example, the following statements produce [Output 14.2.1](#).

```
proc optex data=a seed=61552;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=50 method=fedorov iter=100 keep=10;
run;
```

Output 14.2.1 Efficiencies with Fedorov Algorithm

The OPTeX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.5246	24.5897	96.3915	0.4231
2	46.5241	24.5901	96.3926	0.4233
3	46.5238	24.5844	96.2306	0.4231
4	46.5237	24.5855	96.2318	0.4233
5	46.5219	24.5866	96.4790	0.4233
6	46.5192	24.5832	96.3070	0.4231
7	46.5192	24.5832	96.3070	0.4231
8	46.5190	24.5741	96.1695	0.4232
9	46.5189	24.5841	96.3062	0.4233
10	46.5188	24.5755	96.3020	0.4234

The Fedorov search method for the preceding problem requires a few seconds for 100 tries on a 2.8GHz desktop PC.

For comparison, you can use the METHOD=SEQUENTIAL option in the GENERATE statement, as shown in the following statements, which produce [Output 14.2.2](#).

```
proc optex data=a seed=33805;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=50 method=sequential iter=100 keep=10;
run;
```

Output 14.2.2 Efficiencies with Sequential Algorithm

Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.5246	24.5897	96.3915	0.4231
2	46.5241	24.5901	96.3926	0.4233
3	46.5238	24.5844	96.2306	0.4231
4	46.5237	24.5855	96.2318	0.4233
5	46.5219	24.5866	96.4790	0.4233
6	46.5192	24.5832	96.3070	0.4231
7	46.5192	24.5832	96.3070	0.4231
8	46.5190	24.5741	96.1695	0.4232
9	46.5189	24.5841	96.3062	0.4233
10	46.5188	24.5755	96.3020	0.4234

In a fraction of the run time required by the Fedorov method, the sequential algorithm finds a design with a relative D-efficiency of $46.4009/46.5246 = 99.73\%$ compared to the best design found by the Fedorov method, and with *better* A-efficiency. As this demonstrates, if absolute D-optimality is not required, a faster, simpler search may be sufficient.

Example 14.3: Using an Initial Design to Search an Optimal Design

This example is a continuation of [Example 14.2](#).

See *OPTEX4* in the *SAS/QC Sample Library*

You can customize the runs used to initialize the search in the OPTEX procedure. For example, you can use the INITDESIGN=SEQUENTIAL option to use an initial design chosen by the sequential search. Or you can place specific points in a data set and use the INITDESIGN=SAS-data-set option. In both cases, the search time can be significantly reduced, since the search only has to be done once. This example illustrates both of these options.

The previous example compared the results of the DETMAX and sequential search algorithms. You can use the design chosen by the sequential search as the *starting point* for the DETMAX algorithm. The following statements specify the DETMAX search method, replacing the default initialization method with the sequential search:

```
proc optex data=a seed=33805;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=50 method=detmax initdesign=sequential;
run;
```

The results, which are displayed in [Output 14.3.1](#), show an improvement over the sequential design itself ([Output 14.2.2](#)) but not over the DETMAX algorithm with the default initialization method ([Output 14.2.1](#)). Evidently the sequential design represents a local optimum that is not the global optimum, which is a common phenomenon in combinatorial optimization problems such as this one.

Output 14.3.1 Initializing with a Sequential Design

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.4333	25.0321	95.1371	0.4199

Prior knowledge of the design problem at hand might also provide a specific set of factor combinations to use as the initial design. For example, many D-optimal designs are composed of replications of the optimal saturated design—that is, the optimal design with exactly as many points as there are parameters to be estimated. In this case, there are 10 parameters in the model. Thus, you can find the optimal saturated design in 10 points, replicate it five times, and use the resulting design as an initial design, as follows:

```
proc optex data=a seed=33805;
  model AFR|EGR|SA@2 AFR*AFR EGR+EGR SA*SA;
  generate n=saturated method=detmax;
  output out=b;
run;

data c;
  set b;
  drop i;
  do i=1 to 5; output; end;
run;

proc optex data=a seed=33805;
  model AFR|EGR|SA@2 AFR*AFR EGR+EGR SA*SA;
  generate n=50 method=detmax initdesign=c;
run;
```

The results are displayed in [Output 14.3.2](#) and [Output 14.3.3](#). The resulting design is 99.9% D-efficient and 98.4% A-efficient relative to the best design found by the straight-forward approach ([Output 14.2.1](#)), and it takes considerably less time to produce.

Output 14.3.2 Efficiencies for the Unreplicated Saturated Design

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	41.6990	24.8480	67.6907	0.9508
2	41.4931	22.2840	70.8532	0.9841
3	40.9248	20.7672	62.2177	1.0247
4	40.7447	21.6253	52.7537	1.0503
5	39.9563	20.1557	46.4244	1.0868
6	39.9287	19.5856	45.9023	1.0841
7	39.9287	19.5856	45.9023	1.0841
8	38.9078	13.5976	37.7964	1.2559
9	38.9078	13.5976	37.7964	1.2559
10	37.6832	12.5540	45.3315	1.3036

Output 14.3.3 Initializing with a Data Set

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.4388	24.4951	96.0717	0.4242

Example 14.4: Optimal Design Using an Augmented Best Design

This example is a continuation of Example 14.2.

See OPTEX4 in the SAS/QC Sample Library

You can specify a set of points that you want to be included in the final design found by the OPTEX procedure by using the AUGMENT= option in the GENERATE statement to specify a data set that contains a design to be augmented.

In this case, you can try to speed up the search for a 50-run design by first finding an optimal 25-run design and then augmenting that design with another 25 runs, as shown in the following statements:

```
proc optex data=a seed=36926;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=25 method=detmax;
  output out=b;
run;
```

```

proc optex data=a seed=37034;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=50 method=detmax augment=b;
run;

```

The result (see [Output 14.4.1](#) and [Output 14.4.2](#)) is a design with almost 100% D-efficiency and A-efficiency relative to the best design found by the first attempt. However, this approach is not much faster than the original approach, since the run time for the DETMAX algorithm is essentially linear in the size of the design (see the section “Memory and Run-Time Considerations” on page 1080).

Output 14.4.1 Efficiencies for the 25-Point Design to Be Augmented

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.2975	26.0374	91.1822	0.5849
2	46.2171	25.9733	86.4608	0.5859
3	46.1720	25.9378	88.3293	0.5860
4	46.1374	25.9128	86.1895	0.5866
5	46.0808	22.6647	86.1502	0.6169
6	46.0620	24.7326	89.7179	0.6012
7	45.9992	25.4549	90.3330	0.5946
8	45.9630	24.7610	88.2701	0.5991
9	45.9627	25.5310	88.5737	0.5894
10	45.7994	24.5645	87.7544	0.6005

Output 14.4.2 Efficiencies for the Augmented 50-Point Design

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.4957	25.0858	94.8160	0.4195
2	46.4773	25.0696	95.0646	0.4195
3	46.4684	24.5519	96.1259	0.4234
4	46.4676	24.5002	95.6830	0.4238
5	46.4587	25.0709	94.6650	0.4196
6	46.4555	24.8087	95.7768	0.4209
7	46.4471	24.5460	95.0073	0.4240
8	46.4373	25.0740	94.4640	0.4194
9	46.3899	25.0007	95.2162	0.4201
10	46.3662	24.4013	94.9539	0.4242

Example 14.5: Optimal Design Using a Small Candidate Set

This example is a continuation of [Example 14.4](#).

See *OPTEX4* in the *SAS/QC Sample Library*

A well-chosen initial design can speed up the search procedure, as illustrated in [Example 14.2](#). Another way to speed up the search is to reduce the candidate set. The following statements generate the optimal design with a fast, sequential search and then use the `FREQ` procedure to examine the frequency of different factor levels in the final design:

```
proc optex data=a seed=33805 noprint;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=50 method=sequential;
  output out=b;
run;
proc freq;
  table AFR EGR SA / nocum;
run;
```

Output 14.5.1 Factor-Level Frequencies for Sequential Design

The FREQ Procedure		
AFR	Frequency	Percent
15	19	38.00
16	6	12.00
17	6	12.00
18	19	38.00
EGR	Frequency	Percent
0.02	20	40.00
0.566	9	18.00
1.117	21	42.00
SA	Frequency	Percent
10	19	38.00
28	6	12.00
34	5	10.00
52	20	40.00

From [Output 14.5.1](#), it is evident that most of the factor values lie in the middle or at the extremes of their respective ranges. This suggests looking for an optimal design with a candidate set that includes only those points in which the factors have values in the middle or at the extremes of their respective ranges. The following statements illustrate this approach (see [Output 14.5.2](#)):

```
proc plan;
  factors AFR=4 ordered EGR=4 ordered SA=4 ordered
  / noprint;
  output out=a AFR nvals=(15, 16, 17, 18)
```

```

EGR nvals=(0.020, 0.377, 0.566, 1.117)
SA nvals=(10, 28, 34, 52);
run;
proc optex seed=61552;
  model AFR|EGR|SA@2 AFR*AFR EGR*EGR SA*SA;
  generate n=50 method=detmax;
run;

```

Output 14.5.2 Optimal Design Using a Smaller Candidate Set

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	46.5151	24.9003	96.7226	0.4442
2	46.4997	24.5549	96.1157	0.4478
3	46.4920	24.5530	95.9941	0.4480
4	46.4657	24.8653	95.5627	0.4446
5	46.4547	24.5071	96.0385	0.4481
6	46.4333	25.0321	95.1371	0.4448
7	46.4333	25.0321	95.1371	0.4448
8	46.4333	25.0321	95.1371	0.4448
9	46.3916	24.3617	95.0041	0.4489
10	46.3379	24.8695	94.3115	0.4458

The resulting design is about as good as the best one obtained from a complete candidate set (> 99.9% relative D-efficiency and marginally higher relative A-efficiency) and takes much less time to find.

See the section “Handling Many Variables” on page 1027 for another example of reducing the candidate set for the optimal design search.

Example 14.6: Bayesian Optimal Design

See *OPTEX7* in the *SAS/QC Sample Library*

Suppose you want a design in 20 runs for seven two-level factors. There are 29 terms in a full second-order model, so you will not be able to estimate all main effects and two-factor interactions. If the number of runs were a power of 2, a design of resolution 4 could be used to estimate all main effects free of the two-factor interactions, as well as to provide partial information on the interactions. However, when the number of runs is not a power of two, as in this case, DuMouchel and Jones (1994) suggest searching for a *Bayesian optimal design* by specifying nonzero prior precision values for the interactions. You can specify these values in the OPTEX procedure with the PRIOR= option in the MODEL statement. This says that you want to consider all main effects and interactions as potential effects, but you are willing to sacrifice information on the interactions to obtain maximal information on the main effects. When an orthogonal design of resolution 4 exists, it is optimal according to this Bayesian criterion. You can use the following statements to generate the Bayesian D-optimal design:

```

proc factex;
  factors x1-x7;
  output out=Candidates;
run;

proc optex data=Candidates seed=57922 coding=orth;
  model x1-x7,
        x1|x2|x3|x4|x5|x6|x7@2 / prior=0,16;
  generate n=20 method=m_fedorov;
  output out=Design;
run;

```

With orthogonal coding, the value of the prior for an effect says roughly how many prior “observations’ worth” of information you have for that effect. In this case, the PRIOR= precision values and the use of commas to group effects in the MODEL statement says that there is no prior information for the main effects and 16 runs’ worth of information for each two-factor interaction. See the section “Design Coding” on page 1075 for details on orthogonal coding.

The efficiencies are shown in [Output 14.6.1](#).

Output 14.6.1 Efficiencies for Bayesian Optimal Designs

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	85.1815	74.6705	85.2579	1.1476
2	85.1815	74.6705	85.2579	1.1476
3	85.1815	74.6705	85.2579	1.1476
4	85.0424	73.3109	81.0800	1.1582
5	85.0424	73.3109	81.0800	1.1582
6	84.5680	73.5053	84.1376	1.1566
7	84.4931	72.1671	81.7855	1.1673
8	84.4239	72.4979	81.7431	1.1646
9	84.3919	74.6097	89.3631	1.1480
10	84.3919	74.6097	89.3631	1.1480

Notice that the best design was found in three tries out of ten. It might be a good idea to repeat the search with more tries (see the ITER= option). You can use the ALIASING option of the GLM procedure to list the aliasing structure for the design:

```

data Design; set Design;
  y = ranuni(654231);
proc glm data=Design;
  model y = x1-x7 x1|x2|x3|x4|x5|x6|x7@2 / e aliasing;
run;

```

The relevant part of the output is shown in [Output 14.6.2](#). Most of the main effects are indeed unconfounded with two-factor interactions, although many two-factor interactions are confounded with each other.

Output 14.6.2 Aliasing Structure for Bayesian Optimal Design

```

                                The GLM Procedure

                                General Form of Aliasing Structure

                                Intercept
                                x1 - 0.5*x3*x7
                                x2
                                x3
                                x4 + 0.5*x3*x7
                                x5
                                x6
                                x7
                                x1*x2 - x3*x6 + 0.5*x3*x7 - x4*x7
                                x1*x3 - x2*x6 - x5*x7
                                x2*x3 + x3*x7
                                x1*x4 - x5*x6 + x5*x7 + x6*x7
                                x2*x4 - x3*x6 + 0.5*x3*x7 - x4*x7
                                x3*x4 - x2*x6 - x5*x7
                                x1*x5 - x4*x6 - x3*x7
                                x2*x5 + x2*x6 + x5*x7 + x6*x7
                                x3*x5 + x3*x6 - x3*x7
                                x4*x5 - x1*x6 - x3*x7
                                x1*x7 - x4*x7
                                x2*x7 + x5*x7 + x6*x7

```

Example 14.7: Balanced Incomplete Block Design

See OPTEX8 in the SAS/QC Sample Library This example uses the BLOCKS statement to construct an incomplete block design. An incomplete block design is a design for v (qualitative) treatments in b blocks of k runs each, where $k < v$ so that not all treatments can occur in each block. An incomplete block design is said to be *balanced* when all pairs of treatments occur equally often in the same block. A balanced design is always optimal for any criterion based on the information matrix, although there are many values of (v, b, k) for which no balanced design exists.

One way to construct an incomplete block design with the OPTEX procedure is to include the blocking factor in the candidate set and in the model. For example, the following statements search for a BIBD for seven treatments in seven blocks of size three—that is, $(v, b, k) = (7, 7, 3)$ —using the full set of 49 treatment-by-block combinations for candidates:

```

data Candidates;
  do Treatment = 1 to 7;
    do Block = 1 to 7;
      output;
    end;
  end;
end;

proc optex data=Candidates seed=8327 coding=orth;
  class Treatment Block;
  model Treatment Block;
  generate n=21;
run;

```

By default, the OPTEX procedure performs the search 10 times from different random starting designs. The various efficiencies for each design are listed in [Output 14.7.1](#).

Output 14.7.1 Efficiency Factors for $v = b = 7, k = 3$ Designs

The OPTEX Procedure				
Design Number	D-Efficiency	A-Efficiency	G-Efficiency	Average Prediction Standard Error
1	89.0483	79.1304	82.7170	0.8845
2	89.0483	79.1304	82.7170	0.8845
3	88.4669	76.9882	78.6796	0.8967
4	88.4669	76.9882	78.6796	0.8967
5	88.4669	76.9882	78.6796	0.8967
6	88.4669	76.9882	78.6796	0.8967
7	88.4669	76.9882	78.6796	0.8967
8	88.4669	76.9882	78.6796	0.8967
9	88.1870	76.0262	78.7612	0.9024
10	87.7681	74.2459	73.9544	0.9131

Since the efficiency factors compare the designs to a (hypothetical) orthogonal design, values of 100% are not possible in this case. The OPTEX procedure includes facilities for examining the information matrix for the design; you can use these to verify that the best design found here is, in fact, balanced.

Searching for an optimal design for both treatments and blocks simultaneously has its limitations. Note that the balanced design was found on only two of the ten tries. A more serious limitation is that this approach sometimes fails to find a design with equal-sized blocks. A more efficient and flexible way to construct a block design with the OPTEX procedure is to use the BLOCKS statement.

The following statements use the BLOCKS statement to solve the preceding incomplete block design problem. In this case, the candidate set simply consists of the seven treatment levels.

```

data Candidates;
  do Treatment = 1 to 7;
    output;
  end;
run;

proc optex data=Candidates seed=73462 coding=orth;
  class Treatment;
  model Treatment;
  blocks structure=(7)3;
run;

```

The output again consists of efficiency factors for 10 different tries, but this time the factors are computed from the information matrix for only the treatment effects. In this special case (a single classification effect in the treatment model together with the BLOCKS STRUCTURE= specification), the efficiency of each design as an incomplete block design is also listed (Output 14.7.2).

Output 14.7.2 Efficiency Factors for $v = b = 7, k = 3$ Optimal Blocking Designs

The OPTEX Procedure			
Design Number	Treatment D-Efficiency	Treatment A-Efficiency	Block Design D-Efficiency
1	77.7778	77.7778	100.0000
2	77.7778	77.7778	100.0000
3	77.7778	77.7778	100.0000
4	77.7778	77.7778	100.0000
5	77.7778	77.7778	100.0000
6	77.7778	77.7778	100.0000
7	77.7778	77.7778	100.0000
8	77.7778	77.7778	100.0000
9	77.7778	77.7778	100.0000
10	77.7778	77.7778	100.0000

The 100% efficiency in the fourth column of the output shows that the balanced design was found on all 10 tries.

Since the OPTEX procedure is interactive, you can save the final design in a data set by submitting the OUTPUT statement immediately after the preceding statements. The following statements use the BLOCKNAME= option to rename the block variable:

```

output out=BIBD blockname=Block;
proc print data=BIBD;
run;

```

The final design is shown in Output 14.7.3.

Output 14.7.3 Balanced Incomplete Block Design for $v = b = 7, k = 3$

Obs	BLOCK	Treatment
1	1	1
2	1	4
3	1	7
4	2	6
5	2	3
6	2	1
7	3	2
8	3	5
9	3	1
10	4	6
11	4	2
12	4	7
13	5	5
14	5	4
15	5	6
16	6	5
17	6	7
18	6	3
19	7	4
20	7	3
21	7	2

Although there is no guarantee that the OPTEX procedure will find the globally optimal block design by this method, it usually does find small to medium-sized balanced designs, and it always finds a very efficient design. For example, for the designs given in Table 9.5 of Cochran and Cox (1957), the OPTEX procedure consistently finds the theoretically optimal BIBD in all cases with 10 or fewer treatments. Furthermore, in no case is the D-efficiency relative to the balanced design less than 99%.

Example 14.8: Optimal Design with Fixed Covariates

In addition to finding optimal block designs, you can use the BLOCKS statement to find designs that are optimal with respect to more general covariate models. You can specify the data set containing the covariates with the DESIGN= option in the BLOCKS statement. Covariate models are specified in the same way as the treatment model.

See OPTEX9 in the SAS/QC Sample Library

The following example is based on an example in Harville (1974). Suppose you want a design for five qualitative treatments in 10 runs. The value of a covariate thought to be related to the response has been recorded for each of the experimental units. For instance, if the treatments are different types of animal feed, a typical covariate might be the initial weight of each animal. In the following, the data sets Cov and Treatment are created, containing the covariate values and the candidate treatment levels, respectively. Then the OPTEX procedure is invoked with a simple one-way model for the treatment effect and a quadratic model for the covariate effect.

```

data Cov;
  input u @@;
  datalines;
0.46 0.54 0.58 0.60 0.73 0.77 0.82 0.84 0.89 0.95
;
data Treatment;
  do t = 1 to 5; output; end;
run;
proc optex data=Treatment seed=17364 coding=orthcan;
  class t;
  model t;
  blocks design=Cov;
  model u u*u;
  output out=Design;
run;

proc print data=Design;
run;

```

In this case, the CODING=ORTHCAN option in the PROC OPTEX statement has the same effect as CODING=ORTH, which is to produce orthogonal coding with respect to the candidates. Note that

- the CLASS and MODEL statements that define the treatment model precede the BLOCKS statement
- the MODEL statement that defines the covariate model follows the BLOCKS statement

As a general rule, CLASS and MODEL statements that come before a BLOCKS statement are interpreted as applying to the treatment model, while CLASS and MODEL statements that come after a BLOCKS statement involving the DESIGN= blocks specification are interpreted as applying to the covariate model.

The listing of the efficiency values for the 10 designs found is shown in [Output 14.8.1](#). Note that the efficiencies are the same for all tries. A listing of the design is shown in [Output 14.8.2](#).

Output 14.8.1 Optimal Treatment Efficiency Factors with a Quadratic Covariate Effect

The OPTEX Procedure		
Design Number	Treatment D-Efficiency	Treatment A-Efficiency
1	91.6621	91.1336
2	91.6621	91.1336
3	91.6621	91.1336

6	91.6621	91.1336
7	91.6621	91.1336
8	91.6621	91.1336
9	91.6621	91.1336
10	91.6621	91.1336

Output 14.8.2 Optimal Design with a Quadratic Covariate Effect

Obs	u	t
1	0.46	4
2	0.54	3
3	0.58	1
4	0.60	2
5	0.73	5
6	0.77	4
7	0.82	3
8	0.84	1
9	0.89	2
10	0.95	5

When you use the BLOCKS statement without specifying the GENERATE statement, the full candidate set is used as the treatment set for optimal blocking. If you specify both statements, an optimal design for the treatments ignoring the blocks is first generated, and the result is used as the treatment set for optimal blocking. This enables several options to be combined to evaluate existing designs. For example, the following statements evaluate the optimal design given in Harville (1974) for the preceding situation:

```

data Harville;
  input t @@;
  datalines;
1 2 3 4 5 1 2 3 4 5
;
proc optex data=Treatment coding=orthcan;
  class t;
  model t;
  generate initdesign=Harville method=sequential;
  blocks design=Cov init=chain iter=0;
  model u u*u;
run;

```

The efficiency values for Harville’s design are shown in [Output 14.8.3](#). They are the same as for the design found by the OPTEX procedure.

Output 14.8.3 Treatment Efficiency Factors for Harville’s Design

The OPTEX Procedure		
Design Number	Treatment D-Efficiency	Treatment A-Efficiency
1	91.6621	91.1336

In fact, the optimal design found by OPTEX can be derived from Harville’s design simply by relabeling treatments. In order of increasing U, both designs consist of two consecutive replicates of the treatments, with treatments in both replicates occurring in the same order.

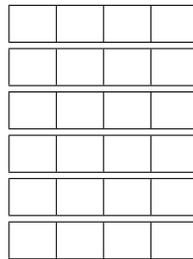

Example 14.9: Optimal Design in the Presence of Covariance

See OPTEX10 in the SAS/QC Sample Library

The BLOCKS statement finds a design that maximizes the determinant $|X'AX|$ of the treatment information matrix, where A depends on the block or covariate model. Alternatively, you can directly specify the matrix A to find the D-optimal design when A is the variance-covariance matrix for the runs. You can specify the data set containing the covariance matrix with the COVAR= option in the BLOCKS statement, listing the variables corresponding to the columns of the covariance matrix in the VAR= option. If you specify n variables in the VAR= option, the values of these variables in the first n observations in the data set will be used to define A .

For example, suppose you want to compare the effects of seven different fertilizers on crop yield, by using seven long, narrow blocks of four plots each, as depicted in Figure 14.6.

Figure 14.6 Block Structure for Neighbor Balance

In this case, it is reasonable to conjecture that closer plots within each block are more correlated. In particular, suppose that the plots are *autocorrelated*, so that the correlation matrix for the four plots in each block is of the form

$$R = \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$$

where $-1 \leq \rho \leq 1$. If there is also an overall fixed effect due to blocks, the information matrix for the effect of fertilizer has the form $X'AX$, where

$$A = \left(V^{-1} - V^{-1}Z(Z'V^{-1}Z)^{-1}Z'V^{-1} \right)^{-}$$

In this formula, V is the block diagonal matrix of the plot-by-plot correlation structure, with seven copies of R_4 on the diagonal. The matrix Z is the design matrix corresponding to the block effect. The optimal design should take into account this neighbor covariance structure as well as the block structure.

The following code uses the SAS/IML matrix language to construct A by using $\rho = 0.1$ and saves it in a data set named `a`:

```

proc iml;
  Blocks = int(((1:28)^-1)/4) + 1;
  z = j(28,1) || designf(Blocks);
  r = toeplitz(0.1**(0:3));
  v = r;
  do i = 2 to 7; v = block(v,r); end;
  iv = inv(v);
  a = ginv(iv-iv*z*inv(z`*iv*z)*z`*iv);
  create A from a;
  append from a;
quit;

```

Note that the data set is created with variables named COL1, COL2 . . . , COL28, by default.

To find an allocation of fertilizers to plots that is optimal for detecting the fertilizer effect in the presence of this autocorrelation, simply specify a one-way model for the treatment effects and specify the data set A as the covariance matrix for the runs with the COVAR= option in the BLOCKS statement, as follows:

```

data Fertilizer;
  do f = 1 to 7; output; end;
run;
proc optex data=Fertilizer seed=56672 coding=orth;
  class f;
  model f;
  blocks covar=A var=(COL1-COL28);
  output out=NBD;
run;

```

The SAS/IML matrix language also provides a convenient way of listing the design.

```

proc iml;
  use NBD;
  read all var {f};
  NBD = shape(f,7,4);
  print NBD [format=2.];

```

These IML statements read in the selected levels of fertilizer and the reshape them into seven 4-run blocks before printing them. The resulting design is shown in [Output 14.9.1](#). Note that it is not only a balanced incomplete block design, but it is also balanced for first neighbors; that is, every pair of treatments occur equally often on horizontally adjacent plots.

Output 14.9.1 Neighbor-Balanced BIBD for $v = b = 7$, $k = 4$, Found by Optimal Blocking

NBD			
7	2	1	5
6	1	7	3
4	7	6	2
1	4	6	5
6	3	5	2
1	3	2	4
7	5	4	3

Example 14.10: Adding Space-Filling Points to a Design

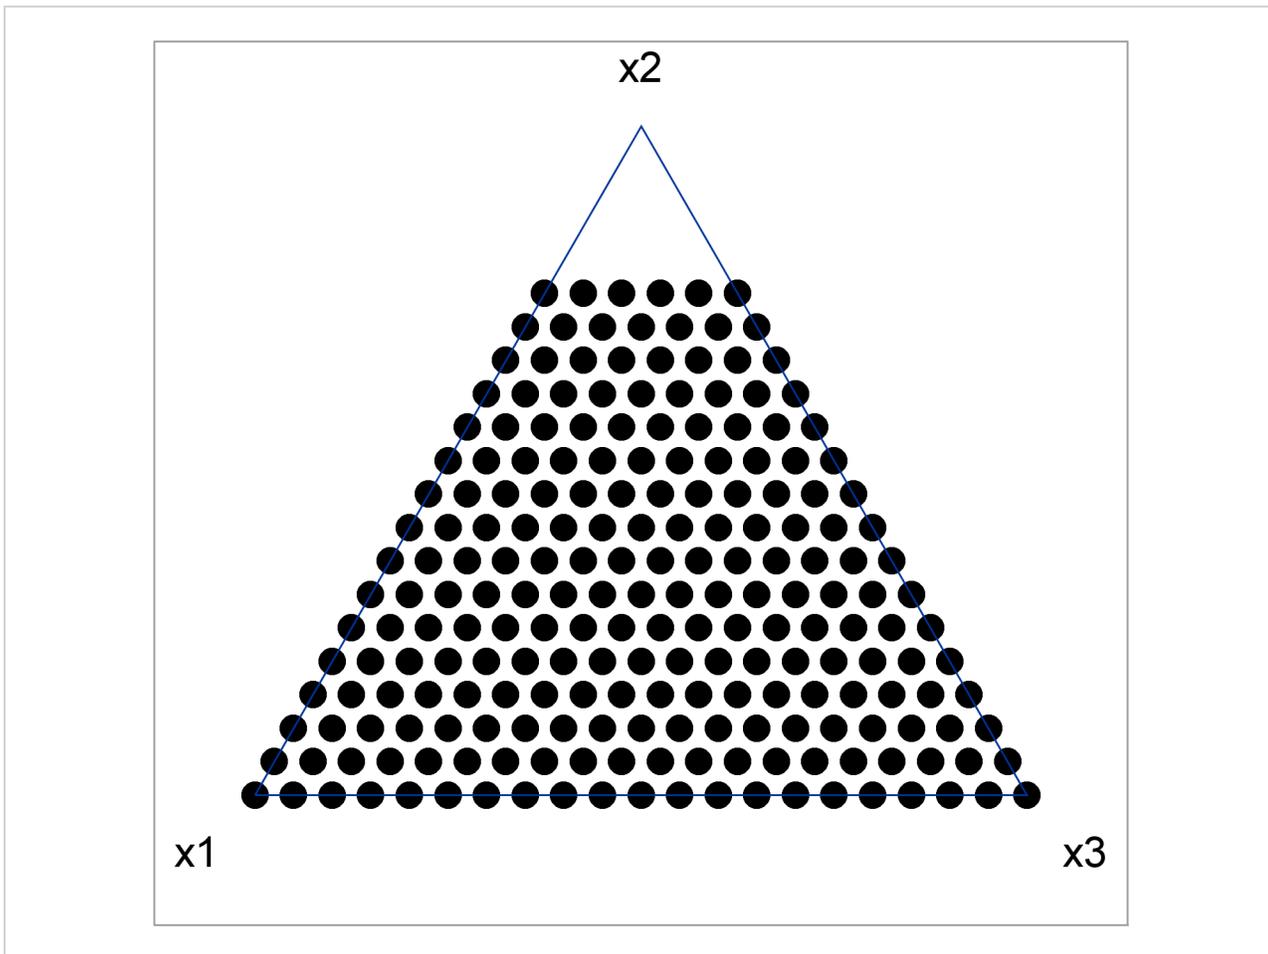

See OPTEX11 in the SAS/QC Sample Library

Suppose you want a 15-run experiment for three mixture factors x_1 , x_2 , and x_3 ; furthermore, suppose that x_3 cannot account for any more than 75% of the mixture. The vertices and generalized edge centroids of the region defined by these constraints make up a good candidate set to use with the OPTEX procedure for finding a D-optimal design for such an experiment. However, information-based criteria such as D- and A-efficiency tend to push the design to the edges of the candidate space, leaving large portions of the interior relatively uncovered. For this reason, it is often a good idea to augment a D-optimal design with some points chosen according to U-optimality, which seeks to cover the candidate region as well as possible.

The following statements create a candidate data set containing 216 points in the region defined by the given constraints $x_1 + x_2 + x_3 = 1$ and $x_3 \leq 0.75$ on the factors:

```
data a;
  do x1 = 0 to 100 by 5;
    do x3 = 0 to 100 by 5;
      x2 = 100 - x1 - x3;
      if (0 <= x2 <= 75) then output;
    end;
  end;
run;
data a; set a;
  x1 = x1 / 100;
  x2 = x2 / 100;
  x3 = x3 / 100;
run;
```

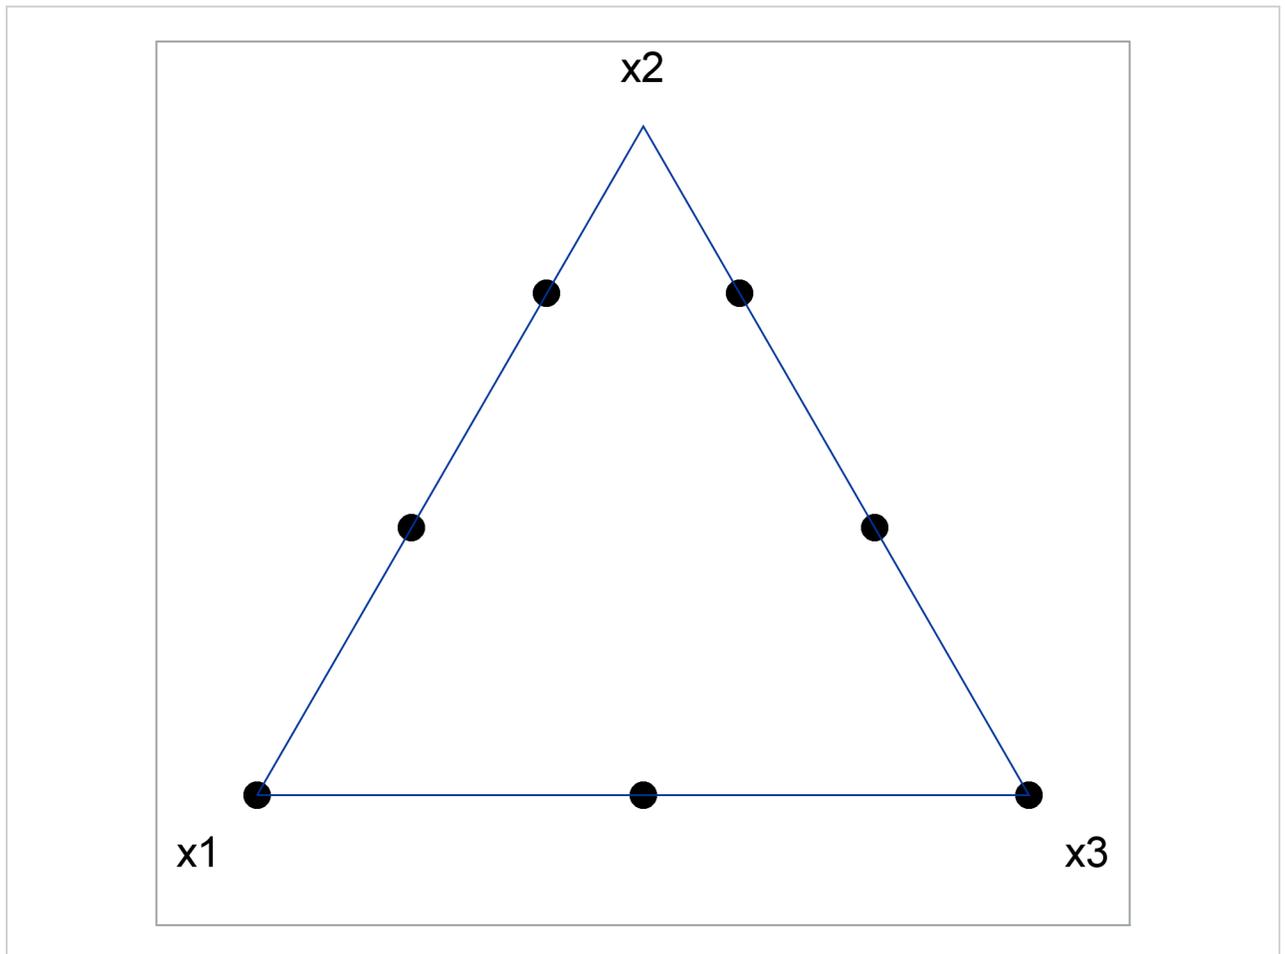

The constraint that the factor levels sum to 1 means that the candidate points all lie on a plane. Thus, the values of all three variables can be displayed in a two-dimensional “mixture plot,” as shown in Output 14.10.1.

Output 14.10.1 Points in the Feasible Region for Constrained Mixture Design

You can use the OPTEX procedure to select 10 points from the mentioned candidate points optimal for estimating a second-order model in the mixture factors.

```
proc optex data=a seed=60868 nocode;
  model x1|x2|x3@2 / noint;
  generate n=10;
  output out=b;
run;
```

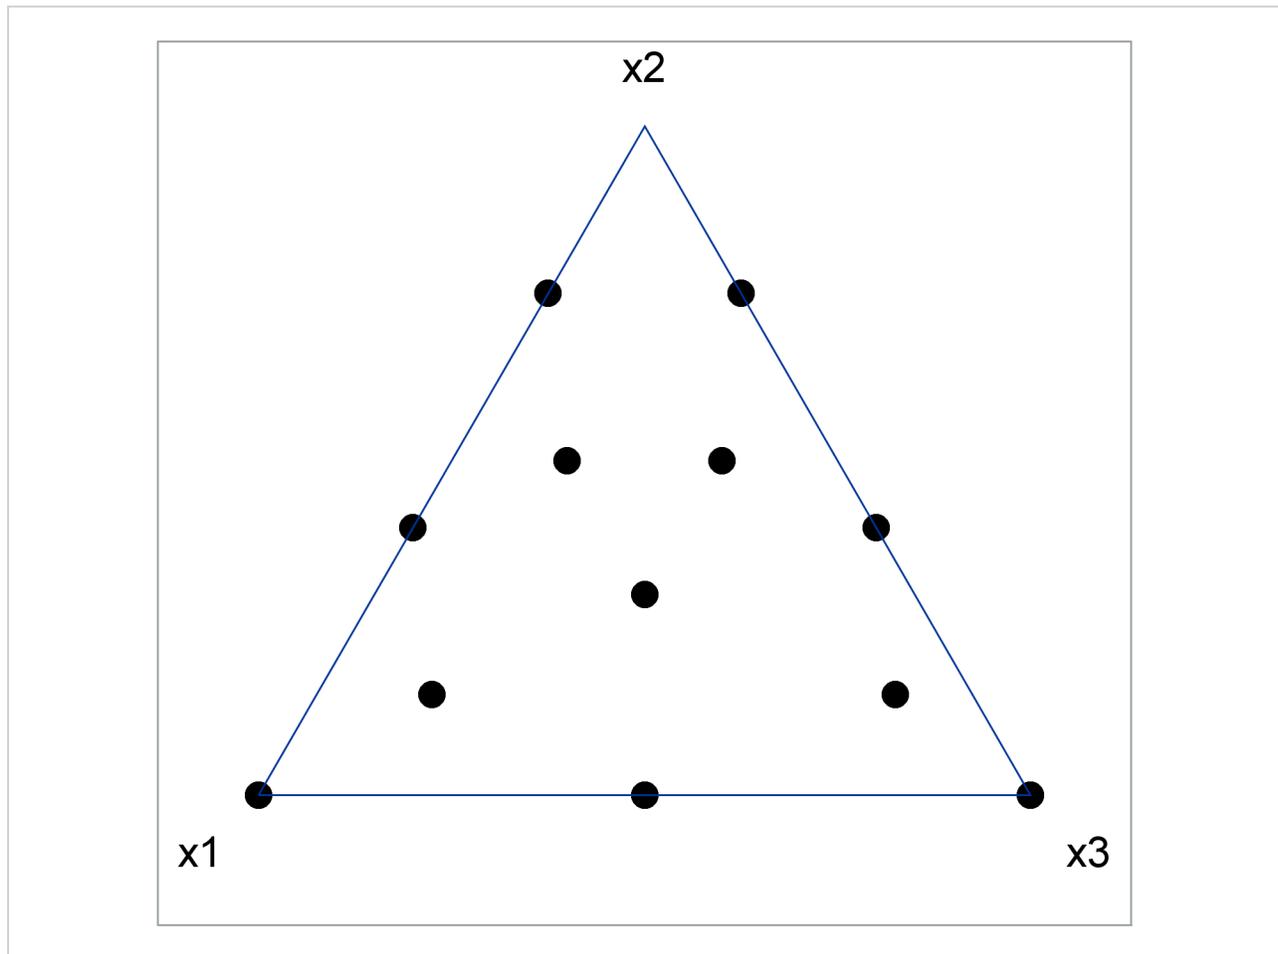

The resulting points are plotted in [Output 14.10.2](#). There are only seven unique points, indicating that the D-optimal design replicates some chosen candidate points.

Output 14.10.2 D-optimal Constrained Mixture Design

The D-optimal design leaves a large “hole” in the feasible region. The following statements “fill in the hole” in the optimal design saved in B by augmenting it with points chosen from the candidate data set a to optimize the U-criterion:

```
proc optex data=a seed=4321 nocode;
  model x1 x2 x3 / noint;
  generate n=15 augment=b criterion=u;
  output out=c;
run;
```

The resulting points are shown in [Output 14.10.3](#). The U-optimal design fills in the candidate region in much the same way that you might construct the design by visually assigning points. That is, the general approach that uses the OPTeX procedure agrees with visual intuition for this small problem. This indicates that the general approach will yield an appropriate design for higher-dimensional problems that cannot be visualized.

Output 14.10.3 D-optimal Constrained Mixture Design Filled in U-optimally

Data Details

Input Data Sets

This section discusses the five input data sets for the OPTEX procedure. Three of the data sets provide points used to generate the design according to the effects you specify in the MODEL statement. Two other data sets provide points used to generate a model for fixed covariates.

Only the DATA= data set is required. If you do not specify a DATA= data set in the PROC OPTEX statement, the procedure uses the last data set created as a set of candidate points for the design. The AUGMENT= data set is optional and contains points that are guaranteed to be included in the final design. The INITDESIGN= data set is also optional and provides an initial design to be used by a search procedure. Variables listed in the MODEL statement must be present in all three of these data sets, and the variable characteristics (type and length) must match across data sets.

Figure 14.7 is a schematic diagram of the roles of the DATA=, AUGMENT=, and INITDESIGN= data sets in constructing the design. Figure 14.8 presents the role of the DESIGN= data set for block designs.

Figure 14.7 Choosing from DATA= Points

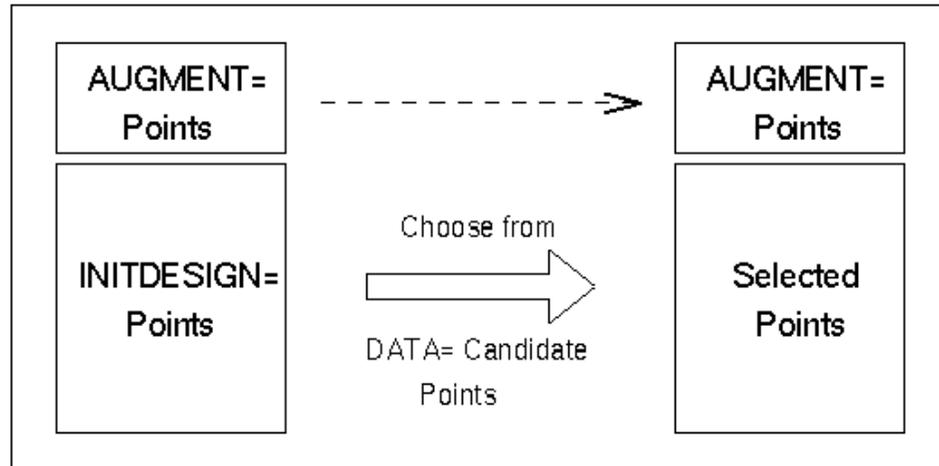

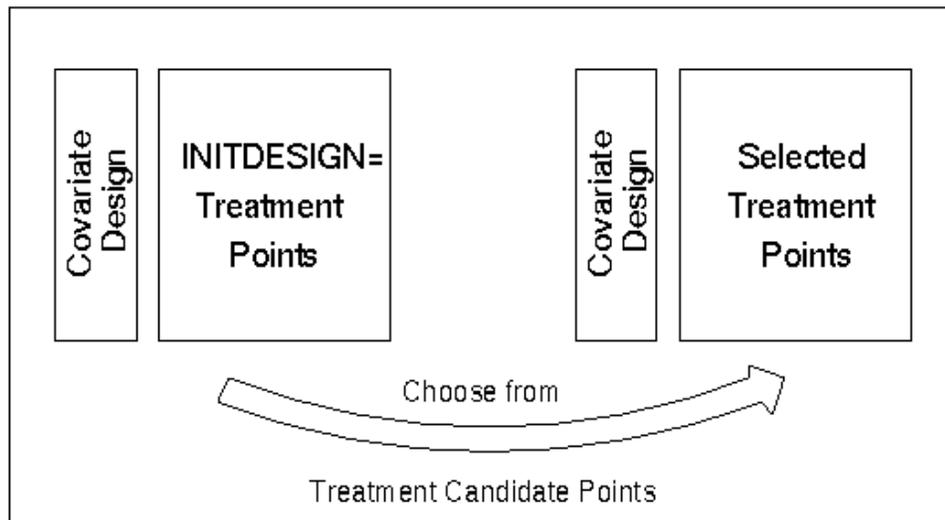

Figure 14.8 Choosing Treatment Candidates

DATA= Data Set

The DATA= data set provides a set of candidate points used to create a design. The OPTEX procedure uses the variables listed in the MODEL statement when creating a design.

The effects specified in a MODEL statement determine the variables used when generating a design. For example, if the DATA= data set contains the variables A, B, and C, but the MODEL statement specifies effects involving only A and B, then the variable C is not considered when generating designs.

Variables in the DATA= data set that are listed in the ID statement are transferred to the OUT= data set (if one is created).

AUGMENT= Data Set

The AUGMENT= data set provides a set of points that must be included in the final design. The OPTEX procedure adds candidate points from the DATA= data set to the points from the AUGMENT= data set when generating designs. The number of points in the AUGMENT= data set must be less than or equal to the number of points for the design (either the default or the number specified with the N= option in the GENERATE statement).

As with the DATA= data set, the effects specified in a MODEL statement determine the variables used when generating a design. The types and lengths of variables in an AUGMENT= data set that are used in the MODEL and ID statements must match the types and lengths of the same variables in the DATA= data set. If you use an ID statement and the AUGMENT= data set contains the ID variables, these variables are transferred to the OUT= data set (if one is created). See the section “Including Specific Runs” on page 1023 for an example that uses an AUGMENT= data set.

INITDESIGN= Data Set

The INITDESIGN= data set provides a set of points that are used as an initial design in the search for an optimal design. These points are not necessarily contained in the final design. The OPTEX procedure uses these points to begin the search for an optimal design. The number of points in the INITDESIGN= data set must be the same as the number of points in the design (either the default or the number specified with the N= option in the GENERATE statement).

As with the DATA= data set, the effects specified in a MODEL statement determine the variables used when generating a design. The types and lengths of variables in an INITDESIGN= data set that are used in the MODEL and ID statements must match the types and lengths of the same variables in the DATA= data set. If you use an ID statement and the INITDESIGN= data set contains the ID variables, these variables are transferred to the OUT= data set (if one is created). See [Example 14.3](#) for an example that uses an INITDESIGN= data set.

If you use an INITDESIGN= data set and also specify METHOD=SEQUENTIAL in the GENERATE statement, no search is performed (you do not have to specify ITER=0 in this case). The INITDESIGN= data set is the final design. In this way, you can use the OPTEX procedure to evaluate an existing design.

BLOCKS DESIGN= Data Set

The DESIGN= data set in the BLOCKS statement contains a set of points that are used to generate a model for fixed covariates. These points are contained in the final design and are transferred to the OUT= data set (if one is created). See [Example 14.8](#) for an example that uses a BLOCKS DESIGN= data set.

BLOCKS COVAR= Data Set

If you specify a COVAR= data set in the BLOCKS statement, the observations for the variables listed in the VAR= option are used to define the assumed variance-covariance matrix for the experimental runs. These observations are *not* transferred to the OUT= data set (if one is created). Note that since covariance matrices are necessarily square, the number of observations in the COVAR= data set must be the same as the number of variables listed in the VAR= option. See [Example 14.9](#) for an example that uses a BLOCKS COVAR= data set.

Output Data Sets

You typically use the OPTEX procedure to create an output data set that contains the design for your experiment. If you use an OUTPUT statement, the variables in the output data set are the factors of the design as well as any ID variables. The values for the ID variables are taken from the input data set (the DATA=, AUGMENT=, or INITDESIGN= data set) that provided the design point. ID variables must be contained in the DATA= data set and can also be contained in the AUGMENT= or INITDESIGN= data set. If an AUGMENT= or INITDESIGN= data set does not contain the ID variables, and points from the data set are used in the final design, values of ID variables for those points are missing.

Since the input data sets provide candidate points for the design, all the observations in the OUT= data set originate in one of the input data sets. The OPTEX procedure does not change the values of variables in the input data sets.

Since you can use multiple OUTPUT statements with the OPTEX procedure, you can create multiple OUT= data sets in a given run of the procedure.

Computational Details

Specifying Effects in MODEL Statements

This section discusses how to specify the linear model that you plan to fit with the design. The OPTEX procedure provides for the same general linear models as the GLM procedure, although it does not use the GLM procedure's *over-parameterized* technique for generating the design matrix (see the section "Static Coding" on page 1076.)

Each term in a model, called an *effect*, is a variable or combination of variables. To specify effects, you use a special notation involving variables and operators. There are two kinds of variables: *classification variables* and *continuous variables*. *Classification variables* separate observations into groups, and the model depends on them through these groups; on the other hand, the model depends on the actual (or coded) values of *continuous variables*. There are two primary operators: *crossing* and *nesting*. A third operator, the *bar operator*, simplifies the specification for multiple crossed terms, as in a factorial model. The @ operator, used in combination with the bar operator, further simplifies specification of crossed terms.

When specifying a model, you must list the classification variables in a CLASS statement. Any variables in the model that are not listed in the CLASS statement are assumed to be continuous. Continuous variables must be numeric.

Types of Effects

Five types of effects can be specified in the MODEL statement. Each row of the design matrix is generated by combining values for the independent variables according to effects specified in the MODEL statement. This section discusses how to specify different types of effects and explains how they relate to the columns of the design matrix. In the following, assume that A, B, and C are classification variables and X1, X2, and X3 are continuous variables.

Regressor Effects

Regressor effects are specified by writing continuous variables by themselves.

X1 X2 X3

For regressor effects, the actual values of the variable are used in the design matrix.

Polynomial Effects

Polynomial effects are specified by joining two or more continuous variables with asterisks.

X1*X1 X1*X1*X1 X1*X2 X1*X2*X3 X1*X1*X2

Polynomial effects are also referred to as interactions or crossproducts of continuous variables. When a variable is joined with itself, polynomial effects are referred to as quadratic effects, cubic effects, and so on. In the preceding examples, the first two effects are the quadratic and cubic effects for X1, respectively. The remaining effects are crossproducts.

For polynomial effects, the value used in the design matrix is the product of the values of the constituent variables.

Main Effects

If a classification variable A has k levels, then its main effect has $k - 1$ degrees of freedom, corresponding to $k - 1$ independent differences between the mean response at different levels. Main effects are specified by writing classification variables by themselves.

A B C

Most designs involve main effects since these correspond to the factors in your experiment. For example, in a factorial experiment for a chemical process, the main effects can be metal type, temperature, pressure, and the level of a catalyst.

For information on how the OPTEX procedure generates the $k - 1$ columns in the design matrix corresponding to the main effect of a classification variable, see the section “[Design Coding](#)” on page 1075.

Crossed Effects

Crossed effects (or interactions) are specified by joining class variables with asterisks.

A*B B*C A*B*C

The number of degrees of freedom for a crossed effect is the product of the numbers of degrees of freedom for the constituent main effects. The columns in the design matrix corresponding to a crossed effect are formed by the horizontal direct products of the constituent main effects.

Continuous-by-Class Effects

Continuous-by-class effects are specified by joining continuous variables and classification variables with asterisks.

X1*A

The design columns for a continuous-by-class effect are constructed by multiplying the values in the design columns for the continuous variables and the classification variable.

Note that all design matrices start with a column of ones for the assumed intercept term unless you use the NOINT option in the MODEL statement.

Bar and @ Operators

You can shorten the specification of a factorial model by using the bar operator. For example, the following statements show two ways of specifying a full three-way factorial model:

```
model a b c a*b a*c b*c a*b*c;
model a|b|c;
```

When the vertical bar (|) is used, the right- and left-hand sides become effects, and their cross becomes an effect. Multiple bars are permitted. The expressions are expanded from left to right by using rules given by Searle (1971). For example, **A|B|C** is evaluated as follows:

$$\begin{aligned} A | B | C &\rightarrow \{ A | B \} | C \\ &\rightarrow \{ A B A*B \} | C \\ &\rightarrow A B A*B C A*C B*C A*B*C \end{aligned}$$

The bar operator does not cross a variable with itself. To produce a quadratic term, you must specify it directly.

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by putting it at the end of a bar effect, preceded by an @ sign. For example, the specification **A|B|C@2** results in only those effects that contain two or fewer variables (in this case A, B, A*B, C, A*C, and B*C).

Examples of Models

Main Effects Model For a three-factor main effects model with A, B, and C as the factors, the MODEL statement is

```
model a b c;
```

Factorial Model with Interactions To specify interactions in a factorial model, join effects with asterisks, as described previously. For example, the following statements show two ways of specifying a complete factorial model, which includes all the interactions:

```
model a b c a*b a*c b*c a*b*c;
model a|b|c;
```

Quadratic Model The following statements show two ways of specifying a model with crossed and quadratic effects (for a central composite design, for example):

```
model x1 x2 x1*x2 x3 x1*x3 x2*x3
      x1*x1 x2*x2 x3*x3;
model x1|x2|x3@2 x1*x1 x2*x2 x3*x3;
```

Design Efficiency Measures

The output from the OPTeX procedure includes efficiency measures for the resulting designs according to various criteria. This section gives the precise definitions for these measures.

By default, the OPTTEX procedure calculates the following efficiency measures for each design found in its search for an optimum design:

$$\begin{aligned} \text{D-efficiency} &= 100 \times \left(\frac{|X'X|^{1/p}}{N_D} \right) \\ \text{A-efficiency} &= 100 \times \left(\frac{p/N_D}{\text{trace}(X'X)^{-1}} \right) \\ \text{G-efficiency} &= 100 \times \left(\sqrt{\frac{p/N_D}{\max_{\mathbf{x} \in \mathcal{C}} \mathbf{x}'(X'X)^{-1}\mathbf{x}}} \right) \end{aligned}$$

where p is the number of parameters in the linear model, N_D is the number of design points, and \mathcal{C} is the set of candidate points. The D- and A-efficiencies are the relative number of runs (expressed as percents) required by a hypothetical orthogonal design to achieve the same $|X'X|$ and $\text{trace}(X'X)^{-1}$, respectively; refer to Mitchell (1974b).

When you specify a BLOCKS statement, the D- and A-efficiencies for the treatment part of the model are calculated. These are calculated similarly to the preceding efficiencies, except that they are based on the information matrix after correcting for block/covariate effect(s). This matrix can be written as $X'A^{-1}X$ for a symmetric, positive definite matrix A that depends on the model for the block/covariate effect(s). If you specify a block structure or a covariate model, then $A = A^{-1} = I - Z(Z'Z)^{-1}Z'$, where Z is the design matrix for the block/covariate effect(s). Alternatively, you can use the COVAR= option to specify the matrix A directly. Given A , the efficiencies in the presence of covariates are defined as follows:

$$\begin{aligned} \text{D-efficiency} &= 100 \times c_D^{-1} \cdot |X'A^{-1}X|^{1/p}/N, & c_D &= \prod_{i=1}^p \lambda_i^{1/p} \\ \text{A-efficiency} &= 100 \times c_A^{-1} \cdot (p/N)/\text{trace}(X'A^{-1}X)^{-1}, & c_A &= \sum_{i=1}^p \lambda_i/p \end{aligned}$$

where $\lambda_1, \dots, \lambda_p$ are the p largest eigenvalues of A^{-1} . If you use the STRUCTURE= block model specification and there is only one classification variable in the treatment model, then the design fits into the traditional block design framework. In this case, the D-efficiency relative to a balanced incomplete block design is also listed.

Because these efficiencies measure the goodness of the design relative to theoretical designs that might be far from possible in many cases, they are typically not useful as absolute measures of design goodness. Instead, efficiency measures should be used relatively, to compare one design to another for the same situation.

For the distance-based criteria, there are no simple measures of design efficiency that can be scaled from 0 to 100. See the section “Output” on page 1085 for a definition of the design measures tabulated for these criteria.

Design Coding

The way the independent effects of the model are interpreted to generate a linear model is called *coding*. The OPTTEX procedure provides for different types of coding. For D-optimality, the type of coding affects only the absolute value of the computed efficiency criteria, not the relative values for two different designs. Thus, different codings do not affect the choice of D-optimal design. In this section, the details and ramifications of the different types of coding are discussed.

Coding the points in a design involves selecting linearly independent columns corresponding to each model term, turning particular values of the factors into a row vector \mathbf{x} . The OPTeX procedure requires a *nonsingular* coding for the design matrix. Because of this, any two coding schemes are related by a nonsingular transformation.

Static Coding

The default coding for the design points is as follows:

- Unless you specify CODING=NONE (or NOCODE) in the PROC OPTeX statement, continuous variables are centered and scaled so that their maximum and minimum values are 1 and -1 , respectively.
- The $k - 1$ columns corresponding to the main effect of a classification variable A are computed as follows: For a design point with A at its i th level, for $1 \leq i \leq k - 1$, the columns of the design matrix associated with A are all 0 except for the i th column, which is 1. When A is at its k th level, all $k - 1$ columns associated with A are -1 . Thus, if α_i denotes the expected response at the i th level of A, the $k - 1$ columns yield estimates of $\alpha_1 - \alpha_k, \alpha_2 - \alpha_k, \dots, \alpha_{k-1} - \alpha_k$.
- Columns for crossed effects are computed by taking the horizontal direct product of columns corresponding to the constituent effects.

This coding corresponds to modeling without *over-parameterization*, by using the same method as the CATMOD procedure in SAS/STAT[®] software. This is different from the method used by the GLM procedure, which uses an over-parameterized model.

Orthogonal Coding

If you specify CODING=ORTH or CODING=ORTHCAN, the points are first coded as described in the previous section and then recoded so that $X'_C X_C = N_C \cdot I$, where X_C is the design matrix for the candidate points, N_C is the number of candidates, and I is the identity matrix. This is required in order for the D- and A-efficiency measures to make sense. For the option CODING=ORTHCAN, this recoding is accomplished by computing a square matrix R such that $X'_C X_C = R'R$ and then transforming each row vector \mathbf{x} as

$$\mathbf{x} \rightarrow \mathbf{x}R^{-1}\sqrt{N_C}$$

If you specify CODING=ORTH, the recoding is done in a similar fashion, except that the matrix R is computed according to $X'_C X_C + X'_A X_A + X'_I X_I = R'R$, where X_A and X_I are the design matrices for the AUGMENT= and INITDESIGN= data sets, respectively (coded as described in the previous section.) Thus, these two orthogonal coding options only differ when there is an AUGMENT= or an INITDESIGN= data set (see page 1040–page 1041); the option CODING=ORTH includes points from these data sets in computing the orthogonal coding, while the option CODING=ORTHCAN uses only the candidates themselves.

Example of Coding

For example, consider a main effect model with one continuous variable X and one three-level classification variable A. The results of the various coding options are shown in Table 14.7.

Table 14.7 Different Types of Design Coding

Original Data		Design Matrix With CODING=NONE				Design Matrix With CODING=STATIC				Design Matrix With CODING=ORTH			
X	A	X	A1	A2	X	A1	A2	X	A1	A2	X	A1	A2
1	1	1	1	1	0	1	-1	1	0	1	-1.464	0.598	-0.707
2	2	1	2	0	1	1	-0.6	0	1	1	-0.878	-0.478	1.414
3	3	1	3	-1	-1	1	-0.2	-1	-1	1	-0.293	-1.554	-0.707
4	1	1	4	1	0	1	0.2	1	0	1	0.293	1.554	-0.707
5	2	1	5	0	1	1	0.6	0	1	1	0.878	0.478	1.414
6	3	1	6	-1	-1	1	1	-1	-1	1	1.464	-0.598	-0.707

The first column in each design matrix is an all-ones vector corresponding to the intercept, the next column corresponds to the linear effect of X, and the last two columns correspond to the two degrees of freedom for the main effect of A.

General Recommendations

Coding does not affect the relative ordering of designs by D-efficiency, and the same is true for G-efficiency and the average standard error of prediction. This is easy to see for the latter two measures, which are based on the variance of prediction, since how accurately a point is predicted should not be affected by how the independent variables are coded. For D-optimality, note again that coding corresponds to multiplying the design matrix on the right by some nonsingular transformation A, which changes the determinant of the information matrix as follows:

$$|X'X| \rightarrow |A'X'XA| = |A'A||X'X| = |A|^2|X'X|$$

Thus, recoding simply multiplies the D-criterion by a constant that is the same for all designs. Note, however, that A-optimality is *not* invariant to coding.

Orthogonal coding will usually be the right one; it is not the default because it depends on the candidate set. Note, however, that for the distance-based criteria, if the distance between two points should be computed in terms of the actual values of the model variables instead of centered and scaled values, then you should specify CODING=NONE or NOCODE. The NOCODE option can also be useful when the NOINT option is specified.

Optimality Criteria

An optimality criterion is a single number that summarizes how good a design is, and it is maximized or minimized by an optimal design. This section discusses in detail the optimality criteria available in the OPTTEX procedure.

Types of Criteria

Two general types of criteria are available: *information-based* criteria and *distance-based* criteria.

The information-based criteria that are directly available are D- and A-optimality; they are both related to the information matrix $X'X$ for the design. This matrix is important because it is proportional to the inverse of the variance-covariance matrix for the least squares estimates of the linear parameters of the model. Roughly, a good design should “minimize” the variance $(X'X)^{-1}$, which

is the same as “maximizing” the information $X'X$. D- and A-efficiency are different ways of saying how large $(X'X)$ or $(X'X)^{-1}$ are.

For the distance-based criteria, the candidates are viewed as comprising a point cloud in p -dimensional Euclidean space, where p is the number of terms in the model. The goal is to choose a subset of this cloud that “covers” the whole cloud as uniformly as possible (in the case of U-optimality) or that is as broadly “spread” as possible (in the case of S-optimality). These ideas of coverage and spread are defined in detail in the section “Distance-Based Criteria” on page 1079. The distance-based criteria thus correspond to the intuitive idea of filling the candidate space as well as possible.

The rest of this section discusses different optimality criterion in detail.

D-optimality

D-optimality is based on the determinant of the information matrix for the design, which is the same as the reciprocal of the determinant of the variance-covariance matrix for the least squares estimates of the linear parameters of the model.

$$|X'X| = 1/|(X'X)^{-1}|$$

The determinant is thus a general measure of the size of $(X'X)^{-1}$. D-optimality is the most commonly used criterion for generating optimal designs. This explains why it is the default criterion for the OPTeX procedure.

The D-optimality criterion has the following characteristics:

- D-optimality is the most computationally efficient criterion to optimize for the low-rank update algorithms of the OPTeX procedure, since each update depends only on the variance of prediction for the current design; see the section “Useful Matrix Formulas” on page 1081.
- $|X'X|$ is inversely proportional to the size of a $100(1 - \alpha)\%$ confidence ellipsoid for the least squares estimates of the linear parameters of the model.
- $|X'X|^{1/p}$ is equal to the geometric mean of the eigenvalues of $X'X$.
- The D-optimal design is invariant to nonsingular recoding of the design matrix.

$$|X'X| \rightarrow |A'X'XA| = |A'A||X'X| = |A|^2|X'X|$$

A-optimality

A-optimality is based on the sum of the variances of the estimated parameters for the model, which is the same as the sum of the diagonal elements, or trace, of $(X'X)^{-1}$. Like the determinant, the A-optimality criterion is a general measure of the size of $(X'X)^{-1}$. A-optimality is less commonly used than D-optimality as a criterion for computer optimal design. This is partly because it is more computationally difficult to update; see the section “Useful Matrix Formulas” on page 1081. Also, A-optimality is *not* invariant to nonsingular recoding of the design matrix; different designs will be optimal with different codings.

G- and I-optimality

Both G-efficiency and the average prediction variance are well-known criteria for optimal design. Both are based on the variance of prediction of the candidate points, which is proportional to $\mathbf{x}'(X'X)^{-1}\mathbf{x}$. As this formula shows, these two criteria are also related to the information matrix $X'X$. Minimizing the average prediction variance has also been called *I-optimality*, the “I” denoting integration over the candidate space.

It is possible to apply the search techniques available in the OPTTEX procedure to these two criteria, but this turns out to be a poor way to find G- and I-optimal designs. One reason for this is that there are no efficient low-rank update rules (see the section “Useful Matrix Formulas” on page 1081, so that the searches can take a very long time. More seriously, for G-optimality such a search often does not converge on a design with good G-efficiency. G-efficiency is simply too “rough” a criterion to be optimized by the relatively short steps of the search algorithms available in the OPTTEX procedure.

However, the OPTTEX procedure does offer an approach for finding G-efficient designs. Begin by searching for designs according to the default D-optimality criterion. Then, from the various designs found on the different tries, you can save the one that has the best G-efficiency by specifying the NUMBER=GBEST option in the OUTPUT statement. Since D- and G-efficiency are highly correlated over the space of all designs, this method usually results in adequately G-efficient designs, especially when the number of tries is large (see Nguyen and Piepel (2005)). See the ITER= option for details on specifying the number of tries.

To find I-optimal designs, note that if the design is orthogonally coded then I-optimality is equivalent to the A-optimality, since the sum of the prediction variances of all points \mathbf{x} in the candidate space \mathcal{C} is

$$\begin{aligned} \sum_{\mathbf{x} \in \mathcal{C}} \mathbf{x}'(X'X)^{-1}\mathbf{x} &= \sum_{\mathbf{x} \in \mathcal{C}} \text{trace}(\mathbf{x}'(X'X)^{-1}\mathbf{x}) \\ &= \text{trace}\left((X'X)^{-1} \sum_{\mathbf{x} \in \mathcal{C}} \mathbf{x}\mathbf{x}'\right) \\ &= \text{trace}\left((X'X)^{-1} X'_C X_C\right) \\ &= N_C \cdot \text{trace}\left((X'X)^{-1}\right) \end{aligned}$$

where N_C is the number of candidate points and X_C is the design matrix for the candidate points. Thus, you can use the option CODING=ORTH in the PROC OPTTEX statement together with the option CRITERION=A in the GENERATE statement to search for I-optimal designs.

Note that both G- and I-optimality are invariant to nonsingular recoding of the design matrix, since the coding does not affect how well a point is predicted.

Distance-Based Criteria

The distance-based criteria are based on the distance $d(\mathbf{x}, \mathcal{A})$ from a point \mathbf{x} in the p -dimensional Euclidean space \mathcal{R}^p to a set $\mathcal{A} \subset \mathcal{R}^p$. This distance is defined as follows:

$$d(\mathbf{x}, \mathcal{A}) = \min_{\mathbf{y} \in \mathcal{A}} \|\mathbf{x} - \mathbf{y}\|$$

where $\|\mathbf{x} - \mathbf{y}\|$ is the usual p -dimensional Euclidean distance,

$$\|\mathbf{x} - \mathbf{y}\| = \sqrt{(x_1 - y_1)^2 + \dots + (x_p - y_p)^2}$$

U-optimality seeks to minimize the sum of the distances from each candidate point to the design.

$$\sum_{\mathbf{x} \in \mathcal{C}} d(\mathbf{x}, \mathcal{D})$$

where \mathcal{C} is the set of candidate points and \mathcal{D} is the set of design points. You can visualize the U criterion by associating with any design point those candidates to which it is closest. Thus, the design defines a *clustering* of the candidate set, and indeed cluster analysis has been used in this context. Johnson, Moore, and Ylvisaker (1990) consider a similar measure of design efficiency, but over infinite rather than finite candidate spaces. Computationally, the U-optimality criterion can be *very* difficult to optimize, especially if the matrix of all pairwise distances between candidate points does not fit in memory. In this case, the OPTeX procedure recomputes each distance as needed. When searching for a U-optimal design, you should start with a small version of the problem to get an idea of the computing resources required.

S-optimality seeks to maximize the harmonic mean distance from each design point to all the other points in the design.

$$\frac{N_{\mathcal{D}}}{\sum_{\mathbf{y} \in \mathcal{D}} 1/d(\mathbf{y}, \mathcal{D} - \mathbf{y})}$$

For an S-optimal design, the distances $d(\mathbf{y}, \mathcal{D} - \mathbf{y})$ are large, so the points are as spread out as possible. Since the S-optimality criterion depends only on the distances between design points, it is usually computationally easier to compute and optimize than the U-optimality criterion, which depends on the distances between all pairs of candidate points.

Memory and Run-Time Considerations

The OPTeX procedure provides a computationally intensive approach to designing an experiment, and therefore, some finesse is called for to make the most efficient use of computer resources.

The OPTeX procedure must retain the entire set of candidate points in memory. This is necessary because all of the search algorithms access these points repeatedly. If this requires more memory than is available, consider using knowledge of the problem to reduce the set of candidate points. For example, for first- or second-order models, it is usually adequate to restrict the candidates to just the center and the edges of the experimental region or perhaps an even smaller set; see the introductory examples in the sections “[Handling Many Variables](#)” on page 1027 and “[Constructing a Mixture-Process Design](#)” on page 1028.

The distance-based criteria (CRITERION=U and CRITERION=S) also require repeated access to the distance between candidate points. The procedure will try to fit the matrix of these distances in memory; if it cannot, it will recompute them as needed, but this will cause the search to be dramatically slower.

The run time of each search algorithm depends primarily on $N_{\mathcal{D}}$, the size of the target design and on $N_{\mathcal{C}}$, the number of candidate points. For a given model, the run times of the sequential, exchange, and DETMAX algorithms are all roughly proportional to both $N_{\mathcal{D}}$ and $N_{\mathcal{C}}$ (that is,

$O(N_D) + O(N_C)$). The run times for the two simultaneous switching algorithms (FEDOROV and M_FEDOROV) are roughly proportional to the product of N_D and N_C (that is, $O(N_C N_D)$). The constant of proportionality is larger when searching for A-optimal designs because the update formulas are more complicated (see “Search Methods,” which follows).

For problems where either N_D or N_C is large, it is a good idea to make a few test runs with a faster algorithm and a small number of tries before attempting to use one of the slower and more reliable search algorithms. For most problems, the efficiency of a design found by a faster algorithm will be within one or two percent of that for the best possible design, and this is usually sufficient if it appears that searching with a slower algorithm is infeasible.

Search Methods

The search procedures available in the OPTTEX procedure offer various compromises between speed and reliability in finding the optimum. In general, the longer an algorithm takes to arrive at an answer, the more efficient is the resulting design, although this is not invariably true. The right search procedure for any specific case depends on the size of the problem, the relative importance of using the best possible design as opposed to a very good one, and the computing resources available.

Useful Matrix Formulas

All of the search algorithms are based on adding candidate points to a design and deleting them from this design. If $V = (X'X)^{-1}$ is the inverse of the information matrix for the design at any stage, then the change in V that results from adding a point \mathbf{x} to a design (which adds a new row \mathbf{x} to the design matrix) is

$$V \rightarrow V - \frac{V\mathbf{x}\mathbf{x}'V}{1 + \mathbf{x}'V\mathbf{x}}$$

and the change in V that results from deleting the point \mathbf{y} from this design is

$$V \rightarrow V + \frac{V\mathbf{y}\mathbf{y}'V}{1 - \mathbf{y}'V\mathbf{y}}$$

It follows that adding \mathbf{x} multiplies the determinant of the information matrix by $1 + \mathbf{x}'V\mathbf{x}$. Likewise, deleting \mathbf{y} multiplies the determinant by $1 - \mathbf{y}'V\mathbf{y}$. For any point \mathbf{z} , the quantity $\mathbf{z}'V\mathbf{z}$ is proportional to the prediction variance at the point \mathbf{z} . Thus, the point \mathbf{x} whose addition to the design maximizes the determinant of the information is the point whose prediction variance calculated from the present design is largest. The point whose deletion from the design costs the least in terms of the determinant is the point with the smallest prediction variance.

Similar rank-one update formulas can be derived for A-optimality, which is based on the trace of the inverse of the information matrix instead of its determinant. However, in this case there is no single quantity that can be examined for both adding and deleting a point. Here, the trace that results from adding a point \mathbf{x} to a design depends on

$$\frac{\mathbf{x}'V^2\mathbf{x}}{1 + \mathbf{x}'V\mathbf{x}}$$

and the trace that results from deleting a point y to this design depends on

$$\frac{y'V^2y}{1 - y'Vy}$$

This complication makes A-optimal designs harder to search for than D-optimal ones.

There are no useful rank-one update formulas for the distance-based design criteria.

Sequential Search Algorithm

The simplest and fastest algorithm is the sequential search due to Dykstra (1971), which starts with an empty design and adds successive candidate points so that the chosen criterion is optimized at each step. You can use the sequential procedure as a first step in finding a design

- to judge the size of the problem in terms of time and space requirements
- to determine the number of design points needed to estimate the parameters of the model

The sequential algorithm requires no initial design; in fact, it can be used to provide an initial design for the other search procedures (see the `INITDESIGN=` option on page 1041). If you specify a data set for an initial design for this search procedure, no search will be made; in this way, the OPTEx procedure can be used to evaluate an existing design.

Since the sequential search method involves no randomness, it requires only one try to find a design. The sequential procedure is by far the fastest of any of the search methods, but in difficult design situations it is also the least reliable in finding a globally optimal design. Also, the fact that it always finds the same design (due to the lack of randomness mentioned previously) makes it inappropriate when you want to find a design that represents a compromise between several optimality criteria.

Exchange Algorithm

The next fastest algorithm is the simple exchange method of Mitchell and Miller (1970). This technique tries to improve an initial design by adding a candidate point and then deleting one of the design points, stopping when the chosen criterion ceases to improve. This method is relatively fast (though typically much slower than the sequential search) and fairly reliable. `METHOD=EXCHANGE` is the default.

DETMAX Algorithm

The DETMAX algorithm of Mitchell (1974a) is the best-known and most widely used optimal design search algorithm. It generalizes the simple exchange method. Instead of requiring that each addition of a point be followed directly by a deletion, the algorithm provides for *excursions* in which the size of the design might vary between $N_D + k$ and $N_D - k$. Here N_D is the specified size of the design and k is the maximum allowed size for an excursion. By default k is 4, but you can change this (see the `METHOD=DETMAX(level)` option on page 1043). For the precise stopping rules for each excursion and for the entire search, refer to Mitchell (1974a). Due to the mentioned excursions, the DETMAX algorithm might not be a good choice when the design you want to construct is saturated or near-saturated.

Fedorov and Modified Fedorov Algorithms

The three algorithms discussed so far add and delete points one at a time. By contrast, the Fedorov and modified Fedorov algorithms are based on simultaneous switching—that is, adding and deleting points simultaneously. These two algorithms usually find a better design than the others, but because each step involves a search over all possible pairs of candidate and design points, they generally run much slower.

From the equations in “Useful Matrix Formulas” earlier in this chapter (see also Nguyen and Piepel (2005), Section 4) it follows that simultaneously adding a point \mathbf{x} and deleting a point \mathbf{y} multiplies the determinant of the information matrix by $1 + \Delta(\mathbf{x}, \mathbf{y})$, where:

$$\Delta(\mathbf{x}, \mathbf{y}) = \mathbf{x}'\mathbf{V}\mathbf{x} - \mathbf{y}'\mathbf{V}\mathbf{y} + (\mathbf{x}'\mathbf{V}\mathbf{y})^2 - (\mathbf{x}'\mathbf{V}\mathbf{x})(\mathbf{y}'\mathbf{V}\mathbf{y})$$

The quantity $\Delta(\mathbf{x}, \mathbf{y})$ is often referred to as Fedorov’s delta function.

At each step, the Fedorov algorithm (Fedorov 1972) seeks the pair (\mathbf{x}, \mathbf{y}) of one candidate point and one design point that maximizes $\Delta(\mathbf{x}, \mathbf{y})$ and then switches \mathbf{x} for \mathbf{y} in the design. Thus, after computing $\Delta(\mathbf{x}, \mathbf{y})$ for all possible pairs of candidate and design points, the Fedorov algorithm performs only one switch.

The modified Fedorov algorithm of Cook and Nachtsheim (1980) computes the same number of Δ ’s on each step but switches each point \mathbf{y} in the design with the candidate point \mathbf{x} that maximizes $\Delta(\mathbf{x}, \mathbf{y})$. This procedure is generally as reliable as the simple Fedorov algorithm in finding the optimal design, but it can be up to twice as fast.

Johnson and Nachtsheim (1983) introduce a generalization of both the simple exchange algorithm and the modified Fedorov search algorithm of Cook and Nachtsheim (1980), which is described later in this list. In the modified Fedorov algorithm, each of the points in the current design is considered for exchange with a candidate point; in the generalized version, only the k design points with smallest variance in the current design are considered for exchange. You can specify k -exchange as the search procedure for OPTEX by giving a value for k in parentheses after METHOD=EXCHANGE. When $k = N_D$, the size of the design, k -exchange is equivalent to the modified Fedorov algorithm; when $k = 1$, it is equivalent to the simple exchange algorithm. Cook and Nachtsheim (1980) indicate that $k < N_D/4$ is typically sufficient.

For a detailed review of the preceding search methods, see Nguyen and Miller (1992).

Optimal Blocking

Building on the work of Harville (1974), Cook and Nachtsheim (1989) give an algorithm for finding D-optimal designs in the presence of fixed block effects. In this case, the design for the original candidate points is called the *treatment* design. The information matrix for the treatment design has the form $X'AX$ for a certain symmetric, nonnegative-definite matrix A that depends on the blocks. The algorithm is based on two kinds of low-rank changes to the treatment design matrix X : *exchanging* a point in the design with a potential treatment point, and *interchanging* two points in the design. Cook and Nachtsheim (1989) give formulas for computing the resulting change in $X'AX$ and $|X'AX|$. These update formulas can be generalized to apply whenever the information matrix for the treatment design has the form $X'AX$, not just when A is derived from fixed blocks. This is the basis for the optimal blocking algorithm in the OPTEX procedure.

Notice that you can combine several options to use the OPTEX procedure to *evaluate* a design with respect to the fixed covariates. Assume the design you want to evaluate is in a data set named Edesign. Then first specify

```
generate initdesign=Edesign method=sequential;
```

This makes the data set Edesign the treatment design. Then specify the following BLOCKS statement options:

```
blocks {block-specification} init=chain iter=0;
```

The INIT=CHAIN option ensures that the starting ordering for the treatment points is the same as in the Edesign data set, and the ITER=0 specification causes the procedure simply to output the efficiencies for the initial design, without trying to optimize it.

Search Strategies

General Recommendations

As with all combinatorial optimization problems, finding efficient experimental designs can be difficult. For this reason, the OPTEX procedure provides a variety of ways to customize the search.

Although default settings make the procedure simple to use “as is,” you can usually improve the search by using knowledge of the specific design problem. For example, if the default algorithm (EXCHANGE) runs quickly but it is not clear whether it finds the best design, you can try a slower but more reliable search method or use more iterations than the default number of 10.

Set of Candidate Points

The choice of candidate points can profoundly affect both the speed with which the search converges at a local optimum and the likelihood that this local optimum is indeed the global optimum. Up to a point, the more candidate points there are, the better the resulting optimum design will be but the longer it will take to find. Any prior knowledge that can be brought to bear on the choice of candidates will almost certainly improve the search. For example, for first- or second-order models it is usually adequate to restrict the candidates to just the center and the edges of the experimental region, or perhaps even less; refer to Snee (1985), and see the introductory examples in the sections “Handling Many Variables” on page 1027 and “Constructing a Mixture-Process Design” on page 1028.

Initial Design

The reliability of the search algorithms in finding the optimal design can be quite sensitive to the choice of initial design. The default method of initialization for each search procedure should achieve good results for a wide variety of situations (see the INITDESIGN= option on page 1041). However, in certain situations it is better to override the defaults. For example, if there are many local optima and you want to find the exact global optimum, it will probably be best to start each try with a completely random design (INITDESIGN=RANDOM). On the other hand, prior knowledge might provide a specific initial design, which can be placed in a SAS data set and specified with the INITDESIGN= option.

Output

By default, the OPTTEX procedure lists the following information for each attempt to find the optimum design:

- the D-efficiency of the design
- the A-efficiency of the design
- the G-efficiency of the design
- the square root of the average variance for prediction over the candidate points

If you specify a BLOCKS statement, then the covariate-adjusted D- and A-efficiencies are also listed.

See the section “[Design Efficiency Measures](#)” on page 1074 for details on the efficiencies. The OPTTEX procedure orders the designs first by the optimality criteria with which they were generated and then by optimality with respect to the other three preceding measures.

If you use the NOCODE option, the OPTTEX procedure lists

- $\log |\mathbf{X}'\mathbf{X}|$
- $\text{trace}(X'X)^{-1}$
- the G-efficiency of the design
- the square root of the average variance for prediction over the candidate points

If you specify one of the distance-based optimality criteria (CRITERION=U or CRITERION=S), then, instead of the preceding efficiencies, alternative measures of coverage and spread are listed. For U-optimality these measures are

- the average distance from each candidate to the nearest design point (this is the U criterion)
- the average harmonic mean distance from each candidate to the design

For S-optimality, the following alternative measures of spread are listed:

- the harmonic mean distance from each design point to the nearest other design point (this is the S criterion)
- the average distance from each design point to the nearest other design point

In addition, the OPTTEX procedure can create an output data set, as described in the section “[OUTPUT Statement](#)” on page 1045 and in the section “[Output Data Sets](#)” on page 1072.

ODS Tables

The following table summarizes the ODS tables that you can request with the PROC OPTTEX statement.

Table 14.8 ODS Tables Produced in PROC OPTTEX

ODS Table Name	Description	Statement	Option
ClassLevels	Classification variable levels	CLASS	default
FactorRanges	Continuous variable ranges	default	default
BlockDesignEfficiencies	Block design efficiency criteria	BLOCK	default
Efficiencies	Efficiency criteria for all designs	GENERATE	default
Criteria	Efficiency criteria for a single design	EXAMINE	default
Points	Design points	EXAMINE	POINTS
Information	Information matrix XPX	EXAMINE	INFORMATION
Variance	Inverse information matrix inv(XPX)	EXAMINE	VARIANCE
Status	Optimization status	PROC	STATUS
Distances	Distance criteria for all designs	GENERATE	CRITERION=U or S

Introduction: PARETO Procedure

The PARETO procedure creates Pareto charts, which display the relative frequency of quality-related problems in a process or operation. The frequencies are represented by bars that are ordered in decreasing magnitude. Thus, a Pareto chart can be used to decide which subset of problems should be solved first or which problem areas deserve the most attention.

Pareto charts provide a tool for visualizing the Pareto principle,¹ which states that a small subset of problems tend to occur much more frequently than the remaining problems. In Japanese industry, the Pareto chart is one of the “seven basic QC tools” heavily used by workers and engineers. Ishikawa (1976) discusses how to construct and interpret a Pareto diagram. Examples of Pareto diagrams are also given by Kume (1985) and Wadsworth, Stephens, and Godfrey (1986).

¹Both the chart and the principle are named after Vilfredo Pareto (1848-1923), an Italian economist and sociologist. His first work, *Cours d'Économie Politique* (1895-1897), applied what is now termed the *Pareto distribution* to the study of income size.

You can use the PARETO procedure to

- construct Pareto charts from unsorted raw data (for instance, a set of quality problems that have not been classified into categories) or from a set of distinct categories and corresponding frequencies
- construct Pareto charts based on the percentage of occurrence of each problem, the frequency (number of occurrences), or a weighted frequency (such as frequency weighted by the cost of each problem)
- add a curve indicating the cumulative percentage across categories
- construct side-by-side Pareto charts or stacked Pareto charts
- construct *comparative Pareto charts* that enable you to compare the Pareto frequencies across levels of one or two classification variables. For example, you can compare the frequencies of problems encountered with three different machines for five consecutive days.
- highlight the “vital few” and the “useful many”² categories by using different colors for bars corresponding to the n most frequently occurring categories or the m least frequently occurring categories.
- create charts as traditional graphics, ODS Graphics output, or legacy line printer charts
- create charts with bars oriented vertically or horizontally
- highlight special categories by using different colors for specific bars
- annotate traditional graphics charts
- inset summary statistics in graphical output
- save traditional graphics output in a graphics catalog for subsequent replay
- display sample sizes on Pareto charts
- display frequencies above the bars
- save information associated with the categories (such as the frequencies) in an output data set
- restrict the number of categories displayed to the n most frequently occurring categories
- create variations on traditional Pareto charts, as described by Wilkinson (2006)

²Juran originally referred to these categories as the “trivial many”; however, because all problems merit attention, the term “useful many” is preferable. Refer to Burr (1990).

PROC PARETO Statement

Overview: PROC PARETO Statement

The PROC PARETO statement starts the PARETO procedure, and it optionally identifies various data sets and requests line printer charts.

To create a Pareto chart, you specify a chart statement (VBAR or HBAR) after the PROC PARETO statement. The chart statement specifies the type of Pareto chart you want to create and the variables in the input data set that you want to analyze. A VBAR statement produces a chart with vertical bars; an HBAR statement produces a chart with horizontal bars. For example, the following statements request a horizontal Pareto chart with blue bars on a green background:

```
proc pareto data=Failures;
    hbar Reason1 / cbars = blue
                  cframe = green;
run;
```

The DATA= option specifies the input data set (Failures) containing the variable (Reason1) to be analyzed.

A Pareto chart has three axes:

- the *category axis*
- the *frequency axis* and
- the *cumulative percent axis*.

On a vertical bar chart the category axis is displayed horizontally at the bottom of the chart. The frequency axis (also called the *primary vertical axis*) is on the left. The cumulative percent axis (or *secondary vertical axis*) is displayed on the right.

On a horizontal bar chart the category axis is displayed vertically on the left side of the chart. The frequency axis (*primary horizontal axis*) is displayed at the top of the chart. The cumulative percent axis (*secondary horizontal axis*) is at the bottom.

Syntax: PROC PARETO Statement

The syntax for the PARETO procedure is as follows:

```
PROC PARETO < options > ;
  BY variables ;
  VBAR < (variable-list) > < / options > ;
  HBAR < (variable-list) > < / options > ;
  INSET keyword-list < / options > ;
```

You must specify the PROC PARETO statement and at least one VBAR or HBAR statement (also referred to as chart statements). All other statements, such as BY, INSET, and TITLE statements, are optional.

The BY statement specifies variables in the input data set that are used for BY processing. A separate analysis is done for each group of observations defined by the levels of the BY variables. The input data set must be sorted in order of the BY variables.

If you specify two or more *variables* in a chart statement, they must be enclosed in parentheses. You can use multiple chart statements with one PROC PARETO statement. An INSET statement must follow a chart statement. It produces an inset displaying information on the chart created by the chart statement it follows. For details on the VBAR, HBAR or INSET statement, read the chapter on that statement.

Summary of Options

The following table lists the PROC PARETO statement options.

For complete descriptions, see the section “[Dictionary of Options](#)” on page 1094.

Table 15.1 PROC PARETO Statement Options

Option	Description
ANNOTATE=	specifies annotate data set for frequency axis
ANNOTATE2=	specifies annotate data set for cumulative percent axis
DATA=	specifies input data set
FORMCHAR=	specifies form character list to enhance line printer charts
GOUT=	specifies graphics catalog for saving traditional graphics output
LINEPRINTER	creates line printer charts

Dictionary of Options

You can specify the following options in the PROC PARETO statement. The marginal notes *Traditional Graphics* and *Line Printer* identify options that apply only to traditional graphics and line printer charts, respectively.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

Traditional Graphics

specifies an input data set that contains annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to customize traditional graphics charts with features such as labels explaining critical categories. The ANNOTATE= data set is associated with the frequency axis. If the annotation is based on data coordinates, you must use the same units as the frequency axis. Features provided in this data set are added to every chart produced in the current run of the procedure.

ANNOTATE2=SAS-data-set

ANNO2=ArgumentSAS-data-set

Traditional Graphics

specifies an input data set that contains annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to customize traditional graphics charts with features such as labels explaining critical categories. The ANNOTATE2= data set is associated with the cumulative percent axis. If the annotation is based on data coordinates, you must use the same units as the cumulative percent axis. Features provided in this data set are added to every chart produced in the current run of the procedure.

DATA=SAS-data-set

specifies an input data set that contains the *process variables* and related variables. If you do not specify a DATA= data set, the procedure uses the most recently created data set.

FORMCHAR='string'

Line Printer

specifies a form character list that enhances the appearance of line printer charts with corner characters and other special characters.

If your device supports the ASCII symbol set (1 or 2), use the following list:

```
formchar = 'B3,C4,DA,C2,BF,C3,C5,B4,C0,C1,D9'X
```

The FORMCHAR= option overrides (but does not alter) the FORMCHAR= option that is specified with an OPTIONS statement such as

```
options formchar = 'B3,C4,DA,C2,BF,C3,C5,B4,C0,C1,D9'X;
```

You can place the OPTIONS statement at the top of your SAS program or in an AUTOEXEC.SAS file.

GOUT=graphics-catalog

Traditional Graphics

specifies the graphics catalog in which to save traditional graphics output.

LINEPRINTER

requests that line printer charts be produced. By default, the procedure creates traditional *Line Printer* graphics. The HBAR statement does not produce line printer output, so you cannot use an HBAR statement when the LINEPRINTER option is specified.

HBAR Statement: PARETO Procedure

Overview: HBAR Statement

The HBAR statement creates a Pareto chart with horizontal bars representing the frequencies of problems in a process or operation. The HBAR statement does not produce line printer charts, so it cannot be used when the LINEPRINTER option is specified on the PROC PARETO statement.

A horizontal Pareto chart has one vertical axis on which the Pareto categories are listed. The primary horizontal axis appears at the top of the chart and is used to read the lengths of the bars on the chart. The secondary horizontal axis is at the bottom of the chart and is used to read the cumulative percent curve.

You have two alternatives for producing Pareto charts with the HBAR statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced if SAS/GRAPH[®] is licensed.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: HBAR Statement

The examples in this section illustrate basic features of the HBAR statement. Complete syntax for the HBAR statement is presented in the section “Syntax: HBAR Statement” on page 1102.

Creating a Pareto Chart from Raw Data

In the fabrication of integrated circuits, common causes of failures include improper doping, corrosion, surface contamination, silicon defects, metallization, and oxide defects. The causes of 31 failures were recorded in a SAS data set called Failure1. *See PARETO4 in the SAS/QC Sample Library*

```
data Failure1;
  length Cause $ 16;
  label Cause = 'Cause of Failure';
  input Cause & $;
  datalines;
Corrosion
```

```

Oxide Defect
Contamination
Oxide Defect
Oxide Defect
Miscellaneous
Oxide Defect
Contamination
Metallization
Oxide Defect
Contamination
Contamination
Oxide Defect
Contamination
Contamination
Contamination
Corrosion
Silicon Defect
Miscellaneous
Contamination
Contamination
Contamination
Miscellaneous
Contamination
Contamination
Doping
Oxide Defect
Oxide Defect
Metallization
Contamination
Contamination
;

```

Each of the 31 observations corresponds to a different circuit, and the value of Cause provides the cause for the failure. These are raw data in the sense that there is more than one observation with the same value of Cause, and the observations are not sorted by Cause. The following statements produce a basic Pareto chart for the failures:

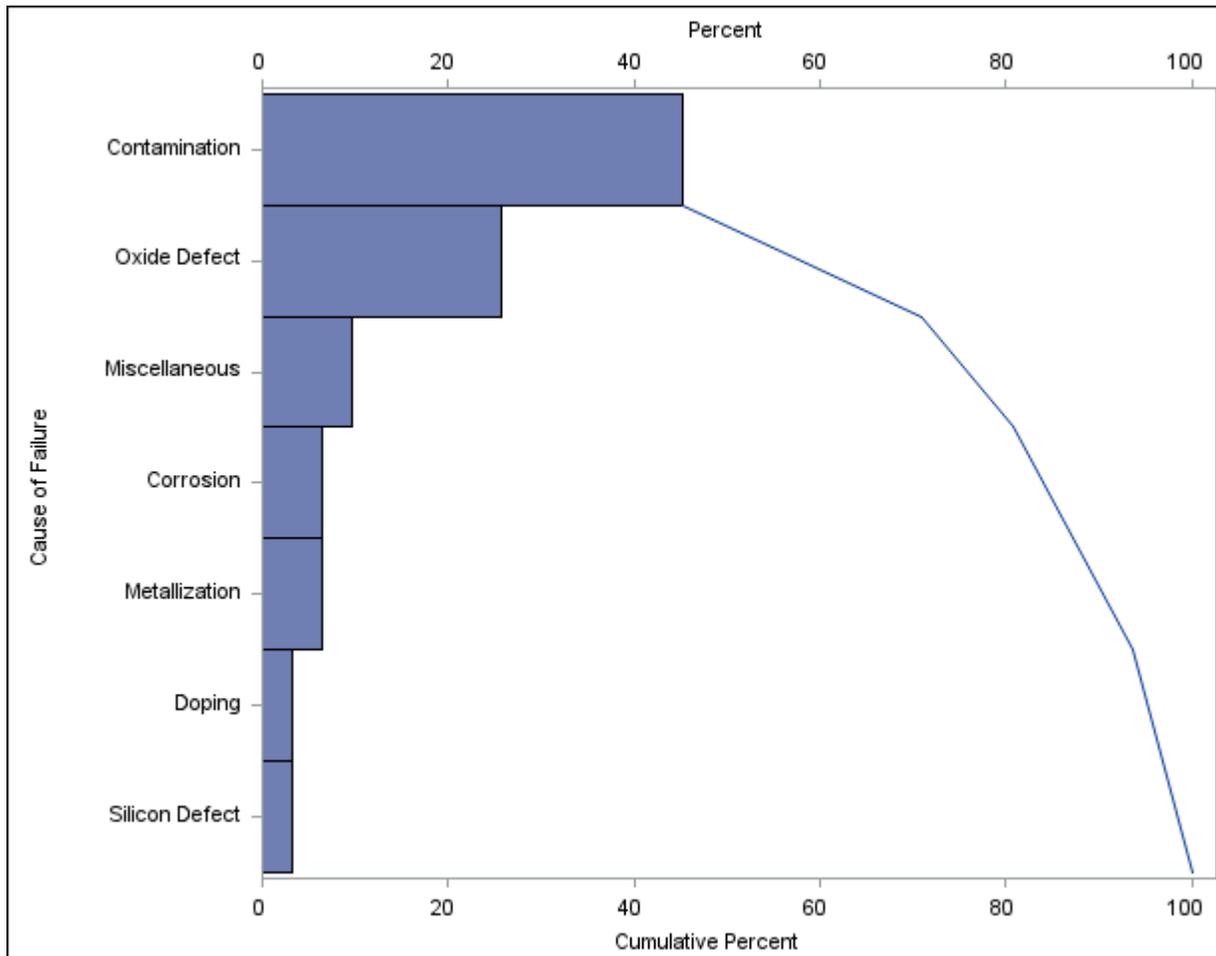

```

ods graphics off;
goptions htext=2.3 pct htitle=3.0 pct;
proc pareto data=Failure1;
    hbar Cause;
run;

```

The PARETO procedure is invoked with the first statement, referred to as the PROC statement. You specify the process variable to be analyzed in the HBAR statement.

The Pareto chart is shown in [Figure 15.1](#).

Figure 15.1 Pareto Chart for IC Failures in the Data Set Failure1

The procedure has classified the values of Cause into seven distinct categories (levels). The bars represent the percent of failures in each category, and they are arranged in decreasing order. Thus, the most frequently occurring category is *Contamination*, which accounts for 45% of the failures. The Pareto curve indicates the cumulative percent of failures from top to bottom; for example, *Contamination* and *Oxide* together account for 71% of the failures.

If there is sufficient space, the procedure labels the bars along the vertical axis as in [Figure 15.1](#). Otherwise the procedure numbers the bars from top to bottom and adds a legend identifying the categories.

A category legend is likely to be introduced when

- the number of categories is large
- the category labels are lengthy. Category labels can be up to 64 characters.
- a large text height is used. You can specify the height with the HEIGHT= option in the HBAR statement or with the HTEXT= option in a GOPTIONS statement.

Creating a Pareto Chart Using Frequency Data

See PARETO5 in the SAS/QC Sample Library In some situations, a count (frequency) is available for each category, or you can compress a large data set by creating a frequency variable for the categories before applying the PARETO procedure.

For example, you can use the FREQ procedure to obtain the compressed data set Failure2 from the data set Failure1.

```
proc freq data=Failure1;
  tables Cause / noprint out=Failure2;
run;
```

A listing of Failure2 is shown in Figure 15.2.

Figure 15.2 The Data Set Failure2 Created Using PROC FREQ

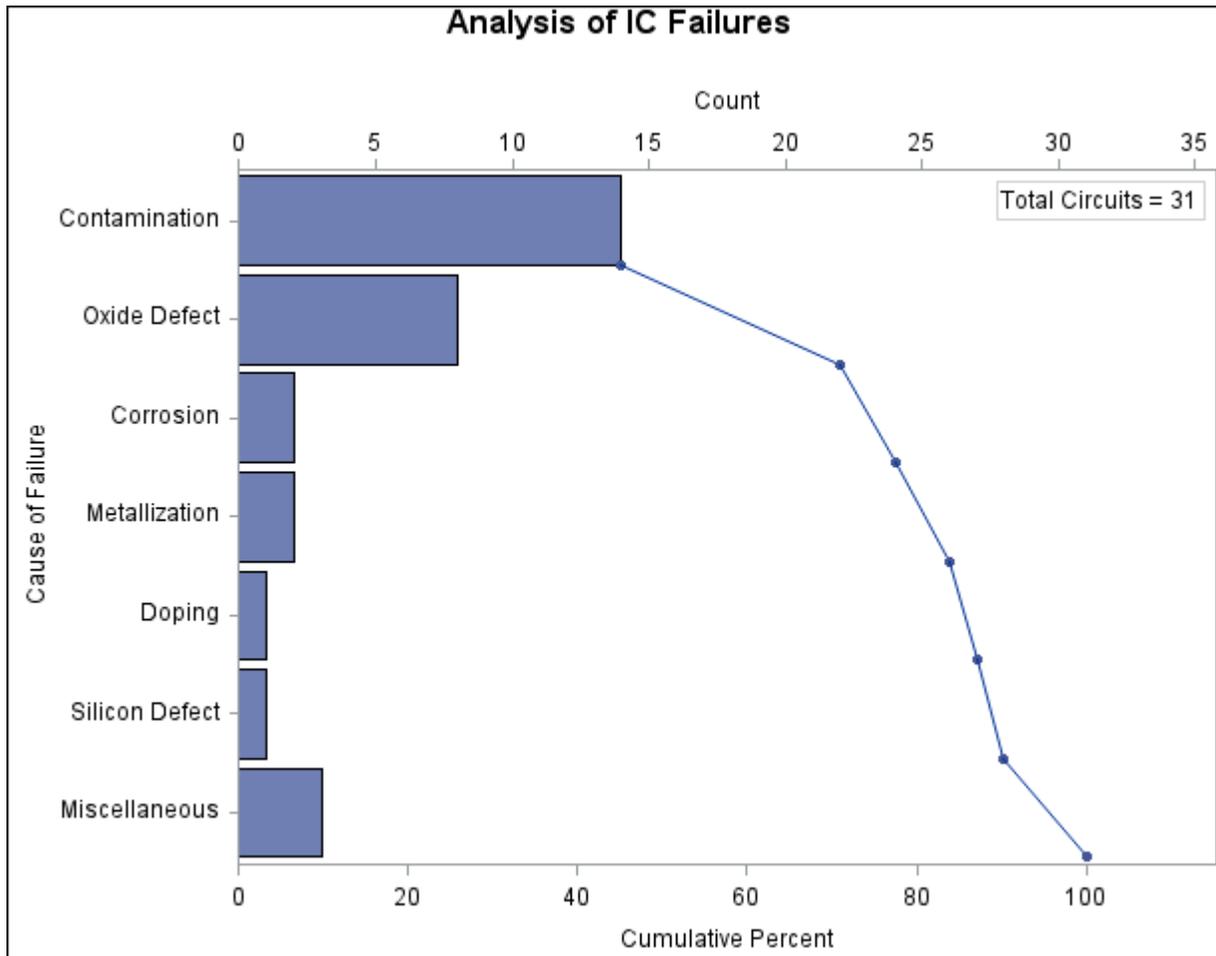

Obs	Cause	COUNT	PERCENT
1	Contamination	14	45.1613
2	Corrosion	2	6.4516
3	Doping	1	3.2258
4	Metallization	2	6.4516
5	Miscellaneous	3	9.6774
6	Oxide Defect	8	25.8065
7	Silicon Defect	1	3.2258

The following statements produce a Pareto chart for the data in Failure2:

```
title 'Analysis of IC Failures';
symbol v=dot;
proc pareto data=Failure2;
  hbar Cause / freq      = Count
  scale      = count
  interbar  = 1.0
  last      = 'Miscellaneous'
  nlegend   = 'Total Circuits'
  cframenleg;
run;
```

The chart is displayed in Figure 15.3.

Figure 15.3 Pareto Chart with Frequency Scale

A slash (/) is used to separate the process variable Cause from the options specified in the HBAR statement. The frequency variable Count is specified with the FREQ= option. Specifying the keyword COUNT with the SCALE= option requests a frequency scale for the horizontal axis.

The INTERBAR= option inserts a small space between the bars, and specifying LAST='Miscellaneous' causes the category *Miscellaneous* to be displayed last regardless of its frequency. The NLEGEND= option adds a sample size legend labeled *Total Circuits*, and the CFRAMENLEG option frames the legend. The SYMBOL statement marks points on the curve with dots.

There are two sets of tied categories in this example; *Corrosion* and *Metallization* each occur twice, and *Doping* and *Silicon Defect* each occur once. The procedure displays tied categories in alphabetical order of their formatted values. Thus, *Corrosion* appears before *Metallization*, and *Doping* appears before *Silicon Defect* in Figure 15.3. This is simply a convention, and no practical significance should be attached to the order in which tied categories are arranged.

Restricting the Number of Pareto Categories

See *PARETO2* in the *SAS/QC Sample Library*. Unlike the previous examples, some applications involve too many categories to display on a chart. The solution presented here is to create a restricted Pareto chart that displays only the most frequently occurring categories.

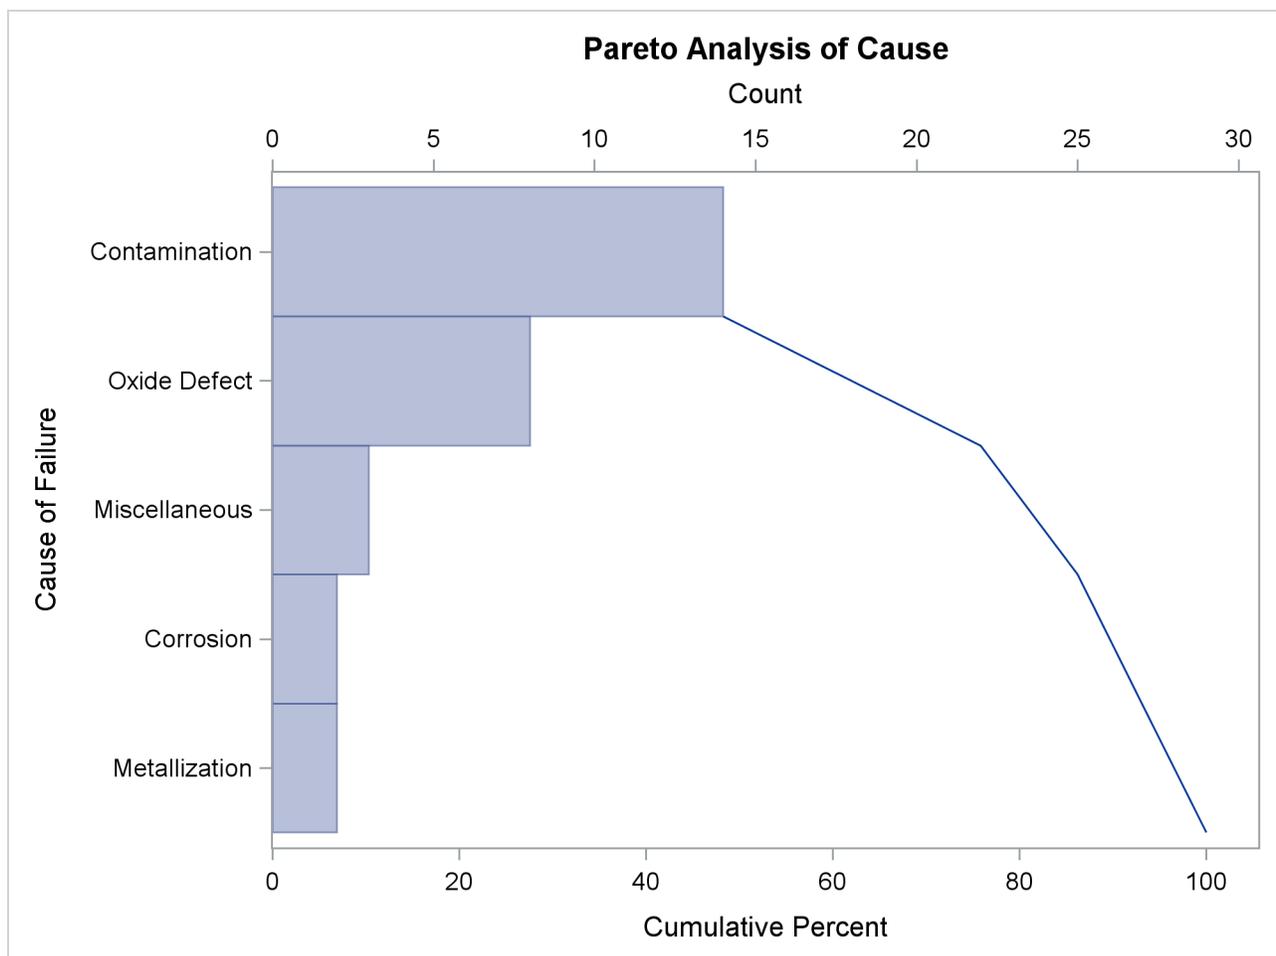

The following statements create a Pareto chart for the five most frequently occurring levels of Cause in the data set Failure2, which is listed in Figure 15.2:

```
ods graphics on;
proc pareto data=Failure2;
  hbar Cause / freq    = Count
                scale  = count
                maxncat = 5;
run;
```

The ODS GRAPHICS ON statement specified before the PROC PARETO statement enables ODS Graphics, so the Pareto chart is created using ODS Graphics instead of traditional graphics.

The MAXNCAT= option specifies the number of categories to be displayed. The chart, shown in Figure 15.4, does not display the categories *Doping* and *Silicon Defect*.

Figure 15.4 Restricted Pareto Chart

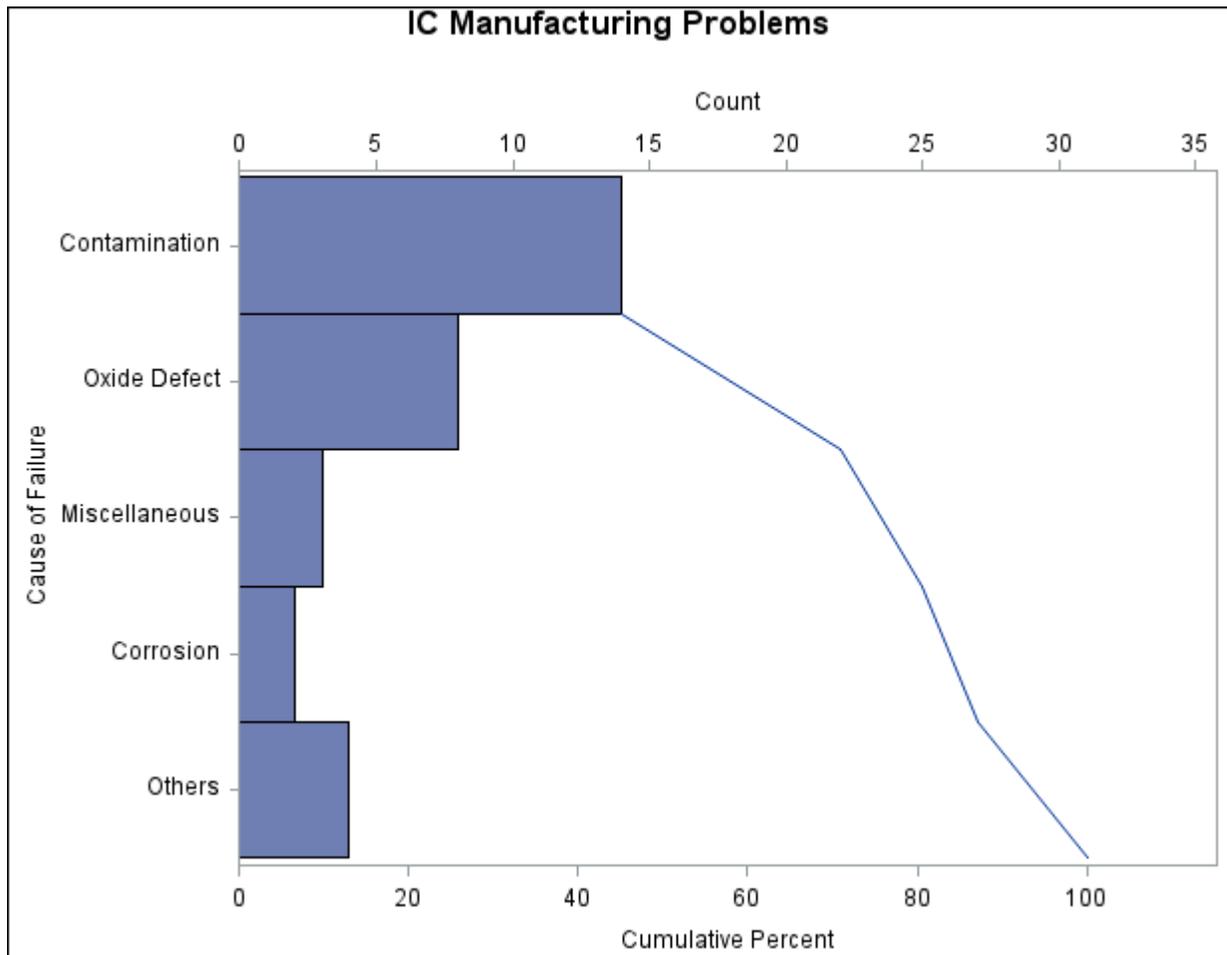

You can also display the most frequently occurring categories and merge the remaining categories into a single *other* category that is represented by a bar. You can specify the name for the new category with the `OTHER=` option. If, in addition, you specify the name with the `LAST=` option, the category is positioned at the bottom of the chart. The following statements illustrate both options:

```
ods graphics off;
title 'IC Manufacturing Problems';
proc pareto data=Failure2;
  hbar Cause / freq    = Count
          scale      = count
          maxncat   = 5
          other     = 'Others'
          last      = 'Others';
run;
```

The chart is shown in Figure 15.5.

Figure 15.5 Restricted Pareto Chart with *Other* Category

The number of categories displayed is five, which is the number specified with the `MAXNCAT=` option. The first four categories are the four most frequently occurring problems in `Failure2`, and the fifth category merges the remaining problems.

Note that *Corrosion* and *Metallization* both have a frequency of two. When the MAXNCAT= option is applied to categories with tied frequencies, the procedure breaks the tie by using the order of the formatted values. Thus *Corrosion* is displayed, whereas *Metallization* is merged into the *Other* category. The MAXNCAT= and related options are described in the section “Restricted Pareto Charts” on page 1176.

Syntax: HBAR Statement

The syntax for the HBAR statement is as follows:

```
HBAR (variable-list) < / options > ;
```

You can use any number of HBAR statements in the PARETO procedure. If you specify two or more *variables* in the HBAR statement, they must be enclosed in parentheses. The components of the HBAR statement are described as follows.

options

specify the layout and features of the chart, and they are listed after a slash (/) that follows the variables to be analyzed.

The section “Summary of Options” on page 1102, which follows, provides summary tables of options organized by function. The section “Dictionary of Options” on page 1106 describes the *options* in detail.

variable-list

specifies the process variables to be analyzed. A chart is created for each *variable*, and the values of each *variable* determine the Pareto categories for that chart. A list of two or more *variables* must be enclosed in parentheses.

The *variables* can be numeric or character, and the maximum length of a character *variable* is 64. Formatted values are used to determine the categories and are displayed in labels and legends. The maximum format length is 64.

Summary of Options

Table 15.2 lists the HBAR statement options by function. For complete descriptions, see the section “Dictionary of Options” on page 1106.

Table 15.2 HBAR Statement Options

Option	Description
Options for ODS Graphics Output	
CATLEGEND=	displays Pareto categories legend
CHARTTYPE=	specifies type of Pareto chart produced
MARKERS	requests markers on cumulative percent curve
ODSFOOTNOTE=	specifies footnote displayed on chart
ODSFOOTNOTE2=	specifies secondary footnote displayed on chart
ODSTITLE=	specifies title displayed on chart
ODSTITLE2=	specifies secondary title displayed on chart

Table 15.2 (continued)

Option	Description
URL=	specifies a variable whose values are URLs to be associated with bars
Options for the Cumulative Percent Curve	
ANCHOR=	specifies corner of topmost bar to which curve is anchored
CCONNECT=	specifies color for curve
CMPCTLABEL	labels curve points with their values
NOCURVE	suppresses curve
NOHLABEL2	suppresses secondary horizontal axis label
NOHTICK2	suppresses secondary horizontal axis tick marks and tick mark labels
Data Processing Options	
FREQ=	specifies frequency variable
MISSING	specifies that missing values of the process variable be treated as a Pareto category
MISSING1	specifies that missing values of the first CLASS= variable be analyzed as a level
MISSING2	specifies that missing values of the second CLASS= variable be analyzed as a level
OUT=	creates output data set that saves information displayed in the Pareto chart
WEIGHT=	specifies weight variables used to weight frequencies
Options for Restricting the Number of Categories	
COTHER=	specifies color for OTHER= bar
LOTHER=	specifies label for OTHER= bar
MAXCMPCT=	displays only the categories with cumulative percentage less than the <i>percent</i> specified
MAXNCAT=	displays only the categories with the <i>n</i> highest values
MINPCT=	displays only the categories with percents greater than the <i>percent</i> specified
OTHER=	merges all categories not displayed
OTHERCVAL=	specifies an OUT= data set character variable value for the OTHER= category
OTHERNVAL=	specifies an OUT= data set numeric variable value for the OTHER= category
POTHER=	specifies pattern for OTHER= bar
Options to Enhance Graphical Output	
ANNOTATE=	specifies annotate data set with primary horizontal axis data units
ANNOTATE2=	specifies annotate data set with secondary horizontal axis data units
CTEXT=	specifies color for text
CTEXTSIDE=	specifies color for row labels
CTEXTTOP=	specifies color for column labels
DESCRIPTION=	specifies description of Pareto chart's GRSEG catalog entry

Table 15.2 (continued)

Option	Description
FONT=	specifies font for text
HEIGHT=	specifies text height in percent screen units
HTML=	specifies a variable whose values create links associated with bars in traditional graphics output
INFONT=	specifies font for text inside frame
INHEIGHT=	specifies text height in percent screen units for text inside frame
NAME=	specifies name of Pareto chart's GRSEG catalog entry
Options for Reference Lines	
CHREF=	specifies color for HREF= and HREF2= lines
CLIPREF	draws reference lines behind bars
CVREF=	specifies color for VREF= lines
FRONTREF	draws reference lines in front of bars
HREF=	requests reference lines perpendicular to primary horizontal axis
HREF2=	requests reference lines perpendicular to secondary horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= lines
VREF=	requests reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies position of VREFLABELS= labels
Options for Comparative Pareto Charts	
ANNOKEY	applies annotation only to the key cell
CFRAMESIDE=	specifies frame color for row labels
CFRAMETOP=	specifies frame color for column labels
CLASS=	specifies classification variables
CLASSKEY=	specifies the key cell
CPROP=	requests proportion-of-frequency bars
CTILES=	specifies colors for tile backgrounds
INTERTILE=	specifies distance in percent screen units between tiles
MISSING1	specifies that missing values of the first CLASS= variable be analyzed as a level
MISSING2	specifies that missing values of the second CLASS= variable be analyzed as a level
NCOLS=	specifies number of columns
NOKEYMOVE	suppresses the placement of the key cell in the top left corner
NROWS=	specifies number of rows
ORDER1=	specifies the order in which values of the first CLASS= variable are displayed

Table 15.2 (continued)

Option	Description
ORDER2=	specifies the order in which values of the second CLASS= variable are displayed
Options for Grids	
CGRID=	specifies color for GRID lines
CGRID2=	specifies color for GRID2 lines
GRID	adds grid corresponding to primary horizontal axis
GRID2	adds grid corresponding to secondary horizontal axis
LGRID=	specifies line type for GRID lines
LGRID2=	specifies line type for GRID2 lines
WGRID=	specifies width of GRID lines
WGRID2=	specifies width of GRID2 lines
Options for Controlling Axes	
ANGLE=	rotates vertical axis tick mark labels
AXISFACTOR=	specifies distance factor between the longest bar and the right frame
CAXIS=	specifies axis color
CAXIS2=	specifies color for secondary horizontal axis and tick marks
CFRAME=	specifies color for area enclosed by axes and frame
HAXIS=	specifies tick mark values for primary horizontal axis
HAXISLABEL=	labels primary horizontal axis
HAXIS2=	specifies tick mark values for secondary horizontal axis
HAXIS2LABEL=	labels secondary horizontal axis
HOFFSET=	specifies horizontal axis offset in percent screen units
NOCHART	suppresses Pareto chart
NOFRAME	suppresses axis frame
NOHLABEL	suppresses primary horizontal axis label
NOHLABEL2	suppresses secondary horizontal axis label
NOHTICK	suppresses tick marks and tick mark labels for primary horizontal axis
NOHTICK2	suppresses tick marks and tick mark labels for secondary horizontal axis
NOVLABEL	suppresses vertical axis label
SCALE=	specifies units in which primary horizontal axis is scaled
VOFFSET=	specifies vertical axis offset in percent screen units
WAXIS=	specifies width in pixels for the axes and frame
Options for Displaying Legends	
BARLEGEND=	displays legend for CBARS= colors or PBARS= patterns
BARLEGLABEL=	displays label for BARLEGEND= legend
CATLEGLABEL=	specifies label for Pareto categories legend
CFRAMENLEG=	frames the sample size legend
HLLEGLABEL=	displays label for the legend that describes colors and patterns of highest or lowest bars
NLEGEND=	requests sample size legend

Table 15.2 (continued)

Option	Description
NOHLLEG	suppresses legend describing colors and patterns of highest or lowest bars
TILELEGEND=	specifies legend for CTILES= colors
TILELEGLABEL=	specifies label for TILELEGEND= legend
Options for Displaying Bars	
BARLABEL=	displays labels for bars
BARLABPOS=	specifies position of BARLABEL= labels
BARS=	specifies variable that groups bars for display using ODS style colors
BARWIDTH=	specifies width (vertical dimension) in percent screen units of the bars
CBARLINE=	specifies color for bar outlines
CBARS=	specifies color for bars
CHIGH(<i>n</i>)=	specifies color for bars with the <i>n</i> highest values
CLOW(<i>n</i>)=	specifies color for bars with the <i>n</i> lowest values
INTERBAR=	specifies distance between bars in percent screen units
LABOTHER=	specifies label for “other” category
LAST=	specifies bottommost category
PBARS=	specifies pattern for the bars
PHIGH(<i>n</i>)=	specifies pattern for bars with the <i>n</i> highest values
PLOW(<i>n</i>)=	specifies pattern for bars with the <i>n</i> lowest values
WBARLINE=	specifies width for bar outlines

Dictionary of Options

The following entries provide detailed descriptions of options you can specify after the slash (/) in the HBAR statement. For example, to request that the bars of your Pareto chart be colored red, use the CBARS= option, as follows:

```
proc pareto data=failure;
  hbar cause / cbars = red;
run;
```

The marginal notes *Traditional Graphics* and *ODS Graphics* identify options that apply to traditional graphics and to ODS Graphics output, respectively.

ANCHOR=BR | LC | RC | TL

specifies where the Pareto curve is anchored to the topmost bar on the chart. The following table lists the possible positions.

Keyword	Anchoring position
BR	bottom right corner
LC	left center
RC	right center
TL	top left corner

See [Output 15.2.1](#) for an illustration. The default is BR.

Note: The ANCHOR= option is not supported for ODS Graphics output. The curve is anchored at the right center of the topmost bar.

ANGLE=*value*

specifies an angle in degrees for rotating the Pareto category labels on the vertical axis. The *value* is the angle between the baseline of the label and the vertical axis. *Traditional Graphics*
for an illustration. The *value* must be greater than -90 and less than 90. The default *value* is zero.

ANNOKEY

specifies that annotation requested with the ANNOTATE= and ANNOTATE2= options is to be applied only to the key cell in a comparative Pareto chart. By default, annotation is applied to all of the cells. *Traditional Graphics*

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set that contains annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to customize traditional graphics. This data set is associated with the primary horizontal axis. If the annotation is based on data coordinates, you must use the same units as the primary horizontal axis. Features provided in the ANNOTATE= data set are added to every chart produced with the HBAR statement. *Traditional Graphics*

ANNOTATE2=*SAS-data-set*

ANNO2=*SAS-data-set*

specifies an input data set that contains annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to customize traditional graphics. This data set is associated with the secondary horizontal axis. If the annotation is based on data coordinates, you must use the same units as the secondary horizontal axis. Features provided in the ANNOTATE2= data set are added to every chart produced with the HBAR statement. *Traditional Graphics*

AXISFACTOR=*value*

specifies a factor used in scaling the primary horizontal axis. This factor determines (approximately) the ratio of the length of the axis to the length of the longest bar, and it is used to provide space for the cumulative percent curve. The *value* must be greater than one.

By default, the factor is chosen so that the curve will be anchored at the bottom right corner of the topmost bar (see also the ANCHOR= option). If this causes the bars to be flattened excessively, however, a smaller default factor is used.

The AXISFACTOR= option is not applicable if the curve is suppressed with the NOCURVE option.

BARLABEL = VALUE | COUNT | CMPCT | (variable-list)

specifies that a label is to be displayed to the right of each bar. If you specify BARLABEL=VALUE, the label indicates the length of the bar in the units used by the primary horizontal axis. See [Example 15.8](#) for an illustration.

If you specify BARLABEL=COUNT, the label displays the count for the bar.

If you specify BARLABEL=CMPCT, the label indicates the cumulative percent associated with that bar. An alternative to BARLABEL=CMPCT is the CMPCTLABEL option, which labels points on the cumulative percent curve with the cumulative percents.

If you specify `BARLABEL= (variable-list)`, the label displays the values of a variable from the input data set. The variable can have a formatted length less than or equal to 32. If a format is associated with the variable, then the formatted value is displayed. The values must be consistent within observations corresponding to a particular Pareto category. The variable is saved in the `OUT=` data set. If you specify more than one process variable in the chart statement, you can specify more than one `BARLABEL=` variable. The `BARLABEL=` and process variables are matched by their positions in the variable lists.

BARLABPOS=HBAR | HFIT | HRIGHT

Traditional Graphics

specifies the position for labels requested with the `BARLABEL=` option.

- `BARLABPOS=HBAR` displays the labels on the bars.
- `BARLABPOS=HFIT` displays the labels on or to the right of the bars, depending on the available space.
- `BARLABPOS=HRIGHT` displays the labels to the right of the bars.

The labels are truncated if necessary. By default, the labels are displayed to the right of the bars.

BARLEGEND=(variable-list)

specifies that a legend is to be added to the chart to explain colors for bars specified with the `CBARS=(variable-list)` option or patterns for bars specified with the `PBARS=(variable-list)` option. The *variable-list* must be enclosed in parentheses even if only one *variable* is specified. See [Output 15.4.1](#) for an illustration.

The values of the `BARLEGEND=` variable provide the explanatory labels used in the legend. The variable can have a formatted length that does not exceed 32. If a format is associated with the variable, then the formatted value is displayed.

The `BARLEGEND=` option is not applicable unless you specify `CBARS=(variable-list)` or `PBARS=(variable-list)` or both. In the `DATA=` data set, the values of the `BARLEGEND=` variable must be identical in observations for which the value of the `CBARS=` variable or the `PBARS=` variable (or the combination of these two values) is the same. This ensures that the legend derived from the `BARLEGEND=` variable is consistent.

If you specify more than one process variable in the chart statement and a corresponding list of `CBARS=` or `PBARS=` variables, you can specify a list of `BARLEGEND=` variables. The number of `BARLEGEND=` variables should be less than or equal to the number of process variables. The lists of variables are matched so that the first `BARLEGEND=` variable is applied to the first process variable and the first `CBARS=` or `PBARS=` variable, the second `BARLEGEND=` variable is applied to the second process variable and the second `CBARS=` or `PBARS=` variable, and so forth. If the list of process variables is longer than the *variable-list* in the `BARLEGEND=` option, the charts for the extra process variables will not display a bar legend.

BARLEGLABEL='label'

specifies the label displayed to the left of the legend created with the `BARLEGEND=` option. See [Output 15.4.1](#) for an illustration.

The `BARLEGLABEL=` option is applicable only in conjunction with `CBARS=` or `PBARS=` variables. The label can be up to 16 characters and must be enclosed in quotes.

If no label is specified with the BARLEGLABEL= option, the label associated with the BARLEGEND= variable is displayed (unless the label is longer than 16 characters, in which case the variable name is displayed). If the BARLEGLABEL= option is not specified and no label is associated with the BARLEGEND= variable, no legend label is displayed. If both labels are specified, the BARLEGLABEL= label takes precedence over the variable label.

BARS=(*variable-list*)

groups bars of the Pareto chart for display using colors from the current ODS style. The BARS= option should not be used when the NOGSTYLE option is in effect, and you cannot specify the BARS= option in conjunction with the CHIGH or CLOW options. Bars corresponding to the same value of the BARS= variable are filled with the same color from the ODS style.

If you specify more than one process variable, you can specify more than one BARS= variable. The number of BARS= variables should be less than or equal to the number of process variables. The two lists of variables are paired in order of specification. If a BARS= variable is not provided for a process variable, the bars for that chart are filled with the default color from the ODS style.

BARWIDTH=*value*

specifies the *width* of the bars in percent screen units. The width of a bar on a horizontal Pareto chart refers to its vertical dimension. By default, the bars are as wide as possible. *Traditional Graphics*

CATLEGEND=ON | OFF

specifies whether a category legend is created for ODS Graphics output. By default, a category legend is not created. This option is ignored if ODS Graphics is not enabled. *ODS Graphics*

CATLEGLABEL=*'label'*

specifies a label for the category legend that is added when there is insufficient space to label the categories along the vertical axis. The *label* can be up to 16 characters and must be enclosed in quotes. The default label is *Categories:*. See [Example 15.3](#) for an illustration. The CATLEGLABEL= option is ignored if it is unnecessary to add the legend.

CAXIS=*color*

CAXES=*color*

CA=*color*

specifies the color for the axis line and tick marks on the chart. This color is also used for bar outlines and grid lines, unless overridden by the CBARLINE=, CGRID=, or CGRID2= options. *Traditional Graphics*

CAXIS2=*color*

specifies the color for the tick mark labels and axis label associated with the secondary axis. By default, the color specified with the CTEXT= option (or its default) is used. *Traditional Graphics*

CBARLINE=*color*

specifies the color for bar outlines. *Traditional Graphics*

CBARS=*color***CBARS=(*variable-list*)***Traditional Graphics*

specifies how the bars of the Pareto chart are to be colored. You can use one of the following approaches:

- You can specify a single color to be used for all the bars with **CBARS=*color***. You can use this option in conjunction with the **CHIGH** and **CLOW** options. See [Output 15.2.1](#) for an illustration.
- You can specify a distinct color for each bar (or combination of bars) by providing the colors as values of a **CBARS=** variable. This variable must be a character variable of length eight. You can use the special value 'EMPTY' to indicate that a bar is not to be colored. Note that the variable name must be enclosed in parentheses. You cannot specify a **CBARS=** variable in conjunction with the **CHIGH** and **CLOW** options. See [Output 15.3.1](#) and [Output 15.4.1](#) for examples.

If you specify more than one process variable, you can specify more than one **CBARS=** variable. The number of **CBARS=** variables should be less than or equal to the number of process variables. The two lists of variables are paired in order of specification. If a **CBARS=** variable is not provided for a process variable, the bars for that chart are not colored.

If you specify one or more **CBARS=** variables, you can also use the **BARLEGEND=** option to add a legend to the chart that explains the significance of each color. Furthermore, you can use the **PBARS=** option to specify patterns in conjunction with the **CBARS=** option. See [Output 15.4.1](#) and [Output 15.5.1](#) for examples.

CCONNECT=*color**Traditional Graphics*

specifies the color for the line segments connecting the points on the cumulative percent curve. You can specify the color for the points themselves with the **COLOR=** option in the **SYMBOL** statement; this is the default color.

CFRAME=*color**Traditional Graphics*

specifies the color for filling the area enclosed by the axes and the frame. The **CFRAME=** option cannot be used in conjunction with the **NOFRAME** option or the **CTILES=** option.

CFRAMENLEG=*color***CFRAMENLEG***Traditional Graphics*

specifies that the legend requested with the **NLEGEND** option be framed and that the frame be filled with the color indicated. If you specify **CFRAMENLEG=EMPTY**, a frame is drawn but is not filled with a color. Specify **CFRAMENLEG** without an argument to fill the frame with a color from the ODS style. See [Figure 15.3](#) and [Output 15.1.4](#) for illustrations.

CFRAMESIDE=*color**Traditional Graphics*

specifies the color for filling the frame area for the row labels displayed along the left side of a comparative Pareto chart requested with the **CLASS=** option. If a label is associated with the classification variable, this color is also used to fill the frame area for this label.

CFRAMETOP=*color**Traditional Graphics*

specifies the color for filling the frame area for the column labels displayed across the top of a comparative Pareto chart requested with the **CLASS=** option. If a label is associated with the classification variable, this color is also used to fill the frame area for this label.

CGRID=*color*

specifies the color for grid lines requested with the GRID option. If you specify the CGRID= *Traditional Graphics* option, you do not need to specify the GRID option.

CGRID2=*color*

specifies the color for grid lines requested with the GRID2 option. If you specify the CGRID2= *Traditional Graphics* option, you do not need to specify the GRID2 option.

CHARTTYPE=CUMULATIVE | INTERVALS*<(intervals-options)>* | **STANDARD**

specifies the type of Pareto chart to be produced. You can specify CUMULATIVE to create a cumulative Pareto bar chart and INTERVALS to create a Pareto dot plot with acceptance intervals. Wilkinson (2006) describes the advantages of both these variations on the traditional Pareto chart. Specifying CHARTTYPE=STANDARD produces a traditional Pareto chart, which is the default. *ODS Graphics*

When you specify CHARTTYPE=INTERVALS, acceptance intervals for the categories are computed using simulation. You can specify the following *intervals-options* for computing acceptance intervals:

ALPHA=*value*

specifies the significance level for the acceptance intervals. The default value is 0.05.

NSAMPLES=*n*

specifies the number of random samples used in the simulation. The default value is 2000.

SEED=*n*

specifies the seed value for the random number generator used in the simulation. By default, or when you specify $n \leq 0$, a seed value is generated by using the system clock.

See [Example 15.9](#) for examples of these alternative Pareto charts.

CHIGH(*n*)=*color***CHIGH**(*n*)

specifies the color used to fill the bars with the *n* highest values. You cannot use the CHIGH(*n*)= option in conjunction with a CBARS= variable, but you can use the CHIGH(*n*)= option together with the CLOW(*n*)= and CBARS=*color* options. See [Output 15.3.1](#) for an illustration. Use the CHIGH(*n*) option without specifying a color to fill the *n* highest bars with a color from the ODS style.

CHREF=*color*

specifies the color for lines requested with the HREF= and HREF2= options. *Traditional Graphics*

CLASS=*variable***CLASS=**(*variable1 variable2*)

creates a comparative Pareto chart using the levels of the *variables*. You must enclose two *variables* in parentheses. See [Example 15.1](#) and [Example 15.2](#).

If you specify a single CLASS= *variable*, the observations in the input data set are classified by the formatted values (levels) of the *variable*. A Pareto chart is created for the process variable values in each level, and these component charts (referred to as cells) are arranged

in an array. The cells are labeled with the levels, and uniform horizontal and vertical axes are used to facilitate comparisons.

If you specify two `CLASS= variables`, the observations in the input data set are cross-classified by the values (levels) of the *variables*. A Pareto chart is created for the process variable values in each cell of the cross-classification, and these charts are arranged in a *matrix*. The levels of the first `CLASS= variable` label the rows, and the levels of the second `CLASS= variable` label the columns. Uniform horizontal and vertical axes are used to facilitate comparisons.

The `CLASS= variables` can be numeric or character. The maximum length of a character *variable* is 32. If a format is associated with a `CLASS= variable`, the formatted values determine the levels. Only the first 32 characters of the formatted value are used to determine the levels. You can specify whether missing values are to be treated as a level with the `MISSING1` and `MISSING2` options.

If a label is associated with a `CLASS= variable`, the label is displayed on the chart, parallel to the column (or row) labels.

CLASSKEY= *'value'*

CLASSKEY=(*'value1' 'value2'*)

specifies the *key cell* in a comparative Pareto chart requested with the `CLASS=` option. The key cell is defined as the cell in which the Pareto bars are arranged in decreasing order. This order then determines the uniform horizontal axis used for all the cells.

If you specify `CLASS=variable`, you can specify `CLASSKEY='value'` to identify the key cell as the level for which *variable* is equal to *value*. The *value* can have up to 32 characters, and you must specify a formatted *value*. By default, the levels are sorted in the order determined by the `ORDER1=` option, and the key cell is the level that occurs first in this order. The cells are displayed in this order from top to bottom (or left to right), and consequently the key cell is displayed at the top or at the left. If you specify a different key cell with the `CLASSKEY=` option, this cell is displayed at the top or at the left unless you also specify the `NOKEYMOVE` option.

If you specify `CLASS=(variable1 variable2)`, you can specify `CLASSKEY=('value1' 'value2')` to identify the key cell as the level for which *variable1* is equal to *value1* and *variable2* is equal to *value2*. Here, *value1* and *value2* must be formatted values, and they must be enclosed in quotes. By default, the levels of *variable1* are sorted in the order determined by the `ORDER1=` option, and then within each of these levels, the levels of *variable2* are sorted in the order determined by the `ORDER2=` option. The default key cell is the combination of levels of *variable1* and *variable2* that occurs first in this order. The cells are displayed in order of *variable1* from top to bottom and in order of *variable2* from left to right. Consequently, the default key cell is displayed in the upper left corner. If you specify a different key cell with the `CLASSKEY=` option, this cell is displayed in the upper left corner unless you also specify the `NOKEYMOVE` option.

For an example of the use of the `CLASSKEY=` option, see [Output 15.1.3](#).

CLIPREF

Traditional Graphics

draws reference lines requested with the `HREF=` and `VREF=` options behind the bars on the Pareto chart. When the `GSTYLE` option is in effect, reference lines are drawn in front of the bars by default.

CLOW(*n*)=color**CLOW(*n*)**

specifies the color used to fill the bars with the *n* lowest values. You cannot use the CLOW(*n*)= option in conjunction with a CBARS=*variable*, but you can use the CLOW(*n*)= option together with the CBARS=*color* and CHIGH(*n*)= options. See [Output 15.3.1](#) for an illustration of the CHIGH(*n*)= option. Use the CLOW(*n*) option without specifying a color to fill the *n* lowest bars with a color from the ODS style.

CMPCTLABEL

labels points on the cumulative percent curve with their values. By default, the points are not labeled.

COTHER=*color*

coloringothercategory*other* category specifies the color for the bar defined by the OTHER= *Traditional Graphics* option. The COTHER= option is not applicable unless a CBARS=*variable* is specified.

CPROP=*color***CPROP**

requests a proportion-of-frequency bar of the specified color displayed vertically along the right side of each tile in a comparative Pareto chart. The length of a bar relative to the height of its tile indicates the proportion of the total frequency count in the chart that is represented by the tile. You can use the bars to visualize the distribution of frequency count by tile. Specify CPROP without an argument to create bars filled with a color from the ODS style. See [Output 15.1.4](#) for an illustration.

The CPROP= option provides a graphical alternative to the NLEGEND options, which display the actual count. The CPROP= option is applicable only with comparative Pareto charts. Empty bars are displayed if you specify CPROP=EMPTY.

CTEXT=*color***CT=*color***

specifies the color for text, such as tick mark labels, axis labels, and legends. The default is *Traditional Graphics* the value specified for the CTEXT= option in the GOPTIONS statement.

CTEXTSIDE=*color*

specifies the color for row labels displayed along the left side of a comparative Pareto chart *Traditional Graphics* requested with the CLASS= option. The default color is the color specified with the CTEXT= option in the HBAR statement or the CTEXT= option in the GOPTIONS statement.

CTEXTTOP=*color*

specifies the color for column labels displayed across the top of a comparative Pareto chart *Traditional Graphics* requested with the CLASS= option. The default color is the color specified with the CTEXT= option in the HBAR statement or the CTEXT= option in the GOPTIONS statement.

CTILES=(*variable*)

specifies a character variable of length eight whose values are the fill colors for the tiles in *Traditional Graphics* a comparative Pareto chart. The CTILES= option generalizes the CFRAME= option, which provides a single color for all of the tiles. The *variable* must be enclosed in parentheses. The values of the *variable* must be identical for all observations with the same level of the

CLASS= variables. You can use the same color to fill more than one tile. You can use the special value 'EMPTY' to indicate that a tile is not to be filled.

The CTILES= option cannot be used in conjunction with the NOFRAME option or the CFRAME= option. You can use the TILELEGEND= option in conjunction with the CTILES= option to add an explanatory legend for the CTILES= colors at the bottom of the chart. See [Output 15.5.1](#) for an illustration. By default, the tiles are not filled.

CVREF=*color*

Traditional Graphics specifies the color for lines requested with the VREF= lines.

DESCRIPTION='string'

DES='string'

Traditional Graphics specifies a description, up to 256 characters long, for the GRSEG catalog entry for a traditional graphics chart.

FONT=*font*

Traditional Graphics specifies a software font for text used in labels and legends. The FONT= option takes precedence over the FTEXT= option in the GOPTIONS statement.

FREQ=*variable*

specifies a frequency variable whose value provides the counts (numbers of occurrences) of the values of the process variable. Specifying a FREQ= variable is equivalent to replicating the observations in the input data set. The FREQ= variable must be a numeric variable with nonnegative integer values. If you specify more than one process variable in the chart statement, the FREQ= variable values are used with each process variable. See the section [“Creating a Pareto Chart Using Frequency Data”](#) on page 1098 for an illustration. If you do not specify a FREQ= variable, each value of the process variable is counted exactly once.

FRONTREF

Traditional Graphics draws reference lines requested with the HREF= and VREF= options in front of the bars on the Pareto chart. When the NOGSTYLE option is in effect, reference lines are drawn behind the bars by default, and can be obscured by them.

GRID

adds a grid to the Pareto chart corresponding to the primary horizontal axis. Grid lines are vertical lines positioned at tick marks on the primary horizontal axis. The lines are useful for comparing the lengths of the bars.

GRID2

adds a grid to the Pareto chart corresponding to the secondary horizontal axis. Grid lines are vertical lines positioned at tick marks on the secondary horizontal axis. The lines are useful for reading the cumulative percent curve.

HAXIS=*value-list*

specifies tick mark values for the primary horizontal axis. The values must be equally spaced and in increasing order, and the first *value* must be zero. You must scale the values in the same units as the bars (see the SCALE= option), and the last *value* must be greater than or equal to the height of the largest bar.

HAXISLABEL='label'

specifies a label, up to 40 characters, for the primary horizontal axis. The default label depends on the value of the SCALE= option, or it is the label associated with the WEIGHT= variable.

HAXIS2=value-list

specifies tick mark values for the secondary horizontal axis. The values must be equally spaced and in increasing order, and the first *value* must be zero. You must scale the values in percent units, and the last *value* must be greater than or equal to 100.

HAXIS2LABEL='label'

specifies a label, up to 40 characters, for the secondary horizontal axis. The default label is *Cumulative Percent* or *Cm Pct*, depending on the space available.

HEIGHT=value

specifies the height in percent screen units of text for labels and legends. This option should be used only in conjunction with the FONT= option. The HEIGHT= option takes precedence over the HTEXT= option in a GOPTIONS statement.

HLLEGLABEL='label'

specifies a label displayed to the left of the legend that is automatically created when you use a combination of the CHIGH, CLOW, PHIGH, and PLOW options. See [Output 15.3.1](#) for an illustration. The *label* can be up to 16 characters and must be enclosed in quotes. The default *label* is *Bars:*.

HOFFSET=value

specifies the length in percent screen units of the offset at the right end of the primary horizontal axis. You can eliminate the offset by specifying HOFFSET=0.

HREF=value-list

specifies where reference lines perpendicular to the primary horizontal axis are to appear on the chart. You must specify the values in the same units used to scale the primary axis. By default, the primary axis is scaled in percent units, but you can specify other units with the SCALE= option. See [Output 15.2.3](#) for an illustration.

HREF2=value-list

specifies where reference lines perpendicular to the secondary horizontal axis are to appear on the chart. You must specify the values in cumulative percent units.

HREFLABELS='label1'...'labeln'

specifies labels for the lines requested with the HREF= option. The number of labels must equal the number of lines requested. Labels can be up to 16 characters and must be enclosed in quotes.

HREF2LABELS='label1'...'labeln'

specifies labels for the lines requested with the HREF2= option. The number of labels must equal the number of lines requested. Labels can be up to 16 characters and must be enclosed in quotes.

HREFLABPOS=*n*

specifies the vertical position of HREFLABELS= labels, as described in the following table.

<i>n</i>	Position
1	along top of chart
2	staggered from top to bottom of chart
3	along bottom of chart
4	staggered from bottom to top of chart

By default, HREFLABPOS=1. **Note:** HREFLABPOS=2 and HREFLABPOS=4 are not supported for ODS Graphics output.

HTML=*variable*

Traditional Graphics

specifies a variable whose values create links associated with Pareto bars when traditional graphics output is directed into HTML. You can specify a character variable or formatted numeric variable. The value of the HTML= variable should be the same for each observation with a given value of the process variable.

INFONT=*font*

Traditional Graphics

specifies a software font for text used inside the frame of the chart, such as sample size legends. The INFONT= option takes precedence over the FONT= option and the FTEXT= option in the GOPTIONS statement.

INHEIGHT=*value*

Traditional Graphics

specifies the height in percent screen units of text used inside the frame of the chart, such as sample size legends and bar labels. This option should be used in conjunction with the INFONT= option.

INTERBAR=*value*

Traditional Graphics

specifies the distance in percent screen units between bars on the chart. By default, the bars are contiguous. See [Figure 15.3](#) for an illustration.

INTERTILE=*value*

specifies the distance in horizontal percent screen units between tiles (cells) in a comparative Pareto chart. By default, the tiles are contiguous. See [Output 15.1.3](#) for an illustration.

LABOTHER = '*other-label*'

is used in conjunction with the BARLABEL=(*variable*) option and specifies a label for the “other” category that is optionally specified with the OTHER= option.

LAST=*'category'*

specifies that the bar corresponding to the *category* is to be displayed at the bottom of the chart regardless of the percent associated with this category. The *category* must be a formatted value of the process variable and must be enclosed in quotes. The *category* can be up to 64 characters. See [Figure 15.5](#) for an illustration.

LGRID=*line-type*

Traditional Graphics

specifies the line type for the grid requested with the GRID option. If you specify the LGRID= option, you do not need to specify the GRID option.

LGRID2=*line-type*

specifies the line type for the grid requested with the GRID2 option. If you specify the *Traditional Graphics* LGRID2= option, you do not need to specify the GRID2 option.

LHREF=*line-type***LH=***line-type*

specifies the line type for lines requested with the HREF= and HREF2= options. *Traditional Graphics*

LOTHER=*'label'*

labelingspecifies a label for the bar defined with the OTHER= option. This label appears in the legend created with the BARLEGEND= option. The *label* must be enclosed in quotes and can be up to 32 characters. The default *label* is the value specified with the OTHER= option. The LOTHER= option is applicable only when a BARLEGEND= variable is specified.

LVREF=*line-type***LV=***line-type*

specifies the line type for lines requested with the VREF= option. See [Output 15.2.3](#) for an *Traditional Graphics* illustration.

MARKERS

specifies that the points on the cumulative percent curve be plotted with markers in ODS *ODS Graphics* Graphics output. You can use a SYMBOL statement to plot the points in traditional graphics.

MAXCMPCT=*percent*

specifies that only the Pareto categories with the *n* highest frequency counts are to be displayed, where the sum of the *n* corresponding percents is less than or equal to the specified *percent*. For example, if you specify

```
proc pareto data=failure;
  hbar cause / maxcmpct = 90;
```

the chart displays only the *n* most frequently occurring categories that account for no more than 90 percent of the total frequency.

You can use the OTHER= option in conjunction with the MAXCMPCT= option to create and display a new category that combines those categories that are not selected with the MAXCMPCT= option. For example, if you specify

```
proc pareto data=failure;
  hbar cause / maxcmpct = 90
             other      = 'Others';
```

the chart displays the categories that account for no more than 90 percent of the total frequency, together with a category labeled *Others* that merges the remaining categories. The MAXCMPCT= option is an alternative to the MINPCT= and MAXNCAT= options.

MAXNCAT=*n*

specifies that only the Pareto categories with the *n* highest frequencies are to be displayed. For example, if you specify

```
proc pareto data=failure;
  hbar cause / maxncat = 20;
```

the chart displays only the categories with the 20 highest frequencies. If the total number of categories is less than 20, all the categories are displayed.

You can use the OTHER= option in conjunction with the MAXNCAT= option to create and display a new category that combines those categories that are not selected with the MAXNCAT= option. For example, if you specify

```
proc pareto data=failure;
  hbar cause / maxncat = 20
              other= 'Others';
```

the chart displays the categories with the 19 highest frequencies, together with a category labeled *Others* that merges the remaining categories. See [Figure 15.4](#) for another illustration.

The MAXNCAT= option is an alternative to the MINPCT= and MAXCMPCT= options.

MINPCT=percent

specifies that only the Pareto categories with frequency percents greater than or equal to the specified *percent* are to be displayed. For example, if you specify

```
proc pareto data=failure;
  hbar cause / minpct = 5;
```

the chart displays only those categories with at least five percent of the total frequency.

You can use the OTHER= option in conjunction with the MINPCT= option to create and display a new category that combines those categories that are not selected with the MINPCT= option. The merged category created by the OTHER= option is displayed even if its total percent is less than the *percent* specified with the MINPCT= option. For example, if you specify

```
proc pareto data=failure;
  hbar cause / minpct = 5
              other = 'Others';
```

the chart displays the categories with percents greater than or equal to five percent, together with a category labeled *Others* that merges the remaining categories.

The MINPCT= option is an alternative to the MAXNCAT= and MAXCMPCT= options.

MISSING

specifies that missing values of the process variable are to be treated as a Pareto category represented with a bar on the chart. If the process variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the process variable is numeric, a missing value is defined as any of the SAS missing values. If you do not specify the MISSING option, missing values are excluded from the analysis.

MISSING1

specifies that missing values of the first CLASS= variable are to be treated as a level of the CLASS= variable. If the first CLASS= variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the first CLASS= variable is numeric, a missing value is defined as any of the SAS missing values. If you do not specify MISSING1, observations in the DATA= data set for which the first CLASS= variable is missing are excluded from the analysis.

MISSING2

specifies that missing values of the second CLASS= variable are to be treated as a level of the CLASS= variable. If the second CLASS= variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the second CLASS= variable is numeric, a missing value is defined as any of the SAS missing values. If you do not specify MISSING2, observations in the DATA= data set for which the second CLASS= variable is missing are excluded from the analysis.

NAME='string'

specifies the name of the GRSEG catalog entry for a traditional graphics chart, and the name of the graphics output file if one is created. The name can be up to 256 characters long, but the GRSEG name is truncated to eight characters. The default name is 'PARETO'. *Traditional Graphics*

NCOLS=*n***NCOL=*n***

specifies the number of columns in a comparative Pareto chart. You can use the NCOLS= option in conjunction with the NROWS= option. See [Output 15.2.3](#) and [Output 15.2.4](#) for an illustration. By default, NCOLS=1 and NROWS=2 if one CLASS= variable is specified, and NCOLS=2 and NROWS=2 if two CLASS= variables are specified.

NLEGEND**NLEGEND='label'****NLEGEND=(variable)**

requests a sample size legend and specifies its form as follows:

- If you specify the NLEGEND option, the form is $N=n$, where n is the total count for the Pareto categories. In a comparative Pareto chart, a legend is displayed in each tile, and n is the total count for that particular cell. See [Output 15.2.1](#) for an illustration.
- If you specify the NLEGEND='label' option, the form is $label=n$, where n is the total count for the Pareto categories. The label can be up to 32 characters and must be enclosed in quotes. For an illustration, see [Figure 15.3](#) or [Output 15.1.4](#).
- If you specify the NLEGEND=(variable) option, the legend is the value of the *variable*, which must be a variable in the DATA= data set whose formatted length does not exceed 32. If a format is associated with the variable, then the formatted value is displayed. This option is intended for use with comparative Pareto charts and enables you to display a customized legend inside each tile (this legend need not provide total count). It is assumed that the values of the *variable* are identical for all observations in a particular class.

By default, the legend is placed in the upper-right corner of the chart. If the NOCURVE option is specified, the legend is placed in the lower-right corner of the chart. You can use the

CFRAMENLEG= option to frame the sample size legend. No legend is displayed if you do not specify an NLEGEND option.

NOCHART

suppresses the creation of a Pareto chart. This option is useful when you are simply creating an output data set.

NOCURVE

suppresses the display of the cumulative percent curve and the secondary horizontal axis. Compare [Output 15.2.1](#) and [Output 15.2.2](#) for an illustration.

NOFRAME

Traditional Graphics

suppresses the frame that is drawn around the chart by default. The NOFRAME option cannot be specified in conjunction with the CFRAME= or CTILES= options.

NOHLABEL

suppresses the label for the primary horizontal axis.

NOHLABEL2

suppresses the label for the secondary horizontal axis. This is useful for avoiding clutter on comparative Pareto charts.

NOHLLEG

suppresses the legend generated by the CHIGH(n)=, CLOW(n)=, PHIGH(n)=, and PLOW(n)= options.

NOHTICK

suppresses the primary horizontal axis label, tick marks, and tick mark labels.

NOHTICK2

suppresses the secondary horizontal axis label, tick marks, and tick mark labels.

NOKEYMOVE

suppresses the rearrangement of cells within a comparative Pareto chart that occurs when you use the CLASSKEY= option. The key cell appears in the top left corner of a comparative Pareto chart unless you use the CLASSKEY= option together with the NOKEYMOVE option.

NOVLABEL

suppresses the label for the vertical axis. This is useful for avoiding clutter in situations where the meaning of the vertical axis is apparent from the labels for the Pareto categories. See [Output 15.2.2](#) for an illustration.

NROWS=*n***NROW=*n***

specifies the number of rows in a comparative Pareto chart. You can use the NROWS= option in conjunction with the NCOLS= option. See [Output 15.2.3](#) and [Output 15.2.4](#) for an illustration. By default, NROWS=2.

ODSFOOTNOTE=FOOTNOTE | FOOTNOTE1 | 'string'

adds a footnote to ODS Graphics output. If you specify the FOOTNOTE (or FOOTNOTE1) *ODS Graphics* keyword, the value of the SAS FOOTNOTE statement is used as the graph footnote. If you specify a quoted string, that is used as the footnote. The quoted string can contain either of the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	is replaced by the analysis variable name.
\l	is replaced by the analysis variable label (or name if the analysis variable has no label).

ODSFOOTNOTE2=FOOTNOTE2 | 'string'

adds a secondary footnote to ODS Graphics output. If you specify the FOOTNOTE2 key- *ODS Graphics* word, the value of the SAS FOOTNOTE2 statement is used as the secondary graph footnote. If you specify a quoted string, that is used as the secondary footnote. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	is replaced by the analysis variable name.
\l	is replaced by the analysis variable label (or name if the analysis variable has no label).

ODSTITLE=TITLE | TITLE1 | NONE | DEFAULT | LABELFMT | 'string'

specifies a title for ODS Graphics output. You can specify the following values: *ODS Graphics*

TITLE (or TITLE1)	uses the value of the SAS TITLE statement as the graph title.
NONE	suppresses all titles from the graph.
DEFAULT	uses the default ODS Graphics title (a descriptive title consisting of the plot type and the analysis variable name).
LABELFMT	uses the default ODS Graphics title with the variable label instead of the variable name.

If you specify a quoted string, that is used as the graph title. The quoted string can contain the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	is replaced by the analysis variable name.
\l	is replaced by the analysis variable label (or name if the analysis variable has no label).

ODSTITLE2=TITLE2 | 'string'

specifies a secondary title for ODS Graphics output. If you specify the TITLE2 keyword, *ODS Graphics* the value of the SAS TITLE2 statement is used as the secondary graph title. If you specify a quoted string, that is used as the secondary title. The quoted string can contain the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	is replaced by the analysis variable name.
\l	is replaced by the analysis variable label (or name if the analysis variable has no label).

ORDER1=INTERNAL | FORMATTED | DATA | FREQ

specifies the display order for the values of the first CLASS= variable. The levels of the first CLASS= variable are always constructed using the formatted values of the variable, and the formatted values are always used to label the rows (columns) of a comparative Pareto chart.

If you specify ORDER1=INTERNAL, the rows (columns) are displayed from top to bottom (left to right) in increasing order of the internal, or unformatted, values of the first CLASS= variable. If there are two or more distinct internal values with the same formatted value, the order is determined by the internal value that occurs first in the input data set. For example, suppose that you use a numeric CLASS= variable called DAY (with values 1, 2, and 3) to create a one-way comparative Pareto chart. Suppose also that you use the FORMAT procedure to associate the formatted values 1 = 'Wednesday', 2 = 'Thursday', and 3 = 'Friday' with the variable DAY. If you specify ORDER1=INTERNAL, the rows of the comparative chart will appear in chronological order (*Wednesday, Thursday, Friday*) from top to bottom.

If you specify ORDER1=FORMATTED, the rows (columns) are displayed from top to bottom (left to right) in increasing order of the formatted values of the first CLASS= variable. For instance, in the previous illustration, if you specify ORDER1=FORMATTED, the rows will appear in alphabetical order (*Friday, Thursday, Wednesday*) from top to bottom.

If you specify ORDER1=DATA, the rows (columns) are displayed from top to bottom (left to right) in the order in which the values of the first CLASS= variable first appear in the input data set.

If you specify ORDER1=FREQ, the rows (columns) are displayed from top to bottom (left to right) in order of *decreasing* frequency count. If two or more classes have the same frequency count, the order is determined by the formatted values.

By default, ORDER1=INTERNAL.

ORDER2=INTERNAL | FORMATTED | DATA | FREQ

specifies the display order for the values of the second CLASS= variable. The levels of the second CLASS= variable are always constructed using the formatted values of the variable, and the formatted values are always used to label the columns of a two-way comparative Pareto chart.

The PARETO procedure determines the layout of a two-way comparative Pareto chart by first using the ORDER1= option to obtain the order of the rows from top to bottom (recall that ORDER1=INTERNAL by default). Then the ORDER2= option is applied to the observations corresponding to the first row to obtain the order of the columns from left to right. If any columns remain unordered (that is, the categories are unbalanced), the ORDER2= option is applied to the observations in the second row, and so on until all the columns have been ordered.

The values of the ORDER2= option are interpreted as described for the ORDER1= option. By default, ORDER2=INTERNAL.

OTHER=*'category'*

specifies a new category that merges all categories not selected with the MAXNCAT=, MINPCT=, or MAXCMPCT= options. See [Figure 15.5](#) for an illustration.

The *category* should be specified as a formatted value of the process variable. The *category* can be up to 32 characters and must be enclosed in quotes. If you specify an OUT= data set, you should also specify an internal value corresponding to the *category* with the OTHERCVAL= option or the OTHERNVAL= option.

The OTHER= option is not applicable unless you specify the MAXNCAT=, MINPCT=, or MAXCMPCT= option. You can use the COTHER=, LOTHER=, POTHER=, OTHERCVAL=, and OTHERNVAL= options with the OTHER= option.

OTHERCVAL=*'value'*

specifies the internal (unformatted) value for a character process variable in the OUT= data set that corresponds to the category created with the OTHER= option. The *category* can be up to 64 characters and must be enclosed in quotes.

The OTHERCVAL= option is not applicable unless you specify the OTHER= and OUT= options. If you specify the OTHER= option but not the OTHERCVAL= option, the default *value* is the *value* specified with the OTHER= option.

OTHERNVAL=*value*

specifies the internal (unformatted) value for a numeric process variable in the OUT= data set that corresponds to the category created with the OTHER= option. The OTHERNVAL= option is not applicable unless you specify the OTHER= and OUT= options. If you specify the OTHER= option but not the OTHERNVAL= option, *value* is assigned a missing value.

OUT=*SAS-data-set*

creates an output data set that contains the information displayed in the Pareto chart. This is useful if you want to create a report to accompany your chart. See [Example 15.8](#) for an illustration.

PBARS=*pattern***PBARS=***(variable-list)*

specifies pattern fills for the bars. You can use one of two approaches:

Traditional Graphics

- You can specify a single pattern to be used for all the bars with the PBARS=*pattern* option. You can use this option in conjunction with the PHIGH and PLOW options.
- You can specify a distinct pattern for *each* bar (or combination of bars) by providing the patterns as values of a PBARS= variable. For example, you might use the solid pattern ('S') to indicate severe problems and the empty pattern ('E') for all other problems. The variable must be a character variable of length eight, and the variable name must be enclosed in parentheses. You cannot specify a PBARS= variable in conjunction with the PHIGH and PLOW options.

If you specify more than one process variable in the chart statement, you can provide more than one PBARS= variable. The number of PBARS= variables should be less than or equal to the number of process variables. The two lists of variables are paired in order of specification. If a PBARS= variable is not provided for a process variable, the bars for that chart are not filled.

If you specify one or more variables with the PBARS= option, you can also use the BAR-LEGEND= option to add a legend to the chart that explains the significance of each pattern. Furthermore, you can use the CBARS= option to specify colors in conjunction with the PBARS= option.

PHIGH(*n*)=*pattern**Traditional Graphics*

specifies the pattern used to fill the bars with the *n* highest values. You cannot specify the PHIGH option in conjunction with a PBARS= variable, but you can specify the PHIGH(*n*)= option together with the PLOW(*n*)= and PBARS=*pattern* options.

PLOW(*n*)=*pattern**Traditional Graphics*

specifies the pattern used to fill the bars with the *n* lowest values. You cannot specify the PLOW option in conjunction with a PBARS= variable, but you can use the PLOW(*n*)= option together with the PHIGH(*n*)= and PBARS=*pattern* options.

POTHER=*pattern**Traditional Graphics*

pattern specifies the pattern used for the bar defined by the OTHER= option. The POTHER= option is not applicable unless a PBARS= variable is specified.

SCALE=PERCENT | COUNT | WEIGHT

specifies the scale for the primary horizontal axis.

If you specify SCALE=PERCENT, the scale is percent of total frequency. If a WEIGHT= variable is used, the scale is percent of total weight.

If you specify SCALE=COUNT, the scale is counts. See [Output 15.1.4](#) for an illustration. This option is not applicable if a WEIGHT= variable is used. You can specify SCALE=FREQUENCY instead of SCALE=COUNT.

If you specify SCALE=WEIGHT, the vertical axis is scaled in the same units as the WEIGHT= variable. This option is not applicable unless you use a WEIGHT= variable.

By default, SCALE=PERCENT. See [Output 15.5.1](#) for an example. Regardless of how SCALE= is specified, the secondary axis is scaled in cumulative percent units.

TILELEGEND=(*variable*)*Traditional Graphics*

specifies a variable used to add a legend for CTILES= colors. The variable can have a formatted length less than or equal to 32. If a format is associated with the variable, then the formatted value is displayed. The TILELEGEND= option must be used in conjunction with the CTILES= option for filling the tiles in a comparative Pareto chart. If CTILES= is specified and TILELEGEND= is not specified, a color legend is not displayed.

The values of the CTILES= and TILELEGEND= variables should be consistent for all observations with the same level of the CLASS= variables. The value of the TILELEGEND= variable is used to identify the corresponding color value of the CTILES= variable in the legend. See [Output 15.5.1](#) for an illustration.

TILELEGLABEL=*'label'**Traditional Graphics*

specifies a label displayed to the left of the legend that is created when you specify a TILELEGEND= variable. The *label* can be up to 16 characters and must be enclosed in quotes. The default *label* is *Tiles:.* See [Output 15.5.1](#) for an illustration.

URL=variable

specifies URLs as values of the specified character variable (or formatted values of a numeric variable). These URLs are associated with bars on the Pareto chart when ODS Graphics output is directed into HTML. The value of the HTML= variable should be the same for each observation with a given value of the process variable. *ODS Graphics*

VOFFSET=value

specifies the length in percent screen units of the offset at both ends of the vertical axis. You can eliminate the offset by specifying VOFFSET=0. *Traditional Graphics*

VREF='value-list'

specifies where reference lines perpendicular to the vertical (Pareto category) axis are to appear on the chart. Character values can be up to 64 characters and must be enclosed in quotes. The values must be values of the process variable even when the bars are numbered and a category legend is introduced.

VREFLABELS='label1'...'labeln'

specifies labels for the lines requested with the VREF= option. The number of labels must equal the number of lines requested. Enclose the labels in quotes. Labels can be up to 16 characters.

VREFLABPOS=n

specifies the vertical positioning of the VREFLABELS= labels. If you specify VREFLABPOS=1, the labels are positioned at the left of the chart, and if you specify VREFLABPOS=2, the labels are positioned at the right. By default, $n = 1$.

WAXIS=n

specifies the line thickness (in pixels) for the axes and frame. This thickness is also used for bar outlines and grid lines, unless overridden by the WBARLINE=, WGRID=, or WGRID2= options. *Traditional Graphics*

WBARLINE=n

specifies the width for bar outlines. *Traditional Graphics*

WEIGHT=variable-list

specifies weight variables used to construct weighted Pareto charts. The WEIGHT= variables are paired with the process variables in order of specification. The WEIGHT= variables must be numeric, and their values must be nonnegative (noninteger values are permitted). If a WEIGHT= variable is not provided for a process variable, the weights applied to that process variable are assumed to be one. See the section “[Weighted Pareto Charts](#)” on page 1176 for computational details.

A WEIGHT= variable is particularly useful for carrying out a Pareto analysis based on *cost* rather than frequency of occurrence. See [Example 15.8](#) for an illustration.

WGRID=n

specifies the width of the primary chart grid lines. If the WGRID= option is specified the GRID option is not required. *Traditional Graphics*

WGRID2=*n**Traditional Graphics*

specifies the width of the secondary chart grid lines. If the WGRID2= option is specified the GRID2 option is not required.

VBAR Statement: PARETO Procedure

Overview: VBAR Statement

The VBAR statement creates a Pareto chart with vertical bars representing the frequencies of problems in a process or operation. A vertical Pareto chart has one horizontal axis on which the Pareto categories are listed. The primary vertical axis appears on the left side of the chart and is used to read the lengths of the bars on the chart. The secondary vertical axis is on the right of the chart and is used to read the cumulative percent curve.

You have three alternatives for producing Pareto charts with the VBAR statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: VBAR Statement

The examples in this section illustrate basic features of the VBAR statement. Complete syntax for the VBAR statement is presented in the section “Syntax: VBAR Statement” on page 1134.

Creating a Pareto Chart from Raw Data

See PARETO4 in the SAS/QC Sample Library

In the fabrication of integrated circuits, common causes of failures include improper doping, corrosion, surface contamination, silicon defects, metallization, and oxide defects. The causes of 31 failures were recorded in a SAS data set called Failure1.

```

data Failure1;
  length Cause $ 16;
  label Cause = 'Cause of Failure';
  input Cause & $;
  datalines;
Corrosion
Oxide Defect
Contamination
Oxide Defect
Oxide Defect
Miscellaneous
Oxide Defect
Contamination
Metallization
Oxide Defect
Contamination
Contamination
Oxide Defect
Contamination
Contamination
Contamination
Corrosion
Silicon Defect
Miscellaneous
Contamination
Contamination
Contamination
Miscellaneous
Contamination
Contamination
Doping
Oxide Defect
Oxide Defect
Metallization
Contamination
Contamination
;

```

Each of the 31 observations corresponds to a different circuit, and the value of Cause provides the cause for the failure. These are raw data in the sense that there is more than one observation with the same value of Cause, and the observations are not sorted by Cause. The following statements produce a basic Pareto chart for the failures:

```

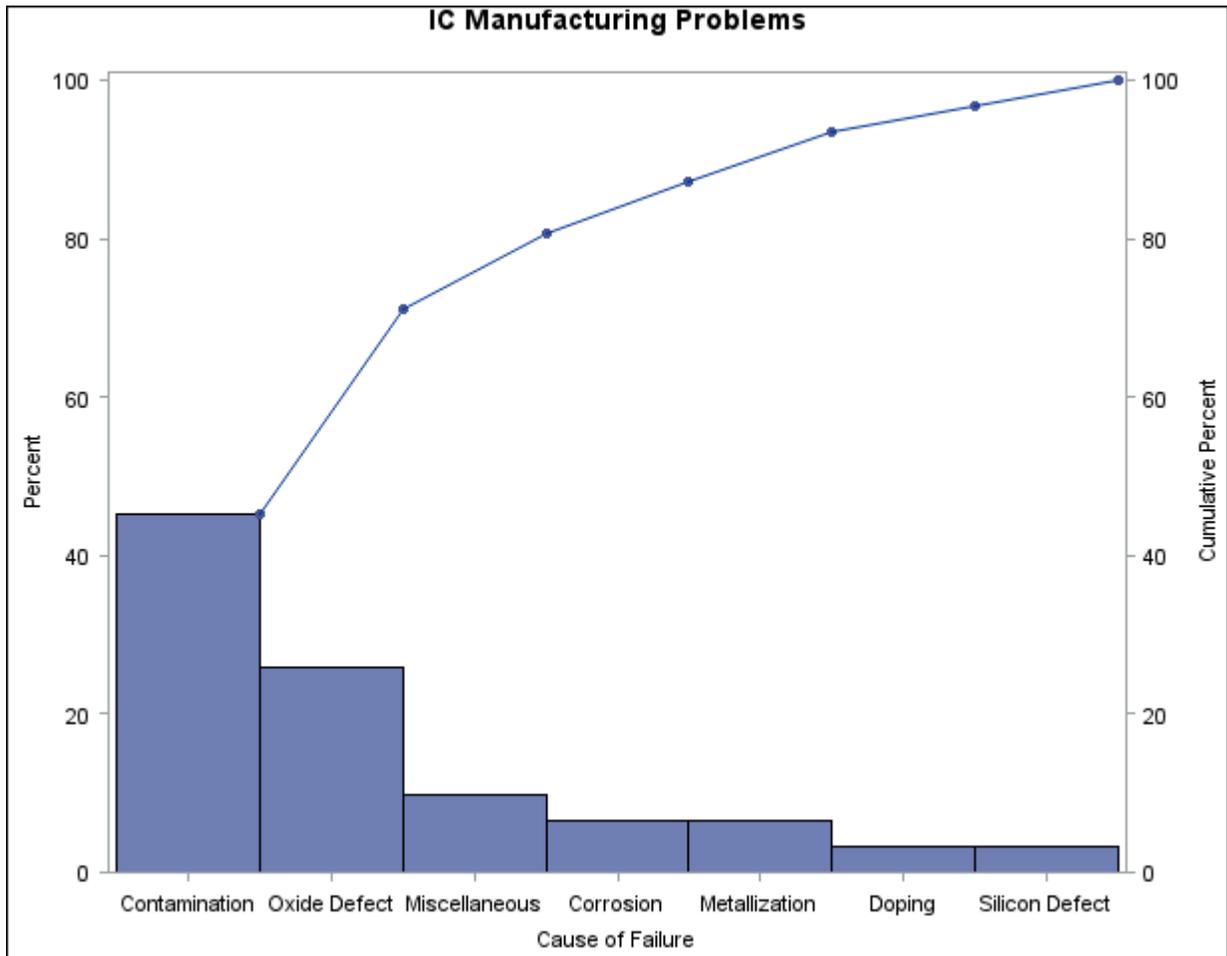

ods graphics off;
symbol v=dot;
proc pareto data=Failure1;
  vbar Cause;
run;

```

The PARETO procedure is invoked with the first statement, referred to as the PROC statement. You specify the process variable to be analyzed in the VBAR statement.

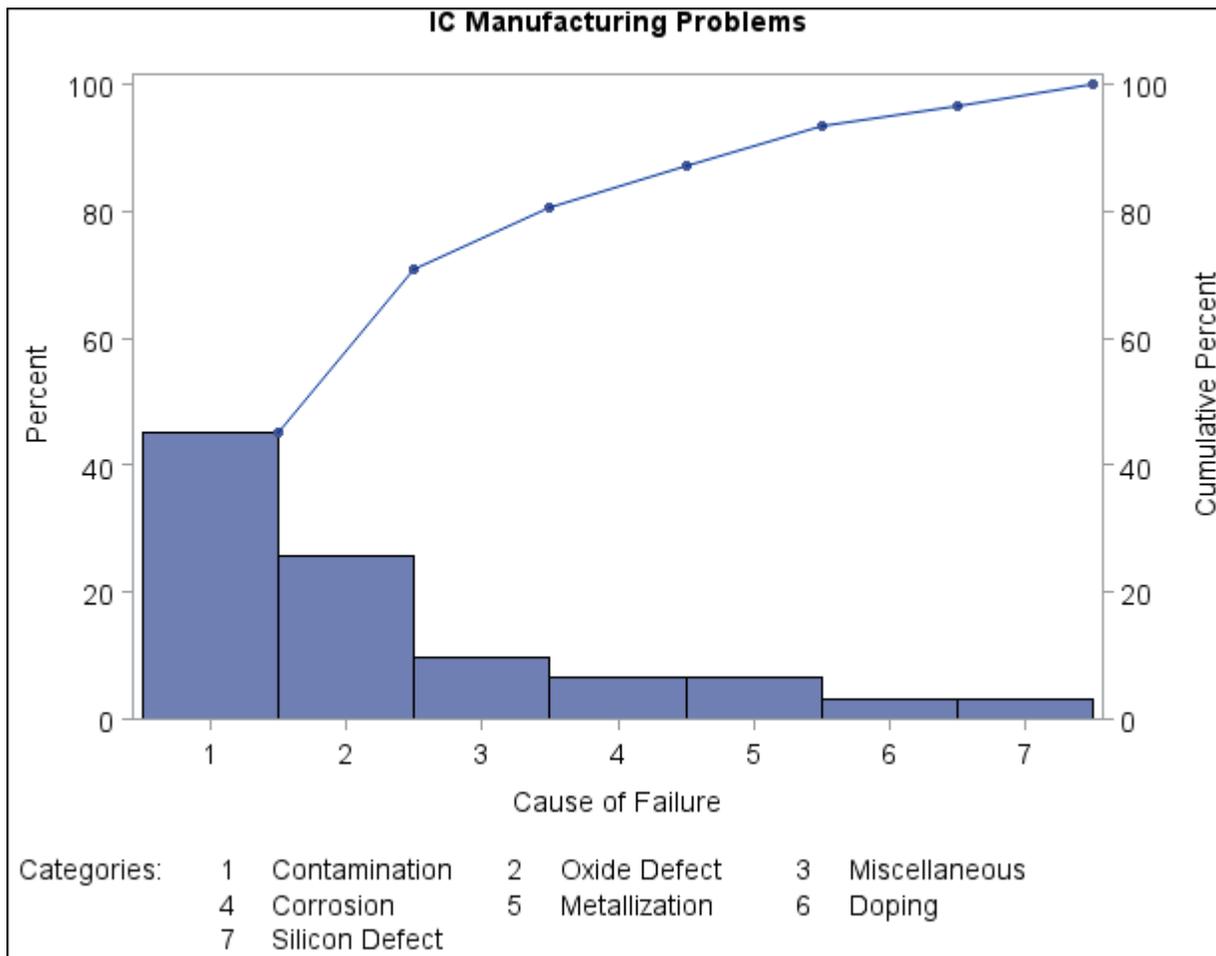

The Pareto chart is shown in [Figure 15.6](#).

Figure 15.6 Pareto Chart for IC Failures in the Data Set Failure1

The procedure has classified the values of Cause into seven distinct categories (levels). The bars represent the percent of failures in each category, and they are arranged in decreasing order. Thus, the most frequently occurring category is *Contamination*, which accounts for 45% of the failures. The Pareto curve indicates the cumulative percent of failures from left to right; for example, *Contamination* and *Oxide* together account for 71% of the failures.

If there is sufficient space, the procedure labels the bars along the horizontal axis as in Figure 15.6. Otherwise, as in Figure 15.7, the procedure numbers the bars from left to right and adds a legend identifying the categories.

Figure 15.7 Pareto Chart with Category Legend

A category legend is likely to be introduced when

- the number of categories is large
- the category labels are lengthy (as in this example). Category labels can be up to 64 characters.
- a large text height is used. You can specify the height with the HEIGHT= option in the VBAR statement or with the HTEXT= option in a GOPTIONS statement (not shown here).

Creating a Pareto Chart Using Frequency Data
